- Identification, categorization and grouping of PIEs
- Identification of the plant functions expected to be credited in the safety analysis and their assignment to a functional DL (DL2, DL3 and DL4)

The fault evaluation scope is the list of potential PIEs generated by the hazards evaluation (see Subsection 15.1.3) and includes:

- Complete range of operating modes
- All radioactivity sources (reactor core and outside core)
- Single failure PIEs, CCF PIEs, and fault sequences developed based on the success or failure of mitigating functions. Single and CCF PIEs include equipment failures and human errors. CCF are analyzed as software platform or mechanical failures.

The output of the fault evaluation is documented in a fault list. The fault list establishes traceability between the plant design and the safety analysis. The fault evaluations start in parallel with or prior to DSA and PSA activities. DSA and PSA mature with the design and the fault list is updated accordingly.

The fault evaluation process used for PIE identification and selection complies with CNSC REGDOC-2.4.1, Section 4.2, "Events to be analyzed" (Reference 15.3-1).

The fault evaluation includes the following activities as shown in Chapter 3, Figure 3.1-2 BWRX-300 Safety Strategy Implementation Process.

- Deterministic PIE Selection
- Complex Sequence Selection
- Severe Accident Scenario Selection

### **Deterministic PIE Selection**

The deterministic PIE selection is the systematic process in organizing and selecting events for deterministic safety analyses. The activities performed during the deterministic PIE selection are described in Subsection 15.2.1. Selected PIEs and fault sequences are allocated to three DSA types in a fault list:

- PIE List for Baseline Deterministic Safety Analysis (BL-DSA)
- PIE/Fault Sequence List for Conservative Deterministic Safety Analysis (CN-DSA)
- PIE/Fault Sequence List for Extended Deterministic Safety Analysis (EX-DSA)

### **Complex Sequence Selection**

Complex sequences are fault sequences involving failures of multiple mitigating features, which have not been included in the deterministic PIE selection but are identified in the Level 1 PSA as having the potential to lead to core damage with a frequency of occurrence or consequences judged to require analysis and DL mitigation function. These complex sequences are added to the fault list and analyzed in the EX-DSA (Subsection 15.1.5).

## **Severe Accident Scenario Selection**

The scope of severe accident sequence selection corresponds to those sequences involving significant core damage, which could lead to a breach of containment and radioactive release in the Level 2 PSA that is described in Section 15.6. To the extent that core damage is not practically eliminated, representative severe accident sequences (DECs with core damage) are postulated and analyzed in the SAA. The primary objective of the severe accident sequence selection is to identify representative core damage scenarios and define corresponding plant damage states that are used as the basis for performing the SAA. The selected SA scenarios are documented in the fault list and are analyzed in the SAA (Subsection 15.1.6).

### **15.2.1 Basis for Categorization of Postulated Initiating Events, Accident Scenarios and Fault Evaluation**

The hazard evaluations described in Subsection 15.1.3 results in the list of potential PIEs. These potential PIEs are evaluated, categorized, and grouped during the fault evaluation in the deterministic PIE selection. The hazard evaluations address a complete range of plant modes of operation, all sources of radioactivity and any consequential failure that occurs because of the PIE. During design development, the hazard evaluation is validated, and PIE selection is updated accordingly.

The activities included in the deterministic PIE selection and their bases are presented below:

1. Fault Sequences development – a Fault Sequence is developed starting with a PIE and considers the success or failure of the required mitigating functions. The DL of each credited mitigating function is established for each Fault Sequence.
2. Fault sequences are grouped into fault groups based on similar impact on a certain plant parameter: for example, events that lead to pressure increase in the reactor such as inadvertent closure of the Turbine Stop Valves and/or Turbine Control Valves or inadvertent closure of the Main Steam Reactor Isolation Valve(s) (MSRIVs) are grouped in the pressure increase fault group. Subsection 15.2.3 includes the output of the grouping activity.
3. Fault sequences are categorized within each fault group as AOO, DBA or DEC based on their frequency of occurrence. Subsection 15.2.2 describes this categorization.
4. Plant conditions are defined corresponding to each PIE supporting the scenario analysis.
5. Any exceptions are applied or justified to the standard PIE selection.

Fault sequences are allocated to three types of DSAs:

- BL-AOO and Baseline Design Basis Accident (BL-DBA) – Baseline DSA
- CN-AOO and CN-DBA –Conservative DSA
- EX-DEC –Extended DSA

A bounding set of PIEs and fault sequences that result in the most significant challenge to the FSFs are selected for evaluation in the DSA. DSA layers and events categories are combined so that limiting baseline events are AOO (BL-AOO), the limiting CN events are DBAs (CN-DBA) and limiting EX events are DECs (EX-DEC). This notation is used to identify the layer and event category.

Subsection 15.2.4 describes the bounding event selection for each fault group that is captured in a fault list. In addition, the fault list includes the complex sequences and the severe accident scenarios specified in Subsection 15.2.4.

A description of the three deterministic safety analyses aligned with the functional DLs (DL2, DL3 and DL4a) is included below.

#### **15.2.1.1 Baseline Deterministic Safety Analysis**

The primary objective of the BL-DSA is demonstrating the effectiveness of the DL2 functions. The scope of BL-DSA includes single failure PIEs categorized as bounding BL-AOOs and BL-DBAs. The BL-DSA models the expected response of the plant (no failure is postulated) to demonstrate that the event meets applicable acceptance criteria. The analysis end point is the controlled state condition. The mitigating DL functions credited in BL-DSA are DL2 functions. If a DL2 function fails or is not effective, then the corresponding DL3 function is credited.

#### **15.2.1.2 Conservative Deterministic Safety Analysis**

CN-DSA primary objective is demonstrating the effectiveness of DL3 functions. The CN-DSA scope includes events categorized as bounding CN-AOOs and CN-DBAs:

- PIEs due to single failure
- PIEs due to spurious CCF in DL2 or DL4a
- Baseline PIEs with postulated passive CCF of DL2 functions that were credited in BL-DSA

The CN-DSA is performed using conservative initial conditions with established acceptance criteria and applying a graded approach in quantifying the uncertainties (see Subsection 15.5.1.1). Single failure criterion is applied to DL3 SC1 SSCs. CN-DSA credits only DL3 mitigation functions. The end point of the analysis is a controlled state condition.

#### **15.2.1.3 Extended Deterministic Safety Analyses**

The EX-DSA primary objective is assessing the effectiveness of DL4 functions. The EX-DSA scope includes events categorized as DEC:

- PIEs due to spurious CCF of DL3 functions
- DBA fault sequences with postulated passive CCF of DL3 mitigating functions
- Complex sequences identified by the Level 1 PSA

An extended sequence for AOOs and DBAs is required in the following conditions:

1. If a DL3 function is credited to mitigate a single failure PIE in the BL-DSA, then the DEC fault sequence assumes a passive CCF in DL3 functions (no additional mitigation single failure is assumed).
2. If the hydraulic scram action is credited in an BL-AOO scenario, then the hydraulic scram action is assumed to have a mechanical CCF of the hydraulic scram where only the Control Rod Drive Motor (CRDM) run-in functions insert control rods. No additional failures are assumed.

#### **15.2.2 Categorization of Events According to Their Frequencies**

One fundamental element of the deterministic PIE selection (Section 15.1) and fault sequence selection is the assignment of fault sequences to categories based on their frequency of occurrence that complies with CNSC REGDOC-2.4.1, Sections 4.2.2.5 and 4.2.3, and CNSC REGDOC-2.5.2, Section 5.4.3:

- Anticipated Operational Occurrence (frequency greater than 1E-02 per reactor-year)
- Design Basis Accident (frequency between 1E-02 and 1E-05 per reactor-year)

- Design Extension Condition (frequency less than 1E-05 per reactor-year)

Qualitative frequencies are adopted as an interim measure and are used in the early design stages to progress the performance of deterministic analyses prior to availability of more mature PSA information. Quantitative frequencies based on Level 1 PSA results are adopted as the final, governing measure of the event sequence category.

A fault sequence consists of a combination of a PIE and can include an assumed failure of a mitigating function(s). The event sequence category is based on the sequence frequency not only the PIE frequency. The event category assigned to an event sequence may be different than the event category assigned to the PIE that initiated the sequence because the event sequence may include additional failures that make the sequence less likely to occur.

In addition to the event categorization frequency, the categorized events are allocated the following DSA types:

- Baseline Anticipated Operational Occurrence (BL-AOO)
- Conservative Anticipated Operational Occurrence (CN-AOO)
- Baseline Design Basis Accident (BL-DBA)
- Conservative Design Basis Accident (CN-DBA)
- Extended Design Extension Condition (EX-DEC)

### **15.2.3 Grouping of Events According to Type**

One of the steps in fault evaluation is grouping the events according to their type. The fault evaluation includes external events, internal events, human operational errors, functional failures evaluated in hazard analysis, Level 1 PSA complex sequences and Level 2 PSA severe accident sequences.

PIEs (faults) are grouped according to the resultant change in plant parameter:

- Temperature decrease events – decrease in core coolant temperature
- Pressure increase events – increase in reactor pressure
- Reactivity increase events – reactivity and power distribution anomalies
- Inventory increase events – increase in reactor coolant inventory
- Inventory reduction events – decrease in reactor coolant inventory
- Non-reactor fault events – these events are non-core related such as fuel handling accident
- Radiological faults having dose consequences

Once the fault groups are identified, then the anticipated core physics response associated with each group is then selected. Once each group is identified, then the bounding fault sequence from that group is selected.

Table 15.2-1 provides the fault groups with an explanation of how anticipated core physics response (reactor response) was considered in development of the groups. Within these groups, fault sequences with similar responses are compared and used to select the bounding events.

#### **15.2.3.1 Core Reactivity Effects of PIEs and Accident Scenarios**

The anticipatory effects of core reactivity response provided in Table 15.2-1 are discussed below with focus on AOOs, DBAs, and DECAs without core damage because these are event categories where the core remains intact, and the reactivity feedback mechanisms are well understood.

##### **Void Reactivity**

Void reactivity is an important reactivity feedback mechanism in BWR transient and accident analyses. The void reactivity feedback is always negative and is typically stronger (more negative void coefficient) at the end of an operating cycle. It is also stronger for reload cores versus an initial reactor core that includes only fresh fuel. This reactivity feedback mechanism is the dominant feedback for some PIE groups. Table 15.2-1 focuses on events initiated from conditions of normal power operation. In the DSA, where it is important, void reactivity is modeled using 3-D kinetics coupled with the thermal hydraulic response analyzed using Transient Reactor Analysis Code General Electric (TRACG), the primary DSA computer code (see Subsection 15.5.1.2).

##### **Moderator Temperature Reactivity**

The moderator temperature coefficient of reactivity is defined as the change in reactivity produced by a unit change in moderator temperature. The value of this coefficient is important during the startup of a BWR. During power operation, the coefficient is not important, because the moderator is boiling and remains at the saturation temperature corresponding to the operating pressure. In addition, moderator density changes caused by boiling are much larger than changes from moderator temperature changes and therefore, mask any effects. The BWRX-300 core is designed and evaluated to conform to regulatory requirements as discussed in Chapter 4, Sections 4.2 - 4.4. Moderator temperature feedback is accounted for in the DSA analysis of startup conditions when coolant temperature is key to the event response and there is no significant voiding in the core. Once core boiling/voiding begins, void reactivity feedback becomes dominant.

##### **Control Reactivity**

Neutron absorbing control rods are the primary means to control reactivity in transient and accident analyses. During events that result in relatively fast positive reactivity feedback, control rods are inserted rapidly using stored hydraulic energy. This is referred to as a “scram”. During events that result in relatively slow positive reactivity feedback and do not require a reactor “scram”, the Fine Motion Control Rod Drive (FMC RDs) that are operated using electric motors can be used for slower control rod insertion, (see Chapter 4, Subsection 4.5.1). Reactivity feedback mechanism is key for some PIEs groups (see Table 15.2-1) in which rods are withdrawn in error. Control reactivity is modeled using 3-D kinetics coupled with the thermal hydraulic response in TRACG.

##### **Doppler Reactivity**

Doppler reactivity is a less important reactivity feedback mechanism in BWR transient and accident analyses than void or control reactivity. Doppler reactivity is negative with an increase in fuel temperature and becomes more important as the fuel temperature continues to increase. In DSA where reactivity feedback is important, doppler reactivity is modeled using 3-D kinetics coupled with the thermal hydraulic response in TRACG.

##### **Boron Reactivity**

For the BWRX-300, boron reactivity insertion (see Appendix 15B) is only needed for long-term shutdown in very low probability events where the hydraulic and electric motors fail to insert a sufficient number of control rods.

## **Xenon Reactivity**

Xenon reactivity feedback is not typically accounted for during events in DSA because the rate of change of reactivity is slow. The effects of xenon are accounted for in analyses of shutdown margin.

### **15.2.4 Postulated Initiating Events and Accident Scenarios**

PIEs and event frequency are first determined qualitatively based on system conceptual design, previous similar designs, and operating experience. PIEs are evaluated in the fault evaluation (see Section 15.2) where they are further screened for inclusion in the fault list.

The bounding event selection is performed for events that are initiated at full power conditions (Mode 1 operating condition) because they are expected to result in the most significant challenge to the fission product barriers.

Bounding events are selected in each fault group, for each event category (e.g., AOO, DBA, DEC without core damage) and for the applicable DSA layer (e.g., baseline, conservative and extended). The resulting events selected are listed in Table 15.2-2 and analyzed in Section 15.5. DEC events with core damage are part of the PSA and SAA.

The bounding event selection is performed for two event categories:

- Transient or non-LOCA described in Sections 15.2.4.1 through 15.2.4.6
- LOCA scenarios described in Section 15.2.4.7

### **Bounding Event Selection for Transient Events**

Bounding events are selected for the transient (non-LOCA) DSA that pose the most challenges in meeting the derived acceptance criteria.

The selected bounding events are summarized in Table 15.2-2. Table 15.2-2 also points to a complete description of the bounding event in the DSA described in Section 15.5.

#### **15.2.4.1 Decrease in Core Coolant Temperature Bounding Event**

Events that result in core coolant temperature decreases are grouped as Temperature Decrease (TD) faults. A reduction in coolant temperature (at the core inlet) has the potential to challenge the fuel cladding barrier due to increasing reactivity as a result of reducing the core coolant void fraction. The Reactor Coolant Pressure Boundary (RCPB) is not challenged because there is not a significant increase in steam flow and normal pressure control is not affected. Because this is a reactivity driven event, it is only of concern when the reactor is not shutdown.

The largest source of coolant supply is from the FW pumps. FW flow enters the RPV downcomer through the FW piping. Extraction steam from the turbine is directed to heat FW in multiple stages of FW heaters. Failures, such as loss of extraction steam, can result in a reduction of the temperature entering the RPV.

The Isolation Condenser System (ICS), Control Rod Drive System (CRD), Reactor Water Cleanup System (CUW) and the Shutdown Cooling System (SDC) also have inflows to or outflows from the RPV that have the potential to reduce the coolant temperature. Inadvertent ICS initiation PIEs are included in the increase in reactor coolant inventory fault group. These systems can only reduce the coolant temperature a small fraction relative to Feedwater Heating (FWH)-related PIEs. Therefore, only FW heater related PIEs are considered potentially bounding.

There is no fault group for increase in core coolant temperature for the following reasons:

1. The Feedwater (FW) temperature is near the highest temperature that is feasible during normal operation.
2. Any increase in FW temperature would increase the core void fraction and reduce core power due to the decrease in void reactivity.
3. An increase in FW temperature does not result in an increase in core temperature because the core is boiling and remains at saturated conditions.

Other than an increase in the FW temperature, the core coolant temperature may increase due to the following conditions:

- Core power increase resulting in a small increase in pressure covered by the reactivity and power distribution anomalies fault group
- Reactor pressure increase that effects saturation temperature covered by increase in reactor pressure fault groups

Therefore, any possible increase in FW temperature is small and results in a small decrease in power and poses no threat to fission product barriers resulting in no need for an increase in core coolant temperature fault group.

The selected events result in the most significant challenge to the fission product barriers in the fault group. The selected events are summarized in Table 15.2-2.

#### **Bounding AOO Event Selection**

The event effect on the fuel Critical Power Ratio (CPR) and core power increase is used in selecting the bounding AOO events for this group.

The AOO that results in the largest reduction in FW temperature is the Loss of Feedwater Heating (LFWH) event. This BL-AOO event described in Subsection 15.5.3.1.1 is the bounding AOO event for this category.

#### **Bounding DBA Event Selection**

The bounding CN-DBA event described in Subsection 15.5.4.1.1 resulting in the largest postulated reduction in FW temperature is the CCF leading to loss of all FW heaters. The event effect on fuel Peak Cladding Temperature (PCT) is used in selecting the bounding DBA in this group.

#### **Bounding DEC Without Core Damage Event Selection**

There are no DEC events in this fault group because the DLs are established in the baseline and conservative DSA. No complex sequences in the fault group are identified.

#### **15.2.4.2 Increase in Reactor Pressure Bounding Event Selection**

Events that result in RCPB pressure increase are referred to as Pressure Increase (PI) faults. During full power operation, steam generated in the reactor exits the RPV through the Main Steam Lines (MSLs). There are normally open valves in the each MSL: Two Main Steam Reactor Isolation Valves (MSRIV) and one main steam Containment Isolation Valve (CIV). Outside containment, there is a main steam header upstream of the Turbine Stop Valves (TSVs). Downstream of the main steam header the TSVs are in series with the Turbine Control Valves (TCVs).

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The MSRIVs and CIVs close to isolate the RPV or containment. The TSVs and TCVs close to protect the turbine. Turbine Bypass Valves (TBVs) located in the main steam equalizing line in the Turbine Building (TB) allow steam to bypass the closed TSV or TCV.

Pressure increase faults are generally caused by closure of valves in the steam flow path. Closure of a single MSRIV terminates steam flow in one of the two MSLs. Closure of any two of these valves in separate MSLs causes a complete isolation of the MSLs upstream of the TBVs. Closure of both TSVs and/or TCVs, terminates steam flow to the turbine. A turbine trip or load rejection signal initiates closure of the TSVs and TCVs, and fast opening of the TBVs. When RPV pressure increases, TBVs are opened by the normally operating Reactor Pressure Control (RPC) which allows up to ~25% of the rated steam flow to the main condenser.

The selected events result in the most significant challenge to the fission product barriers in the fault group. The selected events are summarized in Table 15.2-2.

There is no fault group for decrease in reactor pressure because a pressure decrease reduces reactivity. The decrease in reactor pressure is caused by either:

- Reactor power decrease that is covered by the reactivity at power distribution anomalies fault group
- Reactor coolant inventory is lost that is covered by the decrease in reactor coolant inventory fault groups.

Therefore, there is no need for a decrease in reactor pressure fault group.

#### **Bounding AOO Event Selection**

The event effect on the fuel CPR, core power increase, and the RCPB pressure are used in selecting the bounding AOO events for this group.

There are several AOO events in the PI group in the fault list. Most of the AOOs are PIEs that result in closure of the TSVs, TCVs or both. These events present similar challenge to the cladding and RCPB, and all of them are selected as potentially limiting (bounding) events:

- Turbine trip, load rejection
- Loss-of-preferred power
- Loss of condenser vacuum

Another AOO in this group is the BL-AOO closure of one Main Steam Reactor Isolation Valve (MSRIVC). The MSRIVs do not close as fast as the TCVs or TSVs; however, the MSRIVs are upstream of the TBVs, resulting in this event selected as a potentially limiting.

#### **Bounding DBA Event Selection**

The event effect on PCT and the RCPB pressure are parameters used in selecting the bounding DBA events for this group.

There are several DBA events that result in increased pressure in the PI group. There are two main types assumed in the PI group:

1. AOO events where the TSV or TCV closes with a CCF of the DL2 mitigation equipment
2. CCF results in closure of the MSRIV and FWRIV

Because the TCV fast closure is faster than the MSRIV closure, the closure of the TCVs with failure of the DL2 mitigation functions is a more significant pressure increase event. However,

because several of these events result in similar challenges to acceptance criteria, several CN-DBA events (described in Subsection 15.5.4) are chosen as potentially bounding.

### **Bounding DEC Without Core Damage Event Selection**

The event effect on PCT and the RCPB pressure are parameters used in selecting the bounding DEC events for this group.

The main types of PI group DEC events are:

1. Bounding AOO events with failure of the hydraulic scram due to postulated CCF of the hydraulic components
2. Complex sequence AOO event with half of the control rods fail to insert either by HCUs or with the CRD motors run-in
3. CCF in DL3 functions initiating events

The events assume a CCF of the hydraulic scram that significantly challenges the fuel cladding and RCPB because the CRD motor run-in that backs up the hydraulic scram results in slower negative reactivity insertion. Several of these events are selected as potentially bounding. The event result from CCF in DL3 functions are not concerning because sufficient non-DL3 functions initiate the hydraulic scram.

In the TSV and TCV closure events, pressure control is achieved (at least momentarily) via the TBVs to the main condenser. In the loss of condenser vacuum and LOPP AOO events with failure of the hydraulic scram, the main condenser is available for a limited amount of time. These events result in more severe pressurization and are selected as potentially bounding relative to the turbine trip and load rejection events. The 1MSRIVC AOO with failure of the hydraulic scram is also selected.

A complex sequence is also considered in this fault group based on the PSA evaluation. This event is selected as a potentially limiting event.

### **15.2.4.3 Reactivity and Power Distribution Anomalies Bounding Event Selection**

Events that result in reactivity and power distribution anomalies are grouped as Reactivity Increase (RI) faults. These events include failures in reactivity control that challenge the fuel cladding or RCPB integrity. The BWRX-300 controls reactivity with control rod movement. Normal control is accomplished using FMCRDs, which are individually connected to the control rods. HCUs are used to quickly shutdown the reactor by inserting control rods, ensuring reactivity control during off normal operation. Increases in reactivity can result from control rod withdrawal, an error in fuel loading, or control rod drop.

The selected events result in the most significant challenge to the fission product barriers in the fault group. The selected events are summarized in Table 15.2-2.

### **Bounding AOO Event Selection**

The fault list includes only one RI-AOO. This event is Inadvertent Control Rod Withdrawal at Power – Single Rod (ICRW). However, this event is not evaluated because a protection function of Automatic Thermal Limits Monitor (ATLM) initiates a control rod block. The event conditions remain within normal operation conditions; therefore, no analysis is needed. The design description of the ATLM is found in Chapter 7, Subsection 7.3.3.2.

### **Bounding DBA Event Selection**

The event effect on PCT and cladding integrity are the parameters used in selecting the bounding events for this group.

There are several DBA PIEs in the RI group to postulate in identifying the bounding event including the withdrawal of single or multiple control rods. The DBA PIEs are all mitigated by active DL2 functions ATLM and Multi-channel Rod Block Monitor (MRBM) that result in minimal change to core power in the baseline sequence. The ATLM blocks rod motion before departure from normal operation and MRBM blocks rod motion before significant fuel effects occur. These mitigation functions are reliable resulting in a failure sequence in the DEC frequency range. These events with the failure of ATLM and MRBM are selected as bounding DEC without core damage events because of the low frequency of the sequence. The following fault sequences are evaluated.

1. CCF - All Control Rod Insertion at Power - (CCF-ACRI): For some core conditions, this event may result in a momentary increase in reactivity in the top part of the core because higher density water moves up the core faster than the rod motion. As the rods insert, high density coolant increases the reactivity above the control rods. This is a momentary effect, does not challenge fuel cladding criteria or any other fission product barrier, and is not selected as a bounding event.
2. Fuel Loading Error (FLE): This event postulates that two fuel assemblies are swapped during refueling or a single assembly is inserted in a rotated position (180 degrees from normal). This can result in small local increase in reactivity. This event is selected as a potentially limiting DBA event.
3. Control Rod Drop Accident: (CRDA): This event postulates a fault that allows separation of the control rod from the drive mechanism (design precludes a separation such as this due to a separation detection device). The control rod becomes stuck and remains in its position when the drive mechanism is attempted to be withdrawn. Before the stuck rod is detected and is inserted, the control rod becomes unstuck and falls. This event is not a limiting RI condition and not explicitly analyzed because the design includes separation detection devices that limits the drop to a small distance, resulting in no significant reactivity changes. This event is listed in Mode 2 (startup conditions) because it is limiting at those conditions. However, the event is possible at normal full power operations.

### **Bounding DEC Without Core Damage Event Selection**

The event effect on PCT and cladding integrity are the parameters used in selecting the bounding DEC events for this group. There are two control rod withdrawal error DEC events that are potentially limiting:

- Single rod withdrawal
- Inadvertent withdrawal of all rod groups

These DEC without core damage are compared to applicable acceptance criteria demonstrating that features to prevent core damage are adequate and no further complementary design features are required.

#### **15.2.4.4 Increase in Reactor Coolant Inventory Bounding Event Selection**

Events resulting in an increase in reactor coolant inventory are included as Inventory Increase (II) faults. These events may occur from a FW Inventory Increase. Inadvertent ICS initiation scenarios do not fit well into any fault group and are included in this increase in inventory event category. Inadvertent ICS initiation results in much less Inventory Increase than a FW increase. However, the dynamics of ICS flow into the chimney is different than an increase in FW flow. These scenarios are selected for analysis.

Other systems such as CRD, CUW, SDC or Boron Injection System (BIS) may result in inventory increases. However, these systems have low flow rates compared to FW and are not considered as bounding.

The events selected result in the most significant challenge to fission product barrier in this fault group and the selected events are summarized in Table 15.2-2.

#### **Bounding AOO Event Selection**

There is one BL-AOO event, Inadvertent Isolation Condenser Initiation – One Train, and it is selected for evaluation.

#### **Bounding DBA Event Selection**

The event effect on PCT and coolant inventory are the parameters used in selecting the bounding events in this group.

Two CN-DBA events are selected:

- Inadvertent injection of all ICS trains (bounds one train) (Inadvertent Isolation Condenser Initiation – All Trains (CCF-IIICI))
- Feedwater Flow Increase - All Pumps (CCF-FWFI). This event bounds the CN-DBA event for increase in flow of one FW pump.

#### **Bounding DEC Without Core Damage Event Selection**

There are no DEC events identified in the II fault group because for each single failure AOO or DBA PIE, there are two DLs established that mitigate the event. No AOO events credit the hydraulic scram. For all CCF PIEs, a DL is established.

#### **15.2.4.5 Decrease in Reactor Coolant Inventory Bounding Event Selection**

Events that result in a decrease in reactor coolant inventory are included as Inventory Reduction (IR) events. These events may occur from failures that result in:

- Reduction or loss in FW flow
- Opening of TBVs
- Pipe breaks (LOCA events) (discussed in Subsection 15.2.4.7)
- Misalignment of systems connected to the RPV
- Loss-of-preferred power (this event is included in the PI group)

The IR bounding events selection only includes non-LOCA events. In this fault group, maintaining inventory above the top active fuel ensures fuel cladding integrity. For non-LOCA events, there is no significant challenge to the RCPB or containment.

The selected events result in the most significant challenge to the fission product barriers in the fault group. The selected events are summarized in Table 15.2-2.

#### **Bounding AOO Event Selection**

The event effect on coolant inventory is the parameter used in selecting the bounding AOO events in this group. There are two BL-AOO events in this group:

- FW pump trip - one pump (FWPT)
- Inadvertent opening of one TBV

The FWPT event is selected as potentially limiting because the TBV opening represents less inventory loss than the FW pump trip and FW makes up inventory loss during the TBV opening.

### **Bounding DBA Event Selection**

The event effect on the coolant inventory are the parameters used in selecting the bounding DBA events for this group.

There are several PIEs events in the IR group:

- Loss of all FW flow
- Opening of all TCVs and TBVs
- RPV Pressure Control Open

The selected bounding event is Loss of FW flow (LOFW) CN-DBA event. FW may also be lost by a FW isolation valve closure DL4a CCF (BL-DBA) but is not selected because this is less severe than LOFW. This is also less frequent and is categorized as a DEC when combined with a CCF of DL2 mitigation. The RPV Pressure Control Open (CCF-RPCO) is selected as potentially limiting for events where inventory is lost via the main steam line.

LOCA events bound these events because they result in a more significant challenge to the RPV inventory (fuel cooling and long-term cooling) and challenge containment temperature and pressure. The non-LOCA DBA events are not bounding for this IR fault group.

### **Bounding DEC Without Core Damage Event Selection**

The event effect on PCT and coolant inventory are the parameters used in selecting the bounding DEC events for this group.

The FW Isolation EX-DEC event is selected as a potentially limiting event; however, it is not expected to be a significantly different response than the CN-DBA event. LOCA events bound this event, and the non-LOCA events are not bounding for this IR fault group.

#### **15.2.4.6 Bounding Event Selection for LOCA Scenarios**

The initiating events involving pipe breaks, scram, and trip initiation are identified in the fault list for Baseline (BL), Conservative (CN) and Design Extension Conditions (DECs). The evaluation scenarios are then selected to bound groups of pipe breaks. The consequences of postulated LOCAs are analyzed for fuel cladding and containment integrity and shown to meet the design basis acceptance criteria in Table 15.3-2. CN-DSA LOCA analyses demonstrate that the reactor level does not decrease below the Top of Active Fuel (TAF) or the fuel cladding does not exceed the normal operating temperatures. Meeting these acceptance criteria assures the fuel cooling acceptance criteria in Table 15.3-2 are met. The CN-DSA LOCA analyses also demonstrate that the containment acceptance criteria in Table 15.3-2 are met.

The bounding scenarios for pipe breaks fall into two categories:

- Large breaks inside or outside containment
- Small breaks inside or outside containment

The breaks in each category may be in steam pipes or liquid pipes. CN-DSA sequences are mitigated by DL3 functions alone, assuming a CCF of DL2 functions. EX-DSA fault sequences (DECs) are mitigated by DL2 and DL4a functions (see Table 15.5-50 DL2 and DL4a functions credited).

Pipe breaks attached to the RPV may be as large as the complete rupture of the largest steam or feedwater pipes, or as small as leaks in smaller pipes attached to the RPV. Although the

frequency of the largest breaks is lower than  $1\text{E-}05/\text{year}$ , all sizes of pipe breaks resulting from various PIEs are conservatively analyzed as DBAs. Further, the largest breaks are instantaneous double-ended guillotine ruptures of the large pipes. This assumption is made to bound the thermal hydraulic response of the fuel, RPV and containment for all isolatable pipe breaks.

The bounding LOCA events provided in Table 15.2-2 and evaluated in Subsections 15.5.4.6 (LOCA inside containment) and 15.5.9.2 (LOCA outside containment) provide the assumptions and DL components used in mitigating the event with the corresponding signals, times, and other design parameters.

A break between the RPV and the Reactor Isolation Valves (RIV) is not a credible postulated accident. Breaks inside containment are postulated to occur at any arbitrary location between the outer RIV, or the flow limiter for MS pipes, and the containment boundary.

### **Large Breaks**

Pipes that are larger than 19 mm (0.75 in) inside diameter have two isolation valves attached directly to the RPV. The largest postulated pipe breaks are in the main steam, feedwater, and ICS lines. These pipes have RIVs, which close in less than 5 seconds once they start closing. Another 5-second delay is assumed before a RIV starts closing to account for delays in break detection and signal development. A break between the RPV and RIVs is not credible as a postulated accident in the current fault list.

MS pipes are also equipped with a flow limiter to prevent very large break flow prior to MS RIV closure. The flow limiters are placed close to the RPV. Breaks on the MS pipes are postulated to occur downstream of the flow limiter.

The analytical limit for the high containment pressure setpoint is reached within 1 second for large breaks (steam and liquid). Peak containment pressure occurs at approximately the time RIVs are fully closed and the break is isolated. The largest steam pipe breaks and the largest liquid pipe breaks are the most limiting for containment response because they have the highest mass and energy release until the break is isolated. For medium size breaks that are isolated on high containment pressure, there may be a delay in reaching the containment high pressure setpoint for isolation. However, containment pressure is increasing at a slower rate than it would for a larger break while the RIVs are closing. Because the RIV closure time is the same for all breaks, the containment peak pressure is smaller for a medium size break than it is for a large break.

Since the largest breaks are more limiting for the mass and energy release, fuel integrity and containment integrity, a break spectrum analysis is not required for isolatable breaks. This is also the case for breaks outside containment since they are isolated by the leak detection system in a similar manner.

The leakage detection system is designed to detect breaks in large pipes connected to the RPV. If the break is not detected, a conservative assumption is that the break remains unisolated since no operator action is credited.

For large break LOCAs, RIVs close rapidly and prevent significant loss of RPV inventory. The core remains covered throughout. The remainder of the event after the RIVs are closed is an isolation event during which the ICS has ample capacity to remove the decay heat and depressurize the RPV and maintain fuel cooling for at least 72 hours. Fuel integrity is not a concern for large breaks. In the long-term Passive Containment Cooling System (PCCS) reduces containment pressure.

### **Small Breaks**

The smaller pipes connected to the RPV have an inside diameter  $\leq 19$  mm, do not have automatic RIVs, and are considered unisolated breaks. Small unisolated breaks may also occur in larger pipes. The leakage detection system detects breaks in large pipes connected to the RPV but may not be capable of detecting breaks that are smaller than the area of a circle with a 19 mm diameter. If the break is not detected, it is assumed to remain unisolated for 72 hours for CN sequences because no operator action is credited for this duration.

Small breaks conservatively credit only two of the three isolation condensers even though a break of less than 19 mm equivalent diameter on an isolation condenser does not cause degradation in the isolation condenser heat removal rate. There is sufficient steam in the RPV to feed the condensation in the isolation condenser. Not having sufficient steam in the RPV to feed the isolation condenser can only occur if the RPV is depressurized so far that almost all of the steam is escaping the break. This would be the case if the RPV pressure is even lower than that calculated for an instrument pipe break. However, in this case the break flow is less than the break flow calculated for an instrument pipe break, making the isolation condenser small break less limiting than the instrument pipe break. It can be concluded that whether the break flow rates are the same for a small steam pipe break regardless of the break location, or the RPV pressure is too low to feed the isolation condenser, the breaks on isolation condenser steam pipes are no more limiting than a break on an instrument steam pipe break.

For unisolated breaks, the RPV inventory is depleted faster as the break area becomes larger. The largest of the unisolated breaks is most limiting with respect to RPV inventory. Peak containment pressure is also higher as the break size is increased for an unisolated break.

### **Large and Small Pipe Break Summary**

The largest break sizes are the most limiting for isolatable (i.e., in the large break category) and un-isolatable (i.e., in the small break category) breaks.

In selecting the scenarios to evaluate for the pipe breaks, each of the sequences in the fault list is assessed with respect to the largest mass and energy release to containment and RPV inventory. Additional conservative assumptions that are described in Subsections 15.5.4.6 and 15.5.9 were made in constructing the bounding scenarios to reduce the number of analysis cases. Therefore, the bounding scenarios analyzed for pipe breaks in large and small break categories are scenarios bounding all scenarios in that category. However, the liquid and steam pipe breaks are analyzed separately.

The following common features are used in selecting the bounding sequences for pipe breaks:

1. A pipe break does not cause loss of feedwater or loss of normal containment cooling unless a direct or indirect effect of the pipe break causes the pump(s) to trip. Feedwater and normal containment cooling are lost concurrent with the break for the sequences involving a pipe break concurrent with Loss-of-Preferred Power (LOPP). This observation is used to determine whether the breaks are more limiting with or without LOPP.
2. All scrams credited in the LOCA analyses are direct scrams. A scram signal is initiated when the setpoint of the first scram function is reached for the scram functions that are available in the credited DL. Scram functions and setpoints in each DL and the trip parameters are provided in Subsections 15.5.4.6 and 15.5.9 and meet the guidance of CNSC REGDOC-2.4.1, Section 4.4.4.4.
3. In the CN-DBA sequences, a CCF of DL2 functions concurrent with the pipe break are assumed and credit only DL3 functions.

4. In the EX-DEC sequences, CCF of DL3 functions are assumed in the analysis and credit only DL2 and DL4a mitigation functions.

The guidelines for considering CCFs in the design and safety analyses are discussed in Chapter 3, Subsection 3.1.7.8.

The system responses, including the direct and indirect effects of large and small pipe breaks, are described in Subsections 15.5.4.6 and 15.5.9.

#### **15.2.4.6.1 Large Steam Pipe Breaks**

Large steam pipe breaks are postulated to occur in the following systems:

- Main Steam (MS) pipes
- ICS steam supply pipes

For breaks inside containment, scram is initiated on high containment pressure (DL3-07). For breaks outside containment, scram is initiated on detection of a steam pipe break (DL3-09).

MSRIV closes on high containment pressure for breaks inside containment (DL3-22), and on MS pipe break detection for breaks outside containment (DL3-20). ICS RIVs close for an ICS train when an ICS break inside or outside containment is detected in the respective ICS train (DL3-27, 28 or 29).

Because the isolation valves close rapidly, the effect on isolation condenser availability is not significant for large breaks mass and energy releases. After break isolation, one ICS is sufficient to remove decay heat and depressurize the RPV. As a bounding assumption, only one ICS train is credited for MS and ICS pipe breaks. This assumption is made so that an ICS steam supply break is bounded by an analyzed MS pipe break. One ICS train initiates on high containment pressure (DL3-15) for breaks inside containment. One ICS train initiates on pipe break indication detection (DL3-16) in MS or ICS pipes outside containment.

For a MS pipe break, the total break flow is the sum of break flows from both ends of the break. To bound all break locations, the break location is assumed as close to the RPV as possible, right outside the second or outboard RIV. Because two MS lines are connected through a header, the intact steam pipe also supplies the break location from the turbine side of the break. Break flow from the turbine side of the break is contributed by the flow from the RPV into the intact loop and the initial inventory in the piping. To maximize flow from the turbine side of the break, the isolation valves outside the containment are assumed to remain open, and TSV/TCV close rapidly. Because closure of CIVs outside containment are not credited, the calculated mass and energy release is applicable to breaks inside and outside containment.

If the break occurs when the plant is at very low power or hot shutdown, break flow from an MS pipe break may be higher due to carryover. At low power, there is more saturated water in the RPV to flash. This may increase the two-phase downcomer level much higher than that in the rated initial conditions case, contributing to the break flow due to increased liquid content although the break flow enthalpy is lower. In calculating the radiological consequences for breaks outside containment, the break mass flow rate for hot shutdown initial conditions may be more limiting. Both the rated initial conditions and the hot shutdown initial conditions are included in the bounding scenarios for MS pipe breaks.

The above scenario assumes LOPP concurrent with the break is bounding for the scenario when preferred power is available. If the preferred power is available, FW will continue to be injected to the RPV, which may increase mass release to the containment due to carryover. However, if preferred power is available, TSV/TCV also remains open, discharging much of the steam in the

intact loop to the turbine rather than to the break from the turbine side of the break location. As a result, the break scenario with LOPP is the more bounding scenario.

### **Bounding CN Scenario for Large Steam Pipe Breaks**

The bounding scenario analyzed MS pipe breaks inside and outside containment concurrent with LOPP:

The case is analyzed for rated initial power and hot shutdown conditions. The limiting break scenario is analyzed in Subsection 15.5.4.6.1.

#### **15.2.4.6.2 Large Liquid Pipe Breaks**

Large liquid breaks may occur in:

- FW pipe
- ICS condensate return pipe
- CUW pipe

The largest pipe from this list is the FW pipe and is analyzed in Subsection 15.5.4.6.2.

A large break in the ICS condensate return pipe is listed as a liquid break because the condensate return pipe is filled with water initially. However, this water is highly subcooled. The ICS condensate return valves are normally closed and the steam supply pipe is in communication with the RPV during normal operation. If a pipe break occurs at the condensate return pipe, the highly subcooled water in the condensate pipe is purged. The energy release to containment for a break inside containment or to the ICS pool for a break outside containment from the purged highly subcooled water is insignificant. After the liquid inventory in the pipe is depleted, the break flow becomes steam flow supplied from the RPV through the steam supply pipe until the RIVs close for the broken ICS unit.

The ICS steam supply pipe is fitted with a 70 mm inside diameter orifice at the steam distribution pipes. Therefore, flow from a break in the condensate pipe is only steam flow through a 70 mm orifice after the subcooled water is purged. This is less limiting than a break in the ICS steam supply pipe included in the large steam pipe break cases. This pipe break requires no further analysis because it is included in the large steam pipe break category for CN sequences.

CUW pipe breaks may occur inside or outside the containment. CUW pipe is a smaller-bore pipe and CUW breaks are isolated the same as the FW pipe breaks. Therefore, the CUW pipe breaks inside containment are bounded by the FW pipe breaks. CUW pipe breaks are routed through the same compartments that house the FW pipes in the reactor building. Therefore, CUW pipe breaks outside containment are also bounded by the FW pipe breaks for reactor building pressure and temperatures.

The limiting liquid pipe breaks inside and outside the containment are the FW pipe breaks. The break isolation, scram, and ICS initiating are discussed below.

### **Bounding CN Scenario for Large Liquid Pipe Breaks**

For a pipe break inside containment, scram is initiated on high containment pressure (DL3-07). For breaks outside containment, scram is initiated on pipe break indication in FW or ICS pipes (DL3-09). Scram does not occur for the CUW pipe breaks outside containment.

In accordance with the fault list, preferred power is available for CUW breaks outside containment and FW injection continues.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

LOPP concurrent with a break is assumed for the FW pipe breaks inside the containment. The TCV is conservatively assumed to close rapidly with LOPP. In the LOPP cases, there is flow from the pump side of the break before the CIVs close outside containment at 10 seconds due to pump coast down, but more importantly, due to flashing of the water in the FW piping. If the FW pumps continue running in spite of the break when preferred power is available, there is some increase in flow from the pump side of the break. However, normal containment cooling also continues to run when preferred power is available, compensating for the effect on containment pressure from an increase in the flow from the pump side of the break.

For breaks outside containment in the RB pressure and temperature calculations, the cases with and without FW running are included.

The radiological consequences for breaks outside containment uses the LOPP case that is more limiting. FW pump flow has no consequence because flow coming from the FW pump is decontaminated water and can only retard the break flow coming from the RPV through the intact loop. Only the water leaving the RPV is important in the radiological analyses that is higher if the pump is not running.

For breaks inside containment, RIVs close on high containment pressure (DL3-22). CIVs outside containment also close on high containment pressure (DL3-22).

For FW pipe breaks outside containment, FW RIVs close on break detection. MS RIVs also close on break detection (DL3-21).

For CUW pipe breaks outside containment, only CUW RIVs close on break detection (DL3-26).

For breaks inside containment, ICS is initiated on high containment pressure (DL3-15).

For FW and ICS pipe breaks outside containment, ICS is initiated on-line break detection (DL3-16). For CUW breaks outside containment, ICS initiation is not needed since preferred power is available.

### **Bounding Scenario Summary for Large Liquid Pipe Breaks**

The bounding liquid pipe break for containment response is analyzed for a FW pipe break inside containment:

- Double-ended guillotine FW pipe break inside containment concurrent with LOPP
- TSV/TCV are conservatively assumed to close rapidly retaining more energy
- FW pump trips and coast down
- Scram initiation within 1 second after the break
- ICs initiate on high containment pressure
- MS and FW RIVs start closing in 5 seconds and are fully closed in 10 seconds
- FW CIVs outside containment start closing in 5 seconds and are fully closed in 10 seconds
- FW conservatively assumed to trip at time zero and coasts down with a 3 second time constant

The bounding liquid pipe break scenario outside containment is similar to breaks inside containment with the following differences:

- CIVs are conservatively assumed not to close
- FW pump trip may or may not occur. Area pressure and temperature calculations consider both cases. The radiological analyses conservatively assume a FW pump trip

The above scenario does not rely on any scram or isolation function that is a result of the LOPP. Therefore, the same scenario bounds both preferred power available and LOPP cases.

#### **15.2.4.6.3 Small Breaks**

Small, unisolated steam or liquid pipe breaks may occur in instrument lines. Small breaks in the large pipes may also remain unisolated if they are below the leak detection system threshold, i.e., less than 19 mm inside diameter. The lowest location for a liquid pipe break is four (4) meters above the TAF.

Small breaks are analyzed using conservative assumptions demonstrating that fuel and containment integrity are maintained for at least 72 hours using only passive systems after which injection is recovered and the event is terminated. The LOCA acceptance criterion for demonstrating fuel integrity is to show that fuel cladding does not heat-up beyond normal operating temperature. This satisfies the fuel integrity acceptance criteria in Table 15.3-2 with large margin.

The fault list includes unisolated small breaks inside and outside the containment, with and without concurrent LOPP.

The bounding CN sequences in the fault list for a small break concurrent with LOPP are evaluated with respect to the fuel cladding and containment. For a break inside containment concurrent with LOPP, normal containment cooling system is also assumed to be lost. The energy discharged from the break to containment is removed by the PCCS (discussed in Chapter 6, Section 6.3.3) and through the containment dome. PCCS does not require actuation; it is always in service.

When the preferred power is available, FW continues to run. Because the FW pump can make up for the break flow, fuel integrity is not a concern. If preferred power is available, normal containment cooling also continues to run. If the normal containment cooling and PCCS cannot keep up with the break flow and containment pressure increases, the reactor scrams, isolation condensers initiate and RPV depressurizes reducing the break flow. Containment cooling continues to operate maintaining containment pressure at a lower value than PCCS alone maintains in the LOPP case.

The bounding small liquid and steam pipe break scenarios are the same, the only difference is the discharge from the small liquid pipe break is initially from the liquid water space. It becomes steam flow after level falls below the RPV nozzle elevation of the broken pipe.

Following an unisolated break in an instrument pipe concurrent with LOPP, turbine pressure decreases rapidly resulting in a decrease in the steam pipe pressure and an increase in steam flow. Although a consequential closure of TCVs may occur on LOPP, this is not credited in the analysis. TCV is assumed to remain in its initial position. Scram is initiated when the steam pipe pressure decreases to low steam pipe pressure setpoint (DL3-02) with a 1.7 second delay. Power is assumed to remain at the initial value for an additional 2 seconds to account for the time elapsed until prompt fission power is diminished after the control rods start inserting. MSRIVs also start closing on low steam pipe pressure (DL3-17) over 5 seconds and are fully closed in 10 seconds.

FW pumps trip concurrent with LOPP and coast down with a 3 second time constant.

All available ICS train condensate return valves start opening with a delay of 1 second when the level falls to L2 level setpoint (DL3-14). Only two isolation condenser trains are assumed available. ICS condensate return valves are fully open 10 seconds after they start opening. There are no further actuations assumed for the remainder of the event.

Mass and energy releases from small pipe breaks do not credit containment back pressure for breaks inside containment. In addition, reactor scram and isolations initiated by high containment pressure are also not credited. Therefore, the above scenario applies to breaks outside containment as well as breaks inside containment. Because a break outside containment occurs from a longer pipe, break mass and energy releases calculated for a break inside containment bounds a small break outside containment.

### **Bounding Small Pipe Break**

The bounding scenario is summarized as follows:

- Small steam or liquid pipe break concurrent with LOPP
- FW pump trips and feedwater flow coasts down with a time constant of 3 seconds
- Pressure controller failure, TSV/TCV position remain open at their initial position
- Reactor scrams when steam pipe pressure decreases to low steam pipe pressure setpoint with a 1.7 second delay
- MSRIV closure when steam pipe pressure decreases to low steam pipe pressure setpoint with a 5-second delay
- ICS initiation when level is less than L2

### **Bounding Scenarios for DEC Pipe Breaks**

DECs assume DL3 CCF in addition to the pipe break. Only DL2 and DL4a functions are credited in DECs. There is either a DL2 or DL4a function for all credited DL3 functions in Table 15.5-49, except the isolation condenser pipe breaks. Because the heat removal by the ICs is a higher-class safety function than isolation by a DL4a function, no DL4a associated function exists. An unisolated isolation condenser pipe break is similar to an unisolated MS pipe break and is evaluated separately subject to different acceptance criteria.

DL2 and DL4a functions performing the same function for the credited DL3 functions are listed in Table 15.5-50. The setpoints and timing of these functions are the same as or close to the DL3 functions. Therefore, except for the isolation condenser pipe breaks, the analyzed design basis LOCA analyses bound the DEC pipe breaks for the isolatable large pipe breaks and un-isolatable small breaks.

**Table 15.2-1: Fault or Event Groups and Explanation of Core Reactivity Response Basis**

Name (ID)	Description	Discussion of Reactivity Effects
Temperature Decrease (TD)	Decrease in Core Coolant Temperature	Void reactivity is key. The decrease in temperature results in an increase in the core inlet subcooling. More core thermal power goes into heating up the water and less into void production. The core void fraction decreases and causes the power to increase. This is a relatively slow increase in core power due to the thermal inertia of the coolant.
Pressure Increase (PI)	Increase in Reactor Pressure	Void reactivity is key. Pressurization results in decrease of core voids and increase in core power. For rapid pressurization, control rod scram is needed to mitigate. Core exposure effects on void reactivity and control rod position are important aspects that are modeled and included in the analysis.
Reactivity Increase (RI)	Reactivity and Power Distribution Anomalies	Control rod reactivity is key. Errors or failure in control rod movement are expected event initiators as these events add reactivity and change the local and core wide power. Fuel loading errors are also included.
Inventory Increase (II)	Increase in Reactor Coolant Inventory	Void reactivity is key. An increase in coolant inventory results in a reactor water level increase. The increase in reactor water level normally has the following effects: <ul style="list-style-type: none"> <li>- Core flow increase (small reactivity effect at rated power conditions)</li> <li>- Core inlet subcooling increase (because the additional inventory is expected to be from lower temperature coolant, larger reactivity effect than the core flow increase)</li> </ul> These effects tend to increase void reactivity.
Inventory Reduction (IR)	Decrease in Reactor Coolant Inventory	Void reactivity is key. The decrease in reactor water level has the following potential results: <ul style="list-style-type: none"> <li>- Core flow decrease (small reactivity effect at rated power conditions)</li> <li>- Core pressure decrease (if break in coolant pressure boundary cannot be compensated for by pressure control)</li> <li>- Core inlet subcooling decrease (comes with pressure decrease)</li> </ul> These effects tend to insert negative reactivity, resulting in core power decrease, due to void reactivity. It is typical in loss-of-coolant accident analysis to ignore these effects as the protection systems typically act quickly to insert control rods and shutdown the core before the negative void reactivity feedback has significant effect.
Non-Reactor Faults	Event specific. These events are not core related.	Fuel Handling Accident

### **15.3 Safety Objectives and Acceptance Criteria**

Implementation of the safety objectives established by the IAEA Safety Standards Series No SF-1 Fundamental Safety Principles ensure that the BWRX-300 facility when operated achieves the highest standard of reactor safety that can be reasonably achieved. The IAEA SF-1 Safety Objectives are discussed in Chapter 3, Subsections 3.1.1. and 15.1.2.

The deterministic and probabilistic safety analysis acceptance criteria are based on or derived from ensuring that the dose acceptance criteria of CNSC REGDOC-2.4.1, Section 4.3.2 (Reference 15.3-1), and CNSC REGDOC-2.5.2, Section 4.2.1 (Reference 15.3-2) are met.

#### **15.3.1 Deterministic Safety Analysis Acceptance Criteria**

The BWRX-300 design complies with acceptance criteria of CNSC REGDOC-2.4.1, Section 4.3.2 (Reference 15.3-1), and the established dose acceptance criteria in CNSC REGDOC-2.5.2 Section 4.2.1.

CNSC REGDOC-2.5.2 (Reference 15.3-2) states “that acceptance criteria shall be assigned to each plant state in the design, considering the principle that frequent PIEs have only minor or no radiological consequences, and that any events that may result in severe consequences are of extremely low probability.”

Qualitative acceptance criteria are defined and met for each AOO and DBA to confirm the effectiveness of plant systems in maintaining the integrity of physical barriers against releases of radioactive material. Safety goals are defined in REGDOC-2.5.2, Section 4.2.2 and are discussed in Chapter 3, Section 3.1.2.

Derived qualitative and quantitative acceptance criteria are used to analyze AOOs or DBAs. Qualitative acceptance criteria are supported by experimental data, prescribed by regulatory requirements, or prescribed by applicable codes and standards. The results of the quantitative safety analysis confirm the derived acceptance criteria (i.e., the limiting event in an event group).

Certain accidents with a predicted frequency of occurrence less than  $1\text{E-}5/\text{rx-yr}$  DECAs may be used as design basis events for a safety system. In this case, the results are compared to the DBA dose limits, and qualitative acceptance are established. The DBA derived acceptance criteria are used as screening criteria to evaluate core damage and are used as input in determining the PSA safety goals.

The committed whole-body dose for average members of the critical groups who are most at risk, is calculated in the DSA for a period of 30 days after the analyzed event. As stated in Section 3.1.2, the calculated dose is less than or equal to the dose acceptance criteria of CNSC REGDOC-2.5.2, Section 4.2.1:

- 0.5 millisievert (mSv) for any AOO
- 20 mSv for any DBA

The dose results provided in Section 15.7 from the limiting events identified in Section 15.5 demonstrate that the radiological consequences of the analyzed events do not exceed the AOO, and DBA acceptance criteria listed in Tables 15.3-1 and 15.3-2, respectively.

##### **15.3.1.1 Acceptance Criteria for Analysis of Anticipated Operational Occurrences**

CNSC REGDOC-2.4.1, Section 4.3.2 requires derived acceptance criteria be established for AOOs and DBAs per CNSC REGDOC-2.4.1, Section 4.3.4. The derived acceptance criteria for the DSA of AOOs are shown in Table 15.3-1. These derived acceptance criteria are based upon the fission product barrier or FSF.

#### **15.3.1.2 Acceptance Criteria for Analysis of Design Basis Accidents**

CNSC REGDOC-2.4.1, Section 4.3.2 requires derived acceptance criteria be established for AOs and DBAs per CNSC REGDOC-2.4.1, Section 4.3.4. The derived acceptance criteria for the deterministic safety assessment of DBAs are shown in Table 15.3-2.

#### **15.3.2 Acceptance Criteria for Probabilistic Safety Assessment**

The safety goals for the PSA of core damage frequency, small release and large release frequencies are shown in Table 15.3-3 and are consistent with the quantitative safety goals in CNSC REGDOC-2.5.2, Section 4.2.2.

**Table 15.3-1: Anticipated Operational Occurrence Deterministic Safety Assessment Acceptance Criteria**

Fission Product Barrier or Fundamental Safety Function	Qualitative Acceptance Criteria	Quantitative Acceptance Criteria
General	An AOO will not escalate to a more serious plant condition unless other faults occur independently.	Not applicable
	There is no loss of function of any fission product barrier.	Not applicable
Fuel Rod	Loss of fuel rod mechanical integrity will not occur due to fuel melting.	The calculated maximum fuel center temperature $T_{\text{center}}$ remains below the fuel melting point $T_{\text{melt}}$ . Subsection 4.2.3.4 describes the method used in calculating the maximum fuel pellet temperature.
	Loss of fuel rod mechanical integrity will not occur due to pellet-cladding mechanical interaction.	The cladding strain acceptance criteria defined in Section 5.0 of Reference 15.3-4. Chapter 4, Subsection 4.2.3.4 describes the code methodology used in calculating the cladding strain acceptance criteria.
	Fuel rod failure will not occur due to overheating of cladding	The calculated core Minimum Critical Power Ratio (MCPR) ensures that 99.9% of the fuel rods in the core are not susceptible to boiling transition during AOO events. Chapter 4, Section 4.4.1 describes the establishment of the fuel cladding safety limit. With the reactor steam dome pressure less than 4.72 MPaG (685 psig), the calculated reactor thermal power is less than 25% of rated thermal power.
Reactor Coolant Pressure Boundary	Design conditions of the reactor coolant pressure boundary are not exceeded during the most severe pressurization transient.	The calculated peak pressure associated with the reactor coolant pressure boundary shall not exceed 110% of the design pressure or 11.38 MPaG (1650 psig).
	The reactor coolant pressure boundary maintains sufficient reactor coolant inventory for core cooling.	The calculated reactor water level is maintained at or above TAF.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Fission Product Barrier or Fundamental Safety Function	Qualitative Acceptance Criteria	Quantitative Acceptance Criteria
Primary Containment	Containment integrity is maintained. If an AOO results in an energy release to the containment, or loss of containment heat removal, then containment stresses (i.e., pressure and temperature) are limited such that there is no loss of a containment barrier safety function, and thus, the containment remains within its design limit values.	No AOOs result in a significant energy release to containment, or prolonged loss of normal containment cooling. The normal operation limits and conditions are applied to containment, and no AOO containment quantitative criteria is needed. Chapter 9, Subsection 9A.5.6 describes the containment cooling system functional design.
Long-Term Heat Removal	SSC important for preserving the integrity of the reactor core and the containment are capable of removing residual heat for an extended period both during and after all applicable PIEs considered in all Operational States, including AOOs.	Following AOO events that do not result in shutdown, a controlled condition is achieved.  Following AOO events that require shutdown, the core remains shutdown independent of operator action or offsite support for at least 72 hours.  AOO events that rely on DL3 mitigation for long-term cooling are capable of providing cooling for at least 72 hours without operator action or offsite support.

NON-PROPRIETARY INFORMATION

**Table 15.3-2: Design Basis Accident Acceptance Criteria**

<b>Fission Product Barrier or Fundamental Safety Function</b>	<b>Qualitative Acceptance Criteria</b>	<b>Quantitative Acceptance Criteria</b>
General	Except for fuel cladding, there is no loss of function of any fission product barrier.	Not Applicable
Fuel Rod Failure	The number of fuel rod failures is conservatively estimated for DBAs.	The calculated number of failed rods does not result in exceeding the applicable radiological dose acceptance criteria.
	Mechanical fracturing of a fuel assembly under DBA loading conditions does not result in losing the ability to cool the fuel assembly.	The mechanical integrity of the fuel is established from the mechanical and thermal fuel analysis described in Chapter 4, Subsection 4.2.2.
Fuel Cooling	The calculated fuel cladding temperature is maintained at an acceptably low value and decay heat is removed for the extended period of time required by the long-lived radioactivity remaining in the core.	The calculated PCT remains less than 1204°C (2200°F). The calculated total oxidation of the cladding nowhere exceeds 0.17 times the total cladding thickness before oxidation for DBAs where exceeding the oxidation thickness challenges the capability to cool the core.
Reactor Coolant Pressure Boundary	Design conditions of the reactor coolant pressure boundary are not exceeded during the most severe pressurization transient as a result of a DBA.	The calculated peak pressure associated with the RCPB shall not exceed 120% of the design pressure or 12.41 MPaG (1800 psig).
	The reactor coolant pressure boundary maintains sufficient reactor coolant inventory for core cooling.	Conformance is demonstrated by meeting the fuel cooling and long-term heat removal criteria.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Fission Product Barrier or Fundamental Safety Function	Qualitative Acceptance Criteria	Quantitative Acceptance Criteria
Primary Containment	Containment pressures and temperatures are maintained below the design values.	The calculated containment pressure does not exceed the design pressure 0.414 MPaG (60 psig). The calculated containment shell temperature does not exceed the design temperature 165.6°C (330°F).
	The local combustible gas concentrations in the containment are within the range where deflagration or detonation cannot occur.	Containment atmosphere remains sufficiently mixed such that deflagration or detonation thresholds are not exceeded.
	Containment energy management systems are capable of reducing the containment pressure and temperature following a DBA to minimize the release of fission products to the environment and to preserve containment integrity and leak tightness.	The calculated containment pressure reduces to less than 50% of the calculated peak pressure for the most limiting LOCA within 24 hours.
Reactivity Control	Reactivity control required to bring the reactor to cold shutdown is maintained.	Shutdown margin is established to assure that the reactor can be brought subcritical with the highest-worth control rod pair withdrawn when the core is in its most reactive condition. The subcriticality value is 0.38% $\Delta k/k$ with the highest-worth control rod pair analytically determined.
Long-Term Heat Removal	SSCs important for preserving the integrity of the reactor core and the containment are capable of removing residual heat for an extended period both during and after all applicable PIEs considered in all operational states, and DBAs.	Long-term cooling is maintained for a minimum of 72 hours independent of operator action and offsite support, and for 30 days with credit for operator actions and on-site resources.  For DBA events that result in shutdown, the plant can achieve and maintain safe-shutdown conditions with the average reactor coolant temperature below 215.6°C (420°F).

NON-PROPRIETARY INFORMATION

**Table 15.3-3: Probabilistic Safety Goals**

<b>Qualitative Acceptance Criteria</b>	<b>Derived Quantitative Acceptance Criteria</b>
Core damage frequency	The sum of frequencies of all event sequences that can lead to significant core degradation shall be less than $1\text{E-}5/\text{rx-yr}$ .
Small release frequency	The calculated sum of frequencies of all event sequences that can lead to any release to the environment that requires temporary evacuation of the local population or a release to the environment of more than $1\text{E}15$ becquerels of iodine-131, shall be less than $1\text{E-}5/\text{rx-yr}$ .
Large release frequency	The calculated sum of frequencies of all event sequences that can lead to any release to the environment that requires long-term relocation of the local population or a release to the environment of more than $1\text{E}14$ becquerels of Cesium-137 shall be less than $1\text{E-}6/\text{rx-yr}$ .

## **15.4 Human Actions**

The BWRX-300 design approach minimizes the complexity of the SSC design, while enhancing reliability and reducing the potential for human error. The systems and components are designed to reduce the necessity for human actions (refer to Chapter 18 Human Factors Engineering). Where complexity is necessary in the design (e.g., self-diagnostic tools, redundancy in equipment in a single division), the design complexity is documented and justified for enhancing reliability, surveillance, calibration, and other equipment attributes.

Chapter 18 discusses the human factors engineering and human-machine interface consideration during development of the facility design that facilitate interaction between operating personnel and the plant. Subsection 15.1.3 discusses the human operation hazard evaluation under the safety assessment framework.

Chapter 13 provides a program description to manage operational aspects that are affected by human factor considerations, including the continued review and development of measures in place. The chapter also describes the organizational provisions that ensure operators are able to effectively perform in the main and secondary control rooms and other parts of the plant under all operational circumstances, including proposed shift schemes and rotations, assessment of operator's fitness for duty, and other human factors related issues.

### **15.4.1 Human Actions in Deterministic Safety Analysis**

There are no operator actions credited in responding to the events analyzed in Section 15.5 for the DSA. This assurance is attributed to the following design features:

1. Fail-safe (not reliant on external power) safety system actuations ensure that the FSFs are fulfilled for a DBA
2. Automatic, reliable actuation of the control rods with either stored energy or motors to shut down the reactor and maintain it in a guaranteed shutdown state via latching mechanisms
3. ICS provides passive decay heat removal
4. Fail-safe containment isolation and passive containment heat removal

Critical safety parameter monitoring is provided in the Secondary Control Room (SCR) if the Main Control Room (MCR) becomes uninhabitable.

The HOHE identifies failures that involve an erroneous decision or action taken by a human that can lead to an unplanned plant transient that is evaluated as a PIE in the hazard analysis in Section 15.1.3.

### **15.4.2 Human Actions in Probabilistic Safety Assessment**

Human actions resulting from PSA event evaluations are discussed in Subsection 15.6.1.3.5.

## **15.5 Deterministic Safety Analysis**

### **15.5.1 General Description of the Approach**

The DSA is divided into two parts:

- Part One – the plant response to fault sequences is evaluated and analyzed to confirm the performance of the fission product barriers against the derived acceptance criteria
- Part Two - the event dose consequences resulting from a fission product release or other source of radiation, such as the reactor coolant, is radiologically analyzed

The DSA is performed based on the outputs of the hazard analysis and fault evaluations. There are three layers of DSA performed (see 15.1 and 15.2.1 for additional details) that credit different sets of DLs:

#### *Deterministic Safety Analysis Approach for Non-LOCA Events*

Transient DSA analyzes fault sequences where the reactor coolant pressure boundary remains intact. These events are broken down into groups that result in similar core responses. Section 15.2.4 describes the core response during off-normal conditions, the groups determined for BWRX-300 (Table 15.2-1), and the selected bounding event scenarios for AOO, DBA and DEC without core damage analyses (summarized in Table 15.2-2).

The BWRX-300 scenarios are identified through the fault evaluations. The methods and assumptions described in the TRACG Application for BWRX-300 (Reference 15.5-3) are used to confirm the performance of the fission product barriers for the DSA non-LOCA events. The TRACG Application for both non-LOCA and LOCA event analysis is discussed in Subsection 15.5.1.2.1.

The TRACG Application for BWRX-300 also includes the stability analysis that evaluates potential coupled thermal-hydraulic – neutronic instabilities in the reactor core. TRACG is used to perform transient safety analysis and stability analysis for both forced flow and natural circulation BWR designs. Previous TRACG applications as well as BWRX-300 use the systematic approach developed for the US NRC, called Code Scaling, Applicability and Uncertainty (CSAU) to confirm the applicability of a computer code for DSA. This approach involves systematic evaluation of the phenomena that are important for the plant design and accident scenarios identified. A qualitative process is used to identify and rank the importance of phenomena. Through this process a Phenomenon Identification and Ranking Table (PIRT) is established. The PIRT is used together with the TRACG documentation to systematically demonstrate the applicability of TRACG models and the qualification of the TRACG model to predict the phenomena. Defining the nodalization and evaluation of the effects of scale are included. In addition to code applicability and qualification, the PIRT is also used as the basis to perform quantitative uncertainty analysis of transient scenarios, if needed. Additional information regarding the approach for addressing uncertainty in the DSA is provided in Subsection 15.5.1.1

The TRACG applicability to model phenomena also requires that the code capability be demonstrated to apply the code in the intended manner with a qualifying result achieved. TRACG capability to model phenomena is important to BWRX-300 simulation and is consistent with modern best practices. TRACG qualification is based upon proven practices for verification and validation using acceptable codes and standards (see Chapter 3, Appendix 3G). Experiments and plant events used to validate TRACG provide evidence that TRACG can be applied for the BWRX-300 design.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Integral to the capability of TRACG for transient DSA is the use of three-dimensional nuclear kinetics input. This input comes directly from and essentially uses the same methods as the steady-state core simulator, PANAC11. PANAC11 is used in the BWRX-300 as described in Subsections 4.3.2 and 15.5.1.2.3. Other code interfaces are described in TRACG Application for the BWRX-300 (Reference 15.5-3).

Design control procedures require independent verification of safety analysis calculations to ensure that results are properly summarized from calculations, physically sound/correct, and consistent with expected results when compared to previous calculations. The results are then confirmed to meet the appropriate acceptance criteria. Table 15.5-48 "Conservatisms Used in the Non-LOCA DSA" provide additional insight in conservatisms used in the transient analysis.

*Deterministic Safety Analysis Approach for LOCA Events*

The methods and assumptions of the DSA confirming the performance of the fission product barriers for LOCAs are described in Licensing Topical Report (LTR) NEDC-33922P-A, Revision 3, BWRX-300 Containment Method (Reference 15.5-2).

TRACG calculates the mass and energy release from modeled breaks of various sizes and locations. Atmospheric pressure is used for the TRACG pressure boundary condition for any breaks. This approach provides no credit for the back pressure from containment. Consequently, the retained RPV inventory calculated by TRACG represents the minimum coolant volume. This modeling provides results as if the break occurred outside containment.

Breaks inside containment realistically experience back pressure from containment that reduces the mass and energy calculated by TRACG once the break flow becomes unchoked. However, this effect is not treated explicitly because it requires two-way coupling between the TRACG calculation and the GOTHIC containment calculation. Instead, the methodology has a one-way coupling with the mass and energy release rates conservatively calculated by TRACG that supplies inputs to the GOTHIC calculation up until the point in time when the containment and RPV pressures first equalize. Choked flow naturally satisfies the assumed one-way coupling because choked flow does not depend on the downstream pressure. Select TRACG inputs are specified so that mass and energy release rates are conservatively calculated.

Rapid mass and energy releases into containment occur before a large break is isolated. This leads to the highest containment peak pressure at approximately the same time that the break is isolated. For large breaks, the containment shell is the dominant short-term energy sink, and it causes containment pressure to decrease from its peak value after isolation of the break occurs.

Compared to large breaks, small unisolated breaks have a much slower mass and energy release rate from the RPV into containment. The lowest break on the RPV that remains unisolated and occurs outside containment produces the most limiting scenario for minimum RPV inventory. Regardless of break location and whether it is inside or outside containment, break flow slowly decreases with time because the RPV is being depressurized largely due to the ICS and to a much lesser extent by the break flow.

Containment pressure slowly increases and eventually equals the RPV pressure for breaks inside containment. It is not realistic to use the TRACG break flow that was calculated using an atmospheric pressure boundary condition as input to the GOTHIC containment calculation after the point in time when containment and RPV pressures first equal each other. A better approximation is to assume zero break flow after this point in time, but this could potentially be nonconservative with respect to the longer-term calculated containment pressures. The proposed methodology does not require the GOTHIC calculation to continue beyond the point where the containment and RPV pressures equalize, because the longer-term containment pressure is bounded by the RPV pressure calculated.

The methods and assumption for normal coolant radiological analyses are described for these events in Section 15.7.

#### **15.5.1.1 Safety Margins in Safety Analysis**

The safety margin is the result of the conservative assumptions used in the analysis and design rules applied to the SSC design capabilities. In addition, the DSA demonstrates that the challenges to the physical barriers do not exceed their physical capacity.

Uncertainties in initial conditions and methods are accounted for in the CN-DSA. The BL-DSA and EX-DSA allow best-estimate methods to be consistently applied using REGDOC-2.4.1, Section 4.4.2 guidance. For CN-DSA thermal-hydraulic analysis, a graded approach is used in combining uncertainties. The graded approach involves a qualitative assessment of the safety margin on a case-by-case basis and includes a review of the magnitude of results compared to acceptance criteria along with the judgment of conservatism in the derived acceptance criteria.

The DSA confirms the FSFs successfully keep plant radioactive material releases within the acceptance criteria with adequate safety margins.

##### **15.5.1.1.1 Large Margin**

For events with large margin or substantially non-limiting, there is no need to apply uncertainty to the analysis methodology. Judgment is used to establish what is “large margin” or “substantially non-limiting”. Instead of a quantitative evaluation of uncertainty, the event is dispositioned qualitatively based on the uncertainty evaluation performed for a limiting event of a similar type, historical analysis of similar type, or other qualitative based disposition.

#### **Large Margin Examples**

The inadvertent isolation condenser initiation in Subsection 15.5.4.4.2 and the closure of all MSRIVs and FWIVs in Subsection 15.5.4.2.4 are examples of large margin events. There are many DBA events that have minimal impacts compared to the acceptance criteria.

##### *Inadvertent Isolation Condenser Initiation*

This CN-DBA event results in a peak pressure of 7.32 MPaG, much lower than the acceptance criteria of 12.41 MPaG and is bounded by pressure increase CN-DBA events in Subsection 15.5.4.2.1. Also, the PCT is 307.9°C, much lower than the acceptance criteria in Table 15.3-2 and is bounded by the generator load rejection CN-DBA event in Subsection 15.5.4.2.1. In this event, there is no concern for cladding oxidation, and there is no threat to the containment pressure boundary.

##### *Closure of All Main Steam Reactor Pressure Vessel Isolation Valves and FW Isolation Valves*

This CN-DBA event results in a peak pressure of 8.73 MPa, much lower than the acceptance criteria of 12.41 MPaG. The peak pressure is bounded by other pressure increase CN-DBA events in Subsection 15.5.4.2. Also, the PCT is 312.47°C, much lower than the acceptance criteria in Table 15.3-2. This event has a large safety margin to the DBA acceptance criteria. In this event, there is no concern for cladding oxidation, and there is no threat to the containment pressure boundary. As a result, for the above events and any other events with similar margin, there is no need for any quantification of uncertainty and a qualitative disposition is adequate.

#### **15.5.1.1.2 Medium Margin**

In medium margin scenarios, method uncertainty is addressed by biasing key important phenomena in a conservative direction (typically one or two sigma). Input parameters such as power, pressure, level, temperature are based on using the most limiting normal operating values. In these cases, the selection of key important phenomena is dependent on the specific event evaluated. Important phenomena can be different for the output parameters when multiple output parameters are considered for selecting the bias direction. The selection of the key important phenomena and determining the bounding bias direction is considered for each output parameter that has medium margin and compared to the derived acceptance criteria.

#### **Medium Margin Example**

A medium margin event is the large break inside containment described in Subsection 15.5.4.6.

#### ***Large Pipe Breaks Inside Containment***

There are multiple large pipe breaks inside containment event scenarios evaluated that have commonalities. These events result in no significant fuel cladding heat-up and are not bounding with respect to maintaining inventory above the fuel (to ensure continued cooling). They represent the largest challenge to the containment fission product barrier. These events are treated as medium margin events and the initial conditions and modeling parameters are biased to ensure conservative containment conditions are calculated. The initial conditions used are provided in Table 15.5-1. The modeling parameters biased in this analysis are discussed in NEDC-33922P (Reference 15.5-2). The combination of the conservative biased inputs combined with the observation of the margin available results in conservative analyses.

#### **15.5.1.1.3 Low Margin or Quantitative Evaluation of Uncertainty is Desired**

A proven Monte Carlo technique is used to combine the individual biases and uncertainties into an overall bias and uncertainty for low margin events. This process is described in the TRACG Application for BWRX-300 (Reference 15.5-3). There are no events identified as low margin.

#### **15.5.1.2 Description of the Computer Codes Used in the Safety Analyses**

There is a large amount of data available from operating BWR plants and from the testing and licensing efforts to licence the predecessor BWR/Advanced Boiling Water Reactor (ABWR)/Economic Boiling Water Reactor (ESBWR) designs and individual plants. The vast database of feature performance in licensed reactors, combined with the recent thorough licensing review of the ABWR and ESBWR performed by the USNRC provides an extremely well qualified foundation from which to make the modest extrapolations to the BWRX-300. The following codes, methods, and accompanying assumptions are used in evaluating the performance of the BWRX-300 during postulated initiating events. The radiological responses to DBAs and DECAs are presented in Section 15.7 but use USNRC-accepted RADTRAD and PAVAN codes for doses at the exclusion boundary and atmospheric dispersions, respectively. A description of codes used in the BWRX-300 safety analysis is provided in Chapter 3, Appendix 3G.

#### **15.5.1.2.1 TRACG**

TRACG is a GEH proprietary version of the Transient Reactor Analysis Code (TRAC). TRACG is the primary licensing analysis tool for LOCA and transient analyses for PIEs with a large range of frequencies up to events that do not involve significant core damage (severe accidents). TRACG has been used in a variety of applications for operating BWRs as well as design/analysis for the ESBWR.

TRACG uses advanced realistic one-dimensional and three-dimensional methods to model the phenomena that are important in evaluating the operation of BWRs. It is a best-estimate code for analysis of BWR transients ranging from simple operational transients to design basis LOCAs and failure to scram transients. TRACG has an extensive qualification base for separate effects, BWR fuel and components, and integral tests. It has been reviewed and approved by the US NRC for a number of analysis applications such as AOOs, ECCS/LOCA and failure to scram overpressure (a BDBA event for BWRs) analyses.

TRACG is used to analyze the challenges to the fuel, RPV, and the mass and energy releases to the containment, for LOCA and non-LOCA DSA. TRACG draws from the licensed BWRs database, which includes design features of the BWRX-300 (albeit in various configurations) and appropriate testing and allows direct application to BWRX-300 design and analysis. TRACG is maintained and updated by GEH.

### **Scope and Capabilities**

TRACG is based on a multi-dimensional two-fluid model for the reactor thermal-hydraulics and a three-dimensional neutron kinetics model. The two-fluid model used for the thermal-hydraulics solves the conservation equations for mass, momentum, and energy for the gas and liquid phases. TRACG does not include any assumptions of thermal or mechanical equilibrium between phases. The gas phase may consist of a mixture of steam and a non-condensable gas, and the liquid phase may contain dissolved boron. The thermal-hydraulic model is a multi-dimensional formulation for the vessel component and a one-dimensional formulation for all other components.

The conservation equations for mass, momentum, and energy are closed through an extensive set of basic models consisting of constitutive correlations for shear and heat transfer at the gas/liquid interface as well as at the wall. The constitutive correlations are flow regime-dependent and are determined based on a single flow regime map, which is used consistently throughout the code. In addition to the basic thermal-hydraulic models, TRACG contains a set of component models for BWR components, such as fuel channels, steam separators, and can simulate BWR steam dryers as part of its vessel model. TRACG also contains a control system model capable of simulating the major BWR control systems such as those for pressure and water level.

The neutron kinetics model is consistent with the GEH BWR Core Simulator PANACEA. It solves a modified one-group diffusion model with six delayed neutron precursor groups. Feedback is provided from the thermal-hydraulic model to the kinetics model for moderator density, fuel temperature, boron concentration and control rod position.

The TRACG structure is based on a modular approach. The TRACG thermal-hydraulic model contains a set of basic components, such as pipe, valve, tee, channel, steam separator, heat exchanger and vessel. System simulations are constructed using these components as building blocks. Any number of these components may be combined. The number of components, their interaction, and the detail in each component are specified through code input. Consequently, TRACG has the capability to simulate a wide range of facilities, ranging from simple separate effects tests to complete BWR plants.

TRACG has been extensively qualified against separate effects tests, component performance data, integral system effects tests and full-scale BWR plant data. A detailed documentation of the TRACG qualification is contained in the TRACG Qualification Report (Reference 15.5-1).

The total effort and extent of qualification performed on TRACG, since its inception in 1979, now exceeds, both in extent and breadth, that of any other engineering computer program GE/GEH has submitted to the USNRC for design application approval.

The analysis also determines the most limiting overpressure protection events in terms of peak vessel pressure. The results are used to demonstrate adequate pressure margin to the reactor vessel design limit.

### **Scope of Application of TRACG to BWRX-300**

The PIRT discussed in References 15.5-2 and 15.5-3 identify specific governing phenomena, where a significant fraction were concluded to be "important" in predicting BWRX-300 transient and LOCA performance. Most of these phenomena are common to operating BWRs. This section examines specific SBWR/ESBWR-related tests and test facilities beyond the previous qualification database. Early in the SBWR program, it was identified that there was no information in the data base for a heat transfer correlation for steam condensation in tubes in the presence of non-condensable gases. A Single Tube Condensation Test Program was conducted to secure this information and reported to the USNRC in TRACG Qualification Report for SBWR (NEDC-32725P, Revision 1) and ESBWR NEDC-33080P-A, Revision 2) that are used in the TRACG model for the BWRX-300 as described in LTR NEDC-33922P (Reference 15.5-2).

The test program was conducted to investigate steam condensation inside tubes in the presence of non-condensable gases. The work was independently conducted at the University of California at Berkeley and at the Massachusetts Institute of Technology (MIT). The work was initiated to obtain a database and a correlation for heat transfer and condensation inside tubes. Three researchers utilized three separate experimental configurations at the University of California at Berkeley, while two researchers utilized one configuration at MIT. The researchers ran tests with pure steam, steam/air, and steam/helium mixtures with representative and bounding flow rates and non-condensable mass fractions. The researchers found the system well-behaved for all tests with either of the non-condensable gases. The results of the tests at the University of California at Berkeley are the basis for the condensation heat transfer correlation used in the TRACG computer code.

TRACG ICS modeling is qualified by the PANTHERS IC test using a representative configuration. The steady-state heat exchanger performance was predicted by the PANTHERS IC prototypical geometry full-scale test.

Because the BWRX-300 RPV and ICS are similar to those of the ESBWR, the TRACG method developed for the ESBWR RPV thermal-hydraulics and mass energy release is also used for the BWRX-300 RPV thermal-hydraulics and mass and energy release. The TRACG code and the application method developed for ESBWR was reviewed and approved by the USNRC. That application method was developed using the Code Scaling, Applicability and Uncertainty (CSAU) guidance. GEH Licensing Topical Report NEDC-33922P BWRX-300 Containment Evaluation Method (Reference 15.5-2) provides an overview of the TRACG thermal-hydraulics method for the mass and energy release and its applicability to the BWRX-300 RPV.

#### **15.5.1.2.2 GOTHIC**

Containment analysis is performed by using the GOTHIC code (References 15.5-4 and 15.5-5).

The GOTHIC computer code is a state-of-the-art program for modeling multiphase, multicomponent fluid flow for performing both containment DBA analyses and analyses to support equipment qualification. The GOTHIC code is developed by Numerical Applications Incorporated (NAI), and the development program is sponsored by the Electric Power Research Institute (EPRI).

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The GOTHIC code has a nodding structure that allows both lumped parameter and 3-D modeling capabilities. The multi-dimensional analysis capability facilitates the study of non-condensable gas and stratification and the calculation of flow field details within any given volume. The code has undergone extensive review and validation against a large test array. The validation program scope examines the code capability for predicting pressure and temperature as well as hydrogen distribution and mixing under various conditions.

GOTHIC is a continuously maintained and improved computer code. The GOTHIC code has been developed compliant with US Title 10 Code of Federal Regulations Part 50, Appendix B, Quality, meeting the GEH software quality requirements and complies with REGDOC-2.4.1, Section 4.4.5 / N286.7 (Reference 15.5-6) requirements. The PSAR results generated used GOTHIC Version 8.3 that is the latest released version. Future BWRX-300 containment analyses may be performed using newer versions of the GOTHIC code provided the newer versions meet the same USNRC 10 CFR 50, Appendix B quality and REGDOC-2.4.1, Section 4.4.5 / N286.7 requirements, as well as changes in calculated results for the BWRX-300 containment application caused by any code changes that can be successfully dispositioned.

#### **15.5.1.2.3 PANAC11**

The BWR Core Simulator (PANAC11 or P11) is a steady-state, 3-D coupled nuclear-thermal-hydraulic computer program representing the BWR core exclusive of the external flow loop. An Automated Plant Heat Balance (APHB) is available to model an external flow loop. Provisions are made for fuel cycle and thermal limits calculations. Neutronic parameters used by core simulator are obtained from two-dimensional lattice physics and parametrically fitted as a function of moderator density, exposure, control, and moderator density history for a given fuel type. The simulator is used for detailed 3-D design and operational calculations of BWR neutron flux and power distributions and thermal performance as a function of control rod position, refueling pattern, coolant flow, reactor pressure, and other operational and design variables. A special power exposure iteration option is available for target exposure distribution and cycle length predictions. PANAC11 includes the effect of Doppler broadening as a function of moderator density, exposure, control, and moderator density history for a given fuel type. The lattice physics and core simulator form the nuclear simulator and is used for both core design and core exposure tracking.

The nuclear model is based on a coarse-mesh nodal, 1-1/2 group (quasi-two group), static diffusion theory. The diffusion equations are solved using the fast energy group. Resonance energy and thermal energy neutronic effects are included in the model by relating the resonance and thermal energy fluxes to the fast energy flux. Eigenvalue iteration yields the fundamental mode solution. Control blade history local peaking effects are considered. A pin power reconstruction model is incorporated to account for the effect of flux gradients across the nodes on the local peaking distribution. Instrumentation predictions are made for neutron and gamma sensitive detectors.

Neutronic parameters used by PANAC11 are obtained from the 2-D lattice physics code TGBLA06, as described in the preceding section, and parametrically fitted as a function of moderator density, exposure, control, and moderator density history for a given fuel type.

The nuclear model is coupled to a static, parallel channel, thermal-hydraulics model and is consistent with the approach described in the Global Nuclear Fuel (GNF) BWR steady-state thermal-hydraulic method NEDC-32082P (Reference 15.5-7).

The GE BWR Core Simulator has undergone extensive validation by comparing calculated results with alternate 3-D methods, end of cycle gamma scan data, operating reactor data, and transient experimental data.

PANAC11 is an USNRC-approved method used for production core design and licensing analysis for the fleet of BWRs with GNF fuel. TGBLA06 and PANAC11 form the nuclear simulator and are used for both core design and core exposure tracking. This tracking process is a continuous comparison and validation of the nuclear methods descriptions, a demonstration of methods performance through operational qualification through similar reactors for the BWRX-300, and the quantification of uncertainties that are applicable in thermal margin evaluations that are a function of this performance are provided in NEDC-33939P, "BWRX-300 Darlington New Nuclear Project (DNNP) GNF2 Steady State Nuclear Methods: TGBLA06/PANAC11 Application Methodology," (Reference 15.5-16).

#### **15.5.1.2.4 ANSI/ANS-18.1-2020**

Radiation concentrations in the reactor coolant and steam during normal operations are determined based on ANSI/ANS-18.1-2020 (Reference 15.5-10). This standard provides the bases for estimating typical concentrations of the principal radionuclides that may be anticipated over the lifetime of a BWR plant. The source term data is based on the cumulative industry experience at operating BWR plants, including measurements at several stations. The operating data reflects the influence of a number of observations made during the transition period from operation with fuel of older designs to operation with fuel of current improved designs such as the GNF2 fuel used in the BWRX-300.

#### **15.5.1.2.5 ADDAM**

The ADDAM (Atmospheric Dispersion and Dose Analysis Method) computer code (Reference 15.5-8) computes the statistical distribution of radiation doses to an individual or population after the airborne release of radioactive material into the environment following a design-based nuclear accident at a nuclear facility. The dispersion of the release is highly influenced predominately by different characteristics of release, existing meteorological scenarios, and the overall nearby terrain and building dimensions. Doses can be computed for various age groups, organs, and receptor locations which are classified based on release and exposure pathway. Input data into ADDAM is divided into four sections:

- Meteorological conditions
- Site characteristics
- Release characteristics
- Receptor characteristics

The execution of the ADDAM code is accomplished by the following input data files:

- Meteorological
- Radionuclide
- Release activity
- Stack exit temperature and velocity file
- Release thermodynamic data files

ADDAM complies with the requirements of CSA N288.2-19 (Reference 15.5-9) standard and is the current CANDU Owners Group's Industry Standard Toolset Version for analyses. CSA N288.2-19, Clause 1.5 states that the "standard covers local atmospheric dispersion, which for Gaussian plume models is defined as dispersion that occurs in the range of 300 m to 100 km." While it does not explicitly preclude use below exclusion zone radii below 300 m, it does mention the need for specialized models. The application within is the current recommendations of the standard as implemented in ADDAM. The individual public doses, dilution factors ( $\chi/Q$ ), and deposition factors ( $D/Q$ ) at a 350m exclusion zone boundary radius for a 95th percentile cumulative frequency of occurrence cut-off have been calculated using a modified reference calculation and output options is used for all the production runs for dilution factors and dose assessment as these are standard output options of ADDAM.

### **15.5.2 Analysis of Normal Operation**

The normal operation DSA demonstrates that plant parameters are maintained within specified Operating Limits and Conditions (OLCs) ensuring the plant conforms with the safety analysis assumptions. The main objective of the first defence level of a D-in-D strategy is to prevent challenges to plant equipment and to protect the primary physical barriers – fuel cladding and RCPB. DL1 measures are described in Chapter 3, Section 3.1.6.2.

The measures used to limit radiological releases to the public during normal operations are described in Chapter 11 Management of Radioactive Waste Systems, Chapter 12 Radiation Protection, and Chapter 20 Environmental Aspects.

#### **15.5.2.1 Description of Normal Operational Modes**

Normal operation is defined as operation within specified OLCs. An analysis of normal operation includes all operational modes (Modes 1-6 defined in Chapter 16, Appendix 16A).

#### **15.5.2.2 Method and Scope of Analysis**

The normal operation deterministic safety analysis demonstrates that the plant parameters are maintained within the specified OLCs ensuring that the plant conforms with the safety analysis assumptions. The normal operation of the plant is monitored and controlled so that PIEs that may lead to AOOs are mitigated before evolving into DBAs. OLCs are important DL1 measures that are readily checked by the operators ensuring the facility is operated in accordance with the applicable safety analyses. OLCs define minimum levels and allowable configurations of the plant, equipment, and associated resources needed to enact safety measures. Setpoint limits and conditions define where safety measures are intended to be activated or initiated to protect against or mitigate fault sequence consequences.

Source term analysis is provided in Chapter 11, Section 11.1 for normal operation sources. Radiation protection measures analyzed and implemented for the plant, shielding and radiation zone designation is provided in Chapter 12, Sections 12.4 and 12.5, respectively.

#### **15.5.2.3 Results of Analysis**

The limiting safety system setpoints are determined to demonstrate to the extent practicable that the highest safety class (DL3) systems are only initiated when needed. Process controls and alarms are established that demonstrate their effectiveness in reducing or avoiding the need for safety system actuations. The core parameters evaluation ensures that reactivity control required to bring the reactor to a cold shutdown condition is achieved and maintained. Normal operational doses are provided in Chapter 20, Section 20.8.

#### **15.5.2.4 Stability Analysis**

Part of normal operational analysis is to confirm that the core will remain stable during normal operation. The stability considerations during normal operation are described in Chapter 4, Section 4.8.

The BWRX-300 240-bundle core is evaluated for beginning of cycle (BOC), middle of cycle (MOC) and end of rated power (EOR) exposures in determining both the core-wide decay ratios and regional mode oscillations. The core-wide decay ratios (DR) are evaluated using a step perturbation in pressure while the regional mode decay ratios are evaluated using channel velocity perturbations.

##### **Core-Wide Decay Ratio**

The primary stability evaluation is performed at nominal conditions including nominal feedwater temperature 241.9°C (467.4°F).

Another stability evaluation is performed for the state that is reached after a LFWH AOO. A Select Control Rod Run-In (SCRRI) (described in Chapter 7, Subsection 7.3.3.1) is initiated as a mitigating response for a LFWH AOO with a feedwater temperature reduction of 16.7°C (30.0°F) or higher and a new lower power steady condition is achieved. Once the reactor achieves a new steady-state condition, a step pressure perturbation is applied to evaluate core stability response. The analysis of LFWH AOO described in Section 15.5.3.1.1 assumes that the feedwater temperature is reduced to 191.9°C (377.4°F) at BOC, MOC and EOR.

##### **Core-Wide Dominance**

For the regional mode evaluation, based on the harmonic modes distribution of the core, the inlet velocities for all channels were perturbed by  $\pm 20\%$  at time = 0. This harmonic power distribution is predicted by the steady-state core simulator PANAC11 and results in a line of symmetry between the two halves of the core with higher and lower predicted harmonic power. The velocity perturbations are made positive on one side of the line of symmetry and negative on the other side. This stimulates the potential harmonic oscillations (regional oscillations). The resulting channel power response of limiting channels is evaluated for susceptibility to regional mode oscillations. If the core is not susceptible to regional mode oscillations after a velocity perturbation, the initially symmetric, out of phase channel power responses come into phase after a short duration, confirming the dominance of core-wide oscillations.

#### **Results**

##### **DR / SCRRI**

The maximum nominal core-wide decay ratio design limit is 0.80. The calculated core-wide decay ratios at nominal conditions are below the maximum decay ratio allowed. The calculated DR values at the end of the LFWH event are below the maximum allowed DR and are lower than the DR values at nominal conditions. The calculated DR values at nominal temperature and LFWH conditions are presented in Table 15.5-2. The nominal stability response is presented on Figure 15.5-1 for the MOC exposure. The LFWH stability response is presented on Figure 15.5-2 for the MOC exposure.

## Core-Wide Dominance

A limiting core-wide dominance evaluation is performed at 115% rated power. At MOC, the limiting channel power values follow the expected behavior where initially symmetric, out of phase channel power responses come into phase after a short duration. The core is not susceptible to regional mode oscillations at nominal conditions, and this conclusion also applies to normal operation. The regional stability response using the limiting channels is presented on Figure 15.5-3 at the MOC exposure. This is a hypothetical evaluation, and any growing core-wide oscillations are mitigated by DL3-05 (see Table 15.5-5).

Based on these stability evaluations, the following stability claims are supported:

1. Power oscillations that result in conditions exceeding specified acceptable fuel design limits are not possible
2. Regional instability is not possible
3. Design features prevent the loss of stability margin for upset events

## 15.5.3 Analysis of Anticipated Operational Occurrences

### 15.5.3.1 Decrease in Core Coolant Temperature AOO

This section describes the bounding BL-AOO event for Temperature Decrease (TD) Group.

#### 15.5.3.1.1 Loss of Feedwater Heating AOO

This event is designated as a BL-AOO event. The fault sequence name is Loss of Feedwater Heating (LFWH) and the fault sequence ID is TD-LFWH\_BL-AOO.

Additional LFWH AOO cases support the detailed evaluation and demonstrate the thermal-hydraulic stability of the BWRX after a LFWH AOO (see 15.5.2.4).

## Postulated Initiating Event

The event assumes a loss of FW heating from a single failure of either the closure of one extraction steam valve or the inadvertent bypass of a FW heater. This failure is conservatively modeled as an instantaneous decrease in FW temperature that bounds the maximum FW temperature decrease resulting from a single failure. A PIE with AOO frequency results in the maximum FW temperature reduction identified in Table 15.5-3 from a loss of one feedwater heater.

## Sequence of Events

The event fault sequence summary:

- Loss of FW temperature occurs instantly resulting in an increase in power
- Reactor Level Control (RLC) compensates initially by lowering flow rate minimizing the effect on power
- SCRRRI inserts control rods on indication of FW temperature reduction
- Reactor Pressure Control (RPC) maintains pressure and RLC maintains level
- A new controlled steady-state condition achieved with a new power distribution

Table 15.5-6 lists the sequence of events.

## Identification of Operator Actions

No operator action is required to mitigate the event.

## **Systems Operation**

Credited DL2 functions:

- DL2-27 – SCRR1 on FW Temperature Decrease
- DL2-02 – Maintain Target Level
- DL2-01 – Maintain Target Pressure

## **Core and System Performance**

### *Input Parameters and Initial Conditions*

The event is simulated by decreasing the FW temperature. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The analysis is performed using an equilibrium core design. The event is run at BOC, MOC and EOR cycle exposure conditions.

### *Results*

The results of the simulated loss of FW heating event are presented on Figures 15.5-5 through 15.5-10. The results are presented in Table 15.7.2-1 for the exposure with the limiting CPR response.

The reduced temperature FW enters the core and causes an increase in core inlet subcooling. This increases core power due to the negative void reactivity coefficient. RLC compensates initially by lowering FW flow rate and a SCRR1 is initiated to minimize the core power increase and decrease the final steady-state power. Steam flow and FW flow then stabilize at a lower level. The RPV water level decreases and then returns to normal level. The pressure and level remain well within the RPV water level and RCPB pressure acceptance criteria in Section 15.3.2.

The core power increase is limited. Thermal-mechanical evaluations confirm there is significant margin to centerline fuel temperature or cladding strain acceptance criteria in Section 15.3.2. Limits on the Linear Heat Generation Rate (LHGR) are included each operating cycle ensuring the centerline fuel temperature and cladding strain acceptance criteria are met. The limits on LHGR are included in the Core Operating Limits Report (COLR).

The calculated  $\Delta\text{CPR}/\text{ICPR}$  is provided. This is used to set an OLMCPR ensuring the CPR remains within the MCPR acceptance criterion. This event is potentially limiting for OLMCPR and is evaluated each operating cycle to determine the core OLMCPR. The resulting limiting event OLMCPR is included in the COLR.

Sensitivity studies were performed on maximum FW pump flow (120% of rated), initial FW temperature reduction ( $-6^{\circ}\text{C}$ ), and FW controller settings. The sensitivity studies demonstrated no significant change in the event sequence or results.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there are no radiological consequences associated with this event.

### **15.5.3.2 Increase in Reactor Pressure AOO**

#### **15.5.3.2.1 Generator Load Rejection or Turbine Trip AOO**

This event is in the Pressure Increase (PI) Group and is designated a BL-AOO event. The fault sequence name is Generator Load Rejection or Turbine Trip (LR-TT), and the Fault Sequence ID is PI-LR-TT\_BL-AOO.

#### **Postulated Initiating Event**

The initiating event is either a generator load rejection or a turbine trip. TCVs have a fast closure function to protect the turbine during a generator load rejection. The TSVs close at a fast rate following a turbine trip. RPC remains unaffected and demands the TBVs open to control reactor pressure.

#### **Sequence of Events**

The fault sequence summary for the event:

- TCVs and/or TSVs close quickly causing pressure increase
- Anticipatory scram occurs on indication of a load rejection or turbine trip
- RPC opens TBVs to control pressure
- RLC maintains level
- Controlled state achieved

Table 15.5-7 lists the sequencing of events for this analysis.

#### **Identification of Operator Actions**

No operator action is required to mitigate the event.

#### **Systems Operation**

Credited DL2 functions:

- DL2-02 – Maintain Target Level
- DL2-01 – Maintain Target Pressure
- DL2-08 – Anticipatory Hydraulic Scram on Generator Load Rejection or Turbine Trip Demand
- DL2-09 – TBV Fast Open on Generator Load Rejection or Turbine Trip Demand

#### **Core and System Performance**

##### *Input Parameters and Initial Conditions*

The event is simulated by initiating a generator load rejection or turbine trip resulting in a fast closure of the TCVs or TSVs. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### *Results*

The simulated generator load rejection / turbine trip is presented on Figures 15.5-11 through 15.5-16, and the results are presented in Table 15.7.2-1. The results are shown for the case with the limiting CPR result. Automatic reactor scram occurs following indication of a generator load rejection or turbine trip. Pressure increases but is limited by the TBVs opening.

The core thermal power does not increase above the initial power and there is no concern in approaching the centerline fuel temperature or cladding strain acceptance criteria in Section 15.3. This event is not limiting and is not considered during LHGR limits development

The calculated  $\Delta\text{CPR}/\text{ICPR}$  is provided. This is used to set an OLMCPR ensuring the CPR remains within the MCPR Acceptance Criterion. This event is potentially limiting for OLMCPR and is evaluated each operating cycle for determining the core OLMCPR. The resulting limiting event OLMCPR is included in the COLR.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there are no radiological consequences associated with this event.

#### **15.5.3.2.2 Closure of One Main Steam Reactor Isolation Valve AOO**

This event is in the Pressure Increase (PI) Group and is designated as a BL-AOO event. The fault sequence name is Closure of one Main Steam Reactor Isolation Valve (MSRIV) and the Fault Sequence ID is PI-1MSRIVC\_BL-AOO.

### **Postulated Initiating Event**

There are two main steam lines. The event is an inadvertent closure of one MSRIV that terminates flow in one of the main steam lines. A minimum MSRIV closure time results in the most severe event.

### **Postulated Event**

The fault sequence summary for the event:

- One MSRIV closes causing RPV pressure and power to increase
- ATS scram occurs on MSRIV position
- RLC controls levels
- Second MSRIV in the second steam line closes on leak detection indication (this is assumed because it makes the event more severe)
- One ICS train initiates on high RPV pressure (the simulation is ended before any ICS initiation because the key mitigation DL functions have already been demonstrated and a single ICS train is capable of controlling pressure and removing decay heat as demonstrated in the pressure increase DBA analysis)
- Controlled state achieved

Table 15.5-8 lists the sequencing of events for the closure of one MSRIV.

### Identification of Operator Actions

No operator action is required to mitigate the event.

### Systems Operation

Credited DL2 functions:

- DL2-02 – Maintain Target Level
- DL2-21 – Anticipatory Hydraulic Scram on MSRIV/MS CIV Position
- DL2-31 – ICS Pressure Control on High Reactor Pressure

### Core and System Performance

The event is simulated by initiating a closure of one MSRIV. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

#### *Results*

The simulated closure of one MSRIV is presented on Figures 15.5-17 through 15.5-22 and the results are presented in Table 15.7.2-1. The results are shown for the case with the limiting CPR and reactor pressure response. The neutron flux and pressure increase resulting from the closure of one MSRIV are limited by an anticipatory scram on MSRIV position. The pressure increase is also initially limited because the MSRIV remains open in the second steam line. The second steam line is then assumed to close on main steam line break indication. This conservative assumption makes the event more severe. Pressure then increases and ICS is initiated on high pressure.

The core thermal power increase is not significant and there is no concern for approaching the centerline fuel temperature or cladding strain acceptance criteria in Section 15.3. This event is not limiting and does not need to be considered during development of limits on the LHGR.

The calculated  $\Delta\text{CPR}/\text{ICPR}$  is provided. This is used to set an OLMCPR ensuring the CPR remains within the MCPR acceptance criterion. This event is potentially limiting for OLMCPR and is evaluated each operating cycle for determining the core OLMCPR. The resulting limiting event OLMCPR is included in the COLR.

#### *Barrier Performance*

This event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.3.2.3 Loss of Condenser Vacuum AOO**

This event is in the Pressure Increase (PI) Group and is designated a BL-AOO event. The fault sequence name is Loss of Condenser Vacuum (LOCV) and the Fault Sequence ID is PI-LOCV\_BL-AOO.

### **Postulated Initiating Event**

There are a few potential causes of a loss of condenser vacuum including loss of one or more circulating water pumps. The loss of condenser vacuum results in a turbine trip. The turbine stop valves close at a fast rate following a turbine trip.

### **Sequence of Events**

The fault sequence summary for the event:

- The TSVs close and main turbine trips on low main condenser vacuum causing pressure increase
- Anticipatory scram occurs on a turbine trip
- RPC opens TBVs to control pressure
- RLC maintains level
- TBVs close on high main condenser pressure and pressure increases slowly due to decay heat (the simulation is ended before TBV closure because the key mitigation DL functions are demonstrated, and a single ICS train is capable of controlling pressure and removing decay heat)
- One ICS train initiates on high RPV pressure (the simulation is ended before any ICS initiation because the key mitigation DL functions have already been demonstrated and a single ICS train is capable of controlling pressure and removing decay heat as demonstrated in the pressure increase DBA analysis)
- Controlled state achieved

Table 15.5-9 lists the sequencing of events.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

Credited DL2 functions:

- DL2-02 – Maintain Target Level
- DL2-01 – Maintain Target Pressure
- DL2-13 – Turbine Trip on High Main Condenser Pressure Setpoint 2
- DL2-08 – Hydraulic Scram on Generator Load Rejection or Turbine Trip Demand
- DL2-09 – TBV Fast Open on Generator Load Rejection or Turbine Trip Demand
- DL2-14 – TBV Closure on High Main Condenser Pressure Setpoint 3
- DL2-31 – ICS Pressure Control on High Reactor Pressure

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The loss of condenser vacuum results in a turbine trip. The event is simulated by initiating a turbine trip resulting in a fast TSV closure. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC and EOR cycle exposure conditions.

#### *Results*

The simulated loss of condenser vacuum is presented on Figure 15.5-23 through 15.5-27 and the results are presented in Table 15.7.2-1. The results are shown for the case with the limiting CPR result. The pressure increases due to the fast TSV closure and is limited by the anticipatory scram on indication of a turbine trip. A scram on high main condenser pressure may occur sooner but conservatively not modeled. The pressure increase is also initially limited by the TBVs opening. Condenser vacuum loss is assumed to continue, resulting in TBVs closing. Once TBVs are closed, reactor pressure increases, and one ICS train initiates on high RPV pressure.

The core thermal power does not increase above the initial power and there is no concern for approaching the centerline fuel temperature or cladding strain acceptance criteria in Section 15.3. This event is not limiting and is not considered during LHGR limits development.

The calculated  $\Delta\text{CPR}/\text{ICPR}$  is provided. This is used to set an OLMCPR ensuring the CPR remains within the MCPR acceptance criterion. This event is potentially limiting for OLMCPR and is evaluated each operating cycle for determining the core OLMCPR. The resulting limiting event OLMCPR is included in the COLR.

#### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.3.2.4 Loss-of-Preferred Power AOO**

This event is in the Pressure Increase (PI) Group and is designated a BL-AOO event. The fault sequence name is Loss-of-Preferred Power (LOPP) and the Fault Sequence ID is PI-LOPP\_BL-AOO.

#### **Postulated Initiating Event**

A LOPP is initiated by offsite power supply failure. The loss of power results in the generator output breakers opening and the TCVs fast closure.

#### **Sequence of Events**

The fault sequence summary for the event is:

- LOPP occurs
- TCVs close quickly causing pressure increase
- Feedwater pumps lose power, FW pump discharge check valves maintain coolant inventory
- Circulating water pumps lose power
- Anticipatory scram occurs on generator load rejection
- RPC opens TBVs to control pressure

- TBVs close on high main condenser pressure
- One ICS train initiates on high RPV pressure (the simulation is ended before any ICS initiation because the key mitigation DL functions have already been demonstrated and a single ICS train is capable of controlling pressure and removing decay heat as demonstrated in the pressure increase DBA analysis)
- Controlled state achieved

Table 15.5-10 lists the sequencing of events.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

Credited DL2 functions:

- DL2-01 – Maintain Target Pressure
- DL2-08 – Hydraulic Scram on Generator Load Rejection or Turbine Trip Demand
- DL2-09 – TBV Fast Open on Generator Load Rejection or Turbine Trip Demand
- DL2-31 – ICS Pressure Control on High Reactor Pressure
- DL2-43 – FW Check Valve Closure on Reverse FW Flow

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The LOPP results in the generator output breakers opening and a loss of power to the feedwater pumps. The event is simulated by initiating a FW trip and a load rejection resulting in fast TCVs closure. Anticipatory scram occurs on a generator load rejection. A scram on low bus voltage may occur sooner but is conservatively not modeled. This scram timing is the same as the anticipatory scram on a load rejection. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions. The results are shown for the case with the limiting result for CPR.

#### *Results*

The simulated LOPP is presented on Figure 15.5-28 through 15.5-33 and the results are presented in Table 15.7.2-1. The results are shown for the case with the limiting result for CPR. The pressure increase due to TCV closure is limited by the anticipatory scram on the generator load rejection. Scram on a low electric bus voltage may occur sooner but is conservatively not credited. The pressure increase is also initially limited by the TBVs opening. The TBVs later close on loss of power. Once the TBVs are closed, reactor pressure increases and ICS initiates on high RPV pressure. The ICS continues to limit the pressure increase.

The core thermal power increase is not significant and there is no concern for approaching the centerline fuel temperature or cladding strain acceptance criteria in Section 15.3. This event is not limiting and does not need to be considered during development of limits on the LHGR.

The calculated  $\Delta\text{CPR}/\text{ICPR}$  is provided. This is used to set an OLMCPR ensuring the CPR remains within the MCPR acceptance criterion. This event is potentially limiting for OLMCPR and is evaluated each operating cycle for determining the core OLMCPR. The resulting limiting event OLMCPR is included in the COLR.

#### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

### **15.5.3.3 Decrease in Reactor Coolant Inventory AOOs**

#### **15.5.3.3.1 Feedwater Pump Trip – One Pump**

The section analyzes the bounding BL-AOO event for the Inventory Reduction (IR) group. The fault sequence name is FW Pump Trip – One Pump (FWPT) and the Fault Sequence ID is IR-FWPT\_BL-AOO.

#### **Postulated Initiating Event**

There is one FW pump normally operating and a second FW pump in standby. This event assumes a failure resulting in a trip of the operating FW pump. The RLC remains unaffected by the failure and increases the flow demand on the standby FW pump to maintain RPV water level.

#### **Sequence of Events**

The fault sequence summary for the event:

- One FW trips causing RPV water level decrease
- Standby FW pump starts and increases to rated FW flow
- Power decreases temporarily from a reduction in core flow and core inlet subcooling
- RPC controls pressure
- RLC maintains level
- RPV water low level scram and high-level FW isolation are avoided
- Controlled state achieved

Table 15.5-11 lists the event sequence.

#### **Identification of Operator Actions**

No operator action is required to mitigate the event.

#### **Systems Operation**

Credited DL2 functions:

- DL2-25 – Start Standby FW pump on Loss of Operating FW Pump
- DL2-02 – Maintain Target Level
- DL2-01 – Maintain Target Pressure

## Core and System Performance

### *Input Parameters and Initial Conditions*

The event is simulated by initiating a FW pump trip. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### *Results*

The FW pump trip event is presented on Figures 15.5-34 through 15.5-39 and the results are presented in Table 15.7.2-1 for the exposure with the limiting CPR response. Reduction in FW flow results in a reduction of vessel inventory, causing the vessel water level to drop. The standby FW pump starts on confirmed low FW flow conditions, RPC throttles TCVs to control pressure, and the RLC increases the FW pump flow to rated conditions to maintain level. Low reactor water level (L3) scram is avoided.

The core thermal power does not increase and there is no concern for in approaching the centerline fuel temperature or cladding strain acceptance criteria in Section 15.3.2. This event is not limiting and is not considered during development of LHGR limits.

The calculated  $\Delta\text{CPR}/\text{ICPR}$  is provided. The event is not limiting and is not considered in the OLMCPR development.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

## **15.5.3.4 Increase in Reactor Coolant Inventory AOOs**

### **15.5.3.4.1 Inadvertent Isolation Condenser Initiation – One Train**

This event is designated as a BL-AOO event. The fault sequence ID is II-IIICI-1\_BL-AOO. This event assumes a failure causes a single Isolation Condenser (IC) condensate return valve to open. The event assumes that RLC remains unaffected by the failure and is able to maintain level. The event also assumes that RPC remains unaffected by the failure and is able to maintain pressure.

### **Postulated Initiating Event**

The ICs are normally in standby mode. This event assumes spurious opening of a single ICS condensate return valve, resulting in the introduction of cold water into the reactor. The event assumes that RLC and RPC remain unaffected by the failure and are available to control reactor level and reactor pressure.

### **Sequence of Events**

The fault sequence summary for the II-IIICI-1\_BL-AOO event:

- ICS condensate return valve on one train opens
- Cold ICS condensate water drains into the chimney

- RLC maintains water level
- RPC maintains pressure
- Controlled state achieved

Table 15.5-12 lists the sequencing of events for the feedwater flow increase event.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

The credited DL2 functions:

- DL2-02 – Maintain Target Level
- DL2-01 – Maintain Target Pressure

### **Input Parameters and Initial Conditions**

The event is simulated by opening the ICS condensate return valve on one IC train. The initial conditions are provided in Tables 15.5-3 through 15.5-5.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### **Results**

The inadvertent initiation of one IC train event is presented on Figures 15.5-40 through 15.5-45. Table 15.7.2-1 shows the limiting results for CPR response. When the IC condensate return valve is opened, cold water is introduced into the chimney region. After an initial small perturbation, the increased density in the chimney reduces core flow, water level, and power temporarily. After the initial reduction, core flow, level, and power increase. When the increase in level is sensed, the FW controller starts to demand the operating FW pump to reduce flow. After the initial surge, as condensate water drains into the chimney and IC flow reduces, the FW controller demands the operating FW pump to increase flow. The RPV water level, core flow, and core power settle back to their initial values. RPV pressure increases insignificantly. The level and pressure remain well within the RPV water level and RCPB pressure acceptance criteria in Subsection 15.3.2.

The core power increase is limited. There is no concern for approaching the centerline fuel temperature or cladding strain acceptance criteria in Subsection 15.3.2. This event is not limiting and does not need to be considered during development of limits on the LHGR.

The calculated  $\Delta\text{CPR}/\text{ICPR}$  is provided. This is used to set an OLMCPR ensuring the CPR remains within the MCPR acceptance criterion. This event is potentially limiting for OLMCPR and is evaluated each operating cycle to determine the core OLMCPR. The resulting limiting event OLMCPR is included in the COLR.

### **Barrier Performance**

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. Therefore, these barriers maintain their integrity and function as designed.

### **Radiological Consequences**

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.4 Analysis of Design Basis Accidents**

This section evaluates the bounding BWRX-300 non-LOCA and LOCA PIEs. Subsections 15.5.4.1 through 15.5.4.5 describe the DSA non-LOCA DBAs, while Section 15.5.4.6 describes the DSA LOCAs inside containment. Subsection 15.5.9.2 describes the DSA for LOCAs outside containment.

##### **15.5.4.1 Decrease in Reactor Coolant Temperature Event**

###### **15.5.4.1.1 Loss of All Feedwater Heating**

This event is in the Temperature Decrease (TD) group and is designated CN-DBA event. The fault sequence name is CCF-LFWH, Passive Digital CCF DL2 Technology Platform (CCF-DL2), and the Fault Sequence ID is TD-CCF-LFWH\_CCF-DL2\_CN-DBA.

##### **Postulated Initiating Event**

A CCF results in the loss of all FW heating. Any CCF that results in the loss of all FW heating occurs gradually because of the thermal inertia inherent in the FW heaters. The FW temperature lowers to the main condenser temperature with the assumed time constant shown in Table 15.5-3.

##### **Sequence of Events**

- CCF results in the loss of all FW heating
- FW temperature decreases causing positive reactivity insertion
- RLC and RPC fail as-is
- Scram on high Simulated Thermal Power (STP) causing negative reactivity insertion
- RPV pressure decreases. The downcomer level decreases temporarily to lower than L3 because of void collapse
- Main steam isolation occurs on low RPV pressure
- RLC continues at initial flow causing RPV level to increase
- FW isolation occurs on high RPV level
- An ICS initiates on high pressure. The first IC train fails to actuate (assumed single failure). One of the two remaining ICS trains sufficiently controls pressure (the simulation is ended before any ICS initiation because the key mitigation DL functions have already been demonstrated and a single ICS train is capable of controlling pressure and removing decay heat as demonstrated in the pressure increase DBA analysis)
- Controlled state achieved

Table 15.5-13 lists the sequence of events.

##### **Identification of Operator Actions**

No operator action is required to mitigate the event.

##### **Systems Operation**

Credited DL3 functions:

- DL3-05 – Hydraulic Scram on High Simulated Thermal Power
- DL3-23 – FW Isolation on High RPV Water Level

- DL3-17 – MSRIV/MS CIV Isolation on Low RPV Pressure
- DL3-12 – ICS Train 2 Initiation on High RPV Pressure

## **Core and System Performance**

### *Input Parameters and Initial Conditions*

The event is simulated by decreasing the FW temperature. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### *Results*

The simulated loss of all FW heating event is presented on Figures 15.5-46 through 15.5-51, and the results are presented in Table 15.7.3-1 for the exposure with the limiting PCT response. The reduced FW temperature enters the core and causes an increase in core inlet subcooling. This increases core power due to the negative void reactivity coefficient, and a scram occurs on high STP. MSRIV isolate on low RPV pressure.

FW flow remains at 100% due to the RLC CCF and RPV water level rises until FW isolates on high RPV water level. Decay heat causes RPV pressure to rise and an ICS train initiates. Only one ICS train is needed to prevent RPV pressure increase and maintain long-term cooling. A single failure of an ICS train starting on high RPV pressure does not affect event mitigation.

The long-term core cooling capability is assured by meeting the acceptance criteria for fuel cladding and the RCPB. The reactor integrity is assured by meeting the pressure criteria provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal water reaction.

Because there is significant margin to the acceptance criteria, this event is considered to have large margin and no additional conservatism is applied.

### *Barrier Performance*

This event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

## **15.5.4.2 Increase in Reactor Pressure Events**

### **15.5.4.2.1 Generator Load Rejection or Turbine Trip**

This event is in the Pressure Increase (PI) group and is designated a CN-DBA event. The fault sequence name is Generator Load Rejection or Turbine Trip (LR-TT), Passive Digital CCF DL2 Technology Platform (CCF-DL2) and the Fault Sequence ID is PI-LR-TT\_CCF-DL2\_CN-DBA.

### **Postulated Initiating Event**

The PIE is the same as the BL-AOO event. The event sequence assumes a passive CCF of the DL2 functions. The CCF results in RPC and RLC failing as-is, which are continually operating, and failure of the anticipatory scram.

### **Sequence of Events**

The fault sequence summary for the event is as follows:

- TCVs and/or TSVs close quickly causing pressure and power increase
- RLC fails as-is at initial condition, the TBVs remain closed, and anticipatory scram fails
- Scram occurs on high neutron flux
- After scram, immediate challenge to cladding and RCPB integrity is over
- RPV pressure continues to increase because RPC fails as-is
- RPV level reduces due to the pressure increase
- One ICS train initiates on high pressure. First IC train fails to actuate (assumed single failure). One of the two remaining trains is sufficient to control pressure
- With RLC failing as-is, initial feedwater flow continues causing RPV level to increase
- FW isolates on high RPV water level (L9)
- Controlled state achieved

Table 15.5-14 lists the sequencing of events, for the fast closure of TCV.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

Credited DL3 functions:

- DL3-04 – Hydraulic Scram on High neutron flux
- DL3-23 – FW Isolation on High RPV Water Level
- DL3-12 – ICS Train 2 Initiation on High RPV pressure

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The event is simulated by initiating a fast closure of the TCVs or TSVs. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. This event is limiting for PCT. Therefore, additional initial conditions and phenomena that impact PCT described in the TRACG Application (Reference 15.5-3) are applied in the limiting direction by at least one standard deviation consistent with the approach for an event with medium margin:

- Core void coefficient
- Channel interfacial shear
- Chimney interfacial shear
- Separator steam carry under

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

- Critical quality used in boiling transition correlation
- Channel radial peaking factor
- Hot rod power
- Total initial power

Analysis is performed as needed to confirm the conservative PCT direction. Then a bounding case is created with all inputs in the conservative direction.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

#### *Results*

The simulated generator load rejection / turbine trip is presented on Figures 15.5-52 through 15.5-57 and the results are presented in Table 15.7.3-1. The results are presented for the bounding case described above. Reactor scram occurs following high neutron flux. The neutron flux increases rapidly because of the void reduction caused by the pressure increase. TBVs fail to open; however, ICS limits the pressure increase. Only one ICS train is needed to prevent pressure increase and maintain long-term cooling. A single failure of an ICS train to start on high pressure does not affect the event mitigation.

The long-term core cooling capability is assured by meeting acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the pressure criteria, provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal water reaction.

Applying these conservatisms have little effect on peak pressure because peak pressure is primarily driven by the IC initiation setpoint. Once the pressure setpoint is reached, ICS initiates, and pressure rapidly reduces. For PCT, these uncertainties result in a PCT 91°C (163°F) higher than the base case with conservatisms similar to other DBA analyses. The results are within the acceptance criteria.

#### *Barrier Performance*

The effect of this event does not result in any challenge to the temperature or pressure transient derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.4.2.2 Loss-of-Preferred Power**

This event is in the Pressure Increase (PI) group and is designated a CN-DBA event. The fault sequence name is LOPP, and the Fault Sequence ID is PI-LOPP\_CCF-DL2\_CN-DBA.

#### **Postulated Initiating Event**

The PIE is the same as the BL-AOO event. The event sequence assumes a passive CCF of the DL2 functions. The CCF results in RPC and RLC failing as-is at the initial condition, which are continually operating, and failure of the anticipatory scram.

## Sequence of Events

The fault sequence summary for the LOPP event:

- TCV closes slowly due to loss of turbine control hydraulic pumps
- FW pumps lose power and coast down
- RLC fails as-is at the initial condition, TBVs remain closed, and the anticipatory scram fails
- Scram occurs on high neutron flux
- After scram, immediate challenge to cladding and RCPB integrity is over
- RPV pressure continues to increase because TBVs remain closed
- An ICS train initiates on high pressure. The first IC train fails to actuate (assumed single failure). One of the remaining two trains is sufficient to control pressure
- Controlled state achieved

Table 15.5-15 lists the sequencing of events.

## Identification of Operator Actions

No operator action is required to mitigate the event.

## Systems Operation

Credited DL3 functions:

- DL3-04 – Hydraulic Scram on High Neutron Flux
- DL3-12 – ICS Train 2 initiation on High RPV Pressure
- DL3-39 – FW Isolation on Loss of Normal FW Flow

## Core and System Performance

### *Input Parameters and Initial Conditions*

The event is simulated by initiating a slow closure of the TCVs and feedwater pump trip. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### *Results*

The simulated LOPP is presented on Figures 15.5-58 through 15.5-63 and the results are presented in Table 15.7.3-1. The results are shown for the case with the limiting result for cladding temperature and reactor pressure response. The neutron flux increases rapidly because of the void reduction caused by the pressure increase. Reactor scram occurs following high neutron flux. Bypass valves fail to open; however, the pressure increase is limited by the ICS initiation. Only one ICS train is needed to prevent pressure increase and maintain long-term cooling; therefore, a single failure of an ICS train to start on high pressure does not affect the event mitigation. The closure of the TCVs in the LOPP AOO is due to DL2 active mitigation. In the LOPP CN-DBA sequence, the TCVs close as a result of the PIE. If there is no power to maintain hydraulic pressure, the valves slowly close.

The long-term core cooling capability is assured by meeting the acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the pressure criteria provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal water reaction.

Because there is significant margin to the acceptance criteria, this event is considered to have large margin and no additional conservatism is applied.

#### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient challenge to the derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.4.2.3 RPV Pressure Control Downscale**

This event is in the Pressure Increase (PI) group and is designated a CN-DBA event. The fault sequence name is CCF – RPV Pressure Control Downscale (CCF-RPCD), Passive Digital CCF DL2 Technology Platform (CCF-DL2) and the Fault Sequence ID is PI-CCF-RPCD\_CCF-DL2\_CN-DBA.

#### **Postulated Initiating Event**

The PIE is a spurious CCF of the RPV pressure control. This failure results in a demand to close the TCVs (normal servo closure). This PIE also prevents the TBVs from opening. The event sequence assumes a passive CCF of the DL2 functions. The CCF results in the RLC failing as-is at initial conditions, and failure of the anticipatory scram.

#### **Sequence of Events**

The fault sequence summary for the RPCD event:

- RPC demands TCVs to slow close and the TBVs remain closed
- RLC fails as-is at the initial condition and the anticipatory scram fails
- Scram occurs on high neutron flux
- After scram, immediate challenge to cladding and RCPB integrity is over
- With RLC failing as-is at the initial condition, the initial feedwater flow continues causing RPV level to increase
- FW isolates on high RPV water level
- One ICS train initiates on high pressure. The first IC train fails to actuate (assumed single failure). One of the two remaining ICS trains is sufficient to control pressure
- Controlled state achieved

Table 15.5-16 lists the sequencing of events.

#### **Identification of Operator Actions**

No operator action is required to mitigate the event.

## **Systems Operation**

Credited DL3 functions:

- DL3-04 – Hydraulic Scram on High Neutron Flux
- DL3-23 – FW Isolation on High RPV Water Level
- DL3-12 – ICS Train 2 Initiation on High RPV pressure

## **Core and System Performance**

### *Input Parameters and Initial Conditions*

The event is simulated by initiating a slow closure of the TCVs. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### *Results*

The simulated RPV Pressure Control Downscale is presented on Figures 15.5-64 through 15.5-69 and the results are presented in Table 15.7.3-1. The results are shown with the limiting result for cladding temperature and reactor pressure response. The neutron flux increases rapidly because of the void reduction caused by the pressure increase. Reactor scram occurs following high neutron flux. TBVs fail to open, and feedwater pump trips on high RPV level (L9). Natural circulation continues at a rate consistent with decay heat power. Only one ICS train is needed to prevent pressure increase and maintain long-term cooling; therefore, a single failure of an ICS train to start on high pressure does not affect the event mitigation.

The long-term core cooling capability is assured by meeting the acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the pressure criteria provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal water reaction.

Because there is significant margin to the acceptance criteria, this event is considered to have large margin and no additional conservatism is applied.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.4.2.4 Closure of All Main Steam Reactor Isolation Valves and FW Isolation Valves**

This event is in the Pressure Increase (PI) group and is designated a CN-DBA event. The fault sequence name is CCF-Closure of All MSRIVs and FW isolation valves (CCF-DL4a-MSRIVC-FWIV) and the Fault Sequence ID is PI-CCF-DL4a-MSRIVC-FWIV\_CN-DBA.

### **Postulated Initiating Event**

The PIE is a spurious CCF DL4a function that affects all MSRIV and FW isolation valves.

### **Sequence of Events**

The fault sequence summary for this MSRIV and FWIV closure event:

- Closure of all MSRIV and FW isolation valves
- Scram occurs on high neutron flux
- After scram, immediate challenge to cladding and RCPB integrity is over
- An ICS train initiates on high pressure. The first IC train fails to actuate (assumed single failure). One of the two remaining trains is sufficient to control pressure
- Controlled state achieved

Table 15.5-17 lists the sequence of events.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

Credited DL3 functions:

- DL3-04 - Hydraulic Scram on High neutron flux
- DL3-12 – ICS Train 2 initiation on High RPV pressure

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The event is simulated by initiating a closure of the MSRIV and FW isolation valves. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

#### *Results*

The simulated closure of MSRIVs and FW isolation valves is presented on Figures 15.5-70 through 15.5-75 and the results are presented in Table 15.7.3-1. The results are shown for the limiting case for cladding temperature and reactor pressure response. Reactor scram occurs following high neutron flux. The pressure increase is limited by ICS initiation. Only one ICS train is needed to prevent pressure increase and maintain long-term cooling. A single failure of an ICS train to start on high pressure does not affect event mitigation.

The long-term core cooling capability is assured by meeting the acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the pressure criteria provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal water reaction.

Because there is significant margin to the acceptance criteria, this event is considered to have large margin and no additional conservatism is applied.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient that challenges the derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there are no radiological consequences associated with this event.

### **15.5.4.3 Reactivity and Power Distribution Anomalies (DBA)**

This event group is in the Reactivity Increase (RI) group.

#### **15.5.4.3.1 Fuel Loading Error Event**

The event is designated as a CN-DBA event. The fault sequence name is Fuel Loading Error (FLE) and the Fault Sequence ID is RI-FLE\_CN-DBA.

Both the mislocated and the misoriented fuel bundle events are referred to as the fuel loading error event. For a fuel loading error event, it is assumed that the improper loading of a fuel assembly is not discovered and corrected through the core verification program, and the plant is operated throughout the operating cycle assuming that the design core configuration has been correctly implemented.

#### **Mislocated Fuel Bundle**

The mislocated fuel bundle error involves the loading error of two fuel bundles-the misloaded bundle and the bundle that belongs in that location. The scenario includes: 1) one location loaded with a bundle that operates at a lower power than planned and 2) another location with a bundle operating at a higher power than planned.

Three errors must occur for the mislocated event to take place:

1. Bundle is misloaded into a wrong core position.
2. Fuel bundle is loaded in the location where the first mislocated bundle occurred is overlooked, resulting in another mislocated bundle.
3. Both misplaced bundles are overlooked during the core verification performed following core loading.

The misoriented fuel bundle error involves the loading error of one fuel bundle to be rotated 180 degrees from the intended orientation.

For the misorientation event, two errors must take place:

1. The assembly is rotated while being lowered into position.
2. The misoriented bundle is overlooked during the core verification performed following core loading.

It is assumed that the FLE is not detected and that fuel rods operate above the thermal and mechanical limits. The potential exists that one or more fuel rods experience cladding failure. If this were to occur, the adverse consequences are detectable and can be suppressed during operation similar to leaking fuel rods resulting from other failure mechanisms. For the FLE, the initial adverse consequences consist of perforation of a small number of fuel rods in the assembly. Any perforations in the fuel cladding that occurs is localized and does not propagate to other

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

assemblies. A control rod inserted in the vicinity of the leaking fuel rod(s) suppresses the power in the leaking fuel rod(s) and reduces the fission product release and offgas activity.

The FLE may exceed the operating mechanical LHGR limit because it may have worse peaking than the normally-loaded bundle. If the FLE operates above the operating mechanical LHGR limit, one or more rods may approach the design limit and experience cladding failure. If this occurs, the adverse consequences are the perforation of a small number of fuel rods in the misplaced bundle. The subsequent release of fission products to the reactor coolant is detected by the offgas system and processed accordingly.

### **Sequence of Events**

- Multiple layers of independent administrative controls barrier due to human actions fail
- Startup occurs with a bundle rotated or with two bundles swapped locations
- Bundle swap or rotation results in potential for limited fuel cladding failures
- Rod failures (if they occur) occur over an extended period of time
- Elevated radiation in reactor coolant

### **Identification of Operator Actions**

No operator action is credited for mitigating this event.

### **Systems Operation**

No mitigation functions are credited in this event.

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The core operates at normal conditions during the cycle.

#### *Results*

It is possible that operators recognize the mislocated or misoriented bundle during startup or initial core operation using operating procedures because local monitoring indicates the reactivity anomaly. This allows the reactor operators to mitigate the event, which is not credited in the analysis. It is also possible that the mislocated or misoriented bundles do not result in significant local reactivity changes or fuel cladding failures.

If there is a significant increase in local reactivity, then the fuel could operate above LHGR limits or enter boiling transition. Analysis shows that the possibility of entering boiling transition could occur in relatively hot rods and in one of the mislocated or misoriented bundles and potentially the four face adjacent bundles. The mislocated bundle bounds the misoriented bundle for the potential to increase the local reactivity and result in failed fuel rods.

Even if some rods did enter boiling transition or operate above the LHGR limits, the rod failures occur over an extended time (weeks or months) or fail intermittently. Rod failures may be recognized as essentially fuel leakers. Operators would observe the increase in offgas system activity and take appropriate actions. Once recognized, procedures require the operators to locate the failed rods and, once located, insert a control rod in the location to suppress the power. If power suppression is not successful, the reactor is shutdown. Neither the slow developing fuel failures nor the operator actions are credited in the radiological analysis.

### *Barrier Performance*

The reactor remains at normal operating pressure throughout the event. There is no challenge to the RPV and primary systems such as process barrier stress limitations.

The containment also remains at normal operating pressure and temperature. Containment integrity is not challenged.

As discussed above, there is potential for fuel failure. Analysis of potential mislocated bundles indicates that the number of fuel rod failures is bounded by assuming all the fuel rods in five bundles fail.

### *Radiological Consequences*

A conservative approach is used to evaluate the radiological consequences. Instead of one or two rods failing, the event is analyzed for all the fuel rods in a mislocated or misoriented fuel assembly, and all the rods in the mislocated bundle and the four adjacent fuel assemblies experience instantaneous failure during normal operation.

To further assure that the fuel bundles contain the maximum fission product release, all five bundles (array independent) are multiplied by:

1. A factor of 1.4 to account for variations in fission product inventory over the operational cycle
2. A second factor of 2.5 to account for variations in cycle-dependent bundle power as a ratio to the end of cycle average bundle power

This results in a total factor of  $1.4 \times 2.5 = 3.5$  to bound the bundle end of cycle inventory.

The radiological consequences of failing all of the fuel rods in five fuel bundles have been analyzed to provide results for no isolation trip with the release treated by an augmented offgas system.

The result for this analysis is presented in Table 15.7.3-2.

The radiological consequence of failing all fuel rods in five fuel bundles was analyzed for the case where the plant does not have a main steam line high radiation isolation trip. With no automatic MSIV closure, the activity is transported to an offgas system. The activity release to the environment would occur from the normal offgas release point after holdup in the offgas treatment system.

The results listed in Table 15.7.3-2 demonstrate that the radiological consequence do not exceed the offsite dose requirements for DBAs. The fuel loading error event is not a limiting event for DBA criteria for RCPB or containment integrity because the reactor remains at normal operating pressure throughout the event. There is no challenge to the RPV and primary systems, such as process barrier stress limitations. Containment also remains at normal operating pressure and temperature.

#### **15.5.4.4 Increase in Reactor Coolant Inventory DBAs**

This event group is in the Inventory Increase (II) group.

##### **15.5.4.4.1 Feedwater Flow Increase All Pumps**

This event is designated as a CN-DBA event. The fault sequence name is Feedwater Flow Increase – All Pumps (CCF-FWFI), Passive Digital CCF DL2 Technology Platform (CCF-DL2) and the Fault Sequence ID is II-CCF\_FWFI\_CCF-DL2\_CN-DBA.

### **Postulated Initiating Event**

One FW pump is normally operating and a second FW pump in standby. The RLC adjusts the pump speed to adjust FW flow to maintain RPV water level. This event assumes a spurious CCF that causes both FW pumps to increase flow to maximum speed that results in the maximum FW flow. Although not possible, the increase in flow is assumed to occur instantaneously.

### **Sequence of Events**

The fault sequence event summary:

- Both FW pumps increase to maximum flow causing RPV level increase
- RPC remains as-is at initial condition
- Level, pressure, and power increase
- Automatic FW isolation on high RPV level
- Scram on high simulated thermal power
- RPV pressure and level decrease
- Main steam isolation on low RPV pressure
- An ICS train initiates on high pressure. The first IC train fails to actuate (assumed single failure). One of the two remaining trains is sufficient to control pressure and remove decay heat as demonstrated in the pressure increase DBA analysis (the simulation is ended before any ICS initiation because the key mitigation DL functions have already been demonstrated)
- Controlled state achieved

Table 15.5-18 lists the sequencing of events.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

The credited DL3 functions:

- DL3-05 – Hydraulic Scram on High Simulated Thermal Power
- DL3-23 – FW Isolation on High RPV Water Level
- DL3-17 – MSRIV/MS CIV Isolation on Low RPV Pressure
- DL3-12 – ICS Train 2 Initiation on High RPV Pressure

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The event is simulated by increasing both feedwater pumps flow of to the maximum speed, resulting in the maximum FW flow. The initial conditions and total maximum flow for both FW pumps is provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### *Results*

The simulated maximum FW pumps flow event is presented on Figures 15.5-76 through 15.5-81, and the results are presented in Table 15.7.3-1. The results are shown for the case with the limiting PCT response results. The increase in FW flow causes reactor level, pressure, and power to increase as reactor pressure control and reactor level control are unavailable. FW isolation occurs on high reactor level. Scram occurs on high simulated thermal power. Pressure decreases until MSRV isolation initiation occurs on low pressure. Pressure then increases and one ICS train is initiated on high pressure. Only one ICS train is needed to prevent RPV pressure from increasing and maintaining long-term cooling. A single failure of an ICS train to start on high RPV pressure does not affect the event mitigation.

The long-term core cooling capability is assured by meeting the acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the pressure criteria provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal water reaction.

Because there is significant margin to the acceptance criteria, this event is considered to have large margin and no additional conservatism is applied.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the design criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.4.4.2 Inadvertent Isolation Condenser Initiation – All Trains**

This event is designated as a CN-DBA event. The fault sequence name is Inadvertent Isolation Condenser Initiation – All Trains (CCF-DL4a-IIIC), Passive Digital CCF DL2 Technology Platform (CCF-DL2) and the Fault Sequence ID is II-CCF-IIIC\_CCF-DL2\_CN-DBA.

### **Postulated Initiating Event**

The ICS is normally in standby mode. This event assumes a spurious CCF that causes all ICS condensate return valves to open, resulting in introducing cold water into the reactor.

### **Sequence of Events**

The fault sequence event summary:

- All ICS condensate return valves open
- RLC and RPC fail as-is at the initial condition
- Cold ICS condensate water drains into the chimney
- Core flow, reactor pressure, and power decrease
- RPV water level increases due to RLC failing as-is
- FW isolation occurs on high RPV water level
- Scram occurs on low RPV pressure

- Main steam isolation occurs on low RPV pressure
- Controlled state achieved

Table 15.5-19 lists the sequence of events.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

The credited DL3 functions:

- DL3-23 – FW Isolation on High RPV Water Level
- DL3-02 – Hydraulic Scram on Low RPV Pressure
- DL3-17 – MSRIV/MS CIV Isolation on Low RPV Pressure

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The event is simulated by opening all ICS condensate return valves in one second. The initial conditions are provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

#### *Results*

The inadvertent initiation of all IC trains event is presented on Figures 15.5-82 through 15.5-87, and the results are presented in Table 15.7.3-1. The results are shown for the case with the limiting PCT response results. When the IC condensate return valves are opened, cold water is introduced into the chimney region, reducing reactor power, reactor pressure, and core flow. Reactor scram and MSRIV isolation initiation occurs on low pressure. After an initial reduction in reactor level, level begins to rise as reactor level control is unavailable. FW isolation occurs on high reactor level.

The long-term core cooling capability is assured by meeting the acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the RCPB pressure criteria. The acceptance criteria are provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature where significant oxidation occurs due to metal water reaction.

Sensitivity studies were performed at the ICS minimum initial temperature in Table 15.5-3 and for an assumed increase in ICS return line volume of 50%. There was no significant change in the event sequence or results. Because there is significant margin to the acceptance criteria, this event is considered to have large margin and no additional conservatism is applied.

#### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.4.5 Decrease in Reactor Coolant Inventory – DBAs**

This event group is in the Inventory Reduction (IR) group.

##### **15.5.4.5.1 Loss of Feedwater Flow**

This event is designated as a CN-DBA event. The fault sequence name is CCF Loss of FW Flow (CCF-LOFW), Passive Digital CCF DL2 Technology Platform (CCF-DL2) and the Fault Sequence ID is IR-CCF-LOFW \_CCF-DL2\_CN-DBA.

#### **Postulated Initiating Event**

The event sequence assumes a spurious CCF causes the loss of all FW flow and a passive CCF of the DL2 function results in a fails as-is RPC.

#### **Sequence of Events**

The fault sequence event summary:

- Loss of FW flow causes RPV level and power to decrease
- RPV pressure decreases due to frozen RPC
- Scram occurs on low RPV level
- FW isolation on a loss of normal FW flow indication
- Main steam isolation on low RPV pressure
- All ICS trains initiate on low level
- Controlled state achieved

Table 15.5-20 lists the sequencing of events.

#### **Identification of Operator Actions**

No operator action is required to mitigate the event.

#### **Systems Operation**

Credited DL3 functions:

- DL3-03 – Hydraulic Scram on Low RPV Level
- DL3-17 – MSRIV/MS CIV Isolation on Low RPV Pressure
- DL3-14 – ICS Initiation on Low RPV Water Level
- DL3-39 – FW Isolation on Loss of Normal FW Flow

#### **Core and System Performance**

##### *Input Parameters and Initial Conditions*

The event is conservatively simulated by initiating a trip of all FW pumps. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

#### *Results*

The loss of FW flow is presented on Figures 15.5-88 through 15.5-93 and the results are presented in Table 15.7.3-1 for the exposure with the limiting PCT response. The trip of all FW pumps results in a reduction of vessel inventory, causing the pressure and vessel water level to drop. Reactor scram occurs on low RPV level. FW isolates on loss of normal FW flow. The MSRIV close on low pressure. RPV water level continues to decrease until ICS initiates. Three ICS trains are modeled to open. Only one ICS train is needed to prevent RPV pressure increase and maintain long-term cooling. A single failure of an ICS train to start on low RPV level will not affect event mitigation.

The long-term core cooling capability is assured by meeting the acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the RCPB pressure criteria. The acceptance criteria are provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature where significant oxidation occurs from metal water reaction.

Because there is significant margin to the acceptance criteria, this event is considered to have large margin and no additional conservatism is applied.

#### *Barrier Performance*

This event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there is no radiological consequence associated with this event.

#### **15.5.4.5.2 Reactor Pressure Vessel Pressure Control Open**

This event is designated as a CN-DBA event. The fault sequence name is RPV Pressure Control Open (CCF-RPCO), Passive Digital CCF DL2 Technology Platform (CCF-DL2) and the Fault Sequence ID is IR-CCF-RPCO\_CCF-DL2\_CN-DBA.

#### **Postulated Initiating Event**

The event assumes all TCVs and TBVs are fully opened by a spurious RPC CCF. The event sequence assumes a passive CCF of the DL2 functions resulting in the RLC failing as-is.

#### **Sequence of Events**

The fault sequence event summary:

- All TCVs and TBVs open causing RPV pressure and power to decrease
- FW flow remains at 100% due to DL2 CCF
- Reactor scram and main steam isolation on low RPV pressure
- FW isolates on high RPV level

- An ICS train initiates on high pressure. The first IC train fails to actuate (assumed single failure). One of the two remaining trains is sufficient to control pressure and removes decay heat as demonstrated in the pressure increase DBA analysis (the simulation is ended before any ICS initiation because the key mitigation DL functions have already been demonstrated)
- Controlled state achieved

Table 15.5-21 lists the event sequence.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

Credited DL3 functions:

- DL3-02 – Hydraulic Scram on Low RPV Pressure
- DL3-17 – MSRIV/MS CIV Isolation on Low RPV Pressure
- DL3-23 – FW Isolation on High RPV Water Level
- DL3-12 – ICS Train 2 Initiation on High RPV Pressure

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The event is simulated by fully opening all TCVs and TBVs. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

#### *Results*

The simulated RPV Pressure Control Open event is presented on Figures 15.5-94 through 15.5-99 and the results are presented in Table 15.7.3-1 for the exposure with the limiting PCT response. The opening of the TCVs and TBVs results in a decrease in reactor pressure causing voids to increase and power to decrease. FW remains at 100% rated flow due to the RLC CCF. The reactor scrams and main steam isolates on low RPV pressure. RPV water level rises until FW isolates on high RPV water level. RPV pressure then rises due to decay heat. An ICS train initiates on high RPV pressure after the first IC train fails to actuate (assumed single failure). One ICS train sufficiently controls pressure.

The long-term core cooling capability is assured by meeting the acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the RCPB pressure criteria. The acceptance criteria are provided in Table 15.3-2. The results demonstrate significant margin to the acceptance criteria. The cladding temperature remains well below the temperature where significant oxidation occurs due to metal water reaction.

Because there is significant margin to the acceptance criteria, this event is considered to have large margin and no additional conservatism is applied.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

Because this event does not result in any fuel failures or any release of primary coolant to the environment, there are no radiological consequence associated with this event.

#### **15.5.4.6 Loss-of-Coolant Accidents – DBAs**

The scenarios for LOCA developed in Section 15.2.4 bound the CN-DBA sequences, demonstrating the fuel and containment integrity acceptance criteria are met for at least 72 hours using only passive heat removal systems.

The LOCA method used in containment analyses is described in NEDC-33922P BWRX-300 Containment Methods (Reference 15.5-2). The initial conditions and the modeling parameters are biased to account for uncertainties. The Defense Lines (DL) credited in the conservative LOCA breaks inside containment are identified in Table 15.5-49.

Meeting the acceptance criteria for fuel integrity is demonstrated by showing that level does not fall below the TAF, or fuel cladding temperature does not exceed the fuel cladding temperature during normal operating conditions.

As discussed in Section 15.2.4, all large breaks are isolated rapidly (10 seconds). Therefore, RPV inventory loss does not threaten fuel integrity in a large break LOCA. After RPV isolation, decay heat is removed by the isolation condensers directly from the RPV. The limiting parameters for large break LOCA events is containment pressure and temperature. Containment peak pressure reaches its peak value at approximately the time of RPV isolation.

The LOCA analyses demonstrate the core remains covered or fuel cladding temperature remains below the normal operating temperature for at least 72 hours using conservative assumptions for unisolated small break LOCAs. Therefore, fuel cladding temperature remains well below the fuel acceptance criteria, oxidation does not occur, and there is no hydrogen generation from cladding oxidation.

#### **15.5.4.6.1 Main Steam Pipe Break Inside Containment, Conservative Case**

##### **Postulated Initiating Event**

A break in the main steam pipe occurs at an arbitrary location between the flow limiter, which is placed as close as possible to the RPV and the containment penetration. The most limiting break is the double-ended instantaneous guillotine break of the main steam pipe.

The break flow occurs from both ends of the break. Break flow from the RPV side of the break is choked at the flow limiter. The TSV/TCV is conservatively assumed to close rapidly because this results in retaining more energy in containment. Steam flows from the RPV to the closed TSV/TCV through the intact steam pipe and to the break location in the reverse direction to the normal flow through the broken steam pipe, discharging through the turbine side of the break. Steam flow from the RPV to the intact loop is also choked at the flow limiters. CIV closure is conservatively not credited, and the entire steam line volume inventory contributes to containment pressurization.

## Sequence of Events

The bounding scenario analyzed:

- Double-ended guillotine rupture of main steam line break inside containment concurrent with LOPP
- FW pump trip and coast down
- TSV or TCV start closing rapidly
- Scram initiated from high containment pressure
- Control rods start to insert
- ICS condensate return valve starts opening
- CUW stops
- Controls rods inserted sufficiently to diminish fission from prompt neutrons
- RIVs fully close
- Condensate return valve for one ICS train is fully open
- Peak containment pressure is reached
- Containment pressure starts decreasing

## Identification of Operator Actions

No operator action is required to mitigate the event.

## Systems Operation

As shown on Figure 15.5-102, break flow from the turbine side is generally higher than the break flow from the RPV side of the break because of the pipe inventory, and the break flow continues even after the RIVs are fully closed at 10 seconds.

Feedwater pumps are assumed to trip concurrent with the break initiation because the bounding scenario assumes LOPP concurrent with the pipe break. FW pumps are assumed to trip concurrent with the break initiation since the bounding scenario assumes LOPP concurrent with the break. One isolation condenser is started when the high containment pressure setpoint is reached, which occurs within 1 second. Although two isolation condensers are available, only one isolation condenser is credited to bound the large break case in the isolation condenser steam supply pipe. Figure 15.5-100 shows the heat removal rate of one IC exceeds the power generation decay heat after 20 seconds. As a result, reactor pressure decreases rapidly even after the break isolation shown on Figure 15.5-101. RPV level, labeled as "Collapsed Downcomer Level" on Figure 15.5-103 stabilizes well above the TAF in 3 hours. The decrease in the downcomer level during the first 3 hours is due to the gradual decrease in the void fraction in the core and chimney, not due to RPV water inventory losses. There is no RPV water inventory loss after the RIVs close. Fuel never heats up because the core remains covered throughout the event. After the fission power is diminished, fuel cladding temperature remains near saturation temperature.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Figure 15.5-104 shows the containment pressure in response to a large main steam pipe break inside containment. The break location is assumed away from the containment shell at the lowest main steam pipe elevation and directed upwards as discussed in LTR NEDC-33922P-A. This configuration maximizes containment pressure. The break location is assumed next to the containment shell and directed towards the containment shell in calculating the shell temperature on Figure 15.5-105 as discussed in LTR NEDC-33922P-A. This maximizes shell temperature.

The initial containment pressure includes a bias to account for uncertainties and is assumed at the containment high pressure setpoint for scram, reactor isolation and isolation condenser initiation. Although it appears that the setpoint is reached as soon as the break occurs, this is an artifact of the conservative initial condition assumption. A finite amount of time would have to elapse for containment pressure to reach the setpoint if the containment initial pressure is at the nominal pressure in normal operation. The pressure trend on Figure 15.5-104 shows that the containment pressure increases by 18.5 kPa in less than 1 second, indicating that the containment high pressure setpoint is reached in less than 1 second when the initial containment pressure is at the nominal pressure in normal operation. This confirms the break flow calculation assumption that containment high pressure setpoint will be reached in less than 1 second.

The initial reactor power in the conservative case calculations is 102% of the rated power to account for the power uncertainty. However, hot shutdown conditions may be more limiting for the mass release from the break because the initial RPV void fraction is lower resulting in higher liquid carryover to the break location. This also causes the break flow enthalpy to be lower. Both the rated initial conditions and hot shutdown initial conditions are analyzed. Figure 15.5-104 shows that the rated initial condition is more limiting for containment peak pressure.

PCCS does not require actuation, it is always in service and rejects heat to the equipment pool that is connected to the reactor cavity pool during normal operation. The calculations assume there is no heat loss from the containment shell to the concrete as discussed in the containment method LTR NEDC-33922P-A. Heat removal from containment atmosphere is by the containment shell heating up, by PCCS and through the containment dome to the pool. After RIV closure for large breaks, the only energy addition to the containment is due to the heat transfer from the RPV and hot piping walls. Because only one isolation condenser is sufficient to depressurize the RPV rapidly, heat load to containment also becomes small in the long term.

## **Core, System and Barrier Performance**

### *Results*

Event timing is summarized in Table 15.5-23. Key results are summarized in Table 15.7.3-3. The plots for RPV parameters and containment parameters are shown on Figures 15.5-100 through 15.5-105. The peak pressure is less than the design pressure with more than 20% margin. Containment shell temperature is also well below the containment shell design temperature of 166 °C. Peak accident pressure is approximately 322 kPaG (423 kPa) and half of the peak pressure is approximately 161 kPaG (262 kPa). As shown on Figure 15.5-104 **Error! Reference source not found.**, containment is depressurized rapidly, and containment pressure is reduced to 185 kPa at 6 hours. This meets the acceptance criterion for the containment response to pipe breaks that the containment pressure should be reduced to less than half of the peak pressure in 24 hours.

### *Barrier Performance*

There is no fuel damage as a result of an MSLB inside containment. The only activity available for release is normal reactor coolant concentration in the vessel and piping prior to the break.

### *Radiological Consequences*

The radiological consequences for a MSLB inside containment are bounded by the consequences for MSLB outside containment presented in Subsection 15.5.9.2.1.

#### **15.5.4.6.2 Feedwater Pipe Break Inside Containment, Conservative Case**

##### **Postulated Initiating Event**

A double-ended guillotine break occurs in the larger diameter segment of one feedwater pipe. This is more limiting than a break occurring in the smaller diameter FW pipe segments closer to the RPV. The bounding scenario is the same as that described in Subsection 15.5.4.6.1 for Main Steam Pipe Break Inside Containment

##### **Sequence of Events**

The bounding scenario analyzed:

- Double-ended guillotine rupture of the FW pipe break inside containment concurrent with LOPP
- FW trip and coast down
- TSV and TCV start closing rapidly
- Scram initiated from high containment pressure
- Control rods start inserting on scram initiation
- Condensate return valves on two ICS trains start opening
- Control rods are inserted sufficiently to diminish fission from prompt neutrons
- FWRIVs and CIVs are fully closed
- Peak containment pressure is reached
- IC valves are fully open

##### **Identification of Operator Actions**

No operator action is required to mitigate the event.

##### **System Operation**

RPV and containment response to a large FW break is similar to the RPV and containment response to a large main steam pipe break discussed in Subsection 15.5.4.6.1. Containment pressure reaches the containment high pressure setpoint for scram, reactor and containment isolation, and isolation condenser initiation in less than 1 second. Power generated by prompt fission is diminished in 3 seconds after the break. Condensate return valves in two of the three IC trains start opening in 1 second and fully open in 11 seconds. As shown on Figure 15.5-170, heat removal rate is much larger than the decay heat. As a result (shown on Figure 15.5-171), RPV pressure decreases much faster than the main steam pipe break case. Reactor water level is shown on Figure 15.5-172. The indicated water level stabilizes above the actual collapsed downcomer level. This is because the wide range level is off scale when the actual level falls below the lower tap and no longer indicates level. The actual collapsed downcomer level stabilizes well above TAF.

Break flow from the pump side decreases initially because the break location is far away from the pump and the enthalpy becomes saturated locally right after the break although the pump is still coasting down as shown on Figure 15.5-173. The break flow from the pump side recovers and exceeds that of the RPV break side. This is because the pipe water inventory and the pump coasting down. The break flow becomes zero when the CIV is closed at 10 seconds. Enthalpy value after this point is not meaningful because there is no break flow.

As in the main steam pipe break cases, containment pressure on Figure 15.5-174 and temperature on Figure 15.5-175 are calculated for a break location maximizing pressure and temperature.

An additional feedwater pipe break case was included accounting for the lower initial feedwater temperature because the containment peak pressure may be higher if the FW pipe break occurs when the plant is operating at reduced FW temperature. Break flow rate is higher at higher subcooling. However, break flow enthalpy is also lower. Figure 15.5-174 shows the containment pressure for normal FW temperature and reduced FW temperature. Normal FW temperature results in a higher containment pressure. The peak pressure for both cases is bounded by the peak pressure resulting from a main steam pipe break.

### **Core, System and Barrier Performance**

#### *Results*

Timing of events is summarized in Table 15.5-24. Plots for RPV and containment parameters are shown on Figures 15.5-170 through 15.5-175. Key results are summarized in Table 15.7.3-3 and show that the peak containment pressure and temperature resulting from feedwater pipe breaks are bounded by the main steam pipe breaks. Containment pressure and temperatures are less limiting than the main steam pipe cases and meet the acceptance criteria. Containment pressure calculated for FW pipe break at 6 hours is also less than half the peak containment pressure calculated for the main steam pipe case and decreasing.

#### *Barrier Performance*

There is no fuel damage as a result of an FWLB inside containment. The only activity available for release is normal reactor coolant concentration in the pipe prior to the break.

#### *Radiological Consequences*

The radiological consequences for a FWLB inside containment are bounded by the consequences for FWLB outside containment presented in Subsection 15.5.9.2.2.

#### **15.5.4.6.3 Large Isolation Condenser Pipe Breaks Inside Containment**

An isolation condenser system break larger than the area of a 19 mm equivalent diameter pipe is detected by the leakage detection for each ICS train separately. When a break is detected in one ICS train, both the steam supply pipe and the condensate return pipe of the affected ICS train are closed. The stroke time and delay time assumed for the isolation condenser isolation valves in the analysis are the same as those for all other RIVs and bound all other equipment initiation delays starting from the time of the pipe break. The other two unaffected isolation condensers are available to remove decay heat. For conservatism, the analysis assumes only one of the two remaining isolation condensers is put in-service on high containment pressure. Therefore, the number of isolation condensers available in this case is only one, which is the same as the number of isolation condensers available in the main steam pipe break cases as analyzed for all breaks larger than a 19 mm diameter.

Although the isolation condenser steam supply pipe diameter may be as large as the MS flow limiter diameter, the break flow rate from an isolation condenser steam supply pipe break is less than the break flow rate from the main steam pipe break. This is due to the much larger inventory in the main steam piping connected to both ends of the break.

The liquid in the isolation condenser is subcooled and does not contribute to high energy discharge from the break. Therefore, the main steam pipe break for containment response is more limiting than the isolation condenser steam supply pipe break.

ICS condensate return pipe diameter is much smaller than the FW pipe diameter used in the FWLB analysis. Therefore, large breaks in the isolation condenser condensate return pipe are bounded by large breaks in the FW pipe or MS pipe.

Because the isolation condenser pipe breaks are bounded by either the MS pipe or the FW pipe breaks, no further analysis of isolation condenser pipe breaks is needed.

#### ***15.5.4.6.4 Small Steam and Liquid Pipe Breaks Inside Containment***

##### **Postulated Initiating Event**

A break area of  $\leq 19$  mm equivalent diameter remains unisolated. These breaks are analyzed for fuel integrity and containment integrity for at least 72 hours using conservative assumptions.

All liquid pipe break nozzles are at least 4 meters above TAF. A small pipe break on instrument lines may remain unisolated indefinitely.

A small liquid pipe break and a small steam pipe break have similar break flow rates after the level falls to 4 m above TAF. Because the isolation condensers depressurize the RPV, the break flow becomes very small in a few hours. Fuel heat-up does not occur even without injection to the RPV. Containment heat removal occurs through the PCCS to the equipment pool and through the containment head to the reactor cavity pool.

##### **Sequence of Events – Small Steam and Liquid Pipe Breaks**

The bounding scenario analyzed:

- Small steam pipe break concurrent with LOPP
- Pressure controller remains as-is. TCV remains at initial position, turbine chest pressure decreases rapidly
- FW pump trips and coasts down
- Main steam pipe low pressure setpoint is reached
- Reactor scrams
- MSRIVs are fully closed
- Level decreases to Level 2
- Condensate return valves on two ICS trains are fully open
- Peak containment pressure is reached

##### **Identification of Operator Actions**

No operator action is required to mitigate the event.

## System Operation

The conservative cases assume LOPP concurrent with the pipe break, which is more limiting than the case where preferred power is available (discussed in Section 15.2). TCV/TSV closure is expected to occur as a consequence of the LOPP. However, TCV/TSV closure on LOPP is not credited. Rather, MSRV closure on low steam pipe pressure is conservatively credited in the analysis. The TCV/TSV back pressure is assumed to decrease rapidly maximizing the RPV water inventory loss to the turbine. Reactor scram also occurs on low steam line pressure accounting for the delays after the low steam pipe pressure is reached.

Isolation condenser condensate return valves start opening when the level falls to Level 2. As shown on Figure 15.5-115 and Figure 15.5-116, decay heat is removed by two isolation condensers. RPV depressurizes initially when the sum of the decay heat removal rate by the isolation condensers and the energy discharge from the break exceeds the decay heat power. Isolation condensers remove less power at lower pressure because of the lower temperature difference between the RPV steam and pool water. Reactor pressure stabilizes at a low value and the depressurization rate becomes very small. As shown on Figure 15.5-117, there is a rapid decrease in the collapsed downcomer level. This decrease is primarily due to the void collapse in the RPV. There are two small increases in level at approximately 69000 and 91000 seconds on Figure 15.5-117. These increases are due to void redistribution in the vessel. There is no increase in the RPV water inventory. As shown on Figure 15.5-117, downcomer collapsed level falls below TAF at 206000 seconds. However, the two-phase level in the core remains above TAF. Fuel remains wetted and thus never heats up.

The break mass and energy release are calculated assuming there is no back pressure. This assumption was made to bound breaks outside containment and accounts for the expected lower containment pressure than calculated because of the conservative assumptions used in the containment analyses. Even without break back pressure, Figure 15.5-119 shows that the break flow becomes very small in the long term.

Containment pressure calculated by using conservative assumptions and the small liquid pipe break flow without back pressure is shown on Figure 15.5-120. RPV pressure is also shown on the same figure. The calculated containment pressure increases to the RPV pressure at approximately 232800 seconds. Containment pressure is not higher than the RPV pressure because the break flow stops if the containment pressure becomes equal to the RPV pressure.

However, there is a potential that if ICS depressurizes the RPV faster than PCCS depressurizes containment in the absence of a break, reverse flow from containment to the RPV may occur. Non-condensables ingested into the RPV may collect in the isolation condensers and reduce their efficiency. Both the RPV and the containment could start repressurizing if back flow were to occur. In order to investigate this possibility, the containment pressure is calculated starting from 232800 seconds until the end of the 72 hour period assuming no break flow. The dashed line on Figure 15.5-118 shows that containment is rapidly depressurized in the absence of break flow. Because containment pressure decreases faster than the RPV pressure when there is no break flow, the RPV cannot depressurize below the containment pressure and reverse flow cannot occur. Energy released from the RPV through the break is a small fraction of the decay heat in the long term. A much larger fraction of the decay heat is removed by the isolation condensers. Therefore, RPV pressure calculated with and without a break are approximately the same at the time the RPV depressurizes to near containment pressure.

Figure 15.5-120 shows that containment pressure remains well below 262 kPa in the long term, which is 50% of the peak accident pressure calculated in Subsection 15.5.4.6.1.

Figure 15.5-108 shows that level remains above TAF for small steam pipe breaks. Containment response shown on Figure 15.5-110 and Figure 15.5-111 for a small steam pipe break is similar to the containment response in Figure 15.5-120 and Figure 15.5-121 for a small liquid pipe break.

A small pipe break on an isolation condenser steam pipe does not cause a more limiting core or containment response than an instrument line break. The small breaks conservatively credit only two of the three isolation condensers even though a break of  $\leq 19$  mm equivalent diameter on an isolation condenser does not cause degradation in the isolation condenser. There is sufficient steam in the RPV to feed the condensation in the isolation condenser. Insufficient steam in the RPV to feed the isolation condenser only occurs if the RPV is depressurized to the point where almost all of the steam escapes the break. This is the case if the RPV pressure is lower than that calculated for an instrument pipe break. However, in this case, the break flow is also less than the break flow calculated for an instrument pipe break, resulting in the isolation condenser small break less limiting than the instrument pipe break. Breaks on isolation condenser steam pipes are no more limiting than a break on an instrument steam pipe break. This is because the break flow rates are the same for a small steam pipe break regardless of the break location, or the RPV pressure is too low to feed the isolation condenser.

### **Core, System and Barrier Performance**

#### *Results*

For small steam pipe breaks, timing of events is summarized in Table 15.5-25. Key results are summarized in Table 15.7.3-3. The plots for RPV parameters and containment are shown on Figures 15.5-106 through 15.5-111.

All liquid pipe break nozzles are at least 4 meters above the TAF, and the timing of the events is summarized in Table 15.5-26. Key results are summarized in Table 15.7.3-3. The plots for RPV and containment parameters are shown on Figures 15.5-115 through 15.5-121. A small pipe break on the instrument lines may remain unisolated indefinitely. Since the isolation condensers depressurize the RPV, the break flow becomes very small in a few hours. Fuel heat-up does not occur even without injection to the RPV.

#### *Barrier Performance*

There is no fuel damage as a result of a small liquid and feedwater breaks inside containment. The only activity available for release is normal reactor coolant concentration in the pipe prior to the break.

#### *Radiological Consequences*

The radiological consequences for a small liquid or feedwater breaks inside containment are bounded by the consequences for small liquid and steam pipe breaks outside containment presented in Subsection 15.5.9.2.4.

### **15.5.5 Analysis of Design Extension Conditions Without Core Damage**

The bounding transient event selection in Subsection 15.2.3 determines the list of DEC events evaluated in the following subsections. Tables 15.5-3 through 15.5-4 provide input parameters and initial conditions used in the DEC analyses. Table 15.5-5 provides the DLs used in the DEC analyses. The analysis is performed consistent with the DSA analysis approach described in Subsections 15.1.3 and 15.2.4.

#### **15.5.5.1 Control Rod Drop Accident – Practically Eliminated**

The BWRX-300 GNF-2 fuel has a core design that is similar to the BWR operating fleet.

The FMCRD uses a bayonet style coupling that requires a 45-degree rotation to uncouple. Since the FMCRD is firmly bolted into its position under the reactor vessel and the control rod is constrained from rotation by the fuel assemblies, it is not possible for the control rod to uncouple from the FMCRD during reactor operation. The hollow piston is the component within the FMCRD coupled to the control rod. The hollow piston normally rests on the ball nut internal to the FMCRD. There are dual FMCRD separation switches that sense that the hollow piston along with the associated control rod are resting on the ball nut. If the sensor detects that the hollow piston is no longer on the ball nut, then control rod withdrawal is blocked. Additionally, the hollow piston has latches that prevent inadvertent withdrawal of the assembly when not attached to the ball nut. This essentially limits possible separation such that it is not physically possible for a control rod drop accident involving a single control rod falling completely out of the core to occur.

Control rod ejection is prevented by physical constraints including the attachment of the control rod guide tube to the core plate and the CRD connection to the control rod guide tube. The FMCRD includes a brake that further prevents inadvertent rod withdrawal. The FMCRD also includes an internal ball check valve, which reduces the likelihood of rapid rod withdrawal. The ball check valve is a SC1 DL3 function because it prevents:

- Reverse flow from the scram inlet port against the pressure and flow conditions caused by a break of the scram line
- The loss of pressure from the underside of the hollow piston
- The generation of loads on the drive that could cause a rapid rod withdrawal and associated reactivity insertion

Normal rod movement and the rod withdrawal rate are limited by the FMCRD. The rod control system controls rod patterns and provides control rod blocks limiting the rate and amount of reactivity addition for control rod movement.

The combined features of the CRD system and the rod control system incorporate appropriate limits on the potential amount and rate of reactivity increase. The fine motion movement capability of the FMCRD allows limited reactivity additions from rod withdrawal. Control rod withdrawal sequences and patterns are selected to achieve optimum core performance and low individual rod worth. The BWRX-300 design prevents rod drop and rod ejection events through positive design means. Control rod drop is prevented using a bayonet style coupling, CRD mechanism latches, and CRD separation switches. As a result, the CRDA and control rod ejection event have been practically eliminated.

#### **15.5.5.2 Pressure Increase – DECs**

##### **15.5.5.2.1 Closure of One Main Steam Reactor Isolation Valve**

This event is designated as an EX-DEC event. The fault sequence name is Closure of One MSRIV (1MSRIVC), and the Fault Sequence ID is PI-1MSRIVC\_CCF-Hydraulic-Scram\_EX-DEC.

#### **Postulated Initiating Event**

The PIE is the same as the BL-AOO event. The analysis assumes a CCF hydraulic scram failure. The control rods enter the core using the CRDM run-in function. This event demonstrates that the CRDM run-in function performs the FSF control of reactivity without hydraulic scram.

## Sequence of Events

The fault sequence event summary:

- One MSRIV closes causing pressure and power to increase
- Hydraulic scram signal on MSRIV position. Scram fails
- Hydraulic scram on any signal fails
- MSRIV in the second steam line closes on leak detection indication (assumed because it makes the event more severe)
- CRDM run-in initiation on high flux after scram signal
- All ICS trains initiate on high flux after scram signal
- FW pumps trip on high flux after scram signal
- Controlled state achieved

Table 15.5-27 lists the sequencing of events.

## Identification of Operator Actions

No operator action is required to mitigate the event.

## Systems Operation

Credited DL2 functions:

- DL2-21 – Anticipatory Hydraulic Scram Signal on MSRIV/MSRIV Position (scram fails)
- DL2-43 – FW Check Valve Closure on Reverse FW Flow

Credited DL4a functions:

- DL4a-40 – CRD Fast Motor Run-In on High Flux After Scram Signal
- DL4a-41 – FW Pump/Condensate Pump Trip on High Flux after Scram Signal
- DL4a – ICS Trains 1, 2, and 3 Initiations on High Flux after Scram Signal

## Core and System Performance

### *Input Parameters and Initial Conditions*

The event is simulated by initiating closure of one MSRIV. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR and hot rod power are consistent with the referenced core design.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### *Results*

The simulated closure of one MSRIV is presented on Figures 15.5-124 through 15.5-129 and the results are presented in Table 15.7.3-1. The results are shown for the case with the limiting result for cladding temperature and reactor pressure response. The neutron flux increases rapidly because of the void reduction caused by the pressure increase. The pressure increase is limited due to the initiation of ICS, FW pump trip and CRDM run-in that occur on high flux after scram signal (i.e., indications of high power level post scram initiation). The long-term core cooling capability is assured by meeting the DBA event acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the DBA event RCPB pressure criteria. The

acceptance criteria are provided in Section 15.3. The results demonstrate significant margin to the DBA acceptance criteria. The cladding temperature remains below the temperature at which significant oxidation occurs due to metal water reaction.

This event resulted in the highest peak cladding temperature and peak vessel pressure. Sensitivities are performed to examine cliff edge effects. Sensitivities on key initial conditions and phenomena that impact cladding temperature and peak vessel pressure described in the TRACG Application (Reference 15.5-3) are applied separately by at least one standard deviation:

- Core void coefficient
- Channel interfacial shear
- Chimney interfacial shear
- Separator steam carry under
- Critical quality used in boiling transition correlation
- Hot rod power

Results indicate no significant cliff edge effects. No excessive vessel pressure and no core damage occurs.

#### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the DBA derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

DEC events do not have event specific radiological acceptance criteria. The effects of DEC events are considered in the PSA (Section 15.6).

#### **15.5.5.2.2 Complex Sequence of Generator Load Rejection or Turbine Trip**

This event is designated as an EX-DEC event. The fault sequence name is Complex Sequence Generator Load Rejection or Turbine Trip (LR-TT) plus CCF-Mechanical CRD, and the Fault Sequence ID is CSS-LR-TT\_CCF-Mechanical-CRD\_EX-DEC. This event demonstrates that with multiple failures to insert independent control rods with diverse motive forces combined with a very frequent PIE, that the remaining control rods perform the FSF reactivity control.

#### **Postulated Initiating Event**

The postulated initiating event is the same as for the LR-TT AOO event. Additionally, the event assumes that half of the control rods with the highest rod worth fail to scram and the CRDM run-in fails to insert the rods that failed to scram. No other failures are assumed.

#### **Sequence of Events**

The fault sequence event summary:

- TCVs and/or TSVs close quickly causing pressure and power increase
- Anticipatory scram occurs on indication of a turbine trip or load rejection signal, but half of the control rods fail to insert
- RPC opens TBVs to control pressure

- RLC maintains level
- Controlled state achieved

Table 15.5-28 lists the sequence of events.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

Credited DL2 functions:

- DL2-02 – Maintain Target Level
- DL2-01 – Maintain Target Pressure
- DL2-08 – Anticipatory Hydraulic Scram on Generator Load Rejection or Turbine Trip Demand
- DL2-09 – TBV Fast Open on Generator Load Rejection or Turbine Trip Demand

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The event is simulated by initiating a generator load rejection or turbine trip that results in a fast closure of the TCVs and/or TSVs. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR and hot rod power are consistent with the referenced core design.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

#### *Results*

The simulated generator load rejection / turbine trip is presented on Figures 15.5-130 through 15.5-135 and the results are presented in Table 15.7.3-1. The results are shown for the case with the limiting result for reactor pressure response. Automatic anticipatory reactor scram occurs following indication of a generator load rejection or turbine trip with half of the rods failing to insert. The neutron flux increases rapidly because of the void reduction caused by the pressure increase.

The long-term core cooling capability is assured by meeting the DBA event acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the DBA event RCPB pressure criteria. The acceptance criteria are provided in Table 15.3-2. The results demonstrate significant margin to the DBA acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal water reaction.

A controlled state is achieved with steam bypassed to the main condenser and fed back into the reactor by feedwater. This is maintained for a significant amount of time as long as power is available. Given the conditions, operators initiate additional CRDM run-in signals or manually insert CRDM to insert the remaining control rods into the core. If operator actions are unsuccessful, operators inject boron to shut the reactor down. Another option available to the operators is to decrease power by reducing FW flow. With reduced FW flow, reactor water level decreases, reducing core flow and reducing reactivity through void reactivity feedback until the steam flow matches the FW flow.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the DBA derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

DEC events do not have event specific radiological acceptance criteria. The effects of DEC events are considered in the PSA (Section 15.6).

#### **15.5.5.2.3 Loss of Condenser Vacuum with CCF Hydraulic Scram**

This event is designated as an EX-DEC event. The fault sequence name Loss of Condenser Vacuum (LOCV), CCF-Hydraulic-Scram and the Fault Sequence ID is PI-LOCV\_CCF-Hydraulic-Scram\_EX-DEC. This event demonstrates that the CRDM run-in function performs the FSF controlling reactivity without the hydraulic scram.

### **Postulated Initiating Event**

The PIE is the same as the BL-AOO event. A CCF results in failure of hydraulic scram. The control rods enter the core using the CRDM run-in function. No other failures are assumed.

### **Sequence of Events**

The fault sequence event summary:

- Loss of vacuum results in a turbine trip
- TSVs close quickly causing pressure and power increase
- Hydraulic scram signal on either turbine trip or high main condenser pressure scram fails
- Hydraulic scram fails on any signal
- CRDM run-in initiation occurs on high flux after scram signal
- RPC opens TBVs to control pressure
- RLC maintains level
- ICS initiates on high flux after scram signal
- FW pumps trip on high flux after scram signal
- TBVs close on high main condenser pressure
- Controlled state achieved

Table 15.5-29 lists the sequencing of events.

### **Identification of Operator Actions**

No operator action is required to mitigate the event.

### **Systems Operation**

Credited Defense Line functions:

DL2:

- DL2-02 – Maintain Target Level
- DL2-01 – Maintain Target Pressure

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

- DL2-09 – TBV Fast Open on Generator Load Rejection or Turbine Trip Demand
- DL2-13 – Turbine Trip on High Main Condenser Pressure Setpoint 2
- DL2-14 – TBV Closure on High Main Condenser Pressure Setpoint 3
- DL2-08 – Hydraulic Scram on Generator Load Rejection or Turbine Trip Demand (scram fails)

DL4a:

- DL4a-40 – CRD Fast Motor Run-In on High Flux After Scram Signal
- DL4a-41 – FW Pump/Condensate Pump Trip on High Flux after Scram Signal
- DL4a – ICS Trains 1, 2, and 3 Initiations on High Flux after Scram Signal

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The loss of condenser vacuum results in a turbine trip. The event is simulated by initiating a turbine trip that results in a fast closure of the TSVs. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR and hot rod power are consistent with the referenced core design.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### **Results**

The simulated loss of condenser vacuum is presented on Figures 15.5-136 through 15.5-141 and the results are presented in Table 15.7.3-1. The results are shown for the case with the limiting result for cladding temperature and reactor pressure response. The neutron flux increases rapidly because of the void reduction caused by the pressure increase. However, the pressure increase is initially limited by the TBVs opening. The pressure increase is limited due to the initiation of ICS, FW trip, and CRDM run-in that occur on high flux after scram signal.

The long-term core cooling capability is assured by meeting the DBA event acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the DBA event RCPB pressure criteria. The acceptance criteria are provided in Table 15.3-2. The results demonstrate significant margin to the DBA acceptance criteria. The cladding temperature remains below the temperature at which significant oxidation occurs due to metal water reaction.

#### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the DBA derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

DEC events do not have event specific radiological acceptance criteria. The effects of DEC events are considered in the PSA (Section 15.6).

#### **15.5.5.2.4 Loss-of-Preferred Power with CCF Hydraulic Scram**

This event is designated as an EX-DEC event. The fault sequence name is Loss-of-Preferred Power (LOPP), CCF-Hydraulic-Scram and the Fault Sequence ID is PI-LOPP\_CCF-Hydraulic-Scram\_EX-DEC. This event demonstrates that the CRDM run-in function that performs the FSF controlling reactivity without the hydraulic scram.

#### **Postulated Initiating Event**

The PIE is the same as the BL-AOO event. A CCF results in failure of hydraulic scram. The control rods enter the core using the CRDM run-in function. No other failures are postulated in the event.

#### **Sequence of Events**

The fault sequence event summary:

- LOPP results in generator output breakers opening
- TCVs close quickly
- Feedwater pumps lose power
- Hydraulic scram signal fails on either generator load rejection or low electric bus voltage
- Hydraulic scram fails on any signal
- CRDM run-in initiation on high flux after scram signal
- TBVs close on loss of power
- ICS initiates on high flux after scram signal
- Controlled state achieved

Table 15.5-30 lists the sequencing of events.

#### **Identification of Operator Actions**

No operator action is required to mitigate the event.

#### **Systems Operation**

Credited Defense Line functions:

DL2:

- DL2-01 – Maintain Target Pressure
- DL2-08 – Hydraulic Scram on Generator Load Rejection or Turbine Trip Demand (scram fails)
- DL2-09 – TBV Fast Open on Generator Load Rejection or Turbine Trip Demand
- DL2-43 – FW Check Valve Closure on Reverse FW Flow

DL4a:

- DL4a-40 – CRD Fast Motor Run-In on High Flux After Scram Signal
- DL4a – ICS Trains 1, 2, and 3 Initiations on High Flux after Scram Signal

## **Core and System Performance**

### *Input Parameters and Initial Conditions*

The Loss-of-Preferred Power results in the generator output breakers opening and a loss of power to the feedwater pumps. The event is simulated by initiating a FW pump trip and a load rejection that results in a fast closure of the TCVs. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR and hot rod power are consistent with the referenced core design.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

### *Results*

The simulated Loss-of-Preferred Power with CCF hydraulic scram failure is shown on Figures 15.5-142 through 15.5-147 and the results are presented in Table 15.7.3-1. The results are shown for the case with the limiting result for cladding temperature and reactor pressure response. The rapid closure of the TCVs results in a pressure increase. The neutron flux increases rapidly because of the void reduction caused by the pressure increase. However, the pressure increase is initially limited by the opening of the TBVs. The TBVs later close, ICS initiates, and CRDMs run-in on high flux after scram signal. The ICS continues to limit the pressure increase.

The long-term core cooling capability is assured by meeting the DBA event acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the DBA event RCPB pressure criteria. The acceptance criteria are provided in Table 15.3-2. The results demonstrate significant margin to the DBA acceptance criteria. The cladding temperature remains below the temperature at which significant oxidation occurs due to metal water reaction.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the DBA derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur. Therefore, these barriers maintain their integrity and function as designed.

### *Radiological Consequences*

DEC events do not have event specific radiological acceptance criteria. The effects of DEC events are considered in the PSA (Section 15.6).

## **15.5.5.3 Reactivity and Power Distribution Anomalies – DEC**

### **15.5.5.3.1 All Control Rod Withdrawal at Power (ACRW)**

This event is designated as an EX-DEC event. The fault sequence name is CCF - All Control Rod Withdrawal at Power- All Rods (CCF-ACRW), Passive Digital CCF DL2 Technology Platform (CCF-DL2) and the Fault Sequence ID is RI-CCF-ACRW\_CCF-DL2\_EX-DEC.

### **Postulated Initiating Event**

All control rods inserted in the core start to withdraw due to rod control spurious CCF. A passive CCF of DL2 technology platform results in DL2 function failure.

## Sequence of Events

The fault sequence event summary:

- All control rods start to withdraw resulting in a power increase
- ATLM (Automatic Thermal Limiting Monitor) and MRBM (Multi-Channel Rod Block Monitor) fail to block rod withdrawal
- RPC and RLC fail as-is at the initial condition
- Scram on STP power or neutron flux
- After scram, the immediate challenge to cladding and RCPB integrity is over
- RPV pressure decreases
- RPV level decreases temporarily due to the void collapse in the core and chimney
- Sensed level increases due to continuing FW flow and flashing in the downcomer
- FW isolation occurs on high RPV level
- Main steam isolation occurs on low RPV pressure and pressure slowly increases
- One ICS train initiates on high pressure (the simulation is ended before any ICS initiation because the key mitigation DL functions have already been demonstrated and a single ICS train is capable of controlling pressure and removing decay heat as demonstrated in the pressure increase DBA analysis)
- Controlled state achieved

Table 15.5-31 lists the sequencing of events.

## Identification of Operator Actions

No operator action is required to mitigate the event.

## Systems Operation

Credited DL3 functions:

- DL3-05 – Hydraulic Scram on High Simulated Thermal Power
- DL3-04 – Hydraulic Scram on High Neutron Flux
- DL3-23 – FW Isolation on High RPV Water Level
- DL3-17 – MSRIV/MS CIV Isolation on Low RPV pressure
- DL3-11 – ICS Train 1 initiation on High RPV pressure

## Core and System Performance

### *Input Parameters and Initial Conditions*

The event is simulated by withdrawing all the control rods in the core using the initial conditions, plant parameters, and control rod speed specified in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC and MOC cycle exposure conditions. EOC exposure is not run because all control rods are fully withdrawn.

### *Results*

The simulated ACRW is presented on Figure 15.5-148 through 15.5-153. The analysis results are presented in Table 15.7.3-1. The results are shown for the case with the limiting PCT response result.

When the control rods are withdrawn, the power increases and scram occurs on high simulated thermal power or neutron flux. The RPV water level increases and FW is isolated. RPV pressure decreases and the MSRIVs close. Eventually the RPV pressure increases, and one ICS train initiates. The pressure remains well within the DBA event RCPB pressure acceptance criteria in Subsection 15.3.1. There is no challenge to containment.

The long-term core cooling capability is assured by meeting the DBA acceptance criteria for fuel cladding and RCPB. The reactor integrity is assured by meeting the DBA event RCPB pressure criteria. The results demonstrate significant margin to the DBA acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs due to metal water reaction.

### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the DBA derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed and there is no core damage.

### *Radiological Consequences*

DEC events do not have event specific radiological acceptance criteria. The effects of DEC events are considered in the PSA (Section 15.6).

#### **15.5.5.3.2 Inadvertent Single Control Rod Withdrawal at Power (ICRW) - DEC**

This event is designated as an EX-DEC event. The fault sequence name is Inadvertent Control Rod Withdrawal at Power - single rod (ICRW), and the Fault Sequence ID is RI-ICRW\_CCF\_DL2\_EX-DEC.

### **Postulated Initiating Event**

A control rod inserted in the core is withdrawn due to a failure. A passive CCF of DL2 results in failure of the DL2 functions.

### **Sequence of Events**

The fault sequence event summary:

- Single rod (with highest reactivity worth) starts to withdraw
- ATLM and MRBM fail to block the rod withdrawal
- RPC and RLC are assumed to function normally because this prolongs the event and makes it more severe for cladding temperature effects
- Reactor power increases but the scram level is not reached
- Local power and cladding temperature increase
- Power and the cladding temperature reach a stable level
- Operator action to initiate scram is expected due to the high power level (Not credited in analysis simulation as these DL functions demonstrate achieving and maintaining a controlled state)

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

- After the scram, no credit is taken for RPC or RLC (the simulation is ended because the key mitigation DL functions have already been demonstrated)
- RPV pressure decreases and the RPV level increases (the simulation is ended because the key mitigation DL functions have already been demonstrated)
- FW isolation occurs on high RPV level (the simulation is ended because the key mitigation DL functions have already been demonstrated)
- Main steam isolation occurs on low RPV pressure and pressure slowly increases (the simulation is ended because the key mitigation DL functions have already been demonstrated)
- One ICS train initiates on high pressure (the simulation is ended before any ICS initiation because the key mitigation DL functions have already been demonstrated and a single ICS train is capable of controlling pressure and removing decay heat as demonstrated in the pressure increase DBA analysis)
- Controlled state achieved

Table 15.5-32 lists the sequencing of events.

#### **Identification of Operator Actions**

No operator action is credited.

#### **Systems Operation**

Credited DL3 functions:

- DL3-17 – MSRV/MSIV isolation on Low RPV Pressure
- DL3-23 – FW Isolation on High RPV Water Level
- DL3-11 – ICS Train 1 Initiation on High RPV Pressure

#### **Core and System Performance**

##### *Input Parameters and Initial Conditions*

The event is simulated by withdrawing a single control rod in the core using the initial conditions, plant parameters, and control rod speed specified in Tables 15.5-3 through 15.5-5. The initial CPR and the hot rod power are consistent with the reference core design.

The analysis is performed using an equilibrium core design. The event is run at BOC and MOC cycle exposure conditions. EOC exposure is not run because all control rods are fully withdrawn.

##### *Results*

The simulated ICRW event is presented on Figures 15.5-154 through 15.5-159. The analysis results are presented in Table 15.7.3-1. The results are shown for the case with the limiting PCT response result.

When the control rod is withdrawn, the power increases. The RPV level and pressure vary insignificantly because RLC and RPC function to maintain level and pressure preventing scram, thus maximizing the impact of fuel cladding temperature increase.

In this event, the PCT values are well below the DBA acceptance criteria. The long-term core cooling capability is assured because the effects are local. The reactor integrity is assured by meeting the DBA event RCPB pressure criteria.

Sensitivities are performed examining cliff edge effects. Key initial conditions are conservatively biased to cause transition boiling even though this does not occur at the nominal / realistic conditions associated with DEC conditions. With initial CPR conservatively biased low (by approximately 0.05), and the hot rod power (LHGR) conservatively biased high (approximately 30%), local high cladding temperatures occur in hot rods in a few high power bundles located near the control rod withdrawn in error. This result is expected in fuel cladding failure in a very limited number of rods. However, the fuel failures are localized, the core remains cooled, and no core damage occurs.

#### *Barrier Performance*

There is no challenge to the RCPB and containment. The fuel cladding may experience local failures if initial LHGR and CPR are more severe. The predicted number of rod failures is limited to high-powered fuel rods in a few high-powered bundles near the control rod withdrawn in error. However, the fuel failures are localized, the core remains cooled, and no core damage occurs.

#### *Radiological Consequences*

DEC events do not have event specific radiological acceptance criteria. The effects of DEC events are considered in the PSA (Section 15.6).

#### **15.5.5.4 Decrease in Reactor Coolant Inventory – DEC**

This event is in the IR group and is designated as an EX-DEC event. The fault sequence name is FW Isolation (CCF-FWI-DL3) and the Fault Sequence ID is IR-CCF-FWI-DL3\_EX-DEC.

#### **Postulated Initiating Event**

The event sequence assumes a spurious CCF isolates all FW flow and a passive CCF of the DL3 functions.

#### **Sequence of Events**

The fault sequence event summary:

- FW flow isolation causes RPV water level and power to decrease
- RPC maintains RPV pressure
- Scram and MSRV isolation on sustained low FW flow
- ICS pressure control initiates on high RPV pressure
- Controlled state achieved

Table 15.5-33 lists the event sequence.

#### **Identification of Operator Actions**

No operator action is required to mitigate the event.

#### **Systems Operation**

Credited Defense Line functions:

DL2:

- DL2-01 – Maintains Target Pressure
- DL2-42 – Anticipatory Hydraulic Scram on Sustained Low FW Flow
- DL2-31 – ICS Pressure Control on High Reactor Pressure

DL4:

- DL4a -12 – MSRIV/MS CIV Isolation on Sustained Low FW Flow

### **Core and System Performance**

#### *Input Parameters and Initial Conditions*

The event is simulated by initiating a conservatively fast isolation of all FW flow. The initial conditions and plant parameters are provided in Tables 15.5-3 through 15.5-5. The initial CPR is conservatively biased low, and the hot rod power is conservatively biased high.

The analysis is performed using an equilibrium core design. The event is run at BOC, MOC, and EOR cycle exposure conditions.

#### *Results*

The CCF FW isolation event is presented on Figures 15.5-160 through 15.5-165 and the results are presented in Table 15.7.3-1 for the exposure with the limiting PCT response. The loss of FW flow results in a reduction of vessel inventory, causing the power and RPV water level to decrease. RPC maintains reactor pressure. Reactor scram and main steam isolation occurs based on sustained low FW flow. ICS pressure control initiates based on high RPV pressure.

The long-term core cooling capability is conservatively assured by meeting the DBA acceptance criteria for fuel cladding and RCPB. The reactor integrity is conservatively assured by meeting the DBA event RCPB pressure criteria. The acceptance criteria are provided in Table 15.3-2. The results demonstrate significant margin to the DBA acceptance criteria. The cladding temperature remains well below the temperature at which significant oxidation occurs from metal water reaction.

#### *Barrier Performance*

The effect of this event does not result in any temperature or pressure transient in excess of the DBA derived acceptance criteria for the fuel, pressure vessel, or containment. No fuel failures occur because there is no significant cladding temperature increase. Therefore, these barriers maintain their integrity and function as designed.

#### *Radiological Consequences*

DEC events do not have event specific radiological acceptance criteria. The effects of DEC events are considered in the PSA (Section 15.6).

### **15.5.6 Analysis of Design Extension Conditions with Core Damage**

The analysis of DEC with core damage are addressed in the Level 2 PSA described in Section 15.6.4.

### **15.5.7 Analysis of Postulated Initiating Events and Accident Scenarios Associated with the Fuel Pool**

The analysis fault sequences associated with the fuel pool are DEC analyzed in the Level 1 PSA described in Subsection 15.6.3.

### 15.5.8 Analysis of Fuel Handling Events

The Fuel Handling Accident (FHA) is categorized as a non-reactor group DEC event. The fault sequence ID is FHA\_EX-DEC. The event occurs as a result of a failure of the fuel assembly lifting mechanism, resulting in the drop of a raised irradiated fuel assembly onto the reactor core or into the fuel pool. The dropped irradiated fuel assembly results in cladding failure in the dropped and impacted bundles. The sequence of events for the postulated FHA is provided in Table 15.5-34.

The dose results are conservatively compared to the criterion in Table 15.7.6-1 to demonstrate compliance to the DBA acceptance criterion.

#### **Fuel Damage**

Because of the complex nature of the impact and the resulting damage to fuel assembly components, predicting the number of failed rods is not possible. For this reason, a simplified energy approach is taken. Numerous conservative assumptions are made to assure that the number of failed rods is conservatively analyzed.

The key assumption for the FHA is that during a refueling operation, a fuel assembly is moved over the top of the reactor core or fuel pool. While the fuel grapple is in the over-hoist condition with the bottom of the assembly at the maximum height allowed when using the fuel handling equipment, the main hoist cable and a redundant cable fails. This results in the fuel assembly, the fuel grapple mast and head falling on top of the core impacting a group of four fuel assemblies. The grapple head and mast are fixed vertically to the dropped assembly so that all the kinetic energy is transferred through the dropped assembly to the group of impacted assemblies. The dropped assembly impacts the core at a slight angle and the rods in this assembly might bend. After the assembly impacts the core, the assembly, grapple head and mast fall onto the core horizontally without contacting the side of the pressure vessel or fuel pool.

During refueling operations, the bounding radiological event is a drop over the core due to the maximum drop height.

Fuel rod failure is assumed at 1% circumferential strain. The associated axial strain is  $(0.01)/\nu$ , where  $\nu$  is Poisson's ratio, plastic deformation is assigned a value of 0.5, and the energy per rod failure is expressed by:

$$E_f = \sigma_y \times \epsilon \times V \quad (\text{Equation } E_f)$$

Where:

$E_f$  = energy per rod failure

$\sigma_y$  = yield stress

$\epsilon$  = axial cladding strain

$V$  = volume of fuel cladding

Kinetic energy is calculated for the dropped fuel bundle that accounts for the influences of buoyancy and resistance from the reactor cavity pool water. Finite element analysis simulations are used to determine the kinetic energy based on the drop distance in air or water. The simulation results revealed that the drop distance of a fuel bundle in air is greater than 2.3 m (7.5 ft), while the kinetic energy of the fuel bundle drop in water is less than 50% of that in air. When the bundle drop height is 10.4 m (34.0 ft) the energy is approximately 22% of that in air. This analysis credits a 50% reduction in the kinetic energy of the dropped bundle although the limiting case drop height correlates to a larger reduction.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The fuel assembly wet weight and the mast wet weight are used in applying the 50% kinetic energy reduction to the fuel assembly due to dropping through water that is expressed as:

$$E_1 = \frac{h_{\text{drop}} \times (W_{\text{fuel}} + W_{\text{mast}})}{2}$$

Where:

$E_1$  = energy from initial drop

$W_{\text{fuel}}$  = weight of fuel bundle

$W_{\text{mast}}$  = weight of refueling mast

$h_{\text{drop}}$  = drop height

Substituting numerical values yields Equation  $E_1$ :

It is assumed that half of the energy is absorbed by the cladding. The ratio of the cladding to the non-fuel mass for GNF2 fuel is 0.4997. The calculated yield strength using the methodology described above (see Equation  $E_1$ ) is 37.503 kgf-m/rod (271.26 ft-lbf/rod). Therefore, the number of failed rods in the impacted assemblies from the initial drop is 31 rods.

Additional energy is generated in a secondary impact as the bundle falls over from a vertical orientation to a horizontal orientation, and damages additional rods in the impacted bundles. Incorporating the 50% reduction due to the kinetic energy in water is expressed as:

$$E_2 = 50\% \times (h_{\text{fuel}} \times W_{\text{mast}} + \frac{1}{2} \times h_{\text{fuel}} \times W_{\text{fuel}})$$

Where:

$E_2$  = energy of dropped bundle and mast from secondary impact

$h_{\text{fuel}}$  = height of refueling mast

Fifty percent of the kinetic energy is absorbed by the impacted assemblies resulting in the number of failed rods in the impacted assemblies of 5 rods.

All the rods in the dropped assembly are assumed to fail and are full-length. GNF2 fuel assemblies contain both full-length and part-length rods accounting for the difference in lengths resulting in 85.6 effective full-length rods per bundle. The number of failed rods used in determining the radiological consequences is 128 failed fuel rods or 1.495 failed fuel bundles.

There are 240 fuel bundles in the BWRX-300 core. The fraction of the core damaged in an FHA is determined by:

$$\text{Core Damage Fraction} = \frac{1.495 \text{ bundles damaged}}{240 \text{ bundles in the core}} = 6.23\text{E-}03$$

### **Core Inventory of Isotopes**

A BWRX-300 core inventory of isotopes is calculated using the Oak Ridge National Laboratory code ORIGEN2, version 2.1 and the BWRUE.LIB cross section library in units of Ci/MWth for the bulk operating parameters in Table 15.5-35.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

A subset of the more than 700 isotopes from this inventory are used to model DBA dose consequences. The 60 isotopes used for DBAs are the dominant contributors to immersion and inhalation doses from airborne activity released during a DBA. This set of nuclides consist of 54 isotopes identified in WASH-1400 (NUREG-75/014) and 6 isotopes identified in SAND-85-2575 (NUREG/CR-4467). This is the group of isotopes typically used for alternate source term (AST) dose evaluations.

The BWRX-300 reactor is subcritical for at least 24 hours prior to initiating refueling operations. The BWRX-300 core inventory of the 60 dose-significant isotopes after 24 hours of decay are shown in Table 15.5-36.

### ***Gap Fractions***

For events that are non-LOCAs where some fuel damage is postulated like the FHA, the fractions of the core inventory assumed in the fuel rod gap region for the various radionuclides are taken from USNRC Regulatory Guide (RG) 1.183 and reported in Table 15.5-37.

### **Radial Peaking Factor**

The radioactive material available for release in an FHA is assumed in the analysis to come from assemblies with peak inventory. To simulate this assumption, the inventory is scaled up by the maximum power Radial Peaking Factor (RPF). This represents the maximum achievable operational power history immediately preceding shutdown. Based on prior experience with GNF2 cores, a representative RPF value of 1.70 is assumed for this analysis.

### ***Activity Released from the Fuel***

All particulate isotopes are retained by the water in the fuel pool or reactor cavity water. Thus, only the noble gases and the gaseous form of iodine are available to escape the water. The activity released from the fuel shown in Table 15.5-38. The release is the mathematical product of the core power ( $E_f$ ), RPF, gap fractions (Table 15.5-37), and core damage fraction. With this information, the release from the fuel is calculated as shown in Table 15.5-38.

### ***Pool Scrubbing (Decontamination)***

Credit is taken for retention of some of the released fission gas in the water where it is released from the damaged fuel rods. Because the depth of water above reactor cavity pool and SFP is greater than 7.01 m (23.0 ft), the simple Decontamination Factor (DF) model from USNRC RG 1.183, Appendix B is used.

The activity released from the surface of the reactor cavity pool, shown in Table 15.5-39, is calculated by applying the RG 1.183 DFs to the activity released from the fuel in Table 15.5-38.

### ***Transport in the Reactor Building***

The radioactivity released from the reactor cavity pool is assumed to mix instantaneously with the free air volume of the refueling outage floor and crane area, which is the intermediate volume between the FHA release from the water and the environment. The refueling outage floor and crane area has an approximate air volume of 9,620.25 m<sup>3</sup> (339,736 ft<sup>3</sup>) taking into account the equipment footprint.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The analysis conservatively ignores mixing to account for the possibility of inadequate mixing over the short term. Therefore, crediting for mixing is reduced by 50% by reducing the volume of airspace. There is no mechanical means to ensure the refueling outage floor and crane area airspace is well mixed. To account for the 50% volume reduction of airspace:

$$\text{Credited Refueling Area Volume} = (50\%) \times 9620.25 \text{ m}^3 = 4,810.13 \text{ m}^3 (169,868 \text{ ft}^3)$$

This doubles the concentration of contamination in the leakage from the RB to the environment.

### ***Release Assumptions***

To implement this in the model, a single leakage rate from the reactivity cavity or fuel pool ensures the entire release is transported to the environment from the RB in two hours.

To simulate the leakage to the environment, the following equation is used to calculate a corresponding leakage rate.

This rate is calculated using the equation below, and setting to time (variable "t") to 120 minutes as follows:

$$\frac{C(t)}{C_{ss}} = e^{-Qt/V}$$

Where:

$C(t)$  = evacuation volume transported to the environment at time t

$C_{ss}$  = evacuation volume at time t=0

$C(t)/C_{ss}$  = fraction of evacuation volume remaining at time t (unitless)

$Q$  = constant flow rate out of space ( $\text{m}^3/\text{s}$ )

$V$  = volume of air transported to the environment ( $\text{m}^3$ )

$t$  = time duration of dilution period in minutes (minutes)

As  $C(t)$  approaches steady state or complete transport of the evacuation volume (assume a value of 0.1 %),  $C(t)/C_{ss}$  approaches a value of zero and the previous equation can be simplified to:

$$0.001 = e^{-Qt/V}$$

Substituting the known values and solving for Q:

$$-\ln(0.001) \times \frac{V}{t} = Q$$

The flow rate that transports 99.9% of the contamination released to the RB refueling outage floor and crane area can be transported to the environment in two hours at a flow rate of  $267.9 \text{ m}^3/\text{min}$  ( $9778.4 \text{ ft}^3/\text{min}$ ).

### ***Dispersion in the Environment***

Transport to the EAB and Automatic Action Zone (AAZ) from the BWRX-300 is simulated using atmospheric dispersion factors ( $\chi/Q$  values) that are established for the Darlington site. Dispersion and deposition is determined in the ADDAM code based on 5 years of DNNP site-specific meteorological data. The meteorological data set used complies with the requirements of CSA N288.2:19. The DBA  $\chi/Q$ s are set equal for the OPG 350 m Emergency Zone (EZ).

### ***Dose Calculation***

Because the inventory of isotopes released from the surface of the reactor cavity pool is already determined in Table 15.5-39. The release from the pool to the RB in Table 15.5-39 is modeled at time  $t=0$ .

### ***Breathing Rates***

The postulated FHA breathing rates used are consistent with CSA N288.2. The deterministic calculations conservatively used to demonstrate compliance with CSA N288.2 are in the 95th percentile of the breathing rates for the representative person.

### ***Decay and Daughtering***

This analysis assumes a decay time of 24 hours prior to the removal of spent fuel during refueling, and credit for this decay period is taken in the initial core inventory Table 15.5-36.

Decay and daughtering of nuclides during the FHA are assumed in the ADDAM model for the duration of the event (30 days).

### ***Dose Conversion Factors***

The 30-day committed whole-body dose is compared to the CNSC REGDOC-2.4.1 acceptance criteria. Consistent with REGDOC-2.4.1, the dose contributions include:

- External radiation from cloud and ground deposits
- Inhaled radioactive materials
- Skin absorption of tritium

The ADDAM code uses dose conversion factors that comply with CSA N288.2.

### ***Results***

The BWRX-300 FHA, which is classified as a DEC, meets the Darlington site DBA dose acceptance criteria with considerable margin for the most critical group as demonstrated in Table 15.7.6-1.

## **15.5.9 Analysis of Radioactive Releases from a Subsystem or a Component**

### **15.5.9.1 Analysis of Liquid and Gaseous Radioactive Waste System Scenario Releases**

The radioactive liquid tank and offgas system (OGS) failures are addressed as process system failures. The analysis for these releases is described in Chapter 11, Subsections 11.2.9 and 11.3.13 and Table 11.3-4.

#### ***Liquid Tank Failure***

To prevent tank leakage from exiting the Radwaste Building (RWB), the collection and sample tanks are enclosed with a concrete wall barrier. If a tank failure occurs, the concrete wall containment area prevents any liquid radioactive waste from exiting the RWB. The contents of the tank drain to the nearest radioactive drain system, and any venting is collected in the buildings ventilation exhaust system and processed accordingly.

#### ***Offgas System Failure***

The limiting BWRX-300 OGS failure is an inadvertent bypass of the charcoal delay beds. An evaluation was performed, and the resulting public dose consequences are well below the REGDOC-2.5.2, Section 4.2.1 limits as shown in Chapter 11, Table 11.3-4.

#### **15.5.9.2 Analysis of Loss-of-Coolant Accidents Outside Containment**

As discussed in Subsection 15.5.4.6, the scram and RPV isolation trips occur for the large breaks outside containment within the same time as breaks inside containment.

For large breaks, timing of the break detection is less than 1 s for breaks outside containment that is the same as the time to reach the drywell high pressure setpoint. Because reactor scram and isolation valve closures for breaks inside containment also occur for breaks outside containment, the event progression is no different for breaks outside containment than inside containment. For main steam pipe breaks, the break flow rate calculated for breaks inside containment is also used for breaks outside containment because the MSCIV closure is not credited in the main steam pipe break inside containment. For FW pipe breaks, the only difference between the pipe breaks inside and outside of containment is the closure of the FWCIV. For a FW pipe break outside containment, break flow includes flow from the reactor as well as the pipe inventory.

The isolation condenser pipe break outside containment is limited to the flow passing through the orifices in the steam distribution pipes. During normal operation prior to the break, condensate return valves are closed and remain closed. Isolation steam supply pipe has a guard pipe outside containment so that break flow in the supply pipe upstream of the orifice is not discharged outside containment. A break in the isolation condenser is followed by a discharge of the subcooled water in the isolation condenser into the pool, followed by steam break flow passing through the orifice in the steam supply pipe until the isolation condenser RIVs close on break detection.

Since the small break analyses inside the containment do not credit containment back pressure, the mass and energy release calculated for breaks inside the containment are bounding for breaks outside the containment.

##### **15.5.9.2.1 Main Steam Line Break Outside Containment**

The thermal-hydraulic response of RPV and containment for a MSLB outside containment is bounded by the response to a break inside containment as presented in Subsection 15.5.4.6.1.

##### *Event Description*

The MSLB accident is assumed to occur in the steam tunnel which is the interface between the RB and Turbine Building (TB). The postulated event assumes that a main steam line instantaneously and circumferentially breaks downstream of the outermost MSIV. The plant is designed to immediately detect such an occurrence, initiate isolation of all main steam lines including the broken line. The release of reactor steam and water from the break is assumed to blowdown into the TB airspace where it is released to the environment instantaneously as a ground-level release, with no building holdup credited.

##### *Source Term*

There is no fuel damage as a result of an MSLB outside containment. The only activity available for release from the break is that which is present in the reactor coolant prior to the break. Radiation concentrations in BWRX-300 reactor coolant and steam adequate for use in design basis calculations (such as shielding, equipment design, etc.) are determined based on ANSI/ANS-18.1.

Two cases are considered for conditions when the postulated accident occurs: (1) the maximum equilibrium iodine concentration permitted for continued full power operation, and (2) the iodine concentration corresponding to the conditions of an assumed pre-accident spike. For both cases, the release to the environment is assumed instantaneous and without holdup from the TB coolant radiation concentrations.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

For postulated accidents the design basis BWRX-300 reactor coolant concentrations are adjusted to account for two conditions that may exist when the accident begins:

1. The concentration that is the maximum equilibrium value (typically 0.2  $\mu\text{Ci/gm}$  Dose Equivalent I-131) permitted under plant Operating Limits and Conditions (OLCs).
2. The concentration that is the maximum iodine spike value (typically 4.0  $\mu\text{Ci/gm}$  Dose Equivalent I-131) permitted under plant OLCs.

The plots for RPV are shown on Figures 15.5-100 through 15.5-103 and for containment parameters Figures 15.5-104 through 15.5-105.

#### *Radiological Consequences*

The dose consequences are calculated for the MSLB accident at the proposed BWRX-300 exclusion zone.

The dose consequences of the MSLB are calculated using the ADDAM computer code (refer to Section 15.5.1.2).

#### *Mass Release*

The total mass of coolant released is the amount in the line and connecting lines at the time of the break plus the amount that passes through the RPV isolation valves and the outboard containment isolation valve prior to closure. The masses of coolant and steam released from the postulated MSLB based on preliminary thermal-hydraulic analysis are:

Liquid Release = 15,878 kg

Steam Release = 2,400 kg

Table 15.5-44 provides the activity release from this coolant volume.

This analysis conservatively assumes that all of the liquid released from the break flashes to steam and is available for transport to the environment along with the steam released from the break. The mass release duration from the MSLB is equal to the maximum closure time of the containment isolation valve of 10 seconds.

#### *No Holdup Release to the Environment Flow Rate*

No holdup release to the environment is assumed with a total of 99.9% transport of the TB airspace over a period of 10 minutes after the event. *Breathing Rate*

The postulated MSLB breathing rates used are consistent with CSA N288.2. The deterministic calculations conservatively used to demonstrate compliance with CSA N288.2 are in the 95th percentile of the breathing rates for the representative person.

#### *Decay and Daughtering Nuclides*

Decay and daughtering of nuclides during the MSLB are credited in the dose model for the duration of the event.

#### *Dose Conversion Factors*

The 30-day committed whole-body dose is compared to the CNSC REGDOC-2.4.1 acceptance criteria. The ADDAM code uses dose conversion factors that comply with CSA N288.2.

#### *Results*

This radiological consequence is calculated for the 30-day whole-body dose at the exclusion zone. The results are listed in Table 15.7.7-1 for comparison to the radiological acceptance criteria.

The MSLB accident dose consequences are bounded by the Darlington site DBA dose acceptance criteria with considerable margin as shown in Table 15.7.7-1 for comparison against the radiological acceptance criteria.

#### **15.5.9.2.2 Large Feedwater Pipe Break Outside Containment**

Flow from the RPV side of the break is bounded by feedwater breaks inside containment because of the longer pipe length. The higher pressure losses occur for a break outside containment. No operator actions are required to mitigate the event.

##### *Event Description*

The FWLB accident occurs in the BWRX-300 steam tunnel that interfaces between the RB and TB. An instantaneous circumferential break of a feedwater line is postulated. The plant is designed to immediately detect such an occurrence and initiate FW line isolation. The energetic release of reactor water from the break is assumed to blowdown into the TB airspace where it is instantaneously released to the environment as a ground-level release, with no building holdup credited.

##### *Source Term*

There is no fuel damage as a result of an FWLB outside containment in the BWRX-300. The only activity available for release from the break is that which is present in the reactor coolant prior to the break.

Radiation concentrations in BWRX-300 reactor coolant and steam adequate for use in design basis calculations (such as shielding, equipment design, etc.) are determined based on ANSI/ANS-18.1.

For DBAs, the design basis BWRX-300 reactor coolant concentrations are adjusted to account for two conditions that may exist when the accident begins:

1. The maximum equilibrium value concentration (typically 0.2  $\mu\text{Ci/gm}$  Dose Equivalent I-131) permitted under plant OLCs for continued full power operation.
2. The maximum Dose Equivalent I-131 concentration (typically 4.0  $\mu\text{Ci/gm}$ ) permitted under plant OLCs and corresponds to the conditions of an assumed pre-accident spike.

##### *Mass and Energy Release.*

The total mass of coolant released is the amount in the line and connecting lines at the time of the break plus the amount that passes through the RPV isolation valves and the outboard containment isolation valve prior to closure. The masses of coolant and steam released from the postulated FWLB based on preliminary thermal-hydraulic analysis are:

Liquid Release = 18,090 kg

Steam Release = 733 kg

Break Flow Enthalpy = 1289.1 kJ/kg

The mass release vs. time is shown on Figure 15.5-167.

##### *Flashing of Reactor Coolant to Steam*

The FW break fluid enthalpy varies at saturation conditions at differing pressures. As the coolant exits the break into the steam tunnel, some fraction of the coolant released from the break flashes to steam and becomes available for release to the environment.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The flash fraction (FF) is determined using a constant enthalpy process:

$$FF = \frac{h_{f1} - h_{f2}}{h_{fg}}$$

Where:

$h_{f1}$  = The enthalpy of fluid within the FW line at normal operating conditions in kJ/kg

$h_{f2}$  = The specific enthalpy of water at atmospheric pressure in kJ/kg

$h_{fg}$  = The heat of vaporization at 100 °C in kJ/kg

The flashing fraction applied to the liquid release is 0.390.

*No Holdup Release to the Environment Flow Rate*

No holdup release to the environment is assumed with a total of 99.9% transport of the TB airspace over a period of 10 minute after the event.

*Breathing Rates*

The postulated FWLB the breathing rates used are consistent with CSA N288.2. The deterministic calculations conservatively used to demonstrate compliance with CSA N288.2 are in the 95th percentile of the breathing rates for the representative person.

*Decay and Daughtering Nuclides*

Decay and daughtering of nuclides during the FWLB are credited in the dose model for the duration of the event.

*Dose Conversion Factors*

The 30-day committed whole-body dose is compared to the CNSC REGDOC-2.4.1 acceptance criteria. The ADDAM code uses dose conversion factors that comply with CSA N288.2.

*Radiological Consequences*

The dose consequences were calculated for the FWLB accident outside containment at the proposed BWRX-300 exclusion zone.

Two cases are considered for conditions that may exist when the postulated accident occurs: (1) the maximum equilibrium iodine concentration permitted for continued full power operation, and (2) the iodine concentration corresponding to the conditions of an assumed pre-accident spike. For both cases, the release to the environment is instantaneous and without TB holdup.

Radiation concentrations in BWRX-300 reactor coolant and steam are determined based on ANSI/ANS-18.1.

The dose consequences of the FWLB are calculated using the ADDAM computer code (refer to Section 15.5.1.2).

This radiological consequence is calculated for the 30-day whole-body dose at the exclusion zone. The results are listed in Table 15.7.7-2 for comparison to the radiological acceptance criteria.

*Results*

The FWLB accident dose consequences are bounded by the Darlington site DBA dose acceptance criteria with considerable margin as shown in Table 15.7.7-2.

#### **15.5.9.2.3 Shutdown Cooling System Pipe Break Outside Containment**

The shutdown cooling system (SDC) (Chapter 9, Subsection 9A.2.3) provides decay heat removal for refueling or maintenance. The SDC provides decay heat removal at normal and lower reactor operating pressures. SDC is subjected to high energy conditions for a short time (less than 2% of the plant operating conditions). The system piping is assigned a medium energy line due to the short time that it is subjected to high energy conditions.

The SDC connects to the feedwater system between the feedwater containment isolation and feedwater isolation control valve outside containment. Due to the smaller SDC piping diameter, the feedwater pipe break outside containment discussed previously in Subsection 15.5.9.2.2 bounds the SDC pipe break outside containment.

#### **15.5.9.2.4 Large Isolation Condenser Pipe Breaks Outside Containment**

The isolation condenser pipe configuration outside the containment is under development. For the worst-case scenario, the large isolation condenser pipe break outside containment may be larger than the large isolation pipe breaks inside containment. The mass and energy release from the isolation condenser pipe breaks outside containment are still bounded by the isolation condenser pipe breaks inside containment. Breaks inside containment remain bounding because the isolation condenser pipe breaks do not utilize any DL3 functions that depend on containment parameters, and the containment back pressure is not credited in any of the isolation condenser pipe breaks inside containment.

As is the case for isolation condenser pipe breaks inside containment, core response is not a concern since the break is isolated rapidly. The consequences of large isolation condenser pipe breaks outside containment require an evaluation for the loads, pressures, and temperatures outside containment, and radiological consequences resulting from normal operation coolant activity.

#### **15.5.9.2.5 Small Breaks Outside Containment**

Since the small break analyses inside containment do not credit containment back pressure, the mass and energy release calculated for breaks inside containment are bounding for breaks outside containment.

However, dose analyses are performed for breaks outside containment for two line break cases:

- ICS line break
- Instrument line break

### **ICS Line Break Dose Consequences**

#### *Event Description*

The ICS line break accident analyzed for offsite dose consequences is a postulated break of an ICS steam supply pipe in the ICS pool on the operating deck of the RB. The plant is designed to immediately detect such an occurrence, initiate isolation of the broken line within 5 seconds, and fully isolate the break in 10 seconds. Blowdown steam from the break is directed to the two heat exchangers in one ICS unit and the liquid mass in the heat exchangers is expelled to the ICS pool where it mixes with the pool water without flashing. The energetic release of reactor steam from the break is assumed released to the environment instantaneously as a ground-level release, without holdup.

### *Source Term*

There is no fuel damage as a result of an ICS line break outside containment. The only activity available for release from the break is that which is present in the reactor coolant prior to the break.

Radiation concentrations in reactor coolant and steam are adequate for use in design basis calculations (such as shielding, equipment design, etc.) and are determined based on ANSI/ANS-18.1.

For postulated accidents the design basis reactor coolant concentrations are adjusted accounting for two conditions that may exist when the accident begins:

- The concentration that is the maximum equilibrium value (typically 0.2  $\mu\text{Ci/gm}$  Dose Equivalent I-131) permitted under plant OLC.
- The concentration that is the maximum iodine spike value (typically 4.0  $\mu\text{Ci/gm}$  Dose Equivalent I-131) permitted under plant OLC.

### *Mass Release*

The mass of steam released from the postulated ICS line break is 400.8 kg and is based on preliminary GEH thermal-hydraulic analysis.

### *Release Duration*

The mass release duration from the ICS line break is equal to the maximum closure time of the isolation valves that is 10 seconds.

The mass of steam released from the break is transported to the environment over a 10 minute period which adequately simulates instantaneous transport.

### *Breathing Rates*

The postulated ICS line break breathing rates used are consistent with CSA N288.2. The deterministic calculations conservatively used to demonstrate compliance with CSA N288.2 are in the 95th percentile of the breathing rates for the representative person.

### *Decay and Daughtering Nuclides*

Decay and daughtering of nuclides during the ICS line break are credited in the dose model for the duration of the event.

### *Dose Conversion Factors*

The 30-day committed whole-body dose is compared to the CNSC REGDOC-2.4.1 acceptance criteria. The ADDAM code uses dose conversion factors that comply with CSA N288.2.

### *Results*

The ICSLB accident dose consequences are bounded by the Darlington site DBA dose acceptance criteria with considerable margin as shown in Table 15.7.7-3.

### **Instrument Line Break Dose Consequences**

The dose consequences of an Instrument Line Break Accident (ILBA) at the exclusion zone considers two cases that may exist when the postulated accident occurs: (1) the maximum equilibrium iodine concentration permitted for continued full power operation, and (2) the iodine concentration corresponding to the conditions of an assumed pre-accident spike. For both cases, the line break release to the environment from the RB is instantaneous and without holdup.

The dose consequences of the ILBA are calculated using the ADDAM computer code.

### *Event Description*

A circumferential rupture of an instrument line connected to the primary coolant system is postulated to occur outside primary containment in the RB. The ILBA analysis assumes that the event cannot be isolated, and no fuel damage occurs. The resulting activity is released to the environment directly from the RB with no credit for holdup or filtration. Primary coolant flows at the maximum rate for a typical instrument line that has a 1/4" flow restricting orifice. Saturated water flows in the instrument line into containment that flashes to steam, resulting in the maximum iodine release.

### *Source Term*

There is no fuel damage as a result of this accident. The only activity released from the break is that present in the reactor coolant prior to the break.

Radiation concentrations are determined using ANSI/ANS-18.1-2020 for the reactor coolant and steam used in design basis calculations for shielding and equipment design.

The design basis reactor coolant and steam concentrations are adjusted to account for two conditions that may exist when the postulated accident occurs:

1. The maximum equilibrium value concentration (typically 0.2  $\mu\text{Ci/gm}$  Dose Equivalent I-131) permitted by the plant OLCs.
2. The maximum iodine spike value (typically 4.0  $\mu\text{Ci/gm}$  Dose Equivalent I-131) concentration permitted by the plant OLCs.

The ILBA Airborne Release Source Term for equilibrium and iodine spike is provided in Table 15.5-43A and 15.5-43B, respectively. Only the equilibrium concentrations of iodine and iodine spike activity releases differ. The concentrations of the remaining isotopes are not impacted by iodine behavior.

### *Coolant Mass Release*

The mass of steam released 408.0 kg from the postulated ICS line break is used for the ILBA based on preliminary GEH thermal-hydraulic analysis. The release duration is equal to the maximum closure time of the isolation valves in the ICS break outside containment that is 10 seconds. The mass of released break steam is transported to the environment over a 10-minute period that adequately simulates instantaneous transport.

### *Release Duration*

The steam mass released is transported from the RB to the environment over a 10-minute period that adequately simulates instantaneous transport with no holdup. As a result, the steam release duration to the environment follows the coolant mass release duration.

### *No Holdup Release to the Environment Flow Rate*

No holdup release total transport of 99.9% from the TB airspace to the environment occurs over a period of 10 minute after the event.

### *Breathing Rates*

The postulated ILB breathing rates used are consistent with CSA N288.2. The deterministic calculations conservatively used to demonstrate compliance with CSA N288.2 are in the 95th percentile of the breathing rates for the representative person.

### *Decay and Daughtering*

Decay and daughtering of nuclides during the MSLB event are credited in the dose model for the duration of ILBA event.

### *Dose Conversion Factors*

The 30-day committed whole-body dose is compared to the CNSC REGDOC-2.4.1 acceptance criteria. The ADDAM code uses dose conversion factors that comply with CSA N288.2.

### *Results*

The BWRX-300 ILB dose consequences are bounded by the Darlington site DBA dose acceptance criteria with considerable margin as shown in Table 15.7.7-4.

#### **15.5.9.3 BWRX-300 Out of Core Criticality Analysis**

A representative Out Of Core Criticality (OCC) accident scenario has been analyzed in the BWRX-300 Out of Core Criticality Safety Analysis Demonstration that shows that the dose consequences at the site boundary do not exceed the generic criteria to trigger a public evacuation (see Canadian Guidelines for Intervention During a Nuclear Emergency - Reference 15.5-12). Criticality analyses assess fuel handling activities outside the core for the GE High Density Fuel Storage Racks (HDFS) and the RAJ-II Inner Container (IC). The HDFS rack assessment for the storage of GNF2 fuel analyses resulted in a storage rack maximum  $k_{\text{eff}}$  ( $k_{\text{max}}(95/95)$ ) less than the USL of 0.95 for normal and credible abnormal operation. The OCC analysis demonstrates compliance to REGDOC-2.4.3, Section 2.3.2.2, Part 3 (Reference 15.5-13) by computationally investigating a representative accident scenario that complies with REGDOC-2.4.3, Section 16.4. The representative OCC accident scenario is postulated to occur inside the RB on the refueling floor due to the unsafe stacking of RAJ-II-ICs.

### **Method of Analysis**

The estimated total number of fissions follows the use of a simplified models approach described in BSI ISO 16117:2013 (Reference 15.5-14):

- The estimate of the number of fissions should be based on simplified options providing “order of magnitude” values
- This estimate should rely on the collective experiences from past criticality accidents (Annex B) and criticality experiment results (Annex C) and the possible use of simplified formulae (Annex D)
- When a simplified model is used, the consistency of its area of applicability with the chosen assumptions of the postulated criticality accident shall be justified and documented

The parameters extracted from ISO 16117:2013, Table B.2 (Reference 15.5-14) for the purpose of this analysis is provided in Table 15.5-45. The total number of fissions allows for determining the neutron and photon source term magnitudes that are used subsequently in developing MCNP-06P models that are used to assess the dose consequence.

### **Computational Models**

Computational models have been developed in MCNP-06P to assess the neutron and photon dose consequence of the postulated OCC accident scenario. MCNP-06P is the GEH controlled version of the Los Alamos National Laboratory code MCNP6 (Reference 15.5-15). MCNP6 is a general-purpose, continuous-energy, generalized-geometry, time-dependent, coupled neutron/photon/electron Monte Carlo transport code. All models employ ENDF/B-VII.0 cross section libraries. Compliance with CSA standards is demonstrated and confirmed.

The first computational model is developed for the purpose of tracking the particle flux/dose as a function of distance in air from the accident location (see Figure 15.5-168). The second computational model is developed to study particle flux attenuation as a function of concrete thickness present to predict shielding behavior in the refueling floor area where the accident occurs. The relative decrease in neutron/photon radiation dose rates is utilized to approximate the dose consequence as a result of shielding present.

### **Source Term**

The total number of fissions shown in Table 15.5-46 is used to determine the neutron and photon source term magnitudes utilized in the MCNP-06P calculations. The energy distribution of the neutron source is governed by the Watt energy spectrum. The photon source term is discretized into two energy groups with even probability. The first group is the average energy emitted per prompt fission photon, and the second group is the maximum prompt fission photon energy.

### **Radiation Dose Rates**

For all computational models, the neutron and photon dose rates are computed by utilizing the ANSI/ANS-6.1.1-1977 (Reference 15.5-11) particle flux to dose conversion coefficients in the F4 tallies to yield units of mSv/H. The time-integrated dose is calculated by scaling the total dose rates by the accident duration to yield time-integrated dose units of mSv. The resultant doses at the site boundary are then directly compared to the generic criteria from Canadian Guidelines for Intervention During a Nuclear Emergency (see Table 15.5-47) to show that no protective actions are necessary to ensure the safety of the public in the event of the postulated representative OOC accident.

### **Results**

The results for the total integrated dose provided in Table 15.5-47 are compared directly to the generic criteria for implementing actions to protect the public provided in Table 15.5-48. The total integrated dose is plotted on Figure 15.5-169 with respective error bands to highlight dose behavior as a function of distance from the OOC accident location, with and without the attenuation provided by concrete shielding.

The total integrated doses provided in Table 15.5-46 was conservatively based upon the total number of fissions actually occur during the accident excursion timeframe. These results are deemed to be conservative based on the following:

1. The unsafe stack of RAJ-II ICs is originally confined in space by the gravitational, normal, and static friction forces. The fission force magnitude that occurs during the accident within the critical system will overwhelm the gravitational and normal and frictional forces holding the bundles in their original locations ultimately displacing the fuel far enough apart to yield a subcritical system.
2. There are established RAJ-II IC stacking limits and fuel handling patterns in place to avoid unsafe ICs stacking. In order for an OOC scenario to occur, workers would violate operating procedures or have inadequate training.

In the event that workers violate established operational procedures, there are natural and physical barriers in place mitigate the likelihood of an OOC event sequence. The following physical barriers are DL1 design measures that prevent an OOC occurrence:

1. The time it takes to obtain and arrange RAJ-II ICs in an 8x8 stack on the refuel floor is significant. The ICs must each be handled via crane and cannot easily be displaced. It is quite unlikely that other workers in the reactor building would ignore the workers unsafely stacking ICs during this entire duration. There are safety checks in place and verifications made during the process that prohibit unsafe stacking.
2. The new fuel receipt and handling plan schedule is provided to the plant that contains the number of fuel bundles that arrive on site for the first 14 years of plant operation. There is a limit to how many ICs are allowed on the refuel floor at one time.
3. The criticality analysis was based on an average bundle fuel enrichment of 5 wt% U-235 for each RAJ-II IC in the stack. This is conservative and unlikely as the average enrichment for the BWRX-300 core is less than 5 wt% U-235.

## **Conclusions**

The dose consequence of a representative criticality accident scenario in accordance with REGDOC-2.4.3, Section 16.4.1 shows that the dose consequence at the site boundary does not exceed the generic criterion that would trigger a public evacuation in accordance with Canadian Guidelines for Intervention During a Nuclear Emergency (Reference 15.5-12).

### **15.5.10 Analysis of Internal and External Hazards**

The internal and external hazards portion of the PSA (refer to Subsection 15.6.2.4) explicitly analyzes radionuclide release accidents initiated during power and shutdown operation for internal and external hazards. Malevolent acts are addressed in the Security Annex.

The internal and external hazards is presented in Chapter 3. Sections 3.4 and 3.3, respectively. The design features to mitigate these hazards are provided for the specific hazards in the following subsections.

#### **15.5.10.1 Analysis of Internal Hazards**

The description of internal hazards and design features are described in the following sections:

Fires – Chapter 3, Section 3.4.1 hazard identification, design features Chapter 9A, Section 9A.6

Explosions – Chapter 3, Section 3.4.1 hazard identification, design features in Chapter 9B, Section 9B

Toxic Gas – Chapter 3, Subsection 3.4.1 hazard identification, MCR and SCR design features in Chapter 6, Section 6.4

Internal Flooding – Chapter 3, Subsection 3.4.2 hazard identification, structural design in Chapter 9B, Section 9B

Internal Missiles – Chapter 3, Subsection 3.4.3 hazard identification, structural design in Chapter 9, Section 9B, equipment and pipe design features in Chapter 3, Section 3.6, and Chapter 5

High Energy Line Breaks (HELB) – Chapter 3, Subsection 3.4.4 hazard identification, HELB evaluation in Chapter 3, Subsection 3.6.7

#### **15.5.10.2 Analysis of Natural External Hazards**

The description of external hazards and the structural design features are described in the following sections:

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Seismic – Chapter 3, Subsection 3.3.1 hazard identification, structural design in Chapter 9, Section 9B

Extreme Weather (Hurricanes, Tornadoes, Wind, etc.) – Chapter 3, Subsection 3.3.2 hazard identification, structural design in Section 9B

Hydrogeological (Floods) – Chapter 3, Subsection 3.3.3 hazard identification, structural design in Chapter 9, Section 9B

Aircraft Impact – Chapter 3, Subsection 3.3.4 hazard identification, structural design in Section 9B

Missiles – Chapter 3, Subsection 3.3.5 hazard identification, structural design in Section 9B

Fires – Chapter 3, Subsection 3.3.6 hazard identification, design features in Chapter 9, Section 9A.6

Explosions – Chapter 3, Subsection 3.3.6 hazard identification, structural design in Chapter 9, Section 9B

Toxic Gas – Chapter 3, Subsection 3.3.6 hazard identification, design features in Chapter 6, Section 6.4

#### **15.5.10.3 Analysis of External Human-Induced Hazards**

The external human-induced hazards is described in Chapter 3, Subsection 3.3.7. Malevolent acts is addressed in the PSAR Security Annex.

## **15.6 Probabilistic Safety Assessment**

A principal element of the design process is the development and results of the Probabilistic Safety Assessment (PSA). The PSA provides an integrated review of the plant design, operational safety, and complements the results of the deterministic analyses. The PSA measures how the safety of plant design and operation prevents the risk of releasing radionuclides to the environment. The PSA supports risk-informed design development and with the DSA, demonstrates the success of the design in achieving the design objectives. The PSA assesses design vulnerabilities and optimizes the design using a graded approach consistent with CNSC REGDOC-2.4.2, "Probabilistic Safety Assessment (PSA) for Nuclear Power Plants," (Reference 15.6-1).

CNSC REGDOC-2.4.2, Requirement 3.2 (Reference 15.6-1) requires a Level 1 and Level 2 PSA. The BWRX-300 PSA meets the performance requirements of ANSI/ASME/ANS RA-S-1.4-2021, "Probabilistic Risk Assessment For Advanced Non-Light Water Reactor Nuclear Power Plants Publication," (Reference 15.6-2).

Other important sources of PSA guidance are in USNRC Regulatory Guide (RG) 1.200, "Acceptability of Probabilistic Risk Assessment Results for Risk-Informed Activities" (Reference 15.6-3), USNRC RG 1.206, "Applications for New Power Plants" (Reference 15.6-4), International Atomic Energy Agency (IAEA) SSG-3, "Development and Application of Level 1 Probabilistic Safety Assessment for Nuclear Power Plants" (Reference 15.6-5), and IAEA SSG-4, "Development and Application of Level 2 Probabilistic Safety Assessment for Nuclear Plants," (Reference 15.6-6) provide guidance for performance of Level 1 and Level 2 PSAs. Canadian Standards Association (CSA) N290.17-17, "Probabilistic safety assessment for nuclear power plants" (Reference 15.6-7) provides high-level guidance and guidelines for performing a PSA. These PSA regulatory guides align with CNSC REGDOC-2.4.2 (Reference 15.6-1). The PSA level of detail expands as the design details are finalized in compliance with CNSC REGDOC-2.4.2, Requirement 3.8 (Reference 15.6-1) that states that the level of detail must be consistent with testing, maintenance, configuration management programs, and the intended PSA uses.

CNSC REGDOC-1.1.2, "Licence Application Guide: Licence to Construct a Reactor Facility," Section 4.4.5, (Reference 15.6-8) requires that "the PSAR includes a deterministic safety analysis, a PSA and a hazards analysis that demonstrate all levels of D-in-D" are addressed and confirms that the facility's design is capable of meeting applicable dose acceptance criteria and safety goals.

CNSC REGDOC-1.1.2 (Reference 15.6-8) and CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 15.6-9), require performance of Hazard Analysis, PSA, and DSA. Section 15.6 is a summary of the work performed for the Hazard Analysis Screening and PSA. The PSA is updated for the operating licence application.

The PSA is updated as additional design and site-specific information becomes available for the operating licence application.

### **15.6.1 General Approach to Probabilistic Safety Assessment**

The PSA risk assessments are divided into two levels:

- Level 1 calculates Core Damage Frequency (CDF) inside containment
- Level 2 calculates Small Release Frequency (SRF) and Large Release Frequency (LRF), with the associated release magnitude

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The Level 1 PSA consists of:

1. Initiating Events (IE) –events that may challenge fuel cooling. The initiating events may occur when the unit is at-power, low power, or shutdown.
2. Event Tree Analysis – plant response analysis for mitigating systems credited for maintaining fuel cooling. Mitigating systems failures result in fuel cooling failures and subsequent core damage.
3. Fault Tree Analysis – models mitigating system failure. Fault tree analysis requires human reliability inputs and component failure including CCF.
4. Accident Sequence Quantification – determines frequency of the core damage end states.
5. Uncertainty and Sensitivity Analyses – assesses the statistical and phenomenological uncertainties. Sensitivity analyses determines initiating events, mitigating systems, or phenomena that has major impact on the results.

Level 2 PSA consists of:

1. Reactor Coolant System (RCS) / Containment Response Analysis
2. Developing an interface between Level 1 and Level 2 PSA
3. Identifying and modeling safety functions and operator actions
4. Performing containment performance analysis
5. Developing Containment Event Tree
6. Phenomena Analysis – consisting of accident progression analysis
7. Source term analysis
8. Quantifying the model and results for LRF and SRF and consequences
9. Performing uncertainty and sensitivity analysis for SA release category, character, and quantification.

The PSA is divided into internal and external events. The internal events occur within the plant (e.g., loss-of-coolant, loss of feedwater, internal fire, etc.). External events occur from outside the plant (e.g., seismic, high wind, flood etc.).

Fuel Pool events address spent fuel damage.

The PSAR PSA scope includes:

A. Level 1 PSA hazards:

1. Internal Events are events at-power, low power and shutdown, internal flood at-power, and internal fire at-power
2. External Events are seismic event at-power, and high wind at-power

The development of BWRX-300 PSA models are conducted with Electric Power Research Institute (EPRI) Integrated Risk Technology suite of software packaged under the Phoenix Architecture, which includes the following:

- CAFTA for event tree, fault tree and cut set development and viewing purposes
- Phoenix Application Programming Interface (API) for model integration and one-top development
- PRAQuant for quantification processes, as well as for sensitivity runs

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The PSA model is integrated and quantified using the computer codes CAFTA, PRAQuant, and Fault Tree Reliability Evaluation eXpert (FTREX). These computer codes have been demonstrated throughout the industry to produce appropriate results. No method-specific limitations have been identified with regard to the software tools or the methodology implemented to quantify the model.

Using CAFTA, the BWRX-300 PSA model is developed by merging all model event trees, system fault trees, IEs, passive feature failure results, and associated basic event databases. Using PRAQuant, a top logic fault tree is created. All system fault trees are merged with the top logic fault tree. The model is quantified to arrive at event sequence frequencies for the various accident sequence end states and release categories.

Figure 15.6-1 demonstrates the principal steps in PSA model development.

The BWRX-300 PSA methodology approaches each PSA element. The level of detail for some technical areas does not include all steps but may refer to specific guidance documents or reports. For example, in the fire PSA, the description refers to USNRC NUREG/CR-6850 "EPRI/NRC-RES Fire PRA Methodology for Nuclear Power Facilities," (Reference 15.6-20) and USNRC NUREG/CR-6850 Supplement 1 "Fire Probabilistic Risk Assessment Methods Enhancements" (Reference 15.6-27) that provides details of each fire PSA step. Not all the described methods are applied early in the design.

Hazard and scenarios that are estimated as lower risk for the final design may be initially analyzed early in the design with simplified scoping evaluations, with a detailed PSA performed later in the design phase or during the site-specific PSA. Where these simplifications are applied, this is generally noted in the document. The DNNP PSA evolves with the design and is subject to IAEA-TECDOC 1106, "Living Probabilistic Safety Assessment (LPSA)" (Reference 15.6-10). The PSA is maintained and updated as the design matures and procedures are developed, when the plant(s) is built, Operating Experience (OPEX) is gathered and applied for any design or operating modifications.

External hazards analysis addresses possible combinations of external hazards. For example, high wind causing loss of the external grid is considered in the high wind analysis. Other site-specific combinations (such as snowstorm blocking the diesel generator combustion air intake and frazil ice blocking sea water cooling) are assessed.

The design phase PSA covers both at-power (full and reduced power levels) and low power and shutdown operations, which include outages and transitions between each plant operating state (POS) in accordance with the guidance of CNSC REGDOC-2.4.2, Section 3.10 (Reference 15.6-1). The design phase PSA includes main systems and components (including the reactor and turbine I&C logic), main operator actions, and the relevant event and system dependencies, interconnections, and CCF relationships.

The development of DNNP PSA models is conducted with the EPRI Integrated Risk Technology Phoenix Architecture. The computer codes CAFTA and PRAQuant, and FTREX are used to integrate and quantify results into PSA model. These computer codes are known throughout the industry to produce appropriate results. No method-specific limitations have been identified regarding the software tools or the methodology implemented to quantify the model. Chapter 3, Appendix 3G provides additional discussion about all the computer programs used in the PSA.

The BWRX-300 PSA model is developed by merging all model event trees, system fault trees, initiating events, passive feature failure results, and associated basic event databases. A top logic fault tree is created. All system fault trees are merged with the top logic fault tree. The model is then quantified to arrive at event sequence frequencies for the various accident sequence end states and release categories.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

At a minimum, the following areas are addressed in the design phase PSA:

- DNNP risk results compared to Safety Goals:
  - CDF
  - SRF
  - LRF
- Initiating event selection, grouping, and frequency for each analyzed plant operating state
- Event sequence modeling and quantification for accident sequence end state and release category
- System analysis and system models
- Success criteria
- Component reliability data (including CCF data and modeling principles)
- Human Reliability Analysis (HRA)
- Uncertainty and sensitivity analysis
- Containment analysis
- Mechanistic source term analysis for each release category
- Model documentation

The design phase PSA includes the PSA models as well as documentation describing plant characteristics important to safety, modeling assumptions and techniques, model structure, data values sources used in the model, and the analysis results are explained making it possible to review and replicate the analyses.

CNSC REGDOC-2.4.2, Section 3.3 (Reference 15.6-1) requires that the PSA be conducted under the management system or quality assurance program established in the licensing basis. This section shows how PSA output (in concert with the DSA) provides input into the design that may affect the PSA models. All work for the design phase PSA is performed in accordance with the requirements of the BWRX-300 Quality Assurance Program Plan.

### **Regulatory PSA Requirements**

A PSA is required to be conducted in accordance with the defined requirements for a licence to construct or operate a reactor facility per CNSC REGDOC-2.4.2, Section 1.1 (Reference 15.6-1). CNSC REGDOC-1.1.2, Section 4.4.1 (Reference 15.6-8) states that the PSA is required to support the PSAR.

In reviewing CNSC REGDOC-2.4.2 (Reference 15.6-1) PSA objectives, six of the eight objectives are being met. The two outstanding objectives require detailed Emergency Operating Procedures (EOPs) and Severe Accident Management Guideline (SAMG) procedures that are developed during the final safety analysis. Per CNSC REGDOC-2.4.2, Section 2.0 (Reference 15.6-1), the PSA objectives are:

- A. Providing a systematic analysis in order to give confidence that the reactor facility's design will align with the fundamental safety objectives as established in IAEA No. N-SF-1, Fundamental Safety Principles, including to protect people and the environment from harmful effects of ionizing radiation.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

- B. Demonstrating that a balanced design has been achieved; this can be demonstrated as achieved if no particular feature or postulated IE makes a disproportionately large or significantly uncertain contribution to the overall risk.
- C. Providing confidence that small changes of conditions that may lead to a catastrophic increase in the severity of consequences (cliff-edge effects) are prevented.
- D. Providing assessments of the quantitative safety goals (the probabilities of occurrence for severe core damage states, and the assessments of the risks of radioactive releases to the environment) as defined in CNSC REGDOC-2.5.2 (Reference 15.6-9) or as established in the licensing basis for the facility.
- E. Providing site-specific assessments of the probabilities of occurrence and the consequences of external hazards.
- F. Identifying facility vulnerabilities and systems for which design improvements or modifications to operational procedures could reduce the probabilities of severe accidents or mitigate their consequences.
- G. Assessing the adequacy of EOPs throughout the nuclear power plant lifetime.
- H. Providing insights into the severe accident management program used in the development, implementation, training, and optimization of accident management strategies and measures.

This section provides the hazard analysis summary presenting the methodology, hazard identification and the screening results in compliance with CNSC REGDOC-1.1.2, Section 4.4.1 (Reference 15.6-8).

### **Regulatory Safety Goals**

The CNSC defined safety goals for core damage, small release, and large release frequencies are defined in CNSC REGDOC-2.5.2 (Reference 15.6-9), as follows:

#### *Core Damage Frequency*

The sum of frequencies of all event sequences that can lead to significant core degradation shall be less than  $10^{-5}$  per reactor year.

#### *Small Release Frequency*

The sum of frequencies of all event sequences that can lead to a release to the environment of more than  $10^{15}$  becquerels of iodine-131 shall be less than  $10^{-5}$  per reactor year. A greater release may require temporary evacuation of the local population.

#### *Large Release Frequency*

The sum of frequencies of all event sequences that can lead to a release to the environment of more than  $10^{14}$  becquerels of cesium-137 shall be less than  $10^{-6}$  per reactor year. A greater release may require long-term relocation of the local population.

The DNNP PSA is performed iteratively with the design development to evaluate and improve the risk aspects of the design.

The PSA and severe accident evaluations specific objectives demonstrate that the BWRX-300 is designed with state-of-the-art safety features, incorporating highly reliable and available passive safety functions with significant redundancy and diversity meeting all established safety goals with margin.

The DNNP design PSA uses information available from the BWRX-300 plant design and procedures that meets the intent of CNSC REGDOC-2.4.2, Section 3.4 (Reference 15.6-1), for the PSA to reflect the as-built and as-operated plant. Periodic updates of the PSA (CNSC REGDOC-2.4.2, Section 3.5 (Reference 15.6-1)) are required after the plant begins operation and every five years thereafter. Component failure data and IE frequencies are based on generic U.S. industry data compared to the BWRX-300 design. As required by CNSC REGDOC-2.4.2, Section 3.7 {Reference 15.6-1}, this data and the assumptions used in developing the PSA are selected realistic as practical. Because site or programmatic information is not available during the design, the PSA analyses contains conservative elements (e.g., human error probabilities, maintenance delay or postponement, component failure rates, flood and fire initiation, propagation, and effects).

#### **15.6.1.1 Principal Steps in the Probabilistic Safety Assessment Model Development**

A design process that is “risk-informed” incorporates the results of risk evaluations and PSA where risk is evaluated for both the frequency and consequences of a possible event. In the nuclear industry, where design, operation, and maintenance are generally conducted using a prescriptive set of requirements, risk evaluations provide information on potential vulnerabilities of the design that may not be revealed by the deterministic design process. In using risk evaluations to assess a design, the risk results add to or supplement the design resulting in an increase in its overall reliability and safety. Using the PSA during the design process ensures that no particular feature or postulated IE makes a disproportionately large or significantly uncertain contribution to the overall risk. The application of risk information and PSA to supplement and improve a design during the design process is to risk-inform the design.

A design process that is “performance-based” relies on a process or equipment measurable outcomes as evidence of meeting a requirement or objective. One advantage of a performance-based approach to design is the flexibility available to meet the outcome requirement or objective. This contrasts with a prescriptive requirement where the adherence to the requirement infers an acceptable outcome. A process that is both risk-informed and performance-based uses both the process to inform and improve the design and the design process.

The full benefits of risk-informed, performance-based methods applied to the design for a new reactor are achieved through a disciplined and quantitative evaluation of options considered during the design process. The effectiveness of risk-informed, performance-based methods rely on the presence of four process elements that ensure a minimum necessary structure is available for these evaluations. These four process elements are:

- Design criteria or requirements
- Systems engineering process
- D-in-D
- Sequence-based risk assessment (using PSA)

The design process uses the PSA results at each stage in the design to confirm the design adequacy and to evaluate alternatives being considered during the system engineering and design process. The PSA interfaces with the design requirements, the system engineering process, and D-in-D evaluations. The PSA process and use is described throughout this section.

The internal events at-power model is developed first and covers these principal steps. The internal and external hazard models and the low-power and shutdown models are developed based on the internal events at-power model files.

By using the ASME/ANS standards for LWR PSA, the DNNP PSA is also required to follow what is normally referred to as a Level 2 assessment, which accounts for the response of containment

following core damage events. IAEA SSG-4 (Reference 15.6-6) provides guidance on assessing safety for low power and shutdown states. Where applicable, these guides are used to inform the DNNP PSA efforts.

#### **15.6.1.2 Internal and External Events and Level 1 PSA**

The internal and external hazards portion of the PSA analyzes radionuclide release accidents initiated during power and shutdown operation for the following hazards:

- Internal Hazards:
  - Internal floods
  - Internal fires
- External Hazards:
  - High winds
  - Seismic events
- Other hazards (internal and external). Risk assessment is based on the results of screening analyses that identifies potential significant contributors.

The internal and external hazard analyses are initially bounding assessments that show significant design margin for these hazards. The frequencies of internal events are based on generic industry data or bounding site data and are applied in a bounding manner. The fault trees and event trees developed for the internal events evaluations are used in the internal and external hazards analyses to the extent possible, using logic flags or additional fault tree modeling that account for the failures induced by the internal or external hazard events.

The scoping Seismic PSA used the seismic hazard evaluated at the Darlington site. The scoping Seismic PSA used generic bounding seismic capacities for SSCs that are set conservatively low. Using conservative SSC generic seismic capacities reveals those SSCs that contribute significantly to the seismic safety profile. With this information, the detailed design is performed demonstrating that sufficient hardening already exists (Chapter 9, Section 9B provides additional information regarding hardening) and provides focus for additional design enhancements to achieve the BWRX-300 safety goals through a risk-informed design process.

The internal events PSA analyzes and quantifies initiating internal events. Internal events generally include events occurring within the plant boundary, other than those involving internal hazards such as internal fires or floods. Historically, the internal events PSA includes the analysis of loss of offsite or preferred power, which has potential contributors both on-site (e.g., from the switchyard or switchgear) and offsite (e.g., grid or weather-related losses not involving other external hazards).

##### **15.6.1.2.1 Internal Hazards**

This section summarizes the screening for internal hazards for the BWRX-300 plant. Internal Hazards were screened for both consideration in the Probabilistic Safety Assessment (PSA) and for inclusion in the fault list. In addition, potential non-reactor sources of radioactivity are screened in this section.

From IAEA SSG-64, "Protection against Internal Hazards in the Design of Nuclear Power Plants," (Reference 15.6-11):

"Internal hazards are those hazards to the safety of the nuclear power plant that originate from within the site boundary and are associated with failures of facilities and activities that are under the control of the operating organization."

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

This section documents the screening of internal hazards for the BWRX-300 Standard Plant Design. Because the BWRX-300 PSA is an all-hazards PSA, internal hazards are evaluated for potential PSA development. NEDC-33946P, "BWRX-300 Darlington New Nuclear Project (DNNP) Probabilistic Safety Assessment Methodology" (Reference 15.6-25) provides guidance for screening external hazards; however, the screening approach may be adopted for the screening of internal hazards as well. The PSA Standard, ANSI/ASME/ANS RA-S-1.1-2022, "Standard for Level 1/Large Early Release Frequency Probabilistic Risk Assessment for Nuclear Power Plant Applications" (Reference 15.6-12), Sections 1 and 6 provide several screening criteria.

The general approach screens internal hazards using the following steps:

1. Develop a list of candidate internal hazards.
2. Apply qualitative screening criteria to each of the internal hazards.
3. For those internal hazards remaining unscreened (i.e., pose a credible threat to nuclear safety) from Step 2, consider application of quantitative screening.
4. Any hazards left unscreened after Step 3 are retained as candidates for explicit treatment in the PSA.

In addition, on-site radioactivity sources are screened for potential treatment in the PSA.

### **Scope**

The internal hazard scope assessment applies screening criteria to all hazards originating within the site boundary. Several sources are consulted for developing of the internal hazards list. A list of on-site radioactivity sources is considered for treatment in the PSA. This subsection does not assess external hazards, sabotage/terrorism, nor is it used in the screening of external events.

Because the BWRX-300 uses a standard plant design and because internal hazards apply to those that originate within the site boundary, this screening section applies to both standard plant design and the DNNP.

### **Assumptions**

Administrative controls are implemented to preclude compressed gas cylinders from becoming missiles in areas containing risk-significant mitigating equipment.

1. Valves are designed to prevent removable parts from becoming missiles in the event of failure in accordance with guidance in SSG 64 (Reference 15.6-11).
2. Rotating equipment (excluding the main turbine) is designed such that potential failure-generated missiles are prevented from impacting risk-significant equipment through spatial or engineered means.
3. Administrative controls are placed to ensure stored combustibles are not collected in sufficient quantities to impact nuclear safety if ignited.
4. No risk-significant mitigating equipment resides in the RB Auxiliary Bay Plant Services Area truck bay or the service bay area beneath the truck bay.
5. The on-site radwaste system does not contain radioactivity in sufficient form or quantity to pose a public health hazard to the level of a small or large release as defined by the PSA.
6. Dry casks containing spent fuel, when stored or handled outside the cask pit, is capable of passive cooling and are not vulnerable to potential hazards.

## Hazard List

The preliminary list of BWRX-300 internal hazards is generated from industry guidelines, past studies, and a plant-specific review.

The internal hazards list of sources includes:

1. BWRX-300 Safety Strategy.
2. ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12). This source is an aggregation of hazards based on review of industry studies such as USNRC NUREG/CR-2300, USNRC NUREG-1407, IAEA SSG-3, USNRC NUREG/CR-5042, EPRI 1022997, EPRI 3002005287, and ASAMPSA\_E List of External Hazards.
3. CSA N290.17-17 "Probabilistic safety assessment for nuclear power plants," (Reference 15.6-7).
4. IAEA SSG-3 (Reference 15.6-5), "Development and Application of Level 1 Probabilistic Safety Assessment for Nuclear Power Plants".
5. IAEA SSG-64 (Reference 15.6-11), "Protecting against Internal Hazards in the Design of Nuclear Power Plants".

The initial hazards screening results are provided in Tables 15.6-1 through 15.6-2.

## Qualitative Screening

The following qualitative screening criteria are provided for internal and external hazards. Consideration of internal hazards is not fundamentally different than external hazards from a risk-impact perspective; therefore, these same criteria apply in screening internal hazards:

1. The event is of equal or lesser damage potential than events for which the plant is designed. This requires an evaluation of the plant design basis to estimate the resistance to a particular (internal) event.
2. The event has a significantly lower mean occurrence frequency than similar events included in the PSA and could not result in worse consequences.
3. The event cannot occur close enough to the plant to effect it.
4. The event is included in the definition of another event.
5. The event frequency is sufficiently low when compared to the probabilistic limits defined for the release category frequencies and is included in the PSA.

The following additional qualitative screening criteria are also considered:

1. The event does not result in a plant trip (manual or automatic) or require a plant shutdown.
2. The event develops slowly (DSA and PSA fault sequence figures show event progressions) and it is shown there is demonstrably conservative time margin available to eliminate the source or to provide adequate response.

The following events were assessed qualitatively:

- Release of chemicals from on-site storage
- Turbine-generated missiles
- Other internally-generated missiles from pressure vessels, valve failures, control rods

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

- High speed rotating equipment (e.g., fan blades, turbines, pump impellers, fly wheels, coupling bolts)
- Internal fires are treated in the same manner as external events for BWRX-300 and are thus “screened-in” as part of this analysis alongside external hazards

Most explosions sources are within the Internal Fires PSA scope. Ignition of the following components with explosion potential is considered:

- Batteries
- Diesel generators
- Switchgear
- Hydrogen tanks
- Miscellaneous hydrogen sources
- Offgas/hydrogen recombiner
- Transformers
- Transient combustibles
- Boilers
- Turbine auxiliaries

Explosions are qualitatively screened based on Criteria 1.

The quantitative screening criteria from RA-S-1.4-2021 (Reference 15.6-2) are applied. A hazard screens quantitatively if:

1. Based on absolute risk contribution, an event sequence family subject to screening does not exceed the selected risk significance criteria and has mean occurrence frequencies less than  $1\text{E-}7/\text{plant-year}$ , as estimated using a bounding or demonstrably conservative analysis.
2. The total contribution of all screened out event sequence families does not exceed 1% of the cumulative risk targets included in the absolute risk significance criteria.

The qualitative assessment of the above hazards is summarized in Table 15.6-1.

### **Quantitative Screening**

The quantitative screening criteria for external hazards are also used for internal hazards.

To determine the CDF from turbine-generated missiles, the IE frequency, and Conditional Core Damage Probability (CCDP) are determined.

The CCDP was calculated by assuming a LOPP and failure of diesel generators and was estimated to be approximately  $3.4\text{E-}7$ . Multiplying the CCDP by the IE frequency,  $1\text{E-}4/\text{yr}$ , yields a conservative CDF of  $3.4\text{E-}11/\text{yr}$ . The  $1\text{E-}4/\text{yr}$  frequency is conservative because it does not credit the fractional probability of the turbine missile striking and then damaging the target equipment.

Turbine-generated missile hazards meets the screening criteria, so this hazard screens quantitatively.

Internal flooding hazards are treated explicitly in the PSA. No quantitative screening is performed for internal flooding.

The results of the Internal Hazard quantitative screening analysis are presented in Table 15.6-2.

## **Hazard Combinations**

### *Combinations of External Hazards and Correlated Hazards*

The combinations of external hazards or correlated hazards (referred to below as combinations of hazards) are analyzed for those hazards that have the potential to combine, e.g., heavy winds causing the loss of the external grid, snowstorm drifts blocking the diesel generator combustion air intakes and frazil ice blocking water cooling.

### *Categories of Hazard Combinations*

**Consequential Hazards:** Combinations of consequential (or subsequent) events are defined consistent with IAEA, SSG-64, Appendix I (Reference 15.6-11):

An initial event, e.g., an external or internal hazard, results in at least one further hazard, e.g., another external or internal hazard. Event chains of three or more hazards subsequent to each other are possible.

For the assessment of external hazards combinations, the initial event impacting a nuclear installation is either a natural hazard such as an earthquake or an external flooding, or a human-induced one, such as an accidental aircraft crash or an explosion pressure wave (blast) originating from outside the plant boundary.

The following hazard combinations involving external hazards are possible to occur:

1. Natural hazard and consequential external hazard covering:
  - a. Natural hazard and consequential natural hazard (e.g., earthquake and consequential tsunami)
  - b. Natural hazard and consequential human-induced hazard (e.g., extreme wind and consequential aircraft or helicopter crash)
  - c. Natural hazard and consequential internal hazard (seismic and fire)
  - d. Human-induced hazard and consequential internal hazard (aircraft crash and internal explosion)
2. Correlated Hazards: Combinations of correlated hazards are defined consistent with IAEA, SSG-64, Appendix I (Reference 15.6-11):
  - a. Two or more external and/or internal hazards occur as a result of a common cause initiator. The common cause can be any anticipated event including an external hazard or might be due to an unanticipated dependency. The two or more hazards correlated by this common cause could occur simultaneously.
3. The following hazard combinations involving external hazards may occur:
  - a. A natural hazard or hazard source as common cause for other external and/or internal hazards and/or internal events. Typical examples include an earthquake as the common cause for landslide, external fire, internal fire, internal explosion, and station blackout, as potentially correlated events, or tsunami as the common cause for external flooding, internal flooding, and internal fire as potentially correlated events.
  - b. A human-induced hazard (or hazard source) as common cause for other human-induced and/or internal hazards. Examples are an accidental aircraft crash of a large commercial passenger aircraft as the common cause for an external

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

explosion (outside the plant boundary), a plant internal fire an internal explosion, and a heavy load drop correlated by the aircraft crash, or an electromagnetic interference outside the plant boundary as the common cause for a plant internal electromagnetic interference and internal fire as the two correlated hazards.

4. Independent Hazards: Combinations of unrelated (or independent) events are defined as follows consistent to IAEA, SSG-64, Appendix I (Reference 15.6-11):
  - a. An initial event (e.g., an external or internal hazard) occurs independently from, but simultaneously with another hazard without any common cause. The term 'simultaneously' in this case does not mean that the hazards occur exactly at the same time but rather that the second hazard occurs before the consequences of the previous hazards have been completely mitigated.
5. The following event combinations involving external hazards may occur:
  - a. Natural hazards and independently occurring natural hazards. Typical examples include longer duration riverine flooding and independently occurring extreme weather conditions, such as extreme wind.
  - b. Natural hazard and independently occurring human-induced hazard. Examples are a longer duration hydrological hazard and an independently occurring industry accident (such as an explosion, release of hazardous substances, etc.).

*Identification and Screening of Hazard Combinations*

Event combinations used to develop a list of potential combined hazards is initially based on the identified individual hazards. The number of individual hazards identified to occur at a given plant location is already high. Building combinations of all possible individual hazards result in a number of combined hazards, which is not manageable without applying a systematic approach.

Identification of consequential hazards begins with the unscreened single hazards and determining those hazards that may occur as a result of the initial hazard. This can be performed using a matrix approach, listing the hazards graphically and showing the combinations of two hazards (so-called first order combinations) where the possible combinations are identified. The combined hazards can be further reviewed based on this initial identification to determine additional hazard combinations possible (second-order combinations) or additional identified combinations.

For combinations of correlated hazards, it is not directly possible to build a matrix for these combinations. The analyst starts the combined hazard screening by identifying potential common causes for those individual (single) hazards not screened out for the plant/site and builds a tree-type structure (or similar) for all hazards correlated by such common causes representing the roots of the branches. With such a tree-type structure, higher order combinations of correlated hazards can be built and undergo a screening process.

For the third category of combinations of independent hazards, the same two-dimensional matrix structure is used. The possibility of an event combination is demonstrated by a color change or other designation in the corresponding matrix field. The matrix involves the identification of hazards that may impact the plant/site for a time period longer than 3 days. The likelihood is included in the matrix based on the duration of the first hazard and the likelihood of the second hazard occurring during that time period. Combined events are identified by analyzing the correlations and the effects on the plant. The analysis of possible correlations (dependency) between events is made by assessing the physical bases of the phenomena, observed data, actual operating events, and general knowledge of local conditions.

Expert judgment and rough quantitative analysis are used for estimating correlations. The observed data for intensities relevant to external events PSA is sufficient for order of magnitude correlation estimates.

For example, high wind often results in high water level and organic material in water (e.g., seaweeds, kelp, algae, Asiatic clams, mussels, etc.). The combination may simultaneously endanger offsite power and the diesel generator cooling water intake; therefore, it is analyzed as a combined event.

Extreme wind velocities are measured in winter and could be associated with snowfall resulting in possibility of simultaneous LOPP and loss of the diesel generators due to snowdrift blockage of combustion air intake.

Simultaneous high air and seawater temperature could also endanger plant equipment, e.g., instrument room cooling at units with diverse cooling system heat sinks. Identified hazard combinations are screened similar to single hazards using the process discussed previously.

#### *Evaluation of Risks Associated with Unscreened External Hazards*

For unscreened external hazards and identified combinations of external hazards, a similar model development and quantification processes described previously are adapted to evaluate external hazard risks. The process utilized for hazards combinations is discussed below.

Several external hazards from transportation and nearby facilities are evaluated. These external hazards are evaluated with bounding assumptions and can be modified with plant-specific inputs:

- Airports and airways hazards
- Industrial accidents
- Pipeline accidents
- Hydrogen storage failures
- Transportation accidents

#### *Process for Selection, Screening and Analysis of Combinations of Hazards*

Figure 15.6-2 provides an overall process for selecting, screening, and analyzing combinations of hazards. The quantification of the hazards is performed similar to the quantification of the individual hazards with consideration of the combined hazard on the SSC fragilities, the likelihood of the combined hazards, and the inclusion of these factors in the PSA model.

The process for the specific modeling depends on the hazards, and the supporting single hazard PSA modeling. During the PSA quantification, the quantification steps may be slightly different if the combined hazards PSA results are calculated together with or separately from the single hazards PSA model quantification. For example, if a seismically-induced flooding event PSA model is developed and quantified, it can be quantified as a part of the Seismic PSA or separately where only the accident sequences involving seismically-induced flooding are quantified. There are no requirements in either IAEA-TECDOC-1804, "Attributes of Full Scope Level 1 Probabilistic Safety Assessment for Applications in Nuclear Power Plants" (Reference 15.6-13) or the ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12) to quantify single and combined hazards separately or together. There are advantages of long-term model maintenance in developing and analyzing the combined hazards using a single model. The quantification of each single and combined hazard avoids double counting the results. For example, if the CDF of a single hazard PSA model such as a seismic PSA provides a value of  $1\text{E-}05$  / reactor year, and the combined hazards PSA model for the combination of consequential hazards seismically-induced internal flooding provides a CDF of  $5\text{E-}06$ /reactor year, there is likely some double counting if the final

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

results are equal to the sum of the two CDF values. In this case, a realistic assessment of the single hazard PSA is based on accident sequences where a flooding event does not occur.

The quantification of the combined hazard PSA is performed in a similar manner as the individual hazard PSA, accounting for the conditional probability/frequency of the combined hazard magnitudes. As previously discussed, this can be applied in a variety of approaches, but often specified magnitude ranges or bins are used. The analysis of hazard combinations magnitude ranges or bins include variation of the various hazards and the conditional probability of each hazard in combination with the others.

### **Internal Hazard Combinations**

Heavy load drop-induced floods and structure damage are addressed as part of the heavy loads analysis in the low power/shutdown PSA evaluation.

Turbine-generator missile-induced fires/explosions are addressed in the fire PSA. Pipe whip and jet effects are addressed in the internal flooding PSA.

### **External Hazard Combinations**

The external hazards combinations were identified and screened. The high wind combinations are covered by the high wind PSA.

The BWRX-300 PSA scope includes considerations of radioactive sources outside the core. Since one goal of the PSA is to ultimately evaluate the level of safety to the surrounding populace, only those radioactive sources containing sufficient radioactivity that, if released, would pose a significant health hazard outside the site boundary.

The only significant radiation source in the primary containment is from the reactor core. The reactor core is treated in the PSA. The FMCRD system also contains a radiation source but is not expected to pose an offsite threat.

In the RB, the fuel pool is assumed to contain during some portion of the plant lifetime sufficient radioactivity to pose a public health hazard outside the site boundary. This radiation source is treated in the PSA.

Radioactivity deposited on systems in the plant is not liberated in sufficient quantities to pose a public health hazard. This includes systems such as the fuel pool cooling, reactor water cleanup, main steam, feedwater, and Heating, Ventilation, and Air Conditioning (HVAC) systems.

The radioactive waste system does not contain radioactivity in sufficient form or quantity to pose a public health hazard in the form of a small or large release defined by the PSA.

The potential radionuclide source term from severe damage to spent fuel casks was examined in USNRC NUREG/CR-6451, "A Safety and Regulatory Assessment of Generic BWR and PWR Permanently Shutdown Nuclear Power Plants." (Reference 15.6-14). USNRC NUREG/CR-6451 (Reference 15.6-14) considered tornado missile impact the limiting hazard and the tornado wind speed required to generate a missile with enough force to compromise a cask has never been observed. The judgment that tornado impacts are the limiting physical hazard to spent fuel dry casks is adopted for the BWRX-300 design. Regardless of the ruggedness of the casks, a conditional radionuclide source term was developed for a cask event where all rods of a fuel assembly are compromised. The release fractions for iodine and cesium are less than  $1.5\text{E-}5$  and  $2.25\text{E-}5$  respectively, from the damaged spent fuel assembly in the cask. The Level 2 Probabilistic Safety Assessment estimates that the release fraction for I-131 constitutes a small release of  $1.14\text{E-}3$  and release fraction for Cs-137 constitutes a large release of  $5.20\text{E-}4$  in terms of fractional inventory of the entire core.

Because hazards to spent fuel in dry casks do not result in fuel damage or significant radionuclide releases, dry casks are screened from treatment in the PSA.

#### **15.6.1.2.2 External Hazards**

The BWRX-300 PSA is an all-hazards PSA where external hazards are evaluated for potential PSA development.

The methodology examines the hazards from Appendix 2 “Questionnaire on External Events PSA (Other Than Seismic) of NEA/CSNI/R(2009)4,” “Probabilistic Safety Analysis (PSA) of Other External Events Other Than Earthquake,” (Reference 15.6-15) and applies screening to each hazard according to the rules of ANSI/ASME/ANS RA-S-1.1-2022, Appendix 2 (Reference 15.6-12):

1. A hazard qualitatively screens if demonstratively conservative assessments find the hazard does not impact the plant or is subsumed into a more frequent or more impactful event. Any one of the following qualitative screening criteria may be used:
  - a. The event is of equal or lesser damage potential than events for which the plant is designed. This requires an evaluation of the plant design basis in order to estimate the resistance to a particular (external) event.
  - b. The event has a significantly lower mean frequency of occurrence than similar events included in the PSA and could not result in worse consequences in those events.
  - c. The event cannot occur close enough to the plant to effect it.
  - d. The event is included in the definition of another event.
2. The frequency of the event is sufficiently low in comparison with the probabilistic limits defined for the release category frequencies so that it does not need to be included in the PSA. Hazards that do not screen qualitatively are subjected to quantitative screening. A hazard screens quantitatively if:
  - a. Based on absolute risk contribution, an event sequence family subject to screening that does not exceed the selected risk significance criteria and has mean occurrence frequencies less than  $1\text{E-}7/\text{plant-year}$ , as estimated using a bounding or demonstrably conservative analysis, and.
  - b. The total contribution of all screened out event sequence families may not exceed 1% of the cumulative risk targets included in the absolute risk significance criteria
3. Hazards that screen neither qualitatively nor quantitatively are addressed by detailed PSA. A decision can be made to bypass screening of a hazard and go directly to detailed PSA development.

The NK38-REP-03611-10043 R003, “Hazards Screening Analysis – Darlington” (Reference 15.6-26) site environmental conditions were used for external hazards screening:

1. For the screening assessment of high water level, a 100-year flood is conservatively assumed to flood the site and allow water to enter the RB.
2. The BWRX-300 Diesel Generators (DGs) are air-cooled, and thus operation may degrade or cease in extreme ambient temperature conditions.
3. Given the advent of weather extremes due to global climate change, an extreme high temperature condition of  $37.8^{\circ}\text{C}$  or more is assumed to occur at the site once per 20 years.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

4. Safety SSCs exposed to ambient environmental conditions and required to function in local extreme meteorological events are assumed to be designed for -40°C.
5. For extreme high or low ambient temperatures, a LOPP is assumed to occur due to high energy demand.
6. The DGs, which are air-cooled, are assumed to be unavailable given extreme temperatures at or below -40°C that may lead to station blackout.
7. A northern climate, Toronto Canada, is selected as a representative location for snowfall at the Darlington site. Historical heaviest single day snowfall data for Toronto for the past 169 years indicate that the maximum snowfall episode was 48.3 centimeters on December 11, 1944. Heavy snowfall did not extend beyond or prior to this single day. It is assumed that 48 centimeters is below the design snow load for non-Seismic Category-I (non-SC-I) structures and below the air intakes for the DGs.
8. It is assumed that if heavy snowfall is forecast for multiple days, operator action will initiate shutdown procedures if the integrity of plant structures due to heavy loading is threatened.
9. BWRX-300 structures are designed to withstand credible accumulations of hail stones.
10. It is assumed that all outdoor structures of the BWRX-300 are designed to withstand white frost.
11. It is assumed that the plant is not susceptible to sand accumulation that may affect SSCs.
12. The BWRX-300 plant design protects electrical systems functions from voltage transients, including those caused by lightning.
13. For explosions, it is assumed that the Darlington BWRX-300 site is situated beyond the safe screening distance for explosion 700m and vapor cloud explosion 460m to the Saint Mary's Cement Plant.
14. If an explosion occurs in the vicinity of the site, a loss of all structures other than the reactor building is assumed including the MCR as well as LOPP. The DGs are assumed to remain available as they are in a bunkered area and air-cooled (assumed). Electrical cables and control cables are assumed to not be impacted (e.g., they run underground).
15. For marine transportation accidents, a restricted zone is assumed to exist surrounding the plant intake channel and diffuser that does not allow commercial ships to approach the site shoreline. Therefore, marine vessel explosions will not harm the site.
16. It is assumed that the Darlington site is a safe distance from blasting.
17. The Darlington site is assumed situated beyond the screening distances for explosions after pipeline accidents.
18. Chemical release can occur due to the rail line accidents near the site. The control room HVAC has design provisions to address a chemical release.
19. It is assumed that the site is situated beyond the screening distances for chemical releases after pipeline accidents, and chemical releases to water. There are three pipelines (2 natural gas and one petroleum) that are located beyond the screening distance for the Darlington CANDU reactors.
20. BWRX-300 I&C systems are designed to prevent magnetic disturbance from significantly impacting them.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

21. The RB is designed to withstand large aircraft impact. The RB utilizes steel bricks construction, and the design parameters for the Steel Bricks™, such as steel thickness, steel ductility, and concrete thickness, is selected to withstand RB perforation from aircraft and aircraft engine impact.
22. The potential exists for a direct hit from an aircraft engine to one of the RB exterior doors and subsequent penetration. The CCDP given for an airplane crash is 1.0.
23. It is assumed that the BWRX-300 at Darlington site includes an evaluation that demonstrates no historical evidence of subsidence.
24. It is assumed that BWRX-300 building foundations are designed to address potential soil frost and that pipes are buried below the frost line.
25. The Darlington site is not located near volcanoes. There is no concern for ash to fall on the plant.
26. Darlington topography is relatively flat surrounding the site. No avalanche potential exists.
27. The Darlington site includes consideration of waterline topography with relatively flat topography.
28. The land coverage surrounding Darlington is expected to have minimal vegetation, limited to bushes, and mostly paved in the areas proximal to site buildings. It is assumed there is limited numbers of trees, and that the area is mostly paved and cleared to preclude the possibility of external fires or tornado missiles, causing damage to equipment, or impacting control room operations. As a result of the sparse vegetation, external fire propagation to the site is not credible.
29. It is assumed that plant procedures are in place to preclude damage to underground equipment, such as piping or tanks, from excavation work.
30. It is assumed that plant procedures are in place to preclude damage to underground equipment, such as piping, from heavy transportation within the site.
31. Missile impacts from military activity are assumed to be bounded by the airplane impact hazard.
32. It is assumed that the Darlington BWRX-300 plant will not be contiguous with another existing plant.
33. Lake Ontario that is part of the Darlington site boundary is assumed not to have strong lake water currents.
34. Low water level slowly develops. It is assumed that the plant would be shut down and reach a safe stable state prior to the loss of circulating water or plant cooling water.
35. It is assumed that the Darlington BWRX-300 site waterline topography allows water to drain away from the plant.
36. Surface ice will not affect plant operation. The coolant intake and discharge lines at the intake structure are assumed to be located on the water body floor.
37. It is assumed that the Darlington BWRX-300 site is located a safe distance from shipping lanes.
38. For quantitative screening in which offsite power is lost, the CCDP calculations assume that the offsite power loss is not recovered that is used in the internal events PSA modeling.

OPG has used drones for the Darlington CANDU Vacuum Building inspections. The impact of drones hitting the BWRX-300 Structures Systems and Components (SSCs) is bounded by small aircraft crash.

The USNRC has reviewed impact of drones on U.S. Nuclear Power Plants (Backgrounder – Drones and Nuclear Power Plant Security (Reference 15.6-16)). Their assessment states:

“The technical analysis concluded that U.S. nuclear power plants do not have any risk-significant vulnerabilities that could be exploited by adversaries using commercially available drones to result in radiological sabotage, theft, or diversion of special nuclear material (essentially the reactor fuel)”. Thus, drones are screened out.

## **Results**

The external hazards qualitatively screened out from the PSA are shown in Table 15.6-3. The external hazards quantitative assessment results are shown in Table 15.6-4.

### **15.6.1.3 Level 1 PSA**

#### **15.6.1.3.1 Level 1 PSA At-Power**

One of the first and basic steps in a PSA is the identification and quantification of the IEs used in the sequence analysis. IEs have historically been broadly classified as either “internal” or “external” hazards. An IE may result from human causes, equipment failure from causes internal to the plant (e.g., hardware faults, floods, or fires), or external to the plant (e.g., earthquakes or high winds), or combinations thereof. Internal events PSA assesses events that are caused by systems or components located within the site structures. An exception of this is LOPP that is analyzed in the internal events PSA. Internal and external hazard induced IEs (e.g., seismic events, internal floods) and IEs during shutdown excluding sabotage are discussed in other sections in this report:

- Probabilistic Fire Analysis (internal fire events)
- Probabilistic Flood Analysis (internal flooding events)
- High Wind Risk (including tornado events)
- Seismic PSA (seismic events)
- Shutdown Risk (shutdown IE for internal events)
- Spent fuel damage

#### **15.6.1.3.2 Initiating Events Identification**

To develop a comprehensive accounting of postulated IEs, a systematic approach is used to identify events that challenge normal plant operation and require successful mitigation to prevent radionuclide release. IAEA-TECDOC-1804 (Reference 15.6-13) provides the following IE definition: “an event which could directly lead to core damage or challenges normal plant operation and requires successful mitigation to prevent core damage”.

A comprehensive identification of IEs includes a review of existing BWR PSAs, including the ESBWR, and generic sources. Generic lists of IEs are included in multiple reference documents such as IAEA-TECDOC-719, Purpose of Probabilistic Safety Assessment,” (Reference 15.6-17), USNRC NUREG/CR-5750 and USNRC NUREG/CR-6928, “Industry-Average Performance for Components and Initiating Events at U.S. Commercial Nuclear Power Plants.” (Reference 15.6-19) update 2015.

IEs identified typically include transients of various types, LOCAs, and support system initiators. IEs under low power conditions are also identified and are listed in Table 15.6-5.

All system failures that disturb plant operation (e.g., front-line and support systems) are reviewed, except for those already identified as the source IE based on other analyses.

In addition, planned and unplanned manual shutdowns which seldom place demands on any standby safety equipment are treated as IEs because of their high frequency and because they represent changes in operating states that result in demands on available equipment to reach a safe shutdown condition.

Support system initiators are defined as unplanned normal shutdown resulting from loss of a support system with dependent failures. Related to support system initiators are CCF that are equipment failures that cause an IE and simultaneously degrade equipment credited for mitigating the IE (e.g., failure of balance of plant equipment that could cause a plant trip and preclude use of the normal power conversion system). CCFs are systematically identified and treated in the PSA.

Human error IE is considered for these analyses.

An example list of the general damage definitions of internal IE are shown in Table 15.6-6, which is taken from IAEA-TECDOC-719, Table 3.9 (Reference 15.6-17). This list is supplemented with the other generic sources previously discussed in developing a comprehensive IE list.

#### **15.6.1.3.3 Initiating Events Screening**

The requirements for screening potential IE candidates from the PSA are discussed in IAEA-TECDOC-1804 (Reference 15.6-13) and the ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12).

Based on the references in Subsection 15.6.1.3.2, the IE candidates identified are excluded from further consideration if they meet one of the following criteria:

1. The event does not lead to the IE as defined in the PSA.
2. The event does not correspond to the scope of the PSA.
3. The frequency of the event is less than the truncation value related to the accident sequence frequency, and the event does not involve an interfacing systems LOCA, containment bypass, or RPV rupture. For these events, the truncation value is at least one order of magnitude lower than the truncation value accepted in the PSA.
4. The resulting reactor shutdown during at-power is not an immediate occurrence. The event does not require the plant to transfer to shutdown conditions until a defined amount of time has elapsed, the condition is detectable before plant systems are required to respond, and there is a high degree of certainty (based on supporting calculations) that the condition can be detected and corrected before normal plant operation is affected (either administratively or automatically).

The IE screening is limited to those events that do not lead to an IE defined in the PSA, and those events where a shutdown occurs prior to the conditions being corrected. Screening is carefully and conservatively applied, especially early in design where the impact for an event may not be fully understood without design details that are fully developed.

#### **15.6.1.3.4 Accident Sequence Analysis**

The event trees developed for BWRX-300 are based on the IEs developed in the IE analysis. The event tree models include the set of safety functions needed to mitigate each IE. The accident

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

sequence analysis ensures that the response of the plant systems and operators to an IE is reflected in the risk assessment so that:

1. Operator actions, mitigation systems, and phenomena that influence or determine the course of sequences are appropriately included in the accident sequence model and sequence definition.
2. Plant-specific dependencies due to IEs, human interfaces, functional dependencies, environmental, and spatial impact, and CCFs are reflected in the accident sequence (event tree) structure.
3. The individual function successes, mission times, and time windows for operator actions for each critical safety function modeled in the accident sequences reflects the success criteria evaluated in accordance with the acceptance criteria attributes following.
4. End states are clearly defined as either core/fuel damage or successful prevention with the capability to support the interface between Level 1 and Level 2 PSA.
5. The accident sequences are defined for the selected set of IEs, POSs, and times that a POS can occur.

The resulting accident sequence analysis addresses:

- General assumptions relating to all event tree development
- Sequence end states
- Definition of the type of models produced (e.g., small event trees and large fault trees) and level at which the event tree headings are defined (safety function, system, train)
- The BWRX-300 event trees are generally small event trees developed using the CAFTA software discussed previously. Event tree headings are largely based on top-level system functions with functional fault trees added to connect the models to system and train failure events
- Requirements for developing event sequence diagrams
- Interface between the IE, success criteria, human reliability, system modeling and data analysis tasks

The event sequence analysis meets the ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12).

## **Methodology**

### *Acceptance Criteria*

A formal definition of core damage is defined and justified before the function overall success criteria is established.

Core damage is defined in terms of physical processes, phenomena, and failure mechanisms. The accident analyses and past experiences for similar plants are used in deriving the core damage definition. The physical plant parameters (e.g., highest node temperature) and associated acceptance criteria limit values (e.g., percentage of cladding thickness oxidized) used in determining the core damage definition. The parameters selected in determining core or fuel damage is practical, consistent, and realistic. Best practices and OPEX, conservatism in computer codes, sophistication of models, and sufficient margin for uncertainties are parameters considered in defining core or fuel damage.

The success criteria supporting each event tree and key safety functions are the minimum requirements necessary to achieve safe, stable conditions (i.e., to protect the fuel and prevent

radionuclide releases to the environment). Safe conditions are determined by meeting the following key safety function success criteria, and stable conditions are determined by maintaining each key FSFs for long-term operation:

1. Reactivity Control: Achieve subcriticality and maintain the reactor in a subcritical state (combined with adequate core cooling and/or containment heat removal functions) so that core damage and containment failure are avoided.
2. Core Cooling: Adequate core cooling is provided to prevent core damage and maintain the reactor in a safe-and-stable condition. An example of the overall success criteria for core cooling is ensuring the PCT does not exceed 1200°C and cladding oxidation does not exceed 15%.
3. Containment System Integrity: Ensure that the containment pressure does not exceed the ultimate containment failure pressure, and containment isolation occurs when required.

Success in achieving the FSFs is defined in Chapter 15, Section 15.2.

Other safety functions are developed as needed. For example, the RCPB success criteria is developed and modeled based upon the analyzed maximum pressure increase in the reactor coolant.

### **Accident Sequence Development**

The role of an event tree is graphical expression of IE groups, success criteria, and sequence end points. The basic concept is preparing an event tree for each IE group defined in IE analysis task.

IE group is studied and organized based on following policy based on IAEA-TECDOC-1804 (Reference 15.6-13): "For each IE group for internal events, internal hazards, and external hazards for each POS the accident progression for all sequences is identified and justified. For each IE group the accident sequence models are developed. As models explicitly address realistic plant behaviour in response to IE in terms of normal plant systems operation, operator actions, and mitigation systems that support the key safety functions necessary to achieve a stable safe state."

### **End States of Event Sequences**

The event trees identify the potential sequences that may lead to radionuclide release. Many of the sequences have common characteristics that challenge the containment fission product barrier. These sequences are grouped into damage classes that are analyzed in the release portion of the PSA. The end states of the event sequences developed are defined to facilitate the containment performance analysis and provide the link between core damage and a release category.

Event sequences are then qualitatively analyzed to determine which sequences lead to core damage end states.

The core damage sequences are grouped together based upon the overall challenge to the containment barrier and defined as:

1. OK: The core is successfully cooled, and the containment is intact. There is no core damage in these events.
2. CD I: The containment is intact when core damage occurs and the RPV is at low (or controlled) pressure.

3. CD II: The containment is breached, either due to overpressurization or venting, while the core is successfully cooled. Core damage results from failure of long-term heat removal core cooling.
4. CD III: The containment is intact when core damage occurs and there is high RPV pressure at the time of RPV failure.
5. CD IV: Core damage results from an accident sequence with initial failure of effective reactivity control (CCF failure of hydraulic scram or FMCRD run-in, control rod binding, etc.). This potentially affects containment more severely than CD I or CD III because more energy is deposited into the containment prior to RPV failure. All CD IV end states are treated as CD I or CD III depending on the RPV pressure without affecting the results of the containment analysis. This end state has been retained in this scoping analysis to readily allow sensitivity analyses for reactivity control.
6. CD V: The containment is bypassed at the time of core damage.
7. CD VR: Core damage occurs due to RPV ruptures in the lower or mid-vessel regions.

Sequences where core damage is expected to occur very late are appended with an 'L'. An example of this occurrence is when CRD flow is being relied upon to avoid core damage, but eventually fails due to inventory depletion.

#### **15.6.1.3.5 Success Criteria Analysis**

The main objective of success criteria formulation is determining for given IEs what represents a successful or unsuccessful plant response and translating this information into detailed plant system and operator action success criteria accomplished for at-power or low power/shutdown operation. The BWRX-300 success criteria analysis is integrated with the accident sequence analysis.

Success criteria are defined for several different levels: The highest level of success criteria development determines what mitigates an IE (i.e., aversion of core damage). Using the qualitative description of core damage (e.g., gross fuel/cladding degradation due to failure to adequately remove fission and/or decay heat), a parametric description (e.g., peak core nodal temperature) generated.

Success criteria are developed supporting the functions required to mitigate core damage. An assessment of front-line systems identifies mitigating functions and determines the requirements to fulfill those functions. Best estimate analyses use computer codes or other acceptable calculations in performing this task. Examples include determining how many trains of a system performs a function for IE sub-groups.

Supporting success criteria is determined once the functional success criteria is identified. This includes mission times calculations and human actions, inventory availability determination, and other system or train-level success criteria development.

### **Methodology**

#### ***Definition of Core Damage***

The definition of core or fuel damage is a key aspect in determining the functional success. Core damage is defined by the two key physical parameters: PCT and fuel cladding oxidation.

The above definition and criteria are consistent with the definition in PSA Standard ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12) as "uncovery and heat-up of the reactor core to the point at which prolonged oxidation and severe fuel damage are anticipated and involving enough of the core, if released, to result in offsite public health effects."

### *Functional Success Criteria*

The functional success criteria defines the minimum performance that differentiates the end state when that function succeeds from the end state reached when the function fails. With the parameters that determine core damage and decay heat levels defined, specific success criteria are added defining the necessary capability of SSCs and operator actions in accident sequences.

A mission time is determined to achieve a stable end state after an IE for the accident sequences. As a first approach, a general mission time of 24 hours is assumed for Best Estimate (BE). A longer mission time is used for some accident sequences to achieve stable plant conditions.

Success criteria analysis considers the available inventories needed to support each system or function. The available inventories of fuel, water, or air in tanks etc., are compared with those required to support each success criterion and the model reflects the comparison results.

Analysis models and computer codes are used to model the conditions and phenomena that determine the success criteria. The plant model and parameters used for thermal-hydraulic analyses provides sufficient resolution and reflects the actual design and operational features of the plant.

For each accident sequence condition, the applicability ranges and conditions for each analysis code are reviewed. An assessment is performed ensuring that all accident sequences are within the applicability of the codes used in determining the success criteria. The use of all codes is justified based on this comparison.

Each success criterion in the analysis is based on either a plant design parameter or a thermal-hydraulic calculation. When a success criterion is used to characterize a range of conditions, the limiting parameters are chosen to represent all cases. In addition, representative thermal-hydraulic analyses and offsite dose consequence analyses are run to validate the appropriateness of the success criteria.

#### **15.6.1.3.6 System Analysis**

The system analysis is performed for each plant system represented in the IE analysis and accident sequence analysis for each POS in such a way that:

1. Each safety function in accident sequence models and system models are developed that account for the success criteria.
2. System-level success criteria, mission times, time windows for operator actions, different initial system alignments and assumptions provide the basis for the system logic models reflected in the model. A reasonably complete set of system failure and unavailability modes for each system is represented.
3. Human errors and operator actions that influence the system unavailability or the system contribution to accident sequences are identified for development as part of the HRA element.
4. Intra-system dependencies and intersystem dependencies including functional, human, phenomenological, and CCFs that influence system unavailability or the system contribution to accident sequence frequencies are identified.

Other objectives include:

- Considering credible failure modes
- Modeling each failure mode impact on system performance
- Including support system failure modes in the front-line system fault trees

- Creating linked fault tree models that allow resolution
- Creating fault tree models where cutsets are clear and concise

## **Methodology**

The BWRX-300 system analysis includes systems modeled in the BWRX-300 PSA, which correspond to the functional headings described in the event sequences plus any support systems needed to accomplish those functions. The system modeling methodology follows the guidance in USNRC NUREG/CR-2300, USNRC NUREG/CR-4550 and USNRC NUREG/CR-4551 series. USNRC NUREG-0492 provides additional guidance on fault tree modeling, current information for the system studies, and latest results.

The analysis for each system begins by defining the system functions, system operation modes and alignments, establishing system-level success criteria (in conjunction with the event tree development that addresses operability and survivability), and defines the system boundaries. All system components and system connections that are modeled are described in simplified drawings.

For systems that operate in several different modes or POSs, each mode and the functions performed, are explained. Only those functions that contribute to plant risk defined by the accident sequences are included. The interfaces and system connections of the system with other systems are described. This also includes the support systems and relevant system components required for the operation of the system. Any other relevant aspects of the system operation including system trips, interlocks and procedural restrictions during accident conditions are also addressed.

Necessary operator actions are identified for systems where manual initiation is necessary or manual backup is credited in the PSA. The post-initiator HFEs (Type C) are identified based on operational procedure. Significant pre-initiator HFEs (Type A) are identified by investigating test and maintenance procedures related to the SSCs modeled in fault trees and are identified as part of the system analysis.

The success criteria of front-line systems for each IE are identified in the success criteria analysis task. System success criteria of support system are obtained by following success criteria for front-line systems. Based on these success criteria, necessary system functions are identified. Operability relative to trip setpoint limits and adverse environmental effects impacting all system components survivability are addressed. Any operator interventions that mitigate adverse environmental effects is proceduralized.

Systems models are developed that include all component failure modes and unavailability factors that lead to failing to achieve the system function defined by the system success criteria. Component failures that would be beneficial to system operation are not included in the model.

Database for component failure probability has two general types of failures. One is a demand failure, and the other is a rate failure based on the amount of time a component needs to operate. The reliability models considered to support BEs are not discussed in detail here, but involve exposure-rate for demand failures, exposure-rate or periodic test models for rate failures, and models that account for monitoring and repair. The data that supports the parameters listed are discussed in the data analysis task.

The documentation of the system analysis describes the processes used in modeling and quantification, generic modeling assumptions and is constructed considering future updates and uses in risk-informed applications.

#### **15.6.1.3.7 Fault Trees**

One fault tree for each system function is included in the PSA model. If multiple trains perform the function, then each train is modeled. All the logic for a particular system is contained in a single fault tree file.

The fault trees are constructed using the gate and basic event naming conventions. The fault tree database is stored in the CAFTA database file format.

#### **15.6.1.3.8 Data Analysis**

The data analysis objective is providing estimates for the reliability parameters for the reliability models specified under the systems analysis. The reliability models are used in determining the BEs probabilities of specific equipment failures and unavailability factors.

Data analysis is used in deriving the parameter values that estimate system failure probabilities and accident sequence frequencies. These BEs used in the PSA model are outputs from the IE analysis, accident sequence modeling, and system fault tree modeling discussed previously. The PSA BEs include the IE frequencies, component unavailability, component/train unavailability factors (resulting from testing or maintenance), CCF events, and other types of events. At this stage in the design process, there is no plant-specific reliability data available. Generic data from the nuclear industry and associated uncertainty are used.

Where plant-specific reliability data are not available, mainly generic reliability data are used as discussed below under component reliability database.

In the absence of actual operating experience for the passive plants, Advanced Light Water Reactor (ALWR) Utility Requirements Document (URD) recommends using failure data for components that are most similar to those used in passive plants. Additional adjustments to the generic data are introduced after analyzing the test and maintenance intervals and the environmental factors.

The data and basis for test and maintenance unavailabilities are based on bounding generic values and OLC allowed outage times. Because of limited operating experience and the lack of plant-specific data, the development of failure rates for equipment reflects appropriate characterizations of the associated uncertainties.

The level of redundancy in passive plant design and few critical support systems leads to increased focus on CCFs. CCFs are modeled for the components of the same size and in the same operating environment. The CCF data from the USNRC CCF (Reference 15.6-18) is used in this analysis. Generic CCF factors are used when component-specific data are not available.

### **Methodology**

#### ***Component Reliability Database***

The parameters are estimated using data and other information that is compatible with the definitions of the BEs. The task procedure either contains the definitions of the events or does so by task procedures for systems analysis and IEs. The component boundaries and the interfaces among connected components are identified. Because a component is required for different operating conditions, BEs representing different failure modes is included in the system model.

Components are grouped into population groups for parameter estimation. The rationale for grouping components into a homogeneous population for parameter estimation considers the design, environmental, functional, and operational conditions of the components in the as-built

and as-operated plant. For parameter estimation, components are grouped according to type and to the detailed usage characteristics.

In this analysis, generic reliability data-based USNRC NUREG/CR-6928 (Reference 15.6-19) are used. When data from this USNRC NUREG/CR-6928 (Reference 15.6-19) is not available for a modeled failure mode, data is used from the following resources in this order:

- EPRI TR-016780-V3R8, "T-Book: Reliability Data of Components in Nordic Nuclear Power Plants, 6th Edition"
- USNRC NUREG/CR-4550, "Analysis of Core Damage Frequency From Internal Events: Methodology Guidelines"
- USNRC NUREG/CR-2728, "Interim Reliability Evaluation Program Procedures Guide"
- USNRC NUREG/CR-1740, "Data Summaries of Licensee Event Reports of Selected Instrumentation and Control Components at U.S. Commercial Nuclear Power Plants"
- EGG-SSRE-8875, "Generic Component Failure Data Base for Light Water and Liquid Sodium Reactor PRAs"
- Engineering judgment

### **Dependent Events and Common Cause Failure Analysis**

Dependent events challenge redundancy or diversity and ultimately increase the unavailability of a system. Four dependency types are analyzed in the PSA analysis:

1. Plant-level functional dependencies: Plant-level functional dependencies lead to functional failures as a direct result of a shared IE.
2. Intersystem dependencies: The dependencies of BWRX-300 systems are carefully analyzed in the PSA analysis. Physical and functional intersystem dependencies are incorporated into the system fault trees by using transfer gates. Physical dependencies include spatial interactions, influences for common environment, or impacts from adjacent SSCs. These physical dependencies are important when modeling the impacts from internal and external hazards( fire and flood).
3. Human action dependencies: Dependencies due to human actions (testing, maintenance, diagnostic errors, incorrect calibration of sensors or instrument), which could affect manual actions or actuations of redundant systems, are reviewed in the system PSA analysis and modeled as separate events in the fault trees where necessary. Modeling of human action dependencies is discussed further in Section 15.4.
4. Intra-system dependencies: Intra-system dependencies (CCFs) can lead to multiple component unavailabilities from shared causes. The remainder of this PSAR section discusses the analysis approach for this type of dependency.

#### *Developing the Common Cause Failure Database*

Once the CCF basic events are identified, the model utilizes the CCF tool in CAFTA to automatically identify all the CCF combinations for a given CCF group and places the appropriate CCF BEs into the fault trees. CAFTA is also used to automatically quantify each of the CCF BEs.

As recommended by the CAFTA developers, common cause groups containing more than four components are treated simplistically. CCF events are developed for all combinations of one, two, and three components within the group, with all remaining failure probability assigned to a CCF event of all components failing. This is a conservative representation of the event modeling

all components failing, because the CCF probability of all components is overstated, but greatly simplifies the fault tree modeling.

When this treatment is too conservative, the calculations are completed outside of CAFTA and entered manually. In these cases, the CCF combinations are manually input to the fault trees using the parameters for the actual CCF group size and the CCF equations are directly input into the database file.

#### **15.6.1.3.9 Human Reliability Analysis**

The HRA is performed as part of the BWRX-300 PSA. Human actions play a key role in the risk assessment and may point to plant vulnerability early in the design phase that can be corrected before the design is finalized.

The HRA describes operator failure in a systematic and reproducible manner to facilitate a Human Error Probability (HEP) that is applied to the PSA model. The methodology is described below. Individual failure events generate reports that are presented in appendices to the PSA model.

#### **Scope**

The HRA covers three types of human actions:

- Those performed by maintenance or operations before an event
- Those performed by operations or maintenance to cause an event
- Those performed by operations after an event has occurred

Currently only post-initiator actions are documented given the limited plant design information.

#### **Inputs, Requirements, and Assumptions**

The primary input to the current HRA comes from a review of the success criteria and event sequences documents. These documents discuss the operator actions that are considered for the safe shutdown of the plant. The second resource is examination of the system fault trees to find actions that backup automatic functions. The third resource and the primary resource for pre-initiator actions comes from system engineers and any developed system maintenance schedules. Currently maintenance has not been considered in many of the systems and therefore pre-initiators are not included in the model.

#### **Requirements**

The requirements for the HRA analysis primarily come from the PRA Standard ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12). Due to the PSAR design development stage and emergency procedures that are developed for the final safety analysis, this analysis is not expected to meet all the requirements of the standard at this time.

#### **Assumptions**

Generic assumptions used in the PSA:

1. All human actions are driven by procedure. No actions are considered that are outside operations documentation (e.g., actions based on knowledge, or mitigating actions outside the procedure).
2. Errors of commission are screened out from the analysis because they have negligible probability compared to errors of omission.
3. All persons performing operations or maintenance are adequately trained by an accredited training program.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

4. Post-initiator actions are all conducted from the control room unless otherwise specified in the human failure event report.
5. In the current phase of design, procedures for actions are based on engineering judgment and experience.
6. The pre-initiator HRA for a component that is made unavailable due to testing or maintenance, a restoration error is always possible.
7. The control room displays, and alarm annunciators are well-designed with critical alarms for all human failure events within the safety case identified and shown on the appropriate displays, with color-coding, lighting, and flashing to guide alarm management. Information is displayed in a manner appropriate to the type of display (e.g., large screen versus control desk versus local control panel, etc.).
8. Software-based display screens and control actuations are well-designed with consideration of human factors good practice principles including grouping, labeling, and spacing. In particular, potential selection errors either in screen navigation or in equipment icons on a particular screen are minimized through effective layout, screen item design, and group demarcations.
9. The time required to perform the steps in a task is estimated in most cases based on input from personnel that have BWR PSA human reliability analysis experience, have interacted with nuclear operators and is familiar with BWRs operator actions. Wherever possible, worst-case plant conditions and competing task workload are assumed ensuring conservative estimates. In some cases, the time taken to carry out task steps that are part of a task but are not necessary for successfully completing the specific action identified in the PSA are included in the overall task required time. This is done in cases where members of the HRA team indicate that these actions are likely to be attempted. Task timings are further examined and verified in later iterations of these analyses.
10. Assumptions related to individual dependencies include:
  - a. Although many actions occur over a long period of time, it is assumed that there are no intervening successes between actions
  - b. The same crew is assumed to perform the actions throughout the event
  - c. Cognitive demand is assumed different except where the actions are similar, e.g., alignment of cooling
  - d. Simultaneous actions are assumed when operators are working with multiple, immediate concerns (e.g., pump power and isolation)
  - e. The required resources to perform a task (operators, maintenance personnel, health physics, etc.) are estimated based on experience and engineering judgment
11. Timing overrides are implemented as necessary to place actions into chronological order. In the current model, no overrides are necessary.

## **HRA Discussion**

There are several types of human actions during normal plant operation:

- Those related with the failure to restore equipment to its normal condition following a test or maintenance action
- Those causing an IE

Human actions during an accident are:

- Those performed by operators following established procedures for mitigating the consequences of an accident
- Those performed in the mistaken belief that they are the appropriate actions as indicated in the procedures, but in reality, can worsen the conditions of the accident, thereby complicating the mitigation process
- Those that are not explicitly included in the procedures and are used to recover the operability of failed equipment or use alternative means

Treatment of human actions in the PSA leads key to realistic understanding of event sequences and their relative importance to overall risk. The HRA is performed in a structured framework that allows development of the analysis in an orderly fashion while considering the general boundary of the PSA.

There are three main types of human actions in the HRA:

*Type A: Pre-Initiating Event Human Actions*

Before an IE, plant personnel affect availability of standby systems by inadvertently disabling equipment or failing to restore the correct position during the performance of operational activities in the plant. Example: maintenance staff incorrectly perform a valve lineup after maintenance on a pump. When the pump is needed during an event, it cannot run or is damaged.

*Type B: Initiating Event Induced by Human Actions*

Plant personnel initiate an event through interactions with plant equipment. These typically occur due to a mispositioning or incorrect operation of equipment that inadvertently trips equipment or inserts false control signals. Example: One of three pumps providing service water to a condenser fails and operators do not align a backup in a timely manner. The plant trips on loss of service water.

*Type C: Post-Initiating Event Human Actions*

After an initiating event has occurred, plant operations attempt to place the plant in a safe, stable state using emergency operating procedures. There are two types of errors associated with Type C actions:

1. Commission Errors – By following procedures during the course of an accident, plant personnel operate standby equipment that aggravates the accident. This action, called a commission error, gives rise to a situation in which the operators place the plant in a worse condition than if they had done nothing (i.e., an omission error). The risk of commission errors is considered insignificant when the plant has EOPs that have a symptom-based orientation and the EOPs cover all the possible scenarios in the event sequences analysis.
2. Omission Errors – Failure to perform a step in the procedure, or failure to act in a timely manner results in either equipment damage or core damage. It is imperative that operations perform the correct steps within the time frame before damage occurs.

**Review of Plant Practices**

Once the pre-accident errors are identified as part of the systems analysis, the human reliability analyst examines the pertinent procedures to determine which critical components are placed in off-normal configurations and if not restored to their normal alignment, could render the component, train, or system inoperable. Examples of errors that render components, trains, or system inoperable include:

- Prior to performing maintenance on a pump, the protective tagging order typically involves isolating the pump by closing both the suction and discharge isolation valves, racking out the pump breaker, and placing the pump control switch in pull-to-lock. Failure to return these components to their normal position will result in unavailability of the pump.
- In the case of testing, failure to close the test line isolation valve can result in unacceptable degraded performance of the train or system.
- During instrument calibrations, a I&C technician errantly calibrates an instrument that automatically actuates, automatically trips, or causes some other actuation.
- While performing maintenance on a transmitter, the instrument isolation valves are left closed resulting in erroneous operation or failure to detect system parameter changes such as pressure or level changes.

Plant practices for operating BWRs are used until plant-specific maintenance procedures are developed.

#### **15.6.1.3.10 Event Sequence Frequency Quantification**

The BWRX-300 PSA model consists of event trees and fault trees that are quantified using a fault tree linking process. The calculation of core/fuel damage and release category frequencies is performed as single gate for each sequence and release category. The top gates include all sequences but uses a sequence marker to identify the event tree sequences in the cutsets generated by the single gate. The use of a sequence marker results in retaining all the minimal cutsets for that specific sequence but prevents subsuming of non-minimal cutsets among sequences. This is addressed later in the recovery process. The contribution to risk from these non-minimal sequences is generally small, although this can affect the results for specific hazards, such as earthquakes (seismic).

The sequence logic is set up to exclude any combinations associated with the success branches in the specific sequence. The individual sequence results are then combined for reporting, analyzing, or used as input for the L2 or L3 portions of the PSA.

#### **Methodology**

The purpose of the event sequence frequency quantification is to obtain the Boolean equation corresponding to the radionuclide release. The quantification is developed in terms of minimal cutsets representing the minimal combinations of events that result in radionuclide release.

The following key aspects characterize the release category frequency quantification process:

- Event trees model plant response to each group of IE
- Fault trees model the behaviour of front-line and support systems
- Integration of event tree and fault tree structures into a single linked model
- Quantification of the linked Boolean model with the probabilistic database and boundary condition files (flag files)

#### ***Use of Computer Aided Fault Tree Analysis for Solving the PSA***

The EPRI Integrated Risk Technologies User Group offers the suite of risk software tools (formerly known as R&R Workstation) that are used for the Level 1 PSA model development and quantification. These risk software tools include CAFTA for event tree and fault tree construction and PRAQUANT for master model integration and quantification. Accident sequence frequencies

are derived from the quantification results of a single top master fault tree by post-processing using the sequence markers.

The FTREX code is used in generating Minimal Cutsets (MCS) from fault tree logic models. FTREX uses a zero-suppressed binary decision diagram method for interpreting large fault tree models when developing MCSs. FTREX is built for PSA applications and is applicable to the BWRX-300 PSA without specific limitations.

Chapter 3, Appendix 3G discusses the computer programs used in the PSA.

The reliability databases supporting the BWRX-300 PSA include the IE frequencies, component failure frequencies and probabilities, CCF data, component repair times, test intervals and durations, mission times, maintenance unavailability, unavailability due to testing, and human error data. Uncertainties for data values are also included. All the data sources are justified and documented.

#### *Additional Quantification Steps*

The quantification process used for the PSA is iterative and includes numerous stages where internal and external review is performed before final results are documented. Key steps performed during the quantification include:

1. Circular Logic: It is possible to generate a master fault tree that has circular logic. This is where a gate is used as input to a second gate that happens to also be an input somewhere in the tree of the first gate.
2. Basic Event Consistency Check: The IE frequencies and the probabilities associated with BEs of the model are consistent with the definitions of the events in the context of the logic model. As the PSA cutsets are reviewed, they are reviewed for consistency in terms of the applied assumptions, specific design, and operational experience.
3. Mutually Exclusive Event Review: The model is solved to verify the event combinations are removed.
4. Human Error Dependencies: One example of how human failure error dependencies are determined is summarized:
  - a. All post-initiator HFE probabilities are set to one (or a high value).
  - b. The single top quantification is performed again. The most critical human failure error dependencies align, and this is apparent in the cutset results.
  - c. The PSA then uses the results generated in the cutsets to generate recovery rules that change the probability of these joint failures to a value that better reflects the dependency between these human failure errors taken from the HRA.
5. Recovery Actions: For a design level PSA, equipment recovery is not credited other than operation of backup systems that is addressed in the Type C operator actions. In the site-specific PSA, recovery is possible for longer term accident sequences where equipment recovery is possible.
6. Truncation Justification: To justify an appropriate truncation value is used, a test for CDF convergence is performed. Additionally, the last two convergence runs are used to develop a list of risk-significant accident sequences (e.g., contributing greater than 1%) to ensure no new significant accident sequences are identified by lowering the truncation limit further.

7. Importance Analysis: This analysis documents the overall contribution of basic events to each phase of the PSA including the Level 1, Level 2, and Level 3 PSA. Separate importance results are provided for basic event types such as IE, human errors, event class, release categories, etc. Together with the uncertainty and sensitivity analyses, this satisfies CNSC REGDOC-2.4.2, Requirement 4.10 (Reference 15.6-1).
8. Uncertainty and Sensitivity
9. Review of the results: The U.S. PSA Standard and the IAEA-TECDOC-1804 (Reference 15.6-13) require the review of the results in detail to ensure the results are consistent and justified. For the BWRX-300, the comparison of these results with similar plants is not possible. As a result, a general comparison with the ESBWR or other BWRs using similar components (e.g., ICS) is made.

#### **15.6.1.4 Internal Fire Hazards**

The probabilistic fire analysis was performed with simplifying assumptions because the specifics of cable routings, ignition sources, or target locations in each zone of the plant are still in the design phase. Because of this limitation, a simplified, conservative, and bounding approach is used in this analysis.

The current scope of the analysis is for at-power accident scenarios.

#### **Methodology**

The BWRX-300 internal Fire PRA is performed according to the guidance in USNRC NUREG/CR-6850 (Reference 15.6-20). Other key references may be used:

- USNRC NUREG/CR-6850, EPRI 1019259, Supplement 1, "Fire Probabilistic Risk Assessment Methods Enhancements" (Reference 15.6-27)
- USNRC NUREG-2169, EPRI 3002002936, "Nuclear Power Plant Fire Ignition Frequency and Non-Suppression Probability Estimation Using the Updated Fire Events Database" (Reference 15.6-28)
- USNRC NUREG/CR-7150 Vol 1, BNL-NUREG-98204-2012, EPRI 1026424, "Joint Assessment of Cable Damage and Quantification of Effects from Fire (JACQUE-FIRE) Volume 1: Phenomena Identification and Ranking Table (PIRT) Exercise for Nuclear Power Plant Fire-Induced Electrical Circuit Failure," (Reference 15.6-29)
- USNRC NUREG/CR-7150 Vol 2, BNL-NUREG-98204-2012, EPRI 3002001989, "Joint Assessment of Cable Damage and Quantification of Effects from Fire (JACQUE-FIRE) Volume 2: Expert Elicitation Exercise for Nuclear Power Plant Fire-Induced Electrical Circuit Fire," (Reference 15.6-30)

USNRC NUREG/CR-6850, EPRI 1011989 (Reference 15.6-20) and USNRC NUREG/CR-6850 Supplement 1, EPRI 1019259 (Reference 15.6-27), document state-of-the-art methods, tools, and data for the conduct of a Fire PRA for a commercial nuclear power plant application. The methods have been developed under the fire risk re-quantification study. This study was conducted as a joint activity between EPRI and the U.S. NRC Office of Nuclear Regulatory Research under the terms of an NRC/EPRI memorandum of understanding and an accompanying fire research addendum.

For the BWRX-300 Fire PRA model development, the following USNRC NUREG/CR-6850 (Reference 15.6-20) tasks are applicable:

- Task 1: Plant Boundary & Partitioning

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

- Task 2: Fire PRA Component Selection
- Task 3: Fire PRA Cable Selection
- Task 4: Qualitative Screening
- Task 5: Fire-Induced Risk Model
- Task 6: Fire Ignition Frequencies
- Task 7: Quantitative Screening
- Task 12: Post-Fire HRA
- Task 14: Fire Risk Quantification
- Task 15: Uncertainty and Sensitivity Analyses
- Task 16: Fire PSA Documentation

Some of the above tasks are simplified while others are omitted at this stage of the plant design. Tasks not addressed in this study include:

- Scoping Fire Modeling (Task 8)
- Detailed Circuit Failure Analysis (Task 9)
- Circuit Failure Mode Likelihood (Task 10)
- Detailed Fire Modeling (Task 11) including multi-compartment analysis
- Seismic Fire Interaction (Task 13)
- Support Task A Plant Walk Downs is not performed in the design phase

The Fire PRA database is created with an Access®-driven database (FRANX) that includes all tables that are necessary to develop a scoping-level Fire PRA model. Enhancements to the Fire PRA database are possible in future updates once more details are available for cable tray routes and their contents as well as more detailed ignition source locations.

Fire ignition frequencies for power operation at each plant area (physical analysis unit) are estimated using the USNRC NUREG/CR-6850 (Reference 15.6-20) and USNRC NUREG/CR-6850 Supplement 1 methodology (Reference 15.6-27) and data from USNRC NUREG-2169 (Reference 15.6-28). Fire frequencies for shutdown conditions are not developed at this time.

For a postulated fire, a list of impacted components is generated with the mapping defined in the Fire PRA database. A list of impacted components is also generated with the assumed cable routing. The cable routing is assumed based on the modeled PRA components, their supports, and the general room layout of the BWRX-300 design. Fires are conservatively assumed to propagate unmitigated in each fire area (no suppression is credited) and damage all functions in the fire area. The internal events PRA accident sequence structures and system fault trees and success criteria are used in the calculation of the fire CDF.

The BWRX-300 Fire PSA employs the following EPRI software:

- Fault Tree Reliability Evaluation eXpert. This software generates cutsets from the fault trees produced in CAFTA.
- CAFTA. This software is used to build the logic model of the plant, producing all the fault trees and event trees.

## Assumptions

1. A fire ignition in any fire area may grow into a fully developed fire.
2. The analysis does not take credit for any fire suppression (i.e., self-extinguishment, installed suppression systems, nor manual firefighting activities). All fires disable all potentially affected equipment in the area in the analysis.
3. Unless otherwise stated, a fire causes failures of all fire-susceptible components in the subject fire area and detailed fire modeling is not performed in this revision of the BWRX-300 Fire PRA.
4. Recovery of the failed components or cables after the postulated fire is not credited.
5. Unless otherwise stated, the analysis does not credit the distance between fire sources and targets.
6. All fire-induced equipment damage occurs at time zero in the scenario progression.
7. Cable routing is postulated for PRA purposes using plant general arrangement drawings with major electrical component locations because cable routing is provided later in the design. A list of cables is generated that includes all modeled supports for PRA components included in the current PRA model. This list captures most cables, especially for expected risk-significant components.
8. Fires in the MCR and SCR are currently modeled as impacting components associated with any assumed cable routings that go through the rooms but do not terminate in the MCR or SCR (i.e., the assumed cable route for a bus that goes through the MCR between the TB and the B train MCC room in the CB). The MCR and SCR are not assumed to impact components where control or visualization cables may be in the rooms. This is a realistic treatment because plant design could be similar to the ESBWR where the control room controls are connected to the Distributed Control and Information System (DCIS) rooms (which would be unaffected by a MCR fire), via fiber cables. The loss, including melting, of the fibers or visual display units (VDUs) will not cause inadvertent actuations, nor affect the automatic actuations associated with safety and non-safety equipment. In addition, fires in the MCR and SCR are assumed to fail all modeled human failure events.
9. All finalized details of cable route information are not yet available. Individual routes are assumed based on location of PRA modeled power/signal sources and the component.
10. The cable routings use general separation criteria because of the number of different signal and power divisions where there are physical analysis units with more than one division and power and control cables postulated. As the BWRX-300 design matures, cable routings are refined to include any credited fire barrier(s) within an overall physical analysis unit that serve to separate divisions.
11. Fire ignition frequencies remain constant over time and are based on industry generic fire frequencies. At operating plants, the total ignition frequency is the same among plants for the same equipment type, regardless of differences in the quantity and characteristics of the equipment type that exists among the plants. This is conservative because the BWRX-300 design has significantly fewer pumps, motors, and other active components than earlier plant designs upon which the current plant generic ignition frequencies are based.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

12. All ignition source type bins are applicable to the BWRX-300 plant with the following exceptions:
  - a. Bins 02 and 03 are not applicable since they are used for pressurized water reactor plant designs.
  - b. Bin 22 for scram motor generator sets is not applicable to BWRX-300.
  - c. Bin 04 is not applicable to the BWRX-300 MCR or SCR because the BWRX-300 design is completely digital as opposed to traditional electro-mechanical designs. However, to ensure a conservative analysis is produced, twenty-five percent (25%) of the traditional Bin 04 ignition frequency is assumed to be applicable and is assigned to the BWRX-300 MCR ignition frequency.
13. Although the BWRX-300 plant may be located with existing NPPs, the plant location weighting factors are one because the BWRX-300 plant is designed as a single-unit plant with no shared buildings.
14. Because the BWRX-300 plant is in the preliminary design phase, the count of components is performed with the modeled PRA components as well as preliminary design layout drawings.
15. Because the plant has not operated and no history of maintenance activity is available, the weighting factor evaluation is simplified. It is assumed that all compartments (physical analysis units ) have the same transient fire influencing factors with a value of one is used for all influencing factors.
16. All fires result in a manual reactor shutdown regardless of location or potential induced failures.
17. Full details of electrical cabinet locations are not yet available. Preliminary design information notes the division or train of equipment is used in the development of this revision of the BWRX-300 Fire PRA for electrical cabinet and high energy arching fault counts.
18. The containment is always inerted during power operation. The possibility exists that the containment could be de-inerted in preparation for an outage, or still de-inerted when coming out of an outage. Typically, de-inerting occurs around 2-3 days before an outage that can result in a fire during this time. This time window is not included in the current BWRX-300 Fire PRA but is included in the future shutdown operation BWRX-300 Fire PRA.
19. Cables associated with display or visualization component status or function may be routed between a component or instrumentation location and the MCR or SCR are not impacted by any automatic function of the component.

### **Modeling for Full-Power Condition**

Detailed fire modeling is not performed for this revision of the BWRX-300 Fire PRA for at-power operation. Detailed fire modeling is undertaken when the BWRX-300 design is more mature and additional details on equipment locations and cable tray routes are known with certainty.

For this revision of the BWRX-300 Fire PRA, full room (physical analysis unit) burnout scenarios are used where any PRA-related component and cable within the particular physical analysis unit is failed at the total physical analysis unit ignition frequency during Fire PRA quantification.

### **Evaluation of Multi-Component Scenarios**

Fire propagation cases (multi-compartment scenarios) from one physical analysis unit into another physical analysis unit are not currently postulated for the fire areas listed in the at-power Fire PRA. As the BWRX-300 design matures, this analysis is undertaken.

### **Evaluation of Potential Smoke Damage**

Detailed HVAC system design information is not yet available for the BWRX-300 plant design. Consequential failures from potential smoke damage cannot be assessed. This is provided in future updates to the BWRX-300 Fire PRA as the plant design matures.

### **Detailed Fire Modeling for Shutdown Condition**

The shutdown PRA model is not yet constructed but is expected to be based on the Level 1 internal events PRA model. Detailed fire modeling follows the same process described previously with the exception that the evaluation of the applicability of shutdown conditions in the Fire PRA model is provided in future updates to the BWRX-300 Fire PRA.

#### **15.6.1.5 Internal Flooding Hazard**

The BWRX-300 internal probabilistic flood analysis objective is identifying and providing a quantitative assessment of the radionuclide release risk due to internal flood events. It models potential flood vulnerabilities in conjunction with random failures modeled as part of the internal events PSA. Through this process, flood vulnerabilities that could jeopardize core integrity and containment integrity are identified.

The floods may be caused by large leaks due to rupture or cracking of pipes, piping components, or water/fluid containers such as storage tanks. Another possible flooding cause is the operation of fire protection equipment.

Excluded from this analysis is flooding associated from external sources that is considered under the External Flooding Hazard Analysis for localized flooding events and intense weather events. These external flooding events are reasonably precluded from the BWRX-300 probabilistic flood analysis because the standard plant design prevents external flooding conditions affecting the safe operation of the plant.

### **Methodology**

The internal PSA flooding analysis identifies and classifies potential flooding sources and events. Component location and data is compiled generating a frequency of occurrence that represents the effects associated with each of the potential flooding events. In addition, an evaluation is performed to identify, screen, and quantify specific plant effects/failures associated with each flooding event. Finally, the BWRX-300-specific flooding frequencies and plant effects are applied to the PSA model to obtain risk results. For the BWRX-300 Flooding PSA model development, the following tasks are performed:

- Identification of flood sources
- Development of flooding scenarios
- Development of flooding frequencies
- Analysis of flooding scenarios

The internal PSA flooding analysis is based on the design basis BWRX-300 SSCs. Critical to the flooding analysis is the location of these features and their interaction with other BWRX-300 SSCs. The current list of system components and location of equipment is based on the current

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

design and plant layout drawings and relies on the component location analysis collected for the Fire PSA step (e.g., common spatial information).

The development of BWRX-300-specific flooding scenarios requires a detailed analysis of data including plant component location, system capacity, and potential failure mechanisms. Following the identification of potential flooding scenarios, characteristic scenarios are selected as representative of flood areas and subject to quantitative analysis.

Data is collected from industry sources for the BWRX-300 equipment and system components. Failure data for consideration in the flooding analysis includes piping runs, pumps, valves, tanks, heat exchangers, and circulating water expansion joints to develop the severity and effect of potential flooding scenarios. These failure rates in combination with types and capacity of system components located within specific flood zones are used to develop the flooding frequencies and frequency uncertainties. Flooding frequencies for both large break and small leak scenarios are developed for each flooding scenario.

The flood scenarios for each flood area are quantified to calculate a probabilistic risk value and summed to provide an overall risk analysis. USNRC NUREG/CR-4639 and NSAC-60 provide additional guidance for flooding analysis. The requirements for a flooding PSA are discussed in Section 3 of the PSA Standard ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12).

Walkdowns are a critical task for a mature flooding PSA and is performed and documented after the plant construction is complete.

#### *Key Inputs and Assumptions*

The following are inputs for the BWRX-300 flooding analysis:

- At-power internal events PSA model
- BWRX-300 design features for protection against flooding
- Flood zone spatial information

The following assumptions are used in support of the BWRX-300 flooding analysis:

1. Flooding resulting from component ruptures
2. For each tank rupture, the entire tank inventory is drained
3. Non-qualified submerged equipment (motors or solenoids for valves, control cabinets and circuitry) fails if the water level in the flood zone reaches a level of 1 foot above floor elevation
4. If equipment fails, the equipment fails at the start of the flood
5. The expected effect of flooding electrical equipment such as motor control centers, electrical cabinets, and terminal boxes, is a short to ground, removing power from the loads served by the component (all electrical equipment failures are treated as ground shorts)
6. Flooding and/or spraying of a motor-operated valves (MOVs) causes the valve to fail as-is
7. Passive components, such as pipes and tanks are not considered vulnerable to flooding effects
8. Concrete walls are considered flood barriers, capable of withstanding the expected maximum flood loading, and remain intact throughout a flooding event

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

9. Electrical circuit fault protection provides protection for plant electric circuits via protective relaying, circuit breakers, and fuses and does not result in the loss of the bus that supplies power to the affected component
10. For floor drains, appropriate precautions such as check valves, back flow preventers, and siphon breaks prevent back flow and any potential flooding into connected plant areas (propagation of flooding through the drain system via failed check valves is not considered)
11. Doors in electrical equipment rooms within the RB are evaluated for watertight doors for flooding up to the ground level elevation. For the flooding analysis, the watertight doors are normally closed at-power and opening of these doors generates an alarm in the control room with procedures that direct their immediate closure upon alarm receipt
12. Dry pipe systems (such as a pre-action Fire Protection System) with closed sprinkler headers are not modeled as flood sources due to the low frequency failure of the dry pipe coincident with spurious opening of the actuation valve
13. Equipment located in the yard is not considered susceptible to internal flooding damage
14. Human-induced mechanisms such as overfilling tanks or diversion of flow created by maintenance are not modeled because operating and maintenance procedures have not been developed, and frequency of maintenance and duration of maintenance have not been determined. They are included in the PSA updates when these inputs are available
15. The flood volume retained by the drain system is not credited in the flooding analysis for large flooding scenarios. Therefore, the capacity of the drain system has not been estimated
16. The amount of water retained by sumps, berms, dikes, and curbs is negligible. This is conservative because retained water provides additional time for flooding response
17. Flooding initiator frequencies remain constant over time
18. Among the plant buildings, flooding frequency is the same for the same equipment type, regardless of difference in the quantity and characteristics of the equipment type that may exist among the plant

#### **15.6.1.6 High Wind Hazard**

The BWRX-300 high wind analysis quantifies event sequences and containment releases initiated by both tornado and straight winds. Straight winds are lesser velocity winds that pose minimal challenges to the plant design. Straight-line winds of lesser velocities are not included in the BWRX-300 high wind risk analysis. The consequences of these winds is addressed as part of the weather-related LOPP IE in the at-power internal events PSA model.

#### **Methodology**

The high wind risk analysis involves the following major steps:

- Tornado high wind event frequency
- Tornado-induced plant effects
- Analysis of tornado-induced release category frequencies
- Analysis of straight-line wind effects

The high wind PSA analysis identifies and classifies potential high wind events. Data is then compiled to generate an occurrence frequency that represents each potential high wind events.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

In addition, a qualitative evaluation of the design basis BWRX-300 SSCs is performed identifying specific plant effects/failures associated with each high wind event. A BWRX-300-specific high wind event frequency and plant effects are applied to the at-power model to obtain risk results. High wind hazards are characterized by their impacts (e.g., dynamic load from gusts, averaged loading, rotation velocity, pressure differential, tornado path, missile impact potential).

The BWRX-300 is designed for a tornado wind load that is the maximum wind speed such that it does not challenge safety structures.

ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12), including the guidance in the non-mandatory appendix, provides requirements and guidance on performing detailed high winds PSA. The changes in Part 7 of ASME/ANS PSA Standard are the most significant changes and reflect advancements in high winds PSA. Included in the standard requirements is the consideration of correlated hazards and hazard effects, such as the potential for local flooding associated with high winds or the impact of high wind-driven rain. This standard is utilized for both the screening of potential hazards and the analysis of any unscreened hazards.

The BWRX-300 High Wind PSA uses the following EPRI software:

1. Fault Tree Reliability Evaluation eXpert - this software generates cutsets from the fault trees produced in CAFTA.
2. CAFTA- this software is used to build the logic model of the plant, producing all the fault trees and event trees.
3. ACUBE 2.0 -this software provides a more accurate solution to the cutsets than conventional solutions.

### **Key Inputs**

Site-specific data are inputs for the external hazards PSA analyses. Site-specific wind hazard analysis generally requires the use of regional data. The size of the region requires judgment and depends on the regional climatology and type of wind hazard, the number of years accurate records are available, the extent and quality of the data, and the hazard's spatial variability within the region. In the design phase, it is possible to select a bounding region for a high wind hazard; however, a bounding region for tornadoes may not be the bounding region for hurricanes.

The high winds equipment list is evaluated based on the internal events PSA required functions and supporting SSCs. The internal events PSA is used to quantify the high winds PSA with modification of the damaged or potentially damaged SSCs.

### **Key Assumptions**

The following assumptions were used in conducting the BWRX-300 high wind risk analysis:

1. The winds classification used in the BWRX-300 high wind analysis is based on the Saffir-Simpson scale.
2. The tornado winds classification for the BWRX-300 high wind analysis is based on the recommended wind speed ranges of the Enhanced Fujita scale (EF-scale).
3. All at-power BWRX-300 high wind analyses include high winds assuming the plant is operating. This approach is conservative for the high wind analysis where sufficient advanced warning and procedures allow the plant to be placed into a safe condition (shutdown operations) prior to the high wind event.

4. For the BWRX-300 high wind analysis, the frequency of occurrence data for tornadoes high wind events is compiled from sources based on the Enhanced Fujita scale (EF-scale) for classification of tornadoes. This data is correlated to the BWRX-300 EF-scale of tornado classification.

#### **15.6.1.7 Seismic Hazard**

The scoping Seismic PSA (SPSA) for the BWRX-300 Standard Plant Design describes the methodology used:

- Presents the seismic hazard curve used
- Lists the generic structure and component fragilities and sources
- Presents results by ground motion level and important fragilities
- Documents seismic risk insights
- Identifies plant design requirements

The model used is a preliminary scoping model that provides important insights into plant design. The SPSA activities include:

- Identifying IEs applicable to seismic events
- Developing a seismic equipment list
- Assigning representative fragilities applicable to SSCs
- Adjusting for human error probabilities to reflect increased distractions and stress from the seismic events
- Modeling seismic Level 2 PSA in the updated SPSA

The scoping SPSA is a full-power model. Seismic-induced flooding and fire, contact chatter, building-to-building interactions, and soil liquefaction are addressed qualitatively in the scoping stage.

Although for low ground motion levels offsite power may be available, offsite power is assumed unavailable in all modeled accident sequences.

The plant operational and emergency systems are represented by event and fault trees. The analysis gives insights into the dominant contributors to seismic risk.

#### **Methodology**

The BWRX-300 scoping SPSA development involves four major activities:

1. Probabilistic seismic hazard analysis
2. Seismic fragility analysis
3. Seismic plant response analysis
4. SPSA quantification

The probabilistic seismic hazard analysis identifies ground motion bin IE frequencies that are based on the seismic hazard curve for the Darlington site. This curve is then partitioned into several ground motion bins.

The BWRX-300 SPSA results are reported based on truncating the seismic hazard at the 1E-6/yr earthquake frequency, consistent with IAEA-TECDOC-1791, "Considerations on the Application of the IAEA Safety Requirements for the Design of Nuclear Power Plants" (Reference 15.6-21).

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

For some external hazards, the IAEA Safety Requirements states that “it may not be practical or even possible to demonstrate that the occurrence of a hazard of such severity could cause extensive plant damage leading to a large or early radioactive release and therefore needing to be practically eliminated, is below a threshold of frequency such as  $10^{-6}$ /year”. Seismic events with exceedance frequencies less than  $1\text{E-}6/\text{yr}$  are attended by significant uncertainty. The IAEA guideline is applied to the SPSA results by truncating the seismic hazard. Applying the seismic hazard truncation at the  $1\text{E-}6/\text{yr}$  earthquake frequency results in the sum of the CDFs for seven ground motion bins.

The seismic fragility analysis produces a seismic equipment list that includes a list of plant SSCs related to seismic-induced IEs and SSCs that mitigate plant responses to IEs. Fragilities for the SSCs on the seismic equipment list are selected in the seismic fragility analysis.

The SPSA model is developed from the seismic plant response analysis. The seismic plant response analysis uses a seismic IE tree to model the plant structures that are required to remain intact and the probability of a seismically-induced LOCA, main feedwater line break and main steam line break. A LOPP is assumed to occur for all SPSA modeled sequences. The end states of this event tree that do not go directly to core damage are linked to the appropriate internal event trees.

An updated internal events top logic model is used as input to the SPSA top logic model development update. This updated internal events top logic model is used to update the systems fault trees and PSA event trees reflecting the current evolution of the BWRX-300 design. The internal events top logic addresses:

- Updated system fault trees to reflect current system designs
- Updated Level 1 event trees
- Updated model continues to credit containment vent for decay heat removal
- Updated model continues to credit CRD injection, to control inventory during failure to scram and LOCAs
- Updated model continues to credit ultimate pressure relief for transients, small LOCA and failure to scram

For the SPSA quantification, the FRANX code is used to integrate the seismic hazard with the SSC fragilities to produce the SPSA CDF results.

The BWRX-300 SPSA uses the following EPRI software:

- FRANX uses the internal events model and adds seismic initiators and hazard curves that results in the CDF for each ground motion level
- Fault Tree Reliability Evaluation eXpert generates cutsets from the fault trees produced in CAFTA
- CAFTA is used to build the logic model of the plant, producing all the fault trees and event trees
- ACUBE 2.0 provides a more accurate solution to the cutsets than conventional solutions

## Assumptions

The following principal assumptions are used in developing the seismic PSAs:

1. A LOPP is modeled to occur for all seismic accident sequences. Although offsite power may be available for low ground motion level earthquakes, this assumption is made to simplify the model. A consequence of this assumption is that power conversion system is unavailable. This assumption is made in this scoping model, but in the final model, the offsite power system is modeled explicitly.
2. The seismic-induced failures of the RB, reactor support structure or RPV are assumed to result in core damage and containment bypass.
3. Fragility group MV-MSIV consists of the MSIVs and RIVs. It is conservatively assumed in this assessment that the two sets of valves are similar in design response to be seismically correlated, meaning that if one fails, the other will fail as well. This assumption is revisited in the final model using the methodology discussed in USNRC NUREG/CR-7237, "Correlation of Seismic Performance in Similar SSCs (Structures, Systems, and Components)" (Reference 15.6-22), these valves have uncorrelated fragilities due to dissimilarities. The outboard MSIV and MSRIVs are treated as fully correlated and with further analysis may be treated as partially correlated.
4. Chatter of electrical contacts, such as relay contacts, is not addressed. Contact chatter is not expected to contribute significantly to BWRX-300 seismic risk. The DL4a ICS actuation and the DL4 scram actuation are expected to fail-safe as a result of chatter and that do not include seal in circuits that would interfere with actuation. Contact chatter assessment is addressed in a future revision of the SPSA.
5. The SPSA utilizes fragilities primarily from the ESBWR. Where ESBWR data are not available, representative fragilities from EPRI Report 3002000709, "Seismic Probabilistic Risk Assessment Implementation Guide" (Reference 15.6-23) are used. For risk-significant fragility groups, representative fragilities developed for the BWRX-300 are used.
6. The electrical equipment that supports DL2 and DL3 actuation signals is seismically correlated and is modeled by a fragility group. This modeling is conservative because the equipment is not collocated. DL2 electrical equipment is located in the control building and the DL3 electrical equipment is located in the RB. Although DL3 is designed to fail in the fail-safe condition, DL3 ultimately relies upon digital electrical equipment to function and DL3 actuation is assigned to a fragility group.
7. In this scoping model, the fractions of the small LOCA frequency that occur in the CUW and the CRD systems are the same for seismic events as for random failures. This simplification is compared to plant-specific data in the final model.
8. Dependencies of multiple human failure events in the same cutset are not modeled. Because there are few human failure events in the model, human actions are not as important in the BWRX-300 as they are in most operating plants, and the nominal HEPs are screening values where dependency is not likely to be important.
9. The diesel generators located in the TB are air-cooled. The seismic failure of the TB is modeled to fail both diesel generators. The seismic failure of the intake structure does not impact the diesel generators.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

10. At this stage of the analysis, equipment interaction concerns (e.g., equipment falling on other equipment) are not evaluated. As equipment location is finalized, equipment interaction is addressed.
11. All redundant components in the same system are correlated. This is reasonable for components that are identical, of the same orientation, and on the same floor. The MSIVs and the MSRIVs correlation may be partially correlated as the design evolves. As more detailed designs are developed, other instances of partial correlation may be found and modeled using the USNRC NUREG/CR-7237 methodology (Reference 15.6-22) and re-evaluated in the final model.
12. Generic fragilities are used in the preliminary SPSA. This is sufficient for the scoping study because the fragilities are not site-specific.
13. The DNGS seismic hazard curve is used as input to the BWRX-300 SPSA. In the final model, a site-specific hazard curve is used.
14. A break in the CUW piping could result in a break outside containment if the RWB that is not a safety structure (it is a hardened structure that meets OBE or  $\frac{1}{2}$  SSE earthquake) is damaged or the CUW heat exchangers are damaged. This scenario is evaluated when the design is finalized.
15. The polar crane is designed, or its position administratively controlled by plant procedure during normal operations so that seismic damage of the crane does not impact safety class RB contents, such as the ICS pools and heat exchangers.
16. Equipment anchorages comport with the assigned fragilities, and this is verified as the design progresses.
17. The existing DNGS site has no impact on the SPSA for the BWRX-300 and is a single site.
18. In this current scoping model, equipment screened out of the internal events PSA due to low failure likelihoods, such as ductwork, dampers, piping, and cable trays, are not added and are included in the fragilities that are modeled. In the final model, as more plant-specific fragilities are developed, these components are added.
19. If a building fails, all equipment in that building also fails.
20. If the CB fails, all human failure errors except the human failure errors to align and operate diverse and flexible mitigation strategies (FLEX) fails. The final model addresses whether the CB failure also fails FLEX due to unavailability of operators or lack of a path to the FLEX equipment. Since the HEP for aligning FLEX is 1.0 at the most risk-significant ground motion levels, allowing FLEX with CB failure is of little consequence.
21. A failure of the TB fails both steam lines and feedwater lines because these lines extend into the TB.
22. The FLEX system allows water from Lake Ontario pumped to the reactor, fuel pool, or ICS.
23. Unisolable LOCA is not modeled by the SPSA at this time.
24. Fragility group CR-RODS, Failure of Control Rods to Insert is completely correlated. If control rod scram function is damaged, all control rods are assumed to fail to fully insert.
25. For RPV rupture (fragility group CONRPV), damage occurs in the lower portion of the RPV.

As part of the scoping Seismic PSA, a sensitivity analysis is performed to identify the safety-significant seismic fragility groups. This sensitivity analysis identifies the BWRX-300 SSCs that contribute significantly to the seismic safety profile.

Nine fragility groups are identified by the sensitivity analysis to have seismic safety significance. Of these nine, one group (the reactor building polar crane) is expected to be mitigated by administrative controls rather than seismic design/analysis refinement. The other eight fragility groups are:

- Control Rods
- RIVs/MSIV
- IC HX
- ICS Actuation Valves
- RB
- RPV
- RPV Support Structure
- Scram HCUs

As the detailed design progresses, updated seismic capacities are developed. These seismic capacities are then fed back into the seismic PSA and new risk metrics are recalculated in an iterative process. This risk-informed design process ensures that the DNNP BWRX-300 safety goals are met.

#### **15.6.1.8 Level 1 PSA – Low Power and Shutdown Risks**

The Low Power Shutdown (LPSD) Risk PSA is developed following the requirements of the ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12). Currently, the ASME/ANS standard for LPSD is issued for trial use and pilot application. After the trial use, feedback was provided to the PSA Standard committee and the LPSD standard is being revised.

A detailed PSA is performed to determine the radionuclide release risk during shutdown. Loss of CUW, SDC, Plant Cooling Water System (PCW) and LOPP are all evaluated for radionuclide risk during shutdown. The approach for the LPSD PSA is similar to the Full-Power PSA, involving fault trees and event trees used in determining the shutdown risk for each IE analyzed.

The evaluation encompasses plant operation in hot shutdown, cold shutdown, and refueling modes (Modes 3, 4, 5, 6) while Modes 1, 2, 3, 4 are bounded by the at-power PSA model. During these modes, the plant is transitioned through several POSs that are distinguished in the LPSD PSA by different plant conditions and configurations. The LPSD PSA addresses POSs where there is fuel in the reactor vessel. It includes all aspects of the NSSS, the containment, and all systems that support operation of the NSSS and containment.

The event sequences in the Shutdown PSA are classified according to whether the core is damaged. All shutdown core damage sequences lead directly to a radionuclides release to the environment (containment is assumed to be open at the time of the IE). In the final PSA, this assumption is revisited to accurately assess the PSA results.

The critical safety functions credited in the shutdown model are decay heat removal and inventory control. The containment function is credited for POSs where containment is not open. Because the containment is open for many of the POSs, containment integrity is not relevant to any modeled functions. Reactivity control is assumed to have no significant effect on the shutdown

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

model. Electrical power availability, as well as the availability of other support systems, are modeled for the effect on decay heat removal. LOPP is evaluated as an IE, and power dependencies for systems are included in the model in a similar manner to the at-power PSA.

The LPSD PSA includes fuel and heavy load movements where the PSA analyzes heavy load drops that can cause fuel damage, core damage, or large releases. The PSA results for heavy load drops considers the following events:

- Fuel pool leak due to rupture At-Power
- RPV leak due to rupture (below top of fuel) during Low Power and Shutdown
- RPV leak due to rupture (at feedwater nozzle) during Low Power and Shutdown
- Fuel Pool leak due to rupture during Low Power and Shutdown
- Loss of ICS Train A or SDC during Low Power and Shutdown
- Loss of ICS Train B or SDC during Low Power and Shutdown

### **Methodology**

ANSI/ASME/ANS RA-S-1.1-2022 (Reference 15.6-12) provides input guidance documents for the Low Power and Shutdown PSA model development, including the LPSD PSA Standard, and IAEA-TECDOC-1144, "Probabilistic Safety Assessments of Nuclear Power Plants for Low Power and Shutdown Modes" (Reference 15.6-24).

### **Plant Configurations in Low Power and Shutdown Conditions**

Differences between the Low Power and Shutdown PSA and the Power Operation PSA are attributed to:

- Plant operating mode
- Plant operating state including configuration
- Time after shutdown
- Reactor vessel and containment status
- Vessel and core temperatures
- Fuel location
- Availability of required systems and support systems

This analysis addresses the BWRX-300 risk associated with a refueling outage. The systems modeled are evaluated based on anticipated activities associated with refueling operations.

To develop a suitable shutdown model, multiple bounding plant configurations/POSSs are defined with similar characteristics in relation to the residual heat and the availability of systems.

The outage plant operating mode and POS are used to define the initial plant condition for individual event sequence quantification.

Once the outage POSSs are defined, the duration of each is estimated to determine its contribution to the overall calculation of annual CDF. The duration is expressed in hours per refueling outage.

The Shutdown PSA considers outage plant configurations representative of the possible plant configurations during shutdown.

## **Initiating Events**

The IEs that challenge normal operation including the critical safety functions (e.g., heat removal, inventory control) during shutdown operations are determined. A shutdown IE is defined as any event that challenges normal operation and requires action to prevent core damage.

## **Event Trees**

The LPSD event tree construction considers the following aspects:

- Chronological order of system actuation
- Grouping of mitigating systems by safety functions

The event sequence analysis and end state nomenclature are the same as the at-power PSA. The associated success criteria analysis is performed similar to the at-power success criteria analysis. However, success criteria analysis for LPSD may be approximated by hand calculations.

## **System Analysis**

The unavailability of a system to perform its safety function on demand is evaluated by fault tree analysis similar to the fault tree analysis approach.

The necessary fault trees are identified following construction of the event trees. These fault trees represent the nodes included in the event trees and any required support system fault trees

Maximum use is made of the fault trees developed for the Full-Power PSA. Potential differences between the at-power and the shutdown fault tree models may result from differences in:

- Maintenance unavailabilities
- Success criteria between at-power and shutdown condition
- Initial system configuration between at-power and shutdown condition
- Human actions

Maintenance events used in the at-power model are not adjusted for the LPSD PSA, other than for POSs where some systems are entirely unavailable (for the POS). Additional maintenance events may be possible at LPSD that do not normally occur at full-power. The evaluation of maintenance for each POS is justified and documented.

## **Quantification**

The shutdown event sequence analysis models the effects on the following two critical safety functions during shutdown:

- Decay heat removal
- Containment during configuration changes in the containment boundary and reactor head during refueling

IE, associated frequencies, are identified that challenge the above critical safety functions. Event trees are developed specific to the shutdown configurations and the system fault tree analysis is based on at-power fault tree models adjusted to match shutdown conditions. The model development and quantification are performed using CAFTA and FTREX in a similar manner to the at-power PSA.

### **Start-up and Shutdown Transition Risks**

In the BWRX-300 PSA shutdown models supporting the design, the start-up and shutdown risks are included in the at-power conditions.

Planned shutdown and start-up transition states are difficult to model with PSA for several reasons. The reactor is under continuous transition, e.g., main circulation flow. Temperature and pressure in the reactor vary significantly during the operation. Several manual operator actions and decisions are required. In addition, the operation may require the use of many systems and/or components that are not used during power operation. Identification of risks is also more challenging as it requires detailed understanding of the systems related to process and control. For these reasons, certain assumptions and simplifications are performed to create a usable and practical PSA model.

The new event trees include the same IEs as the previous PSA model, but it also considers transients prior to control rod insertion and failure possibilities related to maneuvering of the control rods. Modeling and quantification of transition modes is similar to the at-power PSA, if quantified.

### **Key Inputs and Assumptions**

- At-Power BWRX-300 PSA models (note external events low power and shutdown models are developed in the external events sections)
- Representative BWRX-300 Refueling Outage Plan Key Assumptions
- Containment is open during the outage

#### **15.6.1.9 Spent Fuel Damage**

Spent fuel damage evaluation is required for the plant-specific BWRX-300 PSA because fuel damage frequency is an important contributor to release risk relative to other low risk contributors. For accidents, where the spent fuel is damaged outside the reactor core, the term spent fuel damage is applied. In particular, the fuel damage frequency may be an important contributor to release risk. The term “fuel damage” represents damage to the fuel outside the reactor vessel, while “core damage” is used for damage inside the vessel.

### **Methodology**

A separate PSA analysis investigates the event sequences leading to spent fuel damage. The analysis estimates the related event sequences and their frequencies, and it is documented separately as part of the PSA. The analysis covers both power operation and outages. Sabotage is explicitly excluded from the calculation of the spent fuel damage frequency.

During the performance of the BWR PSA, the Fuel Pool PSA is performed using the process and requirement of the LPSD PSA including the requirements in the LPSD PSA Standard. In this PSA, the fuel pool is analyzed as a separate POS, and the associated IEs are those that result in an event that challenges the normal operation of the fuel pool cooling or inventory requiring mitigation to prevent fuel damage. The overall process of event tree analysis, success criteria analysis, fault tree analysis, is the same process used in the LPSD PSA. Generally, the time available for responding to a fuel pool IE is much longer than the LPSD IE response.

Event sequences are developed and quantified that credit potential recovery actions taken by the operator.

### **Key Inputs**

- Site-specific external events

- Site-specific spent fuel handling equipment design
- Plant procedure for heavy load lifting and spent fuel handling
- Task outputs and preliminary results

This task develops the Fuel Damage PSA models. A number of IEs are expected to be screened with qualitative assessments.

#### **15.6.1.10 Systems Credited in the PSA**

The following design features are modeled in the PSA.

##### *Isolation Condenser System*

The ICS function modeled in the PSA is removing decay heat from the reactor by condensing steam in the ICS heat exchangers.

##### *Reactor Isolation Function*

The reactor isolation function mitigates the effects of large and medium sized pipe break LOCAs.

The term “RPV isolation system,” is used to refer to RIV closure. The system model is a surrogate for valves that are part of the NBS.

##### *Ultimate Pressure Regulation Function*

The ultimate pressure regulation function of the RPV provides emergency pressure relief in the event of a severe pressure transient.

##### *Control Rod Insertion Function*

The CRD system performs several insertion functions and consists of these design features: FMCRDs, HCU, and the CRD Hydraulic Subsystem.

The PSA-credited function of the control rod insertion is to insert negative reactivity into the reactor core rapidly upon a scram signal. Subcriticality is achieved with the negative reactivity insertion and terminates fission heat generation.

The CRD system also provides an RPV inventory makeup function.

##### *Feedwater Flow Reduction Function*

The feedwater flow reduction provides negative reactivity in a failure to scram condition by reducing feedwater flow resulting in increased core voiding (the BWRX-300 has a negative reactivity void coefficient).

##### *Containment Isolation Function*

The containment isolation function isolates containment in the event of accidents or other conditions and prevents the unfiltered radioactive release before they exceed allowable limits.

##### *Boron Injection System*

The BIS provides a separate, diverse means, D-in-D backup system to the CRD system for manually inserting negative reactivity into the reactor core for BDBAs. All equipment is located outside primary containment to allow easy access for testing and inspection activities during all plant operating conditions.

The BIS utilizes an aqueous solution of highly enriched sodium pentaborate decahydrate for reactivity control. The sodium pentaborate solution temperature is maintained above the solubility temperature due to the placement of the system within the reactor building.

### *CRD Injection Function*

The focus of this system for PSA is the CRD Hydraulic Subsystem that is used for inventory makeup and flow to the SDC pumps.

The CRD Hydraulic Subsystem provides clean, demineralized water that is regulated and distributed to provide charging to the scram accumulators and purge water flow to the FMCRDs during normal operation. The CRD Hydraulic Subsystem is also the source of purging water to the SDC system pumps and the NBS reactor water level reference leg instrument lines. Additionally, the CRD Hydraulic Subsystem provides high pressure injection to the reactor. This makeup water is supplied to the reactor via the drives.

### *Shutdown Cooling System*

The SDC system provides long-term decay heat removal after planned shutdowns. SDC consists of two independent trains designated as Train A and Train B. Each train suction is independently connected to an ICS condensate return line outside containment, downstream of the containment isolation valves.

### *Power Conversion Function*

There is only one function for the power conversion function modeled in the PSA. This function is providing water from the condenser, via the condensate pumps, feedwater heaters and feedwater pumps, to the reactor where it is heated, and steam is produced. Steam is transferred to the condenser via the turbine bypass valves.

Because the PSA model assumes a scram has occurred or is warranted, the full-power function of providing steam to the turbine for power generation is not considered.

### *Cooling Water Systems*

The function of PCW removes heat loads in the RB and TB.

PCW is a closed cooling water system supported by cooling from a portion of the Circulating Water System (CWS).

### *DC Power*

The electrical distribution system is an integrated power supply and distribution system for the power plant. Three plant systems constitute the overall electrical system: Safety Class 1 Electrical Distribution System, Safety Class 2 and 3 Electrical Distribution System and the Non-Safety Electrical Distribution System.

The electrical system powers automatic shutdown and decay heat removal functions. The Safety Class 1 portion of the electrical distribution system (includes the direct current (DC)) is limited to supplying power to Safety Class 1 SSCs within the RB rooms.

Safety Class 1 DC power three division (A, B, and C) arrangement supplies DC power to various loads. Each division has a DC battery and two redundant battery chargers powered from the Safety Class 2 and 3 Electrical Distribution System alternating current (AC) power system.

The primary load of the Safety Class 1 Electrical Distribution system is the Distributed Control and Information System (DCIS).

### *AC Power*

AC power modeled in the PSA, is providing medium and low voltage AC power to plant components.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The following seven AC buses are modeled:

1. Buses A1 and B1 provide 4160V AC power to BOP components such as feedwater pumps and condensate pumps. These buses are not backed by diesel generator.
2. Buses A2 and B2 provide 4160V AC power to other components, such as control rod drive pumps and reactor component cooling pumps. These buses are each backed by a standby diesel generator (SDG) in the event of LOPP.
3. Divisions 1, 2 and 3 provide 480V AC power to Motor Control Centers (MCCs), MOVs, smaller motors, and other plant equipment.

#### *Corium Shield*

The corium shield prevents core melt from damaging the containment liner once the core has broken through the bottom of the RPV.

The corium shield is a complementary design feature that includes a refractory material below the RPV. After core damage, in cases where the RPV is assumed to be at a low enough pressure to preclude direct containment heating, the core debris eventually migrates from the core region to the RPV lower head and exits the through a breach (e.g., lower head failure or CRD housing failure). The refractory material below the RPV prevents molten core concrete interaction and any potential ablation of the basemat and accompanying flammable gas generation.

#### *Passive Containment Cooling System*

The Passive Containment Cooling System (PCCS) rejects heat into the reactor cavity and/or equipment pool above containment. Supply and discharge connections from the pool are connected to closed loop piping within containment. Heat transfer occurs from the containment to the PCCS by natural convection and condensation.

#### *Containment Filtered Venting*

The containment pressure regulation function is venting pressure in the containment as a result of LOCAs, RPV pressure regulation, or core melt. By providing a vent to the containment, pressure, and temperatures are maintained. The release is filtered to reduce the amount of fission products.

Venting is required when no other containment heat removal method succeeds and in certain special situations where there is excessive containment pressure loads beyond the capacity of PCCS. Containment pressure control venting is required to prevent containment overpressurization due to non-condensable gas generation if passive containment heat removal fails. Venting requires operator action to open a pathway to the environment through a hardened vent.

#### *Heating Ventilation and Cooling System*

The HVAC system function is providing normal room atmospheric temperature and ventilation control and room cooling during accident scenarios.

Systems assumed to require HVAC for successful operation have placeholder transfer gates with an assumed failure point-estimate screening value used in PSA model quantifications.

### *Plant Pneumatic System*

The Plant Pneumatic System function provides motive and control air or nitrogen to various plant components. The pneumatic system supports multiple systems valves.

#### **15.6.1.11 Level 2 PSA**

The Level 2 PSA confirms that the BWRX-300 plant for Darlington meets the SRF and LRF safety goals specified by the CNSC.

The development steps of the Level 2 PSA (NEDC-33946P Reference 15.6-25) are:

- Develop an interface between the Level 1 and Level 2 PSA
- Identify and model safety functions and operator actions
- Perform the containment performance analysis
- Perform the accident progression analysis and develop the Containment Event Trees (CETs)
- Perform the source term analysis
- Quantify the model and interpret results

#### **Interface Between Level 1 and Level 2 PSA Event Tree Definition**

The first step in developing the Level 2 PSA is assigning damage classes to the accident sequences resulting in core damage. The BWRX-300 PSA Level 1 Event Tree analysis provides definitions for five damage classes in addition to the successful mitigation state. Table 15.6-6 provides the Level 1 Probabilistic Safety Assessment Damage Class Definitions used in this analysis.

While not strictly required for assessing small and large release frequencies, some element of release timing is also considered in the analysis. For example, if ICS fails to operate during transients, the core can remain adequately cooled for a time by injecting water through the CRD system. If the CRD water inventory is insufficient over the long-term, and if SDC is not initiated before the CRD suction source is depleted, the core can no longer be cooled, and core damage may occur. This is expected to occur significantly later than if CRD did not succeed at all. For this reason, a 'late' designator is appended to damage classes where core damage is significantly delayed. It is expected that this early/late distinction could facilitate applications concerned with dose consequence analysis of reactor accidents.

### *Core Damage Sequences*

Aspects of core damage sequences that are relevant to the potential for radionuclide release characterization are carried forward to the Level 2 PSA. These include:

- RPV pressure at the time of core damage
- Timing of core damage
- Availability/failure of mitigating measures
- Timing of containment failure (relative to core damage)
- Availability of containment isolation

### *RPV Pressure at Core Damage*

If RPV pressure is not lowered substantially during the accident progression, then the potential exists for pressure-driven debris ejection at the time of vessel breach. The resultant fragmentation of the debris may increase the heat transfer to the containment quickly, resulting in a rapid containment heat-up, and pressurization. This direct containment heating is expected to result in containment failure. The potential for this phenomenon warrants development of a CET. The core damage state for high and low RPV pressure are delineated by the accident class. This interface is addressed by developing separate CETs that account for RPV pressure.

### *Timing of Core Damage*

If the core damage occurs very late in the sequence, then these scenarios are given a 'late' designation. This interface is addressed by developing separate CETs that assume core damage occurs very late. The significance of late core damage relative to early core damage scenarios is that protective measures are taken to reduce the impact (e.g., dose to the public) of SA. No quantitative surrogate is developed for what constitutes early versus late damage. Qualitatively, late core damage is assigned for those sequences where safety functions are met initially but fail after a moderate amount of elapsed time (judged to be several hours).

### *Availability/Failure of Mitigating Measures*

Mitigating measures (i.e., equipment and operator actions) and their failures are addressed via fault trees. This interface is addressed inherently by coupling the Level 1 sequences with the Level 2 model so that any basic events relevant to both core damage and radionuclide release will propagate to both levels of the PSA model. To the extent that is possible, the same dependency modeling and basic events are used in both models.

### *Timing of Containment Failure*

If containment is breached or severely degraded as part of the phenomenology of sequence leading to core damage, this interface is addressed by assigning a core damage class that reflects this feature of the sequence.

### *Availability of Containment Isolation*

If core damage occurs as part of a failure to isolate the containment, this interface is addressed by developing a dedicated CET specifically for that class of core damage.

### *Level 2 Mitigation*

The systems and human actions used in the PSA model were taken from the Level 1 PSA (that contains aspects of containment performance, such as containment venting) and no new system or operator actions are developed. The relevant functions to the Level 2 PSA analysis are:

- Late inventory injection
- Containment isolation
- Corium shield
- PCCS
- Containment venting
- RPV depressurization

The effects these functions have on the Level 2 accident sequences is described in the Level 2 Accident Sequence Analysis because their impact on radionuclide release and retention is sequence- specific.

### *Containment Performance*

The following containment failure modes are considered in the Level 2 PSA:

- Overpressure
- Failure of containment isolation
- Basemat melt-through
- Hydrogen deflagration
- Venting
- Steam explosion
- Containment bypass
- Direct containment heating

### *Containment Overpressure*

No detailed ultimate containment performance assessment is available at this stage in the BWRX-300 design. However, the containment failure pressure is assumed to be 1.5 MPa (210 psig) for this evaluation. If the containment vent fails to operate, then the containment is assumed to fail.

Fail-to-scram sequences result in severe dynamic forces inside containment during RPV failure that result in gross containment failure.

### *Containment Isolation/Bypass*

Each core damage scenario requires containment isolation. For core damage scenarios resulting from breaks outside containment (e.g., breaks in the main steam lines outside containment), that the core damage event results in a simultaneous large release due to the inability to isolate containment.

### *Basemat Melt-Through*

BWRX-300 is equipped with a corium shield that covers the basemat. This corium shield prevents MCCI. However, for the corium shield to function, the downward heat flux between the ex-vessel debris bed must be limited by overlying water pool. If debris is not covered with water, then the limited upward heat flux and steaming results in failure to quench the molten debris pool and results in a containment basemat melt-through.

### *Hydrogen Deflagration*

During the SA progression, cladding oxidation results in significant hydrogen generation. If the accident occurs when containment is not inerted (e.g., purging nitrogen from containment prior to a refueling outage), then it is assumed that the hydrogen will ignite, and the dynamic forces result in containment failure.

### *Containment Venting*

In scenarios where the containment pressure is increases beyond the design pressure, the containment vent is initiated. The vent is equipped with a filter. Failure to vent when required is results in containment overpressure.

### *Direct Containment Heating*

Direct containment heating occurs in a SA if the RPV fails while at high pressure. The resultant failure is accompanied by fragmentation of debris and entrainment in any effluent post-RPV

rupture. The increased surface area of the debris results in rapid heat-up and pressurization of containment that leads to gross containment failure.

### *Steam Explosion*

If an unquenched molten pool of corium comes into contact with a pool of water, the potential exists for there to be a rapid boiling event, further fragmenting the corium, increasing the heat transfer surface between debris and water. The fragmentation and entrainment of corium and rapid boiling and expansion of steam and water is a steam explosion. The dynamic effects of this event result in gross containment failure. The likelihood of this event to occur due to reflooding in-vessel is judged to be very small. The likelihood of the event to occur due to vessel failure and debris entry into an underlying pool of water is small, but more likely than in-vessel. While the dynamics of lower head failure are uncertain, it is likely that low pressure vessel failure results in fractional corium relocation to the underlying pool rather than a total “dump” of the entire corium pool. By limiting the amount of corium that relocates to the lower pool at one time, the potential for steam explosions is reduced.

This section describes the Level 2 accident sequences for each CET.

### **Class I/I-L**

Core damage sequences that occur with the RPV at low pressure and that nominally have containment intact are Class I. There are core damage sequences that occur in Class I core damage sequences that occur “late”. As a result a CET is developed for both “early” and “late” Class I core damage. The node descriptions in this section apply to the “early” Class I core damage scenarios. Late core damage sequences have the same general progression, but any early release categories are changed to late releases for late core damage events.

### **Class II**

The containment isolation function is reassigned to the Level 2 CETs and given the definition of Class II core damage (core damage resulting from containment failure due to overpressure). In the BWR operating fleet, Class II core damage may result from injection without containment decay heat removal. The resultant overpressure of containment leads to failure and loss of the injection source due to loss of net positive suction head (NPSH), adverse equipment environments, and disruption of injection lines. Core cooling is provided by ICS, and no separate containment heat removal method is required. If core cooling is provided by CRD, then there must be a letdown path outside containment established to remove inventory heated in the RPV. So, failure of decay heat removal results in core damage due to core cooling failures before containment failure for evaluated sequences in the BWRX-300 PSA.

### **Class III/III-L**

Core damage sequences that occur with the RPV at high pressure and that nominally have containment intact are Class III. There are core damage sequences that occur with Class III that occur “late”, and as a result, CET is developed for both “early” and “late” Class III core damage. The node descriptions in this section apply to the “early” Class III core damage scenarios. Late core damage sequences have the same general progression, but early release categories are changed to late releases for late core damage events.

### **Class IV**

Class IV core damage scenarios are failure to scram scenarios. If core damage occurs from failure to scram scenarios, SA progression results in more severe RPV and containment conditions than those scenarios with successful negative reactivity insertion. Generally, a core damage scenario for failure to scram in a BWRX-300 is expected to have core damage occurring

at elevated RPV pressure or pre-core damage energetic RPV failure due to overpressure/overpower. The containment loading resulting from these scenarios is expected to exceed the containment capacity and gross failure of containment is expected to occur.

### **Class V**

Class V sequences are those with an initial bypass of containment. This containment bypass provides a radionuclide release path, so any Class V sequences result in large early releases.

### **Class VR**

The VR core damage sequences involve excessive LOCAs in the mid and lower vessel regions and successful operation of the containment vent, but due to the size and location of the breaks core damage cannot be prevented.

#### **15.6.1.11.1 Source Term Analysis**

Two releases are of special interest in the source term analysis: small and large releases. Small and large releases are defined in CNSC REGDOC-2.5.2 (Reference 15.6-9). Small releases are considered those that release more than  $10^{15}$  Bq of Iodine-131 to the environment. Large releases are those that release more than  $10^{14}$  Bq of Cesium-137 to the environment. Sequences that meet the criteria for both small and large releases are counted as large releases, rather than both. Source terms are determined using MAAP. Release calculations are performed in MAAP for representative sequences. Release categories are then assigned to those without specific MAAP runs based on the calculations performed. This approach ensures that significant scenarios with realistic release categories are described in detail in the Level 2 PSA.

MAAP generally plots radionuclide release as a fraction of total inventory for select "groups" of fission products. The groups of fission products are subdivided by molecular compound and individual isotopic transport is not specifically tracked. However, MAAP provides the requisite information to understand the fractional distribution of all isotopes of a given element across fission product groups. It is assumed that all isotopes of a given element behave identically for the purposes of group assignment and subsequent transport. For example, if 50% of element X is in Fission Product Group 1, and all of group 1 is released, then 50% of every isotope of X is released in group 1.

Refer to Chapter 3, Appendix 3E for additional discussion regarding the MAAP computer code.

#### **15.6.1.12 Model Integration and Quantification**

The Level 2 PSA model is integrated with the Level 1 PSA model. The Level 1 accident sequences are placed under "collector gates" that group core damage sequences into classes.

The Level 2 ETs are constructed with the entry branch name identical to the applicable Level 1 Core Damage class collector gate. Functional node branches are given names identical to those in the functional fault tree file. When the event trees are converted into fault tree logic (creating accident sequence logic) and merged with functional fault tree logic, an integrated, quantifiable fault tree is developed.

The fault tree is quantified using the following PSA model development codes (see Chapter 3, Appendix 3E):

- CAFTA
- PRA Quant

In addition, FTREX 1.8 is used as the quantification/cutset generation engine and SysImp is used to develop importance measures for systems, components, and HFEs.

Intact, small release, and large release frequencies are quantified at a truncation of 1E-15/yr. The cutsets are examined to ensure there was <5% top event frequency drop if the truncation limit are set to 1E-14/yr. This provides evidence that no risk-significant sequences were truncated.

## **15.6.2 Results of the Level 1 Probabilistic Safety Assessment**

### **15.6.2.1 Initiating Events**

The IEs were derived for internal events at-power and for low power shutdown states. The IEs are tabulated with descriptions and frequencies in Table 15.6-7 and Table 15.6-8.

### **15.6.2.2 Mitigating Systems Modeled**

The following front-line mitigating systems are modeled to mitigate the IEs. These mitigating systems or functions are:

- Shutdown Cooling (SDC)
- Isolation Condenser System (ICS)
- Containment Isolation (CI)
- Ultimate Pressure Relief
- Control Rod Insertion
- Boron Injection
- Control Rod Injection makeup
- Corium Shield
- Containment Venting

### **Level 1 Event Tree Endpoints**

The Level 1 PSA event tree end points end in one success or five core damage states. The five core damage states are described below.

Event sequences are qualitatively analyzed to determine which sequences lead to core damage end states. The core damage sequences are grouped together based upon the overall challenge to the containment barrier and defined as:

1. Containment state: intact or breached
2. RPV pressure

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

3. Energy deposition into containment
4. Containment bypass

The above considerations result in the following event tree end points:

1. OK: The core is successfully cooled, and the containment is intact. There is no core damage in these events.
2. CD I: The containment is intact when core damage occurs and the RPV is at low (or controlled) pressure.
3. CD II: The containment is breached, either due to overpressurization or venting, while the core is successfully cooled. Core damage results from failure of maintaining long-term heat removal.
4. CD III: The containment is intact when core damage occurs and there is high RPV pressure at the time of RPV failure.
5. CD IV: CD IV: Core damage results from an accident sequence with an initial failure of effective reactivity control (failure to scram due to failure of RPS, control rod binding, etc.). This has the potential to affect containment more severely than the CD I and CD III because more energy is deposited into containment prior to RPV failure. All CD IV end states could be treated as CD I or CD III (depending on the RPV pressure) without affecting the results of the containment analysis. This end state is retained in this scoping analysis to more readily allow for sensitivity analyses related to reactivity control.
6. CD V: The containment is bypassed at the time of core damage.
7. CD VR: Core damage occurs due to RPV ruptures in the lower or mid-vessel regions.

**Event Tree Transition – Level 1 to Level 2 PSA**

The core damage Level 2 PSA accident sequence analysis is:

1. Class 1/I-L  
Core damage sequences occur with the RPV at low pressure and nominally have containment intact are Class I. There are core damage sequences that occur with Class I that occur “late” and CET is developed for both “early” and “late” Class I core damage.
2. Class II  
Class II core damage (core damage resulting from containment failure due to overpressure). Class II core damage often results from injection without containment decay heat removal. The resultant overpressure of the containment leads to failure and loss of the injection due to loss of NPSH, adverse equipment environments, and disruption of injection lines similarly to the Level 1 PSA Core Damage Frequencies.
3. Class III/III-L  
Core damage sequences that occur with the RPV at high pressure and that nominally have containment intact are Class III. There are core damage sequences that occur with Class III that occur “late”, and a CET is developed for both “early” and “late” Class III core damage.

4. Class IV

Class IV core damage scenarios are failure to scram and failure to depressurize scenarios. If this core damage scenario occurs, SA progression results in more severe RPV and containment conditions than those scenarios with successful negative reactivity insertion. The containment loading resulting from these scenarios is expected to exceed the containment capacity and gross failure of the containment is expected to occur.

5. Class V

Class V sequences are those with core damage and an initial containment bypass. Containment bypass provides a radionuclide release path. Any Class V sequences result in large early releases.

6. Class VR

Core damage occurs due to RPV ruptures in the lower or mid-vessel regions, the containment vent functions.

### **Small Release Frequencies**

The SRFs for the Level 2 PSA are not reported, because achieving a small release without achieving large release is within a very tight release band. If a sequence becomes SRF, it is expected the SRF sequence deteriorates to LRF.

### **Large Release Frequencies**

The LRF for the Level 2 PSA At-Power, Shutdown and Low Power, seismic, fire, high wind and internal flood are listed Table 15.7.9-2.

### **15.6.3 Probabilistic Safety Assessment Insights and Applications**

The Darlington BWRX-300 PSA activities are ongoing as the design progresses from conceptual to detailed. The PSA scope includes:

- Level 1 PSA
  - Internal Events at-Power and Low Power Shutdown states
  - External Events at-Power and Low Power Shutdown states, (seismic fire, high wind, and flood)
- Level 2 PSA At-Power and Low Power and Shutdown

The CNSC REGDOC-2.4.2, Section 3 (Reference 15.6-1) objectives (a thru h) are:

- a. Provide a systematic analysis
- b. Demonstrate a balanced design that no particular feature or postulated IE makes a disproportionate contribution to overall risk
- c. Provide confidence of no cliff-edge effects
- d. Provide assessments of quantitative safety goals
- e. Provide site-specific assessments of external hazards
- f. Identify facility vulnerabilities and systems where design improvements or modifications to operational procedures could reduce probabilities of severe accidents or mitigate consequences

- g. Assess adequacy of emergency operating procedures
- h. Provide insights into severe accident management

The BWRX-300 PSA assesses the design to meet the CNSC REGDOC-2.4.2 (Reference 15.6-1) objectives. PSA objectives (a to f) are assessed at this stage of the design and objectives (g and h) are assessed once the detailed design and operational procedures are available.

Concern that small changes can lead to large differences in plant effects – i.e., cliff-edge effects are largely ameliorated by the demonstrated margin between plant risk metrics and the CNSC REGDOC-2.5.2 (Reference 15.6-9) safety goals. Within the PSA accident sequence and success criteria analysis, no cliff-edge effects were discovered where plant parameters approach critical thresholds where accident sequences are expected to follow a significantly more severe pathway. However, uncertainty in these analyses will be formally explored in more detail in future PSA work.

Tables 15.7.9-1 and 15.7.9-2 show that the PSA CDF and LRF results to date meet the CNSC safety goals.

CNSC REGDOC-1.1.2, Section 4.4.4 (Reference 15.6-8) states that hazards analyses be performed. As presented in this section, internal and external hazards are identified and screened for PSA. Natural external hazards and human-induced external and internal hazards are assessed. There is limited assessment of external and internal hazards interaction. A more detailed hazard combination assessment is performed commensurate with the design progress.

CNSC REGDOC-1.1.2, Section 4.4.5 (Reference 15.6-8) states that a PSA be included in the Licence to Construct application. The PSA identifies facility vulnerabilities. The PSA application should also:

1. Verify EOPs are adequate during commissioning and future operation
2. Provide insights into the Severe Accident Management (SAM) program
3. Describe how PSA is used during commissioning and future operation

Based on the PSA work to date, CNSC REGDOC-1.1.2, Section 4.4.5 (Reference 15.6-8) requirements are not met at this time because Operating Manuals, EOPs and SAM program are not defined. The PSA is updated when the design matures and operational documents including Operating Manuals, EOPs, and SAM program are developed.

PSA is further updated for the Operating Licence Application as the design is finalized and operational information matures.

#### **15.6.3.1 Summary**

The PSA CDF, SRF, and LRF results to date meet the CNSC safety goals.

Section 15.6 is a high-level summary of the Internal and External Event Hazard Screening, and Level 1 and Level 2 PSA status supporting the BWRX-300 PSAR.

The PSA scope:

1. Level 1 PSA Internal At-Power, Low Power Shutdown States
2. Level 1 PSA for external events includes a power seismic and high wind analysis
3. Level 2 PSA At-Power

The CNSC REGDOC-2.4.2, Section 3 (Reference 15.6-1) objectives are reviewed and six of the eight objectives of CNSC REGDOC-2.4.2 (Reference 15.6-1) are met. Two other objectives (adequacy of EOPs and insights on SAM) are not assessed because the plant design is conceptual and the EOP procedures and SAM program are prepared as the design is finalized.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

CNSC REGDOC-1.1.2, Section 4.4.4 (Reference 15.6-8) requires a hazard analysis. Internal and external hazards are identified and screened. Natural external hazards, human-induced external and internal hazards are assessed.

CNSC REGDOC-1.1.2, Section 4.4.5 (Reference 15.6-8) states a PSA is conducted as required by CNSC REGDOC-2.4.2 (Reference 15.6-1) and includes:

1. Verification that EOPs are adequate during commissioning and future activities
2. Provide insights into severe accident management program
3. Describe how PSA is used during commissioning and future operation to identify design improvements, modifications to operational procedures to reduce probabilities of severe accidents and mitigate consequences.

CNSC REGDOC-1.1.2, Section 4.4.5 (Reference 15.6-8) requirements are addressed after Operating Manuals, EOPs and SAM programs are defined, and the PSA is updated.

The PSA CDF, SRF, and LRF results “to date” indicate that the CNSC safety goals are met.

The SRF is not reported, because achieving a small release without achieving large release would be within a very tight release band. If a sequence becomes SRF, it is expected the SRF sequence deteriorates to an LRF. The LRF requirement is more restrictive than SRF. Therefore, SRF is conservatively grouped with LRF.

The CDF, Small Release Frequency, and LRF results meet the CNSC safety goals as shown in Tables 15.7.9-1 and 15.7.9-2.

<b>Hazard</b>	<b>Screening Criterion (Refer to Subsection 15.6.1.2)</b>
Heavy Load Drop	Not screened qualitatively
Release of Chemicals from On-Site Storage	1
Turbine-Generated Missiles	Not screened qualitatively
Other Internally-Generated Missiles	1, 2
Fires	Not screened qualitatively. Covered by BWRX-300 Internal Fire Scoping Evaluation
Explosions	Not screened qualitatively. Covered by BWRX-300 Internal Fire Scoping Evaluation
Collapse of Structures	4, 5
Pipe Whips	4
Jet Effects	4
Internal Flooding	Not subject to screening

**Table 15.6-2: Internal Hazard Quantitative Screening Analysis**

<b>Hazard</b>	<b>Quantitative Screening Results</b>
Turbine-Generated Missiles	Screened from further PSA analysis
Internal Flooding	Covered by Internal Flooding PSA
Heavy Load Drop	Not screened out quantitatively

**Table 15.6-3: External Hazards Qualitatively Screened Out of the PSA**

Hazard Type	Screen Qualitatively
Individual Hazards	Extreme Snow, Extreme Hail, Mist, White Frost, Drought, Salt Storm, Sand Storm, Lightning, Explosion Outside Plant, Explosion after Pipeline Accident, Chemical Release Outside or Inside Site, Chemical Release after Transportation Accident, Chemical Release after Pipeline Accident, Magnetic Disturbance, Land Rise, Soil Frost, Animals, Volcanic Phenomena, Avalanche, Above-Water Landslide, External Fire, Excavation Work, Direct Impact from heavy transportation within Site, Missiles from military activity, Internal Fire Spreading from Other Plant, Contamination from Chemicals, Strong Water Current, Low Water Level, High Water Temperature, Low Water Temperature, Underwater Landslide, Surface Ice, Frazil Ice, Organic Material in Water, Corrosion from Salt Water, Solid or Fluid Impurities from Ship Release, Chemical Release to Water, Direct Impact from Ship Collision.
Co-Existent Hazards	High Air and Water Temperature; Low Air and Low Water Temperature; Extreme Rain and Lightning; Drought and Low Water Level; Drought and External Fire; Explosion Outside Plant and Chemical Release; Explosion after Transportation Accident and Chemical Release after Transportation Accident; Explosion after Pipeline Accident and Chemical Release after Pipeline Accident; Chemical Release and Contamination from Chemicals; Extreme Snow and Earthquake.

**Table 15.6-4: External Hazards Quantitative Assessment Summary**

Hazard	Initiating Event Frequency (/yr)	CCDP	CDF / LRF (/yr)	Quantitative Screening
Seismic	Ground motion bin frequencies are assigned by the seismic PSA based on the seismic hazard	This hazard is selected for PSA development	This hazard is selected for PSA development	This hazard is selected to proceed directly to detailed PSA
Internal Fire	Fire scenario frequencies are assigned by the fire PSA	This hazard is selected for PSA development	This hazard is selected for PSA development	This hazard is selected to proceed directly to detailed PSA
High Wind, including high wind hazard combinations: Strong Wind and Extreme Air Pressure; Strong Wind and Ice barriers; Tornadoes and Extreme hail; Wind-Driven Precipitation	Wind speed bin frequencies are assigned by the high wind PSA based on the straight wind and tornado hazards	This hazard is selected for PSA development	This hazard is selected for PSA development	This hazard is selected to proceed directly to detailed PSA
High Air Temperature	5.0E-2	3.1E-9	1.5E-10	CDF and LRF are below 1E-8 and 1E-9/yr, respectively. This hazard screens quantitatively.
Low Air Temperature	2.8E-3	3.1E-9	8.5E-12	CDF and LRF are below 1E-8 and 1E-9/yr, respectively. This hazard screens quantitatively.
Meteorite	5.3E-10	1.0E+0	5.3E-10	CDF and LRF are below 1E-8 and 1E-9/yr, respectively. This hazard screens quantitatively.
Explosion after Transportation Accident	3.0E-6	4.1E-7	1.2E-12	CDF and LRF are below 1E-8 and 1E-9/yr, respectively. This hazard screens quantitatively.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Hazard	Initiating Event Frequency (/yr)	CCDP	CDF / LRF (/yr)	Quantitative Screening
Satellite Crash	7.8E-8	4.1E-7	3.2E-14	CDF and LRF are below 1E-8 and 1E-9/yr, respectively. This hazard screens quantitatively.
Airplane crash	3.4E-12	1.0E+0	3.4E-12	CDF and LRF are below 1E-8 and 1E-9/yr, respectively. This hazard screens quantitatively.
High Water Level	1.0E-2	3.1E-9	3.1E-11	CDF and LRF are below 1E-8 and 1E-9/yr, respectively. This hazard screens quantitatively.

(1) The total contribution for quantitatively screened external hazards is also less than 5% of the total 1E-7/yr CDF and LRF assumed for the BWRX-300.

**Table 15.6-5: Generic List of Boiling Water Reactor Transient Initiating Events**

No.	Initiating Event
1	Electric load rejection
2	Electric load rejection with TBV failure
3	Turbine trip
4	Turbine trip with TBV failure
5	MSIV closure
6	Inadvertent closure of one MSIV
7	Partial MSIV closure
8	Loss of normal condenser vacuum
9	Pressure regulator fails open
10	Pressure regulator fails closed
11	Inadvertent opening of a safety/relief valve (stuck)
12	Turbine bypass fails open
13	Turbine bypass or control valves cause increased pressure (closed)
14	Recirculation control failure - increasing flow
15	Recirculation control failure - decreasing flow
16	Trip of one recirculation pump
17	Trip of all recirculation pumps
18	Abnormal start-up of idle recirculation pump
19	Recirculation pump seizure
20	Feedwater - increasing flow at-power
21	Loss of feed water heater
22	Loss of all feed water flow
23	Trip of one feed water pump (or condensate pump)
24	Feedwater - low flow
25	Low feedwater flow during start-up or shutdown
26	High feedwater flow during start-up or shutdown
27	Rod withdrawal at-power
28	High flux due to rod withdrawal at start-up
29	Inadvertent insertion of rod or rods
30	Detected fault in reactor protection system
31	Loss of offsite power
32	Loss of auxiliary power (loss of auxiliary transformer)

NEDO-33965 REVISION 0

No.	Initiating Event
33	Inadvertent start-up of Inadvertent start-up of High Pressure Core Injection System/ High Pressure Core Spray System
34	Scram due to plant occurrences
35	Spurious trip via instrumentation, RPS fault
36	Manual scram- no out-of-tolerance condition
37	Cause unknown

**Table 15.6-6: Level 1 PSA Damage Class Definitions**

<b>Class</b>	<b>Definition</b>
I	The containment is nominally intact when core damage occurs. Core damage occurs with the RPV at low/controlled pressure.
II	The containment is breached due to overpressurization or venting during the accident, but before core damage occurs. Core damage occurs due to failure of long-term decay heat removal post-containment failure.
III	The containment is nominally intact when core damage occurs. Core damage occurs with the RPV at high pressure.
IV	Failure to scram occurs with failure to insert sufficient negative reactivity prior to core damage.
V	Core damage occurs with the containment bypassed.
VR	Excessive LOCAs in mid and lower vessel regions and successful operation of containment vent but due to size and location of the breaks, core damage cannot be prevented.

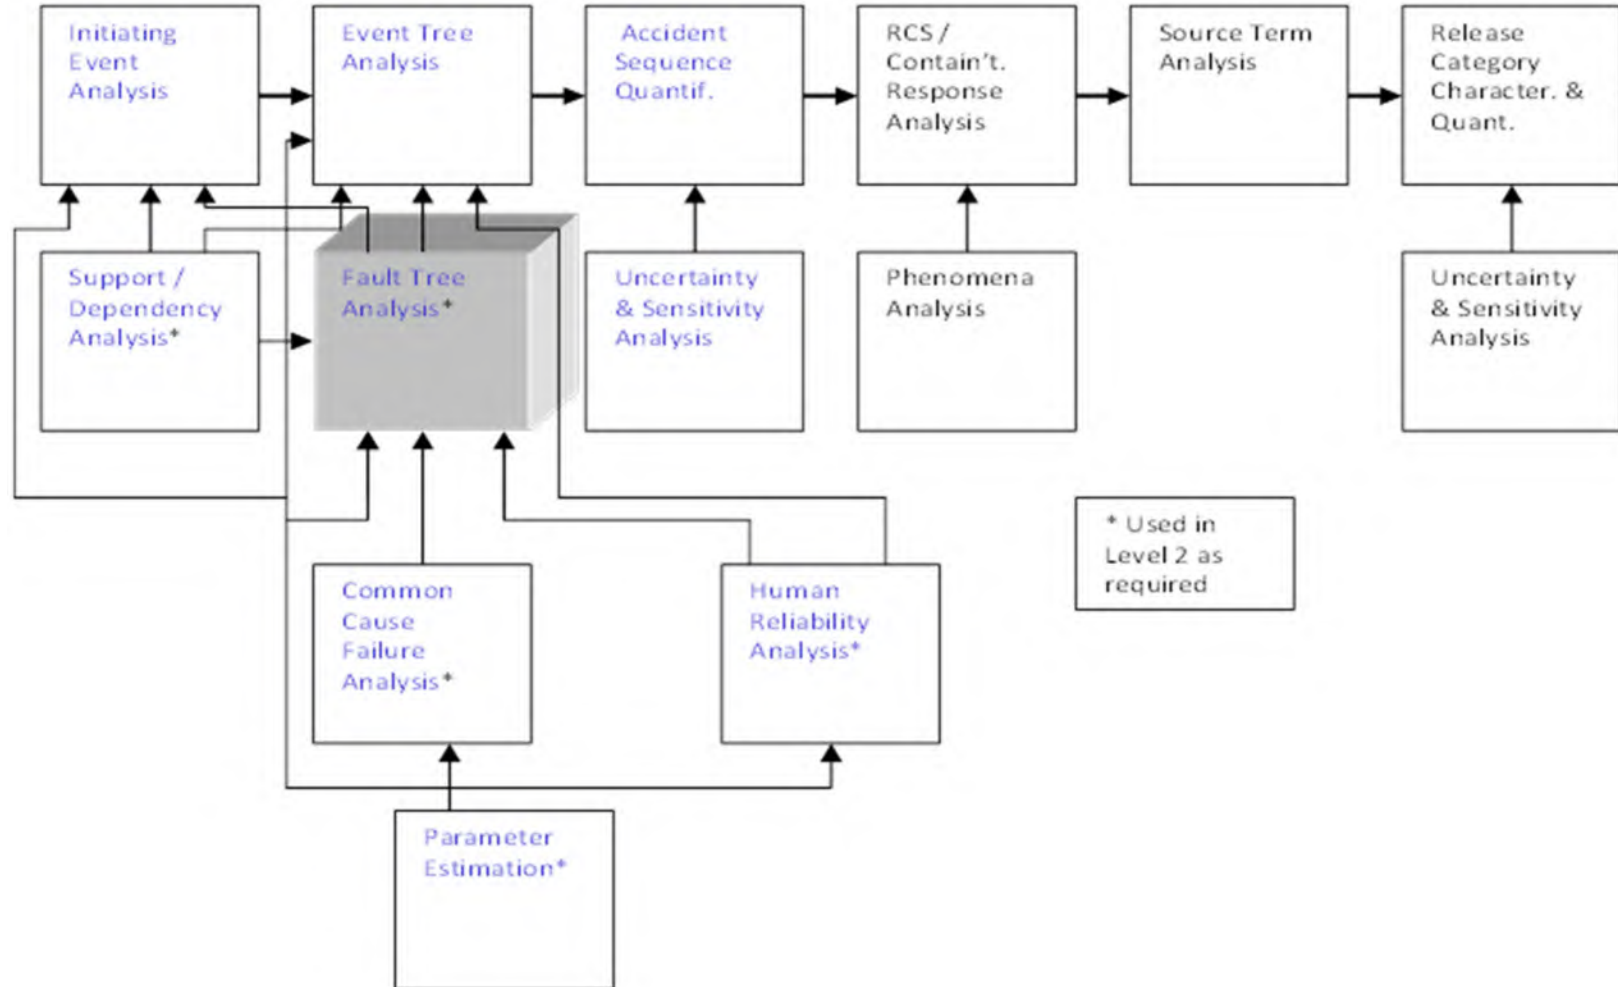

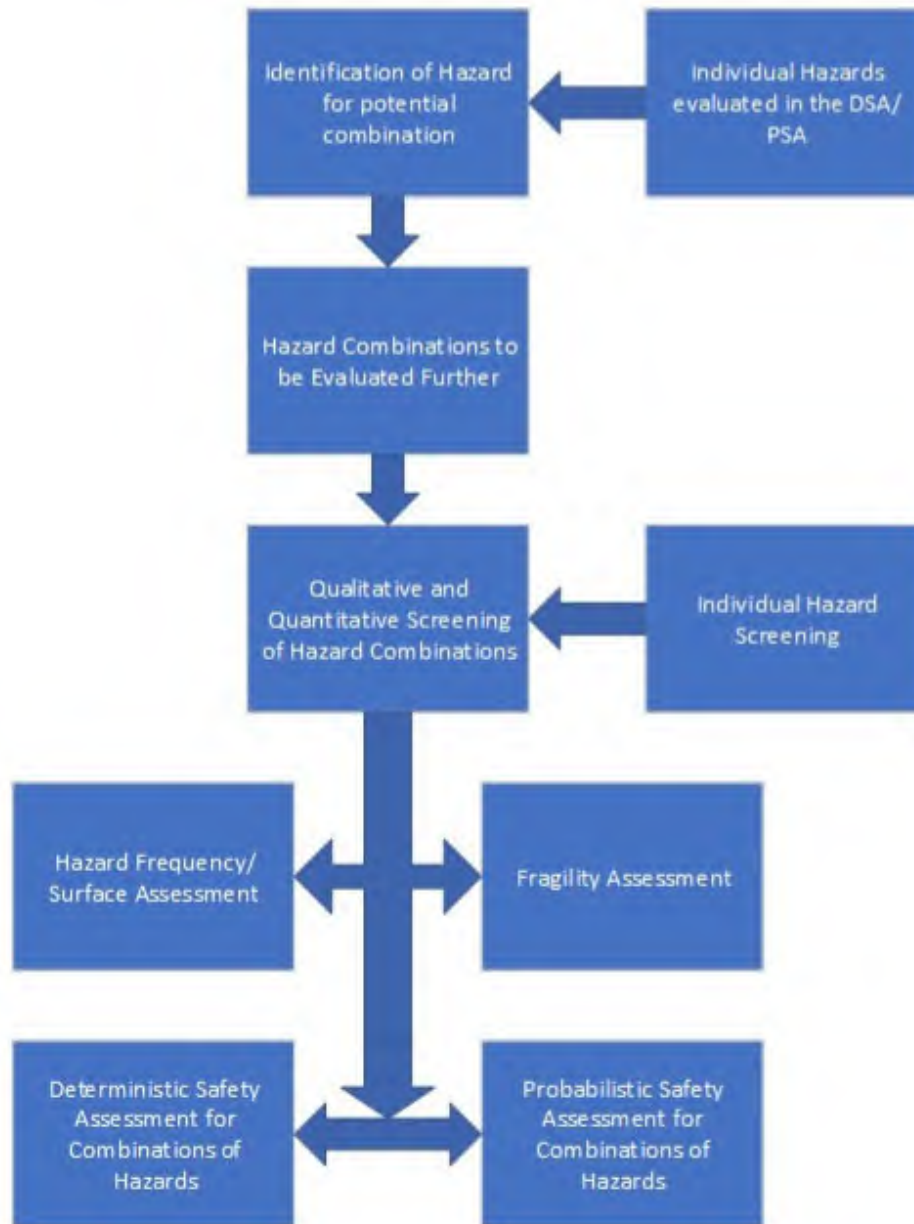

Figure 15.6-1: Principal Steps in Probabilistic Safety Assessment

**Figure 15.6-2: Overall Process for Selection, Screening and Analysis of Hazards**

## **15.7 Results of the Deterministic Safety Analyses and Probabilistic Safety Assessment**

The DSA results for the bounding BWRX-300 events meet acceptance criteria in Tables 15.3-2 and 15.3-3, respectively. Results Summary for the DSA is provided in the following tables:

Table 15.7.2-1	Results Summary of the AOO Safety Analyses
Table 15.7.3-1	Results Summary of DBA and DEC Events for Non-LOCA
Table 15.7.3-2	Results Summary of the Fuel Loading Error Event
Table 15.7.3-3	Results Summary of DBA and DEC Events for LOCA
Table 15.7.6-1	Fuel Handling Accident Dose Consequences
Table 15.7.7-1	BWRX-300 DNNP Main Steam Line Break Outside Containment – Accident Dose Consequences
Table 15.7.7-2	BWRX-300 DNNP Feedwater Line Break Outside Containment - Accident Dose Consequences
Table 15.7.7-3	BWRX-300 DNNP Isolation Condenser System Line Break Outside Containment – Accident Dose Consequences
Table 15.7.7-4	BWRX-300 DNNP Instrument Line Break Outside Containment Accident Dose Consequences

The results for the beyond design basis events evaluated in the PSA are provided in Table 15.7.9-1 “Comparison of PSA Results with CNSC REGDOC-2.5.2 Limits” indicate that the design does not exceed the safety goals in Table 15.3-3.

Implementation of the D-in-D concept ensures multiple, independent layers of protection against unacceptable radiation releases. None of the bounding AOOs, DBAs or DEC Events Without Core Damage analyzed approach the regulatory limits for radioactive releases.

### **15.7.1 Results of Analysis of Normal Operation**

The analysis of normal operations for stability is described in Chapter 4, Section 4.8 and Section 15.5.2.4. Subsection 15.5.2 describes the normal operations DSA. The OLC (Chapter 16) provides the operating limits and parameters ensuring the plant is operating within the design basis.

### **15.7.2 Results of Analysis of Anticipated Operational Occurrences**

The analysis of AOOs is described in Subsection 15.5.3. The resulting maximum neutron flux, dome pressure, RPV bottom pressure, simulated thermal power, and  $\Delta$ CPR/ICPR for AOOs is provided in Table 15.7.2-1.

### **15.7.3 Results of Analysis of Design Basis Accidents**

The analysis of DBAs is described in Subsection 15.5.4. The summary results of maximum neutron flux, maximum dome pressure, maximum RPV bottom pressure, maximum simulated thermal power (%NBR), and peak clad temperature from non-LOCA DBAs are provided in Table 15.7.3-1. The LOCA DBA summary results for peak cladding temperature, peak containment pressure, and peak containment shell temperature are provided in Table 15.7.3-3.

### **15.7.4 Results of Analysis of Design Extension Conditions Without Core Damage**

The analysis description of DEC events without core melting is described in Section 15.5.5. The summary results of maximum neutron flux, maximum dome pressure, maximum RPV bottom

pressure, maximum simulated thermal power, and peak clad temperature from non-LOCA DEC are provided in Table 15.7.3-1.

The LOCA DEC summary results for peak cladding temperature, peak containment pressure, and peak containment shell temperature are provided in Table 15.7.3-3. The summary results of a fuel loading error event DEC are provided in Table 15.7.3-2.

#### **15.7.5 Results of Analysis of Design Extension Conditions with Core Damage**

The analysis description of those DEC events associated with core damage are described in Section 15.6.3 Level 2 PSA.

#### **15.7.6 Results of Analysis of Postulated Initiating Events and Accident Scenarios Associated with the Fuel Pool**

The analysis description of those postulated events and accident scenarios associated with the fuel pool are described in Subsection 15.5.7.

#### **15.7.7 Results of Analysis of Fuel Handling Events**

The analysis of FHA is described in Subsection 15.5.8. The resultant dose consequences from an FHA is provided in Table 15.7.6-1.

#### **15.7.8 Results of Analysis of Radioactive Releases from a Subsystem or a Component**

The analysis description of the liquid and gaseous radioactive waste system process scenario releases from a postulated liquid tank failure or off-gas system failure are described in Chapter 11, Subsections 11.2.9, and 11.3.14, respectively. The off-gas system failure results are provided in Table 11.3-4 and meet the CNSC allowable limits.

#### **15.7.9 Results of Analysis of LOCA Breaks Outside Containment**

LOCA from pipe breaks outside containment described in Subsection 15.5.9.2 result in normal coolant concentration releases that are within allowable limits.

##### **15.7.9.1 Results of Main Steam Line Break Outside Containment**

The analysis of a MSL break outside containment is described in Subsection 15.5.9.2.1 and the results are provided in Table 15.7.7-1.

##### **15.7.9.2 Results of Large Feedwater Pipe Break Outside Containment**

The analysis of a large feedwater pipe break outside containment is described in Subsection 15.5.9.2.2, and the results are provided in Table 15.7.7-2.

##### **15.7.9.3 Results of Large Isolation Condenser Pipe Break Outside Containment**

The analysis of a large ICS pipe breaks outside containment is described in Subsection 15.5.9.2.3 and the results are provided in Table 15.7.7-3.

##### **15.7.9.4 Results of Small Breaks Outside Containment**

The analysis of a small pipe break outside containment is described in Subsection 15.5.9.2.4 and the results are provided in Table 15.7.7-4.

#### **15.7.10 Results of Analysis of Internal and External Hazards**

The description of internal and external hazards and associated design basis SSCs mitigating these hazards are described in Section 15.5.10 for the DSA.

#### **15.7.11 Results of Probabilistic Safety Analysis**

The Level 1 and Level 2 PSA are described in Subsection 15.6.2. The general PSA approach and the insights and applications are described in Subsections 15.6.1 and 15.6.3. The comparison of PSA results with CNSC REGDOC-2.5.2 acceptance criteria is shown in Table 15.7.9-1.

NON-PROPRIETARY INFORMATION

**Table 15.7.9-2: Large Release Frequency Results**

Level 2 PSA Scope	Large Release Frequency (LRF) Events per Year <sup>Note 1</sup>	Comment
Internal Events At Power	1.8E-09	LRF consists of large early and large late release frequency. SRF is not reported because a small release is conservatively assumed to progress into a large release.
Internal Events Low Power & Shutdown	7.0E-10	LRF is same as CDF because containment is conservatively assumed open during low power and shutdown.
Seismic Events	4.8E-08	With seismic hazard truncation.
Fire Events	1.3E-8	LRF is conservatively assumed the same as CDF. CDF is 1.3E-08/yr.
High Wind	4.3E-09/yr. for straight wind 1.3E-10/yr. for tornado	LRF is conservatively assumed the same as CDF.
Internal Flood	5.5E-10	
Fuel and Heavy Load Movements	5.7E-09	
Fuel Pool Events	1.3E-8	

(1) CNSC REGDOC-2.5.2 LRF is 1E-06.

## **Appendix 15A. Reference Source Term for Conditions That Are Practically Eliminated**

A radiological and combustible gas accident reference source term based on a set of representative core damage conditions is established for use in specifying design attributes and/or complementary design features for DECAs as required by Section 7.3.4 of CNSC REGDOC-2.5.2.

### **15A.1 Safety Objectives**

The safety objectives are consistent with CNSC REGDOC-2.5.2, Section 7.3.4 (Chapter 3, Reference 3.1-1) and IAEA SSR-2/1 (Chapter 3, Reference 3.1-5). The BWRX-300 design fault sequences that could lead to early or large radioactive releases are practically eliminated.

### **15A.2 Acceptance Criteria**

Fault sequences with early or large releases are practically eliminated if either of the following criteria are met:

1. It is physically impossible for the relevant fault sequences to occur
2. There is a high level of confidence that these fault sequences are extremely unlikely

### **15A.3 Approach**

Consistent with Chapter 3, Section 3.1.8, the identification of DECAs is commenced early in the design process, with iterations between design activities, DSA, and PSA with an increase in scope and level of detail as the design progresses.

As part of the overall strategy for addressing challenges, plant conditions, and for restoring and maintaining FSFs, the roles of each complementary design feature and other design attributes are defined. The objective is demonstrating that these complementary design features design attributes are reasonably expected to practically eliminate significant radioactive releases for DECAs.

Each complementary design feature or plant attribute is defined as part of the overall plant strategy for addressing challenges, plant conditions, and for restoring and maintaining the FSFs. The objective is demonstrating that the planned operation of these complementary design features or design attributes is reasonably expected to practically eliminate significant radioactive releases for DECAs:

1. The physical conditions, processes, and phenomena associated with the accident progression.
2. Risk significant severe accident scenarios involving hazards selected for analysis.
3. Bounding fault sequences and DSA considered in the plant design envelope and associated attributes.

The outcome is a set of conditions that are considered in the design of corresponding complementary design safety features or design attributes for DECAs and represent a set of bounding conditions that envelope other accidents.

DECAs selected are justified based on engineering judgement, DSA results and insights from the PSA. In addition, the practical elimination concept reinforces D-in-D by providing a focused evaluation of those conditions having the potential for early radioactive release or a large radioactive release.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The initial DEC selection of is based on predecessor BWR reactor research and OPEX for the purpose of framing the conceptual design. A more rigorous selection is achieved with iterations between design activities, DSA, and PSA with an increase in scope and level of detail as the design progresses. The reference source terms for the selected conditions are used to develop and confirm the complementary design features or design attributes

If the accident sequence is practically eliminated as a result of a single initiating event such as the failure of the RPV in all operational states, the demonstration relies on achieving a high level of quality at all stages of the component lifetime.

A condition is practically eliminated by considering:

- DL features consisting of equipment and supporting operational organizational provisions (e.g., SAMGs). Certain equipment types may receive increased DL1 design provisions such as providing highly reliable components that are shown not to fail as part of the DSA.
- DL strength – adequate margins, reliability, and qualification against all operating conditions
- DL independence – redundancy physical separation, diversity, and functionality

#### **15A.4 Practically Eliminated Events**

For the conceptual design, practical elimination considerations are essential in framing conditions where complementary design features or design attributes are used with the accompanying rationale for selecting DEC's that comprise the reference source term.

The following practically eliminated conditions and provisions achieving practical elimination in Table 15A-1 are based on deterministic and probabilistic methods, operational experience, engineering judgement, and the results of research and analysis.

**Table 15A-1: Practically Eliminated Conditions**

<b>Practically Eliminated Conditions</b>	<b>Provisions to Achieve Practical Elimination Complimentary Design Features / Design and Supporting Operating Provisions</b>
A sudden mechanical failure of the RPV that eliminates the capability to hold and cool the core.	<p>DL1 provisions for a strong reactor coolant pressure boundary for all states within the plant design envelope without relying on subsequent DLs, including DEC. The following selection of RPV materials and operational uses throughout the plant lifetime provides greater confidence that the likelihood of sudden RPV failure is extremely unlikely:</p> <ul style="list-style-type: none"> <li>• Material fracture toughness</li> <li>• Tensile properties</li> <li>• Defect free fabrication</li> <li>• Defect tolerance</li> <li>• Structural integrity</li> <li>• Operational limits for all operational conditions (normal, AOOs, DBAs)</li> <li>• Loading conditions</li> <li>• Highest reliability and quality according to ASME BPVC</li> </ul>
A sudden mechanical failure of the RIVs that results in catastrophic failure creating significant early or late containment challenges.	<p>DL1 requirements for the highest reliability and quality according to ASME BPVC Code Class 1 components provides greater confidence that the likelihood of sudden mechanical failure of the RIVs (part of the RCPB) throughout the plant lifetime is extremely unlikely.</p> <p>These requirements provide assurance that the quality, materials of construction, fabrication, installation, testing, examination, repair/replacement, and ongoing inspection, testing, and monitoring are commensurate with the RIV FSF.</p> <p>DL1 design provisions for nozzle elevations significantly above the core, and passive isolation condenser cooling minimize the likelihood of substantial core damage in the event of a coolant loss from RIV failure.</p>
A severe and unlikely condition where more than 50% of the control rods fail to insert leading to an accident with increasing severity that challenges the reactor and containment system is practically eliminated.	<p>The design offers D-in-D with diverse and redundant shutdown systems making multiple sequential failures extremely unlikely. However, conservatively, the design includes complementary design features that provides a diverse means limiting increases in the reactor vessel pressure in the extremely unlikely condition where more than 50% of the control rods fail to insert.</p> <p>DL4a complementary design feature diverse protection system actuation logic that is diverse and independent from the DL3 SC1 I&amp;C System actuation logic that provides greater confidence that the condition is extremely unlikely.</p> <p>DL4a complementary design feature of the FMCRD run-in function provides greater confidence that the condition is extremely unlikely.</p>

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Practically Eliminated Conditions	Provisions to Achieve Practical Elimination Complimentary Design Features / Design and Supporting Operating Provisions
	<p>DL4a complementary design feature of alternate control rod insertion ensures the hydraulic control unit scram pressure is released to the FMCRDs even in the unlikely event of the solenoid pilot valves failing to scram. This provides greater confidence that the condition is extremely unlikely.</p> <p>DL4b ultimate pressure regulation complementary design feature provides a diverse means to limit increases in reactor vessel pressure for this extremely unlikely condition, thus making failure propagation from the reactor pressure vessel to the containment extremely unlikely.</p> <p>DL4b BIS (see Appendix 15B.2) complementary design feature provides a means to place the plant in a stable controlled configuration if control rods fail to insert.</p>
<p>A single control rod falling out of the core and inserting enough positive reactivity to cause a calculated fuel enthalpy rise greater than the lower bound clad failure limits.</p>	<p>DL1 design provision that the control blades include a bayonet style coupling design provision that requires a 45-degree rotation to uncouple, thus making it physically impossible for the control rod blade to become uncoupled from the drive during reactor operation.</p> <p>DL2 dual separation detection devices that sense if the hollow piston is no longer on the ball nut block control rod withdrawal and do not allow a separation distance to occur between the FMCRD and the control rod, or from the ball nut to an unlatched hollow piston. This essentially limits possible separation such that it is not physically possible for a control rod drop accident involving a single control rod falling completely out of the core to occur.</p> <p>Chapter 4, Section 4.5 discusses these design provisions for the FMCRD and the control rods.</p>

Practically Eliminated Conditions	Provisions to Achieve Practical Elimination Complimentary Design Features / Design and Supporting Operating Provisions
<p>Containment heating following a postulated RPV failure does not occur.</p> <p>This chain of events is called a high pressure melt ejection and these four mechanisms may cause a rapid increase in containment pressure and temperature:</p> <ol style="list-style-type: none"> <li>1. Blowdown of the reactor pressure vessel</li> <li>2. Efficient debris-to-gas heat transfer</li> <li>3. Exothermic metal/steam and metal/oxygen reactions</li> <li>4. Hydrogen combustion</li> </ol> <p>These mechanisms lead to increased loads on the containment building that are collectively referred to as direct containment heating.</p>	<p>DL1 design reduces the likelihood of being at a high pressure at the time of vessel failure is eliminated by the large inventory of coolant in the RPV. Core cooling challenges are only possible when corresponding RPV depressurization occurs. With adequate control rod insertion, RPV depressurization is eliminated by the DL3 passive ICS and the DL3 RIV isolation or diverse DL4a RIV isolation.</p> <p>DL4a ICS actuation provides greater confidence that RPV failure occurring at high pressure is extremely unlikely.</p> <p>DL4b RPV ultimate pressure regulation complementary design feature provides a diverse means to limit RPV pressure increases ensuring that there are no credible core damage accident sequences without cooling when the reactor is pressurized, making direct containment heating following a postulated vessel failure highly unlikely with a high degree of confidence.</p> <p>DL4b complementary design feature is the containment ultimate overpressure vent that ensures containment does not overpressurize when RPV ultimate pressure regulation is actuated.</p>
<p>Containment challenges from large steam explosions do not occur.</p> <p>Molten core debris interacting with water can produce explosive interactions as well as non-explosive, dynamic interactions from mutual fragmentation and mixing of the core material and water.</p>	<p>RPV pressure is sufficiently high to suppress explosive conditions where anticipated thermal interactions are dynamic but not explosive.</p> <p>DL1 design provides a strong containment structure and components and sufficiently large containment volume making containment load challenges from large steam explosions physically impossible.</p> <p>DL1 design and operating physical limitations (e.g., no subcooled water pool) associated with explosive interactions preventing containment challenges.</p>
<p>Containment integrity challenges from combustible gas detonation does not occur.</p>	<p>DL1 design provision for an inert containment atmosphere and combustible gas management operating provisions limit concentrations well below detonation levels. This makes containment challenges due to combustible gas detonation physically impossible.</p> <p>DL4b combustible gas mitigation devices (e.g., passive mixing and venting, passive autocatalytic recombiners) are strategically located above the containment head in the vicinity of the pools. This provides greater confidence that any combustible gas leakage from containment does not result in damage to SSCs required for safety.</p>

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Practically Eliminated Conditions	Provisions to Achieve Practical Elimination Complimentary Design Features / Design and Supporting Operating Provisions
Containment failure because of molten core concrete interaction.	If the RPV fails, a DL1 design provision for a corium shield/liner confines and prevents contact between the molten core and the containment liner. The corium shield/liner spreading area is cooled by the over-lying water. Steam is released through the hardened vent preventing containment failure.
Containment failure by quasi-static overpressurization from a long-term loss of containment heat removal (SA with unsuccessful containment isolation and passive containment heat removal).	DL4b complementary design feature of a containment vent and operating provisions make containment failure by quasi-static overpressurization from a long-term loss of containment heat removal physically impossible.
An interfacing system LOCA outside containment.	DL1 design provisions ensures subsystems connected to the RCPB are designed to an ultimate rupture strength at least equal to the reactor coolant system design pressure make an interfacing system LOCA physically impossible.
Containment bypass consequential to SA progression. SA fault sequences leading to or involving RIV leakage and core damage.	DL1 RIV design includes ball valves with hydraulic actuators. Design, qualification, and valve procurement ensures the important FSF of RPV isolation occurs.  DL1 design and operating provisions for a strong RCPB for all states within the plant design envelope are the highest reliability and quality complying with ASME BPVC. The mechanical failure likelihood of the RIV internals throughout the plant lifetime due to SA conditions is extremely unlikely.
A SA with an open containment (plant in shutdown state). SA events during shutdown involve loss of fuel pool cooling sequences or LOCAs leading to drain-down.	DL1 design provisions of a large inventory of available water and operating provisions with slow developing fault sequences provide ample time for several diverse means of providing makeup water and preventing fuel being uncovered in the fuel pool or the reactor core. These design features provide greater confidence that the likelihood of SA with an open containment is extremely unlikely.
Fuel coolant interaction (in-vessel steam explosion).	DL1 design provisions of a passive ICS (ECCS system) with a large water inventory with inherent margins eliminates system challenges leading to loss of adequate core cooling. This provides confidence that the likelihood of an in-vessel steam explosion from loss of core cooling is extremely unlikely.

NON-PROPRIETARY INFORMATION

Practically Eliminated Conditions	Provisions to Achieve Practical Elimination Complimentary Design Features / Design and Supporting Operating Provisions
A high pressure melt ejection with potential for debris dispersion such that debris is not retained in lower containment.	<p>DL4b ultimate pressure regulation complementary design feature provides a diverse means to limit the increase in reactor vessel pressure ensuring that there are no credible core damaging accident sequences without cooling while the reactor is also at high pressure, making containment failure from high pressure melt ejection physically impossible</p> <p>DL4b complementary design feature of a containment vent and operating provisions make containment failure by quasi-static overpressurization from a high pressure melt ejection physically impossible.</p> <p>DL1 design provision for a corium shield/liner supported by operating provisions confine and prevent the spread of a molten core, making containment failure from molten core concrete interaction physically impossible.</p>
An out of core criticality event during fuel handling.	<p>DL1 design provisions and supporting operating provisions provide design and administrative controls that effectively manage factors that influence system reactivity and the likelihood of criticality. These factors are enrichment, mass, moderation, geometry, reflection, interaction, and spacing.</p> <p>Plant procedures prohibit the handling and storage of more than one fuel assembly. The amount of water moderator available from internal flooding is limited by the design of the storage location structures thus making an out of core criticality physically impossible. Refer to Section 15.5.9.3 for the BWRX-300 Out of Core Criticality Analysis.</p>

## **Appendix 15B. Complementary Design Features for Mitigating Design Extension Conditions**

Consistent with CNSC REGDOC-2.5.2, Section 6.1, “Application of a D-in-D,” and Section 6.3 “Accident prevention and plant safety characteristics,” complementary design features are used to prevent accident progression or mitigate the consequences of DEC. In accordance with the BWRX-300 Safety Strategy, complementary design features are identified that address plant challenges, conditions that require restoration, and maintaining the FSFs. These complementary design features can be reasonably expected to practically eliminate or mitigate significant radioactive releases for DEC. Practical elimination of DEC is discussed in the previous Appendix 15A. There are several complementary design features provided ensuring that DEC are either practically eliminated or extremely unlikely to occur. Complementary design features mitigating functions are provided in Table 15B-2.

Most complementary design features are component features such as vents and catalytic recombiners. However, the boron injection system described in the following section is a complete system used in inserting negative reactivity in the core in the highly improbable event where shutdown using CRDs via hydraulic or motor run-in cannot be accomplished.

### **15B.1 Boron Injection System**

The Boron Injection System (BIS) provides a separate, diverse means, D-in-D backup system to for manually inserting negative reactivity into the reactor core. The BIS assures reactor shutdown by mixing a neutron absorber with the primary coolant.

The BIS is only required in the highly improbable event when shutdown using CRDs via hydraulic or motor run-in cannot be accomplished. The system introduces sufficient negative reactivity into the reactor primary system assuring reactor shutdown to a subcritical state with no control rod motion.

Injection of a neutron absorber solution for reactivity control is a DL4b, Safety Category 3 function.

The system achieves cold shutdown conditions with a predetermined mass of water in the reactor vessel using an enriched Boron-10 solution injected into the reactor vessel. The CRD system and the BIS do not share any components.

#### **15B.1.1 Safety Design Bases**

The BIS provides a means of achieving cold subcriticality by mixing a neutron absorber with the primary coolant. This condition creates a design requirement for reactivity control from full power to cold 20°C (68°F) subcritical state using an enriched Boron-10 solution.

The ICS for overpressure control and CRD/HCU/FMCRD for reactivity control address failure-to-scrum impacts or other reactivity events where boron injection provides an additional layer of defence.

The neutron absorber injection is manually initiated by the operator from either the MCR or SCR.

The minimum amount of neutron absorber required to shut down the reactor is calculated based upon the minimum natural boron concentration required for shutdown and the weight of the water in the RPV at normal level including the shutdown cooling loops at cold shutdown conditions. This ensures that total quantity of stored neutron absorber is sufficient to achieve the minimum sodium pentaborate concentration required for shutdown.

The BIS is a complimentary design feature that provides D-in-D for long-term reactivity control DEC.

The BIS system is designated as Safety Class 3.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The BIS can be operated in the event of a LOPP but does not perform any non-safety or safety class functions during off-normal conditions.

The BIS injection line penetrates containment and is directly connected to the reactor vessel through the ICS. This portion of the BIS through the ICS system that requires containment isolation is part of the RCPB and is classified as DL3, Quality Group A, Safety Category 1, and Seismic Category 1-A and 1-B. The ICS equipment is Safety Class 1.

### **15B.1.2 System and Equipment Functions**

The BIS simplified flow diagram of the boron injection mode is shown on Figure 15B-2. The BIS consists of a storage tank, test tank, injection pump, piping, valves, and instrumentation and controls necessary to prepare and inject the neutron absorbing solution into the reactor and for system testing. The air-operated injection valve and the Class 1 injection piping are part of the BIS. The BIS consists of a single, 100% equipment train located in the RB outside containment, tying into an ICS return line between the redundant actuation valves and the RIVs.

The neutron absorber is pumped from the storage tank through the injection valves into the reactor vessel by remote manual operation of the pump, storage tank outlet valve, and injection valve.

The BIS injects the neutron absorber solution into the reactor core compensating for various reactivity effects that could occur during plant operation.

The neutron absorber is an aqueous solution of decahydrate ( $\text{Na}_2\text{B}_{10}\text{O}_{16} \cdot 10\text{H}_2\text{O}$ ). Enriched sodium pentaborate solution is made by mixing granular enriched sodium pentaborate with water. The neutron absorber design concentration has a 4.4°C solution precipitation temperature. This low precipitation temperature eliminates the need for storage tank heating during normal standby conditions or heat tracing the instrument lines and pump suction piping.

The volume versus concentration limits is calculated accounting for normal reactor vessel water volume and water volume in the shutdown cooling piping. This neutron absorber solution quantity is the amount above the pump suction shutoff level in the storage tank. No credit is taken for the portion of the storage tank volume that cannot be injected.

### **15B.1.3 Component Description**

The BIS is a single 100% capacity system that includes:

- A single triplex injection pump capable of 2.27 m<sup>3</sup>/hr (10 gpm) pumping against the maximum reactor pressure of 12.41 MPaG (1800 psig)
- A test tank and associated piping and valves
- An injection line with containment isolation valves
- A demineralized water connection
- A service air connection
- System piping drains and collection subsystem

All equipment is located outside primary containment allowing access for testing and inspection activities during all plant operating conditions.

Operation in the injection mode requires BIS pump start and opening the storage tank outlet valve and injection valves. The storage tank outlet valve and injection valve are air-operated. The air-operated valves open on a system initiation signal, and close [fail as-is] on loss or removal of the pressurized air source or close on a manual valve closure signal.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

The injection location is the condensate return line of the ICS "C" loop downstream of the two ICS condensate return valves, providing a direct flow path into the reactor. The injection location requires a separate containment penetration for the BIS injection line. Overpressure protection of the BIS is provided by a relief valve located on the pump discharge piping. To avoid water hammer at the onset of BIS injection, the piping is fully-filled by a connection with the demineralized water system.

The testing subsystem consists of a test tank containing demineralized water and the associated valves and piping in parallel with the normal suction flow path from the storage tank. During the non-testing phase of system normal operation, the testing network is isolated from the balance of the system by shutoff valves. Periodic operational tests of the BIS are conducted at any time regardless of the state of reactor operation. The testing subsystem demonstrates:

- Pumping demineralized water at rated pressure and flow to and from the test tank
- Pumping demineralized water from the test tank into the reactor vessel against existing reactor pressure (this test may only be performed during reactor shutdown) to ensure a functioning flow path

A tank zero level shutoff prevents damage to pump from insufficient suction. The storage tank, test tank, pump and interconnecting piping and valves are in the Reactor Building on the -8.5 m Level in Room 1551 that is nearest to the ICS connection line. There is a single containment penetration for the BIS injection line. The injection line connects with the ICS "C" return line downstream of the two condensate return valves providing a flow path into the reactor vessel.

#### **15B.1.4 Materials**

System piping meets ASME BPVC Section III, Subsection NC from the storage tank outlet connection up to the air-operated injection valve. The system piping from and including the air-operated injection valve (AOV) to the connection with the ICS is ASME B&PVC Section III, Subsection NB. Containment isolation is provided by a single check valve inside containment for immediate isolation and the check valve and AOV for long-term containment isolation. All system piping is either 304 or 316 stainless steel.

All equipment not required for injection, such as system drains, test equipment, and service air and demineralized water are classified as Quality Group D and designed to ASME B31.1 standard and are 304 or 316 stainless steel.

The BIS meets Seismic Class 1-A for the pump suction piping, pump discharge piping and injection piping up to the connection with the ICS. The AOVs and pump are Seismic Category 1-B. The test tank and test loop piping, demineralized water piping, service air piping, and system drains after the isolation valves are non-seismic.

The storage tank meets ASME B&PVC Section III, Subsection NC standards with 304 or 316 stainless steel and contains a hatch, heater system, sparger, and connections for an outlet, overflow, vent, service air and demineralized water inlet, and associated instrumentation.

The injection pump meets ASME B&PVC Section III, Subsection NC standards and is either 304 or 316 stainless steel for all wetted parts.

All equipment in the BIS in contact with neutron absorbing solution is stainless steel for corrosion protection.

#### **15B.1.5 Interfaces with Other Equipment and Systems**

System interfaces for the boron injection system are shown in Table 15B-2 and Figure 15B-1.

### **15B.1.6 System and Equipment Operation**

The BIS has four operating modes:

- Standby
- System Injection
- Pump Test
- System Injection Test Mode

BIS functions are required during power operation or reactor startup.

### **15B.1.7 Instrumentation and Control**

The BIS has the following instrument and control features:

1. High and low storage tank solution temperature annunciates in the control room at temperatures outside the allowed range
2. High and low storage tank solution level is annunciated in the control room when the level is outside its normal allowed limit
3. Low storage tank level automatically shuts off the injection pump when the solution level in the storage tank is below the zero level

Either the storage tank or test tank discharge valve must be fully open for the pump to run.

The following describes key instrumentation features of the BIS:

1. Storage tank solution is measured by a level transmitter. MCR level indication and high/low level alarms provided in the MCR HSI display.
2. Pump discharge pressure is sensed by a single pressure transmitter that provides MCR pressure indication through the HSI display
3. Storage tank solution temperature is sensed by a temperature element providing MCR storage tank solution temperature through the HSI display
4. Pump flow is sensed by a single flow element and flow transmitter with flow indication in the MCR
5. Pump status indication (energized status) provided in the MCR HSI display
6. System status indication and annunciators through the MCR HSI display for system bypass or inoperable condition
7. Valve position indication through the MCR HSI display for the storage tank outlet valve and test tank outlet valve
8. Pump overload trip or power loss indication provided through the MCR HSI display

A single pressure gauge is locally mounted for pressure indication during the pump test mode and is visible from the test loop control valve aiding control valve positioning.

### **Main Control Room Operation**

Manual initiation, operation, and control of the BIS is from the MCR through the HSI display. The means for manual actuation and for monitoring shutdown status from the MCR meets CNSC REGDOC-2.5.2, Section 8.4.3, addressing monitoring and operator action of shutdown systems.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

BIS actuation is dual-action initiation through the HSI display in the MCR that guards against accidental or inadvertent actuation of the system ensuring intentional system actuation.

Controls for the BIS are located through the HSI display in the MCR facilitating system operation. System and component operating status, including any system bypasses, system out of service, or manual overrides is provided. Manual system initiation and shutdown is provided.

The following BIS displays, alarms and controls are provided in the MCR HSI display:

**System Annunciators**

- High and low alarms for storage tank solution temperature
- High and low alarms for storage tank solution level
- Manual or automatic system out-of-service condition

**System Indication**

- Storage tank solution level
- Pump discharge pressure
- Pump operation (on/off)
- Storage tank and test tank outlet valves position (open/closed)
- Storage tank solution temperature
- System manually out of service
- Pump overload trip or power loss
- Pump flow rate

**Local Panel Operation**

A local panel is provided for the following:

**Controls:**

- Heater controls

**Indications:**

- Status indications for the mixing heater
- Storage tank solution temperature
- Storage tank solution level

**Secondary Control Room**

The BIS is initiated from the SCR if the MCR is not operational.

**15B.1.8 Inspection, Testing and Maintenance**

The BIS is functionally tested to ensure the pump develops rated flow and discharge pressure and the flow path from the pump suction to the RPV without contaminating the reactor with neutron absorber solution during each planned outage or reactor shutdown for refueling. Functional testing is performed by circulating demineralized water from the test tank, return to the test tank for the flow and pressure test, and with the injection valve open for the RPV injection test.

### **Maintenance Provisions**

The BIS design is provided with adequate equipment removal paths and personnel access for repair and replacement. The following features are provided to facilitate component maintenance:

1. The relief valve is provided with flanged inlet and outlet connections facilitating removal for bench testing
2. Isolation valves are provided on the pump suction and discharge side for maintenance
3. The storage tank heater can be removed without draining the tank
4. Sufficient pull space is provided for removing/replacing the storage tank heater
5. The storage tank is fitted with a top-mounted entry hatch and an external ladder for equipment installation, maintenance, and chemical addition
6. In the event of a sodium pentaborate system injection or the sodium pentaborate leakage into the system piping, the demineralized water supply can be used to flush the piping downstream the storage tank outlet valve
7. Sufficient pump room is provided for removing plungers, pistons, rods, crankshaft, and inspecting parts
8. Ample head room is provided above the pump for a crane, hoist, or tackle
9. Sufficient space is provided around the storage tank for inspection and maintenance
10. Sufficient space is provided for access and local instrument calibration
11. System maintenance is performed by closing the storage tank outlet isolation valve
12. A maintenance valve downstream of the inboard containment isolation valve can be closed allowing system maintenance and isolation valve testing
13. Test vents and drains for testing CIVs

Dedicated piping and collection for sodium pentaborate solution is provided where drainage occurs. The collection vessel is a portable stainless steel drum. A low containment surrounds the system preventing the spread of sodium pentaborate leaks. No special temporary or permanent provisions such as ladders, scaffolding, overhead cranes, etc., are required for maintenance.

### **Surveillance Testing and In-Service Inspection Provisions**

All active BIS components can be tested during normal plant operation. Pre-operational tests are conducted demonstrating the system flow path, adequate pump net positive suction head (NPSH), and pressure drops in accordance with system design documents.

Pre-operational and periodic hydrostatic testing of the system per OLCs are performed complying with ASME B&PVC Section III. Periodic testing of the system and components is scheduled at a frequency commensurate with the OLCs and meets the requirements of CNSC REGDOC-2.5.2, Section 8.4.2.

#### **15B.1.9 Radiological Aspects**

There are no radiological releases from a failure in the boron injection system. Breaks outside containment for the injection flow path through the injection location in the condensate return line of the ICS "C" loop downstream of the two ICS condensate return valves through a separate containment penetration is evaluated in Chapter 15, Subsection 15.5.9.2.3.

#### **15B.1.10 Performance and Safety Evaluation**

The BIS injects a neutron absorber quantity into the reactor vessel producing a minimum concentration to achieve a cold shutdown accounting for leakage and imperfect mixing.

The required shutdown concentration is achieved in a mass of water equal to the sum of the mass of water in the reactor vessel plus the mass of water in the SDC system.

The boron injection rate is based on a boron concentration rate of change between 8 to 20 ppm/minute in the reactor water that includes the weight of water in the reactor and shutdown cooling loops at normal level and at 20°C (68°F). The BIS pump can inject the sodium pentaborate solution at all reactor pressures from 12.41 MPaG (1800 psig) (vessel bottom) to zero MPaG.

The BIS can be actuated and operated in the event of LOOP. BIS contains safety features such as containment isolation and reactor coolant pressure boundary piping (Class 1 piping) for the injection line. The BIS injection line is part of the ICS described in Chapter 6, Subsection 6.2.1.

**Table 15B-1: Complementary Design Features Mitigating Functions**

DEC Function	Complementary Design Feature
Reactivity Control	<p>DL4a complementary design feature diverse protection system actuation logic that is diverse and independent from the SC1 actuation logic.</p> <p>DL4a complementary design feature of the FMCRD run-in function.</p> <p>DL4a complementary design feature of alternate control rod insertion ensures the hydraulic control unit scram pressure is released to the FMCRDs even in the unlikely event of the solenoid pilot valves failing to scram.</p> <p>DL4b ultimate pressure regulation complementary design feature provides a diverse means to limit increases in reactor vessel pressure for this extremely unlikely condition, thus making failure propagation from the reactor pressure vessel to the containment extremely unlikely.</p> <p>DL4b BIS complementary design feature (see Section 15B.1) provides a means to place the plant in a stable controlled configuration if control rods fail to insert.</p> <p>Ex-vessel sequences do not result in a critical configuration.</p>
RPV Depressurization	See reactivity control complementary design feature for RPV ultimate pressure regulation.
In-Vessel Core Cooling	ICS includes DL4a actuations ensuring core cooling availability.
Cooling of Corium Debris in the Containment Corium Shield/Liner	<p>The corium/shield liner complementary design feature prevents core melt debris from interacting with the containment liner preventing core-concrete interaction.</p> <p>Debris bed cooling is accomplished by flooding the corium/shield liner with a pool of water following RPV failure. Heat transfer from the corium debris bed to the containment water pool prevents containment temperature rising that occurs due to heat radiated from an uncovered debris bed. In this manner, potential high temperature challenges to mitigating equipment and containment pressure boundary components such as penetrations seals are limited.</p>
Cooling High Pressure Melt Ejection Debris	<p>DL4b ultimate pressure regulation complementary design feature provides a diverse means to limit the increase in reactor vessel pressure ensuring that there are no credible core damaging accident sequences without cooling while the reactor is also at high pressure, making containment failure from high pressure melt ejection physically impossible</p> <p>DL4b complementary design feature of a containment vent and operating provisions make containment failure by quasi-static overpressurization from a high pressure melt ejection physically impossible.</p> <p>DL1 design provision for a corium shield/liner supported by operating provisions confine and prevent the spread of a molten core, making containment failure from molten core concrete interaction physically impossible.</p>

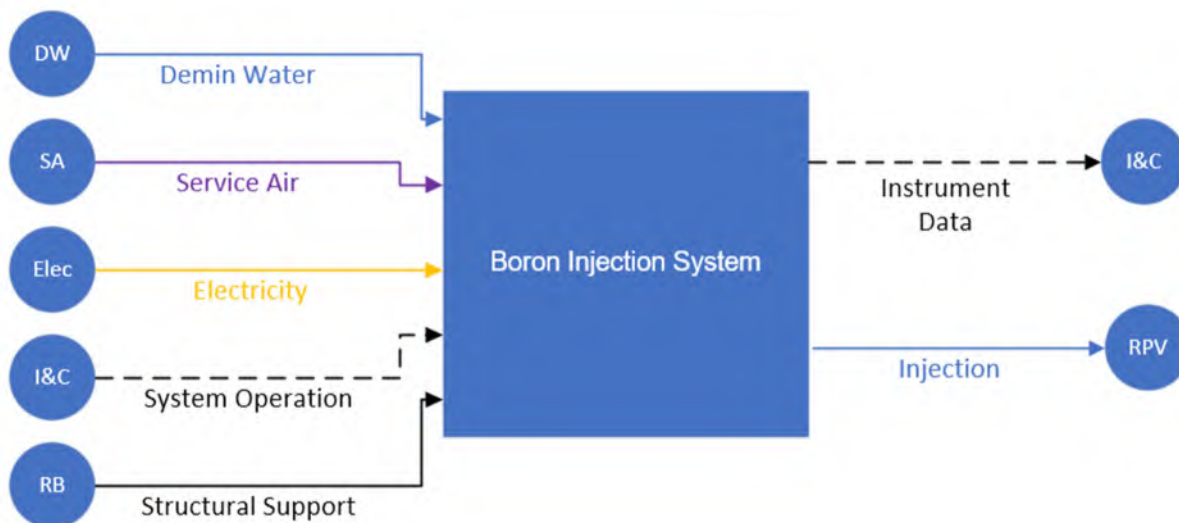

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

DEC Function	Complementary Design Feature
Containment Isolation	<p>DL3 containment isolation is maintained providing a barrier to radionuclide releases to the environment.</p> <p>Diverse independent DL4a isolation functions are provided in the event of a CCF` of DL3 isolation functions. The CIV function includes the containment structure, penetration, valves, and isolation barriers.</p>
Containment Pressure Control:	<p>Containment pressure control via heat removal is required to prevent containment over-pressurization due to steam generation and/or exothermic chemical reactions (non-condensable gas generation).</p> <p>Passive containment cooling is normally in service including an SA event.</p> <p>A DL4b containment ultimate overpressure vent is included to relieve pressure to the reactor cavity and equipment pool to prevent potential containment failure.</p>
Combustible Gas Control	<p>Combustible gas control is present at the start of a potential accident sequence due to the inert containment atmosphere. Hydrogen generation could develop if a SA occurs. Oxygen during a SA is insufficient to create a combustible containment atmosphere.</p> <p>The ICS includes a non-condensable gas removal design feature (autocatalytic recombiner discussed in Section 6.2) that ensures combustible gas concentrations do not develop.</p>
Post-Accident Monitoring	<p>Post-accident monitoring provides information to facilitate post-accident response and evaluation of RPV and containment conditions.</p>

**Table 15B-2: Boron Injection System Interfaces**

<b>Interfacing System</b>	<b>Interface Description</b>	<b>Interface Boundary</b>
Water, Gas, and Chemical Pads	Provide demineralized water for initial storage tank fill and chemical mixing, system flushing, test tank fill for system testing, and maintaining the system full during standby.	The interface is at the upstream side of BIS pressure control valve.
Plant Pneumatics System	Provide service air for periodic storage tank solution mixing through the air sparger in the tank.	The interface is at the upstream side of BIS pressure control valve.
Safety Class 2 and 3 Electrical Distribution System	Electrical power for the BIS pump.	The interface boundary is at BIS equipment terminals.
Non-Safety Electrical Distribution System	Electrical power for the storage tank electric heater.	The interface boundary is at BIS equipment terminals.
Electrical Power	Provide electrical power for operation of the storage tank heater, and injection pump.	The interface boundary is at BIS equipment terminals.
Reactor Building Structure	Provide structural support and protection for BIS equipment.	The interface is at the equipment foundation and support structures for the BIS equipment.
Safety Class 2 and Safety Class 3 Instrumentation and Control	Provide for input and output for BIS instrumentation and controlled components.	The interface is at the DCIS.
Isolation Condenser System	Provide an injection path to the reactor for the neutron absorber solution and system isolation from the reactor system.	At the ICS "C" loop return piping.

Number of motor-driven FW pumps	2
One FW pump is operating, and one FW pump is in standby	

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

Parameter	Value
Maximum flow demanded is between, % Rated	105 - 115
Maximum flow of both FW pumps assuming a CCF, % Rated	220
FW temperature reduction for Loss of Feedwater Heating (LFWH) AOO, °C (°F)	50 (90)
Minimum time constant of FW temperature response, s This value is assumed based on operating experience and allows simplified modeling of the FW temperature response	60
FW pump trip coast down time constant	3
<b>Isolation Condenser System (ICS) Related Parameters</b>	
ICS heat removal capacity per train, MW	33.75
ICS maximum initial temperature, °C (°F)	43.3 (110)
ICS nominal initial temperature, °C (°F) (used in most transient events as the value is not key)	20.85 (69.53)
ICS minimum initial temperature, °C (°F)	10 (50)
ICS condensate return valve maximum opening time, s	10
ICS train condensate return line minimum internal diameter, mm (in)	178 (7.00)
The elevation difference from centerline of the horizontal connections between the ICS steam line distribution header to the centerline of the ICS return injection to the chimney, minimum, m (in)	15.808 (622.362)
<b>Balance of Plant Related Parameters</b>	
TSV minimum fast closure steam flow shutoff rate from rated power, % rated steam flow / s	667
TCV minimum fast closure steam flow shutoff rate from rated power, % rated steam flow / s	667
TCV minimum slow (servo) closure steam flow shutoff from rated power % rated steam flow / s	40
TBV capacity at rated conditions % rated steam flow	25
<b>Miscellaneous Parameters</b>	
Biased initial CPR, (reduction versus nominal initial CPR) Note: the value is approximate because it is slightly different depending on the initial condition. This is used in CN-PA events and some DEC events (as noted in event description)	~0.1
Biased initial hot fuel rod power, (multiplier relative to average rod power). Note: This is used in CN-PA events and some DEC events (as noted in event description). This input is only important if there is boiling transition and a subsequent fuel cladding temperature increase during the event.	1.6

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

**Table 15.5-4: CRD Scram Time**

Reactor Vessel Bottom Gauge Pressure MPaG (psig)	Rod Insertion Position	Required Maximum Time (s) Note 1
≤ 8.75 MPaG (1269 psig)	10%	≤ 0.46
	40%	≤ 1.20
	60%	≤ 1.71
	100%	≤ 3.70
≤ 9.48 MPaG (1375 psig) Note 2	10%	≤ 0.56
	40%	≤ 1.40
	60%	≤ 2.03
	100%	≤ 4.20

- (1) The times include 0.2 s delay from de-energizing the scram pilot valves to control rods movement.
- (2) These times are used in pressurization increase events in the DBA category even if the pressure is not greater than 8.75 MPaG (1269 psig) during the rod insertion.

NON-PROPRIETARY INFORMATION

**Table 15.5-5: Defense Lines Inputs Used in Non-LOCA Analyses**

DL ID	Function Name	Inputs	Setpoint / Delay Analytical Limits
DL2-01	Maintain Target Pressure (Performed by RPC)	Steam flow demand is a function of reactor dome pressure	Target dome pressure is normal dome pressure in Table 15.5-3 Design description of RPC is provided in Chapter 7, Section 7.3.3.2, Item 5
DL2-02	Maintain Target Level (Performed by RLC)	RPV level error (function of core power, reactor water level, steam flow, steam flow enthalpy, FW enthalpy)	Target reactor level is NWL (L5) in Table 15.5-3 Design description of RLC is provided in Chapter 7, Section 7.3.3.2, Item 3
DL2-04	Control Rod Block on ATLM	Determination of the thermal limits or soft duty guidelines violation	Design description of ATLM is provided in Chapter 7, Section 7.3.3.2, Item 21
DL2-05	Control Rod Block on MRBM	Indication of potential fuel damage thermal limits being exceeded	Design description of MRBM is provided in Chapter 7, Section 7.3.3.2, Item 22
DL2-08	Anticipatory Hydraulic Scram on Turbine Trip or Generator Load Rejection Demand	Turbine Trip or Generator Load Rejection Demand	Total time delay = 0.05 s after generator load rejection or turbine trip signal
DL2-09	TBV Fast Open on Turbine Trip or Generator Load Rejection Demand	Turbine Trip or Generator Load Rejection Demand	Before or at the same time as TCV or TSV closure
DL2-13	Turbine Trip on High Main Condenser Pressure Setpoint 2	High Main Condenser Pressure Setpoint 2	No analytical limit
DL2-14	TBV Closure on High Main Condenser Pressure Setpoint 3	High Main Condenser Pressure Setpoint 3	Set to allow for time for bypass to be open after turbine trip signal for expected rates of condenser pressure increase. Total time delay = 1 s
DL2-19	FW and Condensate Pump Trip on High RPV Level	High RPV Water Level (L8)	L8: 22.277 m (877.047 in.) AVZ Total time delay = 1.0 s
DL2-21	Anticipatory Hydraulic Scram on MSRIV/MSCIV Position	MSRIV/MSCIV Position	<90% open Total time delay (scram) = 0.05 s

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

DL ID	Function Name	Inputs	Setpoint / Delay Analytical Limits
DL2-25	Start Standby FW Pump on Loss of Operating FW Pump	Loss of Operating FW Pump	Analysis allows 10 seconds identify and confirm operating pump is lost and to initiate standby pump. Analysis allows 15 seconds to ramp up the standby pump to full flow
DL2-27	Select Control Rod Run-In on FW Temperature Decrease	FW Temperature Decrease	FW temperature reduction of 16.6°C (30°F) or more. Total time delay = 5 s
DL2-31	ICS Pressure Control on High Reactor Pressure	High Reactor Pressure	Settings are not important for Transient DSA results Design description is provided in Chapter 7, Section 7.3.3.2, Item 6
DL2-39	Anticipatory Hydraulic Scram on High RPV Level	High RPV Level (L8)	See DL2-19
DL3-01	Hydraulic Scram on High RPV Pressure	High RPV Pressure (HP1)	7.787 MPaG (1129.4 psig) Total time delay = 0.7 s
DL3-02	Hydraulic Scram on Low RPV Pressure	Low RPV Pressure (LP1)	5.516 MPaG (800.0 psig) Total time delay = 0.7 s The transient analysis used a lower value this value is required consistent with LOCA analyses.
DL3-03	Hydraulic Scram on Low RPV Level	Low RPV Level (L3)	L3: 19.645 m (773.425 in) AVZ Total time delay = 1.0 s
DL3-04	Hydraulic Scram on High Neutron Flux	High Neutron Flux	125% of rated Total time delay = 0.09 s
DL3-05	Hydraulic Scram on High Simulated Thermal Power	High Simulated Thermal Power	115% of rated Signal Time Constant = 7 s Total time delay = 0.09 s
DL3-11	ICS Train 1 Initiation on High RPV Pressure	High RPV Pressure (HP2)	8.289 MPaG (1202.2 psig) Total time delay = 0.7 s
DL3-12	ICS Train 2 Initiation on High RPV Pressure	High RPV Pressure (HP3)	8.504 MPaG (1233.4 psig) Total time delay = 0.7 s
DL3-13	ICS Train 3 Initiation on High RPV Pressure	High RPV Pressure (HP4)	8.719 MPaG (1264.6 psig) Total time delay = 0.7 s
DL3-14	ICS Initiation on Low RPV Water Level	Low RPV Water Level (L2)	L2: 14.224 m (560.0 in) AVZ Total time delay = 1.0 s

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

DL ID	Function Name	Inputs	Setpoint / Delay Analytical Limits
DL3-17	MSRIV/MS CIV Isolation on Low RPV Pressure	Low RPV Pressure (LP1)	5.516 MPaG (800.0 psig) Total time delay = 0.7 s In non-LOCA analysis, this is assumed to occur at a lower pressure that is conservative.
DL3-18	MSRIV/MS CIV Isolation on Low RPV Water Level	Low RPV Water Level (L2)	L2: see DL3-14
DL3-23	FW Isolation on High RPV Water Level	High RPV Water level (L9)	L9: 22.377 m (880.984 in) AVZ Total time delay = 1.0 s
DL4a-12	MSRIV/MS CIV Isolation on Sustained Low FW Flow	Sustained Low FW flow	Analysis allows 70 seconds to confirm sustained low FW flow
DL4a-40	CRD Fast Motor Run-In on High Flux After Scram Signal	High Flux After Scram Signal	Analysis allows 5 s after a scram signal to check for high flux and initiate function
DL4a-41	FW Pump/Condensate Pump Trip on High Flux After Scram Signal	High Flux After Scram Signal	Analysis allows 5 s after a scram signal to check for high flux and initiate function
DL4a	ICS Tran Initiation on High Flux After Scram Signal	High Flux After Scram Signal	Analysis allows 5 s after a scram signal to check for high flux and initiate function

**Table 15.5-6: Sequence of Events for Loss of Feedwater Heating (AOO)**

<b>Time (s)</b>	<b>Event</b>
0	Initiate a 50°C (90°F) temperature reduction in the FW system
5.5	SCRRI inserts control rods on indication of FW temperature reduction
~60	Control rods stop moving
~400	New steady state achieved

**Table 15.5-7: Sequence of Events for Turbine Trip (AOO)**

<b>Time (s)</b>	<b>Events</b>
0.0	Reactor scrams on initiation on turbine trip signal
0.2	Scram rods begin to move
0.25	TSVs begin to close
0.25	TBVs begin to open
0.40	TSVs are closed
>6.0	New steady state

**Table 15.5-8: Sequence of Events for Closure of One Main Steam Reactor Isolation Valve (AOO)**

<b>Time (s)</b>	<b>Event</b>
0.0	Initiate closure of one MSRIV
0.8	Anticipatory scram on MSRIV position
3.0	MSRIV in first steam line is closed
3.0	Closure of MSRIV in second steam line initiated on leak detection indication
6.0	MSRIV in second steam line is closed
>25.0	High RPV pressure reached, ICS train initiated
>25.0	New Steady state

**Table 15.5-9: Sequence of Events for Loss of Condenser Vacuum (AOO)**

Time (s)	Event
0.0	Anticipatory scram initiated on turbine trip signal caused by loss of condenser vacuum
0.2	Scram rods begin to move
0.25	TSVs begin to close
0.25	TBVs begin to open
0.40	TSVs are closed
24.0	TBVs close on high main condenser pressure
≥24.0	ICS initiation on high RPV pressure
>24.0	New steady state

**Table 15.5-10: Sequence of Events for Loss-of-Preferred Power (AOO)**

Time (s)	Event
0.0	FW pumps lose power
0.0	Anticipatory scram initiated on generator load rejection caused by generator output breakers opening on loss of power
0.2	Scram rods begin to move
0.25	TCVs begin to close due to generator load rejection signal
0.25	TBVs begin to open
6.25	TBVs close following loss-of-preferred power
>20.0	ICS initiation on high RPV pressure
>20.0	New steady state

**Table 15.5-11: Sequence of Events for Feedwater Pump Trip (AOO)**

Time (s)	Event
0.0	Initiate FW pump trip
10.0	Standby FW pump starts
25.0	Standby FW pump at 100% rated FW flow
~200	New steady state achieved near 100% power and 100% FW flow

**Table 15.5-12: Sequence of Events for Inadvertent Isolation Condenser Initiation One Train (AOO)**

<b>Time (s)</b>	<b>Event</b>
0	Initiate opening of IC condensate return valve on one train
>150	New steady state achieved near initial conditions

**Table 15.5-13: Sequence of Events for Loss of Feedwater Heating (DBA)**

<b>Time (s)</b>	<b>Event</b>
0	Initiate FW temperature reduction
~90	High STP reached, scram initiated
~110	Low RPV pressure reached, Main Steam isolation initiated
~300	High RPV level L9 reached, FW isolation initiated
> 400	High RPV pressure reached; ICS train initiated (not simulated)

**Table 15.5-14: Sequence of Events for Generator Load Rejection (DBA)**

<b>Time (s)</b>	<b>Event</b>
0.0	TCVs begin to close due to a generator load rejection signal
0.42	High neutron flux reached, Scram initiated
0.62	Control rods begin to move
152	High RPV pressure reached, ICS train initiated
166	High RPV level L9 reached, FW isolation initiated
>300	A controlled state is achieved

**Table 15.5-15: Sequence of Loss-of-Preferred Power (DBA)**

Time (s)	Event
0.0	TCV begin to close, and FW pump trips
0.80	High neutron flux reached, Scram initiated
1.0	Control rods begin to move
152	High RPV pressure reached, ICS train initiated
>300	A controlled state is achieved

**Table 15.5-16: RPV Pressure Control Downscale (DBA)**

Time (s)	Event
0.0	TCVs begin to close, and TBVs remain closed
0.80	High neutron flux reached, Scram initiated
1.0	Control rods begin to move
155	High RPV pressure is reached, ICS train initiated
167	High RPV level L9 reached, FW isolation initiated
>300	A controlled state is achieved

**Table 15.5-17: Closure of All MSRIVs and FW Isolation Valves (DBA)**

Time (s)	Event
0.0	MSRIVs begin to close, and FW isolation valves close
1.09	High Neutron Flux reached, Scram initiated
1.29	Control rods begin to move
122	High RPV pressure reached, ICS initiated
>300	A controlled state is achieved

**Table 15.5-18: Sequence of Events for Feedwater Flow Increase – All Pumps**

<b>Time (s)</b>	<b>Event</b>
0	Initiate instant increase in speed of both FW pumps
~20	High RPV level L9 reached, FW isolation initiated
~30	High STP reached, Scram initiated
~90	Low RPV pressure reached, Main Steam Reactor Pressure Isolation Valve isolation initiated
>200	High RPV pressure reached, ICS train initiated (not simulated)

**Table 15.5-19: Sequence of Events for Condenser Initiation – All Trains**

<b>Time (s)</b>	<b>Events</b>
0	Initiate opening of all IC condensate return valves
~35	High RPV level L9 reached, FW isolation initiated
~55	Low RPV pressure reached, scram, and MSRIV isolation initiated

**Table 15.5-20: Sequence of Events for Loss of Feedwater (DBA)**

<b>Time (s)</b>	<b>Event</b>
0.0	Initiate loss of FW flow
~30	Low RPV level L3 reached, scram initiated
~85	Low RPV pressure reached, MSRIV isolation initiated
~130	Low RPV level L2 reached, all IC Trains initiate
>300	New steady state achieved

**Table 15.5-21: Sequence of Events for RPV Pressure Control Open (DBA)**

Time (s)	Event
0.0	TBVs and TCVs open
~70	Low RPV pressure reached, reactor scram and MSRIV isolation initiated
~225	High RPV level L9 reached, FW isolation initiated
>300	High RPV pressure reached, ICS train initiated (not simulated)

**Table 15.5-22: Not Used**

**Table 15.5-23: Timing of Events for Main Steam Pipe Break Inside Containment, CN-DSA**

Tim (seconds)	Event	Notes
0.0	Double-ended guillotine rupture of main steam pipe break inside the containment	
0.0	FW pump trip and coast down	This is a consequence of LOPP
0.0	TSV or TCV starts closing	Conservative assumption
1.0	Control rods start to insert on scram initiation	High drywell pressure setpoint for scram, reactor isolation and isolation condenser initiation is reached in less than 1 second.
1.0	ICS condensate return valve starts opening	
1.0	CUW stops	
3.0	Control rods are inserted sufficiently to diminish fission from prompt neutrons	This is a conservatively long duration for fission from prompt neutrons to diminish. Fission power starts decreasing when the control rods are partially inserted. In addition, voiding in the core due to rapid depressurization also causes reactor power to decrease rapidly.
5.0	RIVs start to close	The delay time is significantly conservative given that containment pressure reaches the isolation setpoint in less than 1 second.
10.0	RIVs are fully closed	
11.0	ICS condensate return valve is fully open	
12.2	Peak containment pressure is reached	
>12.2	Containment pressure starts decreasing	

**Table 15.5-24: Timing of Events for Feedwater Pipe Break  
Inside Containment, CN-DSA**

<b>Time (seconds)</b>	<b>Event</b>	<b>Notes</b>
0.0	Double-ended guillotine rupture of FW pipe break inside containment concurrent with LOPP	
0.0	FW pump trip and coast down	This is a consequence of LOPP
0.0	TSV or TCV starts closing	Conservative assumption
1.0	Control rods start being inserted on scram initiation	High drywell pressure setpoint for scram, reactor isolation and isolation condenser initiation is reached in less than 1 second
1.0	ICS-A and B condensate return valve starts opening	
3.0	Control rods are inserted sufficiently to diminish fission from prompt neutrons	This is a conservatively long duration for fission from prompt neutrons
5.0	FWRIVs and CIVs start to close	
10.0	FWRIVs and CIVs are fully closed	
10.1	Peak containment pressure is reached	
11.0	Isolation condenser valves are fully open	

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

**Table 15.5-25: Timing of Events for Small Steam Pipe Break  
Inside Containment CN-DSA**

<b>Time (seconds)</b>	<b>Event</b>	<b>Notes</b>
0.0	Small steam pipe break concurrent with LOPP	
0.0	Pressure controller freezes. TCV remains in initial position, turbine chest pressure decreases rapidly	Assuming continued steam discharge to the turbine is conservative. TCV closure as a consequence of LOPP is not credited.
0.0	FW pump trip and coast down	
10.6	Steam line low pressure setpoint is reached	
12.3	Reactor scram, 0.7 s delay after low pressure setpoint is reached and another 1 s for scram delay	
15.6	MSRIVs start closing 5 seconds after steam line low pressure	
20.6	MSRIVs are fully closed	
63.6	Level decreases to Level 2	
64.6	ICS-A and ICS-B condensate return valves start opening	
74.6	ICS-A and ICS-B condensate return valves are fully open	
234000	Peak containment pressure reached	

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

**Table 15.5-26: Timing of Events for Small Liquid Pipe Break Inside Containment, CN-DSA**

<b>Time (seconds)</b>	<b>Event</b>	<b>Notes</b>
0.0	Small liquid pipe break concurrent with LOPP	
0.0	Pressure controller freezes. TCV remains at initial position, turbine chest pressure decreases rapidly	Assuming continued steam discharge to the turbine is conservative. TCV closure as a consequence of LOPP is not credited.
0.0	FW pump trip and coast down	
10.6	Steam line low pressure setpoint is reached	
12.3	Reactor scram, 0.7 s delay after low pressure setpoint is reached and another 1 s for scram delay	
15.6	MSRIVs start closing 5 seconds after steam pipe low pressure	
20.6	MSRIVs are fully closed	
58.9	Level decreases to Level 2	
59.9	ICS-A and ICS-B condensate return valves start opening	
69.9	ICS-A and ICS-B condensate return valves are fully open	
232800	Peak containment pressure occurs	

**Table 15.5-27: Sequence of Events for Closure of One Main Steam Reactor Pressure Isolation Valve (DEC)**

Time (s)	Event
0.0	Initiate closure of one MSIV
0.8	Anticipatory scram signal on MSRIV position. Scram fails
3.0	MSRIV in first steam line is closed
3.0	Closure of MSRIV in second steam line initiated on leak detection indication
5.8	Feedwater pump trips on high flux after scram signal
5.8	All ICS trains initiate on high flux after scram signal
5.8	CRDM run-in initiation on high flux after scram signal
6.0	MSRIV in second steam line is closed
>300	A controlled state is achieved

**Table 15.5-28: Sequence of Events for Complex Sequence Generator Load Rejection (DEC)**

Time (s)	Event
0.0	Scram initiation on load rejection signal
0.2	Control rods begin to move. Half of the control rods fail to insert
0.25	TCVs begin to close
0.25	TBVs begin to open
>200	A controlled state is achieved

**Table 15.5-29: Sequence of Events for Loss of Condenser Vacuum (DEC)**

Time (s)	Event
0.0	Scram fails on initiation on turbine trip signal caused by loss of condenser vacuum
0.25	TSVs begin to close
0.25	TBVs begin to open
0.40	TSVs are closed
5.0	CRDM run-in initiation on high flux after scram signal
5.0	ICS initiation on high flux after scram signal
24.0	TBVs close on high main condenser pressure
>300	A controlled state is achieved

**Table 15.5-30: Sequence of Events for Loss of Preferred Power (DEC)**

Time (s)	Event
0.0	FW pumps lose power
0.0	Scram fails on generator load rejection caused by generator output breakers opening on loss of power
0.25	TCVs begin to close due to generator load rejection signal
0.25	TBVs begin to open
5.0	CRDM run-in initiation on high flux after scram signal
5.0	ICS initiation on high flux after scram signal
6.25	TBVs close following loss-of-preferred power
>300	A controlled state is achieved

**Table 15.5-31: Sequence of Events for All Control Rod Withdrawal at Power (ACRW)**

Time (s)	Event
0.1	Initiate withdrawal of all rods
19	High STP reached, scram initiated
63	High RPV Level L9 reached, FW isolation initiated
84	Low RPV pressure reached, Main Steam isolation initiated
> 200	High RPV pressure reached; ICS train initiates on high pressure (not simulated)

**Table 15.5-32: Sequence of Events for Inadvertent Control Rod Withdrawal at Power Single Rod (ICRW)**

Time (s)	Event
0.1	Initiate withdrawal of one rod
>70	Power reaches a stable level
long term	Operators act to control reactor power

**Table 15.5-33: Sequence of Events for Feedwater Isolation (DEC)**

Time (s)	Event
0.0	Initiate FW Isolation
5	FW flow at zero
~30	Low RPV level L3 reached, no scram (DL3 failure)
65	Reactor scram initiated on sustained low FW flow
70	MSRIV isolation initiated on sustained low FW flow
250	ICS Trains initiate on high RPV pressure
>400	Controlled state achieved

**Table 15.5-34: Fuel Handling Accident Sequence of Events**

Sequence of Events	Elapsed Time
The BWRX-300 reactor is shut down for refueling operations that begins 24 hours after shutdown. Over this period the core isotopic inventory decays.	24 hours
During a refueling operation a fuel assembly is moved over the top of the core or fuel pool, and the fuel bundle, grapple, mast, and head fall on top of the core or spent fuel racks.	0
Rods in the dropped bundle and struck bundles fail, releasing the fission gases in the plenum and gap of the damaged rods to the pool water.	0
Fission gases rise through the pool water to refueling operation floor common airspace surrounding the top of the reactor cavity and spent fuel pool.	0
The building ventilation system high radiation alarm alerts all plant personnel to evacuate, and the Reactor Building (RB) air handling system dampers close to isolate the area.	0
Plant workers evacuate the RB and adjacent areas.	15 minutes

**Table 15.5-35: BWRX-300 Core Parameters**

Parameter/Description	Value
Thermal Power	870(MWth)
Core Size (Number of Bundles)	240
Fuel Type	GNF2
Bundle Average Enrichment	3.84-4.68 <sup>w</sup> ‰ U235
Core Average Exposure	38,000 MWd/Mt

**Table 15.5-45: Description of Criticality Accident Parameters**

Details	Parameters
Site/Date	SACLAY (1960/03/15)
Critical Mass	2200 kg
Critical Geometry	Oxide Fuel in Water
Total # Fissions	$3 \times 10^{18}$
Fission Excursion	< 180 sec.

**Table 15.5-46: Out of Core Criticality Scenario Results**

Total Number of Fissions	$4 \times 10^{19}$ fissions
Excursion Duration	< 180 s
Total Radiation Dose (350 m)	0.4 mSv

**Table 15.5-47: Protective Actions and Generic Criteria for OOC**

Protective Actions	Generic Criteria
Evacuation	50 mSv effective dose in 7 days
Sheltering	5 mSv effective dose in 1 day
Temporary Relocation	50 mSv in the first year

**Table 15.5-48: Conservatisms Used in the Non-LOCA DSA**

Plant State	Conservatism	
	Code	Plant Parameters and System Performances
AOO Base Line Analyses	Best Estimate	<ul style="list-style-type: none"> <li>Rated power initial conditions</li> <li>Conservative setpoints and plant performance parameters</li> <li>Conservatism in the plant parameters and the derived acceptance criteria is established conservatively such that there is no need to account for uncertainties in the analysis method</li> <li>DL2 functions are credited in the analyses, but DL3 functions are credited if needed to meet acceptance criteria</li> </ul>
AOO Conservative	Best Estimate	Fault evaluations indicate that failures in DL2 result in DBA events
DBA Baseline	Best Estimate	<ul style="list-style-type: none"> <li>Rated power initial conditions</li> <li>Conservative setpoints and plant performance parameters</li> <li>Conservatism in the plant parameters and the derived acceptance criteria is established conservatively such that there is no need to account for uncertainties in the analysis method</li> <li>DL2 and DL3 functions are credited if needed to meet acceptance criteria</li> </ul>
DBA Conservative	Graded Approach	<ul style="list-style-type: none"> <li>Conservative initial conditions are established (e.g., bias fuel and reactor pressure initial) for events that are limiting</li> <li>Conservative setpoints and plant performance parameters</li> <li>Analysis method uncertainties are addressed with a graded approach depending on margin to the derived acceptance criteria</li> </ul>
DEC	Best Estimate	<ul style="list-style-type: none"> <li>Rated power initial conditions are used</li> <li>Nominal setpoints and plant performance parameters are used (conservative setpoints and plant performance may be used for convenience/simplification)</li> <li>Sensitivity analyses performed to understand cliff edge effects</li> </ul>

**Table 15.5-49: DL3 Functions Credited in Conservative LOCA Analyses**

<b>Credited Function</b>	<b>Action</b>	<b>Signal</b>	<b>Analytical Setpoint</b>
DL3-02	Hydraulic scram	Low steam pipe pressure	5.617 MPa
DL3-07	Hydraulic scram	High containment pressure	18.5 kPaG (2.8 psig)
DL3-09	Hydraulic scram	Line Break Indication (MS, FW, ICS)	For breaks larger than 19 mm (0.75 in) in diameter (Note 1)
DL3-14	ICS initiation	Low RPV water level	14.22 m
DL3-15	ICS initiation	High Containment pressure	18.5 kPaG (2.8 psig)
DL3-16	ICS initiation	Line Break Indication (MS, FW, ICS)	For breaks larger than 19 mm (0.75 in) in diameter (Note 1)
DL3-17	MS RIV closure (Note 2)	Low steam pipe pressure	5.617 MPa
DL3-18	MS RIV closure (Note 2)	Low RPV water level	14.22 m
DL3-22	Reactor and Containment Isolation Valve closure (Note 2)	High Containment pressure	18.5 kPaG (2.8 psig) (Note 1)
DL3-20 DL3-21	MS RIV closure	Line break indication in MSL, FW or SDC	Within 1 seconds for breaks larger than 19 mm (0.75 in) in diameter
DL3-25	FW and SDC RIV closure	Line break indication in FW or SDC	Within 1 second for breaks larger than 19 mm (0.75 in) in diameter
DL3-26	CUW RIV closure	Line break indication in CUW	Within 1 second for breaks larger than 19 mm (0.75 in) in diameter
DL3-27 DL3-28 DL3-29	ICS RIV closure of the broken ICS train	Line break indication in the respective ICS trains	Within 1 second for breaks larger than 19 mm (0.75 in) in diameter

- (1) This setpoint is reached in less than 1 s in large break cases.
- (2) For large breaks, isolation valves are assumed to start closing with a 5 second delay from the time of pipe break and are fully closed in 10 seconds. For small breaks, the isolation valves start closing with a 5 second delay after the setpoint is reached and are fully closed in another 5 seconds. Containment isolation is credited only for FW pipe breaks. Isolation functions may also include CIVs. This table shows only the valves credited to close by the isolation signal.

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

**Table 15.5-50: DL2 and DL4a Functions Credited in DEC LOCA Analyses**

<b>DL3 Function Failure</b>	<b>Action</b>	<b>DL2 or DL4a Credited Function</b>	<b>Notes</b>
DL3-02	Hydraulic scram on low steam pipe pressure	DL2-08 on turbine trip demand	DL2-08 is initiated on LOPP, and a faster scram than DL3-02 credited in CN-DSA.
DL3-07	Hydraulic scram on high containment pressure	DL4a-05	
DL3-09	Hydraulic scram on Line Break Indication (MS, FW, ICS)	DL4a-26	
DL3-14	ICS initiation on Low RPV water level	DL4a-33	
DL3-15	ICS initiation on High Containment pressure	DL4a-11	
DL3-16	ICS initiation on Line Break Indication (MS, FW, ICS)	DL4a-27 and DL4a-28	
DL3-17	MS RIV closure on Low steam pipe pressure	DL2-41	DL3-17 is credited in small break cases for limiting inventory losses to the turbine. In DL2, the pressure controller throttles the flow until DL2-41 closes the MS RIVs. This combination of functions results in less inventory losses than the CN-DSA sequences.
DL3-18	MS RIV closure on Low RPV water level	DL4a-34	
DL3-22	Reactor and Containment Isolation Valve closure on High Containment pressure	DL4a-16	
DL3-20 DL3-21	MSRIV closure on Line break indication in MSL, FW or SDC	DL4a-14 and DL4a-15	
DL3-25	FW and SDC RIV closure on line break indication in FW or SDC	DL4a-17	
DL3-27 DL3-28 DL3-29	ICRIV closure of the broken ICS train line break indication in the respective ICS train	None	See discussion in 15.2.4.8.1.

--	-------

## **LIST OF FIGURES**

None.

## **16.0 OPERATIONAL LIMITS AND CONDITIONS**

### **16.1 Scope and Application**

The facility safe operating envelope is defined by a detailed safety evaluation (deterministic and probabilistic) and a set of limits and conditions within which the facility must be operated to ensure compliance with the safety analysis. The Operational Limits and Conditions (OLC) are those upon which reactor operation is licenced and can be monitored by or on behalf of the operator and controlled by the operator. Once the safety analysis is complete, the safe operating envelope is finalized and reflected in the Pre-Operational Safety Analysis Report in support of the Licence to Operate.

The OLC are based on the requirements of CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 16.6-1); CNSC REGDOC-1.1.2, "Licence Application Guide: Licence to Construct a Reactor Facility" (Reference 16.6-2); and CNSC REGDOC-1.1.3, "Licence to Operate a Nuclear Power Plant" (Reference 16.6-3). They are derived from the analyses and evaluations summarized in the safety analysis of Chapter 15. The format of the OLC is based on USNCR NUREG-1434, Volume 1, "Standard Technical Specifications – General Electric BWR/6 Plants: Specifications" and Volume 2, "Standard Technical Specifications – General Electric BWR/6 Plants: Bases" (Reference 16.6-4) to the extent practical.

The structure of the first volume (Specifications) of NUREG-1434 (Reference 16.6-4) covers Use and Application, Limiting Condition for Operation (LCO) Applicability and Surveillance Requirement Applicability, Safety Limits, Design Features, and Administrative Controls. In addition, the major portion of this first volume includes Specifications (or OLCs) in areas of Reactivity Control Systems, Power Distribution Limits, Instrumentation, Reactor Coolant System, Emergency Core Cooling Systems, Containment Systems, Plant Systems, Electrical Power Systems, Refueling Operations, and Special Operations. Each Specification OLC consists of a Limiting Condition for Operation (LCO), Applicability, Actions, and Surveillances. The Actions are included in an Action table that describes the Conditions, Required Actions, and Completion Times. The Surveillances are also included in a Surveillance table identifying the Surveillance Requirements and associated Frequency of performance. Additional details of the Specifications or OLCs are provided in Subsection 16.1.1 and Section 16.4.

Use and Application as well as LCO Applicability and Surveillance Requirement Applicability are addressed in Section 16.1.1 and provide general rules that apply to NUREG-1434 (Reference 16.6-4). Safety Limits are addressed in Section 16.3. Administrative Controls are addressed in Section 16.5. Design Features include requirements related to the site location, reactor core, and fuel storage.

The second volume includes the Bases which is further described in Section 16.2.

Each specification OLC is based on one of the following selection criteria from 10 CFR 50.36, "Technical Specifications" (Reference 16.6-5).

- Criterion 1 – Installed instrumentation that is used to detect, and indicate in the control room, a significant abnormal degradation of the reactor coolant pressure boundary.
- Criterion 2 – A process variable, design feature, or operating restriction that is an initial condition of a design basis accident or transient analysis that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.
- Criterion 3 – A structure, system, or component that is part of the primary success path and which functions or actuates to mitigate a design basis accident or transient that either assumes the failure of or presents a challenge to the integrity of a fission product barrier.

NEDO-33966 REVISION 0  
NON-PROPRIETARY INFORMATION

- Criterion 4 – A structure, system, or component which Operating Experience (OPEX) or probabilistic risk assessment has shown to be significant to public health and safety.

Structures, Systems, and Components (SSCs) as well as initial conditions are screened against the criteria and included in the OLCs. SSCs installed to detect and indicate degradation of the reactor coolant pressure boundary are incorporated to satisfy Criterion 1. The OLCs will require the SSCs (Criterion 3) to be operable in conditions where the design basis accident or transient is postulated to occur. The OLCs will also specify requirements for initial conditions (Criterion 2) where events are postulated to occur. This will help ensure the safety criteria of the safety analyses in Chapter 15 are met if a design basis accident or transient occurs.

SSCs are evaluated against Criteria 2 and 3 using the Conservative Safety Analyses from the BWRX-300 Safety Strategy. The focus is on Safety Class 1 equipment performing the credited Defense Line 3 safety functions. The Conservative Safety Analyses addresses sequences that began with either an anticipated operational occurrence or design basis accident. The resulting consequences for these events are well within the specified safety analyses acceptance criteria.

Consistent with the Safety Strategy to include a Defence-in-Depth (D-in-D) approach, Safety Class 2 (Defense Line 4a) SSCs and Safety Class 3 (Defense Line 2) SSCs credited in the Baseline Deterministic Safety Analyses and Extended Deterministic Safety Analyses, respectively are addressed in plant programs. The program ensures Surveillances are performed to confirm proper functionality when required to mitigate transients, and to have pre-planned actions if functionality is degraded.

SSCs credited in the Probabilistic Safety Assessment (PSA) of Chapter 15 having a significant impact on Core Damage Frequency are included in OLCs to satisfy Criterion 4.

#### **16.1.1 Use and Application**

Use and application addresses definitions of important terms used in the Specifications and Bases, use of logical connectors, Completion Times for Required Actions, and Frequency of Surveillance Requirements.

Logical connectors are used in Specification or OLC to discriminate between, and yet connect, discrete Conditions, Required Actions, Completion Times, Surveillances and Frequencies. The only logical connectors that appear are “AND” and “OR.” The physical arrangement of these connectors constitutes logical conventions with specific meanings.

Applicability LCO Applicability are provided that establish the general requirements applicable to all LCOs. LCOs Applicability can be summarized as:

- |           |   |
|-----------|---|
| LCO 3.0.1 | Compliance with an LCO is required during the operational modes or other conditions that are specified in the LCO's applicability statement.  |
| LCO 3.0.2 | Satisfying the requirements of the associated Required Actions within the specified Completion Time constitutes compliance with the Specification.  |
| LCO 3.0.3 | When an LCO and its associated Required Actions are not met, an associated Action is not provided, or if directed by the Required Actions, action must be initiated within specified time intervals to place the unit in an operational mode in which the Specification does not apply.       |
| LCO 3.0.4 | When an LCO is not met, entry into a mode or other specified condition may only be made: <ol style="list-style-type: none"><li>1. When associated actions permit continued operation in the mode or other specified condition in the applicability for an unlimited period of time,</li></ol> |

NEDO-33966 REVISION 0  
NON-PROPRIETARY INFORMATION

2. In accordance with the facility risk management program, or
3. When an allowance is stated in the individual value, parameter, or other specification.

LCO 3.0.5 Equipment removed from service or declared inoperable to comply with actions may be returned to service under administrative control solely to perform testing required to demonstrate its operability or the operability of other equipment.

LCO 3.0.6 When a supported system LCO is not met solely due to a support system LCO not being met, the Conditions and Required Actions associated with this supported system are not required to be entered. Only the support system LCO Actions are required to be entered. This is an exception to LCO 3.0.2 for the supported system. In this event, an evaluation shall be performed to determine if a loss of safety function is determined to exist. If a loss of safety function is determined to exist, the appropriate Conditions and Required Actions of the LCO in which the loss of safety function exists are required to be entered.

LCO 3.0.7 Special Operations LCOs allow specified Specification requirements to be changed to permit performance of special tests and operations. Unless otherwise specified, all other Specification requirements remain unchanged. Compliance with Special Operations LCOs is optional. When a Special Operations LCO is desired to be met but is not met, the Actions of the Special Operations LCO shall be met. When a Special Operations LCO is not desired to be met, entry into a Mode or other specified condition in the Applicability shall only be made in accordance with the other applicable Specifications.

Surveillance Requirement Applicability establish the general requirements applicable to all Surveillance Requirements. Surveillance Requirement Applicability can be summarized as:

SR 3.0.1 Surveillance Requirements apply when the associated LCO applies. Upon discovery that the requirements of a Surveillance cannot be met, the LCO is not met.

SR 3.0.2 Surveillance intervals can be extended to 1.25 times the interval specified in the frequency with two exceptions:

1. If the frequency is specified as "once", the interval cannot be extended, and
2. If the performance interval applies to a Required Action that is performed on a periodic or cyclic basis, the interval cannot be extended on the first performance.

SR 3.0.3 If a Surveillance is missed and the allowed interval has expired, the affected LCO is not immediately declared not met. A delay period is allowed for the performance of the missed Surveillance. The delay may be up to 24 hours or the Surveillance interval, whichever is greater.

SR 3.0.4 An LCO's Surveillances must have been met before the unit enters a mode in which that LCO applies. When an LCO is not met due to Surveillances not having been met, entry into the Applicability is only allowed in accordance with LCO 3.0.4.

Specifications or OLCs are provided with an LCO, Applicability, Required Actions, and Surveillances that define the safe operating envelope covering the following areas:

- Reactivity Control Systems
- Power Distribution Limits

- Instrumentation
- Reactor Coolant System
- Emergency Core Cooling Systems
- Containment Systems
- Plant Systems
- Electrical Power Systems
- Refueling Operations
- Special Operations

Bases are provided for each Safety Limit and Specification that provide background information associated with the limit, discussion of the applicable safety analyses, description of the LCO, Applicability of the LCO, description of the Required Actions and associated Completion Times for each Action, and associated Surveillance Requirements that verify equipment operability or satisfaction of the LCO criteria.

The combination of information provided for use and application and the Bases for each LCO are sufficient to support training, qualification, and certification of personnel.

## **16.2 Bases for Development**

The Bases for the OLCs are provided for the various parts of Specifications. Inclusion of the Bases is required to satisfy the requirements of CNSC REGDOC-2.5.2 (Reference 16.6-1). The Bases provides information necessary for understanding and implementation of the OLC specification requirements. As such, the Bases are not part of the OLC specifications.

Because the Specifications vary in applicability and requirement, the information provided in the Bases differs accordingly providing the following:

1. Discussion of the safety limits and their relationship to the protection of fuel clad integrity, pressure boundary integrity or containment integrity.
2. A background discussion of each specification that describes the system, limit, or function as it relates to the specification including any limits that are protected by the specification and consequences of exceeding the limit.
3. An applicable safety analyses discussion that discusses the analysis and evaluation from which the specification has been derived including, as applicable, design basis accident and transient analyses, major input assumptions, relationship of the Specification to the analysis acceptance criteria, and the appropriate Specification selection criteria.
4. Discussion of the LCO or Safety Limit) with explanation of why the requirement is appropriate, why it was determined to be the lowest functional capability or performance level necessary for safe operation of the facility, the relationship to the protection of fuel clad integrity, pressure boundary or containment integrity and any other facets of the specification required such as:
  - a. Conditions required
  - b. Number of components required
  - c. Required flow paths
  - d. Parameter requirements

NEDO-33966 REVISION 0  
NON-PROPRIETARY INFORMATION

- e. Exceptions or notes
  - f. Specification violation implications
5. Discussion of the Applicability associated with the LCO with explanation of why compliance is required for the given conditions (e.g., Modes 1, 2, or 3) and why not required during other conditions (e.g., Modes 4, 5, and 6)."
  6. Discussion of Actions including:
    - a. For Required Actions to substantiate acceptability of deviation on the basis that protection is still provided, the probability of an event during the period covered or the Required Actions compensate for specification deviation
    - b. Substantiation of acceptability of Completion Times
    - c. Substantiation of Mode changes requirement and corresponding acceptability
    - d. The basis or source of all numbers in the Required Action
  7. Discussion of how the surveillances demonstrate compliance with the specification requirements including the basis of the specified acceptance criteria, justification for surveillance frequencies and parameter values, relationship to any ASME Section XI requirements (if applicable) and why the surveillance is necessary at the frequency specified.
  8. A list of references that provide more detailed information pertinent to the Specification.

### 16.3 Safety Limits

Safety Limits are limits upon important process variables that are necessary to reasonably protect the integrity of certain physical barriers that guard against the uncontrolled release of radioactivity. The conditions for which the Safety Limit is applicable is provided if required. A violation of any Safety Limit requires restoration of the Safety Limit and insertion of all control rods within a specified time period.

Safety Limits are established for fuel cladding integrity, fuel cooling, and reactor coolant system pressure boundary integrity.

The fuel cladding safety limit is based on establishing a margin to the conditions that produce onset to transition boiling. Because fuel damage is not directly observable, a step back approach is used to establish the safety limit for critical power ratio. A thermal power limit is applicable when less than approximately 4.72 MPaG and a minimum critical power ratio limit when greater than approximately 4.72 MPaG.

The fuel cooling safety limit is based on establishing water level above the top of active irradiated fuel to provide core cooling with margin.

The reactor coolant system pressure boundary integrity safety limit is based on protecting the reactor coolant pressure boundary against overpressurization. In the event of fuel cladding failure and release of fission products into the reactor coolant, the reactor coolant system serves as the primary barrier in preventing fission product release into the atmosphere. Establishing an upper limit on reactor vessel steam dome pressure ensures the reactor coolant pressure boundary integrity.

## **16.4 Requirements for Limits and Conditions for Normal Operation, Surveillance and Testing**

### **Limiting Condition for Operation**

The LCO describes as simply as possible the lowest functional capability or performance level of equipment required for safe operation of the facility. Process parameters required to preserve the assumptions of the safety analysis are also the subject of LCOs. Uncertainties are considered and incorporated, such that the condition(s) specified are sufficient to provide a high degree of assurance that corresponding safety analysis limits are not exceeded.

### **Applicability**

An Applicability statement is included for each LCO that consists of a simple listing of the Modes or Conditions during which the LCO is applicable. The Modes are defined in Appendix 16A.

### **Actions**

Conditions use the term inoperable, where appropriate to describe the failure to meet an LCO. Conditions are broken down into separate statements to describe a single condition unless multiple Conditions have identical Required Actions. Conditions are ordered from the least to most degraded condition. Required Actions are established to restore the parameter to within limits, restore SSCs to operable status, or place the plant in a safe condition within specified Completion Time. The Completion Times for the Required Actions are determined based on reliability and PSA. The Completion Times are established to ensure that any increase to risk is kept to an acceptable level.

### **Surveillance Requirements**

Surveillance Requirements consist of short descriptions of each Surveillance and its Frequency of performance and are tabulated from the shortest to the longest frequency interval. Surveillance Requirements fully identify the requirements appropriate to ensure compliance with the LCO. The frequency of surveillance is based on a reliability analysis, PSA, and previous OPEX. If applicable PSA data is not available for equipment, the reliability assessment is based on supplier recommendations.

## **16.5 Administrative Requirements**

Administrative controls address provisions related to responsibility, organization, unit staff qualifications, procedures, programs and manuals, and reporting requirements, as necessary to assure operation of the facility in a safe manner.

## **16.7 Appendix 16A - BWRX-300 Operational Modes**

### **16.7.1 Modes of Normal Operation of the Plant**

The normal BWRX-300 operating modes are defined corresponding to any one inclusive combination of Reactor Mode Switch position, average reactor coolant temperature, and reactor vessel head closure stud tensioning specified in Table 16.7-1 with fuel in the reactor vessel.

#### **16.7.1.1 Mode 1: Power Operation**

Mode 1, Power Operation, is defined with the Reactor Mode Switch in the "RUN" position at any average reactor coolant temperature. The Reactor Mode Switch is not placed in "RUN" position unless the Nuclear Boiler System (NBS) is pressurized and able to turn the main turbine generator. The transition to Mode 1 normally occurs at 10%-12% rated thermal power. A plant scram occurs at approximately 15% RTP when the Reactor Mode Switch is in the Startup position.

During Power Operation, the reactor water level is controlled by the Reactor Level Control function by adjusting the speed of the operating Reactor Feedwater Pump to maintain a normal reactor water level. The reactor pressure is controlled by the Reactor Pressure Control function using reactor steam dome pressure as the input. Reactor power is controlled by the Rod Control and Information System and the Plant Automation System. Normal power maneuvering occurs by moving control rods to achieve the desired power level.

#### **16.7.1.2 Mode 2: Startup**

Mode 2, Startup, is defined with the Reactor Mode Switch in the "STARTUP" position at any average reactor coolant temperature. Startup Operation is also defined with the Reactor Mode Switch in the "REFUEL" position when all the reactor head closure studs are fully tensioned. With the Reactor Mode Switch in the "STARTUP" position additional protection is in place for low power operation however but this mode allows the reactor to start heating up and pressurizing by withdrawing control rods via the Rod Control and Information System. In the "REFUEL" position, a control rod block prevents the withdrawal of more than two control rods at a time.

#### **16.7.1.3 Mode 3: Hot Shutdown**

Mode 3, Hot Shutdown, is defined with the Reactor Mode Switch in the "SHUTDOWN" position at an average reactor coolant  $>215.6^{\circ}\text{C}$  and all Reactor Pressure Vessel (RPV) head closure studs fully tensioned. When the Reactor Mode Switch is placed into the SHUTDOWN position, a reactor scram signal is sent to the control rods. The scram signal is released after all operable control rods have been fully inserted by the hydraulic scram. Once released, the operator can reset the scram signal (if no other scram signals are present) so that the control rod drive system can recharge the scram accumulators and return flow to the reactor to the normal flow rate. A control rod withdrawal block is maintained any time the Reactor Mode Switch is in the "SHUTDOWN" position. The saturation steam temperature associated with the reactor steam dome pressure is used to determine average reactor coolant temperature if the Shutdown Cooling System (SDC) is not in service. If the SDC is in service, the higher of saturation temperature and SDC supply line temperature is used.

All reactor head closure studs are fully tensioned in this mode. This mode is entered after a reactor scram from any power level once the Reactor Mode Switch position is changed from RUN to SHUTDOWN. This mode is not typically entered during a normal transition from Refueling or Cold Shutdown to Power Operation.

#### **16.7.1.4 Mode 4: Stable Shutdown**

Mode 4, Stable Shutdown, is defined with the Reactor Mode Switch in the "SHUTDOWN" position at an average reactor coolant temperature between  $215.6^{\circ}\text{C}$  and  $93.3^{\circ}\text{C}$  and all RPV head closure

studs fully tensioned. Stable Shutdown Operation can be achieved using passive cooling systems through natural circulation. The saturation steam temperature associated with the reactor steam dome pressure is used to determine average reactor coolant temperature if the SDC is not in service. If the SDC is in service, the higher of saturation temperature and SDC supply line temperature is used. This mode is entered during a normal shutdown to Cold Shutdown. The transitions to Cold Shutdown will require active cooling systems through forced circulation. The reactor head closure studs are fully tensioned in this mode. This mode can also be entered when transitioning from Cold Shutdown to Power Operation during heat up before the hand switch has been repositioned from "SHUTDOWN" to the "STARTUP" position.

#### **16.7.1.5 Mode 5: Cold Shutdown**

Mode 5, Cold Shutdown, is defined with the Reactor Mode Switch in the "SHUTDOWN" position at an average reactor coolant temperature  $\leq 93.3^{\circ}\text{C}$  and all RPV head closure studs fully tensioned. In this mode, the temperature of the reactor coolant system is low, and the isolation condensers are not functional. Decay heat removal is accomplished through the SDC.

#### **16.7.1.6 Mode 6: Refueling**

Mode 6, Refueling, is defined with the Reactor Mode Switch in "SHUTDOWN" or "REFUEL" position, and one or more RPV head closure studs are less than fully tensioned. The reactor is in a subcritical state. In this mode the RPV cannot be pressurized, and the isolation condensers are not able to remove heat. Decay heat can be effectively transferred from the fuel and absorbed by the volume of water present in the RPV and Fuel Pool. Temperature control to allow for effective maintenance is accomplished by use of the SDC and the Fuel Pool Cooling and Cleanup System. The containment is not required to be operable during Refueling.

**Table 16.7-1: BWRX-300 Operational Modes**

<b>Mode</b>	<b>Title</b>	<b>Reactor Mode Switch Position</b>	<b>Average Reactor Coolant Temperature (°C)</b>
1	Power Operation	Run	N/A
2	Startup	Refuel <sup>(1)</sup> or Startup	N/A
3	Hot Shutdown <sup>(1)</sup>	Shutdown	> 215.6
4	Stable Shutdown <sup>(1)</sup>	Shutdown	≤ 215.6 and > 93.3
5	Cold Shutdown <sup>(1)</sup>	Shutdown	≤ 93.3
6	Refueling <sup>(2)</sup>	Shutdown or Refuel	N/A

(1) All RPV head closure studs fully tensioned.

(2) One or more RPV head closure studs less than fully tensioned.

## **17.0 MANAGEMENT FOR SAFETY**

The OPG Nuclear Management System is an Integrated Management System that ensures adequate programs and processes are implemented to enable OPG to meet its objectives. OPG has experience and a proven management system framework that complies with the CSA Group (CSA) CSA N286, "Management System Requirements for Nuclear Facilities" (Reference 17.6-1) and Canadian Nuclear Safety Commission (CNSC), REGDOC-2.1.1, "Management System" (Reference 17.6-2), for its existing nuclear facilities. The OPG Nuclear Management System is established by, N-CHAR-AS-0002, "Nuclear Management System" (Reference 17.6-3). This nuclear charter gives authority to nuclear programmatic governance and describes the governing document framework. OPG will utilize applicable programs from this framework, further described throughout this chapter, that comply with associated CSA N286 (Reference 17.6-1) clauses for each nuclear lifecycle activity for the Darlington New Nuclear Project (DNNP).

### **17.1 General Characteristics of the Management System**

OPG has a mature and effective Nuclear Management System. The goal of Nuclear Management System is to establish the governance framework and processes to support OPG nuclear facilities in achieving their health, safety, environment, security, economic and quality objectives. This management system is part of OPG governance that has a hierarchical structure taking authority from OPG-POL-0032, "Safe Operations Policy" (Reference 17.6-4) and the N-POL-0001, "Nuclear Safety & Security Policy" (Reference 17.6-5).

OPG-POL-0032 (Reference 17.6-4) defines the requirement to establish and maintain management systems to ensure that safe operation is the overriding priority in all activities performed at OPG facilities. This policy outlines requirements and accountabilities for the organization to foster high levels of operating performance and reliability, while ensuring compliance with all legal and regulatory requirements. This policy then gives authority to N-POL-0001 (Reference 17.6-5).

N-POL-0001 (Reference 17.6-5) establishes guiding principles for every OPG nuclear employee, person, or entity that supplies a product or service to OPG's nuclear facilities, from initial conception of a nuclear product, through each lifecycle of the facility. This policy states that nuclear safety and security shall be the overriding priorities in all activities performed in support of OPG nuclear facilities and nuclear safety and security shall have clear priority over schedule, cost, and production. The policy requires that everyone demonstrate respect for nuclear safety and security and conduct themselves in a manner consistent with defined traits of a healthy nuclear safety and security culture. In accordance with the policy, the Chief Nuclear Officer is accountable to the Chief Executive Officer and the Board of Directors to establish a management system that establishes nuclear safety and security as the overriding priorities.

The Nuclear Management System charter, N-CHAR-AS-0002 (Reference 17.6-3), takes authority from the N-POL-0001 (Reference 17.6-5). This charter establishes the Nuclear Management System and provides direction regarding administration of nuclear licensing activities and establishes requirements to which OPG nuclear and interfacing organizations shall comply. The accountabilities of the Nuclear Management System are defined in the charter from overall accountability at the Chief Nuclear Officer level down to employees. The Chief Nuclear Officer is accountable for the establishment, implementation of, and effectiveness of the Nuclear Management System and ensures that a foundation of leadership exists to hold those within nuclear and interfacing organizations accountable for the implementation of, and adherence with, the Nuclear Management System. The charter states that every employee that executes and supports licensed activities associated with OPG nuclear facilities is responsible and shall be held accountable for complying with the expectations of the charter and referenced programs, and for

NEDO-33967 REVISION 0  
NON-PROPRIETARY INFORMATION

ensuring their actions are deliberate and consistent with protecting, the health and safety of the workers, the public, and the environment. This responsibility also applies to every person or entity that supplies a product or service to OPG's nuclear facilities. With the support of employees and the effective implementation of the Nuclear Management System, OPG assures compliance with N-POL-0001 (Reference 17.6-5) by all who may have an impact on nuclear safety.

The charter defines the governing document framework of the Nuclear Management System with both nuclear-specific and interfacing organization programs. Program level documents that take authority from a policy or a charter describe the licensing and regulatory requirements and articulate how requirements are fulfilled. Each program is required to identify both implementing and interfacing documents. Implementing documents such as procedures or standards, that take authority from a policy or program, define processes, activities, or behavioral expectations, that can be either facility specific or apply to the entire fleet. Implementing documents also point to applicable governance support documents such as but not limited to:

- Forms
- Lists
- Instructions
- Manuals

Governance support documents that take authority from a procedure or a standard provide detailed instructions, criteria, or requirements for tasks or activities mandated by a governance document.

The OPG Nuclear Management System was established to ensure effective implementation and compliance with CNSC REGDOC-2.1.1 (Reference 17.6-2), and the requirements set out in CSA N286 (Reference 17.6-1). Both the generic and specific CSA N286-12 (Reference 17.6-1) requirements are fulfilled through the implementation of the programs within N-CHAR-AS-0002 (Reference 17.6-3) and apply to all work for OPG nuclear facilities and interfacing/supporting organizations through a graded approach commensurate with risk. Using a graded risk-based approach, all requirements apply to varying degrees depending upon the safety significance and complexity of the work being performed. If a graded approach is used, the criteria and process used for grading is defined within program governance. While safety is the most significant consideration in risk grading, other criteria may also be used, such as but not limited to consequence of error, design complexity, economics, past performance, or whether the work is First of A Kind or First In A While activity.

The DNNP is a large-scale nuclear project that is governed by the OPG Nuclear Management System. The current, PRSL 18.00/2031, "Power Reactor Site Preparation Licence" (Reference 17.6-6) and associated LCH-DNNP-PRSL 18.00 2031 "Licence Condition Handbook (LCH)" (Reference 17.6-7), require the DNNP to follow applicable programmatic elements of the OPG Nuclear Management System to comply with relevant clauses of CSA N286 (Reference 17.6-1) that support site preparation activities. The scope of site preparation activities that commences the development lifecycle activities includes:

- Construction of site access control measures
- Clearing and grubbing of vegetation
- Excavation and grading of the site
- Installation of services and utilities (domestic water, fire water, sewage, electrical, communications, natural gas) to service the future nuclear facility

NEDO-33967 REVISION 0  
NON-PROPRIETARY INFORMATION

- Construction of administrative and support buildings inside the future protected area
- Construction of environmental monitoring and mitigation systems
- Construction of flood protection and erosion control measures

The DNNP is now preparing for the transition to the construction phase that will complete the development lifecycle of this project. The scope of the construction phase activities that will begin upon issuance of a Licence to Construct includes:

- Completion of any remaining site preparation activities
- Construction and the fuel-out commissioning of a single BWRX-300 reactor nuclear generating facility on the DNNP site
- Construction of equipment and structures, such as cooling water systems, to support up to four reactors on the DNNP site

Following completion of the construction phase, the DNNP will transition to the operational phase that will involve fuel-in commissioning, start-up, and commercial operation of the new reactor. Upon completion of the useful life of the reactor, the end of life phase will involve the decommissioning of the reactor facility. The Nuclear Management System governing the DNNP will evolve over the progression of lifecycle activities described above. Details of this progression are outlined in Section 17.2.

## **17.2 Specific Elements of the Management System**

As stated in Section 17.1, the DNNP has been incorporated into the OPG Nuclear Management System to support the requirements of site preparation activities to start the nuclear development lifecycle. The programs that DNNP is utilizing within the Nuclear Management System, as outlined in the site preparation LCH, are compliant with applicable clauses of CSA N286 (Reference 17.6-1) for site preparation activities. These programs have also been identified as those required for use by the DNNP for the Licence to Construct phase. The programs are listed in Table 17.2-1 followed by high-level descriptions of how the programs support the OPG Nuclear Management System. Further details of how the DNNP will utilize these programs are presented in Subsection 17.2.1.1.

### **Nuclear Management System Administration**

N-PROG-AS-0001 (Reference 17.6-8) describes the integration of programs and processes established by OPG to demonstrate effective implementation and compliance with the requirements set out in CSA N286 (Reference 17.6-1). Programs and processes are created such that all applicable regulatory requirements and codes and standards are embedded and integrated within the Nuclear Management System including aspects of health, safety, environment, security, economics, and quality. Reviews are performed on programs within the Nuclear Management System for their overall effectiveness and opportunities for improvement. This program also ensures that Program Owners and Authorization Authorities understand their role in maintaining an effective management system, and that any Nuclear Management System processes are standardized to the greatest extent possible.

### **Human Performance**

N-PROG-AS-0002 (Reference 17.6-9), establishes a systematic framework for human performance management. This program describes key accountabilities, core processes and related activities associated with the conduct of human performance management across all facets of nuclear within OPG. The goal of the program is to continually reduce the frequency and severity of events through the systematic reduction of human error and the management of defences in pursuit of zero events of consequence.

### **Design Management**

N-PROG-MP-0009 (Reference 17.6-10), provides a framework which ensures that changes to plant design are controlled in a manner consistent with plant design and licensing basis. This program provides assurance that design bases, design outputs and design process documentation are prepared, reviewed, approved, and implemented in accordance with approved procedures, applicable regulatory requirements, standards, and industry practices. This program also allows for design agencies to complete work following the Design Management procedures or to approved procedures taking authority from a quality program that has been approved by OPG.

### **Reactor Safety Program**

N-PROG-MP-0014 (Reference 17.6-11), defines the program elements and organizational responsibilities for the implementation and management of Nuclear Safety Analysis and major components of safe operation. It governs Safety Analysis Basis, Safe Operating Envelope, Beyond Design Basis Accident Management, and Nuclear Waste Management Facilities Safety Reports and Safety Analysis. The development and maintenance of program outputs allow OPG to demonstrate management of nuclear safety throughout the life of its nuclear facilities.

### **Consolidated Nuclear Emergency Plan**

N-PROG-RA-0001 (Reference 17.16.12), implements and maintains OPG's emergency response capability to protect the public, employees, and environment in the event of a nuclear emergency. It provides a framework for interaction with external authorities and defines OPG commitments under the Provincial Nuclear Emergency Response Plan. It also represents a basis for controlling changes and modifications to the OPG Nuclear Emergency Preparedness program.

### **Conduct of Regulatory Affairs**

N-PROG-RA-0002 (Reference 17.6-13), ensures OPG complies with the regulatory requirements in an effective and efficient manner. The program describes the procedures related to licensing, regulatory interpretations, event reporting, regulatory approvals, CNSC inspections, issue management, and communications. This includes broad guidelines for evaluating the impact of licence and permit applications and amendments, providing regulatory and legislative interpretations, and monitoring emerging legislative, regulatory, and industry trends. Successful interface with regulatory agencies is critical in meeting OPG's overall objective for its nuclear fleet. The program defines a set of processes to ensure these expectations are met in an effective and efficient manner.

### **Performance Improvement**

N-PROG-RA-0003 (Reference 17.6-14) consists of organizational learning tools and provides a framework to guide development, assessment, and improvement of the performance of OPG nuclear facilities. The framework of processes includes a means to prevent, detect and correct adverse conditions as well as facilitate the communication of lessons learned. This program covers the key areas of performance improvement, namely, corrective action, self-assessment, benchmarking, operating experience, and nuclear safety culture.

### **Independent Assessment**

N-PROG-RA-0010 (Reference 17.6-15), provides independent assessment processes, in order to perform comprehensive and critical evaluation of all activities affecting OPG nuclear facilities. This program also ensures the Nuclear Management System under N-CHAR-AS-0002 (Reference 17.6-3), is reviewed with sufficient frequency to confirm its continuing effectiveness.

### **Nuclear Security**

N-PROG-RA-0011 (Reference 17.6-16), supports the protection of nuclear assets at OPG in accordance with the legislative requirements, OPG-POL-0032 (Reference 17.6-4) and N-POL-0001 (Reference 17.6-5). This program supports the need to protect nuclear assets by:

- Establishing an enhanced state of security readiness, as a result, of potential terrorism and commitments to the CNSC
- Maximizing the response capability to contain, mitigate, and terminate a security event that has either occurred or is in progress
- Minimizing the adverse impact on nuclear plant staff or operations

### **Safeguards and Nuclear Material Accountancy**

N-PROG-RA-0015 (Reference 17.6-17), puts special controls in place to ensure OPG complies with Canada's commitment to the Nuclear Non-proliferation Treaty consistent with International Atomic Energy Agency (IAEA) requirements for storage and handling of nuclear fuel throughout its lifecycle. The program includes the following:

- Communication protocol between the IAEA, CNSC, and Nuclear
- Processes and reporting to meet applicable regulatory requirements and requirements of associated safeguards procedures

## **Training**

N-PROG-TR-0005 (Reference 17.6-18), applies to regular staff, contractors, temporary personnel, and other staff assigned work under OPG's Nuclear Management System. The program provides the structure, processes, and tools for defining, developing, implementing, documenting, assessing, and improving the training required to ensure nuclear staff have the appropriate knowledge, skill, and attitudes.

## **Information Management**

The Information Management Program, OPG-PROG-0001 (Reference 17.6-19), establishes a set of standards and procedures for the management of OPG's information throughout its lifecycle, regardless of media, including systems such as email, SharePoint, and the Intranet to ensure consistent and appropriate use. It establishes processes for the management, maintenance and final disposition of records and documents, as well as the process for the issuance, distribution, and maintenance of governance.

## **Environment Health and Safety Managed Systems**

OPG-PROG-0005 (Reference 17.6-20), establishes process requirements implemented and maintained in order to ensure OPG activities are conducted in a manner that prevents or mitigates conventional health and safety risks to workers, and/or adverse impacts on the natural environment. This program encompasses OPG's Environmental Management System and Health and Safety Managed System and outlines the associated roles and responsibilities within the organization.

## **Items and Services Management**

OPG-PROG-0009 (Reference 17.6-21), supports supply chain activities across OPG. This program ensures that procurement is planned, and that purchased, stored, and issued items and purchased services meet appropriate design and quality requirements. The program also ensures that items, services, and nuclear fuel are purchased in accordance with requirements and controlled through proper identification, receipt, inspection, handling, storage, issuance, and shipping to ensure quality of equipment and components is preserved.

## **OPG Business Planning**

OPG-PROG-0037 (Reference 17.6-22), establishes the framework within which OPG conducts its annual business planning process. This process directs the organization's resources to meet strategic goals aligned with the company's objectives. The program also describes the chief elements and processes as well as the roles and accountabilities of the groups involved and provides a structure for undertaking business planning activities at OPG. Business plans produced through this program reflect prioritized risks to achieve required objectives and include resources to implement applicable risk treatment plans.

## **Project Management**

OPG-PROG-0039 (Reference 17.6-23), sets out the principles and requirements for planning, organizing, and managing resources to ensure the safe, consistent, effective execution and completion of all projects within OPG. The program is structured to ensure that all projects are managed in a consistent manner in accordance with best practices for project management, interfacing corporate governance, and specific requirements of CSA N286 (Reference 17.6-1) related to project management.

## **Cyber Security**

OPG-PROG-0042 (Reference 17.6-24), establishes a framework identifying the processes and overall requirements for an effective cyber security program that supports the protection of cyber assets at OPG from cyber-attacks. This program also ensures protection of nuclear cyber essential assets.

## **Decommissioning Program**

W-PROG-WM-0003 (Reference 17.6-25), describes controls for the decommissioning of OPG's owned nuclear facilities and provides assurance that work will be planned and controlled in accordance with regulatory requirements. This program outlines the organizational responsibilities, interfaces, and key program elements, requirements, and processes for decommissioning.

### **17.2.1 Facility Development Lifecycle Phases and Activities**

#### **17.2.1.1 OPG's Management System**

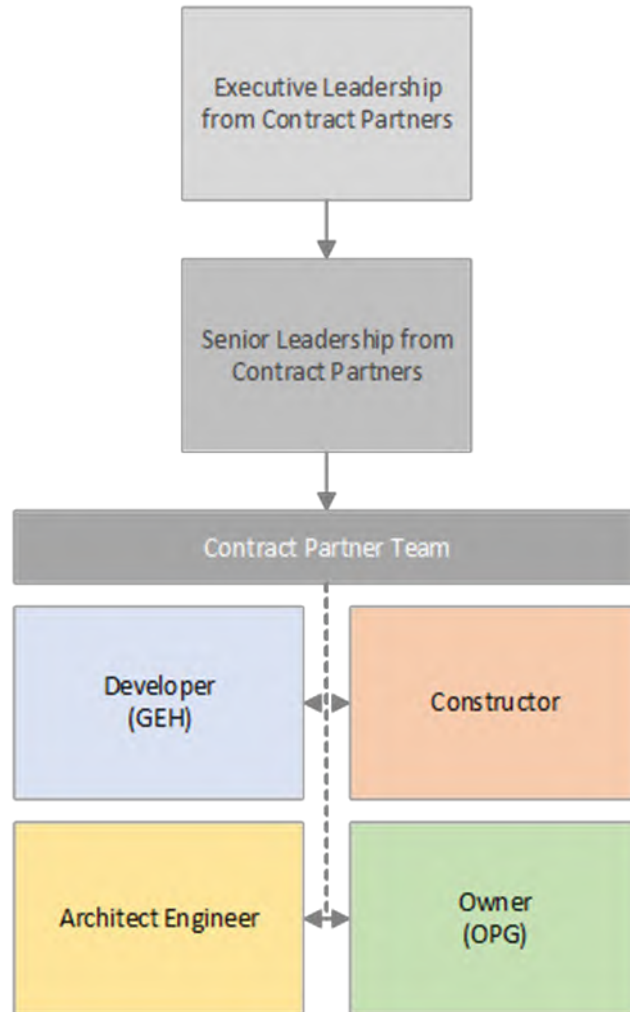

The DNNP will utilize the OPG Nuclear Management System programs listed in Section 17.2 to the extent required of a large-scale nuclear project for the development lifecycle phase. Further details of the use of these Nuclear Management System programs and the basis for selection are described in the, NK054-REP-08130-00004, "DNNP Licence to Construct Management System Report" (Reference 17.6-26).

## **DNNP Program Management**

Following the requirements of OPG-PROG-0039 (Reference 17.6-23), the DNNP has a project governance structure that is described in the NK054-PLAN-01210-00008, "Darlington New Nuclear Project – Program Management Plan" (Reference 17.6-27). This project governance structure includes a project charter, Program Management Plan and Project Management Plans. The Project Management Plan details how DNNP is managed to meet the intent of OPG's Nuclear Management System while establishing program-specific requirements. These plans will be revised routinely as the project progresses to support business planning or significant project milestones. The Project Management Plans describe aspects related to specific sub-projects within the DNNP such as contracting, resourcing, stakeholder management, etc.

## **Project Contract Model**

For the DNNP development lifecycle phase, OPG will utilize a contract model which maximizes integration and collaboration with other contract partners involved with this phase. The contract agreement will describe the relationship and accountabilities of the contract partners including owner, developer, constructor, and Architect Engineer. A visual representation of the contract partner team is provided in Figure 17.2-1 below.

**Figure 17.2-1: Contract Partner Team**

NEDO-33967 REVISION 0  
NON-PROPRIETARY INFORMATION

The roles within the contract partner team are further described below:

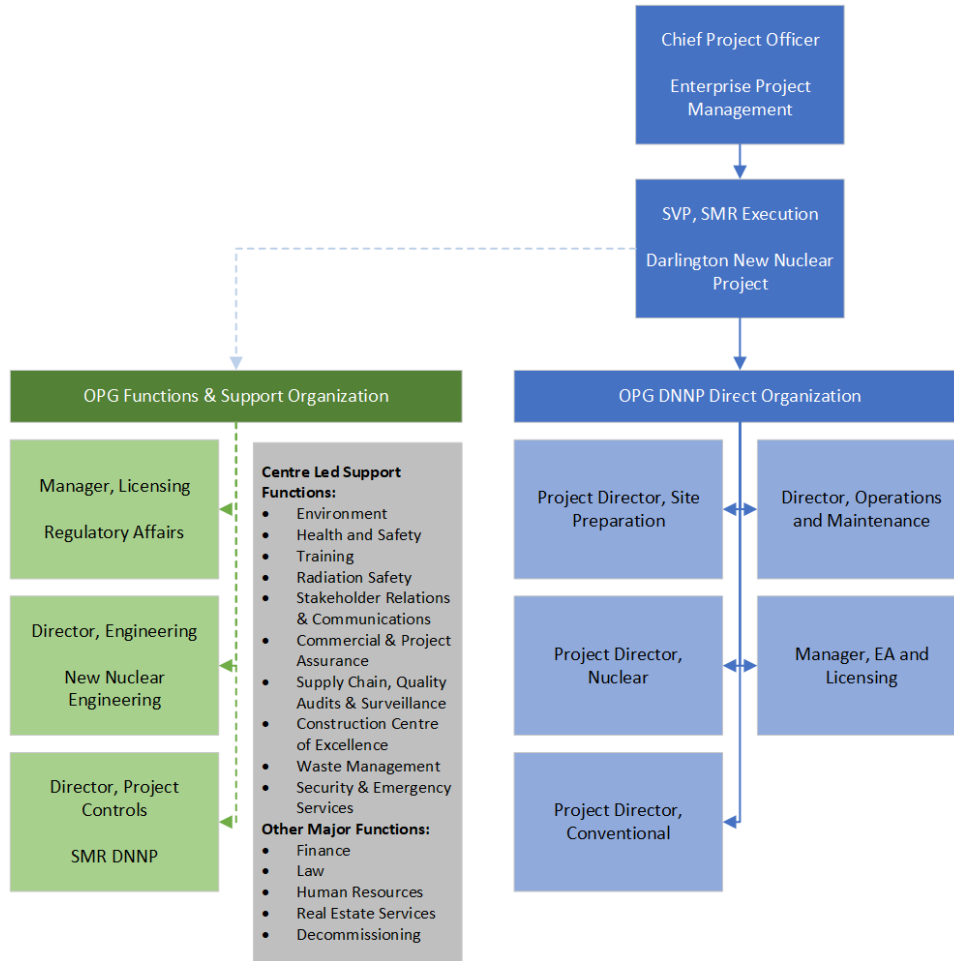

1. The developer (GEH) is the Design Authority for the power block, intake structure, Condenser Cooling Water, and switchyard scope of the project. Activities to be performed by GEH include design, procurement, and commissioning support in accordance with their managed system.
2. The Architect Engineer is responsible for development of the conventional aspects of the detailed design work. The activities associated with this scope include design, procurement, and commissioning support in accordance with their managed system and oversight by GEH as the Design Authority, and OPG as the owner.
3. The constructor is responsible for activities such as procurement, construction, and commissioning that will be performed in accordance with their managed system.
4. The owner (OPG) is also the licensee and is accountable to maintain intrusive oversight and project management of all aspects of the project with increased focus when nuclear safety could be impacted. OPG's Nuclear Management System is utilized to provide the governance, for ensuring contract partners are qualified to perform designated scope throughout the lifecycle of the project per CSA N286 (Reference 17.6-1) requirements. OPG is an informed customer that has developed and continues to increase the in-house knowledge required to provide on-going oversight and technical challenge to ensure licence and regulatory requirements are met. OPG will also retain Design Authority role for areas outside of GEH Design Authority scope, which may involve OPG taking part in similar activities listed above, such as procurement, commissioning support, as applicable. OPG will regain Design Authority for the entire plant prior to start-up.

All contract partners are required to meet the applicable requirements of CSA N286 (Reference 17.6-1) for the activities they will perform. The contract agreement provides information on the applicable management system governance and processes to be met for the licensed construction activities, with OPG continuing to use its Nuclear Management System for oversight and maintain ultimate accountability as the licensee. Project decision making will be prioritized at the appropriate level with escalation of decisions if all contract partner members are not able to agree.

### **OPG's Organization**

OPG has established a project team to manage and oversee the planning and development of the DNNP for the construction of the first Small Modular Reactor (SMR). The organizational structure for the DNNP SMR is presented in Figure 17.2-2. This organizational structure is established to optimize intrusive oversight and project management of all parties for DNNP licensed site preparation and construction activities. It aligns with the contract model which allows for increased collaboration between the owner (OPG), developer (GEH), constructor and Architect Engineer. Owner oversight is maintained separately from the contract partners to ensure independence and ultimate accountability as the licensee. The project team reports under Enterprise Projects to the Chief Project Officer at OPG and contains project management and control staff of the work scope stated in Section 17.1. The project team is supported by dedicated staff that report to fleet organizations. A focus on nuclear safety is maintained throughout the project organization with accountability as the licensee to ensure nuclear safety is maintained as the top priority for all contract partners.

NEDO-33967 REVISION 0  
NON-PROPRIETARY INFORMATION

**Figure 17.2-2: Current Organizational Structure for DNNP Small Modular Reactor Organization**

## **Authority Roles**

At all times, OPG will retain overall accountability for the licensed activities conducted during the development lifecycle phase. As stated previously, the Developer-GEH is the Design Authority of the power block (nuclear and conventional systems in the powerhouse), Condenser Cooling Water, the intake structure, and switchyard systems and structures during the design, construction, inspection and testing, and fuel-out commissioning phases. OPG will provide oversight in the areas of nuclear safety, safe operating envelope, design bases, and licensing basis. Interface requirements between GEH Design Authority scope and OPG Design Authority (DNNP Engineering Director) scope and accountabilities shall be determined to ensure the division of responsibilities between Design Authority scope interfaces. This will be detailed in documents such as a Contract owner Interface Requirements document and detailed interface specifications. Collaborative planning will be required to ensure appropriate input, specifications, communication, Quality Assurance (QA), oversight, and approvals are provided and documented for interfacing systems for both Design Authorities. OPG will retain Design Authority for areas outside of GEH Design Authority scope and be accountable for interface management between the power block and the remaining site works. A turnover strategy describes the transition of the GEH Design Authority to OPG Design Authority prior to plant start-up as per CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants," Section 5.1 (Reference 17.6-28). Design documents will be issued into the OPG approved information management system as part of the Design Authority turnover.

The constructor will lead construction activities with support from GEH and oversight from OPG. Further details of construction and commissioning activities can be found in Chapter 14.

The Operational Authority resides with OPG and authorities of the constructor including site security and health and safety management will transition to the Operational Authority during the construction phase. Further operations aspects of the DNNP can be found in Chapter 13.

## **Oversight**

OPG DNNP Engineering must ensure appropriate interfaces and oversight protocols, as required by N-PROG-MP-0009 (Reference 17.6-10), are maintained throughout the design, procurement, installation, commissioning, and closeout phases. This is required to ensure awareness of activities and decisions in the areas of nuclear safety, safe operating envelope, design basis, and licensing basis. Additionally, this ensures compliance with design requirements, owner's requirements, and managed systems. Level of oversight, support, and depth of planning activities follow a graded approach proportional with the level of risk to DNNP, the complexity of the design, the design's effect on safety, and the past performance of the contractor(s) involved.

Additional intrusive oversight will be provided on interfacing areas between GEH Design Authority and OPG Design Authority. Oversight activities may include but are not limited to:

- Frequent design meetings with GEH at working level
- Review and input on design documentation by Subject Matter Experts
- Completion of oversight reports on Structures, Systems, and Components (SSC)
- Challenge meetings at the end of design phases
- Documented acceptance processes

Non-engineering governance and oversight is governed and performed by other executing organizations, as defined in NK054-PLAN-01210-00008 (Reference 17.6-27) and various Project Management Plans.

As GEH is currently under contract with OPG to perform development lifecycle activities for the DNPP, a description of the GEH management system is provided in Subsection 17.2.1.2.

#### **17.2.1.2 GEH Management System**

GEH is committed to the safety of its employees and the public above all other demands. GEH is committed to achieving the highest quality products and services through the disciplined application of the GEH Quality Management System.

GEH maintains an Integrated Management System documented in the Quality Assurance Program Description (QAPD) and its associated implementing procedures. Together they provide for control of GEH activities that affect the quality of nuclear plant SSC and include all planned and systematic activities necessary to provide adequate confidence that such SSC will perform satisfactorily in service.

The QAPD is divided into the following parts:

- Part I: Introduction
- Part II: QAPD Details
- Part III: Supplemental Details
- Part IV: Regulatory Commitments

**Part I** provides a high-level description of the scope and applicability of the QAPD.

**Part II** describes the portion of the Quality Management System that is required to meet the regulatory requirements. Specifically, it applies to activities involving nuclear facility (e.g., nuclear power plants and fuel reprocessing plants) SSC that prevent or mitigate the consequences of postulated accidents that could cause undue risk to the health and safety of the public. Part II has been developed to comply with regulatory requirements of the United States of America, specifically 10 CFR Part 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants," (Reference 17.6-29) 10 CFR Part 71 Subpart H, "Quality Assurance," (Reference 17.6-30) 10 CFR Part 21, "Reporting of Defects and Noncompliance," (Reference 17.6-31) and American Society of Mechanical Engineers (ASME) NQA-1, "Quality Assurance Requirements for Nuclear Facility Applications" (Reference 17.6-32). Part II is structured in 18 sections that align with 10 CFR 50, Appendix B (Reference 17.6-29) criteria and ASME NQA-1 (Reference 17.6-32) requirements (Reference 17.6-32).

Each of the 18 sections are described below.

**Part III** describes the supplemental portions of the Quality Management System that are not specifically addressed by 10 CFR 50, Appendix B (Reference 17.6-29) or ASME NQA-1 (Reference 17.6-32) to create an integrated quality program for projects that may refer to ISO 9001, "Quality Management Systems - Requirements" (Reference 17.6-33), IAEA GSR Part 2, "Leadership and Management for Safety" (Reference 17.6-34), KTA-1401, "General Requirements for the Quality Assurance" (Reference 17.6-35), or other standards as applicable.

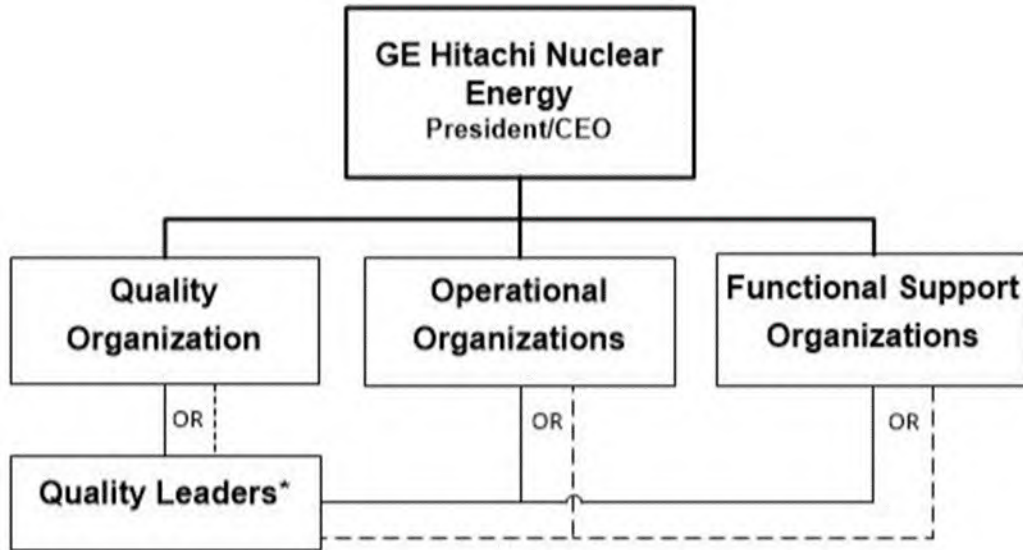

NEDO-33967 REVISION 0  
NON-PROPRIETARY INFORMATION

**Part IV** lists the regulations, standards, and guidance that General Electric companies are committed to comply with through the implementation of the QAPD and its associated implementing procedures.

The GEH management system has been assessed for compliance with the applicable elements of CSA N286 (Reference 17.6-1), CSA N286.7, "Quality Assurance of Analytical, Scientific, and Design Computer Programs" (Reference 17.6-36), and CSA N299.1, "Quality Assurance Program Requirements for the Supply of Items and Services for Nuclear Power Plants, Category 1," (Reference 17.6-37). Mapping is documented in Gap Analysis of GEH Quality Management System for Compliance to CSA N286 (Reference 17.6-1), CSA N286.7 (Reference 17.6-36) and CSA N299.1 (Reference 17.6-37) and are addressed through the implementation of GEH Project Quality Plan for DNNP described in Section 17.3.1.2.

#### Section 1 – Organization

The QAPD, Section 1, establishes the requirements for the organizational structure, functional responsibilities, levels of authority and interfaces for establishing, executing, and verifying the QAPD. The GEH organizational structure for the purposes of managing its Quality Management System is shown in Figure 17.2-3.

\*May report directly or indirectly to SVP of Quality for matters affecting Nuclear Quality; Ref. QAPD Section 1.4.2.6

**Figure 17.2-3: GEH Organizational Structure**

**Operational Organizations** are segments of the broader GEH organization that are established to comply with the regulatory requirements and are responsible for:

- Project management
- Product and services management and delivery
- Continued plant operations support
- Development of new plants, technologies, and related services

Functional Support Organizations are responsible for facilitating and supporting the activities of the Operational Organizations. Functional Support Organizations perform key functions such as quality, Engineering, Manufacturing Operations and Sourcing. Additional support functions include, but are not limited to, Sales, Commercial Operations, Finance, Human Resources, Legal/Compliance, and Government Affairs.

The Quality Organization is responsible for managing and supporting implementation of the Quality Management System and the QAPD with responsibility for quality programs and quality oversight.

Quality Leaders are responsible for supporting the implementation of the quality requirements set forth in this QAPD by verifying that administrative controls are implemented or by assuring that an activity has been correctly performed within their assigned organizations. Verification and assurance activities may include the supervision and oversight of quality engineers, inspection personnel, and the inspections or verification activities performed by independent parties. Quality Leaders typically report to the Quality Organization and indirectly to the Operational or Functional Organizations but, if required, may report directly to the Operational or Functional Organizations.

## Section 2 – Quality Assurance Program

The QAPD, Section 2, establishes the requirements for the QA program, as documented through the QAPD and GEH governance framework.

The GEH governance framework is a hierarchal set of documents known as ‘GEH Procedure Hierarchy’ that is comprised of Defining Documents, Implementing Documents, and Supporting Documents described as follows:

1. **Defining Documents** are the highest tier of documents that establish requirements and commitments. Examples include policies, directives, process descriptions, manuals, and plans.
2. **Implementing Documents** are the middle tier of documents that include steps or instructions that must be executed to meet requirements or commitments. Examples include procedures and work instructions.
3. **Supporting Documents** are the lowest tier of documents that supplement Defining or Implementing Documents that provide and offer content enhancement or clarifying instruction. Examples include forms, charters, guides, handbooks, job aids, lists, templates, and training materials.

### Section 3 – Design Control

The QAPD, Section 3, establishes the requirements for design control including the control of design inputs, design processes, design analyses, design verification, change control, interface control, and documentation and records.

The goal of design control is to ensure the design of nuclear facilities and their associated design documents meet all applicable technical requirements, regulatory requirements, codes and standards, and contractual requirements.

### Section 4 – Procurement Document Control

The QAPD, Section 4, establishes the requirements for ensuring that sufficient technical, quality, and regulatory requirements are included or referenced in the documents for procurement of items and services.

### Section 5 – Instructions, Procedures, and Drawings

The QAPD, Section 5, establishes the requirements to ensure that activities affecting quality are prescribed by and performed in accordance with implementing procedures or work instructions.

### Section 6 – Document Control

The QAPD, Section 6, establishes the requirements to ensure the control of the preparation, issuance, and changes to documents that specify quality requirements or prescribe how activities affecting quality, including organizational interfaces, are controlled to ensure that correct documents are being employed.

### Section 7 – Control of Purchased Material, Equipment and Services

The QAPD, Section 7, establishes the requirements to ensure that purchased items and services meet specified requirements.

### Section 8 – Identification and Control of Materials, Parts, and Components

The QAPD, Section 8, establishes the requirements to provide for the identification and control of materials, parts, and components.

### Section 9 – Control of Special Processes

The QAPD, Section 9, establishes the requirements for the control of special processes such as welding, heat treating, and nondestructive examination.

### Section 10 – Inspection

The QAPD, Section 10, establishes the requirements for the inspection of items and activities to verify conformance to requirements and adherence to documented instructions, procedures, and drawings.

### Section 11 – Test Control

The QAPD, Section 11, establishes the requirements to control testing, to collect data such as for design input or to verify conformance of an item to specified requirements, or to demonstrate satisfactory performance for service.

### Section 12 – Control of Measuring and Test Equipment

The QAPD, Section 12, establishes the requirements, including the procedures, to control the calibration, maintenance, storage, and use of Measuring and Test Equipment.

#### Section 13 – Handling, Storage, and Shipping

The QAPD, Section 13, establishes the requirements to control the handling, storage, packaging, cleaning, shipping, and preservation of items to prevent inadvertent damage or loss, and to minimize deterioration.

#### Section 14 – Inspection, Test and Operating Status

The QAPD, Section 14, establishes the requirements to identify the inspection and test status of individual items and for indicating the operating status of equipment, such as valves and switches. Implementing procedures specify the authority for the application and removal of these status indicators.

#### Section 15 – Control of Nonconforming Items

The QAPD, Section 5 establishes the requirements to control nonconforming items and to prevent inadvertent installation or use.

#### Section 16 – Corrective Action

The QAPD, Section 16, establishes the requirements to establish the necessary measures to promptly identify, control, document, classify, and correct Conditions Adverse to Quality.

#### Section 17 – Quality Assurance Records

The QAPD, Section 17, establishes the requirements to provide provisions for the identification, administration, receipt, storage, preservation, safekeeping, retrieval, and disposition of all records such that damage or loss does not occur.

#### Section 18 – Audits

The QAPD, Section 18, establishes the requirements to verify compliance to QA program requirements, to verify that performance criteria are met, to determine the effectiveness of the program, and to provide a comprehensive independent evaluation of activities and procedures through an established audit program.

### **17.2.1.3 Constructor and Architect Engineering Firm Management System**

Additional organizations outside of OPG or GEH contracted to perform work for the DNNP, such as the Constructor and Architect Engineering Firm, will be required to meet applicable clauses of CSA N286 (Reference 17.6-1) based on their scope of work as defined in associated contractual agreements.

Oversight of such requirements by OPG, will be performed through the processes outlined in OPG-PROG-0009 (Reference 17.6-21).

### **17.2.2 Facility Operational Lifecycle Phases and Activities**

The operational lifecycle phase for the DNNP will consist of activities such as the loading of nuclear fuel, fuel-in commissioning, start-up, and commercial operation of the nuclear facility. During this lifecycle phase, operational programmatic governance will be required to be in place prior to use. Analysis will be completed and included as part of the Licence to Operate application to ensure this operational governance will meet all applicable regulatory requirements, as well as meet the needs of the BWRX-300 reactor technology and facility organizational structure. Operational programmatic governance will include the creation of an Out of Core Criticality program that is a requirement from CNSC REGDOC-2.4.3, “Nuclear Criticality Safety” (Reference 17.6-38).

### **17.2.3 Facility End of Life Lifecycle Phases and Activities**

The end of life lifecycle phase for the DNNP will consist of decommissioning the nuclear facility. Analysis will be completed and included as part of the Licence to Decommission application to ensure that required programmatic governance will meet all applicable regulatory requirements for this lifecycle phase. If vendors are involved during this phase, similar to the development lifecycle phase, their management system requirements based on their scope of work will be defined in contractual agreements.

### 17.3 Quality Management

Within the OPG Nuclear Management System there are several programs that support the quality management of projects such as the design and construction of a new nuclear facility. These programs include OPG-PROG-0039 (Reference 17.6-23), N-PROG-MP-0009 (Reference 17.6-10), and OPG-PROG-0009 (Reference 17.6-21).

OPG-PROG-0039 (Reference 17.6-23), as described in Section 17.2, establishes how the requirements, objectives, and commitments for the management of projects are fulfilled. Such project requirements include the need to follow an appropriate quality program, and that safety and quality take higher priority and are not compromised over schedule or cost. Under this program, any project work performed by a contractor shall be done under an OPG evaluated quality program that meets specified requirements. This may be a singular or multiple documents (manuals, plans, procedures, etc.) that include how they will manage quality through the lifecycle of the contract, how they will apply informed customer principles to procured services and pass quality requirements through to suppliers. The planned measures must also describe controls in their own management system required to execute the contract.

Design activities for a nuclear facility are governed by N-PROG-MP-0009 (Reference 17.6-10), either through full utilization of this program, or in accordance with a contractor quality program approved by OPG. OPG is required to monitor and assess design activities to confirm compliance with procedures.

A contractor's quality program must meet requirements such as CSA N299 (Reference 17.6-37), applicable elements of CSA N286 (Reference 17.6-1), or other appropriate quality standards for the contracted work as stated in contractual agreements. As per the OPG-PROG-0009 (Reference 17.6-21) a contractor's qualification is established based on codes, standards and design and quality requirements. OPG conducts contractor prequalification assessments to evaluate this quality program and performs qualification audits to verify that the contractor's management system meets requirements of CSA N286 (Reference 17.6-1) and other QA requirements as required. The deliverables identified in a contract will be completed under the contractor's programs, and then reviewed and accepted by OPG. OPG applies an informed customer approach. Utilizing this approach, OPG is responsible to clearly define requirements for the procured items/services and control of the supply chain leading to work completion, to monitor work execution and oversee the quality of subcontracted work, including technical review of the work performed by contractors during and after work was completed. Such an oversight is accomplished by a set of processes which includes:

- Supplier evaluation and selection
- Supplier monitoring and Quality Surveillance
- Evaluation and release of final product

Contractors will provide quality control per their quality plans and will have processes to address identified non-conformances. OPG will provide Quality Surveillance ensuring contractor compliance with their quality plans. Quality Surveillance provides assurance that contractor activities meet the specified requirements of the accepted quality standard requirement and OPG's Nuclear Management System.

### **17.3.1 Facility Development Lifecycle Phases and Activities**

#### **17.3.1.1 OPG Quality Management**

Details of how OPG's quality management processes are implemented in the Nuclear Management System are described above in Section 17.3. OPG as the owner and licensee is accountable for the quality program framework and governance that assures compliance with the OPG Nuclear Management System, and for the oversight of design, procurement, construction, and commissioning activities for the DNNP. OPG's oversight activities of a contractor's quality program will ensure that regulatory and contractual requirements are met and that the work is performed by qualified staff.

For the development lifecycle phase, the DNNP shall be implemented using a graded approach commensurate with risk in application of QA requirements as defined in CSA N286 (Reference 17.6-1).

Utilizing OPG's experience with large projects such as the Darlington Refurbishment, the Quality Surveillance process will be implemented using a Systematic Approach to Project Surveillance. This process will be implemented on a risk and sampling basis to address quality and regulatory requirements.

As the project progresses, details on how DNNP will meet the intent of OPG's Nuclear Management System and description of program-specific requirements, including quality management, are introduced in NK054-PLAN-01210-00008 (Reference 17.6-27).

As stated in Section 17.3, any organization outside of OPG contracted to perform project work, such as development lifecycle activities for the DNNP, is required to meet specified quality standard requirements as defined in associated contractual agreements. These are evaluated in accordance with procurement activities required by OPG-PROG-0009 (Reference 17.6-21). As GEH is currently under contract with OPG to perform development lifecycle activities and is the primary contributor of design of the DNNP, a description of the GEH Quality Management System is provided in Subsection 17.3.1.2.

#### **17.3.1.2 GEH Quality Management**

GEH has an established and robust design management and control process that is part of the Integrated Management System described in Section 17.2.1.2 that will be utilized for the development of the BWRX-300 Facility. The design of the BWRX-300 for DNNP will be implemented, using a graded approach, through the following project specific plans:

- DNNP Quality Management Plan
- DNNP Design Management Plan
- DNNP Project Management Plan

The above plans, along with the GEH management system, work together to ensure all requirements of the BWRX-300 facility at the DNNP site are safely and economically implemented in a timely manner.

#### **Quality Management Plan**

GEH activities performed for the DNNP BWRX-300 facility are controlled in accordance with a quality management plan. In the context of the quality management plan, the USNRC approved QAPD is referred to as the GEH Quality Assurance Program.

The quality management plan supplements the QAPD to assure that GEH activities performed for the DNNP comply with project specific (i.e., OPG and CNSC) quality requirements.

The GEH QAPD has been evaluated to CSA N286-12, CSA N286.7, and CSA N299.1-16. Identified gaps are addressed through the implementation of the quality management plan.

The selection of quality requirements for the BWRX-300 facility is governed by the quality management plan.

### **Design Management Plan**

GEH design activities are conducted and controlled in accordance with a design management plan.

The key elements of the Design Management plan that are important to the management of safety are implemented in accordance with supporting plans specific to:

- Design authority
- Requirements Management
- SSC Classification
- Research and Development
- Configuration Management
- Information Management

The above supporting plans are further described below.

### **Design Authority**

The prime responsibility for safety of the facility rests with OPG which is the owner, Operator, and licensee. This responsibility includes design activities performed by OPG and the oversight of design activities performed by contracted organizations, such as GEH.

The Design Authority is the entity that has overall responsibility for the management of design including approving design changes, defining and controlling the design basis, maintaining configuration control, ensuring work is performed by qualified and competent people/organizations, and ensuring that the requisite knowledge is maintained. OPG has identified GEH as Design Authority for scope of work defined by contractual arrangements.

### **Requirements Management**

The approach for managing the flow down of the plant requirements to the system level and respective component level requirements.

Requirements Management tracks the requirements and their attributes from identification to validation and testing. The following are the main objectives of Requirements Management:

Traceability: Establish relationship between requirements and verification and validation.

Change Impact Assessment: Facilitate determination of impact on upstream and downstream requirements when design changes are proposed.

Completeness of Design: Provide confidence that stakeholder requirements are fulfilled in the body of design documentation. This aspect of Requirements Management is sometimes referred to as “forward traceability,” which results in an auditable trail of requirements in the design documentation and evidence that the completed design meets the requirements.

Control of Scope: Help prevent introduction of functions and features that are not required by imposing discipline during the design process such that requirements are not introduced without a basis. This aspect of Requirements Management (RM) is sometimes referred to as “backward traceability.”

Consistency: A defined RM strategy helps ensure that various organizations and disciplines have a common understanding about how requirements are managed, how the requirements architecture is used, and how the RM tools are used.

### **Structures, Systems, and Components Classification**

The BWRX-300 approach to classifying SSC is based on the classification principles contained in IAEA SSR-2/1, “Safety of Nuclear Power Plants: Design” (Reference 17.6-39) and IAEA SSG-30, “Safety Classification of Structures, Systems, and Components in Nuclear Power Plants” (Reference 17.6-40).

See Chapter 3, Section 3.2 for details of the BWRX-300 SSC Classification Methodology.

### **Research and Development**

Research and Development activities are those that support the development and deployment of the BWRX-300.

The BWRX-300 is an evolution of the USNRC certified Economic Simplified Boiling Water Reactor (ESBWR), and existing Boiling Water Reactors (BWR). Operating experience for the fleet of BWRs, Advanced Boiling Water Reactors (ABWR), ESBWR licensing, and decommissioning of BWRs are applied to the BWRX-300 design.

The BWRX-300 Research and Development program applies to all phases of the BWRX-300 lifecycle. The use of Research and Development activities and operating experience to shape BWRX-300 design, testing, and operations decisions is an effort that is not expected to end until all related units have been decommissioned.

The Research and Development program is part of the design process that is part of the GEH management system; however, not all activities in the Research and Development program are considered design activities. The GEH Quality Assurance Program requirements are applied to Research and Development program activities commensurate with the importance of the activity to safety.

### **Configuration Management**

Configuration Management is established and maintained to ensure the design basis of the facility is effectively managed throughout the development of the BWRX-300 Power Block at the DNNP site. It is a key element that ensures the responsibilities of the Design Authority role are sufficiently performed.

An important objective of Configuration Management is to ensure that accurate and current information is available in a timely manner to allow a responsible individual to make safe, knowledgeable, and cost-effective decisions.

NEDO-33967 REVISION 0  
NON-PROPRIETARY INFORMATION

American National Standards Institute/Nuclear Information and Records Management Association (ANSI/NIRMA) CM 1.0, "American National Standard Guidelines for Configuration Management for Nuclear Facilities" (Reference 17.6-41), defines Configuration Management as the systematic approach for identifying, documenting, and changing the characteristics of a Plant's SSC and ensuring that conformance is maintained between the Design Requirements, Physical Configuration, and Facility Configuration Information. This concept is illustrated in Figure 17.3-1 showing that the Configuration Management equilibrium is established when, "what needs to be there" conforms to "what we say is there" conforms to "what is actually there."

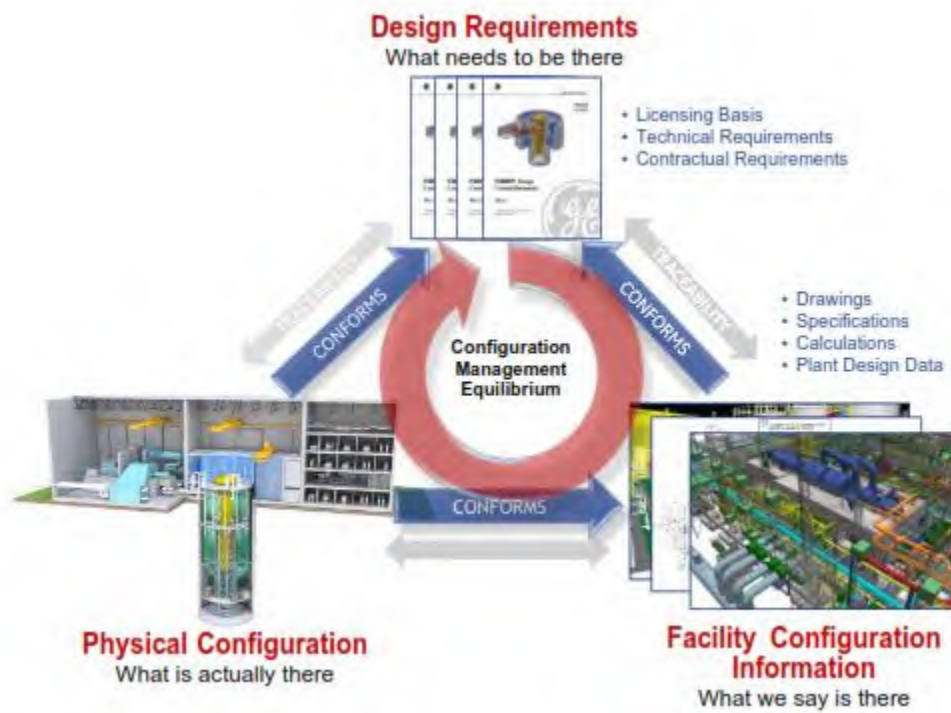

Figure 17.3-1: Configuration Management Model

## **Information Management**

Information management provides the framework, strategy, and implementation plan to deploy and support the overall setup and configuration of the Content Management System for the development of the BWRX-300 at the DNNP site.

Information Management, Design Requirements and Configuration Management work together to ensure Configuration Management equilibrium is achieved.

## **Project Management**

A Project Management Organization is established to plan, execute, control, and monitor work activities; drive conceptual design and estimating objectives; and ensure work is performed in accordance with project requirements. For the purposes of the QAPD, the Project Management Organization is the Operating Organization for the OPG project.

The project work plan is further supported by additional sub-ordinate tools that are key to the management of safety, including but not limited to:

- Project procurement
- Risk management

## **Project Procurement**

Project procurement supports GEH procurement activities performed during the development of the BWRX-300 at the DNNP site.

Its purpose is to provide programmatic instructions and non-technical guidance to GEH team members for preparation and issuance of purchase and construction specifications, development of procurement packages for requests for proposals and request for quotations to potential suppliers, bid evaluations, and contract administration with the selected supplier(s) until delivery of equipment to Darlington OPG Site using established processes for the BWRX-300 project application.

The procurement process is adequately evaluated and reviewed throughout the project lifecycle to ensure the project includes proper strategies, communication, planning, decision making, and timely implementation of project requirements leading to the success of the overall project.

## **Risk Management**

Project risk management describes how the risk management process will be structured and performed for the development of the BWRX-300 and its deployment at the DNNP site.

Risk Management provides a formal process that follows the Project Management Book of Knowledge Guide that will help reduce the overall project risk exposure and increase the likeliness of achieving the project's requirements, cost, and schedule objectives. Along with documenting the process of identifying, assessing, treating, and monitoring risks, key personnel, key performance indicators, review update frequencies, and reporting requirements.

### **17.3.1.3 Constructor and Architect Engineering Firm Quality Management**

The Constructor and Architect Engineering Firm will be required to meet specified quality standard requirements based on their scope of work as defined in associated contractual agreements.

Oversight of such requirements by OPG, will be performed through the processes outlined in the Items and Services Management Program, OPG-PROG-0009 (Reference 17.6-21).

### **17.3.2 Facility Operational Lifecycle Phases and Activities**

The DNNP that will transition from a project to a nuclear facility during the operational lifecycle phase will require operational programmatic governance to be in place prior to use. This transition may warrant changes to the quality management processes. Any required changes to associated governance to support this lifecycle phase will be analyzed as part of the Licence to Operate application process.

### **17.3.3 Facility End of Life Lifecycle Phases and Activities**

The quality management processes utilized by the future DNNP facility may evolve over the lifetime of the facility and continue to meet regulatory requirements. Any required changes to related governance to support this lifecycle phase will be analyzed to support the Licence to Decommission application process.

## **17.4 Measurement, Assessment, and Improvement of the Owner Management System**

OPG is the owner and the licence applicant for the DNNP project. The OPG Chief Nuclear Officer is accountable for the effectiveness of the overall Nuclear Management System and ensuring compliance with the requirements set out in CSA N286 (Reference 17.6-1). The following lists applicable programs given authority from N-CHAR-AS-0002 (Reference 17.6-3) that support the measurement, assessment, and continual improvement of the Nuclear Management System (descriptions of these programs can be found in Section 17.2).

- N-PROG-AS-0001 (Reference 17.6-8)
- N-PROG-RA-0010 (Reference 17.6-15)
- N-PROG-RA-0003 (Reference 17.6-14)

### **17.4.1 Facility Development Lifecycle Phases and Activities**

#### **17.4.1.1 OPG Management, Assessment, and Improvement of the Management System**

Details of how OPG measures, assesses, and improves its Nuclear Management System are described in Section 17.4. For the development lifecycle phase, the DNNP will utilize these programs. As these programs primarily support the Nuclear Management System effectiveness at the program or fleet/site level, the DNNP, will utilize a subset of the Nuclear Management System programs as described in Section 17.2, to the extent required of a project not performing any nuclear activities during this lifecycle phase.

Any documentation that may be produced to support the contract partners for the development lifecycle phase, that could have potential to benefit the operational lifecycle, will be analyzed for inclusion into the programs and/or processes to be utilized by the future nuclear facility as part of the Licence to Operate application process.

As GEH is currently under contract with OPG to perform development lifecycle activities for the DNNP, a description of the GEH performance improvement elements is provided in Subsection 17.4.1.2.

#### **17.4.1.2 GEH Performance Improvement Elements**

Performance Improvement is an integral element of the GEH management system.

As described in Subsection 17.2.1.2 above, Section 16 of the QAPD (further described below) establishes the requirements to establish the necessary measures to promptly identify, control, document, classify, and correct Conditions Adverse to Quality.

The GEH Corrective Action Program utilizes a system of implementing procedures to establish the necessary measures to promptly identify, control, document, classify, and correct Conditions Adverse to Quality.

Implementing procedures for the Corrective Action Program ensure that:

1. Corrective actions from audits and self-assessments, and non-conformances are analyzed to detect conditions or potential Conditions Adverse to Quality
2. Changes in processes or procedures resulting from corrective and preventive actions are implemented and recorded

The Corrective Action Program and related tools are utilized to document, track status, and maintain records of corrective and preventive action activities and results.

Reports of Conditions Adverse to Quality are analyzed to identify trends in quality performance.

Significant conditions and trends adverse to quality are reported to the appropriate level of management.

As described in Subsection 17.2.1.2 above, Section 18 of the QAPD establishes the requirements and processes for a comprehensive audit program to verify implementation of and compliance to all aspects of the quality system including its adequacy and effectiveness. The audit program requirements apply to activities affecting the quality of services, hardware, software, and personnel who perform related activities or may affect quality. Project surveillances are planned, executed, and recorded to evaluate through investigation or examination, the adequacy of activities (design, manufacturing, quality processes, etc.) and the compliance to established procedures, instructions, and other applicable documents.

GEH conducts annual reviews of its management system to ensure its suitability, adequacy, and effectiveness. The review team assesses opportunities for improvement and the need for changes to the quality system, including quality policy and quality objectives.

The performance improvement elements described above are implemented through established processes and provide for a continuous evaluation of the GEH management system to achieve desired business performance.

#### **17.4.1.3 Constructor and Architect Engineering Firm Performance Improvement Elements**

Additional organizations outside of OPG or GEH contracted to perform development lifecycle activities the DNNP, such as the Constructor and Architect Engineering Firm, will be required to meet specified requirements for the measurement, assessment and improvement of their management system based on their scope of work as defined in associated contractual agreements.

Oversight of such requirements by OPG, will be performed through the processes outlined in the OPG-PROG-0009 (Reference 17.6-10).

#### **17.4.2 Facility Operational Lifecycle Phases and Activities**

The DNNP that will transition from a project to a nuclear facility during the operational lifecycle phase, will require operational programmatic governance to be in place prior to use. This transition must maintain the requirement for the measurement, assessment, and improvement of the management system to be in place for the operating life of the facility. Any required changes to associated governance to support this lifecycle phase will be analyzed as part of the Licence to Operate application process.

#### **17.4.3 Facility End of Life Lifecycle Phases and Activities**

The programs and associated processes involved with the measurement, assessment, and improvement of the Nuclear Management System utilized by the future DNNP facility may evolve over the lifetime of the facility and continue to meet regulatory requirements. Any required changes to associated governance to support this lifecycle phase will be analyzed to support of the Licence to Decommission application process.

## **17.5 Fostering a Culture for Safety**

As required by CSA N286 (Reference 17.6-1), and in compliance with CSNA REGDOC-2.1.2, "Safety Culture" (Reference 17.6-42), a management system shall be used to understand and promote a safety culture in every phase of a nuclear facility lifecycle. N-POL-0001 documents OPG's commitment to fostering a safety and security culture and gives authority to the Nuclear Management System. The policy states that:

"Nuclear Safety and Security shall be the overriding priority in all activities performed in support of OPG nuclear facilities. Nuclear Safety shall have clear priority over schedule, cost, and production."

As defined in the policy, the Chief Nuclear Officer is accountable to the Chief Executive Officer and the Board of Directors to establish a management system that fosters nuclear safety and security as the overriding priority. In addition, OPG commits to conducting comprehensive, systematic, and rigorous safety culture assessments at least every 5 years. The policy also makes everyone accountable to conduct themselves in a manner consistent with the following nuclear safety & security culture traits:

- Personal Accountability
- Questioning Attitude
- Effective Safety Communication
- Leadership Safety Values and Actions
- Decision Making
- Respectful Work Environment
- Continuous Learning
- Problem Identification and Resolution
- Environment for Raising Concerns
- Work Processes
- Vigilance

Receiving authority from this policy, N-CHAR-AS-0002 (Reference 17.6-3) defines the framework that establishes the programs and processes required to ensure OPG achieves all safety objectives and continuously monitors performance against these objectives. The charter describes that every employee that executes or supports licensed activities and every person or entity that supplies a product or service for OPG's nuclear facilities is responsible and shall be held accountable for complying with the expectations within the charter and programs that make up the Nuclear Management System. This includes that contract partners demonstrate the attributes of a positive safety culture. The following Nuclear Management System programs further support the implementation and continuous improvement of OPG's safety and security culture (descriptions of these programs can be found in Section 17.2).

- N-PROG-AS-0001
- OPG-PROG-0005
- N-PROG-AS-0002
- N-PROG-RA-0003

## **17.5.1 Facility Development Lifecycle Phases and Activities**

### **17.5.1.1 OPG Safety Culture Elements**

Details of how the OPG nuclear safety and security culture is defined and implemented in the Nuclear Management System are described above in Section 17.5. The DNNP will utilize this Nuclear Management System governance for the development lifecycle phase.

Any organization outside of OPG contracted to perform development lifecycle activities is required to meet the same CSA N286-12 requirement to understand and promote a safety culture. As GEH is currently under contract with OPG to perform development lifecycle activities for the DNNP, a description of the GEH safety culture elements is described in Subsection 17.5.1.2.

### **17.5.1.2 GEH Safety Culture Elements**

Safety Culture is at the core of the GEH organization and is an integral element of its management system being implemented through its highest tier defining document “Nuclear Safety & Security Culture Policy” and Part III of its QAPD.

A key nuclear safety and security culture trait is a safety conscious work environment, which is a work environment where individuals feel free to raise nuclear safety concerns without fear of retaliation, intimidation, harassment, or discrimination. It is GEH’s policy to foster such an environment by encouraging employees to raise nuclear safety and security concerns; providing alternate reporting mechanisms through which those concerns may be raised (e.g., supervision, Corrective Action Program, ombuds program); and, commensurate with their potential nuclear safety and security significance, promptly reviewing, prioritizing, and resolving the concerns with timely feedback to the originator.

Values are premised on the principle that everyone, regardless of position, is responsible for nuclear safety and security and that their behaviors must reflect a strong questioning attitude, conservative decision making, and safety-over-output prioritization.

GEH management performs the following actions to establish the appropriate safety conscious work environment:

1. Ensures common understanding of the key aspects of safety culture within the organization. Provides the means by which the organization supports individuals and teams in carrying out their tasks safely and successfully, taking into account the interaction between individuals, technology and the organization.
2. Reinforces a learning and questioning attitude at all levels of the organization.
3. Provides the means by which the organization continually seeks to develop and improve its safety culture.
4. Provides the means by which the organization assess the performance of its safety culture.

### **17.5.1.3 Constructor and Architect Engineering Firm Safety Culture Elements**

Additional organizations outside of OPG or GEH contracted to perform development lifecycle activities for the DNNP, such as the Constructor and Architect Engineering Firm will be required to meet the same CSA N286(Reference 17.6-1) requirement to understand and promote a safety culture as applicable based on their scope of work. This requirement will be specified, if required, in the associated contractual agreement.

Oversight of such requirements by OPG, will be performed through the processes outlined in OPG-PROG-0009 (Reference 17.6-21).

### **17.5.2 Facility Operational Lifecycle Phases and Activities**

The DNNP that will transition from a project to a nuclear facility during the operational lifecycle phase, will require operational programmatic governance to be in place prior to use. This transition must maintain the requirements for safety culture to be in place for the operating life of the facility. Any required changes to associated governance to support this lifecycle phase will be analyzed as part of the Licence to Operate application process.

### **17.5.3 Facility End of Life Lifecycle Phases and Activities**

The safety culture of the future DNNP facility may evolve over the lifetime of the facility and continue to meet regulatory requirements. Any required changes to related governance to support this lifecycle phase will be analyzed to support the Licence to Decommission application process.

## **18.0 HUMAN FACTORS ENGINEERING**

Preliminary Safety Analysis Report (PSAR) Chapter 18 presents the Human Factors Engineering (HFE) program for the BWRX-300 to demonstrate the adequacy of integration of HFE requirements and analysis results into the plant design. The program of HFE activities and analysis informing the design of the plant Structures, Systems, and Components (SSC) is based on clear definition of the full plant set of users and a clearly defined scope of application across the full plant design, operational modes, and lifecycle stages, with focus on important human actions. The HFE content for this PSAR chapter reflects the level of maturity of the HFE Program, plant design, and safety analyses at the time of submission. The pre-operational safety analysis report details further design and analyses development and summarizes HFE Program progression in support of the Licence to Operate submission.

Chapter 18 provides a summary of the BWRX-300 Human-System Interface (HSI) design goals and bases, analyses undertaken to understand the plant-specific HFE requirements related to task performance, the process for detailed HSI design, and activities supporting effective design implementation. The overall design and implementation process is described in detail in NEDC-33982P, "BWRX-300 Darlington New Nuclear Project (DNNP) Human Factor Engineering Program Plan" (Reference 18.1-1). The Human Factors Engineering Program Plan (HFEPP) presents the comprehensive, iterative design approach used for the development of human-centred interfaces and work environment for the plant.

Note that Section 18.1 provides an overview of the HFE Program and outlines its activities or "technical elements". The remainder of the chapter provides the details, including the scope and summary of methods, of the technical elements outlined in Section 18.1.

### **18.1 Management of the Human Factors Engineering Program**

#### **18.1.1 HFE Program Goals**

The high-level goal of the BWRX-300 HFE Program is to conduct a proportionate, integrated, and effective set of HFE design activities that considers users and all phases of the plant lifecycle and that result in a design that reduces the risks and consequences related to human interactions with the plant to as low as reasonably achievable. The program was developed and conducted in line with multiple nuclear regulatory requirements, particularly those in Canadian Nuclear Safety Commission (CNSC) REGDOC-1.1.2, "Licence Application Guide: Licence to Construct a Reactor Facility" (Reference 18.1-2), CNSC REGDOC-2.5.1, "General Design Considerations: Human Factors" (Reference 18.1-3) and CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 18.1-4).

The HFEPP defines the program and outlines the way that the specified general human-centred HFE design goals are operationalized and verified during the design process. This is achieved, through the application of the HFE analyses, integrated design and safety analysis support, and provision of tools, technical requirements, and guidance to designers. The HFE Program ensures that the plant-level design goals are achieved, including:

1. Design of HSIs reduces the likelihood of error and provides for timely, clear error detection.
2. Tasks can be accomplished within time and performance criteria.
3. Allocation of Function (AOF) and proposed job design (staff complement and job roles) are such that a suitable level of human vigilance is ensured and acceptable workload levels that minimize periods of human underload and overload is provided.
4. Presentation of information supports a high degree of situational awareness of the state of the plant and actions required.

5. HSI design supports the capability of personnel to recover from previous decisions and actions that did not achieve intended results.
6. Application of ergonomic principles to working areas and their environments ensure these areas are safe and designed to support performance of required tasks.

The above HFE goals are embedded into the design through specification of requirements derived from codes, standards, best-practice guidance, and plant-specific HFE analyses, and through integrated HFE team support to the design. Achievement of the goals is confirmed using the design tools, HFE Testing and Evaluation (T&E) throughout the design development, and HFE Verification and Validation (V&V) of the realized design.

### **18.1.2 Program Scope**

The HFE Program scope applies to HSI components and SSC within or that form part of facilities, systems, equipment, and components throughout the plant. HSIs are defined as any region or point at which a person interacts with a system, equipment, or component. System interface means any digital and electronic Instrumentation and Control (I&C) user interfaces, as well as hardware-based user interfaces and design features on panels, equipment, and individual components. This includes HSIs within or forming part of:

- Control facilities for reactor operations
- Facilities for supporting response to accidents and emergencies
- Control room or stations for radwaste processing
- Control room or stations supporting refuelling and maintenance outage work
- Local control stations
- Equipment- and process line-mounted HSIs
- Auxiliary and support facilities and equipment located external to the main reactor and powerhouse buildings

This includes specification to and oversight of HSIs that form part of SSC supplied by external vendors, ensuring that supplied design or selection of standard equipment and components is consistent with the HFE requirements of the HFE Program.

The HFE Program also applies across the full scope of users and activities that support plant operation, testing, inspection, and maintenance, including functions such as fuel handling, chemistry, radioactive waste processing, and radiation protection.

The HFE Program described in this plan applies to design activities that consider Human Factors (HF) risks that might arise in all phases of the plant lifecycle, including:

- Construction
- Commissioning
- Operation
- Decommissioning

The HFE Program applies to all HSIs, including those at the following locations:

- Main Control Room (MCR)
- Secondary Control Room (SCR)

- Emergency Response and Support Facilities
- Radwaste Building Control Room or Control Stations
- Local Control Station interfaces
- Equipment- and process line-mounted interfaces (e.g., control actuators and gauges)
- HSIs related to auxiliary and support facilities located outside of the main buildings (e.g., hydrogen tanks or fuel oil supplies)

The HFE Program applies to all plant conditions in the design basis, including normal, outage (refuelling and maintenance outages, including extended refurbishments), abnormal, emergency, and accident conditions. The scope of the HFE Program is extensive; however, the application of HFE support and activities to the scope of each phase and task location is graded (or proportionate), as discussed in Subsection 18.1.4.2 to apply a higher level of emphasis and rigour for important human interactions that are safety-critical or hazardous.

Note that for some phases of the plant lifecycle, particularly Construction and Decommissioning, the HFE activities are focused at a high level. By nature of the single iteration of these plant stages outside of commercial operations, they generally do not involve analysis of recurring operationally related functions and tasks. HFE in design related to these non-commercial operational phases is centred around providing basic guidelines and ensuring design strategies that aid in the achievability of the overall goals of the phase. For example, for decommissioning, HFE design guidelines and requirements for maintainability may equally apply, especially clearance and access for removal of large components and equipment, and consideration of radiological safety through plant structures and equipment layout.

The same general HFE methodologies and tools described in this chapter are also applied to the HSIs related to security. A risk-based approach to HFE design requirements, task support requirements, and testing methodologies is also applied to security considerations. However, due to the sensitive nature of the specific details of security risk ratings, credited human actions, security success criteria, and testing scenarios, the HFE activities for security are found within the Security Annex.

The HFEPP at the time of this PSAR, and in support of the Licence to Construct application, is focused on the design of the plant. After plant turnover to the utility, the utility HFE Program is defined through suitable processes and procedures to address HFE licenced and operating plant activities such as Human Performance Monitoring (HPM), management of change for operational documentation, and design modification activities.

#### **18.1.2.1 Overview of the Human Factors Engineering Program**

The HFEPP describes the goals and scope of the HFE Program, along with items such as:

1. Assumptions and constraints in conducting the program
2. Coordination of the HFE Program with the overall plant design activities, including coordination with the plant safety analysis
3. Tools and facilities (e.g., mock-ups, computer simulations) used in support of the program
4. Composition, qualifications, and responsibilities of the HFE organization
5. Process and procedures followed including the process for identifying and managing technical and programmatic issues
6. Documentation developed

7. Summary of how the results of the HFE analysis are incorporated into the design, operational documentation, and safety analyses

The HFEPP defines each of the technical elements, the specific activities that comprise the full integrated program, as outlined in the next section.

#### **18.1.2.2 Human Factors Engineering Program Technical Elements**

The technical elements for the HFE Program are described briefly below. The full description of these elements, and how they constitute a comprehensive and robust program of HFE integration across the plant design, forms the remainder of this chapter (Sections 18.2 through 18.6).

1. *Operating Experience Review (OER)* – identification, review and incorporation of any recommendations and learning (positive and negative) from past events and user feedback related to HFE in design (Subsection 18.2.1)
2. *Functional Requirements Analysis (FRA)* – determination of functions required to achieve plant goals in all plant states (Subsection 18.2.2)
3. *Allocation of Function (AOF)* – assigning the identified functions to system (technology) or human, based on respective capabilities and limitations of each (Subsection 18.2.3)
4. *Task Analysis (TA)* – identification of the tasks required to achieve the allocated functions, and decomposition into task steps to allow the identification and characterization of HSIs, personnel, locations, and support equipment (e.g., communications, lighting, personnel protection) required to perform each task successfully (Subsection 18.2.4)
5. *Staffing Analysis* – determination of the numbers and roles of personal required to support optimal task performance in all plant conditions (Subsection 18.2.5)
6. *Treatment of Important Human Actions* – activities supporting and providing input to the BWRX-300 safety analyses to ensure clear identification of human actions important to safety, ensure claimed actions are achievable and identify HSIs requiring the highest level of HFE focus and effort (Subsection 18.2.6)
7. *Human-System Interface (HSI) Design* – identification and management of the set of HFE design requirements from standards, codes, and best-practice guidance, and implementation of those requirements plus results from HFE analyses into the design of HSIs, including integration of HFE team design support; also includes HFE T&E activities (Subsection 18.3.1 through 18.3.6)
8. *Procedures* – process and activities for the development of usable and validated operational documentation, for plant task types (Subsection 18.3.7)
9. *Training and Qualifications* – process and activities for the development of relevant and validated training content, optimized for the plant design, operational documentation, and baseline personnel qualifications and attributes (Subsection 18.3.8)
10. *Human Factors Verification and Validation (V&V)* – detailed, staged set of activities to provide assurance of the correct and sufficient implementation of HFE requirements in the design, and the appropriate design to support required tasks (Section 18.4)
11. *Design Implementation* – support and monitoring of the design from “on paper” to a realized constructed plant, including integration with configuration control to ensure no loss of integrity of the HFE Program goals throughout fabrication and construction (Section 18.5)

12. *Human Performance Monitoring (HPM)* – continuous monitoring of user task performance throughout the lifetime of the plant to ensure optimum plant and organizational design and identify early trends and issues that require HFE design improvements (Section 18.6)

*NOTE: This element is only relevant within the future operational plant HFE Program and therefore not currently included in the HFEPP.*

The scope and nature of the HFE Program, the HFE organization undertaking the program and the technical elements that comprise it, align with regulatory requirements and international standards and guidance, providing assurance that HFE has been suitably and sufficiently integrated into the plant design.

Table 18.1-1 illustrates the alignment of Chapter 18 and the HFE Program technical elements, with the CNSC expectations for HFE, as per CNSC REGDOC-2.5.1 (Reference 18.1-3) and CSA N290.12-14, “Human factors in design for nuclear power plants” (Reference 18.1-5). The PSAR and HFE Program technical elements inform the subsequent pre-operational safety analysis report and ultimately the overall plant lifecycle of HFE activities.

Although arranged somewhat differently in the PSAR chapter and HFE Program, all required elements are included and addressed. The elements are performed in an iterative manner, with activities and outputs progressively evolving with the design and related safety analyses. These elements inform one another, inform, and are informed by plant design and safety analyses, and are aligned with design and engineering processes and requirements, international best-practice guidance, and regulations.

**Table 18.1-1: Mapping of HFE Program Elements with CNSC and CSA Requirements**

### 18.1.3 Team and Organization

The HFE team consists of a core and extended team dedicated to integrating HFE requirements and principles into the design. The core HFE team sits within the organization as a separate engineering team, at an equal level to all other discipline teams. The HFE team holds the technical authority over HFE activities and requirements and has the equal authority and issues resolution mechanisms as any other engineering team. The extended HFE team includes members from other disciplines within the engineering organization. This ensures fully integrated and timely consideration of HFE in the daily engineering design decisions and activities.

The core HFE team is comprised of an HFE Technical Lead and two general roles: HF Engineer or HFE Specialist and HFE Operations/Maintenance. The qualifications for these roles may be met by individuals or collectively by the HFE team. The responsibilities and qualifications of these roles are defined in the HFEPP as summarized below:

1. Technical Lead: Provides technical and program oversight and review; responsible for ensuring that HFE activities, interfaces, and outputs meet HFE requirements and align with HFE Program objectives; point-of-contact for schedule development, integration, and management of the program. This role is expected to have the base qualifications of either the HFE Specialist or HFE Operations/Maintenance role, with additional HFE capability across a breadth of HFE competence areas suitable for the full scope of the HFE Program and experience in project management and managing HFE or other technical, cross-cutting programs.
2. HF Engineer/HFE Specialist: Provide specialized knowledge of human cognitive and physical capabilities and limitations, applicable HFE design and evaluation practices, and HFE principles, guidelines, and standards; develop and perform HFE analyses; identify and participate in the resolution of identified HFE issues and non-compliances. This role requires a bachelor's degree in HFE, Engineering Psychology, or related science with four years of cumulative experience related to the HFE aspects of HSIs (design, development, and T&E), particularly modern digital process control HSIs, and four years of cumulative experience related to the HFE aspects of workplace design.
3. HFE Operations/Maintenance: Provide knowledge of operations and maintenance activities, including task characteristics, HSI characteristics, environmental characteristics, and technical requirements related to operational activities, and apply those insight in support of activities such as development of HSIs, procedures, and training programs. Participate in the development of scenarios for Human Reliability Analysis (HRA) evaluations, task analyses, HSI T&E, validation, and other evaluations. This role requires a bachelor's degree in a technical field; experience as a senior authorized reactor operator, or as a qualified maintenance technician; five or more years of plant experience, preferably in Boiling Water Reactors exposure to plant procedure development, personnel training, and operational nuclear plant programs; and two or more years of experience in one or more areas of HFE analysis, design, T&E, and HFE V&V.

The responsibilities of the HFE team are to establish and perform the activities as defined in this PSAR chapter throughout the design lifecycle to ensure that the facilities, systems, equipment, and tools are designed to be compatible with the capabilities, limitations, and needs of the human. The specific duties of the HFE team are to guide, perform, and support the analysis and design activities, ensuring the execution and documentation of all steps in the activities are performed in accordance with the established program and procedures.

The HFE team is responsible for:

1. Development of HFE plans and procedures including management of any identified HFE issues
2. Oversight, participation in, and review of HFE design, safety analyses, development, T&E activities, including identification of in-process HFE issues
3. Recommendations for, and support to implementation of design-based resolutions for issues identified during the implementation of the HFE requirements and analysis results
4. Verification of correct and robust implementation of HFE requirements, analysis results and issue resolution into the design
5. Assurance that HFE activities comply with HFE plans and procedures
6. Managing documentation of HFE activities and issues management
7. Plan and implement HSI design configuration control during design implementation

To ensure suitably qualified and experienced persons are performing the work, HFE Program activity assignments are allocated by the Technical Lead based on the team member's role and their specific experience. For example, not all the team HF Engineers/HFE Specialists are experienced in HFE safety analysis, identifying, and evaluating important human actions. Only those team members with adequate experience and training (if applicable) in a particular HFE activity will be assigned to those activities. To ensure there are no singleton specialisms within the team and associated vulnerability to knowledge loss, more than one team member will be required to be deemed competent for each activity. Team members that do not meet the full qualification of an HFE team role, or who are not deemed suitably qualified for a specific activity, will receive mentoring and technical oversight to support developing the skills required for the role or work assignment.

#### **18.1.3.1 Cross-Discipline Support and Integration**

Due to the cross-functional nature of a completely integrated HFE design process, HFE activities interface with many other disciplines. In addition, the other disciplines act as extended parts of the HFE team for some aspects of the HFE Program implementation. The integration of related groups with HFE is formally addressed through an integrated detailed schedule, as well as through the HFE technical project management role of the HFE Technical Lead.

Specifically, work activities that require integration of HFE and other disciplines are entered into the resource-loaded schedule by the HFE Technical Lead with all required resources, including those from other teams. Pre-job briefs are held for each group of activities, or workplan, to clearly define the relevant resource roles and responsibilities for the completion of the work. Further detail on GEH and the BWRX-300 project design processes, including inter-discipline communications and issues resolution, are described in Chapter 17, Sections 17.2 and 17.3.

The descriptions of the following disciplines and groups and their contributions to HFE are representative based on best-practice HFE integration principles. The actual engineering design team disciplines may vary, but the scopes described are covered.

1. Mechanical Engineering and Electrical Engineering
  - a. Provide knowledge of the purpose, operating characteristics, and technical specifications of major plant systems
  - b. Provide input to HFE analyses, especially function and task analyses

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

- c. Allocate and implement HFE requirements and recommendations relevant to their scope of design, including management of those requirements provided to suppliers
  - d. Participate in developing scenarios for use in TA, validation, and other analyses
2. I&C Engineering
- a. Provide detailed knowledge of the HSI physical design, including control and display hardware selection, design specification, functionality, and installation
  - b. Support HFE design of information display design, content, and functionality, particularly connection to the underlying I&C platform
  - c. Participate in designing, developing, testing, and evaluating the HSIs
  - d. Provide knowledge of data processing associated with displays and controls
  - e. Allocate and implement HFE requirements and recommendations relevant to their scope of design, including management of those requirements provided to suppliers
  - f. Participate in designing and selecting HSI components, such as controls and displays
  - g. Participate in developing scenarios for HRA, validation, and other analyses involving failures of the HSI data processing systems
3. Civil/Structural Engineering
- a. Provide knowledge of the overall structure of the plant, including performance requirements, design constraints, and design characteristics of the following:
    - Containment structures (i.e., Steel-Plate Composite Containment Vessel)
    - Control Rooms (main and secondary)
    - Local control
  - b. Provide knowledge of the configuration of plant components
  - c. Allocate and implement HFE requirements and recommendations relevant to their scope of design, including management of those requirements provided to suppliers
  - d. Provide input to plant analyses, especially function analysis, TA, and development of scenarios for TA and validation
4. Plant Integration Engineering
- a. Prepare the Deterministic Safety Analysis (DSA) establishing the SSC and human actions that are credited for successful event mitigation
  - b. Provide knowledge of maintenance, inspection, and surveillance activities based on previous plant design and consideration of evolving new plant design, including:
    - i. Development of maintenance and outage strategy and plan documents
    - ii. Expected tasks
    - iii. Relevant SSC and HSIs
    - iv. Task performance requirements
    - v. Workspace environment characteristics
    - vi. Technical information related to the conduct of these activities

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

- c. Allocate and implement HFE requirements and recommendations relevant to their scope of design, including management of those requirements provided to suppliers
  - d. Support Plant Architectural and HFE design, development, and evaluation of the control facilities and other HSIs throughout the plant to provide reasonable assurance that each can be inspected and maintained to the specified reliability
  - e. Provide input regarding maintainability and inspectability during the development of procedures and training
  - f. Participate in the development of scenarios for HSI evaluations including task analyses, HSI design tests and evaluations, and validation
5. Risk and Reliability Engineering
- a. Perform Probabilistic Safety Assessment (PSA) and HRA to quantify the human contribution to risk and inform HFE analyses
  - b. Provide knowledge of plant component and system reliability and availability and assessment methodologies to the HSI development activities
  - c. Participate in the development of scenarios for HSI evaluations, especially validation
  - d. Provide input to the design of HSIs to provide reasonable assurance it meets reliability goals during operation and maintenance and maintains the specified availability
6. Simulation Assisted Engineering
- a. Develop the simulators for HFE T&E and V&V activities

#### **18.1.4 Process and Procedures**

##### **18.1.4.1 Coordination and Documentation of Activities**

The HFE Program is planned and conducted in accordance and alignment with overarching design and quality program processes and procedures, within accredited quality management systems as described in Chapter 17. The work is performed in an integrated manner with HFE as an equal design discipline, whose cross-cutting requirements and support are embedded within all other design disciplines, with activities, inputs, outputs, and dependencies coordinated through a detailed schedule and associated schedule management processes. The schedule includes activities and deliverables for all disciplines and orders them with logical connections to ensure they are completed in the required sequence.

To help ensure cross-discipline communication and coordination, activities include scheduled periodic formal design reviews conducted by representatives of each discipline. Additionally, deliverables are completed in accordance with a deliverable standard, which specifies the required content from all related disciplines, dictates the format for consistency and quality and specifies the required discipline reviewers for each document. This includes other disciplines reviewing and incorporating outputs from HFE documentation and the HFE team reviewing and incorporating outputs from other disciplines, as appropriate and according to the plan.

The documentation for the HFE Program uses a standard design process that includes documenting internal design records to capture inputs and outputs, as well as providing the basis for formal deliverables. The information in the design records is incorporated into the design by HFE and other disciplines as appropriate and in accordance with the BWRX-300 project work breakdown structure. A full description of the management and integration of HFE activities within the project is described in the HFEPP.

In this way, using the project processes and HFE coordination measures described in the HFEPP, the design activities related to HFE are conducted and documented such that design basis, input maturity and rationale for design and analysis scope is provided for HFE design decisions and analysis results. HFE requirements and recommendations are addressed by the requirements management process (Subsection 18.1.4.3), and either incorporated into the design directly or via alternate solutions agreed as acceptable by HFE, or if not implemented, tracked as an HFE issue as described in Subsection 18.1.5.

#### **18.1.4.2 Risk-Based Graded Approach**

A graded (or proportionate) approach to HFE is applied to the conduct of activities within the HFE Program, to provide the appropriate focus for analysis and design. The graded approach provides basic HFE attention to human interactions within the system and provides emphasis and more detailed, rigorous HFE effort on aspects of the plant design related to HSIs used to perform human actions important to safety, or tasks that are novel, complex, or inherently hazardous. The approach uses a risk-based grading system to grade each of the tasks or human actions identified throughout the plant based on four key risk categories:

- Nuclear Safety
- Personnel Safety
- Asset Protection
- Generation Capability

Although Asset Protection and Generation Capability are typically discounted as relating to safety, the HFE Program recognizes that equipment damage creates requirements for forced outages and corrective maintenance, as well as impacting production goals, all of which has an indirect impact on personnel and nuclear safety. Consideration of aspects of equipment protection, reliability, and production risks, also ensures that tasks outside of reactor operations have a decreased likelihood of being classified as Low-Risk Level. Loss of power generation and production shortfalls equate to loss of income for the plant which is recognized to have a direct effect on plant condition, organizational health, and ultimately, nuclear safety culture.

The overall risk level for the human action is determined by the highest risk level assigned to each of the four categories. The base risk level is then used to assign a minimum HFE Application Level. The minimum HFE Application Level dictates the minimum degree of application when considering each HFE technical element. Further detail is provided in Subsection 18.2.3.

In addition to the formal task grading method for determining proportionate effort during design, the scope and level of effort of HFE activities is also proportionate to project lifecycle risk and change management considerations. This is done by applying greater scope, focus and degree of support on HFE activities that occur earlier within the design lifecycle, when changes are more effectively and easily managed. For example, while not all HSIs receive a full HFE V&V, all HSIs receive some degree of HFE support during the design phase.

#### **18.1.4.3 Requirements Management**

HFE requirements management is performed in accordance with a requirements management process that is standardized and controlled across the entire plant design, as described in Chapter 17, Subsection 17.3.1. Requirements management and traceability is developed and maintained to:

- Ensure HFE requirements relevant to each scope of work are clearly identified, allocated, communicated, and understood by all relevant project personnel

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

- Outline how the requirements are met
- Reference evidence that demonstrates compliance has been achieved

HFE requirements are categorized and dispositioned as follows:

- A. Process Requirements – Requirements related to how the HFE Program is conducted and the interfaces among HFE and other disciplines. HFE Process Requirements are allocated to the HFEPP and are fulfilled via the construction and implementation of the architecture and processes defined within this document. As such, all HFE Process Requirements are allocated to and end with the HFEPP.
- B. Product Requirements – Requirements for the design of, or provision for plant workspace and environmental attributes, SSC, and HSIs. Product requirements are either derived from HFE design standards, codes, and guidance, or generated from HFE analyses as required to support successful task performance in the specific context of plant conditions. These requirements are implemented through design requirements specifications or design records communicated to and implemented by the relevant design teams. Requirement traceability and HFE support level is proportionately applied based on the assessed risk-based grading (Subsection 18.4.2).

Where HFE inputs are not in agreement with one another or where they conflict with other discipline design requirements, precedence is given as follows:

- Laws and Regulations
- Regulatory Requirements and Guides
- Requirements related to supporting, maintaining, or recovering the plant in a safe state
- Nuclear Standards
- Nuclear Industry Guidance Documents
- Non-Nuclear Codes, Standards, and Guides

Conflicts between HFE and other design requirements are resolved with the HFE team using the HFE issue resolution process described in Subsection 18.1.5. Decisions regarding trade-offs and design optimizations are conducted within the integrated design process in accordance with standard GEH design procedures.

#### **18.1.5 Issue Tracking**

Included in the HFE Program is the establishment and maintenance of an on-going HFE Issues Tracking System (HFEITS) for documenting HF issues that may be identified throughout the full scope of HFE activities, and the actions taken to resolve those issues.

The HFEITS is used to capture issues related to design and implementation HFE activities and specific Human Engineering Discrepancies (HEDs) identified through HFE V&V. The tracking of issues include:

1. Evaluation of each issue/HED to determine significance and whether it warrants correction when evaluated in the context of the integrated plant design
2. Identification of appropriate solutions to address issues/HEDs, including, as appropriate, changes to HSI design, procedures, staffing/qualifications, or training
3. Verification that the solutions implemented to address the issue/HED resolve the problem without generating additional issues/HEDs

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

4. Documented traceability of the issue/HED resolution process and identification of residual risks associated with it, if necessary

The HFEPP details the HFEITS development and management including:

1. Responsibilities for HFE team members in identifying HFE issues and HEDs
2. The process and criteria for including HFE issues and HEDs within the HFEITS, as opposed to resolving non-compliant design through integrated design teamwork in normal workflow
3. The process for evaluating the priority and adequate resolution of the issue/HED
4. The means for confirming acceptable resolution of the issue/HED, based on the nature of the issue, its priority, and the plant lifecycle stage where the resolution occurs

## **18.2 Human Factors Engineering Analysis**

In this section, six of the HFE Program technical elements are described in depth. The remaining elements are described in other sections. These six elements described in this section include:

- Review of Operating Experience (OE)
- Function Requirements Analysis
- AOF
- TA
- Staffing
- Treatment of Important Human Actions

These are addressed in Subsections 18.2.1 through 18.2.6.

Integrated HFE involvement in, and support of the plant safety analyses also informs these elements. As described in Subsection 18.2.6, the HFE safety analyses activities identify, characterize, and substantiate the human actions that are performed to maintain the plant within or bring it back to a safe state, as described in Chapter 15, Safety Analysis.

### **18.2.1 Review of Operating Experience**

The HFE Program includes the early review of OE to identify applicable HFE issues related to process or personnel safety that can be resolved through design improvements. The issues and lessons learned from the OER provide a basis for improving the plant design in a timely way (i.e., at the beginning of the design process). In addition to the early HFE review of existing OE, the project as a whole has a formal OE identification and management process, which includes HFE team participation in both identifying any OE and implementing HFE-allocated OE items in the HFE Program and design.

#### **18.2.1.1 Objectives and Scope**

The objective of the OER is to obtain information and lessons learned from experience to support design of BWRX-300 SSC. OE related to the following areas are considered in the development of the plant design:

- Predecessor plant(s) and systems
- Experience in industries with applicable SSC
- Applicable Industry HSI design experience
- Risk-important human actions
- Specifically identified applicable industry issues
- Issues identified by predecessor or similar plant personnel
- Specifically identified positive features that support task performance

#### **18.2.1.2 Methodology**

The OER process includes the following:

- Identification of applicable OE sources, leveraging work previously performed for predecessor plant designs

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

- Specific methods for gathering sources and performing reviews of sources since the predecessor plants and systems OER
- Establishing a systematic framework and performing systematic searches of OE sources
- Obtaining and incorporating personnel feedback from predecessor or similar types of reactors
- Conducting reviews of human actions from predecessor designs that are similar to human actions included in the plant safety analyses
- Analyzing and consolidating raw OE data into OE Item Summaries on the OER Capture Sheet
- Allocation of each OE item to the HFE activity or document in which the OE item is dispositioned
- Recipient OE item review and allocation acceptance
- Documentation of the findings within an OER report

Existing and new OE is reviewed by HFE, and relevant, applicable problems, issues, and positive insights are identified and addressed throughout the design process. The OER information is made available to design engineers to support development of design features that are expected to reduce human error. Likewise, positive features of previous designs are communicated so that they can be retained.

#### **18.2.1.3 Results**

The results of the OER are summarized in an OER report. The report provides the OER process description along with the review methods that were used. The results include:

1. Sources of OER information
2. Summaries of OER issues and improvements
3. List of issues from the OER requiring special attention in the design process based on the grading process
4. Information gathered from personnel interviews conducted at predecessor plants

Implementation of the OER results into the design is managed and tracked through the assignment of and reference to a unique OE identification number. Communication and allocation of the results to the appropriate design team and design requirements document is managed by the HFE team.

The HFEPP provides additional details of the OER activity.

### **18.2.2 Functional Requirements Analysis**

#### **18.2.2.1 Objectives and Scope**

FRA is performed to define the necessary functions that enable the achievement of the plant safety and commercial goals. These principal design requirements are necessary to meet plant goals and objectives in all normal and postulated accident conditions. They include meeting regulatory and customer requirements that are documented in plant and product level design requirements specifications.

### **18.2.2.2 Methodology**

FRA is conducted as an integral part of the overall engineering design process specified by standard design process documents, and in particular part of the BWRX-300 requirements management process. The requirements management process as described in Chapter 17, Subsection 17.3.1 consists of the following activities, which apply equally to all types of requirements including the functional ones: elicitation, analysis, documentation, allocation (to specific system(s)), tracing, and requirements V&V. This process is a multi-discipline activity jointly undertaken by all design teams, including the HFE team. Note that, because BWRX-300 is an evolutionary plant with some of the same or similar plant- and system-level safety and performance goals, FRA elicitation is not required to the extent it would be for a completely new design. Eliciting functional requirements from existing design is done through importing functions that exist in current plant designs and are expected to apply to BWRX-300.

### **18.2.2.3 Results**

The result of the multi-disciplinary FRA activities is the definition of the full set of functions that support achievement of the plant goals and can be traced to the principal design requirements of the BWRX-300. Plant- and system-level requirements documents list the functional requirements associated with each system. Through the requirements management process described in Chapter 17, Subsection 17.3.1 the project has also captured system functional performance requirements which includes the full list of plant functions, with reference and traceability back to the source documents where the requirements were elicited.

These functions from the FRA are captured in a report that also includes the results from the AOF (see next section) and assigning HFE Application Levels to tasks (Subsection 18.1.4.2). The results are input into the AOF process as described in the next section. The output from the FRA and AOF process also contains the full list of functions with characterizations of relevance to HFE, particularly those required to perform AOF and feed to the TA and HSI design activities.

### **18.2.3 Allocation of Function**

#### **18.2.3.1 Objective and Scope**

AOF establishes a plant control scheme that enhances plant safety and reliability by taking advantage of human and system strengths and avoiding human and system limitations. The overall allocation can also enhance plant performance and safety by specifying overlapping and redundant responsibilities to the human and system.

The AOF strives to provide personnel with groups of logical, coherent, and meaningful tasks within their capabilities, and ensures a design that maintains human vigilance and situational awareness for any functions allocated to the system. The goal of the AOF is to provide acceptable workload levels per job role that minimize periods of human underload and overload to the extent possible. This is done through review of the initial allocation as a whole and using expert judgement to determine if the assigned functions per job role are suitable and sufficient. Further analysis of workload and requirements for situational awareness are then undertaken through downstream activities such as TA, HFE T&E and HFE V&V.

The AOF also allows the risk-based task grading, which determines the HFE proportionate, graded approach to activities, as described in Subsection 18.1.4.2.

#### **18.2.3.2 Methodology**

The AOF process for BWRX-300 is based on the relevant best-practice methodology presented in IAEA-TECDOC-668, "The role of automation and humans in nuclear power plants" (Reference

18.2-1). The methodology identifies functions that should not be assigned to humans due to criteria such as:

- Physical demands (forces, posture)
- Cognitive demands (multitasking, stress, situational awareness, and vigilance)
- Combination of physical and cognitive demands (accuracy, response time)
- Environmental conditions (temperature, radiation)

The AOF process also uses criteria from USNRC NUREG/CR-2623, "The Allocation of Functions in Man-Machine Systems: A Perspective and Literature Review," (Reference 18.2-2) that limit or preclude human participation in a function or, conversely, that make human participation mandatory. These combined criteria form the top-level, overriding criteria in the AOF process.

The FRA process provides the list of functions input to the AOF, as described in Subsection 18.2.2. The AOF process is composed of two stages: the first stage establishes an initial (hypothesized) allocation; the second stage evaluates the hypothesized AOF to determine its adequacy and validate that it is optimized within the larger integrated task performance and work environment.

The initial AOF is determined following a formal decision flow with key allocation criteria informing each decision point. The decisions are based on expert judgement formed by a panel that includes an HF Engineer/HFE Specialist, an HFE Operations/Maintenance representative, a Plant Integration Engineering representative, and a System Engineer for the respective system. The expert panel accounts for the mandatory criteria when hypothesizing the initial allocation. The panel also makes use of OE to determine how functions were allocated in previous or similar applications and evaluate how they have performed.

The second stage of the AOF process is the AOF evaluation. This stage is performed later in the design and HFE T&E process, following completion of system level and integrated TA. The AOF evaluation is a structured examination of function and task groupings that is used to assess allocations in a collective manner within an integrated work environment, instead of on a single function basis, where overload issues are less likely to be revealed. Functions and tasks allocated to humans are considered in combination using scenario development. The scenarios are then evaluated to determine acceptability based on expected concurrent task performance, workload (physical and cognitive), vigilance, and situation awareness.

As part of the AOF activity, functions are decomposed to tasks, and multiple tasks may be necessary to support each function. For example, to fulfil a core protection function, a task to perform a system readiness surveillance test supports the eventual task of safety system initiation. The function tasks require a "task allocation" that uses the same criteria applied at the overall AOF level. The safety analyses also provide input to the AOF, specifying when human actions are required to backup automatic (i.e., system) actions.

In addition to allocation, within the AOF activity, task grading is completed. As described in Subsection 18.1.4.2, a graded approach to HFE is applied to the BWRX-300 project. The human actions resulting from the AOF process described above are graded based on four key risk categories:

1. Nuclear Safety
2. Personnel Safety
3. Asset Protection
4. Generation Capability

The characteristics of the human actions are assessed against criteria in each category that results in an initial High, Medium, or Low numerical risk rating. This gives the overall minimum HFE Application Level for activities within the HFE Program for each human action. The scope and level of detail for each HFE technical element is defined for each of these HFE Application Levels.

When the risk is assessed numerically using the initial ranking criteria, the result is a minimum HFE Application Level. The HF Engineer/HFE Specialist reviews the rating and the associated HFE scope and level of effort for each technical element and takes into consideration other HFE risk factors to determine if the HFE Application Level needs to be increased for that specific technical element. The additional risk factors include:

- Complexity of the action
- Anticipated complexity and constraints of HSI
- Complexity of the system
- Frequency of the task
- Physical environment
- Cognitive environment
- Novelty of the action, system, or HSI technology
- Time sensitivity of the action

The review of an individual HFE technical element for each human action may increase an HFE Application Level but not reduce it. For example, a particular human action may have a low minimum application level based on the broad key risk criteria, but because it is a complex or novel task, it is raised to a higher application level for the TA activity.

#### **18.2.3.3 Results**

Output from the first stage of AOF is the initial AOF to human, system, or shared (both human and system). For system or shared allocations, it may be necessary to establish backup actions when redundant functions with like allocations is not possible or reasonable. For these cases, the shared and backup allocation categories are used.

The initial allocation for each system AOF is documented in a workbook which is formally managed as an internal design basis record. The workbook is communicated to all relevant stakeholders (Mechanical and I&C engineers, as well as HFE analysts) to be used as the basis for the design and TA. The initial allocation is revised and refined as necessary as the plant design and safety analyses progresses.

The results from the AOF evaluation are a final refinement of the initial allocation, including design and safety analysis modifications where necessary to support changes to allocation outcome. The final optimal AOF is used for Integrated System Validation (ISV) testing to confirm that performance, workload, and situation awareness are suitable.

The results of the AOF development and refinement activities, and specification of the final AOF are provided in a summary report.

#### **18.2.4 Task Analysis**

TA is the identification of task requirements to accomplish the functions and tasks that have been allocated in whole, or in part, to humans. These are designated in the AOF results as Human, Shared, or System with Human Backup.

TA assigns tasks to the job positions specified by the staffing process. TA determines the steps needed to accomplish human actions and documents the task details and required task support (HSI controls, indications, and alarms). The TA process also assesses the graded HFE Application Level to determine if a change to is warranted based on task characteristics.

#### **18.2.4.1 Objectives and Scope**

The TA plan establishes:

1. Methods for conduct of the TA consistent with accepted HFE practices and principles
2. Scope of the TA including actions performed at the MCR, SCR, and at other control facilities, including those required to support response to accidents and emergencies
3. Range of plant operating conditions, including start-up, normal and abnormal operations, transients, refuelling, lower power, and shutdown conditions, and emergency or accident conditions
4. HSI operations during periods of maintenance, testing, and inspection of plant SSC
5. Links among task descriptions and safety importance, function achievement, human error potential, and impact of task failure
6. Descriptions of the personnel activities required for successful completion of tasks
7. Requirements for alarms, displays, data processing, and control

#### **18.2.4.2 Methodology**

The task inputs provided by the AOF and Task Grading process form the starting point for TA. These tasks are divided into levels of effort as defined through the task grading portion of the AOF process, as described in Subsection 18.2.3. All tasks regardless of HFE Application Level receive a TA. However, the level of detail within the TA varies based on HFE Application Level. For example, those at the lowest risk level may be performed by the responsible System Engineer and reviewed by HFE for acceptability.

There are two levels of TA: Basic TA and Detailed TA. Human actions ranked at the lowest HFE Application Level undergo a Basic TA; human actions at the medium and highest HFE Application Levels undergo a Detailed TA. The Detailed TA also includes preliminary workload analysis and assessment of requirements for situational awareness. In addition to the Detailed TA, the highest HFE Application Level requires additional link Analysis and timeline Analysis to be performed to evaluate and inform the layout of HSIs to optimize task performance.

Basic TA consists of:

- Task Selection
- Task Step Sequence Narrative, including:
  - Descriptive narrative of the task
  - Cue that determines the need for the task
  - Action to be taken
  - Prerequisites for the task
  - Time available versus time required to complete

Detailed TA consists of:

- Task Selection

- Task Step Sequence Narrative, as per Basic TA
- Task-Level Support, Job Design, Workload, and Workplace Definition including:
  - Information needed
  - Controls needed
  - Alarms needed
  - Personnel involved
  - Communication needs
  - Location and access considerations
  - Workspace needed
  - Job aids, tools, or equipment needs
  - Environmental considerations and potential hazards
  - Special clothing or personal protective equipment needs
  - Time available versus time required to complete (if needed on a step basis)

The Detailed TA is coordinated with the qualitative human error analysis, which is informed by and used to substantiate the quantitative HRA, as described in Subsection 18.2.6. The TA also identifies critical task steps where incorrect or incomplete actions might lead to undesired or unsafe consequences.

The TA activity also includes Integrated TA. Integrated TA is conducted for those operations that require interaction with multiple systems and a coordinated response that may involve multiple plant personnel. The Integrated TA takes the system-level TAs and the results from the human error analyses (described in Subsection 18.2.6) and performs higher-level whole sequence analyses, including integrated workload analysis and timeline analysis. The Integrated TAs, at a minimum, include each event sequence that contains an HFE Application Level 1 human action and each unique scenario described in the plant safety analyses.

#### **18.2.4.3 Results**

The BWRX-300 TA procedure defines set templates for capturing the TA, which are combined with the AOF results workbook, documenting the full set of analysis activities. The activities are iterative and progressive, and the workbook method allows timely and effective update of the TA and distribution of the results. The TA workbook is functionally divided into subsets of information needed to process the output activities from TA, including input to:

- Staffing and qualifications
- HSI development, including I&C Data Connection Tables (DCTs)
- Training development
- Procedure development

The results from the additional link, timeline and preliminary workload analyses in the Detailed TAs are also used to further inform the HSI design requirements, confirm or identify issues with the AOF, and provide a baseline for HSI T&E activities. The Integrated TA results provide an input into group-use and aggregate HSI designs, control facility and plant location and workspace design considerations, development of plant-level procedures, and the scenarios selected for ISV.

The results of all the TA activities, when they are complete, are summarized in a TA summary report.

### **18.2.5 Staffing**

The required and expected number of personnel available to achieve plant functions and goals is an important consideration throughout the design process and in HFE analyses. BWRX-300 staffing assumptions and analysis results are used to frame the future plant operating organization during TA, HRA, and HSI design.

Features of the BWRX-300, such as passive safety systems, increased automation, and simplified HSIs, information systems and content, decrease the assumed initial staffing requirements relative to previous Boiling Water Reactors. For example, TA done as part of the HFE safety analysis work, described in Subsection 18.2.6, may show that the extended time for safety actions may reduce the number of personnel needed for local actions. Safety analyses and identification of human actions may show that some actions that were important in previous boiling water reactor designs have been eliminated in the plant design.

#### **18.2.5.1 Objectives and Scope**

Staffing analysis is conducted to determine the minimum staff complement. The minimum staff complement is defined as the minimum number of workers with specific qualifications who are available to the site at all times. The minimum staff must be able to operate and maintain the plant within its defined safe operating envelope and to successfully respond to all postulated events in the safety analyses, in any plant state.

For staffing assumptions where minimum staff can be varied for different operational states, the most resource-intensive events for each plant mode are analyzed. The Staffing Analysis technical element also determines the maximum staffing in collaborative areas such as control rooms, workshops, and air locks. This informs the needed space, facilities, and other support features.

#### **18.2.5.2 Methodology**

The Staffing Analysis for BWRX-300 is conducted in accordance with a plan that was developed to meet the expectations and requirements of CNSC REGDOC-2.2.5, "Minimum Staff Complement" (Reference 18.2-3). The process takes place in three major steps: Expert Panel Staffing Assessment; Staffing Analysis in TA and HSI design; and Staffing Analysis in the HFE V&V Process.

The process starts with an assumed initial staff complement taken from predecessor and similar plants, and representative OE from the operating fleet. Using this information, the initial staffing is optimized, considering the modern design features and new systems of the BWRX-300.

The optimized initial staffing level is subject to an Expert Panel Staffing Assessment that evaluates the minimum staffing to cope with selected credible events. The goal is to perform early and iterative assessments as the design progresses such that the risk of less than adequate staffing is reduced in part with each evaluation. The evaluations are performed as a desktop (talk-through) exercise led by the expert panel. The expert panel is made up of personnel from the HFE team, supported by personnel from Plant Integration Engineering and Risk and Reliability Engineering.

The next steps take place in conjunction with the TA and HSI design process. During TA, task steps are defined, and personnel assignments are made. The TA forms the basis for job design and qualifications for each role. With the TA, timeline analysis is conducted for the most resource-intensive credible events. These events are selected by the expert panel, and the expert panel

also performs a review of the timeline analysis and input TA data to evaluate whether the minimum staff complement is adequate.

After this, scenarios for a wider range of events are created and analyzed in the T&E phase of the TA and HSI design process. This allows further evaluation of the minimum staff complement against the most challenging credible events. HSI tests evaluate, using platforms and mock-ups that replicate the interface design, the timing of activities, workload, and other factors such as situation awareness that can lead to changes in the minimum staff complement and job design.

In the final analysis stage, the minimum staff complement is evaluated through the HFE V&V activities. This occurs during early validation in accordance with the multiphase validation approach (Section 18.4), culminating with the ISV. ISV demonstrates the adequacy of the final staffing levels that resulted from the analysis.

#### **18.2.5.3 Results**

The staffing analysis results are recorded in a series of reports capturing each Expert Panel Assessment, and a further report capturing the Expert Panel Review of the related staffing analysis activities. In addition to these reports, outputs and reports that are created for the TA and HSI design process and HFE V&V in accordance with those associated technical element descriptions, include results related to or impacting the staffing analysis results.

The confirmed job role and complement determination is also used as an input to training and qualification program development, where base qualifications are established, and the training program is designed (Subsection 18.3.8).

#### **18.2.6 Treatment of Important Human Actions**

Consideration and integration of HFE within the safety analyses, and consideration of the results and assumptions of the safety analyses within the other HFE activities both comprise the technical element of Treatment of Important Human Actions. The set of activities supporting this HFE technical element was developed based on requirements for HFE expertise in safety analyses per IAEA SSG-51, "Human Factors Engineering in the Design of Nuclear Power Plants" (Reference 18.2-4), CNSC REGDOC-2.5.1, "General Design Considerations: Human Factors" (Reference 18.2-5), CSA N290.12-14, "Human factors in design for nuclear power plants" (Reference 18.2-6), and international best practice.

##### **18.2.6.1 Objectives and Scope**

HFE safety analysis activities, including review of safety analyses outcomes, provides assurance that the full set of human actions that are important to safety are explicitly identified, characterized, and substantiated as achievable within the task performance requirements.

The important human actions are determined using both deterministic and probabilistic means and include identification of the human actions that might cause or contribute to the cause of postulated initiating events. Inclusion in the DSA, PSA, or Severe Accident Analysis (SAA), or other identified contribution to risk determines the risk level in the Nuclear Safety category for determining the initial HFE Application Level to apply to the HFE activities (Subsection 18.1.4.2). Comprehensive, systematic identification and substantiation of human actions claimed within the safety analyses, coupled with the risk-based graded approach described in Subsection 18.1.4.2, ensures that HSIs and tasks associated with important human actions are analyzed and designed with a full detailed and robust HFE effort.

#### **18.2.6.2 Methodology**

The safety functions that are performed to maintain the plant within or return it to a safe operating envelope are identified through various means using DSA, PSA, and SAA, as described in Chapter 15, Safety Analysis.

HFE safety analysis activities use the various safety analyses, available system design information, particularly that related to HSIs, and any available and applicable TA results (Subsection 18.2.4) as inputs.

The activities that form part of this technical element include:

1. Perform a Human Operation Hazard Evaluation
2. Review the DSA for explicit and implied human actions, e.g., human actions related to maintenance that ensure safety-class SSC availability, and ensure claimed human actions are achievable through qualitative human error analysis
3. Review the PSA and HRA for:
  - a. Ensuring event sequences introduce a Human Performance Limiting Value
  - b. Perform qualitative human error analysis to substantiate or refine the human error probabilities used for all human actions claimed in the HRA
  - c. Provide HFE qualitative basis and substantiation for any dependency assumptions and analysis
  - d. Provide HFE qualitative basis and substantiation for any timeline assumptions and analysis
4. Review the SAA, including Level 2 and Level 3 PSA, to identify explicit and implied human actions, determine task achievability in required timescales, and capture input for procedure development (Subsection 18.3.7) and emergency planning and response (as described in Chapter 19)
5. Compile a database of all important human actions claimed in the safety analyses, including the source of the claim, their key characteristics, related assumptions and any associated HSIs

For each of the above activities, the task performance criteria are defined to enable the HFE analysis to determine the acceptable achievability of each identified human action. Task performance requirements depend on the plant conditions the task is performed in (normal versus abnormal versus emergency or accident conditions), and for events, are defined by the related safety analysis the HFE analysis is underpinning. For example, for precursor human actions, performance requirements are usually "performed correctly" or "performed in accordance with maintenance schedule timelines". For post-initiating event human actions, the requirements are defined by the event conditions. Tasks must be achievable, completed successfully and, where dictated by the related analysis, must be completed within the required time based on the event timeline.

#### **18.2.6.3 Results**

The outputs from the activities that form this technical element includes:

1. A Human Operation Hazard Evaluation report that documents the methods used and the evaluation results
2. Design records capturing results of safety analyses reviews

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

3. Design records capturing HFE qualitative human error analysis and other substantiation of claimed human actions in the various safety analyses
4. A Human Action Claims database containing all important human actions and critical information for each, allowing for adequate and robust consideration in the design
5. A summary report, which summarizes the methods, results, and issues from each of the above outputs

The results are communicated directly to the appropriate design, safety analysis and other HFE team members performing related technical elements, to ensure timely consideration of the full set of human actions important to safety in their respective activities. The outputs from each activity and the Human Action Claims database capture the source of the identified human actions within the safety analysis to allow full traceability from the origin through HFE safety analysis and forward to any design requirements or safety analysis modifications.

In addition to specific HFE safety analysis activities described in this section, the full complement of safety analysis outcomes, including the PSA and HRA, informs and acts as input to the other HFE technical elements, as applicable.

### 18.3 Design of the Human-System Interface

This section describes the process by which HSI designs are established and evaluated. The HSI design process for BWRX-300 is governed by a process methodology report that outlines the required design inputs, design procedure to be followed, design outputs, and the process for conducting HFE T&E during design development. The HSI design process sits within and is fully integrated into the overall plant design process specified through standard engineering design process and procedure documents, as well as the relevant project-specific design process plans. General design principles and processes are described in Chapter 3, particularly Subsection 3.1.7.

#### 18.3.1 Design Goals and Design Bases

The primary goal of the HSI design process is to facilitate safe, efficient, and reliable user task performance during plant normal operational states, abnormal events, and accident conditions. To achieve this goal, HSIs throughout the plant are designed and implemented consistent with HFE core principles and user-centred design practices. The following specific design bases are adopted for the plant:

1. HSI design promotes efficient and reliable operation through application of automated operation capabilities.
2. HSI design uses only proven technology.
3. The workstation and HSI layouts reflect I&C separation restrictions.
4. HSI design is highly reliable and provides functional redundancy such that sufficient displays and controls are available in the MCR and SCR and remote locations to conduct an orderly reactor shutdown and to cooldown the reactor to safe shutdown conditions, even during design basis equipment failures.
5. The principal functions of the Safety Parameter Display System (SPDS) as required by CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 18.3-1) are integrated into the HSI design.

*NOTE: Historically, the SPDS has provided an overview display of important plant parameters during transients and accidents on a separate panel with separate safety categorization due to the safety analysis outcomes for full-scale plants. The SPDS terminology is used in this PSAR for consistency with regulatory documents. However, the BWRX-300 SPDS functionality does not require a different safety classification and is an integral part of, and included with the SC3 displays (see Subsection 18.3.5). There is no separate panel or system.*

6. Accepted HFE principles and methods are used for ensuring HFE is integrated into the design, in alignment with international best practice and meeting the requirements of CNSC REGDOC-2.5.1, (Reference 18.3-2).
7. HFE design requirements are based on international standards and applicable CNSC regulatory requirements, as outlined in the HFEPP.
8. The design basis for accident and emergency control and monitoring facilities meets international standards as well as CNSC REGDOC-2.5.2 (Reference 18.3-1), and CNSC REGDOC-2.10.1, "Nuclear Emergency Preparedness and Response" (Reference 18.3-3).

Task performance criteria developed through the HFE Program analysis activities, in conjunction with those described in Chapter 3, Section 3.1 and Chapter 15, Subsections 15.3.2 and 15.3.3

are used to govern and direct HSI design specifications. These detailed task performance criteria, along with requirements specified in HFE standards and codes, encompass the set of necessary and sufficient design requirements that maintains the implemented plant SSC and HSIs in compliance with accepted HFE principles.

### **18.3.2 Human-System Interface: Design Inputs**

The inputs to the HSI design are derived from several sources. These include specific information relating to the performance of tasks, as well as design requirements and guidance specific to the plant design and a defined full set of plant user characteristics, but not related to task performance. In addition to these documented input sources, the integrated set of HFE Program activities includes HF Engineer/HFE Specialist support to designers for instances where the correct application of the set requirements is not clear or where design conflicts exist, and suitable alternative design solutions are required. Finally, HSI design updates are made based on results from HFE T&E and HFE V&V activities, as described in Subsection 18.3.4 and Section 18.4, respectively.

#### **18.3.2.1 Task-Related Input**

A primary input to HSI development is the user task information and control needs established during TA (see Subsection 18.2.4). TA provides the following information that forms the HSI Task Support Inventory:

- Information determining the need to initiate a task
- Control needs to accomplish the task steps
- Information feedback to confirm that task step control actions have been accomplished
- Information for determining that task steps are accomplishing their intended objectives
- Information for determining when tasks may be terminated
- System and component alarms
- Information on task performance requirements for group-use and aggregate HSIs
- Information regarding where manual tasks need to be performed (remote or local)

#### **18.3.2.2 Design Requirements and Guidance Input**

The second main input to HSI design is the full set of HFE design requirements derived from international codes, standards, regulations, and best-practice guidance, that are applicable to the defined user group characteristics and the types of HSIs used throughout the plant. These requirements are managed through the formal requirements management process for the plant design that allows traceability from source to implementation. The HFE Design Requirements Document provides an extract from the requirements management database, providing a single repository of these common requirements (i.e., applicable to all SSC).

For the design of HSIs, the requirements in the HFE Design Requirements Document do not provide the entire basis for developing display interfaces. For example, within “requirement-compliant” screen designs, there are any number of acceptable ways to layout and create screen artefacts, for example, variations in colour, size, font, and placement. Further inputs are required that ensure consistent and intuitive HSI designs across the plant. The requirements for this part of the HSI design process are defined in the project HSI Style Guide.

For digital software-driven HSIs, the style conventions are further developed into an HSI Element Library, which contains HSI display templates and HSI elements (e.g., symbols, numerical displays, graphs) that the display designer uses to assemble the display content. The HSI

Element Library contains both HSI elements for primary interfaces (those that represent direct interface to the system and plant HSI) as well as secondary interfaces (such as navigation, which do not directly relate to system equipment).

The HSI Style Guide is also used to maintain consistency for hardware-based controls and indicators, where suitable components are selected and, along with HSI panel templates, their specifications are included in the HSI Element Library.

#### **18.3.2.3 Human Factors Engineering Concept of Operations**

The HSI concept design scope includes development of the HFE Concept of Operations (COO) which defines the physical and cognitive characteristics of the standardized plant full user population. The HFE COO provides user population anthropometrics for the full range of 5<sup>th</sup> percentile female to 95<sup>th</sup> percentile male users, for the worldwide population specified in ISO 7250:3. Other user population characteristics are provided, including population stereotypes (i.e., expectations of interface functionality of the whole user population based on country or nuclear industry norms).

#### **18.3.2.4 Human Factors Engineering Support**

The final input is provided by the HFE team members on an as-required basis. This input is specific to each design challenge or designer technical query. The integration of the HFE team with the other disciplines provides the mechanism for designers to request HF Engineer/HFE Specialist support for instances where is not clear, for the HSI design aspect they are implementing, how the pre-specified requirements are correctly or effectively applied. Designers also request support when they identify conflicting design criteria that limit or prevent implementing the HFE design requirements as specified. In such cases, they need HF Engineer/HFE Specialist advice on the most suitable alternative design solutions.

#### **18.3.2.5 Results from Testing, Evaluation, Verification and Validation**

Throughout the design development, HFE T&E is performed (Subsection 18.3.4). Later in detailed design, early HFE V&V activities start. The results from these HFE T&E and V&V activities may be the identification of an HFE issue with the design or an HED. Recommended resolutions requiring HSI design improvement form the inputs to further design development.

### **18.3.3 Human-System Interface: Detailed Design and Integration**

In accordance with the HFEPP and the HSI design methodology, HSI designs are created through the interaction and coordination of the HFE team and discipline engineers. Degree and type of interaction is based on the risk-based HFE Application Level as described in Subsection 18.1.4.2.

#### **18.3.3.1 Objectives and Scope**

The objectives of the HSI design process are to:

1. Translate codes and standards, as well as functional and task requirements, into HSI characteristics, displays, software, and hardware that enhance safety and reduce the risk of human error to as low as reasonably achievable through design
2. Support the principal objectives of the HSI design to provide the indications, controls, and status displays necessary for tasks allocated to each user, for all the required plant functions during all plant conditions, and to provide the user with accurate, complete, and timely information regarding the functional status of plant equipment and systems
3. Ensure design trade-offs are resolved during the HSI design activities through the systematic application of HFE principles and criteria, and with HF Engineer/HFE Specialist support

4. Maximize the plant capacity factor in the HSI design by:
  - a. Facilitating planned operations, maintenance, inspection, and testing
  - b. Minimizing the occurrence of any undesired power reduction or plant trip caused by erroneous decision-making and actions
  - c. Permitting plant commissioning to take place effectively and allowing timely modifications and maintenance of the HSIs

The scope of the HSI design process is to specify requirements for HSIs throughout the plant. For hardware-based HSIs, the HFE team supports other discipline designers in designing and selecting HSIs. In the case of software-based HSIs, developing the optimized displays are HFE team responsibility. As with all other HFE Program activities, the scope and methods used for HSI design are graded based on HFE Application Level (Subsection 18.1.4.2). The HFEPP details the level of effort and scope for HSI design per HFE Application Level.

#### **18.3.3.2 Methodology**

The HSI design products are created through the interaction and coordination of the HFE team and discipline engineers. Degree and type of interaction is based on the HFE Application Level.

The HFE team provides design and task support requirements (Subsection 18.3.2).

Depending on the HFE Application Level and the nature of the HSI, the HFE team:

1. Provides design requirement-compliant, application-specific wireframes, and templates for HSI displays, panel layouts, and HSI elements, housed within the HSI Element Library
2. Works with the System Engineer to implement the HFE requirements in the requirements management database (as compiled in the HFE Design Requirements Document) that apply to the discipline and system, allowing them to design or specify and select compliant SSC or HSIs and to develop compliant system and equipment layouts
3. Depending on HFE Application Level, reviews, tests, and verifies all HSI design work to ensure acceptable requirements are implemented and compliance is documented or performs proportionate design work audits using the Design and Task Support Evaluation Checklists to ensure acceptable requirements are implemented and compliance is documented

Depending on the HSI type and the HFE Application Level, the same process is followed but the primary and secondary designers/engineers may vary.

The HFE Program HSI Design technical element includes roll-out of the HFE requirements and support to their implementation for other disciplines. For hardware HSIs, including plant layout and physical environment, direct physical SSC interfaces and HSIs that form part of COTS or bespoke design systems and equipment, the responsible discipline engineer includes the applicable task-based and HFE Design Requirements Document requirements as part of their system and component level design requirements. The applicable HFE requirements are included in "lower" level system and component requirements specifications, including procurement specifications, ensuring consistency of application throughout the plant design. This is managed using the design requirements management tool, the standard content for system design specifications, and the integrated HFE design support activities and issues management process outlined in HFEPP.

The HSI design process for software-based HSI display designs, which are the responsibility of the HFE team, is to create each system User Interface Specification (UIS), which contains a DCT.

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

The DCT lists the I/O points associated with a HSI element on a display or panel and provides a mapping of instrumented parameters and controlled components to individual HSIs as follows:

1. Assemble inputs and requirements following the UIS input gathering procedure
2. Complete the system UIS and the DCT. The UIS provides detailed renderings of the HSI display and panel layouts, including the components and parameters to be included on the HSI displays and panels. A UIS is created for each system, and a UIS is also created for the plant-level displays as a part of control room system design.
3. Integrate the UIS and DCT for each system

The complete UIS standard deliverable provides the data, templates, and formats necessary for the development of the software and I/O points to drive the user display interfaces. The UIS standard deliverable consists of:

- HSI Task Support Inventory
- HSI Task Support Inventory – Key Parameters
- DCT
- HSI display screenshot

The HSI display screenshot is a record of the actual HSI display, contained in a software file, delivered with the UIS to the I&C team for data connection with the logic modules.

The HSI design process also includes development of an Alarm Management Design Guide during the concept design stage. The guide provides detailed alarm system and alarm presentation guidance, including outlining the principles for alarm identification, prioritization, filtering, and suppression, in line with human cognitive capacity and required response.

For HSI design, applicable requirements are applied to the developing design, and compliance is documented and maintained by the relevant engineering discipline. Where exception to a requirement is needed, HFE provides design support to the other disciplines to develop and document an HFE-approved justification for an HFE design requirement exception.

The HFE design requirements apply equally to the HSIs of COTS equipment and components. Ability of COTS equipment and component HSIs to meet the HFE design requirements is one of the standard selection criteria. However, it is recognized that not all COTS items require the same level of rigour; standard items that do not include HFE as part of their specification require HFE evaluation for non-compliance with the HFE design requirements. When evaluating COTS products that do not comply with HFE design requirements, special considerations are applied by the HFE team to determine and document acceptability of the discrepancy; these include:

1. Trade-off of benefits of using a proven, standard solution compared to the benefits of a custom solution that more closely meets the HFE design requirements
2. Analysis of COTS vendor HFE design basis and documentation in relation to HFE codes, standards, and relevant good practice
3. Evaluation of COTS HSI design applicability to the defined user population, conventions, and stereotypes
4. Degree of design and task support integration and consistency between the COTS product and the rest of the HSIs
5. Identification of usability or human performance concerns with the proposed application of the COTS product

To accommodate these evaluations, where COTS products are considered, this is determined as early as possible in the design lifecycle, following completion of the HFE COO and other HSI design input documents as soon as the relevant System Engineer specifies that such products will be used.

The individual system and integrated plant-level UIs, hardware-based HSI designs and COTS HSIs, and the plant-level HFE requirements (e.g., those related to workspace layout and working environment), are also integrated into relevant control facility HFE design specifications. The design process for the MCR and SCR are described in Subsections 18.3.5 and 18.3.6; the design for other control facilities, including those for responding to accidents and emergencies follows a similar process, with graded level of effort based on complexity of the HSIs. The facilities for supporting emergency and accident response are in early concept design as described in Chapter 7, Section 7.7 and Chapter 19, Section 19.2.

#### **18.3.3.3 Results**

The process and the rationale for the HSI design are documented and managed under GEH Quality Assurance and BWRX-300 specific design plans, as described in Chapter 17. The HSI design process uses the following templates within the TA and HSI Design workbook to create the UIS:

- HSI Task Support Inventory
- HSI Task Support Inventory Key Parameters
- DCT

The specific controls, indications, displays, panels, and HSI elements designed to support the user tasks are documented in the HSI Task Support Inventory table. Data in the table documents that the designer confirmed that the HSI characteristics are appropriate for the specific use application. The table looks at display and panel locations to confirm that information that needs comparison is located on the same display or panel and that information used in related task actions are located on the same display or panel or are available for concurrent display on adjacent video display units or panels.

In addition to the templates, a screenshot of the resulting HSI display is included in the workbook. The HSI design for displays performed by the HFE team also results in the HSI display software file.

To support the standard plant alarm system logic implementation, a detailed alarm presentation specification is produced in line with the Alarm Management Design Guide. The specification includes rationalization and prioritization evaluation results, providing alarm filtering and presentation requirements as input to the I&C team alarm system design activities.

Other outputs include the design documentation (system design specifications, system and component requirements documents, purchase specifications, and drawings and models), as appropriate to the discipline and HSI type being designed. The results of any non-compliance evaluations and design trade-off decisions are recorded in design records and (where appropriate) the HFEITS (Subsection 18.1.5).

#### **18.3.4 Human-System Interface: Tests and Evaluations**

T&E is an integral part of the HFE design process, with the results of evaluation T&E efforts leading to early and effective modification to requirements and design improvements.

#### **18.3.4.1 Objectives and Scope**

The purpose of HFE T&E is to find and address issues early, rather than waiting for HFE V&V activities near the end of the project (Section 18.4). It is the means to test the feasibility of concepts and early prototypes and to facilitate reaching design decisions. Another difference from the V&V is that design and HFE engineers involved during the design stages are not excluded from being test participants.

The scope of the HFE T&E includes:

- Defining the HSI prototypes and simulation testbeds
- Defining the HFE T&E team and participants
- Establishing HFE T&E methods
- Performing HSI selection and prioritization
- Performing HSI evaluation and user-based testing
- Collecting and analyzing data
- Documenting results, and communicating them to the relevant stakeholders

HFE T&E scope ranges in complexity from simple user questionnaire responses and comments to empirical, performance-based techniques to assess how the user responds to the design under increasingly realistic conditions. The level and complexity of HFE T&E is based on design phase, task complexity, integration of the design feature to be assessed, and design and project risk (new HSI, new systems, high HFE risk grading).

#### **18.3.4.2 Methodology**

To maximize the effectiveness of HFE T&E, HSIs are selected based on prioritization criteria. Primarily selection and prioritization of the HSIs are based on the HFE Application Level (Subsection 18.1.4.2). Where HSIs support more than one task, which means they may have more than one associated HFE Application Level, the worst-case (highest risk) level is used.

Beyond this grading, additional HSI are selected for HFE T&E inclusion based on consideration of any HSI design assumptions that require T&E. Assumptions made during the design phase are identified and refined so that they are specific enough for testing. The design assumptions are weighted to determine test priority (similar to the grading of human actions based on risk). The T&E focuses on the assumptions that have the highest impact if incorrect and the shortest time to learning the HSI.

Some examples of candidate HSI design assumptions include the following:

- Colours and status coding (short time to learning; medium impact if false)
- Hardware HSIs basis ergonomic check (short time to learning; high impact if false)
- Safety HSIs (long time to learning; high impact if false)
- HSIs related to the highest risk-level graded tasks (long time to learning high impact if false)
- New system functionality (long time to learning; high impact if false)

The T&E program is comprised of multiple assessment methods, with the most dominant being performance-based testing. Performance-based testing consists of observing users, given a goal to achieve, interacting with a suitable representation of the HSI design. Members of the test team

observe the user's actions without intervening, recording what transpires. Post-test analysis focuses on any difficulties encountered by the user, both qualitatively and quantitatively obtained, depending on test stage and testbed fidelity. The results are used to highlight differences between the design team assumptions in developing the HSI and actual user behaviour when using it, indicating potential human error traps in the design.

During design development, the performance-based testing may be formative in nature. This type of testing allows for quick low-fidelity prototyping and problem resolution. During formative testing the test administrator and user both participate in the test. The administrator may prompt for information on what and why a user is performing actions to understand the thought process as well as to understand better the prototype or conceptual design limitations.

At appropriate points in the detailed design, testing is done with a summative approach. During summative testing the test administrator does not participate to limit test bias. Several users are tested separately to allow assessment of error variances and statistical comparison of test results.

Each performance-based test cycle begins with the development of a test plan that outlines the purpose, equipment needed, design features being tested, test and data collection methods, performance measures and acceptance criteria, as well as any testing material where appropriate. Design features selected for user testing, the test fidelity, user representatives chosen, testbed used, and performance measure(s) and acceptance criteria all depend on the maturity of the design at the stage of the testing.

Considerations for test design include:

1. Availability of plant modeling software and integrated HSI design status
2. Availability and fidelity of a mock-up
3. Availability of control area and equipment 3D modeling
4. Availability of procedures, procedure types, and training material
5. Availability of a sufficiently diverse participant population pool that is representative of the user population to the level required for the testing stage
6. Develop an observation and evaluation plan. The observation plan includes written test plans, scripts for observers and evaluators, standardized training for participants, and the same observers or proctors for all runs of an evaluation (whenever possible).

Once the test plan is complete and the testbed selected or designed, the T&E team develop an observation and evaluation plan. The observation plan includes written test plans, scripts for observers and evaluators, standardized training for participants, and the same observers or proctors for all runs of an evaluation whenever possible.

The test is then conducted in accordance with the plans.

The HFE T&E program uses a variety of methods and tools for analyses, reviews, and evaluations of the HFE T&E performed throughout the design process.

Data collection methods are selected appropriate to the type of test or evaluation being conducted, as detailed in the T&E plan. Techniques appropriate for the evaluation of HSI include:

- Participant questionnaires and interviews
- Direct observation of user behaviours (e.g., task time, task errors, HSI interaction or navigation errors)
- Simulation instructor console data

The following criteria are used to select the data collection methods:

- Safety and risk significance
- Type of design (depending on the type of design, there are some methods that may not apply)
- Type of technology
- Relative time to perform the test or evaluation
- Relative complexity
- Relative cost and value

In addition to performance-based user testing, the HFE T&E team conducts formal trade-off evaluations to determine the relative benefits of potential design alternatives. Trade-off evaluations are conducted by a multi-discipline group of relevant stakeholders – HFE, other discipline engineering experts, HSI designers, and samples of end users. The trade-off evaluation is conducted using a standard trade-off tool, ranking the design alternatives against weighted key HFE criteria. The output of the trade-off tool is used as the basis to make the HSI design alternative trade-off decision. If there are several closely ranking alternatives, further HFE review or analysis is undertaken to determine. HFE issues resulting from this evaluation are recorded and tracked using the HFEITS. Those that are not resolved at the time include the necessary information to address them in future project stages.

#### **18.3.4.3 Results**

The results from any HFE T&E are documented in design records and on associated test forms design to support the T&E process. Any issues and recommendations resulting from the HFE T&E activities related to design improvement are communicated directly to the applicable HSI designer, used as input to further design development (as per Subsection 18.3.2.5). When the T&E for each design stage is complete, a T&E summary report is prepared that summarizes all T&E activities and their results).

#### **18.3.5 Human-System Interface: Design of the Main Control Room**

The current concept of the MCR is described in Chapter 7, Section 7.5. The MCR design features are based upon proven technologies and are demonstrated, through broad scope control room dynamic simulation during HFE T&E and V&V, to satisfy the HSI design goals and design bases. Validation of the implemented MCR design includes evaluation of the design features, the user job roles, staff complement, and procedures, performed as part of the HFE V&V process as defined by the test specification and performance measures specified for each validation activity (Section 18.4).

The HSI design implementation activities include support to the development of dynamic models for evaluating the overall plant response as well as individual control systems, including operator actions. These dynamic models are used to:

- Analyze both steady state and transient behaviours
- Confirm the design of the advanced alarm system concepts
- Confirm the adequacy of control schemes
- Confirm the allocation of control to a system or an operator
- Develop and validate system and plant-level operating procedures

Using part-task simulation, system models are developed, and linked to the HFE-designed the HSI displays. The part-task simulator is used in preliminary plant design and includes design features specific to BWRX-300.

As the design progresses, the part-task simulator proceeds through a series of iterative evaluations resulting in the development of a full-scope simulator. As soon as available, simulators are the preferred testbed for T&E, allowing for progression from static to dynamic testing.

Safety margins used in the DSA account for uncertainty and provide an added margin to ensure that the various limits or criteria important to safety are not challenged. Suitable margin is also added to the HFE analysis of human actions (during TA and human error analysis, per Subsections 18.2.4 and 18.2.6) by ensuring suitable conservatism is included in things like the timeline analysis or the generation of human error probabilities.

Design goals and design bases for the design of HSIs in the MCR and SCR and in other applicable facilities are established in Subsection 18.3.1, based on the HFEPP.

#### **18.3.5.1 Objectives and Scope**

The primary goal of HSI design and HFE input to design of the MCR is to facilitate safe, efficient, and reliable user performance during all phases of normal plant operation, abnormal events, and accident conditions. To achieve this goal, information displays, controls and other interface devices in the control rooms and other plant areas are designed and implemented in a manner consistent with best HFE practices. Further, the following specific design bases are adopted:

1. HSI design promotes efficient and reliable operation through application of automated operation capabilities.
2. HSI design uses only proven technology.
3. Safety-related systems monitoring, and control capability is provided in full compliance with regulations regarding divisional separation, and independence.
4. HSI design is highly reliable and provides functional redundancy such that sufficient displays and controls are available in the MCR, or as a backup, in the SCR and remote locations to conduct a reactor shutdown and to ensure the reactor achieves and maintains safe shutdown conditions, even during postulated accidents.
5. The MCR remains habitable and protected for all events and accidents during which it is required to be used (habitability of the MCR is described in Chapter 6).
6. The principal functions of the SPDS as required by CNSC REGDOC-2.5.2 (Reference 18.3-1) are integrated into the HSI design.
7. Accepted HFE principles and methods are used for integrating HFE into the MCR design, in accordance with international best practice and meeting the requirements of CNSC REGDOC-2.5.1 (Reference 18.3-2).
8. HFE design requirements are based on international standards and applicable CNSC regulatory requirements, as outlined in the HFEPP.
9. The principal functions of the SPDS as required by CNSC REGDOC-2.5.2 (Reference 18.3-1) are integrated into the HSI design.
10. The design basis for accident and emergency control and monitoring facilities meets international standards as well as CNSC REGDOC-2.5.2 (Reference 18.3-1), and CNSC REGDOC-2.10.1 (Reference 18.3-3).

The evaluation of the integrated MCR design provides confirmation that the MCR HSIs and other design features are compliant with the HFE Design Requirements Document and any analysis-based design requirements. Refer to Chapter 7 for description of I&C system content and to Chapter 13 for the Conduct of Operations.

#### **18.3.5.2 Methodology**

The MCR concept outlined in Chapter 7 contains a group of workspaces and individual HSIs, which form the foundation for the detailed HSI design. The development of the MCR workspaces and HSI design features is accomplished through:

- Consideration of existing control room OE
- Review of trends in control room designs and existing control room data presentation methods
- Evaluation of modern HSI technologies, including alarm system design, particularly alarm reduction and presentation methods
- Application of relevant compiled requirements from the HFE Design Requirements Document
- Design or specification and selection of individual HSIs
- Specification of the integrated HFE design requirements for the MCR as a whole
- Testing of a dynamic MCR prototype (full-scope simulator)

Detailed task performance criteria are specified as part of the TA (Subsection 18.2.4) and qualitative human error analysis (Subsection 18.2.6). These criteria are used to govern and direct all plant control room designs. These detailed task performance criteria, along with requirements specified in HFE standards and codes, encompass the set of necessary and sufficient design requirements that maintain the implemented plant control room designs in compliance with accepted HFE principles. This includes ensuring that any HSIs required to provide manual backup control to safety systems are identified and provided in a location and using technology (e.g., hardware-based high-reliability controls and displays) that are available in the postulated task conditions.

The full-scope simulator is evaluated under normal and abnormal reactor operating conditions by participants suitably representative of the defined user population, as described in the HFE T&E process in Subsection 18.3.4. Following the completion of the HFE T&E and V&V on the full-scope simulator, the MCR workspace, and HSI design features are finalized.

#### **18.3.5.3 Results**

The results from design MCR design activities are the same as those for the overarching HSI design process as described in Subsection 18.3.3.3. This includes the outputs from the related HFE T&E and V&V activities, and identification and tracking of design-related HFE issues and HEDs.

#### **18.3.6 Human-System Interface: Design of the Secondary Control Room**

The SCR provides means to safely shut down the plant from outside the MCR in a location that is protected and not impacted by the same scenarios that makes evacuation of the MCR necessary. The SCR provides the HSIs for the plant systems needed to bring the plant to hot shutdown, with the subsequent capability to attain safe shutdown, if the MCR becomes uninhabitable. The SCR is in early concept at the time of issuing this PSAR. The current concept

is described in Chapter 7, Section 7.6. Habitability of the SCR and protection of the route between the MCR and SCR is described in Chapter 6, Section 6.4.

#### **18.3.6.1 Objectives and Scope**

The SCR provides means to safely shut down the plant from outside the MCR in a location that is protected and not impacted by the same scenarios that makes evacuation of the MCR necessary. The SCR provides the HSIs for the plant systems needed to bring the plant to hot shutdown, with the subsequent capability to attain safe shutdown, if the MCR becomes uninhabitable. The SCR is in early concept at the time of issuing this PSAR. The current concept is described in Chapter 7, Section 7.6. Habitability of the SCR and protection of the route between the MCR and SCR is described in Chapter 6.

#### **18.3.6.2 Methodology**

The methodology for design of the SCR is the same as that for the MCR (Subsection 18.3.5.2) and more generally for HSI design (Subsection 18.3.3.2). As with all HFE Program activities, a proportionate, graded approach is taken to the design of the SCR. Due to the nature and purpose of the SCR and the plant conditions expected when it needs to be used, the human actions are by default important to safety and if incorrectly performed, lead to significant consequences and as such receive the highest HFE Application Level.

#### **18.3.6.3 Results**

The results are captured in the same means as for the MCR design (Subsection 18.3.5.3).

### **18.3.7 Procedure Development**

Procedure development for the BWRX-300 is performed by the HFE team in accordance with a plan that details the inputs, method, and scope of procedure development activities.

#### **18.3.7.1 Objectives and Scope**

The objective of procedure development is to apply HFE principles and guidance to the development of procedures such that they are technically accurate, comprehensive, explicit, easy to use, and validated. The process for procedure development follows applicable requirements from IAEA-TECDOC-1058, "Good Practices with Respect to the Development and Use of Nuclear Power Plant Procedures" (Reference 18.3-4).

The plant procedures are developed as an integral part of the HSI design development. The procedures are developed either as new or modified from predecessor plants. Existing procedures are modified to reflect the characteristics and functions of the plant task types, modes and conditions, and any applicable OE related to procedure design.

The HFE Program includes activities to verify that all functions and tasks assigned to the plant personnel are included in the procedures. The HFE V&V activities include validation of the procedures using the mock-ups, part-task, and full-scope simulators to confirm their usability and accuracy. Procedure development is iterative and progressive, in line with the developing design and results from progressive HFE analyses.

The scope of procedure development addresses all tasks required to meet functional goals in operations, maintenance, inspection, testing, and accident management of the plant. The scope includes development of:

- Procedures Writer's Guides
- Plant and System Operations Procedures (start-up, normal (at power operations), and shutdown)

- Maintenance, Inspection, Testing and Surveillance Procedures (including Refuelling and Outage Planning Procedures)
- Alarm Response Procedures
- Abnormal Operating Procedures
- Emergency Procedure Guidelines for Emergency Operating Procedures (EOP) development
- (EOPs)
- Severe Accident Management Guidelines
- Emergency Mitigating Equipment Guidelines

The procedure development process does not include specific requirements for the development or procurement and implementation of a Computer-Based Procedures (CBPs) platform or tool. However, the Procedure Writer's Guide specifies basic HFE requirements for usability of the CBP interface (the same as any other user interface) and the development of the content and format for any CBP inputs follows the same requirements for each procedure type given in the above list.

#### **18.3.7.2 Methodology**

The procedures development methodology establishes the process for developing technical procedures that are complete, accurate, consistent, and easy to understand and follow.

For each procedure type, a Procedure Writer's Guide is established. The Procedure Writer's Guide establishes objective criteria so that the procedures developed with it are consistent in organization, style, and content. The Procedure Writer's Guide provides instructions for procedure content and format, writing of steps, and specifying lists of terms used.

Procedures are then written after the associated TAs are finished. TA is an iterative process due to the amount of information that is created at any point in the design process. TA is conducted in a prioritized manner and done on a per task, per system basis. System Design Descriptions are used along with the TA output to give a complete understanding of the system and its operation. These inputs provide understanding of each system, its associated tasks, and its interrelationship to other systems, which allows the development of system level and then integrated operations procedures.

As the TA progresses beyond operations, when the System Engineers have defined test, inspection, and maintenance requirements and the iterative safety analyses have sufficiently matured, procedures are developed for other than normal operations (e.g., test, maintenance, surveillance, alarm response, outages and any other conditions that are not included in the scope of normal plant operations). Procedures that support important human actions for the higher HFE Application Levels are developed by the HFE team based on the detailed TA and qualitative human error analysis. Procedures to support human actions for the lowest HFE Application Level are developed by the responsible System Engineer or the vendor, based on the Basic TA (Subsection 18.2.4).

Initial procedures are tested and evaluated for their usability and efficacy using physical mock-ups, simulation, and plant 3D models early in the design, through the HFE T&E activities. The HSI design and procedures are evaluated together to make a more cohesive model of the future operational plant. This provides contextual feedback for both the HSI design and the procedure, allowing optimization of the design of both simultaneously.

The developed procedures are verified and validated as part of the HFE V&V program (Section 18.4), culminating in ISV. Procedures that support important human actions for the higher HFE Application Levels are validated by individuals that are independent of the design. Individuals that participate in validation of these levels of procedures include representatives of the end users. Final procedure validation is done on the installed physical plant hardware as part of the HFE design implementation once the plant has been built. Procedures to support human actions for the lowest HFE Application Level are validated by the designer.

The final procedure validations are done as specified by the plant pre-operational testing and start-up testing programs. Following ISV, the procedures are used as the basis for pre-operational testing, start-up testing, and operation of the plant. Once a procedure is validated and declared complete, procedure maintenance and control of updates is governed by the engineering change management process ensuring that changes to individual procedures are reflected throughout the full suite of related procedures, and that changes are confirmed as accurate and supported by the design and TA. Validated procedures are provided to operations for training and use.

#### **18.3.7.3 Results**

The results of the procedure development process are the final set of procedures and any procedure support documentation developed using the procedure development methodology.

The output documents include the following:

- Procedure Writer's Guides
- Plant and system operations procedures
- Maintenance, Inspection, Testing and Surveillance Procedures (including Refuelling and Outage Planning Procedures)
- Alarm Response Procedures
- Abnormal Operating Procedures
- EPGs
- EOPs
- Severe Accident Management Guidelines
- Emergency Mitigating Equipment Guidelines

#### **18.3.8 Training and Qualification Program Development**

Training and qualification program development is coordinated with the other elements of the HFE Program, for example by using HFE TAs to conduct a systematic analysis of job and task requirements. The program of analysis and training material development is conducted by the Training team, in accordance with a plan that provides the methods and framework for ensuring the program meets its requirements and technical basis. The HFE team provide inputs to the training analysis activities and provide support to the Training team in conducting the training program development activities.

##### **18.3.8.1 Objectives and Scope**

The aim of the BWRX-300 training and qualification program development is to systematically incorporate information from the other HFE design tasks to support development of accurate and applicable training content and implementation of effective personnel training. The training program development process is intended to produce a program that:

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

- Identifies all performance requirements of a job or duty area relating to licenced activities
- Defines and documents the training based on a TA that provides the information to establish the knowledge, skills, and abilities to perform each task including identifying the safety-related attributes if any
- Ensures that the training is designed, developed, and implemented to meet the qualification requirements
- Ensures instructors meet and maintain documented qualification requirements, particularly in areas of subject matter expertise and instructional skills
- Ensures that formal evaluation methods are used to confirm and document workers qualifications
- Implements a change management control system that systematically identifies changes to tasks and task lists for revisions of training
- Ensures continuing training is provided as deemed necessary through training needs analysis
- Evaluates training regularly and incorporate the results of the evaluation into a training improvement process
- Ensures that workers training and qualifications records are established and maintained
- Ensures that workers have a level of training related to nuclear safety corresponding to their position including but not limited to radiation safety, fire safety, onsite emergency training, and conventional health and safety

The training and qualification program development includes the following stages:

- Analysis
- Design
- Development
- Implementation
- Evaluation

The overall scope of the resulting training and qualification program includes the following:

1. All categories of personnel conducting tasks within the plant, including the full range of job roles whose actions may affect plant safety
2. The full range of plant conditions (normal operational, outage, abnormal, accident, and emergency)
3. All activities conducted throughout the plant (e.g., operations, radwaste processing, outage refuelling, online and offline maintenance, testing, and inspection)
4. The full range of plant functions and systems
5. The full range of relevant HSIs

The scope of the training and qualification program development plan does not include the specific requirements for certification of plant personnel specified in CNSC REGDOC-2.2.3, "Personnel Certification, Volume III: Certification of Reactor Facility Workers" (Reference 18.3-5). The requirements for certification are incorporated as part of the overall program; however, they

do not need to be derived through the defined development process, since they are already specifically defined. The final training and qualification program specific to the operational goals of the plant and developed from the HFE and design inputs, as described in this section, are augmented by the general and specific training and certification requirements specified in CNSC REGDOC-2.2.3, Volume III (Reference 18.3-5).

#### **18.3.8.2 Methodology**

The training and qualification program development follows the fundamentals of the systematic approach to training method. The development process complies with the requirements of CNSC REGDOC-2.2.2, "Personnel Training" (Reference 18.3-6).

The Analysis Stage provides the identification of training needs, tasks, or competencies required for training and the knowledge, skills, and abilities required to perform a specified job position based on assigned tasks. Tasks that support plant functions are identified as part of Detailed and Basic TA, described in Subsection 18.2.4. Tasks are selected for training based on difficulty, importance, and frequency analysis. Depending on the difficulty, importance, and frequency ranking, a decision is made to determine if initial training and periodic retraining is needed. This evaluation of training tasks is the training equivalent to grading human actions (Subsection 18.1.4.2). The results of the TA, including identification of critical steps, inform the difficulty, importance, and frequency analysis and resulting rankings.

Depending on the difficulty, importance, and frequency ranking, a determination is made if initial and periodic retraining is required. Tasks that are selected for training are then analyzed to determine the required knowledge, skills, and attributes. The knowledge, skills, and abilities necessary for each job position, including entry-level education, training, and experience, is established to support training design. Any changes to the iterative HFE or system design inputs to the analysis phase are required to be assessed for impact on the training analysis.

During the Design Stage, learning objectives are developed and a description of the plan for training, including purposed methods and settings, is established. Specifically, the Design Stage includes the following activities:

- Determine the scope, purpose, and timeframe of the training
- Determine the ideal training environment
- Select training methods and instructional strategies in accordance with the environment
- Determine and group the job role knowledge, skill, and attributes addressed by each training module
- Determine the final and partial learning objectives for each training module, including defining performance statements, conditions statements and performance standards
- Prepare the table of contents and scope for each training module; scope includes number and type of documents developed in the next phase
- Prepare master training procedures and formats to ensure consistency across the course materials
- Prepare the training plans for each job position; plans comprise learning objectives, contents, learning activities, training equipment, and a list of materials needed for training, including guidance for their use

The completion of the Design Stage establishes the input that is needed for the Development Stage.

NEDO-33968 REVISION 0  
NON-PROPRIETARY INFORMATION

In the Development Stage, detailed lesson plans and instructional materials are created, including any on-the-job training documents, and knowledge and performance assessment tests are established. The materials developed must incorporate the required features specified in the Design Stage. The materials are developed such that they have the following attributes:

- Course material content supports mastery of the subject learning objectives.
- Course materials are structured to provide consistent presentation.
- Course material presentation sequence supports effective learning.
- Course materials support successful presentation in the specified venue(s) the course is to be provided.
- Instructor certifications and training required to present training is specified for each course and supports successful presentation in the required venue. Instructors are trained during this phase.
- Exam question banks and examination structure and content are developed to adequately evaluate, and document trainee mastery of the course and job performance objectives associated with the training.

At the end of the Development Stage, the training package is reviewed, piloted on trainees, and revised if necessary.

In the Implementation Stage, instructors prepare for and deliver the training. Trainees are tested to determine if they have mastered the objectives. The results of trainee tests are examined during the Evaluation Stage. The Evaluation Stage examines the effectiveness of the training as delivered. This appraisal is done through the review of training results, training feedback, and continual monitoring of work performance (Section 18.6).

The training and qualification program, developed as discussed above, provides assurance that plant personnel have the capability and competence needed to perform their roles and responsibilities. Participants used for ISV, as described in Section 18.5, are trained using this program and provide validation of the integrated design.

#### **18.3.8.3 Results**

The specific program outputs include documentation defining the overall program goals and course structure, as well as the specific job role qualification and training requirements and developed course materials. In addition to the training program content itself, the results of the training and qualification program development are summarized in a report which documents the process and activities used in development, including any inputs used, issues identified, and recommendations made.

## **18.4 Human Factors Verification and Validation**

HFE V&V is a critical HFE design assurance activity applied to the realized design of the plant HSIs and the working environment where those HSIs are used. The HFE V&V program evaluates the plant design (in parts and as an integrated whole) against HFE design principles and requirements, user task requirements, job design and staff complement, procedural accuracy and usability, and effectiveness of training.

### **18.4.1 Objectives and Scope**

The HFE Verification is conducted through two activities with the following objectives:

1. Task Support Verification (TSV) verifies that the HSIs, as defined and baselined in the HSI inventory and characterization, include the necessary features (e.g., controls, information displays, and alarms) required to support tasks and that there are no unnecessary features.
2. HFE Design Verification verifies that the HSIs and plant SSC, are compliant with the applicable HFE design requirements contained in the HFE Design Requirements Document and design-to-analysis requirements input as a result of HFE analysis activities. Verification activities include identifying changes to the design that impact HSIs and other features due to competing design constraints, and checking for due consideration of OE items, user stakeholder input and HFE T&E results.

HFE Validation is conducted through staged activities, as follows:

1. Early and Partial System Validation activities are performed in advance of the full-scope simulator and fully constructed plant and are generally performed only on partial systems. Although they require a sufficient maturity of the design, HFE participants from the V&V team, and end users with enough level of familiarity with the system, they do not require the full integrated system. The purpose of these validation activities is to identify and solve HFE issues in advance of a fixed design.
2. ISV is the performance-based evaluation of the fully integrated system design. Simulations and virtual reality models are used to validate the ability of personnel, trained using the training and qualification program material, to use the integrated HSIs and finalized procedures in accordance with the task and scenario performance requirements. ISV is intended to evaluate those integrated aspects that were verified and validated singly through earlier, partial means.

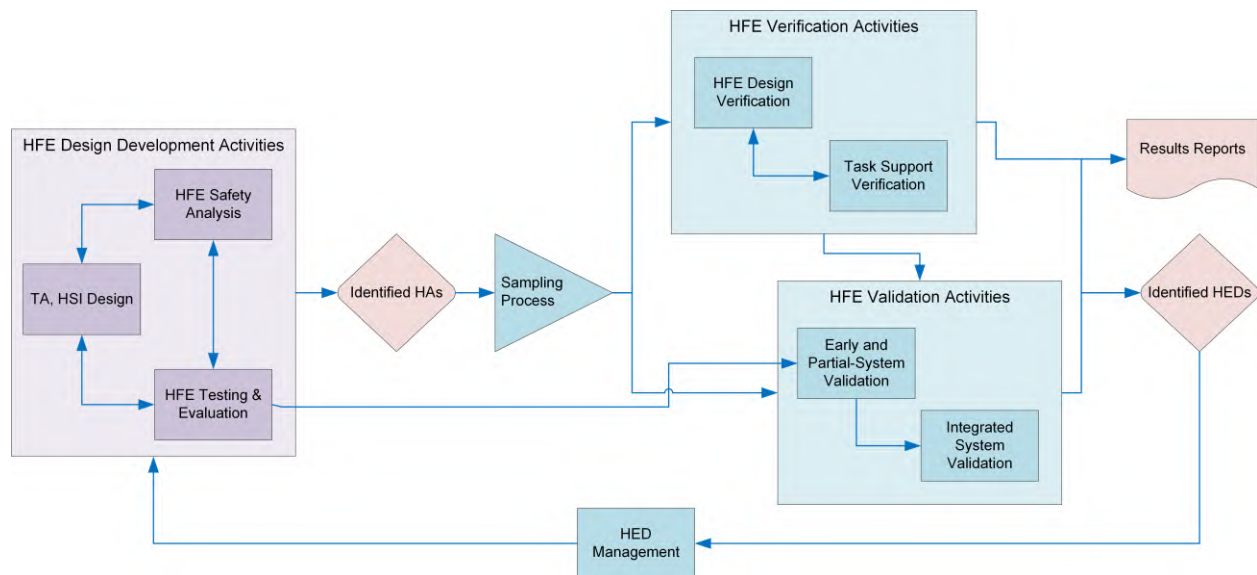

HFE Validation ensures that the design, particularly the HFE-specified aspects, accomplishes its intended goals for usability and reducing the risk of human error to as low as reasonably achievable. Validation is an integrated, dynamic, performance-based test activity in which participants are subjected to a set of simulated scenarios that represent a realistic, challenging, and generalizable set of conditions to ensure that the integrated HSI supports safe operation of the plant.

The scope of the HFE V&V activities applies to user interactions with the plant when performing operations, maintenance, testing, and inspection activities. The HFE V&V activities are applied to HSIs within scope of the HFE Program. As with the other HFE Program activities, the application of HFE V&V is graded to focus on the HSIs, tasks, and plant conditions that involve important human actions, are complex or novel, or are inherently hazardous. The same risk-based approach described in Subsection 18.1.4.2 is applied to the HFE V&V activities to determine the appropriate scope, rigour, and level of detail for each activity.

## 18.4.2 Methodology

The HFE V&V program is conducted in accordance with a structured, systematic plan. The program was developed to meet the requirements and best-practice guidance specified in CNSC REGDOC-2.5.1, "General Design Considerations: Human Factors" (Reference 18.4-1), CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 18.4-2), CSA N290.12-14, "Human factors in design for nuclear power plants" (Reference 18.4-3), IEC 61771, "Nuclear power plants – Main Control Room – Verification and validation of design" (Reference 18.4-4), and IAEA SSG-51, "Human Factors Engineering in the Design of Nuclear Power Plants" (Reference 18.4-5). The program adopts a risk-based graded and multi-staged approach to V&V.

The V&V program plan specifies overall process used for HFE V&V, and the scope, inputs, methods, and outputs to be used for each V&V activity. The overall process is shown in Figure 18.4-1.

**Figure 18.4-1: BWRX-300 HFE V&V Process Overview**

The Sampling Process is a support activity that establishes the scope of the HFE V&V activities. In a new plant design, the number of scenarios and HSIs is too large to effectively perform HFE V&V to the same degree on all of them. The purpose of the Sampling Process is to focus on the significant, novel, and complex HSIs and tasks, ensuring a full breadth of HFE V&V scope but removing any duplication, thus improving the efficacy of the HFE V&V activities.

The Sampling Process selects the inputs that bound the scope of the HFE V&V activities. The verification activities target a selection of HSIs (e.g., displays, panel layouts, equipment-mounted controls, and indications) and the validation activities target a selection of scenarios. The goal of sampling is to maximize sample relevance and significance while ensuring that the sample is sufficiently broad and diverse, so that the HFE V&V results are generalizable to the overall population of HSIs and scenarios.

TSV compares the HSI elements (alarm, control, information and equivalent) identified during the detailed analysis of a task to the designed HSIs to ensure that all components needed to safely and efficiently complete the tasks present in the final design. The task support inventory and verification criteria are identified during TA (Subsection 18.2.4).

In HFE Design Verification, various aspects of HSI and plant SSC design are compared to the relevant design requirements specified during the design development (Subsections 18.3.1 through 18.3.6). The aspects verified include:

- Static and dynamic HSI features, including HSI-specific and standardized features
- Interface management features such as navigation and data retrieval
- Workstations and workspace anthropometrics
- Global workspace features (i.e., layout, workplace environment, lighting, noise)
- Effects of degraded HSI and plant workplace conditions

During HFE Design Verification, the HFE verifier documents each HSI, or plant SSC element being evaluated (including document and page numbers, screenshots, or photographs as applicable), which subset of HFE Design Requirements Document requirements were applied, and whether the HSI or SSC element passed or failed each requirement.

Early Validations form an essential part of the HFE Validation activities; they are performed to identify and solve HFE issues in advance of a fixed design. They require a sufficient maturity of the design, HFE participants from the V&V team, and end users with enough level of familiarity with the system. However, they do not require the full integrated system, including trained users and final procedures, that the ISV requires. Early Validations are expected to progress HFE T&E activities and results (Subsection 18.3.4), using higher fidelity testbeds and more cohesive scenario-based sets of tasks. The general method for conducting the Early Validations is the same as that for ISV, without the requirements for a complete integrated system and complex high-fidelity testing environments.

ISV is the performance-based evaluation of the fully integrated system design. Simulations and virtual reality models are used to validate the ability of personnel, trained using the training and qualification program material (Subsection 18.3.8), to use the integrated HSIs and finalized procedures such that they support safe plant functionality. ISV is intended to evaluate those integrated aspects that were verified separately through earlier, partial means (i.e., through HFE T&E, TSV, Early Validation). ISV is performed using high-fidelity simulators, task trainers or virtual reality labs (i.e., for scenarios outside of control rooms and control stations). The ISV is the final activity that ensures the integrated design is fulfilling its intended function and demonstrates that claims made in the safety analyses are achievable to the performance requirements specified.

The general method for conducting either early validations or ISV is:

1. Perform preliminary activities
  - a. Scenario identification and development
  - b. Testbed verification
2. Perform testing
  - a. Participant selection
  - b. Scenario definition and documentation
  - c. Performance measures
  - d. Test design
  - e. Pilot testing
3. Perform data analysis and document results

Any issues or non-compliances identified during the HFE V&V activities are identified as a HED. HEDs are processed using the HFEITS process as described in Subsection 18.1.5.

#### **18.4.3 Results**

The results of all the HFE V&V activities are captured in the following indicative documents:

1. HFE Verification Results Report
2. HFE Early and Partial Validation Result Report(s)
3. HFE ISV Test Specification
4. HFE ISV Summary Report

Another output of the HFE V&V activities is identified HEDs, which are captured in the HFEITS and managed through the process described in Subsection 18.1.5.

## **18.5 Design Implementation**

Design Implementation addresses the implementation of the HFE design requirements in the final realized design.

### **18.5.1 Objectives and Scope**

The HFE Design Implementation activities have the following objectives:

1. Confirm that the final realized HSIs, plant SSC, procedures, and training conform to the design requirements and design documents resulting from the HFE Program activities
2. Identify any deviations from the design during implementation and assess their impact on the HFE aspects of the design
3. Perform final procedure validation on the physical plant hardware
4. Verify aspects of the design that may not have been evaluated previously in the V&V process, i.e., any HSIs that were absent or modified from the simulator-based ISV, or any plant physical or work environment (e.g., noise, lighting, thermal) characteristics; verification of items not previously identified as needing evaluation uses the same grading process as the original verification during the design stage
5. Verify and document the resolution of all remaining HFE issues and HEDs (Subsection 18.1.5)
6. Verify HFE Application Levels (Subsection 18.1.4.2) are correct based on the final version of documents and data used as input to determine the levels

The scope of the design implementation is the full set of HFE aspects of the plant including design of the HSIs and plant SSC, plant procedures, and finalized training documentation.

### **18.5.2 Methodology**

Unlike the other HFE technical elements, Design Implementation is performed after the design is complete, immediately prior to commencement of commercial operations. Despite the plant being built and undergoing start-up testing and commissioning, the HFE team still performs the Design Implementation activities. The process follows the HFE V&V process. In this case, the Sampling Process includes identifying any changes to the standardized plant design (documented through engineering configuration control process) and assessing impact on HFE aspects of the design. The Sampling Process also identifies aspects of the design that were not able to be previously verified and validated. Additional items not previously identified for V&V but determined to require it are also added to the scope for Design Implementation HFE V&V.

The list of methods used are similar to those described for the HFE Program activities, particularly HFE V&V, Staffing Analysis, Procedure Development, Training and Qualification Program Development, and HFE Issues Tracking.

At this stage, the plant design is in formal engineering configuration control, as described in Chapter 17.

### **18.5.3 Results**

The results of the Design Implementation activities match the outputs for the same activities conducted during the design phase. They are recorded in a summary report. Any remaining HFE issues or HEDs are recorded in the HFEITS for turnover to the plant operating organization, and further mitigation through operating arrangements as required.

## **18.6 Human Performance Monitoring**

The HPM strategy links HFE methods used during the design with methods for monitoring user task performance during operation. The HPM program is fully developed by the licence applicant as part of the future licencing stage.

### **18.6.1 Objectives and Scope**

The purposes of HPM are:

1. To ensure that the high safety standards established by the HFE Program during the design of the plant are maintained even when changes are made to the plant
2. To detect any deterioration of task performance that may be attributable to latent or slow-developing HFE design issues
3. To provide adequate assurance that the safety bases remain valid during the operational phase of the plant

There is no intent for the HSI designer or the applicant to periodically repeat a full set of ISV activities. The strategy is to provide a monitoring plan, building upon the HFE activities during the design that can be carried forward into the operational phase, using industry accepted methods. HPM incorporates the monitoring strategy into the problem identification and corrective action program, which identifies and classifies human errors, provide for evaluation of the root cause, and supports effectiveness verification and documentation of the corrective action.

The scope of the performance monitoring strategy provides reasonable assurance that:

1. The HSI design is effective during:
  - a. Normal operations
  - b. Maintenance, Inspection, Testing, and Surveillance
  - c. Anticipated Operational Occurrences
  - d. Design Basis Accidents
  - e. Design Extension Conditions
  - f. Severe Accidents
2. Human actions, using HSI information, cues and controls can accomplish tasks while maintaining margin for time and performance criteria.
3. Acceptable performance levels established during the HFE ISV are maintained.
4. Changes made to the initial HSIs, user group definition, job design, procedures, and training do not have adverse effects on personnel task performance (e.g., a change interferes with trained skills, or a fatigue management policy is not implemented, contrary to what was assumed in the HFE COO).

### **18.6.2 Methodology**

The HPM program aligns with the overall quality program and condition reporting methods. The program includes:

- Data collection
- Importance screening
- Event analysis to determine causes

- Trend analysis
- Corrective action development

The HPM strategy collects data to trend task performance, particularly seeking issues with design root causes due to non-compliance with or inappropriate application of HFE principles. The HPM program uses existing utility or industry programs (e.g., corrective action, programs, or operator training) for data collection where appropriate. The HPM program is designed to ensure that:

1. Human actions are monitored commensurate with their safety importance.
2. Feedback of information and corrective actions are accomplished in a timely manner.
3. Degradation in performance is detected and corrected before plant safety is compromised.

*NOTE: The HFE-based HPM does not seek personnel behaviour-based corrective actions. It is focused solely on issues related to the design of HSIs and organizational arrangements that lead to human error.*

The HPM program maintains a database of event causes and corrective actions taken. Such data supports trending of performance anomalies.

The HPM identifies and establishes corrective actions that reduce the potential for incident recurrence. The program systematically identifies the cause of the failure or degraded performance. The corrective actions are derived by:

1. Addressing the significance of the failure through application of PRA/HRA importance measures
2. Classifying the causes and circumstances surrounding the failure or degraded human performance
3. Illuminating the characteristics of the failure (e.g., being task specific or due to design issues)
4. Determining whether the failure is isolated or has generic or common cause implications

### **18.6.3 Results**

The HPM program activities and outputs align with the overall condition reporting requirements. They are expected to include specific incident or trend analysis reports, a recommendations and action tracking database, and periodic summary reports.

## **19.0 EMERGENCY PREPAREDNESS AND RESPONSE**

The purpose of Chapter 19, Emergency Preparedness and Response, is to provide sufficient information on emergency arrangements, demonstrating in a reasonable manner during a nuclear or radiological emergency, all actions necessary for the protection of workers, the public, and the environment could be taken; and the decision-making process for the implementation of these actions would be timely, disciplined, coordinated, and effective.

To maintain consistency throughout the OPG Nuclear fleet, including the Darlington New Nuclear Project (DNNP), the content of Chapter 19 is based on the current OPG Nuclear emergency management program documented in N-PROG-RA-0001, "Consolidated Nuclear Emergency Plan (CNEP)" (Reference 19.6-1), which is compliant with Canadian Nuclear Safety Commission (CNSC) REGDOC-2.10.1, "Nuclear Emergency Preparedness and Response" (Reference 19.6-2); CSA Group (CSA) N1600, "General requirements for nuclear emergency management programs" (Reference 19.6-3); and "Provincial Nuclear Emergency Response Plan (PNERP): Master Plan" (Reference 19.6-4).

During construction and fuel-out commissioning phases, as defined in CNSC REGDOC-2.3.1, "Conduct of Licensed Activities: Construction and Commissioning Programs" (Reference 19.6-6) of the project, the potential for nuclear and radiological emergencies will be the result of incidents from Darlington Nuclear Generating Station (DNGS) only. Since an event at DNGS, which includes site facilities listed in Chapter 2, Subsection 2.2.5, may affect personnel at DNNP, emergency response protocols are considered for both the DNNP and DNGS sites. Therefore, all personnel at DNNP will appropriately respond to emergency tones and announcements emerging from DNGS. This follows the requirements of NK054-PLAN-01210-00002, "DNNP Nuclear Emergency Preparedness Plan" (Reference 19.6-5).

In support of the Licence to Construct (LTC) application, Chapter 19 complies with CNSC REGDOC-1.1.2, "Licence Application Guide: Licence to Construct a Reactor Facility" (Reference 19.6-15), specifically Section 4.10, Emergency Management and Fire Protection and Subsection 4.3.5, Accident and Severe Accident Management and Recovery, CNSC REGDOC-2.3.1 (Reference 19.6-6), specifically Subsection 3.3.5, Emergency Management and Fire Protection, CNSC REGDOC-2.3.2, "Operating Performance – Accident Management" (Reference 19.6-13), and applicable Sections of CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 19.6-8). In addition, other applicable regulatory documents, codes, and standards related to emergency preparedness and response are referred to in the specific discussion topics throughout this chapter.

### **19.1 Arrangements for Performing Functions Essential for the Emergency Response**

The CNEP (Reference 19.6-1) describes concepts, structures, roles, and processes to implement and maintain an effective OPG response in the unlikely event of a nuclear or radiological emergency that could endanger on-site staff, the public, or the environment. The CNEP provides a framework for interaction with external authorities and defines OPG commitments under the PNERP Master Plan (Reference 19.6-4).

The PNERP provides the off-site planning basis for nuclear emergencies with the goal of ensuring public safety in the event of a nuclear emergency. The PNERP Master Plan (Reference 19.6-4) establishes the principles, concepts, organization, responsibilities, policy, functions, and inter-relationships, which govern all off-site nuclear emergency planning, preparation, and response in Ontario.

As part of DNNP Site Preparation Commitment D-P-5.1, OPG developed the DNNP Nuclear Emergency Preparedness Plan (Reference 19.6-5), which takes its program authority from the

NEDO-33969 REVISION 0  
NON-PROPRIETARY INFORMATION

CNEP (Reference 19.6-1). The plan provides a written basis to document the concepts, roles, and resources required by OPG to implement and maintain its emergency response on the DNNP site to protect employees, visitors, and contractors in the event of a nuclear emergency originating from DNGS operations. The document describes the different phases of the DNNP Site Preparation, Construction, Commissioning and Operations, and how the nuclear emergency preparedness program will transition from construction to fuel-in commissioning when the site will become a Class I nuclear facility.

Under Commitment D-O-2 (Reference 19.6-6), submitted with the Licence to Operate application, OPG will develop or revise the CNEP (Reference 19.6-1) to address site specific emergency planning for the DNNP including the following:

- The basis for emergency planning
- Selection and qualification of workers
- Emergency preparedness and response organization
- Emergency training
- Drills and exercises
- Emergency procedures
- Assessment of emergency response capability
- Assessment of accidents
- Activation and termination of emergency responses
- Protection of facility workers and equipment
- Interface with off-site organizations
- Recovery program
- Public education program

The nuclear emergency plan for BWRX-300 will comply with CNSC REGDOC-2.10.1 (Reference 19.6-2) and the PNERP Master Plan (Reference 19.6-4).

OPG has a Memorandum of Understanding in place with the Province of Ontario to revise the PNERP prior to fuel-in commissioning, as defined in CNSC REGDOC-2.3.1 (Reference 19.6-6) to include DNNP and issue a revised Darlington Implementing Plan or a separate Implementing Plan for DNNP.

The basis for emergency response is to implement plans and procedures to protect site personnel, the public, the environment, and to minimize adverse effects to structures, systems, and components within the site perimeter and beyond.

The OPG Emergency Response Organization (ERO) is responsible for the following:

- Initial notifications
- Performing site surveys
- Bringing the incident unit under control
- Any immediate personnel protective actions for the site
- Providing data for off-site agencies to make public protection decisions

NEDO-33969 REVISION 0  
NON-PROPRIETARY INFORMATION

Some or all of these actions will apply to the BWRX-300 and will be determined as information becomes finalized.

The integration of resources and support from both internal and external parties are essential to ensure on and off-site measures are administered per the CNEP (Reference 19.6-1), PNERP Master Plan (Reference 19.6-4) and CNSC REGDOC-2.10.1 (Reference 19.6-2).

The purpose of the OPG Nuclear emergency management program (Reference 19.6-1) is to implement plans and provide trained personnel to address nuclear events by controlling releases and minimizing effects of radioactive releases. OPG also works with government agencies, regional partners, and other stakeholders to protect the public and plan for recovery following a nuclear emergency.

To remain consistent with OPG Nuclear emergency response practices, similar response processes will be employed at DNNP. The DNNP senior authorized person on shift during a declared emergency performs the following:

1. Assumes command and control of emergency response operations from the outset of the emergency
2. Be located in either the Main Control Room (MCR), Secondary Control Room (SCR) or on-site Emergency Operations Centre (EOC)
3. Fulfills the responsibilities of the emergency response Commander until relieved by the call-in emergency response Commander supported by the augmented ERO
4. Until relieved, executes both the senior shift licence duties and specific responsibilities of the emergency response Commander (e.g., off-site interface role, overall site commander and chief of response)

The DNNP senior authorized person on shift performs an emergency assessment, including classification and categorization, in order to determine the following:

1. Extent of the on-site response and staff mobilization required for the protection of on-site personnel and equipment
2. Notification category necessary for the Province of Ontario to determine the off-site response required for the protection of the public and the environment

To generate the appropriate level of response to an incident, the DNNP senior authorized person on shift must first identify the significance of the incident (D-INS-03490-10009, "Shift Manager" (Reference 19.6-11)). The processes used are termed "Classification" and "Categorization". The actual or potential threat to employee and public safety will determine the event classification and categorization.

Classification determines the level of on-site response, whereas categorization determines the level of off-site response.

The classification depends on in-plant circumstances. Should the event be classified as a Station Emergency, the Station Emergency Tone (D-INS-03490-10007, "Response to Warning Signal" (Reference 19.6-14)) will be sounded (or other established on-site notification protocols).

NEDO-33969 REVISION 0  
NON-PROPRIETARY INFORMATION

A Station Emergency is a radiological or non-radiological incident (e.g., fire, explosion, flood, tornado, seismic event, hazardous material, major system/equipment failure, security breach, etc.) where one or more of the following emergency response activities are required, more quickly than could be activated via normal supervisory contact:

- Assembly of personnel to designated safe areas
- Accounting of personnel
- Mobilization of ERO resources to manage the situation

First, the process of OPG emergency classification is completed. Then, a second process is undertaken to determine the Provincial notification category and associated default off-site protective actions. The assessment process for off-site categorization is governed by the criteria set by the PNERP (Reference 19.6-4). OPG has a Memorandum of Understanding with the Province of Ontario to review the PNERP categorizes in order to develop site specific instructions applicable to DNNP.

The Shift ERO will initially assume command and control of the site emergency. Augmented ERO personnel will be called in to form the Site Management Centre staff to support the shift organization. The Shift ERO will transfer coordinated site response to the Site Management Centre when it becomes operational. See Section 19.2 for Emergency Response Facilities description.

The Site Management Centre staff ensures coordinated site response occurs and site commitments under the emergency plan are met. The Site Management Centre staff will assume responsibility for on-site personnel protective actions, coordination of site evacuation, direction of operational recovery, responsibility for communications and interface between the station and the off-site Emergency Response Facility (ERF), as well as with external organizations.

Staff in the ERO, as indicated above, are relieved by replacement staff depending on the duration of the response.

OPG has established plans and procedures to coordinate with the appropriate off-site organizations. These plans and procedures will be used as a framework for development of BWRX-300 site specific procedures per this chapter and Chapter 13, Subsection 13.4.3, Procedures and Guidelines for Operating the Plant During Accidents.

Categorization determines the level of off-site response as defined in the PNERP (Reference 19.6-4) and based on the order of significance as follows:

- Reportable event
- Abnormal incident
- On-site emergency
- General emergency

Details of the notification requirements for the four defined categories are as defined in the PNERP (Reference 19.6-4). See subsequent discussion on notification target times.

NEDO-33969 REVISION 0  
NON-PROPRIETARY INFORMATION

As previously stated, on-site emergency arrangements, including programs on training and exercises, will be submitted with the Licence to Operate application under Commitment D-O-2 (Reference 19.6-5). This will ensure emergency preparedness and response is in place prior to fuel-in commissioning, which is within the scope of the Licence to Operate. Additionally, OPG will meet the requirements of CNSC REGDOC-2.3.1 (Reference 19.6-6), which includes testing emergency management provisions before the commencement of fuel loading.

CNSC REGDOC-2.10.1 (Reference 19.6-2) and PNERP (Reference 19.6-4) encompasses several national and international standards and guidelines, including International Atomic Energy Agency (IAEA) Safety Standards Series No. GS-G-2.1, "Arrangements for Preparedness for a Nuclear or Radiological Emergency" (Reference 19.6-7). Additional standards are referenced in other nuclear programs, including those for radiation protection.

Analysis of Design Basis Accidents (DBAs), Design Extension Conditions (DECs) and Beyond Design Basis Accidents (BDBAs), including severe accidents for the BWRX-300, is discussed in Chapter 15, Safety Analysis. The systematic approach to develop the Emergency Operating Procedures (EOPs), Emergency Mitigating Equipment Guidelines (EMEGs) and Severe Accident Management Guidelines (SAMGs) to manage DBAs and BDBAs, including DECs and severe accidents, in accordance with CNSC REGDOC-2.5.2 (Reference 19.6-8) and CNSC REGDOC-2.3.2 (Reference 19.6-13), is noted in Chapter 13, Subsection 13.4.3 and Chapter 18, Subsection 18.3.6.

As noted in preceding discussion, the DNNP senior authorized person on shift is responsible for classifying the level of on-site response and categorizing the event which determines the level of off-site response per the PNERP (Reference 19.6-4).

Off-site emergency notifications are made following categorization. The time requirement for the plant to notify the Provincial contact point is within 15 minutes after the event has been categorized. This is the Provincially set target for notification performance, and a regulatory requirement as noted in CNSC REGDOC-2.10.1 (Reference 19.6-2). The information identified in the official notification form should be confirmed as part of the notification process. The designated regional contact points also receive the same emergency notification shortly after the province. Regulatory notification to the CNSC is made after the off-site agency and ERO notifications have been completed. CNSC notification target time is within 15 minutes of ERO activation.

The communication systems provide intra-plant and plant-to-offsite communications during normal operation, transients, fire, accidents, off-normal phenomena, and security related events are described in Chapter 9A, Subsection 9A.9.1.

OPG implements radiological protective measures to As Low As Reasonably Achievable (ALARA). During the control of an emergency, the applicable emergency dose limits shall be treated as discrete and separate from the normal occupational dose limits prescribed in N-PROC-RA-0019, "Dose Limits and Exposure Control" (Reference 19.6-9).

The design provides safety features for ensuring that doses to operating personnel at the nuclear power plant will be maintained below the dose limits and will be kept ALARA, and that the relevant dose constraints are taken into consideration. The design features for radiation protection are described in Chapter 12, Section 12.3.

NEDO-33969 REVISION 0  
NON-PROPRIETARY INFORMATION

During nuclear emergency events, OPG has a responsibility to communicate with the public, media, stakeholders, and employees. N-STD-AS-0010, "Nuclear Crisis Communications Standard" (Reference 19.6-10) governs public communications on behalf of OPG Nuclear in the event of a nuclear emergency and ensures consistent and coordinated public information response. OPG also supports the province and municipalities who provide coordinated communications under the jurisdiction of the PNERP (Reference 19.6-4). A Joint Information Centre, coordinated by the Provincial Chief Information Officer, may be established with support from OPG and other stakeholders.

Information related to nuclear emergency response is collected for permanent storage once the event has been terminated.

## 19.2 Emergency Response Facilities

The BWRX-300 ERFs including backups meet the requirements of CNSC REGDOC-2.10.1 (Reference 19.6-2) with the intent of remaining consistent with existing OPG Nuclear ERFs:

1. EOC located on-site and referred to as the ERF in CNSC REGDOC-2.5.2 (Reference 19.6-8). The EOC is located near the MCR, where site shift staff assemble to manage and coordinate event response.
2. Site Management Centre located on-site, but outside of the protected area. It is referred to as the Technical Support Centre in CNSC REGDOC-2.5.2 (Reference 19.6-8). The Site Management Centre is staffed with on-call teams of ERO personnel, which includes technical support.

Note that CNSC REGDOC-2.5.2 defined the emergency support facilities as consisting of an on-site ERF (item 1) and a Technical Support Centre (item 2).

3. An ERF located off-site and outside of the plume exposure planning zone. As the design progresses, further details will be included in the Pre-Operational Safety Analysis Report.

The EOC and Site Management Centre contain the equipment necessary to gather, store and display data needed in these facilities to analyze plant conditions. This equipment serves the same function as a Safety Parameter Display System (SPDS), described in Chapter 7, Section 7.3, similar to that in the MCR. Information on radiological conditions in the plant and its immediate surroundings, and about meteorological conditions in the vicinity of the plant, are accessible from the EOC and Site Management Centre. The plant information necessary to support overall emergency response from the MCR, SCR, EOC, Site Management Centre and ERF located off-site and outside the plume exposure planning zone is provided either directly by the Unit Data Highway or via the Plant Data Highway unidirectional boundary device interface, depending on security and Instrumentation and Control requirements related to each location. Further details of instrumentation and controls are described in Chapter 7.

The EOC and Site Management Centre includes secure means of communication with the MCR, SCR and other important points in the plant, and with on-site and off-site EROs per CNSC REGDOC-2.5.2 (Reference 19.6-8). See Chapter 9A, Subsection 9A.9.1 for further details of the communication systems.

The BWRX-300 design includes an MCR, as well as an SCR that is physically and electrically separate from the MCR. The concept of having both the MCR and SCR is no single event can affect both.

The BWRX-300 MCR, located in the Control Building (CB), is the primary location for plant monitoring and control.

In the current concept design, the SCR is located in the Reactor Building. A qualified route exists from the MCR to the SCR for events which necessitate evacuation of the MCR. An alternate route exists for fire events which does not go through the same fire zones as the primary route (refer to Chapter 6, Section 6.4).

The instrumentation and controls in the MCR and SCR are described in Chapter 7, Sections 7.5 and 7.6, respectively.

### **19.3 Capability of the Operating Organization for the Assessment of Potential Radioactive Releases in Accident Conditions**

Accident assessment techniques are employed to determine the extent of on-site radiation impact and to predict the off-site radiation consequence to the public. Processes and methodology include determination of system status from plant parameters, radiological source term measurements, core or fuel damage assessment techniques, meteorological information, off-site dose projections and dose assessment verification using off-site survey results.

The Automated Near Boundary Gamma Monitoring System is located around the DNGS nuclear facility perimeter. This fixed radiological detection and monitoring system may be utilized for BWRX-300 in order to meet CNSC REGDOC-2.10.1 (Reference 19.6-2) requirement to have real-time fixed radiological detection and monitoring capabilities around the nuclear facility perimeter with appropriate backup power. Use of DNGS monitoring system will be assessed as part of BWRX-300 detailed design. In the event of an accident release of radiation, the monitoring system is capable of providing data needed to characterize radiological conditions around the plant and assess the need for off-site action – see Chapter 12, Subsection 12.5.1. During the response phase, technical data, including survey results, shall be made available to the Provincial EOC and CNSC.

In compliance with CNSC REGDOC-2.5.2 (Reference 19.6-8), Instrumentation and Control equipment are provided such that essential information is available to support plant procedures during normal operations and following DBAs and DEC's.

Refinement and selection of designated instruments and displays for accident monitoring and control are based on those deemed necessary to provide the parameters required to accomplish the goals of EOPs and SAMGs. Functional requirement analysis, allocation of functions, and task analysis identify an independent list of the necessary parameters using human factors principles. The preliminary list of accident monitoring variables is provided in Chapter 7, Table 7.3-2.

In compliance with CNSC REGDOC-2.10.1 (Reference 19.6-2), sufficient Personal Protective Equipment (PPE) and provisions to respond to emergencies and protect the emergency responders for the first 72 hours without off-site assistance are provided. The PPE and response equipment are maintained, calibrated (e.g., electronic dosimeters, radiation instrumentation) and staged for use in an emergency. Habitability design requirements in compliance with CNSC REGDOC-2.5.2 (Reference 19.6-8) for the EOC and Site Management Centre will be included in the Pre-Operational Safety Analysis Report.

#### **19.4 Emergency Preparedness for Multiple Unit Sites**

As noted in Section 19.1, on-site emergency arrangements will be submitted with the Licence to Operate application under Commitment D-O-2 (Reference 19.6-5), to ensure emergency preparedness and response is in place prior to fuel-in commissioning.

Additional staffing required for the BWRX-300 specific ERO will be determined. The ERO staffing requirements will be developed through systematic analysis, as described in Chapter 18, Subsection 18.2.4.

Off-site emergency service agreements are described in Chapter 2, Subsection 2.11.5, Administrative Measures with External Organizations. OPG continues to collaborate with the Province of Ontario and other external organizations responsible for off-site nuclear emergency planning to ensure the implementation of their respective emergency plans and related protective actions will accommodate the lifecycle of BWRX-300.

Mutual aid agreements exist in current staffing plans and response procedures. The non-incident station or departments and corporate office may provide spokespeople and technical staff for communication and media centre support.

By virtue of the authority and mandate, the off-site ERF is able to draw on the collective aid of all OPG Nuclear staff and resources for emergency response purposes. This also extends into the entire resource pool of OPG to support an incident at a nuclear generating site.

As stated in CNSC REGDOC-2.10.1 (Reference 19.6-2), an effective response to an emergency requires strong linkages between accident management, which is covered in CNSC REGDOC-2.3.2 (Reference 19.6-13) and emergency preparedness. Control of severe plant conditions, including prevention of accident progression and mitigation of the consequences of severe accidents are part of Defense Line 4 (DL4) of the defence-in-depth approach (refer to Chapter 3, Subsection 3.1.6). The fourth DL is split into DL4a and DL4b, providing independent provisions for prevention and mitigation of DEC. DL4a is for DEC that occur without core damage, and DEC progressing to core damage are DL4b. The use of non-permanent equipment, known as Emergency Mitigating Equipment (EME), is an acceptable DL4b provision to restore lost safety functions, but not to be the regular means to achieve these functions in accident conditions. In compliance with CNSC REGDOC-2.3.2 (Reference 19.6-13), BWRX-300 will have EME, and its use is covered in EMEGs. EME will continue to be assessed as part of BWRX-300 design.

### **19.5 Emergency Preparedness for Internal Fire Hazards**

A comprehensive fire protection program covers control of combustible materials, control of ignition sources, as well as fire response strategies, to meet the requirement of CSA N293S1, "Supplement No. 1 to N293-12, Fire protection for nuclear power plants (application to small modular reactors)" (Reference 19.6-12). As stated in Chapter 3, Subsection 3.4.1, this program will provide additional layers of defence in addition to the fire protection features in place against internal fire hazards. The program aims to prevent, mitigate, and manage emergencies that arise from internal fire hazards that may lead to radiological and nuclear emergencies. Refer to Chapter 9A, Section 9A.6 for the description of the Fire Protection System.

## **LIST OF FIGURES**

None.

## **20.0 ENVIRONMENTAL ASPECTS**

### **20.1 Introduction**

This Chapter discusses the environmental aspects related to the construction, operation and decommissioning of the Boiling Water Reactor, 10th Design – 300 MWe (BWRX-300) Small Modular Reactor (SMR).

A brief overview of OPG's Environmental Management System, site characteristics including relevant meteorological data and environmental assessment follow-up program are included. Environmental impacts of construction, normal operation, accidents, and decommissioning are summarized.

### **20.2 General Aspects of the Environmental Assessment**

The Darlington New Nuclear Project (DNNP) Environmental Assessment (EA), including the Environmental Impact Statement (EIS) (Reference 20.2-1), was submitted in 2009 and accepted by the Government of Canada in 2012. The Environmental Assessment assessed the impact of the preparation of the site; construction of up to four new reactors with a maximum generation capacity of 4800 MW(e), and associated facilities; the operation and maintenance of the reactors and related facilities for approximately 60 years, the management of conventional and radioactive waste; and the decommissioning of the nuclear reactors and associated facilities. The EIS concluded DNNP does not have significant adverse environmental effects if the mitigation measures proposed are implemented.

A number of reactor technologies were considered in the EA. For assessment purposes, a Plant Parameter Envelope was used to provide a bounding framework of plant design and site parameter values from the multiple reactor technologies.

The DNNP – Site Preparation Licence Renewal Activity Report – Environment (NK054-REP-01210-00110) (Reference 20.2-2) concludes that any minor changes in baseline conditions since the time the EA was conducted are adequately addressed by existing commitments and do not alter the residual adverse effects of the project.

The current Nuclear Power Reactor Site Preparation Licence 18.00/2031 for the DNNP was renewed in 2021 and expires on October 11, 2031 (Reference 20.2-3).

The BWRX-300 SMR was selected for DNNP in 2021. A comprehensive review of the EIS confirms that results of the EIS remain valid for deployment of the BWRX-300. The EIS review is submitted to the CNSC to support the Licence to Construct application.

#### **20.2.1 References**

- 20.2-1 NK054-REP-07730-00029, "Environmental Impact Statement New Nuclear – Darlington Environmental Assessment," Ontario Power Generation.
- 20.2-2 NK054-REP-01210-00110, "DNNP – Site Preparation Licence Renewal Activity Report – Environment," Ontario Power Generation.
- 20.2-3 PRSL 18.00/2031, "Power Reactor Site Preparation Licence," Ontario Power Generation

### **20.3 Environmental Principles and Regulations**

The construction, operation, and decommissioning of the BWRX-300 at OPG complies with the regulations and guidance for protecting the environment at the DNNP site listed in Chapter 1, Appendix B.

### **20.4 Environmental Management System**

As outlined in OPG's Environmental Policy (Reference 20.4-1), OPG shall meet compliance obligations, including any environmental commitments that it makes, with the objective of exceeding these compliance obligations, where it makes business sense. The Environmental Policy applies to all OPG, contractor, and subcontractor employees working on DNNP activities.

Ontario Power Generation's Environment Health and Safety Managed Systems program (Reference 20.4-2) governs the design and execution of OPG's Environmental Management System in accordance with OPG-POL-0021, Environmental Policy (Reference 20.4-1). The scope of OPG's Environmental Management System includes the management of activities related to design, supply chain, construction, commissioning, operation (including emissions, effluent, waste management, and other support processes), and decommissioning of electricity generating stations, and associated properties, auxiliary buildings, and structures solely owned and/or operated by OPG, or sites operated by OPG on behalf of OPG's partner owners.

The Environmental Management System is consistent with the CNSC Regulatory Document REGDOC-2.9.1 (Reference 20.4-3). Additionally, this program is registered to and compliant with the International Organization for Standardization (ISO) 14001 Environmental Management Systems standard (Reference 20.4-4).

All phases of the DNNP will be executed in a manner that conforms to the requirements of OPG's Environmental Policy and Environmental Management. In the case where OPG is an owner in an integrated project delivery contract, it is OPG's responsibility to ensure ongoing oversight through its management system. The other contract parties will define and implement their own management system compliant with applicable current standards or implement an alternative management system as agreed to by the project partners. Ontario Power Generation provides other contract parties with the DNNP Environmental Management and Protection Plan (Reference 20.4-5), which defines OPG's expectations to ensure protection of the environment.

The ISO 14001 standard (Reference 20.4-4) requires that any person performing work or services on an OPG site, where such work or service has the potential to cause a significant environmental impact, should be aware of the requirements and importance of the Environmental Management System and be competent to perform the work assigned. Any contractor who performs an operation or activity that has the potential for significant environmental impacts shall implement measures and controls to minimize the environmental risk (e.g., documented procedure controls).

## **20.5 Site Characteristics Important to Environmental Impact**

The site characteristics that are important in terms of environmental impact are addressed in detail in Chapter 2, Section 2.8. The information is summarized below.

Relevant meteorological characteristics include temperature, precipitation, wind speed and wind direction:

1. Temperature: From 2016-2019, the highest (21.5°C) and the lowest (-4.1°C) 4-year average monthly temperatures at the Darlington Nuclear site occurred in the months of July and January, respectively. The mean daily maximum temperature (23.0°C) was recorded in August 2016, and the mean daily minimum temperature (-6.4°C) was recorded in January 2019 (Reference 20.5-1).
2. Precipitation: The 1981-2010 climate normal data from the Bowmanville Mostert station reported an average annual precipitation of approximately 866 mm. Snowfall represented less than 11% of total precipitation. Total monthly precipitation averages range from approximately 50.5 mm in February to approximately 98.7 mm in September (Reference 20.5-1).
3. Wind Speed: From 2013-2019, the average wind speed measured at the on-site meteorological towers was approximately 2.4 m/s; calm winds of less than 2 m/s were reported ~37% of the time. The prevailing winds for these years were also measured to be from the North-West sector; North (9.6% of the time), followed by the West direction (8.9% of the time) (Reference 20.5-1).
4. Wind Direction: In 2021, the landward sector at the Darlington Nuclear site that wind predominantly blew towards, was the East-North-East sector (wind from West-South-West), based on the average annual wind frequencies at a 10 m height. Over all sectors, the wind predominantly blew from the North and West sectors; the dominant wind direction was North-North-West (10.38% of the time), followed by West (9.98%) and North-West (9.82%) (Reference 20.5-2).

Relevant hydrological characteristics include stormwater runoff, municipal water supply sources, lake currents and temperature, and water intake and return structures. In the developed parts of Darlington Nuclear, stormwater is collected in natural channels/swales and constructed outfalls and conveyed off-site to Lake Ontario. The lake current in the nearshore region is overall easterly; for the 2012-2016 period, speeds typically ranged from about 9-18 cm/s. Lake-wide surface temperatures typically range from freezing in the winter to approximately 20°C in the summer. The water temperatures recorded from December 2011 to March 2012 and from December 2011 to April 2012 in the Darlington Nuclear study area had an average temperature of 3.8°C and 4.4°C, respectively. Water is drawn from the lake by Darlington Nuclear Generating Station (DNFS) via an 80-m diameter, porous bottom, submerged intake structure located at a distance of 700 m from the shoreline at a depth of approximately 10 m. Cooling water is returned to Lake Ontario from DNFS via a 900-m long submerged diffuser extending approximately 1,600 m from the shoreline (Reference 20.5-1).

Relevant hydrogeological characteristics include aquifer type and groundwater flow. Groundwater aquifers at the Darlington Nuclear site has been categorized into three hydrostratigraphic units: Shallow/Water Table, Interglacial Deposits, and Shallow Bedrock. Within the Shallow/Water Table hydrostratigraphic units, groundwater flows from north to south approaching Lake Ontario. General flow patterns within the interglacial deposits hydrostratigraphic units and shallow bedrock hydrostratigraphic units are similar to the shallow/water table hydrostratigraphic units (Reference 20.5-3).

NEDO-33970 REVISION 1  
NON-PROPRIETARY INFORMATION

The dominant ecological feature of the Darlington Nuclear site is meadow (24%), followed by thicket (14%), woodland (5%), and swamp (5%). In general, the Darlington Nuclear site has four main areas: in the northwest there are sports fields, a large settling pond (Coot's Pond), and Bobolink Hill comprised of cultural meadow and cultural thicket; in the north-east there are agricultural fields, cultural thicket, and deciduous forest as well as three constructed wetland ponds (Treefrog, Dragonfly and Polliwog ponds); the south-east is mostly cultural meadow; and in the south center and south-east is the DNGS (Reference 20.5-2).

The census data for the region used in the most recent Darlington Nuclear Site-Specific Survey are for 2016. A population of approximately 500,000 resides within a 30 km radius of the Darlington Nuclear site, based on 2016 census data. The bulk of this population (approximately 88% or 478,634 individuals) resides West of the Darlington Nuclear site, in the West-South-West to North-North-West sectors, while approximately 12% (64,575 individuals) reside East of the Darlington Nuclear site in the North to East North-East sectors. The majority of residents in Durham Region live in urban areas. Over 90% of the population in Pickering, Ajax, Oshawa, and Whitby reside in urban areas, whereas, the townships of Brock, Scugog and Uxbridge represent the greatest percentage of the rural population in Durham. Children under the age of 15 comprised 18.0% of Durham's population in 2016, while young persons (aged 15-29), adults (aged 30-64) and older adults (aged 65+) comprised 19.2%, 49.4% and 14.4%, respectively (Reference 20.5-1).

## **20.6 Best Available Technology and Techniques Economically Available Design Features**

BWRX-300 design features that reduce effluent emissions, which may be considered Best Available Technology and Techniques Economically Available include:

- Material selection – keeps the concentration of radiation in the coolant low
- Fuel reliability - programs and procedures that govern operational activities associated with BWRX-300 core management regarding fuel reliability are based on guidelines established by GEH utilizing decades of experience with Global Nuclear Fuel
- Gaseous radwaste management - the Offgas system (OGS) is a state-of-the-art feature that holds up the release of noble gases enabling them decay to low levels before being released to the environment
- Liquid Waste Management System (LWM), and minimal release philosophy – state-of-the-art liquid waste management design that minimizes liquid releases
- Leak detection systems – prevents and mitigates leaks that could reach the environment
- Reactor coolant cleanup systems – the Condensate Filters and Demineralizers system is a state-of-the-art design that capture contamination and lowers effluent releases
- Heating Ventilation and Air Conditioning (HVAC), High Efficiency Particulate Air (HEPA) and charcoal filtration systems – filtering of HVAC discharge to the environment
- The Process Radiation and Environmental Monitoring System (PREMS) provides continuous and periodic monitoring to allow determination of the content of radioactive material in various gaseous, liquid process, and effluent streams

The Best Available Technology and Techniques Economically Available principle was applied via an assessment completed in 2013 to meet D-C-1.1, which compared Once Through Cooling and Mechanical Draft Cooling Towers. Once Through Cooling was recognized as the better performing option with respect to the following evaluation areas: visual effect, local climate change, terrestrial habitat, and excavated materials. The difference between the two options for impacts on fish (impingement, entrainment, and thermal plume) was minimal and did not compensate for the better environmental performance of the Once Through Cooling system. Following the decision to consider and SMR for the DNNP site, a review of the Best Available Technology and Techniques Economically Available work was completed in 2021 to confirm that the conclusions of the original Best Available Technology and Techniques Economically Available work were unchanged and that D-C-1.1 could remain closed.

## **20.7 Environmental Impact of Construction**

The DNNP is not expected to contribute radiological releases during the construction stage. Potential sources of radiation during construction include adjacent nuclear facilities and sealed radioactive sources used during the plant construction. Adjacent nuclear stations to DNNP land include DNGS, as well as the Tritium Removal Facility and Darlington Waste Management Facility immediately to the West. Pickering Nuclear Generating Station is approximately 30 km West-South-West. The environmental impacts of these stations on the surrounding environment are well characterized in Environmental Monitoring Program reports and Environmental Risk Assessments (ERA). The results of the 2021 Environmental Monitoring Program relating to Darlington Nuclear are summarized in Chapter 2, Subsection 2.9.1. The DNNP is not being constructed within the existing operating Darlington Nuclear site facilities, so construction activities will not impact the operation of DNGS, Darlington Waste Management Facility, or the Tritium Removal Facility.

The only anticipated potential radiological impacts from the construction phase may be through disruption and excavation of contaminated soil due to the proximity of DNGS, and potential redirection of the groundwater flow during excavation activities. To determine an updated soil quality baseline, a soil sampling program was conducted in 2019 and a soil characterization program was conducted in 2021 at the DNNP site. In the 2019 program, both conventional and radiological parameters were measured. Screening against appropriate benchmarks indicated that soils were found to be of good quality with the exception of one area identified as the yard waste and building materials storage area where the following parameters exceeded the conventional benchmarks (Reference 20.7-1):

- Cyanide
- Arsenic
- Cadmium
- Chromium
- Cobalt
- Copper
- Lead
- Molybdenum
- Nickel
- Selenium
- Tin
- Zinc
- Petroleum hydrocarbons

In the 2021 soil characterization program, only conventional parameters were measured as assessment showed there are no potential concerns for radiological contaminants. Exceedances in shallow soil (copper, zinc, arsenic, petroleum hydrocarbon F1, petroleum hydrocarbon F2) were identified at seven sampling locations in the DNNP Lands South, which includes two parking lot areas (petroleum hydrocarbon exceedances). In general, the soil exceedances identified above were only marginally above the Ontario Ministry of the Environment, Conservation and Parks

NEDO-33970 REVISION 1  
NON-PROPRIETARY INFORMATION

Table 3 Standards for soil, and would be considered a non-hazardous waste; however, these soils are potentially suitable for reuse at the DNNP site (Reference 20.7-2).

The Environmental Management and Protection Plan (Reference 20.7-3) outlines requirements for soil management and mitigation measures to be followed, such as soil handling, sampling, and disposal procedures, as well as dust control. Therefore, it is not anticipated that there will be impacts from radiological or hazardous material during excavation as part of DNNP construction.

Groundwater flow on the DNNP site may be altered during excavation activities, redistributing any existing radiation in the groundwater. However, groundwater monitoring results at DNNP site for tritium were non-detectable from 2016-2020 (References 20.7-1, 20.7-4 and 20.7-5). Groundwater flow is expected to return to near pre-development conditions within a couple of years after construction is completed.

Construction activities are discussed at a management systems level in Chapter 14, Section 14.2. Field sources such as those used in portable gauges and radiography devices may be used during construction activities and will be operated under separate CNSC issued licences.

During the construction phase of DNNP, management and monitoring of releases from DNNP construction activities is addressed by the DNNP Environmental Management and Protection Plan and Environmental Assessment follow-up monitoring program as well as compliance with the relevant environmental permits and Environmental Compliance Approvals.

Maximum emission rates of environmental pollutants during site preparation and construction, based on industry data for emissions are estimated in Table 20.7-1. Estimates are for activities such as, material handling, grading, and dozing, rock blasting, crush and screen, worker parking lot, parking lot tailpipe, unpaved roads, haul truck tailpipe, paved roads, paved road tailpipe, stationary equipment tailpipe, non-road tailpipe and concrete batching. Tailpipe emissions are from industrial machinery, haul trucks, and worker vehicles driving on the paved parking lot, roads, or on the unpaved roads. The non-road tailpipe activities, such as the “worker parking lot” or “unpaved roads”, are the dust emissions that arise from driving, based on assumed silt content and other parameters.

(1) Crushing and screening will not be conducted on site.

## **20.8 Environmental Impact of Normal Operation**

Liquid and gaseous discharges to the environment, due to normal operational activities will be monitored for conformance with OPG's Environmental Health and Safety Managed Systems (Reference 20.8-1).

### **20.8.1 Direct Radiation from Buildings and Facilities**

Sources of radiological emissions to the environment during operation of the BWRX-300 SMR include radiation from buildings and facilities.

- Radiation shine from buildings and facilities are shielded. The buildings containing radioactive materials are discussed in Chapter 12, Section 12.2. These include:
  - Containment Radiation Sources: Reactor Core, Control Rod Drive System and Reactor Startup Source
  - Reactor Building and Plant Services Area Radiation Sources: Fuel Pool Cooling and Cleanup System and Fuel Pool
  - Turbine Building Source Terms: Reactor Water Cleanup System Radiation Sources, Main Steam and Feedwater Lines, Normal Operating Sources
  - Radwaste Building Radiation Sources: Normal Operating Sources represent sources for off-site release which are low-consequence, low-frequency events
  - Plant Services Area Sources: Contains the Reactor Auxiliary Bay where new and spent fuel is moved in and out of the reactor building

### **20.8.2 Radiological Airborne and Liquid Effluent Releases**

This subsection deals with the sources and parameters required to evaluate radiological airborne and liquid releases during normal plant operation. During operation, effluent releases must be below release limits, which are calculated based on CSA-N288.1 (Reference 20.8-2) to meet dose limits for effluent release cited in SOR/2000-203 (Reference 20.8-3).

The public dose from gaseous and liquid effluent releases during normal operation is expected to be well below regulatory limits.

Annual average gaseous and liquid effluent releases for long-term normal operation of BWRX-300, including Anticipated Operational Occurrences (AOOs), are included in Appendices A and B, respectively. The annual gaseous and liquid effluent releases are the basis for determination of dose consequences to the public from routine releases of airborne and liquid effluents from the BWRX-300 DNNP plant. For the purposes of this PSAR, the gaseous and liquid effluent releases including AOOs are used as conservative inputs for the estimate of normal operational dose from the BWRX-300 at the DNNP site.

The gaseous and liquid effluent release analyses are performed with the GALE-BWR methodology in U.S. Nuclear Regulatory Commission (NRC) NUREG-0016, Revision 2 (Reference 20.8-4). GALE-BWR calculates expected releases based on 1) standardized coolant activities derived from BWR operating data, 2) release and transport mechanisms that result in the appearance of radioactive material in liquid and gaseous waste streams, 3) plant-specific design features used to reduce the quantities of radioactive materials ultimately released to the environs, and 4) information received on the operation of nuclear power plants.

Description, validation, and extent of application of the GALE-BWR 3.2 code (Reference 20.8-4) is provided in Chapter 3, Appendix 3F.

#### **20.8.2.1 Radiological Airborne Releases**

BWRX-300 annual airborne effluent release activities including AOOs are reported in Table 20.13-2. The annual airborne effluent release activities are calculated using the normal operation coolant concentrations provided in Chapter 11, Section 11.1, and the calculation is described in detail in Appendix A. The BWRX-300 plant releases airborne effluents through the plant stack.

#### **20.8.2.2 Radiological Liquid Releases**

The LWM described in Chapter 11, Section 11.2 is designed to monitor and process all radioactive liquid streams and provide wastewater management for those streams. Under normal operation conditions, water management does not result in routine release of radioactive effluents. Under some conditions where high wastewater inventory is processed (refueling or abnormal conditions), some processed radioactive liquid effluents may be released. By administrative control, the discharge of these effluents through the discharge line is adjusted so that the discharge meets the regulatory limits.

BWRX-300 annual average liquid effluent release activities including AOOs are reported in Table 20.14-1. The annual average liquid effluent release activities are calculated using the normal operation coolant concentrations provided in Chapter 11, Section 11.1, and the calculation is described in detail in Appendix B.

The BWRX-300 LWM implements a minimal release plan for the treatment of liquid radwaste. Minimal release is a philosophy of processing wastewater such that it is sent back into the system and released into local bodies of water. Thus, the release of liquid effluents determined in this analysis is assumed for conservatism. If a liquid discharge from the LWM were to occur, it would be diluted and discharged in the plant cooling water discharge stream.

#### **20.8.2.3 Airborne and Liquid Effluent Doses for Members of the Public**

Doses to members of the public are modeled with the IMPACT code in accordance with the CANDU Owners Group Derived Release Limit Guidance Document (Reference 20.8-5) and CSA-N288.1 (Reference 20.8-2). For the purposes of this PSAR, the annual release of airborne and liquid effluents including AOOs from Tables 20.13-2 and 20.14-1, were used as conservative inputs for the estimate of dose during normal operations to off-site members of the public, known as potential critical groups. The potential critical groups considered in the dose model align with those identified in the Environmental Monitoring Program (Reference 20.8-6).

The critical group dose from the operation of one BWRX-300 at the DNNP site (including AOOs) is conservatively estimated to be 4.87E-04 mSv per year. This is a very small fraction of the regulatory dose limit of 1 mSv per year cited in SOR/2000-203 (Reference 20.8-3).

### **20.8.3 Control of Radioactive Discharges to the Environment**

On-site and off-site process radiation systems and environmental monitoring programs are discussed in Section 20.11. As indicated in Chapter 11, Section 11.5, PREMS monitors the release of airborne and liquid effluents from the station, alarming upon the release of activity concentration above action levels.

As described in Chapter 12, Section 12.3, design features and measures within the plant minimize radiation and contaminants that could lead to discharges to the environment. These include:

1. Sump vents are located near the room exhaust vent register to control airborne radioactivity released from discharges to the sump.
2. All contaminated or potentially contaminated systems shall be isolated from the outside environment or are otherwise equipped with isolation devices to control their discharges.
3. Systems designed to discharge to the environment are equipped with radiation monitoring devices to automatically isolate the discharge if high activity is detected.
4. To prevent radiation overexposure to detect leaks, and to prevent high-activity discharge, the atmospheres of the rooms and stacks are monitored for particulates, noble gases, and iodine.
5. Effluents from radioactive waste tanks of the LWM are discharged to the tank room in the general vicinity of the room's ventilation exhaust register. Tank vents are designed such that liquid and entrained solids do not splash out (e.g., use of baffle plates). Hard connections directly to the ventilation system are avoided to ensure liquid or moisture does not propagate through the ventilation system damaging the HEPA filters.
6. During normal operation purging, the containment exhausts air through the HVAC HEPA filter unit prior to stack discharge.
7. The ventilation system is designed to sweep air from the Spent Fuel Pool surface, thereby removing the major portion of potential airborne contamination.
8. The derivation of trip setpoints for effluent and discharge radiation monitors will be specified in the plant operating procedures. Setpoints will be established on the basis of discharge flow rates and the resulting off-site doses.

Environmental worker qualifications and training is addressed in OPG-PROG-0005 (Reference 20.8-1).

### **20.8.4 Non-Radioactive Contaminants**

Maximum emission rate from fuel combustion contaminants during operations and maintenance phase are estimated in Table 20.8-1. Sources of fuel combustion contaminants include vehicles, standby emergency power generators, fire pump diesel engines and security diesel generator. Estimates in Table 20.8-1 are based on industry data for emissions.

The DNNP on-site chemicals and gases include, nitrogen, hydrogen, diesel fuel, turbine oil, sodium hypochlorite, sodium bisulphite, Captor (R) calcium thiosulphate, gasoline, propylene glycol, tetrafluoroethane (R134a Refrigerant), Noble Metal Solution and depleted zinc oxide. These DNNP on-site gases and chemicals are itemized in Chapter 2, Section 2.4, Table 2.4-1. Depleted zinc oxide is deposited on plant surfaces of reactor vessel components; some depleted zinc oxide is removed by the reactor water cleanup system (Cleanup water) and some is removed in solid waste. Sodium hypochlorite, sodium bisulphite and Captor (R) calcium thiosulphate are released into the lake in compliance with an approved Permit. Propylene Glycol is not released to the environment. Tetrafluoroethane (R134a Refrigerant) is used in the chiller system for the

Radwaste Building, this is a closed system, and therefore tetrafluoroethane is not released to the environment. Noble Metal Solution deposits on the surfaces of reactor vessel components. The zinc and the Noble Metal Solution both deposit on the fuel surfaces and are not released to the environment. The containment system is inerted with nitrogen during different modes and is purged to the environment via the plant ventilation system, while being monitored to ensure there is no radiological release. Hydrogen is released to the environment through the OGS. Diesel fuel and gasoline are used for engines and diesel generators and are protected from accidental release to the environment. Turbine oil is contained in the plant and is protected from accidental release to the environment.

There are no other non-radiological contaminants that would be released as effluents to the air or water.

Appropriate design measures will be taken to control the release of non-radioactive contaminants to the environment. OPGs Spill management program and chemistry control standard will apply for control of non-radioactive contaminants.

#### **20.8.5 Authorized Limits and Operational Targets for Discharges and Releases**

The DNNP will not generate emissions or contribute releases of nuclear or hazardous substances during the construction phase. Ontario Power Generation will develop authorized release limits and action levels for DNNP's radiological releases prior to the operations phase, in accordance with the relevant regulatory documents and standards in place at that time.

Release limits for non-radiological (hazardous) substances will be determined in accordance with relevant Environmental Compliance Approvals and other licences, permits, and regulatory requirements and standards for each phase (site preparation, construction, fuel-out commissioning, operation).

#### **20.8.6 Radiological Impacts of Normal and Abnormal Operation**

The ALARA design requirements, keep radiation exposures ALARA during normal operation or anticipated operational occurrences. Planned radioactive material releases are kept below regulatory limits. Normal operation doses are discussed in Subsection 20.8.2. Abnormal and accident doses are discussed in Section 20.9.

#### **20.8.7 Measures and Controls to Limit Adverse Impacts During Operation**

Design measures to control gaseous and liquid radioactive discharges to the environment during normal operation are described in Chapters 11 and 9A and summarized below.

The OGS, described in Chapter 11, Section 11.3, processes, and controls the release of gaseous radioactive effluents to the site environment, thereby maintaining exposure of persons in unrestricted areas to radioactive gaseous effluents ALARA and within prescribed limits during reactor power operation per CNSC REGDOC-2.5.2, Section 8.11.3 (Reference 20.8-7).

The OGS minimizes the release of radioactive material into the atmosphere by delaying release of the offgas process stream. This delay, using activated charcoal adsorber beds, is sufficient to achieve adequate decay before the process offgas stream is discharged from the plant. The OGS is designed with redundant components to ensure system operation continues in the event of failure of these components and for accessibility for maintenance.

Chapter 9A, Section 9A.5 describes the Station Heating, Ventilation, and Cooling System (HVS) which serves various areas of the power block during normal operation. The HEPA filters from the Exhaust Air Handling Units at each building assist in ensuring radioactive material entrained in gaseous effluent will not exceed the limits specified in SOR 2000-203 (Reference 20.8-3), for normal operations and anticipated operational occurrences. All radiologically controlled areas

NEDO-33970 REVISION 1  
NON-PROPRIETARY INFORMATION

requiring vent to the Continuous Exhaust Air Plenum which collects, mixes, and dilutes potentially radioactive discharge air from various buildings and releases the mixed air to atmosphere via the Plant Vent Stack. The Plant Vent Stack is monitored by PREMS as discussed in Chapter 11, Subsection 11.5.

The gaseous effluent treatment systems are designed to limit the dose to off-site persons from routine station releases to significantly less than the limits in SOR 2000-203 (Reference 20.8-3).

The LWM, described in Chapter 11, Section 11.2, collects liquid radioactive waste generated throughout the plant as a result of normal operation, separates and filters the waste, then returns the filtered water to the plant systems for reuse. The BWRX-300 is designed such that under normal conditions the need to release liquid effluent to the environment is minimized. In cases where liquid effluent is released, the PREMS system monitors the effluent stream sending a signal to automatically isolate the discharge line if it senses radioactivity above action levels.

Ontario Power Generation's Standard Controlling Radiation Exposure to the Public and the Environment to ALARA establishes the minimum requirements to keep radiological exposures and doses to the public and the environment ALARA, taking social and economic factors into account.

**Table 20.8-1: Maximum Emission Rates from Fuel Combustion During Operations and Maintenance Phase**

Contaminant	24-hour (g/s)	Annual (g/s)
Acrolein	1.11E-04	1.11E-04
Carbon Monoxide	1.26E+01	3.50E+00
Nitrogen Oxides	1.46E+01	6.31E-01
SPM	4.92E-01	2.01E-02
PM10	4.92E-01	2.01E-02
PM2.5	4.53E-01	1.57E-02
Sulphur Dioxide	5.18E-03	5.18E-03

## **20.9 Environmental Impact of Postulated Accidents Involving Radioactive Releases**

### **20.9.1 Design Basis Accidents**

The analysis of Design Basis Accidents (DBA) is described in Chapter 15, Subsections 15.7.7 and 15.7.8. Radioactive releases from the bounding DBAs analyzed are below the authorized limits. There are no DBAs that cause environmental releases from inside containment. Design Basis Accidents are outlined in Chapter 15, Subsection 15.5.4 for loss-of-coolant outside containment accident and Subsection 15.5.8 for fuel handling accident.

### **20.9.2 Design Extension Conditions**

The analyses of Design Extension Conditions (DEC) events without core damage are described in Chapter 15, Subsection 15.5.5. There are currently no DEC accidents described with core melting, as indicated in Chapter 15, Subsection 15.6.2. Radioactive releases from the bounding DEC events analyzed are below the authorized limits. There are no anticipated adverse impacts on the environment, as a result of the analyzed postulated initiating events.

### **20.9.3 Measures and Controls to Limit Adverse Impacts During Accidents**

Off-site monitoring of potential radioactive releases in accident conditions is discussed in Chapter 19, Section 19.3. The design of the BWRX-300 includes provisions to prevent and to mitigate the consequences of accidents and to ensure the likelihood is extremely low that an accident will have harmful consequences. The primary means of preventing and mitigating the consequences of accidents is through the application of Defence-in-Depth described in Chapter 3, Subsection 3.1.6.

### **20.9.4 Emergency Actions in Response to External Events**

The off-site emergency actions which are taken in response to an event at the station are discussed in Chapter 19. These off-site emergency actions are governed by and documented in N-PROG-RA-0001 Consolidated Nuclear Emergency Plan (Reference 20.9-1), which provides a written basis to document the concepts, roles, and resources required by OPG nuclear to implement and maintain its emergency response capability to protect the public, employees, and the environment in the event of a nuclear emergency. N-PROG-RA-0001 (Reference 20.9-1) provides a framework for interaction with external authorities and defines OPG's commitments under the Provincial Nuclear Emergency Response Plan.

### **20.9.5 References**

- 20.9-1 N-PROG-RA-0001, "Consolidated Nuclear Emergency Plan," Ontario Power Generation.

## **20.10 Environmental Impact of Facility Decommissioning**

The information related to decommissioning available at this time is preliminary. Therefore, the assessment of potential environmental effects of decommissioning activities related to DNNP is presented at a conceptual level. The Preliminary Decommissioning Plan submitted to the CNSC separately describes the activities required to decommission the facilities associated with DNNP, and to restore the DNNP site for other OPG uses.

The decommissioning strategy for DNNP will be selected based on an assessment of relevant factors and will be documented in the Preliminary Decommissioning Plan. Decommissioning of the facility will occur in three phases: Transition from Operations to Decommissioning; Safe Storage and Monitoring (if required), and Dismantling, Disposal and Site Restoration (Reference 20.10-1). Chapter 21, Section 21.6 includes a discussion of the decommissioning activities expected for DNNP.

Prior to beginning decommissioning, a Detailed Decommissioning Plan and other documents will be prepared and submitted to the CNSC (Reference 20.10-1).

The primary concern during decommissioning is the potential release of radioactivity into the environment, including exposure to humans and non-human biota. During the Transition from Operations to Decommissioning phase, potential hazards are expected to be associated with residual radioactivity in systems and components; handling used fuel, filters, and resins; and decontamination activities. After approximately one year from shutdown, gamma radiation is expected to become the only residual external radiation hazard in the plant's vicinity other than the used fuel storage facility, due to decay of residual radiation fields. Radiation and industrial hazards during the Dismantling, Disposal and Site Restoration Phase are likely to be associated with dismantling, waste handling, transportation, and disposal (Reference 20.10-1).

The potential impacts from decommissioning to various environmental media are expected to be (Reference 20.10-1):

1. **Atmospheric Impacts:** Some dust and particulate matter may be released to the atmosphere during dismantling and demolition operations. Heavy equipment and vehicles used for transport of waste and other materials may release exhaust gases into the atmosphere. The nature and extent of these releases will depend on the type of equipment used and the intensity and duration of their operations. Construction equipment and blasting may result in increased noise levels during dismantling and demolition work. Good Industry Management Practices will be applied and can reasonably be expected to mitigate any adverse atmospheric effects of decommissioning beyond the Darlington Nuclear site.
2. **Surface Water Impacts:** A temporary increase in turbidity may result from filling and sealing the cooling water intake and discharge structures, as well as from runoff during dismantling and site restoration work. In addition, other dismantling activities may change the site topography and possibly increase site runoff. However, erosion control techniques and other practical measures are available which can effectively mitigate any adverse environmental effects. Good Industry Management Practices will be applied during decommissioning to ensure compliance with applicable water quality criteria, including treatment of surface water discharges, as required, before they are released to the environment.
3. **Aquatic Impacts:** Some increase in turbidity of the water along the shoreline may result from filling and sealing of the plant's cooling water intake and discharge structures as well as from runoff during the dismantling and site restoration work. Changes in runoff from

NEDO-33970 REVISION 1  
NON-PROPRIETARY INFORMATION

the site may potentially affect local aquatic life and thus may need to be mitigated. Erosion control and other practical measures will be applied to mitigate any adverse effects.

4. **Terrestrial Impacts:** The dust produced during demolition and site restoration work may temporarily affect some of the vegetation within the Darlington Nuclear site. These areas will be restored when the dismantling and cleanup is complete. Increased vehicular traffic during active phases of the decommissioning program, and associated traffic noise, activity, and vehicle/animal collisions, may also affect local wildlife. However, this disturbance would be temporary and wildlife populations would be expected to recover and return to the site at the end of decommissioning.
5. **Geological and Hydrogeological Impacts:** It is not expected that decommissioning activities will involve substantial alteration of the topography of the Darlington Nuclear site. Therefore, any potential effects of decommissioning on soil quality, groundwater quality and groundwater flow conditions will be bounded by the already-assessed effects of site preparation and construction.
6. **Land Use Impacts:** In general, it is assumed that any potential effects of DNNP decommissioning on adjacent off-site land uses will be bounded by the effects of site preparation and construction. Radioactive and hazardous wastes generated during decommissioning will be transported to appropriate off-site facilities for long-term storage or disposal. It is expected that non-radioactive waste from demolition of buildings and other structures will be recycled or reused, both on and off the site (e.g., concrete crushed and used for roadways, metal and wood components salvaged and/or remanufactured, etc.) or disposed of at appropriate off-site disposal facilities.

A number of activities will be undertaken during the decommissioning process to prevent environmental impacts from decommissioning (Reference 20.10-1).

1. **Transition from Operations to Decommissioning:** external non-fixed surface contamination will be removed from accessible areas of the station. Internal chemical decontamination will remove most of the radioactive material contained within contaminated systems. Most of the other hazardous, non-nuclear materials are removed. During this period, the normal station environmental surveillance and monitoring program are maintained.
2. **Safe Storage and Monitoring (if required):** Environmental surveillance and monitoring will be carried out during the safe storage period to ensure that potential releases of radioactive material to the environment are detected and controlled if they occur. Routine radiological monitoring of contaminated structures and systems will also be performed, as required, depending on the length of the Safe Storage and Monitoring activity. Procedures for responding to unanticipated changes in the radiological environment of the site and potential releases to the environment will be prepared and implemented if required.
3. **Dismantling, Disposal and Site Restoration:** By the end of this activity, the site will be free of industrial hazards. The site will be remediated and restored to a state suitable for other OPG uses, and it will meet the criteria established by the CNSC to release from regulatory control. Restoration work may include cleaning the site to remove any remaining inactive waste and debris, covering the site with gravel and topsoil and establishing a covering of vegetation to prevent soil erosion.

The DNNP decommissioning process will result in a staged reduction of material and radioactivity at the site. Accordingly, there will be a staged reduction in emissions and exposures to workers, the public and the environment. The radiological effects are expected to be well below applicable regulatory limits. Furthermore, radiological effects are expected to be substantially less than the

NEDO-33970 REVISION 1  
NON-PROPRIETARY INFORMATION

effects associated with operation and maintenance of the DNNP station, which are already expected to be very low (Reference 20.10-1).

Decommissioning, when properly planned and carried out with effective control and mitigation, is likely to result in only minor adverse environmental effects. Specific effects which may eventually be caused by DNNP decommissioning will be assessed more fully as the beginning of decommissioning approaches (Reference 20.10-1).

20.10-1 NK054-REP-07730-00029, "Environmental Impact Statement New Nuclear – Darlington Environmental Assessment," Ontario Power Generation.

## **20.11 Environmental Measurements and Monitoring Programs**

Environmental measurements and monitoring programs for activities related to the BWRX-300 SMR are discussed in the subsections below.

### **20.11.1 Darlington New Nuclear Plant Environmental Assessment Follow-up Program**

The Darlington New Nuclear Project Environmental Assessment Follow-Up Plan outlines the scope for environmental monitoring activities for the DNNP. The activities presented in the Environmental Monitoring and Environmental Assessment Follow-Up Plan address the DNNP Environmental Assessment follow-up monitoring requirements and associated baseline activities. Some of these activities will also be conducted to fulfill other requirements, such as monitoring required by CNSC licences; applicable federal, provincial, or municipal laws; and other monitoring as part of due diligence by OPG for the DNNP and overall Darlington Nuclear site. Monitoring activities outlined in the Environmental Monitoring and Environmental Assessment Follow-Up Plan include those that take place prior to site preparation and during the site preparation, construction, and operations phases of the DNNP (Reference 20.11-1).

The overall goal of the Environmental Monitoring and Environmental Assessment Follow-Up program is to confirm the validity of EIS conclusions, and the effectiveness of mitigation measures implemented. The data collected will provide the necessary information needed to determine the effectiveness of mitigation measures, as well as provide understanding of whether actual effects are equal to or less than those predicted (Reference 20.11-1).

OPG's Environmental Monitoring and Environmental Assessment Follow-Up program (Reference 20.11-1) for DNNP will be implemented under existing program governance within the Environmental Management System, OPG-PROG-0005 (Reference 20.11-2). The monitoring elements in the Environmental Monitoring and Environmental Assessment Follow-Up Plan (Reference 20.11-1) will be conducted in accordance with existing environmental monitoring programs at Darlington Nuclear, primarily Management of the Environmental Monitoring Programs, N-PROC-OP-0025 (Reference 20.11-3) and other programs such as Contaminated Lands and Groundwater Management, N-PROC-0044 (Reference 20.11-4).

Monitoring activities in the Environmental Monitoring and Environmental Assessment Follow-Up Plan are considered supplementary studies to the Environmental Monitoring Program and as such will be implemented through the existing Darlington Nuclear Environmental Monitoring Program. Once the objective of each supplementary study is achieved, a determination would be made, based on the results of the study, to either close off the study or integrate it into the routine Environmental Monitoring Program (Reference 20.11-1).

Activities under the Environmental Monitoring and Environmental Assessment Follow-Up Plan will be designed to meet one or more of the following objectives, as applicable by monitoring activity (Reference 20.11-1):

1. Identify adequate baseline characterization data for use in follow-up monitoring
2. Verify predictions of environmental effects identified in the environmental assessment
3. Determine the effectiveness of mitigation measures in order to modify or implement new measures where required
4. Support the implementation of adaptive management measures to address previously unanticipated adverse environmental effects

5. Provide information on environmental effects and mitigation that can be used to improve and/or support future environmental assessments including cumulative environmental effects assessments
6. Support environmental management systems used to manage the environmental effects of projects (i.e., DNNP activities)

The details for implementing the Environmental Monitoring and Environmental Assessment Follow-Up Plan activities are provided in associated monitoring plan/methodology reports.

#### **20.11.2 Environmental Monitoring Program**

The existing Darlington Nuclear Environmental Monitoring Program identifies the contaminants and physical stressors to be monitored for the operating OPG nuclear facilities and conducts monitoring in the environment surrounding the Darlington Nuclear site. The Environmental Monitoring Program design was developed using the guidance in CSA N288.4 (Reference 20.11-5) to address site-specific objectives covering the aspects of regulatory requirements, Environmental Risk Assessment (ERA) results, confirmation of effluent control, areas of regulatory interest, and stakeholder commitments. The Environmental Monitoring Program design uses a risk-based approach. Locations considered to be outside the influence of Darlington Nuclear site operations are also monitored to allow for a comparison with background values (Reference 20.11-6). The Darlington Nuclear Environmental Monitoring Program is governed by the Environmental Monitoring Program procedure, Management of the Environmental Monitoring Programs (N-PROC-OP-0025) (Reference 20.11-3).

The Environmental Monitoring Program is maintained in accordance with the DNGS operating licence. Environmental Monitoring Program reports are prepared and submitted to the CNSC in accordance with CNSC REGDOC-3.1.1 (Reference 20.11-7).

The Darlington Nuclear Environmental Monitoring Program is developed to satisfy the following primary objectives (Reference 20.11-6):

1. To assess the impact on human health and the environment of contaminants and physical stressors of concern resulting from operation of OPG nuclear facilities.
2. To demonstrate compliance with limits on the concentration and/or intensity of contaminants and physical stressors in the environment or assess their effect on the environment.
3. To demonstrate the effectiveness of containment and effluent control and provide public assurance of the effectiveness of containment and effluent control, independent of effluent monitoring.
4. To verify predictions made by ERAs, refine the models used in ERAs, or reduce uncertainty in the predictions made by ERAs.

Ontario Power Generation's existing environmental monitoring systems is comprised of on-site and site boundary monitoring system. Detailed information about environmental monitoring systems and sampling programs, including environmental sampling locations, sampling frequency, the number of samples taken, the media sampled, the sampling method, and the radionuclides monitored can be found in the 2021 Environmental Monitoring Program report (Reference 20.11-6), and are summarized in Chapter 2, Section 2.9. They consist of atmospheric, aquatic, and terrestrial sampling programs.

### **20.11.3 Effluent Monitoring Program**

The existing Darlington Nuclear Effluent Monitoring Program is governed by N-STD-OP-0031 Monitoring of Nuclear and Hazardous Substances in Effluents (Reference 20.11-8). This OPG standard outlines minimum requirements to establish an appropriate surveillance and monitoring program for nuclear and hazardous substances in airborne and waterborne effluents from operating OPG nuclear facilities, including DNGS, and will be extended to DNNP, under normal and abnormal operating conditions, in accordance with CSA N288.5 (Reference 20.11-9). The Darlington Nuclear Effluent Monitoring Program will be updated to encompass non-radiological releases from DNNP prior to fuel-out commissioning and will be further updated to encompass radiological releases from DNNP prior to DNNP operations.

The objectives of the Effluent Monitoring Program are to (Reference 20.11-8):

1. Demonstrate compliance with authorized release limits and any other regulatory requirements (e.g., action levels) concerning the release of nuclear and hazardous substances from the source
2. Demonstrate adherence to internal objectives and targets set on release amounts, for purposes of effluent control
3. Confirm the adequacy of controls on releases from the source
4. Provide an indication of unusual or unforeseen conditions that might require corrective action or additional monitoring
5. Provide data to assess the level of risk on human health and safety, and the potential biological effects in the environment of the nuclear and hazardous substances of concern released from facility
6. Confirm predictions in the EIS made through the Environmental Assessment process
7. Provide assurance to the public on the effectiveness of effluent control
8. Provide data which, when combined with the results of environmental monitoring and modeling, may be used to test or refine the models of the environment used in the ERA or dose assessments
9. Address any other objective identified by the site (e.g., demonstrating due diligence, meeting a stakeholder commitment, or other business reasons)

Documentation requirements for the effluent monitoring program are discussed in Section 20.12.

### **20.11.4 Groundwater Monitoring Program**

Ontario Power Generation has a groundwater monitoring program, which outlines directions and accountabilities for establishing and managing a groundwater monitoring program on OPG sites. This procedure discusses the program design, sampling and analysis requirements, and Quality Assurance/Quality Control requirements for the groundwater management program. It also covers the requirements for inspection and maintenance of wells, management of waste, reporting, program review, qualifications, and training.

Groundwater monitoring will be compliant with N288.7, Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills (Reference 20.11-10).

The groundwater monitoring wells are in key areas of the Darlington Nuclear site including the DNGS protected area (near the reactor buildings), controlled area (farther away from the reactor buildings but within the fence), and the site perimeter (Reference 20.11-11). Wells on DNNP lands are also sampled.

NEDO-33970 REVISION 1  
NON-PROPRIETARY INFORMATION

The groundwater monitoring program monitors the on-site groundwater quality changes over time and examines the chemical, radiological, and physical characteristics of the groundwater beneath the site. The specific objectives of the groundwater monitoring program are (Reference 20.11-11):

1. Objective 1: Confirm predominant on-site groundwater flow characteristics
2. Objective 2: Monitor changes to on-site groundwater quality to ensure timely detection of inadvertent releases to groundwater
3. Objective 3: Ensure that there are no adverse off-site impacts from Darlington Nuclear groundwater

The design of the Darlington Nuclear groundwater monitoring program is risk-based in nature.

A groundwater monitoring report is written annually and is submitted to the CNSC and Ministry of Environment, Conservation and Parks, as required, based on previous site commitments with regulatory agencies (Reference 20.11-4).

#### **20.11.5 Monitoring Systems and Alarms**

As previously discussed in Chapter 11, Section 11.5, PREMS provides continuous monitoring to allow determination of the content of radioactive material in various gaseous, liquid process, and effluent streams. Inspection, testing and maintenance of PREMS is discussed in Chapter 11, Subsection 11.5.8.

Monitoring systems and components for the BWRX-300 plant are required to be redundant, diverse, independent, separate and of quality commensurate with safety category, seismic category, and quality category, as described in Chapter 3, Section 3.6. Seismic qualification of BWRX-300 equipment and associated systems are discussed in Chapter 3, Subsection 3.9.3. Environmental Qualification, discussed in Chapter 3, Subsection 3.9.4, is established to ensure that BWRX-300 Safety Class 1 Structures, Systems and Components (SSC) can perform their fundamental safety functions during and after exposure to a harsh environment resulting from a DBA during and after which they are required to operate. A preliminary safety classification list of SSC that are important control measures is in Chapter 3, Appendix 3A.

The alarm systems that are required for monitoring of unplanned radioactive releases are discussed in Chapter 11, Section 11.2 for LWM, Chapter 11, Section 11.3 for OGS, Chapter 9A, Section 9A.5 for the HVS and Chapter 11, Section 11.5 for PREMS.

## **20.12 Records of Radioactive Releases and Availability of Information to the Authorities and the Public**

Records of routine radioactive releases from the site are made in accordance with the procedure for Management of the Environmental Monitoring Programs (N-PROC-OP-0025) (Reference 20.12-1) and Monitoring of Nuclear and Hazardous Substances in Effluents (N-STD-OP-0031) (Reference 20.12-2).

### **20.12.1 Record Storage and Retention**

As outlined in the Environmental Monitoring Program (EMP) procedure, reporting for OPG facilities shall be completed in accordance with the operating licence requirements. The procedure (Reference 20.12-2) refers to CNSC REGDOC-3.1.1 (Reference 20.12-3); Reporting Requirements for Nuclear Power Plants. The contents of the annual EMP report are to include, as a minimum, the reporting requirements defined in CNSC REGDOC-3.1.1, including:

1. A summary of the results of the environmental protection program and an analysis of the significance, with respect to the health and safety of persons and the protection of the environment, of the results of the Environmental Monitoring Program
2. The amount of nuclear substances, in International System of Units (SI), released to the environment and monitored as part of the effluent monitoring program, presented on an appropriate basis (weekly or monthly), along with a comparison to regulatory release limits
3. The amount of nuclear substances measured in the environment, in SI units, as part of the Environmental Monitoring Program
4. The results and calculations of the annual radiation doses to the representative persons and/or critical group or groups in comparison to the regulatory public dose limit with a description of the environmental transfer/exposure pathways associated with the operation of the nuclear power plant, including the dispersion and dosimetric models used
5. The amount of hazardous substances, in SI units, released to the environment and monitored as part of the effluent monitoring program, and measured in the environment as part of the Environmental Monitoring Program
6. For each parameter reported as part of the effluent/emission monitoring and EMP, a description of the characteristics of the monitoring results, including but not limited to the sample frequency (e.g., daily, monthly, semi-annually), sample type (e.g., grab, composite, activity counts over time), statistical quantity reported (e.g., weekly/monthly mean, annual average, annual total)
7. A description of any significant events, findings, or results, in respect to the conduct of the Environmental Monitoring Program
8. A summary of any proposed changes to the Environmental Monitoring Program

Ontario Power Generation will continue to meet the record keeping and reporting requirements of CNSC REGDOC-3.1.1 (Reference 20.12-3) through all phases of the DNNP.

The Environmental Monitoring Program procedure also outlines requirements for record storage and retention, including how records are to be filed, how document numbers are assigned, and the record retention period.

In accordance with the effluent monitoring standard (N-STD-OP-0031) (Reference 20.12-2), the minimum period of retention for sampling and monitoring records directly related to the effluent monitoring program shall span the pre-operational phase, operations phase, and decommissioning of the facility. For all other records not related to monitored data (e.g., training

NEDO-33970 REVISION 1  
NON-PROPRIETARY INFORMATION

records, sample collection, and analytical procedures), retention periods should be specified in the program documentation or in equivalent documentation, in line with Clause 10.4.3 of CSA N288.5-11 (Reference 20.12-4).

The procedure for Records and Document Management (OPG-PROC-0019) provides direction to ensure that records in the custody or control of OPG are consistently managed, protected, and accessible throughout their life cycle (Reference 20.12-5). These include higher-level requirements for management of records and documents, including environmental data records and documents as listed above. This procedure states that records shall comply with the requirements of legal and regulatory agencies, codes, standards, and corporate requirements that identify any records that need to be created or retained by OPG (Reference 20.12-5). Electronic records adhere to OPG-STD-0057, Electronic Document Management, which defines the requirements for managing electronic documents across OPG (Reference 20.12-6).

### **20.12.2 Data Availability to External Bodies**

OPG will continue to meet the record keeping and reporting requirements of CNSC REGDOC-3.1.1 (Reference 20.12-3) for the Darlington Nuclear site through all phases of the DNNP. Measures to make appropriate data available to authorities and the public will be consistent with operating OPG nuclear facilities.

As required in CNSC REGDOC-3.1.1 (Reference 20.12-3) the operating station shall submit routine scheduled reports on various topics that are required for longer-term compliance monitoring. The scheduled environmental reports specified in CNSC REGDOC-3.1.1 are (Reference 20.12-3):

1. Quarterly report on safety performance indicators (refer to Section 3.1 of CNSC REGDOC-3.1.1). In these reports, airborne and waterborne radiological release data are reported quarterly to the CNSC.
2. Annual report on environmental protection (refer to Section 3.5 of CNSC REGDOC-3.1.1). As prescribed in CNSC REGDOC-3.1.1, this report shall contain the results of the environmental protection program, the amount of nuclear and hazardous substances released to and measured in the environment, and the results of the annual radiation doses to the representative persons and/or critical groups.
3. Site environmental risk assessment (refer to Section 4.3 of CNSC REGDOC-3.1.1).

The document N-PROC-RA-0005 (Reference 20.12-7), Written Reporting to Regulatory Agencies, describes the processes for complying with regulatory requirements for written event reports to regulatory agencies and for scheduled reports to the CNSC. Regulatory Agencies include the following:

- Canadian Nuclear Safety Commission
- Ministry of Environment, Conservation and Parks
- Environment and Climate Change Canada
- Ministry of Labour
- Transport Canada (with respect to dangerous occurrences)
- Electrical Safety Authority

The Environmental Monitoring Program report for the Darlington Nuclear site shall be submitted to the CNSC by May 1st of the year following the reporting period. The annual Environmental Monitoring Program reports for Darlington Nuclear site should be posted to the OPG website in

NEDO-33970 REVISION 1  
NON-PROPRIETARY INFORMATION

accordance with the Ministry of Energy's prescribed reporting dates for the year following the reporting period (Reference 20.12-1). Results of the DNNP EA follow-up monitoring program will be summarized in an annual report submitted to the CNSC. OPG also submits Environmental Compliance Approval annual reports and Emission Summary and Dispersion Modeling to the Ministry of Environment, Conservation and Parks prior to June 1st of each year (Reference 20.12-8). These reports are made available to the public upon request.

OPG's N-STD-AS-0013, Nuclear Public Information and Disclosure (Reference 20.12-9), documents OPG's process to meet regulatory and OPG disclosure requirements for effective and timely external communications to the public related to operations, health, safety, security, and the environment. This standard ensures that there are consistent standards and procedures for compliance with:

1. CNSC REGDOC-3.1.1 Reporting Requirements for Nuclear Power Plants (Reference 20.12-3)
2. ISO 14001 Standard requirements for communications with stakeholders and public (Reference 20.12-10)
3. Ontario Ministry of the Environment and Climate Change Environmental Compliance Approvals requirements regarding environmental complaints and concerns

Public information and disclosure, includes the provision to provide, in a timely and transparent manner, accurate information to stakeholders and the public in the vicinity of OPG's nuclear facilities regarding events, activities and operations. In terms of nuclear public information disclosure and transparency, OPG commits but is not limited to:

1. Report and post various emissions and spills on a quarterly and annual basis, depending on requirements, through established notification protocols with regulatory and municipal and provincial agencies
2. Post and communicate annual Environmental Monitoring Program reports
3. Post and communicate quarterly performance reports on facilities operations

Reports such as Environmental Monitoring Program reports, and Public Environmental Release Data Reports are posted online on a quarterly basis for public access, and information related to radioactive effluents and spills to the environment are made available to the public through OPG's website.

## **20.13 Appendix A: Annual Average Gaseous Effluent Releases for BWRX-300**

### **20.13.1 Methodology**

This analysis is performed with the GALE-BWR methodology in U.S. Nuclear Regulatory Commission (NRC) NUREG-0016 (Reference 20.13-1). The GALE-BWR method implements the assumptions outlined in NRC Regulatory Guide 1.112 (Reference 20.13-2). GALE-BWR calculates expected releases based on 1) standardized coolant activities derived from ANSI/ANS-18.1-2020 (Reference 20.13-3) Working Group recommendations, 2) release and transport mechanisms that result in the appearance of radioactive material in liquid and gaseous waste streams, 3) plant-specific design features used to reduce the quantities of radioactive materials ultimately released to the environs, and 4) information received on the operation of nuclear power plants.

The calculations are based on data generated from operating reactors, field tests, laboratory tests, and plant-specific design considerations incorporated to reduce the quantity of radioactive materials that may be released to the environment. The GALE-BWR method determines the release of radioactive materials (noble gases, particulates, carbon-14, tritium, argon-41, and iodine) in gaseous effluents from normal operation including anticipated operational occurrences from the following sources: main condenser OGS, turbine gland sealing system, mechanical vacuum pumps, and ventilation exhaust air from buildings in the BWRX-300 power block (the Reactor Building, Plant Services Area, Turbine Building, and Radwaste Building). For the purpose of this evaluation the BWRX-300 Plant Services Area is treated as an auxiliary building as defined in NUREG-0016 Revision 2. The BWRX-300 does not have a wetwell or suppression pool, so all of containment is a drywell as defined in NUREG-0016 Revision 2 (Reference 20.13-1).

The results determined in this analysis include:

- Annual airborne release for off-site dose evaluations
- Annual airborne release radionuclide totals
- Annual airborne release radionuclide concentrations

The operating data in NUREG-0016 is taken from large BWRs and is limiting for the much smaller BWRX-300 plant. As such, the data is subject to relaxations as newer data applicable to smaller BWRs is identified and validated for applicability to the BWRX-300.

### **20.13.2 Results**

The BWRX-300 annual average airborne release activities from various plant systems are shown in Table 20.13-1. The BWRX-300 total annual average airborne release activities and the airborne concentrations are shown in Table 20.13-2.

## **20.14 Appendix B: BWRX-300 Annual Average Liquid Effluent Activity Releases for BWRX-300**

### **20.14.1 Methodology**

This analysis is performed with the GALE-BWR 3.2 code described in U.S. Nuclear Regulatory Commission (USNRC) NUREG-0016 Revision 2 which implements the analysis methods and assumptions for liquid effluent releases in Regulatory Guide 1.112 (References 20.14-1 and 20.14-2).

The GALE code is a mathematical model for calculating the release of radioactive material in gaseous and liquid effluents from Boiling Water Reactors (BWR). The calculations are based on operating data from existing BWRs, field tests, laboratory tests, and plant-specific design considerations incorporated to reduce the quantity of radioactive materials that may be released to the environment.

GALE calculates expected releases based on:

1. Standardized coolant activities derived from ANSI/ANS-18.1-2020 standard (Reference 20.14-3) Working Group recommendations
2. Release and transport mechanisms that result in the appearance of radioactive material in liquid and gaseous waste streams
3. BWRX-300 LWM design features used to reduce the quantities of radioactive materials ultimately released to the environment
4. Operating data from existing BWRs

All liquid effluent releases from the BWRX-300 occur through the LWM.

### **20.14.2 Results**

The BWRX-300 annual average liquid effluent release activities from various waste streams are shown in Table 20.14-1.

## **21.0 DECOMMISSIONING AND END OF LIFE ASPECTS**

### **21.1 Introduction**

Ontario Power Generation (OPG) is committed to effective and efficient life cycle management of nuclear facilities, which is in keeping with the evolution of international best practices in the nuclear industry. This chapter applies to decommissioning of the BWRX-300 facility at the end of its lifecycle.

The scope of decommissioning includes buildings used for operating the BWRX-300 at the Darlington New Nuclear Project (DNNP) site. These buildings include the Reactor Building, Turbine Building, Control Building, Radwaste Building, and the plant services area. Systems, components, piping, reactor vessel and reactor internals will be removed and appropriately packaged prior to disposal. Different decommissioning strategies are discussed, as well as the issues to be considered prior to determining the final decommissioning strategy. Human and organizational factors, records and financial guarantees are also discussed. Waste estimates will be provided in a separate submission to the Canadian Nuclear Safety Commission (CNSC).

### **21.2 General Principles and Regulations**

All decommissioning activities will be performed in compliance with relevant legislation, regulations, codes, and standards at the time of decommissioning.

The CNSC identifies the regulatory basis for decommissioning, as defined in the following key references:

- CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 21.2-1)
- CNSC REGDOC-2.11.2, "Decommissioning" (Reference 21.2-2)

#### **21.2.1 CSA Group**

In addition to the publications produced by the CNSC, decommissioning activities will also be performed in compliance with the CSA Group (CSA) standard below:

- CSA N294, "Decommissioning of Facilities Containing Nuclear Substances" (Reference 21.2-3).

#### **21.2.2 References**

- 21.2-1 CNSC Regulatory Document REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants."
- 21.2-2 CNSC Regulatory Document REGDOC-2.11.2, "Decommissioning."
- 21.2-3 CSA N294, "Decommissioning of Facilities Containing Nuclear Substances," CSA Group.

## **21.3 Incorporation of Decommissioning in the Design**

### **21.3.1 Introduction**

Operating Experience (OPEX) demonstrates that decommissioning of reactor facilities is facilitated if considered during the design phase. Assessment of future facility decommissioning and dismantling activities at the design phase includes consideration of OPEX gained from the decommissioning of existing facilities, as well as those facilities that are in long-term safe storage. The consideration of decommissioning at the design phase is expected to result in lower worker doses, reduced environmental impacts, and improved life cycle management of the facility (CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 21.3-1)).

The following are considerations of future plant decommissioning and dismantling activities, outlined in Section 7.24 of CNSC REGDOC-2.5.2 (Reference 21.3-1):

1. Materials are selected for the construction and fabrication of plant components and structures with the purpose of minimizing eventual quantities of radioactive waste and assisting decontamination.
2. Plant layout is designed to facilitate access for decommissioning or dismantling activities, including for plants with multiple units at a site, in periods when some units are operating, and some are under decommissioning.
3. Consideration is given to the future potential requirements for storage of radioactive waste generated as a result of new facilities being built or existing facilities being expanded.

### **21.3.2 BWRX-300 SMR Decommissioning Design Elements**

Decommissioning considerations made during the BWRX-300 Small Modular Reactor (SMR) design phase are discussed in this subsection.

#### **21.3.2.1 Site Plot Plan**

The BWRX-300 design has been optimized for constructability, which may be beneficial for dismantling the facility during decommissioning. Space allocations is considered to accommodate construction activities (i.e., access area around the plant, areas for laydown, etc.), thereby facilitating the ability to decommission and dismantle the plant once a Licence to Decommission the plant is granted.

#### **21.3.2.2 Modular Construction**

A modularization strategy will be used to design and construct the BWRX-300 at the DNNP site. The module and skid assemblies are intended to be built off-site, transported to the site, and erected on-site. This modularization strategy will provide guidance in selection of disassembly methods employed during decommissioning.

#### **21.3.2.3 Control of Materials During Design**

Specific guidance for plant systems materials to minimize corrosion products during plant operation is a design requirement, which provides restrictions regarding use of cobalt-based alloys and cobalt in stainless steel and nickel base alloys. These restrictions reduce personnel dose exposure during plant operation and decommissioning activities.

#### **21.3.2.4 Decommissioning Considerations for As Low As Reasonably Achievable**

Decommissioning considerations made to comply with the principle of As Low As Reasonably Achievable (ALARA), in the design of the BWRX-300, include the following aspects outlined in Chapter 12, Subsection 12.3.12:

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

1. Shielding design considers protection during maintenance, inspection, decommissioning and operations.
2. To facilitate decommissioning, the Reactor Building, Turbine Building, and Radwaste Buildings are designed for large equipment removal, consisting of entry doors from the outside and numerous cubicles with equipment hatches inside the buildings.
3. To facilitate decommissioning and ease of access, the radwaste process systems are skid-mounted and located in the Radwaste Building to allow truck access, and system skid loading and unloading.

**21.3.2.5 Design Features that Facilitate Decommissioning**

BWRX-300 design features that facilitate decommissioning by maintaining low occupational exposures are in Chapter 12, Subsection 12.1.5. Excerpts from Chapter 12, Subsection 12.1.5 are:

- Provisions for draining, flushing, and decontaminating equipment and piping
- Design of equipment to minimize the buildup of radioactive material and to facilitate flushing of piping systems
- Shielding that provides protection during maintenance, inspection, and operations, that may facilitate decommissioning
- Provision for adequate space for utilization of movable shielding
- Separation of more highly radioactive equipment from less radioactive equipment
- Provision for separate shielded compartments for adjacent items of radioactive equipment
- Provision for access hatches for the installation or removal of plant components
- Provision for the Reactor Water Cleanup System, Shutdown Cooling System, and the condensate demineralizer to minimize crud buildup

BWRX-300 design objectives that minimize radioactive contamination include:

1. Provide containment in areas where leaks and spills are most likely to occur.
2. Provide leak detection capability for prompt detection of leakage from Structures, Systems, and Components (SSC).
3. Use leak detection methods (e.g., instrumentation, automated samplers) capable of early detection of leaks in areas where it is difficult (inaccessible) to conduct regular inspections (such as the Spent Fuel Pool and buried, embedded, or subterranean piping) to avoid release of contamination. BWRX-300 active liquid waste is kept within the radwaste building in tanks located in cubicles.
4. Facilitate decommissioning by minimizing embedded piping, sumps, or buried equipment.

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

5. Design the plant to facilitate the removal or replacement of equipment or components during facility operation or decommissioning.
6. Minimize the generation of radioactive contamination and waste during operation and decommissioning by reducing the volume of components and structures that become contaminated during plant operation.

- 21.3-1 CNSC Regulatory Document REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants."

## **21.4 Long-Term Irradiated Fuel Storage**

The Nuclear Waste Management Organization is responsible for designing and implementing Canada's plan for the safe, long-term management of used nuclear fuel. The plan, known as Adaptive Phased Management, requires used fuel to be contained and isolated in a Deep Geological Repository. It also calls for a comprehensive process to select a site with informed and willing hosts for the project.

For used fuel storage, prior to moving the BWRX-300 fuel to a long-term Deep Geological Repository, the BWRX-300 design incorporates equipment and facilities necessary to load used nuclear fuel into containers for transfer to a licenced on-site independent spent fuel storage installation or licenced off-site waste management facility. Criticality safety requirements are considered throughout the life cycle of the fuel.

As part of the decommissioning plan, the last several fuel cycles of irradiated fuel will remain in the Spent Fuel Pool until they can be transported directly to the Nuclear Waste Management Organization Deep Geological Repository or stored in a licenced waste facility, until they can be accepted by the Nuclear Waste Management Organization. Spent fuel is an operational waste stream. The last cycle of irradiated fuel prior to plant shutdown will remain in the Spent Fuel Pool for a minimum of 2.5 years until it can be transported to a more permanent storage facility. Decommissioning activities can commence after used fuel is removed from the Spent Fuel Pool.

The 2.5-year period for storage of spent fuel in the Spent Fuel Pool is a theoretical minimum wet storage time. Factors that impact the spent fuel storage period include:

1. Burn-up time for fuel bundles
2. Spent Fuel Pool capacity
3. Type of flask used impacts the allowed minimum wet time as there should be consideration for both thermal rejection to the environment and radiation shielding

## **21.5 Decommissioning Strategy and Rationale**

The BWRX-300 SMR decommissioning strategy draws upon the lessons learned and experiences from decommissioning of similar reactors. With the removal of fuel from the reactor, activities associated with contaminated SSC are considered first when deciding on a decommissioning strategy.

In compliance with CNSC REGDOC-2.11.2, "Decommissioning" (Reference 21.5-1), BWRX-300 SMR decommissioning options considered include:

- Immediate (prompt) decommissioning
- Deferred decommissioning
- In-situ decommissioning

Note: In-situ decommissioning is not considered a reasonable decommissioning option for future facilities, except in exceptional circumstances, as per CNSC REGDOC-2.11.2 (Reference 21.5-1). In-situ decommissioning is not considered or evaluated for the DNNP facility.

### **21.5.1 Objective of Decommissioning**

The objective of the decommissioning program is to permanently retire the DNNP facility from service in a manner that will ensure the health, safety, and security of workers, the public and the environment are protected.

During decommissioning, radioactive and other hazardous materials, will be removed if present, and the DNNP facility site will be restored to meet the radiological release criteria approved by the CNSC. Upon completion of the decommissioning program, the DNNP facility will be in a condition that will support an application to the CNSC for release from regulatory control. OPG will retain ownership of the DNNP facility site, and it will then be available for other OPG uses.

The objective of decommissioning will be documented in the Preliminary Decommissioning Plan and will be reviewed and updated as necessary, with regular updates to the Preliminary Decommissioning Plan.

### **21.5.2 Selection of Decommissioning Strategy**

A decommissioning strategy will be selected early in the BWRX-300 SMR life cycle, to form the basis for planning for decommissioning and facilitate achieving the desired end-state of the decommissioning project. The following strategy options are considerations for selection individually or in combination:

1. Immediate (prompt) decommissioning:
  - a. To decontaminate, dismantle, or clean-up without any planned delays
2. Deferred decommissioning:
  - a. To place the facility, location, or site in a period of Storage with Surveillance (sometimes referred to as care and maintenance), followed by decontamination, dismantling, or clean-up
  - b. To conduct activities directed at placing certain buildings or facilities, locations, or sites in a safe and secure interim end-state, followed by a period of Storage with Surveillance, and ultimately, decontamination, dismantling and/or clean-up

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

3. In-situ decommissioning:

- a. To place the facility, location, site, or portions thereof, in a safe and secure condition in which some or all radioactive contaminants are disposed of in place, which may result in the creation of a waste disposal site

Note: As mentioned above, In-situ decommissioning is not considered or evaluated for DNNP.

Decommissioning strategies are evaluated in a systematic and traceable fashion so that the relative advantages and disadvantages of each strategy can be objectively compared. When determining the appropriate decommissioning strategy, the following are to be considered, as appropriate:

- Public and Indigenous engagement
- Potential impacts on Indigenous or treaty rights
- Operational experience and lessons learned
- Forms and characteristics of radioactive and non-radioactive contamination
- Integrity of containment and other SSC over time
- Availability of decontamination, disassembly, and clean-up technologies
- Potential for recycling or re-use of equipment and materials
- Availability of knowledgeable staff
- Potential environmental impacts
- Potential worker and public radiological doses
- End-state objectives and site redevelopment plans
- Potential revenues, costs, and available funding
- Availability of waste management facilities, locations, or sites
- Interdependencies with other facilities, locations or infrastructure located at the same site
- Assurance that the BWRX-300 site is maintained in a safe configuration
- Principles of radiation protection, justification, optimization, and application of dose limits

The DNNP facility decommissioning strategy will be documented in the Preliminary Decommissioning Plan and will initially be selected based on a high-level review of the above factors. In-depth studies will be performed as warranted over the life cycle of the plant, to refine and solidify the recommended decommissioning strategy as part of the regular review cycle to account for the following issues, which may have relevant consequences for decommissioning:

- Changes in site conditions, or incidents and events
- Changes to the proposed decommissioning objectives
- Changes to ownership or management structure
- Advances in decommissioning technology
- Significant modifications to the facility, location, or site
- Updated schedule, cost, and funding information

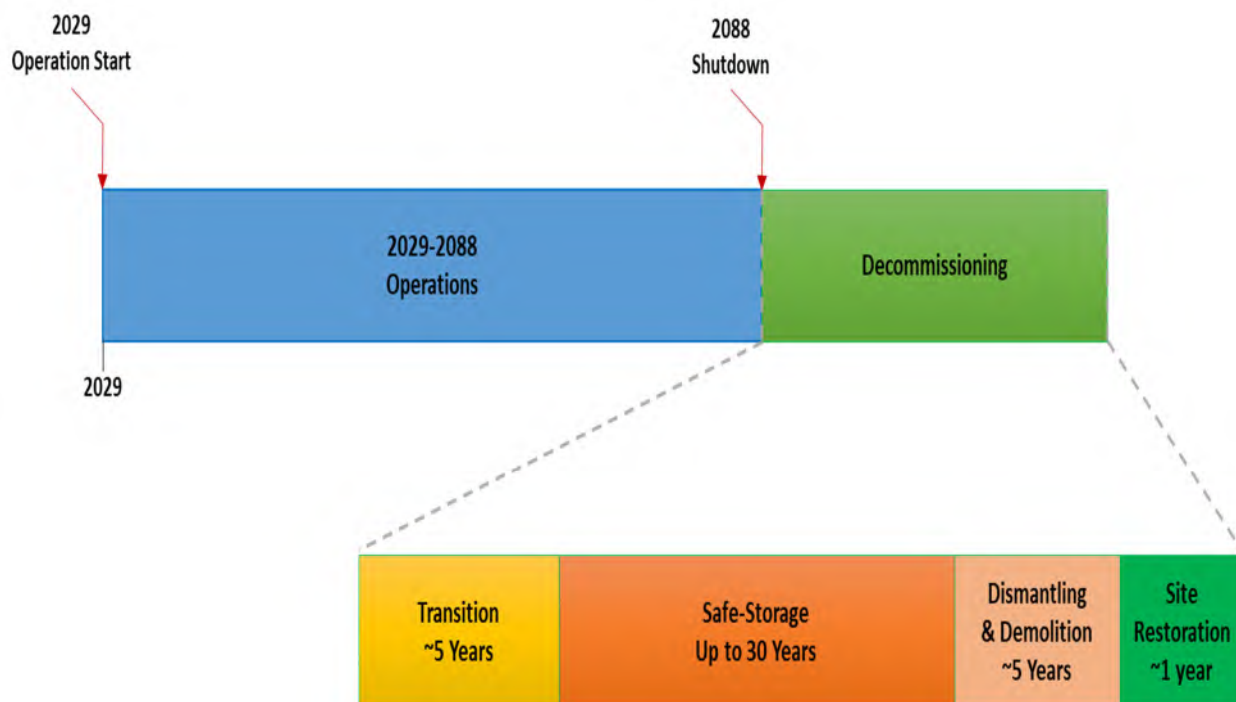

- Operational experience and lessons learned
- Revised regulatory requirements
- Availability of facilities, locations, or sites for the management of radioactive waste

Options for decommissioning are being considered and would be assessed as part of the Preliminary Decommissioning Plan.

### 21.5.3 Description of Planned Decommissioning Activities

This section outlines the major activities that will be performed during decommissioning of the BWRX-300 at the DNNP facility. The activities are described at a conceptual level with more detail being presented in the Preliminary Decommissioning Plan once it is prepared. All timing should be considered approximate and used for planning purposes only.

The anticipated major project milestones for decommissioning the DNNP facility are shown in Figure 21.5-1. More detailed schedules of decommissioning activities will be submitted to the CNSC as part of the Detailed Decommissioning Plan at the time of dismantling.

**Figure 21.5-1: Conceptual Planned Project Milestones Related to the Decommissioning of DNNP Facility**

OPG will prepare and submit a Detailed Decommissioning Plan to the CNSC for acceptance, two to five years prior to decommissioning, as part of OPG's application for a licence to perform decommissioning activities. The transition from operations to decommissioning is assumed to take five years once it has been shut down.

For planning purposes, a Storage with Surveillance period of up to 30 years will be assumed, followed by an assumed Dismantling and Demolition (D&D) period of five years. Site restoration and final surveys are assumed to take one year.

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

Table 21.5-1 shows the conceptual DNNP facility decommissioning timelines compared to the Darlington Nuclear Generating Station and the Darlington Nuclear Waste Facility on the Darlington site, based on current planning assumptions for the three facilities.

The DNNP facility Preliminary Decommissioning Plan development ensures better alignment for future updates of the Darlington site decommissioning plans.

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

**Table 21.5-1: Conceptual DNNP Facility Decommissioning Schedule Compared to Decommissioning Schedule for Darlington Nuclear Generating Station and Darlington Waste Management Facility**

<b>Phase</b>	<b>DNNP Facility (Conceptual Schedule Only)</b>	<b>Darlington Nuclear Generating Station</b>	<b>Darlington Waste Management Facility</b>
Shutdown	December 2088	Last Unit shut down December 2056	2082
Transition	Approximately five years	January 2057 – December 2057	Preparation for dismantling 2086 - 2089
Storage with Surveillance	Up to 30 years	January 2058 – December 2086 (Includes dry storage of used fuel at beginning of Storage with Surveillance and preparation for D&D at the end of Storage with Surveillance)	Not applicable
Dismantling and Demolition	Approximately five years	January 2087 – March 2089	2089
Site Restoration	Approximately one year	April 2089 – July 2092 (Includes final surveys)	2090

#### **21.5.4 Transition to Decommissioning**

OPG implements a program to incorporate industry OPEX and lessons learned from previous shutdowns and transitions to decommissioning as appropriate.

##### **21.5.4.1 Stabilization**

The transition, or Stabilization of the DNNP facility, will commence immediately following the end of commercial operations and be complete once the physical, operational, and administrative transition is confirmed.

Some of the key Stabilization activities are defueling and dewatering, radiation surveys, and removal of hazardous material. At the end of Stabilization, an Interim End-State Report will be produced and submitted to the CNSC to document the work that was executed.

The Stabilization goals and objectives include, but are not limited to:

- Defuel and removal of fluids, gases, hazardous materials, and other substances (e.g., resins) from the systems
- Continue to safely, and securely, store nuclear substances such as irradiated fuel until it can be removed to dry storage
- Maintain the facility in a safe and stable condition while creating no new hazards
- Reduce the footprint of the station in preparation for the next phase of decommissioning
- Protect workers, the public, and the environment from residual radioactive sources and hazardous materials remaining at the DNNP facility and maintain exposures ALARA

As Stabilization activities progress, systems that are no longer required to support the operation of the station will be placed into an inactive safe state. That is, they will be de-energized, drained of gas or fluids and isolated from operational systems. The operational, inspection, and maintenance requirements (as needed) for each system (or groups of related systems) will be identified and documented. Thereafter, the following activities will take place, as necessary:

1. Completing a Predictive Effects Assessment to proactively assess the potential environmental impacts resulting from the physical/operational changes to the station
  - a. Results of the assessment will identify environmental monitoring studies or mitigation measures required to manage the predicted effects.
2. Reviewing and revising operational programs to ensure requirements for the remaining phases of decommissioning are met
  - a. Examples include, but are not limited to environmental monitoring, radiation protection, emergency response, and fire protection. Plans and protocols, developed during the detailed planning phase, for monitoring the following would be submitted to the CNSC for acceptance:
    - i. Work hazards during decommissioning
    - ii. Personnel dosimetry
    - iii. Environmental emissions and effluents
    - iv. Materials, sites, and structures to be cleared from regulatory control

3. Developing a safety assessment framework to manage the nuclear and reactor safety aspects of Stabilization activities
4. Engaging stakeholders, including the public, and indigenous groups in transition planning activities

In support of transition to decommissioning, a safety assessment is also completed, including controls and approvals, to facilitate the shutdown and stabilization of the station. The objectives for the safety assessment include:

1. Demonstrate that applicable regulatory requirements are met throughout Stabilization
2. Demonstrate through systematic hazard analyses that the risks posed by hazards due to both Stabilization activities and for accident conditions are understood and managed
3. Identify necessary mitigating measures, limit controls and conditions to meet safety criteria throughout Stabilization
4. Quantify the hazard reduction to be achieved through Stabilization activities

#### **21.5.4.2 End-State of Stabilization**

By the end of the Stabilization period, all used fuel is planned to have been removed from the facility. The facility will remain intact with the structures and systems maintained in a safe condition. An Interim End-State Report indicating the current status of the facility will be prepared at the end of the Stabilization period for submission to the CNSC.

#### **21.5.5 Storage with Surveillance**

The Storage with Surveillance duration will be detailed in the Preliminary Decommissioning Plan and would delay the dismantling phase for a period of time. The Storage with Surveillance period allows for some decay of residual activation and fission products that remain in the station's systems prior to commencing D&D activities.

During Storage with Surveillance, SSC that would remain necessary to support continued operations (i.e., in active safe state) to meet operational demands will be modified or reconfigured, as necessary.

Programs will continue to support station operations and will be revised as necessary, similar to what is performed for Stabilization, as identified above. Programs and procedures will be adapted to meet regulatory requirements, while remaining commensurate with the complexity and risks of the Storage with Surveillance operations, and any revisions to these programs and procedures will require acceptance by the CNSC, where applicable.

During the Storage with Surveillance phase, OPG performs continuous monitoring and surveillance of the facility to ensure worker, public, and environmental safety is maintained.

An adequate level of security will be provided during Storage with Surveillance. Fire and radiation alarms are also to be monitored and maintained. Adequate plant staff will be available during this period to support the maintenance, inspection, and surveillance programs, as necessary.

#### **21.5.6 Planning for Dismantling, Demolition and Site Restoration**

Prior to the D&D phase, OPG will make detailed preparations for the dismantling, and the disposal of the waste. The Detailed Decommissioning Plan will be developed two to five years prior to dismantling operations and submitted to the CNSC for acceptance per regulatory requirements. A plan will be developed for the orderly progression D&D operations, including staff augmentation and any required plant system or service re-activation. Detailed work plans will be prepared to ensure that they remain appropriate with respect to improved knowledge of the condition of the

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

DNNP facility and the hazards that might be encountered during dismantling. Decommissioning Contractor(s) will be hired to manage and perform the D&D and Site Restoration. The activities performed by the Decommissioning Contractor(s) include, but are not limited to, updating procedures for characterization surveys, dismantling work, waste packaging, disposal, site restoration and final surveys. The D&D operations are designed to accomplish the required tasks while maintaining doses ALARA. Procedures will also address the continued protection of the health, safety, and security of workers, the public, and the environment.

During this phase of the work, OPG staff or Decommissioning Contractor(s) will take necessary actions, such as:

1. In consultation with the CNSC OPG will comply with applicable laws and regulations at the time of decommissioning, and will determine the requirements for performing an assessment of effects, to ensure that adequate provisions for the protection of the environment and the health and safety of persons are made prior to D&D
2. Develop a detailed schedule of activities with sequential planning of activities to minimize conflicts with simultaneous tasks
3. Reactivate, refurbish, or procure essential plant services necessary for dismantling
4. Review the results of the DNNP facility characterization and address any gaps or deficiencies in the information required to plan the decontamination, dismantling, demolition, and disposal
5. Prepare work packages for Decontamination, D&D, and disposal activities
6. Prepare detailed work procedures for the decontamination of SSC and procure decontamination equipment
7. Prepare detailed work procedures and sequences for the removal of systems and components
8. Perform a safety assessment to evaluate the processes for decontamination and dismantling the station, including waste handling, conditioning, and on-site processing
9. Evaluate the options for the disposal of the reactor vessel and its internals
10. Evaluate the options for the removal, handling, and disposal of other large radioactive components
11. Implement a graded approach for reviewing and revising station drawings, consistent with the need to maintain configuration control of the facility
12. Design, procure, and test the tooling and equipment (including remotely operated equipment) that will be used during the dismantling work
13. Procure needed D&D equipment
14. Procure or design and fabricate shielding and contamination control envelopes in support of removal and transportation activities
15. Develop procedures for occupational dose control, contamination control, industrial safety, environmental protection, fire protection, and emergency response
16. Develop or revise the emission monitoring program

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

17. Develop or revise the waste management program so that it covers the following processes, as applicable:
  - a. Characterization
  - b. Classification
  - c. Minimization
  - d. Segregation
  - e. Clearance
  - f. Handling
  - g. Volume reduction
  - h. Treatment
  - i. Packaging
  - j. Storage
  - k. Transportation
  - l. Final disposition
18. Develop a waste management plan, which typically includes but is not limited to:
  - a. Develop a plan for both the short term and, where possible, the long term, for management of all decommissioning waste
  - b. Develop the procedures for processing radioactive waste such as resins, filter media, and metallic and non-metallic waste generated during the dismantling work
  - c. Determine the transport and disposal container requirements for radioactive materials and hazardous wastes, including the requirements for shielding and stabilization of the waste
  - d. Procure and test the transportation and disposal containers for radioactive materials and hazardous waste
  - e. Prepare the detailed procedures for the packaging, removal, and disposal of radioactive materials, hazardous waste, and construction debris
  - f. Assess or investigate decontamination methods such as chemical cleaning, electro polishing, mechanical abrasion or melting. These decontamination methods may be used to decontaminate scrap metal if the reduction in the volume of the scrap is sufficient to justify further processing. Depending on the efficiencies achieved, metals will be considered as either radioactive wastes for controlled disposal, lightly contaminated (or activated) for consideration for re-use within the controlled nuclear environment, or metals that are decontaminated to levels below the clearance levels will be released for recycling in the open market
19. Prepare plans for site remediation
20. Obtain additional licences, permits, or approvals that are required and complete other regulatory processes that are applicable

#### **21.5.7 Detailed Decommissioning Plan**

A Detailed Decommissioning Plan is prepared and submitted for CNSC acceptance approximately two to five years prior to start of decommissioning. Towards the end of the

transition period, the Detailed Decommissioning Plan will be revised to describe OPG's detailed plan for managing the arrangements and activities conducted in support of the D&D and Site Restoration phases. The Detailed Decommissioning Plan will be prepared to meet the requirements of CNSC REGDOC-2.11.2 (Reference 21.5-1) and CSA N294, "Decommissioning of Facilities Containing Nuclear Substances" (Reference 21.5-2).

The Detailed Decommissioning Plan establishes criteria (i.e., clearance levels) that are used to determine if the material is suitable for uncontrolled release. The Detailed Decommissioning Plan also establishes the clearance levels and end-state criteria that are used to determine if the DNNP facility itself is suitable for release from further regulatory control.

The safety assessment for the DNNP facility decommissioning will be prepared in conjunction with the Detailed Decommissioning Plan, consider identified uncertainties, and address them as the decommissioning activities progress. Uncertainties regarding the radioactive inventory and the condition of the facility would be reduced as decommissioning progresses. The decommissioning safety assessment addresses potential radiological hazards to workers, the public, and the environment, from both routine decommissioning activities and credible accidents during decommissioning utilizing the defence-in-depth principle. The decommissioning safety assessment also identifies the mitigating methods to address the risks associated with these hazards and residual risks to the public once decommissioning is complete. The safety assessment will be reviewed, revised, or updated, as required, when additional information becomes available and as conditions change.

The environmental impact of facility decommissioning is discussed in Chapter 20, Section 20.10.

#### **21.5.8 Dismantling, Demolition and Site Restoration Period**

Dismantling work begins after collection of necessary permits and any other government approvals. Dismantling work has six conceptual steps:

1. Prepare the buildings and site
2. Decontaminate and dismantle nuclear systems
3. Dismantle non-nuclear systems
4. Demolish buildings
5. Manage and dispose of the waste
6. Restore the site

Work in the above steps may occur in parallel. Remedial action to support surveys for radioactive and other hazardous materials will be performed throughout the dismantling work, up to the final survey.

##### **21.5.8.1 Dismantling**

Dismantling activities are anticipated to involve the following:

1. Construct temporary facilities, modify existing storage facilities, and erect and place scaffolding in and around components to be dismantled to support the dismantling and decontamination activities. These may include a cutting station (as needed for large components), additional change rooms and contaminated laundry facilities for increased work force, establishment of laydown areas to facilitate equipment removal, upgrading roads to facilitate hauling and transportation, and modifications to the Reactor Building to facilitate access of large/heavy equipment.

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

2. Modify containment to support segmentation activities and prepare rigging for segmentation and extraction of heavy components.
3. Conduct decontamination of components and piping systems as required to control (minimize) worker exposure. Remove, package and dispose of all piping and components that are no longer essential to support dismantling operations. It is anticipated that radioactive corrosion products on inner surfaces of piping and components will not have decayed to levels that will permit unrestricted use or allow conventional removal. These systems and components are surveyed as they are removed and disposed of in accordance with the radiological clearance levels that have been developed.
4. Remove systems and associated components as they become non-essential, such as related to decommissioning activities or worker health and safety. Remove systems (piping and components) utilizing contamination control practices, remote tooling, and packaging in approved transportation containers for disposal.
5. Remove reactor vessel and reactor internals. Package in Low-Level Waste (LLW) or Intermediate-Level Waste containers (as appropriate).
6. Remove activated and accessible contaminated concrete. Remove those portions of the associated enclosures necessary for access and component extraction.
7. Remove all remaining LLW and Intermediate-Level Waste along with any remaining hazardous materials. Material removed in the decontamination and dismantling of the nuclear unit will be routed to an on-site central processing area. Material that meets clearance criteria will be released for unrestricted disposition (e.g., as scrap, recycled or general disposal). Contaminated material will be characterized and packaged for controlled disposal at the long-term disposal facilities for respective LLW and Intermediate-Level Waste.
8. Remove remaining components, equipment including tools used in D&D, and plant services in support of the area release survey(s).
9. Conduct final radiation surveys to ensure that all radioactive materials in excess of permissible residual levels have been remediated.

Dismantling work performed on contaminated nuclear systems will be conducted in a manner that will minimize the spread of contamination and in accordance with OPG's Radiation Protection Program. Appropriate contamination control techniques, including the use of portal monitoring systems at controlled egress points, temporary enclosures, local ventilation, Personal Protective Equipment, and contamination monitoring, will be used when the work is performed.

#### **21.5.8.2 Demolition**

Once contaminated systems, structures and non-nuclear systems have been dismantled and final surveys have confirmed that the remaining structures are below radioactive and hazardous materials release limit, demolition activities may begin.

Efficient removal of the contaminated materials and verification that residual radionuclide concentrations are below regulatory limits will result in substantial damage to many of the structures. Remaining buildings and above ground structures will be removed using conventional demolition techniques.

Remaining structures (including buildings that were not contaminated and temporary structures) will be demolished by general demolition crews. Waste blocks will be sized so that they can be handled and moved by the available technologies. Foundation and exterior walls will be removed to the nominal one-meter removal depth below grade whenever possible. At-grade foundation

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

slabs exceeding one meter in thickness will be abandoned in place and covered with a one-meter-thick layer of backfill, as needed. Concrete rubble and clean fill produced by demolition activities may be used to backfill voids. Suitable materials will be used for filling, otherwise the rubble will be trucked off-site for disposal as construction debris.

Piping that exceeds the release criteria will be removed and disposed of appropriately. Clean metal piping will be considered scrap or will be recycled. Road and parking areas with asphalt or concrete surfacing are broken up and the rubble used for backfilling on-site if needed or disposed of appropriately.

Once demolition is complete, an Interim End-State Report will be prepared for submission to the CNSC. Waste management is discussed in Section 21.8.

#### **21.5.8.3 Restore the Site**

Depending on the nature of the future activities that will be carried out at the site of the DNNP facility, restoration work may include:

- Breaking up road and parking areas covered with asphalt or concrete surfacing and using the rubble for backfilling, if needed
- Cleaning the DNNP facility to remove any remaining inactive waste and debris
- Covering the filled excavations with gravel (for drainage) and topsoil
- Abandoning water drain holes at the bottom of all subgrade structures
- Restoring the lake front property (including the water inlets and outlets, as required) to inhibit erosion and potential detrimental impacts on fish, fowl, or other wildlife
- Grading the area to prevent ponding and inhibit the refloating of subsurface material
- Establishing a covering of vegetation to prevent soil erosion

Soil and structural surfaces within authorized limits may remain following D&D activities. The DNNP facility will be demonstrated to meet final clearance levels in support of release from further regulatory control.

#### **21.5.9 Final End-State**

The proposed end-state of the DNNP facility is that OPG will decommission and restore the site to an industrial end-state status suitable for other OPG uses, commonly known as “brownfield”. As per nuclear industry practice, a brownfield is defined as a former industrial land that has the potential to be developed for new industrial uses. By the end of the D&D and Site Restoration periods, the DNNP facility will be free of industrial and radiological hazards. Station SSC will have been dismantled.

Radioactive contamination in excess of established clearance levels and other hazardous materials will have been removed from the DNNP facility. The clearance level used for the clean-up of the facility should not require institutional controls after the release from regulatory control. Station systems will have been dismantled and buildings demolished. Subsurface structures will have been drained and de-energized. These subsurface structures will also have been surveyed for contamination, decontaminated, if required, and dismantled to a nominal depth of one meter below grade (consistent with international practices), backfilled with clean concrete rubble and soil, and graded over. The remaining facility will have been backfilled to prevent future subsidence and restored to a state suitable for other OPG uses. By the end of this phase, the end-state objectives defined in the Detailed Decommissioning Plan will be verified to have been achieved and the DNNP facility will meet the criteria for release from regulatory control.

#### **21.5.10 Release from Regulatory Control**

Upon completion of decommissioning, the DNNP facility will be in a condition to support its removal from regulatory control. A Final End-State Report (or site abandonment plan) on the decommissioning program will be prepared. The Final End-State Report will describe the decommissioning work that has been performed and the outcome of that work, the results of the final surveys that were performed, and the interpretation of those results (i.e., whether the results meet the end-state objectives defined in the Detailed Decommissioning Plan). Other information required by applicable regulations will also be included in the report. A Final End-State Report will be submitted to the CNSC as part of the request for a release from regulatory control. Institutional controls are not expected to be required.

#### **21.5.11 Reference**

- 21.5-1 CNSC Regulatory Document REGDOC-2.11.2, "Decommissioning."
- 21.5-2 CSA N294, "Decommissioning of Facilities Containing Nuclear Substances," CSA Group.

## **21.6 Human and Organizational Factors**

The period of transition from operations to decommissioning poses different Human and Organizational Factors challenges to OPG compared to the operational phase because of the complex process necessary to complete decommissioning.

OPG ensures Human and Organizational Factors issues are considered throughout the planning and execution of the project. Prior to decommissioning, OPG will establish a Human Factors Engineering Program Plan (HFEPP) for the decommissioning of the DNNP facility according to the guidance in CNSC REGDOC-2.5.1, "General Design Considerations: Human Factors" (Reference 21.6-1); CNSC REGDOC-2.2.1, "Human Performance Management: Human Factors" (Reference 21.6-2); and lessons learned from decommissioning of Boiling Water Reactors, Pickering Nuclear Generating Station, and international OPEX. The details of the HFEPP will be included in the Detailed Decommissioning Plan. Special attention will be given to knowledge retention to minimize potential problems resulting from the loss of experienced personnel over time. Furthermore, a plan to manage staff reductions during the period following shutdown will be implemented. Risks associated with the decommissioning activities will be managed as per OPG's risk management process to ensure these risks are identified, analyzed, and documented and appropriate measures are put in place to mitigate these risks.

It is anticipated that the organization to oversee the decommissioning program will be assembled from available OPG station staff and outside OPG resources as needed. Decommissioning Contractor(s) will be hired to perform the D&D and Site Restoration work. OPG will provide the necessary oversight during this period. The Decommissioning Contractor(s) will be a company or consortium selected based on factors such as decommissioning experience, safety record, overall approach, and cost. OPG will remain the owner and licensee of the DNNP facility throughout the course of the decommissioning, but the Decommissioning Contractor(s) will be given charge and control of the facility during the D&D and Site Restoration periods. Other contractors may also be given charge and control of designated portions of the DNNP facility during the earlier phases of decommissioning. During these periods, the contractor will become the Constructor for the decommissioning work as defined by the Construction Safety Regulations made pursuant to the Occupational Health and Safety Act. The Decommissioning Contractor(s) and sub-contractors will be required to comply with OPG procedures related to Nuclear Energy Workers and other federal and provincial regulations.

OPG and the contractor(s) will ensure workers are qualified to perform the work assigned to them. Workers will be provided with training on the hazards associated with their work and the procedures that may be used to protect against those hazards. Training will include:

- Radiation protection
- Construction safety
- Workplace Hazardous Materials Information System
- Emergency Procedures
- Other appropriate topics

Staffing plans, which include clearly defined training requirements, are being developed by OPG to cover a 10-year rolling window and these plans will be updated annually. Staffing plans and associated training requirements will ensure training can be delivered within the specified timeframe to assure capability is maintained, and that sufficient resources are available for safe and reliable operation.

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

Detailed descriptions of the required training for D&D will be included in the Detailed Decommissioning Plan that is expected to be available two to five years prior to entering the phase.

**21.6.1 References**

- 21.6-1 CNSC Regulatory Document REGDOC-2.5.1, "General Design Considerations: Human Factors."
- 21.6-2 CNSC Regulatory Document REGDOC-2.2.1, "Human Performance Management: Human Factors."

## **21.7 Records**

Records filing and retention are governed by OPG's Information Management program, OPG-PROG-0001, "Information Management" (Reference 21.7-1), which identifies that records relevant to decommissioning are permanent records. Decommissioning-related documentation are managed and maintained in accordance with CNSC REGDOC-2.11.2, "Decommissioning" (Reference 21.7-2) and CSA N294, "Decommissioning of Facilities Containing Nuclear Substances" (Reference 21.7-3). These records will contain historical information that may be required in the future to update the Preliminary Decommissioning Plan, prepare the Detailed Decommissioning Plan, and ultimately facilitate successful decommissioning.

International decommissioning experience identifies retaining operational records improves future decommissioning. It is recognized that there is a potential for information about the DNNP facility to be lost as work transitions through the life cycle of the facility, and staff change, including the anticipated decrease in staffing numbers during the decommissioning period. It is therefore necessary that measures are taken to preserve records pertinent to decommissioning, capturing, and maintaining all potentially relevant information.

Records pertinent to decommissioning will be kept in the storage medium in standard use. All records will be assembled and maintained in accordance with the document and record management process and governance. The Preliminary Decommissioning Plan will document the operating and decommissioning records that will be retained, and the method of retention.

### **21.7.1 References**

- 21.7-1 OPG-PROG-0001, "Information Management," Ontario Power Generation.
- 21.7-2 CNSC Regulatory Document REGDOC-2.11.2, "Decommissioning."
- 21.7-3 CSA N294, "Decommissioning of Facilities Containing Nuclear Substances," CSA Group.

## **21.8 Waste Management**

The waste material inventory of the facility at the time of shutdown will depend on both the design and the operating history of the unit. The radioactive inventory will decrease over time due to the removal of activity by any decontamination work that is performed and the natural decay of the radioactive material. Estimates of the decommissioning waste inventory (i.e., the types and volumes of waste) will be prepared for the initial decommissioning plan supporting Licence to Operate and will be updated as needed based on survey and sampling information and operating history. Detailed characterization surveys will also be performed prior to the start of the D&D phase. The acquired characterization field data will permit an appropriate assessment of the radiological and conventional hazards that can affect workers, the public and the environment, and be used to develop the detailed decommissioning waste inventory for waste management planning.

Regarding disposal of radioactive decommissioning waste, OPG is exploring options after the cancellation of the Deep Geologic Repository for LLW and Intermediate-Level Waste at the Bruce Nuclear Site and remains committed to the permanent and safe disposal of its future decommissioning waste, including the DNNP facility waste.

OPG is also participating in Natural Resources Canada's work in public engagement on the existing Radioactive Waste Policy to ensure OPG is meeting international best practices. The Nuclear Waste Management Organization was asked to lead a dialogue to develop an integrated strategy for Canada's radioactive waste through close collaboration among waste owners and producers (including OPG), Indigenous people, and other interested Canadians. Progress on the Policy and Integrated Strategy will be taken into consideration in OPG's decommissioning waste disposal strategy.

For financial planning purposes, the LLW and Intermediate-Level Waste generated during decommissioning is assumed to be transferred to long-term disposal facilities for respective LLW and Intermediate-Level Waste.

Hazardous wastes generated during the D&D and Site Restoration periods of the decommissioning will likely be limited to hazardous materials originally used as building materials. Volumes of these wastes are likely to be small, since very few hazardous materials are expected to be used in the construction of the plant. Dry active waste such as combustibles (paper, cloth, wood, filter cartridges) could also be generated in the removal of plant systems.

The bulk of the non-hazardous waste materials generated during decommissioning will be produced during the D&D and Site Restoration periods of the decommissioning, although some are likely to be produced during the transition from operations period.

Appropriate disposal facilities for hazardous wastes will be identified prior to the beginning of the decommissioning project. Hazardous wastes will be packaged for transport and disposal according to the requirements of the applicable provincial regulations. All hazardous wastes, including nonradioactive hazardous wastes, will be transferred to an appropriate, licenced waste management facility for storage or disposal at approved disposal facilities. Waste manifests will be prepared and submitted as required by provincial regulations. Mixed waste (i.e., radioactive waste mixed with clean waste that is also hazardous) will be transferred to an appropriate long-term disposal facility.

If the volume or value of the contaminated scrap metal generated during decommissioning is sufficient to justify further processing, then chemical cleaning, electro polishing, mechanical abrasion, or melting might be used to decontaminate scrap metal. Metals that are decontaminated to levels below the clearance levels established in the Detailed Decommissioning Plan will be released for recycling or disposal.

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

Non-hazardous wastes that meet established clearance levels will be reused or recycled wherever possible or disposed of at approved disposal facilities. Clean concrete rubble may be used to fill the demolished DNNP facility or disposed according to applicable regulations. Other non-contaminated materials will be released for disposal according to the applicable regulations.

Existing site programs, instructions, and procedures will be evaluated to reflect the addition of the BWRX-300 plant for the handling of radioactive waste. Existing site programs, instructions and procedures will be evaluated and revised if necessary.

**21.8.1 Waste Estimates**

Volumes of radioactive decommissioning waste will be provided at a future licensing phase.

## **21.9 Financial Guarantee**

OPG established and maintains a financial arrangement that assures adequate funding of the decommissioning program (included in the Preliminary Decommissioning Plans) for the activities encompassed by the licence. The objective of OPG's Financial Guarantee is to ensure that sufficient funds are estimated, collected, and administered for the management of liabilities associated with operating and decommissioning of its nuclear facilities. The Financial Guarantee is prepared for OPG owned or leased facilities and makes specific financial provisions for the decommissioning of the facility. The facility's Preliminary Decommissioning Plan described in this Chapter forms the basis for establishing and maintaining an acceptable Financial Guarantee in support of the Licence to Operate.

In addition to the decommissioning program, OPG's Financial Guarantee also covers financial provisions for the long-term management (storage and eventual disposal) of operational and decommissioning wastes (e.g., Used Fuel, Low-Level and Intermediate-Level Wastes).

OPG's Financial Guarantee is prepared and maintained in accordance with the requirements set out in CSA N294, "Decommissioning of Facilities Containing Nuclear Substances" (Reference 21.9-1); CNSC REGDOC-2.11.2, "Decommissioning" (Reference 21.9-2) and CNSC REGDOC-3.3.1, "Financial Guarantees for Decommissioning of Nuclear Facilities and Termination of Licensed Activities" (Reference 21.9-3). OPG also provides an annual Financial Guarantee Report to the CNSC detailing the status of the guarantee, including the amounts accumulated in segregated funds and the value of the Provincial guarantee required. The Financial Guarantee Report compares the amount of the liabilities and the financial resources available to discharge obligations.

The Financial Guarantee provisions for the facility demonstrate that the current level of funding is adequate for decommissioning the station and returning the site to an end-state agreed upon with the Regulators. OPG will continue to provide annual Financial Guarantee reports to the CNSC detailing the status of the guarantee, including the amounts accumulated in segregated funds and the value of the Provincial Guarantee (if required).

The process described above is applicable for the Financial Guarantee for the facility prior to the start of operation. An appropriate financial instrument will be provided by OPG for the Financial Guarantee to meet the decommissioning liability for the construction phase of the DNNP project.

OPG reviews the Preliminary Decommissioning Plan as necessary, update the document to reflect new information and submits the Preliminary Decommissioning Plan to the CNSC for acceptance every five years, or as requested by the CNSC. The Preliminary Decommissioning Plan will be updated based on the following aspects, which can have consequences for decommissioning:

- Changes in site conditions, or incidents and events
- Changes to the proposed decommissioning objectives
- Changes to ownership or management structure
- Advances in decommissioning technology
- Significant modifications to the facility, location, or site
- Updated schedule, cost, and funding information
- Operational experience and lessons learned
- Revised regulatory requirements

NEDO-33971 REVISION 0  
NON-PROPRIETARY INFORMATION

- Availability of facilities, locations, or sites for the management of radioactive waste

OPG will progressively update the Preliminary Decommissioning Plan, where needed, to reflect the appropriate level of detail required for the licenced activities. Prior to the decommissioning phase, OPG will prepare a Detailed Decommissioning Plan.

**21.9.1 References**

- 21.9-1 CSA N294, "Decommissioning of Facilities Containing Nuclear Substances," CSA Group.
- 21.9-2 CNSC Regulatory Document REGDOC-2.11.2, "Decommissioning."
- 21.9-3 CNSC Regulatory Document REGDOC-3.3.1, "Financial Guarantees for Decommissioning of Nuclear Facilities and Termination of Licensed Activities."

### **21.10 Conclusion**

The BWRX-300 design incorporates design elements that allow for decommissioning. A conceptual facility decommissioning schedule has been prepared and will be revised prior to decommissioning of the BWRX-300 plant. As the design progresses, design elements that support decommissioning will be continually evaluated and incorporated. Options for decommissioning will be assessed as part of the Preliminary Decommissioning Plan. OPG maintains a Financial Guarantee for licenced activities in compliance with CNSC regulations.

## 1.0 INTRODUCTION

Information is presented in this Safeguards Annex to demonstrate how Ontario Power Generation Inc. (OPG) supports compliance with the International Atomic Energy Agency (IAEA) safeguards agreement in connection with the Treaty (Reference SG.1) on the Non-Proliferation of Nuclear Weapons (Safeguards Agreement (Reference SG.2)) and the Additional Protocol (Reference SG.3) to the Safeguards Agreement (Reference SG.2). Under the Nuclear Safety and Control Act (NSCA) (Reference SG.4), the Canadian Nuclear Safety Commission (CNSC) has the mandate to achieve Canadian conformity with such international obligations.

Specifically, this Safeguards Annex describes information related to the BWRX-300 reactor facility at the Darlington New Nuclear Project (DNNP) to demonstrate compliance with the Safeguards Agreement (Reference SG.2) and the Additional Protocol (Reference SG.3), as well as compliance with the responsibilities included in the NSCA (Reference SG.4) and the General Nuclear Safety and Control Regulations (Reference SG.5).

This Safeguards Annex includes operational information based on OPG's Darlington Nuclear Generating Station practices. Although the high-level OPG safeguards program applies, the lower tier implementing documents are to be customized, as necessary, for the BWRX-300 Small Modular Reactor (SMR).

For clarification and consistency of terms used in this Safeguards Annex, Table 1.0-1 includes explanation of selected terms used by the IAEA for safeguards purposes.

**Table 1.0-1: Selected Terms Used by the IAEA for Safeguards Purpose**

(Source: IAEA Safeguards Glossary (Reference SG.10))

Term	Explanation
Containment	Structural features of a facility, containers or equipment which are used to establish the physical integrity of an area or items (including safeguards equipment or data) and to maintain the continuity of knowledge of the area or items by preventing undetected access to, or movement of, nuclear or other material, or interference with the items. Examples are the walls of a storage room or of a storage pool, transport flasks and storage containers. The continuing integrity of the containment itself is usually assured by seals or surveillance measures (especially for containment penetrations such as doors, vessel lids and water surfaces) and by periodic examination of the containment during inspection.
Surveillance	The collection of information through inspector and/or instrumental observation aimed at detecting movements of nuclear material or other items, and any interference with containment or tampering with IAEA equipment, samples, and data. Surveillance may also be used for observing various operations or obtaining relevant operational data. IAEA inspectors may carry out surveillance assignments continuously or periodically at strategic points.
Containment/ surveillance device (C/S device)	An item of equipment used to perform a C/S function and capable of providing its own C/S results

NEDO-33972 REVISION 0  
NON-PROPRIETARY INFORMATION

Term	Explanation
Containment/ surveillance measures (C/S measures)	<p>The application of containment and/or surveillance to complement nuclear material accountancy. The use of C/S measures is aimed at verifying information on movement of nuclear or other material, equipment and samples, or preservation of the integrity of safeguards relevant data. In many instances C/S measures cover the periods when the inspector is absent, thus ensuring the continuity of knowledge for the IAEA and contributing to cost effectiveness. Containment/surveillance measures are applied, for example:</p> <ul style="list-style-type: none"> <li>(a) During flow and inventory verification, to ensure that each item is verified without duplication and that the integrity of samples is preserved</li> <li>(b) To confirm that there has been no change to the inventory previously verified and thus reduce the need for remeasurement</li> <li>(c) To ensure that IAEA equipment, working papers and supplies have not been tampered with</li> <li>(d) If necessary, to isolate ('freeze') nuclear material that has not been verified until it can be measured</li> </ul>
System of containment/ surveillance measures (C/S system)	<p>A combination of containment and/or surveillance measures (see No. 8.6 [of Reference SG.10]). Each C/S system is designed to meet a purpose specified in the IAEA's safeguards approach. To increase reliability, a C/S system can include one or several C/S devices (see No. 8.3 [of Reference SG.10]). Containment/surveillance devices and containment may be used in such a way that each plausible diversion path (see No. 3.7 [of Reference SG.10]) is covered by at least one device (single C/S). For redundancy purposes, C/S devices may be backed up (duplicated) by a similar device. In a dual C/S system, each plausible diversion path is covered by two C/S devices that are functionally independent and are not subject to a common tampering or failure mode (dual C/S), e.g., two different types of seal, or seals plus surveillance. Dual C/S is normally applied where the verification of nuclear material is difficult to perform, in order to increase confidence in the C/S results and reduce the requirements for periodic reverification.</p>
Seal	<p>A tamper indicating device used to join movable segments of a containment in a manner such that access to its contents without opening the seal or breaking of the containment is difficult. A sealing system comprises the containment enclosing the material to be safeguarded, the means of applying the seal (e.g., a metal wire) and the seal itself. All three components must be examined in order to verify that the sealing system has fulfilled its function of ensuring continuity of knowledge of the identity and integrity of the material concerned. Seals in use by the IAEA include metal cap seals with tamper indicating features, as well as ultrasonic and electronic seals with fibre optic loops, and, for short time applications, tamper indicating paper tape seals. Sealing systems may be applied:</p> <ul style="list-style-type: none"> <li>(a) On safeguarded material or equipment to maintain the continuity of knowledge of the sealed contents between inventory verifications, and during shipment from one facility to another</li> <li>(b) On the operator's equipment (e.g., a crane) to monitor any use that would make possible the undeclared removal of nuclear material</li> <li>(c) On IAEA property (equipment, samples, standards, data, etc.) to prevent undetected tampering with it</li> </ul>

## **1.1 Scope**

The scope of this document covers safeguards information for OPG's BWRX-300 facility at the DNNP site, including:

1. Classification of nuclear material and categorization of licensees – Section 2.0
2. Safeguards design information – Section 3.0
3. Safeguards operational information – Section 4.0
4. Nuclear fuel life cycle – Section 5.0
5. Provision of access and assistance to the IAEA – Section 6.0
6. OPG's program on nuclear material accountancy – Section 7.0
7. Safeguards interface with safety, security – Section 8.0
8. Safeguards and Import and Export aspects – Section 9.0

## **1.2 Relevant Legislations and Obligations**

Subsection 1.2 describes the applicable legislations and regulations requirements and guidance related to safeguards, and the IAEA safeguards agreements.

### **1.2.1 Legislations and Regulations**

The following provisions of the NSCA (Reference SG.4) and the General Nuclear Safety and Control Regulations (Reference SG.5) made under it apply to this Safeguards Annex:

1. Subparagraph 9(a)(iii) of the NSCA establishes that one of the objectives of the CNSC is to "achieve conformity with measures of control and international obligations to which Canada has agreed."
2. Paragraph 24(4)(b) of the NSCA states that "[n]o licence shall be issued, renewed, amended, or replaced unless, in the opinion of the Commission, the applicant will, in carrying on that activity, make adequate provision for measures required to implement international obligations to which Canada has agreed."
3. Paragraph 26(a) of the NSCA states that "[s]ubject to the regulations, no person shall, except in accordance with a licence, (a) possess, transfer, import, export, use or abandon a nuclear substance, prescribed equipment, or prescribed information."
4. Paragraph 27(b) of the NSCA states that "[e]very licensee and every prescribed person shall (b) make the prescribed reports and file them in the prescribed manner."
5. Paragraph 12(1)(i) of the General Nuclear Safety and Control Regulations states that "[e]very licensee shall take all necessary measures to facilitate Canada's compliance with any applicable Safeguards agreement."
6. Section 30 of the General Nuclear Safety and Control Regulations identifies situations in which safeguards reports shall be provided by licensees to the Commission.

Subsection 4.13 of CNSC REGDOC-1.1.2 (Reference SG.15) requires the successful implementation of the obligations arising from the Non-Proliferation of Nuclear Weapons Treaty (Reference SG.1), Canada/IAEA Agreement (Reference SG.2), and the Additional Agreement (Reference SG.3), as well as the conformance with the requirements of the NSCA (Reference SG-4) and associated Regulations (Reference SG.5).

CNSC REGDOC-2.5.2 (Reference SG.14) requires, under Subsection 7.23, the BWRX-300 facility design and design process to allow for the permanent installation of IAEA safeguards equipment and the provision of services required for the ongoing operation of that equipment.

CNSC REGDOC-2.13.1 (Reference SG.6), on safeguards and nuclear material accountancy, sets out CNSC's requirements and guidance for the:

- Establishment and maintenance of a safeguards program
- Requirements for event and compliance monitoring reporting by licensees

Since the BWRX-300 is a SMR, CNSC REGDOC-1.1.5 (Reference SG.7) also allows for defining and using a graded approach commensurate with the risk when applying requirements and guidance contained in regulatory documents. However, it emphasizes that "[t]he use of a graded approach is not a relaxation of requirements, but rather the application of requirements in a manner commensurate with the risks and characteristics of a facility or activity."

This Safeguards Annex demonstrates how OPG satisfies the requirements of international obligations and regulatory requirements.

### **1.2.2 International Atomic Energy Agency Safeguards Agreements**

The Safeguards Agreement (Reference SG.2) came into force on February 21, 1972, while the Additional Protocol (Reference SG.3) became effective on September 8, 2000.

The Safeguards Agreement (Reference SG.2) describes the safeguards system to which Canada shall adhere, including what materials are subject to safeguards, and what information shall be reported to the IAEA. The objective of IAEA safeguards is "the timely detection of diversion of significant quantities of nuclear material from peaceful nuclear activities to the manufacture of nuclear weapons or of other nuclear explosive devices or for purposes unknown, and deterrence of such diversion by the risk of early detection."

The Additional Protocol (Reference SG.3) covers further requirements for the provision of information and access to the IAEA, including the obligation to allow access to some locations on a 24-hour notice, and the obligation to provide information on and access to certain nuclear manufacturers and researchers, neither of which involve nuclear material. These tools allow the IAEA to have confidence that there is no undeclared nuclear material or nuclear activities in Canada, in compliance with the Safeguards Agreement (Reference SG.2).

IAEA guidelines for reactor facilities safeguards are offered in IAEA Technical Reports Series (TRS) No. 392 (Reference SG.8). It explains how information for new facilities is to be developed and proposes a schedule for submitting information to the IAEA. While these IAEA guidelines are applicable to the nuclear facility designs in the 1500 MWe size range, the report recognizes that smaller reactors passive safety features are being considered. On its website (Reference SG.9), the IAEA explains that "(t)here are challenges associated with performing nuclear verification at SMRs, including the use of new nuclear fuels, and irradiated fuel management considerations. However, by working with the IAEA at an early stage in reactor design, safeguards considerations can be embedded into the design of these reactors, so that nuclear verification activities are performed in the most effective and efficient way with minimal burden on the operator." Consequently, since the BWRX-300 is ~300 MWe SMR facility, it is possible that certain of the IAEA safeguards guidance would be implemented in a graded approach based on larger nuclear power plant designs addressed by the IAEA TRS No. 392 (Reference SG.8). This is in concert with CNSC REGDOC-1.1.5 (Reference SG.7).

NEDO-33972 REVISION 0  
NON-PROPRIETARY INFORMATION

The information presented in this Safeguards Annex demonstrates adherence to the obligations of the Safeguards Agreement (Reference SG.2) and the Additional Protocol (Reference SG.3), as well as in accordance with the guidance of IAEA TRS No. 392 (Reference SG.8).

### **1.3 Limitations on Use**

The Safeguards Annex is a high-level summary document developed to support the Licence to Construct activities for the DNNP-1 nuclear facility. The Safeguards Annex shall not be used for technical or construction purposes.

## **2.0 CLASSIFICATION AND CATEGORIZATION**

### **2.1 Nuclear Material Classification**

The BWRX-300 SMR facility utilizes Global Nuclear Fuels (GNF) GNF2 fuel. As listed in Chapter 1, Table 1.5-1, GNF2 fuel has an assembly-average enrichment of less than 5 per cent U-235. Such fuel is classified in CNSC REGDOC-2.13.1 (Reference SG.6) as Group 1A material, and thus is subject to full-scope safeguards of routine verification by the IAEA and detailed accountancy of nuclear material. Chapter 4, Subsection 4.2.2, and NEDO-33270 (Reference SG.17) provide detailed information regarding GNF2 fuel characteristics and design.

Before the initial nuclear fuel load and before each refueling cycle, the fresh fuel is shipped to the BWRX-300 facility and stored in the fuel pool, as described in Subsection 5.1.2. As listed in Chapter 1, Table 1.5-1, the irradiated fuel is stored in the fuel pool that is designed with a capacity for up to approximately eight (8) years of full operation. The irradiated fuel is then moved to a licensed on-site dry storage facility, as described in Subsection 5.1.4.2. The irradiated fuel will permanently be stored in a deep geological repository when it becomes available in Canada, as summarized in Subsection 5.1.4.5. Additional information on the fuel life cycle is found in Section 5.0.

Sensing, start-up or shielding equipment containing nuclear materials are managed, per CNSC REGDOC-2.13.1 (Reference SG.6), as Group 1A or Group 1B materials which also are covered under OPG's Safeguards and Nuclear Material Accountancy Program.

### **2.2 Categorization of Licensees**

Following the categorization of licensees described in Section 3.0 of CNSC REGDOC-2.13.1 (Reference SG.6), OPG is categorized as "facility for safeguards purpose" since the DNNP location will:

1. Include a reactor facility (that is, the BWRX-300 SMR) and a separate irradiated fuel dry storage installation
2. Be where Group 1A material in amounts greater than 1 effective kilogram are customarily used

### **3.0 SAFEGUARDS IN DESIGN**

The BWRX-300 facility design information includes:

1. Identification of the facility, stating its general character, purpose, nominal capacity and geographic location, and the name and address to be used for business purposes.
2. Description of:
  - a. The general arrangement of the facility, including site and building maps as needed, with reference to:
    - The form, location, and flow of nuclear material
    - The general layout of important items of equipment which are used to handle, produce, or process nuclear material
  - b. Features of the facility relating to nuclear material accountancy, as well as Containment and Surveillance (C/S)
  - c. Procedures used at the facility for nuclear material accountancy and control, with special reference to the structure of Material Balance Areas and Key Measurement Points, organizational responsibility, measurements of nuclear material, the random and systematic uncertainties of such measurements, and procedures for Physical Inventory Taking
3. Health and safety procedures

As the operator of the BWRX-300 facility, OPG ensures that the CNSC is in possession of up-to-date design information, specifically an IAEA Design Information Questionnaire (DIQ), the contents of which are described in Appendix I of IAEA TRS No. 392 (Reference SG.8).

#### **3.1 Design Information Requirements**

To enable planning its safeguards approach for a new reactor facility such as the BWRX-300 facility, the IAEA provides guidance in TRS No. 392 (Reference SG.8) for the establishment of a rolling program for the provision of design information. The information provided by such a program creates confidence in the peaceful purpose of the facility, and is intended to provide an adequate lead time to:

1. Ease the incorporation into the facility design, including the design of the nuclear material accountancy system and features which make it easier to implement safeguards at the facility
2. Allow time for safeguards research and development work that may be necessary
3. Enable the IAEA to carry out the budgetary planning necessary for effective and efficient implementation of safeguards
4. Permit the identification and scheduling of actions which need to be taken jointly by OPG and the IAEA, including:
  - a. Installation of safeguards equipment during construction of the facility
  - b. Verification of information on the design of the facility

The IAEA expects, on an iterative basis, information regarding safeguards relevant features of the facility design is made available early in the project definition, preliminary design, construction, and commissioning phases of BWRX-300.

During the project definition phase, the IAEA is provided with an initial DIQ, consisting of:

NEDO-33972 REVISION 0  
NON-PROPRIETARY INFORMATION

1. The identification of the facility and a short description of its general character, purpose, nominal capacity, and geographical location
2. The form, location, and movement of nuclear material
3. The general layout of important items of equipment which use, produce, or process nuclear material

During the subsequent preliminary design phase:

1. Discussion occurs with the IAEA on the safeguards approach to be used at the facility
2. Appropriate information on the design is provided to the IAEA as the design develops
3. Design incorporates the IAEA equipment or instrumentation required for safeguards purposes

The initial IAEA DIQ is based on the initial design and construction plan, and is provided to the IAEA, through the CNSC, at least 180 days prior to the start of construction. An update to the DIQ based on the "as-built" design and construction is then re-submitted, through the CNSC, to the IAEA approximately 180 days before the first receipt of nuclear material at the DNNP site. The CNSC coordinates with the IAEA and OPG for completion of the responses to the IAEA DIQ.

### **3.2 Design Information**

The initial DIQ, based on the summary of information requested in Appendix I of TRS No. 392 (Reference SG.8), is developed for the BWRX-300 for submission to the CNSC no later than 270 days before the start of construction. Note that CNSC recommends that the applicant submit the DIQ either before or concurrent with the Licence to Construct application (refer to Subsection 4.13.1 of CNSC REGDOC-1.1.2 (Reference SG.15)). The DIQ is a separate, non-public submittal.

The BWRX-300 DIQ is based on safeguards relevant preliminary design information of the BWRX-300 facility, as described in:

- Chapter 1, Section 1.5 for general BWRX-300 Power Block description
- Chapter 2, Subsection 2.1.2 for site and facility layouts
- Chapter 3, Subsection 3.5.5 for Reactor Building (RB)
- Chapter 4, Sections 4.2 and 4.3 for fuel system and nuclear design
- Chapter 5, Sections 5.4 for Reactor Pressure Vessel (RPV) and internal components
- Chapter 9A, Section 9A.1 for fuel storage and handling systems
- Chapter 9B, Section 9B.2 for integrated RB design
- Chapter 15, Subsections 15.5.7 for fuel pool deterministic safety analysis and the results thereof

Design information requested by the IAEA (Reference SG.8) to be reported in the BWRX-300 DIQ includes:

1. General information about the facility, such as location, owner, operator, purpose, main features, schedules for construction/commissioning/operation, operating modes, site layout, and reactor facility layout

NEDO-33972 REVISION 0  
NON-PROPRIETARY INFORMATION

2. Reactor data, such as general flow diagrams, thermal and electricity outputs, number of reactor units, type of reactor and of fueling, core enrichment, reactor coolant and moderator
3. Description of the nuclear material, such as the fresh fuel and its enrichment, nominal weight of fuel in element/assemblies, physical and chemical form of the fresh fuel
4. With relevant drawings attached under reference numbers, description of reactor assemblies, and fresh fuel elements
5. Description of elements exchange in assemblies, basic accounting unit, and means of nuclear material identification, as well as other nuclear material in the facility
6. Information on nuclear material flow, such as:
  - a. Diagrams attached under reference numbers identifying, for example, Material Balance Areas, Key Measurement Points
  - b. Inventory and locations of fresh fuel, in-core fuel, irradiated fuel, refueling, burnup, storage of irradiated fuel
  - c. Reactor load factor, core loading, refueling, and burnup
  - d. Whether the irradiated fuel is processed or stored
7. Handling of fresh and irradiated fuel information, including, fresh fuel transport and storage, locations in reactor vessel, transfer to fuel pool, nuclear material testing areas, relevant instrumentation to measure safeguards key parameters
8. Reactor and fuel pool coolant data, such as mass flow, temperature, and pressure at major or key locations
9. Information on nuclear material accountancy and control
10. Measures to protect and secure nuclear material, confine, and contain safeguards equipment, and protect health and safety of inspectors during compliance
11. Other measures that are deemed necessary or specific for the BWRX-300 facility or the DNNP site

Information included in the DIQ is used by the IAEA to prepare the safeguards approach and to serve as the basis for preparing a draft for inspection goals and procedures, including planning for site visits, inspections, and audits.

### **3.3 Design Information Examination and Verification**

The IAEA verifies design information through the physical examination of the BWRX-300 facility during construction, commissioning, operation, and subsequent phases.

A design information examination is a review to determine whether further information is necessary for the IAEA to establish adequate safeguards and to identify features of the facility and the nuclear material handling and storage procedures which may have an impact on the safeguards approach and methods.

A Design Information Verification is an on-site verification by the IAEA to ensure that the information is sufficiently complete and correct and satisfies IAEA needs as specified in the Safeguards Agreement (Reference SG.2). This verification is performed during a visit, which is different than other IAEA inspections that are arranged for specific purposes.

NEDO-33972 REVISION 0  
NON-PROPRIETARY INFORMATION

Before an on-site visit, the IAEA performs specific actions such as:

1. Examining the design information provided in the DIQ to establish its completeness and its self-consistency
2. Determining whether any additional information or clarification is required that could have an effect on safeguards; and requesting formally such additional information from the CNSC, as needed
3. Preparing a preliminary safeguards approach for the BWRX-300 facility, based on the design information included in the initial DIQ and other relevant information available which considers specific features of the facility and other relevant features and elements indicated in the Safeguards Agreement including:
  - a. Determination of possible diversion strategies, identification of possible diversion paths, and specification of the detection goals (detection times, significant quantities, and detection probabilities) to be achieved for the BWRX-300 facility
  - b. Analysis of the identified possible diversion paths
4. Preparing the draft Facility Attachment (employing the model Facility Attachment described below), the design information, the goals and procedures and any other relevant facility information
5. Planning the on-site verification activities

A model for the Facility Attachment, to be prepared by the IAEA, is proposed in IAEA TRS No. 392 (Reference SG.8) to contain, among other things:

1. A short description of the facility
2. A provision to submit to the IAEA changes in the information on the facility
3. The accountancy measures to be used at the facility
4. Provisions for the C/S measures
5. Specific provisions and criteria for the termination of and exemption from safeguards of nuclear material
6. Description of the records and reports system
7. Description of the mode and the scope of IAEA routine inspections
8. Provisions for administrative and financial procedures concerning the application of safeguards at the facility

During the IAEA on-site visit to perform verification of the design information prior to and/or during construction, the IAEA will, for example:

1. Identify in sufficient detail those features affecting the application of safeguards to ensure that the safeguards objectives, as laid down in the Safeguards Agreement (Reference SG.2) are met and the IAEA safeguards goals are fulfilled
2. Determine the Material Balance Areas used for IAEA accounting purposes and select Key Measurement Points used to determine the flow and inventory of the nuclear material. When determining a Material Balance Area, the following criteria are considered:
  - a. The size of any Material Balance Area is based on the material balance accuracy obtainable

NEDO-33972 REVISION 0  
NON-PROPRIETARY INFORMATION

- b. The use of C/S measures to ensure the completeness of flow measurements, and to simplify the application of safeguards and focus measurement efforts at the Key Measurement Points
- c. The number of Material Balance Areas at the BWRX-300 facility or at other defined locations which may be combined into one Material Balance Area if the IAEA determines that this is feasible
- d. Establishment of:
  - i. A special Material Balance Area, at the request of the CNSC, around a process step involving commercially sensitive information
  - ii. Nominal timing and procedures for taking physical inventory for IAEA accounting purposes
  - iii. Requirements for records and reports and the evaluation procedures
  - iv. Requirements and procedures for flow and inventory verification, specifying quantities and identifying the locations of nuclear material
- e. Selection of appropriate combinations of C/S methods and techniques and the strategic points at which they are to be applied

Furthermore, during the IAEA on-site visit and to the extent practicable, the planned IAEA safeguards approach and inspection goals as well as procedures are checked against the design information and any additional information received on BWRX-300 practices or "State System Accounting and Control" activities (which means, in this Safeguards Annex CNSC activities). Features of the BWRX-300 that are of special interest include:

1. C/S features and provisions
2. Operational practices, including Material Balance Areas and Key Measurement Points established by OPG and as used by the CNSC
3. The flow of nuclear material, its type, and its physical and chemical form (refer to Section 5.0)
4. Possible identification methods of items and batches
5. Measurement methods used and their accuracy
6. Sampling procedures and methods for ensuring the integrity of samples
7. Methods of storage and containment of nuclear material from the viewpoint of measurement techniques used by the IAEA
8. Recording and reporting procedures
9. Possibilities of using C/S equipment

As the operator of the BWRX-300, OPG responds promptly to IAEA requests for additional information on the IAEA examination of the design information contained in the DIQ, as well as on operational information relevant to safeguards. OPG assists and provides access to IAEA personnel to facilitate the IAEA planned or supplemental on-site visits. Additional information on these aspects is found in Sections 4, 6, and 7.

## **4.0 SAFEGUARDS AND OPERATION**

Section 4 of CNSC REGDOC-2.13.1 (Reference SG.6) specifies that the licensee (that is OPG) maintains a documented Safeguards and Nuclear Material Accountancy Program which fulfills applicable safeguards requirements. For the BWRX-300 facility and locations outside BWRX-300 facility as well as other facilities, OPG has a safeguards program (Reference SG.16) which meets the applicable safeguards requirements as follows:

- Safeguards Equipment and Seals (Subsection 6.1)
- IAEA Access (Subsection 6.2)
- Nuclear Material Accountancy (Section 7.0)
- Provision of Information (Subsection 7.2)
- Retention of Records (Subsection 7.3)

The health of the program is reviewed and assessed quarterly and annually by OPG using a set of Key Performance Indicators. Areas of the program that require performance improvement are routinely listed and tracked to completion using action plans.

The Safeguards and Nuclear Material Accountancy Program establishes OPG's implementing and reporting processes and procedures that are used to ensure Canada's fulfillment of its obligations for Nuclear Material Accountancy. The program outlines roles and responsibilities for individuals and organizations mandated to meet the requirements and guidance of CNSC REGDOC-2.13.1 (Reference SG.6).

The current OPG Safeguards, and Nuclear Material Accountancy Program applies to the following five OPG "Facilities", as per the classification and categorization of Section 2.0:

- Darlington Nuclear Generating Station
- Pickering Nuclear Generating Station
- Nuclear Sustainability Services Darlington (used fuel storage)
- Nuclear Sustainability Services Pickering (used fuel storage)
- Nuclear Sustainability Services Western (used fuel storage)

Each of these facilities is designated as a Material Balance Area for which a dedicated Safeguards Officer is responsible for:

- Accountancy of nuclear materials
- Facilitating IAEA access
- Maintaining provisions of information
- Retention of records

OPG employees who access areas or work around areas with IAEA C/S equipment are trained to identify such equipment and to not manipulate the equipment without appropriate notification.

OPG Safeguards Officers or Delegates, in collaboration with OPG operations and maintenance organizations, facilitate and provide access to the IAEA for Unannounced Inspections, Short Notice Random Inspections, planned inspections or maintenance, and for Complementary Access (CA) requests as required by CNSC REGDOC-2.13.1 (Reference SG.6).

#### **4.1 Operational Information Requirements**

The OPG Safeguards and Nuclear Material Accountancy Program (Reference SG.16) meets the requirements in Section 4 of CNSC REGDOC-2.13.1 (Reference SG.6). This is achieved through:

1. Strict inventory tracking of nuclear materials by using a nuclear material accountancy software
2. Training of staff involved with the maintenance, inspection, verification, or movement of nuclear materials on the requirements of reporting and tracking information using either software or physical means
3. Site specific operating procedures that provide instructions on meeting the established safeguards agreement
4. Strict access control to areas that contain nuclear materials
5. Clearly identifying facility personnel with safeguards roles and responsibilities

The nuclear material accountancy software provides the Safeguards Officers tools to generate reports required in Section 8 of CNSC REGDOC-2.13.1 (Reference SG.6).

Furthermore, OPG submits documents to facilitate Canada's fulfillment of its Safeguards and Nuclear Material Accountancy obligations. Safeguards related information is maintained on the Nuclear Material Accountancy Software, which provides near real-time inventory of:

- Fresh and irradiated fuels
- Fuel that is in the reactor core
- Fuel that is located anywhere else within the facility to support operations
- Other non-fuel nuclear materials required to support operations

OPG's Safeguards and Nuclear Material Accountancy Program (Reference SG.16) provides direction for Site Safeguards Officers to perform their day-to-day duties. To support submission of required documents listed in Appendix D: Table D1 – Reporting Frequency for Nuclear Material Accountancy Reports of CNSC REGDOC-2.13.1 (Reference SG.6), OPG maintains an action tracking system to ensure that documents are completed and appropriately submitted.

#### **4.2 Operational Information**

OPG Safeguards Officers submit to the CNSC by September 30<sup>th</sup> of each year an operational program for the BWRX-300 facility (refer to Subsection 8.3 of CNSC REGDOC-2.13.1 (Reference SG.6)). This operational program is updated to ensure it remains current. This operational program outlines:

1. Preferred date of the Physical Inventory Taking for the upcoming calendar year
2. Anticipated shutdown periods during the upcoming calendar year
3. Information on expected transfer of nuclear materials in the next calendar year
4. Updates on current or upcoming projects of relevance to safeguards

These annual operational program submissions are traced through action tracking software that requires, prior to closing out an action, closure notes confirming that the action has been completed. Additional information about the nuclear material accountancy software and inventory tracking is found in Subsection 5.2, and Subsection 7.1, respectively.

#### **4.3 Operational Information Examination and Verification**

OPG Safeguards Officer promptly facilitates access required for the CNSC or the IAEA to confirm the accuracy of operational information submitted annually as per Subsection 4.2. Access to such information is facilitated through an Unannounced Inspection, a Short Notice Random Inspection, or a CA. As a good industry practice, OPG updates the operational program when changes occur that are of relevance to safeguards, or on a quarterly basis confirming no changes. Where safeguards relevant changes occur, OPG notifies the CNSC of such changes.

## 5.0 NUCLEAR FUEL LIFE CYCLE

The BWRX-300 is an “off-load reactor” as defined in IAEA TRS No. 392 (Reference SG.8). Refueling operations, and associated fuel movements for the BWRX-300 are conducted using 12-24 months fueling cycles Chapter 1, Table 1.5-1, and with a large number of assemblies moved during refueling. Refueling operations occur with an open RPV and fuel transfers occur in transparent water shielding. This combination of off-load refueling and transparent water shielding permits direct visual observations for safeguards purposes.

The BWRX-300 integrated reactor building structure consists of the RB, containment, and containment internal structures. As described in Chapter 9B, Subsection 9B.2.3, and shown in Figure 9B-1, the cylindrical-shaped below-ground portion of the RB structure houses the primary reactor system, reactor support and safety systems, reactor containment, and most of the associated essential power supplies and equipment. The rectangular prism-shaped above-ground portion of the RB structure houses the refueling floor, refueling and fuel handling systems, and an overhead crane.

Among its primary functions, the RB houses and structurally supports the RPV, the containment vessel, the reactor support structure of the primary reactor system, fuel pool, fuel handling and storage equipment, biological shielding, and associated equipment and structures. The RB also provides protection for safeguards equipment from environmental and external hazards such as floods, winds, tornadoes, and earthquakes.

The BWRX-300, for the safeguards purposes, is a “Type I facility design” (Reference SG.8) since the fuel pool is within the RB. As such, the safeguards C/S measures (Reference SG.10) apply at all times to fresh fuel receipts, core fuel during refueling and irradiated fuel in the fuel pool.

As described in Chapter 4, Subsection 4.1.4, the reactor core arrangement contains enriched fuel assemblies as well as reactivity control rods. The coolant which acts also as moderator is light water that flows upward past the fuel rods. The core arrangement and coolant are contained within a heavy walled RPV, as shown in Chapter 4, Figure 4.1-1, and detailed in Chapter 5, Section 5.4. The BWRX-300 fuel assemblies are designed to maintain fuel cooling and to avoid fuel damage under normal operation and anticipated operational occurrences, as described in Chapter 4, Subsection 4.4.1.

The BWRX-300 reactor core comprises two hundred forty (240) fuel assemblies and fifty-seven (57) control rods with an N-lattice configuration (see Chapter 4, Figure 4.2-2) and is designed to utilize commercially available Boiling Water Reactor (BWR) fuel (refer to Chapters 4, Subsection 4.2.1 for fuel system design bases information, Subsection 4.2.2.2, for additional information on GNF2 fuel cladding, Subsection 4.3.5 for key features of the BWRX-300 reactor core, and Subsection 4.4.1 for steady-state operation). Information on the nuclear boiler system is found in Chapter 5, Subsection 5.3.1.

OPG has a fuel management plan that addresses the safety, reliability, and security implications, as well as allowances for operational procedures. The significance of the fuel management plan persists for the fuel life cycle, including long-term storage of irradiated fuel assemblies. Current OPG fuel management plan is to be updated or a new plan is to be developed with specific DNNP site and BWRX-300 nuclear fuel information to support OPG’s application for a “Licence to Operate”, as per Section 4.0 of CNSC REGDOC-1.1.3 (Reference SG.18).

As described in Subsection 2.1, BWRX-300 uses Group 1A nuclear material. Group 1 material is uranium, plutonium-239, and thorium that are sufficiently pure to be used for fuel fabrication or for isotopic enrichment. This includes all materials in the nuclear fuel cycle past the point of core concentrate, or anything created from such materials, including depleted uranium. As such, a fuel

management plan describing the flow and storage of nuclear material is a key aspect that is considered in the design and operation of BWRX-300 facility and is part of satisfying the requirements of CNSC REGDOC-2.13.1 Safeguards and Nuclear Material Accountancy (Reference SG.6).

The fuel handling and storage systems, described in Chapter 9A, Section 9A.1, are designed to address nuclear safety, security, and IAEA safeguards, as well as prevent inadvertent criticality and maintain shielding and cooling of irradiated fuel as necessary to meet operating and off-site dose constraints.

## **5.1 Flow and Storage of Nuclear Fuel**

Fabrication, movement, handling, and storage are important activities for accounting for the nuclear fuel. This subsection describes such activities as they apply to the BWRX-300 design.

### **5.1.1 Fabrication and Transport**

The BWRX-300 GNF2 fuel is manufactured by GNF. The GNF2 fuel has features used in previous GNF fuel designs including Zirconium-lined barrier cladding, high performance spacers, water rods, part length rods, thick corner/thin wall channel, and customized assembly nuclear designs.

Refer to Chapter 4, Subsection 4.2.2, for information regarding GNF2 fuel assemblies.

Each fuel assembly has a serial number (or handle ID) that is unique to each fuel assembly. The serial number provides for traceability of an assembly throughout the life cycle from manufacturing to long-term storage.

The fresh fuel assemblies are packaged by GNF in approved shipping containers and transported to OPG's DNNP site. These GNF and OPG activities are performed under separate provisions of import and export requirements, as well as governed by licenses to transport issued by relevant regulatory authorities in the United States and Canada.

The number of fresh fuel assemblies required to maintain reliable production for BWRX-300 is based on core nuclear design, which is described in Chapter 4, Subsection 4.3.2. The fresh fuel assemblies are shipped and stored on-site upon receipt in advance of the initial core fueling and in advance of refueling outages, prior to loading fuel into the reactor. Upon arrival of the fresh fuel shipment at the site entry-point gate, a receiving survey is performed by radiation protection and security. Once radiation protection receiving is completed, the shipment proceeds with radiation protection, security, safeguards, and operations oversight to a designated on-site truck receiving area. The shipment is then subject to inspection and temporary staging as described in Subsection 5.1.2.

### **5.1.2 Fresh Fuel Staging and Storage**

Fresh fuel staging and storage plans are developed and will be finalized prior to the first fresh fuel shipment. The planned process of handling and staging the BWRX-300 fresh fuel for inspection involves unloading the fresh fuel containers from the receiving truck through post shipment arrival inspections and ends when the fresh fuel assemblies are stored in the fuel pool racks for the initial core fueling or in advance of a refueling outage. The process described in the subsequent paragraphs is based on experience at existing BWR nuclear plants and is expected to be representative of the process that will be employed for the BWRX-300 facility.

Each fresh fuel shipment is accompanied by a document which includes all necessary information to meet the requirements of CNSC REGDOC-2.13.1 (Reference SG.6). Upon receipt inspection, the received nuclear material is added to OPG inventory by updating the nuclear material accountancy software (refer to Subsection 5.2).

NEDO-33972 REVISION 0  
NON-PROPRIETARY INFORMATION

Representative licensed fresh fuel shipping containers can hold a maximum of two BWRX-300 fuel assemblies. Each container has both an inner and an outer box. A receiving inspection is completed on the inside, and outside of the shipping containers. Inner boxes, each containing a maximum of two fuel assemblies, are removed, and stacked at the end of the receiving area. The outer boxes stay staged in the location waiting the empty inner boxes at the completion of the fuel receiving activities.

For a BWR nuclear plant, the fresh fuel is routinely staged in the fuel pool prior to the first fueling and subsequent refueling outages. Receiving fresh fuel typically follows a planned path of movement involving several steps for receiving, staging, inspection, and storing in the fuel pool. Such steps are generally applicable to the BWRX-300 planning for receipt of fresh fuel, as follows:

1. Inner boxes are moved through the RB equipment hatch and set in the RB.
2. Inner boxes are then lifted up to the refuel floor and staged in stacks in accordance with a box-stacking plan.
3. Moving fresh fuel to the fuel pool begins by selecting the first fresh fuel inner box, which is moved to a staging location on the refuel floor designated for one box.
4. That inner box lid is removed, the box is inspected to verify conditions, the box is up-righted using the overhead crane and placed in a dry up-righting inspection stand. Typically, up to two fuel assemblies are now vertical in the inner box with bail handles on top. Trained fuel inspectors prepare the two fresh fuel assemblies for inspection, inventory, and installation into the fuel pool.
5. Fresh fuel assemblies are moved into a location known as fuel channel storage within the fuel pool. The serial numbers of the channeled fresh fuel assemblies are checked against the tracking documents (which may be referred to as "move sheets") and then recorded using OPG's inventory sheet. Fresh fuel is then moved to the fuel pool for storage until the outage.

The fuel pool comes equipped with two fuel elevators, also known as fuel preparation machines that are attached to a wall of the fuel pool (refer to Chapter 9A, Subsection 9A.1.2.3). The primary use of the fuel preparation machine is in loading fresh fuel into specific storage pool locations prior to a refueling outage.

Once all fresh fuel inspection is completed, and the fresh fuel assemblies are loaded into the fuel pool, the shipping containers are moved and prepared for return shipment. This activity completes the receiving, and inventories of the fresh fuel. At this time, the locations of the new fresh fuel assemblies are logged in the OPG nuclear material accountancy software.

The BWRX-300 planned design lifecycle is 60 years during which fresh fuel arrives, and irradiated fuel is discharged from the reactor core to the fuel pool in fueling cycles in accordance with a fuel management plan that is developed specifically for the BWRX-300 facility.

Irradiated fuel assemblies are moved into casks for dry storage, as explained in Subsection 5.1.4.

The design and implementation of handling and storage of the fresh fuel, as described in Subsections 5.1.1 and 5.1.2, satisfy the requirements of Subsection 8.12.1 of CNSC REGDOC-2.5.2 (Reference SG.14).

Measures and verification activities related to nuclear material accountancy regarding receiving fresh fuel or shipping nuclear material off-site are detailed in Subsection 7.2.1.

### **5.1.3 Core Fuel Shuffling/Refueling**

The BWRX-300 RB design has a refueling machine for fuel movement and servicing. The refueling machine is a gantry crane, which spans the RPV and the fuel pool. A telescoping mast and grapple suspended from a trolley system is used to lift and orient fuel assemblies for placement in the core or storage racks.

A position indicating system and travel limit computer locate the grapple over the RPV core and prevent collision with pool obstacles. The mast grapple has a redundant load path so that no single component failure results in a fuel assembly drop. Interlocks on the fueling machine:

1. Prevent hoisting a fuel assembly over the vessel unless an all-control-rod-in permissive is present
2. Limit vertical travel of the fuel grapple to provide shielding over the grappled fuel during transit
3. Prevent lifting of fuel without grapple hook engagement and load engagement

These measures for core fuel shuffling and refueling satisfy the requirements of Subsection 8.12.1 of CNCS REGDOC-2.5.2 (Reference SG.14).

Upon completion of fuel movement operations, it is important that a core verification task is accomplished in which individual fuel assemblies are verified to be installed in the correct position, using serial numbers, consistent with the core reload analysis. At this time, the current and new locations of the nuclear fuel assemblies are updated/logged in the nuclear material accountancy software.

### **5.1.4 Irradiated Fuel Storage**

Irradiated fuel storage includes wet storage in the fuel pool as described in Subsection 5.1.4.1 and long-term dry storage as it becomes available as described in Subsection 5.1.4.5. The information in the following subsections is based on proven BWR designs and operating experience and, since the BWRX-300 is the tenth evolution of BWR nuclear plants, is applicable to the BWRX-300 for fuel storage planning. Factors such as pool cooling (refer to Chapter 9A, Subsection 9A.1.3.2), and rack spacing rules, are considered to establish, in a timely manner, a plan for cask campaigns to remove irradiated fuel from the fuel pool to short-term or long-term irradiated fuel storage facilities.

#### **5.1.4.1 Wet Storage**

The BWRX-300 utilizes a fuel pool for the interim storage, and cooling of the irradiated fuel. As described in Chapter 1, Subsection 1.5.2.1, the BWRX-300 fuel pool is located in the RB.

The fuel pool size is determined largely by the volume of cooling water needed for a 7-day coping period. Fuel preparation machines are located on the fuel pool periphery. Used reactor core instruments are also stored in the pool and cut up and packaged, as needed. There are no through-wall penetrations in the fuel pool, and the design of the fuel pool gate prevents leakage during any line-break accidents. Monitoring and controlling the water level in the fuel storage pool is discussed in Chapter 9A, Subsection 9A.1.3.

The racks in the fuel pool have sufficient capacity to accommodate wet storage of at least 8 years of operation plus one core load of fresh fuel and one full core off-load, as indicated in Chapter 1, Table 1.5-1. The BWRX-300 fuel pool racks have a storage capacity of approximately 250% of core capacity, which is equivalent to a minimum of 600 fuel assemblies.

The serial number on top of the bail handle, which is part of the upper tie plate of every fuel assembly, is used to specify each assembly's location in the core for each cycle. As the operator

of the BWRX-300, OPG strictly follows all special nuclear material accountancy rules, always retains records for every movement of an assembly over the assembly's life and updates the nuclear material accountancy software to reflect field conditions.

The Fuel Pool Cooling and Cleanup System (FPC) removes decay energy from the fuel pool (refer to Chapter 9A, Section 9A.1.3 for further information on Fuel Pool Cooling and Cleaning System).

A full array in the loaded fuel rack is designed to be subcritical by at least 5%  $\Delta k$  under all normal, and abnormal conditions, and safety analyses are performed using validated codes, as described in Chapter 9A, Subsection 9A.1.2.2.

The fuel pool is protected from malevolent acts, seismic activity, internal and external missiles, and loss of cooling due to anticipated operational occurrences. Relevant design and safety aspects are found in Chapter 3, Section 3.5, and Chapter 15, Sections 15.5 and 15.7.

The design and operational measures described in this subsection meet the requirements and guidance of Subsection 8.12.2 of CNSC REGDOC-2.5.2 (Reference SG.14) for handling and storage of irradiated fuel.

#### **5.1.4.2 Dry Storage**

As described in Chapter 9A, Subsection 9A.1.2.3.5, spent fuel is transferred from the fuel pool in a transfer cask using a single failure proof Polar Crane. Handling systems for fuel cask loading do not perform any Safety-Category function during normal or off-normal conditions. The system and equipment functions associated with the handling system for fuel cask loading, provide the means to transfer spent fuel located in the fuel pool into a spent fuel storage cask and transport of the spent fuel storage cask to a location for long-term storage. Refer to Chapter 9A, Subsection 9.1.4 for detailed information for demonstrating compliance to fuel cask loading requirements in CNSC REGDOC-2.5.2, Subsection 8.12.1.

If irradiated fuel is managed in another Material Balance Area, the nuclear material is removed from the nuclear material accountancy inventory following transfer to dry storage (Reference SG.16). The nuclear material is added to the Material Balance Area for the dry fuel storage by an Inventory Change Document. The process is completed by the submission of an Inventory Change Document to the CNSC and to the recipient who is responsible for the Material Balance Area for the dry fuel storage. If OPG has dry fuel storage within the same Material Balance Area, positions are updated in the nuclear material accountancy software, under new Key Measurement Point.

#### **5.1.4.3 Canister Loading**

Canister loading is described in Chapter 9A, Subsection 9A.1.4.3.2.

Some fuel canisters may contain damaged fuel assemblies depending on OPG's specific fuel loading schemes.

#### **5.1.4.4 Canister Movement to Dry Storage**

Canister movement from the fuel pool to an on-site dry storage installation (regulated under a separate licence) is performed under the guidance and participation of OPG Radiation Protection, Security, Safeguards and Health Physics. The RB Polar Crane is used to lift a transfer cask to the refuel floor and subsequently to the truck bay. Once the dry, sealed, and decontaminated canister is placed in the transfer cask, the transfer cask is picked up by the hauler and moved to the dry storage installation. The canister is transferred from the transfer cask to the storage cask on the dry storage pad.

#### **5.1.4.5 Long-Term Storage**

The Nuclear Waste Management Organization (NWMO) is a not-for-profit organization established in 2002 by Canada's nuclear electricity producers in accordance with the Nuclear Fuel Waste Act (Reference SG.11) and is responsible for designing and implementing Canada's plan for the safe, long-term management of used nuclear fuel. The plan, known as Adaptive Phased Management, requires used fuel to be contained and isolated in a deep geological repository. The plan also employs a comprehensive process to select a site with informed and willing hosts for the project. Current NWMO design is focused on receiving, transporting, preparing, and burying CANDU fuel assemblies which are significantly smaller than BWRX-300 fuel assemblies. Evaluation of NWMO potential design for dealing with the BWRX-300 irradiated fuel assemblies includes options such as, but is not limited to, the following:

1. Using an elongated CANDU fuel canister, maintaining the diameter and materials of construction while lengthening the canister to accept BWRX-300 fuel, most likely three fuel assemblies
2. Using the canister currently used in Finland designed to accommodate 12 BWR fuel assemblies. This canister has a larger diameter, longer length, and different materials of construction
3. Cutting BWRX-300 fuel assemblies to fit inside the current proposed CANDU fuel canister
4. Developing a segmented fuel product line with the ability to fit the segments into a CANDU fuel canister

#### **5.2 Nuclear Material Accountancy Software**

A nuclear material accountancy Software, which is subject to OPG quality management described in Chapter 17, Subsection 17.2.1.1, is used by OPG to track the fuel from the manufacturing point to the ultimate long-term storage. Communication and coordination are established between the manufacturer of the fresh fuel and OPG, the owner-operator of the BWRX-300 facility. The coordination includes information on, for example:

- Nuclear material accountancy
- Fuel Flow
- Fuel loading analysis
- Fuel burnup
- Foreign obligations / origin obligations

Such information is recorded, stored, and secured against physical and electronic sabotage in accordance with established OPG management system, as described in Section 4.0 and Section 7.0.

**Figure SG-5.1.1-1: Top of Fuel Assembly**

## **6.0 ACCESS AND ASSISTANCE TO THE IAEA**

The Safeguards and Nuclear Material Accountancy Program of OPG outlines the requirements for assistance and access to the IAEA for inspection or maintenance activities at OPG facilities (refer to Section 6 of CNSC REGDOC-2.13.1 (Reference SG.6)). An OPG Safeguards Officer is responsible to facilitate access to the IAEA for all reasonable requests, with the support of affected work groups.

Such access requires OPG qualified security or radiological escort to accompany the IAEA inspectors while they are on OPG sites. OPG's radiation protection program outlines requirements for accessing OPG facilities, and provisions are in place for IAEA inspector access. Safeguards Officers are responsible for facilitating access via OPG's Facility Access and Working Rights (Radiological) procedures. Safeguards Officers ensure that IAEA inspectors obtain access and radiological protection through cooperation with impacted work groups. A security or radiological escort assists the IAEA in completing their inspection or maintenance activities.

### **6.1 Safeguards Equipment and Seals**

Section 5 of CNSC REGDOC-2.13.1 (Reference SG.6) requires OPG to implement safeguards measures, install safeguards equipment, and provide services to such equipment at licensed facilities, with consultation and agreement with the CNSC. In support of such activities, OPG's Safeguards, and Nuclear Material Accountancy Program (Reference SG.16) provides direction inhibiting OPG personnel from damaging or interfering with IAEA equipment or seals. Individuals who operate or work in safeguards equipment are trained to identify, and not manipulate IAEA equipment or seals.

IAEA equipment and seals are within the access controlled protected area of the BWRX-300 facility, meaning that only individuals with appropriate clearance and training can access areas with such equipment or seals.

### **Safeguards Containment and Surveillance Equipment**

The Safeguards and Nuclear Material Accountancy Program of OPG (Reference SG.16) requires that individuals who work on, around, or near IAEA C/S equipment are trained to identify and not manipulate any IAEA C/S equipment. Such equipment is within the protected area, requiring appropriate clearance (security clearance or with a security escort) and radiological protection. As such, these areas are strictly access controlled, ensuring that untrained individuals or individuals with gaps in safeguards knowledge are not able to manipulate or impact the operation of IAEA C/S equipment. OPG develops operating procedures that outline required responses and notifications in the event that services are lost, or damage occurs to IAEA C/S equipment.

### **6.2 International Atomic Energy Agency Access**

Direction is provided in OPG's Safeguards and Nuclear Material Accountancy Program (Reference SG.16) for Safeguards Officers and Operations and Maintenance organizations to facilitate requests for access from the IAEA in a timely fashion (refer to Section 6 of CNSC REGDOC-2.13.1 (Reference SG.6) for relevant requirements). Requests involving unannounced inspections, short notice random inspections, and CA prompt OPG to provide prompt access to facilities and locations outside facilities under such requests. A longer period of planning is required for maintenance of safeguards equipment to ensure IAEA inspectors or maintainers are qualified to perform work under various regulations.

### **Inspection and Verification**

As detailed in Section 3.0, design information is provided to the IAEA via the DIQ, which is established for the pre-construction design of the facility. During construction, any changes that would impact the DIQ are communicated via the CNSC to the IAEA in a DIQ revision. During construction, the IAEA may arrange field activities to verify that the details in the DIQ match the on-site construction.

### **Complementary Access**

Subsection 6.3 of CNSC REGDOC-2.13.1 (Reference SG.6), requires that when a request for CA is received by OPG, prompt access, within 24 hours, is facilitated by an OPG Safeguards Officer, unless specified otherwise on the notice or within 2 hours if the inspector is already on site for another inspection.

### **Access to IAEA Equipment**

OPG is required to provide IAEA inspectors access, for all reasonable requests on short notice, to IAEA equipment following notification and identification of scope of activities. Where required, OPG facilitates the provision of ladders, scaffolding, lifting, or training. (Refer to Subsection 6.4 of CNSC REGDOC-2.13.1 (Reference SG.6)).

## **7.0 NUCLEAR MATERIAL ACCOUNTANCY**

Nuclear material and accountancy, including reporting, is driven by OPG's Safeguards and Nuclear Material Accountancy Program (Reference SG.16) – a program that applies at a high level to the DNNP, albeit the implementation means are tailored to the BWRX-300 facility.

### **7.1 Measurement of Nuclear Material**

The IAEA equipment is maintained by the IAEA on their own schedule, as required.

#### **Electronic Inventory Tracking**

The nuclear material accountancy software of OPG produces up-to-date List of Inventory Items that covers Group 1, 1A and 1B material in the BWRX-300 facility. The List of Inventory Items is submitted annually to the CNSC within seven business days after the physical inventory is completed, or at the request of the CNSC.

This nuclear material accountancy software also produces various inventory information such as:

- Key Physical Measuring Points Inventory Summaries
- General Ledgers, which show inventory changes including nuclear gains and losses
- Inventory Change Documents for receipt or shipment of nuclear materials

#### **Physical Inventory Taking**

A Physical Inventory Taking is conducted by OPG each calendar year and no greater than 14 months from the previous Physical Inventory Taking. Depending on operational considerations, the preferred Physical Inventory Taking date is reported by OPG in the operational program (refer to Subsection 4.2) that is submitted to the CNSC by September 30<sup>th</sup> of each year, which also outlines the activities of the subsequent year. During a Physical Inventory Taking, a review of the Group 1 material on the List of Inventory Items is conducted. The Safeguards Officer confirms the serial numbers and unique identifiers of the nuclear material along with their location against the List of Inventory Item. The Physical Inventory Taking is intended to verify that no Group 1 material is present that has not been included in the List of Inventory Items. Physical Inventory Takings are verified by the CNSC or IAEA inspectors under a CNSC or IAEA physical inventory evaluation or a physical inventory verification.

#### **Inventory Difference**

Although there is no expectation for a facility for safeguards purpose such as the BWRX-300 to have any material unaccounted for, if an inventory difference is discovered during a Physical Inventory Taking, OPG reports the inventory difference as required by Subsection 7.4 of CNSC REGDOC-2.13.1 (Reference SG.6).

#### **Foreign Obligations**

OPG verifies the serial numbers and unique identifiers of all material that is received by OPG at the facility. OPG also verifies the manufacturer information which outlines Canada's foreign obligations under foreign Nuclear Cooperation Agreements. Foreign materials under any nuclear cooperation agreement are tracked in a similar manner to that of all nuclear materials; that is, via the Nuclear Material Accountancy Program. This program identifies all foreign obligated materials at all Material Balance Areas and Key Measurement Points throughout the facility. Foreign obligated materials are reported annually via an Obligated Material Inventory Summary as required by Subsection 8.1.7 of CNSC REGDOC-2.13.1 (Reference SG.6).

## **7.2 Provision of Information**

The Safeguards and Nuclear Material Accountancy Program of OPG (Reference SG.16), along with the associated nuclear material accountancy software, facilitate the generation of required nuclear material accountancy reports for the BWRX-300 facility.

### **7.2.1 Nuclear Material Accountancy Reports**

OPG submits to the CNSC reports as outlined in CNSC REGDOC-2.13.1 Appendix D: Table D1 – Reporting Frequency For Nuclear Material Accountancy Reports. These electronic reports include the BWRX-300 facility data required by CNSC REGDOC-2.13.1 Appendix D: Table D2 – Labels and Data Elements Used in Nuclear Material Accountancy Reports (Reference SG.6).

#### **Electronic Reporting**

Subsection 8.1.1 of CNSC REGDOC-2.13.1 (Reference SG.6) requires OPG to report nuclear material accounting via CNSC's nuclear material accountancy reporting e-business system website. The nuclear material accountancy software generates these reports in the accepted formats.

#### **Inventory Change Document**

As required by Subsection 8.1.2 CNSC REGDOC-2.13.1 (Reference SG.6), OPG submits Inventory Change Documents for every increase or decrease, in terms of batches, of the nuclear material inventory. The nuclear material accountancy software generates an Inventory Change Document based on incoming information and verification upon receipt of new nuclear material, as well as upon shipment off-site of nuclear material to another location or a Material Balance Area.

Fresh fuel will have the tamper seals and serial numbers verified upon receipt. Shipment details from the vendor provide total amounts of nuclear material within the fresh fuel, including foreign obligated materials. The shipment information, including date, time, and amounts of nuclear material is uploaded to the Nuclear Material Accountancy Software, and the total amount of nuclear material accounted for increases accordingly. The nuclear material accountancy software generates a receipt Inventory Change Document in a predetermined CNSC and IAEA format. All fields of the Inventory Change Document are completed using codes defined in CNSC REGDOC-2.13.1 Appendix D: Table D3 – Inventory Change Codes

For shipments off-site, the nuclear material accountancy software generates the shipper Inventory Change Documents and provides necessary details for the receiving Material Balance Area to create a receipt Inventory Change Document. When nuclear material is removed from site, it is deducted from the total nuclear inventory for the Key Measurement Points for the Material Balance Areas. All Inventory Change Documents are submitted to the CNSC and IAEA via nuclear material accountancy reporting within one business day of the inventory change.

#### **General Ledger**

OPG Safeguards Officer submits, monthly, a General Ledger outlining all inventory changes that occurred in the BWRX-300 facility reporting month, including opening, and closing balance of nuclear material - as required by Subsection 8.1.3 of CNSC REGDOC-2.13.1 (Reference SG.6). The nuclear material accountancy software generates the General Ledger and manages via operator and Safeguards Officer inputting the amounts of nuclear material moved in or out of the Material Balance Area.

All transfers of nuclear material moved into or out of the Material Balance Area require an Inventory Change Document generated by the nuclear material accountancy software. The General Ledger is generated and reviewed by an OPG Safeguards Officer against all Inventory

Change Document information from the reporting period to verify the accuracy of the report. Once the accuracy of the report is verified it is then submitted to CNSC and IAEA via nuclear material accountancy reporting.

### **List of Inventory Items**

OPG submits a List of Inventory Items on an annual basis following the completion of a Physical Inventory Taking (refer to Subsection 8.1.4 of CNSC REGDOC-2.13.1 (Reference SG.6)).

Group 1A material List of Inventory Items is generated, reviewed, verified, and submitted after a Physical Inventory Taking is completed annually. Group 1B List of Inventory Items is generated and provided upon request from the CNSC.

### **Physical-Key Measurement Point Inventory Summary**

It is required, per Subsection 8.1.5 of CNSC REGDOC-2.13.1 (Reference SG.6), that OPG generates and submits to the CNSC and the IAEA a Physical-Key Measurement Point Inventory Summary that abridges the List of Inventory Item by grouping items with the same material codes into batches. The Physical-Key Measurement Point Inventory Summary is an output by the nuclear material accountancy software in an .xml format, to meet the schema outlined by the CNSC and IAEA.

### **Reconciliation Statement**

Annually, OPG submits to the CNSC a reconciliation statement following a Physical Inventory Taking of Group 1A material, as required by Subsection 8.1.6 of CNSC REGDOC-2.13.1 (Reference SG.6). The reconciliation statement calculates the inventory difference between the book ending inventory derived from the General Ledgers and Inventory Change Documents, and the physical ending inventory derived from the Physical-Key Measurement Point Inventory Summary or the List of Inventory Item.

### **Obligated Material Inventory Summary**

An Obligated Material Inventory Summary is generated before January 31 by the nuclear material accountancy software and is reviewed/verified by an OPG Safeguards Officer to ensure accuracy, and then submitted to the CNSC via the nuclear material accountancy reporting e-business. (Refer to Subsection 7.5 and Subsection 8.1.7 of CNSC REGDOC-2.13.1 (Reference SG.6).)

## **7.2.2 Design Information**

Section 3.0 describes in detail the design information that is provided to the CNSC via the submission of a DIQ. The DIQ is updated for reasons such as:

- Changes in field conditions
- Changes in essential information or parameters
- Requests for clarification from the CNSC or IAEA

## **7.2.3 Operational Information**

Operational information is provided to the CNSC annually by September 30<sup>th</sup> via the completion of the operational program (refer to Subsection 4.2). This operational program is also updated and provided to the CNSC once per quarter by the 15<sup>th</sup> of March, June, September, and December.

#### **7.2.4 Information Required by the Additional Protocol**

Subsection 8.4 of CNSC REGDOC-2.13.1 (Reference SG.6) requires OPG to submit a report to the CNSC by March 15<sup>th</sup> of each year with Canada's update as per the terms of the Additional Protocol (Reference SG.3). This includes the following information:

1. A general description of, and information specifying, the location of nuclear fuel cycle-related research and development activities, as defined in Appendix B: List of Nuclear Fuel Cycle-Related Research and Development Activities.
2. Current drawings of the site, a general description of each building on the site, including its use and, if not apparent from that description, its contents. Note that current site drawings need only be submitted if previously submitted site drawings are no longer accurate.
3. A description of the scale of operations for each location engaged in the activities specified in CNSC REGDOC-2.13.1 Appendix A: List of Declarable Nuclear-Related Manufacturing Activities.
4. Information regarding Group 1B material, as follows:
  - a. For materials exempted from safeguards pursuant to Article 37 of the Safeguards Agreement, the quantities, uses, and locations of such material
  - b. For materials exempted from safeguards pursuant to Article 36 of the Safeguards Agreement, but where the material is not yet in a non-nuclear end-use form, information regarding the quantities and uses at each location
5. Information regarding the location or further processing of intermediate or high-level waste containing plutonium, high enriched uranium-235 or uranium-233 on which safeguards have been terminated pursuant to Article 11 of the Safeguards Agreement.
6. General plans for the succeeding 10-year period relevant to the development of the nuclear fuel cycle (including planned nuclear fuel cycle-related research and development activities) when approved by the appropriate authorities in Canada.

#### **7.3 Retention of Records**

OPG Safeguards and Nuclear Material Accountancy Program (Reference SG.16) specifies the requirements for retention of records, as required by Section 9 of CNSC REGDOC-2.13.1 (Reference SG.6). Safeguards Officers maintain records in digital format on site specific shared drives. Records relevant for safeguards information is stored for the life of the facility.

## **8.0 SAFETY, SAFEGUARDS AND SECURITY INTERFACES**

In accordance with the requirements of Subsection 4.3.4 of CNSC REGDOC-2.5.2 (Reference SG.14), safety and nuclear security measures for the purposes of BWR-300 safeguards aspects are designed and implemented in an integrated manner as follows:

1. The BWRX-300 facility layout and site characteristics (refer to Chapter 2, Subsection 2.1.2) consider for the purpose of safeguards certain design requirements in an optimized configuration, such as:
  - a. Access routes for normal operational activities
  - b. Access control to minimize radiation exposures
  - c. Actions taken in response to internal or external hazards and operational events
  - d. Egress routes
  - e. Movement of hazardous substances, nuclear materials, and radioactive materials
  - f. Movement of authorized and unauthorized personnel
  - g. Interaction of building and support activities
2. Civil structures design, reactor design, safety analysis, and fuel handling and storage design taking into consideration safeguards requirements such as accessibility to, and effectiveness of safeguards equipment. (Refer to Chapters 3, Section 3.5 for general design aspects for civil engineering works of seismic category buildings and civil engineering structures; Chapter 4, Section 4.1 regarding a summary description of the RPV; Chapter 5, Section 5.1 concerning a summary description of the nuclear boiler system and associated systems; Chapter 15, Section 15.5 regarding deterministic safety analysis, and Chapter 9A, Section 9A.1 respecting information on fuel storage and handling systems.)
3. Security of safeguards information on nuclear material is governed by GEH and OPG procedures and is contained as part of a security annex to the Preliminary Safety Analysis Report. Cyber security is also included as part of that security annex. The information in a security annex is prescribed.

OPG procedures for the protection of safeguards information are based on the General Nuclear Safety and Control Regulations (Reference SG.5), Section 21(1)(a) and (d) for prescribed information, and Sections 23(1)(a)(iii) and 23(2) for transfer and disclosure.

## **9.0 SAFEGUARDS, AND IMPORT AND EXPORT**

Measures are established by OPG to proceed with:

1. The import of the un-irradiated BWRX-300 GNF2 fuel from the United States to Canada, in accordance with CNSC REGDOC-2.13.2 Safeguards and Non-proliferation - Import and Export (Reference SG.12) and the Nuclear Non-proliferation Import and Export Control Regulations (Reference SG.13).
2. An application for a separate CNSC licence to possess, transport, transfer, use, and store the GNF2 fuel in accordance with the requirements of the NSCA (Reference SG.4), and the General Nuclear Safety and Control Regulations (Reference SG.5).
