**REVISION SUMMARY**

<b>Revision #</b>	<b>Section Modified</b>	<b>Revision Summary</b>
0	All	Initial Release
1	Section 1.5 Section 1.6.2	Incorporate corrections per customer acceptance review.
2	Section 1.5 Section 1.11	Incorporate corrections per customer acceptance review.

### ACRONYM LIST

Acronym	Explanation
ACI	American Concrete Institute
ALARA	As Low As Reasonably Achievable
ANS	American Nuclear Society
ANSI	American National Standards Institute
AOO	Anticipated Operational Occurrence
ASCE	American Society of Civil Engineers
ASME	American Society of Mechanical Engineers
ASTM	ASTM International
BIS	Boron Injection System
BPVC	Boiler and Pressure Vessel Code
BWR	Boiling Water Reactor
CANDU	CANada Deuterium Uranium
CB	Control Building
CNSC	Canadian Nuclear Safety Commission
CRD	Control Rod Drive
CSA	CSA Group
DBA	Design Basis Accident
DBE	Design Basis Earthquake
DEC	Design Extension Condition
D-in-D	Defence-in-Depth
DL	Defense Line
DNGS	Darlington Nuclear Generating Station
DNNP	Darlington New Nuclear Project
EME	Emergency Mitigating Equipment
EOC	Emergency Operations Centre
EOP	Emergency Operating Procedure
EPRI	Electric Power Research Institute
ESBWR	Economic Simplified Boiling Water Reactor
FMCRD	Fine Motion Control Rod Drive
FPC	Fuel Pool Cooling and Cleanup System
FSF	Fundamental Safety Function

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

Acronym	Explanation
GEH	GE Hitachi Nuclear Energy
GSS	Guaranteed Shutdown State
HCU	Hydraulic Control Unit
HX	Heat Exchanger
IAEA	International Atomic Energy Agency
IC	Isolation Condenser
ICC	ICS Pool Cooling and CleanUp System
ICRP	International Commission on Radiological Protection
ICS	Isolation Condenser System
IEC	International Electrotechnical Commission
IEEE	Institute of Electrical and Electronics Engineers
ISFSI	Independent Spent Fuel Storage Installation
ISO	International Organization for Standardization
LCH	Licence Conditions Handbook
LOCA	Loss-of-Coolant Accident
LTC	Licence to Construct
MCR	Main Control Room
NBS	Nuclear Boiler System
NEI	Nuclear Energy Institute
NERC	North American Electric Reliability Corporation
NFPA	National Fire Protection Association
NPP	Nuclear Power Plant
NRCC	National Research Council of Canada
NSCA	Nuclear Safety and Control Act
OER	Operating Experience Review
OPG	Ontario Power Generation
PCCS	Passive Containment Cooling System
PIE	Postulated Initiating Event
PLSA	Plant Services Area
PSA	Probabilistic Safety Assessment
PSAR	Preliminary Safety Analysis Report
RB	Reactor Building

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
RCPB	Reactor Coolant Pressure Boundary
RG	Regulatory Guide
RPV	Reactor Pressure Vessel
RWB	Radwaste Building
SAMG	Severe Accident Management Guideline
SCA	Safety and Control Area
SCCV	Steel-Plate Composite Containment Vessel
SCN	Non-Safety Class
SCR	Secondary Control Room
SDC	Shutdown Cooling System
SFPE	Society of Fire Protection Engineers
SMR	Small Modular Reactor
SSC	Structures, Systems, and Components
TB	Turbine Building
USNRC	U.S. Nuclear Regulatory Commission

## **1.0 INTRODUCTION AND GENERAL CONSIDERATIONS**

### **1.1 Introduction**

The Darlington New Nuclear Project (DNNP) will provide a new Class I nuclear facility, as defined by the Nuclear Safety and Control Act (NSCA), that is a critical new source of clean electricity for the Province of Ontario's future energy needs and achieving Canada's commitment to be Net-Zero by 2050. The DNNP will be implemented at the existing Darlington Nuclear site that is owned and operated by Ontario Power Generation (OPG).

The Darlington Nuclear site (see Appendix A Figure A1.1-1), is located in the township of Darlington, on the north shore of Lake Ontario at Raby Head, approximately 70 km east of Toronto. The site is approximately 5 km southwest of the community of Bowmanville and 10 km southeast of the City of Oshawa. Immediately to the east of the site is St. Marys Cement limestone quarry and processing plant. The site is traversed by an east-west operating Canadian National (CN) railway and a 8.5m high berm that provides the site protection in the event of a railway accident. The site is also traversed by the Lake Ontario Waterfront Trail, which is a multi-use recreation trail extending from Niagara-on-the-Lake to the Quebec border along the north shores of Lake Ontario and the St. Lawrence River.

Currently, the Darlington Nuclear site (see Appendix A Figure A1.1-2) is home to the 3512 megawatt-electric Darlington Nuclear Generating Station (DNGS), comprised of four operating CANada Deuterium Uranium (CANDU) pressurized heavy water generating reactors, the Tritium Removal Facility (TRF) that serves all of Ontario's CANDU nuclear reactors, and the Nuclear Sustainability Services-Darlington that stores spent nuclear fuel from the DNGS. The DNNP site is in the eastern one-third of the site bounded by the site property limits to the east and north, by Lake Ontario to the south, and by Holt Road to the west.

The DNNP site is also owned by OPG. OPG is the holder of a Nuclear Power Reactor Site Preparation Licence 18.00/2031. This licence permits OPG to perform activities to prepare the DNNP site for the future placement of a nuclear facility. In December 2021, OPG announced that the selected technology for this nuclear facility to be the grid-scale BWRX-300 Small Modular Reactor (SMR), designed by GE-Hitachi Nuclear Energy Americas, LLC (GEH). The BWRX-300 is approximately 300 megawatt-electric in size and, is capable of preventing between 0.3 and 2 megatonnes of carbon dioxide emissions per year, depending on the kind of alternative power generation technology it is displacing. OPG also announced that it will submit a Licence to Construct (LTC) application in accordance with the NSCA, Class I Nuclear Facilities Regulations (SOR/2000-204) and CNSC REGDOC-1.1.2 by the end of 2022. Once granted, the LTC will permit the construction of one BWRX-300.

In accordance with paragraph 5(f) of SOR/2000-204, this Preliminary Safety Analysis Report (PSAR) supports OPG's LTC application and demonstrates the adequacy of the design of BWRX-300. This PSAR has been prepared collaboratively between GEH and OPG and in accordance with the guidance of the International Atomic Energy Agency (IAEA) as documented in their Specific Safety Guide No. SSG-61, Format and Content of the Safety Analysis Report for Nuclear Power Plants.

#### **1.1.1 Format of the Safety Analysis Report**

It is recognized by the CNSC Regulatory Framework and IAEA guidance that Safety Analysis Reports (SARs) are developed in an iterative manner to support the appropriate licensing activities at the appropriate time. Since this release supports OPG's LTC application, this version of the SAR is a PSAR and contains sufficient design information commensurate with the stage of the design progression to assess and demonstrate that the plant can be safely constructed. The

PSAR will be updated to a Pre-Operational Safety Analysis Report with more detailed design information to support OPG's Licence to Operate application at the appropriate future time.

The following describes the format of the DNNP SAR and includes a brief description of the content of each chapter. Information presented in each chapter is commensurate with its importance to nuclear safety and PSAR purposes.

### **Chapter 1: Introduction and General Considerations**

Information in this chapter describes the DNNP and the PSAR, including their purposes and objectives. It describes DNNP facilities at a high level and the national and international guidance applied to the BWRX-300.

### **Chapter 2: Site Characteristics**

Information in this chapter describes the characteristics of the DNNP site on which the BWRX-300 facility is planned to be constructed. The information represents the baseline data which is used to ensure that site-related uncertainties are addressed and dispositioned in the final design and safety assessment of the BWRX-300 facility. This chapter describes the geological, seismological, hydrological, meteorological, and geotechnical features of the DNNP site and the surrounding region. It also describes the site-specific natural and human-induced external hazards including radiological conditions due to external sources and their dispersion characteristics. Furthermore, this chapter describes present and projected population distribution and land use relevant to the safe design and operation of the BWRX-300 facility over its expected 60-year operational life.

### **Chapter 3: Safety Objectives and Design Rules for Structures, Systems, and Components**

This chapter is specific to the BWRX-300 and introduces the safety objectives and the safety strategy framework to meet those objectives for its design and construction at DNNP. Additionally, this chapter describes the design rules for classification of Structures, Systems, and Components (SSC) important to safety, and the design principles and safety requirements established for the BWRX-300.

### **Chapter 4: Reactor**

This chapter is specific to the BWRX-300 and describes the design of its reactor and fuel assembly in more detail. It also provided the relevant information on the reactor that demonstrates its capability to fulfil relevant safety functions throughout the design life in all plant states.

### **Chapter 5: Reactor Coolant System and Associated Systems**

This chapter is specific to the BWRX-300 and describes Nuclear Boiler System (NBS) and interfacing systems that form the Reactor Coolant Pressure Boundary (RCPB). Further, the information in this chapter demonstrates that the functional and structural integrity aspects of the various NBS SSC are designed with robustness, quality, independence, redundancy, and diversity to maintain adequate reactor coolant inventory during Anticipatory Operational Occurrences (AOOs), Design Basis Accidents (DBAs), and Design Extension Conditions (DECs).

### **Chapter 6: Engineered Safety Features**

This chapter is specific to the BWRX-300 and describes its engineered safety features provided to mitigate the consequences of AOOs and DBAs. The engineered safety features are divided into three general groups: (1) Containment and Associated Systems; (2) Isolation Condenser System (ICS) functioning as the Emergency Core Cooling System; and (3) Control Room Habitability.

### **Chapter 7: Instrumentation and Control**

This chapter is specific to the BWRX-300 and describes its Instrumentation and Control (I&C) systems. The information in this chapter is organized to systematically present the I&C design bases in the necessary context to support an understanding of the individual I&C system designs and safety features.

### **Chapter 8: Electrical Power**

This chapter is specific to the BWRX-300 and describes its electrical system and requirements and how they interface with Darlington Nuclear site and Ontario's electrical transmission system.

### **Chapter 9A: Auxiliary Systems**

This chapter is specific to the BWRX-300 and describes its auxiliary systems (e.g., fuel handling, water, air, HVAC, fire protection, diesel generators, cranes, etc.) that support its safe and reliable operations.

### **Chapter 9B: Civil Engineering Works and Structures**

This chapter is specific to the BWRX-300 and describes how its general seismic design requirements are complied with in the design of the Reactor Building (RB). Information is also provided describing the general civil and structural design requirements for the Radwaste Building (RWB), Control Building (CB), Turbine Building (TB), Plant Service Area (PLSA), Intake and Discharge Structures, Forebay and tunnels to and from the lake and Fire Pump Enclosure.

### **Chapter 10: Steam and Power Conversion Systems**

This chapter is specific to the BWRX-300 and describes design of the power conversion system, including the Main Turbine Equipment, which is comprised of the High Pressure and Low Pressure Turbines, Turbine Gland Seal System, Turbine Lubricating Oil System, Extraction Steam System, Electro-Hydraulic Controls System, and Turbine Auxiliary Steam Subsystem.

### **Chapter 11: Management of Radioactive Waste**

Information in this chapter describes the main sources of liquid, gaseous and solid radioactive waste including the radiological source term used in calculating liquid and airborne effluent. Also described are the radioactive waste processing systems (i.e., pretreatment, treatment, and conditioning systems) as well as temporary waste storage located on the site. The SSCs that monitor and sample the process and effluent streams to measure and control the discharge of radioactive materials generated in operational states and accident conditions are described.

The measures proposed for the safe management of radioactive and hazardous waste of all types that will be generated throughout the lifetime of the plant as well as how these measures meet the relevant safety requirements including the measures taken for the safe management and disposal of this waste are described in OPG's Waste Management Program.

### **Chapter 12: Radiation Protection**

Information in this chapter describes the administrative programs and procedures, in conjunction with facility design, that ensures occupational radiation exposure to personnel is kept As Low As Reasonably Achievable (ALARA). The systematic application of the ALARA philosophy during the design phase of the BWRX-300 that establishes the basic design criteria observed to reduce occupational exposure during plant operation and maintenance, decommissioning and post-accident ALARA are described.

### **Chapter 13: Conduct of Operations**

Information in this chapter describes how OPG fulfils its prime responsibility for safety in the operation of the BWRX-300. Specifically, this chapter describes important operational issues relevant to nuclear safety, approaches adopted by OPG to address these issues through its operational programs and provisions made by OPG that establish and maintain an adequate number of qualified staff. The preparation of OPG operating procedures for the BWRX-300 that ensure its safety is supported by GEH.

### **Chapter 14: Plant Construction and Commissioning**

Information in this chapter describes how OPG assures that the BWRX-300 will be suitable for service prior to entering the construction, commissioning, and operational stages. The commissioning program and organization intended to verify and validate the plant's performance against the design prior to the turnover of the facility to OPG for operation are described. Additionally, information is provided on how OPG qualified operating personnel at all levels are trained and directly involved in the commissioning process.

### **Chapter 15: Safety Analysis**

This chapter is specific to the BWRX-300 and describes the results from the BWRX-300 plant safety analyses that includes the Deterministic Safety Analysis, Severe Accident Analysis, Hazard Analysis and Probabilistic Safety Assessment (PSA). It describes how the safety analysis verifies, throughout the iterative design and analysis process, that the design of the BWRX-300 adequately performs the Fundamental Safety Functions (FSF) of controlling reactivity, fuel cooling, long-term heat removal, and containment of radioactive materials.

### **Chapter 16: Operational Limits and Conditions for Safe Operation**

Information in this chapter describes how the facility's safe operating envelope is evaluated and implemented through a set of operational limits and conditions that prescribe boundaries within which OPG must operate the BWRX-300 to assure compliance with the safety analysis inputs, assumptions, and results. The full set of operational limits and conditions are a key element of the licensing basis for a Licence to Operate.

### **Chapter 17: Management for Safety**

Information in this chapter describes how the overall management of all safety related activities is assured throughout the entire lifecycle of the facility. It describes the general, specific, quality management, performance improvement, and safety culture elements of the management systems of OPG and the organizations, such as GEH, that support the development, operation, and eventual retirement of DNNP facilities.

### **Chapter 18: Human Factors Engineering**

This chapter is specific to the BWRX-300 and describes the Human Factors Engineering program for the development lifecycle phases (i.e., design, construction, and commissioning) of the BWRX-300. This chapter demonstrates the effective integration of Human Factors Engineering requirements and analysis results into the design of the plant in an iterative process.

### **Chapter 19: Emergency Preparedness and Response**

Information in this chapter demonstrates that in a very unlikely nuclear or radiological emergency occurring at the DNNP facility, timely and effective actions are taken that protect workers, the public, and the environment coordinated with off-site government agencies and supported by a documented decision-making process.

## **Chapter 20: Environmental Aspects**

Information in this chapter describes the environmental aspects important for the development, operation, and retirement of the DNNP facilities. General aspects of the Environmental Impact Assessment, applicable principles, and regulations, OPG's Environmental Management System, and site characteristics are described. Features that minimize environmental impact of the facility throughout its entire lifecycle, including postulated accidents, are also described.

## **Chapter 21: Decommissioning and End of Life Aspects**

Information in this chapter demonstrates their commitment to the production of energy in a sustainable manner through the effective and efficient life-cycle management of the nuclear facilities. The planning for decommissioning and end-of-life management of DNNP facilities, including the BWRX-300 reactor, is an integral aspect of the facility life-cycle management process that is described in this chapter.

## **Safeguards Annex: Safeguards and Nuclear Material Accountancy**

Information is presented in the Safeguards Annex to demonstrate how OPG supports compliance with the IAEA safeguards agreement in Connection with the Treaty on the Non-Proliferation of Nuclear Weapons and the Additional Protocol to the Safeguards Agreement. Under the NSCA, the CNSC has the mandate to achieve Canadian conformity with such international obligations. Specifically, this Safeguards Annex describes information related to the BWRX-300 reactor facility at the DNNP to demonstrate compliance with the international agreements, as well as compliance with the responsibilities included in the NSCA and the General Nuclear Safety and Control Regulations (SOR-2000-202).

## **Security Annex: Darlington BWRX-300 Security Assessment**

Detailed information about the protected area and vital areas, including their structures and/or barriers, are provided in a separate security annex since the content contains prescribed information as defined by Section 21 of the General Nuclear Safety and Control Regulations (SOR/2000-202).

### **1.1.2 DNNP Project Delivery**

OPG will implement DNNP through a project delivery model described in Section 1.2 having a target in service date as early as 2028. The DNNP is composed of the following five key projects that will assure its safe and efficient implementation:

1. Site Preparation Project
2. Power Block Project
3. Switchyard & Grid Connection Project
4. Intake / Discharge Water System Project
5. Digital Strategy Project

### **1.1.3 PSAR Verification Scope**

The PSAR is a licensing basis document that is prepared, validated, and approved in accordance with GEH's Quality Assurance Program, which assures:

1. Accuracy of information against verified engineering source documentation
2. Sufficient information to support the Licence to Construct (LTC) in accordance with CNSC REGDOC-1.1.2

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

3. Alignment with the stage at which the design has progressed and its supporting safety analysis

**1.1.4 PSAR Limitation of Use**

The PSAR is a high-level summary document developed to support the LTC application activities for DNNP only. It is released for information and licensing purposes only and shall not be used for technical or construction purposes.

## **1.2 Project Implementation**

For the DNNP development lifecycle phase, OPG will utilize an Integrated Project Delivery contract model which maximizes integration and collaboration with other contract partners involved with this phase. The Integrated Project Delivery contract agreement describes the relationship and accountabilities of the contract partners including Owner (OPG), Developer (GEH), Constructor, and Architect Engineer.

Key principles of the contract model include collaborative behaviours, common information systems, best athlete approach to staffing positions, risk and reward sharing, transparency between partners, and maximizing efficiencies.

Roles and responsibilities for all contract partners are defined and accepted through contractual agreements for the project. The partner roles are further described in Chapter 17, Subsection 17.2.1.

### **1.3 Identification of Interested Parties Regarding Design, Construction and Operation**

The Developer, GEH, is the Design Authority for scoped design activities in accordance with the project execution model until turnover.

The Constructor is responsible for procurement, construction, and support of commissioning activities.

An Architect Engineering firm performs design and engineering activities required for the project.

The owner and the licence applicant, OPG, is ultimately responsible for DNNP operation and retains the overall accountability for ensuring the project lifecycle is executed with quality and safety.

The contractual agreement between the stakeholders details specific responsibilities and interfaces are further detailed in Chapter 17.

## **1.4 Information on the Plant Layout and Other Aspects**

The DNNP site layout, infrastructure, intake and discharge water, Switchyard, BWRX-300 Power Block, and their respective interfaces are shown in Appendix A (see Figures A1.4-1 and A1.4-2).

Descriptions of the site layout, infrastructure, intake and discharge water, and Switchyard are provided in this Section.

Descriptions of the BWRX-300 Power Block are provided in Section 1.5.

### **1.4.1 Site Layout and Infrastructure**

The DNNP site will contain infrastructure, including additional buildings, to support operations inside the Power Block.

Currently anticipated services include:

1. A demineralized water supply pipeline extending from the Darlington Demineralized Water Plant eastwards approximately 400m towards the DNGS/DNNP property line along the Third Line Road corridor. The demineralized water is used for the Power Block operations.
2. A potable water pipeline extension tying into the existing municipal water supply just south of the CN railway and west of Holt Road bridge on the west side of the road. This pipe carries potable water for use inside the power block as well as various outbuildings around the DNNP property including the administration building, warehouse, temporary construction buildings, and potentially other buildings to be determined.
3. Sanitary sewer connections to the existing Darlington East Sewage Lift Station are planned. These carry sewage from inside the power block as well as the administration building, warehouse, and potentially other buildings not yet determined, to the lift station. From here the effluent is pumped north and west towards the Courtice Water Pollution Control Plant for treatment and eventual discharge to Lake Ontario.
4. Fibre-optic cables for a business Local Area Network and copper telephone/public address cables to create a communications link between DNGS and DNNP. These run from the DNGS Engineering Support Services Building in an underground duct bank eastwards approximately 400m towards the DNGS/DNNP property line mostly along the Second Line Road corridor.
5. Additional fibre-optic cables for a security Local Area Network are brought from the Darlington Main Security Building approximately 600m east towards the DNGS/DNNP property line in an underground duct bank mostly along the Second Line Road corridor.
6. Up to 10MW of construction power are brought from the existing 54M15 feeder through Darlington DS5 substation at 13.8kV, located near the intersection of Park Road and Second Line, approximately 1km east to a new switchgear to be located near the northeast corner of the Nuclear Sustainability Services-Darlington. This switchgear is planned to feed construction loads as well as the new administration building and warehouse. A second feed will be taken from the same 54M15 through the existing Darlington DS1-F1 substation at 8.32kV and will supply construction loads including the construction trailers.

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

Planned structures/features include:

1. An administration building with office spaces and a simulator training space. The simulator space will support the SMR full scope simulator and desktop simulator plus limited maintenance training space.
2. A warehouse is necessary to provide long term storage space for SMR components and equipment. It has some maintenance space and a calibration shop suitable for the service of non-contaminated equipment.
3. There is a parking lot near the administration building. There is an existing parking lot south of the Canadian National Railway near the border between DNNP and St. Marys Cement that will also be utilized.
4. A Steel Bricks production facility is planned to be constructed on the northwest quadrant of the intersection of Maple Grove Road and Second Line. This facility produces the Steel Bricks components for the construction of the reactor building.
5. A concrete batching plant will be provided suitably located if it is determined that onsite concrete batching is required.
6. Holt Road will be improved in two phases:
  - a. Phase 1 - The Holt Road extension is a new stretch of road to be built from the intersection of Second Line and Old Holt Road at the northwest corner of DNNP property. This will extend south along the DNGS/DNNP property line between the Nuclear Sustainability Services-Darlington and the SMR facility until it reaches Lake Ontario. At this point it turns west and continues until it connects with the existing Lakeshore Road. The portion of Holt Road along Lake Ontario will be reinforced, and form part of the heavy haul route used to transport heavy components from the DNGS wharf to DNNP.
  - b. Phase 2 - The Holt Road expansion will add an additional northbound lane from Second Line north towards Highway 401. This additional lane will end south of Energy Drive and will be used by soil transport trucks to place soil onto the northern parts of DNNP property forming the spoils piles. There will also be a new southbound left turn lane to be created just south of the Holt Road bridge to aid traffic turning onto DNNP property.
7. The existing Old Holt Road that stretches diagonally across DNNP property will be kept intact up to the point it joins the ring road around the Power Block facility.
8. The heavy haul road along Lakeshore Road will extend east onto DNNP property to support the construction of the Power Block. It is planned to extend as far east as the Power Block facility and then extend only as far north as necessary to support the Power Block facility construction.
9. Maple Grove Road is planned to be improved and extended south and then west to join the heavy haul road at the south part of the DNNP property. The improvements will likely include a new bridge to cross over the Canadian National Railway.
10. A soil conditioning pile is created from excavated earth during the site preparation phase and located at the southeast quadrant of the Maple Grove Road and Second Line intersection. This soil will be reconditioned and placed back into the SMR facility foundation.

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

11. A soil spoils pile is located in the northern part of DNNP property south of Energy Drive and west of Maple Grove Road. Excavated earth from the site preparation phase will be placed here.
12. Storm water management features are part of the overall site layout. One known feature is the relocation of the existing Bowmanville SS drainage ditch that currently runs from Bowmanville SS through DNNP property, southeast along Old Holt Road and draining into Lake Ontario. This will be relocated west to run along the eastern edge of the new Holt Road Extension.

#### **1.4.2 DNNP Switchyard**

The local DNNP switchyard (see Appendix A, Figure A1.4-2) is located North of the SMR Facility, East of the Extended Holt Rd and South of the CN Rail tracks. The local switchyard consolidates power produced by the Power Block facility. The Power Block facility has two 230kV lines connected to the local DNNP switchyard. One line connects the Facility Generator Step Up Transformer, and one line connects to the Reserve Auxiliary Transformer. The local switchyard has two redundant 230kV connections with the transmitter. The transmitter is working to connect these lines to Clarington TS, 22km North of the DNNP site.

The operating organization is responsible for the ownership and operation of the local DNNP switchyard, containing the high voltage circuit breakers and disconnect switches, in addition to equipment within the Power Block facility. Hydro One, the transmitter for the electrical grid, is responsible for the ownership and operation of the two redundant 230kV lines connecting the local DNNP switchyard with Clarington Transformer Station.

#### **1.4.3 Normal Heat Sink**

The normal heat sink removes excess heat to a large water body. For the DNNP, water withdrawn from Lake Ontario flows through the plant surface condensers to remove the excess energy of the turbine exhaust steam. The amount of heat removed during this process depends on the flow rate and the temperature rise of the water passing through the condensers. The plant heat is rejected to Lake Ontario.

Cooling water from Lake Ontario is delivered to an intake structure for the nuclear facility through an intake tunnel. The intake structure sends the cooling water to the Pumphouse/Forebay that contains circulating water pumps which deliver the cooling water to plant surface condensers before returning the heated water back to the lake through the discharge tunnel.

The Normal Heat Sink includes, but is not limited to the following:

1. Intake Tunnel, located deep in Lake Ontario to meet regulatory commitments (D-C-1) to decrease potential impacts to fish habitat and is sized to provide the required flow of cooling water to the plant. It is also constructed to minimize the intake velocity to prevent impingement and entrainment of fish and effect on local currents.
2. Discharge Tunnel and diffusers are constructed deep in Lake Ontario to meet regulatory requirements by limiting the temperature increase to minimize thermal and flow effects of the plant cooling water discharge to ensure surface water temperature does not exceed 2 degrees C above ambient surface temperature and minimize impact to aquatic habitat.
3. Pumphouse/Forebay is composed of the forebay, pump bays and superstructures to house the Circulating Water System pumps and related equipment.

#### **1.4.4 Security Building**

A security building, known as the Protected Area Access Building, is provided on the protected area boundary to allow for ingress and egress to and from the protected area. Additionally, a sally port is provided adjacent to the security building to allow for vehicular traffic to enter the protected area. Detailed information about the protected area and vital areas, including their structures and/or barriers, are provided in a separate security annex since the content contains prescribed information as defined by Section 21 of the General Nuclear Safety and Control Regulations (SOR/2000-202).

## **1.5 General BWRX-300 Power Block Description**

The BWRX-300 is a Boiling Water Reactor (BWR) that employs natural circulation and passive emergency cooling features and is rated at approximately 300 megawatts-electric.

The passive design features of the BWRX-300 provide decay heat removal capability using only installed systems with no reliance on operator actions or external resources for at least 72-hours. For the BWRX-300, a safe stable condition ("stable shutdown") is defined as safe shutdown with average reactor coolant temperature  $\leq 215.6^{\circ}\text{C}$  ( $420^{\circ}\text{F}$ ). Following 72-hours post-accident, on-site or off-site resources are used to power non-safety equipment for proceeding to cold shutdown conditions, as needed.

The BWRX-300 design applies a defence-in-depth process for safety assessment and safety analysis to ensure that radiological acceptance criteria are met. The leveraging of passive design features greatly simplifies the design and results in a significant reduction in total number active SSCs compared to conventional Nuclear Power Plants (NPPs).

The overall safety objectives and the safety strategy employed in the development of the BWRX-300 design are described in detail in Chapter 3.

### **1.5.1 Basic Technical Characteristics**

The principal technical characteristics of the BWRX-300 are provided in Table 1.5-1.

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 1.5-1: Principal Characteristics of Interest for the DNNP BWRX-300**

Parameter Description	Value	Comments
Type of plant	Boiling Water Reactor	
Core coolant	Light Water	
Neutron moderator	Light Water	
Nuclear Steam Supply System layout	Direct-Cycle	
Primary circulation	Natural	
Thermodynamic cycle	Rankine	
Type of containment structure	Dry	
Reactor thermal power level	870 MWth	
Normal Heat Sink	Once Through Cooling System using water from Lake Ontario	
Ultimate Heat Sink	ICS pools	Pools are vented to atmosphere
Plant gross electrical power output	~ 300 MWe	
Plant Footprint	~ 9,800 m <sup>2</sup>	Rectangular building envelope
Site Footprint	~ 30,000 m <sup>2</sup>	Fenced area
Design life	60 years	
Exclusion Zone	350 m (radius)	Measured from exterior of the Reactor Building
Seismic Design (DBE)	0.310 g (horizontal and vertical)	Bounding rock peak ground acceleration
	0.532 g (horizontal)	Bounding surface peak ground acceleration
	0.516 g (vertical)	
Reactor Design Pressure	10.3 MPa	
Fuel	UO <sub>2</sub> pellets	
Fuel enrichment	<5% U-235	
RPV diameter (ID)	~ 4 m	
RPV height (Inside)	~ 26 m	
Control rod drive type	Fine Motion Control Rod Drive (FMCRD)	
Containment Vessel type	Steel-plate Composite	
Fuel pool capacity	Up to 8 years of full-power operation	Fuel pool accommodates up to 8 years of spent fuel plus one core load of new fuel and one full core off-load
Refueling cycle	12 - 24 months	

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

Parameter Description	Value	Comments
Emergency Power Supply	Safety Class 1 DC batteries	Capable of sustaining required loads for 72 hours

### 1.5.2 Primary Drawings

An overview of the primary buildings/structures in the Power Block of the BWRX-300 is shown in Figure A1.5-1 of Appendix A and is discussed below. The Reactor Building, Turbine Building, Radwaste Building, Control Building, and Plant Services Area (PLSA) are specifically referenced in the descriptions below.

The plant grade elevation of the power block is approximately 88 meters Canadian Geodetic Vertical Datum of 1928. The overall Power Block length is approximately 143 meters and width is approximately 69 meters. The approximate dimensions of the power block buildings are provided in Table 1.5-2.

**Table 1.5-2: Approximate Dimensions of Power Block Buildings**

Building	Length (m)	Width (m)	Highest Roof Elevation (m)
Reactor Building <sup>(1)</sup>	36 (Diameter)	36 (Diameter)	30 (Exterior Dome Top)
Turbine Building	70	69 <sup>(3)</sup>	30 <sup>(4)</sup>
Radwaste Building <sup>(2)</sup>	38	25	24 <sup>(5)</sup>
Control Building	35	69 <sup>(3)</sup>	10 <sup>(5)</sup>
Reactor Auxiliary Bay <sup>(6) +</sup>	38	18 <sup>(7)</sup>	10 m at the highest roof

- (1) The bottom elevation of the Reactor Building foundation is approximately 36 m below grade.
- (2) The Radwaste Building wraps around the Reactor Building. Width of Radwaste Building is given as the shortest dimension of the building measured in the east-west direction.
- (3) The Turbine Building and Control Building width include portions of the Plant Services Area.
- (4) The height of the Turbine Building does not include the stacks or stairwells.
- (5) The height of the Radwaste Building and Control Building does not include chillers, ductwork, or other items on the roof.
- (6) The Reactor Auxiliary Bay is a portion of the Plant Services Area, to the east of the Reactor Building, that is supported on an independent foundation with respect to the surrounding Reactor Building, Control Building, and Turbine Building.
- (7) The Reactor Auxiliary Bay wraps around the Reactor Building. The width of Reactor Auxiliary Bay is given as the largest dimension of the building measured in the east-west direction.
- (8) For consistency, the length and width values in the table are all in the same direction. For DNNP-1, length is north-south, and width is east-west.

Refer to Chapter 3, Subsection 3.3.1, and Chapter 9B, Section 9B.2 and 9B.3 of the PSAR for additional information on seismic design of structures.

#### **1.5.2.1 Reactor Building**

The RB is a Safety Category 1 and Seismic Category A structure. It is a cylindrical shaped structure embedded in a vertical shaft to a depth of approximately 36 m below grade. The Reactor Pressure Vessel (RPV), Steel-plate Composite Containment Vessel (SCCV) and other important systems and components are located in the deeply embedded RB vertical right-cylinder shaft to mitigate effects of external events, including aircraft impact, adverse weather, fires, and earthquakes. The Secondary Control Room (SCR) is located in the RB. The below-grade portion also contains reactor support and safety class systems and the Safety Class 1 power supply and equipment. The reactor cavity pool is above the containment dome. Also, within the RB, three separate Isolation Condenser System (ICS) pools sit next to the reactor cavity pool above the SCCV, with one isolation condenser located in each pool. The Fuel Pool is also located in the RB.

#### **1.5.2.2 Turbine Building**

The TB houses the steam turbine generator, standby diesel generators, main condenser, condensate and feedwater systems, turbine-generator support systems, and parts of the Offgas System (excluding the offgas charcoal adsorbers).

While considered a separate functional area from the Turbine Building, the northern portion of the PLSA is structurally integrated with the Turbine Building. See Section 1.5.2.5 for a description of the PLSA.

The TB is a Safety Class 2 structure and is categorized as Non-Seismic. Additionally, it is evaluated for seismic interaction to ensure that it will not compromise the structural integrity and safety functions of the adjacent Seismic Category A RB following a Design Basis Earthquake (DBE) or extreme Tornado wind conditions.

#### **1.5.2.3 Control Building**

The CB houses the MCR, Emergency Operations Centre (EOC), electrical, control, and instrumentation equipment. The CB is a Safety Class 2 structure and is categorized as Non-Seismic. Additionally, it is evaluated for seismic interaction to ensure that it does not compromise the structural integrity and safety functions of the adjacent Seismic Category A RB following a DBE or extreme Tornado wind conditions. The CB serves as main entrance and exit for the Power Block unit during normal operations.

While considered a separate functional area from the Control Building, the southern portion of the Plant Services Area (PLSA) is structurally integrated with the Control Building. See Section 1.5.2.5 for a description of the PLSA.

#### **1.5.2.4 Radwaste Building**

The RWB houses rooms and equipment for handling, processing, and packaging liquid and solid radioactive wastes as well as the Offgas System charcoal adsorbers that are used for processing radioactive gas. Some of these systems contain highly radioactive materials. The RWB is classified as a Safety Class 3 building and categorized as RW-IIa in accordance with Regulatory Guide (RG) 1.143, Rev. 2, "Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light Water-Cooled Nuclear Power Plants." Additionally, it is also evaluated for seismic interaction to ensure that it will not compromise the structural integrity or safety functions of the adjacent Seismic Category A RB following a DBE or extreme Tornado wind conditions.

#### **1.5.2.5 Plant Services Area and Reactor Auxiliary Bay**

The PLSA houses a decontamination area, a contaminated part/tool storage room, a I&C calibration room, a truck space for cask removal, a hot machine shop, laydown areas for new fuel and the Fine Motion Control Rods Drives (FMCRD), and a miscellaneous storage area.

While the PLSA is a separate functional area from the CB and TB, the northern portion of the PLSA shares a foundation and is structurally integrated with the TB and the southern portion of the PLSA shares a foundation and is structurally integrated with the CB (see Figure A1.5-1).

A portion of the PLSA, the Reactor Auxiliary Bay, is constructed on a separate foundation with respect to the portions of the PLSA that are adjacent to the CB and TB. The functions performed in the Reactor Auxiliary Bay include new fuel and spent fuel cask transit, equipment ingress and egress to the RB, and personnel access to the RB. The Reactor Auxiliary Bay is a Safety Class 2 structure and is categorized as Non-Seismic. Additionally, it is evaluated for seismic interaction to ensure that it does not compromise the structural integrity and safety functions of the adjacent Seismic Category A RB following a DBE or extreme Tornado wind conditions.

## **1.6 Comparison with Other Plant Designs**

The BWRX-300 is based on the U.S. Nuclear Regulatory Commission (NRC) licensed, 1520 MWe Economic Simplified Boiling Water Reactor (ESBWR). The ESBWR is an evolution of the 600 MWe Simplified Boiling Water Reactor (SBWR) that has a significant testing and qualification program directly applicable to the BWRX-300.

The BWRX-300 is the tenth generation of the Boiling Water Reactor (BWR) that incorporates the lessons learned in design, construction, operations, and maintenance from over 100 previous BWRs that have been built, operated, and in some cases, decommissioned.

The BWRX-300 is specifically designed to enhance safety through simplification and reducing its dependence on human intervention. This is achieved through increasing its reliance on natural circulation and natural phenomena-driven safety systems. These safety enhancements, in combination with its reduction in scale and complexity, enable the reductions in operating staff, maintenance, and security requirements as well as being easier to decommission.

The BWRX-300 provides clean and flexible baseload electricity at a lifecycle cost that is much lower than the previous generation of NPPs operating today and competitive with other forms electricity generation such as natural gas combined-cycle plants and renewables.

### **1.6.1 Enhancements in Safety System Design**

Though mostly traditional in BWR design, the BWRX-300 includes several design features that simplify the design and enhance safety, such as:

1. **Reactor Isolation Valve location:** The BWRX-300 RPV is equipped with Reactor Isolation Valves which rapidly isolate a ruptured pipe to help mitigate the effects of a LOCA. All large fluid pipe systems are equipped with double isolation valves which are integral to the RPV. The valves are located as close as possible to the RPV.
2. **No Safety Relief Valves:** Safety relief valves have been eliminated from the BWRX-300 design. The large capacity Isolation Condenser System (ICS) provides overpressure protection in accordance with American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code (BPVC), Section III, Class 1 equipment. Historically on BWRs, the safety relief valve inadvertent actuation has been the most likely cause of a LOCA and have, therefore, been eliminated from the BWRX-300 design.
3. **Dry containment:** The BWRX-300 has a dry containment that is cooled through natural circulation during DBAs. This has been proven to effectively contain the releases of steam, water, and fission products after a LOCA.
4. **No external reactor recirculation loops:** Elimination of external reactor recirculation pumps and associated piping and a reimagined reactor pressure vessel provides a relatively large inherent reactor coolant volume and nozzle elevations significantly above the core. These features with a reliable passive emergency core cooling system provided by the isolation condensers eliminates the need for active emergency core cooling injection systems while ensuring larger safety margins than predecessor BWRs.
5. **No need for emergency diesel generators:** Elimination of active emergency core cooling systems eliminates the need for onsite emergency power systems. Standby diesel generators are provided for asset protection only.

Table 1.6-1 demonstrates how the BWRX-300 design has evolved to maximize passive safety features to achieve FSF in comparison to the design of previous BWR and other types of NPPs.

**Table 1.6-1: Comparison of BWRX-300 to Other NPP Types**

<b>Fundamental Safety Function</b>	<b>BWRX-300</b>	<b>BWRs</b>	<b>PWRs</b>	<b>CANDU</b>
Control Reactivity	Two Independent Means of Shut Down	Two Independent Means of Shut Down	Two Independent Means of Shut Down	Two Independent Means of Shut Down
Fuel Cooling	Passive Natural Circulation	Active Forced Circulation	Active Forced Circulation	Active Forced Circulation
Contain Radioactivity	Dry  Passive Cooling	Wet  Active Cooling	Dry  Active Cooling	Dry Reactor Building Wet Vacuum Building Active Reactor Building Cooling

## 1.6.2 Industry Incident Reviews

Station Blackout events have historically been the most demanding for BWRs to cope with and have usually been the dominant sequence for Severe Accident scenarios. The BWRX-300 is an advanced passive reactor design that does not require active safety systems. The BWRX-300 design carried forward the passive ICS and containment cooling concepts from the ESBWR. DC power sources are assumed to be available. The systems that support FSF and plant monitoring are designed to operate for 72-hours, without AC power, and without an intake structure that normally provides cooling water. The ICS pools and spent fuel pool have enough inventory to provide adequate decay heat removal and fuel cooling for seven days, after which alternate water makeup sources (e.g., flexible mitigation/EME) are used to refill the pools. The Passive Containment Cooling System (PCCS) is designed to passively limit containment pressure and temperature by transferring heat to the equipment pool. The demonstration of plant safety functions during a beyond design basis external event such as an earthquake that creates these conditions is typically part of the diverse and flexible coping strategies that form the basis for compliance of regulatory requirements related to the Fukushima tsunami event.

In April 2012, the Institute of Nuclear Power Operations conducted an independent review of the Fukushima nuclear accident with the purpose of identifying operational and organizational lessons learned from the accident. The results of this review are well documented.

The Fukushima accident was a Beyond Design Basis event. Design extension conditions are a selected subset of Beyond Design Basis accident conditions.

The BWRX-300 is designed for Design Extension Conditions, and these are described in detail in the BWRX-300 Safety Strategy.

## **1.7 Drawings and Other More Detailed Information**

A simplified representation of the major BWRX-300 systems and the flow of the reactor coolant is provided in Figure 1.7-1. A summary description of the major nuclear steam supply systems and components is provided below. Each of these systems are described in detail in applicable chapters of the PSAR.

### **1.7.1 Reactor Pressure Vessel and Internals**

The RPV is a vertical, cylindrical pressure vessel fabricated with forged rings and rolled plate welded together, with a removable top head, head flange, seals, and bolting. The vessel also includes penetrations, nozzles, and the shroud support. The RPV has a minimum inside diameter of approximately 4 m, a wall thickness of approximately 14 cm with cladding, and a height of approximately 26 m. The bottom of the active fuel region is approximately 5.2 m from the bottom of the vessel and the active core is 3.8 m high. The vertical orientated and tall vessel permits the development natural circulation driving forces to produce sufficient core coolant flow.

A diagram of the BWRX-300 RPV assembly is shown in Figure 1.7-2. The RPV, together with its internals, provides guidance and support for the Fine Motion Control Rod Drives (FMCRDs).

The major reactor internal components include:

- Core (fuel, channels, control rods and instrumentation)
- Core support and alignment structures (shroud, shroud support, top guide, core plate control rod guide tube, CRD housings, and orificed fuel support)
- Chimney
- Chimney head and steam separator assembly
- Steam dryer assembly
- Feedwater spargers
- In-core guide tubes

The fuel assemblies (including fuel rods and channels), control rods, chimney head, steam separators, steam dryer, and in-core instrumentation assemblies are removable when the reactor vessel is opened for refueling or maintenance. The RPV shroud support is designed to support the shroud, as well as the components connected to the shroud, including the steam separator, chimney, core plate, and top guide. The fuel bundles are supported by the orifice fuel support, the control rod guide tube, and the CRD housing.

### **1.7.2 Reactor Pressure Vessel Isolation Valves**

The BWRX-300 reactor incorporates isolation valves attached directly to the RPV. The function of the isolation valves is to close, limiting the loss of coolant from large and medium pipe breaks. The RPV isolation concept consists of two Reactor Isolation Valves in series. Each of the Reactor Isolation Valves is independently able to isolate the line.

### **1.7.3 Control Rod Drive System**

The CRD system includes three major elements: FMCRD mechanisms; Hydraulic Control Unit (HCU) assemblies; and the Control Rod Drive Hydraulic subsystem. The FMCRDs are designed to provide electric-motor-driven positioning for normal insertion and withdrawal of the control rods and hydraulic-powered rapid control rod insertion (scram) in response to manual or automatic signals. The hydraulic power required for scram is provided by high-pressure water stored in the individual HCUs. In addition to hydraulic-powered scram, the FMCRDs also provide electric-motor-driven run-in of all control rods as a path to rod insertion that is diverse from the hydraulic-powered scram.

### **1.7.4 Isolation Condenser System**

The ICS removes decay heat after any reactor isolation and shutdown event during power operations. The ICS decay heat removal limits increases in steam pressure and maintains the RPV pressure and water inventory at an acceptable level. The ICS consists of three independent loops that each contain a Heat Exchanger (HX) with capacity of approximately 33 MW, or approximately 3.7% of rated thermal power. Thermal energy removal condenses steam on the tube side and transfers heat by heating/evaporating water in the Isolation Condenser (IC) pools which are vented to atmosphere. The arrangement of the ICS HX is shown in Figure 1.7-3.

### **1.7.5 Instrumentation and Control**

The BWRX-300 Distributed Control and Information System (DCIS) is an integrated control and monitoring system for the power plant. The DCIS is arranged in three safety classified DCIS segments and a non-safety class segment with appropriate levels of hardware and software quality corresponding to the system functions they control and their DL location, as described in Chapter 3, Section 3.2. The DCIS provides control, monitoring, alarming and recording functions. The various bus segments of the integrated DCIS are designed to operate autonomously.

Control of reactivity in various postulated events is achieved by the instrumentation and control systems. Channels, trip logic, trip actuators, manual controls, and scram logic circuitry initiates the rapid insertion of control rods by hydraulic force to scram the reactor when unsafe conditions are detected. The hydraulic scram is actuated on signals derived from safety analyses and includes signals such as high core neutron power, RPV pressure, low RPV level, high containment temperature, high steam line flow, etc.

### **1.7.6 Containment**

The BWRX-300 Primary Containment Vessel encloses the RPV and some of its related systems and components. The Primary Containment Vessel is a leak-tight nitrogen inerted gas space surrounding the RPV and the Reactor Coolant Pressure Boundary (RCPB). It provides a leak-tight barrier to prevent the release of radioactive fission products, steam, and water in the unlikely event of a Loss of Coolant Accident (LOCA). The BWRX-300 uses a traditional containment system for the ultimate containment of radioactive materials for various postulated events. The containment shape is a vertical cylinder approximately 18 meters outside diameter and 38 meters high. It is integral to and surrounded by the Reactor Building (RB).

### **1.7.7 Passive Containment Cooling System**

The Passive Containment Cooling System (PCCS) is a passive containment heat removal system that maintains the containment within its pressure limits for design basis accidents such as a LOCA. It consists of several low-pressure natural circulation heat exchangers that transfer heat from the containment to the reactor cavity pool which is located above the containment upper head and is filled with water during normal operation. The reactor cavity pool is vented to the atmosphere. PCCS operation requires no sensing, control, logic, or power actuated devices for operation.

### **1.7.8 Boron Injection System**

The Boron Injection System (BIS) is a complementary design feature that provides an additional means to place the plant in a cold shutdown mode. The BIS provides an additional means of negative reactivity insertion to bring the reactor subcritical during events when the control rod insertion (hydraulic and motor) is not successful.

### **1.7.9 Reactor Water Cleanup System**

The Reactor Water Cleanup System provides the design functions of a cleanup flow path from the RPV to filter/demineralizer skids during most reactor operating modes. The cleanup or filtration function and ion removal function is performed by the condensate system.

### **1.7.10 Shutdown Cooling System**

The Shutdown Cooling (SDC) System is designed to support RPV Startup and Shutdown/Cooldown Operations. The SDC consists of two independent trains with a motor driven pump, a heat exchanger, required valves, piping, controls, and power inputs.

### **1.7.11 ICS Pool Cooling and Cleanup System**

The Isolation Condenser Pool Cooling and Cleanup System (ICC) is designed to maintain the water in the ICS pools cool and clean.

The primary function of the ICC is to remove heat from the Isolation Condenser System (ICS) pools such that the bulk temperature of water in the pools is maintained below prescribed limits, and thereby ensure the readiness of the ICS to perform its safety function. Secondary functions of the ICC include maintaining the cleanliness of the ICS pool water and providing the capability to add clean makeup water during normal reactor operations to offset the routine and minor loss of water inventory due to evaporation.

### **1.7.12 Fuel Pool Cooling and Clean System**

The Fuel Pool Cooling and Cleanup System (FPC) provides continuous cooling by removal of the decay heat from the spent fuel and maintains the Fuel Pool temperature below specified values. The system also maintains water level and water quality in the fuel pool, and reactor cavity pool. The FPC consists of one cooling and clean-up train provided with 100% capacity during normal operation (including pool maximum heat load).

### **1.7.13 Containment Inerting System**

The Containment Inerting System precludes the combustion of hydrogen and prevents damage to essential equipment and structures. It establishes and maintains an inert atmosphere ( $\leq 4\%$  dry-basis-percent (DB%) oxygen) within containment during plant operating modes except during shutdown for refueling/maintenance and for limited periods of time during low power operation for inspection. The system also maintains a slightly positive pressure in containment to prevent air (oxygen) in-leakage into the inerted spaces from the Reactor Building.

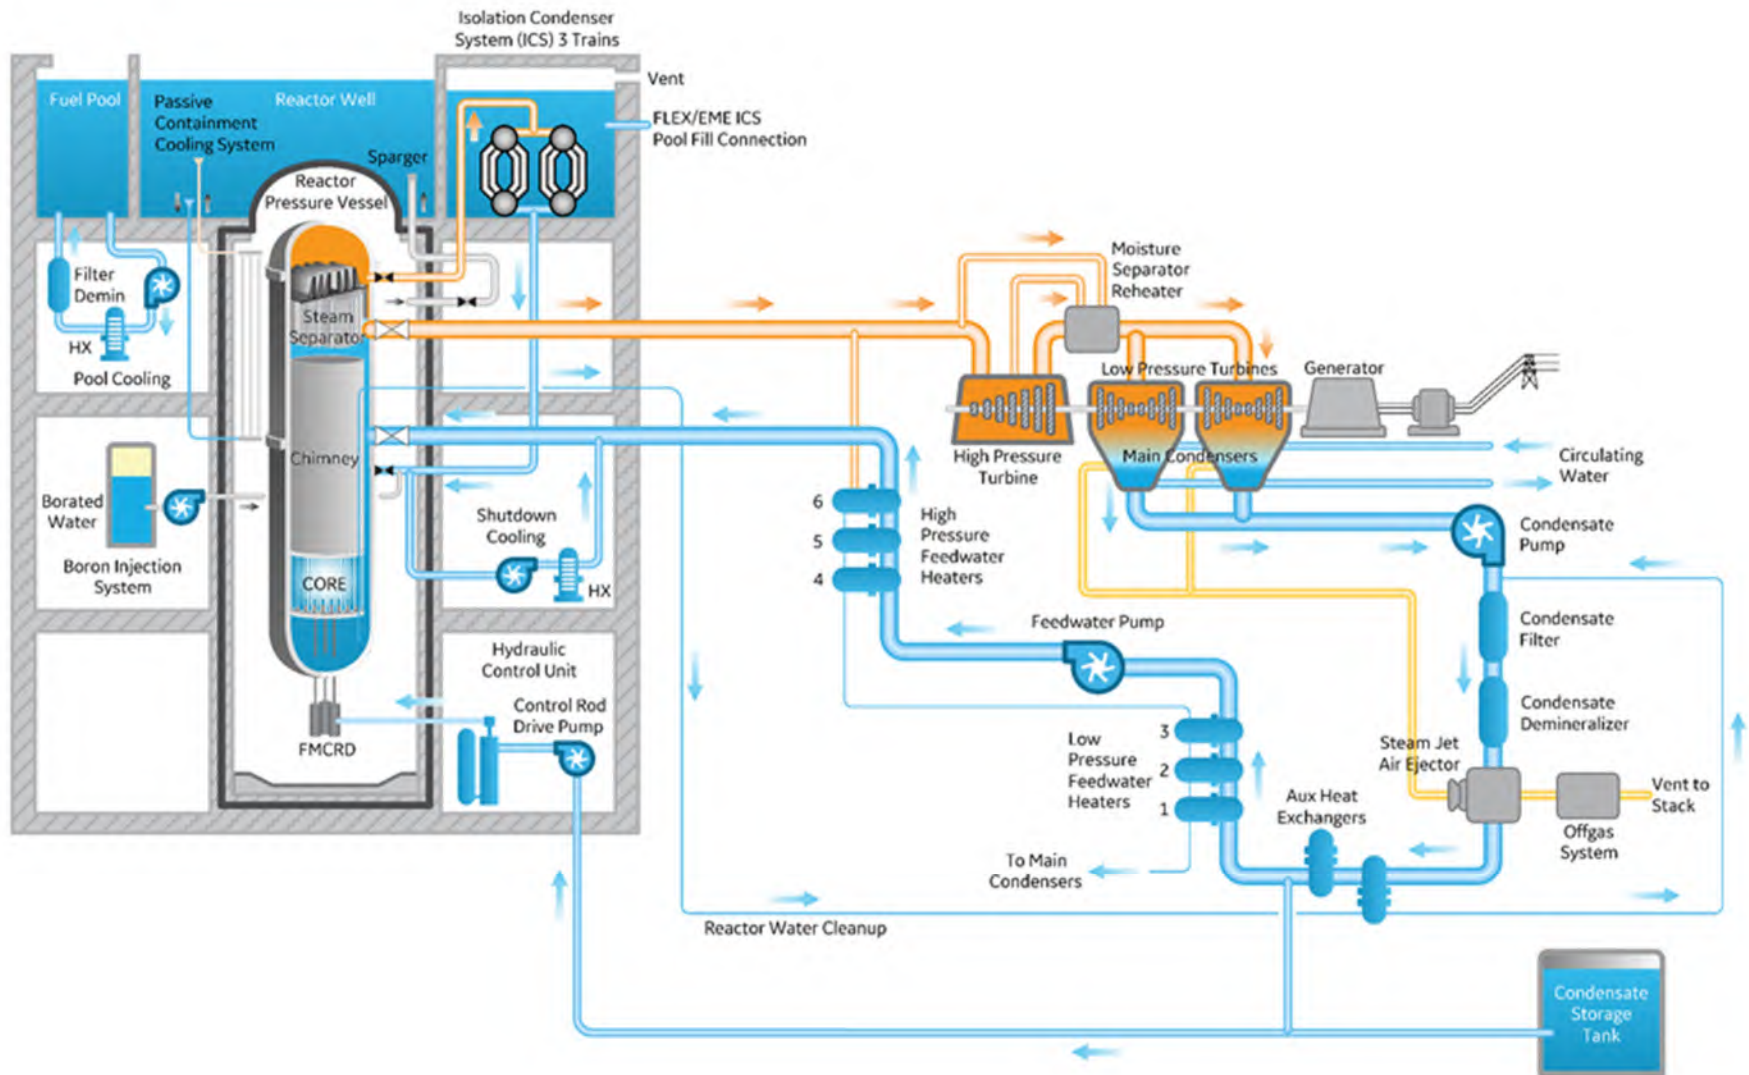

Figure 1.7-1: BWRX-300 Major Systems

Figure 1.7-2: BWRX-300 RPV and Internals

**Figure 1.7-3: Isolation Condenser System**

### **1.8 Modes of Normal Operation of the Plant**

The normal operating modes are listed below and described in detail in Chapter 16. Chapter 15 includes a discussion of the plant design envelope, which comprises all plant states considered in the design, normal operation, Anticipated Operational Occurrence (AOO), Design Basis Accident (DBA), and Design Extension Condition (DEC).

Specific operational states and accident conditions and responses to these events for the BWRX-300 design are described in the deterministic safety analyses in Chapter 15.

The normal plant operational modes are listed below:

- Mode 1        Power Operation
- Mode 2        Startup
- Mode 3        Hot Shutdown
- Mode 4        Stable Shutdown
- Mode 5        Cold Shutdown
- Mode 6        Refueling

## **1.9 Principles of Safety Management**

The prime responsibility for safety of the facility rests with OPG which is the owner, operator, and licensee. This responsibility includes operating activities performed by OPG and the oversight of activities performed by contracted organizations, such as design, procurement construction, commissioning, and decommissioning. All activities performed, either directly by OPG or indirectly under OPG's oversight, are controlled in accordance with OPG's N-CHAR-AS-0002, "Nuclear Management System" (Reference 1.9-1), which is the top management system of the facility. The system is implemented by a series of program documents which in turn define the required implementing procedures and standards. Chapter 17 of this PSAR provides details regarding the management for safety, including the different management processes aimed at ensuring safety is given the highest priority, the specific elements of the management system, quality management, and the nuclear safety culture framework.

The management system promotes safety culture by committing workers to adhere to its implementing practices that contribute to the excellence in worker performance, supporting workers in carrying out their tasks safely and successfully, and monitoring to improve the culture. The organizational structure implements the programs that make up the OPG management system with the Chief Nuclear Officer accountable for its implementation and effectiveness.

A structured operating organization is established having defined authorities, managerial responsibilities, interfaces between organizations and policies for use of contracted resources such that safety is the overriding priority. An organizational approach is taken that assures the required capabilities and qualifications necessary to always maintain nuclear safety and the integrity of the safety case. This includes maintaining sufficient capability within the operating organization to effectively manage the design and licensing basis of the facility and preventing the over-reliance on contractors. Additionally, the operating organization ensures changes having any potential impact on the safety of the public and workers, the environment, and Canada's international obligations are thoroughly assessed and demonstrated to be acceptable throughout the life of the facility.

### **1.11 Conformance with Applicable Regulations, Codes and Standards**

The Nuclear Safety and Control Act (NSCA) establishes the Canadian Nuclear Safety Commission (CNSC) and provides the CNSC with the authority to regulate the development, production and use of nuclear energy and the production, possession and use of nuclear substances, prescribed equipment, and prescribed information in Canada. Class I Nuclear Facilities Regulations (SOR/2000-204) are applicable to nuclear fission reactors that includes the BWRX-300 at the DNNP facility. It provides the requirements for the different types of applications for Class I nuclear facilities.

The CNSC's regulatory framework, shown in Figure 1.11-1 below, consists of laws passed by Parliament that govern the regulation of Canada's nuclear industry, and regulations, licences, and documents that the CNSC uses to regulate the industry. The CNSC publishes regulatory documents (REGDOCs) that are instruments that clarify, resulting in consistent implementation of, regulatory requirements and expectations. Regulatory requirements and expectations are further supported by codes and standards published by domestic and international agencies.

**Figure 1.11-1: CNSC Regulatory Framework**

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

Laws, regulations, codes, and standards are one of numerous sources of design requirements that the design of a Nuclear Power Plant (NPP) must satisfy. The RCS applicable to the licensing basis and the design basis of SSCs within the Protected Area are managed in accordance with the GEH BWRX-300 requirement management plan that is depicted in Figure 1.11-2 below.

The identification and implementation of design requirements, which includes applicable RCS, is an iterative process that evolves with the maturity of the design and is managed throughout the design lifecycle. To align with the requirements management plan, the following levels of RCS are defined in support of the licensing process and the PSAR development:

- Source Level RCS (licensing basis)
- Plant Level RCS (design basis)
- System Level RCS (design basis)
- Component Level RCS (design basis)

Source Level RCS are those applicable jurisdictional requirements that establish part of the licensing basis of the SSCs within the Protected Area.

Plant System, and Component Level RCS are those that govern the design of the facility that establishes the design basis. As described above, the identification and implementation of the relevant level RCS is dependent on the maturity of the design and may not have been implemented from the onset of the design. For the purposes of the LTC and the PSAR, Plant Level RCS is commensurate with the state of design progression.

The above levels recognize that the identification and implementation of RCS is a managed and iterative process. As indicated in Figure 1.11-2, decisions that support the identification, selection, and implementation of design requirements, including RCS, at the various levels are documented and controlled. The repository used for the management of applicable RCS, including supporting decisions, throughout the design lifecycle of the facility is the requirements management tool.

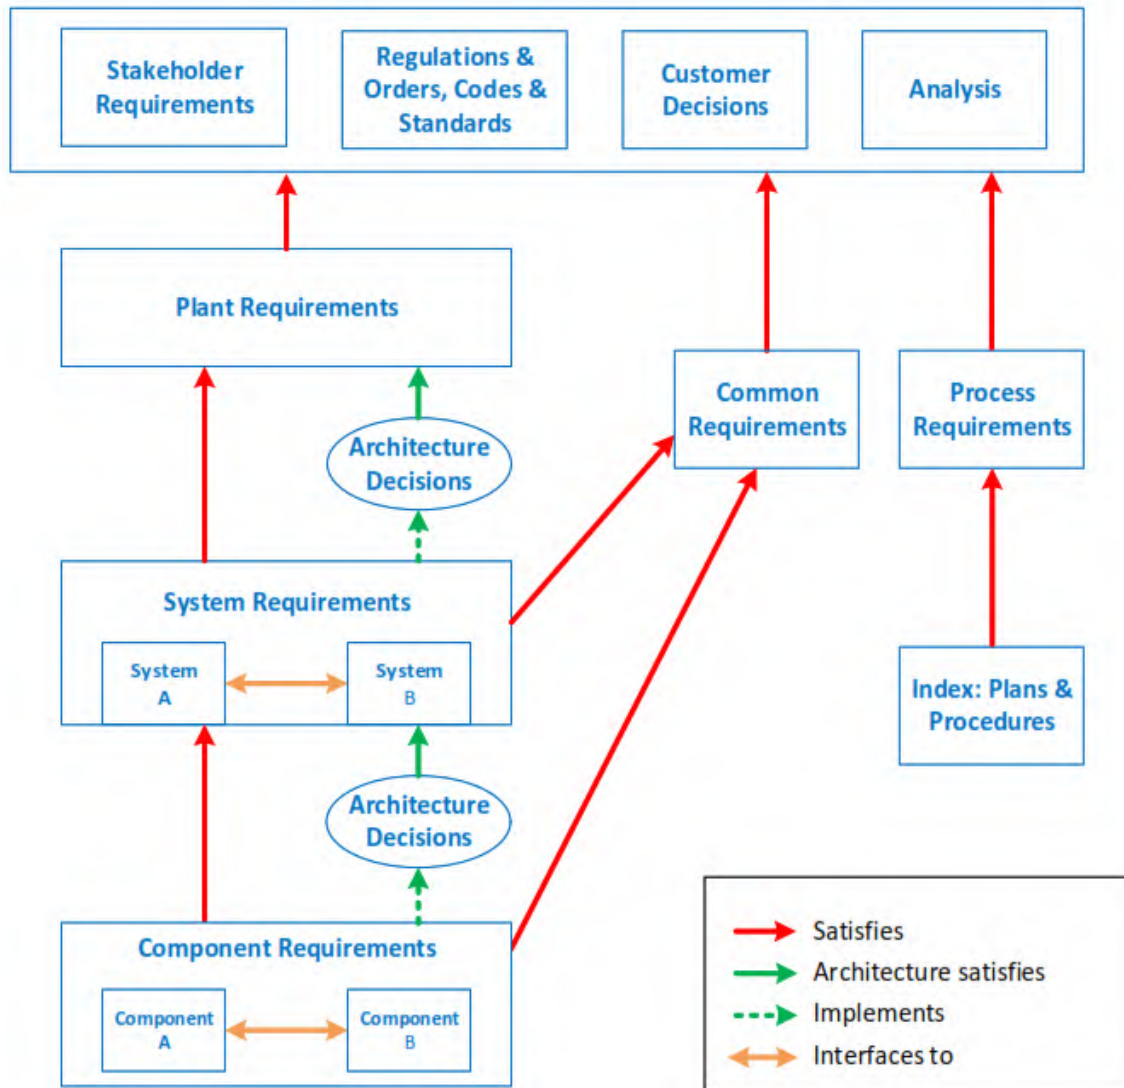

Figure 1.11-2: GEH Requirements Hierarchy

NEDO-33950 REVISION 2  
NON-PROPRIETARY INFORMATION

The Source Level licensing basis RCS that are applicable to the LTC of the facility along with the methodology used in its development are documented in NK054-REP-01210-00137, "DNNP License to Construct Regulatory Documents, Codes & Standards," (Reference 1.11-1).

The design basis RCS that governs the design of the facility, including the BWRX-300 reactor, are documented in Appendix B. These RCS contain design related requirements applicable to the facility. RCS reference throughout the PSAR, not listed in Appendix B, are used for guidance only.

Table B1.11-1 includes the list of applicable Source Level design basis REGDOCs that originates from Source Level licensing basis REGDOCs documented in Reference 1.11-1 that are screened to eliminate those not applicable to the design of Power Block.

Table B1.11-2 includes the list of applicable Plant Level design basis codes and standards that originates from Source Level licensing basis codes and standards documented in Reference 1.11-1 that are screened to eliminate those not applicable to the design of the facility.

Table B1.11-3 includes the list of Plant Level US regulatory codes that are applicable to the facility. The method used to develop the lists followed this general process:

The strategy used to evaluate codes and standards for their applicability, sufficiency, and adequacy for the OPG BWRX-300 design is based on the licensing basis codes and standard provided by OPG.

1. The licensing basis list is evaluated to determine which of the codes and standards forms the design basis.
2. Subsequent review of the GEH documentation is completed to determine the remaining codes and standards to develop the plant level design basis.
3. The system level list is next developed with the codes and standards from the system design documentation.
4. Each code and standard are reviewed for applicability with the responsible design engineer.

**REVISION SUMMARY**

<b>Revision #</b>	<b>Section Modified</b>	<b>Revision Summary</b>
0	All	Initial Release
1	Section 2.1.2 Section 2.2.3 Section 2.5.1 Section 2.6.4 Section 2.6.5 Section 2.6.8 Section 2.6.9 Section 2.7.1 Section 2.7.2 Section 2.7.3 Section 2.8.2 Section 2.11.4 Section 2.12.1 Section 2.12.5 Section 2.12.8	Incorporated corrections per customer acceptance review
2	All	Edited to improve readability, streamline the text, and ensure consistency across all sections of Chapter 2
	All	Several paragraphs are deleted for they became irrelevant, outdated, or obsolete due to the incorporation of recent (2022 and 2023) information generated in works involving DNNP site-specific investigations, analyses, and assessments.
	All Summary Tables	The tables at the beginning of each section are updated to reflect the edited and added contents of corresponding texts in that section.
	All Other Tables	Other tables are updated or replaced with inputs from new characteristics and parameters generated in the site-specific studies completed in 2022 and 2023.
	All Figures	Updated or replaced to reflect the new information resulted from several 2022 and 2023 assessments, investigations, and analyses
	Acronym List	Updated to include added acronyms

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

<b>Revision #</b>	<b>Section Modified</b>	<b>Revision Summary</b>
	Section 2.0	Chapters 7, 19 and 20 added to the list of key chapters, and edits involving details are made to previously listed chapters
	Section 2.1.1	Paragraphs added on Site Topography regarding the different grade elevations at and around the Darlington Nuclear site
	Section 2.1.1	Edited to incorporate information in Reference 2.1-7
	Section 2.1.2	Edited to reflect current contents of Chapter 9B, and to incorporate the information in the 2022 Environmental Impact Assessment in Reference 2.1-4
	Section 2.1.2.1	Edited to incorporate information in the 2022 References 2.1-4, 2.1-5, and 2.1-6
	Section 2.1.2.3	A new bullet added to reflect information on the heavy haul routes described in Reference 2.1-4
	Section 2.1.2.4	Added bullets number 6 And 7 regarding not using the cooling towers and combing the primary and secondary heat transport systems
	Section 2.1.10	Added seven new References 2.1-4 to 2.1-9
	Section 2.2.2	Added a paragraph on the 2022 DNNP Hazard Analysis Methodology (Reference 2.2-10)
	Section 2.2.3.2	Edited to incorporate information in the 2022 assessments reported in Reference 2.2-11 and Reference 2.2-12
	Section 2.2.5.2	Edited to incorporate information in the 2022 PNGS re-assessment documented in Reference 2.2-13
	Section 2.2.11	Three references added: 2.2-13, 2.2-14 and 2.2-15
	Section 2.4.2	Paragraphs added to reflect information in the 2022 EIS in Reference 2.4-2
	Section 2.4.3	Two references added: the 2022 Reference 2.4-2 and the 2009 Reference 2.4-3
	Section 2.5.2.1	Edited and updated to incorporate information in the 2022 Flood Hazard Assessment documented in Reference 2.5-18
	Section 2.5.3 and associated subsections	Edited and updated to incorporate information in the 2022 Reference 2.5-18, Reference 2.5-19
	Section 2.5.3.1	Deleted DNGS information that became irrelevant

NON-PROPRIETARY INFORMATION

Revision #	Section Modified	Revision Summary
	Section 2.5.3.3	A new Table 2.5-2 is added
	Section 2.5.3.4	Deleted DNGS information that became irrelevant and edited to incorporate information in the 2022 Reference 2.5-18
	Section 2.5.4	Edited and updated to incorporate information in the 2022 Reference 2.5-18 and the 2023 Climate Change Impact Strategy documented in Reference 2.5-20
	Section 2.5.5 and associated subsections	Edited and updated to incorporate information in the 2022 References 2.5-18 and 2.5-21
	Section 2.5.6 and associated subsections	Edited and updated to incorporate information in the 2022 Reference 2.5-18
	Section 2.5.7	Added four new References: 2.5-18 and 2.5-21
	Section 2.6.2	Edited and updated to incorporate information in the 2022 Flood Hazard Assessment in Reference 2.6-17
	Section 2.6-4	Edited and updated to incorporate information in the 2022 Reference 2.6-17
	Section 2.6-5	Edited and updated to incorporate information in the 2022 Wind Gust Analysis in Reference 2.6-14
	Section 2.6-5	Added new Table 2.6-3 and Table 2.6-4
	Section 2.6.9	Edited and updated to incorporate information in the 2022 Winter PMP Validation in (Reference 2.6-15)
	Section 2.6.9	Added new Table 2.6-7
	Section 2.6.12	Edited to incorporate information in the 2023 Climate Change Impact Strategy in Reference 2.6-19
	Section 2.6.13	Added six new References: 2.6-14, 2.6-15, 2.6-16 and 2.5-18
	Section 2.7	<p>The entire Section 2.7 is re-configured to incorporate new information documented in:</p> <ol style="list-style-type: none"> <li>1. The 2023 DNNP Foundation Interface Analysis (FIA) Report (Reference 2.7-38).</li> <li>2. The 2022 DNNP geotechnical investigations and test results, Phase-1 Power Block (Reference 2.7-39)</li> <li>3. The 2023 offshore geotechnical investigations (Reference 2.7-40)</li> </ol>

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Revision #	Section Modified	Revision Summary
		<p>4. The 2022 DNNP-specific Probabilistic Seismic Hazard Assessment (PSHA) (Reference 2.7-41)</p> <p>5. The 2022 DNNP seismically-induced soil liquefaction assessment (Reference 2.7-42)</p> <p>Added referencing to the 2022 and 2023 completed DNNP/BWRX-300 investigations, analyses, and assessments.</p>
	Section 2.7.1	Deleted irrelevant DNGS information and outdated information
	Section 2.7.2.4	Added information based on the 2023 offshore investigations (Reference 2.7-40), and deleted outdated information
	Section 2.7.3.1	Updated relevant figures, and added information based on the 2022 BWRX-300 Power Block geotechnical investigations (Reference 2.7-39)
	Section 2.7.3.2	Edited and added new information, including Table 2.7-1, Table 2.7-2, and Table 2.7-3, documented in the results and figures from the 2022 Power Block geotechnical investigations (Reference 2.7-39)
	Section 2.7.3.3	Deleted outdated information, made edits, and added new information, per in the results and figures in the 2023 FIA Report (Reference 2.7-38), and the 2022 Power Block geotechnical investigations (Reference 2.7-39)
	Section 2.7.4.1	Introduced the 2022 DNNP PSHA (Reference 2.7-41)
	Section 2.7.4.3	Added information and updated relevant figures based on information in the 2022 PSHA (Reference 2.7-41)
	Section 2.7.4.4	Added information and updated relevant figures based on the 2022 PSHA (Reference 2.7-41)
	Section 2.7.4.6	<ul style="list-style-type: none"> <li>This subsection is currently dedicated to present the results of the work performed in the 2022 PSHA report (Reference 2.7-41)</li> </ul> <p>Outdated information deleted</p>
	Section 2.7.4.7	<ul style="list-style-type: none"> <li>Added information under “Surface Faulting” based on findings reported in the 2022 geotechnical investigations (Reference 2.7-39)</li> <li>Added information on potential liquefaction based on the results reported in the 2022 Soil Liquefaction Assessment report (Reference</li> </ul>

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Revision #	Section Modified	Revision Summary
		2.7-42) and the 2022 PSHA (Reference 2.7-41) Added new figures
	Section 2.7.4.8	<ul style="list-style-type: none"> <li>This subsection is discontinued</li> </ul> <p>Previous information in Subsection 4.7.4.8 pf Revision 1 was merged into other Subsections of Section 2.7</p>
	Section 2.7.5	<ul style="list-style-type: none"> <li>Added referencing to the 2022 NK054-REP-01210-00175 Phase I Geotechnical Investigations (Reference 2.7-39) and the 2023 DNNP FIA report (Reference 2.7-38)</li> <li>Focus is on providing DNNP and BWRX-300 characteristics and parameters</li> </ul> <p>Information on “Bounding Design” is deleted as such information is detailed in Chapter 3, Section 3.3.1.1</p>
	Section 2.7.5.1	<p>New information added and updates made based on the 2023 FIA (Reference 2.7-38) and the 2022 DNNP Power Block geotechnical investigations (Reference 2.7-39); ); including:</p> <ul style="list-style-type: none"> <li>2.7.5.1.2 Bearing Capacity Evaluation for Proposed Foundations</li> <li>2.7.5.1.3 Earth Pressure</li> </ul> <p>2.7.5.1.4 Time-Dependent Deformation for Proposed Foundations</p>
	Section 2.7.5.2 and associated Subsections	<p>Outdated information deleted, new information added, and updates made based on the 2023 FIA (Reference 2.7-38) and the 2022 DNNP Power Block geotechnical investigations (Reference 2.7-39); including:</p> <ul style="list-style-type: none"> <li>2.7.5.2.1 Subgrade Profiles Stratigraphy</li> <li>2.7.5.2.2 Equivalent Linearized Static Properties of Soil and Engineered Fill Materials</li> <li>2.7.5.2.3 Equivalent Linearized Static Properties of Rock</li> <li>2.7.5.2.4 Dynamic Subgrade Properties</li> <li>2.7.5.2.5 Seismic Design Parameters</li> </ul> <p>2.7.5.2.6 Groundwater Level</p>
	Section 2.7.5.3	<p>New information added and updates made based on the 2022 DNNP Power Block geotechnical investigations (Reference 2.7-39)</p>

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

<b>Revision #</b>	<b>Section Modified</b>	<b>Revision Summary</b>
	Previous Section 2.7.5.4	Information in Revision 1, Subsection 2.7.5.4 titled “Site Response Analysis” is deleted, since it is covered in Chapter 3, Subsection 3.3.1.1.2
	Previous Section 2.7.5.5	Information in Revision 1, Subsection 2.7.5.5 titled “Design Response Spectra for BWRX-300 at DNNP Site” is deleted and replaced with new information in Subsection 2.7.5.2.5.1 on Ground Motion Spectra
	Previous Section 2.7.5.6	Information in Revision 1, Subsection 2.7.5.6 on “Strain-Compatible Subgrade Profiles for BWRX-300 at DNNP Site” is deleted and replaced with new information in Subsection 2.7.5.2.5.2 on Strain-Compatible Soil properties
	Section 2.7.6	<ul style="list-style-type: none"> <li>Due to the reconfiguration of Section 2.7, several references in Revision 1 are deleted since they are not referenced anymore in Revision 2. The previous identifying numbers of such Revision 1 references were 2.7-20, -22, -23, -27, -28, -29, -33, -38, -39, -40, -42, -43, -44, -45, -46, -47</li> </ul> <p>New references added, from the current Reference 2.7-31 to Reference 2.7-43, inclusive</p>
	Section 2.8	Added Bullet number 6 for and edited the text based on the information in the 2022 DNNP EIS (Reference 2.8-10)
	Section 2.8.7	Added (Reference 2.8-10) regarding the 2022 DNNP EIS
	Section 2.9	Added a new bullet for and edited the text based on the information in the 2022 DNNP EIS (Reference 2.9-16)
	Section 2.9.3	Added (Reference 2.9-16) regarding the 2022 DNNP EIS
	Section 2.10	Introduced and added Table 2.10-1 titled Summary of DNNP Site Relevant Characteristics and Parameters
	Section 2.11.3	Introduced the work completed on FIA (Reference 2.11-19) and the Geotechnical investigations in (Reference 2.11-20)

### ACRONYM LIST

Acronym	Explanation
3D	Three-Dimensional
AOO	Anticipated Operational Occurrence
BDBA	Beyond Design Basis Accident
BDBE	Beyond Design Basis Earthquake
BL-AOO	Baseline Abnormal Operational Occurrence
BWR	Boiling Water Reactor
BWRX-300	Boiling Water Reactor, 10 <sup>th</sup> Design – 300 MWe
CANDU	CANada Deuterium Uranium
CAV	Cumulative Absolute Velocity
CB	Control Building
CEUS	Central Eastern United States
CGD	Canadian Geodetic Datum
CNEP	Consolidated Nuclear Response Plan
CNSC	Canadian Nuclear Safety Commission
CWS	Circulating Water System
DBA	Design Basis Accident
DBE	Design Basis Earthquake
DEC	Design Extension Condition
D-in-D	Defence-in-Depth
DNGS	Darlington Nuclear Generating Station
DNNP	Darlington New Nuclear Project
DRL	Derived Release Limit
DSA	Deterministic Safety Analysis
DWMF	Darlington Waste Management Facility
EA	Environmental Assessment
EIS	Environmental Impact Statement
EME	Emergency Mitigating Equipment
EMP	Environmental Monitoring Program
EPRI	Electric Power Research Institute
ERA	Environmental Risk Assessment
FHA	Fire Hazards Assessment

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
FIA	Foundation Interface Analysis
FPC	Fuel Pool Cooling and Cleanup System
HCSC	Hazard-Consistent, Strain-Compatible
HU	Hydrostratigraphic Unit
HVAC	Heating, Ventilation, and Air Conditioning
IAEA	International Atomic Energy Agency
IC	Isolation Condenser
ICC	ICS Pool Cooling and Cleanup System
ICS	Isolation Condenser System
INPO	Institute of Nuclear Power Operations
LOCA	Loss-of-Coolant Accident
LOPP	Loss-of-Preferred Power
LTC	Licence to Construct
MCA	Main Condenser and Auxiliaries
MCR	Main Control Room
NHS	Normal Heat Sink
NSCA	Nuclear Safety and Control Act
OPG	Ontario Power Generation
PCW	Plant Cooling Water System
PEOC	Provincial Emergency Operations Centre
PIE	Postulated Initiating Event
PMF	Probable Maximum Flood
PMP	Probable Maximum Precipitation
PNERP	Provincial Nuclear Emergency Response Plan
PNGS	Pickering Nuclear Generating Station
POSAR	Pre-Operational Safety Analysis Report
PPE	Plant Parameter Envelope
PSA	Probabilistic Safety Assessment
PSHA	Probabilistic Seismic Hazard Assessment
RB	Reactor Building
RPV	Reactor Pressure Vessel
RWB	Radwaste Building

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
SA	Severe Accident
SAA	Severe Accident Analysis
SAM	Severe Accident Management
SAMG	Severe Accident Management Guideline
SCR	Secondary Control Room
SMR	Small Modular Reactor
SPT	Standard Penetration Test
SRA	Site Response Analysis
SSI	Soil-Structure Interaction
SSC	Structures, Systems, and Components
TB	Turbine Building
TLD	Thermoluminescent Dosimeter
UCS	Uniaxial Compression Stress
UHRs	Uniform Hazard Response Spectrum
USNRC	United States Nuclear Regulatory Commission
WPCP	Water Pollution Control Plant

## TABLE OF CONTENTS

<b>2.0</b>	<b>SITE CHARACTERISTICS .....</b>	<b>2-1</b>
2.1	Geography and Demography .....	2-5
2.1.1	Darlington Nuclear Site Context and Surrounding Land Uses .....	2-8
2.1.2	BWRX-300 Facility Layout and Exclusion Zone .....	2-10
2.1.3	Population Distribution and Density .....	2-12
2.1.4	Municipal Services .....	2-12
2.1.5	Site Access and Transportation Networks .....	2-13
2.1.6	Public Transit .....	2-13
2.1.7	Active Hiking and Cycling Trails.....	2-14
2.1.8	Park Spaces and Waterbodies .....	2-14
2.1.9	Industrial Facilities .....	2-14
2.1.10	References.....	2-14
2.2	Evaluation of Site-Specific Hazards .....	2-22
2.2.1	Introduction .....	2-22
2.2.2	External Hazards Evaluation Methodology .....	2-26
2.2.3	Characterization of Hazards from Transportation Accidents, Including Toxic Chemicals or Gas Releases/Explosions.....	2-27
2.2.4	Characterization of Stationary Non-Nuclear Accidents Hazards.....	2-31
2.2.5	Characterization of Stationary Nuclear Accidents Hazards .....	2-32
2.2.6	Characterization Industrial Hazards .....	2-35
2.2.7	Characterization of Biological, Animal, and Frazil Ice Hazards.....	2-35
2.2.8	Characterization of Ice Storm Hazard .....	2-36
2.2.9	Characterization of Electromagnetic Interference Hazard .....	2-37
2.2.10	Characterization of On-site Methane Hazard.....	2-37
2.2.11	References.....	2-38
2.3	Proximity of Industrial, Transportation and Other Facilities.....	2-39
2.3.1	Transportation Network.....	2-39
2.3.2	Industrial Facilities .....	2-39
2.3.3	Darlington Nuclear Generating Station Site .....	2-40
2.3.4	References.....	2-40
2.4	Plant Site Activities Influencing Plant Safety .....	2-41
2.4.1	Site Hazards .....	2-41
2.4.2	Measures of Site Protection.....	2-45

## 2.0 SITE CHARACTERISTICS

Information in Chapter 2 details the site characteristics and their evaluation in support for the design, safety assessment and periodic safety review (Reference 2.0-4) of the Boiling Water Reactor, 10<sup>th</sup> Design – 300 MWe (BWRX-300) facility (also known as BWRX-300 facility). Over the planned design life (refer to Chapter 1, Table 1.5-1) of the BWRX-300 facility, the information in Chapter 2 will periodically be updated (Reference 2.0-4) to risk-inform the evaluation and implications of any such updates on safety.

Chapter 2 includes the following characteristics of Ontario Power Generation's (OPG) Darlington New Nuclear Project (DNNP) site and the surrounding region:

- Geography and Demography (Section 2.1)
- Evaluation of Site-specific Hazards (Section 2.2)
- Proximity of Industrial, Transportation and Other Facilities (Section 2.3)
- Plant Site Activities Influencing Plant Safety (Section 2.4)
- Hydrology (Section 2.5)
- Meteorology (Section 2.6)
- Geology, Seismology, and Geotechnical Engineering (Section 2.7)
- Potential Effects of Nuclear Power Plants in the Region (Section 2.8)
- Radiological Conditions due to External Sources (Section 2.9)
- Site-related Issues in Emergency Preparedness and Response, and Accident Management (Section 2.10)
- Monitoring of Site-related Parameters (Section 2.11)

Chapter 2 also includes Section 2.12 which describes OPG's disposition plans to finalize remaining DNNP site-specific characterization work including, for example, Foundation Interface Analysis (FIA), confirmatory site geological and seismic hazard investigations, and climate change effects on-site hydrological and meteorological parameters.

The following key chapters should be referred for additional information relevant to the material reported in Chapter 2:

1. Chapter 1: Introduction and General Considerations

Information in Chapter 1, Sections 1.4 and 1.5 describes the DNNP site layout, as well as the BWRX-300 facility footprint, key parameters, and basic dimensions of key buildings in the Power Block.

2. Chapter 3: Safety Objectives and Design Rules for Structures, Systems, and Components

Chapter 3, Section 3.3 includes information on the BWRX-300 design approach to prevent and mitigate the effect of external hazard on safety-classified structures, systems, and components (SSCs). Also, Chapter 3, Subsection 3.5.5.2 describes the design loads and load combinations on the deeply embedded Reactor Building (RB) structure.

3. Chapter 6: Engineered Safety Features

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Information is provided in Chapter 6, Section 6.2 on the design of the Isolation Condenser System; and in Section 6.4 on the BWRX-300 control room habitability features including missile protection, radiation shielding, radiation monitoring, air filtration and ventilation systems, lighting, and fire protection.

4. Chapter 7: Instrumentation and Control

Measures for fire protection and qualification for electromagnetic compatibility are described in Chapter 7.

5. Chapter 9A: Auxiliary Systems

Chapter 9A presents information on the BWR-X-300 fuel storage and handling system in Subsection 9A1.2, Fuel Pool Cooling and Cleanup System (FPC) in Subsection 9A1.3, Plant Cooling Water System (PCW) in Subsection 9A.2.1, Normal Heat Sink (NHS) in Subsection 9A.2.5, Isolation Condenser System Pool Cooling and Cleanup System (ICC) in Subsection 9A.2.6, Heating, Ventilation, and Air Conditioning (HVAC) Systems in Section 9A.5, Fire Protection Systems, in Section 9A.6.

6. Chapter 9B: Civil Engineering Works and Structures

General design requirement information is provided in Chapter 9B, Section 9B.2 on the integrated RB, and Section 9B.3 on other structures including other buildings in the Power Block, the Pumphouse/Forebay as well as the intake and discharge tunnels.

7. Chapter 10: Steam and Power Conversion Systems

In Chapter 10, information related to equipment functions, design basis, operation, and maintenance is presented in Section 10.5 for the Main Condenser and Auxiliaries (MCA) system, and in Section 10.8 for the Circulating Water System (CWS).

8. Chapter 15: Safety Analysis

Chapter 15, Subsection 15.5.3 documents the Deterministic Safety Analysis (DSA) of bounding Baseline Abnormal Operational Occurrences (BL-AOOs), while 15.5.4 evaluates the bounding BWRX-300 Design Basis Accidents (DBAs) involving Loss-of-Coolant Accidents (LOCA) and non-LOCA. Also, Subsections 15.5.5 and 15.5.6 present analyses of Design Extension Conditions (DECs) with and without core damage, respectively. Furthermore, Subsection 15.6.1 described the general approach to the Probabilistic Safety Analysis (PSA) while Section 15.7 includes results of analyzed DSA and PSA bounding events. Finally, Appendix 15A demonstrates implementing Defence-in-Depth (D-in-D) provisions ensures protection against unacceptable radiation releases

9. Chapter 19: Emergency Preparedness and Response

The development of the DNNP nuclear emergency response plan is presented in Section 19.1, the emergency response facilities are described in Section 19.2, and the accident assessment techniques are detailed in Section 19.3.

10. Chapter 20: Environmental Aspects

Chapter 20 describes OPG's Environmental Monitoring Program in Subsection 20.11.2, Effluent Monitoring Program in Subsection 20.11.3, and Groundwater Monitoring Program in Subsection 20.11.4.

11. BWRX-300 Security Annex

The prescribed information in the Security Annex documents the analysis of a large commercial aircraft crash.

## Scope

Chapter 2 scope includes the establishment of site characteristics that comprise information such as:

1. The site location, the area under control of OPG, and the area surrounding the DNNP site including activities which impact BWRX-300 facility operation, population distribution and density (Section 2.1), and the locations and transport routes that present potential risk for the facility (Section 2.3).
2. The site-specific external hazard evaluation (Section 2.2) for events of natural and human-induced origin during the planned lifetime of the facility, and any process or activity at the site that affects the operation of the facility (Section 2.4).
3. The collection of DNNP site-specific baseline data such as hydrological (Section 2.5); meteorological (Section 2.6); as well as geological, seismological, geotechnical (Section 2.7) information.
4. The description of the site and the surrounding environment (Sections 2.8), and of external sources related to the dispersion of radioactive material in air, water, and soil (Section 2.9).
5. The feasibility of emergency preparedness as related to accessibility and transport of any pertinent equipment to the DNNP site and the BWRX-300 facility (Section 2.10).
6. The arrangements for monitoring site-related parameters (Section 2.11) throughout the lifetime of the facility.

## Relevant Legislations and Regulations

The following provisions of the Nuclear Safety and Control Act (Reference 2.0-1), the General Nuclear Safety and Control Regulations (Reference 2.0-2) and the Class I Nuclear Facilities Regulations (Reference 2.0-3) are relevant to Chapter 2.

- Subsection 44(1) of the NSCA (Reference 2.0-1) states that “[t]he Commission may, with approval of the Governor in Council, make regulations.  
(e) Respecting the location, design, construction, installation, operation, maintenance, modification, decommissioning, abandonment and disposal of a nuclear facility or part of a nuclear facility.  
(o) Establishing requirements to be complied with by any person who possesses, uses, packages, transports, stores, or disposes of a nuclear substance or prescribed equipment or who locates, designs, constructs, installs, operates, maintains, modifies, decommissions, or abandons a nuclear facility or nuclear-powered vehicle.
- Section 3 of the Class I Nuclear Facilities Regulations (Reference 2.0-3) states that “[a]n application for a licence in respect of a Class I nuclear facility, other than a licence to abandon, shall contain the following information in addition to the information required by Section 3 of the General Nuclear Safety and Control Regulations (Reference 2.0-2):
  - a. A description of the site of the activity to be licensed, including the location of any exclusion zone and any structures within that zone
  - b. Plans showing the location, perimeter, areas, structures, and systems of the nuclear facility
  - c. Proposed management system for the activity to be licensed, including measures to promote and support safety culture

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

- d. Name, form, characteristics, and quantity of any hazardous substances that may be on the site while the activity to be licensed is carried on
- e. Proposed worker health and safety policies and procedures
- f. Proposed environmental protection policies and procedures
- g. Proposed effluent and environmental monitoring programs
- Section 5 of the Class I Nuclear Facilities Regulations (Reference 2.0-3) states that: “[a]n application for a licence to construct a Class I nuclear facility shall contain the following information in addition to the information required by Section 3:
  - a. Description of the proposed design of the nuclear facility, including the manner in which the physical and environmental characteristics of the site are considered in the design
  - b. Description of the environmental baseline characteristics of the site and the surrounding area
  - c. Effects on the environment and the health and safety of persons that may result from the construction, operation and decommissioning of the nuclear facility, and the measures that will be taken to prevent or mitigate those effects
  - d. Proposed location of points of release, the proposed maximum quantities and concentrations, and the anticipated volume and flow rate of releases of nuclear substances and hazardous substances into the environment, including their physical, chemical, and radiological characteristics

## **2.1 Geography and Demography**

Section 2.1 details the geographical and demographical baseline characteristics of the DNNP site and the surrounding regions. It contains the following information:

- Darlington Nuclear site context and surrounding land uses - Subsection 2.1.1
- BWRX-300 facility layout and the exclusion zone - Subsection 2.1.2
- Population distribution and density - Subsection 2.1.3
- Municipal services - Subsection 2.1.4
- Site access and transportation networks - Subsection 2.1.5
- Public transit – Subsection 2.1.6
- Active hiking and cycling trails - Subsection 2.1.7
- Parks spaces and waterbodies - Subsection 2.1.8
- Industrial facilities - Subsection 2.1.9

Table 2.1-1 lists key geographic and demographic characteristics and parameters within a 10-km survey area surrounding the Darlington Nuclear site.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 2.1-1: Site Layout, Geographic, and Demographic Characteristics and Parameters**

Characteristic	Value/Description	
Land Size	Darlington Nuclear site	Approximately 4.9 km <sup>2</sup>
	DNNP	Approximately 1.8 km <sup>2</sup>
	DNGS	Approximately 3.1 km <sup>2</sup>
Exclusion Zone	BWRX-300	350 m (radius) from the RB outside wall
	DNGS	914 m
Topography	<ul style="list-style-type: none"> <li>Current parking and storage areas east of the DWMF is at approximately 88 m (Canadian Geodetic Datum of 1928 (CGVD28), or simply CGD))</li> <li>Further east, the terrain rises to 102 m CGD close to the Darlington Creek watershed</li> <li>Extreme berm of elevation from 100 to 110 characterize the north boundary of the southern portion of the site to the railway tracks The northern portion of the site is bounded the north by Energy Road and to the south by the Railway tracks</li> <li>East of Holt Road, the terrain peaks at 120 m CGD and slopes down to the east to roughly 86 m CGD</li> </ul>	
Grade Elevation	Plant (BWRX-300 Facility)	88 m CGD (Refer to Subsection 2.7.1)
Population Distribution and Density (2021), for the Municipality of Clarington	Courtice	28,545

Characteristic	Value/Description	
	Private Dock	Private dock on St. Marys facility
Public Transit	Bus (902A King bus line)	One stop at Old Holt Road and King Street
	Transit-on-demand	Request pick up to nearest transit stop
	Rural-on-demand	Request pick up at current location
	88 GO Bus	Multiple stops along Bowmanville Avenue and King Street
	GO Transit's Lakeshore East Rail Service (planned for operation in 2026)	Courtice GO Station Bowmanville GO Station
Hiking and Cycling Trails	Darlington Waterfront Trail	Pedestrian and cyclists trail
Parks Spaces and Waterbodies (Note: A complete list is provided in Appendix C)	Provincial Parks	One – Darlington Provincial Park
	Recreational Facilities	Darlington Hydro Soccer Field and Bowmanville Baseball Fields
	Conservation Areas	Five in Bowmanville and two in Oshawa
	Beaches	Three – Two in Bowmanville and one in Oshawa
Industrial Facilities within 10 km	<ul style="list-style-type: none"> <li>• Directly adjacent industrial facilities, refer to Subsection 2.1.1</li> <li>• A complete list of industrial facilities falling within the surveyed area is found in Appendix A.</li> <li>• Pickering Nuclear Generating Station, about 25 km west of DNNP</li> </ul>	

## **2.1.1 Darlington Nuclear Site Context and Surrounding Land Uses**

### **Site Topography**

The Darlington Nuclear site topography is briefly described in Subsection 2.7.1. The 2022 Flood Hazard Assessment NK054-REP-02730-00001 (Reference 2.1-9) provides in this Subsection 2.1.1 additional information on the site topography including key detailed terrain elevations, as briefly recapped in the following paragraph.

The Darlington Nuclear site is situated in an undulating to moderately rolling limestone till plain, although its natural contours have been extensively graded. The existing 4-unit Darlington Nuclear Generating Station (DNGS) is located at elevation of about 78 m CGD. This is the lowest elevation area of the southern portion of the Darlington Nuclear site. From this location, the site slopes upward to the northwest, north and east. To the east, the terrain steadily slopes upward along the Lake Ontario shoreline, forming a bluff. The DNNP site, currently a parking and storage area southeast of the Darlington Waste Management Facility (DWMF), is just north of shoreline bluff, at approximately 88 m CGD. Farther east, the terrain rises to elevation 102 m CGD at the boundary of the Darlington Creek watershed before sloping down to its main branch near the eastern boundary of the site. The north boundary of the southern portion of the Darlington Nuclear site is characterized by an extensive berm that ranges in elevation from 100 m CGD to 110 m CGD and separates the southern portion of the site from the transecting Canadian National Railway tracks. The northern portion of the site is bounded to the north by Energy Drive and to the south by the Canadian National Railway tracks. Between Crago Road and Park Road, there is a large ridge rising to 132 m CGD. Between Park Road and Holt Road, the terrain ranges from 98 m to 130 m CGD. East of Holt Road, the DNNP terrain peaks at 120 m CGD and slopes downward to the east to roughly 86 m CGD.

### **Area and Bounding Roads**

The Darlington Nuclear site is approximately 4.9 km<sup>2</sup> in size and located within the Municipality of Clarington, Regional Municipality of Durham, Province of Ontario, Canada. OPG also owns and operates the eight-unit Pickering Nuclear Generating Station (PNGS) (refer to Subsection 2.2.5.2) within the City of Pickering which is located approximately 25 km to the west of the Darlington Nuclear site, as shown in Figure 2.1.1-1.

The Darlington Nuclear site encompasses both the DNGS and the DNNP lands as shown in Figure 2.1.1-2. The Darlington Nuclear site is bounded by Crago Road to the west, Energy Drive to the north, St. Marys Cement to the east and Lake Ontario to the south. The existing DNGS site is approximately 3.1 km<sup>2</sup> in size and is located west of Holt Road on the western portion of the Darlington Nuclear site, whereas the DNNP land of approximately 1.8 km<sup>2</sup> is located east of Holt Road. Figure 2.1.1-2 shows also the 914-meter DNGS exclusion zone, which partly overlaps the location where the BWRX-300 first unit is to be built in the southwestern corner of the DNNP site as shown in Chapter 1, Figure A1.1-2.

### **Industrial Facilities**

The major industrial facilities in the vicinity of the Darlington Nuclear site, as shown in Figure 2.1.1-3, include:

1. St. Marys Cement Group which is located directly east of the DNNP site on Bowmanville Avenue, and is an active quarry for resources servicing the aggregate and concrete industry
2. The lands designated as Clarington Energy Business Park which is located directly west of the DNGS and includes:

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

- a. Covanta Durham York Energy Centre which manages household waste from the regions of Durham and York
  - b. OPG's Darlington Energy Complex, an approximately 27,900 m<sup>2</sup> multi-use building that provides offices and services supporting the Darlington Refurbishment project
  - c. CoPart, a vehicle auction and recycling facility
  - d. East Penn, a warehousing facility for batteries
  - e. Courtice Water Pollution Control Plant (WPCP), a wastewater treatment facility commissioned in late 2007, with an average day rated capacity of 68.2 million liters per day with a peak flow capacity of 180 million liters per day (Reference 2.1-7)
  - f. Planned location for a project that is being evaluated involving an Anaerobic Digester facility (Reference 2.1-7) to treat raw sludge collected from Courtice WPCP
3. OWASCO RV, which is a recreational vehicle sale and service centre, located north of Highway 401

There are some industrial developments in the Courtice Employment Area located northwest of the Darlington Nuclear site, including warehousing and automobile dealerships. All of the industrial facilities falling within the surveyed area are listed in Appendix A.

### **Developmental Activities**

OPG actively reviews planning applications in the Municipality of Clarington to monitor sensitive land use developments within 3 km of the DNGS and DNNP facilities. Additionally, OPG reviews planning applications within 10 km of the Darlington Nuclear site in the Municipality of Clarington and the City of Oshawa. These applications include official plan amendments, zoning by-law amendments, draft plans of subdivision and condominium, and other miscellaneous planning related documents.

OPG completes an annual development activity report detailing all proposed developments in the municipalities of Clarington and Oshawa within 10 km of the Darlington Nuclear site. In such a report, OPG reviews the:

- a. Type and location of proposed application
- b. Date on which the application was submitted
- c. Details of the proposed application
- d. Status of the application

### **Urban Communities and Rural Areas**

The urban communities of Oshawa and Courtice are located northwest of the Darlington Nuclear site, while the urban community of Bowmanville is located to the northeast of the DNNP site. A rural area separating the Clarington urban areas of Courtice and Bowmanville is located immediately north of the DNNP site. The community of Newcastle is also located east of the DNNP site within the survey area; albeit only a portion is included in the survey area. For the purposes of Section 2.1 and Section 2.3, the geographic limits defined for the survey area are approximately 10 km from the site and include Taunton Road to the north, Simcoe Street to the west, an approximate border of Darlington Clarke Townline Road to the east, and Lake Ontario to the south (refer to Figure 2.1.1-4).

## **Land Use Assessment for Environmental Effects**

The 10 km survey area is consistent with the Land Use Assessment Zone, which was the furthest distance that measurable effects on planned land use structure as well as impacts on sensitive land uses are identified in the proximity to the Darlington Nuclear site. The Land Use Assessment of Environmental Effects Technical Support Document completed in 2009 identified the Regional Study Area as being approximately 50 km from the Darlington Nuclear site as shown in Figure 2.1.1-4. The DNNP Land Use Environmental Assessment Follow-Up Monitoring Plan / Methodology Report was developed in 2022 NK054-CORR-00531-10635 (Reference 2.1-3) to fulfill the requirement of OPG Commitment D-P-12.7 in the 2021 NK054-REP-01210-00078 (Reference 2.1-2). As per the 2022 NK054-CORR-00531-10635 (Reference 2.1-3), OPG will continue to monitor planning development in land use in proximity to the DNNP site, and regularly consult with the Municipality of Clarington, City of Oshawa and the Regional Municipality of Durham on proposed land use changes. The effects on implementation of emergency plans will be investigated throughout the site preparation and construction phases.

### **2.1.2 BWRX-300 Facility Layout and Exclusion Zone**

The layouts of the DNNP site and BWRX-300 Unit 1 as well as associated infrastructures are described in Chapter 1, Section 1.4, and Section 1.5 satisfy the regulatory requirements of Sections 4.5.4 and 4.5.5 of REGDOC-1.1.2 (Reference 2.1-1). The selected location, in the southwestern corner of the DNNP area, limits the amount of spoilage to remove and avoids encroachment on the Bank Swallow habitat. This location is also in proximity to DNGS ensuring effective connections to DNGS available infrastructure. The DNNP site also incorporates considerations that support a total of four BWRX-300 units, as conceptually shown in Figure 5 of the 2022 DNNP BWRX-300 Environmental Impact Statement (EIS) NK054-REP-07730-00055 (Reference 2.1-4).

The deployment of the BWRX-300 facility does not require expanding the DNGS switchyard. Rather, a new 230 kV switchyard is to be located East of the Extended Holt Rd and South of the Canadian National Railway tracks, adjacent to the BWRX-300 facility buildings, as shown in Chapter 1, Figure A1.1-2 and Figure A1.4-2 for one unit and conceptually shown in Figure 7 of the 2022 NK054-REP-07730-00055 (Reference 2.1-4) for four units.

Existing roads are being used to the maximum extent practicable and no new off-site roadways are required.

The Pumphouse/Forebay structure is positioned outside the northwestern corner of the protected area. As described in Chapter 9B, Subsection 9B.3.5.2, onshore vertical shafts are designed to facilitate the operation of up to four BWRX-300 units and the construction of the intake and discharge tunnels. The intake tunnel conveys cooling water from the lakebed intake structure to the onshore intake vertical shaft. The discharge tunnel conveys the discharge water from the onshore discharge vertical shaft to the discharge tunnel and diffusers. The discharge structure is located near the lakeshore and does not require lake infill.

#### **2.1.2.1 Required Exclusion Zones**

The exclusion zone is established at 350 m from the RB outside wall. For the BWRX-300 first unit, the exclusion zone partly overlaps the eastern portion of the DNGS site, as shown in Chapter 1, Figure A1.1-2. The exclusion zone of 350 m for the conceptual layout of four units shown in Figure 5 of the 2022 NK054-REP-07730-00055 (Reference 2.1-4) is within the DNNP eastern boundary with St. Mays Cement industrial facility.

The rationale for determining the exclusion zone is discussed in Section 8 of the 2022 NK054-REP-01210-00142 (Reference 2.1-5), and considers the security requirements, evacuation

needs, land usage needs, and environmental conditions, in accordance with Section 6.5 of REGDOC-2.5.2 (Reference 2.1-8). Note the BWRX-300 Small Modular Reactor (SMR) is built within the DNNP site boundary with a smaller footprint of approximately 9,800 m<sup>2</sup>, per the 2022 NK054-REP-01210-00142 (Reference 2.1-5), compared with the original application involving much larger nuclear power plants, per the 2010 NK054-REP-01200-10000 (Reference 2.1-6).

Chapter 15, Section 15.7 includes tabulated summaries listing the DSA results for bounding BWRX-300 AOO and DBA event sequences. Also, Chapter 15, Appendix 15A demonstrates implementation of the D-in-D provisions ensures protection against unacceptable radiation releases. Chapter 15, Section 15.7 thus concludes all BWRX-300 analyzed bounding AOOs, DBAs or DECAs without core damage have met the dose acceptance criteria for the 350 m exclusion zone.

#### **2.1.2.2 Security Requirements**

The security requirements for the DNNP site and the BWRX-300 facility and how such security requirements are met are described in the Security Annex, which is an OPG Confidential Protected Security document.

#### **2.1.2.3 Description of Site Layout**

The high-level description of the DNNP site layout includes:

- The Power Block that encompasses several buildings and a plant services area (refer to Chapter 1, Figure A1.5-1)
- Locations of the site vehicle entrance (sally port) as well as roads to allow access of trucks and individuals to Power Block buildings, with the Protected Area Access Building located west of the sally port (refer to Chapter 1, Figure A1.4-1)
- Locations of the irradiated fuel dry storage (which is regulated under a separate licence), Pumphouse/Forebay, intake shaft and tunnel, discharge structure and tunnel, and switchyard and transmission lines (refer to Chapter 1, Figure A1.1-2)
- Heavy haul routes for the construction phase of Unit 1 as shown in Chapter 1, Figure A1.1-2, and for the construction phases of Units 2, 3, and 4, as shown in Figure 5 of the 2022 EIA (Reference 2.1-4).

#### **2.1.2.4 Minimizing Environmental Impacts**

Measures are included in the DNNP site layout and BWRX-300 design to minimize the impact on the surrounding region and the environment, per the 2022 NK054-REP-07730-00055 (Reference 2.1-4), for example:

1. The location and placement of the lakebed intake structure regarding the commitment for fish entrainment and impingement as well as the discharge diffusers to meet the commitment for effluent plume in the 2021 NK054-REP-01210-00078 (Reference 2.1-2)
2. Consideration of sensitive land features, such as shoreline bluffs and Bank Swallows, habitat to the extent practicable
3. A smaller BWRX-300 footprint which does not need any additional land area that could be obtained from lake infill
4. Designing into the site storm water management provisions for the construction and post construction phases

5. Minimizing the area of disturbance for permanent structures as well as the areas for spoils on the DNNP site by optimizing the BWRX-300 footprint
6. Cooling towers are not used for the BWRX-300 for either the normal or ultimate heat sinks, per Table 3 of the 2022 EIS NK054-REP-07730-00055 (Reference 2.1-4); thus, the adverse effects associated with cooling towers (e.g., effects on the visual landscape and socio-economic conditions) are not applicable
7. The primary and secondary heat transport systems are combined, and use is made of natural circulation and passive safety systems resulting in an optimized size of the facility and contributing to lowering the risk of normal and abnormal operating conditions

### **2.1.3 Population Distribution and Density**

The Municipality of Clarington and the City of Oshawa have both experienced steady growth over the last ten years.

According to recently released Statistics Canada data, Clarington's population was 101,427 in 2021, which is an increase of 10.2% from that in 2016 when the population was recorded at 92,130. The rural area of Clarington had a population of 11,297 in 2021. The Municipality of Clarington Official Plan forecasts that Clarington will have a population of 140,340 by 2031, with 124,685 in its urban areas and 15,655 in its rural areas. The 2021 population data listed in Table 2.1-2 for the Municipality of Clarington is distributed amongst four urban areas including Courtice, Bowmanville, Orono, and Newcastle as shown in Figure 2.1.3-1.

**Table 2.1-2: Population Data for the Municipality of Clarington for 2021**

Urban Area	Population
Courtice	28,545
Bowmanville	47,176
Orono	2,476
Newcastle	11,933
Total	90,130

The population of the City of Oshawa was 149,607 in 2011 and grew to 159,458 in 2016, which was a 6.6% increase. The City of Oshawa's Official Plan provides population forecasts of 174,695 in 2021, 184,460 in 2026 and 197,000 in 2031.

Refer to Subsection 2.8.4 for detailed 2016 population data that is broken into sectors by distance and direction for use in air dispersion modeling within a 30 km radius of the Darlington Nuclear site.

### **2.1.4 Municipal Services**

Within the 10 km survey area, there are 17 education institutions available for students: 12 primary schools and five secondary schools. As well, there are six fire emergency stations (excluding OPG's on-site Darlington fire station) and one regional police station (plus one administrative police department). Additionally, there is one hospital - Lakeridge Health in Bowmanville.

### **2.1.5 Site Access and Transportation Networks**

The Darlington Nuclear site can be accessed via two roads. Holt Road runs north to south and allows for direct access to the site. Energy Drive runs west to east and connects to Park Road for access to the site. Multiple parking lots are present on the site.

Within 10 km of the site, there are many arterial roads, minor arterial roads, highways, residential roads, and rural roads. These roads fall within the borders of the 10 km survey area defined in Subsection 2.1.1. A complete list of roads falling within the surveyed area can be found in Appendix B.

Transportation networks of significance are listed in the following:

1. Three 400-series highways are located within 10 km of the site - Highways 401, 407, and 418 (refer to Subsection 2.3.1(b) for supplementary information on Highway 401).
2. Two railway lines are located within 10 km of the site which converge and run adjacent to one another east of Lakeshore Road, Newcastle:
  - a. The Canadian Pacific line runs west east, which is located just north of Highway 401, and is used for trains transporting cargo.
  - b. The Canadian National line runs west east, which is located south of Highway 401 and used for trains transporting people and cargo, and part of which bisects the DNNP and DNGS sites (refer to Subsection 2.3.1 for further information, and Subsection 2.2.3.2(a) for hazards related to potential railway accidents).
3. Oshawa Executive Airport is located at the southeast corner of Taunton Road and Thornton Road North. The airport is located just outside the 10 km survey area (refer to Subsection 2.3.1(c) for additional information).
4. The Port of Oshawa East Pier (at the bottom of Simcoe Street South) is located west of the site and allows cargo ships to receive/deliver shipments.
5. St. Marys Cement has a private dock at its facility to the east of the DNNP site for the shipment of aggregate from its operations.

### **2.1.6 Public Transit**

The closest regional transit stop to the site is located at Old Holt Road and King Street, approximately 5 km north of the site. The stop is part of the 902A King bus line offered by Durham Regional Transit and runs west east through the Durham Region. Additionally, the region introduced two types of on-demand transportation services in the Durham Transportation Master Plan (2017): transit on-demand and rural on-demand. Transit on-demand allows riders to request a ride with pickup located at their nearest transit stop, while rural on-demand allows riders to request a ride with pickup at their current location. The region also has a park and ride station within the survey area located at Courtice Road north of Highway 401.

The closest transit stop to the site is a GO Bus stop located at Bowmanville Avenue and Baseline Road. The stop is part of the 88 GO Bus Route that is running from Oshawa to Peterborough with multiple bus stops located north of the site along Bowmanville Avenue and King Street. Additionally, there are two proposed GO Transit stations within the survey area. GO Transit's Lakeshore East Rail Service will operate on the Canadian Pacific rail line north of Highway 401, which will include service to the two proposed stations: Courtice GO (Courtice Road north of Baseline Road) and Bowmanville GO (Bowmanville Avenue north of Aspen Spring Drive). Per correspondence with Durham Region staff, the Courtice and Bowmanville GO stations are

projected to be operational in 2026. Furthermore, two secondary plans are currently being developed for the areas adjacent for each proposed GO station.

### **2.1.7 Active Hiking and Cycling Trails**

As shown in Figure 2.1.8-1, the Darlington Waterfront Trail, part of the Great Lakes Waterfront Trail, is a multi-use path that forms part of the recently approved Durham Regional Cycling Plan. The trail is used by pedestrians and cyclists for transportation or recreational purposes, provides direct access to the Darlington Nuclear site and falls within OPG owned lands. Additionally, hiking trails are available near Lakeview Park in Oshawa, as the Larry Ladd Harbour Trail connects to Lakeview Beach. The Primary Cycling Network Durham currently provides over 400 km of cycling infrastructure in the region.

### **2.1.8 Park Spaces and Waterbodies**

There is abundance of parks, greenspaces, conservation areas, and waterbodies located within the 10 km survey area, with multiple public recreational spaces directly adjacent to Darlington Nuclear site. As detailed in Subsection 2.1.7, part of the Darlington Waterfront Trail runs through the Darlington Nuclear site. Directly adjacent to the west of the DNGS site is Alijco Beach, a beachfront which can be accessed by users for recreational purposes. Other park spaces and waterbodies are dispersed throughout the rest of the survey area, with places of significance listed below:

1. One provincial park falls within the survey area - Darlington Provincial Park.
2. The Darlington Hydro Soccer Fields facility (owned by OPG and licensed to the Municipality of Clarington) falls within the survey area, as does Bowmanville's Baseball Fields Complex (located at Green Road just north of Highway 401).
3. Five conservation areas fall within the survey area: three are located in Bowmanville (Bowmanville Valley Conservation Area, Bowmanville Westside Conservation Area, Stephen Gulch's Conservation Area) and two are located in Oshawa (Harmony Valley Conservation Area, Oshawa Valleylands Conservation Area).
4. Three beaches fall within the survey area: two are located in Bowmanville (Alijco Beach, Port Darlington Beach) and one is located in Oshawa (Lakeview Beach).

A complete list of park spaces and water bodies falling within the surveyed area can be found in Appendix C.

### **2.1.9 Industrial Facilities**

The industrial facilities that are within the survey area of 10 km and directly adjacent to Darlington Nuclear site are discussed in Subsection 2.1.1.

Other industrial facilities are dispersed throughout the rest of the survey area, with most facilities located west of the site in Oshawa. A complete list of industrial facilities falling within the surveyed area is found in Appendix A.

While not located in the survey area, the PNGS is located approximately 25 km west of the Darlington Nuclear site (refer to Subsection 2.1.1 and Subsection 2.2.5.2).

## **2.2 Evaluation of Site-Specific Hazards**

Section 2.2 characterizes and quantifies site-specific hazards that are used in the design of the BWRX-300 and builds upon the 2022 DNNP Hazard Analysis Methodology NK054-REP-01210-00144 (Reference 2.2-10). As the DNNP and DNGS share the Darlington Nuclear site (refer to Subsection 2.1.1), the DNGS 2019 Hazard Screening Analysis NK38-REP-03611-10043 (Reference 2.2-5) is used in support of Section 2.2 and to inform the DNNP hazard screening analysis. All such site characteristics are validated for the BWRX-300 Unit 1 design and its location on the DNNP site, as shown in Chapter 1, Figure A1.1-2.

### **2.2.1 Introduction**

Section 2.2 includes the methodology used for and the results of the evaluation of site-specific external hazards associated with the DNNP site and the BWRX-300 facility. Such evaluation is derived from previous DNNP hazards assessment work completed in the 2009 NK054-REP-01210-00008 (Reference 2.2-1) and the 2009 NK054-REP-01210-00019 (Reference 2.2-2) as well as from a 2019 DNNP site preparation licence renewal activity report NK054-REP-01210-00108 (Reference 2.2-3). The evaluation addresses specific items relevant to DNNP site-specific external hazards, as identified in the 2020 OPG's application to renew the DNNP site preparation licence NK054-CORR-00531-10533 (Reference 2.2-4).

The methodology used to evaluate external hazards is described in Subsection 2.2.2.

The hazards identified for further evaluation are:

- Subsection 2.2.3: Transportation Accidents, Including Toxic Chemical or Gas Releases / Explosions Hazards
- Subsection 2.2.4: Stationary Non-nuclear Accidents Hazards
- Subsection 2.2.5: Stationary Nuclear Accidents Hazards
- Subsection 2.2.6: Industrial Hazards
- Subsection 2.2.7: Biological, Animal, and Frazil Ice Hazards
- Subsection 2.2.8: Ice Storm Hazard
- Subsection 2.2.9: Electromagnetic Interference Hazard
- Subsection 2.2.10: On-site Methane Hazard

A summary results and follow-up considerations of the hazards listed above are provided in Table 2.2-1.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 2.2-1: Screening and Validation of CNSC–Identified DNNP  
Site-Specific Hazards**

2.2.2 External Hazards Evaluation Methodology			
Methodology	The methodology and criteria used in the 2019 DNGS NK38-REP-03611-10043 (Reference 2.2-5) Comparable methodology and criteria developed in the 2022 BWRX-300 DNNP NK054-REP-01210-00144 (Reference 2.2-10)		
Screening Criteria	Qualitative Criteria – QL-1 to QL-7 Quantitative criteria – QN-1 to QN-5		
2.2.3 Characterization of Hazards from Transportation Accidents, Including Toxic Chemicals or Gas Releases/Explosions			
2.2.3.1 Hazards from Air Transportation Accidents			
Small aircraft	Screened out	QL-1: Equal or lesser damage than similar design basis event	The small aircraft crash is screened out as the BWRX-300 is designed to withstand site-specific automobile tornado missiles, per Subsection 2.6.6.
Large military aircraft	Screened out	QL-3: Cannot occur at or close enough to the site to affect BWRX-300	Large bombers, large cargo planes, fuel tankers, or heavily armed jet fighters do not fly in the vicinity of the Bowmanville airspace
Large civil aircraft	Screened out	QN-5: Frequency of <1.0E-7/yr	NOTE: Malevolent large aircraft crash is analyzed in the Security Annex.
2.2.3.2 Characterization of Hazards from Rail Transportation Accidents			
Release of toxic gases	Screened in as DEC	Hazard frequency is estimated at 1.9E-06 occ./yr. Thus, this hazard is a Beyond Design Basis Accident (BDBA) DEC, as documented in NK054-REP-01210-00150 (Reference 2.2-11)	
Explosions	Screened in as DEC	Hazard frequency is estimated at 9.0E-07 acc./yr Thus, this hazard is a BDBA DEC, as documented in NK054-REP-01210-00149 (Reference 2.2-12)	
2.2.3.3 Characterization of Hazards from Road Transportation and Traffic Accidents			
Release of toxic or asphyxiant material	Screened out	QL3: Cannot occur on or close enough to the site to affect the plant	The location of the Darlington Nuclear site is about 1.0 km away from Highway 401.
2.2.3.4 Characterization of Marine Transportation			
Chemical Leak	Screened out	QL3: Cannot occur on or close enough to the site to affect the plant QL6: Does not cause an initiating event	Commercial shipping is approximately 27 km away for the DNNP. The consequence of a chemical leak from a tanker or a cargo ship, would be mostly an environmental hazard, and would not have an impact on safe operation of the station.
Release of toxic gases	Screened out	QL3: Cannot occur on or close enough to the site to affect the plant	The location of the DNNP is about 27 km away from the general tanker or cargo ship commercial routes in Lake Ontario.
Explosion	Screened out	QL3: Cannot occur on or close enough to the site to affect the plant	The location of the DNNP is about 27 km away from the general tanker or cargo ship commercial routes in Lake Ontario.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Physical Damage	Screened out	QL3: Cannot occur on or close enough to the site to affect the plant  QL1: Bounded by the impact of damage caused by frazil ice described in Subsection 2.2.7.2	Hazards from accidents involving recreational boats or vessels pose no significant threat to the BWRX-300 safe operation, even if the accidents occur near the lake water intake structure.  Also, a restricted zone is established around the BWRX-300 offshore structures.
<b>2.2.4 Characterization of Stationary Non-Nuclear Accidents</b>			
2.2.4 Fire – Natural Gas Pipelines	Screened out	QL6: Does not cause an initiating event or relevant safety function	There are no substantial pipelines carrying large quantities of natural gas, close enough to the site.
2.2.4.1 Release of toxic gases or chemical from commercial outlets in the area	Screened out	QL3: Cannot occur on or close enough to the site to affect the plant  QL5: The event is slow to develop so there is sufficient time to eliminate the source of adequately respond	There are no industrial toxic gas or chemical storage tanks or pipelines carrying significant quantities of natural gas close enough to the site.  Assumed St. Marys toxic release is not close enough to the site to affect the plant
2.2.4.2 Explosion – Shock Waves	Screened out	QL3: Cannot occur on or close enough to the site to affect the plant	Distances between DNNP and: <ul style="list-style-type: none"><li>• Cigas Propane tanks are about 3.6 km far from the DNNP site</li><li>• St. Marys diesel fuel tanks is greater than 700 m from the Power Block of multi-unit layout (Reference 2.2-16).</li></ul>
2.2.4.2 Explosion - Missiles Hydrogen used for Tritium Removal Facility	Screened out	QL3: Large Missiles - Cannot occur on or close enough to the site to affect the plant  QL4: Small Missiles - Bounded by design basis tornado in Subsection 2.6.6	The Tritium Removal Facility is located approximately 1.0 km west of the DNGS vacuum building.
<b>2.2.5 Characterization of Stationary Nuclear Accidents Hazards</b>			
2.2.5.1 Cameco's Port Hope Uranium Conversion Facility	Screened out	The facility is located on the north shore of Lake Ontario, approximately 40 km east of Darlington Nuclear site. The Cameco plant is a chemical processing facility with negligible radioactive releases.	
2.2.5.2 PNGS	Screened out	Any hazard from PNGS irradiated fuel still within an irradiated fuel bay or a dry storage facility is bounded by the much closer event from DNGS. Based on (Reference 2.2-5), PNGS radioactive release event is characterized as a slow developing event, allowing sufficient time for operators to take appropriate actions (if warranted), and can therefore be screened out.	
2.2.5.3 DNGS – Exclusion Zone	Screened in	The DNNP site is partly within the exclusion zone of DNGS.	
<b>2.2.5.4 Characterization of Other Radiological Hazards from DNGS</b>			
2.2.5.4.1 DNGS – Tritium Removal Facility – Tritium Release	Screened out	Evaluations in (Reference 2.2-1) and (Reference 2.2-5) determined that regulatory dose limits at the site boundary apply to all these nuclear events with negligible impact to DNNP.	

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

2.2.5.4.2 DNGS – Irradiated Wet Fuel Storage Facility	Screened out		
2.2.5.4.3 DNGS – Irradiated Dry Fuel Storage Facility	Screened out		
2.2.5.4.4 DNGS – Radioactive Waste Storage	Screened out		
2.2.6 Characterization Industrial Hazards (St. Marys)			
St. Marys Cement Plant – Uncontrolled blasts	Screened in	St. Marys Cement commits to carry out blasts with a maximum allowable horizontal, vertical, longitudinal, and radial velocities of less than 3 mm/s measured at the Darlington Nuclear site property boundary with St. Marys.	
2.2.7 Characterization of Biological, Animal and Frazil Ice Hazards			
2.2.7.1 Water-based Biological	Screened out	QL4: Bounded by the impact of damage caused by frazil ice described in Subsection 2.2.7.2	Hazards associated with blockage of intake cooling water resulting in the loss of heat sink
2.2.7.1 Airborne birds or insects	Screened out	QL-1: Equal or lesser damage than similar design basis event	This event is equivalent to outside air damper isolation during off-normal conditions
2.2.7.2 Frazil Ice	Screened in	Frazil ice is considered a potential hazard for causing water intake blockage to DNNP.	
2.2.8 Characterization of Ice Storm Hazard			
Ice Storm	Screened out	QL-1: Equal or lesser damage than similar design basis event	For the DNNP BWRX-300, the loss of the switchyard is part of the Loss-of-Preferred Power (LOPP), an Anticipated Operational Occurrence, which is the Pressure Increase Group and is designated as a BL-AOO event
2.2.9 Characterization of Electromagnetic Interference Hazard			
Electromagnetic Interference	Screened in	Since electromagnetic interference sources (e.g., high-voltage transmission lines and communication towers) are continuously present, the risk of electromagnetic interference at the site must be addressed in the design basis of the BWRX-300	
2.2.10 Characterization of On-site Methane Hazard			
During construction	Screened in	Methane gas is harmful to the health of humans and is combustible. Methane gas must be monitored during excavation, especially for the RB, since the methane is expected to dissipate quicker than what was observed in the boreholes due to the significantly larger air space.	
Post construction	Screened in	Methane in bedrock during operation is added as a hazard to be considered during design	

### **2.2.2 External Hazards Evaluation Methodology**

The 2019 Hazards Screening Analysis reported in the 2019 NK38-REP-03611-10043 (Reference 2.2-5) provides a comprehensive assessment of the hazards associated with the DNGS site. Given that the DNNP site is within the Darlington Nuclear site (refer to Chapter 1, Figure A1.1-2) and in geographic proximity with the DNGS site, this analysis is deemed applicable to support and inform the evaluation of the external hazards listed in Subsection 2.2.1 for the DNNP site. In addition, since the DNGS external hazard screening methodology NK38-REP-03611-10043 (Reference 2.2-5) is aligned with the 2022 BWRX-300 DNNP Hazard Analysis Methodology NK054-REP-01210-00144 (Reference 2.2-10), the results of the 2019 DNGS analysis in NK38-REP-03611-10043 (Reference 2.2-5) are used to supplement and validate the DNNP site-specific external hazards evaluation reported in the 2022 DNNP NK054-REP-01210-00144 (Reference 2.2-10).

In the 2019 Site Preparation Licence Renewal Activity Report NK054-REP-01210-00108 (Reference 2.2-3), detailed DSA and PSA are performed during the BWRX-300 design phase. The DSA and PSA updates are performed in compliance with CNSC REGDOC-2.4.1 (Reference 2.2-14) and REGDOC-2.4.2 (Reference 2.2-15), respectively, and are tracked under the 2021 DNNP Commitment D-C-3 NK054-REP-01210-00078 (Reference 2.2-8). With respect to external hazards, DNNP Commitment D-C-3 also requires “the design of the new plant must demonstrate that it can mitigate the identified hazards to ensure that the required safety goals are met.”

The screening methodology and criteria used to assess hazards are described is found in Section 1.0 of the DNGS 2019 NK38-REP-03611-10043 (Reference 2.2-5). The screening technique involved a systematic approach starting with a qualitative assessment of the impacts of hazards on the safe operation of the station, followed by a quantitative screening of hazards not being screened out qualitatively. The methodology follows OPG’s PSA guides for screening of internal and external hazards.

The 2022 BWRX-300 DNNP Hazard Analysis Methodology NK054-REP-01210-00144 (Reference 2.2-10) builds on the 2019 Darlington screening technique NK38-REP-03611-10043 (Reference 2.2-5) and devises comparable criteria for the BWRX-300 facility. The developed qualitative and quantitative screening criteria are applicable to screening internal and external hazards, as listed in Appendix B of the 2022 NK054-REP-01210-00144 (Reference 2.2-10).

The following criteria are used for qualitative screening of hazards in the 2019 NK38-REP-03611-10043 (Reference 2.2-5):

- QL-1: The event is of equal or lesser damage potential than similar events for which the plant has been designed.
- QL-2: The event has a significantly lower reactor sources likelihood than another event that has been screened out, and yet the event could not result in worse consequences than the other event.
- QL-3: The event cannot occur at the site or close enough to the site to affect the plant.
- QL-4: The event is included in the definition of another event.
- QL-5: The event is slow in developing such that it can be demonstrated that there is sufficient time to eliminate the source of the threat or provide an adequate response.
- QL-6: The event does not cause an initiating event (including the need for a controlled shutdown) as well as safety system function losses needed for the event.
- QL-7: The consequences to the plant do not require the actuation of front-line systems.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

NOTE: QL-1 to QL-5 apply to both the reactor and non-reactor sources. QL-6 and QL-7 apply only to reactor sources and not to the non-reactor sources.

The following criteria are used for quantitative screening in the 2019 NK38-REP-03611-10043 (Reference 2.2-5).

- QN-1: Severe Core Damage Frequency  $< 1.0E-6/\text{yr}$ . Applies only to reactor sources and not to non-reactor sources.
- QN-2: Design Basis Hazard Frequency,  $< 1.0E-5/\text{yr}$  and Conditional Core Damage Probability  $< 0.1$ . Applies to reactor sources only and not to non-reactor sources.
- QN-3: Severe Core Damage Frequency  $< 10^{-7}/\text{yr}$ . Applies to the reactor sources only. An equivalent QN for non-reactor sources of Low Release Frequency (LRF)  $< 1.0E-7/\text{yr}$  is considered.
- QN-4: Design Basis Hazard Frequency,  $< 1.0E-6/\text{yr}$  and Conditional Core Damage Probability  $< 0.1$ . Applies to reactor sources only. An equivalent QN for non-reactor sources is considered as follows: Design Basis Hazard Frequency,  $< 1.0E-6/\text{yr}$  and conditional large release probability (CLRP)  $< 0.1$ .
- QN-5: Initiating Event or Hazard Frequency may be screened out if it can be shown that their frequency is  $< 1.0E-7/\text{yr}$ . Applies to both reactor and non-reactor sources.

The application of this methodology results in hazards being “screened out” or “screened in.” “Screened out” implies that the hazard does not pose any safety concerns. “Screened in” implies further assessment is required to address the hazards. Hazards which are neither qualitatively nor quantitatively screened out, are addressed during detailed Probabilistic Safety Assessments (for example, seismic, high winds).

### **2.2.3 Characterization of Hazards from Transportation Accidents, Including Toxic Chemicals or Gas Releases/Explosions**

Evaluations of hazards from transportation accidents are detailed as follows:

- By air - Subsection 2.2.3.1
- By train - Subsection 2.2.3.2
- By road - Subsection 2.2.3.3
- By marine – Subsection 2.2.3.4

Previous assessment results for DNNP hazards associated with transportation events are provided in the 2009 NK054-REP-01210-00008 (Reference 2.2-1) and the 2009 NK054-REP-01210-00019 (Reference 2.2-2). The evaluations presented in Subsection 2.2.3 address the specific issues identified by the CNSC in Subsections 4.6.1, 4.6.2 and 4.6.3 of the 2020 Renewal Application for DNNP Site Preparation Licence NK054-CORR-00531-10533 (Reference 2.2-4).

Aircraft crashes and ship accidents were evaluated for the DNNP site in Section 4.3 and 4.4 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1). The evaluation did not consider the impact from toxic chemicals or gas releases/explosions specific to these accidents. However, the impact from toxic chemicals or gas releases/explosions from transportation accidents were implicitly assessed in Section 4.6 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1).

Further, Section 4.6 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1) evaluated the risks associated with hazardous fluids, including toxic clouds from the release of toxic gases, deflagrations (explosions) from the release of liquified petroleum gases and flammable pressure

liquified gases. The evaluation determined toxic gas clouds reaching the DNNP site at high enough concentrations have the potential to impact the Main Control Room (MCR) and Secondary Control Room (SCR) habitability of the proposed plant (that is, the BWRX-300 nuclear facility). Refer to Chapter 6, Section 6.4 for further details on habitability of the MCR and SCR.

With respect to explosions, the evaluation in the 2009 NK054-REP-01210-00008 (Reference 2.2-1) identified potential damage to buildings from missiles resulting from Boiling Liquid Expanding Vapour Explosion (i.e., tanks containing liquified petroleum); when travelling at high velocity, these missiles can damage outdoor and indoor equipment. The evaluation determined that the overpressure effects due to explosion on the building must be mitigated. Mitigation may require the use of an appropriate physical barrier or the physical separation of important safety equipment/systems. The evaluation stated that requirements for this hazard is to be considered during the detailed design phase of the project (that is, BWRX-300). The 2019 DNGS Hazards Screening Analysis NK38-REP-03611-10043 (Reference 2.2-5) also assessed the release of toxic chemicals and gas/release explosions from transportation accidents. The data used for DNGS hazards analysis supplement the DNNP site-specific data that are employed in the design and safety analysis stage of the DNNP BWRX-300, as applicable.

For additional information specific to toxic gas and chemical hazards, refer to Subsection 2.2.3.2 for rail transportation accident hazards, Subsection 2.2.4.1 for release from stationary hazards, and Subsection 2.4.1 for on-site hazards.

#### **2.2.3.1 Characterization of Hazards from Air Transportation Accidents**

Two types of aircraft are examined: small and large (both civil and military).

1. The small aircraft crash is screened out qualitatively as not having an impact on the safe operation of the facility, based on the screening criterion QL1 that the event is of equal or lesser damage potential than similar events for which the plant is designed. Per Section 3.1 of the 2019 Darlington hazard screening analysis (Reference 2.2-5), small aircraft impact is bounded by tornado missiles. The small aircraft crash is therefore screened out as the BWRX-300 will be designed to withstand automobile tornadoes missiles (refer to Subsection 2.6.6).
2. Large aircraft (military) aviation accidents are not a concern for the Darlington Nuclear site, as there are no large bombers, large cargo planes or fuel tankers, or heavily armed jet fighters flying in the vicinity of the Bowmanville airspace, per the 2020 NK054-CORR-00531-10533 (Reference 2.2-4).
3. Large aircraft (civil) accidents are screened out under screening criterion QN5 (refer to Subsection 2.2.2) based on a hazard frequency of  $<1.0E-7/\text{yr}$ .

#### **2.2.3.2 Characterization of Hazards from Rail Transportation Accidents**

As described in Subsection 2.1.5, two railway lines run within the 10 km study area surrounding the Darlington Nuclear site. Of particular relevance is the Canadian National Railway line which bisects the Darlington Nuclear site and passes approximately 600 m north of the DNNP site. This railway line has potential hazards associated with assumed derailment accidents involving one or more cargo cars.

Rail transportation accidents are assessed in the 2019 DNGS Hazards Screening Analysis NK38-REP-03611-10043 (Reference 2.2-5), the 2022 DNNP Rail Transportation – Toxic Gas/Chemical Release Hazard Assessment NK054-REP-01210-00150 (Reference 2.2-11), and the 2022 DNNP Rail Transportation – Explosion Hazard Assessment NK054-REP-01210-00149 (Reference 2.2-12). The objective is to address hazards associated with train derailment and crash, including

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

cold or hot toxic gas releases, as well as Vapour Cloud Explosions, Boiling Liquid Expanding Vapour Explosion, and other types of explosions.

The assessments considered the two rail lines running “east-west” directly north of Darlington Nuclear site. Of particular interest is the Canadian National Railway Toronto to Montreal main line which passes through the OPG DNGS and DNNP sites, as shown in Figure 2.1.1-2.

One of the hazards analyzed in the 2022 NK054-REP-01210-00150 (Reference 2.2-11) is the possibility of a large toxic gas/chemical release. A consequential harm from this hazard could be a toxic gas/chemical release that would be airborne toward the DNNP site with the capacity for widespread and distant impact. Another hazard is the potential of large explosion, analyzed in NK054-REP-01210-00149 (Reference 2.2-12), involving explosive commodities being transported by the railway line, occurring in the vicinity of DNNP BWRX-300 structures and components. The following toxic gas release and explosion scenarios are assessed in the 2019 NK38-REP-03611-10043 (Reference 2.2-5), the 2022 NK054-REP-01210-00150 (Reference 2.2-11), and the 2022 NK054-REP-01210-00149 (Reference 2.2-12), for applicability to DNNP:

1. Cold Toxic Gases Release: Release and dispersion of airborne toxic chemicals or asphyxiants toward the BWRX-300 HVAC intakes that could expose the station staff to toxic chemicals and result in challenging the habitability of work areas.
2. Hot Toxic Gas Release: Similar to cold toxic gas releases, if the train derailment accident involves fire, it could result in hot toxic gas releases. Combustible chemicals could result in releasing an intense heat, causing secondary combustion of other materials (e.g., insulations, containers and covers), and such releases usually involve other chemicals that can have a wide range of toxicities. Heavy hydrocarbons produce a significant amount of carbon dioxide, carbon monoxide and soot when they catch fire. Some chemicals may produce toxic byproducts while burning, such as hydrazine (combustion byproducts include nitrogen dioxide, which is highly toxic).
3. Hydrocarbon Explosions: Release of light hydrocarbons with high vapour pressures (flammable), when transported under high pressure (e.g., liquefied petroleum gas), can produce two types of explosions:
  - a. Boiling Liquid Expanding Vapour Explosion: Boiling Liquid Expanding Vapour Explosions could generate missiles, fireballs, and blast waves. Missiles could travel hundreds of meters from the source. Blast waves from Boiling Liquid Expanding Vapour Explosions are normally localized.
  - b. Vapour Cloud Explosion: With Vapour Cloud Explosions, vapour cloud ignition is delayed after the cloud has dispersed somewhat and mixed with air. Vapour Cloud Explosions produce blast waves that could damage buildings and equipment.
  - c. Confined Explosions: A flammable fluid can produce a confined explosion if it becomes airborne, mixes with air, and is ignited in a confined space. This would produce a so-called Confined Explosion. Such an explosion could arise in a building, a room, or the vapour space of a storage tank. Blast waves from confined explosions are localized.

The hazard from the release of toxic gases resulting from Canadian National Railway assumed transportation accidents close to the DNNP site have an estimated frequency of 1.9E-06 occ./yr, per the 2022 NK054-REP-01210-00150 (Reference 2.2-11). Thus, it is screened out from design basis input since it is assessed as a Beyond Design Accident (BDBA) DEC, per REGDOC-2.4.1 (Reference 2.2-14).

Similarly, the explosion hazard from a Canadian National Railway derailment accident near the DNNP site has an estimated frequency of  $9.0\text{E-}07$  occ./yr, per the 2022 NK054-REP-01210-00149 (Reference 2.2-12). Consequently, it is screened out from design basis input based on the assessment that it is a BDBA DEC, per REGDOC-2.4.1 (Reference 2.2-14).

#### **2.2.3.3 Characterization of Hazards from Road Transportation and Traffic Accidents**

Road transportation and traffic accidents are assessed in 2019, and results for DNGS are reported in Subsection 3.2.3 of per the 2019 NK38-REP-03611-10043 (Reference 2.2-5). The assessment considered the location of the Darlington Nuclear site, also encompassing the DNNP site, which is about 1.0 km away from the Macdonald–Cartier Freeway (also known as Highway 401) and one of the busiest highways in Canada.

The event scenario considered involves two tractor trailers crash (or rollover), such that multiple containers are damaged, consequential toxic or asphyxiant materials are released into the atmosphere, and the wind (2 m/s) disperses the airborne chemicals toward the BWRX-300 HVAC systems intakes (refer to Chapter 9A, Section 9A.5 for information on BWRX-300 HVAC systems).

Highway 401 is about 1.0 km north of the DNNP site. The impact of two tractor trailer crash is therefore screened out based on distance. Explosion or release of toxic/asphyxiant materials from the colliding two tractor trailers depends on the size of insuring breaks and the consequential amount of material released (via leaking or 100% break), wind direction and speed, and the degree of dilution due to dispersion. This scenario is therefore screened out based on distance and low impact without performing confirmatory assessment.

#### **2.2.3.4 Characterization Hazards from Marine Transportation**

The cargo vessels move along shipping lanes which are designated by the Ministry of Transport, and the nearest approach is about 27 km from the Darlington Nuclear site, per Section 3.3 of the 2019 NK38-REP-03611-10043 (Reference 2.2-5). Therefore, scenarios involving tankers or cargo ships are, in general, screened out based on distance, per screening criterion [QL3]

The consequences of a chemical leak from a tanker or a cargo ship would be mostly an environmental hazard. Depending on the exact nature, severity, and progression time of the accident as well as the consequential amount of leaked material, lake current and degree of dilution, such scenarios would have negligible impact on the quality, or the quantity of the cooling water supplied to the BWRX-300. A tanker or cargo ship accident resulting in chemical leak is screened out based on screening criterion [QL6].

The hazard of an explosion onboard a cargo ship and subsequent release of toxic gases is screened out based on screening criterion [QL3], that is, the event cannot occur at the site or close enough to the site to affect the plant.

As described in the 2019 NK38-REP-03611-10043 (Reference 2.2-5), a large number of small or large recreational boats or vessels travel across Lake Ontario, Winter conditions limit this traffic to about 8 months of the year. Hazards from accidents involving such recreational boats or vessels pose no significant threat to the BWRX-300 safe operation, even if the accidents occur near the lake water intake structure. St. Marys Cement Company Limited owns a pier that is about 700 m to the east of the DNNP site. Bulk carriers may load cement or unload gypsum or coal at this dock. Also, a restricted zone is established around the BWRX-300 offshore structures. The consequence of such accidents is bounded by a frazil ice hazard, and therefore, associated hazards are screened out based on criterion [QL1]

#### 2.2.4 Characterization of Stationary Non-Nuclear Accidents Hazards

The evaluation of hazards associated with stationary non-nuclear accidents is based on the results of the assessment reported in the 2019 NK38-REP-03611-10043 (Reference 2.2-5) for DNGS. Since DNNP is also located within the Darlington Nuclear site boundary, the results of the DNGS assessment are relevant to DNNP.

Event scenarios that can result in an accidental fire, explosion, or a release of hazardous material from stationary sources have been assessed in Section 3.5 of the 2019 NK38-REP-03611-10043 (Reference 2.2-5). The locations of the initiating mechanism for these sources are constrained to tank farms and forest fires.

The main stationary sources of external hazardous material near the Darlington Nuclear site are:

1. Regional Water Treatment Plants which generally have a large inventory of Chlorine for treatment of water.
2. Cigas Propane, which is located 3.6 km away from Darlington Nuclear site, where a large inventory of propane gas is stored.
3. St. Marys Cement plant located about 1.5 km east of the DNGS site and approximately 700 m from the DNNP site. The plant stores large inventories of a variety of hazardous chemicals on-site. The main toxic and hazardous materials are as follows (Reference 2.2-16):
  - Aqueous (19%) ammonia ( $\text{NH}_4\text{OH}$ ) tank with capacity of up to 38 000 L
  - Diesel fuel storage tanks with capacity of up to 50 000 L used for heating and fueling mobile equipment.
4. The DNGS Tritium Removal Facility where chemicals and fuel stored could potentially pose hazards to DNNP BWRX-300 resulting from the release of toxic chemicals, hydrocarbon explosions (Boiling Liquid Expanding Vapour Explosions and Vapour Cloud Explosions), or confined explosions (refer to Subsection 2.2.5.4 for additional information on DNGS potential hazards).

Substantial pipelines carrying large quantities of natural gas do not run close enough to the Darlington Nuclear site. Therefore, the risk of fire due to pipelines ruptures poses a negligible incremental risk to the DNNP site and, thus, it was screened out based on screening criterion [QL-6] (Subsection 2.2.2).

##### 2.2.4.1 Characterization of Toxic Chemicals Releases from Stationary Hazards

As described in the 2019 NK38-REP-03611-10043 (Reference 2.2-5), the event scenario assessed involves a local accident in one of the regional water treatment plants (for example, Courtice WPCP) or in the St. Marys Cement plant, resulting in the release of chlorine gas ( $\text{Cl}_2$ ) or gas/aqueous ammonia ( $\text{NH}_3/\text{NH}_4\text{OH}$ ), respectively. Combustion of  $\text{NH}_3$  in the air could result in  $\text{NO}$  or  $\text{NO}_2$ , in the presence of appropriate catalysts. Nitrogen dioxide is toxic by inhalation, but it is easily detectable by smell at low concentrations. The combustion of ammonia in air is difficult in the absence of a catalyst, as the temperature of the flame is usually lower than the ignition temperature of the ammonia-air mixture.

The accident is assumed to include multiple containers. As such, the airborne toxic material, chlorine, or ammonia, released into the atmosphere could disperse toward the BWRX-300 HVAC intakes. Depending on the size and nature (i.e., severity and time frame) of the release, wind direction and wind speed, the concentration of toxic chemicals varies.

For the chlorine hazard, the nearest water treatment plant, the Courtice WPCP, is approximately 5 km west of the BWRX-300 HVAC intakes. Thus, this hazard is screened out under screening criterion [QL-3] (Subsection 2.2.2) as the event cannot occur at the site or close enough to the site to affect the plant.

With respect to the ammonia hazard associated with accidents at the St. Marys Cement plant which is located approximately 700 m east of DNNP site boundary (Reference 2.2-16) and considering the total low-level of inventory of ammonia at the St. Marys plant, the toxic release is screened out from further assessment under screening criterion [QL-1] (Subsection 2.2.2).

#### **2.2.4.2 Characterization of Explosions from Stationary Sources**

The event scenario involves the explosion of multiple propane tanks at the Cigas Propane storage facility, or the explosion of multiple diesel fuel tanks located at the St. Marys Cement plant as per Subsection 3.5.2 of the 2019 NK38-REP-03611-10043 (Reference 2.2-5). As multiple tanks are damaged, there are missiles potentially generated by the explosions, as well as shockwaves, which can damage SSCs several hundred meters away.

The screening distances for different types of explosions, per the 2019 NK38-REP-03611-10043 (Reference 2.2-5) are estimated at 1600 m for Boiling Liquid Expanding Vapour Explosion, 700 m for explosions equivalent to 61.5 Mg trinitrotoluene, and 460 m for Vapour Cloud Explosion. For the DNNP, considering the distances of the hazardous sites (3,600 m for Cigas Propane, and greater than 700 m for St. Marys Cement), both scenarios for Boiling Liquid Expanding Vapour Explosion due to propane tanks explosions at Cigas Propane, and explosions due to diesel fuel tanks at St. Marys Cement were screened out, based on distance screening criterion [QL3]. (NOTE: The St. Marys Cement does not store large quantities of pressurized light hydrocarbons (unlike that in Cigas Propane.)

An assessment of missiles generated from an explosion associated with hydrogen used in the Tritium Removal Facility was performed in 2019 for DNGS in NK38-REP-03611-10043 (Reference 2.2-5). The Tritium Removal Facility is located directly west of the DNGS vacuum building. The assessment determined that missiles generated by an explosion in the Tritium Removal Facility are bounded by missiles generated by a design basis tornado, for which DNGS is protected.

The DNNP facility is approximately 1.0 km away from the Tritium Removal Facility, and the DNGS and its vacuum building provide an obstruction between the Tritium Removal Facility and the DNNP BWRX-300 facility. As such, this hazard is screened out based on [QL-3] for large missiles since the event cannot occur on or close enough to the DNNP site to affect the BWRX-300 facility. Small missiles generated by an explosion at the Tritium Removal Facility can also be screened out for the DNNP BWRX-300 design, using screening criterion [QL-4], since such small missiles are bounded by the design basis tornado automobile missiles (refer to Subsection 2.6.6).

#### **2.2.5 Characterization of Stationary Nuclear Accidents Hazards**

Stationary nuclear accident sources within the vicinity of DNNP that pose potential hazards from nuclear accidents are:

1. Cameco's Port Hope Uranium Conversion Facility – located about 40 km east of the Darlington Nuclear site where the DNNP is located
2. PNGS – located about 25 km west of the Darlington Nuclear site where the BWRX-300 is to be built
3. DNGS – located within one kilometer west of the BWRX-300 footprint

The Cameco facility and PNGS were assessed in the 2019 Hazard Screening Analysis NK38-REP-03611-10043 (Reference 2.2-5) performed for DNGS.

#### **2.2.5.1 Evaluation of Cameco's Port Hope Uranium Conversion Facility Hazard**

Cameco's Port Hope uranium conversion facility is a nuclear substance processing facility licensed to process uranium trioxide ( $\text{UO}_3$ ) into both uranium dioxide ( $\text{UO}_2$ ) and uranium hexafluoride ( $\text{UF}_6$ ). Natural  $\text{UO}_2$  is used to manufacture CANDU fuel for nuclear power reactors in Canada, while  $\text{UF}_6$  is exported to companies in other countries for enrichment and fabrication into fuel for international nuclear power reactors. The facility is located on the north shore of Lake Ontario, approximately 40 km east of Darlington Nuclear site. The Cameco plant is a chemical processing facility with negligible radioactive releases, and therefore it is not included in the screening analysis for DNGS. Based on the DNNP proximity to DNGS, the screening results for DNGS are directly applicable to DNNP and hence screened out from further evaluation both deterministically and probabilistically.

#### **2.2.5.2 Characterization of Pickering Nuclear Generating Station Hazards**

PNGS is located on the shores of Lake Ontario, approximately 25 km west of Darlington Nuclear site. The PNGS is an eight-unit station with six operating CANDU reactors with a total output of 3100 MWe, and two units in safe storage. OPG is conducting a re-assessment, per the 2022 P-CORR-00531-23042 (Reference 2.2-13), involving a comprehensive technical examination of the potential for refurbishing Units 5, 6, 7 and 8 of PNGS. The results including recommendations of such an assessment are to be reported in 2023.

As described in the 2019 NK38-REP-03611-10043 (Reference 2.2-5), the accidental release of radioactive materials at PNGS can be screened out for DNGS given it is a slow developing event, and there are mitigating features as well as enough time for operators to take proper actions. As the DNNP is farther from PNGS and similar mitigation measures, if warranted, are implemented, the radiological hazards associated with such events are also screened out for DNNP. Any hazard from PNGS used CANDU fuel still within an irradiated fuel bay or a dry storage facility is bounded by the much closer event from DNGS discussed in Subsection 2.2.5.4.2.

#### **2.2.5.3 Characterization of Darlington Nuclear Generating Station Hazard**

The BWRX-300 Unit 1 footprint resides partly within the DNGS exclusion zone (nominally 914 m), that is within DNGS controlled area, per Subsection 5.10 of the 2020 NK054-CORR-00531-10533 (Reference 2.2-4). The closeness of DNNP to DNGS means that in the event of a nuclear accident within DNGS the ability to maintain safe operation of DNNP can potentially be affected.

#### **2.2.5.4 Characterization of Other Radiological Hazards from DNGS**

Potential radiological hazards in the area that could affect the safe operation of the new nuclear plant were evaluated in Section 4.8 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1). Nuclear events at the DNGS considered in this assessment were as follows:

- Tritium Removal Facility accidents leading to release of tritium
- In-plant fire near a storage area of active liquid waste
- Used irradiated fuel accident
- Design basis reactor accidents
- Beyond design basis reactor accidents which include severe accidents that have the potential for a significant off-site release of radioactive materials

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

The assessment determined these events do not pose a concern to equipment but would likely impact the operating staff of the proposed plant (that is, the BWRX-300 facility). Four specific events as listed below are discussed in more details:

- Tritium Removal Facility – Subsection 2.2.5.4.1
- Irradiated Fuel Storage Facility – Subsection 2.2.5.4.2
- Used Fuel Dry Storage – Subsection 2.2.5.4.3
- Radioactive Waste Storage -Subsection 2.2.5.4.4

In October 2021, DNGS Power Reactor Operating Licence PROL 13.02/2015 was amended to authorize unit 2 to produce molybdenum-99, an isotope used in the medical industry for diagnostics. The CNSC decision concludes that the licensed activities will have a negligible effect on severe core damage frequency and large release frequency (Reference 2.2-17). In the future, DNGS may pursue production of other isotopes and/or molybdenum-99 in other units.

***2.2.5.4.1 Characterization of Tritium Removal Facility Hazard***

The Tritium Removal Facility is located within the boundary of the DNGS site, to the west side of the DNGS vacuum building. Release of tritium from an accident at the Tritium Removal Facility was evaluated in Section 4.8 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1). The assessment concluded that accidents leading to a tritium release do not pose concern to equipment but have the potential to impact operators. (Refer to Chapter 6, Subsections 6.4.1.1 and 6.4.1.2 for information on the BWRX-300 MCR and SCR habitability provisions, respectively.)

Helium-3 (He-3) is also extracted from tritium storage containers at the Tritium Removal Facility for medical and commercial uses. He-3 is a non-radioactive, inert, and non-toxic gas and therefore accidental release does not contribute any additional risk.

***2.2.5.4.2 Characterization of Irradiated Fuel Storage Facilities Hazards***

Following its useful life in the DNGS reactors, used CANDU fuel bundles are discharged from the fueling machine heads and initially stored underwater in modules in irradiated fuel bays at the West and East Fueling Facility Auxiliary Areas, located inside the DNGS protected area, adjacent to Unit 1 and Unit 4, respectively. Then the used fuel modules are transferred to and placed into seismic stacking frames inside the main irradiated fuel storage bays where the water in the bays removes heat produced by the decaying used fuel and provides shielding for workers. After a specified number of years, based on bays capacity and operational needs, the used fuel is transferred to an on-site irradiated fuel dry storage facility for short-term storage, and ultimately to an off-site long-term dry storage facility when it becomes available in the future. The hazards posed by both the irradiated fuel bays and the on-site irradiated fuel dry storage facility are analyzed in NK38-REP-03611-10043 (Reference 2.2-5).

Radiological releases from used fuel accidents were also evaluated in Section 4.8 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1). It was determined that used fuel accidents posed no concern for DBAs.

Analysis of human-induced hazards and natural hazards for the DNGS irradiated fuel bays was performed and documented in Section 5 and Section 6, respectively of the 2019 NK38-REP-03611-10043 (Reference 2.2-5). All human-induced hazards analyzed have been screened out (Table 5-1 of the 2019 NK38-REP-03611-10043 (Reference 2.2-5)), which is applicable to DNNP as well. For natural hazards, Table 6-1 of the 2019 NK38-REP-03611-10043 (Reference 2.2-5) summarizes hazards which are not screened out. Irradiated fuel bay accident analysis is documented in Subsection 3.6.4 of the 2017 NK38-SR-03500-10002 (Reference 2.2-9).

#### ***2.2.5.4.3 Characterization of Used Fuel Dry Storage Hazard***

Analysis of human-induced hazards and natural hazards for irradiated CANDU fuel dry storage facility was performed and documented in Section 7 and Section 8, respectively, of the 2019 NK38-REP-03611-10043 (Reference 2.2-5). All human-induced and natural hazards analyzed have been screened out as not having a safety impact on DNGS. The results are directly applicable to DNNP BWRX-300 and have been screened out, as per Table 5-1 of the 2019 NK38-REP-03611-10043 (Reference 2.2-5).

#### ***2.2.5.4.4 Characterization of Radioactive Waste Storage Hazard***

The scenario analyzed in Section 4.8 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1) for radioactive waste storage accidents is an in-plant fire near a storage area of active liquid waste. This event poses no concern for DBAs.

### **2.2.6 Characterization Industrial Hazards**

The primary industrial hazard of concern is uncontrolled underground blasting associated with the St. Marys Cement plant.

This hazard was assessed in Section 3.6 of the 2019 DNGS Hazard Screening Assessment NK38-REP-03611-10043 (Reference 2.2-5). The results of the assessment indicated blasting at St. Marys quarry leads to shock waves in the ground travelling to the Darlington Nuclear site.

Vibration monitors on the Darlington Nuclear site at the St. Marys' property boundary are designed to record the amplitude and frequencies of such shock waves, originating from the St. Marys Cement plant. St. Marys Cement commits to not carry out blasts that may exceed the maximum allowable horizontal, vertical, longitudinal, and radial velocities of 3 mm/s measured at the Darlington Nuclear site property boundary with St. Marys.

This agreement was originally put in place to avoid turbine trips at DNGS. Since DNNP is in geographic proximity to DNGS and is closer to St. Marys Cement plant than DNGS, this hazard is applicable to the BWRX-300 facility.

The agreement noting 3 mm/s is between OPG and St. Marys and is therefore applicable to DNNP.

The maximum allowable horizontal, vertical, longitudinal, and radial velocities of 3 mm/s measured at OPG's Darlington Nuclear site property boundary is screened in and shall be considered in the design of the BWRX-300 facility.

### **2.2.7 Characterization of Biological, Animal, and Frazil Ice Hazards**

Lake Ontario is the reservoir of cooling water for the DNNP BWRX-300 facility. Fouling of the intake structures and components from growth of biological species (e.g., algae, mussels, or clams) and the presence of animals (e.g., birds, fishes, or other wildlife) impede the availability of water for heat sink purposes. Also, the formation of frazil ice at the intake can restrict or block supply to the Circulating Water System (CWS) (refer to Subsection 2.5.2). Both potential hazards are evaluated in the following two subsections.

#### **2.2.7.1 Characterization of Biological and Animal Hazard**

##### **Biological Hazards**

A variety of sources of organisms or organic material that could contribute to biofouling associated with cooling water systems originate from the pathway represented by Lake Ontario, thus restricting or blocking water supply to the BWRX-300 facility.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

The impact of biological and animal hazards on the safe operation of DNNP was considered and documented in the 2009 NK054-REP-01210-00019 (Reference 2.2-2), the 2020 NK054-CORR-00531-10533 (Reference 2.2-4), the 2009 NK054-REP-01210-00018 (Reference 2.2-7), and the 2021 NK054-REP-01210-00078 (Reference 2.2-8).

Section 2 of the 2009 NK054-REP-01210-00018 (Reference 2.2-7) assessed the hazards associated with blockage of cooling water intake. The primary species that can contribute to biofouling have been identified and assessed. Biofouling was identified as a potential hazard that can result in loss of cooling and fouling of cooling equipment, such as lines and heat exchangers.

Section 3.5 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1) considered the adequacy of water supply affected by biofouling, where several species were assessed.

Further discussion on the prevention of biofouling for the cooling water intake is provided in Subsection 2.5.2.2.

#### Animal Hazards

Airborne animal hazards (e.g., birds or insects) have the ability to block the screens of the MCR air ventilation intakes. This event is equivalent to outside air damper isolation during off-normal conditions, as described in Chapter 9A, Subsection 9A.5.2.1.4. The airborne animal hazard is therefore screened out using screening criterion [QL6].

#### **2.2.7.2 Characterization of Frazil Ice Hazard**

Section 3.5 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1) states frazil ice forms in turbulent, supercooled water (water temperatures of  $-0.01^{\circ}\text{C}$  to  $-0.05^{\circ}\text{C}$ ). To generate these conditions, hydro-meteorological conditions must be such that there is sufficient heat loss from the water to cause water temperature to decrease to the freezing point. The physical parameters relevant to the formation of frazil ice include water temperature, air temperature, wind speed, and humidity.

In lakes, blockages of intakes are associated with open water, low temperatures, and clear nights. They also are often associated with strong winds, which increase the rate of heat loss at the water surface as well as potentially provide turbulence that can mix the supercooled water to the depth of the intake. The intake flow can also entrain the supercooled water if it is of sufficient velocity. The depth at which a lake intake will be free from the impacts of frazil ice is also dependent on other factors, such as lake bottom topography and intake structure dimensions.

Frazil ice is considered a potential hazard for causing water intake blockage to the BWRX-300 facility.

#### **2.2.8 Characterization of Ice Storm Hazard**

The impact of ice storms on the safe operation of the reactors at the Darlington Nuclear site was considered in the 2009 NK054-REP-01210-00008 (Reference 2.2-1) for DNNP and assessed in the 2019 NK38-REP-03611-10043 (Reference 2.2-5) for DNGS.

Section 3.2 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1) considered ice storms as part of the freezing rain assessment under rare meteorological events. The major ice storm event on record for the Darlington Nuclear site occurred in January 1998, over a period of 5 days. During the storm event, 80 -100 mm of freezing rain affected areas from Kingston to Granby, Quebec. On average, Toronto Pearson Airport recorded 17.1 hours of freezing rain per year, 8.8 days per year; while Trenton airport reported 21.9 hours of freezing rain per year and 11.4 days per year, as per the 2021 NK054-REP-01210-00078 (Reference 2.2-8).

Freezing rain totals ranging from 50 mm to 75 mm have been reported on few occasions in southern Ontario; whereas 10 mm of freezing rain is to be expected occasionally and up to 20 mm of freezing rain is highly likely to occur over the time the site will be operational. Historically, freezing rain events with more than 50 mm have been observed in the same broad climatological region but are not frequent, with maximal amounts near 100 mm (refer to the 2009 NK054-REP-01210-00008 (Reference 2.2-1)).

The ice storm hazard for DNGS was assessed in the 2019 Darlington Hazards Screening Analysis NK38-REP-03611-10043 (Reference 2.2-5) and documented there in Subsection 4.5.5. The analysis reviewed OPG and CANDU Owners Group operating experience databases, as well as databases for other power plants. The review showed ice storms have not had an impact on the plants, but severe storms were seen to lead to losses of off-site power and switchyard failures in several cases. In 1998, Hydro Quebec experienced a loss of grid for several days due to an ice storm. During this ice storm, 40 mm of freezing rain was observed in Kingston, Ontario, and as much as 120 mm of freezing rain was observed in certain parts of Quebec.

For the DNNP BWRX-300, the LOPP event, an Anticipated Operational Occurrence (AOO), which is in the Pressure Increase Group and is designated as a BL-AOO event (refer to Chapter 15, Subsection 15.5.3.2.4).

### **2.2.9 Characterization of Electromagnetic Interference Hazard**

Electromagnetic interference can affect the functionality of instrumentation and control equipment and can be initiated by both on-site sources, such as high-voltage switchgear and off-site sources such as communication networks. It has the potential of disrupting electrical components and instrumentation leading to potential impairment of critical plant control signals. This hazard was assessed in the 2009 NK054-REP-01210-00008 (Reference 2.2-1), the 2009 NK054-REP-01210-00019 (Reference 2.2-2), and the 2020 NK054-CORR-00531-10533 (Reference 2.2-4) for DNNP and in the 2019 NK38-REP-03611-10043 (Reference 2.2-5) for DNGS.

Section 2.1 of the 2009 NK054-REP-01210-00019 (Reference 2.2-2) identified this hazard for consideration in the design to provide the required shielding of critical components and “fail safe” wherever required.

Section 4.9 of the 2009 NK054-REP-01210-00008 (Reference 2.2-1) assessed external sources of electromagnetic interference including high-voltage transmission lines at DNGS and telecommunications towers. The assessment concluded that since electromagnetic interference sources are continuously present (including lightning induced electromagnetic interference), the risk of electromagnetic interference at the site must be addressed in the design basis of the new plant (currently, that is the BWRX-300 facility).

### **2.2.10 Characterization of On-site Methane Hazard**

During initial site investigation, naturally occurring gas (methane) was found at/or near the bedrock/overburden interface in Boreholes DN-34, DN-41, DN-44, DN-48, DN53, DN-57, and DN-60 as described in Subsection 5.3.1 and Section 9.3 of the 2009 NK054-REP-01210-00011 Site Evaluation (Reference 2.2-6). Methane gas is harmful to the health of humans and is combustible. Methane is naturally produced at low-level from the bedrock by decaying vegetation from long ago.

Excavation near the bedrock/overburden interface will monitor for the methane gas and precautionary measures during construction will be taken per work documentation as required by the Canadian Centre for Occupational Health and Safety. For the RB excavation, the methane is expected to dissipate quicker than what was observed in the boreholes due to the significantly larger air space.

## **2.3 Proximity of Industrial, Transportation and Other Facilities**

Information in Section 2.3 describes potential hazards associated with transportation network, industrial facilities and the DNGS which are proximate to the DNNP site.

### **2.3.1 Transportation Network**

There are multiple transportation networks within, adjacent to, and around the Darlington Nuclear site that present potential risks to the BWRX-300 facility operation.

#### **a. Canadian National Railway**

The Canadian National Railway line bisects the Darlington Nuclear site and is primarily used to transport commuters (VIA Rail) with services from Toronto to Kingston, Montreal, and Ottawa. Significant number of passengers travel this route annually and tremendous cargo is transported annually on the line, including coal, forest products (e.g., lumber), chemicals, petroleum products (e.g., asphalt), automotive parts/products, and agricultural goods (e.g., fertilizer).

Given the high frequency of both commuter and cargo traffic on this railway line, there is a potential risk of train derailment at the site. This risk is mitigated to some degree as the railway line is well buffered by berms on both sides of the railway corridor that would involve any possible derailment. In addition, VIA Rail announced in 2021 it was embarking the High Frequency Rail project that will divert a portion of the commuter rail to a separate line to relieve congestion on the current line and avoid congestion risks with cargo/freight shipments.

Additional information on hazards related to rail transportation accidents is provided in Subsection 2.2.3.2.

#### **b. Highway 401**

Highway 401, its official name Macdonald–Cartier Freeway, is a controlled-access 400-series highway stretching from Windsor in the west to the Ontario–Quebec border in the east. The highway runs along the north of the Darlington Nuclear site boundary as a six lane (three east-bound lanes and three west-bound lanes) highway.

Information on transportation risk associated with the 401 highway is described in Subsection 2.2.3.3.

#### **c. Oshawa Executive Airport**

The Oshawa Executive Airport, owned and managed by the City of Oshawa, is located northwest of the Darlington Nuclear site. It is located on an approximately 2.0 km<sup>2</sup> site with a modern terminal building and dual runways measuring approximately 1296 m and 809 m, respectively, to service different types of aircraft. The airport is required by the federal government to operate until 2047 but may close prior to 2047 (but not before 2033 at the earliest) if Pickering airport is opened. In 2018, total aircraft movement at the airport was over 78,000.

Information on risk associated with air transportation is presented in Subsection 2.2.3.1.

### **2.3.2 Industrial Facilities**

There are few industrial facilities in proximity to the east of the DNNP site and to the west of the DNGS site that could cause potential risks to the BWRX-300 operation. Details are presented on such facilities in Subsection 2.1.1, and on pertinent potential hazards in Subsection 2.2.4 and Subsection 2.2.6.

### **2.3.3     Darlington Nuclear Generating Station Site**

There are numerous activities at the DNGS that may impact the operation of the BWRX-300. The following activities apply:

- a. OPG uses arial photography drones, for inspection of the exterior of some of the DNGS buildings, as well as systems and components. The hazard of such drone crashing on the BWRX-300 buildings is bounded by the design basis automobile tornado missiles (refer to Subsection 2.6.6).
- b. Chemicals and gases used at the 2019 DNGS NK38-REP-03611-10043 (Reference 2.3-1) are screened out on the basis:
  - That their impact is bound by the impact of similar chemicals on the BWRX-300 (refer to Section 2.4, Table 2.4-1)
  - Of distance from the DNNP site
  - Of the probability of occurrence of relevant accidents.

Refer to Subsection 2.2.5.3 and Subsection 2.2.5.4 for additional and detailed coverage of other hazards related to the operation of the DNGS, or activities being undertaken at the DNGS site.

### **2.3.4     References**

- 2.3-1     NK38-REP-03611-10043 R003, 2019, "Hazard Screening Analysis - Darlington," Ontario Power Generation.

## **2.4 Plant Site Activities Influencing Plant Safety**

Section 2.4 includes two subsections:

- Subsection 2.4.1, which evaluates processes and activities at the DNNP site that, if incorrectly carried out, could affect or influence the safe operation of the BWRX-300 facility
- Subsection 2.4.2, which discusses measures for site and shoreline protection.

### **2.4.1 Site Hazards**

Subsection 2.4.1 is limited to processes and activities at the DNNP site. Activities at DNGS or other off-site industrial locations are considered in Section 2.3. Subsection 2.4.1 information is focused on the following site-specific sources of hazards:

- Potentially explosive gases – Subsection 2.4.1.1
- Flammable vapour clouds – Subsection 2.4.1.2
- Toxic chemicals – Subsection 2.4.1.3
- Fire and smoke – Subsection 2.4.1.4

Table 2.4-1 provides a listing of gases and chemicals stored on the DNNP site.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 2.4-1: Summary of Gases and Chemicals Stored on DNNP Site**

<b>Chemical/Material (Formula/Trade/State)</b>	<b>Location (subject to change)</b>	<b>Quantity</b>	<b>Hazard Screening</b>
Nitrogen	Gas Storage Area West of TB	Approximately 50 m <sup>3</sup> (Cryogenic Storage Tank)	Nitrogen is evaluated as potential asphyxiant concern for MCR and SCR habitability.
Hydrogen	Gas Storage Area West of TB	Each cylinder stores 356.1 standard cubic meters (SCM).	Hydrogen is a potential explosive and fire concern. Minimum separation distance between the cylinders and the BWRX-300 RB wall is determined based on explosive potential.
Diesel Fuel	Tank North of the Protected Area Access Building	Approximately 114 000 L Tank	Not a toxic or explosive hazard. Potential of fire hazard is addressed in Chapter 9A, Section 9A.6.
Turbine Oil	Tank North of the Protected Area Access Building	Approximately 20 000 L tank (volume of the tank does not impact MCR habitability)	Not a toxic or explosive hazard. Potential fire hazard is addressed in Chapter 9A, Section 9A.6.
Sodium Hypochlorite (7 to 15% Solution)	Adjacent to Pumphouse/Forebay, and Intake Shaft	Approximately 4000 L tank	Sodium hypochlorite is not considered a hazard due to being a liquid at 37.8 °C (100 °F) and normal atmospheric pressure. Sodium hypochlorite has a relatively low vapour pressure. Due to the relatively low vapour pressure, no significant unreported and prolonged release that could affect MCR habitability would be expected even in the event of a major spill.
Sodium Bisulphite (24 – 38% Solution)	Adjacent to Pumphouse/Forebay, and Intake Shaft	Approximately 11 400 L tank	Based on chemical safety data sheet sodium bisulphite is relatively stable. Sodium bisulphite is not considered a hazardous substance based on an absence of associated Immediately Dangerous to Life and Health exposure limits in National Institute of Occupational Safety and Health.
Captor Thiosulphate Dichlorination	Adjacent to Pumphouse/Forebay, and Intake Shaft	Approximately 11 400 L tank	Based on chemical safety data sheet captor thiosulphate is not a toxic hazardous substance.
Gasoline	Vehicle Maintenance Garage	Approximately 20 L containers	Gasoline is a potential explosion and fire concern. Small quantities do not pose a significant hazard.
Propylene Glycol	Within the P25, Chilled Water System, throughout the Power Block	39 000 L	Based on chemical safety data sheet propylene glycol is not a toxic hazardous substance for MCR habitability.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Chemical/Material (Formula/Trade/State)	Location (subject to change)	Quantity	Hazard Screening
Tetrafluoroethane (R-134a Refrigerant)	P25 Chillers on RadWaste Building Roof	Each Chiller contains a refrigerant charge of 250 kg	R134a is not a toxic hazard for MCR habitability. Release of the entire contents of the R-134a into the Control Building does not result in an oxygen-deficient environment in the MCR.
Noble Metal Solution	Reactor Building	Approximately 38 L of 1% noble metal solution is utilized over a 2-week time frame per year.	The noble metal solution is not considered a hazard to MCR habitability based on an absence of associated Immediately Dangerous to Life and Health exposure limits in National Institute of Occupational Safety and Health. A potential release will be relatively confined to the RB and not impact MCR habitability.
Depleted Zinc Oxide	Turbine Building (TB)	90 kg dissolution vessel (quantity does not impact MCR habitability)	Zinc oxide is not considered a hazard to MCR habitability based on an absence of associated Immediately Dangerous to Life and Health exposure limits in National Institute of Occupational Safety and Health. A potential release of zinc oxide dust will be relatively confined to the Turbine Building and not impact MCR habitability.

#### **2.4.1.1 Potentially Explosive Gases**

The nearest source of potentially explosive gases is the hydrogen gas storage cylinders for the Reactor Water Chemistry System. Table 2.4-1 lists the maximum quantity of hydrogen stored at this location. The hydrogen is stored in several cylinders.

The safe separation distance between the hydrogen storage area and nearest safety-related structure is determined using a methodology such as the approach in EPRI NP-5283-SR, Guidelines for Permanent BWR Hydrogen Water Chemistry Installations, September 1987 (Reference 2.4-1). In the 1987 EPRI NP-5283-SR (Reference 2.4-1) the required separation distance is determined for two different considerations. The first consideration is the required separation distance such that the safety-related structure is not adversely affected by the postulated hydrogen explosion. The second consideration is the required separation distance to air pathways into safety-related structures versus the internal diameter of leaking high-pressure piping. The results of the determination of required separation distance are considered in establishing the layouts for the DNNP site and BWRX-300 facility.

#### **2.4.1.2 Flammable Vapour Clouds**

There are no liquids stored on the DNNP site that can generate a significant quantity of flammable vapour.

#### **2.4.1.3 Toxic Chemicals**

Table 2.4-1 identifies the chemicals on the DNNP site that are considered in the evaluation of potential toxic chemical hazards. Table 2.4-1 identifies the chemical, the quantity, and how the chemical is dispositioned. Chemicals are initially evaluated based on relative location, quantity stored, toxicity, and properties such as vapour pressure. As shown in Table 2.4-1, from a toxic chemical perspective, the potential hazards at the DNNP site except for nitrogen are dispositioned as not being hazardous for control rooms habitability. The liquid nitrogen, however, cannot be screened out and requires a detailed evaluation.

The threat from nitrogen is displacement of oxygen. No specific acceptance criterion is provided for limiting concentrations, and nitrogen is not considered a toxicity hazard. Nitrogen impacts control room habitability if it displaces sufficient quantities of air to the extent that oxygen levels in the room decrease below a specified threshold. Chemicals are asphyxiating if they result in an oxygen-deficient atmosphere of less than 19.5% oxygen by volume, as defined by the Canadian Centre for Occupational Health and Safety.

As described in Chapter 6, Section 6.4, control room habitability is served by a combination of individual systems that collectively ensure that continued occupancy in the MCR or SCR is possible under Postulated Initiating Events (PIEs) for a minimum of 72 hours as required by REGDOC-2.5.2 (Reference 2.4-4).

Two different scenarios are considered: a tank burst and a tank leak. In the tank burst scenario, all the contents of the tank are instantaneously released. For the tank leak scenario, the nitrogen is leaked at a constant mass flow rate until the tank is empty over an assumed time. Inputs to the analyses include meteorological stability classification, wind speed, air temperature, and the assumed leak rate for the tank leak scenario. Several sensitivity cases are run to determine the limiting input values. For each location, the control room ventilation system is modeled in the analyses to credit the effects of intake and dilution within the control room atmosphere during the passage of the plume.

The limiting results from the analyses of the postulated nitrogen tank burst and leak scenarios are used to confirm that the placement of the tank relative to the MCR and SCR ventilation intakes is acceptable.

#### **2.4.1.4 Fire and Smoke**

On-site flammable and combustible liquid or gas storage facilities are designed in accordance with applicable fire codes, and plant safety is not jeopardized by fires or smoke in these areas. A detailed description of the fire protection system, as well as the Fire Hazard Assessment (FHA) methodology is presented in Chapter 9A, Section 9A.6.

#### **2.4.2 Measures of Site Protection**

As described in Subsection 2.7.1, the plant grade elevation at 88 m CGD is established using grading and engineered fill. Excavation is performed to depths to reach materials of specific properties suitable for buildings foundations. Materials removed during the excavation are reconditioned for use as backfill material if the material meets the required specifications or are disposed as spoils. Engineered fill material requirements are specified in Subsection 2.7.5.2.1.

The hydrology for the site and vicinity is described in Section 2.5. The site does not credit dams or dikes for flood protection. As described in Section 2.5 the topography and grading at the plant site are considered in the site flooding analyses to demonstrate the plant is adequately protected from precipitation events.

As described in the 2022 NK054-REP-07730-00055 DNNP Environmental Impact Statement [EIS] Review Report for BWRX-300 (Reference 2.4-2), the BWRX-300 deployment will not require lake infilling and, consequently, the associated adverse effects on site drainage and water quality will not occur. The BWRX-300 deployment will still require some shoreline protection works, but such works are expected to be smaller in scale resulting in smaller residual adverse effects on shoreline processes than those assessed in the 2009 EIS for no specific reactor technology NK054-REP-07730-00029 (Reference 2.4-3).

The construction of the first BWRX-300 would provide an opportunity to retain the Bank Swallow nesting habitat as the bluff would be remaining in place and as the impact of excavation and construction activities will be kept to a minimum, per the 2022 NK054-REP-07730-00055 (Reference 2.4-2). When the DNNP site is built out to include a total of four BWRX-300 reactors, additional shoreline protection is to be implemented to stabilize the shoreline as described in the 2022 NK054-REP-07730-00055 (Reference 2.4-2).

The specific extent and location of the shoreline protection works is determined in later phases of the project.

## **2.5 Hydrology**

### **2.5.1 Introduction**

Section 2.5 describes the hydrological conditions and their potential implications relevant to the DNNP site. Section 2.5 includes information on:

- The adequacy of the cooling water supply from Lake Ontario along with risks to the water supply (i.e., biofouling and frazil ice) - Subsection 2.5.2
- The potential flooding hazards, including the Probable Maximum Precipitation (PMP), Probable Maximum Flood (PMF), as well as flooding potential from runoffs, rivers, waves, storm surge and seiche, tsunami, and ice jamming - Subsection 2.5.3
- The potential impact of climate change - Subsection 2.5.4
- Assessment and monitoring of radionuclide dispersion in the groundwater – Subsection 2.5.5
- Assessment and monitoring of radionuclide dispersion in surface water – Subsection 2.5.6

Key hydrological characteristics and parameters described in Section 2.5 relevant to the DNNP site and the surrounding area are summarized and listed in Table 2.5-1. The list includes information on Lake Ontario adequacy as a water supply for use as a heat sink, maximum precipitation and flooding and associated probabilities, as well as surface and subsurface geotechnical properties relevant to transport of radionuclides.

**Table 2.5-1: Hydrological Characteristics Summary of DNNP Site and Surrounding Area**

2.5.2 Description of Heat Removal Methods and Heat Sink			
Normal Heat Removal / Normal Heat Sink	The NHS is a once-through cooling water source from Lake Ontario to the CWS and the PCW		
Ultimate Heat Removal / Ultimate Heat Sink	The Isolation Condenser System consists of three high-pressure reactor isolation loops that passively remove heat from the reactor when the normal heat removal system is unavailable.		
2.5.2.1 Description of Lake Ontario Water Levels and Adequacy of Water Supply			
Water Level	Controlled by the International Joint Commission		
Variability of Water Level (at the intake)	Lowest water level	73.71 m (statistical data at Cobourg Water Level Station) (Reference 2.5-18)	→ 73.71 m
	Impact of seiche	0.75 m (reduction)	→ 72.96 m
	Wave trough (1 s passage)	4.08 m (reduction)	→ 68.88 m
	Spring tides	Less than 5 cm (hidden as part of normal fluctuation)	→ 68.88 m
	Wave downwash	Close to the shoreline with no effect	→ 68.88 m
	Tsunami	No risk expected	→ 68.88 m
Water Depth Available	Normal Conditions 73.71 – 62.50 m	11.21 m above the intake level of 62.50	Therefore, water supply is adequate under normal and extreme conditions
	Impact of Seiche 72.96 – 62.50 m	10.46 m above the intake level of 62.50	
	Impact of Wave Trough (1s duration) 68.88 – 62.50 m	6.38 m above the intake level of 62.50 m	
2.5.2.2 Potential Impacts of Biofouling on Water Supply			
Algae	Algae have the potential to be entrained at cooling water and water supply system intakes, resulting in blockage or restriction issues.		
Micro-biologicals	Biological coatings or biofilms and particulate deposition on tube surfaces can cause lost flow capacity, extensive repairs and material replacement costs in heat exchangers, fire protection systems, storage vessels, intakes, and water distributions systems.		
Macrophytes	Macrophytes can contribute to macrofouling through sticks, leaves and other plant constituents from either terrestrial or aquatic sources that become a component of lake drift and debris material.		
Mollusks	Zebra and quagga mussels can clog water intake structures, such as screens, tunnels and pipes.		
Fish	Various life stages of fish can be taken into a cooling water system with the cooling water (entrainment), and consequently fish reach screens that protect the cooling water and other water systems (impingement). An excessive load of fish can cause blockage to the screening system and sump. In extreme events where screens become overloaded water supply can be reduced with associated reduction in power supply.		
2.5.2.3 Potential Impacts of Frazil Ice Accumulation on Water Supply			
Frazil Ice Accumulation	Accumulation of frazil ice on the intake trash rack, which can partially or completely block the trash rack and rapidly and unexpectedly shut down the intake facility		

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

2.5.3 Description of Potential Sources of Flooding		
2.5.3.1 Flooding Due to PMF	PMP	420 mm 12-hour precipitation, equivalent to 420 mm of total rainfall, with 51% in the 6 <sup>th</sup> hour with a return period of 1:1,000,000 year (Reference 2.5-19)
	Design Basis Flood	<u>Conservative Rainfall</u> : Standardized value of 12-hour PMP in Ontario of 420 mm, with zero infiltration (which greatly exceeds Hurricane Hazel in depth and intensity)
	PMF – Screened in	The event scenario involves a large volume of water runoff flooding the site (based on the application of PMP), while the drainage systems are blocked (due to debris or ice pellet), the soil nearby is saturated, and the lake water level is at 100-year high. Also, it is conservatively assumed that there is no time for implementing preventative measures or taking mitigating actions. The PMF sequence is expected to be worse than a lake level increase or heavy precipitation alone, and the event is not bounded by any other events. As such, flooding due to PMF could not be screened out based on screening criteria [QL1] through [QL5].
	Design Basis Flood Level	Using design basis flood (that is, PMP with zero infiltration), for modeling drainage for BWRX-300 Unit-1 or an assumed 4-unit layouts, Section 5.4.3 of Reference 2.5-18 resulted in flood water levels of up to 87.93 m CGD, considering realistic assumptions for stormwater infrastructure, including factors such as culverts sizing, conveyance, routing, and ponds.
2.5.3.2 Flooding Due to Runoffs	Natural or via Stormwater Management and infrastructure	<ul style="list-style-type: none"> <li>• Five of nine catchments drain directly to Lake Ontario or to Darlington Creek watershed.</li> <li>• Remaining four catchments close to the BWRX-300 development area drain through a stormwater infrastructure directly to Lake Ontario and via engineered culverts stormwater infrastructure running to the southeast of DWMF to Lake Ontario (Reference 2.5-18).</li> <li>• Measures are proposed to mitigate the impact of PMP flooding due to runoff.</li> </ul>
	Screened out, per [QL2]	PMF bounds flooding caused by runoffs.
2.5.3.3 Flooding Due to Rivers	Screened out, per [QL3]	The distance, infrastructure, and topography between the Tooley Creek watercourse and the DNNP site precludes Tooley Creek as the source of a flood hazard. There is not any history of severe flooding along Darlington Creek within the recorded history of the area. This is confirmed by the (2022) Flood Hazard Assessment (Reference 2.5-18) that modeled drainage of Darlington Creek watershed under 100-year recurrence PMP.
2.5.3.4 Flooding Due to Waves	Screened in (related to Shoreline Protection issue)	Wave height of 6.1 m and peak period of 9.2 s is recommended (Reference 2.5-18) Data and models suggest wave uprush between 3.5 to 11.3 m, and overlapping from 0.015 to 0.591 m <sup>3</sup> /s/m. (Reference 2.5-2)
2.5.3.5 Flooding Due to Storm Surge and Seiche	Screened out	Models of most severe weather systems predicted a highest water level from storm surge or seiche of 0.75 m, per (Reference 2.5-2), and (Reference 2.5-18). The margins between the lake level and the top of the DNNP breakwater works are larger than 0.75 m.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

2.5.3.6 Flooding Due to Tsunami	Screened out, per [QL3]	A tsunami in Lake Ontario is an improbable event for DNNP.
2.5.3.7 Flooding Due to Ponds, Dams or Dikes	Screened out, per [QL3]	There are no large permanent human-made water storage ponds, dams or dikes near the Darlington Nuclear site that can threaten the site.
2.5.3.8 Flooding Due to Ice Jamming	Screened out per [QL2] or [QL3]	Bounded by the detailed PMF analysis (Reference 2.5-4); or based on the conclusion of negligible ice forming in Lake Ontario near the DNNP region (Reference 2.5-18).
2.5.4 Potential Effects of Climate Change		
Effect on Temperature, Precipitation. Lake Water Level	Screened in	<ul style="list-style-type: none"><li>Some models showed increase in the intensity (about 14%) and frequency (about 22%) of extreme precipitation in southern Ontario (Reference 2.5-2)</li><li>Maximum found historical lake water level is 75.6 m, which should be used as low estimate (Reference 2.5-13)</li><li>For additional information, refer to the 2022 "Flood Hazard Assessment NK054-02730-00001 (Reference 2.5-18) and the 2023 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts NK054-PLAN-07007-00001 (Reference 2.5-20)</li></ul>
2.5.5 Groundwater		
2.5.5.1 Groundwater Conditions	Described in detail in Subsection 2.7.3.2.4.	
Groundwater Flow System	Categorized into three hydrostratigraphic units: Shallow/Water Table; Interglacial Deposits; and Shallow Bedrock. In general, groundwater flows from north to south, and discharges toward Lake Ontario.	
Groundwater Level	Groundwater is anticipated to be present between elevation 80 to 85 m corresponding to depths of between 3 and 8 m below the plant grade at elevation 88 m.	
Monitoring	Environment Monitoring Program is employed along with the use of groundwater wells that are located in key areas of the Darlington Nuclear site, including protected areas, controlled areas, and site perimeter.	
2.5.6 Surface Water		
2.5.6.1 Surface Water Properties		
Water movement near the site is predominantly along the shore, occurring for 73% of the time (35% to the west and 38% to the east).		
Depth Averaged Speed – all directions	12.4 cm/s	
Depth Averaged Speed – Easterly	14.1 cm/s	
Depth Averaged Speed – Westerly	11.3 cm/s	
Temperature	Lake-wide surface temperatures typically range from freezing in winter to approximately 20 °C in summer.	
Ice Conditions	Typically, are limited to the nearshore areas at the eastern end of the lake within the Kingston Basin.	
2.5.6.2 Surface Water Monitoring		
Lake Current Monitoring	A real-time current profile measurement system to be used in the event of a radiological liquid emission.	
Monitoring	Environment Monitoring Program is employed along with the Lake Current Monitoring system which a real-time current profile measurement system to be used in the event of a radiological liquid emission.	

## **2.5.2 Description of Heat Removal Methods and Heat Sink**

The NHS System that is described in Chapter 9A, Subsections 9A.2.5 provides cooling water source and heat rejection means to support the function of the Circulating Water System (CWS) (Chapter 10, Section 10.8) to supply cooling water to the MCA system (Chapter 10, Section 10.5), as well as to interface with the PCW (Chapter 9A, Subsection 9A.2.1). The NHS is a once-through cooling system using water from Lake Ontario. The water flows through the intake tunnel via the onshore intake vertical shaft to the Pumphouse/Forebay where the circulating water pumps deliver the cooling water to the MCA and PCW heat exchangers before returning the heated water back to the lake via the onshore discharge vehicle shaft through the discharge tunnel to the risers/diffusers.

The BWRX-300 Isolation Condenser System (ICS), described in Chapter 6, Section 6.2, consists of three independent trains, each containing a heat exchanger or Isolation Condenser (IC) that is submerged in a dedicated pool of water. The ICS provides the ultimate heat sink for protecting the reactor core for any off-normal event where the main condenser is not available, and the Reactor Pressure Vessel (RPV) is isolated.

The ICS Pool Cooling and Cleanup System (ICC) that is described in Chapter 9A, Subsection 9A.2.6 is designed to precondition and maintain the ICS pools in a state of readiness for postulated events that require reactor decay heat removal.

The FPC, as described in Chapter 9A, Subsection 9A.1.3, has a primary function to provide continuous cooling of the water volume in the fuel pool to remove decay energy from irradiated fuel, and to provide replacement coolant inventory from a variety of sources, both to ensure irradiated fuel is kept cool and submerged under water throughout the life of the plant.

### **2.5.2.1 Description of Lake Ontario Water Levels and Adequacy of Water Supply**

Lake Ontario is one of the main reservoirs of cooling water for the DNNP site. An assessment for the adequacy of water supply to DNNP was completed in the 2009 NK054-REP-01210-00018 (Reference 2.5-1) and validated in the 2022 Flood Hazard Assessment NK054-REP-02730-00001 (Reference 2.5-18), as described in the following paragraphs.

The water level in Lake Ontario is regulated by the International Joint Commission to reduce damages along the shores of the lake and the St. Lawrence River, per the 2022 Flood Hazard Assessment NK054-REP-02730-00001(Reference 2.5-18). The control of water levels by the International Joint Commission continues in the future and, though the plan for regulation may change, the fundamental function of eliminating extreme lake levels remains. However, the International Joint Commission acknowledges that it may become increasingly difficult to maintain levels within their currently defined operating band depending on the relevant impact of climate change in the future (refer to Subsection 2.5.4 which discusses the impact of climate change on Lake Ontario water levels). Careful consideration of the International Joint Commission study for management options, which included robust modeling of potential future levels under a range of stochastically generated hydrological and meteorological conditions, led to estimates greater than 100-year recurrence low water levels at 73 m as reported in Subsection 5.1.5 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2). However, analysis of historical data at the Water Survey of Canada Cobourg Water Level Station shows a minimum water level of 73.71 m, as reported in the 2022 Flood Hazard Assessment, NK054-REP-02730-00001 (Reference 2.5-18).

Additional factors which influence the minimum water level at the intake were considered in the 2009 NK054-REP-01210-00018 (Reference 2.5-1) as follows:

1. A numerical model of the hydrodynamics of Lake Ontario was developed to assess the potential for generation of surge and seiche in response to extreme severe weather

systems tracking through the region. The maximum wave heights expected at the intake location will be depth limited. The lowest water level of 73.71 m, further lessened by 0.75 m due to seiche, yields an elevation of 72.96 m or a depth of 10.46 m at the intake of an elevation of 62.50 m.

2. Estimating wave breaking at about 0.78 times the water depth of 10.46 m yields maximum wave heights of about 8.08 m. An associated wave trough, taken as half the maximum wave height (that is 4.8 m), might reduce the depth to 6.38 m, though it is noted that the passage of large waves would be short-lived and on the order of 1s. (Note: The 8.16 m Maximum wave height is more conservative than the maximum wave height of 6.1 m recommended in Subsection 2.5.3.4.)
3. The largest spring tides in Lake Ontario are less than 5 cm in height and these minor variations are hidden by greater fluctuations in lake levels produced by wind and barometric pressure changes. Consequently, Lake Ontario is considered to be essentially non-tidal.
4. Wave downrush would occur within a relatively close distance to the shoreline and would have no effect on the water level near the intake.
5. The 2009 flood hazard assessment (Reference 2.5-2) concluded there is no risk of tsunamis so that there is no drawdown potential from that phenomenon that could affect nearshore lake levels. The 2022 Flood Hazard Assessment (Reference 2.5-18) also concluded the Darlington Nuclear site lies in a region with a low probability of tsunamis.

Consequently, even under the extreme scenario considered in the 2009 NK054-REP-01210-00018 (Reference 2.5-1) and the 2022 NK054-REP-02730-00001 Flood Hazard Assessment (Reference 2.5-18), a depth of more than 6 m remains over the intake at the lakebed elevation. Therefore, lake water supply is adequate for the DNNP cooling water intake.

Given the adequacy of the water supply from Lake Ontario, the potential for using groundwater sources in extraordinary situations is not considered.

Consideration for additional factors which might impact the availability of the cooling water supply were also assessed in the 2009 NK054-REP-01210-00018 (Reference 2.5-1), namely concerns related to biofouling and frazil ice conditions. These are discussed separately in the following two subsections.

Additional information on Lake Ontario's current, temperature, and ice conditions is provided in Subsection 2.5.4.2.

#### **2.5.2.2 Potential Impacts of Biofouling on Water Supply**

1. Algae: The Lake Ontario shoreline provides a favorable growth environment for *Cladophora* which are prominent nuisance filamentous algae that have the potential to affect the DNNP. *Cladophora* characteristically grows attached to hard surfaces within the littoral zone and where habitat conditions are optimal, thick mats of the algae can form across the lake substrates and become attached to infrastructure features. During mid-summer and fall, *Cladophora* senesces, the algae become detached from the substrate and drift in a suspended manner with waves and currents.

The loose filaments as well as more substantial clumps of algae have the potential to be entrained at cooling water and water supply system intakes, resulting in blockage or restriction issues at the inlet as well as further blockage and organic material loading at the trash racks or travelling screen system.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

2. Micro-biologicals: Biofilms consist of microorganisms immobilized at a substratum surface, typically embedded in an organic polymer matrix of bacterial origin. Such biofilms are ubiquitous in flowing aqueous environments, are not necessarily uniform in time and space, and may trap inorganic substances within the polymer matrix. Biofilms develop on virtually all surfaces immersed in natural aqueous environments, irrespective of whether the surface is biological (aquatic plants and animals) or abiological (stones, particles, metal, and concrete, etc.). Extensive bacterial growth, accompanied by excretion of copious amounts of extracellular polymers, thus leads to the formation of visible slimy layers (biofilms) on solid surfaces.

Thin biological coatings or biofilms associated with microorganisms can reduce the efficiency of heat exchangers (forcing shutdowns or de-rating), enhance silt and particulate deposition on tube surfaces (causing fouling and pipe wall pitting), lost flow capacity, extensive repairs and material replacement costs in heat exchangers, fire protection systems, storage vessels, intakes, and water distributions systems.

3. Macrophytes: Both terrestrial and aquatic plants can contribute to floating and suspended plant material that becomes susceptible to entrainment at water intakes. A variety of rooted aquatic macrophytes are common to Lake Ontario. The existing DNGS forebay was shown to contain a community of Eurasian watermilfoil (*Myriophyllum spicatum* L.), the only rooted plant observed. The biomass of this material was estimated at 1.5 tons providing an indication of the potential availability of organic mass that can contribute to the load on the screening system. A future regional increase in aquatic plants and algae was concluded as being a reasonable expectation as the lake water clarity increases with the filtering effects of the exotic invader zebra and quagga mussel.

Macrophytes can contribute to macrofouling through sticks, leaves and other plant constituents from either terrestrial or aquatic sources that become a component of lake drift and debris material. During the fall season when macrophytes typically senesce, the organic material of the plant stems and foliage have the potential to fragment and block travelling screens.

4. Mollusks: Lake Ontario contains confirmed populations of non-native invasive nuisance mussels including the zebra mussel, *Dreissena polymorpha*, and the quagga mussel, *Dreissena rostriformis bugensis*, inadvertently introduced to North America in the ballast water of oceangoing ships. More recent colonization has involved the quagga mussel, which has a preference for deeper, cooler water as compared to the zebra mussel and has now largely replaced the zebra mussel. Given the record of non-native introductions to Lake Ontario, additional nuisance mollusk species may appear in the future. The Asiatic clam *Corbicula fluminea* has been recorded in North America the longest of the three key invasive species arriving on the west coast in the 1920s and reaching the east coast by 1980s; however, it has not yet been reported as an issue in Lake Ontario.

*Dreissena* species ability to rapidly colonize hard surfaces causes serious economic problems and potential reduced efficiency of water supply systems. These major biofouling organisms can clog water intake structures, such as pipes and screens, therefore reducing pumping capabilities for power and water treatment plants. Power plant features that may become fouled include crib structures, trash bars, screenhouses, steam condensers, heat exchangers, penstocks, service water systems and water level gauges.

5. Fish: Lake Ontario hosts a diverse population of both warm and cold-water fish species, many of which may utilize the project area either as local residents or seasonal migrants. During impingement investigations at DNGS operations from 1993 to 1995, fish encountered at the mitigative screen system and in sumps included at least 17 species. The predominant species were generally of a smaller body size which included alewife, shiner species and smelt, all representatives of the abundant forage fish-based community of the lake. Major community changes occurred with the introduction of non-native species through opening of waterways, intentional stocking, and unintentional introduction through ballast water of international shipping. This may have a bearing on future operational management systems at DNNP depending on the habits and productivity of a particular species.

Various life stages of fish can be taken into a cooling water system with the cooling water (entrainment), and consequently fish reach screens that protect the cooling water and other water systems (impingement). An excessive load of fish can cause blockage to the screening system and sumps contributing to maintenance requirements. In extreme events where screens become overloaded water supply can be reduced with associated reduction in power supply.

*NOTE: The 2009 report NK054-REP-01210-00018 (Reference 2.5-1) concludes that mitigation measures have been successfully applied at power generating facilities along the north shore of Lake Ontario to address the various forms of biofouling.*

#### **2.5.2.3 Potential Impacts of Frazil Ice Accumulation on Water Supply**

As described in the 2009 NK054-REP-01210-00018 (Reference 2.5-1), operating water intakes in lakes and rivers in northern regions is complicated by the presence of ice. Controlling the generation and accumulation of frazil ice affects both navigation and power generation. The cooling water intake tunnel can accumulate frazil ice on the intake trash rack, which can partially or completely block the trash rack and rapidly and unexpectedly shut down the intake facility.

#### **2.5.3 Description of Potential Sources of Flooding**

Subsection 2.5.3 describes the assessment of potential flood hazards at the DNNP site. (Refer to Subsection 2.1.1 for information on the topography of the Darlington Nuclear and DNNP sites.)

The review of the flood hazard assessment performed in support of the 2020 DNNP Power Reactor Site Preparation Licence (Reference 2.5-3) against the 2019 codes and standards concluded there is no impact on the conclusion of the 2009 Flood Hazard Assessment NK054-REP-01210-00012 (Reference 2.5-2) as documented in the 2019 DNNP Site Preparation Licence Renewal activity report NK054-REP-01210-00108 (Reference 2.5-7).

Also, as stated in Subsection 4.5.3 of the 2020 NK054-CORR-00531-10533 (Reference 2.5-3), the results of the 2019 Darlington Hazard Screening Analysis NK054-REP-03611-10043 (Reference 2.5-4) apply to the DNNP site since the DNNP site is encompassed in the Darlington Nuclear site.

As described and assessed in the 2019 NK054-REP-03611-10043 (Reference 2.5-4), and in the 2022 NK054-REP-02730-00001 Flood Hazard Assessment (Reference 2.5-18), the DNNP flooding hazards are:

- Flooding due to PMF - Subsection 2.5.3.1
- Flooding due to Runoffs - Subsection 2.5.3.2
- Flooding due to Rivers - Subsection 2.5.3.3

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

- Flooding due to Waves - Subsection 2.5.3.4
- Flooding due to Seiche - Subsection 2.5.3.5
- Flooding due to Tsunami - Subsection 2.5.3.6
- Flooding Due to Ponds, Dams or Dikes - Subsection 2.5.3.7
- Flooding due to Ice Jamming - Subsection 2.5.3.8

These hazards are addressed in the following subsections.

#### **2.5.3.1 Flooding Due to Probable Maximum Flood**

As described in Section 5.4 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2), the design storm event used to determine the flood hazard is the PMF event in the 2011 International Atomic Energy Agency (IAEA) SSG-18 (Reference 2.5-10). This is a specific hydrologic term that is defined in conjunction with the PMP, as per the following paragraphs.

The PMF is the flood that may be expected from the most severe combination of critical meteorological and hydrologic conditions that are reasonably possible in a particular drainage area. The PMP is defined as the greatest depth of precipitation for a given duration meteorologically possible for a given size storm area at a particular location at a particular time of year, with no allowance made for long-term climatic trends. It is a common practice that the PMF is the flood which is a direct result of the PMP. The PMP is applied to sub-basin delineations that account for variations in soil type, land use, size and shape of the watershed, and average watershed slope to generate PMF flows.

There are two considerations when determining the PMP for a given application, the site location, and the duration of the storm event. Based on the 2017 Lakes and Rivers Improvement Act Technical Guidelines (Reference 2.5-11), for watershed areas less than 1295 km<sup>2</sup>, the PMP maximum precipitation duration of 6 or 12 hours is normally used as it produces the highest peak flood flow

Subsection 4.4.1 of the 2019 NK054-REP-03611-10043 (Reference 2.5-4) states that the Review Level Condition assumes no runoff in the worst hour of the 12-hour PMP; therefore, the flood depth is 51% of the total 12-hour PMP of 420 mm, which is approximately 214 mm, per Table 5.4-1 of the 2022 NK054-REP-02730-00001 (Reference 2.5-18). The PMF event scenario involves a large volume of water runoff flooding the site, while the sewer systems are blocked (due to debris or ice pellet), the soil nearby is saturated, and the lake level is at 100-year high. This PMF sequence is expected to be worse than a lake level increase or heavy precipitation alone, and the event is not bounded by any other events. Finally, it is conservatively assumed that there is no time for implementing preventative measures or taking mitigating actions. As such, flooding due to PMF could not be screened out based on screening criteria [QL1] through [QL5] (refer to Subsection 2.2.2 for descriptions of the screening criteria).

The PMF values which are commonly estimated using a combination of flood-inducing drivers such as snowmelt and rainfall can alternatively be estimated using an extreme rainfall outside the snow season that is higher than spring values. In Subsection 5.4.1 of the 2022 NK054-REP-02730-00001 (Reference 2.5-18), it is assumed that the summer PMP produces extreme floods (i.e., PMFs) at least comparable to the spring PMFs that consider snowmelt. This assumption was verified by comparing the precipitation values of spring (March-April) with summer-fall (May-November); so that a summer PMP can be deemed as the key driver of the PMF, per the 2022 NK054-REP-02730-00001 (Reference 2.5-18).

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

As described in Subsection 2.1.1 of the 2022 NK054-REP-02730-00002, PMP Validation (Reference 2.5-19), the PMP for watershed areas in the vicinity of and the DNNP site is a 12-hour precipitation equivalent to 420 mm of total rainfall, with 51% of the storm falling in the sixth hour, with a return period of 1:1,000,000. This value is on the conservative side considering the historical observed 24-hour point rainfall in the region is 212 mm (hurricane Hazel).

The design basis flood is the flood resulting from the PMP assuming zero infiltration in the drainage areas on site. In Subsection 5.4.1 of the 2022 Flood Hazard Assessment NK054-REP-01730-001 (Reference 2.5-18) design flood values in the DNNP site region are based on the 1:100-year return period storm or Hurricane Hazel, whichever is the greater. The 1:100-year return period storm was used to calibrate a Darlington Creek model, and as a comparison to the PMP results (refer to Table 2.5-2 under Subsection 2.5.3.3). For small watersheds such as Darlington Nuclear site, where no stream gauge is available, 1:100-year return period rainfall is assumed to produce a 1:100-year return period flood. Since the 420 mm, 12-hour duration PMP greatly exceeds Hurricane Hazel in depth and intensity, Hurricane Hazel was not used in this assessment. the 420 mm, 12-hour duration PMP was selected with zero infiltration as the current design basis storm for the DNNP, as shown in Table 2.5-2.

### **2.5.3.2 Flooding Due to Runoffs**

#### **Existing Pre-development Catchments and Flood Hazard**

Section 3.2 of the 2022 NK054-REP-02730-00001 Flood Hazard Assessment (Reference 2.5-18) identified in Section 3.2 nine delineated catchments (A through I) for the pre-developed DNNP site, as shown in Figure 2.5.3.2-1. Information related to catchments A to I are provided in Table 3.2-1 of (Reference 2.5-18), such as area size, land use, soil/surface conditions and runoff. The runoff from Catchment A drains directly into Lake Ontario close to the DNGS forebay. The runoffs from Catchments B, C, D, and E in the north and east flow via the Canadian National Railway right-of-way ditch or through a wetland discharging into the Darlington Creek watershed. The runoffs from Catchments F, G, and H, which are former lay down areas in the DNNP site, flow through culverts southeast of the DWMF building and drain directly into Lake Ontario. The last runoff from Catchment I, a former lay down area, drains through various outlets into Lake Ontario. Potential existing on-site flood hazards include:

- Runoff from Catchments C and D overflowing the Canadian National Railway right-of-way ditch
- Capacity of designed stormwater infrastructure to convey potentially increased peak flows due to proposed DNNP site development.

Subsection 5.4.3 of the 2022 Flood Hazard Assessment (Reference 2.5-18) describes the flood hazard associated with a design basis flood involving PMP falling directly on the DNNP site, assuming 100% impervious land cover. The flood hazard due to direct precipitation is related to the ability of the site development to convey stormwater runoff through the site.

A nodal model (PCSWMM), per Subsection 5.4.3. of the 2022 Flood Hazard Assessment (Reference 2.5-18), of the nine catchments conveyance and retention as well as drainage structures was used to evaluate on-site flood hazards and to size conveyance and retention elements of stormwater for pre-development conditions.

The pre-development results indicate:

- None of Catchments A, B, E, G, and I pose a PMP flood risk on the DNNP site (refer to Table 5.4-11 of Reference 2.5-18)

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

- Catchments C and D showed significant overflow into the Canadian National Railway right-of-way ditches with no flooding (refer to Table 5.4-12 of Reference 2.5-18)
- While the stormwater infrastructure in Catchment F performs adequately under, for instance, the 1:100-year storm, significant PMP/PMF overflow occurred between its sub-catchments or into neighboring Catchment H, suggesting development is necessary to alter Catchment F and its drainage system (refer to Table 5.4-13 of Reference 2.5-18)
- The stormwater conveyance and retention capacity of Catchment H represents a significant potential overflow under the PMP, between its sub-catchments within the existing infrastructure (refer to Table 5.4-14 of Reference 2.5-18)

These results were carried forward to explore and compare with the post-development results.

*Post-development of BWRX-300 Unit 1 Catchments and Flood Hazard*

A large portion of the pre-development areas of Catchments F and H would be replaced by Catchment N, within which the BWRX-300 Unit 1 footprint would almost entirely be contained, as shown in Figure 2.5.3.2.2. The runoff from Catchment N flows through a series of culverts, roadside ditches, and a pond to a southern outlet into Lake Ontario. The proposed site layout of the BWRX-300 Unit-1 facility will therefore have significant impact on-site catchments and runoff flow directions. Though the upstream reaches of these catchments will still mostly be intact, most of the pre-development of Catchment F and roughly half of Catchment H will be covered by the footprint of the BWRX-300 facility Unit-1 (refer to Figure 3.2-1 in Reference 2.5-18). Conveyance and retention structure of such catchments would consequently require re-configuration.

The same nodal model PCSWMM) was used for post-development conditions including Catchment N. Culvert locations, diameters, conveyance (in  $\text{m}^3/\text{s}$ ) and ditch depths were considered in the assessment. The post-development results for BWRX-300 Unit 1 indicate:

- Catchments A, B, C, D, E, G, and I do not represent a flood hazard for the DNNP site (refer to Subsection 5.4.3.4.1 in Reference 2.5-18)
- Under the PMP, there is significant flooding through the sub-catchments of Catchment F, and to Catchment G (refer to Table 5.4-16 in Reference 2.5-18)
- Current configuration of conveyance and retention structures in Catchment H will experience under the PMP significant flooding into its sub-catchments that may overtop into Catchment G (refer Table 5.4-17 in Reference 2.5-18)
- Catchment N system, comprising ditches, culverts, flood routes and storages, is sized to convey and retain adequately the PMP and is split into 12 sub-catchments described as follows:
  - Sub-catchment N\_1 contains an administrative building and a parking lot and drains south through a culvert into N\_10
  - Sub-catchment N\_2 is a large laydown area, drains through ditch and outlets into N\_12. In the model, all the flow within N\_2 passes through a culvert adjacent to the Power Block, which is a conservative assumption to ensure N\_2 runoff does not flood the Power Block area
  - Sub-catchments N\_3 through N\_7 contain the Power Block area, and each drain through a dedicated culvert into various downstream sub-catchments, with the culvert sizes chosen to ensure zero flooding of the Power Block area
  - Sub-catchment N\_8 is a parking or laydown area draining through a culvert into N\_12

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

- Sub-catchment N\_9 is a parking or laydown area draining through a culvert in N\_10
- Sub-catchment N\_10 is a low area adjacent to the Power Block containing a storm water management pond that drains to the south through a culvert into N\_12
- Sub-catchment N\_11 is a low area immediately south of the Power Block accepting flow from N\_5 and N\_7 and conveying through a culvert to N\_12
- Sub-catchment N\_12 is a perimeter ditch, accepting flows from the remainder of Catchment N and conveying toward the Catchment H outlets to Lake Ontario

**Post-development BWRX-300 Unit 1 Modeled Available Freeboard**

The post-development peak flow and flooding results for Catchment N, shown in Table 5.4-18 of (Reference 2.5-18), indicate with “realistic” assumptions (i.e., the largest culvert in the system is 1 m in diameter) for sizing of conveyance and retention structures, the maximum flood level within the Catchment N system is 87.93 m CGD. This provides 0.07 m of freeboard below the 88 m CGD construction grade which is a flood hazard, but by increasing the conveyance and retention capacity of the system, this freeboard can be brought to a comfortable level.

**Comparison of Pre- and Post-development of BWRX-300 Unit 1 Results**

Comparison of pre-developed and post-developed modelling results of BWRX-300 Unit 1 indicate (refer to Subsection 5.4.3.5 and Table 5.4-22 of Reference 2.5-18):

- There are no changes in Catchments A, B, C, D, E, G, and I.
- Maximum flood depth elevation changes between -0.02 m to +0.06 m in Catchment F since it is reconfigured from pre-development conditions.
- Maximum flood depth elevation changes between -0.23 m to +0.17 m occurred in Catchment H since it is also changed in post-development conditions, and it must convey and retain runoff from Catchment F and some runoff that may overtop into Catchment G.

**Impact of Modeling of Four BWRX-300 Units**

Additional modeling analysis showed with proper sizing and arrangement of additional conveyance and retention infrastructure in future site plans, the construction of additional three BWRX-300 units will not impact the functionality of the stormwater infrastructure protecting the first BWRX-300.

**Proposed Flood Mitigation, Proofing, and Practice for DNNP**

In Section 6 of the 2022 Flood Hazard Assessment (Reference 2.5-18), flood mitigation or flood proofing practices applicable to the DNNP as well as mitigation measures are proposed. Options for flood mitigations applicable to the DNNP site include:

- Constructing barriers to stop floodwater from entering the structure/site areas
- Constructing retention and detention ponds to slow and/or stop floodwaters entering the site area
- Wet Flood Proofing whereby floodwaters are allowed to enter the structure/site area, but ensuring that there is no or minimal damage to the building's structure/site and to its contents
- Emergency management/flood forecasting.

Summary of Flood Hazard for the DNNP Site

Table 6.2-2 in the 2022 Flood Hazard Assessment (Reference 2.5-18) summarizes the primary source of flood hazards for the DNNP site due to runoff. In essence, the flood hazards would be to backwatering and flooding of various sub-catchments causing overtopping of the receiving catchments or overloading the existing stormwater management infrastructure. Proposed mitigation includes measures such as:

- Increase the size of specific culverts draining into specific sub-catchments
- Increase the storage capacity of one or more stormwater management ponds
- Route runoff from specific catchments into other specific catchments
- Ensure progressing designs have sufficient conveyance and detention capacity and the stormwater infrastructure is adequate.

Per Subsection 5.4.1 of the 2022 Flood Hazard Assessment NK054-REP-01730-001 (Reference 2.5-18), the PMF, mentioned in Subsection 2.5.3.1, includes a design basis flood (involving a PMP and zero infiltration) concurrent with disabled sewer and drainage systems due to, for example, debris. Therefore, the flooding due to runoff can be screened out based on screening criterion [QL2]. The PMF assessment is the bounding assessment that includes the impacts of potential runoffs.

NON-PROPRIETARY INFORMATION

**Figure 2.5.3.2-2 Post-development Darlington Nuclear Site Drainage (Reference 2.5-18)**

### 2.5.3.3 Flooding Due to Rivers

Section 3.1 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2) names two riverine systems within the local regional drainage basin: Tooley Creek and Darlington Creek.

The distance, infrastructure, and topography between the Tooley Creek watercourse and the proposed DNNP site precludes Tooley Creek as the source of a flood hazard.

Regarding Darlington Creek, the Central Lake Ontario Conservation Authority indicated there is not any history of severe flooding along Darlington Creek within the recorded history of the area. Figure 3.1-6 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2) illustrates the current regulatory and 100-year recurrence floods inundation limits and shows that the inundation limits associated with these events do not represent a flood hazard to the DNNP site.

Subsection 5.4.2 in the 2022 Flood Hazard Assessment, NK054-REP-02730-00001 (Reference 2.5-18), describes comprehensive hydrologic and hydraulic models that are used to estimate drainage for the Darlington Creek watershed and its associated 14 sub-watersheds under 100-year recurrence PMP conditions, as replicated in Table 2.5-2. The models considered parameters such as length and slopes of the feeding reaches, time of concentration, storage coefficient, and future 100-year timeframe land use and development. The modelled Darlington Creek flood water elevations under PMP conditions in the future is estimated at 88.5 CGD at a stream gauge cross-section located just south of Highway 401. This is above the DNNP site construction grade of 88 CGD. However, to overtop into the DNNP site, flood waters would have to surpass the lowest elevation along the boundary separating the DNNP site from Darlington Creek, which is 95 CGD. Therefore, no external flood hazard to the DNNP site has been identified from Darlington Creek.

Thus, flooding due to the Tooley Creek and Darlington Creek is screened out for the DNNP site.

**Table 2.5-2 Key Modelling and Assessment Parameters for Darlington Creek and On-site External Flood Hazards (Reference 2.5-18)**

Parameter	Darlington Creek	On-site
Design Storm(s)	2.5-Hour 1:100-Year Storm (4 mm)	12-Hour PMP (420 mm)
	6-Hour PMP (405 mm)	
	12-Hour PMP (420 mm)	
Land Cover	Existing and Future Conditions	Zero infiltration
Threshold Water Level Constituting Flood Hazard	Above 95 m CGD	Above 88 m CGD

### 2.5.3.4 Flooding Due to Waves

The potential for flooding due to waves is discussed in Section 5.3 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2):

1. Subsection 5.3.1 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2) describes the data and models used to assess the flooding hazard by waves, including the Lake Ontario wind and wave hindcast developed by the Wave Information Studies of the Office, Chief of Engineers, U.S. Army Corps of Engineers. The Simulating Waves Nearshore model was used to propagate extreme wave conditions from a selected 'offshore' wave information studies node to the shoreline, using the SPLASH numerical model for calculations of wave uprush and wave overtopping on shoreline beaches and structures.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

2. Subsection 5.3.2 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2) describes the wave hindcast extreme analysis and determines that it is appropriate to use the wave information studies #192 100-year  $H_s$  of 4.7 m with peak wave period  $T_p$  of 9.7 s as input from the SW ( $225^\circ$  N) to wave propagation/overtopping models.
3. Subsection 5.3.3 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2) describes the wave propagation modeling for two water level scenarios and two site layout scenarios.
4. Subsection 5.3.4 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2) describes the wave uprush and overtopping estimates.

Based on these scenarios, the wave uprush estimates range from 3.5 m to 11.3 m, and wave overtopping estimates range from 0.015 to 0.591 m<sup>3</sup>/s/m.

In the 2022 Flood Hazard Assessment in NK054-REP-02730-00001 (Reference 2.5-18), the calculated wave heights extreme values were based on the latest hindcast data from two stations closest to the DNNP for the period from January 1979 to January 2020. Using a specific fitted method, wave heights were calculated for selected return periods of 10, 50 and 100 years. Based on the results, it was recommended to use an updated design wave of 6.1 m from the SW ( $225^\circ$  N) with peak wave period  $T_p$  of 9.2 s to account for a more conservative estimate of the wave flooding potential at the DNNP site.

#### **2.5.3.5 Flooding Due to Storm Surge and Seiche**

Storm surges may cause seiches, because as a storm moves past the lake, the wind and pressure are no longer pushing the water, therefore the piled-up water moves toward the other end of the lake. The water sloshes from one end of the lake to the other few times until the water level is returned to normal. This sloshing back and forth is called a seiche. Seiches can be created due to other meteorological effects, seismic activities, or also tsunamis.

Section 5.2 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2) describes the numerical hydrodynamic model of Lake Ontario which was developed to assess the potential for generation of storm surge and seiche response to extreme severe weather systems tracking through the region. The model was implemented on a bathymetric grid of Lake Ontario with a 2.7 km resolution.

The most severe types of weather systems in the region of Lake Ontario are:

1. Post Tropical Storms: A good example of a post tropical storm with very severe wind conditions for Lake Ontario was Hurricane Hazel (1954). A storm like Hazel would typically approach Lake Ontario from between the southeast and south. A Hazel-like post tropical storm with extremely severe characteristics could have sustained winds up to 100 km/h and a pressure drop as low as 95 kPa.
2. Alberta Clippers: They are compact fast moving winter storms with sustained winds up to about 80 km/h and a pressure drop of about 97 kPa. They would typically track from northwest to west-southwest.
3. Colorado Lows: They are less compact than the Alberta Clippers but have otherwise similar characteristics and would track from the southwest or south-southwest.
4. Gulf Lows: A good example of a very severe Gulf low is the Great Blizzard of 1978. The pressure dropped down to the extremely low value of 95.8 kPa. Characteristic severe sustained winds were up to about 100 km/h.

The parameters used to represent the four idealized storms listed above are shown in Table 5.2-1 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2). The highest predicted water level at Darlington Nuclear site resulting from surge or seiche is about 0.75 m. This level can be produced either directly as a surge by a storm of Hazel-type tracking from the south over the western end of the lake, or indirectly after an Alberta Clipper from the west builds up a large surge at the eastern end of the lake resulting in a seiche of large amplitude. The 2022 Flood Hazard Assessment in NK054-REP-02730-00001 (Reference 2.5-18) also recommended 0.75 m as the highest water level produced by storm surge or seiche, in concurrence with the value predicted in the 2009 NK054-REP-01210-00012 (Reference 2.5-2).

Table 4.2 of the 2019 Darlington Hazard Screening Analysis NK054-REP-03611-1004 (Reference 2.5-4) shows the margin between the lake level and the top of the breakwater works at Darlington Nuclear site. As the margins are larger than the 0.75 m highest water level resulting from surge or seiche, the potential flood impacts are screened out.

#### **2.5.3.6 Flooding Due to Tsunami**

As described in Section 5.7 of the 2009 NK054-REP-01210-00012 (Reference 2.5-2), tsunamis are long period gravity waves generated by seismic disturbances of the sea bottom or shore, or landslides resulting in a sudden displacement of the water surface with the resulting wave energy spreading outwards across the ocean or lake at high speed. An additional consideration is the potential for a tsunami to occur as a series of waves (rather than a single wave) with associated increased impact from cumulative damage or flooding effects.

Due to the geological stability of the Great Lakes region where the largest measured seismic activity results in only small earthquakes typically of magnitude 3 or 4, the 2009 flood hazard assessment NK054-REP-01210-00012 (Reference 2.5-2) concludes a tsunami in Lake Ontario is an improbable event for DNNP. This conclusion is confirmed in the 2022 Flood Hazard Assessment NK054-REP-02730-00001 (Reference 2.5-18).

#### **2.5.3.7 Flooding Due to Ponds, Dams or Dikes**

As noted in Subsection 4.4.7 of the 2019 NK054-REP-03611-10043 (Reference 2.5-4), there is no large permanent human-made water storage pond or dam near the Darlington Nuclear site that can threaten the site. Therefore, this potential flood mechanism is screened out. Per the 2020 NK054-CORR-00531-10533 (Reference 2.5-3), this conclusion is applicable to the DNNP site since it is encompassed by the Darlington Nuclear site. Subsection 5.5.1 of the 2022 NK054-REP-02730-00001 (Reference 2.5-18) also concluded no hazard assessment for the failure of human-made structures such as dams or dikes is required for the DNNP site.

Any temporary ponds and body of water that could potentially be created during a severe storm (for example on the rail track, by the embankments, overflowing culverts) are addressed in the 2009 hydrological assessment NK054-REP-01210-00012 (Reference 2.5-2) and the 2022 Flood Hazard Assessment NK054-REP-02730-00001 (Reference 2.5-18) (refer to Subsection 2.5.3.2).

#### **2.5.3.8 Flooding Due to Ice Jamming**

As described in Subsection 4.4.8 of the 2019 NK054-REP-03611-10043 (Reference 2.5-4), this event scenario is concerned with late winter conditions when large ice blocks, accumulated over winter, melt rapidly as the weather temperature rises above the freezing point.

The 2014 DNGS hydrological assessment NK38-REP-03611-10094 (Reference 2.5-12) examined the worst-case scenarios and concluded that a summer PMP, with storm drains blocked, would bound winter PMP with snow covering the ground and ice blocking the drains. The event consequences of ice jamming at the lakeshore, and rapid melting of the accumulated

ice blocks may result in localized high water levels and flooding, but the consequences are not worse than the PMF assessed in the DNGS hydrological assessment.

Therefore, the hazard is screened out based on screening criterion [QL2], as both types of consequences (accumulation on the roof tops, and accumulation at the lakeshore) have consequences less severe than the events assessed in the 2014 DNGS hydrological assessment (Reference 2.5-12). This conclusion can be applicable to the DNNP site due to proximity to the DNGS site, per the 2020 NK054-CORR-00531-10533 (Reference 2.5-3).

The 2022 Flood Hazard Assessment in the 2022 NK054-REP-02730-00001 (Reference 2.5-18) states that in the DNNP site area, Lake Ontario freezing starts from the Bay of Quinte, east of the DNNP site. The ice then propagates eastward to the St. Lawrence River. As shown in Figure 5.6-2 of the 2022 Flood Hazard Assessment in the 2022 NK054-REP-02730-00001 (Reference 2.5-18), the ice coverage over Lake Ontario is about 17% by mid-February with an average of 10% coverage for the winter period. Ice breaking accelerates in early March. Thus, the DNNP site region of Lake Ontario is ice-free year-round, in an average year. This is mirrored in the fact that, on a weekly basis, between December 4 and May 14, the median ice concentrations near the DNNP site are 0%. Furthermore, Lake Ontario is the smallest Great Lake in terms of surface, but it is the second deepest and as such, has a large volume compared to its surface area, resulting in an exceptionally high heat storage capacity. Temperature changes occur at a much lower rate in Lake Ontario compared to the other Great Lakes.

Therefore, the 2022 Flood Hazard Assessment in the 2022 NK054-REP-02730-00001 (Reference 2.5-18) confirms that the flood hazard due to ice jamming is screened out based on the basis of screening criterion [QL3].

#### **2.5.4 Potential Effects of Climate Change**

The potential impacts of climate change are discussed and summarized in Subsections 7.2 of the 2022 NK054-REP-02730-00001 (Reference 2.5-18), where Subsections 7.2.1 and 2.7.2 address the effect of climate change on temperature and precipitation.

The total annual precipitations are forecast to slightly increase (+3% to 10%) in 2071-2100 compared to present-day conditions. However, precipitations are expected to remain stagnant during summer, hence resulting in higher percentage increases for other seasons (from +2% to 21%) depending on the emission scenario chosen. Considering that temperature is also forecast to significantly increase during winter, more liquid precipitations are to be expected as well.

Maximum daily precipitations are expected to vary from -4% to +25% depending on season and emission scenario. The seasonal trend follows a similar pattern as total precipitations with stagnant conditions during summer (-4% to 0% compared to present-day conditions) in contrast to spring and winter for example (from +10% to 25%).

Although maximum daily precipitations should not increase by much during fall and especially summer, these seasons remain the period when this extreme weather event will occur. While the projected increase in daily 1:100-year return period precipitation is up to 10.7% by 2100 in the high greenhouse gas emissions scenarios, the PMP evaluated is not anticipated to be exceeded due to climate change, and no additional flood hazard is identified on account of climate change.

Subsection 5.1.2.5 of the 2022 NK054-REP-02730-00001 (Reference 2.5-18) describes a 2014 plan that was adopted in 2017 to allow for control of extreme low or high water level conditions. Under the modelled conditions in the 2014 plan, the weekly mean water levels would never have exceeded 75.8 m. However, since the adoption of the new plan in 2017, water level exceeded the previous maximum on two occasions, in 2017 and 2019. Climate change was identified as the probable cause of these maximum water levels.

Subsection 7.2.5 of the 2022 NK054-REP-02730-00001 (Reference 2.5-18) discusses the impact of climate change on Lake Ontario water levels. Lake Ontario water levels are primarily controlled by variations in precipitation, runoff, and evaporation over the watershed. Climate change influences these parameters that control lake water level fluctuations. Climate change would contribute to increasing low and high extremes in Lake Ontario water levels. Anticipated increases in precipitation would contribute to high Lake Ontario water levels. The report recommends higher lake levels experienced recently in 2017 and 2019 should be considered as appropriate design lake levels for shoreline assessment and design bases.

According to the 2019 IAEA Site Evaluation for Nuclear Installations Safety Requirements for Flood Hazard (Reference 2.5-14), the reference water level upon which the computed surge or seiche is superimposed should be selected to have a sufficiently low probability of being exceeded. Usually the 100-year recurrence monthly average high water is adopted or, if the water level is controlled, the maximum controlled water level is used. However, the International Joint Commission Lake Ontario 2021 plan (Reference 2.5-13) allows deviations, so that no maximum level is set, and a stochastic approach is still necessary. In this case the controlled water level with a probability of exceedance of 1% is 75.6 m; however, the highest level during a century is about 76.6 m. In addition, measured water levels at Cobourg have exceeded 75.6 m for duration of about three months in 1973.

Therefore, 75.6 m may be a low estimate, and 76.6 m should be used, which is close to the maximum found in the historic data and greater than the 100-year recurrence level. This level assumes the International Joint Commission Lake Ontario continues with the current water level control plan.

The 2023 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts, NK054-PLAN-07007-00001 (Reference 2.5-20) is developed to address the potential impact of climate change on external hydrological and meteorological hazards. The strategy summarizes life cycle considerations including long-term monitoring (Subsection 2.11.9) and describes the plan to ensure the BWRX-300 facility is resilient to climate change as a potential external hazard.

The 2023 NK054-REP-07007-1049426 DNNP Hazard Bounding Analysis (Reference 2.5-22) presents a bounding analysis of climate change impacts and establishes probable extreme values for climate hazards where feasible. The 2022 NK054-REP-07007-1028871 DNNP Gradual Climate Change and Natural Hazard Identification (Reference 2.5-23) describes the process used in identifying a comprehensive list of natural external events for DNNP, which are screened for climate change impact for evaluation against the DNNP BWRX-300 design basis.

## **2.5.5 Groundwater**

Relevant to the assessment of radioactive material transported through the groundwater system and potentially dispersed in the environment, the following subsections discuss the characterization of the hydrogeological subsurface properties as well as relevant monitoring programs.

The in-situ soil properties are derived based on existing subsurface investigations completed at the DNNP site and in the vicinity of the BWRX-300 SMR location, as described in Subsection 2.7.3.2.4.

### **2.5.5.1 Groundwater Conditions**

The groundwater conditions are described in detail in Subsection 2.7.3.2.4. Groundwater flow maps are available in Section 2.7, Figures 2.7.3.2-3 to 2.7.3.2-9. In general, groundwater on the site flows from north to south, and discharges toward Lake Ontario, as confirmed in the 2022 DNNP Phase 1 Geotechnical Investigation Report NK054-REP-01210-00175 (Reference 2.5-21).

The predominant groundwater flow patterns reported in the 2022 geotechnical investigation NK054-REP-01210-00175 (Reference 2.5-21) remain unchanged from the historical interpretations of groundwater flow conditions documented in the 2009 NK054-REP-01210-00011 (Reference 2.5-15) and the 2009 NK054-REP-07730-00005 (Reference 2.5-16).

Relevant information is provided in Subsection 2.8.2.2 on the impact of hydrogeological conditions on the dispersion of radioactive material.

#### **2.5.5.2 Groundwater Level**

Based on the groundwater conditions at the DNNP site presented in Subsection 2.7.3.2.4 and Table 2.7-11, groundwater is anticipated to be present approximately between elevation 80 m to 86 m corresponding to depths between about 2 m and 8 m below the plant grade at elevation 88 m. (refer to Subsection 2.7.5.2.6)

#### **2.5.5.3 Groundwater Monitoring**

The OPG Environmental Monitoring Program (EMP) N-REP-03443-10027 (Reference 2.5-17) examines the chemical, radiological, and physical characteristics of the groundwater beneath the Darlington Nuclear site. The groundwater monitoring wells are located in key areas of the Darlington Nuclear site including the protected areas (near the RBs), controlled areas (farther away from the RBs but within the fence), and the Darlington Nuclear site perimeter. Wells on DNNP site are considered site perimeter wells (refer to the NK38-REP-10140-10032 (Reference 2.5-8)).

#### **2.5.6 Surface Water**

As related to the assessment of radioactive material transported through the surface water system and potentially dispersed in the environment, this subsection discusses the characterization of the surface water properties in Subsection 2.5.6.1, as well as the relevant monitoring programs in Subsection 2.5.6.2.

##### **2.5.6.1 Surface Water Properties**

The pertinent properties of the surface water (i.e., Lake Ontario) are described below:

###### **1. Lake-Wide Circulation**

The Darlington Nuclear site is situated on the northern shore of Lake Ontario where the lake-wide circulation is generally eastward from the Niagara River to the discharge to the St. Lawrence River, per the 2021 D-REP-07701-00001 (Reference 2.5-9). Water movement near the site is predominantly along the shore, occurring for 73% of the time (35% to the west and 38% to the east), as described in the 2012 NK054-REP-01210-00016 (Reference 2.5-5). Onshore and offshore movement occurs about 15% of the time, as reported in the 2012 NK054-REP-01210-00016 (Reference 2.5-5). Table 2.7 in the 2021 D-REP-07701-00001 (Reference 2.5-9) shows the frequency of lake current flowing toward each direction and the maximum speed that occurred in each direction, per the 2021D-REP-07701-00001 (Reference 2.5-9). Table 2.5-3 shows the averaged lake current direction and speeds.

**Table 2.5-3 Summary of Lake Ontario Depth Averaged current speed and direction  
(Reference 2.5-9)**

Month	Direction	Depth Averaged Speed All Directions	Depth Averaged Speed Easterly	Depth Averaged Speed Westerly
	Degree from North	cm/s	cm/s	cm/s
January	142	17.5	20.6	12.4
February	145	16.2	18.9	13.1
March	159	13.5	15.5	12.7
April	165	11.8	12.7	12.3
May	181	9.4	12.0	7.8
June	177	9.5	10.5	9.7
July	183	13.3	16.0	11.4
August	193	10.9	12.2	11.1
September	196	9.9	10.3	10.9
October	170	11.8	13.0	11.9
November	159	11.5	13.2	9.8
December	169	12.9	14.4	12.5
Annual Average		12.4	14.1	11.3

**2. Lake Water Temperature**

Lake Ontario is classified as a dimictic lake because it undergoes a complete cycle of isothermal and vertically stratified conditions every year. The thermal structure depends on the season because of large annual variation in surface heat fluxes. Lake-wide surface temperatures typically range from freezing in winter to about 20 °C in summer, per the 2021 D-REP-07701-00001 (Reference 2.5-9). Statistical summary of ambient water temperatures near Darlington Nuclear site (from 1984 to 1996 and 2011 and 2012) is provided in Table 2-9 of the 2021 D-REP-07701-00001 (Reference 2.5-9).

**3. Ice Conditions**

Ice formation in winter is typically limited to the nearshore areas at the eastern end of the lake within the Kingston Basin, per the 2021 D-REP-07701-00001 (Reference 2.5-9) and the 2022 NK054-REP-02730-00001 (Reference 2.5-18).

**2.5.6.2 Surface Water Monitoring**

As described in Subsection 3.2.2 of the 2019 NK38-OM-61100 (Reference 2.5-6), the Lake Current Monitoring system is a real-time current profile measurement system to be used in the event of a radiological liquid emission. Further details of the radiological baseline conditions of lake water at the Darlington Nuclear site are provided in Subsection 2.9.1.1.

The OPG EMP N-REP-03443-10027 (Reference 2.5-17) identifies the contaminants and physical stressors to be monitored in the environment surrounding the site. Locations considered to be outside the influence of site operations are also monitored to allow for a baseline comparison with

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

background values. This includes monitoring and sampling of lake water, municipal drinking water, and other means of aquatic sampling. Further details on the EMP are provided in Chapter 20, Subsection 20.11.2.

## **2.6 Meteorology**

### **2.6.1 Introduction**

Section 2.6 describes the meteorological aspects relevant to the DNNP site based on the consideration of the local climatic effects. Details are included in Section 2.6 on the characterization of extreme values of meteorological events in relation to potential hazards to the BWRX-300 facility, as well as in relation to the transportation of radioactive materials and the dispersion of radionuclides with the potential to impact the DNNP site. The meteorological characteristics and conditions included in the following list are assessed in relation to the design and the evolution of extreme parameters over the lifetime of DNNP BWRX-300:

- Temperature (Subsection 2.6.2)
- Humidity (Subsection 2.6.3)
- Rainfall (Subsection 2.6.4)
- Wind Speed (Subsection 2.6.5)
- Tornadoes and Hurricanes (Subsection 2.6.6)
- Waterspouts (Subsection 2.6.7)
- Dust Storms and Sandstorms (Subsection 2.6.8)
- Snow Load and Ice Load, Freezing Rain, and Ice Storm (Subsection 2.6.9)
- Lightning (Subsection 2.6.10)
- Windborne Debris (Subsection 2.6.11)
- Climate Change (Subsection 2.6.12)

Key metrological characteristics and parameters relevant to the DNNP site and the surrounding area are listed in Table 2.6-1. The list includes characteristics such as temperature, humidity, precipitation, high wind, tornadoes, snowfalls, lightning, and climate change impact.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 2.6-1: Meteorological Characteristics Summary of DNNP Site and Surrounding Area**

Characteristic	Value/Description				
2.6.2 Temperature	Highest ever recorded	Toronto Bowmanville		36 °C 40.6 °C	
	Extreme minimum	-40 °C, with annual degree-days below 18 °C of 4130 degree-days			
	Maximum	Dry bulb 37 °C		Wet bulb 23 °C	
	Design Basis Duration at low Temperature		Temperature	Duration	
			-40 °C	1 h	
			-35 °C	5 h	
			-30 °C	10 h	
			-25 °C	20 h	
			-20 °C	70 h	
	-15 °C	150 h			
Safety Class 1 SSC Design Conditions	Highest 40 °C		Lowest -40 °C		
Impact of extreme temperatures	Mist and white frost during winter		Heatwaves during summer		
Impact of Climate Change by 2100	Increase between 2 °C and 5 °C (References 2.6-3 and 2.6-4) Recent analysis: increase by up to 7.2 °C (Reference 2.6-17)				
2.6.3 Humidity	Lowest	During winter and air is quite dry due to Arctic air from the north			
	Highest	During summer and fall due to the air from the Gulf of Mexico.			
	Mean value	65 to 80% throughout the year			
	Design Conditions	No indication of extreme conditions that require design mitigation			
2.6.4 Rainfall / Precipitation	Mean annual	Oshawa 877.9 mm		Toronto 800 mm	
	Maximum daily	Oshawa 88.6 mm		Toronto 79.3 mm	
	Average (DNGS PO-SAR)	145 days/yr, with of 800 mm average, with 20% due to snowfall			
	Greatest per day	In Oshawa, 144.8 mm			
	PMP (vicinity of DNNP)	420 mm in 12-hours, with 51% in the 6 <sup>th</sup> hour, for a watershed area of < 1295 km <sup>2</sup>			
	Severe flooding	PMP conditions, combined with a 1 in 100-year recurrence lake level high, and storm surge			
	Extreme Daily	Unlikely to exceed the PMP value in a 100-year recurrence for DNNP			
	For roof design	16 mm in 5 min – 50-year, 5-minute storm 25 mm in 15 min - 50-year return, 15-Minute storm 47 mm in 60 min – 50-year return 1-hour storm 210 mm in 24 h – Regional storm (Hurricane Hazel)			
	Climate Change Impact by 2100	Increase in heaviest precipitation intensity and frequency of 12% and 22%, respectively. Plausible increase in extreme precipitation amount over southern Ontario by 14% (7 mm) (Reference 2.6-3).			

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 2.6-1: Meteorological Characteristics Summary of DNNP Site and Surrounding Area**

Characteristic	Value/Description	
		Recent analysis indicates total precipitation and maximum 24-hour re anticipated to increase by up to 25% (Reference 2.6-17). The 12-hour PMP of 420 mm remains bounding of this increase as the summer and fall projections (when PMP would occur) are lower, up to +10%, and the PMP value is conservative (Reference 2.6-18). Such predicted changes is to be considered in the design and monitored for long term as discussed in Subsection 2.11.9.
<b>2.6.5 Wind and Wind Speed</b>	Typical	The prevailing winds were from the north-westerly quarter (10.38% of the time) and from the west quarter (9.98% of the time) (Refer to Subsection 2.8.1.3)
	Average and Clam	Approximately 2.4 m/s (~8.6 km/h) and less than 2 m/s (~7.2 km/h), respectively at 10 m level (Refer to Subsection 2.8.1.3)
	Maximum	64 km/h at 10 m level and 80 km/h at 50 m level (for a 100-year return period)
	Wind 3-sec Gust	Extreme gusts – Occur mostly in the West, Southwest, and Northwest directions Speeds exceeding 120 km/h are rare Higher speeds of up to 174.4 km/h occurred in some instances
	Climate Change Impact by 2100	Wind speeds are expected to change due to climate change. Decline in average wind speed over the years in a warmer world
<b>2.6.6 Tornadoes and Hurricanes</b>	Maximum Pressure Drop	6.3 kPa
	Maximum Rotational Speed	257.4 km/h
	Maximum Transitional Speed	64.4 km/h
	Maximum Wind Speed	321.8 km/h (Upper limit - Enhanced Fujita scale 4 (EF-4) tornado)
	Radius of Maximum Rotational Speed	45.7 m
	Rate of Pressure Drop	2.5 kPa/s
	Design Basis – Tornado Missile Spectrum types	Schedule 40 pipe, Automobile 5 m x 2 m x 1.3 m, and Solid Steel Sphere (Refer to Table 2.6-6)
	Hurricanes, Cyclones, Tropical Storms, Tropical Depression	Very low probability of an actual hurricane directly impacting the DNNP site, and it describes the probable maximum tropical cyclone as unlikely to yield gusts of more than 100 km/h - lower than that of the design basis tornado. As such, wind hazard from a hurricane is not considered further.
<b>2.6.7 Waterspouts</b>	A tornado that forms over water that are rarely reported. Covered by the design basis tornado	
<b>2.6.8 Dust and Sandstorms</b>	Not identified as phenomena for southern Ontario, and as such are not identified as potential hazards for DNNP.	
	Average daily snowfall	3 cm to 5 cm from December to March

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 2.6-1: Meteorological Characteristics Summary of DNNP Site and Surrounding Area**

Characteristic	Value/Description	
<b>2.6.9 Snow and Ice Load, Freezing Rain, and Ice Storm</b>	Highest Daily snowpack	Mean value of 8.6 cm in January
	Darlington Nuclear site characteristic Value	2.2 kPa
	Combined snow load and winter PMP event	1.80 kPa for 50-year recurrence 1.71 kPa for 100-year recurrence, without Winter PMP
	Freezing Rain	Screened out due to low frequency
	Ice Storm	This issue is resolved as part of Pressure Increase Group (refer to Subsection 2.2.8).
<b>2.6.10 Lightning</b>	Frequency	2 to 3 cloud-to-ground flashes per year per square km, causing induced fires and electromagnetic compatibility. Screened out due to low hazard to the site.
<b>2.6.11 Windborne Debris</b>	Wind-propelled missiles are similar to tornado missiles which is assessed as part of the high wind PSA.	
<b>2.6.12 Climate Change Impact</b>	Impact of climate change is considered in the 2023 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts NK054-REP-07007-00001 (Reference 2.6-19) which summarizes life cycle considerations including long-term monitoring, described in Subsection 2.11.9	

## 2.6.2 Temperature

Since DNNP is in proximity to DNGS within the Darlington Nuclear Site, similar meteorological conditions are expected. The highest temperatures ever recorded at Bowmanville, and Toronto are 36 °C and 40.6 °C, respectively per Subsection 2.1.1 of the 2019 NK054-REP-01210-00108 (Reference 2.6-2). As shown in Table 2-1 of Part 2 of the 2018 NK38-SR-03500-10001 DNGS Safety Report (Reference 2.6-7), the extreme minimum temperature chosen for DNGS was -40°C, with annual degree-days below 18 °C of 4130 degree- days. Per Subsection B.8.4. Table 3 of the 2010 N-REP-01200-10000 (Reference 2.6-9), the Darlington Nuclear site characteristic value for maximum dry bulb temperature is 37°C, and the maximum wet bulb temperature is 23°C. The design basis durations at low temperature for DNGS site in the 2018 NK38-SR-03500-10001 (Reference 2.6-7), which are applicable to the DNNP site, are listed in Table 2.6-2.

**Table 2.6-2: DNGS Design Basis Durations at Low Temperature Applicable to DNNP**

Temperature	Duration
-40°C	1 h
-35°C	5 h
-30°C	10 h
-25°C	20 h
-20°C	70 h
-15°C	150 h

According to Subsection 4.5.1 of the 2012 NK054-REP-01210-00016 (Reference 2.6-6), Safety Class 1 (SC1) SSCs that are exposed to ambient environment conditions in DNGS are designed for extreme temperatures of -40 °C during the winter and +40 °C during the summer. The design temperature for the DNNP SSCs is -40 °C, while the design temperature of +40 °C is approximately the same as the highest recorded temperature of 40.6 °C as baseline data on extreme conditions. Although the HVAC system efficiency is generally reduced due to extreme high temperature conditions, the system is expected to provide sufficient cooling to maintain design limits for equipment rooms and to support control rooms habitability. This information is also relevant to DNNP SSCs which require the implementation of appropriate mitigating measures, as necessary.

Refer to Chapter 9A, Section 9A.5 for information on the functions, design bases, description, maintenance, performance, and safety evaluation of the BWRX-300 HVAC systems.

Furthermore, global climate models projected in 2009 an increase of the temperatures in southern Ontario of between 2 °C and 5 °C over the next century, due to rising greenhouse gas emissions, as indicated in Subsection 7.2.8 of the 2009 NK054-REP-01210-00012 (Reference 2.6-3). This information is in line with the contents in Subsection 4.1.2.2 of the 2009 NK054-REP-01210-00013 (Reference 2.6-4), which stated temperatures in the vicinity of DNNP site were expected to rise by 2 °C in 2040 and by as much as 5 °C in 2100 during winter and summer months. In the 2022 NK054-REP-02730-00001 Flood Hazard Assessment (Reference 2.6-17), Subsection 7.2.3 indicates temperatures at the DNNP site are anticipated to increase by up to 7.2 °C by 2100. Mitigation of these environmental changes is to be provided at DNNP. Subsection 2.11.9 describes the long-term monitoring of parameters susceptible to be impacted by climate change,

as mentioned in the 2023 DNNP Strategy for Addressing Climate Change Impacts, NK054-PLAN-07007-00001 (Reference 2.5-20).

The extreme temperatures expected in the vicinity of DNNP site have the potential to result in mist and white frosts during winter, and heatwaves during summer, per Subsection 4.5.1 of the 2019 NK38-REP-03611-10043 (Reference 2.6-1). In the event of extremely high temperature conditions, an extended heatwave could lead to a high demand on the transmission lines, which could potentially cause a loss of grid condition.

Temperatures Normals at and near the Darlington Nuclear site are described in Subsection 2.8.1.1, as related to the meteorological impact on the dispersion on radioactive material.

### **2.6.3 Humidity**

The 2009 Site Evaluation of Meteorological Events NK054-REP-01210-00013 (Reference 2.6-4) states the average relative humidity in the vicinity of DNNP is the lowest during winter, as the air is quite dry due to the Arctic air moving down from the north; the highest humidity values occur during summer and fall as the humid air from the Gulf of Mexico moves across southern Ontario.

Currently, humidity values are not recorded on-site by the meteorological tower as indicated in Subsection 2.2.1 of the 2012 NK054-REP-01210-00016 (Reference 2.6-6). However, this information is available from several Environment Canada stations such as Oshawa WPCP and Toronto Island. Based on the available data, the mean relative humidity ranges from 65 to 80% throughout the year, per Section 2.2 of the 2009 NK054-REP-01210-00008 (Reference 2.6-5). Section 3.11 of the 2009 NK054-REP-01210-00008 (Reference 2.6-5) also states the meteorological values evaluated with respect to humidity show no indications of extreme conditions requiring design mitigation. Based on Subsection 4.5.2 of the 2020 NK054-CORR-00531-10533 (Reference 2.6-8), no further evaluation is required on the impact of humidity, as the design of the BWX-300 facility is expected to fit within the Plant Parameter Envelope (PPE) values per commitment D-C-3 in the 2021 NK054-REP-01210-00078 DNNP Commitments Report (Reference 2.6-10).

### **2.6.4 Rainfall / Precipitation**

The Bowmanville Mosert climate station is the closest to the Darlington Nuclear site. The Precipitation Normals (from 1981 to 2010) are described in Subsection 2.8.1.2, where the monthly averages and daily extremes (for precipitation (mm), rain (mm), and snow (cm)) are listed in Table 2.8-3.

The concept of PMP is defined in the 2009 NK054-REP-01210-00012 (Reference 2.6-3) as the greatest depth of precipitation possible for a given storm area at a particular location and time of the year (refer also to Subsection 2.5.3.1 for details on PMP and PMF definitions and values). According to Section 4.1 of the 2019 NK38-REP-03611-10043 (Reference 2.6-1), the PMP for watershed areas less than 1295 km<sup>2</sup> in the vicinity of DNNP site has been estimated as a 12-hour precipitation equivalent to 420 mm of total rainfall (with 51% in the 6th hour). Hence, based on the maximum daily precipitation predicted in Subsection 3.4.3 of the 2009 NK054-REP-01210-00013 (Reference 2.6-4) using data from the monitoring stations in Toronto Island and Oshawa (79.3 mm and 88.6 mm, respectively), it is unlikely for extreme daily precipitations to exceed the 420 mm PMP value in a 100-year period for DNGS. This conclusion, which is also applicable to DNNP given its proximity to DNGS, is confirmed in the 2022 DNNP Flood Hazard Assessment in NK054-REP-02730-00001 (Reference 2.6-17).

Precipitation, along with other meteorological factors such as wind direction and speed, influence dispersion and, in case of precipitation, especially deposition. Radioactive materials tend to flow toward low-pressure systems and rainfall often occurs around those systems. Having the PMP

value for the DNGS site available for the DNNP PPE ensures that this (maximum probable) value is considered in the DNNP's dispersion (and deposition) models. Models/codes (such as ADDAM and PAVAN) would use the precipitation rate as input to wet deposition. Precipitation Normals at and near the Darlington Nuclear site are described in Subsection 2.8.1.2, as related to the meteorological impact on the dispersion on radioactive material.

According to Table 3-1 in the 2022 PMP Validation reported in NK054-REP-02730-00002 (Reference 2.6-18), the DNNP storm values to be considered as part of roof design are as follows:

- 210 mm in 24 h – Regional storm (Hurricane Hazel)
- 47 mm in 60 min – 50-year return 1-hour rainfall
- 25 mm in 15 min - 50-year return 15-Minute storm
- 16 mm in 5 min – 50-year 5-minute storm

In relation to the changes in precipitation over time, few studies have examined changes in precipitation over Canada. The 2009 site evaluation report on flood hazard assessment, NK054-REP-01210-00012 (Reference 2.6-3) provides references to a number of studies in Subsection 7.2.1. Based on the conclusions in this report, the heaviest precipitation events are becoming more frequent during the spring and summer, and less frequent during the winter. The information provided indicates a reported increase in extreme precipitation intensity and frequency of 12% and 22%, respectively. In addition, Subsection 7.2.8 of the 2009 NK054-REP-01210-00012 (Reference 2.6-3) states some models show a plausible increase in the amount of precipitation for the most extreme precipitation events over southern Ontario by 14% (7 mm). In the 2022 NK054-REP-02730-00001 DNNP Flood Hazard Assessment (Reference 2.6-17), Subsection 7.2.3 indicates the total precipitation and the maximum 24-hour for certain seasons to increase by up to 25% by 2100. The PMP event is not coincident with this increase and remains conservative considering anticipated coincident increases. Consequently, no additional flood hazard is considered for rainfall increase due to climate change. However, as discussed in Subsection 2.11.9, long-term monitoring of precipitation is included as part of the 2023 DNNP Strategy for Addressing Climate Change Impacts NK054-PLAN-07007-00001 (Reference 2.6-19).

### **2.6.5 Wind and Wind Speed**

Wind data sets at a standard height of 10 m are collected from Darlington Nuclear site meteorological tower as well as from nearby monitoring stations. The Darlington Nuclear site average and calm wind speeds and wind direction data are presented in Subsection 2.8.1.3. The maximum wind speed at 10 m level and 50 m level at Darlington Nuclear site was estimated to be 64 km/h and 80 km/h, respectively, for a 100-year return period, per the 2009 NK054-REP-01210-00013 (Reference 2.6-4).

Wind gust analysis is performed in the 2022 NK0054-REP-02730-00003 (Reference 2.6-14) for the DNNP site. Although wind speed was collected at the DNGS for 12 years at 15-minutes intervals, 3-second wind gust data were not available. In the 2022 NK0054-REP-02730-00003 (Reference 2.6-14) high-quality Government of Canada publicly available 3-second wind gust data were used from four different stations located within 100 km from DNNP: the three airports in Toronto, Peterborough, and Trenton, as well as the Toronto City Centre. Wind roses were used to analyze the gust magnitude and frequency for each station in eight gust directions. Annual Maximum Series data were then extracted and statistically tested and analyzed. Based on the summary of the maximum and mean of gust Annual Maximum Series, extreme gusts were found to occur mostly in the West, Southwest, and Northwest directions.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

To estimate the extreme design gust speeds for various return periods, the Extreme Value Type I model (known as Gumbel distribution model) was fitted to the extracted Annual Maximum Series values, as described in the 2022 NK0054-REP-02730-00003 Wind Gust Analysis (Reference 2.6-14). The extreme design gust speeds were then calculated for various return periods, particularly, for the design of reactor buildings based on ASCE7 IV risk category which corresponds to 3000-year return period. Other commonly used values corresponding 300-, 700-, and 1700-year return periods were also estimated. Finally, Inverse Distance Weighted interpolation technique was applied to transfer the estimated 3-second gust values from the four selected stations to the DNNP site; the results are listed in Table 2.6-3. Also, bounding envelop 3-second gust extreme values were computed for the DNNP site, as listed in Table 2.6-4. The envelop values are found to be on average 6% higher than the values estimated through interpolation for the DNNP site. Hence, for the design to be conservative, the 2022 NK0054-REP-02730-00003 Wind Gust Analysis (Reference 2.6-14) recommends using the envelop values.

Table 3-5 of the 2009 NK054-REP-01210-00008 (Reference 2.6-5) presents the historical data available for wind gusts in the nearby area to the Darlington Nuclear site. Similar to the methodology used in Subsection 3.4.2 of the 2009 NK054-REP-01210-00013 (Reference 2.6-4) and the 1990 N-REP-NGD-IR-61100-0002 (Reference 2.6-11), site-specific 3-second gust wind speeds of more than 120 km/h or more are rare. However, 3-second gust wind speeds have occurred in some instances with a maximum historical wind gust in the area of 154 km/h. This is consistent with Table 4-4 of the 2022 NK0054-REP-02730-00003 (Reference 2.6-14), as presented in Table 2.6-3, noting maximum speeds of up to 174.4 km/h occurred in some instances.

[The hazards associated with high winds were not addressed in the 2019 DNGS hazard screening analysis report NK38-REP-03611-10043 (Reference 2.6-1). However, there is a commitment in place by OPG to perform a high wind PSA as part of the Licence to Construct application, as indicated in Subsection 4.5.2 of the 2020 NK054-CORR-00531-10533 (Reference 2.6-8). The high wind PSA will consider the impact from wind pressure-loading effects and wind-propelled missile analysis from various categories of high wind, and their impact on severe core damage and large release analysis.

The review of literature and simulations from Environment Canada indicated in Subsection 7.2.8 of the 2009 NK054-REP-01210-00012 (Reference 2.6-3) points to expected changes in wind speed due to increased greenhouse gas emissions. The same subsection states the global average winds are expected to decrease in a warmer world due to the decrease in temperature differential between the equator and poles. In the 2022 NK054-REP-02730-00003, Wind Gust Analysis (Reference 2.6-14), it was reported that Lake Erie shores will experience a decrease in wind speeds of 5% by 2071-2100, while other areas in Ontario like James Bay and Georgian Bay will experience an increase in wind speeds ranging from 1.4% to 10%.

## 2.6.6 Tornadoes and Hurricanes

### Tornadoes

As discussed in Section 3.2 of the 2009 NK054-REP-01210-00008 (Reference 2.6-5), tornadoes are characterized as a rare and non-negligible threat, and a study of a design basis tornado was conducted to estimate the probability of occurrence at the DNNP site. The results of this study are presented in Table 3-7 of the 2009 NK054-REP-01210-00008 (Reference 2.6-5).

The DNNP site characteristics associated with the design basis tornado are outlined in Table 3 of the 2010 N-REP-01200-10000 (Reference 2.6-9), summarized in the following, and listed in Table 2.6-5 and Table 2.6-6):

1. Maximum Pressure Drop – The design assumption for the decrease in ambient pressure from normal atmospheric pressure due to the passage of the tornado
2. Maximum Rotational Speed – The design assumption for the component of tornado wind speed due to the rotation within the tornado
3. Maximum Translational Speed – The design assumption for the component of tornado wind speed due to the movement of the tornado over the ground
4. Maximum Wind Speed – The design assumption for the sum of maximum rotational and maximum translational wind speed components
5. Radius of Maximum Rotational Speed – The design assumption for distance from the centre of the tornado at which the maximum rotational wind speed occurs
6. Rate of Pressure Drop – The assumed design rate at which the pressure drops due to the passage of the tornado
7. Tornado Missile Spectra – The design assumptions regarding missiles that could be ejected either horizontally or vertically from a tornado. The spectra identify mass, dimensions, and velocity of credible missiles

The DNNP site characteristics values in the 2010 N-REP-01200-10000 (Reference 2.6-9) are based on the U.S. NRC Regulatory Guide 1.76 Rev 1 (Reference 2.6-13), Region 2 design basis tornado values. The characteristics, and appropriate reasoning are summarized from the 2022 NK054-CORR-01210-1015770 Engineering Direction for DNNP Design Basis Tornado Values (Reference 2.6-12). The DNNP site is conservatively assumed to have the Site Characteristic Maximum Wind Speed Site Characteristic value of 321.8 km/h for maximum wind speed. This is supported by the following reasons:

- The Maximum Wind Speed of 321.8 km/h is the upper limit for an Enhanced Fujita scale 4 (EF-4) tornado.
- The Maximum Wind Speed of EF-4 is a conservative value for the Darlington Nuclear site, as the Maximum Wind Speed value is not a measured value for the site.
- The assessment performed of the occurrence of tornadoes within an area of 100 000 km<sup>2</sup> of the Darlington Nuclear site during the past 50 to 60 years indicated two category Enhanced Fujita scale 4 (EF-4) tornadoes were observed within 180 km of the site during that period.
- A probability of approximately 0.01% per year was predicted corresponding to an EF-4 category of damage for the Darlington Nuclear site.
- The U.S. NRC RG-1.76 Rev1 (Reference 2.6-13) values for the two subregions adjacent to the Eastern Great Lakes and the northeastern boundary of Region 1 are 327 Km/h and

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

296 km/h, respectively. This further supports the use of 321.8 km/h as a bounding value for Darlington Nuclear site.

The missile spectrum in Table 2.6-6 is extracted from Table 2 of U.S. NRC RG-1.76 Rev1 (Reference 2.6-13), Region 2 values, which correspond to a maximum wind speed of 321.8 km/h.

**Table 2.6-5: DNNP Site Characteristics for Design Basis Tornado (Reference 2.6-9)**

Parameter	Value
Maximum Pressure Drop	6.3 kPa
Maximum Rotational Speed	257.4 km/h
Maximum Translational Speed	64.4 km/h
Maximum Wind Speed	321.8 km/h
Radius of Maximum Rotational Speed	45.7 km/h
Rate of pressure Drop	2.5 kPa/s

**Table 2.6-6: DNNP Site Tornado Missiles Spectrum for Maximum Horizontal Speed (Reference 2.6-9)**

Missile Type	Dimensions	Mass	Horizontal Velocity ( $V_{mh}^{max}$ )	Vertical Velocity ( $0.67$ of $V_{mh}^{max}$ )
Schedule 40 Pipe	0.168 m dia x 4.58 m long	130 kg	34 m/s	22.8 m/s
Automobile 5 m x 2 m x 1.3 m	5 m x 2 m x 1.3 m	1810 kg	34 m/s	22.8 m/s
Solid Steel Sphere	2.54 cm dia	0.0669 kg	7 m/s	4.7 m/s

### Hurricanes

A tropical cyclone is a rapidly rotating storm system characterized by a low-pressure centre. Depending on the wind speed, it can be designated as hurricanes, tropical storms, or tropical depressions. Based on the information presented in Subsection 3.5.2 of the 2009 NK054-REP-01210-00013 (Reference 2.6-4), there is a very low probability of a hurricane directly impacting the DNNP site, and it describes the probable maximum tropical cyclone as unlikely to yield gusts of more than 100 km/h which is lower than that of the design basis tornado. As such, wind hazard from a hurricane is not considered further.

Additionally, the 2009 NK054-REP-01210-00013 (Reference 2.6-4) states that a tropical storm such as Hazel, which occurred in 1954, would be the worst-case scenario from systems of tropical origin. During this storm, Toronto Pearson reported over 150 mm of rain in 2 days with sustained winds of 92 km/h for 2 hours and multiple hours with winds of over 70 km/h, per Subsection 3.5.2 of the 2009 NK054-REP-01210-00013 (Reference 2.6-4). Precipitation caused from a tropical cyclone is covered in Subsection 2.5.3.5.

### **2.6.7 Waterspouts**

A tornado forming over water is a waterspout. The Site Evaluation on Nuclear Safety Considerations in the 2009 NK054-REP-01210-00008 (Reference 2.6-5), Section 3.2, states tornadoes over water or waterspouts generally leave no trace and are rarely reported. Additionally, the report states it is less likely for tornadoes to form over water than over land.

However, the report assumes an equal distribution of tornadoes and waterspouts for a given area and calculates the probability of a tornado at DNNP site. It then concludes that with such a frequency, tornadoes can be characterized as a rare, but non-negligible threat and a study of a design basis tornado was required in order to estimate the probability of occurrences on-site. The DNNP site characteristics for design basis tornado is described in Subsection 2.6.6.

### **2.6.8 Dust Storms and Sandstorms**

The assessment for the potential of dust storms or sandstorms was captured in the 2009 NK054-REP-01210-00013 (Reference 2.6-4) where Subsection 3.5.5 states a lack of evidence of these phenomena was identified from an extensive search through the available meteorological information relevant to southern Ontario. Hence, neither dust storms nor sandstorms were identified as potential hazards since the possibility of occurrence for these phenomena at the DNNP site is deemed to be highly unlikely.

### **2.6.9 Snow and Ice Load, Freezing Rain, and Ice Storm**

#### **Snow and Ice Load**

The average daily snowfall recorded at the nearest monitoring station to the Darlington Nuclear site is between 3 cm and 5 cm from December to March, per Section 2.2 of the 2009 NK054-REP-01210-00008 (Reference 2.6-5). Similarly, the daily snowpack is typically recorded at the same location, and its highest point tends to occur in January, with a mean value of 8.6 cm.

Table 2.6-7 shows under Loading 1 the characteristic value of 2.2 kPa for snow and ice load for reactor designs considered for the DNNP site, per Subsection B.1.3, Table 3 of the 2012 N-REP-01200-10000 (Reference 2.6-9).

The 2019 DNGS hazard screening analysis report NK38-REP-03611-10043 (Reference 2.6-1) used the 1975 NBCC design criteria for the snowpack of 2.1 kPa (Loading 2 in Table 2.6-7).

For the DNNP, Subsection 4.5.2 of the 2020 NK054-CORR-00531-10533 (Reference 2.6-8) assumed that similar snowfall conditions to the ones experienced in DNGS are expected to occur at DNNP due to their proximity. In 2022, a study was performed in NK054-REP-02730-00004 Winter PMP Validation (Reference 2.6-15) where a 50-year recurrence snow fall depth and maximum one-day late winter rain load nearby Oshawa are used to calculate the roof loading. The resulting loading is 1.8 kPa, as shown in Table 2.6-7, Loading 3. Furthermore, Loading 4 of 1.71 kPa in Table 2.6-7 represents the calculated DNNP snow load based of an NBCC 100-year recurrence, following the recommendation of CSA N291:19 (Reference 2.6-16) and employing a 50- to 100-year conversion multiplying factor of 1/0.82, as described in the 2022 NK054-REP-02730-00004 Winter PMP Validation (Reference 2.6-15), noting CSA N291:19 (Reference 2.6-16) does not require adding WPMP. The DNNP estimated snow loads and winter PMP values listed in Table 2.6-7 for 50-year recurrence or 100-year recurrence with or without WPMP are equal or lower than the Darlington Nuclear site characteristic value (Loading 1) of 2.2 kPa listed in Subsection B.1.3, Table 3 of the 2012 N-REP-01200-10000 (Reference 2.6-9).

**Table 2.6-7: Snow Loads and Winter PMP Values for DNGS and DNNP (Reference 2.6-15)**

Loading ID	Nuclear Site	Values	Compliance Notes
1	Darlington Nuclear	<b>2.2 kPa</b>	Characteristic value for reactor designs considered for the site (2010 PPE - Reference 2.6-9)
2	DNGS	<b>Snow: 2.1 kPa</b>	Meets the 1975 NBCC requirements (2019 SNGS - Reference 2.6-1)
3	DNNP (50-year recurrence)	Snow: 1.4 kPa + WPMP: 0.4 kPa <b>= Total: 1.8 kPa</b>	Meets 2015 NBCC requirements for 50-year recurrence snowpack, plus 50-year recurrence winter PMP near Oshawa (2022 DNNP - Reference 2.6-15)
4	DNNP (100-year equivalent recurrence)	Snow: (1.4/0.82) <b>= Total 1.71 kPa</b>	Meets 2015 NBCC requirements and CSA N291:19 requirements using a multiplying ASCE/SEI 7-10 factor of 1/0.82 to calculate the 100-year recurrence snowpack (2022 DNNP - Reference 2.6-15), noting N291:19 does not require adding WPMP.

#### Freezing Rain

With respect to freezing rain, Subsection 4.5.2 of the 2020 NK054-CORR-00531-10533 (Reference 2.6-8) indicates this item was considered for assessment as part of the safety analysis for DNNP. The hazards associated with freezing rain were also screened out for DNNP due to low consequence, as indicated in the 2019 hazard screening analysis report NK38-REP-03611-10043 (Reference 2.6-1) and in the 2019 Site Preparation Nuclear Safety Licence Renewal Activity Report NK054-REP-01210-00108 (Reference 2.6-2).

#### Ice Storm

Ice storms present a potential hazard for the systems located outside the DNNP BWRX-300, as indicated in Subsection 4.5.2 of the 2020 NK054-CORR-00531-10533 (Reference 2.6-8). According to Subsection 4.5.5 of the 2019 NK38-REP-03611-10043 (Reference 2.6-1), a review of operating experiences indicates minor ice storms have not had an impact on other plants, but significant storms have caused losses of off-site power and switchyard failures. This event is described as an LOPP and is covered in Chapter 15, Subsection 15.5.3.2.4.

### **2.6.10 Lightning**

The assessment of lightning strikes is provided in Subsection 3.5.3 of the 2009 NK054-REP-01210-00013 (Reference 2.6-4) in the context of frequency of occurrence, where Table 3.5.10 provides estimates of the cloud-to-ground flashes for Toronto and Trenton, while Figure 3.5.8 displays graphically the Average Annual Flash Density in southern Ontario. Based on the data evaluated, the vicinity of the DNNP site will likely experience a frequency of 2 to 3 cloud-to-ground flashes per year per square kilometer. The 2020 DNNP lightning data collected and evaluated per NK054-CORR-00531-10533 (Reference 2.6-8) confirmed lightning occurrences are frequent in southern Ontario.

Subsection 4.5.7 of the 2019 Hazard Screening Assessment NK38-REP-03611-10043 (Reference 2.6-1) for DNGS summarizes the potential consequences of lightning occurrences as induced fires and electromagnetic compatibility issues affecting the functionality of electrical

systems. As shown in Table 4-3 of the 2019 NK38-REP-03611-10043 (Reference 2.6-1), the criterion assigned for lightning events is screening criterion QL-1 for DNGS, which is described as “an event of equal or lesser damage potential than similar events for which the plant has been designed.” This screening criterion is applicable to the DNNP site on the basis that adequate measures, such as fire barriers and qualification for electromagnetic compatibility, are incorporated in the BWRX-300 design, as described in Chapter 7, Section 7.1 and Section 7.3.

#### **2.6.11 Windborne Debris**

An analysis of windborne debris from various categories of high wind, also known as wind-propelled missiles, is assessed as part of the 2020 high wind PSA per NK054-CORR-00531-10533 (Reference 2.6-8). This assessment evaluated the impact of windborne debris on severe core damage and large release analysis. Tornado windborne missile hazard design basis is described in Table 2.6-6 in Subsection 2.6.6, Tornadoes and Hurricanes.

#### **2.6.12 Climate Change Impact**

As described in Subsection 2.5.4, the 2023 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts NK054-PLAN-07007-00001 (Reference 2.6-19) is developed with the objective of summarizing life cycle climate change considerations including relevant long-term monitoring that is described in Subsection 2.11.9.

## 2.7 Geology, Seismology and Geotechnical Engineering

Section 2.7 covers the following DNNP site-specific information:

- Site Location and Description - Subsection 2.7.1  
Subsection 2.7.1 presents a general description of the site and identifies the study areas considered for the characterization of the site geological and geotechnical conditions
- Geological Characteristics - Subsection 2.7.2  
Subsection 2.7.2 contains the geological characteristics of the site including descriptions of the site physiography, surficial and bedrock geology, and offshore bathymetric contours and lakebed geology
- Geotechnical Characteristics - Subsection 2.7.3  
Subsection 2.7.3 describes the geotechnical and geological data collected at the site, presents subsurface soil and rock profiles and groundwater conditions, and provides an assessment of potential geotechnical hazards on structures
- Seismology Characteristics - Subsection 2.7.4  
Subsection 2.7.4 summarizes the seismological characteristics of the site including descriptions of the regional geology and tectonic history, hazard models, regional seismicity and seismic sources, ground motion characterization, methodologies used for the PSHA, and geological hazards that could potentially affect the site and the plant design.
- Geotechnical and Seismological Requirements and DNNP Site Parameters - Subsection 2.7.5  
Subsection 2.7.5 presents geotechnical and seismological parameters for the DNNP site including evaluation of bearing capacity and settlement, static and dynamic properties of rock, soil and engineered fill materials, geotechnical variability and uncertainty, Site Response Analysis (SRA), and groundwater level

The presented summary of geological, seismological, and geotechnical characteristics of the DNNP site and the surrounding region are based on:

- Site-specific characteristics from DNNP documents including the PSHA and the geological mapping of subsurface soil layers and bedrock, as well as relevant Darlington Nuclear site data.
- Available information developed during the DNNP site selection and preparation stages

In 2022 and 2023, several DNNP site-specific investigations and studies are completed as follows:

1. NK054-REP-01210-00175 R001, 2022, "Phase I Geotechnical Investigation (Power Block) Darlington New Nuclear Project," Volumes 1 of 2 and 2 of 2 (Reference 2.7-39)
2. NK054-REP-10180-00001 R000, 2023 "Offshore Geotechnical Investigation," (Reference 2.7-40)
3. NK054-REP-03500.8-00001 R000, 2022, "Darlington New Nuclear Project - Site-Specific Probabilistic Seismic Hazard Assessment", (Reference 2.7-41)
4. NK054-REP-03500.8-00002 R000, 2022, "Darlington New Nuclear Project - Seismically-Induced Soil Liquefaction Assessment," (Reference 2.7-42)

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

5. NK054-REP-03500.8-00003, 2023, "Darlington New Nuclear Project Foundation Interface Analysis (FIA) Report," (Reference 2.7-38)

These investigations, assessments and analyses are used to validate and update DNNP-specific geological and geotechnical characteristics and parameters of subgrade materials, results of PSHA, potential of liquefaction underneath the BWRX-300 facility buildings, as well as Lake Ontario bathymetry and lakebed geology.

### **2.7.1 Site Location and Description**

The Darlington Nuclear site, where the DNNP BWRX-300 facility is to be built, is located about 65 km east of the City of Toronto on the north shore of Lake Ontario in the Municipality of Clarington, Region of Durham in Ontario, Canada. The DNNP site is located to the east of the existing DNGS as shown in Chapter 1, Appendix A, Figure A1.1-2. The site is at latitude 43° 53' north and longitude 78° 43' west, per the 2009 site geotechnical aspects evaluation NK054-REP-01210-00011 (Reference 2.7-1). (Refer to Section 2.1 for further information on the Darlington Nuclear site and the DNNP site description, layout, geography, and demography.)

The topography of the Darlington Nuclear site, shown in Figure 2.7.1-1, based on the Darlington Topographic Drawing NK054-DRAW-01210-00003 (Reference 2.7-26), indicates a gentle slope rising upward towards the east from an approximate elevation of 80 m to 88 m CGD, in a horizontal distance of about 400 m. Further east, the existing ground rises substantially to an elevation of about 100 m CGD near the east site boundary. The existing shoreline along the Darlington Nuclear site consists of a narrow beach with steep bluffs. Additional information about the Darlington Nuclear site topography is provided in Subsection 2.1.1.

The site is situated in an undulating to moderately rolling glacial till plain. However, the upper soils at the site are glaciolacustrine, indicating the site is in the Iroquois Plane. The previously irregular terrain was graded for the existing DNGS to an elevation of about 78 m CGD. For the DNNP, the terrain is planned to be graded to a grade elevation of 88 m CGD. The surface elevation for the DNNP site rises towards the north with a mean elevation of 100 m CGD just south of the Canadian National Railway tracks. To the north of the railway tracks, the ground is irregular ranging from 98 m to 106 m CGD. A higher ridge, starting from the shore just east of Raby Head, extends diagonally across the site in a northwesterly direction with levels of up to 15 m above the surrounding ground. Offshore from the site, the Lake Ontario bottom slopes away gradually reaching a depth of 6 m at about 425 m from shore and 14 m at approximately 1.2 km from shore. Offshore bathymetry is discussed in Subsection 2.7.2.4.

### **2.7.2 Geological Characteristics**

Summaries based on the information in the 2009 DNNP Site Geotechnical Aspects Evaluation NK054-REP-01210-00011 (Reference 2.7-1), the 2013 DNNP Geotechnical Data Report NK054-REP-01210-00098 (Reference 2.7-29), the 2023 NK054-REP-10180-00001 Offshore Geophysical Investigation Report (Reference 2.7-40), and the 1989 DNGS Preoperational Summary Report No. 89575 (Reference 2.7-2) are presented in:

- Subsection 2.7.2.1 - Surficial Geology
- Subsection 2.7.2.2 - Site Physiography
- Subsection 2.7.2.3 - Bedrock Geology
- Subsection 2.7.2.4 - Offshore Bathymetric Contours / Lakebed Geology

These summaries furnish a framework within which the geological characteristics of the DNNP site and the surrounding region are described.

### **2.7.2.1 Surficial Geology**

The regional surficial geology, for an area within an approximately 50 km radius from the DNNP site, is shown in Figure 2.7.2-1, as replicated from the 2009 NK054-REP-01210-00011 (Reference 2.7-1).

For the surficial geology, there are three general physiographic regions:

- The Oak Ridges Moraine on the north side of the regional study area
- The South Slope in the middle
- The Iroquois Plain, a wide belt along Lake Ontario in the south

#### **The Oak Ridges Moraine Physiographic Region**

The Oak Ridges Moraine is a significant geologic/hydrogeologic feature specific to southern Ontario. The moraine is a major source of groundwater recharge, and many creeks and rivers are derived from groundwater discharge from the moraine. It was formed by regional glaciation, the advance and recession of several ice sheets and the subsequent melting of the glaciers. The moraine marks the boundary between the Lake Simcoe ice lobe advancing from the north and the Lake Ontario ice lobe advancing from the south. It is a ridge of high land separating drainage northward to Lake Simcoe and southward to Lake Ontario.

The moraine consists of interbedded layers of glacial till, sand and gravel. The moraine has a distinctive hummocky terrain with knobs and kettles. The southern flank of the moraine is covered by the Halton Till, a silty to silt-clay till.

#### **The South Slope Physiographic Region**

The South Slope fills the area between the moraine and the Iroquois Plain. It consists of gentle to steep slopes but is more uniform compared to the irregular terrain of the moraine. It contains a number of drumlins which point to the southwest, indicating the general direction of glacier movement.

#### **The Iroquois Plain Physiographic Region**

The Iroquois Plain, an 8 to 12 km wide plain, lies between the former shoreline of Lake Iroquois and present-day Lake Ontario. Shoreline deposits and glaciolacustrine sediments are found in this area overlying the glacial tills. The shoreline deposits include sand and gravel bars and beach terraces as well as some deltas from former rivers and creeks flowing into Lake Iroquois. The lacustrine deposits, consisting of silts and clays overlying till are found further from the former shoreline. In the area of the site, the Iroquois Plain contains drumlins with a southeast orientation indicating the northwest glacial advance.

### **2.7.2.2 Site Physiography**

The DNNP site is generally covered by upper and lower till deposits, per the 2009 NK054-REP-01210-00011 (Reference 2.7-1), as described in the following paragraphs.

The surface till in the DNNP area is similar to the Newmarket Till, a sandy silt to silt till. An earlier dense, to very dense, sandy silt to hard silty clay till overlies the bedrock. Bounded between the upper and lower tills are deposits of water-bearing sand or sand and gravel.

Earlier deposits of lacustrine varved silt and clay and stratified fine to medium sand overlie the upper till at lower elevations near the DNNP BWRX-300 location, as described in the 2013 NK054-REP-01210-00098 (Reference 2.7-29). These surficial lacustrine deposits consist of varved silt and clay and fine to medium sand of variable thickness, per the 2013 NK054-REP-01210-00098 (Reference 2.7-29).

Fill material of variable composition is present at the ground surface over portions of the DNNP site, as described in the 2013 NK054-REP-01210-00098 (Reference 2.7-29). The fill consists of a mixture of clay, silt, sand, and gravel.

Overburden thickness varies significantly from the north to the south. Overburden thickness in the Oak Ridges Moraine is approximately 200 m reducing in thickness towards the south with about 10 m of overburden at Lake Ontario.

### **2.7.2.3 Bedrock Geology**

The bedrock is completely covered by Quaternary deposits and bedrock outcrops are found only in local quarries, as described in the 2009 NK054-REP-01210-00011 (Reference 2.7-1). The bedrock surface, from east to west, consists of the Simcoe Group overlain by the younger Blue Mountain (formerly the Whitby Formation) and Georgian Bay Formations. The Simcoe Group consists of the Gull River, Bobcaygeon, Verulam and Lindsay Formations (from deep to shallow). The dip of the bedrock formations is approximately 0.5 percent to the southwest.

The Blue Mountain Formation is a shale formation. The lower 2 m to 3 m includes what was formerly known as the Whitby Formation, a black, petroliferous calcareous shale which tends to weather grey on exposure. The shale is fissile and fossiliferous. The Lindsay Formation is a grey argillaceous limestone with a full formation thickness of approximately 67 m.

The Verulam, Bobcaygeon and Gull River Formations lie below the Lindsay Formation. They are shale and limestone formations. The Shadow Lake Formation, a sandstone and shale formation, lies unconformably on the Precambrian Basement, as explained in the 2009 NK054-REP-01210-00011 (Reference 2.7-1).

Based on the described bedrock geology, the bedrock at the site of the DNNP is mainly the Lindsay Formation overlying the Verulam and Bobcaygeon and Gull River Formations. The upper few meters of bedrock are shaley limestone and shale of the Blue Mountain Formation that overlies the Simcoe Group, as detailed in the 2013 NK054-REP-01210-00098 (Reference 2.7-29).

### **2.7.2.4 Offshore Bathymetric Contours / Lakebed Geology**

The bathymetric contours of the lakebed along Lake Ontario shoreline of the Darlington Nuclear site are provided in the 2023 NK054-REP-10180-00001 Offshore Geophysical Investigation Report (Reference 2.7-40). This investigation was conducted to characterize the lakebed and sub-bottom materials and profile the depth to bedrock. The offshore geophysics methods used were:

- Seismic reflection
- Sub-bottom profiling
- Electrical resistivity tomography
- Multi-beam echosounder
- Side scan sonar
- Magnetometer

The most prominent feature of the lakebed topography reported in the 2023 NK054-REP-10180-00001 Offshore Geophysical Investigation Report (Reference 2.7-40) is a crescent shaped ridge and peninsula of shallower depths which wraps from the northeast to the west of the surveyed area. The shape of this ridge creates a deeper “bay” in the central west part of the surveyed area; to the southeast the lakebed drops off into deeper water, as shown in Figure 2.7.2-3 and Figure

2.7.2-4. The results are aligned with previous studies of the offshore bathymetry and lakebed surface geology, per the 1989 Report No. 89575 (Reference 2.7-2), as depicted in Figure 2.7.2-5 and Figure 2.7.2-6.

### **2.7.3 Geotechnical Characteristics**

Subsection 2.7.3 includes the following information related to the geotechnical characteristics of the DNNP site:

- Subsection 2.7.3.1 describes available geotechnical and geological data collected for the DNNP site
- Subsection 2.7.3.2 presents subsurface stratigraphic soil and rock profiles and groundwater conditions at the DNNP site
- Subsection 2.7.3.3 provides an assessment of potential geotechnical hazards on the DNNP structures

#### **2.7.3.1 Geotechnical Information Collected at the DNNP Site**

Multiple geotechnical investigations have been completed for the DNNP site. The data compiled in the investigations described in this subsection are used in determining the static and dynamic subgrade properties of the DNNP site presented in Subsection 2.7.5.

##### ***2.7.3.1.1 CH2MHILL (2007, 2008) Study***

The investigation was performed by CH2MHILL in late 2007 and early 2008 and included installing monitoring wells in 11 borings. The results of this study are presented in two reports, the 2009 DNNP Geotechnical Aspects Site Evaluation NK054-REP-01210-00011 (Reference 2.7-1) and the 2009 DNNP Geological and Hydrogeological Environment NK054-REP-07730-00005 (Reference 2.7-30). These boreholes covered an area larger than the boundary of the DNNP site. The locations of the monitoring wells and the corresponding borehole numbers (DN) within the area planned for the construction of the DNNP in the CH2MHILL study, are marked with red circles in Figure 2.7.3.1-1.

##### ***2.7.3.1.2 AMEC (2012) Study***

Three vertical boreholes completed within the DNNP area by AMEC in the 2012 DNNP Geologic and Geophysical Evaluation NK054-REF-01210-0418696 (Reference 2.7-28) are used to obtain subsurface information to the depth of the Precambrian Basement rock. The results of this study are presented in the 2012 NK054-REF-01210-0418696 (Reference 2.7-28). The locations of these deep borings are shown in Figure 2.7.3.1-2. The boreholes included: AMC-01 to a depth of 231.6 m, AMC-02 to a depth of 239.6 m, and AMC-03alt to a depth of 239.6 m. This study provides detailed boring logs, downhole geophysical measurements including televiewer data, surface geophysical measurements, and laboratory testing results. The data compiled in this study was mainly used to characterize the bedrock units. The geotechnical data provided in this AMEC study for the soil units are limited.

##### ***2.7.3.1.3 EXP Service INC. (2013) Study***

In the 2013 DNNP Geotechnical Data Report NK054-REP-01210-00098 (Reference 2.7-29), eight sampled boreholes were drilled at locations within the DNNP area as shown in Figure 2.7.3.1-3. The drilled boreholes were advanced to various depths between 34 m to 85 m below the surface. The geotechnical data include detailed stratigraphic information, results of in-situ Standard Penetration Tests (SPTs) with calibrated hammers, and data from laboratory testing of soil and rock samples. Subsurface cross-section diagrams developed as part of the EXP study are presented in Figure 2.7.3.1-4 and Figure 2.7.3.1-5.

#### **2.7.3.1.4 WSP GOLDER (2022) Phase 1 Geotechnical Investigation Report**

In the 2022 Geotechnical Investigations NK054-REP-01210-00175 (Reference 2.7-39), extensive drilling was conducted at locations within the DNNP area to determine engineering properties of soil and rock, with specific focus on the first BWRX-300 location as shown in Figure 2.7.3.1-6. The stratigraphic units identified for the DNNP site and corresponding description are listed in Table 2.7-1. The site investigation followed the guidelines of NEDO-33914-A (Reference 2.7-27), Section 3.1, to ensure an adequate characterization of the subsurface conditions that meet additional requirements specific to the BWRX-300 design as a deeply embedded Small Modular Reactor (SMR).

Sampling was conducted in conjunction with in-situ SPTs performed with calibrated automatic hammers and data from laboratory testing of soil and rock samples are outlined in Section 4 and Section 5 of the 2022 Phase-1 investigations report (Reference 2.7-39).

The methodology for the in-situ and laboratory test are outlined in Volume 1 – Factual Geotechnical Data Report of NK054-REP-01210-00175 (Reference 2.7-39). The types of tests conducted include:

- Soil chemical analysis for the following constituents:
  - Soil pH of soil for corrosion
  - Water-soluble sulfate
  - Chloride in water
  - Sulfate in water for concrete
- Soil resistivity analysis
- Vane shear tests (cohesive soils)
- Pressuremeter testing (soil), dilatometer testing (rock), piezocone soundings (soil), soil resistivity, packer testing (rock), over-coring stress testing (rock)
- Uniaxial Compression Stress (UCS) testing (rock)
- Triaxial compression stress testing (soil)
- Constant stress direct shear creep testing on rock joints
- Swell testing (rock)

#### **2.7.3.2 Subsurface Stratigraphic Profile**

##### **2.7.3.2.1 Profiles for the DNNP Site (2022)**

The stratigraphy for the DNNP site soil and bedrock units listed in Table 2.7-1 is developed based on the work performed in the 2022 Geotechnical Investigations NK054-REP-01210-00175 (Reference 2.7-39).

Details of the in-situ stratigraphic layers average and range of thicknesses are provided in Table 2.7-2 for the soil units and in Table 2.7-3 for the rock units. The interpreted soil and rock stratigraphy are presented in east-west oriented and north-south oriented cross-sections in Figure 2.7.3.2-1 and Figure 2.7.3.2-2, respectively. Further details for subsurface soil and bedrock profiles are described in the following paragraphs.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Unit 1 – Topsoil/Fill

The uppermost layer is topsoil and/or fill consisting of either poorly graded sand with gravel or sandy lean clay. Unit 1 was encountered at ground surface at all boreholes drilled for the 2022 Phase 1 Geotechnical Report NK054-REP-01210-00175 (Reference 2.7-39). This layer has an average thickness of 1.59 m ranging from 0.53 m in borehole 27 to 3.53 m in borehole 67.

Units 2a and 2b – Surficial Glaciolacustrine Deposits

Two glaciolacustrine deposits are found below the upper topsoil and fill. The upper deposits (Unit 2a) are encountered below the topsoil/fill layer. Unit 2a consists of silt, clay, fine to coarse sand and trace to some subrounded to subangular gravel. The lower deposits (Unit 2b) consist of silt with some clay, fine to coarse sand and subrounded to angular, fine to coarse gravel.

In some boreholes, Units 2a and 2b were observed to be interlayered. The combined thickness of Units 2a and 2b averages 1.74 m, and is ranging from zero in borehole 6, to 6.1 m in borehole 5.

Unit 3 - Upper Till

Deposits of silty sand with gravel to sandy lean clay with gravel are encountered below Units 2a and 2b. Unit 3 is described as a till layer generally consisting of a heterogeneous mixture of dense to very dense gravel, boulders, and cobbles in a matrix of silty sand. This deposit consists of silt, clay, fine to coarse sand and subrounded to subangular to angular, fine to coarse gravel. Unit 3 ranges in thickness from zero in borehole 4 to 13.49 m in borehole 17, with an average thickness of 7.35 m.

Units 4a and 4b – Intermediate Glaciolacustrine Deposits

Two distinct glaciolacustrine deposits are founded below Unit 3. The upper deposit, Unit 4a consists of silt, clay, fine to coarse sand and subrounded to angular, fine to coarse gravel. Boulders and cobbles are also present within Unit 4a. Below Unit 4a is Unit 4b which consists of silt, clay, fine to coarse sand and trace to some subrounded to angular gravel.

In some boreholes, Units 4a and 4b were observed to be interlayered. The combined thickness of units 4a and 4b averages 11.3 m, and ranges between zero in borehole 11SB to 17.7 m in borehole 27.

Unit 5 – Lower Till

Below the intermediate glaciolacustrine deposits (Units 4a and 4b), a deposit of very dense silt and sand to hard lean clay (Unit 5) is encountered. Unit 5 is described as a lower till layer generally consisting of a heterogeneous mixture of gravel, boulder, and cobbles in a matrix of silt sand and silty clay. This deposit consists of silt, clay, fine to coarse sand, and subrounded to angular, fine to coarse gravel. It has an average thickness of 3.57 m, ranging from zero in borehole 16 to 6.63 m in borehole 15.

Unit 6a – Blue Mountain Formation Bedrock

The top of the bedrock is at an average elevation of 64.20 CGD, ranging from 62.72 m CGD in borehole 6 to 65.80 m CGD in borehole 70.

Below Unit 5, is a moderately weathered to fresh, very thinly to medium bedded, fine grained, faintly porous, slightly to moderately reactive to hydrogen chloride, weak to strong shale with thin, limestone interbeds. Unit 6a has an average thickness of 2.98 m, ranging from 1.38 m in borehole 73 to 5.87 m in borehole 30.

**Unit 6b – Lindsay Formation Bedrock**

Below Unit 6a is a slightly weathered to fresh, very thinly to medium bedded, fine to medium grained, faintly porous, slightly to moderately reactive to hydrogen chloride, weak to medium strong to very strong limestone with shale interbeds, Unit 6b has an average thickness of 61.36 m, ranging from 60.61 m in borehole 16 to 61.93 m in borehole 65.

**Unit 6c – Verulam Formation Bedrock**

Below Unit 6b is a fresh very thinly to medium bedded, grey, fine to medium grained, faintly porous, moderately reactive to hydrogen chloride, medium strong to very strong limestone with shale interbeds. Full thickness of Unit 6c was not tested.

**Table 2.7-1: Stratigraphic Units for the DNNP Site**

Unit No.	Description
1	Topsoil / Fill
2a	Surficial Glaciolacustrine Deposits – Sandy Lean Clay to Lean Clay
2b	Surficial Glaciolacustrine Deposits – Silty Clayey Sand to Silty Sand/Sandy Silt
3	Upper Till
4a	Intermediate Glaciolacustrine Deposits – Silty Sand to Sandy Silt
4b	Intermediate Glaciolacustrine Deposits – Sandy Lean Clay to Lean Clay
5	Lower Till
6a	Blue Mountain Formation Bedrock
6b	Lindsay Formation Bedrock
6c	Verulam Formation Bedrock

Notes:

1. Includes borings BH 9, BH 10, BH 11, BH 11S, BH 11 SB, BH 12, BH 14 (Reference 2.7-39)

2. Includes borings BH 2, BH 4, BH 5, BH 9, BH 10, BH 11, BH 11S, BH 11SB, BH 12, BH 13, BH 14, BH 18, BH 19, BH 67, BH 68, BH 71, BH 73, BH 78 (Reference 2.7-39)

3. Includes borings BH 2, BH 4, BH 5, BH 6, BH 8, BH 7, BH 9, BH 10, BH 11, BH 11S, BH 11SB, BH 12, BH 13, BH 14, BH 15, BH 16, BH 17, BH 18, BH 19, BH 20, BH 66, BH 66S, BH 66SB, BH 67, BH 68, BH 71, BH 73, BH 77, BH 78 (Reference 2.7-39)

4. All boreholes considered in the study area in (Reference 2.7-39)

**Table 2.7-3: Rock Units Stratigraphy (Reference 2.7-39)**

	Layer Thickness or Depth (m)	
	Average	Range
<b>Elevation</b> Top of Bedrock	64.20 (CGD)	62.72 (BH 6) - 65.80 (BH 70)
<b>Thickness</b> Unit 6a - Blue Mountain Formation	2.98	1.38 (BH 73) - 5.87 (BH 30)
<b>Thickness</b> Unit 6b - Lindsay Formation	61.36	60.61 (BH 16) - 61.93 (BH 65)

Notes:

1. Full thickness of the Verulam Formation (Unit 6c) was not tested (Reference 2.7-39)
2. Lindsay formation thickness determined from small sample ~ (15%) of boreholes which extended fully through the formation (Reference 2.7-39)

#### **2.7.3.2.2 Planned As-Built Soil Profile**

Stratigraphic Units 1 and 2 are generally loose, have liquefaction potential (Subsection 2.7.4.7.6), and are not suitable for supporting the heavy foundations of the power block buildings. As a result, during site development, these soil layers will be excavated and replaced with compacted engineered fill.

Consequently, the as-built conditions at the site after construction of the BWRX-300 facility are anticipated to include compacted engineered fill from about elevation ranging between 80 m to 82 m CGD to the final grade at elevation 88 m CGD. The excavated soil from this site may be used as compacted engineered fill material if it meets the engineered fill gradation requirements outlined in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

#### **2.7.3.2.3 Bedrock Profile**

The bedrock profile was developed based on readily available top-of-rock information from boreholes drilled for the geotechnical study in the 2022 NK054-REP-01210-00175 (Reference 2.7-39). Data between boreholes have been interpolated.

The top of the bedrock surface undulates relatively locally and slopes gently to the south from an elevation of 67 m CGD near the northern extent of the site to an elevation of 64 m CGD. This bedrock surface is consistent with the mapped sub-horizontal dip of the Paleozoic sequence observed within the vicinity of the project area.

Subsurface rock conditions may vary between and beyond the borehole/drillhole locations. The interpreted stratigraphy is therefore a simplification of the subsurface bedrock contacts. Variations in the stratigraphic boundaries between boreholes/drillholes will exist and are to be expected. Table 2.7-3 presents the top of bedrock elevation and bedrock thicknesses.

The BWRX-300 deeply embedded RB is anticipated to extend through the Blue Mountain Formation (Unit 6a) and be founded in the Lindsay Formation (Unit 6b) at 52.93 m CGD. The top of the Blue Mountain Formation near the BWRX-300 RB is anticipated to be at about 64 m CGD based on the depth to bedrock at BH 10, BH11 and BH 12 (refer to Figure 2.7.3.1-6), as explained

in the 2022 Power Block geotechnical investigations NK054-REP-01210-00175 (Reference 2.7-39).

#### **2.7.3.2.4 Groundwater Conditions**

Based on the information provided in the 2022 DNNP Phase 1 Geotechnical Investigation Report NK054-REP-01210-00175 (Reference 2.7-39), the following three groundwater flow patterns are identified:

- The Unit 3 water table (shallow groundwater), shown in Figure 2.7.3.2-3
- Unit 4a groundwater flow in the integrated deposits, shown in Figure 2.7.3.2-4
- Unit 5 groundwater in the interglacial deposits located above the bedrock, shown in Figure 2.7.3.2-5
- Units 6a-6b groundwater in bedrock, shown in Figure 2.7.3.2-6

The groundwater flow interpretations in these figures (Figures 2.7.3.2-3 to 2.7.3.2-6) are based on a monitoring well-network with only a few months of monitoring data. The actual long-term interpretation may change. The contours are based on data from the new monitoring wells installed within the investigation area, which are limited in aerial extent, and have not been considered with contemporary groundwater elevation data from the pre-existing monitoring well-network at the site.

As shown on the figures, the groundwater flow direction in the upper and lower till (Units 3 and 5, respectively) is inferred to be toward the southwest and, in the intermediate glaciolacustrine deposits (Unit 4a) and shallow bedrock (Units 6a and 6b), to be toward the south-southeast.

Regional groundwater flow and flow at the DNNP site generally follows topography from higher elevations in the north towards the south, per the 2009 DNNP Geological and Hydrogeological Environment NK054-REP-07730-00005 (Reference 2.7-30). In general, this flow is driven by recharge from rainfall and snowmelt infiltration across the area and at higher elevations along the Oak Ridges Moraine north of the DNNP site with discharge, ultimately, to Lake Ontario to the south. The shallow groundwater system at the DNNP site deviates from this flow pattern near surface water conveyances and local recharge areas. Interpreted regional groundwater flow patterns documented in the 2009 report NK054-REP-01210-00011 (Reference 2.7-1) are shown in Figures 2.7.3.2-7, 2.7.3.2-8 and 2.7.3.2-9 for shallow water table, interglacial deposits, and shallow bedrock groundwater, respectively.

The hydro-stratigraphic units at the DNNP site follow the soil and geologic units. The upper till (Unit 3) forms an aquitard or confining layer at the site which restricts downward groundwater flow from the upper fill and glaciolacustrine materials. The interglacial deposits (Units 4a-4b) are the most significant hydrogeologic unit at the site since they extend across the site and to the recharge areas north of the site, as described in the 2009 NK054-REP-07730-00005 (Reference 2.7-30). There may be significant groundwater flow in the interglacial deposits due to the higher gradient and higher permeability of the materials. The lower till (Unit 5) beneath the interglacial deposits is also considered an aquitard with low permeability. Although flow in the upper till is downward due to under-draining by the interglacial deposits, there may be an upward component of flow through the lower till in some areas from the underlying upper bedrock aquifer, per the 2009 NK054-REP-07730-00005 (Reference 2.7-30).

The upper bedrock is likely fractured and weathered with higher secondary permeability and transmissivity compared to the intact bedrock. Flow in the upper bedrock is expected to be enhanced in areas where the lower till is absent, and the upper bedrock is in direct contact with the more permeable interglacial deposits. The lower bedrock at the DNNP site generally has low

permeability and does transmit much groundwater. The groundwater conditions in the deeper bedrock formations below the Lindsay Formation have not been considered for study.

### **2.7.3.3 Evaluation of Geological Hazards on DNNP Structures**

Subsection 2.7.3.3 provides an assessment of geological hazards that could impact the DNNP structures.

#### **2.7.3.3.1 Karst Cavities**

No evidence of significant karst cavities was encountered in the 2022 geotechnical boreholes (Reference 2.7-39). Some zones of lost core were encountered in the boreholes generally within 40 m of the ground surface and ranging from 5 cm to 66 cm in height, but no noticeable drop in the drilling rods was noted and therefore these are thought to be associated with zones of weathered and fragmented rock that had been washed out by the core drilling.

In addition, the previous geophysical reports associated with this site indicate the absence of anomalies in the rock that could indicate the presence of depressions or voids that may be indicative of large karst or faults. There is good seismic coverage with nine seismic refraction lines being executed at the site.

Review of the previous surface geophysical data as well as the numerous boreholes drilled in 2021 to 2022 for the power block, and the associated data (Reference 2.7-39) confirm the absence of karst features at this site.

#### **2.7.3.3.2 Ground Frost**

The conventional approach for protection of building foundations against frost action is to locate base of foundations and/or the base of grade beams (supported on deep foundation) at a depth at least equal to the depth of frost penetration. A minimum frost penetration depth of 1.3 m is therefore recommended, in accordance with OPSD 3090.101 (Foundation Frost Penetration Depths for Southern Ontario), as per the 2022 Geotechnical Investigation Report NK054-REP-01210-00175 (Reference 2.7-39). Partial or complete frost protection may also be achieved by using rigid polystyrene insulation.

Frost heaving may occur in fine grained soils where ice lenses occur when moisture is drawn to freezing horizons. Based on the existing site subsurface conditions, shallow silty fine sand and silt deposits below surficial granular fill are generally expected to be moderately to highly frost susceptible to heaving under freezing conditions. Therefore, adequate frost cover of 1.3 m depth is required for all foundations exposed to frost conditions.

#### **2.7.3.3.3 Bearing Failure (Collapse)**

The 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38) evaluated the bearing capacities for the RB foundation and resulting bearing capacities for the Turbine Building (TB), Control Building (CB), Radwaste Building (RWB), and Reactor Auxiliary Bay foundations surrounding the deeply embedded RB using data reported in the 2022 geotechnical site investigations (Reference 2.7-39). The anticipated bearing pressure and bearing capacity for each building in the power block is summarized and discussed in Subsection 2.7.5.1.

#### **2.7.3.3.4 Stability of Foundation**

The 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38) provides the anticipated maximum uniform and differential settlements of the RB, TB, CB, RWB, and Reactor Auxiliary Bay foundations. The anticipated bearing pressure and associated settlements are summarized and discussed in Subsection 2.7.5.1.

#### ***2.7.3.3.5 Stability Of Subgrade Surrounding the Reactor Building***

A stability analysis was performed following the guidelines of NEDO-33914-A (Reference 2.7-27), Section 4.0, using the finite element software PLAXIS (Bentley) to perform advanced non-linear Soil-Structure Interaction (SSI) numerical modeling. In addition to the stability analysis, the potential for instability of the potentially unstable blocks or wedges surrounding the RB deep excavation were performed using UnWedge (RocScience), a 3D stability analysis and visualization program. The stability analysis is discussed further in Subsection 2.7.5.1 and all the analyses are detailed in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

#### ***2.7.3.3.6 Transitional Ground Heave and Settlement***

As part of site grading and development, there will be unloading and transitional ground heave resulting from excavation of the upper soft-to-loose soil layers of Units 1 and 2 at the site. Additionally, some of the heave will be offset by settlement, which will occur on completion of backfilling. Depending on the net change in the overall effective stress profile, net ground heave is expected to occur due to reduction in the finished ground level compared to existing levels.

During the process of unloading and re-loading, stratigraphic Units 3, 4 and 5 are expected to react quickly to the changes in the ground stresses with minimal lag. Hence, long-term consolidation or heave is not expected to occur. Rather only transitional elastic rebound, and compression are expected to occur, as documented in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

It is anticipated that there will be about 10 mm of heave from offloading due to excavation and some nominal heave/settlement after the completion of fill placement. There may be some ongoing creep settlement from the fill placement; however, ground movements will be small and the impact on structures founded on or in the overburden soils will be insignificant, as described in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

#### ***2.7.3.3.7 Stability of Natural Slopes***

The structures located within the power block are level at finished grade and over 100 m away from the shoreline. The structures are expected to be founded on or in either engineered fill, very dense native Unit 3 soil or deeply embedded in strong to very strong bedrock. Therefore, slope instability will not be threat to these power block structures. However, the natural shoreline is prone to erosion, especially the steep bluffs to the east of the power block area. Erosion of the shoreline has the potential to pose a hazard eventually, through gradual reduction of the ground pressure, if allowed to progress over long periods. This is discussed in the 2022 NK054-REP-03500.8-00002 Darlington New Nuclear Project - Seismically-Induced Soil Liquefaction Assessment (Reference: 2.7-42). Prevention of erosion is to be achieved through the establishment of engineered shoreline protection. The steep bluffs as a slope do not pose a hazard to the first BWRX-300 unit planned, and design of subsequent units will mitigate the hazard as required.

#### ***2.7.3.3.8 Stability of Cut and Fill Slopes***

The existing ground to the east of the existing DNGS will be excavated to form a large level area for the DNNP and its associated structures. For preliminary design purposes, cut slopes into the competent interglacial/till deposits will be at a general inclination of 1V:3H (18.4°). The excavated soils will be partially stored at the north-east part of the site. The fill slopes will be designed to ensure stability.

#### **2.7.3.3.9 *Stability of Dikes and Dams***

No dams are currently present or planned for the DNNP. No dikes are currently present or planned on DNNP, and lake infilling is no longer planned for the project.

#### **2.7.4 Seismology Characteristics**

Subsection 2.7.4 summarizes findings of past seismic hazard investigations as well as of the 2022 site-specific PSHA (Reference 2.7-41) that were performed for the DNNP and DNGS site.

Subsection 2.7.4 includes:

- Subsection 2.7.4.1 - provides background seismological information and data collected since 1997
- Subsection 2.7.4.2 - describes the regional geological structure and tectonic history of the Darlington Nuclear site
- Subsection 2.7.4.3 - presents information on the seismicity of the region surrounding the site and the development of earthquake catalogue
- Subsection 2.7.4.4 - describes the seismic hazard model containing regional and local sources
- Subsection 2.7.4.5 - describes aspects related to ground motion characterization
- Subsection 2.7.4.6 - discusses the PSHA methodology and the results for the DNNP site
- Subsection 2.7.4.7 - describes protentional geological and seismological aspects at the DNNP site

##### **2.7.4.1 Background and Data Collection**

In 2009, the Darlington Nuclear site was evaluated for suitability for the DNNP. A PSHA was performed, per the 2009 NK054-REP-01210-00014 (Reference 2.7-4) in accordance with:

- CNSC Regulatory Document RD-346 Site Evaluation for New Nuclear Power Plants (Reference 2.7-5), which is superseded by CNSC's REGDOC 1.1.1 Site Evaluation and Site Preparation for New Reactor Facilities (Reference 2.7-6)
- IAEA NS-R-3 (Reference 2.7-7), which is superseded by SSR-1 (Reference 2.7-8)

The 2009 PSHA (Reference 2.7-4) details assembly of the geological, geophysical, and seismological data collection for the region, near region and vicinity of the DNNP site. The approach adopted utilized the 1997 study (Reference 2.7-3) as a starting point. The database assembled for that study was updated, and the effects of the updates of regulatory requirements in CNSC RD-346 (Reference 2.7-5) and IAEA NS-R-3 (Reference 2.7-7) were evaluated, and changes were incorporated. The 2009 PSHA was thereafter revised three times: in 2011 in NK38-REP-03611-10041 R000 (Reference 2.7-9), in compliance with CSA Standard N289.2 (Reference 2.7-31); in 2019 in NK38-REP-03611-10041 R002 (Reference 2.7-10), and in 2021 in NK38-REP-03611-10041 R003 (Reference 2.7-11), with minor changes to address CNSC comments not previously incorporated. The PSHA updates in both the 2019 NK38-REP-03611-10041 R002 (Reference 2.7-10) and the 2021 NK38-REP-03611-10041 R003 (Reference 2.7-11) include:

- Updates to the Earthquake Catalogue
- Updates to the Maximum Magnitude Assessment
- Updates to Earthquake Occurrence Rates

- Application of the Next Generation Attenuation -East Ground Motion Model

In 2022, a DNNP site-specific PSHA (Reference 2.7-41) was conducted in accordance with the requirements of CNSC REGDOC 2.5.2 and CSA N289 series, as well as with the BWRX-300 SMR specific design requirements listed in NEDO 33914-A (Reference 2.7-27). In addition, the 2022 PSHA study (Reference 2.7-41) used the 2001 NUREG/CR-6728 (Reference 2.7-20) to develop site-specific ground motions considering local site conditions.

## **2.7.4.2 Regional Geological Structure and Tectonic History**

### ***2.7.4.2.1 Regional Geological Structure Stratigraphy***

The Darlington Nuclear site lies within the western Lake Ontario region in the tectonically stable interior of the North American continent, which is characterized by low rates of historical seismicity, as described in the 1994 EPRI TR-102261-V1 (Reference 2.7-12). The region is underlain by middle Proterozoic (about 900 to 1600 million years ago) Grenville basement rock and overlying Paleozoic (about 250 to 570 million years ago) shallow-water sedimentary strata.

The Grenville Province formed in response to several phases of compression and metamorphism. The “Grenville Front” and “Grenville Front Tectonic zone”, shown in Figure 2.7.4.2-1, is the contact between the Grenville Province to the east and the continental Eastern Granite-Rhyolite provinces to the west. Rocks of the Central Gneiss Belt are between the “Grenville Front Tectonic Zone” and the Central Metasedimentary Belt Boundary Zone. The Central Metasedimentary Belt Boundary Zone underlies the western end of Lake Ontario, and the Central Metasedimentary Belt underlies the rest of Lake Ontario and the site study region. The Central Metasedimentary Belt is an intensely faulted and folded zone formed less than 1,300 million years ago. The southeastern portion of the Central Metasedimentary Belt consists of slightly younger rock. The Grenville orogeny (mountain-building episode) is widely attributed to a continental collision; however, deformation occurred in several episodes of extension and compression.

The Grenville Province’s crustal structure is characterized by north-northeast-striking, relatively shallow east-southeast-dipping ductile thrust faults that developed at mid- to lower-crustal depths during the middle Proterozoic Grenville orogeny. Prominent north-northeast-trending geophysical anomalies associated with exposed Grenville structures extend southward beyond the Canadian Shield and beneath the unconformable lower Paleozoic cover rocks. Regional geologic maps (e.g., Ontario Geological Survey, 1991) indicate that the overlying Paleozoic rocks are, with few exceptions, relatively flat-lying and laterally continuous, indicating that no large-scale, major faulting has occurred in the region since they were deposited.

The notable exception to the lack of regional-scale faulting in southern Ontario and Quebec occurs within the St. Lawrence rift system, as described in the 1966 Canadian Journal of Earth Sciences, Volume 3, No. 5 (Reference 2.7-13), which is a remnant of the late Proterozoic/early Paleozoic Iapetus passive margin, as described in the 1996 published article of R.L. Wheeler (Reference 2.7-14). The St. Lawrence rift system comprises abundant large-scale normal faults displacing lower Paleozoic strata and underlying Grenville basement on the order of many hundreds of meters along the Ottawa, Champlain, St. Lawrence, and Saguenay River valleys (Reference 2.7-13). These extensional faults generally cut discordantly across Grenville-aged structures instead of reactivating them. Mesoscopic-scale faulting of the lower Paleozoic strata, with fault displacements ranging from less than a meter to several tens of meters, has been recognized locally throughout much of the Lake Ontario region outside of the St. Lawrence rift system. The St. Lawrence rift system is associated with zones of elevated and persistent seismicity, per Slemmons, D.B., et al. in 1991 (Reference 2.7-15).

Worldwide, the seismic potential of a stable continental region varies according to the degree of crustal extension that it experienced in the geologic past, and to a lesser extent, the age of the

crust, per the 1994 EPRI TR-102261-V1 (Reference 2.7-12). Three types of crust are identified in eastern North America, per the 1994 EPRI TR-102261-V1 (Reference 2.7-12):

- Unrifted - the craton and the Appalachian fold belt
- Failed intracontinental rifts—the Ottawa and Saguenay aulacogens and the Reelfoot rift complex
- Rifted passive continental margin—the Atlantic passive margin produced by the present opening of the Atlantic Ocean in the late Mesozoic, and a relic passive margin produced by lapetan rifting in the late Proterozoic/early Paleozoic

The north-northeast-trending faults along the Champlain and St. Lawrence River valleys, once attributed to a two-sided, failed intracontinental rift, are now recognized as part of the southeast-facing lapetan margin, per R. L. Wheeler, in 1996 (Reference 2.7-14). The present-day Atlantic passive margin comprises transitional crust (continental-oceanic) and the extended and faulted inboard continental shelf.

Evidence of lapetan rifting of the craton adjacent to the northern Appalachians is recorded within the St. Lawrence rift system (Reference 2.7-13) in the form of rift-related extensional structures, sediments, and magmatic/volcanic products that developed along the ancient continental margin. The rift structures include zones of echelon faults parallel to the ancient margin, possible fracture zones transverse to the ancient margin, and two well-defined aulacogens (failed rifts)—the Ottawa and Saguenay grabens.

The Appalachian orogen lies approximately 400 km east of the Darlington Nuclear site. Northern Appalachian orogenic events occurred from Ordovician to Permian time and consisted of several distinct tectonic episodes. As discussed in the 2022 DNNP PSHA NK054-REP-03500.8-00001 (Reference 2.7-41), the key structural elements that mark the boundaries of the various crustal provinces (e.g., the western limit of Mesozoic extensional structures) are used to define regional seismic source zones that are characterized by similar crustal properties (for an example of one boundary interpretation, refer to Figure 2.7.4.2-2).

#### **2.7.4.2.2 *Neotectonics Setting***

The geologically most recent evidence for major tectonic activity in the region is Alleghanian (late Permian) thrust faults formed in the Appalachian foreland basin and late Triassic to late Jurassic normal faults along the Atlantic margin related to continental rifting and the subsequent opening of the Atlantic Ocean, per the 2009 NK054-REP-01210-00014 DNNP PSHA (Reference 2.7-4). However, historical seismicity along the St. Lawrence rift system, in the Charleston, South Carolina, area, and in other concentrated zones; local geologic evidence of Cenozoic reactivation of faults; evidence of seismically-induced liquefaction in susceptible sands and silts; and geologic and geodetic data indicative of regional and local crustal deformation suggest continuing neotectonic activity, albeit at much lower rates than during the last episode of major tectonic deformation.

Slemmons, D.B., et al. in 1991 (Reference 2.7-15) have reported that most large historical and instrumental earthquakes in eastern Canada have occurred near Paleozoic or younger rift zones. This is similar to stable continental region earthquakes worldwide, as described in the 1994 EPRI TR-102261-V1 (Reference 2.7-12). The early Paleozoic St. Lawrence rift system, which is delineated by a persistent pattern of seismicity, is the postulated source of numerous large, historical earthquakes in southeastern Canada, per Slemmons, D.B., et al. in 1991 (Reference 2.7-15). Seismicity along this rift system appears to be concentrated in a number of well-defined clusters, including the Ottawa River, Charlevoix, and lower St. Lawrence River seismic zones, which are all separated by relatively aseismic regions.

Equivocal evidence for neotectonism, per Thomas, R.L., et al. in 1993 (Reference 2.7-16), has been found in the Lake Ontario region, and there are difficulties in distinguishing between deformation related to glacial processes and that related to deep-seated tectonic processes.

East-northeast/west-southwest-trending lakebed features in the Rochester basin of Lake Ontario and the Hamilton-Presqu'île fault zone, along with some of the features observed in western Lake Ontario, have been proposed by Thomas, R.L., et al. in 1993 (Reference 2.7-16), as neotectonic evidence for the southwest continuation of the St. Lawrence rift system through Lakes Ontario and Erie.

The postulated northwestern boundary of the late Proterozoic/early Paleozoic lapetan rifted margin tectonic province lies approximately 80 km east of the site, per Wheeler, R.L. in 1995 (Reference 2.7-17). There also is deep seismic evidence suggesting that the western boundary of the lapetan margin may lie farther to the west, along the Central Metasedimentary Belt Boundary Zone of the Grenville province as described by Milkereit, B., et al. in 1992 (Reference 2.7-18). These alternative boundaries are considered in defining regional seismic source zones (for an example of one boundary interpretation, refer to Figure 2.7.4.2-2).

The rate of historical seismic activity in the Grenville Province west of the lapetan rifted margin is low and appears typical of stable cratonic crust, per the 1994 EPRI TR-102261-V1 (Reference 2.7-12). In general, seismic activity and the geologic conditions most associated with earthquake activity in the stable continental region of Central and Eastern North America increase towards the east, away from the Precambrian central craton and towards the rifted passive continental margin.

#### **2.7.4.3 Seismicity**

Characterization of the seismicity of the region surrounding the DNNP site forms an essential part of the assessment of the seismic hazard. The primary means of characterization of seismicity is the use of the earthquake catalogue to assess earthquake occurrence rates and maximum magnitudes for earthquake sources.

In the Darlington Nuclear site PSHA studies, presented in the 2019 NK38-REP-03611-10041 R002 (Reference 2.7-10) and the 2021 NK38-REP-03611-10041 R003 (Reference 2.7-11), the 2012 NUREG-2115 (Reference 2.7-21) earthquake catalogue was updated to include independent earthquakes from the end of 2008 through 20 May 2019. The earthquake catalogue was again updated in the 2022 NK054-REP-03500.8-00001 DNNP PSHA (Reference 2.7-41) to extend the duration of the catalogue to the end of December 2021 using the:

1. National Earthquake Database of Canada
2. U.S. Geological Survey earthquake catalogue
3. Weston Observatory earthquake catalogue

The 2012 NUREG-2115 (Reference 2.7-21) contains data collected through mid-2009. Expected moment magnitudes were determined for the added earthquakes as described in 2022 PSHA NK054-REP-03500.8-00001 (Reference 2.7-41).

Figure 2.7.4.3-1 depicts the spatial distribution of earthquakes in the updated de-clustered catalogue exclusively in the time window between 2008 and December 31, 2021, as described in the 2022 DNNP PSHA NK054-REP-03500.8-00001 (Reference-2.7-41).

The maximum magnitude ( $M_{\max}$ ) distributions for the distributed seismicity sources (seismicity source zones) were obtained using the project earthquake catalogue and the methodology developed in NUREG-2115 (Reference 2.7-21). The project earthquake catalogue was also used to obtain updated earthquake recurrence assessments for the seismic sources

#### **2.7.4.4 Seismic Source Characterization**

The seismic source zonation model used in the 2022 DNNP PSHA NK54-REP-03500.8-00001 (Reference 2.7-41) is that presented in the 2021 Darlington PSHA NK38-REP-03611-10041 R003 (Reference 2.7-11) with the exception of updates to the 2020 Geological Survey of Canada historical seismicity zonation (H model) based on Adams, et al. (Reference 2.7-19). The seismic source characterization model comprises regions of distributed seismicity and local sources representing identified geological/geophysical features. An overview of the information in the 2022 DNNP PSHA (Reference 2.7-41) with respect to the regional and local seismic sources is summarized in the following paragraphs.

##### ***2.7.4.4.1 Regional Source Zones***

Three alternative approaches to regional seismic zonation are used to represent the sources of distributed seismicity throughout the study region. Figure 2.7.4.4-1 presents the logic tree structure used in the 2022 DNNP PSHA (Reference 2.7-41) as well as previous PSHA studies in the Darlington Nuclear site area, representing the epistemic uncertainty in regional seismic source zonation. The three alternative approaches are used to define the source zonation for distributed seismicity sources as follows:

1. The favored approach (weight 0.8) was to define source zones on the basis of seismotectonic evaluations. Epistemic uncertainty in defining the boundaries between these seismotectonic sources led to the set of alternative zonations.
2. An alternative approach (weight 0.1) was to use the historical seismicity zonation developed by the Geological Survey of Canada as part of the Canadian National Earthquakes Hazards Program (Adams, J., et al., 2019) (Reference 2.7-19) These regional Seismicity Zones are shown in Figure 2.7.4.4-2.
3. The third alternative was to use a zoneless model (weight of 0.1) in which seismicity parameters were defined for individual cells comprising 1 degree longitude by 1 degree latitude within the study region shown in Figure 2.7.4.4-3.

##### ***2.7.4.4.2 Local Source Zones***

There are six potential local seismic source zones that are defined based on their identified geological/geophysical features, per the 2022 DNNP PSHA NK054-REP-03500.8-00001 (Reference 2.7-41). These six source zones are: Clarendon-Linden Fault System, Georgian Bay Linear Zone, Hamilton-Presqu'île Fault, Mississauga Magnetic Domain, Niagara-Pickering Linear Zone, and Wilson-Port Hope Magnetic Lineament. These sources act as potential concentrators of seismic activity and are critically assessed for their seismogenic potential. The locations of these sources have been extracted from the 2022 DNNP PSHA (Reference 2.7-41) and are depicted in Figure 2.7.4.4-4.

#### **2.7.4.5 Ground Motion Characterization**

Ground motion models are needed to calculate the effects at the site of earthquakes occurring in the characterized seismic sources. Two aspects are considered as follows:

1. Estimation of the amplitude of ground motions as a function of earthquake size and the source-to-site distance that is provided by ground motion models
2. Assessment of the effect of the local site conditions on the generic hard rock ground motions by results of site response analyses performed in a manner that achieves hazard-consistent ground motions at the site surface

In active tectonic environments, ground motion models are often developed from the analysis of recorded strong motion data. The seismic hazard was computed using the Pacific Earthquake Engineering Research Center model documented in the 2018 PEER Report No. 2018/08 by Goulet, C., et al. (Reference 2.7-22). The model is the most comprehensive ground motion model available for Central and Eastern United States (CEUS) Seismic Source Characterization.

#### **2.7.4.6 PSHA Results for the DNNP Site**

The 2022 PSHA study in NK054-REP-03500.8-00001 (Reference 2.7-41) presents the seismic hazard characterization for the deeply embedded BWRX-300 RB at the DNNP site. The study meets the requirements and follows the guidance of CNSC REGDOC-2.5.2 (Reference 2.7-32), CSA N289 Series (Reference 2.7-31, 2.7-32, and 2.7-33), and the Licensing Topical Report NEDO-33914-A (Reference 2.7-27).

The PSHA presented in the 1994 EPRI TR-102261-V1 (Reference 2.7-12) and the 2021 Darlington Risk Assessment (Reference 2.7-11), developed Uniform Hazard Response Spectra (UHRS) for rock outcropping motions at the anticipated level of the foundation of the DNGS plant at the top of the Paleozoic bedrock strata. The DNGS foundation level is not at the same elevation as the foundation of the BWRX-300 deeply embedded RB.

The seismic hazard model used in the 2022 DNNP PSHA (Reference 2.7-41) is based on the seismic hazard model employed in the 2021 Darlington Nuclear site PSHA (Reference 2.7-11) and is updated using new data and information. Differences between the two seismic hazard models, overall, are minor and include:

- Recalculated earthquake recurrence parameters, such as rates, maximum magnitude ( $M_{\max}$ ), and spatial distributions, using the updated earthquake catalogue
- Slight increase in the probability that the Wilson-Port Hope local source is associated with small magnitude earthquake, resulting from additional earthquakes being recorded in the region (this produces a minor increase in the overall probability of activity for this source)
- The source zone geometry for zonation based on historical seismicity is updated to be consistent with the 6<sup>th</sup> Generation of seismic hazard maps of Canada, H2 model for source zonation, per Adams, J., et al. (Reference 2.7-19).

The approach to site-specific hazard differs between the 2022 DNNP PSHA NK054-REP-03500.8-00001 (Reference 2.7-41) and the 2021 Darlington site PSHA NK38-REP-03611-10041 (Reference 2.7-11). In the 2021 Darlington site PSHA (Reference 2.7-11) site-specific hazard results were obtained solely for the reactor basemat elevation for the existing DNGS using the two options for application of the EPRI 2006 Cumulative Absolute Velocity (CAV) model specified in USNRC (2012a) (Reference 2.7-35):

- Option 1 specified computing the hazard integrating from a minimum magnitude of M 5 (M 4 was used) but only applying the CAV filter to the contributions from magnitudes less than M 5.5
- Option 2 specified computing the hazard integrating from a minimum magnitude of M 5 without applying the CAV filter. Deterministic site amplification functions from reference rock were computed using a site profile truncated at the reactor foundation elevation.

Epistemic uncertainty in site amplification scaling reference rock motions to foundation level motions was incorporated into the CAV calculations but aleatory variability in amplification was not included. Vertical motions were obtained by applying mean V/H ratios to the horizontal UHRS.

#### **2.7.4.6.1 Site Response Analysis**

Site-specific hazard in the 2022 DNNP PSHA (Reference 2.7-41) is computed only using USNRC (2012a) (Reference 2.7-35) Option 2, integration of hazard from M 5 without applying the EPRI (2006) (Reference 2.7-36) CAV filter. Site amplification was computed using NUREG/CR-6728 Approach 3, per McGuire et al., in 2001 (Reference 2.7-20). This approach develops the SRA in which probabilistic site amplification functions defining both median amplification and aleatory variability in amplification were convolved with the reference rock hazard to produce site-specific hazard at the target elevations. Epistemic uncertainty in site amplification was modeled.

The site response model was extended to finish grade to represent anticipated as-built site conditions with reactor basemat elevation for the planned BWRX-300 is located approximately 12 m below the top of rock at the DNNP site while the reactor foundation levels at the existing DNGS site are at or near top of rock. Minimum epistemic uncertainty in site amplification was applied in both studies, with the updated value used for the DNNP study being 50 percent larger than the value used in the 2021 NK38-REP-03611-10041 (Reference 2.7-11). Seismic hazard results for vertical motions were computed by convolving probabilistic V/H ratios with the horizontal hazard rather than applying mean V/H ratios.

Per guidance of NEDO 33914-A (Reference 2.7-27), Section 5.2.2, the site-specific hazard is defined for the following three horizons at:

- The RB foundation bottom elevation 52.93 m CGD
- The soil/rock interface elevation 64 m CGD
- The finished grade elevation 88 m CGD

There are only slight differences between the reference rock and site-specific hazard curves at the RB base and soil/rock interface as presented in the 2022 DNNP PSHA report (Reference 2.7-41). The horizontal mean hazard curves were interpolated to obtain UHRS for an Annual Frequency of Exceedance (AFE) of 1E-2, 1E-3, 1E-4, 1E-5, 1E-6, and 1E-7 for the RB base, soil / rock interface, and finished grade elevations, respectively. The results of the UHRS curves at the horizontal and vertical of the three targeted horizons are provided in Figure 2.7.4.6-1 through Figure 2.7.4.6-8.

Seismic hazard results were produced in the 2022 DNNP PSHA report NK054-REP-03500.8-00001 (Reference 2.7-41) for Design Basis Earthquake (DBE) seismic inputs to design and Beyond Design Basis Earthquake (BDBE) seismic inputs for the evaluations of the Design Extension Conditions (DEC) as per REGDOC-2.5.2 (Reference 2.7-32) and to the Checking Level Earthquake as per CSA N289.1:18 (Reference 2.7-33). Section 9.2 of NK054-REP-03500.8-00001 (Reference 2.7-41) describes the development of DBE and BDBE ground motion response spectra. Figure 2.7.4.6-9 through Figure 2.7.4.6-11 compare the DBE and BDBE horizontal ground motion spectra with the corresponding UHRS with 1E-4 and 1E-5 AFE for the three elevations mentioned above.

Subsection 2.7.5.3.5.1 presents the DBE and BDBE response spectra that define the amplitude and frequency content of the DBE and BDBE ground motion. The DBE horizontal ground motion spectra meet the minimum earthquake requirement by enveloping the CSA N289.3 minimum spectrum as shown in Figure 2.7.4.6-12 and Figure 2.7.4.6-13.

Subsection 2.7.5.2.5.2 presents the hazard-consistent, strain-compatible dynamic soil properties used as input for the seismic response analysis and design of BWRX-300 RB that were also developed for both the DBE and BDBE levels of motion using the results of the site response analyses.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Augmentations were applied to the DBE and BDBE RB base motions, as described in Section 9.4 of NK054-REP-03500.8-00001 (Reference 2.7-41), to produce foundation input response spectra which meet the requirements of the 2010 USNRC DC/COL ISG-017 (Reference 2.7-37) for hazard consistency of foundation input response spectra for SSI analyses following guidance of NEDO 33914-A, Section 5.3.4.1. Finally, sets of recorded ground motions were recommended for use as seed motion in developing time histories for seismic analyses.

Table 2.7-4 identifies the figures which present UHRS based on the mean hazard results, reproduced from the 2022 PSHA NK054-REP-03500-.8-00001 (Reference 2.7-41).

**Table 2.7-4: Figures Presenting UHRS Based on Mean Hazard Results.**

<b>Elevation (m CGD)</b>	<b>Orientation</b>	<b>Figure</b>
52.93	Horizontal	2.7.4.6-1
52.93	Vertical	2.7.4.6-2

64	Horizontal DBE and BDBE	2.7.6.4-10
88	Horizontal DBE and BEBE	2.7.6.4-11

#### **2.7.4.7 Potential Seismically Related Hazards**

Several geological hazards and seismicity-related phenomena that could potentially affect the suitability of the DNNP site and the plant design are evaluated.

##### **2.7.4.7.1 *Volcanism***

A methodology for initial investigation of volcanism suggests evaluating within a 150 km radius of the site, per the 2009 DNNP Flood Hazard Assessment NK054-REP-01210-00012 (Reference 2.7-23). The methodology states that if there is no evidence of Cenozoic era (i.e., within the last 65 million years), volcanic rocks or volcanism in the region, no further investigations are required. Geological Map 1860a from Natural Resources Canada in the 2009 DNNP NK054-REP-01210-00012 (Reference 2.7-23) does not identify Cenozoic era formations within 150 km of the site. Hence, volcanism at the DNNP site is considered an improbable hazard with no associated seismic activity.

##### **2.7.4.7.2 *Tsunami***

Tsunamis are long period gravity waves generated in oceans or lakes by seismic disturbances or landslides resulting in a sudden displacement of the water surface. The resulting wave energy spreads across the ocean or lake at high speed. Tsunami occurrences in Canada are rare, with the Pacific Coast at greatest risk due to the higher occurrence rate of earthquake and landslide activity. The magnitude 7.2 Grand Banks earthquake of 1929 produced tsunami effects on the Burin Peninsula of Newfoundland. The Great Lakes are on the edge of the Canadian Shield, a

geologically stable, mid-continental region where the rate of occurrence of earthquakes is about one tenth of that at tectonic plate boundaries.

The Lake Ontario shorelines are not generally susceptible to shore slope failure or landslide. Review of U.S. National Geophysical Data Center Lake Ontario bathymetry gave no evidence of submarine landslides or other surface disturbance in the post-glacial period, per the 2009 NK054-REP-01210-00012 (Reference 2.7-23). Around the perimeter of Lake Ontario, "Quaternary sediments are relatively thin or absent, and bedrock exposures are common, possibly reflecting the effects of sub-glacial erosion and subsequent abrasion by lacustrine waves and currents."

The Natural Hazards Database at the U.S. National Geophysical Data Center reports one 1755 "tsunami run-up event" in Lake Ontario, though this appears to have been a seiche-like event. The event, for a location about 50 km northwest of Rochester, N.Y. is coded as "an event that only caused a seiche or disturbance in an inland river", source "unknown." "In Lake Ontario the water repeatedly rose in an unusual way to the height of about 1.5 m, no shock is mentioned. Exact latitude and longitude are unknown."

In the absence of tsunami reports in Lake Ontario and the lack of shoreline or lakebed evidence of tsunami initiators, tsunamis are considered improbable events with no associated flood hazard potential at the site.

#### **2.7.4.7.3 Seiches**

Storm surge and seiche effects in Lake Ontario resulting for various scenario storms were considered in the 2009 NK054-REP-01210-00012 (Reference 2.7-23). The maximum storm-induced surge and seiche at the Darlington shore is 0.75 m. The 1755 event where 1.5 m high seiche-like oscillations in Lake Ontario were reported may not have been seismically-induced as no shock is mentioned. A review of historical earthquake records in the 2009 DNNP PSHA NK054-REP-01210-00014 DNNP PSHA (Reference 2.7-4) identified an event on January 9th, 1847, in Grafton Harbour where with "Lake Ontario calm under a north wind, suddenly the lake level descended, exposing the lakebed for upwards of about 107 m". In moments it recoiled, rushing towards the shore in one unbroken wave about 1.2 m above normal. This wave accompanied by a heavy noise crashed over the wharf and washed inland about 91 m. This happened about 8 or 9 times, each with "diminishing force." The editor of the Cobourg Star reminded his readers that something similar had occurred in Cobourg and Port Hope in 1845. An apparently related report described "some commotion" at Rice Lake about 19 km north of Grafton Harbour, during which the 0.46 m of ice on Rice Lake began "to undulate". Eventually the ice burst with "a noise like thunder" and chunks in the center of the lake were tossed into a pile about 3.1 m high. These reports do not mention ground shaking, although noise is mentioned.

Based on the historical evidence, seiche events have occurred in Lake Ontario; therefore, shoreline protection at DNNP is considered in the design as discussed in Subsection 2.4.2.

#### **2.7.4.7.4 Dams and Landslides**

There are no human-made water retaining structures within the Darlington Creek watershed or other site vicinity watersheds, as described in the 2009 Flood Hazard Assessment NK054-REP-01210-00012 (Reference 2.7-23). Hence, there are no flooding hazards associated with seismically-induced failure of human-made water retaining structures. Additionally, the flooding threat due to seismically-induced landslide at the site is minimal, per the 2009 NK054-REP-01210-00012 (Reference 2.7-23). These conclusions are validated in Section 5.6 of the 2022 DNNP Site Evaluation Update Summary Report NK054-REP-01210-00142 (Reference 2.7-43).

#### **2.7.4.7.5 Surface Faulting**

At present, there is no known evidence of larger, pre-historic earthquakes that have resulted in surface fault rupture because such earthquakes have not occurred, or the evidence for surface rupture or coseismic damage is not preserved, or the studies needed to identify past large earthquakes is insufficient to recognize these events.

Given the relatively stable geological setting of the region surrounding the Darlington site, the recency of the post-glacial landscape that might preserve past large earthquake effects, it is expected that evidence for large earthquakes if they have occurred, would be difficult to identify. The 2022 Geotechnical Investigation Report NK054-REP-01210-00175 (Reference 2.7-39) confirms the absence of historical evidence for surface rupture within the Darlington site, including any absence of faults within the boreholes as logged.

The onshore and offshore boreholes and mapping of the DNGS excavations did not indicate offsets in the stratigraphic units, shear zones, or deep depressions in the bedrock surface, hence no near surface faulting has occurred in the bedrock at the site, as described in the 1981 DNGS Geotechnical Mapping of Bedrock Excavation NK38-02004P (Reference 2.7-24). There is no evidence of post-glacial fault-related scarps in the overburden or of solution-weathered cavities in the bedrock, as reported in the 1977 DNGS Geology and Seismicity - Hydro Geotechnical Engineering Dept. Report 77110 (Reference 2.7-25).

The stratigraphic continuity of the upper Paleozoic bedrock in the site vicinity conformed to the regional dip of about 5 m/km to the south. Minor changes in thickness and position of marker units were evident, but the differences were well within the limits of variation expected for sedimentary rock formations in southern Ontario. No vertical dislocation or displacement was evident in the upper Paleozoic bedrock formations, indicating that faulting has not propagated through the sedimentary rock strata from the Precambrian basement rock.

Mapping of marker units in the DNGS intake and discharge tunnels that extend over 1 km south of the site showed continuity consistent with the regional dip. Jointing in the rock is tight and water ingress is insignificant.

Regional geologic maps, e.g., Ontario Geological Survey, 1991, indicate that the Paleozoic rocks are, with few exceptions, relatively flat-lying and laterally continuous, indicating that no large-scale, major faulting has occurred in the region since they were deposited.

The 2022 DNNP Geotechnical Investigation NK054-REP-01210-00175 (Reference 2.7-39) reaffirmed the conclusions from the 2009 investigations and it is concluded that there is no evidence of surface faulting in the overburden or bedrock at the site or site vicinity.

#### **2.7.4.7.6 Liquefaction Potential of Foundations**

The RB foundation is to be founded on sound limestone bedrock. Foundations of other structures are to be founded on dense to very dense till deposits, and/or engineered fill. As such, the liquefaction potential of foundations will be low.

The 2022 DNNP Liquefaction Assessment Report NK054-REP-03500.8-00002 (Reference 2.7-42) assessed seismically-induced liquefaction hazards of foundation soils for the DNNP to support the Licence to Construct (LTC) application. The assessment considered the latest seismic hazard values reported in the 2022 DNNP PSHA NK054-REP-03500.8-00001 DNNP PSHA (Reference 2.7-41). The detailed liquefaction assessment of foundation soils was performed for the structures No. 1 to No. 6, namely, (1) RB, (2) TB, (3) RWB, (4) CB, (5) Reactor Auxiliary Bay, and (6) Independent Spent Fuel Storage Installation (ISFSI), as labelled in Figure 2.7.4.7-1 and Figure 2.7.4.7-2. In addition, for the potential Emergency Mitigating Equipment (EME) Access Routes at the site, all boreholes within the project boundary were evaluated for liquefaction potential.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

The following conclusions were derived from the results of the liquefaction assessment (Reference 2.7-42).

- For the DBE event, foundation soil liquefaction is not expected for the structures within the power block including the RB, TB, RWB, CB, and Reactor Auxiliary Bay, based on available soil data and the plan for the power block area to be over-excavated approximately to elevation 81 m CGD and then backfilled to plant grade elevation of 88 m CGD. For the foundation soil below the structures No.2 to No.5, the estimated seismically-induced settlement is typically less than 5 mm with a maximum of 8 mm, and the seismically-induced lateral displacement is expected to be up to 28 mm under DBE event
- For the DBE event, soil in the vicinity of the ISFSI structure (Structure No. 6) is expected to experience liquefaction, particularly in the surficial glaciolacustrine deposit (Unit 2 from the expected finished grade at elevation 88 m down to about 5 m depth). The estimated seismically-induced settlement is up to 154 mm and the lateral spreading displacement is up to 1.67 m.
- For the BDBE event, foundation soil liquefaction is not expected for the following structures:
  - RB (Structure No. 1), founded directly on bedrock
  - TB (Structure No. 2)
  - RWB (Structure No. 3)
- For the BDBE event, liquefaction potential exists at only one data point (isolated and limited extent of zones) for foundation soils in the vicinity of the following structures:
  - CB (Structure No. 4) - The liquefaction data point is at about elevation 69.1 m CGD, about 18.9 m depth from the finished grade.
  - Reactor Auxiliary Bay (Structure No. 5) - The liquefaction data point is at about elevation 69.9 m CGD, about 18.1 m depth from the finished grade.
- For the BDBE event, the foundation soil of the structures No.2 and No.5 in the power block area is calculated to have typically less than 17 mm and up to 27 mm of seismically-induced settlement, and the displacement due to lateral spreading that is calculated to be typically less than about 0.05 m and up to about 0.09 m displacement, as per the detailed liquefaction assessment of the available geotechnical data.
- For the BDBE event, significant liquefaction and seismically-induced deformation is expected in the vicinity of the proposed location for the ISFSI structure (Structure No.6).
- For the EME access routes, liquefaction susceptibility and screening assessment was performed considering all boreholes (forty-eight in total) at the site except for those within the power block area. Figure 2.7.4.7-1 and Figure 2.7.4.7-2 show the locations of the boreholes which are susceptible to liquefaction for the DBE and BDBE events respectively.

In Section 7.2 of the 2022 DNNP Geotechnical Investigation Report (Reference 2.7-39), it is indicated the upper clayey, sandy, and silty deposits (i.e., Units 2a and 2b) are potentially liquefiable during the 10,000-year design earthquake event. However, approximately 8 m of soil will be removed from beneath the power block and replaced by engineered fill. Excavating the aforementioned soil units by the specified 8 m will mitigate the potential for liquefaction. It is therefore concluded that the soil under the power block is considered non-liquefiable under the 10,000-year design earthquake for the RB, TB, RWB, CB, and the Reactor Auxiliary Bay.

### **2.7.5 Geotechnical and Seismological Parameters**

Subsection 2.7.5 describes the site-specific information used for developing the geotechnical and seismological parameters for the in-situ site conditions prior to construction of and the anticipated as-built conditions after the construction of the BWRX-300 facility. The in-situ conditions are characterized based on the information described in Subsection 2.7.3, including the results reported in the 2022 NK054-REP-01210-00175 Phase I Geotechnical Investigation Report (Reference 2.7-39) and the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

Subsection 2.7.5 is divided into the following subsections:

- Subsection 2.7.5.1: Assessment of As-Built Conditions at the DNNP Site, including a description of the over-excavation and fill replacement, evaluation of bearing capacity and time-dependent deformation for the proposed foundations, and evaluation of the anticipated earth pressure on structures.
- Subsection 2.7.5.2: Geotechnical and Seismological Site Properties, including subgrade stratigraphic profiles, static and dynamic properties of rock and soil; and groundwater level
- Subsection 2.7.5.3: Geotechnical Variability and Uncertainty, including potential sampling bias, inherent variability of samples and possible measurements errors consideration, including the main source of epistemic and aleatory uncertainties

#### **2.7.5.1 Assessment of As-Built Conditions at DNNP Site**

The site geotechnical investigations, presented in Subsection 2.7.3, are used to characterize the stratigraphy of subsurface materials at the area of the DNNP site where the first BWRX-300 unit is to be constructed. The data collected from the 2022 geophysical investigations NK054-REP-01210-00175 (Reference 2.7-39) provide comprehensive understanding of the subsurface soil and the deep bedrock conditions at the site.

The DNNP site subsurface soil and rock profiles are presented in Subsection 2.7.3.2. The DNNP site consists of approximately 25 m of soil deposits overlaying bedrock. Both the soil and bedrock materials are characterized as flat laying to slightly dipping toward the south. The top and surficial soil deposits may not have the required capacity to support the near surface mounted foundations of the BWRX-300 RWB, TB, CB and Reactor Auxiliary Bay (refer to Chapter 1, Figure A1.1-2, Figure A1.4-1 and Figure A1.5-1 for site and BWRX-300 Unit 1 layouts). Bearing capacity and settlement confirmatory calculations were performed, as part of the 2022 geotechnical work NK054-REP-01210-00175 (Reference 2.7-39) and the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38), considering approximate dimensions, bearing pressure demands and stratigraphy of the soil materials under the RWB, TB, and CB and the Reactor Auxiliary Bay foundations.

The results of the geotechnical investigations that are reported in the 2012 NK054-REF-01210-0418696 (Reference 2.7-28), the 2013 NK054-REP-01210-00098 (Reference 2.7-29), and the 2022 geotechnical investigations and tests (Reference 2.7-39) do not indicate the presence of rock cavities, voids, large open fractures, significant eroded zones, shear zones, or joint configurations that would have a potential for causing rock instability and thus jeopardizing the integrity or the safety functions of the deeply embedded BWRX-300 RB.

##### ***2.7.5.1.1 Over-excavation and Fill Replacement***

The range of SPT blow count numbers (as low as 6) and laboratory tests results indicate that the topsoil and fill materials may contain organic clays and be soft or very loose sands, which is not suitable for supporting the near surface mounted foundations of RWB, TB, CB, and Reactor

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Auxiliary Bay. As described in Subsection 2.7.3.1, beneath the topsoil and fill materials, two layers of surficial lacustrine soil materials that differ in clay content and plasticity were identified:

- The layer at the top (Unit 2a) consists of sandy lean clay to lean clay soil with soft to very stiff consistency
- The layer below (Unit 2b) consists of cohesionless silty gravel to silty sand materials, with compactness varying from very loose to very dense

The SPT blow counts taken for the two surficial lacustrine soil layers (Units 2a and 2b) show low values indicating that these materials may not be suitable for supporting the RWB, TB, CB, and Reactor Auxiliary Bay foundations and may liquefy during a DBE level event. The results of field and laboratory tests performed for the upper till (unit 3), intermediate glaciolacustrine (Units 4a and 4b), and lower till (Unit 5) indicate dense and stiff materials surrounding the deeply embedded RB that have no potential for liquefaction during a DBE event and are suitable for supporting the foundations of the RWB, TB, CB, and other power block structures.

As a result, site preparation for construction of the BWRX-300 SMR is anticipated to include excavation at the power block area of the weaker surficial soils to an elevation between 80 m and 82 m CGD. The excavated surface soils will be replaced with engineered fill to bring the site grade back to elevation 88 m CGD. The dense upper till, intermediate glaciolacustrine and lower till soils below elevations 80 m to 82 m CGD would remain in place. The BWRX-300 RB would then be constructed in a vertical right cylinder shaft excavation that extends to a depth of about 35.2 m or elevation 52.8 m CGD. At this depth, the bottom of deeply embedded BWRX-300 RB is anticipated to extend through the compacted or engineered fill and in-situ soils and into the underlying bedrock.

The RWB, TB, CB, and other power block structures surrounding the deeply embedded RB are anticipated to be supported by shallow foundations on the engineered fill.

Information detailed in the 2021 licensing topical report on BWRX 300 Advanced Civil Construction and Design Approach, NEDO-33914-A (Reference 2.7-27) describes the approach to be used for monitoring the effects of excavation and construction on the properties of subsurface materials; specifically in its Subsection 3.4 Field Instrumentation Plan, and Section 4.0 Foundation Interface Analysis.

#### ***2.7.5.1.2 Bearing Capacity Evaluation for Proposed Foundations***

##### ***2.7.5.1.2.1 Shallow Foundation***

As documented in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38), based on engineering assessment, conventional spread and strip footings located in the power block area which are founded on engineered fill can be designed using ultimate bearing capacities ( $q_u$ ):

- 1.0 m wide with depths of 1.3 to 2.5 m: 1857 to 3642 kPa
- 2.0 m wide with depths of 1.3 to 2.5 m: 1854 to 3493 kPa
- 3.0 m wide with depths of 1.3 to 2.5 m: 1834 to 3509 kPa
- 4.0 m wide with depths of 1.3 to 2.5 m: 1854 to 3422 kPa
- 5.0 m wide with depths of 1.3 to 2.5 m: 1891 to 3393 kPa

Raft foundations can be used for heavily loaded structures where conventional spread or strip footings are not adequate to support. Raft foundation founded on engineered fill can be designed for the following ultimate bearing capacities ( $q_u$ ):

- 68 x 70 m TB raft foundation with depths of 1.3 to 2.5 m: 5672 to 6917 kPa
- 30 x 48 m RWB raft foundation with depths of 1.3 to 2.5 m: 3986 to 4978 kPa
- A factor of safety of 3.0 is recommended to be used for the service limit state, and a resistance factor of 0.5 is recommended to calculate the ultimate limit state

#### ***2.7.5.1.2.2 Reactor Building Deeply Embedded Foundation***

The proposed elevation for the RB foundation is at elevation of approximately 53 m CGD, corresponding to a depth of about 35 m below grade. At this elevation/depth, the Lindsay Formation has Rock Quality Designation values ranging from 90% to 100% and discontinuity spacing is considered to be 1 m to 3 m, per the 2022 Power Block geotechnical investigations (Reference 2.7-39).

Considering a mean UCS of 75 MPa and 48 MPa (Reference 2.7-39), the allowable bearing capacity ( $q_a$ ) for the RB is 7.5 MPa and 4.8 MPa, respectively.

For a conservative bearing capacity estimate, using a minimum UCS of 48 MPa and bearing capacity factor ( $K_{sp}$ ) of 0.1, an allowable bearing capacity of 4.8 MPa will be used for the Reactor Building foundation design.

#### ***2.7.5.1.2.3 Pile Foundation***

Pile foundations may also be considered for other heavily loaded power block structures. These structures may be supported on drilled caissons founded on competent undisturbed very dense/hard glacial till (with minimum 1 m embedment) or bedrock (with 1 m embedment recommended) with the over-excavation and backfill for soil deposits above elevation 80 m to 82 m CGD. End-Bearing Caissons founded on native undisturbed lower till deposit (Unit 5) at about 20 m depth can be designed for a factored geotechnical compression resistance 1100 kN. Alternatively, end-bearing caissons advanced to about 25 m depth, at least 1.0 m socket into bedrock (Unit 6a – Blue Mountain Formation), can be designed using a factored geotechnical compression resistance of 620 kN. The ultimate end-bearing resistance in bedrock is estimated to be approximately 20 MPa and a resistance factor of 0.4 is used to calculate the factored geotechnical compression resistance. These will form predominantly end-bearing foundations and therefore larger diameters (minimum 0.76 m in diameter) are recommended. Relatively undisturbed (clean) caisson bases should be ensured prior to concrete placement to minimize any potential settlement under maximum applied loads. The end-bearing caissons with at least 1 m embedment below weathered and/or fractured bedrock is estimated and presented in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

Uplift forces of cast-in place concrete caissons will be resisted by the weight of the foundation and friction along its embedment surface area. Estimation of uplift resistance of 1.0 m diameter caissons are presented in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

#### ***2.7.5.1.3 Earth Pressure***

The anticipated earth pressure considering the in-situ stress, ground conditions, soil shoring system, RB stiffness, and loads from surrounding buildings along the depth of the RB has been conservatively evaluated based on results of non-linear FIA, as presented in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38) and is displayed in Figure 2.7.5.1.3-1.

The horizontal pressure was found higher in bedrock compared to the soil. This is due to the higher in-situ stress locked in the bedrock as a result of past tectonic activities. The earth pressure at the interface of the RB wall in the bedrock presented in Figure 2.7.5.1.3-1 represents a bounding post-construction stage scenario that assumes no stress release occurs in the bedrock

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

during excavation so all the in-situ stresses locked in the rock would be fully transferred to the RB wall. Reinforcement in the bedrock is to be incorporated in updates to the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38) that estimates stress release in the bedrock at the end of the excavation once the rock reinforcement is designed. A field instrumentation plan is to be implemented, per guidance in Section 3.4 of NEDO-33914-A (Reference 2.7-27), to monitor the deformations of the rock during the excavation. These measurements will be used to calibrate the FIA model.

#### **2.7.5.1.4 Time-Dependent Deformation for Proposed Foundations**

##### **2.7.5.1.4.1 Elastic Settlement Method**

The elastic settlement is presented in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38) and summarized in Table 2.7-5

**Table 2.7-5 Deformation for Proposed Foundations (Reference 2.7-38)**

<b>Building Structures</b>	<b>Structural Bearing Pressure, Upper Bound (kPa)</b>	<b>Proposed Foundation (Width, Depth) (m)</b>	<b>Estimated Elastic Settlement (mm)</b>
Control Building	28.7	Spread footing (3, 1.3)	1
Turbine Building	270	Raft Foundation (68X70, 1.3)	41
	150		23
	80		12
RAD Waste Building	162	Spread Footing (3, 1.3)	5
	162	Raft Foundation (48X30, 1.3)	16
Reactor Auxiliary Bay	36.8	Spread Footing (3, 1.3)	1

The expected settlement of raft foundation was analysed for the non-uniform structural load as documented in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

##### **2.7.5.1.4.2 Consolidation Settlement Method**

As detailed in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38), it is anticipated that much of the consolidation settlement occurs in the lean clay deposit (Unit 4b). Given the Over-Consolidation-Ratio for Unit 4b is between 1.8 and 2.2, the lean clay deposit is over consolidated. Since the final effective pressure caused by the structural pressure is estimated to be lower than the pre-consolidation pressure in the deposit, the consolidation settlement is therefore estimated using the reconsolidation index (Cr). Annual secondary (creep) consolidation settlement is negligible.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

The estimated consolidation settlement of different building structures is summarized in Table 2.7-6.

**Table 2.7-6 Consolidation Settlement Method (Reference 2.7-38)**

<b>Building Structures</b>	<b>Structural Bearing Pressure, Upper Bound (kPa)</b>	<b>Proposed Foundation (Width, Depth) (m)</b>	<b>Estimated Consolidated Settlement (mm)</b>
Control Building	28.7	Spread Footing (3, 1.3)	5
Turbine Building	270	Raft Foundation (68X70, 1.3)	51
	150		31
	80		17
RAD Waste Building	162	Spread Footing (3, 1.3)	9
	162	Raft Foundation (48X30, 1.3)	45
Reactor Auxiliary Bay	162	Spread Footing (3, 1.3)	2

The expected settlement of raft foundation was analysed for the non-uniform structural load. The maximum total settlement (elastic and consolidated settlement) of the TB is approximately 92 mm, and the differential settlement is approximately 61 mm.

The settlement of raft foundations is also dependent on the rigidity of the foundation, homogeneity of the subgrade material and the construction method. Following the guidance of Section 4.0 of NEDO-33914-A (Reference 2.7-27), a 3-D non-linear FIA is to be performed to develop settlement contours of the raft foundations at a later design stage.

#### **2.7.5.2 Geotechnical and Seismological Site Design Parameters**

Subsection 2.7.5.2 presents the geotechnical and seismological properties for the seismic and structural analysis, and design, including:

- Subgrade profiles – Subsection
- Equivalent linearized static properties of soil and engineered fill materials – Subsection 2.7.5.2.2
- Equivalent linearized static properties of rock – Subsection 2.7.5.2.3
- Dynamic subgrade properties – Subsection 2.7.5.2.4
- Seismic Design Parameters – Subsection 2.7.5.2.5
- Groundwater Level – Subsection 2.7.5.2.6

#### **2.7.5.2.1 Subgrade Profiles Stratigraphy**

The design analyses of the deeply embedded BWRX-300 RB consider subgrade profiles to account for the variations of the soil and rock properties with depth at the DNNP site. The soil profiles represent “as-built” conditions at the DNNP site after construction of the BWRX-300 facility, where the engineered fill replaces the excavated top in-situ upper lacustrine or fill units. The stratigraphy of the as-built subgrade profiles consists of:

- Engineered fill that is for the upper 6 m to 8 m from elevation 80 m to 82 m CGD, as required to the final grade at elevation 88 m CGD.
- In-situ soils consisting of upper till (Unit 3), intermediate glaciolacustrine soils (Units 4a and 4b), and the lower till unit (Unit 5).
- Rock units including Blue Mountain (Unit 6a), Lindsay (Unit 6b), Verulam (Unit 6c), Bobcaygeon, Gull River, Shadow Lake and Genesis formations.

The engineered fill will comprise either commercial crusher run, or pit run granular fill or select excavated material meeting the requirements of engineered fill described under “Planned As-Built Soil Profile” in Subsection 2.7.3.2. Placement of the fill will be controlled based on in-situ testing and monitoring by the geotechnical engineer as described in the 2023 DNNP FIA Report NK054-REP-03500.8-00003 (Reference 2.7-38).

The BWRX-300 RB vertical cylindrical shaft deep excavation is to be extended through the Blue Mountain Formation (Unit 6a) and founded in the Lindsay Formation (Unit 6b). The Gneiss formation – the deepest investigated unit - is taken as the hard rock basement with shear wave velocities that are greater than or equal to 3000 m/s, per the 2012 Field Work – Geology and Geological Evaluation NK054-REF-01210-0418696 (Reference 2.7-28).

The pre-excavation in-situ site stratigraphy for soil layers are presented in Table 2.7-2. The adopted in-situ soil layer thicknesses are based on the 2022 Geotechnical Investigation Report NK054-REP-01210-00175 (Reference 2.7-39).

The stratigraphy of the rock units at the DNNP site including rock formations and thicknesses are presented in Table 2.7-3. The bedrock stratigraphy is based on the discussion presented in Subsection 2.7.3.2. The elevation of top of upper rock unit, the Blue Mountain (Whitby) Formation, considered as “top of rock” is expected to be about 64.2 m CGD with a variability of  $\pm 2$  m. The variation in the thickness layer of  $\pm 3$  m is based on the results of the 2022 DNNP Geotechnical Investigation reported in NK054-REP-01210-00175 (Reference 2.7-39).

#### **2.7.5.2.2 Equivalent Linearized Static Properties of Soil and Engineered Fill Materials**

Upper Bound and Lower Bound equivalent linearized properties representing the pressure of the soil and rock materials under long-term (static) loads are established based on measurements obtained from the different field and laboratory tests executed during the 2022 geotechnical investigation NK054-REP-012010-00175 (Reference 2.7-39). Upper and lower values are directly from the measured values. Further statistical analysis is completed to account for uncertainty as required during detailed design.

The static Elastic Modulus  $E_{st}$  values for soil materials are obtained from the results of field and laboratory tests. Initial Tangent Elastic Modulus values for the soil materials are established by Triaxial Compression Testing and Pressuremeter Testing, respectively. Initial Tangent Elastic Modulus is interpreted from consolidated anisotropic drained triaxial testing of reconstituted specimen. This is representative of in-situ conditions where the specimen is consolidated to approximate in-situ vertical effective stress.

Poisson's ratio  $\nu_{st}$  values are determined by compression and shear wave velocities measured during triaxial compression testing. Effective friction angle and Coefficient Lateral Earth Pressure at Rest is determined by Triaxial Compression Testing and Pressuremeter Testing during the 2022 geotechnical investigation NK054-REP-01210-000175 (Reference-2.7-39).

A summary of linearized static properties for engineered fill and in-situ soil layers in the as-built profiles are provided in the Table 2.7-7.

#### ***2.7.5.2.3 Equivalent Linearized Static Properties of Rock***

The 2022 geotechnical investigation NK054-REP-01210-00175 (Reference 2.7-39) studied the linearized static properties of rock on the DNNP site, with focus around the BWRX-300 power block area. The linearized  $E_{st}$  and  $\nu_{st}$  values of the rock masses are evaluated from UCS testing and triaxial compression testing. The intact rock modulus was measured through UCS testing of intact rock samples. The intact rock modulus was then adjusted to evaluate the rock mass deformation modulus by two different methods:

- Evaluation of the Geologic Strength Index (two separate ways) and further calculation
- Directly measured through pressuremeter testing.

Total or bulk unit weight was measured during the uniaxial and triaxial compressive strength testing. Table 2.7-8 presents a summary of linearized static properties for the rock layers.

#### ***2.7.5.2.4 Dynamic Subgrade Properties***

The measured values for dynamic properties of rock are presented in Table 2.7-9a and Table 2.7-9b. The measured small-strain in-situ soil dynamic properties are listed in Table 2.7-10a and Table 2.7-10b. The compression wave velocities, shear wave velocities for the soil and bedrock rock units are obtained from the measurements during the 2022 geotechnical investigation NK054-REP-01210-00175 (Reference 2.7-39). Poisson's Ratio, Young's Modulus, Shear Modulus and Bulk Modulus are presented as calculated in the 2022 Geotechnical Investigation Report NK054-REP-01210-00175 (Reference 2.7-39).

#### **2.7.5.2.5 Seismic Design Parameters**

Two sets of seismic design parameters were developed based on the results of the site response analyses described in Subsection 2.7.4.6.1 for DBE seismic design and BDBE DEC seismic evaluations:

- Ground motion spectra defining the amplitude and frequency content of the DBE and BDBE ground motion at the DNNP site
- Hazard-Consistent, Strain-Compatible (HCSC) profiles defining the variation with depth of the dynamic properties of DNNP subgrade materials compatible to the strains generated by DBE and BDBE levels

##### **2.7.5.2.5.1 Ground Motion Spectra**

Per guidance of NEDO 33914-A, Section 5.2.2, three sets of response spectra are developed, as described in Section 9.2 of the 2022 DNNP PSHA NK054-REP-03500.8-00001 (Reference 2.7-41), defining the amplitude and frequency content of the DNNP site-specific DBE and BDBE ground motion:

1. Foundation Input Response Spectra at RB foundation bottom elevation of 52.93 m CGD presented in Figure 2.7.5.2.5-1
2. Performance Based Intermediate Response Spectra at the soil / rock interface elevation 64 m CGD, located 24 m below planned finished grade presented in Figure 2.7.5.2.5-2
3. Performance Based Surface Response Spectra at the finished grade elevation of 88 m CGD presented in Figure 2.7.5.2.5-3

##### **2.7.5.2.5.2 Strain-Compatible Soil Properties**

Profiles of HCSC dynamic subgrade properties, needed for the SSI analyses, are developed based on the results from the site response analyses described in Section 2.7.4.6. The profiles defining the variation with depth of subgrade shear wave velocities compatible to the DBE and BDBE strain levels are presented in Figure 2.7.5.2.5-4. The profiles of subgrade compression wave velocities for the DBE and BDBE strain levels are presented in Figure 2.7.5.2.5-5. Figure 2.7.5.2.5-6 presents the subgrade damping profiles representing the dissipation of energy in the subgrade materials for the DBE and BDBE levels. The presented HCSC dynamic subgrade properties are per Section 9.3 (Table 9-40 through Table 9-45) of the 2022 DNNP PSHA NK054-REP-03500.8-00001 (Reference 2.7-41).

##### **2.7.5.2.6 Groundwater Level**

The groundwater elevations are listed in Table 3-7 in Volume 2 of 2 of the 2022 Phase 1 Geotechnical Investigation - DNNP (Reference 2.7-39), and is replicated, in part, in Table 2.7-11, which provides samples of groundwater elevation and hydraulic vertical gradient at BH12 area which is located on the western side of the RB perimeter, as shown in Figure 2.7.3.1-6.

**Table 2.7-11 Samples of Groundwater Elevation and vertical Hydraulic Gradients, BH12 Area (Reference 2.7-39, Table 3-7)**

Date	Groundwater Elevation (m)				Vertical Gradient (m/m)		
	Unit 3 <sup>1</sup>	Unit 4a <sup>2</sup>	Unit 5 <sup>3</sup>	Unit 6 <sup>4</sup>	Unit 3 to 4a (down)	Unit 4a to 5 (Down)	Unit 5 to 6 (Down)
	BH12-1	BH12-2	BH12-3	BH14			
<b>29NOV21</b>	85.47	83.89	79.47	77.09	-0.25	-0.71	-0.28
<b>05JAN22</b>	85.72	84.03	82.47	78.56	-0.27	-0.25	-0.46
<b>07FEB22</b>	85.24	83.66	79.18	78.41	-0.25	-0.72	-0.09
<b>17FEB22</b>	85.46	83.81	79.29	78.52	-0.26	-0.73	-0.09

1. Upper Till
2. Surficial Glaciolacustrine Deposits
3. Lower Till
4. Bedrock

Based on the groundwater information at the DNNP site presented in Subsection 2.7.3.2 and Table 2.7-11, an upper bound groundwater level at elevation of 85.74 m CGD (or approximately 86 m CGD) corresponding to a depth of 2.26 m (or approximately 2 m) below the plant grade at elevation 88 m CGD is to be used for design.

### 2.7.5.3 Geotechnical Variability and Uncertainty

Geotechnical variability and uncertainty are considered in detail in the 2022 Geotechnical Investigation NK054-REP-01210-00175 (Reference 2.7-39).

When sampling the soil and rock there can be sampling bias that is introduced in the sample selection process. In general, DNNP project samples were selected based on predetermined testing requirements for each borehole and samples were selected from a variety of depths within each borehole. In some cases, such as the shale from the Blue Mountain Formation, it is not possible to test the weaker rock as intact samples of this material cannot properly be prepared for testing (typically breaking apart along weaker bedding planes). In these cases, sensitivity analysis and engineering judgement are required during design to account for the fact that the range in the data may not capture the minimum values.

When in-situ and laboratory methods are used to measure soil and rock attributes, the inherent variability along with measurement error typically led to data scatter. Measurement error may result from equipment errors and procedural or operator errors. Measurement error is minimized through equipment calibration, standardized procedures, laboratory accreditation, etc.

In-situ and laboratory methods are also subject to statistical uncertainty, which may be reduced by increasing the sampling frequency. Further, certain in-situ and laboratory measurements are transformed for design purposes through empirical or other correlation methods.

Geotechnical variability and uncertainty are addressed using a two-pronged approach:

- Reduction in uncertainty through the use of reliable, calibrated equipment, precision in measurement and testing procedures and sufficient quantity of sampling/testing.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

- Consideration of total variability associated with each geotechnical property/parameter, including evaluation of statistical parameters and identification of sources of uncertainty particular to each property/parameter.

## **2.8 Site Characteristics Impact on Dispersion of Radioactive Material**

The dispersion of radioactive material in water, air, and soil is affected by natural and physical characteristics of the site and the surrounding environment, including meteorology and climate, hydrological and hydrogeological parameters, as well as land cover and use (e.g., vegetation and structures). Population and receptors also influence the potential effects of dispersion of radioactive material. The baseline conditions for these characteristics are established in the:

1. Darlington New Nuclear Project (DNNP) Environmental Impact Statement (EIS), completed in 2009 in NK054-REP-07730-00029 (Reference 2.8-1)
2. Updates to the baseline conditions since the EA was conducted, as discussed in detail in documentation including the 2020 Environmental Risk Assessment (ERA) for the Darlington Nuclear Site, D-REP-07701-00001 (Reference 2.8-2)
3. Yearly Environmental Monitoring Program (EMP) reports, per N-REP-03443-10027 (Reference 2.8-3)
4. DNNP – Site Preparation Licence Renewal Activity Report – Environment, completed in 2020 in NK054-REP-01210-00110 (Reference 2.8-4)
5. Darlington New Nuclear Project Supporting Environment Studies – Environment, completed in 2020, NK054-REP-01210-0001 (Reference 2.8-5)
6. Darlington New Nuclear Project Environmental Impact Statement (EIS) Review Report For Small Modular Reactor BWRX-300, completed in October 2022, per NK054-REP-07730-00055 (Reference 2.8-10)

The 2020 DNNP Site Preparation Licence Renewal Activity Report NK054-REP-01210-00110 (Reference 2.8-4) concluded the baseline conditions have not changed since the DNNP EA that was conducted in 2009 NK054-REP-07730-00029 (Reference 2.8.1) – a conclusion that is confirmed in the 2022 EIS Review Report NK054-REP-07730-00055 (Reference 2.8-10).

The impact of baseline characteristics of the DNNP site and surrounding environment on dispersion of radioactive material are summarized as follows:

- Impact of meteorology and climate, including Temperature Normals, Precipitation Normals, and Wind Speed and Direction – Subsection 2.8.1
- Impact of hydrology and hydrogeology – Subsection 2.8.2
- Impact of land cover and use – Subsection 2.8.3
- Impact of population, including numbers, locations, ages, and critical groups – Subsection 2.8.4
- Impact of accident scenarios and dispersion models – Subsection 2.8.5
- Impact of biological data – Subsection 2.8.6

Table 2.8-1 lists key characteristics and parameters within the Survey Areas of 10 km and 30 km of the Darlington Nuclear site that encompasses both the Darlington Nuclear Generating Station (DNGS) and DNNP sites.

NEDO-33951 REVISION 2

**Table 2.8-1: DNNP and Darlington Nuclear Sites Characteristics and Parameters**

Characteristic	Value/Description	
2.8.2 Impact of Hydrology and Hydrogeology		
2.8.2.1 Impact of Hydrology	Lake current	Easterly – near shore Speed in all direction 9 to 18 cm/s
	Lake water temperature	Surface – Freezing to 20 °C Ambient (Winter) – 0.5 °C in January to 7.7°C in November
	Surface Drainage	South of railway – slopes toward Lake Ontario Northeast of railway – slopes toward the east
	Stormwater	Collected in natural channels or swales and constructed outfalls and conveyed to the lake; or ponds
2.8.2.2 Existing Hydrogeological Conditions	Groundwater aquifers	South of railway – north to south Northeast of railway – toward the east Flows are impacted by subsurface structures of BWRX-300 facility.
	Urban areas water supply	Municipal water supply for Lake Ontario
	Rural areas water supply	Surface water intake (lakes) or ground water wells
2.8.3 Impact of Land Cover and Use		
Terrain Type – Water	Lake Ontario – South of the site from the E to the WSW sectors	
Terrain Type – Ploughed land	Within 3 km – Open grassland, farmland, residential homes, parking lots, and industrial land with low-elevation or low-density buildings to the north of the site from the W to the ENE sectors	
Cities	All are farther than 3 km: W and WNW – Oshawa, Whitby, NW – Courtice, and NE – Bowmanville	
Rural Areas	With tall trees, North of the site – NW to NNE, and ENE sectors	
Ecological Features	Meadow (24%), thicket (14%), woodland (5%), and swamp (5%)	
Vegetation communities	Bluff communities	West and east – cover <1% of the Darlington Nuclear site, shrubs with 10% tree cover
	Beach communities	Cover <1% of the Darlington Nuclear site, exposed to the lake with patchy vegetation cover
	Forested areas	Cover about 3% of the Darlington Nuclear site, with 60% tree cover with variable substrate types and conditions
	Cultural communities (resulting from cultural or anthropogenic disturbances)	Cover much of the site, include meadows (24%), thickets (14%), woodlands (5%)

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 2.8-1: DNNP and Darlington Nuclear Sites Characteristics and Parameters**

Characteristic	Value/Description	
	March areas and swamps	3.7% and 5.4%, respectively of the Darlington Nuclear site
Land use in Durham Region and Clarington Municipality	Variety of landscape and lakeshore communities of small rural towns, as well as villages, hamlets, and farm holdings in the northern portion	
	Residential, industrial, and commercial areas	Generally located in Courtice (6.4 km NW of the site), and Bowmanville (4 km NE of the site)
	Agriculture	Predominant land use in Clarington
<b>2.8.4 Impact of Population</b> (Based on Site-specific Survey (2018) and Pathway Analyses (2016))		
Numbers (2016 census)	Within 30 km	<ul style="list-style-type: none"> <li>- Approximately 500,000 within 30 km radius (88% WSW to NNW, 12% E to NE, and 0.0% [Lake Ontario] SW to E of the site)</li> <li>- 90% of population reside in urban areas</li> </ul>
	Within 10 km	Approximately 100,000 residents
	0 to 2.0 km	Only 20 residents
By age (2016 census)	Durham Region	Children (aged under 15) (18%), Young persons (aged 15-29) (19%), Adults (aged 30-64) (49%), Older adults (aged 65+) (14)
By Gender (2018 survey)	Ontario	Largest age group is 20 to 24 for males; 55 to 59 for females
	Durham Region	Largest age group is 50 to 59 for males; 50 to 54 for females
Public Dose Assessment	Critical Groups (site-specific surveys) (NOTE: Annual site-specific survey reports dose for the top three critical groups, as well as specifically for the dairy farm potential critical group)	1. Rural Residents 2. Oshawa/Courtice Residents 3. Bowmanville Residents 4. Local Farms 5. Local Dairy Farms 6. West-East Beach Residents 7. Darlington Provincial Park Campers 8. Sport Fisher 9. Industrial/Commercial Workers
	Site-specific survey (2018) and pathway analyses (2016)	Done about every 5 years Within each critical group, 3 age classes are used – 0-5 years (Infant), 5 to 15 years (child), 16 to 70 years (adult) Group and age classes with highest dose are reported as the site dose for the given year
<b>2.8.5 Impact of Accident Scenarios and Dispersion Models</b>		

**Table 2.8-1: DNNP and Darlington Nuclear Sites Characteristics and Parameters**

Characteristic	Value/Description
	Refer to Chapter 15, Section 15.5 for DBAs and DECAs with and without core melt; as well as events related to irradiated fuel pool and fuel handling
	<b>2.8.6 Impact of Biological Data</b> The baseline terrestrial flora, fauna, and food chain data as well as baseline aquatic biota and food chain data were updated in 2020 in NK054-CORR-00531-10533 (Reference 2.8-9) and did not change the conclusion of the 2009 EIS of NK054-REP-07730-00029 (Reference 2.8.1) as evidenced in the 2022 EIS documented in NK054-REP-07730-00055 (Reference 2.8-10)

## 2.8.1 Impact of Meteorology and Climate

Meteorological characteristics are relevant to the dispersion of material in water, air, and soil as they directly impact the characteristics of the plume, including distance, direction, deposition, and ground concentrations. Relevant meteorological characteristics include temperature, precipitation as well as wind speed and direction.

The Darlington Nuclear site is in Southern Ontario on the north shore of Lake Ontario (refer to Subsection 2.1.1 for additional information). The Darlington Nuclear site displays a humid continental climate with four distinct seasons. In general, Southern Ontario climate is highly modified by the influence of the Great Lakes which results in uniform precipitation amounts year-round, delayed spring and autumn, and moderated temperatures in winter and summer, as described in D-REP-07701-00001 (Reference 2.8-2).

Refer to Section 2.6 for additional DNNP site information relevant to local and regional meteorological characteristics, hazards from meteorological events, and extreme values of meteorological parameters.

### 2.8.1.1 Temperature Normals

The most recent Canadian Climate Normals available span the 1981-2010 period. The meteorological stations at Oshawa and Bowmanville represent the local climate conditions at the Darlington Nuclear site, while the meteorological station at Toronto's Pearson Airport represents the regional conditions. The highest mean temperatures, both regionally and locally, occurred in July, and the lowest mean temperatures occurred in January, as shown in Table 2.8-2. Similar to the local and regional conditions, the highest (21.5 °C) and the lowest (-4.1 °C) 4-year average monthly temperatures at the Darlington Nuclear site occurred in July and January, respectively. The mean daily maximum temperature (23.0 °C) was recorded in August 2016, and the mean daily minimum temperature (-6.4 °C) was recorded in January 2019, as reported in D-REP-07701-00001 (Reference 2.8-2).

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

4. Darlington Nuclear, 2016-2019 (2017 data from Darlington Nuclear site on-site meteorological tower, while 2016, 2018, 2019 data from Pickering Nuclear on-site meteorological tower).

### 2.8.1.2 Precipitation Normals

The Bowmanville climate station is the closest to the Darlington Nuclear site. The 1981-2010 climate normal precipitation data, listed in Table 2.8-3, from the Bowmanville Mostert Station are used to characterize precipitation patterns for the Darlington Nuclear site. During this period the Bowmanville station reported an average annual precipitation of approximately 866 mm; with snowfall representing less than 11% of the total precipitation measured. Total monthly precipitation averages range from approximately 50.5 mm in February to approximately 98.7 mm in September, per D-REP-07701-00001 (Reference 2.8-2).

**Table 2.8-3: Precipitation at Bowmanville Mostert Station (1981-2010)**

Month	Monthly Averages			Daily Extremes		
	Precipitation (mm)	Rain (mm)	Snow (cm)	Precipitation (mm)	Rain (mm)	Snow (cm)
January	63.1	32.2	31	46.2	46.2	29

Annual Total	866.4	773.5	93.1	-	-	-

### 2.8.1.3 Wind Speed and Direction

As discussed in the annual EMP report N-REP-03443-10027 (Reference 2.8-3), the wind speed, direction, and frequency are measured continuously at meteorological towers at the Darlington Nuclear site. As shown in Table 2.8-4 for the year 2021, the landward sector at the Darlington Nuclear site the wind predominantly blew toward was the ENE sector (wind from WSW), based on the average annual wind frequencies at a 10 m height. Over all sectors, the wind predominantly blew from the north and west sectors. The dominant wind direction was NNW (10.38% of the time), followed by W (9.98% of the time) and NW (9.82% of the time).

**Table 2.8-4: Darlington Nuclear – 2021 Annual Average Wind Frequency by Direction (at 10 m height)**

<b>Direction Wind Blowing From</b>	<b>Darlington Nuclear Wind Frequency (%)</b>
N	7.22
NNE	3.09
NE	3.65
ENE	8.48
E	8.25
ESE	4.60
SE	3.43
SSE	2.25
S	2.33
SSW	2.35
SW	6.65
WSW	<b>9.18</b>
W	9.98
WNW	8.34
NW	9.82
NNW	10.38
Total	100

Notes:

- (1) Shaded fields indicate landward wind sectors.
- (2) Bolded values indicate landward wind sectors with the highest wind frequency.

As reported in the 2020 ERA for the Darlington Nuclear site D-REP-07701-00001 (Reference 2.8-2), wind speeds were measured from 2013-2019 at the Darlington Nuclear on-site meteorological towers at a height of 10 m. The average wind speed was approximately 2.4 m/s. Calm winds of less than 2 m/s were reported approximately 37% of the time. The prevailing winds for these years were measured to be from the north-west sector – the north direction (9.6% of the time) followed by the west direction (8.9% of the time). The wind rose for the 2013-2019 data is provided in Figure 2-8 of D-REP-07701-00001 (Reference 2.8-2).

## **2.8.2 Impact of Hydrology and Hydrogeology**

Hydrological and hydrogeological characteristics are relevant to the dispersion of material in water. These characteristics influence the flow and concentration of radioactive and conventional contaminants, as well as impact the populations that are affected. Relevant characteristics include aquifer type, groundwater flow, stormwater runoff, municipal water supply sources, lake currents and temperature, and major lake water intake and discharge structures.

Refer to Section 2.5 for further information on the implication of hydrological and hydrogeological conditions, including abnormal phenomena at the DNNP site on the design and safe operation of the BWRX-300 facility.

### **2.8.2.1 Impact of Hydrology**

There is very little current net flow along the northern shore of Lake Ontario. However, the current in the nearshore region is overall easterly and is influenced by brief patterns of strong winds exerting stress at the water surface. Lake current speeds for all directions for the 2012-2016 period typically ranged from about 9 to 18 cm/s and were typically slower during spring and early summer, (May through June) than during late summer, fall and winter (August through April), as described in the 2020 ERA D-REP-07701-00001 (Reference 2.8-2).

Lake-wide surface temperatures typically range from freezing in the winter to approximately 20 °C in the summer. Ice formation in the winter is typically limited to the nearshore areas at the eastern end of the lake within the Kingston Basin. Average ambient water temperatures in the winter have varied from 0.5 °C in January to 7.7 °C in November. The water temperatures recorded from December 2011 to March 2012 and from December 2011 to April 2012 in the Darlington Nuclear study area had an average temperature of 3.8 °C and 4.4 °C, respectively, per the 2020 ERA D-REP-07701-00001 (Reference 2.8-2).

The intake pumphouse/forebay of the BWRX-300 facility provides the transition of water flowing from the intake tunnel up to the Circulating Water System pumps (refer to Subsection 2.5.2) via an onshore vertical shaft. The intake offshore tunnel transitions into a porous veneer intake. Similarly, the submerged discharge tunnel connects to a discharge shaft that is located near the shoreline bluff, to convey returned heated water to the diffusers. Refer to Chapter 9B, Subsection 9B.3.5, for design information on the BWRX-300 pumphouse/forebay, intake and discharge shafts and tunnels, lakebed intake structure and discharge diffusers.

The surface drainage at the Darlington Nuclear site is divided by the Canadian National Railway line which runs east to west across the site (refer to Section 2.1, and Figure 2.1.1.2). The area south of the railway tracks generally slopes toward Lake Ontario while the area north of the railway tracks and east of Holt Road slopes toward the east. In the developed parts of Darlington Nuclear site including the DNGS areas, stormwater is collected in natural channels/swales and constructed outfalls and conveyed to Lake Ontario. Currently, a stormwater pond is located to the south of the Engineering Support Services Building and another pond is associated with the Darlington Waste Management Facility (DWMF). Another stormwater pond is located north of the lagoons which collect runoff from adjacent parking lots and from the railroad tracks (refer to the 2020 ERA D-REP-07701-00001 (Reference 2.8-2)). These features could change as the DNNP site is further developed, and the BWRX-300 design progresses.

To support the Site Preparation Licence renewal application in 2020, OPG obtained hydrological data, surface water data, and sediment quality data in the site, as well as in the local, and regional study areas, as provided in the 2009 DNNP EIS NK054-REP-07730-00029 (Reference 2.8-1).

The 2022 EIS in NK054-REP-07730-00055 (Reference 2.8-10) reports that the BWRX-300 deployment will have no residual adverse effects on site drainage and identified minor changes

in DNNP flows and the number of days per year that an area of land is wet can be mitigated using best industry practices.

#### **2.8.2.2 Existing Hydrogeological Conditions**

The information on existing groundwater conditions discussed in the 2020 ERA D-REP-07701-00001 (Reference 2.8-2) and the 2009 DNNP Supporting Environment Studies NK054-REP-01210-0001 (Reference 2.8-5) is detailed in Subsection 2.5.5.

Inside the protected area at DNGS, groundwater flow is further influenced by anthropogenic subsurface features such as foundations, drain systems and sumps, and the vacuum building.

For the protected area at the DNNP, the Power Block footprint is smaller than the DNGS footprint. Also, the Reactor Building (RB) is embedded in the soil and extends to bedrock, impacting connection between groundwater flows at the north and south of the structure, per the 2020 ERA D-REP-07701-00001 (Reference 2.8-2). Such anthropogenic DNNP structures would influence the hydrostratigraphic layers and the neighboring groundwater flows. (Refer to Chapter 1, Subsection 1.5.2, and Table 1.5.2 for dimensions of the RB and other buildings in the Power Block).

Recharge of precipitation is expected to be low at the Darlington Nuclear site in areas where till is encountered at surface. Within these areas most precipitation runs off to surface water ditches or yard drainage features, as described in the 2020 ERA D-REP-07701-00001 (Reference 2.8-2). (Refer to Subsection 2.5.3 for additional information on potential sources of flooding).

Since the Site Preparation Licence renewal application in 2020 included in NK054-CORR-00531-10533 (Reference 2.8-9), OPG examined groundwater flow characteristics at the Darlington Nuclear site as part of annual groundwater monitoring (refer to Subsection 2.5.5.3). Furthermore, additional geotechnical investigations are completed for the DNNP's onshore Power Block area, with the results documented in the 2022 NK054-REP-10180-00001 DNNP Geotechnical and Seismic Hazard Investigation Plan – Phase 1 (Reference 2.8-11).

Groundwater on the Darlington Nuclear site is not used as drinking water and is not considered to be potable.

Annual groundwater quality monitoring (described in Subsection 2.5.5.3) is carried out across the site study area. Recent monitoring results, such as the levels of tritium, Volatile Organic Components, Benzene, Toluene, Ethylbenzene and Xylene, Petroleum Hydrocarbons, sodium, chloride, and metals in groundwater, are used to establish the groundwater quality baseline. Based on the annual groundwater monitoring results for the period of 2019 to 2021, groundwater quality remains consistent with that documented in the licence to prepare site application, per the 2020 Site Preparation Licence Renewal Activity Report NK054-REP-01210-00110 (Reference 2.8-4). The tritium concentrations at the sampled perimeter groundwater locations remained low in 2021. This is aligned with a trend observed indicating the tritium levels over time have remained nearly steady or decreased, which indicates stable or improved environmental performance. The groundwater quality results were compared to the Ministry of Environment, Conservation and Parks' Provincial Water Quality Objectives, based on the assumption that groundwater pumped during construction or in the long term will be discharged to the natural environment. Some groundwater samples exhibited elevated concentrations of total metals, dissolved metals, phenols, and toluene above the selected Provincial Water Quality Objectives. Several samples exhibited pH outside the acceptable Provincial Water Quality Objectives range of 6.5 to 8.5. However, given that the water is not used for drinking and is not considered potable, the conclusions of the original Site Evaluation, reported in the 2020 renewal of licence to prepare site application NK054-REP-01210-00110 (Reference 2.8-4), are valid.

Urban areas such as Bowmanville to the east and Courtice to the west of the Darlington Nuclear site rely on municipal water supply from a Lake-Ontario-based source. The more rural areas of Durham are supplied by individual water supply systems from either surface water intakes (lakes) or ground water wells. There are rural and farm residents in rural areas in all landward wind sectors around the site at distances of about 2 km to 5 km. Residents in these areas obtain at least a portion of their water supply from wells, and use it for drinking, bathing, and irrigation. However, there are no potable groundwater supply wells within or downgradient of potential source areas on-site. As water on the Darlington Nuclear site is not used for human consumption, the only on-site pathway for human exposure to groundwater would be from ingestion of water from Lake Ontario after dilution of the groundwater in the lake. Off-site drinking water wells are influenced by atmospheric tritium, but this makes a negligible contribution to dose. Concentrations of potential chemical stressors in off-site drinking water wells are not influenced by the Darlington Nuclear site, refer to the 2020 ERA D-REP-07701-00001 (Reference 2.8-2).

### **2.8.3 Impact of Land Cover and Use**

Land cover and use characteristics are relevant to the dispersion of material in water, air and soil as these characteristics define the terrain cover and impact deposition. Relevant characteristics include terrain type, vegetation type, vegetation height, building height, and locations.

The terrain cover surrounding the Darlington Nuclear site is broadly characterized for air dispersion modelling (refer to Subsection 2.8-5) in the Derived Release Limits and Environmental Action Levels for DNGS NK38-REP-03482-10001 (Reference 2.8-6). The major terrain types are as follows:

- Water: Lake Ontario to the south of the site from the E to the WSW sectors
- Ploughed Land: At the site boundary to a distance of 3 km, open grassland, farmland, residential homes, parking lots, and industrial land with low-elevation or low-density buildings to the north of the site from the W to the ENE sectors

At distances further than 3 km from the site boundary, inspection of aerial photographs shows cities with larger buildings, including Oshawa and Whitby to the W and WNW of the site, and Bowmanville to the NE of the site. Rural areas with tall trees, including Ganaraska Forest, are located north of the site from the NW to the NNE sectors and ENE sectors.

The dominant ecological feature of the Darlington Nuclear site is meadow (24%), followed by thicket (14%), woodland (5%), and swamp (5%). In general, the Darlington Nuclear site has four main areas, per NK054-REP-01210-0001 (Reference 2.8-5):

1. In the northwest there are sports fields, a large settling pond (Coot's Pond), and Bobolink Hill comprised of cultural meadow and cultural thicket
2. In the northeast there are agricultural fields, cultural thicket, and deciduous forest as well as three constructed wetland ponds (Treefrog, Dragonfly and Polliwog ponds)
3. In the southeast there are mostly cultural meadows
4. In the south centre and southeast is the DNGS

There are various terrain types and vegetation communities on or immediately surrounding the Darlington Nuclear site, including bluffs, beach, forest, cultural woodland, cultural meadow, cultural thickets, marshland, swamp, and urban areas. The dominant vegetation cover surrounding the Darlington Nuclear site relates to agricultural use, including row crops and pastureland, as detailed in D-REP-07701-00001 (Reference 2.8-2).

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Bluff communities are present west and east of the Darlington Nuclear site and cover a very small portion (<1%) of the Darlington Nuclear site. Bluff communities are characterized by variable vegetation cover that can range from patchy and barren to herbaceous cover. Generally, bluffs have no more than 10% tree cover because of erosion which results in steep, sometimes near vertical faces that are more than 2 meters in height. The bluff community on the west side of the Darlington Nuclear site is dominated by shrubs, mostly willows with Red-Osier Dogwood and Nannyberry. The bluff community on the east side of the Darlington Nuclear site is characterized by open or sparsely vegetated land due to ongoing erosional disturbance. The most abundant vegetation on these bluffs is Colt's Foot, refer to D-REP-07701-00001 (Reference 2.8-2).

The beach community covers a very small fraction (<1%) of the Darlington Nuclear site and much of the area is relatively exposed to the lake. The beach community is characterized by patchy vegetation cover that varies from sparse cover to areas with treed cover equal to or less than 60%, as described in D-REP-07701-00001 (Reference 2.8-2).

Forested areas cover about 0.16 km<sup>2</sup> (about 3%) at the Darlington Nuclear site. The forest community is characterized by a high level of tree cover (more than 60%) as well as variable substrate types and conditions and is classified as a coniferous, deciduous, or mixed forest type, as detailed in D-REP-07701-00001 (Reference 2.8-2).

Much of the Darlington Nuclear site vegetation communities are characterized as cultural communities such as cultural meadows, thickets, and woodlands (including plantations) that generally resulted from or are maintained by cultural or anthropogenic disturbances. Cultural woodlands, meadows, and thickets arise following anthropogenic disturbance. Cultural woodlands cover approximately 5% of the Darlington Nuclear site. They are characterized by a relatively open canopy (less than 60% cover). Cultural meadows cover approximately 24% of the Darlington Nuclear site. There are many types of cultural thickets that cover approximately 14% of the Darlington Nuclear site. They are formed during early successional stages following anthropogenic disturbance. Shrubs generally comprise the bulk of the vegetation cover and include a high proportion of non-native species, refer to D-REP-07701-00001 (Reference 2.8-2) for additional information.

Marsh areas cover over approximately 0.2 km<sup>2</sup> on the Darlington Nuclear site, or 3.7% of the total area. Swamp areas are the most dominant of the Wetland Community Classes at the Darlington Nuclear site, covering approximately 0.25 km<sup>2</sup>, or 5.4% of the total Darlington Nuclear site. Swamps are characterized by the presence of wetland trees and shrubs and a low proportion of tree and shrub cover, as reported in D-REP-07701-00001 (Reference 2.8-2).

Durham Region is characterized by a variety of landscapes and communities including major lakeshore urban communities in the southern portion, and small rural towns, villages, hamlets and farm holdings in the northern portion of the region. Urban land uses are generally parallel the shoreline of Lake Ontario in the communities of Pickering, Ajax, Whitby, Oshawa and Clarington, while rural land uses are found in the communities of Brock, Scugog and Uxbridge in the northern portion of the region, all are described in D-REP-07701-00001 (Reference 2.8-2).

Urban land uses in the Municipality of Clarington, including residential, commercial, and industrial, are generally located in Courtice, located approximately 6.4 km northwest of the Darlington Nuclear site, and Bowmanville, located approximately 4 km northeast of the site. Agriculture is a predominant land use in the Municipality of Clarington and is less predominant in the City of Oshawa west of the site, per D-REP-07701-00001 (Reference 2.8-2). (Refer to Subsection 2.1.1 for recent and forecast land use data for the Municipality of Clarington and the City of Oshawa.)

#### **2.8.4 Impact of Population**

Population characteristics are relevant to the determination of the potential effects of the dispersion of material in water, air, and soil as the dispersion of radioactive and conventional contaminants affects the population surrounding the Darling Nuclear site. Relevant characteristics include population numbers, locations, ages, and critical groups.

The census data for the region used in the most recent Review of the Darlington Nuclear Site-Specific Survey, reported in NK38-REP-03443-10004 (Reference 2.8-7), are for 2016.

A population of approximately 500,000 resides within a 30 km radius of the Darlington Nuclear site, based on 2016 census data shown in Table 2.8-5. The bulk of this population (approximately 88% or 478,634 individuals) resides west of the Darlington Nuclear site, in the west-south-west to north-north-west sectors, while approximately 12% (64,575 individuals) reside east of the Darlington Nuclear site in the north to east north-east sectors. Areas south and east of the Darlington Nuclear site (south-west to east) are occupied by Lake Ontario. Only 20 residents reside within a 0 to 2 km radius of the centre of Darlington Nuclear site and approximately 99,953 individuals reside within 10 km of the Darlington Nuclear site, as documented in D-REP-07701-00001 (Reference 2.8-2).

The majority of residents in the Durham Region live in urban areas. Over 90% of the population in Pickering, Ajax, Oshawa, and Whitby resides in urban areas, whereas, the townships of Brock, Scugog and Uxbridge represent the greatest percentage of the rural population in Durham. Urban/rural population trends for Durham indicate this trend will continue into 2031, per D-REP-07701-00001 (Reference 2.8-2).

Children under the age of 15 comprised 18.0% of Durham's population in 2016, while young persons (aged 15-29), adults (aged 30-64) and older adults (aged 65+) comprised 19.2%, 49.4% and 14.4%, respectively. Ontario Population Estimates for 2018 indicate the 20 to 24 age group is the largest age group for males and 55 to 59 for females in Ontario, while in Durham Region the largest age group was 50 to 59 for males and 50 to 54 for females, refer to D-REP-07701-00001 (Reference 2.8-2).

In public dose assessments, "critical groups" are used to estimate the mean realistic impacts of emissions on the most affected individuals. The site-specific surveys identify the potential critical groups for Darlington Nuclear site. Approximately every five years the site-specific surveys and pathway analyses are reviewed to ensure the public dose accurately represents the public living near Darlington Nuclear site. Site-specific surveys were most recently reviewed in 2018 and pathway analyses were last updated in 2016. The EMP design reviews were conducted in 2018, and minor changes are implemented in 2019 which primarily affect which potential critical groups are used for reporting purposes, as documented in N-REP-03443-10027 (Reference 2.8-3).

An individual with the average characteristics of the critical group is known as the "Representative Person" as described in CSA N288.1-14 (Reference 2.8-8). Dose estimates are calculated for a number of potential critical groups for Darlington Nuclear site, and for three age classes within each potential critical group. The three age classes are 0-5 years (infant), 6-15 years (child), and 16-70 years (adult). The dose estimates to these three age groups are sufficient to characterize doses to the public. For practical implementation in dose calculations, the dose coefficients, and characteristics for a one-year-old infant, a 10-year-old child, and an adult are used to represent the three age classes. The group and age class with the highest dose is reported as the site public dose for the given in year, as described in N-REP-03443-10027 (Reference 2.8-3). (Refer to Subsection 2.9.1.2 for information on radiological dose to the public).

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Nine potential critical groups are identified for the Darlington Nuclear site. The list of potential critical groups around Darlington Nuclear site includes the following, per NK38-REP-03443-10004 (Reference 2.8-7):

1. Rural Residents
2. Oshawa/Courtice Residents
3. Bowmanville Residents
4. Local Farms
5. Local Dairy Farms
6. West-East Beach Residents
7. Darlington Provincial Park Campers
8. Sport Fisher
9. Industrial/Commercial Workers

The annual public dose is calculated for specific three potential critical groups only, which have yielded the highest dose estimates in recent years. These are the Farms, the West/East Beach Residents, and the Rural Residents, as described in N-REP-03443-10027 (Reference 2.8-3). Additionally, the annual public dose is also calculated for the local dairy farm potential critical group as the dairy farm group is exposed to the most media types and pathways.

NEDO-33951 REVISION 2

### **2.8.5 Impact of Accident Scenarios and Dispersion Models**

Accident scenarios and associated dispersion models are described in Chapter 15, Section 15.5, for Design Basis Accidents (DBAs), Design Extension Conditions (DECs) with and without core melt, as well as for irradiated fuel pool and fuel handling events for BWRX-300 site-specific application.

### **2.8.6 Impact of Biological Data**

The biological characteristics of the site were documented in the 2009 DNNP EIS, NK054-REP-07730-00029 (Reference 2.8-1), to support the original application of the Site Preparation Licence. The report includes both baseline of terrestrial flora, fauna and food chain data, as well as baseline aquatic biota and habitat, and food chain data. The biological characterization underwent a baseline update for the 2020 Site Preparation Licence renewal, which is provided in NK054-CORR-00531-10533 (Reference 2.8-9). The 2020 updated baseline conditions will not change the conclusion with respect to residual adverse effects of the on the environment nor the conclusions of the original Site Evaluation. The same conclusion is confirmed the recent 2022 EIS documented in NK054-REP-07730-00055 (Reference 2.8-10).

## 2.9 Radiological Conditions Due to External Sources

Section 2.9 details information on:

- Radiological Conditions in the Environment – Subsection 2.9.1, including
  - Radiological Baseline Conditions – Subsection 2.9.1.1
  - Radiological Dose to Public Due to Activities on DNGS Site – Subsection 2.9.1.2
- Radiation Monitoring Systems – Subsection 2.9.2, including
  - Environmental Monitoring Program – Subsection 2.9.2.1
  - TLD Monitoring – Subsection 2.9.2.2
  - Gamma Monitoring – Subsection 2.9.2.3
  - Effluent Monitoring – Subsection 2.9.2.4

Table 2.9-1 lists key characteristics and parameters for the radiological conditions due to sources external to the DNNP site.

**Table 2.9-1: DNNP Site Radiological Conditions in 2021**

Characteristic	Value/Description		
2.9.1 Radiological Conditions in the Environment			
Sources of Baseline radiation and Radioactivity	<ul style="list-style-type: none"><li>Natural background</li><li>Nuclear testing, nuclear facilities</li><li>DNGS, Tritium Removal Facility, DWMF</li></ul>		
Radiological Emissions	Small fraction of the Derived Release Limit (DRL) <ul style="list-style-type: none"><li>2016 to 2019 &lt;0.01 – 0.41% of the DRLs</li><li>In 2021 &lt;0.01 – 0.53% of the DRLs</li></ul>		
2.9.1.1 Radiological Baseline Conditions			
NOTE: The unit Bq/kg-C means becquerels per each kilogram of Carbon			
Air Samples – Concentrations	tritium	Range: 0.2 to 1.8 Bq/m <sup>3</sup>	Average: 0.87 Bq/m <sup>3</sup>
	C-14	Range: 206 to 248 Bq/kg-C	Average: 230 Bq/kg-C
	Ar-41, Xe-133, Xe-135, and Ir-192		Estimated to be below detection
Terrestrial Samples – Concentration	Average tritium	In fruits	17.8 Bq/L
		In vegetables	17.5 Bq/L
		In milk	4.3 Bq/L
		In animal feed	8.6 Bq/L
	Average C-14	In fruits	230 Bq/kg-C
In vegetables		248 Bq/kg-C	
In milk		229 Bq/kg-C	
In animal feed		236 Bq/kg-C	
Soil Sampling in 2017 (every 5 years)	<ul style="list-style-type: none"><li>Cs-137, background values (from 1.7 to 9.0 Bq/kg) are present as results of historic weapon testing and around DNGS (5.1 to 7.2 Bq/kg)</li></ul>		

**Table 2.9-1: DNNP Site Radiological Conditions in 2021**

Characteristic	Value/Description	
		<ul style="list-style-type: none"> <li>Co-60 and Cs-134, due to emission from DNGS and other nuclear sites, neither detected.</li> </ul>
Aquatic Samples – Concentration	tritium	<ul style="list-style-type: none"> <li>All nearby water Supply plants – Average is below provincial standard of 7,000 Bq/L</li> <li>Bowmanville, Newcastle, and Oshawa water supply plants, range from 4.6 to 6.6 Bq/L</li> <li>Well Water – Average 12.0 Bq/L</li> <li>Lake Water – Average 9.6 Bq/L</li> <li>Fish – Average &lt;3.4 Bq/L</li> </ul>
	C-14	<ul style="list-style-type: none"> <li>Fish – Average 243 Bq/kg-C</li> </ul>
	C-137	<ul style="list-style-type: none"> <li>Fish – Average 0.2 Bq/kg</li> <li>Sand Beach – (&lt; 0.1) to 0.2 Bq/kg</li> </ul>
	Co-60 and Cs-124	<ul style="list-style-type: none"> <li>Fish – Not detected</li> <li>Sand Beach – Not detected</li> </ul>
	Gross beta activities	All nearby water Supply plants – Average 1 Bq/L, which is below Health Canada Guideline for drinking water
<p><b>NOTES:</b></p> <ol style="list-style-type: none"> <li>In 2021 ground water monitoring program, tritium concentrations at the sampled Darlington Nuclear site perimeter groundwater locations remained low.</li> <li>In general, tritium trends over time show levels have remained nearly steady or decreased, indicating stable or improved environmental performance</li> <li>Where unexpected tritium concentrations are identified, investigations are completed to determine the root cause and to implement corrective measures.</li> <li>Ongoing results confirm that tritium in groundwater is mainly localized within the station protected area and the site perimeter tritium concentrations remain low</li> </ol>		
<b>2.9.1.2 Radiological Dose to the Public</b>		
<p>Public dose for the Darlington Nuclear site was 0.6 µSv/year (represented by the adult farm resident critical group); which is</p> <ul style="list-style-type: none"> <li>&lt;0.1% of the regulatory limit of 1,000 µSv/year for a member of the public</li> <li>&lt;0.1% of the background radiation around Darlington Nuclear site</li> </ul>		
<b>2.9.2 Radiation Monitoring Systems</b>		
<b>2.9.2.1 Environmental Monitoring Program</b>		
<b>2.9.2.1.1 Atmospheric Sampling</b>	tritium	Active samplers at six site boundary locations. Samples are collected and analysed monthly
	C-14	Monitored at four boundary locations and analysed each quarter
	Noble gases	8 detectors that monitor gamma radiation dose rate continuously

**Table 2.9-1: DNNP Site Radiological Conditions in 2021**

Characteristic	Value/Description	
2.9.2.1.2 <i>Aquatic Sampling</i>	Drinking water	Samples taken every 8-12-hour shift. Weakly composites are analysed weekly for tritium and monthly for gross beta activates
	Well water	Collected from four wells and analysed monthly for tritium
	Lake water	Sampled from two beaches and analysed monthly for tritium
	Fish	At DNGS – Muscle-tissue eight replicated target fish species are collected for tritium, C-14, Co-60, Cs-134, Cs-137, and Potassium-40 (K-40) measurements
	Sand	Samples collected from three beaches and analysed annually using gamma spectrometry to detect Cs-137
	Groundwater	81 monitoring locations are sampled each year for tritium.
2.9.2.1.3 <i>Terrestrial Sampling (tested for tritium and C-14)</i>	Fruits and Vegetables	Sampled three times from each of five locations representing the growing season
	Milk	Samples collected monthly from three dairy farms around the site
	Animal feed	Samples collected form four dairy farms with two replicates per visit. Dry feed and wet feed are collected separately
	Eggs	Sampled quarterly with three samples replicated per visit. Poultry samples collected annually with eight samples replicated per visit
<b>2.9.2.2 Thermoluminescent Dosimeter (TLD) Monitoring</b>		
Located around the site and off-site. TLD cards are analysed annually when they are changed. They are located around the DWMF fence line		
<b>2.9.2.3 Gamma Monitoring System</b>		
The automated fixed monitors provide real-time gamma dose rate measurements		
<b>2.9.2.4 Effluent Monitoring Program</b>		
Establishes surveillance and monitoring of effluents, refer to Chapter 20, Subsection 20.11.3.		

### 2.9.1 Radiological Conditions in the Environment

To characterize the potential effects of the BWRX-300 operation on the surrounding environment, the baseline conditions must first be identified, described and delineated. Baseline radiation and radioactivity in the area of the DNNP site includes:

- Natural background
- Background from anthropogenic sources (fallout from nuclear testing and releases from other nuclear sites)
- Releases from activities on the Darlington Nuclear site, including operation of the existing DNGS, Tritium Removal Facility, and DWMF

Radiological emissions from the Darlington Nuclear site, including the DWMF, represented a small fraction of the DRLs. The four-year period 2016 – 2019 emissions ranged from 0.01 to

0.41% of the DRLs, as reported in the 2020 ERA for the Darlington Nuclear site D-REP-07701-00001 (Reference 2.9-1). The 2021 emissions were from 0.01 to 0.53% of the DRLs, as noted in the annual report on the results of the EMP N-REP-03443-10027 (Reference 2.9-2).

The radiological baseline conditions were established in the 2009 DNNP Environmental Impact Statement (EIS) – DNNP Environmental Assessment (EA) NK054-REP-07730-00029 (Reference 2.9-3). Updates to the radiological baseline conditions since the 2009 EIS-EA was conducted are discussed in detail in documentation including:

- The annual EMP report N-REP-03443-10027 (Reference 2.9-2)
- The 2020 ERA for the Darlington Nuclear site D-REP-07701-00001 (Reference 2.9-1)
- The 2020 DNNP – Site Preparation Licence Renewal Activity Report – Environment NK054-REP-01210-00110 (Reference 2.9-4)
- The 2020 DNNP Supporting Environment Studies – Environment NK054-REP-01210-0001 (Reference 2.9-5)
- The 2022 DNNP EIS NK054-REP-07730-00055 (Reference 2.9-16)

The 2020 Site Preparation Licence Renewal Activity Report NK054-REP-01210-00110 (Reference 2.9-4) concludes the radiological baseline conditions have not changed since the 2009 EIS-EA, per NK054-REP-07730-00029 (Reference 2.9-3). The same conclusion is reached in the 2022 DNNP EIS NK054-REP-07730-00055 (Reference 2.9-16). Details of these conditions are summarized in the following Subsections 2.9.1.1 and 2.9.1.2.

#### **2.9.1.1 Radiological Baseline Conditions**

The radiological baseline conditions in the area surrounding the Darlington Nuclear site are discussed in detail in the annual EMP report N-REP-03443-10027 (Reference 2.9-2), which demonstrates that all levels of radionuclides monitored around the Darlington Nuclear site remained stable since 2009 NK054-REP-07730-00029 (Reference 2.9-3). A Mann-Kendall trend analysis at the 95% confidence level did not indicate any statistically significant trends over the past 10 years for tritium in any medium sampled. For C-14, a Mann-Kendall trend analysis at the 95% confidence level over the past 10 years of data either indicated a statistically significant downward trend (C-14 in air at the Darlington Nuclear site boundary, C-14 in milk at dairy farms) or did not indicate any statistically significant trends (C-14 in fruit and vegetables, and C-14 in fish). A similar analysis was not conducted for noble gas parameters, as measurements taken at the Darlington Nuclear site boundary had average dose rates that were typically below detection limits.

Summaries are presented in the following paragraphs of the results of the annual results of the EMP report N-REP-03443-10027 (Reference 2.9-2), where sampling locations are available – as shown Figure 2.9-1.

#### **Air Samples**

Samples of air are collected to monitor the environment around the Darlington Nuclear site.

1. The 2021 tritium in air annual average concentrations measured at Darlington Nuclear site boundary locations ranged from 0.2 to 1.8 Bq/m<sup>3</sup>, with an average concentration of 0.87 Bq/m<sup>3</sup>. The 2021 annual average C-14 in air concentrations measured at Darlington Nuclear site boundary locations ranged from 206 to 248 Bq/kg-C, with an average concentration of 230 Bq/kg-C.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

2. The annual boundary average noble gas dose rate is estimated from the monthly data from each detector. The Darlington Nuclear site boundary average dose rates for Ar-41, Xe-133, Xe-135, and Ir-192 are typically below the detection limits.

## **Terrestrial Samples**

Terrestrial baseline sampling is done in fruits and vegetables, milk, animal feed, eggs and poultry, and soil around the Darlington Nuclear site.

### **Fruits and Vegetables**

Fruits and vegetables, the 2021 average concentration for tritium near the Darlington Nuclear site was 17.8 Bq/L in fruits and 17.5 Bq/L in vegetables. The 2021 average concentration of C-14 was 230 Bq/kg-C in fruits and 248 Bq/kg-C in vegetables. A Mann-Kendall trend analysis of average fruit and vegetable activity at the 95% confidence level did not indicate any statistically significant trend over the past 10 years for tritiated water tritium and C-14.

### **Milk**

The 2021 average concentration of tritium was 4.3 Bq/L based on three dairy farms around the Darlington Nuclear site. The 2021 average concentration of C-14 in milk from dairy farm locations in the vicinity of the Darlington Nuclear site was 229 Bq/kg-C. A Mann-Kendall trend analysis of average milk activity at the 95% confidence level did not indicate any statistically significant trend over the past 10 years for tritium and C-14.

### **Animal Feed**

The average tritium concentration was 8.6 Bq/L for wet feed (forage). No dry feed samples were available in 2021. The average C-14 concentration in animal feed was 236 Bq/kg-C for wet feed (forage). No trend analysis was performed on animal feed since, beginning in 2013, wet feed and dry feed have been sampled separately, resulting in changes to sampling frequency and replicates.

### **Eggs and Poultry**

The concentration of tritium in eggs was 4.4 Bq/L and tritium in poultry was 10.3 Bq/L. Concentration of C-14 in eggs was 230 Bq/kg-C and in poultry was 229 Bq/kg-C. No trend analysis was performed as less than 10 years of data have been collected from sampling locations thus far.

### **Soil**

Soil is sampled every five years to identify possible radionuclide accumulation over time. The last soil sampling took place in 2017. Background values of Cs-137 are present in the soil as a result of historic weapons testing fallout. Co-60 and Cs-134, if detected, would be a result of emissions from the DNGS or other nuclear stations. In 2017, Cs-137 concentrations in background soil samples taken at provincial background locations ranged from 1.7 to 9.0 Bq/kg. All measured Cs-137 concentrations at locations around the Darlington Nuclear site in 2017 were within the range of values seen at the background locations, ranging from 5.1 to 7.2 Bq/kg. There is no indication of a buildup of activity in soil. Neither Cs-134 nor Co-60 were detected in any soil samples in 2017. Therefore, the Cs-137 measured in these soil samples is from historic weapons testing fallout and not from OPG Operations, as documented in the annual EMP report N-REP-03443-10017 (Reference 2.9-6).

## **Aquatic Samples**

Aquatic baseline sampling is done at nearby water supply plants, in well water, lake water, fish, and beach sand. As a result of the location of the Darlington Nuclear site, there are no depositional sediment locations near enough that are appropriate for sampling due to the high wave energy environment.

### Water Supply Plants

The impact of tritium emissions from OPG stations on the nearby water supply plants varies depending upon their distance from the station, lake current direction, location and depth of the water supply plant intake pipe as well as general dispersion conditions. Annual average tritium levels at all nearby water supply plants are well below the Ontario Drinking Water Quality Standard of 7,000 Bq/L. Annual average tritium concentrations measured at the Bowmanville, Newcastle, and Oshawa water supply plants in 2021 ranged from 4.6 to 6.6 Bq/L. Mann-Kendall trend analysis at the 95% confidence level does not indicate any statistically significant trend for tritium at any water supply plant near Darlington Nuclear site. Annual average gross beta activity levels at water supply plants were 0.11 Bq/L. This is well below the gross beta activity screening level of 1 Bq/L, which is a drinking water level recommended by Health Canada in the Guidelines for Canadian Drinking Water Quality: Guideline Technical Document.

### Well Water

The 2021 annual average tritium concentration observed in well water samples collected from the Darlington Nuclear site area was 12.0 Bq/L. Based on the past 10 years of data, a Mann-Kendall trend analysis at the 95% confidence level does not indicate any statistically significant trend for tritium in well water.

### Lake Water

The 2021 annual average tritium concentration observed in lake water samples collected from two beaches near the Darlington Nuclear site was 9.6 Bq/L. Based on the past 10 years of data, a Mann-Kendall trend analysis at the 95% confidence level indicates no statistically significant trend for Darlington Nuclear site tritium in lake water.

### Fish

The 2021 tritium levels in the Darlington Nuclear site diffuser fish samples averaged <3.4 Bq/L, while the annual average C-14 level in same samples was 243 Bq/kg-C. Based on the past 10 years of data, a Mann-Kendall trend analysis at the 95% confidence level does not indicate any statistically significant trend for tritium or C-14 in Darlington Nuclear site fish. Cs-134 and Co-60, which are indicative of reactor operation, were not detected in any fish samples at Darlington Nuclear site in 2021. This is similar to past years. The average Cs-137 value for fish was 0.2 Bq/kg. The presence of Cs-137 in fish is primarily due to nuclear weapons testing and not reactor operation.

### Beach Sand

The average concentration of Cs-137 measured at beaches near the Darlington Nuclear site ranged from below detection (< 0.1) to 0.2 Bq/kg in 2021. Similar to previous years, there was no Co-60 or Cs-134 detected in any of the samples.

### Groundwater

In 2021, Darlington Nuclear site completed its annual groundwater monitoring program to evaluate groundwater quality and flow across the site and to detect any emergent issues. Tritium

concentrations at the sampled perimeter groundwater locations remained low. In general, tritium trends over time show that levels have remained nearly steady or decreased, indicating stable or improved environmental performance. There have been isolated cases within the DNGS protected area where tritium concentrations have shown increases, as reported in REP-07701-00001 (Reference 2.9-1). Where unexpected tritium concentrations are identified, investigations are completed to determine the root cause and to implement corrective measures. Ongoing results confirm that tritium in groundwater is mainly localized within the station protected area and the site perimeter tritium concentrations remain low.

### **2.9.1.2 Radiological Dose to the Public Due to Activities on DNGS Site**

The radiological public dose resulting from the operation of existing facilities on the Darlington Nuclear site is calculated annually and the results are published and made available to the public in the annual report summarizing the results of the EMP, per N-REP-03443-10027 (Reference 2.9-2). The dose calculations consider all significant pathways of exposure. Such calculations use the environmental pathway and dosimetric models and parameters that are provided in CSA N288.1-14 (Reference 2.9-7). The data used in the calculations consist of measurements of radionuclides released from the facility in environmental media obtained from the results of the yearly EMP report and consider background contributions where such data are available. For pathways or radionuclides where measured environmental data are not available, the dose is modelled from measured radionuclide emissions data reported in N-REP-03443-10027 (Reference 2.9-2).

Site public dose remains a small fraction of both the annual regulatory dose limit and annual natural background radiation in the area. The results of the annual EMP report N-REP-03443-10027 (Reference 2.9-2) conclude that the 2021 public dose for the Darlington Nuclear site was 0.6  $\mu\text{Sv}/\text{year}$  (represented by the adult farm resident critical group). The Darlington Nuclear site dose is <0.1% of the regulatory limit of 1,000  $\mu\text{Sv}/\text{year}$  for a member of the public, and <0.1% of the background radiation around Darlington Nuclear site. As can be seen in the 2016-2021 EMP reports, the 2016 to 2021 public dose estimates for the critical groups are at most approximately 0.08% of the regulatory public dose limit of 1,000  $\mu\text{Sv}/\text{year}$ , and at most approximately 0.06% of the dose from background radiation (1.4 mSv/year) in the vicinity of Darlington Nuclear site.

The public dose is also reported in the Darlington Nuclear site ERA, which is routinely updated in accordance with REGDOC-3.1.1 (Reference 2.9-8). A CSA N288.6-12 (Reference 2.9-9) compliant ERA was produced for the Darlington Nuclear site in 2020 D-REP-07701-00001 (Reference 2.9-1) and included a human health risk assessment and ecological risk assessment for both radiological and non-radiological parameters and physical stressors. The ERA concluded that the Darlington Nuclear site is operating in a manner that is protective of human and ecological receptors residing in the surrounding area. No discernable health effects are anticipated due to the exposure of potential critical groups to the radiological effluent from the Darlington Nuclear site. Demonstration that the critical groups are protected implies that other receptor groups near the Darlington Nuclear site are also protected.

### **2.9.2 Radiation Monitoring Systems**

OPG's radiation monitoring systems, which are currently used for DNGS, comprise on-site, site boundary, and off-site monitoring systems. Detailed information about environmental sampling locations, sampling frequency, the number of samples taken, the media sampled, the sampling method, and the radionuclides monitored can be found in CSA N288.4 on Environmental Monitoring Programs at Nuclear Facilities and Uranium Mines and Mills (Reference 2.9-10). Summaries of four specific aspects of the radiation monitoring systems are presented as follow:

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

1. Environmental monitoring systems, including the environmental off-site and site boundary monitoring as well as samples taking and analysis – Subsection 2.9.2.1
2. The off-site and site boundary TLD sites – Subsection 2.9.2.2
3. The Automated Near Boundary Gamma Monitoring System, located around the Darlington Nuclear site boundary – Subsection 2.9.2.3
4. The site Effluent Monitoring Program – Subsection 2.9.2.4

#### **2.9.2.1 Environmental Monitoring Program**

The environmental monitoring systems and sampling programs detailed in the annual EMP report N-REP-03443-10027 (Reference 2.9-2) include off-site and site boundary monitoring and are summarized here. Samples taken are analysed at certified laboratories or laboratories with documented comprehensive quality assurance and quality control programs, in accordance with clause 8.3.2 of CSA N288.4 (Reference 2.9-10). The Canadian Association for Laboratory Accreditation certified OPG Health Physics Laboratory, and external contractors, perform the sample collection and analysis for Darlington Nuclear site and provincial EMPs, as per N-PROC-OP-0025 R012 (Reference 2.9-11). Sampling locations are shown in Figure C1 in Appendix C of N-REP-03443-10027 (Reference 2.9-2), which is replicated in Figure 2.9-1.

##### **2.9.2.1.1 Atmospheric Sampling**

Concentrations in air are sampled to monitor the environment around the Darlington Nuclear site. Tritium, C-14, and noble gases are measured and reported in N-REP-03443-10027 (Reference 2.9-2).

1. The active tritium in air sampler collects water vapor by passing air continuously at a steady rate through two molecular sieve canisters in series. The active samplers are located at six site boundary EMP monitoring locations around the Darlington Nuclear site. These samples are collected and analysed monthly.
2. C-14 in air is sampled using passive sampling technology. The passive C-14 sampler works by absorption of CO<sub>2</sub> in air into soda lime pellets exposed for a period of an annual quarter. Samples are analysed after each quarter. C-14 in air is monitored at four boundary locations for the Darlington Nuclear site.
3. External gamma radiation doses from noble gases and Ir-192 are measured using sodium iodide (NaI) spectrometers set up around the Darlington Nuclear site. There are a total of eight detectors around the Darlington Nuclear site that monitor the dose rate continuously.

##### **2.9.2.1.2 Aquatic Sampling**

Samples of drinking water sources (municipal and well water), lake water, beach sand and fish are collected to monitor the aquatic environment around the Darlington Nuclear site. Tritium, gross beta, C-14, and gamma activity are measured and reported in N-REP-03443-10027 (Reference 2.9-2).

1. Samples of drinking water are taken during each 8-12-hour shift at water supply plants that supply water to Durham Region the Bowmanville water supply plant, the Newcastle water supply plant, and the Oshawa water supply plant. Weekly composites of these samples are analysed for tritium, and monthly composites are analysed for gross beta activity.
2. Monthly well water samples are collected from four wells around the Darlington Nuclear site area. Samples are analysed monthly for tritium.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

3. Lake water for recreational use is sampled from two beaches in the vicinity of the Darlington Nuclear site on a monthly basis and analysed for tritium. It is used to assess the water immersion dose exposure pathway from swimming in lake water.
4. At the Darlington Nuclear site, fish sampling takes place over the cooling water discharge diffuser. The target fish species to be collected at Darlington Nuclear site and at background locations is White Sucker, with Brown Bullhead as the backup species. Eight replicate fish samples are collected and analysed at each location. A sample consists of the fish muscle tissue only, and excludes the head, skin, fins, and as many bones as possible. Tritium, C-14, Co-60, Cs-134, Cs-137, and Potassium-40 (K-40) measurements are performed on each fish sample.
5. Sand from three beaches around the Darlington Nuclear site is collected annually to represent a potential pathway for external dose. Eight replicates are collected per sampling location. Gamma spectrometry is performed on these samples. Beach sand samples were collected at a background location to determine the Cs-137 concentrations in sand due to atmospheric weapons test fallout.
6. Groundwater monitoring occurs of each year, with 81 groundwater monitoring locations at Darlington Nuclear site sampled in 2021 for tritium, the key parameter of concern, refer to NK38-REP-10140-10031 (Reference 2.9-12). Annual water level measurements are also conducted.

#### **2.9.2.1.3 Terrestrial Sampling**

Samples of soil, fruits, vegetables, animal feed, milk, eggs, and poultry are collected to support the public dose calculation for the Darlington Nuclear site. Terrestrial biotas receive exposure from both airborne and waterborne emissions. Tritium and C-14 are measured, per N-REP-03443-10027 (Reference 2.9-2).

1. Fruits and vegetables are sampled three times from each location for a representation of the entire growing season. Each sample is analysed for C-14 and tritium. A total of five locations for fruit and vegetable were sampled around the Darlington Nuclear site.
2. Milk sampling is used to estimate the portion of dose received from milk ingestion for the dairy farm potential critical group. Milk samples are collected on a monthly basis from dairy farms around the Darlington Nuclear site and analysed for tritium and C-14. Samples are collected from three dairy farms around the Darlington Nuclear site.
3. Locally grown animal feed is collected from four dairy farms around the Darlington Nuclear site, twice a year, with two replicates collected per visit. Since 2013, dry feed (grains, hay, etc.) and wet feed (forage) are collected separately. Animal feed is analysed for tritium and C-14.
4. Eggs are sampled on a quarterly basis and three sample replicates are collected per visit. Poultry is collected annually with eight sample replicates collected per visit. Both eggs and poultry are analysed for tritium and C-14. One farm location around the Darlington Nuclear site is sampled for eggs.

#### **2.9.2.2 Thermoluminescent Dosimeter Monitoring**

TLDs are located around the Darlington Nuclear site perimeter as well as at off-site locations. The TLDs contain field cards that passively monitor the airborne dose over the course of a year. Cards are read and analysed annually when they are changed. The net readings for the four elements from the field card readings are input to an algorithm that converts the readings into air kerma (short for Kinetic Energy Released per unit mass of Air, which is a measure of energy in

joules (J) deposited in a unit mass (kg) of air; thus, in J/kg), ambient dose equivalent and directional dose equivalent, as described in N-PROG-RA-0001 (Reference 2.9-13).

Also, TLDs are located around the DWMF fence line. The DWMF perimeter dose rates are measured and reported quarterly.

#### **2.9.2.3 Gamma Monitoring System**

The Automated Near Boundary Gamma Monitoring System, located around the Darlington Nuclear site boundary, is a fixed radiological detection and monitoring system designed to provide real-time gamma dose rate measurements, as reported in N-PROG-RA-0001 (Reference 2.9-13). Refer to Chapter 19, Section 19.3 for additional relevant information.

#### **2.9.2.4 Effluent Monitoring Program**

The Darlington Nuclear Site Effluent Monitoring Program is governed by OPG's N-STD-OP-0031 Monitoring of Nuclear and Hazardous Substances in Effluents (Reference 2.9-14). This standard establishes minimum requirements to establish an appropriate surveillance and monitoring program for nuclear and hazardous substances in airborne and waterborne effluents from operating OPG Nuclear facilities, including the DNGS, in accordance with CSA N288.5-11 (Reference 2.9-15). The effluent monitoring program is further discussed in Chapter 20, Subsection 20.11.3.

## 2.10 Site-Related Issues in Emergency Preparedness and Response and Accident Management

The information presented in Section 2.10 includes:

- General Consideration – Subsection 2.10.1
- Feasibility of Emergency Preparedness and Response – Subsection 2.10.2
- Evacuation Time Estimates and Route – Subsection 2.10.3
- Support Networks in the Vicinity of the Site – Subsection 2.10.4
- Administrative Measures with External Organizations – Subsection 2.10.5

In Table 2.10-1, a summary description is included of site-related emergency preparedness and response feasibility, relevant evacuation time estimates; supporting agencies and services; communication systems; provincial and on-site plans; and other nuclear organization.

**Table 2.10-1: Summary of DNNP Site Relevant Characteristics and Parameters**

Characteristic	Value/Description		
2.10.2 Feasibility of Emergency Preparedness and Response			
Accessibility	<ul style="list-style-type: none"><li>• Studies considered number of personnel on site, regional population change, infrastructure updates, geography, and weather patterns.</li><li>• Main entrance: Holt Road South via Energy Drive, or Highway 401, or Park Road via Highway 401 to Energy Road.</li></ul>		
DNNP Traffic Management Plan	Developed to guide site transportation demands during various phases of project, including construction		
BWRX-300 Design	<ul style="list-style-type: none"><li>• Incorporates reliable and passive safety functions with redundancy and diversity that satisfy safety goal requirements</li><li>• Informed by DSA and Probabilistic Safety Assessment (PSA) results to develop optimized accident management strategies and measures.</li></ul>		
2.10.3 Evacuation Time Estimates and Route			
Estimates	<ul style="list-style-type: none"><li>• Provides off-site emergency planners with projections on how long it may take for various emergency planning sectors and the Detailed Planning Zone (DPZ) to evacuate.</li><li>• Considered various scenarios as time of day, day of week, road restrictions, special event assemblies and weather conditions.</li></ul>		
Routes	<ul style="list-style-type: none"><li>• On-site process and travel route for site evacuations are documented in site-specific instructions, including DNNP site during various phases of the project.</li><li>• Measures to evacuate publicly accessible areas on the Darlington Nuclear site.</li></ul>		
Infrastructure	Impacted local businesses and transportation networks

### 2.10.1 General Consideration

In accordance with Subsection 4.10.2 of REGDOC-1.1.2 (Reference 2.10-17), OPG, as the licensee for the BWRX-300 facility, has established an effective DNNP Nuclear Emergency Preparedness Plan NK054-PLAN-01210-00002 (Reference 2.10-1) which is governed by OPG CNEP N-PROG-RA-0001 (Reference 2.10-2). These two plans cover aspects such as:

- Feasibility of emergency preparedness and response
- Local infrastructure for evacuation adequacy
- Availability of support networks in the vicinity of the site
- Availability of transport, communication and infrastructure external to site
- Need for administrative measures
- Roles of response organization other than OPG

Elaboration on these aspects and associated detailed information are included in the following Subsections 2.10.2 to 2.10.5.

### 2.10.2 Feasibility of Emergency Preparedness and Response

The BWRX-300 facility accessibility for OPG personnel, contractors, and response crews, as well as for the transport of any equipment necessary in an emergency, is critical for the purposes of emergency preparedness and response at the DNNP site. Such accessibility is considered by OPG in the design of the BWRX-300 facility for the construction, commissioning, operation, and decommissioning phases. In this regard, events at both the DNNP site and the existing DNGS site are considered since an event at one site may affect personnel and the emergency response at the other site. Emergency response is, therefore, considered for the entire Darlington Nuclear site. Protocols throughout the project phases are included in the DNNP Nuclear Emergency Preparedness Plan NK054-PLAN-01210-00002 (Reference 2.10-1).

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

To ensure accessibility for both off-site emergency responders and on-site personnel to and from the DNNP site, OPG conducted studies that considered estimated number of all personnel in the Darlington Nuclear site, regional population changes, infrastructure updates, geography, and weather patterns. The results of these studies are formalized into plans and reports to assist with emergency planning; primarily in, DNGS Development of Evacuation Time Estimates, per NK38-REP-03490-10133 (Reference 2.10-3), Summary Report: Site Evaluation Studies for Nuclear Installations at Darlington External Human Induced Events NK054-REP-01210-00010 (Reference 2.10-4), Darlington New Nuclear Project Traffic Management Plan NK054-PLAN-08965.4-00001 (Reference 2.10-5) and Updated Traffic Management Plan NK054-REP-07730-0969014 (Reference 2.10-20). In addition, detailed analysis of the DNNP site accessibility is noted in Site Evaluation for OPG New Nuclear at Darlington – Nuclear Safety Considerations NK054-REP-01210-00008 (Reference 2.10-6).

The main entrance to the DNNP site is per the existing entrance to the entire Darlington Nuclear site via Holt Road South in Bowmanville, Ontario. Holt Road South is accessible via Energy Drive eastbound on Highway 401 and has a direct off-exit of Highway 401 westbound. An alternate access point from westbound Highway 401 to Energy Drive is Park Road. Park Road traverses the western part of the Darlington Nuclear site, crossing 2<sup>nd</sup> Line, which then connects to Holt Road. Energy Drive west of Park Road is named Megawatt Drive. Additional detailed information on transportation networks on the Darlington Nuclear site and in the surrounding area is provided in Subsection 2.1.5.

For the purpose of Subsection 2.10.2, a generic site map displaying the Darlington Nuclear site in relation to major roadways is shown in Figure 2.10.2-1, where the area allotted to DNNP is shaded in yellow east of the DNGS area, and the DNGS exclusion zone of 914 m is shown, per D-PLAN-00120-0001 (Reference 2.10-7).

The DNNP Traffic Management Plan (Reference 2.10-5) was initiated by OPG to guide, in a safe manner, site transportation demands during various phases of the BWRX-300 facility including construction. This Traffic Management Plan assesses the impact of traffic within the vicinity of the DNNP site, in the area noted in Figure 2.10.2-2.

Chapter 15, Subsection 15.6.1 states that the specific objectives of the PSA and severe accident analysis (SAA) are to demonstrate that the BWRX-300 facility is designed with features that incorporate highly reliable and available passive safety functions with significant redundancy and diversity to comply with the safety goal requirements in REGDOC-2.5.2 (Reference 2.10-9).

Further, as described in Chapter 15, Subsection 15.1.5, DEC's are identified to aid in designing and implementing safety features (complementary design features) to mitigate the consequences of DEC's. The Severe Accident Management (SAM) program is informed by the insights of the Deterministic Safety Analysis (DSA) and results of the PSA for the development, implementation, training and optimization of accident management strategies and measures, as identified in Chapter 15 Subsection 15.6.1.

Additionally, Chapter 13, Subsection 13.4.3 discusses the programmatic approach to develop emergency operating procedures and severe accident management guidelines (SAMG) in accordance with REGDOC-2.3.2 (Reference 2.10-21).

### **2.10.3 Evacuation Time Estimates and Route**

OPG made available to off-site planning authorities a revised Darlington Site Evacuation Time Estimate, per NK38-REP-03490-10133 (Reference 2.10.3) using the 2016 National Census Data with per decade population projections out to 2088, as well as current and forecasted infrastructure.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

The estimate provides off-site emergency planners with projections on how long it may take for current emergency planning sectors and the DPZ to evacuate if required. Variables such as time of day, day of week, road restrictions, special event assemblies and weather were assessed as to how those factors may impact the evacuation duration. In the first quarter of 2023, OPG will issue an updated Darlington Site Evacuation Time Estimate based on the 2021 national census data and will subsequently be shared with stakeholders.

On-site, the process and travel route for site evacuations are described in D-INS-0349-10030 (Reference 2.10-10). The current revision of such OPG's instructions considers the DNNP site during various phases of the project. The main exit routes are via:

1. Park Road to Energy Drive to Highway 401 westbound
2. Old Holt Road, continuing onto Holt Road northbound of Highway 401 east and westbound

During an evacuation from the Darlington Nuclear site, Energy Drive will be closed, as necessary, by local police between Park Road to Holt Road to control traffic volume and delays. Additionally, procedures exist for OPG to evacuate publicly accessible areas on the Darlington Nuclear site, per INS-03490-10015 (Reference 2.10-11), including the Darlington Waterfront Trail and the Hydro Soccer Fields (refer to Subsections 2.1.7 and 2.1.8).

Local infrastructure within the vicinity of the DNNP site is described in Section 2.3, which includes local businesses, and transportation networks that are impacted by an emergency on-site in their current and future expanded state.

#### **2.10.4 Support Networks in the Vicinity of the Site**

Collaboration of OPG with local government agencies and businesses is essential to the DNNP emergency response capabilities. Shared roads, emergency services, communication networks, and transportation networks are utilized to assist with site response, evacuation, and relocation services, as required.

During construction, prior to turnover to Operations, the fire protection controls and response are primarily the responsibility of the prime contractor or constructor, per CSA N293-12 (Reference 2.10-18). Once handover to Operations occurs, OPG's own fire protection program, with its necessary updates for the BWRX-300 facility, will be in place and be compliant with CSA N293S1:21 (Reference 2.10-19).

Arrangements also exist for local ambulance service and hospital support for casualties from the Darlington Nuclear site. Toronto Hospital Corporation, Western Division, has been provincially designated and funded as the radiation trauma centre for Ontario. This includes the capability to deal with contaminated casualties, trauma, and acute radiation syndrome. Lakeridge Health—Bowmanville Hospital is the primary local hospital designated to receive contaminated casualties from DNGS. DNNP is expected to be included in this agreement, encompassed under the Darlington Nuclear site. Agreements are also in place to provide support to the site from the local police force in the event of an on-site security event (Reference 2.10-2). Subsection 2.1.4 and Subsection 2.1.6 provide, respectively, additional details on Municipal Services local to the area as well as on public transit.

To communicate with off-site emergency responders during an event, OPG currently uses Durham NEXGEN P-25 Radio system – part of the Durham Emergency Communication. As the DNNP progresses, and prior to Operations, these systems will be assessed for future use.

As noted in Chapter 9A, Subsection 9A.9.1.3, the off-site communication system is designed to satisfy emergency plan requirements for accident conditions, including notification of personnel and implementation of evacuation procedures. This capability includes communications support

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

to both on-site and off-site emergency response facilities; at least one on-site and one off-site communications system, each with a backup power source. The on-site communications involve immediate notification process and secondary communication methods to alert all on-site personnel in all vital areas during the full spectrum of accident or incident conditions under maximum potential noise levels. This capability also includes communications support for firefighting, including support of alternative and dedicated shutdown capabilities.

As noted in Subsection 2.10.2, the SAMG is informed by the insights of the DSA and results of the PSA for the development, implementation, training and optimization of accident management strategies and measures. This includes review of the existing Beyond Design Basis Accident telecommunications equipment designated for DNGS, which also are considered for DNNP and rely on external infrastructure to function.

Durham Region and the Province of Ontario manage alerting systems to let the public know when a nuclear emergency occurs. Durham Region's public alerting system includes loud sirens, located within the Automatic Action Zone of the Darlington Nuclear site and an automated landline telephone calling system. The automated telephone system sends a recorded message to landline phones in the DPZ area around the nuclear station. The Province of Ontario manages the Alert Ready system. These alerts broadcast through television, radio, and cellphones. The off-site public alerting systems are currently applicable to DNGS but expected to be utilized for DNNP. Prior to fuel-in commissioning, this will be identified as part of the revised PNERP (Reference 2.10-12).

The DNGS station has an established Potassium Iodide Program, which satisfies the requirements of the PNERP (Reference 2.10-12) and REGDOC-2.10.1 (Reference 2.10-13), both are encompassed by the CNEP (Reference 2.10-2). The program is supported by designated municipalities to ensure continued availability of Potassium Iodide to residents of the DPZ and Ingestion Planning Zone, and information is available to the general public, including on-line, as per N-GUID-03491-10011 (Reference 2.10-14). Similar to the public alerting systems, this program is currently applicable to DNGS, but expected to be utilized for DNNP. Prior to fuel-in commissioning, this will be identified as part of the revised PNERP.

The PNERP (reference 2.10-12) outlines the requirements for designated municipalities and host municipalities to include provisions for Emergency Worker Centres, Evacuation Centres, and Reception Centres in the unlikely event of an evacuation, as noted in D-INS-0349-10030 (Reference 2.10-10). OPG supports these Off-site Centres by providing personnel and resources for personal monitoring and decontamination. The current facilities applicable to the DNGS are listed in Appendix C3.4 of CNEP (Reference 2.10-12). It is to be determined whether such facilities are required for DNNP which, if so, will be reflected in a future revision of the PNERP. Additionally, OPG has two Mobile Monitoring and Decontamination Units that are poised and ready for deployment when designated by the Provincial Emergency Operations Centre (PEOC). OPG deploys on-site and off-site radiation survey teams to the area, if required.

The Joint (Emergency) Information Centres intending to disseminate Information to the media are also set up between OPG, the Province of Ontario, and local municipalities. Refer to the CNEP (Reference 2.10-2). OPG's Nuclear Crisis Communication Standard (Reference 2.10-15) provides corporate direction for assisting with site emergencies. This standard outlines how information is passed between the incident station, emergency response facilities, Corporate Media Desk, and the public domain.

There are no known issues at this time that would hinder the implementation of DNNP emergency response actions. OPG is currently working with the Province of Ontario to develop timelines for PNERP revisions to incorporate a separate implementing plan for the DNNP site or as part of the DNGS site implementing plan.

Descriptions of the development of the DNNP emergency response plan, and the emergency response facilities are detailed in Chapter 19, Sections 19.1 and 19.2, respectively.

#### **2.10.5 Administrative Measures with External Organizations**

In the Province of Ontario, Canada, the PNERP (Reference 2.10-12) provides the off-site planning basis for nuclear emergencies with the goal of ensuring public safety in the event of a nuclear emergency. The PNERP Master Plan (Reference 2.10.12) establishes the principles, concepts, organization, responsibilities, policy, functions, and interrelationships which govern all off-site nuclear emergency planning, preparation, and response in Ontario. Each nuclear facility identified in the PNERP has its own implementing plan which is site-specific in nature and deals with local characteristics, planning and operational particulars. OPG has a memorandum of understanding in place with the Province of Ontario to revise the PNERP prior to fuel-in commissioning to include DNNP and issue a revised Darlington implementing plan or a separate implementing plan for DNNP (Reference 2.10-1).

OPG continues to collaborate with the Province of Ontario and other external organizations responsible for off-site nuclear emergency planning to ensure the implementation of their respective emergency plans and related protective actions accommodate the lifecycle of BWRX-300 facility built on the DNNP site.

Other nuclear partners within Canada are requested to respond where necessary, for any assistance in a nuclear event at DNGS and DNNP, as per the existing mutual aid response memoranda of understanding.

OPG also has arrangements for support and technical assistance with the CANDU Owners Group members and INPO, a consortium of nuclear utilities, to obtain any necessary support available from the industry during an emergency. INPO operates a 24-hour emergency assistance line and an Emergency Response Centre in Atlanta, Georgia, USA, to provide support to member utilities.

Further information on external administrative assistance is provided in the Emergency Planning and Preparedness Technical Support Document: New Nuclear – Darlington Environmental Assessment NK054-REP-07730-00021 (Reference 2.10-8), and the DNNP Nuclear Emergency Preparedness Plan NK054-PLAN-01210-00002 (Reference 2.10-1).

## 2.11 Monitoring of Site-Related Parameters

Section 2.11 provides a description of the strategy for monitoring site-related parameters relevant to the DNNP site, with emphasis on the site parameters that need to be monitored for the hazards identified in Section 2.2 which affect the DNNP through the lifecycle of the BWRX-300 facility. The information in Section 2.11 satisfies the requirements of Subsection 4.5.2 of REGDOC-1.1.2 (Reference 2.11-15) and the guidance of Subsection 7.4.2 of REGDOC-2.5.2 (Reference 2.11-16).

The information in Section 2.11 covers:

- Volcanic Phenomena Monitoring – Subsection 2.11.1
- Surface Faulting Monitoring – Subsection 2.11.2
- Seismic and Geotechnical Monitoring – Subsection 2.11.3
- Meteorological Monitoring – Subsection 2.11.4
- Hydrological monitoring – Subsection 2.11.5
- Radiation Monitoring – Subsection 2.11.6
- Environmental Monitoring – Subsection 2.11.7
- Biological Organisms and Human Induced Hazards Monitoring – Subsection 2.11.8
- Long Term Monitoring Program – Subsection 2.11.9

Table 2.11-1 summarizes key DNNP characteristics and the approach for monitoring key site parameters.

**Table 2.11-1: DNNP Site Characteristics and Parameters Monitoring Approach**

Characteristic	Monitoring Approach
2.11.1 Volcanoes Monitoring	Hazard Screened out – No site-specific parameter to be monitored
2.11.2 Surface Faulting Monitoring	Hazard Screened out – No site-specific parameter to be monitored. Any changes will be evaluated within the long-term monitoring program.
2.11.3 Seismic and Geotechnical Monitoring	<ul style="list-style-type: none"> <li>• Southern Ontario Seismic Network stations on Darlington Nuclear site</li> <li>• Current site-specific information is used during construction, with monitoring of excavation and blasting effects.</li> <li>• The Foundation Interface Analysis (FIA) work in (Reference 2.11.19) is fed by the site-specific parameters reported in (Reference 2.11-20) and will be updated by monitored specific geotechnical and seismic parameters during operation.</li> <li>• In-service monitoring approach of and instrumentation for BWRX-300 structures include testing and surveillance programs for below-grade structures and foundations over their design lives</li> </ul> <p>Field instrumentation system with recordings is benchmarked against design estimates of settlement and vertical and horizontal movement around the deeply embedded RB and the foundations of the Control Building (CB), TB, and RWB</p>

**Table 2.11-1: DNNP Site Characteristics and Parameters Monitoring Approach**

Characteristic	Monitoring Approach	
2.11.4 Meteorological Monitoring	<ul style="list-style-type: none"> <li>On-site meteorological tower</li> </ul> Environment Canada maintained stations, and notification on severe weather conditions

2.11.6 Radiation Monitoring (refer to Section 2.9)	<ul style="list-style-type: none"> <li>Environmental off-site and site boundary monitoring and sampling</li> <li>Off-site and site boundary TLD sites</li> <li>Automated Gamma monitoring system</li> </ul> Effluent Monitoring Program	
2.11.7 Environmental Monitoring	Environmental Monitoring Program, detailed in Chapter 20, Subsection 20.11.2	
2.11.8 Biological Organisms and Human Induced Hazards Monitoring	Waterborne, and Airborne Hazards and Biological Organisms	Monitored and controlled in a manner to enable the continued safe operation of the BWRX-300
	Human Induced Hazards—General	Screened out based on Design Mitigation – No Site-specific parameter to be monitored
	Air Transportation activities	Hazard Screened out – No site-specific parameter to be monitored
	Chemical Explosions	Screened out based on Design Mitigation – No Site-specific parameter to be monitored
	Activities at nearby industrial and other facilities	St. Marys Cement plant seismic monitoring station
2.11.9 Long Term Monitoring Program	To be determined potential impacts of climate changes on BWRX-300 operation via long-term monitoring, review, and updates	

### 2.11.1 Volcanic Phenomena Monitoring

There are no volcanic structures or active volcanoes in the vicinity of the DNNP site. Therefore, the volcanic hazard is not a potential hazard to the DNNP site, and no site-specific parameter to be monitored for this hazard as it is screened out, as per the 2020 DNNP application to renew the Site Preparation Licence NK054-CORR-00531-10533 (Reference 2.11-2).

### 2.11.2 Surface Faulting Monitoring

There are no active surface faults or tectonic plates in the vicinity of the DNNP site. Therefore, there is no site-specific parameter to be monitored for surface faulting hazard at the DNNP site as this is screened out, as described in the 2020 NK054-CORR-00531-10533 (Reference 2.11-2). Any changes in this hazard are to be evaluated as part of the long-term monitoring program.

### 2.11.3 Seismic and Geotechnical Monitoring

Site-related parameters are monitored to account for effects from seismic or geotechnical hazards, including earthquakes. Characterization of the seismicity of the region surrounding the

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

site, using the Southern Ontario Seismic Network stations on Darlington Nuclear site, forms an essential part of the assessment of the seismic hazard.

Considering the proximity of the DNNP and DNGS sites, the updated hazard curve characterizing the seismic conditions for DNGS in the 2021 Darlington Risk Assessment NK38-REP-03611-10041 (Reference 2.11-1) is deemed applicable to the DNNP site and, thus, is to be utilized during the design and construction stages of the BWRX-300 facility.

The DNNP site-specific geotechnical considerations are discussed in Section 9.3 of the 2009 DNNP Site Evaluation of geotechnical aspects NK054-REP-01210-00011 (Reference 2.11-3). During the construction of the BWRX-300 facility, the effects of any excavation or blasting is to be monitored for their impact on the existing DNGS Power Blocks.

All permanent cut/fill slopes within the areas for DNNP site are to be instrumented and monitored regularly during and after completion of construction and during operation of the BWRX-300 facility (Reference 2.11-3). The information in NEDO-33914-A (Reference 2.11-4) identifies the BWRX-300 advanced civil construction and design approach.

The activities during construction and commissioning are to be monitored to identify the surfaces of civil structures that are exposed to soil, backfill or engineered fill, rock, and groundwater. The monitoring results are evaluated to determine susceptibility of the civil structures surfaces material to deterioration, and the ability to perform the intended design function under the anticipated conditions. An FIA is described in Section 4 of NEDO-33914-A (Reference 2.11-4), The FIA is further advanced specifically for the DNNP BWRX-300 in the 2023 NK054-REP-03500.8-00003 DNNP FIA report (Reference 2.11-19) by running analytical models which employed site-specific parameters that are reported in the 2022 geotechnical investigation and laboratory tests (Reference 2.11-20). The 2023 DNNP FIA report (Reference 2.11-19) analysed the subsurface soil and rock interface with the structures of the Power Block buildings including the deeply embedded RB, and new loads arising during the operational life of the BWRX-300, such as loads from ground motions, pressures, and from potential subsurface deformations that originate from subgrade instabilities and potential liquefaction (Reference 2.11-22). (Additional information on FIA as related to the DNNP and BWRX-300 is provided in Subsection 2.7.3.2, Subsection 2.7.3.3, and Subsection 2.7.5.1).

The in-service monitoring approach, presented in Section 3.3 of NEDO-33914-A (Reference 2.11-4) for the BWRX-300 also covers post-construction testing and in-service surveillance programs for below-grade structural members and foundation. Some of such activities include periodic examination of inaccessible areas, monitoring of groundwater chemistry, and monitoring of settlements and differential displacements. The purpose of the in-service monitoring programs is to monitor the condition of BWRX-300 structures over their design lives to ensure the credited safety functions as well as the overall structural integrity are maintained. The overall integrity of all civil structures, regardless of safety classification, is critical for plant personnel to safely maintain plant facilities during service and through decommissioning.

Additionally, DNNP will have a field instrumentation system related to the BWRX-300 deeply embedded RB. As described in NEDO-33914-A (Reference 2.11-4), field instrumentation that is beyond the current regulatory guidelines, is deployed to monitor the magnitude and distribution of pore pressure and amount of deformation during excavation, construction, loading and continuing through the BWRX-300 plant operation. The instrumentation provides recordings that are frequently benchmarked against design estimates. Short-term and long-term settlement monitoring plans are developed that can detect both vertical and horizontal movements in and around the structures, as well as differential distortion across the foundation footprint and differential settlements between the foundations of the CB, Turbine Building (TB), RWB and RB.

Free field and in-service seismic instrumentation are further discussed in Chapter 3, Subsection 3.3.1.5 as follows:

- Location and description of instrumentation – Subsection 3.3.1.5.1
- Design and installation – Subsection 3.3.1.5.2
- Maintenance and testing – Subsection 3.3.1.5.3
- Arrangement for control room operator notification – Subsection 3.3.1.5.4
- Comparison of measured and predicted responses – Subsection 3.3.1.5.5

#### **2.11.4 Meteorological Monitoring**

With respect to meteorological factors, data such as temperature, wind speed, and wind direction are required for monitoring the direction of dispersion of any potential containment release from the DNNP site to the surrounding environment. The meteorological data are used to calculate DRLs and dose to the public through off-site radiological environmental monitoring. In the event of an accidental release off-site, the meteorological factors provide data to support the CNEP N-PROG-RA-0001 (Reference 2.11-9).

The meteorological tower at the Darlington Nuclear site described in the 2009 NK054-REP-01210-00013 (Reference 2.11-5) is located just north of the site, just southeast of the intersection of Highway 401 and Holt Road (main access to the site). The tower has no significant obstructions from nearby buildings. Meteorological data available from the site consist of wind speed and direction at two heights (10 m and 50 m) and temperature at one height (10 m). Humidity, air pressure, and precipitation are currently not logged on-site by the meteorological tower. However, the information is readily available from Environment Canada stations as listed in Section 2.2.1 of the 2012 NK054-REP-01210-00016 (Reference 2.11-6). The data collected from the Darlington Nuclear site, per NK054-REP-01210-00013 (Reference 2.11-5) are used and adapted for to the DNNP site characteristics and the BWRX-300 design. The development of a DNNP on-site meteorological program progresses, tracked by CNSC commitment D-C-8, Meteorological Monitoring Station.

Additionally, notifications from Environment Canada for existing OPG facilities are received on severe weather which allow OPG to enter the severe weather emergency preparedness procedure N-PROC-RA-0095 (Reference 2.11-18).

#### **2.11.5 Hydrological Monitoring**

The assessment of the potential flood hazards at DNNP is described in the 2022 NK054-REP-02730-00001, Flood Hazard Assessment (Reference 2.1-21)

The BWRX-300 does include precipitation as a site-related parameter for monitoring and is assessed against the flooding hazard as part of the safety analysis as the detailed design progresses, as described in the 2020 Application to renew DNNP Site Preparation Licence NK054-CORR-00531-10533 (Reference 2.11-2). As noted in Subsection 2.11.4, precipitation is monitored through local Environment Canada weather stations.

Groundwater flow and groundwater hydrology were assessed as a part of the 2020 NK054-CORR-00531-10533 (Reference 2.11-2), and conditions monitoring with respect to hydrology, boreholes and wells were fitted with equipment for sampling and level monitoring purposes. Sections 3.5 and 3.6 of Volume 2 of the 2022 DNNP Geotechnical Investigation (Power Block) NK054-REP-01210-00175 (Reference 2.11-21) updated the information and database on groundwater flow and hydrostratigraphic units. Annual groundwater monitoring has occurred across the DNNP site study area since the original 2009 Site Evaluation NK054-REP-01210-

00011 (Reference 2.11.3). Additional information is presented on groundwater conditions, flow, and hydro-stratigraphy in Subsection 2.5.5 and Subsection 2.7.3.2.4. Further information on the groundwater monitoring program is provided in Chapter 20, Subsection 20.11.4.

Levels in Lake Ontario are monitored by various organizations, including the Canadian Hydrographic Service, National Oceanic and Atmospheric Administration and Environment Canada as described in Section 8.2 of the 2009 NK054-REP-01210-00012 (Reference 2.11-13). The water level of Lake Ontario is controlled by the International Joint Committee— a joint group between Canada and the USA. Additional information is presented in Subsection 2.5.2.1 on how Lake Ontario water level is monitored and regulated.

The current in Lake Ontario is also monitored using the Lake Current Monitoring System as described in the 2019 NK38-OM-61100 (Reference 2.11-10) which resides in the lake approximately 1.6 km offshore of the Bowmanville Water Supply Plant, east of Darlington Nuclear site. The Lake Current Monitoring System real-time current profile measurement system is used in the event of a radiological liquid emission from Operations that takes place on the DNNP site. The Lake Current Monitoring System consists of an Acoustic Doppler Current Profiler and a Remote System Manager base station. The data acquired from Lake Current Monitoring System is also applicable to the DNNP given it is part of the Darlington Nuclear site.

#### **2.11.6 Radiation Monitoring**

Radiation Monitoring is comprised of on-site, site boundary, and off-site monitoring systems and programs. Information on radiation monitoring is available in the following subsections:

1. The environmental off-site and site boundary monitoring systems and sampling programs (Environmental Monitoring Program) – Subsection 2.9.2.1
2. The TLDs that are located around the Darlington Nuclear site perimeter as well as at off-site locations – Subsection 2.9.2.2
3. The Automated Near Boundary Gamma Monitoring System, located around the Darlington Nuclear site boundary – Subsection 2.9.2.3
4. Site Effluent Monitoring Program – Subsection 2.9.2.4

#### **2.11.7 Environmental Monitoring**

The Darlington Nuclear Environmental Monitoring Program identifies the contaminants and physical stressors to be monitored and conducts monitoring in the environment surrounding the site. The Environmental Monitoring Program is discussed in detail in Chapter 20, Subsection 20.11.2.

#### **2.11.8 Biological Organisms and Human Induced Hazards Monitoring**

##### **2.11.8.1 Biological Organisms**

Biological hazards specific to the DNNP site are similar to those of the 2019 DNGS NK38-REP-03611-10043 (Reference 2.11-7), given the two sites proximity.

Examples of such hazards are waterborne (e.g., fish, algae, zebra-mussel, or biofouling), large animals (e.g., herds of deer) or flying birds/insects (e.g., flocks of geese). These biological hazards are monitored and controlled in a manner enabling the safe operation of the plant.

Biofouling control typically involves appropriate biomonitoring and application of appropriate biocides/antimicrobials specific to the circuits and sensitivity of the system components. The control of the biofilms is a standard operational procedure at facilities supplied by water from Lake Ontario, and accordingly this form of biofouling is manageable for the BWRX-300 using available

technology, as described in the 2009 DNNP Site Evaluation on nuclear safety considerations NK054-REP-01210-00008 (Reference 2.11-8).

Additional information on the impact of biological and animal hazards on the safe operation of BWRX-300 facility is provided in Subsection 2.2.7.1, and on potential biofouling hazard and its impact on cooling lake water supply is presented in Subsection 2.5.2.2.

#### **2.11.8.2 Human Induced Hazards**

With respect to non-malevolent human induced hazards, all events were screened out, per the 2019 Hazards Screening Analysis NK38-REP-03611-10043 R003 (Reference 2.11-7) from the need to perform a PSA. As discussed in the following subsections, human induced hazards are screened out qualitatively or quantitatively based on the design and robustness of the BWRX-300 facility. No specific parameters are to be monitored for external human induced hazards.

##### ***2.11.8.2.1 Air Transportation Activities***

As discussed in Subsection 2.2.3.1, hazards from air transportation accidents are screened out. No site-specific parameter is expected to be monitored for aircraft/flight impacts for the DNNP site. Refer to Subsection 2.2.3.1 for additional information.

##### ***2.11.8.2.2 Chemical Explosions***

The DNNP site has various shipping lanes, which carry bulk marine shipments and the Canadian National Railway which runs within the exclusion zone of the site. The probability of accidents posing significant threat to the site is low, per the 2019 NK38-REP-03611-10043 (Reference 2.11-7). Transport vehicles carrying toxic and hazardous materials (mainly gaseous) pose a threat to worker safety which is recognized in the Site Evaluation. No site-specific parameter is expected to be monitored for chemical explosions for impacts on the DNNP site. For additional information on hazards resulting from transportation accidents refer to Subsections 2.2.3.2, 2.2.3.3, and 2.2.3.4, and from stationary non-nuclear accident refer to Subsection 2.2.4.

##### ***2.11.8.2.3 Activities at Nearby Industrial and Other Facilities***

The St. Marys Cement plant is located on the east side of DNNP site, about 700 meters from the proposed BWRX-300 location. This cement plant performs blasting at the quarry that leads to shock waves in the ground that could travel up to the BWRX-300 structures. Such shock waves are monitored using vibration monitors at a seismic monitoring station on the St. Marys property boundary. The St. Marys Cement plant is also committed to comply with the agreement established with OPG, which states that the cement plant should not carry out blasts that may exceed the maximum allowable horizontal, vertical, longitudinal, and radial velocities of 3 mm/s, per the 2019 NK38-REP-03611-10043 (Reference 2.11-7). As part of the DNGS seismic hazard curve provided in the 2021 NK38-REP-03611-10041 (Reference 2.11-1) to be used also for the DNNP site, underground shock wave effects are to be addressed through the PSA. Refer to Subsection 2.2.6 for additional information.

#### **2.11.9 Long Term Monitoring Program**

The work conducted in the 2023 report on Climate Change Impact NK054-PLAN-07007-00001 (Reference 2.11-20) confirmed the low impact of climate change stipulated in Subsection 2.5.4. Such work included climate modelling and reviewed published articles to evaluate the anticipated impact of climate change on the DNNP site and surrounding area.

Long term monitoring (periodic review/update) of applicable site-specific hazards is an inherent feature of the PSA process. As per REGDOC-2.4.2 (Reference 2.11-14), the PSA models for nuclear stations are updated every 5 years, or sooner if the facility undergoes major changes and are managed by the 2021 Preparation, Maintenance and Application of Probabilistic Safety

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

Assessment N-STD-RA-033 (Reference 2.11-11). As part of this process, site-related parameters that feed into the hazard screening are revisited for new modelling methods or for any changes in the site parameters. The screening criteria for the PSA are updated every 5 years as per the 2018 OPG's Probabilistic Safety Assessment Guide N-GUID-03611-10001 (Reference 2.11-12). For cases in which data are regularly monitored at the site (e.g., wind speed or other meteorological data), and cases for which data are collected from external sources (e.g., air traffic in the vicinity of the site), the new data are assessed as part of the hazard screening for the DNGS site. A similar long-term approach is applied for the DNNP site to assess all site-related parameters for any changes.

Long term monitoring of climate change data is to be performed in accordance with REGDOC-1.1.1 (Reference 2.11-17) which requires the Site Evaluation and Site Characterization be revisited at each licensing phase to confirm it remains valid with changing environmental conditions. REGDOC-1.1.2 (Reference 2.11-15) reinforces this requirement for the Licence to Construct application and requires site characteristics be confirmed for the construction phase. REGDOC-2.5.2 (Reference 2.11-16) also requires the design of a nuclear power plant to consider all site characteristics that may affect the safety of the plant and monitoring of site-related parameters be in place throughout the lifecycle of the plant. Hazards that are applicable to the DNNP site and affected by climate change are to be monitored. Parameters associated with these climate change hazards (e.g., meteorological, lake temperature) are to be obtained from a variety of sources, including but not limited to, site-located instrumentation and local weather data. The frequency at which a climate change hazard is to be measured and analysed will depend on the nature of the hazard and its impact on the DNNP facility (e.g., nuclear safety impact, commercial impact). Climate change hazards will undergo risk assessment and where suitable will be subject to risk treatment (e.g., adaptive action or a risk monitoring plan). Where a risk monitoring plan is in place the trigger point for an adaptive action will be specified with consideration for the duration required to implement the action. The 2023 NK054-PLAN-07007-00001 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts (Reference 2.11-20) provides additional information on lifecycle considerations including long term monitoring.

## **2.12 Ongoing Work Plans**

### **2.12.1 Introduction**

Section 2.12 details information on plans to complete ongoing DNNP specific works involving geotechnical investigations, laboratory tests, analyses, and assessments to validate and update existing DNNP parameters or generate new site-specific characterizations and parameters to supplement and update existing database. Each disposition plan provides:

- Background information on the ongoing work
- The schedule and workflow by which the ongoing work is to be completed
- Risks associated with the ongoing work
- Chapter 2 sections impacted by the ongoing work
- Progress of work, including deliverables

Details of each work is provided as follows:

Subsection 2.12.2 – Foundation Interface Analysis (FIA)

Subsection 2.12.3— Site Geotechnical and Seismic Hazard Investigation Plan, which includes

- Geotechnical investigations (Power Block) and laboratory tests
- Offshore geotechnical investigation
- Site-specific Probabilistic Seismic Hazard Assessment (PSHA)
- Seismically-induced liquefaction assessment

Subsection 2.12.4— Flood Hazard Assessment

Subsection 2.12.5 – Climate Change Impact

Subsection 2.12.6 – 3-second Wind Gust Validation

Subsection 2.12.7- Winter PMP Validation

Subsection 2.12.8 – PMP Validation

The results of each completed work are incorporated into the impacted sections in Chapter 2. A summary description of each work along with the deliverables are provided in Table 2.12-1.

## **2.12.2 Foundation Interface Analysis**

### **2.12.2.1 Background**

OPG has undertaken a site-specific, non-linear FIA, to ensure the stability of structures, supporting media, soil, and rock per NUREG-800 SRP 2.5.4 guidance. The FIA results support the evaluation of the construction plan, the stability of the excavation, ground improvements and the design of excavation support systems. Also, the results of ground pressure demands on the below-grade exterior walls of the RB are used to validate ground pressure design loads. The FIA is performed with three dimensional models representing the site conditions at all project stages, including design, construction, and operation.

The schematic workplan for the FIA modelling is shown in Figure 2.12.2-1.

All relevant available reports describing ground conditions and structural details are reviewed including but not limited to: Geotechnical Investigation Factual and Interpretation Reports, NEDO 33914 Licensing Topical Report [1], and relevant nuclear standards/guidelines. The factual data are summarized and classified for each geological unit and the input parameters required for FIA numerical modelling are calculated or extracted from the laboratory and in-situ test results. The structural information such as the shoring design, construction staging, and the structure details are reviewed and summarized in our FIA interaction modelling activity.

All relevant available reports describing ground conditions and structural details are reviewed, including but not limited to:

- Geotechnical Investigation Factual and Interpretation Reports, NEDO 33914 Licensing Topical Report (Reference 2.12-1)
- Relevant nuclear standards/guidelines.

This information is used to develop the Finite Element Analysis method and 3D framework in Plaxis 3D, allowing full FIA interaction modelling.

The Technical Report is prepared based on the FIA modelling, includes the results of the FIA of the deeply embedded BWRX-300 RB and the surrounding Power Block foundations at the DNNP site. The report discusses:

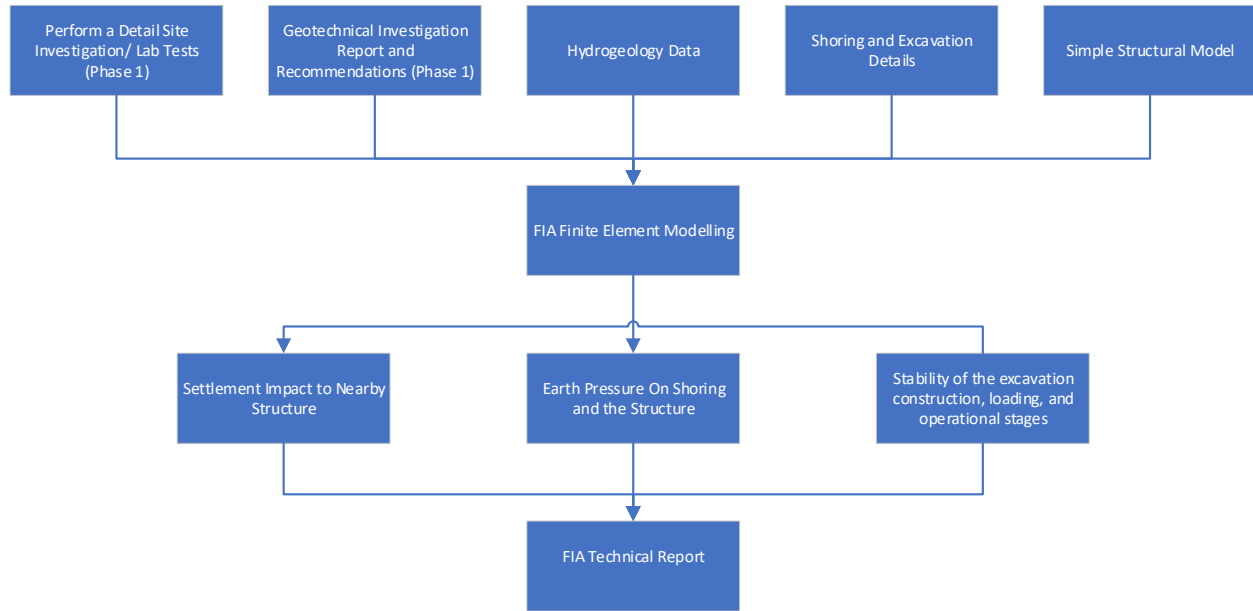

1. Effects of excavation, dewatering (based on hydrogeology report) and construction on subgrade material properties
2. Evaluations of potential for unstable rock mass or unstable blocks and wedges including the joints and sizes of the potential blocks or wedges
3. Results of the FIA of the site characterization, excavation, construction, loading, operation stages
4. Inputs and results of sensitivity FIA or additional stability analysis

### **2.12.2.2 Project Schedule and Logic**

The report concludes the results of the FIA for the deeply embedded BWRX-300 RB and the surrounding Power Block foundations at the DNNP site. The schematic workplan for the FIA modelling is shown in Figure 2.12.2-1.

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

**Figure 2.12.2-1: FIA Modelling Workflow and Deliverables**

#### **2.12.2.3 Risks**

Project timeline is dependent on DNNP confirmatory geotechnical investigation results (Laboratory Test Results and In-Site Test Results) (refer to Subsection 2.12.3). Any delays to the geotechnical investigation may cause a delay to the FIA final deliverable (Technical Report)

#### **2.12.2.4 Impacted Chapter 2 Sections**

Section 2.7 – Geology, Seismology, and Geotechnical Engineering.

#### **2.12.2.5 Progress of Work**

1. Review completed of recent reports by Golder Associates Ltd. (refer to Subsection 2.12.3) that includes site-specific results of geotechnical investigations and laboratory tests
2. Information received on shoring and excavation details from AECON
3. A simple structural model is tested and verified
4. FIA Finite Element modelling is developed
5. Technical memoranda developed, circulated for review and comments, on the following topics:
  - a. Bearing Capacity Evaluations of the BWRX-300 RB and the Surrounding Power Block Foundations at the DNNP Site
  - b. Settlement Evaluations of the BWRX-300 RB and the Surrounding Power Block Foundations at the DNNP Site
  - c. Excavation and Construction Stages of the BWRX-300 RB Shaft
  - d. FIA Numerical Modelling
6. Additional key parameters are sought and confirmed for use as input to the FIA model

7. Final report is complete

Work is complete and closed. The results are incorporated in Section 2.7.

Deliverables:

The following report was submitted by the outsourced contactor, and was reviewed and accepted by to OPG:

1. NK054-REP-03500.8-00003, 2023, "Darlington New Nuclear Project Foundation Interface Analysis (FIA) Report," Ontario Power Generation

### **2.12.3 Site Geotechnical and Seismic Hazard Investigation Plan**

#### **2.12.3.1 Background**

##### Geotechnical Program

OPG has undertaken a detailed site geotechnical program which provides information on the soil physical, mechanical, and dynamic properties of overburden and rock material. The program assesses whether there are karstic features in the local bedrock at the site. The program is linked to the existing CNSC commitment D-P-9 Site Geotechnical and Seismic Hazard Investigation (Reference 2.12-2). The schematic workplan for OPG's Geotechnical Program is shown in Figure 2.12.3-1.

The geotechnical and seismic hazard investigation program, undertaken by OPG, has primary goals to gather sufficient geological data for the proposed DNNP site, identify potential geotechnical and seismic related hazards, and perform the necessary safety evaluations, analyses, and assessments. Investigation methods used included compilation, review and evaluation of existing/historical documents, detailed geophysical and geotechnical site exploration, and extensive in-situ and laboratory testing. Each of these methods are applicable to all stages of the Site Evaluation process, but to varying extents. The main deliverables of OPG's Site Geotechnical and Seismic Hazard Investigation are as follows:

- Perform Geophysical Survey and Mapping of Subsurface Strata
- Detailed Site Investigation and Geotechnical Lab Tests
- Excavation and Stockpile / Earth Removal
- Geological Hazard Scenarios
- Liquefaction Potential Assessment
- DNNP Probabilistic Seismic Hazard Analysis
- DNNP Specific Seismic Hazard

The results of the OPG's Geotechnical and Seismic Hazard Investigation feed into Section 2.7 Geology, Seismology, and Geotechnical Engineering.

#### **2.12.3.2 Project Schedule and Logic**

OPG's Geotechnical Program for Phase 1 is demonstrated in the Project Logic of Figure 2.12.3-1. DNNP's Geotechnical and Seismic Investigations are linked to the existing DNNP CNSC commitment D-P-9 Site Geotechnical and Seismic Hazards Investigations (Reference 13-3).

#### **2.12.3.3 Risks**

Delays in completing this program may impact completing OPG work on FIA discussed in Subsection 2.12.2.

#### **2.12.3.4 Impacted Chapter 2 Sections**

Subsection 2.7.3 Geotechnical Characteristics

#### **2.12.3.5 Progress of Work**

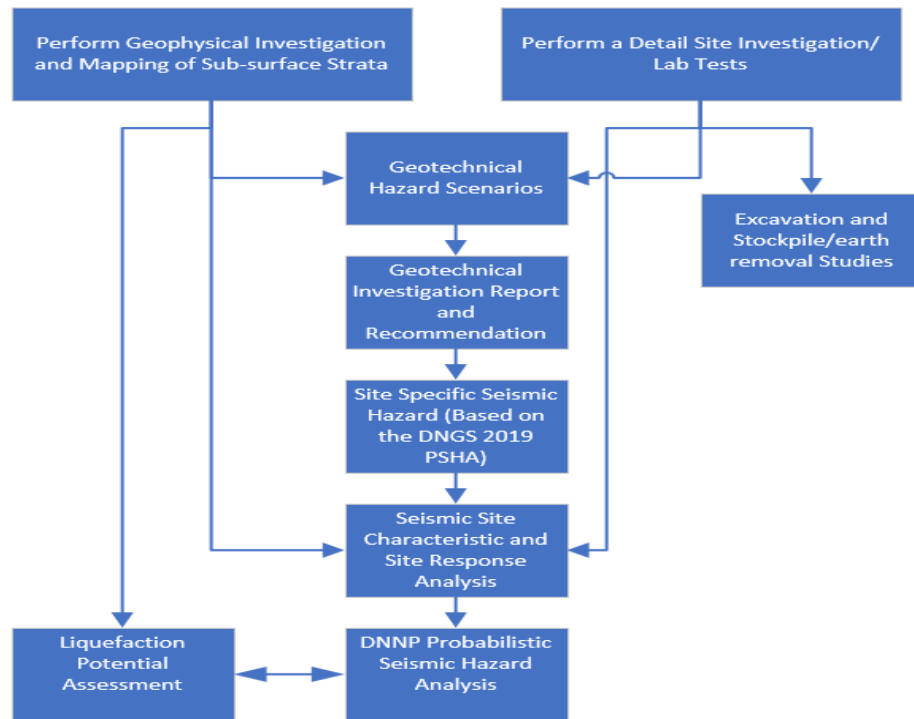

1. Completed geophysical investigation and mapping of subsurface strata
2. Completed detailed site investigation and laboratory tests
3. Drafted report on the geophysical investigation and laboratory tests as well as recommendations
4. Excavation and earth removal studies continue
5. Site-specific characteristics and site response analysis is progressing
6. DNNP PSHA is progressing
7. Liquefaction potential is being assessed and is progressing

Work is complete and closed. The results are incorporated in Section 2.7.

#### **Deliverables**

The reports were submitted by the outsourced contactor, and were reviewed and accepted by OPG:

1. NK054-REP-01210-00175 R01, (Golder 2022) "Phase I Geotechnical Investigation (Power Block) Darlington New Nuclear Project," Volumes 1 and 2, Ontario Power Generation.
2. (NK054-REP-10180-00001) Golder Associates Ltd. (Golder), 2023, Offshore Geotechnical Investigation Darlington New Nuclear Project, Revision 0.
3. NK054-REP-03500.8-00001 R00, 2022, Kinectrics Inc., K-620423/RP/0001 R01, "Darlington New Nuclear Project— Site-Specific Probabilistic Seismic Hazard Assessment," Ontario Power Generation.
4. (NK054-REP-03500.8-00002) Kinectrics Inc., K-620423/RP/0002 R00, "Darlington New Nuclear Project— Seismically-Induced Soil Liquefaction Assessment," 2022

**Figure 2.12.3-1: Workflow for the Geotechnical Program**

## **2.12.4 Flood Hazard Assessment**

### **2.12.4.1 Background**

A Flood Hazard Assessment is required for Section 2.5 Hydrology.

A previous DNNP Flood Hazard Assessment was completed (Reference 2.12-4) as part of the original Site Evaluation in 2009 included in the EIS and Licence to Prepare Site process, which reflects a site build for up to 4800 mWe of either an EPR, AP-1000, ACR or EC-6 reactor type.

The construction of a 300 mWe BWRX-300 Small Modular Reactor at the DNNP site, led to different site layout, plant grade, and topography to that previously evaluated in Reference 2.12.4. This requires an update to the Flood Hazard Assessment.

OPG has contracted an outsource to complete the Hydrological Analysis which followed a similar format to the original flood assessment covering:

- Review of existing work and data
- Completion of a gap analysis to determine if additional modelling and analysis is required
- Completion of required modelling and analysis
- Organization of information, identification of flood hazards and mitigations, meeting the requirements outlined in REG-DOC1.1.1 and IAEA Nos. NS-R-3, SSG-18, and other regulatory documents

- Identification of Flooding Hazards
- Description of DNNP Site Layout
- Assessment of Flooding Hazards
- Flood Protection
- Modification of the Flood Hazard over time
- Monitoring and Warning for Plant Protection
- Conclusions and Recommendations

#### **2.12.4.2 Project Schedule and Logic**

The following deliverables close this ongoing work:

- Draft Flood Hazard Assessment report
- Final Flood Hazard Assessment report

#### **2.12.4.3 Risks**

None.

#### **2.12.4.4 Impacted Chapter 2 Sections**

Section 2.5 Hydrology.

#### **2.12.4.5 Progress of Work**

1. Work is completed and a final report is delivered and accepted by OPG
2. OPG issued, in December 2022, the report as NK054-REP-02730-00001, "Flood Hazard Assessment," Ontario Power Generation.
3. The report has the following contents
  1. Introduction
  2. General Site Description and Characteristics
  3. Existing Site Conditions – Potential Flood Hazards
  4. Post-Development Site Layout
  5. Assessment of Flood Hazards
  6. Mitigation Measures
  7. Modification of the Flood Hazard with Time
  8. Monitoring and Warning for Plant Protection
  9. Conclusions and Recommendations
  10. References

Work is complete and the results are incorporated in impacted sections of Chapter 2

#### ***Deliverables:***

1. NK054-REP-02730-00001 R000, 2022, "Flood Hazard Assessment", Ontario Power Generation (SNC Lavalin ID 690633-0000-4HER-001 R01).

## **2.12.5 Climate Change Impact**

### **2.12.5.1 Background**

The potential effects of climate change on external natural hazards such as flooding and temperature as well as life cycle considerations including long-term monitoring programs (refer to Subsection 2.5.4, Subsection 2.6.4, Subsection 2.6.12, and Subsection 2.11.9) are linked to the existing commitment D-C-7, Contingency Plan for Flooding and Other Extreme Weather Hazards (Reference 2.12-2). To address this commitment, OPG has developed NK054-PLAN-07007-00001 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts (Reference 2.12-5), which describes the plan for fulfilling the requirements of commitment D-C-7, and consequently ensuring the DNNP facility is resilient to climate change hazards. Additional information on long term monitoring of climate change hazards is provided in Section 2.11.9.

The DNNP Strategy for addressing Climate Change Impact consists of the following three phases:

1. Phase 1 – Climate Change Risk Assessment

The purpose of this phase is to perform a climate change risk assessment for the DNNP facility to identify climate change hazards, bounding values/ranges, and vulnerable structures, systems, and components. There are two main activities in this phase, the Hazards Identification and Bounding Analysis. Hazard Identification will identify climate change related hazards that can affect DNNP site (e.g., hydrological, meteorological, etc.). Bounding Analysis report will then determine bounding values/ranges for the hazards that pose nuclear safety, commercial, or operational impacts. The values from the bounding analysis will feed into the Plant Envelope Assessment to determine which systems may be vulnerable to climate change hazards.

2. Phase 2 – Climate Change Risk Treatment

The phase analyses the design margins of vulnerable structures, systems and components and develops risk treatments as required. These risk treatments can include adaptation of the design or implementation of risk monitoring plans. The completion of Phase 2 will provide the necessary information that will comply with addressing the effects of climate change on-site.

3. Phase 3 – As Required Work

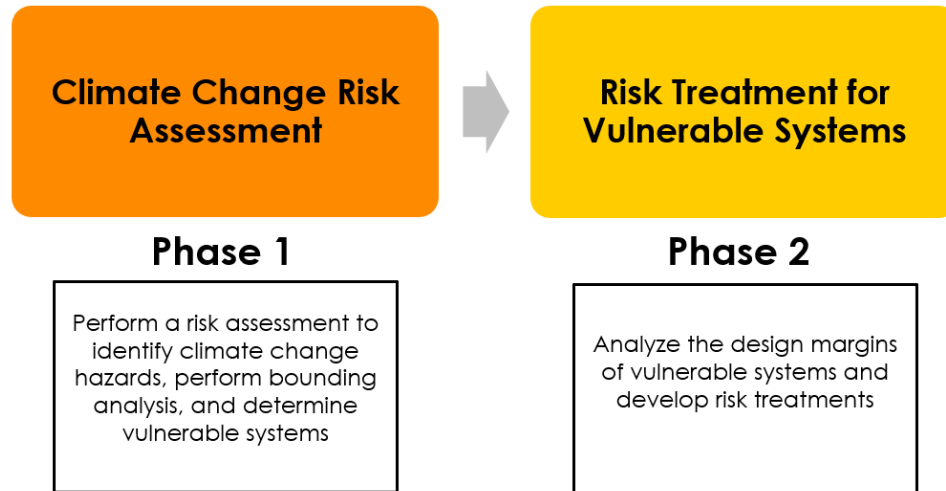

Work will be performed on an as required basis to integrate climate change assessments into the current nuclear safety framework.

The results of this work are used to confirm low impact of climate change. Where structures, systems, and components are potentially vulnerable to climate change hazards, appropriate risk treatments are developed to ensure climate change resilience is implemented within the design.

To ensure alignment with the regulator, OPG will submit three deliverables to the CNSC. The first being the 2023 NK054-PLAN-07007-00001 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts (Reference 2.12-5) which provides the CNSC a description of the proposed methodology for the close-out of commitment D-C-7. The second deliverable will be a summary report of Phase 1, which outlines the results from the Hazard Identification, Bounding Analysis, and Plant Envelope Assessment. The Phase 1 report will be submitted to the CNSC to progress closure of D-C-7. Lastly, the third deliverable will be a summary report of Phase 2, which will summarize the risk assessment of vulnerable structures, systems, and components and their risk treatment plans. The Phase 2 report will be submitted to the CNSC for closure of DNNP commitment D-C-7. CNSC feedback will be obtained on strategy and deliverables for D-C-7 prior to licence to the start of construction.

### 2.12.5.2 Project Logic

Phase 1 Climate Change Risk Assessment and Phase 2 Risk Treatment for Vulnerable Systems are to be completed in 2023. This work will be tracked according to the 2023 NK054-PLAN-07007-00001 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts to align with the closing of existing commitment D-C-7 prior to the start of construction.

**Figure 2.12.5-1: Risk Roadmap for OPG Strategy on Addressing Climate Change Impacts**

### 2.12.5.3 Risks

None.

### 2.12.5.4 Impacted Chapter 2 Sections

Subsection 2.6.2 Temperature

Subsection 2.6.4 Rainfall

Subsection 2.11.9 Long Term Monitoring Program

### 2.12.5.5 Progress of Work

OPG issued, in January 2023, the plan as NK054-PLAN-07007-0001, "Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts," Ontario Power Generation

The plan has the following contents

1. Introduction
2. Objective
3. Regulatory and Governance Drivers
4. Strategy Overview
5. Lifecycle Considerations
6. Strategy Partners
7. Definitions and Acronyms
8. References

Work is complete and results are incorporated in Subsection 2.5.4, Subsection 2.6.4, Subsection 2.6.12, and Subsection 2.11.9

Phase 1 and 2 of the 2023 NK054-PLAN-07007-0001 Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts are to be completed and tracked to the existing commitment D-C-7.

**Deliverables:**

1. (NK054-PLAN-07007-00001 R000), 2023, "Darlington New Nuclear Project Strategy for Addressing Climate Change Impacts", Ontario Power Generation.
2. NK054-REP-07007-1049426 R001, 2023, "Darlington New Nuclear Project – Hazard Bounding Analysis," Ontario Power Generation
3. NK054-REP-07007-1028871 R000, 2022, "Darlington New Nuclear Project— Gradual Climate Change and Natural Hazard Identification," Ontario Power Generation

## **2.12.6 3-Second Wind Gust Speed**

### **2.12.6.1 Background**

Chapter 2, Subsection 2.6.5 requires description of the site characteristic for 3-second wind gust speed. While maximum wind speed is an instantaneous wind speed, the 3-second gust value is a sustained wind speed. Maximum wind speed is shown in Subsection 2.6.5.

Calculation of the site characteristic for 3-second gust wind is in progress and will be added in a future revision.

### **2.12.6.2 Project Logic**

Completion of calculations is undergoing and will be updated in the subsequent revision of PSAR Chapter 2.

### **2.12.6.3 Assumptions**

None.

### **2.12.6.4 Risks**

None.

### **2.12.6.5 Impacted Chapter 2 Sections**

Subsection 2.6.5 – Wind Speed

### **2.12.6.6 Progress of Work**

1. Work is completed and a final report is delivered and accepted by OPG
2. OPG issued, in December 2022, the report as NK054-REP-02730-00003, "Wind Gust Analysis," Ontario Power Generation.
3. The report has the following contents
  1. Introduction
  2. Study Site and Data
  3. Wind Rose Diagram
  4. Frequency Analysis

5. Conclusions
6. References

Work is complete and results are incorporated in impacted sections Chapter 2

Deliverables:

1. NK054-REP-02730-00003 R000, 2022, "Wind Gust Analysis", Ontario Power Generation (SNC Lavalin ID 690633-0000-4HER-003 R01)

## **2.12.7 Snow Load and Coincident Winter Probable Maximum Precipitation**

### **2.12.7.1 Background**

Work is ongoing to finalize appropriate consideration for snow load with a Winter PMP event. DNNP considers this a review level condition.

### **2.12.7.2 Project Logic**

Completion of calculations is undergoing and will be updated in a subsequent revision of PSAR Chapter 2.

Winter PMP Validation - The requirements of N291 for safety related structures other than containment for 100 years snow loading is not mentioned nor the guidance in it to extrapolate the National Building Code of Canada (NBCC) 50-years value if the 100-years site snow values are not available. N291 mention this for the snow component, however, it is silent about associated rain.

For safety related structures, 100 years snow with 100 years associated rain would be required for the design.

It is recommended that OPG follow the General-Electric Hitachi recommendation in the Design Input Request for Non-Seismic External Hazards at DNNP Site document to determine the following site-specific parameters:

- 100-year return period ground snowpack
- Historical maximum snowpack, including the month of occurrence • 100-year return period ground snowfall
- Historical maximum ground snowfall
- 48-hour Winter PMP over a 25.9-square-kilometer (10-square-mile) area at this location during those months with the historically highest snowpacks.

The depth, area, and duration curves of the probable maximum storm event equivalent to the Winter PMP should be identified. (OPG, 2017)

The anticipated resulting roof loading will be situated in the range of 3.0-4.5 kPa.

### **2.12.7.3 Risks**

None.

### **2.12.7.4 Impacted Chapter 2 Sections**

Subsection 2.6.9 – Snow and Ice Load

### **2.12.7.5 Progress of Work**

1. Work is completed and a final report is delivered and accepted by OPG

2. OPG issued, in December 2022, the report as NK054-REP-02730-00004, "Winter PMP Validation," Ontario Power Generation.
3. The report has the following contents
  1. Introduction
  2. Existing Values
  3. Winter PMP Usage
  4. Conclusions
  5. References

Work is complete and results are incorporated in impacted sections Chapter 2

**Deliverables:**

1. NK054-REP-02730-00004 R000, 2022, "Winter PMP Validation", Ontario Power Generation (SNC Lavalin ID 690633-0000-4HER-004 R01)

**2.12.8 Confirmation of Probable Maximum Precipitation**

**2.12.8.1 Background**

Subsection 2.6.4 describes the rainfall and PMP for the Darlington Nuclear site (which includes the DNNP site). Also, Subsection 2.12.4 describes an ongoing work to update the PMP and Probable Maximum Flood for the DNNP site for BWRX-300 unit 1, with potential three additional units.

This information is being supplemented by PMP Validation work being added to Subsection 2.12.4. The supplementary work is to satisfy the requirements of N291 of 100 years return period for safety related structures (similar to wind and snow), and to ensure information in: the recommendation of 21 mm for storm H (in Table 3-1 of the contractor's preliminary report) meets the NBCC as a minimum (as NBCC value for 15 min is 23mm).

**2.12.8.2 Project Schedule and Logic**

Confirmation work is ongoing. Subsection 2.6.4 is expected to be updated, as required, in the subsequent revision of the PSAR Chapter 2.

**2.12.8.3 Assumptions**

None

**2.12.8.4 Risks**

None

**2.12.8.5 Impacted Chapter 2 Sections**

Subsection 2.6.4 – Rainfall

**2.12.8.6 Progress of Work**

1. Work is completed and a final report is delivered and accepted by OPG
2. OPG issued, in December 2022, the report as NK054-REP-02730-00002, "PMP Validation," Ontario Power Generation.
3. The report has the following contents
  1. Introduction

NEDO-33951 REVISION 2  
NON-PROPRIETARY INFORMATION

2. Storms
  - a. PMP Validation
  - b. Plant Parameter Envelop Storms
  - c. National Building Code of Canada Storms
3. Conclusions
4. References

Work is complete and results are incorporated in impacted sections Chapter 2

**Deliverables:**

1. NK054-REP-02730-00002 R000, 2022, "PMP Validation", Ontario Power Generation (SNC Lavalin ID 690633-0000-4HER-002 R01)

**Ontario Power Generation Inc.  
Darlington New Nuclear Project  
BWRX-300 Preliminary Safety Analysis Report:**

**Chapter 3  
Safety Objectives and Design Rules for  
Structures, Systems and Components**

**IMPORTANT NOTICE REGARDING CONTENTS OF THIS REPORT**

**Please Read Carefully**

The design, engineering, and other information contained in this document is furnished for the purpose of obtaining the applicable Nuclear Regulatory Authority review and determination of acceptability for use for the BWRX-300 design and licensing basis information contained herein. The only undertakings of GEH with respect to information in this document are contained in the contracts between GEH and its customers or participating utilities, and nothing contained in this document shall be construed as changing those contracts. The use of this information by anyone for any purpose other than that for which it is intended is not authorized; and with respect to any unauthorized use, no representation or warranty is provided, nor any assumption of liability is to be inferred as to the completeness, accuracy, or usefulness of the information contained in this document. Furnishing this document does not convey any license, express or implied, to use any patented invention or, except as specified above, any proprietary information of GEH, its customers or other third parties disclosed herein or any right to publish the document without prior written permission of GEH, its customers or other third parties.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

**REVISION SUMMARY**

<b>Revision #</b>	<b>Section Modified</b>	<b>Revision Summary</b>
0	All	Initial Release
1	3.0	Updated to 300 MWe.
	3.1.6.2	Included full acronym name for Reactor Pressure Vessel for first time use.
	3.1.7.4	Updated acronym use of DL1.
	3.1.7.9.2	Updated use of RPV acronym.
	3.2.1.1	Edited Safety Category 3 wording.
	3.2.1.3	Edited Primary Function wording.
	3.2.1.4	Added details to Delayed Functions.
	3.2.1.6	Updated, added text and added reference to Table 3.2-2.
	3.2.3	Included full acronym name for Design Basis Earthquake and a pointer to Section 3.3-1.
	3.2.3.1	Added CSA N289.3 reference and updated text.
	3.2.4	Updated reference to Table 3.2-3 (from Table 3.2-2).
	3.2	Added new Table 3.2-2 for Safety Class for SSC.
	Acronym List	DGRS and NBC acronyms added.
	3.3	Updated pointer to Subsection 3.3.7.4
	3.3.1 – 3.3.7	Cross-references to Chapter 2 updated as required.
	3.3.1.1, 3.3.1.1.1-3.3.1.1.4	Updated to incorporate bounding information previously documented in Chapter 2, Section 2.7.
	3.3.1.1.6	Updated content on development of dynamic subgrade profiles and included pointer to Subsection 3.5.2.2.
	3.3.2.1 – 3.3.2.5	Updates made to decouple from Chapter 2 and present bounding design parameters.
	3.3.6.1	Removed reference to Chapter 19 for Fire Protection Program.
	3.3.8	References 3.3-12 to 3.3-20 and 3.3-26 and 3.3-28 added.
	Table 3.3-1	Added reference to CSA N289 series for basis.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

Revision #	Section Modified	Revision Summary
	Table 3.3-2 to 3.3-5	Tables added to supplement added bounding information content in 3.3.1.1.1 – 3.3.1.1.4.
	Figure 3.3-1, 3.3-2, 3.3-5, 3.3-12	Figures added to supplement added bounding information content in 3.3.1.1.1 – 3.3.1.1.4.
	3.4.1.1	Removed reference to Chapter 19 for Fire Protection Program.
	3.4.4	Rephrased reference to areas where postulated pipe breaks are excluded to indicate future analyses are required.
	3.4.4.2.2	Edited Location of Postulated Pipe Break subsection.
	3.4.4.2.3	Edited Location of Postulated Pipe Crack subsection.
	3.5.1, 3.5.2.7 and 3.5.4.1	Reference to NEDC-33926P added.
	3.5.2.2	Revised to incorporate bounding information previously documented in Chapter 2, Section 2.7. Additional text added regarding upper bound nominal water table levels.
	3.5.2.2.1	Bounding Equivalent Subgrade Static Profile Subsection updated.
	3.5.2.2.3	Edited to remove content covered in 3.5.2.2.1.
	3.5.4 and 3.5.4.4.1	Updated containment internal structure descriptions included.
	3.5.5.2.1	Pointer to Design Basis Threat subsection revised.
	3.5.5.4.1	Seismic and Extreme Wind sub-heading revised.
	3.5.7	References 3.5-11, 3.5-12 and 3.5-14 through 19 added to supplement Subsection 3.5.2.2 and 3.5.2.2.1 added information.
	Table 3.5-1 and 3.5-2	Tables added to supplement content update in 3.5.2.2.1.
		Minor editorial updates throughout.
	3.6.3.12	Safety Class 1 updated to Safety Category 1
	3.6.7.2.5	Editing Safety Category wording.
	3.9.2	Updated scope for DEC assessments.
	3.9.3.1	Added RD-2.5.2 reference and updated seismic categorization text.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

Revision #	Section Modified	Revision Summary
	3.9.3.2	Seismic interaction equipment details removed.
	3.9.3.2.1	Seismic test details added and edits made.
	3.9.3.3	Section 3.3.1.3 pointer added.
	3.9.3.5	Renamed from Seismic Margin to Beyond Design Basis Earthquake and updated content.
	3.9.4.1	Revised content and included additional references.
	3.9.4.4.1	Revised content including DBA groupings.
	Minor editorial updates made including Safety Class 1 updated to SC1 throughout	
	Table 3.12-1	SSC classification table updated to include the latest information (Radiation Monitoring Systems, Wide range pool level instrumentation, Leak detection equipment updated).
	Sections 3.13 – 3.18	Appendices 3B – 3G identifying and describing computer software have been updated to align with the latest information. Where there is a discrepancy identified between software version numbers in these appendices and other PSAR chapters, this appendix should be taken as correct.
	Appendix 3C	Title updated.
	Section 3.14	Introduction description of scope edited.
	Appendix 3D	Title updated.
	Section 3.15	Introduction description of scope edited.
	Appendix 3E	Title updated.
	Section 3.16	Introduction description of scope edited.
	Sections 3.16.18 and 3.17.10	Computer code descriptions updated.
	Appendix 3F	Title updated.
	Section 3.17	Introduction description of scope edited.
	Editorial changes made throughout.	

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

**ACRONYM LIST**

<b>Acronym</b>	<b>Explanation</b>
AC	Alternating Current
AEF	Annual Exceedance Frequency
ALARA	As Low As Reasonably Achievable
ALWR	Advanced Light Water Reactor
ANS	American Nuclear Society
ANSI	American National Standards Institute
AOO	Anticipated Operational Occurrence
API	American Petroleum Institute
ARS	Acceleration Response Spectra
ASCE	American Society of Civil Engineers
ASME	American Society of Mechanical Engineers
ATH	Acceleration Time History
ATWS	Anticipated Transient Without Scram
AWWA	American Water Works Association
BDBA	Beyond-Design Basis Accident
BDBE	Beyond-Design Basis Earthquake
BDBT	Beyond-Design Basis Threat
BE	Best Estimate
BIS	Boron Injection System
BPVC	Boiler and Pressure Vessel Code
BWR	Boiling Water Reactor
BWRX	Boiling Water Reactor, 10th Design
CB	Control Building
CAD	Computer-Aided Design
CCF	Common Cause Failure
CAFTA	Computer Aided Fault Tree Analysis
CANDU	CANada Deuterium Uranium
CB	Control Building
CEPSS	Containment Equipment and Piping Support Structure
CGD	Canadian Geodetic Datum
CIV	Containment Isolation Valve

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
CLE	Checking Level Earthquake
CNSC	Canadian Nuclear Safety Commission
CPR	Critical Power Ratio
CR	Control Room
CRD	Control Rod Drive
CSA	Canadian Standards Association
CUW	Reactor Water Cleanup System
CWS	Circulating Water System
D-in-D	Defence-in-Depth
DBA	Design Basis Accident
DBE	Design Basis Earthquake
DBT	Design Basis Threat
DCIS	Distributed Control and Information System
DEC	Design Extension Condition
DGRS	Design Ground Response Spectrum
DL3	Defense Line 3
DL	Defense Line
DNGS	Darlington Nuclear Generating Station
DNNP	Darlington New Nuclear Project
ECCS	Emergency Core Cooling System
EPRI	Electric Power Research Institute
EQ	Environmental Qualification
FE	Finite Element
FIA	Foundation Interface Analysis
FIRS	Foundation Input Response Spectra
FMCRD	Fine Motion Control Rod Drive
FMEA	Failure Modes and Effects Analyses
FPC	Fuel Pool Cooling and Cleanup System
FSF	Fundamental Safety Function
FW	Feedwater
GEH	GE-Hitachi Nuclear Energy
GMRS	Ground Motion Response Spectra

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
GUI	Graphical User Interface
HCLPF	High Confidence of Low Probability of Failure
HCU	Hydraulic Control Unit
HELB	High Energy Line Break
HEPA	High Efficiency Particulate Air
HFE	Human Factors Engineering
HRA	Human Reliability Analysis
HVAC	Heating, Ventilation and Air Conditioning
I&C	Instrumentation and Control
IAEA	International Atomic Energy Agency
IC	Isolation Condenser
ICS	Isolation Condenser System
IEC	International Electrotechnical Commission
IEEE	Institute of Electrical and Electronics Engineers
ILRT	Integrated Leak Rate Test
ISRS	In-Structure Response Spectra
LB	Lower Bound
LL	Live Load
LMP	Licensing Modernization Program
LMS	Lumped Mass Stick
LOCA	Loss-of-Coolant Accident
LOOP	Loss-of-Offsite Power
LOPP	Loss of Preferred Power
LR	Lower Realization
LS	Level Switch
LWR	Light Water Reactor
MAAP	Modular Accident Analysis Program
MAPE	Mean Annual Probability of Exceedance
MCA	Main Condenser and Auxiliaries
MCNP	Monte Carlo N-Particle
MCR	Main Control Room
MS	Main Steam

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
NBC	National Building Code of Canada
NPP	Nuclear Power Plant
NSCA	Nuclear Safety and Control Act
NS-DBE	Non-Seismic Design Basis Earthquake
OBE	Operating Basis Earthquake
OLC	Operational Limits and Conditions
OPG	Ontario Power Generation
P&ID	Piping and Instrumentation Diagram
PAM	Post-Accident Monitoring
PBIRS	Performance Based Intermediate Response Spectra
PBSRS	Performance Based Surface Response Spectra
PCW	Plant Cooling Water System
PIE	Postulated Initiating Event
PLSA	Plant Services Area
PMF	Probable Maximum Flood
PRA	Probability Risk Assessment
PSA	Probabilistic Safety Assessment
PSAR	Preliminary Safety Analysis Report
PSHA	Probabilistic Seismic Hazard Assessment
QA	Quality Assurance
RAM	Reliability, Availability, and Maintainability
RB	Reactor Building
RBV	Reactor Building Vibration
RCS	Reactor Coolant System
RG	Regulatory Guide
RIV	Reactor Isolation Valve
RPV	Reactor Pressure Vessel
RWB	Radwaste Building
SC	Safety Class
SC1	Safety Class 1
SC2	Safety Class 2
SC3	Safety Class 3

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
SCCV	Steel-plate Composite Containment Vessel
SCN	Non-Safety Class
SCR	Secondary Control Room
SDC	Seismic Design Category
SDE	Site Design Earthquake
SEI	Structural Engineering Institute
SIL	Safety Integrity level
SIR	Seismic Interface Restraint
SIT	Structural Integrity Test
SMAMP	Structures Monitoring and Aging Management Program
SMR	Small Modular Reactor
SPSA	Seismic Probabilistic Safety Assessment
SRA	Site Response Analysis
SRSS	Square-Root-of-the Sum of the Squares
SSC	Structures, Systems, and Components
SSI	Soil-Structure Interaction
SSSI	Structure-Soil-Structure Interaction
TB	Turbine Building
TBD	To Be Determined
TBV	Turbine Bypass Valve
TCV	Turbine Control Valve
TRACG	Transient Reactor Analysis Code General Electric
UB	Upper Bound
UHRS	Uniform Hazard Response Spectrum
UL	Underwriters Laboratory
UR	Upper Realization
USNRC	U.S. Nuclear Regulatory Commission
V/H	Vertical to Horizontal
ZPA	Zero Period Acceleration

## TABLE OF CONTENTS

<b>3.0</b>	<b>SAFETY OBJECTIVE AND DESIGN RULES FOR STRUCTURES, SYSTEMS, AND COMPONENTS.....</b>	<b>3-1</b>
3.1	General Safety Design Basis .....	3-1
3.1.1	Safety Objectives .....	3-1
3.1.2	Radiation Protection and Radiological Acceptance Criteria.....	3-2
3.1.3	Plant States Considered in the Design Basis .....	3-3
3.1.4	Prevention and Mitigation of Accidents .....	3-5
3.1.5	Fundamental Safety Functions .....	3-5
3.1.6	Defence-in-Depth .....	3-6
3.1.7	Application of General Design Requirements and Technical Acceptance Criteria .....	3-12
3.1.8	Practical Elimination.....	3-17
3.1.9	Safety Margins and Avoidance of Cliff-Edge Effects.....	3-18
3.1.10	Design Approaches for the Reactor Core and for Fuel Storage .....	3-18
3.1.11	Considerations of Interactions Between Multiple Units .....	3-20
3.1.12	Design Considerations for Ageing Management.....	3-20
3.1.13	References.....	3-21
3.2	Classification of Structures, Systems and Components .....	3-26
3.2.1	Safety Classification Background.....	3-26
3.2.2	Safety Classification Process.....	3-29
3.2.3	Seismic Categories .....	3-30
3.2.4	Quality Group .....	3-31
3.2.5	References.....	3-32
3.3	Protection Against External Hazards .....	3-38
3.3.1	Seismic Design .....	3-38
3.3.2	Extreme Weather Conditions .....	3-75
3.3.3	Extreme Hydrological Conditions .....	3-77
3.3.4	Aircraft Crash .....	3-78
3.3.5	Missiles .....	3-78
3.3.6	External Fires, Explosions and Toxic Gases.....	3-80
3.3.7	Other External Hazards .....	3-81
3.3.8	References.....	3-82
3.4	Protection Against Internal Hazards.....	3-120
3.4.1	Internal Fires, Explosions and Toxic Gases.....	3-120

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

3.4.2	Internal Flooding .....	3-124
3.4.3	Internal Missiles .....	3-124
3.4.4	Pipe Breaks.....	3-125
3.4.5	Other Internal Hazards.....	3-135
3.4.6	References.....	3-136
3.5	General Design Aspect for Civil Engineering Works of Seismic Category Buildings and Civil Engineering Structures .....	3-138
3.5.1	General Design Principles for Seismic Category A Structures .....	3-139
3.5.2	Foundations .....	3-144
3.5.3	Containment.....	3-148
3.5.4	Containment Internal Structures .....	3-154
3.5.5	Reactor Building.....	3-156
3.5.6	Robustness Design of Seismic Category A Structures .....	3-160
3.5.7	References.....	3-164
3.6	General Design Aspects for Mechanical Systems and Components.....	3-180
3.6.1	Special Topics for Mechanical Components .....	3-184
3.6.2	Dynamic Testing and Analysis of Systems, Components, and Equipment.....	3-187
3.6.3	Codes for ASME BPVC Section III Division 1, Class 1, 2 and 3 Components, Component Supports and Core Support Structure.....	3-190
3.6.4	Control Rod Drive System .....	3-201
3.6.5	Reactor Pressure Vessel Internals .....	3-202
3.6.6	Functional Design, Qualification and In-service Testing Programs for Pumps, Valves, and Dynamic Restraints .....	3-202
3.6.7	Piping Design .....	3-202
3.6.8	Threaded Fasteners – Codes for ASME BPVC Section III Division 1 Class 1, 2, and 3 .....	3-211
3.6.9	References.....	3-212
3.7	General Design Aspects for Instrumentation and Control Systems and Components.....	3-227
3.7.1	Performance .....	3-227
3.7.2	Design for Reliability .....	3-227
3.7.3	Independence .....	3-227
3.7.4	Qualification .....	3-227
3.7.5	Verification and Validation .....	3-227
3.7.6	Failure Modes .....	3-227

### 3.0 SAFETY OBJECTIVE AND DESIGN RULES FOR STRUCTURES, SYSTEMS AND COMPONENTS

This chapter introduces the safety objectives and the Safety Strategy to meet those objectives for the design and construction of the Boiling Water Reactor, 10th Design – 300 MWe (BWRX-300) Small Modular Reactor (SMR) facility at the Darlington site in Ontario, Canada.

Additionally, this chapter describes the methodology for classification of Structures, Systems, and Components (SSC), the design measures for protection against external and internal hazards, the general design aspects, and codes and standards applied to the BWRX-300 design to meet the requirements of the Nuclear Safety and Control Act (NSCA) and associated Canadian Nuclear Safety Commission (CNSC) Regulations and relevant Regulatory Documents.

#### 3.1 General Safety Design Basis

The overall safety philosophy for the design of the BWRX-300 is referred to as the Safety Strategy. The objective of the Safety Strategy is to establish a design with a high level of safety. This is accomplished through incorporation of design requirements as set forth in CNSC REGDOC-2.5.2, (Reference 3.1-1) which to a large degree are based on the principles set forth in the International Atomic Energy Agency (IAEA) document SSR-2/1 (Reference 3.1-2).

The establishment of the BWRX-300 design basis is achieved through an iterative safety framework wherein the design is implemented to meet defined safety objectives and safety goals that are confirmed via deterministic and probabilistic safety analyses. Results of safety analyses then provide feedback into the design and the process is repeated as required until adequate design and regulatory safety margins are achieved.

##### 3.1.1 Safety Objectives

In CNSC REGDOC-2.5.2 Section 4 (Reference 3.1-1), the CNSC endorses the safety objectives established by the IAEA Safety Standards Series No. SF-1, Fundamental Safety Principles (Reference 3.1-3) which when followed ensure that reactor facilities are operated, and activities conducted to achieve the highest standards of safety that can be reasonably achieved. These safety objectives are described below:

**General Nuclear Safety Objective:** Reactor facilities are designed and operated in a manner that will protect individuals, society, and the environment from harm by establishing and maintaining effective defences against radiological hazards due to ionizing radiation. The general nuclear safety objective is supported by the following three complementary safety objectives:

1. **Radiation Protection Objective:** Radiation exposures within the reactor facility during normal operations, during anticipated operational occurrences or due to any planned release of radioactive material from the reactor facility are kept below prescribed limits and As Low As Reasonably Achievable (ALARA). Provisions are made for the mitigation of the radiological consequences of accidents.
2. **Technical Safety Objective:** All reasonably practicable measures are taken to prevent accidents in the reactor facility and to mitigate the consequences of events should they occur.
3. **Environmental Protection Objective:** All reasonably practicable mitigation measures to protect the environment during the operation of a reactor facility and to mitigate the consequences of an accident are provided. The design includes provisions to control, treat and monitor releases to the environment and minimize the generation of radioactive and hazardous wastes.

The high-level safety objectives inform the principal safety objectives in the design and safety analyses.

### **3.1.2 Radiation Protection and Radiological Acceptance Criteria**

#### **3.1.2.1 Radiation Protection**

The BWRX-300 is designed to meet the Radiation Protection Objective by ensuring that potential radiation dose to workers and the public is kept below prescribed regulatory limits per the Radiation Protection Regulations (Reference 3.1-4) and ALARA.

This is achieved by a comprehensive and appropriately conservative source term derivation identifying radiation sources during the design phase to ensure means are provided to reduce occupational exposure during plant operation, maintenance, and decommissioning.

Safety features and measures include:

- Passive engineered safety features
- Active engineered safety features
- Administrative safety measures

Engineered safety features include shielding, containment, ventilation, remote handling, and interlocks. Administrative safety measures that reduce exposure to the hazard during planned operations include restrictions on occupancy, monitoring arrangements, pre-planning of exposure and the use of barriers and notices. Passive engineered safety measures (e.g., containment or shielding) are preferred before active engineered safety features and administrative safety measures. Human factors considerations are incorporated into the engineered and administrative measures (See Chapter 18 for details).

System design evaluations are performed in parallel with other activities to ensure systems support operational objectives. These evaluations include the development of reasonable and practical measures to achieve minimal dose to workers and the public.

Details on how radiation protection is considered in the design for operational states and accident conditions are provided in Chapter 12.

#### **3.1.2.2 Radiological Acceptance Criteria**

Limits on radiation dose are established by the CNSC through the Radiation Protection Regulations (Reference 3.1-4). The expectation established is that during normal operation, including maintenance and decommissioning, dose to workers and the public are ALARA.

Per CNSC Radiation Protection Regulations (Reference 3.1-4), the effective dose limit for a nuclear energy worker is an average of 20 mSv effective dose per year over a five-year period (100 mSv over five consecutive years), with no single year exceeding 50 mSv effective dose. The effective dose limit for a member of the public is 1 mSv per year from all sources of radiation other than natural background and medical exposures. Additional details are provided in Reference 3.1-4.

In addition to design features, administrative measures such as radiation protection and environmental protection programs are established to ensure worker and public dose is maintained below limits. Action levels are established for effluent releases and expressed in a form that compliance can be demonstrated in a practical manner. These action levels are not limiting but, are values at which actions must occur to reduce the effluent releases from the plant. Chapter 20 discusses Effluent Dose Levels to the General Public.

Deterministic safety analyses are conducted in accordance with CNSC REGDOC-2.4.1 (Reference 3.1-5) to confirm that the BWRX-300 is designed to ensure that potential radiation doses to the public from Abnormal Operating Occurrences (AOOs) and Design Basis Accidents (DBAs) (defined in Subsection 3.1.3) do not exceed dose acceptance criteria per Section 4.2.1 of CNSC REGDOC-2.5.2 (Reference 3.1-1). In the deterministic safety analysis, the committed whole-body dose for average members of the critical groups who are most at risk, at or beyond the site boundary, is calculated for a period of 30 days after the analyzed event to confirm that for AOOs and DBAs, doses are less than or equal to the following:

- 0.5 millisievert (mSv) for any AOO or
- 20 mSv for any DBA

Chapter 15, Subsection 15.3.1, describes the dose calculation methodology used in the deterministic safety analysis. Results of the analyses are summarized in Section 15.7 demonstrating that the radiological consequences of the analyzed events do not exceed the acceptance criteria for AOOs and for DBAs.

### 3.1.2.3 Safety Goals

In addition to the deterministic dose acceptance criteria, Probabilistic Safety Analysis (PSA) is used to assess risks posed by reactor facility operation through the application of quantitative safety goals. These include core damage frequency, and small and large release frequency.

Core damage frequency is a measure of the capability of the design to prevent an accident that leads to core damage. Small release frequency and large release frequency are measures of the plant's accident mitigation capabilities. They also represent measures of risk to society and to the environment due to the operation of reactor facilities. The quantitative goals as established by CNSC REGDOC-2.5.2, Section 4.2.2 (Reference 3.1-1) are:

- **Core damage frequency** - The sum of frequencies of all fault sequences that can lead to significant core degradation shall be less than 1E-5 per reactor-year.
- **Small release frequency** - The sum of frequencies of all fault sequences that can lead to a release to the environment of more than 1E15 becquerels of Iodine-131, shall be less than 1E-5 per reactor-year.
- **Large release frequency** - The sum of frequencies of all fault sequences that can lead to a release to the environment of more than 1E14 becquerels of Cesium-137 shall be less than 1E-6 per reactor-year.

The PSA is described in detail in Chapter 15, Section 15.6, Probabilistic Safety Analyses.

### 3.1.3 Plant States Considered in the Design Basis

The range of conditions and events considered are categorized into plant states based on their frequency of occurrence. Plant states include operational states and accident conditions. Operational states included in the design basis are Normal Operation and AOOs. Accident conditions considered in the design basis are DBAs. Design Extension Conditions (DECs) are accident conditions considered in the design but are outside of the design basis based on their lower expected frequency of occurrence.

These four plant states considered in the BWRX-300 Safety Strategy as described below are consistent with CNSC REGDOC-2.5.2, Section 7.3 (Reference 3.1-1):

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

- **Normal Operation** is operation within specified Operational Limits and Conditions (OLCs) (see Chapter 16) and includes the following Normal Plant Operational Modes: Power Operation, Startup, Hot Shutdown, Stable Shutdown, Cold Shutdown, and Refueling. (The normal plant operating modes are described in Chapter 16).
- **Anticipated Operational Occurrences** are deviations from normal operation that are expected to occur at least once during the operating lifetime of the reactor facility but that, with the appropriate design measures, do not cause any significant damage to safety class components, or lead to accident conditions.
- **Design Basis Accidents** are conditions for which a reactor facility is designed according to established design criteria, and for which damage to the fuel and the release of radioactive material are kept within regulated limits.
- **Design Extension Conditions** are postulated accident conditions that are less frequent than DBAs. DECAs are a subset of beyond-design-basis accidents (BDBA), and are therefore, not part of the design basis. DECAs are considered in the design process of the facility in accordance with best-estimate methodology DECAs can occur without core damage or with core damage where releases of radioactive material are reasonably contained and kept within acceptable limits.

BDBAs other than DECAs are accidents for which confinement of radioactive materials cannot be reasonably achieved. These are referred to as severe accidents and involve a catastrophic failure, core damage, and fission product release. A severe accident is generally considered to begin with the onset of core damage.

Representative DECAs with core damage are postulated to provide inputs for the design of the containment and of the safety features ensuring containment functionality. This set of accidents is considered in the design of corresponding safety features for DECAs and represents a set of bounding cases that envelope other severe accidents with more limited degradation of the core.

These accidents scenarios are considered for practical elimination as described in Subsection 3.1.8.

Events are assigned to a plant state based on the expected frequency of the fault sequence, which includes a Postulated Initiating Event (PIE) and, in some cases, additional failures of mitigating functions. As described in CNSC REGDOC-2.5.2, Section 7.4 (Reference 3.1-1), PIEs are the events that lead to deviations from normal operation. PIEs originate from operating errors, equipment failures, or internal or external hazard of natural or human origin.

Frequency ranges for plant states are:

- AOO (greater than 1E-02 per reactor-year)
- DBA (1E-02 to 1E-05 per reactor-year)
- DEC (less than 1E-05 per reactor-year)

The design requirements of SSC are developed to ensure that the plant is capable of meeting applicable requirements for each plant state. This is demonstrated through safety analyses as described in Chapter 15.

The facility is operated, monitored, and maintained within safe operating configurations or is transitioned to a safe operating configuration in accordance with operating procedures that are consistent with the design. (See Chapter 13, Section 13.4 for details.)

Acceptance criteria are assigned to each plant state in the design, considering the principle that frequent fault sequences have only minor or no radiological consequences, and that any fault sequences that may result in severe consequences are of extremely low probability.

For normal operating modes, the OLCs serve as acceptance criteria as they are the set of limits and conditions within which the facility must be operated to ensure it is operated safely. OLCs are established as discussed in Chapter 16.

For each AOO and DBA fault sequence, acceptance criteria are defined and met to confirm the effectiveness of plant systems in maintaining the integrity of physical barriers against releases of radioactive material. These acceptance criteria are discussed and summarized in Chapter 15, Section 15.3.

For DEC fault sequences, the safety objectives are to prevent significant core damage, mitigate accident consequences, and protect containment integrity. These objectives are demonstrated in PSA by showing that the plant meets the established safety goals (described in Subsection 3.1.2.3). (PSA is described in detail in Chapter 15, Section 15.6.) Also, it is demonstrated that procedures and equipment put in place to handle accident management needs are effective in responding to DEC. This is accomplished through the operating procedures described in Chapter 13 and through complementary design features described in Chapter 15, Appendix 15B.

The general approach to defining the design basis for the BWRX-300 involves establishing the plant states described above, identifying the PIEs leading to a deviation from normal operation and categorizing mitigating functions based on their ability to prevent and mitigate the progression of events ensuring that the safety objectives are met.

### **3.1.4 Prevention and Mitigation of Accidents**

The design of the BWRX-300 includes provisions to prevent and to mitigate the consequences of accidents and to ensure that the likelihood that an accident will have harmful consequences is extremely low.

The primary means of preventing and mitigating the consequences of accidents is through the application of Defence-in-Depth (D-in-D). The application of D-in-D for the BWRX-300 design is described below in Subsection 3.1.6.

### **3.1.5 Fundamental Safety Functions**

The design of the BWRX-300 fulfills Fundamental Safety Functions (FSFs) at all plant states (defined in Section 3.1.3) which ensures the design meets the safety objectives consistent with CNSC REGDOC-2.5.2, Section 6.2 (Reference 3.1-1). The FSFs for the BWRX-300 are:

- Control of reactivity
- Removal of heat from the fuel (in the reactor, during fuel storage and handling, and including long-term heat removal)
- Confinement of radioactive materials, shielding against radiation and control of planned radioactive releases, as well as limitation of accidental releases

The FSF prevent or mitigate radiological releases by ensuring the physical barriers to releases (fuel matrix, fuel cladding, Reactor Coolant Pressure Boundary (RCPB), and containment) remain effective. In addition to the protection of barriers, a means of monitoring the status of key plant parameters is provided for ensuring that the FSF are fulfilled. From this perspective, the monitoring function is treated as inherent to the design of the FSF. Other considerations for the monitoring function are as follows:

1. If a manual operator action plays a role in performing an FSF, the monitoring function of the equipment used to display key plant parameters that are necessary for the operator to perform the manual action successfully are also considered part of the FSF.
2. Certain monitoring functions allow the operator to confirm ongoing effectiveness of the FSFs during all plant states, to implement post-accident procedures, and to make decisions in support of emergency planning.
3. Post-Accident Monitoring (PAM) is important for operator decision making such as taking manual actions and implementing functions. Therefore, the designation, treatment and display of certain plant parameters or measurements as post-accident monitoring variables is a supporting design feature.
4. A minimum set of monitoring functions and display of parameters that do not support the operator actions are provided to support accident assessment.

Preservation of the FSFs is intrinsic to BWRX-300 Safety Strategy. A systematic approach is taken to identify the FSFs and those SSC necessary to fulfill the FSFs following a PIE. This systematic approach is detailed in the D-in-D discussion below.

### **3.1.6 Defence-in-Depth**

#### **3.1.6.1 BWRX-300 Defence-in-Depth Concept**

The implementation of D-in-D in the BWRX-300 design is the basis for the Safety Strategy for ensuring an adequate level of safety is achieved by the design.

The concept of D-in-D (consistent with CNSC REGDOC-2.5.2, Section 6.1 (Reference 3.1-1)) involves the provision of multiple layers of defence against some undesirable outcome rather than a single, strong defensive layer. In the case of a nuclear power plant, the undesirable outcome is the exposure of workers, the public or the environment to radioactivity exceeding levels determined to be safe.

There are two types of defensive layering considered:

1. Physical barriers in place to prevent the release of radioactivity: The fuel matrix, fuel cladding, RCPB, and containment. The integrity of one or more physical barriers must be maintained to prevent unacceptable releases.
2. A combination of active, passive, and inherent safety features used to minimize challenges to the physical barriers, to maintain the integrity of the barriers and, in case a barrier is breached, to ensure the integrity of the remaining barriers.

While the physical barriers themselves represent multiple layers of defence against radioactive releases, in the BWRX-300 D-in-D application, the physical barriers are not themselves referred to as “defense lines”. That term is reserved for the layers of defence comprising features, functions and practices that protect the integrity of the barriers. The D-in-D concept applied is largely focused on identifying and organizing features, functions, and practices into defense lines without explicit acknowledgment of the physical barriers. The fundamental purpose of the defense lines is to ensure the integrity of the physical barriers by applying multiple levels of protection.

The BWRX-300 D-in-D concept uses the FSFs described above to define the interface between the defense lines and the physical barriers. In a given plant scenario, if the FSFs are performed successfully, then the corresponding physical barriers remain effective.

### 3.1.6.2 Defense lines

Five Defense Lines (DLs) (or levels), DL1 through DL5, are adopted consistent with CNSC REGDOC-2.5.2, Section 6.1 (Reference 3.1-1) and IAEA SSR-2/1 (Reference 3.1-2). Figure 3.1-1 illustrates the defense lines as they correspond to the plant states.

The first defense line (DL1) does not include plant functions. It minimizes potential for PIEs to occur in the first place and minimizes potential for failures to occur in subsequent defense lines by assuring high quality and conservatism in design, construction, and operation. The second, third, and fourth defense lines (DL2, DL3, and DL4) comprise plant functions that act to prevent PIEs from leading to significant radioactive releases. The fifth defense line (DL5) involves off-site emergency preparedness to protect the public in case a substantial radioactive release occurs.

The defense lines include measures such as engineering and operational practices, plant features, and plant functions. These measures are incorporated such that:

- The normal operation of the plant is monitored and controlled such that PIEs that lead to AOOs can be mitigated before evolving into DBAs
- The consequences are limited if a DBA does develop
- Multiple defense lines are capable of independently performing the FSFs. While this means that more than one DL is capable of independently performing the FSFs for D-in-D, DL independence from all other DLs is based on how specific DLs are credited for specific fault sequences.

Table 3.1-1 provides a high-level description of the objective, and the design means and operational means for supporting the defense lines. The following is a brief description of each of the defense lines.

#### Defense Line 1 (DL1)

The purpose of the first level of defence is to prevent deviations from normal operation and the failure of important SSC. This is achieved through the quality measures taken to minimize potential for failures and for initiating events to occur in the first place and to minimize potential for failures to occur in subsequent lines of defence. These quality measures cover the design, construction, inspections, operation, use of operational experience, periodic safety reviews, and maintenance, and testing of the plant.

DL1 measures may support the basis for assumptions made in safety analyses. For example, the use of a high-quality design process and stringent equipment qualification for the most important components support the assumption that only a single failure is considered in the Conservative Deterministic Safety Analysis discussed in Chapter 15, Subsection 15.2.1.

Examples of DL1 measures include:

- The clear definition of normal and abnormal operating conditions
- Maintenance and implementation of a quality assurance program consistent with nuclear regulations and industry standards
- Application of appropriate industry standards to the design of SSC
- Adequate design margins
- Robust design processes including design verifications
- Comprehensive testing programs

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

- Provisions for adequate time for operators to respond to events and appropriate human-machine interfaces, including operator aids, to reduce the burden on the operators
- Deterministic safety analyses including appropriate conservatism, supplemented by Probabilistic Safety Analysis to produce risk insights
- Categorization and qualification of SSC according to their safety significance
- Operational Limits and conditions
- Application of lessons learned through operating experience

**Defense Line 2 (DL2)**

The purpose of the second level of defence is to detect and control deviations from normal operational states to prevent AOOs from escalating to accident conditions. Functions that normally operate to maintain key reactor parameters (e.g., pressure, reactor level, and reactivity) within normal ranges are part of DL2.

Examples of DL2 measures include:

- Anticipatory plant trips
- Maintain target power
- Maintain target level
- Maintain target pressure
- Control Rod Block

**Defense Line 3 (DL3)**

For the third level of defence, it is assumed that, although very unlikely, the escalation of certain AOO or DBA PIEs might not be controlled at a preceding level and that an accident could develop. In the design of the plant, such accidents are postulated to occur. DL3 contains plant functions that act to mitigate a PIE by preventing fuel damage, when possible, which assures the integrity of the release barriers are maintained, and the plant is maintained in a safe state until normal operations are resumed.

The systems and equipment involved in performance of DL3 functions are designed for high reliability. Examples include eliminating the need for active support systems such as power supplies, ventilation, or cooling water, and minimizing the need for active control functions such as pumps and actively controlled valves.

The DL3 functions and equipment performing those functions are subject to functional and design requirements derived from the Conservative Deterministic Safety Analysis as described in Chapter 15, Subsection 15.2.1.

Examples of DL3 measures include:

- Reactor Scram
- Isolation Condenser Initiation
- Main Steam isolation
- Containment Isolation
- Reactor Pressure Vessel (RPV) Isolation

#### **Defense Line 4 (DL4)**

The purpose of the fourth level of defence is to mitigate DEC's.

For the BWRX-300, DL4 is comprised of two subsets of functions that are designated as DL4a and DL4b functions. DL4a functions mitigate DEC's that occur without core damage. DEC's progressing to core damage are mitigated by DL4b functions.

##### **DL4a**

DL4a functions are those that place and maintain the plant in a safe state in scenarios involving:

- DBAs sequences combined with multiple failures that prevent the DL3 SSC from performing their intended function (i.e., Common Cause Failure (CCF) which is a failure of two or more SSC due to a single specific event or cause.)
- DEC PIEs considered as credible events that may involve multiple failures causing the loss of a FSF to be fulfilled as part of normal operation

Examples of DL4a measures include:

- Diverse means of achieving the FSFs that are independent of and diverse from the SSC carrying out the DL3 functions that are presumed to have failed.
- Scrams initiated by the Diverse Protection System

##### **DL4b**

DL4b includes:

- Functions provided in scenarios leading to core damage to limit the radiological releases in case of core damage and are aimed at maintaining the containment functions for extreme events, multiple events, or multiple failures that defeat DL2, DL3, and DL4a.
- Functions provided to mitigate the effects from a damaged core and to preserve the FSF of confinement of radioactive material while limiting radioactive releases to acceptable levels.
- Safety features designated for DEC's with core damage may, if practicable and available, also be used for preventing or minimizing significant core damage if it can be demonstrated that such use will not undermine the ability of these systems to perform their primary functions if conditions evolve into a severe accident.

Examples of DL4b measures include:

- DL4b measures carried out by complementary design features such as diverse and flexible equipment and portable components such as, portable uninterruptible power supplies and portable pumps
- Containment venting and overpressure protection
- Boron injection

A list of complementary design features is provided in Chapter 15, Appendix 15B.

#### **Defense Line 5 (DL5)**

The purpose of the fifth and final level of defence is to mitigate the radiological consequences of radioactive releases that could potentially result from accidents.

DL5 includes emergency preparedness measures to cope with potential unacceptable releases in case the first four defense lines are not effective. These are largely off-site measures taken to protect the public in a scenario involving substantial release of radiation.

Examples of DL5 measures:

- Severe accident management procedures
- Emergency response procedures and equipment (peripheral systems such as meteorological monitoring)
- On/off-site emergency response facilities, and certain communication systems may play a role in DL5. Chapter 19 discusses emergency response arrangements such as procedures and facilities. Communication systems are discussed in Chapter 9A, Section 9A.9.1. (Note that these measures may be initiated earlier in an event prior to progression to a severe accident)

### **3.1.6.3 Defense Line Independence**

The BWRX-300 design incorporates independence in the application of D-in-D. Defense lines that mitigate the same event are independent as far as is practicable to avoid the failure of one level reducing the effectiveness of other levels. Some examples include:

1. Among DL2, DL3 and DL4a, at least one defense line can mitigate a PIE caused by or concurrent with a CCF in another defense line, with the mitigation means being independent from the effects of the initiating CCF.
2. All PIEs with a frequency greater than  $1\text{E-}05$  caused by a single failure can be mitigated by DL3 and independently by DL2, DL4a, or a combination of DL2 and DL4a functions that are unaffected by the PIE. To the extent practicable, DL3 functions are independent and diverse from those in DL2 and from those in DL4a. This is because DL3 functions provide a backup to DL2 functions, and DL4a functions provide a backup to DL3 functions but DL4a functions are not needed to provide a direct backup to DL2 functions to maintain D-in-D for the same event.
3. The DL4b functions intended for mitigating DECIs are functionally and physically separated from the systems intended for other DL functions.
4. DL4b features specifically designed to mitigate the consequences of accidents with core damage are independent from systems used in normal operation or used to mitigate AOOs as far as is practicable and with exceptions justified.
5. Exceptions to rules of independence are described, assessed, and justified. If equipment supports functions in more than one defense line, there is an increased focus on their reliability in the application of DL1 compared to a design feature credited in only one defense line.

### **3.1.6.4 Safety Strategy Process for Implementing Defence-in-Depth**

The BWRX-300 Safety Strategy implements the D-in-D concept into the design through evaluations and analyses as shown in Figure 3.1-2. These include:

- Hazard Evaluations
- Fault Evaluation
- Deterministic Safety Analyses
- PSA

The elements of Figure 3.1-2 are briefly described below.

#### **3.1.6.4.1 Hazard Evaluations**

The first step is to identify PIEs using a systematic methodology considering both direct and indirect events through hazard evaluations. The BWRX-300 Safety Strategy includes the following four types of hazard evaluations which are summarized in Chapter 15, Subsection 15.1.3:

- Functional Failure Hazard Evaluation – assessment of failures of SSC
- External Hazard Evaluation - assessment of external events such as earthquakes or aircraft crashes that have the potential to impact plant safety
- Internal Hazard Evaluation – assessment of hazards originating within the facility such as missiles from rotating equipment, fires, collapse of structures
- Human Operation Hazard Evaluation – human errors which could reasonably be expected to occur based on industry operating experience

The output of the four hazard evaluations are the potential PIEs for consideration in the Fault Evaluation.

#### **3.1.6.4.2 Fault Evaluation**

The Fault Evaluation process evaluates the PIEs determined as a result of the hazard analyses. PIEs are selected and organized along with fault sequences. As used herein, a fault is essentially a failure or a hazard and could be the initiator for or result from a PIE. A PIE is an event that initiates a fault sequence. A fault sequence consists of a PIE, and responses by mitigation functions (including both failed responses and successful responses). This is consistent with the description of event combinations per CNSC REGDOC-2.4.1, Section 4.2.2.5 (Reference 3.1-5).

The Fault Evaluation establishes traceability between the plant design and the safety analysis bases. The Fault Evaluation process including the selection and categorization of PIEs and fault sequences for deterministic safety analysis is described in Chapter 15, Section 15.2.

#### **3.1.6.4.3 Deterministic Safety Analyses**

The objective of deterministic safety analysis for nuclear power plants is to confirm that:

- FSFs can be performed
- SSC performing the FSF are designed with adequate margins
- physical barriers to radioactive release maintain their integrity as required

Deterministic safety analysis is supplemented by insights obtained from fabrication, testing, inspection, operating experience, and PSA. It demonstrates that the source term and the potential radiological consequences of different plant states are acceptable. It also demonstrates that the possibility of certain conditions arising that could lead to an early or a large radioactive release can be considered as 'practically eliminated'.

The output of the Fault Evaluation process which includes the selection of PIEs and fault sequences organized by frequency are analyzed in deterministic safety analysis. Chapter 15, Subsection 15.2.1, provides more detail on the deterministic safety analysis process.

#### **3.1.6.4.4 Probabilistic Safety Analyses**

PSA are performed to understand the overall risk presented by the facility and to allow comparisons to be made against safety goals (defined in Section 3.1.2.3) They also provide

essential understanding of strengths and weaknesses of a design with complex systems and interdependencies. They are used for evaluating complementary design feature concepts or changes in operating conditions and have many other applications to enhance safety decision

To supplement quantitative PSA results, a severe accident analysis is performed to understand the complex physical phenomena associated with a reactor core damage scenario. This analysis supports confirmation that the radioactive release sequences modeled in the Level 2 PSA adequately reflect associated phenomena.

Severe accident analyses are used to complement the design deterministic safety and PSA in situations where the consequence is large, even if the calculated risks are low and/or the deterministic safety analysis provides a robust demonstration of fault tolerance. The severe accident analysis is not considered standalone piece of analysis deriving scenarios from first principles, but instead builds upon other types of analysis to create an overall safety case that is adequate in its coverage.

Detailed discussion of PSA and Severe Accident Analysis is provided in Chapter 15, Section 15.6.

### **3.1.7 Application of General Design Requirements and Technical Acceptance Criteria**

#### **3.1.7.1 Deterministic Design Principles in Codes & Standards**

A fundamental aspect of the BWRX-300 Safety Strategy is that the overall plant design applies good engineering practices for design, construction, operation, maintenance, and testing which relates to conformance to regulatory requirements, as well as industry codes and standards and norms for achieving high dependability in performance.

Engineering design rules are established and applied, as appropriate by the specific design discipline based on relevant codes, standards, and proven engineering practices.

Because codes or standards for the different design disciplines (e.g., mechanical, civil, and electrical) are not always based on compatible safety criteria, consistent acceptance criteria are established, and good engineering practices are used, to provide consistency in the application of selected codes and standards in design. Analyses and evaluation of the codes and standards to be applied in the design, fabrication and construction of the plant is performed. The results of this analysis and evaluation are documented as part of the management system.

The plant architecture and systems design specifications demonstrate that the plant and the SSC are designed, implemented, constructed, installed, operated, and maintained safely with respect to their application and maintenance of these guiding fundamental design principles that follow. Additionally, changes are performed using the same guiding fundamental design principles, using the same or better methods and processes to avoid compromising safety.

#### **3.1.7.2 Minimize Probability of Failure Structures, Systems, and Components**

The probability of failure of systems and equipment is minimized through a design which provides predictable and repeatable performance of the FSFs. This is achieved by deploying highly reliable and dependable SSC.

DL3 systems and equipment are designed to fail to a safe state or to a known, defined state to ensure safety is not jeopardized. Thus, reactor trip systems fail to the safe state, but engineered safety features systems may fail-safe or are non-actuated (e.g., isolation condenser cooling function). Fail-safe design is achieved through systematic identification of failure modes through Failure Modes and Effects Analyses (FMEA).

Systems are required to be testable to provide assurance of continued operability and availability when required. System maintainability is a fundamental aspect of the design, extending down to software by ensuring documented, well-designed, understandable code.

Chapter 13 describes how fitness for service is addressed in established programs that include: Reliability, Maintenance, Aging Management, Chemistry Control, Periodic and In-Service Inspections. Programmatic requirements addressing fitness for service span the full life cycle of the facility beginning with inclusion in facility design decision making.

#### **3.1.7.3 Independence**

The most plausible reason for the failure of FSFs is the occurrence of dependent failures. Dependent failures are identified, and where practicable, measures are implemented in design, construction, and operation to eliminate the dependencies or reduce their potential effect. The application of independence is used in the Safety Strategy to enhance reliability and reduce potential for dependent failures. Independence is an essential aspect of effectiveness in the implementation of D-in-D.

The determination of independence of SSC required to mitigate the consequences of a single or a likely combination of internal or external hazards on the plant is conducted through the Fault Evaluation introduced in Section 3.1.6.4.2 and described in more detail in Chapter 15, Section 15.2 and confirmed via the PSA in Chapter 15, Section 15.6.

The PSA is also used to confirm the adequacy of the independence measures.

Independence is achieved by addressing the main causes of CCFs: functional, spatial, inherent, and human error dependencies as discussed in Subsection 3.1.7.5.

#### **3.1.7.4 Diversity**

Diversity is the provision of dissimilar means of achieving the same objective. Diversity involves the use of design features which differ in the physical means of achieving a specific objective or use of different equipment made by different manufacturers. Diversity is achieved by incorporating different attributes into the systems or components. Such attributes could be different principles of operation, different physical variables, different conditions of operation, or production by different manufacturers, for example. It is necessary to ensure that the diversity attribute achieves the desired increase in reliability in the as-built design. For example, to reduce the potential for CCFs the designer should examine the application of diversity for any similarity in materials, components and manufacturing processes, or subtle similarities in operating principles or common support features. If diverse systems or components are used, there is a consideration that reasonable assurance that such additions are of overall benefit, including consideration of the associated disadvantages such as the increased operational complication, additional maintenance and test procedures, and the potential for lower reliability.

Diversity is considered for digital equipment and active mechanical/electrical equipment. Diversity is not included for passive equipment such as pipes and tanks. Diversity is a DL1 provision used to strengthen subsequent defense lines.

#### **3.1.7.5 Separation**

Functional isolation is used to reduce the likelihood of adverse interactions between equipment and components resulting from normal or abnormal operation or failure of any component in the systems. For example, in a power supply, functional isolation is commonly achieved using fuses and circuit breakers.

Separation supports defense line function independence discussed in Subsection 3.1.6.3. System layout and design uses physical separation to increase assurance that independence will be achieved, to preclude certain CCFs.

- Physical separation includes separation by geometry (such as distance or orientation); barriers; or a combination of these. The choice of the means of separation will depend on the PIEs considered in the design basis, such as the effects of fire, chemical explosion, aircraft crash, missile impact, flooding, extreme temperature, or humidity.
- In a redundant system and despite diverse provisions, the threat of CCFs from hazards such as fire may be reduced by system segregation. Segregation is the separation of components by distance or physical barriers. An example is the use of fire barriers to indicate individual fire zones, which may also serve as barriers to other hazards.
- Plant barriers that provide protection against certain faults or hazards are assessed to ensure that the barriers remain operable and accessible in the event of those faults or hazards occurring. This is particularly important where SSC that perform defense line functions are co-located with other plant equipment that do not.

### **3.1.7.6 Redundancy**

Redundancy is the provision of more than the minimum number of nominally identical equipment items required to perform a specific safety function. Such redundant provisions allow a safety function to be satisfied when one or more systems or components (but not all) are unavailable, due to a variety of unspecified potential failure mechanisms or maintenance (e.g., identified faults or hazards). Redundancy enables failure or unavailability of at least one set of systems or components without loss of the function. For example, three or four pumps may be provided for a particular function when any two would be capable of carrying it out. For the purposes of redundancy, identical or diverse components may be used.

The application of independence, diversity, separation, and redundancy in the design is described in each system design description.

### **3.1.7.7 Single Failure Criterion**

The BWRX-300 design addresses the single failure criterion through design and safety analyses to ensure reliability of DL3 functions. Consistent with CNSC REGDOC-2.5.2, Section 7.6.2, each safety group (DL3 function) is assessed for capability in fulfilling its required function even if a failure of a single component occurs within this group.

A single failure is one which results in the loss of capability of a single system or component to perform its intended DL3 function(s), and any consequential failure(s) which result from it.

For the BWRX-300, the single failure criterion is considered in two ways:

1. As a design attribute that is typically achieved through redundancy in the system architecture of the SSC carrying out DL3 functions. This involves a systematic search for potential single failure points and their effects on prescribed missions (i.e., FMEA).
2. As an assumption made in the conservative deterministic safety analysis, in addition to the PIE and any additional failures, all identifiable undetectable faults are included to demonstrate a high degree of confidence that acceptance criteria will be met.

During the design process, systems that are designed to carry out a DL3 function must be capable of carrying out their mission despite the failure of any single component within the system or in an associated system that supports its operation. Design measures for ensuring high reliability

of SSC carrying out DL3 functions include incorporating, independence, diversity, and redundancy, and also through the incorporation of passive and fail-safe features.

The PSA is used for identifying single failures for consideration in the deterministic safety analysis and is also a complementary means of demonstrating the insensitivity to single failures.

### **3.1.7.8 Common Cause Failures**

#### ***3.1.7.8.1 Background Information and General Approach***

CCFs are functional failures of multiple components due to a single specific event or cause. Such failures may affect several different safety class components simultaneously or may affect multiple components of the same type at the same time.

The event or cause of CCFs may be a design deficiency, a manufacturing deficiency, an operating or maintenance error, a natural phenomenon, a human induced event or an unintended cascading effect from any other operation or failure within the plant. Appropriate measures to minimize the effects of CCFs, such as the application of redundancy, diversity, and independence, are taken as far as practicable in the design.

Multiple failures can occur due to common weaknesses or dependencies shared by components. Such failures can cause failure of all redundant components in a single protection system or failure of components in more than one system. Dependent failures can considerably reduce the reliability of the protection systems relative to that expected from consideration of random failure mechanisms occurring in isolation. Identification of dependent failures is assessment by Functional Failure Hazards Evaluations.

The main types of failure dependencies that can cause a potential loss of safety function are as follows:

- **Functional Dependencies**, which arise from shared or common functional features such as a common electrical power source, a common cooling water system or a shared process fluid.
- **Spatial Dependencies**, which arise from physical features shared by components located in a common location such as common radiation or chemical conditions, a common environment and common support structures, and vulnerability to leaks of dangerous fluids (high temperature, corrosive or toxic).
- **Inherent Dependencies**, which arise from shared characteristics such as a common principle of operation or technical embodiment and a common failure mechanism such as mechanical overload or overpressure.
- **Human Error Related Dependencies**, which arise from human errors affecting some shared or common human process such as human error in design or manufacture, or operating staff error during operation and maintenance.

The general protective approach used for addressing postulated vulnerabilities to CCFs is diversity in the design. Dissimilarities in technology, function, implementation, and so forth, can mitigate the potential for common faults. The diversity approach to ensuring safety uses different (e.g., dissimilar) means to accomplish the same or equivalent function to compensate for a CCF that disables one or more levels of defence. Diversity is complementary to the principle of defence-in-depth, and it increases the chances that a defense line function will be available when needed. Different defense lines that mitigate the same event are diverse from each other to the extent practicable.

Another means of protecting against CCF is through feedback from operating experience that could identify weaknesses in the design, construction, operation and testing of equipment. In addition, conducting periodic inspection, surveillance, and testing provides opportunities to detect degradation or common causes before failures of SSC. Quality assurance and quality control measures applied to SSC commensurate with their importance help reduce preclude potential CCFs.

#### ***3.1.7.8.2 Common Cause Failures of Digital Instrumentation and Control Software***

The BWRX-300 approach to assessment of CCF of Digital Instrumentation and Control (I&C) software is through a consequence-based approach.

Even when functional dependencies are addressed through rigorous design and application of codes and standards, operating experience shows that software CCFs occur. Validating assumptions and modeling of software CCF modes can be challenging due to uncertainty as each Digital I&C system is unique, and extrapolation of failure data from one system to another may not be meaningful making the identification of failure scenarios difficult. Analyzing each postulated CCF scenario is not practicable; therefore, using a consequence-based approach can limit the number of CCF scenarios is considered. This approach considers the radiological or dose consequences that could result due to CCFs in the software.

#### ***3.1.7.8.3 Defense Line Approach to Common Cause Failure***

A multi-pronged approach and the systematic integration of CCFs in defense line functions, both as PIEs and as failures affecting fault sequence mitigation, are applied in deterministic safety analyses for prevention and mitigation in the D-in-D approach. Examples include:

1. DL3 systems and functions are designed and rigorously qualified to be resistant to the effects of environments that could cause common failures, including DBA environments.
2. For internal and external events resulting in DECAs, the design includes independent and diverse system functions to cope with the effects of common cause failure (e.g., DL4a).
3. Diverse accident monitoring instrumentation for severe accident management (e.g., DL4b) is provided.

The defence-in-depth approach is designed to include analyses of a reasonable set of CCF scenarios to provide assurance that the plant is protected against CCF phenomena. This approach is implemented using a set of CCF application guidelines to define the CCF modes that are included, how the failure modes are applied, and which assumptions can be made regarding equipment operability.

#### **3.1.7.9 Other Approaches for Ensuring Safety**

In addition to the design principles discussed above, the BWRX-300 design incorporates the following approaches to ensure safety.

##### ***3.1.7.9.1 Simplicity in Design***

An implicit approach to reliability is to deploy the design with minimal complexity, with the knowledge that complexity may be required to enhance reliability or reduce the potential for human error. Where complexity is required (e.g., self-diagnostics, redundancy within the equipment in a single division), the complexity is documented and justified as necessary and appropriate for enhancing reliability, surveillance, calibration, and other required system or equipment attributes. There are tradeoffs in complexity, such as increasing the complexity by designing the system to reduce the human actions necessary for surveillance which also decreases the potential for human error, which enhances system reliability.

The BWRX-300 is specifically designed to enhance safety through simplification and reducing its dependence on human intervention. This is achieved through increasing its reliance on natural circulation and natural phenomena-driven safety systems (these are passive features as discussed below). These safety enhancements, in combination with its reduction in scale and complexity including a reduction in total number of active SSC, simplifies operations and maintenance. Some of the simplified design features are described in Chapter 1.

#### **3.1.7.9.2 *Passive Safety Features***

The design of the BWRX-300 uses passive functions that do not require external sources of power or operator actions. DL3 functions are passive to the extent that is practicable and, therefore, have significantly less reliance on supporting systems or operator actions.

Examples of the BWRX-300 passive design features include:

1. Safety Class 1 batteries are capable of powering loads for a minimum of 72 hours. The design ensures that plant safety is maintained even after battery depletion.
2. BWRX-300 utilizes natural circulation and passive natural circulation for fuel cooling and passive containment heat removal. The plant is designed with the capability to cope with decay heat for seven days using only installed systems with no reliance on significant operator actions or external resources.

The mitigation of loss-of-coolant accidents is built on utilization of inherent margins (e.g., larger water inventory) to eliminate system challenges, reduced number, and size of RPV nozzles as compared to predecessor designs, and elimination of fluid system nozzles located below a level well above the top of active fuel to conserve inventory. The relatively large reactor pressure volume of the relatively tall chimney region provides a substantial reservoir of water above the core. This ensures the core remains covered following fault sequences involving feedwater flow interruptions or loss-of-coolant accidents without the need for active components (such as pumps). Additionally, the RPV is equipped with isolation valves attached directly to the reactor vessel for large bore piping systems to preserve reactor coolant inventory ensuring that adequate core cooling is maintained.

The application of these design concepts is described in each system design description.

#### **3.1.7.10 Technical Acceptance Criteria**

To meet the radiological acceptance criteria, derived accepted criteria are defined for the fuel pellet, fuel cladding, RCPB and containment. Deterministic safety analyses are performed to demonstrate that these criteria have been met. A description of acceptance criteria is provided in Chapter 15, Section 15.3. Details of the deterministic safety analysis are presented in Chapter 15 Section 15.3. Table 15.3-1 for AOOs and 15.3-2 for DBAs.

#### **3.1.8 Practical Elimination**

Consistent with CNSC REGDOC-2.5.2 Section 7.3.4 (Reference 3.1-1) and IAEA SSR-2/1(Reference 3.1-5), the BWRX-300 design is such that fault sequences that could lead to an early or large radioactive release are practically eliminated.

The definition of early and large radioactive release (from IAEA SSR-2/1) (Reference 3.1-5) in this context are:

1. An early radioactive release is a release of radioactive material for which off-site protective actions would be necessary but would be unlikely to be fully effective in due time.

2. A large radioactive release is a release of radioactive material for which off-site protective actions that are limited in terms of lengths of time and areas of application would be insufficient for the protection of people and of the environment.

Fault sequences with early or large releases could be considered to have been practically eliminated if either of the following apply:

- It is physically impossible for the accident sequence to occur.
- The fault sequence can be considered with a high degree of confidence to be extremely unlikely to arise.

Practical elimination is considered to refer only to those fault sequences leading to or involving core damage (e.g., a severe accident) for which the confinement of radioactive materials cannot be reasonably achieved.

The aim of the practical elimination concept is to reinforce D-in-D by focused analysis of those conditions having the potential for early radioactive release or a large radioactive release.

The justification of practical elimination preferably relies on a demonstration of physical impossibility for the accident sequence to occur. If this is not achievable, a demonstration of an extremely low likelihood of occurrence with a high level of confidence is provided. Sufficiently robust arguments and evidence are used to demonstrate the reliability of the lines of defence. If additional features are identified that prevent accidents or mitigation accident consequences, these features are considered for implementation as far as practicable.

The set of individual fault sequences that might lead to an early radioactive release or a large radioactive release are grouped to form a limited number of bounding cases or type of accident conditions.

Severe accident phenomena based on operating experience with predecessor advanced light water reactors serve as a starting point for consideration for practical elimination. Analyses demonstrating practical elimination are described in Chapter 15, Appendix 15A.

### **3.1.9 Safety Margins and Avoidance of Cliff-Edge Effects**

A cliff-edge effect is described as a small change of conditions that may lead to a significant increase in the severity of consequences per CNSC REGDOC-3.6 (Reference 3.1-7).

In the BWRX-300 Safety Strategy, the principle of multiple physical barriers to the release of radioactive material and protection of those barriers is incorporated in the design as a DL1 measure. Margins are incorporated into the design of the physical barriers to demonstrate their capability in postulated scenarios that are more severe (by a small amount) than those in the design basis without incurring cliff-edge effects.

Conservative safety margins and sensitivity analyses are applied in safety analyses to account for assumptions and uncertainties. Additional details on the application of safety margins in Deterministic Safety Analysis are described in Chapter 15, Subsection 15.5.1.1. As part of the PSA, sensitivity and uncertainty analysis is conducted to demonstrate consideration of potential cliff-edge effects. (See Chapter 15, Subsection 15.6.1).

### **3.1.10 Design Approaches for the Reactor Core and for Fuel Storage**

#### **3.1.10.1 Design Approach for Reactor Core**

The reactor core is designed to maintain the integrity of the fuel and the fuel cladding. The fundamental safety functions of control of reactivity, removal of heat from the reactor and fuel, and confinement of radioactive materials are inherent design features for the reactor core.

The reactor core, the fuel, and fuel assemblies, including fuel channels and control blades, are designed such that the reactor can be shut down, cooled, and held subcritical with adequate margin in operational states, DBAs, and DECAs. Reactivity control ensures shutdown margin for shutdown states and any credible changes in core configuration. The design ensures that the fission chain reaction is controlled during operational states. The design limits positive reactivity through inherent neutronic and thermal-hydraulic characteristics, means of shutdown, and control to protect the reactor pressure boundary and prevent fuel damage.

The reactor core (including associated structures and cooling systems) is designed to withstand static and dynamic loading and vibration, to be compatible with expected chemicals, and to meet thermal material and radiation damage limits.

The reactor core design also provides for certain operator actions in accident scenarios to maintain the reactor in a shutdown condition, such as actions that might be addressed in emergency operating procedures or severe accident management guidelines.

### **3.1.10.2 Design Approach for Fuel Handling and Storage**

The design of fuel handling and storage systems is consistent with the D-in-D approach applied to the reactor core with slightly different fundamental safety functions.

The design approach is to identify fuel handling and storage SSC that are necessary to fulfill the following fundamental safety functions for all plant states:

- Maintaining subcriticality of the fuel
- Removal of the decay heat from irradiated fuel
- Confinement of radioactive material, shielding against radiation as well as limitation of accidental radioactive releases

The Safety Strategy principle for fuel handling and storage is to leverage design and safety features in relation to fuel handling and storage that have been proven either in predecessor BWR applications or are based on operating experience.

Subcriticality is maintained by preventing criticality through use of geometrically safe configurations. The design of fuel storage systems considers the use of physical means or physical processes to increase subcriticality margins in normal operation to avoid reaching criticality during PIEs, including those PIEs arising from the effects of internal hazards and external hazards.

Fuel handling and storage systems are designed to maintain adequate fuel cooling capabilities for irradiated fuel ensuring that the fuel cladding temperature limits and/or the coolant temperature limits, as defined for operational states and accident conditions, are not exceeded.

The fuel storage and handling, radioactive waste, and other systems that may contain radioactivity are designed to assure adequate safety under normal and postulated accident conditions. These systems are designed:

- With a capability to permit appropriate periodic inspection and testing of components safety features,
- With suitable shielding for radiation protection,
- With appropriate containment, confinement, and filtering systems,

- With a residual heat removal capability having reliability and testability that reflects the importance to safety of decay heat and other residual heat removal, and
- To prevent significant reduction in fuel storage coolant inventory under accident conditions.

Appropriate systems are provided in fuel storage and radioactive waste systems and associated handling areas:

- To detect conditions that may result in loss of residual heat removal capability and excessive radiation levels and
- To initiate appropriate safety actions

Refer to Chapter 9A, Section 9A.1 for a detailed description of the Fuel Handling and Storage Systems.

### **3.1.11 Considerations of Interactions Between Multiple Units**

Operating experience has demonstrated that interactions or shared equipment between multiple units can cause problems for the plant and for personnel. Lessons learned include:

- Significant interactions between multiple co-located radiological sources (e.g., reactor units, spent fuel pools, or dry fuel storage facilities) could result due to concurrent or consequential initiators.
- The timing of concurrent accident sequences involving multiple radiological sources on a site can challenge shared SSC, as well as resources available for severe accident management and emergency response to the event.

Site evaluations would address multiple reactors or other co-located facilities and determine if these need to be treated as external hazards (e.g., external radiation sources) in the design of the BWRX-300. See Chapter 2, Subsection 2.2.5 for more details.

Each BWRX-300 unit would have its own safety class systems and its own safety features for DEC's.

If multiple units are to be co-located, emergency planning and design and safety analyses, including consideration of CCFs in similarly design units, would demonstrate that sharing resources of equipment and personnel, including temporary equipment and emergency response personnel, would not be detrimental to plant operation, fuel storage, emergency planning, or accident management.

### **3.1.12 Design Considerations for Aging Management**

Aging of SSC is considered in the basic assumptions and in the input data to the safety, thermohydraulic and stress analyses. All system and component design specifications reference design requirements on aging, including those in the applicable codes and standards.

Aging and equipment qualification considerations are important aspects, complementary to each other in plant design. Equipment qualification is discussed in Section 3.9.

In designing components, system designers consider aging mechanisms and their effects on the safety, reliability, and performance of SSC for those that are well known and understood. Additionally, system designers collect information from operations feedback, research and development, vendor recommendations, maintenance and operating manuals, and expert insight, and make design decisions based upon shared knowledge. For BWRX-300 there exists significant operating experience and insights regarding individual degradation mechanisms that have been considered in the aging management programs. For example, the United States

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

Nuclear Regulatory Commission has developed a consistent approach to aging management in connection with licence renewal for operating plants.

Known aging phenomena are quantified and considered in the design of SSC. The design includes the effects of wear and all other known age-related degradation to ensure that safety and performance are maintained for the duration of their lifetime. If the component lifetime extends to the plant service life, as is the case for passive non-replaceable components, the design considers all normal and transitory operating conditions, including testing stressors, maintenance interventions and the consequences of plant and system outages. Analyzed DBAs are considered as part of the operating life and hence part of the design calculations.

In general, margins consist of design margins, operational margins, and safety margins. They account for uncertainties, assumptions, instrument feedback tolerances and ranges, unexpected transitory peaks, contingencies, and operating flexibility. Margins are mainly set to minimize the probability of component failure. Only the unquantifiable aging effects are included in the margin estimates.

Design documents include as a minimum, the following aging management topics:

1. A recommended strategy for aging management and prerequisites for its implementation.
2. Identification of safety class SSC in the plant that could be affected by aging.
3. Proposals for appropriate materials monitoring and sampling programs, where aging may affect the capability of critical SSC to perform their functions throughout the lifetime of the plant.
4. Appropriate consideration of operating experience with respect to aging.
5. Recommendations for aging management for safety class SSC (concrete structures, mechanical components, electrical and instrumentation and control components, cables, etc.) and measures to monitor and mitigate their degradation.
6. Equipment qualification requirements of safety class SSC.
7. General principles stating how the environment of structures, systems, and components are to be maintained within specified service conditions (location of ventilation, insulation of hot SSC, radiation shielding, damping of vibrations, submerged conditions and water chemistry, selection of cable routes, etc.).

### **3.2 Classification of Structures, Systems and Components**

The BWRX-300 approach to classifying SSC is consistent with IAEA SSR-2/1 (Reference 3.2-1) and IAEA SSG-30 (Reference 3.2-2) and aligns with CNSC REGDOC-2.5.2 (Reference 3.2-3). Classification of SSC is conducted to identify the importance of the SSC with respect to safety.

This section described how BWRX-300 SSC are classified by:

- Safety Class (SC)
- Seismic Category
- Quality Group

Classification of SSC provides a means for applying appropriate design requirements and establishes a graded approach in the selection of materials, and application of codes and standards used in design, manufacturing, construction, testing and inspection of individual SSC. Sections 3.5 through 3.8 describe the codes and standards applicable to civil, mechanical, I&C, and electrical SSC based on classification.

The classification of SSC also determines the degree of redundancy, diversity, separation, and reliability/availability required as described in Subsection 3.1.7. The requirement for environmental qualification is based on the classification of SSC as described in Section 3.9. In addition, SSC classification informs procurement and quality assurance requirements as discussed in Chapter 17.

#### **3.2.1 Safety Classification Background**

The BWRX-300 approach to classifying SSC by safety class is based primarily on deterministic methods and is directly traceable to the safety functions performed by the SSC. This approach aligns with CNSC REGDOC-2.5.2, Section 7.1, as it reflects:

- Consequences of the SSC failure to perform its safety functions
- Expected frequency of the SSC being called upon to perform its safety functions
- Time following a PIE at which, or the period for which, the SSC may be called upon to perform a safety function

A fundamental element of the BWRX-300 SSC classification approach is the direct correlation between the Defense Line in which an SSC performs a function, and the relative safety importance of that function. Functions are categorized into three safety categories, Safety Category 1, Safety Category 2, and Safety Category 3, with Safety Category 1 being the most important.

##### **3.2.1.1 Primary Function Categorization**

Primary functions are those that directly perform the FSFs in support of DL2, DL3, DL4a or DL4b. Safety Categories are applied to the primary functions as follows:

1. Safety Category 1 is assigned to DL3 primary functions. DL3 functions assure the integrity of the barriers to release, place and maintain the plant in a safe state, and provide independence and diversity for all DL2 and DL4a functions caused by a single failure (and many CCFs). Accordingly, DL3 primary functions are the most important from a safety standpoint.
2. Safety Category 2 is assigned to DL4a primary functions. Both DL2 and DL4a provide a redundant means to address PIEs (generally independent of DL3 functions) and are therefore important from a safety standpoint, although less important than DL3 functions.

DL4a functions are a backup to DL3 functions, in the unlikely event a DL3 functions fails, and therefore have a higher consequence of failure than DL2 functions and are more important from a safety standpoint than DL2 functions.

3. Safety Category 3 is assigned to DL2 and DL4b primary functions as they are relatively the least important. DL4b functions address severe accidents, which are extremely unlikely because failure of both DL3 and DL2 or DL4a functions would have to occur. Accordingly, DL4b functions are considered relatively the least important defense line functions, despite the high consequence of failure.
4. Non-Safety Category is assigned to all other functions.

The assignment of DL4a functions to Safety Category 2, to address the low probability but high consequences of failure, and the assignment of DL4b functions to Safety Category 3, based on the extremely low probability of being called upon, is consistent with CNSC REGDOC-2.5.2, Section 7.1 (Reference 3.2-3), which provides guidance on the treatment of complementary design features called upon to mitigate DEC's.

In addition to categorizing primary functions by the defense line they support, function that provide a supporting role and functions that are not immediately required following a PIE are assigned to a Safety Category as described below and summarized in Table 3.2-1.

### **3.2.1.2 Integral Support Functions**

Integral support functions are functions that support the primary function and are required to be performed concurrently with the primary function (e.g., an HVAC system maintaining the temperature of a space or area within an acceptable range during performance of the primary function (i.e., following the initiating event) to maintain equipment in an acceptable condition).

Integral support functions are considered part of the defense line function (and therefore subject to defense line function "rules," such as independence and diversity) and are assigned the same safety category as the primary function they support.

### **3.2.1.3 Make-Ready Support Functions**

Make-ready support functions are continuously available online functions that maintain the primary function, or a component required to perform the primary function, in a state of readiness but are not required to be performed at the time the primary function is performed. Make-ready functions must have monitoring, such that plant operators would be alerted if the make-ready support function were lost, or the readiness of the primary function or component were compromised. For example, maintaining the temperature of a pool of cooling water within acceptable limits, with monitoring by pool temperature indication is an example of a make-ready support function.

Make-ready functions are not required at the time the primary function is performed and are not considered part of the defense line function (and therefore not subject to defense line function "rules," such as independence and diversity). The primary function would eventually be considered unavailable if the make-ready function were compromised to the extent that the primary function might be compromised. Accordingly, make-ready functions are not required to be assigned the same safety category as the primary function. However, make-ready functions are important and are therefore assigned to safety categories as follows:

- Make-ready functions that support DL3 or DL4a functions are assigned to Safety Category 3
- All other make-ready functions can be assigned to Safety Category N.

#### **3.2.1.4 Delayed Functions**

Delayed functions are primary or support functions that are not required to be performed until sometime after the initiating event. Because there would be ample time during the event to ensure these functions are available, delayed functions are not required to be assigned the same safety category as functions required immediately after the initiating event. If the function is not needed until after 72 hours into the event (but before seven days), it can be classified as Safety Category 2 (instead of Safety Category 1), and if the SSC is not needed until after seven days into the event, it can be classified as Safety Category 3 (instead of Safety Category 1 or Safety Category 2). Delayed functions are not subject to defense line function “rules,” such as independence and diversity.

#### **3.2.1.5 Normal Functions**

Normal functions that perform an FSF during normal plant operation or that maintain key reactor parameters (e.g., reactor pressure and temperature) within normal ranges, and their integral support functions, are assigned to Safety Category 3. Make-ready functions for normal functions can be assigned to Safety Category N. If failure of a normal function would likely result in an initiating event that could challenge an FSF, the function should be assigned to Safety Category 3.

#### **3.2.1.6 Assignment of Safety Class to Components**

Safety Class is assigned to components based on the safety category of the functions they perform as follows:

- Safety Class 1 (SC1) is assigned to SSC that perform a Safety Category 1 function
- Safety Class 2 (SC2) is assigned to SSC that perform a Safety Category 2 function
- Safety Class 3 (SC3) is assigned to SSC that perform a Safety Category 3 function
- Non-Safety Class (SCN) is assigned to all other SSC

Just as with functions, a time-dependency is introduced for components that perform or support DL3 and DL4a functions. Specifically, if the component is not needed until after 72 hours into the event (but before seven days), it can be classified as SC2 (instead of SC1), and if the component is not needed until after seven days into the event, it can be classified as SC3 (instead of SC1 or SC2) because there would be ample time during the event to ensure those components are available. (See Table 3.2-2)

Functions typically have a mission time, which is the time period during which the function is required to be performed. Only SSCs that are required during the mission time of the function are required to be assigned to the safety classes discussed above.

Some component classifications are made for components that perform FSFs but may not be explicitly defined as part of a defense line function. For example:

- Components that are part of design provisions that perform a FSF, whose failure is considered “practically eliminated,” are assigned to SC1. An example is the RPV.
- Components that make up the fission product barriers are assigned to SC1.
- Components that are part of the RCPB are assigned to SC1.

The safety classification of a system is the highest safety classification of any components within the system; however, the component safety classification, and not the system safety classification, defines the design rules applied to components. Assignment of safety

classifications to systems is for convenience in understanding the relative importance of plant systems.

Not all components or parts of a system are necessarily assigned to the same safety class as the system itself. For example, a process system may be classified as SC 1 because one or more of its components support a DL3 function; however, the system may also contain components that support functions associated with other defense lines or components that support no defense line functions. These components are classified in accordance with the defense line functions they support.

Appendix 3A provides a list of the BWRX-300 principal components organized by system and includes their safety classification.

Structures are assigned a safety classification based on the highest safety classification of the components they house or support, excluding components whose failure, due to loss of functionality of the structure, would result in fail-safe performance of the component's safety category function(s). Design rules and performance requirements for structures are derived from their seismic category. Seismic categorization methodology is described in Subsection 3.2.3. The seismic category assigned to a structure is commensurate with its safety classification as listed in Section 3.3, Table 3.3-1.

### **3.2.2 Safety Classification Process**

In alignment with both IAEA and CNSC guidance, this method of classifying the safety significance of SSC is based primarily on deterministic methods because the DL functions are identified using deterministic safety analyses. The deterministic methods are complemented (where appropriate) by probabilistic methods and engineering judgment.

Design rules are then applied to SSC based on their safety classification and the DL functions they support. The safety classification process is iterative with the deterministic and probabilistic safety assessment and is maintained and updated throughout the design phase.

The following outlines the BWRX-300 classification process.

**Review and Definition of PIEs** – Hazard evaluations are performed (as introduced in Section 3.1.6.4.1) to identify hazards with potential to challenge an FSF. The output of these hazard evaluations are potential PIEs.

**Grouping and Identification of Bounding PIEs** – Potential PIEs are grouped by plant effect and occurrence frequency. Bounding or representative PIEs and fault sequences are selected for deterministic safety analyses as described in Chapter 15, Section 15.2.

**Identification of Plant-Specific Safety Functions to Prevent or Mitigate the PIEs** – The deterministic safety analyses are performed and updated iteratively with design activities to establish the plant-specific functions responsible for maintaining the FSFs during PIEs and fault sequences. The identification of plant-specific functions and their assignment to a Defense Line is carried out in the Fault Evaluation described in Chapter 15, Section 15.2 with traceability of each function to each PIE and PIE sequence in which it is credited.

**Safety Categorization of the Safety Functions** – Functions are categorized in accordance with their safety significance and role in performing FSFs. As such, each function receives a safety categorization directly based on its assignment to a DL (as described in Subsection 3.2.1 above).

### **Identification of SSC that Provide the Safety Functions**

Plant-level requirements are created for each DL function and decomposed into system-specific functional requirements to implement the credited DL functions, consistent with the plant

performance modeled in the safety analyses. These requirements are then allocated to the applicable system design description which identifies the components that support the system DL functions.

### **Assignment of SSC to a Safety Class Corresponding to the Safety Category**

Safety Class is assigned to SSC based on the SSC's role in ensuring plant safety, and the defense line and FSF supported as described in Subsection 3.2.1.6 above.

### **Verification of SSC Classification**

The deterministic safety analyses are maintained and updated as the plant design matures. Confirmation of SSC classification is achieved when the deterministic safety analyses models reflect the final plant design and demonstrate compliance to the analysis acceptance criteria (which include rules governing how classified equipment can be credited in each analysis case). This verification is complemented, as appropriate, by insights from the PSA.

### **Identification of Engineering Design Rules for Classified SSC**

Engineering design rules are applied to SSC based on several factors including their SC, their DL role, their status as a pressure boundary component, their role during and following earthquakes, and their operational environment. The design rules establish the scope of codes and standards applied to an SSC, as well as requirements for reliability, diversity, redundancy, and independence applicable to an SSC. These design rules are discussed in Subsection 3.1.7.

### **3.2.3 Seismic Categories**

Seismic Category reflects SSC requirements during and after a seismic event and governs how the SSC is seismically designed and qualified. Seismic Category is assigned based on the regulatory guidance of CNSC REGDOC-2.5.2, Section 7.13 (Reference 3.2-3), and CSA N289.1, Clause 5.2.5.2 (Reference 3.2-4) as follows:

1. **Seismic Category A/B** - DL3 functions are credited with remaining operable during and after a seismic event associated with a Design Basis Earthquake (DBE) as defined in Section 3.3.1. Accordingly, SSC that perform or support DL3 functions are categorized as Seismic Category A for passive SSC or Seismic Category B for active SSC. Other SSC that are classified as SC1 per Subsection 3.2.1.6, are categorized as Seismic Category A or B. Any other SSC that are a significant contributor to PSA risk for seismic events are categorized Seismic Category A or B.
2. **Seismic Category RW-IIa** - SSC for management and storage of radiological material that, if released would exceed the dose limits defined in CNSC REGDOC-2.5.2, Section 4.2.1, are categorized as Seismic Category RW-IIa per guidance in U.S. Nuclear Regulatory Commission (USNRC) Regulatory Guide (RG) 1.143, (Reference 3.2-7). These RW-IIa SSC are seismically qualified for one-half of the site-specific DBE. This approach is in accordance with CNSC REGDOC-2.5.2, Section 7.13.1, which permits the use of ASCE/SEI 43 (Reference 3.2-8) graded approach for the seismic classification of SSCs with justification. Based upon the consequences of failure, one-half of the site-specific DBE is justified as it would bound the ground motion spectra for seismic categories identified in ASCE/SEI 43 (Reference 3.2-8) for SSCs used for handling and storage of highly radioactive materials. This justification is described in NEDC-33974P (Reference 3.2-18).
3. **Non-Seismic** - All other SSC are categorized as Non-Seismic and are designed based on applicable non-nuclear requirements, such as those stipulated in the National Building Code of Canada (Reference 3.2-19).

The BWRX-300 Containment and the Reactor Building (RB) are the only structures that house, support, or protect Seismic Category A or Seismic Category B SSC. These two structures are therefore categorized as Seismic Category A structures in the BWRX-300 design per Clause 5.2.5.2 of CSA N289.1 (Reference 3.2-4).

### **3.2.3.1 Seismic Interaction**

SSC that are not Seismic Category A or B but whose failure during a seismic event could adversely affect the ability of any Seismic Category A or B SSC to accomplish its safety function are evaluated for seismic interaction to demonstrate that these SSC:

- Will not collapse or collide with the Seismic Category A and Seismic Category B SSC and will maintain their stability during a DBE or other relevant extreme external hazard event; or
- Impact loads that result from collapse or collision on the Seismic Category A and Seismic Category B SSC are either negligible or smaller than those considered in the design.

In accordance with requirements of Clause 7.2.1.2 of CSA N289.3 (Reference 3.2-6) and Section 6.0 of NEDO-33914 (Reference 3.2-9), interaction evaluations are performed of the Power Block structures and foundations adjacent to the Seismic Category A RB, as described in Subsection 3.3.1.2.8, to ensure:

- These structures and foundations do not collapse to compromise the safety functions of those SSC that are required to remain functional following a DBE or design tornado level event for the first 72 hours.
- The CB structure, which includes the Main Control Room (MCR) does not collapse and result in incapacitating injury to the main control room occupants or prevent their egress to the RB.

Table 3.3-1 in Section 3.3 lists the seismic category and seismic interaction evaluation requirements for structures..

Evaluations for seismic interaction of systems and components is conducted as the design advances and details supporting these evaluations are available.

### **3.2.4 Quality Group**

In alignment with CNSC REGDOC 2.5.2, Section 7.7 (Reference 3.2-3), BWRX-300 pressure-retaining components are designed to ensure they are protected against overpressure conditions, and are classified, designed, fabricated, erected, inspected, and tested in accordance with established standards. The selection of codes and standards is commensurate with the safety class and is adequate to provide confidence that plant failures are minimized. CNSC REGDOC-2.5.2 points to ASME Boiler and Pressure Vessel Code (BPVC) (Reference 3.2-11) to meet the requirements of different classes of pressure-retaining systems, components, piping and their supports.

BWRX-300 design utilizes a Quality Group designation per the guidance in USNRC RG-1.26 (Reference 3.2-10) as a method for establishing the appropriate codes and standards based on the importance of the pressure-retaining function of the component. Items are classified as Quality Group A, B, C or D. The guidance and classification method are used with some clarification based on the unique design of the BWRX-300.

Table 3.2-3 tabulates the design and fabrication requirements for each Quality Group. For mechanical equipment that does not fall within the scope of USNRC RG 1.26 (Reference 3.2-10),

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

appropriate industrial codes and standards are applied. Per CNSC REGDOC-2.5.2, alternative codes and standards may be used with justification and consistent with a graded approach.

Appendix 3A provides a list of the BWRX-300 principal components organized by system and includes their Quality Group. The Quality Group for structures is listed in Section 3.3, Table 3.3-1.

### **3.3 Protection Against External Hazards**

Complying with Section 7.4.2 of CNSC REGDOC-2.5.2 (Reference 3.3-1), the BWRX-300 design considers natural and human-induced external hazards that may be linked with significant radiological risk. This section discusses external hazards relevant to the DNNP site and the BWRX-300 approach to prevent and mitigate their effects on Safety Class 1 (SC1) Structures, Systems and Components (SSC). SC2/SC3 SSC that are credited in the fault evaluation with mitigating fault sequences initiated by external hazards, and SSC whose failure can affect the structural integrity or safety class functions of adjacent SC1 SSC are also protected against external hazards.

The determination of the external hazards considered in the BWRX-300 design relies on the collection of the geotechnical, seismological, hydrological, hydrogeological, and meteorological reference data, and human-induced external events presented in Chapter 2, Section 2.2, Section 2.4, Section 2.5, Section 2.6 and Section 2.7. For external hazards, the main protection is provided by the civil structures. The design against external hazards is such that a design basis external hazard does not lead to a Design Basis Accident (DBA) or a Beyond Design Basis Accident (BDBA). Significant safety margins are included in the evaluation of the design basis external hazards and the associated design aspects to ensure a conservative design. Assurance that the overall reactor plant is resilient to external hazards is provided by the demonstration that SSC do not fail when subject to these hazards and generated loadings. Demonstration of the adequacy of protection measures is provided in the applicable PSAR chapters covering the design of SSC.

Malevolent acts considered in the robustness design are discussed in Subsection 3.3.7.4.

Protection and mitigation methods considered in the design are in line with the design safety objectives and Defence-in-Depth (D-in-D) concept discussed in Subsections 3.1.1 and 3.1.6, respectively. They include the use of physical separation, barriers/shielding, qualification of equipment and instrumentation for the hazards environment and monitoring programs to preclude unacceptable radiation releases following accidents due to external hazards.

When applicable, loads generated by external hazards are considered in the BWRX-300 design following requirements in Section 7.15.1 of CNSC REGDOC-2.5.2 and CSA N291 (Reference 3.3-2). Combination of loads from randomly occurring individual external hazards is considered in the design to ensure structures are adequately protected against external hazards.

A principal safety objective of the BWRX-300 Safety Strategy is the demonstration that the overall reactor plant design is resilient to hazards through D-in-D. This means that the design provisions optimize protection to provide the highest level of safety that can reasonably be achieved such that relevant dose targets on-site and off-site are met and the resilience of the reactor plant to external hazards reduces risk. The process of demonstrating that the reactor plant is resilient starts with the systematic identification of Postulated Initiating Event (PIEs) with a potential to challenge a fundamental safety function, and to organize them into the fault list developed as per Chapter 15, Section 15.2. Combinations of randomly occurring individual events are considered in these evaluations in accordance with requirements in CNSC REGDOC-2.5.2, Section 7.4.3. Deterministic and probabilistic safety analyses are then performed as discussed in Chapter 15, Sections 15.5 and 15.6 to confirm the design adequacy and its resilience to these hazards. Summary of results of the safety assessments are presented in Section 15.7.

#### **3.3.1 Seismic Design**

For seismic design, BWRX-300 SSC are categorized as Seismic Category A, Seismic Category B, Seismic Category RW-IIa and/or Non-Seismic Category as discussed in Subsection 3.2.3. This

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

seismic categorization reflects SSC's functional and performance requirements during or after a seismic event and impacts their design.

Following the regulatory guidance of CNSC REGDOC-2.5.2, Section 7.13.1, CSA N289.1 (Reference 3.3-3) and U.S. NRC RG 1.208 (Reference 3.3-4), Seismic Category A and Seismic Category B SSC are seismically qualified to withstand the effects of a Design Basis Earthquake (DBE) that is developed:

1. Based on the geological, seismological, and geotechnical conditions at the site described in Chapter 2, Section 2.7
2. Following the performance-based approach of ASCE/SEI 43 (Reference 3.3-5) Section 2 for development of DBE for seismic design of structures achieving a target performance goal of  $1E-5$  per year
3. Meets the minimum earthquake requirements of CSA N289.3 (Reference 3.3-6), Clause 4.2

The development of the 5% damped Acceleration Response Spectra (ARS) defining the amplitude and frequency content of the bounding site-specific DBE input ground motion used for the seismic qualification of Seismic Category A and B SSC is discussed in Subsection 3.3.1.1.

Table 3.3-1 provides the seismic categorization of BWRX-300 structures. Per Subsection 3.2.3, the containment, and Reactor Building (RB) are the only structures that house, support, or protect Seismic Category A or Seismic Category B SSC. As a result, the integrated RB structure, which consists of the RB, containment and containment internal structures is the only structure categorized as Seismic Category A in the BWRX-300 design. As shown in Table 3.3-1, the seismic design of the Seismic Category A structures considers Limit State LS-D response defined in Table 1-2 of ASCE/SEI 43 as essentially elastic response without any significant permanent deformation. According to U.S. NRC RG 1.208, this ensures a consistent level of safety from earthquake-caused failures defined by level of response resulting in an onset of significant inelastic deformations with a probability of unacceptable performance:

- Less than 1% for a DBE ground motion level
- Less than 10% for ground motion with 1.5 times the DBE intensity

The Radwaste Building (RWB) which processes and houses liquid, solid and gaseous radwaste is categorized as Seismic Category RW-IIa as shown in Table 3.3-1. The remaining BWRX-300 Power Block structures, which consist of the Control Building (CB), Turbine Building (TB) and Reactor Auxiliary Bay (See Chapter 1, Appendix A, Figure A1.4-1) are categorized as Non-Seismic.

Due to their proximity to the Seismic Category A RB, the RWB, CB, TB and Reactor Auxiliary Bay are evaluated for interaction with the integrated RB structure per the requirements in SSR-2/1 (Reference 3.3-7), Section 5.19, as discussed in Subsection 3.2.3.1. The interaction evaluation methodology is presented in Subsection 3.3.1.2.8. Table 3.3-1 summarizes the seismic design basis for the BWRX-300 structures based on their seismic categories. Per Table 3.3-1, the RW-IIa structures are designed per CSA N291 and U.S. NRC RG 1.143 (Reference 3.3-8), while Non-Seismic Category structures are designed in accordance with the National Building Code of Canada (NBC) (Reference 3.3-9). The primary focus of this section is on the seismic qualification of Seismic Category A and Seismic Category B SSC. The seismic design of the RW-IIa and Non-Seismic Category structures is further discussed in Chapter 9B, Section 9B.3.

Seismic robustness of Seismic Category A structures is evaluated for a Design Extension Condition (DEC) Checking Level Earthquake (CLE) as described in Subsection 3.5.6.1.

The BWRX-300 design considers Operating Basis Earthquake (OBE) and Site Operating Earthquake loads as 1/3 of the DNNP site-specific DBE. Per Appendix S to 10 CFR 50 (Reference 3.3-10), design load combinations that consider OBE and Site Operating Earthquake loads are not required, except for the design of metal containment components where the OBE loads are considered for post-flooding condition and cyclic loading considerations, as noted in Table 9B-1 in Chapter 9B. OBE is not used as reference earthquake for the BWRX-300 DNNP plant shutdown.

The DNNP BWRX-300 seismic instrumentation is discussed in Subsection 3.3.1.5. As described in Subsection 3.3.1.5, the criteria for seismic instrumentation, plant shutdown, evaluation and inspection are in accordance with the guidelines of CSA N289.5 (Reference 3.3-11) and Clause 6.5 of CSA N289.1.

#### **3.3.1.1 Bounding Seismic Design Parameters**

Consistent with the regulatory guidance of CNSC REGDOC-2.5.2, Section 7.13.1, the design of the BWRX-300 is based on DNNP site-specific geotechnical and seismic inputs. Bounding seismic design parameters are developed based on the data that was available prior to the completion of the characterization of geotechnical and seismic conditions at the DNNP site presented in Chapter 2, Section 2.7. These conservative site-specific seismic inputs adequately address uncertainties related to the use of incomplete (preliminary) characterizations of the DNNP geotechnical and seismic conditions.

The 5% damped spectra defining the magnitude and frequency content of the DNNP bounding site-specific design ground motion are developed based on the results of probabilistic Site Response Analysis (SRA) presented in Subsection 3.3.1.1.2 using as input the dynamic subgrade properties dynamic subgrade properties described in Subsection 3.3.1.1.1.

The results of the probabilistic SRA are also used for the development of bounding stiffness and damping properties of subgrade materials that are compatible with the free-field strains generated by a typical design level earthquake event.

The bounding DBE ground motion response spectra in Subsection 3.3.1.1.3 and the bounding strain-compatible dynamic subgrade profiles discussed in Subsection 3.3.1.1.6 provide a conservative seismic design that adequately address the aleatory variabilities and epistemic uncertainties in the geotechnical properties of the DNNP site.

Five sets of ground motion time histories compatible to the bounding DBE ground motion response spectra are developed, as described in Subsection 3.3.1.1.4, for use as input for the linear seismic Soil-Structure Interaction (SSI) analysis.

##### **3.3.1.1.1 Bounding Dynamic Subgrade Properties**

The bounding seismic design parameters are developed using dynamic properties for the subgrade rock, in-situ soil, and engineered fill that are determined based on the data obtained from multiple geotechnical investigations that were completed at the vicinity of the DNNP site prior to the geotechnical site investigations and laboratory tests described in Chapter 2 Section 2.7.3.

For use as input for the probabilistic SRA described in Subsection 3.3.1.1.2, bounding subgrade dynamic profiles are developed reflecting anticipated as-built conditions at the site after construction of the BWRX-300 SMR that include compacted fill from about elevation 80 to 82 m Canadian Geodetic Datum (CGD) to the final grade at elevation 88 m CGD. The layering of the in-situ soil materials is determined based on the stratigraphy obtained from the studies presented in:

- NK054-REP-01210-00098 (Reference 3.3-12) providing data from multiple borings near the proposed BWRX-300 SMR site (B-104, B-113, B-116, and B-118), and

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

- NK054-REF-01210-0418696 (Reference 3.3-13) providing data from deeper borings close to the BWRX-300 SMR (AMC-03ALT).

It is anticipated that the loose surficial soil materials that are not competent for supporting the heavy foundations of the power block buildings and have potential for liquefaction during earthquakes will be excavated and replaced with an engineered fill obtained by reconditioning and compacting the in-situ soils from the fill layer, surficial lacustrine layer, and upper till materials excavated from the upper 6 to 8 m of the site. Results of compaction tests of the in-situ soil materials in 2009 NK054-REP-07730-00005 (Reference 3.3-14) are used as basis for development of the engineered fill dynamic properties.

The probabilistic SRA, described in Subsection 3.3.1.1.2, explicitly consider the epistemic uncertainties in the estimation of subgrade dynamic properties by using 50th percentile Best Estimate (BE), 10th percentile Lower Realization (LR), and 90th percentile Upper Realization (UR) values for the shear wave velocities and kappa representing the dissipation of the energy for the site. For the different subgrade materials, standard deviation for the natural log of the shear wave velocity is assigned to adequately define the aleatory variability of subgrade dynamic stiffness properties.

The profile of bounding rock dynamic properties is developed directly from the recommended shear wave velocity profiles in 2012 NK054-REF-01210-0418696 (Reference 3.3-13). The Base Case values and variations for dynamic properties of rock are presented in Table 3.3-2. The compression wave velocities, shear wave velocities, and Poisson's ratio for the bedrock rock units are obtained from the measured values from 2012 NK054-REF-01210-0418696 (Reference 3.3-13) without modification. The rock Poisson's ratio was calculated from the measured compression and shear wave velocities following the recommendation of the NEDO-33914 (Reference 3.3-15).

The profile of base case dynamic properties presented in Table 3.3-2 considers the following:

1. The "Top of Bedrock Rock" elevation is 64.1 m CGD with a  $\sigma_{TOR}$  of  $\pm 1$  m
2. The variation in the rock layers assumes  $\pm 2$  m
3. The  $\sigma_{\mu \ln}$  represents the epistemic uncertainty for estimating LR (10th percentile) and UR (90th percentile) profiles
4. The  $\sigma_{\ln V_s}$  represents the aleatory uncertainty for randomization of the shear wave velocities.

Epistemic uncertainty in the distribution of the shear wave velocity profiles ( $\sigma_{\mu \ln}$ ) was estimated based on the range of  $V_s$  values measured in each bedrock layer; however, the estimated values were lower than the typical estimate of 0.35 in the 2013 EPRI TR-1025287 (Reference 3.3-16). Based on a comparison with the estimated  $\sigma_{\mu \ln}$  values, a  $\sigma_{\mu \ln}$  of 0.10 is selected based on the similar results from all three borings, as described in the 2012 NK054-REF-01210-0418696 (Reference 3.3-13). Using a higher  $\sigma_{\mu \ln}$  value was not justified by the site data. Aleatory uncertainty considers a standard deviation for the natural log of the shear wave velocity ( $\sigma_{\ln V_s}$ ) of 0.15 for the bedrock layers based on the 2013 EPRI TR-1025287 (Reference 3.3-16).

Table 3.3-3 presents the small-strain dynamic properties of the engineered fill and the in-situ soil. The small-strain values of the soil materials are estimated from the measured SPT N60 values provided in the NK054-REF-01210-0418696 (Reference 3.3-13) and the NK054-REP-01210-00098 (Reference 3.3-12). Three sets of shear wave velocities are estimated for each soil layer using the average, lowest, and highest N60 values. The results for the average, lower, and upper estimates were then combined using weights of 0.4, 0.3, and 0.3, respectively, to approximate a normal distribution, per the 2013 EPRI TR-1025287 (Reference 3.3-16).

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

The uncertainty in the estimates of soil  $V_s$  is considered using a  $\sigma_{\mu \ln}$  of 0.35 to 0.40. Per recommendations in the 2013 EPRI TR-1025287 (Reference 3.3-16), a value of 0.35 is intended for sites with limited shear wave velocity data while a value of 0.50 is appropriate for a site without shear wave velocity data. The selected  $\sigma_{\mu \ln}$  values generally cover the range of estimated  $V_s$  values in each soil layer at the 10th and 90th percentile.

Dynamic fill properties are estimated from the  $N_{60}$  values. Two correlations are used to estimate  $V_s$  for the  $N_{60}$  values, per the 2012 PEER Report 2012/08 (Reference 3.3-17). The selected  $V_s$  correlations use the  $N_{60}$  values and are appropriate for fill using a range of soils. The average of the two correlations was used as the shear wave velocity in each fill layer. A  $\sigma_{\mu \ln}$  of 0.40 was selected. The selected  $\sigma_{\mu \ln}$  value is considered reasonable due to the limited information on the fill materials. A  $\sigma_{\ln V_s}$  value of 0.25 is used for the fill and upper till and a value of 0.15 is used for the deeper in-situ soil layers.

The BE, LR, and UR variations of the kappa parameter, used to establish consistent damping ratios for the rock layers at the site are presented in Table 3.3-4. The kappa value was estimated following the guidance of the 2013 EPRI TR-1025287 (Reference 3.3-16) for CEUS firm rock profiles with a thickness of less than 1000 m and a total standard deviation of 0.47 for kappa based on the 2014 PEER Report No. 2014/12 (Reference 3.3-18).

The BE, LR and UR of the shear wave velocity profile representing the assumed as-built conditions are presented in Figure 3.3-1.

The dynamic subgrade stiffness properties of in-situ soil and engineered fill materials in Table 3.3-3 correspond to small-strain levels. To account for the nonlinearity of the engineered fill and in-situ soil materials. The following two sets of strain-dependent property curves are recommended in EPRI TR-1025287 (Reference 3.3-16, Section B-3.3):

- EPRI curves from the 1993 EPRI TR-102293, "Guidelines for determining design basis ground motions (Reference 3.3-19)
- Peninsular Range curves, Silva, W.J., N. Abrahamson, G. Toro and C. Costantino. (1996). Description and validation of the stochastic ground motion model (Reference 3.3-20)

The Peninsular Range curves are used for the development of bounding seismic design parameters to account for the strain-dependance of the soil and engineered fill dynamic stiffness and damping properties. The EPRI curves are not considered because the results of SRA indicated excessive softening of the soil and fill layers which can result in unconservative estimates of the seismic response at the ground surface, per the 2013 EPRI TR-1025287 (Reference 3.3-16, Section 5.0, and Figure 5-7).

#### **3.3.1.1.2 Site Response Analyses**

Probabilistic Site Response Analyses (SRA) are performed to accommodate the effects of overlying materials on the seismic hazard considering the epistemic uncertainties and aleatory variabilities in the site parameters to preserve the desired hazard levels and performance goals per requirements of CSA N289.2 (Reference 3.3-21) and regulatory guidelines of U.S. NRC RG 1.208. These SRA consider as-built conditions at the DNNP site after the excavation, construction, and backfilling. The equivalent linear approach is used for the SRA to account for the non-linear response of the soil. Curves representing the shear modulus reduction ( $G/G_{max}$ ) and damping of the soil materials as a function of strain are used to iteratively adjust the shear modulus and damping ratio of the soil based on the calculated effective soil shear strain until convergence is obtained.

As discussed in Subsection 3.3.1.1.1, epistemic uncertainties in the shear wave velocities and the dissipation of energy for the site represented by the coefficient kappa are explicitly considered in

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

the evaluation of DNNP bounding seismic parameters. To account for the epistemic uncertainties, the probabilistic SRA consider three sets of values BE, LR, and UR for shear wave velocity, presented in Figure 3.3-1 and kappa values presented in Table 3.3-4, resulting in a total of 9 sets of base case analyses. Per 2013 EPRI TR-1025287 (Reference 3.3-16), weight factors of 0.4, 0.3, and 0.3 are assigned for the BE, LR and UR cases, respectively. The cases considered for the epistemic uncertainties and their associated weight factors are presented in Figure 3.3-2.

The SRA consider aleatory variabilities related to variations in layer thicknesses including rock depth, shear wave velocities, non-linear degradation curves for the engineered backfill and soil layers, and rock damping. The aleatory variabilities are included in the site response analysis by randomization of the BE, LR and UR shear wave velocity base case profiles, using a sample size of 60 with log-normal distributions.

The range of simulated shear wave velocities is limited to two log-standard deviations above and below the specified median value to bound the randomized profiles within physically plausible limits.

Toro's site variation model (Reference 3.3-22) is used for the randomization of the thickness of soil and rock layers. The site variation model parameters are modified to capture a value of 1 m for the variation of rock depth without regards to the thickness variation in the soil layers above or the rock layers below the rock top elevation. This is a reasonable approximation since:

- The top layer is engineered backfill
- The effects of the thickness variations within the soil and rock layers on the site response are insignificant compared to the variation of the elevation of the rock and soil interface

Figure 3.3-3 shows the suite of 60 random shear wave profiles that include the thickness variations obtained from the randomization of the BE shear wave and BE kappa value (BE-BE) base case profile. The thick black line in the plot designates the resulting mean profile.

The curves representing the shear modulus reduction ( $G/G_{max}$ ) and damping of the soil materials with strain are randomized into 60 realizations with correlated log-normal distribution using the Darendeli model (Reference 3.3-23). The damping of subgrade materials is limited to 15% in accordance with the regulatory guidance of ASCE/SEI 4 (Reference 3.3-24), Section C5.2 and U.S. NRC RG 1.208, Appendix E. Figure 3.3-4 shows examples of randomized modulus reduction and material damping curves. The thick black lines in these plots designates the resulting mean curves.

Approach 1, from the approaches defined in NUREG/CR-6728 (Reference 3.3-25), is implemented for the SRA, where the reference site Uniform Hazard Response Spectra (UHRS) with Mean Annual Probability of Exceedance (MAPE) of  $1E-3$ ,  $1E-4$  and  $1E-5$ , are directly used as input control motions and propagated from the bedrock with reference shear wave velocity of 2,800 m/sec through the randomized subgrade profiles. This allows the 5% damped ARS results of Approach 1 SRA to be directly used for the development of the UHRS representing the seismic hazard at the horizons of interest.

Approach 1 is selected as appropriate approximation for the purposes of development of bounding seismic parameters using a preliminary site information.

The reference site UHRS at  $1E-03$ ,  $1E-04$ , and  $1E-05$  MAPE levels are developed using the results of the PSHA documented in NK38-REP-03611-10041 (Reference 3.3-26). Between the different options considered in this PSHA, Option 2 for CAV filtering of magnitudes 5 and above is used as input for the Approach 1 SRA, as it provides the greater seismic hazard. Figure 3.3-5 shows the bedrock UHRS used as input for the SRA.

Using the random vibration theory, power spectral density functions for the reference site motions are calculated iteratively from the input UHRS and propagated throughout the randomized shear wave profiles to calculate power spectral density functions at the horizons of interest. 5% damped ARS at each horizon of interest are then calculated from their corresponding power spectral density functions implementing the random vibration theory approach.

For each of the 9 base cases shown in Figure 3.3-2 and MAPE considered, log-mean ( $\mu_i$ ) and log-Standard Deviation ( $\sigma_i$ ) 5% damped ARS results are calculated from the SRA of the 60 random profiles. UHRS representing the mean estimate of the seismic hazard at the horizons of interest are calculated by applying weight factors ( $w_i$ ) to the log mean ARS results from the different base case analyses as follows:

$$UHRS = \sum_i w_i \mu_i$$

Figure 3.3-6 and Figure 3.3-7 show with thick solid red lines the MAPE 1E-4 and 1E-5 UHRS representing the seismic hazard at the ground and top of rock surfaces, respectively, together with the corresponding log-mean ARS calculated from the analyses of 9 base cases.

Log-Standard Deviation values  $\sigma_T$  and  $\sigma_{Ep}$  are calculated as follows, representing the composite (total) uncertainty and epistemic uncertainty of the calculated hazard at the horizons of interest, respectively:

$$\sigma_T = \sqrt{\sum_i w_i ((\mu_i - \mu_T)^2 + \sigma_i^2)}$$

$$\sigma_{Ep} = \sqrt{\sum_i w_i (\mu_i - \mu_T)^2}$$

Figure 3.3-8 and Figure 3.3-9 present the composite and epistemic uncertainties for the MAPE 1E-4 and 1E-5 seismic hazard for the responses at the ground and top of rock surfaces, respectively. The figures also show the log-Standard Deviation of the ARS results for the 9 base cases.

Upper Bound (UB) estimates of the UHRS ( $UHRS_{UB}$ ) are developed to account for the epistemic uncertainties related to the site inputs and simplified SRA methodology by applying one epistemic log-normal Standard Deviation ( $\sigma_{Ep}$ ) increments to the mean hazard estimate UHRS as follows:

$$UHRS_{UB} = UHRS \times e^{\sigma_{Ep}}$$

Figure 3.3-6 and Figure 3.3-7 show with thick dashed lines the UB UHRS for MAPE 1E-4 and 1E-5 representing the UB estimates of the seismic hazard at the ground and top of rock surfaces, respectively.

### 3.3.1.1.3 Design Basis Seismic Ground Motion Response Spectra

Acceleration response spectra at 5% damping define the amplitude and frequency content of the BWRX-300 design ground motion consistent with Clause 4.3 of CSA N289.3. In accordance with the regulatory guidance of CNSC REGDOC-2.5.2, Section 7.13.1, the horizontal ground motion design spectra are developed following the methodology specified in Section 2 of ASCE/SEI 43 using the UHRS results with annual probability of exceedance of 1E-4 and 1E-5 per year.

Additional requirements for developing the site-specific DBE for the design of the deeply embedded Seismic Category A integrated RB structure are provided in Section 5.2.2 of NEDO-33914 Revision 2 (Reference 3.3-15).

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

The following horizontal and vertical spectra define the amplitude and frequency content of the DNNP site-specific DBE ground motion for the SSI analysis of the BWRX-300 deeply embedded RB structure:

1. Foundation Input Response Spectra (FIRS) defining the DBE ground motion at bottom of RB Foundation.
2. Performance Based Surface Response Spectra (PBSRS) defining the DBE ground motion at the finished plant grade elevation.
3. Performance Based Intermediate Response Spectra (PBIRS) defining the DBE ground motion at intermediate embedment depth elevation established, following the guidelines in NEDO-33914 Revision 2, Section 5.2.2 at the top of the rock elevation having a significant contrast between rock and overlaying soil shear wave velocities.

The purpose of PBIRS is to ensure the ground motions used as input for the SSI analyses of deeply embedded structures are adequate throughout the depth of the embedment.

Horizontal FIRS, PBSRS and PBIRS are developed following the performance-based approach criteria of ASCE/SEI 43, Section 2 for DBE with a target performance goal of  $1E-5$ . Instead of using UHRS representing the mean estimate of the seismic hazard as mandated by ASCE/SEI 43, the bounding FIRS, PBSRS and PBIRS are conservatively developed using the  $1E-4$  and  $1E-5$  MAPE UHRS representing UB estimates of the seismic hazard. These UB UHRS are developed as described in Subsection 3.3.1.1.2 to account for the epistemic uncertainties related to the site inputs and simplified SRA methodology. The resulting horizontal Ground Motion Response Spectra (GMRS) are further adjusted to meet the minimum required response spectra requirement using the generic spectrum in CSA N289.3, Clause 4.3.2 anchored at the minimum peak ground acceleration value of  $0.1g$ .

Horizontal reference site hard rock GMRS is also developed following the ASCE/SEI 43 performance-based approach using the UHRS obtained from the PSHA documented in NK38-REP-03611-10041 (Reference 3.3-26) representing the reference site hazard with MAPE of  $1E-4$  and  $1E-5$ . This reference site hard rock spectrum is used to conservatively neglect the de-amplifications of the reference hazard motion as it propagates through the rock column. A single rock design ground motion response spectrum is developed as a conservative representation of the amplitude and frequency content of the horizontal rock GMRS by enveloping, as shown in Figure 3.3-10 the three GMRS representing the seismic hazard at FIRS, PBIRS and reference site hard rock horizons.

The horizontal PBSRS representing the amplitude and frequency content of the design motion at the ground surface are increased to conservatively account for the uncertainties in the soil column properties that may result in spectral peak shifts by connecting the spectral peaks in the PBSRS at frequencies of 8.3 Hz and 20.4 Hz using linear interpolation in the logarithmic space.

Figure 3.3-11 presents the development of the enveloping 5% damped PBSRS representing the amplitude and frequency content of the horizontal design ground motion at the finished grade elevation.

Vertical rock GMRS and PBIRS are developed by applying frequency-dependent Vertical-over-Horizontal (V/H) ratios to the bounding horizontal spectra, in accordance with the requirements of CSA N289.3, Clause 4.3.3.3 and U.S. NRC RG 1.208.

The rock V/H ratios that are used for calculation of vertical rock GMRS, are constructed using the CEUS hard rock V/H ratios from NUREG/CR-6728 (Reference 3.3-25). The vertical PBSRS are calculated using soil V/H that are constructed following the methodology for CEUS soil sites using the procedure outlined in Appendix J of NUREG/CR-6728 (Reference 3.3-25). The rock and soil

V/H ratios used for calculation of the bounding vertical ground motion design spectra are presented in Figure 3.3-12.

Figure 3.3-13 presents the site-specific horizontal and vertical rock Design Ground Response Spectrum (DGRS) and PBSRS defining the bounding design ground motion for the seismic analysis of the BWRX-300 Seismic Category A structures and for the seismic interaction evaluations discussed in Subsection 3.3.1.2, and compares these bounding values to the corresponding ground motion response spectra developed using the latest available geotechnical and seismological data (described in Chapter 2, Section 2.7), which were not available at the time of development of the bounding seismic design parameters.

The bounding horizontal and vertical peak ground accelerations for the rock design ground motion is 0.31 g. For the surface ground motion, the bounding peak accelerations are 0.532 g and 0.516 g for the horizontal and vertical directions, respectively. Peak ground acceleration values are defined as the ground motion acceleration values at 100 Hz.

NEI checks are performed following the procedure described in Section 5.3.4 of NEDO-33914 Revision 2 to ensure the ground motion used as input for the deterministic SSI analyses of deeply embedded RB structure at the RB foundation bottom elevation meets the regulatory guidance of U.S. NRC DC/COL-ISG-017 (Reference 3.3-27) to be hazard consistent with the results of probabilistic SRA. Horizontal and vertical rock design GMRS input motions are propagated upward through the strain-compatible soil profiles, developed as described in Subsection 3.3.1.1.6, from the bottom of foundation to the profiles surface. The envelope of the 5% damped ARS results for the responses at surface of the profiles are compared to the PBSRS. When the enveloped ARS do not meet or exceed the PBSRS, the design spectra are augmented to ensure that the augmented motion satisfies the NEI check. The augmented spectra are further increased to smooth spectral peaks and fill the valleys. Figure 3.3-14 presents the NEI check augmented and smoothed horizontal and vertical 5% damped spectra defining the amplitude and frequency content of the SSI input control motion applied to the SSI model at the RB foundation bottom.

As shown in Figure 3.3-13, in the frequency range of 0.5 to 50 Hz, which is of interest for the seismic design, the bounding horizontal Rock DGRS and PBSRS envelop the corresponding updated design response spectra discussed in Chapter 2, Section 2.7. Exceedances can be observed in the vertical Rock DGRS of up to 10% for frequencies up to 15 Hz. There are also exceedances in the vertical PBSRS of up to 20% for frequencies ranging from 2 Hz to 30 Hz.

The results of the sensitivity evaluation discussed in Chapter 9B Appendix 9B.C indicate the conservatism introduced in the bounding DNNP site-specific seismic design by using the enhanced input ground motion in Figure 3.3-14. Considering this and the other sources of conservatism in the analysis inputs and methodology as well as the considerable margins in the site-specific design of the RB integrated structures demonstrated by the structural design evaluations discussed in Chapter 9B Appendices 9B.E – 9B.G, the conclusions of the bounding seismic SSI evaluations are not expected to be affected by the relatively small exceedances of bounding ground motion Design Response Spectra observed in Figure 3.3-13.

#### **3.3.1.1.4 Design Time Histories**

Design ground motion acceleration time histories used as input to the seismic SSI analyses of RB are developed by spectral matching seed ground motion records to the ground motion design response spectra presented in Figure 3.3-14. Per the guidelines of NEDO-33914 Revision 2, Section 5.2.3, five sets of three design motion time histories, in the two horizontal and in the vertical directions, are developed for the design to mitigate uncertainties due to the phasing of the time history frequency components.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

Time histories are developed by fitting recorded seed time histories to the 5% damped target design spectra to meet the requirements of Clause 4.4.4 of CSA N289.3 and Section 5.2.3 of NEDO-33914 Revision 2.

Per the recommendations of NEDO-33914 Revision 2, seed time histories are selected from the NUREG/CR-6728 database of ground motion records. The selected seed time histories include records with different magnitude and distance bins that have spectral shapes reasonably consistent with the spectral shape of the design target spectrum over the frequency range of interest and characteristics that reasonably represent the earthquake motions expected at the site. Since only a limited number of records for moderate and larger magnitude earthquakes are available for the Central and Eastern United States in the NUREG/CR-6728 database, transformed records from the Western United States are used. The transformation of these time records is performed to modify the spectra to correspond to Central and Eastern United States site conditions while preserving the realistic phase and amplitude relationships of the original records. Based on the DNNP PSHA deaggregated seismic hazard results, the selection of seed time records considered multiple bins for rock seed time histories, including records from magnitude 6 to 7 earthquakes at distances of 10 to 50 km, and the magnitude 7+ earthquakes at 10 to 50 km, 50 to 100 km, and 100 to 200 km.

Table 3.3-5 provides details of the selected five sets of time history records used for the development of the design time histories for SSI analyses of DNNP BWRX-300 RB. The five selected time histories are all from the 1999 Chi-Chi Taiwan earthquake (magnitude 7.6) that had a reverse fault mechanism that is appropriate for eastern North America. These time history records had sampling rates ( $\Delta t$ ) of 0.005 seconds, with a Nyquist frequency of 100 Hz, and were typically longer duration recordings. Records from the shorter distances of 10 to 50 km and 50 to 100 km better matched the shape of the bounding ground motion response spectra once scaled to match the target spectrum at 100 Hz. The magnitude 7+ earthquakes at shorter distances than the scenario earthquakes (e.g., 10 to 50 km) are consistent with the target ground motion response spectra that represent an UB estimate of the seismic hazard. Smaller magnitude earthquakes were not selected because of a deficit of low frequency energy and the need for larger scaling factors. Table 3.3-5 provides the scaling factors applied to the time histories prior to spectral matching to better align the seed response spectrum shapes to the target spectra.

The spectral matching procedure is implemented for fitting the seed time histories to the 5% damped target spectra that retains the phase spectra of the seed time histories, preserving the relative phasing between horizontal and vertical components, as well as, preserving the non-stationarity and randomness characteristics. The modified time histories are checked as follows to ensure they meet the criteria specified in CSA N289.3, Clause 4.4 and ASCE/SEI 43, Section 2.4:

1. The 5% damped ARS of the modified seed time history are computed at a minimum of 100 points per frequency decade per CSA N289.3, Clause 4.4.4.3, uniformly spaced over the log frequency scale. The average of 5% damped ARS of the five Acceleration Time Histories (ATHs) are compared to the 5% damped target acceleration spectrum at each frequency point in the range of 0.1 Hz to 100 Hz to ensure that:
  - a. The average ARS does not fall below the target spectra by more than 10% at any frequency point
  - b. The average ARS does not fall below the target spectra at more than nine adjacent frequency points and 6% of the total number of points where the ARS is calculated satisfying the requirements of CSA N289.3, Clause 4.4.4.4.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

2. In accordance with Clause 4.4.4.5 of CSA N289.3, the power spectral density of the modified ground motion history is computed as described in ASCE/SEI 4, Section 2.6.2, and shown not to have significant gaps in energy at any frequency over this frequency range.
3. The total duration of time histories has to be no less than 15 seconds with minimum strong motion duration of 6 seconds per CSA N289.3, Clause 4.4.4.2 and long enough to provide an adequate representation of the Fourier components at low frequency.
4. Time histories used as input for the seismic response analyses have a strong motion duration, and ratios  $V/A$  and  $AD/V^2$  (where  $A$ ,  $V$ , and  $D$ , are the peak ground acceleration, velocity, and ground displacement, respectively) that are consistent with those of appropriate controlling events developed using the disaggregation data from in NK38-CORR-03611-0847339 (Reference 3.3-28)
5. The set of three modified ATHs representing the ground motion in the three orthogonal directions (two horizontal and one vertical) are statistically independent. Each pair of ground motion histories is considered statistically independent when the absolute value of their correlation coefficient does not exceed 0.16, satisfying the requirement of CSA N289.3, Clause 4.4.4.6.
6. The ATHs are baseline corrected to ensure the ground velocity converges to zero at the end of the earthquake record and maintains a zero-mean value over the time history duration.

Per recommendations of NEDO-33914 Revision 2, Section 5.2.3, the time step of the modified time histories is refined to 0.0025 seconds for the purposes of calculating high frequency in-structural responses, which exceeds the requirements of CSA N289.3, Clause 4.4.4.2.

Spectral matching of the seed time histories is completed using the time domain spectral matching procedure proposed by Lilhanand and Tseng (Reference 3.3-29) and later modified by Abrahamson (Reference 3.3-20) and Al Atik and Abrahamson (Reference 3.3-31). Figure 3.3-151, Figure 3.3-16, and Figure 3.3-17 present an example comparison of the original and spectrally matched time histories for the HWA026 records matched to the target rock design ground motion response spectrum. These plots demonstrate the non-stationary characteristics of the time histories are preserved. The most noticeable changes to the time histories are due to low frequency wavelets added at later portions of the time histories.

Response spectrum of the generated acceleration time histories are computed and compared to the appropriate target response spectra. A small scaling factor is applied to the time histories to increase the spectra and meet the design criteria. Finally, the cross-correlation coefficients, peak values, Arias Intensity, and Power Spectral Density function are computed for the spectrally matched time histories.

Figure 3.3-18 presents the normalized Arias Intensity, and the power spectral density function for the horizontal HWA026 components that are spectrally matched to the rock design ground motion response spectrum. Figure 3.3-19 presents the response spectra for spectrally matched horizontal and vertical components of record HWA026.

#### **3.3.1.1.5 Percentage of Critical Damping**

Consistent with the regulatory guidance of CNSC REGDOC-2.5.2, Section 7.13.1, damping values assigned to the structures and components in the SSI analysis model are in accordance with provisions of CSA N289.3, Clause 6.6, and ASCE/SEI 43, Section 3.3.3. The damping ratio values specified in Table 4(a) of CSA N289.3, Table 3-1 of ASCE/SEI 43, and U.S. NRC RG 1.61 (Reference 3.3-32) are used to represent the dissipation of energy in different elements. Consistent with the regulatory guidance of CNSC REGDOC-2.5.2, Section 7.13.1, lower (Response Level 1) damping ratios are used for generating in-structure demands for qualification

of equipment and systems. The higher (Response Level 2) damping values can be used for development of seismic demands for structural design per ASCE/SEI 43, Section 3.3.3 and U.S. NRC RG 1.61, Section C.1.2, respectively.

The damping properties assigned to soil materials in the SSI analysis model take into account the stress-strain properties corresponding to the level of seismic input per requirements of CSA N289.3, Clause 6.6.3. Stiffness and damping properties of subgrade materials compatible to the strains generated by design level earthquake event are developed based on results of Approach 1 SRA in Subsection 3.3.1.1. The strain-compatible damping of the subgrade materials is limited to 15% in accordance with the recommendations of ASCE/SEI 4, Section C5.2 and the regulatory guidance of U.S. NRC RG 1.208, Appendix E.

Table 3.3-6 lists damping values used in the seismic analysis of structures and components. These damping values are applicable to all modes of a structure or component constructed of the same material.

Damping values for subsystems including piping and equipment are obtained using the procedures described in Subsection 3.3.1.3.

#### **3.3.1.1.6 Supporting Media for Seismic Category A Structures**

Consistent with regulatory guidelines of CNSC REGDOC-2.5.2, Section 7.13.1, the input subgrade properties for the site-specific SSI analysis of the BWRX-300 integrated RB structure are based on the geological, seismological, and geotechnical investigations and take into account the random nature and inherent uncertainties of soil material properties.

In accordance with the regulatory guidelines of CNSC REGDOC-2.5.2, Section 7.13.1, the SSI analysis uses at least three sets of subgrade profiles representing BE, UB, and Lower Bound (LB) estimates of the subgrade material properties. These profiles are representative of the as-built conditions at the DNNP site. The LB and UB shear wave velocities and damping reflect a minimum coefficient of variation of each layer properties of  $\pm 50\%$ . In accordance with CSA N289.3, Clause 5.2.3, the design uses an envelope of results from the SSI analysis of BE, LB and UB subgrade profiles to account for the variation and uncertainty in subgrade properties.

The effects of primary non-linearity of subgrade materials response are addressed by using dynamic stiffness and damping properties which are compatible to the free-field strains induced by an DBE level seismic event.

The strain-compatible subgrade dynamic properties for the DNNP soil materials are calculated in accordance with the requirements of CSA N289.3, Clause 5.2 and ASCE/SEI 4, Section 2.4. These properties are developed at strain levels consistent with the estimated site PBSRS based on the results of the probabilistic SRA presented in Subsection 3.3.1.1.2. The strain-compatible subgrade dynamic properties are developed using the approach described in Appendix B of the Screening Prioritization and Implementation Details document (Reference 3.3-19) as follows:

1. Strain-compatible shear wave velocity and damping ratios are obtained consistent with the 1E-04 and 1E-05 MAPE from the results of SRA of the BE-BE, LR-BE, and UR-BE randomized soil profiles discussed in Subsection 3.3.1.1.2.
2. The logarithmic mean and logarithmic standard deviation of the strain-compatible shear wave velocity and damping ratios at 1E-04 and 1E-05 MAPE are calculated for the considered cases at each soil layer. The results from different soil cases are combined using weight factors of 0.4, 0.3, and 0.3 for the BE-BE, LR-BE, and UR-BE base cases, respectively. The LR and UR kappa base cases (e.g., BE-LR and BE-UR) are not considered given their small effects on site response analysis results when compared to the alternative cases for shear wave velocity. The weighted logarithmic mean and logarithmic standard deviations of the strain-compatible

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

properties are calculated at 1E-04 and 1E-05 MAPE. The weighted average logarithmic mean and logarithmic standard deviation profiles for shear wave velocity and damping ratio at 1E-04 and 1E-05 MAPE are presented in Figure 3.3-20 through Figure 3.3-23, respectively.

3. The logarithmic mean and logarithmic standard deviation of shear wave velocity and damping ratio at strains that are compatible with the 100 Hz value of PBSRS are calculated by linear interpolation in the logarithmic space between those compatible with the 100 Hz values at 1E-04 and 1E-05 UHRS.
4. The exponential of the logarithmic mean profiles shear wave velocity profile calculated above is referred to as the median shear wave velocity and is selected as the 100 Hz BE shear wave velocity profile ( $V_{SBE}$ ). The LB and UB shear wave velocity profiles are calculated as the 16th and 84th percentiles, respectively, using the following equations:

$$V_{SLB} = \min \left\{ e^{\ln(V_{SBE}) - \sigma}, \frac{V_{SBE}}{\sqrt{1.5}} \right\}$$

$$V_{SUB} = \max \left\{ e^{\ln(V_{SBE}) + \sigma}, V_{SBE} \times \sqrt{1.5} \right\}$$

where  $\sigma$  is the logarithmic standard deviation and the terms  $V_{SBE} \times \sqrt{1.5}$  and  $V_{SBE}/\sqrt{1.5}$  reflect the minimum variation requirement of  $C_v = 0.5$  on the shear modulus as specified in CSA N289.3, Clause 5.2.3 to ensure that adequate uncertainty in the shear modulus of the soil profiles are included.

The 100 Hz strain-compatible LB, BE, and UB shear wave velocity profiles are presented in Figure 3.3-24.

5. The BE, LB, and UB profiles for damping ratio are calculated similar to step 4, except that no minimum variations of  $C_v = 0.5$  are used, and the damping ratios are limited to a maximum of 15%, based on the recommendations of ASCE/SEI 4, Section C5.2 and regulatory guidance of U.S. NRC RG 1.208, Appendix E. Consistent with non-linear behavior of soil layers, the 16th percentile of damping ratio profile is associated with the UB profile and the 84th percentile of damping ratios are associated with the LB profile. For the linear rock layers, a damping ratio logarithmic standard deviation of 0.6 is adopted. The 100 Hz strain-compatible LB, BE, and UB damping ratio profiles are presented in Figure 3.3-24.

$$D_{LB} = e^{\ln(D_{BE}) + \sigma}$$

$$D_{UB} = e^{\ln(D_{BE}) - \sigma}$$

6. The BE, LB, and UB profiles considering the interpolation at 1 Hz are established using the same approach described in Steps 3, 4 and 5 above.
7. The final BE profiles are calculated as the average of the BE profiles considering the 100Hz interpolated values and 1 Hz interpolated values. Similarly, the final LB and UB profiles are calculated as the average of their corresponding profiles for the 100 Hz and 1 Hz interpolations.
8. The compression wave velocity profiles ( $V_p$ ) are calculated using the final strain-compatible shear wave velocity profiles ( $V_s$ ) obtained in Step 7 and the Poisson's ratios ( $\nu$ ) recommended for each layer using the following equation. Note that below-ground water table, the minimum of the compression wave velocity of water (1,463 m/sec) and the compression wave velocity corresponding to a maximum Poisson's ratio of 0.48 is used.

The latter criterion is adopted to avoid numerical problems in subsequent SSI analysis of the structure.

$$V_P = V_S \sqrt{\frac{2(1-\nu)}{1-2\nu}}$$

9. The P-wave damping values used as input to the SSI analysis are limited to a maximum of 10% at large strains for soil layers above the ground water table.

The development of dynamic subgrade profiles considers the soils located below the nominal groundwater table to be fully saturated. The groundwater level at elevation of 85 m CGD corresponding to a depth of 3 m below the plant grade at elevation 88 m CGD is considered as noted in Subsection 3.5.2.2. Figure 3.3-25 presents the strain-compatible shear wave velocity, compression wave velocity and damping ratio profiles used for the bounding design seismic analyses of BWRX-300 Seismic Category A structures discussed in Subsection 3.3.1.2.

### **3.3.1.2 Seismic Analysis of Seismic Category A Structures**

This section discusses the seismic analysis of the Power Block Seismic Category A structures which consist of the RB, containment, and containment internal structures.

In accordance with CSA N289.3, Clause 6.2.3, the seismic demands for the design of the BWRX-300 Seismic Category A and Seismic Category B SSC are obtained from the seismic response analyses of the Seismic Category A structures that consider:

- Effects of interactions of the structures and the foundations with the surrounding subgrade
- Variation in the soil and structural parameters
- Hydrodynamic loads (mass and stiffness effects)
- Structure-Soil-Structure Interaction (SSSI) effects with the adjoining RWB, CB, TB, and Reactor Auxiliary Bay structures

Per Subsection 3.2.3, the BWRX-300 Seismic Category A and B SSC are hosted in the integrated RB structure, with the majority of them, including most of the Reactor Pressure Vessel (RPV) and the containment structure, being located below the plant grade elevation.

Because a significant part of the RB structure is located below grade, the interaction of the structure with the surrounding soil is a very important factor for the integrity of the RB structure, its seismic response, and the distribution of seismic stress demands.

In order to adequately account for the SSI and SSSI effects per guidance of NEDO-33914 Revision 2, Section 5.1, the one-step approach, as defined in Section 3.1.2 of ASCE/SEI 4, is implemented for the design of the integrated RB structure. Seismic structural stress demands are obtained directly from the results of SSI analyses of combined models that include 3-Dimensional (3-D) Finite Element (FE) representations of the integrated RB structure and the surrounding soil and Power Block structures. The surrounding subgrade is represented by layered half-space continuum with equivalent linear elastic stiffness properties and complex damping. Simplified FE models represent the dynamic properties of the surrounding Power Block structures and their foundations.

The methodology used for development of the 3-D integrated RB FE model is described in Subsection 3.3.1.2.2, and the SSI modeling assumptions are presented in Subsection 3.5.1.1.2.

#### **3.3.1.2.1 Seismic Analysis Method**

##### **One-Step Seismic Analysis Method**

Seismic demands for the design of Seismic Category A and B SSC are obtained from SSI analyses performed in accordance with the provisions of CSA N289.3, Clause 5.3, and ASCE/SEI 4, Section

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

5, following the regulatory guidance of CNSC REGDOC-2.5.2, Section 7.13.1, and U.S. NUREG-0800 (Reference 3.3-33), SRP 3.7.2.

The BWRX-300 one-step seismic SSI analysis approach provides demands for the seismic design and qualification of SSC for all frequencies of interest and adequately captures the effects of SSSI for the integrated RB with adjacent structures and foundations. The BWRX-300 seismic analysis approach follows the guidance of NEDO-33914 Revision 2, Section 5.0 to address current limitations in U.S. NUREG-0800 SRP 3.7.2 when capturing the effects of seismic interaction of the deeply embedded RB structure with adjacent structures through the subgrade, as identified in NUREG/CR-7193 (Reference 3.3-34), Section 1.5.11.

The seismic SSI analyses are performed using the sub-structuring method in CSA N289.3, Clause 5.3.5, and ASCE/SEI 4, Section 5.4 and the ACS SASSI (a system for analyses of soil-structure interaction, see Appendix 3B) computer program to calculate the seismic response of the RB SSI system. The SSI analysis model consists of the integrated RB structure, the surrounding subgrade and the excavated volume of the subgrade materials replaced by the embedded portion of the RB structure, near field backfill materials and the models representing the dynamic properties of the foundations and structures surrounding the RB.

The sub-structuring method allows the seismic response of the SSI system to be obtained by subdividing the problem into a series of simple subproblems that can be solved separately. Using the principle of superposition, the results of different sub-analyses are combined to obtain the final solution for the SSI problem. The solution for the seismic response of the BWRX-300 RB structure, is obtained in the frequency domain for a selected set of frequencies and then interpolated for other frequency points.

The linear elastic SASSI analyses are performed on one-step structural models that accurately represent the geometry and dynamic properties of the integrated RB structure and its interaction with the subgrade. These structural models have a refined FE mesh that is identical to the mesh of the models used for the static analyses, and that can transmit the entire frequency range of interest for the seismic design of the RB SSC. These models assume isotropic elastic material properties of structural members and surrounding subgrade and neglect any non-linearity at the soil-structure contact interfaces.

The linear elastic assumption allows a set of design and sensitivity SASSI one-step approach analyses to be performed on refined RB structural models with a large number of interaction nodes. The superposition principle, which is applicable only for linear elastic analyses, allows the SASSI stress results obtained from different dynamic and static analyses to be combined with the results of static analyses in seismic design load combinations.

Far-field interaction nodes are established at the surface of each soil layer through the RB shaft embedment depth to capture the horizontal and vertical components of the far-field motion in the SSI model. The responses calculated from these far-field interaction nodes are used to monitor the propagation of the input control motion through the RB embedment depth.

To account for the non-linear response of subgrade materials, strain-compatible subgrade properties are used that are developed based on the results of equivalent linear probabilistic SRA as described in Subsection 3.3.1.1. The uncertainties related to variation of soil and rock properties are addressed in the design of RB SSC by using seismic demands calculated as an envelope of the results obtained from SSI analysis cases of BE, LB, and UB subgrade dynamic profiles.

Input ground motion ATHs are applied to the SASSI model at the RB foundation bottom elevation as vertically propagating coherent:

- Shear waves for horizontal components of the input motion
- Compression waves for the vertical component of the input motion

The horizontal control motion is applied to the SASSI model in a manner that is consistent with the 1-D wave propagation SRA approach discussed in Subsection 3.3.1.1.

As described in Subsection 3.3.1.1, five sets of three input motion ATHs are used as input for the SSI analyses to mitigate the uncertainty in the computed responses due to the phasing of the time history frequency components.

As described in Subsection 3.3.1.2.3, uncertainties related to variations of the input SSI parameters are addressed by results of sensitivity analyses following the recommendations in Section 5.3 of NEDO-33914 Revision 2.

### **Frequencies of Analysis**

Following the guidance of CNSC REGDOC-2.5.2, Section 7.13.1, the frequency range considered in the seismic SSI analysis is based on the frequency content of the input ground motion, the soil properties, the building dynamic properties, including properties of the subsystems, and the response parameter of interest.

The solution for the response of the SSI system is obtained at a selected set of frequency points and then interpolated for other frequency points. The analysis is performed for a cut off frequency value established based on the largest value required by the following four criteria of ASCE/SEI 4, Section 5.3.5(b):

1. Twice the highest dominant frequency of the coupled soil-structure system or
2. The highest structural frequency of interest, or
3. The frequency at which the Fourier amplitude of input motion has passed its peak value and has reached 10% of the peak value, and
4. 20 Hz.

Criteria used to determine the highest dominant frequency and lower cutoff frequency values are described in Section 5.3.2 of NEDO-33914 Revision 2.

Sensitivity SSI analyses required to determine lower cutoff frequency values are performed for the stiffest UB subgrade profile that provides bounding responses at high frequencies.

The value of cutoff frequency determined by the criteria described above is used for the analysis of the UB subgrade profile. The analyses of the softer BE and LB profiles may use lower values for the cutoff frequency. In this case, it shall be demonstrated that the analysis of the UB profile provides responses that are bounding for frequencies higher than the cutoff frequencies used for the analyses of the softer subgrade profiles by comparing transfer function and 5% damped In-Structure Response Spectra (ISRS) results for responses at key locations within the building, selected as described in Subsection 3.3.1.2.5.

The frequencies of analysis are selected at sufficiently small frequency intervals. Transfer function amplitude results for responses at the key locations, selected as described in Subsection 3.3.1.2.5, are inspected to detect any numerical anomalies in the interpolated transfer functions (e.g., sharp narrow spikes) that can potentially affect the accuracy of results. If present, the effects of these anomalies in the interpolated transfer function results are evaluated using additional frequencies of analysis to ensure the anomalies in the transfer function interpolations do not affect the accuracy of the calculated responses.

Acceleration transfer functions and 5% damped ARS are also calculated for the response of SSI model free-field interaction nodes to check the amplitude and frequency content of the in-column free-field motion throughout the RB embedment depth.

#### **3.3.1.2.2 Procedures Used for Analytical Modeling**

SSI analyses of the integrated RB structure, which is primarily constructed of Steel Bricks™ as described in Subsection 3.5.1, are performed on 3-D FE models that meet the structural modeling requirements of CSA N289.3, Clauses 5.3.2 and 6.2, and ASCE/SEI 4, Section 3.

In addition to the integrated RB structures, simplified models of the surrounding RWB, CB, TB, and Reactor Auxiliary Bay structures and their foundations are included in the model to capture the SSSI effects in the RB seismic design.

#### **Dynamic Finite Element Modeling of Integrated RB Structure**

In accordance with requirements of Clause 6.10.4 of CSA N291, U.S. NUREG-0800, SRP 3.7.2, Subsection III.3.D, and ASCE/SEI 4, Section 3.4.2, the integrated RB structural FE model represents all mass expected to be present at the time of the earthquake including mass due to:

- Weight of the structure
- Weight of permanent equipment
- Mass equivalent to floor load of 2.4 kPa for miscellaneous dead weights such as minor equipment, piping, and raceways
- Weight of building elements not represented in the structural model (e.g., secondary members, siding partitions)
- Expected live load, not less than 50% of the live load specified for the design
- At least 25% of the specified design snow loads

The dynamic FE model also includes the inertia associated with the hydrodynamic effects of the fluids contained in various pools inside the RB and tanks in the RWB. The hydrodynamic effects that consist of the impulsive and convective (or sloshing) components are considered in accordance with the requirements of Clause 6.9 of CSA N289.3, Section 3.6.3 of ASCE/SEI 4, and Chapter 5 of ACI 350.3 (Reference 3.3-35). The hydrodynamic mass is included in the model by.

- Distributing the horizontal impulsive fluid mass over the pool and tank walls that are perpendicular to the direction of motion in accordance with the guidelines in ACI 350.3
- Lumping the entire vertical fluid mass on the pool slab or tank bottom.

The convective (sloshing) component of the hydrodynamic mass is not explicitly included in the global analysis model since its contribution is small and is associated with very low frequencies insignificant for the overall response. To account for the sloshing hydrodynamic effects, the design considers quasi-static sloshing pressure loads applied on the pool and tank walls in accordance with Section 9.4 of ASCE/SEI 4.

Beam and shell elements are used to adequately represent the configuration of all main structural members in the integrated RB. The FE model includes gross discontinuities such as large openings and member eccentricity. Thick shell elements are used to model the Steel Bricks™ shear walls, slabs, and mat foundation. 3-D beam elements are used to model the steel columns, beams, and trusses. The shell and beam elements are established at the centreline of the wall, slab, beam, column, and truss elements. Rigid beam and shell elements are used to model

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

member eccentricities and offsets or the section properties of the centreline modeled elements are appropriately adjusted to account for the effect of member offsets.

Local spring elements represent the stiffness of the connections between different structural members, such as the connections of the SCCV with the internal structures, RB walls and slabs that are designed to relief stresses due to thermal expansion.

Contact springs with stiffness properties appropriate to capture the interaction at the soil-structure interface connect the RB structural and subgrade FE models. The results obtained from the contact spring elements serve to:

- Calculate dynamic earth pressures on the below grade RB shaft exterior wall and basemat and
- Determine whether separation between RB shaft wall and soils occurs under DBE loading as discussed in Subsection 3.3.1.2.4.

The evaluation of effects of conditions at the contact interfaces with surrounding subgrade on the RB seismic response is discussed in Subsection 3.3.1.2.4.

The values of Young's modulus and Poisson's ratio representing the structural material stiffness properties are determined in accordance with the governing design codes in Section 3.5. BE stiffness properties are assigned to the concrete made structures in accordance with ASCE/SEI 4, Section 3.3.2.

The effective stiffness for analysis for the thick shell elements representing Steel Bricks™ members is determined in accordance with guidelines in ANSI/AISC N690 (Reference 3.3-36), Appendix N9, or equivalent guidelines that reflect the expected behavior of the structural components during the applicable loads. These guidelines are the same as those in NEDC-33926P (Reference 3.3-37), the licensing topical report providing design requirements for steel-plate composite containment vessel. The stiffness calculations account for the expected state of stress and level of cracking for different loading conditions during normal operation and accident conditions. An effective in-plane shear stiffness determined from ANSI/AISC N690 code Equation A- N9-12, may be used if seismic load is considered in combination with accident thermal loading.

ANSI/AISC N690, Equation A-N9-8 is used to calculate the effective flexural stiffness of Steel Bricks™ members based on the cracked transformed section, which accounts for stiffness from the steel faceplates as well as the cracked concrete infill. This equation is also used to account for reduction of flexural stiffness due to additional concrete cracking due to conditions related to accident thermal loading. The additional reduction in flexural stiffness due to accident thermal can be ignored for operating thermal conditions where thermal gradients are small and develop over longer periods of time.

For structural components whose behavior is controlled by membrane behavior, the effective stiffness for analysis for applicable loading conditions includes considerations to realistically represent the membrane stiffness calculated in accordance with industry accepted guidelines.

The effects of variation of structural stiffness and damping properties is considered in the modeling of the integrated RB structure to ensure accuracy of the calculated seismic responses and seismic demands. Section 5.3.5 in NEDO-33914 Revision 2 describes methods used and sensitivity analyses performed to evaluate possible amplifications of in-structure responses and load demands on the members due to the load redistribution effects.

The FE models used for seismic SSI analyses have a sufficiently refined mesh to be capable of transmitting the entire frequency range of interest for the seismic design of the RB SSC. In accordance with the requirements of ASCE/SEI 4, Section 5.3.4, the FE mesh is smaller than or

equal to one-fifth of the smallest wavelength transmitted through the soil model, i.e., the maximum mesh size:

$$d_{max} \leq \frac{V_s}{5 f_{cutoff}}$$

where:  $V_s$  is the shear wave velocity of the transmitting soil material; and

$f_{cutoff}$  is the cutoff frequency of analysis determined as described in Subsection 3.3.1.2.1

Consistent with requirements of CSA N289.3, Clause 5.3.4.4, the integrated RB FE model is sufficiently refined to ensure:

- Accuracy of SSI solution and ability to capture modes of vibrations up to frequencies that are important for the design
- SSI model can accurately transmit seismic waves with frequencies equal or higher than the cutoff frequency of analysis

Finer meshes are used around penetrations and openings that are larger than half of the wall or slab thickness. Meshes of major walls and slabs consists of at least four shell elements along the short direction and at least six shell elements along the long direction.

The lower boundary of the SSI model is established at a distance that is deeper than at least two times the depth of the RB embedment and at least three times the largest foundation dimension from the bottom of the slab in accordance with requirements of CSA N289.3, Clause 5.3.4.3.

### **Dynamic Modeling of Subsystems, Components and Equipment**

The dynamic properties of subsystems, components, and equipment are included in the integrated RB structural model based on the decoupling criteria of CSA N289.3, Clause 6.3, and ASCE/SEI 4, Section 3.7, depending on the ratios of the mass and first natural frequency of the subsystem, component, or equipment to those of the supporting structure. To capture the dynamic coupling effects of the RPV, the dynamic properties of the RPV and its components are represented by a Lumped Mass Stick (LMS) model capable of capturing all significant modes of the RPV seismic response. Procedures used to develop this LMS model are presented in Subsection 3.3.1.3. The RPV LMS model is connected to the RB structural model using local spring elements, representing the stiffness of the RPV support skirt and the horizontal stabilizers.

#### **3.3.1.2.3 Seismic SSI Analyses Results and Comparison of Seismic Responses**

##### **Key Seismic Responses**

Responses at key nodal locations are calculated to check the accuracy of the SSI analysis and to evaluate seismic responses and effects of variations of different SSI parameters. These key locations are selected based on the following criteria:

1. Nodes at intersections of main structural members (main structural walls) at ground and other major floor elevations to illustrate global responses that exclude possible local effects due to out-of-plane vibrations of slabs and walls, openings or connections with columns, beams or subsystem supports.
2. At least two roof nodes, one central and one corner node, to show all important modes of seismic response of structure including the effects of rocking and torsion.

3. At least two basemat nodes, one central and one corner node, to show the SSI effects on the translational as well as the rotational (rocking and torsion) responses of foundation.

The seismic demands on the below grade portion of the RB structure are affected by the deformations resulting from the response of the SSI system. Therefore, besides the in-structural responses, main stress demand components, such as in-plane shear force and vertical bending moment demands, are also compared to be able to gain a complete understanding of the effects of SSI parameters variations on the structural design. These comparisons are performed for the main below grade structural members at selected design cross-sections subjected to high seismic stress demands.

### **Seismic SSI Analyses Results**

Refer to Appendix 9B.B in Chapter 9B for results obtained from the Seismic SSI Analyses of BWRX-300 Seismic Category A structures.

#### **3.3.1.2.4 Seismic Soil-Structure Interaction Parameters**

The following are key requirements and approaches considered in the seismic SSI analyses to ensure the structural integrity and stability of the deeply embedded BWRX-300 RB structure throughout the life of the plant and to address specifics related to its design and construction.

#### **Implementation of ISG-017 Guidance**

BWRX-300 approaches for meeting U.S. NRC DC/COL-ISG-017 guidance and addressing current limitations in DC/COL-ISG-017 related to the seismic analysis of deeply embedded structures, as identified in NUREG/CR-7193, Section 1.5.8 are described in NEDO-33914 Revision 2, Section 5.3.4.

The intent of U.S. NRC DC/COL-ISG-017 is to ensure that the deterministic SSI analysis of the embedded RB structure uses ground motion inputs that are hazard consistent with the results of probabilistic SRA at the foundation bottom elevation and at ground surface.

The consistency between free-field motion at the bottom of the RB foundation used as input for the deterministic SSI analysis and probabilistic SRA is checked as described in Subsection 3.3.1.1, using the procedure described in Section 5.3.4.1 of NEDO-33914 Revision 2.

The augmented and smoothed horizontal and vertical 5% damped spectra presented in Figure 3.3-14 define the amplitude and frequency content of the SSI input control motion applied to the SSI model at the RB foundation bottom that is hazard consistent with the results of the probabilistic SRA described in Subsection 3.3.1.1.

#### **Coupling of Soil and Structures**

The seismic SSSI of the RB with the adjacent RWB, CB, TB, and Reactor Auxiliary Bay is explicitly considered in the seismic analysis and design.

Simple FE models representing the BE dynamic properties of the surrounding buildings and foundations are included in the integrated RB FE model used for the seismic SSI analysis. These simple models are sufficiently refined to capture all global modes of vibration of the RWB, CB, TB and Reactor Auxiliary Bay structures with significant (> 20%) modal mass participations in the three orthogonal directions.

Subsection 3.3.1.2.8 presents the approach for addressing the requirements related to the seismic interaction of the RB with the surrounding RWB, CB, TB, and Reactor Auxiliary Bay structures and foundations.

#### **3.3.1.2.5 Effects of Parameter Variation on Responses**

This section covers the effects of concrete cracking, excavation support and backfill, groundwater variation, soil separation, non-vertically propagating seismic waves and soil secondary non-linearity on the seismic response and design of the BWRX-300 RB. The evaluations are performed in accordance with the requirements of ASCE/SEI 4, Section 5.1, following the guidelines of NEDO-33914 Revision 2, Section 5.3. They are based on comparisons of key in-structure responses, defined in Subsection 3.3.1.2.5, obtained from sensitivity SSI analyses as described below.

#### **Effects of Variation of Structural Stiffness and Damping Properties**

Effective structural stiffness and damping properties developed as discussed in Subsections 3.3.1.2.2 and 3.3.1.2.3 are assigned to the SSI model following the recommendations in Section 5.3.5 of NEDO-33914 Revision 2. Effective stiffness assigned to concrete members takes into account the level of stress in the concrete members due to the most critical seismic load combinations.

To address the effects of structural stiffness variations, sensitivity SSI analyses are performed on models representing lower structural stiffness properties corresponding to accident thermal and high intensity load conditions. Higher Response Level 2 damping properties may be used for the analysis of the model with LB structural stiffness.

These sensitivity analyses are performed for BE subgrade profile to evaluate the significance of the structural stiffness variations on the RB in-structure responses and redistribution of load demands on the structural members. The effects of structural stiffness variations are assessed by comparing key in-structure responses, defined in Subsection 3.3.1.2.5, of the two sensitivity analyses of models with reduced stiffness properties with results of the design basis analysis performed on the model with effective stiffness properties.

#### **Excavation Support and Backfill Effects**

Excavation support and backfill effects are to be addressed following the guidelines of NEDO-33914 Revision 2, Section 5.3.8. Sensitivity seismic SSI analyses are to be performed using BE properties of surrounding in-situ subgrade materials on a RB FE model that includes the excavation support structure and the fill concrete to assess their effect on the BWRX-300 RB seismic response. Shell and beam elements are to be used to represent the BE dynamic properties of the excavation support structure. Solid elements are to be used to represent BE, and the dynamic properties of concrete fill material. The geometry of the excavation support and the lean concrete are to be modeled based on the nominal dimensions obtained from excavation plan drawings. To address the uncertainties related to the modeling of friction at the RB shaft interfaces, the sensitivity SSI analyses are performed considering two bounding conditions:

- A. Fully bonded conditions assuming no slippage between the RB shaft and surrounding materials
- B. No-friction conditions assuming no friction resistance of RB shaft exterior walls

Results of these sensitivity analyses for key in-structure responses, defined in Subsection 3.3.1.2.5, are compared with the corresponding results of the design basis SSI analyses of FE model that excludes the excavation support and the fill concrete. If the comparisons show significant exceedances ( $> 10\%$ ) in the RB seismic response due to the interaction with the excavation support and fill concrete, the results of these sensitivity analyses are included in the RB seismic design basis.

### **Groundwater Variation Effects**

The potential effects of groundwater level variability on the seismic design of the BWRX-300 RB are addressed as described in Section 5.3.10 in NEDO-33914 Revision 2.

The seismic design of RB is based on analysis of SSI models that reflect fully saturated conditions for all soil materials located below the nominal groundwater elevation. The potential effects of groundwater level variability on the seismic design are addressed by comparing the seismic responses obtained from two sensitivity analyses of:

- A. Fully saturated soil profile with BE soil dynamic properties representative of accidental flood groundwater level
- B. Dry soil profile with BE soil dynamic properties representative of the extreme conditions when the groundwater is located below the RB foundation bottom elevation

Results of these two sensitivity analyses for key in-structure responses, defined in Subsection 3.3.1.2.5, are compared with the results of the design bases SSI analyses based on fully saturated soil profiles below the nominal groundwater elevation. If the comparisons show that the effects of groundwater variation significantly exceed (>10%) the design basis, the results of the two sensitivity analyses are included in the RB seismic design basis.

### **Soil Separation Effects**

The SSI analysis of the BWRX-300 RB addresses the uncertainties related to the inability of linear models used for the seismic design SSI analysis to explicitly represent the separation between the soil and the structure in accordance with the guidance of ASCE/SEI 4, Section 5.1.9(b).

The approach described in Section 5.3.9 of NEDO-33914 Revision 2 is followed to determine if the separation at soil-structure interfaces can have significant effect on the seismic response. A sensitivity SSI analysis is performed on a model where portions of the below grade shaft wall that may experience separation from the subgrade soil are assumed to remain unbonded for the total duration of the earthquake. The extent of soil separation is assessed by comparing the maximum lateral earth pressure calculated from the seismic SSI analysis of BE subgrade profile with a LB estimates of static earth pressures. The static lateral pressures calculated from static design SSI analysis with 1-g loading, described in Subsection 3.5.2.4, are reduced by 10% to account for uncertainties in calculation of soil unit weights and surcharge loads. The regions where the static lateral pressure is lower than the seismic lateral pressure are considered separated in the model used for the sensitivity analysis.

The key in-structure responses, defined in Subsection 3.3.1.2.5, and stress demands calculated from this sensitivity analysis are compared to the corresponding results of the SSI analysis of the model with BE properties representing fully bonded conditions. If the comparisons indicate that the seismic in-structure responses and stress demands from the fully separated model exceed those obtained from the SSI analysis of fully bonded models by more than 10%, the results of this sensitivity analysis are included in the RB seismic design basis.

### **Effects of Non-Vertically Propagating Seismic Waves**

The potential for non-vertically propagating seismic waves at the DNNP site is to be assessed following the guidelines in Section 5.3.3 of NEDO-33914 Revision 2 based on the geological and seismological conditions of the site. The available site information does not indicate presence of dipping soil and rock layers or local seismic sources that can result in significant non-vertical seismic wave propagation at the DNNP site

#### **3.3.1.2.6 Three Components of Design Ground Motion**

Earthquake motion is three-dimensional and seismic design takes into account the effects of three orthogonal components (two horizontal and one vertical) of the prescribed design earthquake.

The SSI analyses are performed separately for each of the three directional components of input ground motion using five sets of time histories per Subsection 3.3.1.1. For each set of time histories used as analysis input, the seismic response parameters obtained from the analysis of each of the three ground motion components are combined to get the total co-directional response with either of the three methods permitted under ASCE/SEI 4, Section 4.2.2.

1. The time histories of responses due to the three earthquake components are combined algebraically on the time-step-by-time-step approach.
2. The maximum co-directional responses can be combined using the 100-40-40 method.
3. The maximum responses due to the three earthquake components can be combined using the Square-Root-of-the Sum of the Squares (SRSS) method.

The absolute sum method used in time domain may also be implemented (e.g., for calculations of seismic demands for foundation bearing pressure and stability evaluations) as a conservative alternative to performing the algebraic sum method for all possible combinations of the input motion directions.

#### **3.3.1.2.7 Development of In-Structure Responses**

ISRS and ATHs are developed from the seismic analysis to serve as input for the seismic design and evaluation of subsystems, components, and equipment.

##### **In-Structure Response Spectra**

The ISRS for the seismic design and evaluation of subsystem, components, and equipment are developed in accordance with the requirements of CSA N289.3, Clause 6.5.2.3 and ASCE/SEI 4, Section 6.2.

A set of ISRS are developed for required damping levels defining the amplitude and frequency content of in-structure design motion at different locations within the RB, in the two horizontal and the vertical directions for seismic qualification of substructures, systems, and components.

The ISRS for the design of subsystems for which dynamic properties are included in the global dynamic model using LMS models, are developed as an envelope of responses at the node locations where these LMS models are connected to the supporting structure provided that, per ASCE/SEI 4, Section 3.7.1(d), the LMS model adequately represents the major effects of interaction between the equipment and supporting structure.

The ISRS for the seismic design and evaluation of subsystems that are decoupled from the global model, and which location is known, are developed as an envelope of responses at the perimeter of the support footprint area to capture the effects of in-structure rotations. If the equipment or component is supported by flexible slabs or attached to flexible walls, ISRS are developed considering additional nodal responses that capture the local effects of out-of-plane vibrations of the supporting slab or wall.

If the LMS models are used to model the structure, substructure, or subsystem in the global dynamic model, the ISRS are developed as envelope of the responses of outrigger nodes located at the edges of the structure or subsystem.

In accordance with the requirements of ASCE/SEI 4, Section 6.2.1.1(a) and (b), the ISRS are developed from the calculated nodal in-structure responses by:

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

1. First combining in the time domain the three co-direction responses due to the three orthogonal components of seismic input motion as an algebraic sum at each time step and then calculating the ARS of the combined ATHs, or
2. Combining the co-directional ARS results obtained from the analysis with the three orthogonal components of seismic input motion using the SRSS method specified in Subsection 3.3.1.2.6.

The spectra are calculated for frequencies ranging from 0.1 Hz to the highest frequency of interest meeting the requirements specified in Table 2 of CSA N289.3. In addition, the ISRS are developed at small frequency intervals to ensure they are sufficiently close to the peak response frequencies of the supporting structure. To satisfy this requirement, the ISRS are calculated at 301 frequency points equally distributed on the logarithmic scale at the frequency range from 0.1 Hz to 100 Hz.

The ISRS are calculated as an envelope of the results from the seismic design basis SSI analysis of all subgrade profiles. In accordance with the requirements of Clause 6.5.2.3 of CSA N289.3, the peaks of the enveloping ARS are broadened by a minimum of +/-15% to address uncertainties related to the modeling of natural frequencies of the supporting structure and the SSI analysis methodology. The sharp valleys between peaks are filled to account for the uncertainties in subgrade properties.

### **In-Structure Acceleration Time Histories**

In accordance with the requirements of ASCE/SEI 4, Section 6.3, time histories used in the analysis of subsystems are obtained either:

- Directly from the results of the SSI analysis as time histories of nodal responses at reference of subsystem support locations; or
- By generating synthetic time histories compatible to multi-damping ISRS developed as described above.

When obtained directly from the SSI analysis results:

- Time histories of the co-directional in-structure responses due to the three components of the SSI analysis input motion are combined in the time domain
- Time histories are obtained from SSI analysis cases that are critical for the designed subsystem and include those obtained from BE soil case
- Time histories obtained from the BE soil case only can be modified by using time-shifting factors to address uncertainties related to the modeling of natural frequencies of supporting structure

### **Relative Displacements**

Relative Displacement between different support points of subsystems with multiple or distributed supports are evaluated using displacement time histories.

The time history of the relative displacements corresponding to each SSI analysis is obtained by algebraic calculation of the different displacement time histories at the support locations. Directional combination of the support displacement time histories is carried on a time-step-by-time-step basis. Maximum design relative displacements are calculated as an envelope of the maximum relative displacements obtained for each SSI analysis case.

#### **3.3.1.2.8 Seismic Interaction Evaluation**

Consistent with CNSC REGDOC-2.5.2, Section 7.13.1, the BWRX-300 design ensures the ability of the RWB, CB, TB, and Reactor Auxiliary Bay to prevent adverse interactions with the Seismic category A and B SSC during a DBE event.

To meet the interaction requirements in Subsection 3.2.3.1, evaluations are performed of the lateral load resisting system of the RWB, CB, TB, and Reactor Auxiliary Bay structures following the approach in NEDO-33914 Revision 2, Section 6.2. These evaluations are based on seismic responses of RWB, CB, TB, and Reactor Auxiliary Bay obtained from the SSSI analyses that incorporate the dynamic response of the RB and surrounding Power Block structures. As described in Subsection 3.3.1.2.2, models used in the SSI analyses of the RB include FE representations of the surrounding RWB, CB, TB, and Reactor Auxiliary Bay structures and foundations. The FE models of the RWB, CB, TB, and Reactor Auxiliary Bay are refined sufficiently to provide accurate stress demands on the major lateral load resisting structural members and accurate seismic displacements in the direction of the adjacent RB.

The seismic interaction evaluations consider limited permanent deformations (LS-C) structural response to calculate DBE demands for the main lateral load resisting structural members in accordance with the guidance of NEDO-33914 Revision 2, Section 6.2.

The stability of RWB, CB, TB, and Reactor Auxiliary Bay foundations is checked following criteria in Subsection 3.5.2.2 using demands calculated per Subsection 3.3.1.2.10. No reductions are applied to seismic driving force demands used for the stability evaluations to account for inelastic responses of these structures.

The resistance to sliding is calculated as summation of the effective cohesion and static frictional resistance between foundation and subgrade. The frictional resistance is based on the effective weight of the building and includes the buoyancy and seismic loads in the vertical direction. The lateral passive resistance of the foundation embedment soil is also considered, as applicable.

The overturning stability evaluation is performed for each orthogonal horizontal axis of the building using the overturning demands calculated per Subsection 3.3.1.2.10 and the restoring moments calculated using the effective weight of the building. The energy method described in BC-TOP-4A (Reference 3.3-38) can be used for overturning stability evaluation, where factors of safety against overturning are calculated by comparing the maximum kinetic energy driving the system to overturning during a seismic event with the potential energy required to prevent overturning of the structure and foundation. For this approach, the minimum overturning factor of safety of 1.25 is used, consistent with CSA N289.3.

The gaps between the RB and adjacent structures are evaluated per guidance in NEDO-33914 Revision 2, Section 6.2, to ensure no physical interaction between the RB structure and surrounding structures. The gaps are evaluated along the entire height of the adjacent structures considering construction tolerances, inelastic deformations, and possible differential settlements.

#### **3.3.1.2.9 Methods to Account for Torsion**

Considerations are given in the modeling of the integrated RB structure to represent the actual locations of the centre of masses and centres of rigidity of structural elements to account for torsional effects.

In accordance with the requirements of ASCE/SEI 4, Section 3.1, the seismic design of the RB structure also considers accidental torsion to account for:

- Non-vertically propagating seismic waves
- Rotational components of ground motion

- Possible distributions of structural mass and stiffness that differ from those represented in the 3-D FE model used for the seismic response analysis per the requirements in Clause 6.10 of CSA N289.3

Accidental torsional moment demands may be calculated at each floor level as the product of the story shear and 5% of the floor plan dimension perpendicular to the story shear direction. Alternatively, the horizontal shear force demands on all walls may be conservatively increased by 5% to account for the accident torsion.

#### **3.3.1.2.10 *Determination of Seismic Overturning Movement, Sliding Forces and Dynamic Bearing Pressures***

Contact spring elements installed in the SSI models at interfaces between the structure and the subgrade are used for calculation of seismic driving forces and overturning moments on the BWRX-300 foundations. As described in Subsection 3.3.1.2.6, time histories of the horizontal and vertical seismic forces in the three directions are calculated as the algebraic sum of the spring forces in the three directions at each step for all contact spring elements. Overturning moments about the two horizontal axes are calculated as the algebraic sum of the moments resulting from each spring force with respect to the foundation bottom centreline. Conservatively, the spring force results for calculation of seismic driving force demands may be combined using the absolute sum time domain method instead of using the algebraic sum method for all possible combinations of the input motion directions.

The seismic inertia forces and overturning moments for the foundation stability evaluations and seismic bearing pressure calculations are obtained from SSI models with higher (Response Level 2) structural damping values.

Seismic stability of the surface mounted foundations surrounding the RB are evaluated by calculating safety factors for seismic sliding and overturning stability for each time step. These safety factors are calculated for the total duration of each of the five sets of ATHs described in Subsection 3.3.1.1. The average value of the minimum safety factors obtained from the five sets of ATHs is used to demonstrate the seismic stability criteria described in Subsection 3.5.2.2 are met.

The seismic bearing pressure demands are also calculated in the time domain. Maximum bearing pressure values are calculated for the total duration of earthquake for each of the five sets of ATHs used as input for the SSI analysis discussed in Subsection 3.3.1.1. The dynamic bearing pressure demand under each foundation is defined as the average of the results obtained from the five sets of ATHs.

#### **3.3.1.3 *Seismic Analysis of Seismic Category A and B Subsystems***

This section applies to the Seismic Category A and Seismic Category B subsystems. Input motions for the qualification of these systems are usually in the form of floor response spectra or ATHs obtained from the primary system dynamic analysis discussed in Subsection 3.3.1.2. Input motions in terms of acceleration time histories are generally used. Dynamic qualification can be performed by analysis, testing, or a combination of both, or by the use of experience data. This section addresses the aspects related to analysis only.

##### **3.3.1.3.1 *Seismic Analysis Methods***

Seismic analysis of subsystems can be performed using one of the following methods:

- Time History Analysis
- Response Spectrum Analysis

- Static Coefficient

The time history and the response spectrum methods are utilized in the piping analysis as required. The procedure for multi-support excitation described in Subsection 3.3.1.3.9 is followed with both methods. When the multi-support Response Spectrum Method is used to calculate the dynamic response of the piping system, all multi-support response spectra components are simultaneously applied to each piping model for each load case.

The time history and Response Spectrum Methods are also utilized in the equipment analysis as required. When the equipment is supported at two or more points located at different elevations in the building, the response spectrum for the most severe single point of attachment is chosen as the design spectra. Alternatively, the multi-support excitation procedure described in Subsection 3.3.1.3.9 is used.

Vertical analyses of the RPV and internals are performed using in-structure responses obtained from the results of one-step analyses of the RB discussed in Subsection 3.3.1.2.

RPV and internal components such as fuel, guide tubes, and Control Rod Drive (CRD) System housing are included in the integrated RB model as discussed in Subsections 3.3.1.2 and 3.3.1.3.3. As a result, the evaluation of RPV internals components in the horizontal direction is performed using a Two-Step analysis approach, where seismic loads are applied to more detailed horizontal beam models of the RPV and internals. The first step of the Two-Step analysis consists, therefore, of obtaining ATHs or ISRS developed as described in Subsection 3.3.1.2 at the RPV/RB interface locations from the RB SSI analyses discussed in Subsection 3.3.1.2. The second step is a multi-support excitation time history analysis of the RPV, and internals subjected to the ATHs generated in the first step. The procedure for multi-support excitation time history analysis, as described in Subsection 3.3.1.3.9, is followed in the second step analysis of the RPV and internals.

### Time History Analysis

Assuming velocity proportional damping, the dynamic equilibrium equations for a lumped mass, distributed stiffness system are expressed in matrix form as:

$$[M] \{ \ddot{u}(t) \} + [C] \{ \dot{u}(t) \} + [K] \{ u(t) \} = \{ P(t) \}$$

Where:

- $\{ u(t) \}$  = time dependent displacement of nonsupport points relative to the supports.
- $\{ \dot{u}(t) \}$  = time dependent velocity of nonsupport points relative to the supports.
- $\{ \ddot{u}(t) \}$  = time dependent acceleration of nonsupport points relative to the supports.
- $[M]$  = mass matrix.
- $[C]$  = damping matrix.
- $[K]$  = stiffness matrix.
- $\{ P(t) \}$  = time dependent applied force column vector.

The above equation can be solved by modal superposition or direct integration in the time domain.

Modal Superposition involves two steps. First, the characteristic equation corresponding to undamped, free vibration of the model is solved to obtain the eigenvalues, eigenvectors, and generalized masses. The system coupled equations are then decoupled via the eigenvector transformation matrix which is simply the matrix of eigenvectors written as columns. The equations are decoupled in the generalized coordinate system because of the orthogonality of the matrix of eigenvectors with respect to the “weighted” mass and stiffness matrices. The decoupled modal

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

equations are then solved independently to obtain the generalized coordinates. The physical solution is then given by the eigen transformation once the generalized coordinates are known.

The direct integration method involves the numerical integration of the simultaneous differential equations of equilibrium in their original form, without transformation to the generalized coordinates. For systems subjected to short duration, high frequency excitation (such as those due to LOCA acoustic, blast and jet loads), the direct integration method requires less computation and is recommended over the modal superposition method.

For the time domain solution, the numerical integration time step is sufficiently small to accurately define the dynamic excitation and to render stability and convergence of the solution up to the highest frequency (or shortest period) of significance. This condition is satisfied if  $\Delta t$  is selected to limit the amplitude decay per cycle of free vibration of the highest significant mode to less than 20 percent. This corresponds to approximately 3.5 percent numerical damping for that highest significant mode. The integration time step for both the direct numerical integration of the system coupled equations of motion and the numerical integration of the  $n$  decoupled equations (Modal Superposition) satisfies the following requirement:

$$\Delta t \leq T_m/10$$

where  $\Delta t$  is the numerical integration time step magnitude and  $T_m$  is the period of the highest significant mode considered in the analysis or the reciprocal of the cutoff frequency in Hz as defined in Subsection 3.3.1.3.4.

### **Response Spectrum Analysis**

This method is used if only peak dynamic responses are required.

The response spectrum method is a modal superposition analysis in which only the peak values of the solution of the decoupled modal equations are obtained. The method is based on writing the solution of each decoupled modal equation in terms of the convolution integral. The major advantage of this form of solution is that for a given input motion the only variables under the integral are the damping factor and the frequency. Thus, for a specified damping factor, it is possible to construct a curve which gives the maximum value of the integral as a function of frequency. This curve is called a response spectrum for the particular input motion and the specified damping factor. The integral has units of velocity, consequently the maximum of the integral is called the spectral velocity.

For a subsystem analysis of a secondary system the input floor response spectra, obtained from a time history analysis of the primary system, is broadened  $\pm 15$  percent to account for modeling uncertainties in both the primary and secondary systems in accordance with ASCE/SEI 4, Section 6.2.3.

Using the calculated natural frequencies of vibration of the system, the maximum values of the modal responses are determined directly from the appropriate response spectrum. The modal maxima are then combined as discussed in Subsection 3.3.1.2.

### **Static Coefficient**

The static coefficient method may be applied to certain equipment in lieu of the required dynamic analysis. Response loads are determined statically by multiplying the equipment mass by a static coefficient equal to 1.5 times the maximum spectral acceleration that corresponds to the first mode of the equipment. This coefficient is intended to account for the effect of both multi-frequency excitation and multi-mode response. This method is applicable only to equipment corresponding

to a simple column, beam, or frame type structure supported at a single point. Justification is required for applying this method or coefficient to equipment having configurations other than simple frame or beam type structures.

A factor of less than 1.5 may also be used if adequate justification is provided. For example, if the equipment is simple enough such that it behaves essentially as a single degree-of-freedom model and is greater than the seismic excitation frequency, the factor 1.0 can be used instead of 1.5.

If the fundamental frequency of the equipment is greater than the cutoff frequency but less than the Zero Period Acceleration (ZPA) frequency, the static coefficient can be taken as 1.5 times the peak spectral acceleration which occurs between the cutoff frequency and the ZPA frequency in the equipment input response spectra.

#### **3.3.1.3.2 Determination of Number of Earthquake Cycles**

The BWRX-300 Seismic Category A and Seismic Category B SSC are seismically qualified to withstand the effects of the DBE defined in Subsection 3.3.1.1. RW-IIa SSC are seismically qualified for one-half (1/2) of this DBE as stated in Table 3.3-1.

The determination of the number of earthquake cycles for subsystem analysis is in accordance with U.S. NUREG-0800, SRP 3.7.3.

#### **3.3.1.3.3 Procedures Used for Analytical Modeling**

The mathematical model for each Seismic Category A and B component to be analyzed is prepared to realistically reflect the dynamic characteristics of that component. Each component is discretized into a series of interconnected beam elements or finite elements. The node points are generally selected to coincide with the locations of large masses, such as at structure floors or at heavy equipment supports, and at all points corresponding to any significant change in physical geometry.

The number of mass node points in the model is sufficient if additional node points (independent of number) do not result in more than 10 percent increase in the responses in the frequency range below the cutoff frequency specified in Subsection 3.3.1.3.4.

The node point spacing is selected such that the maximum length  $L$  of the finite element between any two node points, in the direction of the stress wave propagation, satisfies the condition

$$L \leq \frac{\lambda}{4} = \frac{v}{4f} = \frac{vT}{4}$$

where:  $\lambda$  and  $v$  are the wavelength and wave velocity, respectively.

The frequency  $f$ , or period  $T$ , correspond to the cutoff frequency of Subsection 3.3.1.3.4.

#### **Modeling of Equipment**

For dynamic analysis, Seismic Category A and B equipment is represented by lumped mass systems which consist of discrete masses connected by weightless beam elements and/or by any other appropriate finite element representation. The criteria used to lump the masses are:

- A. The number of modes of dynamic system is controlled by the number of masses used. Therefore, the number of masses is chosen so that all significant modes are included. The modes are considered as significant if the corresponding natural frequencies are less than the cutoff frequency specified in Subsection 3.3.1.3.4.
- B. Mass is lumped at any point where a significant concentrated weight is located.

- C. For equipment with a free-end overhang span whose flexibility is significant compared to the centre span, a mass is lumped at the overhang span.
- D. When a mass is lumped between two supports, it is located at a point where the maximum displacement is expected to occur. This tends to conservatively lower the natural frequencies of the equipment. Similarly, in the case of live loads and a variable support stiffness, the location of the load and the magnitude of support stiffness are chosen to yield the lowest frequency content for the system.

### **Modeling of Piping Systems**

Mathematical models for Category A and B piping systems are constructed to realistically reflect the dynamic characteristics of the system. The continuous system is modeled as an assemblage of pipe elements (straight sections, elbows, and bends) supported by hangers and anchors, and restrained by pipe guides, struts, and snubbers. Pipe and fluid masses are lumped at the nodes and connected by the weightless elastic beam elements which reflect the physical properties of the corresponding piping segment. The mass node points are selected to coincide with the locations of large masses, such as valves, pumps, and motors, and with locations of significant geometry change. All concentrated weights on the piping system, such as the valves, pumps, and motors, are modeled as lumped mass rigid systems if their fundamental frequencies are greater than the cutoff frequency in Subsection 3.3.1.3.4. The torsional effects of valve operators and other equipment with off-set centre of gravity with respect to the piping centreline are included in the analytical model. The pipe length between mass points is no greater than the length with a fundamental frequency equal to the cutoff frequency stipulated in Subsection 3.3.1.3.4 when calculated as a simply supported beam with uniformly distributed mass.

Branch lines with a run to branch moment of inertia ratio of 25 to 1 or greater are excluded from the piping model of the main line in accordance with CSA N289.3.

All pipe guides and snubbers are modeled to produce representative stiffness to reduce model uncertainties. Snubbers are modeled with an equivalent stiffness based on dynamic tests or on data provided from the vendor. The stiffness of the supporting structures is included in the analysis unless the supporting structure is shown to be rigid.

### **Modeling of Reactor Pressure Vessel and Internals**

Because of the significant dynamic interaction between the RB and RPV and internals, the latter are integrated into the RB model as discussed in Subsection 3.3.1.2.

The mathematical model of the RPV and internals consists of a LMS model connected by linear elastic members and 3D finite element models. Using the elastic properties of the structural components, the stiffness properties of the model are determined. This includes the effects of both bending and shear.

To facilitate hydrodynamic mass calculations, mass points (e.g., representing the fuel, shroud, vessel) are selected at the same elevation. The various lengths of CRD housings are grouped into two representative lengths. These lengths represent the longest and shortest housings to adequately represent the full range of frequency response of the housings. In order to reduce the complexity of the dynamic model, the light components (such as in-core guide tubes and housing, sparger, and their supply headers) are excluded from the RPV mathematical model. However, the dynamic response of selected components is determined from a subsystem analysis after the system response is found.

Dynamic effects of water enclosed by the RPV are accounted for by introduction of a hydrodynamic mass matrix, which serves to link the acceleration terms of the equations of motion of points at the same elevation in concentric cylinders with a fluid entrapped inside the RPV vessel. Although the

dynamic coupling between the vertical hydrodynamic masses is not considered, the vertical hydrodynamic masses themselves are properly accounted for. Dynamic loads due to vertical motion are added to, or subtracted from, the static weight of component, whichever is more conservative.

The shroud support plate is modeled as a rigid link in the translational direction since it is loaded in its own plane during a horizontal dynamic event. The shroud support legs, and the local flexibilities of the vessel and shroud contribute to the rotational flexibilities and are modeled as an equivalent torsional spring.

Due to the small clearances in the horizontal directions, the fuel assembly is adequately modeled as a linear system for subsystem and system analysis. In the vertical direction, the fuel assembly has the potential to lift off from its seat and a non-linear representation is required if the vertical applied and reaction forces are sufficient to cause fuel lift. Furthermore, the interface between the fuel channel and lower plate tie plate is not rigid and a non-linear model to account for slippage may be appropriate.

The weight of asymmetric secondary components, such as attached equipment, is uniformly redistributed around the node point circle. Asymmetric equipment is modeled using finite element or LMS methods.

#### **3.3.1.3.4 Basis of Selection of Frequencies**

The cutoff frequency selected in the time history and response spectrum analyses ensures that all significant modes are included in the superposition. Higher modes which cumulatively contribute less than 10% of the total system response are not considered in the superposition of the individual modal values.

The cutoff frequency for seismic and other dynamic loads follows Subsection 3.3.1.2. For seismic load, it is estimated that all modes up to 100 Hz are included.

For all other dynamic analysis, it is estimated that the cutoff frequency will be 100 Hz, as long as no more than 5 percent of the total strain energy of the system remains beyond this cutoff frequency.

Where practical, to avoid adverse resonance effects, equipment and components are designed/selected such that their fundamental frequencies are approximately less than half or more than twice the dominant frequencies of the support structure. Moreover, in any case, the equipment is analyzed or tested or both to demonstrate that it is adequately designed for the applicable loads considering both its fundamental frequency and the forcing frequency of the applicable support structure.

#### **3.3.1.3.5 Analysis Procedure for Damping**

##### **Damping of Primary Subsystems**

Primary Subsystems consist of the RPV and internals.

Damping values for seismic analysis of primary subsystems using the Modal Superposition are presented in Table 3.3-7. These damping values are in accordance with ASCE/SEI 43 and CSA N289.3.

$\alpha$ ,  $\beta$  –damping curves for the axis-symmetric finite element analysis of primary subsystems completed by Direct integration are defined per Table 3.3-8 and the following equation:

$$\lambda = \frac{\alpha}{2\omega} + \frac{\beta\omega}{2}$$

Damping values for dynamic loading beam analysis, performed by modal superposition, are identical to those for DBE provided in Table 3.3-7.

### **Damping of Secondary Subsystems**

Damping coefficients used in the seismic analysis of Seismic Category A and B piping, equipment, equipment supports and intermediate structures between subsystems are presented in Table 3.3-9.

Damping coefficients used for all other non-seismic loads are presented in Table 3.3-10.

These damping values are in accordance with ASCE/SEI 43 and CSA N289.3.

#### **3.3.1.3.6 Three Components of Design Ground Motion**

Applicable methods for spatial combination of responses due to each of the three input motion components are described in Subsection 3.3.1.2.

#### **3.3.1.3.7 Combination of Modal Responses**

Applicable methods for combination of modal responses are described in Subsection 3.3.1.3.1.

#### **3.3.1.3.8 Interaction of Other Subsystems with Seismic Category A and B SSC**

Non-Seismic Category systems are designed to be isolated from Seismic Category A and B systems by either a constraint or barrier or are remotely located with regard to the Seismic Category A and B systems.

If it is not feasible or practical to isolate the Seismic Category A or B system, adjacent Non-Seismic Category systems are analyzed according to the same seismic criteria as applicable to the Seismic Category A and B systems. Consistent with the approach used for evaluation of structures discussed in Subsection 3.3.1.2, limited inelastic deformation responses LS-C are considered for the seismic interaction evaluations of equipment by using inelastic absorption factors per ASCE/SEI 43, Section 8.2.2.2, and Table 8-1. For Non-Seismic Category systems attached to Seismic Category A and B systems, the dynamic effects of the Non-Seismic Category systems are simulated in the modeling of the Seismic Category A or B system. The attached Non-Seismic Category systems, up to the first anchor beyond the interface, are also designed in such a manner that during DBE level event it does not cause failure of the Seismic Category A or B system.

#### **3.3.1.3.9 Multiply Supported Equipment and Components with Distinct Inputs**

This section discusses the analytical method used for obtaining multi-support loadings and for dynamically analyzing Category A and B systems with multiple supports (or one support with many excitations), with different dynamic excitations. This analytical method is in accordance with CSA N289.3.

The time history Direct Integration, time history Modal Superposition and Response Spectrum Modal Superposition methods discussed in Subsection 3.3.1.3.1 can all be used in Multi-Support Excitation analysis. However, the mode superposition procedure described in Section 3.3.1.3.1 for an applied load vector is replaced with the corresponding mode superposition procedure for multi-support excitation analysis.

When using the time history method, the following methods are acceptable:

- A. The time histories corresponding to the envelopes of the ISRS for all attachment points in each of the three directions are applied at each attachment point simultaneously.
- B. The time histories corresponding to the envelopes of the ISRS for each attachment point in each of the three directions are applied at each corresponding attachment point simultaneously.

The above time history methods of analysis are performed such that primary (inertial) and secondary (static stresses due to differential displacements) are separated. The inertial forces are used for primary stress calculations. Secondary stresses are first computed for each natural mode of the supporting structures and for each excitation direction. The total secondary stress for triaxial excitation is then computed as the SRSS of the resultant secondary stresses for each excitation direction. The ASME BPVC Code Section III requires that the secondary stresses must be combined with the primary stress.

The inertia (primary) and displacement (secondary) stresses are dynamic in nature and their peak values are not expected to occur at the same time. Hence combination of the peak values of inertia stress and anchor displacement stress using the SRSS method is quite conservative. In addition, anchor movement effects are computed from static analyses in which the displacement are applied to produce the most conservative loads on the components.

Using the response spectrum method, support points response spectra are generated from support point acceleration time histories. In accordance with the requirements of Clause 6.5.2.3 of CSA N289.3,  $\pm 15$  percent peak broadening is applied to the spectra to account for the RB support structure modeling uncertainties. In general, using the SRSS method to combine modal responses is conservative since the maximum modal responses due to each component of multi-support excitation do not occur simultaneously. For certain "closely spaced" support with highly correlated support excitations, the SRSS superposition may yield unconservative responses. In this case, the modal responses of the "closely correlated" supports are combined algebraically first. Then, correlated sums are combined with the contributions for uncorrelated supports using the SRSS method.

#### **3.3.1.3.10 Use of Equivalent Vertical Static Factors**

Equivalent vertical static factors are used when the requirements for the static coefficient method in Subsection 3.3.1.3.1 are satisfied.

#### **3.3.1.3.11 Torsional Effects of Eccentric Masses**

Torsional effects of eccentric masses are considered in the modeling of subsystems as discussed in Subsection 3.3.1.3.3.

#### **3.3.1.3.12 Effects of Differential Building Movements**

In most cases, subsystems are anchored and restrained to floors and walls of buildings that may have differential movements during a seismic event.

Differential endpoint or restraint deflections cause forces and moments to be induced in the system. As discussed in Subsection 3.3.1.3.9, the stress thus produced is a secondary stress. It is justifiable to place this stress, which results from restraint of free-end displacement of the system, in the secondary stress category because the stresses are self-limiting and, when the stresses exceed yield strength, minor distortions or deformations within the system satisfy the condition which caused the stress to occur.

Refer to Subsection 3.3.1.2 for the methodology used to obtain differential displacements used in the evaluation of subsystems.

#### **3.3.1.4 Seismic Analysis of Other Subsystems**

Seismic demands for the evaluation of other subsystems are developed based on ISRS, ATHs and relative displacements calculated with the Response Level 1 structural damping values in accordance with CNSC REGDOC-2.5.2, Section 7.13.1. The use of models with higher (Response Level 2) damping values can be justified based on the level of stress response as applicable to these structures.

Per Clause 6.5.2 of CSA N289.3, the seismic input at support points for the dynamic analysis of decoupled subsystems are ISRS or time histories representing the in-structure design translational motion in the two horizontal and the vertical directions due to the three components of the input earthquake motion.

If the in-structure rotations are significant, rotational ISRS and ATHs are developed and used for the design of the decoupled subsystems. Relative displacements between different support points of subsystems with multiple or distributed supports are also considered in the evaluation.

#### **3.3.1.5 Seismic Instrumentation**

In accordance with the requirements in CNSC REGDOC-1.1.2 (Reference 3.3-39), Section 4.5.6, and CNSC REGDOC-2.5.2, Section 7.13.1, seismic instrumentation is used to monitor the seismic activity at the site for the lifecycle of the reactor facility, starting from commissioning, including outages, until fully decommissioned.

The design of BWRX-300 seismic instrumentation satisfies the more stringent requirements for large reactors in CSA N289.5, Clause 5 in addition to Clauses 1 to 3 and 8 to 10.

The handling of seismic instrumentation system data records is in accordance with requirements of Clause 10 of CSA N289.5. When required, the seismic instrumentation requirements of CSA N289.5 are augmented by the requirements of U.S. NRC RG 1.12 (Reference 3.3-40).

The required actions after an earthquake follow the provisions of CSA N289.1.

##### **3.3.1.5.1 Location and Description of Instrumentation**

#### **Free-Field Instrumentation**

In accordance with the requirements of Clause 5.2.2 of CSA N289.5, at least two triaxial accelerometers are installed outside of the structure-ground interaction influence of the Power Block, but as close as practicable to the reactor to monitor the free-field ground motion at the BWRX-300 site at the plant grade and close to the RB bottom elevations.

In accordance with U.S. NRC RG 1.12, Section C.1.2, because the deeply embedded RB is founded at a depth more than 12 m below finished grade elevation, installation of a second free-field downhole accelerometer is considered at the bottom of the RB foundation, below the free-field accelerometer at finished grade level.

#### **Structure and Equipment Instrumentation**

In accordance with the requirements of Clause 5.2.3.1.2 of CSA N289.5 and Section C.1.2 of U.S. NRC RG 1.12, triaxial accelerometers are installed at several locations inside the RB including:

- One at the top of the mat foundation
- One on the containment internal structure close to the reactor vessel
- One close to the top of the containment internal structure
- One close to the top of the containment structure
- One at the operating floor elevation

Also, in accordance with Clause 5.2.3.1.3 of CSA N289.5, three additional triaxial accelerometers are installed outside of the RB, either at locations of seismically qualified SSC or at other locations that are deemed important.

The specific locations for instrumentation are determined to obtain the most pertinent information consistent with the selected key locations in the RB model to enable easy comparison between

the measured and calculated in-structure responses. The sensors are installed such that occupational radiation exposures associated with their location, installation, and maintenance are maintained as low as is reasonably achievable.

Structure and equipment instrumentation stations recording are configured to be accessible for maintenance during full-power operation in compliance with the guidance of U.S. NRC RG 1.12. For sensors installed in inaccessible areas, provisions for data recording and an external remote alarm indicating actuation are provided.

### **Recording and Playback Equipment**

Recording and playback units are provided for multiple channel recording and playback of the triaxial accelerometer signals. Characteristics and installation requirements of the recording and playback equipment follow the guidelines in U.S. NRC RG 1.12.

Accelerometers can measure acceleration amplitudes of at least 2g in accordance with Clause 5.1.6.1 of CSA N289.5.

### **Power Sources**

In accordance with Clause 5.1.7.2 of CSA N289.5, a dedicated standby power source is provided for the seismic instrumentation. This backup power source can provide a minimum of 6 hours of continuous operation of any accelerometer or a minimum of 24 hours of continuous operation of any accelerograph in the event of failure of all external power sources.

The central unit of the seismic instrumentation system incorporates a self-contained seismically qualified standby power source dedicated for providing the system a minimum of 6 hours of continuous operation in the event of failure of all external power sources.

#### **3.3.1.5.2 Design and Installation**

In accordance with the requirements of Clause 8 of CSA N289.5, all components of the seismic instrumentation system and their supports are designed and installed to maintain their structural integrity, and to remain operational during and following a DBE. Accessibility for servicing and recalibration, anchorage and protection from adverse conditions that can affect their performance are also considered in the design.

Prior to the installation, the operational reliability of the seismic monitoring instrumentation is demonstrated, in accordance with Section C.4.7 of RG 1.12, by using prototype, environmental, vibratory, or historical test results.

#### **3.3.1.5.3 Maintenance and Testing**

Maintenance and testing of seismic instrumentation are defined in accordance with the requirements in Clause 9 of CSA N289.5, documented before the first facility startup, and updated as necessary following any modification to the system. All components of the seismic instrumentation system are maintained and tested to ensure that a maximum number of instruments are kept in-service during plant operation and shutdown.

The operability of each of the seismic instrumentations is demonstrated by performing channel checks every two weeks for the first three months of service after startup. After the initial three-month period and three consecutive successful checks, the channel checks are performed on a monthly basis. The channel calibrations are performed every 24 months or during each refueling outage. The channel functional test is performed every 6 months. At least once a year, the system is operated continuously on the standby power source to verify the required backup power availability per CSA N289.5, Clause 9.2.2.

The guidance of Appendix A to U.S. NRC RG 1.166 (Reference 3.3-41) is followed for instrumentation found to be out of service during an earthquake.

#### **3.3.1.5.4 Arrangements for Control Room Operator Notification**

In accordance with the guidance of U.S. NRC RG 1.12, Section C.4.13, the triaxial accelerograph system is triggered whenever a threshold free-field acceleration of not more than 0.01 g is exceeded for any of the three axes. A higher threshold value can be used if 0.01 g is impracticable due to the site geological or geotechnical conditions or the ambient noise at instrument locations.

Activation of the seismic trigger causes an audible and visual annunciation in the control rooms to alert the plant operator that a felt earthquake has occurred in accordance with Clause 5.1.3 of CSA N289.5. Authorities having jurisdiction as well as the local and regional emergency response agencies are advised of the plant status if an earthquake exceeds the threshold acceleration per Clause 6.5.4 of CSA N289.1.

#### **3.3.1.5.5 Comparison of Measured and Predicted Responses**

The appropriate response after a felt seismic event is determined by the level of shaking. In accordance with Clause 6.5.1 of CSA N289.1, the BWRX-300 post-seismic plant operation manual defines the response associated with each level of shaking. The required operator actions after a felt earthquake are in accordance with Clause 6.5.7 of CSA N289.1.

Per Clause 6.5.5 of CSA N289.5, an immediate shutdown of the plant is not mandatory if during and following an earthquake the plant continues successful operation. The plant is shut down if it is determined that the earthquake intensity exceeded the DBE or if there is evidence of damage impacting the safety systems.

In the event of a plant trip, all records pertaining to fuel and reactor internals systems are compared to the data that are recorded during a normal shutdown and/or previous plant trips. The intensity of the earthquake and any evidence of damage will dictate if a detailed inspection is required or if a restart is allowed. Prior to startup, the availability of all safety class SSC is confirmed to ensure they can perform their intended functions.

#### **Immediate Response Following a Seismic Event**

If the plant remains online following a seismic event, the immediate response is to stabilize the plant in accordance with Clause 6.5.7.1.1 of CSA N289.1 by:

- Testing all systems required to perform nuclear safety functions
- Initiating inspections performed in accordance with the provisions of ANSI/ANS-2.23 (Reference 3.3-42) to assess the intensity of the seismic events and the effects on essential systems

Recorded earthquake data from the seismic instrumentation, coupled with information obtained from a plant walkdown, are used to make the initial determination of whether the plant should be shut down, if it has not already been shut down by operational perturbations resulting from the seismic event.

#### **Seismic Design Basis Exceedance**

Following a seismic event, records of free-field ground motion and in-structure responses are reviewed in accordance with Clause 6.5.6.1 of CSA N289.1.

Cumulative absolute velocity calculated in accordance with Section 6.4.1 of ANSI/ANS-2.23 and peak ground velocity are generated from all free-field ground motion to be used as damage

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

indicators. Damage criteria for Heavy industrial SSC in Section 6.5.6.2.1 of CSA N289.1 are also considered to help determine seismic design basis exceedance.

The DBE is considered exceeded when the measured free-field motion in any of the three directions (two horizontal and one vertical) exceeds the following limits:

1. Response spectrum limit that is exceeded if:
  - a. At frequencies between 2 and 10 Hz, the recorded response spectral accelerations of 5% damping exceed the corresponding DBE design acceleration response spectrum or 0.2 g, whichever is greater or
  - b. At frequencies between 1 and 2 Hz, the recorded response spectral velocities of 5% damping exceed DBE velocity response spectrum or 152 mm/sec, whichever is greater
2. Cumulative absolute velocity limit that is exceeded if the cumulative absolute velocity value calculated in accordance with Clause 6.5.6.1 of CSA N289.1 is greater than 0.16 g-s, or the peak ground velocity is greater than 50 mm/s.

The DBE exceedance is checked for measurements taken from the free-field plant grade accelerometers and downhole accelerometers using the corresponding design response spectra defining the DBE ground motion at the plant grade and RB foundation bottom elevations.

In addition to the criteria above, the following is also used to determine DBE exceedance:

- The inspection of the seismically qualified SSC shows evidence of overstressing, large displacement, yielded supports, etc.
- If the data collected from the monitoring instruments installed at different elevations in the plant exceed the DBE response parameters at the corresponding locations

#### **Required Pre-Shutdown Earthquake Actions**

Prior to the shutdown, the availability of safety class systems required for shutdown and the availability and integrity of the containment system are confirmed by performing pre-shutdown checks in accordance with the provisions of CSA N289.1, Clause 6.5.7.2.

#### **Post-Shutdown Earthquake Response Actions**

While the plant is shut down, a detailed inspection and evaluations are performed to assess the state of the plant in accordance with the provisions of CSA N289.1, Clause 6.5.7.3.

Post-shutdown actions include:

- Focused inspections of a preselected set of SSC that are representative of a broad cross section of equipment and structures in nuclear and conventional power plants
- Expanded inspections if damage is found in focused inspections
- Further graded inspections, tests, and analyses that are guided by the damage and earthquake levels

Focused inspections include detailed, visual inspections and tests of a preselected sample of representative structures and equipment, selected to sample all types of safety class and SCN SSC that are considered most likely to be damaged due to earthquake shaking. SCN SSC that experience has shown to be of low seismic capacity to serve as earthquake damage indicators are also included in the focused inspections.

Expanded inspections and tests are performed if significant physical or functional damage is found during the focused post-shutdown inspections. The expanded inspections include all accessible safety class equipment and structures as well as non-safety-class balance-of plant equipment that is important to safe operation of the plant. Expanded inspections and tests may not be performed if the damage observed as part of the focused inspections is isolated to a specific class of SSC and if the cause of the damage is attributable to a specific design or installation deficiency, such as lack of equipment anchorage, improper installation of expansion bolts, etc. In this case, the design or installation deficiency is corrected for all SSC in the classes involved, and inspections of other undamaged classes may not need to be expanded.

If damage to safety class SSC is observed, the reactor vessel is opened, and reactor vessel internals and fuel are inspected using methods normally employed for in-service inspections.

If the DBE is reached, the plant restart is only allowed after ensuring that the allowable design stresses of seismically qualified SSC are not exceeded.

Results of post-shutdown inspections and tests are documented and reported to the authorities having jurisdiction. Results of inspections are compared with results of previous baseline inspections.

### **3.3.2 Extreme Weather Conditions**

This section presents the design basis weather conditions considered in the design of the BWRX-300 SSC for the bounding extreme meteorological hazards identified in Chapter 2, Section 2.6.

#### **3.3.2.1 Temperature and Humidity**

The extreme temperatures and humidity levels specified in Chapter 2, Table 2.6-1 are considered in the BWRX-300 design in accordance with CNSC REGDOC-2.5.2, Sections 7.4.2 and 7.15.1. Conservative safety margins are considered in the evaluations and design of SSC to ensure their availability and efficiency under extreme temperature and humidity conditions.

#### **3.3.2.2 Rain**

Rain load is considered in the design of the BWRX-300 building structures.

The RB roof is designed to minimize or eliminate rain loading in accordance with U.S. NRC RG 1.102 (Reference 3.3-43), regulatory position 3, considering rain intensity and duration (PMP) values listed in Chapter 2, Table 2.6-1.

Design for rain loading on the RWB roof is performed in accordance with CSA N291 Clause 6.2, considering PMP values specified in Chapter 2, Table 2.6-1.

The design of the remaining Power Block roofs to minimize and evaluate the potential of ponding follows the guidance in the NBC, Section 4.1.6.4.

#### **3.3.2.3 Snow and Ice**

The RB structure is designed using ground snow loads for normal and extreme winter precipitation events of 2.5 kPa and 5.0 kPa, respectively. These loads envelop those used in the design of the nearby Darlington Nuclear Generating Station listed in Chapter 2, Subsection 2.6.9. For the RB structure, ground snow loads are converted to roof snow loading in accordance with the methodology specified in the ASCE/SEI 7 (Reference 3.3-44) referenced in U.S. NRC DC/COL-ISG-7 (Reference 3.3-45).

For the RB structure, the normal roof snow load is considered as a normal live load for all normal operating load combinations considered in the design. The extreme roof snow load is considered as an extreme load for the extreme environmental combinations (See Chapter 9B, Table 9B-4), without concurrent seismic or tornado loads.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

For the RWB design, snow load (including snow drifting conditions, as applicable) is computed in accordance with the methodology specified in CSA N291, Clause 6.3 and NBC, and based on 100 years occurrence specified in Chapter 2, Table 2.6-1.

For the design of other Non-Seismic Category Power Block structures, the design snow load is determined in accordance with the methodology specified in NBC considering 50 years recurrence. The Importance Factor for Snow,  $I_s$ , assigned to these structures is based on Table 4.1.6.2-A of NBC for Post-Disaster importance category.

#### **3.3.2.4 Wind**

In accordance with REGODOC-2.5.2, Section 7.15.1, wind loads are considered in the design of the BWRX-300 building structures and components.

Site-specific wind speeds for the RB structure are translated into structural loading in accordance with the methodology specified in ANSI/AISC N690. The RB is designed as an ASCE/SEI 7 (referenced in ANSI/AISC N690), Risk Category IV structure (3000-year return period), for severe wind load of 257.5 km/h with 3-second gust basic wind speed that is bounding the site-specific design basis wind speed values in Chapter 2, Table 2.6-1.

Wind loads for the design of the RWB are determined in accordance with the methodology specified in CSA N291, Clause 6.3 and NBC, and based on 100 years return period wind pressure specified in Chapter 2, Table 2.6-1.

Wind loads for the design of other Non-Seismic Category Power Block structures are determined in accordance with the methodology specified in the NBC, Section 4.1.7. The reference wind speed is based on 50-year return period one-hour mean reference design wind. The Importance Factor for Wind,  $I_w$ , assigned to these structures is based on Table 4.1.7.3 of NBC for Post-Disaster importance category.

#### **3.3.2.5 Tornado**

In accordance with CNSC REGDOC-2.5.2, Section 7.15.1, tornado loads are considered in the design of BWRX-300 building structures and components based on their pertinent Seismic Category listed in Table 3.3-1.

Tornado loads included in the design of the Seismic Category A RB structure include:

- Tornado wind pressures
- Differential pressure loads due to rapid atmospheric pressure change
- Tornado-generated missile impact

The design input tornado wind parameters and tornado missile spectrum applicable to the Seismic Category A RB structure are provided in Chapter 9B, Table 9B.9-2 and Table 9B.9-3. These parameters are based on Region I values from U.S. NRC RG 1.76 (Reference 3.3-47). These values bound the DNNP site-specific parameters listed in Chapter 2, Table 2.6-5, and Table 2.6-6.

The RW-IIa RWB which houses rooms and equipment for handling, processing, and packaging liquid and solid radioactive wastes is designed for the site-specific tornado wind and missile spectrum modified per the requirements of Table 2 of RG 1.143.

The RWB, CB, TB, and Reactor Auxiliary Bay are evaluated for the design basis tornado wind loads applicable for the RB so that their interaction with the RB does not adversely affect the ability of the Seismic Category A and B SSC to perform their safety functions. The interaction evaluation follows the guidance of NEDO-33914 Revision 2, Section 6.3.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

The structural integrity of the CB is maintained in the event of a design basis tornado missile to allow egress of operators to the Secondary Control Room (SCR) in the RB and to ensure availability of SSC providing post-disaster mitigation functions. For the special hardening provisions considered in the design of the CB, refer to Chapter 9B, Section 9B.3.2.2.

For a discussion of tornado dampers used to protect the Heating, Ventilation and Air Conditioning (HVAC) openings in the RB and CB to improve their survivability under tornado, refer to Chapter 9A, Section 9A.5.

The procedures for transforming tornado wind speed into pressure-induced forces to apply to structures and the distribution across the structures are based on BC-TOP-3-A (Reference 3.3-46). U.S. NRC RG 1.76 provides guidance to determine the pressure drop and rate of pressure drop caused by the passage of a tornado.

Missiles created as a result of components and cladding failing during a tornado wind event are considered enveloped by the design basis missile spectrum considered for the RB.

### **3.3.2.6 Hurricanes**

Hurricanes at the DNNP site are considered bounded by tornado loads discussed in Subsection 3.3.2.5.

### **3.3.2.7 Lightning**

Complying with Section 7.4.2 of CNSC REGDOC-2.5.2, grounding and lightning protection systems are used to protect structures, transformers and equipment against lightning induced surges as described in Chapter 8, Section 8.6.

Protection measures against fires and electromagnetic compatibility issues that could affect the functionality of electrical systems as a result of lightning are addressed in Subsections 3.3.6 and 3.3.7.1.

### **3.3.2.8 Extreme Wind Interaction**

As described in Subsection 3.3.2.5, evaluations are performed to ensure that there is no adverse interaction between the RWB, CB, TB and Reactor Auxiliary Bay and the RB under design basis tornado wind loads applicable for the RB.

### **3.3.3 Extreme Hydrological Conditions**

Potential sources of external floods considered in the BWRX-300 design are discussed in Chapter 2, Subsection 2.5.3.

To conform with Section 7.4.2 of CNSC REGDOC-2.5.2 and in accordance with U.S. NRC RG 1.102, Seismic Category A and RW-IIa structures are designed to include protective features that are used to mitigate or eliminate the adverse consequences of flooding due to external sources.

Conforming with CNSC REGDOC-2.5.2, Section 7.15.1, the integrated RB structure is designed to withstand the maximum external flood and groundwater levels specified in Chapter 2, Section 2.5.3.1.

Protection measures considered for the integrated RB structure against underground water includes the use of:

1. Hydrostatic and hydrodynamic loads to design walls below flood level in conformance with CNSC REGDOC-2.5.2, Section 7.15.1
2. Suitable provisions to ensure water tightness of external surfaces and penetrations below design basis maximum flood and groundwater levels

3. No exterior access openings below grade

In accordance with U.S. NRC RG 1.143, the RWB is designed for one-half of the Probable Maximum Flood (PMF) listed in Chapter 2, Subsection 2.5.3.1.

Because plant grade is above design flood level, the Power Block structures remain accessible during postulated flood events. Thus, no emergency actions are required due to flooding to ensure the safe operation of the BWRX-300 plant.

**3.3.3.1 Analysis Procedure**

The BWRX-300 RB is analyzed and designed to withstand the effects of the maximum external flood and highest groundwater levels specified for the plant. The maximum flood and highest groundwater levels listed in Chapter 2, Subsection 2.5.3.1 are considered in defining the input design parameters for the structural design to account for flood and groundwater loadings.

Because the flood level at the DNNP site is below the finished grade level, only hydrostatic effects are considered in the analysis and design of structures, while dynamic phenomena associated with a flooding event, such as currents, wind waves, and their hydrodynamic effects are not considered. The hydrostatic pressure associated with the design flood level or with the design groundwater level is considered as a structural load on the basemat and basement walls for structural design in accordance with CNSC REGDOC-2.5.2, Sections 7.4.2 and 7.15.1. Uplift or floating of structures is considered and the total buoyancy force is based on the hydrostatic pressure due to the design flood level, excluding wave action, or the design groundwater level. The lateral, overturning and upward hydrostatic pressures acting on the side walls and on the foundation slab, respectively, are also considered in the structural design of these elements.

**3.3.4 Aircraft Crash**

This section discusses non-malevolent, general aviation crashes in compliance with requirements in CNSC REGDOC-2.5.2, Section 7.4.2. For robustness against malevolent acts, including aircraft crashes, refer to Subsection 3.3.7.4.

Small aircraft crashes are considered in the BWRX-300 design but are screened out per Chapter 2, Subsection 2.2.3.1. The design considers these aircraft crashes as missiles bounded by the design basis tornado missiles discussed in Subsection 3.3.2.5.

To mitigate their potential of equipment damage and fire impacts, the design of the BWRX-300 Seismic Category A structures addresses penetration resistance of buildings and considers physical separation of redundant or backup equipment, where applicable.

**3.3.5 Missiles**

**3.3.5.1 Missiles Generated by Extreme Winds**

Refer to Subsection 3.3.2.5 for details.

**3.3.5.2 Site Proximity Missiles (Except Aircraft)**

The design considers site proximity missiles to be bounded by the design basis tornado missiles discussed in Subsection 3.3.2.5.

Due to the distance between the sites, the maximum turbine missile from the existing Darlington site does not impact the DNNP site.

**3.3.5.3 Structures, Systems and Components to be Protected from Externally Generated Missiles**

Seismic Category A, RW-IIa, and portions of the TB and CB structures are designed to withstand the effects of externally generated missiles. For Seismic Category A SSC, the tornado wind

characteristics and tornado missile spectra considered in the design are listed in Chapter 2, Table 2.6-3 and Table 2.6-4. Tornado wind and tornado missile spectra design input values considered in the design of the RWB are listed in Table 2 of RG 1.143.

The response determination methodology due to missile impact loading on the RB structure, consisting of Steel Bricks™ modules, is in accordance with ANSI/AISC N690, Appendix N9.1, Section 6c.

The response determination methodology due to missile impact loading on the RWB and portions of the TB and CB is in accordance with CSA N291, Annex A.

#### **3.3.5.4 Barrier Design Procedures**

In accordance with CSA N291, Clause A.5, barrier design for impact loads satisfies the criteria for local and overall effect. The procedures for designing barriers to withstand the effects of missile impacts are per U.S. NUREG-0800, SRP 3.5.3.

##### **3.3.5.4.1 Local Damage Prediction**

The prediction for local damage in the impact area depends on the basic material of construction of the barrier.

#### **Concrete Barriers**

Sufficient thickness of concrete is provided to prevent perforation, spalling, or scabbing of the barriers in the event of missile impact.

Per CSA N291, Clause A.5.2.3, empirical formulas are applicable over a limited range of missile and target parameters.

Required concrete barrier thicknesses are determined in accordance with U.S. NUREG-0800, SRP 3.5.3 and are in no case less than those of Region I listed in Table 1 of U.S. NUREG-0800, SRP 3.5.3. In accordance with CSA N291, Clause A.5.2.4, the required barrier or wall thickness to prevent perforation is at least 20% greater than the calculated thickness from the applicable empirical formulas. Also, the required barrier or wall thickness to mitigate missile penetration is at least 50% greater than the calculated thickness from the applicable empirical formula.

#### **Steel Barriers**

Steel barrier thicknesses are determined using the Stanford equation (Reference 3.3-48) in accordance with the regulatory guidance of U.S. NUREG-0800, SRP 3.5.3.

#### **Composite Sections**

Composite section barriers are utilized in the BWRX-300 for missile protection when the residual velocity of the missile perforating the first element is considered as the striking velocity for the next element for prediction of local damage in accordance with the regulatory guidance of U.S. NUREG-0800, SRP 3.5.3.

##### **3.3.5.4.2 Overall Damage Prediction**

The BWRX-300 design for impactive loads satisfies the criteria for the overall effect of Clause A.5.3 of CSA N291. Dynamic effects of impactive loads are evaluated by dynamic analysis in accordance with Clause A.4.1.1 of CSA N291 or the equivalent static load approach mentioned in Clause A.4.1.2 of CSA N291.

#### **3.3.5.4.3 External Doors**

The RB external doors are designed to resist tornado missiles unless shielded by external stair towers or elevator shafts. External stair towers or elevator shafts credited for shielding are evaluated for tornado missiles.

#### **3.3.6 External Fires, Explosions and Toxic Gases**

In line with requirements of CNSC REGDOC-2.5.2, Section 7.4.2, damages due to fires, explosions, and release of toxic gases as a result of transportation and industrial accidents at or near the DNNP site are considered in the BWRX-300 design. The following subsections provide information on measures considered to protect and mitigate the effects of:

- External fires – Subsection 3.3.6.1
- Explosions – Subsection 3.3.6.2
- Release of toxic gases – Subsection 3.3.6.3

##### **3.3.6.1 External Fires**

Per Chapter 2, Subsections 2.2.3, 2.2.4, 2.4.1 and 2.6.10, sources of external fires at the DNNP site include fireballs as a result of a rail transportation accident, forest fires, lightning and accidental fires in on-site storage areas of hydrogen, liquid waste or fuel oil. As mentioned in Chapter 2, Subsection 2.2.4, the risk of fire due to pipeline ruptures close to the DNNP site is negligible and is therefore not considered in the design.

Chapter 9A, Section 9A.6 describes the BWRX-300 fire protection systems implemented to resist and mitigate the effects of external fires. Buildings and structures within the protected area are supplied fire water from redundant loops by two fire water storage tanks (See Chapter 9A, Section 9A.6.6) providing suction to fire pumps located in a Fire Pump Enclosure structure (See Chapter 9B, Section 9B.3.6).

Figure A1.4-1 in Appendix A of Chapter 1 shows the location of the fire water storage tanks and Fire Pump Enclosure at the DNNP site.

Protection measures against the release of toxic gases as a result of external fires are discussed in Subsection 3.3.6.3.

##### **3.3.6.2 Explosions**

The RB structure is designed to withstand impulsive and impactive loads as discussed in Subsection 3.5.5.4.

##### **3.3.6.3 Release of Toxic Gases**

On-site activities that could result in release of toxic gases that could impact the safe operation of the BWRX-300 DNNP are summarized in Chapter 2, Section 2.4. External sources of toxic gases and chemicals are discussed in Chapter 2, Section 2.2.

Mitigation measures considered in the design of MCR/SCR are referenced in Chapter 6, Section 6.4.

#### **3.3.7 Other External Hazards**

##### **3.3.7.1 Electromagnetic Interference**

Protection against electromagnetic interference caused by lightning, high-voltage transmission lines at DNGS and telecommunication towers (See Chapter 2, Subsection 2.2.9) is provided through the use of appropriate shielding and qualification of equipment.

Safety Class SSC are protected against electromagnetic interference to enable them to perform their intended design functions and remain fit for purpose in the conditions under which they are expected to perform.

For a description of plant grounding, lightning protection and electromagnetic compatibility systems and their design requirements, refer to Chapter 8, Section 8.6.

#### **3.3.7.2 Biological Phenomena**

In accordance with CNSC REGDOC-2.5.2, Section 7.4.2, the Pumphouse/forebay structure is designed to prevent clogging by algae and exceptional quantities of fish and to stop them from entering the cooling systems. Measures considered to mitigate the effects of such clogging include locating the intake tunnel and lakebed intake structure at an adequate depth in the lake and the installation of traveling water screens to prevent intake of biofouling material as described in Chapter 9B, Subsection 9B.3.5.

As shown in Chapter 1, Appendix A, Figure A1.4-1, the BWRX-300 protected area is fenced which, in turn, prevents entry of large animals into the plant.

Screens or equivalent engineered features are also provided to prevent blockage of outside air intakes by non-human biota.

#### **3.3.7.3 Collisions of Floating Bodies and Frazil Ice with Water Intakes**

To satisfy requirements in CNSC REGDOC-2.5.2, Section 7.4.2, the design of the intake structure includes measures to mitigate the potential risk of blockage by frazil ice accumulations and physical damages as a result of a marine accident.

Measures considered to preclude blockage by frazil ice include a proper design of the Circulating Water System (CWS) recirculation line to prevent the formation of frazil ice in the forebay. Refer to Chapter 10, Section 10.8 for information related to the CWS.

To prevent marine transportation accidents, a restricted zone is established around the BWRX-300 lakebed intake structure and discharge diffusers to stop commercial ships from approaching offshore structures as stated in Chapter 2, Subsection 2.2.3.4.

#### **3.3.7.4 Robustness Against Malevolent Acts**

The BWRX-300 design provides robust physical features for the protection against malevolent actions found in the Design Basis Threats (DBTs) and Beyond Design Basis Threats (BDBTs). This results in the following fundamental capabilities remaining available after malevolent actions intended to cause substantial radiological releases:

- Ability to shut down the reactor and maintain sub-criticality
- Ability to cool irradiated fuel, both in the core and in the fuel pool
- Ability to limit or prevent the release of radioactivity affecting public health and safety

The ultimate gauge of success of the above three key functions is the prevention of radioactive releases that impact the health and safety of the public.

The BWRX-300 development has included a security by design approach from the early stages of design that uses sound engineering principles to demonstrate that, within an acceptable margin of confidence, sufficient capabilities are available to perform the above functions over a wide range of threats. This approach focuses on protecting the passive plant features and other key reactor components from hostile action by creating a robust perimeter.

The following are examples of features that enhance protection against malevolent actions:

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

- Much of the RB structure, including the portion housing the RPV, is embedded underground, thereby naturally limiting access pathways.
- The number of entrances to the RB are minimized while maintaining emergency exits for personnel safety.

The BWRX-300 Security Annex further describes structures and features to detect, assess, impede, and delay threats up to and including the design basis threat for radiological sabotage in compliance with CNSC REGDOC-2.5.2, Section 7.22.1.

### **3.4 Protection Against Internal Hazards**

This section discusses design basis internal hazards that could compromise the safety functions of SC1 SSC and preventive, and mitigation measures implemented in the design to eliminate their adverse effects. SC2/SC3 SSC credited in the fault evaluation with mitigating fault sequences initiated by internal hazards are also protected against internal hazards. Forbdba internal hazards, refer to Chapter 15, Sections 15.5 and 15.6.

The list of internal hazards considered in the BWRX-300 design is generated from the industry guidelines and the specifics of the BWRX-300 technology. These hazards are in accordance with CNSC REGDOC-2.5.2 (Reference 3.4-1), Section 7.4.1 supplemented by IAEA SSG-64 (Reference 3.4-2), which supersedes IAEA NS-G-1.11 (Reference 3.4-3) referenced in CNSC REGDOC-2.5.2. Screening methodology of internal hazards for safety analysis purposes and ultimately confirmation of adequacy of protection measures is identical to that of the external hazards presented in Section 3.3.

Protection and mitigation methods considered in the design are in line with the design safety objectives and D-in-D concept discussed in Subsections 3.1.1 and 3.1.6, respectively. They include the use of separation, barriers/shielding and monitoring programs as described in Subsection 3.1.5 to preclude unacceptable radiation releases following accidents due to internal hazards.

When applicable, loads generated by internal hazards are considered in the BWRX-300 design in compliance with requirements in Section 7.15.1 of CNSC REGDOC-2.5.2 and CSA N291 (Reference 3.4-4). Combination of loads from randomly occurring individual internal hazards is also considered in the design to ensure structure are adequately protected against internal hazards.

#### **3.4.1 Internal Fires, Explosions and Toxic Gases**

Protection and mitigation measures considered in the BWRX-300 design against internal fires, explosions, and toxic gases to comply with CNSC REGDOC-2.5.2, Section 7.4.1 are discussed in Subsections 3.4.1.1 through 3.4.1.3.

##### **3.4.1.1 Internal Fires**

Protection against internal fires is provided by:

1. A fire protection system to detect, notify, and suppress internal fires and the implementation of a comprehensive fire protection program.
2. Designing, locating, and compartmentalizing SSC to minimize the probability and effect of fires and explosions. Separation is provided between defense lines to the extent that defense lines are credited in the fault evaluation to mitigate the same event. Separation is provided using passive fire barriers to subdivide the plant into separate areas. Separation also confines the effects of fires to a single compartment or area minimizing the potential for adverse effects from fires on redundant SSC.

The fire protection system comprises fire alarms, automatic fire suppression, smoke removal, yard fire main with hydrants, building standpipe and hose stations, fire pumps, water supply and fire extinguishers. Details including design features and parameters of the fire protection system are provided in Chapter 9A, Section 9A.6.

The comprehensive fire protection program covers administrative controls, procedures, periodic inspections, maintenance, testing and training of personnel to ensure a safe shutdown of the plant and the health and safety of plant operators and the public. This program ensures the following life safety performance objectives are met during all operational modes and plant configurations:

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

- Fire hazard controls are included in design and operational stages
- Fire notification means are provided
- Safe egress and/or areas of refuge are provided for occupants for use in the event of a fire
- A safe environment and other required support are provided for essential staff so they can perform all necessary plant control functions during and following a fire
- Protection for personnel performing emergency services is provided both during and following a fire
- Access and emergency lighting are provided for all areas where manual firefighting, evacuations, or operation field actions are expected

The fire safety assessments form a key element in the fire protection program. The fire safety assessments document a systematic review of the fire hazards at DNNP and the potential consequences of design basis fire events.

To satisfy requirements in CSA N293 (Reference 3.4-5) and CSA N293S1 (Reference 3.4-6), a fire hazard assessment is performed as discussed in Chapter 9A, Subsection 9A.6.10 to identify the specific fire hazards and fire protection capabilities for the plant. Chapter 9A, Subsection 9A.6.10 also discusses the fire safe shutdown analysis that evaluates fire effects on the safe shutdown systems to demonstrate compliance to the related requirements of the CSA N293 standard. Methodology for these evaluations is illustrated in Chapter 9A, Figures 9A.6.10-1 and 9A.6.10-2.

The BWRX-300 fire protection design satisfies requirements in CSA N293, CSA N293S1 and the applicable clauses of the NBC (Reference 3.4-7). The D-in-D principle discussed in Subsection 3.1.6 is used to achieve a high degree of fire protection by providing redundancy, diversity and balance in the fire protection measures included in the design to prevent, detect, suppress, and limit the effects of fires. A summary of fire protection measures for the Power Block buildings is provided in Subsections 3.4.1.1.1 and 3.4.1.1.2. Fire protection design features are discussed in Chapter 9A, Section 9A.6 and Chapter 9B, Sections 9B.2 and 9B.3.

#### **3.4.1.1.1 General Protection Measures for Power Block Building Structures**

The Power Block buildings are generally steel frame construction except for the RWB and the TB portion enclosing the main steam line which are of reinforced concrete construction, and the RB which is constructed using Steel Bricks™. To satisfy requirements in Section 7.12.1 of CNSC REGDOC-2.5.2, the walls, floors, and ceilings are designed to have 3-hour fire resistance ratings where required based on high combustible loadings (lubrication oil tank, for example) in the room or where an adjacent room contains equipment or systems from a different safety class division.

Corridors, stair enclosures and elevator hoistways that do not communicate between areas of different safety class divisions may have walls with a 2-hour minimum fire rating. Non-concrete interior walls are constructed of metal studs and gypsum wallboard to the required fire resistance rating.

Doors, including frames and hardware, penetrating rated fire barriers comply with the NBC or equivalent National Fire Protection Association (NFPA) ratings for that barrier.

The fireproofing of structural steel members where required by calculation based on combustible loading, is accomplished by application of an Underwriters Laboratory (UL) of Canada or equivalent UL - listed or Factory Mutual approved cementitious or ablative material, or by UL -

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

listed or Factory Mutual approved boxing design. The required fire rating determines the fireproofing material thickness.

To satisfy requirements in Section 6.8.1.4 of CSA N293, wall and ceiling surface finishes are specified to meet flame spread index of 0-25 and smoke-developed index of 0-100 in accordance with CAN/ULS-S102 (Reference 3.4-8). Floor finishes have a flame spread rating of 0-300 and a smoke development classification less than 450 when tested in accordance with ASTM E648 (Reference 3.4-9) and ASTM E662 (Reference 3.4-10).

Suspended ceilings, including the lighting fixtures are of non-combustible construction in accordance with Section 5.7.1.1 of CSA N293.

To prevent the spread of spilled flammable and combustible liquids, including contaminated firefighting water, diking, draining or a combination of both is used to contain and control the volume of liquids in the buildings. Spill control measures are also included in the design to contain the contents of any above grade oil-filled vessel or tank larger than 208 liters and all tanks containing chemicals used in water/wastewater treatment or quality control.

#### **3.4.1.1.2 General Protection Measures for Systems and Components**

Complying with Section 6.8.4.1 of CSA N293, the BWRX-300 design minimizes the use of plastics, wood and other combustible materials in electrical equipment, cable raceways and wiring racks. Non-combustible and heat-resistant materials are used wherever practical throughout the unit.

Electrical cable in open tray raceways is limited to low voltage cable and meets IEEE 383 standards (Reference 3.4-11) in accordance with Section 6.8.4.4 of CSA N293. Vertical cables have a maximum vertical char of 1.5m when tested in accordance with the vertical flame tray test (Method 2-FT4) test in CSA C22.2 No. 2556 (Reference 3.4-12). Circuitry over 1000 volts is in conduit.

Certain areas of the plant have cable trays in stacked array. Where stacking of trays occurs, power cable, which is the most susceptible to internally generated fires, is routed in the uppermost tray to the greatest extent possible to provide isolation from other trays in the stack. A vertical separation is provided between horizontal cable trays. Groups of stacked trays for redundant SCN cables are separated horizontally.

Piping and cable tray penetrations are provided with fire-stops when penetrating fire rated barriers in accordance with Section 6.5.2.1 of CSA N293. Electrical cable fire-stops are tested to demonstrate a fire rating equal to the rating of the barrier they penetrate in accordance with Section 6.5.2.1 of CSA N293. As a minimum the penetrations meet the requirements of NUREG-1552 (Reference 3.4-13), including Supplement 1 of CSA C22.2 No 0.3 (Reference 3.4-14). The tests are performed or witnessed by a representative of a qualified, independent testing laboratory. The documented test results for the acceptable fire-stops are made a part of the plant design records.

To satisfy requirements in Section 6.3.1.1 of CSA N293, control, power, or instrument cables and equipment of redundant systems used for achieving and maintaining safe shutdown, are separated from each other by three hour rated fire barriers, except within inerted containment. Where the equipment of more than one division is required to be located within a single fire area (Control Room), cables are within conduit or a floor trench.

Fire separations are required to separate redundant fire safe shutdown systems and separate safe shutdown systems from other hazards.

Suitable design of the ventilation systems limits the consequences of a fire by preventing the spread of the products of combustion to other fire areas. Means are provided to ventilate,

exhaust, or isolate the fire area as required, with consideration given to the consequences of ventilation system failure caused by the fire, resulting in a loss of control for ventilating, exhausting, or isolating a given fire area.

Filter media (excluding charcoal filters and High Efficiency Particulate Air (HEPA) filters) used in air handling systems meet the combustibility requirements of Class I in accordance with CAN/ULC-S111(Reference 3.4-15).

HVAC penetrations through 2-hour or 3-hour rated fire barriers are provided with fire/smoke dampers compatible with the rating of the fire barrier.

In accordance with Section 6.8.4.2 of CSA N293, electrical cabinets are designed to limit flame spread across cabinets.

#### **3.4.1.2 Internal Explosions**

The BWRX-300 fire hazard assessment evaluates the combustible loading along with the associated suppression requirements for each of the Power Block significant rooms and document the findings on the room data sheets.

Potential explosions of the following components are considered in the design:

- Batteries
- Diesel generators
- Switchgear
- Hydrogen tanks
- Miscellaneous hydrogen fires
- Offgas/hydrogen recombiners
- Transformers
- Transient combustibles
- Turbine auxiliaries

To satisfy requirements of CNSC REGDOC-2.5.2, Section 7.4.1, separation is provided between defense lines to the extent that defense lines are credited in the fault evaluation to mitigate the same event. Design measures considered include the use of fire barriers and blowout doors where flammable and combustible materials are located, and redundancy to enhance the reliability of systems.

Non-combustible and heat-resistant materials are also used, wherever practical throughout the Power Block, particularly in locations such as the containment and control rooms to reduce the risk of fires and explosions.

Administrative controls are also implemented to ensure stored chemicals and combustibles cannot ignite or react in sufficient quantities to impact nuclear safety. Collapse of structures, pipe whip, jet effects, and internal flooding as a result of internal explosions is also considered in the design.

#### **3.4.1.3 Release of Internal Hazardous (Toxic) Gases**

Plant personnel are protected from the adverse effects due to uncontrolled release of hazardous substances as a result of fires or internal explosions in compliance with CNSC REGDOC-2.5.2, Sections 7.4.1, 7.12.1 and 7.12.2.

Preventive and mitigation measures against the release of hazardous and toxic gases include a proper design of ventilation systems to exhaust smoke, heat, and gaseous combustion products from inside the Power Block to the outside atmosphere in the event of a fire. Refer to Chapter 9A, Sections 9A.5 and 9A.6 for details of the BWRX-300 HVAC and fire protection systems, respectively.

Complying with CNSC REGDOC-2.5.2, Sections 8.10.1 and 8.10.2, the habitability of the MCR and SCR is ensured by designing the HVAC systems in these rooms to detect and limit the introduction of airborne radioactivity, toxic gas or smoke into the rooms as described in Chapter 6, Section 6.4. As stated in Chapter 6, Section 6.4.2.1, habitability requirements in the control rooms are maintained without credit for any breathing apparatus or protective clothing.

HVAC systems also supply outside air into the SCCV via the containment inerting system and exhaust inerting gases to provide a habitable environment for maintenance personnel during outage and maintenance periods.

### **3.4.2 Internal Flooding**

SC1 SSC and SC2/SC3 SSC credited with flood event mitigation in the fault evaluation are protected against internal flooding in compliance with CNSC REGDOC-2.5.2, Sections 7.4.1 and 7.15.1.

Appropriate means are included in the design to prevent failure of SSC that are not designed to be submerged or exposed to spray as a result of flooding. They include the use of redundant system trains or divisions, structural barriers or compartments, curbs and elevated thresholds, and a leak detection system.

The design of the integrated RB structures considers the loads associated with the post-accident internal flooding of the containment following a DBA. The hydrostatic loads from the maximum possible water level are applied as pressures to the affected walls and mat foundation and applicable loads are also used for design of containment metal components.

The BWRX-300 internal flooding analysis identifies flooding sources, equipment in each area, and maximum internal flood levels in each area. The sources of internal flooding hazards include:

- Leaks and breaks in pressure retaining components
- High-energy piping breaks and cracks
- Moderate-energy piping through-wall cracks
- Pump mechanical seal failures
- Failure of isolating devices
- Storage tank ruptures
- Actuation of fire protection system
- Flow from upper elevations and nearby areas

The flood level in each internal area is determined by evaluating the inflow due to internal flooding sources, outflow from area compartment, and accumulation in each compartment area due to net flow.

### **3.4.3 Internal Missiles**

Complying with CNSC REGDOC-2.5.2, Sections 7.4.1 and 7.15.1, the BWRX-300 design includes preventive and mitigation measures against internal missiles. The methodology used to

determine internal missiles is discussed in Subsection 3.4.3.1, while Subsection 3.4.3.2 provides the general preventive and mitigation measures considered in the design.

#### **3.4.3.1 Sources of Internal Hazards**

Potential missiles inside and outside containment and turbine missiles are identified, and their statistical significance determined. A statistically significant missile is defined as a missile that could cause unacceptable plant consequences or exceedance of radiological release limits. Criteria for determining statistically significant missiles are obtained from applicable portions of U.S. NUREG-0800 (Reference 3.4-16), SRP 3.5.1.1 through 3.5.1.3.

These missile sources could result from in-plant component overspeed failures or high-pressure system ruptures in compliance with CNSC REGDOC-2.5.2, Section 7.4.1. Rotating equipment failures include evaluations of pumps, fans, blowers, diesel generators, compressors, and turbines. Potential missiles from failure of pressurized components include valve bonnets, valve stems, pressure vessels, thermowells, retaining bolts, and blowout panels.

#### **3.4.3.2 Protection from Internal Missile Hazards**

Preventive and mitigative measures considered in the BWRX-300 design against internal missiles include the following:

- Locating the system or component in an individual missile-proof structure
- Physically separating redundant systems or components of the system from the missile trajectory path or calculated range
- Providing localized protection shields or barriers for systems or components
- Designing the particular structure or component to withstand the impact of the most damaging missile
- Providing design features on the potential missile source to prevent missile generation
- Orienting the potential missile source to prevent unacceptable consequences caused by missile generation

Refer to Subsection 3.3.5.4 for barrier design procedures for impactive loads, including internal missiles.

#### **3.4.4 Pipe Breaks**

BWRX-300 SC1 SSC and SC2/SC3 SSC credited with event mitigations in the fault evaluation are adequately protected from the consequences associated with a postulated rupture of high-energy piping and crack of moderate-energy piping inside and outside containment in compliance with Sections 7.4.1 and 7.7 of CNSC REGDOC-2.5.2 and IAEA SSG-64. Design bases and measures used to protect these SSC, referred to in the following subsections as essential SSC, are discussed in Subsections 3.4.4.1 and 3.4.4.2.

Effects that may result from a postulated rupture of high-energy piping include (1) pipe whipping, (2) pipe break reaction forces, (3) jet impingement forces, (4) blast waves, (5) sub-compartment pressurization, (6) decompression waves, (7) Missile generation, (8) environmental effects and (9) Flooding.

In the BWRX-300 design, a whipping pipe may hit a target and cause secondary failure in the target object depending on the thrust force, materials and sizes of the pipe/target. Severance in the target may occur and form a missile. A pipe whipping about a plastic hinge is not assumed to cause severance at the plastic hinge. Therefore, a break cannot cause the whipping pipe to act

as a missile. Criteria related to the evaluation of and protection against missiles, including those resulting from jet impingement or a whipping pipe, are provided in Subsection 3.4.3.

Protection against flooding and environmental effects as a result of high-energy pipe breaks are discussed in Subsections 3.4.2 and 3.9.4, respectively.

#### **3.4.4.1 Plant Design for Protection Against Postulated Piping Failures in Fluid Systems Inside and Outside Containment**

##### **3.4.4.1.1 Design Basis**

In addition to meeting requirements in CNSC REGDOC-2.5.2 and IAEA SSG-64, the BWRX-300 pipe break event protection also conforms to 10 CFR 50 Appendix A (Reference 3.4-17), General Design Criterion 4. To supplement the guidance provided in IAEA SSG-64, the design bases for this protection are in compliance with NRC Branch Technical Position (BTP) 3-3 (Reference 3.4-18) and BTP 3-4 (Reference 3.4-19) included in Subsections 3.6.1 and 3.6.2, respectively, of U.S. NUREG 0800. BTP 3-4 describes an acceptable basis for selecting the design locations and orientations of postulated breaks and cracks in fluid systems piping. Standard Review Plan Subsections 3.6.1 and 3.6.2 describe acceptable measures that could be taken for protection against the breaks and cracks and for restraint against pipe whip that may result from breaks.

Protection against pipe break event dynamic effects is provided to fulfill the following objectives:

1. Assure that the reactor can be shut down safely and maintained in a safe shutdown condition and that the consequences of the postulated piping failure are mitigated to acceptable limits with Loss of Preferred Power (LOPP).
2. Assure that containment integrity and leak tightness are maintained.

##### **3.4.4.1.2 Design Evaluation**

An analysis of pipe break events is performed to identify those essential systems, components, and equipment that provide protective actions required to mitigate, to acceptable limits, the consequences of the pipe break event.

Pipe break events involving high-energy fluid systems are evaluated for the effects of pipe whip, jet impingement, flooding, sub-compartment pressurization, and other environmental effects. Pipe break events involving moderate-energy fluid systems are evaluated for wetting from spray, flooding, and other environmental effects.

Adequate protection is provided against the effects of pipe break events for essential SSC to an extent that their ability to shut down the plant safely or mitigate the consequences of the postulated pipe failure is not impaired. This is accomplished by means of design features such as physical separation, jet shields and pipe whip restraints or by designing the SSC to accommodate applicable loads due to postulated pipe failure.

##### **3.4.4.1.3 General Protection Measures**

The direct effects associated with a particular postulated break or crack are mechanistically consistent with the failure. Thus, actual pipe dimensions, piping layouts, material properties, and equipment arrangements are considered in defining the following specific measures for protection against actual pipe movement and other associated consequences of postulated failures:

1. Protection against the dynamic effects of pipe failures is provided in the form of pipe whip restraints, equipment shields, and physical separation of piping, equipment, and instrumentation.

2. As an alternative to protective measures, SSC identified as essential targets under postulated pipe breaks are analyzed to show that the essential functionality remains available under all applicable loading conditions resulting from the pipe break.
3. The precise method chosen depends largely upon limitations placed on the designer such as accessibility, maintenance, and proximity to other pipes.
4. Protection of SCN systems and components from the effects of postulated pipe breaks is considered where a resulting failure of the SCN system or component could lead to failure of an essential SSC. This includes consideration of coatings and insulation materials which could result in debris generation

### **Separation**

To meet requirements in CNSC REGDOC-2.5.2, Section 7.6.1.1, the plant layout arrangement provides physical separation and segregation of essential SSC to the extent practicable to provide sufficient distance such that the effects of the failure cannot impair their essential functionality.

Physical separation between redundant safety class systems supporting Defense Line 3 (DL3) with their related auxiliary supporting features is another basic protective measure incorporated in the design to protect against the dynamic effects of postulated pipe failures.

### **Pipe Whip Restraints**

Pipe whip restraints are used where pipe break protection requirements could not be satisfied using spatial separation, barriers, shields, analysis of the SSC or enclosures alone, and when it is necessary to limit the piping movement (pipe whip) following a postulated break. Restraints are located based on the specific postulated break locations determined in accordance with Subsection 3.4.4.2. After the restraints are placed, the piping and essential SSC are evaluated for jet impingement and pipe whip. For those cases where unacceptable jet impingement damage could still occur, barriers, shields, or enclosures are utilized in conjunction with pipe whip restraints.

The design criteria for restraints are given in Subsection 3.4.4.2.

### **Barriers, Shields, and Enclosures**

Protection requirements are met through the protection afforded by the walls, floors, columns, abutments, and foundations in many cases. Where adequate protection is not already present because of spatial separation or existing plant features, additional barriers, deflectors, shields, or guard pipes are provided as necessary to meet the functional protection requirements of essential targets.

Structures acting as barriers, shields, or enclosures are designed to withstand the consequences of postulated pipe failures (i.e., pipe whip, jet impingement, pressurization of compartments, water spray, and flooding, as appropriate) in combination with other internal hazards such as missiles and loadings associated with the DBE within their respective design load limits. Procedures used to design these structures are provided in Subsection 3.3.5.4.

The BWRX-300 barrier design ensures a resistance to impulsive loads that is at least 20% greater than the steady-state magnitude of the impulsive load in accordance with regulatory guidance of U.S. NRC RG 1.243 (Reference 3.4-20), Regulatory Position 11.1.2 and provisions of CSA N291, Clause A.3.5.1.

#### **3.4.4.1.4 Protective Features and Operator Actions**

All available systems are considered for mitigating the consequences of a failure. In judging the availability of systems, account is taken of the postulated failure and its direct consequences such

as unit trip and LOPP, and of the assumed single active component failure and its direct consequences.

As stated in Chapter 15, Section 15.5, no operator actions are required to mitigate the effects of high-energy pipe breaks.

#### **3.4.4.2 Determination of Rupture Locations and Dynamic Effects Associated with the Postulated Rupture of Piping**

This section discusses the location criteria and methods of analysis needed to evaluate the dynamic effects associated with postulated breaks and cracks in high and moderate - energy fluid system piping inside and outside of the primary containment. This information provides the design basis for the requirements for protection of essential SSC.

##### **3.4.4.2.1 Criteria Used to Define Break and Crack Location and configuration**

The following subsections establish the criteria for the location and configuration of postulated breaks and cracks.

#### **Definition of High-Energy Fluid Systems**

High-energy fluid systems are defined to be those systems or portions of systems that, during normal plant conditions (as defined in Subsection 3.1.4), are either in operation or are maintained pressurized under conditions where either or both of the following are met:

- Maximum operating temperature exceeds 93.3°C; and
- Maximum operating pressure exceeds 1.9 MPaG.

#### **Definition of Moderate-Energy Fluid Systems**

Moderate-energy fluid systems are defined to be those systems or portions of systems that, during normal plant conditions (as defined in Subsection 3.1.4), are either in operation or are maintained pressurized (above atmospheric pressure) under conditions where either or both of the following are met:

- Maximum operating temperature is 93.3°C or less; and
- Maximum operating pressure is 1.9 MPaG or less.

Piping systems are classified as moderate-energy systems when they operate as high-energy piping for only short operational periods in performing their system function but, for the major operational period, qualify as moderate-energy fluid systems. An operational period is considered short if the total fraction of time that the system operates within the pressure-temperature conditions specified for high-energy fluid systems is less than 2% of the total time that the system operates as a moderate-energy fluid system.

#### **Postulated Pipe Breaks and Cracks**

A postulated pipe break is defined as a sudden gross failure of the pressure boundary either in the form of a complete circumferential severance (guillotine break) or a sudden longitudinal split without pipe severance and is postulated for high-energy fluid systems only. For moderate-energy fluid systems, pipe failures are limited to postulation of cracks in piping and branch runs; these cracks affect the surrounding environmental conditions only and do not result in whipping of the cracked pipe. High-energy fluid systems are also postulated to have cracks for conservative environmental conditions in a confined area where high and moderate-energy fluid systems are located.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

The following high-energy piping systems are considered as potential candidates for a postulated pipe break during normal plant conditions and are analyzed for potential damage resulting from damage effects:

- Main Steam
- Isolation Condenser System
- Control Rod Drive System
- Reactor Water Cleanup System
- Condensate Feedwater System
- Condenser Offgas System (in TB)

Moderate-Energy piping systems considered as potential candidates for a postulated pipe crack include the following:

- Boron Injection
- IC Pool Cooling
- Shutdown Cooling
- Fuel Pool Cooling
- Passive Containment Cooling
- Containment Inerting

#### **3.4.4.2.2 Location of Postulated Pipe Breaks**

Postulated pipe breaks are selected as follows:

##### **Piping in Containment Penetration Areas**

Regions of high energy piping associated with reactor containment penetrations will consider analytical concepts to eliminate the need to consider postulated breaks. .

##### **ASME Code Section III Class 1 High-Energy Piping in Areas Other Than Containment Penetration**

With the exception of those portions of piping identified above as containment penetration areas, breaks in ASME Code, Section III, Class 1 piping (Reference 3.4-21) are postulated at the following locations in each piping and branch run:

- At terminal ends
- At intermediate locations where the maximum stress range or fatigue usage values exceed the limits specified in BTP 3-4

##### **ASME Code Section III Class 2 and 3 High-Energy Piping in Areas Other Than Containment Penetration**

With the exception of those portions of piping identified above as containment penetration areas, breaks in ASME Code, Section III, Class 2 and 3 piping (Reference 3.4-22) are postulated at the following locations in those portions of each piping and branch run:

- At terminal ends
- At intermediate locations where the maximum stress values exceed the limits specified in BTP 3-4

### **Non-ASME High-Energy Piping**

Breaks in seismically analyzed non-ASME high-energy piping systems are postulated according to the same criteria as for ASME Code Section III, Class 2 and 3 high-energy piping systems.

Breaks in non-seismically analyzed, non-ASME high-energy piping systems are postulated at each terminal end and at each intermediate location of potential high stress or fatigue, such as pipe fittings, valves, flanges, and welded-on attachments

#### **3.4.4.2.3 Location of Postulated Pipe Cracks**

Postulated pipe crack locations are selected as follows:

#### **Piping in Containment Penetration Areas**

Regions of high energy piping associated with reactor containment penetrations will consider analytical concepts to eliminate the need to consider postulated cracks.

#### **High-Energy Piping in Areas Other Than Containment Penetrations**

With the exception of those portions of piping identified above as containment penetration areas, cracks in high-energy piping are postulated as follows:

1. For ASME BPVC Code, Section III Class 1 piping, at axial locations where the calculated stress range values exceed the limits specified in BTP 3-4.
2. For ASME BPVC Code, Section III Class 2 and 3 or non-ASME class piping, at axial locations where the calculated stress values exceed the limits specified in BTP 3-4.
3. For piping which has not been evaluated to obtain stress information, through-wall cracks are postulated at axial locations that produce the most severe environmental effects.

#### **Moderate-Energy Piping in Areas Other Than Containment Penetrations**

With the exception of those portions of piping identified above as containment penetration areas, through-wall cracks in moderate-energy piping adjacent to safety class SSC are postulated except where:

1. For ASME BPVC Code, Section III, Class 1 piping the calculated stress range values are less than the limits specified in BTP 3-4.
2. For ASME BPVC Code, Section III, Class 2 or 3 and non-ASME class piping, the calculated stress values are less than the limits specified in BTP 3-4.

Through-wall cracks, unless the piping system is exempted above, are postulated at axial and circumferential locations that result in the most severe environmental consequences.

Through-wall cracks are postulated in fluid system piping designed to non-seismic standards as necessary to assure that essential system and component functionality is maintained following a piping failure assuming a concurrent single active failure.

#### **Moderate-Energy Piping in Proximity to High-Energy Piping**

In cases where both high-energy and moderate-energy piping systems exist in a confined area, cracks are postulated in the piping system which leads to the more conservative environmental conditions.

#### **3.4.4.2.4 *Types of Breaks and Cracks to be Postulated***

##### **Pipe Breaks**

The following criteria are used to postulate breaks in high-energy fluid system piping at the identified locations:

1. For the purposes of considering dynamic effects, circumferential breaks are postulated only in piping having a nominal diameter greater than 25 mm.
2. Longitudinal breaks are postulated only in piping having a nominal diameter equal to or greater than 100 mm.
3. Longitudinal breaks are not postulated at terminal ends.
4. Circumferential breaks are assumed at all terminal ends.
5. At each of the intermediate postulated break locations identified to exceed the stress and usage factor limits of the criteria in Subsection 3.4.4.2.2, consideration is given to the occurrence of either a longitudinal or circumferential break. Examination of the state of stress in the vicinity of the postulated break location is used to identify the most probable type of break based on the BTP 3-4 rules.
6. Where breaks are postulated to occur at each intermediate pipe fitting, weld attachment, or valve without the benefit of stress calculations, only circumferential breaks are postulated.
7. For a circumferential break, the dynamic force of the jet discharged at the break location is based upon the effective cross-sectional flow area of the pipe and on a calculated fluid pressure as modified by an analytically or experimentally determined thrust coefficient.
8. For longitudinal breaks, the dynamic force of the fluid jet discharge is based on a circular or elliptical (2D x 1/2D) break area equal to the effective cross-sectional flow area of the pipe at the break location and on a calculated fluid pressure modified by an analytically or experimentally determined thrust coefficient as determined for a circumferential break at the same location.

##### **Pipe Cracks**

The following criteria are used to postulate through-wall leakage cracks in high- or moderate-energy fluid system piping at the identified locations:

1. Leakage cracks are only postulated in piping having a nominal diameter greater than 25 mm.
2. The postulated cracks are oriented circumferentially to result in the most severe environmental consequences.
3. Crack openings are assumed as a circular orifice of area equal to that of a rectangle having dimensions one-half-pipe-diameter in length and one-half-pipe-wall thickness in width.
4. The flow from the crack opening is assumed to result in an environment that wets all unprotected components within the compartment, with consequent flooding in the compartment and communicating compartments, based on a conservatively estimated time period to effect corrective actions.

#### **3.4.4.2.5 Analysis Methods to Define Blowdown Forcing Functions and Response Models**

##### **Analytic Methods to Define Blowdown Forcing Functions**

Analytical methods used to establish pipe rupture blowdown and jet thrust forcing forces are in accordance with ANSI/ANS 58.2 (Reference 3.4-23), Section 6.2.

The rupture of a pressurized pipe causes the flow characteristics of the system to change, creating reaction forces that can dynamically excite the piping system. The reaction forces are a function of time and space and depend upon fluid state within the pipe prior to rupture, break flow area, frictional losses, plant system characteristics, piping system, and other factors.

Criteria used for calculation of fluid blowdown forcing functions include the following:

1. Circumferential breaks are assumed to result in pipe severance and separation amounting to at least a one-diameter lateral displacement of the ruptured piping sections unless physically limited by piping restraints, structural members, or piping stiffness as may be demonstrated by inelastic limit analysis (e.g., a plastic hinge in the piping is not developed under loading).
2. For a circumferential break, the dynamic force of the jet discharge at the break location is based on the cross-sectional flow area of the pipe and on a calculated fluid pressure as modified by an analytically or experimentally determined thrust coefficient. Line restrictions, flow limiters, positive pump-controlled flow, and the absence of energy reservoirs are taken into account, as applicable, in the reduction of jet discharge.
3. All breaks are assumed to attain full size within one millisecond after break initiation.

##### **Pipe Whip Dynamic Response Analysis Criteria**

Dynamic forces are assumed to cause pipe whip reaction whenever moments cause excessive plastic deformation and the formation of a plastic hinge. Significant motion occurs only when the thrust force acts through an arm of sufficient length to induce a plastic hinge. This length is called the plastic hinge length. When the stiffness of a piping system is such that a plastic hinge cannot form, the pipe lateral displacement is assumed to be equal to the pipe diameter.

Pipe whip restraints are used to prevent piping from deforming plastically by forming hinges. They absorb blowdown force energy and limit jet impingement's zone of influence.

The prediction of time dependent and steady thrust reaction loads caused by blowdown of subcooled, saturated, and two-phase fluid from ruptured pipe is used as an input to evaluate the pipe whip dynamic response.

Pipe motion following circumferential breaks are assumed in the plane defined by the initial axis of the jet thrust force and rotation about a plastic hinge point, or at an intermediate point, such as the second change in direction, where the moment resisting capacity is less than straight pipe, provided the distance to this point is not significantly less than the plastic hinge length. The arc of the whipping pipe for planar motion is assumed to be limited to 180 degrees due to crimping at the plastic hinge and the pipe folding back against itself. Where a system consisting of piping, restraints and supporting structures is so complex that the assumption of planar motion is neither conservative nor realistic, the whip zone of influence can be conservatively enlarged to a region approaching a sphere with a radius equal to the distance between the break point and the first restraint. In lieu of this assumption, a more detailed elastoplastic analysis may be performed.

Longitudinal breaks in the form of axial split without pipe severance are postulated in the centre of the piping at two diametrically opposed points (but not concurrently) located so that the reaction force is perpendicular to the plane of the piping configuration and produces out-of-plane bending.

Alternatively, a single split is assumed at the section of highest tensile stress as determined by detailed stress analysis (e.g., finite element analysis).

For restrained longitudinal breaks or those breaks for which it can be shown that the pipe resists bending elastically, the zone of whip influence is taken to be all points within a distance of one pipe diameter from the axis of the pipe, unless physically limited by piping restraints, structural members or piping stiffness. For unrestrained longitudinal breaks in elbow fittings, the out-of-plane forces are assumed to cause whipping through a zone of influence described by the rotation of the fitting through 360 degrees about an axis which connects the two plastic hinges formed in the attached legs of piping.

A whipping pipe is considered capable of rupturing impacted pipes of smaller nominal pipe diameter, and of developing through-wall cracks in impacted pipes of equal or larger nominal pipe sizes with thinner wall thickness.

If a whipping pipe contains a large in-line mass (such as a valve), or if there is a change in the pipe shape (e.g., an elbow) near the end of the pipe, rupture of target pipes which are equal to or larger than the whipping pipe is considered.

### **Pipe Whip Dynamic Response Methods**

Analytical models used to evaluate pipe whip dynamic response adequately represent the mass, inertia and stiffness properties of the piping system accounting for interaction effects of both the piping and pipe whip restraint.

Analytical methods used for piping response are based on those defined in ANSI 58.2, Section 6.3 and include complete system dynamic analysis, simplified dynamic analysis, quasi-dynamic analysis, energy balance analysis, and static analysis.

In cases where it is necessary to calculate stresses at locations which are far away from the break (e.g., in containment penetration break exclusion area), a more extensive model of the ruptured piping, supports, and pipe whip restraints is necessary.

If the snubbers or other seismic restraints are included in the piping model, they are modeled with the same stiffness used in the seismic analysis of the pipe. However, credit for seismic restraints cannot be taken if the applied load exceeds the ASME BPVC Code Section III (Reference 3.4-21, Reference 3.4-22 and Reference 3.4-24) Service Level D rating.

### **Pipe Whip Analysis Material Properties**

Strain rate effects and other material property variations are considered in the pipe whip analysis of piping and pipe whip restraints.

Material properties and design limits consistent with those stated in ANSI/ANS 58.2, Sections 6.6.2 and 6.6.3 are applied for plastic deformation design of piping and pipe whip restraint design under dynamic and steady-state loading conditions.

#### **3.4.4.2.6 *Dynamic Analysis Methods to Verify Integrity and Operability***

### **Jet Impingement Analyses and Effects on Essential Components**

For each postulated circumferential and longitudinal break, an evaluation of jet impingement effects on essential targets including jet impinging force, thermal energy, and moisture is completed in accordance with the methodology criteria in this section.

In the case of circumferential breaks, jets are assumed to be oriented axially with respect to the pipe. In the case of longitudinal breaks, jets are assumed to be oriented radially.

Potential targets, or portions of targets adjacent to the jet boundary, are assumed to be impinged upon when reasonable variations in jet geometry or pipe movement are considered.

In evaluating the potential for jet impingement on specific targets, consideration is given to the movement of the jet centreline due to pipe whip, including pipe-restraint interaction.

Thermal and moisture effects on essential targets are determined in accordance ANSI/ANS 58.2, Section 7.4 and 7.5.

Modeling of the jet geometry and determination of the jet impingement force acting on a target is calculated according to ANSI/ANS 58.2, Sections 7.2, 7.3, and Appendices C and D, with modifications applied as identified in NUREG/CR-7275 (Reference 3.4-25).

### **Pipe Whip Effects on Essential Structures, Systems and Components**

This section provides the criteria and methods used to evaluate the effects of pipe displacements on essential SSC following a postulated pipe rupture.

Pipe whip (displacement) effects on essential SSC can be placed in two categories: (1) pipe displacement effects on components (nozzles, valves, tees, etc.) which are in the same piping run that the break occurs in; and (2) pipe whip or controlled displacements onto external components such as building structure, other piping systems, cable trays and conduits.

#### **(1) Pipe Displacement Effects on Components in the Same Piping Run**

Essential components located in the same run as the postulated break meet the applicable ASME Code class limits for Service Level D and limits to ensure required operability.

#### **(2) Pipe Displacement Effects on Essential Structures, Systems, and Components**

The criteria and methods used to calculate the effects of pipe whip on external components consist of the following:

1. The effects on barriers, shields, or enclosures credited for protecting essential SSC are evaluated in accordance with the barrier design procedures given in Subsection 3.3.5.4.
2. If the whipping pipe impacts an essential system or component, mitigating measures are established to ensure essential functionality is not lost for the postulated break scenario.

### **Loading Combinations and Design Criteria for Pipe Whip Restraint**

Pipe whip restraints are non-ASME code class components. As a result, other methods (i.e., testing) such as the use a reliable database may be used instead of the rules applied to ASME code class components for their design and sizing.

Pipe whip restraints are designed for both the thrust force at the pipe rupture location and the impact force of the pipe. The magnitude of these forces is a function of the pipe size, fluid temperature, and operating pressure.

Pipe whip restraints, as differentiated from piping supports, are typically designed only to function, and carry loads for an extremely low probability gross failure in a piping system carrying high-energy fluid. They are also required to remain functional following an earthquake up to and including the design basis DBE.

Pipe whip restraints are designed with sufficient clearances to prevent an increase in the pipe stresses by their presence during any normal mode of reactor operation or condition and are designed to allow for in-service inspection of the process piping with minimal obstruction.

#### **3.4.4.2.7 Analytic Methods to Define Blast Wave Interaction to SSC**

Sub-compartment pressurization due to postulated pipe breaks is considered where applicable.

#### **3.4.4.2.8 Sub-compartment Pressurization**

As discussed in Chapter 6, Subsection 6.3.2.2, the BWRX-300 containment sub-compartments do not contain large high-energy pipes and are, therefore, not subject to sub-compartment pressurization loads. For breaks outside the containment, mass and energy releases into the sub-compartments are calculated as described in Chapter 15, Subsection 15.5.9.2. Pressurization of the sub-compartments of the reactor building is calculated using the GOTHIC code described in Chapter 15, Subsection 15.5.1.2. The GOTHIC model of the RB includes all sub-compartments of the RB as lumped parameter volumes, including all flow passages between the rooms. This includes all doors and blowout panels which may be closed normally but may open if a pressure differential develops between the sub-compartments.

#### **3.4.4.2.9 Decompression Waves**

3-D thermal hydraulic code TRACG (See Chapter 15, Subsection 15.5.1.2) generates pressure time history in the annular region between chimney/shroud and RPV due to acoustic decompression wave as a result of a pipe break. Generated time history is part of the inputs to RPV primary structural FE model along with jet impingement, jet reaction and pipe whip restraint loads inputs to determine dynamic effects on RPV components, RPV internals and nozzles/pipings attached to RPV.

### **3.4.5 Other Internal Hazards**

#### **3.4.5.1 Hard Object Impact**

Complying with CNSC REGDOC-2.5.2, Section 7.15.3 and IAEA SSG-64, the BWRX-300 design considers hard object impact loads resulting from the drop of heavy loads lifted and handled in areas where SSC required for safe shutdown of the plant are located.

Drops considered are those most likely to occur during the handling of plant equipment for maintenance or during spent fuel transfer operations. Other drops considered are drops as secondary effects of other internal hazards or external hazards discussed in Section 3.3.

In accordance with U.S. NRC RG 1.244 (Reference 3.4-26), the BWRX-300 heavy load is defined per the provisions of U.S. NUREG-0612 (Reference 3.4-27) as any load, carried in a given area after a plant becomes operational, that weighs more than the combined weight of a single spent fuel assembly and its associated handling tool.

Critical heavy load handling evolutions considered are those where inadvertent operations or equipment malfunctions, separately or in combination, could:

- Cause a release of radioactivity
- Cause a criticality accident
- Cause the inability to cool fuel within the reactor vessel or within the Fuel Pool
- Prevent a safe shutdown of the reactor

Measures considered to reduce the potential of heavy load drops in the RB meet the D-in-D guidelines in U.S. NRC RG 1.244 and Section 5.1 of US NUREG-0612. They include a proper plant arrangement, the implementation of a heavy loads program as part of the plant procedures and effective means of lifting and transporting heavy loads designed to satisfy the single failure proof guidelines of Section 5.1.6 of US NUREG-0612.

Chapter 9A, Subsection 9A.8.1 provides an overview of the BWRX-300 heavy load program which identifies all heavy loads lifted during operation of the plant and the safe travel paths determined for their lifting. This program also manages the safe execution of heavy load evolutions.

Chapter 9A, Subsection 9A.8.1 describes the various cranes and hoists used to lift and transport heavy loads and applicable guides and standards used for their design. The RB polar crane main and auxiliary hoists meet the requirements of single failure proof systems in accordance with ASME NOG-1 (Reference 3.4-28). The refueling platform main hoist meets the requirements of a single failure proof hoist. Periodic inspection and maintenance of cranes are also planned to ensure their safe functioning.

#### **3.4.5.2 Failure of Non-Structural Element**

The failure of non-structural elements is considered in the BWRX-300 design.

Staircases and elevator shafts are evaluated and designed for interaction with plant Seismic Category A or B SSC in the event of DBE.

Architectural components and shielding blocks whose failure or dislocation could affect the safe operation of any Seismic Category A or B SSC are also evaluated for seismic interaction.

Scaffolding and other temporary structures considered a temporary alteration in support of maintenance are evaluated for seismic interaction as well, following the plant temporary structures procedure.

#### **3.4.5.3 Electromagnetic Interference**

Internal electromagnetic interference is caused by induction or radiation from installed equipment.

Complying with CNSC REGDOC-2.5.2, Section 7.5, safety class SSC are protected against electromagnetic interference to enable them to perform their intended design functions and remain fit for purpose in the conditions under which they are expected to perform.

Qualification requirements for protection against electromagnetic interference are presented in Subsection 3.9.5.

Plant grounding, lightning protection and electromagnetic compatibility systems and their design requirements are discussed in Chapter 8, Section 8.6.

### **3.5 General Design Aspect for Civil Engineering Works of Seismic Category Buildings and Civil Engineering Structures**

This Section presents the design principles, design basis requirements, criteria and applicable codes and standards used in the design of the BWRX-300 civil structures, including their foundations in compliance with requirements in CNSC REGDOC-1.1.2 (Reference 3.5-1), Section 4.5.5.

Below are the key PSAR sections that impact the BWRX-300 Civil/structural design that should be reviewed along with this section:

- Chapter 1 which provides the DNNP general site and facility layout, a description of the BWRX-300 buildings, plant operational modes, principles of safety management and applicable codes & standards utilized in the design
- Chapter 2 which described the characteristics of the DNNP site on which the BWRX-300 facility is constructed
- Chapter 3, Section 3.1, which provides the general design aspects and D-in-D safety framework utilized in the BWRX-300 design
- Chapter 3, Section 3.2, which provides the general classification of BWRX-300 SSC and the approach used to establish these classifications
- Chapter 3, Sections 3.3 and 3.4, which provide methodology and general design requirements for protection against the effects of external and internal hazards
- Chapter 9B which provides specific information on compliance with the design rules for civil engineering works and structures

From the site layout presented in Chapter 1, Appendix A, Figure A1.4-1, the primary buildings in the BWRX-300 Power Block consist of the Reactor Building (RB) which houses the containment, Radwaste Building (RWB), Control Building (CB), Turbine Building (TB), and Reactor Auxiliary Bay. In the following sections, reference to the integrated RB structure is inclusive of the RB, containment, and containment internal structures, whereas RB is used to refer to the part of the integrated structure located outside of containment.

The seismic categorization of these structures is provided in Table 3.3-1. Per Subsection 3.2.3 and Table 3.3-1, the Seismic Category A integrated RB housing SC1 SSC has the utmost importance to safety and is credited for the safety analysis of the BWRX-300. RWB structures that support and protect equipment and components for storage and processing of highly radioactive gas, liquids and solid materials are categorized as RW-IIa. The CB, TB and Reactor Auxiliary Bay categorized as Non-Seismic structures are not credited in the safety analysis but are relied upon for their D-in-D function since they house and protect SC2 or SC3 systems and components. The RWB, CB, TB, and Reactor Auxiliary Bay can also affect the BWRX-300 safety considering their proximity to and interaction with the integrated RB structure.

Other civil structures for which design basis requirements are provided are the Pumphouse/Forebay structures and tunnels that support the condenser cooling and plant cooling water systems, and the Fire Pump Enclosure. For the location of these structures, refer to Chapter 1, Appendix A, Figure A1.4-1.

In accordance with Section 3.1 of CNSC REGDOC-1.1.5 (Reference 3.5-2) and Section 5.4 of CNSC REGDOC-3.5.3 (Reference 3.5-3), design principles for BWRX-300 structures are provided in a graded manner commensurate to their importance to safety. The primary focus of this Section is for the Seismic Category A integrated RB. Design principles for the RWB, CB, TB,

Reactor Auxiliary Bay, Pumphouse/Forebay and Fire Pump Enclosure structures are provided in Chapter 9B, Section 9B.3.

Remaining plant structures shown in Chapter 1, Appendix A, Figure A1.4-1 are not covered since they are not credited in the safety analysis.

### **3.5.1 General Design Principles for Seismic Category A Structures**

The BWRX-300 Seismic Category A integrated RB structure is designed to meet the serviceability, strength, and stability requirements for all possible load combinations under the categories of normal operation, Anticipated Operational Occurrence (AOO) and DBA in compliance with requirements in CNSC REGDOC-2.5.2 (Reference 3.5-4), Sections 7.15.1 and 7.7. The robustness of the design to prevent potential release of radioactivity to the public and environment under Design Extension Condition (DEC) is considered in compliance with requirements in CNSC REGDOC-2.5.2, Sections 7.7 and 7.15.1 and is discussed in Subsection 3.5.6.

The integrated RB structure and its common foundation are primarily constructed using an advanced steel-plate composite system called Steel Bricks™. The Steel Bricks™ system has a configuration similar to the typical steel-plate composite system except that the tie-rods in the typical steel-plate composite system are replaced by diaphragm plates created by bending the plates that facilitates the fabrication process. The Steel Bricks™ modules used to construct the integrated RB comprise of a pair of steel faceplates, shear connectors, diaphragm plates, and concrete fill. The faceplates and concrete fill act as the composite system to provide strength and stability to the Steel Bricks™ system. The shear connectors facilitate the composite action between the faceplates and concrete fill, and the diaphragm plates act as shear reinforcement besides holding the system together. The design of the structures serving as the containment pressure boundary is performed in accordance with the provisions of ASME Boiler and Pressure Vessel Code (BPVC) as described in NEDC-33926P (Reference 3.5-5). The Steel-plate Composite Containment Vessel (SCCV) is designed in accordance with NEDC-33926P, as described in Subsection 3.5.3.1.

Similarly, the Class MC containment metal components are designed in accordance with the provisions of ASME BPVC, Section III, Division 1, Subsection NE (Reference 3.5-6).

ANSI/AISC N690 (Reference 3.5-7) that has been endorsed by U.S. NRC RG 1.243 (Reference 3.5-8), along with NEDC-33926P provide the specifications for the design, fabrication, construction, examination, and inspection of RB Steel Bricks™ and steel structures that do not provide the containment pressure boundary and for the containment internal structures.

These U.S. codes and standards are adopted for the BWRX-300 steel-plate composite structures (Steel Bricks™) since there are no equivalent standards or regulatory guidance in Canada.

Clause 6.1.2 of CSA N291 (Reference 3.5-9) permits the use of alternate design methods for design of nuclear structures and concrete containments in Canada. Requirements for design, fabrication, construction, examination, and testing of containment, containment internal structures, RB, and their foundations presented in Subsections 3.5.2 through 3.5.5 ensure compliance to the regulatory requirements in CNSC REGDOC-2.5.2 and meet the intent and ensure a level of safety and performance commensurate with the applicable Canadian standards.

#### **3.5.1.1 Structural Analysis Criteria for Seismic Category A Structures**

In accordance with requirements in CNSC REGDOC-1.1.2, Section 4.5.5 and CNSC REGDOC-2.5.2, Sections 7.13.1, 7.15.1, 7.22 and 8.6, the RB, containment and the containment internal structures are analyzed as one integrated structure, using ANSYS and ACS SASSI computer programs, to determine structural design demands resulting from various design loads and design

load combinations. Evidence of qualification of these computer programs, including a description of the programs and extent of use, is presented in Appendix 3B.

The following Finite Element (FE) analyses are performed to obtain stress demands for the design of the BWRX-300 RB, containment, and containment internal structures:

- 1-g static SSI analyses
- Static and quasi-static analyses
- Thermal stress analyses
- Seismic SSI analyses

Static analyses provide design demands on the RB integrated structures from dead loads, live loads, earth pressure loads, hydrostatic and hydrodynamic loads, severe and extreme environmental loads, plant operating loads during normal operation, testing and abnormal plant conditions. Thermal analyses provide stress demands due to normal operating and accidental load conditions. Design Basis Earthquake (DBE) seismic demands are obtained directly from the results of one-step approach SSI seismic analyses discussed in Subsection 3.3.1.2.

The effect of interaction with the surrounding subgrade is incorporated in the analyses of the deeply embedded integrated RB by considering the surrounding soil and rock as a layered half-space continuum. The geotechnical design parameters used as input for the static and thermal analyses are developed as described in Subsection 3.5.2.2.

#### **3.5.1.1.1 FE Model of Integrated RB Structure**

To determine internal forces resulting from various loads and loading combinations, a detailed structural model is developed for the integrated RB, containment, and containment internal structures, including their foundations, penetrations, and openings, following the general FE modeling guidelines for the integrated RB structure discussed in Subsection 3.3.1.2 and NEDO-33914 Revision 2 (Reference 3.5-10), Section 5.1.1. The integrated structural FE model adequately represents the RB structural configuration for all main structural members and meets the mesh refinement and quality attributes required for calculation of structural stress demands. The use of the common model enables the FE results obtained from the different analyses to be directly combined in design load combinations per governing design codes.

Materials properties assigned to the integrated RB model depend on the analyzed loads and resulting stress responses. Unit weight properties are assigned to the models used for the 1-g static SSI analyses to adequately simulate gravity and earth pressure loads. The dynamic model of the integrated RB used for the seismic SSI analyses is assigned seismic mass inertia properties as discussed in Subsection 3.3.1.2.

As discussed in Subsection 3.3.1.2, stiffness properties are assigned to the SCCV and RB to reflect effective stiffness for load combinations without accidental thermal load. For load combinations with accidental thermal load, reduced stiffness is considered to account for the cracking effects on the redistribution of forces and moments. Spring elements are also used in the integrated FE element model to represent the stiffness of the connections between the different structural members that are designed to relieve stresses due to thermal expansion.

#### **3.5.1.1.2 1-g Static SSI Analyses**

Stress demands for the design of the integrated RB structure from dead loads and earth pressure design loads are obtained by applying the Earth gravity (1-g) load in the vertical direction to the SSI model described in Subsection 3.5.1.1. The 1-g static SSI analyses utilize the same substructuring method as the seismic SSI analyses described in Subsection 3.3.1.2. LB equivalent

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

linear stiffness properties and UB unit weight properties assigned to the subgrade model used in the analyses are discussed in Subsection 3.5.2.2.

Maximum dynamic responses of the SSI system that are equivalent to its static response under 1-g gravity load are calculated by applying on the 1-g SSI analyses model an equivalent static 1-g excitation in the vertical direction as vertically propagating compression wave. To simulate 1-g excitation, a harmonic acceleration time history is used with:

- A low frequency equal to the analysis frequency increment, and
- An amplitude equal to the Earth's gravity (g).

The 1-g excitation is applied at control point located at the surface of the site free-field model.

Stress demands obtained from the one-step 1-g static SSI analyses include the effects of static earth pressures simulated by the interaction of the integrated RB structural model with the subgrade FE model. Shell elements at the surface of the subgrade are included in the SSI model to simulate the applicable overburden inertia loads from the surrounding Power Block foundations and other surcharge loads.

Contact springs are used at the interfaces of the RB structure with the surrounding subgrade as discussed in Subsection 3.3.1.2. In accordance with the FE modeling guidance in NEDO-33914 Revision 2, Section 5.1.1, the following stiffness properties are assigned to the contact springs in the models used for the 1-g static SSI analyses to provide UB lateral soil pressures on the RB below grade exterior walls:

1. The contact springs in the direction normal to the RB exterior walls are assigned properties representing UB stiffness conditions at the SSI interfaces.
2. The friction at the RB exterior walls is not considered by assigning very low stiffness properties to the contact springs in vertical and tangential direction.

Results obtained from these contact spring elements serve for calculation of earth pressures on the below grade RB shaft exterior wall and mat foundation.

#### **Subgrade Modeling Assumptions for Deeply Embedded RB**

Per NEDO-3914, Section 5.1.2, the following assumptions related to the modeling of the subgrade are introduced in the 1-g Static SSI analyses to enable an efficient calculation of stress demands on the RB structure due to pressure loads from soil and rock surrounding and supporting the RB shaft:

1. The properties of the subgrade materials are represented by linear elastic constitutive models
2. The non-linearities at soil-structure interfaces are not considered
3. The rock mass is assumed continuous and the presence of cavities, fracture zones, joints, bedding planes, discontinuities and other weak zones is not considered

The soil and rock strata in the 1-g static SSI models are modeled based on the principles of continuum mechanics using isotropic linear elastic properties. Possible fracture zones, joints, bedding planes, discontinuities and cavities in the rock are not explicitly included in the design SSI analyses models. Bounding properties assigned to the soil and rock materials are discussed in Subsection 3.5.2.2.

The effects of non-linearities at soil-structure interfaces are addressed by using elastic contact spring stiffness properties that provide bounding structural demands.

Rock with disadvantageous fracture zones, joints, bedding planes and discontinuities is reinforced to create a more self-supporting rock mass. If needed, rock reinforcements are provided as initial ground support. The rock reinforcements and any other support provided during the excavation and construction may degrade and is inaccessible after construction. Therefore, the design addresses the rock loads remaining after the initial ground support degrades by including the potential weight of the rock in the static 1-g SSI analysis or by applying additional pressures on the RB outer shaft wall. Additional horizontal pressure loads are also applied on the model to account for possible residual stresses in the DNNP rock mass.

### **RB Design Earth Pressure Load Validation**

Validations of the earth pressure loads are to be performed following the guidelines in Section 5.1.3 of NEDO-33914 Revision 2 to ensure the 1-g SSI static analysis provides conservative earth pressure design demands on the deeply embedded RB structure.

In accordance with requirements in CNSC REGDOC-2.5.2, Section 7.13.1 and NEDO-33914 Revision 2, Section 4, Foundation Interface Analyses (FIA) are performed on models representative of the non-linear constitutive behavior of soil and rock materials surrounding the RB shaft and employ non-linear interface modeling features capable of capturing the effects of non-linearities at the subgrade structure contact surfaces. The results of the FIA are to be used for validation of the design earth pressures following the guidance of Section 5.1.3 of NEDO-33914 Revision 2.

#### **3.5.1.1.3 Static and Quasi-Static Load Analyses**

In accordance with requirements in CNSC REGDOC-2.5.2, Section 7.15.1, the following static and quasi-static analyses are performed on the integrated RB FE model to calculate structural stress demands due to:

- Live loads
- Crane loads
- Structural Integrity Test (SIT) and accident condition containment internal pressure load including differential containment and RB sub-compartment loads
- Horizontal hydrostatic pressure loads on pool walls
- Groundwater pressure loads on the integrated RB common mat foundation and below-ground exterior wall
- Extreme wind and tornado loads on RB roof and exterior wall
- Rain and snow loads
- Seismic water sloshing and breathing mode quasi-static pressure loads on pool walls
- Quasi-static pressure High Energy Line Break (HELB) loads (jet impingement, blast loads)
- Equipment and pipe reaction loads including RPV reaction loads.
- Post-accident internal flooding loads

The analyses of global static and quasi-static loads that can affect the global response of the integrated RB consider the effect of subgrade stiffness. Following the sub-structuring methodology, design demands from these loads are obtained from subgrade stiffness impedance analyses performed on models consisting of two parts:

- Super-element representing LB stiffness of the subgrade surrounding the RB, and

- Integrated FE model of the RB, containment and containment internal structures described in Subsection 3.5.1.1.1.

The super-elements define the stiffness of the subgrade at the nodes of the RB interfaces with the surrounding soil. The stiffness properties of the super-elements are developed using a layered 3-D solid FE model. Subgrade stiffness properties assigned to the super-elements are described in Subsection 3.5.2.2. To adequately simulate half-space boundary conditions, the depth of these models is deeper than three times the largest foundation dimension. The horizontal extent of these models is more than three times the RB shaft diameter.

The nodes of the super-element are coincident with the nodes of the integrated RB FE structural model. The coincident super-element and structural model nodes are connected by contact spring elements as described in Subsection 3.5.1.1.2. LB stiffness properties are assigned to these contact spring elements to yield larger structural deformations and conservative design stress demands. Equivalent linear subgrade stiffness properties assigned for the subgrade stiffness impedance static analyses are discussed in Subsection 3.5.2.2.

Fixed bases analyses are performed for the local loads with smaller magnitudes that do not affect the Integrated RB mat common mat foundation or global response.

Demands due to hydrostatic lateral pressure loads are obtained from static analyses of the integrated RB model with vertical supports applied to all mat foundation nodes. Demands from the upward buoyant pressures on the mat foundation are obtained from a static analysis of the integrated RB structural model with vertical supports at the nodes connecting the RB exterior wall with the mat foundation and horizontal supports established at the central node of the mat. The results from the two groundwater load analyses are enveloped and then combined with the results of the 1-g SSI analysis cases to obtain earth pressure and groundwater load demands for the design of integrated RB structure.

Additional Rock Pressure load analyses are performed to account for possible residual horizontal stresses in the DNNP rock strata. Two boundary conditions are considered for these analyses that result in conservative stress demands:

1. Vertical supports established at all mat foundation nodes and horizontal supports established at the central node of the mat; and
2. Vertical supports at the nodes connecting the RB exterior wall with the mat foundation and horizontal supports established at the central node of the mat.

The results of these two sets of additional static rock pressures analyses are enveloped and then combined with the results of the 1-g SSI analyses to ensure the RB structural design adequately addresses the effects of anisotropic and heterogenous rock behavior and accounts for potentially unstable rock mass loads.

#### **3.5.1.1.4 Thermal Stress Analyses**

To calculate structural stress demands due to the normal operating and DBA temperature loads, sub-structuring thermal stress analyses are performed on the integrated RB FE structural model coupled with super-element representing UB stiffness of the subgrade.

Stiffness properties are assigned to the Steel Bricks™ shell elements to account for the stiffness reduction effects under normal operating and DBA temperature loads. The corresponding structural stiffness conditions are used for the analyses for design loads that occur in combination with the normal and accident thermal loads.

For the thermal analyses, UB stiffness properties are assigned to the super-element modeling the subgrade and to the contact elements modeling the soil-structure interfaces resulting in

conservative thermal stress demands for the design of the RB and containment structures. Equivalent linear subgrade stiffness properties assigned for the thermal stress analyses are discussed in Subsection 3.5.2.2.

### **3.5.2 Foundations**

This section presents general design rules for the common Steel Bricks™ mat foundation supporting the integrated RB structure. Design rules for other foundations are discussed in Chapter 9B, Section 9B.3.

#### **3.5.2.1 Applicable Codes, Standards and Other Specifications**

Applicable codes, standards and specifications for the containment and RB common Steel Bricks™ foundation are the same as those for the superstructures.

The jurisdictional boundary for the application of the NEDC-33926P to the containment is the portion within the perimeter or exterior surface of the SCCV as shown in Figure 3.5-1.

The jurisdictional boundary for application of the ANSI/AISC N690 to the non-pressure retaining portion of the common foundation is the portion spanning from the exterior surface of the SCCV to the exterior surface of the RB (See Figure 3.5-1).

#### **3.5.2.2 Bounding Subgrade Design Parameters**

Bounding subgrade parameters are determined based on data available prior to the completion of the complete characterization of geotechnical and seismic conditions at the DNNP site presented in Chapter 2, Section 2.7. These conservative subgrade property inputs adequately address uncertainties related to the use of incomplete characterizations of the DNNP site geotechnical and seismic conditions.

Based on the information from the available groundwater flow patterns and conditions at the DNNP site provided in NK054-REP-01210-00011 (Reference 3.5-11) and NK054-REP-07730-00005 (Reference 3.5-12), an Upper Bound groundwater level at elevation 85 m CGD corresponding to a depth of 3 m below the plant grade at elevation 88 m CGD is considered a parameter for the bounding design.

The geotechnical and hydrological investigations of the DNNP site have been completed and bounding subgrade design parameters determined (see Chapter 2, Subsection 2.7.5). The data collected from ground water measuring wells at the DNNP site indicate an upper bound nominal water table at a shallower depth of 2 m. The increase of an additional meter in the nominal ground water table elevation results in a 6% higher magnitude of the total force from ground water pressure load than the one calculated using the bounding design ground water table at 3 m depth.

The exterior RB wall is the main structural member resisting the below grade lateral pressures applied on the RB integrated structures. These below grade lateral loads include the static earth pressure, ground water hydrostatic pressure, and additional rock pressure that account for a large majority of the demand on the below grade portion of the exterior RB wall in approximately equal shares. Therefore, the effect of the marginal 6% increase in the ground water pressure, that represents no more than a third of the total structural demand on the exterior RB, is negligible and well bounded by the available structural design margins (see Chapter 9B, Appendix 9B.G).

Identification and evaluation of potentially liquefiable cohesionless soil strata under the BWRX-300 Power Block structures is performed in accordance with CSA N289.3 (Reference 3.5-13) and in compliance with requirements of CNSC REGDOC-2.5.2, Section 7.15.1.

#### **3.5.2.2.1 Bounding Equivalent Linear Subgrade Static Profiles**

As described in Subsection 3.5.1.1, the structural design demands due to static earth pressures on the RB below grade exterior walls are obtained from the 1-g static analyses of the integrated RB FE model embedded in a layered half-space continuum model representing the surrounding soil and rock. To account for the interaction of the RB integrated structures with the surrounding subgrade, super-elements representing the stiffness properties of the layered subgrade materials are used in the static and thermal analyses, as described in Subsection 3.5.1.1.

The 1-g static SSI analyses, subgrade impedance analyses and thermal stress analyses use profiles of bounding equivalent linear soil and rock properties developed using information from the existing laboratory tests and in-situ measurements taken in the vicinity of the DNNP site and following the recommendations of NEDO-33914 (Reference 3.5-10), Section 5.2.1. They consist of:

- Effective unit weight that for soil materials below groundwater table are calculated as the total unit weight of soil minus the unit weight of water
- Elastic and shear Modulus representing linearized stiffness properties of the soil and rock for long-term static loading conditions
- Soil and rock Poisson's ratios representative of at-rest lateral pressure conditions

The bounding equivalent linear subgrade static profiles reflect anticipated as-built conditions at the site after construction of the BWRX-300 SMR that include engineered fill from about elevation 80 to 82 m CGD to the final grade at elevation 88 m CGD. The layering of the engineered fill, in-situ soil and rock materials in these bounding subgrade static profiles corresponds to the layering of dynamic subgrade properties described in Subsection 3.3.1.1.1 that are used as input for the DNNP site-specific seismic analyses.

Bounding static soil properties of in-situ soil materials are determined based on the results of in-situ tests and laboratory test results presented in the 2012 NK054-REF-01210-0418696 (Reference 3.5-14) and the 2013 NK054-REP-01210-00098 (Reference 3.5-15). SPT N-values are converted to  $N_{60}$  values (N value at 60 percent hammer energy) based on measured or assumed hammer energies for the automatic hammer and drill rigs used in the investigation, per the 2012 NK054-REF-01210-0418696 (Reference 3.5-14).

The drained friction angles for the soil layers are estimated using correlations based on relative density,  $N_{60}$ , and vertical effective stress for cohesionless soils provided in the 1986 DM 7.01 (Reference 3.5-16), the 1990 EPRI EL-6800 (Reference 3.5-17) and the 2016 Soil Properties and their Correlations (Reference 3.5-18). The different correlations are equally weighted to determine the final average drained friction angle value. The values for the coefficient of earth pressure at rest ( $K_0$ ) are determined using effective angle of friction ( $\phi_s$ ) and over-consolidation ratio based on the 2021 NEDO-33914 (Reference 3.5-10).

Bounding properties of the engineered fill are developed based on the information obtained from compaction tests that were completed for the upper till, intermediate glacio-lacustrine, and lower till units presented in the 2009 DNNP Existing Environmental Conditions NK054-REP-07730-00005 (Reference 3.5-12). Based on the result from standard compaction tests, the relative density ( $D_r$ ) and  $N_{60}$  values of the compacted soils are estimated. Relative density is estimated using the empirical relationship between  $D_r$  and compaction in the 2009 NK054-REP-07730-00005 (Reference 3.5-12). A relative compaction range of 85 to 100 percent is considered reasonable to cover the potential variations in placement and compaction of the on-site soils. The  $E_{st}$  of the compacted fill is determined from the estimated  $N_{60}$  values described in the 2016 Soil Properties and their Correlations (Reference 3.5-18) similar to the in-situ soils. The drained

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

friction angle for the engineered or compacted fill is assumed to be similar to the in-situ soils that will be excavated.

Bounding values for the linearized  $E_{st}$  of the rock masses at the DNNP site are estimated based on the intact rock modulus ( $E_{ri}$ ) and the rock mass classification determined from results of the site investigation program and an estimated Geologic Strength Index for the different bedrock formations. Results of Uniaxial Compression Tests performed on intact rock specimens and  $V_s$  and  $V_p$  measurements can serve as the basis for development of  $E_{ri}$  values. The  $\nu_{st}$  values for rock masses are developed based on  $V_s$  and  $V_p$  measurements and the level of rock fracturing.

The intact rock elastic properties are estimated from shear wave velocities using elastic theory as outlined in the 2021 NEDO-33914 (Reference 3.5-10). Results of laboratory measurements on recovered rock provided in the 2012 NK054-REF-01210-0418696 (Reference 3.5-14) and the 2013 NK054-REP-01210-00098 (Reference 3.5-15) are also used to estimate the intact rock elastic properties of the Blue Mountain (Whitby) and Lindsay Formations. The laboratory measured elastic modulus values in the Blue Mountain (Whitby) and Lindsay Formations were, on average, 94 and 75 percent, respectively, of the estimated values from the  $V_s$ . This comparison likely represents the different strain levels as well as potential damage from rock coring. Based on this comparison, the estimates of the modulus for intact rock from bedrock units below Lindsay Formation are reduced by a factor of 0.75. In the Blue Mountain (Whitby) and Lindsay Formations (Lindsay 1), the lower intact rock deformation modulus from the laboratory testing results is used.

The rock  $\nu_{st}$  values are based on the laboratory measured values and the estimates from  $V_s$  and  $V_p$  measurements. Based on this comparison the seismic wave estimated values are used without modification. Blue Mountain (Whitby) Formation is assigned  $\nu_{st}$  value of 0.58 based on an at-rest stress ratio ( $K_0$ ) that includes the estimated horizontal rock stresses at the site provided by Lo and Lukajic in (Reference 3.5-19) that are higher than the vertical stresses.

Table 3.5-1 provides a summary of bounding linearized static properties for in-situ soil and engineered fill layers in the as-built profiles. The summary of bounding static properties for the rock layers at the DNNP site are provided in Table 3.5-2.

UB values for soil effective unit weight and Poisson ratio are used as input for the static 1-g SSI analysis to conservatively address uncertainties in the consideration of earth pressure loads. In accordance with the guidance of NEDO 33914, Section 5.2.1.1, the soil Poisson ratios ( $\nu_{st}$ ) are calculated as follows using the at-rest lateral ( $k_0$ ) coefficient values provided in Table 3.5-1:

$$\nu_{st} = \frac{K_0}{1 + K_0}$$

LB soil and rock stiffness properties are used for the static analyses including the 1-g SSI analyses resulting in larger deformation at soil-structure interfaces and conservative design stress demands. Thermal stress analyses are performed using UB soil and rock stiffness properties resulting in conservative thermal stress demands.

### **3.5.2.2.2 Soil Bearing Stability**

The stability of soil supporting the BWRX-300 structural foundations is demonstrated in compliance with requirements in CNSC REGDOC-2.5.2, Section 7.12.2 and per the regulatory guidance of US NUREG-0800 (Reference 3.5-20), SRP 2.5.4.10, and IAEA Safety Guide No. NS-G-3.6 (Reference 3.5-21).

The bearing capacity of the rock supporting the RB mat foundation is discussed in Chapter 2, Subsection 2.7.3.3.

Since the RB is deeply embedded, the bearing surface of the common foundation is below the depth of frost action to meet the requirements of NBC (Reference 3.5-22), Article 4.2.4.4.

Chapter 2, Subsection 2.7.3.3 also discusses the bearing capacity of the component in-situ soil materials supporting the shallow foundations surrounding the RB.

The calculation of the dynamic bearing pressure demands under DBE loads from the results of the seismic SSI analyses is described in Subsection 3.3.1.2.

Per Article 4.35 of IAEA Safety Guide No. NS-G-3.6, safety factors against potential bearing capacity failure of the subsurface materials depend on the method of bearing capacity evaluation and site conditions. If a conventional bearing capacity method is used, safety factors are not less than 3 under static loads and 1.5 under loads that include DBE.

### **3.5.2.2.3 Foundation Stability**

Foundation stability is assessed against sliding and overturning due to earthquakes, wind and tornados, and flotation in compliance with requirements in CNSC REGDOC-2.5.2, Section 7.12.2, following the regulatory guidance of US NUREG-0800, SRP 3.8.5 and in accordance with Clause 5.9 of CSA N289.3.

Explicit sliding and overturning stability evaluations are not performed for the deeply embedded RB since, in accordance with Sections 7.2.1 and 7.2.2 of ASCE/SEI 43 (Reference 3.5-23), its centre of gravity is below the grade elevation, and the structure is inherently stable against sliding and overturning. The foundation stability of the surrounding RWB, CB, TB, and Reactor Auxiliary Bay that are supported by surface mounted foundations is checked to ensure that there is no adverse interaction with the Seismic Category A RB during a DBE level event. Stability of the surface mounted foundations surrounding the RB under DBE loads is evaluated using the results of the seismic SSI analyses as described in Subsection 3.3.1.2.

Safety factors against sliding and overturning under normal operating conditions that include unfactored combination of dead loads, soil pressure loads, and design wind, and accidental conditions that include combination of dead loads, soil pressure loads, and DBE loads are presented in Table 3.5-3.

### **3.5.2.3 Loads and Load Combinations**

#### **3.5.2.3.1 Design Loads**

Design loads of the containment and RB common mat foundation are those of the superstructures described in Subsections 3.5.3.2 and 3.5.5.2.

For foundation stability against flotation, the site-specific design basis flood is considered.

#### **3.5.2.3.2 Design Load Combinations**

Design load combinations of the containment and RB common mat foundation are those of the superstructures described in Subsections 3.5.3.2 and 3.5.5.2.

For the stability against flotation of the integrated RB foundation, the load combination is in accordance with U.S. NUREG-0800, SRP 3.8.5, where the design basis flood is considered in combination with the dead load.

### **3.5.2.4 Design and Analysis Procedures**

The design of the deeply embedded foundation and foundation stability evaluations are in compliance with requirements in CNSC REGDOC-2.5.2, Section 7.15.1 and follow the BWRX-300 specific criteria and guidelines in NEDO-33914 Revision 2.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

The containment and RB common mat foundation is analyzed using the methods where the transfer of loads from the foundation mat to the supporting foundation media is determined by elastic methods. Demands for the design of the common mat foundation are obtained from the structural analyses described in Subsection 3.5.1.1 performed on the integrated RB structural model that include the effects of interaction of the structure with the surrounding subgrade and the effects of the foundations of the surrounding Power Block buildings.

The common Steel Bricks™ foundation mat is represented by thick shell elements in the integrated FE model. Properties assigned to the shell elements representing the common Steel Bricks™ foundation in the dynamic FE model used for the seismic SSI analyses are described in Subsection 3.3.1.2. Properties assigned to the foundation shell elements in the integrated FE models used for the static and thermal stress analyses are described in Subsection 3.5.1.1.

The containment foundation is designed in accordance with NEDC-33926P, consistent with U.S. NRC RG 1.136 (Reference 3.5-24). The non-pressure retaining portion of the containment-RB common foundation mat is designed to ANSI/AISC N690, supplemented by U.S. NRC RG 1.243 and NEDC-33926P.

Effects of normal and differential settlement of BWRX-300 structures is considered in the design and include consideration of the effects of fluctuating ground water on the foundations per CNSC REGDOC-2.5.2, Section 7.15.1, and CSA N291, Clause 6.4.3.

As mentioned in Subsection 3.5.1.1, contact springs are used to represent the stiffness properties of the foundation-subgrade interface. Vertical spring force results obtained from these spring elements serve for calculations of foundation bearing stresses.

### **3.5.2.5 Foundation Design Criteria**

The structural acceptance criteria for the containment and RB common foundation are the same as those for their respective superstructures. Refer to Subsection 3.5.2.2 for safety factors considered for soil bearing and foundations stability.

### **3.5.2.6 Materials, Quality Control and Special Construction Techniques**

#### **3.5.2.6.1 Foundation Materials**

Materials used for the construction of the containment and RB common foundation mat are the same as those of the superstructures discussed in Subsections 3.5.3.5 and 3.5.5.5.

#### **3.5.2.6.2 Foundation Quality Control**

Refer to Subsections 3.5.3.5 and 3.5.5.5 for discussion.

#### **3.5.2.6.3 Foundation Special Construction Techniques**

Refer to NEDO-33914 Revision 2, Section 1.4 for the preferred construction approach for the deeply embedded RB.

### **3.5.2.7 Testing and In-Service Inspection Requirements**

The foundation inspection and testing follow the guidance of NEDO-33914 Revision 2, Sections 3.2.1 and 3.4, and also NEDC-33926P.

## **3.5.3 Containment**

The BWRX-300 containment comprises a Steel-plate Composite Containment Vessel (SCCV), a steel containment closure head and other Class MC components. As described in Subsection 3.5.1, the BWRX-300 SCCV is constructed of Steel Bricks™.

### **3.5.3.1 Applicable Codes, Standards and Other Specifications**

Codes, standards, specifications, and regulations applicable for the analysis, design, fabrication, construction, testing, and in-service inspection of the BWRX-300 containment are listed in Chapter 1, Appendix B.

The design of the BWRX-300 containment boundary structures, including the SCCV, containment closure head and other Class MC components complies with the regulatory requirements in CNSC REGDOC-2.5.2. The analysis and design, fabrication and testing of the SCCV is in accordance with the provisions of NEDC-33926P, which are based on analytical and engineering principles, including use of experimental results. Additional analysis and design requirements in U.S. NUREG-0800, SRP 3.8.1 and U.S. NRC RG 1.136 for concrete containment are also met, as applicable. The compliance with the provisions of NEDC-33926P and the regulatory guidance of U.S. NUREG-0800, SRP 3.8.1 and U.S. NRC RG 1.136 ensures a level of safety and performance for the SCCV compliant with CNSC REGDOC-2.5.2.

The containment closure head, and the other Class MC components that are part of the containment pressure boundary are analyzed, designed and inspected following the provisions of ASME Section III, Division 1, Subsection NE, ensuring compliance with the regulatory guidance of CNSC REGDOC-2.5.2.

#### **3.5.3.1.1 Containment code Jurisdictional Boundary**

For code applicability, the SCCV is designed in accordance with ASME BPVC Section III requirements. The code jurisdictional boundary for application of Section III of ASME BPVC to the SCCV is shown in Figure 3.5-1. The SCCV boundary extends to the:

1. Outside diameter of the SCCV wall from mat foundation to containment top slab including the welds connecting the SCCV with the RB structural members
2. Portion of the foundation mat foundation under SCCV including the welds connecting the SCCV portion of the mat foundation with the remaining part of the RB mat foundation
3. Containment top slab from containment closure head opening to the outside diameter of the SCCV including the welds connecting the slab with the RB structural members

The BWRX-300 containment closure head and other containment boundary metal components are ASME Code Class MC. The code jurisdictional boundary for application of ASME BPVC Section III, Division 1, Subsection NE, Class MC to the containment closure head, access hatches and penetrations are shown in Figure 3.5-2, Figure 3.5-3 and Figure 3.5-4, respectively.

The SCCV along with the containment closure head, access hatches and penetrations, provide the primary containment function as a leak-tight pressure boundary confining radioactive substances in different plant conditions. Although the internal RPV support pedestal, bioshield and other containment internal structures are completely within the containment, these internal structures do not serve any pressure retaining function and are, thus, outside the scope of ASME Code applicability. The design of welds connecting the containment internal structures to the containment pressure boundary are under ASME jurisdiction. The connections of the RB walls and floors to the outside face of the SCCV wall are outside ASME code jurisdiction, with the exception of attachment welds. Attachment welds are designed to follow ASME quality assurance and welding procedures and inspection requirements.

### **3.5.3.2 Load and Load Combinations**

#### **3.5.3.2.1 Containment Design Loads**

Loads used in the design of the BWRX-300 containment structures, comprised of the SCCV, containment closure head, and other Class MC components, satisfy the loading requirements of

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

the applicable regulations, design codes and standards in Subsection 3.5.3.1. These loads are in accordance with the provisions of ASME III Division 1, Subsection NE, ASME III Division 2 (Reference 3.5-25) and NEDC-33926P.

Loads considered in the design of the BWRX-300 containment structures are:

- Normal Loads:
  - Dead load (D) which includes permanent dead weight of structural and shielding elements, permanently located equipment and hydrostatic pressure of liquids in various pools
  - Live loads (L,  $L_o$ ) which include any moveable equipment loads and other loads that vary in intensity and occurrence
  - Indirect Snow (S) and Rain (R) Loads
  - Thermal ( $T_o$ ) effects and loads during normal operating, startup, or shutdown conditions
  - Pressure ( $P_o$ ) loads resulting from the pressure difference between the interior and exterior of the containment, considering both interior pressure changes because of heating or cooling and exterior atmospheric pressure variations
  - Pipe reactions ( $R_o$ ) during normal operating or shutdown conditions based on the most critical transient or steady-state conditions
  - Construction loads applied to the containment from start to completion of construction. The definitions for D, L and  $T_o$  given above are applicable, but are based on actual construction methods and/or conditions
  - Pressure Variant loads ( $P_v$ ) which are the external pressure loads arising from variation either inside or outside the SCCV
    - Indirect Lateral Soil and groundwater pressure loads (H)
- Pre-operational Testing Loads:
  - Thermal ( $T_t$ ) effects and loads during the SIT or Integrated Leak Rate Test (ILRT)
  - Test Pressure ( $P_t$ ) Loads applied during the SIT or ILRT
- Severe Environment Loads:
  - Indirect design Wind Load (W) defined in Subsection 3.3.2
- Extreme Environmental Loads:
  - Indirect Tornado ( $W_t$ ) Loads defined in Subsection 3.3.2
  - DBE seismic ( $E_s$ ) loads determined for DNNP site-specific conditions taking into account SSI effects, as discussed in Subsection 3.3.1, and include associated hydrodynamic loads and dynamic incremental soil pressures
- Abnormal Plant Loads:
  - Accidental Thermal effects ( $T_a$ ) due to LOCA
  - Accidental Pressure ( $P_a$ ) loads within the containment generated by a LOCA
  - Accidental Pipe ( $R_a$ ) reaction loads that consist of pipe reactions (including  $R_o$ ) from thermal conditions generated by design basis accidents such as LOCA and DBE

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

- Local effects on containment due to LOCA ( $R_r$ ) and Blast Loads ( $R_b$ ) which includes:
  - $R_{rr}$  load on the containment generated by the reaction of a ruptured high-energy pipe during the postulated event of the DBA
  - $R_{rj}$  Load on the containment generated by the jet impingement from a ruptured high-energy pipe during the postulated event of the DBA
  - $R_{rm}$  load on the containment resulting from the impact of a ruptured high-energy pipe during the DBA
  - Additional blast loads that may result from a postulated instantaneous break of a large pipe that could occur prior to the jet loads and that do need to be combined with the other loads
- Internal flooding loads resulting from a DBA
- Hard objects drop impact loadings, as applicable

Loads associated with DEC representing a subset of beyond design basis accident conditions are discussed in Subsection 3.5.6.

#### **3.5.3.2.2 Design Load Combinations for the SCCV**

The SCCV portion of the BWRX-300 containment is designed for load combinations and associated load factors for applicable loading conditions in accordance with NEDC-33926P, supplemented by U.S. NRC RG 1.136.

#### **3.5.3.2.3 Design Load Combinations for the Containment Closure Head and Other Class MC Components**

Load combinations and associated load factors used in the design of the containment closure head and other Class MC components are in compliance with U.S. NRC RG 1.57 (Reference 3.5-26) and U.S. NUREG-0800, SRP 3.8.2.

The portion of the BWRX-300 containment closure head and other Class MC components backed by concrete are designed for the load combinations and associated load factors in accordance with NEDC-33926P, supplemented by US NRC RG 1.136.

#### **3.5.3.3 Design and Analysis Procedures**

##### **3.5.3.3.1 Containment Structural Analysis Procedures**

As mentioned in Subsection 3.5.1.1, the BWRX-300 RB, including the containment, the containment internal structures and their common foundation, are analyzed as one integrated structure.

The connections between the SCCV and the RB members in the integrated FE model are modeled to reflect the appropriate load transfer for gravity, lateral and thermal loads.

Analysis procedures for the integrated structure are discussed in Subsection 3.5.1.1.

##### **3.5.3.3.2 Structural Design Method for SCCV**

The design of the SCCV structure conforms to the requirements of NEDC-33926P and meets the acceptance criteria discussed in Subsection 3.5.3.4.

Membrane forces, shear forces and bending moments used in the design of SCCV sections are obtained from the linear elastic computer analyses for the integrated RB and SCCV FE model discussed in Subsection 3.5.1.1. Subsection 3.5.5.3.2 provides further details for the critical section identification and design.

### **3.5.3.3.3 *Structural Design Methods for Containment Closure Head and Other Class MC Components***

The design procedures for the containment closure head and other Class MC components are as shown in Figure 3.5-5 and Figure 3.5-6, respectively.

The BWRX-300 containment closure head and other Class MC components are designed in accordance with ASME BPVC, Section III, Division 1, Subsection NE, Subarticles NE-3100 (General Design), NE-3200 (Design by Analysis), and NE-3300 (Design by Formula), as applicable. The design meets the acceptance criteria discussed in Subsection 3.5.3.4, including buckling and fatigue evaluations as required. The design by analysis utilizes the demands from the analyses of appropriate finite element models as described in Subsection 3.5.1.1. The stresses, including discontinuity stresses induced by the combination of applicable loads during different plant conditions, are evaluated, as applicable.

The access hatch cover with the bolted flange is designed in accordance with Subarticle NE-3326 of ASME BPVC, Section III, Division 1, Subsection NE.

### **3.5.3.4 *Structural Acceptance Criteria***

#### **3.5.3.4.1 *Design Basis Acceptance Criteria for SCCV***

The acceptance criteria for the design of the SCCV are in accordance with NEDC-33926P. The allowable stresses and strains in NEDC-33926P, for service and factored loads used in the design of the SCCV are provided in Table 3.5-4.

#### **3.5.3.4.2 *Design Basis Acceptance Criteria for Containment closure Head and Other Class MC Components***

The acceptance criteria for the design basis loads of the steel containment closure head and other MC components are the allowable stress limits specified in ASME BPVC, Section III, Division 1, Subsection NE-3220. The structural acceptance criteria for the Post-flooding condition, which is only applicable for other Class MC components excluding the containment closure head, is in accordance with U.S. NUREG-0800, SRP 3.8.2. Table 3.5-5 and Table 3.5-6 summarize the acceptance criteria for testing, design, Level A, C and D, and Post-flooding conditions, as applicable, for the containment closure head and other Class MC components, respectively. Stability against compression buckling is assured by an adequate factor of safety.

#### **3.5.3.4.3 *Containment Seismic Design Criteria***

The Seismic design criteria for the BWRX-300 containment are summarized in Table 3.3-1.

The seismic design of the BWRX-300 containment considers LS-D response in accordance with ASCE/SEI 43, ensuring an essentially elastic response without any significant permanent deformation when subjected to DBE, and complying with the regulatory requirements in CNSC REGDOC-2.5.2, Section 8.6.2.

Per CSA N289.3, Clause 7.5, the seismic design of the:

- SCCV is in accordance with NEDC-33926P
- Steel components at the containment boundary not backed by SCCV is in accordance with provisions of ASME BPVC, Section III, Division 1, Subsection NE

Also, in compliance with CNSC REGDOC-2.5.2, Section 8.6.2, the BWRX-300 containment meets the deformation acceptance criteria of ASCE/SEI 43, Section 5.2.3 and possesses ductility and energy absorbing capacity which permits inelastic deformation without failure under DEC's.

#### **3.5.3.4.4 Containment Design Criteria for Impulsive and Impactive Loads**

The BWRX-300 containment is designed for impulsive and impactive loads in compliance with requirements of Sections 7.15.1 and 7.15.3 of CNSC REGDOC-2.5.2 and the regulatory guidelines of U.S. NUREG-0800, SRP 3.8.1, Appendix A.

The design of the SCCV for impulsive and impactive loads follows the applicable requirements of the SCCV NEDC-33926P.

The design of the steel components of the containment not backed by SCCV follows the relevant regulatory guidance of U.S. NRC RG 1.57 and provisions of ASME BPVC, Section III, Division 1, Subsection NE.

#### **3.5.3.4.5 Containment Robustness Acceptance Criteria**

Complying with CNSC REGDOC-2.5.2, Section 6.1, the Level Four D-in-D described in Subsection 3.1.6 requires that the containment design be robust to provide adequate protection for the confinement function, including the use of complementary design features to prevent accident progression and to mitigate the consequences of DEC and BDBAs. Refer to Subsection 3.5.6.1 for a detailed discussion of the robustness design and acceptance criteria for the BWRX-300 containment. These acceptance criteria satisfy the requirements in CNSC REGDOC-2.5.2, Sections 7.22.3 and 8.6.12, ensuring there is sufficient structural integrity to protect important systems in event of a design basis threat.

The leak tightness at the boundary of the containment structure, including the SCCV, containment closure head, and other Class MC components, under DEC internal pressure loads meets the requirements of CNSC REGDOC-2.5.2 and U.S. NRC RG 1.216 (Reference 3.5-27).

### **3.5.3.5 Materials, Quality Control and Special Construction Techniques**

#### **3.5.3.5.1 Containment Materials**

Materials used in the construction of the SCCV portion of the containment structure are in accordance with NEDC-33926P and U.S. NRC RG 1.136.

Steel materials used in the fabrication of the containment closure head and other Class MC components are in accordance with ASME Section III Subsection NE, Article NE-2000.

Details of materials used in the construction of the containment structures are provided in Chapter 9B, Subsection 9B.2.1.4.

#### **3.5.3.5.2 Containment Quality Control**

Quality control procedures are established for the containment structure in the construction, fabrication and installation specifications and implemented during fabrication, construction, installation, and inspection. These specifications cover the fabrication, furnishing, and installation of each structural item and specifies the inspection and documentation requirements to ensure that the requirements of NEDC-33926P, Articles NE-4000 and NE-5000 of ASME Section III, Division 1, Subsection NE, U.S. NRC RG 1.28 (Reference 3.5-28), U.S. NRC RG 1.136, and U.S. NUREG-0800, SRP 3.8.2 are met.

#### **3.5.3.5.3 Containment Special Construction Techniques**

The integrated RB, SCCV, RPV pedestal, and other structural components are constructed using modular construction technique as described in Subsection 3.5.5.5.

#### **3.5.3.6 Testing and In-Service Inspection Requirements**

Concrete and concrete constituents in the Steel Bricks™ modules of the SCCV are examined and tested in accordance with NEDC-33926P, as supplemented by the concrete sampling

requirements in NEDO-33914 Revision 2. Inspection of Steel Bricks™ welds is in accordance with NEDC-33926P.

#### **3.5.3.6.1 Structural Integrity Test (SIT)/PRE-Operational Proof Test**

The SCCV pre-service SIT plan and instrumentation is in compliance with NEDC-33926P and U.S. NRC RG 1.216. The SIT ensures compliance with containment pressure structure capability requirement for pressure tests in CNSC REGDOC-2.5.2, Section 8.6.3.

In accordance with NEDC-33926P, deformation, stress and strain measurements are made to evaluate the behavior of the containment and confirm that the actual structural response is within the limits predicted by analysis.

#### **3.5.3.6.2 Containment Pre-Service and In-Service Inspection**

The SCCV pre-service and periodic in-service inspection plan is in accordance with NEDC-33926P to comply with the requirements of CNSC REGDOC-2.5.2.

#### **3.5.3.6.3 Integrated Leak Rate Testing**

The SCCV is designed such that the periodic ILRT can be conducted at the design pressure to demonstrate the leak tightness integrity of the containment boundary in compliance with Section 8.6.4 of CNSC REGDOC-2.5.2. The ILRT is performed per criteria outlined in Chapter 6, Subsection 6.3.7.

The flange seals of the containment closure head and Class MC components that have potential for significant contribution to leakage are designed to be individually testable. Where resilient seals such as elastomeric seals are used, they have the capability for performing leak testing at the containment design pressure in compliance with Section 8.6.5 of CNSC REGDOC-2.5.2.

### **3.5.4 Containment Internal Structures**

The BWRX-300 containment internal structures comprise the Steel Bricks™ RPV pedestal, the steel-plate composite bioshield surrounding the RPV pedestal and structural steel Containment Equipment and Piping Support Structure (CEPSS), including the support floor at Level -8.5 m, and support floors at Level -21 m and -29 m.

#### **3.5.4.1 Applicable Codes, Standards and Other Specifications**

Codes, standards, specifications, and regulations applicable for the analysis, design, fabrication, construction, testing, and in-service inspection of the BWRX-300 containment internal structures are listed in Chapter 1, Appendix B.

Similar to RB, the analysis and design, fabrication and testing of the containment internal structures is in accordance with the ANSI/AISC N690, including the supplemental requirements in U.S. NRC RG 1.243 and NEDC-33926P. This methodology ensures a level of safety and performance for the containment internal structures commensurate to that required by CSA N291 and ensures compliance with CNSC REGDOC-2.5.2.

Refer to Figure 3.5-1 for the jurisdictional boundary for the RPV pedestal, the bioshield and internal structural steel.

#### **3.5.4.2 Loads and Load Combinations**

Since the containment internal structures are completely contained within and are integrated with the RB and SCCV, the design of containment internal structures considers both design loads applied directly to the containment internal structures and those applied indirectly through the RB and SCCV.

#### **3.5.4.2.1 Design Loads**

Refer to Subsections 3.5.3.2 and 3.5.5.2 for the description of design loads applicable for the SCCV and RB structures that are also generally applicable for the design of containment internal structures. Since containment internal structures are inside the containment, some of the design loads applicable for the RB are not directly applicable for the containment internal structures. Additionally, the internal flooding condition associated with post-accident flooding is not considered in accordance with U.S. NUREG-0800, SRP 3.8.1 as noted in Table 9B-1 in Chapter 9B.

The design loads also include the reactions from the RPV at the support locations on the containment internal structures and other bracket and attachment loads applicable during different plant conditions. The RPV lumped mass beam model representing the mass and stiffness properties of the RPV is included in the integrated FE model discussed in Subsection 3.3.1.2, and the dead load and seismic load reactions from the RPV are obtained directly from the static and seismic analyses. Other normal and accidental plant operating loads are applied to the model as reaction force loads.

#### **3.5.4.2.2 Design Load Combinations**

Load combinations and load factors for the design of the Steel Bricks™ structures and structural steel that form the containment internal structures are in accordance with ANSI/AISC N690, including the supplemental regulatory guidance of U.S. NRC RG 1.243.

#### **3.5.4.3 Design and Analysis Procedures**

##### **3.5.4.3.1 Structural Analysis Procedures**

Analysis procedures for the containment internal structures are the same as those for the integrated RB structure discussed in Subsection 3.5.1.1 since containment internal structures are included in the integrated FE model used in the analyses.

The connections between the containment internal steel structures and the RPV, RPV pedestal, bioshield and SCCV are appropriately modeled in the integrated FE model to reflect the appropriate load transfer for gravity and lateral loads.

Local models may be used, if needed, for detailed design at opening and connection locations.

##### **3.5.4.3.2 Structural Design Methods**

For the design of containment internal structures, the design methodology is the same as that used for the design of the RB structure, discussed in Subsection 3.5.5.3.

#### **3.5.4.4 Structural Acceptance Criteria**

##### **3.5.4.4.1 Design Basis Acceptance Criteria**

The design basis acceptance criteria of the containment internal structures, including the Steel Bricks™ RPV pedestal, the steel-plate composite bioshield and containment internal steel structures, are same as those for the corresponding RB structural components described in Subsection 3.5.5.4.

##### **3.5.4.4.2 Robustness Acceptance Criteria**

The methodology and acceptance criteria for the robustness of the containment internal structures are described in Subsection 3.5.6.1.

### **3.5.4.5 Materials, Quality Control and Special Construction Techniques**

#### **3.5.4.5.1 Materials**

The concrete and structural steel materials used for the construction of containment internal structures are same as those for the RB structure as described in Subsection 3.5.5.5, except that pool liners are not applicable.

#### **3.5.4.5.2 Quality Control**

The quality control requirements for containment internal structures are same as those for the RB structure as described in Subsection 3.5.5.5.

#### **3.5.4.5.3 Special Construction Techniques**

The integrated RB, SCCV, RPV pedestal, and other structural components are constructed using modular construction technique as described in Subsection 3.5.5.5.

#### **3.5.4.6 Testing and In-Service Inspection Requirements**

A formal program of testing and in-service inspection is not required for containment internal structures since they are not directly related to the functioning of the containment system. However, during the operating life of the plant, the condition of the containment internal structures is monitored per 10 CFR 50.65 in accordance with U.S. NRC RG 1.160 (Reference 3.5-29).

### **3.5.5 Reactor Building**

#### **3.5.5.1 Applicable Codes, Standards and Other Specifications**

Codes, standards, specifications, and regulations applicable for the analysis, design, fabrication, construction, testing, and in-service inspection of the BWRX-300 RB are listed in Chapter 1, Appendix B.

Specifically, the analysis and design, fabrication and testing of the RB structure (including the Steel Bricks™ walls, slabs and mat foundation and the structural steel components, see Figure 3.5-1) is in accordance with the ANSI/AISC N690, including the supplemental requirements in U.S. NRC RG 1.243 and NEDC-33926P. This methodology ensures a level of safety and performance for the RB commensurate to that required by CSA N291 and ensures compliance with CNSC REGDOC-2.5.2.

The RB polar crane is designed and constructed to meet the requirements of ASME NOG-1 (Reference 3.5-30).

Crane loading is developed in accordance with NBC and ASCE/SEI 7 (Reference 3.5-31), Section 4.9.

#### **3.5.5.2 Loads and Load Combinations**

In addition to the loads applicable directly to the RB, loads considered in the design of the RB include loads applied to the SCCV that have an effect on the RB structure due to the common mat foundation, floor slabs, RB shear walls and other integrating structural components.

##### **3.5.5.2.1 Design Loads**

The RB structure is analyzed and designed in accordance with ANSI/AISC N690 for design basis load cases in compliance with CSA N291.

Loads, such as accident pressure and thermal transient loads due to a LOCA, internal to SCCV are considered for the design of structural components of the RB that are integrated with the SCCV.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

RB design loads consist of:

- Service category of loads that occur during construction, pre-operational testing, or normal operation. They include:
  - Dead loads (D) which consist of the weight of structures, weight of permanently attached major equipment, tanks, machinery, and cranes; weight of piping, cable, cable trays, duct supports; and hydrostatic pressure of liquids in various pools
  - Live loads ( $L$ ,  $L_r$ ) which consist of floor area loads, laydown loads, nuclear fuel, and equipment handling loads
  - Lateral Soil and groundwater pressure loads (H)
  - Snow/rain loads (S/R) discussed in Subsection 3.3.2
  - Normal plant operation and pre-operation pressure testing loads which consist of operation service pressure loads, pre-operation proof test pressure load, normal thermal conditions ( $T_o$ ) and operation service pipe reaction loads ( $R_o$ )
  - Construction Loads
  - Settlement Loads
  - Crane Loads developed as discussed in Subsection 3.5.5.1.
- Abnormal and environmental category of loads that occur during postulated accident and/or severe or extreme environmental events. They include:
  - Abnormal plant operation loads which include accident pressure ( $P_a$ ) and thermal ( $T_a$ ) loads, accident pipe reaction loads ( $R_a$ ), missile generation, pipe whip ( $Y_r$ ), jet impingement from large pipe breaks ( $Y_j$ ), blast pressure ( $Y_m$ ), compartment pressurization and drop of large loads
  - Wind and Tornado loads ( $W$ ,  $W_t$ ) discussed in Subsection 3.3.2
  - Seismic loads ( $E_s$ ) discussed in Subsection 3.3.1, including hydrodynamic loads on the pool walls calculated based on the approach described in ASCE/SEI 4 (Reference 3.5-32) and ACI 350.3 (Reference 3.5-33), and dynamic incremental soil pressures
- Hard objects drop impact loadings, as applicable
- Design Basis Threat loads discussed in Subsection 3.3.7.4

Loads associated with DEC representing a subset of beyond design basis accident conditions are discussed in Subsection 3.5.6.

#### **3.5.5.2.2 Design Load Combinations**

Load combinations and load factors for the design of the Steel Bricks™ module structures and structural steel in the RB are in accordance with the provisions of ANSI/AISC N690, Chapter NB2.6 including the supplemental regulatory guidance of U.S. NRC RG 1.243, Regulatory Positions 2.1 and 2.2.

#### **3.5.5.3 Design and Analysis Procedures**

##### **3.5.5.3.1 Structural Analysis Procedures**

Refer to Subsection 3.5.1.1 for analysis procedures.

#### **3.5.5.3.2 Structural Design Methods**

The design of the RB structure conforms to the requirements of ANSI/AISC N690, including the regulatory guidance in U.S. NRC RG 1.243 and meets the acceptance criteria discussed in Subsection 3.5.5.4 to ensure a level of safety and performance commensurate with the requirements in CSA N291.

Membrane forces, shear forces and bending moments used in the design of the RB Steel Bricks™ and steel sections are obtained from the linear elastic computer analyses for the integrated RB FE model discussed in Subsection 3.5.1.1.

Results from the FE analyses are evaluated to identify critical cross-sections where maximum structural demands occur for different controlling loads and load combinations. Key responses reviewed include:

- Membrane forces for the SCCV,
- In-plane shear demands at the base of major walls and at rock-soil interface elevation,
- Vertical bending moments and out-of-plane shear demands on the RB outer shaft and SCCV walls, at base of walls and at intermediate floor elevations and
- Out-of-plane demands for major floor slabs and RB foundation mat at mid-span and support locations.

The structural demands at the critical locations are used to perform the design of the critical cross-sections and connections using the applicable codes of record.

#### **3.5.5.4 Structural Acceptance Criteria**

##### **3.5.5.4.1 Design Basis Acceptance Criteria**

The RB Steel Bricks™ module structures and structural steel, including welded and bolted connections, are designed to meet the acceptance criteria outlined in ANSI/AISC N690.

The RB structure is evaluated for serviceability considerations including deflection, vibration, permanent deformation, cracking, and settlement. Serviceability evaluations meet the acceptance criteria in ANSI/AISC N690, Chapter NL.

#### **Seismic Design Criteria**

The Seismic design criteria for the BWRX-300 RB are summarized in Table 3.3-1.

The seismic design of the RB structure considers LS-D response in accordance with ASCE/SEI 43, ensuring an essentially elastic response without any significant permanent deformations when subjected to DBE and complying with the regulatory requirements in CNSC REGDOC-2.5.2, Section 8.6.2.

The BWRX-300 RB structure meets the deformation acceptance criteria of ASCE/SEI 43, Section 5.2.3 and possesses ductility and energy absorbing capacity which permits inelastic deformations without failure under DEC.

#### **Evaluation Criteria for Structure Interaction Under Seismic and Extreme Wind**

The interaction of the RB structure with the adjacent RWB, CB, TB and Reactor Auxiliary Bay is discussed in Subsections 3.3.1.2 and 3.3.2.8.

The stability of foundations under DBE and design basis tornado wind loads are checked following the criteria in Subsection 3.5.2.2.

## **RB Design for Impulsive and Impactive Loads**

The RB structure is designed for impulsive and impactive loads per the requirements of Sections 7.15.1 and 7.15.3 of CNSC REGDOC-2.5.2 and the regulatory guidelines of U.S. NUREG-0800, SRP 3.8.4.

The RB design for impulsive and impactive loads follows the provisions of ANSI/AISC N690 and the relevant regulatory guidance of U.S. NRC RG 1.243.

Criteria used to define the heavy loads considered in the RB design are described in Subsection 3.4.5.1.

### **3.5.5.4.2 Robustness Acceptance Criteria for RB Structure**

Refer to Subsection 3.5.6.1 for a detailed discussion of the robustness design and acceptance criteria for the BWRX-300 RB structure, which satisfy the requirements in CNSC REGDOC-2.5.2, Section 7.22.3.

## **3.5.5.5 Materials, Quality Control and Special Construction Techniques**

### **3.5.5.5.1 Materials**

Materials used in construction of the RB structure outside of the containment are in accordance with ANSI/AISC N690, Section NA3.

Details of materials used in the construction of the RB are provided in Chapter 9B, Subsection 9B.2.3.4.

### **3.5.5.5.2 Quality Control**

Quality control procedures are established and implemented during the construction and inspection phases of the RB structure. These procedures cover the fabrication, furnishing, and installation of each structural item in the RB and specify the inspection and documentation requirements in accordance with the requirements in ANSI/AISC N690, Section NA5, Chapter NN with supplemental guidance provided in U.S. NRC RG 1.243.

### **3.5.5.5.3 Special Construction Techniques**

The BWRX-300 Seismic Category A structures at the DNNP site are built using a modular construction technique using Steel Bricks™. (see Section 3.5.1).

The quality control procedures used in the structural modularization process implemented in the construction of the Steel Bricks are outlined in Subsection 3.5.5.5.2. These procedures are employed at the fabrication shop and the construction-site (both outside and inside the deep excavation pit necessary for the construction of RB), including pre-fabrication and pre-assembly, to ensure the Steel Bricks™ modular assemblies meet the necessary material quality, fabrication, and installation requirements per the applicable code of records.

For the preferred method of construction for the deeply embedded BWRX-300 RB shaft, refer to Section 1.4 of NEDO-33914 Revision 2.

For plant construction and commissioning activities, refer to Chapter 14.

### **3.5.5.6 Testing and In-Service Inspection Requirements**

Per CNSC REGDOC-2.5.2, Section 7.15.2, periodic inspection, and in-service monitoring programs are implemented to ensure the RB structure continues to meet its functional and performance requirements.

Sections 3.2 through 3.4 of NEDO-33914 Revision 2 describe the approaches and guidelines for the BWRX-300 in-service testing, monitoring, and monitoring programs.

NEDC-33926P describes the in-service inspection and testing guidelines for the Steel Bricks™ to ensure that the integrated RB structures satisfy their functional and performance requirements through all phases of the plant's life cycle. The BWRX-300 implements a Structures Monitoring and Aging Management Program (SMAMP) that monitors the condition of structures and manages aging effects in accordance with CSA N291, clauses 9 and 10 and in compliance with CNSC REGDOC-2.5.2, Section 7.17. The program demonstrates that the facility is constructed to the requirements in the design drawings and specifications. A research and development program is also established to demonstrate the adequacy of Steel Bricks™ to maintain the structural integrity of the integrated RB structures and of inspection methods used in compliance with CNSC REGDOC-2.5.2, Section 5.4.

### **3.5.6 Robustness Design of Seismic Category A Structures**

Consistent with the Level Four D-in-D requirements discussed in Subsection 3.1.6 and in Section 6.1 of CNSC REGDOC-2.5.2, the BWRX-300 containment and RB are robust structures, tolerant of a large spectrum of faults with a gradual degradation in their effectiveness, that would not fail catastrophically under operational states, DBAs and DEC.

Evaluations performed to establish an understanding of safety margins, or the robustness of the design are consistent with the regulatory guidance of CNSC REGDOC-2.4.1 (Reference 3.5-34), Section 4.2.3 and U.S. NUREG-0800, SRP 19.0.

#### **3.5.6.1 Design Extension Conditions**

In accordance with Section 7.15.1 of CNSC REGDOC-2.5.2, DEC considered in the design of the BWRX-300 Seismic Category A structures include severe accident conditions due to both internal and external hazards, whose probability of occurrence is lower than the probability of occurrence of the DBA.

Loads, load combinations, strength and safety requirements for assessing the BWRX-300 Seismic Category A structures (i.e., the integrated RB) are defined in accordance with Clause 6.1.4 of CSA N291.

Consistent with Section 7.3.4 of CNSC REGDOC-2.5.2 and Clause 5.6 of CSA N290.16 (Reference 3.5-35), deterministic safety analyses are used to determine the applicable DEC and evaluate the consequences of the DEC.

In accordance with the guidelines of CSA N290.16, Clause 4.3.5, a best estimate approach is used to obtain a reasonable confidence in the assessed response to DEC.

A reasonable level of survivability of the structure under postulated DEC is demonstrated following requirements of Clause 6.1.3.1 of CSA N290.16. Per Clause 4.5 of CSA N290.16, less stringent assumptions than those applied for design basis, such as the permissible variances in Annex C of CSA N290.16, may be used when evaluating SSC performance under DEC.

##### **3.5.6.1.1 Containment Severe Design Extension Condition Evaluations**

Complying with Section 8.6.12 of CNSC REGDOC-2.5.2, the BWRX-300 containment design ensures the ability of the containment system to withstand loads associated with DEC.

Consistent with CNSC REGDOC-2.5.2, Section 8.6.2, the containment structure is designed to possess ductility and energy absorbing capacity, which permits inelastic deformation without failure under DEC.

The beyond design basis evaluations of the containment ensure the structural integrity and leak tightness of the containment structure under all applicable DEC loading cases in compliance with the regulatory guidance of CNSC REGDOC-2.5.2.

### **Containment Ultimate Pressure Capacity**

The ultimate internal pressure capacity of the containment structure, including the SCCV, containment closure head and penetrations, is determined to ensure its structural integrity and leak tightness under DEC internal pressure loads to meet the requirements in CNSC REGDOC-2.5.2, Section 7.15.1, U.S. NRC RG 1.216, and U.S. NUREG-0800, SRP 3.8.1.

This ultimate pressure capacity is obtained from the results of non-linear finite element analysis consistent with the guidelines of Regulatory Position 1 of U.S. NRC RG 1.216.

### **Robustness Against Combustible Gas Pressure Loads**

The BWRX-300 design demonstrates the ability of the containment to withstand DEC loads associated with combustion of gases consistent with requirements of Section 8.6.12 of CNSC REGDOC-2.5.2.

The containment is designed to ensure that its structural integrity is maintained to sustain the combustible gas pressure loads applicable for BWRX-300 consistent with the requirements in U.S. NRC RG. 1.136 and U.S. NRC RG 1.57.

### **Containment Severe Accident Performance Goal**

Consistent with guidance in CNSC REGDOC-2.5.2, Section 8.6.12, the BWRX-300 design is a fail-safe design that ensures that under DEC conditions with core damage, the containment:

- A. Maintains its role as a reliable leak-tight barrier for a minimum of 24 hrs following the onset of core damage
- B. Continues to provide a barrier against the uncontrolled release of fission products following the initial 24 hrs period

The methodology used to evaluate the robustness of the containment is per Regulatory Position 3 of U.S. NRC RG 1.216. The evaluation identifies pressure and temperature loadings associated with the more likely DEC challenges by considering the sequences of plant damage states that represent 90% or more of the core damage frequency. Analyses of global and local finite element models are performed to calculate the enveloping containment response for the identified accident challenges.

Criteria for factored load category in NEDC-33926P for the SCCV is used to demonstrate the containment deterministic performance goal for the initial 24 hours. The deterministic performance goal after the initial 24-hour period is demonstrated by showing that the containment leakage in a severe accident remains below the design leakage rate limit, consistent with CNSC REGDOC-2.5.2, Sections 8.6.4 and 8.6.12, for sufficient time to allow implementation of emergency measures.

During an extremely improbable severe accident in the BWRX-300, molten core debris may be present on the containment floor. A protective layer of refractory concrete prevents corium (as shown in Chapter 9B, Figure 9B-1) from degrading the SCCV inner steel faceplate that acts as the primary leak-tight boundary. Additional protection is provided by the outer steel faceplate for the SCCV foundation mat. The lower SCCV design has a provision for the installation of a severe accident core melt capture and retention structure with a spreadable area to prevent contact between the molten core and the containment liner and concrete. Refer to Chapter 15, Appendix 15B for more details on this corium shield and other complementary design features for BDBAs.

#### **3.5.6.1.2 Beyond Design Basis Seismic Robustness**

In accordance with CNSC REGDOC-2.5.2, Section 7.13.1, the design of the BWRX-300 Seismic Category A and Seismic Category B SSC credited to function during and after a Beyond-Design

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

Basis Earthquake (BDBE) ensures their capability to maintain their structural integrity and to perform their intended safety function.

The BDBE is defined to meet the DEC identification requirements of CNSC REGDOC-2.5.2, Section 7.3.4. Per CNSC REGDOC-2.5.2, Section 7.13.1, a High Confidence ( $\geq 95\%$ ) of Low Probability ( $\leq 5\%$ ) of Failure (HCLPF) of at least 1.67 times that for the DBE is demonstrated for the SSC credited to function during and after a BDBE.

The methodology in Electrical Power Research Institute (EPRI) TR-103959 (Reference 3.5-36), TR-1002988 (Reference 3.5-37) and TR-1019200 (Reference 3.5-38), consistent with the recommendations of TR- 3002012994 (Reference 3.5-39) is used for the evaluations of seismic fragilities of BWRX-300 Seismic Category A and B SSC.

Following the regulatory guidance of CNSC REGDOC-2.5.2, Section 7.13.1, to ensure adequate margins for the BDBE, the seismic design satisfies the ductility detailing and design requirements for steel and steel-plate composite structures of ANSI/AISC N690, with the supplementary guidance of U.S. NRC RG 1.243 and NEDC-33926P. This approach meets the intent of CSA S16 (Reference 3.5-40), for Seismic Category A steel structures members and connections.

### **Checking Level Earthquake**

Per Clause 5.4.5 of CSA N289.1 (Reference 3.5-41), a Checking Level Earthquake (CLE) defines the earthquake level for BDBE evaluations to ensure prescribed safety margins for earthquakes exceeding the DBE.

The BWRX-300 plant is assessed during the design process, in accordance with Clause 8.2 of CSA N289.3, using CLE to:

- Provide detailing for post-elastic behavior and energy absorption during BDBE events
- Identify any SSC that can have insufficient seismic ruggedness, ductility, or inelastic response capability to withstand and perform their safety function during and after BDBE
- To ensure no cliff-edge effects

The site-specific CLE ground motion spectra are defined as 1.5 times the DBE, which is at a level sufficiently larger than the DBE to support meeting the acceptable plant HCLPF criteria of CNSC REGDOC-2.5.2, Section 7.13.1. The site-specific CLE is representative of a seismic hazard exceedance probability that is lower than the seismic hazard probability of the DBE and meets the requirements of Clause C.3.3 of CSA N289.1.

The selected CLE maintains consistency with the performance objectives expressed in Chapter 1 of ASCE/SEI 43 and the precedence set for definition of BDBE motion in Chapter 9 of ASCE/SEI 43. The performance objectives in ASCE/SEI 43 aim to achieve 10% unacceptable performance for 150% of DBE level per U.S. NRC RG 1.208 (Reference 3.5-42). It is recognized that the redundancy in the SSC credited to function during and after a CLE is included in the calculation of a plant level HCLPF of at least 1.67 times the DBE.

CLE in-structure demands for BDBE evaluations are obtained from BE approach seismic response analyses performed following the guidance of CSA N289.1, Clause C.4.2, consistent with the criteria in Subsection 3.3.1.3. The SSI input soil profiles for the BDBE evaluations are obtained at strain levels consistent with the CLE motion. The SSI analyses for BDBE evaluations may use Response Level 3 damping values in accordance with ASCE/SEI 43

In accordance with Section 5.2.7 of CSA N289.1, CLE is considered in combination only with normal operating loads.

### 3.5.6.2 Design for Malevolent Acts

The BWRX-300 uses a security by design process that involves security reviews during plant design to resolve DBT and BDBT security issues at the earliest stage, when changes have the least impact on cost and performance. Placement and number of doors, wall thicknesses to optimize resistance to explosive breaching, and equipment placement to facilitate better target set diversity are all achievable when security is integrated at an early stage. Continual design reviews against the DBT and BDBT capabilities during the entire design evolution ensure that emergent issues are identified and addressed as early in the process as possible.

The defensive strategy approach focuses on protecting the passive plant features and other key reactor components from hostile action by creating a robust perimeter. By analyzing the potential adversary pathways to critical components, determining adversary resources required to execute the path, and slowing the adversary movements and depleting the adversaries' resources before the path can be completed to the extent possible, the design limits the ability of malicious individuals to cause damage to key systems. This, along with the inherent slower accident progression of the BWRX-300 reactor, reduces or eliminates the reliance on immediate on-site armed responders to prevent substantial off-site radiological releases, which allows for longer term off-site response, interdiction, and neutralization.

#### Malevolent Acts Design Methods

The BWRX-300 design for DBTs and BDBTs satisfies the requirements of CNSC REGDOC-2.5.2, Section 7.22.2.

The design considers the following two types of structural failure modes with distinct loading characteristics and structural responses:

1. Local effects that in general would not result in structural collapse but may affect the functions of safety class SSC
2. Global failure modes characterized by major structural damage, such as significant perforation or collapse of large portions of the building walls, floors, and load carrying frames

These failure modes are considered separately with a consideration given that for some threats, such as an aircraft crash, they may act simultaneously or quasi-simultaneously.

Applicable local damage modes are considered in the design and empirical formulas are used to assess the structural behavior under local and concentrated loading.

The BWRX-300 design applies the Nuclear Energy Institute's methodology in NEI 07-13 (Reference 3.5-43) for aircraft crash evaluations with CNSC input and other detailed computer analytical methods, where appropriate, to evaluate the consequences of regulatory defined threats on a BWRX-300 reactor site. The CNSC acceptance criteria are then applied to the results.

Evaluations include:

- RB structural integrity including enclosed safety features as applicable:
  - Global failure (plastic collapse)
  - Local perforation (hard missile)
  - The acceptance criteria for both local and global behavior are satisfied simultaneously
- Containment and fuel pool heat removal capability
- Reactivity control following regulatory defined threats

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

- Containment isolation following regulatory defined threats
- Fuel intrusion prevention
- Shock and vibration impact of critical equipment
- Short and long-term mitigation efforts required following commercial aircraft impact

### **Malevolent Acts Design Acceptance Criteria**

The design of the BWRX-300 Seismic Category A structures meets the following acceptance criteria for local response under malevolent acts depending on the structural system used:

1. For DBTs, no scabbing of the rear face of structural elements, possibly with limited, easily repairable, superficial spalling of concrete
2. For severe BDBTs, no scabbing of the rear face of structural element, or possible limited scabbing if confined by the steel liner that should remain leak-tight
3. For extreme BDBTs, no perforation, according to the applicable formula with a corresponding increase factor of 1.2 applied to the calculated thickness
4. For Steel Bricks™ members, the steel faceplate thickness to prevent perforation is at least 1.25 times that required by use of rational methods in accordance with ANSI/AISC N690 and NEDC-33926P

The structural acceptance criteria for global response are related to:

- The limitation of structural deflections for DBT and severe BDBT; or
- Overall damage for extreme BDBT

Special attention is given to:

- Damage to the containment and internal structures due to extensive deformations of the containment
- Shock damage to fragile components directly attached to the containment wall
- Induced vibration
- Post-event fireball explosions or blast waves
- Structural integrity of the polar crane

The acceptance criteria for local and global structural response are satisfied simultaneously.

Design criteria for the BWRX-300 RB specifies no global failure, no perforation, no spalling, and no fuel intrusion from the regulatory defined threats.

The design of BWRX-300 containment meets the malevolent acts acceptance criteria in NEDC-33926P that is consistent with the regulatory guidance in Table 1 of CNSC REGDOC-2.5.2, Appendix A.

The BWRX-300 Security Annex describes design methods and acceptance criteria for malevolent acts in greater details.

### **3.6 General Design Aspects for Mechanical Systems and Components**

Section 3.6 provides the general design aspects used for safety class and non-safety class mechanical systems and components. It includes special considerations for mechanical components, dynamic testing and analysis of structures, systems, and components, required codes for ASME BPVC Section III Division 1 Class 1, 2, and 3 components, and component supports, including core support structures. In addition, general design aspects for Control Rod Drive System, Reactor Vessel Internals, system piping, and threaded fasteners are presented. Further, this section discusses the functional design, qualification and in-service testing program requirements for pumps, valves, and dynamic restraints.

Chapter 1 provides the codes and standards and editions that are applicable to the design of mechanical systems and components and is used as input to Section 3.6.

Sections 3.1 and 3.2 are used as input to Section 3.6 and provide the general design principles, criteria, and classification used for design of mechanical systems and components. Among these principles are design for robustness, reliability, and fail-safe operation. Additionally, the systems and components are required to be redundant, diverse, independent, separate and of supply quality commensurate with the safety classification, seismic category, and supply category. The design and qualification of mechanical components is performed using a graded approach with the highest level of rigor applied to Safety Class 1 (SC1) components.

Subsection 3.3.1 develops the seismic input criteria and building spectra used as input to Section 3.6 for seismic qualification of Seismic Category B active mechanical components and system functionality. Additionally, Seismic Category A passive mechanical component supports, and equipment supports use the seismic spectra for qualification.

Section 3.9 provides the equipment qualification requirements including environmental, dynamic, functional qualification, and Electromagnetic Compatibility (EMC), which are used as input to Section 3.6.

#### **Codes and Standards Used in the Design of Mechanical Systems and Components**

ASME BPVC Section III Division 1, ASME B31.1 (Reference 3.6-10), and ASME B31.3 (Reference 3.6-12) are applied for the design of mechanical systems, components and piping including piping components.

Table 3.6-1 provides the pressure boundary codes and standards utilized in the BWRX-300 mechanical system and component design.

#### **Mechanical Equipment Separation for Safety Class 1**

Mechanical equipment separation measures for the BWRX-300 contribute to system reliability in the performance of any Safety Category 1 function including (but not necessarily limited to) interconnecting piping, valves, and associated mechanical controls and instrumentation. Additionally, where necessary adjacent systems are considered in mechanical equipment separation (as related to human factors, mechanical maintenance, and seismic interaction).

Principles of physical separation include:

- A. Separation by geometry (layout, distance, orientation, elevation, and including separate structures)
- B. Separation by barriers (e.g., walls, shields), both vertical and horizontal
- C. Separation by a combination of (A) and (B)

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

Per CNSC REGDOC-2.5.2, Section 7.4.1 (Reference 3.6-16), the plant design takes into account the potential for internal hazards such as flooding, missile generation, pipe whip, jet impact, fire, smoke, and combustion by-products, or release of fluid from failed systems or from other installations on the site. Appropriate preventive and mitigation measures are provided to ensure that nuclear safety is not compromised.

Per CNSC REGDOC-2.5.2, Section 7.6.1.1, vertical separation, or other protection is provided where physical separation by horizontal distance alone may not be sufficient for some common cause failures such as flooding.

Defense Line (DL) functions that mitigate the same event are independent from each other to the extent practicable. All PIEs with a frequency greater than 1E-05 can be mitigated by functions in DL3 and separately by functions in either DL2 or 4a. Therefore, SSC performing DL3 functions are separate, to the extent practicable, from SSC that perform Safety Category functions in DL2 and DL4a. Separation is also provided between redundant SSC that perform DL3 functions (Safety Category 1) to the extent practicable.

The redundancy methods are used to protect from Single Active Failures or events; examples include utilization of safety class structures, spatial separation, three-hour rated fire barriers, and isolation devices.

The application of the single failure criterion to fluid systems is described in Subsection 3.1.7.5.

Separation of components may be by physical distance or by barriers. An example is the provision of principal fire barriers to delineate individual fire zones; such barriers may also serve as barriers to other hazards, as per CNSC REGDOC-2.5.2 Section 7.6.1.1.

The following SC mechanical equipment items are considered:

- Piping Systems
- Valves
- Rotating Equipment
- Vessels
- Ductwork Systems
- Instrumentation

### **Piping Systems**

Piping systems include piping to and from SC and SCN SSC. These include their connected bellows, mechanical connections, support guides, and structural supports. They may include wall or floor sleeves and penetrations, pipe fittings including wells and branch connections, structural restraints (and appurtenances), and attached sampling. Piping systems also include vent/drain/test/flush/clean-out taps including closures, instrument sensing line piping or tubing and instrument racks. Finally, they also include pneumatic or hydraulic system tubing, manifolds and controls appurtenances.

### **Valves**

Valves include those that control fluid flow to and from SC and SCN SSC. Valves include the valve body assembly, actuators, appurtenances, and all non-electrical connections.

### **Rotating Equipment**

Rotating equipment includes pumps, fans and compressors, gear sets or power coupling subsystems, and electric motors or other rotary-power driven subsystems. Their components include rotating casing, including base, frame, supports and drive.

### **Vessels**

Vessels include heat exchangers and tanks, including their supports, filter assemblies, and nozzles.

### **Ductwork Systems**

Ductwork systems include:

- Duct runs
- Active and pre-set dampers
- Fire dampers
- Screens
- Vents/reliefs/blow out panels
- Filters or air filtration assemblies/subsystems

### **Instrumentation**

Instrumentation includes:

- Mechanically activated instruments used to monitor reactor and plant processes
- The associated non-electrical transmission
- Sensors
- Actuator systems
- In-line instruments with associated taps

### **Zone of Influence**

The degree and type of separation required varies with the following potential hazards in a power plant zone:

1. **Missiles** - A missile is an unrestrained mass with sufficient kinetic energy to cause damage to the safety systems or required safety components. Definition of missile and missile protection requirements are addressed in Subsection 3.3.5
2. **Pipe Whip** - Pipe whip is usually consequent to a pipe failure resulting in a complete segment separation break. The area in the vicinity of the postulated break of high-energy piping is defined as the pipe whip damage zone. Pipe whip protection requirements are addressed in Subsection 3.4.4.
3. **Fluid Jet** - The fluid jet is usually consequent to a high-energy pipe break but may also be the result of intentional equipment action. Jet impingement protection requirements are addressed in Subsection 3.4.4

### **Fire Area and Fire Zone**

A fire area is an area sufficiently bounded to withstand the hazards associated with the fire area and, as necessary, to protect important equipment within the fire area from a fire outside the area. A fire zone, however, is a subdivision of fire area(s) for analysis purposes that is not necessarily bound by fire-rated barriers.

Fire zone protection requirements are addressed in Chapter 9A, Section 9A.6. Separation of vulnerable mechanical equipment from areas containing significant combustible materials is provided by fire barrier materials or housings, fire-rated walls or doors (including consideration for ductwork isolations), barrier piping around processes containing flammable or combustible fluids to isolate the hazard, and in certain locations by atmospheric inerting (oxygen concentration suppression below combustible level or replacement with nitrogen, such as in containment).

### **Flood Zone**

Internally generated flooding may occur by pipe or tank failure, fire suppression system operation, misaligned systems with openings in the affected zone, maintenance errors, or failure of a drainage system. Flood protection requirements are addressed in Subsections 3.3.3.1 and 3.4.2.

Separation by flood hazard containment walls, dikes, curbs, trenches or pits, watertight doors, elevated equipment mounting location (mezzanine or different floor) or pedestals or placing vulnerable equipment in watertight housings may be used.

### **Design Load and Load Combination for Mechanical Systems and Components**

Design loads and loading combinations are based on normal operation and off-normal operation. Subsection 3.6.1.1 below provides the operational transients, resulting loads, and load combinations.

Design loads and load combinations for fixed mechanical equipment are provided in Table 3.6-2. Fixed equipment includes the mechanical, electrical, and instrument components, and the component housings and structural supports that are anchored to civil structure(s) but are not a part of the civil structure itself, such as mechanical or electrical penetrations. Examples include the reactor pressure vessel (RPV), RPV Internals, RPV supports, instrumentation, piping, electrical equipment, and the component supports.

A discussion of plant normal and off-normal operation can be found in Chapter 1, Section 1.8, and Chapter 6, Sections 6.2 and 6.4.

### **Design for System Duty of Mechanical Systems Based on Event Frequencies**

Table 3.6-3 is used as a general event list for all hardware system duty design specifications. Events are mainly classified into:

- Design Condition 1 (DC-1): Normal Planned Operation
- Design Condition 2 (DC-2): Anticipated Operational Occurrence
- Design Condition 3 (DC-3): Design Basis Accident
- Design Condition 4 (DC-4): Design Extension Condition

The BWRX-300 utilizes the four Service Levels used in the ASME Code, Levels A, B, C and D, as well as testing conditions, in the design of fixed equipment. The design basis specifies the capabilities that are necessary for the plant in various operational states.

Conservative design measures and sound engineering practices are applied in the design basis for plant states. This approach provides a high degree of assurance that no significant damage

will occur to the reactor core, and that radiation doses will remain within established regulatory limits.

### **3.6.1 Special Topics for Mechanical Components**

This subsection addresses information concerning methods of analysis for components and supports.

#### **3.6.1.1 Computer Programs Used in Analyses**

The major computer programs used in the mechanical system and component analyses of the major safety class components are described in Chapter 3, Appendix 3C .

The computer programs used in the analyses of Seismic Category A and B components are maintained either by General Electric Company (GE) or by outside computer program developers.

The GEH Software is controlled under NEDO-11209-A (Ref. 3.6-17). CSA N286.7 (Ref. 3.6-14) is used to determine acceptability of code use for the BWRX-300 in Canada. In either case, the quality of the programs and the computed results are controlled. The programs are verified for their application by appropriate methods, such as hand calculations, or comparison with results from similar programs, experimental tests, or published literature.

#### **3.6.1.2 Operational Transients, Resulting Loads and Load Combinations**

The plant duty cycles represent transient conditions that are used for development of the BWRX-300 system and component design during Normal Operation, Anticipated Operational Occurrence (AOOs), Design Basis Accidents (DBAs), and Design Extension Conditions (DECs), which are Beyond Design Basis Events. Requirements are evaluated for the system design and performance as it relates to complete reactor operation. The duty is recorded as inputs to the system design for each specific primary and auxiliary hardware system. Duty can be defined from a pressure and temperature perspective, mostly when variations in either variable are expected in important locations for the reactor.

The number of cycles associated with each event for the design of the Reactor Pressure Vessel (RPV), Reactor Coolant Pressure Boundary (RCPB), and other ASME pressure boundary components designed for fatigue are listed in Table 3.6-9. Tables 3.6-4 through Table 3.6-8 break down the operational cycles by plant condition. The plant operating conditions are identified as normal, AOO, DBA, DEC, or testing as defined in Subsection 3.6.3.2. Appropriate Service Levels (A, B, C, D, or testing), as defined in the ASME BPVC, are designated for design limits. The design and analyses of ASME Class piping and equipment using specific applicable thermal-hydraulic transients, which are derived from the system behavior during the events listed in Table 3.6-3, are documented in the design specifications and/or stress reports of the respective equipment. Table 3.6-2 shows the load combinations and the standard acceptance criteria for ASME Section III components. Tables 3.6-10, 3.6-11, and 3.6-12 provide the specific load combinations and acceptance criteria for piping systems.

#### **3.6.1.3 Experimental Stress Analysis**

Experimental stress analysis methods are used in compliance with the provisions of ASME BPVC Section III Division 1, Mandatory Appendix II (Reference 3.6-9). ASME Class 1 and some ASME Class 2 mechanical components that require both functionality and adequate structural capacity during seismic events, are laboratory tested in accordance with CSA N289.4 (Reference 3.6-13) and ASME Standard QME-1 (Reference 3.6-20) as discussed in Subsection 3.9.3.2.1.

#### **3.6.1.4 Considerations for the Evaluation of Fault Conditions**

All equipment designed to ASME BPVC Section III Division 1 is evaluated for the faulted (Service Level D) loading conditions. In all cases, the calculated actual stresses are compared to the allowable ASME BPVC Section III Division 1 Service Level D limits. The following subsections address the evaluation methods and stress limits used for the equipment and identify the major components evaluated for faulted conditions.

Deformations under faulted conditions are evaluated in critical areas and the necessary design deformation limits, such as clearance limits, are satisfied.

##### ***3.6.1.4.1 Fine Motion Control Rod Drive***

The Fine Motion Control Rod Drive (FMCRD) major components that are part of the RCPB are analyzed and evaluated for the ASME Service Level D faulted conditions in accordance with the ASME BPVC Section III Division 1, Subsection NB (Reference 3.6-3). Refer to Chapter 4, Subsection 4.6.2.1.1 for FMCRD mechanism details.

##### ***3.6.1.4.2 CRD Hydraulic Control Unit***

The Hydraulic Control Unit (HCU) is analyzed and tested for withstanding the faulted condition loads. Dynamic tests that are part of the seismic and dynamic qualification program establish the loads in the horizontal and vertical directions as the HCU capability for the frequency range that is likely to be experienced in the plant. These tests also ensure that the reactor trip function of the HCU can be performed under these loads. Dynamic analysis of the HCU with the mounting beams is performed to assure that the maximum faulted condition loads remain below the HCU capability. Refer to Chapter 4, Subsection 4.6.2.1.3 for HCU details.

##### ***3.6.1.4.3 Reactor Pressure Vessel Assembly***

The design of the RPV assembly, out to and including the integral Reactor Isolation Valves (appurtenances), RPV Top Head, and housings for FMCRD and in-core Nuclear Instrumentation complies with Subsections NB and NG of the ASME BPVC Section III Division 1 as applicable. For faulted conditions, the reactor vessel is evaluated using elastic analysis.

Elastic analysis methods and standard design rules, as defined in the ASME BPVC, are utilized in the analysis of the pressure boundary, Seismic Category B, ASME BPVC Section III, Division 1, Class 1 valves. The ASME BPVC Section III Division 1 allowable stress is applied to assure integrity under applicable loading conditions including faulted condition. The functional qualification of the Reactor Isolation Valves (RIVs), is analyzed and/or tested for seismic and other dynamic conditions.

##### ***3.6.1.4.4 Core Support Structures and Other Safety Class Reactor Internal Components***

The core support structures, the internal portion of Nuclear Instrument and CRI housings, and other safety class reactor internal components are evaluated for faulted conditions. The basis for determining the faulted loads for seismic events and other dynamic events is given in Subsection 3.6.2.3 and Subsection 3.6.2.2, respectively. The allowable Service Level D limits for evaluation of these structures are per ASME BPVC Section III Division 1, Service Level D equations.

For the shroud support, an elastic analysis is performed, and buckling is evaluated for compressive load cases for certain locations in the assembly.

##### ***3.6.1.4.5 RPV Stabilizers, Reactor Skirt and FMCRD Housing and Nuclear Instrumentation Housing Restraints (Supports)***

The calculated maximum stresses to meet the allowable stress limits are based on the ASME BPVC Section III Division 1, Subsection NF (Reference 3.6-7), for the RPV stabilizer, RPV skirt

and supports for the FMCRD housing and Nuclear Instrumentation housing for faulted conditions. These supports restrain the components during earthquake, pipe rupture or other Reactor Building Vibration events.

**3.6.1.4.6 Reactor Isolation Valves, and Other ASME BPVC Section III Division 1 Class 1 and 2 Valves**

Elastic analysis methods and standard design rules, as defined in the ASME BPVC, are utilized in the analysis of the pressure boundary, Seismic Category B, ASME BPVC Section III Division 1 Class 1 and 2 valves. The ASME BPVC Section III Division 1 allowable stresses are applied to assure integrity under applicable loading conditions including faulted condition. The functional qualification of the major active valves, including Reactor Isolation Valve (RIVs), Containment Isolation Valves (CIVs), ICS Purge valves, and ICS Condensate Return valves are analyzed and/or tested for seismic and/or other dynamic conditions.

**3.6.1.4.7 Fuel Storage and Refueling Equipment**

The fuel storage and fuel handling equipment is described in detail in Section 9A.1. This includes the Fuel Pool structure, Fuel Racks, Fuel Cooling system, and Fuel Handling Equipment.

CNSC REGDOC 2.5.2 Section 6.2, Subsection 7.3.4.1, and Subsection 8.12.2, require that the same Section 3.1 fundamental safety functions as those that apply to the Reactor be utilized for fuel storage and handling. Due to physical and structural separation, Safety Class equipment cannot be affected by a fuel handling accident.

A summary of the design considerations used to establish nuclear criticality safety under all operational and faulted (ASME Service Level D) conditions is described below.

All fuel storage racks are designed and qualified to operate within their performance requirements under the anticipated ranges of the normal, abnormal or accident plant environments and are designed to withstand a Design Basis Earthquake (DBE) without failure of the basic structure or damage to the active region of irradiated fuel.

**3.6.1.4.8 Fuel Assembly (Including Channel)**

The Fuel Assembly including channel is described in detail in Section 4.2.3.

The channel is subjected to mechanical tests to demonstrate the adequacy of the GNF2 channel for seismic/dynamic loads. The channel was tested to determine the allowable bending load that could be sustained without buckling or collapsing the channel.

The Fuel Assemblies are designed for worst-case conditions that evaluate maximum stresses, fatigue, control rod insertion, fretting, corrosion/hydriding, and compatibility/dimensional changes. The results of the testing and analysis requires that the safety class components maintain the required functionality and structural capacity during ASME Level D service conditions.

**3.6.1.4.9 ASME BPVC Section III Division 1 Class 2 and 3 Vessels**

Elastic analysis methods are used for evaluating faulted loading conditions for Class 2 and 3 vessels. The equivalent allowable stresses using elastic techniques are obtained from Articles NCD-3300 and NCD-3200 of the ASME BPVC Section III Division 1 Subsection NCD (Reference 3.6-4).

**3.6.1.4.10 ASME BPVC Section III Division 1 Class 2 and 3 Pumps**

Elastic analysis methods are used for evaluating faulted loading conditions for Class 2 and 3 pumps. The equivalent allowable stresses for nonactive pumps using elastic techniques are obtained from Article NCD-3400 the ASME BPVC Section III Division 1 Subsection NCD.

#### **3.6.1.4.11 ASME BPVC Section III Division 1 Class 2 and 3 Valves**

Elastic analysis methods and standard design rules are used for evaluating faulted loading conditions for Class 2 and 3 valves. The equivalent allowable stresses for valves using elastic techniques are obtained from Article NCD-3500 of the ASME BPVC Section III Division 1 Subsection NCD.

#### **3.6.1.4.12 ASME BPVC Section III Division 1 Class 1, 2 and 3 Piping**

Elastic analysis methods are used for evaluating faulted loading conditions for Class 1, 2, and 3 piping. The equivalent allowable stresses using elastic techniques are obtained from Article NB-3600 (for Class 1 piping) of the ASME BPVC Section III Division 1 Subsection NB and Article NCD-3600 (for Class 2 and 3 piping) of the ASME BPVC Section III Division 1 Subsection NCD.

#### **3.6.1.4.13 Inelastic Analysis Methods**

Inelastic analysis is only applied to BWRX-300 components to demonstrate the acceptability of two types of postulated events. Each event is an extremely low-probability occurrence and the equipment affected by these events would not be reused. These two events are as follows:

- Postulated gross piping failure
- Postulated blow out of a Control Rod Drive housing caused by a weld failure

The design criteria for pipe failure effects and mitigating features are provided in Subsection 3.4.4.1. Except for the analysis of pipe failures, inelastic methods are not used in BWRX-300 piping design.

The mitigation of the CRDH attachment weld failure relies on components with regular functions to mitigate the weld failure effect. The components are specifically:

- Core support plate
- Control Rod Guide Tube
- CRD Housing
- Control Rod Drive (CRD) outer tube
- Bayonet Fingers

Only the bodies of the CRGT, CRDH, and CRD outer tube are analyzed for energy absorption by inelastic deformation.

### **3.6.2 Dynamic Testing and Analysis of Systems, Components, and Equipment**

This Subsection 3.6.2 presents the criteria, testing procedures, and dynamic analyses employed to ensure the structural and functional integrity of piping systems, mechanical equipment, reactor internals, and their supports (including supports for conduit and cable trays, and ventilation ducts) under vibratory loadings, including those due to fluid flow and postulated seismic events. Structural requirements for conduits and cable tray supports and Heating, Ventilation and Air Conditioning duct supports are developed as discussed in Subsection 3.6.2.5.7.

#### **3.6.2.1 Piping Vibration, Thermal Expansion and Dynamic Effects**

The overall test program is divided into two phases:

1. Pre-operational test phase
2. Initial startup test phase

Piping vibration, thermal expansion, and dynamic effects testing is performed during both of these phases. Discussed below are the general requirements for this testing. It is noted that because one goal of the dynamic effects testing is to verify the adequacy of the piping support system, such components are addressed in the subsections that follow.

#### ***3.6.2.1.1 Vibration and Dynamic Effects Testing***

The purpose of these tests is to confirm that the piping, components, restraints, and supports of specified high- and moderate-energy systems have been designed to withstand the dynamic effects of steady-state Flow Induced Vibration (FIV) and anticipated operational transient conditions.

#### ***3.6.2.1.2 Seismic Qualification of Safety Class Mechanical Equipment***

Section 3.9 provides methodology for qualification of SC1 Mechanical equipment.

#### ***3.6.2.1.3 Tests and Analysis Criteria and Methods***

Section 3.9 provides tests and analysis criteria methods.

### **3.6.2.2 Qualification of Safety Category Mechanical Equipment**

The following subsections discuss the testing or analytical qualification of the safety class major mechanical equipment, and other ASME BPVC Section III Division 1 equipment including equipment supports.

#### ***3.6.2.2.1 CRD and CRDH***

The qualification of the CRDH (with enclosed FMCRD) is done analytically, and the stress results of the analysis establish the structural integrity of these components. Dynamic tests are conducted to verify the operability of the CRD during a dynamic event. A simulated test, imposing dynamic deflection in the fuel channels up to values greater than the expected seismic response, is performed.

The correlation of the test with analysis is via the channel deflection, not the housing structural analysis, because insert ability is controlled by channel deflection, not housing deflection.

#### ***3.6.2.2.2 Core Support (Fuel Support and Control Rod Guide Tube)***

A detailed analysis imposing dynamic effects due to seismic and other RBV events is performed to show that the maximum stresses developed during these events are much lower than the maximum allowed for the component material.

#### ***3.6.2.2.3 CRD Hydraulic Control Unit***

The HCU is analyzed for the seismic and other RBV loads in the faulted condition and the maximum stress on the HCU frame is calculated to be below the maximum allowable for the faulted condition.

#### ***3.6.2.2.4 Fuel Assembly (Including Channel)***

The Fuel Assembly (including channel) qualification for seismic and faulted load conditions is described in Chapter 4, Subsections 4.2.2 and 4.2.3.

#### ***3.6.2.2.5 Containment Isolation Valves and Reactor Isolation Valves***

The CIVs for main steam and other process system piping that penetrates containment, and RIVs are qualified for seismic and other RBV loads. The fundamental requirement following a Design Basis Earthquake (DBE) or other faulted RBV loadings is to close and remain closed after the event. This capability is demonstrated by the test and analysis.

#### **3.6.2.2.6 Other ASME BPVC Section III Division 1 SSCs**

Other equipment, including associated supports, is qualified for seismic and other RBV loads to ensure its functional integrity during and after the dynamic event. The equipment is tested, if necessary, to ensure its ability to perform its specified function before, during, and following a seismic event.

Dynamic load qualification is done by testing, analysis, or both as described in Section 3.9.

Refer to Section 3.9 for additional information on the dynamic qualification of valves.

#### **3.6.2.2.7 Supports**

Analyses or tests are performed for component supports to assure their structural capability to withstand seismic, faulted, and other dynamic excitations. Pre-qualified manufactured standard component supports, or engineered component supports that are qualified to specified required service levels for seismic, faulted, and dynamic excitation do not require additional analyses or testing.

#### **3.6.2.3 Dynamic Response of Reactor Internals Under Operational Flow Transients and Steady-State Conditions**

The major reactor internal components within the vessel are subjected to extensive testing, coupled with dynamic system analyses, to properly evaluate the resulting FIV phenomena during normal reactor operation and from anticipated operational transients.

##### **3.6.2.3.1 Initial Startup Flow Induced Vibration Testing of Reactor Internals**

A reactor internals vibration measurement and inspection program is conducted only during initial startup testing. These reactor internal inspections and tests consist of evaluating Flow Induced Vibrations, including any flow excited acoustic and structural resonance that is detected in initial startup testing. Analytical thermal-hydraulic fluid models are developed that replicate plant startup conditions to predict resonance effects on the reactor internals. These predictive models are used in design to eliminate undesired acoustics and structural resonances to a practical extent.

##### **3.6.2.3.2 Initial Startup Testing**

Vibration measurements are made during reactor startup at conditions up to 100% rated flow and power. Steady-state and transient conditions of natural circulation flow operation are evaluated. The primary purpose of this test series is to verify the anticipated effect of single- and two-phase flow on the vibration response of internals.

##### **3.6.2.3.3 Dynamic System Analysis of Reactor Internals Under Faulted Conditions**

The loads to the Reactor Internals that occur because of faulted events and the deterministic analyses performed to determine the response of the reactor internals are as follows:

- Reactor Internal Pressures
- External Pressure and Forces on the Reactor Vessel
- LOCA Loads
- Seismic Loads

##### **3.6.2.3.4 Correlations of Reactor Internals Vibration Tests with the Analytical Results**

Prior to initiation of the instrumented vibration measurement program for a prototype plant, extensive dynamic analyses of the reactor and internals are performed. The results of these

analyses are used to generate the allowable vibration levels during the vibration test. The vibration data obtained during the test are analyzed in detail.

The results of the data analyses, vibration amplitudes, natural frequencies, and mode shapes are then compared to those obtained from the theoretical analysis.

Such comparisons provide the analysts with added insight into the dynamic behavior of the reactor internals. The additional knowledge gained from previous vibration tests has been used in the generation of the dynamic models for seismic and LOCA analyses for this plant. The models used for this plant are similar to those used for the vibration analysis of earlier prototype BWR plants.

### **3.6.3 Codes for ASME BPVC Section III Division 1, Class 1, 2 and 3 Components, Component Supports and Core Support Structure**

Subsection 3.6.3 discusses the structural integrity and/or functional integrity requirements of pressure-retaining components, their supports, and core support structures that are designed in accordance with the rules of the ASME BPVC Section III Division 1.

The ASME BPVC Section III Division 1, Section III, requires that a design specification be prepared for ASME BPVC Section III Division 1 Class 1, 2 and 3 components. The design specifications for ASME BPVC Section III Division 1 Class 1, 2 and 3 components, supports, and appurtenances are prepared under administrative procedures that meet the ASME BPVC Section III Division 1 rules. The specifications conform to and are certified to the requirements of the applicable subsection of the ASME BPVC Section III Division 1. The ASME BPVC Section III Division 1 also requires design reports for Class 1, 2 or 3 components be prepared which demonstrate that the as-built components satisfy the requirements of the respective ASME design specification for each component and the applicable ASME BPVC Section III Division 1. These design specifications and the design reports are completed by the licence applicant, or the applicant's authorized agent, in accordance with the responsibilities outlined under the ASME BPVC Section III Division 1. The ASME BPVC Section III Division 1 design reports include the record of as-built reconciliations, for example, the evaluations of changes to piping support locations, the pre-operational testing, and results, and reported construction deviation resolution, and includes the small-bore piping analysis.

#### **3.6.3.1 Loading Combinations, Design Transients and Stress Limits**

Subsection 3.6.3.2 delineates the criteria for selection and definition of design limits and loading combinations associated with Normal Operation, Anticipated Operational Occurrence (AOO), Design Basis Accidents (DBAs), Design Extended Conditions (DECs) and specified seismic and other RBV events for the design of safety ASME BPVC Section III Division 1 components (except containment components which are discussed in Section 3.5).

This section discusses the ASME BPVC Section III Division 1 Class 1, 2, and 3 equipment and associated pressure-retaining parts and identifies the applicable loadings, calculation methods, calculated stresses, and allowable stresses. A discussion of major equipment is included on a component-by-component basis to provide examples. Design transients and dynamic loading for ASME BPVC Section III Division 1 Class 1, 2 and 3 equipment are covered in Subsections 3.6.1, 3.6.3.6 and 3.6.3.7. Seismic-related loads and dynamic analyses are discussed in Subsection 3.3.1. Table 3.6-9 presents the plant events to be considered for the design and analysis of all BWRX-300 ASME BPVC Section III Division 1 Class 1, 2, and 3 components, component supports, equipment, and core support structures per ASME BPVC Section III Division 1 Subsection NG (Reference 3.6-8). Specific loading combinations considered for evaluation of specific equipment are derived from Table 3.6-2 and are contained in the design specifications and design reports for the respective equipment. For Class 1 components where analysis for

cyclic operation is evaluated in accordance with ASME BPVC Section III Division 1 subarticle NB-3222.4, the fatigue usage evaluation includes the use of environmental fatigue curves.

Specific load combinations and acceptance criteria for Class 1 piping are shown in Table 3.6-10. Also, for Class 1 piping, the operating temperatures above ambient or below ambient are included in the fatigue analysis. The installation temperature state for the piping system is defined as a temperature of 21 C for Class 1, 2, 3 or ASME B31.1 piping.

The design life for the BWRX-300 Standard Plant is 60 years. A 60-year design life is a requirement for all major plant components. Additional life is added for components required during decommissioning. However, all plant operational components and equipment except the reactor vessel are designed to be replaceable. The design life requirement allows for refurbishment and repair, as appropriate, to assure that the design life of the overall plant is achieved.

### **3.6.3.2 Events Considered in Evaluating Effect of Loads on Fixed Equipment**

All events that the BWRX-300 might credibly experience during a reactor-year are evaluated in Chapter 15, to establish the plant design basis, including plant fixed equipment. The associated loads and duty cycles associated with each event are considered in combination with additional events in load combinations as applicable. These event combinations are divided into the four plant conditions with associated frequency of occurrence and ASME BPVC Section III Division 1 design levels.

The following are the plant condition events and transients associated with the BWRX-300 design:

#### ***3.6.3.2.1 Normal Operation***

Normal planned operation is operation under any condition permitted within specified Operational Limits and Conditions (OLCs) irrespective of the anticipated frequency of occurrence of that condition, which is planned and deliberate and not in specific response to Postulated Initiating Events (PIEs). Normal planned operations include startup, power operation, shutting down, shutdown, maintenance, testing, and refueling.

Adequate evaluation of normal operation loads includes loads due to dead weight, temperature, prestress, pressure, fluid flow (including FIV when applicable), thermal and fluid reaction forces and other loads due to moving parts within a component or system. Such loads are considered in the design, installation, and mounting, of equipment and components.

#### ***3.6.3.2.2 Anticipated Operational Occurrences***

Anticipated Operational Occurrences (AOO) are those operating transient events that are expected to occur more frequently than 1E-02 per reactor-year. Chapter 15, Subsection 15.5.3 provides event analyses of Level B PIE AOOs.

Adequate evaluation of associated loads, load combinations, and duty cycles of the AOO transient effects are considered in the design, installation, and mounting, of equipment and components.

#### ***3.6.3.2.3 Design Basis Accident Events***

Design Basis Accidents (DBA) are those events with frequencies of occurrence between 1E-02 to 1E-05 per reactor-year DBAs are mitigated by Defense Line 3. Chapter 15, Subsection 15.5.4 provides event analyses of Level C PIE DBAs.

#### ***3.6.3.2.4 Design Extension Condition Events (DEC)***

Design Extension Conditions (DEC) are events that are less frequent than 1E-05 reactor-year. DEC event analyses demonstrate the capability of the plant to cope with scenarios involving

Defense Line 3 Common Cause Failures (CCFs) and provide a systematic evaluation of potential cliff-edge effects outside the plant design bases. DEC transient events are mitigated by SSC associated with Defense Line 4a and DL2 functions that are unaffected by the PIE and additional failures identified in the event sequence. Chapter 15, Subsections 15.5.5 through 15.5.9 provides event analyses of Level D PIE DEC.

#### **3.6.3.2.5 Seismic Events**

Seismic design parameters and associated seismic events defined in Subsection 3.3.1 are used in qualification of mechanical system components. The magnitude of seismic events is determined by Ground Response Spectra accelerations applied to Building Structures and creating Amplified Response Spectra (ARS) accelerations at various building elevations where the components are located. These ARS accelerations are used in qualification of Mechanical systems and equipment and a determination of component and system structural and/or functional capacity is determined. Seismic Category A (passive components) require only structural code adequacy. Seismic Category B (active components) such as valves and pumps require both structural code adequacy and functional capacity under seismic demand. Chapter 3, Subsection 3.9.3 provides seismic qualification methodology to assure both component structural and/or functional capacity under seismic operational conditions are met.

The seismic categorization of SSC is defined in Section 3.2 and related to the seismic category to the more general safety strategy defense lines. In summary, Defense Lines 3 and 4b are generally Seismic A or B and Defense Line 4b also has an additional requirement of satisfying the plant-level High Confidence of Low Probability of Failure (HCLPF) criteria.

#### **3.6.3.2.6 Non-LOCA Fault**

Non-LOCA Fault consists of any DEC event not considering a LOCA which has a significantly low frequency of occurrence to be considered as a faulted event.

#### **3.6.3.2.7 Plant Testing**

Plant testing events are occasional operating loads imposed during pre-operational testing or periodic operational testing.

### **3.6.3.3 Classification of Components**

All SSC of the BWRX-300 design are designated by Safety Class, Quality Group, and Seismic Category according to guidance in Section 3.2 which are consistent with their Defence-in-Depth categorization defined in the BWRX-300 Safety Strategy, in Section 3.1. Appendix 3A provides the Classification Table for Plant SSC.

### **3.6.3.4 Establishment of Design, Service, and Test Loadings and Limits**

Design, Service, and Test Loadings and Limits for fixed equipment components and supports are in accordance with ASME BPVC Section III Division 1 (Reference 3.6-5).

For IEEE Equipment, SC1 electrical equipment is evaluated with respect to the load combinations in this document using IEC/IEEE 60980--323 and IEC/IEEE 60980--344 Acceptance Criteria, Codes and Standard (References 3.6-18 and 3.6-19).

For SC1, actuators and power operated valve assemblies are evaluated with respect to the load combinations in this document in accordance with the provisions of ASME Standard QME-1.

### **3.6.3.5 Acceptance Criteria**

Components and supports comply with the design rules established for design, service, and test loadings in the appropriate with the appropriate subsection of the ASME BPVC, Section III, Division 1 (References 3.6-1 through 3.6-8).

Design documentation is completed in accordance with the requirements of the Subsection of the ASME BPVC applicable to the component or support.

### **3.6.3.6 Loading Criteria**

#### **3.6.3.6.1 Loading Conditions**

The loadings that are considered in designing a component include, but are not limited to, those in (a) through (g) below:

- a. Internal and external pressure
- b. Impact loads, including rapidly fluctuating pressures
- c. Weight of the component and normal contents under operating or test conditions
- d. Superimposed loads such as other components, operating equipment, insulation, corrosion resistant or erosion resistant linings, and piping
- e. Wind loads, snow loads, vibrations, and earthquake loads, where specified
- f. Reactions of supporting lugs, rings, saddles, or other types of supports
- g. Temperature effects

As appropriate ASME BPVC, Division 1, Section III, Paragraph, NB-3111, NCD-3111, NE-3111, NF-3111 or NG-3111, is applied for a complete list of required load conditions to consider.

Consistent with the ASME BPVC Section III Division 1, the stresses resulting from differential anchor movements during dynamic events are considered secondary stresses.

#### **3.6.3.6.2 Design Loadings**

The Design Loadings are established in accordance with ASME BPVC Section III Division 1, Paragraph NB-3112, NCD-3112, NE-3112, NF-3112 or NG-3112, as applicable.

#### **3.6.3.6.3 Service Conditions**

The Design Loadings are established in accordance with ASME BPVC Section III Division 1, Paragraph NB-3113, NCD-3113, NE-3113, NF-3113 or NG-3113, as applicable.

Each service condition to which the components may be subjected is classified in accordance with Service Limits designated in the Component Design Specifications in such detail as will provide a complete basis for design, construction, and inspection.

For ASME BPVC Section III Division 1, Class 1 Components, the requirements of (1) and (2) below apply.

1. Level B Conditions. The estimated duration of service conditions for which Level B Limits are specified are included in the Design Specifications.
2. Level C Conditions. The total number of postulated occurrences for all specified service conditions for which Level C Limits are specified are limited to no more than 25 stress cycles having a  $S_a$  value greater than that for  $10^6$  cycles from the applicable fatigue design curves of Section III Appendices, Mandatory Appendix I.

When the Component Design Specification requires computations to demonstrate compliance with specified Service Limits, the Component Design Specification provides information from which Service Loadings can be identified (pressure, temperature, mechanical loads, cycles, or transients).

**Design Pressure** - The specified internal and external Design Pressure is not to be less than the maximum difference in pressure between the inside and outside of the item, or between any two chambers of a combination unit, which exists under the most severe loadings for which the Level A Service Limits are applicable.

The Design Pressure includes allowances for pressure surges.

**Design Temperature** - Except as otherwise defined in ASME BPVC, Division 1, NB-3112 for Class 1 components, the specified Design Temperature is not less than the expected maximum mean metal temperature through the thickness of the part considered for which Level A Limits are specified.

**Design Mechanical Loads** - The specified Design Mechanical Loads are in accordance with NCA-2142.1C.

#### **3.6.3.6.4 Test Loadings**

**Test Pressure** - The specified internal and external test pressures are as required by the ASME BPVC, Section III, Division 1.

**Test Loads** - Loads due to other types of required tests are included as required by the ASME BPVC, Section III, Division 1.

**Test Temperature** - Test temperature is defined to ensure that thermal effects are considered in test loads.

#### **3.6.3.7 Loading Phenomena**

Section 3.6.3.7 describes the types of load phenomena, that is considered for components, as applicable.

##### **3.6.3.7.1 Flow Induced Vibration**

Flow of fluids past objects creates local pressure disturbances, which exert forces on the object. These forces can cause dynamic responses depending on the forcing function and dynamic characteristics of the object. Flow induced vibrations have been noted in nuclear power plant systems, which produce vortex shedding (e.g., heat exchangers), pump (reciprocating or centrifugal), and thermodynamic instability conditions. Design changes are reviewed for potential FIV mechanisms, evaluating all modes of system operation including both normal and abnormal conditions. Requirements for vibration monitoring are not within the scope of this document.

FIV loads may be associated with Service Level A for those structures (e.g., reactor internals) where the loads exist during normal operation. For FIV loads associated with transients that are not considered part of normal operation, the FIV loads are evaluated as part of the alternative service level.

#### **Vortex Shedding**

Vortex shedding occurs at certain fluid velocities when a fluid flows past objects. The dynamic response is controlled by proper spacing of the support plates for the tube bundle. The vibration cannot be eliminated but it can usually be controlled. It is important that these cases consider all potential modes of component operation. Vortex shedding hydrodynamic mass effects are

considered. Other components susceptible to flow induced vibration are pressure, flow, and temperature sensors, which encroach upon the flow stream.

### **Pressure Fluctuations**

Pressure fluctuations in a vapor or gas-state fluid (e.g., steam) occur due to flow past branch piping connections and branch connected components (e.g., safety valve “bell chamber” resonance), flow through short radius elbow fittings that induce flow separation effects, flow passing through valve chambers, flow past sharp-edged in-line pipe components (e.g., orifices, weld joint backing rings, valve seat rings), or two or more individual flows entering a common header or drum that generates an acoustic response. These various flow disturbances generate acoustic waves that can travel forward and backward in a piping system. If of sufficient strength and at a component’s susceptible frequency, these acoustic resonances can cause cyclic fatigue and result in component failure.

Pumps create pressure fluctuations in a fluid system. In most system designs, these fluctuations are insignificant. However, the possibility exists that these fluctuations, coupled with unintentional but improper system or component structural characteristics, can cause resonant vibrational response in the system or component. Component structural characteristics are designed to assure a resonance value sufficiently high to avoid excitation by evaluated system fluid fluctuations. Pressure attenuation devices are used as applicable to significantly reduce the effects of this phenomenon.

### **Thermodynamic Instability**

Under certain system design features and operating modes, fluid dynamic forces can be generated, which create large pressure variations. These have been noted in certain feedwater systems where a relatively cold fluid layer is in contact with a relatively hot steam region; under certain operating modes significant water-hammer-type phenomena have occurred causing a breach of the pressure-retaining boundary.

#### **3.6.3.7.2 Rapid Valve Closure or Opening**

Extremely rapid valve closure or opening in a fluid system can create large pressure waves which can propagate through a piping system and into connected components. This rapid motion could be caused by operating characteristics of the valve (e.g., stiffness of diaphragm in pneumatic operators), the fluid flow forces acting on the valve parts during all modes of operations.

For example, TSV closure has been identified as being capable of generating large pressure waves which could cause significant dynamic response. Prior to TSV closure, saturated steam flows through main steam piping at nuclear boiler rated pressure and mass rate. Steam flow to the turbine comes to a stop at the instant the turbine stop valve closes. The flow of steam travels in the main steam line through the vessel nozzle and into the vessel. This results in a compressive acoustic load on steam dryer outer hood, as well as steam impingement load on steam dryer outer hood. Additionally, repeated reflections of the compression wave in the main steam line generate time-varying forces in the main steam piping. System, components, and structures in the Reactor Building, Steam Tunnel and Turbine Building may be affected.

#### **3.6.3.7.3 Isolation Condenser Operation**

The thermal effects associated with operation of ICS and the loads such as pressure resulting from operation of ICS are considered. Loads associated with the breaks of ICS high pressure lines in the pool are considered. The major loads imposed on ICS result from:

- Sudden reactor isolation at power operating conditions
- During station blackout (i.e., unavailability of all alternate current power)

- Failure to Scram
- LOCA

#### **3.6.3.7.4 Failures of High-Energy Fluid System Piping**

The effects of postulated pipe breaks in high-energy fluid systems as well as measures used to protect SSCs are defined in Subsection 3.4.4.

#### **3.6.3.7.5 Failures of Moderate-Energy Fluid System Piping**

The effects of postulated pipe cracks in moderate-energy fluid systems as well as measures used to protect SSCs are defined in Subsection 3.4.4.

#### **3.6.3.7.6 Fuel Lift Loads**

Fuel lift is the postulated process under which a combination of vertical motion of the RPV support, scram uplift forces on the fuel assemblies and vertical hydraulic forces result in fuel assemblies lifting off from their seating surfaces on the fuel support. The reaction load of the fuel on the core support structures is considered.

#### **3.6.3.8 Safety Class Functional Criteria**

For any normal or off-normal design condition event, safety class equipment and piping can accomplish the safety class functions as required by the event and incurring no permanent changes that could deteriorate the ability to accomplish safety class functions as required by any subsequent design-condition event.

For any emergency or faulted design-condition event, safety class equipment, and piping are capable of accomplishing their safety class functions as required by the event, but repairs could be required to ensure their ability to accomplish safety class functions as required by any subsequent design-condition event.

#### **3.6.3.9 Reactor Pressure Vessel Assembly**

The reactor vessel assembly includes: the RPV pressure boundary out to and including the nozzles, the RIV's, and the housings for FMCRD and nuclear instrumentations. The RPV assembly is an ASME BPVC Section III, Division 1, Class 1.

The feedwater nozzle design does not allow incoming feedwater flow to have direct contact with the nozzle bore region. A double thermal sleeve design provides protection against thermal cycling on the nozzle bore. The ICS Condensate Return nozzles use a similar single thermal sleeve design to mitigate thermal cycling of the nozzle bore during initial IC train operation when accumulated condensate is draining.

The stress analysis is performed on the RPV for various plant operating conditions (including faulted conditions) by using elastic methods, except as noted in Subsection 3.6.1.4.3. Loading conditions, design stress limits, and methods of stress analysis for the core support structures and other reactor internals are provided in Table 3.6-2.

The RPV internals are classified in Chapter 3, Section 3.2, and Appendix 3A. Complete stress reports on these components are prepared in accordance with the ASME BPVC Section III, Division 1, requirements.

#### **3.6.3.10 Main Steam Piping**

The MS piping trains extending from the outboard MSRIV to and including Seismic Interface Restraints (SIR) that are outboard of the MSCIVs are designed and constructed in accordance with the ASME BPVC Section III Division 1 rules for Class 2 Nuclear Components. Stresses are

calculated on an elastic basis for each service level and evaluated in accordance with NCD-3600 of the ASME BPVC Section III Division 1. Table 3.6-11 shows the specific load combinations and acceptance criteria for Class 2 piping that apply to this piping.

The MSCIVs, are designed and constructed in accordance with the ASME BPVC III Division 1, NCD-3500 requirements for Class 2 components.

The MS system piping extending from the outboard SIR to the turbine stop valve is constructed in accordance with the ASME B31.1 Criteria.

### **3.6.3.11 Other Components**

#### **3.6.3.11.1 Isolation Condenser System (ICS) Condenser and Piping**

The ICS piping inside the primary containment between the RPV and the Isolation Condenser Heat Exchanger is designed and constructed in accordance with the ASME BPVC Section III Division 1 requirements for Class 1 piping. The isolation condenser and piping outside containment are designed and constructed in accordance with ASME BPVC Section III Division 1 Class 2 requirements.

#### **3.6.3.11.2 CUW System Heat Exchangers**

The CUW heat exchangers (regenerative) are not part of a safety system. However, the heat exchangers are Seismic Category NS equipment. The ASME BPVC Section III Division 1 requirements for Class 3 components are used in the design and construction of the CUW System heat exchanger components.

#### **3.6.3.11.3 SDC System Pump and Heat Exchangers**

The SDC heat exchangers (nonregenerative) are not part of a safety system. However, the pumps and heat exchangers are Seismic Category NS equipment respectively. The ASME BPVC Section III Division 1 requirements for Class 3 components are used in the design and construction of the SDC System pump and heat exchanger components.

#### **3.6.3.11.4 ASME BPVC Section III Division 1, Class 2 and 3 Vessels**

ASME BPVC Section III Division 1, Class 2 and 3 vessels are constructed in accordance with the ASME BPVC Section III Division 1. The analysis of these vessels is performed using elastic methods.

#### **3.6.3.11.5 ASME BPVC Section III Division 1, Class 1, 2 and 3 Valves**

ASME BPVC Section III Division 1, Class 1, 2, and 3 valves are constructed in accordance with the ASME BPVC Section III Division 1.

All valves and their extended structures are designed to withstand the accelerations due to seismic and other RBV loads. The analysis of these valves is performed using elastic methods. Refer to Subsection 3.6.3.9 for additional information on valve operability.

#### **3.6.3.11.6 ASME BPVC III Division 1, Class 1, 2 and 3 Piping**

ASME BPVC Section III Division 1, Class 1, 2 and 3 piping is constructed in accordance with the ASME BPVC Section III Division 1. For ASME BPVC Section III Division 1, Class 1 piping, stresses are calculated on an elastic basis and evaluated in accordance with NB-3600 of the ASME BPVC Section III Division 1, and fatigue usage is determined. For ASME BPVC Section III Division 1, Class 2 and 3 piping, stresses are calculated on an elastic basis and evaluated in accordance with NCD-3600 of the ASME BPVC Section III Division 1. If a NB-3600 analysis is performed for ASME BPVC Section III Division 1, Class 2 or 3 pipe, all analyses required for ASME BPVC Section III Division 1, Class 1 pipe as specified in this document and the ASME

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

BPVC is performed. Tables 3.6.10 and 3.6.11 shows the specific load combinations and acceptance criteria for ASME BPVC Section III Division 1, Class 1, 2, and 3 piping systems.

### **3.6.3.12 Valve Operability Assurance**

This subsection discusses operability assurance of active ASME BPVC Section III Division 1 valves, including actuators (Refer to Subsection 3.9.6.2).

Valves that perform an active Safety Category 1 function are functionally qualified to perform their required functions. For valve designs developed for the BWRX-300 that were not previously qualified, the qualification programs meet the requirements of ASME QME-1 (For valve designs previously qualified to standards other than ASME QME-1), the following approach is used:

1. Qualification specifications (e.g., design specifications) consistent with Appendices QV-I and QV-A of QME-1 are prepared to ensure the operating conditions and safety class functions for which the valves are to be qualified are communicated to the manufacturer or qualification facility.
2. Suppliers are required to submit, for review and approval, application reports, as described in QME-1, that describe the basis for the application of specific predictive methods and/or qualification test data to a valve application.
3. The application reports provided by the suppliers are reviewed for adherence to specification requirements to ensure the methods used are applicable and justified and to verify any extrapolation techniques used are justified. A gap analysis is performed to identify any deviations from QME-1 in the valve qualification. Each deviation is evaluated for impact on the overall valve qualification. If the conclusion of the gap analysis is that the valve qualification is inadequate, then the valve may be qualified using a test-based methodology, as allowed by QME-1.

Functional qualification addresses key lessons learned from industry efforts, particularly on air- and motor-operated valves, many of which are discussed in Section QVG of QME-1. For example:

1. Evaluation of valve performance is based on a combination of testing and analysis, using design similarity to apply test results to specific valve designs.
2. Testing to verify proper valve setup and acceptable operating margin is performed using diagnostic equipment to measure stem thrust and torque, as appropriate.
3. Sliding friction coefficients used to evaluate valve performance (e.g., disk-to-seat friction coefficients for gate valves and bearing coefficients for butterfly valves) account for the effects of temperature, cycle history, load, and internal parts geometry.
4. Actuator sizing allows margin for aging/degradation, test equipment accuracy and other uncertainties, as appropriate.
5. Material combinations that may be susceptible to galling or other damage mechanisms under certain conditions are not used.

Subsection 3.9 provide details on the seismic qualification of valves and on the Environmental Qualification of valves.

The major safety class active valves are the RIVs, Condensate Return Valves and CIVs. These valves are designed to meet the ASME BPVC Section III Division 1 BPVC requirements and perform their mechanical motion in conjunction with a dynamic (SSE and other RBV) load event. The dynamic qualification for operability is unique for each valve type; therefore, each method of qualification is provided individually below.

### **3.6.3.13 Main Steam Containment Isolation Valves**

The MSCIVs are evaluated by analysis and test for capability to operate under the design loads that envelop the predicted loads during a Design Basis Accident (DBA) and DBE.

### **3.6.3.14 Other Active Valves**

Other safety class active valves are ASME BPVC Section III Division 1 Class 1, 2 or 3 and are designed to perform their mechanical motion during dynamic loading conditions. The operability assurance program ensures that these valves operate during a dynamic seismic and other RBV event.

#### **3.6.3.14.1 Procedures**

Qualification tests accompanied by analyses are conducted for all active valves. Procedures for qualifying electrical and instrumentation components, which are depended upon to cause the valve to accomplish its intended function, are developed to assure these functions are accomplished.

#### **3.6.3.14.2 Tests**

Prior to installation of the SC1 valves, the following tests are performed at the factory facility as required in the field:

- Shell hydrostatic test to the ASME BPVC Section III Division 1 requirements
- Seat leakage tests
- Obturator hydrostatic test
- Functional tests to verify that the valve opens and closes within the specified time limits when subject to the design differential pressure

The results of all required tests are properly documented and included as a part of the operability acceptance documentation package.

#### **3.6.3.14.3 Check Valves**

Due to the simple characteristics of the check valves, the active check valves are qualified by a combination of the following tests and analysis:

- Stress analysis including the dynamic loads where applicable
- In-shop hydrostatic tests
- In-shop seat leakage test

### **3.6.3.15 Qualification of Electrical and Instrumentation Components Controlling Valve Actuation**

A practical problem arises in attempting to describe tests for simple devices (e.g., relays, motors, sensors, etc.) as well as for complex assemblies such as control panels. It is reasonable to assume that a simple device, that is an integral part of an assembly, may be subjected to the same dynamic load tests while in an operating condition. Thus, the performance of a simple device may be monitored during the test. However, for complex panels, such a test is not always practical. In this situation, the following alternate approach may be followed.

The individual devices are tested separately in an operating condition and the test levels recorded as the qualification levels of the devices. The panel, with similar but inoperative devices installed, is vibration tested to determine if the panel response accelerations. Installing the non-operating devices assures that the test panel has representative structural characteristics of a production

panel. The accelerations are measured by accelerometers installed at the device attachment locations. The accelerations are less than the levels at which the devices were qualified. If the acceleration levels at all the device locations are found to be less than the levels to which the devices are qualified, then the total assembly is considered qualified. Otherwise, either the panel is redesigned to reduce the acceleration level to the device locations and retested, or the devices are requalified to the higher levels.

#### **3.6.3.16 Design of Pressure Relief Devices**

The NBS system does not utilize safety or relief valves for overpressure relief. During normal operation, the mainsteam flow to the turbine is throttled to control system pressure. Chapter 6, Section 6.2 describes the method of overpressure relief.

#### **3.6.3.17 Component Supports**

The establishment of the design/service loadings and limits is in accordance with the ASME Section III, Division 1, Article NCA-2000 and Subsection NF. These loadings and stress limits apply to the structural integrity of components and supports when subjected to combinations of loadings derived from plant and system operating conditions and postulated plant events. The combination of loadings and stress limits are included in the Design Specification of each component and support.

ASME Section III component supports are designed, manufactured, installed, and tested in accordance with all applicable codes and standards. Supports include hangers, snubbers, struts, spring hangers, frames, energy absorbers and limit stops, Pipe whip restraints are not considered as pipe supports.

The design of bolts for component supports is specified in the ASME BPVC III Division 1, Subsection NF. Stress limits for bolts are given in NF-3225. The rules and stress limits which must be satisfied are those given in NF-3324.6 multiplied by the appropriate stress limit factor for the particular service loading level and stress category specified in Table NF-3225.2-1.

#### **3.6.3.18 Piping Supports**

Supports and their attachments for ASME BPVC Section III Division 1 Class 1, 2, and 3 piping are designed in accordance with Subsection NF up to the interface of the building structure, with jurisdictional boundaries as defined by Subsection NF. The building structure component supports (connecting the NF support boundary component to the existing building structure) are designed as specified in Section 3.5.

The design of supports for the non-nuclear piping satisfies the requirements of ASME B31.1 Power Piping Code, Paragraphs 120 and.

#### **3.6.3.19 Reactor Pressure Vessel Stabilizer**

The RPV stabilizer is designed as a SC1 linear type component support in accordance with the requirements of ASME BPVC Section III Division 1 Subsection NF. The stabilizer provides a reaction point near the upper end and lower end of the RPV to resist horizontal loads caused by effects such as earthquake, pipe rupture, and RBV. The design loading conditions, and stress criteria and the calculated stresses will meet the ASME BPVC Section III Division 1 allowable stresses in the critical support areas for various plant operating conditions.

#### **3.6.3.20 Floor-Mounted Major Equipment**

The condenser modules in the Isolation Condenser System (ICS) are analyzed to verify the adequacy of their support structure under various plant operating conditions. The analysis applies

the maximum shear, moment, and accelerations calculated from the seismic response analysis for the Reactor Building at the attachment locations on the pool floor for the ICS.

In the ICS module analysis, no credit is taken for damping effects of the pool water. Additionally, the mass of the condensers is increased by an amount equivalent to the weight of water they displace. This conservative factor accounts for the hydrodynamic effects that include impulsive loads and convective loads (sloshing of the pool water).

In all cases, the load stresses in the critical support areas of the ICS modules are maintained within ASME BPVC Section III Division 1 allowable.

#### **3.6.3.21 Other ASME BPVC Component Supports**

The ASME BPVC Section III Division 1 component supports and their attachments (other than those discussed in the preceding subsection) are designed in accordance with ASME BPVC Section III Division 1, Subsection NF up to the interface with the building structure. The loading combinations for the various operating conditions correspond to those used to design the supported component. The component loading combinations are discussed in Table 3.6-2. Active component supports are discussed in Subsection 3.6.3.18. The stress limits are per ASME BPVC Section III Division 1, Subsection NF, and NB-3600 and NCD-3600. The supports are evaluated for buckling in accordance with ASME BPVC Section III Division 1.

### **3.6.4 Control Rod Drive System**

The CRD system consists of mechanical components that provide the means for movement of the control rods. The CRD system provides one of the independent reactivity control systems. The control rods and the drive mechanisms are capable of reliably controlling reactivity changes either under conditions of AOOs, or under DBA conditions. A positive means for inserting the rods is always maintained to ensure appropriate margin for malfunction, such as stuck rods. Because the CRD system is a safety class system and portions of the CRD system are a part of the RCPB, the system is designed, fabricated, and tested to quality standards commensurate with the safety class functions to be performed. This provides an extremely high probability of accomplishing the safety class functions either in the event of AOOs or in withstanding the effects of DBAs and natural phenomena such as earthquakes.

The CRD system includes the FMCRD mechanisms, the HCU assemblies, and the CRD hydraulic system. The system extends inside the RPV to the coupling interface with the control rod blades.

#### **3.6.4.1 Descriptive Information on Control Rod Drive System**

Descriptive information on the FMCRDs as well as the entire CRD system is contained in Chapter 4, Subsection 4.6.

#### **3.6.4.2 Applicable Control Rod Drive System Design Specification**

The CRD system, which is designed to meet the functional design criteria outlined in Chapter 4, Subsection 4.6.1, consists of the following:

- Electro-hydraulic fine motion control rod drive
- Hydraulic Control Unit (HCU)
- Hydraulic pumps
- Electric power supply R20 system to the FMCRD motors – CRD Boundary is at the motor
- Interconnecting piping

- Flow control valves
- Instrumentation

Those components of the CRD system forming part of the primary pressure boundary are designed according to ASME BPVC Section III Division 1 BPVC, Class 1 requirements.

The quality group classification of the components of the CRD system is outlined in Appendix 3A and are designed to the codes and standards in accordance with their individual quality groups.

Pertinent aspects of the design and qualification of the CRD system components are discussed in the following locations: transients in Chapter 3, Subsections 3.6.1.1, 3.6.3.6 and 3.6.3.7, faulted conditions in Chapter 3, Subsections 3.6.1.4.1 and 3.6.1.4.2, and seismic testing in Chapter 4, Subsections 4.6.1 and 4.6.2.

### **3.6.4.3 Design Loads and Stress Limits**

#### **3.6.4.3.1 Allowable Deformations**

The ASME BPVC Section III Division 1, Subsection NB components of the CRD system are evaluated analytically and the design loading conditions, and stress criteria are as given in Table 3.6-2.

### **3.6.5 Reactor Pressure Vessel Internals**

Reactor pressure vessel internals are described in Chapter 5, Section 5.4.

### **3.6.6 Functional Design, Qualification and In-service Testing Programs for Pumps, Valves, and Dynamic Restraints**

Chapter 3, Section 3.9, Equipment Qualification provides the methodology for qualification of Pumps and Valves. The qualification involves both determining component functionality while maintaining structural integrity. Seismic testing of components is performed as well as use of analytical methods.

Chapter 3, Subsection 3.6.3.17 discusses methodology for qualification of dynamic restraints.

In-service Testing Programs are developed for required operability and functional tests for components as described in Chapter 3, Subsection 3.10.3.

### **3.6.7 Piping Design**

The design of safety class piping systems, piping components and pipe supports is based on the code rules established under the ASME BPVC Section III, Division 1 code for Class 1, Class 2, and Class 3 nuclear piping, components and supports. For non-ASME Code class components, ASME B31.1 power piping, and ASME B31.3 process piping codes are used. Safety classifications of safety, seismic categories, and quality groups for piping SSCs are established within the system chapters. The simplified schematic diagrams within the system chapters identify the system safety class, seismic class, and quality boundaries. The functional, operational, and safety requirements are unique to each system and the required loading conditions are applied as specified in the specific ASME Code class sections.

#### **3.6.7.1 ASME Class 1 Piping Design Rules and Analysis**

ASME Class 1 piping design conforms to the requirements of ASME BPVC Section III Division 1 Paragraph NB code rules that covers both piping and piping components. The pipe supports attached to the ASME Class 1 piping meet the appropriate requirements of ASME BPVC Section III Division 1, Paragraph NF. The anchor sleeve of the containment structure penetrations meets the requirements of ASME BPVC Section III Division 1, Paragraph NE (Reference 3.6-6).

#### **3.6.7.1.1 Overpressure Protection**

The details and certification of Overpressure Protection design for each piping system are in the System Overpressure Protection Reports.

#### **3.6.7.1.2 Boundaries**

The boundaries of the Class 1 piping in each system are outlined in the system Piping and Instrumentation Diagrams (P&IDs).

Support design jurisdictional boundaries at interfaces between piping and structure by intervening elements that are defined per ASME BPVC Section III Division 1 - Subsection NF – Supports, Subarticle NF-1130. If piping supports transmit loads to surface-mounted baseplates as discussed in Subparagraph NF-1132(d), the baseplates are within the building structure jurisdiction.

Where ASME BPVC Section III Division 1 Class 2 piping is connected to ASME BPVC Section III Division 1 Class 1 piping, the rules for expansion and flexibility for A ASME BPVC Section III Division 1 Class 1 piping applies out to the first anchor in the ASME BPVC Section III Division 1 Class 2 piping system. However, the resulting solution of forces and moments are used to evaluate stresses in accordance with the allowable criterion of ASME BPVC Section III Division 1 Subarticle NCD-3650.

#### **3.6.7.1.3 Classifications**

##### **Code Classification**

Piping that is classified as Quality Group A meets the requirements for ASME BPVC III Division 1 Class 1 components provided in ASME BPVC Section III Sub Article NB-3600.

The pipe supports attached to Quality Group A piping meet the appropriate requirements of ASME BPVC Section III Paragraph NF.

##### **Seismic Classification**

Seismic categories are to be in accordance with those listed on the system P&ID.

##### **Energy (High/Moderate) Classification**

Piping is classified as High or Moderate-Energy for use in pipe failure postulation. Refer to Section 3.4.4.2 for further explanation.

#### **3.6.7.1.4 Material Requirements**

The material properties used in Class 1 analyses is in accordance with ASME BPVC Section II – Materials – Part D – Properties (Metric).

##### **Examination and Repair**

The examination and repair of all Class 1 materials and welds is performed using the methods and acceptance standards as specified in ASME BPVC Section III Subarticle NB-2500.

In-service inspection requirements for Class 2 and 3 piping and components are defined in Subsection 3.10.5.

##### **Fracture Toughness Requirements**

Pressure-retaining ferritic material, and material welded thereto are impacted tested in accordance with the requirements of NB-2300 and NB-2400 to ensure adequate fracture toughness properties.

#### **3.6.7.1.5 Design Conditions**

##### **Design Service Life**

The design service life of the BWRX-300 Nuclear Power Plant is 60 operational years. Additional time in-service for startup and decommissioning activities is included as applicable.

##### **Design Pressure and Temperatures**

The design pressures and temperatures of each piping system are identified in the respective system design documentation.

##### **Design Duty Cycles**

The pressure-temperature duty cycles to be used in the fatigue analysis are specified in the respective system Pressure-Temperature Duty Cycle drawings. Assumptions regarding the pressure and temperature cycles used to determine allowable stress reduction factors or any other analysis input are included in the design report with a basis of 60 years design life.

##### **Environmental Conditions**

All SC1 piping, and components, are capable of performing their safety class functions when exposed to specified environmental conditions specified in the Environmental Qualification Envelope. Piping system active components are environmentally qualified as specified in Subsections 3.9.3 and 3.9.4.

#### **3.6.7.1.6 Test Loads**

The only test loads on the piping system are due to hydrostatic testing. The loads due to hydrostatic testing are in accordance with NB-6000.

#### **3.6.7.1.7 Static Loads**

##### **Pressure**

The design pressure and operating pressure for each system/component are as specified in the respective system design documentation.

##### **Weight**

The weight of the piping system includes the weight of the pipe, in-line components, fluid contents, and insulation, as applicable. In addition, the weight of support components attached to the pipe are considered.

Support systems for piping that normally carries steam but will be filled with water during a hydrostatic test and/or refueling outage are designed to accommodate the increased weight.

##### **Thermal Expansion**

The analysis of thermal expansion includes all thermal operating modes, environmental conditions, cold water modes, and thermal attenuation.

Sufficient thermal expansion cases shall be established to account for various operating conditions and for calculating the range of thermal expansion stresses between all pairs of load sets.

The installation temperature for the piping systems is defined as a temperature of 21° C for Class 1 piping unless basis is provided to use a higher temperature. The ambient state shall be included as an analysis load set with defined cycles.

Applicable equipment nozzle movements are considered for their effect with respect to each operating mode.

Support movements due to thermal expansion are included in the design.

### **Thermal Attenuation/Stratification**

Thermal attenuation/stratification are considered in the design whenever fluids at different temperatures mix.

On run/branch connections where there is a closed valve and the resulting "dead leg" temperature tends toward ambient, the temperature distribution in the run/branch line are considered and properly included in the thermal expansion analysis.

#### **3.6.7.1.8 Dynamic Loads**

Dynamic loads include both the inertial effect and support displacements (i.e., anchor movement). Categories of loads and load conditions considered include (but are not limited to) the following:

- Seismic
- Loss-of-Coolant Accident Loads
- Reactor Pressure Vessel and Containment Isolation Valve Transients
- Thermal Stratification

#### **3.6.7.1.9 Plant Events and Load Combinations**

Plant states are based on expected frequency of occurrence of Postulated Initiating Events (PIEs) which are the plant events that lead to deviations from normal operation (AOOs, DBAs or DECAs depending on the additional failures that occur) and are related to ASME service levels as shown in Table 3.6-3.

Load combinations and acceptance criteria for the BWRX-300 Class 1 piping are provided in Table 3.6-10.

#### **3.6.7.1.10 Analytical Computer Codes Used for Piping Stress, Component Stress, and Support Structural Qualifications**

Chapter 3, Appendix 3C provides a listing of and description of applicable safety computer codes used for qualification of piping, mechanical components, and pipe supports.

#### **3.6.7.1.11 Analysis Methodology and Stress Reports**

Piping system stresses shall be calculated on an elastic basis for each service level.

For ASME BPVC Section III Division 1 Class 1 piping systems and components, stress reports are prepared in accordance with ASME BPVC Section III Division 1 Class 1 requirements and include applicable equipment qualification reports for active components.

### **3.6.7.2 ASME BPVC Section III Division 1 Class 2/3 Piping Design Rules and Analysis**

ASME BPVC Section III Division 1 Class 2/3 piping design conforms to the requirements of ASME BPVC Section III Division 1 Subsection NCD that covers both piping and piping components. Load combinations and acceptance criteria for the BWRX-300 Class 2 piping are provided in Table 3.6-11.

The containment penetration sleeve of ASME Class 2 piping is an anchor for the piping. The sleeve of the containment structure penetrations meets the requirements of ASME BPVC Section III Division 1, Subsection NE (Reference 3.6-6).

#### **3.6.7.2.1 Overpressure Protection**

The details and certification of Overpressure Protection design for each piping system are in the System Overpressure Protection Reports.

#### **3.6.7.2.2 Boundaries**

The boundaries of the Class 2 and 3 piping in each system are outlined in the system P&IDs and simplified diagrams shown in the system PSAR chapters.

Support design jurisdictional boundaries at interfaces with piping, structure, or intervening elements are defined in ASME BPVC Section III Division 1, Subsection NF-1130. If piping supports transmit loads to surface-mounted baseplates as discussed in Subsection NF-1132(d), the baseplates are within the building structure jurisdiction.

#### **3.6.7.2.3 Classifications**

##### **Code Classifications**

Detailed classifications of pipe and components are defined in the system design documents. Piping that is classified as ASME BPVC Section III Division 1 Class 2 or ASME BPVC Section III Division 1 Class 3 meet the requirements for ASME BPVC Section III Division 1 Class 2 and 3 components provided in Subsection NCD-3600 of the ASME Code.

Where ASME BPVC Section III Division 1 Class 2 piping is connected to ASME BPVC Section III Division 1 Class 1 piping, the rules for expansion and flexibility for Class 1 piping apply out to the first anchor in the ASME BPVC Section III Division 1 Class 2 piping system. However, the resulting solution of forces and moments are used to evaluate stresses in accordance with the allowable criterion of NCD-3650.

The pipe supports attached to the ASME BPVC Section III Division 1 Class 2 and 3 piping meet the appropriate requirements of Subsection NF of the ASME Code.

##### **Seismic Classification**

Seismic categories are to be in accordance with those listed on the system design documents.

##### **Energy (High/Moderate) Classification**

Piping is classified as High or Moderate-Energy for use in pipe failure postulation. Refer to Subsection 3.4.4.2 for further explanation.

#### **3.6.7.2.4 Materials**

##### **Material Specifications**

The material properties used in Class 2 or 3 analyses are in accordance with ASME BPVC Section II – Materials – Part D – Properties (Metric) (Reference 3.6-1).

##### **Examination and Repair**

The examination and repair of all Class 2 and 3 materials and welds are performed using the methods and acceptance standards as specified in NCD-2500.

In-service inspection requirements for Class 2 and 3 piping and components are defined in Subsection 3.10.5.

##### **Fracture Toughness Requirements**

Pressure-retaining ferritic material, and material welded thereto are impact tested in accordance with the requirements of NCD-2300 and NCD-2400 to ensure adequate fracture toughness properties.

#### **3.6.7.2.5    *Design Conditions***

##### **Design Service Life**

The design service life of the BWRX-300 Nuclear Power Plant is 60 operational years plus any additional time in-service for startup and decommissioning activities as applicable.

##### **Design Pressures and Temperatures**

The design pressures and temperatures of each piping system are identified in the respective system design documents.

##### **Design Duty Cycles**

Assumptions regarding the pressure and temperature cycles used to determine allowable stress reduction factors or any other analysis input are included in the design report with a basis of 60 years design life.

##### **Environmental Conditions**

All SC1 piping, and components, are capable of performing their Safety Category functions when exposed to the environmental conditions.

#### **3.6.7.2.6    *Design Input Loads***

##### **Test Loads**

The only test loads on the piping system are due to hydrostatic testing. The loads due to hydrostatic testing are in accordance with NCD-6000.

##### **Static Loads**

##### **Pressure**

The design pressure and operating pressure for each system/component are as specified in the respective System Line list.

##### **Weight**

The weight of the piping system includes the weight of the pipe, in-line components, fluid contents, and insulation, as applicable. In addition, the weight of support components attached to the pipe are considered.

Support systems for piping that normally carries steam but will be filled with water during a hydrostatic test and/or refueling outage are designed to accommodate the increased weight.

##### **Thermal Expansion**

The analysis of thermal expansion includes all thermal operating modes, environmental conditions, cold water modes, and thermal attenuation.

Sufficient thermal expansion cases are established to account for various operating conditions to determine the maximum range of thermal expansion stresses.

The installation temperature for the piping systems is defined as a temperature of 21 °C for Class 2 and 3 piping.

Applicable equipment nozzle movements are considered for their effect with respect to each operating mode.

Support movements due to thermal expansion are included in the design. Thermal anchor movements of less than 1.6 mm are considered negligible and do not need to be considered in the analysis.

### **Thermal Attenuation/Stratification**

Thermal attenuation/stratification are considered in the design whenever fluids at different temperatures mix.

On run/branch connections where there is a closed valve and the resulting "dead leg" temperature tends toward ambient, the temperature distribution in the run/branch line are considered and properly included in the thermal expansion analysis.

#### **3.6.7.2.7 Dynamic Loads**

Dynamic loads include both the inertial effect and support displacements (i.e., anchor movement).

Categories of loads and load conditions considered include (but are not limited to) the following:

- Seismic
- Loss-of-Coolant Accident Loads
- Turbine Stop Valve Closure
- Reactor Pressure Vessel and Containment Isolation Valve Transients

#### **3.6.7.2.8 Plant Events and Load Combinations**

Plant states are based on expected frequency of occurrence of Postulated Initiating Events (PIEs) which are the plant events that lead to deviations from normal operation (AOOs, DBAs or DECAs depending on the additional failures that occur) and are related to ASME service levels as shown in Table 3.6-3.

### **Load Combinations**

The load combinations and acceptance criteria in Table 3.6-11 are applicable to all ASME BPVC Section III Division 1 Class 2 and 3 piping systems, structures, and components.

#### **Load Combinations for Piping and Components**

The load combinations and acceptance criteria in Table 3.6-11 are applied to the analysis of ASME BPVC Section III Division 1 Class 2 and 3 piping systems and components.

#### **3.6.7.3 ASME B31.1 Piping Design Rules and Analysis**

Non-Safety class power piping conforms to ASME B31.1 code.

Load combinations and acceptance criteria for the BWRX-300 Class 1 piping are provided in Table 3.6-12.

Each Non-Safety class power piping systems includes the piping, pipe supports, penetrations, and welds joining the piping to adjacent components within the prescribed boundaries.

Descriptions of systems that contain ASME B31.1 piping and components including their functions are described in the system chapters.

##### **3.6.7.3.1 Overpressure Protection**

The details and certification of overpressure protection design for each piping system are in the System Overpressure Protection Reports.

##### **3.6.7.3.2 Boundaries**

The boundaries of the ASME B31.1 piping in each system are outlined in the respective system P&ID and indicated in the simplified diagrams provided in each chapter.

### **3.6.7.3.3 Classifications**

#### **Code Classification**

Detailed classifications of pipe and components are defined in the system design documents.

Portions of the ASME BPVC Section III Division 1 Class 2 or 3 piping system analysis may contain ASME B31.1 piping beyond a normally closed valve which may define the boundary out to the first anchor in the ASME B31.1 piping system.

The pipe supports attached to the ASME B31.1 piping meet the appropriate requirements of ASME B31.1.

#### **Seismic Classification**

Seismic categories are to be in accordance with those listed on the system design documents.

#### **Energy (High/Moderate) Classification**

Piping is classified as High or Moderate-Energy for use in pipe failure postulation. Refer to Subsection 3.4.4.2 for further explanation.

### **3.6.7.3.4 Materials**

#### **Material Specifications**

The material properties used in ASME B31.1 system analysis are in accordance with ASME B31.1.

#### **Examination and Repair**

The examination and repair of all ASME B31.1 piping materials and welds are performed using the methods and acceptance standards as specified in ASME B31.

The recommended practice for operation, maintenance, and modification of ASME B31.1 piping, and components is in accordance with the applicable local jurisdiction standard and code.

#### **Fracture Toughness Requirements**

The requirements of ASME B31T, *Standard Toughness Requirements for Piping*, Paragraphs 3, 4, and Appendix A are met.

### **3.6.7.3.5 Design Conditions**

#### **Design Service Life**

The design service life of the BWRX-300 Nuclear Power Plant is 60 operational years plus any additional time in-service for startup and decommissioning activities as applicable.

#### **Design Pressures and Temperatures**

The design pressures and temperatures of each piping system are identified in the respective system design documents.

#### **Design Duty Cycles**

Assumptions regarding the pressure and temperature cycles used to determine allowable stress reduction factors or any other analysis input are included in the design report with a basis of 60 years design life.

#### **Environmental Conditions**

Consideration of environmental conditions for functional qualification is not applicable to ASME B31.1 piping systems.

Recommended practices related to the protection of piping systems against detrimental effects of environmental conditions are provided in ASME B31.1 Appendices IV and V.

#### **3.6.7.3.6 Design Input Loads**

##### **Test Loads**

The only test loads on the piping system are due to hydrostatic testing.

##### **Static Loads**

###### **Pressure**

The design pressure and operating pressure for each system/component are as specified in the respective Process Flow Diagram.

###### **Weight**

The weight of the piping system includes the weight of the pipe, in-line components, fluid contents, and insulation, as applicable. In addition, the weight of support components attached to the pipe is considered.

Support systems for piping that normally carries steam but will be filled with water during a hydrostatic test and refueling outage is designed to accommodate the increased weight.

###### **Thermal Expansion**

The analysis of thermal expansion includes all thermal operating modes, environmental conditions, cold water modes, and thermal attenuation.

Sufficient thermal expansion cases are established to account for various operating conditions to determine the maximum range of thermal expansion stresses.

The installation temperature for the piping systems is defined as a temperature of 21° C for non-nuclear (ASME B31.1) piping.

Applicable equipment nozzle movements are considered for their effect with respect to each operating mode.

Support movements due to thermal expansion are included in the design. Thermal anchor movements of less than 1.6 mm are considered negligible and do not need to be considered in the analysis.

###### **Thermal Attenuation/Stratification**

Thermal attenuation/stratification are considered in the design whenever fluids at different temperatures mix.

On run/branch connections where there is a closed valve and the resulting "dead leg" temperature tends toward ambient, the temperature distribution in the run/branch line are considered and properly included in the thermal expansion analysis.

#### **3.6.7.3.7 Dynamic Loads**

Dynamic loads include both the inertial effect and support displacements (i.e., anchor movement). Categories of loads and load conditions considered include (but are not limited to) the following:

- Seismic
- Turbine Stop Valve Closure
- Reactor Pressure Vessel and Containment Isolation Valve Transients

#### **3.6.7.3.8 *Plant Events and Load Combinations***

Plant states are based on expected frequency of occurrence of Postulated Initiating Events (PIEs) which are the plant events that lead to deviations from normal operation (AOOs, DBAs or DECAs depending on the additional failures that occur) and are related to ASME service levels as shown in Table 3.6-3.

#### **Load Combinations**

The load combinations and acceptance criteria presented in this specification are applicable to all ASME B31.1 piping systems, structures, and components within the scope of this document.

#### **Load Combinations for Piping and Components**

The load combinations and acceptance criteria in Table 3.6-12 are applied to the analysis of ASME B31.1 piping systems and components.

### **3.6.8 Threaded Fasteners – Codes for ASME BPVC Section III Division 1 Class 1, 2, and 3**

#### **3.6.8.1 Material Selection**

Material used for threaded fasteners complies with the requirements of ASME BPVC Section III Division 1 Article NB-2000, NCD-2000, or NF-2000 as appropriate. Fracture toughness testing is performed in accordance with ASME BPVC Section III Division 1 Subarticle NB-2300, or NCD-2300, as appropriate. For verification of conformance to the applicable ASME BPVC requirements, a chemical analysis is required for each heat of material and testing for mechanical properties is required on samples representing each heat of material and, where applicable, each heat-treat lot.

The criteria of ASME BPVC Section III Division 1 Subarticle NB-2200, or NCD-2200, rather than the material specification criteria applicable to the mechanical testing is applied if there is a conflict between the two sets of criteria. For threaded fasteners, documentation related to fracture toughness (as applicable) and certified material test reports are provided as part of the ASME BPVC Section III Division 1 records that are provided at the time the parts are shipped and are part of the required records that are maintained at the site.

Threaded fasteners are selected for compatibility with the materials of the component being joined and the piping system fluids. The selection process considers deterioration that may occur during service as a result of corrosion, radiation effects, or instability of material.

#### **3.6.8.2 Special Materials Fabrication Processes and Special Controls**

The design of threaded fasteners complies with ASME BPVC Section III Division 1 Article NB-3000 or NCD-3000, as appropriate. Fabrication of threaded fasteners complies with ASME BPVC Section III Division 1 Article NB-4000, NCD-4000, as appropriate. Inspection of threaded fasteners complies with ASME BPVC Section III Division 1 NB-2500, or NCD-2500, as applicable.

#### **3.6.8.3 Pre-service and In-service Inspection Requirements**

Pre-service and In-service requirements of ASME BPVC Section III Division 1 Class 1, 2, and 3 Mechanical Systems and Components are based on a graded approach with SC1 equipment receiving the most pre-service required qualification. Chapter 3, Section 3.9 Equipment Qualification provides the required qualifications and tests for safety components. Chapter 3, Subsection 3.10.5 provides the In-service Inspection requirements for SSCs.

**Table 3.6-10: Load Combinations and Acceptance Criteria for ASME  
BPVC Section III Division 1 Class 1 Piping Systems**

Condition	Load Combination for all Terms <sup>(2)(3)</sup>	Acceptance Criteria per ASME Code <sup>(1)(4)</sup>
Design	PD + WT	NB-3652
Service Level A and B <sup>(5)</sup>	PP, TE, $\Delta T1$ , $\Delta T2$ , TA-TB, AOO, DBEI, DBED	NB-3653
Service Level B	PP + WT + AOO	NB-3654
Service Level C	PP + WT + DBA Where DBA includes but is not limited to: LOCA DBE	NB-3655
Service Level D	PP + WT + DEC Where DEC includes but is not limited to: SRSS (DBE+LOCA)	NB-3656

(1) Fatigue usage and stress limits are reduced for piping locations exempt from pipe break consideration.

(2) Where:

- a. WT = Dead Weight
- b. PD = Design Pressure
- c. PP = Peak Pressure or the Operating Pressure Associated with that transient
- d. DBEI = Design Basis Earthquake (inertia Effect)
- e. DBED = Design Basis Earthquake (Anchor Displacement Loads)
- f. DBE = Design Basis Earthquake includes both DBEI and DBED which are combined using SRSS method
- g. AOO = Anticipated Operational Occurrence
- h. DBA = Design Basis Accident
- i. DEC = Design Extension Condition

(3) LOCA is intended to represent loads and the appropriate combination of loads resulting from postulated line breaks including but not limited to Acoustic Inertial, Jet Reaction, and Jet Impingement loads

(4) ASME BPVC SECTION III NB-2021

(5) DBEI and DBED are Service Level C loads but must be considered for fatigue usage.

(4) ASME BPVC SECTION III NCD-2021

(5) Stress limits are reduced for piping locations exempt from pipe break consideration.

**Table 3.6-12: Load Combinations and Acceptance Criteria for Non-Safety Class Power Piping Systems**

Description	Load Combination	Acceptance Criteria per ASME Code <sup>(2)</sup>
Sustained	Design Pressure + Weight + other Sustained Loads	Paragraphs 102.3 and 104.8.1
Occasional	Design Pressure + Weight + Other Sustained Loads + Seismic	Paragraphs 102.3 and 104.8.2
Occasional	Design Pressure + Weight + Occasional event other than Seismic	Paragraphs 102.3 and 104.8.2
Thermal	Displacement Load Ranges	Paragraphs 102.3 and 104.8.3
Test	Test Pressure + Weight	Paragraph 102.3.3

(1) Stated in CSA N289.3: Clause 7.5.1 (Reference 3.6-15). For Class 6 piping in accordance with ASME B31.1-2020 rules, the k factor in the equation for stresses due to occasional loads including seismic loading is increased to 1.8. Alternatively, a conservative approach can be adopted in which the seismic stresses in the stress combination for occasional loads can be multiplied by factor 2/3 with the k factor equal to 1.2.

(2) ASME B31.1-2020

### **3.7 General Design Aspects for Instrumentation and Control Systems and Components**

The BWRX-300 Distributed Control and Information System (DCIS) is an integrated control and monitoring system for the power plant. The DCIS is arranged in three safety classified DCIS segments that have appropriate levels of hardware and software quality corresponding to the system functions they control and their allocation to the Defense Lines (DL). The DCIS provides control, monitoring, alarming and recording functions. Although normally integrated, the various components of the DCIS are designed to operate independently.

The relationship between Instrumentation and Control (I&C) Functions and plant-level DLs is described in Chapter 7, Section 7.1.1. The classification of I&C systems is described in Chapter 7, Section 7.1.2, and is based on the general classification criteria described in Sections 3.2.1 and 3.2.2. The I&C system of systems is described in Chapter 7, Section 7.2. The individual I&C systems are described in Chapter 7, Section 7.3.

#### **3.7.1 Performance**

The system design bases, and associated safety functions, are described for the DL3 systems in Chapter 7, Subsection 7.3.1.2, for the DL4a systems in Subsection 7.3.2.2, for the DL2 systems in Subsection 7.3.3.2, and for the non-classified systems in Subsection 7.3.4.2.

#### **3.7.2 Design for Reliability**

The system reliability requirements and associated design features are described for the DL3 systems in Chapter 7, Subsection 7.3.1.3.2, for the DL4a systems in Subsection 7.3.2.3.2, for the DL2 systems in Subsection 7.3.3.3.2, and for the non-classified systems in Subsection 7.3.4.3.2.

#### **3.7.3 Independence**

The system independence requirements and associated design features are described for the DL3 systems in Chapter 7, Subsection 7.3.1.3.3, for the DL4a systems in Subsection 7.3.2.3.3, for the DL2 systems in Subsection 7.3.3.3.3, and for the non-classified systems in Subsection 7.3.4.3.3.

#### **3.7.4 Qualification**

The system qualification requirements are described for the DL3 systems in Chapter 7, Subsection 7.3.1.3.1, for the DL4a systems in Subsection 7.3.2.3.1, for the DL2 systems in Subsection 7.3.3.3.1, and for non-classified systems in Subsection 7.3.4.3.1.

#### **3.7.5 Verification and Validation**

The system verification and validation requirements for I&C systems are described in Chapter 7, Section 7.4.3.

#### **3.7.6 Failure Modes**

The application of the single failure criterion to DL3 systems is described in Chapter 7, Subsection 7.3.1.3.3. The effects of failures and associated design features to minimize or eliminate adverse effects of anticipated failures are described for the DL4a systems in Subsection 7.3.2.3.3, for the DL2 systems in Subsection 7.3.3.3.3, and for the non-classified systems in Subsection 7.3.4.3.3.

The use of diversity to eliminate common cause failure vulnerabilities or minimize the effects of postulated common cause failures is described for the DL3 systems in Chapter 7, Subsection 7.3.1.3.5, for the DL4a systems in Subsection 7.3.2.3.5, for the DL2 systems in Subsection 7.3.3.3.5, and for the non-classified systems in Subsection 7.3.4.3.5.

### **3.7.7 Control of Access to Equipment**

The system security requirements (including control of access) are described for the DL3 systems in Chapter 7, Subsection 7.3.1.3.4, for the DL4a systems in Subsection 7.3.2.3.4, for the DL2 systems in Subsection 7.3.3.3.4, and for the non-classified systems in Subsection 7.3.4.3.4.

### **3.7.8 Quality**

The codes and standards used for the I&C systems are described in Chapter 7, Section 7.1.3. The system quality requirements are described for the DL3 systems in Chapter 7, Subsection 7.3.1.3.1, for the DL4a systems in Subsection 7.3.2.3.1, for the DL2 systems in Subsection 7.3.3.3.1, and for the non-classified systems in Subsection 7.3.4.3.1.

### **3.7.9 Testing and Testability**

The system testing requirements (including design features to support testability) are described for the DL3 systems in Chapter 7, Subsection 7.3.1.3.2, for the DL4a systems in Subsection 7.3.2.3.2, for the DL2 systems in Subsection 7.3.3.3.2, and for the non-classified systems in Subsection 7.3.4.3.2.

### **3.7.10 Maintainability**

The system maintainability requirements and associated design features are described for the DL3 systems in Chapter 7, Subsection 7.3.1.3.2, for the DL4a systems in Subsection 7.3.2.3.2, for the DL2 systems in Subsection 7.3.3.3.2, and for the non-classified systems in Subsection 7.3.4.3.2.

### **3.7.11 Identification of Items Important to Safety**

The I&C system classification information is described in Section 7.1.2.

### **3.8 General Design Aspects for Electrical Systems and Components**

The BWRX-300 electrical power system has been designed as a minimum to meet the requirements of CNSC REGDOC 1.1.2 and CNSC REGDOC 2.5.2.

The electrical power system design is a 60 Hz Alternating Current (AC) power system, with 4.16 kV for the Medium Voltage (MV) level and 600 V for the Low Voltage (LV) level.

The off-site electrical system is provided and managed by OPG. The function of the BWRX-300 off-site electrical system is to provide electrical power to the Hydro One managed grid that is compatible and consistent for OPG purposes. The output of the BWRX-300 is monitored for over voltage and over/under current as protective design features to prevent possible grid disruptions. The off-site power system can be automatically or manually disconnected from the grid if the electrical power is found to be disrupted for any reason.

On-site electrical systems are designed to support the normal operations of the BWRX-300. A unique feature of the BWRX-300 plant is that the on-site AC power system is not required to be operational to support the safe shutdown of the reactor and for at least the first 72 hours following shutdown. The reactor cooldown is accomplished through natural circulation and passive cooling via the ICS system.

The off-site preferred power system is designed to provide a continuous source of power to the on-site AC power system throughout plant startup, normal operation (including shutdown), and abnormal operations. The off-site power system provides no credited safety function. As a result, the total loss-of-offsite power results in no impact on nuclear safety.

Refer to Chapter 8 – Electrical Power for a detailed discussion on the Electrical power systems for the BWRX-300.

The on-site AC power system consists of SCN, SC1, SC2, and SC3 power systems. The two off-site power sources provide the normal preferred and alternate preferred AC power to SCN, SC1, SC2 and SC3 loads.

The normal preferred off-site power source is connected to the GSU, which is connected to the plant generator and the UAT. The normal preferred power source is distributed from the UAT secondary windings to MV SCN busses, which further distribute the power to SCN loads and the SC3 LV busses. The SC3 LV busses serve LV SC3 loads and provide normal AC power to the SC1 and SC2 electrical power systems.

The alternate preferred off-site power source is connected to the RAT, which has two MV secondary windings like the UAT. The RAT provides alternate power feeds to the MV SCN busses for cases when the UAT is not in-service.

The SC3 LV busses also have backup power in the form of standby diesel generators. Each SC3 LV bus is connected to a standby diesel generator that automatically starts and loads if the normal power to the SC3 LV bus becomes unavailable (loss of power or degraded).

There are three divisions of SC1 DC power, two load groups of SC2 DC power, and 2 sets of SCN DC power connected to the diesel-backed SC3 busses. Add that each DC power system includes battery chargers, batteries, and UPSs to supply uninterruptible AC and DC power during loss of power events.

The BWRX-300 electrical AC power systems (on-site or off-site) are not relied upon to support the safe shutdown and cooldown of the reactor in the event of a design basis accident. No operator actions are credited in the safe shutdown or cooldown of the reactor in the event of a design basis accident.

### **3.8.1 Redundancy**

As discussed above, two off-site power sources provide the normal preferred and alternate preferred AC power to SCN, SC1, SC2 and SC3 loads. In the event of total loss-of-offsite power sources SC3 standby diesel generators are provided to power the plant SC1, SC2 and SC3 loads.

Three divisions of SC1 DC power are not only redundant to each other, but also have redundant UPSs in each divisions for further reliability. The SC2 DC power load groups are redundant to each other as well. There are also two sets of SCN DC systems that can provide redundant power to select equipment as needed.

There are two redundant SC2 Direct Current (DC) load groups and one SC3 Direct Current (DC) load group each with a UPS to provide power to the respective SC2 and SC3 loads.

There are three independent SC1 Direct Current (DC) divisions with UPS to provide power to SC1 loads.

Redundancy for the BWRX-300 electrical power systems is discussed in more detail in Chapter 8.

### **3.8.2 Independence**

As discussed above, in the event of total loss-of-offsite power sources two on-site SC3 standby diesel generators are provided to power the plant SC1, SC2 and SC3 loads. Either SDG can support the required SC1, SC2, and SC3 loads needed for active decay heat removal. The SDG's are located in independent fire-barriered rooms.

The 3 divisions of SC1 DC power are electrically and physically independent from each other. There are no electrical connections between the divisions and the equipment is located by division in separate fire and flood-barriered rooms.

It is also the same for the SC2 load groups, (i.e., the two SC2 load groups are similarly independent from each other).

There are two independent SC2 Direct Current (DC) load groups and one SC3 Direct Current (DC) load group each with a UPS to provide power to the respective SC2 and SC3 loads.

There are three independent SC1 Direct Current (DC) divisions with UPS to provide power to SC1 loads.

Independence of the electrical power systems and components is discussed in more detail in various Chapter 8 sections. Refer to Chapter 8 for further discussion of this topic.

### **3.8.3 Diversity**

The EDS is designed along a Defence-in-Depth philosophy and along Defense Lines. Section 3.6 provides a discussion on philosophy. The electrical systems are diverse from each based on defense lines.

### **3.8.4 Controls and Monitoring**

On-site and Off-site electrical power system controls and monitoring for the BWRX-300 will be accomplished by both Main and Secondary Control rooms monitors or controls that are remote "at the panel" monitoring and controls should it be necessary to operate the electrical systems in a remote "away from the CR" fashion.

Controls and Monitoring is discussed in Chapter 8.

### **3.8.5 Identification**

Refer to Section 8.4 for details on the electrical system safety classification and a description of the major electrical power system equipment.

### **3.8.6 Capacity and Capability of Systems for Different Plant States**

The capacity and capability of the Electrical Power Systems is designed to provide a minimum of 100% of the required electrical loading needed for the normal operation of the BWRX-300. Equipment sizing includes consideration of design margin as appropriate for all facets of plant operation.

As stated above, the BWRX-300 does not rely on electrical power to safely shutdown and cool the reactor. Electrical power is not relied upon to place the reactor into a safe shutdown and to maintain the reactor in a safe shutdown condition.

As mentioned previously, SDG capacity can support required SC1/2/3 loads needed for active decay heat removal.

DC power from batteries will be used primarily to monitor the cooldown and condition of the reactor.

The capacity and capability of electrical power system is further discussed in Chapter 8.

### **3.8.7 External Grid and Related Issues**

External Grid operation and management is the responsibility of OPG. The BWRX-300 safety design does not require off-site power to be present to mitigate any design basis accidents.

OPG's grid connection project is currently in the conceptual and planning stage.

With input and interfacing support, OPG plans on designing and building a local switchyard to consolidate power output from the BWRX-300 SMR Facility and connect it with Ontario electrical power grid. Hydro One is the grid transmitter and the Independent Electricity System Operator (IESO) is the electrical system operator.

At this time, OPG is expected to be the operator of the local switchyard via the Main Control Room (MCR) in the SMR Facility. The SMR Facility electrical AC power system will have two high voltage connections with the local switchyard at a 230kV voltage level. One line to output power from the Generator Step Up Transformer (GSU) and one line to supply power to the Reserve Auxiliary Transformer (RAT). The local switchyard will have two redundant 230kV connections with the transmitter. Each line will be designed to transmit the full generation capacity of the SMR Facility. The transmitter is responsible for building the transmission infrastructure needed to connect the local switchyard to Clarington TS, 22km North of the DNNP site. The two lines are expected to share the same tower structure. *(The 230kV voltage level and connection with Clarington TS is to be confirmed in 2022 through an IESO Feasibility Study.)*

The local switchyard will be of an indoor Gas Insulated Switchgear type, following a breaker and half arrangement with two redundant busses. The local switchyard will be designed to have local and remote-control capability. The plan for the local DNNP switchyard is that it will be located North of the SMR Facility, East of the Extended Holt Rd and South of the CN Rail tracks. The local switchyard control and protection designs will be coordinated with the SMR Facility controls and protections to meet IESO, NPCC and NERC codes and standards.

**Power Quality**

The BWRX-300 electrical power systems will be monitored for power quality issues (voltage/frequency/harmonics) that may arise and maintained such that any abnormal fluctuations in the voltage, current or capacity is alarmed in the Main Control Room so operators can evaluate and manually respond to the alarm condition.

### **3.9 Equipment Qualification**

#### **3.9.1 Purpose**

This section defines the requirements related to equipment qualification in alignment with CNSC REGDOC-2.5.2, Section 5.5 (Reference 3.9-1).

Equipment qualification is the process carried out (including the generation and maintenance of evidence) to ensure SSC can perform their intended design functions and remain fit for purpose in the conditions under which they are expected to perform.

The conditions impacting equipment qualification include seismic/dynamic, environmental, functional/aging stressors, and electromagnetic interference.

#### **3.9.2 Scope**

Equipment qualification requirements are applied to BWRX-300 equipment based on the assigned safety classification and seismic categorization of SSC (as described in Section 3.2), and to certain post-accident monitoring equipment.

Equipment qualification considers all normal operating conditions in which the SSC are expected to operate including conditions arising from maintenance and testing, and also, the conditions arising from AOOs, DBAs, and internal and external hazards.

While DEC conditions are generally considered outside of the scope of a qualification program, guidance is provided for demonstrating with reasonable assurance that equipment credited to perform under DEC conditions will survive to perform its function. See Subsection 3.9.3.5 for consideration of a Beyond-Design Basis Earthquake (BDBE) and Subsection 3.9.4.1 for Environmental Qualification considerations.

The focus of this section is on qualification of mechanical and electrical equipment. Mechanical equipment consists of items of a facility including pumps, valves, vessels, and piping whose function is required to ensure the safe operation or safe shutdown. Electrical equipment consists of all electrical power and Instrumentation and Control (I&C) equipment, which includes all analog (non-digital) and digital I&C components. Computer-based I&C equipment is a subset of digital I&C components.

Qualification of civil structures is covered in Section 3.3.

#### **3.9.3 Seismic**

##### **3.9.3.1 General**

Seismic qualification is a subset of equipment qualification that is the verification, through testing, analysis, or other methods, of the ability of an SSC to perform its intended function during and/or following a designated earthquake. The dynamic loads of Reactor Building Vibrations (RBVs) and events caused by hydrodynamic loads are also considered. Seismic and dynamic qualification of BWRX-300 equipment and associated supports meets the requirements and recommendations of the CSA N289 series (References 3.9-2 To 3.9-6) as endorsed by CNSC REGDOC-2.5.2 (References 3.9-1), and IEC/IEEE 60980-344 (Reference 3.9-7).

The requirement for seismic qualification is based on the seismic categorization of SSC and the earthquake level they are required to withstand during and/or after the seismic event. Seismic categorization of BWRX-300 SSC is described in Section 3.2. Seismic Category A and Seismic Category B SSC are most important and have the most stringent requirements for functional integrity during and following a seismic event. Per regulatory guidance of CNSC REGDOC-2.5.2, Section 5.13.1 (Reference 3.9-1), SSC that are classified as Seismic Category A and Seismic

Category B are seismically qualified to withstand the effects of a DBE. The site-specific DBE is defined in Subsection 3.3.1.

BWRX-300 equipment Seismic Categories are identified in Appendix 3A Table 3.12-1. Seismic Categorization of Structures is provided in Section 3.3, Table 3.3-1.

### **3.9.3.2 Methods for Seismic Qualification**

Seismic and dynamic qualification of equipment and associated supports are accomplished by test, analysis, or a combination of testing and analysis. Seismic and dynamic qualification of equipment and associated supports designated as SC1 is accomplished by testing. Seismic and dynamic qualification of equipment and associated supports designated as SC2 may be accomplished by analysis or a combination of testing and analysis.

Qualification by actual seismic experience (also referred to as seismic qualification by similarity), as described in IEC/IEEE 60980-344 (Reference 3.9-7) and CSA N289.1 (Reference 3.9-2), is also utilized as appropriate considering the limitations identified in CSA N289.1, Annex D.3 (Reference 3.9-2).

The selection of qualification method to be used is largely a matter of engineering judgment for cases where testing is not required. When both test and analysis are defined as acceptable methods, the deciding factors considered (as applicable) for choosing between tests or analysis include magnitude and frequency of seismic and RBV dynamic loadings, environmental conditions associated with the dynamic loadings, nature of the safety category function(s), size and complexity of the equipment, dynamic characteristics of expected failure modes (structural or functional), and partial test data upon which to base the analysis.

Tests or analyses of assemblies are preferable to tests or analyses on separate components (e.g., a motor and a pump, including the coupling and other appurtenances, should be tested or analyzed as an assembly), unless deemed not practical. Equipment that has been previously qualified by means of tests and analyses equivalent to those required for the current qualification program are used if proper documentation of such tests and analyses is available.

For equipment defined as requiring test for qualification, analysis by similarity may be used if similar equipment is being or has been qualified by test.

#### **3.9.3.2.1 Testing**

Testing of BWRX-300 SSC for seismic qualification is conducted in accordance with CSA N289.4 (Reference 3.9-5) IEC/IEEE 60980-344 (Reference 3.9-7).

Seismic qualification by testing is typically used for SSC that will be performing an active function and are required to change state during or following a seismic event to perform a safety category function, while maintaining structural and/or pressure boundary integrity. Seismic testing can identify contact chatter or unauthorized change of state of contact in electrical and I&C components during seismic excitation.

The dynamic test sequence includes as applicable, vibration conditioning, exploratory resonance search, low-level earthquake loading (one-half DBE) including Reactor Building Vibrations (RBV) dynamic loads and the DBE loading including RBV dynamic loads.

Dynamic tests are performed with the equipment subjected to nominal operating service conditions. Significant, normal operating loads such as electrical, mechanical, pressure, and thermal are included. Where normal operating loads cannot be included in the dynamic tests, supplemental analysis is used to qualify the equipment for those effects. If there is any dynamic coupling due to interacting equipment, it is considered.

For equipment located in multiple locations, the enveloping upper bound seismic condition limits are used to eliminate the need for multiple qualification tests, unless otherwise specified.

### **Resonance Tests**

When required, exploratory resonance search tests (such as sine sweeps or random vibration) are used for equipment to help determine the method of test or analysis that would be best for qualification and/or determine the dynamic characteristics such as the resonance frequencies of the equipment, mode shapes and damping values.

Sine sweep resonance search is the preferred method and is performed by running a continuous sweep frequency search using a sinusoidal steady-state input at the lowest possible amplitude at which resonance can be determined.

Resonance searches may be performed prior to and after the seismic test to determine any shifts in frequency caused by testing.

If resonance frequencies are present, the transmissibility between the input and the location of the equipment is determined by measuring the accelerations at the equipment location and calculating the magnification between it and the input.

Floor-mounted frequency testing can be used as another method to determine the resonance or natural frequencies for equipment.

### **Seismic Input Motion**

Dynamic load conditions are simulated by testing, using independent, random multi-frequency input or single frequency input motion (within equipment capability) over the frequency range of interest.

Acceptable justification for use of single frequency input includes, but is not limited to:

1. The characteristics of the required input motion are dominated by one frequency.
2. The anticipated response of the equipment is adequately represented by one mode.
3. The input has sufficient intensity and duration to excite all modes to the required magnitude so that the testing response spectra envelop the corresponding response spectra of the individual modes.
4. The time phasing of the inputs in the vertical or horizontal directions will be such that a purely rectilinear resultant input is avoided.

The actual input motion used during testing, for both multi and single frequency, envelops the applicable input motion (floor, wall, response, etc.) at the location(s) of the equipment under test.

When the equipment is qualified by dynamic test, the In-Structure Response Spectra (ISRS) or time histories, developed from the results of Soil-Structure Interaction (SSI) analyses as described in Section 3.3.1.2.7, representing the in-structure seismic response of the attachment point is used in determining required response spectra of input motion used for the test.

For the case of equipment having multiple supports with different dynamic motions, the effects of the multiple support attachment points must be considered in the dynamic qualification and can be accounted for by selecting an upper bound envelope of all the individual response spectra for these locations to calculate the maximum internal responses applicable to the equipment, unless otherwise specified.

Past testing demonstrates that Seismic Category A electrical equipment has critical damping ratios equal to or less than 5%. Hence, the required response spectra at 5% or less critical damping ratio are developed as input to the equipment base, unless identified otherwise.

### **Seismic Test**

The preferred test method for seismic qualification is shake table testing. Seismic testing is performed in a manner that demonstrates dynamic response characteristics and acceptability of the test specimen to withstand and maintain its function as required during the expected level of shaking. Test requirements are normally specified in the form of required response spectra at a specified damping value and confirmed by a Test Response Spectra (TRS) generated from the table motion.

The seismic test for DBE produces a TRS that envelops the applicable portion of the required response spectra as defined in the test specification (typically by a factor of 1.1) per CSA N289.4 (Reference 3.9-5). The approach is to apply 10% to the acceleration of the ISRS, developed from the results of SSI analyses as described in Section 3.3.1.2.6, which meets the recommendations of IEC/IEEE 60780-323 (Reference 3.9-8).

Testing for low-level earthquake loading and RBV dynamic loads is performed to demonstrate that the low-level earthquake loads combined with RBV dynamic loads do not degrade the continued structural and functional integrity of the equipment.

Testing for DBE loading and RBV dynamic loads are performed to demonstrate that equipment would perform its intended function(s) through DBE combined with RBV dynamic loads.

For both low-level earthquake and DBE seismic test runs, the input excitation TRS is required to envelop the specified required response spectra levels in accordance with CSA N289.4 (Reference 3.9-5) and Section 9 of IEC/IEEE 60980-344, (Reference 3.9-7).

If the TRS do not meet the requirements (i.e., do not envelop the required response spectra, do not demonstrate stationarity, do not demonstrate statistical independence) for the seismic test run, the test run is documented as unacceptable, adjustments may be required, and then the test is repeated.

Alternatively, per Clause 5.1.2.2.4 of CSA N289.4 (Reference 3.9-5), for acceptance in cases where TRS does not envelop required response spectra, the following criteria are applied:

- The number of points below the required response spectra shall not exceed 5
- The points shall not fall below the required response spectra by more than 10%
- Any two points below the required response spectra shall be at least 1 octave apart
- The points adjacent to the points that fall below the required response spectra shall be at least 10% above the required response spectra

For equipment that is subjected to vibration in its in-service condition, vibrational aging to its end of life condition must be completed prior to seismic testing (both low-level earthquake and DBE load tests).

For seismic qualification, the seismic input consists of five one-half DBE amplitude events (low-level earthquakes) followed by one DBE event. Alternatively, in accordance with Annex E of IEC/IEEE 60980-344 (Reference 3.9-7), a number of fractional peak cycles equivalent to the maximum peak cycles for five one-half DBE events may be used followed by one full DBE event; however, in this case the amplitude shall not be below the minimum of one-half the DBE input motion.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

The preferred method for seismic testing is to use triaxial, multi-frequency testing. However, if justified, biaxial and single-axis testing is acceptable.

Multi-frequency, multi-axis dynamic tests (triaxial or biaxial) are used to qualify equipment with a single resonance or multiple resonances within the frequency range of interest or if the critical resonance frequencies cannot be ascertained.

Single frequency testing is allowed if:

1. It can be demonstrated that the component is subjected to no resonances, or one predominant resonance frequency that is not in the frequency range of interest, or if the resonance frequencies are widely separated and do not interact to reduce the fragility level in the frequency range of interest, or if otherwise justified.
2. Single-axis tests can only be used if the tests are designed to conservatively reflect the dynamic event at the equipment mounting locations or if the equipment being tested can be shown to respond independently in each of the three orthogonal axes or otherwise withstand the dynamic event at its mounting location.

Equipment is tested in a functionally operable condition to allow for the monitoring of safety requirements throughout the seismic testing.

Equipment is operated at appropriate times (as necessary) to demonstrate the ability to perform its safety category function throughout the seismic testing.

For Seismic Category A and B mechanical and electrical equipment, it is defined if the equipment must perform its safety category function before, during, and after seismic events (typical for most equipment), or only before and after seismic events (applicable to some equipment such as plant status display equipment).

The equipment damping value used for dynamic qualification is established in accordance with Section 5 of IEC/IEEE 60980-344 (Reference 3.9-7).

Documentation of seismic testing is in accordance with Section 13 of IEC/IEEE 60980-344, (Reference 3.9-7) and include, at minimum, locations of accelerometers, any existing resonance frequency(s) and transmission ratios, equipment damping coefficients if there is resonance over the range of the test response spectra, test equipment used, any modifications made to test specimen, hardware interface requirements, test methods, approval signature and dates, description of test facility, summary of results, equipment seismic qualification conclusions (including RBV dynamic loads), anomalies and their resolution, test data, and justification for using single-axis or single frequency tests for all items that are tested in this manner.

#### **3.9.3.2.2 Selection of Test Specimen**

Test specimens are selected as representative samples of the production equipment and supports that are covered by the qualification program. Test specimens are manufactured using the same process that are implemented for the production units. Variations in the configuration of the equipment are analyzed with supporting test data. For example, these variations may include mass distributions that differ from one cabinet to another. From test or analysis, it is determined which mass distribution results in the maximum acceleration or frequency content, and this worst-case configuration is used as the test specimen. The test report includes a justification that this configuration envelopes all other equipment configurations.

#### **3.9.3.3 Seismic Analysis**

Dynamic analysis or an equivalent static analysis is employed to qualify the equipment when analysis is chosen as the method for qualification per CSA N289.3, Section 6 (Reference 3.9-4).

The decision on using dynamic versus static analysis is typically defined based on whether the equipment is rigid or flexible.

If the fundamental frequency of the equipment is above the input excitation frequency (cutoff frequency of required response spectra) the equipment is considered rigid.

The search for the natural frequency is done analytically, if the equipment shape can be defined mathematically, or by prototype testing.

If the equipment is determined to be a rigid body (i.e., shown to have no resonance frequency within the expected frequency range) the static analysis method is able to be applied in place of dynamic analysis.

If the equipment is determined to be flexible (i.e., with the fundamental frequency of the equipment within frequency range of the input spectra) and not simple enough for equivalent static analysis, a dynamic analysis method is applied, unless justified otherwise.

If it is determined that either dynamic or static analysis can be used, in general, the choice of the analysis is based on the expected design margin, as the static coefficient method is more conservative than the dynamic analysis method.

For static analysis, the dynamic forces on each component can be obtained by concentrating the mass at the center of gravity and multiplying the mass by the appropriate floor acceleration. The dynamic stresses are then added to the operating stresses and a determination made of the adequacy of the strength of the equipment.

A static coefficient analysis may also be used for certain equipment in lieu of the dynamic analysis. No determination of natural frequencies is made in this case. The seismic loads are determined statically by multiplying the actual distributed weight of the equipment by a static coefficient equal to 1.5 times the peak value of the required response spectra at the equipment mounting location, at a conservative and justifiable value of damping.

Both types of analyses verify integrity of the equipment is maintained under low-level earthquake loads including appropriate RBV dynamic loads in combination with normal operating loads and normal operating and DBE loads including appropriate RBV dynamic loads, unless otherwise justified.

See Section 3.3.1.3 for additional details and discussion of Seismic Analysis of Seismic Category A and B Subsystems.

#### **3.9.3.4 Seismic Qualification by Combined Testing and Analysis**

Qualification by combined testing and analysis is used as a method for qualification for complex or large equipment where it is not practical to test the entire assembly or it is too large to be tested at once, unless another method of qualification is justified.

One method of combined qualification is to use a representative prototype portion or scaled-down prototype of the assembly that is subjected to type testing. The data from the type testing is then used to develop and validate an analytical model of the prototype. The prototype analytical model is then extrapolated to represent the larger assembly and then using the results to justify qualification of the equipment based on prototype testing.

A second method of combined qualification is to mount the full assembly to a rigid floor to simulate service mounting and then a portable shaker test (or an impact or pull test if justified) is performed to excite the natural or resonance frequencies of the specimen. The amplification of resonance motion is used to determine the appropriate modal frequency and damping for a dynamic analysis of the equipment.

For equipment with multiple site configurations the combined qualification method can be applied to reduce the number of configurations to be tested. In this case, an evaluation must be performed to determine the enveloping “worst-case” configuration(s), which is then tested. Analysis is then used to justify the various configurations based on the “worst-case” configuration(s).

The combination method can be used for qualification of larger electrical equipment support assemblies containing Seismic Category A or B equipment. For this case, a test is run to determine if there are natural frequencies in the support equipment within the critical frequency range. If the support is determined to be free of natural frequencies in the critical frequency range, then it is assumed to be rigid and a static analysis is performed and calculations of transmissibility and responses to varying input accelerations are determined to see if Seismic Category A or B equipment mounted in the assembly would operate without malfunctioning.

#### **3.9.3.5 Beyond Design Basis Earthquake**

REGDOC-2.5.2 Section 7.13 (Reference 3.9-1) states that for a beyond-design-basis earthquake (BDBE), demonstration that there is a high confidence of low probability of failure (HCLPF) of the SSC that are credited to function during and after the event. This demonstration need not be seismic qualification by testing. BDBE is identified as a Checking Level Earthquake (CLE). Typically, the CLE (as discussed in Section 3.5.6.1.2) is considered a DEC. DEC for seismic events are a subset of beyond design basis seismic events that are considered in the evaluation of the facility using best-estimate methodology to keep releases of radioactive material within acceptable limits.

If determined to be useful, fragility testing per IEC/IEEE 60980-344 (Reference 3.9-7) may be used as a qualification method. Fragility testing is a form of vibration testing of an SSC to determine the point where it can no longer perform its function, whether due to electrical or mechanical malfunction, or excessive structural deformation or destruction. Where fragility testing is performed, it provides useful information about margin to failure. Knowledge of the seismic fragility of an SSC is useful in determining its seismic margin to failure and in providing determination of SSC functionality in BDBE evaluations (per CSA N289.1 (Reference 3.9-2).

Seismic PSA is used to analyze the plant response to seismic hazards as discussed in Chapter 15, Section 15.6.

#### **3.9.3.6 Documentation**

Seismic qualification documentation including identification of seismic equipment, test/analysis plans and reports, technical specifications, data sheets, engineering standards, and component specific seismic qualification parameters, and requirements for inspection, maintenance and procurement are prepared in an auditable summary report in accordance with Clause 7 of 289.4 (Reference 3.9-5).

Documentation of seismic testing is in accordance with CSA N289.4 Section 5.8 (Reference 3.9-5) and IEC/IEEE 60980-344, Section 13 (Reference 3.9-7) and include, at minimum, locations of accelerometers, any existing resonance frequency(s) and transmission ratios, equipment damping coefficients if there is resonance over the range of the test response spectra, test equipment used, any modifications made to test specimen, hardware interface requirements, test methods, approval signature and dates, description of test facility, summary of results, equipment seismic qualification conclusions (including RBV dynamic loads), anomalies and their resolution, test data, and justification for using single-axis or single frequency tests for all items that are tested in this manner.

### **3.9.4 Environmental Qualification**

#### **3.9.4.1 Scope**

Environmental Qualification is a subset of equipment qualification specifically addressing equipment exposure to a harsh environment. In alignment with CNSC REGDOC-2.5.2 Section 7.8 (Reference 3.9-1) and CSA N290.13 (Reference 3.9-9), Environmental Qualification is established to ensure that BWRX-300 SC1 SSC can perform their FSFs during and after exposure to a harsh environment resulting from a DBA during and after which they are required to operate. Equipment whose failure due to the harsh environment could impair the ability of qualified equipment to perform safety category functions are also considered for Environmental Qualification. Equipment that is not significantly impacted by the increased stress due to the harsh environment, or for which there are not credible failure modes induced by the harsh environment preventing the equipment from performing its FSF are exempt from Environmental Qualification. The effects of normal service conditions including that of AOOs, and the impact of aging are considered in the SSC ability to perform their safety category functions.

While Environmental Qualification is not required to be established for equipment responding to DECAs as stated in CSA N290.13 (Reference 3.9-9), equipment survivability assessments are used to provide reasonable confidence that equipment will function in response to the DEC within the time span required and that instrumentation will function with reasonable accuracy per REGDOC-2.5.2 (Reference 3.9-1). IEC/IEEE 60780-323 (Reference 3.9-8) provides considerations for qualifying equipment for DECAs and guidance is provided in Annex B of CSA N290.13 (Reference 3.9-9), and CSA N290.16 (Reference 3.9-10).

#### **3.9.4.2 Environment Parameters**

A harsh environment occurs as a result of a subset of DBAs for which ambient and operational service conditions change significantly as a result of the DBAs, DBAs considered in the BWRX-300 design are discussed in Chapter 15. Environmental parameters considered when screening for a harsh environment include:

- Temperature
- Steam
- Condensing Humidity
- Pressure
- Submergence
- Radiation
- Chemistry

Table 3.9-1 lists harsh environment screening criteria for environmental parameters based on the guidance in CSA N290.13 Annex A (Reference 3.9-10).

Per CSA N290.13, (Reference 3.9-10), a mild environment is one that would at no time be significantly more severe than the environment that would occur during the normal plant operation, including during AOOs, and would not give rise to significant aging mechanisms. For equipment located in a mild environment during and after a DBA for which it is required to function, Environmental Qualification is not required.

Per the description of mild environment qualification in CNSC REGDOC-2.5.2, Section 7.8 (Reference 3.9-1), for equipment not requiring Environmental Qualification per the scope of CSA N-290.13 (Reference 3.9-9) as described herein, the environmental conditions for its expected

function would be identified in its design specification and a manufacturers certification that the equipment meets the specification would be provided.

### **3.9.4.3 Objectives**

The objectives of Environmental Qualification of BWRX-300 SSC include:

1. Identification of SSC required to be environmentally qualified
2. Establishment of the safety category functions, performance requirements, normal service conditions, and post-accident harsh environment conditions for SSC identified as requiring qualification
3. Documentation of objective evidence verifying that the identified SSC are capable of performing credited safety category functions under the relevant harsh conditions, including consideration of age-related degradation during normal service
4. Controls and evidence to ensure that SSC are installed considering identified configuration and interface requirements
5. Controls and evidence to ensure that qualification of the equipment is preserved throughout the design life including aging and obsolescence

### **3.9.4.4 Requirements for Environmental Qualification**

#### **3.9.4.4.1 DBA Identification**

BWRX-300 DBAs that produce a harsh environment with potential to cause common cause failures are identified and analyzed at the appropriate design phase. Documentation of the basis for classifying an accident as harsh is included.

#### **3.9.4.4.2 Defining Normal and Accident Environmental Envelope**

At the appropriate design phase an environmental envelope that includes a listing of all areas of the facility in which SSC are expected to fulfill safety category functions during and after a DBA is identified and documented. For each identified area, the ambient environmental and operational conditions are provided for normal conditions (normal operating modes and AOOs), and for DBA conditions based on the limiting parameters identified from DBA identification.

#### **3.9.4.4.3 Identification of Equipment Requiring Harsh Environment Qualification**

At the appropriate design stage, BWRX-300 equipment requiring Environmental Qualification (as described in 3.9.4.1) is identified and documented. The list also includes equipment whose failure due to the harsh environment could impair the performance of qualified equipment. Equipment that is not significantly impacted by the increased stress due to the harsh environment, or for which there are not credible failure modes induced by the harsh environment preventing the equipment from performing its safety category function is exempt from Environmental Qualification. A basis for exempting equipment from qualification (e.g., failure modes, environmental conditions, materials, etc.) will be documented.

Information documented in the list of environmentally qualified equipment includes:

- Equipment identification
- Safety category function
- Applicable DBA
- Mission time
- Normal and accident service conditions

#### **3.9.4.4 Qualified Life**

Qualified life is established for equipment determined to be susceptible to age-related degradation for the specified service conditions. The equipment included within the scope of the Environmental Qualification program is analyzed based on an expected plant life of 60 years or is subject to replacement or evaluation of the effects of aging and obsolescence on a periodic basis.

#### **3.9.4.5 Establishing Environmental Qualification**

Methods for demonstration that equipment is environmentally qualified include testing, analysis, by operating experience, or by a combination of these methods in accordance with CNSC REGDOC-2.5.2 (Reference 3.9-1), CSA N290.13 (Reference 3.9-9), Reg. Guide 1.89 (Reference 3.9-11), and IEC/IEEE 60780-323, (Reference 3.9-8).

##### **3.9.4.5.1 Qualification By Testing**

Type testing is the preferred method for demonstrating that equipment is Environmentally Qualified. A type test subjects a representative sample of equipment, including interfaces, to a series of tests, and include simulating the effects of significant aging mechanisms during normal operation. The sample is subsequently subjected to conditions that simulate DBA harsh conditions and thereby establishes the tested configuration for installed equipment service, including mounting, orientation, interfaces, conduit sealing, and expected environments. A type test demonstrates that the equipment performs the intended safety category function(s) for the required operating time before, during, and/or following the DBA, as appropriate.

Type tests are performed in accordance with applicable industry standards, such as CSA N290.13 (Reference 3.9-9) and IEC/IEEE 60780-323 (Reference 3.9-8).

A typical sequence includes, but is not limited to the following:

- Initial inspection
- Baselines functional test
- Normal radiation exposure
- Accident radiation exposure
- Accelerated thermal aging
- Other aging simulation as applicable
- Post-aging functional test
- Accident simulation
- Final inspection

##### **3.9.4.5.2 Qualification by Analysis**

Qualification by analysis requires the construction of a valid mathematical model of the equipment to be qualified, in which the performance characteristics of the equipment are dependent variables, and the environmental influences are the independent variables. The validity of the mathematical model is justified by test data, operating experience, vendor data, and established engineering principles that support the analytical assumptions and conclusions.

Consistent with CSA N290.13 (Reference 3.9-9), the qualification of complex equipment by analysis only is not used because of the great difficulty in developing an accurate analytical model, unless it can be justified that using only analysis is sufficient.

#### **3.9.4.5.3 Qualification by Operating Experience**

Qualification by use of operating experience requires documented data to be available confirming that the product providing the operating experience is identical or justifiably similar to the equipment to be qualified, the product providing the operating experience has operated under service conditions which equal or exceed, in severity, the service conditions and performance requirements for which the product is to be qualified, and the installed product must, in general, be removed from service and subjected to partial type testing to include the DBA environments for which the product is to be qualified. Operating experience may also provide information on limits of extrapolation, failure modes, and failure rates.

#### **3.9.4.5.4 Combined Qualification**

Equipment may be qualified by test, analysis, operating experience, or any combination of these methods. Combined qualification may be used to supplement existing test data. Partial type testing may be augmented by tests of components where size, applications, time, or other test limitations preclude the use of a full type test. Examples of combined qualification include separate effect tests with extrapolation or analysis, operating experience with extrapolation or analysis, and type tests supplemented with tests of components and analysis.

#### **3.9.4.5.5 Aging Considerations**

Significant aging mechanisms are considered in establishing Environmental Qualification for the specified service conditions and in defining the qualified life of equipment and components. An aging mechanism is significant if subsequent to manufacture, while in storage, and/or in the normal and abnormal service environment, it results in degradation of the equipment that progressively and appreciably renders the equipment vulnerable to failure to perform its safety category function under harsh environmental DBA conditions. These typically include thermal, radiation, and operation induced degradation. Age conditioning is used during qualification to simulate these effects.

Accelerated thermal aging is used to simulate the deterioration due to temperature during the normal service life of equipment. The use of the Arrhenius Equation is the recognized method.

The effects of radiation are simulated during qualification testing for equipment exposed to radiation in normal or accident conditions. Radiation qualification considers that equipment damage is a function of total integrated dose and can be influenced by dose rate, energy spectrum, and particle type. The radiation qualification includes doses from all potential radiation sources at the equipment location. The assessment of accelerated aging effects due to normal radiation exposure is performed separately from or included as part of the accident radiation exposure.

Cycle aging conservatively simulates the degradation during the required operating cycles for the equipment. The number of cycles required for equipment is based on the design specification.

For equipment that cannot meet the required cycles for the 60-year life, a shorter qualified life is established, and the effects of physical aging and obsolescence are reflected in the maintenance, surveillance, and replacement program.

Age conditioning considers sequential, simultaneous, and synergistic effects to achieve the worst state of degradation.

Age conditioning is not required for equipment with no determined aging mechanisms.

#### **3.9.4.5.6 Environmental Margins**

Margin is applied during Environmental Qualification to account for unquantified uncertainties such as normal variations in equipment production, inaccuracies in measurement and test instrumentation and reasonable errors in defining satisfactory performance. Current qualification practices do not require statistical or reliability data when establishing Environmental Qualification. Instead, conservatism and margins are intended to provide reasonable assurance that the installed equipment can perform as required.

The following margins as recommended in CSAN290.13 (Reference 3.9-9) may be applied to simulated accident conditions during qualification testing or considered when performing qualification by analysis.

The margin applicable to a specific parameter is determined based on the peak conditions as follows:

- Temperature: + 10% of peak temperature to a maximum of 8°C
- Pressure: + 10% of peak gauge pressure to a maximum of 70kPa
- Radiation: + 10% of the total integrated accident dose
- Mission Time: + 10% of the required mission time (up to the maximum)

#### **3.9.4.6 Documentation of Environmental Qualification**

Documentation is required to ensure an auditable proof of performance under DBA conditions is developed and maintained for equipment requiring Environmental Qualification. The following subsections provide a general description of the expected information. The organization or format of the documentation is not intended to be prescriptive.

##### **3.9.4.6.1 Equipment Specifications for Environmental Qualification**

Plant specific equipment specifications for Environmental Qualification are developed and include essential information about the equipment to be qualified. The following is included as applicable:

- Details of aging stressors resulting from normal environmental conditions
- Details of aging stressors resulting from normal operating conditions
- Details of in-plant configuration, including mounting
- Description of control, indication, and other auxiliary devices required for proper operation
- Functional requirements under the defined normal and accident service conditions
- Required qualified life for the equipment or maintenance intervals for specific components, or both
- Details of DBA stressors resulting from accident environmental conditions
- Details of DBA stressors resulting from accident operating conditions
- Performance requirements and acceptance criteria
- Mission time(s) for relevant safety category functions of equipment
- Provision for condition monitoring

#### **3.9.4.6.2 Qualification Plan**

Prior to starting the qualification of equipment, plans are developed detailing the qualification method. If the qualification method is by test, the qualification plan is incorporated into the test plan. The following is included:

- Equipment identification
- Equipment qualification specifications requirements for Environmental Qualification as described above
- Scope of qualification
- Documentation for traceability of equipment and of all polymeric or elastomeric material
- A description of the components of the equipment
- Qualification method selected and justification for the selection of a method if it is other than testing
- When analysis is the chosen method, a description of the analytical methods to be used
- Age conditioning limits/parameters, including qualified life objective, peak aging temperature limits, radiation dose, and condition-based qualification methods, if applicable
- Evaluation of identified synergistic effects

#### **3.9.4.6.3 Test Report**

For qualification by test, a test report is developed after the completion of testing.

A test report includes the test plan and provides a detailed summary of the testing performed and the test results to demonstrate the equipment is successfully qualified for the environmental conditions specific to the testing. As a minimum it includes:

- Approved and dated certification sheet
- Identification of equipment tested
- Identification of test specimen
- The range of types or sizes covered
- The qualification requirements
- Results of initial and final inspection
- Description of mounting configuration during testing
- The simulated aging and accident environmental conditions as a function of time
- Results of all functional tests
- A description of the test facility
- A description of the test facility's QA program
- Calibration details for test equipment
- Disposition of any anomalous test results and variance from the test plan
- Details of any maintenance performed

- A summary of the testing program
- A conclusion stating compliance/non-compliance with acceptance criteria and test plan
- Details of connections and interfaces with the tested equipment
- A determination of the qualified life of the equipment under specified service conditions

#### **3.9.4.6.4 Analysis Report**

For qualification by analysis, an analysis report is developed providing a detailed summary of the analytical method used (including identification of any software used), calculations performed, and the results to demonstrate the equipment is successfully qualified for the environmental and/or seismic/dynamic condition(s) specified by the analysis.

#### **3.9.4.6.5 Qualification Summary Report**

An Environmental Qualification summary report provides documented assurance in an auditable format that equipment requiring Environmental Qualification should function as required under the relevant service conditions for its required mission time. It establishes the basis for equipment configuration, maintenance and procurement requirements providing the means to ensure that Environmental Qualification of the equipment is maintained for the station's life. Information contained in the summary report includes:

1. Equipment identification and description including function, location, mounting and interfaces, any required enclosures/shielding consistent with qualification basis
2. The qualification basis for the equipment including methodology, documentation from testing, analysis, and other supporting documentation supporting qualification
3. An overall conclusion on the qualified status of the equipment, including any limitations on use, operating constraints, or restrictions
4. Identification of any specific maintenance, replacement, and surveillance activities necessary to ensure that the qualification of the equipment is preserved throughout its installed life
5. Identification of any specific procurement requirements necessary to ensure that replacement equipment or components are procured in a manner that is consistent with the qualification basis
6. Identification of any handling and storage requirements

### **3.9.5 Electromagnetic Compatibility**

Accepted industry codes and standards are applied to establish an electromagnetic compatible environment applicable to electrical and I&C equipment. EMC qualification involves two elements:

1. Testing to assess susceptibility of equipment to interference levels that bound the expected electromagnetic environment
2. Testing to assess emissions of equipment to ensure that the contribution to the electromagnetic environment does not invalidate bounding interference levels applied for susceptibility testing

Susceptibility testing allows assessment of equipment immunity to Electromagnetic and Radio-Frequency Interference (EMI/RFI) and confirmation of its Surge Withstand Capability. Emissions testing provide assurance that equipment is compatible with the expected electromagnetic environment.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

Consistent with CNSC REGDOC-2.5.2 (Reference 3.9-1), EMI/RFI is addressed through recognized industry standards. NRC Reg Guide 1.180 (Reference 3.9-12) provides appropriate guidance for the EMC testing, describing methods and procedures considered acceptable for demonstrating EMC compliance based on the endorsement of IEC standards IEC 61000-2 / 4 (References 3.9-13 and 3.9-14), Military Standards MIL-STD (Reference 3.9-15) EPRI Topical Report TR-102323 (Reference 3.9-16) and IEEE Standard 627 (Reference 3.9-17) for test methods consistent with specific equipment requirements.

Chapter 2, Section 2.2.9 characterizes the site-specific electromagnetic hazards for which the design must consider and for which EMC qualification must address.

Chapters 7 and 8 describe the design of the I&C systems and the Electrical systems, respectively. As part of the design process, layout strategies are developed to ensure that the design considers interaction between SSC, and as the design is constructed, elements such as grounding and shielding are incorporated to meet the EMC/EMI standards (prior to testing).

Chapters 7, Subsections 7.3.1.3.1, 7.3.2.3.1, and 7.3.4.3.1 discuss design and quality measures for I&C systems as they relate to qualification measures that confirm I&C systems and equipment are capable of reliably performing the design basis functions for which they are credited over the range of environmental conditions postulated for the plant state and for the area in which they are located. Chapter 7, Table 7.1-1 provides System and Equipment standards to be followed in the design that ensures qualification measures are applied.

Chapter 8, Section 8.6 provides electrical system design information on grounding and EMC. Chapter 8, Section 8.1.1.2 describes how electrical systems are designed to accommodate grid disturbances. The electrical design includes considerations for the environmental conditions postulated for plant states in the areas in which components are located and credited to function.

The standards referenced provide detailed test conditions to ensure equipment is tested in the environments in which they are expected to function and provide post-installation practices for maintaining qualification including handling and storage requirements.

### **3.9.6 Specific Equipment Requirements**

Specific equipment categories may have additional requirements not applicable generically across all qualification programs. The Electrical and I&C equipment must meet the guidance provided in CSA N289 series (References 3.9-2 through 3.9-6) and the CSA N290 series standards (Reference 3.9.18 through Reference 3.9-22).

#### **3.9.6.1 Mechanical Equipment**

Safety Class mechanical equipment, which has the sole safety category function of maintaining pressure integrity, and which is designed, fabricated, and qualified consistent with ASME Boiler and Pressure Vessel Code, Section III (Reference 3.9-23), is considered qualified as specified in CSA N290.13 (Reference 3.9-9).

Mechanical equipment can be qualified by presenting historical performance data if it is demonstrated that the equipment satisfactorily sustains dynamic loads which are equal to or greater than those specified for the equipment and that the equipment performs a function equal to or better than that for which it is specified.

For mechanical equipment where the loading under normal service is more severe than loading under DBA, then the loading under normal service must be considered in addition to the loading under DBA by test and/or analysis.

For mechanical equipment, the loading and capability under DBA conditions is analyzed in the qualification process to establish the suitability of materials, parts, and equipment needed for

safety category functions, and to verify that the design of such materials, parts, and equipment is adequate.

The qualification of mechanical equipment includes, as applicable, materials that are sensitive to environmental effects (e.g., seals, gaskets, lubricants, fluids for hydraulic systems, and diaphragms), required operating time, non-metallic subcomponents of such equipment, the environmental conditions and process parameters for which this equipment must be qualified, non-metallic material capabilities, and the evaluation of environmental effects.

In addition, the qualification guidance provided in ASME QME-1, Qualification of Active Mechanical Equipment Used in Nuclear Power Plants, (Reference 3.9-24), is considered for qualification of active mechanical equipment. Mechanical pipe supports of SC1 equipment that are susceptible to environmental degradation are seismically and environmentally qualified.

### **3.9.6.2 Electrical Equipment**

Additional qualification guidance is considered for specific electrical equipment, if applicable, as follows:

- SC1 Batteries and their supporting element – IEEE 535 (Reference 3.9-25)
- SC1 Transformers IEEE 638 – (Reference 3.9-26)
- Static battery chargers and inverters – IEEE 650 (Reference 3.9-27)
- Electric penetration assemblies – IEEE 317 (Reference 3.9-28)
- SC1 Actuators – IEEE 382 (Reference 3.9-29)
- SC1 Continuous duty motors – IEEE 334 (Reference 3.9-30), as endorsed by Reg Guide 1.40 (Reference 3.9-31)
- SC1 Motor Control Centers (MCCs) – IEEE 649 (Reference 3.9-32)
- For the electrical equipment described above, excluding motors, the EMC qualification guidance provided in Reg Guide 1.180, (Reference 3.9-17) is considered

### **3.9.6.3 Instrumentation & Control Equipment**

Additional qualification guidance is considered for specific I&C equipment, if applicable. For example, control boards, panels, and racks classified as SC1 components utilize IEEE 420, (Reference 3.9-33) for their qualification program.

Qualification of computer-based I&C systems is in accordance with CNSC REGDOC-2.5.2, (Reference 3.9-1), CSA N290.13 (Reference 3.9-9), and IEEE 7-4.3.2 (Reference 3.9-34) which is consistent with the EMC requirements specified in Reg Guide 1.180 (Reference 3.9-12) and described in Subsection 3.9.5.

When computer based I&C systems environmental type testing is performed:

1. The system under test demonstrates that it functions and performs with safety software that has been validated and verified and is representative of the software to be installed in-service.
2. The testing demonstrates performance of all safety category functions that may be impacted by environmental factors under the environmental service conditions specified in the design specification. Software algorithms, that are tested during verification and validation testing, are not required to be tested unless their outputs exercise different hardware components which may be impacted by environmental conditions.

3. The testing exercises all portions of the system that are necessary to accomplish the safety category functions and those portions whose operation or failure could impair the safety category functions.
4. The testing confirms the response of digital interfaces and verify that the design accommodates the potential impact of environmental effects on the overall response of the system.

The testing of a complete system is preferred. When testing of a complete system is not practical, confirmation of the dynamic response to the most limiting environmental and operational conditions is based on type testing of the individual modules and analysis of the cumulative effects of environmental and operational stress on the entire system to demonstrate required safety performance.

#### **3.9.6.4 Cables, Raceways, Supports, etc.**

For qualification of SC1 cables, the qualification guidance provided in CSA N290.13, (Reference 3.9-10) and IEEE 383 (Reference 3.9-35) are considered.

Supports (hangers) that support trays or conduit that carry safety circuits are designed and analyzed to demonstrate qualification in accordance with IEEE 628 (Reference 3.9-36).

Supports used for Non-Safety Class raceway (conduit and cable tray) in Seismic Category A structures are analyzed to withstand the effects of a DBE and evaluated for seismic interaction as applicable.

SC1 connection assemblies consider the qualification guidance provided in IEEE 572, (Reference 3.9-37) as endorsed by Reg Guide 1.156, (Reference 3.9-38) for their qualification program.

#### **3.9.6.5 Line-Mounted Equipment**

Guidance in IEEE 572 (Reference 3.9-37) and IEC/IEEE 60980-344 (Reference 3.9-9.) identifies that special consideration is required for line-mounted (pipe-supported) equipment regarding seismic qualification as the most critical seismic loading condition will occur as a result of the piping or duct system.

Guidance and further clarification for special considerations for line-mounted equipment is provided in IEEE 572 (Reference 3.9-33) and IEC/IEEE 60980-344 (Reference 3.9-8) as well as IEEE 382 (Reference 3.9.10.11-29).

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

**Table 3.9-1: Harsh Environment Parameter Conditions**

Parameter		Condition
Temperature		10°C above normal ambient and $\geq 50^{\circ}\text{C}$ <sup>(1)</sup>
Pressure		>4 kPa(g) (or 10%) increase or decrease from normal ambient pressure due to a DBA <sup>(2)</sup>
Humidity		100% Relative Humidity or condensing steam conditions <sup>(3)</sup>
Submergence		Any <sup>(4)</sup>
Radiation	Non-electronic equipment	DBA Total integrated accident dose (TIAD) > 170 Gy (17 krad) <sup>(5)</sup>
	Electronic equipment	TIAD > 10 Gy (1krad) <sup>(6)</sup>
Chemistry		Significant change in chemistry of the ambient environment or operating conditions

- (1) Temperature criteria are based on 10°C as a significant increase in normal ambient temperature added to the typical 40°C ambient temperature rating of most industrial EI&C equipment.
- (2) Typically, pressure change must be coincident with other DBA stressors to be considered harsh.
- (3) If steam is present under normal conditions, it is not a harsh DBA stressor. If condensing humidity condition do not change following a DBA, it is not a harsh DBA stressor.
- (4) Submergence is not harsh if it also occurs under normal operation.
- (5) Based on the radiation threshold of the most radiation-sensitive polymer.
- (6) Based on the radiation threshold of integrated circuits.

### **3.10 In-Service Monitoring, Tests, Maintenance, and Inspections**

#### **3.10.1 Safety Design Bases and Requirements**

Ontario Power Generation DNNP-1 Project Quality Plan identifies the controls and describe the quality requirements to be implemented throughout the development of the BWRX 300 SMR project. This Project Quality Plan supplements NEDO 11209-A (Reference 3.10-12), for the execution of GEH design activities that are associated with the BWRX-300 project. NEDO 11209-A has been approved by the U.S. Nuclear Regulatory Commission (NRC). In addition, the CSA Group (CSA) Standard N299 Series (Reference 3.10-7 Thru 3.10-9) defines a consistent set of Canadian quality assurance program requirements for the provision of items and services for nuclear power plants.

The Canadian Nuclear Safety Commission (CNSC) governs the Canadian nuclear industry regulations and has jurisdictional authority. Canadian suppliers comply with CNSC regulations. U.S. based suppliers who export to Canada may request a waiver from U.S. CFRs, RGs, and NUREG and comply with CNSC regulations. In addition, CSA Standards N299.1, N299.2, and N299.3, defines the Canadian quality assurance program requirements for the provision of items and services for nuclear power plants, Categories 1, 2, and 3, respectively.

CNSC REDOC 2.6.1 (Reference 3.10-17), Section 3, is used as guidance for establishment of inspections, tests, modeling, and monitoring programs for the DNNP BWRX-300 Nuclear Power plant. Chapter 13 provides the specific features of the programs.

CNSC REGDOC-2.5.2, Version 1 (Reference 3.10-16) and CNSC REGDOC-2.6.2 (Reference 3.10-18) provide the primary requirements for addressing In-Service Monitoring, Tests, Maintenance, and Inspections.

SSCs that have shorter service lifetimes than the plant lifetime will be identified and described in the design documentation.

Design requirements associated with In-service Monitoring, Tests, Maintenance, and Inspections involve accessibility, ALARA, aging management and easy-removable insulation for inspection, testing, and maintenance. In cases where SSCs are of safety class and cannot be designed to support the desirable testing, inspection, or monitoring schedules, one of the following approaches shall be taken:

1. Proven alternative methods, such as surveillance of reference items or use of verified and validated calculation methods, shall be specified.
2. Conservative safety margins shall be applied, or other appropriate precautions shall be taken, to compensate for possible unanticipated failures.

#### **3.10.2 In-Service Monitoring**

The BWRX-300 levels of in-service monitoring for SSC is related to the Defence-in-Depth Defense Levels (DL) that are specified in Section 3.1 and associated classifications of SSCs in Section 3.2. Specifics on In-service monitoring are developed in the other PSAR chapters.

The design provides facilities for monitoring chemical conditions of fluids and of metallic and non-metallic materials. The means for adding or modifying the chemical constituents of fluid streams is specified in Chapter 13, Subsection 13.3.2.3 programmatic requirements for in-service monitoring.

#### **3.10.3 In-Service Testing**

IST of certain ASME Boiler and Pressure Vessel Code (BPVC) Section III Division 1 (Reference 3.10-1) pumps, valves, and snubbers (dynamic restraints) as applicable is performed in

accordance with the ASME OM code. In addition, IST is performed in accordance with applicable Canadian Codes and Standards, and IAEA Safety Standards.

Pre-service test results will be documented and used as a baseline for periodic in-service testing.

The design of BWRX-300 structures, systems, and components provides access for the performance of IST to the extent practicable.

The IST Program includes periodic tests and inspections that demonstrate the operational readiness of certain SSC that perform a function in shutting down the reactor to a safe shutdown condition, maintaining a safe shutdown condition, or mitigating the consequences of an accident.

Specific required in-service tests are established in other PSAR chapters involving SSCs.

Chapter 13, Subsection 13.3.2.3, provides programmatic requirements for in-service testing.

#### **3.10.4 In-Service Maintenance**

CNSC REGDOC-2.6.2 (Reference 3.10-16) forms the regulatory bases for the requirements of the Canadian Nuclear Safety Commission (CNSC) regarding maintenance programs for nuclear power plants (NPPs). This document also provides information and guidance on how the requirements may be met. The DNNP BWRX-300 Nuclear Power plant will abide by the recommendations of CNSC REGDOC-2.6.2 which are based in part on the following publications:

- CNSC, REGDOC-2.6.1, Reliability Programs for Nuclear Power Plants (Reference 3.10-15).
- CNSC, REGDOC-2.5.2, Version 1, Design of Reactor Facilities: Nuclear Power Plants (Reference 3.10-14).
- CNSC, REGDOC-1.1.2, Licence Application Guide: Licence to Construct a Reactor Facility, Version 2 (Draft) (Reference 3.10-13).
- International Atomic Energy Agency (IAEA), TECDOC-658, Safety Related Maintenance in the Framework of the Reliability Centered Maintenance Concept, Vienna, 1992 (Reference 3.10-10).
- IAEA Safety Standards Series, No. NS-G-2.6, Maintenance, Surveillance, and In-service (Reference 3.10-11).
- CSA N286-12, Management system requirements for nuclear facilities (Reference 3.10-6).

Baseline data will be gathered during initial testing and system commissioning of SSCs.

Chapter 13, Subsection 13.3.3, provides programmatic requirements for in-service maintenance.

#### **3.10.5 In-Service Inspection**

Mechanical components and equipment including heat exchangers, pipe supports, pumps, valves, and vessels, that are classified as ASME BPVC III Division 1 Class 1, 2, or 3 are designed and provided with accessible openings for ISI and testing, to justify the operational readiness of components and equipment as set forth within ASME BPVC III- Division 1.

Components and equipment, that require inspections and testing to satisfy ASME BPVC-XI-Division 1 requirements, are examined by appropriate ISI and testing techniques, including ASME BPVC III Division 1, ASME Code OM, CNSC REGDOC-2.5.2, and CNSC REGDOC 2.6.2 required examinations, prior to the component or equipment leaving the manufacturer's facility.

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

ASME BPVC-XI-2021, ASME Code OM, CNSC REGDOC-2.5.2, and CNSC REGDOC 2.6.2 inspection and testing requirements do not replace or change ASME BPVC III required examinations.

Nondestructive Examination (NDE) methods are described within ASME BPVC-V (Reference 3.10-2) and ASME BPVC-XI.

Component and equipment procurement specifications provide detailed requirements, which are to be used during the manufacturing phase and installation at the plant site.

Chapter 13, Subsection 13.3.2.3, provides programmatic requirements for ISI.

### **3.11 Compliance with National and International Standards**

Chapter 1, Appendix B Tables B1-11 through B1.11-3 Conformance with Applicable Regulations, codes, and standards, describes the applicable CNSC Regulatory documents, codes and standards used in the design of the OPG DNNP BWRX-300 plant. CNSC REGDOC 1.1.2 Draft Version 2 and CNSC REGDOC 2.5.2 Draft Version 2 form the basis of the Canadian regulatory requirements. The CSA Group (CSA) standards form the detailed bases of code and standard methodology to comply with the regulatory requirements and compared to the standards (both National and International) used in the BWRX-300 design. Many CSA standards refer to the use of U.S. codes in the design of Canadian Nuclear Plants. Alternative codes, standards, and methodology not addressed by CSA standards are reviewed against CNSC REGDOC requirements and justified through a design assessment process for use. Chapter 17 on Safety in Design discusses the overall design process.

As stated in Chapter 1, section 1.11, CNSC Regulatory Documents, applicable IAEA and U.S. regulatory documents, and industry codes and standards used in the OPG BWRX-300 design, grouped by Safety and Control Area (SCA), are listed in Appendix B Tables B1.11-1 through 1.11-3. These tables represent all 14 SCAs that form the bases for CNSC safety reviews. The tables list the codes and standards by the organization that represents the applicability to design type such as Mechanical, Electrical, Civil, Nuclear I&C and others. The tables clarify any specific details associated with the code and/or standard use.

The specific PSAR chapters provide prescriptive details that related to the BWRX-300 design features and their alignment with Canadian regulations including compliance with both national and international standards. Chapter 3, Safety Objectives and Design Rules for Structures, Systems and Components forms the majority of requirements for other chapters used in the design of the DNNP BWRX-300 new nuclear plant.

- 3.11-2 CNSC Regulatory Document REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants."

## **APPENDIX 3A – PRELIMINARY CLASSIFICATION OF STRUCTURES, SYSTEMS AND COMPONENTS**

### **3.12 Introduction**

The BWRX-300 approach to classifying Structures Systems and Components (SSC) is consistent with IAEA SSR-2/1, "Safety of Nuclear Power Plants: Design" (Reference 3-12-1) and IAEA SSG-30, Safety Classification of Structures, Systems, and Components in Nuclear Power Plants," (Reference 3.12-2) and aligns with CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants," Section 7.1 (Reference 3.12-3). Classification of SSC is conducted to identify the importance of the SSC with respect to safety.

The methodology for classification of BWRX-300 SSC is discussed in Section 3.2. in accordance with:

- Safety Class (SC)
- Seismic Category
- Quality Group

Table 3.12-1 provides a preliminary list of the principal BWRX-300 components organized by system. Classification of Structures is presented in Section 3.3, Table 3.3-1.

NOTES:

1. SC determination and methodology is discussed in Subsections 3.2.1 and 3.2.2.
2. Location Codes:
  - a. SCCV: Containment Vessel
  - b. RB: Reactor Building
  - c. TB: Turbine Building
  - d. CB: Control Building
  - e. RWB: Radwaste Building
  - f. OO: Outdoors On-site
  - g. OL: Any Other Location
  - h. ALL: All locations
3. Quality group classifications is discussed in Subsection 3.2.4.
4. Seismic categories are discussed in Subsection 3.2.3. Any items classified as NS are subject to evaluations for Seismic Interaction as discussed in Subsection 3.2.3.1.
5. Structures, systems and components required to be designed in accordance with Radioactive Waste Management requirements from RG 1.143 for Category RW-IIa, shall meet the guidance of NRC Regulatory Guide 1.143, as applied to radioactive waste management systems, with regard to quality, seismic, and quality group requirements.
6. Other abbreviations.
  - a. TBD: To Be Determined – classification information is to be provided later in the BWRX-300 design process
  - b. NA: Not Applicable
7. Components classified as SC1 may be assigned to a Seismic Class lower than A or B provided they are of a fail-safe design such that the failure of those component(s) does not adversely affect the ability to achieve the safety function.
8. Although these components are not SC1, they are seismically qualified because they are credited with monitoring leakage of reactor coolant under the scope of Regulatory Guide 1.45 or are related to handling and storage of used nuclear fuel.

## **APPENDIX 3B – COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSIS OF SEISMIC CATEGORY STRUCTURES**

### **3.13 Introduction**

This appendix describes the major computer programs used in the analysis and design of the BWRX-300 Seismic Category structures. The programs are verified for their application by appropriate methods, such as hand calculations, or comparison with results from similar programs, experimental tests, or published literature, including analytical results or numerical results to the benchmark problems. The computer codes used for design and safety analysis are qualified in accordance with NEDO-11209-A, "GE Hitachi Nuclear Energy Quality Assurance Program Description" (Reference 3.12-4) that complies with ASME NQA-1, "Quality Assurance Requirements for Nuclear Facility Applications" (Reference 3.12-18) and CSA N286.7-16, "Quality Assurance of Analytical, Scientific, and Design Computer Programs" (Reference 3.12-12).

GEH maintains an ISO 9001:2015, "Quality Management Systems - Requirements," International Organization for Standardization" (Reference 3.12-5) Certificate of Approval by U.S. Lloyd's Registrar QA (Identify Number: 10068327), with the following scope of approval applicable to:

- Design, Engineering, Procurement, and Servicing of Nuclear Power Plants, Related Systems and Components
- Design and Manufacturer of Nuclear Fuel
- Design and Development of Associated Software

The GEH design control measures are presented in Appendix A to reflect GEH's capabilities to meet the management system and high energy reactor facilities requirements described in CSA N286-12, "Management System Requirements for Nuclear Facilities" (Reference 3.12-6).

#### **3.13.1 ACS SASSI v4**

**Description:** ACS SASSI is a finite element computer code on the Microsoft Windows PC platforms for performing 3D dynamic soil-structure interaction (SSI) analysis to analyze the effect of seismic ground motions on structures. The analysis is performed in the frequency domain using linear or equivalent-linear material properties for the structure and soil.

**Validation:** The software is approved for production use under GEH procedure on engineering software for design and analysis software.

**Extent of Application:** ACS SASSI is used to perform seismic and static SSI and structure-soil-structure-interaction (SSSI) analyses, as applicable.

#### **3.13.2 ANSYS v17**

**Description:** ANSYS, INC. Multiphysics computer program. ANSYS is a general-purpose large-scale finite element analysis computer program and has interactive capabilities. Finite element analysis is a numerical method for analyzing structure, thermal, fluid flow and other physical problems. The analysis method is based on displacement formulation of the finite element method. Typical applications include finding stress, deformation, thermal analysis, and modal analysis with user inputs of geometrical dimensions, element type, material properties, boundary conditions, and loadings.

**Validation:** The software is approved for production use under GEH procedure on engineering software for design and analysis software.

**Extent of Application:** This program is used to model the structure and the hydrodynamics within the BWR and perform structural analysis for applicable loads.

### **3.13.3 Ansys LS-Dyna v2021**

**Description:** Ansys LS-DYNA is an explicit simulation program capable of simulating the response of materials to short periods of severe loading. Its many elements, contact formulations, material models and other controls can be used to simulate complex models with control over all the details of the problem. Ansys LS-DYNA applications include explosion/penetration, impact analysis, and non-linear explicit structural analysis.

**Validation:** This software is not approved for production use under GEH procedure on engineering software for design and analysis software and requires output verification in accordance with the design process.

**Extent of Application:** Ansys LS-DYNA is used to analyze BWRX-300 structures for effects of blast loading and aircraft impact.

### **3.13.4 SSI-StressCoord v1**

**Description:** The STRESS\_POST program is an auxiliary program to post-process the ACS SASSI NQA V4 STRESS result binary database. The STRESS\_POST program includes an ensemble of STRESS database processing functionalities which were customized for the GEH engineers for application to the BWRX-300 SMR seismic SSI analysis projects. The STRESS\_POST customized program is based on specific implementations incorporated in the ACS SASSI NQA V4 User Interface (UI) capabilities, such as the CTVEC and the CTCCV commands, and existing STRESS binary database verification tools used in-house during the development over years of the STRESS module.

**Validation:** The software is approved for production use under GEH procedure on engineering software for design and analysis software.

**Extent of Application:** This STRESS\_POST Program is used for post-processing the ACS SASSI STRESS binary databases for Integrated RB Walls and Floors in batch mode.

### **3.13.5 GT STRUDL**

#### **3.13.5.1 Description**

GT STRUDL® is structural engineering software offering a complete design solution, including 3D CAD modeling and 64-bit high-performance computation solvers into all versions. GT STRUDL includes all the tools necessary to analyze a broad range of structural engineering and finite element analysis problems, including linear and non-linear static and dynamic analysis.

#### **3.13.5.2 Validation**

This software is not approved for production use under GEH procedure on engineering software for design and analysis software and requires output verification in accordance with the design process.

#### **3.13.5.3 Extent of Application**

GT STRUDL is used to for the structural analysis and design of non-Seismic Category A structures.

## **APPENDIX 3C – COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSIS OF MECHANICAL STRUCTURES, SYSTEMS AND COMPONENTS**

### **3.14 Introduction**

As discussed in Subsection 3.6.1.1, this appendix describes the major computer programs used in the analysis of mechanical SSC.. The programs are verified for their application by appropriate methods, such as hand calculations, or comparison with results from similar programs, experimental tests, or published literature, including analytical results or numerical results to the benchmark problems. The computer codes used for design and safety analysis are qualified in accordance with NEDO-11209-A, “GE Hitachi Nuclear Energy Quality Assurance Program Description” (Reference 3.12-4) that complies with ASME NQA-1 Quality program (Reference 3.12-18) and CSA N286.7-16 (Reference 3.12-12).

GEH maintains an ISO 9001:2015 (Reference 3.12-5) Certificate of Approval by U.S. Lloyd’s Registrar QA (Identify Number: 10068327), with the following scope of approval applicable to:

- Design, Engineering, Procurement, and Servicing of Nuclear Power Plants, Related Systems and Components
- Design and Manufacturer of Nuclear Fuel
- Design and Development of Associated Software

The GEH design control measures are presented in Appendix A to reflect GEH’s capabilities to meet the management system and high energy reactor facilities requirements described in CSA N286-12 (Reference 3.12-6).

#### **3.14.1 ANSYS v17**

**Description:** ANSYS, INC. Multiphysics computer program. ANSYS is a general-purpose large-scale finite element analysis computer program and has interactive capabilities. Finite element analysis is a numerical method for analyzing structure, thermal, fluid flow and other physical problems. The analysis method is based on displacement formulation of the finite element method. Typical applications include finding stress, deformation, thermal analysis, and modal analysis with user inputs of geometrical dimensions, element type, material properties, boundary conditions, and loadings.

**Validation:** The software is approved for production use under GEH procedure on engineering software for design and analysis software.

**Extent of Application:** This program is used to model the structure and the hydrodynamics within the BWR and perform structural analysis for applicable loads.

#### **3.14.2 PBLE v1**

**Description:** Steam Dryer Analysis

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** PBLE calculates the acoustic loads on a steam dryer based on measurements of pressure along the main steam lines or pressures measured directly on the face of the steam dryer. The loads are then used in a finite element model to calculate the stresses in the dryer.

#### **3.14.3 SIMCENTER 3D Acoustics v2022**

**Description:** Used for modeling dryer acoustic loads and instrumentation diagnostics. Simcenter 3D is a unified, scalable, open and extensible environment for 3D CAE with connections to design,

1D simulation, test, and data management. Fast and accurate solvers power structural, acoustics, flow, thermal, motion, and composites analyses, as well as optimization and multi-physics simulation.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent Of Application:** SIMCENTER Finite elements acoustic software will be used to model and calculate acoustic wave propagation in fluid (steam, water) mediums.

#### 3.14.4 GT STRUDL

**Description:** GT STRUDL® is structural engineering software offering a complete design solution, including 3D CAD modeling and 64-bit high-performance computation solvers into all versions. GT STRUDL includes all the tools necessary to analyze a broad range of structural engineering and finite element analysis problems, including linear and non-linear static and dynamic analysis.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** GT STRUDL will be used to perform structural analysis and qualification of supports.

#### 3.14.5 HyperMesh

**Description:** HyperMesh is the market-leading, multi-disciplinary finite element pre-processor which manages the generation of the largest, most complex models, starting with the import of a CAD geometry to exporting a ready-to-run solver file. With its advanced geometry and meshing capabilities, HyperMesh provides an environment for rapid model generation.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** HyperMesh is a tool which will be used to generate mechanical models for complicated mechanical components. This tool will serve as a pre-processor to build mesh models, no calculations get performed with Hypermesh.

#### 3.14.6 ERSIN v3

**Description:** Piping Analysis Software. Secondary Response Spectra for control panels, equipment racks, etc.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** ERSIN is used to generate secondary response spectra for pipe and floor mounted equipment. Example applications include control panels, equipment racks, Main Steam Isolation Valves (MSIVs), Safety Relief Valves (SRVs), Hydraulic Control Units (HCUs), et cetera. ERSIN03P software has three input options: 1) card decks, 2) SAP software decks, and 3) PISYS software decks. ERSIN03P can be used with SAP version 4G07P (Ref. 5-1) and PISYS version 08P (Ref. 5-2) structure/piping models only. If a card input is used, a mass normalized mode shape is required. ERSIN03P is not applicable for axisymmetric analyses using a Fourier Decomposition technique.

#### 3.14.7 RINEX Computer Program

**Description:** RINEX is a computer code used to interpolate and extrapolate amplified response spectra used in the response spectrum method of dynamic analysis. RINEX is also used to generate response spectra with non-constant model damping. The non-constant model damping

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

analysis option can calculate spectral acceleration at the discrete eigenvalues of a dynamic system using either the strain energy weighted modal damping or the ASME BPVC-III Code Case N-411-1, "Alternative Damping Values for Response Spectra Analysis of Class 1, 2, and 3 Piping, Section III, Division 1, ERRATA SUP 13" (Reference 3.12-20) damping values.

**Validation:** Hand calculations and test cases analyzed are used to demonstrate the program's applicability and validity.

**Extent of Application:** This program is used to generate multiple damping spectra for piping.

### 3.14.8 PDA (Civil)

**Description:** Pipe Dynamic Analysis (PDA) Pipe Whip Restraint Analysis

**Validation:** This software is not approved for production use under GEH procedure CP-23-400, Engineering Software for Design and Analysis Software and requires output verification in accordance with the CP-03-100 Design Process.

**Extent of Application:** GEH in-house program for calculating pipe whip response under postulated break conditions. Determines response for a standard configuration which utilizes U-type pipe whip restraint.

### 3.14.9 PIPESTRESS

**Description:** PIPESTRESS (developed under a Quality Assurance Program compliant with the ASME NQA-1 (Reference 3.12-18) standard along with 10 CFR 21, "Reporting of Defects and Noncompliance" (Reference 3.12-9) and 10 CFR 50 Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants" (Reference 3.12-10)) is a pipe stress and flexibility analysis program, used for the evaluation of structural response and stress levels of piping systems against the requirements of industry codes and standards.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The plant layout, isometric drawings, P&ID, PFD, etc. will be used to build the piping model in PIPESTRESS, then PIPESTRESS will calculate the displacement, force/moment and stress. This software has the piping information, pipe routing & system information for BWRX-300 & some equipment information.

### 3.14.10 FLOMASTER v2021.1

**Description:** Uses simulation to offer reliable & accurate solvers and solutions for fluids engineering

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** Simcenter Flomaster is a unique thermo-fluid system simulation software tool used to simulate thermo-fluid systems; facilitating upfront engineering to reduce cost and lead times in product development and maintenance. It has an extensive library of component models, pre-populated with reliable performance data, Flomaster allows fluid system design to start before CAD data is available and component suppliers have been selected.

### 3.14.11 Ansys LS-Dyna v2021

**Description:** Ansys LS-DYNA is an explicit simulation program capable of simulating the response of materials to short periods of severe loading. Its many elements, contact formulations, material models and other controls can be used to simulate complex models with control over all

the details of the problem. Ansys LS-DYNA applications include explosion/penetration, impact analysis, and non-linear explicit structural analysis.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** Ansys LS-DYNA will be used to analyze BWRX-300 structures for effects of blast loading and aircraft impact.

#### **3.14.12      3KeyMaster v2021 (ICE/Plant Integration Engineering/Systems Engineering)**

Description: Plant-wide physics-based simulation supporting engineering design options, confirmation, and future reactor operator training full scope simulator (FSS) in accordance with ANS Std 3.5.

Validation: This software is not approved for production use under GEH procedure CP-23-400, Engineering Software for Design and Analysis Software and requires output verification in accordance with the CP-03-100 Design Process.

Extent of Application: 3KeyMaster is used to generate plant layout schematics & run test simulations for new plant setups through variable/parameter manipulation for OPG.

## **APPENDIX 3D – COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSIS OF ELECTRICAL STRUCTURES, SYSTEMS AND COMPONENTS**

### **3.15 Introduction**

This appendix describes the major computer programs used in the analysis of electrical SSC. The programs are verified for their application by appropriate methods, such as hand calculations, or comparison with results from similar programs, experimental tests, or published literature, including analytical results or numerical results to the benchmark problems. The computer codes used for design and safety analysis are qualified in accordance with NEDO-11209-A, "GE Hitachi Nuclear Energy Quality Assurance Program Description" (Reference 3.12-4) that complies with ASME NQA-1 Quality program (Reference 3.12-18) and CSA N286.7-16 (Reference 3.12-12).

GEH maintains an ISO 9001:2015 (Reference 3.12-5) Certificate of Approval by U.S. Lloyd's Registrar QA (Identify Number: 10068327), with the following scope of approval applicable to:

- Design, Engineering, Procurement, and Servicing of Nuclear Power Plants, Related Systems and Components
- Design and Manufacturer of Nuclear Fuel
- Design and Development of Associated Software

The GEH design control measures are presented in Appendix A to reflect GEH's capabilities to meet the management system and high energy reactor facilities requirements described in CSA N286-12 (Reference 3.12-6).

#### **3.15.1 ETAP v2021.1 (ICE Systems/I&C Tech)**

**Description:** Electrical Transient Analyzer Program (ETAP) is an electrical network modeling and simulation software tool used by power systems engineers to create an "electrical digital twin" and analyze electrical power system dynamics, transients and protection.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** ETAP is the Global Market and Technology Leader of power systems solutions for a broad spectrum of sectors including Generation, Transmission, Distribution, Transportation, Industrial, and Commercial. The most comprehensive and integrated model-driven solutions for design, simulation, analysis, optimization, monitoring, operation, and automation of electrical power systems.

#### **3.15.2 LDRA (I&C Tech/ICE Systems)**

**Description:** Liverpool Data Research Associates is a provider of software analysis, and test and requirements traceability tools for the Public and Private sectors and a pioneer in static and dynamic software analysis.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** LDRA is a tool used to perform unit/module testing on software functions and components. It allows us to create and store test cases so we can perform regression testing, and it also allows us to execute the test cases on the target hardware (in this case an ARM Cortex-A9 processor).

#### **3.15.3 Quartus II (I&C Tech/ICE Systems)**

**Description:** Tools that provide FPGA compiler, simulation, and programming capabilities.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** Quartus is a tool used to develop applications for programmable logic devices such as PLDs and FPGAs. Applications in this case means the logic that the device implements. For example, it could be logic that provides a 2 out of 3 votes, it could be something that processes digital communications such as our fibre optic links, etc. Included in the software is something called timing analysis, which is a methodology for ensuring the logic inside the device meets timing characteristics. It also includes support for a simulator. The simulator allows engineers to evaluate the functionality of their logic by specifying input and examining how the logic reacts (e.g., verify the correctness of the design). The simulator does not require a physical device.

## **APPENDIX 3E – COMPUTER PROGRAMS USED IN THE DESIGN AND ANALYSES STRUCTURES, SYSTEMS AND COMPONENTS – NUCLEAR FUELS**

### **3.16 Introduction**

This appendix describes the major computer programs used in the analysis of nuclear fuels. The programs are verified for their application by appropriate methods, such as hand calculations, or comparison with results from similar programs, experimental tests, or published literature, including analytical results or numerical results to the benchmark problems. The computer codes used for design and safety analysis are qualified in accordance with NEDO-11209-A, "GE Hitachi Nuclear Energy Quality Assurance Program Description" (Reference 3.12-4) that complies with ASME NQA-1 Quality program (Reference 3.12-18) and CSA N286.7-16 (Reference 3.12-12).

GEH maintains an ISO 9001:2015 (Reference 3.12-5) Certificate of Approval by U.S. Lloyd's Registrar QA (Identify Number: 10068327), with the following scope of approval applicable to:

- Design, Engineering, Procurement, and Servicing of Nuclear Power Plants, Related Systems and Components
- Design and Manufacturer of Nuclear Fuel
- Design and Development of Associated Software

The GEH design control measures are presented in Appendix A to reflect GEH's capabilities to meet the management system and high energy reactor facilities requirements described in CSA N286-12 (Reference 3.12-6).

#### **3.16.1 EPRI: Acube v11**

**Description:** Advanced cutset upper bound estimator

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use ACUBE to post-process result cutsets using a Binary Decision Diagram method which will provide a more accurate point estimate of the results. ACUBE is a post-processing software that analyzes minimal cutsets and returns an estimate of the probability for a given top event using the BDD method. The BDD method is more accurate estimation than the approximation calculations used in baseline results. The software can be used with manual inputs but typically is used with intermediate quantification software such as FRANX or PRAQuant.

#### **3.16.2 EPRI: CAFTA v11**

**Description:** CAFTA is an integrated tool to perform Probabilistic Risk Analysis, incorporating linking event tree/fault tree methodology.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The CAFTA software will be qualified to complete all designed functions within the software. The use of the CAFTA software will be acceptable for use as is. Note that the testing will not cover every possible variation or combination of use for the software but it will validate the software operates as intended for within the standard operating configuration of the software.

### 3.16.3 EPRI: MAAP v5

**Description:** The Modular Accident Analysis Program (MAAP) Version 5 - an Electric Power Research Institute (EPRI) owned and licenced computer software - is a fast-running computer code that simulates the response of light water and heavy water moderated nuclear power plants for both current and Advanced Light Water Reactor (ALWR) designs. It can simulate Loss-Of-Coolant Accident (LOCA) and non-LOCA transients for Probabilistic Risk Assessment (PRA) applications as well as severe accident sequences, including actions taken as part of the Severe Accident Management Guidelines (SAMGs).

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use MAAP to analyze reactor thermal-hydraulic and containment response to transients as well as severe accident sequence progressions. MAAP is used to predict the timing of key events, evaluate the influence of mitigative systems, evaluate effectiveness of operator actions, predict magnitude and timing of fission product releases, and investigate uncertainties in severe accident phenomena.

### 3.16.4 EPRI: PRAQuant v11

**Description:** Accident Sequence Quantification. In performing a fault tree based analysis it is often necessary to solve the fault tree several times, using different subtrees, boundary conditions, truncations or other assumptions about the model. These solutions can be performed manually in the CAFTA software, but it is often difficult to track and document the numerous results. PRAQuant is a general tool to configure several fault tree analysis solutions in advance, and to track the completion and results from each run.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use PRAQuant in the processing of the combined hazard model to generate a combined hazard cutset output. PRAQuant is a processing software to configure several fault tree analysis solutions and track the completion and results from each run. The software is capable of defining specific criteria to be applied in each fault tree analysis solution (e.g., flag files, recovery rules, output file name, truncation, etc.) and processes the supplied inputs into a format that a quantification engine (e.g., FTREX) is capable of processing. Once the quantification engine generates an output cutset file, the software can interface with QRecover to apply recovery rules before saving the final output to a defined directory.

### 3.16.5 FURST (Core & Fuel)

**Description:** Static & dynamic modeling

**Validation:** The software is approved for production use under GEH procedure CP-23-400, Engineering Software for Design and Analysis Software.

**Extent of Application:** Mechanical design of core internals loads, deflections, and stress analysis for X300

### 3.16.6 GTRAC v1

**Description:** Post-processing TRACG graphics file to edit desired output

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** GTRAC01P is a computer program that accepts binary graphics files generated by compatible versions of TRACG04P as input, and outputs user requested portions of those results into ASCII and CEDAR formats suitable for further post-processing. The data quantities residing on a TRACG graphics file are referred to as labels. An input file is used to request desired data using the corresponding label names in accordance with the structure defined in the TRACG User's Manual. If the labels on the graphics file are unknown, GTRAC01P can provide a listing of labels present on the file without actually outputting any label data, or users can use wildcard and pattern matching to request any labels that match a provided pattern. Some additional data is available on the graphics file, including a short description of the data set, and the units associated with data.

### 3.16.7 MACCS v4

**Description:** The MELCOR Accident Consequence Code Systems (MACCS) code, and its successor code, MACCS2, are based on the straight-line Gaussian plume model was developed originally for the Nuclear Regulatory Commission (USNRC). MACCS2 evaluates doses and health risks from the accidental atmospheric releases of radio nuclides. The principal phenomena considered in MACCS2 are atmospheric transport and deposition under time-variant meteorology, short-term and long-term mitigative actions and exposure pathways, deterministic and stochastic health effects, and economic costs.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** MACCS will be used as part of the licensing basis events analysis in radiological consequences.

### 3.16.8 MCNPX v6

**Description:** Monte Carlo N-Particle Transport is a general-purpose, continuous-energy, generalized-geometry, time-dependent, Monte Carlo radiation transport code designed to track many particle types over broad ranges of energies and is developed by Los Alamos National Laboratory.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** MCNP will be used for performing criticality and shielding analyses. MCNP can be used in several transport modes: neutron only, photon only, electron only, combined neutron/photon transport where the photons are produced by neutron interactions, neutron/photon/electron, photon/electron, or electron/photon. The neutron energy regime is from 10<sup>-11</sup> MeV to 20 MeV for all isotopes and up to 150 MeV for some isotopes, the photon energy regime is from 1 keV to 100 GeV, and the electron energy regime is from 1 KeV to 1 GeV. The capability to calculate keff eigenvalues for fissile systems is also a standard feature.

### 3.16.9 ORIGEN v1

**Description:** ORIGEN is a one-group depletion and radioactive decay computer code. ORIGEN is used to calculate the radionuclide composition and other related properties of nuclear materials (irradiated fuel isotope inventory).

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** ORIGEN is used for calculating core inventories of isotopes, and sometime for performing activation analyses of various materials or components.

### **3.16.10 PANAC v11**

**Description:** PANAC (PANACEA) is the computer program used for the detailed nuclear calculations of the BWR Core. It is a steady-state, three-dimensional, one and one half energy group, diffusion theory computer program with coupled nuclear and thermal-hydraulic representation of the reactor Core.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** The BWR Core Simulator (PANAC11A/P) is a steady-state, three-dimensional coupled nuclear-thermalhydraulic computer program representing a BWR core. An automated plant heat balance option is used for modeling of the external flow loop. Provisions are made for fuel cycle and thermal limits calculations. The program is used for detailed three-dimensional design and operational calculations of BWR neutron flux and power distributions and thermal performance as a function of control rod position, refueling pattern, coolant flow, reactor pressure, and other operational and design variables. A special power exposure iteration option is available for target exposure distribution and cycle length predictions. PANAC11A/P includes the effect of Doppler broadening as a function of moderator density, exposure, control and moderator density history for a given fuel type. The nuclear model is based on coarse-mesh nodal, improved 1-1/2 group (quasi-two group), static diffusion theory. The diffusion equations are solved using the fast energy group. Resonance energy neutronic effects are included in the model by relating the resonance fluxes to the fast energy flux. The thermal flux is represented by an asymptotic expansion using a slowing down source from the epithermal region. A spectral history reactivity model and control blade history reactivity model are included. Control blade history local peaking effects are also incorporated in the nuclear model. A pin power reconstruction model is implemented to account for the effect of flux gradients across the nodes on the local peaking distribution. Neutronic parameters used by PANAC11A/P are obtained from the two-dimensional lattice physics code (TGBLA06) and parametrically fitted as a function of moderator density, exposure, control and moderator density history for a given fuel type.

### **3.16.11 PRIME v3**

**Description:** The PRIME03P computer program is used to calculate the thermal/mechanical response of nuclear fuel to time varying power histories.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** PRIME03P is used for steady-state and transient licensing analysis of UO<sub>2</sub> and (U,Gd)O<sub>2</sub> fuel with (and without) additive material. PRIME03P is used for steady-state and transient licensing analysis as well as qualification cases of Recrystallized Annealed Zircaloy-2 cladding. Additionally, PRIME03P may be used with Stress-Relieved Annealed Zircaloy-4 cladding of either 70 % or 30 % cold work for qualification cases, but not for licensing analysis.

### **3.16.12 RAMP: GALE v3.2**

**Description:** The Gaseous and Liquid Effluents (GALE) series of codes consists of four codes that calculate the gaseous and liquid effluent releases from pressurized-water reactors (PWRs) and boiling-water reactors (BWRs)

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** GALE uses a combination of input data and hardwired parameters to calculate the source term of radionuclides generated by a nuclear power plant during routine operation. Parameters that vary from plant to plant are treated as "inputs"; GALE asks the

operator for input values on each run. Hardwired parameters are plant characteristics that are assumed to be the same for all reactors.

#### **3.16.13 RAMP: HABIT v2.2**

**Description:** HABIT v2.2 is a suite of computer codes to assist in evaluating Light Water Reactor (LWR) control room habitability in the event of accidental spills of toxic chemicals or the accidental release of radionuclides, including noble gas.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** HABIT v2.2 also uses a heavy-gas dispersion model, unifies the input screen of EXTRAN, DEGADIS, and SLAB, and incorporates Bitter Mc-Quaid calculation to determine which model needs to run and plot the concentration versus time outputs.

#### **3.16.14 RAMP: DandD v2.1**

**Description:** A code for screening analyses for licence termination and decommissioning.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The DandD software automates the definition and development of the scenarios, exposure pathways, models, mathematical formulations, assumptions, and justifications of parameter selections documented in Volumes 1 and 3 of USNRC NUREG/CR-5512, "Residual Radioactive Contamination From Decommissioning" (Reference 3.12-15).

#### **3.16.15 RAMP: GENII v2.10**

**Description:** GENII Version 2.10 is now part of the Radiation Protection Computer Code Analysis and Maintenance Program (RAMP) at the U.S. Nuclear Regulatory Commission.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** GENII is a documented set of programs for calculating radiation dose and risk from radionuclides released to the environment. Although the code was initially developed for the U.S. Environmental Protection Agency, regulators and decision makers in other federal agencies, including several outside the U.S., employ this state-of-the-art, technically peer reviewed system to analyze hazards and design controls to prevent or mitigate potential accidents.

#### **3.16.16 RAMP: MILDOS v4**

**Description:** Radiological dose commitment calculation code

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The MILDOS-AREA computer code calculates the radiological dose commitments received by individuals and the general population within an 80-km radius of an operating uranium recovery facility. In addition, air and ground concentrations of radionuclides are estimated for individual locations, as well as for a generalized population grid. Extra-regional population doses resulting from transport of radon and export of agricultural produce are also estimated.

**3.16.17 RAMP: NRC-RADTRAN v6.02.1**

**Description:** Risk & Consequence analysis code

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The USNRC Radioactive Material Transport (NRC-RADTRAN) computer code is used for risk and consequence analysis of radioactive material transportation. A variety of radioactive material is transported annually within this country and internationally. The shipments are carried out by overland modes (mainly truck and rail), marine vessels, and aircraft. Transportation workers and persons residing near or sharing transportation links with these shipments may be exposed to radiation from radioactive material packages during routine transport operations; exposures may also occur as a result of accidents. Risks and consequences associated with such exposures are the focus of the NRC-RADTRAN code.

**3.16.18 RAMP: PIMAL v4.1.0**

**Description:** GUI with pre-processor and post-processor capabilities which assists users in developing MCNP input decks and running the codes.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The PIMAL code is a graphical user interface with pre-processor and post-processor capabilities which assists users in developing MCNP input decks and running the codes. It allows users to easily generate quantitative figures of merit regarding positioning arms and legs in difference geometries. PIMAL software is considered an efficient and accurate tool for performing dosimetry calculations for radiation workers and exposed members of the public.

**3.16.19 RAMP: TurboFRMAC v2021 11.0.2**

**Description:** Radiological Hazard evaluation code

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The Turbo FRMAC analysis tool performs complex calculations to quickly evaluate radiological hazards during an emergency response by assessing impacts to the public, workers, and the food supply. Turbo FRMAC can be used to evaluate the hazard from a wide variety of radiological incidents, such as:

- Radiological Dispersal Devices (RDDs)
- Nuclear Power Plant Emergencies
- Fuel Handling Accidents
- Transportation Accidents
- Nuclear Detonations

Turbo FRMAC calculations are based on methods established by the Federal Radiological Monitoring and Assessment Center (FRMAC).

**3.16.20 RAMP: VARSKIN v1.0**

**Description:** Occupational Dose Analysis Code

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** VARSKIN+ is used to calculate occupational dose to the skin resulting from exposure to radiation emitted from hot particles or other contamination on or near the skin. These assessments are required by 10 CFR 20.1201(c), "Occupational dose limits for Adults" (Reference 3.12-11), which states that the assigned shallow dose equivalent is to the part of the body receiving the highest exposure over a contiguous 10 cm<sup>2</sup> of skin at a tissue depth of 0.007 centimeters (7 mg/cm<sup>2</sup>).

#### **3.16.21      SAP4G07P v7**

**Description:** SAP4G07P has been tested for a range of applications for static and dynamic analyses of structural and piping systems. SAP4G07P is generated in FORTRAN.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** SAP4G07P has been tested for a range of applications for static and dynamic analyses of structural and piping systems. SAP4G07P is generated in FORTRAN and has been compiled and run on Windows 7 (32 bit), Windows 7 (64 bit), and Windows 2003 and 2012 servers.

#### **3.16.22      SCALE v6**

**Description:** A Comprehensive Modeling and Simulation Suite for Nuclear Safety Analysis and Design. Scale6.1 (KENO/ORIGEN-ARP/S).

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** SCALE (KENOVI) is a Monte Carlo program for solving the neutron transport equation for an eigenvalue problem. The code implements the Monte Carlo process for neutron, photon, electron, or coupled transport involving all these particles, and computes the eigenvalue for neutron-multiplying systems. KENOVI uses the pointwise (i.e., continuous) cross-section data, and all reactions in a given cross-section evaluation (e.g., ENDF/B-VII.0) are considered.

#### **3.16.23      TGBLA v6**

**Description:** LANCR will replace TGBLA. Calculates lattice parameters for fuel bundles and the output is used by PANACEA to model the behavior of the fuel in the core

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** TGBLA06 is a lattice design computer program for conventional BWRs, which have the following lattices: 7x7, 8x8, 9x9, or 10x10. Water rods, including large central water rods and approximations for centered and offset water boxes, may be introduced into cells of the 2D mesh, which TGBLA06 solves. The 8x8 lattice can have up to four cells per water rod; the 9x9 lattice can have up to 3.5 cells per water rod; the 10x10 lattice can have up to four cells per water rod. Lattices with vanishing rods, thick-thin channels, or some water cross designs such as 8x8 and 10x10 water cross lattices, are qualified. TGBLA06 is qualified for water box designs where the water box is simulated by the use of nine water rods. Although TGBLA06 is capable of analyzing 11x11 and 12x12 lattices, MOX fuel and other design configurations, it has not been qualified for them. TGBLA06 solves 2D diffusion equations with diffusion parameters corrected by transport theory to provide the multiplication factor, the fission density distribution, the neutron balance, and the homogenized cross sections. Also, TGBLA06 performs burnup calculations for generating input to the BWR 3D simulator. In addition, TGBLA06 generates the rod-by-rod neutron cross sections, gamma smeared power distributions and flux discontinuity factors. The ring-by-ring gamma source distribution in gadolinium rods is not correct and should not be used.

#### **3.16.24 TRACG v4**

**Description:** TRACG is a GEH version of the Transient Reactor Analysis Code representing a best-estimate code for the analysis of BWR transients. It is based on a multi-dimensional two-fluid model for the reactor thermal hydraulics and a three-dimensional neutron kinetics model.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** TRACG04 is a computer program applicable for the calculation of thermal-hydraulic parameters and reactor power during BWR transients. TRACG04 is intended to be used as a 'best-estimate' system computer code, with capabilities for three-dimensional hydrodynamic calculations in the vessel components, and one-dimensional calculations in the other components. A full two-fluid representation supplemented by air and boron models is employed for the characterization of two-phase flow, allowing application to transients where thermal non-equilibrium and counter-current flow between phases is significant. TRACG04 has point, 1-D, and 3-D neutron kinetics models for simulating the feedback effects of moderator density, fuel temperature, boron, and control blade movement on the core power. TRACG04 has a control system model capable of simulating the BWR feedback control system. TRACG04 is capable of modeling standard BWR fuels and advanced fuel designs including part length fuel rods and large water rods. In addition to modeling the BWR, TRACG04 is also applicable to experimental test facilities constructed from components representative of a BWR.

#### **3.16.25 SEISM v5**

**Description:** The SEISM program can be used for the non-linear response prediction of structural system with spring, damper, friction & stop element, under dynamic loads. The program employs the component element method and can account for impact and friction forces effect. SEISM program performs calculations in double precision.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** SEISM can be used for the non-linear time history response prediction of structural systems with spring, damper, friction and stop elements under dynamic loads. The program employs the component element method and can account for impact and friction force effects. When running SEISM, the user can select to run any of its four modules (CRTFI, SEPRE, SEISM, SEPST) individually or combined within a single session. Output of one module may be passed to and used as input to the next module.

#### **3.16.26 DECAY v1**

**Description:** DECAY01A calculates the decay heat power fraction after certain operation period and exposure of a fissile core.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** DECAY01A is an Engineering Computer Code developed by GE Hitachi Nuclear Energy (GEH) as a method to determine the decay heat (shutdown power) for BWR fuel. The code was created in response to USNRC IN96-39, "Estimates of Decay Heat Using ANS 5.1 Decay Heat Standard May Vary Significantly" (Reference 3.12-16) that brought attention to the extreme variation in decay heat calculations throughout the country. This was due to either overly conservative assumptions or a misapplication of the ANS Decay Heat Standards. The DECAY01A code has therefore gone to great lengths to assure both the validity and applicability of its calculations. DECAY01A works as a function of both the ANSI/ANS-5.1-1979, "American National Standard Decay Heat Power in Light Water Reactors" (Reference 3.12-17) or ANSI/ANS-5.1-1994 (Reference 3.12-17) decay heat standards used for domestic and advanced reactor

designs respectively. These standards set forth values of decay heat from fission products of  $^{235}\text{U}$ ,  $^{239}\text{Pu}$ ,  $^{238}\text{U}$  and  $^{241}\text{Pu}$ ; and decay heat from actinides  $^{239}\text{U}$  and  $^{239}\text{Np}$ . DECAY01A also includes the decay heat contribution from other Actinides (in addition to  $^{239}\text{U}$  and  $^{239}\text{Np}$  which are specified in the Standard) as well as from Activation Products. In addition to the decay heat, DECAY01A evaluates the one-sigma uncertainty in the decay heat and adds a user-specified multiple of this uncertainty (usually 2 sigma) to the decay heat power.

### **3.16.27 GTRAC v1**

**Description:** Post-processing TRACG graphics file to edit desired output

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** GTRAC01P is a computer program that accepts binary graphics files generated by compatible versions of TRACG04P as input, and outputs user requested portions of those results into ASCII and CEDAR formats suitable for further post-processing. The data quantities residing on a TRACG graphics file are referred to as labels. An input file is used to request desired data using the corresponding label names in accordance with the structure defined in the TRACG User's Manual. If the labels on the graphics file are unknown, GTRAC01P can provide a listing of labels present on the file without actually outputting any label data, or users can use wildcard and pattern matching to request any labels that match a provided pattern. Some additional data is available on the graphics file, including a short description of the data set, and the units associated with data.

## **APPENDIX 3F – COMPUTER PROGRAMS USED IN ENVIRONMENTAL AND RADIOLOGICAL ANALYSES SUPPORTING THE DESIGN OF STRUCTURES, SYSTEMS AND COMPONENTS**

### **3.17 Introduction**

This appendix describes the major computer programs used in deterministic and probabilistic safety analyses. The programs are verified for their application by appropriate methods, such as hand calculations, or comparison with results from similar programs, experimental tests, or published literature, including analytical results or numerical results to the benchmark problems. The computer codes used for design and safety analysis are qualified in accordance with NEDO-11209-A, "GE Hitachi Nuclear Energy Quality Assurance Program Description" (Reference 3.12-4) that complies with ASME NQA-1 Quality program (Reference 3.12-18) and CSA N286.7-16 (Reference 3.12-12).

GEH maintains an ISO 9001:2015 (Reference 3.12-5) Certificate of Approval by U.S. Lloyd's Registrar QA (Identify Number: 10068327), with the following scope of approval applicable to:

- Design, Engineering, Procurement, and Servicing of Nuclear Power Plants, Related Systems and Components
- Design and Manufacturer of Nuclear Fuel
- Design and Development of Associated Software

The GEH design control measures are presented in Appendix A to reflect GEH's capabilities to meet the management system and high energy reactor facilities requirements described in CSA N286-12 (Reference 3.12-6).

#### **3.17.1 ADDAM Version 1.4.2**

**Description:** The ADDAM (Atmospheric Dispersion and Dose Analysis Method) computer code computes the statistical distribution of radiation doses to an individual or population after the airborne release of radioactive material into the environment. See Chapter 15, Subsection 15.5.1.2.5 for a description.

#### **Validation**

Validation of this tool is in compliance with the OPG project quality plan.

#### **Extent of Application**

See Chapter 15, Subsection 15.5. for extent of application.

#### **3.17.2 DECAY v1**

**Description:** DECAY01A calculates the decay heat power fraction after certain operation period and exposure of a fissile core.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** DECAY01A is an Engineering Computer Code developed by GE Hitachi Nuclear Energy (GEH) as a method to determine the decay heat (shutdown power) for BWR fuel. The code was created in response to USNRC IN96-39 (Reference 3.12-16) that brought attention to the extreme variation in decay heat calculations throughout the country. This was due to either overly conservative assumptions or a misapplication of the ANS Decay Heat Standards. The DECAY01A code has therefore gone to great lengths to assure both the validity and applicability of its calculations. DECAY01A works as a function of both the ANSI/ANS-5.1-1979 (Reference

3.12-17) or ANSI/ANS-5.1-1994 (Reference 3.12-17) decay heat standards used for domestic and advanced reactor designs respectively. These standards set forth values of decay heat from fission products of <sup>235</sup>U, <sup>239</sup>Pu, <sup>238</sup>U and <sup>241</sup>Pu; and decay heat from actinides <sup>239</sup>U and <sup>239</sup>Np. DECAY01A also includes the decay heat contribution from other Actinides (in addition to <sup>239</sup>U and <sup>239</sup>Np which are specified in the Standard) as well as from Activation Products. In addition to the decay heat, DECAY01A evaluates the one-sigma uncertainty in the decay heat and adds a user-specified multiple of this uncertainty (usually 2 sigma) to the decay heat power.

### **3.17.3 RADTRAD (Analytical Methods/ Radiological Analysis)**

**Description:** RADTRAD uses a combination of tables and numerical models of source term reduction phenomena to determine the time-dependent dose at user-specified locations for a given accident scenario. It also provides the inventory, decay chain, and dose conversion factor tables needed for the dose calculation.

**Validation:** The software is approved for production use under GEH procedure CP-23-400, Engineering Software for Design and Analysis Software.

**Extent of Application:** The RADTRAD code is used for calculating accident doses, calculating transport of fission products inside the plant after an accident, performing filter loading calculations for post-accident.

### **3.17.4 RAMP: GALE v3.2**

**Description:** The Gaseous and Liquid Effluents (GALE) series of codes consists of four codes that calculate the gaseous and liquid effluent releases from pressurized-water reactors (PWRs) and boiling-water reactors (BWRs)

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** GALE uses a combination of input data and hardwired parameters to calculate the source term of radionuclides generated by a nuclear power plant during routine operation. Parameters that vary from plant to plant are treated as “inputs”; GALE asks the operator for input values on each run. Hardwired parameters are plant characteristics that are assumed to be the same for all reactors.

### **3.17.5 RAMP: HABIT v2.2**

**Description:** HABIT v2.2 is a suite of computer codes to assist in evaluating Light Water Reactor (LWR) control room habitability in the event of accidental spills of toxic chemicals or the accidental release of radionuclides, including noble gas.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** HABIT v2.2 also uses a heavy-gas dispersion model, unifies the input screen of EXTRAN, DEGADIS, and SLAB, and incorporates Bitter Mc-Quaid calculation to determine which model needs to run and plot the concentration versus time outputs.

### **3.17.6 RAMP: DandD v2.1**

**Description:** A code for screening analyses for licence termination and decommissioning.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The DandD software automates the definition and development of the scenarios, exposure pathways, models, mathematical formulations, assumptions, and

justifications of parameter selections documented in Volumes 1 and 3 of NUREG/CR-5512 (Reference 3.12-15).

#### **3.17.7 RAMP: GENII v2.10 (Analytical Methods/Radiological Analysis)**

**Description:** GENII Version 2.10 is now part of the Radiation Protection Computer Code Analysis and Maintenance Program (RAMP) at the U.S. Nuclear Regulatory Commission.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** GENII is a documented set of programs for calculating radiation dose and risk from radionuclides released to the environment. Although the code was initially developed for the U.S. Environmental Protection Agency, regulators and decision makers in other federal agencies, including several outside the U.S., employ this state-of-the-art, technically peer reviewed system to analyze hazards and design controls to prevent or mitigate potential accidents.

#### **3.17.8 RAMP: MILDOS v4**

**Description:** Radiological dose commitment calculation code

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The MILDOS-AREA computer code calculates the radiological dose commitments received by individuals and the general population within an 80-km radius of an operating uranium recovery facility. In addition, air and ground concentrations of radionuclides are estimated for individual locations, as well as for a generalized population grid. Extra-regional population doses resulting from transport of radon and export of agricultural produce are also estimated.

#### **3.17.9 RAMP: NRC-RADTRAN v6.02.1**

**Description:** Risk & Consequence analysis code

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The NRC Radioactive Material Transport (NRC-RADTRAN) computer code is used for risk and consequence analysis of radioactive material transportation. A variety of radioactive material is transported annually within this country and internationally. The shipments are carried out by overland modes (mainly truck and rail), marine vessels, and aircraft. Transportation workers and persons residing near or sharing transportation links with these shipments may be exposed to radiation from radioactive material packages during routine transport operations; exposures may also occur as a result of accidents. Risks and consequences associated with such exposures are the focus of the NRC-RADTRAN code.

#### **3.17.10 RAMP: PIMAL v4.1.0**

**Description:** GUI with pre-processor and post-processor capabilities which assists users in developing MCNP input decks and running the codes.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The PIMAL code is a graphical user interface with pre-processor and post-processor capabilities which assists users in developing MCNP input decks and running the codes. It allows users to easily generate quantitative figures of merit regarding positioning arms

and legs in difference geometries. PIMAL software is considered an efficient and accurate tool for performing dosimetry calculations for radiation workers and exposed members of the public.

### **3.17.11 RAMP: TurboFRMAC v2021 11.0.2**

**Description:** Radiological Hazard evaluation code

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** The Turbo FRMAC analysis tool performs complex calculations to quickly evaluate radiological hazards during an emergency response by assessing impacts to the public, workers, and the food supply. Turbo FRMAC can be used to evaluate the hazard from a wide variety of radiological incidents, such as:

- Radiological Dispersal Devices (RDDs)
- Nuclear Power Plant Emergencies
- Fuel Handling Accidents
- Transportation Accidents
- Nuclear Detonations

Turbo FRMAC calculations are based on methods established by the Federal Radiological Monitoring and Assessment Center (FRMAC).

### **3.17.12 RAMP: VARSKIN v1.0**

**Description:** Occupational Dose Analysis Code

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** VARSKIN+ is used to calculate occupational dose to the skin resulting from exposure to radiation emitted from hot particles or other contamination on or near the skin. These assessments are required by 10 CFR 20.1201(c) {Reference 3.12-11), which states that the assigned shallow dose equivalent is to the part of the body receiving the highest exposure over a contiguous 10 cm<sup>2</sup> of skin at a tissue depth of 0.007 centimeters (7 mg/cm<sup>2</sup>).

### **3.17.13 SAP4G07P v7**

**Description:** SAP4G07P has been tested for a range of applications for static and dynamic analyses of structural and piping systems. SAP4G07P is generated in FORTRAN.

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** SAP4G07P has been tested for a range of applications for static and dynamic analyses of structural and piping systems. SAP4G07P is generated in FORTRAN and has been compiled and run on Windows 7 (32 bit), Windows 7 (64 bit), and Windows 2003 and 2012 servers.

### **3.17.14 SCALE v6**

**Description:** A Comprehensive Modeling and Simulation Suite for Nuclear Safety Analysis and Design. Scale6.1 (KENO/ORIGEN-ARP/S).

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** SCALE (KENOVI) is a Monte Carlo program for solving the neutron transport equation for an eigenvalue problem. The code implements the Monte Carlo process for neutron, photon, electron, or coupled transport involving all these particles, and computes the eigenvalue for neutron-multiplying systems. KENOVI uses the pointwise (i.e., continuous) cross-section data, and all reactions in a given cross-section evaluation (e.g., ENDF/B-VII.0) are considered.

### 3.17.15 TGBLA v6

**Description:** LANCR will replace TGBLA. Calculates lattice parameters for fuel bundles and the output is used by PANACEA to model the behavior of the fuel in the core

**Validation:** Validation of this tool is in compliance with the OPG project quality plan.

**Extent of Application:** TGBLA06 is a lattice design computer program for conventional BWRs, which have the following lattices: 7x7, 8x8, 9x9, or 10x10. Water rods, including large central water rods and approximations for centered and offset water boxes, may be introduced into cells of the 2D mesh, which TGBLA06 solves. The 8x8 lattice can have up to four cells per water rod; the 9x9 lattice can have up to 3.5 cells per water rod; the 10x10 lattice can have up to four cells per water rod. Lattices with vanishing rods, thick-thin channels, or some water cross designs such as 8x8 and 10x10 water cross lattices, are qualified. TGBLA06 is qualified for water box designs where the water box is simulated by the use of nine water rods. Although TGBLA06 is capable of analyzing 11x11 and 12x12 lattices, MOX fuel and other design configurations, it has not been qualified for them. TGBLA06 solves 2D diffusion equations with diffusion parameters corrected by transport theory to provide the multiplication factor, the fission density distribution, the neutron balance, and the homogenized cross sections. Also, TGBLA06 performs burnup calculations for generating input to the BWR 3D simulator. In addition, TGBLA06 generates the rod-by-rod neutron cross sections, gamma smeared power distributions and flux discontinuity factors. The ring-by-ring gamma source distribution in gadolinium rods is not correct and should not be used.

### 3.17.16 TRACG v4

**Description:** TRACG is a GEH version of the Transient Reactor Analysis Code representing a best-estimate code for the analysis of BWR transients. It is based on a multi-dimensional two-fluid model for the reactor thermal hydraulics and a three-dimensional neutron kinetics model.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** TRACG04 is a computer program applicable for the calculation of thermal-hydraulic parameters and reactor power during BWR transients. TRACG04 is intended to be used as a 'best-estimate' system computer code, with capabilities for three-dimensional hydrodynamic calculations in the vessel components, and one-dimensional calculations in the other components. A full two-fluid representation supplemented by air and boron models is employed for the characterization of two-phase flow, allowing application to transients where thermal non-equilibrium and counter-current flow between phases is significant. TRACG04 has point, 1-D, and 3-D neutron kinetics models for simulating the feedback effects of moderator density, fuel temperature, boron, and control blade movement on the core power. TRACG04 has a control system model capable of simulating the BWR feedback control system. TRACG04 is capable of modeling standard BWR fuels and advanced fuel designs including part length fuel rods and large water rods. In addition to modeling the BWR, TRACG04 is also applicable to experimental test facilities constructed from components representative of a BWR.

### 3.17.17      **IMPACT**

**Description:** IMPACT is a customizable tool that allows the user to assess the transport and fate of contaminants through a user-specified environment.

**Validation:** The software is not qualified under the engineering software process and the output of the software will be verified with each use per the design process.

**Extent of Application:** IMPACT performs the calculations for CSA N288.1:14, "Guidelines for Calculating Derived Release Limits for Radioactive Material in Airborne and Liquid Effluents for Normal Operation of Nuclear Facilities", R2019 (Reference 3.12-14). The code calculates the doses from routine effluent emission from a plant that are the results of normal operation.

## **APPENDIX 3G – COMPUTER PROGRAMS USED IN THE DESIGN OF COMPONENTS, SYSTEMS AND STRUCTURES IN SAFETY ANALYSES (PRA AND DETERMINISTIC)**

### **3.18 Introduction**

This appendix describes the major computer programs used in the analysis of the safety-related components, equipment, and structures. The programs are verified for their application by appropriate methods, such as hand calculations, or comparison with results from similar programs, experimental tests, or published literature, including analytical results or numerical results to the benchmark problems. The computer codes used for design and safety analysis are qualified in accordance with NEDO-11209-A, “GE Hitachi Nuclear Energy Quality Assurance Program Description” (Reference 3.12-4) that complies with ASME NQA-1 Quality program (Reference 3.12-18) and CSA N286.7-16 (Reference 3.12-12).

GEH maintains an ISO 9001:2015 (Reference 3.12-5) Certificate of Approval by U.S. Lloyd’s Registrar QA (Identify Number: 10068327), with the following scope of approval applicable to:

- Design, Engineering, Procurement, and Servicing of Nuclear Power Plants, Related Systems and Components
- Design and Manufacturer of Nuclear Fuel
- Design and Development of Associated Software

The GEH design control measures are presented in Appendix A to reflect GEH’s capabilities to meet the management system and high energy reactor facilities requirements described in CSA N286-12 (Reference 3.12-6).

#### **3.18.1 EPRI: Acube v11**

**Description:** Advanced cutset upper bound estimator

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use ACUBE to post-process result cutsets using a Binary Decision Diagram method which will provide a more accurate point estimate of the results. ACUBE is a post-processing software that analyzes minimal cutsets and returns an estimate of the probability for a given top event using the BDD method. The BDD method is more accurate estimation than the approximation calculations used in baseline results. The software can be used with manual inputs but typically is used with intermediate quantification software such as FRANX or PRAQuant.

#### **3.18.2 EPRI: CAFTA v11**

**Description:** CAFTA is an integrated tool to perform Probabilistic Risk Analysis, incorporating linking event tree/fault tree methodology.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The CAFTA software will be qualified to complete all designed functions within the software. The use of the CAFTA software will be acceptable for use as is. Note that the testing will not cover every possible variation or combination of use for the software but it will validate the software operates as intended for within the standard operating configuration of the software.

### 3.18.3 EPRI: FRANX v11

**Description:** Development of PRA Hazards models (Fire, Flood, High Winds, Seismic, etc.)

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use FRANX in the development of the Internal Fire, Internal Flood, Seismic, and High Winds hazard analyses. Specifically, FRANX will be used to build hazard specific scenarios and generate one-top models for later combination into an integrated hazard model. The FRANX software is a tool for analyzing external event risk. This tool is used to manage and develop the scenarios, calculate the probabilistic impact on core damage, and generate one-top solution models.

### 3.18.4 EPRI: FTREx v1.8

**Description:** FTREX reads a fault tree that consists of Boolean equations for system failure and generates cut sets that are minimal combinations of component failures that cause system failure.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** This software will have all functionality qualified and be valid for use with the necessary interfacing software (e.g., FRANX, CAFTA, PRAQuant) or independently of those software. The software must be accessible from the interfacing software locations as well as have permission to read and write files to a temp directory and a defined output file directory.

### 3.18.5 EPRI: HRA Calculator

**Description:** Supports development of PRA Human Reliability Analyses

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use the HRA Calculator to develop the human reliability analysis, calculate the human error probabilities, and develop a dependency analysis for the credited operator actions. The HRA Calculator provides a step by step process for developing the HRA applying one of the following methods: CBDTM, HCR/ORE, ASEP, SPAR-H, THERP.

### 3.18.6 EPRI: MAAP v5

**Description:** The Modular Accident Analysis Program (MAAP) Version 5 - an Electric Power Research Institute (EPRI) owned and licenced computer software - is a fast-running computer code that simulates the response of light water and heavy water moderated nuclear power plants for both current and Advanced Light Water Reactor (ALWR) designs. It can simulate Loss-Of-Coolant Accident (LOCA) and non-LOCA transients for Probabilistic Risk Assessment (PRA) applications as well as severe accident sequences, including actions taken as part of the Severe Accident Management Guidelines (SAMGs).

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use MAAP to analyze reactor thermal-hydraulic and containment response to transients as well as severe accident sequence progressions. MAAP is used to predict the timing of key events, evaluate the influence of mitigative systems, evaluate effectiveness of operator actions, predict magnitude and timing of fission product releases, and investigate uncertainties in severe accident phenomena.

### 3.18.7 EPRI: PRAQuant v11

**Description:** Accident Sequence Quantification. In performing a fault tree based analysis it is often necessary to solve the fault tree several times, using different subtrees, boundary conditions, truncations or other assumptions about the model. These solutions can be performed manually in the CAFTA software, but it is often difficult to track and document the numerous results. PRAQuant is a general tool to configure several fault tree analysis solutions in advance, and to track the completion and results from each run.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use PRAQuant in the processing of the combined hazard model to generate a combined hazard cutset output. PRAQuant is a processing software to configure several fault tree analysis solutions and track the completion and results from each run. The software is capable of defining specific criteria to be applied in each fault tree analysis solution (e.g., flag files, recovery rules, output file name, truncation, etc.) and processes the supplied inputs into a format that a quantification engine (e.g., FTREX) is capable of processing. Once the quantification engine generates an output cutset file, the software can interface with QRecover to apply recovery rules before saving the final output to a defined directory.

### 3.18.8 ActivePoint HMI/CIMPLICITY 11

**Description:** Digital user interface design and display software by GE Power that runs using GE Digital CIMPLICITY HMI/SCADA automation platform.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The HFE team is using the software to design the BWRX-300 digital user interfaces. The scope of the interfaces is all display screens run by the DCIS, and any other platforms that can communicate directly with CIMPLICITY.

### 3.18.9 Control ST – ToolboxST Tool

**Description:** GE Power's ControlST\* software suite provides the foundation for the Mark\* V1e Control System in a wide range of applications, including control, safety integrity level, monitoring, and protection of assets. ToolboxST is one of the tools within ControlST, used for process configuration and diagnostics software for process, SIL, excitation and power conversion

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** For BWRX-300, the HFE team is using ToolboxST to provide early dynamic features and testing capability for the digital user interfaces designed using ActivePoint HMI/CIMPLICITY. The tool allows emulation of "live" screen features without the need for a plant simulation model driving the software. This allows early usability testing of digital user interfaces, as part of the HFE design testing and evaluation set of activities. The software is not used in production.

### 3.18.10 EPRI: SysImp v11

**Description:** Analysis of PRA Importance Measures. SysImp is a software tool used to calculate the importance of basic events, or collections of those events, in a risk model. SysImp is designed for risk models where components, equipment trains, and systems are represented by groups of basic events.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use SysImp to preform risk importance sensitivities, calculations, and grouping system importance. SysImp allows for deriving insights from risk importance rankings, estimating total plant risk given a specific change, and collective risk importance measures.

### **3.18.11      EPRI: UNCERT v11**

**Description:** PRA Uncertainty Propagation analysis tool. Uncertainty Evaluation Tool (UNCERT). UNCERT can read the cut set or sequence data created from CAFTA and calculate the uncertainty of the cut set result.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project will use UNCERT to perform the parametric uncertainty calculations on the output cut sets. The UNCERT software will take a defined input (e.g., cut set file and associated CAFTA RR database) and perform the uncertainty analysis utilizing either a Monte Carlo or Latin Hypercube sampling method. The output will calculate the metrics for the cut set using that defined method.

### **3.18.12      GOTHIC v8**

**Description:** GOTHIC is a procured software from Zachry Nuclear Engineering, Inc. for design, licensing, safety and operating analysis of nuclear power plant containments, confinement buildings and system components.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** GOTHIC is used to perform a sensitivity analysis for the passive containment cooling system while developing the design.

### **3.18.13      MACCS v4**

**Description:** The MELCOR Accident Consequence Code Systems (MACCS) code, and its successor code, MACCS2, are based on the straight-line Gaussian plume model was developed originally for the Nuclear Regulatory Commission (NRC). MACCS2 evaluates doses and health risks from the accidental atmospheric releases of radio nuclides. The principal phenomena considered in MACCS2 are atmospheric transport and deposition under time-variant meteorology, short-term and long-term mitigative actions and exposure pathways, deterministic and stochastic health effects, and economic costs.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** MACCS will be used as part of the licensing basis events analysis in radiological consequences.

### **3.18.14      RAMP: NRC-RADTRAN v6.02.1**

**Description:** Risk & Consequence analysis code

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The NRC Radioactive Material Transport (NRC-RADTRAN) computer code is used for risk and consequence analysis of radioactive material transportation. A variety of radioactive material is transported annually within this country and internationally. The shipments are carried out by overland modes (mainly truck and rail), marine vessels, and aircraft. Transportation workers and persons residing near or sharing transportation links with these shipments may be exposed to radiation from radioactive material packages during routine transport operations; exposures may also occur as a result of accidents. Risks and consequences associated with such exposures are the focus of the NRC-RADTRAN code.

### **3.18.15      SCALE v6**

**Description:** A Comprehensive Modeling and Simulation Suite for Nuclear Safety Analysis and Design. Scale6.1 (KENO/ORIGEN-ARP/S).

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** SCALE (KENOVI) is a Monte Carlo program for solving the neutron transport equation for an eigenvalue problem. The code implements the Monte Carlo process for neutron, photon, electron, or coupled transport involving all these particles, and computes the eigenvalue for neutron-multiplying systems. KENOVI uses the pointwise (i.e., continuous) cross-section data, and all reactions in a given cross-section evaluation (e.g., ENDF/B-VII.0) are considered.

### **3.18.16      TRACG v4**

**Description:** TRACG is a GEH version of the Transient Reactor Analysis Code representing a best-estimate code for the analysis of BWR transients. It is based on a multi-dimensional two-fluid model for the reactor thermal hydraulics and a three-dimensional neutron kinetics model.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** TRACG04 is a computer program applicable for the calculation of thermal-hydraulic parameters and reactor power during BWR transients. TRACG04 is intended to be used as a 'best-estimate' system computer code, with capabilities for three-dimensional hydrodynamic calculations in the vessel components, and one-dimensional calculations in the other components. A full two-fluid representation supplemented by air and boron models is employed for the characterization of two-phase flow, allowing application to transients where thermal non-equilibrium and counter-current flow between phases is significant. TRACG04 has point, 1-D, and 3-D neutron kinetics models for simulating the feedback effects of moderator density, fuel temperature, boron, and control blade movement on the core power. TRACG04 has a control system model capable of simulating the BWR feedback control system. TRACG04 is capable of modeling standard BWR fuels and advanced fuel designs including part length fuel rods and large water rods. In addition to modeling the BWR, TRACG04 is also applicable to experimental test facilities constructed from components representative of a BWR.

### **3.18.17      VTR.LMP**

**Description:** Package of functions and data frames supporting VTR LMP applications. This package was developed using open-source code R. Currently only functions on a Mac platform.

**Validation:** The software qualification process is being followed and verification and validation is in progress.

**Extent of Application:** The BWRX-300 project currently does not use this code package; however, developmental work is in progress to explore the application of this software to BWRX-

NEDO-33952 REVISION 1  
NON-PROPRIETARY INFORMATION

300. The VTR.LMP R code package contains the processing commands necessary for gathering the inputs and running them through the LMP code package functions. The final licensing basis events are processed in this code package for use with the Frequency-Consequence plot.

Note: There is a developmental X300.LMP that would be the starting point for future applications of this code package.

## **4.0 REACTOR**

Chapter 4 describes the components of the nuclear fuel, reactor, and reactor core, including the fuel rods, fuel assemblies, reactivity control system, nuclear design, and thermal-hydraulic design including requirements pertaining to safety.

The reactor assembly consists of the Reactor Pressure Vessel (RPV), pressure-containing appurtenances including Control Rod Drive (CRD) housings, in-core instrumentation housings, and reactor internal components (Figure 4.1-1). A summary of the important design and performance characteristics of the reactor and plant is given in Table 1.5-1.

A brief overview of the BWRX-300 reactor is provided in Section 4.1. The reactor materials, internal components, specifications, controls on welding, non-destructive examination, fabrication, and materials are described in Chapter 5, Section 5.2. The reactor internal components are described in Chapter 5, Subsection 5.4.2. The RPV design is described in Chapter 5, Section 5.4.

The fuel assembly and control rods are described in Section 4.2 including the design basis requirements, analytical methods, and evaluation results. Aspects pertaining to the nuclear design of the core, including the reference BWRX-300 design used for safety analysis, are described in Section 4.3. The thermal-hydraulic design basis requirements and important methodologies are described Section 4.4, and thermal-hydraulic stability is discussed in Section 4.8. The core monitoring function is described in Section 4.7. A description of the CRD system and associated requirements is provided in Section 4.6.

The design bases and functional requirements applied in the nuclear design of the fuel, core and reactivity control system comply with CNSC REGDOC-2.5.2 (Reference 4.1-1), Section 8.1.

### **4.1 Summary Description**

Chapter 4 describes the components of the nuclear fuel, reactor, and reactor core, including the fuel rods, fuel assemblies, reactivity control system, nuclear design, and thermal-hydraulic design including requirements pertaining to safety.

The reactor assembly consists of the RPV, pressure-containing appurtenances including CRD housings, in-core instrumentation housings, and reactor internal components (Figure 4.1-1). A summary of the important design and performance characteristics of the reactor and plant is given in Table 1.5-1.

#### **4.1.1 Reactor Pressure Vessel**

The BWRX-300 RPV is a vertical, cylindrical pressure vessel fabricated with forged rings or rolled plate welded together with a removable top head by use of a head flange, seals, and bolting. The RPV also includes penetrations, nozzles, and reactor internals support.

The increased RPV height, relative to forced circulation Boiling Water Reactors (BWRs), is achieved by a “chimney” in the space that extends from the top of the core (top guide) to the entrance to the chimney head and steam separator assembly. The natural circulation flow resulting from the tall RPV results in adequate thermal margins during power operation and off-normal conditions as described in Section 4.3.

The RPV design and description are provided in Chapter 5, Section 5.4.

#### **4.1.2 Reactor Internal Components**

The major reactor internal components are described Chapter 5, Section 5.4, including:

- Core components (control rods and nuclear instrumentation)
- Core support structures (shroud, shroud support, top guide, core plate, control rod guide tubes, control rod drive housings, fuel support castings, and orificed/peripheral fuel supports)
- Chimney
- Chimney head and steam separator assembly
- Steam dryer assembly

Except for the Zircaloy in the reactor core, these reactor internals are stress corrosion-resistant stainless steels or other high alloy material. The fuel assemblies (including fuel rods and channels), control rods, chimney head and steam separator assembly, chimney assembly, steam dryers and in-core instrumentation assemblies are removable when the reactor vessel is opened for refueling or maintenance.

#### **4.1.3 Reactor Core**

The reactor core is comprised of 240 fuel assemblies arranged to form an upright cylinder. Additionally, movable control elements are inserted or withdrawn for reactivity control. The fuel assemblies are comprised of hermetically sealed fuel rods in a square array along with upper & lower tie plates, water rods, fuel rod spacers, fuel channel and connecting components. The fuel assemblies are supported by the reactor internals. The reactor internals also direct the flow of the coolant into the fuel assembly past the fuel rods. The coolant is light water and serves as both the working fluid and moderator. Boiling within the fuel assembly results in a two-phase mixture that exits the top of the fuel assembly that then enters the steam separators after traversing the axial extent of the chimney. The resulting dry steam at the exit of the steam dryers is then sent to the turbine to drive the turbine generator. The RPV and major components are depicted in Figure 4.1-1.

#### **4.1.4 Fuel Assembly and Control Rod Assembly**

A BWRX-300 GNF2 fuel assembly consists of 92 fuel rods and two large central water rods that occupy eight (8) fuel rod locations contained in a 10x10 array (i.e., 100 lattice locations). Fourteen fuel rod locations are occupied by part length fuel rods.

The fuel rod consists of uranium dioxide in the form of cylindrical pellets contained in Zircaloy tubing. The tubing is plugged, sealed, and welded at the ends to encapsulate the fuel. Fuel rods are pressurized internally with helium during fabrication to reduce clad creepdown and promote heat transfer.

Key attributes of the GNF2 fuel assembly are summarized in Table 4.1-1.

The control rods are cruciform shaped and reside in the intra-assembly gap. As such, the control rod geometric envelope is separated from that of the fuel assembly. A control rod is associated with four (4) fuel assemblies that, together, constitute the fundamental BWR cell.

The design of the fuel and control rods is described in Section 4.2.

The CRD mechanisms used to withdraw and insert the control rods are of the fine motion type providing fine reactivity control, fast scram and redundant insertion means. The CRD system is described in Section 4.6

#### **4.1.5 Nuclear Instrumentation**

The performance of the core is monitored by fixed neutron detectors within the core. The in-core nuclear instrumentation provides input to automatic reactor core control functions. The BWRX-300 nuclear instrumentation consists of Power Range Neutron Monitoring System (PRNM), Gamma Thermometers (GTs), and Wide Range Neutron Monitors.

The PRNM provides neutron monitoring power signals to the SC1 I&C protection systems. The PRNM also provides signals for post-accident monitoring purposes and, through isolated one-way optical data, links to the core monitoring three-dimensional power distribution program and to the control rod blocking systems.

GTs are in-core devices that convert local gamma flux to an electrical signal that supplies information required to calibrate the Local Power Range Monitors (LPRM) in the PRNM system. They also provide input to the SC2 I&C protection systems for various trip and monitoring functions.

The Wide Range Neutron Monitor system is a redundant pair of industrial computers with a real time operating system that monitors the fixed neutron detectors in the core. The detectors are distributed radially in the core at fixed heights. Each detector is sensitive to neutrons from below criticality to approximately 20% thermal power. The core monitoring function design is provided in Sections 4.7 and Chapter 7, Section 7.3.

#### **4.1.6 Analysis Techniques**

The analytical techniques employed in core design are comprised of the computer codes summarized in Table 4.1-2 and engineering design practices. The computer codes in Table 4.1-2 are further described in Chapter 3, Appendix 3G.

## **4.2 Fuel System Design**

The fuel system consists of the fuel assembly and the reactivity control assembly (i.e., the control rods). The fuel assembly is comprised of a fuel bundle, a channel that surrounds the fuel bundle, and a channel fastener that attaches the channel to the bundle. The fuel bundle is comprised of fuel rods (some of which contain burnable neutron absorbers), upper and lower tie plates, water rods, spacers, springs, and assembly fittings.

The BWRX-300 reactor core is fueled with commercially available BWR fuel currently in production for forced circulation BWRs (e.g., GE BWR/4-6 and Advanced Boiling Water Reactor (ABWR)). The reference fuel design for reactor licensing is GNF2 (Figure 4.2-1). GNF2 is the third evolution of the Global Nuclear Fuel (GNF) 10x10 fuel design and was first deployed in batch quantities in 2007

GNF2 fuel conforms with the requirements stipulated in Licensing Topic Report "General Electric Standard Application for Reactor Fuel" (Reference 4.2-1). GEH BWR fuel designs have been developed to conform to the New Fuel Licensing requirements stipulated in GESTAR as per (Reference 4.2-1) NEDC-33270P. GESTAR is the framework for implementing U.S. regulatory requirements and consistent with international standards as evidenced by the multiple jurisdictions in which GNF fuel has been deployed. Furthermore, the requirements in GESTAR are evaluated in (Reference 4.2-2) which shows that the fuel meets the requirements in the CNSC REGDOC-2.5.2. (Reference 4.1-1).

### **4.2.1 Design Bases**

#### **4.2.1.1 Fuel Assembly Design Bases**

The fuel assembly design bases are established to satisfy the performance and safety criteria presented in CNSC REGDOC-2.5-2 (Reference 4.1.-1).

The fuel assembly is designed to:

- Support self-sustaining fission chain reaction, thereby producing energy in the form of heat
- Maintain its integrity to retain fission products generated in the fuel during normal operation and operational transients or during Anticipated Operational Occurrence AOO conditions

The fuel rod design considers all applicable effects such as fuel density changes, fission gas release, clad creep, and other physical properties which vary with burnup. The integrity of the fuel rods is achieved by designing to prevent excessive fuel temperatures, internal gas pressure due to fission gas releases, cladding stresses, strains, and strain fatigue. The fuel rods are designed so that the conservative design bases of the limiting set of events envelop the lifetime operating conditions of the fuel. For each design basis, the performance of the limiting fuel rod, with appropriate consideration for uncertainties, does not exceed the limits specified by the design basis (as discussed in Section 4.2). The detailed fuel design also establishes such parameters as pellet size and density, clad/pellet diametral gap, gas plenum size, and helium pre-pressurization level.

The fuel assembly structure integrity is assured by setting limits on stresses and deformations due to various loads and by preventing the assembly structure from interfering with the functioning of other components. The fuel assembly is designed to withstand the following loads:

- Non-operational loads occurring in shipping and handling
- Normal and abnormal loads occurring in startup testing, normal operation, AOOs
- Abnormal loads occurring in infrequent events and accidents

Chapter 4 establishes the fuel design criteria. Specifically, Section 4.2 identifies fuel damage criteria. Section 4.3 establishes fuel criteria for axial offset anomaly. Section 4.4 provides specific thermal-hydraulic criteria.

#### **4.2.1.2 Control Rods Design Bases**

The control rods are designed to control the fission chain reaction. The rods, along with the control rod drive system (Section 4.6), provide stable and automatic control of reactor core power, spatial instabilities, and local power density during normal operation. The control rods also shut down the reactor and maintain the core subcritical.

The control rod design meets the following acceptance criteria:

- Control rod stresses, strains, and cumulative fatigue are evaluated to not exceed the ultimate stress or strain limit of the material, structure, or welded connection
- The control rod design is evaluated to be capable of insertion into the core during all modes of plant operation within the limits assumed in the plant analyses
- Control rod materials are shown to be compatible with the reactor environment
- Control rod reactivity worth is included in the plant core analyses

The following bases are established for the above acceptance criteria.

#### **Stress, Strain, and Fatigue**

The control rod design is evaluated to assure that it does not fail because of loads due to shipping, handling, normal operation, including the effects of AOOs, Postulated Accidents (PAs) and Design Extension Conditions (DECs). To ensure that the control rods do not fail, these loads must not exceed the ultimate stress and strain limit of the material, structure, or welded connection. Fatigue must not exceed a fatigue usage factor of 1.0.

The loads evaluated include those from normal operational transients (scram and rod maneuvering), pressure differentials, thermal gradients, flow, and system induced vibration, and irradiation growth in addition to the lateral and vertical loads expected for each condition. Fatigue usage is based upon the cumulative effect of the cyclic loadings. The analyses include corrosion and crud deposition as a function of time, as appropriate.

Conservatism is included in the analyses by including margin to the limit or by assuming loads greater than expected for each condition. Higher loads can be incorporated into the analyses by increasing the load itself or by statistically considering the uncertainties in the value of the load.

#### **Control Rod Insertion**

The control rod design is evaluated to assure that it can be inserted during normal operations including the effects of AOOs, PAs and DECs. These evaluations include a combination of analyses of the geometrical clearance and actual testing. The analyses consider the effects of manufacturing tolerances, swelling and irradiation growth.

#### **Control Rod Material**

The external control rod materials must be capable of withstanding the reactor coolant environment for the life of the control rod. Effects of crud deposition, crevices, stress corrosion and irradiation upon the material must be included in the control rod design and core evaluations. Irradiation effects to be considered include material hardening and absorber depletion and swelling.

## **Reactivity**

The reactivity worth of the control rod design is determined by the initial amount and type of absorber material and irradiation depletion. Scram time insertion performance must also be included in the plant core analyses including the effects of normal operations, AOOs, PAs and DEC's.

### **4.2.2 Fuel Assembly and Control Rods Description**

#### **4.2.2.1 Fuel Assembly Description**

The reference GNF2 fuel assembly components are shown on Figure 4.2-1, and consists of a fuel bundle, a channel that surrounds the fuel bundle, and a channel fastener that attaches the channel to the bundle. The fuel rods and water rods are spaced and supported by upper and lower tie plates and intermediate spacers. The lower tie plate has the function of supporting the fuel assembly in the reactor. The upper tie plate has a handle for transferring the fuel bundle from one location to another.

The identifying fuel assembly serial number is engraved on the top of the handle with no two assemblies bearing the same serial number. This unique numbering supports the programmatic requirements for nuclear material accountancy required in CNSC REGDOC-2.13.1, Safeguards and Nuclear Material Accountancy, Section 7 (Reference 4.2-12). A projection from one side of the handle ensures proper orientation of the assembly in the core.

The materials used in the GNF2 fuel assemblies are listed in Table 4.2-1. Water chemistry controls used to minimize adverse effects on materials are described in Chapter 9A, Sections 9A.8, 9A.9, and 9A.10 and Chapter 13, Subsection 13.3.2.

#### **4.2.2.2 Fuel Bundle**

The GNF2 fuel bundle is comprised of fuel rods that contain a cladding tube that house the  $\text{UO}_2$  fuel pellets with some  $\text{UO}_2$  pellets containing gadolinia. Each fuel rod is hermetically sealed with welded upper and lower end plugs. The cladding and end plug material is Zircaloy-2 with a zirconium liner for pellet-clad interaction resistance. All fuel rods are inerted with helium before sealing.

##### **4.2.2.2.1 Normal Full-Length Rods**

There are 70 normal full-length rod locations in the GNF2 fuel bundle and reside in holes in the upper and lower tie plates. An expansion spring is installed onto the upper end plug that interacts with the upper tie plate exerts a downward force maintaining the axial position of the fuel rod while accommodating irradiation growth. The active fuel length is 381 cm. The plenum also contains a retention spring that protects the column of fuel pellets during transportation from the manufacturing facility to the reactor site.

##### **4.2.2.2.2 Tie Rods**

Tie rods are normal full-length rods except both the upper and lower end plugs are threaded. The lower end plug is screwed into matching threads that are machined into the lower tie plate. The tie rod upper end plug protrudes through the upper tie plate and is secured with nuts. There are eight (8) tie rods located symmetrically along the bundle periphery.

#### **4.2.2.2.3 *Gadolinia (Burnable Absorber) Rods***

Gadolinia rods are essentially normal full-length rods with normal fuel pellets except sections of the fuel column contain pellets with Gd<sub>2</sub>O<sub>3</sub> homogeneously blended with the UO<sub>2</sub> powder. The resultant pellets that function as a burnable neutron absorber controlling excess reactivity in the fresh fuel. The Gd<sub>2</sub>O<sub>3</sub> concentration is effectively depleted by the end of the first bundle operation cycle and is cycle length dependent.

#### **4.2.2.2.4 *Part Length Rods***

Partial length fuel rods were introduced to reduce the two-phase pressure drop for improved stability (i.e., lower decay ratios as described in Section 4.8) and retained in all subsequent fuel products.

Additionally, partial length fuel rods improve nuclear efficiency by better matching the axial hydrogen-to-fissile uranium ratio (H/U) ratio in BWR fuel with axially varying moderator density. Partial length fuel rods also reduce core reactivity in the cold condition and increase cold shutdown margins.

GNF2 has eight (8) long-partial length fuel rods and six (6) short-partial length fuel rods that have fuel column lengths that are approximately two thirds (2/3) and one third (1/3) of 381 cm (150-inch) active fuel length, respectively. The two lengths are used for fuel efficiency to better match the axial H/U ratio axially as the moderator density decreases. The long partial length fuel rods in GNF2 are located adjacent to the intra-assembly bypass gap (i.e., bundle periphery) and the short partial length fuel rods are located adjacent to the central water rods for improved reactivity margins.

#### **4.2.2.2.5 *Water Rods***

The GNF2 assembly is designed with two large circular water rods that are centrally located and occupy 8 fuel rod lattice positions (i.e., each water rod occupies 4 fuel rod locations).

These holes allow water to be channeled from the bottom end of the bundle to the upper part of the bundle, without boiling, for improved neutron moderation which increase moderation and results in improved reactivity and improves cold shutdown margins. The water rods are hollow Zircaloy tubes with several holes around the circumference near each end allowing coolant flow through. The water rod flow is controlled by the number and diameter of the inlet holes at the lower end. Both water rods are screwed into the lower tie plate, and one is designed to position the eight spacers axially. Tabbed water rods that position the spacers are designed with a D-shaped upper end plug and with spacer positioning tabs. These tabs are welded to the tube exterior above and below each spacer location (see Figure 4.2-1). The tabbed water rod (spacer-positioning) is prevented from rotating by the engagement of its D-shaped upper end plug with a D-shaped hole in the upper tie plate. The non-tabbed water rod has a round shank upper end plug and no spacer-positioning tabs. An expansion spring is located between the water rod shoulder and upper tie plate allowing for differential axial expansion.

The single-phase (i.e., liquid) water that flows through the water rod increases neutron moderation and further thermalizes the neutron energy spectrum, improving nuclear efficiency. Water rods in the fuel assemblies also function to increase moderation for improved reactivity and improved cold shutdown margins.

#### **4.2.2.2.6 Spacers**

The GNF2 fuel design uses 8 spacers with integral springs made of Alloy X-750. The integral spring construction results in significantly fewer parts. The spacer spring force prevents fretting wear on the fuel rods due to fuel rod vibration. Flow diversion devices added to the top of the spacer improves liquid droplet deposition onto the surface of the fuel rods in the two-phase flow region.

The GNF2 bundle design has a non-uniform axial spacing of the 8 spacers optimizing critical power performance. The spacers axial separation in the lower region of the bundle prevents excessive fuel rod bow during operation. The spacers are positioned closer to each other in the upper region of the bundle for increased liquid droplet deposition in the annular flow regime. The GNF2 spacer exhibits low hydraulic resistance (i.e., pressure drop). Alloy X-750 is resistant to hydrogen pickup and maintains strength and ductility through the operating lifetime and while in storage.

#### **4.2.2.2.7 Upper Tie Plate**

The type-304 stainless steel upper tie plate supports the weight of the fuel assembly and positions the rod ends laterally during operation and handling. The upper tie plate has an internally threaded corner post fabricated to accept the channel fastener bolt. The upper tie plate is synergistically designed with two large central water rods and the partial length fuel rods maximizing flow area and minimizing two-phase pressure-drop.

#### **4.2.2.2.8 Debris Filter Lower Tie Plate**

The type-304 stainless steel lower tie plate, in conjunction with the upper tie plate, supports the weight of the fuel assembly and positions the rod ends laterally during operation and handling. Figure 2.7 of NEDC-33270, GNF2 Advantage Generic Compliance with NEDE-24011-PA (GESTAR II), (Reference 4.2-1) is an assembly consisting of a machined casting, non-removable debris filter cartridge, and a welded cover plate. The debris filter component is specifically designed to maximize filtration efficacy and the hydraulic resistance (i.e., pressure drop) is explicitly modeled in core performance and safety analyses.

#### **4.2.2.2.9 Channel and Channel Fastener**

The BWR fuel channel (Figure 4.2-1) performs the following functions:

1. Forms the fuel bundle coolant flow path outer periphery
2. Provides a surface for control rod guidance in the reactor core
3. Provides structural lateral stiffness to the fuel bundle
4. Controls, in conjunction with the lower tie plate, coolant bypass flow at the channel/lower tie plate interface

The channel is open at the bottom and makes a sliding seal fit over the lower tie plate. At the top of the channel, two opposite corners have welded clips. These clips support the weight of the channel on the upper tie plate posts. One of the clips has a hole for attaching the channel fastener to the bundle. The channel design incorporates a uniform thickness bottom end. The remainder of the channel has corners, sidewalls and sidewall grooves at the control blade roller, and symmetric locations providing sufficient strength in the regions of highest stress while minimizing material that absorbs neutrons.

The overall stiffness of the fuel assembly is almost entirely a function of the channel stiffness. The GNF2 channel stiffness and the fuel assembly stiffness is essentially the same as previous fuel assemblies. The NSF (GNF proprietary zirconium-based alloy channel material) that is standard for GNF2 was introduced in reload quantities in 2016 following U.S. Nuclear Regulatory Commission (USNRC) approval. The design mitigates excessive channel deformation in-service and minimizes channel/control blade interference. The technical basis for replacing Zircaloy-2 and Zircaloy-4 with the NSF channel material is provided in NEDE-33798 (Reference 4.2-3).

The GNF2 channel fastener assembly consists of a stainless-steel casting (or fastener guard), a one-piece Alloy X-750 leaf spring with two active leaves at right-angles, a spring lock washer, and a fastener bolt attaching the fuel channel to the upper tie plate.

The channel fastener casting (or guard) fits over the top of the channel and bolts through the channel clip into the upper tie plate. The fastener guard serves as a reaction support for the leaf springs, provides a captive housing and lead-in for the fastener spring, and protects the springs from being overstressed. The fastener bolt attaches the channel to the bundle and remains captive in the casting, even if the fastener bolt were to fail.

#### **4.2.2.3 Control Rods**

The control rods (Figure 4.2-2) perform dual functions of power distribution shaping and reactivity control. Power distribution in the core is controlled during operation of the reactor by manipulation of selected patterns of control rods. These rods are positioned to counterbalance steam voids in the top of the core and effect significant power flattening. These groups of control elements, used for power flattening, experience a somewhat higher duty cycle and neutron exposure than the other rods in the control system.

The reactivity control function requires that all control rods be available for either reactor “scram” (i.e., prompt shutdown) or reactivity control. Because of this, the control elements are mechanically designed to withstand the dynamic forces resulting from a scram. They are connected to bottom-mounted, electro-hydraulically actuated drive mechanisms that allow either electric motor controlled axial positioning for reactivity regulation or hydraulic scram insertion. The design of the rod-to-drive connection permits each control rod to be coupled or uncoupled from its drive without disturbing the remainder of the control system. The bottom-mounted drives permit the entire control system to be left intact and remain operable for tests with the reactor vessel open.

The core reactivity control requirements are met by use of the combined effects of the movable control rods, supplementary burnable neutron absorber (i.e., Gadolinia Rods in the fuel bundle described in Subsection 4.2.2.2.3), and the reactor coolant natural flow.

The control rod main structure consists of a top handle, an absorber section, and a bottom connector assembled into a cruciform shape. The top handle contains a grapple opening for handling. The absorber section is an array of stainless-steel tubes filled with boron carbide powder capsules or a combination of boron carbide powder capsules and hafnium rods. The connector is positioned on the bottom of the control rod for coupling to the control rod drive. While being inserted into the core, the control rod is restricted to the cruciform envelope created by the fuel bundles. Handle pads guide the control rod along the channels and connector rollers guide the control rod within the guide tube as the control rod is inserted and withdrawn from the core. Configuration of the control rod is shown in Figure 4.2-3.

The BWRX-300 employs the Ultra-HD control rod, which is based on the Ultra-HD control rod designed for the BWR/2 through BWR/6. That design has been approved by the USNRC and applied to operating plants. The GEH Ultra-HD control rod is a derivative of prior designs incorporating the full-length hafnium rods in outer edge, high depletion tube locations. A detailed description is given in (Reference 4.2-4), NEDE-33284 Supplement 1P-A, "Marathon-Ultra Control Rod Assembly."

#### **4.2.3 Fuel Design Evaluation**

The GNF2 fuel design is the result of over 50 years of BWR fuel design, fabrication, and operational experience. The BWR fuel design process, comprised of engineering methods, analyses and test, is mature and generically applicable to the BWRX-300. The methods applied in the design of BWR fuel are documented in various Licencing Topical Reports that were submitted to the USNRC as needed. In addition, GNF developed a fuel licensing framework with the USNRC, and other regulatory authorities, called GESTAR, NEDE-24011-P-A-31 (Reference 4.4-8). The GESTAR licensing framework defines the generic requirements and approved methods for designing BWR fuel.

Most of the fuel rod thermal mechanical design analyses are performed using the PRIME fuel rod thermal-mechanical methodology. The method, qualification and application of the PRIME methodology are described in NEDC-33256P-A, NEDC-33457P-A, NEDC-33458P-A and NEDC-33840P-A (References 4.2-5, through 4.2-8). The PRIME methodology is approved for application to AOO transients (Reference 4.2-8, NEDC-33840P-A). This methodology is applicable to the analysis of the fuel rod response for all transient events and has been qualified for performing fuel analysis for BWRX using US NQA-1 standard, which is equivalent to Canadian standard CSA N286.7. PRIME analyses are performed for the following conditions:

1. For each analysis, fuel rod input parameters are based on either the most unfavorable manufacturing tolerances (i.e., 'worst tolerance' analyses) or statistical distributions of the input values. Calculations are performed providing either a 'worst tolerance' or statistically bounding tolerance limit for the resulting output parameter(s)
2. Operating conditions are postulated that cover the conditions anticipated during normal operating conditions and AOOs

Fuel rod design evaluations establish an upper bound power history envelope for the different fuel rod types. These power histories are used for fuel rod thermal mechanical design analyses evaluating the fuel rod design features and demonstrating conformance to the design criteria. These power histories are applied as a design constraint in the development of any BWR core design, including the reference BWRX-300 core described in 4.3.

The PRIME analysis assumes that during the fuel rod operating lifetime, the fuel rod (axial) node with the highest power operates on the limiting power-exposure envelope.

##### **4.2.3.1 Worst Tolerance Analyses**

The analyses apply worst tolerance assumptions to the cladding circumferential strain during an AOO. In this case, the important PRIME inputs are all biased to the fabrication tolerance extreme in the direction that produces the most limiting circumferential strain. The biases are discussed in detail in NEDC-33258P-A (Reference 4.2-7).

##### **4.2.3.2 Statistical Analyses**

For PRIME analyses are performed using standard error propagation statistical methods. The statistical analysis procedure is presented in NEDC-33258P-A (Reference 4.2-7).

#### **4.2.3.3 Fuel Lift and Seismic and Dynamic Load Analysis**

The fuel lift and seismic and dynamic load analyses are completed prior to fuel release for transportation. The fuel lift seismic and dynamic load analysis evaluates whether these loads are sufficient to unseat the fuel assembly from the lower tie plate, and if so, the maximum vertical lift distance and maximum fuel dynamic acceleration resulting from reseating. The acceptance criteria for this analysis are:

1. Vertical fuel lift is less than the engagement between the fuel support and the lower tie plate
2. Peak horizontal and vertical accelerations are less than the fuel demonstrated acceleration capabilities

#### **4.2.3.4 Cladding Strain**

The cladding strain analysis is performed using the PRIME code and the worst tolerance methodology discussed previously. For each fuel rod type, as described in Subsection 4.2.2.2, the cladding strain is calculated at various exposure points where transient overpower is assumed relative to the limiting power history. The magnitude of the overpower event is increased until the cladding strain approaches, but does not exceed, the limits described in NEDC-33258P-A (Reference 4.2-7) at the most limiting exposure to establish the mechanical overpower. Mechanical overpowers may also be defined as a function of exposure, ensuring that cladding strain does not exceed the limits described in NEDC-33258P-A (Reference 4.2-7) at any exposure point.

#### **4.2.3.5 Fuel Rod Internal Pressure**

The fuel rod internal pressure analysis is performed using the PRIME code and the statistical methodology discussed previously. The fuel rod internal pressure nominal value and standard deviation are determined at various fuel rod exposure points. At each of these exposure points, the nominal values and standard deviation of the fuel rod internal pressure that would cause the cladding to creep outward at a rate equal to the fuel pellet irradiation swelling rate (the critical pressure) are calculated. A design ratio is defined from the rod internal pressure and the critical pressure with their standard deviations. This design ratio limit of no more than 1.0 at a 95% confidence level, ensures that the fuel rod cladding does not creep out at a rate greater than the fuel pellet irradiation swelling rate.

#### **4.2.3.6 Fuel Pellet Temperature**

The fuel pellet temperature analysis is performed statistically using the PRIME code. For each fuel rod type the fuel pellet centerline temperature is statistically calculated at various exposure points assuming an overpower relative to the limiting power history. The lower 95% value for margin to fuel melting is calculated based on these statistical distributions. The overpower event magnitude is further increased until the lower 95% melt margin approaches zero but remains positive at the most limiting exposure point. The result from this analysis establishes the thermal overpower discussed below. Thermal overpowers may also be defined as a function of exposure, ensuring that lower 95% melt margin remains positive at all exposure points.

#### **4.2.3.7 Cladding Fatigue Analysis**

The cladding fatigue analysis is performed statistically using the PRIME code. Variations in power, coolant pressure and coolant temperature are superimposed on the limiting power history for calculating the cladding fatigue.

Cladding strain cycles are analyzed in NEDC-33270P (Reference 4.2-1) using the fuel duty cycles shown in NEDC-33258P-A (Reference 4.2-7). The duty cycles represent conservative assumptions regarding power changes anticipated during normal reactor operation and AOOs, planned surveillance testing, normal control blade maneuvers, shutdowns and load following. Fatigue analyses explicitly account for daily load following using the BWRX-300 plant duty cycles specification, with 347 cycles per year. The analyses of GNF2 fuel show that the cladding fatigue capability accommodates the expected fatigue duty for the projected life and operation of the fuel with sufficient margin (Reference 4.2-11, NEDC-33941P).

#### **4.2.3.8 Cladding Creep Collapse**

Cladding creep collapse occurs when excessive in-reactor fuel pellet densification causes fuel column axial gaps. This phenomenon has been observed in some pressurized water reactor fuel rods. The cladding creep collapse analysis consists of a detailed finite element mechanics analysis of the cladding. This evaluation is described in NEDC-33139P-A (Reference 4.2-9).

#### **4.2.3.9 Fuel Rod Stress Analysis**

The fuel rod stress analysis is performed using the Monte Carlo statistical methodology and addresses local fuel rod stress concerns, such as the stresses at spacer contact points, that are not directly addressed by the PRIME code. Results from PRIME analyses are used to generate inputs for the stress analysis. The cladding stress analysis is described in NEDC-33270-P (Reference 4.2-1).

#### **4.2.3.10 Thermal and Mechanical Overpowers**

Analyses are performed to establish the values of the maximum overpower magnitudes that do not result in violation of the cladding circumferential strain criterion or the incipient fuel centerline melting criterion. As part of the core design and AOO analysis, the calculated core mechanical and thermal overpowers defined in NEDC-33258P-A (Reference 4.2-7) and NEDC-33840P-A (Reference 4.2-8) are compared with the thermal overpower and mechanical overpower criteria and confirm conformance to these criteria. PRIME transient analyses performed per NEDC-33840-P-A (Reference 4.2-8) may also use worst-tolerance and statistical assumptions, consistent with those used in determination of thermal overpower and mechanical overpower criteria. This method confirms compliance by comparing worst-tolerance strain directly to strain limits and lower 95% melt margin criterion.

#### **4.2.3.11 Fretting Wear**

Testing assures that the mechanical design features, particularly those related to spacers and tie plates, do not result in significant vibration and consequent fretting wear, particularly at spacer–fuel rod contact points. The GNF2 fuel design vibration response has been compared to a reference design that has demonstrated satisfactory performance through discharge exposure.

#### **4.2.3.12 Water Rods**

Analyses are performed to determine component stresses at the bounding load conditions and compared to applicable criteria, such as yield and ultimate stresses. The load conditions consider shipping and handling loads, seismically induced bending moment, and the pressure differential across the water rod. The design is also evaluated using finite element analysis to determine the critical buckling load to ensure axial loads resulting from differential growth of water rods and other fuel assembly components are adequate.

#### **4.2.3.13 Tie Plates**

Tie plate adequacy is demonstrated by detailed finite element analysis and mechanical testing for bounding fuel handling and seismic load conditions.

#### **4.2.3.14 Spacers**

Tests are performed to demonstrate that the spacer design can withstand design basis loading without any significant deformation. The bounding load condition is seismic loading. Tests are conducted to demonstrate spacer fatigue capability and compliance with load limits and to demonstrate that a coolable geometry is maintained by showing minimal deformation at the combined load condition. Fretting wear is addressed by performing flow induced vibration tests and evaluating the results relative to spacer designs that have demonstrated acceptable performance. The results of flow induced vibration testing for GNF2 are summarized in NEDC-33270P (Reference 4.2-1).

#### **4.2.3.15 Channel**

Channel adequacy relative to applicable design criteria is confirmed by performing the following evaluations:

- Calculating elastic stress and deflection caused by channel wall pressure difference
- Calculating thermal stresses due to the various temperature gradients that the channel is subjected to during normal operation and handling
- Calculating fatigue and stress rupture considering the combined effect of pressure temperature cycling and hold time
- Calculating elastic-plastic and creep of channel wall permanent deflection
- Calculating channel stress due to control rod contact
- Analyzing channel/lower tie plate differential thermal expansion

The GNF2 Fuel Assembly Mechanical Design Report for BWRX-300 (Reference 4.2-10) provides additional discussion addressing the design features that preclude excessive channel bowing from preventing control blade insertion.

#### **4.2.3.16 Conclusion**

The BWRX-300 reactor is designed to accept conventional BWR fuel and GNF2 has been established as the reference fuel design. Fuel mechanical and fuel rod thermal mechanical evaluations, summarized in NEDC-33270P (Reference 4.2-1), demonstrate compliance with regulatory requirements and are applicable to GNF2 operation in the BWRX-300. Detailed technical information pertaining to fuel assembly mechanical (NEDC-33940P) and fuel rod thermal-mechanical performance (NEDC-33941P) is provided in (References 4.2-10 and 4.2-11).

#### **4.2.4 Control Rods Design Evaluation**

The control rod design is evaluated against the acceptance criteria and bases described in Subsection 4.2.1.2. Design compliance with these criteria constitutes the basis for acceptance and approval of the design. The control rods for the BWRX-300 are based on the design used in the operational BWR fleet. This well understood fleet operational data is utilized in the methods to design, evaluate, and analyze the control rods.

#### **4.2.4.1 Scram**

The dynamic loads on the control rods are bounded by the Fine Motion Control Rod Drive (FMCRD) imposed loads (scram loads) in the vertical direction. The BWRX-300 inoperative buffer loads are the highest vertical loads experienced by the control rod due to the high terminal velocity. The control rod is evaluated using a dynamic analysis in (Reference 4.2-4). The resultant loads are evaluated using the material properties and geometry for the area subject to the load. The effective stress is determined using distortion energy theory. The limit is the material ultimate stress or strain.

#### **4.2.4.2 Seismic**

Fuel channel deflections which result from seismic and Loss-of-Coolant Accident events impose lateral loads on the control rods (Reference 4.2-4). The BWR/2 through BWR/6, ABWR and BWRX-300 have similar channel lengths and deflections.

The seismic analysis is performed by evaluating the strain in the Ultra-HD control rod absorber section when deflected. During a seismic event, it is assumed the seismic deflections could be added to any preexisting channel bow. The absorber section strain has been analyzed for channel deflections due to seismic and channel bow deflections when deflected by a bounded value and found to be acceptable, (Reference 4.2-4).

Testing was performed on the ABWR Marathon control rod to confirm seismic scram capability. The ABWR Marathon control rod was tested at fuel channel oscillation amplitudes representing SSE conditions. The scram times were found to be acceptable, and the control rod was not damaged. The BWRX-300 channels will experience reduced creep bulge as the channel wall pressure differential (i.e., the pressure differential across the channel wall) is low due to natural circulation flow. Since the Ultra-HD geometry and bending stiffness are nearly identical to the tested Marathon, the ABWR Marathon control rod seismic scram capability testing is conservative in relation to the BWRX-300 conditions.

#### **4.2.4.3 Stuck Rod**

Compression caused by a stuck rod at the time of scram is controlled by the FMCRD. Assuming the FMCRD exerts the same compression loads, the control rod does not buckle if the entire load is applied to one wing, (Reference 4.2-4).

#### **4.2.4.4 Absorber Irradiated Related Loads**

The absorber containment licenced in NEDE-33284 (Reference 4.2-4) is applicable to the BWRX-300 Ultra HD control rod. The same methodology is used for the BWRX-300 Ultra HD control rod in (Reference 4.2-4). The absorber tube and B4C capsule design accommodates irradiation-induced swelling of boron carbide, such that a clearance exists between the inner capsule and outer absorber tube up to the maximum local 10B depletion. The analysis conservatively assumes worst-case dimensions plus a bounding boron carbide irradiation swelling rate. As such, all stresses on the outer absorber tube associated with boron carbide swelling are eliminated, which drastically reduces the likelihood of Irradiation-Assisted Stress Corrosion Cracking relative to previous BWR control rod designs. Absorber tube stresses due to helium gas generation and moisture vapor heating are considered. The resulting stresses due to helium pressure are small compared to tube material strengths. Therefore, the Ultra HD absorber containment design is adequate for the nuclear design life of the control rod.

#### **4.2.4.5 Load Combinations and Fatigue**

The BWRX-300 Ultra-HD control rod is designed to withstand load combinations including AOOs and fatigue loads associated with those combinations. Absorber tube loads are evaluated during a scram, in a cell with severe channel bow near end of control rod life when absorber burn-up helium gas generation is highest. Absorber tube loads are evaluated during a seismic event near the end of control rod life when absorber burn up helium gas generation is highest. Absorber section to connector welds and absorber section to handle loads are evaluated during a scram when the absorber helium gas build up is highest. Per NEDE-33284 (Reference 4.2-4), the BWRX-300 Ultra-HD control rod does not exceed the ultimate stress or strain limit of the material. Based on the reactor cycles, the combined loads are then evaluated for the cumulative effect of the cyclic loadings in (Reference 4.2-4). The fatigue usage is evaluated against a limit of 1.0.

#### **4.2.4.6 Handling Loads**

The BWRX-300 Ultra-HD control rod is designed to accommodate three times the weight of the control rod, (Reference 4.2-4).

#### **4.2.4.7 Hydraulics**

Inspection experience over 60 years has shown the control rod is not damaged by the vibrations or cavitations set up by coolant velocities and velocity distributions in the bypass region between fuel channels.

#### **4.2.4.8 Materials**

The absorber tubes are made from high purity 304, stainless steel. These tubes are loaded with either, 1) capsules containing B<sub>4</sub>C, or 2) Hafnium rods. Further description is provided in NEDE-33284 (Reference 4.2-4).

Materials selected for use in the Ultra-HD control rod components are chosen to minimize the component end of life radioactivity to reduce personnel exposure during handling on-site, and for final offsite shipping and disposal. All Ultra-HD control rod materials are low weight percent cobalt. The average niobium content for the handle and absorber section, less boron carbide and hafnium has a low weight percent.

Materials with low activation characteristics are specified for use in the control rod. Depleted control rods that are discharged are categorized as high-level radiological waste.

#### **4.2.4.9 Nuclear Performance**

The nuclear lifetime of the initial BWRX-300 control rod type is established as a 10 percent reduction in reactivity worth ( $\Delta k/k$ ) relative to the initial reactivity worth in any quarter axial segment, (Reference 4.2-4).

#### **4.2.4.10 Mechanical Compatibility**

Similar to the control rods supplied for the ABWR and BWR/2 through BWR/6, the BWR X-300 Ultra-HD control rod is designed to be compatible with core and reactor internal interfaces.

The Ultra-HD control rod is designed to be compatible with the Control Rod Guide Tube cylindrical boundary, to provide a seat with the guide tube base during FMCRD removal, to provide lower guide rollers for smooth transitions, and to have clearance with the orificed fuel support for insertion and withdrawal from the core.

The control rod coupling socket provides a compatible interface with the FMCRD. The coupling engages the FMCRD by rotating. With the FMCRD, Control Rod Drive Housing (CRDH), and Control Rod Guide Tube positively assembled, any orientation of the cruciform control rod between the fuel assemblies is a coupled position, and rotation to an uncoupled position is not possible during reactor operation. The four lobes of the FMCRD coupling spud are in line with the four wings of the control rod in the coupled position.

The control rod is designed to permit coupling and uncoupling of the control rod drive from below the vessel for FMCRD servicing without necessitating the removal of the reactor vessel head. The control rod is also designed to allow uncoupling and coupling from above the vessel using control rod handling tools.

The control rod is positively coupled to the FMCRD and is designed to remain coupled during all scrams and loading conditions, including inoperative buffer scram loads. The control rod withstands the loads induced by the FMCRD without exceeding the structural design criteria.

The control rod is dimensionally compatible with the fuel assemblies (unirradiated and irradiated). The control rod is guided, rotationally restrained, and laterally supported by the adjacent fuel assemblies. The control rod is designed and constructed to establish and maintain the alignment of the control rod drive line (Control Rod Drive Mechanisms, Control Rod Guide Tube, and the fuel assemblies) so that control rod insertion and withdrawal is predictable. The top of the active absorber of a fully withdrawn control rod is below the Bottom of the Active Fuel. Absorber gap requirements are placed on the control rod in the operating condition to be compatible with the core nuclear design requirements.

#### **4.2.5 Inspection and Testing**

##### **4.2.5.1 Quality Assurance Program and Quality Control**

The Quality Assurance Program applicable to the fabrication of fuel and control rod assemblies for the BWRX-300 is summarized in Chapter 17.

The program provides for control over activities affecting product quality, starting with design and development, continuing through procurement, materials handling, fabrication, testing, and inspection, storage, and transportation. The program also provides for training of personnel and for the auditing of activities affecting product quality through a formal auditing plan.

The mechanical drawings and product, process, and material specifications identify the inspections performed.

The following subsections describe the general quality control inspections.

##### **4.2.5.2 Fuel System Components and Parts**

The characteristics inspected depend on the component parts. The quality control includes dimensional and visual examinations, review of supplier documentation, material certification, and nondestructive examination. Once supplier processes have been qualified, changes are subjected to GNF review and approval. Suppliers are periodically audited to assure that the process and Quality programs at the manufacturing facilities meet the requirements for GE GNF's Quality program.

The material used in the BWRX-300 core is ultimately accepted and release by Quality Control.

#### **4.2.5.2.1 Pellet**

Pellet Inspection is performed for dimensional characteristics such as diameter, density, length, and squareness of ends. Additional visual inspections are performed for cracks, chips, and surface conditions according to approved standards. Density is determined using qualified equipment with known verification and calibration standards based. Chemical analyses are performed on a specified sample basis throughout pellet production.

#### **4.2.5.2.2 Fuel Rod Inspection**

Fuel rod inspections consists of the following nondestructive examination techniques and methods, as applicable:

- Each rod is leak tested at the assembly level using a calibrated mass spectrometer, with helium being the detectable gas
- Fuel rod welds are inspected by ultrasonic test in accordance with a qualified technique and GE specifications
- Fuel rods are visually inspected for scratches, dents, and rod bow
- Dimension control on newly fabricated fuel rods is maintained by limiting the allowed variation on the dimensions of the supplied or fabricated components
- Reworked rods are dimensionally inspected prior to final release to verify acceptable length
- Fuel rods are inspected by scanning to verify proper enrichment, burnable absorber poison concentration, and zone length. Scanning also checks for the presence of misplaced pellets or gaps in the fuel column
- Traceability of rods and associated rod components is established by quality control

#### **4.2.5.2.3 Assemblies**

Components for each bundle are visually inspected prior to use in manufacturing.

Bundles are in-process verified during assembly and then final inspected prior to packing into the fresh fuel shipping container.

Shipping containers are licenced and refurbished prior to each use to assure compliance to the Safety Analysis Report.

#### **4.2.5.2.4 Other Inspections**

As part of the routine inspection operation, the following inspections are performed:

1. Tool and gauge inspection and control, including standardization to primary and/or secondary working standards. Tool inspection is performed at prescribed intervals on serialized tools. Complete records are kept of calibration and conditions of tools.
2. Audits are performed of inspection activities and records to confirm that prescribed methods are followed and that records are correct and properly maintained.
3. Surveillance inspection, where appropriate, and audits of outside contractors are performed to confirm conformance with specified requirements.

#### **4.2.5.2.5 Process Control**

To prevent the possibility of mixing enrichments during fuel manufacture and assembly, strict enrichment segregation and other process controls are implemented.

The uranium dioxide powder is kept in sealed containers. The contents are fully identified both by descriptive tagging and unique barcode numbers. Isotopic content is confirmed by analysis.

Powder mixing (enrichment blending or homogenization) is performed to a system generated blend plan. The production control system verifies that only containers in the active blend plan are moved to the process station. The production control system captures the actual weight of each addition to the blend and will abort the blend plan if the weight is out of tolerance. Personnel are assigned roles based upon their work area after qualification/certification; unqualified personnel cannot perform a task as the production software system will prevent the transaction.

Finished pellets are placed on trays identified with a unique barcode identifier that maintains traceability in the production control system. Samples from each pellet lot are tested for isotopic content and impurity levels based upon a sampling plan prior to release of the pellets to rod loading.

Loading of pellets into the cladding is controlled by the production control system which receives the nuclear design from engineering. Each rod is verified to have the correct mass, enrichment, burnable absorber content, and zone length of fuel when the pellets are loaded into the cladding. Traceability is maintained to the pellet trays used to load each zone. Each cladding tube is barcoded, and this barcode is used by the production control system for traceability. An alpha-numeric serial number is placed on the lower plug; this serial number is linked to the barcode identification at the lower end plug ("first") weld process. The upper end plug is inserted and then welded (in an inert gas atmosphere) to seal the tube; during the upper end plug welding the rod is pressurized with Helium as specified by the fuel rod design.

#### **4.2.5.3 Control Rod and Components**

All raw material and purchased component parts are fully inspected and accepted for control rod manufacture. Inspection includes dimensional and visual examinations, review of supplier documentation, material certification, and nondestructive examination. Supplier processes are qualified and cannot be changed without GEH review and approval. Suppliers are periodically audited to assure that the processes and quality programs at the manufacturing facilities meet the requirements for GEH's quality program.

All material used in the BWRX-300 control rods is ultimately accepted and released by GEH supplier quality control.

##### **4.2.5.3.1 Control Rod Absorber Materials**

BWRX-300 control rods use both boron carbide powder and solid hafnium rods as neutron absorbers. Prior to use, boron carbide powder is inspected for chemical content, impurities, water content, isotopic content, and grain size. Several grain sizes are then mixed and vibratory compacted inside stainless steel capsules to achieve the specification-required average density. Similarly, hafnium rods are inspected for chemical content, impurities, and dimensions prior to use. An independent quality overcheck is performed to ensure the correct loading of all absorber materials into each control rod assembly.

#### **4.2.5.3.2 Absorber Tube Inspection**

The manufacture of drawn absorber tubes used in control rod assemblies is controlled to ensure defect-free tubes. Supplier raw material production, welding, drawing and heat treatment process, as well contacting material, and inspection processes, are controlled and approved by GEH. Absorber tubes are inspected both visually and using ultrasonic inspection. Traceability of all absorber tubes is maintained by raw material and tube manufacturing lot.

#### **4.2.5.3.3 Control Rod Assemblies**

The laser weld process used to join absorber tubes into the cruciform control rod assembly is tightly controlled. Periodic weld samples and process tracking are performed to ensure specification weld penetration requirements are met, and to ensure weld quality. Both visual and eddy current inspection is used to ensure continuous welds, with no holes or gaps in finished control rod assemblies. A helium leak check is used to further ensure the integrity of finished control rods.

**Figure 4.2-2: Ultra-HD-Control Rods Distributed Throughout Core**

**Figure 4.2-3 Ultra-HD-Ultra Control Rod**

### **4.3 Nuclear Design**

This section describes the design bases and functional requirements used in the nuclear design of the fuel, core, and reactivity control system that complies with the requirements of CNSC REGDOC-2.5.2, Revision 1, Section 8.1 (Reference 4.1-1). The Nuclear Design Report for BWRX-300 Equilibrium Cycle, NEDC-33985P (Reference 4.3-1) provides detailed results for the reference equilibrium cycle.

#### **4.3.1 Design Bases**

The design bases require the plant to operate while meeting all safety requirements:

1. The reactivity bases prevent an uncontrolled positive reactivity excursion and stipulate subcriticality requirements
2. The overpower bases ensure the core will operate within fuel integrity limits

##### **4.3.1.1 Reactivity Feedback Bases**

Reactivity coefficients representing the differential changes in reactivity produced by differential changes in core conditions are used for calculating stability parameters and evaluating the response of the core to external disturbances. The base initial condition of the system and the postulated initiating event determine which of the several defined coefficients are significant in evaluating the response of the reactor. The coefficients of interest are the Doppler, moderator temperature, and the moderator void reactivity coefficient. Also associated with the BWR is a power reactivity coefficient. The power coefficient is a combination of the Doppler and moderator void reactivity coefficients in the power operating range and is not explicitly evaluated.

The fuel reactivity acceptance criteria are established in GESTAR (Reference 4.4-8) and each of the following fuel parameters must be negative throughout the life of the core:

- Doppler reactivity coefficient for all operating conditions
- Core moderator void reactivity coefficient resulting from boiling in the active flow channels for any operating conditions
- Moderator temperature coefficient for temperatures equal to or greater than hot standby
- Power coefficient, as determined by calculating the reactivity change resulting from an incremental power change from a steady-state base power level for all operating power levels above hot standby
- Net prompt reactivity feedback originating from prompt heating of the moderator and fuel for a super prompt critical reactivity insertion accident (e.g., control rod drop accident)

The Doppler coefficient, the moderator void coefficient and the moderator temperature coefficient of reactivity are negative for power operating conditions, thereby assuring negative reactivity feedback characteristics.

##### **4.3.1.2 Control Requirements (Shutdown Margins)**

It is required that the core can be shut down and remain subcritical with the minimum margin as specified in the plant Operating Limits and Conditions (Chapter 16), with the highest worth control rod, or rod pair associated with the common Hydraulic Control Unit (HCU) postulated stuck in the full out position.

#### 4.3.1.3 Control Requirements (Overpower Bases)

It is required that the core operate within an absolute power and power distribution envelope to ensure fuel integrity is maintained. This is controlled through two nuclear design basis parameters: the Maximum Linear Heat Generation Rate (MLHGR) Limit and Minimum Critical Power Ratio (MCPR). The MCPR and Linear Heat Generation Rate (LHGR) limit are determined with 95% confidence that the fuel does not exceed Operational Limits and Conditions during AOOs. These constraints must then be met under normal operating conditions.

Explicit Maximum LHGR Limit and MCPR parameter definitions are provided as follows:

**Maximum Linear Heat Generation Rate Limit:** The LHGR limit is the maximum allowable linear heat generation for each fuel rod in the bundle. The LHGR operating limit is bundle type-dependent and is a function of gadolinia content and exposure. The LHGR is monitored, and the fuel is not operated at MLHGR values greater than those found acceptable by the safety analysis under normal operating conditions. Under AOO conditions, including the maximum overpower condition, the calculated overpower is confirmed to neither cause fuel melting nor exceed the stress and strain limits as discussed in Subsection 4.2.3.

**Minimum Critical Power Ratio:** MCPR is the minimum CPR allowed for a given bundle type to avoid boiling transition. The CPR is a function of several important parameters: bundle power, bundle flow, rod power peaking distribution, and bundle mechanical design. The plant Operating Limit Minimum Critical Power Ratio (OLMCPR) is established by considering the limiting AOOs for each operating cycle. The OLMCPR is determined to avoid boiling transition for 99.9% of the rods during the limiting analyzed AOO transient discussed in Chapter 15, Subsection 15.5.3.

#### 4.3.2 Core Nuclear Design Description

The core is light-water moderated and fueled with low enriched uranium dioxide fuel assemblies. The use of light water as a moderator produces a neutron energy spectrum where fissions are caused principally by thermal neutrons. At normal operating conditions, the moderator boils, producing a spatially variable distribution of steam voids in the core. The void reactivity feedback effect is an inherent safety feature of the BWR system. Any system change that increases reactor power, either locally or core-wide, produces additional steam voids and reduces power.

The reactor core is arranged as an upright cylinder containing fuel assemblies located within the core shroud. The coolant flows upward through the core. The reactor core includes fuel assemblies, control rods, and nuclear instrumentation. The arrangement of fuel assemblies/core loading map is the same as the forced flow Kernkraftwerk Mühleberg Nuclear Power Plant (KKM) BWR in Switzerland and is displayed in Figure 4.3-1.

The core nuclear design of any BWR core for an operating cycle is comprised of the following elements:

- Core arrangement, lattice type and fuel product line that combine to establish the detailed geometry of the reactor core
- The energy utilization plan that defines the energy requirements
- Core coolant hydraulics (e.g., core flow, pressure, and inlet temperature)
- Nuclear design (i.e., enrichment and burnable poison distribution) of the fresh fuel
- Core loading pattern of fresh and exposed fuel
- Planned control rod patterns during power operation

An equilibrium cycle is a reactor state in which the same fresh fuel assemblies are loaded into the same locations, the exposed fuel is shuffled to the same locations and the cycle is depleted in the same way until an equilibrium state is achieved producing essentially identical results (e.g., energy generated, power distributions, reactivity margins, etc.) cycle after cycle. An equilibrium cycle is the best representation of the core over the life of the reactor. A reference equilibrium core as shown in Figure 4.3-2 has been developed for safety analysis to demonstrate that the BWRX-300 conforms to all regulatory requirements with high confidence. The reference BWRX-300 equilibrium cycle has been selected to be an annual cycle (i.e., 12-month refueling interval) with high, albeit normal, discharge exposure. Alternate refueling intervals (e.g., 18, or 24 months) may be applied to the BWRX-300 and conforms to all regulatory requirements.

The reference equilibrium cycle is loaded with multiple fresh nuclear fuel bundle types of various enrichments and gadolinia burnable poison designs that satisfy a multitude of requirements and objectives, including to optimize the core burnup while maintain core performance. The core loading pattern, operating control rod patterns, and core performance results are described in the Nuclear Design Report, NEDC-33985P (Reference 4.3-1) and the nuclear design of the fresh fuel assemblies is provided Fuel Bundle Information Report (Reference 4.3-6). The BWRX-300 core configuration, including a representative in-core instrumentation design and rod patterns, are depicted in Figure 4.3-1 and Figure 4.3-3 respectively. Select nuclear design information and core performance results are depicted in Figure 4.3-4 through Figure 4.3-9.

#### **4.3.2.1 Refueling Interval**

BWRs operate on distinct refueling intervals. At the end of a normal operating cycle, after shutdown, the reactor is disassembled, then generally the lowest reactivity fuel is discharged and new reload fuel is inserted and the fuel is shuffled into the core configuration for the upcoming cycle. The reactor is then reassembled, and the startup of the next cycle can commence. This activity, from shutdown of any operating cycle to startup of the next, is termed the refueling outage. Inspections and maintenance are also typically performed during the refueling outage on intervals specific to each piece of equipment or component.

For BWRs, there is not a specific limit on the length of an operating cycle, or planned refueling interval; however, requirements governing inspection and surveillance frequency must be satisfied and the safety analyses that constitute the safety basis must encompass the planned operating cycle length. Cycle specific operating limits are established to span the planned operating cycle length and provision is made for cycle extension (e.g., power coast down) as specified by the reactor owner.

Any planned operating cycle length must:

1. Support requirements governing inspections of the reactor internals & equipment
2. Reside within evaluated space (i.e., the technical inputs to the safety analyses must envelope the planned operating cycle length)

The cycle specific operating limits are derived from AOO analysis of the actual core design. Any refueling interval that results in acceptable thermal operating limits that conform to the Specified Acceptable Fuel Design Limits (SAFDL) can be supported.

BWRs operate on approximately 12-, 18-, or 24-month refueling intervals; however, operating cycles longer than 24 months have been conducted as well as intermediate lengths. The reference BWRX-300 equilibrium core design to support safety and performance evaluations was established to be a 12-month cycle because it illustrates the highest degree of operational flexibility associated with excess thermal margins (e.g., Figure 4.3-7 shows ~30% excess thermal margin compared to a normal design target of MFLPD < 0.9), where MFLPD is the Maximum Fraction Limiting Power Density, which is equivalent to the maximum ratio of any LHGR in the core compared to its exposure dependent, LHGR limit).

The safety analyses that are generally affected by increasing the operating cycle length, along with areas that are part of the operating envelope, are denoted in Table 4.3-1.

#### **4.3.3 Core Nuclear Analytical Methods**

The analytical methods used in the design and analysis of the BWRX-300 core during all states of normal operation are summarized below and described in detail in NEDC-33939 "Steady State Nuclear Methods" (Reference 4.3-2).

##### **4.3.3.1 Steady-State**

The principal tools used in the steady-state nuclear core analysis are the three-dimensional (3-D) BWR Core Simulator PANAC11 and the two-dimensional lattice physics code TGBLA06. The BWR Core Simulator is a coupled nuclear-thermal-hydraulic computer program representing the BWR core exclusive of the external flow loop.

Natural circulation flow is determined by the Transient Reactor Analysis Code General Electric (TRACG) described in NEDE-32176P (Reference 4.3-3). The associated core flow is used as an input to the core simulator.

The simulator computes core reactivity, power distributions, exposure, and reactor thermal-hydraulic characteristics, with spatially varying voids, control rods, and burnable poisons as described in the nuclear libraries and other constitutive state variables. The simulator is used to calculate reactivity variations through the cycle, shutdown margins and compliance with thermal limits (i.e., LHGR Limit and MCPR).

PANAC11 and the associated nuclear libraries produced by TGBLA06 have undergone extensive validation by comparing calculated results with alternate methods, end-of-cycle gamma scan data, and operating reactor data. PANAC11 is a USNRC approved method used for production core design, licensing analysis, and core exposure tracking for the BWR fleet. The exposure tracking process provides the opportunity for continuous comparison and validation of the nuclear methods against operating data.

Validation of the adequacy of PANAC11 and associated compliance with CNSC guidance is demonstrated in NEDC-33939P (Reference 4.3-2).

##### **4.3.3.2 Reactivity Coefficient**

The lattice physics and 3D core simulator are used in computing the change in neutron multiplication (i.e., reactivity inserted) caused by a change in state (e.g., change in fuel temperature, in-channel void fraction, etc.) when determining the reactivity coefficients.

#### **4.3.4 Core Nuclear Design Evaluation**

##### **4.3.4.1 Reactivity Coefficient**

The safety analysis methods are based on system and core models that include an explicit representation of core space-time kinetics. Therefore, the reactivity coefficients are not directly used in the safety analysis methods but are useful in the general understanding and discussion of core response to perturbations.

The reactivity coefficients evaluation is performed as part of new fuel design development assuring consistency with safety objectives. The GNF2 results are documented in NEDC-33270P, GNF2 Advantage Generic Compliance with GESTAR II, which concludes that all the criteria defined in GESTAR II have been met for the GNF2 fuel design (Reference 4.2-1).

##### **4.3.4.2 Reactivity Variation**

The excess reactivity needed to deliver the target cycle energy while maintaining rated thermal power is controlled by the control rod system supplemented by fuel rods containing a burnable absorber. When applied to any specific fuel cycle, these integral fuel burnable absorber rods are used to provide partial control of the excess reactivity available during power operation. The burnable absorber lowers the reactivity of fresh fuel and is designed to be largely depleted by the end of the first cycle of operation. Control rods are used during the cycle to compensate for the remaining hot excess reactivity and reactivity changes due to burnup. Control rods may also be used to control the power distribution. The burnable absorber design is established such that the remaining hot excess reactivity is consistent with target control patterns during steady-state power generation. The hot excess reactivity and associated control rod patterns for the reference BWRX-300 equilibrium cycle are documented in the Nuclear Design Report for BWRX-300 Equilibrium Cycle. Examples of typical control rod patterns are presented in Figure 4.3-3.

##### **4.3.4.2.1 Core Reactivity Effects**

###### **Control Reactivity**

Neutron absorbing control rods are the primary means to control reactivity in transient and accident analyses. During events that result in relatively fast positive reactivity feedback, control rods are inserted rapidly using stored hydraulic energy. This is referred to as a scram. During events that result in relatively slow positive reactivity feedback and do not require a reactor “scram”, the FMCRDs that are operated using electric motors can be used for slower control rod insertion, (see Chapter 4, Subsection 4.5.1). Reactivity feedback mechanism is key for some Postulated Initiating Event groups (see Table 15.2-1) in which rods are withdrawn in error. Control reactivity is modeled using 3-D kinetics coupled with the thermal hydraulic response in TRACG.

###### **Doppler Reactivity**

Doppler reactivity is a reactivity feedback mechanism in BWR transient, and accident analyses associated with changes in fuel temperature. Doppler reactivity is negative with an increase in fuel temperature and becomes more important as the fuel temperature continues to increase. In Deterministic Safety Analysis (DSA) where reactivity feedback is important, doppler reactivity is modeled using 3-D kinetics coupled with the thermal hydraulic response in TRACG.

### **Void Reactivity**

Void reactivity is an important reactivity feedback mechanism in BWR transient and accident analyses. The void reactivity feedback is always negative and is typically stronger (more negative void coefficient) at the end of an operating cycle. It is also stronger for reload cores versus an initial reactor core that includes only fresh fuel. This reactivity feedback mechanism is the dominant feedback for some Postulated Initiating Event groups. Table 15.2-1 focuses on events initiated from conditions of normal power operation. In the DSA, where it is important, void reactivity is modeled using 3-D kinetics coupled with the thermal hydraulic response analyzed using TRACG, the primary DSA computer code (see Subsection 15.5.1.2) that complies with CSA 286.7 on computer code quality assurance.

### **Moderator Temperature Reactivity**

The moderator temperature coefficient of reactivity is defined as the change in reactivity produced by a unit change in moderator temperature. The value of this coefficient is important during the startup of a BWR. During power operation, the coefficient is not important, because the moderator is boiling, and primarily remains at the saturation temperature corresponding to the operating pressure. In addition, moderator density changes caused by boiling are much larger than changes from moderator temperature changes and therefore, mask any effects. Moderator temperature feedback is accounted for in the DSA analysis of startup conditions when coolant temperature is key to the event response, and there is no significant voiding in the core. Once core boiling/voiding begins, void reactivity feedback becomes dominant.

### **Boron Reactivity**

For the BWRX-300, boron reactivity insertion (see Chapter 15, Section 15B), is only needed for long-term shutdown in very low probability events, where the hydraulic, and electric motors fail to insert a sufficient number of control rods.

### **Xenon Reactivity**

Xenon reactivity feedback is not typically accounted for during events in DSA because the rate of change of reactivity is slow. The effects of xenon are accounted for in analyses of shutdown margin. Xenon reactivity impacts are also considered during core design and monitoring.

Also refer to Chapter 15, Subsection 15.2.4.1 for discussion regarding the effects of core reactivity on AOOs and DBAs.

#### **4.3.4.3 Shutdown Margin**

The minimum cold shutdown margin for the reference BWRX-300 equilibrium core is presented in Figure 4.3-9 and documented in the Nuclear Design Report, NEDC-33985P (Reference 4.3-1).

#### **4.3.4.4 Thermal Limit**

The margins to thermal limits for the reference BWRX-300 equilibrium core are presented in Figure 4.3-7 through Figure 4.3-9 and documented in the Nuclear Design Report (Reference 4.3-1).

#### **4.3.4.5 Xenon Stability**

BWRs are not susceptible to xenon oscillations. The xenon stability evaluation has been demonstrated by:

- No observed xenon instabilities in operating BWRs
- Special tests conducted on operating BWRs forcing the reactor into xenon instability demonstrate that xenon transients are highly damped by the large negative moderator void feedback
- Simulation calculations

All these indicators demonstrate that xenon transients are highly damped in a BWR due to the large negative moderator void feedback. Moreover, the BWRX-300 reactor core, fueled with GNF2, is evaluated to be less susceptible to xenon oscillations as compared to KKM (that never experienced an oscillation mode) as the void fraction is expected to be higher and the corresponding void reactivity coefficient more negative.

#### **4.3.4.6 Thermal-Hydraulic Stability**

The most limiting stability condition in the BWRX-300 normal operating region is at rated power/flow condition. The BWRX-300 core remains stable throughout the entire operating domain. Refer to Subsection 4.4.8 for a discussion of thermal-hydraulic stability.

#### **4.3.4.7 Load Following Operation**

Core power maneuvering is a normal occurrence for BWRs in response to several motivations (e.g., periodic surveillance testing, managing equipment performance degradation, control rod exchanges to reduce fuel duty, low electricity demand, etc.). The load follow operation involves a rapid power increase or reduction. The thermal limits established for the fuel are developed to assure conformance to regulatory requirements during all modes of operation, including load following. Additionally, BWR Operating Guidelines have been developed to assist in mitigating low frequency Stress Corrosion Cracking Pellet Clad Interaction and are encoded into the core monitoring function such that predictions may be performed in advance of power maneuvers.

The fuel rod thermal-mechanical operating limits described in Section 4.2 have been established to be applicable to all modes of operation, including frequent power cycles associated with load following. The principal performance evaluation affected by frequent fuel rod power cycling pertains to material fatigue. The GNF2 fuel rod thermal-mechanical suite of analyses includes a fatigue evaluation assuming frequent power cycling and is discussed in the GNF2 Fuel Rod Thermal Mechanical Design Report, (Reference 4.2.11). Note that fuel rod performance degradation associated with material fatigue has not been encountered in BWR operation.

The thermal-hydraulic limits established for every operating cycle (e.g., the OLMCPR) are developed to assure the Fuel Cladding Integrity Safety Limit described in Section 4.4 is maintained during all conditions of power operation above the Low Power Thermal Limit. The OLMCPR is developed including provision for AOOs that initiate when the core is operating at off-rated power & flow conditions and are applicable load following.

During periods of frequent core power maneuvering, transient xenon affects the core reactivity and power distribution. The effects of transient xenon are predicted by the core monitoring function prior to performing the core power maneuver and control rod adjustments are applied to maintain the core power at specified levels.

#### **4.3.5 Changes from Previous Reactor Design**

The BWRX-300 reactor core operates via natural circulation flow and is considered a composite design comprised of the most desirable features developed and applied to the BWR fleet. The key features are:

1. There are 240 fuel assemblies arranged identically to the KKM reactor core.
2. The lattice type is the N-lattice that originated with the ABWR. The N-lattice provides additional moderator volume in the intra-assembly bypass gap as compared to earlier lattice types.
3. The core flow results from natural circulation and the nominal bundle flow during power operation is lower than forced circulation reactors.
4. The core average power density is low compared to most forced circulation BWRs and approximately 20% lower than KKM (i.e., 870 MWth vs. 1097 MWth).
5. The CRDs are fine motion that were developed for the ABWR.
6. GTs are used in-lieu of the traversing in-core probe system for neutron instrument calibration.
7. The reference control rod type is the most modern commercially available control rod – the Ultra-HD.

While the exact configuration of the BWRX-300 reactor core is new, the configuration is similar to the BWR operating fleet, and the performance of all principal aspects have been proven in fleet application. Any differences from KKM are encompassed within the current approved nuclear methods.

#### **4.4 Thermal and Hydraulic Design Basis**

The thermal and hydraulic design of the reactor core provides adequate heat transfer from the fuel to the heat removal system, NBS, normal Shutdown Cooling System (SDC), or Isolation Condenser System during normal operation and AOOs.

##### **4.4.1 Design Bases**

Loss of fuel rod cladding integrity is not expected during normal reactor operation and AOOs. To satisfy this requirement, the following design bases have been established for the thermal and hydraulic design of the reactor core.

The core thermal-hydraulic design establishes thermal-hydraulic operating limits used in assuring safety margin in accordance with CNSC REGDOC-2.5.2, Version 1 (Reference 4.1-1). The core thermal-hydraulic stability performance addresses CNSC REGDOC-2.5.2 requirements in Subsection 4.4.8 Thermal-Hydraulic Stability.

Margin to the SAFDL is maintained during normal steady state operation when the MCPR is greater than the required OLMCPR and the MLHGR is maintained below the maximum LHGR limit(s). The steady state OLMCPR and Thermal Mechanical Operating Limit are established for the most limiting AOO and are analyzed in Chapter 15, Subsection 15.5.3 including uncertainties that provide reasonable assurance that no fuel damage results during AOOs.

##### **4.4.1.1 Critical Power**

The objective for normal operation and AOOs is maintaining nucleate boiling and precluding boiling transition.

The figure of merit confirming compliance with this objective is the CPR. The CPR is the ratio of the bundle power where at least one fuel rod point within the assembly experiences the onset of boiling transition to the operating bundle power. A calculated CPR of 1.0 corresponds to the best estimate value for the onset of boiling transition as determined by the product-specific GEXL correlation (e.g., GEXL17 for GNF2).

CPR limits are specified for maintaining adequate margin to the onset of the boiling transition. Adequate margin is defined to be a 95 % probability at a 95 % confidence level that no fuel rods are susceptible to boiling transition. These limits are calculated based on the three-step process defined in the sections that follow.

##### **4.4.1.1.1 Fuel Cladding Integrity Safety Limit**

The Fuel Cladding Integrity Safety Limit is calculated so that no significant fuel damage occurs during normal operation and AOOs on a cycle-independent basis. The Fuel Cladding Integrity Safety Limit is defined as the MCPR that ensures there is a 95% probability at a 95% confidence level that no fuel rods are susceptible to boiling transition. This limit is also referred to as Safety Limit MCPR or  $MCPR_{95/95}$ . The value is dependent only on the fuel design and establishes a lower limit for the cycle-specific  $MCPR_{99.9\%}$  value.

##### **4.4.1.1.2 $MCPR_{99.9\%}$**

The  $MCPR_{99.9\%}$  is determined on a cycle-specific basis to support the determination of the Operating Limit MCPR (OLMCPR). The  $MCPR_{99.9\%}$  ensures that 99.9 % of the fuel rods in the core are not susceptible to boiling transition when considering the nuclear core design, plant system uncertainties, manufacturing uncertainties, and calculational uncertainties.

#### **4.4.1.1.3 Operating Limit Minimum Critical Power Ratio**

A cycle-specific OLMCPR provides adequate assurance that the  $MCPR_{99.9\%}$  is not exceeded during normal operation and AOOs. By operating with the MCPR at or above the OLMCPR, the Fuel Cladding Integrity Safety Limit for that plant is not exceeded during normal operation and AOOs. This operating limit is obtained by combining the maximum Delta Critical Power Ratio Over Initial Critical Power Ratio ( $\Delta CPR/ICPR$ ) (the change in CPR through the transient divided by the Initial CPR (ICPR)) value for the most limiting AOO and the  $MCPR_{99.9\%}$ . The significance of the  $\Delta CPR/ICPR$  is that it measures the transient response. The maximum  $\Delta CPR/ICPR$  from the AOOs is used in combination with the  $MCPR_{99.9\%}$  to establish the OLMCPR on a cycle-specific basis.

#### **4.4.1.2 Maximum LHGR**

The Maximum LHGR (MLHGR) bases are described in Subsection 4.3.1. Thermal mechanical operating limits ensure margin to design limits for circumferential cladding strain and centerline fuel temperature. The adequacy of LHGR limits is evaluated for the most severe AOOs providing assurance that no fuel damage results during these postulated events.

#### **4.4.1.3 Void Fraction Distribution**

The void fraction in a BWR fuel bundle has a strong effect on the neutron flux and power (or fission rate) distribution. Accurate prediction of the void fraction is important for evaluating the performance of the BWR reactor and fuel. The void fraction is evaluated using correlations based on the characteristic dimensions of the fuel bundle and hydraulic properties of the two-phase flow in the fuel bundle.

#### **4.4.1.4 Core Pressure Drop and Hydraulic Loads**

An accurate model of core pressure drop is essential for modeling natural circulation flow, fuel and core inlet flow, and hydraulic loads for input to other evaluations.

#### **4.4.1.5 Core Coolant Flow Distribution**

Based on the prediction of core pressure drop, the distribution of flow into the fuel channels and the core bypass regions are calculated. The core coolant flow distribution forms the basis for predicting steady-state and transient MCPR and void fraction.

#### **4.4.1.6 Fuel Heat Transfer**

Engineering models in both steady state and transient analysis tools predict heat transfer between fuel pellet, cladding gap, cladding, fuel rod surface and the coolant in the evaluation of core and fuel safety criteria.

#### **4.4.1.7 Summary of Design Bases**

Steady-state operating limits ensure the design bases are satisfied during normal operation and the most limiting AOO. These limits are determined using analytical methodologies to evaluate core flow distributions, void fraction distributions, and fuel heat transfer rates as a function of both cycle exposure and core state.

The limiting AOO effects are confirmed maintaining compliance with the design acceptance criteria for the fuel, the RPV, and containment set forth in Chapter 15, Subsection 15.3.1. The barriers maintain their integrity and function.

#### **4.4.2 Thermal and Hydraulic Methods**

The analytical methods described in this section are qualified according to the provisions of American Society of Mechanical Engineers (ASME) NQA-1 which are equivalent to the provisions of CSA N286.7 (Reference 4.4-1). These methods have been approved by the USNRC (the country of origin) and are generally accepted for use by other countries with operating BWRs (e.g., Mexico, Spain, Switzerland).

##### **4.4.2.1 Fuel Bundle Critical Power Methods**

The critical power is the fuel bundle thermal power at the onset of boiling transition. Maintaining the bundle power below the critical power during steady-state operation and AOOs precludes the onset of boiling transition and satisfies the SAFDL pertaining to heat transfer from the fuel to the coolant (i.e., the Fuel Cladding Integrity Safety Limit). The methods applied in determining the bundle critical power and the associated operating limits are described below.

###### **4.4.2.1.1 Fuel Bundle Critical Power Performance**

The bundle critical power performance methodology was originally described in NEDO-10958-A (Reference 4.4-2). This original methodology evolved into the current form of the correlation, i.e., the GEXL correlation. The GEXL correlation is a critical quality and boiling length correlation used to predict the occurrence of boiling transition in BWR fuel. Each fuel bundle design has a specific set of correlation coefficients developed from full-scale test data. The specific GEXL correlation applied in analyzing GNF2 for all BWR types, including BWRX-300, is designated GEXL17 NEDC-33292 (Reference 4.4-3). The GEXL17 correlation application range established for fleetwide application envelopes the hydraulic conditions that the BWRX-300 experiences during normal operation and AOOs.

###### **4.4.2.1.2 Fuel Cladding Integrity Safety Limit Method**

The fuel cladding integrity safety limit, named the  $MCPR_{95/95}$ , ensures there is a 95% probability at a 95% confidence level that no fuel rods are susceptible to boiling transition using a limit that is derived from comparing the predicted critical power to the experimental data for a specific fuel bundle design. The Experimental CPR is defined as the ratio of the calculated critical power as determined by the GEXL correlation to the experimental critical power.

Each experimental data point has a predicted value and associated Experimental CPR. The Experimental CPR is evaluated for all the points in the dataset resulting in a probability distribution. The Experimental CPR probability distribution serves as the basis for the correlation uncertainty. Thus, for a given critical power correlation, a limit that bounds 95% of a correlation's Experimental CPR distribution at a 95% confidence level is determined and set as the  $MCPR_{95/95}$ .

The determination of the  $MCPR_{95/95}$  is further described in TSTF-564 (Reference 4.4-9).

###### **4.4.2.1.3 $MCPR_{99.9\%}$**

The cycle specific  $MCPR_{99.9\%}$  limit is established as described in NEDC-33939, Appendix C (Reference 4.3-2).

###### **4.4.2.1.4 OLMCPR Calculation Method**

BWRX-300 AOOs are analyzed using the TRACG model described in NEDE-32176P (Reference 4.3-3). The application of TRACG to AOO analyses is described in TRACG Application for BWRX-300, NEDO-32082 (Reference 4.3-4) along with the process to calculate the  $\Delta CPR/ICPR$ .

This OLMCPR is obtained by combining the maximum  $\Delta\text{CPR}/\text{ICPR}$  value for the most limiting AOO and the  $\text{MCPR}_{99.9\%}$ . The OLMCPR is specified in one of two ways. It can be conservatively defined as the most limiting combination of  $\Delta\text{CPR}/\text{ICPR}$  and  $\text{MCPR}_{99.9\%}$  over an entire cycle, or it is defined on a cycle exposure-dependent basis using combinations of cycle exposure-dependent values of  $\Delta\text{CPR}/\text{ICPR}$  and/or  $\text{MCPR}_{99.9\%}$ . Chapter 15, Section 15.5 provides the analysis of limiting AOOs.

#### **4.4.2.2 Maximum Linear Heat Generation Rate Method**

The MLHGR methods are described in Subsection 4.3.1. Margin to design limits for circumferential cladding strain and centerline fuel temperature is evaluated for AOOs in accordance with the TRACG Application for BWRX-300 (Reference 4.3-4).

#### **4.4.2.3 Void Fraction Distribution Methods**

The empirical correlations used for the calculating void fraction are the GEH void fraction correlation used in the 3D core simulator, steady-state thermal hydraulic calculations, and the correlations for the interfacial shear used in TRACG. The TRACG void fraction model is described in NEDE-32176P (Reference 4.3-3). The core simulator model is described in NEDC-33939P (Reference 4.3.2).

#### **4.4.2.4 Core Pressure Drop and Hydraulic Loads Methods**

The total bundle pressure drop is defined as the sum of four components: friction, elevation, acceleration, and local losses. In these models, the bundle is also divided into control volumes where the four components of total pressure drop are evaluated separately. This allows capturing the effects on pressure drop of axially variable geometry parameters such as flow area, hydraulic diameter, wetted/heated perimeters, heat flux, and spacer elevations. The hydraulic diameter is defined as four times the axial flow area divided by the wetted perimeter, at any axial location and includes the fuel rod, channel inner wall, and water rod perimeters. The geometry of heated surfaces consists of the number of fuel rods and the fuel rod diameter in a fuel assembly. For fuel assembly types with partial length rods, the number of partial length rods and the associated length(s) are also accounted for in defining fuel assembly hydraulic diameter.

The TRACG methods for core pressure drop modeling are described in NEDE-32176P (Reference 4.3-3). The TRACG hydraulic formulation for core pressure drop is identical to the model used in the core design analysis except for the acceleration pressure drop component. The models used in the core design analysis are described in NEDE-333939 (Reference 4.3-2). The fuel design specific loss coefficients and assembly pressure drop models are developed from and confirmed by data from full scale testing of prototypical assemblies spanning the range of hydraulic conditions where hydraulic models are applied. The adequacy of the pressure drop model applied to GNF2 fuel is summarized in GNF2 pressure drop characteristics and is inclusive of the BWRX-300 operating conditions in GNF2 Pressure Drop Calculations, NEDO-32082 (Reference 4.4-4).

Hydraulic loads are determined based on the reactor internal pressure differences. The TRACG computer code is used to analyze the transient conditions within the reactor vessel following AOOs.

#### **4.4.2.5 Core Coolant Flow Distribution Methods**

The core coolant flow distribution methods used in TRACG are described in NEDE-32176P, Chapters 6 and 7 (Reference 4.3-3). TRACG treats all fuel channels as one-dimensional (axial) components, but the vessel is modeled as a three-dimensional component. Hence, the pressure drop across two planes in the vessel is the same at all radial and azimuthal locations if the geometry of the components in the vicinity of these planes has radial and azimuthal symmetry. Otherwise, this pressure differential displays some (locally) radial and azimuthal non-uniformity.

The flow distribution to the fuel assemblies and bypass flow paths in the core simulator model is calculated assuming the pressure drop across all fuel assemblies and bypass flow paths is the same. The bundle pressure drop evaluation includes frictional, local, elevation, and acceleration losses described above. The core inlet flow is an input to the core simulator. The value used in core design analysis is determined based on the TRACG prediction of the natural circulation core inlet flow. In operation, the core monitoring function determines core inlet flow based on plant instrumentation discussed in Chapter 7, Subsection 7.3.3.2.

The bypass flow methodology is described in NEDE-32176P (Reference 4.3-3), Subsection 7.5.1. The same methodology is used in the core simulator model.

#### **4.4.2.6 Fuel Heat Transfer Methods**

The Jens-Lottes heat transfer correlation is used to determine the cladding-to-coolant heat transfer coefficients for nucleate boiling as described in (Reference 4.4-5). For the single-phase convection or liquid region, the Dittus-Boelter correlation is used. The methodology for fuel cladding, gap and pellet heat transfer is described in Subsection 4.4.1.1.4 and (References 4.2-5 through 4.2-8).

### **4.4.3 Description of the Thermal and Hydraulic Design of the Reactor Core**

Several metrics of interest for the BWRX-300 are compared against a typical BWR/6 plant and the ABWR in Table 4.4-1.

#### **4.4.3.1 Reactor Coolant System**

The Reactor Coolant System is described in Chapter 5. The BWRX-300 reactor coolant system is shown in Figure 4.1-1. The BWRX-300 thermal hydraulic design is similar to operating BWRs except that it does not require recirculation pumps or associated coolant piping. Circulation of the reactor coolant through the BWRX-300 core is accomplished via natural circulation. Natural circulation is enabled mainly by the addition of a tall chimney between the top of the core at the top guide plate of the core to the bottom of the chimney head and steam separator assembly. The natural circulation flow rate depends on the difference in water density between the regions. The core flow varies according to the power level because fluid density changes with the power level. Therefore, a core power-flow map reduces to a single line and there is no active control of the core flow at any given power level, as shown in Figure 4.4-2.

#### **4.4.3.2 Core Hydraulics**

Accurate prediction of bundle flow and power distributions is important in the calculation of margin to the thermal limits of each fuel bundle. Pressure drop characteristics are included in plant cycle specific analyses for the calculation of the Operating Limit MCPR.

Because of the channeled configuration of BWR fuel assemblies, there is no assembly-to-assembly cross flow inside the core. The only issue of hydraulic compatibility of various bundle types in a core is the bundle inlet flow rate variation and its impact on margin to thermal limits (i.e., MCPR or MLHGR). The coupled thermal-hydraulic-nuclear analyses are performed each cycle to determine fuel bundle flow and power distribution. The analyses use the various bundle pressure loss coefficients to determine the flow distribution required to maintain total core pressure drop boundary conditions applied to all fuel bundles. The margin to thermal limits of each fuel bundle is determined using this consistent set of calculated bundle flow and power.

The flow distribution to the fuel assemblies and bypass flow paths is calculated using various pressure drop models that include friction loss coefficients, local loss coefficients, two-phase multipliers, and void-quality correlations. These models are developed from pressure drop data with a best-fit basis. Pressure drop measurements made in operating reactors, confirm that the total measured and calculated core pressure drops agree. This information is collected normally as part of core management activities and its purpose is to identify anomalous behavior. There is reasonable assurance, therefore, that the calculated flow distribution throughout the core is in close agreement with the actual flow distribution of an operating reactor.

An iteration is performed on flow through each flow path (fuel assemblies and bypass flow paths), which equates the total differential pressure (plenum to plenum) across each path and matches the sum of the flows to the total core flow. The total core flow less the control rod cooling flow enters the lower plenum. A fraction of this passes through various bypass flow paths. The remainder passes through the orifice in the fuel support casting and/or peripheral fuel support (experiencing a pressure loss) where some of the flow exits through the fit-up between the fuel support and lower tie plate and through the lower tie plate holes into the bypass flow region. All fuel bundles have lower tie plate holes. Most of the flow continues through the lower tie plate (experiencing a pressure loss) where some flow exits through the flow path defined by the fuel channel and lower tie plate into the bypass region.

The unique GNF2 fuel assembly hydraulic characteristics include the inlet orifice, lower tie plate, upper tie plate, spacers, water rod, and various leakage paths. The hydraulic characteristics of these components flow paths have been developed and confirmed by test comparisons. These unique GNF2 hydraulic characteristics are used in all analysis models and methods where the fuel assembly hydraulics are needed.

The analytical methods used in the analysis of the BWRX-300 reactor are Global Nuclear Fuels Americas LLC (GNF A) standard codes in use throughout the industry and licenced in other jurisdictions.

Flow pressure drop characteristics shall be included in plant cycle specific analyses for the calculation of the Operating Limit MCPR

#### **4.4.3.3 Core Response in Transient and Accident Analysis**

Core and fuel response to postulated AOOs and accident events is explicitly modeled via the TRACG computer code employing three-dimensional kinetics that is consistent with the BWR Core Simulator PANAC11. A description of the core response during off-normal condition is provided in Chapter 15, Subsection 15.2.4 The results of AOO and DBA analyses are presented in Chapter 15, Subsections 15.5.3 and 15.5.4.

#### **4.4.3.4 Physics and Reactivity Coefficients Including Effects or Power Coefficient of Reactivity**

The principal reactivity coefficient for the BWRX-300, and any BWR, is the void coefficient, which is the dominant constituent of the power coefficient of reactivity and required to be negative under all reactor states.

Power control to ensure compliance with LHGR limits, including aspects of loss of reactivity control, is based on the use of cruciform shaped control rods (which are sometimes referred to as blades), like other BWR types, for reactor thermal power, power distribution, and control of the BWRX-300 core. Fast acting shutdown capability is provided using stored hydraulic energy HCUs as a diverse motive force relative to the FMCRDs, as described in Section 4.6. The Core Monitoring function (Chapter 7, Section 7.3) in concert with reactor operators ensure compliance with requirements implemented by the thermal limits described in Subsections 4.3.1 (MLHGR) and 4.4 (MCPR) during power operation.

#### **4.4.3.5 Operation Limits and Conditions for Core, Core Instrumentation and Control, and Nuclear Fuel**

The core design strategy for various refueling cycle intervals is based on management of thermal limit margins for fuel design.

Plant OLMCPR is established by considering the limiting AOOs for each operating cycle. This may be calculated as a function of exposure. Reports are normally prepared for reactor operators in implementing the Cycle Management Report (CMR) requirements for each refueling cycle interval.

For each new fuel design, the applicability of generic or country-specific MCPR analyses are confirmed for each operating cycle, or a plant-specific analysis is performed.

#### **4.4.3.6 Load Following Characteristics**

The thermal-hydraulic limits established for every operating cycle (e.g., the OLMCPR) are developed to assure the Fuel Cladding Integrity Safety Limit described in Section 4.4 is maintained during all conditions of power operation above the Low Power Thermal Limit. The OLMCPR is developed including provision for AOOs that initiate when the core is operating at off-rated power & flow conditions and are applicable load following.

The BWRX-300 is a natural circulation BWR. The power-flow map depicted in Figure 4.4-2 illustrates that the core flow is fairly constant in the normal range of core thermal powers associated with load following. As the reactor power is the principal parameter that varies, and reactor coolant flow is fairly constant, compliance to thermal limits is readily maintained during periods of off-rated power operation. Further discussion of load following is provided in Subsection 4.3.4.7.

### **4.4.4 Thermal and Hydraulic Evaluation**

#### **4.4.4.1 Critical Power Evaluations**

Compliance to representative steady-state MCPR operating limits is demonstrated for a typical simulation of an equilibrium cycle described in Section 4.3, Core Nuclear Design. The typical OLMCPR evaluation process is outlined in the sections that follow.

##### ***4.4.4.1.1 Fuel Cladding Integrity Safety Limit Evaluation***

The GNF2 Fuel Cladding Integrity Safety Limit value is 1.07 as per TSTF-564-A (Reference 4.4-9).

#### **4.4.4.1.2 *MCPR<sub>99.9%</sub>***

The MCPR<sub>99.9</sub> is evaluated for a specific core design with uncertainties documented in (Reference 4.3-2), NEDC-33939. The MCPR<sub>99.9</sub> limit is computed on a cycle-specific basis and reported in a cycle specific Core Operating Limits Report (COLR).

#### **4.4.4.1.3 *Minimum Critical Power Ratio Operating Limit Evaluation***

The MCPR Operating Limit is computed on a cycle-specific basis and reported in a cycle specific COLR. The expected range of cycle-specific OLMCPRs for the reference BWRX-300 equilibrium cycle is depicted in Figure 4.3-6.

#### **4.4.4.2 Maximum Linear Heat Generation Rate Evaluations**

Compliance to steady-state MLHGR limits is demonstrated for the reference equilibrium cycle in Section 4.3 and the Nuclear Design Report (Reference 4.3-1). The AOO analysis for the reference equilibrium cycle is documented in Chapter 15, Subsection 15.5.3. Compliance to design limits for circumferential cladding strain and centerline fuel temperature during AOO events are confirmed on a cycle-specific basis and associated limits are reported in the COLR.

#### **4.4.4.3 Void Fraction Distribution Evaluation**

The void fraction distribution is dependent upon the reactor state and varies throughout an operating cycle. The calculation of the void fraction distribution is integral to the TRACG methodology and the 3D core simulator, PANAC11. Representative values for the core average axial void fraction are depicted in Figure 4.4-4.

#### **4.4.4.4 Core Pressure Drop and Hydraulic Loads Evaluations**

The expected operating pressure for the BWRX-300 is within the qualification basis of the pressure drop methods. The MCPR<sub>99.9%</sub> calculation method also assumes pressure drop uncertainty.

#### **4.4.4.5 Core Coolant Flow Distribution Evaluation**

The core coolant flow distribution (i.e., the inlet flow to each fuel assembly) is determined by the coupled nuclear and thermal hydraulic steady-state methods in NEDC-33939 (Reference 4.3-2) and in the design and analysis of the reference core nuclear design summarized in Section 4.3.

#### **4.4.4.6 Fuel Heat Transfer Evaluations**

Fuel heat transfer evaluations are dependent upon the reactor state. The calculation of fuel heat transfer is integral to the TRACG methodology and the 3D core simulator, PANAC11.

#### **4.4.5 Evaluation of the Validity of Thermal and Hydraulic Design Techniques**

The thermal and hydraulic design technique comprises qualified analytical methods employed in developing a self-consistent set of design outcomes that conform to design bases. The TRACG method described in Subsection 4.4.2 demonstrates accurate model system performance in BWRs. The thermal hydraulic design bases evaluated for the BWRX-300 described in Subsection 4.4.1 are applicable and adequate to those established for the operating fleet. The BWRX-300 reactor core was developed from applying qualified analytical methods and the results demonstrate compliance to the design bases that are used in BWRs.

#### **4.5 Reactor Internals Material**

The materials used in the reactor internals are described in Chapter 5, Subsection 5.2.5, and Table 5.2-3.

The materials comprising the fuel and control rod assemblies are described in 4.2, and associated references.

The reactor coolant pressure boundary components of the FMCRD, consists of the lower component housing and the upper component's middle flange. These components are made with 300 series stainless steel materials compatible with the reactor coolant in accordance with ASME Code, Section III. The installation bolts used to attach the middle flange and lower component to the CRD housing are low alloy steel material.

##### **4.5.1 References**

None.

## **4.6 Design of Reactivity Control Systems**

Reactivity Controls consist of:

- Control rods (Section 4.2) and Control Rod Drive Systems
- Supplementary reactivity control in the form of gadolinia-urania fuel rods (Section 4.2.2)

This section describes the CRD system design, including the design bases, functions, system configuration & operation.

### **4.6.1 Control Rod Drive Design Bases**

The CRD system provides the primary means of reactivity control during normal, abnormal and accident conditions. The system design basis includes two diverse motive forces for the CRD insertion (scram) using high pressure water from the HCU's, and control rod insertion using the FMCRD motor. Incorporated into the design are positioning and protective features that prevent inadvertent withdrawal, drop, and ejection of the control rod due to a component break or other malfunction. Complete system functionality is described below in Subsection 4.6.2.

### **4.6.2 Description**

The CRD system includes three major elements:

- Electro-hydraulic FMCRD mechanisms
- HCU
- CRD hydraulic subsystem

The FMCRDs provide electric-motor-driven positioning for normal insertion and withdrawal of the control rods and hydraulic-powered rapid insertion (scram) of control rods.

The hydraulic power required for scram is provided by high pressure water stored in the individual HCU's. Each HCU contains a scram accumulator (nitrogen-water), charged to high pressure and the necessary valves and components to scram two FMCRDs. Additionally, during normal operation, the HCU's provide a flow path for purge water to the associated FMCRDs.

The CRD hydraulic subsystem provides clean, demineralized water that is used to charge the scram accumulators and purge water flow to the FMCRDs during normal operation. The CRD hydraulic subsystem is also the source of pressurized water for purging the SDC pumps and filling the Nuclear Boiler System (NBS) reactor water level reference leg instrument lines.

The CRD system performs the following functions:

1. Control changes in core reactivity by positioning neutron-absorbing control rods within the core in response to control signals from the Rod Control and Information System (RC&IS).
2. Provides positioning of control rods in increments to enable optimized power control and core power shape in response to control signals from RC&IS.
3. Provides the ability to position large groups of rods simultaneously in response to control signals from RC&IS.
4. Supplies rod status and rod position data for rod pattern control, performance monitoring, operator display, and scram time testing to the RC&IS.
5. Supplies purge water flow to the FMCRDs for cooling and foreign material exclusion.
6. Supplies water for sampling to the Process Radiation Monitoring System (PRM).

NEDO-33953 REVISION 0  
NON-PROPRIETARY INFORMATION

7. Supplies a continuous flow of water to the NBS to keep the reactor water level reference leg instrument lines filled.
8. Supplies charging water to fill and pressurize the HCU accumulators.
9. Supplies a makeup source for the RPV pressure test.
10. The FMCRD maintains Reactor Coolant Pressure Boundary (RCPB) integrity.
11. The FMCRD prevents rod ejection from the core due to a break in the drive mechanism pressure boundary or a failure of the attached scram line.
12. Supplies purge water for the SDC pumps.
13. Performs the scram follow function following any hydraulic scram signal.
14. Provides the capability for hydraulic scram in response to signals from the Anticipatory Trip System.
15. Provides the capability for Selected Control Rod Rapid Insertion (SCRR) in response to signals from the Anticipatory Trip System.
16. In conjunction with RC&IS and the Emergency Rod Insertion Control Panel (ERICP), the CRD system blocks the withdrawal of control rods in response to signals from the Advanced Thermal Limit Monitor (ATLM) and the Multichannel Rod Block Monitor (MRBM).
17. In conjunction with RC&IS, the CRD system detects separation of the hollow piston from the ball nut or separation between the control rod blade and the hollow piston and imposes a rod withdrawal block.
18. Provides the capability for hydraulic scram upon receiving a scram signal from the SC1 I&C system.
19. Provides the capability for hydraulic scram that is independent from the SC1 hydraulic scram upon receiving the scram signal from the Diverse Protection System.
20. Performs the Alternate Rod Insertion (ARI) function to provide an alternate means of hydraulic scram.
21. Provides the capability for fast run-in of the FMCRDs upon receiving a signal from the FMCRD controllers with input from the ERICPs.
22. Provides maximum available flow to the RPV (as part of DL4b when a signal is received from the I&C systems).

The design bases and further discussion of both the RC&IS and the hydraulic scram function as well as their control interfaces with the CRD system, are presented in Chapter 7.

The CRD system separates the SC1 equipment from the rest of the system. The FMCRDs are mounted to the reactor vessel bottom head inside containment. The HCUs are housed in four rooms located directly outside of containment in the Reactor Building. These rooms are arranged around the periphery of the containment wall. The HCUs are connected to the FMCRDs by the scram insert piping that penetrates containment.

The balance of the hydraulic system equipment (e.g., pumps, valves, filters) is physically separated from the HCUs by barriers and is connected to the HCUs via the purge water header, scram accumulator charging water header and scram air header.

The system interfaces of the CRD system are shown in Figure 4.6-1.

#### **4.6.2.1 Fine Motion Control Rod Drive Mechanism**

The FMCRD used for positioning the control rod in the reactor core is an electro-hydraulic actuated mechanism (Figure 4.6-2 and Figure 4.6-3). An electric motor-driven ball nut and ball screw assembly positions the drive at both nominal increments and continuously over its entire range at a nominal speed. The FMCRDs also have the capability for motor-driven fast control rod insertion. Hydraulic pressure from the HCU is used for scrams. A single HCU powers the scram action of two FMCRDs, except for the FMCRD in the center of the core which has its own HCU. The FMCRD penetrates the bottom head of the RPV. The FMCRD does not interfere with refueling and is operative even when the head is removed from the RPV.

#### **4.6.2.2 FMCRD Components**

Simplified schematic of the FMCRD is provided in Figure 4.6-3. The basic elements of the FMCRD are as follows:

- Components required for electrical rod positioning or fine motion control (including the motor, brake release, ball screw, ball nut and hollow piston)
- Components required for hydraulic scram (including hollow piston and buffer)
- Components required for pressure integrity (including the middle flange, installation bolts and lower component)
- Rod position indication (position signal detectors)
- Reed position switches for scram surveillance and full-in indication
- Control rod separation detection devices (dual FMCRD separation switches)
- Bayonet coupling between the hollow piston and control rod
- Brake mechanism to prevent rod ejection in the event of a break in the FMCRD primary pressure boundary
- Ball check valve to prevent rod ejection in the event of a failure of the scram insert line
- Integral internal drive blowout support (to prevent drive blowout)
- Magnetic coupling

These features and functions of the FMCRD are described below.

#### **Components for Fine Motion Control**

The fine motion capability is achieved with a ball nut and ball screw arrangement driven by an electric motor. The ball nut is keyed to the guide tube (roller key) to prevent its rotation as it traverses axially as the ball screw rotates. A hollow piston rests on the ball nut and upward motion of the ball nut drives the control rod into the core. The weight of the control rod keeps the hollow piston and ball nut in contact during withdrawal.

The drive motor, located outside the pressure boundary, is magnetically coupled to the drive shaft located inside the pressure boundary. A splined coupling connects the drive shaft to the ball screw. The lower half of the splined coupling is keyed to the drive shaft and the upper half keyed to the ball screw. The tapered end of the drive shaft fits into a conical seat on the end of the ball screw to keep the two axially aligned. A drive shaft thrust bearing carries the entire weight of the control rod and drive internals.

NEDO-33953 REVISION 0  
NON-PROPRIETARY INFORMATION

The axially moving parts are centered and guided by radial rollers. The ball nut and bottom of the hollow piston includes radial rollers bearing against the guide tube. Radially adjustable rollers at both ends of the labyrinth seal keep the hollow piston precisely centered in this region.

A stationary guide supports the top of the rotating ball screw against the inside of the hollow piston. A hardened bushing provides the circumferential bearing between the rotating ball screw and stationary guide. Rollers of the guide engage with axial grooves in the hollow piston to prevent the guide from rotating with the ball screw.

### **Components for Scram, Scram Follow, and Run-In**

Opening of the scram valve in the HCU initiates the hydraulic scram action. High pressure water lifts the hollow piston off the ball nut and drives the control rod into the core. A spring washer buffer assembly stops the hollow piston at the end of its stroke. Departure from the ball nut releases spring-loaded latches in the hollow piston that engage slots in the hollow piston guide tube. These latches support the control rod and hollow piston in the inserted position. Simultaneous with the initiation of any hydraulic scram, a scram follow signal is generated such that each FMCRD motor drives the ball nut upward to a position just below the fully inserted and latched hollow piston. With the ball nut below the hollow piston, the piston remains latched to maintain the control rod in the fully inserted position.

The automatic run-in of the ball nut using the electric motor drive following the hydraulic scram provides a diverse means of rod insertion as a backup to the accumulator scram. During motor run-in, the hollow piston remains in contact with the upper surface of the ball nut. This results in the weight of the hollow piston/control rod assembly being supported by the ball nut with the hollow piston latches remaining in the retracted position.

Table 4.6-2 shows the scram performance requirements for the CRD system in terms of the maximum elapsed time for each control rod to attain the listed scram position (percent insertion) after loss of signal to the scram solenoid pilot valves (time zero).

### **FMCRD Pressure Boundary**

The ASME Section III Class 1 RCPB components include the CRD housing (attached to the RPV), the FMCRD middle flange including the ball check valve, and the FMCRD lower component housing (which encloses the lower part of the drive). The middle flange is attached to the CRD housing by four threaded bolts. The lower housing is held to the middle flange and secured to the CRD housing by a separate set of eight main mounting bolts that become a part of the reactor pressure boundary. This arrangement permits removing the lower housing without disturbing the rest of the drive. Removing the lower housing transfers the weight of the drive line from the drive shaft to a seat in the middle flange. Both the ball screw and drive shaft are locked to prevent rotation while the two are separated.

The part of the drive inserted into the CRD housing is contained within the outer tube. The outer tube is the drive hydraulic scram pressure boundary, eliminating the need for designing the CRD housing for scram pressure. The outer tube is welded to the middle flange at the bottom and is attached at the top with the CRD blowout support, which bears against the CRD housing (refer to Figure 4.6-8). The blowout support and outer tube are attached by a slip-type connection that accounts for any slight variation in length between the drive and the CRD housing.

Purge water continually flows through the drive. The water enters through the ball check valve in the middle housing and flows around the hollow piston into the reactor. O-rings seal the lower housing. A labyrinth seal near the top of the drive restricts the flow into the reactor. During a scram, the labyrinth seals discharge the high-pressure scram water into the RPV without adversely affecting the movement of the hollow piston.

### **Rod Position Indicator**

Control rod position indication is provided by the FMCRDs to the control system by a position detection system that consists of position detectors and position signal converters.

Each FMCRD provides two position detectors, one for each control system channel, in the form of signal detectors directly coupled to the motor shaft. This configuration provides continuous detection of rod position during normal operation.

### **Scram Position Indicator**

Scram position indication is provided by a series of magnetic reed switches to allow for measurement of adequate drive performance during scram. The magnetic switches are located at intermediate intervals over 60% of the drive stroke. They are mounted in a probe exterior to the CRD housing. A magnet in the hollow piston trips each reed switch in turn as it passes by.

As the bottom of the hollow piston contacts and enters the buffer, a magnet is lifted that operates a reed switch indicating scram completion. This continuous full-in indicating switch (shown on Figure 4.6-4) provides indication whenever the drive is at the full-in latched position or above. In the event of failure of the buffer mechanism a buffer contact reed switch is positioned above the full-in switch to provide failed buffer indication.

### **Control Rod Separation Detection**

Two redundant switches are provided to detect the separation of the hollow piston from the ball nut or between the control rod blade and the hollow piston (see Figure 4.6-5). The separation switches function to detect a detached control rod and cause a rod withdrawal block, thereby preventing a rod drop accident. Actuation of either switch also initiates an alarm in the Main Control Room (MCR).

During normal operation, the weight of the control rod and hollow piston resting on the ball nut causes the ball screw assembly to compress a spring on which the lower half of the splined coupling between the drive shaft and ball screw assembly rests (the lower half of the splined coupling is also known as the "weighing table"). When the hollow piston separates from the ball nut, or when the control rod separates from the hollow piston, the spring is unloaded and pushes the weighing table and ball screw assembly upward. This action causes a magnet in the weighing table to operate the reed switches located outside the lower housing.

### **Bayonet Couplings**

There are two bayonet couplings associated with the FMCRD. The first is the FMCRD/control rod guide tube/housing interface (see Figure 4.6-8). This bayonet locks the FMCRD and the base of the control rod guide tube to the CRD housing and functions to retain the guide tube during normal operation and dynamic loading events. The bayonet also holds the FMCRD against ejection in the event of a hypothetical failure of the CRD housing weld. The locating pin on the core plate that engages the flange of the control rod guide tube and the bolt pattern on the FMCRD/housing flange, assure proper orientation between the control rod guide tube and the FMCRD to confirm that the bayonet is properly engaged.

The second bayonet (Figure 4.6-6) is located between the control rod and FMCRD. The coupling spud at the top end of the hollow piston engages and locks into a mating socket at the base of the control rod. The coupling requires a 45° rotation for engaging or disengaging. Once locked, the drive and rod form an integral unit that must be manually unlocked by specific procedures before the components can be separated.

The FMCRD design allows the coupling integrity of this second bayonet to be checked by driving the ball nut down into an overtravel out position. After the weighing spring has raised the spindle assembly to the limit of its travel, further rotation of the spindle in the withdraw direction will drive the ball nut down away from the piston (assuming the coupling is engaged). If the hollow piston is not properly coupled to the control rod, the hollow piston will remain in contact with the ball nut and move with it to the overtravel position. A reed switch at the overtravel position will detect this movement of the hollow piston and provide alarm in the MCR.

### **FMCRD Brake and Ball Check Valve**

The FMCRD design incorporates an electromechanical brake (Figure 4.6-7) keyed to the motor shaft. The brake is normally engaged by passive spring force when the FMCRD is stationary. It is disengaged for normal rod movements by signals from the RC&IS. Disengagement is caused by the energized magnetic force overcoming the spring load force. The braking torque and the magnetic coupling torque between the motor and the drive shaft are sufficient to prevent control rod ejection in the event of failure in the pressure retaining parts of the drive mechanism. The brake is designed so that its failure will not prevent the control rod from rapid insertion (scram) or motor run-in. The brake is a unidirectional mechanism that allows the motor to drive the control rod only in the insert direction if the brake is unintentionally engaged.

The electromechanical brake is located in the motor unit. The stationary spring-loaded disk and coil assembly is contained within the brake mounting bolted to the bottom of the motor unit top flange. The rotating disk is keyed to the motor unit output shaft.

A ball check valve is located in the middle flange of the drive at the scram inlet port. The check valve actuates to close the scram inlet port under conditions of reverse flow caused by a break of the scram line. This prevents the loss of pressure to the underside of the hollow piston and the generation of loads on the drive that could cause a rod ejection.

### **Integral Internal Blowout Support**

The CRD blowout support (Figure 4.6-8) is designed to prevent ejection of the FMCRD and the attached control rod in the unlikely event of:

- A failure of the weld between the CRD housing and the stub tube penetration of the bottom head, or a failure through the housing along the fusion line of the weld
- A total failure of all flange bolts attaching the lower component flange and middle flange to the CRD housing flange

The internal CRD blowout support utilizes the FMCRD outer tube integral with support internal to the RPV to provide the anti-ejection support. The outer tube, which is welded to the drive middle flange, attaches by a bayonet lock to the control rod guide tube base. The core plate in turn supports the control rod guide tube.

With a CRD housing failure, the weight plus pressure load acting on the drive and housing would tend to eject the drive. In this event, the control rod guide tube base remains supported by the intact housing extension inside the RPV and the FMCRD remains supported in turn by its positive lock to the control rod guide tube base. Coolant leakage is restricted to the small annular area between the CRD outer tube and the inside of the CRD housing. In the event of a total failure of the weld itself, with the entire CRD housing intact, the housing would tend to be driven downward by the total weight plus RPV pressure. However, after the interconnected assembly of the housing, FMCRD and control rod guide tube move down a short distance, the flange at the top of the control rod guide tube contacts the core plate and stops further movement of the assembly. Since the FMCRD is positively locked to the control rod guide tube base, it cannot eject. In this case, the housing that bears on top of the blowout support is also prevented from leaving the

penetration. Coolant leakage for this condition is restricted to the small annular area between the outside of the CRD housing and the inside of the penetration stub tube.

The FMCRD design provides an anti-rotation device that engages when the lower component is removed for maintenance (Figure 4.6-11). This device prevents rotation of the ball screw and hence prevents control rod motion when the lower component is removed. The anti-rotation device consists of:

- The coupling piece on the bottom of the ball screw that engages with the lower component drive shaft
- The back seat of the middle flange

The coupling between the lower component drive shaft and ball screw is splined to permit removal of the lower housing. The underside of the coupling piece on the ball screw has a circumferentially splined surface that engages with a mating surface on the middle flange backseat when the ball screw is lowered during lower component removal. When engaged, ball screw rotation is prevented. In the unlikely event of total failure of all the drive flange bolts attaching the lower component flange and middle flange of the drive to the housing flange, the anti-rotation device will engage when the lower component falls. The middle flange/outer tube/CRD blowout support will be restrained by the control rod guide tube base bayonet coupling, thus preventing rod ejection.

### **Magnetic Coupling**

The magnetic coupling is located at the bottom of the lower component (Figure 4.6-3). It is employed to achieve leak-free operation of the FMCRD without seals. The magnetic coupling consists of an inner and an outer rotor. The inner rotor is located inside the lower component pressure boundary. The outer rotor is located outside the pressure boundary. Each rotor has permanent magnets mounted on it. As a result, the inner and outer rotors are locked together by the magnetic forces acting through the pressure boundary and work as a synchronous coupling. The outer rotor is coupled with the motor unit and driven by the motor such that the inner rotor follows the rotation of the outer rotor.

The magnetic coupling is designed so that its maximum coupling torque exceeds the maximum torque of the motor unit to prevent decoupling or slippage due to motor torque.

The magnetic coupling is designed to not have any undesirable effects on other magnetic sensitive subcomponents.

### **Materials of Construction**

The materials of construction for the FMCRD components which form part of the RCPB are discussed in Chapter 4, Section 4.5. For the non-pressure retaining FMCRD components, materials are selected for compatibility with the reactor coolant, wear resistance, corrosion resistance and material strength to ensure reliability and design life requirements are met in the BWRX-300 environment.

#### **4.6.2.2.1 Hydraulic Control Units**

Upon receipt of a scram signal, each HCU furnishes pressurized water for hydraulic scram to two FMCRD units (except for the FMCRD in the center of the core which has its own HCU). Additionally, each HCU provides the capability to adjust purge flow to the two drives. A test port is provided on the HCU for connection to a portable test station to allow for controlled venting of the scram insert line to test the FMCRD ball check valve during plant shutdown. The check valves shown inside the HCU boundary function to close under system pressure, fluid flow and temperature conditions during scram. The check valves ensure that the water stored in the HCU

accumulator is delivered to the FMCRDs to accomplish the scram function. A simplified single line diagram of the HCU is provided in Figure 4.6-9. The major components of each HCU are provided below.

### **Scram Solenoid Valve Assembly**

The scram solenoid valve assembly consists of two solenoid valves which control the position of the scram valve. The solenoid valves are normally energized and closed. Upon loss of power to the solenoids, the valves open which vents air to open the scram valve. The assembly is designed so that the power must be removed from both solenoids before air pressure can be discharged from the scram valve operator. This prevents the inadvertent scram of the drives associated with a given HCU in the event of a failure of one of the valve solenoids.

### **Scram Valve**

The scram valve opens to supply pressurized water to the bottom of the drive piston. This quick opening globe valve is operated by an internal spring and system pressure. It is closed by air pressure applied to the top of its diaphragm operator. A position indicator switch on this valve energizes a light in the MCR as soon as the valve starts to open.

### **Scram Accumulator**

The scram accumulator stores sufficient energy to fully insert two control rods at any anticipated reactor pressure. The accumulator is a hydraulic cylinder with a free-floating piston. The piston separates the water on top from the nitrogen below. A check valve in the accumulator charging line prevents loss of water pressure in case charging water header pressure is lost. During normal plant operation, the accumulator piston is seated at the bottom of its cylinder. Pressure sensors provide local and MCR nitrogen pressure indication. Loss of nitrogen decreases the nitrogen pressure, which actuates a pressure switch and sounds an alarm in the MCR. The alarm would prompt operator action to repressurize the nitrogen bottle using an external supply of nitrogen gas. To ensure that the accumulator is always able to produce a scram, it is continuously monitored for water leakage. A level sensor actuates an alarm in the MCR if water leaks past the piston barrier and collects in the accumulator instrumentation block.

### **Purging Panel**

The purging panel controls the purge water flow to the associated FMCRDs. Each panel has a restricting orifice in the purge water line to control the purge water flow rate. This orifice maintains the flow at a constant value while the drives are stationary. A bypass line containing a solenoid-operated valve is provided around this orifice. The valve is signaled to open and increase the purge water flow whenever either of the two associated FMCRDs is commanded to insert by the RC&IS. During FMCRD insertion cycles, the hollow piston moves upward, leaving an increased volume for water within the drive. Opening of the purge water makeup valve increases the purge flow to offset this volumetric increase and precludes the backflow of reactor water into the drive, thereby preventing long-term drive contamination.

#### ***4.6.2.2.2 Control Rod Drive Hydraulic Subsystem***

The CRD hydraulic subsystem supplies clean demineralized water to the following:

1. HCU accumulators for charging
2. FMCRDs for purge water
3. RPV for makeup
4. SDC pumps for seal purge water

NEDO-33953 REVISION 0  
NON-PROPRIETARY INFORMATION

5. NBS reactor water level reference leg instrument lines
6. PRM for sampling

The subsystem consists of two trains, each providing the required functions with the pumps, valves, filters, piping, and instrumentation described below. A simplified single line diagram for the CRD is provided in Figure 4.6-10.

The equipment and arrangement are comprised of the following:

1. CRD system pump suction piping from the Condensate and Feedwater Heating System (CFS) or the Condensate Storage Tank (CST).
2. Two 100% capacity trains. One train is normally operating, and the other train is in standby. Each train consists of the following:
  - a. One 100% capacity purge water pump with a suction and discharge filter
  - b. One 100% capacity charging water pump with a suction and discharge filter
  - c. Each purge pump has a minimum flow line at its discharge which is routed to the condenser or the CST
  - d. Each purge water and charging water pump has discharge pressure sensor that provides indication locally and in the MCR
  - e. Each charging water pump has a bypass line at its discharge which is routed to the CST
  - f. The distribution piping, branching off the main discharge line is downstream of the purge water pump discharge filter, and provides:
    - i. Purge water flow to the SDC pumps
    - ii. Purge water flow to the reactor water level reference leg instrument lines
    - iii. Sample water to the PRM system
  - g. Downstream of the purge water filters is a pressure sensor used to start the standby purge pump in the event of failure of the in-service purge pump
  - h. A flow element and sensor are used to control the position of a flow control valve which controls the total purge water flow rate to all the HCU's
3. The common purge water header directs purge water flow to the individual HCUs, where it is then directed to the FMCRDs via the scram insert piping.
4. The common charging water header includes a bladder-type nitrogen accumulator used to maintain charging water header pressure when the charging pump is not running.
5. Piping connections are provided between the individual HCUs and their respective FMCRDs
6. A scram air header, containing redundant pressure control valves, is connected to the scram valves in the individual HCUs
7. Solenoid-operated ARI valves are positioned in the scram air header to depressurize and isolate the scram air header on receipt of a scram signal

#### **4.6.2.2.3 Control Rod Drive System Operation**

The operating modes of the CRD system are described in this subsection.

##### **Normal Operation**

Normal operation is defined as operating periods where the CRD system provides charging pressure to the HCU and supplies purge water to the FMCRDs, the SDC pumps, the NBS reactor water level reference leg instrument lines, and the PRM.

One of the two purge water pumps is operating to pressurize the purge water header from the CFS or CST. The other purge water pump is shut down and on standby. A constant portion of the purge water pump discharge is continuously bypassed back to the condenser or CST in order to maintain a minimum flow through the pump. This prevents overheating of the purge pump if the discharge line is blocked. The standby purge water pump provides a full capacity backup capability to the operating pump and starts automatically if failure of the operating pump is detected by pressure instrumentation located in operating pump's discharge piping. The purge water flow control valve automatically regulates the purge water flow to the FMCRDs. The purge water flow rate is indicated in the MCR.

To maintain the ability to scram, the charging water header pressure is maintained by one of the two charging water pumps. The charging pumps are designed for intermittent operation. These pumps also draw water for the CFS or CST, with pump bypass line returning to the CST. The charging water header is maintained at the pressure required for the scram accumulators to scram the control rods. The HCU scram valves remain closed except during scram. During normal operation, no flow passes through the charging water header. A separate accumulator, located on the charging water header, assists with maintaining the header at the required pressure. When intermittent pump operation is used the pump automatically starts on low charging water pressure and stops when pressure is restored. Pressure in the charging water header is monitored continuously and displayed in the MCR along with a low-pressure alarm.

##### **Control Rod Insertion and Withdrawal**

The FMCRD design provides the capability to move a control rod in fine steps. Normal control rod movement is under the control of the RC&IS. The RC&IS controls the input of actuation power to the FMCRD motor from the electrical power supply to complete a rod motion command. The FMCRD motor rotates a ball screw, which in turn causes the vertical translation of a ball nut on the ball screw. This motion is transferred to the control rod via a hollow piston that rests on the ball nut. Thus, the hollow piston with the control rod is raised (inserted) or lowered (withdrawn) depending on the direction of rotation of the FMCRD motor and ball screw.

During a control rod insertion, the solenoid-operated purge water makeup valve within the associated HCU is opened to increase the purge water flow to the FMCRD. The increased flow offsets the volumetric displacement within the FMCRD as the hollow piston is inserted into the core and prevents reactor water from being drawn back into the drive.

##### **Scram**

In response to an automatic or a manual scram the power is interrupted to both scram solenoid valve assembly coils which vent the air from the scram valve operator in each HCU. Venting of the air causes the scram valves to open by spring action. When the scram valve opens in the associated HCU, hydraulic pressure provides an insertion force to the respective FMCRD. When the hydraulic force is applied, the FMCRD's hollow piston lifts off the ball nut and inserts the control rod rapidly. The water displaced from the FMCRD is discharged into the RPV. Indication that the scram has been successfully completed (i.e., all rods full-in position) is displayed in the MCR.

Simultaneously with the hydraulic scram, each FMCRD motor is signaled to start from the ERICP. This signal causes the FMCRD motor to drive the ball nut upward to a position just below the fully inserted and latched hollow piston. This action is known as the scram follow function.

After reset of the scram logic, each scram valve recloses and the CRD charging water pump recharges the HCU accumulators.

Reactor scram logic is described in Chapter 7.

### **Select Control Rod Rapid Insertion**

During SCRRI, a predefined set of control rods insert rapidly. Upon receipt of the SCRRI initiation signal, the CRD purge water flow control valve opens to provide increased purge water flow to the associated HCUs. At those HCUs, the solenoid-operated purge water makeup valve opens to increase the purge water flow to the FMCRD to prevent reactor water from being drawn back into the drives.

### **Alternate Rod Insertion**

The ARI function of the CRD System is initiated by the ERICP which provides an alternate, diverse and independent means for actuating hydraulic rod insertion. The signals to initiate the ARI function are the same as those for automatic and manual scrams. Following receipt of any scram signal, the ARI solenoid-operated valves on the scram air header actuate to depressurize the scram air header which opens all HCU scram valves. The FMCRDs then insert the control rods hydraulically. The same signals that initiate ARI simultaneously initiate an FMCRD scram follow function. Each vent path has two valves in series such that both valves are required to actuate to cause depressurization to prevent spurious ARI actuation.

#### **4.6.2.3 Instrumentation and Control**

##### ***4.6.2.3.1 Safety Class 1 Instrumentation and Control System***

The SC1 I&C system is described in Chapter 7.

##### ***4.6.2.3.2 Safety Class 2 and 3 Instrumentation and Control System***

The SC2 and SC3 instrumentation and control for the CRD system is described in Chapter 7, Section 7.3.

#### **4.6.2.4 Power Supplies**

The SC2 and SC3 electrical distribution system provides power to the CRD purge pump motors, CRD charging water pump motors, and CRD FMCRD motors.

#### **4.6.2.5 Qualification**

Equipment qualification requirements, including environmental, dynamic, functional, and Electromagnetic Compatibility (EMC) is described in Chapter 3, Section 3.9. The qualification requirements are based on equipment classifications described in Chapter 3, Section 3.2, Appendix 3A.

### **4.6.3 Safety Evaluation of the CRD System**

#### **4.6.3.1 Scram Time**

The control rod scram function of the CRD system provides the negative reactivity insertion required by the Safety Design Bases in Subsection 4.6.1. The required scram time is used in the Chapter 15 safety analyses.

#### **4.6.3.2 Scram Reliability**

Key system features resulting in high scram reliability include:

- Scram valves open by spring action and are normally held closed by pressurized control air
- To cause hydraulic scram, a de-energizing reactor trip signal is provided to solenoid-operated pilot valves that vent the control air from the scram valves for opening
- The SC1 I&C hydraulic scram is designed so that the HCU scram signal independently initiates a hydraulic scram demand, from whatever source, regardless of any other rod positioning signal
- The FMCRD hollow piston and guide tube are designed so they do not restrain or prevent control rod insertion during scram
- Each FMCRD mechanism initiates electric motor-driven insertion of its control rod simultaneous with the initiation of hydraulic scram upon receipt of I&C signal. This provides a diverse means to assure control rod insertion
- The system is “fail-safe” in that loss of either electrical power to the scram solenoids, or loss of control air pressure to the scram valve operator, causes a scram
- Departure from the ball-nut releases spring-loaded latches in the hollow piston to engage slots in the guide tube
  - These latches support the hollow piston in the fully inserted position
  - Following a hydraulic scram insertion, the control rod cannot be withdrawn until the ball-nut is driven up, re-engaged, and the hollow piston de-latched from the guide tube
- The design also includes ARI pilot valves on the control air header, which serves all 29 scram valves
  - The ARI pilot valves are energized-to-actuate, and provide an alternate path to vent control air and open all scram valves resulting in hydraulic insertion of all control rods

#### **4.6.4 Testing, Inspection, and Maintenance**

The BWRX-300 inspection requirements provide mandatory Preservice Inspection, In-Service Inspection (ISI), and In-Service Testing (IST) requirements for components and systems. Preservice Inspection, ISI, and IST requirements are consistent with ASME BPVC, Section XI and ASME Operation and Maintenance of Nuclear Power Plants (OM Code).

The Preservice Inspection, ISI, and IST requirements include examinations, inspections, and testing of the SC1 portions of the CRD system that are designed and installed in accordance with ASME BPVC Section III, applicable Canadian codes and standards, and International Atomic Energy Agency (IAEA) Safety Standards. In addition, this specification includes basic design control considerations within ASME NQA-1, Part 2.

Any required surveillance and post-maintenance testing are determined as part of the work planning / work release approval process.

#### **FMCRD Maintenance**

The FMCRD is designed to permit coupling and uncoupling of the control rod from either below the reactor vessel without necessitating the removal of the reactor vessel head or above the reactor vessel with the reactor vessel head removed.

NEDO-33953 REVISION 0  
NON-PROPRIETARY INFORMATION

Maintenance procedures prohibit coincident removal of the control rod and FMCRD of the same assembly. In addition, contingency procedures address core and spent fuel cooling capability and mitigative actions during FMCRD replacement with fuel in the vessel.

The FMCRD design also allows for separate removal of the motor unit, position indicator probe, Separation Indicator Probe, and lower component for maintenance during plant outages without disturbing the upper assembly of the drive. While these FMCRD components are removed for servicing, the associated control rod is maintained in the fully inserted position by one of two mechanical locking devices that prevent rotation of the ball screw and drive shaft.

## **4.7 Core Monitoring**

Core monitoring is a function of the plant computer system that provides three-dimensional core power monitoring. Core monitoring provides confidence that the plant is operating in conformance to SAFDL. Core monitoring obtains instrumentation information from the Distributed Control and Information System (refer to Chapter 7, Subsection 7.3.3.2), calculates power distributions and resulting thermal limits. These power distributions are adapted to signals from plant GTs and LPRMs as applicable.

### **4.7.1 System and Equipment Functions**

The core monitoring function acquires live reactor data from site plant data acquisition systems as required, to define the reactor state for use by the core simulator. The acquired data are validated within acceptable ranges. Core monitoring calculates the accumulated thermal and electrical energy produced by the plant from the beginning of an operating cycle. On a periodic basis, upon user request, or when triggered by a system event, a core simulator determines current core characteristics based on the current reactor state and the previous history of the following core components:

- Thermal limit monitoring
- Fuel conditioning
- GT processing
- Prediction at achievable operating regimes
- Tracking of local and global xenon behavior
- Identification of LPRM drift
- Power adaption based on in-core power measurements
- Graphical display of data
- Power / flow tracking
- BWR operating guidelines implementation
- Isotopic tracking

Core parameters are calculated either by the core simulator or during post processing (including parameters associated with fuel bundles, fuel channels, GTs, LPRMs, and control rods). The core monitoring function then compares these core parameters against technical specifications, licensing limitations, manufacturer's guidelines, and site-specific limits. If user actions are required, the system generates alerts, warnings, and notifications. The primary core monitoring functions are:

- Calculation of current core parameters
- Prediction of future core parameters
- Calculation of LPRM calibration factors
- Calculation and tracking of the isotopic inventory of the fuel
- Generation of visualizations and reports on core performance
- Generates core technical information for use by other plant systems as required

The core monitoring function uses live reactor and in-core information, and coupled with a three-dimensional BWR simulator model, produces current and predicted core performance information. When the live plant input data, including LPRM, control rod position, and core power are not available, the core monitoring function still performs a core performance calculation using the Manual Monitor option. The performance information includes standard visualizations such as thermal-hydraulic parameters, thermal margins, fuel conditioning margins, fuel burnup, LPRM information, control rod position information and power/flow maps. Information from the core monitoring function is used by the Licenced Plant Operator and the Reactor Engineer in the reactor operational decision-making process, for both steady-state operation and during plant maneuvers, to ensure compliance with licenced limits.

Core monitoring also supports the calibration process for LPRMs by processing GT data and live LPRM data to yield individual LPRM calibration factors. The core monitoring function does not directly calibrate the LPRMs, instead the calibration adjustments require operator action to be implemented in the LPRM systems.

The core monitoring function uses a coupled nuclear thermal-hydraulic diffusion theory model, to provide a three-dimensional simulation of BWR core characteristics performance. The accuracy of the modeling is enhanced by adaptive algorithms that conform results to measured plant data from the LPRMs and GTs. Instrument signals are compared to simulator predictions and outlier data are rejected as anomalous. Unavailability or failure of a limited number of LPRM and GT signals does not significantly affect plant operation.

#### **4.7.1.1 Safety Design Bases**

The core monitoring function provides a calculation of core performance parameters, such as the Maximum Fraction Limiting Critical Power Ratio (MFLCPR), the Maximum Fraction of Linear Power Density (MFLPD), and margin to fuel conditioning limits. These values are monitored and used by Reactor Engineers and Licenced Plant Operators to ensure that, during steady-state operation and any reactor maneuvers, these parameters are within the licenced and administrative plant limits.

#### **4.7.1.2 Licencing Basis and Operational Experience**

The current core monitoring function embodiment for the operating fleet and the BWRX-300 is named ACUMEN [GESTAR II Rev 23 with ACUMEN SLMCPR AM 42 approval by the U.S. NRC]. ACUMEN has been performing as the official core monitoring function of record at three BWRs since March and April of 2017 and October of 2019, respectively. In all these applications, ACUMEN replaced 3D Monicore and has been built on the experience gained from GNF's legacy core monitoring system which has a rich history and experience of operating at 20+ BWRs for more than 30 years.

The ACUMEN core monitoring and prediction system monitors and predicts fuel performance based on neutron instrumentation inputs and provides reactor engineers and operators with data to optimize the performance of the core. ACUMEN is designed to utilize GNF's 3-D core simulator PANAC11 to compute thermal limits, predict reactor operations using ACUMEN's Predictor feature, utilize failed fuel prevention techniques in Predictor, and monitor for streamlined failed fuel management.

#### **4.7.1.3 Equipment Interfaces**

The standard core monitoring function interface provides a means by which to integrate with other systems, including, but not limited to, the plant Distributed Control and Information System. Core monitoring includes a high performance and redundant hardware platform designed to meet the requirements of high availability and redundancy, as well as implement the cyber security requirements of CNSC REGDOC- 2.5.2 (Reference 4.1-1).

#### **4.7.1.4 Core Monitoring Operation**

Plant operating conditions that utilize the core monitoring function includes reactor shutdown, ascension to power, steady-state operation, and reactor maneuvering.

In the reactor shutdown mode, all control rods are inserted, the reactor fission power is essentially zero, and the core is subcritical. In this condition, the core monitoring function can perform predictive calculations to confirm required shutdown margin.

At initial start-up of the reactor, the core monitoring function performs predictive calculations of core reactivity for each incremental control rod withdrawal during the approach to initial criticality. High incremental changes in reactivity associated with steps in the control rod withdrawals that would cause a short reactor period can be identified and mitigated. The core monitoring function calculations address the impact of the actual coolant temperature associated with the criticality calculations.

Once the reactor power reaches approximately 5% of the rated thermal power level, the live plant thermal-hydraulic data (temperatures, flow rates, pressure) for the reactor system and the LPRM data become available. The details of the live data and the plant heat balance is monitored by the core monitoring function.

Once the heat balance is stable, the core monitoring function can monitor the core power distribution and margin to operating guidelines and thermal limits (MFLCPR, MFLPD). In addition to providing predictions of the core power distribution, the core monitoring function also tracks the nodal xenon concentration in the core. It is generally not required to monitor thermal margins (e.g., MFLCPR) at very low power levels.

Once the neutronic instrumentation data are judged validated, core monitoring performs a power distribution calculation and adapts the core power distribution calculation to the data. LPRM readings are compared to the GT data, and LPRMs are calibrated to match the full-core normalized GT data.

During power ascension, control rod adjustments are made. The core monitoring function is used during the power ascension to compute core performance so that thermal margins and fuel conditioning limits can be monitored. The Predictor function of core monitoring can be used to analyze and optimize the planned power ascension. The core monitoring and Predictor functions used during plant start-up are also used during plant maneuvers, including load following, periodic maintenance and/or periodic control rod sequence maneuvers during the operating cycle.

#### **4.7.2 References**

None.

## **4.8 Thermal-Hydraulic Stability**

### **4.8.1 Background**

Under certain conditions, BWRs can be susceptible to coupled neutronic/thermal-hydraulic instabilities. These instabilities are characterized by periodic power and flow oscillations and are the result of density waves (i.e., regions of highly voided coolant periodically sweeping through the core). If the power and flow oscillations become large enough, and the density waves contain a sufficiently high void fraction, the fuel cladding integrity safety limit could be challenged.

### **4.8.2 Design Bases**

The reactor core and associated coolant, control, and protection systems are designed with appropriate margin to assure that SAFDL are not exceeded during any condition of normal operation, including the effects of AOOs.

The reactor core and associated coolant, control, and protection systems are designed to assure that power oscillations that could result in conditions exceeding SAFDL are either not possible or can be reliably and readily detected and suppressed.

### **4.8.3 Types of BWR Oscillations**

There are two types of oscillations associated with BWR stability.

Type 1 instabilities experienced during startup do not result in a reactivity/power response. Type 1 oscillations are characterized by initiation of vapor production in the chimney region leading to a reduction in hydrostatic head in the chimney and a resultant core flow increase, which, in turn, could cause voids to collapse in the chimney. The BWRX-300 reactor goes through an unstable phase during startup. This type of oscillation is unavoidable in a natural circulation reactor because the unstable power/flow region must be crossed prior to establishing a steady two-phase voided region in the chimney; however, the magnitude of the flow oscillations is typically very small. As Type 1 oscillations do not result in a change in core moderator density, there is no power response and, as a result, the Fuel Cladding Integrity Safety Limit is maintained.

Type 2 oscillations are characterized by periodic power and flow oscillations and are the result of density waves (i.e., regions of highly voided coolant periodically sweeping through the core). In Type 2 instability, if the power and flow oscillations become large enough, and the density waves contain a sufficiently high void fraction, the fuel cladding integrity safety limit could be challenged.

Within the Type 2 domain, there are three (3) modes of oscillation:

1. Core-wide (or in-phase) mode oscillations are dominated by the fundamental mode of the neutron dynamics and are detected by the Average Power Range Monitor (APRM) system.
2. Regional (or out-of-phase) mode oscillations, with parallel channel momentum dynamics as the dominant feedback loop and reinforced by a subcritical mode of the neutronics, are not easily detected by the APRM system since the reactor powers in each half of the reactor core along the harmonic axis of oscillations tend to cancel out each other.
3. Single channel thermal-hydraulic mode oscillations are related to the momentum dynamics of heated channel in a two-phase flow regime. The oscillations are purely hydraulic in nature, and with no power response, they are not easily detected by the APRM system.

#### 4.8.4 Design Criteria

The most limiting stability condition in the BWRX-300 normal operating region is at the rated power/flow condition. The BWRX-300 is designed so that the core remains stable throughout the entire operating domain. In the time domain analysis, decay ratio is defined as the ratio of the amplitude of the first two successive peaks. For the BWRX-300, the decay ratio is averaged over the first few peaks.

Conservative design criteria are imposed on the core-wide, regional, and single-channel decay ratios under all conditions of normal operation and anticipated transients. The limiting mode (i.e., highest decay ratio) for thermal-hydraulic instabilities (Type 2 oscillations) is the core-wide mode. The channel and regional modes are highly damped.

#### 4.8.5 Stability Solution Design

The stability licensing criterion for all nuclear power plants is set forth in CNSC REGDOC-2.5.2, Section 8.1 (Reference 4.1-1) requiring assurance that the safety functions prevent unacceptable instabilities during normal operation, AOO conditions, and DBA conditions. An unacceptable oscillation is characterized by an amplitude that grows and may challenge SAFDL. CNSC REGDOC-2.5.2 (Reference 4.1-1) also stipulates that power oscillations that can result in conditions exceeding SAFDL are reliably and readily detected and suppressed. The limiting stability condition in the BWRX-300 during normal power operation region is at the rated power. Therefore, the BWRX-300 is designed so that unacceptable coupled neutronic and thermal-hydraulic power oscillations are not possible throughout the entire operating region. The BWRX-300 is designed to protect acceptable fuel design limits during AOOs. As a Defence-in-Depth feature, the BWRX-300 implements a stability monitoring function to detect instabilities should they occur (Refer to Chapter 7, Subsection 7.3.3) to inform operator action. This solution is similar to the Option I-D long-term stability solution in the U.S. (Reference 4.4-8).

The BWRX-300 design has features that result in stable behavior in normal operation and minimize the effects of potential oscillations in off-normal conditions include:

- Small Core

The small core size and higher inlet orifice pressure drop of the BWRX-300 reduces the likelihood of regional mode instabilities. Conservative analyses are performed to confirm that regional mode oscillations are not possible and that core oscillations would be core-wide dominant. Any unacceptable core-wide oscillation is mitigated by the high flux scram.

  - Tighter neutronic coupling precludes regional mode oscillations
  - Core-wide oscillations are the dominant mode
- Natural circulation
  - No recirculation pump trips that result in significant change from stable to unstable conditions
  - Loss of Feedwater Heating (LFWH) AOO impact on stability is mitigated by SCRR operation for a feedwater temperature reduction of 16.7°C or higher. The SCRR function is described in Chapter 7, Subsection 7.3.3.2. The loss of feedwater heating AOO analysis is described in Chapter 15, Subsection 15.5.3.1.1

- Tall chimney
  - Increases volume of water
  - Increases driving head and natural circulation flow
  - Dampens oscillations
- Large downcomer area
  - Reduces flow restrictions
- High inlet orifice pressure drop
  - Improves two-phase to single phase pressure drop ratio
- Balanced feedwater temperature
  - Neither thermal margins nor decay ratios are compromised
  - Minimizes normal operation inlet subcooling
- Less subcooling

Compliance with CNSC REGDOC-2.5.2 (Reference 4.1-1) is assured by implementing design criteria for the decay ratio. The stability acceptance criterion for the current GEH fleet of BWRs is a calculated core decay ratio of  $\leq 0.80$  for normal operation and AOOs considering uncertainties. The BWRX-300 has been established to provide margin to the decay ratio criterion.

#### **4.8.6 Stability Analysis Methods**

A detailed discussion of the methods used to analyze BWRX-300 thermal-hydraulic stability is presented in TRACG Application for BWRX-300 (Reference 4.8-1).

TRACG is a GEH proprietary version of the Transient Reactor Analysis Code (TRAC). TRACG uses a multi-dimensional, two-fluid model for the reactor thermal-hydraulics and a three-dimensional reactor kinetics model. The models can be used to accurately simulate a large variety of test and reactor configurations. These features allow for realistic simulation of a wide range of BWR phenomena and are described in detail in the TRACG Model Description Licensing Topical Report (Reference 4.3-3).

TRACG has been extensively qualified against separate effects tests, component performance data, integral system effects tests and operating BWR plant data. The details are presented in the TRACG Qualification Licensing Topical Report (Reference 4.4-7). The USNRC has approved TRACG for application to Economic Simplified Boiling Water Reactor (ESBWR) stability analysis, NEDC-33083P-A (Reference 4.4-6).

TRACG is qualified to accurately model natural circulation for a wide application range that encompasses the BWRX-300. The TRACG qualification bases, NEDE-32177P (Reference 4.4-7) include benchmarking natural circulation flow and instability onset (FRIGG-4 FT-36C Onset of Instability Tests) in which TRACG conservatively predicts the power at the onset of limit cycle oscillations (over a range of system pressures and inlet subcooling) to be reasonably close to measured values.

#### **4.8.7 Stability Evaluation**

To determine whether core-wide oscillation is the dominant mode, the flow velocity for symmetric channels on opposite sides of the core are perturbed out of phase. If the core is not susceptible to regional mode oscillations after such a flow velocity perturbation, then symmetric out of phase channels come into phase after a short duration. This analysis confirms that regional mode oscillations are not possible. As such, only the core-wide mode is applicable to the BWRX-300.

##### **4.8.7.1 Stability Performance During NO**

Stability analyses are performed at rated conditions and at multiple exposure points during the cycle. Stability analyses are performed by perturbing the system and assessing the core response. Such perturbations might include pressure pulse perturbation or variation in feedwater temperature. The response to a pressure perturbation in the steam line is analyzed to obtain the decay ratio for the BWRX-300 stability analysis.

The resulting decay ratios affirm stable operation, with margin to the stability decay ratio criteria, as described in Chapter 15, Subsection 15.5.2.4.

##### **4.8.7.2 Stability Performance Evaluation During AOOs**

In general, the stability margin reduces when the reactor power to flow ratio increases and/or core flow reduces or the core inlet subcooling increases (that also results in power increase). As the BWRX-300 is a natural circulation reactor, recirculation pump trip transients are not applicable and the key state variable that affects decay ratio is the inlet subcooling. As such, the loss of feedwater heating AOO is the limiting transient for stability.

The loss of feedwater heating event increases core inlet subcooling (i.e., the inlet temperature decreases) and increases core power. The BWRX-300 has been established to initiate a SCRR in response to a loss of feedwater heating AOO that mitigates the increase in core thermal power. Stability analyses for the LFWH AOO with SCRR affirm the stability decay ratio criterion is met and the results are summarized in Chapter 15, Subsection 15.5.2.4.

## 5.0 NUCLEAR BOILER SYSTEM AND ASSOCIATED SYSTEMS

This chapter describes the BWRX-300 Nuclear Boiler System (NBS) which generates and delivers steam to the turbine for power generation. The NBS and interfacing systems form the Reactor Coolant Pressure Boundary (RCPB). The Reactor Pressure Vessel (RPV) forms the major portion of the RCPB and contains the path for reactor coolant flow through the fuel and generates steam. Further, this chapter addresses the functional and structural integrity aspects of the various NBS Structures, Systems, and Components (SSC) that are designed with robustness, quality, independence, redundancy, and diversity to maintain adequate reactor coolant inventory during Normal Operation, Anticipated Operational Occurrences (AOOs), Design Basis Accidents (DBAs), and Design Extension Conditions (DECs). The NBS and RCPB design utilize the Safety Strategy Defence-in-Depth (D-in-D) Defense Lines (DLs) as described in Chapter 3, Section 3.1 to meet Canadian regulatory requirements and expectations.

The portion of the NBS and system interfaces located in the Reactor Building (RB) is illustrated in Figure 5.1-2 and described in Chapter 5. The portion of NBS located in the Turbine Building is presented in Figure 5.1-3 and discussed in detail in Chapter 10, Section 10.4.

The functional aspects of the fuel and reactivity control within the RPV are discussed in Chapter 4. The BWRX-300 design includes Engineered Safety Features (ESFs) that mitigate the consequences of AOOs or postulated DBAs without any core damage. The ESFs associated with the NBS interfacing systems are described in Chapter 6, Section 6.2.

### 5.1 Summary Description

The BWRX-300 Nuclear Boiler System (NBS) is comprised of three primary subsystems: Reactor Pressure Vessel (RPV), Main Steam (MS), and NBS instrumentation. In addition to these subsystems, the NBS also provides RPV head venting and RPV head flange seal leak detection features. Within the NBS, the SC1 Reactor Isolation Valves (RIVs) are mechanically redundant and Instrumentation and Control (I&C) diverse. These RIVs interface with the following subsystems and systems: Main Steam (MS), RPV Head Vent, Isolation Condenser System (ICS) Supply, ICS Return, Condensate and Feedwater Heating System (CFS), and Reactor Water Cleanup System (CUW). The Nuclear Boiler System and associated systems are designed in accordance with requirements of ASME BPVC, "Section III- Rules for Construction of Nuclear Facility Components, Subsection NB: Class 1 Components" (Reference 5.1-1) and ASME BPVC-III NCD, "BPVC Section III-Rules for Construction of Nuclear Facility Components-Division 1- Subsection NCD-Class 2 and Class 3 Components" (Reference 5.1-2).

The BWRX-300 NBS and interfacing systems are a unique design which mitigates LOCAs that could impact Reactor Vessel Water Levels by providing double RIVs directly flanged to the integral RPV nozzles. The RIVs are closer to the RPV compared to predecessor Boiling Water Reactor (BWR) designs (i.e., there is no piping between the RPV and RIVs). Figure 5.1-1 provides the input-output block diagram that lists all intersecting systems with the NBS and describes the interfaces between systems. The portion of the NBS (Main Steam Section) from the Seismic Interface Resistant (SIR) to the Turbine Stop Valves (TSV), Turbine Bypass Valves (TBV), and other steam loads is addressed in Chapter 10, Section 10.4.

The NBS is built on utilization of inherent margins (e.g., larger water inventory) to eliminate system challenges, and reduce the number and size of RPV nozzles as compared to predecessor designs. All nozzles are located significantly above the top of active fuel (TAF). The relatively large RPV volume, along with the relatively tall chimney region, provides a substantial reservoir of water above the core. This ensures the reactor water level is maintained above TAF and fuel cladding temperature is maintained within normal operating temperature range following

transients involving Feedwater (FW) flow interruptions or LOCAs. These design safety features preserve reactor coolant inventory to ensure that adequate core cooling is maintained.

Innovative features related to BWRX-300 are the partitionless RPV chimney region flow characteristics (see Subsection 5.4.3); RIV qualification (see Section 5.10) and the RPV water level measurement in the core region (see Subsection 5.4.9). The large RPV volume enhances safety by reducing the rate at which reactor pressurization occurs if the reactor is suddenly isolated from its normal heat sink. The containment isolation function is addressed separately in Chapter 6, Subsection 6.3.4.

Figure 5.1-2 provides the portion of the NBS that is described in Chapter 5 and shows the double isolation RIVs of those systems that intersect the reactor pressure vessel. Additionally, Figure 5.1-4 provides the extent of the RCPB.

The relevant CNSC Regulatory Documents (REGDOCs), codes, standards have been identified and description of their applicability to design and construction activities as part of establishing the LTC Licensing Basis is documented in NK054-REP-01210-00137, "DNNP License to Construct Regulatory Documents, Codes & Standards" (Reference 5.1-3).

#### **5.1.1 Reactor Coolant Pressure Boundary**

The RCPB (see Section 5.3), contains all pressure-retaining components such as:

- The Reactor Pressure Vessel (RPV)
- The integral Reactor Isolation Valve (RIV)
- The piping from the outboard RIVs up to each respective containment isolation valve (CIV)
- The outboard CIVs for Main Steam (MS), Isolation Condenser System (ICS) to Shutdown Cooling System (SDC), ICS to Boron Injection System (BIS), Reactor Water Cleanup System (CUW), and Condensate and Feedwater Heating System (CFS)
- The Isolation Condenser System (ICS) steam supply lines, isolation condensers, purge lines, and condensate return lines
- The head vent piping to the Main Steam Line (MSL) and boundary valves for the Quench Tank
- The reactor instrumentation lines
- The control rod drive interface flanges/housings
- The nuclear instrumentation interface flanges/housings

The RCPB is presented in Figure 5.1-4.

#### **5.1.2 Reactor Pressure Vessel and Appurtenances**

The RPV is used as a pressure-retaining barrier of primary coolant in a BWRX-300 reactor. The vessel contains the light water coolant and moderator and forms the path for core recirculation flow. The vessel also contains nuclear fuel, saturated steam, fuel supporting structures, and internals required for safe operation of the reactor. Production of thermal energy from the nuclear fission process takes place within the vessel. The above function requires that the vessel be a Safety Class (SC) 1 vessel, designed to meet the requirements of ASME BPVC Section III, Division 1, Subsection NB (see Figure 5.4-1 for the major components contained in the RPV). A more detailed description of the reactor pressure vessel and its major components is provided in Section 5.4.

The RPV has integral isolation valves attached directly to and are considered appurtenances of the RPV. The SC1 RIVs are mechanically redundant and Instrumentation and Control (I&C) diverse.

The RPV design is such that the physical level of all nozzles are located significantly above TAF. In addition to multiple system interfaces via the RPV nozzles, a flanged connection is provided in the RPV bottom head for each Fine Motion Control Rod Drive (FMCRD) and each neutron monitoring detector.

The RPV head vent subsystem (SC1) includes piping internal to the RPV head, two RIVs in-series flange-mounted on the reactor, and piping to one of the MS lines and the Quench Tank, both connections located inside the Primary Containment System (PCS).

The major safety consideration for the reactor pressure vessel is the ability of the vessel to function as a radioactive material barrier under Normal, AOO, DBA, and DEC plant states as described in Chapter 3, Section 3.1.

### **5.1.3 Main Steam Subsystem**

The Main Steam (MS) subsystem consists of two steam lines from the discharge flange of the outboard main steam reactor isolation valves (MSRIVs) to the Turbine Stop Valves (TSVs), the Turbine Bypass Valves (TBVs), the Main Steam Line (MSL) drains, and other load isolation/maintenance valves. The supply lines to these loads, all connecting branch lines up to and including their respective isolation valves, and all associated piping supports are also part of the MS subsystem.

The MSL drains remove any condensate from the MSLs to the main condenser during startup, low power operation, normal power operation, and shutdown. A reduction in power to a low-level, results in the automatic opening of the air-operated drain line valves, thereby establishing drain flow to the main condenser.

The portion of the MS piping from the outboard MSRIVs to the Seismic Interface Restraint (SIR) outboard of the main steam containment isolation valves (MSCIVs) is SC1 and designed to meet the requirements of ASME BPVC Section III, Division 1, Class 2. The remaining MS piping from the SIR to the TSVs, the TBVs, the MSL drains, and other load isolation/maintenance valves is designed to meet the requirements of ASME B31.1, "Power Piping" (Reference 5.1-4) as described in Chapter 10, Section 10.4.

### **5.1.4 Nuclear Boiler System Instrumentation Subsystem**

The NBS is the source of the reactor water level, reactor pressure, temperature, and steam flow information. The NBS instrumentation consists of sensors to measure and monitor parameters including reactor coolant pressure, flow, temperature, water level, and reactor power. Additionally, there are sensors to measure and monitor MSL pressure, flow, drain temperature, RPV metal temperatures, RPV head flange seal pressure (leak detection), RPV head venting, steam tunnel temperature, and Turbine Building (TB) temperatures near the MSLs for leak detection purposes.

Neutron flux detectors for reactor power provide signals to the C10 Power Range Neutron Monitoring system (PRNM) and the C20 Wide Range Neutron Monitoring system (WRNM) (refer to Chapter 7, Subsection 7.3.3.2 for detailed discussion). The non-neutron flux sensors provide data to instruments or signal conditioning and data acquisition equipment that are typically mounted on instrument racks outside of containment. The instruments are appropriately separated and divided into Defense Lines (DLs) and safety classifications.

The NBS also has control requirements for valves (RIVs, CIVs, and drain valves) that are repositioned as the plant is brought from cold to full power or that respond to unplanned transients. Control design requirements include that SC1 equipment is optically isolated from the SC3 C20 Plant Automation System (PAS). Therefore, provisions are made to operate the valves manually by the reactor operator as prompted by the PAS or C10 Visual Display Units (VDUs). The SC3 valves may be operated by the PAS.

The nuclear boiler controller logic architecture (see Chapter 7, Subsection 7.2.1) uses Triple Modular Redundant technology and is dual ported to the plant nuclear segment network. As with all Triple Modular Redundant controllers, extensive hardware and software diagnostics are provided to provide for operator monitoring and alarms. There is no connection between DL3/SC1 and the nuclear segment controllers and no sensors or actuators are in common.

#### **5.1.4.1 Reactor Pressure Vessel Level Instrumentation**

Normal operations (DL1) for RPV water level is controlled by reactor level control system (as described in Chapter 7, Section 7.3). Water level measurement by differential pressure is also used for transient/AOO (DL2) and DBA (DL3) monitoring. The Differential Pressure (dP) instrumentation is setup to provide a more accurate narrow range (NR) measurement as well as a less accurate, but otherwise sufficient wide range (WR) measurement. The BWRX-300 is designed to have no RPV penetrations below top of active fuel + 4.0 m (TAF+4m). This is a plant design requirement to preserve sufficient condensate inventory for analyzed events and accidents. Because there are not any operator actions associated with water level between TAF and TAF+4m, there are no water level measurements available in this range.

In the case of DL4 (i.e., Beyond Design Basis Accident (BDBA) and DEC) events, Gamma Thermometers (GTs) will be utilized for the fuel zone water level measurements. The GT is an extension of the local power range monitoring (LPRM) calibration system within the core. The water level inside of the core will show adequate coverage for core cooling without the need for an extra system in the downcomer or on the RPV Outside Diameter (OD). It is generally considered that the level inside of the core provides the best information.

The water inventory in the RPV is credited for normal operations and AOOs as described in Chapter 15, Subsection 15.5.3 (decrease/increase in reactor coolant inventory). The reactor level control remains unaffected by these failures and is able to maintain level. As demonstrated in Chapter 15, Section 15.3, the RCPB maintains sufficient coolant inventory for core cooling as long as reactor level is maintained at or above top of the active fuel (the derived acceptance criteria for AOOs).

#### **5.1.4.2 Nuclear Boiler System Pressure, Flow, and Temperature**

The other NBS instrumentation functions are to measure reactor coolant pressure, flow, and temperature. More details are provided in Subsection 5.3.1.3.

#### **5.1.5 Main Steam Flow Restrictors**

The main steam flow restrictors are located in the RPV MS nozzles. They perform functions in various safety classifications and corresponding defence levels. The SC1 functions are to limit the overall steam flow through one steam line when the steam flow exceeds preselected operational limits (if a large break of a MSL is sensed) and the corresponding MSRIVs and MSCIVs have not closed. The other SC1 function is to provide that same sensing function to the SC1 MSRIV and MSCIV isolation system. The SC2 steam flow function also supplies the same sensing functions for MSRIV and MSCIV isolation in addition to the already discussed SC1 isolation function. The SC3 steam flow function supports the overall reactor water level controller that maintains target water level as one of the inputs to that controller.

The main steam flow restrictor provides low-pressure sensing taps for instrumentation lines for differential pressure transmitters that are used to measure steam flow. Main steam flow is measured through the MS nozzle venturis using Bernoulli's equation of differential pressure to derive the MS mass flow.

The main steam flow restrictor is designed in accordance with the Report of ASME Research Committee on Fluid Meters and has no moving parts. Required plant duty cycles associated with MS flow restrictors and other ASME BPVC Section III, Division 1, Class 1 components are provided in Chapter 3, Section 3.6.

#### **5.1.6 Reactor Isolation Valves and Main Steam Containment Isolation Valves**

A novel feature of the BWRX-300 is the integral RIVs that are directly flanged to nozzles on the reactor vessel instead of welding a pipe to the vessel nozzle and then connecting the isolation valve to the pipe at some distance from the reactor. As appurtenances to the RPV, the RIVs allow large pipe break LOCAs to be quickly isolated, thereby, retaining the fluid inventory in the vessel for core cooling. Each RPV nozzle with an internal bore greater than DN20 is required have two integral RIVs flanged directly to the nozzle. The main function of the isolation valves is to close and mitigate the effects of LOCAs from large and medium pipe breaks. The RPV automatic isolation concept consists of two RIVs in series and is single failure proof. With each of the RIVs independently able to isolate the line. RIVs are placed inboard of each large and medium sized pipe that is connected to the RPV.

The BWRX-300 design includes one Main Steam Containment Isolation Valve (MSCIV) for each main steam line outside the containment. If a main steam line break occurs inside the containment, closure of all outside Containment Isolation Valves (CIVs) seals the containment.

Additionally, all RIVs with the exception of the ICSRIVs and ICRRIVs will automatically close to isolate the RCPB at the RPV when a pipe break occurs either inside or outside of containment. This action limits the loss of reactor coolant and the release of radioactive materials. Further discussion on operation of the RIVs and MSCIVs is provided in Section 5.10.

#### **5.1.7 Control Rod Drive System**

The control rod drive (CRD) contains components which form part of the reactor coolant pressure boundary, along with components which are important to safety to shut down the reactor. Those portions of the CRD are classified as DL3/SC1.

Operation of the CRD system is further discussed in Chapter 4, Section 4.6.

#### **5.1.8 Reactor Water Cleanup System**

The Reactor Water Cleanup System (CUW) provides blowdown-type cleanup flow for the RPV during the reactor power operating mode. CUW also provides an overboarding flowpath (i.e., excess RPV coolant inventory discharge for level control) to the condenser hotwell or Liquid Waste Management System (LWM) directly from the RPV lower region.

Detailed design description of CUW is provided in Chapter 9A, Subsection 9A.2.2.

#### **5.1.9 Isolation Condenser System**

The Isolation Condenser System (ICS) removes decay heat after any reactor isolation and shutdown event during power operations when the main condenser is not available. The ICS is connected to the RPV by steam supply piping and condensate return piping. The large ICS heat removal capacity limits increases in RPV pressure and maintains the RPV pressure at an acceptable level. The Isolation Condensers (IC) condense steam from the RPV and transfer thermal energy by convection to the ICS pool water.

ICS is responsible for protecting the integrity of the RCPB in the event of a large line break LOCA that results in the isolation of the RPV.

During shutdown modes, ICS will perform the RPV isolation function for a line break within the Shutdown Cooling (SDC) system by isolating the ICS-SDC interface valves. This function prevents an ICS train from being rendered inoperable by what otherwise would be an RIV closure in the case of an SDC LOCA. As described in Chapter 15, Subsection 15.5.4.6, ICS removes decay heat generated in the core and does not require coolant injection to mitigate pipe breaks and transients.

The ICS is an Emergency Core Cooling System (ECCS) that also provides RPV overpressure protection for which further details can be found in Chapter 6, Section 6.2.

#### **5.1.10 Piping and Instrumentation Schematics**

Piping and instrumentation schematic diagrams covering the systems included within NBS and connected systems are presented as follows:

- Nuclear Boiler System (Figure 5.1-2 and Figure 5.1-3)
- Isolation Condenser System (Chapter 6, Figure 6.2-6)
- Reactor Water Cleanup System (Chapter 9, Figure 9A.2.2-1)
- Shutdown Cooling System (Chapter 9, Figure 9A.2.3-1)

#### **5.1.11 Elevation Schematics**

The elevation schematic showing the principal features of the reactor and connecting systems in relation to the containment are provided in Chapter 1, Figure 1.7-1.

NOTES:

1. EQUIPMENT, PIPING, & VALVES WITH BOLDED LINES DEPICT THE REACTOR COOLANT PRESSURE BOUNDARY.
2. ENTIRE REACTOR COOLANT PRESSURE BOUNDARY IS CLASSIFIED AS SAFETY CLASS 1 (SC1).
3. THE RPV LEVEL INSTRUMENTATION SENSING LINES ARE CLASSIFIED AS ASME BPVC SECTION III CLASS 2 PER ASME BPVC SECTION III PARAGRAPH NB-3630(D).
4. THE PIPING OUTBOARD OF THE RIV'S ARE CLASSIFIED AS ASME BPVC SECTION III AS CLASS 2, EXCLUDING ICS PIPING UP TO ISOLATION CONDENSERS.

5. THE IC IS DESIGNED TO BOTH ASME SECTION III, SUBSECTION NB, CLASS 1 AND ASME SECTION III, SUBSECTION NCD, ASME CLASS 2 AND 3. THE STEAM SUPPLY AND PURGE LINE AND THEIR ASSOCIATED COMPONENTS ARE DESIGNED TO CLASS 1 THROUGH THE CONTAINMENT BOUNDARY UP TO AND INCLUDING THE FOUR FLOW RESTRICTORS.

6. THE IC IS DESIGNED TO ASME CLASS 2 DOWNSTREAM OF THE FLOW RESTRICTORS, INCLUDING THE UPPER HEADER, CONDENSER TUBES, LOWER HEADER, VENT LINES, AND THE TWO CONDENSATE DRAIN LINES UP TO THE POINT WHERE THEY RECOMBINE INTO A SINGLE LINE. THE IC DESIGN RETURNS TO ASME CLASS 1 STARTING AT THE CONDENSATE TEE BACK THROUGH THE CONTAINMENT PENETRATION THROUGH THE ICRRVS INTO THE REACTOR.

## **5.2 Material Requirements Associated with the NBS and RCPB**

The material and process control requirements for the BWRX-300 components have been defined to ensure the reliability of the plant operations through its design life, by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials, specifically from Intergranular Stress Corrosion Cracking (IGSCC) through material chemistry, heat treatment, contamination, and material processes controls.

The BWRX-300 NBS employs proven BWR materials and processes which have been refined to meet reactor requirements.

The basic design principle for materials selection is for the materials to be capable of maintaining reliable operation of plant systems and equipment during the design life of each component. In principle, carbon steels including atmospheric corrosion resistant carbon steels and low alloy steels are used as basic materials. In order to minimize levels of radiation from corrosion products, reactor internals are made of austenitic stainless steel. Materials selection and controls address materials degradation issues in the reactor system such as Stress Corrosion Cracking (SCC), general corrosion, and Flow Accelerated Corrosion (FAC).

SCC is considered the dominant form of corrosion in a BWR. Significant efforts through the years have been expended to understand it and control SCC. It is a complex phenomenon that involves mechanical, electrochemical, and metallurgical factors. SCC is usually characterized by localization of the cracked region near welds or near regions of high surfaces strains or stresses. For SCC to occur, it requires three necessary components to be simultaneously present. The elimination of any one of these factors, or reduction of one of these factors below a threshold level eliminates the risk of SCC. These three necessary conditions for SCC as schematically shown in Figure 5.2-1 are (1) Susceptible material; (2) Tensile Stress (applied or residual) and (3) Corrosive environment.

The different degradation mechanisms that potentially affect the integrity of the construction materials that are used in the BWRX-300 are discussed in the subsequent sections.

### **5.2.1 Basis of Material Selection and Component Fabrication**

The structural materials used for the RPV and its attachments, the core support structure, internals, and the piping in the BWRX-300 design are selected and fabricated to meet the design requirements of the reactor components while maintaining high resistance to known degradation mechanisms during plant operation. Seals, gaskets, and fasteners are selected based on experience and industry acceptance. To monitor material degradation, guidelines for surveillance programs for BWRX-300 are informed by ASME and industry guidelines.

The BWR uses high purity water as the fluid to transfer thermal energy. The quality of water to which the component is exposed, to a large extent, determines the reliability and lifetime of that component. Generally, corrosion effects stem from the combination of materials selected, the stresses or duty applied, and the environment to which the component is exposed. The extent of materials corrosion from its environment is a function of impurity and its concentration, temperature, and time. Water of required quality is achieved by the use of appropriate water treatment equipment and systems, as well as the application of appropriate materials in system construction.

The material selections for the BWRX-300 reactor system are made without taking credit for the IGSCC suppression benefits of Hydrogen Water Chemistry. However, it is recognized that Hydrogen Water Chemistry does provide an additional margin of IGSCC resistance for most components exposed to reactor water. Additionally, Hydrogen Water Chemistry in conjunction

NEDO-33954 REVISION 0  
NON-PROPRIETARY INFORMATION

with noble metal technology, e.g., NobleChem™ or noble metal alloys, provides the ability to achieve Hydrogen Water Chemistry benefits while limiting radiation dose in the steam lines.

The BWRX-300 builds on a long history of material experience and refinement of material alloy chemistry to assure the best characteristics to preclude long-term material degradation. These materials include wrought alloys as well as weld metals used in the construction. Given the decades of experience as well as the strength of utility interactions through EPRI and research efforts by GEH and its licensees, there is high confidence that degradation will be very limited if not eliminated for the life of the plant. In addition, water chemistry environment controls to address potential degradation mechanisms are being implemented.

Subsection 5.2.3 covers low alloy steels and carbon steels with the associated weld metals used for the RPV, piping and vessel attachments (including nozzles and bolting). Subsection 5.2.4 includes a discussion of the potential degradation mechanisms. Subsection 5.2.5 discusses austenitic stainless steel and nickel-based alloys used for reactor internal components such as the core shroud, chimney, core support structure and control rod and instrumentation hardware as well as several piping systems. Relevant degradation mechanisms are discussed in Section 5.2.6, in particular SCC are discussed for these austenitic components.

All pressure boundary material specifications used in the BWRX-300 are as per ASTM/ASME standards. Pressure boundary materials are selected with consideration to environment compatibility with an emphasis for limiting the effects of corrosion in the reactor coolant environment due to contaminants and radiolytic products. This is especially true for ferritic low alloy steels and carbon steels.

In the case of stainless steels, the major environment-related materials performance issue encountered to date in the RCPB of BWRs has been IGSCC of sensitized austenitic stainless steel. IGSCC has been discovered in sensitized material adjacent to welds in Type 304L and Type 316L stainless steel piping systems. Substantial research and development programs have been undertaken to understand the IGSCC phenomenon. Remedial measures have been developed and implemented for the BWRX-300. IGSCC resistance is achieved through the use of IGSCC resistant materials such as Type 316L stainless steel with controlled composition. Welding controls are also implemented to ensure that welding filler materials, welding techniques and controlled post-weld heat treatment are utilized to minimize the potential for IGSCC. Additionally, weld locations in the reactor internals welds are strategically placed to limit further sensitization from irradiation. Water chemistry is also tightly controlled to minimize the existence of an environment that could promote IGSCC.

The BWRX-300 water chemistry program follows the best industry water chemistry guidelines and it is designed to analyze and monitor system chemistry for trending with alarm notification so actions can be taken to stay within operating specifications. This supports minimizing corrosion from chemical contaminants and monitoring chemical additives used to limit corrosion and radiation buildup.

Different materials are used to manufacture the reactor components, the reactor pressure vessel, piping, and reactor internals. Additionally, the typical materials used for gaskets, seals, and fasteners will vary dependent on the location and environmental conditions. For the primary components, the key materials, typical composition limits and ASME/ASTM specifications along with the fabrication processes are used to meet the requirements for the BWRX-300 application to assure resistance to different types of degradation. GEH specified materials and process controls are used to define the requirements related to service conditions. The ASME Code specifications and material alloy chemistry, define their chemical, physical and mechanical properties, that produce resistance to corrosion, dimensional stability, and desired toughness in

the fabricated components. Key microstructural features resulting from the material fabrication processing methods are also critical to achieving resistance to degradation over the plant lifetime.

### **5.2.2 Material Properties**

Nuclear power plant components may be exposed to environmental factors whose single and combined cumulative effects cannot be predetermined for the operating lifetime of the plant. The most important environmental factors are stress, high temperature, irradiation, operating transients, hydrogen absorption, corrosive attack, vibration, and fretting, with all these factors depending on time and operating history. These environmental factors can result in changes to material properties caused by irradiation or thermal embrittlement, corrosion fatigue and potentially lead to the initiation and growth of flaws. Therefore, the fracture toughness properties and the operating temperature of ferritic materials are controlled to ensure adequate toughness to minimize the possibility of brittle fracture of the NBS and RCPB components.

Materials used in the construction of the portion of the NBS that provide a safety class function or materials that are in contact with the process fluid, are selected based on suitability for the service based on the requirements of the applicable codes and standards. NBS piping is designed using materials selected to prevent erosion caused by high local steam flow velocity.

Materials used for the PCS, penetration piping and the associated supports are designed in accordance with the rules and requirements of ASME BPVC, "Section II, Materials" (Reference 5.2-1).

Where applicable, materials are impact tested in accordance with ASME BPVC Section III, Division 1, Class 1, and Class 2 components, using instruments and equipment certified to meet the same ASME BPVC requirements.

The RPV also complies with the toughness requirements for Class 1 vessels per ASME BPVC Section III. This includes plates, forgings, weld material, and the heat affected zones. Minimum toughness values at various locations of the RPV are confirmed through Charpy V-notch testing, as per ASME BPVC Section III. Charpy curves and fracture toughness specimens are used for evaluation of radiation effects on embrittlement with operating time. Consideration has been given to the effects of irradiation on beltline fracture toughness by controlling the chemical composition of vessel beltline materials.

Safety class pressure boundary components are designed and manufactured to ASTM/ASME fabrication and material specifications. This ensures that the elastic analysis methods of ASME BPVC Section III, including stress intensity factors are valid and offer a high degree of conservatism.

The surveillance test program specimens are used to monitor the radiation-induced changes in the mechanical properties of the core beltline region materials of the RPV. Part of the specimens that are exposed to irradiation are installed in removable specimen capsules at the inside vessel wall opposite the active core. The remaining unirradiated baseline specimens establish material are used to establish reference data.

The impact of irradiation on ferritic pressure boundary materials is described in ASME Section III, Non-mandatory Appendix W, Paragraph W-3300. As part of the design, vessel irradiation (neutron irradiation) is calculated over the 60-year design life of the plant. Because the core is the source of the neutrons, the fluence will be at a maximum in the region surrounding the active core, which is consistent with all previous BWR designs.

Surveillance specimen materials are prepared from samples are taken from the actual materials used to fabricate the beltline of the RPV. The weld and Heat Affected Zone (HAZ) samples are supplied if they are exposed to neutron fluence  $1.0E17$  n/cm<sup>2</sup> over the design life of 60 years.

The predicted changes from the initial properties are a function of chemical composition and the neutron fluence during reactor operation. The base and weld material with the highest predicted adjusted reference temperature at end of life are selected for the surveillance program. The prediction of adjusted reference temperature shift is in accordance with peak neutron fluence value specified in the vessel irradiation data drawing.

### **5.2.3 Overview of Reactor Pressure Vessel and Pressure Boundary Components**

The RPV and associated core support structures and piping are designed to:

- Withstand static and dynamic loading, including thermal expansion and contraction
- Withstand vibration (such as flow induced and acoustic vibration)
- Ensure chemical compatibility, including service-related contaminants
- Meet thermal material limits
- Meet radiation damage limits

The primary materials used in the RPV and pressure boundary components are listed in Table 5.2-1, together with the applicable specifications. The RPV materials comply with the provisions of ASME BPVC Section III and shall also meet the requirements of ASME BPVC “Section II Materials” (Reference 5.2-1). The RPV materials also meet the additional requirements to address potential degradation mechanisms. These materials provide adequate strength, fracture toughness, fabricability, and compatibility with the BWR environment. Their suitability has been demonstrated by long-term successful operating experience in reactor service.

#### **5.2.3.1 Reactor Pressure Vessel and Nozzles**

The RPV is constructed from low alloy, high strength steel forgings or plates. Forgings are ordered to ASME material specification SA-508M, Grade 3, Class 1, while plates are ordered to ASME SA-533M, Type B, Class 1. This material is melted to fine grain practice and is supplied in the quenched and tempered condition. Further restrictions include a requirement for vacuum degassing to lower the hydrogen level and improve the cleanliness of the low alloy steels. Table 5.2-1 lists the specifications for the RPV Vessel and Nozzle materials. Nominal compositions for these low alloy steel and carbon steel materials used in reactor components are presented in Table 5.2-2. The details of all smaller components such as low alloy steel studs, nuts, and other components are consistent with the material in Table 5.2-1. Welding electrodes for low alloy steel are low hydrogen type ordered to ASME SFA-5.5, and weld filler metal to SFA-5.23 and SFA-5.28. All forgings and bolting are 100percent ultrasonically tested and surface examined as required by ASME BPVC Section III, Division 1 (Reference 5.2-2). Fracture toughness properties of materials are also measured and controlled in accordance with ASME BPVC Section III, Division 1 as discussed in Subsection 5.2.4.

#### **5.2.3.2 Alloy Steel, Stainless Steel and Carbon Steel Piping**

The information for the main components provided in Tables 5.2-1 and 5.2-2 include the specifications and typical chemistry of stainless steel, low alloy steel and carbon steel piping components. These piping components are processed to achieve a fine grain, microstructure.

#### **5.2.3.3 Reactor Pressure Vessel Weld Materials**

Weld materials used for the RPV construction as well as the RPV nozzle attachment processes are contained in Tables 5.2-1 and 5.2-2. The ASME/ASTM specifications are listed that provide the details for the type of weld material, covered electrode or filler metal, that are used in making the weld attachments.

#### **5.2.3.4 High Strength Reactor Pressure Vessel Bolting Materials and Fasteners**

The high strength low alloy bolting materials used in the RPV closure or for flange application are generally Type 4140 or Type 4340 high strength steels. The typical specifications and compositions are listed in Tables 5.2-1 and 5.2-2.

The maximum measured yield strength and surface hardness of the stud bolting materials (studs, nuts, and washers) shall meet ASME Code requirements. Each stud is tested after rough machining on the outside surface and the center of an end position. Hardness tests is performed on all main vessel closure bolting to demonstrate that heat treatment has been properly performed. Given their importance, studs, nuts, and washers are individually tested to assure they meet specification limits.

#### **5.2.4 Degradation Mechanisms for Reactor Pressure Vessel and Pressure Boundary Components**

Component degradation mechanisms that are applicable to both the steel vessel and piping materials are assessed and controlled to assure component integrity. Degradation mechanisms include radiation embrittlement, general corrosion, and FAC. RPV fracture toughness can be affected by the operating environment; therefore, fracture toughness requirements are specified.

##### **5.2.4.1 Reactor Pressure Vessel Toughness Requirements**

ASME Section III requirements apply to all pressure boundary materials. Specific toughness values at the Reference Nil-ductility Transition Temperature ( $RT_{NDT}$ ) are determined to assure the RPV maintains adequate fracture resistance at the lowest use temperatures. The different product forms have specific requirements that are evaluated, including the beltline shell courses, nozzle forgings, safe ends, and weld filler metal.

To assure that the steel components have adequate toughness, impurity limits are set on Cu, P and S for the base metal and Cu, P, V and S limits for the weld filler metal.

##### **5.2.4.2 Radiation Embrittlement (Vessel Beltline) and Loss of Toughness**

For all material exposed to a neutron fluence of more than  $1 \times 10^{17}$  n/cm<sup>2</sup> for which impact tests are required, fracture toughness ( $K_{IC}$ ) shall be established as a function of temperature over the range of  $RT_{NDT}$  to  $RT_{NDT} + 33^{\circ}\text{C}$ . Testing requires the use of specimens with adequate thickness with details given in ASME BPVC, "Section II Materials" (Reference 5.2-1) and Subsection 5.11.8.2 entitled RPV Materials Surveillance Programs.

##### **5.2.4.3 General Corrosion**

The BWRX-300 addresses time dependent corrosion, other than localized corrosion degradation, such as IGSCC, TransGranular Stress Corrosion Cracking and Irradiation Assisted Stress Corrosion Cracking (IASCC). For various operating conditions, corrosion allowances are incorporated into the design process. These allowances need to account for the impact of the Hydrogen Water Chemistry operating environment as well as the flow rates associated with standard operation (Hydrogen Water Chemistry might affect these rates). During design, general corrosion allowances for operation and shutdown are also considered. Alternate design allowances for specific components or systems are applied based on the local environment and operating conditions. To determine the total corrosion allowance, appropriate operating allowances for all plant conditions are added together to develop the overall required allowance.

##### **5.2.4.4 Flow Accelerated Corrosion**

General corrosion for the plant components is managed in the design process based on the ASME Code as stated in the previous section. However, under certain conditions of water chemistry,

system flow, geometry, and component material, FAC can degrade piping and components made of carbon steel (with low chromium composition). The typical compositions for the carbon steel and alloy steel that are used for piping and piping components are given in Table 5.2-2. Options to ensure mitigation against FAC include increasing piping diameter, increasing elbow radius, using higher alloyed steels, or using stainless steel.

For piping made of carbon steel, extensive research has been performed to avoid FAC. The key factors that can affect the FAC rate are: (1) Temperature; (2) Material Composition; (3) Flow rate; (4) pH of the water; and (5) oxygen content. Each of these factors is discussed below:

- Temperature – generally in the range of 100°C to 150°C (can also occur at higher temperatures, but becomes less significant)
- Material Composition – materials containing <0.25 wt percent of chromium
- Flow Rate – Fully developed turbulent flow (example: Reynolds number > 150,000)
- pH – environments with a pH <8
- Dissolved Oxygen – Concentrations < 30 ppb

These parameters provide the necessary understanding to allow the design team to assure that the concerns for any carbon steel lines are managed for the BWRX-300.

#### **5.2.4.5 Additional Time Sensitive Degradation**

Other than the risks of SCC, material data is required to address the effects of thermal conditions that could change the microstructure thereby reducing the ductility and toughness of the materials. This is applicable to the ferrite levels in cast stainless steel materials as controlled by the specifications USNRC NUREG-1801, "Generic Aging Lessons Learned (GALL) Report" (Reference 5.2-3). As discussed, FAC is a specific concern for carbon steels. Additionally, there are other types of loading that can affect material integrity. Specifically, cyclic loading, commonly referred to as fatigue, occurs in different regions and components in the BWR. These are addressed using ASME Code design rules.

#### **5.2.4.6 Bolting Relaxation**

Concerns for fastener relaxation are addressed by the initial material selection process, the design process that sets the applied stresses to assure elastic loading and the installation sequence and loading process. The design process also addresses any relaxation attributable to the operating environment. These guidelines are also complemented with the use of continual review of fastener performance in current operating BWRs.

### **5.2.5 Overview of Core Structural Component Materials**

It is important that the materials to be used in the BWRX-300 are capable of maintaining reliable operation of plant systems and equipment during the design life of each component. For the reactor internals, austenitic stainless steel is primarily used to minimize levels of radiation from corrosion products generated in the core. Where higher strength requirements than those for standard austenitic stainless steels are needed, nickel base alloys, nitrogen strengthened austenitic alloys, or precipitation hardening stainless steels are used.

Materials selection with composition controls and defined fabrication processes is used to address materials degradation issues in the reactor system specifically SCC and irradiation SCC. Figure 5.2-1 shows the three factors that lead to degradation. Selection of the materials is directed toward minimizing their susceptibility. Design guidelines and controlled fabrication processes are used to manage the component stresses, with emphasis on surface stresses. It should be noted that the impact of the coolant environment is addressed using Hydrogen Water Chemistry/OLNC.

The stainless steel structural materials used in the BWRX-300 reactor core internals are primarily wrought materials along with their weld metals although Cast Austenitic Stainless Steels are used as well. It is noted that no Cast Austenitic Stainless Steels will be used for the reactor pressure vessel. However, Cast Austenitic Stainless Steels may be utilized in other pressure-retaining, cyclic, and/or dynamic load applications when supported by appropriate design analysis evaluations.

With respect to reactor internals and/or core support applications (see Subsection 5.2.5), Cast Austenitic Stainless Steels may be utilized. As an example, fuel supports are subject to some cyclic and dynamic loads during reactor operation and operating events. Cast Austenitic Stainless Steels is used for the fuel support due to the complexity of the part and challenges fabricating from wrought material. Appropriate chemistry controls to mitigate material degradation concerns will be applied. Operating experience with this material over the past 60 years supports its use in this application.

Table 5.2-3 lists the materials used for the typical internal components including the shroud, chimney, steam dryer, top guide, core support, CRD housings and instrumentation housings. The table lists the material product form as well as representative ASME/ASTM specifications. Table 5.2-4 lists typical compositions for these austenitic reactor component materials.

#### **5.2.5.1 Wrought Austenitic Stainless Steels**

The primary alloys to be used for reactor internal components are austenitic structural alloys. Specifically, the wrought austenitic stainless steel components are Type 304, 304L, 316, 316L and potentially 316L with higher nitrogen content.

These materials have a long history of use in all past BWR applications. For L grade materials, the primary controlled constituent is carbon. Carbon is restricted to 0.03 weight percent to provide resistance to sensitization during welding while still being able to meet the specified strength levels at the use temperature. For applications in high fluence regions of the core, residual elements are controlled to reduce the susceptibility of the steel. The efforts to maintain higher strength at temperature led to the development of special versions of Type 316L (originally designated Nuclear Grade which include nitrogen additions to maintain high temperature strength in these low carbon alloys). The chemistry of Type 316/316L material for components is also controlled to have positive ferrite potential as determined by ASTM A800/A800M-20, "Standard Practice for Estimating Ferrite Content of Stainless Steel Castings Containing Both Ferrite and Austenite" (Reference 5.2-4) or the use of an approved alternate ferrite diagram for composition control with a target level of 3 percent. This is necessary to assure good weldability. The additional controls on alloy composition are also given in notes to Table 5.2-3. These austenitic materials are given a solution heat treatment at a temperature range with a hold time designed to achieve a full solution annealed condition while minimizing grain growth. The heat treatment is then followed by accelerated cooling to avoid any sensitization. It should be noted that Alloy XM-19 with its higher strength, developed for control rod drive components, will be used in special locations due to its excellent IGSCC resistance.

#### **5.2.5.2 Cast Austenitic Stainless Steel**

These cast versions of the wrought materials rely on carbon control and the presence of ferrite to assure IGSCC resistance which requires the ferrite level of 8 percent minimum for SCC. Additionally, the ferrite levels are also restricted to less than 20 percent to assure adequate toughness after long-term exposure to higher temperatures. The castings are given solution annealing to maintain IGSCC resistance. Prior operating experience has validated resistance to IGSCC (ASTM STP 756, "Intergranular Stress-Corrosion Cracking Resistance of Austenitic Stainless Steel Castings" (Reference 5.2-5)).

### **5.2.5.3 Nickel Base Alloys**

Similar composition controls and product form processing to stainless steels are used to assure that wrought Ni-Cr-Fe Alloy 600 (including modified Alloy 600) and the associated Weld Metal Alloy 82 (ASME BPVC, "Case N-580-2 Use of Alloy 600 with Columbium Added Section III, Division 1" (Reference 5.2-6)) are free of any sensitization risks. Nickel base wrought materials are Alloy 600 with niobium modified chemistry. Specifically, the materials need to have a stabilizing ratio  $(Nb + 2 \cdot Ti/C) > 92$ . Additionally, nickel base filler metals are to be Alloy 82 (ERNiCr-3) with a stabilizing ratio that also follows the same requirements.

### **5.2.5.4 High Strength Alloys**

In special locations, higher strength Alloy X-750 is used for bolting and fastener type applications. The main approach used to prevent SCC susceptibility is accomplished by limiting the applied stresses in the design process. High strength austenitic Alloy X-750 is procured and processed to assure adequate SCC resistance. Additionally, Alloy 718 is considered to be used for high strength applications. Alloy 17-4PH is a martensitic precipitation hardening stainless steel of high strength, therefore, potentially susceptible to SCC if the hardness is not limited.

## **5.2.6 Overview of Design and Fabrication Process for SCC Controls in Reactor Core Components**

To prevent SCC, the third factor that is necessary is the presence of elevated surface stresses. These residual stresses are often introduced by fabrication such as welding, surface grinding or forming operations. These types of stresses will support crack initiation on the wetted surface. For austenitic stainless steels or nickel base alloys, construction process controls are applied during various stages of component manufacturing and reactor construction to avoid these fabrication-induced surface stresses that could lead to SCC initiation.

These processing steps can also introduce localized sensitization. The processes that need to be controlled include bending or forming, final machining, grinding, polishing, and welding. Each type of operation and an overview of the controls to be applied are summarized in more detail below.

### **5.2.6.1 Forming Processes**

These processes are required for piping or cylindrical structures. It is important that forming is controlled and does not introduce significant strains that could lead to SCC initiation if the shape is not given a post forming solution anneal. These processes are limited to 2.5 percent total strain to prevent future SCC. The GEH materials and process controls define these limits.

### **5.2.6.2 Machining, Grinding and Polishing**

Surface machining, and grinding are required as part of large component fabrication. Specific procedures employing specific media and subsequent polishing using increasingly finer media and decreasing material removal are also specified. These polishing procedures are particularly used following welding in the fabrication of reactor internal components such as the core shroud. Process qualification always precedes actual practice. The primary regions of potential susceptibility are the welds and their HAZ regions. Specifically, abrasive grinding of stainless steel HAZ regions is minimized to the extent possible. When grinding is applied to the weld regions, care is taken to confine grinding to the weld metal region only and limit grinding of the adjacent base metal. This is necessary to meet the required fabrication and examination requirements of ASME. Grinding abrasives are controlled to avoid detrimental effects on austenitic materials. Grinding is followed by polishing processes to further reduce the risks of SCC.

The use of the final polishing processes is restricted to those with qualified procedures. The procedure contains methods that involve finishing the ground surface with successively finer grit size such that the bulk of any surface cold work is removed. Finishing with each grit size continues until evidence of the previous grit is removed.

#### **5.2.6.3 Welding Processes**

Over the history of BWR plant construction and operation, GEH has refined the technologies for fabrication, maintenance, and repair of welded components in nuclear reactors. Each process improvement has increased margins against SCC in BWRs by controlling residual stresses, alloy chemistry, and microstructure for the welds and surrounding HAZ regions. GEH developed specialized narrow groove welding technology, which is an automated welding technology addressing these three critical factors. Specifically, it produces compressive stresses in the weld root regions. The narrow weld joint design improves fabrication productivity and reduces weld shrinkage distortion. The low heat input, combined with special welding parameters, also limits HAZ residual strains and sensitization in addition to the compressive stresses, which will further prevent SCC. Since its development, the process has been used across the power generation industry.

#### **5.2.6.4 Electro-Discharge Machining**

Under special circumstances, Electro-Discharge Machining (EDM) is used. Specific controls, developed in previous BWR applications, are used on nickel base alloys to prevent surface degradation such as microfissuring.

In summary, GEH uses developed fabrication processes with a long history of refinement to prevent SCC initiation in components made using austenitic structural alloys. These fabrication processes are also used to prevent IASCC and TransGranular Stress Corrosion Cracking.

#### **5.2.6.5 Additional IASCC Material Controls**

As with SCC, the parameters that contribute to IASCC in a BWR environment are material selection with its processing, the applied and residual stresses in the components, and the magnitude of the neutron radiation exposure. Type 316L is the alloy of choice for the core region.

Table 5.2-4 includes a listing of special chemistry controls on silicon for Type 316L when used for reactor internals subjected to IASCC. The benefits of the control of silicon are confirmed by research and are used in core components, specifically the core shroud.

#### **5.2.6.6 Specific TransGranular Stress Corrosion Cracking Fabrication Controls**

IGSCC and TransGranular Stress Corrosion Cracking often occur in the same alloys depending on the environment or the microstructure. However, cases of TransGranular Stress Corrosion Cracking in small lines and other components, have been associated with contaminants such as chlorides that can be present on the material surface.

These contaminants, related to salts or marking materials, are also controlled during fabrication as well as operation. Miscellaneous non-metallic materials, used for the fabrication and assembly of reactor system components, are also controlled to minimize contamination with species known to have detrimental effects on alloys such as stainless steels and nickel alloys.

Those materials which come in contact with stainless steel or nickel alloys during these processes are either low in halogens, sulfur, and lead or other low melting alloys or need to be removed in the final cleaning of the part or assembly. The known contaminants of concern are chlorine, fluorine, sulfur, lead, mercury, and all other low melting point metals. In addition, when welding or solution heat treatment is involved, phosphates and carbonaceous materials are to be removed prior to welding or heat treatment.

#### **5.2.6.7 Sensitivity to Fracture**

The alloys used in BWR systems other than the RPV and steel components are predominantly alloys with lower strength and high ductility. These alloys are not susceptible to rapid fracture as substantiated by the excellent operating history of BWR components fabricated from austenitic stainless steel and nickel base alloys. The only components that show loss of ductility and reduced fracture resistance are the core components, particularly the core shroud, which is subjected to irradiation. The irradiation leads to material changes, hardening and grain boundary segregation, that in, turn, increase the strength significantly and reduces the ductility. The same factors that increase the risk of IASCC, also reduces fracture resistance. The shroud design takes these factors into account to assure adequate robustness. The design also positions the shroud welds to reduce the fluence experienced by the weld region. Cast Austenitic Stainless Steels material compositions restrict the ferrite level to assure toughness is not lost with thermal aging.

#### **5.2.7 Gasket, Seal, and Fastener Materials**

##### **5.2.7.1 Gaskets and Seals**

These non-metallic engineered materials used in association with reactor system components are controlled to minimize or eliminate potential for detrimental effects on metallic reactor components. These materials which include gaskets, packing, bushings, etc., that are installed within the reactor system such that they are in contact with reactor water conform to the chemistry controls of specifications. Examples of the specific materials used include Viton, Buna-N, EPDM and graphite non-metallic seals as well as metallic seals including silver plated Alloy 718. The specifications set limits on halogens, sulfur, and nitrates in the non-metallic materials. There are also specific prohibitions or limitations on the use of chlorine and fluorine bearing materials such as Teflon and polyvinyl chloride. Exceptions are allowed but must be evaluated on an individual basis considering such factors as location, radiation dose, temperature, and successful operating history.

##### **5.2.7.2 Fasteners**

Sections 5.2.3 and 5.2.5 include discussion of low alloy steel and austenitic high strength materials, respectively, that are used as fasteners. There is extensive experience in operating BWRs with these materials that are used as the basis for fastener selection for use in the BWRX-300. Tables 5.2-1 through 5.2-4 include the specifications and compositions of these special use materials.

**Figure 5.2-1: The Three Necessary Factors to Produce Stress Corrosion Cracking**

### 5.3 Nuclear Boiler System

The NBS is comprised of three primary subsystems: RPV, MS, and RPV instrumentation. In addition to these subsystems, the NBS also provides RPV head venting and RPV head flange seal leak detection features. Within the NBS are the redundant with diverse instrument and electrical features, safety class reactor isolation valves interfacing with the subsystem and systems listed below:

- MS (Subsection 5.7.1.4 and Chapter 10, Section 10.4)
- RPV head vent (Subsection 5.12.3)
- ICS steam supply (Section 5.7 and Chapter 6, Section 6.2)
- ICS condensate return (Section 5.7, Chapters 6 and 9)
- Condensate and Feedwater Heating System (CFS) (Chapter 10, Subsection 10.3.2)
- CUW (Subsection 5.12.2 and Chapter 9A, Subsection 9A.2.2)

#### 5.3.1 Nuclear Boiler System Configuration

The NBS (see Figure 5.1-2) consists of the RPV, two main steam lines, MSRIVs, FWRIVs, IC Supply RIVs (ICSRIV), IC Return RIVs (ICRRIV), CUWRIVs, MSCIVs, steam line drain subsystem, RPV Head Vent RIVs and Head Vent subsystem, a Head Flange Leak Detection subsystem, nuclear instrumentation, and reactor pressure, reactor water level, steam, temperature, and leak detection instrumentation.

The CFS provides high purity feedwater to the RPV at the required flow rate, pressure, and temperature. The CFS interfaces with the NBS just before injection into the reactor vessel located in the Reactor Building. The CFS receives main steam from the NBS for high-pressure Feedwater Heater (FWH) number 6. Only the portion of the CFS from the CFS CIVs to the outboard FWRIVs outboard flange to is part of the RCPB as indicated in Section 5.1, and it is described further in Chapter 9A.

##### 5.3.1.1 Reactor Pressure Vessel Description

The NBS utilizes an RPV to house and support the core and internals, provide a pressure boundary and flow path for reactor coolant, interface with CFS as the coolant supply, generate steam for the main turbine, and provide emergency core cooling via the ICS. The RPV nozzles greater than DN20 are flanged to two integral in-series RIVs. The nozzles are for the MS (N1), ICS Supply (N2), FW (N3), ICS Return (N4), CUW (N5), and Head Vent (N6) systems or subsystems. Nozzles with a bore less than DN20 are not required to have integral in-series RIVs. The DN20 and below nozzles are for Level Low-Pressure or reference leg (N7), Level High-Pressure or variable leg (N8), and Head Flange Leak Detection (N9).

There is one nozzle (N10) greater than DN20 that does not have RIVs and is located at least TAF+4m. The purpose of the N10 nozzle is for required prototype testing that supports the internal vibration monitoring. That nozzle would normally have a blind flange installed. When the internal vibration program is in operation, another flange is installed that has individual holes for the instrument cabling installed through interfacing bolts.

##### 5.3.1.2 Main Steam Subsystem

The MS subsystem is comprised of two main steam lines that are routed from the outboard MSRIV discharge through the outboard MSCIV out to the TSVs, associated branch piping, and the MSL drains.

The MS piping (in Containment and RB) from the discharge of the outboard MSRV to the Seismic Interface Restraint (SIR) is designed to ASME BPVC Section III, Division 1, Class 2, Seismic Category A requirements following USNRC NUREG-0800 BTP 3-3, "Protection Against Postulated Piping Failures in Fluid Systems Outside Containment" (Reference 5.3-1) guidance. The MS piping from the outboard MSRV discharge to the low point of the piping just inside the TB is designed to have a negative slope such that any steam condensate will drain outwards to the MS drain lines.

The MS piping in the TB, including all the connecting branch lines up to the various steam loads and their respective isolation valves (see Chapter 10) is designed to ASME B31.1, "Power Piping" (Reference 5.3-2), which has non-seismic category requirements. The MS equalizing header supplies high-pressure steam via branch piping to the TBVs, the moisture separator reheater (MSR), the number 6 Feedwater Heater (FWH), and the Turbine Auxiliary Steam Subsystem (TASS).

The MS pipeline routing includes sufficient length such that the MSL minimum volume requirements are met using the pipe sizes designated from the system Piping and Instrumentation Diagram (P&ID) and Process Flow Diagram (PFD).

The MS subsystem is designed so that the pressure drop through the piping at 100 percent Rated Thermal Power (RTP) condition does not exceed the minimum or maximum limits.

MSLs are designed to minimize the potential for water (steam) hammer through the implementation of specific design features and system layout(s). The design also complies with USNRC NUREG-0927, "Evaluation of Water Hammer Occurrence in Nuclear Power Plants" (Reference 5.3-3) as applicable.

The BWRX-300 design includes an outboard MSCIV (see Figure 5.1-3) on each MSL. The MSCIVs provide SC1 containment isolation for accidents or events to prevent unfiltered release of radiological contaminants through the MSLs that exceed limits. This containment isolation is single failure proof. The MSCIVs are fast-closing and fail-closed type valves. These isolation valves outside of containment are located as close to the containment as practical to satisfy the containment isolation design requirements.

The MSCIVs are designed in accordance with the rules and requirements of ASME BPVC, Section III, Division 1, Subsection NCD, Class 2 and Class 3 Components (Reference 5.3-4), in accordance with their quality group classification. The MSCIVs are designed for Seismic Category B and certified by a qualification program prepared and performed in accordance with ASME QME-1, "Qualification of Active Mechanical Equipment Used in Nuclear Facilities" (Reference 5.3-5).

The MS drain lines provide the ability to drain the condensate from the MS lines to the condenser in a controlled manner during startup, lower power operation (approximately 40 percent RTP for drain valves control), normal power operation, and shutdown. The MSL drain isolation valves incorporate control logic interlocked to support automatic plant startup and shutdown operation.

### **5.3.1.3 Nuclear Boiler System Instrumentation Subsystem**

#### **5.3.1.3.1 Reactor Water Level**

The water level in the reactor vessel is measured by the temperature compensated dP devices (calibrated for specific RPV pressure and temperature conditions).

Historically, BWR water level has been monitored over both NR and wide range (WR). Previous RPV designs have multiple taps to cover the different ranges. The NR is calibrated for a smaller range of elevations and therefore can be held to a higher accuracy than WR. This is because the

measurement accuracy is linearly related to the overall differential height of the sensor pair. During normal operations, NR is used to control the target water level and FW flow. WR level monitoring is used during off-normal events. In the case of BWRX-300, the added safety features of not having RPV penetrations below TAF + 4m, as well as minimizing the number of nozzles, results in having only one set of nozzles for each division of water level monitoring. Therefore, NR and WR for each division are taken from the same set of nozzles.

The reactor water level measuring system is classified SC1 and is monitored by the C10 Distributed Control and Information System (DCIS). The C20 DCIS is also used to monitor the water level for both SC2 and SC3 functions. The BWRX-300 is designed to have three divisions for monitoring and control of SC1 functions, as well as redundancy within each division (refer to Chapter 7 for detailed description of control logic architecture).

Another key function of the water level measurement system is to provide shutdown range water level monitoring as the RPV is flooded up before the head is removed. It will also monitor water level during refueling and support post-outage restart. This is a SC3 function with two pressure transducer pairs.

Water level measurement is not required between TAF and TAF + 4m because there are no operator actions associated with this range. In the case of a BDBAs and DECAs where monitoring water level in the core (also known as fuel zone range) is necessary, it will be accomplished with GTs. The GTs are configured with a heater wire to provide a heated junction to every location on a string used to support water level monitoring even when gamma flux is low, and also to provide testing and calibration capability.

#### **5.3.1.3.2 Reactor Pressure Instrumentation**

RPV steam dome pressure is measured using wide range and narrow range differential pressure instruments to provide pressure indication in Modes 1 through 5. The RPV steam dome pressure measurement supports Post-Accident Monitoring (PAM) system.

#### **5.3.1.3.3 Core Flow Instrumentation**

Mass core flow in the BWRX-300 RPV is not measured directly but is calculated from an aggregation of temperature measurements throughout the core and RPV pressure. The core flow is calculated by the heat balance core flow methodology using the core inlet temperature measurement as input to determine core inlet enthalpy. The methodology provides a verified basis for calculated core flow.

#### **5.3.1.3.4 Main Steam Flow Instrumentation**

The main steam flow restrictors are located in the RPV MS nozzles. They perform functions in various safety classifications and corresponding defence levels. The SC1 functions are to limit the overall steam flow through one steam line when the steam flow exceeds preselected operational limits (i.e., if a large break of a MSL is sensed). The other SC1 function is to provide that same sensing function to the SC1 MSRIV/MSCIV isolation system. The SC2 steam flow function also supplies the same sensing functions for MSRIV/MSCIV isolation in addition to the already discussed SC1 isolation function. The SC3 steam flow function supports the overall reactor water level controller that maintains target water level as one of the inputs to that controller.

The main steam flow restrictor provides low-pressure sensing taps for instrumentation lines of differential pressure transmitters that are used to measure steam flow. Main steam flow is measured through the RPV nozzle flow restrictors using Bernoulli's equation of differential pressure to derive the MS mass flow. The mass flow can then be calculated by knowing the steam properties based on RPV pressure and temperature.

#### **5.3.1.3.5 Reactor Power Instrumentation**

Reactor power instrumentation is described in Subsection 5.4.2.

#### **5.3.1.3.6 RPV Metal Temperature Instrumentation**

The RPV outside surface (metal) temperatures are measured at the head flange and the bottom head locations in order to comply with plant Operational Limits and Conditions (OLC) (Technical Specification) surveillance RPV heat-up and cooldown requirement limits which define allowable operating regions and permits a large number of operating cycles while also providing a wide margin to nonductile failure.

### **5.3.2 NBS Classification of SSC**

The overall NBS is classified as a SC1 system following the methodology for classification of BWRX-300 Structures, Systems and Components (SSCs) as discussed in Chapter 3, Section 3.2. Table 3A.5-1 provides a list of the primary BWRX-300 SSCs and their classification in accordance with safety class, seismic category, and quality group.

### **5.3.3 NBS Functions**

The NBS components are designed, specified, procured, fabricated, tested, installed, and commissioned in accordance with the codes and standards specified in Chapter 1, Appendix B. Chapter 1, Appendix B lists the approved codes and standards and identifies the applicable editions used for the design of mechanical systems and components of the BWRX-300 including those described in Chapter 5. The pressure boundary codes and standards are listed in Table 3.6-1 of Chapter 3, Section 3.6.

#### **5.3.3.1 Normal Functions (Non-safety Category)**

The NBS is designed to fulfill the following normal and off-normal safety functions. The normal operating modes including description of how the plant operates in these different operating modes is provided in Chapter 16, Appendix 16A.

- The BWRX-300 RPV operates through natural recirculation
- NBS converts heat energy resulting from the fission process in nuclear fuel into heat energy for electric power production in Mode 1
- NBS separates, removes, and recycles the entrained moisture and discharges dry steam into the main steam subsystem in Mode 1
- NBS provides the ability to produce the steam flow capacity and conditions to the main turbine for electric power production as defined in the reactor heat balance in Mode 1
- NBS transports steam generated in the RPV to the main turbine for electric power production in Mode 1
- NBS vents the non-condensable gases through the RPV head to the main steam piping in Mode 1
- NBS detects leakage from the RPV O-ring seal in Modes 1, 2, 3, 4, and 5
- Upper reactor internals are removable to facilitate the refueling operation

#### **5.3.3.2 Normal Functions (Safety Category)**

- NBS provides the reactor coolant pressure boundary for the cooling water and steam that prevents the nuclear fuel from overheating in Modes 1, 2, 3, 4, and 5

- NBS provides the core support structure to enable the control rods to stop the nuclear reaction when driven into the core by their respective Hydraulic Control Units (HCU) in Modes 1, 2
- NBS provides the core support structure in Modes 1, 2, 3, 4, 5, and 6
- NBS provides the flow path to enable the core coolant to keep the core cool using natural circulation in Modes 1, 2, 3, 4, 5, and 6 (Note: The control rods provide the negative reactivity into the core to allow for the control of reactor power)
- Main steam has the ability to be isolated independent of offsite power and if the condenser is used for decay heat removal in Mode 4

#### **5.3.3.3 Off-Normal Functions (Non-Safety Category)**

The system does not perform any safety functions during off-normal conditions.

#### **5.3.3.4 Off-Normal Functions (Safety Category)**

The NBS performs DL3 SC1 functions that support high availability of the BWRX-300 Fundamental Safety Functions (FSF) as listed below:

- Control of reactivity
- Fuel Cooling
- Long-term heat removal
- Containment of radioactive materials (isolation of RCPB)

As described in Chapter 3, Subsection 3.1.6, the allocation of defense line functions to system function categorization and system classification is as follows:

- SC1 equipment is located in DL3
- SC2 equipment is located in DL4a
- SC3 equipment is located in DL2

### **5.3.4 System Operations**

#### **5.3.4.1 Initial Configuration (Pre-Startup)**

System configuration is established per plant procedures. Operating modes are defined in Chapter 16, Appendix 16A.

#### **5.3.4.2 System Startup**

Startup of the NBS begins with reactor operations in Mode 2. System startup consists of reactor startup from cold shutdown (RPV coolant bulk temperature less than or equal to 90.0°C) or hot shutdown conditions (bulk temperature greater than 215.6°C). All components and instruments of the NBS are operable and valves are aligned to the positions (open or closed) required.

During startup operation, the NBS is heated to 90°C and condenser vacuum established so the RPV can be deaerated before nuclear heating is started. At this time the MSRIVs and MSCIVs are opened. Reactor startup is begun by withdrawing control rods in a predetermined sequence to achieve core criticality and continued to the onset of coolant boiling. The heat-up rate after boiling onset is automatically controlled using the TBVs and condenser. The reactor water level is controlled by manual operator or automatic direction to maintain the level in the normal range during the transition from SDC to FW injection. Continued control rod withdrawal raises core thermal power up to and not exceeding 12 percent RTP.

RPV level control is performed by regulating the FW flow. With the reactor core power stable at about 12 percent RTP, preparations are made for turbine roll and generator synchronization. The MSL drain line valves and the isolation valves to other system interfaces are open. The MSL drains remain open to approximately 40 percent RTP to remove excess moisture carryover.

#### **5.3.4.3 Normal Operations**

Power Operation (Mode 1) consists of normal operation, planned transients, AOOs and infrequent events (unplanned transients), and on-line testing. Normal operation includes steady-state operation at a given power level up to RTP. All required components and instruments of the NBS are operable and are aligned as required for system operation. Subcooled FW is provided by the CFS system to keep the RPV level in the normal operating range. The reactor pressure is controlled at 7.17 MPa with a constant steam mass flow rate.

As the water boils in the core, the chimney provides an area of expansion such that the velocity lowers and allowing the void fraction to increase. The NBS also provides the means for separating the steam from the liquid and drying the steam by channeling flow through the steam separator and steam dryer before it goes to the MS lines and the turbine. The MS subsystem transports steam generated in the RPV through PCS discharging from the RPV nozzles through the MSRIVs, traveling through the MSLs and MSCIVs to provide the steam to drive the main turbine. Steam is directed through the open maintenance block valves to the MSR, number 6 FWH, and TASS. MS line drain line valves open and close as a function of the level of condensed steam in the drain pot up to about 40 percent power where they are verified closed.

During power operation, the non-condensable gases generated in the RPV will be vented through the RPV head to the MS piping.

#### **5.3.4.4 Off-Normal Operations**

##### ***5.3.4.4.1 Planned Transients***

Planned transients include reduction or increases in power, rod pattern changes, reduction to 0 percent power and hot standby.

Reductions in power to 50 percent by rod pattern changes have no effect on NBS operation.

Reduction in power to 40 percent and below results in automatic opening of the drain orificed line valves to the main condenser.

The TBVs open whenever the TSVs and TCVs close, bypassing steam to the condenser.

##### ***5.3.4.4.2 Unplanned Transients***

Unplanned transients are listed in Chapter 15, Section 15.5.

#### **5.3.4.5 System Shutdown**

System Shutdown contains three (3) states:

- Hot Shutdown
- Stable Shutdown
- Cold Shutdown

##### ***5.3.4.5.1 Hot Shutdown***

During Hot Shutdown (Mode 3), the NBS is intact and available to be pressurized.

Reactor shutdown from the power operation begins with the reactor at rated pressure and temperature and the reactor Mode Switch in RUN position. Rod insertions reduce plant power

until the turbine is taken offline. RPV coolant level is normally controlled using FW to provide reactor water level control if the main condenser is available to reject core decay heat. CUW can be used to overboard excess coolant level if the RPV is pressurized.

Insertion of control rods is performed to establish a reactor cooldown rate and slowly depressurize the reactor. After all control rods are inserted, the reactor is placed in the Hot Shutdown position. If conditions require operator action to expedite core shutdown, the control rods are rapidly inserted by a trip signal initiated by placing the reactor Mode Switch to the SHUTDOWN position.

In Hot Shutdown, the RPV coolant bulk average temperature is less than rated conditions but greater than 215.6°C. The NBS continues to provide steam paths for the removal of core decay heat by the main condenser or by the ICS, depending on the status of the NBS isolation subsystems. Makeup is provided as required either from the CFS or from CRD system.

#### **5.3.4.5.2 Stable Shutdown**

Entering Stable Shutdown (Mode 4), starts with the reactor exiting Hot Shutdown usually before the reactor Mode Switch is placed in the SHUTDOWN position. The NBS is intact and able to be pressurized. Insertion of control rods is continued to establish a reactor cooldown rate and slowly depressurize the reactor. If FW is available, decay heat can be removed using the TBVs to discharge steam to the condenser and return back using FW and/or condensate. MS may or may not be isolated depending on the availability of offsite power and whether the condenser is available for decay heat removal. If offsite power is not available, decay heat removal is performed by the ICS.

#### **5.3.4.5.3 Cold Shutdown**

Normally, the reactor design is to be cooled down from the HOT SHUTDOWN condition by opening one or more TBVs to direct steam to the main condenser. RPV cooldown is carefully controlled so that it is less than the design limit of 55.5°C/hr. SDC initially provides a small assist to this cooling. When the reactor pressure reaches approximately the pressure at which turbine gland sealing steam is no longer effective at maintaining vacuum in the main condenser, the remaining residual heat in the reactor is within the capability of SDC. Both FW lines provide a path for SDC flow to return to the RPV. Reactor cooldown continues with SDC until entering Cold Shutdown (Mode 5) with reactor bulk coolant temperature at or below 93.3°C. Coolant temperature is maintained above the design minimum temperature with the head bolts tensioned. The NBS instrumentation monitors the reactor water level, temperature, and pressure.

### **5.3.5 Refueling Mode Operation**

When the RPV is to be filled for refueling, the RPV is further cooled to near temperature inside containment using SDC. When the reactor vessel head stud de-tensioning begins, the plant operating state is Refueling Mode (Mode 6). The NBS instrumentation is used to monitor the reactor water level and temperature. No further NBS action is needed unless RIV maintenance is planned in which case nozzle plugs are installed.

### **5.3.6 Testing and Maintenance**

This section provides, in part, the basis for preparation of detailed maintenance procedures. It defines the maintenance philosophy, outlines the procedures for scheduled (preventative) and unscheduled (corrective) maintenance, and ISI and surveillance. It also identifies interfacing systems needed to support maintenance operations.

The BWRX-300 in-service inspection requirements specification provides mandatory Pre-Service Inspection, In-Service Inspection (ISI), and In-Service Testing (IST) requirements for components and systems. Pre-Service Inspection, ISI, and IST requirements are consistent

NEDO-33954 REVISION 0  
NON-PROPRIETARY INFORMATION

with ASME BPVC, Section XI (Reference 5.3-6) and ASME OM, "Operation and Maintenance of Nuclear Power Plants," (Reference 5.3-7).

The Pre-Service Inspection, ISI, and IST requirements include examinations, inspections, and testing of the Reactor Pressure Vessel (RPV) and reactor coolant transporting systems, components, piping, and pipe supports, which are designed and installed in accordance with ASME BPVC, Section III, and applicable codes and standards listed in Chapter 1, Appendix B. In addition, this specification includes basic design control considerations within ASME NQA-1, "Quality Assurance Requirements for Nuclear Facility Applications", Part 2 (Reference 5.3-8). The ISI requirements ensure plant nuclear safety, minimal radiation exposure to the general public, and plant personnel, and proactive management of potential adverse plant system deterioration and aging effects.

Any required surveillance testing is determined as part of the work planning / work release approval process. Post-Maintenance Testing is determined as part of the maintenance review and approval process.

Pre-service and in-service inspection are performed in accordance with ASME BPVC Section XI.

The RIVs have appropriate access platforms and load handling equipment to assist valve assembly maintenance and load transport inside the containment.

The NBS water quality meets the requirements delineated in the BWRX-300 Water Quality Design Specification.

Areas requiring ISI inspection are provided with access spaces/routes and with removable and reusable insulation coverings.

## **5.4 Reactor Pressure Vessel**

The BWRX-300 RPV (Figure 5.4-1) assembly consists of the vessel with nozzle integral RIVs and its other appurtenances, a removable head, the reactor internals and supports and instrumentation. The RPV instrumentation that monitors the conditions within the RPV is designed to cover the full range of reactor power operation. The RPV, together with its internals, provides guidance and support for the FMCRDs.

The RPV is a vertical, cylindrical pressure vessel fabricated from forged rings or rolled and welded plate rings joined together, with a removable top head by use of a head flange, seals, and bolting. The RPV also includes penetrations, nozzles including RIVs, and reactor internals support. The reactor vessel is relatively tall which permits natural circulation driving forces to produce core coolant flow.

The reactor pressure vessel is designed to keep its structural integrity during all specified loading conditions. It also maintains its integrity against nonductile failure including consideration of material embrittlement due to neutron irradiation during its design life.

A longer internal recirculation flow path (relative to forced-circulation BWRs) is provided by a “chimney” in the space that extends from the top of the core to the entrance of the steam separator assembly. The top guide, the chimney, chimney head and steam separator assembly are supported by a shroud assembly that extends to the bottom of the core.

### **5.4.1 Major Reactor Internal Components**

This section addresses the RPV internals which consist of all the structural and mechanical elements inside the RPV.

The core support structures and reactor vessel internals (exclusive of fuel, control rods, and in-core nuclear instrumentation) are as follows:

- Core support structures (shroud support, core plate, shroud, top guide, chimney, control rod guide tubes, control rod drive housing, orificed fuel supports and peripheral fuel supports)
- Internal structures (chimney head and steam separator assembly, steam dryer assembly, feedwater spargers, internal piping, nuclear instrumentation, in-core guide tube stabilizers, surveillance sample holders)

A simplified representation of the BWRX-300 RPV and internal component locations is shown in Figure 5.4-1.

### **5.4.2 Core Components (Control Rods and Nuclear Instrumentation)**

Major Core Components including, Fuel Bundles and Control Rods are discussed in Chapter 4. The control rods (see Chapter 4, Figure 4.1-1) insert negative reactivity into the core to control reactor power.

The nuclear (in-core) instrumentation consists of the PRNM, GTs, and WRNM.

The PRNM provides neutron monitoring power signals to the C10 Protection System. The PRNM also provides signals for post-accident monitoring purposes and, through isolated, one-way optical data links to the core monitoring three-dimensional power distribution program and to the DL2 control rod blocking systems.

GTs are an in-core device that converts local gamma flux to an electrical signal; gamma flux and neutron flux are both representative of core thermal power. It represents a completely diverse

technology to the neutron detecting LPRMs used in DL3 PRNM system. They supply information needed to allow for calibration of the LPRMs in the PRNM system.

The WRNM system is a redundant pair of industrial microcomputers with a real time operating system that each monitor all of the WRNM neutron monitoring detectors in the core. The detectors are distributed radially in the core at fixed heights with at least three detectors in each quadrant. The detectors can be bypassed but the bypass switches are arranged such that only one detector can be bypassed at a time in any quadrant. Each detector is sensitive to neutrons from below criticality to approximately 20 percent RTP – a range of over 11 decades. Their absolute value is indicative of reactor power.

### **5.4.3 Core Support Structures**

The basic core support structure components consist of the core support legs, lateral braces, core support ring, core plate, shroud, top guide, chimney, and the orificed fuel supports, peripheral fuel supports, the control rod guide tubes, and non-pressure boundary portion of control rod drive housings.

The core support structure includes the chimney and two basic structures. The chimney is an extended height cylindrical component mounted on the top guide and attached to the top of the shroud. It provides the necessary additional volumetric space within the RPV that permits natural circulation driving forces to produce core coolant flow. The first structure horizontally restrains the entire core and vertically supports the peripheral fuel assemblies. The second structure provides vertical support for the remainder of the core by supporting the fuel assemblies in independent groups of four.

The first structure consists of the support legs, support ring, lateral braces, core plate (with peripheral fuel supports), shroud, top guide, and the hardware necessary to assemble these components. The support legs are affixed to the bottom of the RPV, and the support ring is attached on top of the legs. The support legs and support ring provide a mounting point for the core plate and vertically support the core plate and components above it. Lateral braces are mounted to stiffen the support structure and provide lateral restraint of horizontal loads from the internals and the core.

The second structure consists of the orificed fuel supports, the control rod guide tubes, and the upper portion of the control rod drive housings inside the RPV.

Core support structures perform a safety function and are classified as SC1. Core support structures are Seismic Category A.

The reactor internals are classified as core support structures according to the ASME BPVC, Section III, Division 1, Paragraph NG-1121, Core Support Structures (Reference 5.4-1). They are designed, fabricated, and examined in accordance with the provisions of ASME BPVC Section III, Division 1, Subsection NG (Reference 5.4-1).

The design criteria, loading conditions, and analyses that provide the basis for the design of reactor internals (other than the core support structures) meet the guidelines of the ASME BPVC, Section III, Division 1, Subsection NG-3000 (Reference 5.4-1), are constructed so as to not adversely affect the integrity of the core support structures. If other guidelines (e.g., manufacturer standards or empirical methods based on field experience and testing) are the bases for the stress, deformation, and fatigue criteria, those guidelines are identified, and their use justified in the design. For non-ASME Code core structures, components and supports, design margins presented for allowable stress, deformation, and fatigue are equal to or greater than margins for other plants of similar design with successful operating experience. Specific reactor internals of a specific safety class will be designed, fabricated, and examined in accordance with the

applicable codes and standards, such as ASME BPVC Section III, Division 1 for Light Water Reactors (LWR).

#### **5.4.3.1 Shroud**

The SC1 shroud (Figure 5.4-1) is the cylindrical support of the reactor core. It is supported by the shroud support assembly. The core plate is between the shroud and the shroud support, and these three pieces are bolted together. The top guide is between the shroud and the chimney barrel, and these three pieces are bolted together.

#### **5.4.3.2 Shroud Support**

The SC1 shroud support (Figure 5.4-1) is a circular assembly with vertical legs that are welded to the reactor bottom head. The shroud support provides the vertical and lateral support for the shroud, and other components like the top guide and core plate. It also supports the chimney and chimney head and steam separator assembly, and steam dryer assembly.

#### **5.4.3.3 Core Plate**

The SC1 core plate (Figure 5.4-1) is at the bottom of the reactor core area. It provides the lateral support for the fuel assemblies and control rods through the orificed fuel supports, provides vertical and lateral support for the nuclear instrumentation, and provides vertical and lateral support the startup sources, and for the peripheral fuel supports and fuel bundles.

#### **5.4.3.4 Top Guide**

The SC1 top guide (Figure 5.4-1) is at the top of the reactor core and consists of a circular plate with square openings for fuel. It provides the lateral support for the fuel assemblies, nuclear instrumentation, startup sources, and control rods.

The top guide is mechanically attached to the top of the shroud and provides a flat surface for the chimney flange.

#### **5.4.3.5 Control Rod Guide Tube**

The SC1 control rod guide tubes (Figure 5.4-1) fit in holes in the core plate and rests on the control rod housings that are welded to the reactor bottom head. They provide the lateral support by these upper and lower intersections. The control rod guide tubes channel water to the control rods as they move up and down within the core to change the reactor power levels. The control rod guide tubes also provide vertical support to the orificed fuel supports and to four fuel bundles landed on each orificed fuel supports.

#### **5.4.3.6 Control Rod Drive Housing**

The SC1 control rod drive housings provide an extension of the RPV pressure boundary at the bottom head for installation of FMCRDs (Figure 5.4-1). They also support the weight of a control rods, FMCRDs, control rod guide tubes, orificed fuel supports, and four fuel assemblies per orificed fuel supports. Finally, the control rod drive housing flanges also provide the ports for the attachment of CRD hydraulic supply lines.

#### **5.4.3.7 Orificed and Peripheral Fuel Supports**

The SC1 orificed fuel supports (Figure 5.4-1) rest inside the respective control rod guide tubes with a flanged top end that sets down onto the control rod guide tubes top end that transfers vertical load. They provide a slot for the lower end of each fuel assembly to rest and, also provide cruciform slots to guide the control rod blade as it raises or lowers to respectively increase or decrease. The orificed fuel supports slots are crucial to keeping the control rods properly aligned between the four bundles for rapid insertion into the core from fully withdrawn.

The peripheral fuel supports rest in the core plate around the outside of the orificed fuel supports and fuel bundles. A single fuel bundle rests in each peripheral fuel support. Their function is the same as an orificed fuel supports.

#### **5.4.4 Chimney**

The SC1 chimney (Figure 5.4-1) is a long cylinder mounted to the top guide that supports the steam separator assembly. The chimney forms the annulus separating the subcooled recirculation downward flow from the upward steam-water mixture flow exiting the core. The recirculation flow consists of reactor coolant returning from the steam separators and feedwater makeup. The cylinder is flanged at the bottom and top for attachment to the top guide and the chimney head, respectively. Lateral support brackets are located around the periphery of the chimney exterior beneath the flange and attached at the vessel shell internal surface. These brackets brace the chimney and the chimney head – steam separator assembly against horizontal motion.

The chimney is a unique feature to natural-circulation BWRs. It is used to extend the area of the RPV above the core and below the separator to increase the thermal driving head for natural circulation (and thereby drive a higher core flow). The OPEX with chimneys in natural-circulation BWRs is from several reactors such as the Vallecitos BWR, Humboldt Bay, and Dodewaard. The previous natural-circulation BWRs designs used chimneys with flow partitions. For the BWRX-300 chimney design, the chimney partitions are removed, which simplifies construction and installation, eliminates the need to remove the chimney during refueling outages, simplifies core alterations, and shortens the overall outage schedule.

#### **5.4.5 Chimney Head and Steam Separator Assembly**

The chimney head and steam separator assembly does not perform a safety function and provides a path for the steam flowing from the core to the steam dryer assembly. The steam separator part of the assembly uses centrifugal force to decrease most of the moisture in the steam before it enters the steam dryer assembly.

#### **5.4.6 Steam Dryer Assembly**

The steam dryer assembly does not perform a safety function and completes the task of removing the moisture from the steam before it exits the reactor. The moisture content is lower than 0.1 percent at 100 percent RTP when the steam leaves the reactor on its way to the main high-pressure turbine.

The steam dryer is supported by a set of brackets equally spaced around the vessel shell internal wall. The dryer support ring rests on these brackets. Additional hold-down brackets are mounted inside the vessel head to restrain vertical movement of the dryer under seismic or dynamic loads. These hold-down brackets are installed so that they are over the lifting lugs of the steam dryer. Horizontal motion due to seismic or dynamic loads is limited by seismic blocks mounted to the steam dryer support ring.

#### **5.4.7 Feedwater Spargers**

The feedwater spargers do not perform a safety function. Each of two feedwater lines is connected to spargers through four RPV nozzles. The feedwater spargers deliver makeup water to the reactor during plant start up, power generation and plant shutdown modes of operation.

#### **5.4.8 Internal Water Piping**

The reactor contains two internal suction lines that are routed down to the bottom head area of the reactor from the two N5 reactor nozzles. These two nozzles are located above TAF+4m, which is consistent with the BWRX-300 design requirement for minimum nozzle height.

The two internal suction lines are routed from flange connection inside the vessel for each respective nozzle, through an inverted loop, and down the vessel shell internal wall to the periphery of the CRD penetrations in the RPV bottom head. The piping for each internal drain line is attached to the vessel shell internal wall by brackets, spaced to provide support for anticipated loads and to inhibit pipe fatigue due to flow induced vibration. The brackets are designed to the rules ASME BPVC Section III, Division 1, Subsection NF (Reference 5.4-2), categorized as SC1, and Seismic Category A.

Each of the two suction lines also contain a vacuum breaker hole at the top of the pipe loop immediately inside of the two nozzles to prevent inadvertent draining. These two suction lines are connected externally to the reactor through the associated RIVs to the CUW. The two suction lines internal to the reactor allow the CUW to remove water from the RPV bottom head area.

#### **5.4.9 Reactor Pressure Vessel Head Vent**

The SC1 internal vent piping ducts non-condensable gas flow down the inside of the RPV closure head, into a discharge line that is integrated into and through the bracket of one of the internals guide rods, and to the discharge through the head vent nozzle. The internal piping is, thus, split into a portion mounted inside the RPV closure head and a portion mounted below the vessel flange with an intersection of the internal piping at a guide rod bracket where the two ends are joined. The piping in the RPV closure head is mounted with brackets that hold the vent in place while allowing for thermal expansion and mitigating flow induced vibration effects. The head vent piping penetrates the RPV through a nozzle on the side of the reactor with two RIVs flange-mounted in series. These RIVs are SC1 and perform the RPV single failure proof automatic isolation function.

#### **5.4.10 Nuclear Instrumentation Tubes and Stabilizers**

The nuclear instrumentation tubes are SC1 components, and the stabilizers do not perform a safety function. The tubes protect the nuclear instrumentation from the flow of water in the bottom head plenum and provide a means of positioning fixed detectors in the core. The nuclear instrumentation tubes extend from the bottom head to the top guide. The PRNM detectors and the WRNM detectors are inserted through the guide tubes.

A latticework below the core plate consisting of clamps, tie bars, and spacers give lateral support and rigidity to the guide tubes.

#### **5.4.11 Surveillance Sample Holders**

The surveillance sample holders are welded baskets containing impact, notch-sensitivity, and tensile specimen capsules. The baskets hang from brackets that are attached to the inside of the reactor vessel wall and centered mid-height of the active core. The radial positions are chosen to expose the specimens to the same environment and maximum neutron fluence experienced by the reactor vessel itself.

NON-PROPRIETARY INFORMATION

**Figure 5.4-1: BWRX-300 Reactor Pressure Vessel and Internals**

## **5.5 Reactor Coolant Pumps or Recirculation Pumps**

Reactor coolant flow through the BWRX-300 core is by natural circulation, meaning pumps (reactor coolant or recirculation) are not required to force reactor coolant through the core. Natural circulation is enabled mainly by the addition of a high chimney between the top of the core at the top plate to the bottom of the steam separator.

## **5.6 Reactor Coolant Piping**

There is no specific ASME BPVC Section III, Division 1, Class 1 reactor coolant piping as part of the NBS. The BWRX-300 RCPB is described in Subsection 5.1.1. Following insertion of control rods, the BWRX-300 cools and depressurizes the reactor by natural circulation with decay heat removal by the ICS or balance of plant. During overpressure events or loss of normal heat sink events, the ICS is used to quickly depressurize the RCPB and cool the core.

The ICS is designed to both ASME BPVC Section III, Division 1, Subsection NB (Class 1) (Reference 5.6-1) and ASME BPVC Section III, Division 1, Subsection NCD (Class 2) (Reference 5.6-2) as described in Chapter 6, Subsection 6.2.3.

### **5.6.1 References**

## **5.7 Reactor Pressure Control**

### **5.7.1 System and Equipment Functions**

This section describes systems that protect the RCPB from overpressurization. Defense Lines (DL) 1 through 4 are discussed in Chapter 3, Section 3.1.

DL1 operational state is normal operation (prevention of abnormal operation and failures) where pressure control is provided by modulating the Turbine Control Valves (TCVs).

DL2 operational state occurs during AOOs (control of abnormal operation and detection of failures) for which the plant design is to limit pressure deviations and restore normal pressure.

SC3 I&C control system regulates RPV pressure by controlling the position of the TCVs or Turbine Bypass Valves (TBVs).

During plant startup, once boiling commences, the RPV continues to heat up and pressurize to the rated pressure. The TBVs are initially used to control pressure with the NBS kept at saturated conditions. As power increases, the TCVs are gradually opened causing the TBVs to gradually close.

The RPV pressure is normally held constant by positioning the TCVs, so the turbine steam flow always follows the reactor. The TCVs are modulated by their control system to regulate the demand steam flow.

Further discussion on pressure control functions is provided in Chapter 7, Section 7.3.

### **5.7.2 Safety Design Bases**

Overpressure protection for the RCPB is provided through a combination of the NBS, the ICS, and SC1 I&C control system to limit peak pressure during AOOs to less than or equal to 110 percent of RPV design pressure as defined by the ASME BPVC, Section III, Division 1, Article NB-7000, subparagraphs NB-7120(b) and NB-7120(c) (Reference 5.7-1).

Refer to Chapter 6, Section 6.2 for overpressure engineered safeguard functions.

### **5.7.3 Description**

Reactor pressure is controlled from a cold vessel through pressurization and heat up to power operation by the SC3 I&C control system for reactor pressure control using the TBVs and TCVs. The SC3 I&C control system during normal power operation controls reactor pressure using the TCVs. Refer to Chapter 10, Subsections 10.2.6 and 10.7.6 for normal operation and startup, respectively.

The SC3 I&C System Isolation Condenser (IC) Throttling Pressure Controller performs the functions to prevent exceeding the reactor cooldown rate. Detailed description is provided in Chapter 7, Section 7.3.

### **5.7.4 Interfaces with Other Equipment or Systems**

Figure 5.1-1 NBS Input-Output provides the NBS interfaces with other systems and equipment.

### **5.7.5 System and Equipment Operation**

Chapter 7, Subsection 7.3.3 describes normal pressure control provided by the TCVs. Chapter 6, Subsection 6.2.2 describes the overpressure engineered safeguard features and functions.

### **5.7.6 Instrumentation and Control**

The SC1, SC2 and SC3 I&C Systems (refer to Chapter 7, Section 7.3) provide control of RPV pressure using NBS pressure sensing instrumentation as described in Subsection 5.3.1.3.

#### **5.7.6.1 Leak Detection**

Means are provided for detecting and, to the extent practical, identifying the location of the source of reactor coolant leakage. The components of the RCPB, including the ICS and reactor isolation valves are designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed in accordance with recognized codes and standards, and under an approved quality assurance program with approved control of records.

#### **5.7.6.2 Reactor Pressure Vessel Flange Leak Detection**

The RPV head/shell flange detects leakage any time the reactor is in Operating Modes Power Operation, Startup, and Hot Shutdown.

#### **5.7.7 Monitoring, Inspection, Testing, and Maintenance**

Section 5.11 describes the pre-service and in-service inspection and system pressure test programs for NRC Quality Group A, ASME BPVC, Division 1, Class 1 piping, and components. It describes these programs implementing the requirements of Subsection IWB of the ASME BPVC Section XI Division 1 (Reference 5.7-2).

#### **5.7.8 Radiological Aspects**

Chapter 12, Subsection 12.3.8.2 describes the various system and major component design considerations of the NBS related to plant radiation protection. Chapter 12, Subsection 12.1.5.4 provides information the design provisions and measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are As Low As Reasonably Achievable (ALARA) in operational states and in accident or post-accident conditions.

The radiological consequences of large ICS breaks outside containment are discussed in Chapter 15, Subsection 15.5.9.2.3 while small ICS line breaks are described in Chapter 15, Subsection 15.5.9.2.4. The events considered do not result in any fuel failures or any release of primary coolant to the environment; therefore, there are no radiological consequence associated with these events.

#### **5.7.9 Performance and Safety Evaluation**

This section evaluates systems that protect the RCPB from over pressurization. DL2 is an AOO state for which the plant is designed to limit pressure deviations and restore normal pressure. The evaluation of overpressure control in this section satisfies the AOO response. The bounding events for AOO pressure increase mitigation are described in Chapter 15, Subsection 15.5.3.

The BWRX-300 DSA Deterministic Safety Analysis, presented in Chapter 15, Section 15.5, is the analysis of record for responses to off-normal events and provides the information required to demonstrate that regulatory acceptance criteria are met. The selected bounding events resulting in the most significant challenges to the fission product barriers (including the RCPB) are summarized in Table 15.2-3. LOCA postulated initiating events where piping breaks occur in high-pressure pipes connected to the RPV, are discussed in Subsection 15.5.4.6.

The use of an ICS design for BWRX-300 overpressure protection addresses the need for a reliable pressure mitigation which enhances the safety of the design. This is demonstrated by the safety analysis in Chapter 15, Subsection 15.5.4 which concludes that there is no radiological release consequence for postulated pressure increase events.

The reactor integrity is assured by meeting the pressure criteria, provided in Chapter 15, Section 15.3. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal

water reaction. The effect of this event does not result in any challenge to the temperature or pressure transient derived acceptance criteria for the fuel or pressure vessel. Therefore, these barriers maintain their integrity and function as designed.

## **5.8 Isolation Condenser System**

The ICS is part of the RCPB and provides a DL barrier for overpressure due to AOO, DBA, and DEC events. If an MSL break occurs or the normal reactor cooling path is unavailable during an AOO or accident response, the ICS is credited for cooling and pressure protection of the RPV and the RCPB. Chapter 6, Subsection 6.2.1 describes the engineered safety function and operation provided of the ICS in mitigating overpressurization of the RCPB.

## **5.9 Reactor Pressure Vessel Component Supports and Restraints**

### **5.9.1 Reactor Pressure Vessel Pedestal**

The RPV pedestal is equipped with a RPV Bracket, where the RPV skirt is anchored using anchor bolts. The RPV pedestal provides structural support for the lower RPV Stabilizers and for the upper containment access platform module which supports the upper RPV Stabilizers. The RPV pedestal is a cylindrical, steel-plate composite structure that supports the RPV. The RPV pedestal, enclosed within the primary containment, is welded to a steel-plate composite basemat that is connected with the Steel-Plate Composite Containment Vessel (SCCV). For additional description of the RPV pedestal refer to Chapter 9B.2.2.

### **5.9.2 Reactor Pressure Vessel Pedestal Safety Basis**

The primary safety functions of the RPV pedestal are as follows:

- The RPV pedestal provides structural support to SSCs such as the RPV, RPV Stabilizers and miscellaneous platforms.
- The RPV pedestal provides some radiation shielding to limit radiation dose within the applicable regulatory standards in different plant states, including normal operation, AOOs, DBAs, and DECAs.

The RPV pedestal is a SC1 and Seismic Category A structure.

The RPV pedestal does not serve any pressure-retaining function and is outside the scope of ASME Code applicability. Codes, standards, specifications, and regulations applicable for the analysis, design, fabrication, construction, testing, and in-service inspection of the BWRX-300 containment internal structures are listed in Chapter 1, Appendix B.

Chapter 3, Subsection 3.6.3 discusses the structural integrity and/or functional integrity requirements of pressure-retaining components, their supports, and core support structures that are designed in accordance with the rules of the ASME Section III, Division 1.

### **5.9.3 Reactor Pressure Vessel External Supports**

#### **5.9.3.1 Reactor Pressure Vessel Support Skirt**

The RPV is supported above the vessel core beltline region and has stabilizer brackets near the top and the bottom of the vessel that provide lateral support. The support system is a support skirt or apron-type that is connected to an attachment on the cylindrical portion of the vessel. The support skirt attachment knuckle is integrally forged with the vessel cylinder. The PCS provides vertical and lateral RPV support. The PCS is completely enclosed within the deeply embedded RB, and also includes containment penetrations and other safety components. The PCS houses the steel-plate composite internal pedestal that supports the RPV, and also acts as a biological shield.

The vessel support skirt is a truncated conical support appurtenance of the RPV. The support skirt is designed to the rules ASME BPVC Section III, Division 1, Subsection NF (Reference 5.9-1), and is categorized as SC1 and Seismic Category A. The support skirt is attached to the cylindrical shell of the vessel by a weld joint to a circumferential knuckle forged into the vessel. The bottom of the skirt has an attached ring that forms a foot which rests on a structural support plate and transmits the vertical vessel load to the vessel support pedestal. The connection is designed to allow for radial movement due to thermal expansion and contraction of the vessel shell during operational heat-up and cooldown evolutions.

#### **5.9.3.2 Reactor Pressure Vessel Stabilizers**

The BWRX-300 has two sets of horizontal motion stabilizers with a set of stabilizers located above the RPV bottom head and a second set of six stabilizers located below the main steam nozzles. The stabilizer design is based on existing proven hardware design from the BWRs operating experience. The stabilizers are designed to the rules ASME BPVC Section III, Division 1, Subsection NF, and are categorized as SC1 and Seismic Category A. The main function of the stabilizers is to provide horizontal support to limit vessel motion by transferring load from the vessel to the adjacent civil structure. The upper and lower vessel stabilizers function independently, depending on the direction of vessel motion due to an applied dynamic force, but horizontally and vertically parallel stabilizers will act with combined resistance against vessel motion.

Refer to Chapter 9B, Subsection 9B.2.2 for further details.

#### **5.9.4 Reactor Pressure Vessel Internal Supports**

##### **5.9.4.1 Chimney Support Brackets**

Lateral support brackets are located around the periphery of the chimney barrel exterior beneath the flange and attached at the vessel shell internal surface. These brackets brace the chimney and the chimney head – steam separator assembly against horizontal motion. The brackets are designed to the rules ASME BPVC Section I, Division 1, Subsection NF, categorized as SC1, and Seismic Category A.

##### **5.9.4.2 Steam Dryer Support Brackets**

The steam dryer is supported by a set of brackets equally spaced around the vessel shell internal wall. The dryer support ring rests on these brackets. Additional hold-down brackets are mounted inside the vessel head to restrain vertical movement of the dryer under seismic or dynamic loads. These hold-down brackets are installed so that they are over the lifting lugs of the steam dryer. Horizontal motion due to seismic or dynamic loads is limited by a set of seismic blocks mounted to the steam dryer support ring. The brackets are designed to the rules ASME BPVC Section III, Division 1, Subsection NF, categorized as Safety Class SC1, and Seismic Category A.

##### **5.9.4.3 Internal Piping Support Brackets**

###### ***5.9.4.3.1 Reactor Water Cleanup System Internal Piping***

Two CUW internal suction lines are routed from flange connection inside the vessel to each respective nozzle, through inverted loops, down the vessel shell internal wall, and to the RPV bottom head. The piping for each internal suction line is attached to the vessel shell internal wall by brackets, spaced to provide support for anticipated loads and to inhibit pipe fatigue due to flow induced vibration. The brackets are designed to the rules ASME BPVC Section III, Division 1, Subsection NF, categorized as SC1, and Seismic Category A.

###### ***5.9.4.3.2 Head Vent Internal Piping***

The internal head vent piping inside the RPV closure head is a discharge line that is integrated into and through the bracket of one of the guide rods. The internal piping is split into a portion mounted inside the RPV closure head and a portion mounted below the vessel flange with an intersection of the internal piping at a guide rod bracket where the two ends are joined. The piping in the RPV closure head is mounted with brackets that hold the vent in place while allowing for thermal expansion and mitigating flow induced vibration effects. The brackets are designed to the rules ASME BPVC Section III, Division 1, Subsection NF, categorized as SC1, and Seismic Category A.

### **5.9.5 Materials**

Refer to Table 5.2-3 for reactor internal components materials listing.

### **5.9.6 Interfaces with Other Equipment or Systems**

The BWRX-300 RPV pedestal and bioshield are integrated with the RB and PCS common mat foundation as shown in Figure 9B-1 and the RPV pedestal interfaces with the RPV through the RPV skirt support and horizontal stabilizers. Further description is provided in Chapter 9B, Subsection 9B.2.2.5.

### **5.9.7 Monitoring, Inspection, Testing, and Maintenance**

RPV internal and external component supports are subject to an inspection program as described in Section 5.11.

As described in Chapter 3, Subsection 3.5.4.6, a formal program for monitoring, testing and inspection is not required for PCS internal civil structures.

### **5.9.8 Radiological Aspects**

Refer to Subsection 5.7.8.

### **5.9.9 Performance and Safety Evaluation**

The RPV support design uses a conical skirt to support vertical load and horizontal stabilizers to minimize vessel motion due to horizontal load. The design is based on long operating experience with supports of the same basic design. The RPV support skirt design concept is a standard textbook method for mounting a pressure vessel that is employed in industries other than commercial nuclear power. The conical skirt shape permits the mid-vessel mounting of the skirt with the support ring foot set on the bracket attached to the cylindrical RPV pedestal. The support skirt is the primary interface with the civil structure supporting the RPV assembly and a transfer point for seismic accelerations from the RB to the RPV assembly. The support skirt and horizontal stabilizer brackets are SA-508M, Grade 3, Class 1 material to match the RPV material. The support skirt flange is integral to the RPV shell forging. The horizontal stabilizer assembly is predominantly fabricated from SA-105M carbon steel forgings.

The load of the BWRX-300 is more complex because of the relatively high locations of the vessel nozzles relative to the core and that there are large valves directly mounted to the vessel shell. Generally, BWR vessel load is concentrated below the vertical axis center point because of the mass of the core and the large liquid water volume in the lower vessel regions. However, the BWRX-300 has an additional large load concentration above the centerline because of the RIVs. The combined low and high mass centers result in a relatively higher RPV assembly mass centroid in the BWRX-300 design.

It is also known that RPV assembly response to dynamic or seismic accelerations in the horizontal direction is lowered by placing the attachment of the support skirt closer to the centroid of the RPV assembly mass (Reference 5.9-2). The BWRX-300 RPV support skirt is attached at a mid-vessel elevation to place it much closer to the centroid than would be achieved with a traditional skirt attachment that is just above the bottom head. Because of the height of the natural-circulation RPV (which is taller than a forced-circulation RPV due to the additional chimney component height) the BWRX-300 RPV is equipped with both upper and lower sets of horizontal stabilizers. The dual stabilizer sets design provides more control of vessel horizontal motion to limit vessel shell twisting or rocking around the skirt attachment. This limitation on motion also mitigates the dynamic input loads to the RPV nozzles to control the stress on the nozzle connections to the vessel shell. Further, limiting input motion to the RPV nozzles also limits the

acceleration input into the RIV masses and provides greater assurance of reliable RIV function during postulated seismic and dynamic events.

The internal components support brackets are sized based on the static loads of the supported components. Mechanical analysis is performed using loads and loading combinations based on those stated in Chapter 3 Table 3.6-2. The analysis results are used to confirm the bracket sizing of the internal components.

## **5.10 Nuclear Boiler System Connected Valves**

The BWRX-300 design focuses on the mitigation of LOCAs by reducing the number and size of RPV nozzles as compared to previous designs and limiting nozzle penetrations to the upper regions of the vessel. The RPV has integral isolation valves attached directly to the RPV as appurtenances for piping systems greater than DN20 nominal pipe diameter. The BWRX-300 design also includes an outboard MSCIV on each MSL.

### **5.10.1 Reactor Isolation Valves**

The NBS RIVs are part of a fail-safe system designed to isolate the RPV during Service Levels A through D under the full range of reactor pressures and flows. The isolation system consists of the MSRIVs, FWRIVs, ICRRIVs, ICSRIVs, CUW RIVs and the RPV Head Vent RIVs. All of the RIVs are classified as SC1.

RIVs and CIVs function to limit the loss-of-coolant from large and medium pipe breaks. Small pipe breaks are defined as those lines size DN20 and under.

Each NBS RIV assembly is connected to the outboard piping using bolted flange connections. The RIVs are connected directly to the reactor vessel using bolted flange connections and are classified as break exclusion areas. All of the RIVs except for those to / from ICS are fail-closed type valves.

The design for these valves is two valves in series that are independently able to isolate the respective nozzle. The RIVs are designed in accordance with the rules and requirements of ASME BPVC, Section III, Division 1, Subsection NB, Class 1 Components (Reference 5.10-1) and Seismic Category B.

This design feature allows the reactor to be isolated, quickly stopping leakage from the vessel following a transient or downstream pipe break. The BWRX-300 Reactor Isolation Valve design considers the following design features:

- Isolation Valve integral to each RPV large-bore process nozzle
- Redundant, leak proof valves
- Passively or automatically activated

Figure 5.10-1 shows an example of RIV double valve bodies attached to the RPV using flange connections

### **5.10.2 Main Steam Containment Isolation Valves**

The BWRX-300 design includes an outboard MSCIV on each MSL. The MSCIVs provide the SC1 single failure proof isolation of the PCS in the event of accidents or other conditions and prevent the unfiltered release of containment contents. This containment isolation is single failure proof. The MSCIVs are fast-closing and fail-closed type valves. The MSCIVs are fast-closing and fail-closed type valves.

These isolation valves outside of containment are located as close to the containment as practical to satisfy the PCS isolation requirements.

The MSCIVs are designed in accordance with the rules and requirements of ASME BPVC, Section III, Division 1, Subsection NCD, Class 2 and 3 Components (Reference 5.10-2), in accordance with their quality group classification. The MSCIVs are designed for Seismic Category B and certified by a qualification program prepared and performed in accordance with ASME Standard QME-1 (Reference 5.10-3).

The MSRIVs and MSCIVs provide isolation of the MSLs. MSCIVs provide containment isolation, when required during plant shutdown conditions.

All CIVs have individual leakage testing performed to support the overall requirement to verify containment leakage is within the allowable limits. Chapter 6, Subsection 6.3.4 describes containment isolation in detail

### **5.10.3 Safety Design Bases**

The RPV isolation function is designed as SC1 in accordance with the plant design requirement. All of the RIVs except those for the ICS nozzles have fail-closed type actuators with automatic isolation signals. The ICS nozzles must remain open during events requiring ICS to function and use fail-as-is actuators but have individual train automatic isolation on detection of a pipe leak or break in the train. The RIVs of each RPV nozzle are installed using flanged connections and mounted in a double valve body or two valves in a tandem configuration.

The RIVs also constitute the inboard CIV, where applicable, to provide the double isolation of the piping PCS penetration.

The ICS RIVs are normally open during operation. Isolation during on-line operation is normally controlled by the ICS condensate return valves. If called upon by an isolation signal, all other RIVs close. The ICS RIVs are designed to fail as-is, which is the normally open position. Flow will be initiated by the opening of the ICS condensate return valves. The only time the fail as-is position would be non-conservative is if the ICS RIVs are closed for maintenance but that would already be accounted for by the planning of the maintenance in accordance with the Operating Limits and Conditions (OLC).

The BWRX-300 design provides direct position indication of the RIVs. The ICS response time of each required division will be verified within design limits per the IST program. Figure 5.10-1 shows an example of RIV double valve bodies attached to the RPV using flange connections.

Design of the CIVs, with the exception of the RIVs, meets the rules and requirements of ASME BPVC, Section III, Division 1, Subsection NCD, Class 2 and 3 Components.

### **5.10.4 Materials**

Materials are provided in Section 5.2.1. Material specifications used for the RIVs and the CIVs are in accordance with approved processes and with the rules and requirements of ASME BPVC, Section II, Material Specifications (Reference 5.10-4).

### **5.10.5 Interfaces with Other Equipment or Systems**

Figure 5.1-2 provides the interfaces with the RPV.

### **5.10.6 Instrumentation and Control**

Each NBS MSRIV and MSCIV have automatic and manual control capability, with separate pilot valves, and independent test logic control.

The SC1 close function of the MSRIVs and MSCIVs is independent from the other control architecture.

Each NBS MSRIV and MSCIV is capable of isolating the main steam piping in the event of a LOCA (or other events requiring containment or system isolation) to limit the release of reactor coolant.

#### **5.10.7 Monitoring, Inspection, Testing, and Maintenance**

NBS power-operated valves inside the RB are equipped for remote manual functional testing from the Main Control Room (MCR). The ASME Class 1 valves undergo functional testing using equipment qualification methods that examine functionality and structural capacity under seismic and AOO loads, and accident loading conditions. Functional testing evaluates any identified leakage found during post-test inspections.

NBS is designed with provisions for initial and periodic testing of the ASME Code Class 1 and Class 2 system equipment, including hydrostatic test in accordance with the requirements of ASME BPVC Section III, Division 1.

#### **5.10.8 Radiological Aspects**

Refer to Subsection 5.7.8.

#### **5.10.9 Performance and Safety Evaluation**

All NBS RIVs fail-closed except for the ICS RIVs which fail as-is. The ICS RIVs fail as-is because they perform safety functions during DBAs. The ICS RIVs automatic closure function relies on the SC1 I&C system when initiated by the leak detection instrumentation. The NBS CIVs fail-closed design provides conservative isolation of the PCS.

For small pipe breaks, the BWRX-300 design provides a substantial reservoir of water above the core that is sufficient to ensure RPV water level is maintained at or above a safe level following a LOCA. For larger pipe breaks, the respective RIVs, dependent on the location of the pipe break, will close rapidly to prevent significant loss of RPV inventory. In conjunction with RPV isolation, ICS will be actuated to maintain adequate core cooling. If the large break is located on an ICS line, the RIV associated with the train containing the line break will close. If the large break occurs inside containment, the MS CIVs and MSL RIVs will close to prevent unacceptable releases of containment contents.

The RPV RIVs and MSCIVs are single failure proof. The actuation signals for the RIVs are diverse. The RIV design includes redundancy in I&C components and features resulting in a worst-case single failure impacting only one RIV at each RPV nozzle. Diversity for penetrations where RIVs are credited as one of the CIVs have separate and diverse control systems that are single failure proof.

Chapter 15, Subsection 15.5.4 evaluates the bounding DBAs. The scenarios for LOCA events are described in Chapter 15, Subsection 15.5.4.6 and conclude that during large break LOCAs, RPV inventory loss does not threaten fuel integrity. After RPV isolation, decay heat is removed by the ICS from the RPV. The LOCA analyses demonstrate that either the core remains covered, or fuel cladding temperature remains below the normal operating temperature for at least 72 hours using conservative assumptions for unisolated small break LOCAs. Therefore, fuel cladding temperature remains well below the fuel acceptance criteria, oxidation does not occur, and there is no hydrogen generation from cladding oxidation. The evaluation results for non-LOCA events demonstrate significant margin to the acceptance criteria, and barriers maintain integrity and functionality.

## **5.11 Access and Equipment Requirements for Inspection and Maintenance**

The NBS is designed to provide adequate equipment removal paths and personnel access for maintenance, inspection, and replacement of components. The overall layout of mechanical equipment, piping, valves, and instrumentation is arranged so as not to interfere with operation and maintenance activities.

Pre-Service Inspection and In-Service Inspection (ISI) requirements for components and systems for the BWRX-300 are consistent with ASME BPVC, Section XI, Division 1 (Reference 5.11-1). In-Service Testing (IST) requirements for components and systems for the BWRX-300 are consistent with ASME OM Code (Reference 5.11-2). These Pre-Service Inspection, ISI, and IST requirements include examinations, inspections, and testing of the Reactor Pressure Vessel (RPV) and reactor coolant transporting systems, components, piping, and pipe supports, which are designed and installed in accordance with ASME BPVC, Section III, Division 1 and applicable codes in Chapter 1, Appendix B.

### **5.11.1 Accessibility**

ASME BPVC Section III Class 1, 2, and 3 mechanical components and equipment (e.g., heat exchangers, pipe supports, pumps, valves, and vessels) are designed with accessible openings for ISI testing, which supports evaluations that justify the operational readiness of components and equipment.

Manufacturers of components and equipment, which require inspections and examinations to satisfy ASME BPVC Section XI, Division 1 requirements, are examined by appropriate inspection and testing methods, as applicable per the ASME BPVC Section III and ASME OM Code.

The RPV engineering design includes provisions for the following ISI access requirements:

1. Access to the annulus between the reactor pedestal wall and vessel is provided from below the vessel by provision in the bottom head insulation to access this region.
2. Access to the RPV exterior above the RPV pedestal wall is provided by provision of removable insulation to access inspection regions.
3. Removable insulation is provided on NBS piping and valves, which extends to the MSCIV.

### **5.11.2 Reactor Coolant Pressure Boundary Components**

The components, which form the RCPB, are designed to permit the following:

1. Periodic inspection and testing of important areas (such as pressure boundary welds and flanges during the post-outage leakage test) and features, to assess their leak-tightness and structural integrity
2. Establish a material surveillance program for the RPV

### **5.11.3 Reactor Coolant System and Connected Systems**

The Reactor Coolant System (RCS) is defined as the components necessary to provide and maintain adequate core cooling conditions (pressure, temperature, and coolant flow rate) for the fuel in power operation. It includes the RPV, the MSLs, and feedwater lines up to and including the outermost CIV. These components form a major portion of the RCPB as described in Section 5.10.

Isolation and maintenance devices and valves are provided in the system to allow for maintenance of the RCS components.

NEDO-33954 REVISION 0  
NON-PROPRIETARY INFORMATION

The following list contains the more important maintenance operations that must be performed on the RCS components:

1. Servicing of RIVs and CIVs
2. Servicing and replacement of level, temperature, and pressure sensors
3. Servicing and replacement of solenoid elements in valve and pilot operators
4. Adjustment and servicing of valve operators, including limit and position switches
5. Cleaning drain line strainers
6. Adjustment and replacement of valve stem packing
7. Major overhaul of all power-operated valves and hydraulically operated valves

Sufficient space, and the additional process system component facilities, is provided between penetration isolation valves and the PCS boundary to permit:

In-service inspection of non-isolable welds:

- In-service inspection of non-isolable welds
- Access and facilities to perform local leak rate testing of isolation valves
- Access to operate local manual controls
- Access to perform isolation valve assembly maintenance
- Cutout and replacement of isolation valves using standard pipe cutting equipment, pipe fitting tools and equipment, and piping component welding equipment

ASME BPVC Section XI, Division 1, Class 1, and Class 2 RCS equipment is designed and arranged to provide ISI accessibility.

Areas requiring ISI inspection are provided with access spaces/routes and with removable and reusable insulation coverings.

#### **5.11.4 Examination Categories and Methods**

The design of each component and system considers the non-destructive examination (NDE) method that is used to fulfill Pre-Service Inspection and ISI examination requirements. Chapter 3, Subsection 3.10, describes requirements for in-service monitoring, testing, inspection, and maintenance programs for the BWRX-300. Chapter 3, Subsection 3.10.5, In-Service Inspection, states the requirements applied to components designated ASME BPVC Section III, Division 1 Class 1, 2 or 3 and their Subsection NF supports (Reference 5.11-3). In addition, the design considers the operational and radiological concerns associated with the selected examination method to ensure that the performance of the required examination is practical during normal plant operation. The 3D layout of the plant includes acceptance criteria regarding access for inspection equipment and personnel. The examinations detect flaws, surface and volumetric discontinuities/imperfections, and original component position discrepancies, including conditions such as:

- Cracks, wear, laps, seams, cold shuts, laminations, physical damage
- Corrosion type or erosion, debris
- Leakages
- Clearances, settings, physical displacements

- Loss of integrity at bolted or welded connections
- Missing or lost parts

NDE methods provide the best technique for inspecting components and equipment that have been disassembled or installed during maintenance.

#### **5.11.4.1 Reactor Pressure Vessel Welds**

Reactor pedestal wall and the RPV insulation mounted around the vessel inside the pedestal wall provide access for remotely operated Ultrasonic Testing (UT) examination devices.

#### **5.11.4.2 Reactor Pressure Vessel Head, Studs, Nuts, and Washers**

The RPV head, studs, nuts, and washers are dry stored on the refueling floor during refueling operations. RPV studs, nuts, and washers are cleaned, lubricated, inspected, and reused, if acceptable.

Replacement or repair of RPV studs, nuts, and washers is subject to additional Repair/Replacement Plan requirements per the ASME BPVC Section XI, Division 1, Article IWA-4000. The design provides for removable insulation to ensure access for manual UT examinations of the RPV head welds.

RPV studs are volumetrically examined in place or when removed.

RPV nuts and washers are accessible for visual examinations.

#### **5.11.4.3 Bottom Head Welds**

Access to the bottom head-to-shell weld is provided from the undervessel area through removable insulation around the bottom head, the CRD housings and nuclear instrument housings of the RPV. This design provides access for manual or automated UT examination equipment.

These welds are required to be accessible in order to perform ASME BPVC Section XI, Division 1, VT-2 examinations during system leakage testing in accordance with ASME BPVC Section XI, Division 1, Table IWB-2500-1.

Access to welds inside the bottom head is made through the respective housings during undervessel maintenance work. Access is provided for nozzle weld examinations.

#### **5.11.4.4 Reactor Vessel Support**

Access is provided for visual examination of the RPV support structure.

#### **5.11.4.5 Piping, Valves and Supports**

Design and physical arrangement of piping, valves, and supports provide personnel access to each weld location to perform NDE.

Working platforms facilitate servicing of valves and supports. Platforms and ladders provide access to piping welds, including the pipe-to-reactor vessel nozzle welds.

Removable thermal insulation is provided on welds and components, which require access for examination or are located within high radiation areas.

Welds are located to permit UT examination from at least one side.

A 100 percent volumetric in-service examination of all pipe welds is conducted during each inspection interval as defined within ASME BPVC Section XI, Division 1, Subarticle IWA-2400.

#### **5.11.4.6 Augmented In-Service Examinations**

##### ***5.11.4.6.1 High-Energy Piping***

NBS piping located between the CIVs, and extending to the Seismic Interface Restraint, is seamless (no longitudinal welds). After installation, circumferential welds in the aforementioned piping are subjected to 100 percent Radiographic Testing in accordance with ASME BPVC Section III, Division 1, Subparagraph NCD-5211.1 (Reference 5.11-4).

##### ***5.11.4.6.2 Flow Accelerated Corrosion Examinations***

ASME BPVC Section III, Division 1, Class 1, 2, and 3 piping systems, including piping and components, may be susceptible to FAC. This wear mechanism compromises the structural integrity (wall thinning) of high-energy carbon steel piping systems and components.

#### **5.11.4.7 Non-destructive Examination Methods**

NDE methods (surface, visual, and volumetric examinations) are described within ASME BPVC Section V (Reference 5.11-5), ASME BPVC Section XI, Division 1, and applicable codes and standards in Chapter 1, Appendix B.

For ASME BPVC Section III, Division 1, Class 1 and Class 2 welds, UT or Radiographic Testing examinations are selected for ISI examinations.

Radiographic Testing examinations are primarily used as a volumetric method. In addition, Radiographic Testing examinations supplement UT examinations to improve coverage of the required examination volume.

##### ***5.11.4.7.1 Surface Examination Methods***

Surface examinations of welds and bolts indicate the presence of surface discontinuities, which are performed by using Eddy Current Testing, Liquid Penetrant Testing, Magnetic Particle Testing, or UT methods.

Any linear flaw detected within a component by non-destructive techniques, which exceeds the allowable linear surface flaws standards is recorded.

##### ***5.11.4.7.2 Visual Examination Methods***

Visual examinations indicate the presence of surface discontinuities and imperfections, leakage from pressure-retaining components, and the general mechanical and structural condition of components.

##### ***5.11.4.7.3 Volumetric Examination Methods***

Volumetric examinations indicate the presence of discontinuities throughout the volume of the material, which are performed by using an Acoustic Emission (AE), Eddy Current Testing, Radiographic Testing, or UT method. Volumetric examinations are used for the examination of welds of vessels, piping, studs, and bolts.

#### **5.11.5 Inspection Intervals**

The ISI examination and system pressure test intervals, and percentage of examinations should conform with ASME BPVC Section XI, Division 1, Subarticles IWB-2400, IWC-2400, IWD-2400, IWF-2400, ASME OM Code, Subsections ISTC, ISTD, ISTF, and applicable codes and standards in Chapter 1, Appendix B. Inspection intervals are a nominal length of 10 years with allowance for up to a year variation to coincide with refueling outages.

MSRIVs and MSCIVs are periodically local leak rate tested (LLRT) to meet the leak rate acceptance criteria in accordance with the design requirements.

The MSRIVs and MSCIVs are diagnostically tested to verify that the MSRIVs and MSCIVs are properly adjusted to perform their respective safety MSL isolation functions, and to monitor for performance degradations.

MSL isolation trip channels are tested periodically to verify that MSRIV and MSCIV control pilots respond and position instrumentation is capable of providing required position signals to the respective control systems for required alarms and automatic trip functions.

MSRIV and MSCIV leakage rate testing is based on MSL cumulative allowable leakage rate established by DBA dose evaluation. Individual valve leak rate testing for diagnostic and rework/refurbishment is based on the design performance criteria.

FWRIVs leakage rate testing is based on total allowable leakage established by design analysis for PCS total leakage. Individual valve leak rate testing for diagnostic and rework/refurbishment is based on the design performance criteria.

NBS power-operated valves inside the RB are capable of remote manual functional testing. These valves are designed to be tested from the MCR. This testing verifies that proper position indication is displayed in the MCR.

#### **5.11.6 Provisions for Evaluating Examination Results**

Examination results are evaluated and accepted in accordance with ASME BPVC, Section XI, Division 1, Articles IWA-3000, IWB-3000, IWC-3000, IWD-3000, and IWF-3000, with repairs based on the requirements of IWA-4000, and applicable codes and standards listed in Chapter 1, Appendix B.

Recorded results meet the acceptance standards specified within ASME BPVC, Section XI, Division 1, Subarticles IWB-3400 and IWB-3500, IWC-3400 and IWC-3500, IWD-3400 and IWD-3500, IWF- 3400, and applicable codes and standards listed in Chapter 1, Appendix B.

Components containing flaws or relevant conditions and accepted for continued service are subjected to successive period examinations.

#### **5.11.7 System Pressure Tests**

NBS is designed with provisions for initial and periodic testing of the ASME BPVC Section III, Division 1, Class 1 and Class 2 equipment, including hydrostatic testing.

ASME system pressure tests (hydrostatic test, leakage test or pneumatic tests) are performed in accordance with ASME BPVC, Section XI, Division 1, Articles IWA-5000, IWB-5000, IWC-5000, IWD-5000, and applicable codes and standards listed in Chapter 1, Appendix B to ensure leak-tightness of components, equipment, mechanical and welded joints, integral support-piping attachment welds (i.e., lugs), and piping.

ASME system pressure-retaining boundaries are defined within ASME BPVC, Section XI, Division 1, Paragraphs IWA-5220, IWB-5222, IWC-5222, and IWD-5222.

VT-2 examinations are performed in accordance with ASME BPVC, Section XI, Division 1, Paragraphs IWA-2212, and applicable codes and standards listed in Chapter 1, Appendix B.

System hydrostatic test for RCPB systems is performed at a pressure and temperature, which corresponds to ASME BPVC, Section XI, Division 1, Subarticle IWB-5230, Table IWB-5230-1, ASME OM Code, Subsections ISTC, ISTF, and applicable codes and standards listed in Chapter 1, Appendix B.

#### **5.11.8 Surveillance Program Requirements and Overview**

The surveillance programs that are established address the several aspects of the materials used in the BWRX-300. Chapter 3, Section 3.10 provides additional information. Specifically, there is a need for:

1. Monitoring the integrity of the pressure-retaining RPV and its attachments
2. Monitoring the time limiting aging impact of the RPV
3. Monitoring of the integrity of the reactor internals
4. Monitoring the piping components for degradation
5. Monitoring the water chemistry program for its mitigation effectiveness
6. Monitoring for FAC

A discussion of the key elements of each surveillance program is presented in the next sections.

##### **5.11.8.1 Pressure-Retaining In-service Inspection Program**

There are ISI requirements based on the ASME BPVC, Section XI, Division 1 for pressure-retaining components and their integral attachments in the BWRX-300. This program serves as a model for the surveillance program that will include periodic visual, surface, and/or volumetric examination and leakage tests of the pressure-retaining components including the RPV, nozzles and attachments. The surveillance program will include specific scope for each of the pressure-retaining components. The program also will include defined preventative actions which include adequate methods to detect degradation that will occur with plant aging. The program will include defined monitoring and trending aspects, and specific correction action plans to address degradation identified. Finally, the program will track operating experience in these pressure-retaining components and use this information to update the ISI program.

##### **5.11.8.2 Reactor Pressure Vessel Material Surveillance Programs**

The material surveillance program monitors fracture toughness property changes of ferritic materials in the RPV beltline region resulting from exposure to neutron irradiation, including thermal information requirements pertaining to materials and surveillance capsules. The RPV material surveillance specimens are provided in accordance with requirements of the ASTM E185 standard and contain materials representative of the materials and material conditions used in the RPV beltline region. The plan accounts for the entire lifetime of the plant.

##### **5.11.8.3 BWRVIP-Type Reactor Internals Surveillance Inspections**

The reactor internal components are susceptible to aging degradation mechanism, particularly SCC and for the core shroud, and IASCC. While efforts are made to minimize degradation through material selection, component fabrication and the use of Hydrogen Water Chemistry/OLNC, the Boiling Water Reactor Vessel and Internals Project (BWRVIP) has developed inspection programs to monitor components for the impact of environmental degradation during plant operation in current operating BWRs in key internal components. The USNRC NUREG-1801, "Generic Aging Lessons Learned (GALL) Report" (Reference 5.11-6), provides an overview of these programs. These existing programs are used as the initial basis to develop BWRX-300 surveillance inspection plans for the different reactor internal components. The BWRVIP program includes inspection and flaw evaluation approaches that provide assurance of the long-term integrity. The guidelines provide information on component description and function, susceptible locations, and safety consequences of failure. They also provide recommendations for methods, extent, and frequency of inspection. The programs are focused on managing the effects of cracking due to SCC, IGSCC, or Irradiation Assisted Stress

Corrosion Cracking (IASCC), cracking due to fatigue, and loss of toughness due to neutron and thermal embrittlement. The BWRVIP program includes components such as the core shroud, core plate, core shroud support, top guide, core plate, steam dryer, and CRD housings.

#### **5.11.8.4 BWR Piping and Safe End Welds/HAZs Surveillance Inspections**

The BWRVIP following NRC guidance has developed inspection programs to monitor piping weld regions for the impact of environmental degradation, particularly IGSCC, during plant operation. These programs augment the ASME BPVC, Section XI, Division 1, ISI program to address IGSCC concerns. Chapter 5, Subsection 5.2.6 discusses the key measures that are taken to significantly reduce susceptibility of BWRX-300 piping components to SCC. The existing BWRVIP programs for ISI can be used as the initial basis to develop the BWRX-300 surveillance inspection plans for the different stainless steel piping welds/HAZ regions to minimize any SCC risks for degradation over the plant operating lifetime.

#### **5.11.8.5 Water Chemistry Monitoring/OLNC Effectiveness**

Generic Aging Lessons Learned (GALL) Report, NUREG-1801, Revision 2 establishes that water chemistry is key to the BWR aging management plan for operating BWRs. This will also be the case for the BWRX-300. The BWRX-300 will comply with the BWR Water Chemistry Guidelines which address parameters for sample, frequency, and action levels. The guidelines provide proactive water chemistry guidance for mitigating environmentally assisted corrosion, maintaining fuel integrity, controlling FAC and controlling radiation fields.

#### **5.11.8.6 Flow Assisted Corrosion Monitoring**

For carbon steel piping, the FAC surveillance program defines key piping inspection locations, to evaluate and monitor wall thinning.

#### **5.11.9 Program and Milestone Implementation**

Refer to Chapter 13, Subsection 13.3.3.

## **5.12 Reactor Auxiliary Systems**

### **5.12.1 Chemical and Inventory Control Systems for the Reactor Coolant**

IGSCC can occur in BWR startup and at-power environments. The normal BWR environment during power operation is 286°C water containing dissolved oxygen, hydrogen, and small concentrations of ionic and non-ionic impurities. Increasing levels of many ionic impurities influence SSC behavior of RCPB materials and may also affect fuel performance. Reactor water conductivity is maintained at or below the defined limits.

Besides being a major contributor to IGSCC of sensitized stainless steels, reduction of oxygen content is known to reduce the tendency for pitting and cracks of most plant materials. During power operation, most of the oxygen content of reactor water is due to the radiolysis of water in the core and, therefore, oxygen control cannot be achieved through traditional chemistry and operational practices. Reactor water oxygen control to low, plant-specific levels can be obtained through hydrogen injection from a Hydrogen Water Chemistry System. Hydrogen Water Chemistry is an established technique for mitigating and reducing the growth rates of IGSCC in reactor vessel internals. Control of reactor water oxygen during startup/hot standby is accomplished by utilizing the deaeration capabilities of the condenser. Refer to Chapter 9A, Subsection 9A.9.8 for further information.

In order to reduce the risk of IGSCC in reactor vessel internals, the BWRX-300 plant chemistry regime includes Hydrogen Water Chemistry System and On-Line NobleChem™ (OLNC). The OLNC operates in conjunction with the Hydrogen Water Chemistry System; although, they are both completely separate systems which have no mechanical or electronic interrelationships.

The OLNC provides a means for the injection of a noble metal salt solution directly into the reactor coolant flow path. In combination with Hydrogen Water Chemistry injection, the noble metal deposition in the reactor provides a catalyst effect on vessel surfaces to facilitate the recombination of free hydrogen and oxygen molecules to minimize the oxygen available to initiate or encourage IGSCC crack growth. Based on the catalytic surface recombination efficiency provided by OLNC, less hydrogen is required to mitigate IGSCC initiation and reduce IGSCC crack growth rates. Due to the requirement for lower hydrogen, MSL dose rates are also lower.

The BWRX-300 water chemistry sampling and monitoring program is designed to analyze and monitor system chemistry for trending with alarm notification so actions can be taken to stay within operating specifications. The water chemistry control parameters, recommended operating limits, and recommended monitoring frequencies are developed to minimize the potential for IGSCC by controlling both ionic impurity and oxidizing radiolysis product concentrations in the reactor water. The Chemistry Control Program supports minimizing corrosion from chemical contaminants and monitoring chemical additives used to limit corrosion and contamination buildup. Chapter 13, Subsection 13.3.2.3 provides further details.

### **5.12.2 Reactor Water Cleanup System**

The Reactor Water Cleanup System (CUW) provides blowdown-type cleanup flow for the RPV during the reactor power operating mode. CUW also provides an overboarding flowpath (i.e., excess RPV coolant inventory discharge for level control) to the condenser hotwell or Liquid Waste Management System (LWM) directly from the RPV lower region.

During normal operating mode, the CUW system is in-service, with flow intake from the bottom of the RPV through two lines. The two inlet lines join into a single line outside the RPV where it exits the containment vessel, routes through piping in the steam tunnel and into the TB. Water flows through piping internally mounted inside the RPV downcomer region and exits the RPV greater than TAF+4m. At the top of this piping outside the RPV, there are double isolation valves integral

to the vessel, which close to prevent RPV inventory from exiting the CUW line in case of a pipe break.

CUW piping can be utilized to reduce reactor temperature stratification with reverse flow from the Shutdown Cooling System (SDC). To help reduce vessel stratification, the SDC water can be routed to the RPV lower region through the normal CUW inlet lines. This system operation is designed to provide flow to the bottom head region during startup to reduce thermal stratification caused by the continuous input of cold-water flow through the CRD seals.

### **5.12.3 High Point Vents of the Nuclear Boiler System**

The RPV head vent subsystem includes piping internal to the RPV head, two flange-mounted in-series RIVs, and piping to the MSL or Quench Tank, both located inside PCS. This vents non-condensable gases from the reactor steam dome via a connection to one of the MSL during plant operation. It permits the gases to be released from the RPV so that the RPV can be filled with water for hydrostatic testing and provides the upper tap for RPV level measurement during reactor shutdown. In addition, the horizontal portions of the head vent line piping to either the Quench Tank or the MSL have a downward slope in the direction of normal flow ensuring that no condensate stays in the line and prevents hydrogen from collecting.

A vacuum breaker is provided to equalize head vent line pressure with the PCS following cessation of flow through the vent line to the Quench Tank. The vacuum breaker is installed to prevent bypass leakage from the vent line to the PCS, or deposition of crud or debris in the vacuum breaker from the outlet side. The RPV head vent vacuum breaker is located at a high point near the downstream side of the Quench Tank pipe branch outboard isolation valve.

During reactor shutdown, reactor water level can be measured using the vent connection as the upper tap for the level instrumentation sensor. Also, during shutdown the NBS head vent connection permits air and non-condensable gases to be released from the RPV into the Quench Tank inside the PCS. The NBS head vent allows air to enter the RPV through the head vent connection when draining the RPV. During at-power operation, the NBS head vent connection permits and non-condensable gases to be released from the RPV into the MSL.

The non-condensable gases are extracted by differential pressure between the reactor head and the steam lines and then swept from the steam lines to the condenser.

### **5.12.4 Control Rod Drive System**

The CRD system contains components which form part of the reactor coolant pressure boundary, along with components which are important to safety to shut down the reactor. Those portions of the CRD system are classified as DL3/SC1.

The RPV provides integral CRD housing flanges for mounting the FMCRD to the vessel. The housing provides guidance and support for the FMCRDs in support of the normal control rod movement and scram functions. The RPV also provides mechanical interface at the coupling between the FMCRD and control rod, and at the coupling between the FMCRD and control rod guide tubes. These mechanical interfaces prevent ejection of a control rod in the event of a postulated failure of a CRD housing.

The FMCRDs provide electric-motor driven positioning for normal insertion and withdrawal of the control rods and hydraulic-powered rapid insertion (scram) of control rods during off-normal conditions. The FMCRD major components that are part of the RCPB are analyzed and evaluated for the Service Level D conditions in accordance with ASME BPVC.

The CRD system materials specifications are discussed in Chapter 4, Section 4.5. The design of the CRD system is further described in Chapter 4, Subsection 4.6.

## **6.0 ENGINEERED SAFETY FEATURES**

The BWRX-300 incorporates Engineered Safety Features (ESFs) which mitigate the consequences of Anticipated Operational Occurrences (AOOs) or postulated Design Basis Accidents (DBAs) without any core damage. Information on the ESF materials is outlined in Section 6.1. Next, information on the Isolation Condenser System (ICS), which functions as the BWRX-300 Emergency Core Cooling System (ECCS), is captured in Section 6.2. The information on fission product containment and associated systems are presented in Section 6.3. Finally, the Control Room Habitability (CRH) function is outlined in Section 6.4. Supporting information is also described in Chapters 4, 5, 9A, 9B, 12, and 19.

ESF design features include passive systems that do not require dependence on external sources of power or operator actions fulfilling the Fundamental Safety Function (FSF). The BWRX-300 design does not require immediate operator responses for safety as reactor shutdown with passive vessel and containment heat removal are automatically initiated. ESFs mitigate the consequences of accidents that may cause major fuel damage and cannot be safely shut down by the Safety Class 1 (SC1) function alone. Features include the prevention of radioactive material release and plant personnel protection from radiation exposure. The engineered safety features are:

- Isolation Condenser System outlined in Section 6.2
- Containment and Associated Systems outlined in Section 6.3
- Control Room Habitability outlined in Section 6.4

The BWRX-300 design is inherently safe precluding the necessity for non-condensable gas control in the containment atmosphere following postulated DBA. Design Extension Conditions (DECs) or Beyond Design Basis Accidents (BDBAs) are described and analyzed in Chapter 15, Section 15.6. An overview of ESF materials selected in the BWRX-300 design is also included below.

### **6.1 Engineered Safety Feature Materials**

Materials used in the ESF components ensure that material interactions do not impair ESF operation. The selection of materials used in ESF functions is based on existing, historical Operating Experience (OPEX) for Boiling Water Reactors (BWRs). Quality standards are used for the design, fabrication, erection and testing of ESF components using applicable codes and standards for the safety class identified. Materials are selected to withstand the environmental conditions encountered during normal operation and postulated accidents, including Loss-of-Coolant Accidents (LOCAs). Material compatibility with core coolant water and the effects of radiolytic decomposition products are also evaluated.

The design, fabrication, erection and testing of the Reactor Coolant Pressure Boundary (RCPB) ensures a low probability of abnormal leakage or rapidly propagating failure or gross rupture.

Coatings used on exterior surfaces within the Primary Containment System (PCS) are suitable for expected environmental conditions.

### **6.1.1 Metallic Materials**

Materials selected in the design of the BWRX-300 Nuclear Boiler System (NBS) builds on a history of BWR material OPEX. RCPB materials are provided in Chapter 5, Section 5.2. Refer to Chapter 5, Table 5.2-1, *Typical Materials for Reactor Pressure Vessel Components* for the list of principal pressure-retaining materials and appropriate material specifications for the RCPB components. Refer to Chapter 5, Table 5.2-3, *Typical Reactor Internal Components and Materials* for the principal materials and associated specifications for the reactor internal components.

Details on material selection for ESF Structures, Systems, and Components (SSCs), including details on metallic and organic materials used in the ESF systems, are compatible for the intended use and described in the Pre-operational Safety Analysis Report (POSAR) in support of the Licence to Operate application.

All materials of construction used in ESF systems are resistant to corrosion, both in the medium contained and the external environment. General corrosion of all materials, except carbon and low alloy steel, is negligible. Conservative corrosion allowances are provided for all exposed surfaces of carbon and low-alloy steel.

Demineralized water is employed in the Feedwater (FW) system. Refer to Chapter 10, Section 10.3 for a description of the water quality requirements. Based on OPEX, chloride leaching from concrete and other substances is not significant in BWRs.

No detrimental effects occur to any ESF materials from containment environment that affects the FW system. The materials are compatible with the post- LOCA environment.

### **6.1.2 Organic Materials**

ESF equipment materials are selected considering the effects of radiolytic and pyrolytic decomposition and attendant effects on safe operation of the system. Refer to Chapter 12, Section 12.3 for As Low As Reasonably Achievable (ALARA) design considerations.

Other organic materials in the containment are qualified to containment environmental conditions and are described in the POSAR.

#### **6.1.2.1 Evaluation of Materials for Engineered Safety Features**

Materials are specified to withstand expected radiation doses during the plant lifetime without any significant radiation-induced damage. The specified integrated radiation doses for design basis events are provided in the POSAR Chapter 15, Section 15.7.

Containment post-accident environment consists of hot water, nitrogen, and steam, no significant chemical material degradation is expected, due to strict inspection and testing. Solid debris from organic materials are unlikely.

## **6.2 Isolation Condenser System (BWRX-300 Emergency Core Cooling System)**

The BWRX-300 safety design philosophy for mitigating LOCAs credits conservative safety margins (e.g., larger water inventory), eliminates system challenges, and reduces the number and size of Reactor Pressure Vessel (RPV) nozzles relative to predecessor designs. In addition, all fluid system nozzles are located no less than four meters above the Top of Active Fuel (TAF). The large RPV volume, along with the tall chimney region, provides a substantial water reservoir above the core.

A Reactor Isolation Valve (RIV) assembly configuration is shown on Figure 6.2-1. These design features preserve reactor coolant inventory ensuring that adequate core cooling is maintained by isolation condensers removing the decay heat, following a LOCA.

The large RPV volume also reduces the rate that reactor pressurization occurs if the reactor is isolated from its normal heat sink. If isolation occurs due to a design basis event, the hydraulic scram function initiates reactor shut down and the Isolation Condenser System (ICS) functioning as the Emergency Core Cooling System (ECCS) removes reactor heat. The slower pressurization rate, hydraulic scram function, and ICS eliminate the need for relief and safety valves for pipe breaks and RPV isolation events. Refer to Chapter 15, Subsection 15.4.3 and Subsection 15.4.4 for further analysis of AOOs and DBAs.

The ICS consists of three independent trains, each containing a heat exchanger or Isolation Condenser (IC) that is submerged in a dedicated pool of water that provides the ultimate heat sink for protecting the reactor core for any off-normal event where the main condenser is not available, and the RPV is isolated.

The single smallest inner pool volume combined with the outer pool volume provides reactor decay heat removal for a minimum of three days. The inventory of the two smallest inner pool volumes, combined with the outer pool volume, supports reactor decay heat removal for a minimum of seven days. Each inner and outer ICS pool is connected through two in-series SC1, one-way flow devices that prevent backflow from the inner pools to the outer pools.

The heat rejection process is continued beyond seven days if the ICS inner pool inventory is replenished from an outside source. The ICS pools are located above ground and are not pressurized. Clean makeup water can be added directly to the ICS cubicles using diverse and readily available sources.

The Isolation Condenser Cooling & Cleanup System (ICC) (Chapter 9A, Section 9A.2.6) provides demineralized water makeup from the Water, Gas, and Chemical Pads (WGC) system (Chapter 9A, Section 9A.9) which compensates for the relatively minor evaporative water inventory losses occurring under normal reactor operating conditions.

ICS removes decay heat generated in the core and does not require coolant injection into the RPV to mitigate pipe breaks and transients. Refer to Chapter 15, Subsection 15.5.4 for small steam and liquid pipe breaks inside containment.

### 6.2.1 Isolation Condenser System – General Description

The ICS removes sensible and core decay heat from the reactor passively without any loss of reactor coolant inventory when the main condenser is unavailable. Reactor heat is transferred from each IC heat exchanger to the IC pool water by condensation and natural circulation. No forced circulation equipment is required when the ICS is in-service following these events:

- Reactor isolation at power operating conditions
- Loss of all alternating current (AC)
- Failure to Scram, (BDBA as described in Chapter 15, Section 15.6)
- LOCAs

Similar isolation condenser systems have been used in early BWRs (BWR/2 and BWR/3) as the emergency heat removal systems successfully for over 40 years. The genesis of the BWRX-300 IC is the Simplified Boiling Water Reactor IC design which was tested extensively for performance and other operating characteristics. The same IC design is specified in the Economic Simplified Boiling Water Reactor (ESBWR). The ESBWR IC heat transfer capacity was increased or uprated by the addition of rows of tubes within the original array. This power-uprated ESBWR IC version is used in the BWRX-300. Other modifications in the BWRX-300 IC design include design pressure (higher for BWRX-300), return into the chimney instead of the downcomer (refer to Section 6.2.6) and hardware material selections made to enhance the design.

### 6.2.2 Safety Design Bases

The BWRX-300 ICS is designed as a Defense Line (DL) 3 SC1 system that removes sensible and decay heat and provides RPV overpressure protection.

The ICS system meets the requirements of REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*, Section 8.5 (Reference 6.2-1). The technical justification and U.S. Nuclear Regulatory Commission (USNRC) acceptance of the ICS functioning as the ECCS is provided in NEDC-33911P-A, Rev. 3, *BWRX-300 Containment Performance* (Reference 6.2-2). ICS DL functions during normal and off-normal reactor plant operating conditions are organized by plant safety functions. While the reactor is at normal power operations, the ICS is in standby with the pressure boundary intact and ready to initiate on either a manual or automatic initiation signal.

The USNRC Safety Evaluation of NEDC-33910P-A, Rev. 2, *BWRX-300 Reactor Pressure Vessel Isolation and Overpressure Protection* (Reference 6.2-3) justifies the ICS RPV overpressure protection for the American Society of Mechanical Engineers (ASME) Code Class 1 reactor pressure boundary. Refer to Chapter 15, Subsection 15.5.4 for limiting DBA overpressure events.

The single smallest inner pool volume combined with the outer pool volume provides reactor decay heat removal for a minimum of 72 hours without operator action. In plant modes where the Shutdown Cooling (SDC) is in-service, the ICS performs the SC1 DL3 function of isolating the interface connection(s) to the SDC in the event a pressure boundary leak is detected. This function ensures that passive failure or misalignment in a lower safety class system cannot disable the higher safety class ICS. The function is most critical when the RPV head is still tensioned, making it an important plant mode-related function.

ICS electrical and mechanical equipment is qualified in accordance with the BWRX-300 Equipment Qualification Specification using the established environmental conditions at the ICS pools and associated equipment locations so that they remain functional during post-accident environmental conditions, in addition to the normal conditions. Refer to Table 6.2-1 for the ICS SSC Classification.

NEDO-33955 REVISION 0  
NON-PROPRIETARY INFORMATION

During normal plant operations, the ICS is in standby condition and performs the following safety functions:

- ICs and the condensate return lines are filled with water up to the steam distribution headers.
- Condensate return valves are closed, operable, and ready to open when ICS is initiated on a demand signal from interfacing DL2, DL3, and DL4a control systems.

Standby gas purge isolation valves are open venting gasses to the NBS main steam lines, operable, and ready to close when ICS is initiated on a demand signal from interfacing DL3 and DL4a control systems.

ICS pools at or above their minimum level and at or below their maximum temperature.

Check valves prevent backflow from each inner pool to the outer pool set are operable and preserve minimum inner pool inventory for DL2, DL3, and DL4a decay heat removal and RPV overpressure protection functions.

When SDC is not operating, interface connections to the lower safety class SDC system are isolated and perform their DL3 and DL4a reactor coolant pressure boundary integrity function.

During shutdown plant operation, the ICS provides a suction path from the RPV chimney internal region to SDC for the DL2 decay heat removal function.

In response to AOO or DBA events, ICS safety functions are confinement of radioactive materials (through overpressure protection and RCPB integrity), fuel cooling, and long-term heat removal. These functions are performed responding to various DL initiating events:

- ICS provides overpressure protection by maintaining RPV pressure below design limits. The overpressure protection function is performed in conjunction with the hydraulic scram function for overpressure event scenarios that progress to DL3. ICS overpressure protection is active in response:
  - a. RPV operating pressure setpoints exceeded (DL2)
  - b. RPV high pressure setpoints exceeded (DL3)
- ICS performs reactor coolant inventory addition and decay heat removal functions in response to:
  - a. RPV coolant level below setpoint (DL3 & DL4a)
  - b. Containment high pressure setpoint exceeded (DL3 & DL4a)
  - c. Line break indication (NBS main steam line, feedwater line, cleanup water, ICS) detected (DL3 & DL4a)
  - d. Main Steam Reactor Isolation Valve (MSRIV) or Main Steam Containment Isolation Valve (MSCIV) position out of range (DL4a)
- When SDC is in operation, ICS maintains the integrity of the RCPB in response to a FW or SDC line break by automatically isolating the interface connection to the affected SDC train (DL3 and DL4a).

### **6.2.3 System and Equipment Function Description**

The IC units located in the Reactor Building (RB) are submerged in an IC pool as shown in Figure 6.2-2 and simplified ICS system diagram in Figure 6.2-3. The ICs condense steam on the tube side and heat is transferred to the IC pool water which boils, and steam is vented to the atmosphere. The ICS pool arrangement provides the ultimate heat sink for protecting the reactor core for any AOO or DBA event where the main condenser is not available and the RPV is isolated. The IC is placed at an elevation above the steam source (RPV) so that this process is driven passively by gravitational force. When the steam is condensed, the condensate is returned to the RPV chimney via a condensate return pipe as shown in Figure 6.2-2. The steam side connection between the RPV and the IC is normally open, and the condensate return line is normally closed. This allows the IC and condensate return piping to fill with condensate that is maintained at a subcooled temperature by the ICS pool water during normal reactor operation. This is the standby mode or condition for the ICS.

The ICS is placed in operation by opening the condensate return line to the RPV. The subcooled condensate that is stored in the system during the standby state enters the RPV chimney interior providing additional inventory while quenching steam and lowering pressure at the reactor core exit. Simultaneously, steam from the RPV enters the IC where it is condensed in the tubes and returned to the RPV in a continuous cycle. If the RPV conditions fall below the saturation point, the ICS enters an idle state until decay heat drives conditions back to saturation, automatically and passively placing the ICS back into operation.

#### **6.2.3.1 Isolation Condenser System Pools**

The ICS pools consist of three main or inner pools and three expansion or outer pools. The inner pools are train specific, in that each only supplies cooling water inventory to the corresponding IC located within the pool compartment. Each IC pool is separated by a reinforced structural wall so that the ICs are not vulnerable to common cause failure. The ICS pools bidirectionally communicate with each other above their respective weir elevations through the outer pools. The weir level maintains pool separation. If a failure occurs in an outer pool, the inner pool level is maintained at no lower than the weir height, thus maintaining the inner pool volume supporting the system SC1 function.

The outer pools are cojoined above and below the weir elevation sharing cooling water with all inner pools and ICs. Each outer pool shares nomenclature with the adjacent inner pool even though the outer pools provide cooling water to all inner pools. The outer pools:

- Physically protect the inner pools from outside effects
- Provide water from all pools (inner and outer) to the ICC
- Provide water inventory for a minimum of seven days for ICS decay heat removal, even when assuming one ICS train is unavailable

Each outer ICS pool is connected to a cojoining inner ICS pool through doubly redundant, unidirectional, self-actuating flow devices that only permit flow from the outer pool to the inner pool, preventing inner pool inventory losses to a breached outer pool. The outer-to-inner pool one-way cross-connections are located within the pool compartments at an elevation that is below the IC tube vertical half-way point. This half-way point elevation defines the usable pools volume for boiloff heat removal capacity.

The simplified system diagram shown in Figure 6.2-4 illustrates the ICS pools arrangement. Note that "Inner Pool C" is the smallest of the three pools, as outlined in Figure 6.2-4. The minimum effective pool volume is down to the vertical half-way point of the IC tubes at an integrated reactor decay heat.

The ICS pools atmospheric vent piping originates from the ceiling of the ICS expansion pools and is routed vertically along the reactor building outside wall (refuel floor area) where it exits to the outside environment at an elevation below the polar bridge crane.

#### **6.2.3.2 Steam Supply, Condensate Return and Standby Purge Piping**

The steam supply, condensate return, and standby purge piping is designed to ASME Boiler and Pressure Vessel Code (BPVC) Section III, Subsection NB (Class 1) (Reference 6.2-4). The steam supply and condensate return piping extends from the outboard RIVs to the respective connection points with the associated IC subcomponents. The standby purge piping extends from the connection point with IC standby purge line subcomponent to the outlet of the outboard standby purge isolation valve.

The condensate return piping is routed from the connection point with the IC vertically or with downward slope in its entirety to the condensate return valves and loop seal. From the condensate return valves and loop seal, it is routed vertically connecting with the RIVs where any subcooled condensate forming at the steam to loop seal interface gravity drains to the RPV. The condensate return piping stored water volume is a critical parameter credited in the safety analyses, resulting in design constraints placed on the inside diameter piping and total length. The dynamic head losses or pipe friction losses of the piping are important to the safety analyses and are modeled in Transient Reactor Analysis Code General Electric (TRACG) analysis that forms the safety basis for the ICS design (Reference 6.2-5).

#### **6.2.3.3 Isolation Condenser Description**

The IC is designed to both ASME BPVC Section III, Subsection NB (Class 1) and ASME BPVC Section III, Subsection NCD (Class 2) (Reference 6.2-4 and 6.2-6). The steam supply and purge interconnection pipes are designed to Class 1 through the containment boundary up to and including the steam distributor and its integral flow restricting venturis. The purge line taps into the steam distributor and is routed back down through the annular area between the steam supply pipe and the penetration guard pipe to a connection point with the system standby purge piping. In effect, the purge line never traverses the containment boundary. The IC is designed to Class 2 downstream of steam distributor flow restricting venturis, including the upper header, condenser tubes, lower header, vent lines, and the two condensate drain lines up and not including the condensate tee and integral flow restricting orifices. The IC design returns to Class 1 starting with the condensate tee and includes the condensate piping, that routes back through the containment penetration to a connection point with the system condensate return piping.

Each ICS train has heat removal capacity greater than the reactor core decay heat at one minute after reactor shutdown with all control rods inserted. The known heat removal capacity of the ICs is established by full-scale prototype testing. The ICS core decay heat removal capability at one minute is outlined in Chapter 15, Section 15.5. IC heat removal capability increases when steam supply pressure increases, and it decreases when steam supply pressure decreases. The ICS trains have no common valves, piping, or RPV nozzles.

#### **6.2.3.4 Condensate Return Valves and Loop Seal**

Each ICS train has two 100 percent flow capacity condensate return valves installed in parallel. The two condensate return valves are remotely actuated with each designed to fail open upon a loss of control signal, control power, pneumatic supply, or hydraulic supply as applicable to the valve actuator design. One valve is designed for throttling while the other is a full-open/full-closed design. Both valves fail to the fully open position by stored spring energy. The valves are both located in horizontal runs of piping that are the lowest elevation of the condensate return piping, and the connection to the RIVs. This geometry creates a loop seal (discussed below) ensuring that the valves always have subcooled water on either side of their sealing surfaces, while the ICS is in standby, and while the reactor is in operation.

To place an ICS train in service, at least one of the two condensate return valves must open. The two valves installed in parallel ensure that no single active failure can cause the loss of any single train. The parallel valves and actuators are diversely designed, but both valves fail to the fully open position on a loss of pneumatics, control power, or control signal. Once the valves fully open, they stay fully opened until they are reclosed intentionally by the operator.

The water loop seal achieves two primary functions. First the loop seal performs a function under long-term operating conditions where the condensate return line liquid is low density and potentially in a two-phase state instead of a solid subcooled liquid column. The loop seal ensures a pocket of subcooled liquid exists in the condensate return line that prevents steam bypass conditions that would short circuit the system and lower heat removal performance. The vertical distance from the bottom of the loop seal to the RPV nozzle prevents steam bypass directly from the chimney region of the RPV to the isolation condenser by way of the condensate return line. Secondly, in the ICS standby condition, the loop seal ensures there is subcooled water on both sides of the condensate return valve seats that is nearly the same temperature. This eliminates valve body and seat distortion that could cause valve leakage.

#### **6.2.3.5 Standby Gas Purge Piping and Isolation Valves**

Whenever the ICS is in standby, and the reactor is critical, radiolytically-generated gases (hydrogen and oxygen) tend to accumulate in the upper point of the ICs where the steam to condensate interface exists within the steam distributor and associated piping subassembly. To prevent gas buildup eventually filling the distributor and the vertical steam supply line, a continuous gas purge is required. The purge line taps into the center region of the steam distributor and is routed back down into the Steel-Plate Composite Containment Vessel (SCCV) inside the penetration space between the vertical steam supply pipe and the outer guard pipe. The purge line is routed to the Main Steam Line (MSL) at a location between the RIV and the containment penetration.

The purge lines for ICS trains A and B connect to MSL A and the ICS train C purge line connects to MSL B. The pressure drop that occurs between the interior of the RPV and downstream of the RIV induces purge gas flow from the IC steam distributor to the MSL. Inside the SCCV, the gas purge line contains two automatic isolation valves installed in series that fail close on a loss of signal or power. The two in-series valve design provides redundancy in the event of a single active failure of one valve to close on demand. At least one of these valves close whenever the reactor is isolated, and the ICS is placed into service. The valve(s) close to prevent loss of inventory when the RPV is isolated.

The IC has an integrally mounted catalytic recombiner device that processes radiolytic gases when the system is in operation, eliminating the need to vent non-condensable gas. The catalytic recombiner does not alter the IC heat transfer characteristics.

#### **6.2.4 Materials**

ICS electrical and mechanical equipment is qualified using environmental conditions where they are located. ICS components functioning under faulted conditions remain functional under the post-accident environmental conditions in addition to the normal conditions. The IC is a full-scaled prototype tested component. The material specifications for system and subcomponents design pressures/temperatures are provided in the POSAR. The seismic integrity of the ICS pools is discussed in Chapter 9, Section 9B.2.3.

#### **6.2.5 Interfaces with Other Equipment or Systems**

Figure 6.2-5 identifies the ICS system interfaces and Table 6.2-2 summarizes the system interfaces. Each ICS train directly interfaces with RPV, and the Boron Injection System (BIS) or SDC.

##### **6.2.5.1 Interface Connections with Shutdown Cooling**

ICS trains A and B each have two series isolation valves outside the containment penetrations in the interface lines to the SDC trains A and B (refer to Chapter 9A, Section 9A.2.3) that provides a SDC suction path from the RPV chimney interior. The interface piping in the ICS is a connection located in the loop seal region between the condensate return valves and the RIVs. The interface piping is routed through a containment penetration and includes two in-series outboard remote-actuated isolation valves. The actual ICS to SDC boundary occurs at the outlet of the most outboard isolation valve for each train.

The double isolation in-series valve design provides redundancy in the event of a single active failure to one valve. The isolation valve closest to the SCCV penetration has two safety class functions. One function is normal containment isolation where the valve works in tandem with its associated RIV. The other function is terminating inventory loss in the event of a SDC pressure boundary failure outside containment when the plant is shut down and relies on the SDC for decay heat removal and cooldown. For this function, the two outside isolation valves work in tandem, providing redundancy in the event of a single active failure. Even though the RIV and outside containment isolation valve can provide the same redundant protection against a SDC breach, the ICS train associated with that interface would not be functional for decay heat removal. The availability of a functional ICS train is especially critical while the RPV head is still installed or prior to flood up.

Refer to Subsection 6.3.4 for containment isolation functions of the SDC interface valves.

##### **6.2.5.2 Interface Connection with Boron Injection System**

ICS train C interfaces with the BIS in a similar fashion as the SDC. The system boundary isolation valves are part of the BIS, and the system interface occurs inside the containment building (refer to Appendix 15B). The BIS system has one remote isolation valve outside containment and one check valve inside containment. The BIS system interfaces with the check valve inboard side.

#### **6.2.6 System and Equipment Operation**

Upon receipt of a RIV actuation, at least one condensate return valve in one ICS train opens and at least one standby gas purge isolation valve in each train closes. The subcooled condensate stored in the system during the standby state enters the RPV chimney interior providing additional inventory while quenching steam and lowering pressure at the reactor core exit. Simultaneously, steam from the RPV enters the IC where it condenses in the tubes and returns to the RPV in a continuous cycle. If the RPV conditions fall below the saturation point, the ICS enters an idle state until decay heat drives conditions back to saturation, automatically and passively placing the ICS back into operation.

NEDO-33955 REVISION 0  
NON-PROPRIETARY INFORMATION

With ICS in operation (one, two or three trains as required), decay heat removal does not exceed the plant Operational Limits and Conditions (OLCs) for RPV cooldown rate. One ICS condensate return valves in each train is used to throttle flow to maintain RPV pressure, producing the desired RPV cooldown rate. Eventually, one ICS train is sufficient to remove reactor decay heat. When the ICS is operating, the purge isolation valves close preventing the loss of RPV inventory. Radiolytic hydrogen and oxygen are recombined with passive catalytic recombiners installed integral to each of the ICs.

ICS control system functions are described in Subsection 6.2.7.

Because there is no significant oxidation, the only non-condensable gases that may migrate into the IC tubes are the radiolysis products following a design basis LOCA. The build-up of hydrogen and oxygen in steam following a 19 mm liquid break is analyzed using TRACG (Reference 6.2-5). TRACG shows that the radiolytic gas build up in the IC does not cause a significant degradation in the IC performance because any potential buildup occurs downstream of the heat exchanger tubes in the lower drum where the radiolytic gases are removed by catalytic recombination. Furthermore, the sensitivity calculations demonstrate that the effects of the potential degradation in the IC performance resulting from the presence of radiolytic gases are small even for much higher than reasonably expected radiolytic gas concentrations. The design limits the radiolytic gas volume fraction in the IC lower drum to less than 4%.

Unlike hydrogen generated from cladding oxidation, hydrogen and oxygen liberate from radiolysis at a slow rate and distribute over a relatively large region. The gas becomes mixed in water both in steam and liquid phases. The well-mixed hydrogen and oxygen in steam also migrates into the ICs when the ICs are in-service. The hydrogen and oxygen concentration in steam may increase as the steam condenses in the IC tubes. Because hydrogen and oxygen are mixed in water when they are formed near the core region, they do not separate from water or steam again until the steam condenses.

Since the ICS is a closed system attached to a high purity reactor coolant system, it is not subject to flow blockages, particularly since the steam intake is from a high elevation in the RPV and the condensate discharge is to an elevation above the TAF.

An ICS train can only be isolated automatically if a detectable leak or break occurs.

### **6.2.7 Instrumentation and Control**

The ICS provides emergency core cooling and is also the primary system preventing RPV overpressure. Diversity, redundancy, and backup power is supplied for the instrumentation and controls ensuring ICS operation when initiation occurs.

#### **6.2.7.1 Steam Condensate Temperature Instrumentation**

Each ICS train has temperature instrumentation installed on the steam supply line and condensate return lines. The temperature instrumentation installed on the steam supply lines is located as close to the containment penetration as practicable. The temperature instrumentation location allows for determining whether the steam line is sufficiently heated during startup and low power reactor operation.

Each IC train has temperature instrumentation installed on the upper and lower headers that measures the temperature of the bulk fluid. Temperature measurement of the lower header provides confirmation that the catalytic recombiner is functional and prevents buildup of non-condensables when the ICS is in operation.

#### **6.2.7.2 Isolation Condenser System Pool Level and Temperature**

Each ICS inner pool is equipped with narrow range level instrumentation at the weir elevation. Each ICS inner pool is equipped with level instrumentation that measures the wide range pool level while the ICS is in operation.

Each ICS inner pool is equipped with bulk pool temperature instrumentation.

#### **6.2.7.3 RPV Isolation from ICS Following an ICS Line Break**

The safety design basis assumes an ICS train failure occurs at the pressure boundary that necessitates quick closure of the RIVs for that train steam supply and condensate return lines to terminate a LOCA. In this event, the other two ICS trains remain intact and are not inadvertently isolated to mitigate the event (cool and depressurize the RPV). To ensure that inadvertent isolation of an ICS train does not occur at any time, two important features exist in the physical design and associated logic:

- The RIVs that interface with ICS are designed to fail as-is and are open under normal operating modes. This contrasts with all other RIVs, which have a fail-closed design.
- Redundant and diverse instrumentation and controls are provided.

The ICS RIVs closing function is described in Chapter 7, Section 7.3.

Each ICS train is equipped with two flow detection elements in the form of 90-degree bends that have impulse lines with three parallel Differential Pressure Transmitters (DPTs). One flow detection device is located in the steam supply line, and another located in the condensate return line. These DPTs detect flow within the system. If the ICS train is in standby and flow is detected, a line break is indicated and the control system for this line initiates RIV closure for this train only. ICS leak detection is not active during ICS operation, because the heat removal FSF is prioritized over LOCA mitigation and no automatic closure of RIV occurs. An ICS line leak occurring during ECCS FSF is a BDBA.

#### **6.2.7.4 System Actuation, Opening the Condensate Return Valves and Closing the Gas Purge Isolation Valves**

As indicated in Subsection 6.2.6, when an ICS initiation event occurs, two initiations occur that place the ICS into alignment for event mitigation:

- At least one condensate return valve in one ICS train opens
- At least one standby gas purge isolation valve in each train closes.

The number of ICS trains placed into service depends on the event severity as a result of RPV pressurization rate. In the most severe event, condensate return valves in each train may open on a staggered basis. The parallel redundancy of the condensate return valves and the series redundancy of the standby gas purge isolation valves ensure that any single active failure does not disable any of the ICS trains.

The ICS operational logic places into service only the number of train(s) required to limit an RPV pressure increase and then holds pressure stable at a predetermined value, or lowers pressure at a prescribed rate, depending on the event circumstances. Both the modulating and full-open demand setpoints are staggered across all condensate return valves by train. The established setpoints modulate valves in all three trains initially limiting and then controlling RPV pressure with each train's setpoint incrementally higher than the lowest. Controlling RPV pressure is a DL2 function and is controlled by the SC3 Isolation Condenser Throttling Pressure Controller (refer to Chapter 7, Subsection 7.3.3).

Should the RPV pressure fail to stabilize or continue increasing, setpoints are reached that trigger both condensate return valves in each train to fully open in an incrementally staggered sequence by train. Refer to Chapter 7, Table 7.3-1, *C10 SC1 I&C Functions and Initiation Signals*. The full open condensate return valve is a DL3 function (full open or close only valve) and a DL4a function controlled by the diverse protection system (DPS) control platform (both full open/close and modulating valves).

### **6.2.8 Monitoring, Inspection, Testing and Maintenance**

Pre-operational and in-service testing for the ICS include:

- Instrumentation calibration
- Instrumentation and equipment operation combinations using logic and instrument channel trip
- Instrumentation and alarm monitoring functionality and availability
- Valve operation and timing
- Verification that steam flow paths from the ICS pools to atmosphere are unobstructed
- Verification that IC steam and condensate return piping flow passages are unobstructed
- IC pool level control operation
- Verification that IC pool sub-compartment valves are locked open
- IC containment isolation valves close upon simulated isolation signal receipt
- Instrument channel response times measured from each process variable input signal to the process actuator confirmation signal
- Periodic stroke testing of each normally closed condensate return valve during normal plant operations with the RIVs closed preventing unnecessary system piping and components thermal cycling
- Periodic stroke testing of each normally open standby IC gas purge valves during normal plant operations

Periodic heat removal testing of each IC is performed on a rotating basis at an operating cycle interval.

The ICS is an SC1, Quality Group A and B system that is designed and constructed as ASME BPVC Class 1 and 2 (Reference 6.2-4 and 6.2-6). OLC surveillance tests include in-service component tests and in-service pressure boundary component inspections (piping welds). The design and construction of the ICS integrates features that prevent thermal fatigue and permit tests and inspections.

Monitoring, inspection, testing, and maintenance are planned and performed to meet system reliability and availability targets. Refer to Chapter 16 for a discussion on OLCs.

### **6.2.9 Radiological Aspects**

Large ICS breaks outside containment and small ICS line breaks are discussed in Chapter 15, Subsection 15.5.9.

The mass and energy release from the isolation condenser breaks outside containment are bounded by the isolation condenser pipe breaks inside containment that are described in Chapter 15, Subsection 15.5.4. The isolation condenser pipe breaks do not use any DL3 functions that depend on containment parameters and the containment back pressure is not credited in any isolation condenser pipe break analyses.

As is the case for isolation condenser pipe breaks inside containment, core response is not a concern since the break is isolated rapidly. The consequences of large isolation condenser pipe breaks outside containment are evaluated for loads, pressures, and temperatures outside containment and radiological consequences resulting from normal operation coolant activity.

Since the small break analyses inside containment do not credit containment back pressure, the mass and energy release calculated for breaks inside containment are bounding for breaks outside containment. The ICS break analyzed for offsite dose consequences is a postulated break of an IC steam side component within the ICS pool compartment of the RB. The break is immediately detected and RIV isolation occurs in 10 seconds. Refer to Chapter 15, Subsection 15.5.9 for ICS. As shown in Chapter 15, Table 15.7.7-3, *BWRX-300 DNNP Isolation Condenser System Line Break Outside Containment Accident Dose Consequences*, the dose consequences are bounded by the Darlington site DBA dose acceptance criteria with considerable margin.

#### **6.2.10 Performance and Safety Evaluation**

In general, any one ICS train can mitigate AOOs. Two ICS trains are required for LOCA mitigation (analysis assumes one of the three ICS trains has a single failure). All three ICS trains are credited for beyond design basis events and the IC pool inventories can be replenished indefinitely. Functions of the ICS satisfy the analysis assumptions for AOOs, and DBAs as described in Chapter 15, Section 15.5. For BDBAs, refer to Chapter 15, Section 15.6.

**Table 6.2-2: ICS System Interfaces**

<b>Interfacing System</b>	<b>Interface Description</b>	<b>Interface Boundary</b>
Nuclear Boiler System	Decay heat removal, receive steam, return condensate. Accept standby mode IC gas purge.	RIVs, steam supply and condensate return RPV nozzles. Gas purge to main steam lines at a location between the RIVs and the containment penetration.
Safety Class 1 Instrumentation and Control	Safety Class 1 Instrumentation and Control System to receive/provide signals to Safety Class 1 instrumentation and controls in ICS.	Interface boundary is at the input/output terminations in the Distributed Control and Instrumentation System cabinets within the scope of the SC1 I&C control equipment.
Safety Class 2 and 3 Instrumentation and Control	Safety Class 2 and 3 Instrumentation and Control System to receive/provide signals to Safety Class 2 and 3 instrumentation and controls in ICS.	Interface boundary is at the remote multiplexer unit associated with the instrument or control equipment.
Process Radiation and Environmental Monitoring System	Monitor ICS pool compartments for elevated radiation levels that may indicate ICS pressure boundary leakage.	Radiation detectors mounted in the ICS pool compartments or atmospheric vent line.
Boron Injection System	<p>ICS serves as a boron injection point via the train C condensate return line to the RPV chimney interior.</p> <p>The ICS condensate return piping for train C provides the interface between the BIS and the RPV. This interface avoids the need dedicated RPV penetration for BIS. The ICS provides the interface piping that extends from the condensate return line to a system boundary isolation valve that is in the scope of the BIS and is located inside the containment vessel.</p> <p>The ICS interface piping to the BIS connects to the condensate return piping between the condensate return valves and the RIVs at the lowest horizontal section of piping that includes the return isolation valves, effectively in the zone of the loop seal. This ensures that all of the interface piping to the BIS contains subcooled water.</p>	Pipe connection on the ICS train C condensate return line at a location between the condensate return valves and the RIVs.

NEDO-33955 REVISION 0  
NON-PROPRIETARY INFORMATION

Interfacing System	Interface Description	Interface Boundary
ICS Pool Cooling and Clean up System	Provide ICS pool water continuous cleanup to meet water quality standards and maintains the pool water below the temperature limit. Also, provides normal operational makeup water to maintain pool water levels.	The interface occurs through seismically qualified suction and discharge connections to the ICS pools.
Shutdown Cooling System	<p>ICS serves as a Shutdown Cooling suction point via the trains A and B condensate return lines from the RPV chimney interior.</p> <p>The ICS condensate return piping for trains A and B provides the interface between the SDC system and the RPV. This interface avoids the need for two RPV penetrations dedicated to shutdown cooling. The ICS provides the interface piping that extends from the condensate return line and out through the containment vessel where the connections to SDC occur. There are two ICS scope remote-actuated isolation valves outside of containment in each interface line. (Requirements pertaining to the outside containment isolation valves are located in Chapter 5, Section 5.10.) The SDC system begins at the outlet of the most outboard valve. This arrangement maintains the SC1 and SC2 piping and components within the scope of the ICS.</p> <p>The ICS interface piping to the SDC system connects the condensate return piping between the condensate return valves and the RIVs in the lowest horizontal section of piping that includes the return isolation valves, effectively in the zone of the loop seal. This ensures that all of the interface piping to SDC contains subcooled water.</p>	Pipe connection on the ICS trains A and B condensate return lines at a location between the condensate return valves and the RIVs.
Liquid Waste Management System (LWM)	Provide a storage vessel for ICS pool water that may need to be relocated to facilitate component maintenance or inspection that is located within the pool compartments, such as the ICs.	At this time the interface is made by temporarily installed pump taking suction from the refueling floor elevation and discharging through a flexible connection to installed piping that is in the scope of LWM system.

NEDO-33955 REVISION 0  
NON-PROPRIETARY INFORMATION

Interfacing System	Interface Description	Interface Boundary
Plant Pneumatics System	<p>Provide pressurized nitrogen gas to charge accumulators for the condensate return valve actuators and the SDC interface isolation valve actuators.</p> <p>The function of supplying nitrogen to the condensate return valves is non-safety class. The valves are held closed for the standby mode by nitrogen pressure, so the plant pneumatics function is important to prevent inadvertent actuation of the system. An accumulator and its inlet check valve, which are in the scope of ICS, store an adequate supply of nitrogen as a coping measure in the event that the plant pneumatics nitrogen source is lost. Since the condensate return valves fail to the open or safe position on loss of pneumatics, the nitrogen supply piping, accumulator, and check valve are not SC components</p>	Interface boundary is at the inlet of the Safety Class N backflow preventors.
Safety Class 1 Electrical Distribution System	Safety Class 1 Electrical Distribution System and batteries provide power to Safety Class 1 electrical loads in the ICS system.	Interface boundary is at the input to the local breaker at the Motor Control Center termination.
Primary Containment System	Provide the piping penetration sleeves and connections to ICS system piping ensuring a leak tight barrier.	Interface occurs at the penetration sleeve to piping weld.
Reactor Building Structure (RBS)	Provides ICS pool compartments and ICS support structure overall support (e.g., IC supports, piping supports)	Interface occurs at the ICS component support to RB structure attachment points (e.g., fasteners, welds).

### **6.3 Containment and Associated Systems**

The BWRX-300 containment pressure boundary provides a SC1 leak-tight barrier to prevent the release of radioactive material to the environment in the event of a failure of the RCPB. The containment structure maintains its functional integrity during and following peak transient pressures and temperatures that could occur following postulated DBAs. The containment integrity is assured by the isolation of mechanical systems penetrating containment for Postulated Initiating Events (PIEs) that could result in an uncontrolled release of radioactive materials to the environment. Other containment systems support the passive removal of heat generated from AOOs, DBAs, and DECAs, and the control of hydrogen and other combustible gases from Severe Accident (SA) or BDBAs.

#### **6.3.1 Containment Functional Requirements**

The PCS design limits are established and confirmed by Deterministic Safety Analysis (DSA) for postulated AOOs and DBAs (refer to Chapter 15, Section 15.5). The PCS provides the FSF of confinement that achieves the following confinement functions:

- Control of pressure and temperature
- Isolation of the confinement boundary
- Leak-tightness of the confinement boundary
- Controlled point of release
- Control of combustible sources
- Reduction of the concentration of free radioactive material in the confinement boundary
- Protection against external events
- Radiation shielding

The BWRX-300 PCS:

- Encloses and supports the NBS, the RPV and connected piping systems.
- Provides radiation shielding.
- Serves as a boundary for radioactive contamination released from the NBS, or from portions of connected systems located inside the PCS.

##### **6.3.1.1 Energy Management**

Post-accident energy management is described in Subsection 6.3.3 for Passive Containment Cooling System (PCCS). The heat removal capabilities of the Passive Containment Cooling System (PCCS) have been analyzed and accepted by the US NRC in NEDC-33922P-A, Revision 3, *BWRX-300 Containment Evaluation Method* (Reference 6.3.2-1). The analysis of PCCS heat removal capabilities from normal operation, DBAs, or DECAs is addressed in Chapter 15, Section 15.5 for DSA. PCCS heat removal during severe accident (SA) or BDBA is confirmed in Chapter 15, Section 15.6 for Probabilistic Safety Assessment (PSA).

##### **6.3.1.2 Management of Radioactive Material**

For AOOs and DBAs, the PCS contains and confines any radioactive materials in accordance with REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*, Section 8.6 (Reference 6.3.2-2).

### **6.3.1.3 Management of Combustible Gases**

For DECAs and BDBAs, the control of combustible gases is analyzed in Chapter 15, Section 15.6 with a description of the combustible gas system in Subsection 6.3.5.

### **6.3.1.4 Management of Severe Accidents**

SA and BDBA management are analyzed and described in Chapter 15, Section 15.6 for PSA.

## **6.3.2 Primary Containment System**

PCS encompasses the RPV, attached piping, equipment, and the RIVs, making a leak-tight boundary. The PCS is the fourth fission product barrier (preceded by the fuel pellet, fuel clad, and RPV), and is also a floodable volume to assure core coverage in response to BDBAs. The PCS is a SC1 system that assures the integrity of the barriers prevents releases and maintains the plant in a safe state.

The leak-tight containment vessel confines fission product releases from the core and prevents the release of radioactive contamination to the environment. The PCS outlined in red on Figure 6.3.2-1 is a dry, inerted containment with active and passive cooling features that dissipates normal (power operation) and off-normal (transient or accident) heat loads. Table 6.3.2-1 provides key parameters used in the developing the BWRX-300 SCCV design.

### **6.3.2.1 Safety Design Bases**

The PCS meets the requirements of REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*, Section 8.6 (Reference 6.3.2-2):

- **Leak-Tight Boundary:** Provides a leak-tight boundary in conjunction with other safety class systems/features limiting the radiological effects of contamination released from the NBS and connected systems inside of containment to meet the requirements of REGDOC-2.5.2, Section 8.6.4 and Section 8.6.12. All boundary components including the SCCV inner wall, containment closure head, equipment and personnel access airlocks, electrical and piping penetrations ensure leak-tight integrity. The PCS establishes the maximum allowable leakage rate under specified parameters for all boundary forming components and provides containment pressure monitoring during all normal and off-normal conditions.
- **Structural Integrity:** Maintains structural integrity of the pressure boundary preventing structural failures. Structural pressure boundary components including the SCCV, containment closure head, equipment and personnel access airlocks, electrical and piping penetrations, and Containment Isolation Valves (CIVs) maintain structural integrity under all specified normal and off-normal static and dynamic loading conditions, to meet the requirements of REGDOC-2.5.2, Section 8.6.2 (refer to Chapter 9, Section 9B.2.1).
- **Capability for Pressure Tests:** the PCS is subject to pressure testing, at a specified pressure to demonstrate structural integrity. Testing is conducted before plant operation commences, and at appropriate intervals, to meet the requirements of REGDOC-2.5.2, Section 8.6.3 and 8.6.5. Refer to Subsection 6.3.7.
- **Radiation Shielding:** Provides permanent radiation shielding within and outside containment limiting doses ALARA. Containment shielding is provided within the RPV core region, and the SCCV structural concrete also functions as radiation shielding external to the containment, to meet the requirements of REGDOC-2.5.2, Section 8.13.

- Equipment and Personnel Access: Access openings are sized accommodating repair/replacement activities. A removable opening (containment closure head) in the upper containment region allows access to the RPV for refueling outage activities, to meet the requirements of REGDOC-2.5.2, Section 8.6.7.
- Structural Support: Provides structural support to safety class SSCs within containment, including the RPV, as well as anchorage for connected piping systems and components, to meet the requirements of REGDOC-2.5.2, Section 8.6.8.
- Off-Normal Containment Cooling: Maintains the pressure and temperature within acceptable limits through the PCCS during all off-normal conditions, to meet the requirements of REGDOC-2.5.2, Section 8.6.9.
- Leak Detection: Detects leaks within the containment boundary by means of pressure detection and containment sump level detection.

### **Steel-Plate Composite Containment Vessel Safety Design Basis**

The dry, inerted SCCV pressure containing single chamber configuration is designed to accomplish the following safety design basis for structural integrity:

- SCCV safety functions rely on passive design features and natural forces.
- SCCV structure design accommodates the full range of loading conditions consistent with normal plant operation, AOOs and all DBA design loads.
- SCCV structure is sized and equipped to contain the mass and energy released by a large-break LOCA, and for small breaks.
- SCCV structure accommodates the maximum external negative pressure difference relative to the enclosing structure surrounding the SCCV.
- SCCV is protected from or designed to withstand hypothetical missiles from internal and external sources or the uncontrolled motion of broken pipes.
- SCCV pressure boundary wall has an integral or external passive cooling, using air or water, necessary by design analysis and plant layout constraints.
- SCCV forms a fission products release barrier discharged from the RCPB into the SSCV volume as a result of an accident up to and including the defined DBA events.
- SCCV accommodates flooding for long-term core cooling and permits recovery actions up to and including fuel assembly removal following a postulated DBA.

The PCS is designed to accomplish its functions following the initiation of a DBA event. Refer to Table 6.3.2-1 for the preliminary primary containment key design parameters.

The containment performance is demonstrated in Chapter 15, Section 15.5 and 15.6. Refer to Chapter 15 for DEC, in accordance with REGDOC-2.5.2, Section 8.6.12.

#### **6.3.2.2 System and Equipment Descriptions**

The PCS is located in a Seismic Category A below-grade silo and constructed using Steel Bricks™ as a SCCV (Figure 6.3.2-1) within the Reactor Building (Refer to Chapter 3, Subsection 3.5.1). The PCS is part of the nuclear island design and arranged so that the major pools of the nuclear island are above containment. This layout provides protection for PCS and equipment and components from external hazards. This arrangement uses safety class passive cooling methods for the core, RPV and the SCCV.

NEDO-33955 REVISION 0  
NON-PROPRIETARY INFORMATION

The PCS design uses a nitrogen-inerted containment atmosphere during most operating modes. Atmosphere control is provided by the Containment Inerting System (CIS) (refer to Chapter 9A, Section 9A.4.2 for the CIS system description). The CIS establishes and maintains an inerted nitrogen atmosphere for the prevention of hydrogen combustion in a post SA condition. The inert atmosphere design minimizes long-term corrosion and degradation of the SCCV and the contained components by limiting oxygen exposure during plant operating service life.

The PCS has provisions for personnel access and habitability during plant outages to perform maintenance, inspections, and tests required to assure SCCV integrity and reliability, and the integrity and performance reliability of interfacing SSCs contained inside the PCS boundary.

The PCS is comprised of the following components:

- Steel-Plate Composite Containment Vessel
- Containment Closure Head
- Personnel and Equipment Airlocks
- Mechanical Penetrations
- Electrical Penetrations
- Refueling Bellows Seal
- Integrated Leak Rate Penetration (refer to Subsection 6.3.7)
- Containment Corium Shield / Liner (refer to Chapter 15, Appendix 15A)
- Core Region Biological Shield (Bioshield, refer to Chapter 9B, Section 9B.2.2)
- Passive Containment Cooling System (refer to Subsection 6.3.3)
- Containment Support Structures
- Maintenance Structures
- RPV Vertical and Lateral Support Structures

Figure 6.3.2-1 and Figure 6.3.2-2 show a cross sectional views of containment within the reactor building, and Figure 6.3.2-3 is a simplified diagram of the containment SSCs.

The sub-compartments in containment are the compartments below the RPV and inside the RPV support structure, the spacing between the RPV and RPV Pedestal, and containment dome above the refueling bellows. Containment sub-compartments do not have large high energy pipes. Therefore, the sub-compartment boundaries are not subject to large transient loads resulting from pipe breaks inside the sub-compartments. Pipe breaks outside the sub-compartments may result in transient loads on the sub-compartment boundaries. However, since the pipe breaks occur in a large volume and since the sub-compartments have sufficiently large openings, these loads are not large in magnitude. The pressure differential across the boundaries is evaluated in Section 6.6.1 of NEDC-33922P-A (Reference 6.3.2-1) for the most limiting case and are small. The sub-compartment design includes the resulting differential pressures from pipe breaks outside the sub-compartments.

#### **6.3.2.2.1 Steel-Plate Composite Containment Vessel**

The SCCV is a concrete and steel structure that is a leak-tight containment boundary, providing structural support and radiation shielding external to containment.

The containment structure is composed of an SCCV, which consists of a Steel-Plate Composite cylindrical wall, basemat, top slab, and steel containment closure head. The containment structure is completely enclosed within the deeply embedded RB that includes containment penetrations and other safety components. The containment structure houses the Steel-Plate Composite internal pedestal that supports the RPV and also provides shielding. The SCCV is also integrated with the reactor building, and the integrated structure is supported by a common Steel-Plate Composite basemat.

The SCCV is classified as a SC1 and Seismic Category A structure. The structure description and analysis comply with all applicable codes and standards provided in Chapter 3, Subsections 3.5.3. The SCCV structure is discussed in Chapter 9B, Section 9B.2.1.

The SCCV is designed considering the rules and requirements of ASME BPVC, Section III, Division 2, SCCV Code Case (Reference 6.3.2-3).

#### **6.3.2.2.2    *Containment Closure Head***

The containment closure head is a removable steel dome that covers the opening in the top slab of the SCCV that is over the RPV functioning as a portion of the upper containment boundary. The interface between the closure head and the SCCV is a metal ring that is anchored into the top slab of the SCCV and includes a bolted flange for attachment/removal of the closure head.

The containment closure head is removed during reactor refueling and replaced using the RB crane prior to reactor operation.

The containment closure head forms part of the reactor cavity pool and retains water above PCS during normal operation. The containment closure head is SC1 and Seismic Category A structure.

#### **6.3.2.2.3    *Personnel and Equipment Airlocks***

Two containment airlocks function as a portion of the containment boundary when closed, one in the upper elevation and one in the lower elevation. The containment airlocks are sized to accommodate removal of the most limiting components.

#### **6.3.2.2.4    *Containment, RPV and Maintenance Support Structures***

The internal structural steel is SC1 and Seismic Category A structure that is described in Chapter 9B, Section 9B.2.2.

### **Containment Support Structures**

The internal structural steel, which includes the Containment Equipment and Piping Support Structures (CEPSS) and support floors at level -21 and -29 m, are steel structures located inside containment (refer to Figure 6.3.2-1). The containment internal steel structures are supported by the SCCV wall, RPV pedestal, and the CEPSS which also interface with the RPV at the upper stabilizer locations. The internal structural steel consists of various structural components such as beams and columns.

Refer to Chapter 9B, Section 9B.2.2 for a description of the structural role of the support floors at Level -21 m and -29m, and the primary CEPSS functions.

### **Maintenance Structures**

Platforms, stairs, ladders, or other structural facilities required for personnel entry and work areas performing inspections, tests, and maintenance or modifications on equipment within containment are provided.

Space is provided around equipment locations inside the SCCV allowing removal, servicing, and maintenance. Platforms and staircases for equipment access allow inspection and maintenance.

Platforms are provided for equipment inspection, examination, surveillance, and maintenance. Platforms and structures do not hinder the SCCV performance and considers the effects of high energy jet and impingement loads minimizing missile and debris generation. Removable stairs and platforms are used in place of permanent installations as needed.

The SCCV has installed crane rail(s) and cart track(s) (typically, monorail or mono-track) and pick points for lifting, positioning, and transporting components, equipment, maintenance tools, materials, inspection and test machines, equipment and tools, servicing systems and components inside the SCCV including the interior side of the SCCV boundary.

### **RPV Vertical and Lateral Support Structures**

The RPV pedestal is a SC1 and Seismic Category A structure.

The RPV pedestal is a cylindrical-shaped, steel-plate composite structure that structurally supports the RPV. The RPV pedestal, enclosed within the SCCV, is welded to a Steel-Plate Composite basemat that is connected with the SCCV.

Openings are provided in the RPV pedestal to permit pipe routing to the RPV, permit in-service inspection of the RPV and piping, and ensure personnel access into the under-vessel region.

The RPV Pedestal primary safety functions are:

- Provide structural support to SSCs such as the RPV, RPV stabilizers and miscellaneous platforms.
- In conjunction with the Bioshield, the RPV Pedestal provides radiation shielding to limit radiation dose within the applicable regulatory standards in different plant states, including normal operation, AOOs, DBAs, and DECAs.

Additional description of the RPV support is provided in Chapter 5, Section 5.9. The primary functions of the Bioshield are described in Chapter 9B, Section 9B.2.2.

#### **6.3.2.2.5 Refueling Bellows Seal**

The refueling bellows seal is designed as a mechanical appurtenance to the RPV and forms a seal between the outside RPV wall surface and the upper region of the SCCV during refueling operations when the RPV head is removed.

The refueling bellows assembly accommodates the movement of the vessel caused by operating temperature variations and seismic activity. The refueling bellows provides a 360° structural barrier that retains the refueling cavity water above the SCCV when the SCCV head is removed. The refueling bellows design includes protection from puncture or damage from dropped items during refueling outage activities, or workers performing RPV or SCCV head removal or installation activities. The design includes a drain to remove water from the bellows low point that can be cleaned (i.e., for removal of non-soluble radioactive contamination, including fuel particles, that settle onto the bellows assembly during refueling outages).

#### **6.3.2.2.6 Mechanical Penetrations**

Mechanical penetrations function as a portion of the containment boundary consisting of a metal sleeve that is welded into the SCCV and an attached section of process piping, allowing transfer of the process medium across the containment boundary when isolation valves are open. High temperature mechanical penetrations have an air gap between the sleeve and the process pipe. Cold mechanical penetrations have no air gap and the sleeve itself functions as the process pipe.

As indicated above, containment penetrations are outlined in the PCS Simplified Facility Diagram in Figure 6.3.2-3. Mechanical penetrations are designed maintaining containment integrity under DBAs conditions, including pressure, temperature, and radiation.

All mechanical penetrations are SC1 and Seismic Category A or B structures. Piping systems that penetrate containment pressure boundary are equipped with provisions to automatically and reliably seal preventing leakage.

The SCCV is periodically tested to measure the integrated leakage rate from the SCCV structure to confirm the leak-tight integrity of the pressure boundary.

Refer to Figure 6.3.2-3 for the PCS Simplified Facility Diagram that includes mechanical penetrations.

#### **6.3.2.2.7 *Electrical and Instrument Sensing Line Penetrations***

Electrical penetrations consist of a metal sleeve which is welded into the SCCV. The penetration assembly forms a leak-tight seal with the containment boundary, while allowing the passage of continuous electrical cables across the boundary.

Instrument fluid sensing line penetrations are arranged in ganged-penetration assemblies.

#### **6.3.2.3 Primary Containment System Materials**

Refer to the Subsection 6.3.2.2 for component materials. PCS materials are discussed in Chapter 9B, Section 9B.2.1 in accordance with REGDOC-2.5.2, Section 8.6.11 (Reference 6.3.2-2).

#### **6.3.2.4 Interfaces with Other Equipment or Systems**

Systems interface with the SCCV by directly communicating with the containment atmosphere or penetrating the SCCV pressure boundary for equipment connections located inside the SCCV. See Table 6.3.2-2 for PCS interfaces, Figure 6.3.2-4 and Chapter 9B, Section 9B.2.1.

#### **6.3.2.5 System and Equipment Operation**

The PCS is a passive system.

Containment is inerted with nitrogen supplied by the CIS (refer to Chapter 9, Section 9A.4.2) within 24 hours after the plant reaches 15% reactor power level, in accordance with the OLCs. Prior to reactor shut down, containment is supplied with breathable air during the de-inerting process up to 24 hours prior to descending to 15% reactor power level, in accordance with OLCs. During normal plant operation, CIS maintains the SCCV slightly above atmospheric pressure conditions preventing non-inert air infiltration. Normal containment cooling is performed by the Containment Cooling System (CCS) (Chapter 9A, Section 9A.5.6).

PCS leakage is monitored using the following parameters:

- Containment sump pump-out rate
- Containment sump level changes
- Air-handling unit (AHU) drainage flow rates
- Containment atmosphere fission product sampling

The PCS pressure and bulk average and individual sensor temperature readings are continuously monitored with alerts for pressure and temperature above normal range.

The reactor cavity above the containment is used as a heat sink for long-term cooling in abnormal or accident conditions if the CCS fan coolers become unavailable. The PCCS removes heat from the containment and reduces the containment temperature and pressure in abnormal and accident conditions.

Heat transfer occurs from containment to the PCCS by natural convection and condensation through the PCCS and containment dome to the subcooled water in the equipment pool. There are no active components or actuation signals required, as the PCCS is always in-service.

Fan coolers provide the primary means of heat removal from containment during normal operation (Chapter 9A, Section 9A.5.6 for CCS). Heat is lost to the reactor cavity pool through the containment head.

#### **6.3.2.6 Instrumentation and Control**

Instrumentation for interfacing systems is described in Table 6.3.2-2. Refer to Chapter 12, Subsection 12.3.14 for the Containment Monitoring Subsystem (CMon).

#### **6.3.2.7 Monitoring, Inspection, Testing, and Maintenance**

Containment monitoring, inspecting, testing and maintenance is described in Subsection 6.3.7.

Monitoring, inspection, testing, and maintenance are planned and performed to meet system reliability and availability targets.

#### **6.3.2.8 Radiological Aspects**

The DSA for the PCS and SCCV are described and analyzed in Chapter 15, Section 15.5.

#### **6.3.2.9 Performance and Safety Evaluation**

Containment design pressure and temperature are established with sufficient margin to the calculated peak pressure and temperature for large-break LOCA events. Refer to Chapter 15, Subsection 15.5.4 for large-break LOCA.

The peak containment pressure and temperature mass and energy release resulting from a large-break LOCA are limited by fast closing RIVs.

The PCS total leakage following a DBA is limited to less than leakage rates that result in offsite doses greater than those set forth by REGDOC-2.5.2, Section 4.2.1 (Reference 6.3.2-2). Refer to Chapter 15, Section 15.3 for safety acceptance criteria and Chapter 15, Section 15.7 for the results of both the DSA and PSA compliance with the acceptance criteria.

In the event of pipe failure, the PCS does not have sub-compartments containing large, high-energy pipes preventing dynamic loads from sub-compartments pressurization. The containment shell and the internal structures withstand jet loads resulting from large pipe breaks. The sub-compartments have large openings to the rest of containment preventing a large differential pressure from developing. The pressure differential across the sub-compartment boundaries is evaluated in Section 6.6.1 of NEDC-33922P-A for the most limiting case and found to be small (Reference 6.3.2-8). Refer to Chapter 15, Section 15.5 for further analysis.

Parameter	Value and Units <sup>5</sup>
Free Containment Volume (estimated)	7685.3 m <sup>3</sup> (271,404 ft <sup>3</sup> )
Minimum Free Volume (design)	6960 m <sup>3</sup> (245,790 ft <sup>3</sup> )
Containment Height, excluding the dome	37.985 m (124.6 ft)
Containment Diameter (outer)	17.30 m (56.8 ft)
Containment Shell Plate Thickness	15 mm (0.59 in)
Containment Single Brick Thickness	610 mm (24.02 in)
Containment Closure Head Diameter	7.84 m (25.72 ft)
Number of Manholes on Refueling Bellows	2 (Assumed)
Diameter of the Manholes	0.762 m (2.5 ft) (Assumed)
Containment Atmosphere	Nitrogen with less than 4% Oxygen
Normal Pressure	1.72 - 9.0 kPaG (0.25 - 1.30 psig)
Containment Design Internal Pressure <sup>(1)</sup>	413.7 kPaG (60.0 psig)
Max. Bulk Average Temperature <sup>(2)</sup> (Normal Operating Temperature)	57.2 °C (135 °F)
Max. Average Temperature – Upper Containment	65 °C (150 °F)
Max. Average Temperature – Lower Containment	43 °C (110 °F)
Peak Transient Shell Temperature: 0.0 – 0.01 h	195 °C (383 °F)
Design Temperature: 0.01 - 72 h <sup>(3)</sup> (Design Temperature)	166 °C (330 °F)
Containment Atmospheric Moisture <sup>(4)</sup>	10% Relative Humidity (RH) – 100% RH

- (1) Design pressure is conservatively established with approximately 10-15% margin above the initial thermal-hydraulic analysis peak pressure and the historical BWR Mark I and II containment design pressure values.
- (2) Bulk temperature represents normal plant operating conditions based on historical BWR steel containment temperature records. Bulk average temperature is not indicative of local component thermal environment maximum operating temperature that is evaluated separately.
- (3) Peak transient temperature is used for environmental qualification. Peak temperature for the most severe conditions of BDBAs may exceed this value for a short duration.
- (4) The SCCV atmospheric RH is a low for normal plant operations without leaks. The range is used for component environmental qualification. 100% RH is assumed for corrosion evaluation. Humidity is not specifically controlled during any plant operating mode, but in the dry containment design it is a monitoring parameter for unidentified leakage.
- (5) Numeric values presented are developmental and unconfirmed.

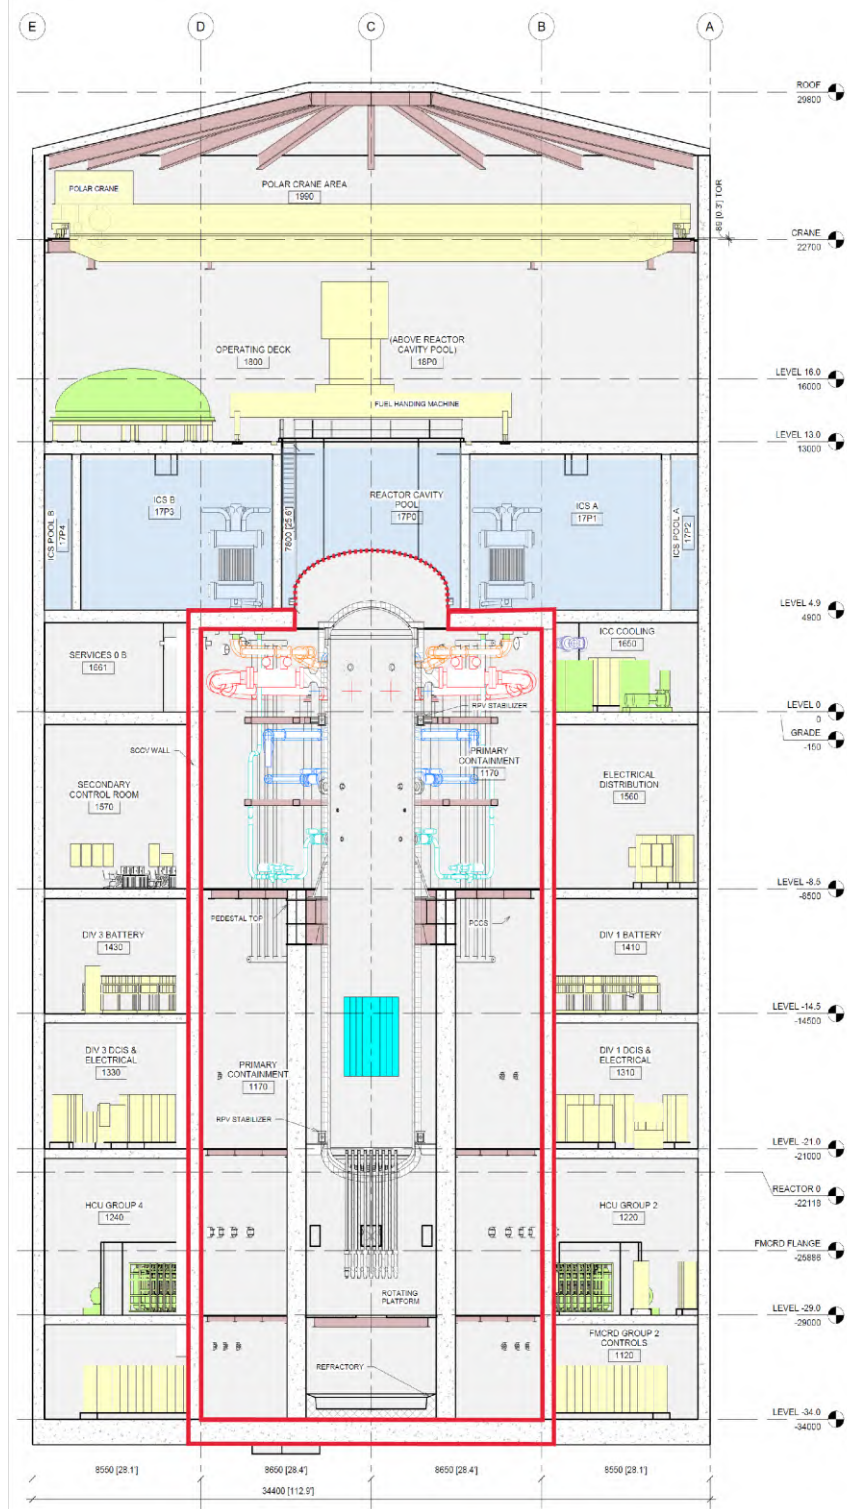

**Table 6.3.2-2: Primary Containment System Interfaces**

Interfacing System	Interface Description
Multiple Systems	Process systems penetrating containment provide containment isolation. Reference Penetration Interfaces on Figure 6.4.2-2: Primary Containment System Simplified Diagram
Multiple Systems	PCS provides structural support for process piping systems within containment
Nuclear Boiler System	NBS provides attachment / support of refueling bellows seal
Nuclear Boiler System	PCS provides vertical and lateral RPV support
Safety Class 1 Instrumentation and Control System	SC1 Instrumentation and Control System receives / provides signals to SC1 instrumentation and controls in PCS
Non-Safety Class (SCN) Instrumentation and Control System	SCN Instrumentation and Control System receives / provides signals to SCN instrumentation and controls in PCS
Process Radiation and Environmental Monitoring System (PREMS)	PREMS monitors containment atmosphere for oxygen, hydrogen, temperature, pressure, humidity, water level, area radiation, and gross gamma radiation
Fuel Pool Cooling and Cleanup System	Fuel Pool Cooling and Cleanup System provides supply water to PCCS
Fuel Pool Cooling and Cleanup System	PCCS returns heated water into the equipment pool

### **6.3.3 Passive Containment Cooling System**

The PCCS maintains temperature and pressure of the PCS through passive cooling during off-normal conditions. The PCCS is based upon proven concepts and simple thermosyphon principles. Heat is rejected to the equipment pool above containment by natural circulation using three independent trains of PCCS pipes as depicted in Figure 6.3.3-1. In Hot Shutdown, Startup, and Power Operation, the reactor cavity equipment pool gate is removed, connecting the equipment pool and reactor cavity pool to provide a heat sink for PCCS. There are no active components or actuation signals required, as the PCCS is always in-service. During normal operation, PCCS does not contribute to heat removal significantly since containment temperature is maintained by the CCS (Chapter 9A, Section 9A.5.6). The PCCS becomes effective when steam is discharged into the containment following a DBA pipe break.

#### **6.3.3.1 Safety Design Bases**

The PCCS removes heat from the containment and reduces the containment temperature and pressure in accident conditions. The reactor cavity and equipment pools above the containment are used as a heat sink for long-term cooling following DBAs or if the CCS fan coolers become unavailable.

#### **6.3.3.2 Description**

The PCCS consists of three independent trains of eight connected pipes with a top and bottom header connected to the equipment pool, which communicates with the reactor cavity pool when the PCCS is required to be operable.

The PCCS units are placed at locations that are not subject to jet loads or protected against them.

Each PCCS train has an isolation valve on the supply and return header outside containment that can be used to manually isolate a train in the event of a PCCS pipe leak or to remove a train from service for maintenance or testing during Cold Shutdown or Refueling Modes when the system is not required. The valves are normally open and are remotely operated from the Main Control Room (MCR). The PCCS isolation valves are located outside containment as close to the containment boundary as practical.

The PCCS inlet piping, on each train features a drain valve attached to the piping upstream of the isolation valve. The drain valve enables each PCCS train to be drained to the Liquid Waste Management System for maintenance and testing during the Refueling Mode when the equipment pool is drained.

The PCCS piping outside the containment boundary is open to the equipment pool. The ends of the supply and return pipes in the equipment pool are flanged / threaded with filters ensuring the piping remains free of debris. Each PCCS train can be pressure-tested during the Refueling Mode after the equipment pool and PCCS system is drained.

#### **6.3.3.3 Materials**

The materials of PCCS are ASTM A312 / ASME SA312, GR TP316/ TP316L Seamless Stainless Steel (SS) nominal size piping.

#### **6.3.3.4 Interfaces with Other Equipment or Systems**

The PCCS is part of the PCS. PCCS interfaces with the equipment pool to maintain containment pressure and temperature within the design limits during accident conditions or loss of active containment cooling. The Fuel Pool Cooling and Cleanup System (FCP) as outlined in Table 6.3.2-2 provides water to the equipment pool and heat sink for PCCS. Refer to Figure 6.3.3-1 for the PCCS piping layout.

#### **6.3.3.5 System and Equipment Operation**

Heat transfer occurs from the containment to the PCCS by natural convection and condensation through the PCCS to the subcooled water in the equipment pool.

The PCCS becomes effective when steam is discharged into the containment following a pipe break. The steam discharged to containment raises containment temperature and increases the steam content for condensation to occur. Condensation heat transfer, even in the presence of non-condensable gas, is much larger than heat transfer from a non-condensable gas at the same temperature. Heat transferred to the PCCS from the containment is removed by the natural circulation of water in single phase flow and rejected to the subcooled water in the reactor cavity equipment pool.

Because the ICs have sufficient capacity to remove decay heat, the majority of the energy during an accident is removed directly from the RPV. PCCS must remove only the energy released from the break to the containment. The energy released from a break is limited for a large break since large breaks are isolated rapidly. Energy released from unisolated small breaks is also limited due to the small break size. Additionally, the ICs depressurize the RPV making the break flow very small within a few hours. Depressurization of the RPV also reduces the RPV temperature, reducing the heat load from hot surfaces. The PCCS has sufficient capacity to reduce the pressure and temperature in the containment, minimizing leakage following an accident and maintaining pressure and temperature below the design limits in isolation events. Calculations for large and small breaks are presented in Chapter 15, Subsection 15.5.4.

During Power, Hot Shutdown, and Stable Shutdown Operations, the PCCS is aligned to allow flow of the equipment pool water that is in communication with the reactor cavity pool through the closed loop within containment. The PCCS is not required to be in-service for Cold Shutdown Operation or in Refueling Mode.

#### **6.3.3.6 Instrumentation and Control**

There are no I&C inputs for PCCS as a passive system.

#### **6.3.3.7 Monitoring, Inspection, Testing and Maintenance**

Monitoring, inspection, testing, and maintenance for PCCS piping are planned and performed to meet system reliability and availability targets. The PCCS pressure test is performed during the modes when PCCS is not required to be operable.

The PCCS is an integral part of the containment boundary and is designed to be periodically pressure tested as part of the overall Containment Leakage Rate Test (Section 6.3.7) program to demonstrate the structural and leak-tight integrity.

#### **6.3.3.8 Radiological Aspects**

The DSA for AOOs and DBAs is discussed in Chapter 15, Section 15.5. No design basis AOOs or DBAs lead to core damage. Breaks outside containment are the only DBAs leading to a normal coolant concentration release evaluated in Chapter 15, Subsection 15.5.9, and this release would not affect the PCCS heat removal performance.

#### **6.3.3.9 Performance and Safety Evaluation**

The PCCS transfers heat from the containment to the reactor cavity and equipment pools to maintain containment pressure and temperature within the design limits during accident conditions or during loss of active containment cooling. The PCCS functions for containment depressurization and heat removal are passive and do not require onsite or offsite electric power system operation.

NEDO-33955 REVISION 0  
NON-PROPRIETARY INFORMATION

The limiting DBAs for containment pressure and temperature are large-break LOCAs from main steam or feedwater pipe breaks. The PCCS rapidly reduces containment peak pressure following a large-break LOCA. Small unisolated breaks may become more limiting in the longer term for containment structure temperature. Containment pressure and temperature resulting from AOOs are bounded by those resulting from DBAs. The PCCS removes the energy from containment. Refer to Chapter 15, Subsection 15.5.4 for further details on DBA LOCA analysis.

The PCCS does not have a high duty function for long-term containment cooling as most of the decay heat from the RPV is removed by the ICS. For RPV isolation and loss of all AC events, containment pressure and temperature are limited by condensation on containment walls and containment heat removal by the PCCS, and by RPV decay heat removal by the ICS. The PCCS rejects heat to the reactor cavity and equipment pools above containment during DBAs as outlined in Chapter 15, Section 15.5 (Reference 6.2-2). Further analysis on the performance of the PCCS is to be developed in detailed design and the results are incorporated in the POSAR.

GOTHIC is used to evaluate the BWRX-300 containment response to mass and energy release from the RPV. The performance of the PCCS is included in the overall containment evaluation method.

**Figure 6.3.3-1: Passive Containment Cooling System**

#### **6.3.4 Containment Isolation**

This section describes the isolation of mechanical systems penetrating primary containment. Containment Isolation Valves (CIVs) are SC valves that prevent the uncontrolled release of containment contents in the event of an accident or other conditions by maintaining the integrity of the containment boundary. Piping systems penetrating primary containment are provided with detection, isolation, and containment functions that are redundant, reliable, and proven performance. CIVs are periodically tested to validate operability and determine if valve leakage is within acceptable limits.

There are several systems with RIV inside containment. The safety analysis assumes that large pipe breaks are quickly isolated by the RIVs following a LOCA preserving reactor coolant inventory before there is any potential for a significant radiological release. For piping that have RIVs, the closest piping terminal end (high stress and fatigue location) to the RPV assembly is located outboard of each set of two in-series RIVs.

Automatic CIVs outside containment are also included even though probability of a pipe break inside containment is small. These CIVs outside containment area are also included for the lines with RIVs. Automatic CIVs outside containment are not fast closing because there is no credible scenario in which fission products greater than what is contained in normal reactor coolant is released to containment. The outside containment automatic CIVs closure time assures containment isolation prior to the first fission product release greater than what is contained in normal reactor coolant in source term evaluations that are completed in the detailed design phase. These closure times are in the order of minutes. Additionally, the valve closing time for all CIVs supports specific break isolation functions balanced with water hammer and valve loading considerations. Small pipes for level instruments use Excess Flow Check Valves (EFCVs).

##### **6.3.4.1 System and Equipment Functions**

The containment isolation function maintains containment integrity by providing protection against the uncontrolled release of radioactive materials from the containment to the environment as the result of an accident.

Lines penetrating containment that provide a potential path for unfiltered radioactive release are automatically isolated by initiating CIVs closure limiting the release of fission products during and after a postulated accident. Redundant CIVs are included in each system line near the containment boundary that close on predefined parameters to prevent releases from containment, and any negative impacts from the system in that line. Penetrations are included at the boundary between the line and the containment limiting leakage at the connection. Penetrations are designed to maintain structural integrity during the extreme environmental conditions resulting from a postulated accident and protect against leakage. The CIVs, piping between the CIVs and penetrations, and the penetrations are included as a part of the containment boundary. together supporting the limited release of fission product leakage during and after an accident.

##### **6.3.4.2 Safety Design Bases**

All mechanical systems with lines penetrating the containment boundary have a SC function supporting containment integrity by isolating and limiting the release of radioactive leakage to within allowable limits during and following an accident. CIVs are periodically tested confirming operability and determining that valve leakage is within acceptable regulatory limits. Containment penetrations with thermal sleeves have resilient seals and expansion bellows permitting periodic inspection and testing.

The containment isolation design complies with the following:

- CNSC REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*, Section 8.6.6 on Containment Isolation and 8.6.10 (Reference 6.3.4-1)
- CNSC REGDOC-1.1.2, Licence to Construct a Reactor Facility, Section 4.5.9 Safety system and safety support systems (Reference 6.3.4-2)

CIVs in lines penetrating the containment boundary meet Canadian regulations and guidance for containment isolation providing protection against uncontrolled releases to the environment and isolating systems that may negatively affect containment. The containment isolation provisions for the ICS steam supply and condensate return lines constitute an appropriate application of the alternative means of meeting REGDOC-2.5.2, Section 8.6.6 (Reference 6.3.4-1). A single failure does not disable the containment isolation function. The two in-series RIVs that function as CIVs remain open during accident conditions allowing the ICS to function as ECCS.

CIV classification is defined by Safety Class, Seismic Category, Quality Group, and location as described in Chapter 3, Section 3.2. Refer to Chapter 15, Section 15.2 for the BWRX-300 Fault Evaluation process. The CIV DL functions are described in the individual fault sequence events in Chapter 15, Section 15.5.

Containment integrity is ensured by containment penetrations, RIVs, CIVs, and the containment piping up to CIVs are designed to Seismic Category A and B per REGDOC-2.5.2 (Reference 6.3.4-1). The penetrations, piping up to CIV's, and valves are designed to ASME BPVC-III NB, Section III - Rules for Construction of Nuclear Facility Components - Division 1 - Subsection NB - Class 1 Components (Reference 6.3.4-3).

#### **6.3.4.3 Containment Isolation Valves**

The following mechanical systems penetrate the containment boundary that require containment isolation:

- Nuclear Boiler System (NBS)
- Process Radiation and Environmental Monitoring System (PREMS)
- Isolation Condenser System (ICS)
- Boron Injection System (BIS)
- Control Rod Drive System (CRD)
- Reactor Water Cleanup System (CUW)
- Condensate and Feedwater Heating System (CFS)
- Chilled Water Equipment (CWE)
- Plant Pneumatic System (PPS)
- Containment Inerting System (CIS)
- Equipment and Floor Drain System (EFS)
- Water, Gas, and Chemical Pads (WGC)
- Passive Containment Cooling System (PCCS)

## **Mechanical System Interface CIVs**

Mechanical system interface for CIVs meet the requirements of the International Atomic Energy Agency (IAEA) SSG-53, Section 4.154 (a) and Section 4.154 (b), where applicable (Reference 6.3.4-4).

### *Nuclear Boiler System*

Two MSLs and a RPV head vent that are included in the RCPB are part of the NBS that penetrates containment. The MSLs CIVs fail in the closed position, with valve actuators that maintain the valves closed by positive mechanical means. This containment isolation is single-failure proof. The main steam CIVs are fast closing and fail-closed type valves.

### *Process Radiation and Environmental Monitoring System*

The Continuous Hydrogen and Oxygen Sample Panel Train A and B lines penetrate containment and are directly connected to the containment atmosphere.

### *Isolation Condenser System*

The ICS steam supply and condensate return lines penetrate containment and are a part of the RCPB. Each ICS train (one steam supply lines and one condensate return line per train) has two inboard automatic isolation valves.

Vent lines from the ICS tie into MSLs between inboard and outboard CIVs and do not penetrate the containment. Each ICS train vents to the MSL and has two series inboard automatic isolation valves.

Each ICS train provides an interface to the RPV with either BIS or SDC. The interface piping is routed through a containment penetration and includes two in series outboard remote actuated isolation valves. The actual ICS to SDC boundary occurs at the outlet of the most outboard isolation valve for each train (refer to Section 6.2 for ICS).

### *Boron Injection System*

A boron injection line has a remote air-operated outboard CIV and a check valve as the inboard containment and RIV. The injection location is in the ICS "C" loop condensate return line downstream of the two ICS condensate return valves, providing a direct flow path into the reactor. The injection location into the ICS condensate return line requires a separate containment penetration for the BIS injection line (refer to Chapter 15, Appendix 15B Complementary Design Features for BDBAs). The air-operated injection valve, when open, provides a flow path to the reactor for injecting a boron solution or demineralized water into the reactor. The injection valve, when closed after an injection event, allows re-establishing containment isolation. Locating a BIS CIV inside containment when needed for beyond design basis accident mitigation is not practical. The ICS RIVs are required to be open for accident mitigation.

### *Control Rod Drive System*

Hydraulic lines for the FMCRD scram function use penetrations without isolation valves based on the closed system piping outside primary containment and RCPB isolation uses internal ball check valves in the drive design. The CRD system and the associated hydraulic insertion line performs a safety critical function by providing high-pressure water to produce a reactor scram. Each FMCRD includes an integral ball check valve at the drive flange insert port. The check ball operation serves to plug the insert line port and limits the reactor coolant discharged in the event of an insert line break. Additionally, manual isolation valves may be used to further isolate the Hydraulic Control Unit (HCU) from the hydraulic insertion line if needed.

### *Reactor Water Cleanup System*

The CUW mid-vessel suction lines penetrate the containment and are a part of the RCPB. Each CUW mid-vessel suction line has two inboard automatic isolation valves. Both CUW mid-vessel suction lines combine inside containment and have one outboard automatic isolation valve for the combined header. The CUW containment isolation valves close upon receiving an isolation signal from SC1, SC2 and SC3 control platforms. The CUW CIVs fail in the closed position, with valve actuators maintaining the valves closed by positive mechanical means.

### *Condensate and Feedwater Heating System*

The FW line CIVs fail in the closed position, with valve actuators maintaining the valves closed by positive mechanical means. Each CFS line has two automatic isolation valves inside containment and two automatic isolation valves outside containment.

### *Chilled Water Equipment*

The CWE supply and return lines penetrate containment and are directly connected to the containment atmosphere if equipment leakage occurs. Each CWE supply line and return line has two inboard and one outboard automatic isolation valve.

### *Plant Pneumatic System*

Containment PPS includes two distinct sections: one supplies nitrogen and instrumentation air connections to the pneumatic valves inside containment and the other supplies service and breathing air inside containment during plant outages. The nitrogen and service air section are aligned to containment during normal operations. The breathing air section is used during plant outages and isolated during normal operations. Both sections are directly connected to the containment atmosphere. Isolation valve arrangements for these two distinct sections:

- Each CIV for the pneumatic nitrogen and instrumentation air section line has at least one automatic CIV inside and outside containment.
- Each CIV for service and breathing air section lines have one locked closed isolation valve inside containment and one automatic isolation valve outside containment. A simple check valve is not used as the automatic isolation valve outside containment.

### *Containment Inerting System*

Each CIS line that penetrates containment is provided with CIVs and connects directly to containment atmosphere. Both isolation valves on these lines are located outside the containment vessel to remove them from the harsh containment environment and protect them from the effects of flood and dynamic effects of pipe breaks.

The valves are located as close as practical to the containment vessel. The piping from the containment vessel up to and including both valves is an extension of the primary containment boundary and is designed in accordance with ASME BPVC-III NB-2021 requirements (Reference 6.3.4-3). The isolation valves arrangement and connecting piping allows for a single active failure of an inboard valve, or a single active or passive failure in the connecting piping or an outboard valve, that does not prevent CIS containment isolation.

#### *Equipment and Floor Drain System*

The EFS line that penetrates containment is provided with CIVs and connects directly to containment atmosphere. There are two CIVs placed in series, located outside containment that are placed as close to the primary containment wall as practical. It is impractical to have an isolation valve inside containment above the floor elevation. The pressurized containment sump tank is credited for containment leak detection. The isolation valves on the EFS containment drain line are normally open to connect the drain line to the pressurized sump. The EFS CIVs close automatically. Upon loss of actuating power, the automatic isolation valves fail closed, providing a greater safety position.

#### *Water, Gas, and Chemical Pads*

The WGC demineralized water supply line that penetrates containment is provided with CIVs and connects directly to containment atmosphere. CIVs include two manual isolation valves with one inboard and one outboard of containment. The WGC System demineralized water manual CIVs are locked closed, only opened during Modes 5 or 6 and are administratively controlled

#### *Passive Containment Cooling System*

Each PCCS (Section 6.3.3) train has an isolation valve on the supply and return header outside containment to isolate a train in the event of a PCCS pipe leak or remove a train from service for maintenance or testing during Cold Shutdown or Refueling Modes when the system is not required. The isolation valves are normally open and are remotely operated from the MCR. The PCCS isolation valves are located outside containment and as close to the containment boundary as practical. Supply and discharge connections from the pool are connected to closed-loop piping within containment.

### **6.3.4.4 Mechanical Penetrations**

Penetrations provide the connection between the containment and penetrating lines to prevent the uncontrolled release of containment contents in the event of an accident or other conditions inside the containment. Refer to Figure 6.3.4-1 for the penetrations view without containment wall.

### **6.3.4.5 Instrument Line Penetrations**

Instrument lines penetrating containment are sized, or an orifice installed that ensures that following a line break outside primary containment during normal operation the leakage is minimized. The rate and extent of coolant loss is within the normal reactor coolant makeup capabilities and the integrity and functionality of containment air treatment systems is maintained. Excess flow check valves are commonly used in BWR fleet instrument lines that:

- Do not close accidentally during normal operation
- Will close readily if the instrument line integrity outside containment is lost during normal operation or accident conditions
- Re-open or can be re-opened when conditions allow

Instrument line penetrations are either single or multiple. The multiple instrument line penetrations have 4, 6, or 8 instrument lines per penetration. Wherever possible, instrument line penetrations are shared minimizing the total quantity of penetrations used. Different systems can share the same penetration but only one system is declared for the penetration designation.

Containment isolation function is applied to all mechanical instrument sensing line penetrations of the SCCV boundary providing the highest reliability for maintaining instrument function while limiting potential radioactive releases if an instrument line is ruptured outside the SCCV boundary.

#### **6.3.4.6 Penetration Sleeves**

Penetration sleeves are used for high energy lines to reduce the effects of high temperature and/or pressure of the penetrating pipe on the containment concrete.

High energy lines are defined for normal plant conditions in system operation where either condition is met:

- Maximum operating temperature exceeds 95°C.
- Maximum operating pressure exceeds 1.9 MPaG. This definition does not apply to accident conditions.

For the BWRX-300 design, each mechanical system line penetration is categorized as either a hot penetration or cold penetration.

Cold penetrations are directly embedded into the SCCV. Hot penetrations are provided with a thermal sleeve that attaches to the SCCV to minimize the conductive heat transfer to the SCCV wall. Penetration sleeves are also used for the CWE lines even though they are not considered high energy lines.

Mechanical system penetrations containing trapped liquid between the CIVs have features that relieve thermally-induced pressurization that comply with IAEA SSG-53, Section 4.160 (Reference 6.3.4-4) that states: "Overpressure protection should be provided for closed systems that penetrate the containment and for isolated parts of piping that might be over pressurized by an increase of the temperature inside the containment atmosphere in accident conditions." A self-relieving penetration is typically selected, and the inboard isolation valve is oriented so that excess fluid is released inward to the containment. Using a separate relief valve provides penetration piping overpressure protection is permissible on a case-by-case basis when no other isolation valve selection option is available.

Mechanical system penetrations arrangements provide clearance for inspections.

#### **6.3.4.7 Containment Isolation Support Piping**

The mechanical system piping supporting containment isolation functions for those systems listed in Subsection 6.3.4.3 is the piping between the inboard and outboard CIVs for most system applications.

#### **6.3.4.8 Materials**

Containment integrity is ensured by the SCCV penetrations, piping, and valves design to ASME BPVC-III NB-2021 – Class 1 Components (Reference 6.3.4-3) with Seismic Category B for valves and Seismic Category A for penetrations and piping (Reference 6.3.4-1).

#### **6.3.4.9 Interfaces with Other Equipment or Systems**

Interfacing mechanical systems penetrating the containment boundary that require isolation are discussed in Subsection 6.3.4.3.

#### **6.3.4.10 System and Equipment Operation**

System and equipment operation is discussed in the following Subsection 6.3.4.11.

#### **6.3.4.11 Instrumentation and Control**

Containment isolation occurs automatically from closure signals generated by analytical limits or by remote manual. CIV closure is completed once an isolation signal is received. After an isolation valve closes, the valve does not open until the signal is removed, or the operator takes action by resetting the switch. The reactor operator cannot override a containment isolation signal to return the valve to the normal operating position by a single action.

##### ***6.3.4.11.1 Isolation Signals***

Isolation valves that are closed automatically for mechanical system lines that penetrate containment are capable of being reopened in the presence of an isolation signal. The controls for resetting an isolation signal do not result in the automatic reopening of CIVs.

Position indication for all power operated CIVs are provided in the control rooms. Position indication for power operated CIVs are based on actual valve position and not on demanded valve position. CIVs are configured to permit visual verification of valve position. Check valve CIVs are equipped with closed and open position indication devices, unless justified as not applicable.

#### **Instrument Lines**

Instrument lines penetrating the primary containment are provided with an automatically operated CIV, or one that an operator can manually operate from a remote location, or an excess-flow check valve. Self-actuated excess flow check valves in instrument lines are designed to close when the flowrate increases to a value representative of a loss of piping integrity outside containment.

Self-actuated excess flow check valves in instrument lines have the capability to automatically reopen when the pressure in the instrument line is reduced after previously closing due to an increase flowrate that was representative of a loss of piping integrity outside containment.

##### ***6.3.4.11.2 Containment Isolation Valves Closure Times***

For system lines that have an open path from the containment to the environment, closure times are defined based upon the deterministic safety analysis (Chapter 15, Section 15.5) minimizing the radiological effects in the event of an accident. The outside containment automatic CIV closure times assures containment isolation prior to the first fission product release that is greater than what is contained in normal reactor coolant source term evaluations. For some cases, the closure times are also determined based on minimizing the effects of containment flooding due to a pipe break within containment.

Total closure times consider both the I&C total time to initiate the valve actuation, and the mechanical total time for the valve to full close:

- I&C time – time it takes for the instrument to identify the trip signal to the actual switch that trips the valve actuator
- Mechanical time – time it takes the actuators to move the valve to fully closed

The following general criteria are used in establishing closure times:

- Established closure times prevent allowable radiological releases from being exceeded.
- For large breaks, the RIVs close rapidly and prevent significant loss of RPV inventory, uncovering the reactor core, or fuel clad heat-up. The largest diameter steam line and FW pipes are selected for DSA are the most limiting RPV blowdown conditions for plant isolation response.

#### **6.3.4.11.3 Valve Position**

For the following plant operational modes, CIVs have a typical valve position:

- Normal Operation
- Shutdown
- Post-Accident
- Loss of Motive Power

The positions are typical and based on plant operation and may vary based on system mode changes.

On loss of motive power each CIV takes the position that provides greater safety.

#### **6.3.4.11.4 Position Monitoring**

The containment isolation function, including provisions for control, indication, and performance under loss/restoration of power conditions, is instrumental in maintaining containment barrier integrity and not interfering with flow paths essential for reactor core cooling.

Position indication for all power-operated CIVs are provided in the MCR. Position indication for power-operated CIVs are based on actual valve position and not on demanded valve position. CIVs are configured to permit visual verification of valve position.

Manually operated valves are locked closed and are administratively controlled.

#### **6.3.4.12 Allowable Leakage**

The BWRX-300 CIVs minimize leakage. This section defines requirements specific to leakage performance. Allowable leakage for containment leak rate testing is provided before pre-operational testing. A discussion on containment leakage testing is included in Subsection 6.3.7.

##### **System Specific Allowable Leakage Requirements**

Leak rates are determined by manufacturer accepted seat leakage test methods for each systems specific design parameters.

##### **General Allowable Leakage Requirements**

Test requirements are determined for preoperational and periodic verification of primary containment SSCs to confirm leak-tight integrity and establishing test acceptance criteria. These tests are performed to assure that (a) leakage through the primary reactor containment and systems and components does not exceed allowable leakage rates values and (b) periodic reactor containment penetrations and isolation valve surveillance is performed so that any necessary maintenance and repairs are identified.

#### **6.3.4.13 Monitoring, Inspection, Testing and Maintenance**

All CIVs have individual leakage tests that are performed supporting verification that containment leakage is within the allowable limits. All CIVs are leak tested as discussed in Section 6.3.7, containment leakage testing in accordance with REGDOC-2.5.2. Design features required to support testing are defined within this section.

To support containment leakage testing, CIVs are manually cycled in the same manner that the valve closes upon receipt of an isolation signal. For example, if a valve closes automatically by pneumatic operation from an isolation signal, then the valve is also closed remotely by manual pneumatic operation.

Mechanical pipelines penetrating containment contain test connections that support CIV leakage testing. This test is performed by applying a test pressure through one test connection in the same direction the valve performs its safety function. A second test connection is located on the opposite side of the valve for line venting.

#### **6.3.4.14 Radiological Aspects**

Penetrations are arranged to provide sufficient space and shielding ensuring planned maintenance and operations is performed minimizing personnel exposure.

#### **6.3.4.15 Performance and Safety Evaluation**

The performance requirements (time to closure) for CIVs are confirmed by the deterministic safety analysis in Chapter 15, Section 15.5.

**Figure 6.3.4-1: Penetration View Without Containment Wall**

### **6.3.5 Systems for Protection Against Overpressure and Underpressure**

The CIS provides overpressure protection for BDBA. This complementary design feature is discussed in Chapter 15, Appendix 15B Complementary Design Features for Beyond Design Basis Accidents. The containment overpressure vent flow path is a hardened vent in SA cases where containment failure from overpressure may occur.

### **6.3.6 Filtered Venting System**

Refer to Chapter 15, Appendix 15B for the filtered venting system, which is to be further analyzed to determine if filtered venting is required for BDBA.

### **6.3.7 Containment Leakage Testing**

Containment Leakage Rate Testing is performed to assure leakage through containment and systems and components penetrating the SCCV does not exceed allowable leakage rate values as specified in plant OLCs and associated bases. The testing measures the rate at which a contained air mass escapes through the containment boundary at a specific pressure using sensitive instrumentation as described in 10 CFR 50, Appendix J (Reference 6.3.7-1) and ANSI/ANS-56.8 (Reference 6.3.7-2). Additionally, periodic surveillance of SCCV penetrations and isolation valves is performed to verify that proper maintenance and repairs are made during the service life of the SCCV.

The Integrated Leak Rate Test (ILRT) consists of the containment leakage rate and local leakage rate testing (LLRT). Testing requirements are in accordance with 10 CFR 50, Appendix J (Reference 6.3.7-1), and ANSI/ANS 56.8, Section 3.2.3 (Reference 6.3.7-2).

This testing is required on all boundaries that serve as barriers to the release of primary containment atmosphere following a design-basis LOCA as identified in 10 CFR 50 Appendix J III.D.2(b)(i) and 10 CFR 50 Appendix J III.C.1 (Reference 6.3.7-1).

Testing is performed prior to placing containment into service and periodically during plant operation, as part of the in-service testing examination and testing program ANSI/ANS-56.8-2020, Section 3.2.2 (Reference 6.3.7-2), and 10 CFR 50 Appendix J III.D.1 (Reference 6.3.7-1), respectively.

#### **6.3.7.1 Preoperational Leakage Rate Testing**

The preoperational ILRT determines whether SCCV structures comply with specified strength and design requirements in accordance with the requirements of ANSI/ANS-56.8, Section 3.2.2 (Reference 6.3.7-2). The preoperational proof and leakage rate testing is performed upon completion of construction and prior to criticality in accordance with the requirements of ANSI/ANS-56.8, Section 3.2.2 (Reference 6.3.7-2).

The preoperational ILRT includes general visual inspection of the accessible interior and exterior surfaces of the SCCV and components prior pressurization. The visual inspection is performed to identify deterioration that may affect leak tightness in accordance with ANSI/ANS-56.8-2020, Section 3.2.1 (Reference 6.3.7-2).

#### **6.3.7.2 Periodic ILRT**

Periodic ILRTs is performed by scheduled test frequency after the SCCV is placed into service. The test includes visual inspection of SCCV as described in Subsection 6.3.7. The test includes a positive pressure test of the containment and penetrations. Results of visual examination and ILRT are reported according to the requirements in ANSI/ANS-56.8-2020, Section 5.11.1 (Reference 6.3.7-2).

### 6.3.7.3 Periodic ILRT Requirements

Containment integrity is verified through pre-operational and periodic leak rate testing using established acceptance criteria as identified in ANSI/ANS-56.8 (Reference 6.3.7-2) and USNRC 10, Appendix J (Reference 6.3.7-1). Testing requirements includes:

- Leakage test requirements
- Test instrumentation
- Test procedures
- Test methods
- Acceptance criteria
- Data analysis
- Inspection and recording test results
- Guidance on required component and pathway testing
- Test frequency

LLRT confirms the SCCV leak-tight integrity boundary in accordance with:

- CNSC REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*, Section 8.6.4 (Reference 6.3.7-3)
- USNRC 10 CFR 50, Appendix J, *Primary Reactor Containment Leakage Testing for Water-Cooled Power Reactors* (Reference 6.3.7-2)
- ANSI/ANS-56.8, *Containment System Leakage Testing Requirements* (Reference 6.3.7-1)

ILRT procedures are written to satisfy the test method guidance of ANSI/ANS-56.8, (Reference 6.3.7-2) and is consistent with USNRC 10, Appendix J (Reference 6.3.7-1). The procedures are used to measure leakage rate of the SCCV boundary and evaluate the results to ensure the maximum allowable containment leakage is not exceeded. Refer to Chapter 3, Section 3.10 for a discussion on in-service monitoring, tests, maintenance, and inspections.

### 6.3.7.4 ILRT Examination Methods

The ILRT test method is the absolute method of leakage determination using the mass plot analysis technique for containment ILRT in accordance with ANSI/ANS-56.8, Section 5.6.2 (Reference 6.3.7-2). The tests are to confirm that the actual containment leak rate does not exceed the maximum allowable leakage at pressure used in the plant safety analysis to demonstrate that release limits are not exceeded, as per ANSI/ANS-56.8, Section 6.4 (Reference 6.3.7-2).

Results of the containment ILRT are validated by the performance of a verification test as per the guidance ANSI/ANS-56.8, Section 5.9.4 (Reference 6.3.7-2). This may be achieved by one of the following methods:

- A. A superimposed known leakage rate
- B. The use of two independent measurement systems to monitor and collect leakage rate data

Verification of test acceptance criteria is performed in accordance with ANSI/ANS-56.8, Section 5.9.4 (Reference 6.3.7-2).

Following a controlled pressure change, the pressure and temperature is allowed to stabilize in accordance with ANSI/ANS-56.8, Section 5.9.3 (Reference 6.3.7-2).

#### **6.3.7.5 Duration of ILRT**

ILRT duration is determined by the ILRT lead based on the allowable leakage rate and the accuracy of measurements established for each test procedure in accordance with ANSI/ANS-56.8, Appendices (Reference 6.3.7-2).

#### **6.3.7.6 Isolation, Repair, or Adjustment to Leakage Path**

Any modification component replacement or repairs or adjustment which could affect SCCV integrity requires appropriate testing to demonstrate that the affected components meet the applicable leakage requirements ANSI/ANS-56.8, Section 2 (Reference 6.3.7-2). These include:

- Any requirements for closure of all containment valves, doors, and hatches
- Requirements for any test boundary isolation that differs from normal operation

#### **6.3.7.7 Pressurized Components**

The primary containment is pressurized at a safe rate with air that is clean, relatively dry, and free of contaminants in accordance with ANSI/ANS-56.8, Section 5.5 (Reference 6.3.7-2).

Sources of compressed gas are isolated or removed otherwise a compressed gas leakage rate test phase is conducted to ensure that valid leakage rates are being measured in accordance with ANSI/ANS-56.8, Section 3.2.6 (Reference 6.3.7-2).

#### **6.3.7.8 Containment Isolation Valve Closure**

Closure of penetration isolation valves is accomplished by normal means and without any preliminary exercising or adjustment. Exercising valves for the purpose of improving leakage performance is not permitted. Repairs of malfunctioning or leaking valves shall be made as necessary as per the guidance in ANSI/ANS-56.8, Section 3.3.3 (Reference 6.3.7-2).

#### **6.3.7.9 Acceptance Criteria**

Acceptance criteria ensures that the measured containment boundary leakage rate does not exceed maximum allowable containment leakage at test pressure. This limit demonstrates that release limits are not exceeded, in accordance with ANSI/ANS-56.8, Section 5.8 (Reference 6.3.7-2).

#### **6.3.7.10 Reporting of Periodic ILRT**

Reports documenting the results of each pre-operational and periodic tests includes a schematic arrangement of the leakage rate measurement system, the instrumentation used, the supplemental test method, and the test program selected as applicable. Additionally, for the periodic test, the report shall include an analysis and interpretation of the ILRT and a summary analysis of LLRTs that were performed since the last ILRT in accordance with 10 CFR 50 Appendix J V.B.1 and 10 CFR 50 Appendix J V.B.2 (Reference 6.3.7-1).

**6.3.7.11 References**

- 6.3.7-1 10 CFR 50 Appendix J, "Primary Reactor Containment Leakage Testing for Water-Cooled Power Reactors."
- 6.3.7-2 ANSI/ANS 56.8, "Containment System Leakage Testing Requirements," American Nuclear Society.
- 6.3.7-3 CNSC Regulatory Document REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants."

## 6.4 Control Room Habitability

The BWRX-300 design does not consider the MCR habitability a SC1 function. The Secondary Control Room (SCR) is physically and electrically separate from the MCR as required by REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*. However, in accordance with REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants*, Section 8.10.2, a physically and electrically separate Secondary Control Room (SCR) is provided in the RB when the MCR becomes uninhabitable. Events that necessitate evacuation to the SCR include fire, malevolent acts, and aircraft impact, as example.

The MCR located in the Control Building (CB) and the SCR located in the RB provide environments to protect the operators during all operational states and maintain the reactor in a safe condition. No DBA and DEC can simultaneously affect both control rooms to the extent that the FSFs cannot be performed as required by REGDOC-2.5.2, Section 8.10 (Reference 6.4-1).

Control Room Habitability (CRH) refers to the conditions required for life support and safe, effective operation of the plant during operational states and accident conditions. CRH is served by a combination of individual systems that collectively provide habitability. These systems are listed below:

- Heating Ventilation and Cooling System (HVS)
- Process Radiation and Environmental Monitoring System
- Lighting System
- Fire Protection System (FPS)

Habitability features include missile protection, radiation shielding, radiation monitoring, air filtration and ventilation systems, lighting, and fire protection.

The design bases and descriptions of the various habitability features are contained in the following sections:

- Conformance with Applicable Regulations, Codes and Standards Section 1.11
- Evaluation of Site-Specific Hazards Section 2.2
- Protection Against External Hazards Section 3.3
- Protection Against Internal Hazards Section 3.4
- Control Room Habitability Function Section 6.4
- Control Building Heating, Ventilation and Air-Conditioning System Subsection 9A.5.2
- Fire Protection System Section 9A.6
- Lighting and Emergency Lighting Systems Subsection 9A.9.2
- Process Radiation Monitoring Subsystem (PRM) Section 11.5
- Design for Radiation Protection Section 12.3
- Shielding Section 12.4
- Area Radiation Monitoring Subsystem (ARM) Subsection 12.3.14

The MCR and SCR instrumentation is described in Chapter 7, Section 7.5, and Section 7.6, respectively. The CB structural evaluation for external hazards is provided in Chapter 3, Section 3.3 Protection Against External Hazards. Refer to Chapter 9B, Section 9B.3.2 for the CB structural integrity, which houses the MCR. There are no fission product releases resulting from a DBA or AOO as described in Chapter 15, Section 15.5.

In addition to the MCR and SCR, the BWRX-300 design incorporates emergency support facilities as required by REGDOC-2.5.2, Section 8.10.3 (Reference 6.4-1) and described in Chapter 19 (referred to as emergency response facilities in REGDOC-2.10.1). Habitability design requirements for emergency support facilities are included in POSAR in support of the Licence to Operate application.

#### **6.4.1 System and Equipment Functions**

The fundamental design philosophy is that the plant is operated from the MCR and only evacuated if necessary. For most PIEs, the operators remain in the MCR to safely operate the plant. If the MCR becomes uninhabitable, is expected to become uninhabitable, or functionality is unacceptably impaired, plant control is shifted from the MCR to the SCR. SCR habitability ensures the plant is maintained in a safe shutdown condition. The facility cannot be operated at power from the SCR.

A qualified route exists from the MCR to the SCR for events which necessitate evacuation of the MCR. An alternate route exists for fire events. MCR and SCR habitability provisions are provided to ensure that continued occupancy in one of the two locations is possible under PIEs for a minimum of 72 hours as required by REGDOC-2.5.2 (Reference 6.4-1).

Refer to Chapter 2, Section 2.2 for the evaluation of site-specific hazards which includes toxic gas assessments. The MCR is the assured operating location for smoke/external fire and toxic gas release event.

Both the MCR and SCR are protected for internal and external hazards and radiological events. The control room design features are based on proven technologies and human factors engineering considerations that are described in Chapter 18, Section 18.3.

A description of equipment to support CRH in the MCR and SCR is detailed below.

##### **6.4.1.1 Main Control Room**

As indicated above, the MCR, located in the CB, is the primary location for plant operators.

The CB is normally air conditioned and heated by 2x100% capacity chilled water supplied AHUs located on the CB roof, discharging through supply ductwork and a return plenum.

To accommodate off-normal MCR habitability contingencies, the following air handling units are provided for the CB:

- CB Toxic Gas Filtration Units (TGFUs) operate automatically when toxic gas is detected at the CB AHU outside air intakes. In this event, normal outside air supply to the operating CB AHU isolates and the TGFU discharge damper opens, allowing the associated TGFU to supply pressurization air to the CB through the normal CB supply AHU that continues to operate during a toxic gas event.
- Main Control Room Envelope (CRE) Emergency Filter Units (EFU) operate automatically upon detection of high radiation level at the operating CB supply AHU outside air intake. The CRE isolation mode initiates when normal CB supply and return air dampers close. The operating CB normal supply AHU intake de-energizes upon high radiation detection and auto-start of the standby unit is defeated. Battery Room exhaust fans continue to operate based on timers.

#### **6.4.1.2 Secondary Control Room**

The SCR, located in the RB, is the assured shutdown location for the plant if habitability and control from the MCR is lost.

The SCR performs the following functions when the MCR is inhabitable:

- Initiate shutdown of the reactor and maintain the plant in a safe shutdown condition
- Monitor FSFs

#### **Emergency Filtration Units**

The SCR is provided with 2x100% EFUs and pressurization fans that supply ventilation air to the operators when automatically placed into service upon radiation, or smoke detection in the normal supply duct. A loss of power to both normal supply AHUs initiates operation of the SCR EFUs and pressurization fans. These two pressurization fans draw outside air through dedicated ducting with blast resistant openings.

#### **Normal Ventilation**

The SCR is normally provided filtered, conditioned air from the operating RB Lower-Level AHU. Normal Ventilation is separate from the emergency ventilation and ensures that the SCR temperature is maintained in a specified range. Electric duct heaters assist in maintaining SCR temperature in a normal range.

#### **Isolation Dampers**

The SCR makeup air handler intake ducts have isolation dampers that are closed on high radiation, smoke, or toxic gas to protect personnel from these hazards.

#### **6.4.2 Safety Design Bases**

Habitability provisions ensure that continued occupancy in one of the two locations remains possible under PIE as required by REGDOC-2.5.2, Section 8.10.2 (Reference 6.4-1). The design provides provisions for both internal and external events that pose a direct threat to continued operation of the MCR and SCR, and practicable measures to minimize the effects of AOOs, DBAs, or DECAs.

MCR and SCR habitability provisions ensure that continued occupancy in one of the two locations is possible under PIEs for a minimum of 72 hours as required by REGDOC-2.5.2 (Reference 6.4-1).

The following Canadian regulations, standards and guidance are evaluated and applied to the BWRX-300 MCR and SCR design:

- CNSC REGDOC-1.1.2, *Licence to Construct a Reactor Facility*, Section 6.15 Control room facilities (Reference 6.4-2)
- CNSC REGDOC-2.5.2, *Design of Reactor Facilities: Nuclear Power Plants* (Reference 6.4-1)
  - Section 7.15 Civil structure
  - Section 8.10.1 Main control room
  - Section 8.10.2 Secondary control room
- CNSC REGDOC-2.4.1, *Deterministic Safety Analysis* (Reference 6.4-3)
  - Section 4.3.2 Anticipated operational occurrences and design-basis accidents
- CSA N293, Fire Protection for Nuclear Power Plants and N293S1:21, Supplement No. 1 to N293-12 (Reference 6.4-4 and 6.4-5)

#### **6.4.2.1 Main Control Room and Secondary Control Room Design Basis**

The BWRX-300 design provides an MCR, from which the plant can be safely operated as required by REGDOC-2.5.2, Section 8.10.1 (Reference 6.4-1). The design provides an SCR, from which the plant can be placed and kept in a safe-shutdown state, when habitability is lost in the MCR, as required by REGDOC-2.5.2, Section 8.10.2 (Reference 6.4-1):

- Radiation exposure in the MCR, and SCR when applicable, to personnel throughout the duration of the postulated DBA does not exceed the dose acceptance criteria of CNSC REGDOC-2.4.1, Section 4.3.2 (Reference 6.4-3).
- The MCR and SCR habitability design features detect and protect personnel from smoke and airborne radioactivity. The MCR habitability design features additionally detect and protects personnel from toxic gas.
- The MCR and SCR habitability requirements are satisfied without the need for individual breathing apparatus or special protective clothing.

Because the BWRX-300 design does not consider control room habitability a SC1 function, the EFUs are not SC1 and are therefore not credited for mitigation of DBAs.

#### **6.4.3 Control Room Descriptions**

The habitability aspects of MCR and SCR HVAC is discussed in Subsection 6.4.3. Descriptions of the control room HVS, FPS and Lighting System are found in Chapter 9A, Sections 9A.5.2, 9A.6 and 9A.9.2, respectively. Descriptions of the ARM and PRM are found in Chapter 11, Section 11.5, and Chapter 12, Subsection 12.3.14. Refer to Chapter 9A, Figure 9A.5.1-1 for the RB HVAC Process Flow Diagram.

##### **6.4.3.1 Main Control Room Description**

The layout of the MCR habitability area in the CB is shown on Figure 6.4-1 to Figure 6.4-3.

CRE isolation and CRE EFU operation provides a pressurized envelope relative to adjacent spaces, maintaining CRE habitability during an airborne radiation release event.

The Main CRE is the area maintained for habitability purposes. Figure 6.4-1 depicts the Main CRE.

### **Emergency Filtration Units**

Main CRE EFUs operate automatically upon high radiation level detection at the operating CB supply AHU outside air intake. The CRE initiates isolation mode when normal CRE supply and return air dampers close. Automatic operation of the CRE EFUs provide suitable atmosphere for habitability and maintains the CRE slightly pressurized. The AHU de-energizes upon high radiation detection at the intake and auto-start of the standby unit is defeated.

### **Radiation Protection**

The CRE isolation and EFU operation provides a pressurized envelope relative to adjacent spaces, maintaining CRE habitability during a radiological release.

### **Fire Protection and Toxic Gas**

The normal outside air intakes are monitored for toxic gases and smoke and isolates the outside air dampers if toxic gas or smoke is detected.

#### **6.4.3.2 Secondary Control Room Description**

The SCR, located in the RB (refer to Figure 6.3.2-1) remains habitable for at least 72 hours following an event requiring activation of the SCR.

The layout of the SCR is shown in Figure 6.4-4.

### **SCR Emergency Filtration Units**

The EFUs outside air supply portion of the control room HVS is SC1 and Seismic Category B. Single active failure protection is provided by using two trains that are physically and electrically redundant and separated. In the event of one train failure, the failed train is automatically isolated, and the alternate train is automatically initiated. Each 100% capacity train is capable of supplying filtered air to the SCR pressure boundary at the required flow rate.

A small amount of leakage out through the SCR pressure boundary is anticipated through door seals, electrical penetrations, and isolation dampers. The exhaust from the SCR is optimized to ensure proper scavenging of air from the SCR in an amount equal to the supply. Backflow prevention through the controlled leak path is not required because the SCR is at positive pressure during normal and emergency operation.

The SCR EFU utilizes a High Efficiency Particulate Air (HEPA) filter, carbon filter, and HEPA post filter to provide radiological protection of the SCR outside air supply. The units, along with the associated intakes, dampers, and ductwork are SC1, Seismic Category B, and meet the requirements of CSA N293-12 (Reference 6.4-4). Safety class equipment such as the SCR EFUs are qualified to operate in the harsh environment that will be encountered at specific locations following a DBA or DEC. Each of the two SCR EFU trains incorporate a 100% capacity pressurization fan powered by separate division power supply. The SCR EFU trains ensure adequate fresh air is delivered and mixed in the SCR habitability area.

### **SCR Pressurization Fans**

The SCR is provided with EFUs and pressurization fans that supply ventilation air to the operators when automatically placed into service upon detection of radiation or smoke at the normal lower-level supply AHUs. A loss of power to both normal supply AHUs will also initiate operation of the SCR EFUs and pressurization fans.

## **Isolation Dampers**

The SCR habitability area pressure boundary includes penetrations, dampers, or valves, interconnecting duct, and related test connections and manual valves. The isolation dampers are classified as SC1 and Seismic Category B. If radiation is detected, the SCR normal supply and exhaust isolation dampers will shut, the SCR pressurization fans will energize supplying the SCR with filtered outside air.

Tornado dampers close automatically and mitigate the effect of external hazards, as required by REGDOC-2.5.2, Section 7.15.1 (Reference 6.4-1).

## **Radiation Protection**

SCR instrumentation for monitoring of radioactivity is provided in Chapter 7, Section 7.6, and Chapter 12, Subsection 12.3.14.

## **Shielding Design**

Shielding design bases is provided in Chapter 12, Subsection 12.4. Descriptions of the design bases source terms and shielding parameters are presented in Chapter 12, Section 12.4 and Chapter 15, 15.7, respectively. The SCR designated radiation zones are shown in Chapter 12, Figure 12.6-5.

## **Fire Protection**

Fire and smoke detectors, and smoke removal descriptions are provided in Chapter 9A, Section 9A.6.

### **6.4.4 Materials**

Refer to Chapter 9A, Section 9A.5.1 for information pertaining to HVS materials.

### **6.4.5 Interfaces with Other Equipment or Systems**

Interfaces are addressed in Chapter 9A Table 9A.5.1-1, *Reactor Building System Interfaces* and Table 9A.5.2-1, *Control Building Heating, Ventilation and Air-Conditioning System Interfaces*.

### **6.4.6 System and Equipment Operation**

SCR and MCR emergency habitability control room HVS (Chapter 9, Section 9A.5.2) do not operate during normal conditions. The control room HVS maintains the air temperature of the control room habitability envelope within a predetermined temperature range using fan cooling units and air handling units that are supplied with chilled water during normal operations and shutdown. This maintains the SCR emergency habitability function passive heat sink at or below a predetermined temperature.

#### **6.4.6.1 Main Control Room**

Figures 6.4-1 and 6.4-2 show the MCR habitability envelope and location of AHUs, toxic gas monitors, TGFUs, and CRE EFUs located in the CB.

## **High Radiation**

CRE EFUs operate automatically upon detection of high radiation level at the operating CB supply AHU outside air intake. The CRE goes into isolation mode when normal CRE supply and return air dampers close.

## **Toxic Gas**

The MCR remains habitable for the duration of a toxic gas release event.

### **Loss of All Alternating Current**

During a loss of all AC, the MCR remains the control location until habitability temperatures are exceeded or controls and indications are lost due to high temperature effects from I&C and electrical components. The control room operators will relocate to the SCR in the RB if the MCR becomes uninhabitable.

#### **6.4.6.2 Secondary Control Room**

Operation of the emergency habitability portion of the SCR HVAC is automatically initiated on any of the following conditions:

- High radioactivity in the operating RB normal supply AHU outside air intake
- Toxic gas detection in supply duct to the RB
- Loss of all AC power

Operation is also initiated manually (Chapter 9A, Figure 9A.5.1-1 for RB HVAC process flow diagram).

### **High Radiation**

Upon receipt of a high radiation in the operating RB normal supply AHU outside air intake, the normal RB supply and exhaust are isolated from the control room habitability envelope by automatically closing the isolation dampers in the system ductwork. Simultaneously, one of two emergency pressurization fan EFUs automatically starts and begins to deliver filtered air from one of the two unique safety category outside air intake locations.

### **Toxic Gas**

The SCR is not inhabited during a toxic gas release event.

### **Loss of all Alternating Current**

The SCR remains habitable for 72 hours during a loss of all AC. During loss of all AC power, AC power is provided from SC1 batteries.

#### **6.4.7 Instrumentation and Control**

Instrumentation required for SCR habitability design features are provided in Chapter 7, Section 7.3. Details of the radiation monitors used to provide indication of actuation of an isolation and EFU initiation are given in Chapter 12, Subsection 12.3.5.

#### **6.4.8 Monitoring, Inspection, Testing and Maintenance**

Monitoring, inspection, testing, and maintenance are planned and performed to meet system reliability and availability targets. Chapter 9A, Section 9A.5.1 describes HVS inspection and testing.

Control room habitability leak testing is included in the POSAR.

#### **6.4.9 Radiological Aspects**

The radiological dose consequences from DBAs are analyzed and evaluated, and the accompanying results are provided in Chapter 15, Sections 15.5 and results are in Section 15.7.

#### **6.4.10 Performance and Safety Evaluation**

Radiation doses to SCR and MCR personnel are calculated for the accident scenarios where the pressurization system provides filtered air pressurizing the CRH envelope. Radiological dose consequences from normal coolant pipe break outside containment are evaluated in Chapter 15, Section 15.5. There are no DBAs or AOOs that lead to fission product releases.

## **7.0 INSTRUMENTATION AND CONTROL**

The Instrumentation and Control (I&C) systems for the BWRX-300 are in fact a system of systems. The information in Chapter 7 is organized to systematically present the I&C design bases in the necessary context to support an understanding of the individual I&C system designs and safety features. Information on the relationship of the I&C systems to plant-level requirements is presented in Section 7.1. Next, information on the architecture of the I&C system of systems is presented in Section 7.2. Then information on the individual I&C systems, including accident monitoring instrumentation, is presented in Section 7.3. The development processes for the digital I&C systems are presented in Section 7.4. The I&C systems in the Main Control Room (MCR) are described in Section 7.5. The I&C systems in the Secondary Control Room (SCR) are described in Section 7.6. The I&C systems in the Emergency Response Facilities are described in Section 7.7. Hazards analyses for the BWRX-300 I&C systems are described in Section 7.8.

### **7.1 Instrumentation and Control Introduction and Overview**

The BWRX-300 Instrumentation and Control (I&C) systems are designed to support the plant safety strategy described in Chapter 3, Section 3.1.

#### **7.1.1 Relationship Between Instrumentation and Control Functions and Plant-Level Defense Lines**

The I&C functions are allocated to the various defense lines.

Defense Line 1 (DL1) includes the quality measures taken to minimize potential for failures and initiating events to occur in the first place and to minimize potential for failures to occur in subsequent lines of defence. These quality measures cover the design, construction, operation, and maintenance of the plant. DL1 also includes the use of conservatism in design and analyses. Accident monitoring instrumentation supports functions in more than one DL and receives DL1 treatment by application of applicable industry standards for accident monitoring instrumentation, as shown in Table 7.1-1.

Defense Line 2 (DL2) contains plant functions (e.g., anticipatory reactor trips) designed to control or initiate responses to Postulated Initiating Events (PIE), especially Anticipated Operational Occurrences (AOO), before any parameters reach a Defense Line 3 (DL3) actuation setpoint. Functions that normally operate to actively control reactor parameters are also part of DL2 (e.g., blocking control rod withdrawal).

DL3 contains plant functions that act to mitigate a PIE (i.e., AOO or Design Basis Accidents (DBA)) by preventing fuel damage when possible, assuring the integrity of the barriers to release, and placing the plant in a safe state. DL3 also includes functions credited to maintain the plant in a safe condition following mitigation of PIE, until normal operations are resumed. Primary DL3 functions include reactor scram, Reactor Pressure Vessel (RPV) and containment isolations, and Isolation Condenser System (ICS) to mitigate the consequences of AOOs or DBAs. DL3 functions are needed when DL2 is not effective at intercepting a PIE or when a PIE is simply beyond the capabilities of the DL2 functions.

DL3 is credited to mitigate PIEs independent of DL2 and DL4a and is therefore required to be independent from DL2 and DL4a to the extent practicable. GEH defines practicable in this context as possible. Exceptions related to the I&C systems are cases where probabilistic safety analyses indicate safety is improved by the sharing of components (e.g., including hydraulic scram in DL2, DL3, and DL4a and using the DL4a Fine Motion Control Rod Drives (FMCRD) Fast Motor Run-in function to back up the hydraulic scram).

DL4 comprises two subsets of functions, designated as Defense Line 4a (DL4a) and Defense Line 4b (DL4b) functions. DL4a functions place and maintain the plant in a safe state in case of PIE with failure of the DL3 functions (i.e., Design Extension Conditions (DEC) without core damage). The need for DL4a functions generally arises when specific, postulated Common Cause Failures (CCF) occurring in DL3. The DL4a functions will actuate for any condition that satisfies the actuation criteria logic.

DL4a is used to mitigate PIEs that are not mitigated by DL2 (e.g., because the baseline plant response would be the actuation of DL3 functions – typically DBAs) and provides a second credited defense line for such PIEs (after DL3). DL4a is designed to work in tandem with DL2 to ensure all AOOs and DBAs resulting from a single failure are mitigated by two defense lines among DL2, DL3, and DL4a. Accordingly, DL4a is not required to be independent and diverse from DL2. DL4a can be used, along with unaffected DL2 functions, to mitigate a PIE as part of the same event sequence (i.e., to act as a single defense line and not as two independent defense lines in an DEC analysis). All AOOs and DBAs resulting from a single failure are required to be mitigated by DL3 and separately by DL2, DL4a, or a combination of DL2 and DL4a. DL2 and DL4a are not credited to mitigate the same PIEs independently of each other and are therefore not required to be independent from each other.

DL4b provides protection for extreme events, multiple (i.e., combined) events, or multiple failures that defeat DL2, DL3, and DL4a. DL4b functions prevent or mitigate a severe accident while keeping radioactive releases to acceptable levels. DL4b is required to be independent of DL2, DL3, and DL4a to the extent practicable, with exceptions documented and justified.

The DL independence requirements are consistent with the defence-in-depth strategy (i.e., the crediting of defense lines in the Fault Evaluation and Deterministic Safety Analyses).

CNSC REGDOC-3.6, "Glossary of CNSC Terminology," (Reference 7.1-1) defines practicable as "Technically feasible and justifiable while taking cost-benefit considerations into account." Although not specifically required by the BWRX-300 Safety Strategy, there is independence between DL2 and DL4a to a level that does meet this definition of practicable; it is not justifiable or cost-effective to require full independence between DL2 and DL4a (i.e., the type of independence required between DL3 and DL2/DL4a). The only aspects of independence required between equipment performing DL2 and DL4a functions are electrical isolation and physical separation. These interface requirements stem from the different safety classifications of the equipment.

Defense Line 5 (DL5) includes emergency preparedness measures to cope with potential unacceptable releases in case the first four DLs are not effective. These are largely off-site measures taken to protect the public in a scenario involving substantial release of radiation. DL5 is supported by the accident monitoring instrumentation.

### **7.1.2 Instrumentation and Control System Classification**

The BWRX-300 Distributed Control and Information System (DCIS) is an integrated control and monitoring system for the power plant. The DCIS is arranged in three Safety Classified DCIS segments and a Non-Safety Class segment with appropriate levels of hardware and software quality corresponding to the system functions they control and their DL location, as described in Chapter 3, Section 3.2. The DCIS provides control, monitoring, alarming and recording functions. The various bus segments of the integrated DCIS are designed to operate autonomously.

The DL3 functions are assigned to Safety Category 1 and performed by Safety Class 1 (SC1) equipment, except with the following exceptions:

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

1. Structures, Systems, and Components (SSC) are only needed after the first 24 hours of the event are classified as Safety Class 2 (SC2), and
2. SSC are only needed after the first 7 days of the event are classified as Safety Class 3 (SC3).

The DL4a functions are assigned to Safety Category 2 and performed by at least SC2 equipment, except for SSC that are only needed after the first 7 days of the event, which are classified as SC3. DL4a functions complete the safety objective via an independent and diverse means of logic and actuation if the DL3 function is not completed due to a C10 failure.

The DL2 functions are assigned to Safety Category 3 and performed by at least SC3 equipment. The safety functions in DL2 must be performed independently from diverse DL3 functions providing protection for the same event.

The DL4b functions are categorized as Safety Category 3 and generally performed by at least SC3 equipment unless other requirements are justified.

The Safety Category 1 DCIS functions are allocated to the C10 system that requires minimal support equipment (e.g., no active systems such as Heating, Ventilation and Air Conditioning (HVAC) or cooling water for at least 72 hours). Safety Category 1 DCIS functions are implemented on C10 SC1 I&C system hardware and software platforms located in three separate divisional fire barrier rooms in the Reactor Building. The DL4a (i.e., Safety Category 2) and DL2 (i.e., Safety Category 3) DCIS functions are implemented in different subsystems of C20. The DL4a DCIS functions are implemented with SC2 equipment. The majority of the C20 SC2 equipment is located in its own fire barrier room in the Control Building with the remainder located in compartmentalized fire barrier rooms in the Reactor Building. The DL2 functions are implemented with SC3 equipment. The C20 SC3 equipment is located in two separate fire barrier rooms in the Control Building.

The C30 controllers for the Non-Safety Class equipment are designed to prevent random I&C component failures from initiating plant transients. Vendor supplied Non-Safety Class functions are input through a C30 gateway. The C30 DCIS functions can be implemented on vendor packages (or skids) located in a separate fire barrier room in the Control Building.

The system designations of C10, C20, and C30 represent an initial decomposition of the overall I&C systems based on safety classification. Further refinement of the system decomposition, based on functional grouping within a safety class and equipment selection, will be performed as the I&C Architecture design process progresses. This process is described in Subsection 7.4.2.2.

The BWRX-300 I&C DLs and classifications are shown in Figure 7.1-1.

### **7.1.3 Regulatory Requirements and Industry Standards**

The BWRX-300 I&C systems also comply with CSA N290.14:15 (Reference 7.1-2) using the International Electrotechnical Commission (IEC) 61513 (Reference 7.1-3) option in Table 1. The BWRX-300 I&C does not rely on IEC 61226:2009 (Reference 7.1-4) for compliance with CSA N290.14:15. Instead, the BWRX-300 uses Section 7 of IEC 61226:2020 (Reference 7.1-5) to identify applicable I&C equipment standards. A summary of the key system and equipment standards applied to the I&C systems based on IEC 61226:2020 is shown in Table 7.1-1. The overall I&C regulatory conformance plan is documented in a BWRX-300 Plant I&C Systems Nuclear Regulations and Standards Conformance Plan. The BWRX-300 I&C systems are based on the requirements of Canadian Nuclear Safety Commission (CNSC) REGDOC-2.5.2 (Reference 7.1-6), and CNSC REGDOC-1.1.2 (Reference 7.1-7).

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

Section 7.3 provides a summary of the alignment for each I&C system to the regulatory guidance in CNSC REGDOC-2.5.2 and the key industry I&C standards IEC 61513, Institute of Electrical and Electronics Engineers (IEEE) Std 603 (Reference 7.1-8), and IEC 63147 (Reference 7.1-9). Section 7.4 provides a summary of the alignment for the I&C system development process to the regulatory guidance in CNSC REGDOC-2.5.2 and the key industry I&C standards IEC 61513 and IEEE Std 603.

**Figure 7.1-1: DCIS Defense Lines and Classifications**

## **7.2 Instrumentation and Control System of Systems**

The three DCIS systems (i.e., C10, C20, and C30) are developed and integrated into the Defence-in-Depth (D-in-D) architecture, as described in Subsection 7.4.2. The DCIS systems are networked using a managed network switch scheme that allows the parts to operate independently and prevent faults from adversely affecting each other while appearing seamless to the plant operator. The BWRX-300 I&C segments are interconnected (networked) to support common services like alarming, Visual Display Units (VDU), recording and sending data to the Emergency Response Facilities while maintaining appropriate separation between the segments and providing for the necessary cyber security.

The BWRX-300 I&C systems architecture incorporates defensive cyber security features designed to meet regulatory requirements, as described in Subsection 7.4.4. Managed network switches are standard industrial components with a proven record for reliable and safe operation in similar network applications. The BWRX-300 cyber security architecture provides cyber security defensive levels. Data flow and communications between defence levels are managed by boundary devices that implement unidirectional flow where required to prevent a lower level from compromising a higher level. Isolation features that are provided at interfaces between systems with different classification levels are classified to the higher classification. Signals used from lower Safety Class equipment are not used to perform higher Safety Category functions in the higher Safety Class equipment.

### **7.2.1 Distributed Control and Information System**

The various DCIS systems are implemented on different hardware and software platforms appropriate to the safety classification of the functions they are performing, as indicated by the following colors in Figure 7.2-1:

- Red – C10, DL3 and SC1
- Green – C20, DL4a and SC2
- Blue – C20, DL2 and SC3
- Black – C30, No DL and Non-Safety Class
- Yellow – Enterprise network

The SC1 DCIS (C10) is completely isolated from the rest of the BWRX-300 DCIS except for the optically isolated data links provided through unidirectional boundary devices to SC3 (C20). The VDUs dedicated to C10 are the only mechanism by which the SC1 systems can be controlled. They can also be monitored by the C10 VDUs and be monitored, alarmed, and recorded in C20. The SC1 DCIS is divided into three divisions and those divisions are separately powered by the three divisions of the R10 electrical system. The three SC1 DCIS divisions operate completely independently from each other (except for voting) and from the lower safety class DCIS. Isolated information only flows in one direction through boundary devices to the SC3 networks so that SC1 system information may be alarmed, monitored, and recorded (but not controlled) with SC2 and SC3 equipment (e.g., VDUs, printers, alarm system, and historians).

C20 is divided into two DLs. One is DL4a and performs Safety Category 2 functions using SC2 equipment. The other is DL2 and performs Safety Category 3 functions using SC3 equipment. DL4a actuation logic operates on an analog-based I&C platform. It communicates status and diagnostic information to the DL2 portion of C20, which is based on digital I&C technology. The C20 DCIS is redundant and segmented into two parts. The two network segments are the Nuclear Segment and the Balance of Plant (BOP) Segment. The two bus segments are classified as SC3. The Nuclear Segment uses controllers classified as SC3. The BOP Segment interfaces with C30

and Non-Safety Class controllers to acquire information to support human-system interfaces (HSI) integration in C20. Both segments have their own redundant Unit Data Highway, and each independently provides the control and monitoring capability of nuclear and BOP I&C for their segment. Each segment has their own redundant network managed switches classified as SC3. Each segment can operate independently of the other (although it appears seamless to the operator). Each segment has associated VDUs, historians, and a common alarm system. The C20 segments use Triple Modular Redundant (TMR) and redundant controller architectures for various functions to support reliability goals or prevent adverse actuations for anticipated hardware component failures.

The Nuclear Segment supports the SC3 controllers (which include the major reactor control systems) by acquiring DL3 data from the C10, SC1 controllers via unidirectional boundary devices. It also acquires DL4a diagnostics.

The BOP Segment provides for control of the Non-Safety Class plant functions and controllers used mainly for power generation. It also provides gateways to interface non-native controllers to the BOP network segment. Although lower classified equipment, these functions use TMR controller architectures (referred to hereafter as TMR controllers) to prevent random I&C component failures from causing plant transients.

The I&C for DL4b is not implemented through the BWRX-300 DCIS.

### **7.2.2 Unit Data Highway Network**

The C20 and C30 DCIS components are connected to the two Unit Data Highway networks shown in Figure 7.2-1 using the general switch arrangement shown in Figure 7.2-2. The components are “dual ported,” specifically they are each connected to separate but redundant network switches. The switches are discussed in the next section, but the important reliability point is that either connection to the network for the component and either network switch provides full functionality; failovers are seamless. The controllers are either dual redundant or TMR and the connections and switches are dual redundant. The design is single-failure proof and components, and connections are monitored and alarmed. The various components can be replaced online without affecting either safety or power generation.

Because of the network managed switches, the network segmentation appears transparent to the operator in normal operation (i.e., any C20 VDU can monitor or control any C20 or C30 function). However, in the unlikely event either of the individual redundant network segments becomes unavailable, the remaining segment remains operational.

### **7.2.3 Network Managed Switches**

The blue lines in Figure 7.2-1 indicate that the redundant C20 networks appear as busses; in fact, they are a rapid spanning tree network of managed Ethernet switches as shown on Figure 7.2-3.

Each managed network switch provides standard Ethernet switch capability but also provides additional cyber security advantages because they have security features. These include identification of authorized equipment addresses (locking out unauthorized equipment even if it is connected to the network), the capability to ignore or not uplink (to other segments), the capability to control which nodes are allowed to communicate and the capability to alarm abnormal network traffic. Each switch is programmed to allow intercommunication only between defined nodes and to refuse communication to or from a node whose identification has not been previously defined (i.e., a “stranger” plugging into the network). Only when a switch determines that an information data packet is destined for a node on another switch (and that communication is allowed) is the information put on an uplink to another switch. The network switches learn and maintain their own forwarding tables containing a list of the nodes and hosts on their respective network

segment. When a network switch receives a data communication packet, it forwards only that data packet to the segment to which the receiving host is connected. These protocols prevent data traffic between devices on the network from affecting devices on other segments of the network.

The uplink ports on the switches are connected radially and in a data communication ring because multiple interconnections increase reliability. Specifically, the switches use a “rapid spanning tree protocol” to automatically enable and disable ports so there is only one path from the nodes of one switch to another. Should a path become disabled, the switches automatically reconfigure to establish another path through the remaining switches and fiber optic cable paths. Reconfiguration requires no operator input and is usually accomplished in much less than a second.

The loss of one switch per segment has no effect on plant operation or data. The failure is indicated and is repairable with the system online. In the highly unlikely event of both switches of a segment simultaneously failing, that segment is lost. However, the remaining segments are unaffected and individual nodes connected to the failed switches can continue to function. The remaining switches then automatically reconfigure their uplink ports such that the remaining segments automatically find available data paths between each other. No switch or network failure can adversely affect DL3 / Safety Category 1 functions because DL3 is isolated from these networks by unidirectional boundary devices.

As described in the previous section, each switch “node” (workstation, display, and controller) is connected to redundant switches of the segment. These connections support normal plant operation. Each switch has redundant power feeds and can work from either power source. The switches and connected controllers support extensive component and data self-diagnostics, and failures are indicated. Finally, the switches are connected to a cyber security monitoring system that provides alarms for intrusion detection (or more likely, intrusion attempts) even if the switches and the network remain unaffected. Additionally, each switch has the capability to monitor, control, reject, and report unexpected and excessive (“data storm”) traffic on its respective network segment.

The BWRX-300 I&C network is not a single network and therefore network failures cannot be the result of a single failure. The networks are redundant and segmented to support the I&C systems with high reliability. The BWRX-300 I&C networks are highly fault tolerant no single network failure can adversely affect plant operation.

#### **7.2.4 Plant Data Highway Network**

Figure 7.2-1 shows the Plant Data Highway. The communications on the nuclear and BOP Unit Data Highways are rigorously controlled and monitored; the managed switches control the information sent to the Plant Data Highway managed switches forming the Plant Data Highway. The Plant Data Highway is used for important but non-essential and non-control services like printers, plotters, long-term data storage (the current requirement is to keep plant data for at least two years). Information sent off-site is through the unidirectional boundary devices, the intent is to send plant data (typically once per second) through the unidirectional boundary device to the server. Various lower cyber security levels of users are connected to the server, including the on-site or off-site Emergency Response Facilities and utility business or engineering networks that may have their own cyber security restrictions. Only the server can respond to off-site requests for information and the only information it has is the data sent to it through the unidirectional boundary devices. No plant DCIS component receives or has to respond to or is able to respond to an off-site data request. No off-site component can “reach” the Plant Data Highway and the network managed switches would not allow any such communication to reach the Plant Data Highway or C20 and C30 Unit Data Highways.

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

Access to plant cyber essential assets is appropriately protected and any external or business networks in the plant, including the control rooms, is always physically “air gapped” with access control such that they cannot be inadvertently connected to the plant DCIS networks even though the network managed switches would support such a connection.

NON-PROPRIETARY INFORMATION

Redundant network UDH nuclear and BOP segments and PDH are actually pairs of network managed switches.

Most equipment and all controllers, operator workstations and historians are dual ported, one port to each switch.

Any redundant switch can be lost without affecting plant operation.

Any segment can be lost without affecting the other segments.

Managed switch uplinks (inter-switch communication) normally allow any segment controller, historian or workstation to send/receive data to any other.

Dark black links indicate normal switch communication, the lighter black links represent possible connections should ports fail or be shut down for self diagnostic monitoring reasons.

Managed switches control which nodes are allowed to communicate and can prevent any unauthorized internal or external communication.

Managed switches have dual power supplies.

Conceptual Cyber Security monitoring connections shown. Other cyber security configurations are possible.

### 7.3 Distributed Control and Information System Functions

The Reactor Mode Switch is an input to the DCIS that inserts or removes operating bypasses for the actuation functions. It is common to the DLs. The Reactor Mode Switch is classified as a C10 SC1 component. The Reactor Mode Switch is a four-position switch with the following positions:

- RUN
- STARTUP
- SHUTDOWN
- REFUEL

The switch is manually positioned by the operator as the reactor is transitioned from cold (refueling outage) to rated power. The switch position determines and provides information to the various controllers needing the Reactor Mode Switch position information to provide the correct interlocks for system operation. As an example, the DL3 logic requires the Reactor Mode Switch position to be in STARTUP to enable a scram at ~15% power and in the RUN position to enable the high power flux scram. DL2 logic requires the Reactor Mode Switch to be in STARTUP to enable the Wide-Range Neutron Monitoring (WRNM) short period anticipatory scram and to disable the short period anticipatory scram in the RUN mode.

A block diagram of the Reactor Mode Switch is shown in Figure 7.3-1. The Reactor Mode Switch is located in the MCR to support normal plant operation. The Reactor Mode Switch is not needed to support any of the functions performed in the SCR.

The switch provides four positions to three divisions of C10 SC1 I&C and isolated signals to an additional four separate systems via separate section of a rotary switch. Each section is isolated from the other sections:

- C10 Three Divisions (DL3 / SC1)
- C20 Diverse Protection System (DPS) (DL4a / SC2)
- C20 Anticipatory Trip System (ATS) DL2 / SC3)
- C20 Automatic Power Regulator DL2 / SC3)
- C20 Rod Control and Information System (RC&IS) (DL2 / SC3)

A contact is closed in the selected switch position to provide “continuity” to or from the receiver. The other three (not selected) received switch positions have no continuity. From the point of view of the receiver there are always three positions with no continuity and one position with continuity. The Mode Switch positions sent to the C20 DL4a (SC2) and C20 DL2 (SC3) systems are received by TMR controllers that are used to validate the Mode Switch input signals.

The receiving system logic determines the resolution of “broken” switch positions. For example, the DL3 fail-safe systems trip for multiple switch positions or no switch positions. Fail-as-is systems generally alarm and stop their processes. The Automatic Power Regulator takes the plant out of automation and the RC&IS blocks control rod motion. The systems alarm for inconsistent switch positions.

#### 7.3.1 System C10 – Defense Line 3 / Safety Class 1

The three divisions of the C10 SC1 I&C systems are powered by three separate divisions of the R10 electrical system. Each of the three divisions uses an Uninterruptible Power Supply (UPS) each backed by its own division of 72-hour batteries. The UPS and the battery chargers can be

powered by off-site power or either of the standby diesel generators. The C10 SC1 I&C system actuation functions are designed as fail-safe if power to the C10 signal acquisition, trip determination, or actuation devices is lost, sensor failure and sensor communication is lost or voting communication is lost the reactor scram, RPV and containment isolations, and the ICS is automatically initiated to remove decay heat. Fail-Safe, as defined for the BWRX-300 design, is the ability of a system or component to move to a predetermined state when a failure occurs that ensures no harm comes to equipment, people, or the environment. This definition is more restrictive than defined for fail-safe in CNSC REGDOC-3.6 (Reference 7.3-1), which is defined as the ability of a system or component to move to a predetermined safe state when a failure occurs, and the most probable failure modes do not result in a reduction of safety.
