Each C10 set of DCIS cabinets, each R10 DL3 UPS, battery chargers, and each R10 DL3 battery is located in a separate, fire barrier area of the Reactor Building. The instrument racks that mount the signal transmitters that provide the C10 measured trip, isolation and initiation signals are located in separate fire barrier rooms in the Reactor Building.

The C10 SC1 I&C system acquires the plant information from the sensors specified for systems performing DL3 functions. The specific list of parameters to be measured, the physical locations of the sensors, and environmental qualification envelope for the equipment is specified as part of the detailed design process. The plant information acquired by C10 is displayed on C10 VDUs and the C20 integrated plant displays developed through the Human Factors Engineering (HFE) process.

#### **7.3.1.1 Systems Architecture**

The main functions of DL3 logic are the initiation of the scram, reactor and containment isolation, and ICS initiation functions. The necessary DL3 parameters are input to the C10 SC1 I&C system per division. The C10 SC1 I&C system (per division) provides signal conditioning and uninterruptible power for C10 sensors. The C10 signals are hardwired per division to the C10 cabinets, and the cabinet outputs are hardwired to their actuators. Remote data acquisition multiplexers are not required because the C10 SC1 I&C system and their signals are mostly located in the Reactor Building. The functional architecture for the C10 SC1 I&C system is shown in Figure 7.3-2.

The sensor trip logic is similar for each function:

- Each division measures a parameter using its own sensors
- Each division compares the measured parameter to a setpoint
- Each division determines if the measured parameter exceeds the setpoint

The three divisions communicate (i.e., vote) among themselves to determine if there have been sensor trips in 2-out-of-3 divisions. Each division independently makes the 2-out-of-3 trip decision. The three-division sensor and logic design is shown in Figure 7.3-3.

The data acquisition functions are implemented on C10 SC1 I&C hardware and software platforms in the C10 cabinets with a common backbone to the C10 communications function. The backbone ensures that C10 SC1 I&C platforms in a division have access to the C10 signals in that division and the communication function ensures that divisional data are isolated and sent through a unidirectional boundary device to the C20 gateways.

As an example, a reactor pressure signal may be used for both the C10 DL3 Hydraulic Scram and ICS initiation. Any C10 SC1 I&C actuation signal within a division is available to any trip logic. Any signal within a division is available for display and alarming (per division) on the appropriate

divisional VDUs. Any C10 SC1 I&C signal is available via an isolated link through unidirectional boundary device to the C20 systems.

The voting communication between divisions is limited to message authentication and divisional or parameter trip status, no other communication is included and if there is a loss of communication from a division, the receiving division assumes a trip.

The divisions have additional logic to support monitoring and include an alarm system for predetermined parameters (per division on the corresponding divisional VDU). This design supports accident monitoring for DL3 / Safety Category 1 signals and the corresponding divisional support systems like electrical supply (R10) status. The operator can input a limited set of commands (per division on the corresponding divisional VDU). The C10 divisions export plant process, accident monitoring, and diagnostic data via dedicated, unidirectional boundary devices to the C20 systems.

Reactor scram, reactor and containment isolation, and ICS initiation can also be initiated without software via hard switches in either plant control room.

### **7.3.1.2 System Design Bases and Associated Safety Functions**

The design basis of the C10 SC1 I&C systems is to mitigate the effects of a PIE (i.e., AOO or DBA and most DEC's) assuming no credit for DL2 (e.g., CCF). The main functions of the C10 SC1 I&C logic are the initiation of the following DL3 functions for reactor scram, reactor and containment isolation, and ICS initiation functions. The C10 SC1 I&C system design includes provision of instrumentation to monitor plant variables and systems over the respective ranges for operational states and PIE in order to ensure that adequate information can be obtained on plant status. DL3 operating by itself ensures that no transient or design basis accident causes a radiation release greater than regulatory requirements. DL3 operates independently of DL2 using diverse equipment to perform required DL3 functions. The supporting safety analyses are described in Chapter 15.

C10 SC1 I&C system is designed to be available during all modes of plant operation. Specific safety functions actions are mode dependent, as determined by the Fault Evaluation process described in Chapter 15, Section 15.2, and specified by the Mode Switch position shown for each function in Table 7.3-1.

The DL3 functions categorized as Safety Category 1 and implemented in C10 with SC1 I&C equipment are:

1. Hydraulic Scram - Initiates a trip when a measured parameter exceeds a predefined setpoint. Initiates a hydraulic scram with a 2-out-of-3 voting logic using the same parameter. The trip logic is used to scram the reactor by hydraulically inserting the control rod blades. Hydraulic Control Units (HCU) are pressurized accumulators used to forcibly drive the control rod blade into the core. Scram initiation is enabled by de-energizing two scram solenoid valves to vent air holding the HCU scram valve closed against a spring force. When the HCU scram valve is opened, two control rod blades are inserted into the core except for one HCU that inserts a single control rod blade. The C10 DL3 Hydraulic Scram functions and initiation signals are listed in Table 7.3-1.

The HCUs are arranged in four spatial groups (3 with 7 HCUs and 1 with 8 HCUs). 29 HCUs are used to drive the 57 control blades. C10 uses a pair of divisional load drivers to de-energize the scram solenoid valves in each group of HCUs.

Simultaneous with the initiation of the DL3 Hydraulic Scram, a scram follow signal is sent to C20 DL4a to have each FMCRD motor drive its ball nut upward to a position just below the fully inserted and latched hollow piston that is coupled to the control rod blade. This signal is

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

a Non-Safety Class function. This signal is sent whenever a hydraulic scram is demanded by C10 SC1 I&C regardless of whether the hydraulic scram actuation has been successful.

More information on the Control Rod Drive System is found in Chapter 4, Subsection 4.5.1.

2. Power Range Neutron Monitoring (PRNM) - C10 SC1 I&C acquires and processes the PRNM neutron monitoring power signals to support the C10 DL3 Hydraulic Scram function. The PRNM consists of 13 vertical “strings” of Local Power Range Monitors (LPRM) arranged radially throughout the BWRX-300 core. Each string has four LPRMs equally spaced vertically and equally along the height of the core. The LPRMs signals are averaged per division to produce an APRM signal. The averaged signal is normalized to thermal power in percent. PRNM provides high power APRM flux trips to C10 DL3 Hydraulic Scram function when that parameter exceeds its setpoint.

PRNM also provides high simulated thermal power trips to C10 DL3 Hydraulic Scram function when that parameter exceeds its setpoint. The APRM signal is put through a (typical) six second time constant to relate it to the heat flux (as opposed to neutron flux) through the fuel to produce the STP signal (also in percent thermal power). PRNM provides high STP trips to C10 DL3 Hydraulic Scram function when that parameter exceeds its setpoint. Because there are transients where neutron flux can spike but thermal flux does not, the STP trip setpoints for C10 DL3 Hydraulic Scram function are set lower than the APRM (neutron) flux signal.

The PRNM also provides signals for accident monitoring purposes and to the 3D core thermal power distribution monitoring program and to the DL2 control rod blocking systems. These additional functions are not required to support any DL3 / Safety Category 1 function; however, C10 SC1 I&C is used to acquire the sensor inputs.

The individual LPRM signals are sent via isolated data links through unidirectional boundary devices to the 3D core thermal power distribution monitoring program. That program determines the information needed to calibrate the LPRMs.

More information on Core Monitoring is found in Chapter 4, Subsection 4.5.3.

3. Reactor, Containment, and System Isolation – C10 SC1 I&C performs the DL3 functions for RPV and containment isolation by closing the Main Steam Reactor Isolation Valves (MSRIV), Main Steam Containment Isolation Valves (MSCIV), Feedwater Reactor Isolation Valves (FWRIV), and Feedwater Containment Isolation Valves (FWCIV) and other valves listed in Chapter 6, Table 6.3.4-1 to limit line break effects both inside and outside containment. The isolation functions and initiation signals are listed in Table 7.3-1. The different isolation signals are initiated when 2-out-of-3 divisions agree on an isolation demand.

More information on the different isolation valves is found in Chapter 5, Section 5.10, and Chapter 6, Subsection 6.3.4.1.

4. Isolation Condenser System Actuation - C10 SC1 I&C performs the DL3 function to initiate ICS, which is comprised of three ICs. The three BWRX-300 ICs are each a simple loop including the vessel steam supply, piping to the radiators (i.e., heat exchangers) submerged in the ICS pools and a line to return the condensed steam to the vessel. Each IC steam supply line and condensate return line are equipped with two series normally open isolation valves mounted directly to the reactor vessel. The ICS is initiated by opening the normally closed condensate return. The C10 SC1 I&C logic activates each IC separately using 2-out-of-3 voting logic. When initiated by high reactor pressure, a different initiation setpoint is used for each IC. An IC is initiated by opening a normally closed condensate return valve per IC. One of the valve solenoids is in division 1 and the other valve solenoid is in division 2. Each solenoid has a normally closed load driver that opens on a 2-out-of-3 vote. Because the ICS

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

is necessary for the Safety Category 1 function, no lesser classified system can isolate them. Only the C10 SC1 I&C system can isolate an IC. The ICS functions and initiation signals are listed in Table 7.3-1.

More information on the ICS is found in Chapter 6, Section 6.2.

5. Diverse Isolation Condenser System Isolation - Because of the importance to BWRX-300 of off-normal heat removal, inventory maintenance, and pressurization limitation, the IC isolations use a fail-as-is design. The C10 SC1 I&C logic actively energizes the isolation valve solenoids to isolate an IC, and each IC is isolated independently and only upon indication of a line break for that IC. The IC isolation controls are placed into two groups. One group has the isolation controls for two ICs, and the second group has the isolation controls for remaining IC. For the first IC group, the normal DL3/SC1 hardware/software platforms perform the IC isolation function. For the second group (one IC), a separate and diverse DL3/SC1 hardware/software platform performs the isolation function. This arrangement ensures that a CCF affecting the normal DL3/SC1 hardware/software platform that causes a spurious isolation of ICs does not lead to a loss of ICS functionality. The diverse hardware/software platform utilizes redundant logic such that a single failure does not cause the isolation of the IC it controls.

More information on the Isolation Condenser System Isolation is found in Chapter 6, Subsection 6.2.7.2.

6. Monitoring – C10 SC1 I&C acquires accident monitoring information associated with Type A, B, and C accident monitoring variables, as defined in IEC 63147 (Reference 7.3-2). Type A variables provide the primary information required to permit the operating staff to take specific planned manually controlled actions for which no automatic control is provided and are required for safety systems to perform their protection functions as assumed in the plant anticipated operational occurrence and accident analysis licensing basis. The BWRX-300 does not have any Type A variables, as noted in Table 7.3-2. Type B are defined variables that provide primary information to the accident management personnel to assess the plant safety functions. These safety functions include accomplishing or maintaining reactivity control, core cooling, reactor coolant system integrity, and containment integrity (including radioactive effluent control). Type C variables provide primary information to the accident management personnel to indicate the potential for breach or the actual breach of fission product barriers (e.g., fuel cladding, reactor coolant system pressure boundary, and containment pressure boundary).
7. Communications - Used to acquire the process, diagnostic, and monitoring signals within the divisional C10 SC1 I&C components and organize them into a predefined message protocol. The divisional communication messaging is then isolated using SC1 hardware and converted into two optical fiber message streams per division. The three redundant pairs of divisional optical fiber message streams are sent to two SC2 gateways and then to the DL2 networks through unidirectional boundary devices. The gateways are redundant such that if one fails, the three divisions of C10 SC1 I&C signals are still available for alarming, recording, and monitoring in the lesser DLs.

The Secondary Control Room HVAC is normally in service and controlled by C20 DL2 equipment. The related C10 I&C logic is used for monitoring, isolation, and initiating filtered air circulation. The logic also monitors for SCR outside air radiation and automatically switch the normal air intakes to filtered outside air. These functions are not yet categorized. More information on the Control Room Habitability System is found in Chapter 6, Section 6.4.

The setpoints for C10 SC1 I&C actuation logic are determined with the setpoint methodology defined in IEC 61888 (Reference 7.3-3) using the final analytical limits from the plant safety analyses and the measurement uncertainties associated with the C10 SC1 I&C equipment (e.g., sensors and processing units). The design basis of DL3 is to act when DL2 is not effective at intercepting a transient or when an event is beyond the capabilities of the DL2 functions. In the event that DL3 completely fails, DL4a is designed to prevent core damage. As such, for common physical parameters measured by the DLs, the DL2 setpoint would be designed to act first, since its design basis is to mitigate/prevent DL3 from needing to respond. DL3 and DL4a would have common analytical limits to simplify transient and accident analyses and application of the formal setpoint methodology. The use of a common analytical basis has no adverse impact on plant operations or safety.

The BWRX-300 does not use interlocks to prevent overpressurization of low-pressure systems, interlocks to prevent overpressurization of the reactor coolant system during low temperature conditions, interlocks to isolate Safety Class systems from Non-Safety Class systems and interlocks to preclude inadvertent interconnections between redundant or diverse safety systems for the purposes of testing or maintenance. No interlocks are required because the BWRX-300 design eliminates to the extent practicable piping systems, major system components (e.g., pumps and valves), and subsystems connected to the reactor coolant pressure boundary to an ultimate rupture strength at least equal to the full reactor coolant pressure, as described in Chapter 5.

#### **7.3.1.3 Fundamental Design Properties in the System Design**

The C10 SC1 I&C system design includes DL1 properties that represent the quality measures implemented to minimize the potential for failures to occur by the use of conservatism in design and analyses. These DL1 properties of qualification, reliability, robustness, security, diversity, and D-in-D features are discussed in the following five subsections.

##### **7.3.1.3.1 *Qualified***

The C10 SC1 I&C equipment is designed for to operate in the environment that would be expected during both normal operations and anticipated off-normal conditions. The C10 SC1 I&C equipment is qualified to perform its intended functions. Qualification addresses both hardware and software aspects of the C10 SC1 I&C system. The C10 SC1 I&C design and manufacturing processes are of sufficient quality to ensure I&C systems can reliably perform their credited protection functions. The C10 SC1 I&C system equipment is designed, developed, fabricated, and tested to quality standards commensurate with the safety significance of the functions to be performed. The C10 SC1 I&C qualification measures confirm that the I&C systems and equipment are capable of reliably performing the design basis functions for which they are credited over the range of environmental conditions postulated for the area in which they are located.

The C10 SC1 I&C hardware platform used to perform its functions is developed in accordance with IEC 60987 (Reference 7.3-4) and meets IEC 61513 (Reference 7.3-5) requirements and the equipment standards defined in Section 7 in IEC 61226 2020 (Reference 7.3-6) for Class 1 systems. DL3 software used to perform its functions is developed in accordance with IEC 60880 Category A requirements (Reference 7.3-7). DL3 hardware used to perform its functions is qualified for environmental conditions in accordance with IEC 60780 (Reference 7.3-8) and seismic interaction in accordance with IEC 60980 (Reference 7.3-9). The C10 SC1 I&C equipment is qualified for electromagnetic compatibility in accordance with IEC 61000-4 (References 7.3-10 through 7.3-26) and IEC 61000-6-2 (Reference 7.3-27).

#### **7.3.1.3.2 Reliable**

The C10 SC1 I&C systems have the required reliability to perform its intended functions. It has an initial quantitative reliability target of less than 1E-4 probability of failure on demand. These reliability targets are achievable based on GEH experience with similar nuclear power plant protection systems. The reliability of the C10 SC1 I&C system is demonstrated as part of the final design.

The reliability analysis of the C10 SC1 I&C systems uses qualitative and quantitative performance measures or criteria, as appropriate, to demonstrate reliability goals. The reliability assessment is used to optimize goals such as minimizing out-of-service time for repair and reducing the frequency of surveillance testing.

The C10 SC1 I&C systems use digital technology and different C10 SC1 I&C functions may be combined on a common platform. It uses three divisions with 2-out-of-3 voting logic for trips and initiations. Spurious actuations due to single hardware failures are prevented.

The C10 SC1 I&C design allows one division of sensors to be bypassed or one division of logic to be bypassed to support maintenance or testing. The sensor and logic bypass switches are used to support these activities. The use of measuring and test equipment that can impair a C10 SC1 I&C function requires deliberate manual intervention via hardware interlock features at the system interfaces.

The individual LPRMs can be bypassed to allow the updated sensor calibrated values to be periodically input to the logic as required by plant Operational Limits and Conditions (OLC). APRM signals are periodically calibrated to current core thermal power. The LPRM averaging logic that is used to calculate the APRM value monitors the number of bypassed LPRMs going into the average. If the number drops below a predefined amount, the average is declared invalid, and the downstream logic assumes an APRM trip for that division. The LPRM signals contributing to the APRM and STP signals can be bypassed one at a time.

Correct functioning of the C10 SC1 digital I&C platforms are continuously monitored by self-testing features rather than by manual surveillance testing. Critical faults detected by the self-testing features trip the outputs of the platform and other faults are alarmed. The C10 system is designed to support required surveillance testing without affecting plant operation. It provides for signal and division bypass to support maintenance and testing. Bypass conditions are alarmed in the MCR. The C10 SC1 I&C design provide for periodic testing of the entire division of instrumentation logic, from sensing device to actuating device.

The C10 SC1 I&C platforms and diagnostics and their communication to the C20 Nuclear Segment are designed to support online and automatic surveillance testing that meets OLC requirements. Testing and performance assessment requirements are developed using the guidance of IEC 60671 (Reference 7.3-28) and IEC 62385 (Reference 7.3-29). Redundant divisions are monitored for deviations by an automated function that is performed continuously in the OLC Monitor described in Subsection 7.3.3. Deviations greater than a specified value are alarmed.

One of the scram solenoids uses a load driver and uninterruptible SC1 power from division 1 and the other load driver from SC1 power from division 2. The division 1 and division 2 load drivers open on a 2-out-of-3 vote from the three divisions communicated via optical fiber. Both scram solenoids per HCU are de-energized to initiate a scram, this design allows surveillance testing of each division through to the solenoid without causing a scram in normal operation. Testing provisions that are permanently connected to safety systems are classified the same as the safety system. The arrangement of the scram solenoid control and power is shown as Figure 7.3-4.

Although Figure 7.3-4 indicates a single load driver in division 1 and in division 2, in fact there are four load drivers in each. The four load drivers in each division are assigned to the scram solenoids in HCUs located in four separate rooms in the Reactor Building. In addition, the reactor can also be shut down with the complete failure of C10 DL3 Hydraulic Scram function with the diverse backup of DL4a. The four groups of cables from the load drivers to the four HCU rooms are in individual grounded conduits to preclude the possibility of a hot short keeping the solenoid incorrectly energized. Specifically, the circuit shown in Figure 7.3-4 is replicated four times per division 1 and division 2.

The Reactor and Containment isolation valves are closed by de-energizing two isolation valve solenoids mounted on the valve actuators. The valve motive power is typically stored nitrogen in accumulators independent of other nitrogen uses. One of the isolation solenoids uses a load driver and uninterruptible power from division 1 and the other solenoid is powered from division 2. The division 1 and division 2 load drivers open on a 2-out-of-3 vote from the three divisions communicated via optical fiber. Both isolation solenoids per isolation valve are de-energized to initiate a valve closure, this allows surveillance testing of each division through to the solenoid without causing an isolation in normal operation. The arrangement of the isolation solenoid control and power is shown as Figure 7.3-5.

The ICS actuation circuits have two normally energized solenoids on the IC open or close valve that keep it normally closed. One of the valve solenoids is in division 1 and the other valve solenoid is in division 2. Each solenoid has a normally closed load driver that opens on a 2-out-of-3 vote from the three divisions communicated via optical fiber. Both solenoids per actuation valve are de-energized to initiate a valve opening, this allows surveillance testing of each division through to the solenoid without causing ICS initiation in normal operation.

Each IC isolation valve is designed with three divisional solenoids, and 2-out-of-3 solenoids must change state for the valve to open or close. Reliable isolation and prevention of inadvertent isolation is achieved by the assignment of the C10 SC1 I&C divisions to solenoid valves that control each IC isolation valve and the mechanical arrangement of the solenoid valves to ensure that a single failure does not result in the unwanted isolation of an IC or prevent a required isolation of an IC. Manual actuation of the IC isolation function can be performed on a train-by-train basis. The manual isolation is a DL4a function, however it is implemented via SC1 equipment, because no lower classified equipment can have the ability to isolate an IC train (which would potentially prevent SC1 actuation of that train).

The C10 SC1 I&C system uses dual power supplies and dual power feeds per chassis to increase system reliability and availability.

#### **7.3.1.3.3 Robust**

Robustness of the C10 SC1 I&C design is the degree to which it can function correctly in the presence of invalid inputs or stressful environmental conditions. The robust C10 SC1 I&C design reflects the use of design methods and adherence to engineering best practices to ensure its functions are achieved for all operational states and accident conditions. The C10 SC1 I&C design requirements address the full range of operating environments associated with normal operation, transient, and accident conditions, as well as foreseeable internal and external hazards.

The C10 SC1 I&C systems has the required separation and independence to perform its intended functions.

The C10 SC1 I&C equipment is located in three separate divisional fire barrier rooms in the Reactor Building. The equipment is separated from the C20 equipment that is located in a separate fire barrier room in the Control Building.

C10 SC1 I&C system uses sensors and actuators independent of the C20 DPS.

The C10 SC1 I&C system provides trip communication between divisions for voting using optical fiber. A unidirectional boundary device provides for isolated optical communications to C20 systems through the C20 gateways to prevent communication from lower safety class systems from affecting C10 SC1 I&C systems. The communication protocols meet the data communication requirements of IEC 61500 for Category A functions (Reference 7.3-30). The C10 isolation devices are classified as SC1.

The logic used to rapidly scram the reactor by hydraulically inserting the control rod blades is separate and independent of the normal FMCRD positioning controls using the RC&IS

Each PRNM string has four LPRMs equally spaced vertically along the approximate 3.7 meter height of the core. The LPRM string is located between the corners of the fuel channels of the adjacent four fuel bundles. The locations are determined such that the 3D core thermal power distribution monitoring program can use mirror and rotational symmetry to virtually rotate and reflect the LPRM readings for unmonitored locations with similar surrounding fuel to gain complete core coverage. Figure 7.3-6 indicates the LPRM locations in the BWRX-300 core.

Each LPRM is individually powered and signal conditioned by its associated division and then averaged to generate APRM and STP values, which are compared to setpoints to determine if a scram is required.

The C10 SC1 I&C physical separation and signal isolation devices meet the requirements of IEC 60709 (Reference 7.3-31).

The C10 SC1 I&C systems are designed with three divisions with 2-out-of-3 voting logic for trips, isolations, and initiations. This redundancy ensures that the protection functions can be actuated even with an assumed single failure. It is only physically possible to bypass one division of sensors or one division of logic at a time, which retains the capability to provide required safety actuations. When a bypass is used, the 2-out-of-3 logic essentially operates as the equivalent of 2-out-of-2 to trip, isolate or initiate. Bypass conditions are alarmed in the MCR. The 3-fold redundancy scheme is acceptable based on high reliability of the DL3 system, administrative controls limit the time allowed for removal from service for maintenance bypass, and the availability of DL4a as D-in-D to ensure that the overall plant safety goals are satisfied.

The C10 SC1 I&C system has the required fail-safe design features to perform its intended functions. Deliberate operator action is required to return the C10 SC1 I&C system to normal after actuation.

The C10 DL3 Hydraulic Scram, PRNM, and Reactor and Containment isolation functions use only fail-safe logic (including loss of sensor and communications data). The C10 DL3 Hydraulic Scram logic is also equipped with individual manual scram switches in division 1 and division 2. These switches interrupt the power to the scram solenoids independently of the C10 DL3 Hydraulic Scram logic and using no software. The switches are included in the SCR and both switches are required to be operated to cause a scram. A loss of uninterruptible power or logic power causes a C10 DL3 Hydraulic Scram and RPV and containment isolation.

The DL3 / Safety Category 1 PRNM logic provides flux related trip signals to C10 DL3 Hydraulic Scram. It also provides signals to Safety Category 3 blocking functions (see Subsection 7.3.3) and to computer functions that determine the 3D power distribution of the core. A block diagram of the PRNM is shown as Figure 7.3-7.

The LPRM averaging logic that is used to calculate the APRM value monitors the number of available LPRMs going into the average to ensure it is representative. If the number drops below

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

a predefined amount, the average is declared invalid, and the downstream logic assumes an APRM trip for that division.

The APRM logic receives inputs from the Reactor Mode Switch position. With the Reactor Mode Switch in RUN, certain APRM trips are enabled and with the Reactor Mode Switch position in STARTUP enables different C10 DL3 trip functions.

The C10 ICS actuation logic initiates the three ICs separately (using 2-out-of-3 voting logic) for both reliability reasons and to allow different initiation setpoints for each IC. A loss of power initiates the ICs. The other condensate return valve is open/close only and is operated by DL3 / Safety Category 1 logic. This ICS actuation function is independent of the ICS throttling function. The logic is similar to the C10 DL3 Hydraulic Scram function logic.

Because of the importance of the ICS to BWRX-300 design to provide heat removal, inventory maintenance, and overpressurization protection, the ICs isolations do not use fail-safe design. Instead, the IC steam supply and IC condensate return isolation valves are fail-as-is to minimize the potential for inadvertent isolation. Additional design features are provided to ensure that the ICS provides the required safety functions. The C10 SC1 I&C logic actively energizes the IC isolation valve solenoids to isolate an IC and each IC is isolated independently and only upon indication of a line break for that IC.

Similarly, the isolation logic and power are fail-as-is. This IC isolation logic works by each division acquiring the isolation parameters and allows the divisional sensor to be bypassed one at a time. Bypass conditions are alarmed in the MCR. The signals are compared to their setpoints and initiate a trip (per division) if the sensed signal exceeds the setpoint. The three divisions communicate their trip decisions, and each division determines if at least two divisions have tripped to initiate an isolation. Unlike 'fail-safe' logic, which treats an invalid input or loss of communication as a vote to trip, fail as-is logic ignores invalid inputs such that the logic always requires two valid trip votes prior to actuation.

Then the load drivers compare their isolation trips from the three divisions, and if at least two divisions have tripped, an isolation is initiated. If logic or valve solenoid power is lost or the logic fails self-diagnostic monitoring, the isolation valves remain at their last position. From this point the fail-as-is logic differs from the fail-safe logic used for C10 SC1 I&C actuation features. The divisional logic outputs change state (open or close the isolation valves) only with active power. If logic or valve solenoid power is lost or the logic fails self-diagnostic monitoring, the isolation valves remain at their last position. Logic and sensor diagnostics are alarmed but do not initiate an isolation. A loss of power to the division or to the solenoids does not initiate an isolation. The isolation is active and latching to fail-as-is. To meet redundancy requirements, there are three solenoids on each isolation valve, and energizing any 2-out-of-3 solenoids cause the valve to change position and latch. Reliable isolation, when required, is achieved by requiring 2-out-of-3 solenoids and 2-out-of-3 divisional logics to initiate an isolation. The 2-out-of-3 logic minimizes the potential for inadvertent isolation for random I&C component failures.

The IC isolation controls are placed into two groups to prevent the remote possibility of a DL3 CCF causing three ICs to be spuriously isolated. One group has the isolation controls for two ICs and the second group has the isolation controls for remaining IC. For the first IC group, the main C10 hardware/software platforms perform the IC isolation function. For the second group (one IC) a separate and diverse hardware/software platform performs the isolation function. The diverse hardware/software platform is internally redundant such that a single failure does not cause the isolation of the IC it controls. The IC isolation function uses 2-out-of-3 logic to isolate an IC. The ICS design ensures that even with a postulated CCF of the primary C10 SC1 I&C platform, at least one IC is maintained operational, and one IC is sufficient to mitigate AOOs.

A critical self-diagnostic hardware or software failure initiates a divisional trip for fail-safe logic circuits. Diagnostic failures may be classified as critical (such as the watchdog timer or loss of communication) and cause a trip in that division. Other diagnostics are non-critical (e.g., one of the redundant power supplies fails) and cause an alarm in that division.

No C10 SC1 I&C function is dependent on whether the optical fiber unidirectional boundary devices are connected or disconnected, whether the fibers are severed, the gateways are powered, or the C20 networks have received the C10 signals.

Analog technology is used in C10 SC1 I&C systems for the bypass of one division of sensor inputs or one division of logic at a time. A software free interface is used in C10 to provide hardwired manual scram and RPV isolation capabilities.

#### **7.3.1.3.4    *Secure***

The C10 SC1 I&C systems have features that adequately addresses access control to limit cyber security vulnerabilities and ensure the system can perform its intended functions. The C10 SC1 I&C design incorporates access control features to support establishment of a secure operational environment. The C10 SC1 I&C software is produced in a secure development environment that prevents the insertion of undocumented codes. The C10 SC1 I&C systems are installed and maintained in accordance with the station administrative procedures and control of access programs.

The C10 SC1 I&C network is isolated from the rest of the BWRX-300 DCIS. The three SC1 DCIS divisions operate completely independently from the SC2 and SC3 DCIS. Information only flows through unidirectional boundary devices from C10 SC1 I&C to the SC3 networks. The C20 Nuclear Segment includes the SC2 gateways receive isolated SC1 signals through a unidirectional boundary device and provide them to the C20 Nuclear Segment. The SC2 gateways are discussed in Subsection 7.3.3. Measured parameters, setpoints, logic and trip status, and diagnostic information are continuously sent through these gateways to the C20 Nuclear Segment OLC Monitor, which can perform online surveillance testing, alarm on discrepancies, and additionally alarm on loss of these expected communications.

#### **7.3.1.3.5    *Defence-In-Depth***

The C10 SC1 I&C system provides the main line of protection for AOOs and DBAs. DL2 Nuclear Segment provides anticipatory trip functions to support the D-in-D concepts. DL2 is designed to prevent or mitigate AOOs before either DL3 or DL4a is required. The design basis of the DL4a systems provide D-in-D for the complete failure of the DL3 / SC1 systems (i.e., CCF). DL4a independently provides comparable DL3 plant protection functions using diverse platforms from DL3.

Diversity measures are incorporated within the C10 SC1 I&C system design as an additional level of protection for potential systematic faults caused by design and implementation defects within redundant divisions of the system. The IC isolation controls are placed into two groups to prevent the remote possibility of a DL3 CCF causing three ICs to be spuriously isolated. One group has the isolation controls for two ICs and the second group has the isolation controls for remaining IC. For the first IC group, the main C10 SC1 I&C hardware/software platforms perform the IC isolation function. For the second group (one IC) a separate and diverse hardware/software platform performs the isolation function. The diverse hardware/software platform is internally redundant such that a single failure does not cause the isolation of the IC it controls. These diversity measures ensure that at least one IC remains operational for any CCF affecting the IC isolation features and one IC is enough to mitigate AOOs.

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

The C10 DL3 Hydraulic Scram function logic is equipped with individual manual scram switches in division 1 and division 2 (as shown on Figure 7.3-4). These switches use a software free method to interrupt the power to the scram solenoids independently of the automatic actuation logic and using no software. The switches are included in the SCR and both switches are required to be operated to cause a scram.

The C10 ICS initiation logic is equipped with individual switches in division 1 and division 2 to open the ICS condensate return line valves. These switches use a software free method to close the valves. The switches are included in the SCR and both switches required to be operated to cause a scram.

The C10 SC1 I&C reactor, containment, and system isolation logic is equipped with individual switches in division 1 and division 2 to close the MSRIV, MSCIV, FWRIV, and FWCIV. These switches use a software free method to close the valves. The switches are included in the SCR and both switches required to be operated to cause a scram.

#### **7.3.1.4 Operator Interface**

C10 SC1 I&C data are available on their appropriate divisional displays and these displays are subject to a HFE evaluation to maximize operator responsiveness. Each division has its own VDU in both the MCR and SCR and locally in the C10 SC1 I&C equipment rooms. Each divisional display is dedicated to monitoring or controlling equipment in its associated division. The C10 displays also include an alarm system to provide for operator awareness and to prompt to the displays containing further information relating to the alarm. C10 SC1 I&C system bypass conditions are alarmed in the MCR. The displays are menu driven and it is possible to switch between related displays without going through the main menu.

A reactor scram, ICS initiation, and reactor, containment, and system isolation can be manually initiated by SC2 switches in the MCR and SC1 switches in the SCR. Manual actuation of the IC isolation function can be performed on a train-by-train basis.

Some C10 SC1 I&C monitoring signals provide necessary information to achieve or verify correct plant response to transients and accidents. The necessary signals are determined through HFE analysis and applicable regulatory requirements and are referred to as accident monitoring signals.

The C10 SC1 I&C signals are alarmed to prompt the operator to an appropriate display (e.g., range check problems or alarm setpoints exceeded). The C10 SC1 I&C signals and the various C10 SC1 I&C components are alarmed for self-diagnostics.

The C10 SC1 I&C monitoring functions are supported for 72 hours by the R10 UPS and batteries with no off-site power available.

C10 SC1 I&C data is also transmitted through an optically isolated data link through a unidirectional boundary device to C20, where the signals are recorded, alarmed, and displayed. The C10 monitoring also includes signals needed to monitor divisional support equipment like the UPS and battery chargers as well as the SC1 equipment room temperatures. The operator can view the C10 information on the C10 VDUs even if C20 is not operational.

The C10 SC1 I&C system acquires and displays the accident monitoring information associated with Type A, B, and C accident monitoring variables.

The BWRX-300 plant-level safety D-in-D design has a direct bearing on the design of the accident monitoring instrumentation. The BWRX-300 passive reactor design automatically actuates DL3 systems that rely solely on natural passive mechanisms based on fundamental physical and thermodynamic principles to mitigate a design basis event (i.e., anticipated operational

occurrences or postulated accident). The BWRX-300 does not require manual actions to mitigate design basis events. Automatic controls perform mitigation functions. As such, no Type A accident monitoring instruments are required. The simplicity of the BWRX-300 safety features to mitigate design basis events and safely shut the plant down, when coupled with the D-in-D framework, ensures the capability to mitigate the effects of design basis transients and accidents even with a coincident loss of a complete DL.

The simplicity and D-in-D framework change the role of the Type B and C accident monitoring instruments for the BWRX-300 accident management strategy. For the BWRX-300, these instruments are only used for immediate verification that DL protection functions have actuated. They are not needed for subsequent operator actions to realign or control more complicated engineered safety features after the initial actuation phase. The multiple DLs and their capability to accommodate the loss of a complete defense line eliminate the need for more immediate operator actions to respond to equipment failures for successful accident management. The specific accident monitoring variables that the operator should monitor to ensure safety during an accident and the subsequent long-term stable shutdown phase are determined through the normal BWRX-300 design process using the human factors engineering process. The Type A (if later required), B, and C accident monitoring information is displayed in both the MCR located in the Control Building and the SCR located in the Reactor Building in the current concept design. The C10 accident monitoring information is sent through qualified isolation devices to I&C system C20, which is SC3.

A preliminary list of the Type B and C accident monitoring variable is provided in Table 7.3-2.

The DL3 operator interface HSI for C10 is described in Sections 7.5 and 7.6 for the MCR and SCR, respectively.

#### **7.3.1.5 Compliance Alignment**

Table 7.3-5 shows how the C10 SC1 I&C system aligns to meet the regulatory guidance in CNSC REGDOC-2.5.2 and the key industry I&C standards IEC 61513 and IEEE Std 603 (Reference 7.3-32).

### **7.3.2 System C20 – Defense Line 4a / Safety Class 2**

Section 7.2 states C20 performs functions that are part of two DLs and is divided into two Safety Classes accordingly (See Subsections 7.3.3 and 7.3.4). These two DLs complement the C10 SC1 I&C systems to provide a high availability for the plant protection functions.

The C20 system acquires the plant information from the sensors specified for systems performing DL4a functions. The specific list of parameters to be measured, the physical locations of the sensors, and environmental qualification envelope for the equipment is specified as part of the detailed design process. The plant information acquired is displayed on the C20 integrated plant displays developed through the HFE process.

#### **7.3.2.1 Systems Architecture**

The functional architecture for the DL4a system is shown in Figure 7.3-8. The splitter architecture used for shared sensors is shown in Figure 7.3-9. A representative DPS block diagram for a reactor scram is shown in Figure 7.3-10 and should be viewed with Figure 7.3-4, which shows the scram solenoid power configuration.

Protection function signals within the DL4a are point-to-point wire or optical fiber, they do not use the plant networks. The RC&IS communicates with the FMCRD motor controllers (which perform a DL4a function) on a dedicated redundant network. The FMCRD network is not part of the plant

DCIS network and does not go through the network managed switches. This communication is not required for any DL4a protection function nor could interfere with any DL4a safety function.

### **7.3.2.2 System Design Bases and Associated Safety Functions**

The design bases of the DL4a systems assume the complete failure of the DL3 / SC1 systems (i.e., CCF). DL4a independently provides comparable DL3 plant protection functions using diverse platforms from DL3. The C20 DL4a system design includes provision of instrumentation to monitor plant variables and systems over the respective ranges for operational states and PIE in order to ensure adequate information can be obtained on plant status. The supporting safety analyses are described in Chapter 15.

C20 Defense Line 4a is designed to be in service during all modes of plant operation. Specific safety functions actions are mode dependent, as determined by the Fault Evaluation process in Chapter 15, Section 15.2, and the initiating signals are enabled based on the Reactor Mode Switch position shown for each function in Table 7.3-3.

The system functions performed by DL4a are:

1. Diverse Protection System - Provides the logic for the DL4a protection functions. The DPS is analog and segmented into three channels. Input signals are measured, sent to comparison logic, and if the signals exceed their setpoints, produce trip or initiation signals per channel. The channel trip and initiation signals are then voted 2-out-of-3 to produce a DPS initiation or trip and to avoid single-failure inadvertent trips. The DPS functions include:
  - a. A hydraulic scram independent of DL3
  - b. RPV, containment, and system isolations independent of DL3
  - c. ICS initiation independent of DL3
  - d. A FMCRD motor fast run-in
  - e. Automatic Rod Insertion (ARI) pilot valve actuation

The hydraulic scram and ARI signals are initiated whenever a DL4a scram is demanded by DL4a regardless of whether the fast motor run-in actuation has been successful. The DL4a safety function for the motor driven fast run-in occurs on any hydraulic scram signal plus a signal on reactor power level indicating that the hydraulic scram was not successful.

The DPS functions and initiation signals are listed in Table 7.3-3. The DPS provides for manual initiations using switches located in the MCR. These are separate from the switches associated with C10 SC1 I&C which are located in the SCR.

2. Gamma Thermometers - Provide electrical signals from in core devices based on local gamma flux which is representative of core thermal power. It represents a completely diverse technology to the neutron detecting LPRMs used in DL3 PRNM system. There are two types of Gamma Thermometers (GT) "strings" located in the core. The first design locates 8 GTs in each of the 13 instrument tubes containing LPRM detectors. The second design locates 8 GTs in each of the 10 instrument tubes containing WRNM detectors. The GT design uses a total of 184 GTs measuring dispersed radial and axial local power in the core. The net result is that both DL2 and DL4a DPS receive four analog signals representing core power using only analog components that are completely diverse from the DL3 LPRMs and APRMs. The GT signals are used as inputs to DPS.
3. Fine Motion Control Rod Drive Motor Control - There are 57 FMCRDs in the BWRX-300 and each one has an individual motor and an individual motor controller. The motor controllers are allocated to DL4a and interface with DPS, Emergency Rod Insertion Panels (ERIP), and

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

RC&IS. Each motor controller uses software to supply the appropriate commands to the FMCRD motors using individual position controllers (i.e., position demand and position feedback). Control rod position indication is provided to RC&IS. Normally the FMCRDs are individually (or in gangs) positioned by the RC&IS to control reactor power in response to either operator or automation system insert and withdraw commands. The motor controller software is required for the motor run-in, but the DPS actuated hydraulic scram does not use software.

4. Emergency Rod Insertion Panels and Emergency Rod Insertion Control Panels - There are four DL4a ERIPs. The ERIPs are relay-based and have two functions. The first is to multiply the ATS, C10 DL3 Hydraulic Scram, and DPS motor run-in demand signals to each of the 57 FMCRD motor controllers. The second is to multiply the Multi-Channel Rod Block Monitor (MRBM) rod block demand signals to each of the 57 FMCRD motor controllers. The MRBM rod block stops the rods from being able to withdraw and in the relay logic, the motor run-in has priority. The circuit design ensures control rod insertion is always available. The scram follow motor run-in is automatically initiated whenever ATS, DPS, or C10 DL3 Hydraulic Scram function initiates a hydraulic scram.

These panels are contact multipliers that each receive manual scram, three rod motor withdraw power block signals and three motor run-in signals from the Emergency Rod Insertion Control Panel (ERICP). The three motor run-in signals and three motor withdraw power block signals are decoded using 2-out-of-3 relay logic to pick up additional relays, 29 in one panel and 28 in the other panel. The design ensures that a relay failure can only affect one FMCRD. The motor run-in can be manually initiated by SC2 switches in the MCR initiate both a hydraulic scram and motor run-in. The motor run-in relays are sealed in once energized to ensure the motors have time to drive the rods full in.

The ERICP sends the manual scram and motor run-in and motor power block signals to the ERIP. The automatic motor run-in signals come from three sources. Two are, respectively, a hydraulic scram initiation signal from DL3/SC1 C10 DL3 Hydraulic Scram function and a hydraulic scram initiation signal from DL2/SC3 (ATS). Both hydraulic scram initiation signals use TMR controllers and point-to-point connections. A third motor run-in signal comes from DL4a/SC2 DPS that is also TMR.

The first two (DL3 Hydraulic Scram and ATS) hydraulic scram initiation signals are shared with DL4a to generate an FMCRD scram follow motor run-in. Simultaneous with the initiation of the DL3 and ATS hydraulic scrams, the scram follow motor run-in provides the additional post scram safety function of automatically driving each FMCRD motor drive its ball nut upward to a position just below the fully inserted and latched hollow piston that is coupled to the control rod blade. This, in addition to the SC1 internal control rod blade full in rod latches, prevents the control rod blade from dropping out of the reactor post scram. This also ensures that any rod scram failure (due to a failed HCU component, for instance) is inserted into the reactor within minutes of the scram signal. The DPS fast motor run-in is completely independent of the DL3 and DL2 scrams and serves as the backup to the complete failure of the hydraulic scram in case of complete failure of the mechanical/hydraulic portions of the Control Rod Drive (CRD) system. This function is performed by the ERICP sending signals to DPS to indicate that a hydraulic scram has been initiated from any source. After receiving such signals, the DPS logic expects its GT inputs to show a decreasing power due to a hydraulic scram. If the GT measurements do not decrease sufficiently within a short time, the DPS generates outputs to the ERICP to order a fast motor run-in. The FMCRD motors should have already started in their scram follow capacity and the DPS order to the ERICP causes the motors to increase insertion speed.

A motor power withdraw block signal comes from the Multi-Channel Rod Block Monitor (MRBM), which stops the rods from being able to withdraw. The circuit design ensures that control rod insertion is always available.

5. Fine Motion Control Rod Drive Motor Uninterruptible Power Supply - These UPS are dedicated to the FMCRD motor controllers and motors and not part of the R10 or R20 normal DCIS uninterruptible power supplies. The FMCRD motors and controllers have four dedicated UPS that can supply the FMCRD motors in the absence of off-site power or the absence of standby diesel generator power. These power sources are dedicated to the FMCRD, not shared with the SC2 R20 UPS that power the DL4a and DL2 DCIS.

The FMCRDs are divided into four groups distributed throughout the core. Each of the four motor and motor controller groups has its own UPS that operates the FMCRDs long enough to fully insert even if both off-site power and standby diesel generator power are lost. The four motor groups of FMCRDs are indicated by color code on the upper right of the core map in Figure 7.3-6.

The setpoints for C20 DPS actuation logic are determined with the setpoint methodology defined in IEC 61888 using the final analytical limits from the plant safety analyses and the measurement uncertainties associated with the DPS equipment (e.g., sensors and processing units). DL4a is designed to prevent core damage for PIE assuming the complete failure of DL3. As such, for common physical parameters measured by DL3 and DL4a would have common analytical limits to simplify transient and accident analyses and application of the formal setpoint methodology. The use of a common analytical basis has no adverse impact on plant operations or safety.

### **7.3.2.3 Fundamental Design Properties in the System Design**

The C20 Defense Line 4a SC2 system includes properties that represent the quality measures implemented to minimize potential for failures to occur by the use of conservatism in design and analyses. These DL1 properties of qualification, reliability, robustness, security, diversity, and D-in-D features are discussed in the following five subsections.

#### **7.3.2.3.1 *Qualified***

The C20 SC2 equipment is designed for to operate in the environment that would be expected during both normal operations and anticipated off-normal conditions. The C20 Defense Line 4a equipment is qualified to perform its intended functions. Qualification addresses both hardware and software aspects of the C20 Defense Line 4a equipment. The design and manufacturing processes are of sufficient quality to ensure I&C systems can reliably perform their credited protection functions. The C20 Defense Line 4a equipment is designed, developed, fabricated, and tested to quality standards commensurate with the safety significance of the functions to be performed. The C20 Defense Line 4a equipment qualification measures confirm the I&C systems and equipment are capable of reliably performing the design basis functions for which they are credited over the range of environmental conditions postulated for the area in which they are located.

The main C20 DL4a hardware platform is analog and meets IEC 61513 requirements and the equipment standards defined in Section 7 in IEC 61226 2020 requirements for Class 2 systems. DL4a software is used in the FMCRD motor controllers and is developed in accordance with IEC 62138 Category B requirements (Reference 7.3-33). DL4a hardware is developed in accordance with IEC 60987. DL4a hardware is qualified for environmental conditions in accordance with IEC 60780 and seismic interaction in accordance with IEC 60980. The C20 Defense Line 4a SC2 system equipment is qualified for electromagnetic compatibility in accordance with IEC 61000-4 and IEC 61000-6-2.

#### **7.3.2.3.2 Reliable**

The C20 Defense Line 4a equipment has the required reliability to perform its intended functions. It has an initial quantitative reliability target of 1E-3 to 1E-4, probability of failure on demand. The reliability analysis of the C20 Defense Line 4a equipment demonstrates it meets its reliability goals using qualitative and quantitative performance measures or criteria, as appropriate. The reliability assessment is used to optimize goals such as minimizing out-of-service time for repair and reducing the frequency of surveillance.

The DPS provides self-diagnostics to C20 for equipment status monitoring and use by RC&IS through qualified isolation features classified as SC2. The DPS is designed to support required surveillance testing without affecting plant operation. It provides for signal and channel bypass to support maintenance and testing. Bypass conditions are alarmed in the MCR. The C20 DL4a design provides for periodic testing of the entire channel of instrumentation logic, from sensing device to actuating device. Testing and performance assessment requirements for DPS are developed using the guidance of IEC 60671 and IEC 62385. The use of measuring and test equipment that can impair a C20 DL4a function requires deliberate manual intervention via hardware interlock features at the system interfaces. Testing provisions permanently connected to safety systems are classified the same as the safety system.

The GT system supports averaging the four groups of GT signals and normalizing the average to core thermal power. The GT system provides for bypassing individual GTs. Bypass conditions are alarmed in the MCR. The GT system provides for the calibration of the GTs. The GT system is designed to support required surveillance testing without affecting plant operation. Provides for GT system self-diagnostics for C20 display.

The FMCRD motor controllers provide self-diagnostics to DL2 C20 for monitoring and use by RC&IS.

The DPS, GTs and ERIPs in DL4a are redundantly and uninterruptedly powered by the two -out-of-three R20 electrical system load groups. The FMCRD motor controllers are normally powered from R20 and have dedicated UPSs. The FMCRD UPS have a capacity that is at least twice as long as the duration of a motor run-in (i.e., rods driven full in by their motors). The DPS, GTs and ERIP UPS are backed by two load groups of 72-hour batteries. The UPS and the battery chargers can be powered by off-site power or either of the standby diesel generators.

#### **7.3.2.3.3 Robust**

Robustness of C20 Defense Line 4a is the degree to which it can function correctly in the presence of invalid inputs or stressful environmental conditions. The robust C20 Defense Line 4a DPS design reflects the use of design methods and adherence to engineering best practices to ensure that the protection functions are achieved for the specified conditions.

The C20 Defense Line 4a systems have the required separation and independence to perform their intended functions as a diverse backup to DL3.

The majority of the C20 DL4a equipment is located in a separate fire barrier room in the Control Building with the remainder located in compartmentalized fire barrier rooms in the Reactor Building. It is separated from DL3 equipment that is located in three separate divisional fire barrier rooms in the Reactor Building. The DL4a equipment is powered by separate power supplies from DL3. The four ERIPs are located in the Reactor Building on opposite sides of the reactor and near the cabinets housing the FMCRD motor controllers.

The DPS uses sensors and actuators that are independent of DL3. Isolated communication is allowed from DL3 to DL4a but not vice versa. This communication cannot prevent either DL from fulfilling its protection functions. DL4a systems do not share any sensors with DL3.

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

DL4a is independent from DL2 to an extent that is practicable in that shared sensors are not credited with mitigation for the same PIE. Some signals shared between DL4a and DL2, as identified in Figure 7.3-8, are used by both DPS and DL2 TMR controllers allocated to each parameter. The shared signals and splitters are located in separate cabinets. The shared signals are developed using TMR architectures. The shared signals are analog signals. Signal sharing is accomplished using non-software, analog splitters and relays that are powered with redundant uninterruptable power supplies. The splitter technology supplies isolated outputs that allow short circuits or common mode voltages up to 300 volts (AC or DC) applied to one output without affecting the other output. The splitter design is shown in Figure 7.3-9. The splitter design ensures a splitter output is unable to adversely affect the other outputs. The C20 isolation features are classified as SC2.

The three channels of the DL4a DPS from the separate DL4a splitters are used by the 2-out-of-3 voting logic for trips and initiations.

The FMCRD motor controllers receive normal control signals from RC&IS in DL2; however, the motor controller SC2 software instructs the controller to ignore the SC3 RC&IS network commands and run the rods in when instructed by the relay-based ERIPs and analog DPS.

The control rods and motors are located inside containment in the Reactor Building. The FMCRD motor controllers are organized into four groups located in four separate rooms in the Reactor Building outside containment.

The DL4a FMCRD UPS provides the necessary independent power to the control rods and monitoring. The FMCRD motors and controllers have four dedicated UPS that can supply the FMCRD motors in the absence of off-site power or the absence of standby diesel generator power. The FMCRD UPS can operate from and be charged by those sources. The power sources are also independent of the normal SC2 R20 UPS that power the DL4a and DL2 DCIS. The four independent and separately located groups of ERIPs, FMCRD motor controllers and the UPS to power them are arranged such that the insertion of any three of the four groups will shut down the reactor.

The DL4a physical separation and signal isolation devices meet the requirements of IEC 60709.

Where software is used, DL4a diagnostics always include watchdog timers, sensor range checks, power supply monitoring, communications, and actuator monitoring. The DPS is analog but is monitored digitally through unidirectional isolated signals. The digital monitoring for self-diagnostics cannot adversely affect DL4a functions. The digital monitoring checks for inconsistencies between redundant signals, performs sensor range checks, and monitors actuator, communication, and power supply status. The relay logic is designed to ensure that a relay failure can only affect one FMCRD. The manual motor run-in can be initiated by SC2 switches in the MCR that initiate both a hydraulic scram and motor run-in. The motor run-in relays are sealed in for at least four minutes once energized to ensure the motors have time to drive the rods full in.

The C20 Defense Line 4a DPS has the required fail-as-is design features to perform its intended functions and avoid spurious actuations. The fail-as-is energize to actuate design is used to prevent lesser classified DPS from creating unnecessary challenges to plant safety (e.g., spurious actuations for expected failures) requiring action by DL3.

Deliberate operator action is required to return the C20 Defense Line 4a Protection System to normal after actuation.

DL4a operating by itself and assuming a complete failure of DL3, ensures that no transient or design basis accident causes a radiation release greater than regulatory requirements. No DL3

equipment can prevent a scram, reactor, and containment isolation, or ICS initiation from DL4a equipment or vice versa.

The C20 Defense Line 4a systems provide diversity to support the D-in-D concepts.

DPS initiates hydraulic scrams, isolations and ICS using the same solenoids as DL3 but using relays instead of load drivers. Independence between these DLs is discussed below.

For diversity, the DL4a is able to independently shutdown the plant using the FMCRD motors. The DL4a ERIPs accept isolated hydraulic scram demand signals from ATS and C10 DL3 Hydraulic Scram to also initiate reactor shutdown using the FMCRD motors. The motor run-in inserts rods even if the hydraulic scram does not work or the entire DL3 systems fail.

GTs provide a diverse technology to the neutron detecting LPRMs used in DL3 PRNM system. The GT system segment supplies two types of outputs: analog average power signals and digital signals of individual sensor measurements. The signals from the 184 GTs are sent to four GT data acquisition cabinets located in four separate rooms of the Reactor Building. The signals are apportioned to the four cabinets such that each cabinet gets a similar allocation of radial and axial GT signals. The signals are conditioned using analog equipment and then the signal paths split. The four analog signals are processed by an averaging circuit with adjustable gain. The averaging circuit averages the un-bypassed GTs and allows the gain to be periodically adjusted/normalized to core thermal power. The output of each cabinet is an analog 4 – 20 mA signal calibrated to 0 – 120% thermal power. DL4a DPS receive this signal representing core power using only analog components that are completely diverse from the DL3 LPRMs and APRMs. The digital GT signals are sent to DL2 via the C20 network.

The ERICP is relay only and not subject to common cause software failure.

#### **7.3.2.3.4    *Secure***

The C20 Defense Line 4a systems adequately address access control to limit cyber security vulnerabilities and ensure the system can perform its intended functions.

The C20 Defense Line 4a DPS uses on analog technology, which eliminates the major cyber security vulnerability for DL4a. The C20 Defense Line 4a FMCRD design incorporates features to support establishment of a secure operational environment. DL4a input signals and protection logic are analog and do not use digital technology, but the isolated diagnostics and internal data are available to the SC3 networks and controllers. The C20 FMCRD software is produced in a secure development environment that prevents the insertion of undocumented codes and precludes their use. The C20 Defense Line 4a digital equipment is installed and maintained in accordance with the station administrative procedures and control of access programs.

#### **7.3.2.3.5    *Defence-In-Depth***

The C20 Defense Line 4a systems provide diverse protection functions to place and maintain the plant in a safe state in the event of PIE concurrent with failure of DL3 functions to support the D-in-D concepts.

The design basis of the DL4a systems provide D-in-D for the complete failure of the DL3 / SC1 systems (i.e., CCF). DL4a independently provides comparable DL3 plant protection functions using diverse platforms from DL3. The DL4a sensors are selected to be as diverse as practical from DL3 sensors. The ERIP provides D-in-D by allowing DPS, C10 DL3 Hydraulic Scram, and ATS to drive in rods by the FMCRDs.

Diversity measures are incorporated within the C20 Defense Line 4a system designs as an additional level of protection for potential systematic faults caused by design and implementation defects within redundant divisions of the C10 SC1 I&C system. The C20 Defense Line 4a method

of actuation is diverse from the method of actuation implemented by C10 DL3 Hydraulic Scram function. The C20 Defense Line 4a actuation relays shown in Figures 7.3-4 and 7.3-5 are configured as energize to actuate whereas C10 SC1 I&C load drivers are configured as deenergize to actuate which provides functional diversity in these actuation circuits. The ARI pilot valves described in Chapter 4, Subsection 4.5.1 are energized to actuate and provide an alternate path to vent control air and open all scram valves resulting in hydraulic insertion of all control rods.

The FMCRD motor controllers are required to be diverse from the DL3 I&C platform equipment only if the DL4a motor run-in function is credited as a required mitigating function for a failure of C10 DL3 Hydraulic Scram function due to CCF in the SC1 I&C platform equipment.

The motor run-in can be manually initiated in the MCR (SC2) and SCR (SC1) with switches going to the ERIPs with no involvement of RC&IS software.

The FMCRD UPSs provide D-in-D if normal power is lost.

#### **7.3.2.4 Operator Interface**

The C20 Defense Line 4a diagnostic information is sent to other digital systems in DL2 to provide recording, monitoring, and alarming functions. C20 DL4a system bypass conditions are alarmed in the MCR. A reactor scram can be manually initiated by SC2 switches in the MCR and SC1 switches in the SCR.

The DL4a operator interface HSI for C20 is described in Sections 7.5 and 7.6 for the MCR and SCR, respectively.

#### **7.3.2.5 Compliance Alignment**

Table 7.3-6 shows how the C20 Defense Line 4a systems align to meet the regulatory guidance in CNSC REGDOC-2.5.2 and the key industry I&C standards IEC 61513 and IEEE Std 603.

### **7.3.3 System C20 – Defense Line 2 / Safety Class 3 / Nuclear Segment**

Section 7.2 states the C20 network is split into two segments: Nuclear and BOP. This section addresses the C20 Defense Line 2 Nuclear Segment, which complement the DL3 C10 SC1 I&C and DL4a C20 systems to provide a high availability for the plant protection functions. It also provides detail for the C20 Nuclear Segment which contains the DL2 ATS, major reactor control systems and the control rod blocking systems.

The C20 system acquires the plant information from the sensors specified for systems performing DL2 functions. The specific list of parameters to be measured, the physical locations of the sensors, and environmental qualification envelope for the equipment is specified as part of the detailed design process. The plant information acquired is displayed on the C20 integrated plant displays developed through the HFE process.

#### **7.3.3.1 Systems Architecture**

The functional architecture for the C20 Nuclear Segment is shown in Figure 7.3-11. Depending on final DCIS design and processor loading, multiple functions may be combined and implemented on a common controller. A representative ATS block diagram for a reactor scram is shown in Figure 7.3-12. This figure should also be viewed with Figure 7.3-4, which shows the scram solenoid power configuration.

The C20 Nuclear Segment employ TMR and redundant controller architectures for processing units to improve reliability or eliminate spurious control actions caused by a single hardware failure, as shown in Figure 7.3.11.

Protection function and control signals needed between controllers for their functions are point-to-point wire or optical fiber.

The design provides both control and monitoring functions and, supports both local and remote data acquisition.

#### **7.3.3.2 System Design Bases and Associated Safety Functions**

The design basis of DL2 is to prevent or mitigate AOOs before either DL3 or DL4a is required. DL2 action precludes the need for other DL intervention. DL2 is classified as SC3 and the DL2 hardware/software platforms are diverse from DL3. The C20 DL2 system design includes provision of instrumentation to monitor plant variables and systems over the respective ranges for operational states and during a PIE in order to ensure that plant status information can be obtained. The supporting safety analyses are described in Chapter 15.

C20 Defense Line 2 is designed to be in service during all modes of plant operation. Specific safety functions actions are mode dependent, as determined by the Fault Evaluation process in Chapter 15, Section 15.2, and specified by the Mode Switch position shown for each function in Table 7.3-4.

The main C20 Nuclear Segment functions are:

1. Anticipatory Trip System - The ATS is designed to perform the protection function of DL2 which is mitigating transients and providing investment protection for expected transients by tripping the plant in advance of any required DL3 or DL4a response. There is no failure of ATS that can adversely affect the protection functions of DL3 or DL4a. ATS uses logic similar to the C10 DL3 Hydraulic Scram function and DPS, in that parameters are measured, compared to a setpoint, voted and an actuator initiated. In the unlikely event the DL2 ATS fails to scram, the other independent and diverse DLs will still scram the reactor on flux or pressure to maintain the plant safety functions (to prevent unacceptable radiation release to the public). An ATS malfunction cannot stop a C10 Hydraulic Scram nor can a C10 DL3 Hydraulic Scram stop a DL2 ATS scram. The ATS scram initiation signals are listed in Table 7.3-4. Simultaneous with the initiation of the ATS hydraulic scram demand, a scram follow signal is generated such that each FMCRD motor drives its ball nut upward to a position just below the fully inserted and latched hollow piston that is coupled to the control rod blade. This signal is sent whenever a hydraulic scram is demanded by ATS regardless of whether the hydraulic scram actuation has been successful.

The C20 Nuclear Segment also provides DL2 non-scram functions, including:

- a. Feedwater runback for various transients
- b. Turbine Trip on Low Main Condenser Vacuum
- c. Turbine Bypass Valves Closure on Low Main Condenser Vacuum
- d. Turbine Bypass Valves Fast Open on Fast Closure of Turbine Control Valve / Turbine Stop Valve Demand
- e. MSRIV/MSCIV Isolation on Low Main Condenser Vacuum
- f. Standby Diesel Generator Start on Low Electrical Bus Voltage
- g. Feedwater and Condensate Pumps Trip on High RPV Level
- h. Feedwater Isolation on High-High RPV Level
- i. Start Standby Feedwater Pump on Loss of Operating Feedwater Pump

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

- j. Fuel Handling Area Ventilation Isolation on Detection of High Refuel Floor Radiation
  - k. Control Room Ventilation Isolation on Detection of High Refuel Floor Radiation
  - l. ICS Pressure Control on High Reactor Pressure
  - m. Maintain Target Reactor Pressure
  - n. Maintain Target Reactor Water Level
  - o. Control Rod Movement blocks
  - p. Select Control Rod Run-In (SCRRI) on Feedwater Temperature Decrease
  - q. Manual Shutdown Cooling System (SDC) Train Initiation
2. Plant Automation System - The Plant Automation System coordinates automatic reactor power control as part of a larger automation scheme, including coordination of C20 control systems (for control of nuclear equipment) and coordination of C30 control systems (for control of BOP equipment). The C20 and C30 control systems must individually be put into automatic mode by the operator for this automation to be functional; without this operator permissive, any commands originating from the Plant Automation System PAS are ignored.

The Plant Automation System provides batch control of the steps needed to automate the plant systems used to bring the reactor from cold conditions to rated power. One of these controllers is Automatic Power Regulator which interfaces with the nuclear control systems. Examples of these Automatic Power Regulator functions include:

- a. Bring reactor to critical
- b. Heatup and pressurization
- c. Increase power to 15%
- d. Roll turbine to rated speed
- e. Synchronize turbine-generator
- f. Increase electrical load to ~ 20%
- g. Automatic Power Regulator switch to power control

The Plant Automation System does not communicate with DL3/SC1 or the DL4a/SC2 I&C systems nor does it control SC1 plant equipment; instead, the operator is prompted to operate the Reactor Mode Switch to provide a necessary permissive before an automated function can occur.

After the minimum 20% power is reached by predefined automation steps, the Automatic Power Regulator accepts reactor power demands from approximately 20% to 100%. The power demand can be % thermal power or desired generator MWe as selected by the operator. If the regulatory body so allows, the desired generator MWe can come from a remote load dispatcher. In this case the operator sets an allowed maximum and minimum reactor power and the allowed rate of change in reactor power that supervises and limits load dispatcher inputs.

3. Reactor Level Control - Provides reactor level monitoring and control from cold conditions through pressurization and heatup to power operation. This system controls reactor level at greater than 10 – 15% power by adjusting the frequency of the adjustable speed drives supplying power to the feedwater pump motors. At lower powers the system uses a low flow control valve supplied with either a condensate pump or feedpump operating at fixed speeds,

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

depending upon reactor pressure. The Reactor Level Control (RLC) also operates level control valves in the shutdown cooling system and the Reactor Water Cleanup System when water is rejected from the reactor vessel during cold and heatup operations. The RLC generates a SCRR demand to RC&IS to obtain a rapid reactor power reduction if required by a feedwater temperature decrease.

4. Feedwater Temperature Control – Provides control of the feedwater temperature delivered to the reactor by the sixth stage feedwater heater by measuring the heater exit temperature and modulating a steam heating valve as required to meet the demanded temperature setpoint. The feedwater temperature is programmed as a function of reactor power and the temperature is held constant between 90 and 100% thermal power and then decreased as power is further reduced. Appropriate function logic features are provided to keep the feedwater nozzle temperatures from changing too rapidly. The controller also provides the sixth stage feedwater heater level control necessary to keep the feedwater heater level at the optimum setpoint for best heat transfer.
5. Reactor Pressure Control - Provides control of reactor pressure from a cold vessel through pressurization and heatup to power operation. During plant operation this system normally controls reactor pressure by sending a flow demand signal to the turbine controller. During plant startup or at other times when the turbine is off-line, Reactor Pressure Control (RPC) adjusts reactor pressure by sending a flow demand signal to the turbine bypass valves.
6. Isolation Condenser Throttling Pressure Control - To meet their safety requirements, the three BWRX-300 ICs have a very large capacity for reactor pressure reduction. While desirable in safety systems, this capacity can result in exceeding the normal allowed cooldown rate for the reactor vessel. The ICs are each initiated with two condensate return valves. One of these valves is “open or close” and can be actuated by DL3 only. The other valve is modulating and controlled by the IC throttling valve controller in DL2 but can be forced open by a DL4a initiation signal. The IC throttling valves can control IC flow by modulating their position. The throttling valves are controlled by a standard pressure controller and have staggered setpoints so that they do not initiate simultaneously but only as the reactor pressure increases. The IC throttling valve control is designed to act before ICS actuation by other DLs.
7. Turbine-Generator Control - The normal function of Turbine-Generator Control is to position the turbine control valves and bypass valves to control reactor pressure. The turbine-generator controller provides the turbine protection functions (e.g., turbine overspeed protection). The turbine-generator controller also provides trip and load rejection signals to the ATS and similar signals to the RPC to quickly open the bypass valves. The controller receives both high reactor level and vacuum trip signals from the DL4a DPS (to ensure these trips occur in the right sequence with other control systems). The turbine-generator controller is involved in plant automation to allow the turbine to be rolled, synchronized, and initially loaded. The operator always deliberately puts the system into automated control and several adverse conditions and diagnostics takes the system out of automation.
8. Rod Control and Information System - Provides the control logic and positions control rods using their fine motion drive motors.

RC&IS stores at least two predefined control rod sequences from all control rods full in (shutdown) to all control rods full out (i.e., end of cycle power operation). The sequences are carefully designed to avoid exceeding thermal limits and to meet fuel operating guidelines concerns under expected conditions of load following and transient xenon. Once a sequence is selected, RC&IS is constrained to operate in that sequence, but as described for the blocking systems, RC&IS is supervised by blocking functions to ensure that the sequences

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

are followed, and no thermal limits or fuel operating guidelines are exceeded. The rod block functions are listed in Table 7.3-4.

In the automatic mode, RC&IS accepts insert and withdraw commands from Automatic Power Regulator, these commands are issued as required to achieve the desired reactor power. Rod motion is constrained to the RC&IS selected sequence and Automatic Thermal Limit Monitor (ATLM) and MRBM are always functioning to supervise and block control rod motion. Only the operator can put the RC&IS into the automatic mode, but certain plant events or diagnostics can take the system out of automation mode.

In the semi-automatic mode, the operator depresses the insert or withdraw pushbuttons in the MCR. Once momentarily depressed the RC&IS inserts or withdraws the rods until the next predefined rod position breakpoint and then stops. Rod motion is constrained to the selected sequence and the ATLM and MRBM are actively enforcing rod motion blocks if unacceptable conditions are detected.

In the manual mode, the operator can move rods out of sequence (until blocked by the ATLM or MRBM) but unlike the other modes, only single (as opposed to ganged) rod motion is allowed. At lower thermal powers, manual movement commands deviating from the selected sequence are blocked. At higher thermal power levels, manual movement commands deviating from the sequence are alarmed.

RC&IS moves the control rods to a predefined rod pattern (by insertion only) when a SCRRI demand is issued. The SCRRI rod pattern is chosen to achieve a specific reactor power.

The RC&IS provides position demands to the control rod motor controllers and drives which are in DL4a. The DL4a design features allow the FMCRDs to be commanded to full in or to be blocked by disabling rod withdrawal regardless of RC&IS status or RC&IS positioning demand signals. The design allows a DL2 system to give commands to a DL4a system since the DL2 system is supervised by the blocking systems and the RC&IS inputs to the FMCRD motor controllers can be bypassed if the blocking systems so dictate.

9. Nuclear Boiler/Containment Inerting System – The nuclear boiler function provides most of the reactor flux, level, pressure, temperature, and flow information. The Nuclear Boiler system only transfers the signals to those systems that acquire and use the monitored signals. The instruments providing the data are typically mounted on instrument racks outside containment or routed from the vessel to outside containment signal conditioning and data acquisition equipment. It also has control requirements for valves repositioned as the plant is brought from cold to full power or respond to unplanned transients. SC1 equipment cannot be controlled by the Safety Category 3 automation function and therefore provision is made to operate the valves manually by the operator (as prompted by the automation system). Non-Safety Class valves and SC3 valves can be operated by the automation system. The containment Inerting function provides monitoring and control for the generation and storage of nitrogen gas to do the initial containment fill and thereafter to make up for the small long-term losses. It also supplies nitrogen to any inside containment pneumatic valves.
10. Control Rod Drive Hydraulic Control – CRD Hydraulic Control normally provides for flow control of the FMCRD purging functions and charging of the HCU accumulators to provide for the reactor hydraulic scram. There are two controllers that control the redundant CRD pumps and valves. The failure of the CRD controller to maintain the charge of the accumulators is alarmed to alert the operator if any of the HCU pressures and levels are too low.
11. Shutdown Cooling System - Provides separate controllers for monitoring and control for the SDC system to remove decay heat from the reactor. There are two separate SDC controllers

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

that respectively operate the redundant SDC. The SDC controllers can receive commands from the Plant Automatic System or can be manually operated.

12. Containment Cooling System - Provides redundant monitoring and control of the redundant containment air handling units with chilled water cooling during normal operation or during an outage.
13. Isolation Condenser System – Provides monitoring and control for the ICS pool redundant heat exchangers and pumps and their associated valves.
14. Fuel Pool Cooling and Cleanup System - Provides monitoring and control for the fuel pool cooling system. The system includes redundant pumps and heat exchangers and filter demineralizers. The controller also includes logic to start a standby pump if an operating pump trips.
15. Plant Service, Closed Cooling Water and Chillers - Provides redundant monitoring and control for service water pumps and valves. It also provides monitoring and control to mixing valves in series and parallel with the closed cooling water heat exchangers to provide a constant cooling water temperature regardless of cooling load. The closed cooling water pumps, the heat exchangers, and their valves are all controlled and monitored. It also provides control of the chillers and associated air-cooling fans and water distribution system valves requiring control and temperature monitoring.
16. R20 Electric Systems - The R20 electric system is divided into two medium voltage busses and their derivative low voltage busses. Also included are the two standby diesel generators. The load breakers on the various medium voltage and low voltage busses are controlled by the system controllers for those loads but the feeder breakers, load centre breakers, motor control centre breakers and diesel generator breakers are controlled by the two R20 controllers. The electric system control is usually by operator manual action except for the diesel generator breakers which close automatically after a loss of associated buss power after the diesel has been started and reached rated speed. The R20 controllers also control the sequencing of the standby diesel generator loads to minimize operator involvement and prevent diesel overload and under or over voltage and frequency. The controller provides the ability to synchronize the standby diesels to an energized bus to allow periodic load testing of the diesel generator. The controllers also provide extensive monitoring of the electric system parameters and for the R20 UPS, battery chargers and batteries.
17. R20 Protective Relaying - The R20 protective relaying function uses digital protective relays that appropriately protect the R20 medium voltage and low voltage loads, busses, feeder circuits and the standby diesel generators. The relays are redundantly powered and trip to protect the associated circuits or equipment but the data source function for I&C is not critical to their operation. Typically, the relays have enough redundancy that plant operation is not adversely affected by single relay failures. The relays are also in the control system architecture because they are networked to the C20 BOP Segment and the source of most of the electrical system parameter measurements. The required I&C function of the R20 Protective Relaying system is to interface the relays through gateways as necessary so the various data are available to I&C to support operator displays and alarms of electrical system status and for advanced condition monitoring.
18. Reactor Building and Control Building HVAC - Provides redundant monitoring and control for automatic operation of the normal Reactor and Control Building HVAC requirements by controlling the redundant cooling of the various Reactor and Control Building air handling units, building intake and exhaust fans, and, if required, recirculating fans. The room and building temperatures are controlled by damper and chilled water control valve operation.

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

19. Process Radiation Monitoring - Provides radiation data to other systems for trips but also provides data for operator monitoring, alarming and recording. The system controller provides for the acquisition of the various process radiation measurements, alarms and diagnostics and transmission of these data to the C20 Nuclear Segment networks with appropriate isolation or using appropriate safety class equipment to generate and transmit the data.
20. Defense Line 3 Gateways - The gateways are used to bring data linked signals to the C20 Nuclear Segment networks. The DL3 signals are isolated with SC1 isolators at the source. The two gateways are DL2 / SC3 components and have three major functions. The first function provides another layer of isolation. This isolation functions also prevents communication back to the C10 sources, which would not accept it in any case. The second function is to provide protocol conversion of the C10 signals to be compatible with the plant networks and package the data into messages for specific C20 controllers. The third function is to accept data links from non-SC1 sources that are input to the C20 Nuclear Segment, for example the data link from the DL4a DPS isolated diagnostics.
21. Automatic Thermal Limit Monitor - Provides redundant protection against critical power ratio (a fuel heat flux to flow consideration) and linear heat generation rate (maximum heat flux through the fuel clad) design limits. This online monitoring of thermal limits and fuel operating guidelines uses LPRM and APRM data sent via qualified isolation devices. The fuel operating guidelines keep the fuel duty per node below previously conditioned power levels to prevent fuel failures. Operation above the preconditioned envelope per node is constrained to slow power changes. The ATLM rod blocks are automatically operative at higher reactor powers. The ATLM receives online LPRM data and uses it with previously stored and periodically updated 3D power distribution and RC&IS data for current rod positions and the next selected rods to be moved to predict the resulting thermal limits and nodal powers for the fuel operating guidelines. The ATLMS are connected to the plant networks.
22. Multi-Channel Rod Block Monitor - Provides redundant protection against critical power ratio and linear heat generation rate design limits. The MRBM rod blocks are automatically operative at higher reactor powers. The MRBM uses LPRM and APRM data redundant pair of processing units with a real time operating system that each monitor LPRMs and APRMs sent via qualified isolation devices and control rod status from RC&IS. The MRBMs operate after receiving a signal from RC&IS that rods have been selected for motion. The MRBMs, using the real time LPRM information received from the gateways the MRBMs identify the LPRMs around the selected rods and normalize their average to a nominal value. As the selected rods are withdrawing, the LPRM average around the selected rods increases in value. If the ratio of the withdrawing average to the initial average increases by too great an amount, it indicates that the local powers have increased by an amount that would violate fuel thermal limits. Under those circumstances, the MRBMs issue a rod block. The MRBMs are connected to the plant networks.
23. Wide-Range Neutron Monitoring - The WRNM function provides redundant monitoring of the fixed neutron monitoring detectors in BWRX-300 core. The detectors are distributed radially in the core at fixed heights with at least three detectors in each quadrant. The detectors can be bypassed but the bypass switches are arranged such that only one detector can be bypassed at a time in any quadrant. Each detector is sensitive to neutrons from below criticality to greater than 100% thermal power. Their absolute value is indicative of reactor power. The WRNM detectors reactor power indication is not accurate given how few detectors are in the core, but they can indicate that the core has been successfully shutdown post rod insertion and for controlling reactor flux rate of change during a reactor startup. The average of the detectors can be related to thermal power by the comparison to APRM data. This relationship is continuously adjusted to ensure that there is always an overlap in the 1 – 10%

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

power region. Although the very localized WRNM absolute values are not required to be accurate, the main use of the detector data is to determine reactor period per detector. These period data are representative of the whole core and are used for monitoring and by Automatic Power Regulator. Both the operator and Automatic Power Regulator use the data when starting the reactor. The WRNMs are connected to the plant networks.

24. Stability Monitoring - Provides redundant operator alarms and takes the plant out of automation mode to ensure potential oscillations are not made worse by the reactor power control system. The design of the BWRX-300 and its core design make it less susceptible to core power oscillations, which are addressed as a fuel and core design criteria. The redundant Stability Monitoring functions check the LPRM signals sent via qualified isolation devices and oscillations and, when warranted, initiate an alarm and automation trip.
25. Safety Parameter Display System (SPDS) – The SPDS provides big picture overview display of plant parameters during transients and accidents. The SPDS terminology is used for consistency with regulatory documents; however, the BWRX-300 SPDS is actually functionality that is included with the C20 SC3 equipment. The BWRX-300 SPDS presents sufficient information on safety-critical parameters and includes display and trending of the parameters associated with the emergency procedure guidelines for the plant. The specific displays are developed in accordance with the Human Factors Engineering process described in Chapter 18. The displays cover the full range expected for the safety-critical parameters, track data trends, indicate when process or safety limits are being approached or exceeded, and display the status of safety systems. The SPDS is designed to use the same accident monitoring information provided to the C10 and C20 operator displays and is available in the Emergency Response Facilities described in Chapter 19
26. Operational Limits and Conditions Monitor – Provides surveillance test support and monitors and alarm deviations from plant OLC requirements for those requirements where appropriate plant signals are available. The redundant OLC Monitors have no signals of their own but instead have access to the signals on the plant networks including three divisions of C10 signals available to the DL2 Nuclear Segment through isolated, unidirectional boundary devices and DL2 gateways. The OLC Monitors are designed to support online and automatic surveillance testing to meet OLC requirements. Redundant input signals from the C10 SC1 I&C divisions used for safety actuation are continuously compared by the OLC Monitors during operation and alarmed for deviations outside of established tolerance. Similarly, the correct functioning of the C10 SC1 digital I&C platforms are continuously monitored by self-testing features rather than by manual surveillance testing. Critical faults detected by the self-testing features trip the outputs of the platform and other faults are alarmed. The OLC Monitors also monitor and alarm for other faults detected by self-testing and loss of communication indicating health and operability from any of the C10 SC1 I&C divisional components and most TMR controllers in the other DLs. The OLC Monitors are a redundant pair of processing units with a real time operating system that each monitor available OLC data. The OLC Monitors communicate among themselves to indicate they are working and agree on their determinations. The OLC Monitors have their own self-diagnostics, and the loss of a OLC Monitor is alarmed.
27. Core Thermal Power/Flow Monitor – Provides reactor thermal power and core flow information using a redundant pair of processing units with a real time operating system that calculates reactor thermal power and core flow. The thermal power is calculated once per second and is made available plant wide over the plant networks. The lowest power levels are estimated from the WRNM system and the intermediate power levels from the low flow feedwater system and bypass valve position. The program seamlessly transitions between the calculation methodologies. In the normal power range, approximately 10 – 100% thermal power, the

calculation is done using a heat balance. There are no assumed inputs or constants, heat balance parameters are measured and, in most cases, redundant. The most important measurements, feedwater flow, feedwater temperature and reactor pressure (used to determine the feedwater and steam enthalpies that account for greater than 99% of the heat balance accuracy) are triply redundant. Alarms are provided if sensed parameters are missing or inconsistent.

Natural circulation core flow is calculated by a heat balance around the core inlet. The important inputs are feedwater flow and enthalpy, steam flow and enthalpy and core inlet enthalpy, the latter using the core inlet temperature measurements in the LPRM and GT strings. A signal representative of core differential pressure (whose square root is proportional to core flow) is continuously calibrated against the heat balance calculation done in steady state. The calibrated differential pressure measurement is used during reactor transients and additionally to determine if the calibration constant changes significantly which may signal a restriction.

The core thermal power/flow monitors have their own self-diagnostics, and the loss of a monitor results in an alarm.

28. Three-Dimensional Core Thermal Power Distribution Monitor - These redundant computers use the thermal power calculation, core flow calculation, isolated (from DL3 and DL4a) GTs and LPRM data and control rod position data to determine the core 3D power distribution. The program runs both periodically (typically every hour) and on demand from the operator or ATLM (discussed above). Thermal limits and other diagnostics are alarmed, and data are recorded in the plant historians. The 3-D core monitors are a redundant pair of processing units with a real time operating system that each provide core monitoring, fuel operating guidelines, and thermal limit information. The core monitors have their own self-diagnostics, and the loss of a monitor results in an alarm.
29. Plant Alarm System - Provides aggregated process alarms and self-diagnostic data from the plant control and monitoring systems over the plant networks. The alarms and data are prioritized and filtered by plant mode and events. The alarm system also provides annunciator displays integrated into the MCR video displays. The purpose of the annunciator displays is to attract operator attention to specific display formats associated with the alarm. The operator can display currently active alarms, acknowledged alarms and "first in" alarms. The alarms are available to the operator and recorded in the plant historians. Alarm information is available in both control rooms and in the Site Management Centre. The alarm systems are redundant pairs of processing units that each monitor plant data. The alarms are available even with a single alarm system failure.
30. Plant Historians and Monitoring – Provides archiving of the plant control, alarm, and monitoring system information. The data is recorded at least once a second, depending on the parameter, (e.g., flux and pressure) some are recorded at higher rates and (e.g., temperature) some are recorded at lower rates. The recording capacity is for longer than a fuel cycle. The historians allow archival storage and playback while the plant is online and support operator-initiated data trending on control room displays or report printouts. The historians are redundant pairs of processing units that each monitor plant data. The stored data is still available even with a single historian failure.
31. DPS Diagnostics – Provides capability to monitor the DPS status and diagnostic information. The digital diagnostic system is data linked through the gateways such that the DPS signals can be monitored, alarmed, and recorded. For example, the OLC Monitors can perform continuous channel deviation checks on the DPS input signals, compare the DL4a and DL2 splitter outputs and monitor DPS power supplies.

32. Fiber Optic Relay Panels - Provides capability to send data across DL boundaries when the use of data links and networks is not indicated. These non-software panels containing optical fiber transmitters and receivers can transmit either analog or discrete contact signals.

The setpoints for C20 ATS actuation logic are determined with the setpoint methodology defined in IEC 61888 using the final analytical limits from the plant safety analyses and the measurement uncertainties associated with the ATS equipment (e.g., sensors and processing units). DL2 is designed to prevent or mitigate anticipated operational transients before either DL3 or DL4a action is required. As such, for common physical parameters measured by the DLs, the DL2 setpoint would be designed to act first, since its design basis is to mitigate/prevent DL3 from needing to respond.

### **7.3.3.3 Fundamental Design Properties in the System Design**

The C20 Defense Line 2 SC3 system includes DL1 properties that represent the quality measures implemented to minimize potential for failures and initiating events to occur in the first place, by the use of conservatism in design and analyses. These DL1 properties of qualification, reliability, robustness, security, diversity, and D-in-D features are discussed in the following five subsections.

#### **7.3.3.3.1 *Qualified***

The C20 SC3 equipment is designed to operate in the environment that would be expected during both normal operations and anticipated off-normal conditions. The C20 Defense Line 2 Nuclear Segment is qualified to perform its intended functions and meets IEC 61513 requirements and the equipment standards defined in Section 7 in IEC 61226:2020 requirements for Class 3 systems. The C20 Defense Line 2 Nuclear Segment software is developed to IEC 62138 Category C requirements. Qualification addresses both hardware and software aspects of the C20 Defense Line 2 Nuclear Segment. The C20 Defense Line 2 Nuclear Segment design and manufacturing processes are of sufficient quality to ensure I&C systems can reliably perform their credited protection functions. The C20 Defense Line 2 Nuclear Segment equipment is designed, developed, fabricated, and tested to quality standards commensurate with the safety significance of the functions to be performed. The C20 Defense Line 2 Nuclear Segment qualification measures confirm the I&C systems and equipment are capable of reliably performing the design basis functions for which they are credited over the range of environmental conditions postulated for the area in which they are located.

The C20 equipment is qualified for seismic interaction in accordance with IEC 60980. The C20 equipment is qualified for electromagnetic compatibility in accordance with IEC 61000-4 and IEC 61000-6-2.

#### **7.3.3.3.2 *Reliable***

The C20 Defense Line 2 Nuclear Segment has the required reliability to perform its intended functions. The main C20 hardware platform uses TMR controllers for the major plant control systems. It has an initial quantitative reliability target of 1E-6 to 1E-7 probability of failure per hour for systems in continuous operation and 1E-2 to 1E-3 probability of failure on demand for standby functions. The reliability analysis of the C20 Defense Line 2 Nuclear Segment demonstrates it meets its reliability goals using qualitative and quantitative performance measures or criteria, as appropriate.

The C20 Defense Line 2 Nuclear Segment process controllers are designed with TMR controllers to prevent random I&C component failures from causing plant transients. The TMR controller outputs are dual ported to the plant C20 Nuclear Segment network. Where a mechanical system has safety functions and is redundant (i.e., "A" and "B"), two controllers are furnished so the

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

redundant components may be operated separately, and the system is not affected by a single failure.

For the functions with TMR controllers, single controller failures (and some double failures) have no adverse effect on system or plant operation and failed controller parts may be replaced online. The controllers are a DL2 / SC3 design with a specific requirement that there be no failures more often than once per 100 years. The intent is that no random controller failure initiates an AOO. The reliability of the controller depends on final design and the formal analyses to determine failure rates are performed as part of the detailed plant design.

C20 Defense Line 2 Nuclear Segment monitoring functions are implemented on redundant processors for reliability. Normally both redundancies are online, and their data continuously compared. Any one redundancy can be bypassed at a time but, if bypassed, it takes the plant out of automation mode.

Design reliability assurance program and reliability, availability, and maintainability plan documents are used to quantify the required failure rates of the DCIS to assure plant safety and plant availability goals. Testing and performance assessment requirements for ATS are developed using the guidance of IEC 60671 and IEC 62385.

Extensive hardware and software diagnostics are provided for the TMR controllers to provide for operator monitoring and alarms.

The feedwater temperature and level controller input signals are triplicated. No signal is derived from any other DL.

The C20 DL2 functions for ATLM, MRBM, WRNM, Stability Monitoring, SPDS, TSM, Core Thermal Power/Flow Monitor, 3-D Core Monitor, Plant Alarm System, and Plant Historians and Monitoring are provided with redundant UPS and power feeds.

#### **7.3.3.3.3 Robust**

Robustness of the C20 Defense Line 2 Nuclear Segment is the degree to which it can function correctly in the presence of invalid inputs or stressful environmental conditions. The robust C20 Defense Line 2 Nuclear Segment design reflects the use of design methods and adherence to engineering best practices to ensure that its functions are achieved for the specified conditions.

The C20 Defense Line 2 Nuclear Segment has the required separation and independence to perform its intended functions. DL2 is independent from DL3. DL2 is also independent from DL4a to an extent that is practicable in that shared sensors are not credited with mitigation of the same PIE. DL2 and DL4a share support equipment. DL2 is designed to ensure that it cannot adversely affect DL3 or DL4a from fulfilling their protection functions. DL2 shares some signals with DL4a sent via qualified isolation devices (as described in Subsection 7.3.2.3.3). DL2 may use signals from DL3 sent via qualified isolation devices (as described in Subsection 7.3.1.3.3) for some control purposes. Plant operation is not adversely affected by the loss or inaccuracy of these individual signals. The C20 DL2 ATS functions do not use any sensors or actuators in common with DL3.

The DL2 equipment is located in two separate fire barrier rooms in the Control Building. The DL3 equipment is located in three separate divisional fire barrier rooms in the Reactor Building. The DL4a equipment is located in a separate fire barrier room in the Control Building.

There is no communication from ATS to DL3 and only rod block or motor run-in initiation (dry contact) communication to the DL4a ERIPs. There is no direct connection between DL3 and the Automatic Power Regulator. The Automatic Power Regulator does use APRM signals from DL3 for power feedback, but it also uses GTs signals and the core thermal power computers for similar

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

feedback. These signals are continuously compared, and any discrepancy takes the plant out of automation mode to prevent any power signal from misleading the control system. Other than the APRM signals, DL3 / SC1 and the Automatic Power Regulator controller have and no sensors or actuators in common. There are no DL2 commands or communication to DL3. The C20 physical separation and signal isolation devices meet the requirements of IEC 60709.

The C20 Defense Line 2 Nuclear Segment has the required fail-as-is design features to perform its intended functions and avoid spurious actuation. The fail-as-is energize to actuate design is used to prevent lesser classified systems (e.g., ATS) from creating unnecessary challenges to plant safety (e.g., spurious actuations for expected failures) requiring action by DL3. Where software is used for diagnostics, DL2 diagnostics always include watchdog timers, sensor range checks and power supply, communications, and actuator monitoring. The ATS is designed to energize its outputs to cause a trip or initiation. Each output is produced separately by a 2-out-of-3 discrete, or median select analog vote from each of the three controllers. The scheme is used to provide reliable trips and avoid inadvertent trips.

The blocking system functions of DL2 (i.e., ATLM, MRBM, and WRNM) are redundant and are used to supervise the control systems and plant conditions. Either of the redundant blocking pair can block rod motion. One of the redundant pair can be bypassed for maintenance activities. The bypass condition automatically takes the plant out of automation mode, which halts automatic control rod motion under command of the Plant Automation System. The remaining component of the blocking pair can still block rod motion in any plant mode. If both blocking pairs are not available semi-automatic and manual control rod motion is halted until at least one is available. The blocking pairs alarm and block if they lose communication with the gateways or RC&IS, cannot receive an update from the core 3D core thermal power distribution monitoring program, or if their internal data do not agree.

Either WRNM can cause a rod withdrawal block (unless bypassed) for a short period and either can cause a hydraulic scram via the ATS for a shorter period. The scram is only available when the Reactor Mode Switch is not in RUN (typically below 15% thermal power as measured by the APRMs). If no WRNM detector is available in any core quadrant, rod motion is prohibited except in manual mode. If no WRNM detector is available in any core quadrant during refueling activities, then fuel movement is halted.

Any one Stability Monitoring function can be bypassed at a time, but if bypassed, automatic control rod motion under command of the Plant Automation System is halted. If both Stability Monitoring functions are not available semi-automatic and manual rod control is halted until at least one Stability Monitoring function is available (later plant design and analysis may conclude that no power restrictions are required). Either Stability Monitoring function (unless bypassed) can cause an alarm and automation trip.

The C20 Defense Line 2 Nuclear Segment is predictable when performing its intended functions. Where ATS or a reactor control system TMR controller uses three signals from DL4a splitters, a fourth DL2 signal is used for the ATS. Typically, these parameters include containment pressure, reactor level, reactor pressure, and condenser vacuum scrams. Each ATS controller and reactor control system validates the analog signal with a range and consistency check, compares each of the four signals to a common setpoint, and then indicates the analog value and trip status. For example, the reactor level and pressure controller analog validation algorithms use the three splitter signals from DL4a, and the fourth signal dedicated to DL2 functions to make a single failure proof control signal that functions even if the splitter signals are lost:

- If four signals are valid, use average of two median signals
- If three signals are valid, use median signals

- If two signals are valid, use average of two signals
- If only one signal is valid, use signal

For trip signals derived from analog inputs the DL2 validation algorithms functions:

- If four signals are valid, use 2-out-of-4 logic
- If three signals are valid, use 2-out-of-3 logic
- If two signals are valid, use 2-out-of-2 logic
- If only one signal is valid, do not trip

The scheme is used to provide reliable trips and avoid inadvertent trips. The simple logic for the ATS TMR controller is faster and acts before the three asynchronous DL3 divisional controllers voting communications and faster than the analog DPS.

The C20 Defense Line 2 Nuclear Segment provides diversity to support the D-in-D concepts. The DL2 C20 hardware and software platforms are diverse from DL3. Aside from common but isolated power supplies and common support equipment like HVAC, DL4a protection functions are mostly analog and any DL4a supporting software is also diverse from DL2 (and DL3). It can be stated that DL2 software and logic is independent of DL4a. The processing units used for the control rod blocking functions are implemented in equipment diverse from the DL3 equipment if it is credited as a backup in the safety analyses. The turbine overspeed protection control logic uses two diverse and independent systems to provide sufficient reliability to eliminate the risk of turbine missile generation and to avoid the need for a mechanical overspeed trip. These turbine overspeed protection systems use TMR control architecture to eliminate random hardware vulnerabilities that could result in spurious turbine trips.

#### **7.3.3.3.4    *Secure***

The C20 Defense Line 2 Nuclear Segment adequately addresses security to limit cyber security vulnerabilities and ensure the system can perform its intended functions.

The C20 Defense Line 2 Nuclear Segment design incorporates features to support establishment of a secure operational environment. It is installed and maintained in accordance with the station administrative procedures and control of access programs.

The BWRX-300 network switches interconnect the C20 segments have security features, as described in Subsection 7.2.3. The communications on the nuclear Unit Data Highways are rigorously controlled and monitored and information sent off-site is through unidirectional boundary devices, as described in Subsection 7.2.4.

#### **7.3.3.3.5    *Defence-In-Depth***

The C20 Defense Line 2 Nuclear Segment provides anticipatory trip functions to support the D-in-D concepts. Examples of anticipatory trips include an ATS scram on loss of off-site power and is initiated before the DL3 and DL4a systems scram the plant on reactor low level on loss of the feedpumps or a high flux resulting from a reactor isolation on loss of vacuum. Another example is the ATS scram on a turbine trip or load rejection before the DL3 and DL4a systems scram the plant on reactor high flux or pressure; this also mitigates the adverse thermal limit response because the reactor is scrammed before the pressurization wave impacts the reactor. The DL2 C20 hardware and software platforms are diverse from DL3. The C20 Defense Line 2 ATS actuation relays shown in Figure 7.3-4 are configured as energize to actuate whereas C10 SC1 I&C load drivers are configured as deenergize to actuate, which provides functional diversity in these actuation circuits.

Diversity measures are incorporated within the C20 Defense Line 2 Nuclear Segment design as an additional level of protection for potential systematic faults caused by design and implementation defects when equipment it is credited to backup' in the safety analyses. Rod blocks are hard wired to RC&IS. The Stability Monitoring function is provided for indication only as additional D-in-D.

The use of a fourth DL2 signal provides immunity a loss of control signal due to the postulated CCF of the DL4a signal splitters.

DL2 can initiate hydraulic and motor run-ins, initiate isolations, and operate the ICS, no DL2 equipment can prevent a scram, isolation, or ICS initiation actuated from DL4a or DL3. Similarly, DL3 or DL4a cannot adversely affect DL2 operation. If DL2 does not send out its anticipatory trip commands, plant safety is ensured by DL3 or DL4a.

Although DL4a, the DL2 Nuclear Segment, and the C30 BOP Segment are powered by the same pair of UPS with 72-hour battery backup, the power supply is redundant, and a single failure does not affect either DL or segment. The UPS and the battery chargers can be powered by off-site power or either of the standby diesel generators. The DLs use double breakers or fuses to separate the DLs and to separate the C20 Nuclear and C20 BOP Segments such that a fault in a DL or segment does not adversely affect the other DLs. No DL4a or DL2 power is shared with DL3.

#### **7.3.3.4 Operator Interface**

The C20 data are available on their appropriate displays. The layout and content of the displays are designed as part of the HFE program of activities integrated into the BWRX-300 design, as described in Chapter 18, Section 18.3. C20 has its own displays in both the MCR and SCR and locally in the C20 equipment rooms. Each divisional display is dedicated to monitoring or controlling its associated division. The C20 displays also include an alarm system to provide for operator awareness and to prompt to the displays containing further information relating to the alarm. C20 system bypass conditions are alarmed in the MCR. The displays are menu driven and it is possible to switch between related displays without going through the main menu.

Some C20 monitoring signals provide necessary information to achieve or verify correct plant response to transients and accidents. The necessary signals are determined through HFE analysis and applicable regulatory requirements and are referred to as accident monitoring signals.

The C20 signals are alarmed to prompt the operator to an appropriate display (e.g., range check problems or alarm setpoints exceeded). The C20 signals and the various C20 components are alarmed for self-diagnostics.

The C20 SC3 system acquires accident monitoring information associated with Type B and C accident monitoring variables from C10 SC1 I&C through isolated interfaces. It also acquires accident monitoring information associated with Type D, E, and F accident monitoring variables from C20 and C30. The aggregated C20 displays of accident monitoring information are provided to the MCR and Site Management Centre located in the Control Building and the SCR located in the Reactor Building in the current concept design. The Type D, E, and F are defined in IEC 63147. Type D variables provide information to accident management personnel to verify safety system status and that indicate the performance of safety systems, required auxiliary support features, and other systems necessary to achieve and maintain a safe shutdown condition. Type E variables provide information to accident management personnel to monitor radioactive releases identified pathways and environmental conditions used to determine the impact of releases in the plant environs and radioactivity levels in the control rooms and selected plant areas where access may be required for plant recovery. Type F variables provide information

that indicates fuel damage and the effects of fuel damage to support accident management response to severe accidents. A preliminary list of the Type D, E, and F accident monitoring variable is provided in Table 7.3-2.

The C20 and C30 DCIS rooms, which include I&C equipment for DL2, some Non-Safety Class equipment, and associated electrical support equipment are SC3 and located in the Control Building. The MCR is used by plant operators unless conditions require relocation to the SCR. The Site Management Centre is used by accident management personnel. The Control Building provides the necessary seismic ruggedness and habitability capabilities to support the expected post-accident conditions with a SC3 level of quality and reliability for required protection functions.

The operator interface HSI for the C20 Nuclear Segment of DL2 is described in Sections 7.5 and 7.6 for the MCR and SCR, respectively.

#### **7.3.3.5 Compliance Alignment**

Table 7.3-7 shows how the C20 Defense Line 2 Nuclear Segment aligns to meets the regulatory guidance in CNSC REGDOC-2.5.2 and the key industry I&C standards IEC 61513 and IEEE Std 603.

#### **7.3.4 System C30 – Non-Safety Class / Balance of Plant Segment**

Section 7.2.1 describes how the C20 network is split into two segments: Nuclear and BOP. This section addresses the C30 BOP controllers that feed the C20 BOP Segment, which contains the control and monitoring systems associated with power generation and support systems

##### **7.3.4.1 Systems Architecture**

The functional architecture for the C30 BOP controllers is shown in Figure 7.3-13. Depending on final DCIS design and processor loading, functions may be combined onto common or shared controllers.

The C30 controllers in the BOP Segment are either TMR controllers or “packaged systems” (typically embedded controllers) provided by an equipment vendor.

Control signals needed between controllers for their functions are point-to-point wire or optical fiber. The signals needed by a controller for its functions are radially connected to the controller and do not use plant networks.

##### **7.3.4.2 System Design Bases and Associated Safety Functions**

The design basis of the C30 controllers is to provide for the control and monitoring of the Non-Safety Class power generation and support equipment. The C30 I&C system design includes provision of instrumentation to monitor plant variables and systems over the respective ranges for operational states in order to ensure that adequate information can be obtained on plant status. This equipment is not credited for protection functions although they may be available for beyond design basis and severe accident scenarios.

The main C30 functions are:

1. Condensate and Feedwater – Provides monitoring and control for the condensate and feedwater systems as the plant is brought from cold to rated power conditions. The condensate and feedwater functions use TMR controllers that are dual ported to the plant C20 BOP Segment network.
2. Feedwater Heater Drains and Extraction Steam – Provides monitoring and active heater level control functions to prevent heater isolation, turbine trip and to provide optimum heat transfer.

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

The feedwater heater drains, and extraction steam function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.

3. Condenser – Provides monitoring and “batch” process functions as the plant is brought from cold to rated power. The condenser also requires extensive monitoring for both condition monitoring and investment protection purposes. The condenser function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
4. Turbine Auxiliaries – Provides control of several auxiliary systems that are controlled for normal plant operation. The turbine auxiliaries also require extensive monitoring for both condition monitoring and investment protection purposes. The turbine auxiliary function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
5. Generator Auxiliaries – Provides control for the stator cooling system and may also provide the interface to the generator exciter to provide generator voltage regulation and reactive power (dispatch as requested by the load dispatcher). The generator auxiliaries also require extensive monitoring for both condition monitoring and investment protection purposes. The generator auxiliary function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
6. Moisture Separator Reheater – Provides reheater stage and the moisture separator level control reheater exit steam temperature control. The Moisture Separator Reheater System (MSR) also requires extensive monitoring for both condition monitoring and investment protection purposes. The MSR function uses TMR controllers that are TMR and dual ported to the plant C20 BOP Segment network.
7. Turbine Bypass Valves – Provides position feedback linear variable differential transformers and servo valves are part of the mechanical turbine bypass valve system. The bypass valve controller is the TMR RPC, but the monitoring is part of the BOP bypass valve control function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
8. Reactor Water Cleanup System – Provides monitoring and control for the Reactor Water Cleanup System (CUW) flow in normal operation to maintain required system flow rates and protect the cooling water temperatures of the regenerative heat exchanger. The CUW function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
9. Circulating Water – Provides monitoring and control of the cooling water flow to the main condenser. The CW function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
10. Intake Structure – Provides monitoring and control for racks and travelling screens to prevent debris from entering the water systems and associated HVAC to maintain the intake building environment. The intake structure function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
11. Turbine and Radwaste Building HVAC – Provides monitoring and control for automatic operation of the plant Non-Safety Class chillers. The Non-Safety Class HVAC control function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
12. Service Air and Instrument Air and Plant Gas Systems – Provides monitoring and control for the Service Air and Instrument Air systems. The Service Air, and Instrument Air control function, uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
13. Condensate Polishing System – Provides control and monitoring of the Condensate Polishing System, which consists of multiple vessels for filtration and demineralization of the condensate water before injection into the reactor. The system is designed to be highly reliable for

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

maintaining reactor chemistry control and to prevent inadvertent operation that could disrupt the condensate/feedwater flow to the reactor vessel. The polishing system vessels are automatically sequenced and regenerated/backflushed by the controller as chemistry dictates. Additionally, the controller provides vessel flow control to provide equal flow such that the resins and filters are not simultaneously depleted. The Condensate Polishing System control function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.

14. R30 Electric System – Provides extensive monitoring of the electric system parameters and for the R30 UPS, battery chargers and batteries. The R30 control function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
15. R30 Protective Relaying – The R30 protective relaying function uses digital protective relays that appropriately protect the R30 medium voltage and low voltage busses and loads, feeder circuits, main and unit auxiliary transformers and the main generator. Where a single failure can cause a plant scram, the main generator, main transformer, and unit transformer are protected with a 2-out-of-3 relaying scheme. The relays are also in the control system architecture because they are networked to the C20 BOP Segment and the source of most of the electrical system parameter measurements. The required I&C function of these systems is to interface the relays through gateways as necessary so the various data are available to I&C to support operator displays and alarms of electrical system status and for advanced condition monitoring.
16. Condensate Storage and Transfer – Provides monitoring and control for the Condensate Storage and Transfer system to store condensate quality water for power generation and transfer the water to its various uses in the power plant. The Condensate Storage and Transfer system control function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
17. Equipment and Floor Drains System – Provides monitoring and control for the plant sumps and drains to collect and release or process depending on the radioactivity and chemistry of the contained water. The equipment and floor drains system control function use TMR controllers that are dual ported to the plant C20 BOP Segment network.
18. Potable Water and Sewage – Provides monitoring and control for the capability to ensure that there is at least a one-week supply of stored water potable available in each control room. The potable water and sewage control function uses TMR controllers that are dual ported to the plant C20 BOP Segment network.
19. Hydrogen Water Chemistry and Noble Metal Injection - Provide a dedicated controller for skid mounted mechanical components that mechanically inject chemicals into the feedwater flow to the reactor. Hydrogen injection is continuous at power and proportional to feedwater flow. Noble metal is injected at commissioning and then periodically over the plant lifetime. The hydrogen water chemistry and noble metal control function uses TMR controllers that are dual ported to the C20 BOP Segment network.
20. Liquid and Solid Waste Management and Offgas – Provides monitoring and control for the offgas system and the liquid and solid waste systems. The offgas controller involves both motor-operated and modulating valves to operate the steam air ejectors and steam dilution systems. The controller provides the systems' monitoring and control capability, specifically included is radiation monitoring before radioactive material or gas is released. The liquid and solid waste systems provide batch controller functions. The liquid and solid waste management and offgas control function uses TMR controllers that are dual ported to the C20 BOP Segment network.

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

21. BOP Gateways – The BWRX-300 may have many packaged systems bought from vendors instead of being designed by GEH. These vendor systems typically include embedded control systems. These vendor systems are integrated into the plant DCIS for both monitoring and control purposes. Each packaged system is connected to the DCIS networks through a gateway to minimize cyber security vulnerabilities. The gateways are designed to provide any needed protocol conversion and cyber security data flow features that limit what the embedded controller can do.
22. Fire Protection (Packaged) – Packaged system that meets local fire safety standards. The system is self-contained with its own operator interfaces (see Chapter 9A, Section 9A.6). A gateway is provided to interface to the plant DCIS so that the operator can monitor the system, obtain immediate fire alarm location and actuation information, and dispatch an appropriate response before the fire protection system console can be manned.
23. Water Treatment (Packaged) – Packaged plant that inputs raw water and makes demineralized water (see Chapter 9, Subsection 9A.9.5). The packaged plant embedded controller controls its pumps and demineralizers and backwashing/regeneration and operates in either batch or continuous mode.
24. Clock (Packaged) – The DCIS includes a set of redundant Global Positioning System satellite synchronized clocks. The main use of the clocks is to distribute network time through gateways to the plant control systems, historians, and electrical system digital protective relays so that signals from different sources are synchronized when recorded and for playback.
25. Equipment Condition Monitoring (Packaged, if provided) – The Equipment Condition Monitoring equipment consists of a central console that receives data from special remote multiplexing units located near power generation rotating machinery including the main turbine, motors, pumps, and fans.
26. Seismic Monitoring System (Packaged) – The Seismic Monitoring System is a packaged system (see Chapter 3, Subsection 3.3.1). It has its own internal UPS, an operator interface, and recording capability. There are two and three axis accelerometers located in various plant locations, including the yard. These are directly wired to the Seismic Monitoring System cabinet. Whenever an accelerometer signal exceeds a predefined value, the Seismic Monitoring System begins recording accelerometer data. The Seismic Monitoring System can also input a contact alarm into the plant DCIS in addition to a datalink through a gateway to the DCIS networks. The alarm alerts plant staff to go to the Seismic Monitoring System operator interface to determine if there is plant damage. The intent of the system is, post-earthquake, to allow the operator or plant engineering staff to determine if the earthquake was above or close to the design basis earthquake. This informs the decision of whether to shut down the plant or how much inspection of plant equipment is required. The Seismic Monitoring System is connected to the plant networks only for alarming purposes.
27. Area Radiation Monitoring System (Packaged) – The Area Radiation Monitoring System (ARMS) is a packaged system with detectors at many plant locations accessible to personnel and subject to potential high radiation. The ARMS cabinet has an operator interface and a datalink to the plant DCIS. There are local radiation detectors mounted in various plant locations with the ability to provide both radiation data and predefined high radiation alarms. (See Chapter 12, Subsection 13.3.14.4)
28. Meteorological Monitoring System (Packaged) – The Meteorological Monitoring System consists of a site tower containing wind speed, wind direction, temperature, and barometric pressure instruments. The data are used with environmental monitoring radiation release

data to predict radiation plume magnitude, direction, and dispersion. (See Chapter 2, Subsection 2.11.8)

29. Environmental Monitoring System (Packaged) – The Environment Monitoring System consists of sensors located at or near site boundaries to monitor plant releases. Radiation releases are typically measured but the system may be used to monitor other parameters required by environmental permits. (See Chapter 20, Subsection 20.11)

#### **7.3.4.3 Fundamental Design Properties in the System Design**

The C30 Non-Safety Class system properties that represent the quality measures implemented to minimize potential for failures and initiating events to occur in the first place by the use of conservatism in design and analyses. These properties of qualification, reliability, robustness, security, diversity, and D-in-D features are discussed in the following five subsections.

##### **7.3.4.3.1 *Qualified***

The C30 controllers are Non-Safety Class. The C30 equipment is designed for to operate in the environment that would be expected during normal operations. The C30 controller design and manufacturing processes are of sufficient quality to ensure that I&C systems can reliably perform their design basis functions. The C30 controller equipment is designed, developed, fabricated, and tested to quality standards commensurate with the safety significance of the functions to be performed. The C30 controller qualification measures confirm that the I&C systems and equipment are capable of reliably performing the design functions for which they are credited over the range of environmental conditions postulated for the area in which they are located.

The C30 controller equipment is assessed as a potential hazard if located near safety classified equipment and, if necessary, qualified for electromagnetic compatibility in accordance with IEC 61000-4 and IEC 61000-6-2 for emissions only.

##### **7.3.4.3.2 *Reliable***

The C30 controllers have the required reliability to perform their intended functions. The reliability analysis of the C20 BOP Segment demonstrates it meets its reliability goals using qualitative and quantitative performance measures or criteria, as appropriate. Separately, the C30 controllers have the required reliability to perform their intended functions.

C30 BOP Segment functions are implemented with TMR controllers where appropriate to ensure that single controller failures have no adverse effect on system or plant operation. The controllers have a specific reliability requirement goal that there be no failures more often than once per 100 years. The intent is that no random controller failure initiates an AOO. The reliability of the controller depends on final design and the formal analyses to determine failure rates are performed as part of the detailed plant design.

Extensive hardware and software diagnostics are provided for the TMR controllers to provide for operator monitoring and alarms. Failed TMR controller parts may be replaced online.

The main C30 controller platforms control and monitoring design supports both local and remote data acquisition, the latter with optical fiber or wire. The intent is that the failure of a C30 controller performing Non-Safety Class control functions never initiate an AOO. The platforms in this category have quantitative reliability targets of 1E-6 to 1E-7 probability of failure per hour for systems in continuous operation and 1E-2 to 1E-3 probability of failure on demand for standby functions.

#### **7.3.4.3.3 Robust**

Robustness of the C30 controllers is the degree to which it can function correctly in the presence of invalid inputs or stressful environmental conditions. The robust C30 controller design reflects the use of design methods and adherence to engineering best practices to ensure that its functions are achieved for the specified conditions.

The C30 controllers have no direct connections (i.e., commands or communication) with the DL3 / SC1 systems (C10).

The C30 controller equipment is in different rooms than the C20 Nuclear Segment rooms and physically separated from DL3 and DL4a rooms. The C30 controller physical separation and signal isolation devices meet the requirements of IEC 60709. Vendor supplied Non-Safety Class functions are implemented on a C30 hardware and connected through a gateway.

#### **7.3.4.3.4 Secure**

The C30 controller design incorporates features to support establishment of a secure operational environment. This equipment is installed and maintained in accordance with the station administrative procedures and control of access programs.

The BWRX-300 network switches that interconnect the C20 BOP Segment have security features, as described in Subsection 7.2.3. The communications on the BOP Unit Data Highways are rigorously controlled and monitored and information sent off-site is through unidirectional boundary devices, as described in Subsection 7.2.4. The vendor packaged C30 controllers are interfaced to the C20 BOP Segment through gateways to provide communication protocol conversion and eliminate cyber security vulnerabilities.

#### **7.3.4.3.5 Defence-In-Depth**

The C30 BOP Segment I&C platform equipment no specific diversity requirements since it performs no credited protection functions.

#### **7.3.4.4 Operator Interface**

The operator interface HSI for the C30 BOP Segment is described in Section 7.5 for the MCR.

#### **7.3.4.5 Compliance Alignment**

Table 7.3-8 shows how the Non-Safety Class C30 BOP Segment aligns to meet the regulatory guidance in CNSC REGDOC-2.5.2 and the key industry I&C standards IEC 61513 and IEEE Std 603.

**Table 7.3-1: C10 SC1 I&C Functions and Initiation Signals**

Initiating Signal	Reactor Mode Switch Position
<b>DL3 Hydraulic Scram</b>	
HIGH RPV pressure [HP1]	RUN or STARTUP
LOW RPV pressure [LP1]	RUN
LOW RPV level [L3]	RUN or STARTUP
HIGH PRNM neutron flux [RUN setpoint]	RUN
HIGH simulated thermal power	RUN
HIGH containment pressure	RUN or STARTUP
HIGH PRNM neutron flux (STARTUP setpoint)	STARTUP
Line break indication (Main Steam Line (MSL), Feedwater (FW), or ICS)	RUN, STARTUP, or SHUTDOWN
<b>Isolation Condenser Actuation</b>	
HIGH RPV pressure [HP2] (ICS Train 1 actuation)	RUN, STARTUP, or SHUTDOWN
HIGH RPV pressure [HP3] (ICS Train 2 actuation)	RUN, STARTUP, or SHUTDOWN
HIGH RPV pressure [HP4] (ICS Train 3 actuation)	RUN, STARTUP, or SHUTDOWN
LOW RPV water level [L2]	RUN, STARTUP, or SHUTDOWN
HIGH containment pressure	RUN, STARTUP, or SHUTDOWN
Line break indication (MSL, FW, or ICS)	RUN, STARTUP, or SHUTDOWN
<b>RPV and Containment Isolation</b>	
LOW RPV level [L2]	RUN, STARTUP, or SHUTDOWN
HIGH containment pressure	RUN, STARTUP, or SHUTDOWN
<b>MSRIV and MSCIV Isolation</b>	
LOW RPV pressure [LP1]	RUN
LOW RPV level [L2]	RUN, STARTUP, or SHUTDOWN
Indication of a MSL break	RUN, STARTUP, or SHUTDOWN
Indication of a FW line break	RUN, STARTUP, or SHUTDOWN
Indication of a SDC line break	RUN, STARTUP, or SHUTDOWN
<b>FWRIV and FWCIV Isolation</b>	
HIGH RPV Level [L9]	RUN, STARTUP, or SHUTDOWN
LOW RPV Level [L2]	RUN, STARTUP, or SHUTDOWN
Loss of Normal FW Flow	RUN, STARTUP, or SHUTDOWN

**Table 7.3-2: BWRX-300 Candidate Accident Monitoring Variables**

Variable	Type	Selection Reason	Critical Safety Functions to Monitor	Estimated Mission Time	EQ	SQ	Remarks
None	A	BWX-300 has no specific planned manually controlled actions for safety systems to perform their safety functions	Not Applicable (NA)	NA	NA	NA	NA
Containment Sump Level	B, C	Boiling Water Reactor (BWR) legacy knowledge	Assess maintenance of reactor coolant pressure boundary function. Indicate potential breach of reactor coolant pressure boundary	< 8 hours after an event involving steam, or water may be discharging into the containment	Y	Y	Designated for monitoring fundamental safety functions during the implementation of emergency operating procedures (EOPs) and severe accident management guidelines (SAMGs) and shall comply with the requirements for safety classifications
Neutron Flux	B	BWR legacy knowledge	Assess shutdown function	< 72 hours after a scram	N	N	NEDO-31558, BWR Owners Group Proposed Neutron Monitoring System Post-Accident Monitoring Functional Criteria
Reactor Pressure	B, C, D	BWR legacy knowledge	Assess maintenance of Reactor Coolant Pressure Boundary (RCPB) function Indicate potential breach of RCPB Confirm ICS operation and performance to accomplish cooldown to stable shutdown state	< 72 hours after an event initiation	Y	Y	Designated for monitoring fundamental safety functions during the implementation of EOPs and SAMGs and shall comply with the requirements for safety classifications

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

Variable	Type	Selection Reason	Critical Safety Functions to Monitor	Estimated Mission Time	EQ	SQ	Remarks
Reactor Pressure Vessel Dome Pressure	B	BWR legacy knowledge	Pressure Control Assess RCPB integrity	< 72 hours after an event initiation	Y	Y	Designated for monitoring fundamental safety functions during the implementation of EOPs and SAMGs and shall comply with the requirements for safety classifications
Reactor Isolation Valve Positions	B	BWR legacy knowledge	Confirm accomplishment of RPV isolation	< 1 hour after isolation actuation demand	Y	Y	Designated for monitoring fundamental safety functions during the implementation of EOPs and SAMGs and shall comply with the requirements for safety classifications
RPV Water Level	B	BWR legacy knowledge	Level Control Assess maintaining adequate core cooling by submergence Indicate potential breach of fuel clad	< 72 hours after an event initiation	Y	Y	Designated for monitoring fundamental safety functions during the implementation of EOPs and SAMGs and shall comply with the requirements for safety classifications
Containment Area Radiation Level	C, E	BWR legacy knowledge	Indicate potential for a breach of fission product barriers (fuel clad, RCPB) Indicate actual breach of fission product barriers (fuel clad, RCPB) Monitor radiation levels and radioactivity in the plant environs	< 72 hours after an event involving elevated radiation	Y	N	
Containment Hydrogen Concentration	C, F	BWR legacy knowledge	Indicate an actual breach of fission product barriers (fuel clad) Indicate potential for a breach of fission product barriers (fuel clad)	< 4 hours after placing monitor in service	Y	N	Provided for severe accident mitigation so commercial grade equipment is acceptable

NEDO-33956 REVISION 0  
NON-PROPRIETARY INFORMATION

Variable	Type	Selection Reason	Critical Safety Functions to Monitor	Estimated Mission Time	EQ	SQ	Remarks
Containment Oxygen Concentration	C, F	BWR legacy knowledge	Indicate an actual breach of fission product barriers (containment) Indicate potential for a breach of fission product barriers (containment)	< 4 hours after placing monitor in service	Y	N	Provided for severe accident mitigation so commercial grade equipment is acceptable
Containment Pressure	C, D	BWR legacy knowledge	Indicate potential breach of reactor coolant pressure boundary. Indicate potential breach of containment boundary. Indicate performance of Primary Containment System	< 72 hours after an event involving elevated containment pressure	Y	Y	Designated for monitoring fundamental safety functions during the implementation of EOPs and SAMGs and shall comply with the requirements for safety classifications
Isolation Condenser Condensate Line Flowrate	C, D	BWR legacy knowledge	Indicate potential for a breach of fission product barriers (RCPB) Indicate actual breach of fission product barriers (fuel clad, RCPB) Indicate performance of ICS safety system	< 72 hours after initiation	Y	Y	
Isolation Condenser Steam Line Flowrate	C, D	BWR legacy knowledge	Indicate potential for a breach of fission product barriers (RCPB) Indicate actual breach of fission product barriers (fuel clad, RCPB) Indicate performance of ICS safety system	< 72 hours after initiation	Y	Y

splitters are SC2 classified

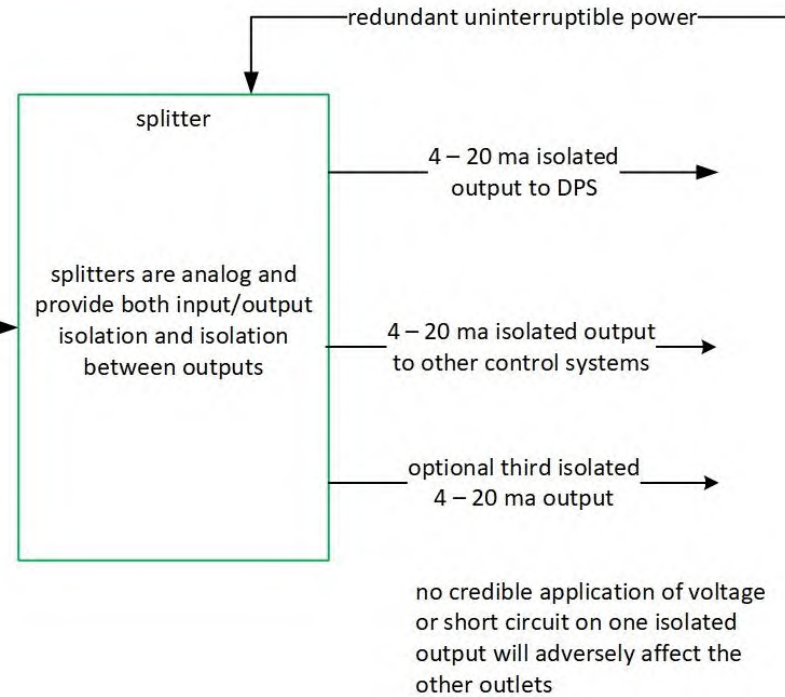

splitters are completely analog and  
do not use software

splitters are per signal and are  
arranged such that a splitter failure  
will not adversely affect other,  
triplicated signals

typical 4 – 20 ma signal

typical signals are directly from a  
transmitter like level, pressure or  
flow

other signal types like RTDs require  
signal conditioning to convert  
them to 4 – 20 ma signals before  
the splitter

## **7.4 Digital Instrumentation and Control System Development Processes**

The BWRX-300 I&C systems design is the result of a past and continuing top – down systematic design process. This process makes risk-informed decisions about the scope and level of design detail required at various stages of the BWRX-300 design process. The BWRX-300 I&C design process is derived from IEC 61513 (Reference 7.4-1). The BWRX-300 I&C design process is informed by first-hand experience and lessons learned from already licensed and delivered BWR I&C designs and proposed new plant I&C designs (e.g., U.S., Finland, Taiwan, and United Kingdom).

### **7.4.1 Design Control**

The BWRX-300 I&C design process is used to ensure that the design and its associated design documentation meet applicable technical requirements, regulatory requirements, codes and standards, and contractual requirements. It is an iterative and recursive design process to allow sequencing and development of requirements. The design process has four design phases (i.e., Requirements, Conceptual, Preliminary, Detailed). The design phases are defined by the maturity of each of the requirement levels, and deliverables are defined for each phase.

1. **Requirements Design Phase:** The requirements design phase focuses on maturity of the requirements of the design using an abbreviated concept design cycle to more closely examine the design and technology selections suited for demonstration on the desired timeline. This phase focuses on rapid study and design of requirements, systems, and component design alternatives to support timely Licence to Construction submittal, and refinement of the selections into an optimized safety and licensing package.
2. **Conceptual Design Phase:** The conceptual design phase focuses on developing the specific design definition of systems and components through component and system level design analysis. This includes detailed system and component analysis, specification and drawing development, detailed manufacturing and fabrication analyses, and long lead procurement activities. Interim verification and validation work is conducted to confirm the adequacy of design requirements and objectives.
3. **Preliminary Design Phase:** The preliminary design phase focuses on the effort to prepare the design for construction, detailed component design, and effort to support equipment procurement/fabrication required at this stage of design. Key system and component design documents and calculations of record are issued to support licensing and construction, and equipment specifications are finalized for procurement. Comprehensive design verification and validation is performed to support submittal of the licence to operate.
4. **Detailed Design Phase:** The detailed design phase focuses on finalization and verification of remaining system and component design in preparation for the complete scope of construction activities. The remaining equipment specifications are finalized and executed for procurements, and remaining system and component design documents and calculations of record are issued.

### **7.4.2 Defence-in-Depth and Architecture Design**

A structured, formal approach to defining the overall I&C architecture is a prerequisite for successful licensing of a new nuclear plant design. The development process output includes a definition of each I&C system in terms of its assigned functions, its safety classification, and its relationships to other systems. The design of the I&C architecture provides a top-level definition of the I&C systems of the BWRX-300 and the communication between BWRX-300 systems. The design process and supporting tools ensure a consistent interface between these systems. The BWRX-300 I&C Architecture Design Process is shown in Figure 7.4-1.

#### **7.4.2.1 Requirements Phase and Activities**

The requirements which define the necessary functions to control, operate or monitor are specified. An I&C functional requirement is defined in such a way that it:

- Gives a complete representation of a functional objective
- Can be categorized according to its degree of importance to safety

Inputs to the I&C Functional Requirements include:

- Process and electrical system design descriptions
- Transient and accident analyses
- Human factors analyses

The requirements which define the I&C systems are required to be independent and diverse from each other are specified. An I&C architectural requirement is defined in such a way that it specifies a safety classification and level of redundancy for each I&C system.

Inputs to the Architectural Requirements include:

- Transient and accident analyses
- Severe accident analyses
- D-in-D concept for the plant
- Canadian and international regulations, guidance, and endorsed standards
- Human factors analyses

These are the constraints placed on the BWRX-300 I&C Architecture from external influences. Examples of external influences include:

- Plant building and room layouts
- Process system interfaces
- Support system designs
- Environmental conditions
- Sources of internal and external hazards
- Concept for online maintenance
- Human factors constraints
- Cyber security constraints

#### **7.4.2.2 Design Phase and Activities**

The allocation of functions activity involves the definition of a set of criteria to govern the process of allocating I&C functions to I&C systems and the act of allocating the I&C functions following the criteria. This can be done initially at the level of control and monitoring functions, but eventually needs to be done for each I&C function. I&C sub-functions are created during this process.

The Definition of Architecture activity is the top-level definition of I&C systems in terms of the functional scope of each I&C system. At a minimum, the definition of an I&C system comprises

its safety classification, its design basis function, and its position in the lines of defence. This work can also include top-level assignment of I&C systems to physical locations in the plant.

Both the allocation of functions and definition of architecture are iterative, both to each other and as the BWRX-300 plant design progresses.

The Definition of Interfaces activity represents the organization and documentation of the interfaces created by the architecture definition and function allocation processes. The key elements to document are 1) basis (need) for the interface, 2) top-level nature of the interface (e.g., hardware, data communication, point-to-point, and switched network), and 3) primary requirements on the interface (e.g., independence, diversity, and failure modes). Interfaces also include support systems for the I&C system.

Human Factor Interfaces are integrated in the Architecture and Design structure for each system control and monitoring areas including the MCR, supplementary control points (e.g., SCR), local control panels, and any emergency control location. The design of the I&C architecture implements the principles for plant operation established in the BWRX-300 plant design including 1) requirements between automatic signals and manually initiated control signals, 2) requirements between the different HSI systems during normal, accident, and post-accident operation, and 3) requirements between normal and backup HSI systems (including any switchover rules). The human factors engineering program is described in Chapter 18.

### **7.4.3 Instrumentation and Control System Life Cycle**

The I&C System Life Cycle applied to each I&C system follows the overall lifecycle of IEC 61513 and the System Engineering “V” model to show top-down design and bottoms up integration for verification and validation testing, as shown in Figure 7.4-2. This plan includes the project timeline in X axis and vertical level project progression with verification and validation arrows included. Configuration management requirements for the project are defined in Configuration Management Plan for the project. The Requirements Management Plan for the project provides direction for managing requirements appearing in project documents developed during execution of the design process.

Each PLICA lifecycle phase within the lifecycle contains activities and output documentation aimed at fulfilling the purpose of the phase. The phases are not strictly sequential in their execution; rather, they are iterative. For example, decisions and discoveries made in a ‘subsequent’ phase can necessitate a return to ‘previous’ phases to modify requirements, design decisions, or output documentation. In some cases, portions of different phases can be executed in parallel. In general, a ‘subsequent’ phase can be started prior to completion of the ‘previous’ phase.

The software related activities in I&C System Life Cycle are shown in Figure 7.4-3.

### **7.4.4 Cyber Security Life Cycle**

The BWRX-300 Cyber Security Program Plan is designed to meet regulatory requirements, relevant industry standards and best practices for the design, operation, and protection of the BWRX-300 I&C systems. The BWRX-300 Cyber Security Program Plan applies advanced security principles throughout the product development and deployment lifecycle of the BWRX-300 I&C systems. The objective of the program plan is to achieve a high assurance that unauthorized access to the protection, control, and adjustment systems of the BWRX-300 is prevented. The program is based on three key principles: 1) regulatory compliance, 2) integration of cyber security controls into the BWRX-300 I&C systems development process, and 3) integration of cyber security features into the BWRX-300 I&C systems.

The BWRX-300 Cyber Security Program Plan recognizes that protecting cyber essential assets is an ongoing program throughout the I&C system development and operations stages. It is designed to:

- Implement security controls to protect the necessary digital assets from cyber attacks
- Apply and maintain D-in-D protective strategies to ensure the capability to detect, respond to, and recover from cyber attacks
- Mitigate the adverse effects of cyber attacks
- Ensure functions of protected assets are not adversely impacted due to cyber attacks

The cyber security life cycle is shown in Figure 7.4-4. The cyber security architecture security boundaries are shown in Figure 7.4-5. BWRX-300 Cyber Security Program Plan classifies the DCIS systems C10, C20 and C30 equipment with functions important to nuclear safety. These systems are protected from lower classified systems by the unidirectional communication flow between Level 3 and Level 2, as shown in Figure 7.4-5 and consistent with zone requirements in CSA N290.7:21 (Reference 7.4-2). The BWRX-300 Cyber Security Program Plan adds an additional layer of protection between C10 SC1 I&C and C20 with unidirectional communication flow between Level 4 and Level 3. Data flow and communications between defence levels are managed by boundary devices that implement unidirectional flow where required to prevent a lower level from compromising a higher level.

#### **7.4.5 Compliance Alignment**

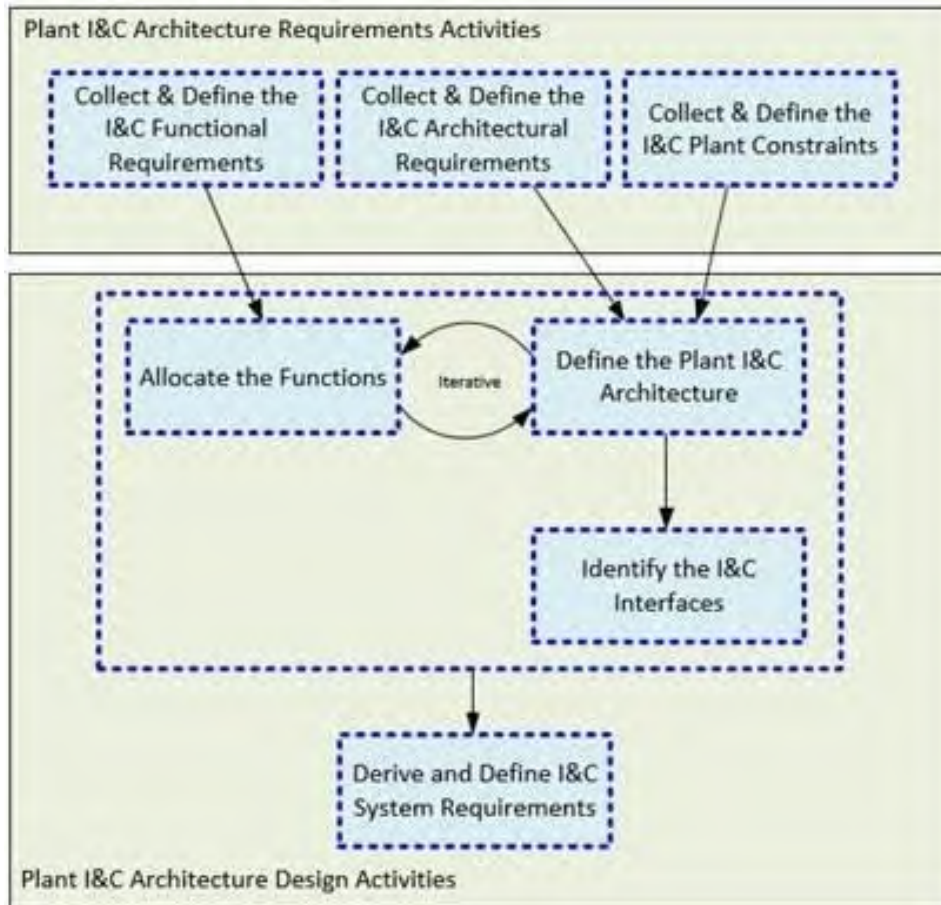

This section describes how the BWRX-300 I&C Development Life Cycle aligns to meet the regulatory guidance in CNSC REGDOC-2.5.2 and the key industry I&C standards IEC 61513 and IEEE Std 603 (Reference 7.4-3), as shown in Table 7.4-1.

## **7.5 Instrumentation and Control in the Main Control Room**

The MCR is located in the Control Building. The MCR is the primary location for plant monitoring and control during normal, abnormal, and emergency conditions. The MCR includes controls, indications and alarms that enable operators to perform the defined set of functions during normal operation modes and PIE conditions. It is expected that the safety and HFE analyses being performed as an integral part of the design of the BWRX-300 will dictate a requirement for an alternate control location; as such, the current concept design includes the SCR. In the event the MCR becomes uninhabitable, or is expected to become uninhabitable, or if functionality is unacceptably impaired, personnel will move to the SCR. The intended functionality of the SCR is to maintain the unit in a safe shutdown condition with the capability to place the unit in a safe shutdown condition. It is not the purpose of the SCR to allow continued operation of the plant at power. Egress from the MCR and access to the SCR is designed such that required minimum operations staffing can safely transition from the MCR to the SCR.

### **7.5.1 Main Control Room Use**

The MCR is designed with HSIs to support the following tasks:

1. Assessing the overall status and performance of the plant in any condition and providing necessary information to support operator actions
2. Monitoring and controlling fundamental safety functions
3. Monitoring the status and trends of key plant parameters (such as reactor power and rates of power change)
4. Operating the plant safely during all operational states, automatically or manually
5. Taking measures to maintain the plant in a safe state or to bring it back into a safe state after design basis events and design extension conditions
6. Maintaining the plant within the specified limits and conditions for the parameters associated with plant systems and equipment
7. Monitoring for failure of critical instrumentation and equipment
8. Confirming safety actions for the actuation of safety systems are automatically initiated when needed and that the relevant systems perform as intended
9. Determining the need and the time for manual initiation or intervention of specified safety actions
10. Implementing emergency operating procedures, emergency mitigating equipment guidelines, and severe accident management guidelines

The MCR is designed to be optimal for nominal shift complement of the control room operator role-holders. The MCR at concept stage is sized and designed to accommodate the expected maximum number of people on a continuous basis. This maximum number will be based on the MCR nominal staffing plus six other people. The basis for six additional people is to allow sufficient space for the supervisory role and five others (e.g., trainees, observers, etc.). The capability for six additional people also provides the necessary facilities to support plant conditions and evolutions that require more than the normal operations complement, for example during pre-operational and startup testing. The size and layout of the MCR are expected to be adjusted as the design progresses as a result of the staffing analysis being conducted as part of the HFE program of activities, as described in Chapter 18, Subsection 18.2.4. The required MCR personnel have workstations designed to support their specific control, information, communication, and work coordination needs. Each MCR workstation also contains space for a

role trainee. The MCR is designed in accordance with current international best practice codes and standards for control room design, integrating results from HFE analyses and specified HFE design requirements as described in Chapter 18, Section 18.3.

### **7.5.2 Main Control Room Layout**

Figure 7.5-1 represents the concept for the MCR. This concept is expected to evolve with the program of safety analyses and HFE activities being performed as an integral part of the BWRX-300 design. The analyses are used to develop an MCR design that optimally supports required personnel roles for all plant conditions.

Key to the MCR layout design is that tasks take place in a position that does not result in blocking views of the Group-View Display. The arrangement of the workstations in the MCR also facilitates communication between all MCR personnel, including direct conversation and visual contact. MCR design also fosters the oversight and command and control responsibilities of the required supervisory roles. The layout of workstations provides sufficient clearance for foot traffic and maintenance between consoles. The layout of workstations provides enough space for the proper storage, placement, and use of tools and procedures in the MCR. The workstations are generally designed for seated operations; however, it is expected that the HFE analysis activities described in Chapter 18 will identify the correct configuration and height required to ensure optimal visibility of individual and shared workspaces within the MCR.

The MCR Group-View Display is an array of large VDUs displaying a consolidated overview of information about plant systems. The purpose of the Group-View Display is to support cohesive situational awareness and crew coordination through shared monitoring of key parameters and alarm information relating to overall plant status, including emergency operating procedure entry conditions.

The Group-View Display VDUs are located and designed to support optimal line-of-sight and viewing angles by the necessary subset of MCR users. Group-View Display and their content are designed and sized to support monitoring and readability of on-screen component labels and indications to the required MCR users. Group-View Display content can be managed at the supervisory workstation via mouse and keyboard interface, including access to closed circuit televisions. Group-View Display VDUs do not have plant control functions, as these are designed for monitoring purposes only. Group-View Display alarms from SC1, SC2, SC3, and Non-Safety Class systems are also included on the Group-View Display VDUs. Additional information about alarms will be accessible at the workstation. The Group-View Display connected to the DCIS are also available at the workstation VDUs. The purpose of the Group-View Display is to be a supplemental, not a sole source, of information.

The MCR operator workstation is made up of three sections: two SC3 workstation sections and one SC1 workstation section. The MCR operator workstations contain the controls and indications needed to perform the assigned MCR tasks. VDU displays are designed using the HFE processes described in Chapter 18, Subsection 18.3.5, and provide easy and simple navigation to available parameters and controls.

In the MCR concept, the SC1 workstation contains the necessary divisionally dedicated VDUs for each of the three SC1 divisions, for a total of six VDUs. The VDUs are divisionally separated so that information from one division does not populate VDUs of another division. Some VDUs are used primarily for monitoring parameters and overall system status indications and for use as a backup if a VDU becomes nonfunctional. Other VDUs are used primarily for controls and confirmatory indications that the control has been actuated, a control signal has been sent, and the control action is having the intended impact on the system. SC1 VDUs are controlled by a

touchscreen interface. Hardware and software-based controls are positioned in compliance with specified HFE design requirements and to preserve sufficient laydown areas for procedures.

The SC3 workstations will contain the necessary VDUs to support monitoring, control, and alarm management of all other plant functions. These VDUs are controlled by an appropriate number of wired keyboards and mouse interfaces. SC3 workstation VDUs are capable of displaying any provided plant and system information, as supported by the I&C architecture. These VDUs only allow for control of SC3 and Non-Safety categorized functions and does not allow more than one operator to control the same equipment at the same time. Non-SC1 VDUs allow for flexible use and are not divisionally separated or dedicated.

MCR SC3 workstation VDUs are sized and positioned in compliance with specified HFE design requirements for viewing angles for frequently used indications and alarms, to support readability, and to preserve line-of-sight to Group-View Display. The arrangement of the SC3 workstations in the MCR facilitates verbal communication.

The MCR SC3 workstations also contain a VDU (each with a mouse and keyboard input device) dedicated for business Local Area Network (LAN) and one of the SC3 workstations contain a VDU (with a mouse and keyboard input device) for the fire protection system. The business LAN has no connection to and is physically separate from the plant I&C networks. The SC3 workstation also contains space for communications equipment, procedure laydown, and administrative tasks.

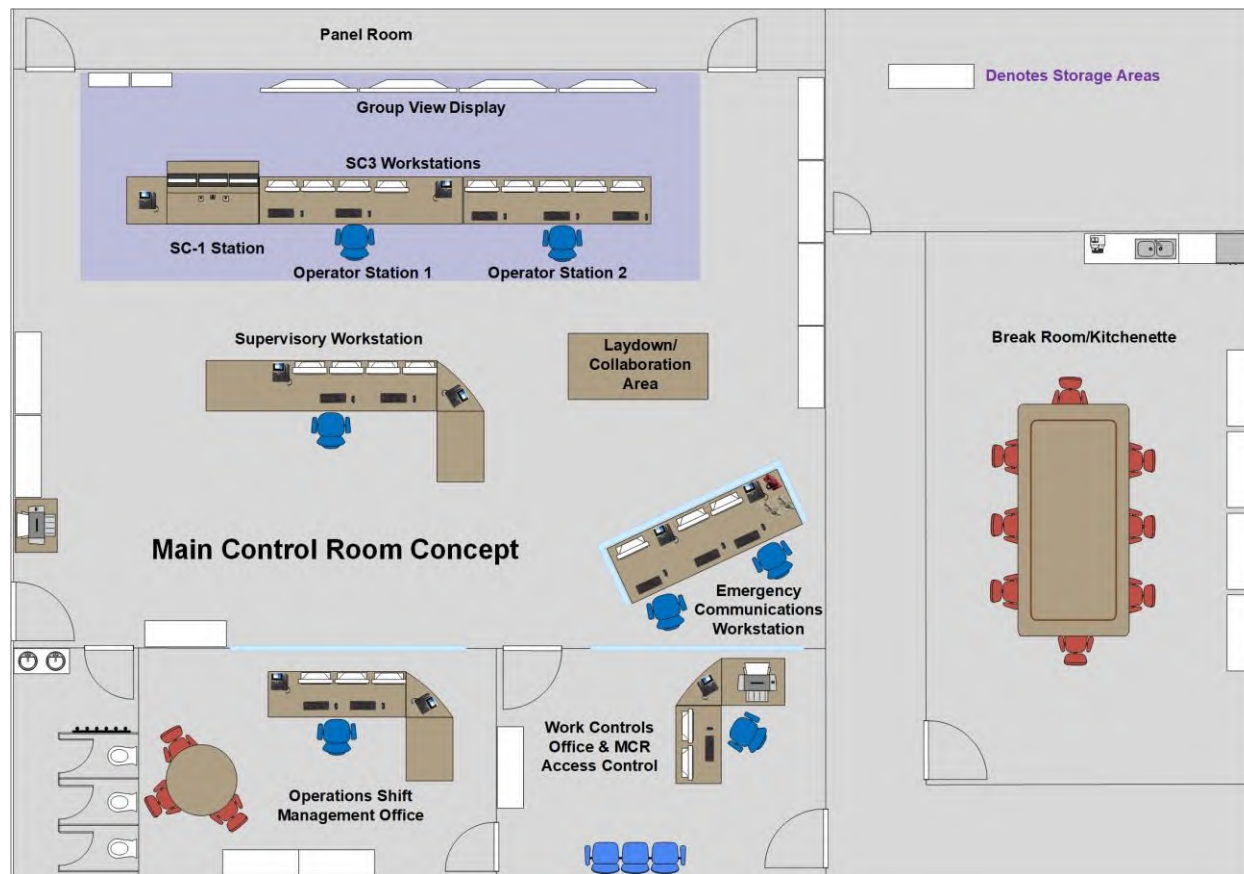

The MCR supervisory role workstation is implemented with SC3 equipment and designed with a work area is large enough to accommodate three seated people. The MCR supervisory workstation is located behind the SC3 workstation; it is suitably positioned to maintain a clear line-of-sight to the SC3 workstations and support verbal communication with the other workstations in the room. The supervisory workstation is also positioned to maintain a clear line-of-sight to the Group-View Display. The MCR supervisory workstation contains at least two VDUs with indications (no control) to monitor operations as they are being performed. The MCR supervisory workstation VDUs are controlled by a wired keyboard and mouse interface. The MCR supervisory workstation also contains two VDUs dedicated to the business LAN, as well as space for communications equipment, procedure and drawing laydown, and administrative tasks.

The MCR also contains an emergency communications workspace. The intent of the workspace is to allow designated personnel as required during events to communicate externally to the MCR, in such a way as to not disrupt the personnel focused on monitoring and controlling the plant in response to the event. The emergency communications workspace is located and designed with suitable provisions to minimize disturbance to the operating crew. The emergency communications workstation contains at least one VDU with indications (i.e., no control) from all Safety Class and Non-Safety Class systems for monitoring plant conditions. The emergency communications workstation also contains at least two VDUs to access the business LAN. The emergency communications workstation VDUs are controlled by a wired keyboard and mouse interface. VDUs are sized and positioned in compliance with specified HFE design requirements. The emergency communications workspace also contains space for all required communications equipment and administrative tasks.

## **7.6 Instrumentation and Control in Secondary Control Room**

In the current concept design, the SCR is located in the Reactor Building. The routes from the MCR to the SCR are described in Chapter 6, Section 6.4. The SCR includes the required HSI that enable operators to perform the defined set of functions required for responding to the identified plant events and conditions for which the MCR cannot be used.

The SCR is designed in accordance with current international best practice codes and standards for control room design, integrating results from HFE analyses and specified HFE design requirements as described in Chapter 18, Section 18.3.

### **7.6.1 Control Transfer Function**

The necessary MCR to SCR control transfer functions are located in a suitable location determined through HFE analysis, either in the SCR or accessible via the qualified access path. Access to the SCR is indicated by alarms in the MCR to ensure unauthorized access is detected. The SCR includes all HSI inventory required to maintain the plant in a safe state for scenarios requiring MCR evacuation.

The necessary MCR to SCR control transfer provisions ensure the availability of necessary HSI after MCR evacuation and access control when the SCR is not activated. Design features that prevent or mitigate spurious actuations due to fire are described in Chapter 9, Subsection 9A.6.6.

### **7.6.2 Secondary Control Room Use**

The SCR is utilized to perform the functions required to keep the plant in a safe state when the MCR is unavailable. The required functions are derived as a result of safety and HFE analyses.

The SCR includes suitable facilities for habitability and well as workspace for tasks to support required usage. The SCR contains a suitable supply of food and water. The SCR also contains adequate space and provisions for sleeping as required by the postulated scenarios in which it is used.

The SCR is designed to accommodate the expected staffing based on HFE staffing analysis for the expected usage conditions, as described in Chapter 18, Subsection 18.2.5. A suitable number of workstations are provided to support the specific task, communication, and work coordination needs for expected personnel.

### **7.6.3 Secondary Control Room Layout**

The layout of the workstations and HSI in the SCR provides the personnel with adequate information to assess the plant state and perform actions maintain the plant in a safe state, if required for the expected usage scenarios.

To reduce the likelihood of human errors and time needed to resume monitoring and control tasks within the SCR, the layout and HSI of the SCR are design to be consistent with the MCR to the extent possible, with differences driven by different purpose and user task needs.

The SCR operator workstation can accommodate two people. The SC1 workstation contains the required HSI to perform the functions expected to be performed in the SCR.

The SCR SC3 workstation section contains two VDUs to support monitoring, control, and alarm management. The SC3 workstation VDUs can display any provided plant and system information, as supported by the I&C architecture, but will only allow for control of SC3 and Non-Safety categorized functions. SC3 VDUs allow for flexible use and are not divisionally separated or dedicated. These VDUs are controlled by a wired keyboard and mouse.

SCR SC3 workstation VDUs are sized and positioned in compliance with specified HFE design requirements for viewing angles for frequently used HSI components. The SCR SC3 workstation suitably positioned to support effective verbal communication with the other workstations in the room. The SCR SC3 workstation also contains space for communications equipment, procedure laydown, and administrative tasks.

The SCR supervisory workstation is implemented with SC3 equipment and large enough to accommodate two people. The supervisory workstation is designed and positioned to maintain a clear line-of-sight to the SCR SC1 and SC3 workstations. The SCR supervisory workstation suitably positioned to maintain a clear line-of-sight to the SC1 and SC3 workstations and support effective verbal communication throughout the room. The supervisory workstation contains two non-safety classified VDUs to provide SPDS indications (i.e., no control) to monitor plant conditions, and a VDU or tablet is provided for business LAN connection. The business LAN has no connection to and is physically separate from the plant I&C networks. The SCR supervisory workstation also contains space for communications equipment, procedure and drawing laydown, and administrative tasks.

All VDUs are controlled by a wired keyboard and mouse interface except, where applicable or dictated by safety requirements. The SC1 VDUs will be a touchscreen type interface. If supplied, tablets are controlled by a touchscreen interface.

The SCR has an emergency communications workspace located and designed with suitable provisions to minimize disturbance to the operating crew. The emergency communications workstation contains VDUs or Wi-Fi-enabled tablets for connection to business LAN with at least one VDU with displaying SPDS indications (i.e., no control) to monitor and report externally on plant conditions. The emergency communications workspace also contains space for communications equipment, procedures, and drawings in support of performing administrative tasks.

## **7.7 Instrumentation and Control in the Emergency Response Facilities**

The BWRX-300 MCR is the primary location for plant monitoring and control during normal, abnormal, and most emergency conditions. The I&C capabilities in the MCR are described in Section 7.5. The SCR is utilized to perform the functions required to keep the plant in a safe state when the MCR is unavailable. The I&C capabilities in the SCR are described in Section 7.6.

The Emergency Preparedness and Response capabilities and associated facilities are described in Chapter 19. The Emergency Operations Centre (EOC) is located on-site near the control room. The Site Management Centre is located on-site, but outside of the protected area. It is provided for use by technical support staff and emergency support staff in the event of an emergency. The EOC and Site Management Centre contain the equipment necessary to display data needed in the facilities to analyze plant conditions. This facility is staffed with on-call teams of Emergency Response Organization personnel that can provide technical support.

An Emergency Response Facility (ERF) is located off-site and outside of the plume exposure planning zone. The SCR is utilized to perform the functions required to keep the plant in a safe state when the MCR is unavailable.

The plant information necessary to support overall emergency response from the MCR, SCR, EOC, Site Management Centre, and ERF is provided either directly via the Unit Data Highway or the Plant Data Highway unidirectional boundary device interface shown in Figure 7.2-1, depending on cyber security requirements and I&C requirements required for to each location.

The MCR emergency communications workspace contains space for communications equipment and administrative tasks. The plant communication systems are described in Chapter 9A, Section 9A.9.1.

## **7.8 Hazard Analysis for Instrumentation and Control Systems**

Hazards for the BWRX-300 I&C systems are addressed in five ways. First, specific system requirements are developed based on plant safety analysis (i.e., plant-level hazards), as described in Chapter 15. These are the actuation functional requirements implemented by DL2, DL3, and DL4a. Specific safety functions actions are mode dependent, as specified by the Mode Switch position shown for each function in Tables 7.3-1, 7.3-3, and 7.3-4. Second, specific hardware and software technology hazards for the digital I&C equipment (i.e., digital technology hazards) as addressed by system level failure modes and effect analyses performed using the methods described in IEC 60812 (Reference 7.8-1). Third, a rigorous development process, as described in Section 7.4, is used to minimize human errors during system development and operation (i.e., systematic hazards). Fourth, the I&C equipment is designed to provide protection against external and internal hazards, as described in Chapter 3, Sections 3.3 and 3.4. And fifth, the I&C equipment is qualified, as described in Chapters 3, Section 3.9, and Section 7.3.

## **8.0 ELECTRICAL POWER SYSTEMS**

This chapter describes the BWRX-300 plant electrical system and provides a description of the BWRX-300 electrical system requirements. Design Requirements, and details of the electrical systems as described in this chapter are derived from and are consistent with plant requirements, design decisions and assumptions documented in references listed in Section 8.8 below. The BWRX-300 Electrical Distribution System (EDS) design complies with Canadian national requirements as described in this document. In addition, provincial requirements within Canada vary and require evaluation for each provincial area.

The EDS architecture is a configuration of generators, busses, transformers, and load centers that supply power to the design loads. The design described in this document is for a 60 Hz Alternating Current (AC) power system, with 4.16 kV for the MV level and 600 Volts Alternating Current (VAC) for the Low Voltage (LV) level.

In addition to describing the electrical systems and associated requirements, this chapter includes plant one-lines that depict the switchyard, switchyard interface, and the MV and LV AC distribution systems, which includes the DC battery systems.

### **8.1 Description of the Electrical Power System**

The BWRX-300 EDS is an integrated power supply and distribution system for the power plant. Because of the integration, this architecture and requirements document describes the three plant systems that constitute the overall electrical system. The three plant systems are grouped based on safety classification.

The three plant systems have appropriate levels of hardware and software quality corresponding to the functions and systems receiving power. The systems provide reliable power to various plant functions (electrical loads) and provide an electrical pathway for the main generator to the utility switchyard/grid. The electrical systems are appropriately protected, monitored, recorded, and controlled by the plant operators. Various segments of the plant electrical system can operate independently.

Figure 8.8-1 depicts the main BWRX-300 plant electrical one-line that implements the above functions and classification and meets the requirements identified in Subsection 8.4.1 (note the Safety Class (SC) boundaries shown on Figure 8.8-1). The Safety Class 1 (SC1) EDS, Safety Class 2 (SC2) and 3 EDS, and Non-Safety Category (SCN) EDS are described in greater detail in the following sections.

#### **8.1.1 Licensing Requirements**

The BWRX-300 electrical system design meets the requirements of CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 8.8-8), Sections 7.10 and 8.9, and complies with the requirements except as indicated. The BWRX-300 electrical system is also designed to meet International Atomic Energy Agency (IAEA) requirements.

Although the BWRX-300 shutdown and heat removal functions can be initiated by active SC1 and SC2 and 3 control systems, loss-of-offsite and on-site electrical power, including battery-backed Uninterruptable Power Supplies (UPSs), automatically causes control rod insertion/plant shutdown and initiates decay heat removal. In any Design Basis Accident (DBA) and Beyond Design Basis Accident, electricity is required for monitoring, alarms, and communications. The heat removal functions can be provided actively by the Standby Diesel Generators (SDGs), which can operate autonomously for one week before requiring refueling.

Per CNSC REGDOC-1.1.2 (Reference 8.8-9), Section 4.5.10, the requirements specified in CNSC REGDOC-2.5.2 (Reference 8.8-8), Sections 7.10 and 8.9 are to be addressed. These requirements for the BWRX-300 electrical systems are discussed below.

#### **8.1.1.1 REGDOC-2.5.2 Section 7.10 Requirements**

CNSC REGDOC-2.5.2 (Reference 8.8-8), Section 7.10 defines requirements for safety support systems.

The BWRX-300 electrical system meets the requirements of CNSC REGDOC-2.5.2 (Reference 8.8-8), Section 7.10 with normal plant power provided via the main generator or offsite power, backup power provided via SDGs, and SC1 emergency power provided by UPSs. The electrical system is designed with sufficient capacity to meet load requirements to support Fundamental Safety Functions. The design incorporates an appropriate Defence-in-Depth strategy to ensure availability and reliability of the supported systems.

For BWRX-300, the SC1 EDS provides at least 72 hours of battery-backed AC and DC power, after which it is supported by the SDGs for at least one week, or alternatively, is supported by connection of portable generators. In a complete loss-of-offsite/generator AC power, batteries are charged via the SDGs or the portable generator connections while also powering the required loads for safety functions.

Capacity margin for the batteries is established by meeting the IEEE Std 485, "IEEE Recommended Practice for Sizing Lead-Acid Batteries for Stationary Applications" (Reference 8.8-20) battery age, temperature, and load margin requirements.

The emergency support systems have been designed to:

- Be independent of normal and backup system
- Support continuity of the Fundamental Safety Functions until long-term (normal or backup) service is re-established:
  - Without the need for operator action to connect temporary on-site services for at least eight hours
  - Without the need for offsite services and support for at least 72 hours
- Have a capacity margin that allows for future increases in demand
- Be testable under design load conditions, where practicable

#### **8.1.1.2 REGDOC-2.5.2 Section 8.9 Requirements**

CNSC REGDOC-2.5.2 (Reference 8.8-8), Section 8.9 defines requirements for electrical power systems.

As described in Subsection 8.4.2.2, the standby and emergency power systems are represented in the SC1 EDS and the SC2 and 3 EDS. The SC2 and 3 EDS encompasses the Defense Line 4A (DL4a) (SC2) and DL2 (Safety Class 3 (SC3)) components, and the SC1 EDS encompasses the DL3 (SC1) components. The design of these systems ensures sufficient capacity to support associated safety functions, and that availability and reliability of the system is commensurate with the safety significance of the connected loads.

The BWRX-300 electrical systems are designed to accommodate grid disturbances within the range of those shown to be possible by transmission operator studies at the point of interconnect. Such studies include maximum and minimum transient and steady-state grid voltages, available fault current, and consideration of the effect of geomagnetic induced currents resulting from coronal mass ejections. The design includes appropriate mitigations based on the results of

studies such as the application of automatic load tap changes, surge suppression, transformer zero sequence current monitoring, and blocking capacitors.

However, in contrast to the guidance of CNSC REGDOC-2.5.2 (Reference 8.8-8), the BWRX-300 design is not required to include two or more independent connections between the plant and the grid because the BWRX-300 plant does not require offsite electrical power to achieve safe shutdown, nor does it require any type of electrical power to protect the public from Severe Accidents. All SC1 power is provided by three divisions of SC1 batteries and UPSs. The batteries are sized for 72 hours, which allows for either of the two SC3 SDGs to start, external portable generators to be connected, or offsite power to be restored. Although the BWRX-300 is not committed to the requirement in the aforementioned regulatory documents that the plant have two offsite power sources, two sources of offsite power are typically used to improve reliability and operational flexibility, as shown in Figure 8.8-1 and Figure 8.8-9.

#### **8.1.1.3 REGDOC-2.5.2 Section 8.9.1 Requirements**

CNSC REGDOC-2.5.2 (Reference 8.8-8), Section 8.9.1 further defines design requirements for electrical power systems with a focus on standby and emergency power systems.

The BWRX-300 electrical systems are designed to meet CNSC REGDOC-2.5.2 (Reference 8.8-8) requirements for standby and emergency power systems. Although the BWRX-300 does not require any on-site or offsite AC power for safety, the permanently installed SDGs provide standby AC power and generally meet all requirements of the referenced section of the REGDOC. Restoring power as soon as possible is desirable. Following a plant Loss-of-Offsite Power (LOOP), the SDGs are expected (although not credited) to automatically start and achieve rated voltage and frequency within 30 seconds. The completion of automatic sequencing is expected (but not credited) to take no longer than two minutes. The permanently installed batteries provide the emergency power required for the SC1, SC2, and SC3 loads to meet plant needs for 72-hours. If offsite power is not restored, AC power is provided via the SDGs or via permanently installed external connections for use with portable generators.

#### **8.1.1.4 REGDOC-2.5.2 Section 8.9.2 Requirements**

CNSC REGDOC-2.5.2 (Reference 8.8-8), Section 8.9.2 further defines requirements for electrical power systems with a focus on DC and uninterruptible power systems.

The BWRX-300 electrical systems are designed to meet CNSC REGDOC-2.5.2 (Reference 8.8-8) requirements for DC and uninterruptible power systems. The BWRX-300 DC systems use two battery chargers, but only a single battery per division. The chargers are arranged such that one can carry the DC loads directly while the other applies an equalizing charge such that the loads do not have to be exposed to the equalizing voltage. It is important to note that this operational feature is optional and is not required to be used. Use of this feature removes the battery from the division. Additionally, the various DC loads are designed for equalizing voltages, if required.

Additional guidance in CNSC REGDOC-2.5.2 (Reference 8.8-8) recommends the uninterruptible power system include a normal AC supply to the inverter and a bypass AC supply with an automatic switchover. The BWRX-300 electrical system design takes exception to this guidance in the design of the SC1 EDS UPS system. While the divisional electrical systems use two redundant UPSs, the bypass line breakers are kept open, and automatic swap over to the bypass AC is not provided. The reason for operating without the bypass breaker closed is in response to the Forsmark event (U.S. NRC ML102070360, "Lessons from Forsmark Electrical Event" (Reference 8.8-10)).

**8.1.1.5 REGDOC-2.5.2 Section 8.9.3 Requirements**

CNSC REGDOC-2.5.2 (Reference 8.8-8), Section 8.9.3 defines requirements for electrical power systems with a focus on alternate AC power supplies.

The BWRX-300 electrical systems are designed to meet CNSC REGDOC-2.5.2 (Reference 8.8-8) requirements for alternate AC power supplies. Permanently installed electrical connections/disconnects are provided for connection of portable generators as required. On-site portable, transportable, or fixed power sources, or offsite portable or transportable power sources, or a combination of these, are provide for this purpose by the utility operator of the power plant.

## **8.2 General Principles and Design Approach**

### **8.2.1 General Principles**

The BWRX-300 is designed using conventional engineering design norms and analyses found in most all similar GEH BWR plants. Analysis techniques utilized are GEH proprietary but utilize standard conventional engineering design techniques. Thorough design analysis is performed to support the design document using approved methods. Design configurations are evaluated to ensure that compatibility with other design features are consistent, and do not create adverse conditions.

### **8.2.2 Electrical System Design Approach**

The BWRX-300 is designed using proven techniques for producing a safe and reliable nuclear power plant. The design approach is focused on safety, reliability, and quality. Specifically, the electrical system design approach considers the following:

1. The electrical system is designed to continue to provide its design basis function commensurate with its SC for the following primary initiating events:
  - a. Grid abnormalities including Grid Transients
  - b. (LOOP)
  - c. Station Blackout (SBO)
  - d. Anticipated Electrical Faults
  - e. Single Failure of SC electrical equipment

2. The impact of such events on the electrical system are described below:

- a. Grid Abnormalities Including Grid Transients

The Unit Auxiliary Transformer (UAT) and Reserve Auxiliary Transformer (RAT) contain automatic load tap changers. The load tap changers monitor the secondary voltage and adjust the transformer tap to maintain the distribution voltage at acceptable levels. For grid events that cannot be addressed by the load tap changers or other means, protective relaying isolates the preferred power source and the SC3 SDGs start and load on busses A21 and B21 as depicted in Figures 8.8-1 and 8.8-3.

- b. LOOP

For a LOOP the protective relaying isolates the preferred power source and the SC3 SDG start and load on busses A21 and B21. Redundant SDGs supply redundant load groups. SC3 equipment is directly supplied by the SDGs and associated busses. SC1 and SC2 equipment is indirectly supplied by the SDGs via battery chargers and UPSs. Each SDG is sufficiently rated to supply 100% of required SC loads for a minimum of seven days following a LOOP.

- c. SBO

During a complete loss of AC power including both SDGs, SC1 and SC2 equipment is served by SC1 and SC2 station batteries. Batteries are sized to provide 100% of the load of their associated SC for a period of 72 hrs. During an SBO event the SC1 power system is sufficient to support all DL3 safety functions for a period of 72 hrs.

d. Anticipated Electrical Faults

Anticipated electrical faults are selectively isolated by protective devices. Such isolation is accomplished by ensuring acceptable coordination between protective devices in accordance with the requirements of IEEE Std 308, "IEEE Standard Criteria for Class 1E Power Systems for Nuclear Power Generating Stations" (Reference 8.8-13), IEEE Std 242, "IEEE Recommended Practice for Protection and Coordination of Industrial and Commercial Power Systems (IEEE Buff Book)" (Reference 8.8-26), and IEEE Std 741, "IEEE Standard for Criteria for the protection of Class 1E Power Systems and Equipment in the Nuclear Power Generating Stations" (Reference 8.8-27).

Bus arrangement, load allocation, and equipment and cable separation ensures that for any single fault performance of the SC function will not be compromised.

e. Single Failure SC Electrical Busses and Components

SC busses and electrical equipment are designed to single failure criteria. The loss of any single bus, train or division will not compromise the ability to perform the SC function.

The electrical power system is designed for reliability. Key reliability design requirements include:

- The UAT and RAT are redundant and sized to carry 100% of the station load
- Medium Voltage (MV) busses and load allocation allow for the loss of any single bus without loss of power to SC busses while minimizing the impact to plant generation
- SC busses and equipment are redundant and physically separated

The SC1 power system is designed and procured such that a Common Cause Failure resulting in the loss of power to SC1 loads performing an active safety function is not credible. This is accomplished by:

1. SC1 power does not require offsite normal, or standby power sources to perform its function
2. The three divisions of SC1 power are physically and electrically separated in accordance with the requirements of IEC 60709, "Nuclear power plants - Instrumentation, control, and electrical power systems important to safety – Separation" (Reference 8.8-15) and IEEE Std 384, "IEEE Standard Criteria for Independence of Class 1E Equipment and Circuits" (Reference 8.8-29)
3. SC1 power system equipment and software is sufficiently simple, of limited functionality, analyzed per the requirements of IEC 62671:2013 Section 7.3, and procured tested commensurate with the requirements of its SC

The portions of the electrical system credited with a safety function are organized by Defense Line and SC. A description of the different electrical system SCs including voltages and divisions is provided in other sections of this chapter.

SC systems design is demonstrated to be adequate to perform its function by ensuring compliance with design criteria through design review, analysis and final system testing and commissioning.

The electrical system is designed with spare capacity to support modifications and upgrades typically expected during the life of the station.

### **8.3 Offsite Power Systems**

Electric power from the utility grid to the plant on-site power system is provided by two preferred power circuits. The transmission system serves the main offsite power circuit (Normal Preferred Power), and the reserve offsite power circuit (alternate preferred power).

The BWRX-300 switchyard design is customer dependent, but the plant design allows significant flexibility. Because of the passive safety design of the BWRX-300 plant, only a single preferred power feed between the plant and switchyard is required. Therefore, the utility is only required to provide one transmission line to the BWRX-300 switchyard from offsite sources. However, two sources of offsite power are typically used to improve reliability and operational flexibility, as shown in Figure 8.8-7.

For Canadian applications, connection of the plant to the grid with only a single transmission line is consistent with the guidance of CNSC REGDOC-2.5.2 (Reference 8.8-8), for passive plants.

#### **8.3.1 Safety and Equipment Functions**

The offsite preferred power system is designed to provide a continuous source of power to the on-site power system throughout plant startup, normal operation (including shutdown), and abnormal operations. The offsite power system provides no credited safety function. As a result, the total LOOP results in no impact on nuclear safety.

#### **8.3.2 Safety Design Bases**

The BWRX-300 safety design does not require offsite power to be present to mitigate any DBAs and therefore has no safety design basis.

#### **8.3.3 Description**

A local switchyard will be built to consolidate power output from the BWRX-300 Small Modular Reactor (SMR) Facility and connect it with Ontario electrical power grid.

The local switchyard will be operated via the Main Control Room (MCR) in the SMR Facility. The SMR Facility has two high-voltage connections with the local switchyard at a 230kV voltage level. One line to output power from the Generator Step Up Transformer (GSU) and one line to supply the RAT. The local switchyard has two redundant 230kV connections with the transmitter.

The local switchyard is an indoor Gas Insulated Switchgear type, following a breaker and half arrangement with two redundant busses. The local switchyard is designed to have local and remote-control capability. The plan for the local Darlington New Nuclear Project switchyard is that is located North of the SMR Facility, East of the Extended Holt Rd and South of the CN Rail tracks. The local switchyard control and protection designs are coordinated with the SMR Facility controls and protections to meet IESO, NPCC and NERC codes and standards.

##### **8.3.3.1 Design Requirements for the Offsite Power Systems**

The offsite power system is designed to provide a continuous and reliable source of power to the on-site power system throughout plant startup, normal operation (including shutdown), and abnormal operations.

The switchyard, to which the main offsite circuits are connected, has two full-capacity main busses.

The switchyard main busses are designed such that any circuit breaker can be isolated for maintenance without interrupting service to any circuit.

Circuit breakers used in the switchyard and connected to the BWRX-300 plant are sized and designed in accordance with IEEE Std C37.06, "IEEE Standard for AC High-Voltage Circuit

Breakers Rated on a Symmetrical Current Basis – Preferred Ratings and Related Required Capabilities for Voltages Above 1000V” (Reference 8.8-28).

Disconnecting switches used in the switchyard and connected to the BWRX-300 plant are sized and designed in accordance with IEEE Std C37.30.1, “IEEE Standard Requirements for AC High-Voltage Air Switches Rated Above 1000 V” (Reference 8.8-11).

#### **8.3.4 Materials**

Materials are expected to be suitable and compatible for use in the switchyard environment. Appropriate Canadian standards (including any Canadian provincial standards) and appropriate international standards are met. The switchyard is a typical switchyard design with commercially available equipment designed for this type of service.

#### **8.3.5 Interfaces With Other Equipment or Systems**

Interfaces with the switchyard are hard I/O with no network connections.

The offsite power system connects to the plant through two transmission lines, one connected to the GSU and one connected to the RAT. Switchyard monitoring parameters available in the MCR include breaker position, voltages, currents, power, and alarms.

The AC and DC power required by the switchyard equipment are separated from plant on-site power systems.

#### **8.3.6 System and Equipment Operation**

Switchyard breakers for the plant connections include design features that allow for remote operation by the plant operators.

#### **8.3.7 Instrumentation and Control**

Switchyard Instrumentation and Control (I&C) is provided in the MCR to monitor and control the breakers that interface with the plant.

#### **8.3.8 Monitoring, Inspection, Testing, and Maintenance**

Monitoring of the offsite power system (i.e., switchyard parameters) (and the switchyard breakers) is made available to the plant operator and the grid operator through separate communication systems. Switchyard monitoring parameters available in the MCR include breaker position, voltages, currents, power, and associated alarms.

Most inspections are primarily visual or infrared but individual breakers can be isolated for more intrusive inspections if needed.

Required electrical system testing is governed by industry standards. The electrical systems are designed to allow required tests to be performed with minimal disturbance to the balance of the system. Specific steps and alignments necessary for the successful performance of testing are to be controlled by plant procedures.

The switchyard system has been designed to be upgraded if necessary, using conventional techniques for upgrading software, or upgrading equipment. Replacement of major equipment (transformers, Breakers, etc.) could require a significant outage to repair/modify/replace the equipment. The switchyard main busses are designed such that any circuit breaker can be isolated for maintenance without interrupting service to any circuit.

#### **8.3.9 Radiological Aspects**

The offsite electrical systems are not normally exposed to radiological environments. Accident doses are expected to be within the normal range of operating envelope (refer to Chapter 3, Section 3.9 for environmental conditions).

#### **8.3.10 Performance and Safety Evaluation**

While there are no safety functions for the offsite power system function, the offsite power systems provide net 300 MW of power to the grid and utilizes offsite power to power plant loads during normal and abnormal operating conditions. Therefore, no performance or safety evaluation is unnecessary. As stated previously, the total LOOP results in no impact on nuclear safety.

## **8.4 On-site Power Systems**

### **8.4.1 On-site Alternating Current Power Systems**

#### **8.4.1.1 System and Equipment Functions**

The on-site AC power system starts at the GSU and RAT Motor Operated Disconnects (MODs) and transitions from there to include the GSU, the main generator, the main generator circuit breaker, the UAT, the RAT and the rest of the plant AC distribution as depicted on Figure 8.8-1.

The on-site power system includes four 4.16 kV MV busses A1, A2 and B1, B2. The normal Preferred Power Supply (PPS) is connected through the UAT to busses A2 and B2. The alternate PPS is connected through the RAT to busses A1 and B1 and serves as backup to the UAT.

The A1 and B1 MV busses are normally supplied by A2 and B2 busses during power operation and provide SCN power required for unit operation.

The A2 and B2 MV busses supply power to LV 600VAC SC3 load centers A21 and B21. The A21 and B21 LV busses can be aligned to the alternate PPS via MV busses A1 and B1.

Both A21 and B21 have dedicated and physically separated SDGs.

The MV AC power level is 4.16 kV and the LV AC power level includes 600VAC, 240/120V and 208/120V.

In addition to providing normal AC power to SC1 electrical equipment, the SC3 AC electrical power system is designed to power both SC2 and SC3 loads. These loads and additional SCN plant investment protection loads are fed from the 600 VAC SC3 A21 and B21 LV busses. The A21 and B21 LV busses are configured as illustrated on Figure 8.8-3. The A21 and B21 LV busses are in fire-barrier separated rooms.

The A21 and B21 LV busses can be supplied by one of two upstream MV busses as shown in Figure 8.8-1. The normal preferred power source is via the UAT and GSU. The alternate preferred power source is via RAT by direct connection to the switchyard. The A21 and B21 LV busses are normally aligned through the MV busses to separate windings of the UAT. The A21 LV bus is normally supplied by MV Bus A2 connected directly to the UAT. The alternate supply to A21 via bus A1 is normally open via the associated A21 main breaker. The B21 LV bus is normally aligned in a similar configuration. In this configuration, faults on MV busses A1 and B1 do not remove power from the MV busses A2 and B2, comprising the normal supply to A21 and B21.

In addition to the preferred power sources from the SCN electrical power system, the A21 and B21 LV busses can also be supplied by SC3 SDGs. The SC3 SDGs are electric start and radiator cooled and do not require plant mechanical support services for operation. Either of the SDGs has sufficient capacity to support all SC1 loads (three divisions) and SC2 and SC3 loads (i.e., either SDG can support active decay heat removal). There is on-site fuel storage for each SDG for at least a week of full power at rated load. Refer to Chapter 9, Subsection 9A.7.3 (Description - Fuel Storage and Transfer System) and Chapter 3, Section 3.8 (General Design Aspects for Electrical Systems and Components).

The A21 and B21 LV SDG backed busses are in separate fire-barrier separated rooms. The A21 and B21 LV SDG backed busses and associated SDGs are located as close as reasonably possible to each other.

A21 and B21 busses provide normal power to the following SC1 and SC2 critical loads:

- SC1 UPSs and battery chargers
- the SC2 LGs
- SC2 supply Fine Motion Control Rod Drive (FMCRD) UPSs

A21 and B21 and derivative busses, SDGs, digital protection relays, and other components are designed, selected, and qualified to the applicable requirements of SC3 or SC2 as applicable

The loads assigned to the SC2 UPSs and battery chargers are required for the BWRX-300 to achieve cold shutdown, and include the power equipment that provides a diverse, active alternative to SC1 vessel injection and vessel and containment heat removal functions.

During a LOOP, the SC3 busses are automatically powered by the associated SDG. The SDG supply breakers to the SC3 busses are interlocked with the normal offsite source breakers to prevent the undesired paralleling of sources, while allowing periodic SDG testing by synchronizing to and loading into either normal power feed.

#### **8.4.1.2 Safety Design Basis**

The BWRX-300 has two connections to the switchyard. The normal preferred power source is connected to the primary side MODs of the GSU; the secondary side of the GSU is connected to the main generator breaker and includes a branch to the UAT of the plant. The alternate preferred power source is connected to the MODs at the RAT primary side. The UAT and RAT secondaries are connected to the plant MV busses. The on-site power systems are not designed to perform any safety functions to mitigate a DBA. The batteries are designed to provide power to post accident monitoring equipment to the control rooms for at least 72 hours.

#### **8.4.1.3 Description**

As discussed previously, the BWRX-300 has two connections to the switchyard. The normal preferred power source is connected to the primary side MODs of the GSU; the secondary side of the GSU is connected to the main generator breaker and includes a branch to the UAT of the plant. The alternate preferred power source is connected to the MODs at the RAT primary side. The UAT and RAT secondaries are connected to the plant MV busses. The configuration is shown in Figure 8.8-1.

The GSU provides transmission of the main generator output to the grid when the plant is online and can provide power to the plant when the main generator is offline via backfeed. When the generator breaker is closed and the plant is synchronized with the grid, the generator gross power output is approximately 300 MWe. When the generator breaker is opened, the switchyard can “backfeed” power to the plant through the GSU and the UAT. The UAT is sized to support 100% of the plant normally operating power generation SCN loads and SC (SC1, SC2, and SC3) loads. The UAT is protected by breakers on both the primary and secondary side. Protection is provided for fault conditions and includes both transient and steady-state overvoltage protection. If a UAT fault occurs, the primary side breaker opens to prevent drawing fault current from the main generator and the grid.

The RAT interface provides an alternate power path from the grid to the plant power distribution system. Like the UAT, the RAT is sized to support 100% of the plant normally operating power generation and SC loads. The purpose of the alternate preferred power source is to provide operational flexibility and reliability to the system. For example, in the event of a failed UAT during power operation, the system isolates the failed UAT and automatically fast transfer to the RAT while the plant continues to operate providing power to the switchyard.

Although the plant transformers are to be monitored by a condition monitoring system, it is expected that the transformer life is approximately 30 years. The design specifically supports changing the transformer during a long outage in 25 – 30 years before the transformer end of life.

The UAT and RAT are equipped with automatic load tap changers that assure the plant busses maintain nominal voltage under all grid or main generator voltage conditions and when the house loads change from power operation to outages. All other on-site transformers in load centers have manual tap changers. However, after initial setup, these should not have to be readjusted.

Figure 8.8-6 depicts the A1 and B1 MV bus configuration for the SCN EDS. The bus configuration and load allocation are such that these busses can be shut down for maintenance during outages and can be shut down one at a time in normal operation while minimizing the impact to plant power generation.

With the plant online providing power to the switchyard, the MV busses A1, A2, B1, and B2 busses are normally aligned to the UAT. With the plant offline, the MV busses are normally aligned to the RAT. The MV busses could also be aligned to the RAT during power generation, either manually or via fast transfer. Another possible alignment is with the plant offline supplying power to the MV busses via the UAT and GSU with the generator breaker open in a backfeed configuration.

The MV busses A1, A2, B1, and B2 protective relays are designed to automatically fast bus transfer between the UAT and the RAT. The fast bus transfer is automatically initiated on loss of power to busses A2 and B2, a faulted circuit in the normal PPS, and on a unit trip. The intent of this automatic action is to minimize the potential for a loss of power to the plant EDS and to minimize entrance into the backfeed operation alignment. The transfer logic is configured in such a way that it only occurs if power is available from the RAT. This prevents a transfer to a dead source. Additionally, to avoid the possibility of cycling between the normal and alternate preferred source, the fast bus transfer is one-directional (i.e., there is no possibility of an automatic transfer from the alternate preferred to the normal preferred source).

#### ***8.4.1.3.1 System Design Requirements for On-site AC Power***

The generic system design requirements for the AC electrical systems are listed below:

1. The LV AC distribution systems are solidly grounded.
2. Load assignments within the plant electrical systems are evenly distributed between the MV busses, to the extent practical, to maintain a reasonable load balance on the UAT and RAT secondary windings.
3. Current-carrying cables in the plant electrical systems are qualified to meet the IEEE Std 383, "IEEE Standard for Qualifying Electric Cables and Splices for Nuclear Facilities" (Reference 8.8-21) requirements for cables and splices for nuclear facilities.
4. The EDS equipment can perform required safety functions when exposed to worst-case environmental conditions of the applicable room/building.
5. The equipment and components in the plant electrical systems are classified to the seismic category appropriate for the safety classification and location of the system.
6. The equipment and components in the plant electrical systems are mounted to maintain the applicable seismic qualification.
7. Standby lighting with a Safety Category 1, 2, or 3 function are powered from busses backed by a standby power source of the same (or higher) safety classification.
8. Normal lighting is powered from the SCN power generation busses to the extent practical.

NEDO-33957 REVISION 0  
NON-PROPRIETARY INFORMATION

In addition to the generic system design requirements listed above, the following design requirements are applicable for the SCN EDS:

1. The UAT is sized to support 100% of the station loads for the worst-case operating scenario.
2. The UAT has a dedicated circuit breaker connected to the primary winding.
3. The UAT includes two secondary windings, both rated at 4.16 kV.
4. The UAT winding configuration is a Delta primary, with two Wye connected secondaries, connected such that high voltage (HV) winding Leads the LV winding by 30 degrees, as described in in IEEE C57.12.00 -2021.
5. The UAT Wye windings neutral bushings are low resistance grounded, as defined by IEEE 142-2007.
6. The UAT includes an automatic load tap changer, with a sensing voltage corresponding to the average voltage of the secondary feeds.
7. The main generator circuit breaker is sized and designed in accordance with IEEE/IEC 62271-37-013-2021.
8. The GSU is comprised of three in-service, single-phase transformers, with one installed single-phase, spare transformer.
9. The installed spare transformer for the GSU is maintained ready for operation with support systems powered such that it can be placed into service within a few days.
10. The GSU winding configuration is a generator connected Delta, with a switchyard connected Wye, connected such that HV winding lagging the LV winding by 30 degrees, as described in IEEE C57.12.00-2021.
11. The GSU Wye windings neutral bushings are solidly grounded.
12. The RAT is sized to support 100% of the station loads for the worst-case operating scenario.
13. The RAT has a dedicated MOD connected to the primary winding.
14. The RAT includes two secondary windings, both rated at 4.16 kV.
15. The RAT winding configuration is a Wye primary, with two Wye connected secondaries.
16. The RAT primary winding neutral bushing is solidly grounded.
17. The RAT secondary Wye windings neutral bushings are low resistance grounded as defined by IEEE 142-2007.
18. The RAT includes an automatic load tap changer, with a sensing voltage corresponding to the average voltage of the secondary feeds.
19. SCN EDS MV busses are used to supply SCN loads required exclusively for power generation.
20. Fast bus transfer between the normal and alternate preferred power source is initiated when bus voltage is lost to the A2 and B2 busses, during a faulted normal preferred power circuit, and during a unit trip.
21. The fast bus transfer is sufficiently fast to prevent downstream loads from dropping off the bus.

NEDO-33957 REVISION 0  
NON-PROPRIETARY INFORMATION

22. The fast bus transfer logic prevents transfer to a dead bus.
23. The fast bus transfer is one-directional from the normal preferred source to the alternate preferred source.
24. Unit substation transformers winding configuration is Delta primary to Wye secondary.
25. Unit substation transformers secondary Wye winding is solidly grounded.

In addition to the generic system design requirements listed above, the following design requirements are applicable for the SC2 and 3 EDS:

1. Provides redundant LV power feeds to each SC1 division, with each feed designed to provide the full power of the respective division
2. Two SDGs provide backup power to the LV A21 and B21 busses for plant mechanical systems, investment protection, and the plant DCIS
3. Each SDG is sized to supply 100% of the required SC1 divisional loads in all three divisions while also supplying power to the required SC2 and SC3 loads during a LOOP event
4. The SDGs provide adequate voltage and frequency regulation during load sequencing and steady-state conditions
5. The SDGs can accept a step change corresponding to the size of the largest load and remain within frequency and voltage limits
6. The SDGs are controllable from the MCR, the Secondary Control Room and locally
7. Once started, SDGs are capable of synchronizing to the plant electrical system for test purposes
8. The SDGs operate without requiring any plant services other than fuel, with the capability of continuous operation for at least one week without any offsite resources
9. The SDGs incorporate protective relaying for protection and control

The on-site AC power systems have appropriate levels of hardware and software quality corresponding to the functions and systems receiving power. The systems provide reliable power to various plant functions (electrical loads) and provide an electrical pathway for the main generator to the utility switchyard/grid. The electrical systems are appropriately protected, monitored, recorded, and controlled by the plant operators. Various segments of the plant electrical system can operate independently.

#### **8.4.1.4 Materials**

Materials to be used are specified and evaluated by GEH for design and commissioning. OPG is responsible for any changes following commissioning and operation. Materials are expected to be suitable and compatible for use in the environment. Appropriate Canadian standards (including any Canadian provincial standards) and appropriate international standards are met. The design utilizes materials typical for this type of service with commercially available equipment.

Materials are associated with the SC of the individual systems. Structures, Systems, and Components (SSC) are evaluated based on the SC and functions. Materials are evaluated and selected based on the environmental conditions and SC of the equipment as discussed in environmental conditions and SC of the equipment as discussed in Chapter 18.

#### **8.4.1.5 Interfaces With Other Equipment or Systems**

The on-site AC power system, interfaces primarily with the following:

1. The Offsite AC Power System
2. The On-site DC Power Systems
3. Plant loads requiring SCN and SC3 power.

The SC3 SDGs are electric start and radiator cooled and do not require plant mechanical support services for operation (such as plant auxiliary cooling or instrument air). Either of the SDGs can support all the SC2 and 3 EDS loads and SC1 EDS loads (three divisions) that require power for completion of Safety Category 1, 2, and 3 functions (i.e., either SDG can support active decay heat removal). There is on-site fuel storage in large storage tanks and day tanks for each SDG. The large storage tanks hold enough fuel for at least seven days of full power operation of the SDGs at rated load. The local day tanks are in addition to the seven-day supply of fuel to support online testing; the day tanks alone provide up to eight hours of full power operation at rated load.

The most important loads on the A21 and B21 busses are the SC1 EDS UPS, battery chargers, and Regulating Voltage Transformers (RVTs). Next in line as a matter of importance are the SC2 EDS LGs that provide power to the SC2 UPSs, battery chargers, and RVTs. Along with the two SC2 EDS LGs, the four FMCRD UPSs are of high importance.

#### **8.4.1.6 System and Equipment Operation**

The normal preferred power source to the plant is via the UAT which is connected to the GSU and the Main Generator. The alternate preferred power source is via the RAT, which is directly connected to the switchyard. With the plant online, the MV SCN busses, and therefore the A21 and B21 LV busses, are normally aligned to the normal preferred power source through separate windings of the UAT. With the plant offline, the MV SCN busses and therefore the A21 and B21 LV busses are aligned to the alternate preferred power source through separate windings of the RAT.

In addition to the typical alignments previously described, it is also possible to align the A21 and B21 busses to the alternate preferred power source through separate windings of the RAT during power operation. This could be accomplished manually via operator actions or automatically via an MV fast bus transformer, such as would occur during a faulted UAT scenario. Finally, with the plant offline, the A21 and B21 busses can be aligned to normal preferred power source through separate windings of the UAT with the Main Generator Breaker open in a backfeed alignment through the GSU. All transfers between the normal preferred power source and the alternate preferred power source occur at the MV busses.

The SC2/SC3 EDS provides power to SC1, SC2, SC3, and SCN loads as needed. SC3 SDGs are utilized as needed to supply power to SC1, SC2, SC3, and SCN functions. However, this power is not needed to support plant shutdown or cooldown functions as previously noted.

#### **8.4.1.7 Instrumentation and Control**

The BWRX-300 on-site AC power systems are to be monitored and controlled by DCIS equipment of a corresponding safety classification. Generally, the DCIS control systems are expected to operate and monitor the plant transformers and feeder breakers, including load breakers for pumps, adjustable speed drives, or other plant equipment.

#### **8.4.1.8 Monitoring, Inspection, Testing, and Maintenance**

If electrical equipment is found to be inoperable or failing, operators would be alerted, and an inspection of the equipment would be initiated. operators would make the decision based on inspection to replace or repair or monitor the equipment for any further degradation.

The design of the plant electrical systems accommodates online testing and inspection to the extent practical. Condition monitoring equipment is included where appropriate.

For the SC2 and SC3 EDS, periodic starting and loading of the SDGs is expected to be required by plant technical specifications. For the SCN EDS, there are no technical specification surveillance requirements.

To the extent practical, the design of the plant electrical systems includes the capability to isolate, maintain, and test individual components and equipment while the plant is online.

Nuclear power plant commissioning usually involves three types of testing, in order of plant completion:

- Construction tests
- Pre-operational tests
- Startup/power ascension tests

The first two test types may overlap, but the last test type requires that the first two be completed before fuel loading is allowed. The plant electrical system is to be involved in all testing but note that no significant plant testing can be done until the plant electrical system is operational. In this context, "operational" implies that the system powers mechanical loads that need testing and power the plant DCIS loads needed to monitor, control, and record the plant systems to be tested. This implies that the plant electrical system should be among the first operational installed systems:

- The design on the on-site AC power systems include provisions for connection to construction power.
- The plant electrical system switchgear and distribution equipment include access points in the front, back, and sides as needed to support efficiency in constructability.

Where possible, it is intended to purchase electrical components that do not require maintenance for a 60-year plant lifetime. The large BWRX-300 plant transformers (GSU, UAT, and RAT) have a realistic 30-year lifetime. Condition monitoring of the transformers and other important equipment is provided to assist in determining appropriate maintenance and replacement intervals.

NOTE: The transformers are expected to be conservatively rated to reduce heat and maximize longevity.

The BWRX-300 plant is designed to meet a 60-year design life assuming required maintenance, operational program requirements, and equipment replacements, as needed, are accomplished. Replacement frequencies follow manufacturer guidance and in combination with available monitoring data if available.

#### **8.4.1.9 Radiological Aspects**

The on-site AC power system is qualified for the safety function, SC and corresponding locations as discussed in Chapter 3, Section 3.9, Environmental Qualification.

#### **8.4.1.10 Performance and Safety Evaluation**

The on-site AC electrical power system is expected to perform their design functions in normal and abnormal conditions. The reliability of items important to safety is to be commensurate with its safety significance.

### **8.4.2 On-site Direct Current Power Systems**

#### **8.4.2.1 System and Equipment Functions**

The on-site direct current power system is divided into three subsystems with three safety classes, SC1, SC2 and SCN. The system and equipment functions are described below:

- SC1 Direct Current Power System

The SC1 DC power system powers the SC1 DCIS equipment responsible for automatic shutdown and decay heat removal. The SC1 DCIS safety functions are typically executed in a fail-safe manner through removal of power. The SC1 EDS is a DL3 system limited to only supply power to SC1 SSC.

- SC2 Direct Current Power System

The loads assigned to the SC2 UPSs and batteries are those required for the BWRX-300 to achieve cold shutdown and include the equipment that provides a diverse, active alternative to SC1 vessel injection and vessel and containment heat removal functions. The SC2 DC power system is a DL4a system.

- SCN Direct Current Power System

The SCN DC power system is designed to provide power to SCN DC loads, such as protective relaying and breaker control power.

#### **8.4.2.2 Safety Design Bases**

The safety design basis criteria are provided below for each of the three direct current subsystems.

- SC1 Direct Current Power System

- The design of the SC1 DC system conforms to the applicable requirements given in IEEE Std 308 (Reference 8.8-13) and IEEE Std 603, "IEEE Standard Criteria for Safety Systems for Nuclear Power Generating Stations" (Reference 8.8-29).
- The SC 1 batteries meet the qualification requirements of IEC/IEEE 60780-323, "IEC/IEEE International Standard - Nuclear facilities -- Electrical equipment important to safety – Qualification" (Reference 8.8-17) and IEC/IEEE 60980-344, "IEEE/IEC International Standard - Nuclear facilities - Equipment important to safety - Seismic qualification" (Reference 8.8-18).
- A single failure in the SC1 EDS that results in a loss of any single divisional AC output shall not result in loss of both AC outputs within that division SC2 Direct Current Power System.
- The SC1 EDS batteries shall have enough stored capacity without chargers to independently supply loads continuously for at least 72 hours with a minimum final discharge voltage sufficient to support the associated loads.
- Each of the SC1 EDS UPSs shall be able to supply 100% of the divisional load.

- The SC1 EDS divisions shall be electrically separate such that no electrical connection exists between a UPS in one SC1 EDS division and a component in another SC1 EDS division.
- SC2 Direct Current Power System
  - The SC2 EDS batteries shall have enough stored capacity without chargers to independently supply loads continuously for at least 72 hours with a minimum final discharge voltage sufficient to support the associated loads
- SCN Direct Current Power System

SCN systems provide no safety function.

#### **8.4.2.3 Description**

The on-site direct current power system description for each of the three subsystems is provided below:

- SC1 Direct Current Power System

Figure 8.8-2, Safety Class 1 Low Voltage Uninterruptible Power Supply Systems represents a typical design of each of the three SC1 EDS divisions. As shown in the main electrical one-line in Figure 8.8-1, and the SC2 and 3 EDS one-line in Figure 8.8.2, the SC2 and 3 EDS provides separate feeds from an SC3 LV bus to the three divisions of the SC1 EDS equipment. Each division can be continuously energized from multiple sources: offsite power (normal supply), standby diesel generator power (backup supply), portable generator power (external building connections), or individual division battery power (emergency supply). Independent of offsite or diesel AC power, the SC1 batteries in the SC1 EDS provide backup power for at least 72 hours for monitoring and mitigation loads required following a loss of AC power event. The 72-hour requirement is consistent with the overall plant design basis and regulatory requirements to preclude the need for AC power for 72 hours, while mitigating the effect of a DBA. The external connections provide for connection of EME/FLEX as needed.

Each SC1 division has its own battery and two redundant UPSs. The two UPSs in each division are primarily for the SC1 DCIS system to provide redundant divisional power feeds. Loss of any individual divisional UPS still allows the DCIS of that division to function. Therefore, reliability is enhanced with the redundant UPSs that provide power to each division of the DCIS. In addition, all UPSs normally operate directly from AC power, allowing the batteries to be fully tested without losing the divisional outputs (albeit the 72-hour coping time is unavailable from the battery in test during that time).

While each SC1 divisional electrical system uses two redundant UPSs, the RVT is de-energized in the normal system lineup and must be manually placed into service. This means automatic swap over to the UPS bypass AC source is not provided, as required by IAEA SSG-34, "Design of Electrical Power Systems for Nuclear Power Plants" (Reference 8.8-22) and the guidance of REGDOC-2.5.2 (Reference 8.8-8). The reason for operating without automatic swap over to the bypass power is to mitigate the Forsmark event (U.S. NRC ML102070360 (Reference 8.8-10)). In that event, electrical transients starting in the transmission system traveled through the plant electrical system and consequently disabled the SC1 inverters. The BWRX-300 battery chargers, UPSs, and RVTs are hardened against such an event with TVSSs on the AC input lines. While the TVSSs are designed to prevent HV spikes from being transferred through the EDS, transients could

NEDO-33957 REVISION 0  
NON-PROPRIETARY INFORMATION

still disable the UPS. The intent of an automatic swap over to the UPS bypass RVT is to maintain the required divisional output should the UPS inverter fail. With the BWRX-300 design, the second UPS in each division serves the same purpose as the automatic swap over to an RVT. However, the second UPS comes with the added benefit that it is already in service, and it is fed from a different power source.

Each SC1 UPS has a separate output bus (distribution panel) for distribution of AC power. Use of a Manual Transfer Switch (MTS) in the UPS output circuit isolates the UPS output from the loads when the RVT is placed in service. In this configuration, the RVT directly powers the respective UPS distribution panel and maintenance or testing of the UPS can be done online without disturbing UPS loads. The AC power supplied through the UPS bypass RVT would be powered from either the SDG backed busses or the portable generator connections.

There are two battery chargers per SC1 division. Each battery charger has the capacity to power all safety functions for the division. The redundant battery chargers and bus configuration are arranged to provide operational flexibility to the system.

The two UPSs per SC1 division provide a single-phase 230 VAC output. The higher voltage was chosen to reduce voltage drops between the UPSs and SC1 loads. The batteries produce 250 VDC (nominal) power connected to a DC distribution bus in each division. The DC distribution bus provides the DC input to the UPSs and to remote DC power panels where needed.

Each SC1 UPS distribution panel feeds multiple power panels to provide redundancy from each division. The power panels ultimately feed the individual SC1 loads. Where required, the UPSs are protected at the individual load level with current limiting fuses such that the resulting fault currents are within the transient rated current capability of the inverter. Individual faults have no effect on other loads on the same power panel. All SC1 DCIS components are redundantly powered from the SC1 EDS divisional UPSs. Loads with the ability to accept only a single supply supplied by a single feed in line with an automatic transfer switch with input separately derived from the two UPS. Therefore, failure of one divisional UPS has no adverse effect on plant operations or safety.

Each of the SC1 divisional electrical systems provide DC power and uninterruptible AC power where needed for SC1 loads. Most SC1 loads are located throughout the RB but can also be located in other areas of the plant like the MCR in the CB.

All SC1 EDS batteries and electrical switchgear components in the RB are in separated rooms that are fire and flood-barriered from each other by division. The SC1 components and equipment in these areas are qualified to environmental and seismic conditions such that no active equipment is needed to maintain or support normal operation or credited post AOO or accident coping period.

The Division 1 and Division 2 electrical system configurations of the SC1 EDS are identical. The Division 3 electrical system configuration has slightly less load. A small selection of loads is allocated only to Division 1 and 2 as described in Chapter 7, Instrumentation and Control. Each division is designed to the maximum load and mission time of the three divisions

- SC2 Direct Current Power System

Figure 8.8-3, Safety Class 3 Low Voltage Busses A21 and B21, depicts the SC3 A21 and B21 LV bus configurations and typical SC2 and 3 EDS loads.

NEDO-33957 REVISION 0  
NON-PROPRIETARY INFORMATION

Figure 8.8-4, Safety Class 2 Low Voltage Uninterruptible Power Supply Systems, depicts the SC2 EDS MCCs for LG A and LG B, with the battery and battery charger configuration.

Figure 8.8-5, Safety Class 2 Low Voltage Uninterruptible Power Supply Distribution, depicts the SC2 EDS UPS distribution configuration for LG A and LG.

The SC2 direct current power system includes two separate load groups (A and B), and four separate UPSs for the FMCRDs. The SC2 load groups A and B are arranged similar to the SC1 Divisions with the exception that each load group contains only a single UPS verses the two per SC1 division. Each load group is independently powered from the associated SC3 AC train A or B. The FMCRD SC2 UPSs are arranged such that two are powered from the SC3 A21 LV bus and two are powered from the SC3 B21 LV bus.

The SC2 LV LGs include surge protection via a transient voltage surge suppressor to prevent HV spikes propagating to the battery chargers, UPSs, and RVTs. Each LG has an individual UPS in support of the respective SC2 DCIS division, along with other loads. The LG UPS provide three-phase 208/120 VAC outputs. Redundant circuits are provided from separate UPSs to support redundant power sources to the DCIS. The SC2 UPSs are the AC power supplies associated with LGs A and B. The LG A MCC is powered from the SC3 A21 LV bus, and the LG B MCC is powered from the SC3 B21 LV bus.

- SCN Direct Current Power System

Figure 8.8-8, SCN 125 VDC System, represents the design of the SCN 125 VDC System. The SCN DC system is designed to provide power to SCN DC loads, such as protective relaying and breaker control power. As shown in Figure 8.8-8, two independent 125 VDC batteries are provided, supplying power to two independent 125 VDC busses. The redundant configuration is compliant with NERC requirements for separate backup power for Bulk Power Systems. A battery mission time of eight hours is selected to align with typical designs for Bulk Power Systems substations. Each DC bus and each battery is normally supplied power and charging current from its associated charger. A standby charger capable of being aligned to either bus or battery is provided in case any given charger is out of service. Each charger is designed to supply 100% of the required load of a single bus, while charging the battery. The two primary chargers derive LV AC power from separate 600 VAC SCN busses. The standby charger is supplied through a transfer switch, which can derive power from either the A21 or B21 SDG backed busses. The standby charger connection to the SDG busses provides operational flexibility in the event of an extended bus outage.

Figure 8.8-9, SCN UPS 208/120 VAC System represents the design of the SCN 208/120 VAC system. The SCN UPS system is designed to provide power to SCN loads. Two independent UPSs are provided that provide a three-phase 208/120 VAC output to independent busses. The UPSs normally derive power from their associated 125 VDC bus. The UPSs are equipped with an MTS aligned to an RVT. The RVTs derive power from a separate AC source than that from which the associated battery charger is supplied.

The following design requirements are applicable to all direct current power systems described above:

1. All EDS batteries and equipment are physically separated and electrically independent in accordance with the requirements given in IEC 60709 (Reference 8.8-15) and IEEE Std 384 (Reference 8.8-30).
2. All battery chargers and UPSs disconnect from the AC input whenever that input varies outside the range of +/-15% voltage from nominal for greater than 60 seconds.

NEDO-33957 REVISION 0  
NON-PROPRIETARY INFORMATION

3. All battery chargers are able to function as battery eliminators.
4. All battery chargers produce a filtered DC output that meets the requirements of IEC 61000-4, "Electromagnetic Compatibility Testing and Measurement Package" (Reference 8.8-31).
5. All battery chargers are housed NEMA Type 1 ventilated enclosures.
6. All battery chargers include overvoltage protection on the output that shuts down the charger upon actuation.
7. All battery chargers are of a current limiting design.
8. All battery banks are designed to permit replacement of individual cells. The plant DC systems consist of an ungrounded system with ground detection.
9. All UPSs maintain rated output voltage  $\pm 5\%$  from zero to rated load.
10. All UPSs are sized to provide the current of a single faulted load in addition to all other normal loads, while still providing normal output voltage.
11. The UPS bypass RVTs maintain a nominal output voltage within  $\pm 5\%$  over an input voltage variation of  $+10\%$  and  $-15\%$ .
12. The battery chargers, UPS, lighting, and convenience power all work continuously without operator intervention.
13. Category B, Transient voltage surge suppressors are used on the input circuit to battery chargers, UPSs, and associated bypass circuits to protect against voltage surges.
14. In accordance with IEEE 1050-2004, adequate filtering is provided by the battery charger, UPS, and regulating transformers to ensure that propagation of EMI/RFI of the levels allowed by IEC 61000-3 (Reference 8.8-32) does not adversely affect other plant equipment.

The following design requirements are applicable to the SC1 DC subsystem:

1. The SC1 DC system meets the recommended practices in IEEE 946-2020 (Reference 8.8-14) for design of DC power systems for stationary applications.
2. SC1 batteries are designed with consideration of the recommended practices in IEEE 484-2019 (Reference 8.8-16) for installation design and installation of vented lead-acid batteries for stationary applications.
3. Maintenance, testing, and replacement activities for the SC1 EDS batteries consider the recommended practices in IEEE 450-2020.
4. The SC1 batteries are sized with an expected service life of 20 years using the methodology given in IEEE 485-2020 (Reference 8.8-20).
5. Each of the SC1 EDS UPSs can supply 100% of the divisional load.
6. The SC1 Divisions are electrically separate such that no electrical connection exists between the DC batteries and UPS in one division and a component in another division.
7. The SC1 UPS outputs provide a single-phase nominal AC voltage of 230 VAC, 60 Hz.

8. The SC1 battery banks are designed to supply DC power at 250 VDC nominal.
9. The SC1 EDS provides battery-backed power to support any accident monitoring and mitigation functions that are a part of DL3. In the event that normal AC power is lost, the SC1 EDS continues to provide uninterruptible power for a minimum mission time of 72 hours.

The following design requirements are applicable to the SC2 DC subsystem:

1. Any SC2 load requiring power for completion of a Safety Category 2 function is powered from the SC2 EDS UPSs or batteries and cannot be powered directly from the SC3 busses. The SC2 and 3 EDS are designed with redundancy such that the failure of a single electrical bus or MCC has no adverse effect on the redundant counterpart.
2. Redundant SC2 battery chargers support equalization and battery testing without impact to downstream loads
3. The SC2 battery banks are designed to supply DC power at 250 VDC nominal
4. The SC2 DC and UPS systems are powered from diesel-backed sources

The following design requirements are applicable to the SCN DC subsystem:

1. The SCN EDS UPS outputs provides a three-phase nominal AC voltage of 208/120 VAC, 60 Hz.
2. The SCN EDS battery banks are designed to supply DC power at 125 VDC nominal.
3. The SCN EDS DC systems supply power to the inverters that are part of the SCN UPS systems.
4. The SCN EDS batteries have enough stored capacity without chargers to independently supply loads continuously for at least eight hours, with a minimum final discharge voltage sufficient to support the associated loads.

#### **8.4.2.4 Materials**

Materials associated with the SC of the individual systems. SSC are evaluated based on the SC and functions. Materials are evaluated and selected based on the environmental conditions and SC of the equipment as discussed in PSAR Chapter 18.

#### **8.4.2.5 Interfaces With Other Equipment or Systems**

The three DC subsystems supply loads of equivalent SC. Input AC power for such systems is derived from AC sources as identified in the figures included in this chapter. The systems also include interface with the DCIS of equivalent SC for control and monitoring.

#### **8.4.2.6 System and Equipment Operation**

The DC subsystems are designed to perform their associated function without operator interaction. Upon loss of AC power, the systems will automatically transition to being supplied by the associated battery.

#### **8.4.2.7 Instrumentation and Control**

The BWRX-300 electrical systems are to be monitored and controlled by DCIS equipment of a corresponding safety classification. Generally, the DCIS control systems are expected to operate and monitor the plant transformers and feeder breakers, including load breakers for pumps, adjustable speed drives, or other plant equipment.

MV breakers are controlled by protective relays established by the designer to protect the electrical system components. For example, the condensate pump motor breaker includes protective relays that monitor overcurrent, balanced phases, undervoltage, underfrequency, and ground and phase faults. The protective relay trips the breaker, and a trip command has precedence over a close command. The plant DCIS can command a breaker to open or close, but a DCIS close command can be overridden by the protective relay. Either a DCIS trip or protective relay trip command opens the breaker.

The protective relays are interfaced to the plant DCIS and can provide multiple signals to the attached plant controller. Potential signals include:

- Phase voltage
- Phase current
- Power factor
- Power
- Apparent power
- Reactive power
- Total running time
- Total off time
- Number of starts

NOTE: These signals are provided “automatically” by the protective relays and no further instrumentation is needed.

Although modern microprocessor based protective relays are considerably more flexible, cost effective, and accurate than older analog designs (that cannot provide equivalent protection), the relays represent a separate DCIS network. The relays are considered critical digital assets in the U.S. and require appropriate cyber security monitoring and physical access protection.

For components and equipment in the plant electrical systems that are monitored by the DCIS, status inputs and alarm indications shall be provided to the plant DCIS.

Refer to Chapter 7 for a detailed discussion of the BWRX-300 I&C System design and operation.

#### **8.4.2.8 Monitoring, Inspection, Testing, and Maintenance**

Condition monitoring equipment is included where appropriate.

The SC1, SC2 and SCN batteries require periodic testing under load to verify capacity. Although the loads are expected to be out of service, the associated DCIS loads can remain powered because the UPSs have bypass AC power available.

The design of the plant electrical systems accommodates online testing and inspection to the extent practical. Condition monitoring equipment is included where appropriate. For the SC1 EDS, the UPSs are in pairs per division, and testing can be done online without losing the complete divisional UPS output.

Required electrical system testing is governed by the plant technical specification and industry standards. The electrical systems are designed to allow required tests to be performed with minimal disturbance to the balance of the system. Specific steps and alignments necessary for the successful performance of testing are to be controlled by plant procedures.

All maintenance can be done during outages. However, given the redundancy in the electrical system, most maintenance can also be done with the plant online and with only a small power reduction. All load centers necessary for power generation can be replaced online, although some replacements may require a plant power reduction.

While the expected service life of the plant batteries is 20 years, occasionally a battery cell may fail. These issues are to be appropriately alarmed by the battery monitoring systems. With optimum environmental conditions (e.g., temperature and humidity), limiting the discharge occasions to periodic surveillance and preventive maintenance testing, and having constant condition monitoring for cell degradation, a 30-year service life of the plant batteries is also possible. All batteries can be replaced either online or during outages.

Depending on the battery type, a battery may periodically need a maintenance equalizing charge that raises battery voltage to levels that can cause unnecessary stress on battery loads. With the redundant battery charger design configuration, one charger can supply the equalizing charge to the battery and be isolated from the DC loads while the other charger carries the DC loads at normal voltages.

#### **8.4.2.9 Radiological Aspects**

The electrical system is expected and designed to function as specified by its SC. The safety function of the electrical SSC must be accomplished for safety for a facility or activity to prevent or to mitigate radiological consequences of normal operation, AOOs and accident conditions.

#### **8.4.2.10 Performance and Safety Evaluation**

The on-site DC power system are expected to perform their design functions in normal and abnormal conditions.

Electrical power is supplied to the I&C systems. Refer to Chapter 7 for a further discussion.

### **8.5 Electrical Cables and Raceways**

#### **8.5.1 System and Equipment Functions**

The cabling for the BWRX-300 provides electrical power to designated loads. Fiber cabling is used for signal transmissions. SC loads are provided appropriate SC power from the EDS. Electrical cables and raceways are passive equipment and do not perform and active functions.

#### **8.5.2 Safety Design Bases**

The cabling and raceways are designed to meet the following SC design requirements:

1. The plant SC electrical systems are designed to meet the applicable requirements of IEC 60709 (Reference 8.8-15) for cabling and system separation and independence of SC systems. Power and signal/control cables will be separated per the guidance provided in IEC 60709 (Reference 8.8-15).
2. Separation for SCN components and systems are derived from the application of IEC 60709 (Reference 8.8-15) as appropriate.
3. Current-carrying cables in the plant electrical systems are qualified to meet the IEEE Std 383 (Reference 8.8-21) requirements for cables and splices for nuclear facilities.

The cables and raceways are designed commensurate with the SC of the loads and functions being provided.

### **8.5.3 Description**

Separation of cables by divisions or load groups are provided by routing in raceways that provide the separation by distance and routing in which the distance is maintained to ensure that the designated SC is maintained. The raceways provide support for the cables commensurate with the SC designations of the individual SC of the cables. Seismic and EQ considerations are also factored into the design of the raceways for proper support and safety functions. Penetrations are designed based on SC considerations.

### **8.5.4 Materials**

Materials are associated with the SC of the individual systems. Materials are evaluated and selected based on the environmental conditions to which the cables/raceways are exposed in conjunction with the SC of the equipment being served. SC of the equipment is discussed in Chapter 3, Section 3.9, Environmental Qualification.

### **8.5.5 Interfaces With Other Equipment or Systems**

Cabling and raceways are passive components that provide power from electrical supplies to components and/or loads.

Electrical cables and raceways are permanently installed passive components to support operation of connected loads.

### **8.5.6 Instrumentation and Control**

While electrical cables transmit I&C signals throughout the plant, there are no instrumentation and control features specific to the electrical cabling and raceway systems.

### **8.5.7 Monitoring, Inspection, Testing, and Maintenance**

Normally the cabling and raceways are designed to not require any inspections once they have passed installation and commissioning testing. However, cabling and raceways are inspected based on operations surveillance programs, maintenance and testing programs during normal operations and outages as appropriate.

Cabling and raceways testing is based on preventive and predictive maintenance programs. Site testing requirements will also be used for post installation testing and inspection.

### **8.5.1 Radiological Aspects**

The cables and raceways are designed for their location to maintain their required function. The cables and raceways are qualified for the anticipated radiological environment expected during the lifetime of the plant.

### **8.5.2 Performance and Safety Evaluation**

The cables and raceways are designed to perform required functions during all plant modes and under all anticipated normal and abnormal conditions.

## **8.6 Grounding, Lightning Protection and Electromagnetic Compatibility**

### **8.6.1 System and Equipment Functions**

The plant grounding system is part of the SCN EDS. Grounding is important for both safety of plant personnel and electrical system protection, and it is critical to the operability and performance of the BWRX-300 DCIS.

As with any grounding system, the overall function of the plant grounding networks is to protect personnel and equipment from induced voltages and currents by providing a low impedance path to the earth.

### **8.6.2 Safety Design Basis**

The overall grounding system consists of a buried grounding grid and includes different types of grounding systems that all connect to a common plant grounding grid.

Building grounds (connections of the building foundations and external structures to the grounding grid) are provided. Equipment grounds (connection of equipment to the internal grounding system of the buildings) are provided for equipment protection. Instrument grounds (separate grounding connection to the grounding grid for analog and digital instrumentation systems) are provided for instrumentation protection and operation. The lightning protection system provides protection for equipment against lightning induced surges.

### **8.6.3 Description**

The electrical grounding system is comprised of the following grounding networks connected to a plant grounding grid:

1. An instrument and computer grounding network
2. An equipment-grounding network for grounding electrical equipment (e.g., transformer, switchgear, motors, distribution panels, cables) and selected mechanical components (for example, fuel tanks, chemical tanks)
3. Building grounds
4. A lightning protection network for protection of all structures, transformers, and equipment

The instrumentation grounding system is provided to include both the plant analog (relays, solenoids, etc.) and digital instrumentation systems. The plant instrumentation is grounded through a separate insulated radial grounding system composed of busses and insulated cables. The instrumentation grounding system is connected to a discrete point of the station grounding grid at a dedicated instrumentation grounding rod by exothermic welding. The instrumentation grounding system is insulated from all other grounding and surge protection circuits up to the point of connection at the ground grid. It is recognized that there are numerous accepted grounding techniques, and that the actual installation of a ground system is made with reference to the recommendations of the I&C equipment manufacturers since the techniques used to solve one problem may result in the creation of a different problem (IEEE Std 1050 (Reference 8.8-25)).

The equipment-grounding network is such that all major equipment, structures, and tanks are grounded with two diagonally opposite ground connections. The ground bus of all switchgear assemblies, motor control centers and control cabinets are connected to the station ground grid through at least two parallel paths. Bare copper risers are furnished for all underground electrical ducts and equipment, and for connections to the grounding systems within buildings. One bare copper cable is installed with each underground electrical duct run, and all metallic hardware in each manhole is connected to the cable.

NEDO-33957 REVISION 0  
NON-PROPRIETARY INFORMATION

A plant grounding grid consisting of bare copper cables is provided to limit step and touch potentials to safe values under all fault conditions. The buried grid is connected to the ground mat at the switchyard and connected to systems within the buildings by a bare copper loop, which encircles each building.

The plant's main generator is grounded with a neutral grounding device to limit the magnitude of fault current due to a solid phase-to-ground fault. The impedance of the neutral grounding device limits the maximum phase-to-ground current under short-circuit conditions.

The on-site, MV AC distribution system is resistance grounded at the neutral point of the LV windings of the UAT and RAT. The neutral point of the generator windings of the standby on-site AC power supply is through neutral resistors, sized for continuous operation in the event of a ground fault.

The neutral point of the LV AC distribution systems is solidly grounded to ensure proper coordination of ground fault protection. The DC systems are ungrounded.

The lightning protection system covers all major plant structures and is designed to prevent direct lightning strikes to the buildings, electric power equipment and instruments. It consists of air terminals, bare downcomers, and buried grounding electrodes. Lightning arresters are provided for each phase of all tie lines connecting the plant electrical systems to the switchyard and offsite lines. These arresters are connected to the high-voltage terminals of the main step up transformers, UAT, and RAT. Plant instrumentation located outdoors or connected to cabling running outdoors is provided with surge suppression devices to protect the equipment from lightning induced surges.

The plant grounding system is part of the SCN EDS. Grounding is important for both safety of plant personnel and electrical system protection, and it is critical to the operability and performance of the BWRX-300 DCIS.

System Requirements for the plant grounding system contain the following:

1. The SCN EDS includes an electrical grounding and lightning protection system with a plant grounding grid.
2. The plant grounding grid meets the applicable requirements of IEEE Std 80, "IEEE Guide for Safety in AC Substation Grounding" (Reference 8.8-1), IEEE Std 81, "IEEE Guide for Measuring Earth Resistivity, Ground Impedance, and Earth Surface Potentials of a Ground System" (Reference 8.8-2), and IEEE 142-2007.
3. The electrical grounding protection system includes an instrument and computer grounding network that is separate from the standard equipment and system ground network.
4. Lightning and surge suppression meets the applicable requirements given in IEEE Std C62.23, "IEEE Application Guide for Surge Protection of Electric Generating Plants" (Reference 8.8-6), IEEE Std 666, "Design Guide for Electric Power Service Systems for Generating Stations" (Reference 8.8-7), IEEE Std 1050 (Reference 8.8-4), IEEE Std 665, "IEEE Guide for Generation Station Grounding" (Reference 8.8-3).

No regulatory guidance is provided for the grounding protection system. Lightning protection is provided in accordance with RG 1.204, "Guidelines for Lightning Protection of Nuclear Power Plants" (Reference 8.8-23). Both systems are designed and installed to the applicable sections of the following codes and standards.

- IEEE Std 80 (Reference 8.8-1)
- IEEE Std 81 (Reference 8.8-2)
- IEEE Std 665 (Reference 8.8-3)
- IEEE Std 1050 (Reference 8.8-4)
- NFPA 780, "Standard for the Installation of Lightning Protection Systems" (Reference 8.8-5)
- IEEE Std C62.23 (Reference 8.8-6)
- IEEE Std 666 (Reference 8.8-7)
- IEC 62305-1, "Protection Against Lightning – Part 1: General Principles" (Reference 8.8-25)

#### **8.6.4 Materials**

A plant grounding grid consisting of bare copper cables is provided to limit step and touch potentials to safe values under all fault conditions. The buried grid is connected to the ground mat at the switchyard and connected to systems within the buildings by a bare copper loop, which encircles each building.

#### **8.6.5 Interfaces With Other Equipment or Systems**

The plant grounding and lightening arresting system is designed to provide protection in the BWRX-300 plant. The grounding system interfaces with all site buildings and structures, all electrical and I&C equipment, and select mechanical equipment needing grounding protection (for example, tanks).

#### **8.6.6 System and Equipment Operation**

The plant grounding and lightening arresting system is designed to provide protection with all equipment and structures in the BWRX-300 plant. As such the system is designed to be passive and does not perform an active safety function. The neutral point of the LV AC distribution systems is solidly grounded to ensure proper coordination of ground fault protection. The DC systems are ungrounded.

#### **8.6.7 Instrumentation and Control**

There are no I&C features required for or applicable to the plant grounding and lightning protection systems.

#### **8.6.8 Monitoring, Inspection, Testing, and Maintenance**

There is no monitoring associated with the plant grounding and lightning protection systems.

Normally the grounding, lightening systems are designed to not require any inspections once they have passed installation and commissioning testing

Much of the grounding systems are underground and inaccessible once installed. Normally the grounding wiring is designed to not require any inspections once they have passed installation and commissioning testing.

NEDO-33957 REVISION 0  
NON-PROPRIETARY INFORMATION

Above ground inspections are conducted based on manufacturer recommendations and industry standard guidance.

There is no testing after installation/construction.

Maintenance of the grounding system is not anticipated after installation/construction.

**8.6.9 Radiological Aspects**

The grounding, lightening protection, and electromagnetic compatibility systems that are exposed to high radiation areas and are designed for the radiological conditions to which they may be exposed.

**8.6.10 Performance and Safety Evaluation**

The electrical grounding system is expected to perform its design functions in normal and abnormal conditions. These systems are completely passive and perform no active functions.

## **8.7 Main Equipment Types**

### **8.7.1 System and Equipment Functions**

The EDS architecture is a configuration of major equipment (MODs, GSU, UAT, RAT, Main Gen. Bkr., Isophase Bus Duct, MV Switchgear, LV Switchgear, battery chargers, batteries, RVTs, UPSs). Refer to Subsections 8.4.1 and 8.4.2 for a discussion of their functions that have been previously discussed.

# SC2 LV LG A UPS Distribution

Configuration shown is applicable for SC2 Load Group A and typical for SC2 Load Group B.

UPS inputs from the battery, MCC, and RVT are not shown. UPS output is 208-120 VAC 3Ø.

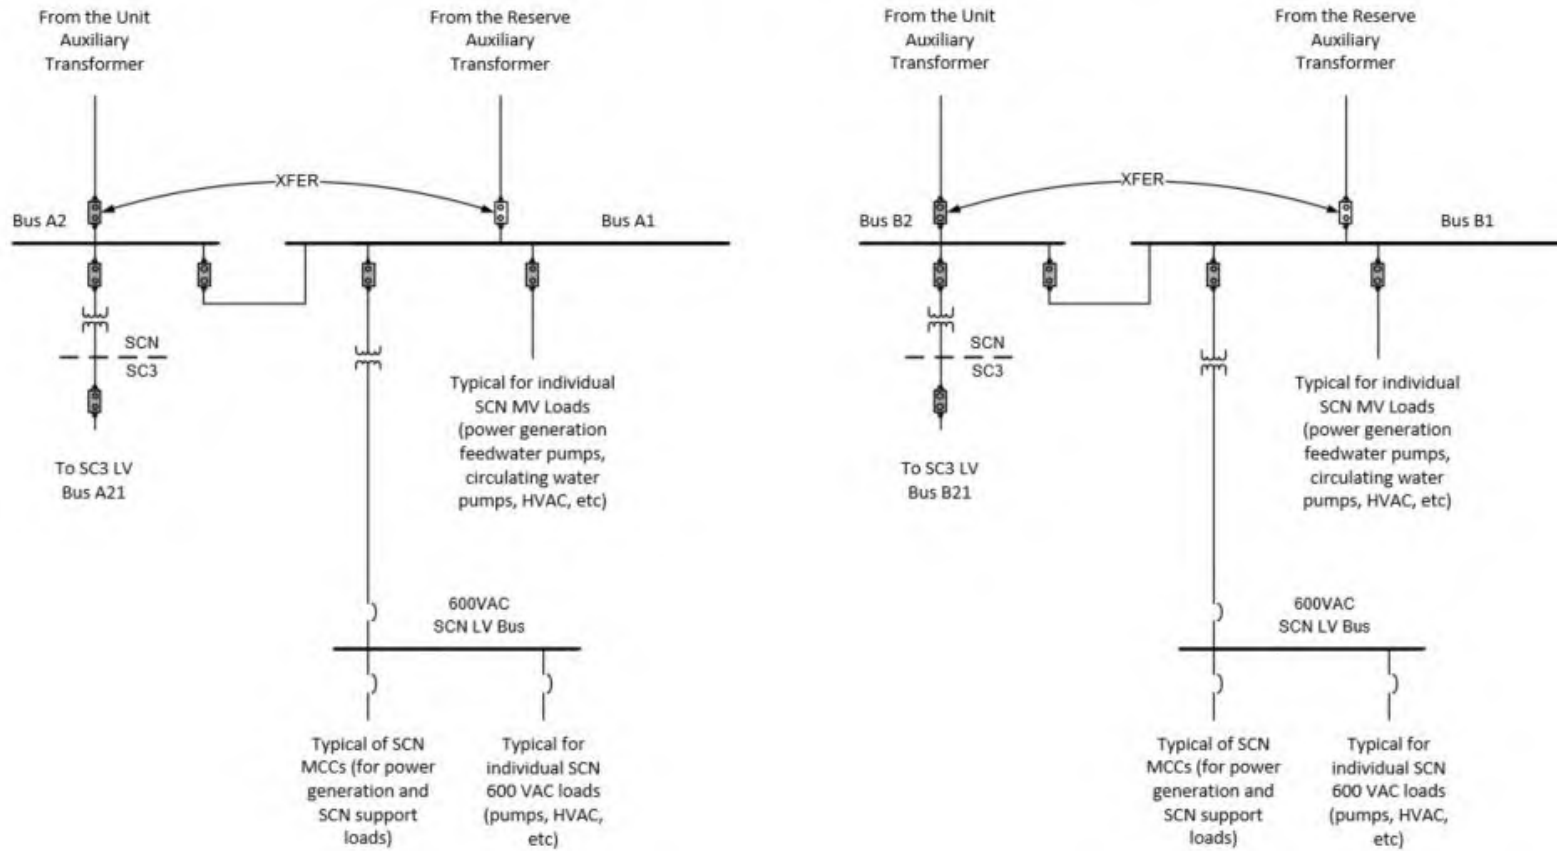

Note(s):

1. The regulating voltage transformer shown is as needed for long distance power panel locations and not required for all power panel feeds.

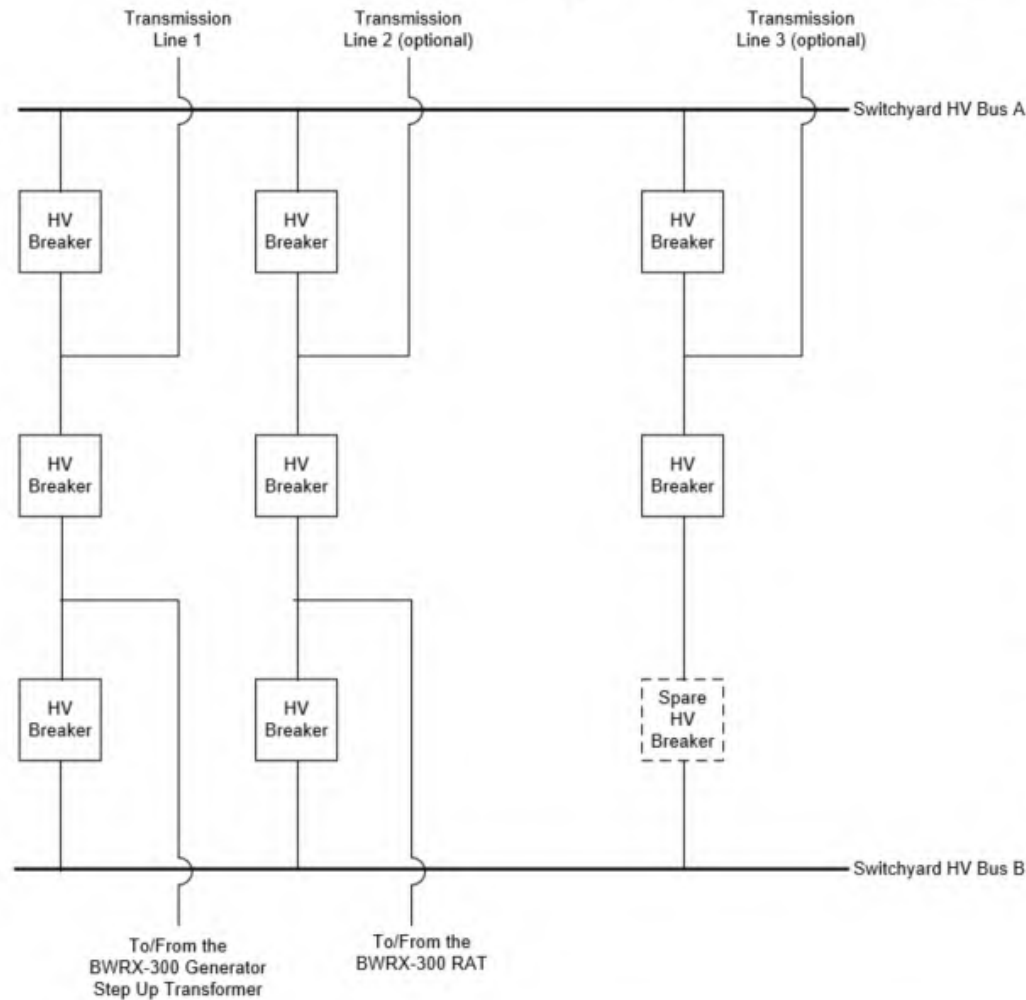

**Figure 8.8-5: Safety Class 2 Low Voltage Uninterruptible Power Supply Distribution**

**Figure 8.8-6: Non-Safety Class Medium Voltage Busses A1-A2 and B1-B2**

### Typical BWRX-300 Switchyard Interface

BWRX-300 only requires one incoming/outgoing transmission line that must be capable of handling the MVA plant output.

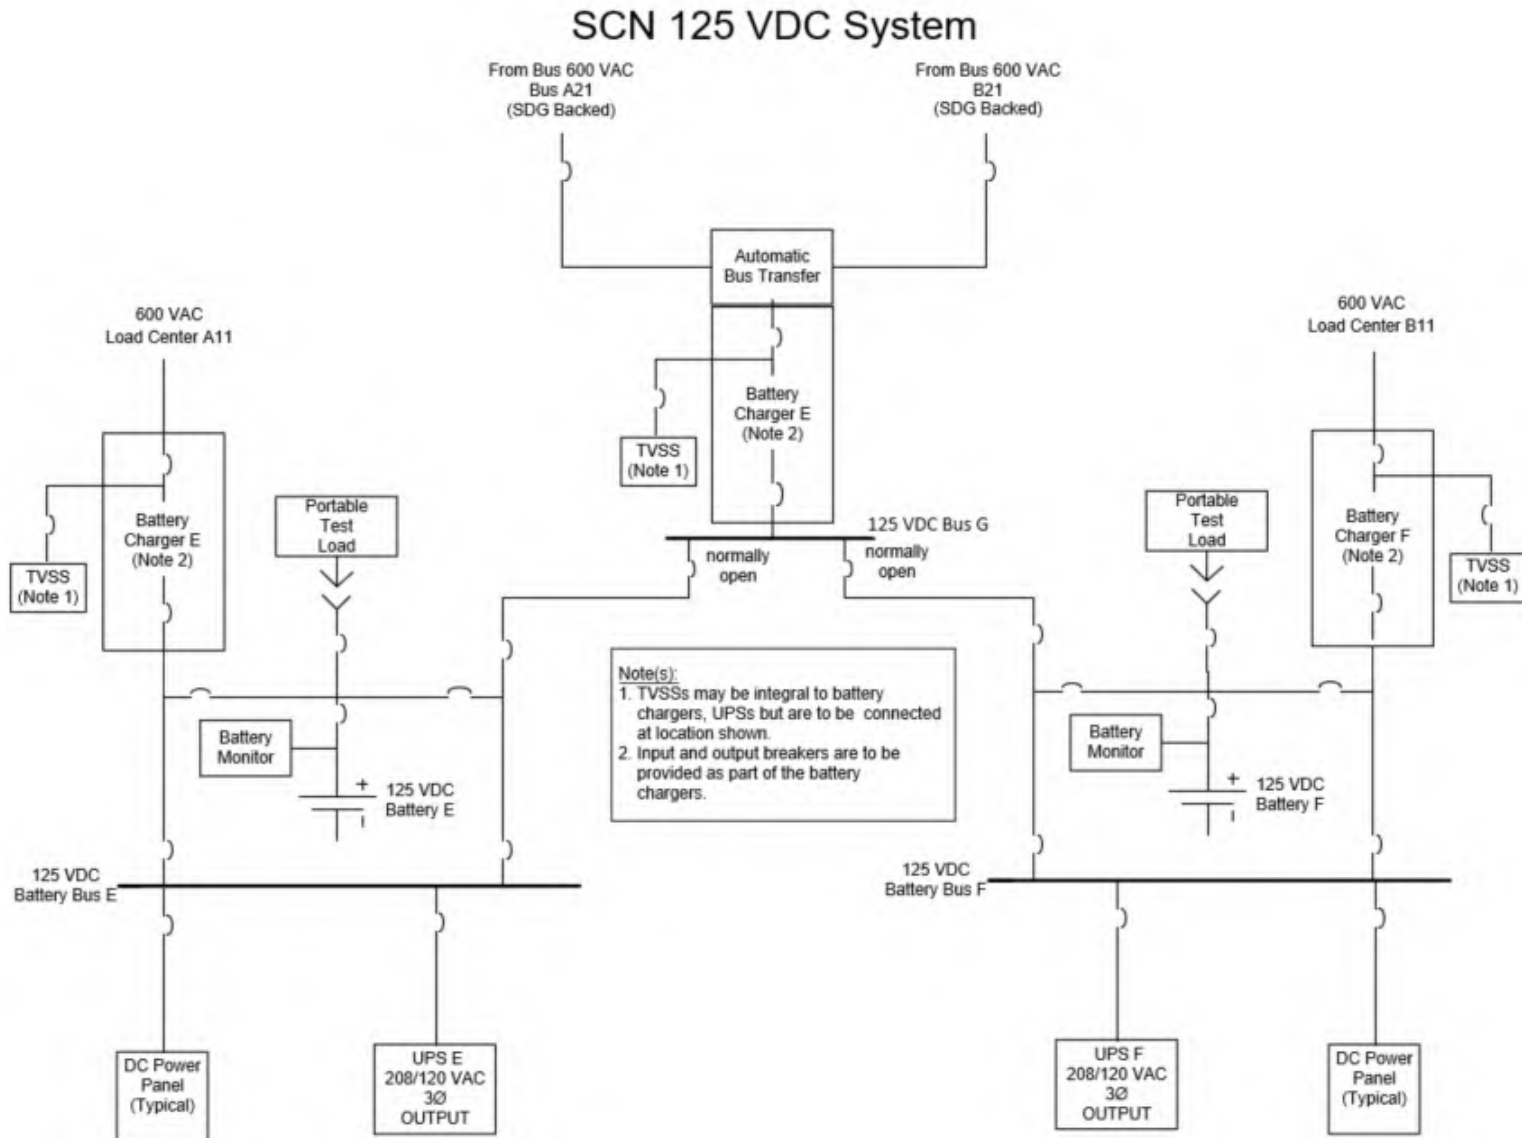

The switchyard may be any voltage or frequency compatible with the plant GSU transformer and may have any number of transmission lines at any voltages at the utility's discretion; the BWRX-300 GSU transformer primary rated voltage will be appropriately changed as needed.

A breaker-and-a-half switchyard breaker scheme as shown is assumed but not required.

Relay house battery chargers and support power should be redundant and can come from a local switchyard transformer or in-switchyard diesel generator, and if necessary, may be powered from a BWRX-300 onsite electrical power system.

## **9A.0 AUXILIARY SYSTEMS**

### **9A.1 Fuel Storage and Handling Systems**

#### **9A.1.1 New Fuel Storage and Handling System**

New fuel receiving is a service and a material handling process that utilizes the Fuel Handling System and equipment described in Subsections 9A.1.2, 9A.1.4 and 9A.8. New fuel receipt is described in Section 5.1 of the Safeguards Annex. The BWRX-300 design does not employ a new fuel storage vault. The new fuel assemblies are stored in fuel storage racks which are located in the Fuel Pool in the Reactor Building. New fuel and spent fuel are stored in the same Fuel Pool. The following information is provided in support of the requirements of CNSC REGDOC-2.5.2 Section 8.12.1 (Reference 9A.1.1-1) relative to new fuel storage and handling:

1. Nuclear criticality safety, refer to Subsection 9A.1.2.3.1
2. Maintenance, periodic inspection, and testing of components important to safety, refer to Subsection 9A.1.2.8 and Section 5 of the Safeguards Annex
3. Inspection of non-irradiated fuel, refer to the Safeguards Annex, Section 5.1.2 and Chapter 4, Subsection 4.2.5.
4. Prevent loss of or damage to the fuel, refer to Subsection 9A.1.2.3.13 and Safeguards Annex Section 7 for information pertaining to prevention of loss of fuel. Subsection 9A.1.4 addresses fuel handling equipment and Subsection 9A.8 addresses movement of heavy loads in the vicinity of the fuel pool
5. Meet Canada's safeguards requirements for recording and reporting accountancy data, and for monitoring flows and inventories related to non-irradiated fuel containing fissile material, refer to Safeguards Annex, Section 4 "Safeguards and Operation" and Section 7 "Nuclear Material Accountancy"

##### **9A.1.1.1 References**

9A.1.1-1 Canadian Nuclear Safety Commission REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants"

#### **9A.1.2 Fuel Storage and Handling System**

The fuel pool is used to store spent fuel after discharging and new fuel after delivery to the site and before core loading. The above grade portion of the Reactor Building (RB) structure houses the refueling floor, refueling and fuel handling systems, fuel pool, and Reactor Building Polar Crane.

##### **9A.1.2.1 System and Equipment Functions**

System and equipment functions associated with the Fuel Storage and Handling System include the followings:

##### **Normal Functions (Non-Safety-Category)**

- Permit disassembly and re-assembly of containment and reactor.
- Permit reactor refueling.
- Permit new and spent fuel storage in fuel pool.
- Permit replacement of reactor mechanical components.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

- Permit replacement of nuclear instrumentation.
- Support various outage maintenance.
- Maintain subcriticality during fuel and core component handling operations.

**Normal Functions (Safety-Category)**

- Fuel Storage and Handling System does not perform any Safety Category functions during off-normal conditions.

#### **Off-Normal Functions (Non-Safety-Category)**

- Fuel Storage and Handling System does not perform any Non-Safety-Category functions during off-normal conditions.

#### **Off-Normal Functions (Safety-Category)**

- Maintain Fuel Pool structural integrity following a seismic event
- Fuel Storage and Handling System does not perform any Safety-Category functions during off-normal conditions.

#### **9A.1.2.2 Safety Design Bases**

The fuel pool is adequately protected against dynamic effects. The fuel pool is designed to ensure that required water levels are maintained in normal and off-normal conditions. Fuel in the fuel pool is protected from damage caused by the postulated drop of fuel assemblies, bundles, or other objects onto stored fuel (Subsections 9A.1.4 and 9A.8) by assessing the impact of the load drop and designing systems to mitigate the effects.

The orientation and location of the turbine shafts are designed such that the fuel storage components are located outside the turbine missile low-trajectory strike zone (Chapter 10, Subsection 10.2.3). Furthermore, the turbine is located in the Turbine Building with Turbine Building and Reactor Building walls between the Fuel Pool and Turbine.

The fuel pool has the following design features: control for airborne release of radioactive material; drains, gates, and weirs that prevents drainage of coolant inventory below an adequate shielding depth; adequate coolant flow provided to the fuel racks; and a system to detect fuel pool leakage.

The addition of water to the fuel pool does not result in a criticality event.

A full array in the loaded fuel rack is designed to be subcritical by at least 5%  $\Delta k$  under all normal and abnormal conditions as per CNSC REGDOC-2.4.3 Section 2.3 (Reference 9A.1.2-1). Safety analyses are performed using validated codes (Chapter 3, Appendix 3E).

Fuel pool storage design meets Canadian Nuclear Safety Commission (CNSC) requirements specified in CNSC REGDOC-2.5.2 Section 8.12 (Reference 9A.1.2-2) as related to ensuring the design and handling of irradiated fuel.

#### **9A.1.2.3 Description of System**

The BWRX-300 Steel-plate Composite Containment Vessel (SCCV) and the main RB structure including the reactor cavity, equipment pool and fuel pool are classified as Safety Class 1 (SC1).

The fuel pool base mat is located at approximately the power block grade elevation. The fuel pool extends up to the refuel floor elevation of approximately 13 metres above grade elevation.

The fuel pool size is determined by the volume of cooling water, size of the fuel storage racks, with control rod blade guides, other equipment required to be stored in the pool, and lay-down areas. Refueling outage equipment such as lights, test weights, dummy fuel bundles, and control blades are also stored in the fuel pool. The fuel preparation machine is located on the fuel pool periphery. The new fuel inspection stand is mounted on the refuel floor away from the fuel pool periphery and only used for new fuel before it is installed into the water and to the fuel prep machine. Used reactor core instruments may also be stored in the fuel pool, until such time as they are cut up and packaged.

Additional information pertaining to the design of the new and spent fuel storage system is presented below.

#### **9A.1.2.3.1 Nuclear Criticality Safety**

Chapter 15, Subsection 15.5.9.3 analyzes the dose consequence of a representative Out-of-Core-Criticality accident scenario compliant with the requirements of CNSC REGDOC-2.4.3 (Reference 9A.1.2-1).

New and spent fuel are stored in storage racks capable of maintaining fuel subcritical. The fuel pool is comprised of a deep pit filled with water which provides shielding in addition to the shielding provided by the pool confinement structure. Within the pool are storage racks in a grid pattern which contain a fixed neutron absorbing material. The storage rack geometry and material are designed to preclude the possibility of criticality under normal and credible abnormal conditions.

A full array in the loaded fuel rack is designed to be subcritical by at least 5%  $\Delta k$ . Monte Carlo techniques are employed in the calculations performed to assure that  $k_{\text{eff}}$  does not exceed 0.95 under all normal and abnormal conditions.

#### **9A.1.2.3.2 Heat Removal in Operational States, Design Basis Accidents and Design Extension Conditions**

Removal of heat from the fuel pool during operational and design basis accident conditions is described in Subsection 9A.1.3. The design of the Fuel Pool contains provisions for Fuel Pool Design Extension Conditions (DECs) by:

1. Ensuring that boiling in the pool does not result in structural damage (Chapter 3, Subsection 3.5.6.1)
2. Providing temporary connections to enable the refill of the pool using temporary supplies (Subsection 9A.1.3.6.4)
3. Providing temporary connections to heat removal systems for power and cooling water (Subsection 9A.1.3.3 discusses redundant cooling trains)
4. Ensuring that the design of the fuel pool is such that a Fuel Handling Accident does not exceed site Design Basis Accident dose acceptance criteria Chapter 15, Subsection 15.5.8
5. Ensuring that severe accident management actions related to the fuel pool can be carried out (Chapter 15, Subsection 15.1.5)

#### **9A.1.2.3.3 Inspection of Irradiated Fuel**

The handling and storage systems are used primarily to support refueling and core shuffling, and the same equipment supports periodic inspections as needed of irradiated fuel. The typical inspection scenario entails the Refueling Platform (Subsection 9A.1.2.3.5) moving fuel to the Fuel Preparation Machine. The Fuel Preparation Machine is typically outfitted with a fuel inspection fixture which is a small rotator installed onto the Fuel Preparation Machine to facilitate fuel inspections. In addition to supporting the loading of new fuel into the fuel pool during outage preparation, the Fuel Preparation Machine supports activities associated with the inspection of irradiated fuel, including removal and reinstallation of the fuel channel to enable access to the bundle/rods. Typically located adjacent to the Fuel Preparation Machine there is a channel handling boom, and below the surface of the fuel pool on the wall, a channel storage rack. When irradiated fuel is moved into the Fuel Preparation Machine for inspection, procedural requirements specify the water coverage that must be maintained over the top of the irradiated fuel. Typically, a mechanical interlock on the drive of the Fuel Preparation Machine is utilized to limit or block raising the bundle above an approved radiologically safe elevation. Plant equipment utilized for servicing irradiated fuel includes the following.

### **Fuel Preparation Machine**

Two Fuel Preparation Machines are provided for handling fuel assemblies while removing or installing channels on the fuel bundles. Each machine consists of a fuel bundle carriage, which rides on a frame that is mounted on the edge of the fuel pool and extends down to depth along the pool wall and a work platform. The work platform includes handrails and extends out over the pool to facilitate viewing of the channeling operations.

### **Fuel Inspection Fixture**

The Fuel Inspection Fixture is used in conjunction with the Fuel Preparation Machine to permit remote inspection of fuel elements. The Fuel Inspection Fixture, when installed, permits rotation of the fuel assembly in the carriage, and in conjunction with the vertical movement of the carriage provides complete access to all quadrants of fuel assembly inspection.

### **New Fuel Inspection Stand**

The New Fuel Inspection Stand is stored on the refueling floor of the reactor building. It consists of a single "U" shaped platform with guardrails, a column which supports two fuel assemblies in a vertical position, and a personnel lift which raises or lowers the work platform along the fuel assemblies for inspection purposes. The lower base of the fuel assembly sits in the fuel seat at the bottom of the stand. The fuel assemblies are mounted on rotatable bearing surfaces which allow for rotation to desired quadrants for inspection.

### **Channel Handling Tool**

The Channel Handling Tool is used in conjunction with the Fuel Preparation Machine to remove, install, and handle fuel channels in the fuel storage pool. The bail hangs from a load balancer on the channel handling boom mounted adjacent to the Fuel Prep Machines.

### **Channel Transfer Grapple**

The Channel Transfer Grapple is an air actuated device consisting of a frame, air cylinder, and two jaws. It is used with the Refueling Platform auxiliary hoist to transport individual irradiated fuel channels between working and storage facilities in the fuel pool.

### **Channel Bolt Wrench**

The Channel Bolt Wrench is a manually operated device used for removing and installing the Channel Fastener.

### **Channel Handling Boom**

The Channel Handling Boom is located in a socket adjacent to the fuel preparation machines and adjacent to the fuel pool. The boom supports the channel handling tool and spring balancer over the Fuel Preparation Machine during channel removal and installation operations.

### **Inspection Camera**

Cameras and tooling for inspections and measurements are curb-mounted next to the Fuel Preparation Machine in support of underwater inspection activities. Assorted hand tools (handling poles) and grapples are used in inspections. Sometimes, inspections are conducted during outages, other times, inspections on discharged fuel occurs post-outage (during the operating cycle).

#### ***9A.1.2.3.4 Periodic Inspection and Testing of Components Important to Safety***

For information pertaining to periodic inspection and testing of components refer to Subsection 9A.1.2.8.

#### **9A.1.2.3.5 Design for Precluding the Dropping of Irradiated Fuel in Transit**

The Reactor Building is supplied with a Refueling Platform for fuel movement and reactor servicing support tasks. Fuel and other components are removed from the reactor core, transported to the fuel pool, and then returned to the reactor as required. Additionally, the Refueling Platform serves as a service area which is used to assist in normal vessel disassembly/reassembly, normal Reactor Pressure Vessel maintenance activities, and in performance of long-term in-vessel inspection and maintenance activities.

The Refueling Platform consists of a bridge which spans the width of the Fuel Pool and Reactor Cavity. A trolley rides on the bridge, traversing the width of the bridge to the maximum width. A full length sized working platform where refueling, servicing, and inspection personnel perform their work support tasks spans the length of the bridge. The Refueling Platform rides on four wheels running on two rails set into the refuel floor.

The Refueling Platform is equipped with a traversing trolley, an operator control console, a main hoist with a telescoping mast and fuel grapple, an auxiliary, and a monorail hoist. An air compressor on the Refueling Platform provides compressed air to the pneumatic system for the fuel grapple and reactor service tooling. A frame mounted hoist and a monorail hoist support handling the smaller core components and tooling.

The Refueling Platform is a rigid structure built to ensure accurate and repeatable positioning during the refueling process. The telescoping mast and grapple are suspended from a trolley system and is used to lift and orient fuel bundles for placement in the core or storage racks. The Refueling Platform includes a control console providing the operator precise control of the motions of bridge, trolley, and all hoists. Bridge, trolley, and mast grapple elevation readouts are located in a clearly understandable and convenient position for the operators to monitor as they position the Refueling platform. The control console includes a light indication to monitor hoist functions and refueling interlocks.

The main hoist and fuel grapple has a redundant load path so that no single component failure results in a fuel bundle drop. Specialized grapple tooling which carries fuel assemblies or control rod blades is designed such that accidental opening is mechanically prevented and, upon loss of power, the grapples fail in the closed position.

Interlocks on the Refueling Platform prohibit bridge movement towards the core when the reactor mode switch is in refueling position and a single control rod is out.

Power shuts off to the main fuel hoist motor when the Refueling Platform is over the core, the hoist load cell is sensing load of a fuel assembly or greater, and the reactor mode switch is in refueling and a single rod is withdrawn.

Hoist motion is prevented when the grapple hooks are not closed, and the fuel hoist senses load of a fuel assembly or greater.

Upon completion of fuel movement operations, a core verification task is accomplished in which individual fuel assemblies are verified to be installed in the correct position using serial numbers assigned to the fuel assemblies. Refer to Subsection 9A.1.4 for information pertaining to the design of equipment and operations associated with precluding dropping of irradiated fuel while in transit.

Spent fuel is transferred from the fuel pool in a Transfer Cask using the single failure proof RB Polar Crane. Refer to Subsection 9A.8.1 for information pertaining to the design and operation of the RB Polar Crane as it relates to precluding the dropping of irradiated fuel while the in transit.

#### **9A.1.2.3.6 Handling Stresses on Fuel Elements or Fuel Assemblies**

The structural adequacy of the fuel assembly components is demonstrated by evaluations (analysis or testing) that specifically address the operational duty that results from the BWRX-300 environment. This duty results from steady-state operation (including handling loads), mechanical loads associated with anticipated transients, and accident loads due to external conditions.

The fuel assembly structural components are evaluated to ensure that the components do not fail due to stresses exceeding the fuel assembly component mechanical capability.

##### **Upper Tie Plate**

The design loading for the Upper Tie Plate is from bundle handling. Specifically, a load equal to three times the bundle weight is applied at the tie plate handle to grapple attachment. The load is reacted at the eight tie-rod locations.

##### **Lower Tie Plate**

The design loading for the Lower Tie Plate is from bundle handling.

##### **Fuel Rod End Plugs**

The design loading for the Fuel Rod End Plugs is from bundle handling.

##### **Plenum Spring**

The Plenum Spring is designed to resist an acceleration of the fuel pellet column while being transported without deflecting the spring.

##### **Expansion Spring**

The Expansion Springs are designed to resist downward forces from grappling and the weight of the suspended components such as the tie plate while allowing expansion from irradiation growth of the individual fuel rods.

##### **Water Rods**

The Water Rod tubing was evaluated for a steady-state differential wall pressure. The maximum load that a Water Rod tab could experience due to operating effects of spacer lift forces from flow or differential thermal expansion between the fuel rods and Water Rods is the load required to simultaneously slide all fuel rods through a spacer.

##### **Spacer**

Tests are performed to demonstrate that the Spacer design can withstand design basis loading without any significant deformation.

##### **Channel**

The design loadings for the Channel include steady-state and transient operating differential pressure. The Channel is tested to demonstrate capability to withstand bending loads from lateral seismic loading.

#### **9A.1.2.3.7 Inadvertent Dropping of Heavy Objects and Equipment on Fuel Assemblies**

Refer to Subsection 9A.8.1 and Chapter 3, Subsection 3.4.4.3, for information pertaining to the inadvertent dropping of heavy objects and equipment on fuel assemblies.

#### **9A.1.2.3.8 Inspection and Safe Storage of Suspect or Damaged Fuel Elements or Fuel Assemblies**

Although rare, mechanical damage to a fuel assembly can occur due to fuel rod cladding wear from fretting or from a fuel handling accident. In the unlikely event that a Fuel Handling Accident (FHA) does occur, visual inspections are performed to assess the extent of damage followed by an action plan. The damaged assembly is recovered under a special written procedure lifting from the normal bail handle and stored in a fuel storage rack.

Failed fuel requires special consideration because of its significance during operations. Fuel failures are first detected via the plant's Offgas System (Chapter 11, Subsection 11.3). In addition, grab samples for measuring individual isotopic activities with spectrometry equipment is typically performed.

Typically, six major nuclides are measured and the sum of these is reported as the total offgas release rate. Xenon-133 is by far the most important isotope among these for determining the presence of fuel failures. Virtually all "indicators" or calculated parameters for fuel integrity monitoring rely on the relative increase in Xe-133 inventory to help detect leaking spent fuel. Whenever the measured isotopic mixture becomes relatively rich in Xe-133 it indicates a cladding perforation and release of stored gas. Fission product activity in the reactor coolant is monitored separately (e.g., iodine, strontium, and cesium isotopes) and typically only shows an increase for more significant failures.

#### **9A.1.2.3.9 Radiation Protection**

Radiation protection complies with the CNSC guidance (Reference 9A.1.2-3) for normal operation and anticipated operational occurrences. Radiation exposure is kept within regulatory limits and As Low As Reasonably Achievable (ALARA) (Chapter 12, Subsection 12.3.1) goals.

Radiation monitoring is provided for the fuel pool storage area and the associated ventilation paths (Chapter 11, Subsection 11.5.3). The Refueling Platform, hoist, and grapple include interlocks to prevent potential refueling errors and reduce the possibility of exposure of plant workers. The Refueling Platform telescoping mast design provides a rigid mechanical stop that makes it physically impossible to raise fuel above the safe level below the water.

The fuel pool is designed to ensure the area dose rate is less than 25  $\mu\text{Sv/hr}$ . Fuel handling equipment design ensures that the operator is not exposed to 25  $\mu\text{Sv/hr}$  when fuel and irradiated components are being stored or handled in accordance with ANSI 57.1, Design Requirements for Light Water Reactor Fuel Handling System (Reference 9A.1.2-5). The BWRX-300 design does not have integrated containment shielding in the fuel transfer zone from the core to fuel pool and over the top of containment. This creates the need for a temporary and removable radiation shielding transfer canal or cattle chute that shields personnel in containment from fuel or irradiated components passing through the fuel transfer zone to the fuel pool. The water coverage over spent fuel assemblies in transit to the fuel pool or core is influenced by the grapple normal up limit and the fuel pool normal water level.

The air above the fuel pool and refuel floor equipment areas is monitored. In the event of a Fuel Handling Accident in the Fuel Handling Machine area, a radiation monitor alarm initiates closure of the RB isolation dampers and securing of the RB upper level supply Air Handling Units.

#### **9A.1.2.3.10 Identification of Individual Fuel Bundles**

Every fuel bundle contains a serial number on top of the bail handle which is part of the upper tie plate. Not only are these serial numbers used to specify each bundle's location in the core for each cycle but ultimately to track every bundle from manufacturing to ultimate disposal. All special

nuclear material accountability rules are strictly followed, and records are retained for every movement of a bundle over the bundle's life. Refer to Safeguards Annex, Section 7 for information pertaining to nuclear material accountancy.

**9A.1.2.3.11 Maintenance and Decommissioning of Fuel Storage and Handling Facilities**

Proper maintenance and operation of Fuel Pool systems is necessary to maintain water quality and radionuclides at acceptable levels. Maintenance of water quality is necessary to prevent degradation of the spent fuel and other materials stored in the fuel pool (i.e., control rod blades or incore instrument strings). Fuel pool water treatment and system maintenance programs prevent the buildup of excessive concentrations of contaminants and radionuclides and mitigate the consequences of any potential release from the fuel pool (Subsection 9A.1.3).

Scheduled maintenance ensures that structures and systems required for containing, cooling, cleaning, level monitoring and makeup of water in the fuel pool are operable consistent with the licensing basis. The application of scheduled maintenance reduces high levels of contaminants and radionuclides in the pool water that can have adverse effects on stored fuel, the fuel pool, fuel transfer components, and related equipment.

Operating procedures coupled with surveillances and observations, indicate changes in fuel pool level. Procedures address appropriate maintenance, calibration, and surveillance of available monitoring equipment.

Plant decommissioning and dismantling activities considered at the design phase include considerations of experience gained from the decommissioning of existing plants, as well as those plants that are in long-term safe storage. Refer to Chapter 21 for information related to decommissioning of the BWRX-300.

**9A.1.2.3.12 Decontamination of Fuel Handling and Storage Areas and Equipment**

Decontamination of fuel handling and storage areas and equipment is performed as required to comply with ALARA requirements as discussed in Chapter 12 and prevent the spread of contamination.

New and spent fuel is stored in the fuel pool. As part of typical operating practice, area's outside of the fuel pool where fuel is handled are surveyed for contamination. The plant is supplied with equipment and features to accomplish effective decontamination without spreading contamination. Wash-down areas and sink drains are routed to the liquid radioactive waste system (Chapter 11, Subsection 11.2). The Reactor Building Ventilation System (Subsection 9A.5.1) maintains negative pressurization of potentially contaminated areas to control leakage of potentially radioactive effluent to the atmosphere. Vendor-supplied services may also be utilized for handling and storage area decontamination.

In the event radiation surveys of tools indicate additional decontamination is required the tools may be sent to a decontamination room for processing.

Design considerations for environment and safety are imposed upon tooling to facilitate operator safety and to ensure ALARA guidance and best practices are incorporated into the design process. Typical design considerations for the decontamination of fuel handling and storage areas and equipment includes:

1. Ease of decontamination
2. Elimination of crevices which facilitates crud removal

3. Minimization of crud buildup which facilitates decontamination and cleaning of equipment, components, and contaminated areas, and helps to prevent airborne contamination dispersion
4. Use of the best construction materials (smooth surface)
5. Use of HEPA filters as required to support cleaning of equipment post use

Criteria for selecting tools, materials, and equipment for use in contaminated areas includes minimizing the use of porous or other materials that are difficult to decontaminate.

**9A.1.2.3.13 Implementation of Adequate Operating and Accounting Procedures to Prevent Loss of Fuel**

Refer to Safeguards Annex, Section 7, for information related to operating and accounting procedures to prevent loss of fuel.

CNSC regulatory document REGDOC-2.13.1 (Reference 9A.1.2-4), on safeguards and nuclear material accountancy, sets out CNSC's requirements and guidance for the:

- Establishment and maintenance of a safeguards program
- Requirements for event and compliance monitoring reporting by licencees

OPG compliance with CNSC REGDOC-2.13.1 is discussed in the "Safeguards Annex."

**9A.1.2.3.14 Measures to Prevent a Direct Threat or Sabotage to Irradiated Fuel**

Information pertaining to the measures to prevent a direct threat or sabotage to irradiated fuel is considered Protected Information and withheld from the public.

**9A.1.2.3.15 Safeguards Requirements for Recording and Reporting Accountancy Data, and for Monitoring Flows and Inventories Related to Irradiated Fuel Containing Fissile Material**

Refer to the Safeguards Annex, Section 4 "Safeguards and Operation" and Section 7 "Nuclear Material Accountancy" for information pertaining to safeguards requirements for recording and reporting accountancy data, and for monitoring flows and inventories related to irradiated fuel containing fissile material.

The fuel pool which is used for fuel storage includes provisions as discussed in the noted sections:

1. Controlling the chemistry and activity of any water in which irradiated fuel is handled or stored (Subsection 9A.1.3, Table 9A.1.3-1)
2. Monitoring and controlling the water level in the fuel storage pool (Subsection 9A.1.3)
3. Detecting Leakage (Subsection 9A.1.2.3.16)
4. Preventing the pool from emptying in the event of a pipe break (Subsection 9A.1.2.2)
5. Sufficient space to accommodate the entire reactor core inventory at all times (Subsection 9A.1.2.3.16)

**9A.1.2.3.16 Component Description**

**Storage Racks**

The fuel racks consist of a stainless steel structure composed of neutron absorbing material in a series of square vertical tubes (cells).

The fuel storage racks are top entry racks with bail extended above the rack and designed to preclude the possibility of criticality.

The fuel assemblies are stored in the fuel storage racks that are arranged in the fuel pool as shown in Figure 9A.1.2-1. The fuel storage racks provide space for storage of fresh fuel as well as space for longer term storage of the spent fuel assemblies for cooling prior to transfer to onsite storage or off-site shipment.

The BWRX-300 design includes storage for approximately 600 bundles. The fuel racks can hold an entire reload of fresh fuel and up to approximately eight years of spent fuel and have space remaining to accept a full core of off-loaded fuel.

### **Liner**

The pool liner is designed to meet Seismic Category B requirements. The fuel pool liner is capable of withstanding all design loads as discussed in Chapter 9B. Under certain conditions the fuel pool boils to provide cooling of the spent fuel. The design of the fuel pool liner is capable of withstanding the high temperatures associated with a boiling pool. A leak detection system is provided to detect fuel pool leaks.

For normal conditions of operation, the spent fuel assemblies are cooled by the Fuel Pool Cooling and Cleanup System (FPC). In the event of a loss of the fuel pool cooling and cleanup functions (such as station blackout) the primary defense line maintaining fuel pool temperature is boiling of the fuel pool. Refer to Subsection 9A.1.3 for a description of the FPC.

### **Refueling Platform**

The refueling platform is a gantry-type crane that spans the reactor vessel cavity and fuel pool and is employed to handle fuel and perform other ancillary tasks in the reactor building. It is equipped with a traversing trolley on which is mounted a telescoping mast and a fuel grapple. The refueling platform is a rigid structure built to precise engineering standards to ensure accurate and repeatable positioning during the refueling process. Additional information pertaining to the refueling platform is provided in Subsection 9A.1.2.3.5.

#### **9A.1.2.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials through material chemistry, heat treatment, contamination, and material processes controls.

#### **9A.1.2.5 Interfaces with Other Equipment or Systems**

Interfaces associated with the Fuel Pool include those identified in Subsection 9A.1.3.5 for the Fuel Pool Cooling and Cleanup System as well as the Fuel Handling Systems for Cask Loading, (Subsection 9.1.4), Reactor Building Polar Crane (Section 9A.8), and RB HVAC (Subsection 9A.5.1).

#### **9A.1.2.6 Systems and Equipment Operation**

Refer to Subsection 9A.1.3 for information related to the operation of the Fuel Pool Cooling and Cleanup System. Refer to Subsection 9A.1.4 for information pertaining to fuel handling operations, Subsection 9A.5.1 for information pertaining to Heating, Ventilation and Cooling System, and Section 9A.8 for information pertaining to the operation of cranes, hoists, and elevators.

#### **9A.1.2.7 Instrumentation and Control**

Subsection 9A.1.3 "Fuel Pool Cooling and Cleanup" describes the fuel pool water temperature and water level instrumentation. Chapter 12, Section 12.3 describes design features for radiation protection. Subsection 9A.5.1.8 describes the Heating, Ventilation and Cooling System instrumentation.

#### **9A.1.2.8 Monitoring, Inspection, Testing, and Maintenance**

The design of the fuel pool liner and fuel storage racks facilitate inspections of the exposed surface of the liner and fuel storage rack.

Neutron absorbing material coupons are provided with the spent fuel racks for the purpose of monitoring for potential degradation of the material over the design life of the equipment.

Refer to Chapter 3, Subsection 3.5.5.6 for information pertaining to testing and in-service inspection requirements related to the RB. The design of the fuel pool provides monitoring for the loss of decay heat removal capability using the temperature measuring instruments in the Fuel Pool Cooling and Cleanup System as described in Subsection 9A.1.3. Radiation monitors are provided in the Fuel Pool area to detect both general area radiation levels and airborne contamination levels as described in Chapter 12, Subsection 12.3.5.4.

#### **9A.1.2.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

The design of the fuel pool minimizes buildup of contamination and provides shielding. The surface finishes of the components for the fuel storage racks are smooth to minimize accumulation of radioactive materials and to facilitate surface decontamination. The depth of the water above the fuel assemblies and the thick concrete walls of the fuel pool provides shielding for the assemblies.

#### **9A.1.2.10 Performance and Safety Evaluation**

The fuel storage racks, and fuel pool (including liner) are located inside of the Reactor Building. The design of the Reactor Building withstands combinations of mechanical, hydraulic, and thermal loads and natural phenomena effects, including severe winds such as hurricanes and tornadoes (Chapter 3, Subsection 3.3.2), floods (Chapter 3, Subsection 3.3.3), external and turbine-generated missiles (Chapter 3, Subsection 3.3.5 and Chapter 10 Subsection 10.2.3), and earthquakes (Chapter 3, Subsections 3.3.1). The Reactor Building protects the fuel pool, liner, and fuel storage racks from these hazards.

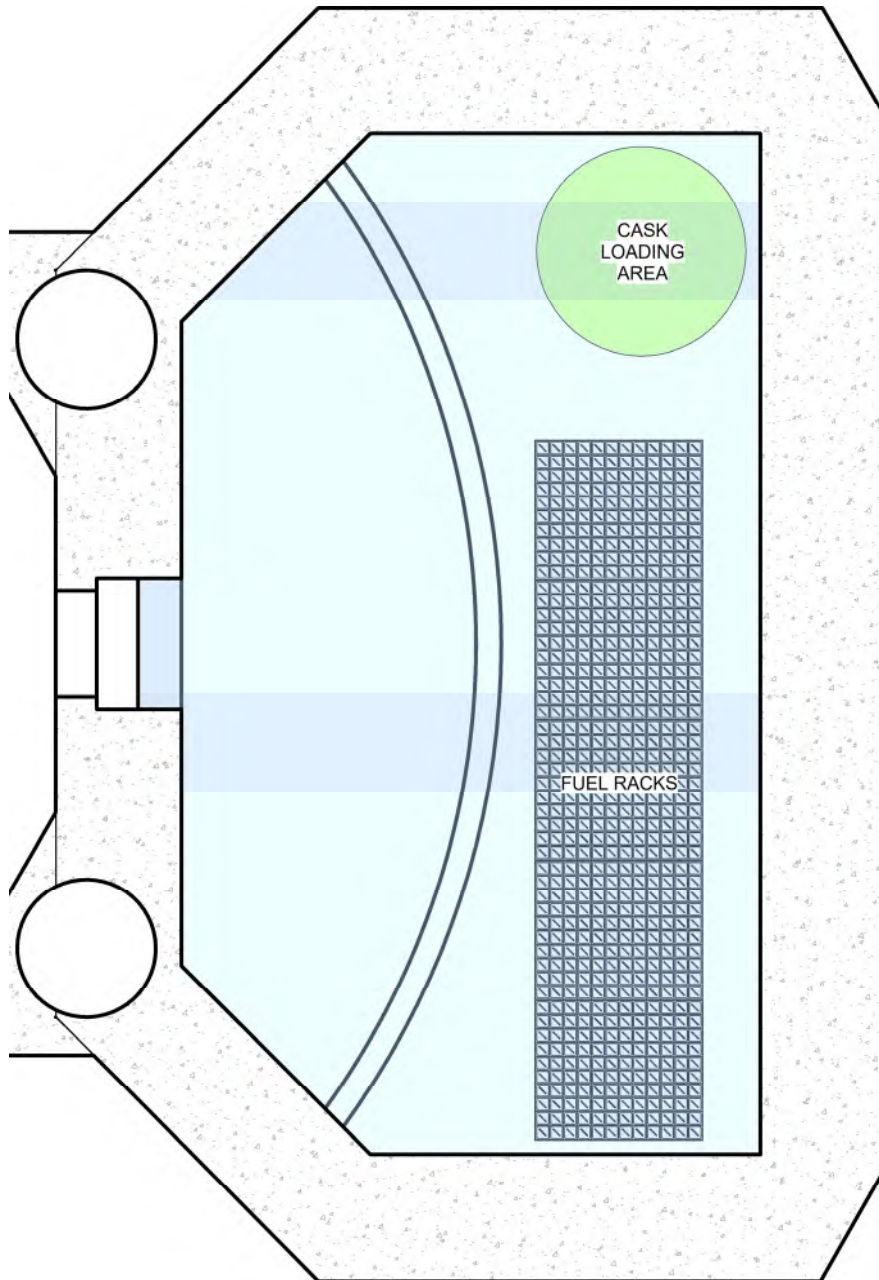

The design of the fuel storage racks is such that  $K_{eff}$  remains less than or equal to 0.95 under design basis conditions, including fuel handling accidents. Drop of a fuel assembly onto fuel assemblies stored in the fuel pool is discussed in Chapter 15, Subsection 15.5.8. Handling equipment capable of carrying loads heavier than fuel components are prevented by design and administrative controls from carrying loads over the fuel pool (Subsection 9A.8).

**Figure 9A.1.2-1: Fuel Pool Arrangement**

### **9A.1.3 Fuel Pool Cooling and Cleanup System**

The primary function of the FPC is to provide continuous cooling of the water volume in the fuel pool to remove decay energy from spent fuel, and to provide replacement coolant inventory from a variety of sources, both to ensure spent fuel is kept cool and submerged throughout the life of the plant. In addition, FPC includes demineralization and particulate filtration to maintain coolant quality and to reduce general area dose. FPC can be realigned to provide cooling and cleanup to the reactor cavity and equipment pools as necessary.

The FPC system is generally classified as Defense Line 2, Safety Class 3 (DL2/SC3) system.

The portion of the system that provides makeup capacity to the pool is classified as Defense Line 4b, Safety Class 3 system.

#### **9A.1.3.1 System and Equipment Functions**

System and equipment functions associated with the FPC system include the following.

##### **9A.1.3.1.1 Normal Functions (Non-Safety-Category)**

1. The FPC system maintains the water quality of the Fuel Pool, Reactor Cavity Pool, and Equipment Pool through filtration and demineralization during Modes 1-6. Refer to Chapter 16, Subsection 16.7 for definitions of operating Modes.

##### **9A.1.3.1.2 Normal Functions (Safety-Category)**

1. The FPC system provides cooling (SC3) of the Fuel Pool, Reactor Cavity Pool, and Equipment Pool during Modes 1-6.
2. The FPC system provides makeup capacity for the Fuel Pool (SC3), Reactor Cavity Pool, and Equipment pool (SC3) during Modes 1-6 delivered directly to the surge tanks and circulated to the pools.
3. The FPC system maintains the water level of the Fuel Pool (SC3) for shielding and cooling.
4. The FPC system provides high heat load cooling of the Fuel Pool and Reactor Cavity Pool during Mode 6 (refueling outage).

##### **9A.1.3.1.3 Off-Normal Functions (Non-Safety-Category)**

1. The FPC system is able to restore the Fuel Pool temperature to normal operating limits from elevated temperatures due to an off-normal event upon restoration of the forced cooling components of the system.

##### **9A.1.3.1.4 Off-Normal Functions (Safety-Category)**

1. The FPC system provides makeup capacity for the Fuel Pool (SC3) during off-normal events, independent of the forced cooling portion of the system.
2. The FPC system maintains the water level of the Fuel Pool (SC3) for shielding and cooling during off-normal events.

#### **9A.1.3.2 Safety Design Bases**

The FPC System provides continuous cooling normal plant operations, and makeup capacity for the fuel pool during normal and off-normal plant operations. Shielding is afforded by maintaining fuel pool water levels. The FPC System provides high heat load cooling of the Fuel Pool and Reactor Cavity Pool during Mode 6 (refueling outage).

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

The fuel pool and its supporting cooling system functions are capable of maintaining the fuel pool temperature within a set upper limit given the:

1. Normal decay heat load that occurs when an accumulation of spent fuel equal to 8 years is in the fuel pool, with the newest batch having just been placed in the pool during refueling within the first 72 hours after shutdown
2. Maximum decay heat load, which is the normal heat load plus the addition of the decay heat from a full core that is off-loaded to the fuel pool 72 hours after shutdown

FPC System provides make up capacity to the fuel pool during off normal events to maintain adequate fuel coverage.

The design of the FPC system meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.12.2 (Reference 9A.1.3-1) as related to the handling and storage systems associated with spent fuel specifically heat removal in operational states. Refer to Subsection 9A.1.4 for information related to the handling of spent fuel and Subsection 9A.1.2 for information related to spent fuel storage systems.

### **9A.1.3.3 Description**

Refer to Figure 9A.1.3-1 which depicts the FPC.

The BWRX-300 includes capabilities for the handling and storage of new and spent fuel to support operation of the plant with fuel cycle durations from 12 to 24 months. The FPC system provides cooling and cleaning of the water in the Fuel Pool, reactor cavity pool, and equipment pool during power operations.

The FPC system and its supporting cooling system functions are capable of maintaining the Fuel Pool temperature within a set upper limit as described in Subsection 9A.1.3.2.

The FPC System provides make up capacity to the Fuel Pool during Off-Normal events to maintain adequate fuel coverage. The FPC system is constructed such that any breach of the system cannot cause draining of the Fuel Pool to a level below 3.05 m above the top of active fuel.

The FPC System consists of two trains of equipment, each with a pump, demineralizer, and heat exchanger. The capability to bypass the demineralizer while providing active cooling to support restoration of the pool temperature from conditions exceeding the demineralizer operational temperature limits is provided. Each set of components are placed in parallel to provide single train operation and cross connecting of trains should a component fail. A single train is sufficient to prevent bulk boiling in the Fuel Pool. If both trains are rendered inoperable, the Fuel Pool is sized such that it can retain sufficient coverage of the fuel for seven days, and FPC can provide makeup capacity independently of the forced cooling trains.

#### **9A.1.3.3.1 Component Description**

The following information is provided relative to the major equipment and components in the FPC.

#### **Surge Tank Description**

The surge tank(s) receive inventory from the reactor cavity and fuel pool as it overflows weirs located near the top of the reactor cavity and fuel pool. Surge tank(s) are utilized to provide protection from a breach in the system draining either pool volume (versus direct suction) and provide a dampening effect for volume changes in the pools due to outage or dry cask evolutions. The primary advantage of a separate surge volume is that the pool level can be constant, while natural evaporation or addition or removal of submerged equipment only varies the level of the

surge tank. Coolant inventory addition can be added directly to the surge tank during normal operating conditions. The FPC system surge tanks meet the requirements of American Society of Mechanical Engineers (ASME) Section III NCA and NCD.

### **Pumps**

Each pump represents the beginning of two separate trains of the FPC system. They can be run individually during normal heat removal and cleanup modes (A1, A2) or in combination for high heat load (B, C) operating modes. Pumps are sized for maximum efficiency at the normal operating point. Pump internal recirculation cavitation is avoided within the entire range of operation. The pump selection, installation and system design assure that the minimum available Net Positive Suction Head (NPSH) and minimum submergence meet the Hydraulic Standards Institute guidelines for all steady-state and transient conditions of operation. If parallel operation is specified, the head rise from rated point to shutoff is at least 10%.

The FPC system pumps meet the requirements of ASME Section III NCA and NCD.

### **Heat Exchangers**

Each train includes two heat exchangers (four in total) used to reject waste heat to the Plant Cooling Water System (PCW) (Subsection 9A.2.1). Each heat exchanger is a shell and tube design, with reactor coolant flowing on the tube side to take advantage of inherent shielding and reduce dose. Each heat exchanger is sized to fit within the Reactor Building hatch to allow removal or replacement during the operating life and decommissioning of the plant. Heat exchangers are designed, manufactured, installed, and tested in accordance with applicable codes and standards, including Thermal Exchanger Manufacturers Association, API-662, ASME Boiler and Pressure Vessel Code (BPVC), Section III and ASME BPVC Section VIII. Large shell and tube heat exchangers are designed with provisions for either tube bundle replacement or individual tube replacement and individual tube plugging in place. Heat exchanger fouling factors are established considering conservative predictions of material buildup based on actual system and equipment designs and expected plant operating conditions. Heat exchanger tubes are seamless.

### **Piping/Valving**

Piping in radioactive systems such as the FPC System have butt-welded connections, rather than socket welds, to reduce crud traps. Features to prevent flow discontinuities that can lead to retention of corrosion products (crud traps) in the walls of the equipment and components are incorporated into the design. Bends, branches, corners, dead legs, and low points are avoided in piping and piping layout. Mitigating engineering features are added where avoidance is not possible. These piping and valve design features reflect implementation of ALARA guidance as presented in Chapter 12, Section 12.1.

FPC system piping potentially containing resin is designed to be continuously sloped downward to the receiving system or tank.

The FPC system piping, and valves meet the requirements of ASME Section III NCA and NCD.

### **Demineralizers / Filters**

Each demineralizer train of FPC system contains a particulate filter and deep bed mixed resin demineralizer which can each support 100% of the train's flow. The filter may be backwashed to the Liquid Waste Management System (Chapter 11, Section 11.2) to remove accumulation and reduce dose. The demineralizers each operate in both normal (A1, A2) and high heat (B) modes, but can also be bypassed if the temperature of the system coolant exceeds the operational limits of the demineralizer (C).

Process equipment that accumulates a radiation source from filtering process streams such as the Condensate Filters and Demineralizers System (CFD) (Chapter 10, Subsection 10.3.1), and the FPC systems are remotely operated, including the backwashing operations. Provisions are made for remotely backflushing the filters and demineralizers. FPC system filters are backwashed into a backwash receiving tank, which then is routed to the Radwaste Systems. All FPC System valves (e.g., inlet, outlet, recycle, vent, and drain) on the filters and demineralizers are located outside the shielded cubicles in a separate shielded cubicle or area together with associated piping, headers, and instrumentation.

The FPC system filter element shell and demineralizer vessel meet the requirements of ASME Section III NCA and NCD.

### **Off-Normal Makeup**

The Off Normal makeup portion of the system represents the seismic DL4b portion of the system intended to provide replacement inventory to the fuel pool. It utilizes multiple sources to maintain pool level in the event of a failure of the active cooling portion of FPC.

#### **9A.1.3.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials specifically from Intergranular Stress Corrosion Cracking (IGSCC) (as applicable) through material chemistry, heat treatment, contamination, and material processes controls.

Features to prevent flow discontinuities that can lead to retention of corrosion products (crud traps) in the walls of the equipment and components are incorporated into the design. Bends, branches, corners, dead legs, and low points are avoided in piping and piping layout.

#### **9A.1.3.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.1.3-1 for FPC interfaces with other equipment or systems.

#### **9A.1.3.6 System and Equipment Operation**

The FPC system is primarily intended to maintain pool temperatures during plant operation and refuel outages. During Modes 1-5, a single train of FPC is running to provide cooling and cleanup of the Fuel Pool, Reactor Cavity, and Equipment Pool inventory (Mode A1 and A2.) Supply to each pool may be balanced based on temperature variations and heat loadings in each volume. During refuel outages (Mode 6) the FPC system may be run in normal (FPC mode A1 or A2) or High Heat Mode (FPC mode B) as the temperature of the Reactor Cavity and Fuel Pool dictates. In the event of elevated pool temperatures, which exceed the operating specifications of the demineralizers such as restoration from an Off-Normal event, the FPC system may be run in High Heat – Bypass (FPC mode C) which utilizes both equipment trains of pumps and heat exchangers to provide maximum cooling without cleanup. Once the pool temperature returns to acceptable levels, the FPC system may then return to Mode B or Mode A as required.

##### **9A.1.3.6.1 Initial Configuration (Pre-Startup)**

As a system intended to always be in operation, there are no specific pre-startup conditions. Operation of the FPC system is independent of reactor operation.

##### **9A.1.3.6.2 System Startup**

Generally, a single train of FPC is running continuously.

During startup of a train, confirmation of the following is obtained:

- Valve alignment for the intended mode
- Sufficient surge capacity
- Pump inlet pressure to avoid cavitation
- Pump start
- Anticipated component performance indications

This same process may be used to add a second train during high heat modes. In the changeover from one train to the other, it is preferable to start the second train and confirm normal operation prior to shutting down the first train.

#### **9A.1.3.6.3 Normal Operations**

During normal operations the FPC system operates in the following modes:

##### **Mode A – Normal Heat Load**

The most frequent mode of operation of the FPC system is “normal heat load” operation, intended to be used during plant operating Modes 1-5. This mode includes a single train of the FPC system operating to remove heat generated by spent fuel stored in the fuel pool, as well as any thermal contribution from the Passive Containment Cooling System (Chapter 6, Subsection 6.3.3) to the equipment pool, or thermal leakage from containment to the reactor cavity pool. Cleanup consisting of particulate filtration and demineralization of 100% of the water passing through the system is performed. During Mode A, coolant inventory can be added from the condensate storage tank as required to makeup evaporation losses or over-boarded to the condensate storage tank after cleanup and cooling to create additional pool volume for submersion of spent fuel dry cask equipment. Mode “A1” and “A2” may be used to signify which train is in operation, both trains function identically.

##### **Mode B – High Heat Load**

Mode B utilizes both trains of FPC equipment running simultaneously to double the volume of water cooled and cleaned. This mode still retains 100% filtration and demineralization and is intended to be used predominately during plant operating Mode 6 “Refueling,” when high activity spent fuel is transferred to the fuel pool, and water clarity and dose are of particular concern. As with Mode A, coolant inventory can be added or overboarded to support outage operations and maintain water level.

#### **9A.1.3.6.4 Off-Normal Operations**

##### **Mode C – High Head Load – Bypass**

Mode C functions identically to Mode B, except the demineralizers are isolated from the system and a bypass is utilized. Mixed bed resin demineralizers tend to have modest thermal operating limits, typically less than 60 °C which when exceeded can cause resin excursions contaminating plant equipment and pools. To retain the high heat removal capacity but prevent damage to the resin beds during high pool temperature events, Mode C may be utilized until the water temperature is restored to a threshold allowing Mode B service.

##### **Mode D – Active Cooling Inoperative**

Mode D is an off-normal condition where the active cooling and cleanup portion of the FPC system is unable to be operated such as during a site blackout. Mode D operations allows for multiple sources of coolant addition directly to the Fuel Pool, bypassing the remaining system or any potential breeches that may have occurred. The plant sources include the condensate storage

tank, and the Fire Protection system. Mode D also includes an Emergency Mitigating Equipment (EME) connection allowing addition of coolant through temporary means. The Fuel Pool volume is intended to contain sufficient water inventory to allow seven days of spent fuel decay heat to be absorbed while maintaining sufficient coverage of 3.05 m over fuel. Operations in Mode D is required for additional inventory to be added to meet the 30-day event criteria.

#### **9A.1.3.6.5 System Shutdown**

The FPC system is intended to operate, with at least a single train, during all modes of plant operation. Individual trains may be idled or placed in standby through shutdown of pumps and isolation of equipment as heat load or maintenance and testing require.

#### **9A.1.3.7 Instrumentation and Control**

As an SC3 system, control of the FPC system is performed through the Safety Class 2 and 3 Instrumentation and Control System indication of pool temperature and water level. During normal operation, pumped capacity is varied through use of one or both system trains, with output balanced through motor operated control valves to the equipment, reactor cavity, and fuel pool to distribute cooled water in a manner best matching the sources of thermal energy. Addition or reduction of inventory, both as a natural function of environmental conditions, as well as supporting maintenance and outage evolutions, can be performed manually.

During off-normal events, with the forced cooling portion of the system assumed to be inoperable, make up capacity can be initiated from various sources, again through the Safety Class 2 and 3 Instrumentation and Control System, as redundant Fuel Pool level indication requires. Major components (pumps, demineralizers, heat exchangers) have performance indication through the Safety Class 2 and 3 Instrumentation and Control System, and component protection such as bypassing of demineralizers if system temperature exceeds limits and stopping of pumps on low flow and low suction pressure signals are automated.

#### **9A.1.3.8 Monitoring, Inspection, Testing, and Maintenance**

Maintenance and testing support equipment reliability. SSC are designed to facilitate operation and maintenance. Trending of operational characteristics of equipment such as demineralizers, filters, and heat exchangers identifies reductions in performance signaling maintenance is required. Trains are switched periodically to balance equipment usage and provide surveillance opportunity to both trains. In-Service Inspection (ISI) and In-Service Testing (IST) requirements are established and include inspection/test frequency for SSC.

Maintenance activities related to the FPC system fall into two categories:

1. Ongoing/Frequent Maintenance: Anticipated maintenance activities such as backflushing of particulate filters, flushing and replacement of spent resin in demineralizers, and decontamination of lines to reduce area dose.
2. Infrequent Maintenance: Anticipated activities that occur during the life of the plant which includes equipment replacement of components such as pump impellers, motors, valves, heat exchangers, and filter cartridges. These maintenance evolutions take place as a response to long-term trending of system performance or as preventive maintenance scheduled based on anticipated component life span.

In both cases, maintenance on the FPC system is performed predominately during Plant Mode 1 operation, when thermal loads in the Fuel Pool are low allowing a single operable train to satisfy plant needs while the other may be isolated for work.

Maintenance practices consider industry best practices and operating experience and conform with plant safety requirements to minimize potential for personnel injury. Maintenance activities implement ALARA practices to minimize work activity dose. Maintenance activities involving plant equipment may require involvement of vendors or industry specialists.

#### **9A.1.3.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions. Chapter 12, Subsection 12.3.8.3 presents Fuel Pool Cooling major ALARA design considerations.

#### **9A.1.3.10 Performance and Safety Evaluation**

The FPC System is designed to perform its function in a reliable and failure tolerant manner. This reliability is achieved with the use of rugged and redundant equipment. Each set of components (pumps, demineralizers, heat exchangers) are placed in parallel to provide single train operation and cross connecting of trains should a component fail. A single train is sufficient to prevent bulk boiling in the fuel pool. If both trains are rendered inoperable, the fuel pool is sized such that it can retain sufficient coverage of the fuel for seven days, and FPC can provide makeup capacity independently of the forced cooling trains.

The FPC System Safety-Category functions during Normal and Off-Normal conditions include providing makeup capacity to the Fuel Pool, maintaining the water level of the Fuel Pool for shielding and providing Fuel Pool Cooling. In addition, Off-Normal makeup piping and valves which are SC3 and Seismic Category A are provided to allow remote addition of water to the Fuel Pool during Off-Normal conditions through temporary means thereby ensuring spent fuel is cooled and fuel pool water levels are maintained.

In the event of an aircraft impact, there are provisions to refill the pool utilizing Emergency Mitigating Equipment (EME) or other equipment and water sources in a suitable time frame such that adequate cooling of the spent fuel is maintained based on keeping the fuel covered with sufficient water.

The Fuel Pool is designed to dissipate the maximum spent fuel decay heat through heat-up and boiling of the fuel pool water. The most conservative heat load for the Fuel Pool occurs when the Fuel Pool contains spent fuel from the normal decay heat load that occurs when an accumulation of spent fuel equal to 8 years is in the fuel pool, with the newest batch having just been placed in the pool during refueling within the first 72 hours after shutdown.

The Fuel Pool is located in the Reactor Building which provides protection against natural phenomena; supporting the ability of the FPC System to perform its Safety-Category functions.

**Table 9A.1.3-1: Fuel Pool Cooling and Cleanup System Interfaces**

<b>Interfacing System</b>	<b>Interface Description</b>	<b>Interface Boundary</b>
Reactor Building, Fuel Pool, Reactor Cavity, and Equipment Pool	Overflow from the Fuel Pool and Reactor Cavity Pool weirs enters skimmer surge tanks and is pumped through cleanup and heat removal subsystems, then returned to the bottom of the Equipment Pool, Reactor Cavity Pool, and Fuel Pool as required.	Boundary from the Reactor Building exists at overflow from pools to Skimmer Surge Tanks. Boundary at supply exists at sparger nozzle(s) submerged in pools.
Liquid Waste Management System (LWM)	Condensate Storage Tank provides additional coolant inventory or storage volume for overboarding to reduce inventory. LWM also supplies liquid for back wash and flushing of cleanup systems.	Boundary exists at first isolation valve at each connection point.
Solid Waste Management System (SWM)	Repository for spent resin from demineralizers and backwash of filter elements. Flushed via piping to SWM using LWM inventory.	Boundary exists at first isolation valve at each connection point.
Offgas System (OGS)	Vent used to allow compressed air circulation of demineralizer resin and venting of volume.	Boundary exists at first isolation valve at each connection point.
Plant Cooling Water System	PCW supply for heat exchangers.	Boundary exists at first isolation valve at each connection point.
Plant Pneumatics System (PPS)	Air supply to allow mixing of demineralizer resin. Air Operated Valve operation as required.	Boundary exists at first isolation valve at each connection point.
Safety Class 2 and 3 Instrumentation and Control	Provides instrumentation and control for Safety Class 3 functions of FPC system.	Boundary exists at each rack prior to multiplexer.
Safety Class 2 and 3 Electrical Distribution System	Electricity supplied to pumps, motorized valves, and instrumentation/control throughout system.	Boundary located at individual component sub feed.
Process Radiation and Environmental Monitoring System (PREMS)	PREMS provides area radiation detector near the demineralizer, process sampling for radiological analysis and chemistry control.	Area radiation detector, process sampling routed to sample station.
Fire Protection System	Provides additional coolant inventory in Off-Normal conditions.	Boundary exists at first isolation valve at each connection point.

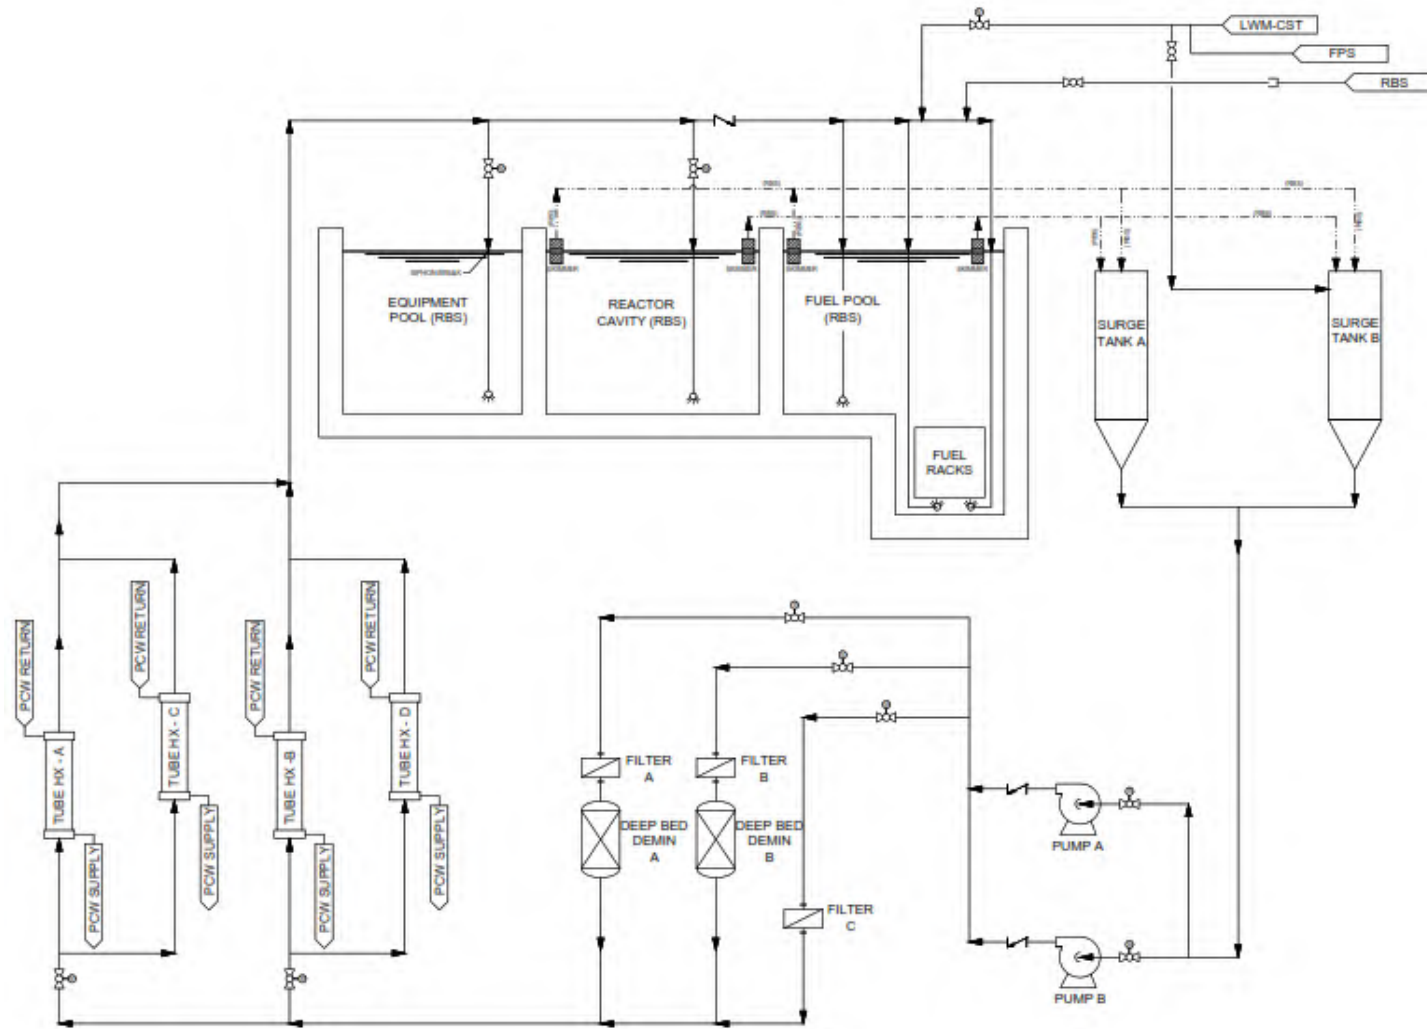

Figure 9A.1.3-1: Fuel Pool Cooling and Cleanup System

#### **9A.1.4 Handling Systems for Fuel Cask Loading**

##### **9A.1.4.1 System and Equipment Functions**

The system and equipment functions associated with the handling system for fuel cask loading, provide the means to transfer spent fuel located in the fuel pool into a spent fuel storage cask and transport of the spent fuel storage cask to a location for long-term storage. The following information is provided relative to demonstrating compliance to the requirements CNSC REGDOC-2.5.2 Section 8.12.1 (Reference 9A.1.4-1) as it pertains to fuel cask loading.

##### **9A.1.4.2 Safety Design Bases**

1. Fuel handling devices have provisions to avoid dropping or jamming of spent fuel assemblies during transfer operations.
2. Handling equipment used to raise and lower spent fuel has a limited maximum lift height so that the minimum required depth of water shielding is maintained.
3. Criticality during fuel handling operations is prevented by maintaining a geometrically safe configuration throughout the spent fuel transfer operation. Operators follow a strict movement plan and procedure and that includes pick up and set down locations for each step and those are followed and verified concurrently as each step is started and completed.
4. In the event of a Safe Shutdown Earthquake (SSE), handling equipment cannot fail in such a manner as to prevent required function of Safety Category 1 SSC.
5. Physical safety features are provided for personnel who operate handling equipment.

Refer to Subsection 9A.1.2.2 for the Safety Design Bases associated with the Fuel Pool. Refer to Section 9A.8 for the Safety Design Bases associated with the Cranes, Hoist, and Elevator System.

##### **9A.1.4.3 Description**

###### **9A.1.4.3.1 Refueling Platform**

The Refueling Platform is a gantry-type crane that spans the reactor vessel cavity, equipment pool, and fuel pool and is employed to handle fuel and perform other ancillary tasks in the reactor building. It is equipped with a traversing trolley on which is mounted a telescoping mast and fuel grapple. A monorail and auxiliary hoist are also provided. The Refueling Platform is a rigid structure built to precise engineering standards to ensure accurate and repeatable positioning during the refueling process. The Refueling Platform does not perform a Safety-Category function but is designed as Seismic Category I.

###### **9A.1.4.3.2 Irradiated Fuel Canister Loading**

The spent fuel is stored in the Fuel Pool before being loaded into a canister. Typical loading of a canister includes the following. Loading of the canister is performed in the Fuel Pool. The canister containing the spent fuel is then loaded into a concrete overpack. Canister loading patterns are determined by the age of fuel, exposure, and decay heat. A campaign normally involves loading the spent fuel canister while the unit is on-line.

An empty canister placed in a transfer cask for shielding is moved into the fuel pool. The selected bundles are moved under water from the spent fuel racks to the allotted location in the spent fuel canister. Once a spent fuel canister is filled with spent fuel, a video recording of the bundle serial numbers is performed, and the lid is placed on the canister. The canister is lifted from the fuel pool, drained, rinsed, and set on the cask pad on the refueling floor where the canister is

decontaminated. The canister is vacuum dried and sealed by welding the lid using remote welding techniques to minimize radiation exposure to workers. The canisters are filled and slightly pressurized with an inert gas, such as helium. The sealed canisters are leak tested and a non-destructive examination is performed on the weld. The shielded canister is installed into an overpack and then fitted with an overpack lid and placed in long-term storage.

Each spent fuel canister may contain several damaged fuel bundles; however, the specific loading is vendor dependent. The failed fuel bundles can stay in the fuel pool indefinitely without any special controls. If desired, fuel bundles can be reconstituted with new fuel or dummy rods replacing damaged rods. This is done on the fuel inspection stands in the fuel pool with long handled tools.

#### **9A.1.4.3.3 Irradiated Fuel Canister Movement to ISFSI Pad**

Typical canister movement from the fuel pool to the Independent Spent Fuel Storage Installation (ISFSI) pad is performed under the guidance and participation of Security and Health Physics. The RB Polar Crane is used to lift the transfer cask to the refuel floor and subsequently to the truck bay. The canister is transferred from the transfer cask to the storage cask and placed in long-term storage.

#### **9A.1.4.3.4 ISFSI Pad**

The ISFSI pad size is related to the vendor selected for the design and manufacturer of the spent fuel casks and the number of fuel assemblies to be stored.

The land usage required to provide long-term dry storage of spent fuel includes the fenced off area necessary to provide an acceptable radiation protection and security zone. Perimeter fencing, intrusion detection system, lighting and cameras are provided as required by CNSC irradiated fuel storage facility requirements.

#### **9A.1.4.4 Materials**

Materials selected for use in the Handling Systems for Fuel Cask Loading are chosen based upon the operating conditions to which they are required to function. The fuel storage racks use surveillance coupons for monitoring and evaluation of neutron absorber material.

#### **9A.1.4.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.1.4-1 for Handling System for Fuel Cask Loading interfaces with other equipment or systems.

#### **9A.1.4.6 System and Equipment Operation**

The handling of new fuel is described in Section 5 of the Safeguards Annex. The handling of irradiated fuel inside the fuel pool is described in Subsection 9A.1.2. Handling of irradiated fuel from the fuel pool to a storage canister is discussed in Section 5.1 of the Safeguards Annex. Handling of the spent fuel storage canister with respect to the transfer of the spent fuel canister to an overpack is discussed in Subsection 9A.1.4.3. Handling of the overpack during transport to long-term storage is discussed in Subsection 9A.1.4.3.

#### **9A.1.4.7 Instrumentation and Control**

Refer to Subsection 9A.1.3.7 for information pertaining to instrumentation and control associated with the fuel pool and Section 9A.8 for information pertaining to instrumentation and control associated with the RB Polar Crane.

#### **9A.1.4.8 Monitoring, Inspection, Testing, and Maintenance**

Maintenance of refueling equipment and tooling is performed prior to an outage to promote optimum reliability.

Refer to Subsection 9A.1.2.8 for information pertaining to the Monitoring, Inspection, Testing, and Maintenance of the fuel pool. Refer to Subsection 9A.8.1.8 for information pertaining to the Monitoring, Inspection, Testing, and Maintenance of Cranes, Hoists and Elevators.

#### **9A.1.4.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.1.4.10 Performance and Safety Evaluation**

The handling of new fuel is described in Section 5 of the Safeguards Annex. The handling of irradiated fuel inside the fuel pool is described in Subsection 9A.1.2. Handling of irradiated fuel from the fuel pool to a storage canister is discussed in SubSection 9A.1.4.3.2. Handling of the spent fuel storage canister with respect to the transfer of the spent fuel canister to an overpack and transport to the Independent Spent Fuel Storage Installation is discussed in Subsection 9A.1.4.3.3:

1. The fuel handling equipment is designed such that probability of dropping a fuel assembly following a safe shutdown earthquake has been minimized.
2. Each fuel assembly and control rod is placed strategically to maintain a non-critical configuration by following a specific fuel movement plan.
3. Underwater transfer of spent fuel assemblies provides radiation shielding. The fuel handling equipment has provisions to limit maximum height to maintain sufficient water inventory above the top of the fuel assembly.
4. The fuel handling equipment includes controls and interlocks that impose limits upon system operations, ensuring clearance between structures, systems, and components, thereby preventing the potential for mechanical damage to fuel during fuel transfer operations.

NON-PROPRIETARY INFORMATION

**Table 9A.1.4-1 Handling System for Fuel Cask Loading Interface**

<b>Interfacing System</b>	<b>Interface Description</b>	<b>Interface Boundary</b>
Fuel Pool Cooling and Cleanup System	FPC provides water clarity for underwater visibility FPC also provides water cooling to support fuel pool cooling activities.	The Handling System for Fuel Cask Loading equipment is immersed in water treated and cooled by FPC.
Core and Fuel	Supports the transfer of fuel assemblies in and out of the reactor core.	The mast of the Refueling Platform engages the bail handle of the fuel assembly.
Plant Pneumatics System	PPS provides pressurized air for powering pneumatic motors and tooling.	Gate seals, nozzle plugs, and tooling.
Non-Safety Electrical Distribution System	Provides electricity to the Handling System for Fuel Cask Loading equipment.	Inspection tooling, underwater lights, refueling platform, auxiliary platform, and tooling.
Grounding and Lightning Protection System	Provides electrical grounding for equipment.	Equipment and inspection equipment.
Cranes, Hoists and Elevators	The RB Polar Crane is used during the disassembly and re-assembly of the Reactor Pressure Vessel.	The Handling System for Fuel Cask Loading equipment couples to RB Polar Crane hook.
Heating Ventilation and Cooling System	Provides control of heat and humidity to work areas.	Ambient condition suitable work.
Reactor Building Structure	Supports the loads of equipment and provides railing for traversing of the Refueling Platform.	Equipment either rests on the refuel floor or its weight is transmitted to the RB walls through the RB Polar crane.

## **9A.2 Water Systems**

### **9A.2.1 Plant Cooling Water System**

The PCW system provides cooling water to Non-Safety and Safety Class 3 components and provides a barrier against radioactive contamination of the Circulating Water System (CWS) (Chapter 10, Section 10.8). It consists of two piping subsystems, Reactor Component Cooling Water Piping Distribution and Turbine Component Cooling Water Piping Distribution, that provide cooling water to various heat exchangers.

The safety classification of the PCW as well as interfacing Structures, Systems, and Components (SSC) is consistent with the requirements of CNSC REGDOC-2.5.2, Section 7.1 (Reference 9A.2.1-1).

#### **9A.2.1.1 System and Equipment Functions**

##### **9A.2.1.1.1 Normal Functions (Non-Safety-Category)**

The PCW circulates cooling water to the Reactor Component Cooling Water Piping Distribution and the Turbine Component Cooling Water Piping Distribution during normal operation and during anticipated operational occurrences, including startup, power operation, hot shutdown, cold shutdown, stable shutdown and refueling. The PCW is responsible for rejecting the total heat load associated with the equipment coolers in the Reactor Component Cooling Water Piping Distribution and Turbine Component Cooling Water Piping Distribution.

PCW operation is normally automatic based on plant operational mode but can be started or stopped manually from the Main Control Room and can operate at any time, regardless of the operational status of the generating unit.

The PCW design supports the redundant Reactor Component Cooling Water Piping Distribution and single Turbine Component Cooling Water Piping Distribution.

The cooling water temperature is maintained by a temperature control valve arrangement that bypasses the PCW heat exchangers with a portion of the return water.

##### **9A.2.1.1.2 Normal Functions (Safety-Category)**

The system provides the following normal safety functions:

- Control of the fuel pool temperature
- The system provides cooling for the SDC heat exchanger
- A barrier against radioactive contamination of the CWS

##### **9A.2.1.1.3 Off-Normal Functions (Safety-Category)**

Upon a Loss-of-Offsite Power (LOOP), the operating PCW pump(s) will trip. The pumps are automatically repowered from the standby diesel generators.

In the event of LOOP, the reactor cooling loops are used to support cooling of the Fuel Pool and Reactor to bring the plant to cold shutdown condition in 36 hours if necessary assuming the most limiting single active failure (single train in use), with use of the Isolation Condenser System (ICS) (Chapter 6, Section 6.2). If both trains are still in use, plant systems provide adequate shutdown cooling capacity to achieve appropriate reactor coolant temperature in 24 hours.

##### **9A.2.1.1.4 Off-Normal Functions (Non-Safety-Category)**

The system does not perform any Safety-Category functions during off-normal conditions.

#### **9A.2.1.2 Safety Design Bases**

The Safety Design Bases for the PCW includes the following Safety Class 3 functions:

- Temperature control of the fuel pool
- Cooling for the SDC heat exchanger

#### **9A.2.1.3 Description**

Figure 9A.2.1-1 depicts the Plant Cooling Water System.

The PCW system consists of two trains, each containing one pump and one heat exchanger, that handle the Reactor Component and Turbine Component cooling loads. One train is normally in operation while the other is on standby, to be started in event the operating train needs to be shutdown.

These independent trains are cross connected using manual cross ties to allow for online maintenance. If necessary, the Turbine Component Cooling Water Piping Distribution can be isolated from each Reactor Component Cooling Water Piping Distribution by closing the supply and return header valves on each train, and each Reactor Component Cooling Water train operates independent of the other.

Cooling water supplied by the PCW is continuously circulated through various auxiliary equipment heat exchangers and rejects the heat transferred to the CWS. The Turbine Component Cooling Water Piping Distribution is a single piping distribution that serves all equipment in the Turbine Building that do not support reactor cooling functions. The Reactor Component Cooling Water Piping Distribution consists of two redundant piping distributions that support all Reactor Building equipment cooling functions, Plant Pneumatic System and any equipment located outside the Reactor Building associated with reactor cooling activities.

Although PCW supports all plant equipment cooling functions, the design redundancy and isolation capability is centered around the ability to provide redundant cooling supply to nuclear systems.

One train of PCW equipment is normally in operation and in the event that train is lost, the standby train is started. During plant shutdown both trains of cooling equipment are used to provide required flow for Turbine Building and Reactor Building cooling functions. The Reactor Component Cooling Water Piping Distribution cools redundant equipment associated with nuclear cooling functions, thus if one train of the Reactor Component Cooling Water Piping Distribution is lost all redundant equipment will operate on the remaining train.

The PCW pumps and heat exchangers are in the Turbine Building. The pumps in each train are powered from separate busses. During a LOOP, the pumps are powered from the two Safety Class 3 standby diesel generators.

The PCW utilizes plate and frame type heat exchangers. This design mitigates cross-contamination of either PCW or CWS.

Temperature control valves in the system are provided to maintain the cooling water temperature within an allowable range.

Surge tanks provide a constant pump suction head and allow for thermal expansion of the PCW inventory. Makeup to the PCW inventory is from the PCW surge tank which is supplied from the Makeup Water System (Subsection 9A.9.5.1) through an automatic level control valve.

A chemical addition tank tie-in allows for manual introduction of corrosion inhibitor and pH control chemicals into the system.

The Turbine Building cooling loop serves but is not limited to the following equipment:

- Feedwater Pump Motors
- Feedwater Pump Variable Frequency Drive
- Condenser Pump Motor
- Vacuum Pump Skid
- Generator Cooler
- Isophase Cooler
- Lube Oil Cooler
- Electro-Hydraulic Control (EHC) Cooler

The redundant Reactor Building cooling loops serve the following equipment:

- Fuel Pool Cooling and Cleanup Heat Exchanger
- Isolation Condenser System Pool Cooling and Cleanup System (ICC) Heat Exchanger
- Shutdown Cooling System (SDC) Heat Exchanger
- Plant Pneumatics System Cooler

PCW equipment is designed for the plant normal operating environmental conditions specified for its location within the Turbine Building and Reactor Building. Refer to Chapter 3, Section 3.9 for information pertaining to Environmental Qualification of BWRX-300 SSC's.

#### **9A.2.1.3.1 Component Description**

##### **PCW Pumps**

The PCW pumps are designed to meet the requirements of ANSI/HI 1.3 (Reference 9A.2.1-2).

The pumps are constant speed, electric motor driven, horizontal centrifugal pumps. Pump impellers are less than the maximum diameter available for the pump casing. The pumps' mechanical seals minimize the potential for leakage and reduce the need to perform maintenance on shaft seal packings.

##### **PCW Heat Exchangers**

The PCW heat exchangers are designed to meet the requirements of ASME BPVC, Section VIII.

PCW is capable of performing design functions during all modes of operation.

Plate and frame heat exchangers are used to minimize the probability of possible cross-contamination between PCW and CWS. Strainers are installed on the raw water side of the exchangers due to the narrow passages plate and frame heat exchangers present. Leakage through holes or cracks in the plates is not considered credible based on industry experience with plate type heat exchangers. In addition, the heat exchangers are designed such that any gasket leakage from either PCW or CWS drains to the EFS (Subsection 9A.9.3).

The CWS water temperature on the other side of the heat exchanger to absorb the heat load. There is a bypass line provided for the PCW Heat Exchangers with an air-operated bypass temperature control valve. The flow of cooling water through the PCW Heat Exchangers is controlled by the PCW Heat Exchanger temperature control system aiming to achieve target

temperature based on the PCW Heat Exchangers outlet temperature readings sent to the Distributed control and Information System.

### **PCW Surge Tanks**

The PCW surge tanks are atmospheric corrosion-resistant tanks which are designed to meet the requirements of American Water Works Association D100. The surge tanks are sized to provide a pump suction head and to allow for thermal expansion. The surge tanks are located above the highest points in the PCW system. The makeup water supply is provided to maintain the water level in the tanks within the correct operating conditions.

### **Piping and Valves**

All Non-Safety-Category function piping is designed to meet the requirements of ASME B31.1, Power Piping.

Isolation valves are provided at the inlet and outlet of each heat exchanger and pump for maintenance and efficiency purposes. Isolation valves are provided at the interfaces with the components being cooled by PCW to allow for maintenance on those items without impact to the PCW system operation. These isolation valves add the ability to remove heat exchangers from the system cooling requirements without shutting down the entire PCW system.

For the PCW pump and heat exchanger train section, there are isolation valves around the pumps and heat exchangers. Each pump discharge line is provided with a check valve to prevent backflow through the pump.

Vents are located in high points and drains are located in all low points. This ensures that the system is completely filled with water and that there are no air pockets. Vents reduce the chance for water hammer after a pump start. Valve opening and closing times are selected to minimize water hammer effects.

Each flow path to the interface system heat exchangers is designed to have flow balancing features that may include fixed plate orifices and/or control or manual valves.

### **Chemical Pot Feeder**

The chemical pot feeder is designed to meet ASME BPVC, Section VIII requirements. The chemical pot feeder is used to manually add corrosion inhibitors, pH control chemicals, and biocides into the system on a periodic basis. Chemicals are compatible with radwaste processing equipment if PCW water becomes contaminated.

#### **9A.2.1.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials through material chemistry, heat treatment, contamination, and material processes controls.

#### **9A.2.1.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.2.1-1 for PCW interfaces with other equipment or systems.

#### **9A.2.1.6 System and Equipment Operation**

##### **9A.2.1.6.1 Normal Operational Concept**

For normal start up, the PCW is filled through the surge tank. When surge tank levels reach low level, the Makeup Water System (Subsection 9A.9.5.1) refills the surge tank through an automatic level control valve.

For normal operation, one train which consists of one pump and one heat exchanger is in operation while the other train is on standby. If one heat exchanger fails, the standby heat exchanger has enough capacity to handle cooling requirements.

Plant cooling water flow through to heat exchangers and coolers throughout the Turbine Building and Reactor Building by way of the Turbine Closed Cooling Water Subsystem piping and Reactor Closed Cooling Water Subsystem piping.

The CWS water flows on the other side of the PCW main heat exchanger to absorb the heat load. There is a bypass line provided for the PCW Heat Exchangers with an air-operated bypass temperature control valve. The flow of cooling water through to the PCW Heat Exchangers is controlled by the PCW Heat Exchanger temperature control system based on the PCW Heat Exchangers outlet temperature.

#### **9A.2.1.6.2 Off-Normal Operational Concept**

For off-normal modes of operation, the PCW system (Reactor Component Cooling Water Piping Distribution) provides Defence-in-Depth (D-in-D) functions to remove decay heat from the reactor, fuel pool, and isolation condenser pools. PCW piping trains are isolated to provide fully independent cooling water loops to both trains of equipment. Both trains of PCW are capable of supporting D-in-D cooling requirements associated with the plant.

In the event of a loss of one train of the PCW cooling system equipment, the standby train is placed into service thereby precluding plant shutdown.

Upon a LOOP, the PCW pumps trip and restart upon power from the standby diesel generators.

Any leakage resulting in a low surge tank level signal, the standby train of PCW isolates the Reactor Component Cooling Water Piping Distribution line and automatically places any non-operating equipment in bypass. The Water, Gas and Chemical Pads (WGC) system provides makeup water to the surge tanks. The train that continues to lose water will eventually trip on low suction head, leaving at least one train of PCW operational to support nuclear D-in-D functions.

In cases of leak detection the two isolation valves responsible for the Reactor Component Cooling Water Piping Distribution train isolation automatically close and the standby train starts and proceeds with cooling of the redundant Reactor Component Cooling Water Piping Distribution coolers.

#### **9A.2.1.7 Instrumentation and Control**

In normal operation one cooling train is operating while being controlled by the Distributed Control and Information System in order to achieve the desired target temperature for each cooled line in the Reactor Component Cooling Water Piping Distribution and Turbine Component Cooling Water Piping Distribution. In events of failure of the operating train or pump discharge pressure drop, an automated process switches operations to the standby train.

Temperature is monitored downstream of each system heat exchanger and readings are reported back to the main control room to monitor the heat exchanger performance.

For designated heat exchangers, bypass and discharge temperature control valves operating in split range control mode are used to control temperature. Instrumentation Temperature monitoring is provided, but not limited to the following locations:

- At the outlets of all equipment coolers
- Downstream and upstream of each PCW heat exchanger

Pressure monitoring is provided, but not limited to the following locations:

- At the suction and discharge of each PCW pump
- Downstream of the PCW heat exchangers

Differential Pressure monitoring provided, but not limited to the following locations:

- Across each PCW heat exchanger
- Across equipment coolers
- Across the pump suction strainers

Flow monitoring provided, but not limited to the following locations:

- At the outlet of each PCW heat exchanger
- At the inlets of selected system heat exchangers as needed

Level monitoring is provided at the following locations:

- On each surge tank

Temperature Control Valves are provided at the following locations:

- Downstream and Across (bypass) each SDC heat exchanger
- Downstream and Across (bypass) the Generator Coolers
- Downstream and Across (bypass) the Lube Oil Coolers
- Downstream and Across (bypass) each PCW heat exchanger

#### **9A.2.1.7.1 Controls**

The PCW system is monitored from the Main Control Room. PCW controls and interlocks for the main components are described below:

1. Temperature monitoring is provided downstream of the PCW heat exchangers on the main cooling water supply line, that send a signal to the DCIS to control cooling water temperature by bypassing a portion of the water around the PCW heat exchangers. This is accomplished using an air-operated temperature control valve on the bypass line and an air-operated temperature control valve at the heat exchanger discharge header, and both are controlled by the DCIS. These valves regulate the supply temperature. The bypass and discharge valve have the ability to be manually controlled. The bypass valve fails closed and the discharge valve fails open.
2. The PCW surge tank makeup flow is controlled by an air-operated block valve. The valve automatically opens and closes and can be manually controlled. The block valve opens when the PCW surge tank level drops to a predetermined low level. The block valve closes when the surge tank level rises to a predetermined high level. The surge tank makeup water inlet block valve fails closed.
3. The cooling water temperature to the Turbine Lube Oil coolers is regulated by two temperature control valves, one at the Turbine Lube Oil cooler discharge and one on the bypass around the cooler, which operate in split range control mode. This type of flow will naturally balance the flow around the coolers. The bypass and discharge valves have the ability to be manually controlled. The bypass valve fails closed and the discharge valve fails open.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

4. The cooling water temperature to the Generator Air Coolers is regulated by two temperature control valves, one at the Generator Air Coolers discharge and one bypass around the coolers, which operate in split range control mode. This type of control will naturally balance the flow around the coolers. The bypass and discharge valves have the ability to be controlled manually. The bypass valve fails closed and the discharge valve fails open.
5. The cooling water temperature to the Shutdown Cooling Heat Exchangers is regulated by two temperature control valves, one at the Shutdown Cooling Heat Exchanger discharge and one bypass around the cooler, which operate in split range control mode. This type of control will naturally balance the flow around the heat exchangers. The bypass and discharge valves have the ability to be controlled manually. The bypass valve fails closed and the discharge valve fails open.
6. Upon a low surge tank level signal, the standby train of PCW isolates the Reactor Component Cooling Water Piping Distribution line and automatically places any non-operating equipment in bypass. The train that continues to lose water will eventually trip on a low suction head signal, but at least one train of PCW is preserved in order to support nuclear defense in depth functions.
7. Normally one PCW pump and heat exchanger train is in service with the other on standby. A pump trip signal results in the starting of the standby PCW train and CWS train.
8. The PCW Heat Exchangers interfaces directly with the CWS system. PCW trains cannot be started until the associated CWS train is running. The system connects such that an automated standby train of either CWS or PCW results in automatic realignment. The isolation valves are automatic with manual overrides available.

PCW controls, displays, and alarms include, but are not limited to, the following:

Main Control Room Panel Controls:

- PCW pump(s) start/stop and pump selection controls
- PCW heat exchanger(s) outlet valve open/close controls
- PCW supply temperature control valve(s) controls
- Surge Tank Makeup water valve open/close control
- PCW Heat Exchanger temperature control Air Operated Valves (AOVs)

Main Control Room Displays:

- PCW pump discharge pressures
- PCW pump operation status
- PCW operating temperatures (All heat exchanger outlet temperatures)
- PCW surge tank levels
- AOV open/close status
- PCW system flow rates

Main Control Room Alarms:

- PCW pump header low/high discharge pressure

- PCW cooling water supply high outlet temperature
- PCW cooling water supply low outlet temperature
- PCW surge tank high and low levels
- PCW heat exchanger high differential pressure

#### **9A.2.1.8 Monitoring, Inspection, Testing, and Maintenance**

The PCW is designed such that major equipment is provided adequate equipment removal paths and personnel access points.

The equipment and components of the PCW are designed for inspection and maintenance during plant operation without requiring complete loss of the Turbine Building cooling loop or the Reactor Building cooling loops.

Provisions to isolate the Turbine Building cooling loop or the Reactor Building cooling loops using AOV is provided. This design feature supports inspection, testing and maintenance activities.

Provisions for PCW drainage to the Equipment and Floor Drain System (EFS) are provided due to its high probability of having chemical content. If the PCW captured water is not chemically contaminated, the water is recycled back to the PCW surge tank.

Routine testing of the PCW system is conducted in accordance with normal power plant requirements for demonstrating system and component functionality and integrity. This includes testing for heat exchanger performance, surge tank levels and water quality standards.

The PCW design includes provisions to take periodic samples for analysis to ensure the water quality meets the chemistry specifications.

#### **9A.2.1.9 Radiological Aspects**

Chapter 12, Section 12.1 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are as low as reasonably achievable in operational states and in accident or post-accident conditions.

#### **9A.2.1.10 Performance and Safety Evaluation**

System reliability is enhanced through the use of periodic system testing, and preventive maintenance.

The PCW includes the components necessary to provide cooling water in support of the redundant Reactor Component Cooling Water Piping Distribution and the Turbine Component Cooling Water Piping Distribution. Portions of the PCW necessary to support Safety Class 3 functions to provide temperature control of the fuel pool, and cooling for the SDC heat exchanger, are designed to Non-Seismic Category, Quality Group D requirements. The redundant design elements of the PCW design ensures that the safety function of the system is maintained.

**Figure 9A.2.1-1: Plant Cooling Water**

## **9A.2.2 Reactor Water Cleanup System**

The Reactor Water Cleanup System (CUW) provides blowdown-type cleanup flow for the Reactor Pressure Vessel (RPV) during the reactor power operating mode. Cleanup or filtration and ion removal is performed by the CFD (Chapter 10, Subsection 10.3.1). The CUW provides an overboarding flow path to the condenser hotwell (condensate pump suction) or Liquid Waste Management System (LWM) (Chapter 11, Section 11.2) directly from the RPV lower region. CUW piping can be utilized to reduce reactor temperature stratification with reverse flow from the Shutdown Cooling System (Subsection 9A.2.3).

### **9A.2.2.1 System and Equipment Functions**

Refer to Chapter 1, Section 1.8 for a description of plant operating modes.

The CUW performs the following functions during normal and off-normal conditions.

#### **9A.2.2.1.1 Normal Functions (Non-Safety-Category)**

- Mode A
  - Normal Reactor Water Cleanup (1% Flow) Plant mode 1, 2, 3, 4)
- Mode B – Overboarding
  - Mode B1-A – Overboarding from Nuclear Boiler System (NBS)(Chapter 5) to Main Condenser and Auxiliaries (MCA) (Chapter 10, Section 10.5) (Plant mode 1, 2, 3, 4)
  - Mode B1-B – Overboarding from NBS to Liquid Waste Management System (LWM) (Chapter 11, Section 11.2) (Plant mode 1, 2, 3, 4)
  - Mode B2-A – Overboarding from SDC through CUW to MCA (Plant mode 2, 3, 4, 5)
  - Mode B2-B – Overboarding from SDC through CUW to LWM (Plant mode 2, 3, 4, 5)
- Mode C
  - RPV thermal stratification reduction (plant mode 2)

### **Overboarding**

During overboarding, the heat exchanger is in service to cool the reactor water to minimize flashing and two-phase flow in the pressure reducing components and downstream piping. Flow can be directed to the condenser hotwell, or in the event high radiation is detected, the overboarding flow is manually shifted to the LWM.

### **Thermal Stratification Reduction**

The system is designed to provide flow through the bottom head connections in the CUW during startup operations to reduce thermal stratification caused by the continuous input of cold Control Rod Drive (CRD) flow through the control rod drives.

### **Cleanup Flow to Condenser**

During Plant Operational Modes 1, 2, 3, and 4, CUW provides the equivalent of one percent of Feedwater (FW) nominal flow to downstream of a condensate pump for remixing and filtration.

#### **9A.2.2.1.2 Normal Function (Safety-Category)**

To ensure the safety of the plant, the system continuously monitors for leakage utilizing density compensated differential flow measurements. If a leak is detected, the containment isolation

function isolates the system from the Reactor Coolant Pressure Boundary (RCPB) through the closure of the containment isolation valve.

#### **9A.2.2.1.3 Off-Normal Functions (Non-Safety Category)**

The CUW system does not perform any Non-Safety-Category functions during off-normal conditions.

#### **9A.2.2.1.4 Off-Normal Functions (Safety Category)**

The CUW system performs Leak Detection and Isolation functions in Off-Normal conditions. Off-Normal functions for leak detection are the same as described in Subsection 9A.2.2.1.3.

Containment isolation is provided in accordance with REGDOC 2.5.2, Section 8.6.6 (Reference 9A.2.2-1). Leak detection is provided in accordance with Chapter 6, Subsection 6.3.2.8. Chapter 6, Subsection 6.3.4 describes the BWRX-300 containment isolation and containment isolation valves.

#### **9A.2.2.2 Safety Design Bases**

The following represents the CUW safety design bases:

1. DL3 leak detection actuates CUW isolation on CUW line break indication in Modes 1, 2, 3, and 4.
2. As part of DL3, the CUW provides a containment isolation valve (Safety Class 1) on piping that penetrates the containment boundary. The containment isolation valves are designed to close upon receiving an isolation signal from Safety Class 1 Instrumentation and Control System.
3. As part of DL3, upon detecting a CUW line break in Modes 1, 2, 3, and 4 the Safety Class 1 Instrumentation and Control System actuates CUW isolation. The CUW isolation valves are designed to close upon receiving an isolation signal from the Safety Class 1 Instrumentation and Control System.
4. Defense Line 4a (DL4a) leak detection actuates CUW line isolation on break indication in the CUW lines in Modes 1, 2, 3, and 4. Upon detecting a CUW line break in modes 1, 2, 3, and 4 the Safety Class 2 and 3 Instrumentation and Control System actuates CUW isolation. The CUW isolation valves are designed to close upon receiving an isolation signal from Safety Class 2 and 3 Instrumentation and Control System.

#### **9A.2.2.3 Description**

Figure 9A.2.2-1 depicts a simplified flow diagram of the CUW and interfacing systems.

The CUW system consists of one train. The CUW receives flow through two nozzles located on the RPV. The train's inlet is independently connected to RPV penetrations located at about the mid-vessel height which take inlet flow from nozzles located near the RPV bottom head. This piping up to the RPV isolation valves are a part of the NBS. The inlet piping connects to the reactor vessel and combines inside containment to form one discharge line. This line is provided with a containment isolation valve where it penetrates containment. This valve will receive a signal from the CUW leak detection system and will close upon a detected leak. CUW continues through a regenerative heat exchanger and a pressure reduction station. The heat exchanger and pressure reduction station are designed to condition the water to acceptable temperatures and pressures for processing to the condensate system or overboarding. The heat exchanger is designed to recover heat back to the condensate and feedwater system. Discharge piping is

connected either to a condensate line for the normal CUW function or routed to the condenser hotwell or LWM for overboarding.

The leak detection and isolation subsystem perform both a DL3 and DL4a function to identify leaks and line breaks in the CUW and to initiate automatic response actions by other systems. For DL3, in MODES 1-4, the detection of a leak or line break in the CUW initiates isolation of the CUW system. For DL4a, in MODES 1-4, the detection of a leak or line break in the CUW initiates isolation of the CUW system.

The leak detection and isolation subsystem utilize a single Flow Element (FE) in the intake flow path and a single FE in each discharge flow path. Each FE serves independent, redundant sets of divisional Flow Transmitters (FTs), three FTs each for the DL3 and the DL4a line break detection functions. The basis for this arrangement is that a leak or break near the end of a discharge flow path may not be detectable by a single FE/FT feature located in the intake location of the system due to the physical distance between those locations. The design is intended to ensure that a leak or break can be identified by any of the FE/FTs at a detection point, or by differential flow between an upstream and downstream FE/FT detection point. Hence the use of detection features at the intake and at the discharge flow paths allows for detection of differential flow between the intake and any discharge flow path, or detection of a leak or break within detection proximity of any single FE.

The FT readings are density compensated by sets of three independent, redundant SC1 Temperature Transmitters. This feature will account for density changes in the water across the heat exchanger that is between the FE located in the intake flow path and the FEs located in each discharge flow path. Density compensation is used to avoid spurious isolation of the CUW and spurious generation of a signal that would initiate unwanted response actions by other systems.

Environmental Qualification of Safety-Class SSC's is provided as applicable as discussed in Chapter 3, Section 3.9.

#### **9A.2.2.3.1 Component Description**

The following provides description of CUW components.

##### **Piping and Valves**

The system piping is sized to ensure it can withstand the maximum pressure and temperature combination while keeping the maximum flow velocities within the acceptable limits.

The piping and the wetted parts of the valves are stainless steel to help with ALARA (Chapter 12, Section 12.3) concerns since this system is in contact with potentially radioactive water. Smooth bends are used instead of welded fittings where practical. At certain locations within the system, stainless steel pipes with electro-polished finish are used to reduce corrosion product buildup.

All valves in the system are used for isolation (on/off) except for a throttling valve in the pressure reduction station. This valve is used to throttle the system to achieve desired flow rates.

The CIVs for CUW fail in the closed position, with valve actuators designed to maintain the valves closed by positive mechanical means.

- Overpressure protection is provided per the applicable design code, as follows:
  - ASME Boiler and Pressure Vessel Code, Section III for Class 1, 2, and 3 piping and components
  - ASME B31.1, Power Piping for Non-Safety-Category function piping
  - ASME BPVC, Section VIII for pressure vessels

Radioactive equipment and piping are designed to minimize crud buildup and to provide for easy decontamination and maintenance.

### **Regenerative Heat Exchanger**

The CUW heat exchanger is a regenerative heat exchanger cooled by the Condensate and Feedwater Heating System flow (Chapter 10, Subsection 10.3.2). The heat exchanger is designed to reduce the temperature of the inlet flow. Most of the heat of the CUW water is transferred to the condensate returning to the reactor, thus losing almost no thermal value.

The CUW heat exchanger is designed, manufactured, installed, and tested in accordance with applicable codes and standards, including Thermal Exchanger Manufacturers Association, API-662, ASME BPVC, Section VIII, Division 1. The heat exchanger tubes are seamless and constructed of stainless steel or titanium to minimize the possibility of failure and reduce maintenance requirements. The heat exchanger is designed with provisions for tube replacement as well as individual tube plugging. An excess of tubes factored into the design of the heat exchanger accommodates tube plugging.

### **System Pressure Reduction Station**

At the pressure reduction station, a breakdown orifice (or pressure reduction valve) is used to reduce pressure before the water enters the CFS downstream of the condensate pumps, where it is mixed with the condensate and cleaned in the CFD cleanup filters and demineralizers. This pressure is greater than condensate pressure at the connection point to ensure positive flow. The breakdown orifice (or pressure reduction valve) and associated instrumentation are located downstream of the heat exchanger and upstream of the condensate pump discharge tie-in location in the TB.

#### **9A.2.2.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials specifically from IGSCC (as applicable) through material chemistry, heat treatment, contamination and material processes controls.

#### **9A.2.2.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.2.2-1 which provides the description and boundary for each interfacing system.

#### **9A.2.2.6 System and Equipment Operation**

##### **9A.2.2.6.1 Initial Configuration (Pre-Startup)**

The CUW is initially idle with the system isolation valves closed. The CUW is shutdown water solid, but because it is idle for long periods, the system pressure may need to be checked to ensure there was no leakage while shutdown. If necessary, the system piping is filled and vented to ensure there is no water hammer upon CUW startup.

##### **9A.2.2.6.2 System Startup**

When the CUW is actuated from the main control room, it first enters a stage of pre-warming. The system SSC are at ambient temperature due to inactivity in Plant Operating Mode 1. The water coming from the RPV is expected to be much warmer; therefore, this pre-warming stage is important to allow the system to gradually heat up to prevent over stressing the components due to thermal growth. The pre-warming is controlled by slowly initiating flow through the CUW through the use of the flow control valve and eventually ramping up to full flow before transitioning to normal operations.

#### **9A.2.2.6.3 Normal Operations**

Operations under normal conditions are described below. Table 9A.2.2-2 presents the plant operating Modes and corresponding CUW operational modes.

Mode A – Power Operation:

During power operation (plant Mode 1), the CUW system is in-service, taking input from the bottom of the RPV through two inlet lines. Water flows through piping internally mounted inside the RPV downcomer region and exits the vessel about four metres above top of active fuel. At the top of the piping outside the RPV, there are double isolation valves integral to the vessel which close to prevent RPV inventory from exiting the CUW line in case of a pipe break. Except for the containment isolation and leak detection related functions, the CUW is an SCN system, and all other system functions defined below are SCN.

The two inlet lines join into a single line outside the RPV where it exits the containment vessel, routes through piping in the steam tunnel and into the Turbine Building. The system contains a regenerative heat exchanger in which the CUW water is cooled by the Condensate and Feedwater Heating System. Most of the heat of the CUW water is transferred to the condensate returning to the reactor. A breakdown orifice is used to reduce pressure before the water enters CFS downstream of the condensate pumps where it is mixed with the condensate and cleaned in the CFD (Chapter 10, Subsection 10.3.1) cleanup filters and demineralizers.

During plant mode 2, 3, & 4 CUW can operate in Mode A. However, due to relying on the reactor for motive pressure for flow through CUW, sufficient reactor pressure is required to overcome system flow resistance for CUW flow to be achieved, with flow being maintained through throttling as reactor pressure increases.

Mode B1-A:

When there is sufficient pressure in the RPV for flow in CUW, CUW can overboard to the condenser hotwell. In this mode CUW operates the same as Mode A, with the exception of flow being diverted to the condenser hotwell. This function is available in plant modes 1, 2, 3, & 4.

Mode B1-B:

When there is sufficient pressure in the RPV for flow in CUW, CUW can overboard to LWM. In this mode CUW operates the same as mode A, except for flow being diverted to LWM. This function is available in plant Modes 1, 2, 3, & 4.

Mode B2-A:

When there is insufficient pressure in the RPV for flow in CUW, SDC can overboard through the CUW to the condenser hotwell. SDC interfaces with CUW in the steam tunnel, and continues on the same path as described in mode B1-A. Mode B2-A is available in plant modes 2, 3, 4, & 5.

Mode B2-B:

When there is insufficient pressure in the RPV for flow in CUW, the SDC can overboard through the CUW to LWM. SDC interfaces with CUW in the steam tunnel, and continues on the same path as described in mode B1-B. Mode B2-B is available in plant modes 2, 3, 4, & 5.

Mode C:

To help reduce vessel stratification, caused by continuous input of cold CRD flow through the control rod drives, while shut down and during preparation for startup, the SDC water can be routed to the RPV lower region through the normal CUW inlet lines. The SDC thermal stratification

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

reduction line interfaces with the CUW system between the regenerative heat exchanger and the isolation containment valve. Mode C is only available in plant mode 2.

**Mode 1 – Power Operation:**

During power operation, the CUW system is in service in system Mode A, with flow from the bottom of the RPV through two inlet lines. Water flows through piping internally mounted inside the RPV downcomer region and exits the vessel about four metres above top of active fuel. At the top of this piping outside the RPV, there are double isolation valves integral to the vessel, which prevents RPV inventory from exiting the CUW line in case of a pipe break.

The two inlet lines join into a single line outside the RPV, and the CUW water then is routed through piping in the steam tunnel. There is a regenerative heat exchanger in which the CUW water is cooled by the CFS. Most of the heat of the CUW water is transferred to the condensate returning to the reactor, thus losing almost no thermal value. A breakdown orifice is used to reduce pressure before the water enters CFS downstream of the condensate pumps, where it is mixed with the condensate and cleaned in the CFD cleanup filters and demineralizers

**Mode 2 – Startup:**

During startup Mode, CUW operation is the same as during power operation. However, due to relying on reactor pressure for flow through CUW, sufficient reactor pressure is required to overcome system flow resistance for CUW flow to be achieved, with flow increasing as reactor pressure increases.

During startup or shutdown, CUW can function to let down (overboard) the excess reactor inventory if there is enough pressure (CUW Mode B1-A and B1-B). If not, the SDC system can be used to let down the excess reactor inventory (CUW Mode B2-A and B2-B). The SDC letdown line interfaces with the CUW system upstream of the regenerative heat exchanger. Overboard flow can be directed to the condenser hotwell or LWM. In this mode, reactor vessel water level is maintained by the control rod drive water.

To help reduce vessel stratification during preparation for startup, SDC water can be routed to the RPV lower region through the normal CUW inlet lines (CUW Mode C).

**Mode 3 – Hot Shutdown:**

During hot shutdown operation, the CUW system is in-service if the RPV is pressurized. This mode is with reactor temperature  $>215.6\text{ }^{\circ}\text{C}$ . Vessel letdown can be performed as discussed above under the startup mode.

**Mode 4 – Stable Shutdown:**

During stable shutdown operation, the CUW system is isolated from the reactor. This mode is with reactor temperature  $\leq 215.6\text{ }^{\circ}\text{C}$  and  $>93.3\text{ }^{\circ}\text{C}$ . If CUW is isolated at the vessel, SDC can be used via CUW if overboarding is required.

**Mode 5 – Cold Shutdown:**

During cold shutdown operation, the CUW system is isolated at the vessel. This mode is with reactor temperature  $\leq 93.3\text{ }^{\circ}\text{C}$ . SDC can be used via CUW if overboarding is required.

**Mode 6 – Refueling:**

During refueling mode, the CUW is not in service.

#### **9A.2.2.6.4 Off-Normal Operations**

No manual operator actions are required to initiate or assure the completion of fundamental safety functions. The RPV isolation valves and containment isolation valve fail in the closed position, with valve actuators designed to maintain the valves closed by positive mechanical means.

For large line breaks, it is noted that for FW line breaks and reactor water cleanup breaks outside of containment, leak detection systems identify the break condition and provide signals to close the affected system isolation valves.

#### **9A.2.2.6.5 System Shutdown**

The system is shut down in plant operating Mode 6.

Upon shutdown, the system isolation valves are closed. The system remains water solid while shutdown.

#### **9A.2.2.7 Instrumentation and Control**

During plant operation and after plant shutdown (with sufficient reactor pressure), CUW removes water from the bottom of the reactor and routes it to the condensate system or overboards excess "swell", when required, to the condenser hotwell or liquid radwaste. These functions require both monitoring and control.

The input signals to the control functions are triply redundant and the actuators receive two out of three voted commands from the CUW controller. The CUW controller is triply redundant and is dual ported to the plant balance of plant segment network. As with all Triple Modular Redundant (TMR) controllers, extensive hardware and software diagnostics are provided for operator monitoring and alarms. The CUW controller is also designed to support plant automation. Refer to Chapter 7 for information pertaining to TMR.

The CUW can be controlled from the main control room. The CUW controller can receive commands from the Plant Automation System (PAS) or be manually operated. The controller automates the operation of the system.

##### **9A.2.2.7.1 Flow**

There is one SC1 flow element along with triply redundant (SC1) transmitters on the system supply line at the containment boundary inside the steam tunnel. This flow indication is used in conjunction with identical flow elements and transmitters located at the end of each flow path. When used as a pair they monitor for system leakage. Main Steam Reactor Isolation Valves (MSRIV) and CUW Isolation are actuated on CUW line break indication in Plant Modes 1-4.

There are triply redundant SC2 transmitters independent from the SC1 flow element on the system supply line at the containment boundary. This flow indication is used in conjunction with identical flow elements and transmitters located at the end of each flow path. When used as a pair they monitor for system leakage. MSRIV Isolation and CUW Isolation are actuated on CUW line break indication in Plant Modes 1-4.

There are triply redundant SCN transmitters used for the control of the pressure reduction station.

##### **9A.2.2.7.2 Temperature**

There are triply redundant SC1 temperature sensors that accompany the SC 1 flow transmitters on the containment boundary and at the end of each flow path. These temperatures are used to provide input for the density compensation of the flow transmitters.

There are triply redundant Safety Class 2 (SC2) temperature sensors that accompany the SC1 flow transmitters on the containment boundary and at the end of each flow path.

There is one SCN temperature sensor downstream of the heat exchanger. This temperature is measured prior to entrance of the pressure reduction station to ensure that the temperature of the fluid is acceptable after the heat exchanger.

#### **9A.2.2.7.3 Pressure**

Pressure Reduction Station Inlet:

One set of triply redundant SCN pressure instruments are provided at the inlet of the pressure reduction station. These pressure instruments are used to control the pressure reduction station.

Pressure Reduction Station Outlet:

Three SCN pressure instruments are provided at the discharge of the pressure reduction station. These pressure instruments are used to monitor the discharge pressure of the pressure reduction station, to monitor status and performance.

#### **9A.2.2.7.4 Radiation**

CUW has a radiation monitor downstream of the heat exchanger provided by the PREMS. This monitor provides input to the Process and Radiation Monitoring Subsystem.

#### **9A.2.2.8 Monitoring, Inspection, Testing and Maintenance**

Maintenance and testing support equipment reliability. SSCs are designed to facilitate operation and maintenance. Maintenance activities, including post-maintenance and post-modification testing, are controlled by plant procedures. Maintenance activities restore SSCs to their original condition or involve a temporary alteration in accordance with plant procedures.

Maintenance practices consider industry best practices such as Institute of Nuclear Power Operations (INPO, etc.) and operating experience, and conform with plant safety requirements to minimize potential for personnel injury. Maintenance activities comply with Technical Specifications as required. Maintenance activities implement plant ALARA practices to minimize work activity dose. Maintenance activities involving critical plant equipment may require involvement of vendors or industry specialists.

The CUW is provided with chemical cleaning and decontamination connections that can utilize condensate to flush piping and equipment prior to maintenance to provide decontamination of the regenerative heat exchanger, pressure reduction station, and associated valves.

Inspections, checks, and tests conducted during the performance of maintenance activities are considered "In-Process Maintenance Tests" and are governed by the in-use maintenance procedures and processes.

Inspections, checks, and tests conducted following the conclusion of maintenance activities are considered "Post-Maintenance Tests" and are governed by plant Post-Maintenance Test procedures. ISI and IST requirements are established and include inspection/test frequency for SSCs. Remote monitoring of key parameters assists in the trending of component performance as part of condition-based predictive maintenance.

#### **9A.2.2.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions. To control and

minimize personnel exposure, radioactive equipment is designed to minimize crud buildup and provide for decontamination and maintenance.

#### **9A.2.2.10 Performance and Safety Evaluation**

System reliability is enhanced through the use of periodic system testing, preventive maintenance, and application of redundant instrumentation.

The CUW SC1 functions during normal conditions and off-normal conditions include continuous monitoring for leakage utilizing density compensated differential flow measurements. If a leak is detected, in either normal or off-normal conditions the system is isolated from the reactor coolant pressure boundary using system isolation and containment isolation valves.

The arrangement of SSCs minimize the possibility of compromising the functionality of both the SC1 functions and their backup systems and equipment for any credible events that could cause damage to one region of the plant. The portions of the CUW responsible for performing containment isolation are located in the Reactor Building which provides protection against natural phenomena ensuring the ability of the CUW to perform its Safety-Category functions.

(2) One or more reactor pressure vessel head closure bolts less than fully tensioned

The diagram illustrates the Reactor Pressure Vessel (RPV) and its associated piping and systems, divided into 'INSIDE REACTOR CONTAINMENT' and 'OUTSIDE REACTOR CONTAINMENT'.

**INSIDE REACTOR CONTAINMENT:**

- REACTOR PRESSURE VESSEL:** The central component, shown as a vertical cylinder with a domed top.
- WARM-UP ISOLATION:** A section of piping containing an **AOV** (Automatic Overpressure Valve) and an **FE** (Flow Element).
- CLEANUP ISOLATION:** A section of piping containing a valve and an **FE**.
- REGENERATIVE HEAT EXCHANGER (RHXR-1):** A circular component with a central coil, connected to two **CFS** (Coolant Flow System) lines.
- PRESSURE REDUCTION STATION:** A section of piping containing an **FCV** (Flow Control Valve), an **RO** (Relief Valve), and a valve.
- LOW PRESSURE OVERBOARD:** A section of piping containing a valve and an **FE**.

**OUTSIDE REACTOR CONTAINMENT:**

- CONDENSER HOTWELL (MCA):** A component connected to the **LOW PRESSURE OVERBOARD** section via a valve and **FE**.
- LWM (Low Water Monitor):** A component connected to the **LOW PRESSURE OVERBOARD** section via a valve and **FE**.
- CUW (Cooling Water) and FW (Feed Water) connections:** Various connections to **CUW** and **FW** systems, including a **MCA** (Master Control Assembly) connection to the **CONDENSER HOTWELL**.

9A-52

### **9A.2.3 Shutdown Cooling System**

The SDC provides for decay heat removal when shutting down the plant. The system is also used to reduce reactor pressure vessel inventory and can be used in conjunction with CUW (Subsection 9A.2.2) piping to reduce reactor pressure vessel thermal stratification.

#### **9A.2.3.1 System and Equipment Functions**

##### **9A.2.3.1.1 Normal Functions (Non-Safety-Category)**

###### **Overboarding**

During reactor startup, it is necessary to remove the CRD purge water injected into the RPV as well as the excess reactor water volume arising from thermal expansion due to reactor heat-up. The SDC accomplishes these volume removals and thereby maintains proper reactor level until the reactor pressure is sufficient to allow use of the CUW overboard flow path.

During overboarding, the heat exchanger is in service to cool the reactor water to minimize flashing and two-phase flow in the downstream piping. The preferred overboarding destination is the hotwell that is part of the CFS (Chapter 10, Subsection 10.3.2); however, in the event high radiation is detected, the overboarding flow is manually shifted to the LWM (Chapter 11, Subsection 11.3).

Overboarding is considered part of SDC Mode B1 and is available in plant operating Modes 2-6.

###### **RPV Thermal Stratification Reduction**

The SDC is designed to provide flow through the CUW inlet lines into the bottom head region of the RPV during startup operations to reduce thermal stratification caused by the continuous input of cold CRD flow through the control rod drives.

Thermal stratification reduction is considered part of SDC Mode B2 and is available in plant operating Mode 2.

##### **9A.2.3.1.2 Normal Functions (Safety-Category)**

The SDC system for the BWRX-300 has two Safety Class functions:

###### **Decay Heat Removal (Defense Line 2/Safety Class 3)**

In conjunction with the heat removal capacity of either the main condenser and/or the isolation condensers, the SDC is used to reduce the RPV pressure and temperature during cooldown operation from the rated design pressure and temperature to below saturation temperature at atmospheric pressure in less than one day.

The shutdown cooling function of the SDC provides decay heat removal capability at normal reactor operating pressure as well as at lower reactor pressures. The redundant trains of SDC permit shutdown cooling even if one train is out of service; however, cooldown time is extended when using only one train.

Decay heat removal is considered part of SDC Mode A1 and is available in plant operating Modes 2-6.

###### **Leak Detection and Isolation (Defense Line 3/Safety Class 1 and Defense Line 4a/Safety Class 2)**

When the SDC is operational, the system continuously monitors for leakage utilizing differential flow measurements. If a leak is detected, the system is isolated from the reactor through a

number of system isolation and containment isolation valves to prevent the excessive reduction of reactor water inventory.

#### **9A.2.3.1.3 Off-Normal Functions (Non-Safety Category)**

If feedwater flow is lost in operating Modes 2-4, the operator initiates either the SDC or ICS (Chapter 5, Section 5.8) to reduce reactor water temperature and pressure.

Upon identification of a small line break inside containment with or without preferred power during operating Modes 3-4, the SDC is initially used for decay heat removal until the containment is isolated at which time the ICS is initiated to remove the decay heat.

#### **9A.2.3.1.4 Off-Normal Functions (Safety-Category)**

The system does not perform any safety category functions during off-normal conditions.

The design of the SDC system meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.6.6 (Reference 9A.2.3-1) as related to the design of containment isolation valves. Refer to Chapter 6, Subsection 6.3.4 for a discussion related to BWRX-300 containment isolation and containment isolation valves.

#### **9A.2.3.2 Safety Design Bases**

The SDC has two Safety-Class functions, Decay Heat Removal, and Leak Detection and Isolation. Refer to Subsection 9A.2.3.1.2 for discussion of SDC Safety-Category functions.

Plant systems retain sufficient heat removal capacity to prevent boiling in the reactor during periods of plant shutdown with the Reactor Pressure Vessel head removed, and to simultaneously prevent boiling in the fuel pool, assuming a Loss of Preferred Power event and the most limiting single active failure.

Defense lines associated with Leak Detection and Isolation are noted below.

1. As part of Defense Line 3 (DL3) 3, the Shutdown Cooling isolation valves are designed to close upon receiving an isolation signal from the Safety Class 1 Instrumentation and Control System.
2. As part of DL4a, the SDC isolation valves are designed to close upon receiving an isolation signal.
3. As part of DL2, the SDC is designed to initiate upon receiving an initiation signal from Safety Class 2 and 3 Instrumentation and Control System.
4. DL2 operators are able to manually initiate SDC train in Modes 2-6.
5. DL3 leak detection actuates MSRV Isolation on FW and SDC Line break indication in Modes 1, 2, 3, and 4.
6. DL3 leak detection actuate FW and SDC line isolation on FW and SDC line break indication in Modes 1, 2, 3, and 4.
7. DL4a Leak Detection actuates MSRV Isolation on FW line break indication / SDC Line break indication in Mode 1-4.
8. DL4a Leak Detection actuates FW Isolation/SDC line isolation on FW line break indication/SDC Line break indication in Mode 1-4.

#### **9A.2.3.3 Description**

The SDC comprises two independent pump and heat exchanger trains. These trains together provide redundant decay heat removal capacity such that each train is designed to remove 100%

of decay heat as soon as 4 hours after reactor shutdown. The major components of each train are a pump and a Heat Exchanger (HX), along with valves, piping, instrumentation and controls, and power inputs. The two trains operating in parallel provide the systems full rated shutdown cooling performance. Bypass lines and valves are included around the tube side of each HX to allow bypassing of the HX for SDC functions such as reducing RPV thermal stratification.

Each train's suction is independently connected to a separate ICS (Chapter 5, Section 5.6) condensate return line outside of containment, and downstream of the ICS containment isolation valves. Each SDC train's return piping is independently connected to a separate CFS (Chapter 10, Subsection 10.3.2) feedwater line outside of the containment isolation valves. This arrangement helps to prevent short circuiting of the flow inside of the RPV since the SDC suction is taken from the ICS return nozzle which originates in the chimney region over the core and the SDC return flow utilizes the CFS return which terminates outside this region in the downcomer area.

Fittings are registered in compliance with Technical Standards and Safety Authority.

Refer to Chapter 3, Section 3.9 for information pertaining to equipment qualification of BWRX-300 SSCs.

#### **9A.2.3.3.1 Decay Heat Removal Subsystem**

The subsystem comprises the flow path from the ICS to the SDC pump, through the tube side of the SDC heat exchanger, and then returned to the RPV through the CFS as depicted in Figure 9A.2.3-1. The subsystem is available in Plant Modes 2 through 6, though the condenser and ICS are expected to be used initially to cool the reactor after shutdown. The subsystem is initially operated at low flow to allow the system Structures, Systems, and Components, to be brought up to operating temperature without overstressing the components. Once the system is up to temperature, the flow rate increases and is controlled to maintain PCW (Subsection 9A.2.1) heat exchanger cooling water exit temperature within the interface requirements of 54.4 °C for two SDC trains running and 60.0 °C for one train running.

#### **9A.2.3.3.2 Overboarding Subsystem**

The overboarding subsystem supports RPV level control during Plant Modes 2 through 6 when the fuel pool gate is installed and the CUW (Subsection 9A.2.2) is not available for use. The subsystem comprises the flow path from the ICS to the SDC pump, through the tube side of the SDC heat exchanger, and then through the overboard flow path (see Figure 9A.2.3-2). The figure shows multiple overboard flow pathways highlighted; however, only one overboard path is implemented at a time by controlling the position of the valves on each flow path. The SDC trains share the overboard control valves and each train has its own isolation valve to prevent inadvertent overboarding. Each overboard flow path has been designed to provide adequate overboarding flow to support the worst-case scenario (fastest) heat-up rate of the reactor combined with the expected water input from the CRD (Chapter 4, Section 4.5).

The preferred overboard flow path is from the SDC to the CFS hotwell; however, in the event that high radiation is detected in the effluent, the flow path is manually switched from the CFS to the LWM system. The overboarding flow pathways through the CUW are utilized in the event of failure of any of the other overboard pathway isolation valves, or if the pressure in the SDC is too high for the interfacing system, in which case, the CUW pressure reduction station is utilized to reduce the fluid pressure to protect the interfacing system.

Each overboard flow pathway from the SDC has two fail-closed valves in series. There are two valves in series to prevent exposing a lower design pressure system or subsystem to a higher design pressure system in the event of an inadvertent opening of a single valve.

#### **9A.2.3.3.3 Thermal Stratification Reduction Subsystem**

The subsystem comprises the flow path from the ICS to the SDC pump, through the SDC heat exchanger bypass line, and then through the overboard flow path through the CUW and back to the RPV through the NBS as depicted in Figure 9A.2.3-3. The subsystem provides approximately 200 gpm to the bottom region of the RPV to counter act the constant 20 gpm flow from the CRD through the control rod drives. The 10:1 flow ratio is expected to provide sufficient heat to overcome the cooling effect of the CRD flow. Also, the velocity at the discharge of the piping into the RPV is sufficient to promote mixing in the bottom head region to minimize thermal stratification.

#### **9A.2.3.3.4 Leak Detection and Isolation Subsystem**

The leak detection and isolation subsystem are comprised of three flow elements per train along with two sets of triply redundant transmitters per flow element to support both DL3 and DL4a leak detection requirements. The readings are utilized to account for temperature change across the heat exchanger. This is done to avoid spurious isolation of the SDC which would reduce the SDC capacity, or if both trains are isolated, would require the restart of ICS. Restart of ICS is only possible if the reactor is still pressurized.

The control system compares the flow readings from the supply flow transmitters against flow readings from the return and overboard flow transmitters. If the system detects a flow differential greater than the acceptable leakage value, the control system actuates MSRIV Isolation, Feedwater Isolation, and SDC Isolation.

#### **9A.2.3.3.5 Component Description**

##### **Shutdown Cooling System Piping and Valves**

The SDC piping material is 304L stainless steel. The pipe wall thickness has been sized to ensure it can withstand the maximum pressure and temperature combination while the diameter has been chosen to ensure the maximum flow velocities stay within the acceptable limits.

The piping and the wetted parts of the valves are stainless steel which supports ensuring ALARA goals since this system is in contact with potentially radioactive water.

All valves in the system are used for isolation (on/off) except for the heat exchanger bypass valve. The bypass valve is used to throttle the bypass around the heat exchanger and can be used in conjunction with the SDC pump speed control to control the exit temperature of the heat exchanger.

SDC decay heat removal piping and valves are designed, manufactured, and tested in accordance with ASME BPVC Section III, Class 3. SDC overboard piping and valves are designed, manufactured, and tested in accordance with ASME B31.1.

##### **Shutdown Cooling System Pumps and Adjustable Speed Drives**

Each train of the SDC contains one SC3 horizontal centrifugal pump sized to allow sufficient flow to remove 100% of the decay heat generated by the core 4 hours after shutdown. The SDC pumps are designed to pump the maximum flow required by the system to meet SDC cooldown requirements for decay heat removal. The pump is installed below the RPV inlet nozzle which provides adequate NPSH at maximum flow conditions. Each pump is paired with an adjustable speed drive to allow for control of the cooldown rate and the reactor temperature during shutdown.

The adjustable speed drive is necessary to allow the flow to be adjusted to meet all expected system flow design points.

SDC pumps are designed, manufactured, and tested in accordance with ASME BPVC Section III, Class 3. SDC pump wetted parts are manufactured from stainless steel.

### **Shutdown Cooling System Heat Exchangers**

Each train of the system contains one SC3 shell and tube heat exchanger sized with sufficient capacity to remove 100% of the decay heat generated by the core 4 hours after shutdown. The heat is transferred from the SDC process fluid to the PCW.

SDC heat exchangers are designed, manufactured, installed, and tested in accordance with ASME BPVC Section VIII, Class 3. SDC heat exchanger tubes are constructed of stainless steel.

#### **9A.2.3.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials specifically from IGSCC through material chemistry, heat treatment, contamination, and material processes controls.

#### **9A.2.3.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.2.3-1 for SDC interfaces with other equipment or systems.

#### **9A.2.3.6 System and Equipment Operation**

Plant cooldown following shutdown is accomplished using a combination of the main condenser, ICS, and SDC systems. Although the SDC system is qualified for high temperature and pressure operation, the main and ICS condensers are the preferred cooldown sources immediately following shutdown.

##### **9A.2.3.6.1 Initial Configuration (Pre-Startup)**

The system is initially idle with the system isolation valves closed. When the system is shutdown, it is water solid, but because it is idle for long periods, the system pressure may need to be checked to ensure there was no leakage while shutdown. If necessary, the system piping is filled and vented to ensure there is no water hammer upon system startup.

##### **9A.2.3.6.2 System Startup**

When the system is actuated from the control room, it first enters a stage of pre-warming. It is expected that the system SSCs are at ambient temperature due to inactivity in Plant Mode 1, but the water coming from the RPV is expected to be much warmer; therefore, this pre-warming stage is important to allow the system to gradually heat up to prevent over stressing the components due to thermal growth. The pre-warming is controlled by initiating low flow through the SDC using the adjustable speed drive and eventually ramping up to full flow before transitioning to normal operations.

##### **9A.2.3.6.3 Normal Operations**

The normal and off-normal operational modes of the SDC are described below. This includes how the plant transitions from a shutdown condition to full power, how steady-state full power operation is maintained, how the transition from full power to shutdown is achieved, and how a refueling outage is performed. Table 9A.2.3-2, "BWRX-300 Mode Table" lists the plant operational modes and the corresponding operational modes of SDC. The SDC system modes and functions are discussed in more detail below.

#### **Plant Mode 1 - Power Operation**

During power operation, the SDC is not in-service.

### **Plant Mode 2 - Startup Mode**

The SDC is a manually initiated system.

During startup operation, the SDC is initially in-service to provide a reactor water reject flow path for RPV level control. The SDC is eventually taken out of service when the RPV pressure is high enough to establish CUW flow and when the SDC has inadequate net positive suction head due to voiding in the chimney section.

If the SDC is required to reduce vessel temperature stratification, SDC Mode B2 is utilized. After flow from SDC enters the CUW it is routed reverse the normal flow direction and discharges from the CUW inlet lines into the RPV bottom head region.

### **Plant Mode 3 - Hot Shutdown Operation**

During hot shutdown operation, the SDC is not normally in-service since heat removal by steam condensation is more efficient. The SDC requires adequate water level in the chimney after shutdown before it is placed into service.

### **Plant Mode 4 - Stable Shutdown Operation**

During hot shutdown operation, the SDC is not normally in-service since heat removal by steam condensation is more efficient. The SDC requires adequate water level in the chimney after shutdown before it is placed into service.

When RPV pressure drops to a point that the normal reactor water reject flow path is ineffective, the SDC can be placed into service to provide this function through an interface connection to the CFS and LWM.

### **Plant Mode 5 - Cold Shutdown Operation**

During cold shutdown operation, the SDC is in-service. Each train of SDC can separately remove 100% of the decay heat generated 4 hours following reactor shutdown. Both trains of the SDC are normally available in cold shutdown conditions, but one train may be taken out of service at a time for maintenance if needed.

With the RPV depressurized, the SDC also provides water reject flow through an interface connection to the CFS and LWM.

### **Plant Mode 6 - Refueling Mode**

At any time when the fuel pool gate is installed and water level is being held constant, the SDC is overboarding to the LWM to offset the CRD purge flow.

During refueling operation, the SDC system is in service. Each train can separately remove 100% of the decay heat 4 hours following reactor shutdown. The SDC system reject flow path is coordinated with the water level in the RPV, position of the FP gate, and availability of the Fuel Pool Closed Cooling and Cleanup System. When fully flooded and connected to the fuel pool, the Fuel Pool Cooling and Cleanup System can maintain a constant level. Refer to table 9A.2.3-3 for information pertaining to SDC configuration during refueling mode.

#### **9A.2.3.6.4 Off-Normal Operation**

##### **Loss of Feedwater Flow Plant Modes 2-4**

Operator initiates SDC or ICS.

##### **Small Line Break Inside Containment Plant Modes 3-4**

On identification of a small line break inside containment with or without preferred power during Plant Modes 3-4, the SDC is used for decay heat removal until the containment is isolated at which time the ICS is initiated to remove the decay heat.

#### **9A.2.3.6.5 System Shutdown**

The SDC is shutdown as the plant heats up in Plant Mode 2. The cooling function is no longer required since heat is being intentionally added to the RPV and the overboarding function transitions from the SDC to the CUW when the RPV pressure is sufficient to drive the necessary flow through the CUW to the overboarding destination. The thermal stratification reduction function won't be necessary once the CUW is overboarding since any cold spots developing near the piping terminations are overboarded or mixed with the flow entering the core.

Upon shutdown, the pump is turned off and the system isolation valves closed. The system remains water solid while shutdown.

#### **9A.2.3.7 Instrumentation and Control**

The SDC is a manually initiated system but is designed for automatic control of functions such as SDC system piping pre-warming, adjusting the system heat removal rate to stay within vessel and HX cooling water limitations, as well as allowing the operator to input a temperature rate setpoint that allows automatic vessel water temperature cooldown rate. Additionally, during reactor heat-up, the SDC controllers receive flow demand signals from the RLC to allow "swell" to be overboarded to maintain reactor level. The SDC can be controlled from the Main Control room as well as the Secondary Control Room.

The SDC has its own (triply redundant) sensors for control and its own actuators. It is possible to validate the temperature signals used for control with reactor water temperature measurements and (when steaming) reactor pressure measurements. The SDC controllers are triply redundant and are dual ported to the plant nuclear segment network. As with all Triple Modular Redundant controllers, extensive hardware and software diagnostics are provided for operator monitoring and alarms. Refer to Chapter 7 for information pertaining to TMR.

##### **9A.2.3.7.1 Flow**

#### **Supply Flow**

There is one SC1 flow element along with triply redundant SC1 transmitters as well as an independent set of triply redundant Safety Class 2 transmitters on the system supply line upstream of each SDC pump. The instruments are used in conjunction with the return flow and overboard flow instruments to support the DL3 and DL4a function of monitoring for system leakage. MSRV Isolation, Feedwater Isolation, and SDC Isolation are actuated on SDC line break indication in Plant Modes 1-4.

The Safety Class 2 transmitters are also used to monitor the system flow rate to help the operator determine that the pump is functioning properly and as input into the control system for automatic control of the pump.

#### **Return Flow**

There is one SC1 flow element along with triply redundant SC1 transmitters as well as an independent set of triply redundant Safety Class 2 transmitters on the system return line downstream of the overboarding branch connection. This flow indication is also used in conjunction with the supply flow and overboard flow instruments to support the DL3 and DL4a function of monitoring for system leakage respectively.

#### **Overboard Flow**

There is one SC1 flow element along with triply redundant SC1 transmitters as well as an independent set of triply redundant SC2 transmitters on the system overboard line upstream of the point where the two system trains connect. This flow indication is also used in conjunction with the supply flow and return flow instruments to support the DL3 and DL4a function of monitoring for system leakage respectively.

#### **Pump Seal Purge Flow**

There is one Non-Safety Class flow element along with one Non-Safety Class flow transmitter on the pump seal purge line. This flow instrument is used to monitor flow from the CRD system to the SDC pump to ensure seal purge flow is within acceptable limits.

#### **9A.2.3.7.2 Temperature**

##### **Heat Exchanger Inlet Temperature**

There are triply redundant SC1 as well as independent triply redundant SC2 temperature sensors upstream of the pump. This temperature is used to provide input for the SC1 and SC2 supply flow transmitters respectively.

The SC2 temperature sensors along with the heat exchanger discharge temperature is used to monitor the performance of the SDC heat exchanger. In Plant Modes 3 and 4, when the SDC is operational, these temperature elements are used to determine the average reactor coolant temperature.

##### **Heat Exchanger Discharge Temperature**

There are triply redundant SC1 as well as independent triply redundant SC2 temperature sensors on the discharge of the heat exchanger. This temperature is used to provide input for the overboard flow and return flow transmitters.

The SC2 temperature sensors along with the heat exchanger inlet temperature is used to monitor the performance of the SDC heat exchanger. This temperature is also used to modulate the heat exchanger bypass valve to allow the combined discharge temperature from the heat exchanger and bypass to meet a pre-set value.

##### **Overboard Temperature**

There is one SCN temperature sensor on the overboard line. This temperature is measured prior to discharge to LWM, and CUW to ensure that the temperature of the fluid is acceptable for the interfacing system.

#### **9A.2.3.7.3 Pressure**

##### **SDC Pump Suction Pressure**

There is one SC3 pressure instrument provided at the suction of each SDC pump. This pressure instrument is used to monitor the suction pressure of the SDC pumps, in order to monitor pump status and performance.

##### **SDC Pump Discharge Pressure**

There is one SCN pressure instrument provided at the discharge of each SDC pump. This pressure instrument is used to monitor the discharge pressure of the SDC pumps, in order to monitor pump status and performance.

##### **Heat Exchanger Differential Pressure**

There is one SC3 differential pressure instrument provided to measure the pressure drop across the tube side of the heat exchanger. This pressure drop is monitored to help inform the operator of needed maintenance.

#### **9A.2.3.7.4 Radiation**

##### **Overboard Radiation Monitoring**

There is one SCN radiation monitor installed on the SDC overboard line to monitor radiation levels. Refer to Chapter 11, Section 11.5 for information pertaining to the functions of the instrument.

#### **9A.2.3.8 Monitoring, Inspection, Testing, and Maintenance**

Maintenance and testing support equipment reliability. SSCs are designed to facilitate operation and maintenance. ISI and IST requirements are established and include inspection/test frequency for SSCs. Remote monitoring of key parameters assists in the trending of component performance as part of condition-based predictive maintenance. Testing is performed to ensure required functional operability is maintained under design conditions. The Safety-Category Functions of the SDC that support decay heat removal are tested in accordance with ASME BPVC Section XI as applicable. Testing is performed in accordance with plant procedures. Testing in support of plant pre-operational testing, startup, and commissioning is addressed in Chapter 14, Section 14.3.

Maintenance practices consider industry best practices and operating experience and conform with plant safety requirements to minimize potential for personnel injury. Maintenance activities implement ALARA practices to minimize work activity dose. Maintenance activities involving plant equipment may require involvement of vendors or industry specialists.

#### **9A.2.3.9 Radiological Aspects**

Chapter 12, Section 12.1 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions. In addition, the following design features are employed to reduce dose:

1. Process piping from the containment penetrations to the overboard lines should be routed through shielded areas or pipe chases to reduce the dose rates to the general areas of the reactor building.
2. Components within a compartment are arranged to facilitate rapid maintenance and inspection and allow for the addition of temporary shielding. Reducing the time for maintenance and inspection activities minimizes the duration and intensity of radiation exposure and assists with meeting ALARA goals.
3. Field located instruments and/or indicators are visibly and conveniently mounted outside of secondary shielding walls. This arrangement avoids unnecessarily exposing personnel to radiation during routine monitoring and maintenance.
4. SDC heat exchangers are manufactured with all-welded construction with flanged connections where accessibility to internal components is required for maintenance, inspection, or replacement. Maximizing welding reduces crevices in the heat exchanger and flanging the connections for accessibility helps reduce maintenance time – both of which support ALARA goals.

#### **9A.2.3.10 Performance and Safety Evaluation**

System reliability is enhanced through the use of periodic system testing, preventive maintenance, and application of redundant instrumentation.

The SDC Safety-Category functions during normal conditions include decay heat removal and, leak detection and isolation as discussed in Subsection 9A.2.3.1.2. There are no Safety-Category functions associated with Off-Normal conditions.

Containment isolation is provided in accordance with CNSC REGDOC-2.5.2 (Reference 9A.2.3-1) Chapter 8, Subsection 8.6.6. Refer to Chapter 6, Subsection 6.3.4 for a discussion related to BWRX-300 containment isolation and containment isolation valves.

The SDC is located in the Reactor Building which provides adequate protection against natural phenomena ensuring the ability of the SDC to perform its Safety-Category functions.

**Table 9A.2.3-1: Shutdown Cooling System Interfaces**

<b>Interfacing System</b>	<b>Interface Description</b>	<b>Interface Boundary</b>
Process Radiation and Environmental Monitoring System	The Shutdown Cooling System provides a sample line to the PREMS for sampling of reactor coolant when SDC is in service. Radiation Monitor on the SDC overboard line provided by PREMS.	The systems connect downstream of the SDC isolation valve. Radiation Monitor on the SDC overboard line.
Isolation Condenser System	The Isolation Condenser System provides a suction flow path from the RPV via the condensate return lines to the Shutdown Cooling System for decay heat removal and overboarding.	The systems connect downstream of the ICS containment isolation valves.
Control Rod Drive System	The Control Rod Drive system provides water to the Shutdown Cooling System pumps for motor cooling and seal purge flow.	The system interface is on the SDC pump purge water line upstream of SDC isolation valves.
Reactor Water Cleanup System	The Shutdown Cooling System flow can be routed to the Reactor Water Cleanup System for overboarding or into the RPV through the CUW inlet lines for thermal stratification reduction.	The system interface is on the SDC overboard lines at the isolation valve between SDC and CUW.
Liquid Waste Management System	The Shutdown Cooling System can overboard to the Liquid Waste Management System reactor water storage tank if overboard flow is contaminated.	The systems interface on the SDC overboard lines downstream of the isolation valve between SDC and LWM.
Condensate and Feedwater Heating System	The Shutdown Cooling System discharges into the Condensate and Feedwater Heating System lines A and B which discharge inside the RPV to complete a closed cooling loop.	The system interface is on the upstream side of the isolation valve between CFS and SDC.
Main Condenser and Auxiliaries	The Shutdown Cooling System can overboard to the Main Condenser and Auxiliaries if available for overboard flow.	The system interface on the SDC overboard lines downstream of the isolation valve between SDC and MCA.
Plant Cooling Water System	The Plant Cooling Water System provides cooling water to the Shutdown Cooling System heat exchangers.	The system interface is located at the SDC heat exchanger nozzles.
Plant Pneumatics System	The Plant Pneumatics System provides air or nitrogen to operate the Shutdown Cooling System air operated valves.	The system interface is located at each valve actuator.

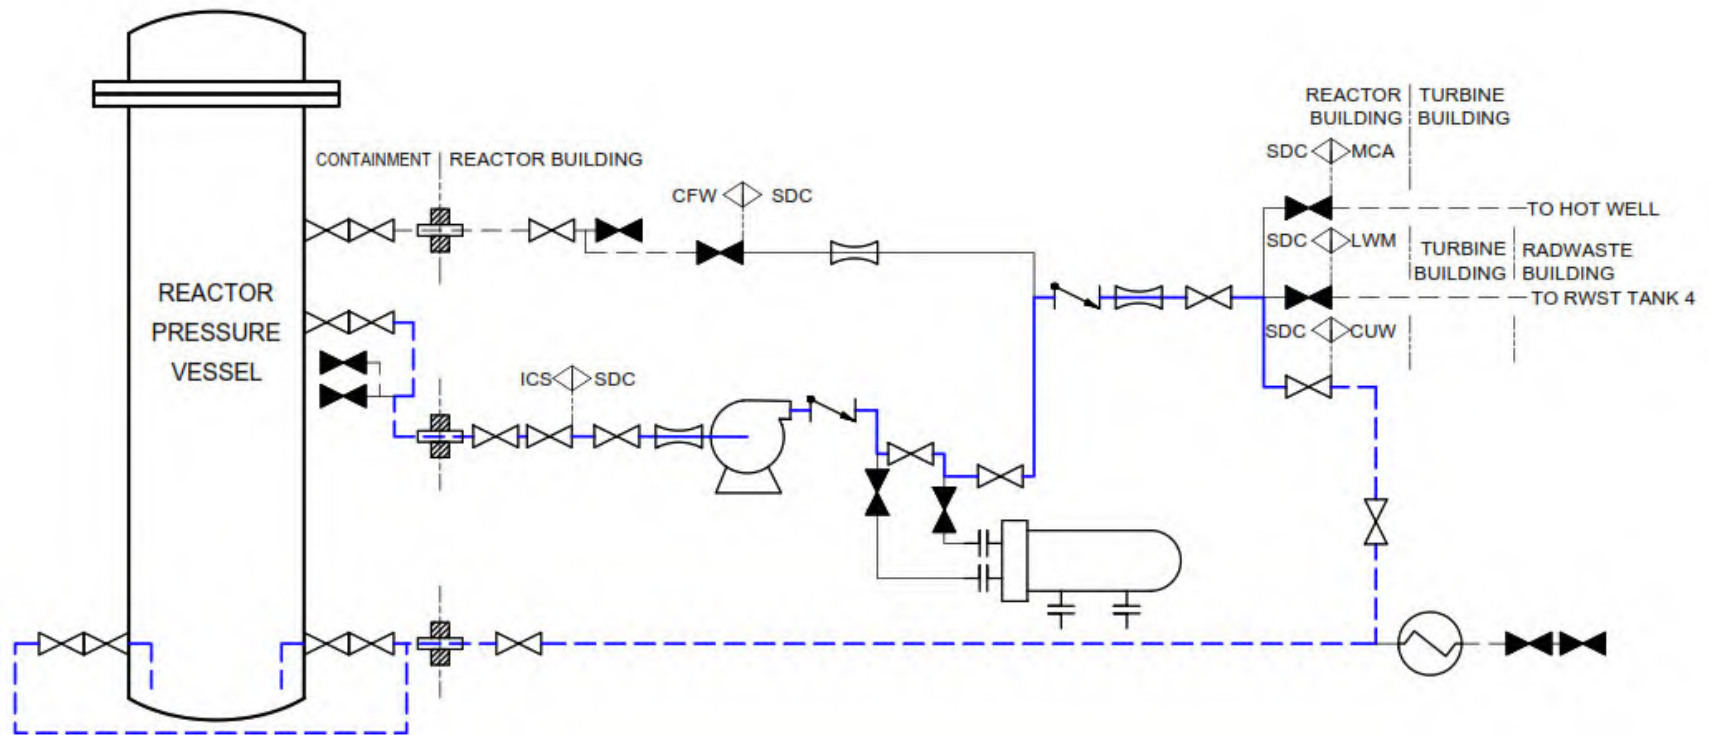

Figure 9A.2.3-3: Thermal Stratification Reduction Subsystem

#### **9A.2.4 Chilled Water Equipment System**

The Chilled Water Equipment (CWE) provides chilled water cooling to the Heating Ventilation and Cooling Systems throughout the plant, to the offgas cooler condenser, to the charcoal adsorber vault Fan Coil Units (FCUs), and to the Containment Cooling System (CCS) in the Reactor Building.

The safety classification of the CWE as well as interfacing SSC is consistent with the requirements of REGDOC 2.5.2, Section 7.1 (Reference 9A.2.4-1).

##### **9A.2.4.1 System and Equipment Functions**

System and equipment functions associated with the CWE are specified as follows. Information pertaining to Defense Lines (DL) is discussed in Chapter 3, Subsection 3.1.6.

###### **9A.2.4.1.1 Normal Functions (Non-Safety-Category)**

CWE provides the following Non-Safety-Category functions:

1. Provides chilled water to cooling coils in HVAC equipment in the following buildings or areas: Control Building (CB), Reactor Building, Turbine Building (TB), and Radwaste Building (RWB)
2. Provides chilled water to selected equipment coolers

###### **9A.2.4.1.2 Normal Functions (Safety-Category)**

The CWE provides the following Safety-Category functions:

1. As part of a Safety-Category (TBD) function, the CWE supplies chilled water to the CCS Air Handling Units (AHUs)
2. The CWE supplies chilled water to the Safety Category (TBD) Instrumentation and Control System, Defense Line 2, Room A, and Safety-Category (TBD) Instrumentation and Control System, Defense Line 2, Room B, Safety Category (TBD) Fan Coil Units
3. The CWE supplies chilled water to the Defense Line 4a Room Fan Coil Units in the Control Building

###### **9A.2.4.1.3 Off-Normal Functions (Non-Safety-Category)**

1. During a LOOP, one chiller/pump set from each chiller train continues to operate and provide cooling to critical Fan Coil Units and AHUs throughout the plant using backup power provided by the standby diesel generators.
2. The rooftop chillers are designed and fabricated to withstand the effects of high winds, earthquakes, and other adverse weather conditions, with the exception of tornado and tornado missiles.
3. During a Toxic Gas Event, the CWE system provides chilled water associated the normal Control Building supply AHU, which continues to operate during the event.
4. In the event of a fire outside the Control Building, the outside air through the normal operating AHU will be secured and the CWE system provides chilled water to operating AHU, which continues to operate in recirculation mode only.

#### **9A.2.4.1.4 Off-Normal Functions (Safety-Category)**

1. As part of Defense Line 3, CWE containment isolation valves are designed to close upon receiving an isolation signal from the Safety Category (TBD) Instrument and Control System.

Containment isolation is provided in accordance with CNSC REGDOC-2.5.2 Section 8.6.6. Refer to Chapter 6, Subsection 6.3.4 for a discussion related to BWRX-300 containment isolation and containment isolation valves.

#### **9A.2.4.2 Safety Design Bases**

As part of DL3, CWE containment isolation valves on piping that penetrate the containment boundary are designed to close upon receiving an isolation signal from the Safety Category (TBD) Instrument and Control System.

#### **9A.2.4.3 Description**

CWE is a closed loop chilled water system that supplies chilled water to various AHU cooling coils and plant equipment coolers in the Turbine Building, Radwaste Building, Reactor Building, and Control Building. Heat absorbed by the CWE is rejected from the CWE chiller condensers mounted on the Radwaste Building roof to atmosphere.

CWE is comprised of four (4) CWE air-cooled chillers, four (4) CWE pumps, two (2) expansion tanks (one per train), four (4) air separators, one (1) chemical bypass feeder, one (1) glycol auto-fill unit, piping, valves, instruments, and controls.

The CWE is split into two trains which allows for the isolation of the two different sets of AHUs and FCUs supporting redundant defence-in-depth equipment. Each CWE train consists of two chillers, two pumps, two air separators, and an expansion tank, while the glycol auto-fill unit and chemical bypass feeder are shared among both trains.

Both CWE trains are cross-tied together with air operated valves, which are normally open, to allow for the three active chillers to evenly share the heat load; however, these valves can be closed for train separation.

Figure 9A.2.4-1 depicts a simplified flow diagram of the CWE System.

Four 33 1/3% capacity air-cooled chillers are provided to reject heat from the closed chilled water loop to the environment. During normal operation, three chillers are in service while the fourth is in standby mode. Each chiller consists of an evaporator section, condenser section, refrigerant compressor, controls, and an integrated waterside economizer which allows for the chillers to run at reduced electrical loads at lower ambient temperatures. The CWE chillers utilize R-134a to exchange heat with the propylene glycol/water mixture. Since these units are mounted outside, the use of R-134a does not pose a risk to plant personnel. Each CWE chiller is provided with built-in protection against freezing.

The four 33 1/3% capacity in-line chiller pumps deliver chilled water from the CWE return header to the dedicated chiller. During normal operation, three pumps are in service while the fourth is in standby mode. Each pump discharge line is provided with a check valve to prevent backflow through the pump.

The CWE system trains are powered by separate generator load groups as part of the defense in depth protection function.

Four air separators are provided to remove entrained air. An air separator is connected to the chilled water return header upstream of each chiller pump. The air that is removed by the air

separators is piped to the train specific expansion tank to provide the gas cushion for chilled water expansion and contraction.

The two expansion tanks are connected to the two main chilled water return lines and provide a reservoir of demineralized makeup water to account for small amounts of system leakage and accommodate thermal expansion and contraction of water within the system while maintaining the system pressure. The expansion tank level is also used to determine the need for additional makeup fluid. Each expansion tank is shrouded to prevent rain, snow, and other debris from collecting in the expansion tank curbed area. The shroud is fitted with sight glasses for operators to manually inspect the curbed area for any liquid that has been collected.

The glycol auto-fill unit has a connection to the Water, Gas, Chemical Pads System (Subsection 9A.9.5) to provide demineralized water to maintain a predetermined propylene glycol/water mixture.

Isolation valves are provided at the interfaces with the components being cooled by CWE to allow for maintenance on those items without impact to the CWE system operation.

The supply and return line penetrations have isolation valves with electrical division 1 and division II connections outside and inside containment respectively, and ASME Class 2 piping into containment. The return piping inside of primary containment is provided with relief valves to protect against overpressure caused by thermal expansion. The system is designed to meet mechanical and electrical separation and redundancy requirements to ensure that the consequences of a single failure, pipe whip, jet forces, missiles, and the effect of failure of any non-Seismic Category I components do not compromise the ability of the system to meet its safety category requirements.

The CWE containment isolation valves are designed to operate in environments associated with the normal and accident conditions in the RB to which they are exposed. Refer to Chapter 3, Subsection 3.9.4 for information pertaining to Environmental Qualification.

The CWE expansion tanks, glycol auto-fill unit, chemical bypass feeder, and chillers pumps are all surrounded by a permanent curb to prevent the accidental excursion of propylene glycol into the Equipment and Floor Drainage System (Subsection 9A.9.3) sumps. To minimize dose exposure to plant personnel, the isolation valves for the FCUs located inside the bioshield area of the Turbine Building are positioned outside the bioshield area.

#### **9A.2.4.3.1 Component Description**

##### **Air-Cooled Chillers**

Four (4) 33% capacity air-cooled chillers are provided. Each chiller consists of an evaporator section, condenser section, refrigerant compressor, and controls. The chillers have individual temperature controls.

The CWE chillers are tested in accordance with Air Conditioning and Refrigeration Institute (AHRI) Standard 550 (Reference 9A.2.4-2) and American Society of Heating, Refrigerating, and Air Conditioning Engineers (ASHRAE) Standard 30 (9A.2.4-3).

Refrigerant piping is designed and fabricated per CSA B52 (Reference 9A.2.4-5).

Each chiller is equipped with pressure relief valves which relieves excess pressure of the refrigerant charge to the atmosphere in accordance with ASHRAE 15 Safety Code and ASME BPVC, Section VIII.

The chiller capacities include a 15% margin to accommodate unaccounted hot surfaces, higher than anticipated latent loads, and other unknown cooling loads

## **Pumps**

Four (4)x33% capacity centrifugal, electric motor driven pumps are provided with variable frequency drivers.

Pumps are factory tested per ANSI/HI 14.6.

The pumps are sized such that two (2) pumps are capable of supplying the necessary flow during a Loss-of-Offsite Power.

## **Chemical Bypass Feeder**

A carbon steel chemical bypass feeder tank is provided to treat the glycol water mixture and prevent the development of organics within the closed cooling water loop.

The bypass feeder tank is designed to meet the requirements of ASME BPVC, Section VIII.

## **Expansion Tanks**

The two atmospheric vessels are designed to meet the requirements of API 650.

## **Glycol Auto Fill Unit**

The packaged, glycol auto fill unit maintains the glycol system pressure by providing glycol make-up automatically upon a drop in system pressure. The glycol auto-fill unit has a connection to the Water, Gas and Chemical Pads system to provide demineralized water to maintain a predetermined propylene glycol/water mixture. Upon a drop in liquid level in the expansion tanks, the integrated side suction peripheral pump starts adding fluid from the glycol auto fill tank to the CWE System expansion tanks until the setpoint level is reached.

## **Piping and Valves**

All non-refrigerant piping is designed in accordance with the requirements of ASME B31.1 with the exception of the containment penetration portion. The containment isolation valves and lines that supply and return chilled water to the containment cooling system cooling coils are Safety Class 1, designed to the requirements of BPVC Section III, Division 1- Subsection NCD; and are Seismic Category I. The containment isolation valves are designed to fail-closed on a loss of air or signal.

Refrigerant piping inside the air-cooled chillers is designed and fabricated in accordance with the requirements of ASHRAE 15(Reference 9A.2.4-2).

Overpressure relief valves are provided on the CWE return lines located both inside and outside of containment.

CWE piping is provided with insulation to prevent pipe sweating as required. The pipe insulation meets the combustibility requirements in compliance with fire protection codes and standards.

### **9A.2.4.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials through material chemistry, heat treatment, contamination, and material processes controls.

Materials are selected in accordance with applicable codes, standards, and industry practice for the design, service, and test conditions and expected ambient conditions. Materials are compatible with the internal process and external environmental conditions during normal, abnormal, accident, and beyond design basis accident conditions as appropriate. Building

construction utilizes noncombustible materials as defined in the fire protection Codes and Standards.

#### **9A.2.4.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.2.4-1 for Chilled Water Equipment interfaces with other equipment or systems.

#### **9A.2.4.6 System and Equipment Operation**

##### ***9A.2.4.6.1 Normal Operational Concept***

Up to three of the four chiller pump sets are placed in normal operation based on the cooling load demand. One chiller pump set is always available in standby. The CWE is designed to operate with N+1 redundancy. Where N is the number of pieces of equipment to meet the baseload demand. N+1 indicates there is one extra piece of equipment provided. Hence during normal operation 3 chillers/pumps will be in service while the 4th be in standby mode.

The chilled water control valves modulate in response to room or supply air temperature controllers for the Control Building and Reactor Building, which are part of the HVS except for the Containment Cooling System (Subsection 9A.5.6) AHUs. The temperature control valve downstream of the CCS AHU cooling coils modulate in response to the air discharge temperature of the CCS AHUs. As the cooling loads decrease, the valves modulate to decrease the chilled water flow causing a differential pressure increase across the supply and return mains.

Chillers are automatically started or stopped, based on the CWE supply header temperature.

The glycol auto-fill unit will automatically be switched on and off based on the level transmitter in the expansion tanks. Upon receiving a low level signal, the glycol auto-fill unit will switch on and add additional fluid to the CWE expansion tanks.

Normally, chiller train A, which consists of chillers and pumps 1 and 2, and expansion tank A; and train B, which consists of chillers and pumps 3 and 4 and expansion tank B are cross-tied together such that flow from the RWB, TB, TB switchgear rooms A and B, RB loops A and B, and CB loops A and B, will be shared proportionally between the two trains based on the number of active chillers in each train.

Depending on the ambient conditions, the chillers are able to operate in one of three different modes: mechanical cooling only, hybrid cooling, or free cooling only. When the ambient temperature is too warm to provide free cooling, an integrated three-way valve at the chiller inlet allows the glycol/water mixture to only run through the condenser coils. When the temperature reaches an ambient temperature where some free cooling is feasible, the three-way valve diverts some flow through the free cooling coils which then enters the chiller evaporator. If further fluid temperature reduction is required, the chillers will perform the remaining mechanical cooling. As the ambient temperature continues to decrease, there will be a point where the supply temperature can be met by free cooling operation alone and the mechanical cooling can be shut off completely. During free cooling mode, the chillers operate using significantly less power because the waterside economizer does not use a refrigerant loop and the section requires fewer hot air discharge fans. When one or multiple FCUs located inside the Turbine Building bioshield area are manually isolated because of a leak, the chilled water trapped between the isolation valves is drained to prevent damage to the CWE distribution pipe or FCUs tubes due to thermal expansion.

##### ***9A.2.4.6.2 Off-Normal Operational Concept***

During a LOOP and turbine trip, one CWE chiller and pump from each chiller train will trip and restart upon receiving power from the standby diesel generators. The inlet guide vane of the non-

operational chillers, and the block valves in the TB, excluding the TB switchgear rooms, and RWB return headers close automatically, so that the CWE flow will only flow through the equipment required for the continued safe operation of the plant.

Upon station blackout, the CWE is not operating.

#### **9A.2.4.7 Instrumentation and Control**

##### **9A.2.4.7.1 Instrumentation**

CWE contains sufficient instrumentation to:

1. Verify chilled water pump performance, by monitoring pump suction and discharge pressure.
2. Verify chiller performance, by monitoring the inlet and outlet pressure, CWE flowrate, and the inlet and outlet temperatures for each chiller.
3. Verify chilled water return and supply header temperatures.
4. Verify pressure loss through the system.
5. Provide remote status indication of the air-operated containment isolation valve to the MCR and SCR.

##### **9A.2.4.7.2 Controls**

System and component operating status, including the state of manual overrides, and the state of the A and B trains are provided at the Main Control Room (MCR) and Secondary Control Room (SCR). Manual initiation and shutdown of CWE is provided from the MCR.

The following CWE primary displays and alarms are provided:

1. MCR and SCR Major Indications:
  - a. Chiller operating status
  - b. Chiller inlet and outlet pressures and temperatures
  - c. CWE system operating pressures and temperatures
  - d. CWE pump suction and discharge pressures
  - e. CWE pump flow rates
  - f. Air-operated containment isolation valve status
  - g. Expansion tank liquid level
  - h. CB, RB, and TB switchgear room loops misaligned (only possible when the chiller headers are isolated)
2. MCR and SCR Alarms:
  - a. Loss of CWE flow to any operating chiller
  - b. Chiller trip and chiller trouble
  - c. High CWE return water temperature
  - d. High or low chiller outlet temperature
  - e. High or low expansion tank liquid level

The CWE is expected to run continuously with three of the four chillers and pumps running while the other chiller and pump are on standby. The operator manually brings the chiller/pump combo online by selecting an operating chiller to put into standby. Upon receiving the standby command, the standby pump will start, followed by the chiller. Once the MCR or SCR receives confirmation that the pump and chiller are both on, the operating chiller will stop, followed by the pump. The chillers and chiller support systems are capable of automatically starting and stopping based on the CWE supply header temperature; however, the chillers and CWE pumps can be operated remotely from the MCR.

A chilled water temperature control valve located in the return piping at each AHU cooling coil bank, is designed to maintain air discharge temperature of the upstream AHU. The chilled water control valves modulate in response to room or supply air temperature controllers, which are part of the HVS except for the CCS AHUs. The temperature control valves downstream of the CCS AHU cooling coils modulate in response to the air discharge temperature of the CCS AHUs. As the cooling loads decrease, the valves modulate to decrease the chilled water flow causing a differential pressure increase across the supply and return mains.

The automatic block valve in each building's chilled water return line is modulated, during plant startup, to balance pressure loss in each building chilled water loop so that flow is adequately distributed to every building.

The temperature control valves in each building's chilled water return line can be modulated to balance pressure loss in each building's chilled water loop so that flow is adequately distributed to every building.

During normal operation, the chillers operate to automatically maintain the chilled water supply temperature at a predetermined value.

The standby chiller pump will auto start upon trip of any operating pump. The CWE pump is tripped on occurrence of any of the following:

- Low CWE pump suction pressure
- A manual stop command
- A protective device trip

The chiller is tripped on occurrence of any of the following:

- Loss of CWE flow
- A failure of the chiller automatic start sequence
- A manual stop command
- High system pressure

The containment isolation valves are automatically closed upon receiving a containment isolation signal and also automatically fail-closed on loss of air or signal.

#### **9A.2.4.8 Monitoring, Inspection, Testing, and Maintenance**

Pre-operational testing is performed in accordance with applicable codes and manufacturer recommendations.

The CWE chillers are tested in accordance with AHRI Standard 550 (Reference 9A.2.4-3) and ASHRAE Standard 30 (Reference 9A.2.4-4).

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

Component specific maintenance procedures are outlined in the vendor manuals provided as part of each procurement package and are a part of a maintenance program conforming to ASME Code OM 2020.

Areas requiring inspection are provided with access and removable insulation.

CWE piping and valves for the containment penetrations are tested in accordance with 10CFR50, Appendix J and CNSC REGDOC-2.5.2. Test and vent connections are provided at the containment isolation valves in order to verify that the valves meet the local leak rate limits.

The containment isolation valve closure time is monitored during the valve operability test and the leakage is monitored or verified during the valve leakage test as specified in the containment leakage testing program. Leak detection and inspection for primary containment isolation features is designed to ASME BPVC Section III, Division 1, Class 1. A test connection is provided to support local leak rate testing of the primary containment boundary. The test connections minimize the amount of water that must be drained to permit periodic testing of containment isolation valves that include operability testing, leak rate testing, valve status verification, and test frequency.

Containment isolation valve testing, stroke time testing, and leakage rate testing are incorporated to ensure proper and safe functionality of the valves.

Isolation valves are provided at each piece of equipment, control valve, and piping circuit so they can be isolated for maintenance and repair.

Chillers and pumps are arranged to provide adequate floor space and unobstructed clearance to permit monitoring, maintenance, and inspection of each unit.

Isolation valves are provided at the interfaces with the components being cooled by CWE to allow for maintenance on those items without impact to the CWE system operation.

#### **9A.2.4.9 Radiological Aspects**

Chapter 12 provides information pertaining to design measures that are taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are As Low As Reasonably Achievable (ALARA).

#### **9A.2.4.10 Performance and Safety Evaluation**

The CWE is split into two trains which allows for the isolation of the two different sets of AHUs and FCUs supporting redundant defense in depth equipment.

CWE is designed with sufficient redundancy to assure that chilled water is normally available during all modes of plant operation, including startup and shutdown. Certain equipment needed during a Loss-of-offsite power are provided Diesel Generator backup power.

As part of DL3, the CWE performs a containment isolation Safety-Category function. The CIVs are designed to close upon receipt of an isolation signal from the Safety Category (TBD) Instrument and Control System. During normal operations the CWE supplies chilled water to the CCS AHUs, DL2 Room A and Room B FCU's, and chilled water to the DL 4a Room FCU in the Control Building.

### **9A.2.5 Normal Heat Sink System**

The Normal Heat Sink (NHS) provides heat rejection for the CWS and the PCW. Refer to Chapter 10, Sections 10.8, and Subsection 9A.2.1 for information related to the CWS and PCW respectively.

Refer to Subsection 9B.3.5 for information pertaining to the Pumphouse, Forebay, and Tunnels.

#### **9A.2.5.1 System and Equipment Functions**

##### **Normal Functions (Non-Safety-Category)**

The NHS provides the supply of cooling water for the circulating water pumps, which removes heat from the condenser and PCW heat exchangers and accepts the circulating water return flow. NHS performs this function at all times for all plant modes of operation.

##### **Normal Functions (Safety-Category)**

The NHS performs the following Safety-Category functions during normal conditions:

- Provides cooling water as a means to reject heat from the MCA to the environment
- Provides cooling water as a means to reject heat from the PCW heat exchangers to the environment

##### **Off-Normal Functions (Non-Safety Category)**

The system does not perform any Non-Safety-Category functions during off-normal conditions.

##### **Off-Normal Functions (Safety-Category)**

Upon a LOOP, NHS continues to provide a cooling water source and heat rejection functions to support CWS interface with PCW.

#### **9A.2.5.2 Safety Design Bases**

The NHS provides cooling water to the two CWS (Chapter 10, Subsection 10.8) plant cooling water supply pumps (2A and 2B), which in turn are relied upon to provide cooling water to the PCW heat exchangers, to support Safety-Category functions for FPC (Subsection 9A.1.3) and SDC (Subsection 9A.2.3).

#### **9A.2.5.3 Description**

The NHS is a once-through cooling water system design. Water will flow into the intake structure forebay from Lake Ontario by means of an intake tunnel. The water is strained prior to pumping by the CWS pumps. Water flows through the CWS system where it absorbs the heat from the main condenser and the PCW heat exchangers. The water is discharged back into Lake Ontario through the discharge structure. A recirculation line from the CWS discharge line to the intake is provided to moderate NHS temperature at the Forebay of the NHS, as needed, during cold weather conditions.

#### **9A.2.5.4 Materials**

Material and process control requirements for the BWRX-300 structures and components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials specifically from corrosion (as applicable) through material chemistry, heat treatment, contamination, and material processes controls.

#### **9A.2.5.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.2.5-1 for system interfaces.

#### **9A.2.5.6 System and Equipment Operation**

The NHS system operates under all normal operating modes of the plant. The Off-normal operational modes include operations following a LOOP event.

##### ***9A.2.5.6.1 Normal Operational Concept***

The NHS has its water pumped by the circulating water pumps to the circulating water supply in the Turbine Building where it absorbs the heat from the main condenser and the PCW heat exchangers. Next, the CWS dedicated PCW and Condenser return lines discharge the circulating water back to the heat sink.

##### ***9A.2.5.6.2 Off-Normal Operational Concept***

Upon a LOOP, NHS continues to provide a cooling water source and heat rejection functions to support CWS interface with PCW.

#### **9A.2.5.7 Instrumentation and Control**

The NHS has no instrumentation and controls associated with the system. All NHS parameters are measured within CWS.

#### **9A.2.5.8 Monitoring, Inspection, Testing, and Maintenance**

Maintenance and inspection is based upon integrating proactive, reactive, preventive, and predictive maintenance and operating experience. Implementation of maintenance and inspection increases the probability that the NHS structures, systems, and components function in the required manner over their design life cycle. Operational testing is performed in accordance with plant procedures.

#### **9A.2.5.9 Radiological Aspects**

Chapter 12, Subsection 12.1 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.2.5.10 Performance and Safety Evaluation**

The NHS is capable of performing its design functions during all modes of operation.

Upon a LOOP, NHS continues to provide a cooling water source and heat rejection functions to support CWS interface with PCW.

**Table 9A.2.5-1: Normal Heat Sink Interfaces**

Interfacing System	Interface Description	Interface Boundary
Circulating Water System	The NHS provides the source of water used as the cooling medium to the CWS pumps and accepts the return flow from the CWS pumps. When required for cold weather operation, CWS is designed to maintain a minimum intake basin temperature through a recirculation line from the CWS discharge line	At the intake and discharge structures

### **9A.2.6 Isolation Condenser System Pool Cooling and Cleanup System**

The primary function of the Isolation Condenser System Pool Cooling and Cleanup System (ICC) is to remove heat from the Isolation Condenser System (ICS) (Chapter 6, Subsection 6.2) pools such that the bulk temperature of water in the pools is maintained below Technical Specifications limits and thereby ensure the readiness of the ICS to perform its Safety-Category function. Secondary functions of the ICC include maintaining the cleanliness of the ICS pool water and providing the capability to add clean makeup water during normal reactor operations to offset the minor routine loss of water inventory due to evaporation.

#### **9A.2.6.1 System and Equipment Functions**

The ICC performs the following functions during normal and off-normal conditions.

##### **9A.2.6.1.1 Normal Functions (Non-Safety-Category)**

1. The ICC extracts heat from the ICS Pool Water to maintain IC (Isolation Condenser) pool temperature within TS limits for maximum pool temperature, and thereby maintains ICS pool readiness for IC deployment.
2. The ICC removes soluble and insoluble impurities from the ICS Pool Water to comply with plant water quality requirements.
3. The ICC provides the capability of adding makeup demineralized water to the ICS pools during normal reactor operations to replace water inventory lost by evaporation from the ICS pool surface.

##### **9A.2.6.1.2 Normal Functions (Safety-Category)**

The Safety-Category functions provided by the ICC are associated with the suction and return pipe penetrations into the ICS pools. The Suction Surge Tank is one of two primary interfaces with the Reactor Building Structure (RBS) ICS Pool Structure and is categorized as SC1 and as a Seismic A component. The Return Guard Pipe is the second of two primary interfaces with the RBS ICS Pool Structure and is likewise categorized as an SC1 and Seismic A component. The principal function of these two components is to prevent draining of the ICS Outer Pools in the event of a break in ICC piping below the ICS pools.

##### **9A.2.6.1.3 Off-Normal Functions (Non-Safety-Category)**

The ICC does not provide any Non-Safety-Category functions during off-normal conditions.

##### **9A.2.6.1.4 Off-Normal Functions (Safety-Category)**

The ICC does not provide any Safety-Category functions during off-normal conditions.

The design of the ICC meets requirements specified in CNSC REGDOC-2.5.2 Section 7.1 (Reference 9A.2.6-1) as related to ensuring that the portions of the ICC, namely the suction and return pipe penetrations into the ICS pools, that interact with the SC1 ICS are also designed to SC1 requirements. Considering that the ICC is of a lower safety classification than the ICS, designing the suction and return pipe penetrations to SC1 requirements ensures that the failure of a lower safety class SSC cannot propagate to an SSC belonging to a higher safety class.

#### **9A.2.6.2 Safety Design Description**

The Safety-Category functions provided by the ICC are associated with the suction and return pipe penetrations into the ICS pools.

The Suction Surge Tank and the Return Guard Pipe are designed to prevent draining of the ICS Outer Pools in the event of a break in ICC piping below the ICS pools. The probability of such

breaks occurring is minimized by locating ICS pool isolation valves as close to the ICS pool penetrations as practicable. In the event of a non-isolable break in the ICC suction piping, it is possible for the ICS Cubicles (i.e., Inner Pools) to drain to the bottom of the connecting weir in the partition wall separating the ICS Cubicles from the ICS Outer Pools, and for the ICS Outer Pools to drain to the top of the Suction Surge Tank. In the event of a non-isolable break in the ICC return piping, the design of the Return Guard Pipe prevents draining the ICS Outer Pools and Cubicles because the top of the Return Guard Pipe is above the maximum pool water level.

ICC suction and return connection interfaces with the Reactor Building Structure are designed such that any failure in the ICC pressure boundary cannot result in draining the ICS Pools.

#### **9A.2.6.3 Description**

The ICC is classified as Non-Safety Class, Non-Seismic Category and Quality Group D. The ICC has no Defense Line Functions. Figure 9A.2.6-1 depicts the ICC.

The ICC consists of two independent and identical 50% capacity trains which service the three Isolation Condenser Cubicle Pools. The two identical thermal processing trains can be operated together or operated with one train and the other train shutdown as needed to maintain conditions in the ICS pools.

Both ICC trains take suction from a single penetration in the Isolation Condenser Outer Pool A. An air-operated ICS Pool Isolation Valve is installed in the main suction pipe to stop flow from Outer Pool A. Processed ICS pool water is returned directly to the three IC cubicles. Return water can be directed to individual IC cubicles by controlling the flow of ICC effluent by aligning IC cubicle isolation valves as desired. The ICS Pool suction and return isolation valves are equipped with manual overrides and handwheels, which allows the valves to be manually operated if the valve actuator fails, thereby increasing system reliability.

Each ICC pump/heat exchanger train can be isolated as needed to maintain ICS readiness to allow both trains to operate simultaneously, or so that one train can operate separately to allow maintenance to be performed on the other train for continuous operation. Each ICC train includes a centrifugal pump with Adjustable Speed Drive (ASD), frame-and-plate HX, associated piping, sensors, and valves. PCW (Subsection 9A.2.1) flows through the HX to extract heat from the ICS pool water which is rejected to the environment. The discharge from the two ICC pump/HX trains is processed by a skid-mounted demineralizer before being returned to the IC Cubicle Pools. All ICC flow passes through the demineralizer except when bypassed. The demineralizer can be bypassed when the temperature of the discharge exceeds the maximum temperature allowed for the demineralizer resins or when chemicals are injected into the water to inhibit corrosion and biological growth in the IC pools and ICC components. The ICC is equipped with a dosing pot for injecting chemicals for corrosion and biological control into the process fluid.

Because the ICC is of a lower safety class and quality group than the ICS and pools, design provisions are provided to ensure that a pressure boundary failure in its piping or components cannot adversely impact the higher safety class system, specifically draining of the ICS pools. This is accomplished by a surge volume (Suction Surge Tank) that is a component of the seismically designed reactor building IC pools structure, from which the ICC takes suction. In the event of a failure in the ICC that creates a drainage path, only the surge volume can be drained with no impact on the safety class IC pools volume, and with minimal impact on the ICC components from flooding. Similarly, the discharge or return piping to the IC pools is routed through the seismic Return Guard Pipe, and then routed near the ceiling of the ICS Outer Pools and across the ICS cubicle wall through the connecting weir at which point the return pipes are submerged and routed to a distribution sparger that discharges the cooled and purified water

directly to the ICS Cubicle near the bottom of the IC. The high point of the return piping contains an anti-siphon feature to prevent backflow in the event of an ICC pressure boundary failure. Additionally, ICS pool isolation valves are located as close as possible to the pipe penetrations to minimize the impact to the ICS pools for any failure of ICC piping beyond the isolation valves.

#### **9A.2.6.3.1 Component Description**

The following information is provided relative to the major components in the ICC system.

##### **Suction Surge Tank**

The Suction Surge Tank is one of the primary interfaces with the ICS Pools and, therefore, is an ICC component with SC1 and Seismic A classifications. The Suction Surge Tank consists of flanged (removable) pipe spools. All Suction Surge Tank components are made of Type 304/304L or 316/316L stainless steel. The main suction pipe penetration into the ICS Outer Pool A inside the Suction Surge Tank is designed to provide a leakage-tight barrier between the ICS Outer Pool A and the underlying ICC Equipment Area. A cover plate with vent tube for the Suction Surge Tank is provided to permit the Suction Surge Tank to be drained for downstream maintenance activities without draining the ICS Outer Pools.

##### **Return Guard Pipe**

The Return Guard Pipe is the second of two primary interfaces with the ICS Pools and, therefore, is an ICC component with SC1 and Seismic A classifications. The Return Guard Pipe consists of flanged (removable) pipe spools. Return Guard Pipe components are made of Type 304/304L or 316/316L stainless steel. The return pipe penetration into the ICS Outer Pool A, inside the Return Guard Pipe is designed to provide a leakage-tight barrier between the ICS Outer Pool A, and the ICC Equipment Area. The Return Guard Pipe includes an attached cover that seals the Return Guard Pipe to prevent water accumulation and debris from entering the Return Guard Pipe.

The Return Guard Pipe cover plate assembly is designed to provide lateral support for the anti-siphon devices in the return piping to meet seismic structural requirements.

##### **Filtration**

A cylindrical metallic screen is installed at the main suction inlet for foreign material exclusion. The foreign material exclusion screen is connected to the main suction pipe by a flanged connection. The foreign material exclusion screen is designed to facilitate periodic cleaning to remove accumulated debris on the outer surface of the screen. In-line filters with replaceable filter cartridges are installed at the inlets to the heat exchangers on both the hot side and the cold side to remove minute suspended particulates to prevent clogging the narrow flow channels between plates in the heat exchangers for maximum heat transfer effectiveness. All filtration components and surfaces in contact with the process fluid is made of Type 304/304L or 316/316L stainless steel.

##### **Adjustable Speed Drive Pump Motors**

The ICC pumps are driven by ASDs with electric motors to provide operational flexibility for: a) optimal performance in restoring ICS Pool Water temperature to TS requirements following deployment of one or more ICs; and b) efficient and economical performance in maintaining ICS Pool Water temperature and cleanliness during normal reactor operations.

##### **Pumps**

Pump suction and discharge connections are flanged. All pump components and surfaces in contact with the process fluid are made of Type 304/304L or 316/316L stainless steel. The ICC pumps are designed to comply with the requirements of ANSI/HI 1.3 (Reference 9A.2.6-2). Each

pump is powered by an Adjustable Speed Drive with electric motor. The pumps have mechanical seals to minimize the potential for leakage and reduce the need to perform maintenance on shaft seal packings. Pumps are installed within catch basins to contain minor leakage. Moisture sensors are installed in the catch basin to inform reactor operators of potential maintenance issue due to water leakage.

### **Heat Exchangers**

Frame-and-plate HXs are used to reject heat from the process fluid in the ICC loop to the PCW. HX components and surfaces in contact with the process fluid are made of Type 304/304L or 316/316L stainless steel. HX inlet and discharge connections are flanged to facilitate removal as necessary for maintenance, repair, and replacement. Drainage taps are provided in HX or piping connections to allow the HX to be drained to facilitate maintenance or repair activities.

### **Demineralizer**

An integrated skid-mounted demineralizer is used to clean the process fluid in the ICC loop. Demineralizer components and surfaces in contact with the process fluid are made of Type 304/304L or 316/316L stainless steel. A drainage tap is provided to allow the Demineralizer tank to be drained to facilitate maintenance or repair activities. The Demineralizer is sized to process the effluent from a single ICC pump train. ICC Demineralizer spent resin media is discharged to the Solid Waste Management System (Chapter 11, Section 11.4).

### **Dosing Pot**

A dosing pot allows chemical injection into the process fluid to inhibit corrosion and biological growth in ICC piping and components and the ICS pools. All dosing pot components and surfaces in contact with the process fluid are made of Type 304/304L or 316/316L stainless steel. A drainage tap is provided to allow the dosing pot to be drained when not in use.

### **Backflow Preventer**

Back flow preventers are installed in the return piping to the IC cubicles to prevent inadvertently draining the IC cubicle pools in the event of an ICC piping failure below the ICS pools. The back flow preventers are installed at the highest elevation of the ICC piping to function as anti-siphon devices. Back flow preventer components are made of Type 304/304L or 316/316L stainless steel. The Back Flow Preventer vent hole is covered by a shield plate located normal to the axis of the vent hole to limit the flow of return processed fluid out of the Back Flow Preventer.

### **Distribution Spargers**

The return water distribution spargers are installed in the IC cubicles near the ICs. The spargers are installed at or near the bottom of the Isolation Condenser cubicles in a manner that promotes bulk flow of the water in the cubicle, particularly with respect to the Isolation Condenser HX. The distribution spargers are fabricated using seamless Type 304/304L or 316/316L stainless steel pipe. The distribution spargers include a flanged end connector to facilitate removal as necessary for maintenance, repair, and replacement.

### **ICC Piping**

Piping in contact with ICS pool water is made of Type 304/304L or 316/316L seamless, stainless steel. ICC piping in contact with PCW on the cold side of the HXs is made of seamless Grade B carbon steel. The ICC piping is designed to comply with ASME B31.1 (Reference 9A.2.6-3) requirements. Drainage taps are provided at low points in the ICC piping to allow the pipes to be drained to facilitate maintenance or repair activities. Vents are provided at the high points in the ICC piping to allow air to be purged from the ICC piping when filling with pool water and to allow

the pool return pipes to be drained to facilitate maintenance or repair activities. Structural supports for piping systems and components inside the ICS Pool Compartment are in accordance with the rules and requirements of ASME BPVC-III NF, Subsection NF, "Supports" (Reference 9A.2.6-4).

### **ICC Valves**

Valve surfaces in contact with ICS pool water are made of Type 304/304L or 316/316L stainless steel. The ICC valves are designed to comply with ASME B31.1 and ASME B16.34 (Reference 9A.2.6-5) requirements. Valve internals in the ICC piping in contact with PCW is made of Type 304/304L or 316/316L stainless steel to maintain leak-tightness. Valves are provided with flanged inlet and outlet connections to facilitate removal as necessary for maintenance, testing, and replacement. The ICS pool suction isolation valve and pool return isolation valves are equipped with manual override and handwheel.

### **Instrument Requirements**

ICC instrument housings and internals in contact with ICS Pool Water are made of Type 304/304L or 316/316L stainless steel. Where possible, instrument housings are provided with flanged connections to facilitate removal as necessary for maintenance, testing, and replacement.

#### **9A.2.6.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, and corrodents through material chemistry, heat treatment, contamination, and material processes controls.

Components and surfaces that come in contact with ICS pool water are manufactured using corrosion-resistant material. Use of corrosion-resistant material reduces iron particulate introduced into the system and Flow Accelerated Corrosion (FAC).

#### **9A.2.6.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.2.6-1 for ICC interfaces with other equipment or systems.

#### **9A.2.6.6 System and Equipment Operation**

The ICC provides active cooling and purification of the ICS pools when it is operating.

The ICC cooling function is required when the ICs are in standby mode due to constant thermal leakage caused by a relatively small amount of condensing steam in the IC during normal reactor operations. The Adjustable Speed Drives allow the ICC to operate at a lower system flow rate during normal operations when the ICs are in standby mode for improved overall plant economy.

The ICC purification function is provided by directing ICC flow through the ICC Demineralizer, which is the normal flow path during routine system operation. The Demineralizer is bypassed for the following conditions:

1. The Demineralizer is bypassed if the temperature of the process fluid exceeds 53.3 °C to prevent thermal degradation of the demineralizer resins and early desorption of adsorbed contaminants that occurs with aging.
2. The Demineralizer is bypassed during the injection of chemicals into the process fluid to inhibit corrosion and biological growth in the ICS Pool Cooling and Cleanup System equipment, piping, and IC pools to prevent chemical degradation of the demineralizer resins.

#### **9A.2.6.6.1 Normal Operation**

Refer to Table 9A.2.6-2, "BWRX-300 Reactor and ICC Operating Modes" which provides a summary of the plant operating modes with corresponding ICC operating modes.

##### **Mode 1: Power Operation**

During Mode 1 power operation, the ICC is in service for all system operating modes:

- ICC Mode A2 – Both ICC trains A and B are operating for maximum heat removal from the ICS pools
  - The Demineralizer is bypassed during Mode A2
- ICC Mode A1a – Only ICC Train A is operating to purify ICS pool water and remove heat
  - The Demineralizer is bypassed if the HX effluent temperature exceeds 53.3 °C
- ICC Mode A1b - Only ICC Train B is operating to purify ICS pool water and remove heat
  - The Demineralizer is bypassed if the HX effluent temperature exceeds 53.3 °C
- ICC Mode A2c – Both ICC trains are operating for injection of water treatment chemicals
  - The Demineralizer is bypassed during chemical injection

One ICC pump/HX train can be isolated as needed for maintenance during power operation. Demineralized makeup water is automatically added to maintain ICS pool inventory during normal reactor operations.

Processed water is returned to individual ICS cubicles as required by aligning the ICS pool isolation valves to the desired ICS cubicle pools.

##### **Mode 2: Startup Operation**

During startup operation, the ICC is in service for all system operating modes described for power operation.

##### **Mode 3: Hot Shutdown Operation**

During hot shutdown operation, the ICC is in service for all system operating modes described for power operation.

##### **Mode 4: Stable Shutdown Operation**

During stable shutdown operation, the ICC is in service for all system operating modes described for power operation. In addition, the ICC can be completely removed from service during stable shutdown operation for system maintenance.

##### **Mode 5: Cold Shutdown Operation**

During cold shutdown operation, the ICC is in service for all system operating modes described for power operation. In addition, the ICC can be completely removed from service during cold shutdown operation for system maintenance.

##### **Mode 6: Refueling Operation**

During refueling operation, ICC is in service for all system operating modes described for power operation. In addition, ICC can be completely removed from service during refueling operations for system maintenance.

#### **9A.2.6.6.2 Off-Normal Operations**

ICC does not have any Off-Normal operating modes.

#### **9A.2.6.6.3 System Shutdown**

The ICC can be completely removed from service for system maintenance during the following plant operating modes:

- Mode 4: Stable Shutdown
- Mode 5: Cold Shutdown
- Mode 6: Refueling

#### **9A.2.6.7 Instrumentation and Control**

Non-Safety-Category function instrumentation and controls (Chapter 7) provides control signals to ICC pumps and valves to initiate system operation and direct flow through system piping branches as needed. The Non-Safety function instrumentation and controls also receives data signals from instruments installed in the ICC piping to measure local process flow variables: water level, temperature, pressure, differential pressure, and conductivity. A local instrumentation monitoring panel is provided in the ICC equipment area for maintenance, diagnostic, and functional testing of the ICC and individual components.

Where possible, instrument housings are provided with flanged connections to facilitate removal as necessary for maintenance, testing, and replacement. Instruments are installed such that there is space surrounding the instrument to facilitate ready access to the instrument and the ability to perform maintenance or replacement.

ICC Control and Alarm and Monitoring functions are identified in Table 9A.2.6-3.

#### **9A.2.6.8 Monitoring, Inspection, Testing, and Maintenance**

Testing of the ICC is performed to demonstrate proper system and component functioning. ICC functionality is continuously demonstrated during normal plant operation. Provisions are made for periodic inspection of major components to ensure the capability and integrity of the system. Service platforms are installed to facilitate inspection of the Surge Tank and Return Guard Pipe. The design of the ICC allows for the inspection and testing of components under normal operating conditions.

Material and equipment selection for the ICC is based on a 60-year design life, with appropriate provisions for maintenance and replacement. Components that require replacement prior to the end of the 60-year design life include, but are not limited to, electrical and electronic equipment, gaskets and seals, lubricants, valve disks and internal components such as seats and packing, and bearings.

Isolation valves are provided near the ICC piping penetrations to the ICS Outer Pool A to permit maintenance and repair activities to be performed on pipe section below the ICS pools. Valves are installed with flanged connections to facilitate removal as needed for testing or repair. In addition, valves and other components are installed with plenty of space surrounding the component to facilitate ready access and the ability to perform maintenance, repair, or replacement activities.

Maintenance isolation valves and flanged connections are provided for the pumps and HXs so they can be isolated and removed for repair or replacement as required. Drain taps are provided at low points in piping sections to evacuate process water for maintenance and repair activities.

A manual crossover feature allows for simultaneous maintenance on the pump of one train with the HX on the other train without interrupting normal cooling and cleanup operation. This design feature adds flexibility for maintenance purposes thereby increasing ICC reliability and availability. The design of the ICC provides adequate equipment removal paths and personnel access for maintenance and repair activities and equipment replacement.

Testing is performed to ensure required functional operability is maintained under design conditions. Testing is performed in accordance with plant procedures. Testing in support of plant pre-operational testing, startup, and commissioning is addressed in Chapter 14, Section 14.3.

#### **9A.2.6.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.2.6.10 Performance and Safety Evaluation**

Two features have been incorporated into the ICC design to increase system reliability.

1. A crossover pipe with manual isolation valve is installed between the A and B trains pump discharge to allow the system to remain operable in the event Pump A and HX B are simultaneously out of service for maintenance activities, or if Pump B and HX A are simultaneously out of service.
2. Manual overrides with handwheels are specified for the main suction and for the return Air-Operated Block Valves to enable manual operation of these valves in the event of actuator failure.

Safety Category functions provided by the ICC are associated with the suction and return pipe penetrations into the ICS pools. The Suction Surge Tank and Return Guard Pipe are categorized as SC1 and Seismic A components and function to prevent draining of the ICS Outer Pools in the event of a break in ICC piping below the ICS pools.

Figure 9A.2.6-1: Isolation Condenser System Pool Cooling and Cleanup System

### **9A.3 Process Auxiliary Systems**

#### **9A.3.1 Process Sampling Systems**

The Process Sampling System is a subsystem of the Process Radiation and Environmental Monitoring System. In addition to the Process Sampling subsystem, the PREMS is comprised of the following subsystems, Process Radiation Monitoring (Chapter 11, Subsection 11.5), Area Radiation Monitoring (Chapter 12, Subsection 12.3.14), and Containment Monitoring (Chapter 12, Subsection 12.3.14).

The Process Sampling subsystem is included in the design of the BWRX-300 based upon the requirements of REGDOC 2.5.2 (Reference 9A.3.1-1) Section 8.13.3 "Radiation Monitoring" as applicable.

The BWRX-300 design does not employ a Post-Accident Sampling System for assessing core damage as per REGDOC 1.1.2 (Reference 9A.3.1-2). In its place is a collection of Post-Accident Monitoring (PAM) inputs utilizing real-time measurements of plant parameters which are deemed more accurate and/or more timely to measure core damage. The sensors and instruments designated for PAM are treated differently by the plant I&C architecture to ensure availability during and after the most severe accident or Beyond Design Basis Accident. Many of the other Post-Accident Sampling System samples were not needed for short severe accident scenario or the information is available from post-accident monitoring instruments such as radiation monitors, (containment, main steam and offgas) temperature and water level as discussed in Reference 9A.3.1-3.

##### **9A.3.1.1 System and Equipment Functions**

The Process Sampling subsystem collects representative liquid and gaseous samples for analysis and provides the analytical information required for monitoring plant and equipment performance. The Process Sampling subsystem performs the following functions during normal and off-normal conditions.

###### **9A.3.1.1.1 Normal Function (Non-Safety Category)**

The Process Sampling subsystem collects representative liquid and gaseous samples for analysis and provides the analytical information required for monitoring plant and equipment performance. This process subsequently guides changes to operating parameters. This subsystem is designed to function during all plant operational modes under individual system requirements. The Process Sampling subsystem does not perform or ensure any Safety Class function. Therefore, this system has no Safety Class design basis.

###### **9A.3.1.1.2 Normal Function (Safety Category)**

This subsystem does not perform any Safety-Category functions during normal conditions.

###### **9A.3.1.1.3 Off-Normal Functions (Non-Safety-Category)**

This subsystem does not perform any Non-Safety-Category functions during Off-Normal conditions.

###### **9A.3.1.1.4 Off-Normal Functions (Safety-Category)**

This subsystem does not perform any Safety-Category functions during Off-Normal conditions unless designated a Post-Accident Monitoring function.

#### **9A.3.1.2 Safety Design Bases**

The Process Sampling subsystem does not perform, ensure, or support any Safety-Category function, and thus, has no safety design bases.

#### **9A.3.1.3 Description**

The Process Sampling subsystem collects representative liquid and gaseous samples for analysis and provides the analytical information required for monitoring plant and equipment performance.

Process streams not requiring continuous sampling or computer monitoring include provisions for obtaining grab samples. Sample lines are routed to a common sample station, local sample station (or simply local sample taps) depending on plant layout and process fluid.

The Process Sampling subsystem consists of the following: permanently installed sample lines, sampling panels with analyzers and associated sampling equipment, provisions for grab sampling, and permanent shielding. The division of sample lines versus grab samples are assessed during detailed design activities based on the availability of automation in the instrumentation, the need to limit personnel access (ALARA), the frequency of needed measurements, and other considerations. Sampling stations and associated process samples are summarized by location below.

Sample Stations:

- Reactor Water Cleanup System
- Shutdown Cooling System
- Control Rod Drive System
- Fuel Pool Cooling and Cleanup System
- Isolation Condenser System
- Isolation Condenser Pool Cooling and Cleanup System
- Condensate and Feedwater System
- Moisture Separator Reheater System
- Heater Drain and Vent System (Condensate and Feedwater subsystem)
- Nuclear Boiler System Main Steam Lines
- Condensate Filter and Demineralizer System
- Main Turbine Equipment
- Main Condenser
- Liquid Waste Management
- Solid Waste Management

Local Grab Sample Stations:

- Plant Cooling Water System
- Water, Gas, and Chemical Pads (Plant Service Water and Makeup Water are subsystems)
- Chilled Water System

- Circulating Water System
- Equipment and Floor Drain System

Containment isolation function is applied to all mechanical instrument sensing line penetrations of the containment boundary in a manner that provides the highest reliability of maintaining instrument function while limiting potential radioactive release if an instrument line is ruptured outside the containment boundary.

The Process Sampling subsystem monitors plant liquids and gases utilizing components designed and installed in such a way as to minimize interconnection of radioactive and non-radioactive systems. To the extent practicable, Process Sampling subsystem interconnections to non-radioactive systems are limited to purge air, purge water and makeup water for filling loop seals. The designs of these interconnections prevent contamination of the non-radioactive system or process due to leakage, spillage, valving errors, or other operating conditions.

The Process Sampling subsystem is designed to minimize facility and environmental contamination and minimize the generation of radioactive waste. These objectives are supported by the procedures for operation, and are controlled as follows:

- Providing atmospheric purging of the internal portion of air sampling skids as necessary
- Providing the ability for liquid flushing of the internal portions of liquid sampling skids as necessary
- Designing the interior portions of liquid and gaseous sampling chambers to minimize the plate out of radioactive material
- Designing sample extraction points such that they minimize the potential for spillage and contamination of adjacent areas
- Minimizing the generation of liquid radioactive waste by minimizing the amount of a sample that needs to be extracted, consistent with laboratory and sensitivity requirements

#### **9A.3.1.3.1 Component Description**

The Process Sampling subsystem consists of sample lines, sampling panels with analyzers and associated sampling equipment, provisions for grab sampling, and shielding.

#### **9A.3.1.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials specifically from IGSCC (as applicable) through material chemistry, heat treatment, contamination and material processes controls.

#### **9A.3.1.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.3.1.1-1 which provides the description and boundary for each interfacing system.

#### **9A.3.1.6 System and Equipment Operation**

The Process Sampling subsystem operates continuously or in grab sample mode when the interfacing system being monitored is operational.

##### **9A.3.1.6.1 Initial Configuration (Pre-Startup)**

The Process Sampling subsystem operates continuously or in grab sample mode.

#### **9A.3.1.6.2 System Startup**

The Process Sampling subsystem operates continuously or in grab sample mode.

#### **9A.3.1.6.3 Normal Operations**

Sampling equipment operates continuously with capability for grab samples from each process stream.

Root valves for process system sampling points are included in the Process Sampling subsystem. The safety requirements for root valves are determined by the safety requirements for the particular system.

#### **9A.3.1.6.4 Off-Normal Operations**

There are no mitigating system functions tied to the Process Sampling subsystem.

#### **9A.3.1.6.5 System Shutdown**

Process Sampling subsystem is performed in accordance with detailed operation procedures.

#### **9A.3.1.7 Instrumentation and Control**

The Process Sampling subsystem is supported by the SCN Distributed Control and Information System (Chapter 7, Subsection 7.3.4). SCN classified functions are implemented on a hardware/software platform to provide the reliability needed to prevent controller failure from becoming an Anticipated Operational Occurrence (AOO).

#### **9A.3.1.8 Monitoring, Inspection, Testing, and Maintenance**

The Process Sampling subsystem design provides continuous availability regardless of the plant operating mode; therefore, Process Sampling subsystem functionality is continuously demonstrated during all phases of normal, shutdown, and off-normal conditions.

Routine maintenance and cleaning of the sampling subsystem is performed. The design accommodates easy access to sensors, instruments, and panels for maintenance. Additionally, devices for lifting or hoisting the Process Sampling subsystem components is provided to facilitate replacement if required.

Instrumentation is designed to facilitate calibration checks and troubleshooting.

Sampling racks and electronic modules are serviced and maintained in accordance with the operational instructions to ensure reliable operation. Such maintenance includes servicing and replacement of defective components and adjustments as required. Periodic testing or calibration checks is performed as part of the maintenance plan.

#### **9A.3.1.9 Radiological Aspects**

Chapter 12, Subsection 12.3.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.3.1.10 Performance and Safety Evaluation**

The system design provides continuous availability regardless of the plant operating mode. SCN functions are implemented on the Non-Safety Instrumentation and Control System which provides the reliability needed to prevent controller failure from becoming an AOO. The Process Sampling subsystem performs no Safety-Category functions and is not required to prevent or mitigate the consequences of a design basis accident, to shut down the reactor and maintain safe shutdown

conditions, or to maintain the integrity of the reactor coolant pressure boundary. Therefore, a nuclear safety evaluation is not required.

## **9A.4 Air and Gas System**

### **9A.4.1 Plant Pneumatic System**

The Plant Pneumatics System provides a continuous supply of compressed air for the majority of the plant air demands. In addition, PPS supplies oil-free air to service boxes for use of portable breathing air filtration systems. The PPS also distributes nitrogen to users inside containment.

#### **9A.4.1.1 System and Equipment Functions**

##### **Normal Functions (Non-Safety-Category)**

PPS provides the following Non-Safety-Category functions:

1. The PPS provides dry, oil-free, filtered compressed air for valve actuators, instrument control functions, air operated tools, and miscellaneous equipment/services outside of containment in Mode 1, 2, 3, 4, 5, and 6.
2. The PPS provides the compressed air for tank sparging, filter/demineralizer backwashing, air-operated tools and other services requiring air of lower quality in Mode 1, 2, 3, 4, 5, and 6.
3. The PPS provides the distribution of gaseous nitrogen, supplied by the Containment Inerting System (CIS) (Subsection 9A.4.2), to primary containment for valve actuators and other primary containment users in Mode 1, 2, 3, 4, and 5.
4. The PPS supplies instrument-quality air to nitrogen consumers when primary containment is open for personal access (e.g., major outages).
5. The PPS supplies oil-free air to service boxes for breathable air.

##### **Normal Functions (Safety-Category)**

The PPS provides dry, oil-free, filtered compressed air for Safety-Category valve actuators and instrument control functions outside of containment (Safety Class 3).

The PPS provides the distribution of gaseous nitrogen, supplied by CIS, to Primary Containment for Safety-Category valves, controls, instrumentation, and other Primary Containment users (Safety Class 3).

While these functional requirements are categorized as SC3, not all associated air demands are expected to be SC3.

##### **Off-Normal Functions (Non-Safety-Category)**

The power supply to the PPS automatically switches to standby AC power during a LOOP.

##### **Off-Normal Functions (Safety-Category)**

As part of Defense Line 3 the PPS provides containment isolation valves on piping that penetrates the containment boundary. These valves are designed to close upon receiving an isolation signal from the Safety Class 1 Instrumentation and Control System (Chapter 7, Subsection 7.3.1).

Containment isolation is provided in accordance with CNSC REGDOC-2.5.2 Section 8.6.6 (Reference 9A.4.1-1). Refer to Chapter 6, Subsection 6.3.4 for information pertaining to containment isolation. In addition, the design of the PPS meets the requirements specified in CNSC REGDOC-2.5.2 Section 7.1 as related to ensuring that the Non-Safety-Category function portions of the PPS are isolated from the Safety-Category function portions of the PPS.

#### **9A.4.1.2 Safety Design Bases**

The PPS is Safety Class 3, providing integral support functions for DL2 functions:

As part of the PPS Safety-Category 3 functions the PPS provides dry, oil-free, filtered, compressed air for valve actuators, Safety-Category instrument control functions, and general instrumentation services outside of the Steel-plate Composite Containment Vessel (SCCV). The PPS provides the distribution of gaseous nitrogen, supplied by the CIS, to SCCV for valve actuators and other SCCV users.

Containment Isolation Valves are provided on piping that penetrates the containment boundary. These valves are designed to close upon receiving an isolation signal from the Safety Class 1 Instrumentation and Control System.

#### **9A.4.1.3 Description**

Figure 9A.4.1-1 depicts the PPS.

The PPS consists of two 100% air compressors, two 100% capacity dryer trains, two service air receivers operating in parallel upstream of the dryers, and two instrument air receivers operating in parallel downstream of the dryers. The PPS provides service and instrument air for the majority of plant air needs.

Each compressor takes suction through an air intake filter/silencer which brings air from outside the TB. The air inlet is fitted with rain hood and bird screen. The lead compressor supplies air to both service air receivers, which will flow through the lead dryer train, to both instrument air receivers.

Distribution piping in the plant is by ring headers which allows for flexibility in distribution locations, maintenance, and ease of accommodating future requirements. The service air receivers distribute air to the service air header demands. The service air subsystem also connects to a separate utility containment penetration to provide service air to the service boxes inside containment. These service boxes are used to supply air to portable breathing air filtration systems to provide breathing air hookups to personnel entering containment when the atmosphere is not yet fully habitable or for areas where high levels of airborne contaminants cannot be eliminated efficiently by the HVAC.

The instrument air receivers will distribute air to the instrument air header demands. The instrument air subsystem also includes piping penetrating containment, connecting the CIS to pneumatic valves and other compressed gas users inside containment. During plant outages, the PPS supplies the pneumatic valves and other compressed gas users inside containment with instrument-quality air while the nitrogen supply from the CIS is isolated from inside containment.

During normal operation, the air supply is isolated from the primary containment vessel via double block and bleed valve configuration so that nitrogen from the CIS can be supplied to nitrogen users inside containment using the PPS primary containment piping penetrations. The block and bleed valves on the air supply prevent air from entering containment during normal operation and posing an explosion and fire risk. During plant shutdown, the nitrogen supply is isolated from the primary containment vessel via double block and bleed valve configuration, so that in the case of a leak in the PPS supply piping to primary containment, the primary containment does not turn into a confined space or pose an asphyxiation risk to plant personnel.

PPS is designed to meet the applicable requirements of Instrument Society of America 7.0.01 (Reference 9A.4.1-2).

#### **9A.4.1.3.1 Component Description**

The following paragraphs provide information that pertains to the major equipment items in the PPS system.

##### **Air Compressors**

The two (2) compressors are oil-free, rotary screw, water-cooled, electric motor driven compressors. Each compressor can supply 100% of the system's continuous air requirements. Noise reduction methods are incorporated to ensure that noise levels in habitable areas near the compressors are within the guidelines for industrial environments. The air compressor units are powered from the two (2) separate electrical busses. The service air piping includes a connection for adding an additional compressor. These compressors are commercially available skid packages.

##### **Air Receivers**

The system includes two service air receivers in parallel and two instrument air receivers in parallel. The design capacity of the receivers includes adequate reserve capacity to provide at least 10 minutes of operating time following a trip with no air compressors in operation before the low pressure set point alarms are sounded in the control room.

The receivers are ASME VIII designed and stamped.

A pressure-relief safety valve is installed on each receiver.

##### **Dryer/Filter Trains**

The PPS utilizes two (2) 100% dryer trains. The dryers are regenerative desiccant air dryers.

The dryer trains include coalescing pre-filters and after-filters. The 100% capacity pre-filters are included to remove water and oil droplets, rust, dust, and other solid objects suspended in the air. The 100% capacity after-filters are included to remove particles of desiccant that may be carried away from the dryer. During normal operation, one dryer/filter train is continuously operating, and the other train is in standby. If both compressors are operating, both dryers are placed in service, if available.

The dryer filter trains deliver compressed air that meets ISA 7.0.01 (Reference 9A.4.1-2) Quality Standards for Instrument Air.

##### **Piping and Valves**

All PPS piping is welded stainless steel material

The piping, other than that required for containment isolation, is designed to meet the requirements of ASME B31.1.

To ensure containment integrity at the Steel Composite Containment Vessel penetrations, the containment piping and isolation valves are designed to Seismic Category A and B, respectively; ASME BPVC, Section III, Division 1-Subsection NCD; and Quality Group B requirements.

PPS containment isolation piping includes an AOV outside of containment and a check valve inside of containment. During a Design Basis Accident (DBA), if the AOV fails to close leakage out from inside containment is stopped by the air system if an air compressor is operating or by the check valve if an air compressor is not operating.

#### **9A.4.1.4 Materials**

The PPS is designed utilizing materials that ensure that the functional requirements of the system are achieved. Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials through material chemistry, heat treatment, contamination, and material processes controls.

#### **9A.4.1.5 Interfaces with Other Equipment or Systems**

Table 9A.4.1-1 identifies PPS interfaces with other BWRX-300 Systems.

#### **9A.4.1.6 System and Equipment Operation**

The PPS operates in the normal plant environment and provides Non-Safety and SC3 functions. With the exception of the containment isolation valves the PPS is not required to operate after a design basis accident.

The system is designed for continuous operation during all modes of plant operation:

##### **Normal Operational Concept**

During normal operation, one 100% capacity air compressor operates to supply both service air receivers, one dryer train, both instrument air receivers, and both instrument and service air system distribution piping.

A compressor is chosen as the lead, continuously operating compressor. The other compressor serves as standby.

The standby compressor automatically starts upon trip of the lead compressor, or when the air pressure in the system drops below the predetermined pressure set point. The assignment for lead and standby air compressors is switched periodically by operators in the MCR.

One 100% dryer/filter train operates, and one serves as standby. Automatic start of the standby dryer skid occurs when the differential pressure across a dryer filter, discharge pressure or the dewpoint reach predetermined setpoints. The assignment for lead and standby dryers is switched periodically by operators in the MCR.

##### **Off-Normal Operational Concept**

The PPS containment isolation valves and associated piping are designed to be functional after a safe shutdown earthquake.

When a LOOP is detected, the operating compressor and dryer both trip and restart when power is received from the backup diesel generators.

#### **9A.4.1.7 Instrumentation and Control**

##### **9A.4.1.7.1 Instrumentation**

The PPS contains instrumentation to remotely monitor (indicate and alarm) and control all equipment performance, control valve status, and necessary system parameters, such as pressure, temperature, and moisture content of the compressed air in the system. Data signals from the PPS instruments and equipment are displayed on the Main Control Room (MCR) and local instrumentation panels. Local control panels for the compressors and dryers are used to operate during testing, calibration, and changing standby compressor and dryer units.

Instrumentation associated with one or more control functions are redundant. For additional information refer to Chapter 7, Subsection 7.3 "Distributed Control and Information System

Functions". This includes instruments such as vendor package (skid) instrumentation that send equipment trip signals or standby equipment start signals upon detecting specified abnormal operating conditions. Additionally, service and instrument air header pressure sensors that provide the main control parameters for the PPS are redundant, described in the Controls section below.

#### **9A.4.1.7.2 Controls**

The PPS is automatically controlled from the plant Distributed Control and Information System (DCIS). The start and stop of the PPS compressors and dryers are automatically or manually operated from the MCR. The instrumentation and control architecture in the PPS is designed to keep the instrument air available in all modes of operation. All automatic or remotely actuated valves in the PPS fail in the position most likely to keep the system operational and controllable with the exception of the PPS containment isolation valves.

The pressure in the service air header is the main control parameter in the system. The operating compressor loads/unloads based on pressure readings from the redundant pressure sensors on the service air header. Upon a loss of both compressors, or at a low pressure setpoint, the normally open service air isolation valve closes to shed the service air system load and conserve air for the instrument air subsystem to maintain control of the plant. Upon a loss of both dryers, or a low-low pressure indication from the redundant instrument air header pressure sensors, the dryer bypass line opens to allow the flow of service air to the instrument air users.

#### **9A.4.1.8 Monitoring, Inspection, Testing, and Maintenance**

All major components have manual isolation valves to permit maintenance activities without having to shut down the PPS. The maintenance boundary between the isolation valves is designed to permit the simultaneous maintenance of the maximum number of components as possible without impacting the ability of the system to remain in service.

PPS piping and valves for the containment penetrations are tested in accordance with 10CFR50, Appendix J and CNSC REGDOC-2.5.2. Test and vent connections are provided at the containment isolation valves and are used to verify that the valves meet the local leak rate limits.

The PPS outboard containment isolation valve is tested to ensure operational integrity by manual operation of the valve. The inboard containment check valve is periodically tested to ensure valve operability.

All PPS equipment is arranged to provide adequate pull space and clearance for personnel and testing equipment access to facilitate, testing, repair, and maintenance.

Breathing air is sampled in accordance with CSA Z180.1:19 to ensure the CSA breathing air quality standards are met.

Instrument air and system functionality is tested in accordance with ISA 7.0.01 (Reference 9A.4.1-2) and associated guidelines to ensure the instrument air quality standards are met.

#### **9A.4.1.9 Radiological Aspects**

Chapter 12, Subsection 12.3 provides information pertaining to design measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.4.1.10 Performance and Safety Evaluation**

The SC1 Safety-Category function performed by the PPS is containment isolation. Containment isolation is provided in accordance with CNSC REGDOC-2.5.2 Section 8.6.6 (Reference 9A.4.1-

1). The PPS CIVs are designed to maintain the leak tightness of the containment in the event of an accident and prevent radioactive releases to the environment that exceed prescribed limits. The PPS incorporates features that ensure its operation over the full range of normal plant operations.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

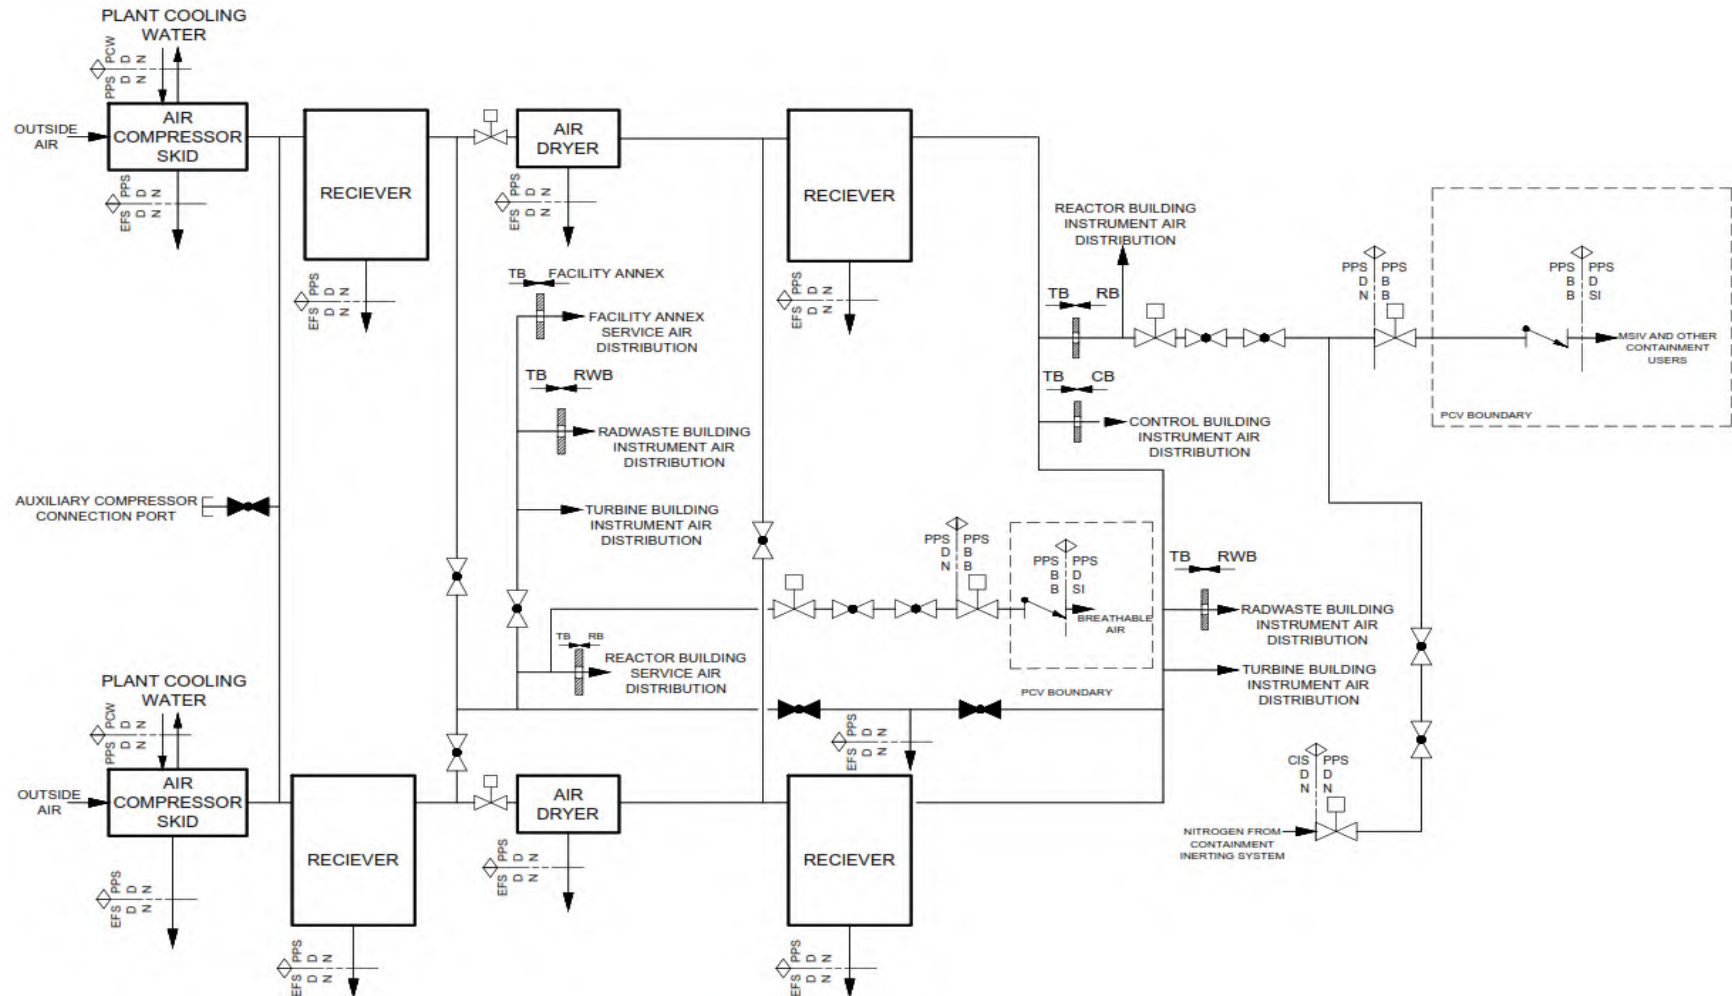

Figure 9A.4.1-1: Plant Pneumatic System

#### **9A.4.2 Containment Inerting System**

The Containment Inerting System is designed to establish and maintain an inert atmosphere (nitrogen) within the Steel-plate Composite Containment Vessel (SCCV). An inert atmosphere is maintained in all operating modes except during plant shutdown for refueling, equipment maintenance, and during limited periods of time to permit access for inspection at low reactor power. Prior to reactor shutdown the CIS can de-inert the SCCV allowing for safe personnel access without the need of a breathing apparatus. The principal objective of the CIS is to preclude the development of a combustible atmosphere by maintaining an oxygen deficient atmosphere inside SCCV.

The containment boundary is classified as Defense Line 3, Safety Class 1 (DL3/SC1) system.

The containment overpressure vent flow path is Defense Line 4b, Safety Class 3 (DL4b/SC3).

The containment supply and exhaust flow paths are (TBD).

##### **9A.4.2.1 System and Equipment Functions**

The BWRX-300 CIS provides the following functions during Normal and Off-Normal conditions.

###### **9A.4.2.1.1 Normal Functions (Non-Safety Category)**

Establish and maintain an inert atmosphere within containment for prevention of hydrogen combustion during post-accident events that may result in fuel damage. There is no significant hydrogen generation during normal operations.

Maintain a positive pressure within containment to prevent the infiltration of non-inert air during all normal plant operating modes, except plant shutdown

Establish a breathable de-inert atmosphere within containment during plant shutdown for refueling and maintenance

###### **9A.4.2.1.2 Normal Functions (Safety Category)**

The CIS penetrates containment and therefore must ensure containment boundary integrity and isolation capability.

###### **9A.4.2.1.3 Off-Normal Functions (Non-Safety Category)**

Maintain containment oxygen concentration below the maximum permissible limit during abnormal and accident conditions to ensure an inert atmosphere.

###### **9A.4.2.1.4 Off-Normal Functions (Safety Category)**

Protect against containment overpressurization, which could occur during degraded core conditions after a severe accident

The CIVs and associated piping and penetrations are designed in accordance with the rules and requirements of ASME BPVC Code, Section III, Division 1, Subsection NE-Class MC Components, and Subsection NCD, Class 2 Components, in accordance with their quality group classification. The containment pipe penetrations are Seismic Category A and the CIVs are Seismic Category B.

The design and application of the CIS system meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.6.10 (Reference 9A.4.2-1) as related to preventing deflagration or detonation that could jeopardize the integrity or leak tightness of the containment. In addition, containment isolation is provided in accordance with CNSC REGDOC-2.5.2 Section 8.6.6.

#### **9A.4.2.2 Safety Design Bases**

The Safety Design Bases of the CIS are as follows:

1. As part of Defense Line 3, the Containment Inerting System provides CIVs on piping that penetrates the containment boundary.
2. As part of Defense Line 3, the Containment Inerting System CIVs are designed to close upon receiving an isolation signal from the Safety Class 1 Instrumentation and Control System.
3. To protect against containment overpressurization a containment overpressure vent flow path is provided. The containment overpressure vent flow path is Defense Line 4b, Safety Class 3 (DL4b/SC3).

#### **9A.4.2.3 Description**

Figure 9A.4.2-1 depicts the CIS. Components of CIS are located both inside and outside the reactor building. The nitrogen storage equipment, including the liquid nitrogen storage tank, nitrogen vaporizer, and heater are located in the yard.

The CIS provides the capability to supply containment with nitrogen to ensure that a noncombustible atmosphere is maintained following an accident that results in 100% reaction between the fuel cladding and water.

The CIS is capable of reducing the containment oxygen concentrations from atmospheric conditions to less than 3.5% by volume in less than 4 hours.

CIS is also capable of de-inerting the inerted containment to above 19.5% oxygen by volume within 4 hours to allow personnel safe access within containment without the use of a breathing apparatus.

The CIS consists of containment supply, containment exhaust, and containment overpressure venting flowpaths.

##### **Containment Supply Flowpath**

The containment supply flow path is used to inject nitrogen into containment for inerting (large nitrogen flow) and makeup (small nitrogen flow), inject breathable air into containment for de-inerting, and supply nitrogen to the PPS (Subsection 9A.4.1) to support actuation of air operated devices located inside containment. The containment supply flow path consists of a pressurized liquid nitrogen storage tank, vaporizer to convert the liquid nitrogen to a gaseous phase, electrical heater, piping, valves, instruments, and controls. Most of the components are located within the Reactor Building except for the storage tank, vaporizer, heater, associated valves, and piping, which are located in the yard. The containment supply flow path terminates in lower containment.

##### **Containment Exhaust Flowpath**

The containment exhaust flow path is available to be used to discharge the containment atmosphere during the inerting, makeup, and de-inerting process. The containment exhaust flow path consists of piping, valves, instruments, controls, and a tee to the containment overpressure vent flow path. All of the components are located within the Reactor Building. The exhaust flow path starts in upper containment on the opposite side of containment from the supply injection point and connects to the Heating Ventilation and Cooling System (Subsection 9A.5) before discharging to the vent stack.

### **Containment Overpressure Vent Flowpath**

The containment overpressure vent flow path is used in case of a severe accident where containment failure by overpressure is threatened. The containment overpressure vent flow path consists of a rupture disc, a locked closed manual bypass valve, pressure indicator, isolation valve, check valve, sparger, and associated piping. The overpressure vent flow path connects to the containment exhaust flow path and terminates in the Reactor Equipment Pool. By relieving pressure into the Reactor Equipment Pool, water scrubbing is expected to occur, thereby reducing the contaminants. Additionally, the Reactor Equipment Pool is located inside the Reactor Building such that further holdup of any potential released contaminants is provided.

The rupture disk is designed in accordance with the rules and requirements of ASME BPVC, Section III, Class 2 Components. The rupture disk is designated Quality Group A. The containment pipe penetrations are Seismic Category A. The CIVs and rupture disk are Seismic Category B.

The over-pressurization vent line and associated sparger are Safety Class 3.

Environmental Qualification of Safety-Class SSC's is provided as applicable as discussed in Chapter 3, Subsection 3.9.

#### **9A.4.2.3.1 Component Description**

The following information is provided relative to the major equipment items in the ICC system.

### **Liquid Nitrogen Storage Tank**

An insulated liquid nitrogen storage tank provides nitrogen supply to support CIS operations. The CIS liquid nitrogen storage tank is sized to provide enough nitrogen to support two consecutive nitrogen purges of containment. The tank includes level and pressure indicators, and the bottom of the tank is sloped to facilitate draining. Pressure is maintained automatically in the tank during nitrogen discharge by a circuit with an ambient heat exchanger fed by a pressure control valve. The vapor space can be manually vented to control tank internal pressure. The tank is fabricated of material suitable for cryogenic service in order to withstand low liquid nitrogen temperatures. The tank is equipped with quick disconnect/connect or equivalent type of connection to support refilling.

### **Vaporizer**

The nitrogen vaporizers are used to convert the liquid nitrogen from the liquid nitrogen storage tank to the gaseous phase. The CIS nitrogen vaporizers are sized to provide at least 2.5 times the containment free volume of nitrogen within the 4-hour inerting period. The CIS nitrogen vaporizers are fabricated of materials suitable for cryogenic service.

### **Heater**

Vaporization of nitrogen for inerting and makeup is provided by an ambient air heat exchanger with auxiliary electrical heating. The CIS nitrogen heaters are designed to heat the nitrogen makeup to a temperature greater than 10 °C. The CIS nitrogen heaters are fabricated of materials suitable for cryogenic service.

### **Rupture Disk**

The rupture disk is part of the containment over-pressurization vent flowpath and provides passive overpressurization protection for containment. The CIS rupture disk burst pressure tolerance at the specified disk temperature does not exceed 5% of marked burst pressure.

#### **9A.4.2.4 Materials**

CIS Structures, Systems and Components are fabricated of materials suitable for cryogenic service as required.

#### **9A.4.2.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.4.2-2 for CIS interfaces.

#### **9A.4.2.6 System and Equipment Operation**

Table 9A.4.2-1, "BWRX-300 Operating Modes" provides a summary of the plant operating modes relative to CIS operations.

##### **Initial Configuration (Pre-Startup)**

The initial configuration of the CIS is set to inerting Mode with the CIVs closed. The CIS is in standby readiness condition prior to reactor startup.

##### **System Startup**

During System Startup (Mode 2), the SCCV hatches are closed and the CIS is in-service. Coming out of shutdown where the SCCV was opened or any condition where the oxygen concentration is above the acceptable level, the CIS is set to inerting mode. Liquid nitrogen from the nitrogen storage tank is vaporized, heated, and subsequently injected into the lower SCCV while exhausting from the upper SCCV until the correct oxygen concentration is reached. The nitrogen is mixed with the SCCV atmosphere by the Containment Cooling System fans. Once the targeted oxygen concentration and pressure levels are reached, the CIS Containment Isolation Valves close.

Once inerting is complete, the CIS can be set to makeup mode to maintain the required oxygen concentration and a slightly positive pressure inside the SCCV to preclude oxygen infiltration from the Reactor Building. Liquid nitrogen from the nitrogen storage tank is vaporized, heated, and subsequently injected into the lower SCCV. During SCCV atmospheric heating conditions during plant startup, the exhaust line is opened to relieve excess SCCV pressure.

##### **Normal Operations**

During Power Operation (Mode 1), the containment vessel hatches are closed, and the CIS is in-service. The CIS makeup mode is activated when the SCCV pressure drops below the desired setpoint and/or the oxygen concentration rises above the desired setpoint. Positive pressure is needed in the SCCV to preclude oxygen infiltration from containment leakage. Liquid nitrogen from the nitrogen storage tank is vaporized, heated, and subsequently injected into lower SCCV. During the maximum containment atmospheric heating conditions, the containment exhaust line is opened to maintain SCCV internal pressure.

During Refueling (Mode 6), the CIS is idle. The containment vessel is open and the CIS is rendered ineffective.

##### **Off-Normal Operations**

In the event of a severe accident, resulting in SCCV flooding and elevated internal SCCV pressure, the rupture disc within the containment overpressure vent flowpath will passively open to vent the internal SCCV pressure. The rupture disc is passive requiring no operator action to open. However, an operator controlled manual bypass valve around the rupture disc can be used as an alternate method of venting.

The SCCV internal pressure is monitored in the main control room or by the local pressure indicator to support manual operation. The overall SCCV pressure decreases as venting continues. Once the SCCV internal pressure has been reduced to a safe level and normal containment heat removal capability has been regained, the containment overpressure protection air-operated isolation valve is closed to reestablish the SCCV pressure boundary. Radiological conditions associated with severe accidents are presented in Chapter 15, Subsection 15.3.

### **System Shutdown**

During System Shutdown (Modes 3, 4, and 5), if the containment vessel hatches are required to be opened to support personnel entry, the CIS is set to the de-inerting mode. De-inerting mode is used to achieve a safe, breathable atmosphere once the reactor reaches a setpoint temperature. In de-inerting mode, the CIS injects breathable air into the lower SCCV while exhausting from the upper SCCV until the correct oxygen concentration is reached. The breathable air is mixed with the SCCV atmosphere by the Containment Cooling System fans. Once the targeted oxygen concentration is reached for a breathable atmosphere, the containment vessel hatches may be opened for personnel entry. Opening the containment vessel hatches will render the CIS ineffective, and thus it will be idle.

If the containment vessel is not required to be opened during System Shutdown (Modes 3, 4, and 5), the CIS may be set to makeup mode to maintain an inerted atmosphere in containment.

Refer to Chapter 1, Subsection 1.8 for a description of the operating modes.

#### **9A.4.2.7 Instrumentation and Control**

The following instrumentation features are included for monitoring CIS operations:

1. Flow transmitters for containment inerting flow indication
2. Temperature elements to monitor the inerting nitrogen supply temperature
3. Pressure transmitters for control of the inerting pressure control valves

Features provided for control of CIS operation include the following:

1. Containment Pressure indication provided by Process and Radiation Monitoring System (Chapter 11, Subsection 11.5)
2. Inerting nitrogen supply temperature and pressure for control of the inerting and makeup process
3. Position indication for all remotely operated valves

The following CIS displays and alarms are provided:

1. Main Control Console Indications:
  - a. Containment inlet flow rate
  - b. Position indication (full open and full closed) for all containment isolation valves
  - c. CIS control valves position indication
  - d. Containment oxygen concentration
  - e. Containment inlet temperature
2. Main Control Room Alarms
  - a. High and low nitrogen discharge temperature

- b. Low nitrogen storage tank liquid level
- c. Low and high containment inlet temperature
- d. CIS valve operation failure
- e. High oxygen levels in containment

#### **9A.4.2.8 Monitoring, Inspection, Testing, and Maintenance**

The following pertains to testing and inspection of CIS components:

1. Periodic testing is performed to demonstrate the ability of CIS to meet design requirements. Each valve is exercised both open and closed and the position indication is verified. Trip and alarm logic signals are also checked. The tests assure correct functioning of all controls, instrumentation, piping and valves. System reference characteristics, such as pressure differentials and flow rates, are documented during the pre-operational tests and are used as baseline for measurements in the subsequent operational tests. Testing is performed both during operations and shutdown.
2. During plant operation, CIS valves, instrumentation, wiring and other components outside the containment can be inspected visually at any time.
3. Containment isolation valves are tested for leakage periodically in accordance with the requirements of 10 CFR 50 Appendix J, "Primary Reactor Containment Leakage Testing for Water-Cooled Power Reactors," Type Test C.
4. The rupture disk is tested and replaced periodically, providing additional confidence of pressure.

Testing in support of plant pre-operational testing, startup, and commissioning is addressed in Chapter 14, Subsection 14.3.

Testing is performed to ensure required functional operability is maintained under design conditions. The Non-Safety-Category functions of the CIS are tested in accordance with ASME Code B31.1. The Safety-Category functions of the CIS are tested in accordance with ASME BPVC-III.

Maintenance practices consider industry best practices and operating experience and conform with plant safety requirements to minimize potential for personnel injury. Maintenance activities implement ALARA practices to minimize work activity dose. Maintenance activities involving plant equipment may require involvement of vendors or industry specialists.

Other maintenance provisions include the following:

1. Isolation valves are provided on both sides of the supply and exhaust control valves to isolate the control valves and allow for maintenance and repair.
2. Pull spaces are provided around valves to allow for removal and maintenance.

#### **9A.4.2.9 Radiological Aspects**

Chapter 12, Section 12.3 provides information pertaining to design measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.4.2.10 Performance and Safety Evaluation**

The CIS Safety-Category functions during normal conditions include ensuring containment boundary integrity and isolation capability. During Off-Normal conditions, CIS Safety-Category functions include providing protection against containment overpressurization.

The following features are incorporated into the design of the CIS to enhance reliability of the CIS Safety-Category functions:

1. Periodic system testing, and preventive maintenance.
2. If the containment supply pressure control valve fails, a manual bypass valve can be opened to supply nitrogen to the containment. Pressure relief valves are positioned downstream of the pressure control valve to protect the downstream piping and provide for pressure control during manual bypass of the pressure control valve. The manual bypass function allows for continuous operation of CIS while the pressure control valve is out of service.
3. The CIS containment isolation valves are located outside of the SCCV which removes them from the harsh environment of the containment and protects them from the effects of flood and dynamic effects of pipe breaks. The CIVs are accessible for inspection and testing during reactor operation. Also, the CIVs fail closed on loss of air or control signal.
4. A manual bypass valve around the containment overpressure vent rupture disc can be used as an alternate method of venting. The bypass line is equipped with a local pressure indicator that can be used to support early containment venting during a beyond design basis accident.

The CIS structures, systems, and components that provide Safety-Category functions are located in the Reactor Building which provides adequate protection against natural phenomena ensuring the ability of the CIS to perform its Safety-Category functions.

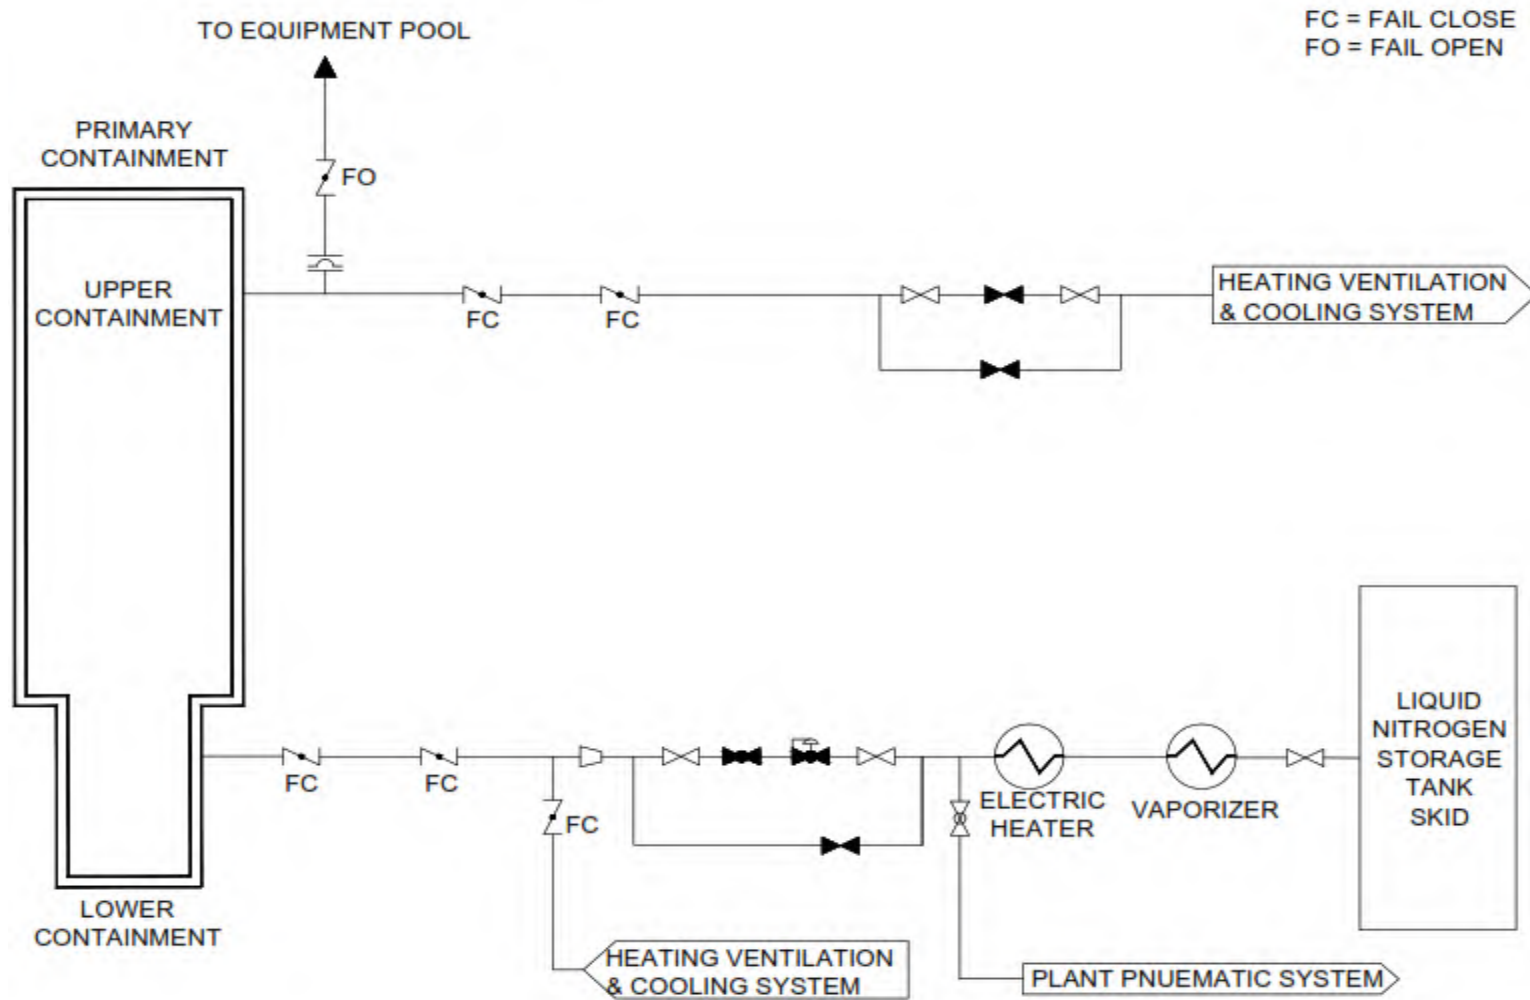

Figure 9A.4.2-1: Containment Inerting System

## **9A.5 Heating, Ventilation and Air Conditioning Systems**

The Heating, Ventilation and Cooling System (HVS) serves all areas of the power block during normal operation, with the exception of the containment which is serviced by the Containment Cooling System (Subsection 9A.5.6). HVS services containment in de-inerted modes of operation cross connected with the Containment Inerting System (Subsection 9A.4.2). The HVS maintains space design temperatures, quality of air and pressurization. It provides a controlled environment for personnel safety and comfort, and for the proper operation and integrity of equipment located in the power block.

The HVS consists of subsystems for fresh air and ventilation of each building. With the exception of the Control Building subsystem (Subsection 9A.5.2), all of the subsystems exhaust to a common plant exhaust stack during all normal operation modes. The plant exhaust stack is monitored for radiation. The Control Building is outside the radiologically controlled area and therefore the exhaust does not require radioactive monitoring.

The HVS is broken down into 6 different areas:

- Control Building
- Reactor Building
- Radwaste Building
- Turbine Building
- Plant Services Area of the Turbine Building (PLSA)
- Plant Vent Stack (PVS)

### **9A.5.1 Reactor Building Heating, Ventilation and Air Conditioning System**

#### **9A.5.1.1 System and Equipment Functions**

RB HVS, system, and equipment functions include the following:

##### **9A.5.1.1.1 Normal Functions (Non-Safety Category)**

1. Provides a controlled environment for personnel comfort and safety and equipment operation. Outside air is provided to meet the ventilation requirements for indoor air quality consistent with the requirements of ASHRAE 62.1 (Reference 9A.5.1-1).
2. Maintains designated clean areas at higher than atmospheric (positive) pressure to minimize the infiltration of outside air.
3. Maintains negative pressurization of potentially contaminated areas to control leakage of potentially radioactive effluent to the atmosphere or to other rooms.
4. The Battery Rooms are ventilated and exhausted by the RB HVS to prevent hydrogen accumulation in the rooms.
5. Reduces the potential spread of airborne contamination by maintaining airflow from areas of lower potential for contamination to areas of greater potential for contamination.
6. Detects and limits the introduction of airborne radioactivity into the SCR.
7. Provides the capability to exhaust smoke, heat, and gaseous combustion products from inside the Power Block to the outside atmosphere in the event of a fire.

8. The HVS is designed such that failure of Non-Safety-Category function equipment does not compromise Safety Category function equipment.
9. The HVS supplies outside air to the Steel-plate Composite Containment Vessel (SCCV) via the Containment Inerting System (Subsection 9A.4.2) and exhausts the SCCV inerting gases to provide a habitable environment for maintenance personnel during outages.

#### **9A.5.1.1.2 Off-Normal Functions (Non-Safety-Category)**

RB HVS systems continue to operate during off-normal conditions until removed from service either manually or automatically.

In the event of a LOOP, the RB HVS continues to function due to its connection to the Diesel Generators which activate and provide backup power to their respective train-supported equipment. This includes the normal AHUs, their associated electric heaters, and Fan Coil Units for the Defense Line 2 (DL2) and DL4a DCIS rooms.

#### **9A.5.1.1.3 Normal Function (Safety-Category)**

The RB HVS provides required cooling to Safety Class rooms with two redundant SC3 FCUs in each room (Figure 9A.5.2-1).

#### **9A.5.1.1.4 Off-Normal Functions (Safety-Category)**

The RB HVS performs Safety-Category (TBD) functions. The RB HVS has sufficient capacity to fulfill its safety function and there are no credible single failures or operator errors that could defeat the performance of the safety function for which the system was designed.

The RB HVS includes two Safety-Category (TBD), 100% capacity pressurization fans with emergency filtration units which supply filtered outside air to the SCR which is used to pressurize the space relative to adjacent spaces, protecting the operators from hazards such as high radiation levels resulting from DBAs, release of radioactive material. These pressurization fans are provided with backup power making them available for use during a LOOP or Station Blackout (SBO).

The SCR and supporting Division 1, 2, and 3 Electrical and Switchgear rooms are provided with passive cooling. Emergency filtration and pressurization systems for the SCR are powered from the SC1 Electrical Distribution System batteries for the required 72 hours.

Tornado dampers are provided at each RB HVS penetration to protect the RB structure.

The RB HVS includes Safety-Category (TBD) supply and exhaust isolation dampers for the RB, which close automatically in the event of a fuel handling accident, isolating the RB. These dampers located at the RB boundary and the associated controls that provide the isolation signal are seismic..

The design of the HVS meets CNSC requirements specified in CNSC REGDOC-2.5.2 (Reference 9A.5.1-2) Section 7.10 as related to providing an HVAC system capable of maintaining the required environmental conditions for systems and components important to safety in all states.

Refer to Chapter 11, Subsection 11.3 for information pertaining to Gaseous Waste Management System.

The design of the RB HVS meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.11.2 as related to providing a ventilation system with a filtration system capable of the following:

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

1. Preventing unacceptable dispersion of airborne contaminants within the plant. Airborne contaminants are contained through the use of two 100% capacity RB Exhaust AHUs with HEPA filtration which take suction on the RB keeping it at negative pressure, ensuring that air flows into the RB from adjacent clean air spaces. The potential spread of airborne contamination is minimized by maintaining airflow from areas of lower potential for contamination to areas of greater potential for contamination.
2. Reducing the concentration of airborne radioactive substances to levels compatible with the need for access to each particular area is achieved by using shielding, ventilation, monitoring instrumentation and ALARA design concepts as discussed in Chapter 12 to ensure the overall design minimizes radiation exposure to workers and to the public.
3. Keeping the level of airborne radioactive substances in the plant below prescribed limits. The concentration of radionuclides in the air in areas accessible to personnel for normal plant surveillance and maintenance is below 0.1 the derived air concentration as specified in 10 CFR 20 Appendix B (Reference 9A.5.1-3) during normal power operation.
4. Application of ALARA design principles in normal operation as discussed in Chapter 12, Subsection 12.1.5.4.
5. Ventilating rooms containing inert or noxious gases without impairing the capability to control radioactive releases by using charcoal filters.

**9A.5.1.2 Safety Design Bases**

1. As part of Safety-Category (TBD) requirements, the RB HVS ensures that a habitable environment is maintained in the SCR for a minimum of 72 hours following an initiating event.
2. As part of Safety-Category (TBD) requirements, the RB HVS ensures that the SCR temperature does not exceed the limiting temperature during a postulated design basis accident event.
3. As part of Safety-Category (TBD) requirements, the RB HVS is designed to ensure that the SCR operators do not receive radiation exposure in excess of 0.05 Sv (5 rem) total effective dose equivalent in a single year.
4. As part of Defense Line 2, the RB HVS provides the capability to isolate ventilation to the SCR when signaled to do so from Safety-Category (TBD) Instrumentation and Control System.
5. Tornado dampers are provided for the RB HVS in support of Safety-Category (TBD) functions.
6. As part of Defense Line 2, the RB HVS provides the capability to isolate ventilation to the refuel floor when signaled to do so from Safety-Category (TBD) Instrumentation and Control System.
7. RB HVS interfaces with the Safety-Category (TBD) Instrumentation and Control System monitor and diagnostics function to monitor Safety-Category (TBD) equipment room temperature information.

8. The RB HVS battery room exhaust fans are powered from the same bus as Safety-Category (TBD) Electrical Distribution System battery chargers associated with the respective divisional room.

#### **9A.5.1.3 Description**

Figure 9A.5.1-1 depicts the Reactor Building HVAC Process Flow Diagram.

The RB, for HVAC purposes, is divided up into two main areas which includes the lower levels and the upper areas.

The RB lower levels are supplied with conditioned air provided by one of two AHUs, located on the Control Building roof. These AHUs supply air through vertical duct chases down to the lowest elevation of the RB. The RB lower-level supply AHUs also supply outside air to the Containment Inerting System (Subsection 9A.4.2) when required for containment de-inerting and to provide a habitable environment for maintenance personnel during refueling and maintenance operations.

Two 100% capacity RB exhaust AHUs with HEPA filtration take suction on the RB keeping it at negative pressure, ensuring that air flows into the RB from adjacent clean air spaces. The operating exhaust AHU discharges through ductwork to the Continuous Exhaust Air Plenum (CEAP) and to the PVS. These AHUs are provided with adjustable speed drives to be able to reduce flow comparable to reduced supply air flow to the RB. The normal lower-level exhaust ductwork also receives air and inerting gases from the CIS when required, which is filtered and exhausted to the Continuous Exhaust Air Plenum and to the PVS.

Each of the three Division Battery Rooms have two 100% capacity exhaust fans which are provided with backup emergency power, exhausting to atmosphere in the event of a Loss-of-Offsite Power through ductwork and a louver mounted in a room up above. The Battery Rooms normally exhaust to the operating RB Exhaust AHU and the PVS. The RB lower-level AHU's also supply conditioned outside air to the Containment Inerting System when needed.

The supply ductwork to each of the three Battery Rooms, (Division 1, 2 and 3 Battery Room) and the Secondary Control Room are each provided with electric duct heaters.

Supplemental cooling and air circulation is provided by fan coil units.

Heating to the RB Stairwells is supplied by electric cabinet heaters while heating to the Entry/Truck Bay is provided by an electric unit heater.

When needed, filtered outside air is supplied to the Secondary Control Room by one of two capacity Pressurization Fans and Emergency Filtration Unit. The two pressurization fans draw outside air through dedicated SC1, Seismic Category B safety-related ductwork with blast resistant openings located in the exterior walls. The two makeup AHUs draw outside air through dedicated Safety-Category 1 ductwork with blast resistant openings.

The operating SCR makeup AHU pressurization fan maintains a minimum positive pressure in the SCR with filtered makeup air, protecting the operators from potential radioactive gases. The SCR is normally provided filtered, conditioned air from the operating RB Lower-Level AHU.

The RB upper levels are supplied with conditioned air provided by AHUs located on the Plant Service Area roof. These AHUs are provided with filters, electric heating coils, and chilled water supplied cooling coils, supplying conditioned outside air to the RB upper levels. These AHUs employ adjustable speed drives to vary flow to the fuel pool as needed during refueling, and to reduce flow during reduced temperature ambient conditions.

Exhaust air from the RB lower levels is combined with exhaust air from the upper levels. Exhaust air is discharged out of the RB building by AHUs. These AHUs are provided with High Efficiency

Particulate Air (HEPA) filters, prefilters and exhaust fans. The discharge is sent to the Continuous Exhaust Air Plenum and PVS.

#### **9A.5.1.4 Component Description**

Design information related to the major components of the Reactor Building HVS is provided below.

##### **9A.5.1.4.1 Filters**

The various building filtration levels are specified within each specific Subsection. Filters meet the applicable efficiency rating as stated below. American Society of Heating, Refrigerating and Air Conditioning Engineers (ASHRAE) Standard 52.2 (Reference 9A.5.3-4) establishes a filter's Minimum Efficiency Reporting Value (MERV) and establishes a filter's Average Atmospheric Dust Spot Efficiency. The following ASHRAE filter classifications are MERV specified (with Dust Spot Efficiency in parenthesis) below:

- Low Efficiency:           MERV 1-4 (Less than 20%)
- Medium Efficiency:      MERV 5-12 (As least 20% but less than 80%)
- High Efficiency:         MERV 13-16 (Greater than or equal to 80%)

HEPA filters are specified for various building filtration systems. Filters meet the applicable efficiency rating as stated below.

Filters with efficiency greater than MERV 16 by ASHRAE Standard 52.2 (MERV 17-20) (Reference 9A.5.1-4) are usually rated by the dioctylphthalate) test method. This test is based on the ability of a filter to remove an aerosol consisting of 0.3 micrometer (micron) particles of a test challenge. HEPA filters are extended-medium dry-type filters in a rigid frame, having minimum particle-collection efficiency of 99.97% on 0.3-micron particles which meets ASME AG-1, Code on Nuclear Air and Gas Treatment, Section FC, HEPA Filters (Reference 9A.5.1-5).

HEPA filters are constructed, qualified, and tested per Underwriters Laboratory-586, High Efficiency, Particulate, Air Filter Units (Reference 9A.5.1-6).

Each of the two SCR Emergency Makeup Filtration Units contains a charcoal filter, located between upstream and downstream banks of HEPA filters. The upstream bank protects the charcoal from clogging. The downstream bank prevents discharging charcoal fines in the SCR. The purpose of the charcoal bed is to remove potentially radioactive gases from the air stream. The charcoal bed also has properties associated with toxic gas adsorption.

##### **9A.5.1.4.2 Air Handler Units**

Each AHU consists of an inlet area, filters (as specified by the system), electric heating coils, (as required) cooling coils (as required) and the respective fans (supply or exhaust). Bag In/Bag Out AHUs and Emergency Filter Units (EFUs) are intended for use in units that contain potentially contaminated filters to facilitate filter changeout without the worker or room being exposed to the potentially contaminated filter.

##### **9A.5.1.4.3 Supply and Exhaust Fans**

The various building ventilation systems are provided with supply and exhaust fans, sometimes incorporated into AHUs. These fans are either centrifugal or axial fans depending on the suitability to the specific system. The fans are designed, manufactured, and supplied in accordance with the standards of the Air Movement and Control Association International. Fans in various areas are equipped with Adjustable Speed Drive mechanisms to control airflows for the specific system application.

#### **9A.5.1.4.4 Heating Coils/Elements**

Various AHUs are equipped with electrical heating coils/elements. Electric coils are designed and supplied to the requirements of Underwriters Laboratory, "Heating and Cooling Equipment" (Reference 9A.5.1-7).

#### **9A.5.1.4.5 Cooling Coils**

The Tubular fin type cooling coils are designed, constructed, and installed in accordance with ASHRAE 33, Methods of Testing Forced Circulation Air-Cooling and Air-Heating Coils (Reference 9A.5.2-8) and ANSI/ARI 410 (Reference 9A.5.2-9) and Underwriters Laboratory (Reference 9A.5.2-7).

Cooling coil condensate is collected in drain pans within the air handler units with the drain pan discharge (condensate) routed to the Equipment and Floor Drain System (Subsection 9A.9.3).

#### **9A.5.1.5 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials through material chemistry, heat treatment, contamination, and material processes controls identified in the equipment and purchase specifications.

#### **9A.5.1.6 Interfaces with Other Equipment or Systems**

Refer to Table 9A.5.1-1 for RB HVS interfaces with other equipment or systems.

#### **9A.5.1.7 System and Equipment and Operation**

##### **9A.5.1.7.1 Normal Operation**

The RB lower elevations will normally be provided heated, conditioned, and filtered once-through supply air from one of two operating AHUs located on the Control Building roof through supply ductwork. AHU cooling is supplemented by cooling provided by chilled water supplied FCUs located in rooms that require extra cooling, with FCUs being controlled by room thermostats. An electric duct heater in the supply duct to each Battery Room and to the SCR is expected to normally be operating as required to maintain SCR habitability and Battery Room temperatures as recommended by the battery manufacturer.

The RB upper elevations, consisting mainly of the fuel handling area operating deck, will normally be provided heated, conditioned, and filtered once-through supply air from one of two operating AHUs located on the Plant Service Area roof through supply ductwork. For each of the operating RB upper-level supply AHUs, the second supply AHU will normally be in standby, ready for auto-start should the operating AHU fail.

The Truck Bay, in addition to being provided conditioned air from the operating upper-level supply AHU, is heated by an electric unit heater, controlled by local thermostat.

Air will normally be exhausted from the RB upper and lower levels, including the Battery Rooms, from one of two operating exhaust AHUs discharging ultimately to atmosphere from the PVS.

For each of the RB supply and exhaust AHUs, the second AHU will normally be operational, in standby, ready for auto-start should the operating AHU fail.

##### **9A.5.1.7.2 Off-Normal Operation**

In the event of a LOOP, power is maintained to both RB exhaust AHUs, and all four RB supply AHUs and associated heating coils for the 4 supply AHUs.

In the event of a SBO, power is lost to the RB exhaust AHUs as well as the upper and lower-level supply AHUs which normally provide heating and air conditioning for the RB, as well as electric duct heaters for the Battery Rooms.

Each Battery Room, normally exhausted via the RB exhaust AHU, continues to be exhausted via one of two 100 percent capacity exhaust fans, powered from its backup power source, for the purpose of being placed into service during loss of power events. These fans are controlled by ON/OFF/AUTO-switches located in the SCR, with fan auto-starts initiated by undervoltage on the RB exhaust AHUs' power supply.

In the event of a loss of the MCR in the CB, the SCR in the RB is activated, and its dedicated HVAC system is placed into service. The emergency pressurization fans with charcoal radioactive iodine gas filtration, and backed up by battery power, will also be placed into service automatically upon a loss of power to the RB lower-level normal supply AHUs or detection of radiation, at the RB lower-level normal supply AHU intakes.

The Secondary Control Room pressurization EFUs and emergency pressurization fans, including the intake, ductwork, and power supplies are designed to operate for up to seventy-two hours without normal AC power.

In the event of a fuel handling accident on the refueling floor in the Fuel Handling Machine area, a radiation monitor alarm initiates closure of the RB isolation dampers and securing of the RB upper level supply AHUs.

#### **9A.5.1.8 Instrumentation and Control**

The following signals are provided as inputs to the control logic:

1. Temperature elements to monitor space or duct air temperatures, and to control cooling water control valves, electric heating elements, or control fan speeds.
2. Moisture element in the SCR room to engage RB lower-level supply AHU dehumidification control.
3. Differential pressure transmitters and air flow instruments, as required, to monitor fan operation.
4. Differential pressure transmitters to monitor pressure drop across AHU filters.
5. Intake, exhaust, and return air damper position monitoring
6. Duct mounted smoke detectors to shut down fans as required

Manual initiation and shutdown of the RB HVS are provided at the Temperature Control Panel.

The following control features are implemented in the RB HVS:

1. The RB AHUs, FCUs, and exhaust fans are operated from the RB temperature control panels. An AHU start request automatically opens all associated shutoff dampers. A damper operating failure (any associated damper not 100% open while fan is running) automatically trips that particular AHU.
2. Any AHU trip automatically closes all its associated shutoff dampers.
3. Any AHU started in standby because of a low air flow condition automatically trips the AHU that generated the low flow condition after proof that the standby AHU is running. To avoid spurious standby starts and AHU trips, all air flow logic incorporates time delays to allow fans to generate steady-state flow.

4. Duct mounted temperature elements monitor the operation of the RB AHUs.
5. Local wall mounted temperature elements in the SCR and Battery Rooms control the electric duct heaters in the supply air ducts to those rooms.
6. Control valves in RB AHU cooling coil supply return waterlines are modulated to maintain a constant coil leaving air temperature. If the outside air temperature is less than a predetermined temperature, the control valve supplying the RB supply AHU cooling coils is 100% closed; otherwise, the valve is modulated.
7. The FPS provides a signal to shut down the RB AHUs in the event of a fire. The Battery Room exhaust fans continue to operate, preventing a potentially explosive hydrogen concentration from occurring. Smoke removal is also performed in conjunction with the FPS. Duct mounted smoke detectors provide a smoke detected signal to the FPS local fire protection panels.
8. The Battery Room exhaust fans operate off timers. Failure of any Battery Room exhaust fan is annunciated via a common HVS alarm in the MCR.
9. The lower RB supply AHU intakes are monitored for toxic gas and radiation. If toxic gas or radiation are detected, the lower RB supply AHU turns off and the isolation dampers shut. Additionally, the SCR normal supply and exhaust isolation dampers shut, the SCR pressurization fans energize, supplying the SCR with filtered outside air.
10. Upon high radiation detection in the Operating Deck area of the RB, the RB upper level supply and exhaust isolation dampers automatically close, and associated supply AHUs are secured, isolating supply and exhaust air to/from that area. These dampers along with associated actuators are SC3, seismically qualified, and fail shut on a loss of power or signal.

Instrumentation is designed to support human performance. Alarms and notifications are clearly labeled and identifiable.

The RB HVS system is installed and located in physically accessible locations whenever possible. Otherwise, the means by which operators and personnel can access equipment is provided.

The MCR is provided with a Master Alarm indicator from each temperature control panel. The Master Alarm indicator prompts operators to conduct further review at the local temperature control panel. The local temperature control panel provides additional information and the means of resetting alarm conditions on a return-to-normal transition.

Any Safety-Category functions or other required functions happen automatically with notification provided to operators.

#### **9A.5.1.9 Monitoring, Inspection, Testing, and Maintenance**

##### **9A.5.1.9.1 System Level Requirements**

A positive pressure test is performed on RB HVS serving contaminated areas in the RB. This test is performed as required.

Plant-level HVAC inspection and maintenance is conducted in accordance with ASME N511 (Reference 9A.5.1-10).

##### **9A.5.1.9.2 Component Level Requirements**

Air handlers are field tested as required per ASME N511, (Reference 9A.5.1-10).

Charcoal beds used for filtration of radiological effluents support meeting ALARA requirements as discussed in Chapter 12, Section 12.1.

Component specific maintenance procedures are outlined in the vendor manuals provided as part of each procurement package.

Personnel and lay-down access are provided around instruments to allow adequate space for maintenance purposes.

HEPA filters conform to the requirements of ASME of AG-1 (Reference 9A.5.1-4).

#### **9A.5.1.10 Radiological Aspects**

Chapter 12, Section 12.1 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.5.1.11 Performance and Safety Evaluation**

The RB HVS has sufficient capacity to fulfill its safety function and there are no credible single failures or operator errors that could defeat the performance of the safety function for which the system is designed. The RB HVS is designed with redundancy to assure that subsystems are normally available during all modes of plant operation, including startup and shutdown.

The RB HVS ensures that a habitable environment is maintained in the SCR for a minimum of 72 hours following an initiating event. The SCR and supporting Division 1, 2, and 3 Electrical and Switchgear rooms are provided with passive cooling systems powered from the Safety-Category (TBD) Electrical Distribution System batteries for the required 72 hours. The supplemental passive cooling system also ensures that the SCR temperature does not exceed limiting temperature limits during a postulated design basis accident.

The RB HVS is designed to preclude SCR operators from receiving radiation exposures in excess of 0.05 Sv (5 rem) total effective dose equivalent in a single year by utilizing two Safety-Category (TBD), 100% capacity pressurization fans which supply filtered outside air to the SCR which pressurizes the space relative to adjacent spaces. This design feature protects operators from radiation associated with a Design Basis Accident.

The RB HVS includes supply and exhaust isolation dampers which close automatically in the event of a fuel handling accident, isolating the RB upper levels. These dampers are located at the RB boundary. In addition, the RB HVS provides the capability to isolate ventilation to the SCR. In both cases, the associated controls that provide the isolation signal is supplied from the Safety-Category (TBD) Instrumentation and Control System.

Tornado dampers are provided for the RB HVS supporting Safety-Category (TBD) functions.

The Safety-Category (TBD) Instrumentation and Control System monitors and provides diagnostic functions relative to RB HVS Safety-Category (TBD) equipment room temperature.

Battery room exhaust fans are powered from the same bus as the Safety Class 1 Electrical Distribution System battery chargers associated with the respective divisional room. This requirement prevents hydrogen production from battery charging operations if the exhaust fans stop working due to a loss in the bus power.

## **9A.5.2 Control Building Heating, Ventilation and Air Conditioning System**

### **9A.5.2.1 System and Equipment Functions**

#### **9A.5.2.1.1 Normal Functions (Non-Safety Category)**

1. Provides a controlled environment for personnel comfort and safety and equipment operation. Sufficient outside air is provided to meet the ventilation requirements for acceptable indoor air quality consistent with the applicable requirements of ASHRAE 62.1 (Reference 9A.5.2-1).
2. Provides a controlled environment for operation of equipment in the Power Block during normal, startup and shutdown operations.
3. Provides isolation features to support testing and maintenance.
4. The CB HVS supply ductwork to all the Battery Rooms, are provided electric duct heaters for more precise temperature control in those rooms.
5. The Battery Rooms are ventilated and exhausted to maintain hydrogen levels below required limits in the rooms.
6. The CRE in the Control Building is maintained at a higher pressure than surrounding areas with the CRE EFUs in service.
7. Detects and limits the introduction of airborne hazardous materials (toxic gas, radioactivity, or smoke) into the Control Room in the Control Building.
8. The HVS is designed such that failure of Non-Safety-Category function equipment does not compromise Safety-Category function equipment.
9. Provides the capability to exhaust smoke, heat, and gaseous combustion products from inside the power block to the outside atmosphere in the event of a fire.

#### **9A.5.2.1.2 Off-Normal Functions (Non-Safety Category)**

The Control Building HVS performs several Non-Safety-Category functions during off-normal conditions. The CB HVS continues to operate during off-normal conditions until removed from service either manually or automatically.

CB HVS equipment that is normally in standby that is required to function during off-normal events include the following:

1. In the event of a fire outside the CB, the outside air through the normal operating AHU is secured and the operating AHU continues to operate in recirculation mode only.
2. In the event of a fire inside the Control Building but outside of the Control Room Envelope (CRE), a Control Room Envelope Emergency Filtration Unit can be placed in-service, thereby supplying the CRE in pressurization mode with the CRE isolated.
3. The CB is provided ventilation air during toxic gas events as follows. The CB toxic gas filtration units operate automatically when toxic gas is detected at the CB AHU outside air intakes. Normal outside air supply to the operating CB AHU isolates and the toxic gas filtration units discharge damper opens, allowing the associated toxic gas filtration unit to supply filtered outside pressurized air to the entire Control Building through the normal CB supply AHU which continues to operate during a toxic gas event. The toxic gas filtration units are equipped with HEPA and charcoal filters to remove toxic and radioactive gases and material from the outside air supply to the normal CB AHUs.

4. In the event of high radiation detected at the CB normal air intake, the CB normal supply AHU isolates and a CRE-EFU unit auto starts to provide pressurization air to the CRE. CRE-EFU contain charcoal filtration permitting removal of radioactive iodine.
5. The CB HVS provides the capability to exhaust smoke, heat, and gaseous combustion products from inside the Control Building.
6. Battery room exhaust fans continue to operate regardless of the operational mode of the CB AHUs, or CRE EFUs. Battery room exhaust fans operate on a timer to only energize after a set period of time (determined by the offgassing rate of the batteries) and only to be energized for the minimum time needed to reduce H<sub>2</sub> concentration to below 1%.
7. In the event of a buildup of smoke inside the CB requiring a purge, two exhaust fans are manually operated to remove smoke. During this time, the AHUs providing supply operate as 100% outside air with no recirculation until such time as the smoke has been sufficiently removed from the building.
8. In the event of a LOOP, the Diesel Generators activate and provide backup power to their respective train-supported equipment. This includes the normal AHUs, Control Room Envelope Emergency Filter Units including their associated electric heaters, and FCUs for the DL2 and DL4A rooms.

**9A.5.2.1.3 Normal Functions (Safety Category)**

1. The CB HVS provides required cooling to the DL4a Room in the CB with two redundant Safety-Category (TBD) FCUs.
2. The CB HVS provides required cooling to the Safety-Category (TBD) Instrumentation and Control System DL2 Room A and Safety-Category (TBD) Instrumentation and Control System DL2 Room B with redundant Safety-Category (TBD) FCUs in each room.

**9A.5.2.1.4 Off-Normal Functions (Safety Category)**

SC3 Functions:

1. The normal CB outside air intakes are monitored for airborne radioactivity. Upon detection of a high radiation condition, the operating normal supply AHU will de-energize, auto-start of the standby unit is defeated, and the CRE goes into isolation mode with normal CB supply and return isolation dampers closing. In addition CRE EFUs automatically start, pressurizing the CRE with filtered supply air, utilizing a mixture of approximately 90% return air from the CRE. The 10% outside air passes through the CRE-EFU with potential radioactive iodine being removed via charcoal filtration.
2. Tornado dampers are provided at each CB HVS outside air interface to protect the CB structure.

The design of the CB HVS meets CNSC requirements specified in CNSC REGDOC-2.5.2, Section 8.11.2 (Reference 9A.5.2-2) as related to providing a ventilation system with a filtration system capable of the following:

1. Preventing unacceptable dispersion of airborne contaminants within the plant by monitoring the normal CB outside air intakes for radioactivity. Upon detection of radioactivity the CRE goes into isolation mode with normal CB supply and return isolation dampers going closed. CRE-EFU automatically starts, pressurizing the CRE

with filtered supply air, utilizing a mixture of approximately 90% return air from the CRE. The 10% outside air passes through the CRE-EFU with potential radioactive iodine being removed via charcoal filtration.

2. Reducing the concentration of airborne radioactive substances to levels compatible with the need for access to each particular area is achieved by using shielding, ventilation, monitoring instrumentation and ALARA design concepts as discussed in Chapter 12 to ensure the overall design minimizes radiation exposure to workers and to the public.
3. Keeping the level of airborne radioactive substances in the plant below prescribed limits. The concentration of radionuclides in the air in areas accessible to personnel for normal plant surveillance and maintenance is below 0.1 the derived air concentration as specified in 10 CFR 20 Appendix B (Reference 9A.5.2-3) during normal power operation.
4. Application of ALARA design principles in normal operation as discussed in Chapter 12, Subsection 12.1.5.4.
5. Ventilating rooms containing inert or noxious gases without impairing the capability to control radioactive releases by using charcoal filters that have properties for toxic gas adsorption.

#### **9A.5.2.2 Safety Design Bases**

The safety design bases associated with the Control Building HVS include the following:

1. The Safety-Category (TBD) CB HVS ensures that a habitable environment is maintained in the MCR.
2. The CB HVS maintains a slight positive pressure in the CRE during emergency events.

#### **9A.5.2.3 Description**

Figure 9A.5.2-1 depicts the Control Building HVAC Process Flow Diagram.

The Control Building HVS subsystems are comprised of redundant trains of equipment that support all CB HVS functions during normal operating modes.

The Battery Room exhaust fans in the Control Building are backed up by batter power.

The CRE in the Control Building is maintained at a higher pressure than surrounding areas with the CRE-EFU in service.

The Control Room HVS detects and limits the introduction of airborne hazardous materials (radioactivity, or smoke) into the Control Room in the Control Building. This system is designed with the capability to exhaust smoke, heat, and gaseous combustion products from inside the Power Block to the outside atmosphere in the event of a fire. Smoke control and removal functions are in accordance with National Fire Protection Association (NFPA); NFPA 92A and CSA N293/293S1 and National Building Code of Canada (NBCC) and National Fire Code of Canada as described in Subsection 9A.6).

The MCR is provided filtered, conditioned air from two 100% capacity AHUs via supply and return ductwork. Refer to Chapter 6, Subsection 6.4 for information pertaining to Control Room Habitability.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

The battery rooms are each provided with two 50% capacity exhaust fans which operate based off timers. Other exhaust fans are provided for the restroom/shower areas and the control room restroom/janitor's closet.

The CB is a single-story building. Some rooms contain significant quantities of electrical equipment and associated heat dissipation loads. Other rooms, such as the MCR, Radiation Protection offices, and Conference Room, contain areas of less heat density. The Battery Rooms, Restrooms, Break Room, and Janitor's Closet are also low heat density rooms and will be served by exhaust fans exhausting to the outdoors.

The CB is normally air conditioned and heated by 2 x 100% capacity chilled water supplied AHUs located on the CB roof, discharging through supply ductwork and a return plenum. Approximately 10% fresh makeup air is brought into the operating AHU. In addition to the chilled water coils, the AHUs contain electric heating coils, humidification/dehumidification features, filtration, and isolation dampers. Supply ductwork upstream of the MCR and offices is provided with Volume Control Units to vary supply air flow based on thermostatic control. AHU cooling in the high heat load rooms is supplemented by chilled water supplied FCUs with a Train A and a Train B FCU located in each of these rooms.

The Battery Rooms are maintained at the battery manufacturer recommended room temperature. Battery Room temperatures are maintained via Battery Room supply duct electric duct heaters and thermostats located in the rooms.

The outside air intake is instrumented to analyze for toxic gases and for airborne radioactivity as applicable. To accommodate MCR habitability contingencies the following additional AHUs are provided for the CB:

1. CRE-EFU that operate automatically upon detection of high radiation level at the operating CB supply AHU outside air intake. The CRE goes into isolation mode with normal CB supply and return air dampers going closed. A mixture of approximately 90% return air from the CRE and 10% outside air will pass through the EFU with potential radioactive iodine being removed via charcoal filtration. EFU operation maintains the CRE slightly pressurized. The operating CB normal supply AHU de-energizes upon high radiation detection at the intake and auto-start of the standby unit is defeated. Battery Room exhaust fans continue to operate based off timers.
2. CB toxic gas filtration units that operate automatically when toxic gas has been detected at the CB AHU outside air intakes. In this event, normal outside air supply to the operating CB AHU isolates and the toxic gas filtration unit discharge damper opens, allowing the associated toxic gas filtration unit to supply pressurization air to the CB through the normal CB supply AHU, which continues to operate during a toxic gas event.

The CB normal supply AHUs are provided ASD to be able to reduce flow as conditions change.

CRE isolation and CRE-EFU operation provide a pressurized envelope with respect to adjacent spaces, maintaining CRE habitability during an airborne radiation event. Toxic gas filtration unit operation maintains the entire CB pressurized, maintaining CB habitability during a toxic gas event.

Two smoke exhaust fans are provided for the CB. During recovery from a fire, smoke is exhausted from the CB by operating a CB normal supply AHU in 100% outside air mode in conjunction with operation of two CB smoke exhaust fans.

The CB HVS is provided tornado rated dampers as necessary to withstand high wind events.

#### **9A.5.2.3.1 Component Description**

##### **Filters**

The various building filtration levels are specified within each specific Subsection. Filters meet the applicable efficiency rating as stated below. American Society of Heating, Refrigerating and Air Conditioning Engineers Standard 52.2 (Reference 9A.5.2-4) establishes a filter's MERV and establishes a filter's Average Atmospheric Dust Spot Efficiency. The following ASHRAE filter classifications are MERV specified (with Dust Spot Efficiency in parenthesis) below:

- Low Efficiency:           MERV (Less than 20%)
- Medium Efficiency:   MERV (As least 20% but less than 80%)
- High Efficiency:       MERV (Greater than or equal to 80%)

HEPA Filters are specified for various building filtration systems. Filters meet the applicable efficiency rating as stated below.

Filters with efficiency greater than MERV 16 by ASHRAE Standard 52.2 (MERV 17-20) (Reference 9A.5.2-4) are usually rated by the dioctylphthalate test method. This test is based on the ability of a filter to remove an aerosol consisting of 0.3 micrometer (micron) particles of a test challenge. HEPA filters are extended-medium dry-type filters in a rigid frame, having minimum particle-collection efficiency of 99.97% on 0.3-micron particles which meets ASME AG-1, Code on Nuclear Air and Gas Treatment, Section FC, HEPA Filters (Reference 9A.5.2-5).

HEPA filters are constructed, qualified, and tested per Underwriters Laboratory-586, High Efficiency, Particulate, Air Filter Units (Reference 9A.5.2-6).

##### **Air Handler Units**

Each AHU consists of an inlet area, filters (as specified by the system), heating elements (coils), cooling coils (as required) and the respective fans (supply or exhaust). The Air-Cleaning Units and Components are designed in accordance with ASME/ANSI AG-1-2019 Code on Nuclear Air and Gas Treatment (Reference 9A.5.2-7).

##### **Supply and Exhaust Fans**

The various building ventilation systems are provided with supply and exhaust fans, which are sometimes incorporated into AHUs. These fans are either centrifugal or axial fans depending on the suitability to the specific system. The fans are designed, manufactured, and supplied in accordance with the standards of AMCA. Fans in various areas are equipped with Adjustable Speed Drive mechanisms to control airflows for the specific system application.

##### **Heating Coils/Elements**

Various AHUs are equipped with electrical heating coils/elements. Electric coils are designed and supplied to the requirements of Underwriters Laboratory, Heating and Cooling Equipment (Reference 9A.5.2-8).

##### **Cooling Coils**

The cooling coils are designed, constructed, and installed in accordance with ASHRAE 33 (Reference 9A.5.2-9), Methods of Testing Forced Circulation Air-Cooling and Air-Heating Coils, and ANSI/ARI 410 (Reference 9A.5.2-10) and Underwriters Laboratory (Reference 9A.5.2-8).

Cooling coil condensate is collected in drain pans within the air handler units with the drain pan discharge (condensate) routed to a floor drain located within the room. These floor drains connect to the EFS (Chapter 9, Subsection 9A.9.3).

#### **9A.5.2.4 Materials**

Refer to Subsection 9A.5.1 for information pertaining to HVS materials.

#### **9A.5.2.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.5.2-1 for Control Building HVS interfaces with other equipment or systems.

#### **9A.5.2.6 System and Equipment Operation**

##### **9A.5.2.6.1 CB HVS Normal Operations**

The CB HVS is provided heated, conditioned, and filtered supply air from one of two operating AHUs through supply ductwork, with approximately 90% of the air recirculated back to the units. The second AHU is in standby, ready for auto-start should the operating unit fail. The remaining 10% of the supply air is made up by outside air brought into the operating AHU located on the CB roof. The two exhaust fans provided for each Battery Room are operating based off timers, exhausting to the outdoors. Exhaust fans for the restrooms, break room, and janitors' closet are all expected to be operating continuously, exhausting to the outdoors. An electric duct heater in the supply duct to each Battery Room is normally operating as required to maintain Battery Room temperatures near the optimal battery temperature as recommended by the battery manufacturer.

##### **9A.5.2.6.2 CB HVS Off-Normal Operations**

In the event of an SBO, power is lost to the CB AHUs which normally provide heating and air conditioning for the CB, as well as electric duct heaters and cabinet heaters. The restroom, break room, and janitors closet exhaust fans become inoperable. The Control Room operators relocate to the SCR in the RB if the MCR becomes uninhabitable.

In the event of a CB normal outside air intake radiation monitor alarm, the operating normal supply AHU de-energizes and any associated toxic gas filtration units also de-energize, and the same train CRE-EFU automatically starts. The CRE isolation dampers close in conjunction with the start of the CRE-EFU. Diesel generator backup power is provided to the CRE-EFU supply fans and associated heating coils. Restroom, break room, and janitors closet exhaust fans become inoperable. The Battery Room exhaust fans continue to operate off timers using backup power, preventing possible accumulations of off-gassed hydrogen to the rooms; the timers ensure the exhaust fans only run as needed to eliminate hydrogen buildup. Electric duct and cabinet heaters are de-energized.

In the event of a CB normal outside air intake toxic gas detection, the operating normal AHU normal outside air intake closes, and the same train toxic gas filtration unit automatically starts and its associated motor control dampers automatically open, providing an alternate source of filtered outside air for CB pressurization. Diesel Generator backup power is provided to the CB normal supply AHU fans and associated heating coils, as well as the associated Toxic Gas Filtration Unit fan. Restroom, break room, and janitors closet exhaust fans become inoperable. The Battery Room exhaust fans continue to operate off timers using backup power, preventing possible accumulations of off-gassed hydrogen to the rooms; the timers ensure the exhaust fans only run as needed to eliminate hydrogen buildup. Electric duct and cabinet heaters are de-energized. Positive pressure is maintained in the CB by way of providing outside air through the normal supply AHU, the toxic gas filtration unit, or the CRE-EFU.

#### **9A.5.2.7 Instrumentation and Control**

The following signals are provided as inputs to the control logic:

1. Temperature elements to monitor space or duct air temperatures, and to control cooling water control valves, electric heating elements, or control fan speeds."

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

2. Moisture element in the MCR to engage the CB Normal Supply AHU humidification and dehumidification control.
3. Differential pressure transmitters and air flow instruments, as required, to monitor fan operation.
4. Differential pressure transmitters to monitor pressure drop across AHU filters.
5. Intake, exhaust, and return air damper position monitoring.
6. Duct mounted smoke detectors to shut down fans as required.

The HVS subsystems have dedicated control panels that regulate the temperature of the spaces to within specified ranges.

Manual initiation and shutdown of the CB HVS is provided from the CB Temperature Control Panel located in the Technical Support Center.

The following control features are implemented in the CB HVS:

1. The CB AHUs, supply fans, and exhaust fans have the capability of being remotely started from the Emergency Operations Center temperature control panel. Bathroom exhaust fans are wired directly from lighting panel, locally controlled with no DCIS. To avoid air infiltration from the surrounding areas, all rooms in the CB with the exception of the janitor's closet, restrooms, breakroom, Battery Rooms and stairwell are positively pressurized by the introduction of filtered outside air and by maintaining the pressure boundary integrity.
2. Battery Room exhaust fans operate off timers. Failure of any Battery Room exhaust fan is annunciated via a common CB HVS alarm in the MCR.
3. Any fan started in standby because of a low airflow condition automatically trips the fan that generated the low flow condition after confirmation that the standby fan is running. To avoid spurious standby starts and fan trips, all airflow logic incorporates time delays to allow fans to generate steady-state flow.
4. The CB differential pressure transmitters are used to monitor the pressure in the MCR and alarm low differential pressure.
5. Control valves located at the cooling coils modulate the flow of chilled water in AHUs in response to air temperature signals from the CB HVS subsystems .
6. Local temperature switches cycle ON/OFF electric cabinet heaters cycle "ON/OFF."
7. The humidifiers in the CB AHU are controlled by the moisture elements located in the MCR.
8. The outside air normal intake dampers to the CB AHUs cannot be opened if smoke, toxic gas, or radiation is detected.
9. The CB recirculation air damper cannot be closed if radiation or smoke is detected in the outside air intake.
10. Upon detection of toxic gas at an outside air normal intake, the normal outside air intake damper closes and the associated toxic gas filtration unit and its associated suction and discharge dampers open, providing an alternate, filtered source of outside makeup air to the operating normal supply AHUs.

11. Upon receipt of an outside air normal intake radiation monitor alarm, the operating normal supply automatically stop, and the associated same train automatically starts, pressurizing the CRE and protecting CRE staff from possible radioactive iodine.
12. The Fire Protection System provides a signal to shut down the CB normal and most HVAC fans in the event of a fire. The Battery Room exhaust fans continue to operate, preventing a potentially explosive hydrogen concentration from occurring. Smoke removal is also performed in conjunction with the FPS. Duct mounted smoke detectors provide a smoke detected signal to the FPS local fire protection panels.

#### **9A.5.2.8 Monitoring, Inspection, Testing, and Maintenance**

Air handlers are field tested per ASME N511, In-Service Testing of Nuclear Air – Treatment, Heating, Ventilating, and Air Conditioning Systems (Reference 9A.5.2-11).

Component specific maintenance procedures are outlined in the vendor manuals provided as part of each procurement package.

Personnel and lay-down access are provided around instruments to allow adequate space for maintenance purposes.

##### **Component Level Requirements**

Charcoal beds used for filtration of radiological effluents meet ALARA requirements as discussed in Chapter 12, Section 12.3.

#### **9A.5.2.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.5.2.10 Performance and Safety Evaluation**

In the event of a LOOP, diesel generator backup power is provided to the CB AHU supply fans. In the event of an SBO, power is lost to the CB AHUs. However, for both the LOOP and SBO cases the Battery Room exhaust fans continue to operate off timers using backup battery power in order to prevent potential accumulations of off-gassed hydrogen to the Battery Rooms. The timers ensure the exhaust fans only run as needed to eliminate hydrogen buildup. In the event the MCR becomes uninhabitable the Control Room operators relocate to the SCR in the RB.

CB HVS design includes:

1. Redundant Safety-Category (TBD) FCUs which provides cooling to the DL4a room.
2. Redundant Safety-Category (TBD) FCUs which provides required cooling to the Safety-Category (TBD) Instrumentation and Control System DL2 Room A and Safety-Category (TBD) Instrumentation and Control System DL2 Room B.

The RB HVS includes Safety-Category (TBD), 100% capacity pressurization fans with emergency filtration units that supply filtered outside air to the SCR needed to pressurize the space relative to adjacent spaces, protecting the operators from hazards such as release of radioactive materials, fire, or smoke in the RB. The pressurization fans are provided with backup power making them available for use during a LOOP or SBO.

9A-150

### **9A.5.3 Radwaste Building Heating, Ventilation and Air Conditioning Systems**

The Radwaste Building contains room-temperature tanks and small to medium-sized pumps. The RWB is not normally occupied. However, plant personnel access and spend time in the Chem Lab and dress out areas within the RWB. As such, most of the building is ventilated to five air changes/hour.

The RWB Chem Lab is provided an electrical cabinet heater and a Fan Coil Unit to supplement AHU HVAC needs. The Chem Lab fume hood exhaust to the RWB exhaust AHU suction, with final discharge to the PVS.

#### **9A.5.3.1 System and Equipment Functions**

##### **9A.5.3.1.1 Normal Functions (Non-Safety Category)**

1. The RWB HVS provides a controlled environment for personnel comfort and safety and equipment operation. Sufficient outside air is provided to meet the ventilation requirements for acceptable indoor air quality consistent with the applicable requirements of ASHRAE 62.1 (Reference 9A.5.3-1).
2. The RWB HVS provides a controlled environment for the proper operation and integrity of equipment in the RWB during normal, startup and shutdown operations.
3. The RWB HVS provides necessary isolation features to support testing and maintenance.
4. The RWB HVS minimizes exposure to personnel during inspection and maintenance by locating equipment and instrumentation as far as practical from potential sources of high radiation.
5. The RWB HVS maintains designated clean areas higher than atmospheric (positive) pressure to minimize the infiltration of air.
6. The RWB HVS maintains negative pressurization of potentially contaminated areas to control leakage of potentially radioactive effluent to the atmosphere, or other rooms needing to be maintained at negative pressure including the Charcoal Adsorber Vault.
7. The RWB HVS provides the capability to exhaust smoke, heat, and gaseous combustion products from inside the Power Block to the outside atmosphere in the event of a fire.

##### **9A.5.3.1.2 Off-Normal Functions (Safety-Category)**

The RWB HVS does not perform any Safety-Category functions.

The Radwaste Building HVS is not required to operate during or after a design basis event. The design of the RWB HVS meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.11.2 (Reference 9A.5.3-2) as related to providing a ventilation system with a filtration system capable of the following:

1. Preventing unacceptable dispersion of airborne contaminants within the plant through the use of the exhaust AHUs to maintain a negative pressure in clean areas, resulting in air transferring from clean to "dirty" areas."
2. Reducing the concentration of airborne radioactive substances to levels compatible with the need for access to each particular area is achieved by using shielding, ventilation, monitoring instrumentation and ALARA design concepts as discussed in

Chapter 12 to ensure the overall design minimizes radiation exposure to workers and to the public.

3. Keeping the level of airborne radioactive substances in the plant below prescribed limits. The concentration of radionuclides in the air in areas accessible to personnel for normal plant surveillance and maintenance is below 0.1 the derived air concentration as specified in 10 CFR 20 Appendix B (Reference 9A.5.2-3) during normal power operation.
4. Application of ALARA design principles in normal operation as discussed in Subsection 12.1.5.4.
5. Ventilating rooms containing inert or noxious gases without impairing the capability to control radioactive releases using HEPA filters. The HEPA filters associated with the RWB HVS exhaust AHUs assist in ensuring radioactive material entrained in gaseous effluent does not exceed the limits specified in SOR 2000-203 (Reference 9A.5.3-4), for normal operations and anticipated operational occurrences.

#### **9A.5.3.1.3 Normal Function Safety-Category**

The RWB HVS does not perform any Safety-Category functions.

#### **9A.5.3.1.4 Off-Normal Function Non-Safety-Category**

The Radwaste Building HVS no longer receives chilled water support during off-normal conditions and is removed from service either manually or automatically.

### **9A.5.3.2 Safety Design Bases**

The Radwaste Building HVS does not perform, ensure, or support any Safety-Category function, and thus, has no safety design bases.

### **9A.5.3.3 Description**

Figure 9A.5.3-1 depicts the Radwaste Building HVAC Process Flow Diagram.

RWB HVS is comprised of two 100% capacity supply AHUs and two 100% capacity exhaust AHUs with HEPA filtration, functioning in a push-pull manner. In general, clean filtered outside air, heated when needed, is supplied through ductwork to the lobby and Chem Lab, pressurizing those areas. The exhaust AHUs take suction on the potentially contaminated tank and pump rooms, creating negative pressures in those spaces, resulting in air transferring from clean to "dirty" areas." ASDs are provided for each of the four AHUs, permitting air flow to be ramped down in the wintertime, saving on heating load. Cooling in the lobby area and the Chem Lab is supplemented by chilled water supplied FCUs. The Chem Lab is also provided a small cabinet heater, and the lobby area is provided with electric unit heaters for exterior wall heating.

During recovery from a fire, smoke is exhausted from the RWB by operating the normal supply AHUs in 100% outside air mode in conjunction with the RWB exhaust AHUs.

#### **9A.5.3.3.1 Component Description**

##### **Filters**

RWB HVS filters meet the applicable efficiency rating as stated below. ASHRAE Standard 52.2 (Reference 9A.5.3-5) establishes a filter's MERV and establishes a filter's Average Atmospheric Dust Spot Efficiency. The following ASHRAE filter classifications are MERV specified (with Dust Spot Efficiency in parenthesis) below:

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

Low Efficiency:	MERV 1-4 (Less than 20%)
Medium Efficiency:	MERV 5-12 (As least 20% but less than 80%)
High Efficiency:	MERV 13-16 (Greater than or equal to 80%)

HEPA filters are specified for various building filtration systems. Filters meet the applicable efficiency rating as stated below.

Filters with efficiency greater than MERV 16 by ASHRAE Standard 52.2 (MERV 17-20) (Reference 9A.5.3-5) are usually rated by the dioctylphthalate test method. This test is based on the ability of a filter to remove an aerosol consisting of 0.3 micrometer (micron) particles of a test challenge. HEPA filters are extended-medium dry-type filters in a rigid frame, having minimum particle- collection efficiency of 99.97% on 0.3-micron particles which meets ASME AG-1, Code on Nuclear Air and Gas Treatment, Section FC, HEPA Filters (Reference 9A.5.3-6).

HEPA filters are constructed, qualified, and tested per Underwriters Laboratory-586, High Efficiency, Particulate, Air Filter Units (Reference 9A.5.3-7).

### **Air Handler Units**

Each AHU consists of an inlet area, filters (as specified by the system), heating elements (coils), cooling coils (as required) and the respective fans (supply or exhaust). The Air-Cleaning Units and Components are designed in accordance with ASME/ANSI AG-1 Code on Nuclear Air and Gas Treatment (Reference 9A.5.3-8).

### **Supply and Exhaust Fans**

The various building ventilation systems are provided with supply and exhaust fans, which are sometimes incorporated into AHUs. These fans are either centrifugal or axial fans depending on the suitability to the specific system. The fans are designed, manufactured, and supplied in accordance with the applicable standards of AMCA. Fans are equipped with Adjustable Speed Drive mechanisms to control airflows for the specific system application.

### **Heating Coils/Elements**

Various AHUs are equipped with electrical heating coils/elements. Electric coils are designed and supplied to the requirements of Underwriters Laboratory, Heating and Cooling Equipment (9A.5.3-6).

### **Cooling Coils**

The cooling coils are designed, constructed, and installed in accordance with ASHRAE 33, Methods of Testing Forced Circulation Air-Cooling and Air-Heating Coils (Reference 9A.5.3-9), and ANSI/ARI 410 (Reference 9A.5.3-10) and Underwriters Laboratory, (Reference 9A.5.3-11).

Cooling coil condensate is collected in drain pans within the air handler units with the drain pan discharge (condensate) routed to a floor drain located within the room. These floor drains connect to the EFS (Subsection 9A.9.3) subsystem.

#### **9A.5.3.4 Materials**

Refer to Subsection 9A.5.1 for information pertaining to HVS materials.

#### **9A.5.3.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.5.3-1 for Radwaste Building HVS interfaces with other equipment or systems.

### **9A.5.3.6 System and Equipment Operation**

#### **9A.5.3.6.1 Normal Operations**

The RWB will normally be provided heated, filtered once-through supply air from two 50% capacity operating AHUs located on the second elevation of the RWB through supply ductwork. Outside air will be drawn in the RWB supply AHUs through suction ductwork and intake louvers located in the nearby exterior wall.

Air is exhausted from the RWB through two 50% capacity operating exhaust AHUs located on the RWB roof, which discharge to atmosphere from the PVS. AHU cooling provided by ventilation air is supplemented by cooling provided by FCUs. FCUs are controlled by room thermostats. AHU heating is supplemented by electric unit heater.

The RWB Chem Lab is provided an electrical cabinet heater and an FCU to supplement AHU HVAC needs, both are controlled by local thermostats. The Chem Lab fume hood exhausts to RWB exhaust AHU suction, with final discharge to the PVS.

#### **9A.5.3.6.2 Off-Normal Operations**

In the event of a LOOP or SBO, power is lost to all the RWB HVS equipment including the supply and exhaust AHUs, FCUs, electric unit heaters, and the Chem Lab cabinet heater and fume hood.

#### **9A.5.3.7 Instrumentation and Control**

The following signals are provided as inputs to the control logic:

1. Temperature elements to monitor space or duct air temperatures, and to control electric heating elements, or control fan speeds.
2. Differential pressure transmitters and air flow instruments, as required, to monitor fan operation.
3. Differential pressure transmitters to monitor pressure drop across AHU filters.
4. Intake, exhaust, and return air damper position monitoring.

Duct mounted smoke detectors to shut down fans as required.

Manual remote initiation and shutdown of the RWB HVS is provided from the RWB temperature control panel located in the Chem Lab.

The following control features are implemented in Radwaste Building HVS:

Controls for RWB HVS supply and exhaust AHUs are located in the RWB Chem Lab. All RWB AHUs have the capability of being manually started or stopped from the RWB temperature control panel.

RWB HVS AHU Operation and Interlocks:

1. Failure to start an AHU automatically starts the other AHU
2. An AHU cannot start until its shutoff dampers are confirmed 100% open
3. An AHU start request automatically opens as associated shutoff damper
4. Low flow at the inlet of the AHU trips the AHU. AHU trip initiates startup of the standby AHU
5. Redundant AHU has a "standby" or "auto" mode of operation
6. An AHU trip automatically closes its associated dampers

7. The Fire Protection System (Section 9A.6) provides a signal to shut down the RWB AHUs and most HVAC fans in the event of a fire. Smoke removal also is also performed in conjunction with the Fire Protection System. Duct mounted smoke detectors provide a smoke detected signal to the Fire Protection System local fire protection panels.

Radwaste Building HVS unit heater operation and interlocks:

- A unit heater is started automatically by a local thermostat when heating is needed.

#### **9A.5.3.8 Monitoring, Inspection, Testing, and Maintenance**

Air handlers are field tested per ASME N511, In-Service Testing of Nuclear Air – Treatment, Heating, Ventilating, and Air Conditioning Systems (Reference 9A.5.3-12).

Component specific maintenance procedures are outlined in the vendor manuals provided as part of each procurement package.

Personnel and lay-down access are provided around instruments to allow adequate space for maintenance purposes.

#### **9A.5.3.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.5.3.10 Performance and Safety Evaluation**

The radwaste building HVAC system does not perform any Safety-Category functions and therefore requires no nuclear safety evaluation.

Operational failure of any single unit of the RWB HVS does not prevent Safety Class equipment from performing any Safety-Category function.

## **9A.5.4 Turbine Building, Heating, Ventilation and Air-Condition System**

### **System and Equipment Functions**

#### **9A.5.4.1 System and Equipment Functions**

##### **9A.5.4.1.1 Normal Functions (Non-Safety Category)**

1. The TB HVS provides a controlled environment for personnel comfort and safety and equipment operation. Sufficient outside air is provided to meet the ventilation requirements for acceptable indoor air quality consistent with the applicable requirements of ASHRAE 62.1 (Reference 9A.5.4-1).
2. The TB HVS provides a controlled environment for the proper operation and integrity of equipment in the TB during normal, startup and shutdown operations.
3. The TB HVS provides redundant active components to increase reliability, availability, and maintainability of the ventilation system.
4. The TB HVS provides isolation features to support testing and maintenance.
5. The TB HVS minimizes exposure to personnel during inspection and maintenance by locating equipment and instrumentation as far as practical from potential sources of high radiation.
6. The TB HVS maintains designated clean areas higher than atmospheric (positive) pressure to minimize the infiltration of air.
7. The TB HVS maintains negative pressurization of potentially contaminated areas to control leakage of potentially radioactive effluent to the atmosphere, or other rooms needing to be maintained at negative pressure
8. The TB HVS provides the capability to exhaust smoke, heat, and gaseous combustion products from inside the Power Block to the outside atmosphere in the event of a fire.
9. The TB Battery Room is ventilated and exhausted to maintain hydrogen levels below required limits in the room.
10. The TB Continuous Exhaust Air Plenum collects and mixes potentially radioactive discharge air from various buildings and releases the mixed air to atmosphere via the PVS.

##### **9A.5.4.1.2 Normal Functions (Safety-Category)**

The TB HVS provides a controlled environment for the proper operation and integrity of Safety Class instrumentation located in the TB during normal, startup and shutdown operations.

##### **9A.5.4.1.3 Off-Normal Functions (Non-Safety-Category)**

TB HVS systems continue to operate during off-normal conditions until removed from service either manually or automatically.

##### **9A.5.4.1.4 Off-Normal Functions (Safety-Category)**

1. The TB HVS includes supply and exhaust isolation dampers for the TB, which close automatically in the event of a TB high radiation input from the PREMS (Subsection 9A.3.1), isolating the TB.
2. Tornado dampers are provided at the TB Diesel Generator room for the outside air intake and the DG heat exhaust louver to protect the DG structure.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

The TB HVS is not required to operate during or after a design basis event. The design of the TB HVS meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.11.2 (Reference 9A.5.4-2) as related to providing a ventilation system with a filtration system capable of the following:

1. Preventing unacceptable dispersion of all airborne contaminants within the plant using air flow to effect transfer of air from clean areas to potentially contaminated areas.
2. Reducing the concentration of airborne radioactive substances to levels compatible with the need for access to each particular area is achieved by using shielding, ventilation, monitoring instrumentation and ALARA design concepts as discussed in Chapter 12 to ensure the overall design minimizes radiation exposure to workers and to the public.
3. Keeping the level of airborne radioactive substances in the plant below prescribed limits. The concentration of radionuclides in the air in areas accessible to personnel for normal plant surveillance and maintenance is below 0.1 the derived air concentration as specified in 10 CFR 20 Appendix B (Reference 9A.5.2-3) during normal power operation.
4. Application of ALARA design principles in normal operation as discussed in Subsection 12.1.5.4.
5. Ventilating rooms containing inert or noxious gases without impairing the capability to control radioactive releases using HEPA filters. The HEPA filters associated with the TB HVS exhaust AHUs assist in ensuring radioactive material entrained in gaseous effluent does not exceed the limits specified in SOR 2000-203 (Reference 9A.5.3-4), for normal operations and anticipated operational occurrences.

#### **9A.5.4.2 Safety Design Bases**

The TB HVS is not required to operate during or following a Design Basis Accident. The safety design bases associated with the TB HVS is provided below:

1. Safety-Category (TBD) Tornado dampers are provided at the TB DG room for the Outside Air intake and the DG heat exhaust louver to protect the DG structure.
2. As part of Defense Line 2, the TB HVS provide the capability to isolate ventilation to the TB when signaled to do so from the Safety-Category (TBD) Instrumentation and Control System.
3. TB HVS maintains temperatures in the TB required to support operation of Safety Class instrumentation.

#### **9A.5.4.3 Description**

Figure 9A.5.4-1 depicts the Turbine Building HVAC Process Flow Diagram.

The TB is a large building with significant cooling loads. It is divided into two main areas: The potentially contaminated areas inside the shield area, which houses the Main Turbine, Main Condenser, Moisture Separator Reheater, Feedwater Heaters and other significant heat loads. Outside the shield area includes the Main Generator, Air Compressor area, assorted electrical pumps and heat exchangers, and assorted electrical equipment. There are also two isolated Diesel Generator Rooms located on the Ground Floor, plus four enclosed stairwells. There is also a Battery Room on the Ground Floor. There are also two Switchgear Rooms located on the mezzanine level. Each is provided with chilled water supplied Fan Coil Units, and a small amount of supply air from two of the six TB AHUs for pressurization.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

The main generator is air-cooled and does not use hydrogen as the coolant. Therefore, there are no special requirements for hydrogen controls in the area.

The TB is supplied with outside air using six supply AHUs. These AHUs are provided with electric heating coils to provide a reasonable supply air temperature, and upstream prefilters to keep dirt off the coils, and for building cleanliness. The supply air is distributed through ductwork to areas both inside and outside the shield area. Most floors in the TB consists of metal grating, allowing supply air provided to lower elevations to increase in temperature and elevate naturally. Air is exhausted from the building via four AHUs with HEPA filtration located on the TB roof, taking suction from roof penetrations or suction ductwork. Air flow rates to areas have been chosen to effect transfer air from clean areas outside the shield area to potentially contaminated areas inside the shield area. TB supply and exhaust AHUs are provided AFDs to be able to reduce flow as permitted by plant operation and reduced ambient temperature conditions.

The PVS is located towards the north end of the TB roof. It is provided exhaust air from PVS exhaust fans venting the potentially radioactive air up and away from the TB. Each of the PVS exhaust fans takes suction on the Continuous Exhaust Air Plenum, which receives and mixes discharge air from the various building exhaust AHUs. The PVS radiation monitor is addressed in Chapter 11, Subsection 11.5.

The Diesel Generator Rooms are located in the TB. The Diesel Generator rooms are heated using electric unit heaters. The ventilation design of the Diesel Generator Rooms is for air to enter each room through two inlet air dampers connected to upstream ductwork and a common intake louver, providing outside air for both heat removal and for the combustion of diesel fuel. A small part of the exhaust air from the room exits from a wall mounted exhaust fan, located high on the wall. Most of the exhaust air from the rooms exits from the diesel generator as either radiator exhaust, ducted out the room through a wall-mounted louver/damper, or hard piped out the room through combustion piping/silencer.

The TB Battery Room is ventilated and conditioned by two mini-split HVAC systems, one for Train A and one for Train B, each system with an outdoor wall-mounted condenser unit and an indoor wall-mounted AHU, connected by refrigerant piping. Each AHU brings a small amount of filtered, conditioned outside air into the room, maintaining a slight positive pressure in the space. The room is heated by electric unit heaters.

The walls of the TB Battery Room and each of the two DG Rooms are constructed leak-tight relative to the TB to maintain radioactively clean environments.

#### **9A.5.4.3.1 Component Description**

Filters for the TB meet the applicable efficiency rating as stated below. ASHRAE Standard 52.2 (Reference 9A.5.4-5) establishes a filter's MERV and establishes a filter's Average Atmospheric Dust Spot Efficiency. The following ASHRAE filter classifications are MERV specified (with Dust Spot Efficiency in parenthesis) below:

Low Efficiency:	MERV 1-4 (Less than 20%)
Medium Efficiency:	MERV 5-12 (As least 20% but less than 80%)
High Efficiency:	MERV 13-16 (Greater than or equal to 80%)

HEPA (High Efficiency Particulate Air) Filters are specified for various building filtration systems. Filters meet the applicable efficiency rating as stated below.

Filters with efficiency greater than MERV 16 by ASHRAE Standard 52.2 (MERV 17-20) (Reference 9A.5.4-5) are usually rated by the dioctylphthalate test method. This test is based on

the ability of a filter to remove an aerosol consisting of 0.3 micrometer (micron) particles of a test challenge. HEPA filters are extended-medium dry-type filters in a rigid frame, having minimum particle- collection efficiency of 99.97% on 0.3-micron particles which meets ASME AG-1, Code on Nuclear Air and Gas Treatment, Section FC, HEPA Filters (Reference 9A.5.4-6).

HEPA filters are constructed, qualified, and tested per Underwriters Laboratory-586, High Efficiency, Particulate, Air Filter Units (Reference 9A.5.4-7).

### **Air Handler Units**

Each AHU consists of an inlet area, filters (as specified by the system), heating elements (coils), cooling coils (as required) and the respective fans (supply or exhaust). The Air-Cleaning Units and Components are designed in accordance with ASME/ANSI AG-1 Code on Nuclear Air and Gas Treatment (Reference 9A.5.4-8).

### **Supply and Exhaust Fans**

The various building ventilation systems are provided with supply and exhaust fans, which are sometimes incorporated into AHUs. These fans are either centrifugal or axial fans depending on the suitability to the specific system. The fans are designed, manufactured, and supplied in accordance with the applicable standards of AMCA (Air Movement and Control Association International). Fans are equipped with mechanisms to control airflows for the specific system application.

### **Heating Coils/Elements**

Various AHUs are equipped with electrical heating coils/elements. Electric coils are designed and supplied to the requirements of Underwriters Laboratory, Heating and Cooling Equipment (9A.5.4-6).

### **Cooling Coils**

The cooling coils are designed, constructed, and installed in accordance with ASHRAE 33, Methods of Testing Forced Circulation Air-Cooling and Air-Heating Coils (Reference 9A.5.4-9), and ANSI/ARI 410 (Reference 9A.5.4-10) and Underwriters Laboratory, (Reference 9A.5.4-11).

Cooling coil condensate is collected in drain pans within the air handler units with the drain pan discharge (condensate) routed to a floor drain located within the room. These floor drains connect to the EFS (Subsection 9A.9.3) subsystem.

#### **9A.5.4.4 Materials**

Refer to Subsection 9A.5.1 for information pertaining to HVS materials.

#### **9A.5.4.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.5.4-2 for Turbine Building HVS interfaces with other equipment or systems

#### **9A.5.4.6 System and Equipment Operation**

##### **9A.5.4.6.1 Normal Operation**

The TB is normally provided heated, filtered once-through supply air from six normally operating AHUs located on the mezzanine level of the TB, which supply through ductwork to areas both inside and outside the radiological area. Air is exhausted from the same spaces through four normally operating exhaust AHUs located on the Turbine Building low bay roof, taking suction either directly through a TB roof penetration, or through suction ductwork connecting to the TB high bay. These exhaust AHUs discharge to the atmosphere from the PVS. AHU cooling provided by ventilation air is supplemented by cooling provided by FCUs located in areas that

require extra cooling, with FCUs being controlled by local thermostats. AHU heating is supplemented by electric unit heaters. Circulating fans are provided and used to mitigate hot spots within the building.

Exhaust air from potentially contaminated areas including the TB, RB, RWB, and Plant Service Area is filtered by AHUs using HEPA filters before being exhausted to the Continuous Exhaust Air Plenum. The Continuous Exhaust Air Plenum serves as a large mixing box where potentially contaminated air will be mixed and diluted. During normal operation, up to three PVS fans take suction on the Continuous Exhaust Air Plenum and discharge to the nearby PVS. The HEPA filters from the exhaust AHUs at each building assist in ensuring radioactive material entrained in gaseous effluent will not exceed the limits specified in SOR 2000-203 (Reference 9A.5.4-4), for normal operations and anticipated operational occurrences. The PVS fans are provided ASDs to be able to maintain the Continuous Exhaust Air Plenum negatively pressurized relative to the outside and to adjust to varying flow inputs, which may vary based on the operation of the exhaust AHUs at each building.

There are also two Switchgear Rooms. Each is provided with chilled water supplied FCUs, and a small amount of supply air from two of the six TB AHUs for pressurization.

Each enclosed stairwell is provided electric cabinet heaters to maintain space minimum temperature. These heaters are controlled by local thermostat.

Each of the two Diesel Generator Rooms located in the TB are provided two inlet air motor-controlled dampers, each with upstream ductwork leading to a common outside air intake louver. Each room has an exhaust fan discharging to the outdoors, and two electric unit heaters to maintain space design temperatures, controlled by local thermostat. An additional motor-controlled damper is designed to auto-open on Diesel Generator start and auto-close on DG stop with a time delay. This motor-controlled damper is provided in the Diesel Generator radiator cooling discharge ducted flow to the outdoors through a wall louver.

#### **9A.5.4.6.2 Off-Normal Operation**

In the event of an SBO, power is lost to all the TB HVAC equipment, Supply and exhaust AHUs and fan, electric unit heaters, FCUs, and all circulating fans.

In the event of a LOOP, with the exceptions of the Diesel Generator Room exhaust fans and motor-controlled dampers, two PVS Fans, and the operating Train A or B Battery Room mini-split cooling system, power is lost to all the TB HVAC equipment; Supply and exhaust AHUs, electric unit heaters, the FCUs, and all circulating fans.

A radiation monitor alarm in the TB initiates closure of the TB isolation dampers and secures the supply and exhaust AHUs. Refer to Chapter 11, Section 11.5 for information pertaining to radiation monitoring.

#### **9A.5.4.7 Instrumentation and Control**

The following describe key control features and the operational requirements for the TB HVS:

1. The TB HVS is operated from the Temperature Control Panel located near the Diesel Generator Rooms. TB Temperature Control Panel alarms are forwarded to the Main Control Room Panels.
2. TB supply AHUs are provided with Adjustable Speed Drives to ramp down air flow as outside air temperatures lower, prior to energizing integral electric heating coils.
3. AHU starting is not permitted until all associated isolation dampers are full open.

4. An AHU start request automatically opens all associated isolation dampers.
5. Failure of an operating damper automatically trips its associated AHU.
6. Failure of an operating AHU automatically closes all its associated isolation dampers.
7. To avoid spurious standby starts and fan trips, all airflow logic incorporates time delays to allow fans to generate steady-state flow.
8. TB FCUs are operated from TCPL.
9. TB Battery Room Train A and Train B mini-split systems are operated from TCPL.
10. TB Battery Room Train A and Train B mini-split systems are operated from the TB TCPL or from nearby touchpads.
11. Train B diesel generator room outside air inlet dampers and exhaust fans are operated from TCPL.
12. The Fire Protection System (Section 9A.6) provides a signal to shut down the turbine building AHUs in the event of a fire. Smoke removal is also performed in conjunction with the FPS. Duct mounted smoke detectors provide a smoke detected signal to the FPS local fire protection panels.
13. The supply AHUs are interlocked with the exhaust AHUs to ensure that the exhaust AHUs are running before a supply fan is started.

#### **9A.5.4.8 Monitoring, Inspection, Testing, and Maintenance**

The TB HVS provides isolation features to support testing and maintenance.

Air handlers are field tested per ASME N511, In-Service Testing of Nuclear Air – Treatment, Heating, Ventilating, and Air Conditioning Systems (Reference 9A.5.2-12).

Component specific maintenance procedures are outlined in the vendor manuals provided as part of each procurement package.

Personnel and lay-down access are provided around instruments to allow adequate space for maintenance purposes.

#### **9A.5.4.9 Radiological Aspects**

Chapter 12, Section 12.1 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.5.4.10 Performance and Safety Evaluation**

The TB HVS is not credited for mitigation of design basis accidents and not required to be operated during off-normal events.

HEPA filters associated with the TB HVS exhaust AHUs assist in ensuring radioactive material entrained in gaseous effluent does not exceed the limits specified in SOR 2000-203 (Reference 9A.5.3-4), for normal operations and anticipated operational occurrences. The exhaust air from the TB HVS is monitored for radioactivity prior to discharge to the plant vent. Alarms annunciate in the MCR upon detection of high radiation.

NON-PROPRIETARY INFORMATION

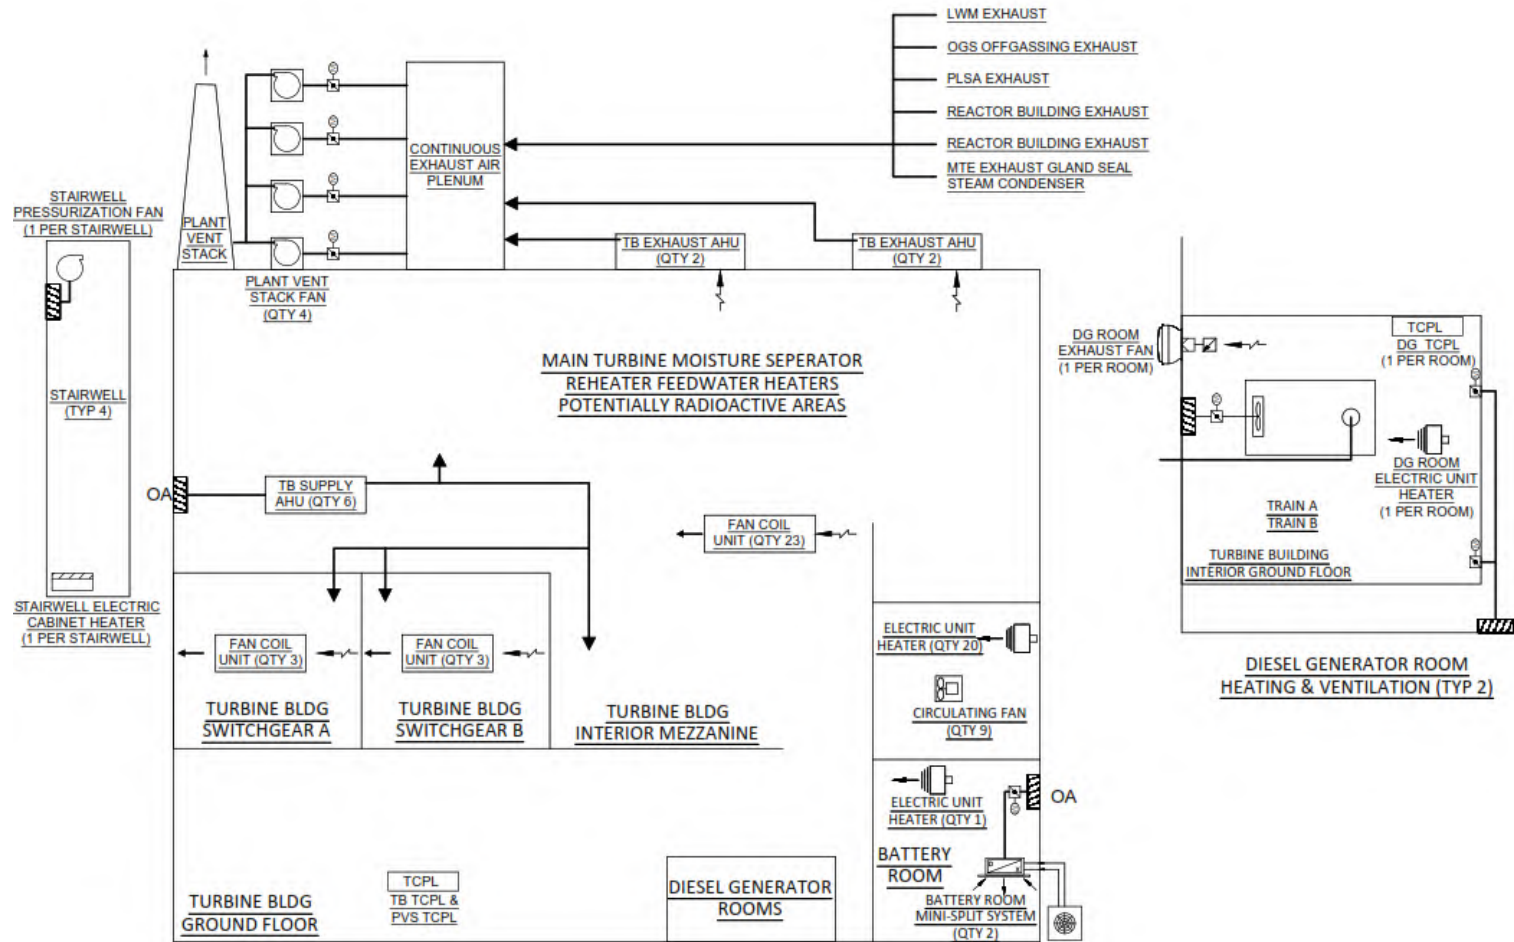

Figure 9A.5.4-1: Turbine Building HVAC

### **9A.5.5 Plant Services Area Heating, and Ventilation Systems**

The Plant Services Area is supplied by a 100% capacity makeup AHU and a 100% capacity exhaust AHU with HEPA filtration, functioning in a push-pull manner. Clean filtered outside air, heated when needed, is supplied through ductwork and supply registers to all spaces within the PLSAs. The exhaust AHU takes suction on these same spaces providing differential pressures resulting in flows from "clean" to "dirty" areas." AFDs are provided for each of the AHUs, permitting air flow to be ramped down in the wintertime, saving on heating load. Heating is supplemented by electric unit heaters located in most of the PLSA rooms. Baseboard heating units supplement the AHU heating in the Office and Auxiliary RCA Access Control Room. An electric unit heater is located near the exterior door of the hallway addressing the entryway into the North end of the building as well as along the various exterior walls of the rooms without baseboard heating.

Air discharged from the exhaust AHU is directed through ductwork to the Continuous Exhaust Air Plenum, where the air gets mixed with discharges from other building, before being exhausted out the PVS.

During recovery from a fire, smoke is exhausted from the PLSA by operating the supply AHU in 100% outside air mode in conjunction with operation of the exhaust AHU.

#### **9A.5.5.1 System and Equipment Functions**

##### **9A.5.5.1.1 Normal Functions (Non-Safety Category)**

1. The PLSA HVS provides a controlled environment for personnel comfort and safety and equipment operation. Sufficient outside air is provided to meet the ventilation requirements for acceptable indoor air quality consistent with the applicable requirements of ASHRAE 62.1 (Reference 9A.5.5-1).
2. The PLSA HVS provides a controlled environment for the proper operation and integrity of equipment in the PLSA during normal, startup and shutdown operations.
3. The PLSA HVS provides necessary isolation features to support testing and maintenance.
4. The PLSA HVS minimizes exposure to personnel during inspection and maintenance by locating equipment and instrumentation as far as practical from potential sources of high radiation.
5. The PLSA HVS maintains designated clean areas higher than atmospheric (positive) pressure to minimize the infiltration of air.
6. The PLSA HVS maintains negative pressurization of potentially contaminated areas to control leakage of potentially radioactive effluent to the atmosphere, or other rooms needing to be maintained at negative pressure.
7. The HVS reduces the potential spread of airborne contamination by maintaining airflow from areas of lower potential for contamination to areas of greater potential for contamination.
8. The PLSA HVS is designed such that failure of SCN equipment does not compromise or otherwise damage Safety-Class equipment.
9. The PLSA HVS provides the capability to exhaust smoke, heat, and gaseous combustion products from inside the Power Block to the outside atmosphere in the event of a fire.

#### **9A.5.5.1.2 Normal Functions (Safety-Category)**

The PLSA HVS does not perform Safety-Category functions.

#### **9A.5.5.1.3 Off-Normal Functions (Non-Safety-Category)**

PLSA HVS continue to operate during off-normal conditions until removed from service either manually or automatically.

#### **9A.5.5.1.4 Off-Normal Functions (Safety-Category)**

The PLSA HVS does not perform any Safety-Category functions.

The PLSA HVS is not required to operate during or after a design basis event. The design of the PLSA HVS meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.11.2 (Reference 9A.5.5-2) as related to providing a ventilation system with an appropriate filtration system capable of the following:

1. Preventing unacceptable dispersion of all airborne contaminants within the plant through the use of the exhaust AHUs to maintain a negative pressure in clean areas, resulting in air transferring from clean to "dirty" areas."
2. Reducing the concentration of airborne radioactive substances to levels compatible with the need for access to each particular area is achieved by using shielding, ventilation, monitoring instrumentation and ALARA design concepts as discussed in Chapter 12 to ensure the overall design minimizes radiation exposure to workers and to the public.
3. Keeping the level of airborne radioactive substances in the plant below prescribed limits. The concentration of radionuclides in the air in areas accessible to personnel for normal plant surveillance and maintenance is below 0.1 the derived air concentration as specified in 10 CFR 20 Appendix B (Reference 9A.5.2-3) during normal power operation.
4. Application of ALARA design principles in normal operation as discussed in Chapter 12, Subsection 12.1.5.4.
5. Ventilating rooms containing inert or noxious gases without impairing the capability to control radioactive releases using HEPA filters. The HEPA filters associated with the PLSA HVS exhaust AHUs assist in ensuring radioactive material entrained in gaseous effluent does not exceed the limits specified in SOR 2000-203 (Reference 9A.5.3-4), for normal operations and anticipated operational occurrences.

#### **9A.5.5.2 Safety Design Bases**

The PLSA HVS does not perform, ensure, or support any Safety-Category function, and thus, has no safety design bases.

#### **9A.5.5.3 Description**

Figure 9A.5.5-1 depicts the PLSA HVAC Process Flow Diagram.

The PLSA are provided filtered, heated air from a normally operating supply AHU located on the Plant Services Area roof, supplying through ductwork. Air is exhausted from the spaces by a normally operating exhaust AHU with HEPA filtration also located on the roof, taking suction through ductwork, discharging ultimately to the outdoors through the PVS. Heating is supplemented by electric unit heaters and baseboard heaters.

The PLSA Temperature Control Panel is provided in the Plant Services Area Office and is used to control the supply and exhaust AHU.

#### **9A.5.5.3.1 Component Description**

##### **Air Handling Units**

Each AHU consists of an inlet area, filters, heating elements (coils), cooling coils (as required) and the respective fans (supply or exhaust). The Air-Cleaning Units and Components are designed in accordance with ASME/ANSI AG-1 Code on Nuclear Air and Gas Treatment (Reference 9A.5.5-5).

##### **Supply and Exhaust Fans**

The various building ventilation systems are provided with supply and exhaust fans, which are sometimes incorporated into AHUs. These fans are either centrifugal or axial fans depending on the suitability to the specific system. The fans are designed, manufactured, and supplied in accordance with the standards of AMCA. Fans are equipped with ASD mechanisms as required to control airflows for the specific system application.

##### **Heating Coils/Elements**

Various AHUs are equipped with electrical heating coils/elements. Electric coils are designed and supplied to the requirements of Underwriters Laboratory, Heating and Cooling Equipment (Reference 9A.5.5-6).

#### **9A.5.5.4 Materials**

Refer to Subsection 9A.5.1 for information pertaining to HVS materials.

#### **9A.5.5.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.5.5-1 for PLSA HVS interfaces with other equipment or systems.

#### **9A.5.5.6 System and Equipment Operation**

##### **9A.5.5.6.1 Normal Operation**

The PLSA is provided filtered, heated air from a normally operating supply AHU located on the PLSA roof, supplying through ductwork. Air is exhausted from the space by a normally operating exhaust AHU also located on the roof, taking suction through ductwork, discharging ultimately to the outdoors through the PVS. Heating in each of the ventilated rooms is supplemented by electric unit heaters or baseboard heaters located in each room. The PSA supply AHU and exhaust AHUs are controlled at the Temperature Control Panel in the PLSA Office. The unit heaters are all controlled by local thermostats.

##### **9A.5.5.6.2 Off-Normal Operation**

In the event of a LOOP or SBO, power is lost to the Plant Services Area HVAC equipment including the supply and exhaust AHUs, electric unit heaters, and baseboard heaters.

#### **9A.5.5.7 Instrumentation and Control**

Manual initiation and shutdown of the PLSA AHUs is provided from the PLSA temperature control panel located in the Plant Services Area Office. System and component operating status for the AHUs is displayed in the MCR:

1. Manual initiation and shutdown of the Plant Services Area AHUs is provided from the Plant Services Area Temperature Control Panel located in the Plant Services Area Office.

2. An AHU start request automatically opens all associated isolation dampers.
3. Failure of an operating damper automatically trips its associated AHU.
4. Failure of an operating AHU automatically closes all its associated isolation dampers.
5. To avoid spurious standby starts and fan trips, all airflow logic incorporates time delays to allow fans to generate steady-state flow.
6. Electric Unit Heaters are controlled from local wall-mounted thermostats.
7. The FPS provides a signal to shut down the Plant Services Area AHUs in the event of a fire. Duct mounted smoke detectors provide a smoke detection signal to the Fire Protection System local fire protection panels.

#### **9A.5.5.8 Monitoring, Inspection, Testing, and Maintenance**

The PLSA HVS provides necessary isolation features to support testing and maintenance

Air handlers are field tested per ASME N511, In-Service Testing of Nuclear Air – Treatment, Heating, Ventilating, and Air Conditioning Systems (Reference 9A.5.5-7).

Component specific maintenance procedures are outlined in the vendor manuals provided as part of each procurement package.

Personnel and lay-down access are provided around instruments to allow adequate space for maintenance purposes.

#### **9A.5.5.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.5.5.10 Performance and Safety Evaluation**

The PLSA HVS does not perform any Safety-Category functions and therefore requires no nuclear safety evaluation.

The PLSA HVS is not credited for mitigation of design basis accidents and not required to be operated during off-normal events.

HEPA filters associated with the PLSA HVS exhaust AHUs assist in ensuring radioactive material entrained in gaseous effluent does not exceed the limits specified in SOR 2000-203 (Reference 9A.5.3-4), for normal operations and anticipated operational occurrences. The exhaust air from the PLSA HVS is monitored for radioactivity prior to discharge to the plant vent. Alarms annunciate in the MCR upon detection of high radiation.

## **9A.5.6 Containment Cooling System**

The Containment Cooling System is a closed loop cooling system that recirculates air/nitrogen with no outside air introduced into the system except during outages.

### **9A.5.6.1 System and Equipment Functions**

The CCS supports performance of the following functions during operating conditions through the entire operating range, from startup to full load condition to refueling:

#### **9A.5.6.1.1 Normal Functions (Non-Safety-Category)**

The CCS performs the following Non-Safety-Category functions during normal operations.

- CCS aids in purging of nitrogen from the containment during shutdown

#### **9A.5.6.1.2 Normal Functions (Safety-Category)**

The CCS performs the following Safety-Category functions during normal operations:

- CCS maintains temperature in the upper containment and control rod drive area at the required target temperature and below the specified maximum temperature limit during normal operation
- CCS maintains operation temperature envelope in the Steel-plate Composite Containment Vessel (SCCV) to support Environmental Qualification (EQ) of Safety-Category function related equipment during Modes 1-5

#### **9A.5.6.1.3 Off-Normal Functions (Non-Safety-Category)**

The CCS performs the following Non-Safety-Category functions during Off-Normal operations:

- CCS supports heat removal during outages, if available

#### **9A.5.6.1.4 Off-Normal Functions (Safety-Category)**

The CCS performs the following SC3 Safety-Category functions during off-normal operations:

- CCS assists with containment cooldown following a Loss-of-Offsite Power (LOOP) during the period from hot shutdown to cold shutdown if available
- CCS limits containment temperature during a LOOP.

### **9A.5.6.2 Safety Design Bases**

The CCS is classified as Defense Line 2 and Safety Class 3 (DL2/SC3). The CCS performs the Safety-Category function of heat removal in the containment.

### **9A.5.6.3 Description**

Figure 9A.5.6-1 depicts the CCS.

The design of the CCS provides cooling to the containment consistent with the requirements of REGDOC 2.5.2 Section 7.10 (Reference 9A.5.6-1).

The CCS is Safety Class 3. The CCS is used to ensure the containment conditions are maintained, which includes the EQ temperatures envelope for Safety-Category function related equipment.

The CCS provides containment cooling using AHU that reject heat to the CWE (Subsection 9A.2.4) during all modes of operation. The CCS is a closed loop recirculating cooling system.

The CCS is comprised of four (4) 50% capacity AHUs and is divided into two trains of two (2) AHUs. Each train is cooled by a corresponding chilled water train so that SCCV cooling is still possible even with loss of one train of CWE or one train of CCS. Each AHU can be powered from one of the standby diesel generators of the Safety Class 2 and 3 Electrical Distribution System.

During normal operation, only one train of CCS is operating while the other is in standby. The train in standby automatically starts upon loss of the lead train or upon temperature exceeding target. All AHUs can be in service at the same time, if needed.

Each AHU has a condensate collection pan. The condensate collected from the AHUs is drained to a hub location inside of containment, then is piped to the Equipment and Floor Drain System (Subsection 9A.9.3) sump located outside containment where it is discharged.

The CCS air distribution ductwork is constructed of hot-dipped galvanized sheet metal and uses manual balancing dampers to control the distribution of air to the various containment locations.

Backdraft dampers are provided on each fan suction to prevent reverse rotation of a non-operating fan.

The system is classified as Seismic Interaction which requires evaluation to ensure that during a seismic event there are no adverse interactions with the ability of SSCs classified as Seismic A or B to perform their functions. Refer to Chapter 3, Subsection 3.2 for additional information pertaining to Seismic Interaction.

The CCS ductwork and equipment are designed in accordance with ASHRAE (Reference 9A.5.6-2) for the reactor building environment to support the operation and integrity of equipment during normal, startup and shutdown operations.

#### **9A.5.6.3.1 Component Description**

##### **Air Handling Units**

The CCS is comprised of two trains of AHUs. Each AHU is cooled by the corresponding CWE system train. The AHU cooling coils are to be designed, constructed, and installed in manner that facilitates coil cleaning and supports ease of replacement as required. A manual damper is installed at the AHU suction for isolation during maintenance.

Low efficiency air filter sections are provided upstream of the cooling coil sections to permit installation of temporary filters during testing and outages.

##### **Supply Fans**

There are four (4) 50% capacity recirculating supply air fans in CCS. The supply fans are located downstream of their respective AHU coils. A totally enclosed fan cooled motor is provided for the fan.

##### **Cooling Coils**

CCS has four (4) cooling coils per train. Supply fans are located downstream of the cooling coils. These coils use CWE chilled water as the heat sink.

Condensate from the cooling coils is routed to the bottom of the containment, then through piping to the EFS sump located outside of containment. All cooling coils are provided with stainless steel condensate drain pans.

##### **Air Filters (Temporary)**

Low efficiency air filter sections are provided upstream of the cooling coil sections. Low efficiency air filters are used during construction and post-construction testing of CCS to protect the cooling

coils. After the above test, the air filters are removed since it is not necessary to filter the recirculating air during normal plant operation. If necessary, during a refueling outage, temporary air filters can be installed in the filter section.

### **Piping, Valves, and Ductwork**

CCS piping and valves are classified as follows:

CCS cooling coil condensate drain piping is SCN and designed to meet ASME B31.1 Power Piping requirements.

CCS ductwork and dampers are classified as follows:

CCS ductwork and dampers are designed, installed and inspected according to ASHRAE Fundamentals, SMACNA, HVAC System Duct Design, and SMACNA Duct Construction Standards. The ductwork is seismically supported so that in the event of a failure of CCS Structures, Systems, or Components during a seismic event does not adversely affect the ability of any Seismic Category A or B Structure, System or Component to accomplish its Safety Class function.

#### **9A.5.6.4 Materials**

Selection of radiation-resistant materials of construction is included in individual equipment specifications.

Material and equipment selection for CCS components is based on a 60-year plant life, with appropriate provisions for maintenance and replacement. Components which may require periodic replacement and/or maintenance prior to the end of plant life are dampers, damper linkages, AHUs, bearings, and motors.

Aluminum ducting is not allowed inside containment.

Materials are selected in accordance with applicable codes, standards, and industry practice for the design, service, and test conditions and expected ambient conditions.

Materials selected are compatible with the internal process and external environmental conditions during normal, abnormal, accident, and beyond design basis accident conditions as appropriate.

#### **9A.5.6.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.5.6-2 for CCS interfaces with other equipment or systems.

#### **9A.5.6.6 System and Equipment Operation**

CCS is designed for continuous operation for the following operating modes.

##### **Normal Operational Concept**

CCS normal plant operation includes startup, power operation, hot shutdown, cold shutdown, and refueling. In normal operation mode, one (1) of the two (2) trains operates as lead while the other train is in standby. The lead train is initiated remotely from the Main Control Room. The standby train is automatically started when containment temperature reaches limit or upon tripping of the lead train to maintain the normal operation temperature envelope and support environmental qualification of Safety-Category function related equipment. The assignment for lead and standby train is switched periodically. Both trains can also operate simultaneously.

##### **Off-Normal Operational Concept**

The CCS AHUs and supporting chillers are provided with backup power from the diesel generators. The CCS remains operational during a Loss-of-Offsite Power. This supports

maintaining the containment environment from exceeding design conditions. The CCS assists with containment cooldown following a Loss-of-Offsite Power during the period from hot shutdown to cold shutdown.

#### **9A.5.6.7 Instrumentation and Control**

CCS provides the instrumentation to control and monitor system operation.

Operation of the CCS is controlled remotely from the Main Control Room. Each AHU has a local disconnect switch to facilitate maintenance. Temperature elements are provided to indicate and alarm on loss of train or temperature over target and energize the standby fan motor. Containment electrical penetrations are used to route the cable from the control elements in the ductwork to the Main Control Panel. There will be no CCS local control panels.

#### **9A.5.6.8 Monitoring, Inspection, Testing, and Maintenance**

The cooling coils can be accessed for cleaning. Only water can be used for cleaning. No compressed air is allowed. There is no need for duct cleaning since no outside air is introduced during operation.

Pick points for heavy equipment are provided. The equipment and components of the CCS are designed for inspection and maintenance accessibility. Additionally, fans, motors, coils, filter section, and dampers and damper actuators can be removed for maintenance and repair.

To minimize maintenance (e.g., changing/adjusting belts) and contribute to ALARA goals, the CCS fans are equipped with a quick disconnect on the motor leads and a motor terminal junction box. The fans are provided with full manual control for testing and maintenance. Ductwork is arranged to facilitate AHU maintenance.

To allow testing and balancing, small holes may be drilled on the side of the CCS ductwork to take readings with temporary instrumentation. The holes are capped after the testing and balancing is completed.

AHUs are inspected and maintained according to the manufacturer's requirements.

CCS piping is installed and inspected according to ASME B31.1. CCS ductwork is installed and inspected according to Sheet Metal and Air Conditioning Contractors National Association, Inc.

#### **9A.5.6.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to ALARA design measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.5.6.10 Performance and Safety Evaluation**

CCS equipment is classified as Safety Class 3 and seismic classification "Seismic Interaction" which entails an evaluation as discussed in Chapter 3, Subsection 3.2 to ensure that in the event CCS Structures, Systems and Components, fail during a seismic event there are no adverse interactions with the ability of any Seismic Category A or B Structure, System, or Component to accomplish their Safety-Class function.

The CCS is designed with N+1 redundancy for asset protection. In the event of one train failure or shut down for maintenance, the train in standby automatically starts and maintains full operation of the system to protect the EQ equipment inside the SCCV.

## **9A.6 Fire Protection Systems**

### **Introduction**

This section provides information on the BWRX-300 fire protection system design. It also confirms that the design meets the Canadian Nuclear Safety Commission (CNSC) expectations for fire protection system design.

The BWRX-300 fire protection system is comprised of an integrated complex of components and equipment provided for detection, notification, annunciation, and suppression of fires.

This document addresses the requirements of CNSC REGDOC-2.5.2, Design of Reactor Facilities: Nuclear Power Plants (Reference 9A.6.11-3), by providing a set of comprehensive design requirements and guidance that is risk-informed to align with accepted international codes and practices.

The guidance in this document is consistent with international best practices and the recommendations of the International Atomic Energy Agency and International Commission on Radiological Protection.

This section provides criteria pertaining to the safe design of the BWRX-300 in Canada. Aspects of the BWRX-300 design are considered, and multiple levels of defence are promoted in design considerations.

A summary description of the BWRX-300 fire protection system design is provided below. In addition, more detailed information describing the salient features of the overall BWRX-300 Fire Protection Program (FPP).

This discussion focuses on fire protection design consisting of the following:

- General design approach and strategy for fire protection
- Structural aspects of fire protection
- Description of fire protection measures inside confinement and containment
- Strategy and measures for alerting staff of fire events or conditions that may potentially trigger a fire event
- Strategy and measures for control of fire protection systems
- Human factors considerations in the design for fire protection, and
- Description of fire protection systems interface with other systems, including inter-unit interfaces, where common systems are shared including these systems which have a Safety Class classification.

### **Fire Protection Program General Information**

The BWRX-300 fire protection system is comprised of an integrated complex of components and equipment provided for detection, notification, annunciation, and suppression of fires. The Fire Protection Program is different than the Fire Protection System (FPS) which is a system of mechanical equipment and piping used to provide fire detection and suppression to fight a fire at the plant.

The OPG DNNP Fire Protection Program includes the concepts of design and layout implemented to prevent or mitigate fires, administrative controls and procedures, and the training of personnel to combat fires. Refer to Chapter 3, Subsection 3.4.1 for a discussion of the Fire Protection design

requirements and features for SSCs for the BWRX-300. Additional discussion of the Fire Protection Program is provided in Chapter 19, Section 19.5.

The fire protection program design addresses protection from fire by demonstrating that a Defence-in-Depth (D-in-D) approach has been implemented. The Fire Protection Assessment ensures implementation of the fire protection program through delivery of supporting documents including a comprehensive design report, code compliance review, a fire hazard assessment, and fire safe shutdown analysis.

The PSAR includes results of an independent third-party review of the design, assessing compliance against the applicable fire codes and standards used in the design for protection from fires and explosions. Refer to Section 9A.6.10 for a discussion of the third-party review.

#### **9A.6.1 System and Equipment Functions**

The FPS performs the following functions during normal and off-normal conditions.

##### **Normal Functions (Non-Safety Category)**

FPS Provides the following safety class functions:

1. Detect and locate fires by fire area or fire zone and actuate alarms promptly (excluding the inerted Primary Containment).
2. Provide automatic and manual fire suppression systems, where required by the Fire Hazard Assessment (FHA) of the BWRX-300 as well as in those areas as defined by other future life safety and fire task analysis.
3. Provide manual backup to automatic fire suppression systems.
4. Limit the spread of fires.
5. Suppress fires which do occur, thereby minimizing the adverse effects of fire on structures, systems, and components important to safety and to production of electricity and economic loss.
6. Ensure that one of the redundant divisions necessary to achieve safe shutdown is free of fire damage.
7. Minimize radioactive or hazardous chemical exposure to personnel and radioactive or hazardous chemical release to the environment as the result of a fire.
8. Provide firewater supply and distribution of firewater to all suppression circuits.

##### **Normal Functions (Safety Category)**

The FPS does not perform any safety class functions.

##### **Off-Normal Functions (Non-Safety Category)**

The FPS continues to perform its functions in off-normal conditions including a Loss-of-Offsite Power (LOOP). Electronic elements of the system have their own batteries or are electrically supplied from the uninterruptible power supply portion of the electrical system (Refer to Chapter 8).

##### **Off-Normal Functions (Safety Category)**

The FPS does not perform any Off-Normal safety category functions.

## **9A.6.2 Safety Design Bases**

### **Fire Protection System Objective**

The BWRX-300 Fire Protection System (FPS) is comprised of an integrated complex of components and equipment provided for detection, notification, annunciation, and suppression of fires.

### **Safety Design Bases**

The FPS does not perform any SC1 or SC2 functions.

### **Power Generation Design Bases**

In accordance with CSA N293, Fire protection for nuclear power plants and N293S1, Supplement No. 1 to N293 (References 9A.6.11-1 and 9A.6.11-7), Fire protection for nuclear power plants (application to small modular reactors) the FPS uses the concept of D-in-D to achieve the required degree of reactor safety by using administrative controls, fire protection systems and features, and safe shutdown capability. These D-in-D principles achieve the following objectives:

- Prevent fires from starting:
  1. And rapidly detect, control, and extinguish promptly those fires that do occur
  2. To provide protection for structures, systems, and components important to safety so that a fire that is not promptly extinguished by the fire suppression activities does not prevent the safe shutdown of the plant and does not significantly increase the risk of radioactive release to the environment.
- Provide timely identification and suppression of fires:
  1. To provide automatic fire detection and annunciation for selected areas of the plant as required by the FHA for personnel safety and fire brigade notification.
  2. To supply the maximum firewater demand at any point throughout the system, with one fire pump out of service.
  3. To maintain the ability to safely shut down the reactor and keep it shut down by providing the capability to control the spread of and extinguish the postulated fires in all plant areas by the use of fixed and/or portable firefighting equipment. This capability is achievable during all modes of plant operation.
  4. To prevent inadvertent operation of the FPS from jeopardizing the capability to achieve safe shutdown of the plant.
  5. To ensure a continuous firewater supply for the fire pumps in the event of failure of one firewater source. Two separate firewater sources are connected to FPS such that there is no interruption in supply and that failure of one water source or its piping does not drain the other sources.
  6. To provide manual suppression capability to all plant areas, including those that have automatic fire suppression systems.
  7. To ensure at least one effective hose stream can reach any location containing SC1 or SC2 equipment, for preventing a fire exposure hazard to the equipment.
  8. To permit isolation from the fire main or outside hydrants for maintenance or repair without interrupting FPS water supply.

- Ensure that the plant can be safely shutdown in the event of a fire:
  1. To maintain the ability to safely shut down the reactor and keep it shut down by providing adequate separation of SC1 or SC2 equipment. This capability is to be achievable during all modes of plant operation.
  2. To minimize the probability of the spread of fire by the use of fire barriers between areas of significant combustible loading.
  3. To maintain the ability to minimize the potential for radioactive releases to the environment in the event of a fire.
  4. To preclude damage to plant SC1 or SC2 structures, systems, or components caused by seismic loading of the FPS.
  5. To keep equipment required for safe shutdown free from fire damage during a Safe Shutdown Earthquake (SSE). To this end, one source of firewater supply, including a water source, two fire pumps and their associated suction and discharge lines; and firewater lines, including standpipes and hose connections, are designed, and analyzed to remain functional after an SSE. This includes analysis to the first isolation valve on all branches connected to the seismically analyzed firewater lines.
  6. To have a useful life of 60 years with normal maintenance and replacement of parts/components subject to normal wear and deterioration.

#### **Fire Protection System Design Codes and Standards**

Mechanical System Codes and Standards utilized for conceptual design are listed in PSAR Chapter 1. A subset of this list addresses relevant FP design codes and standards. The applicable BWRX-300 FP design codes and standards are provided Table 9A.6.2-1.

Chapter 9A, Table 9A.6.2-1 also provides a list of key documents applicable to BWRX-300 FPS design.

A preliminary Code Compliance Review has been performed as part of the FPP development and list the codes and standards required for BWRX-300 FP system design and program development. This document defines code compliance or lists open items, exemptions or alternatives that depart from Canadian codes and standards and how the intent of the requirements is met using equivalent or alternative means.

This Fire Hazard Assessment (FHA) (Reference 9A.6.11-5) establishes and evaluates distinct fire areas for the Reactor Building, Radwaste Building, Turbine Building, Control Building, PLSA and Fire Pump Enclosure for OPG DNNP BWRX-300 plant.

### **9A.6.3 Description**

#### **Fire Safety System Design Objectives**

The primary objectives of BWRX-300 FPS are to minimize both the probability of occurrence and the consequences of fire. To meet these objectives, the FPP is designed to provide reasonable assurance, through D-in-D, that a fire does not prevent the necessary safe shutdown functions from being performed and that radioactive releases to the environment in the event of a fire is minimized.

#### **Development of Fire Protection Performance Criteria and Assessment Metrics**

##### **Nuclear Safety Objectives**

In the event of a fire, the plant is capable of:

- Achieving and maintaining the reactor in subcritical conditions
- Achieving and maintaining decay heat removal
- Maintaining the integrity of the fission product boundaries
- Limiting the release of radioactive materials

### **9A.6.4 Materials**

Noncombustible and heat-resistant materials are used wherever practical throughout the unit, particularly in locations such as the containment and control rooms. Fire detection and firefighting systems of appropriate capacity and capability are provided and designed to minimize the adverse effects of fires on SSCs important to safety. The firefighting systems are designed to ensure that their rupture or inadvertent operation does not significantly impair the safety capability of these SSCs.

### **9A.6.5 Interfaces with Other Equipment or Systems**

#### **Fire Protection System Interdependencies with Other Systems**

Fire Protection interfaces are listed in PSAR Table, System Interfaces (Chapter 9A, Table 9A.6.2-2)

### **9A.6.6 Fire Protection System and Equipment Operation**

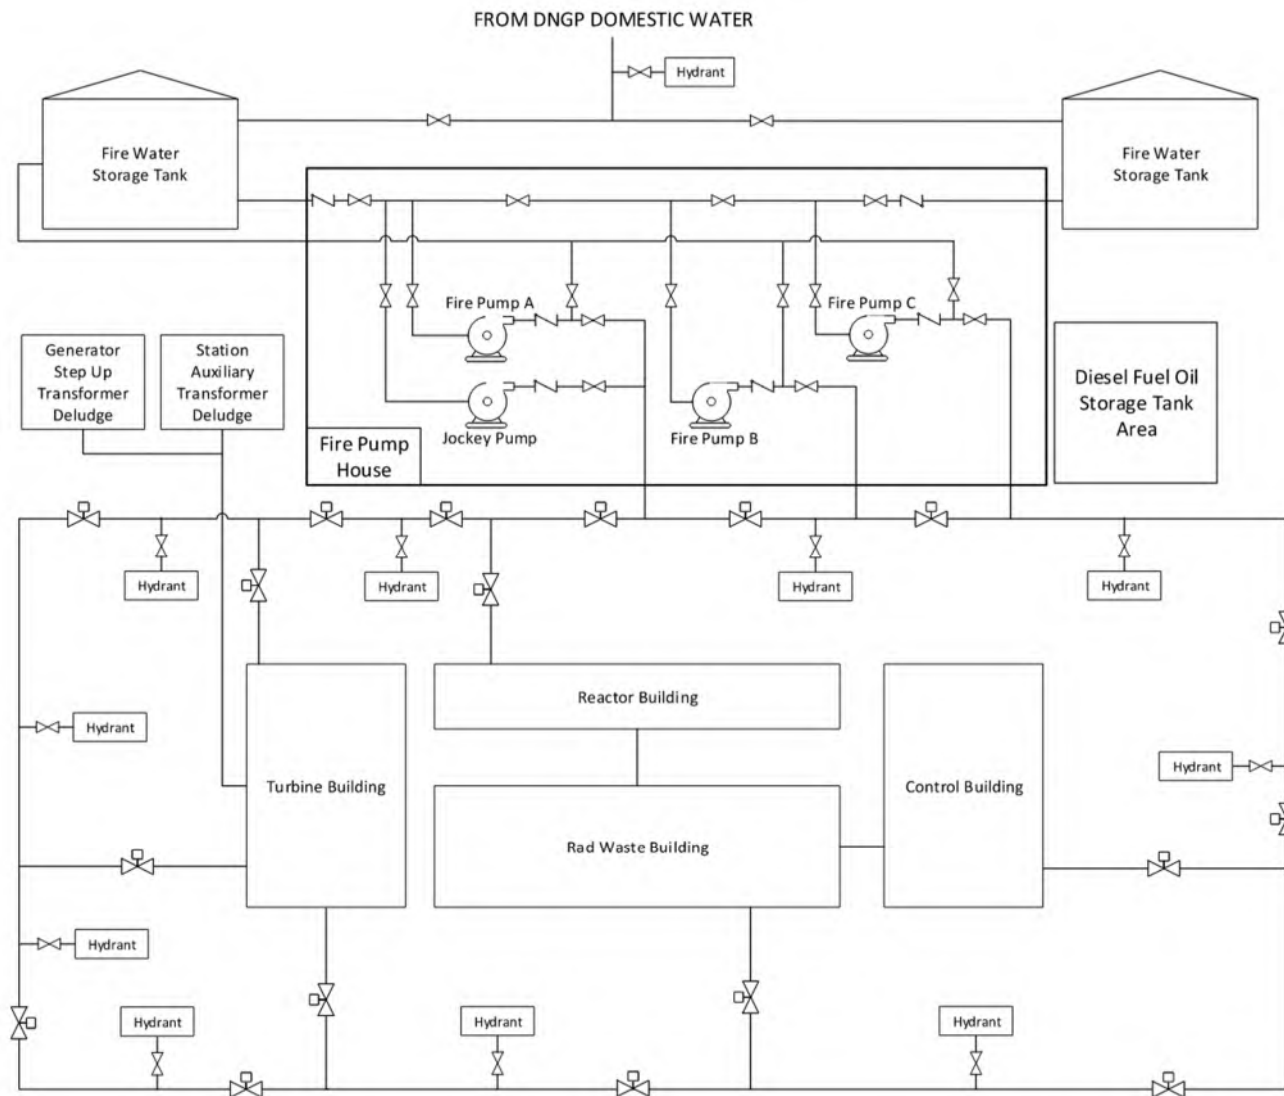

#### **Codes, Standards, and Regulatory Guidance**

Table 9A.6.2-1 lists the codes, standards and guidelines used in the fire protection FPS design.

#### **System Description**

Figure 9A.6.6-1 shows the FPS simplified system diagram for the BWRX-300 Standard Plant facilities. Table 9A.6.2-3 lists the major FPS component design characteristics.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

**Figure 9A.6.6-1: BWRX-300 Fire Protection System Schematic**

The FPS is the integrated complex of equipment and components that provides early fire detection and suppression to limit the spread of fires. The FPS is part of the overall fire protection program including the plant design and layout to prevent or mitigate fires and includes administrative controls and procedures.

The type of fire suppression is based on the combustible loading and the extent of SC1 or SC2 equipment within a fire area. Use of automatic fire suppression is also determined based on life safety requirements defined in NFPA 101, NFPA 804, CSA N293, CSAN293S1, NBCC or NFCC. Fixed automatic fire suppression systems are installed in areas identified as having a high fire hazard rating by the FHA. Building standpipes and hose stations are provided in major buildings. Portable fire extinguishers are strategically located throughout the plant in accordance with NFPA 10, except in highly radioactive areas.

An automatic fire detection, alarm, supervisory control, and indication system is also provided in selected areas of the plant, as required by the FHA for personnel safety and fire brigade notification.

A Main Fire Alarm Panel (MFAP) located in the Main Control Room (MCR), monitors, and receives system actuation, supervisory, and trouble alarm signals from the individual local panels.

### **Facility Feature for Fire Protection**

Consistent with applicable SC1 or SC2 requirements, structures, systems, and components are designed and located to minimize the probability and effect of fires. To the maximum extent practical, noncombustible, and fire-resistant materials minimize the combustible loading and thereby reduce the expected duration, severity, and intensity of fires.

Exposed structural steel protecting areas containing SC1 or SC2 equipment is fireproofed with material with a fire rating of up to three hours as determined from the FHA.

Access stairwells are enclosed in minimum 2-hour rated firewalls and equipped with self-closing fire-rated doors. Openings in fire barriers or firewalls are equipped with fire doors, frames, and hardware rated the same as the barriers they penetrate.

Seismically supported SC1 or SC2 circuits and circuit routing that contain raceways comply with Branch Technical Position (BTP) SPLB 9.5 1, unless justified under the FHA.

A general intent for BWRX-300 fire protection is to avoid the use of electrical raceway fire barrier systems, relying instead on divisional separation by fire area and structural fire barriers.

### **Fire Protection Water Supply System**

Figure 9A.6.2-1 provides a simplified diagram of the firewater supply piping and supply piping for BWRX-300 Standard Plant facilities.

#### **Water Source**

The FPS includes two (2) firewater storage tanks. These tanks are designed in accordance with NFPA 22. These tanks meet NFPA 804/ CSA N293 requirements for the total water demand for a period of 120 minutes. They have a capacity greater than 2,000,000 liters (526,000 gals.) per NFPA 804/ CSA N293.

Physical separation of redundant storage tanks ensures protection against common cause failures such as seismic events and tank rupture. Each tank is equipped with a freeze protection system as necessary based on local climate conditions.

Fire department connections on all major buildings allow a fire department pumper truck to pump water into the FPS as an additional fire protection water supply source.

Freeze protection is provided for the firewater storage tanks and exposed piping.

### **Fire Pumps**

Three fire pumps each provide 60% of the firewater demand to the worst-case fire within the RB, TB, CB, RWB or Facility Annex Building. Fire pumps are capable of delivering the flow and pressure required to the location that is the most hydraulically remote from the firewater supply source. The fire pumps are located in the yard near the firewater storage tanks. Two of the three fire pumps are required to supply sprinklers and standpipe system. There is a combination of electric and diesel-driven fire pumps. The diesel-driven pump is an air-cooled pump with skid-mounted auxiliaries and a gravity-drain fuel oil supply.

There is a total of three (3) firewater pumps being either electric or diesel. Per CSA N293 (Reference 9A.6.11-1), where more than two pumps are provided, and the largest pump is unavailable for service, then the remaining pumps combined should be capable of providing at least 120% of the necessary, designed flow rate. The designed flow rate is to be based on the scenario of a Turbine fire, which has been determined to be the bounding worst-case fire within the Power Block. Any combination of 2 of the 3 pumps is able to achieve 120% of the needed design flow rate. All fire pumps are capable of delivering the flow and pressure required to the location that has the most limiting combination of distance, line size and/or flow rate. Firewater pumps and accessory components comply with the requirements of NFPA 20. Diesel engines comply with NFPA 20.

An electric fire pump is to be located in the fire-rated firewater pump enclosure (FPE), adjacent to the firewater storage tank and near the power block. The FPE is mounted on a separate foundation. A diesel-driven fire pump is to be located in a fire-rated structure. All pumps are separated by a 3-hour fire-rated fire barrier. Diesel-driven fire pump(s) provide(s) firewater in the event of failure of any electrically driven fire pump or LOOP.

Fire barriers between the fire pumps and their associated equipment as necessary to prevent common cause failures. The diesel-driven fire pump provides firewater in the event of failure of the electrically driven fire pump of the same load group.

The fuel oil day tank for a diesel-driven fire pump is designed in accordance with NFPA 20 and have a capacity sufficient to allow operation of the diesel engine for a minimum of 8 hours before refilling based on fuel consumption at rated pump capacity.

The fuel oil day tank(s) are/is included for the diesel-driven fire pump(s). The fuel oil day tank(s) for the diesel-driven fire pump(s) are/is designed in accordance with NFPA 20 and has a capacity sufficient to allow operation of the diesel engine(s) for a minimum of 8 hours before refilling based on fuel consumption at rated pump capacity. Diesel-driven fire pumps contain chillers that function passively during operation of the pumps.

For a fire within the protected area, an electric pump is designed to start first followed by a second pump, if the first pump fails to start or extra capacity is needed. The third fire pump is designed to start in the event of a failure in either of the other two pumps. Any fire pump may be started manually from the Main Fire Alarm Panel in the control building control room (MCR), from the secondary control room (SCR), or locally. All fire pumps can only be stopped manually.

The associated pressure maintenance (jockey) pump is used to maintain pressure in the system at all times.

Remote signals of fire pump status are provided in the MCR and SCR in accordance with NFPA 20.

The diesel-driven fire pump meets the emissions requirements for the year they are manufactured per NFPA 20.

The non-safety power Distribution System provides power to the motor-driven fire pumps, booster pumps, and jockey pumps. The pumps are powered by the controllers.

### **Firewater Supply Piping, Yard Piping, Valves, Sprinklers, and Yard Hydrants**

Figure 9A.6.6-1 provides a simplified diagram of the firewater supply piping and supply piping for BWRX-300 Standard Plant.

The fire water supply piping consists of a buried yard main loop that feeds supplemental loops in the power block. Check valves are provided between each building connection from the main yard piping loop.

The reactor building piping consists of welded carbon steel piping in accordance with ASME B31.1. The yard main consists of buried Class 200 high-density polyethylene (HDPE) piping or other code compliant pipe material, FM approved for fire main service, in accordance with NFPA 24. Other piping located in buildings consist of carbon steel piping in accordance with NFPA 13, 14 and 15.

The sprinkler systems are designed and installed to meet the requirements of NFPA 13. The deluge systems are designed and installed to meet the requirements of NFPA 15 and/or NFPA 16. Fuel tank foundations and supports meet NFPA 30. Foam injection systems, if installed, are provided to inject foam concentrate into the fire protection water of a foam-water system for distribution over areas protected by foam-water. Foam injection systems are designed in accordance with NFPA 11. Additionally, fixed suppression piping located within the power block is designed and installed in accordance with ASME B31.1. The systems are designed so that an SSE does not cause failures which could impair the functionality of nearby safety class and safe shutdown related structures, systems, and components. Isolation valves which, if closed, would prevent fixed suppression system operation, have tamper switches to monitor their normal position as required by NFPA 13/CSA N293. Isolation valves that control only water supplies to a fire hydrant are post indicating valves and may be locked open in lieu of fire alarm supervision to satisfy CSA N293 (Reference 9A.6.11-1). Fixed suppression systems have provisions to properly drain all parts of the systems. Clean Agent Fire Extinguishing Systems that meet the requirements of NFPA 2001 may be used in addition to the sprinkler-based systems noted below or in areas where sprinkler-based systems are not required per NFPA 804/CSA N293 Fire suppression protection for Canadian BWRX-300 plants meet the provisions given under CSAN293 (Reference 9A.6.11-1).

Standpipes and hose connections in the reactor building are designed to maintain pressure integrity and operability following an SSE in accordance with NFPA 14 and CSA N293. The piping in these areas is designed and installed in accordance with ASME B31.1. Standpipe sizes are at least 150 mm (6 inch) if the building height exceeds 30.5 metres (100 feet). Standpipe sizes for other buildings are at least 100 mm (4 inch) however designed to perform per CSA N293 and NFPA 14 requirements. Drain valves are provided at the bottom of each standpipe to allow for drainage. Fire hoses and accessories are provided in accordance with CSA N293 (Reference 9A.6.11-1) and the FHA. Each hose station has a 65 mm (2-1/2 inch) hose valve with cap rooms and inside entrances for normally occupied rooms.

Fire hydrants located at approximately 75 m (250 ft) intervals along the yard main loop provide firefighting capability, especially in the vicinity of buildings or structures containing combustible materials. The fire hydrants are located no closer than 12.2m (40 ft) from the buildings and structures protected by the hydrants.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

All yard fire main piping is designed and installed to NFPA 24. Fire hydrants are designed and installed to comply with NFPA 24, NFPA 804, and local fire department requirements.

Fire hydrants are protected against freezing and damage from vehicles.

### **Manual Suppression Means**

Manual fire suppression means are provided for all plant areas. The sprinkler systems and the hose station standpipes have separate connections to the firewater main; therefore, no single failure can impair both systems.

### **Standpipe and Hose Systems**

Standpipe and hose stations are provided in all major buildings. Standpipes in areas adjacent to stairways and other locations provide sufficient hose coverage.

The wet standpipes and hose stations are designed to NFPA 14 Class III Service.

Areas containing equipment required for safe shutdown, standpipes and hose connections for manual firefighting remain functional following an SSE. Provisions are made to supply water to at least two standpipes and hose connections for manual firefighting in areas containing equipment required for safe plant shutdown in the event of an SSE. The piping system serving such hose stations is analyzed for SSE loading and is provided with supports to ensure system pressure integrity. The piping and valves for the portion of the hose standpipe system affected by this functional requirement, as a minimum, satisfy ASME B31.1 Requirements.

All rooms within the plant buildings are within the reach of at least one effective hose stream from a Class III hose station unless evaluated as acceptable under the FHA. Effective hose streams from two separate hose stations cover each room that contains equipment required for safe shutdown that is not protected by a fixed fire suppression system. The need for two-hose-station coverage is also based upon the fire hazard present. Rooms not covered by a fixed fire suppression system and with coverage by only one hose station are furnished with portable fire extinguishers for secondary coverage.

Hose stations also provide secondary coverage for fixed suppression systems.

Hose stations are located outside of highly radioactive areas where possible; however, hose stations are located such that any location that contains or could present a hazard to SC1 or SC2 equipment can be reached by at least one effective hose stream 30.5 metres (100 feet) with a maximum of 30.5 metres (100 feet) of hose.

Standpipes and hose stations external to containment and portable extinguishers provide protection during refueling and maintenance operations. Hose stations are located such that any location within containment can be reached by two effective hose streams with a maximum of 30.5 metres (100 feet) of hose.

Fixed fog hose nozzles protecting high-voltage electrical equipment rooms preclude electrical shock hazards with shutoff capability isolation valves. Adjustable fog and straight stream nozzles are provided for all hose stations located away from high-voltage electrical equipment.

### **Fire Extinguishers**

Portable fire extinguishers for manually extinguishing fires are strategically placed throughout the plant in accordance with NFPA 10 and NBCC, except in highly radioactive areas. Portable fire extinguishers are readily available outside the highly radioactive areas, so that they can be accessible when needed.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

Portable Class ABC multipurpose dry chemical-type fire extinguishers are provided for all general hazard areas throughout the buildings in the plant.

Portable Carbon Dioxide Class B, C fire extinguishers are provided for electrical areas.

Special use portable fire extinguishers are provided based upon the hazard present (e.g. – Class D fire extinguishers for a Hot Machine Shop).

### **Water Spray for Charcoal Filters**

Water spray systems are provided for the fire protection of charcoal filters in the HVS, and offgas systems as required. The water is supplied to the filters by means of a fixed piping network extending to a valve station near the exterior of the protected equipment (with manual shutoff valves) and then to open sprinklers or nozzles in the filter enclosure. Drainage is provided for the enclosure.

### **Fixed Automatic Water Extinguishing Systems**

The selection of specific types of fire suppression systems and the areas requiring protection are based on equipment arrangements and combustible loading in each fire area.

Sprinkler piping for areas containing SC1 or SC2 equipment meets the requirements of NFPA 13 (assurance that any failure of FPS piping caused by an earthquake does not damage a SC1 or SC2 item).

Fixed automatic fire suppression systems are provided in all areas identified as having a high fire hazard rating where the combustible loading exceeds 700 MJ/m<sup>2</sup> for non-electrical areas or 1400 MJ/m<sup>2</sup> for electrical equipment areas or elsewhere as required by the FHA.

### **Wet Pipe Sprinkler System**

Automatic sprinklers provide protection for the areas identified in the FHA, except where conditions dictate the use of other types of systems or fire suppression agents.

Each wet pipe sprinkler system consists of an alarm check valve, thermally actuated closed-head sprinklers, and attached piping network containing water under pressure. Water discharges immediately from sprinklers opened by heat from a fire. The wet pipe sprinkler system meets the requirements of NFPA 13.

### **Precision Sprinkler System (Manual or Automatic)**

Precision sprinkler systems are provided for plant areas where it is necessary to prevent serious water damage to equipment or contents that could occur with other sprinkler systems as a result of leaking automatic sprinkler heads, pipe breaks, or inadvertent actuation. Each precision sprinkler system consists of a deluge valve, means to contain precision air (such as a precision check valve), thermally actuated closed-head sprinklers or spray nozzles, and attached piping containing air under pressure (the air pressure serves to monitor the integrity of the piping and provides a supervisory alarm in the event of trouble). Fire detectors are installed in the same room as the sprinklers.

### **Deluge System (Manual and/or Automatic)**

Deluge systems are provided in high fire hazard areas where required by the system design, such as transformers. Deluge systems apply water or foam-water solutions immediately over the entire hazard. Foam-water solutions may be used for areas that contain Class II combustible liquids (such as fuel oil) or flammable liquids (except diesel-driven fire pumps). Each deluge system consists of a deluge valve, open-head sprinklers or nozzles, and a dry piping network which is connected to the firewater supply. Fire detectors are installed to monitor the protected equipment or be in the same room as the nozzles and activate the system.

### **Foam System (As Required)**

A foam system is provided for concentrated fuel oil or lube oil hazards.

Fire detectors are used for fire detection that actuates precision foam-water sprinkler or deluge foam-water spray systems to protect against inadvertent actuation.

A foam hose rack is located outside each diesel generator area for manual fire protection. Each foam hose rack consists of a foam playpipe, hose, and rack. Foam hose racks are designed in accordance with NFPA 14.

A foam hose rack is located outside each diesel-driven fire pumps enclosure area for manual fire protection. Each foam hose rack consists of a foam playpipe, hose, and rack. Foam hose racks are designed in accordance with NFPA 14.

A foam hose rack is located outside the turbine lube oil skid for manual fire protection. Each foam hose rack consists of a foam playpipe, hose, and rack. Foam hose racks are designed in accordance with NFPA 14.

### **Fire Detection and Fire Alarm System**

The fire alarm system is to provide a two-stage operation, as follows: (a) first stage — an alert signal, and (b) second stage — an alarm signal. The alert signal is directed to MCR staff and may remain silent throughout the balance of the building to suit the requirements of the plant's emergency notification procedures. On receipt of an alert signal, MCR staff has the capability to immediately provide a voice announcement over the fire alarm system, throughout the protected

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

area and external areas of the BWRX-300 plant with the exception of the main and secondary control rooms. The alarm signal is activated automatically in the event that MCR staff do not acknowledge the signal within 5 min of initial fire alarm system activation. The alarm signal is supplemented by voice announcements. There is essentially no delay in the ability to override the alarm signal and operate voice communication functions. This fire alarm and voice communication systems with integrated, supervised, one-way voice communications is provided in all structures and exterior areas within the protected area, as well as structures and areas external to the protected area where SSCs directly support the plant. Fire and voice signals are to be distinctive and not easily confused with other alarm signals. Accessible spaces, with the exception of the main and secondary control rooms, are to be equipped with audible and/or visual fire alarm signal devices. Design, installation, and inspection of the fire alarm system comply with CAN/ULC-S524 and CAN/ULC-S537.

Fire detectors for very early warning and annunciation of fire conditions are separate from fire detection and releasing devices for suppression system actuation. The fire detection system is electrically supervised to detect circuit breaks, ground faults, and power failure.

Deluge and preaction fire detection systems have a 90-hour (minimum) backup battery packs (with 10 minutes of alarm) located at the local fire control panel (releasing panels). The remainder of the fire detection and alarm system has a 24-hour (minimum) backup battery packs (with 5 minutes of alarm) located at each local fire control panel (supervisory panels) and at the MFAP. Immediately following this 24-hour period, emergency battery power under full load is available for not less than 2 hours. Primary power is provided from the plant Uninterruptible AC Power Supply.

Manual fire alarm stations (pull box stations) are located at all exits as required by the NBCC. Where the 60-metre (200-feet) exit rule is used, manual fire alarm stations are located along each main aisle so that the maximum travel distance from the aisle to the manual fire alarm station is not more than 30 metres (100 feet) for areas without sprinklers and not more than 45 metres (150 ft) in areas with sprinklers throughout all normally occupied buildings to meet CSA N293 (Reference 9A.6.11-1). Visible fire notification is provided in manned office areas and other areas of the plant where reasonable.

Smoke detection in ventilation systems is provided to meet NFPA 90A/92A requirements. Smoke detection for elevator equipment is provided to meet ASME A17.1/CSA B44 requirements.

Primary Containment is inerted during normal operation. Portable detection equipment and fire watches, as required, are used inside containment during maintenance outages when the space is not inerted.

Manual fire alarm stations (pull box stations) are provided at the normal exit paths or every 61 metres (200 feet), whichever is less, throughout normally occupied buildings. Manual fire alarm stations (pull box stations) are provided at exit paths only for unoccupied buildings. Visible fire notification is provided in manned office areas such as in the CB and the Plant Service Area.

### **Fire Barriers**

Fire barriers of three-hour fire resistance rating are provided separating:

SC1 or SC2 systems from any potential fires in SC3 areas that could affect the ability of SC1 or SC2 systems to perform their safety function.

Redundant divisions or trains of SC1 or SC2 systems from each other to prevent damage that could adversely affect a safe shutdown function from a single fire.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

Components within a single SC1 or SC2 electrical division that present a fire hazard to components in another SC1 or SC2 division.

Electrical circuits (SC1, SC2 and SC3) whose fire-induced failure could cause a spurious actuation that could adversely affect a safe shutdown function.

Penetrations through fire barriers are sealed or closed to provide fire resistance ratings at least equal to that of the barrier. Only noncombustible materials qualified per CAN/ULC-S102 are used for construction of fire barriers. Fire dampers protect ventilation duct openings in fire barriers as required by CSA N293 (Reference 9A.6.11-1) and CSA N293S1 (Reference 9A.6.11-7).

Design features that prevent or mitigate spurious actuations include:

The FPS is part of the overall plant Fire Protection Program, which ensures the safety of personnel/public, the protection of property/environment, and the continuity of electric power production. In addition to the FPS equipment and components, the Fire Protection Program (FPP) includes combustible inventory control, divisional separation, plant layout and equipment location considerations, fire barriers, training, and administrative controls. The overall Fire Protection Program provides assurance, through defense in depth, that the plant can achieve and maintain a safe shutdown condition in the event of a fire and that radioactive releases to the environment in the event of a fire are minimized.

The Fire Safe Shutdown Analysis (9A.6.11-5) considers multiple hot shorts for safe shutdown equipment that has hard wires for its power or control circuits that could cause equipment to either actuate or not actuate which could result in the equipment not being able to be placed in its safe shutdown position. Hard wires that are in conduit do not have to consider hot shorts from conductors/cables that are outside of the conduit. Hard wires in cabinets/panels that are in wire bundles are considered for hot shorts. CSA N293 / N293S1 separation criteria such as three-hour fire barrier separation between redundant success paths is considered in the safe-shutdown circuit analysis.

The Fire Safe Shutdown Analysis uses a deterministic analysis approach for the safe-shutdown circuit analysis and, therefore, does not use any performance-based approach like fire modeling that considers the location of cables and equipment.

### **Building Ventilation**

Fire protection/smoke control provisions for ventilation for the various building areas are designed as follows:

The Plantwide HVS removes smoke from fire areas. Duct mounted smoke detectors transmit an alarm signal to the local fire control panel upon detection of smoke.

FPS provides fire suppression for the Secondary Control Room (SCR) Makeup AHU filters, annunciation and isolation of Main Control Room (MCR) and Secondary Control Room (SCR) ventilation under fire, smoke purge mode for U41 systems, and interfaces for down-powering ventilation fans from Fire Alarm Panels. The Turbine Building, Reactor Building, Radwaste Building, Control Building and Facility Annex Building are provided with pressurized stairwells to create smoke free egress routes in the event of a fire.

Safe egress and safe smoke refuge areas during a fire incident are provided in accordance with CSA N293 / N293S1 (References 9A.6.11-1 and 9A.6.11-7), NBCC and NFCC guidelines for building occupants and the fire brigade. The Turbine, Reactor, Radwaste Control and Plant Service Area Buildings are provided with pressurized stairwells, in accordance with NFPA 101 and CSA N293 / N293S1 Guidelines are utilized for the design and labeling of safe egress routes.

Smoke removal meets CSA N293 / N293S1 requirements. Automatic sprinkler protection is provided as directed by the FHA for the high-density cable tunnels, fuel oil tank rooms, diesel generator rooms, and a significant portion of the Turbine Building to limit heat and smoke generation.

Procedures for manual smoke control by manual actions of the fire brigade for all plant areas are in accordance with CSA N293 / N293S1 guidelines.

#### **9A.6.7 Instrumentation and Control**

The Fire Protection System (FPS) provides detection, suppression and notification of smoke and fire incidents within the power block and supporting facilities of the BWRX-300.

Each fire suppression system automatically actuated by a fire detection system has the control logic and the capability for manual actuation available at the local fire panel for the protected room. Automatic sprinkler systems which do not require separate detection systems for actuation are generally not equipped with manual actuation means. All instrumentation for fire detection or automatically actuated fire suppression systems is either FM Approved or UL Listed or both.

There are three primary types of FPS instrumentation: instrumentation supporting fire detection, instrumentation supporting automatic suppression systems, and instrumentation supporting firewater delivery.

Instrumentation for the fire detection system provides early detection and warning alarms of fires. Each room containing safety-related equipment has a fire detection system comprised of multiple detectors. Heat and smoke detectors are supervised by local fire panels per NFPA 72/CSA N293 / N293S1 guidelines. The local panels are in turn be connected to the MFAP via a dedicated FPS data link. Signals transmitted include detector status (normal, alarm, supervisory, trouble) as well as local fire panel status. A complete listing of fire detector selection by fire area and/or room number is found in the FHA.

Instrumentation for fixed fire suppression systems provide local and remote monitoring capability for the suppression system status. Alarm check valves are used to indicate that a sprinkler head has opened for wet-pipe sprinkler systems. Pressure/flow sensors are also be used to provide local and remote indication of wet-pipe sprinkler systems. High and low pressure sensors monitor the instrument air pressure in preaction sprinkler systems. High pressure sensors monitor the system pressures downstream of deluge valves. Pressure and level sensors are used for remote and local monitoring of the foam injection systems status. All instruments for automatic suppression systems are wired to the local fire panels for control.

Instrumentation supporting firewater delivery provides status indication of firewater tank level, firewater main pressure, jockey pump status, and main fire pump status conditions.

The MFAP is directly connected to the MCR panels to display common fire alarm, supervisory, and trouble conditions.

The safety class 2 and 3 distributed control and instrumentation system provides HVS system shutdown interfaces from the local fire panels, upon fire detection within HVS ductwork where required by end equipment safety classification.

The non-safety class distributed control and instrumentation system provides HVS system shutdown interfaces from the local fire panels, upon fire detection within HVS ductwork, for equipment not supported by the C20 system.

### **9A.6.8 Monitoring, Inspection, Testing, and Maintenance**

#### **Monitoring**

The FPS is monitored to continue to meet Canadian and NFPA requirements during all modes of construction, operation, and decommissioning.

#### **Inspection**

The FPS is periodically inspected to continue to meet Canadian and NFPA requirements during all modes of construction, operation, and decommissioning.

#### **Testing and Maintenance**

The FPS is maintained as necessary to continue to meet Canadian and NFPA requirements during all modes of construction, operation, and decommissioning.

The following NFPA tests, which are required by code, are performed as a minimum part of the inspection and maintenance requirements for the system:

- a. Waterflow alarm tests of sprinkler systems – NFPA 25
- b. Foam concentration tests, as required – NFPA 25
- c. Deluge waterflow alarm and operational tests – NFPA 25
- d. Foam injection system tests, as required – NFPA 25
- e. Fire detection and alarm system tests – NFPA 72/ CAN/ULC-S537
- f. Smoke removal system/fire damper/smoke dampers – NFPA 92A
- g. Flow testing of fire pumps – NFPA 25

#### **Temporary Configurations**

Temporary configurations controlled by plant procedures.

#### **Required Surveillances**

There are no Technical Specification surveillances required for fire protection.

#### **Maintenance**

The equipment and components of the FPS are designed for easy inspection and maintenance during plant operation. System and equipment manuals are supplied that provide instructions and procedures for installation, operation, and maintenance, and include identification of recommended tools and spare parts.

##### **9A.6.8.1 Post-Maintenance Testing**

Post maintenance testing is controlled by plant procedures.

##### **9A.6.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are As Low As Reasonably Achievable (ALARA) in operational states.

##### **9A.6.10 Performance and Safety Evaluation**

The Fire Protection System does not perform a Safety Category function. The Fire Protection system is sufficiently separated and/or isolated from Safety Category function SSC to preclude

the possibility of a failure in the FPS from impacting the ability of a Safety Category function SSC from performing its Safety Category function. A failure of the FPS cannot initiate an event more severe than has been considered in the safety analyses and cannot degrade the operation of Safety Category function systems.

### **Nuclear Safety Performance**

**Reactor shutdown** - Means are provided to rapidly insert negative reactivity into the reactor core to achieve and maintain subcritical conditions and ensure fuel design limits are not exceeded.

**Decay heat removal** - Means are provided to ensure that fuel is in a safe and stable condition, through the maintenance of sufficient coolant levels and the removal of decay heat from the reactor.

**Barrier to fission product release** – Means are provided to ensure that nuclear reactor systems that contain radioactive materials or fission products, including the reactor coolant system and reactor auxiliary systems, are not breached. There is no leakage of coolant beyond the capability of the pressure and inventory makeup system.

**Support services** – Means for supply the necessary power, water, compressed air, and other support functions is provided to ensure that the above criteria are met.

### **Nuclear Safety Assessment Metrics**

1. Protect the operability of the success path to fire safe shutdown for systems and subsystems, including components and cables, of the fire safe shutdown systems that together are sufficient to meet the nuclear safety performance criteria.
2. Meet the criteria under National Building Code of Canada (NBCC) and National Fire code of Canada (NFCC) for fire barrier, detection, suppression systems and maintain criteria in FHA for areas containing radioactive materials.

### **Life Safety Objectives**

The following life safety performance objectives are met during all operational modes and plant configurations:

1. Fire hazard controls are included in design and operational stages
2. Fire notification means are provided
3. Safe egress and/or areas of refuge are provided to occupants for use in the event of a fire
4. A safe environment and other required supports are provided for essential staff so that they can perform all necessary plant control functions during and following a fire
5. Protection for personnel performing emergency services are provided both during and following a fire
6. Access and emergency lighting is provided for all areas where manual firefighting, evacuations, or operator field actions are expected

### **Life Safety Criteria**

The life safety objectives are met using either the prescriptive requirements or performance-based criteria outlined in the NBCC and NFCC.

### **Life Safety Assessment Metrics**

Life Safety Assessment Metrics are met with the criteria under the prescriptive requirements or performance-based criteria outlined in the NBCC and NFCC.

### **Fire Protection Critical Design Features**

Fire protection systems and practices, and design features to prevent the spread of fires in the BWRX-300, are provided for assurance of safe shutdown capability, prevention of radioactive release to the public, personnel safety, investment protection, and plant availability. These design features include all the following:

1. Noncombustible and heat-resistant materials are used wherever practical throughout the unit.
2. Fire barriers that are rated by approved laboratories in hours of resistance to fire and are used to prevent the spread of fire.
3. SSC important to safety are designed and located to minimize the probability and effect of fires and explosions. The concept of compartmentalization uses passive fire barriers to subdivide the plant into separate areas or to confine the effects of fires to a single compartment or area minimizing the potential for adverse effects from fires on redundant SSC important to safety.
4. The BWRX-300 safety assessment demonstrates that an adequate level of safety is achieved by the design and it can be used to satisfy the CNSC safety objectives. This assessment is also used to determine whether region or province specific design changes are needed. One key safety objective established for the BWRX-300 is the implementation of an explicitly defined D-in-D concept to ensure multiple, independent layers of protection against radiation releases outside the bounds of regulatory limits. As such, the BWRX-300 safety assessment includes an approach to deterministic safety analysis involving layered analyses that correspond to levels of defence.
5. Considering the consequences of a fire in a given fire area during the evaluation of the safe shutdown capabilities of the plant, the BWRX-300 design demonstrates that one success path of SSC that can be used to bring the reactor to hot shutdown or hot-standby conditions remains free of fire damage.
6. The BWRX-300 design layout provides adequate means of access to all plant areas for manual fire suppression. The plant layout allows for safe access and egress to areas for personnel performing safe shutdown operations. Considerations include fire and post-fire habitability in safe shutdown areas, protection or separation from fire conditions of access and egress pathways to safe shutdown SSC, and potential restrictions or delays to safe shutdown area access potentially caused by security locking systems.
7. Systems containing flammable or combustible liquids are designed to minimize leakage of these liquids. In locations where an uncontrolled leakage of the liquid could jeopardize fire safe shutdown systems, the design provides devices to collect, divert, and safely contain leakages from pressurized and non-pressurized components in order to prevent ignition or limit the size of fire and achieve fire safe shutdown.
8. Suitable design of the ventilation systems limit the consequences of a fire by preventing the spread of the products of combustion to other fire areas. Means are provided to ventilate, exhaust, or isolate the fire area as required with consideration

given to the consequences of ventilation system failure caused by the fire, resulting in a loss of control for ventilating, exhausting, or isolating a given fire area.

Refer to Chapter 3, Section 3.5 for additional discussion of Fire Protection Design Features for the BWRX-300 SSCs.

### **Models Used for Design Decisions and Activities**

#### **Deterministic Fire Model**

The BWRX-300 FPA complies with the FPA described in CSA N293, Fire Protection for NPPs [Reference 9A.6.11-1] and CSA N293S1, Supplement No. 1 to N293, Fire Protection for Nuclear Power Plants (application to small modular reactors) [Reference 9A.6.11-7] and takes a deterministic approach that when combustible material is present, a fire is postulated and damage to a Safety Class SSC assessed. As described in CNSC REGDOC-2.4.1, Deterministic Safety Analysis [Reference 9A.6.11-2], deterministic safety analysis methods can be applied to a wide range of plant operating modes and events, including normal operation and abnormal operation resulting from equipment failure, operator errors and challenges arising from events like fires, floods, or earthquakes.

#### **Probabilistic Fire Model**

The BWRX-300 Internal Fires Probabilistic Safety Assessment (IFPSA) is performed using the current information available from the BWRX-300 plant design and procedures, meeting Requirement 4.3 of CNSC REGDOC-2.4.2 [Reference 9A.6.11-4]. Periodic update of the Probabilistic Safety Assessments (PSA) (Requirement 4.4 of REGDOC 2.4.2 [Reference 9A.6.11-4]) will be performed after the plant begins operation.

Probabilistic FP models are also applied to the BWRX-300 design.

These assessments are used in most cases to supplement a deterministic FPA and provide valuable insights into plant design and operation, including the identification of dominant risk contributors, comparison of the options for risk reduction, and consideration of the cost versus risk and benefit analysis.

Fire PSA does not necessarily address compliance with the FP Codes, Standards, and Regulations.

Guidelines for the preparation and regulatory review of PSAs are available in documents such as NFPA 805 and IAEA Safety Report Series No. 10, "Treatment of Internal Fires in Probabilistic Safety Assessment."

#### **Development of Fire Protection Program**

The BWRX-300 FPP is developed and implemented in a coordinated manner that considers the various fire protection activities of different engineering disciplines, functional groups, and other organizations.

The BWRX-300 FPP details how the program is implemented, managed, monitored, and modified during each phase of the life cycle of a plant. Activities specified in the FPP for each phase is discussed in PSAR Chapters 3 and 19.

#### **Methodology for Fire Hazard Assessment**

The BWRX-300 design utilizes the methodology described in CSA N293 [Reference 9A.6.11-1] for the development of the BWRX-300 Fire Hazard Assessment (FHA). This methodology is illustrated in Figure 9A.6.10-1, BWRX-300 Fire Hazard Assessment Methodology.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

The FHA objective is to identify the specific fire hazards and fire protection capabilities in each area of the plant to demonstrate that potential damage is limited by various active and passive fire protection measures, such that the fire protection goals are achieved.

The FHA addresses all plant building areas and outdoor areas with equipment or storage. The FHA address the goals of nuclear safety, life safety, and impact to the environment. The FHA could also address the goal of minimizing economic loss.

There are specific cases of SSC that are exceptions to the application of CSA N293, classified as two types of exceptions. SSC located outside of the PA and directly support the nuclear facility are included in the scope of CSA N293, and SSCs located inside of the PA that have no nuclear safety concerns and do not directly support the nuclear facility are excluded from the scope of CSA N293.

The content of the BWRX-300 FHA includes the following elements and attributes:

The applicability of CSA and CNSC FP requirements and guidance are evaluated.

1. In situ and potential transient fire and explosion hazards, including amounts, types, configurations, and locations of flammable and combustible materials (e.g., electric cable insulation and jacketing material, lube oil, diesel fuel oil, flammable gases, chemicals, building materials and finishes) associated with operations, maintenance, and refueling activities are identified. The continuity of combustible materials (e.g., exposed electrical cables that span the distance between redundant trains), the potential for fire spread, and sources of ignition are identified and described in the analysis.
2. External exposure hazards (e.g., flammable and combustible liquid or gas storage, adjacent industrial facilities or transportation systems, natural vegetation, and adjacent plant support facilities) that could potentially expose SSC important to safety to damage from the effects (e.g., heat, flame, smoke) of fires are identified.
3. The design, installation, operation, testing, and maintenance of automatic fire detection and suppression capabilities is addressed. The FHA describes the level of automatic protection (e.g., water spray density, gaseous agent concentration) provided relative to the specific fire hazards that are identified.
4. The layout and configurations of SSC important to safety are depicted. The protection for safe shutdown systems within a fire area are determined on the basis of the worst-case fire that is likely to occur and the resulting damage. The FHA explains and documents the extent of such damage. The analysis considers the degree of spatial separation between redundant shutdown systems, the presence of in situ and transient combustibles, the available FP systems and features, sources of ignition, and the susceptibility to fire damage of the cables, equipment, systems, and features in the area that are related to safe shutdown.
5. Reliance on and qualifications of fire barriers, including fire test results, the quality of the materials and barrier system, and the quality of the barrier installation is described.
6. Fire area construction (walls, floor, and ceiling materials, including coatings and thicknesses; fireproofing of structural members; area dimensions and volume; normal ventilation and smoke removal capability; and level of congestion as it applies to access for manual firefighting activities) is described. The FHA provides sufficient information to determine that fire areas are properly selected, based on the fire hazards present and the need for separation of SSC important to safety.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

7. Manual fire suppression capability, including systems (e.g., hydrants, standpipes, extinguishers), fire brigades, manual firefighting equipment, plans and procedures, training, drills, mutual aid, and accessibility of plant areas for manual firefighting are identified. The FHA lists the location and type of manual firefighting equipment and accessibility for manual firefighting.

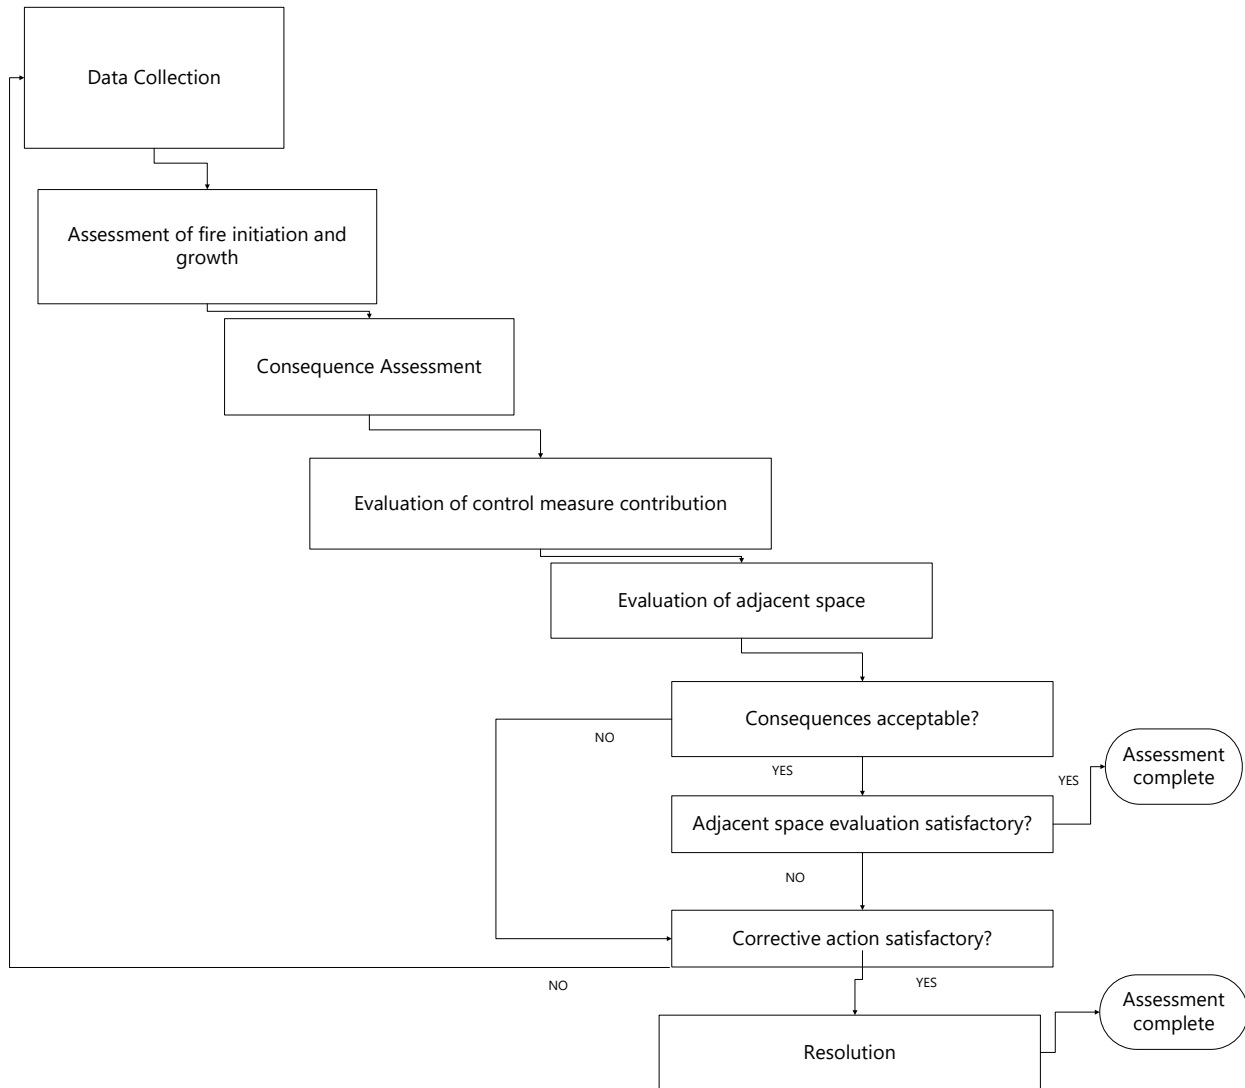

Potential fire impacts on operations are identified, including the following:

1. Fire in control rooms or other locations where operations important to safety are performed
2. Fire conditions that may necessitate evacuation from areas that are required to be attended for safe shutdown, and
3. Lack of adequate access or smoke removal facilities that impede plant operations or fire extinguishment in plant areas important to safety
4. Potential disabling effects of fire suppression systems on safe shutdown capability are identified, including damage to equipment from the normal or inadvertent operation of fire suppression systems. The FHA addresses the effects of firefighting activities.
5. Explosion-prevention measures in areas subject to potentially explosive environments from flammable gases or other potentially energetic sources (e.g., chemical treatment systems, ion exchange columns, high-voltage electrical equipment) are listed.
6. The availability of oxygen (e.g., inerted containment) is identified
7. Alternative or dedicated shutdown capability for those fire areas where adequate separation of redundant safe shutdown systems cannot be achieved is identified.
8. The analysis assumes fire initiation at the location within each fire area or zone that produces the most severe fire with the potential to adversely affect SSC important to safety. Fire development considers the potential for involvement of other combustibles, both fixed and transient, in the fire area. Where automatic suppression systems are installed, the analysis evaluates the effects of the assumed fire, with and without actuation of the automatic suppression system.

The FHA separately identifies hazards and provides appropriate protection in locations where losses of SSC important to safety can occur as a result of the following:

1. Concentrations of combustible contents, including transient fire hazards of combustibles expected to be used in normal operations, such as refueling, maintenance, and modifications
2. Continuity of combustible contents, furnishings, building materials, or combinations thereof in configurations conducive to fire spread
3. Exposure to fire, heat, smoke, or water, including those that may necessitate evacuation from areas that are required to be staffed for safe shutdown
4. Fire in control rooms or other locations having critical functions important to safety
5. Lack of adequate access or smoke removal facilities that impeded plant operations or fire extinguishment in plant areas important to safety
6. Lack of explosion-prevention measures
7. Loss of electric power or control and instrumentation circuits

8. Inadvertent operation of fire suppression systems

**Figure 9A.6.10-1: BWRX-300 Fire Hazard Assessment Methodology**

### **Methodology for Fire Safe Shutdown Analysis**

The BWRX-300 design utilizes the methodology described in CSA N293 [Reference 9A.6.11-1] for the development of the BWRX-300 Fire Safe Shutdown Analysis (FSSA) (9A.6.11-5). This methodology is illustrated in Figure 9A.6.10-2, BWRX-300 Fire Safe Shutdown Analysis Methodology. The FSSA process includes the following steps further defined in NEI 00-01.

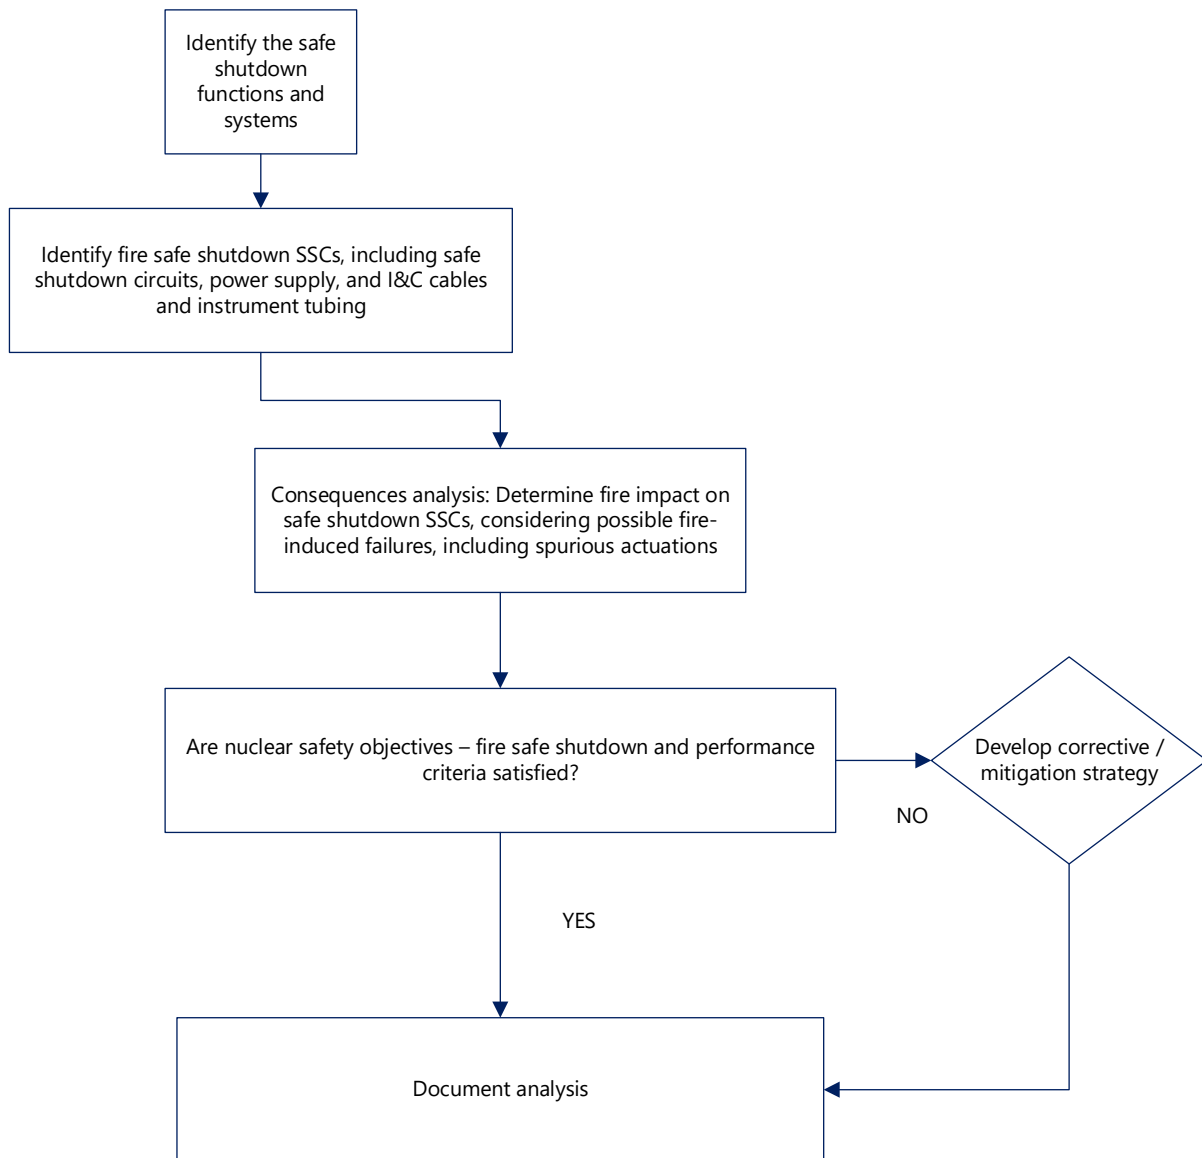

Identify fire safe shutdown systems:

1. Perform consequence assessment to identify the impact of each design basis fire on fire safe shutdown systems and demonstrate that one success path to fire safe shutdown remains available and radioactive materials listed in FHA do not result in unacceptable radiological exposure,
2. Assess manual actions and emergency procedures step required to achieve fire safe shutdown,
3. Consequence acceptability to determine that remaining SSC and cables provide at least one success path to fire safe shutdown
4. Corrective actions if FSSA can not ensure at least one success path remains available for fire safe shutdown including removal or reduction of fire hazards, enhanced fire protection control measures, relocation or protection of exposed FSS component or addition of alternate components

The FSSA demonstrates that at least one means of achieving nuclear safety objectives and performance criteria is available in the event of a fire. The FSSA scope is limited to plant areas where fires have a potential impact on SSC required to perform the fire safe shutdown functions.

It is a general conclusion of this FSSA (Reference 9A.6.11-5) that the station has the capability to safely shutdown the operating unit in the event of a fire. The results of this conceptual study show that the BWRX-300 plant is inherently safe with respect to internal fire events. This is due in large part to the passive safety features of the BWRX-300 plant design which builds on prior ESBWR and Boiling Water Reactor (BWR) Nuclear Power Plant (NPP) design insights.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

**Figure 9A.6.10-2: BWRX-300 Fire Safe Shutdown Analysis Methodology**

#### **9A.6.10.1 Results of the Third-Party Review of BWRX-300 Fire Protection System**

A third-party review of the BWRX-300 Fire Protection system was conducted by Hatch LTD. (Reference 9A.6.11-9) to ensure that the applicable codes and standards were being applied and that adequate design principles were being utilized as specified by the codes and standards.

Hatch LTD. reviewed the following documents OPG DNNP BWRX-300 Fire Hazard Assessment Requirements Document (Reference 9A.6.11-8), OPG DNNP-1 BWRX-300 Fire Safety Shutdown Requirement and Analysis Document (Reference 9A.6.11-5), and DNNP Preliminary Fire Protection Code Compliance Review Report (Reference 9A.6.11-6). All these documents are currently at the Revision 0 status for Licensing use only.

The Fire Hazards Assessment and Code Compliance Review Report met the requirements described in CSA N293 and CSA N293 Supplement 1 but required more detailed information for final determination of compliance with the Canadian standards. These details will be available as the design of the Fire Protection System and program are completed.

The Fire Safety Shutdown Requirement and Analysis Document complies with Canadian Regulations, Codes and Standards. It follows the methodology in NEI 00-01, Guidance for Post Fire Safe Shutdown Circuit Analysis. The documentation for Fire Safe Shutdown is still being developed, but no issue was identified that could impose a significant hurdle to achieving and maintaining fire safe shutdown.

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

**Table 9A.6.2-3: FPS Component Design Characteristics**

Principal Components	Safety Class	Location	Quality Group	Supply Category	Seismic Category	Notes
U43 Fire Protection System	SCN					
Primary Firewater Pump	SCN	FPH	D	TBD	TBD	
Secondary and Tertiary Firewater Pumps	SCN	FPH	D	TBD	TBD	
Firewater Storage Tanks	SCN	YARD	D	TBD	TBD	
Piping, Valves, and Sprinklers	SCN	CB, SCR, seismically qualified access/egress paths, seismically qualified inst. rooms, RB	D	TBD	TBD	
Piping, Valves, and Sprinklers	SCN	Areas containing SSC	D	TBD	TBD	DL 2 for coverage of SSC
Piping, Valves, and Sprinklers	SCN	All other areas	D	TBD	TBD	
Main Fire Alarm Panel	SCN	CB	D	TBD	TBD	
Secondary Fire Alarm Panel	SCN	RB	D	TBD	TBD	

- (1) Fire pump provided in accordance with NFPA 20 with the FP water pumping system design capable of 120% of total required flow at design pressure.
- (2) As a minimum, the fire protection water pumping system consists of at least one diesel-engine-drive fire pump set and one electric-motor-drive fire pump set.
- (3) The water supply system for fire protection is provided with an automatic pressure maintenance method such as jockey pumps independent of the fire pumps.
- (4) The fire protection water supply volume is calculated based on the largest expected flow rate for a period of 2 hr. The expected flow rate is based on the largest concurrent design demand of any automatic water-based suppression system designed in accordance with CSA N293, taking into account that the allowance for manual hose streams (minimum hose stream demand of 2850 L/min (750gpm)).
- (5) The OPG BWRX-300 FPS design meets the requirements of N293 section 7.3.2 for the water source. This includes redundancy. Where reservoirs or tanks are used, two separate reservoirs or tanks, each having 100% of the supply volume required in Clause 7.3.2.1.2, is provided unless a lesser redundancy is deemed acceptable as demonstrated by the FPA. A SMR should require less fire water than a legacy nuclear plant. It is expected that a lesser volume from CSA N293 section A7.3.2.1 recommending 2,000,000 L (526,000 gal) water storage can be justified in the BWRX-300 FHA.

## **9A.7 Supporting Systems for Diesel Generators (Storage and Transfer, Cooling Water and Cooling Air, Starting, Lubrications, Combustion Air Intake and Exhaust)**

### **9A.7.1 System and Equipment Functions**

The BWRX-300 contains two Safety Class 3 (SC3) Standby Diesel Generators (SDGs). These diesel generators provide SC3 electrical power directly supporting DL2 and DL4a functions. The SDGs backup the SC3 busses which directly power SC1 equipment. Ideally, the SDGs power SC1, SC2, and SC3 loads in the same manner (by providing backup power to the SC3 busses). Whether its normal AC power or diesel AC power, it is the same path from the SC3 busses to SC1 equipment, the SC2 equipment, and the SC3 equipment. Further details are provided in Chapter 8.

The auxiliary systems supporting the SDGs include:

- Generator fuel oil storage and transfer system
- Generator cooling water or cooling air system
- Generator starting system
- Generator lubrication system
- Generator combustion air intake system
- Generator emissions

Except for the fuel oil storage and transfer system, these subsystems are provided with the engine skid and do not require auxiliary plant system connections.

The SC3 standby diesel generators are electric start and radiator cooled and do not require plant mechanical support services for operation (such as plant auxiliary cooling or instrument air). Either of the standby diesel generators can support all the SC2 and 3 EDS loads and SC1 EDS loads (three divisions) that require power for completion of Safety Category 1, 2, and 3 functions (i.e., either standby diesel generator can support active decay heat removal). There is onsite fuel storage in large storage tanks and day tanks for each standby diesel generator. The large storage tanks hold enough fuel for at least seven days of operation of the standby diesel generators at required load. The local day tanks are in addition to the seven-day supply of fuel in order to support online testing; the day tanks alone provide up to eight hours of full power operation at rated load.

Standby diesel generator starting time is not important to plant safety. However, when the associated bus loses power, the standby diesel generator automatically starts after a short delay to allow any fast transfer schemes to work. The standby diesel generator start and achievement of rated voltage and frequency is expected (although not credited) to be accomplished within 30 seconds. Specific loads on the A21 and B21 LV busses (and the derivative MCCs) are automatically sequenced after the standby diesel generator successfully starts. The completion of automatic sequencing is expected (but not credited) to take no longer than two minutes. The standby diesel generators can also be manually started/controlled from the MCR, the SCR, and locally.

### **9A.7.2 Safety Design Bases**

For BWRX-300, the SC1 EDS provides at least 72 hours of battery backed AC and DC power, after which it is supported by the standby diesel generators for at least one week, or alternatively, is supported by connection of portable generators. In a complete loss-of-offsite/generator AC

power, batteries are charged via the standby diesel generators or the portable generator connections while also powering the required loads for safety functions.

Although the BWRX-300 does not require any onsite or offsite AC power for safety, the permanently installed standby diesel generators provide standby AC power and generally meet all requirements of the referenced section of the REGDOC. Restoring power as soon as possible is desirable. Following a plant LOOP, the standby diesel generators are expected (although not credited) to automatically start and achieve rated voltage and frequency within 30 seconds. The completion of automatic sequencing is expected (but not credited) to take no longer than two minutes. The permanently installed batteries provide the emergency power required for the SC1, SC2, and SC3 loads to meet plant needs for 72-hours. If offsite power is not restored, AC power is provided via the standby diesel generators.

The SDGs and their auxiliary systems are SC3, who's primary function is to provide power directly to SC3 loads supporting DL2 functions. The SDGs also provides a backup source of power SC1 and SC2 loads.

### **9A.7.3 Description**

#### **Fuel Storage and Transfer System**

A storage tank is provided, which holds sufficient fuel oil to operate the SDGs for a minimum of seven days without refueling. A day storage tank is also provided for fuel oil. Transfer pumps supply fuel oil to each day tank from the fuel oil storage tank. An engine-driven fuel oil booster pump supplies fuel from the day tank to the diesel engine fuel manifold then to the engine fuel injector pumps and injectors.

#### **Generator Cooling Water or Cooling Air System**

Each of the SDGs is equipped with an engine radiator cooling system. This system is self-contained on the engine skid-mounted package with no plant auxiliary connections required.

#### **Generator Starting System**

Each of the SDGs is equipped with its own dedicated electric start system. This system is self-contained on the engine skid-mounted package with no plant auxiliary connections required. Dedicated batteries, mounted inside, are Lead Acid batteries.

#### **Generator Lubrication System**

Each of the SDGs is equipped with a dedicated lubrication system. This system is self-contained on the engine skid-mounted package with no plant auxiliary connections required. All lubricating and fuel handling pumps are API pumps with double seals.

#### **Generator Combustion Air Intake System**

Each of the SDGs is equipped with its own air intake system. This system is self-contained on the engine skid-mounted package with no plant auxiliary connections required.

#### **Generator Exhaust System**

The Standby Diesel Generator Exhaust system directs diesel exhaust gases away from the SDGs and out of the building. The purpose of this building is to provide protection of the SDGs from ambient environmental effects and to allow the SDGs to perform their functions. The exhaust system design is capable to meet occupational requirements for personnel hearing, emissions, and pollution. Refer to 9A.7.11 on emissions.

#### **9A.7.4 Materials**

Materials for the SDGs and fuel system are purchased in accordance with the requirements of Safety Class 3.

#### **9A.7.5 Interfaces with Other Equipment or Systems**

The SDGs are package skid mounted systems requiring limited interface with other equipment or systems. The SDGs interfaces with plant protective relaying and the DCIS for protection, control, and instrumentation.

The fuel system interfaces with the plant DCIS for control and monitoring.

#### **9A.7.6 System and Equipment Operation**

The SDGs are capable of being manually started and aligned to their respective busses via a local control panel or remotely from the Main and (Secondary) control room. During a loss-of-offsite power, the SDGs automatically start and load on their respective bus via the automatic load sequencer.

Diesel fuel oil is supplied by a delivery system from a 7-day storage tank that is monitored periodically to ensure sufficient fuel oil is available. A supply of lubricating oil is available for the SDGs operating for 7-day operation.

#### **9A.7.7 Instrumentation and Control**

Sufficient instrumentation and controls are available locally to start and operate the SDGs. Additionally, control and instrumentation interfaces are provided to the DCIS such that remote control and monitoring from the Main and (Secondary) Control Room is possible.

Indication and alarms for the fuel supply levels in the fuel storage and day tanks are provided.

#### **9A.7.8 Monitoring, Inspection, Testing, and Maintenance**

Monitoring, Inspection, Testing, and Maintenance activities are provided to ensure that the SC3 SDGs and fuel system can perform their intended support functions.

The SDGs are also redundant and normally in standby. Any required maintenance can be done online. Specific circumstances of standby diesel generator maintenance are dictated by plant technical specifications and controlled by plant procedures.

#### **9A.7.9 Radiological Aspects**

There are no radiological aspects to this system.

#### **9A.7.10 Performance and Safety Evaluation**

The SDGs are sized to carry 100% of the required load following an SBO with sufficient fuel to carry the required load for 7 days.

#### **9A.7.11 Diesel Engine Emissions**

The diesel engine exhaust configuration is covered by NFPA 20 S 11.5.2. Emission data is supplied by the diesel engine manufacturer. Required emission limits are given by local jurisdictions. Diesel engine emissions are rated with the applicable EPA regulations in the year of supply.

#### **9A.7.12 References**

9A.7.12-1 CNSC Regulatory Document REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants."

## **9A.8 Overhead Lifting Equipment**

### **9A.8.1 Cranes, Hoists and Elevators**

Cranes, Hoists, and Elevators (CHE) are located throughout the plant and provide the means to lift and lower equipment and materials and move them horizontally along safe load paths. The principal equipment is the Reactor Building Polar Crane, Turbine Building Overhead Bridge Crane and various hoists and monorails. Table 9A.8.1-1 identifies the CHE components.

The Reactor Building Polar Crane is designed to lift heavy loads. A heavy load is defined as a load whose weight is greater than the combined weight of a fuel assembly and the associated handling device. Refer to Chapter 3, Subsection 3.4.4.3 for additional information pertaining to heavy loads.

The CHE provide a safe and effective means for transporting loads including the handling of new and spent fuel, plant equipment, service tools and spent fuel transfer casks and canisters. Safe handling includes design considerations for maintaining occupational radiation exposure as low as practicable during transportation and handling.

#### **9A.8.1.1 System and Equipment Functions**

The system and equipment functions associated with the lifting of loads includes the following:

##### **9A.8.1.1.1 Normal Functions (Non-Safety-Category)**

The CHE system continuously operates during all modes of normal power plant operation, including startup and shutdown, controlling the movement of lifted loads throughout the plant. The CHE system carries out the following functions:

- System for lifting and lowering a load and moving it horizontally, with the hoisting mechanism being an integral part of the system
- Load handling system includes rigging components such as slings, shackles, and eyebolts which connect a load to a lifting device and any lift fixture
  - The CHE system also includes building elevators for passenger and freight movement.

##### **9A.8.1.1.2 Normal Functions (Safety-Category)**

The system does not perform any Safety-Category functions during normal conditions.

##### **9A.8.1.1.3 Off-Normal Functions (Non-Safety-Category)**

The CHE equipment is capable of operation during all modes of off-normal power plant operation.

##### **9A.8.1.1.4 Off-Normal Functions (Safety-Category)**

The system does not perform any Safety-Category functions during off-normal conditions.

The design of the CHE meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 7.15.3 (Reference 9A.8.1-1) as related to lifting and handling of large and heavy loads and ensuring design margin exists as well as interlocks to accommodate lifting of loads. Information pertaining to the impact of hard objects upon SSCs is presented in Chapter 3, Subsection 3.4.4.3.

#### **9A.8.1.2 Safety Design Bases**

The CHE system is classified as SCN. The Reactor Building Polar Crane is designed, fabricated, erected, and tested to appropriate quality standards such that its failure does not impact the function of other Safety-Category function systems.

The Reactor Building Polar Crane is designed to meet the applicable requirements provided in NUREG-0554 (Reference 9A.8.1-2). Structures, Systems, and Components compliant with NUREG-0554 are considered single failure proof. The Reactor Building Polar Crane is designed to support a critical load regardless of the failure of any single component used in normal operation. A critical load as discussed in NUREG-0554 (Reference 9A.8.1-2) is a load being handled by a crane that can be a direct or indirect cause of release of radioactivity.

The consequences of a postulated load drop are considered acceptable when the four evaluation criteria of NUREG-0612 (Reference 9A.8.1-3), Paragraph 5.1, are satisfied.

Plant arrangement and the design of heavy load handling systems are based on the following criteria:

- To the extent practicable, heavy loads are not carried over or near Safety-Category function components, including irradiated fuel and safe shutdown components. Safe load paths are designated for heavy load handling in Safety-Category function areas.
- The likelihood of a load drop is extremely small (that is, the handling system is single failure proof), or the consequences of a postulated load drop are within acceptable limits.
- Single-failure-proof systems can stop and hold a critical load following the credible failure of a single component.
- Single-failure-proof systems can support a critical load during and after a safe shutdown earthquake.

#### **9A.8.1.3 Description**

A description of the CHE system is provided below. Location, safety class and seismic category for system components are summarized in Table 9A.8.1-1.

##### **9A.8.1.3.1 Reactor Building Lifting Devices**

#### **Reactor Building Polar Crane**

The Reactor Building Polar Crane is designed according to NUREG-0554 (Reference 9A.8.1-2) supplemented by ASME NOG-1 (Reference 9A.8.1-4) for a Type I single failure proof crane. Crane Manufacturers Association of America Specification 70 (Reference 9A.8.1-5), and to the applicable ANSI standards.

The Reactor Building Polar Crane is composed of an overhead bridge of two deep girders supporting a trolley with a main and auxiliary hook. The top of a circular rail is located at approximately elevation 22.7 m. This rail supports the two girders allowing the crane bridge 360 degrees of rotation. The bridge structure spans the full width of the refueling floor. The crane is classified as Seismic Interaction to maintain structural integrity and single failure proof to mitigate the probability of a load drop event. Seismic Interaction evaluations ensure that in the event SSCs, fail during a seismic event there are no adverse interactions with the ability of any Seismic Category A or B SSC to accomplish its Safety Class function. Refer to Chapter 3, Subsection 3.2 for additional information pertaining to Seismic Interaction. Design for both the main and auxiliary hoists is in accordance with ASME NOG-1 requirements which provides a high degree of reliability and safety. Redundancy and other features ensure that the failure of a single component in the load path does not result in the loss of capability to stop and hold a critical load. The principal heavy loads handled by this crane consist of the components associated with reactor vessel refueling, including the reactor head; reactor vessel internals including dryer/separators; fuel assemblies (associated with new fuel receipt), and various containment support components. During spent fuel handling activities, the cranes maximum load is the combination of the spent

fuel cask, transfer cask, and lifting yoke, which weighs less than the cranes overall capacity. Weight of the spent fuel cask is dependent upon the selected manufacturer. The crane will have access to a truck bay for fuel transfer to spent fuel shipping and/or transfer casks, new fuel assemblies, and replacement components.

#### **Jib Crane**

A jib crane is located in the truck bay near the equipment hatch. The jib crane performs rigging services for replacement of components, materials, and supplies to and from the truck bay to the lower levels of the Reactor Building.

#### **Load Handling**

Overhead pad eyes and rigging beams are located below the concrete slab at elevation 4.9 m. These components are used to manipulate the piping, valves, and equipment at the top of the reactor vessel in the primary containment during outage maintenance activities.

#### **Battery Room Monorails**

A monorail system located above battery racks for battery handling during maintenance activities is provided.

#### **Elevator**

A service elevator is provided.

#### **9A.8.1.3.2 Turbine Building Lifting Devices**

##### **Turbine Building Overhead Bridge Crane**

The Turbine Building Overhead Bridge Crane spans the operating deck above the generator, High Pressure Turbine, Low Pressure Turbines and Condenser. The bridge structure consists of steel girders supporting a trolley with a main hoist and auxiliary hoist. The principal heavy loads handled by this crane consist of components of the turbine-generator system. The heaviest component being the Low Pressure Turbine bladed rotor.

Vertical and horizontal hook travel limits are based on Turbine-Generator equipment requirements as well as the other components located on the operating deck.

CSA B167, (Reference 9A.8.1-6), as well as ASME/ANSI B30.2 (Reference 9A.8.1-7) are used for general construction and installation requirements.

##### **Turbine Building Jib Crane**

The Turbine Building Jib Crane is located at the north end of the operating floor. The Turbine Building Jib Crane performs lifts from ground level to the operating deck for maintenance and operation activities such as transport of inspection materials, toolboxes, and other components.

##### **Diesel Generator Monorails**

Overhead monorails are located above each Diesel Generator. The monorails are used for engine maintenance activities.

##### **Condenser Monorails**

Overhead monorails are located above the circulating water piping elbows directly east of the condenser.

### **Battery Room Monorails**

A monorail system located above battery racks for battery handling during maintenance activities is provided.

### **Hot Machine Shop Overhead Bridge Crane**

An overhead bridge crane is provided in the hot machine shop for maintenance support services.

### **Elevator**

A service elevator is provided.

#### ***9A.8.1.3.3 Radwaste Building Lifting Devices***

### **Tank Filter Monorail**

A Tank Filter Monorail hoist is located above concrete hatches adjacent to the concrete tank wall on elevation 13m of the Radwaste Building. The Tank Filter Monorail hoist is used to lift concrete hatches above the condensate pre-filter tanks.

### **Elevator**

A service elevator is provided.

#### ***9A.8.1.3.4 Control Building Lifting Devices***

Battery room monorails in the Control Building are provided for battery handling during maintenance activities.

#### ***9A.8.1.3.5 Power Block Pre-Qualified Lift Points***

Existing steel or concrete structures throughout the plant have pre-qualified lift points for maintenance activities. The rated load for each lift point is appropriately tagged or stenciled to the building concrete or steel member. Rigging attached to lift points allow for equipment to be moved for repair and/or replacement maintenance activities.

#### ***9A.8.1.3.6 Component Description***

This subsection describes CHE components.

### **Hook**

The hook is a device for grabbing and lifting loads by means of a device such as a hoist or crane. A lifting hook is typically equipped with a safety latch to prevent the disengagement of the lifting wire rope sling, chain or rope to which the load is attached.

The hook is designed to withstand stress imposed under normal operating conditions while handling loads within the rated load. The minimum hook design factor conforms to those specified for the equipment or system in which the hook is a component.

### **Monorails**

Monorails are used for lifting and lowering a load and moving the load horizontally, suspended from a single track. The combined load on all hoists on the monorail do not exceed the rated load of the monorail.

Monorail systems conform to the minimum design parameters as specified in The Steel Construction Manual (Reference 9.8.1-8), Crane Manufacturers Association of America No. 74 (Reference 9A.8.1-9), ANSI MH27.1 (Reference 9A.8.1-10), or ANSI MH27.2 (Reference 9A.8.1-11), as applicable.

## **Hoist**

A hoist is a suspended machinery unit that is used for lifting or lowering a freely suspended (unguided) load. The hoist and appurtenances are designed to withstand the stresses imposed under normal operating conditions while handling loads within the rated load.

### **Hand Chain-Operated Chain Hoist**

A hand chain-operated chain hoist is a suspended machinery unit that is used for lifting or lowering a freely suspended (unguided) load.

### **Electric Powered Chain Hoist**

An electric powered chain hoist is a suspended machinery unit that is used for lifting or lowering a freely suspended (unguided) load.

### **Below-the-Hook Lifting Devices**

A below-the-hook lifting device is used for attaching loads to a hoist. The device contains components such as slings, hooks, and rigging hardware. The design of below-the-hook-lifting devices are in accordance with ASME BTH-1 (Reference 9A.8.1-12).

#### **9A.8.1.4 Materials**

Cranes are fabricated using materials that are designed to meet operating stress limits plus margin. The CHE System equipment and associated structural components are designed to meet the 60-year plant life, with appropriate provisions for maintenance and replacement.

#### **9A.8.1.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.8.1-2 for Cranes, Hoists, and Elevators interfaces with other equipment or systems.

#### **9A.8.1.6 System and Equipment Operation**

##### **9A.8.1.6.1 Normal Operations**

Operators are trained, qualified, and cognizant of the load handling equipment interlocks and protective devices. Interlocks and protective devices are not overridden or bypassed unless authorized by an approved Work Order. Elevators that serve floor elevations above the first floor that are equipped with an automatic emergency recall feature are equipped with smoke detectors installed in the elevator lobbies on the recall level. In-car emergency switches are provided for in all elevator cars.

##### **9A.8.1.6.2 Off-Normal Operations**

Load handling systems are operational unless scheduled for a maintenance.

#### **9A.8.1.7 Instrumentation and Control**

##### **9A.8.1.7.1 Instrumentation**

The following information does not pertain to manual or portable hoists in the CHE system.

The Reactor Building Polar Crane and Turbine Building Overhead Crane control circuits are arranged so that tripping of an overload relay or limit switch defeats the permissive to all crane controllers. Overload relay or limit switch operation does not interrupt lighting circuits.

The avoidance of two-blocking for the RB Polar Crane is accomplished using single-failure-proof features and does not rely on any action by the operator. The normal hoist limit switch is

supplemented by an independent final hoist limit switch operated by the load block to remove power from the hoist motor and brakes.

The prescribed path for Reactor Building Polar Crane hook travel is enforced by limit switches for hook travel in both vertical and horizontal directions.

#### **9A.8.1.7.2 Control**

The following information does not pertain to manual or portable hoists in the CHE system.

The Reactor Building Polar Crane and Turbine Building Overhead Cranes are controlled by a local master control panel on the crane bridge. Primary control of crane motions is directed from a cab located on the crane bridge and remote control with backup pendant control. The cab, remote and pendant controls provide for bridge, trolley, main hoist, hook rotation (cab and radio control only), and auxiliary hoist motions. Pendant controls are back up for cab/remote and are isolated during normal operation by a transfer switch on the pendant. Remote control utilizes lever switch technology.

The Reactor Building Polar Crane electrical system is designed so it is possible for the operator to stop and hold a critical load regardless of the failure of any single component used in normal operation. The operator can stop all motors without a time delay using the emergency stop.

The Reactor Building Polar Crane control system uses a programmable logic controller, housed in a bridge control panel. The programmable logic controller is integral to a restricted zone scheme for the crane which is activated during critical lift evolutions such as movement of the spent fuel cask.

#### **9A.8.1.8 Monitoring, Inspection, Testing, and Maintenance**

Elevators are registered in compliance with Technical Standards and Safety Authority.

Surveillances of a load handling system are performed in accordance with plant load handling procedures. The surveillance is a visual check of the overall configuration of the load handling system. Inspections and tests of the load handling system is performed in accordance with Operations and Maintenance Manual requirements as well as load handling procedures.

A maintenance program based on manufacturers' recommendations, integrating proactive, reactive, preventive, and predictive maintenance and operating experience, is established to increase the probability that CHE structures, systems and components function in the required manner over the design life cycle. The program includes procedures which ensure that records are retained, and test and inspection discrepancies are documented and corrected. Any crane, hoist or monorail found in an unsafe operating condition is tagged out and removed from service until repaired. All repairs are made by qualified personnel in accordance with the manufacturers' instructions. Rigging hardware used for load handling systems is maintained in a similar fashion.

Maintenance activities for CHE load handling systems which are either preventive or the result of adverse conditions determined through an inspection program are corrected by adjustment, repair, or replacement of components before continuing the use of the system/component. Operational testing is performed in accordance with plant procedures.

CHE load handling systems which are altered, repaired, and modified are required to be operationally tested for the functions affected by the alteration, repair, or modification, as determined by a qualified person. In addition, load testing of altered, repaired, and modified load handling systems, may be limited to the functions affected by the alteration, repair, or modification, as determined by a qualified person.

#### **9A.8.1.9 Radiological Aspects**

For purposes of meeting ALARA guidelines the Cranes, Hoists and Elevators include hoisting/transport mechanisms to handle parts and components in decontamination areas, in the contaminated storage areas and in the active workshops.

The Cranes, Hoists and Elevators use remotely operated electric hoists where possible for tasks/equipment associated with general area dose rates in excess of 1 mSv/hr.

Refer to Chapter 12, Subsection 12.1.5.4 for information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.8.1.10 Performance and Safety Evaluation**

The Reactor Building Polar Crane is designed to be single failure proof to improve operational reliability, which is generally implemented by adding design margin, and by increasing material inspection and testing above that found in Crane Manufacturers Association of America Specification 70 (Reference 9A.8.1-5) and other standards invoked by Crane Manufacturers Association of America Specification 70. The RB Polar Crane electrical system is designed so that it is possible for the operator to stop and hold a critical load regardless of the failure of any single component used in normal operation.

Based upon guidance provided in NUREG-0612 (Reference 9A.8.1-3); Safe load paths are defined. Use of load handling procedures, training of crane operators, guidelines on slings and special lifting devices, periodic inspection and maintenance of the crane are provided to ensure safe crane operations.

Interfacing System	Interface Description	Interface Boundary
Non-Safety Electrical Distribution System	Non-Safety Electrical Distribution System provides power	Crane bridge or Elevator control panel
	The Turbine Building Overhead crane and the Reactor Building Polar Crane are supplied with an A or B train electrical power transfer switch	Crane bridge
	Communications to elevators	Elevator car enclosure
Reactor Building Structure	The Reactor Building provides shelter and structural support to the components of the Cranes, Hoists and Elevators System	Runway for crane or monorail, Elevator supporting steel or concrete structure
Turbine Building Structure	The Turbine Building provides shelter and structural support to the components of the Cranes, Hoists and Elevators System	Runway for crane or monorail, Elevator supporting steel or concrete structure
Control Building Structure	The Control Building provides shelter and structural support to the components of the Cranes, Hoists and Elevators System	Runway for monorail
Radwaste Building Structure	The Radwaste Building provides shelter and structural support to the components of the Cranes, Hoists and Elevators System	Runway for monorail, Elevator supporting steel or concrete structure
Fire Protection System	The Fire Protection System provides for elevator emergency functions, i.e., smoke detectors installed in elevator lobbies for auto return	Elevator car enclosure

#### **9A.8.2 Fuel Building Crane**

The BWRX-300 does not have a Fuel Building and as such does not have a Fuel Building Crane. New fuel is received onsite and is brought into the Reactor Building (RB) through RB hatch. Spent fuel is removed from the Fuel Pool in a cask. Cask loading and transport activities involve use of the Reactor Building Polar Crane located inside of the Reactor Building. Refer to Subsections 9A.1.1 "New Fuel Storage and Handling System," 9A.1.2 "Fuel Storage and Handling System," and 9A.1.4 "Handling Systems for Fuel Cask Loading," and 9A.8.1 "Cranes, Hoists and Elevators," for additional information pertaining to new and spent fuel handling operations.

## **9A.9 Miscellaneous Auxiliary Systems**

### **9A.9.1 Communication Systems**

The communications systems provide effective intraplant communications and effective plant-to-offsite communications during normal operation, maintenance, transients, fire, and accidents conditions including LOOP.

A typical Communication System consists of the following subsystems:

- Wireless telephone system
- Telephone/page system
- Private branch exchange system
- Sound-powered system
- Emergency offsite communications
- Security communication system

#### **9A.9.1.1 System and Equipment Functions**

System and equipment functions associated with the Communication System include the following:

##### **Normal Functions (Non-Safety-Category)**

The communications systems provide intraplant and plant-to-offsite communications during normal operation.

##### **Normal Functions (Safety-Category)**

The communications systems provide no Normal Safety-Category functions.

##### **Off-Normal Functions (Non-Safety-Category)**

The communications systems provide intraplant and plant-to-offsite communications during transients, fire, accidents, off-normal phenomena, and security-related events.

##### **Off-Normal Functions (Safety-Category)**

The communications systems provide no Off-Normal Safety-Category functions.

The Communications System is designed considering the requirements of REGDOC-2.5.2 (Reference 9A.9.1-1) Section 7.20 "Escape routes and means of communication" by providing diverse methods of communication within the plant and in the immediate vicinity as well as to offsite agencies. In addition, the Communications Systems are designed to provide secure communications channels to emergency support facilities and offsite response organizations consistent with the requirements of REGDOC-2.5.2 Section 8.10 "Control Facilities."

#### **9A.9.1.2 Safety Design Bases**

The Communication System does not perform or ensure any Safety-Category function, and thus has no safety design bases.

#### **9A.9.1.3 Description**

The communication system provides the means to conveniently and effectively communicate between various plant locations and with offsite locations during normal, maintenance, transient, fire, and accident conditions under maximum potential noise levels. The communication system

NEDO-33958 REVISION 1  
NON-PROPRIETARY INFORMATION

allows guards and watchmen on duty to maintain continuous communication with personnel in manned alarm stations, and offsite/onsite agencies. This is typically accomplished by either private automatic branch (telephone) exchange or wireless communication system.

The Communication System is designed to support Emergency Preparedness and Response requirements for accident conditions, including notification of personnel and implementation of evacuation procedures. This capability includes communications support to both onsite and offsite emergency centers as well as provisions for onsite and offsite communications system, each with a backup power source. Refer to Chapter 19 for information related to Emergency Preparedness and Response.

The Communication System is designed to support the coordination between plant personnel during accident or incident conditions under maximum potential noise levels. This capability also includes communications support for firefighting, including support of alternative and dedicated shutdown capabilities. Refer to Subsection 9A.6 for information related to Fire Protection.

The Communication Systems are designed to support coordination of security activities both within the plant and with external security and law enforcement organizations.

The Communications Systems are designed to generally recognized codes and standards.

The Communication Systems are separated from one another, such that a failure in one system does not degrade the performance of the other systems.

The Communication System is designed to remain functional during a LOOP.

The Communications Systems use conventional equipment that have a history of successful operation at similar industrial settings.

On-site plant communications systems are backed up by the standby diesel generators during a LOOP. Most of the communications equipment is located in the Control Building and the Communications Room both of which have standby diesel generator backed redundant power panels and Uninterruptible Power Supply (UPS) backed redundant power panels. Portions of the Communication Systems are operated on battery backed 72-hour uninterruptible power supplies.

#### **9A.9.1.3.1 Component Description**

##### **Wireless Telephone System**

A typical wireless telephone system consists of wireless portable handsets, hands-free type portable headsets, a comprehensive antenna system, and necessary electronics equipment. The wireless telephone system is the primary means of communication for plant operations and maintenance personnel. The telephone-page, private branch exchange telephone, and sound-powered communication systems are for general plant communications and serve as a backup to the wireless system.

A typical wireless telephone system has the ability to dial fixed private branch exchange telephone stations and vice versa. The wireless system has the capability to access the telephone-page system and the capability to access offsite emergency communication links.

##### **Telephone/Page System**

A typical telephone/page system consists of handsets, amplifiers, loudspeakers, and associated electronic equipment. The system supports paging and party lines without crosstalk or interference.

### **Private Branch Exchange System**

A typical private branch exchange system provides communication between the system stations, with capability for transferring calls and providing conference calls. The private branch exchange system typically interfaces with the following communication systems:

- The wireless telephone system
- Redundant connectivity to commercial telephone services
- Access to the telephone page system
- Direct extensions from the private branch exchange locations exterior to the plant

The separate, redundant connections between the private branch exchange and commercial telephone service provides communications between the Main Control Room and the headquarters or other facilities in case of a single fault.

Commercial telephone lines are provided by the local area telephone company.

### **Sound-Powered System**

The sound-powered telephone system provides voice service to key locations throughout the plant. This system uses portable sound-power telephones that can plug into local terminal jacks. The system allows uninterrupted communications. The system does not rely on external power supply for operation.

### **Security Communication**

A typical security communication system utilizes the common site private branch exchange, public address, and sound power phone circuits to facilitate a portion of their communications needs. Typically, Security has a dedicated radio system providing continuous communications between each onsite security officer, watchman, or armed response individual and an individual in each continuously manned alarm station. These radio systems are typically powered by the security power system.

### **Emergency Communications**

There is an emergency communications workspace provided in the MCR to accommodate two people. The emergency communications workspace contains space for communications equipment and administrative tasks.

#### **9A.9.1.4 Materials**

The Communication System is designed using materials that ensure operability in nuclear and industrial environments.

#### **9A.9.1.5 Interfaces with Other Equipment or Systems**

The communication system derives its power from the Electrical Distribution System. Refer to Chapter 8, Subsection 8.1 for information pertaining to the Electrical Distribution System.

#### **9A.9.1.6 System and Equipment Operation**

##### **Normal Operation**

The Communication Systems operation is checked as part of normal daily usage.

Voice and data communications systems and equipment are provided to support all phases of plant operations and maintenance, including emergency operations.

Portable, wireless communication capability is provided using equipment typically supported by base stations, antennas, amplifiers, and repeaters. This is typically the means of communication among control room operators, equipment operators, radiation protection, and maintenance technicians for routine and emergency operations, including surveillance tests, startup and shutdown operations, refueling, job coverage, and emergency or accident conditions.

Communication channels accommodate the expected message load including task requirements in critical or emergency situations, plus allow margin for expansion and contingency. The system provides the capability for open channel, or "party line" communication.

The Communications Systems function in all ambient noise level environments. The equipment allows communication from high-noise areas consistent with performing other tasks in those areas. Adequate means are provided to alert personnel to the use of communication equipment.

The design of the Communication Systems takes into account the applicable requirements of NUREG-0700 (Reference 9A.9.1-2).

#### **Off-Normal Operation**

The Communication Systems will fail in a predictable manner with failure alarms alerting users to failed or degraded system status. The system is checked for functionality as part of daily usage; therefore, system degradation is self-revealing.

##### **9A.9.1.7 Instrumentation and Control**

No special instrumentation is required for the Communication System.

##### **9A.9.1.8 Monitoring, Inspection, Testing, and Maintenance**

Communication Systems equipment is designed to operate reliably within the environment in which it is installed including environmental conditions such as temperature, humidity, radiation, and noise. Furthermore, the Communication Systems are designed to operate taking into account placement of barriers such as shield walls. Communication System equipment is accessible to personnel for operation, inspection, maintenance, and testing.

The Communications System is pre-operational tested. The systems described above are conventional and have a history of successful operation at similar plants. These systems are used and maintained routinely to ensure their availability.

The power sources for the plant page/party-line telephone system and the private branch exchange are tested separately during the pre-operational and startup test program. Measurements or tests required to identify long-term deterioration are performed on a periodic basis.

##### **9A.9.1.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

##### **9A.9.1.10 Performance and Safety Evaluation**

The Communication Systems do not perform Safety-Category functions. The failure of any Communication System does not adversely affect safe shutdown capability. It is not necessary for plant personnel in Safety-Category function areas of the plant to communicate with the control room to achieve safe shutdown of the plant.

Diverse Non-Safety-Category function power supplies connected to the plant standby diesel generators, power the plant page/party-line telephone, Private automatic branch (telephone) exchange and plant radio systems. Failure of any or all of its components does not affect any Safety-Category functions.

#### **9A.9.1.11 References**

9A.9.1-1 CNSC Regulatory Document REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants."

9A.9.2-1 NUREG-0700, "Human-System Interface Design Review Guidelines"

#### **9A.9.2 Lighting and Servicing Power System**

The plant Lighting and Servicing Power System includes normal and emergency lighting in addition to providing service power throughout the plant. The normal lighting provides illumination during plant operating, maintenance, and test conditions. The emergency lighting provides illumination in areas where emergency operations are performed upon loss of normal lighting. Security aspects of the Lighting and Servicing Power System are considered Security Related Information and are addressed in the Security Annex.

##### **9A.9.2.1 System and Equipment Functions**

###### **Normal Functions (Non-Safety Category)**

The Lighting and Servicing Power System provides illumination throughout the plant as required during Non-Safety Category normal conditions.

###### **Normal Functions (Safety Category)**

The Lighting and Servicing Power System does not perform a Safety Category function during normal conditions.

###### **Off-Normal Functions (Non-Safety Category)**

The Lighting and Servicing Power System provides illumination during Non-Safety Category, off-normal conditions, including fire, transient and accident conditions.

###### **Off-Normal Functions (Safety Category)**

The Lighting and Servicing Power System does not perform a Safety Category function during off-normal conditions.

The design of the Lighting and Servicing Power System is consistent with the requirements of REGDOC 2.5.2, (Reference 9A.9.2-1) Section 7.12.2 relative to lighting infrastructure, Section 7.20 relative to emergency lighting, and Section 8.10 relative to Control Facility lighting.

##### **9A.9.2.2 Safety Design Bases**

The Lighting and Servicing Power System does not perform or ensure any Safety Category function, and thus has no safety design bases.

The Lighting and Servicing Power System does not perform any Safety Category functions during or after a design basis accident. Failure of the lighting systems does not compromise Safety Category functions from being performed, nor does it prevent the safe shutdown of the reactor.

The plant illumination levels provided by the lighting systems are in accordance with the applicable lighting levels specified in NUREG-0700 (Reference 9A.9.2-2).

### 9A.9.2.3 Description

The lighting equipment is designed to provide illumination throughout the plant that is equal to or greater than those recommended by the Illuminating Engineering Society of North America.

Emergency lighting is provided in areas where emergency operations are performed and for personnel safety during a power failure. The individual rooms receive lighting appropriate to their contents. The Lighting and Servicing Power System is comprised of the following lighting systems:

- Normal lighting system - The normal lighting system is used to provide illumination in all areas of the plant except the Main Control Room and the Secondary Control Room (the emergency lighting system provides both normal and off-normal lighting in the control room). The normal lighting system is available under normal plant operating, maintenance, and testing conditions and during off-normal conditions if normal AC power remains available. The normal lighting system does not have a backup power source.
- Emergency lighting system - The emergency lighting system is used to provide acceptable levels of illumination in the control rooms during normal operating conditions while also providing acceptable levels of illumination in the control rooms and other areas of the plant when the normal lighting system is not available. Emergency lighting is available in areas where emergency operations are performed, including the access and egress routes to and from those areas. Upon loss of the normal lighting system (including loss of power events), the emergency lighting system provides illumination for the control rooms, remote shutdown areas, battery rooms, and containment. Emergency lighting has a backup source of power that is either diesel backed or battery backed.

The BWRX-300 uses Light Emitting Diode (LED) lighting that is operated from low voltage power panels where the lighting loads are shared with other loads (e.g., controllers and convenience outlets). These various power panels are powered by three sources:

- Offsite power (derived from busses A1 and B1 – Non-Safety Electrical Distribution System)
- Standby diesel generator (derived from busses A21 and B21 – Safety Class 2 and 3 Electrical Distribution System)
- Uninterruptible Power Supplies – either Safety Class 2 and 3 Electrical Distribution System or Safety Class 1 Electrical Distribution System that are backed by 72-hour batteries and most closely associated with emergency lighting

These panels are distributed in most rooms such that lighting for that room can be easily obtained. Extensive emergency lighting is provided since LED loads are small and insignificant to the diesel or battery loading.

The lighting is designed in accordance with applicable industry standards and is provided in all areas using an appropriate mixture of SCN, SC3 diesel backed and SC2 and SC1 battery backed lighting for the specific plant areas.

The lighting equipment and installation inside and outside the control room is designed to remain functional during design basis events and withstand the seismic loads of a design basis earthquake. Lighting fixtures located in the vicinity of Safety-Category function equipment is supported so that they do not adversely impact the equipment when subjected to seismic loading of a safe shutdown earthquake.

The MCR and SCR lighting over the SC1 video display units and the communications console are powered from the Safety Class 1 Electrical Distribution System. The remaining MCR and SCR lighting is split between the redundant diesel backed Safety Class 2 and 3 Electrical Distribution System power feeds. All control room lighting is part of the emergency lighting system since all control room lighting has a backup power source.

#### **9A.9.2.4 Materials**

The plant lighting is designed using materials that ensure operability in nuclear and industrial environments.

#### **9A.9.2.5 Interfaces with Other Equipment or Systems**

The plant lighting derives its power from the Electrical Distribution System (Chapter 8, Subsection 8.1).

#### **9A.9.2.6 System and Equipment Operation**

The plant lighting includes normal and emergency lighting. The normal lighting provides illumination during all plant operating conditions, including off-normal conditions if normal AC power is available. The emergency lighting provides illumination in the control rooms during all normal and off-normal conditions while also providing illumination in other areas of the plant during off-normal plant operating conditions when the normal lighting system is not available. Off-normal plant conditions for emergency lighting include fire, transient and accident conditions.

#### **9A.9.2.7 Instrumentation and Control**

No special instrumentation is required for the lighting system. The emergency lighting automatically actuates on the loss of normal plant lighting.

#### **9A.9.2.8 Monitoring, Inspection, Testing, and Maintenance**

Pre-operational testing verifies that the normal lighting system provides illumination under normal plant operating, maintenance, and testing conditions, and that the emergency lighting system provides illumination where required throughout the station, including areas where emergency operations are performed. System operability is demonstrated by normal use during plant operation. The normal lighting system and the control room portion of the emergency lighting system is normally energized continuously and requires only routine maintenance or testing.

#### **9A.9.2.9 Radiological Aspects**

There are no radiological aspects associated with the design and operation of the lighting system.

#### **9A.9.2.10 Performance and Safety Evaluation**

The lighting equipment used is conventional equipment that has a history of successful operation at similar nuclear and industrial settings. This equipment is used and maintained routinely to ensure its availability.

The lighting system has no Safety-Category functions and therefore requires no nuclear safety evaluation. Failure of the lighting system or its components will not affect the ability of Safety Category systems to perform their intended function.

#### **9A.9.2.11 References**

- 9A.9.2-1 CNAS Regulatory Document REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants."
- 9A.9.2-2 USNRC NUREG-0700, "Human-System Interface Design Review Guidelines."

### **9A.9.3 Floor Drain System**

The purpose of the Equipment and Floor Drain System is to provide equipment to drain, collect, and transport liquid waste from the floor drains to the Liquid Waste Management System (Chapter 11, Subsection 11.2) for processing.

#### **9A.9.3.1 System and Equipment Functions**

##### **9A.9.3.1.1 Normal Functions (Non-Safety-Category)**

The EFS is designed to perform the following:

Collect radioactive or potentially radioactive liquid wastes generated in the plant during normal operation, anticipated operational occurrences, startup, hot shutdown, cold shutdown, and refueling, and transfer these wastes to the Liquid Waste Management System for processing or to an appropriate disposal system.

Collect oily wastes from the Electro-Hydraulic Control Unit, Diesel Generators, and Turbine Lube Oil skid during all modes of plant operation for transfer to the SWM (Chapter 11, Subsection 11.4).

##### **9A.9.3.1.2 Normal Functions (Safety-Category)**

The system does not perform any Safety-Category functions during normal conditions.

##### **9A.9.3.1.3 Off-Normal Functions (Non-Safety-Category)**

The system does not perform any Non-Safety-Category functions during off-normal conditions. The system is designed to collect spills and leaks via floor drains during off-normal conditions.

##### **9A.9.3.1.4 Off-Normal Functions (Safety-Category)**

As part of Defense Line 3 the EFS provides containment isolation valves on piping that penetrates the containment boundary. These valves are designed to close upon receiving an isolation signal from the Safety Class 1 Instrumentation and Control System (Chapter 7, Subsection 7.3.1). The EFS can perform this function during and after a Design Basis Event requiring containment isolation.

The design of the EFS meets CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.6.6 as related to containment isolation. (Reference 9A.9.3-1).

#### **9A.9.3.2 Safety Design Bases**

As part of Defense Line 3 the EFS provides containment isolation valves on piping that penetrates the containment boundary.

#### **9A.9.3.3 Description**

Refer to Figure 9A.9.3-1a which depicts a typical drain sump and Figure 9A.9.3-1b which depicts the containment drain sump.

The EFS consists of the drainpipes, collection sumps, sump pumps, interconnecting piping, and instrumentation to provide for the collection and removal of liquid waste in the plant. The EFS is provided for the Reactor Building, Turbine Building, Radwaste Building and PLSA.

#### **General Floor Drains and Sumps**

All liquid waste collected in the radioactive drains are treated as High Conductivity Waste (HCW). Liquid waste is floor drain wastes, equipment drains, and process drains collected throughout the entire facility. These wastes are collected by drains and drain headers, routed by gravity drainage piping to a sump, and pumped to LWM for processing. All liquid waste is considered HCW in the

BWRX-300 with the exception of a small subset of potentially clean drains and sumps that are used to keep chemicals from mixing with radwaste and to reduce the amount of waste sent to processing. Liquid waste testing is utilized in order to test for radioactive contamination among the potentially clean collection samples.

The EFS continuously collects the liquid waste that is generated throughout the plant during all modes of plant operation. The sumps receive and store the liquid wastes until the contents are pumped to the LWM. Each sump has a cover to prevent debris from entering the sump. The sumps are vented to their associated HVAC exhaust systems for control of airborne contamination. The sumps are also provided with flush capability to minimize the solid deposit within the sump and transfer piping. Clean flush water can be added to clean out a sump prior to maintenance activities.

Open drainage lines from areas that are required to maintain an air pressure differential but drain to the system are provided with a water seal.

### **Oily Wastes Drains and Sump**

Dedicated oily waste collection sumps are provided at the base of the EHC unit, lube oil skid and diesel generators in case of a leak. A temporary pump is required to pump oily waste from the sump pit to a collection barrel for transport to the SWM (Chapter 11, Subsection 11.4) drum evaporator for de-watering and disposal.

### **Pressurized Containment Sump**

Three divisionally separated sumps are included in the basement floor of the RB. One of the sumps is a pressurized containment sump. The EFS has drain piping in the SCCV floor to drain any leakage or condensation collected in containment to the pressurized sump. The pressurized sump is also used for containment leak detection and measurement. The pressurized sump's upstream piping penetrates the SCCV which requires the use of redundant isolation valves to ensure containment isolation. The isolation valves fail closed and automatically close upon receiving an isolation signal from the Safety Class 1 Instrumentation and Control System (Chapter 7, Section 7.3).

#### ***9A.9.3.3.1 Component Description***

### **Sump Pumps**

The sump pumps are vertical, centrifugal types, driven by electric motors. Two parallel 100% capacity pumps (run pump and standby pump) are provided for each sump.

Maintenance valves and flanged connections are provided for sump pumps so that they can be isolated and removed from the sumps for maintenance and repair. Check valves in the pump discharge piping prevent backflow of waste into the sump.

### **Collection Sumps**

The sumps are sized to accommodate the normal anticipated daily inputs without overflow in conjunction with operation of one sump pump.

Collection sumps are lined cavities in the floor slab of their respective building. The sumps have tight fitting, but not gastight, steel plate covers to prevent the entrance of debris as well as to minimize airborne contamination. The sumps have vents that are piped to the building HVAC interfacing exhaust. The sumps are provided with grab sampling connections.

The pressurized containment sump is designed in accordance with ASME Boiler and Pressure Vessel Code Section VIII, Division 1 (Reference 9A.9.3-3). The pressurized sump vessel is steel

lined and shielded due to its interface with the primary containment. Any leakage from the pressurized sump is contained in the lined cavity, eliminating direct contact with the bare concrete.

A pressurized vessel is used in place of a traditional sump in the Reactor Building basement due to its open interface with primary containment during normal operation. The pressurized sump is located outside containment to maintain a dry containment. The pressurized vessel provides an interface for a drain line, flush water, level transmitters and pump connections.

### **Piping and Valves**

All piping is in accordance with the requirements of ASME B31.1 (Reference 9A.9.3-4) except for the containment penetration. As part of Defense Line 3, the EFS provides containment isolation valves on piping that penetrates the containment boundary. Accordingly, the piping penetrating containment, up to and including both isolation valves, is Safety-Class 1.

The EFS piping penetrating containment is an extension of the containment boundary and is designed to Category A; ASME BPVC Section III, Division 1, Class 2 requirements. The arrangement of the isolation valves and connecting piping is such that a single active failure or passive failure in the connecting piping or an outboard valve, cannot prevent isolation of the EFS containment penetrations. The containment isolation valves are classified as Seismic Category B.

The floor drain line in containment connects directly to the containment atmosphere, penetrates the primary reactor containment, and is provided with containment isolation valves. There are two containment isolation valves placed in series, located outside the containment vessel, and placed as close to the primary containment wall as practical.

These isolation valves are located to provide accessibility for maintenance, inspection, and testing during all modes of reactor operation.

The pressurized sump system is credited for unidentified leak measurement, so the isolation valves on the EFS containment drain line are designed to be normally open to connect the drain line to the pressurized sump. To ensure a power source availability for the containment isolation valves, the isolation valves are supplied by different power source divisions. The EFS containment isolation valves have provisions to close automatically. Upon loss of actuating power, the automatic isolation valves are designed to fail closed, taking the position that provides greater safety.

All ESF piping is stainless steel to minimize corrosion.

Piping entering the collection sumps is turned down and terminated below the lowest sump fluid level to which the sump pump can draw. This provides a water seal to prevent gas flow and cross-contamination of building areas.

#### **9A.9.3.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing corrodents and mitigating the degradation of materials through material chemistry, heat treatment, material processes controls and periodic inspection. The ESF piping is manufactured from stainless steel and the sumps are manufactured using materials which have a high degree of resistance to effluents treated by the system. Proper selection of radiation-resistant materials of construction is included in individual equipment specifications as all liquid collected is treated as potentially contaminated.

#### **9A.9.3.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.9.3-1 for ESF interfaces.

#### **9A.9.3.6 System and Equipment Operation**

##### **Normal Operational Concept**

The ESF operates automatically in the same manner under all normal operating modes of the plant (startup, power operation, hot shutdown, cold shutdown, and refueling). Liquid wastes generated in the plant are directed into drain fixtures and drain piping. The ESF continually collects these radioactive or potentially radioactive liquid wastes and convey the wastes via gravity drainage piping systems to their respective collection sumps. Each pump is sized to accommodate the normal anticipated daily inputs into the sump. The system is not designed to accommodate fire suppression water. However, the system design features prevent drain or flood water from backing up in the drainage system into areas housing Safety-Category function SSC's.

No credit is taken for the drainage system in the internal flooding analysis.

Dual 100% capacity sump pumps are provided on each sump pump to pump liquid waste to LWM. The second pump automatically starts on sump high-high water level, provides redundancy in the event of sump pump failure, and assists the single pump when abnormally high inputs into the sump occur.

##### **Off-Normal Operational Concept**

In the event of a Loss-of-Coolant Accident (LOCA) signal, the containment isolation valves perform a Safety-Category function and close, thereby maintaining the integrity of the SCCV.

Under Design Basis Event (DBE) conditions and assuming the unavailability of normal power, the ESF does not operate, nor is it required to be functional. The containment isolation valves fail closed.

All drainage piping whose collapse could result in a loss of function of Safety-Category function SSC equipment, is seismically analyzed to remain intact following an SSE.

#### **9A.9.3.7 Instrument and Control**

##### **Instrumentation**

Redundant level sensors and transmitters are provided for each sump. Redundancy is appropriate for ensuring reliability and availability of the I&C systems. Level signals are used to start and stop the sump pumps based on High and Low setpoints. The level transmitters on the pressurized containment sump are also used to detect, measure, and trend leakage inside containment. Pump run timers are provided for each sump pump.

Local pressure transmitters are provided in the discharge piping of each sump pump which display the pressure remotely in the Main Control Room. Additionally, the pressurized sump that penetrates the SCCV is provided with discharge flow transmitters that displays the flow remotely in the Main Control Room.

Isolation diaphragms are installed between all gauges or transmitters and the piping, to avoid contaminating the instrument.

##### **Controls**

The following describes the key control features of the EFS.

Sump pump operations automatically maintain the sump level. The lead sump pump starts upon a high level indication and stops on low level indication. When the capacity of one sump pump is exceeded and the sump level rises above the high level, a high-high level setting is reached, and the standby pump starts. Both pumps operate until the low level is reached, causing both pumps

to stop. Alarms are annunciated at the high-high level to notify the operator of potential sump overflow and at the low-low level to notify the operator of potential air cross-contamination due to the loss of water seal. Sump pump controls are in the Main Control Room.

Where needed, sumps are provided with remote flush capability to clean out sumps prior to maintenance activities to minimize solid deposits.

The EFS containment isolation valves are controlled via the Safety Class 1 Instrumentation and Control System, and close upon receiving an isolation signal. These valves can also be remotely operated from the control rooms.

#### **9A.9.3.8 Monitoring, Inspection, Testing, and Maintenance**

The containment isolation valve closure time is measured during the valve operability test and the leakage is measured during the valve leakage test as specified in the containment leakage testing procedures. Each sump in the EFS utilizes recirculation lines with a grab sample tap to test/analyze the contents of the sump. Leak detection and inspection for primary containment isolation features comply with the requirements of ASME Boiler and Pressure Vessel Code Section III, Division 1, Class 2 (Reference 9A.9.3-2). A test connection is provided between the isolation valves to support local leak rate testing of the primary containment boundary.

#### **9A.9.3.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.9.3.10 Performance and Safety Evaluation**

As part of DL3, the EFS performs a containment isolation Safety-Category function. The CIVs are designed to close upon receipt of an isolation signal from the Safety Class 1 Instrument and Control System. The CIVs are designed to maintain the leak tightness of the containment in the event of an accident and prevent radioactive releases to the environment that exceed prescribed limits.

#### **9A.9.4 Interfacing Water Systems**

##### **9A.9.4.1 Potable Water System**

The Potable Water System design is dependent on the site-specific water pathways. The system is designed to supply the required volume of potable water during peak demand periods.

##### **9A.9.4.2 System and Equipment Functions**

###### **Normal Functions (Non-Safety-Category)**

Provides for potable water distribution inside the power block. The Potable Water System brings potable water to the power block from the city water source.

###### **Normal Function (Safety Category)**

There are no Safety-Category functions related to the Potable Water System.

###### **Off-Normal Functions (Non-Safety Category)**

There are no specific off-normal functions related to the Potable Water System.

###### **Off-Normal Functions (Safety Category)**

There are no Safety-Category functions related to the Potable Water System.

The safety classification of the Potable Water System is consistent with the requirements of CNSC REGDOC-2.5.2, Section 7.1 (Reference 9A.9.4.12-1).

##### **9A.9.4.3 Safety Design Bases**

The Potable Water System does not perform, ensure, or support any Safety-Category function, and thus has no safety design bases.

##### **9A.9.4.4 Description**

The potable water system provides potable water to the power block. The system includes faucets, toilets, showers, and hot water heaters.

The potable water system provides makeup water to the demineralized water trailers if needed.

The Potable Water System consists of potable water supply piping from the Municipality of Durham. The supply line includes isolation valves, flow totalizer and instrumentation. Heat tracing is provided for all outside above ground piping and instrumentation. A distribution header supplies the power block and other onsite buildings. Provisions are made in the distribution header to accommodate future demand.

Potable water supplies the following areas:

1. Mobile demineralized water trailers as required to supplement Darlington Nuclear Generating Station (DNGS) demineralized water supply
2. Restrooms, food service equipment and battery room safety showers in the Control Building
3. Water is supplied to the toilet in the Main Control Room

###### **9A.9.4.4.1 Component Description**

The Potable Water System components include: underground supply lines, isolation valves, and necessary instrumentation. Heat tracing is provided for all outside above ground piping and

instrumentation. Where required, back flow preventers are installed. Hot water heaters, faucets and showers are installed where needed.

Piping and valves associated with the Potable Water System are designed and manufactured in accordance with applicable codes and standards for the applications involved. These codes and standards include but are not limited to ASME B31.1 Power Piping (Reference 9A.9.4.12-2), National Plumbing Code of Canada (Reference 9A.9.4.12-3), Regulation 332/12 Ontario Building Code (Reference 9A.9.4.12-4), and American Society for Testing and Materials D3350-14 Standard Specification for Polyethylene Plastics Pipe and Fittings Material (Reference 9A.9.4.12-5).

#### **9A.9.4.5 Materials**

The Potable Water System provides piping, valves, and other control components to distribute potable water to final use locations. Potable water system component materials are built to the Canadian National Building Code.

#### **9A.9.4.6 Interfaces with Other Equipment or Systems**

The potable water system interfaces with the following other systems:

Demin Water – There is a potable water connection to provide for temporary potable water supply to portable demineralizer trailers.

Sanitary Sewer – Potable water supplies water to toilets, sinks, showers which drain to the sanitary sewer system.

Electrical – Low voltage power from the Non-Safety Electrical Distribution System is supplied to components in the system to provide for heating of water.

#### **9A.9.4.7 System and Equipment Operation**

The potable water system relies on system pressure being supplied from the Municipality of Durham. Hot water heaters are provided where necessary. The hot water heaters temperature is automatically controlled.

The Potable Water System is designed for operation in all modes.

#### **9A.9.4.8 Instrumentation and Control**

Instrumentation for the potable water system includes flow metres to track usage of water, back flow preventers where required by code, temperature control thermostats in the hot water heaters, and relief valves in the system where required.

Instrumentation such as valve position switches, pressure gauges, and temperature sensors are located throughout the system.

#### **9A.9.4.9 Monitoring, Inspection, Testing, and Maintenance**

The potable water system is tested and commissioned in accordance with the National Plumbing Code of Canada and Ontario's Watermain Disinfection Procedure. Commissioning includes hydrostatically tested for leak-tightness, disinfection, and flushing of the system.

Periodic testing for residual chlorine and micro biologics is done in accordance with the Safe Drinking Water Act, the Ontario Drinking Water Quality Management Standard, and Guidelines for Canadian Drinking Water Quality.

#### **9A.9.4.10 Radiological Aspects**

The Potable Water System has no interconnections to systems with the potential for containing radioactive material.

Chapter 12, Subsection 12.3 provides information pertaining to design measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.9.4.11 Performance and Safety Evaluation**

There is no potable water piping in the reactor building. Potable water is limited to Non-Safety-Category function areas of the plant. The MCR washroom and kitchen area sinks, and potable water piping are sufficiently remote from the control system to eliminate the potential for interactions.

### **9A.9.5 Makeup Water System**

The Makeup Water System consists of supply piping from the Darlington Nuclear Generating Station (DN GS) site, trailer hookup piping, storage tank, transfer pumps, and distribution piping.

#### **9A.9.5.1 System and Equipment Functions**

##### **Normal Functions (Non-Safety-Category)**

Provides for demineralized water storage and distribution.

##### **Normal Function (Safety Category)**

The system does not perform any Safety-Category functions during normal conditions.

##### **Off-Normal Functions (Non-Safety Category)**

Following a reactor trip with no condenser available, the Makeup Water System provides makeup to the Isolation Condenser pools (Chapter 5, Subsection 5.8).

##### **Off-Normal Functions (Safety Category)**

The Makeup Water System provides containment isolation of Makeup Water System piping penetrating the SCCV. This isolation is provided by two locked closed manual isolation valves which are Safety Class 1 and Defense Line 3 – one valve inboard and one valve outboard of the Primary Containment. The containment isolation valves are only open during Mode 5 or 6.

The Makeup Water System is not required to operate during or after a design basis event except for performing the containment isolation function. The design of the Makeup Water System meets

CNSC requirements specified in CNSC REGDOC-2.5.2 Section 8.6.6 as related to containment isolation. (Reference 9A.9.5.11-1).

#### **9A.9.5.2 Safety Design Bases**

The Makeup Water System containment penetration and isolation valves perform the safety function of maintaining containment integrity.

#### **9A.9.5.3 Description**

The makeup water supply from the DNGS site is sized to provide for normal makeup water needs for the unit as well as additional capacity to refill the ICS pools in a reasonable timeframe following a typical initiation. During certain shutdown/refueling/startup mode evolutions the increases in plant water consumption may require use of a temporary demineralization subsystem to be used as a supplemental water source.

Demineralized water of the proper water quality specification is supplied to the single demineralized water storage tank located in the site yard. The tank is heated to prevent freezing. Two 100% pumps supply the demineralized water system.

The demineralized water system provides makeup water to: Condensate Storage Tank, Isolation Condenser Pools, Ventilation Humidification, Chilled Water and Plant Cooling Water surge tanks, Boron Injection Tank, and washdown stations on the refuel floor and in containment. Additional demineralized water connections are located where needed for maintenance of systems.

The makeup water equipment and associated piping in contact with demineralized water are fabricated from corrosion-resistant materials to prevent contamination of the makeup water.

Piping and valves associated with the Makeup Water System are designed and manufactured in accordance with applicable codes and standards for the applications involved. These codes and standards include but are not limited to ASME B31.1 Power Piping (Reference 9A.9.5.12-2), National Plumbing Code of Canada (Reference 9A.9.5.12-3) – American Water Works Association D100 (Reference 9A.9.5.12-4).

#### **9A.9.5.4 Materials**

Water quality requirements are used in the selection of Makeup Water System components.

#### **9A.9.5.5 Interfaces with Other Equipment or Systems**

Refer to Table 9A.9.5-1 for Makeup Water System interfaces with other systems.

#### **9A.9.5.6 System and Equipment Operation**

The demineralized water storage tank is filled as necessary from the DNGS water treatment plant. Filling of the tanks is a batch process that is manually controlled. Level alarms prompt the operator to secure filling when needed.

Normal plant operation includes Power Operation, Startup Operation, Hot Shutdown Operation, Stable Shutdown Operation, Cold Shutdown Operation, and Refueling Operation. During normal operations the Makeup Water System provides demineralized water storage and distribution to required systems and equipment in the plant.

The demineralized water in containment is only used when the plant is shutdown. During plant operation both inside and outside manual containment isolation valves are locked closed.

#### **9A.9.5.7 Instrumentation and Control**

Level alarms on the demineralized water storage tank alert the operator to high or low level situations.

The storage tank heater as well as heat trace on above ground yard piping is automatically controlled.

#### **9A.9.5.8 Monitoring, Inspection, Testing, and Maintenance**

Containment Isolation Valves are periodically tested to validate operability and determine if valve leakage is within acceptable limits. Test and vent connections are provided at the containment isolation valves to verify that the valves meet the local leak rate limits.

Makeup water is monitored and tested to ensure it meets the water quality requirements for interfacing systems.

Periodic and condition-based maintenance are completed for instrumentation, pump vibrations, and other equipment to ensure the proper performance of the system.

#### **9A.9.5.9 Radiological Aspects**

Chapter 12, Subsection 12.3 provides information pertaining to design measures that can be taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are as ALARA in operational states and in accident or post-accident conditions.

#### **9A.9.5.10 Performance and Safety Evaluation**

The Makeup Water System performs the containment isolation Safety-Category function using two manual valves. The containment isolation valve arrangement meets the requirements of Section 8.6.6 of REGDOC-2.5.2 (Reference 9A.9.5-1).

NON-PROPRIETARY INFORMATION

**Table 9A.9.5-1: Makeup Water System Interfaces**

<b>Interfacing System</b>	<b>Interface Description</b>	<b>Interface Boundary</b>
Non-Safety Instrumentation and Control System	Provides all SCN Instrumentation and Control for the demineralized water equipment, potable water, sewage treatment, and hydrogen subsystems	Non-Safety Class Instruments
Non-Safety Electrical Distribution System	Provides power to demineralized water transfer pumps and tank/piping heating	SCN Pumps and heater, and controls
Process Radiation and Environmental Monitoring System	Provides demineralized water to Process and Radiation Monitoring for process sampling	Sampling points and RWB chemical Laboratory
ICS Pool Cooling and Cleanup System	Provides Demineralized water to the IC pools through the ICS Cooling and Cleanup system	Interface valve
Boron Injection System	Provides demineralized water to the Boron Injection Sodium Pentaborate Storage Tank for filling	Interface valve
Plant Cooling Water System	Provides demineralized water to the surge tanks	Interface valve
Chilled Water Equipment System	Provides demineralized water to the glycol auto fill unit	Interface valve
Heating, Ventilation and Cooling System	Provides demineralized water to CB AHUs used for space humidification	AHUs
Liquid Waste Management System	Provides demineralized water to the Condensate storage tank	Interface valve
Refueling Equipment and Servicing	Provides demineralized water connections on the refueling floor for use during outages	Interface valve
Main Condenser and Auxiliaries	Provides fill and makeup water to the condenser vacuum skids for seal water separators	Interface valve
DNGS Demineralized Water System	System is supplied demineralized water from the DNGS Demineralized Water System	Yard demineralized water tie-point connection

## **9A.9.6 Sanitary Water Systems**

### **9A.9.6.1 System and Equipment Functions**

#### **Normal Functions (Non-Safety Category)**

Provides for sewage water collection and delivery to the existing DNGS East Sewage Lift Station.

#### **Normal Function (Safety Category)**

There are no normal Safety-Category functions related to the Sanitary Water System.

#### **Off-Normal Functions (Non-Safety Category)**

There are no off-normal functions related to the Sanitary Water System.

#### **Off-Normal Functions (Safety Category)**

There are no specific off-normal functions related to the Sanitary Water System.

The safety classification of the Sanitary Waste System is consistent with the requirements of CNSC REGDOC-2.5.2, Section 7.1 (Reference 9A.9.6.11-1).

### **9A.9.6.2 Safety Design Bases**

The Sanitary Water System does not perform, ensure, or support any Safety-Category function, and thus, has no safety design bases.

### **9A.9.6.3 Description**

The Sanitary Sewer Collection and Delivery Subsystem collects sewage from the facility washrooms and break areas and transfers the sewage to the existing DNGS East Sewage Lift Station. The sewage system is a non-radiologically contaminated system and collects sewage only from areas outside of any radiologically controlled areas in the CB. This subsystem is sized for normal plant operation of the CB. The Administration Building and the Security Building sewage system is provided by OPG.

The Sanitary Sewage Handling Subsystem is designed to prevent raw sewage overflow in the event of a power outage.

Piping and valves are designed and manufactured in accordance with applicable codes and standards for the applications involved. These codes and standards include National Plumbing Code of Canada (Reference 9A.9.6.11-2), and Regulation 332/12 Ontario Building Code (Reference 9A.9.6.11-3).

### **9A.9.6.4 Materials**

The water quality requirements are used in the material selection and design of the water treatment systems.

### **9A.9.6.5 Interfaces with Other Equipment or Systems**

The sanitary water system interfaces with the DNGS waste treatment system.

### **9A.9.6.6 System and Equipment Operation**

The Sanitary Water System is designed for operation in all modes.

Sanitary waste drains are gravity drained through underground piping to a lift station which is part of the DNGS waste treatment system.

#### **9A.9.6.7 Instrumentation and Control**

Alarm indication is provided as needed to inform the operator of the status of the DNGS East Lift Station pump.

#### **9A.9.6.8 Monitoring, Inspection, Testing, and Maintenance**

Inspection and testing of the Sanitary Water System is performed in accordance with the applicable requirements of the Ontario Building Code.

#### **9A.9.6.9 Radiological Aspects**

The Sanitary Water System is a non-radiologically contaminated system and only collects sanitary waste from areas outside of any radiologically controlled areas in the CB.

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.9.6.10 Performance and Safety Evaluation**

The Sanitary Water System does not perform, ensure, or support any Safety-Category function; therefore a Safety Evaluation is not required.

#### **9A.9.6.11 References**

- 9A.9.6.11-1 CNSC Regulatory Document REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants."
- 9A.9.6.11-2 "National Plumbing Code of Canada," Canadian Commission on Building and Fire Codes, National Research Council of Canada.

## **9A.9.7 Chemistry Systems**

### **9A.9.7.1 Primary Coolant**

Not Applicable, the terminology "Primary Coolant" refers to a Pressurized Water Reactor.

### **9A.9.7.2 Secondary Coolant**

Not Applicable, the terminology "Secondary Coolant" refers to a Pressurized Water Reactor.

## **9A.9.8 Other Process Media and Other Materials**

### **9A.9.8.1 Hydrogen Water Chemistry**

#### **9A.9.8.1.1 *System and Equipment Functions***

The Hydrogen Water Chemistry System adds hydrogen into the feedwater system at the Reactor Feed Pump suction and oxygen (as a constituent of air) into the Offgas System (Chapter 11, Section 11.3) via the Service Air System (Subsection 9A.4.1). The Hydrogen Water Chemistry System is included in the BWRX-300 design for the purpose of reducing and mitigating IGSCC in reactor vessel internals.

#### **9A.9.8.1.2 *Safety Design Bases***

The Hydrogen Water Chemistry System does not perform, ensure, or support any Safety-Category function, and thus, has no safety design bases.

#### **9A.9.8.1.3 *Description***

The Hydrogen Water Chemistry System provides for an established technique for reducing and preventing the growth rates of Intergranular Stress Corrosion Cracking (IGSCC) in reactor vessel internals. The mitigation of IGSCC is achieved from the reduction of oxygen and other oxidizing species (oxidants) in the reactor coolant. This is accomplished by injecting hydrogen into the feedwater at the feedwater pump suction. The injected hydrogen suppresses the radiolytic formation of oxidants in the reactor core. To compensate for any excess hydrogen which may travel downstream and be removed from the main condenser by the Offgas System, a corresponding amount of oxygen, as a constituent of injected air provided by the Service Air System, is injected into the Offgas System prior to Offgas Recombiner.

Reduction of oxidants results in a reduction of the Electrochemical Corrosion Potential, which is the measurement that is used to predict initiation and growth of IGSCC. When the Electrochemical Corrosion Potential is reduced to an acceptable level, IGSCC crack initiation stops, and crack growth rates are minimized. The BWRX-300 design employs NobleChem™ technology as a means to provide for the injection of noble metal(s) into the reactor to aid in the protection of reactor vessel internals from IGSCC in combination with the addition of hydrogen by the Hydrogen Water Chemistry System. As a result of NobleChem™ injection, the noble metal deposition in the reactor provides a catalyst effect on vessel surfaces to facilitate the recombination of free hydrogen and oxygen molecules to minimize the oxygen available to initiate and encourage IGSCC crack growth. Refer to Subsection 9A.9.9 for a description of the application of NobleChem™ technology.

The Hydrogen Water Chemistry System injects hydrogen into the feedwater system at the Reactor Feed Pump (RFP) suction to mitigate IGSCC in the reactor internals. The injected hydrogen causes a reduction in dissolved oxygen and other oxidants within the reactor internals by lowering the radiolytic production of hydrogen and oxygen in the vessel core region.

Hydrogen addition to the feedwater results in an excess ratio of hydrogen to oxygen at the entrance to the Offgas System. The Hydrogen Water Chemistry System injects a stoichiometric

amount of oxygen (as a constituent of air) upstream of the offgas recombiner to combine with the hydrogen reaching the recombiner. The amount of air (oxygen) can be determined from the hydrogen injection rate and is controlled by the Hydrogen Water Chemistry System utilizing time delays in the controls to ensure that hydrogen and oxygen reach the offgas recombiner in balanced amounts. The net result is that with air (oxygen) injection, the Offgas System operates at conditions (relative to gas constituents needed to recombine to form water vapor) very much like the conditions without Hydrogen Water Chemistry System. For most BWRs that use NobleChem™ technology with a Hydrogen Water Chemistry System featured with air injection into the offgas system, the actual air flow injection can be determined from the hydrogen injection rate and condenser air inleakage and, is controlled by the Hydrogen Water Chemistry System controller to maintain sufficient percent oxygen exit downstream of the offgas recombiner.

The Hydrogen Water Chemistry System consists of a Main Control Panel, a Hydrogen Isolation Module (to isolate the hydrogen supply from the power plant buildings if necessary), a Hydrogen Flow Control Module, which controls the flow of hydrogen into the Feedwater System, and an Air Flow Control Module, which controls air flow to the Offgas System. Note that Hydrogen Area Monitors are also included in the system which monitor for local hydrogen in the areas of susceptible system equipment.

#### **9A.9.8.1.4 System and Equipment Operation**

##### **Power Operation**

The Hydrogen Water Chemistry System can only be operated during power operations. The Hydrogen Water Chemistry System begins operation when the RFP pump is in service and Steam Jet Air Ejectors (SJAE) and Offgas System are in-service during plant startup.

#### **9A.9.8.1.5 Instrumentation and Control**

Instrumentation is provided to control the injection of hydrogen and the injection of oxygen (as a constituent of air) via the Service Air System. Automatic control features in the Hydrogen Water Chemistry System minimize the need for operator attention and improves performance.

#### **9A.9.8.1.6 Monitoring, Inspection, Testing, and Maintenance**

The Hydrogen Water Chemistry System is demonstrated functional by its use during normal operation.

#### **9A.9.8.1.7 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.9.8.1.8 Performance and Safety Evaluation**

The Hydrogen Water Chemistry System does not perform a Safety-Category function. However, the Hydrogen Water Chemistry System is used, along with other measures, to reduce the likelihood of corrosion failures that would adversely affect plant availability. The means for storing and handling hydrogen utilizes the guidelines in Electric Power Research Institute (EPRI) Report "Guidelines for Permanent BWR Hydrogen Water Chemistry Installations" (Reference 9A.9.8-1).

#### **9A.9.8.1.9 References**

- 9A.9.8-1 EPRI Report NP-5283-SR-A, "Guidelines for Permanent BWR Hydrogen Water Chemistry Installations," Electric Power Research Institute.

### **9A.9.9 NobleChem™ Injection**

#### **9A.9.9.1 System and Equipment Functions**

On-Line NobleChem™ (OLNC) provides a means for the injection of noble metal salt solution directly into the reactor coolant flow path. The purpose of injecting noble metal into the reactor is to aid in the protection of reactor vessel internals from IGSCC in combination with the addition of hydrogen by the Hydrogen Water Chemistry System (Subsection 9A.9.8.1).

#### **9A.9.9.2 Safety Design Bases**

The OLNC does not perform, ensure, or support any Safety-Category function, and thus, has no safety design bases.

#### **9A.9.9.3 Description**

The OLNC application process deposits noble metal salt solution directly into the reactor coolant flow path. The resulting noble metal deposition in the reactor provides a catalyst effect on vessel surfaces to facilitate the recombination of free hydrogen and oxygen molecules to minimize the oxygen available to initiate and encourage IGSCC crack growth. Due to the catalyst effect from noble metal loading, utilizing OLNC in conjunction with a Hydrogen Water Chemistry System mitigation strategy results in a much lower amount of injected hydrogen required to achieve IGSCC mitigation levels than the use of Hydrogen Water Chemistry System alone. This need for less hydrogen to provide mitigation results in lower main steam line dose rates.

OLNC operates in conjunction with the Hydrogen Water Chemistry System although they are both separate systems which have no mechanical or electronic interrelationships. The Hydrogen Water Chemistry System is used to provide a ratio of hydrogen to oxygen in excess of the stoichiometric balance which causes a significant decrease in the electrochemical corrosion potential of the reactor vessel and internal components. As long as excess hydrogen is maintained, crack initiation and growth are greatly reduced, even at high bulk liquid oxidant levels. OLNC injection provides a catalytic surface on reactor vessel internals to enhance the function of the Hydrogen Water Chemistry System. Based on the catalytic surface recombination efficiency provided by OLNC, less hydrogen is required (from the Hydrogen Water Chemistry System) to establish the Electrochemical Corrosion Potential to mitigate IGSCC initiation and significantly reduce IGSCC crack growth rates.

The OLNC injection skid is installed as permanent plant equipment outside of the Steel-plate Composite Containment Vessel in a Non-Safety-Category area as close as possible to the Feedwater injection tap(s). A direct connection to a supply of demineralized water provides the carrier flow to lessen the residence time of the noble metal solution in the injection line. The effluent from the OLNC injection skid is injected into a tap (or taps) in the Feedwater System (via an injection quill) at a point that lessens the loss of noble metal prior to entering the reactor.

Once the flow from the injection skid reaches the Feedwater System, the process employs the reactor coolant as the transport medium to deposit noble metal on the surface of all wetted reactor components and inside existing cracks.

The boundary between OLNC and the Condensate and Feedwater Heating System (Chapter 10, Subsection 10.3.2) is downstream of the isolation and root valves to the CFS to a shared flange with the CFS (and also includes the injection quill). A single input tie for demineralized water as well as plant electrical power from the Non-Safety Electrical Distribution System is provided to support operation of the system.

#### **9A.9.9.4 System and Equipment Operation**

##### **Power Operation**

The OLNC injection is designed to be performed during power operations.

#### **9A.9.9.5 Instrumentation and Control**

Instrumentation is provided to monitor and control the injection of a noble metal solution into the reactor coolant flow path at the injection skid.

#### **9A.9.9.6 Monitoring, Inspection, Testing, and Maintenance**

OLNC injection is demonstrated functional by its use during normal operation.

#### **9A.9.9.7 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states and in accident or post-accident conditions.

#### **9A.9.9.8 Performance and Safety Evaluation**

OLNC does not perform a Safety-Category function. The OLNC Injection System is used, along with the Hydrogen Water Chemistry System to reduce the likelihood of IGSCC.

#### **9A.9.10 Chemical Bases of Water Treatment**

Refer to Chapter 13, Subsection 13.3.1 for information pertaining to the Chemistry Control Program.

#### **9A.10 Storage System for Non-Permanent Equipment Used in Design Extension Conditions**

The storage system for non-permanent equipment used in Design Extension Conditions is developed based upon Emergency Mitigating Equipment requirements. The design of the storage system takes into consideration the aggregate set of on-site and off-site resource considerations for the hazards that are applicable to the site as well as final BWRX-300 design considerations. These factors plus consideration for the following are used as design inputs to size, locate, deploy, and operate the storage system”

- Protection of EME
- Deployment of EME
- Procedural Interfaces
- Utilization of off-site resources
- Use of existing site facilities for storage

**REVISION SUMMARY**

<b>Revision #</b>	<b>Section Modified</b>	<b>Revision Summary</b>
0	All	Initial Release
1	Section 9B.4	Reference correction per customer acceptance review.
2	Acronym list	Updated to include added acronyms.
2	Table of Content, List of Tables and List of Figures	Updated.
2	Section 9B.1	Added reference to Section 9B.3.
2	Section 9B.1.1	Edited to remove reference to RB walls.
2	Subsection 9B.1.2	Added reference to Table 3.5-1 and 3.5.2. Edited to include reference to Chapter 2, Subsection 2.7.4.7.6.
2	Subsection 9B.1.3	Added reference to Figure 9B-1 and details on mat foundation. Added wing walls to lateral load resisting systems.
2	Subsection 9B.1.5	Edited to include reference to integrated RB structures.
2	Subsection 9B.1.6	Edited for clarity on structural design of the common mat foundation.
2	Subsection 9B.1.9	Edited to include reference to Chapter 2, Subsection 2.11.3.
2	Section 9B.2	Edited to include RB exterior wall terminology.
2	Subsection 9B.2.1.2	Added flooding to list of internal hazards and reference to Chapter 3, Section 3.3 and Chapter 6, Subsection 6.3.5.
2	Subsection 9B.2.1.3	Added reference to Chapter 6, Subsection 6.3.4.
2	Subsection 9B.2.1.4	Edited to include reference to design specifications and removed details on concrete used for shielding purposes.
2	Subsection 9B.2.1.4.1	Modified heading for Subsection 9B.2.1.4.1.
2	Subsection 9B.2.1.4.2	Updated steel faceplates properties and references consistent with 9B-4.
2	Subsection 9B.2.1.4.3	Updated references consistent with 9B-4.
2	Subsection 9B.2.1.4.4	Updated references consistent with 9B-4.

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

Revision #	Section Modified	Revision Summary
2	Subsection 9B.2.1.5	Removed the word “accurately” and updated reference consistent with 9B-4.
2	Subsection 9B.2.1.8	Edited details in reference to Chapter 3, Subsection 3.5.5.6.
2	Subsection 9B.2.1.9	Added details and reference to Subsection 9B.2.2.3 and Figure 9B-1.
2	Subsection 9B.2.1.10	Removed the word “expected” and updated reference consistent with 9B-4.
	Subsection 9B.2.1.10.1	Updated references consistent with 9B-4.
2	Subsection 9B.2.1.10.2	Added details in reference to Appendix 9B.A and Appendix 9B.E. Removed reference to Open Item.
2	Subsection 9B.2.1.10.3	Modified Heading. Added details and paragraph summarizing plots presented in Appendix 9B.E.
2	Subsection 9B.2.1.10.4	Added reference to containment criteria in Chapter 3, Subsection 3.5.6. Removed reference to Open Item.
2	Subsection 9B.2.2.3	Clarified how containment internal structures are supported. Added detail on bioshield separation from RPV pedestal, and reference to Appendix 9B.G.
2	Subsection 9B.2.2.4	Added reference to high density concrete.
2	Subsection 9B.2.2.5	Edited to streamline text in reference to 9B.2.2.3.
2	Subsection 9B.2.2.6	Added details and reference to Appendix 9B.A.
2	Subsection 9B.2.2.10.2	Added detail in reference to Appendix 9B.A and Appendix 9B.F. Removed reference to Open Item.
2	Subsection 9B.2.2.10.3	Added detail to summarize plots in Appendix 9B.F.
2	Subsection 9B.2.3.3	Edited to reflect steel beam and RB exterior wall terminology.
2	Subsection 9B.2.3.4.1	Modified heading for Subsection 9B.2.3.4.1.
2	Subsection 9B.2.3.4.2	Added reference to Type B (studs).
2	Subsection 9B.2.3.4.4	Added reference to A325 Type 1.
2	Subsection 9B.2.3.4.6	Added reference to Clause 6.9.2 of CSA N291.

## **9B.0 CIVIL ENGINEERING WORKS AND STRUCTURES**

Chapter 9B describes how the general design requirements specified in Chapter 3, Section 3.5 for the Seismic Category A integrated Reactor Building (RB) are complied with in the design of the structure, with Section 9B.1 focusing on the common mat foundation supporting the integrated RB and Section 9B.2 focusing on each of the RB integrated structures. As mentioned in Chapter 3, Section 3.5, reference to the integrated RB is inclusive of the RB, containment, and containment internals, whereas RB is used to refer to the RB structure outside of containment.

Also presented in Chapter 9B are the general design requirements for the Radwaste Building (RWB), Control Building (CB), Turbine Building (TB), Reactor Auxiliary Bay, Pumphouse/Forebay structures and tunnels, and Fire Pump Enclosure. Information presented for these structures in this chapter is commensurate with their importance to safety. Remaining plant structures shown in Chapter 1, Appendix A, Figure A1.4-1 are not covered since they are not credited in the safety analysis.

Below are the key PSAR chapters that should be reviewed along with this chapter:

1. Chapter 1 which provides the Darlington New Nuclear Project (DNNP) general site and facility layout, a description of the BWRX-300 buildings, plant operational modes, principles of safety management and applicable codes and standards utilized in the design.
2. Chapter 2 which describes the characteristics of the DNNP site on which the BWRX-300 facility is constructed.
3. Chapter 3, Section 3.1, which provides the general design aspects and Defence-in-Depth safety framework utilized in the BWRX-300 design.
4. Chapter 3, Section 3.2, which provides the general classification of BWRX-300 Structures, Systems and Components (SSC) and the approach used to establish these classifications.
5. Chapter 3, Sections 3.3 and 3.4, which provide methodology and general design requirements for protection against the effects of external and internal hazards.
6. Chapter 3, Section 3.5, which provides general design aspects including methodology and codes and standards used in the design of seismic category buildings and civil engineering structures.
7. Chapter 6 which describes the containment and its associated systems, engineered safety features included to mitigate the consequences of anticipated operational occurrences or postulated design basis accidents, and habitability systems.
8. Chapter 9A which discusses BWRX-300 auxiliary systems including the Heating, Ventilation and Air-Conditioning (HVAC), the Fire Protection systems, overhead lifting equipment and floor drain systems.
9. Chapter 12 which describes the administrative programs and procedures, in conjunction with facility design, that ensure occupational radiation exposure to personnel is kept As-Low-As Reasonably Achievable (ALARA).
10. Chapter 15 which discusses Design Extension Conditions (DECs) and Beyond Design Basis Accidents (BDBAs) considered in the design and documents safety analysis results used to confirm adequacy of design.
11. BWRX-300 Security Annex, which evaluates the ability of the integrated RB to withstand regulatory defined threats.

## **9B.1 Foundations**

This section demonstrates how the design of the common Steel Bricks™ mat foundation supporting the integrated RB structure complies with the design requirements in Chapter 3, Subsection 3.5.2. For the design of the adjacent Power Block foundations, refer to Section 9B.3.

### **9B.1.1 Structural Role**

The common Steel Bricks™ mat foundation supports the deeply embedded integrated RB structure and provides the mechanism for transferring all applicable loads from the integrated RB structure to the surrounding subgrade.

### **9B.1.2 Safety Design Bases**

The seismic category of the containment and RB common mat foundation is the same as that of the superstructures. In compliance with Section 7.15.1 of CNSC REGDOC-2.5.2 (Reference 9B.4-1), the common mat foundation is evaluated and designed to ensure the stability and structural integrity of the integrated RB under normal operation, Anticipated Operational Occurrences (AOO) and Design Basis Accidents (DBAs). The robustness of the common mat foundation design under DEC is also considered in compliance with requirements in CNSC REGDOC-2.5.2, Section 7.15.1 and is discussed in Subsection 9B.2.1.10.

Since the integrated RB is deeply embedded in soil and rock, extensive geotechnical investigations are performed following the guidelines in NEDO-33914 (Reference 9B.4-2) to ensure proper soil and rock parameters, and subgrade modeling assumptions, are established for the Soil-Structure Interaction (SSI) of the deeply embedded integrated RB including foundation. Bounding site-specific subgrade parameters used in the analysis and design of the integrated RB are presented in Chapter 3, Tables 3.5-1 and 3.5-2. Subgrade modeling assumptions for the SSI of the deeply embedded integrated RB are described in Chapter 3, Subsection 3.5.1.1.

Stability evaluation of the common mat foundation is performed using the criteria in Chapter 3, Subsection 3.5.2.2. Consistent with CNSC REGDOC-2.5.2, Section 7.15.1, a potential liquefiable evaluation of the soil strata is performed, as discussed in Chapter 2, Subsection 2.7.4.7.6, and the effects of fluctuating groundwater are considered, in the evaluation of soil capacity. This is done to preclude total and differential settlement of the common mat foundation that can challenge the functions of Seismic Category A or B SSC in the integrated RB.

### **9B.1.3 Structural Description**

The deeply embedded cylindrical integrated RB structure is founded on a common circular mat foundation that supports the containment, containment internal structures and RB. This common mat foundation is made of Steel Bricks™ modules, same as the supported superstructures, and is deeply embedded in the rock. As mentioned in Chapter 3, Subsection 3.5.2.1, the containment boundary for the common mat foundation extends to the outer perimeter of the Steel-plate Composite Containment Vessel (SCCV) as shown in Figure 9B-1. The mat foundation supporting the SCCV is referred to as the inner mat foundation (See Figure 9B-2). The mat foundation outside of the containment boundary is referred to as the outer mat foundation.

The walls of the RB and containment structures carry the vertical loads from the structures to the deeply embedded common mat foundation. Lateral loads are transferred to these walls and to wing walls by the roof, floor diaphragms and Containment Equipment and Piping Support Structure (CEPSS). The below grade RB exterior wall and mat foundation transmit, in turn, the loads to the surrounding subgrade. The transfer of the lateral loads is affected by the interaction of the deeply embedded integrated RB structure with the surrounding soil and rock materials as discussed in Chapter 3, Subsection 3.5.1.1.

Figure 9B-1, Figure 9B-2 and Table 1.5-2 in Chapter 1 provide dimensions, plan, and section views of the integrated RB common foundation.

#### **9B.1.4 Materials**

Refer to Sections 9B.2.1.4 and 9B.2.3.4 for a description of materials used for the common mat foundation supporting the BWRX-300 integrated RB. The selection of these materials takes into account the environmental effects in compliance with CNSC REGDOC-2.5.2, Section 7.15.1.

#### **9B.1.5 Interfaces with Other Equipment or Systems**

The behaviour of contact interfaces between the common circular mat foundation supporting the integrated RB structures and the surrounding supporting media is considered in the SSI analyses discussed in Chapter 3, Subsection 3.5.1.1. These analyses consider Structure-Soil-Structure Interaction (SSSI) due to the closeness of the RWB, CB, TB, and Reactor Auxiliary Bay to the RB as described in Chapter 3, Subsection 3.5.1.1.

To protect the mat foundation from damage following core melt, a corium shield (See Figure 9B-1) is installed at the lower portion of the SCCV, and Reactor Pressure Vessel (RPV) pedestal as described in Chapter 3, Subsection 3.5.6.1.

#### **9B.1.6 System and Equipment Operation**

Not applicable to structural design of the common mat foundation.

#### **9B.1.7 Instrumentation and Control**

As described in Chapter 3, Subsection 3.3.1.5, seismic instrumentation is installed inside the RB at the top of the common mat foundation in accordance with Clause 5.2.3 of CSA N289.5 (Reference 9B.4-3) to monitor the seismic motions that may occur for the lifecycle of the reactor facility, starting from commissioning to decommissioning.

Piezometers, settlement sensors and extensometers are also used as described in Subsection 9B.1.8 to monitor the magnitude and distribution of pore pressure and amount of deformation of the subgrade materials surrounding the integrated RB.

#### **9B.1.8 Monitoring, Testing, Inspection and Maintenance**

Complying with requirements of Section 7.14 in CNSC REGDOC-2.5.2, monitoring, testing, inspection, and maintenance programs are implemented in the BWRX-300 design to avoid settling and degradation of the common mat foundation.

As mentioned in Subsection 9B.1.7, field instrumentation is installed inside and outside of the RB shaft to measure the distribution of pore pressures around and below the RB shaft, total settlement and tilt of the RB shaft including foundation, and measurement of the surrounding structures following the recommendations in NEDO-33914, Section 3.4. The instrumentation provides recordings during excavation and continuing through the BWRX-300 plant operation that can be benchmarked against design estimates using results of Foundation Interface Analyses (FIA) as described in NEDO-33914, Section 4.3.4. Short-term and long-term settlement monitoring plans are also developed to detect both vertical and horizontal movements in and around the integrated RB, as well as differential distortion across the foundation footprint and differential settlements between the containment and RB portions of the common mat foundations.

Refer to Chapter 3, Subsections 3.5.5.5 and 3.5.5.6 for a description of the minimum requirements for construction, in-service testing and inspection procedures for the Steel Bricks™ structures.

### **9B.1.9 Performance and Safety Evaluation**

In order to address the specific requirements for the design of the BWRX-300 deeply embedded RB, subsurface site investigations are performed as described in Chapter 2, Section 2.7, following the guidelines of NEDO-33914, Section 3.1, considering the combined footprint areas of the integrated RB common foundation and the adjacent RWB, CB, TB and Reactor Auxiliary Bay foundations. The extended area considered by the BWRX-300 subsurface site investigation ensures an adequate characterization of the subsurface conditions under the RWB, CB, TB and Reactor Auxiliary Bay foundations and resulting surcharge loads, which are important for the design of the deeply embedded RB structure and seismic design of integrated RB Seismic Category A and B SSC.

Stability evaluations for the common mat foundation under external hazards specified in Chapter 3, Section 3.3 are performed using results from the FIA (See Chapter 2, Subsection 2.11.3). Allowable bearing capacities for the common mat foundation taking into account the dry and submerged conditions at the site are presented in Chapter 2, Subsection 2.7.5.1. Stability and bearing capacity evaluations are performed for the integrated RB discussed in Section 9B.2 to ensure that the factors of safety listed in Chapter 3, Table 3.5-3 are met.

The design of the mat foundation portion within the perimeter or exterior surface of the SCCV, i.e., within the containment boundary, meets the design requirements of NEDC-33926P (Reference 9B.4-4). The design of the remaining portion meets the design requirements of ANSI/AISC N690 (Reference 9B.4-5) and NEDC-33926P.

Suitable provisions are provided to ensure that the common mat foundation is watertight as discussed in Chapter 3, Subsection 3.3.3.

### **9B.2 Integrated Reactor Building**

The integrated RB structure consists of the containment, containment internal structures and RB. The containment structure presented in Subsection 9B.2.1 protects and acts as a leak-tight boundary for the containment and associated systems discussed in Chapter 6, Section 6.3. Internal structures housed in the containment are described in Subsection 9B.2.2 and include the pedestal that supports the RPV and structures supporting piping and equipment within the containment.

The containment structure is completely enclosed within the deeply embedded RB structure presented in Subsection 9B.2.3. The RB is designed to protect the containment structure from external hazards (e.g., wind loads, tornado loads, aircraft hazard, missiles) and external beyond design basis scenarios. Besides the connection at the common mat foundation, the RB and containment structures are also connected at the top slab and through the RB wing walls and floor slabs at intermediate floor levels. The containment top slab directly supports the reactor cavity pool and Isolation Condenser System (ICS) pools and extends beyond the containment wall boundary to the RB exterior wall providing support for the fuel pool.

#### **9B.2.1 Containment**

As mentioned in Chapter 3, Subsection 3.5.3, the BWRX-300 containment comprises the SCCV, a steel containment closure head and other Class MC components.

##### **9B.2.1.1 Structural Role**

The primary functions of the containment structure are:

1. To enclose and support the RPV and its connected piping systems

2. To act as a leak-tight pressure boundary confining radioactive substances in different plant states, including normal operation, AOO, DBAs, and DEC's
3. To provide radiation shielding to limit radiation dose within the applicable regulatory standards in different plant states, including normal operation, AOO, DBAs, and DEC's
4. To provide in conjunction with the surrounding RB, protection for plant safety equipment and systems against external hazards and human induced events described in Chapter 3, Section 3.3

#### **9B.2.1.2 Safety Design Bases**

Per Chapter 3, Table 3.3-1, the BWRX-300 containment is a Seismic Category A structure.

As mentioned in Section 9B.2.1.1, the main function of the containment structure is to enclose and support containment systems and piping, and to act as a leak-tight pressure boundary confining radioactive substances in the four plant states groups identified in CNSC REGDOC-2.5.2, Section 7.3 (normal operation, AOOs, DBAs, and DEC's) in compliance with CNSC REGDOC-2.5.2, Section 8.6.2.

To perform its intended safety functions, the containment structure is designed to resist potential internal flooding, overpressures, underpressures, temperatures and dynamic effects as a result of internal missile generation and high energy line breaks discussed in Chapter 3, Section 3.4, with sufficient margins of safety in compliance with requirements in Section 8.6.2 of CNSC REGDOC-2.5.2. Being enclosed within the RB, the containment is also protected from the external hazards discussed in Chapter 3, Section 3.3.

The design bases and the various modes of operation of safety features and systems used to ensure the confinement functions and leak tightness of the containment are described in Chapter 6, Section 6.3.

Design bases for the robustness of the containment against overpressure, combustible gas pressures, seismic, elevated temperature and malevolent acts are discussed in Chapter 3, Subsection 3.5.6, Chapter 6, Subsection 6.3.5, and in Subsection 9B.2.1.10.

Design bases for the RB enveloping the containment structure and protecting it from external hazards and external beyond design basis scenarios are discussed in Subsection 9B.2.3.

#### **9B.2.1.3 Structural Description**

The BWRX-300 uses a traditional containment system for the ultimate containment of radioactive materials for various postulated events. The BWRX-300 containment is a vertical cylinder comprised of the SCCV, consisting of Steel Bricks™ cylindrical wall, mat foundation, and top slab, and a steel containment closure head (See Figure 9B-1). The containment structure is completely enclosed within the deeply embedded RB and includes personnel/equipment hatches, containment penetrations, and other safety components as shown in Figure 9B-1. The SCCV is also integrated with the RB and the integrated structure is supported by a common Steel Bricks™ mat foundation.

The containment closure head that covers the opening in the SCCV top slab over the RPV is a removable steel torispherical head anchored to the SCCV top slab using a pair of mating flanges. It is designed for removal during reactor refueling and for replacement prior to reactor operation using the RB polar crane. Provisions are made for testing the flange seals to ensure the containment closure head can perform its pressure retaining functions. Stainless steel cladding is fixed to the outer surface of the containment closure head to protect it from the water in the reactor cavity pool above during normal operation and the clad thickness is determined in

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

accordance with ASME Boiler and Pressure Vessel Code (BPVC) Section III, Division 1, Subsection NE-3122 (Reference 9B.4-6).

As shown in Figure 9B-1, two access hatches are provided in the containment structure, at Level -8.5 m and Level -29.0 m, to provide access to the upper and lower portions of the containment. These access hatches serve the dual purpose of allowing personnel access to the containment and for movement of equipment. Each access hatch has two pressure-seated doors interlocked to prevent simultaneous opening of both doors and to ensure that one door is completely closed before the opposite door can be opened. The door operation is designed and constructed so either door may be operated from inside the containment, inside the lock, or from outside the containment. Also, each access hatch has a barrel, which is an inner round portion that is slid into the fixed portion of the sleeve that is embedded in the SCCV wall. The barrel of the access hatch can be removed if large equipment needs to be transported during outages.

The number of penetrations in the containment structure is kept to a minimum and the containment penetrations are designed for loading conditions applicable for the containment structure and to allow for periodic inspection and testing in compliance with Section 8.6.5 of CNSC REGDOC-2.5.2. Figure 9B-1 depicts some of these containment penetrations. The major piping penetrations through the SCCV are associated with main steam and feedwater lines. Piping and electrical penetrations into the SCCV are categorized into two basic types, depending on whether the penetration is subjected to a hot or cold operational environment. Cold penetrations pass through the SCCV wall and are embedded directly in it. Hot penetrations do not come in direct contact with the SCCV wall but are provided with a thermal sleeve, which is attached to the SCCV wall. The thermal sleeve is attached to the process pipe at distance from the SCCV wall to minimize conductive heat transfer to the SCCV wall. The sleeve length for hot penetrations is designed to meet the concrete temperature limitations specified in NEDC-33926P. SCCV electrical penetrations are sealed to the interior side of the SCCV pressure boundary. For more information on containment penetrations, refer to Chapter 6, Subsections 6.3.2.2 and 6.3.4.

#### **9B.2.1.4 Materials**

The SCCV is constructed using Steel Bricks™ that are advanced steel-plate composite elements comprised of inner and outer steel faceplates, a continuous diaphragm plate through the thickness of section (resulting from the bending and welding of steel faceplates), shear connectors, and the fill concrete. The inner and outer faceplates maintain their structural integrity to perform the load resisting function while the inner steel faceplates of the SCCV also perform a liner function to provide a leak-tight boundary.

The containment closure head and other Class MC components are made of steel. Stainless steel cladding is fixed to the outer surface of the containment closure head to protect it from the water in the reactor cavity pool above as discussed in Subsection 9B.2.1.3.

Complying with Sections 7.15.1 and 8.6.11 of CNSC REGDOC-2.5.2, the selection of containment design materials takes into account service temperatures and other conditions of the containment pressure boundary during operation, maintenance, testing, and postulated accident conditions to ensure fulfillment of its functions. Uncertainties in determining material properties, residual, steady-state and transient stresses, and the size of flaws are also considered in the design material selection. For more information on the coverings, coatings and materials used for the containment engineered safety features, refer to Chapter 6, Section 6.1.

The impact testing requirements for SCCV steel faceplates are in accordance with NEDC-33926P. The impact testing requirements for containment closure head and Class MC components steel materials is in accordance with ASME Section III Subsection NE-2300 for Class MC components.

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

Corrosion protective coatings and systems are applied on the exposed surface of the SCCV steel faceplates and interior surface of the containment closure head and Class MC components to protect the metal from corrosion and facilitate decontamination. Guidelines in U.S. NRC RG 1.54 (Reference 9B.4-7) and ASTM D5144 (Reference 9B.4-8) are used, as applicable, for application, maintenance, and qualification of permanent corrosion protective coatings.

For fire protection measures considered for the containment structure, refer to Subsection 9B.2.1.10.

Design specifications covering materials are in sufficient detail to ensure the structural design requirements are met. Properties of materials used in the construction of the containment are provided in the following subsections.

**9B.2.1.4.1 Steel Bricks™ Concrete Infill**

Design compressive strength for the concrete used for the construction of the SCCV is 34.5 MPa at 28 days.

For those areas of SCCV, portions of mat foundation within the SCCV, and other adjacent structural features subjected to elevated temperatures for long durations of time, the aggregates in concrete do not contain pyretic materials.

All concrete materials are approved prior to start of construction on the basis of their characteristics in test comparisons using applicable ASTM standard methods. Concrete aggregates and cement, conforming to requirements in material specifications, are obtained from approved sources. All structural concrete is batched and placed in accordance with NEDC-33926P.

Supplementary concrete sampling requirements are used as described in Section 3.2.1 of NEDO-33914 to address the effect of small volume of concrete placed for the BWRX-300.

**9B.2.1.4.2 Containment Steel Bricks™ Steel**

Steel Bricks™ steel components conform to the following:

- Steel faceplates/diaphragm plate: ASME SA-738 (Reference 9B.4-9), Grade B
- Studs: ASTM A108, Type B (Reference 9B.4-12) as permitted by ASME Section III, Division 2, Subsection CC (Reference 9B.4-13), MANDATORY APPENDIX D2-1, Table D2-1-2.2

**9B.2.1.4.3 Structural Steel and Appurtenances for the SCCV**

The structural steel and other appurtenances for the SCCV other than the primary Steel Bricks™ steel components covered above conform to the following:

- Structural Steel embedded plate and attachments: ASTM A572 (Reference 9B.4-14) Gr. 50 per ASME Code Case N-632 (Reference 9B.4-15)
- Penetrations: ASME SA-516 (Reference 9B.4-16) Gr. 60 or Gr. 70 or SA537 (Reference 9B.4-17) Class 2

**9B.2.1.4.4 Structural Steel and Appurtenances for the Containment Closure Head and Other Class MC Components**

Structural steel and other appurtenances for the containment closure head and other Class MC components conform to the following:

- Structural Steel: ASME SA-516 Gr. 60 or Gr. 70, SA537 Class 1 or Class 2 or SA-738 Gr. B

- Attachments: ASTM A572 Gr. 50
- Stainless Steel Cladding: ASME SA-240 (Reference 9B.4-18) Type 304L; cladding in accordance with ASME SA-264 (Reference 9B.4-19). Maximum carbon content of Type 304L  $\leq 0.020$  percent
- Bolting: ASME SA-193 (Reference 9B.4-20), Gr. B8, SA-437 (Reference 9B.4-21) Gr. B4B

#### **9B.2.1.5 Interfaces with Other Equipment or Systems**

The BWRX-300 containment is completely enclosed within the RB, with both structures resting on the common mat foundation that also supports the containment internal structures. As shown in Figure 9B-1 and Figure 9B-2, the containment is integrated with the RB structure at the common mat foundation, at the top slab, at the connections of wing walls and at intermediate floor levels. In addition to interfacing with the RPV pedestal at the mat foundation, the containment also interfaces with the containment internal steel structures at various elevations (See Figure 9B-1) and with the main steam and feedwater piping and other electrical and piping lines penetrating through the containment wall. Chapter 6, Subsection 6.3.2.2 provides more information on penetrations and piping into the containment structure.

The integrated RB model used in the SSI analyses discussed in Chapter 3, Subsection 3.5.1.1 appropriately incorporates the interfaces between the containment structure, containment internal structures, and RB to represent the vertical and lateral load transfer between these different structures for applicable internal and external loads as requested by CNSC REGDOC-1.1.2 (Reference 9B.4-22), Section 4.5.5.

The connections of the RB walls and floors to the outside face of the SCCV wall are outside ASME code jurisdiction, with the exception of attachment welds. Attachment welds are designed to follow ASME quality assurance and welding procedures, and inspection requirements.

#### **9B.2.1.6 System and Equipment Operation**

Refer to Chapter 6, Section 6.3 for a discussion of containment systems designed to ensure its safety functions, including confinement, under accident conditions.

#### **9B.2.1.7 Instrumentation and Control**

In accordance with Clause 5.2.3 of CSA N289.5, seismic instrumentation is installed close to the top of containment as described in Chapter 3, Subsection 3.3.1.5 to monitor the seismic motions during the lifecycle of the reactor facility.

Refer to Chapter 6, Section 6.3, and Chapter 7 for a discussion of systems and instrumentations used to monitor pressure inside the containment.

#### **9B.2.1.8 Monitoring, Testing, Inspection and Maintenance**

Containment safety functions are ensured throughout the life of the plant through monitoring, testing, inspections, and maintenance in compliance with CNSC REGDOC-2.5.2, Sections 7.14 and 8.6.3.

Testing and In-service inspection of the containment structure are performed per the criteria in Chapter 3, Subsection 3.5.3.6.

As stated in Chapter 3, Subsection 3.5.5.6, a research and development program is established to demonstrate that the design, testing and inspection methods of the Steel Bricks™ containment meet all applicable safety design requirements in compliance with CNSC REGDOC-2.5.2, Section 5.4.

The Structural Integrity Test (SIT)/Pre-Operational Proof Test pressure a) is at least 1.15 times the positive design pressure and b) is the negative design pressure, where applicable in compliance with NEDC-33926P.

Instrumentation provided to evaluate behaviour of the structure and the actual stress values during Pre-Operational Proof Test is also used to monitor the deformation of the containment structure at the time of the Integrated Leak Rate Test (ILRT) to ensure the elastic behaviour of the containment structure. The ILRT is performed as described in Chapter 6, Subsection 6.3.7.

Refer to Chapter 6, Section 6.3 and Chapter 7 for a discussion of engineered safety features, systems and instrumentation used to maintain the containment barrier for radiation control and protection.

#### **9B.2.1.9 Radiological Aspects**

The SCCV is designed to withstand the highest design basis accident pressure. The BWRX-300 SCCV is provided with overpressure protection by means of a containment inerting system as discussed in Chapter 9A, Subsection 9A.4.2. The design basis accident pressure for containment is evaluated in Chapter 15, Section 15.5 and the containment design pressure is discussed in Chapter 6, Subsection 6.3.2.

Containment response to radiological events such as Loss-of-Coolant Accident (LOCA) is discussed in Chapter 15, Subsection 15.5.4.6.

As mentioned in Chapter 6, Subsection 6.3.2, permanent radiation shielding is provided within and outside of the containment to limit doses to ALARA, with the SCCV structural concrete functioning as radiation shielding external to the containment, along with bioshield and the RPV pedestal (see Subsection 9B.2.2.3 and Figure 9B-1). Radiation dose varies in the containment structure by locations and the SCCV minimum wall and top slab thickness and minimum steel faceplate thicknesses are selected to provide a proper radiation shielding. For containment shielding evaluations, refer to Chapter 12, Section 12.4. For other design features used for radiation protection, including the ALARA structures criteria observed in the BWRX-300 design, refer to Chapter 12, Section 12.3.

The lower portion of the SCCV and RPV pedestal is also provided with a corium shield to prevent contact between the molten core and the Steel Bricks™ faceplates and concrete and RPV pedestal to mitigate the consequences of severe accident conditions as described in Chapter 3, Subsection 3.5.6.1. For more details on this corium shield, refer to Chapter 15, Appendix 15.B.

#### **9B.2.1.10 Performance and Safety Evaluation**

The BWRX-300 containment structure, including isolation of containment penetrations, is of a fail-safe design such that confinement of radioactive material can be achieved for a minimum of seven (7) days under worst-case environmental conditions, without credit taken for mitigating operator action.

To meet its functional and performance requirements listed in Subsection 9B.2.1.2, the BWRX-300 containment structure is evaluated and designed per the requirements in Chapter 3, Subsection 3.5.3, and its robustness evaluated for the DECAs described in Chapter 3, Subsection 3.5.6. To meet safety margin requirements in CNSC REGDOC-1.1.2, Section 4.5.5 and CNSC REGDOC-2.5.2, Sections 7.5 and 7.7, the containment design pressure is selected to bound DBAs with sufficient margin. As shown in Chapter 15, Subsection 15.5.4.6, the containment peak pressure resulting from the most limiting design basis accident is at least 10% lower than the containment design pressure. Similarly, the containment design temperature bounds the accident peak values in Chapter 15, Subsection 15.5.4.6.

Being enclosed within the RB, the containment structure is protected against external hazards discussed in Chapter 3, Section 3.3. The containment structure is also designed for reaction forces stemming from the pipe movements, jet impact, pipe whip and other internal missiles described in Chapter 3, Subsections 3.4.3 and 3.4.4.

The SCCV is designed as a floodable volume to assure core coverage in response to an accident, as described in Chapter 6, Subsection 6.3.2 and Table 9B-1.

Complying with CNSC REGDOC-2.10.1 (Reference 9B.4-23), CSA N293 (Reference 9B.4-24) and CSA N293S1 (Reference 9B.4-25), containment walls are to be fire rated with steel plates exposed to fire as discussed in Chapter 3, Subsection 3.4.1.1. Doors or HVAC dampers isolating the containment are also designed to be fire rated with fire/smoke dampers compatible with the rating of the fire barrier. Containment atmosphere is nitrogen-inerted during normal operation to preclude the initiation or propagation of a fire. Portable detection equipment and fire watches used inside containment during maintenance outages when the space is not inerted are discussed in Chapter 9A, Subsection 9A.6.6.

#### **9B.2.1.10.1 Design Loads and Load Combinations for Containment Structure**

The containment structure is analysed and designed for all credible conditions of loading, including normal loads, pre-operational testing loads, loads during severe and extreme environmental conditions and loads during abnormal plant conditions in compliance with CNSC REGDOC-2.5.2, Section 7.15.1. Loads used in the analysis and design of the containment are described in Chapter 3, Subsection 3.5.3.2.

Load combinations considered in the design take into account the probability of occurrence, loading time history and sequence of loads, as applicable, meeting the requirements in CNSC REGDOC-2.5.2, Section 7.15.1. Table 9B-1 presents load combinations used in the design of the SCCV portion of the containment. Table 9B-2 and Table 9B-3 summarize the load combinations and associated load factors used in the design of the containment closure head and other Class MC components, respectively. As shown in Table 9B-2 and Table 9B-3, combined loadings are categorized according to Level A, C and D service limits as defined in Subsection NE-3113 of ASME BPVC, Section III, Division 1. Since the Operating Basis Earthquake (OBE) is set at one-third of the Design Basis Earthquake (DBE) for design purposes as described in Chapter 3, Subsection 3.3.1, OBE load combinations are not considered. For the design of Class MC components (excluding containment closure head), the load combination involving post-flooding condition is considered in accordance with U.S. NUREG-0800 (Reference 9B.4-26), SRP 3.8.2.

As discussed in Chapter 3, Subsection 3.5.3.2, the portion of the BWRX-300 containment closure head and other Class MC components backed by concrete are designed for the load combinations and associated load factors in accordance with NEDC-33926P, supplemented by RG 1.136 (Reference 9B.4-27), as summarized in Table 9B-1.

The design of the containment structure, including SCCV, containment closure head, and other Class MC components, also meets thebdba/dec requirements as discussed in Chapter 3, Subsection 3.5.6 to comply with CNSC REGDOC-2.5.2, Section 7.15.1.

#### **9B.2.1.10.2 Containment Analysis and Design**

The design of the containment structure is based on the membrane forces, shear forces, and bending moment demands from the loads and load combinations defined in Subsection 9B.2.1.10.1.

These demands are obtained from the set of analysis described in Chapter 3, Subsection 3.5.1.1 performed using the Finite Element (FE) model of the integrated RB structure developed following

the criteria in Chapter 3, Subsections 3.3.1.2 and 3.5.1.1 (See Appendix 9B.A for details of model). As mentioned in Chapter 3, Subsection 3.3.1.2, larger penetrations, and openings are also included in the model.

The state of stress and behaviour of the containment around these openings is determined by use of acceptable analytical techniques, including but not limited to, the use of refined local shell or solid FE models incorporating the imposed displacements calculated from the global integrated FE model.

Key demands used in the design of the SCCV structure are provided in Appendix 9B.E. Design evaluation of the containment closure head, and Class MC components of the containment will be reported in the Preliminary Operating Safety Analysis Report (POSAR) in support of the Licence to Operate application.

#### **9B.2.1.10.3 Structural Design Margins**

To meet the structural integrity requirement in CNSC REGDOC-2.5.2, Section 7.15.1, safety margins of the containment structure are ensured by satisfying the requirements and acceptance criteria discussed in Chapter 3, Subsection 3.5.3.4. Bounding demand-to-capacity ratios for key components of the SCCV are provided in Appendix 9B.E to demonstrate the adequacy of the design.

Per the plots presented in Appendix 9B.E, the design of the BWRX-300 SCCV at the DNNP site include safety margins of at least 30% for the testing conditions, 40% for normal operating conditions, and 20% for abnormal conditions. The most critical loading conditions for the SCCV are the loads associated with containment DBA conditions, primarily the accident temperature loading and to a lesser extent the accidental pressures. The DNNP site-specific bounding seismic loads have a less significant impact on the design of the SCCV.

#### **9B.2.1.10.4 Robustness**

The robustness of the containment structure is evaluated per criteria outlined in Chapter 3, Subsections 3.3.7.4 and 3.5.6. Being enclosed in the lower portion of the deeply embedded RB, the containment structure is protected against malevolent acts, such as a large airplane crash, as demonstrated in the BWRX-300 Security Annex.

Design evaluation results demonstrating the robustness of the containment design per criteria outlined in Chapter 3, Subsection 3.5.6 will be provided in the POSAR in support of the Licence to Operate application.

The containment is designed to maintain its role as a leak-tight barrier for DECAs with severe core damage for a period that allows sufficient time for the implementation of offsite emergency procedures following the onset of core damage in compliance with CNSC REGDOC-2.5.2, Section 7.3.4.1. The Level 2 Probabilistic Safety Assessment (PSA) performed for the POSAR describes the severe accident sequences leading to core damage and demonstrates operators have sufficient time to bring the plant to safe shutdown because the severe accidents are slow progressing for the BWRX-300.

Other design features included to ensure robustness of the containment are discussed in Chapter 15, Appendix 15A and Appendix 15B.

### **9B.2.2 Containment Internal Structures**

The BWRX-300 containment internal structures include the RPV pedestal, the bioshield surrounding the RPV pedestal, and the containment internal structural steel which consists of the CEPSS and the support floors at Level -21 m and -29 m as shown in Figure 9B-1.

#### **9B.2.2.1 Structural Role**

The primary functions of the RPV pedestal are:

1. To provide structural support to SSC such as the RPV, RPV Skirt Support, CEPSS, Stabilizers, and miscellaneous platforms
2. In conjunction with the bioshield, to provide radiation shielding to limit radiation dose within the applicable regulatory standards in different plant states, including normal operation, AOO, DBAs, and DEC conditions

The primary functions of the bioshield are:

1. In conjunction with the RPV pedestal, to provide radiation shielding to limit radiation dose within the applicable regulatory standards in different plant states, including normal operation, AOO, DBAs and DEC conditions
2. To provide structural support to miscellaneous platforms

The primary functions of the CEPSS are:

1. To provide supports for SC1, SC2 and Non-Safety Class (SCN) piping, RPV Stabilizers, SC1 RPV isolation valves including actuator, and other components
2. To serve as support for miscellaneous platforms and associated floor grating, ladders/stairs and other apparatus needed for personnel access and equipment inspection and maintenance

The primary functions of the support floors at Level -21 m and -29 m are:

1. To provide support for components, including fans and coolers, associated with the SC3 Component Cooling System at Level -21 m
2. To provide support for miscellaneous SCN components at Level -29 m

#### **9B.2.2.2 Safety Design Bases**

As indicated in Chapter 3, Table 3.3-1, the BWRX-300 containment internal structures are Seismic Category A structures designed to support SSC inside the containment. The RPV pedestal and bioshield are also designed to provide radiation shielding to limit radiation dose during normal operation, AOO, DBAs and DEC conditions.

#### **9B.2.2.3 Structural Description**

The RPV pedestal is the cylindrical-shaped Steel Bricks™ structure that structurally supports the RPV and is integrated into the common mat foundation as shown in Figure 9B-1.

The RPV pedestal is equipped with a structural steel RPV bracket that runs on the inside at the top of the RPV pedestal and where the RPV skirt is anchored using anchor bolts. The RPV pedestal also provides structural support for the RPV bottom stabilizers and the CEPSS. The part of the RPV pedestal surrounding the core region of RPV helps to attenuate the radiation emanating from the RPV. Openings are provided in the RPV pedestal to permit the routing of necessary piping to the RPV, to permit in-service inspection of the RPV and piping, and to ensure personnel access into the under-vessel region.

The bioshield is an independent cylindrical-shaped steel-plate composite structure that surrounds the RPV pedestal (See Figure 9B-1), with both structures integrated into the common mat foundation. The bioshield is separated from the RPV pedestal by a seismic gap. The primary function of the bioshield is to attenuate the radiation emanating from the RPV in conjunction with the RPV pedestal. The bioshield also provides support to the steel platforms at levels -21 m and

-29 m. Similar to the RPV pedestal, openings are provided in the bioshield to permit the routing of necessary piping to the RPV, to permit in-service inspection of the RPV and piping, and to ensure personnel access into the under-vessel region.

Rigid overstrength connections (See Appendix 9B.G, Subsection 9B.12.5) are used to connect the RPV pedestal and bioshield to the common mat foundation.

The CEPSS is supported primarily by the RPV pedestal as shown in Figure 9B-1. The CEPSS framing connects directly to the RPV pedestal and bypasses the bioshield so that the latter remains independent of the RPV pedestal. Shear lug support connections with the SCCV are used to allow free thermal expansion of the CEPSS. The CEPSS consists of various structural components such as beams and columns as shown in Figure 9B-3. Hollow structural steel sections are used for the CEPSS beams and columns that are welded together with moment continuity. Wide flange or hollow structural steel sections are used to support the steel platform floors at Level -8.5 m, -21 m and -29 m. The steel platform at Level -8.5 m is supported by the CEPSS. The steel platform beams at level -21 m and -29 m are supported by the bioshield and SCCV wall. RPV stabilizers installed at the top of the CEPSS provide horizontal bracing close to the top of the RPV and another set of stabilizers supported from the RPV pedestal provide support near the bottom of the RPV.

#### **9B.2.2.4 Materials**

The BWRX-300 RPV pedestal is a Steel Bricks™ structure, the bioshield is a steel-plate composite structure, while the CEPSS and the support floors at Level -21 m and -29 m are made of steel.

Refer to Subsection 9B.2.3.4 for properties of steel and concrete materials used in the construction of the BWRX-300 containment internal structures. The selection of these materials takes into account the environmental effects in compliance with CNSC REGDOC-2.5.2, Section 7.15.1.

High density concrete used for shielding purposes is designed in accordance with U.S. NRC RG 1.69 (Reference 9B.4-28).

#### **9B.2.2.5 Interfaces with Other Equipment or Systems**

The RPV pedestal interfaces with the RPV through the RPV skirt support and horizontal stabilizers.

The CEPSS interfaces with the RPV at the upper stabilizer locations. Containment internal structures also interface with the support piping, equipment and general access platforms and stairs needed for personnel access and equipment inspection and maintenance.

#### **9B.2.2.6 System and Equipment Operation**

Supplemental equipment loads have been added to the structural FE models as discussed in Appendix 9B.A, Subsection 9B.6.1.5 to support mechanical and electrical equipment.

#### **9B.2.2.7 Instrumentation and Control**

In accordance with Clause 5.2.3 of CSA N289.5, seismic instrumentation is installed on the containment internal structures as described in Chapter 3, Subsection 3.3.1.5 to monitor the seismic motions during the lifecycle of the reactor facility.

For instrumentation used to monitor containment pressure and temperature, refer to Chapter 6, Subsection 6.3.2.6.

#### **9B.2.2.8 Monitoring, Testing, Inspection and Maintenance**

As described in Chapter 3, Subsection 3.5.4.6, a formal program for monitoring, testing and inspection is not required for containment internal structures. For more details, refer to Chapter 3, Subsection 3.5.4.6.

#### **9B.2.2.9 Radiological Aspects**

Penetrations through the containment wall are shielded to reduce radiation streaming in line with the ALARA criteria discussed in Chapter 12, Subsection 12.3.6.

Corrosion protective coatings and systems are also applied on the exposed surface of the steel faceplates of the RPV pedestal to protect the metal from corrosion and facilitate decontamination.

#### **9B.2.2.10 Performance and Safety Evaluation**

##### ***9B.2.2.10.1 Loads and Load Combinations***

Complying with CNSC REGDOC-2.5.2, Section 7.15.1, the BWRX-300 containment internal structures are designed for all applicable load combinations, with due consideration given to the probability of concurrence, loading time history and sequence of loads, as applicable.

Load combinations and load factors for the containment internal structures are covered by the comprehensive set of load combinations listed in Subsection 9B.2.3.10 used for the design of the RB structure, considering the difference in applicable design loads for the containment internal structures compared to the RB.

##### ***9B.2.2.10.2 Analysis and Design Procedures***

As mentioned in Chapter 3, Subsection 3.5.4.3, the containment internal structures are analysed and designed using the integrated RB FE model and following the same modeling and structural analysis procedures as for the RB (See Appendix 9B.A for details of the model)

Internal structural steel supporting piping systems within the containment are designed to carry piping dynamic loads without buckling and while remaining elastic. Beams and columns supporting pipe whip restraints allow inelastic deformations due to pipe rupture loads. Seismic Category A and B SSC impacted by these inelastic beam deformations are evaluated to verify that their safety functions are not compromised.

Key demands used in the design of the RPV pedestal are summarized in Appendix 9B.F. Design evaluation of other containment internal structures will be reported in the POSAR in support of the Licence to Operate application.

##### ***9B.2.2.10.3 Structural Design Margins***

To meet the structural integrity requirement in CNSC REGDOC-2.5.2, Section 7.15.1, safety margins of the containment internal structures are ensured by satisfying the requirements in Chapter 3, Subsection 3.5.4.4. Bounding demand-to-capacity ratios are provided in Appendix 9B.F to demonstrate the adequacy of the design of the RPV pedestal.

As demonstrated by the plots in Appendix 9B.F, the design of the RPV pedestal includes safety margins of at least 20%. Seismic loads in combination with the other abnormal condition loads govern the design of the RPV pedestal.

#### **9B.2.3 Reactor Building**

##### **9B.2.3.1 Structural Role**

The primary functions of the RB are:

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

1. To house and structurally support the reactor vessel, the containment structure, the reactor support structure of the primary reactor system and fuel handling equipment, biological shielding, and associated equipment and structures.
2. To provide adequate space for the operation, maintenance, and removal of equipment housed within the containment structure during periodic maintenance.
3. To provide protection for safety equipment from environmental and natural hazards phenomena, such as floods, winds, tornadoes, and earthquakes.
4. To provide protection for safety equipment from external (e.g., explosions and missiles from nearby transportation/industry or aircraft impact) and internal (e.g., pipe break or heavy load drop) hazards.
5. To support habitability functions for Secondary Control Room (SCR) such as radiological shielding and toxic gas isolation and passive cooling for human occupancy in addition to Environmental Qualification (EQ) for equipment.

#### **9B.2.3.2 Safety Design Bases**

Per Chapter 3, Table 3.3-1, the BWRX-300 RB is a Seismic Category A structure.

As mentioned in Subsection 9B.2.1.1, the main function of the RB structure is to protect the reactor vessel, the containment and safety class systems and equipment from external hazards that might impair their safety functions during normal operation, AOOs, DBAs, and DECAs in compliance with CNSC REGDOC-2.5.2, Section 7.3.

External hazards considered in the design of the RB are described in Chapter 3, Section 3.3.

#### **9B.2.3.3 Structural Description**

The RB is a cylindrical building made of Steel Bricks™ floors and walls, with steel beams supporting the Steel Bricks™ roof modules.

The cylindrical-shaped, below grade portion of the RB structure encloses the containment and protects the RPV, reactor support and safety systems, and the majority of vital and non-vital power supplies and equipment. While the majority of the RPV and SCCV is located below grade, the top elevation of the RPV and SCCV top slab is above grade. In addition, the above grade portion of RB structure houses the refueling floor, refueling and fuel handling systems, fuel pool, and polar crane.

Chapter 1, Table 1.5-2 provides key dimensions of the RB while Figure 9B-1 presents an elevation sectional view of the structure. Figure 9B-1 depicts the separation of the RB structure code boundary from the containment pressure boundary discussed in Subsection 9B.2.1.3. RB structural boundary includes the following areas:

1. Steel Bricks™ mat foundation between the SCCV wall and the RB exterior wall that functions as a common foundation for the RB and SCCV structures
2. RB below grade (from the mat foundation) to the support for the polar crane, including the roof, composed of Steel Bricks™ modules, with structural steel beams
3. ICS pools, fuel pool, equipment pool, and the reactor cavity pool composed of Steel Bricks™ walls that are lined for corrosion protection with leakage detection system as applicable
4. Rooms at several elevation levels outside the containment, structurally integral with the containment structure

As shown in Figure 9B-1, the SCCV and the RB structure are integrated at the connections of wing walls and elevated slabs between the mat foundation and the reactor cavity pool top slab elevation of the structure. The structures share a common mat foundation as discussed in Section 9B.1.

#### **9B.2.3.4 Materials**

This section presents the properties of materials used in the construction of the RB. The selection of these materials takes into account the environmental effects described in Chapter 3, Sections 3.3 and 3.4 in compliance with CNSC REGDOC-2.5.2, Section 7.15.1.

The RB is designed to withstand intrusion by regulatory defined threats by selecting design parameters for the Steel Bricks™, such as steel thickness, steel ductility, and concrete thickness. The ability of Steel Bricks™ to resist malevolent acts is demonstrated in the BWRX-300 Security Annex.

##### **9B.2.3.4.1 Steel Bricks™ Concrete Infill**

Design compressive strength for the self-consolidating concrete used for the construction of the RB is 34.5 MPa at 28 days.

Concrete ingredients used in the RB Steel Bricks™ modules are tested, batched, and mixed in accordance with ACI 349 (Reference 9B.4-29).

##### **9B.2.3.4.2 Steel Bricks™ Steel**

Steel Bricks™ steel components conform to the following:

- Steel faceplates/diaphragm plate: ASTM A572 Gr. 50
- Studs: ASTM A108, Type B

##### **9B.2.3.4.3 Structural Steel**

Structural steel conforms to ASTM A572 Gr.50.

##### **9B.2.3.4.4 Steel Connections**

Bolts used in structural steel bolted connections are ASTM F3125 (Reference 9B.4-30), Grade A325 Type 1.

Bolts of the following grades may be used otherwise, when deemed necessary:

- ASTM F3125, Grade A490 Type 1 or A325 Type 1
- ASTM A354 (Reference 9B.4-31), Grade BD
- ASTM A449 (Reference 9B.4-32), Type 1
- ASTM A193, for high service temperature applications, grade is subject to specific design requirements.

For SC1 structures, ASTM A307 (Reference 9B.4-33) carbon steel fasteners are not to be used in structural connections.

##### **9B.2.3.4.5 Welding**

Welding materials for the RB structure are in compliance with the requirements of ANSI/AISC N690.

#### **9B.2.3.4.6 Pool Liners and Appurtenances**

Construction, fabrication, and installation of metallic liners, non-metallic liners, coatings, joint sealants, and other suitable water tightness measures for structures where leak tightness is critical meet requirements of CSA N291 (Reference 9B.4-34), Clause 6.9.2.

Pool liners are selected to withstand the environmental conditions they are to encounter during the life of the facility. Pool liners, and their connections, are designed to maintain leak tightness and maintain the pool inventory at acceptable levels during and after normal operating, AOO and design basis events.

#### **9B.2.3.5 Interfaces with Other Equipment or Systems**

The RB is in close proximity to the RWB, CB, TB, and Reactor Auxiliary Bay. The interaction of the RB with the adjacent structures under seismic and extreme tornado wind conditions is evaluated per criteria in Chapter 3, Subsections 3.3.1.2 and 3.3.2.8 to ensure these structures will not collapse or collide with the RB and impair the safety functions of Seismic Category A or B SSC.

Adequate gaps are provided between the RB and the surrounding structures to prevent collision between structures. These gaps are evaluated along the entire height of the adjacent structures considering inelastic deformations, construction tolerances, and possible differential settlements as described in Chapter 3, Subsection 3.3.1.2.8.

#### **9B.2.3.6 System and Equipment Operation**

Dynamic mass of the polar crane during the DBE is considered in the seismic analysis. Crane payload analysis will be included in the final design that will be reported in the POSAR in support of the Licence to Operate application.

#### **9B.2.3.7 Instrumentation and Control**

Not applicable to design of RB structure.

#### **9B.2.3.8 Monitoring, Testing, Inspection and Maintenance**

The structural integrity of the RB structure is ensured throughout the life of the plant through monitoring, testing, inspections, and maintenance in compliance with CNSC REGDOC-2.5.2, Section 7.14.

Testing and in-service inspection of the RB structure are performed per the criteria outlined in Chapter 3, Subsection 3.5.5.6.

Field monitoring of the settlement and tilt of the RB shaft is performed as described in Subsection 9B.1.8.

#### **9B.2.3.9 Radiological Aspects**

Design measures that enable the RB to provide flow resistance in contaminated areas that hold up radioactive releases from the containment are discussed in Chapter 12, Subsection 12.3.10. They include the use of a suitable shielding for the fuel pool and associated equipment in addition to using a system for detecting fuel pool leakage.

The design of the SCCV, RPV pedestal and the bioshield, including their selected materials and geometric configuration, ensures that these structures provide a proper shielding from radiation emanating from the fuel core in the RPV.

Shielding of personnel in the SCR is discussed in Chapter 12, Section 12.4.

#### **9B.2.3.10 Performance and Safety Evaluation**

To meet its functional and performance requirements listed in Subsection 9B.2.3.1, the BWRX-300 RB is evaluated and designed for the design loads described in Chapter 3, Subsection 3.5.5.2 and its robustness evaluated for the DEC loads described in Chapter 3, Subsection 3.5.6.

Design basis loads for the RB include loads generated by external and internal hazards identified in Chapter 3, Sections 3.3 and 3.4. Potential combination and interaction of the various hazards on the structure are considered in the design load combinations presented in Subsection 9B.2.3.10.1.

As described in Chapter 9A, Subsection 9A.5.1, the RB HVAC is provided tornado rated dampers at RB penetrations to withstand high wind events and protect its structure in accordance with CNSC REGDOC-2.5.2, Section 7.15.1.

To prevent and resist the spread of internal fires within the building, the RB is supplied with fire detection and suppression systems in compliance with CNSC REGDOC-2.10.1 and CSA N293 and as described in Chapter 3, Subsection 3.4.1.1 They include manual fire alarm boxes installed at each stair door on each level and smoke/fire detectors in various rooms. Smoke and heat detectors are also provided for its service elevator, while occupant notification is provided throughout the building.

Fire protection water for the RB to support automatic fire suppression and manual firefighting is supplied from two separate connections from the site loop. The fire loop feeds the RB on the east side through the exit passageway extending through Plant Service Area (PLSA), and directly into Stair A. The fire loop feeds the RB on the west side through the RWB and CB, to Stair B. A main extends through the RB, between the two stair enclosures, on the south side, for redundancy of supplies. Details associated with fire protection system design for this structure are provided in Chapter 9A, Section 9A.6.

Also, in accordance with Chapter 3, Subsection 3.4.1.1, walls, floors, ceilings, doors, HVAC dampers and penetrations in the RB are fire rated, as required under the fire hazard assessment. Fire barriers are also employed to prevent the spreading of fires from a non-safety room to a room with safety class system or equipment and between redundant safety class fire zones.

For flood protection measures for the RB, refer to Chapter 3, Subsections 3.3.3 and 3.4.2. As mentioned in Chapter 3, Subsection 3.3.3, suitable provisions are provided below flood elevation to ensure the water tightness of the RB and prevent any water ingress from the surrounding soil.

The following sections provide more details on the RB evaluation and design.

##### **9B.2.3.10.1 RB Design Loads and Load Combinations**

In compliance with CNSC REGDOC-2.5.2, Section 7.15.1, the BWRX-300 RB is designed for all applicable load combinations, with due consideration given to the probability of concurrence, loading time history and sequence of loads, as applicable.

Loads and load combinations considered in the design of the RB are described in Chapter 3, Subsection 3.5.5.2 and include loads applied to the SCCV that have an effect on the RB structure due to the common mat foundation, top slab, and other integrating structural components.

Load combinations used for the design of the RB are listed in Table 9B-4.

##### **9B.2.3.10.2 RB Analysis and Design**

Membrane forces, shear forces, and bending moments used in the design of the RB structure are obtained from the set of analysis described in Chapter 3, Subsection 3.5.1.1 performed using the

FE model of the integrated RB structure developed as described in Chapter 3, Subsections 3.3.1.2 and 3.5.1.1. Details of this FE model are presented in Appendix 9B.A. Key seismic analysis results for the integrated RB are provided in Appendix 9B.B, while interaction evaluation results demonstrating how the structural integrity of the surrounding Power Block structures is maintained under design basis seismic and tornado events are provided in Appendix 9B.C. Demands used in the design of key members within the RB are summarized in Appendix 9B.G.

Seismic demands for the design and evaluation of the structure include seismic inertia load demands related to the response of the seismic mass inertia properties assigned in the FE model, the dynamic earth pressure load demands that include SSSI effects with surrounding Power Block structures and foundations and demands from the impulsive portion of the hydrodynamic pressure load (See Appendices 9B.A and 9B.B). Non-seismic demands include demands due static, quasi-static land thermal loads discussed in Chapter 3, Subsection 3.5.1.1 (See Appendix 9B.D).

The circular design of the embedded section of the BWRX-300 RB structure provides significant torsional support for the building. Accidental torsional moment demands at each floor level are computed as described in Chapter 3, Subsection 3.3.1.2.

As mentioned in Chapter 3, Subsection 3.5.2.2, due to its deep embedment, the sliding and overturning stability of the integrated RB is considered satisfied without the need for explicit sliding and overturning stability evaluations.

#### **9B.2.3.10.3 Structural Design Margins**

Safety margins of the RB structure are ensured by satisfying the design basis and beyond design basis requirements in Chapter 3, Subsection 3.5.5.4 to meet the regulatory requirement in CNSC REGDOC-2.5.2, Section 7.15.1. Bounding demand-to-capacity ratios for key structural components within the RB are provided in Appendix 9B.G to demonstrate the adequacy of the design.

The demand-to-capacity ratio plots presented in Appendix 9B.G indicate design margins for the RB structure of at least 15% with load combination representing normal operating conditions being more critical for the design than the abnormal load combination including earthquake loads in combination with containment DBA thermal and pressure loads. The largest demand-to-capacity ratios that are calculated for the below grade portion of the RB exterior wall are mainly associated with earth pressure loads. The earth pressure loads include a conservative estimate of the additional anisotropic pressure load applied on the RB exterior wall that account for the potentially undissipated portion of in-situ pressures locked in the DNNP site rock as a result of past seismic activities in the region.

The plots also indicate that the site-specific seismic demands have a less significant impact on the design of the below grade portion of the RB exterior wall and mat foundation. The seismic loads in combination with the other abnormal condition loads govern the design of the above grade portion of the RB exterior wall and wing walls, with a maximum recorded demand-to-capacity ratio less than 0.8 for these structures. This indicates that the DNNP RB structure has more than 20% safety margins available for the DNNP bounding seismic demands.

#### **9B.2.3.10.4 Robustness**

The robustness of the RB structure is evaluated as discussed in Chapter 3, Subsections 3.3.7.4 and 3.5.6. The RB is designed to resist global failure, perforation, spalling, and fuel intrusion from the regulatory defined threats to protect the containment structure housed within its structure. For more details on the robustness of the RB structure against malevolent acts, refer to the BWRX-300 Security Annex.

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

Design evaluation results demonstrating the robustness of the RB design per criteria outlined in Chapter 3, Subsection 3.5.6, and against climate change conditions and DEC conditions resulting from a rail derailment accident discussed in Chapter 2, will be reported in the POSAR in support of the Licence to Operate application.

### **9B.3 Other Structures**

#### **9B.3.1 Radwaste Building**

The RWB houses the offgas system charcoal adsorbers, refueling water storage tanks, and rooms and equipment for handling, processing, and packaging liquid and solid radioactive wastes.

The RWB location is shown in Chapter 1, Appendix A, Figure A1.4-1. General dimensions of the building are listed in Chapter 1, Table 1.5-2.

The RWB structure consists of reinforced concrete walls and floor slabs supported on a shallow reinforced concrete mat foundation with roof joists and composite roof decking. The lateral force resisting system of the structure consists of concrete shear walls, concrete floors, and a composite roof deck acting as a diaphragm.

Because of its main function which consists of processing and housing liquid, solid and gaseous radioactive wastes, the RWB is categorized as a RW-IIa structure per U.S. NRC RG 1.143 (Reference 9B.4-35). Per Chapter 3, Subsection 3.2.3.1, the RWB is also evaluated for seismic interaction due to its proximity to the RB.

Seismic design bases for the RWB based on its seismic categorization are summarized in Chapter 3, Table 3.3-1. The RWB is designed in accordance with CSA N291 and associated design codes and standards modified by the graded design approach in U.S. NRC RG 1.143. Seismic analysis of the RWB is performed in accordance with CSA N289.3 (Reference 9B.4-36) and ASCE/SEI 4 (Reference 9B.4-37). Seismic interaction evaluation of the RWB follows the requirements in Chapter 3, Subsection 3.3.1.2.8.

The RWB design also considers tornado and missile impact in accordance with requirements in U.S. NRC RG 1.143.

Loads and load combinations used in the design of the RWB are in accordance with CSA N291, with design earthquake and tornado loads applicable to RWB defined per the provisions of U.S. NRC RG 1.143. Environmental load combinations per Table 3 of CSA N291 are considered for interaction evaluations of RWB with RB under DBE and design basis tornado wind conditions.

Design and detailing of the RWB structural steel are in accordance with CSA S16 (Reference 9B.4-38) and in accordance with CSA A23.3 (Reference 9B.4-39) for structural concrete.

The RWB forms part of the combined model for the seismic analysis of the BWRX-300 Power Block structures accounting for SSI and SSSI effects as described in Chapter 3, Subsection 3.3.1.2. The design and seismic interaction evaluation of the RWB structure are performed following the linear elastic analysis methodology using a standalone FE model with a sufficient level of refinement to allow for the accurate estimation of design stresses and forces. The ASCE/SEI 4 Two-Step analysis approach is used for the seismic qualification of the RWB structure where seismic demands in the form of RWB zero period accelerations or foundation acceleration response spectra are developed from the RB SSI analyses for responses of the RWB simplified dynamic model discussed in Chapter 3, Subsection 3.3.1.2.3. A fixed base quasi-static analysis using the maximum nodal accelerations or response spectrum analysis using the input foundation response spectrum enveloped with the RWB design earthquake is then performed on the standalone refined FE model of the RWB. Resulting forces and stresses are used for the seismic design of the RWB. The demands for the RWB foundation design are taken directly from the RB SSSI analysis, with input corresponding to the RWB design earthquake.

The interaction and structural integrity evaluations are performed for DBE loads using the results of the SSI analysis discussed in Chapter 3, Subsection 3.5.1.1 and for design basis tornado loads. As mentioned in Chapter 3, Subsection 3.3.1.2.8, a clear gap is maintained between the RB and

the RWB to prevent any physical contact during a seismic or tornado event. Clear gaps also separates the RWB from the adjacent CB and TB.

Design features for radiation protection in the RWB are discussed in Chapter 12, Subsection 12.3.9.

As mentioned in Chapter 3, Subsection 3.4.1.1.1, the RWB is designed to have a 3-hour fire resistance rating. Fire protection features for the RWB comply with requirements in CNSC REGDOC-2.10.1 and CSA N293 and include fire alarms and suppression systems as discussed in Chapter 3, Subsection 3.4.1.1. Fire alarm and smoke detectors are installed, with occupant notification provided, throughout the building. Sprinklers and spatial separation are used in various areas of the building to prevent the spread and damage due to fires. Fire protection water supplied to the RWB comes from separate standpipes, one through the RB and one through the CB. Details associated with fire protection system design for this structure are provide in Chapter 9A, Section 9A.6.

#### **9B.3.1.1 Foundation Design Basis**

Geotechnical design of the RWB concrete foundation is in accordance with Canadian Foundation Engineering Manual (Reference 9B.4-40).

Structural design and analysis of the foundation is in accordance with CSA N291, with applicable associated provisions in the National Building Code of Canada (NBC) (Reference 9B.4-41) and CSA A23.3 to ensure the structural integrity of the RWB. Loads, load combinations and acceptance criteria for the RWB foundation design are the same as those used for the design of the super structure.

Stability evaluations of the RWB foundation against sliding and overturning due to DBE, wind, and tornadoes and against floatation due to flooding are performed to ensure the foundation stability requirements in Chapter 3, Subsection 3.5.2.2 are met. The liquefaction potential of the RWB foundation is assessed in Chapter 2, Subsection 2.7.4.7.6 in accordance with Clause 5.6 of CSA N289.3 to ensure a proper siting of the RWB. The RWB foundation rests on overlies material not susceptible to frost action, at a level below which damage due to frosting does not occur in accordance with requirements in ASCE/SEI 32 (Reference 9B.4-42), Canadian Foundation Engineering Manual and NBC Part 4 of Division B (Reference 9B.4-43).

Groundwater effects on the shallow foundation are considered in the settlement analysis and the evaluation of soil capacity as discussed in Chapter 2, Subsection 2.7.3.3.

#### **9B.3.2 Control Building**

The CB houses the Main Control Room (MCR), Emergency Operations Centre, electrical, control, instrumentation equipment, and various other functional areas. The CB location is shown in Chapter 1, Appendix A, Figure A1.4-1. General dimensions of the building are listed in Chapter 1, Table 1.5-2.

As indicated in Chapter 3, Table 3.3-1, the CB is categorized as a Non-Seismic Category structure and is evaluated for seismic interaction due to its proximity to the RB per Chapter 3, Subsection 3.2.3.1. Seismic interaction evaluation of the CB follows the requirements in Chapter 3, Subsection 3.3.1.2.8. The CB is considered a post-disaster building per NBC.

The CB structure consists of a building frame system with perimeter reinforced concrete wall, interior steel columns, beams/girders, roof bar joists, and steel-concrete roof deck as a gravity load carrying system. The CB is founded on reinforced concrete mat foundation. The lateral force resisting system of the structure consists of reinforced concrete shear walls and a steel-concrete roof deck as a diaphragm. A portion of the CB on the east side, consists of a steel frame

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

structure connected to the east perimeter concrete wall. This portion of the structure represents the southern portion of the PLSA as described in Chapter 1, Subsection 1.5.2.3. The lateral force resisting system of this portion consists of reinforced concrete shear wall with parallel braced steel bay on exterior column row and roof deck as a diaphragm.

Due to its proximity to the RB, the CB is designed to maintain its structural integrity under DBE and extreme tornado wind conditions to prevent injuries to control room occupants and to not compromise the structural integrity and safety functions of the adjacent Seismic Category A or B SSC. To ensure the safety of operators in the MCR, the MCR is surrounded by reinforced concrete shear wall. Per Chapter 6, Section 6.4, operators are expected to remain in the MCR and safely operate the plant for most of the Postulated Initiating Events (PIEs). For more details on the conditions that necessitate an evacuation of the MCR, and on travel routes provided to ensure safe egress of operators, refer to Chapter 6, Section 6.4. For special hardening provisions considered in the design of the CB, refer to Subsection 9B.3.2.2.

The CB analysis and design are based on requirements in the NBC for a post-disaster building. Seismic design basis for the CB based on its seismic categorization are summarized in Chapter 3, Table 3.3-1. The CB is also designed as a barrier free structure per NBC Section 3.8.

The CB design meets design requirements stipulated in the NBC Part 4 of Division B. Loads and load combinations used in the design of the CB are in accordance with the NBC. Environmental load combinations per Table 3 of CSA N291 are considered for interaction evaluations of CB with RB under DBE and design basis tornado wind conditions.

Design and detailing of the CB structural steel is in accordance with CSA S16 and in accordance with CSA A23.3 for structural concrete.

The CB forms part of the combined model for the seismic analysis of the BWRX-300 Power Block structures accounting for SSI and SSSI effects as described in Chapter 3, Subsection 3.3.1.2. For the NBC design and seismic interaction evaluation, analysis and design of the CB structure is performed following linear elastic analysis methodology.

The seismic analysis and design of the CB structure is performed in accordance with the NBC using a site-specific Non-Seismic Design Basis Earthquake (NS-DBE). This site-specific NS-DBE is defined based on 2% probability of exceedance in 50 years (i.e., the uniform hazard response spectra with return period of 2475 years or annual probability of exceedance of  $4E-4$ ) as specified in Section 4.1.8.4 of the NBC. Ground motion parameters are determined based on the site designation at the DNNP site. Ground motion time histories used as input in the dynamic time history analysis are selected and scaled to be compatible with the NS-DBE per the guidelines in the NBC, Part 4 of Division B. Additionally, the CB is verified using a 5%-damped input motion based on a 5% probability of exceedance in 50 years in accordance with NBC, Section 4.1.8.23 Sentence (2), as applicable. Non-Seismic structures are not explicitly analysed and designed to resist vertical ground motions consistent with the NBC.

The interaction and structural integrity evaluations are performed for DBE using the results of the SSI analysis discussed in Chapter 3, Subsection 3.5.1.1, and design basis tornado loads. As mentioned in Chapter 3, Subsection 3.3.1.2.8, a clear gap is maintained between the RB and the CB to prevent any physical contact during a seismic or tornado event. Clear gaps also separates the CB from the adjacent RWB and Reactor Auxiliary Bay.

Design features for radiation protection in the CB are discussed in Chapter 12, Subsection 12.3.11. Design features for habitability of the MCR are described in Chapter 6, Section 6.4.

As mentioned in Chapter 3, Subsection 3.4.1.1.1, the CB is designed to have a 3-hour fire resistance rating. Fire protection features in the CB comply with requirements in CNSC REGDOC-

2.10.1 and CSA N293 and include fire alarms and suppression systems as described in Chapter 3, Subsection 3.4.1.1. Fire alarm and smoke detectors are installed, with occupant notification provided, throughout the building. Sprinklers are installed within the building, with exception of the Control Room where portable fire extinguishers are provided. Fire protection water supplied to the building comes from two directions, one through the RWB and one from the site loop on the south side of the building. Details associated with fire protection system design for this structure are provide in Chapter 9A, Section 9A.6.

#### **9B.3.2.1 Foundation Design Bases**

Design bases for the CB foundation are similar to those for the RWB foundation discussed in Subsection 9B.3.1.1.

Stability evaluations of the CB foundation against sliding and overturning due to DBE, wind, and tornadoes and against floatation due to flooding are performed to ensure the foundation stability requirements in Chapter 3, Subsection 3.5.2.2 are met. Potential strata liquefaction under the CB foundation is assessed in Chapter 2, Subsection 2.7.4.7.6 in accordance with Clause 5.6 of CSA N289.3 to ensure a proper siting of the CB. The CB foundation rests on overlies material not susceptible to frost action, at a level below which damage due to frosting does not occur in accordance with requirements in ASCE/SEI 32, Canadian Foundation Engineering Manual and NBC Part 4 of Division B.

Groundwater effects on the shallow foundation are considered in the settlement analysis and the evaluation of soil capacity as discussed in Chapter 2, Subsection 2.7.3.3.

#### **9B.3.2.2 Special Hardening Provision for Control Room Habitability and Post-Accident Response Requirements**

In accordance with CNSC REGDOC-2.5.2, Section 8.10.1, to ensure the habitability of the MCR and post-accident requirements, the CB is hardened by design for the full tornado (1E-7 per year return period) effect. Area(s) required to be hardened are to be designated during design development.

Structures of hardened areas are designed to remain functional before, during and after the design tornado event. Interaction criteria discussed in Chapter 3, Subsections 3.2.3.1 and 3.3.1.2.8 apply under this loading event.

As discussed in Chapter 9A, Subsection 9A.5.2, the CB HVAC is provided tornado rated dampers as necessary to withstand high wind events in accordance with CNSC REGDOC-2.5.2, Section 7.15.1.

#### **9B.3.3 Turbine Building**

The TB encloses the turbine generator, main condenser, condensate and feedwater systems, condensate purification system, offgas catalytic recombiner, cooling condenser, refrigerant dryer, turbine generator support system and bridge crane. Per Table 3.3-1 of Chapter 3, the TB is categorized as a Non-Seismic Category structure and is evaluated for seismic interaction, similar to the CB. The TB is considered a post-disaster building per NBC.

The layout and key dimensions of the TB are shown in Chapter 1, Appendix A, Figure A1.4-1 and Chapter 1, Table 1.5-2, respectively.

The TB structure is divided into three structural supporting systems:

1. The TB shell structure which consists of a steel frame system with steel columns, beams/girders, roof bar joists, and floor/roof decks as gravity load carrying systems. The lateral force resisting system consists of braced frames and floor/roof decks as

diaphragms. The low-rise steel frame structure on the east side of the TB connecting to, and integrated with, its eastern shell structure side represents the northern portion of the PLSA as discussed in Chapter 1, Subsection 1.5.2.2. The lateral force resisting system of this portion consists of parallel braced frame on exterior column row and roof deck as a diaphragm.

2. The shielding wall area which consists of reinforced concrete shear walls surrounding and supporting the portion of the structure containing radioactive steam and water for shielding (turbines, condenser, offgas vessels, heater tanks, and associated piping). This area includes some gravity load carrying internal steel columns and is isolated from the TB steel structure, despite sharing a common mat foundation with the TB shell structure.
3. The reinforced concrete pedestal supporting the turbine, generator, and exciter within the TB shell structure and the shielding walls area. This turbine generator foundation is structurally isolated from both the shielding walls and the TB shell structure for vibration control. However, its dominant dynamic characteristics are included in the SSSI model.

The analysis and design approaches and requirements for the TB and its foundation, including the interaction evaluations for DBE or design basis tornado loads, are the same as those for the CB discussed in Subsection 9B.3.2, excluding the special hardening provisions. The turbine generator foundation is sized and designed to additionally meet the applicable static and dynamic performance requirements by the turbine generator manufacturer, and to have adequate structural integrity and stability to withstand applicable loads and associated load combinations imposed during the service life of the plant. Local hardening is provided for systems in the TB as required. Like the CB, the TB is also separated from the RB by a clear gap to prevent any physical contact during a seismic or tornado event. Clear gaps also separates the TB from the adjacent RWB and Reactor Auxiliary Bay.

The TB is also designed to resist damage and the spread of fires as discussed in Chapter 3, Subsection 3.4.1.1 and in compliance with CNSC REGDOC-2.10.1 and CSA N293. Fire alarm and smoke detectors are installed, with occupant notification provided, throughout the building. Areas housing the turbine generator and associated ancillary process equipment and electrical equipment rooms in the building are designed to have a 3-hour fire resistance rating. Fireproofing of structural steel members under design basis turbine lube oil fire is as discussed in Chapter 3, Subsection 3.4.1.1.

To satisfy CSA N293 requirements, sprinklers are provided in the turbine generator underfloor area below the operating floor, in the steam turbine shielded area, in the freight elevator hoistway and in the machine room. Lube oil system continuing out of the shielded area go to the bearings associated with the generator.

The largest flow rate is anticipated to be the simultaneous operation of a turbine underfloor system (both levels) and the turbine bearing system, including hose streams. Methodology used to calculate this flow is per CSA N293 and CSA N293S1.

Fire protection water is supplied to the TB from three separate connections from the site loop which feed into Stairs C, B and A.

Radiological aspects of the TB are discussed in Chapter 12, Subsections 12.2.1.3 and 12.2.2.2.

#### **9B.3.4 Reactor Auxiliary Bay**

The Reactor Auxiliary Bay is the independent structure east of the RB shown in Chapter 1, Appendix A, Figure A1.4-1. As indicated in Chapter 3, Table 3.3-1, the Reactor Auxiliary Bay is categorized as a Non-Seismic Category structure and is evaluated for seismic interaction, similar to the CB and TB. The Reactor Auxiliary Bay is considered a post-disaster building per NBC.

The Reactor Auxiliary Bay structure consists of a one-story structural steel building with a combination of moment frame and braced frame systems in the transverse (short) direction and braced bays in the longitudinal direction, with the roof deck acting as the diaphragm. The Reactor Auxiliary Bay rests on a shallow foundation isolated from the adjacent building foundations. The roof elevation of the Reactor Auxiliary Bay is flush with the CB roof.

The analysis and design approaches and requirements for the Reactor Auxiliary Bay and its foundation, including the interaction evaluations for DBE and design basis tornado loads, are the same as those for the CB and TB discussed in Subsections 9B.3.2 and 9B.3.3. A clear gap separates the Reactor Auxiliary Bay from the adjacent RB to prevent any physical contact between the buildings during a seismic or tornado event.

Radiological aspects of the Reactor Auxiliary Bay are discussed in Chapter 12, Subsection 12.2.2.5.

Fire protection design features in this area are as described in Chapter 3, Subsection 3.4.1.1 and include the use of wet pipe sprinklers. As mentioned in Chapter 3, Subsection 3.4.1.1.1, the Reactor Auxiliary Bay is designed to have a 3-hour fire resistance rating.

### **9B.3.5 Pumphouse/Forebay and Tunnels**

#### **9B.3.5.1 Pumphouse/Forebay**

The Pumphouse/Forebay structure is composed of the Forebay, pump bays, and superstructures housing the Circulating Water System (CWS) pumps and related electrical equipment. For the location of the Pumphouse/Forebay structure, refer to Chapter 1, Appendix A, Figure A1.4-1.

The Forebay provides the transition for the water flowing from the intake tunnel to the pump bays. Pump bays are provided for the large CWS pumps supplying water to the main condenser and the smaller CWS pumps that provide water to the Plant Cooling Water System (PCW) heat exchangers. The top elevation of the pump bay foundation is based on pump minimum submergence depth, minimum liquid depth, and low water level of the lake.

To prevent the intake of biofouling material and mitigate the probability of clogging, design considerations regarding the intake tunnel and lakebed intake structure depths in Lake Ontario are employed. At the same time, traveling screens in the Pumphouse/Forebay are used to mitigate clogging probability. If the lakebed intake structure screens are deemed insufficient for biofouling material intake prevention during the design phase, a fish return system, or slew, may be provided to safely return large fish to Lake Ontario to meet DNNP regulatory commitment D-C-1 (Reference 9B.4-44).

#### **9B.3.5.2 Tunneling**

##### **9B.3.5.2.1 Vertical Shafts**

The onshore vertical shafts are designed to facilitate the operation of up to four Small Modular Reactor (SMR) units and facilitate the construction of the intake and discharge tunnels. The intake tunnel connects to the onshore vertical intake shaft to convey cooling water to the Pumphouse/Forebay. Similarly, the onshore vertical discharge shaft connects to the discharge tunnel to convey heated water through the discharge tunnel to the diffusers.

The depth of the onshore vertical shafts is based on the required depth of the intake and discharge tunnels. The required depth of the tunnels is based on anticipated subsurface conditions below the lake determined by the offshore geotechnical investigation discussed in Chapter 2, Subsection 2.5.2.1.

#### **9B.3.5.2.2 Intake Tunnel**

The intake tunnel conveys cooling water from the lakebed intake structure to the onshore intake vertical shaft. The intake tunnel is located beneath Lake Ontario and is to be lined with concrete.

#### **9B.3.5.2.3 Discharge Tunnel and Diffusers**

The discharge tunnel conveys the discharge water from the onshore discharge vertical shaft to the discharge risers/diffusers. The discharge tunnel is located beneath Lake Ontario and the tunnel is to be lined with concrete.

The diffuser arrangement is to be finalized after completion of thermal plume modeling during design.

#### **9B.3.5.3 Design Considerations**

There are no Safety Category 1 functions provided by the BWRX-300 water intake structures and associated systems and components. The PCW and CWS housed in the Pumphouse/Forebay are SC3 systems as indicated in Chapter 3, Appendix 3A, Table 3.12-1. As a result, the Pumphouse/Forebay is categorized as a Non-Seismic structure and is designed in accordance with the NBC.

#### **9B.3.6 Fire Pump Enclosure**

As shown in Chapter 1, Appendix A, Figure A1.4-1, the fire pumps are housed in an enclosure located within the protected area of the plant. A description of the Fire Pump Enclosure structure and design is covered in the POSAR in support of the Licence to Operate application.

## **APPENDIX 9B.A – FINITE ELEMENT MODEL USED IN STRUCTURAL ANALYSES OF INTEGRATED REACTOR**

### **9B.6 Introduction**

This appendix presents the 3-Dimensional (3-D) FE models developed for the analysis and design of the integrated RB structures, which comprise the RB, containment, containment internal structures and their common mat foundation. Methodology used to develop these models are presented in Chapter 3, Subsections 3.3.1.2.2 and 3.5.1.1.1.

The integrated RB FE model used to perform the various structural analyses discussed in Chapter 3, Subsection 3.5.1.1 is presented in Subsection 9B.6.1. This model is developed using appropriate element types to represent the mass, stiffness, damping characteristics of the integrated RB structures for the analysed loads being evaluated and resulting stress responses. The model has a sufficiently refined mesh to accurately capture the dynamic response of the structures over the frequency range of interest and to enable accurate calculation of structural stress demands. Mesh refinements in areas of geometric structural discontinuities are used, as applicable.

Table 9B.6-1 summarizes the integrated RB modeling requirements for the various analysis cases performed. Subsection 9B.6.2 presents the 3-D FE model used for the seismic SSI analysis of the integrated RB. Subsection 9B.6.3 presents the 3-D FE model used for the 1-g static SSI analyses. Subsection 9B.6.4 presents the 3-D FE models used for static and quasi-static analyses, while Subsection 9B.6.5 presents the 3-D FE models used for thermal stress analysis.

### **9B.6.1 Integrated Reactor Building Finite Element Model**

#### **9B.6.1.1 Model Overview**

The integrated RB FE model is developed using ANSYS (See Chapter 3, Appendix 3B for description) and represents the major structural elements of the integrated RB structures as described in Chapter 3, Subsection 3.3.1.2. The origin of the model is defined at the centre of the integrated RB structure with the Z-origin defined at grade (Level 0 m) and the global X- and Y-axes pointed in the South, and East directions, respectively.

The integrated RB FE model is developed using wall centrelines and approximate centrelines of slabs. Slab centrelines used in the integrated RB model are approximations of the weighted average centreline of slabs with varying thicknesses.

Figure 9B.6-1 is a 2/3 slice of the integrated RB FE model showing the major structural components of the model. Containment mechanical and electrical piping penetrations are incorporated in the integrated RB FE model as shown in Figure 9B.6-2.

The RPV and internals, including fuel, valve mass and supports, are integrated into the integrated RB FE model using a Lumped Mass Stick (LMS) model developed as described in Chapter 3, Subsection 3.3.1.3.3 and shown in Figure 9B.6-1. Subsection 9B.6.1.4 discusses the connections used to integrate the LMS and the integrated RB models.

#### **9B.6.1.2 Model Properties**

Material properties used in the construction of the integrated RB are described in Subsection 9B.2. Properties assigned to the integrated RB FE model reflect these properties and are computed in accordance with the guidelines of ANSI/AISC N690.

Response Level 1 and Level 2 damping values applicable to the integrated RB model are listed in Chapter 3, Table 3.3-6 and Table 3.3-7.

#### **9B.6.1.2.1 Steel Bricks™ Equivalent Properties**

Geometric details of a typical Steel Bricks™ module are illustrated in Figure 9B.6-3. A typical Steel Bricks™ module consists of individual U-shaped bricks. The modules are fabricated by first cutting steel plate to desired shape or section. Welding shear studs to the inside of the plates is followed. It is then folded in press to create an L-Shaped section. After that the two L sections are welded to form a U-shaped brick. Finally, multiple modules are stacked and welded to form wall or flooring members. The welding takes place externally with no need for operators to be inside the panels.

The lateral and vertical resisting system elements are modeled using elastic shell elements with an equivalent thickness, elastic modulus, and material density calibrated to match the Steel Bricks™ effective stiffness and mass properties developed using ANSI/AISC N690, Appendix N9. The effective axial stiffness of these elements is developed using the method outlined in AISC Engineering Journal Article (Reference 9B.4-47).

Effective material properties used for the operating conditions represent the Best Estimate (BE) structure stiffnesses. Effective material properties for the fully cracked condition are referred to as the Lower Bound (LB) structure stiffnesses. For operating conditions, the effective flexural stiffness of the composite Steel Bricks™ section combines both the steel and concrete stiffnesses. The fully cracked condition is simulated by ignoring the contribution of concrete infill flexural stiffness.

Wall curvatures are not considered in the mathematical formulations of Steel Bricks™ properties. The contribution of shear connectors and Steel Bricks™ diaphragms to flexural stiffness are also not considered. The effects of liners used for corrosion and shielding protections is not considered in the calculation of FE properties.

#### **9B.6.1.3 Steel-Plate Composite Connections**

Full-strength welded (rigid) and bolted (semi-rigid) connections are used to connect the Steel Bricks™ structural elements in the integrated RB. Semi-rigid connections are typically used below grade to release some of the thermal induced stresses from the SCCV. Above grade, all connections are full-strength welded connections.

The integrated RB model captures the semi-rigid connections with six linear springs, with three translational and rotational stiffnesses each, at each pair of near coincident nodes where the walls and floors meet. The stiffnesses of the semi-rigid connections are estimated based on the component based model approach explained in Article 6.3 of the Eurocode 03 Part 8 (Reference 9B.4-48) and in Reference 9B.4-49.

The current floor-to-wall semi-rigid connections provide some flexibility in the floor in-plane and axial direction degrees of freedom, and in the floor out-of-plane bending. Similarly, wall-to-wall semi-rigid connections provide some flexibility in the wall axial and in-plane degrees of freedom, and in the wall out-of-plane bending. Each degree of freedom of the spring element is assigned either a semi-rigid stiffness or a rigid stiffness consistent with the orientation of release.

The integrated RB model captures the full-strength welded connections (rigid connections) with shared nodes or with a pair of rigid linear spring elements (translational and torsional) to restrain all six degrees of freedom. These rigid linear springs are also used at the intersection corners of the below grade RB floors and walls.

Figure 9B.6-4 shows the semi-rigid connection locations in the integrated RB model.

#### **9B.6.1.4 Reactor Pressure Vessel and CEPSS Connections**

The BWRX-300 RPV is supported vertically and laterally through the RPV skirt and laterally only through the top and bottom stabilizers as shown in Figure 9B-1. The RPV steel skirt is designed to allow thermal expansion in radial direction reducing the loads on the RPV pedestal. The bottom stabilizers are also used as shown in Figure 9B-1 to provide a lateral support to the control rod drive housing (CRDH) located below the RPV. The RPV is free for radial movement at the stabilizers and CRDH supports. The skirt, bottom stabilizers, and CRDH lateral support transfer lateral load directly to the pedestal. The upper stabilizers transfer lateral load to the CEPSS. The CEPSS framing is vertically and laterally supported by the pedestal and tangentially restrained by the SCCV wall through shear lugs that allow the CEPSS framing to radially move for thermal.

The RPV LMS model was initially developed with a single horizontal spring in each direction at the stabilizers, skirt, and CRDH locations. During its incorporation into the integrated RB FE model, these single springs were adapted so that the RPV lateral load can be transferred to the pedestal or CEPSS framing shown in Figure 9B.6-1. The RPV piping stiffness is considered to be decoupled for the bounding analyses.

#### **9B.6.1.5 Static and Dynamic Mass Properties**

The integrated RB model is analysed for the design loads described in Chapter 3, Section 3.5. These loads are assigned to the integrated RB model as static and dynamic masses.

Dead loads include self-weight and supplemental weight added to represent equipment and non-structural (i.e., staircases, steel platforms, partition walls, radiation shielding plates) dead loads. Static dead load analysis is performed by applying a 1-g acceleration to the static SSI model including all dead load masses. The dead load model masses also contribute to the seismic inertial loads and remain in the integrated RB dynamic model. Fifty percent of the live load and twenty-five percent of snow loads are modeled as equivalent mass in the integrated RB dynamic model.

As stated in Chapter 3, Subsection 3.3.1.2.2, the inertia associated with the vertical hydrostatic and horizontal impulsive hydrodynamic effects of the fluids contained in various RB pools are included in the integrated RB FE model. Methodology used to account for these loads is discussed in Chapter 3, Subsection 3.3.1.2.2.

Hydrostatic and hydrodynamic loads act on the pool floors and walls. Hydrostatic loads on the pool floors are captured by modeling the fluid volume in each of the pools as a vertical only mass during 1-g static SSI analyses. Hydrostatic loads on the pool walls are analysed as a pressure load during the structural analyses as demonstrated in Appendix 9B, Subsection 9B.9.2.3.

The hydrostatic fluid volume masses also act as the seismic inertial mass in the vertical direction during seismic analysis. The hydrodynamic impulsive loads are captured during seismic response analysis by assigning masses to the pool walls consistent with the impulsive pressure distribution. Hydrodynamic convective loads on the pool walls are analysed as a pressure load during structural analysis.

#### **9B.6.2 Seismic SSI Analysis Model**

Since the integrated RB is deeply embedded, the interaction of the structure with the surrounding subgrade is important for its structural integrity and its response under static and dynamic loads. In accordance with the guidance of NEDO-33914, Section 5.1, the one-step approach, as defined in Section 3.1.2 of ASCE/SEI 4, is implemented for the design of the BWRX-300 integrated RB structures to adequately account for the SSI effects requiring the development of a model that includes FE representations of the integrated RB (discussed in Subsection 9B.6.1) and the surrounding subgrade. To account for the SSSI effects with the surrounding Power Block

structures as discussed in Chapter 3, Subsection 3.3.1.2.1, coarse dynamic FE models of the RWB, CB, TB, and Reactor Auxiliary Bay structures, including foundations are added to the SSI model. These coarse mesh models represent the overall stiffness and mass distribution necessary to capture the global dynamic behaviour of the RWB, CB, TB and Reactor Auxiliary Bay structures. The models are inserted into the integrated model with the centreline of their mat foundations set a grade elevation (Level 0 m) and are separated from the RB model by a minimum gap of 760 mm in line with the discussion in Chapter 3, Subsection 3.3.1.2.8.

Figure 9B.6-5 shows an overview of the FE model developed for the seismic SSI analysis of the integrated RB structures. This model is assigned BE structure stiffnesses with static and dynamic masses and is referred to as the dynamic SSI model. The model is developed in ANSYS and then translated into ACS SASSI (see Chapter 3, Appendix 3B) format for the SSI analyses.

As described in Subsection 9B.3.3, the foundation supporting the turbine generator is structurally isolated from both the turbine shielding walls and shell structure for vibration control. Figure 9B.6-6 shows the LMS model used to represent the turbine generator pedestal structure and the isolated FE model used to model its isolated foundation in the seismic SSI analysis model.

#### **9B.6.2.1 Modeling of Soil-Structure Interfaces**

The soil and soil-structure interfaces of the seismic SSI analysis model consists of the following:

- Free-field subgrade model representing the properties of the subgrade materials that are approximated as continuum infinite horizontal layers resting on surface of uniform half-space
- Near-field subgrade volume representing the properties of subgrade materials below the RB and adjacent Power Block foundations and around the RB below grade exterior wall
- Excavated soil volume representing the properties of the volume of far-field subgrade replaced by the RB and adjacent near-field volume elements, and
- Contact spring elements connecting the near-field subgrade volume and the structures at interface nodes

##### **9B.6.2.1.1 Free-field Subgrade**

The free-field subgrade is represented in ACS SASSI by half-space continuum of horizontally infinite layers with uniform linear elastic properties resting on uniform elastic half-space. A viscous lower boundary of the subgrade model is established at depth that is at least three times the largest foundation dimension from the bottom of the foundation as discussed in Chapter 3, Subsection 3.3.1.2.2.

##### **9B.6.2.1.2 Near-field Subgrade Volume**

A single layer of near-field solid elements is placed below the BWRX-300 Power Block foundations and around the below grade portion of the RB exterior wall representing the properties of the near-field subgrade materials as shown in Figure 9B.6-5.

At the excavated volume perimeter, the FE of excavated soil volume (see Subsection 9B.6.2.1.3) and the near-field volume share the same nodes. The mesh of these two subgrade volumes aligns with every other mesh element of the RB exterior wall and mat foundation. Having the FE mesh of the near-field volume and excavated volume being twice the size of the refined one-step approach RB structural model helps reduce the ACS SASSI dynamic soil impedance calculations to practically reasonable durations. The mesh of the near-field volume aligns with the mesh of the surface mounted Power Block foundations.

Per guidance of NEDO-33914, Section 5.5, the BWRX-300 design conservatively does not consider the resistance of the temporary construction elements such as the excavation support structure and the lean concrete material used to fill the gap between the excavation edge and the RB exterior wall. As a result, the near-field soil volume in the FE model used for the design basis seismic SSI analysis is assigned the same properties as the far-field soil.

#### **9B.6.2.1.3 Far-Field Subgrade Excavated Volume**

The excavated volume model (see Figure 9B.6-7) consists of 3-D solid FEs representing the part of the horizontally layered subgrade displaced by the near-field volume and the embedded portion of the RB structure. The mesh of the excavated subgrade volume aligns with the layering of the far-field subgrade profiles and the near-field subgrade volume shown. The meshes of the excavated and near-field volumes are aligned at the perimeter, where the excavated volume and near-field volume solid elements share the same nodes.

#### **9B.6.2.1.4 Near-Field-Structure Interfaces**

Three contact linear spring elements are assigned at all near coincident nodes between the near-field volume and the FE models of the RB and adjacent Power Block structures as well at the nodes of the RB exterior wall to represent normal (radial) and friction (vertical and tangential) interaction mechanisms. Contact spring elements are assigned at near coincident nodes between the near-field volume mesh and every other node on the RB exterior wall and mat foundation mesh.

For seismic analysis, all contact springs in the dynamic SSI model are assigned high stiffnesses to simulate fully bonded conditions between the near-field volume solid elements and the structural shell elements to emphasize the effects of SSI and SSSI on the seismic response of the deeply embedded RB.

### **9B.6.3 1-g Static SSI Analysis Model**

The 1-g static SSI analysis provides design demands for gravity inertia loads and static earth pressure loads including surcharge loads from the foundations of adjacent Power Block buildings.

Two sets of 1-g static SSI analysis are performed to evaluate the unfactored and factored gravity demands on the integrated RB (see Table 9B.6-1) requiring the development of two 1-g static SSI analysis models.

The 1-g static SSI models have the same configuration and FE attributes as the dynamic SSI model developed for the seismic analysis described in Subsection 9B.6.2. The structural members of the 1-g static SSI models are assigned the same BE effective stiffness properties as the dynamic model. Differences between the static and dynamic models consist of the following adjustments made to the unit weight properties of shell and lumped mass elements of the 1-g SSI models:

- The removal of the live and snow mass properties from the 1-g static SSI Models. The fluid horizontal dynamic masses are not removed from the models since these are not activated in 1-g gravity analysis.
- The RPV total mass is increased to reflect the bounding refueling condition.
- The total mass of adjacent Power Block structures is increased by 10% in the unfactored and factored 1-g SSI analysis models for added safety margin. The 10% increase in the factored model is increased by an additional 33% due to factoring of loads for a total mass increase of 46%.

Per recommendations of NEDO-33914, Section 5.1.2, stiffness properties assigned to the contact springs in the 1-g static SSI models provide SSI interface conditions that emphasize the lateral earth pressure loads on the RB exterior wall below grade. A high stiffness is assigned to the contact spring elements in the direction normal to the RB exterior wall and mat foundation to simulate bonded conditions. The friction at the RB exterior wall and mat foundation is not considered by assigning very low stiffness properties to the contact springs in the vertical and tangential direction. Similarly, contact springs at the bottom of the surface mounted foundations of the surrounding Power Block structures are assigned a high stiffness in the vertical direction and low stiffness in the horizontal direction to maximize the effects of the surcharge loads on the lateral earth pressures on the RB exterior wall.

#### **9B.6.4 Static and Quasi-Static Analysis Models**

The static and quasi-static analyses provide design demands for static normal operating and accidental conditions loads, excluding thermal loads, not captured in the 1-g static SSI analysis. For more information on load cases considered in the analyses, refer to Chapter 3, Subsection 3.5.1.1.3 and Table 9B.6-1.

Static and quasi-static analyses are performed on standalone models of the integrated RB with either BE stiffness properties representative of low stress response conditions or LB structure stiffness properties representative of fully cracked concrete conditions when the structural members experience high stresses.

Static and Quasi-static analyses are performed using the subgrade stiffness sub-structuring method as discussed in Chapter 3, Subsection 3.5.1.1.3 in which the subgrade represented by solid FEs (see Figure 9B.6-8) is condensed into a single matrix element, called a super-element. This super-element is shown in Figure 9B.6-9 and represents the SSI impedance at nodes coincident with every other node of the RB exterior wall and mat foundation. For static and quasi-static analyses, the super-element is assigned LB subgrade stiffness properties to emphasize the deformations at the subgrade-structure interfaces resulting in conservative estimate of the member force and moment demands on the RB integrated structure.

#### **9B.6.5 Thermal Stress Analysis Model**

Thermal analyses provide stress demands due to normal operating and accidental load conditions as indicated in Table 9B.6-1.

Thermal stress analyses are performed on standalone models of the integrated RB that have the same configuration and FE attributes as the models developed for static and quasi-static analyses discussed in Subsection 9B.6.4. The standalone integrated RB model used for normal operating thermal analysis is developed with BE structure stiffness properties. The standalone integrated RB model used for the accidental thermal analysis is developed with LB structure stiffness properties assigned to the exterior pool walls, SCCV wall, inner mat foundation and SCCV top slab, and BE structure stiffness properties elsewhere.

Thermal stress analyses use super-elements assigned with upper bound subgrade stiffness properties to emphasize the constraints at the subgrade-structure interfaces against the thermal expansion resulting in upper bound estimates of thermal stresses in the RB structures.

#### **9B.6.6 Validation of FE Models**

##### **9B.6.6.1 Validation of Integrated Reactor Building Model Translation into ACS SASSI Format**

The validation of the translation of the integrated RB dynamic model into the ACS SASSI format is performed by comparing the results of:

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

- A fixed base eigenvalue analyses of the dynamic model in the ANSYS format, and
- A SASSI analysis of the integrated RB dynamic model resting on the surface of a very stiff half-space simulating fixed base conditions.

Eigenvalue analyses are performed in ANSYS using the Block Lanczos method for the first 500 modes up to 35.2Hz, where a minimum of 85% cumulative mass participation ratio is reached (See Figure 9B.6-10). The integrated RB significant mode frequencies and mass participation ratios in each orthogonal direction are as follows:

- Primary X mode occurs in the RB, SCCV and CEPSS at a frequency of 2.25 Hz with a 58% mass participation.
- Primary Y mode occurs in the RB, SCCV and CEPSS at a frequency of 2.30 Hz with a 41% mass participation.
- Primary Z (vertical) mode occurs in the RB, SCCV and pedestal at a frequency of 7.73 Hz with a 57% mass participation.

ACS SASSI analyses of “fixed base” surface mounted RB dynamic model is performed from 0.1 to 70Hz and Acceleration Transfer Functions (ATFs) amplitudes for the responses in the three orthogonal directions at key nodal locations plotted. Figure 9B.6-10 compares the normalized transfer functions at the integrated RB roof node #129688 (see Appendix 9B.B, Figure 9B.7-3) with fixed base eigenvalue cumulative mass ratio plots for each of the three orthogonal directions. As shown in Figure 9B.6-10, the first peaks of the transfer functions occur at 2.2Hz and 6Hz with the second peaks occurring at 7.3Hz and 7.7Hz in the horizontal and vertical directions, respectively. The fixed base integrated RB structure transfer function peaks are consistent with the primary modes of the eigen value analysis.

#### **9B.6.6.2 Validation of ACS SASSI Stress Results**

The accuracy of stress results obtained from the ACS SASSI translated model are validated by comparing element stress responses obtained from the two following analyses of the integrated RB model:

- ANSYS static analysis of a fixed base model with 1-g gravity loads applied in the three orthogonal directions and
- ACS SASSI quasi-dynamic analysis of the model resting on very stiff half-space with 1-g acceleration applied in each of the three orthogonal directions.

Locations selected for comparison of stress results include the SCCV top slab (Elevation 4.9 m), northern and southern wing walls below grade, RB exterior wall below grade, SCCV wall and RPV pedestal. For each location, the critical load path is selected for each direction of loading and then compared side by side as shown in Figure 9B.6-11 for the SCCV top slab.

As demonstrated in Figure 9B.6-11, all side-by-side comparisons performed for each of the critical load paths are consistent between ANSYS and SASSI in terms of magnitude and distribution of demands. This confirms the translation of the integrated RB dynamic model was properly performed.

#### **9B.6.6.3 Validation of Incorporation of RPV Lumped Mass Stick Model**

The incorporation of the RPV LMS model with the supporting integrated RB model is validated by comparing the dynamic characteristics of the RPV LMS model within the integrated RB model with benchmark results the eigenvalue analysis of the standalone RPV LMS model.

Table 9B.6-2 reports the fundamental modes of the RPV LMS model and pairs each mode with its corresponding mode observed in the modal analysis described in Section 9B.6.6.1. As shown in Table 9B.6-2, the modal frequencies from these two sources are within the 10% variation requirement in Section 5.3 of NEDO-33914.

#### **9B.6.6.4 Validation of Dynamic Models of Adjacent Power Block Structures**

The coarse FE models of the adjacent Power Block structure that are coupled with the integrated RB are required to represent their global dynamic properties for use in seismic SSI analyses. Consequently, validation analyses are performed to demonstrate that these dynamic models can capture all important global modes of vibration of the Power Block structures by comparing results from:

- Fixed base eigenvalue analyses of refined design basis dynamic FE models of the adjacent Power Block structures, and
- SASSI analyses of the coarse dynamic FE models resting on the surface of a very stiff half-space simulating fixed base conditions.

Validation results demonstrate that the dynamic characteristics of the coarse dynamic models match reasonably well in total mass and dominant dynamic response with those from the refined models as demonstrated in Figure 9B.6-12, Figure 9B.6-13, Figure 9B.6-14, Figure 9B.6-15 and Figure 9B.6-16. Therefore, the coarse FE models of the adjacent Power Block structures provide an adequate representation of the global dynamic properties for the SSI analyses of the integrated RB.

## **APPENDIX 9B.B – SEISMIC SOIL-STRUCTURE INTERACTION ANALYSIS**

### **9B.7 Introduction**

This appendix documents the results of the seismic SSI analysis of the integrated RB.

#### **9B.7.1 SSI Analysis Methodology**

Seismic demands for the design of the Seismic Category A and B SSC at the DNNP site are obtained from the seismic SSI analysis of the FE model discussed in Appendix 9B.A, Subsection 9B.6.2, evaluated for the site-specific bounding input ground motions and subgrade properties presented in Chapter 3, Subsection 3.3.1.1. These parameters are developed to conservatively cover the variabilities and address uncertainties in the geotechnical properties of the subsurface materials and seismicity of the DNNP site.

The seismic SSI analysis is performed using the one-step analysis approach discussed in Chapter 3, Subsection 3.3.1.2.1 which allows seismic stress demands to be obtained directly from the results of the SSI analysis. Frequencies selected for each of the subgrade profile cases in the seismic SSI analysis are provided in Subsection 9B.7.4.

##### **9B.7.1.1 Stress Calculation**

Shell element forces and moments obtained from the seismic SSI analysis are provided at the centre of the element with respect to the element local coordinate system. To calculate the co-directional stress demands, the time histories of responses due to the three earthquake components are combined algebraically for each element using the time-step-by-time-step approach as discussed in Chapter 3, Subsection 3.3.1.2.6. The combined stress demands are then transformed from the local coordinate system into a global cartesian or cylindrical coordinate system for use as input for the design of the structural members.

Average stress results from the five sets of Acceleration Time Histories (ATHs) used as input to the seismic SSI analysis represent the response of the structure for each SSI analysis case considered. Stress results obtained from the analyses of the three subgrade profile cases are enveloped to provide enveloping DNNP site-specific seismic stress demands that account for the uncertainties and variations of the subgrade properties.

##### **9B.7.1.2 In-Structure Response Spectra Calculation**

Per Chapter 3, Subsection 3.3.12.7, the In-Structure-Response Spectra (ISRS) are calculated at 301 frequency points equally distributed on the logarithmic scale at the frequency range from 0.1 Hz to 100 Hz to ensure the ISRS are sufficiently close to the peak response frequencies of the supporting structure. The ISRS are calculated at equipment locations for multiple damping ratios spanning the range corresponding to that of equipment under consideration.

The SSI analysis is performed separately for each one of the three directional components of input ground motion using each of the five sets of ATHs for each subgrade profile analysis case. For each set, the ISRS obtained from the analysis of each of the three ground motion components are combined to get the total co-directional response using the Square-Root-of-the-Sum-of-Squares (SRSS) method. For each subgrade profile analysis, an average ISRS is computed from the five sets of ATHs to represent the amplitude and frequency content of the in-structure motion at a particular location as illustrated in Figure 9B.7-1. The ISRS from the bounding site-specific subgrade profile analysis cases are then enveloped as illustrated in Figure 9B.7-2. To address uncertainties related to the modeling of natural frequencies of the supporting structure and the SSI analysis methodology, peaks of the enveloping ISRS are broadened by  $\pm 25\%$  which exceeds the 15% requirement specified in Chapter 3, Subsection 3.3.1.2.7. Sharp valleys between peaks are also filled, as shown in Figure 9B.7-2, to account for the uncertainties in subgrade properties.

### **9B.7.1.3 Relative Displacement Calculation**

Relative displacements are calculated for key nodal locations throughout the RB relative to the free-field at mat foundation elevation. For each set of ATHs, the maximum relative displacement obtained from the analysis of each of the three ground motion components are combined using the SRSS method to get the total co-directional response. From the results of the analysis of each subgrade profile, average relative displacements from the five sets of ATHs are computed representing the maximum relative displacement for the considered subgrade profile. The relative displacements obtained from the analysis of the LB, BE and UB subgrade profile cases are enveloped to provide DNNP site-specific relative displacement demands that account for the uncertainties and variations of the subgrade properties.

### **9B.7.2 Key Nodal Locations**

As stated in Chapter 3, Subsection 3.3.1.2.5, responses at key nodal locations are used to demonstrate the accuracy of the seismic SSI analysis results, to determine analysis cutoff frequencies, and to evaluate the effects of SSI parameters variations based on comparisons of results from different seismic SSI analysis cases.

Key nodal locations selected per the criteria in Chapter 3, Subsection 3.3.1.2.5 for the verification and validation of the integrated RB seismic SSI analysis and results are provided in Table 9B.7-1 and illustrated in Figure 9B.7-3.

### **9B.7.3 Key Structural Members**

Seismic stress demands are calculated for key structural members and compared between SSI analysis cases to understand the effects of subgrade properties on the seismic response of the soil-structure system.

Table 9B.7-2 presents the key structural members selected based on their critical support function of safety-related equipment, critical importance within the lateral force resisting system, or critical location along the seismic load path. These key structural members are also illustrated in Figure 9B.7-3.

### **9B.7.4 Design Basis Seismic Analysis Cases and Selected Frequencies of Analysis**

Three seismic SSI analysis cases, representing the LB, BE and UB subgrade profile cases discussed in Chapter 3, Subsection 3.3.1.1.5, form the design basis for the integrated RB at the DNNP site.

The three seismic SSI analysis cases are performed for frequencies starting at 0.006 Hz to the respective cutoff frequency for each of the subgrade profile cases. Following the selection criteria in Chapter 3, Subsection 3.3.1.2.1, the following cutoff frequencies are adopted for the analysis:

- 22 Hz for the LB case
- 41 Hz for the BE case
- 68 Hz for the UB case

To evaluate the adequacy of these selected cutoff frequencies, the normalized ATFs and ISRS results from the analyses of the LB, BE and UB subgrade profiles are compared as explained in Subsections 9B.7.4.1 and 9B.7.5.2. The comparisons of the normalized ATHs and ISRS results in Subsections 9B.7.4.1 and 9B.7.5.2 show that the selected cutoff frequencies for the LB and BE subgrade profile cases of 22 Hz and 41 Hz are adequate for calculation of enveloping SSI responses. The SSI analysis of the UB subgrade profile provides bounding responses at frequencies significantly higher than the cutoff frequencies of the LB and BE subgrade profiles resulting in enveloping SSI results that bound the effects of variation of subgrade properties at the DNNP site.

The SASSI frequency domain analysis calculates the response of the system at selected “Structure” frequencies defined as the number of frequencies necessary to adequately characterize the response of the full SSI system. The results for the response at frequencies between the selected frequencies are interpolated. The ATF results for the responses at key nodal locations are plotted and inspected to ensure the accuracy of the transfer function interpolation as illustrated in Figure 9B.7-4 for the RB roof. The dots in the ATF plots in Figure 9B.7-4 represent the calculated “Structure” frequencies, and the lines show the interpolated ATFs. The smooth curves and the presence of calculated frequencies near peaks, troughs and inflection points indicate that the spacing of analysis frequencies is adequate for capturing the seismic response of the analysed soil-structure system over the frequency range of interest.

#### **9B.7.4.1 Subgrade Properties Variation Effects**

Figure 9B.7-5 compares the ATFs representing the co-directional responses at the edge of the RB roof in the three orthogonal directions obtained from the analysis of the LB, BE and UB subgrade profile cases. These ATFs are normalized with respect to the free-field response at surface by removing the large amplitude ATF peaks at the embedment soil column frequencies to better depict the peak responses of the RB structure.

The plots in Figure 9B.7-5 show distinct dominant frequencies for the SSI system depending on the subgrade profile analysis. Following the expected trend, ATF peak frequencies obtained from the LB profile analysis are associated with the lowest frequency, followed by higher ATF peak frequencies for the BE and UB cases as shown in Figure 9B.7-5 and shown in Table 9B.7-3. Frequencies for the horizontal direction of motion, associated with the shear-wave velocity for the subgrade, are also found to be smaller than those for the vertical direction, associated with the larger compression wave velocity for the subgrade.

As illustrated in Figure 9B.7-5, the amplitudes of the normalized ATFs obtained from the LB and BE subgrade profile analysis cases fall well below unity at frequencies that are smaller than their respective cutoff frequencies (22 Hz for LB and 41 Hz for BE), thus confirming the adequacy of the selected cutoff frequencies. The plots also show that the amplitudes of the normalized ATFs obtained from the UB subgrade profile analysis govern the seismic response at higher frequencies, and therefore capture the governing seismic demands up to its cutoff frequency of 68 Hz.

#### **9B.7.5 DNNP Seismic Response Characteristic**

##### **9B.7.5.1 Seismic Structural Stress Responses**

This section presents plots of main stress components in key structural members to depict the characteristics of how the RB integrated structures resist the DNNP site-specific seismic loads. Member force and moment results obtained from the analysis of the LB, BE and UB subgrade profile cases are compared to evaluate the effect of subgrade variations on the seismic stress responses of the RB integrated structures.

Figure 9B.7-6 through Figure 9B.7-17 compare the in-plane and out-of-plane membrane forces and bending moments on the above and below grade portions of the RB exterior wall obtained from the LB, BE and UB subgrade profiles. Due to the cylindrical shape of the wall, the out-of-plane dynamic pressure forces applied on the below grade portion of the RB exterior wall are primarily resisted by tangential (hoop) membrane forces as shown in Figure 9B.7-6 through Figure 9B.7-8. Comparing the forces due to the LB, BE and UB cases in these figures, the LB case is found to provide the largest seismic demands followed by the BE and UB cases. This can be attributed to the combined effect of the larger dynamic earth pressures applied on the deeply embedded structure supported by the softer soil layers. On the other hand, the vertical and in-plane shear forces are generally largest for the UB case, particularly at the transition between the above grade and below grade portion of the wall where

the stiffer UB case subgrade profile provides a stronger support resulting in larger forces in the exterior RB wall.

The plots in Figure 9B.7-15 through Figure 9B.7-17 show that the out-of-plane moments on the RB exterior wall are of a small magnitude with peak amplitudes at the connections of the RB exterior wall with the interior floors and wing walls. An abrupt reduction in force magnitudes is noticed in these figures below the depth of 24.4 m where the higher magnitude dynamic earth pressures from the softer in-situ soils end and the much lower magnitude dynamic pressures from the stiff the rock formation start.

The RB cylindrical shape together with the softer connections between the SCCV and RB walls and slabs help reduce the demands on the RB wing walls although these are located on the load path for resisting earth pressures. This is demonstrated in Figure 9B.7-18 through Figure 9B.7-20 where wing walls are found to be subjected to relatively lower in-plane shear forces than the RB exterior wall which resists most of the dynamic earth pressure loads.

#### **9B.7.5.2 Seismic In-Structure Responses**

5% damped ISRS for responses at key nodal locations obtained from the analysis of the LB, BE and UB subgrade profile cases are compared as shown in Figure 9B.7-21 and Figure 9B.7-22 to evaluate the effect of subgrade variations on the RB in-structure response. As shown in these figures, these ISRS are also compared to the corresponding enveloped and broadened ISRS developed as described in Section 9B.7.1.2 to determine whether the broadened spectra can capture possible shifts of the ISRS peak frequencies.

The comparisons show that the first ISRS peaks are at frequencies that coincide with the SSI system response dominant frequencies listed in Subsection 9B.7.4. In the high-frequency range, at frequencies higher than 8 Hz and 20 Hz in the horizontal and vertical direction, respectively, and for the overall largest ISRS amplitude, the UB case provides the highest ISRS.

One exception is the vertical ISRS for the vertical response at the top of the pedestal, shown in Figure 9B.7-21, where the analysis of the LB subgrade profile has an ISRS peak that exceeds the ISRS obtained from the analysis of the UB and BE subgrade profile cases. This peak response is a result of resonance between the structural frequency of the pedestal and the secondary dynamic mode of the LB subgrade profile at that frequency. Nevertheless, this peak ISRS frequency of 16 Hz is significantly lower than the cutoff frequency of 22 Hz used for the analysis of the LB subgrade profile, thus demonstrating that the selected cutoff frequency for the LB profile analysis is adequate for the calculation of enveloping SSI responses.

#### **9B.7.5.3 Seismic Relative Displacements**

Relative displacements obtained from the analysis of the LB, BE and UB subgrade profile cases are compared to evaluate the effect of subgrade variations on the seismic displacement response of the RB integrated structures.

Table 9B.7-4 presents the estimated maximum relative displacements at the operating floor slab (Node 106595; 4.9 m above grade), at the centre of the roof (Node 129688; 30.5 m above grade) and at top of the RPV pedestal (Node 89097; 8.3 m below grade). As can be seen from this table, the largest relative horizontal and vertical displacements are provided by the BE and UB cases.

Considering that the magnitudes of the estimated relative displacements are very small, smaller than 20 mm at the RB roof, the observed response demonstrates the relatively stiff structural characteristics of the RB.

### **9B.7.6 Sensitivity Analysis Cases**

Following Chapter 3, Subsection 3.3.1.2.4, sensitivity evaluations are performed to investigate the effects of structural stiffness variation, soil-structure interface conditions, soil separation and groundwater variations, and excavation and backfill properties on the seismic response and design of RB SSC.

The sensitivity evaluations are based on results of sensitivity SSI analyses performed using the BE subgrade profile properties and SSI analysis models representing conditions that bound the variation of the evaluated SSI parameter. The sensitivity evaluations are performed by comparing in-structure responses at key locations and stress demands for key structural members within the RB. Subsection 9B.7.6.1 through Subsection 9B.7.6.4 summarize the findings of these sensitivity evaluations.

Per guidance of NEDO-33914, Section 5.3, the results of the sensitivity analysis are included in the RB seismic design basis when comparisons show significant exceedances, greater than 10%, in the RB seismic response due to any of the examined effects. To do so, results of the sensitivity cases are enveloped with those of the design basis analyses of LB, BE and UB subgrade profiles. The enveloped results are then used to develop seismic member force and moment demands, and design ISRS, following the methodology in Subsections 9B.7.1.1 and 9B.7.1.2 to provide a bounding basis for the site-specific seismic design of the Seismic Category A and B SSC at the DNNP site. Subsection 9B.7.6.5 provides a sample of bounding seismic design basis ISRS developed to account for observed exceedances at a given location.

#### **9B.7.6.1 Structural Stiffness Variation Effects on Responses**

As stated in Appendix 9B.6, Subsection 9B.6.1.2, shell elements modeling Steel Bricks™ members of the RB integrated structures are assigned BE effective stiffness properties and Level 1 damping value of 3% in the structural model used for the design basis seismic analysis cases. To evaluate the structural stiffness variation effects on the integrated RB responses, a sensitivity case is performed on an SSI analysis model representing LB stiffness properties of integrated RB structures. In this model, all Steel Bricks™ members are considered fully cracked in flexure and in-plane shear and are assigned a higher level 2 damping value of 5% to reflect the higher level of energy dissipation as a result of concrete cracking. Both analyses are performed for the BE subgrade profile using structural models with effective stiffness properties.

The comparisons of stress responses obtained from the models with BE (Effective) and LB (Reduced) stiffness properties at the RB exterior wall, the RPV pedestal and at the SCCV top slab show that the overall effects of stiffness reduction in Steel Bricks™ members are small. The comparisons show very small differences in the magnitude and distribution of the membrane force and out-of-plane moment demands on the RB exterior wall as demonstrated by Figure 9B.7-23 and Figure 9B.7.24. Figure 9B.7-25 indicates minimal differences in the out-of-plane bending magnitudes at the SCCV top slab due to the structural stiffness reduction. The most noticeable differences due to stiffness reduction, albeit limited, are observed in the stress demands on the RPV pedestal, where a small increase in vertical forces and in-plane shear forces is observed at the bottom half of the pedestal as shown in Figure 9B.7-26 and Figure 9B.7-27.

5% damped ISRS in the three orthogonal directions obtained from the “Effective Stiffness” and “Reduced Stiffness” models are compared at the operating floor slab, at the top of the RPV pedestal and at the edge of the RB roof to assess the amplifications and peak frequency shifts in the in-structure responses induced by concrete cracking. These ISRS are also compared with the broadened 5% damped ISRS, developed as described in Subsection 9B.7.1.2 as the envelope of the three design basis SSI analyses of LB, BE and UB subgrade profiles, to determine if the enveloping and broadening bound the shift in peak response frequencies.

Comparisons indicate small shifts of peak responses to lower frequencies in the horizontal direction, with a few of the exceedances surpassing 10% at the peak responses. These exceedances are nevertheless mostly enveloped by the bounding ISRS. In the vertical direction, similar exceedances are also observed, with the ISRS at the operating floor the most notable at a frequency of about 13 Hz (See Figure 9B.7-28), where a shift to a lower peak frequency occurs reflecting the softer “Reduced Stiffness” properties for the slab and supporting structure.

#### **9B.7.6.2 Soil Separation Effects on Responses**

The linear elastic SSI analyses use models that assume a perfect bond between the embedded RB exterior wall and the subgrade, where rigid springs connect the RB exterior wall to the surrounding soil layers. Considering the possibility of the RB exterior wall separating in parts from the surrounding soil or rock over short instances of time, a sensitivity evaluation is performed following the guidance of NEDO-33914, Section 5.3.9, to investigate the effects of soil separation on the seismic response of the integrated RB at the DNNP site.

To assess the extent of soil separation, the maximum dynamic lateral earth pressures obtained from the design basis SSI analysis of the BE subgrade profile are compared in Figure 9B.7-29 with LB estimates of the lateral static stress in the subgrade and lateral static earth pressure. The depth of approximately 15 m at which the seismic pressure exceeds the static pressure (see Figure 9B.7-29) is adopted as a separation depth for the evaluation of soil separation effects on the seismic response of the RB at the DNNP site.

Both analyses are performed for the BE subgrade profile using structural models with effective stiffness properties. The model for the soil separation sensitivity SSI analysis is developed by reducing the stiffness of the springs connecting the RB exterior wall to the surrounding subgrade from finished grade down to the depth of 15 m to a very small value.

Comparisons of stress responses at the RB exterior wall, the RPV pedestal and SCCV top slab obtained from the “Bonded” and “Separated” models show that, as expected, the tangential (hoop) force on the RB exterior wall below grade decreases due to soil separation. On the other hand, the soil separation can result in significant increases in the vertical membrane (25%) and in-plane shear (70%) forces on the wall portion between grade level and depth of separation (See Figure 9B.7-30 and Figure 9B.7-31). This increase is attributed to the transfer of the dynamic forces from the top 15 m of soil including from the surrounding Power Block structures to the exterior wall portion that is fully bonded with soil starting at a depth of 15 m.

The effects of soil separation on the SCCV top slab and RPV pedestal are minimal as demonstrated by Figure 9B.7-32 and Figure 9B.7-33.

To assess possible amplifications and peak frequency shifts in the in-structure responses due to soil separation, comparisons are made of 5% damped ISRS obtained at the top of the RPV pedestal, at grade elevation of the RB exterior wall and at the edge of the RB roof from the “Bonded” and “Separated” models. The broadened 5% damped ISRS, developed as described in Subsection 9B.7.1.2 as the envelope of the three design basis SSI analyses of LB, BE and UB subgrade profiles, are also compared with the ISRS from the “Separated” model to determine if the enveloping and broadening bound the shifts in peak response frequencies.

The comparisons of horizontal ISRS at all three locations show shifts of the ISRS peaks to slightly lower frequencies that are due to the reduced depth of support provided by the subgrade embedment. The frequency shifts in the vertical ISRS peaks are less pronounced. In general, the shifts in peak frequency responses are bounded by the broadening of the ISRS calculated as envelope of the three design basis SSI analyses.

Noticeable ISRS peak amplifications of more than 10% are observed in the horizontal and vertical responses of the RB exterior wall at grade presented in Figure 9B.7-34.

The effects of soil separation on the horizontal responses inside of the RB structure are not significant. However, the frequency shift in the vertical response of the RPV pedestal shown in Figure 9B.7-35 is significant (>40%) due to resonance effects. Figure 9B.7-35 shows that this amplification in the vertical ISRS is bounded by the enveloping and broadening of the design basis analyses ISRS.

#### **9B.7.6.3 Groundwater Variation Effects on Responses**

The design basis seismic analysis cases of the RB reflect fully saturated conditions for all soil materials located below the DNNP site-specific nominal groundwater table elevation that is located 3 m below the plant grade (See Chapter 3, Subsection 3.3.1.1.6). The saturated soil dynamic properties are simulated by increasing the Poisson's ratios to reflect the compression wave velocity of water in the LB, BE and UB compression wave velocity subgrade profiles used for the design basis analyses.

A sensitivity evaluation is performed following the guidelines of NEDO-33914, Section 5.3.10 to examines the potential effects of groundwater level variability on seismic design. The evaluation is based on results of sensitivity SSI analysis of the BE soil profile reflecting unsaturated conditions for all soil materials down to the surface of the first rock, at a depth of 24 m from the plant grade.

Unsaturated soil conditions are simulated by adjusting the Poisson's ratios of the soil materials resulting in compression wave velocities of soil materials lower than those in the BE subgrade profile used for the design basis analysis as shown in Figure 9B.7-36.

Stress responses at the RB exterior wall, the RPV pedestal and SCCV top slab obtained from the "Saturated" and "Unsaturated" subgrade profiles are compared. The comparisons show that the smaller values of the Poisson's ratios for the soil materials in the unsaturated BE profile reduce the lateral support these soil layers provide to the RB exterior wall, which increases seismic stress demands on the below grade portion of the wall as shown in Figure 9B.7-37 and Figure 9B.7-38. Figure 9B.7-39 shows significant increases in moment demands on the SCCV top slab which are associated with the response in the vertical direction. The effects of groundwater variation on the membrane forces in the RPV pedestal are minimal as demonstrated by Figure 9B.7-40.

To assess possible amplifications and peak frequency shifts in the in-structure responses due to variations of groundwater table, comparisons are made of 5% damped ISRS obtained for the operating floor slab, the top of the RPV pedestal and at grade elevation of the RB exterior wall from the "Saturated" and "Unsaturated" BE subgrade profiles. The broadened 5% damped ISRS, developed as described in Subsection 9B.7.1.2 as the envelope of the three design basis SSI analyses of LB, BE and UB subgrade profiles representing saturated soil conditions, are also compared with the ISRS from the "Unsaturated" subgrade profile to determine if the enveloping and broadening bound the shifts in peak response frequencies.

The comparisons of the horizontal ISRS results show that the effects of the groundwater table variation at the DNNP site on the response of the BWRX-300 RB in the horizontal direction are minimal as shown in Figure 9B.7-41 and Figure 9B.7-42. This is because the shear-wave velocities that govern the horizontal SSI response are not affected by the groundwater table. Limited exceedances are observed in Figure 9B.7-41 in the horizontal response of the RB exterior wall at grade at frequencies greater than 10 Hz.

The comparisons of the vertical ISRS in Figure 9B.7-41 and Figure 9B.7-42 show that the effect of groundwater table variation on the response to the vertical motion can be significant. This is because the vertical SSI responses are affected by the compression wave velocities of the softer soil materials that are affected by the unsaturated conditions. The figures indicate that the consideration of unsaturated soil conditions through the depth of the embedment can result in significant (>10%)

increases in peak ISRS amplitudes, in particular for the ISRS representing out-of-plane slab responses, such as seen in Figure 9B.7-42 for the operating floor slab.

#### **9B.7.6.4 Excavation Support and Backfill Effects on Responses**

As stated in Chapter 3, Subsection 3.5.1.1.2, the BWRX-300 design conservatively does not consider the resistance provided by the excavation support or the lean concrete fill used to backfill the gaps between the RB exterior wall and the excavated soil and rock. The excavation support is designed for temporary use and is excluded from the SSI analysis models because the excavation support and the concrete fill are not expected to maintain their structural integrity throughout the operational life of the plant. A sensitivity evaluation is performed following the guidelines of NEDO-33914, Section 5.2.8, to examine the potential effects the presence of the excavation support and lean concrete fill may have on the seismic response and design of the deeply embedded RB at the DNNP site.

As noted in Appendix 9B.6, Subsection 9B.6.2.1, a ring of solid elements is included in the SSI analysis model around the RB exterior wall below grade to represent the backfill material. For the design basis SSI analysis cases, the near-field elements are assigned the same properties as the surrounding far-field subgrade model. To examine the effects of excavation support and concrete fill on the seismic response of the RB, a sensitivity analysis is performed on an SSI model where the near-field solid elements are assigned lean concrete properties. Since the design of the excavation support has not been finalized yet, this is considered an approximation for simulating stiffer backfill and excavation support conditions. Both analyses are performed for BE subgrade profile using structural models with effective stiffness properties.

Stress responses at the RB exterior wall, the RPV pedestal and SCCV top slab obtained from the design basis SSI model without excavation support and backfill and the sensitivity SSI analysis model with excavation support and backfill are compared. The comparisons show that the additional lateral stiffness provided by the near-field elements simulating concrete fill and excavation support results in a significant decrease in the seismic stress demands on the below grade portion of the RB exterior wall (See Figure 9B.7-43 and Figure 9B.7-44). This decrease is attributed to the stronger lateral support provided to the RB by the temporary construction elements. The decrease in stress demands extends to the containment internal structures, such as the RPV pedestal, as shown in Figure 9B.7-45. The effects of the excavation support and backfill on the stress demands in the SCCV top slab out-of-plane responses that are governed by the RB response in the vertical direction are minimal as shown in Figure 9B.7-46.

To assess possible amplifications and peak frequency shifts in the in-structure responses due to the presence of the temporary construction elements, comparisons are made of 5% damped ISRS obtained from the analysis of the design basis model without excavation support and backfill and the sensitivity analysis model with excavation support and backfill around the RB exterior wall. The broadened 5% damped ISRS, developed as described in Subsection 9B.7.1.2 as the envelope of the three design basis SSI analyses of LB, BE and UB subgrade profiles, are also compared with the ISRS from the model with excavation support and backfill to determine if the enveloping and broadening bound the shifts in peak response frequencies.

The comparisons of the horizontal ISRS indicate that the stiffness provided by the temporary construction elements generally reduces the in-structure response of the RB resulting in ISRS with smaller amplitudes. The stiffer near-field conditions result in shifts of the horizontal ISRS peaks to higher frequencies that are well bounded by the broadening of the ISRS obtained from the design basis analyses as shown in Figure 9B.7-47.

Significant decreases in the vertical ISRS amplitudes due to the stiffness of the temporary construction elements are also observed in the lower (<10 Hz) frequency range. The comparisons also indicate that the additional stiffness of the near-field elements may amplify the in-structure responses in the

higher frequency range. Figure 9B.7-47 shows a significant amplification of the operating floor slab vertical response with an exceedance of the peak ISRS amplitude at 13 Hz of more than 30%.

#### **9B.7.6.5 Effects of Enhanced Input Ground Motions**

To address the regulatory guidance of DC/COL ISG-017 (Reference 9B.4-50) discussed in Chapter 3, Subsection 3.3.1.2.4 in the SSI analyses of the deeply embedded RB at the DNNP site, the Nuclear Energy Institute check approach specified in NEDO-33914, Section 5.3.4.1 is implemented by applying at the bottom of the RB foundation augmented input control motions compatible to the Rock Design Ground Response Spectrum presented in Chapter 3, Figure 3.3-14.

To evaluate the level of conservatism introduced in the results of the bounding DNNP site-specific SSI analyses using the augmented input ground motions in Chapter 3, Figure 3.3-14, a sensitivity analysis is performed for the BE subgrade profile where the Performance Based Surface Response Spectra (PBSRS) compatible ground motion is applied at the surface of the SSI model. The level of conservatism is evaluated by comparing ISRS results obtained from the analysis of the design basis model with augmented input motion applied at the bottom of the RB foundation with those from the sensitivity analysis with PBSRS compatible motion applied at the ground surface. Comparisons of 5% damped ISRS are performed at the operating floor slab, at the RB exterior wall at grade and at the edge of the RB roof. The broadened 5% damped ISRS, developed as the envelope of the three design basis SSI analyses of LB, BE and UB subgrade profiles as discussed in Subsection 9B.7.1.2, are also compared with the ISRS from the “surface” sensitivity analysis to illustrate the degree of conservatism in the enveloped and broadened ISRS.

As demonstrated in Figure 9B.7-48, the conservatism introduced in the design basis analyses by the use of augmented input motion at the bottom of the RB foundation, results in ISRS with significantly larger amplitudes. Shifts of vertical ISRS peaks to lower frequencies can also be observed in the “surface” analysis results that are well bounded by the broadening of the ISRS obtained from the design basis analyses.

#### **9B.7.6.6 Development of Bounding Seismic Design Basis ISRS for Use in Design of Seismic Category A and B SSC**

As discussed in Subsections 9B.7.6.1 through 9B.7.6.4, some exceedances in terms of stresses and ISRS demands are observed when comparing to the seismic design basis BE case. To account for these exceedances, bounding seismic design basis demands are increased for each of the key locations where exceedances are observed following the methodology discussed in Subsection 9B.7.6.

Figure 9B.7-49 provides an example for the development of a bounding seismic design basis ISRS at the RB exterior wall at grade. At this location, soil separation effects result in an increase of the horizontal design basis ISRS at a frequency of around 3 Hz, whereas soil separation and groundwater variation effects contribute to an increase in the vertical design basis ISRS.

#### **9B.7.7 Bounding DBE Structural Stress Demands**

This section presents the bounding seismic design basis structural force and moment demands for key structural members within the integrated RB structures. These bounding seismic design basis stresses account for effects of variation of important SSI parameters at the DNNP site discussed in Subsection 9B.7.6

##### **9B.7.7.1 Containment Stress Demands**

Figure 9B.7-50 presents the bounding seismic moment demands for the SCCV top slab, while Figure 9B.7-51 and Figure 9B.7-51 present the bounding seismic membrane forces and moment demands for the SCCV wall.

#### **9B.7.7.2 Containment Internal Structures Stress Demands**

Figure 9B.7-53 presents the bounding seismic membrane forces for the RPV pedestal.

#### **9B.7.7.3 Reactor Building Stress Demands**

Figure 9B.7-54 and Figure 9B.7-55 present the bounding seismic membrane forces and moment demands for the RB Exterior Wall, while Figure 9B.7-56 presents the bounding seismic membrane forces for RB wing walls.

#### **9B.7.8 Bounding DBE In-Structure Demands**

This section presents the bounding ISRS developed to serve as input for the seismic design and qualification of Seismic Category A and B SSC at key locations within the integrated RB. These bounding ISRS are developed as described in Subsection 9B.7.1.2 for eight damping levels (0.5%, 2%, 3%, 4%, 5%, 7%, 10% and 15%) and account for effects of variation of important SSI parameters at the DNNP site discussed in Subsection 9B.7.6.

##### **9B.7.8.1 Containment In-Structure Demands**

Figure 9B.7-57 presents the bounding ISRS at the centre of the common mat foundation, at Node 47963 located within the containment boundary.

##### **9B.7.8.2 Containment Internal Structures In-Structure Demands**

Figure 9B.7-58 presents the bounding ISRS at the top of the RPV pedestal (Node 89097), where the RPV is supported.

##### **9B.7.8.3 Reactor Building In-Structure Demands**

Figure 9B.7-59 presents the bounding ISRS at the edge of common mat foundation (Node 50190). Figure 9B.7-60 presents the bounding ISRS for the operating floor slab (Node 106595). Figure 9B.7-61 presents the bounding ISRS at the centre of the RB roof (Node 129688).

#### **9B.7.9 Maximum DBE Displacements**

Table 9B.7-5 presents the amplitudes of the bounding seismic displacements at key locations within the RB integrated structures. These displacements are computed relative to the free-field ground motion defined at the bottom of the RB foundation using the methodology discussed in Subsection 9B.7.1.3.

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

**Table 9B.7-1: Key Nodal Locations**

Node Number	Location Description	Elevation [m]
47693	Centre of common mat foundation	-34.15
50190	Edge of common mat foundation	-34.15
89097	RPV support at top of pedestal	-8.27
101747	RB exterior wall at grade	0.00
106595	Operating floor slab	4.90
125319	Edge of roof	27.38

## APPENDIX 9B.C – INTERACTION EVALUATIONS RESULTS

### 9B.8 Introduction

The BWRX-300 design prevents the collapse or collision of adjacent Power Block structures and foundations with the RB to prevent impairment of the structural integrity or safety functions of Seismic Category A and B SSCs during and after a DBE or design basis tornado wind events. The RWB, CB, TB and Reactor Auxiliary Bay, referred to in this appendix as the Power Block structures, are all supported by near-surface mat foundations as discussed in Subsection 9B.3.

This appendix provides the seismic interaction evaluations performed to evaluate the structural integrity and stability of the Power Block structures and their foundations during and after a DBE. The evaluations are performed following the guidelines of NEDO-33914, Section 6.2.

#### 9B.8.1 Seismic Interaction Evaluations

##### 9B.8.1.1 Structure-Soil-Structure Interaction Effects

As noted in Appendix 9B.A, Subsection 9B.6.2, the SSSI effects of the Power Block structures on the seismic response of the RB integrated structures are explicitly captured in the bounding DBE demands presented in Appendix 9B.B.

Following the guidance of NEDO-33914, Section 6.2, seismic responses obtained from the design basis analysis of the LB, BE and UB profiles for the coarse dynamic FE models representing the Power Block structures are used to evaluate:

- the seismic sliding and overturning stability of the surface mounted Power Block foundations
- the seismic bearing pressure demands under the surface mounted Power Block foundations and
- the maximum displacement demands for the seismic gaps between the Power Block structures and the neighboring RB exterior wall

##### 9B.8.1.2 Seismic Stability of Power Block Surface Mounted Foundations

The seismic driving forces acting on the Power Block surface mounted foundations are calculated from the results of the contact spring elements at the interfaces of the Power Block foundations and the subgrade. To calculate the co-directional force demands, the time histories of responses due to the three earthquake components are combined algebraically for each element using the time-step-by-time-step approach. The resulting forces are summed up in the time domain for all spring elements under each structure. Maximum resulting driving forces in the three orthogonal directions are recorded for each of the five ATHs for each subgrade profile case and then averaged for the five sets of ATHs.

Seismic driving forces in the three orthogonal directions obtained from the analysis of the LB, BE and UB subgrade profile cases are compared for each of the adjacent Power Block structures to evaluate the effect of subgrade variations. These forces are divided by the corresponding weight of each structure to estimate the effective accelerations at the foundation interface. As demonstrated by Table 9B.8-1 for the TB, the effective accelerations are largest in all three directions for the UB subgrade profile case, followed by the BE and LB cases. This is in line with expectations since base shear forces are associated with high-frequency response. The seismic forces at the base of the Power Block structures, calculated as the envelope for the three subgrade profile cases, are reported in Table 9B.8-2, and the corresponding effective accelerations are reported in Table 9B.8-3.

##### 9B.8.1.2.1 Sliding Stability

Following the methodology in Chapter 3, Subsection 3.3.1.2.10, safety factors for seismic sliding are calculated for each time step, with a minimum safety factor recorded for the duration of each of the

five sets of ATHs. The average value of the minimum safety factors obtained from the five sets of ATHs is used to demonstrate the seismic stability of the structure. The safety factors for sliding stability are calculated using a value of 0.5 for the coefficient of friction between the concrete foundations and the underlying engineered fill.

Table 9B.8-4 presents the results of the sliding stability calculations for the Power Block structures. As shown in Table 9B.8-4, all sliding stability safety factors for the Power Block structures are below the required minimum of 1.1. This indicates that the friction resistance at the base alone is not sufficient to prevent sliding of the near ground surface mounted Power Block foundations. More refined stability evaluations that consider resistance provided by other mechanisms such as foundation side friction, foundation base roughening or shear keys, are to be considered in the next phase of the Power Block surface foundations design.

#### **9B.8.1.2.2 Overturning Stability**

The overturning stability is evaluated by using the energy approach to calculate for each of the Power Block structures a safety factor against overturning. Assuming no soil slip failure occurs, overturning of the structure can be caused only by the centre of gravity of the structure moving far enough horizontally to cause instability.

The mechanism of the rocking motion that may lead to overturning is like an inverted pendulum and its natural period is long compared with the linear, elastic dynamic structural response. Thus, with regard to overturning, the structure can be treated as a rigid body dynamic system for which the maximum kinetic energy is conservatively estimated as follows:

$$E_s = \frac{1}{2}M[V_H^2 + V_V^2]$$

Where: M is the total mass of the structure

$V_H$  and  $V_V$  are the maximum horizontal and vertical velocities, respectively

To simplify calculations,  $V_H$  and  $V_V$  are conservatively calculated from the results of the SSI analyses for the responses at the roof elevation of the structure. The velocity in each of the three orthogonal directions is calculated at each time step of the ATH as the summation of the contribution from each of the three orthogonal input motions. The maximum absolute value for each ATH is recorded and then averaged over the five sets of ATHs. The horizontal velocity  $V_H$  is considered the maximum of the two orthogonal velocities,  $V_X$  and  $V_Y$ .

Given that the bottom elevations of all Power Block foundations are located above the nominal groundwater table elevation, the effect of buoyancy is immaterial, and the resisting energy is calculated as:

$$E_o = Mgh$$

Where: g is the acceleration of gravity

h is the height to which the centre of the structure has to be lifted to reach the overturning position

The overturning height h is estimated as follows:

$$h = h_o - h_s$$

Where:  $h_s$  is the height of centre of mass of the structure

$h_o$  is the SRSS of  $h_s$  and half the width of the foundation footprint.

The safety factor against overturning is calculated as the ratio of the resisting energy  $E_o$  to the maximum kinetic energy  $E_s$  and is required to be larger than 1.1. The calculation is performed for each of the subgrade profile cases and the lowest safety factor is recorded for each structure. Table 9B.8-5 presents the resulting safety factors against overturning for all Power Block structures. As shown in Table 9B.8-5, the computed safety factors are all much larger than the required safety factor of 1.1. This indicates that overturning instability is not a critical failure mode for any of the Power Block structures.

#### **9B.8.1.3 Seismic Bearing Pressure Demands for Surface Mounted Power Block Foundations**

Table 9B.8-6 presents the average seismic bearing pressures under each of the Power Block near-surface mounted foundations. The seismic bearing pressures are calculated as the vertical dynamic force at the base of each structure, reported in Table 9B.8-2, divided by the foundation footprint area.

As shown in Table 9B.8-6, the largest pressure observed is under the RWB foundation and is 54.1 kPa. This pressure is within the allowable serviceability and factored limit states listed in Chapter 2, Subsection 2.7.5.1.

#### **9B.8.1.4 Relative Displacement**

Seismic horizontal relative displacements are calculated for each of the Power Block structures relative to the nearby RB exterior wall using results from the LB, BE and UB subgrade profile cases. Relative displacements are computed between a node on the roof of the considered structure and the nearest node of the RB exterior wall.

For each set of ATHs, the maximum relative displacement obtained from the analysis of each of the three ground motion components are combined to get the total co-directional response using the SRSS method. For each subgrade profile analysis, average relative displacements from the five sets of ATHs are computed representing the maximum relative displacement for the considered subgrade profile case.

As demonstrated by Table 9B.8-7 presenting the maximum relative displacements between the RB and TB, the analysis of the LB subgrade profile case provides the largest relative displacements in all three directions followed by the results of the BE and UB profiles.

Table 9B.8-8 presents the maximum seismic relative displacements computed for the Power Block structures relative to the RB structure. As noted in this table, the seismic gaps between the RB exterior wall and the stiff RWB and CB reinforced concrete shear wall structures are adequate to accommodate the DBE generated relative displacements, which based on the bounding SSI analysis results are less than 21 mm. The large maximum relative displacements of 74 mm and 53 mm listed in Table 9B.8-8 for the TB and Reactor Auxiliary Bay, respectively, are primarily due to the deformation of these flexible structures. These relative displacements indicate the need for increasing the lateral stiffness of the TB and Reactor Auxiliary Bay structures in the next phase of the design to prevent the closing of the seismic gap between these buildings and the RB.

## APPENDIX 9B.D – RESPONSES TO STATIC LOADS

### 9B.9 Introduction

This appendix documents the 1-g static SSI, static and quasi-static and thermal analyses performed for the design of the integrated RB structures. The analyses are performed per the methodology presented in Chapter 3, Subsection 3.5.1.1, using the FE models described in Appendix 9B.A, Subsections 9B.6.3 through 9B.6.5, and design parameters discussed in Subsection 9B.9.1.

The 1-g static SSI, static and quasi-static and thermal analyses are performed for the applicable loads listed in Chapter 3, Subsection 3.5, excluding the crane payload, tornado missiles, flooding, accidental loading outside of containment, and piping reaction loading for which information is not available. These loads are judged to be non-governing for the bounding design of the integrated RB structures and will be considered in the final design of the structures.

#### 9B.9.1 Design Parameters Considered in the Structural Analyses

##### 9B.9.1.1 Bounding Equivalent Linear Static Subgrade Properties

The bounding site-specific geotechnical parameters presented in Chapter 3, Table 3.5-1 and Table 3.5-2 are used to develop input for the 1-g static SSI and subgrade impedance analyses used to evaluate the structural response to significant static and thermal design loads. The use of the bounding parameters results in force/moment demands that conservatively envelop those obtained using the geotechnical properties of the subsurface materials at the DNNP site.

Table 9B.9-1 identifies the equivalent linear static subgrade profiles used for each of the structural analyses. The LB and UB elastic moduli ( $E_{st}$ ) in Table 9B.9-1 represent the lower and upper bound moduli from as-built static subgrade properties in Chapter 3, Table 3.5-1 and Table 3.5-2. The range of at-rest lateral earth pressure coefficients are used to calculate the upper soil layer's UB and LB static Poisson ratio's, respectively. The effective (submerged) soil unit weights in Table 9B.9-1 are based on UB soil weight estimates calculated from the average soil weights in Chapter 3, Tables 3.5-1 and Table 3.5-2.

LB  $E_{st}$  stiffness properties are used for the 1-g SSI, static and quasi-static analyses to emphasize the deformations at the subgrade-structure interfaces resulting in UB estimates of member forces and moment demands. LB Poisson ratios are used for the static and quasi-static analyses to emphasize the lateral deformations of the RB integrated structures under mechanical design loads. The 1-g SSI analyses use UB Poisson ratios to emphasize the lateral earth pressures applied from the subgrade on the RB exterior wall. UB subgrade stiffness properties UB  $E_{st}$  and UB  $\nu_{st}$  are considered for the thermal stress analyses to emphasize the restraint from the subgrade against the thermal expansion of the containment resulting in UB thermal stress demands on the RB integrated structures.

##### 9B.9.1.2 Nominal Groundwater Table Elevation

The nominal water table depth considered in the bounding design of the integrated RB at the DNNP site is set at 3 m below grade as stated in Chapter 3, Subsection 3.5.2.2.

##### 9B.9.1.3 In-Situ Residual Rock Pressure

Residual horizontal stresses with magnitudes that exceed the magnitude of the vertical stresses may be present in the rock masses at the DNNP site that are due to the past seismic activities. Results of past studies indicate that these stresses are anisotropic in nature, i.e., with different pressure magnitudes in the two orthogonal horizontal directions.

Rock excavation can relieve the residual horizontal stresses due to deformation of the rock mass. However, the magnitude of the rock mass displacements and resulting relief of residual rock stresses depends on the duration of the excavation and rock reinforcement that may be used to secure the

excavation. The durability of the temporary rock reinforcement elements during the life of the plant is not guaranteed. To account for possible decay of rock reinforcement with time, horizontal in-situ residual rock stresses are applied on the RB exterior wall.

The bounding residual rock pressures without consideration for relief during excavation are estimated using the Poisson's ratios for the DNNP site that include (0.43) and exclude (0.30) in-situ residual stresses. The design of the RB integrated structure conservatively considers that 50% or less of the bounding residual in-situ stresses can conservatively account for the residual rock pressure that may be applied on the RB exterior wall during the operational life of the BWRX-300.

Lateral compression pressures applied to the model to account for these residual rock pressures are:

- 350 kPa in the N70E and S70W directions
- 250 kPa in the N20W and S20E directions

These loads are applied uniformly along the depth of the embedded RB exterior wall starting at depth of 23.9 m. The magnitude of the external rock pressure at any other direction is computed using linear interpolation between these two values.

#### **9B.9.1.4 Ambient Temperature**

The stress-free temperature for the design of the RB and the SCCV is 15.5°C. Per Chapter 2, Table 2.6-1, ambient design temperatures considered in the thermal analyses are -40°C in winter and 40°C in summer.

#### **9B.9.1.5 Precipitation Design Parameters**

The site-specific design of the DNNP RB uses normal and extreme ground snow loading of 2.5 kPa and 5.0 kPa, respectively. These values bound the ground snow loading at the DNNP site as discussed in Chapter 3, Subsection 3.3.2.3.

#### **9B.9.1.6 Wind and Tornado Parameters**

The integrated RB is designed for a wind load based on a 257.5 km/h 3-sec gust wind, which bounds the 3-sec gust wind for the DNNP site as discussed in Chapter 3, Subsection 3.3.2.4.

The design basis tornado wind and tornado missiles used in the design of the integrated RB are listed in Table 9B.9-2 and Table 9B.9-3, respectively. These parameters are based on Region I parameters listed in Tables 1 and 2 of US NRC Guide 1.76 (Reference 9B.4-51) and envelop those of the design basis tornado for the DNNP site presented in Chapter 2, Subsection 2.6.6, categorized as equivalent to Region-II of U.S. NRC RG 1.76.

The current tornado missile analysis does not assess the impact of an automobile striking the RB from the east side or the impact of rigid missiles (Schedule 40 pipe and 1" solid sphere) on RB walls and roof thicknesses. These assessments are considered to have minor effects on the current design of the integrated RB and will be considered in the final design of the structure.

#### **9B.9.1.7 Pool Water Levels**

Pool water levels used for the hydrostatic load case are based on normal operating levels and are as follows:

- 7.2 m for the ICS Pool
- 7.8 m for the equipment and reactor cavity pools
- 12.7 m for the fuel pool

#### **9B.9.1.8 Containment Internal Pressure Loading**

Containment pressure loading considered in the analyses are presented in Table 9B.9-4.

Conservatively, the negative containment pressure which does not occur under normal operation but can occur during AOO is considered for the normal operating load case.

Test pressure load ( $P_t$ ) applied to the SCCV is defined as 1.15 times the containment design pressure as stated in Subsection 9B.2.1.8.

#### **9B.9.1.9 Thermal Conditions**

Table 9B.9-5 and Table 9B.9-6 summarize the design winter and summer thermal conditions inside and outside the integrated RB during normal operations and DBAs, respectively, considered in the analyses.

#### **9B.9.2 1-g Static SSI Analysis**

The 1-g SSI analysis is performed using the ACS SASSI (See Chapter 3, Appendix 3B) flexible volume sub-structuring method to consider the interaction of the deeply embedded RB with the surrounding Power Block structures and subgrade under 1-g loads. The model used for the 1-g SSI analyses is described in Appendix 9B.A, Subsection 9B.6.3. The soil and rock layers of the far-field, near-field and excavated volumes of the model are assigned the equivalent linear elastic subgrade properties summarized in Table 9B.9-1 and provided in Chapter 3, Table 3.5-1 and Table 3.5-2. Structural elements of the model are assigned BE stiffness properties as discussed in Appendix 9B.A, Subsection 9B.6.3. Submerged unit weight properties are assigned to the subgrade materials located below the bounding nominal groundwater level specified at depth of 3 m below the plant grade as noted in Subsection 9B.1.2.

The subtraction method approximation is used for the 1-g SSI analysis with interaction nodes being specified only at the interface of the excavated volume with the far-field. The use of the subtraction method approximation for the 1-g SSI analysis is adequate since the analyses consider the response at very low frequencies.

As described in Chapter 3, Subsection 3.3.1.2.1, the results of different sub-analyses, are combined using the principle of superposition to obtain the final solution for the response of the SSI system under the 1-g quasi-static excitation.

##### **9B.9.2.1 Analysis Cases**

Two sets of vertical 1-g static SSI analyses are performed for the unfactored and factored gravity inertia load conditions as discussed in Appendix 9B.A, Subsection 9B.6.3 and shown in Appendix 9B.A, Table 9B.6-1. Demands obtained from the 1-g static SSI analysis are from:

- The dead load from the self-weight and weight of permanent equipment and components
- The vertical fluid load on pool slabs from the weight of the water in the pools
- The static earth pressure load due to submerged weight of the soil and rock
- The surcharge lateral pressure load from the surrounding Power Block surface mounted foundations conservatively captures by assigning higher mass density properties as discussed in Appendix 9B.A, Subsection 9B.6.3.

In the model used to analyse the factored load combination, the submerged unit weight properties of the subgrade and surrounding structures is increased by 33% ( $1.6 / (1.2 = 1.33)$ ) to account for the higher factored lateral earth pressure loads.

### 9B.9.2.2 Frequencies of Analysis

The 1-g SSI analyses are performed for a total of seven frequencies of analysis from the first frequency of analysis with frequency equal to the frequency step,  $\Delta_f = 0.06$  Hz, to the cutoff frequency of 1.8 Hz. The low range of frequencies of analysis helps simulate a quasi-dynamic response of the SSI system under gravity load by avoiding response amplification at resonance frequencies.

### 9B.9.2.3 1-g Load Simulation

To simulate the 1-g gravity load, an acceleration time record in ACS SASSI is applied in the free-field location located at the ground surface in the form of a sine function at a very low frequency of 0.012 Hz. The low frequency content of the input motion helps avoid any dynamic effects in the calculated response due to resonance with the soil-structure system. Slightly different peak acceleration values of -1.005 g to 0.995 g are applied on the 1-g SSI analysis model in the negative and positive directions, respectively, to obtain amplitudes of the stress responses that correspond to the downward applied 1-g gravity load.

### 9B.9.2.4 Response and Demands from Dead Load and Earth Pressure Loads

This section reviews the unfactored demand results on the RB exterior wall below grade and SCCV wall because these are the primary resisting systems for both loads.

Figure 9B.9-1 illustrates the compression hoop forces acting on the RB exterior wall as a result of compressing static earth pressures. The change in distribution occurs at the floor elevations where the static earth pressure is transferred to the slabs. Figure 9B.9-2 illustrates the vertical compression forces in the RB exterior wall that increase as the depth increases reflecting the accumulation of the dead load within the RB integrated structures. Figure 9B.9-3 illustrates the horizontal bending moments about the tangential axis that peak at floor slab locations. Figure 9B.9-4 illustrates the radial out-of-plane shear on the RB exterior wall that peak at slab locations.

Figure 9B.9-5 illustrates that some of the static earth pressure is transferred from the RB exterior wall to the SCCV wall through the RB floor slabs as evident from the hoop force. The vertical compression force on the SCCV wall shown in Figure 9B.9-6 is more uniform than on the RB exterior wall (see Figure 9B.9-2). Horizontal moments and out-of-plane shear forces on the SCCV wall also peak at internal wall and at slab locations, respectively, similar to the RB exterior wall.

Trends observed with factored demands are similar to the trends observed for the unfactored demands presented in this section.

### 9B.9.3 Static and Quasi-Static Analysis

The analyses of static and quasi-static loads are performed on the FE models described in Appendix 9B.6, Subsection 9B.6.4. As stated in Subsection 9B.6.4, the analysis of the static and quasi-static loads that have global effect on the response of the integrated RB structural model are performed using the subgrade impedance sub-structuring method that accounts for the subgrade stiffness at the interfaces with the RB structure. Linear elastic contact springs connect the integrated RB structural model and subgrade FE models are developed using the subgrade stiffness impedance methodology. Stiffness properties are assigned to the contact springs to adequately represent the interaction mechanism between the RB structure, backfill, and subgrade.

Analyses performed to determine force/moment demands due to load cases for which the interaction with the surrounding soil is not important are performed on models with prescribed boundary conditions as described in Subsection 9B.6.4.

Table 9B.6-1 summarizes the modeling requirements for the various static and quasi-static analysis cases required for the design of the integrated RB structures.

### **9B.9.3.1 Analysis Cases**

Table 9B.9-7 presents the static and quasi-static load cases that are considered bounding for the design of the BWRX-300 integrated RB structures. As mentioned in Section 9.9, structural analyses evaluating the impacts of crane payload, tornado missiles, flooding, accidental loading outside of containment, and piping reaction loading, for which information is not available, will be performed as the design progresses.

The following subsections present responses and demands obtained from the load cases governing the design of the integrated RB structures.

### **9B.9.3.2 Response and Demands from Horizontal Pool Water Load Cases**

Horizontal pool water loads applied on the integrated RB model consist of the horizontal hydrostatic loads ( $F_h$ ) and sloshing and breathing mode hydrodynamic pressures due to seismic (DBE) excitation.

Pool water levels used for the hydrostatic load case listed in Subsection 9B.9.1.7 are considered to begin at the centreline of the refueling slab so that there is net zero hydrostatic pressure on interior pool walls that share a common wall with other pools. The hydrostatic pressure is applied as normal pressure with a gradient equal to the density of water at approximately 15 degrees Celsius ( $9.8 \text{ kN/m}^3$ ) multiplied by the distance below the centreline of the refueling deck slab. A hydrostatic pressure load is also applied to the containment closure head.

The deformed shape response of the pool walls due to hydrostatic loads is shown in Figure 9B.9-7. The outward expansion of the pool walls is consistent with the loading. The peak out-of-plane bending moments occur on the vertical and lower horizontal edges of the pool walls as expected for fixed-fixed-fixed-free two-way plates. The pool wall out-of-plane moments and associated transverse shear loads transfer to the walls and slabs that they intersect.

Hydrodynamic pressures on pool walls due to the vertical DBE excitation, referred to as breathing water pressure loads, are obtained by scaling the hydrostatic response with vertical response spectra.

### **9B.9.3.3 Responses and Demands from Containment Internal Pressure Load Cases**

The containment pressure loading listed in Table 9B.9-4 are applied normal to the SCCV wall, SCCV top slab, inner mat foundation, and containment closure head.

The integrated RB deformed shape response due to accidental pressure loading is shown in Figure 9B.9-8.

Results indicate a stress concentration on the pool wall as a result of the SCCV expanding upward. Higher bending moments occur in places where the expansion of the SCCV is constrained such as at the mat foundation and fuel pool walls and slabs.

### **9B.9.3.4 Responses and Demands from Groundwater and Rock Pressure Loads**

The lateral groundwater pressure is applied as an inward normal pressure with a gradient equal to the density of water at approximately 15 degrees Celsius ( $9.8 \text{ kN/m}^3$ ) multiplied by the distance starting from 3 m below grade down to the centreline of the common mat foundation.

The 31 meters of groundwater causing buoyancy uplift pressure on the mat foundation is applied as an upward normal load on the mat foundation model.

The in-situ residual rock pressure discussed in Subsection 9B.9.1.3 is applied as an inward normal pressure with a gradient applied circumferentially between 350 kPa and 250 kPa with linear interpolation in between. The rock pressure is applied to all nodes on the RB exterior wall at a depth of 23.9 m below the grade centreline and the centreline of the mat foundation.

Responses and demands due to groundwater and rock pressure loads are consistent with the loading.

The integrated RB deformed shape response due to groundwater lateral pressure is shown in Figure 9B.9-9. Groundwater pressure loads are transferred from the RB exterior wall to the SCCV wall through the RB floor slabs, which transfer the later loads in compression. Bending moment about the longitudinal axis of the RB outer peak at internal wall locations causing tension on the outer face of the RB exterior wall. Bending moments about the tangential axis of the RB exterior wall peak with outer face tension at the slab locations and inner face tension between slabs. Moments on the SCCV wall peak at RB wall and slab locations.

The uplift pressure causes minimal hoop forces in the RB exterior wall. The SCCV wall experiences compression forces as a result of buoyancy uplift. Positive bending on the mat foundation is observed resulting in tension on the top surface. The buoyancy uplift pressure loads are localized to the mat foundation and the walls at the floors. The magnitude of buoyancy uplift loads in walls is overcome with dead and live loads.

The integrated RB deformed shape response due to the additional rock lateral pressure is shown in Figure 9B.9-10. The force and moment demands for rock pressure are similar in distribution and order of magnitude to the groundwater lateral pressure demands.

#### **9B.9.4 Thermal Stress Analysis**

Thermal stress analyses are performed on the standalone FE models described in Appendix 9B.6, Subsection 9B.6.5. Modeling requirements for thermal load cases considered for the design of the integrated RB structures are presented in Table 9B.9-8.

##### **9B.9.4.1 Analysis Cases**

Table 9B.9-8 presents the thermal stress load cases considered for the boundary design of the BWRX-300 integrated RB structures. Excluded from this table is the accidental thermal loading outside of containment that is judged to be non-governing for bounding design of the structures.

Thermal loads are applied by assigning the temperature to the front and back faces of the element using structural temperature body loads. The thermal loads applied consider a stress-free reference temperature of 15°C. If the element is assigned different temperatures on either face, it results in a linear gradient.

Assumptions considered in the thermal stress load cases considered for the bounding design of the integrated RB structures include the following:

- Temperature loads are applied based directly on the specified bounding design temperatures neglecting the transient and steady-state effects of heat transfer which generally results in conservative estimates of thermal stress demands. This simplifying assumption will be verified by the results of the heat transfer analysis as the design progresses.
- The extreme winter conditions are considered to provide bounding thermal stress demands on the integrated RB structures since because of their larger thermal gradients when compared with summer ones. This assumption will be verified by subsequent analysis using precise thermal loading conditions.
- The DBA thermal stress evaluation considers only the condition when the containment experiences accidental temperature load inside the containment and the pool water temperature remains equal to the normal operating temperature. This assumption is expected to yield largest thermal stress responses on the SCCV wall and top slab. Additional DBA thermal stress analyses are to be performed as the design progresses considering differing temperature configurations associated with a variety of DBA conditions.

#### **9B.9.4.2 Response and Demands from Thermal Loads**

The deformed shapes for all normal operating and DBA thermal conditions during winter are shown in Figure 9B.9-11 and Figure 9B.9-12. The expansion and contraction of the outer RB is consistent with the effect of the differential temperatures exterior and interior to the RB. The RPV pedestal and bioshield appear to experience the highest expansion deformations because of the higher temperatures in the SCCV.

The accidental temperature load case during winter is used as representative of the other thermal loads since it results in the highest overall demands on the structures. In-plane forces and out-of-plane bending moments due to the accidental temperature load case during winter are shown in Figure 9B.9-13 and Figure 9B.9-14, respectively.

Figure 9B.9-13(a) illustrates the hoop forces in the concentric walls that peak in tension at the refueling floor level because of the contraction of the exterior walls and expansion of pool walls. Figure 9B.9-13(b) illustrates the vertical forces in the concentric walls and tangential in-plane forces in the slabs. The SCCV wall is generally in compression because of the constraints from the slabs and pool walls above. The inner mat foundation is also in high compression. The out-of-plane moments peak at the ICS pool wall behind the fuel pool (Figure 9B.9-14(a)) and at the RB exterior wall at grade (Figure 9B.9-14(b)). The SCCV is under biaxial bending throughout its height as a result of constraints from the RB slabs. The accidental thermal demands during winter are found to be about two times higher than the normal operating winter demands.

#### **9B.9.5 Conclusions**

Selecting bounding conditions for most design parameters provides conservative bounding demands for the design of the BWRX-300 Seismic Category A structures at the DNNP site. Stress concentrations observed in some of the members force and moment results are due to singularities in the FE solution and may be interpreted as unrealistically high demands that, in turn, lead to the observance of high demand-to-capacity ratios in the design evaluations.

Of all the load cases considered in the bounding design of the integrated RB structures, the structural demands obtained from the accidental thermal load case exceed the average peak demands of the next highest tier of loads by a minimum factor of two. The second highest tier of structural demands includes normal operating temperature demands, testing pressure demands, and accidental pressure demands. The third tier of demands with average peaks at approximately half of the second-tier demands are obtained from the unfactored dead and static earth pressure loads, hydrostatic groundwater loads, rock pressure loads, and accidental seismic torsion loads. The lowest tier includes average peak structural demands that are equal to or under one-quarter of the Tier 2 demands. This fourth tier is obtained from live loads, buoyancy load, normal operating pressure loads, sloshing loads, design snow loads, extreme snow loads, wind and tornado wind loads.

Peak membrane forces and out-of-plane bending moments in the SCCV (inner) mat foundation are dominated by the accidental temperature demands. Accidental temperature demands are approximately double peak demands from the normal operating temperature load case with the latter being approximately four times higher than the next largest demand from rock pressure and groundwater demands. All other mechanical demands are significantly less than the groundwater demands. Out-of-plane shear force demands in the SCCV mat foundation are dominated by the accidental and testing pressures followed by the 1-g static and accidental temperature load cases.

The accidental temperature load case also causes the largest membrane forces in the SCCV top slab, followed by the normal temperature load case, followed by the accidental and testing pressure load cases. All other mechanical demands are marginally less than the pressure demands with the largest coming from the static 1-g load case. Out-of-plane bending moments in the SCCV top slab are dominated by the accidental temperature demands which are approximately double the demands from

NEDO-33959 REVISION 2  
NON-PROPRIETARY INFORMATION

the accidental pressure. The normal operating temperature load case provides the next largest demands, with minimal demands obtained from all other mechanical loads. Out-of-plane shear demands in the SCCV top slab occur in localized areas due to the accidental temperature load case and to a lesser extent, the accidental pressure, or testing pressure load cases; followed by demands from the 1-g static dead and static earth pressure loads.

The SCCV wall membrane forces are dominated by accidental temperature demands which are approximately double the demands from normal operating temperature, accidental, or testing pressure. The next largest demands in the SCCV wall come from the 1-g static load case followed by groundwater, or rock pressure. All other mechanical demands are significantly less than these demands. Out-of-plane bending moments and out-of-plane shear forces in the SCCV wall are dominated by the accidental temperature load case followed by the normal operating temperature load case at approximately half. The accidental pressure and testing pressure, groundwater, rock pressure, and 1-g static demands are all within range of one another.

The RB (outer) mat foundation is dominated by the demands from the accidental temperature load case followed by the normal operating load case at approximately half the peak accidental temperature demands. The rock pressure and groundwater demands follow at approximately 1/5th of the accidental temperature load case, followed by the 1-g static and accidental pressure load cases. The out-of-plane bending moments and out-of-plane shear forces in the outer mat foundation are dominated by the accidental temperature load case followed by the normal operating temperature load case at approximately half. The rock pressure, groundwater, and 1-g static load case demands are each approximately half or less than the normal operating temperature demands.

Peak membrane demands in the RB exterior wall from the accidental temperature, rock pressure, groundwater, and 1-g static load cases are all in the same range, with the next largest demands coming from the accidental pressure and incidental torsion at about a quarter of the primary demands. Out-of-plane moment demands in the RB exterior wall from the accidental temperature, rock pressure, groundwater, and 1-g static load cases are also all in the same range, with the next largest demands coming from the normal operating temperature and incidental torsion. Out-of-plane shear demands in the RB exterior wall are dominated by the 1-g static and incidental torsion load cases, with the next largest demands coming from the accidental thermal, rock pressure, and groundwater pressure load cases.

## **APPENDIX 9B.E – DESIGN DETAILS AND EVALUATION RESULTS FOR THE CONTAINMENT**

### **9B.10 Introduction**

This appendix focuses on the design evaluation of the SCCV portion of the containment as discussed in Subsection 9B.2.1.10.2 and provides bounding estimates of the available margins for the structure.

Design demands used in the evaluations are obtained from the structural analyses discussed in Appendices 9B.B and 9B.D, performed using the one-step approach and the FE models discussed in Appendix 9B.A. The design demands are obtained from bounding design load combinations selected to assess the operational and accidental structural demands on the structure.

Demand-to-capacity ratios are calculated in accordance with NEDC-33926P.

#### **9B.10.1 SCCV Design Methodology**

The design, detailing and geometric requirements for the SCCV are in accordance with Section 4.0 of NEDC-33926P.

Table 9B.10-1 shows the design parameters used in the Steel Bricks™ design evaluation.

#### **9B.10.2 Bounding Load Combinations and Design Demands**

The evaluation of the SCCV is based on results from four bounding load combinations, SCCV-1, SCCV-3, SCCV-7 and SCCV-11, presented in Table 9B-1. SCCV-1 is for testing category at service condition, SCCV-3 for normal category at service condition, SCCV-7 for abnormal load category at factored condition and SCCV-11 for abnormal/extreme environmental load category at factored condition.

Per NEDC-33926P, In-plane membrane forces, out-of-plane moments, and out-of-plane shear forces may be obtained by averaging the results over panel sections that are no larger than twice the section thickness in length and width. Near openings and penetrations, and in connection regions, the required strength may be averaged over panel sections no larger than the section thickness in length and width.

For evaluation purposes, design demands are conservatively presented on element-by-element basis without averaging of the results across adjacent elements as allowed by the NEDC-33926P.

#### **9B.10.3 Structural Capacity of SCCV Steel Bricks™**

Steel Bricks™ sections capacities are computed, and the design evaluated per NEDC-33926P, Section 4.0. Acceptance criteria for the design of the SCCV are per Chapter 3, Table 3.5-4.

Individual strength checks include axial (tension and compression), flexural and shear (in-plane and out-of-plane) strength checks. Combined design checks include out-of-plane shear interaction and in-plane forces and out-of-plane moments interactions.

Force and moments induced in the SCCV Steel Bricks™ by factored and service load combinations are calculated in the sections radial and meridional directions in unit widths. Demands are then divided between the Steel Bricks™ two notional halves, each consisting of single faceplate and half concrete thickness, as discussed in NEDC-33926P. To evaluate the limitations of the Steel Bricks™ steel plates, principal stresses in steel plates are used to calculate the von Mises stress for each of the plates to ensure that this stress does not exceed the allowable stresses for factored and service load combinations summarized in Chapter 3, Table 3.5-4. The principal stresses in the concrete infill are also checked to ensure they too do not exceed the allowable stresses listed in Chapter 3, Table 3.5-4.

The principal stresses for concrete infill and von Mises stresses for steel plates are used to evaluate the in-plane membrane and out-of-plane moment interactions.

#### **9B.10.4 Structural Design Evaluation**

The evaluation of the SCCV structure is performed by calculating and plotting demand-to-capacity ratios for the individual loads and interaction checks discussed in Subsection 9B.10.3 for the SCCV wall, top slab and inner mat foundation. The demand-to-capacity ratios identify critical locations and vulnerabilities for specific limit states. For each load combination, multiple patterns of load application are considered, depending on their severity for a particular limit state.

The evaluation is performed for factored, or service loads classified as “Primary” for (1) membrane forces alone and (2) membrane forces plus bending moments against the allowable for factored or service primary forces class. The evaluation is performed once more whenever volume changing secondary forces (e.g., Thermal loading) are in the load combinations for the allowable under factored or service primary plus secondary forces class. For factored loads, where volume changing secondary forces are included, the strain limit for mechanical (net) strain is twice the yielding strain. However, the total strain (mechanical plus volume changing strain) is compared to the same limit as a conservative approach. The highest demand-to-design ratio for the steel plates and concrete infill, if any, are reported in this appendix.

Per NEDC-33926P, Section 4.0, SCC-3523.1, interaction checks are not performed if any of the two shear components on each direction of an element is less than the concrete capacity. In this case a zero demand-to-capacity ratio is reported in the plots.

Figure 9B.10-1 through Figure 9B.10-7 present bounding demand-to-capacity ratios for the SCCV wall, top slab and inner mat foundation for the selected load combinations listed in Subsection 9B.10.2.

The demand-to-capacity ratio plots developed for the testing load category (SCCV-1) indicate that the design of the SCCV structure includes adequate safety margins as demonstrated by Figure 9B.10-1 and Figure 9B.10-2. Figure 9B.10-1 and Figure 9B.10-2 present the in-plane forces and out-of-plane moment interaction checks for the steel plates of the SCCV wall and top slab, respectively. As shown in Figure 9B.10-1, the maximum demand-to-capacity ratio recorded for the in-plane forces and out-of-plane moment interaction for the steel plates of the SCCV wall is 0.7, except at vicinity of openings due to singularities in the FE solution. From Figure 9B.10-2, the maximum demand-to-capacity ratio recorded for the in-plane forces and out-of-plane moment interaction for the top slab’s steel plates is 0.6. For both structural components and for the inner mat foundation, the demand on the concrete infill is minimal.

Figure 9B.10-3 presents the highest demand-to-capacity ratio recorded in the interaction checks of key SCCV components for the normal load category. The demand-to-capacity ratio of 0.6 is computed for the concrete infill of the inner mat foundation.

Figure 9B.10-4(a) indicates that the out-of-plane flexural demand in the inner mat foundation under the abnormal load category is generally small, with a demand-to-capacity ratio less than 0.8 observed at the intersection with the RPV pedestal and bioshield. The in-plane forces and out-of-plane moment interaction checks for the mat’s concrete infill shown in Figure 9B.10-4(b) also record a maximum demand-to-capacity ratio of 0.6. Demands on the mat’s steel plates are minimal with demand-to-capacity ratios governed by the primary component allowable limit. Figure 9B.10-5 and Figure 9B.10-6 present the out-of-plane shear checks that govern the design of the SCCV wall and top slab. As demonstrated by these figures, the demand-to-capacity ratios for the out-of-plane shear in these structures are generally less than 0.6, with some regions indicating a no requirement for biaxial shear interaction check. The small stress concentrations observed in Figure 9B.10-5 and Figure 9B.10-6 occur within the intersecting depth of the mat foundation (in Figure 9B.10-5) and at the slab intersection with the different pool walls and containment head (in Figure 9B.10-6) and do not affect the design.

Figure 9B.10-7 presents the out-of-plane shear check at the SCCV top slab for the abnormal/extreme environmental load category. As shown in this figure, the maximum demand-to-capacity for out-of-plane shear in the structure is generally less than 0.5, except for the stress concentrations at the intersection with the different pool walls and containment head due mainly to singularities in the FE solution.

The evaluation results presented in this appendix show that the overall demand-to-capacity ratio for the SCCV structure is less than one. This demonstrates that the design of the SCCV structure is robust and includes adequate safety margins in conformance with REGDOC-2.5.2, Section 7.15.1.

#### **9B.10.5 Critical SCCV Steel Brick™ Connections**

The SCCV wall is connected to the RB wing walls and floor slabs at various levels and shares the mat foundation with the RB.

SCCV wall-to-mat foundation and SCCV top slab-to-wall full-strength connections are designed for a demand of 125% of the smaller of the corresponding nominal strengths of the connected parts. SCCV wall-to-wing walls and SCCV wall-to-floors connections are identical to those connecting the floors to the RB exterior wall discussed in Appendix 9B.G, Subsection 9B.12.5.4.

##### **9B.10.5.1 SCCV Wall-to-Mat Foundation Connection**

The SCCV wall-to-mat foundation connection, referred to as T connection, is subject to LOCA accident conditions (e.g., accidental pressure ( $P_a$ ) and accidental temperature ( $T_a$ )).

The design of the Steel Bricks™ T connection is performed using the full-strength design philosophy. In this approach, the connection is considered to sustain loads until the full-strength of the weaker of the two connected parts is achieved. The T connection is idealized using the model shown in Figure 9B.10-8. In this model, the two ends of the SCCV wall at the T connection are considered fixed. Design demands and required strength for each individual demand acting on the connection are calculated by identifying the applicable force transfer mechanism and evaluating the potential failure mode or mechanism of the connection. Connection capacities are taken as 1.25 times the smaller of the two connected components capacities.

**Table 9B.10-1: Design Parameters for the SCCV Steel Bricks™**

SCCV Structural Component	Member Thickness mm	Faceplate Thickness, mm	Steel Faceplate Grade	Yield Strength (MPa)	Tensile Strength (MPa)	Diaphragm Spacing (Brick width) (mm)
SCCV wall	914	15.0	ASME SA738 Grade B	414 <sup>1</sup>	448	457
Inner mat foundation	1219	12				609
SCCV top slab	914	15				457

(1) For Load combinations with accidental thermal loading, a reduced yield strength of 353 MPa is used for the ASME SA738 Grade B steel

## **APPENDIX 9B.F – DESIGN DETAILS AND EVALUATION RESULTS FOR THE CONTAINMENT INTERNAL STRUCTURES**

### **9B.11 Introduction**

This appendix focuses on the design evaluation of the Steel Bricks™ RPV pedestal as discussed in Subsection 9B.2.2.10.2 and provides bounding estimates of the available margins for the structure.

Design demands used in the evaluations are obtained from the structural analyses discussed in Appendices 9B.B and 9B.D, performed using the one-step approach and the FE models discussed in Appendix 9B.A. The design demands are obtained from bounding design load combinations selected to assess the operational and accidental structural demands on the structure.

#### **9B.11.1 Pedestal Design Methodology**

The design of the RPV pedestal is in accordance with ANSI/AISC N690, similar to the RB structure. Design parameters used in the design evaluation of the RPV pedestal are provided in Table 9B.11-1.

#### **9B.11.2 Bounding Load Combinations and Design Demands**

The evaluation of the RPV pedestal is based on design demands obtained from the bounding load combinations RB-2/3 and RB-9 (See Table 9B-4) selected for the evaluation of the RB structure as discussed in Appendix 9B.G, Subsection 9B.12.2.

#### **9B.11.3 Pedestal Steel Bricks™ Capacity**

The design of the Steel Brick™ modules used in the RPV pedestal satisfies the requirements of ANSI/AISC N690 and the regulatory guidance of U.S. NRC RG 1.243, similar to the RB structure. Refer to Appendix 9B.G, Subsection 9B.12.3 for more details.

#### **9B.11.4 Structural Design Evaluation**

Figure 9B.11-1 and Figure 9B.11-2 present the governing demand-to-capacity ratios for the design of the RPV pedestal for the selected load combinations RB-2/3 and RB-9.

As shown in these figures, the in-plane forces and out-of-plane moment interaction demands in the RPV pedestal under the two load conditions considered are generally small, except for the lower region of the pedestal, where a maximum demand-to-capacity ratio less than 0.8 is noted in Figure 9B.11-2. Higher stress concentrations observed in Figure 9B.11-2 are at the connections with the mat foundation and are, therefore, not relevant for the design of the pedestal.

The 0.8 ratio demonstrates that the design of the RPV pedestal is robust and includes an adequate design margin of 20% in conformance with REGDOC-2.5.2, Section 7.15.1.

**Table 9B.11-1: Design Parameters for Steel Bricks™ in the Reactor Building**

Structural Component	Member Thickness ( $t_{sc}$ ) (mm)	Faceplate Thickness ( $t_p$ ) (mm)	Steel Faceplate Grade	Yield Strength (MPa)	Tensile Strength (MPa)	Diaphragm Spacing (Brick Width) (mm)
RPV Pedestal	970	19.1	ASTM 572 Grade 50	345 <sup>1</sup>	448	970

(1) For Load combinations with accidental thermal loading, a reduced yield strength of 293 MPa is used for the ASTM 572 Grade 50 steel

**Figure 9B.11-1: Demand-to-Capacity Ratios for In-Plane Forces and Out-of-Plane Moment Interaction for the RPV Pedestal Under Normal Load Category (RB-2/3)**

**Figure 9B.11-2: Demand-to-Capacity Ratios for In-Plane Forces and Out-of-Plane Moment Interaction for the RPV Pedestal Under Abnormal Load Category (RB-9)**

## **APPENDIX 9B.G – DESIGN DETAILS AND EVALUATION RESULTS FOR THE REACTOR BUILDING STRUCTURE**

### **9B.12 Introduction**

This appendix evaluates the design and provides bounding estimates of the available margins for key structural members of the RB.

Design demands used in the evaluations are obtained from the structural analyses discussed in Appendices 9B.B and 9B.D, performed using the one-step approach and the FE models discussed in Appendix 9B.A. The design demands are obtained from bounding design load combinations selected to assess the operational and accidental structural demands on the structure.

#### **9B.12.1 Design Methodology for the Reactor Building**

The design of the RB structure is in accordance with ANSI/AISC N690 and U.S. NRC RG 1.243. Design parameters used in the design evaluation of the RB Steel Bricks™ are provided in Table 9B.12-1.

#### **9B.12.2 Bounding Load Combinations and Design Demands**

The evaluation of the RB structure is based on results from the bounding load combinations RB-2/3 and RB-9 presented in Table 9B-4. Load combination RB-2/3 is considered bounding for all load combinations for normal load category presented in Table 9B-4. Load combination RB-9 is selected to demonstrate the ability of the integrated RB structures to resist abnormal loading conditions including seismic loadings. This load combination bounds other severe environmental and extreme environmental load combinations listed in Table 9B-4.

Per ANSI/AISC N690, App.N9.2.5, design demands obtained from the various structural analyses may be averaged over panel sections that are no larger than twice the section thickness in length and width. Near openings and penetrations, and in connection regions, the required strength may be calculated by averaging the demand over panel sections no larger than the section thickness in length and width.

Similar to the SCCV, design demands are conservatively presented on element-by-element basis without averaging of the results across adjacent elements as allowed by the ANSI/AISC N690.

#### **9B.12.3 RB Steel Bricks™ Capacity**

The capacities of the RB Steel Bricks™ sections are computed, and the design evaluated per ANSI/AISC N690 in conjunction with ANSI/AISC 360 (Reference 9B.4-52).

Similar to the SCCV, design capacities of the RB Steel Bricks™ sections are determined for each notional half per ANSI/AISC N690, Section N9.3.6b. Strength checks performed for the structure include axial (tension and compression), flexural (out-of-plane), shear (in-plane and out-of-plane) strength checks as well as out-of-plane shear force interaction and in-plane forces and out-of-plane moments interactions.

#### **9B.12.4 Structural Design Evaluation**

The evaluation of the RB structure is performed using the same methodology as for the SCCV described in Appendix 9B.E, Subsection 9B.10.4. Key RB components considered in the evaluation include the RB exterior wall above and below ground, the outer mat foundation and wing walls.

Figure 9B.12-1 through Figure 9B.12-7 present bounding demand-to-capacity ratios for the RB key components for the selected load combinations RB-2/3 and RB-9.

Figure 9B.12-1 presents the governing demand-to-capacity ratio for the design of the outer mat foundation for the normal load category. As shown in this figure, the maximum recorded demand-to-

capacity ratio for the mat's out-of-plane shear is 0.6, with a few stress concentrations observed at the connections of wing walls with the RB and SCCV walls. These stress concentrations are not relevant for the design since they occur entirely within the thickness of the connecting members. As shown in Figure 9B.12-2 and Figure 9B.12-3, the maximum demand-to-capacity ratio for the RB exterior wall below and above grade, respectively, for the same load category is about 0.8 for the in-plane forces and out-of-plane moment interaction. The small stress concentrations observed in Figure 9B.12-3 occur at the connections with the crane supports. The in-plane forces and out-of-plane moment interaction, the most bounding demand for the design of the RB wing walls are generally small, with a maximum demand-to-capacity ratio computed for the structures of 0.3.

For the abnormal load category, Figure 9B.12-4 indicates that the highest demand-to-capacity ratio for the out-of-plane shear, the most governing demand for the design of the outer mat foundation, is less than 0.75. The demand-to-capacity exceedances observed in Figure 9B.12-4 are mainly concentrated around the wing wall junctions and cover an area that is within a distance of 800 mm or less. These exceedances are justified by the modeling approach of element-to-element interaction regions and can be averaged, based on the mat thickness, over a distance up to 1200 mm at connection regions and 2400 mm at other regions. The highest demand-to-capacity ratios computed for the RB wall below and above grade under the abnormal load category are obtained from the in-plane forces and out-of-plane moment interactions shown in Figure 9B.12-5 and Figure 9B.12-6, respectively, and are found to be generally less than 0.8. Demand-to-capacity exceedances observed in Figure 9B.12-6 are at the connections with the crane supports and refuel floor slab. Figure 9B.12-7 also indicates that the in-plane and out-of-plane moment interaction demands on the RB wing walls under the same load category are generally small resulting in a maximum demand-to-design ratio of 0.6 for these structures. Exceedances observed in Figure 9B.12-7 occur at the connection with the mat foundation and SCCV wall and are not relevant to the design since they are within the thickness of connecting elements.

As demonstrated by these evaluation results, the design of the RB structure is robust and includes adequate safety margins in conformance with REGDOC-2.5.2, Section 7.15.1. Demand concentrations observed in Figure 9B.12-1 through Figure 9B.12-7 are either singularities or occur entirely within connecting member thicknesses and can be averaged through the member's thickness and beyond as permitted by ANSI/AISC N690.

### **9B.12.5 Critical Steel Brick™ Connections in the Reactor Building**

The RB exterior wall is connected to wing walls and floor slabs at several elevations and share the same mat foundation with the SCCV as shown in Figure 9B-1. All connections of Steel Bricks™ panels in the RB are rigid except for the semi-rigid connections shown in Figure 9B.6-4. This section provides an overview of methodologies used to model and design the various Steel Bricks™ connections in the RB.

Per ANSI/AISC N690, Appendix N9.4, rigid connections are classified either as full-strength connections with design demand of 125% of the smaller of the corresponding nominal strengths of the connected parts, or as overstrength connections with design demands of 200% of the required strength due to seismic loads plus 100% of the required strength due to non-seismic loads (including thermal loads).

#### **9B.12.5.1 RB Exterior Wall-to-Mat Foundation Connection**

An idealized model is developed for the design of the full-strength rigid RB exterior wall-to-mat foundation connection, referred to as L connection. Figure 9B.12-8 presents the idealized model used for the design of the L connection. As shown in Figure 9B.12-8, the end of the L connection is considered fixed.

Per the full-strength design concept, the weaker of the connected components (RB exterior wall and mat foundation) is expected to fail first. Consequently, design demands and required strength for each individual demand acting on the connection are calculated by identifying the applicable force transfer mechanism and evaluating the potential failure mode or mechanism of the connection.

#### **9B.12.5.2 Wing Wall-to-Mat Foundation Connections**

Overstrength rigid connections are used at the interface between the RB wing walls and the mat foundation to facilitate construction and fabrication. The governing code for the design of this type of connection is ANSI/AISC N690 in conjunction with ANSI/AISC 360. Figure 9B.12-9 presents a schematic for a typical RB wing wall-to-mat foundation connection.

As illustrated in this figure, a steel baseplate is welded to the internal wing wall and is anchored, using cast-in-place steel anchors, to the Steel Bricks™ concrete infill. The design of the overstrength rigid connections at the interface of the wings walls and the mat foundation is governed by the shear strength of the steel anchors, the bearing capacity of concrete and yielding of the base plate.

#### **9B.12.5.3 Wing Walls-to-Floors Connections**

As discussed in Appendix 9B.A, Subsection 9B.6.1.3, semi-rigid connections are used for wing walls-to-floors to reduce the axial and flexural stresses induced due to thermal loadings. Semi-rigid connections between wing walls and floors are identical to floors-to-RB exterior wall connections discussed in Subsection 9B.12.5.4.

#### **9B.12.5.4 Wing Walls and Floors Connections to RB Exterior Wall**

As discussed in Appendix 9B.A, Subsection 9B.6.1.3, semi-rigid connections are used in wing walls-to-RB exterior wall and floors-to-RB Exterior wall junctions to reduce the axial and flexural stresses due to thermal loadings. Figure 9B.12-10(a) presents typical floor-to-RB exterior wall connection details. The governing code for the design of this type of connection is ANSI/AISC N690 in conjunction with ANSI/AISC 360. As shown in Figure 9B.12-10(a), a stiffened angle cleat is used to connect the floor plates to the outer shaft.

As shown in Figure 9B.12-10(b), Wing walls-to-SCCV wall connections are similar to floors-to-RB exterior wall connections, with vertical angles used in the connections being welded to the outer face plate of the SCCV wall and bolted to wing walls plates. Weld quality assurance, procedure and inspection for the connections to SCCV wall follow ASME requirements as stated in Chapter 3, Subsection 3.5.3.1.1.

**Table 9B.12-1: Design Parameters for Steel Bricks™ in the Reactor Building**

RB Structural Component	Member Thickness (mm)	Faceplate Thickness (mm)	Steel Faceplate Grade	Yield Strength (MPa)	Tensile Strength (MPa)	Diaphragm Spacing (Brick Width) (mm)
RB exterior wall (below grade)	610	10	ASTM 572 Grade 50	345	448	305
RB exterior wall (above grade)	610	15.9				610
Outer mat foundation	1219	15.0				609
Wing walls	457	10				457

## **10.0 STEAM AND POWER CONVERSION SYSTEMS**

### **10.1 Role and General Description**

The components of the power conversion system are designed to produce electrical power utilizing the steam generated by the reactor. This chapter includes the Main Turbine Equipment (MTE) along with the systems listed below.

The MTE is comprised of the following:

- High Pressure (HP) and Low Pressure (LP) Turbines, casings, Main Steam (MS) stop and control valves, non-return valves, reheat steam stop (intermediate stop) and intercept valves, and turning gear
- Turbine Gland Seal Subsystem (TGSS)
- Turbine Lube Oil System (TLOS)
- Extraction Steam System
- Electro-Hydraulic Controls (EHCs) Subsystem

MS piping is not part of the MTE System, refer to Section 10.4 for additional information.

Load rejection capabilities are discussed in Section 10.7.

Other systems described in the sections below include:

- Feedwater (FW) Systems in Section 10.3
- Main Condenser and Auxiliaries (MCA) in Section 10.5
- Moisture Separator Reheater System (MSR) in Section 10.6
- Circulating Water System in Section 10.8

Radiation shielding for personnel protection is provided for all required components as discussed in Chapter 12, Subsection 12.3.2.

## **10.2 Turbine Generator System**

This section describes portions of the MTE, and the Generator and Exciter System is described in Section 10.9. Section 10.4 describes the MS System and Section 10.7 describes Turbine Auxiliary Systems.

The turbine generator consists of a 377 rad/s (3600 rpm) turbine, generator, control valves and associated subsystems.

The turbine has a single flow HP turbine and two double flow LP turbine units in tandem. The generator is direct driven, three-phase, 60 Hz, synchronous generator water cooling system, with an air-cooled stator and rotor.

The TLOS provides 100 percent of the lube oil required by the turbine and generator bearings and turning gear during all modes of operation.

The Extraction Steam System transports extraction steam to the MSR, and FW heaters.

The EHC provides HP hydraulic fluid to actuate the actuators on the main turbine stop and control valves, intermediate stop, and intercept valves, and the Turbine Bypass Valves (TBVs). The EHC subsystem is also used to actuate the trip devices in the trip and overspeed detection system.

### **10.2.1 System and Equipment Functions**

The system and equipment functions associated with the MTE are identified below.

#### **10.2.1.1 Normal Functions (Non-Safety Category)**

The MTE performs the following Non-Safety Category functions:

- Limits the atmospheric air in-leakage through the turbine glands
- TLOS removes water and impurities from the turbine lube oil
- Delivers clean lubricating oil from the lube oil reservoir to the main turbine generator bearings
- The EHC controls rolling the turbine to the rated speed

#### **10.2.1.2 Normal Functions (Safety Category)**

The MTE performs the following Safety Category normal functions.

- Controls Reactor Pressure Vessel (RPV) pressure
- Converts thermal energy contained in the MS and hot reheat steam into rotational torque on a shaft connected to the main generator
- Provides extraction steam from the various stages of the turbine to the first through fifth stages of FW heaters
- Exhausts (extracts) steam to the MSR for reheating (TBD)
- Exhausts steam to the main condenser (from the LP turbine)
- Minimizes radioactive steam leakage from the turbine shaft/casing and valve stems
- Limits atmospheric air in-leakage through the turbine glands
- Delivers clean lubricating oil from the Lube Oil Reservoir to the main turbine generator bearings

- Provides HP hydraulic fluid to actuate the Turbine Stop Valves (TSVs) and TCVs, intermediate stop and intercept valves, and the TBVs

#### **10.2.1.3 Off-Normal Functions (Non-Safety Category)**

This system does not perform any Non-Safety Category functions during off-normal conditions.

#### **10.2.1.4 Off-Normal Functions (Safety Category)**

This system does not perform any Safety Category functions during off-normal conditions.

### **10.2.2 Safety Design Bases**

The MTE is designed to fulfill the safety functions in Subsection 10.2.1.2.

The design of the MTE is such that protection of Safety Category function Structures, Systems, and Components (SSC) from the effects of turbine missiles is afforded as a result of the perpendicular orientation of the turbine to the reactor. The MTE employs redundant turbine overspeed protection system to minimize the probability of turbine missile generation. The favorably oriented turbine generator is located such that the containment and most Safety Category function SSC outside containment are excluded from the low trajectory hazard zone of a potential turbine missile. The turbine is designed to minimize the possibility of failure of a turbine blade or rotor. Turbine integrity is discussed in Subsection 10.2.4. The effects of potential high energy missiles are discussed in Chapter 3, Section 3.5, and Subsection 10.2.4.2.

Safety requirements include the following:

1. Anticipatory scram on fast closure of TCVs/TSVs demand in Mode 1 (Power Operation) is actuated.
2. TCV fast closure on generator load reject in Mode 1 (Power Operation) is actuated.
3. TSV fast closure on main turbine trip in Mode 1(Power Operation) is actuated.
4. Turbine trip on high main condenser pressure in Mode 1 (Power Operation) is actuated.
5. The plant design provides the capability for load following during at least 90% of the plant design life, the plant is capable of a 24-hour load cycle with the following electrical power profiles:
  - a. Starting at 100% power, power ramps down to 50% in two hours
  - b. Power remains at 50% for two to ten hours
  - c. Power then ramps up to 100% in two hours
  - d. Power remains at 100% for the remainder of the 24-hour cycle

The plant design can accommodate a minimum of 20,805 equivalent daily load following cycles.

The main turbine steam flow shutoff characteristics, in collaboration with turbine bypass capacity, and bypass opening response characteristics is designed to prevent a reactor trip from occurring as a result of a load rejection or turbine trip below or at 25% output.

The MS turbine control and protection systems are designed such that a single failure will not result in a main turbine trip.

The main turbine generator system and component designs provide sufficient margin and/or redundancies to account for anticipated abnormal operating conditions and component degradation to avoid limiting conditions of operation over the entire operating cycle.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

The main turbine is designed to include a corrosion allowance for materials in contact with water or steam systems.

The design of the MTE considers applicable international standards such as compliance with U.S. Nuclear Regulatory Commission (USNRC) Regulatory Guide 1.115, (Reference 10.2-2) "Protection Against Turbine Missiles" (Reference 10.2-2) which invokes compliance with 10 CFR 50 Appendix A(4), "Environmental and Dynamic Effects Design Bases" (Reference 10.2-5).

The design of the MTE System meets Canadian Nuclear Safety Commission (CNSC) requirements specified in CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants," Section 8.3.3 (Reference 10.2-1), as it relates to providing provisions for overspeed protection and minimization of missiles due to a turbine break-up. Minimization of potential missile impacts is also afforded through the favorable perpendicular orientation of the turbine to the SSC performing safety functions.

### **10.2.3 Description**

MTE design parameters are summarized in Table 10.2-1. A power cycle schematic is presented in Figure 10.2-1.

The turbine is a 3600 rpm, single-shaft, tandem compound, impulse-reaction, two stage reheat, condensing steam turbine. The turbine generator and associated piping, and valves, are located completely within the Turbine Building (TB). Refer to Section 10.4 for information pertaining to the MS system interface with the turbine generator.

The MTE begins at the two MS TSVs and control valves, which admit steam through separate steam leads to two inlet nozzles of the single flow HP turbine. Steam within the HP turbine is extracted for first stage MSR reheating and for fifth stage FW heating. HP turbine exhaust steam is directed to the MSR (Subsection 10.6.2) where the steam is dried and goes through two stages of reheating before entering the two LP turbines. Some HP turbine exhaust steam is also routed to the fourth stage FW heater. Steam within each of the two LP turbines is extracted for the first, second and third stages of FW heating. Exhaust steam from the LP turbines is directed to the condenser.

The main turbine is equipped with a turning gear which is used to rotate the turbine generator shafts slowly and continuously, as needed when the main turbine is not in-service, such as the early part of turbine warming and after the rotor has stopped at shutdown.

The system's physical layout provides protection to essential systems and components, as required, from the effects of high and moderate energy turbine generator system piping failures or failure of the connection(s) from the LP turbine exhaust hoods to the condenser. Essential systems are also protected from turbine missiles due to overspeed events. Failure of turbine generator equipment does not preclude safe shutdown of the reactor systems.

The design and control of the turbine valves is such that there is redundancy from the input device to the signal going back out to the three servo valves, with the first possible single failure point being the mechanical portion of the servo valve itself. The servo is biased to fail closed on loss of all electrical signals and on failure to drain on loss of servo valve jet lube oil flow.

The turbine generator is oriented within the TB to minimize the potential of turbine missiles damaging any Safety Category function equipment or structures. Favorably oriented turbine generators are located such that the containment and Safety Category function SSC outside containment are minimized from the low trajectory hazard zone (See Subsection 10.2.4.2 for discussion of turbine missiles).

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

Material and equipment selection for the MTE components is based on a 60-year design life, with appropriate provisions for maintenance and replacement.

The MTE is designed for an operating life based on continuous plant operation at full power for a 24-month cycle, including a refueling outage of approximately fourteen (14) days.

#### **10.2.3.1 Turbine Gland Seal Subsystem**

The TGSS components are designed to Category Non-Nuclear Seismic.

The TGSS supplies sealing steam to the turbine shaft/casing to prevent the escape of radioactive steam and to prevent air in-leakage through sub atmospheric turbine glands.

The TGSS takes sealing steam from the Turbine Auxiliary Steam Subsystem (TASS) only in low power conditions and during full power the sealing steam comes from the seals at the HP side of the HP turbine. The TASS takes steam from the MS equalizing header. The Steam Jet Air Ejectors (SJAEs) and offgas take steam from the TASS.

#### **10.2.3.2 Turbine Lube Oil System Description**

The TLOS supplies the lube oil to the turbine, generator, and exciter bush bearings. The TLOS skid includes redundant pumps to continuously supply oil to the bearings to protect against commercial losses. The lube oil skid also contains storage tank and heat exchangers which support the TLOS. An oil conditioning system is provided with TLOS.

#### **10.2.3.3 Extraction Steam Subsystem**

The purpose of the Extraction Steam System is to provide the means to transport extraction steam from the steam turbine to the MSR first stage reheater and FW heaters for regenerative FW heating and protect the steam turbine against overspeed and water induction conditions.

Exhaust steam from the HP turbine is directed to the FW Heater No. 4 and the moisture separator input of the MSR, the extraction steam from the HP turbine is directed to the FW Heater No. 5 and 1st stage reheater of the MSR. Extraction steam from the LP turbines provides heating steam to the first, second, and third stage FW heaters.

#### **10.2.3.4 Electro-Hydraulic Controls**

The EHC subsystem provides HP hydraulic fluid to position the TSVs and TCVs, intermediate stop and intercept valves, and the TBVs. The turbine hydraulic system is also used to actuate the trip devices in the trip and overspeed protection circuits for the turbine.

The EHC system tubing and components are designed to Category Non-Nuclear Seismic.

#### **10.2.3.5 Component Description**

The following defines the requirements specific to the major equipment items in the MTE System.

##### **10.2.3.5.1 Main Steam Turbine Stop and Control Valves**

Two hydraulically operated MS turbine stop, and control valves (four valves total) admit steam to the HP turbine. The primary function of the MS TSVs is to isolate the MS from the turbine and quickly shut off the steam flow to the turbine under emergency conditions. The primary function of the control valves is to control steam flow to the turbine in response to the Turbine Generator Control System (TGCS).

The MS turbine stop and control valves and their supports are designed such that excessive vibration cannot result from excitation caused by turbine operating harmonics and hydraulic instabilities in the valves or steam flows.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

Limit switches and valve position logic indication used on these valves are based on proven experience and satisfy triple redundancy criteria. Leak tight enclosures are provided for local turbine control and test logic limit switches and field termination junction boxes.

Valves which incorporate a pilot valve are designed based on proven experience.

The MS TSVs are hydraulically operated by HP fire-resistant hydraulic fluid in an open-closed mode either by the turbine overspeed protection in response to a turbine trip signal, fast-acting valve for tripping, or by a small solenoid valve for testing. The disks are unbalanced and cannot open against full differential pressure. A bypass is provided to pressurize the below seat areas of the two valves and supply steam for turbine casing and steam chest warming. Springs provided with the valves are designed to close the MS turbine control valves under emergency conditions.

The stop valves provide a method to allow prewarming during turbine startup.

Each MS turbine stop valve contains a steam strainer and integral screens to prevent foreign matter from entering the MS turbine control valves and turbine.

The control valves are designed to provide steam shutoff adequate for turbine speed control. The valves are of sufficient size, relative to their cracking pressure, to require partial balancing.

Each control valve is hydraulically operated by HP fire-resistant hydraulic fluid supplied through a servo valve. The control valves are designed to close in 2.5 seconds and fast-close in 0.08 seconds.

The turbine control valves are capable of full stroke opening and closing times with the reactor at 100% power, including load following.

The turbine control valves are designed to withstand extended periods of operation at less than full load, including load following.

The MS turbine stop and control valves will not produce unacceptable stress or reactions on the bearings during testing. Valve testing does not result in bearing temperature alarms or vibration alarms.

The MS turbine stop and control valves are designed to be compatible with control functions of the Reactor Pressure Control (RPC).

#### **10.2.3.5.2 Intermediate Stop and Intercept Valves**

One hydraulically operated reheat Intermediate Stop and Intercept Valve is provided for each LP turbine. The valves are located as close to the LP turbine as required to control turbine speed and protect the turbine against overspeed from steam and water energy stored between the MS stop and control valves and the intermediate stop and intercept valves.

The reheat intermediate stop and intercept valves are designed to close rapidly to control turbine overspeed. Upon loss of load, the valves first close then throttle steam to the LP turbine as required to control speed. The valves close on a turbine trip or if the valves fail to operate properly to control overspeed. Each valve is capable of opening against full system pressure and capable of opening against a pressure differential of approximately 15 percent of the maximum expected system pressure.

The reheat intermediate stop and intercept valves and their supports are designed such that excessive vibration cannot result from excitation caused by turbine operating harmonics and hydraulic instabilities in the valves or steam flows.

Valve operating mechanisms are of a fail-safe (i.e., fail closed) design that minimizes the use of complicated valve linkages and uses components that are based on proven experience.

Limit switches and valve position indication used on these valves is based on proven experience and satisfy the triple redundancy criteria. Leak tight enclosures are provided for local turbine control and test logic limit switches and field termination junction boxes. Refer to Chapter 7 for information pertaining to triple redundancy.

Intermediate stop valves which incorporate a pilot valve are designed based on proven experience.

#### **10.2.3.5.3 Main Turbine (High and Low Pressure)**

The turbine is capable of startup from cold conditions to full load within twelve hours, including rotor preheating.

The turbine is designed to separate water from the steam and internally drain it to the next lowest extraction point.

The HP turbine receives steam through two steam leads, one from each control valve outlet. The steam is expanded axially across several stages of stationary and moving blades. Extraction steam from the HP turbine is used to supply the fifth stage of FW heating and MSR first stage reheater heating steam. HP turbine exhaust steam is collected in a cold reheat pipe and routed to the MSR inlet.

Two units of LP turbines coupled together with the HP turbine shaft convert thermal energy into mechanical rotational energy to drive the generator. Each LP turbine receives hot reheat steam from its connected MSR outlet through the intermediate stop and intercept valves. Each LP turbine is a double flow with six extraction points for FW heating. Each LP turbine exhausts directly to the main condenser connected underneath each LP turbine.

#### **10.2.3.5.4 Turning Gear**

The main turbine is equipped with a turning gear. The primary function of the turning gear is to rotate the turbine generator shafts slowly and continuously, as needed during shutdown periods. Use of the turning gear during startup eliminates the necessity of "breaking away" the turbine generator from standstill with steam, and thereby provides a more uniform and controlled startup. The turning gear may also be used to rotate the rotor incrementally at desired intervals for inspection and also prevents rotor bowing.

Interlocks preventing turning gear operation under conditions which may cause equipment damage, such as loss of lubricating or lift oil, are included in the design of the main turbine.

The turning gear has the ability to engage and start upon zero turbine rotor speed and sufficient lube oil pressure and disengage at startup.

#### **10.2.3.5.5 Extraction Steam Non-return Valves**

The extraction check valves are installed in the appropriate turbine extraction lines supplying steam to FW heaters. The valves prevent backflow of steam from FW heaters to the main turbine after sudden load reductions or turbine trip. The disks of the extraction non-return valves are furnished with air operators allowing them to operate freely when the cylinders are supplied with instrument air pressure controlled by the turbine control system. Upon loss of air pressure or upon equalization of the air pressure on both sides of the piston, the cylinder springs and associated linkage initiate and assist in closure of the valves.

#### **10.2.3.5.6 Piping and Valves**

The turbine system piping includes the MS connections from the MS control valves to the HP turbine steam inlet nozzles, and HP turbine and LP turbine exhaust hoods instrumentation piping.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

The MS control valves are mounted on the HP turbine steam inlet nozzles.

Drain piping is provided for each turbine drain location. The drain piping is large enough to ensure an adequate flow area for the maximum amount of water to be handled under any operating condition and minimal pressure differential conditions. Continuous bleed type bypass is used in areas where water can collect during operation.

The flow area of the main turbine piping provides an acceptable steam velocity based on successful operating experience, considering expected fluid conditions (pressure, temperature, and moisture levels) and considering the specified material requirements.

The turbine system piping is designed to the requirements of American Society of Mechanical Engineers (ASME) B31.1, "Power Piping" (Reference 10.2-3).

Pipe thicknesses are calculated with the appropriate erosion-corrosion allowance to preclude failure during design life.

Double isolation valves are provided, where necessary or where required by code, to facilitate online maintenance of HP/high temperature systems.

Wherever possible, long radius bends (1.5 times nominal pipe size) are used. Piping layouts that result in 90° elbows, miters, etc. are also minimized.

#### **10.2.3.6 Turbine Gland Seal Steam System**

The TGSS is capable of providing sealing steam to and from all HP and LP turbine gland seals.

The TGSS is designed to provide sealing steam to the HP turbine shaft seals in a range of turbine shell pressures from full vacuum to full-load operating pressure. The LP turbine shaft seals normally operate against a vacuum.

The TGSS has two independent sources of steam:

- The HP turbine packing leakoff supply steam, which is available to TGSS during normal and transient operating conditions
- The Main Steam Line (MSL) during startup operation condition

Means for automatically and manually controlling gland steam are provided to maintain proper gland steam conditions during normal and transient operating conditions.

The turbine seals are also supplied with a partial vacuum maintained by the Gland Steam Condenser (GSC) using redundant exhaust blowers to prevent steam leakage in TB atmosphere. The GSC is designed to prevent the entrainment of air in the gland steam condensate.

TGSS piping is designed to meet the requirement of ASME B31.1 (Reference 10.2-3) as applicable.

Corrosion/erosion resistant materials are used for components exposed to wet steam or flashing liquid flow where significant erosion could occur. The degree of corrosion/erosion resistance of the material is consistent with the temperature, moisture content and velocity of the wet steam to which the component is exposed.

Relief valves on the seal steam header prevent excessive seal steam pressure, which protects the system from malfunction and mis-operation. The relief valves limit the steam seal header pressure to a safe level.

#### **10.2.3.7 Gland Steam Condenser**

The GSC is a shell and tube heat exchanger designed to condense the maximum leakoff steam as required, contained within the air-steam mixture withdrawn from the HP and LP turbine gland seals and the stem leak-offs of the TSVs, TCVs, intermediate stop and intercept valves, and TBVs as required. The air-steam mixture is drawn into the GSC where steam is condensed on the outside of the tubes and air and non-condensables exit to the GSC exhaust blowers. The condensed steam is drained through a trap to the main condenser. Heat is rejected to the condensate flowing through the GSC tubes.

The outer leakoff annulus region of the glands of the turbine are connected to the GSC.

The GSC drain piping is routed and continuously pitched downward to the main condenser. The drain piping is provided with a loop seal to isolate the GSC from the lower pressure of the main condenser. The GSC loop seal is installed with a telltale. The telltale prevents water from rising in the GSC due to a GSC tube rupture. This excludes the possibility of flooding the GSC, adversely impacting the performance of the exhaust fan and the suction line (leakoff) at the turbine gland seal. The overflow is directed toward the nearest sump of the Equipment and Floor Drain System (EFS) (Chapter 9A, Subsection 9A.9.3). The loop seal is filled with demineralized water before the GSC exhaust blower is placed in operation. The GSC is mounted on a pedestal, or an opening provided to accommodate the loop seal below the GSC body.

The GSC is a constant flow type, which means the condenser is located in the Condensate and FW Heating System (CFS) (Subsection 10.3.2) auxiliary condensate loop so that it is supplied with a constant amount of condensate during all operation modes. To maintain condensate flow through the GSC, the water box is supplied with a loop seal to limit the flow to the condenser during operation.

#### **10.2.3.8 Gland Steam Condenser Exhaust Blowers**

Two 100% capacity Alternating Current (AC) motor-driven GSC exhaust blowers maintain a slight vacuum on the GSC shell to remove non-condensable gases. The GSC exhaust blowers are centrifugal type.

Non-condensable gases are removed from the GSC and exhausted to the stack by two parallel, redundant, 100% GSC exhaust blowers. The GSC exhaust blower suction piping pitches downward away from the blower to a low point drain before entering the fan. The low point drain is drained to the main condenser and includes a trap, which prevents condensate from running back to the blower from the vent piping and prevents air from being drawn into the main condenser.

The GSC exhaust blowers have a manual butterfly valve at the inlet and a free-swing check valve in the discharge lines. The check valves prevent recirculation of air through the idle blower when the other is running.

#### **10.2.3.9 Turbine Gland Seal Steam System Piping and Valves**

The TGSS includes an air-operated pressure regulating feed valve for the TASS.

The TGSS piping is designed to have sufficient flexibility for expansion of turbine parts due to thermal growth.

A continuous orifice drain to the main condenser is located on the inlet side of the steam seal feed valve extraction, and steam seal feed valve to avoid accumulation of water at the feed valves.

The steam seal feed valve has a bypass which is located at the highest point in its pipeline.

TGSS includes an air-operated seal steam dump valve for the steam seal header. the seal steam dump valve acts as unloading valve when, at higher turbine loads, more steam is leaking from the pressure packing than is required by the vacuum packing.

The seal steam dump valve has a bypass.

The piping to the turbine shaft packing connections is run from the steam seal header piping, between the feed and dump valves. The steam seal header incorporates a minimum of one low point drain. The steam seal header is drained to the main condenser via this low point drain utilizing a continuous drain to prevent the buildup of water in the steam seal header during normal operation.

The TGSS includes test connections to permit performance testing.

#### **10.2.3.10 Turbine Lube Oil System**

The TLOS provides 100% of the oil required by the turbine generator bearings during turning gear, startup, shutdown, normal, and emergency operating conditions. Sufficient flow margin is provided to account for anticipated off design operating conditions and wear.

The TLOS contains lube oil primary and secondary pumps, an emergency Direct Current (DC) powered pump, a lube oil heat exchanger, and a lube oil conditioner system that removes water and impurities from the oil.

A full-flow filtration system downstream is provided to meet the filtration requirements. The system is provided with the capability for cleaning the filters while online without interrupting oil flow by switching from one cooler/filter assembly to the other.

To minimize corrosion due to moisture contamination, a lube oil conditioner system with water removal capability is provided.

TLOS oil coolers and heaters maintain supply oil temperature within operating limits. A high temperature alarm functions during all design operating conditions.

In the event that the Primary and Secondary AC Bearing Oil Pumps are inoperative due to AC power loss, or a turbine trip due to loss of lube oil pressure, the DC motor-driven Emergency Bearing Oil Pump is sufficiently sized and automatically starts to ensure the lube oil is supplied to the bearings continuously during rotor coast down to prevent damage. Manual controls for this pump are also provided.

Primary and Secondary Lift Oil Pumps are provided for the turbine and generator bearings for turning gear operation as required.

The top of the Lube Oil Reservoir is provided with gravity-closed doors with seals to prevent contamination.

A means for removal of water from the lube oil at the end of an outage is provided to prevent water contamination.

Provisions for the flushing of the Lube Oil Reservoir, supply lines, and return lines is provided to ensure acceptable contaminant levels for operation.

Provisions for heating the lube oil during flushing are provided on the Temporary Flushing Skid.

The Secondary Lube Oil Vapor Extractor is powered from a different bus than the Primary Lube Oil Vapor Extractor.

Provisions for obtaining representative samples of lube oil are included to ensure requisite quality is maintained.

#### **10.2.3.11 Lube Oil Pumps**

TLOS Primary and Secondary AC Bearing Oil Pump capacities are identical and are sufficient to maintain oil pressure and adequately lubricate the shaft bearing, and turning gear during startup, shutdown, and normal operation.

In the event of either pump failure or maintenance, pumps can be used interchangeably for supplying the TLOS during all modes of operation. The discharge of the Primary and Secondary AC Bearing Oil Pumps enters the Lube Oil Coolers first, then through the full-flow filters, and then is supplied to the bearing header. The Primary and Secondary AC Bearing Oil Pumps are self-venting to prevent air from becoming trapped in the piping.

The DC Emergency Bearing Oil Pump is a DC motor-driven pump that prevents the loss of bearing oil flow by providing emergency backup upon loss of AC power.

Primary and Secondary Lift Pumps are AC motor driven, positive displacement pumps that supply lube oil to the rotor bearings when the turbine is on turning gear.

The Secondary AC Bearing Oil Pump motor is powered from a different bus than the Primary AC Bearing Oil Pump motor.

The power to the Primary and Secondary AC Bearing Oil Pumps is independent and different from that used to control and power the DC Emergency Bearing Oil Pump. This ensures that a failure of a single power source does not affect both the Primary and Secondary AC Bearing Oil Pumps and the DC Emergency Bearing Oil Pump.

The AC and DC motor-driven oil pumps are continuously vented to remove entrained air and the vent line is of sufficient size to prevent plugging.

#### **10.2.3.12 Lube Oil Reservoir Skid**

The Lube Oil Reservoir Skid contains a reservoir with sufficient capacity to contain all oil required by the system for normal operation, turbine trip and to provide submergence of the pumps located in the reservoir. The capacity of the reservoir results in considerable oil above the pump inlets and a low recirculation rate with positive time for air detrainment.

The Lube Oil Reservoir Skid is located below the turbine operating floor so that all oil drains back to the reservoir by gravity.

#### **10.2.3.13 Lube Oil Filters**

The filtration system consists of two 100% capacity in-line full-flow duplex filters. Contamination or plugging of the filter element in-service requires the backup filter element be manually brought into service. Connected to the filters, an oil vent with orifice to continuously drain lube oil back to the reservoir is provided.

#### **10.2.3.14 Turbine Lube Oil System Piping and Valves**

TLOS supply and drain piping is comprised of all welded construction to the maximum extent possible to eliminate possible leakage pathways such as threaded and flange connections.

Pressurized oil lines in the vicinity of hot parts of the turbine are enclosed in a guard line to the maximum extent possible. The guard lines are designed such that in the event of a ruptured pressure line, the pressurized oil drains into the guarding pipe and returns to the reservoir. Pressurized oil lines not in the vicinity of hot parts of the turbine are not required to be enclosed in guarding lines.

TLOS piping downstream of the full-flow filters are corrosion resistant stainless steel, to prevent contamination of lube oil due to pipe corrosion.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

With the Lube Oil Vapor Extractor maintaining a negative pressure in the Lube Oil Reservoir, this arrangement assists in holding a slight negative pressure within all drain enclosures, thereby, preventing oil and vapor leakage from drain piping.

A separate vent for TLOS is provided. Location of the vent is such as to prevent accidental contact of discharge vapors and gases with fire or sparks. The vent is located away from air intakes for facilities or equipment. TLOS vent is provided with a high efficiency mist eliminator and dual vapor extractors, packaged in a single unit mounted on top of the tank.

A Cooler/Filter Selector Valve is used to switch flow from one oil cooler/filter to the standby combination. The Cooler/Filter Selector Valve assembly allows for full volume flow while switching to the alternate cooler/filter.

The Bearing Pressure Regulator Valve self-regulates the bearing header pressure. This valve has an external orifice which provides minimum necessary oil flow when the valve is not in-service. Adjustments and maintenance are performed through an access cover in the tank top.

The Vapor Extractor Inlet Valve is a manual valve that regulates the amount of vacuum created in the tank by the Vapor Extractor. This valve is accessible from the top of the reservoir.

Oil drain lines pitch downward toward the Lube Oil Reservoir.

#### **10.2.3.15 Extraction Steam System Piping and Valves**

Flow Accelerated Corrosion (FAC) resistant materials are used for all components exposed to wet steam or flashing liquid flow where significant erosion could occur. The degree of FAC resistance of the material is consistent with the temperature, moisture content and velocity of the wet steam to which the component is exposed.

Extraction drains consist of a drain pot or orifice and a drain line.

Extraction motor-operated isolation valves are provided to prevent water induction into the turbine. The extraction isolation valves are designed to permit a functional test during plant operation without tripping the turbine.

The extraction air-assisted non-return valves limit contributions to turbine overspeed from steam and water in the extraction lines and FW heaters in the event of a turbine generator trip signal. The air-assisted non-return check valve air pistons go through full stroke in the closing direction within two seconds of tripping the air relay dump valve.

Non-return valves are located five pipe diameters downstream from flow disturbances, such as tees and elbows, and ten pipe diameters downstream from control valves, in accordance with EPRI-NP-5479, "Application Guide for Check Valves in Nuclear Power Plants" (Reference 10.2-4).

The Extraction Steam System, where required, has a motor-operated isolation valve and an air-assisted non-return valve located in extraction line from the turbine to the FW heaters to prevent water induction backflow and overspeed of the turbine.

The design of the extraction piping, valves, drains and associated controls are in accordance with ASTM TDP-2, "Prevention of Water Damage to Steam Turbines Used for Electric Power Generation: Nuclear-Fueled Plants" (Reference 10.2-6).

A drain is located at each low point in the extraction steam piping system where water may collect during startup, shutdown, or normal operation. For extraction lines with isolation valves located at an elevation higher than its associated FW heater, the extraction piping between the isolation valve and the FW heater is sloped to eliminate possible low points.

#### **10.2.3.16      Electro-Hydraulic Control System**

The EHC system consists of hydraulic fluid, Hydraulic Power Unit (HPU), Trip Manifold Assembly (TMA), Fluid Actuator Supply tubing, Fluid Actuator Drain tubing, Emergency Trip System tubing, and associated tubing, valves, and instrumentation.

The HPU consists of a fluid reservoir, redundant pumping systems, fluid coolers, accumulators, space heaters, air dryer, and a fluid transfer and filtering unit (transfer and Fuller's earth filtration unit). The transfer and Fuller's earth filtration unit consists of a transfer pump, Fuller's earth filters, backup filter, and associated valves. The HPU Fluid Actuator Supply for the TSVs, TCVs, and intermediate stop and intercept valves is capable of isolation from the fluid actuator supply for the TBVs. The HPU is located at a low elevation. The HPU is located such that all hydraulic Fluid Actuator Drain lines pitch downward.

The TMA consists of two parallel triple redundant circuits (Circuits A and B). Each TMA circuit consists of three Electronic Trip Device solenoid valves. Refer to Chapter 7 for information pertaining to triple redundancy. The TMA also includes (total for both circuits) six pairs of isolation valves, a continuous-flow transfer valve assembly, and two air relay dump valves. The TMA is located on the HPU skid.

The EHC system includes in-line full-flow filters for the control of the particulate contaminants in supply lines to ensure 100% of the hydraulic fluid is filtered. Parallel filters and valving are provided to allow cleaning of a filter without interrupting fluid flow while online.

The HPU coolers are water-cooled shell and tube heat exchangers.

The EHC system includes means for the control of hydraulic fluid chemistry and removal of moisture from the hydraulic fluid to prevent corrosion of the system which contaminates the fluid. Provisions for sampling the hydraulic fluid is provided to enable the verification of chemistry and moisture content.

The EHC system design includes redundant instrumentation with a coincident logic trip system to improve system reliability by reducing false and spurious trips.

Each trip initiating signal from the EHC system is monitored to identify the source of the trip signal.

The EHC system provides an independent and redundant backup electrical overspeed trip circuit, to quickly close the TSVs, TCVs, intermediate stop and intercept valves, to quickly shut down the turbine in the event of an unsafe condition. The EHC system is designed to minimize false and spurious trips during normal operation and testing of the trip system.

The EHC system is provided with redundancies such that a failure or malfunction of a single component or power source does not result in an unsafe overspeed or trip actuation of the turbine.

The EHC system includes provisions for online testing of trip devices to verify the system is operable and will function correctly.

The EHC system supports the hydraulic controllers for the TSVs, TCVs, intermediate stop and intercept valves, and TBVs that close or open the valves (as applicable) sufficiently after receipt of a trip signal to preclude an unsafe turbine overspeed. The response of the controllers takes into account the residual steam in the piping between the valves and the turbine.

The EHC includes turbine trip indication devices for an electric solenoid trip.

### **10.2.3.17      Hydraulic Power Unit**

The major components of the HPU include a fluid reservoir, two independent and parallel pumping systems, fluid coolers, bladder accumulators, electric space heater, air dryer-breather, and a built-in fluid transfer and filtering unit.

The drain for the HPU is manually connected to drums to drain the reservoir.

The HPU supplies HP hydraulic fluid directly to the control solenoid on the TSVs, TCVs, intermediate stop and intercept valves, and TBVs for actuator control, and to the trip devices in the TMA. The unit can accommodate both steady-state and transient requirements.

The fluid is supplied to all components at the correct temperature and required cleanliness. The unit is equipped with chemically active filters to maintain the properties of the fluid over long service times. The two completely redundant pumping systems allow online maintenance of the standby pumping system. The HPU has alarms and pressure transmitters which auto start the standby pumping system. The EHC trips the turbine should a malfunction occur where the EHC cannot maintain and/or develop adequate pressure.

The reservoir has sufficient capacity to hold all of the hydraulic fluid for the turbine hydraulic system.

The reservoir is fabricated out of stainless steel.

The reservoir includes a cover plate to provide access to the reservoir for cleaning and inspection.

The reservoir includes internal baffling to allow any entrapped air in the return fluid adequate time to detrain before passing into the pump suction line and to separate the hot drain fluid from the rest of the fluid.

The reservoir contains a float type level gauge and level transmitter that determines the correct reservoir fluid level. This level transmitter incorporates low-low/low/high level switches that alarm.

The reservoir includes a temperature element that alarms for high and low fluid temperature.

A pressure compensator on each pump maintains a preset pressure throughout the delivery range i.e., as system demand changes, the pump automatically adjusts its stroke to meet the flow demand while maintaining system pressure.

If the pump dead heads, the pump is automatically shut off.

A wire mesh suction strainer is installed in the pump intake. The suction strainer provides a visual condition indicator during operation, showing suction status.

A full-flow HP filter is installed on the outlet of the pump. The full-flow HP filter includes an electric differential pressure switch that will alarm when the differential pressure has reached the maximum set point, indicating that the element requires changing.

Pumping discharge tubing includes relief valves that discharge the pump output back into the reservoir if pump pressure exceeds the setting of the valves.

Pump discharge tubing includes an automatic air bleed valve that discharges into the reservoir.

Two 100% capacity fluid-to-water shell and tube heat exchangers are provided to cool the fluid returning to the reservoir from the valve actuators and trip devices. One fluid cooler is used while the other is on standby.

Bladder type accumulators are connected to the hydraulic header in the supply manifold to provide an immediately available reserve of fluid for transient flow requirements.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

Isolation valves in the tubing permit accumulators to be serviced while the HPU is in operation. The valves also permit checking of the pre-charge pressure by isolating an accumulator group and bleeding its fluid contents to drain.

Two redundant electric space heater units are included on the HPU.

The space heater units keep the fluid in the reservoir, accumulators, and tubing of the standby system warm during cold weather operation.

The space heaters are operated automatically by a thermostatic control in the HPU. The control senses temperature in the fluid reservoir and keeps the heaters on whenever the fluid temperature is below the low temperature set point.

An air dryer removes moisture from the air breathed by the fluid reservoir during HPU operation.

A built-in, dual operating-mode transfer and Fuller's earth filtration unit consists of a motor-driven transfer pump, relief valves, a filling and discharge hose, Fuller's earth filters, and a backup filter.

The reservoir is filled and drained by the transfer and Fuller's earth filtration unit.

The transfer filtering operation mode is used to filter the hydraulic fluid to a low particle size and contaminant level while the reservoir is being filled or drained. For this operation, fluid is passed through the Fuller's earth filters and the backup filter to the reservoir.

The Fuller's earth filtering operation mode maintains the fluid at a low neutralization number by absorbing acids and water and maintaining the chlorine content of the fluid within the recommended specifications. During the filtering operation, fluid from the reservoir flows through the Fuller's earth cartridges in filter housings through the backup filter and then back to the reservoir. The Fuller's earth filtering system is in operation during the Turbine Hydraulics system flush, and then kept in continuous operation when the turbine is in-service. For extended maintenance outages, the Fuller's earth filtering system is operated to maintain fluid operating conditions.

#### **10.2.3.18 Trip Manifold Assembly**

The TMA is designed as the final control element of the TGCS emergency overspeed protection system. The TMA consists of a duplex (parallel) arrangement of two triple redundant Electronic Trip Device solenoid valve circuits, Circuits 'A' and 'B', configured as a single integrated hydraulic circuit. The design is optimized for normal turbine generator operation with both circuits in-service but is capable of operating with one circuit isolated for online maintenance. Refer to Chapter 7 for information pertaining to triple redundancy.

Each TMA circuit includes three Electronic Trip Device valve assemblies, which are arranged hydraulically for two-out-of-three voting. The three pairs of isolation valves per circuit are arranged in a normally closed two-out-of-three voting circuit separating the Fluid Actuator Supply fluid supply from the Emergency Trip System header. Each two-out-of-three hydraulic circuit arrangement results in three parallel flow paths, each path passing through two valves in series. Trip and reset valve position transducers are provided for indication, fault annunciation, and test permissives for online test sequencing.

The TMA has a continuous-flow transfer valve assembly allowing for pressure isolation of either Electronic Trip Device circuit to permit online service.

The Electronic Trip Device solenoid valves direct Emergency Trip System fluid pilot pressure to the air relay dump valves, dump valves, and shut-off valves.

### **10.2.3.19 Electro-Hydraulic Control Valves and Tubing**

Electronic Trip Device solenoid valves are arranged for two-out-of-three voting logic in the TMA. The Electronic Trip Device solenoids are controlled by TGCS and by the diverse overspeed trip system. When the TMA is in normal operation with the Electronic Trip Devices energized, the Emergency Trip System fluid flows to pilot the air relay dump valves, flow through the fast-acting solenoid valves, hold the dump valves closed with the Emergency Trip System fluid pressure, and flow to pilot the shut-off valves to allow fluid actuator supply fluid to flow either to the applicable solenoid operated test valves or the servo valves.

The fast-acting solenoid valves, solenoid operated test valves, servo valves, dump valves, and shut-off valves are located with their associated actuators on the TSV, TCV, intermediate stop and intercept valves, and TBV.

Emergency trip system header dump valves are pilot operated with customized spools to maintain two separate and isolated flow paths. The dump valves are held closed by the Emergency Trip System fluid pressure. The dump valves have a spring bias to rapid close the TSVs, TCVs, intermediate stop and intercept valves with the release of the Emergency Trip System fluid pressure.

Air relay dump valves are Emergency Trip System fluid pilot-operated valves and used to establish the Emergency Trip Air System pressure in order to operate the extraction system non-return check valves. Actuation of the air relay dump valves causes the non-return valves air cylinders to be vented, allowing the non-return valves to close thereby preventing turbine overspeed.

Fluid actuator supply header isolation valves are two-way pilot-operated unbalanced logic cartridge valves arranged in pairs to simulate a single four-way valve. Each valve pair is piloted by a single Electronic Trip Device.

Emergency Trip System header shut-off valves are Emergency Trip System fluid pilot-operated with separate and isolated flow paths to admit the applicable fluid actuator supply fluid supply to the solenoid operated test valves or the servo valves for TSV, TCV, and intermediate stop and intercept valve actuation.

The transfer valve assembly consists of continuous-flow inlet and discharge valves that are used to hydraulically isolate either hydraulic Circuit A or B during normal operation without interruption of the fluid supply to the Emergency Trip System header.

Turbine hydraulic system tubing is designed to the requirements of ASME B31.1 (Reference 10.2-3).

The design of the hydraulic lines is fail-safe, meaning that loss of hydraulic pressure results in a turbine trip. All hydraulic tubing is constructed of stainless steel. HP hydraulic tubing is installed with welded connections where possible to reduce the potential for leaks. The tubing is supported in such a manner as to prevent vibration yet provide adequate flexibility to permit movement of end connections to valves. Where tubing passes through clearance holes in the floor or walls, the tubing is located such that the maximum tubing motion due to expansion does not result in interference between the tubing and the side of the clearance hole. All vent lines are routed such that air flow is not blocked by fluid pockets.

## **10.2.4 Turbine Integrity**

### **10.2.4.1 Materials Selection**

Turbine rotor integrity is provided through the combined use of selected materials with suitable toughness, analyses, testing, inspections, and operating procedures. Turbine components and

valves facilitate in-service testing and inspection (including all high stress regions) at intervals in accordance with industry practice (i.e., Boiling Water Reactor Owner's Group (BWROG) guidance) or as required to meet turbine missile generation probability requirements.

#### **10.2.4.2 Turbine Missile Probability Analysis**

Refer to Chapter 15, Subsection 15.6.1.2 which presents the methodology for performing a qualitative assessment for determining the probability of turbine generated missiles and associated results.

#### **10.2.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.2-2 for system interfaces.

#### **10.2.6 System and Equipment Operation**

##### **10.2.6.1 Normal Operation**

During normal operation, the MS TSVs and intermediate stop and intercept valves are fully open, with control valves modulating as required to maintain reactor pressure. Specifically, in normal operation, the RPC sends a flow demand signal to the turbine generator controller that changes a flow demand signal into a turbine control valve position demand signal. Because of the BWR's strong negative void coefficient, the control scheme in normal power operation cannot be "boiler follows turbine," since opening the control valves would lower reactor pressure and increase voiding which lowers reactor power and opposing the desired change. Instead, the design is "turbine follows boiler." Reactor power is first changed, and the turbine control valves open or close, appropriately increasing or decreasing load.

Operation of the turbine generator is controlled by the TGCS.

The reactor pressure controller controls the turbine control valves through the TGCS to regulate reactor pressure. The normal function of the TGCS is to generate the position demand signals for the main stop valves, main control valves, and the intermediate stop and intercept valves.

The Primary AC Bearing Oil Pump automatically supplies the turbine generator bearings and turning gear, if needed, with lube oil at the required pressure and temperature. If the Primary AC Bearing Oil Pump should fail, then the Secondary AC Bearing Oil Pump automatically supplies the system with lube oil.

During all operating modes, the lube oil is purified and conditioned by the integrally mounted lube oil conditioner. Lube oil is continuously circulated to the reservoir by a jockey pump that is located on the lube oil conditioner and drained back to the reservoir by gravity.

During Extraction Steam System normal operation, heating steam is transported to the FW heaters, with the exception of the No. 6 heater, and the MSR second stage reheaters. Both the motor-operated isolation valves and air-assisted non-return valves are open. Drain line valves are open and close as a function of the level of condensed steam in the drain pot. Extraction Steam System normal operation also includes isolating heaters:

1. LP FW Heaters Isolated: The LP FW heater is isolated when a high-high level setpoint is detected by the level transmitters in any of the three stages of LP FW heaters. This isolation protects the turbine from water induction. High-high level FW isolation results in the following actions:
  - a. The air-assisted non-return valve is released to close in the extraction line of the affected FW Heater No. 3
  - b. The remaining first and second stage extraction lines remain in normal operation

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

- c. The drain valve in the drain line upstream of the air-assisted non-return valve are signaled open
2. HP FW Heaters isolated: HP FW Heaters No. 4 and No. 5 are individually isolated when a high-high level setpoint is detected by their associated level transmitters. This trip protects the turbine from water induction. High-high level FW heater isolation results in the following actions:
  - a. The extraction isolation valves close, and the air-assisted non-return valve are released to close in the extraction lines to the affected FW Heaters No. 4 and No. 5. The sixth stage FW heater does not contain an air-operated non-return valve.
  - b. The drain valves in the drain lines upstream of the extraction isolation valves are signaled open

During normal operation, one pump from the EHC Pump Unit is sufficient to supply the Fluid Actuator Supply fluid for the HP hydraulic system. The pumps have a capacity of 100% duty each. The standby pump provides a reliable backup should the operating pump fail to provide the necessary pressure. Pressurized fluid from the HPU is pumped to the servo valves on the TCVs, intercept valves, and TBVs; the solenoid operated test valves on the TSVs and intermediate stop valves; and to the EHC.

During EHC normal operation, all Electronic Trip Devices are energized open, all shut-off valves are open, and all dump valves are held closed by the Emergency Trip System fluid, enabling the pressurization of the turbine EHC header. Also, during EHC normal operation, the air relay dump valves are reset to establish the Emergency Trip Air System pressure, which assists the extraction system non-return check valves in fast closure. The EHC system is able to support testing for the fast closure of the TSVs, TCVs, and the intermediate stop and intercept valves and fast opening of the TBVs. The EHC system has the ability to test the TMA when the turbine is online.

#### **10.2.6.2 Normal and Emergency Shutdowns**

In the event of an unsafe operating condition, the TGCS controls initiate trip signals to the turbine. The TGCS provides automatic and manual controls to unload the unit during controlled shutdowns.

The main turbine stop and control valves, and intermediate stop and intercept valves close upon actuation of the Emergency Trip System within a time period to preclude unsafe turbine overspeed.

In the event of a turbine trip with the closure of TSVs and TCVs, TASS provides sealing steam to the turbine until main condenser vacuum break. However, in the event of a turbine trip with a closure of the Main Steam Reactor Isolation Valves and/or Main Steam Containment Isolation Valve (MSCIV), the main condenser vacuum will break on loss of offgas steam, but the condenser vacuum pumps will be automatically started.

During a plant shutdown, the Primary or Secondary AC Bearing Oil Pump and the Primary or Secondary Lift Pump supply lube oil to the turbine generator bearings, couplings, and turning gear until the turbine speed is zero. The Primary or Secondary Lift Pump automatically start when the main turbine rotor speed decreases to near the point of an oil wedge breakdown.

During shutdown, the Extraction Steam System motor-operated isolation valves and air-assisted non-return valves are closed. Extraction line drain valves are open during shutdown. The shutdown of the system is carried out with the shutdown of the plant. The condensate produced during shutdown is drained to the condenser.

A turbine trip signal automatically isolates the shell side of FW Heaters No. 4 and No. 5 by closing the motor-operated isolation valves. The drain line valves are open.

The turning gear also operates during shutdown as long as the turbine is not under maintenance. During turning gear operation, the Primary Lift Pump supplies lube oil to the turbine generator rotor to reduce the turning gear torque requirements when the turbine is not in operation. If the Primary Lift Pump should fail, then the Secondary Lift Pump supplies oil to the bearings.

During a turbine trip, the HPU continues to supply Fluid Actuator Supply fluid to the servo valves on the TBVs to keep them open to discharge steam to the main condenser.

During shutdown, the HPU continues to supply hydraulic fluid to the TSVs, TCVs, intermediate stop and intercept valves and TBVs for actuation.

### **10.2.6.3 Off-Normal Operational Concept**

#### **10.2.6.3.1 Turbine Overspeed Protection System**

The following component redundancies are employed to provide turbine overspeed protection:

- Main stop valves/control valves
- Intermediate Stop and Intercept Valves
- Normal speed control/Primary overspeed trip/Emergency overspeed trip
- Fast-acting solenoid valves/emergency trip fluid system

In addition to the normal speed control function provided by the TGCS, a separate and redundant turbine overspeed protection system is included to minimize the possibility of turbine rotor failure and turbine missile damage. Additionally, the valve arrangements and closure times are such that a failure of any single valve to close will not result in unsafe turbine overspeed in the event of a trip signal.

The normal speed control system comprises a first line of defense against turbine overspeed. This system includes the MS control valves, intermediate stop and intercept valves, and fast-acting valve-closing functions within the TGCS. An increase in speed above the setpoint results in the closure of the main turbine control valves and intermediate stop and intercept valves in proportion to the speed increase. Rapid turbine acceleration resulting from a sudden loss of load at higher power levels normally initiates the fast-acting solenoids via the normal speed control system. The fast-acting solenoids rapidly close the main turbine control and intermediate stop and intercept valves irrespective of the current turbine speed. The normal speed control system is designed to limit peak overspeed resulting from a loss of full load, to at least 1% below the overspeed trip set point. Typically, this peak speed is in a range of 106-109% of rated speed, with the overspeed trip set point at 110% of rated speed. All turbine steam control valves and intermediate stop and intercept valves are fully testable during normal operation. The fast-closing feature, provided by action of the fast-acting solenoids, is testable during normal operation.

If the normal speed control should fail, the overspeed trip devices close the steam admission valves including the main and intermediate stop valves. This turbine overspeed protection system comprises the second line of defense against turbine overspeed (redundant and highly reliable). The overspeed protection system is designed to ensure that failure of the normal speed control system does not result in turbine speed exceeding 120% of rated speed. In addition, the components and circuits comprising the turbine overspeed protection system are testable when the turbine is in operation.

The failure of any single component does not cause the rotor speed to exceed the emergency overspeed.

The overspeed sensing devices are located in the turbine front bearing standard and are therefore protected from the effects of missiles or pipe breakage.

The hydraulic units are fail-safe, any loss of hydraulic pressure results in a turbine trip.

The main stop valves and control valves provide full redundancy in that these valves are in series and have independent control signals and operating mechanisms. Closure of both or either stop valves or control valves effectively shuts off all MS flow to the HP turbine. The intermediate stop and intercept valves are also in series and have independent control signals and operating mechanisms. Closure of either valve or both valves in each of the two intermediate stop and intercept valves effectively shuts off steam flow to the two LP turbines. This arrangement is such that failure of a single valve to close does not result in a maximum speed exceeding 120% of rated speed. The turbine is designed for a 120% overspeed.

#### ***10.2.6.3.2 Turbine Lube Oil System Off-Normal Operation***

The DC Emergency Bearing Oil Pump starts automatically and provides the lube oil required by the turbine generator in the event that the Primary and Secondary AC Bearing Oil Pumps are inoperative or in a loss of AC power. A controlled shutdown is initiated in the event that the DC Emergency Bearing Oil Pump is the only operable pump supplying lube oil, as failure of this pump will result in loss of oil to the bearings during coast down.

### **10.2.7 Instrumentation and Control**

#### **10.2.7.1 Instrumentation**

This section describes the instrumentation associated with the MTE. Instrumentation is provided for monitoring of thermal and hydraulic parameters and initiating alarms and automatic shutdown of the turbine in the event of an unsafe condition.

##### ***10.2.7.1.1 Main Turbine Equipment***

The main turbine contains instrumentation to:

- Monitor and control system operations
- Alarm abnormal system operation

Turbine generator supervisory instrumentation is provided for operational analysis and malfunction diagnosis.

The TSV and TCV are provided with pressure transmitters on the outlet of the valves.

The turbine contains Turbine Supervisory Instrumentation which monitors the following parameters:

- Vibration and eccentricity
- Thrust bearing wear
- Exhaust hood temperature
- Bearing metal temperatures
- Shell temperature
- Valve positions
- Shell and rotor differential expansion
- Shaft speed, and control valve inlet pressure indication

- Steam chest pressure

#### **10.2.7.1.2 Turbine Gland Seal System**

TGSS pressure transmitters are provided for the following:

- GSC exhaust blower suction pressure
- Steam seal header pressure
- TASS supply pressure
- Seal Steam dump valves differential pressure

A pressure indicator and transmitter is provided for the GSC exhaust blower suction pressure. Temperature indicators and transmitters are provided for the following:

- Steam seal header temperature
- GSC exhaust blowers suction temperature

A level indicator and level transmitter is provided for the GSC.

#### **10.2.7.1.3 Turbine Lube Oil System**

The instrumentation features of the TLOS include application of pressure transmitters for the following:

- Primary AC Bearing Oil Pump discharge pressure
- Secondary AC Bearing Oil Pump discharge pressure
- DC Emergency Bearing Oil Pump discharge pressure
- Lift Oil Pump discharge pressure
- Lift Oil Pump suction pressure
- Lube Oil Transfer Pump discharge pressure
- Lube Oil Transfer Pump suction pressure
- Filter 'A' differential pressure
- Filter 'B' differential pressure
- Lube Oil Conditioner filter differential pressure
- Lube Oil bearing header supply pressure
- Lube Oil Reservoir vacuum monitoring

Temperature elements are provided for the following:

- Lube Oil Reservoir immersion heater control

Temperature elements and transmitters are provided to indicate the following:

- Cooler outlet oil temperature
- Lube Oil Reservoir temperature
- Main Turbine bearing drain oil temperature (typical for all bearings including the Thrust Bearing)

Level transmitters are provided for the following:

- Lube Oil Reservoir level

Level gauges and transmitters are provided for the following:

- Lube Oil Storage Tank clean compartment
- Lube Oil Storage Tank dirty compartment
- Lube Oil Reservoir
- Lube Oil Conditioner water drain level

Flow gauges and transmitters are provided for the following:

- Lube Oil cooler 'A' oil vent flow
- Lube Oil cooler 'B' oil vent flow
- Lube Oil filter 'A' vent flow
- Lube Oil filter 'B' vent flow
- Bearing drain oil flow
- Lube Oil Conditioner drain water flow

#### **10.2.7.1.4 Extraction Steam System**

Pressure transmitters are provided to monitor the following:

- Pressure upstream of the drain line for LP FW Heater No. 3
- Pressure upstream of the drain line for HP FW Heater No. 4
- Pressure upstream of the drain line for HP FW Heater No. 5
- Pressure at the inlet of LP FW Heater No. 3
- Pressure at the inlet of HP FW Heater No. 4
- Pressure at the inlets of HP FW Heater No. 5

Temperature elements and transmitters are provided to monitor the following:

- Temperature at the extraction inlet nozzles of LP FW Heater No. 3
- Temperature at the extraction inlet nozzles of HP FW Heater No. 4
- Temperature at the extraction inlet nozzles of HP FW Heater No. 5

Test points and transmitters are provided to test the following:

- Temperature outside the condenser, but upstream of the drain line for LP FW Heater No. 3
- Temperature upstream of the drain lines for HP FW Heater No. 4
- Temperature upstream of the drain line for HP FW Heater No. 5.

#### **10.2.7.1.5 Electro-Hydraulic Control**

Pressure transmitters are provided for the following:

- HPU pump discharge pressure

- Fuller's earth filter differential pressure
- Backup filter differential pressure
- TMA Circuit 'A' pressure
- TMA Circuit 'B' pressure
- HPU pump filter differential pressure
- Hydraulic header pressure

Temperature element, gauge and transmitters are provided for the HPU fluid reservoir temperature.

Level transmitters are provided for the following:

- HPU fluid reservoir low-low level
- HPU fluid reservoir low level
- HPU fluid reservoir high level

Level gauges, transmitters, and position elements are provided for the following:

- TMA Circuit 'A' reset position
- TMA Circuit 'B' reset position
- TMA Circuit 'A' trip position
- TMA Circuit 'B' trip position

#### **10.2.7.2 Controls**

##### **10.2.7.2.1 Main Turbine Equipment**

The following turbine system conditions are alarmed in the Main Control Room (MCR):

- Loss of speed signal
- High thrust bearing wear
- Excessive rotor/shell/differential expansion
- High exhaust hood temperature
- High condenser pressure
- Overspeed
- High vibration
- High bearing temperature
- Zero rotor speed
- High rotor eccentricity
- Power Load Unbalance

The turbine stop and control valves and the intermediate stop and intercept valves close to trip the turbine on the following signals:

- Emergency trip push buttons in control room

- High moisture separator level
- High condenser pressure
- Low lube oil pressure
- High LP turbine exhaust hood temperature
- High reactor water level
- Excessive thrust bearing wear
- Overspeed (Primary and Emergency trip systems)
- Manual trip from the front standard
- Loss of stator coolant
- Low hydraulic fluid pressure
- Any generator trip
- Loss of TGCS electrical power
- Excessive turbine shaft vibration
- Loss of two speed probes – both within the primary set, or within the emergency set
- Loss of two pressure control channels

#### **10.2.7.2.2 Turbine Gland Seal System**

TGSS MCR Alarms include the following:

- High GSC blower suction pressure
- Low steam seal header pressure
- High GSC discharge radiation
- High and low steam source temperature and pressure
- High and low GSC level

TGSS MCR displays include the following:

- Status of blowers
- Status of all steam feed valves
- Status of all steam feed isolation valves
- Steam seal header pressure and temperature
- Pressure and temperature of steam sources
- GSC blowers suction pressure

The following paragraphs describe key control features of the turbine system.

The turning gear is provided with manual and automatic controls. When in automatic control, the turning gear engages and starts upon zero turbine rotor speed and sufficient lube oil pressure and disengages at startup.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

During low load operations, the air-operated pressure control steam seal feed valve provides steam seal header pressure control using steam taken from the TASS. The TASS comes off of the MSL equalizing header which is upstream of the TSV/TCV. This valve fails open on loss of signal or air. The steam seal feed valve seals the turbine by feeding steam up to 50% rated throttle pressure operating conditions. The steam seal feed valve can also operate with 100% rated throttle pressure during a full-load rejection. The steam seal feed valve has the ability to reduce the TASS source pressure by throttling.

At light loads and startup, the seal steam dump valve is closed, and the steam seal feed valve regulates the steam seal header pressure. If required during very low steam supply pressure conditions or with worn packing clearances, the bypass is used in parallel with steam seal feed valve when operating conditions are below 50% rated throttle pressure. When TASS pressure is high enough to maintain the steam seals automatically, the bypass is closed.

A manually controlled isolation valve is located upstream of steam seal feed valve.

TASS may be used at all loads as a sealing steam source if required. Steam is supplied by the air-operated pressure control Steam Seal Auxiliary Feed Valve. A manually controlled, air-operated valve is located downstream for auxiliary steam isolation.

The valves are arranged for fail-safe operation to protect the turbine. The feed valves fail open on the loss of either signal or supply air, and the seal steam dump valve closes with diaphragm failure. If, for any reason the automatic valves are out of order, control of the steam seal header pressure is achieved by operation of the bypass.

One GSC blower is operating whenever the TGSS is in-service with the other in standby. The standby blower automatically starts on trip of the lead blower.

The blower automatically stops on detection of blower discharge high radiation level.

#### **10.2.7.2.3 Turbine Lube Oil System**

TLOS provides a signal to control cooling water through the Lube Oil Coolers based on lube oil outlet temperature.

Primary and Secondary AC Bearing Oil Pumps automatic pump control:

1. The Primary and Secondary AC Bearing Oil Pumps are arranged in parallel with only one pump operating at a time.
2. Should the operating pump fail, the standby pump automatically starts due to low discharge oil pressure.

DC Emergency Bearing Oil Pump automatic pump control:

1. Should both the Primary and Secondary AC Bearing Oil Pumps fail, the DC Emergency Bearing Oil Pump automatically starts upon low oil pressure.
2. The DC Emergency Bearing Oil Pump automatically starts upon loss of all AC power.

TLOS design includes the ability to test the LP standby start functions of the Primary and Secondary AC Bearing Oil Pumps, and DC Emergency Bearing Oil Pump. The design also includes the ability to test the trip function of the Lift Pumps.

The following primary TLOS displays include the following:

- Primary AC Bearing Oil Pump status
- Secondary AC Bearing Oil Pump status

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

- DC Emergency Bearing Oil Pump status
- Primary Lift Oil Pump status
- Secondary Lift Oil Pump status
- Lube Oil Transfer Pump status
- Main bearing oil header pressure
- Lube Oil Cooler oil discharge temperature
- Vapor Extractor status

MCR Alarms include the following:

- Low bearing header oil pressure
- Low-low bearing oil pressure (turbine trip)
- Low Lube Oil Reservoir temperature
- High Lube Oil Reservoir temperature
- Low Lube Oil Reservoir level
- Low-low Lube Oil Reservoir level
- High Lube Oil Reservoir level
- High full-flow duplex filter A/B differential pressure
- Low Primary or Secondary Lift Pump discharge pressure
- High bearing oil drain temperature
- Lube Oil Cooler high discharge oil temperature
- Any Lube Oil pump auto start
- Trip of any TLOS pump

#### **10.2.7.2.4 Extraction Steam System**

The Extraction Steam System is operated and monitored from the MCR. Extraction Steam System controls and interlocks for the main components are described below:

1. The LP extraction line motor-operated block valve located in FW Heater No. 3 extraction line is used for Turbine Water Induction Protection. It is normally open and controlled from the MCR. The LP extraction motor-operated block valve is automatically closed if the turbine trips or upon receipt of an isolation signal from any level transmitter associated with the LP FW heater. The valve is fails-as-is.
2. The HP extraction line motor-operated block valve is used for Turbine Water Induction Protection. It is normally open and controlled from the MCR. The HP extraction motor-operated block valve is automatically closed if the turbine trips, upon receipt of an isolation signal from the level transmitters associated with the affected HP FW heater, or the condensate isolation valves to the FW heater are not 100% open. The valve is fails-as-is.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

3. Each air-operated level-controlled drain-pipe block valve is normally closed. They open automatically if the extraction isolation valve is not open, upon a high-high drain level signal, upon a turbine trip, or a low turbine load. The valves fail open.
4. The air-assisted non-return check valves are used to prevent turbine overspeed. The valves are controlled by the TGCS and when a turbine trip is detected, the valve closes. The air-assisted non-return check valves are released to close when a high-high level signal is received. These valves fail close.

Extraction Steam System displays, and alarms include, but are not limited to:

1. MCR displays
  - a. Measurements from all instruments described in Subsection 10.4.7.2
  - b. Motor-operated valve position
  - c. Air-assisted check valve position
  - d. Air-operated drain valve position
  - e. FW heaters turbine water induction prevention valves in test
2. MCR Alarms
  - a. LP in the extraction line
  - b. Extraction isolation valves not 100% open
  - c. High level in the extraction drain level line

#### **10.2.7.2.5 Electro-Hydraulic Control**

The EHC system provides a signal to maintain water flow through the HPU coolers based on hydraulic fluid outlet temperature.

HPU Main Pumps automatic pump control:

1. The HPU Main Pumps are arranged in parallel with only one pump operating at a time.
2. If the operating pump fails, a drop in hydraulic fluid pressure provides a signal to automatically start the standby pump.

When the TMA system receives a signal from TGCS on a loss of pressurized fluid, the turbine hydraulic system:

1. Trips the turbine by releasing the Emergency Trip System fluid pressure below each Dump Valve at the TSV, TCV, and Intermediate Stop and Intercept Valve control solenoid
2. Trips the pilot-operated air relay dump valves to allow for fast closure of the extraction system non- return valves

The MCR displays include, but are not limited to, the following:

1. HPU Main Pumps operating parameters, including discharge pressure, operating mode, and status
2. HPU Main Pumps motor operating parameters, including current and electrical equipment status
3. Hydraulic header pressure
4. Hydraulic fluid reservoir temperature

The MCR Alarms include, but are not limited to, the following:

- Low hydraulic fluid header pressure
- Low HPU fluid reservoir temperature
- High HPU fluid reservoir temperature
- Low HPU fluid reservoir level
- Low-low HPU fluid reservoir level
- High HPU fluid reservoir level
- High HPU full-flow filter differential pressure

### **10.2.8 Monitoring, Inspection, Testing, and Maintenance**

Turbine Water Induction Prevention valve testing for feedwater heaters is performed as required.

Component level inspections consist of visual, surface, and volumetric examination as discussed below:

- Visual, magnetic particle, and ultrasonic examination of all accessible surfaces of rotors
- Visual and magnetic particle or liquid penetrant examination of all turbine blades
- Visual and magnetic particle examination of couplings and coupling bolts

The ISI of valves important for avoiding overspeed includes the following:

1. The MS TSVs and control valves, and intermediate stop and intercept valves are tested under load. Test controls installed on the MCR panel permit full stroking of the stop valves, control valves and intermediate stop and intercept valves. Valve position indication is provided on the panel. Testing considers all resulting impacts, including level disturbances in the FW heaters due to fluctuating extraction pressures.
2. MS turbine stop and control valves, and intermediate stop and intercept valves are exercised at least once within each calendar quarter (or as required by the turbine missile probability analysis) by closing each valve and observing the remote valve position indicator for fully closed position status. This test also verifies operation of the fast-close function of each MS turbine stop and control valve and intermediate stop and intercept valves during the last few percent of valve stem travel. Fast closure of the intermediate stop and intercept valves is tested in a similar way if they are required to have a fast-close function different from the test exercise. This testing frequency complies with the BWROG turbine surveillance test program.
3. Tightness tests of the MS turbine stop and control valves are performed at least once per maintenance cycle by checking the coast down characteristics of the turbine from no load with each set of two valves closed alternately or using warm-up steam as an indicator with the valves closed.
4. All MS TSVs, control valves, and intermediate stop and intercept valves are disassembled and visually inspected once during the first two refueling or extended maintenance shutdowns. Subsequent inspections are scheduled in accordance with the BWROG turbine surveillance test program. The inspections are conducted for:
  - Visual and surface inspections of valve seats, disks and stems including:
    - Wear of linkages and stem packings

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

- Erosion of valve seats and stems
- Deposits on stems and other valve parts which could interfere with valve operation
- Distortions, misalignment, or cracks
- Inspection and cleaning of valve bushings
- Confirmation of bore diameters for proper clearance

Routine testing of the TLOS is conducted in accordance with normal power plant requirements for demonstrating system and component operability and integrity. Routine testing includes tests of the AC pumps and Emergency DC pump.

Routine testing of the EHC is conducted in accordance with normal power plant requirements for demonstrating system and component operability and integrity. The EHC is tested while the turbine is online to verify the system functions properly.

### **10.2.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are As Low As Reasonably Achievable (ALARA) in operational states.

Chapter 12, Section 12.2 describes the radioactive source terms in the BWRX-300 TB. The main potential source of airborne radioactivity within the TB is leakage from valves on large lines carrying HP steam. Noble gas airborne concentrations are expected to be negligible throughout the TB except for inside the SJAE cubicles. These areas are not normally occupied during operation, and the exhaust from these cubicles is exhausted to the environment after filtration to eliminate the possibility of contamination of adjoining areas.

As stated in Chapter 11, Subsection 11.5.5.7 the Process Radiation Monitoring Subsystem (PRM) provides radiation monitoring for the Main Turbine Gland Seal Steam Condenser Exhaust flow path.

The PRM and Area Radiation Monitoring Subsystem provide general monitoring located in the TB as discussed in Chapter 11, Subsection 11.5.5.

### **10.2.10 Performance and Safety Evaluation**

The turbine generator is not needed to effect or support a safe shutdown of the reactor. The turbine is designed, constructed, and inspected to minimize the possibility of any major component failure. The turbine has a redundant, diverse, and testable overspeed trip system to minimize the possibility of a turbine overspeed event.

Instruments, controls, and protective devices are provided to confirm reliable and safe operation. Redundant, fast actuating controls are installed to prevent damage resulting from overspeed and/or full-load rejection. The control system initiates a turbine trip upon reactor trip.

The turbine generator equipment shielding requirements and the methods of access control for required areas of the TB ensure that the dose limits for operating personnel are not exceeded. All areas in proximity to TG equipment are zoned according to expected occupancy times and radiation levels anticipated under normal operating conditions.

The MTE's physical layout provides protection to essential systems and components, as required, from the effects of high and moderate energy turbine generator system piping failures or failure of the connections(s) from the LP turbine exhaust hoods to the condenser due to missile

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

protection and overspeed. Failure of turbine generator equipment does not preclude safe shutdown of the reactor systems.

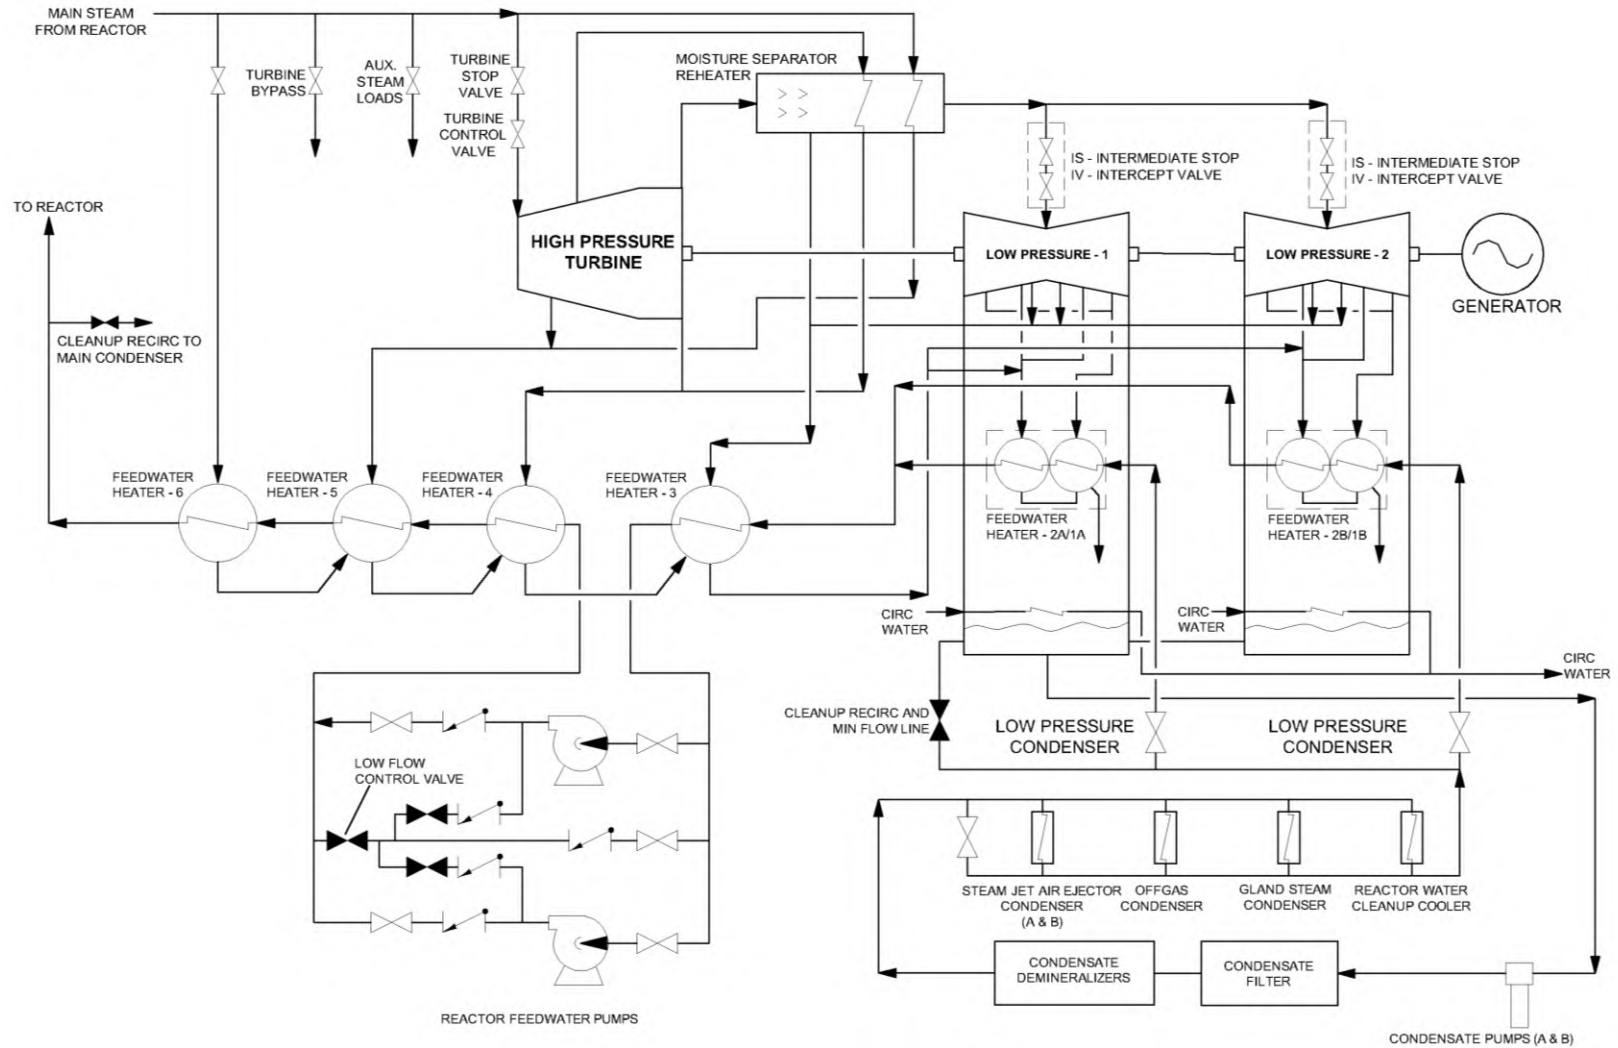

Figure 10.2-1: Power Cycle Schematic

### **10.3 Feedwater Systems**

#### **10.3.1 Condensate Filters and Demineralizer System**

The Condensate Filters and Demineralizers System (CFD) purifies the condensate to maintain reactor FW purity. The CFD uses filtration to remove suspended solids, including corrosion products, and ion exchange resin to remove dissolved solids from condenser leakage and other impurities. The CFD is a full-flow system that consists of high efficiency backwash type filters followed by mixed bed demineralizers.

##### **10.3.1.1 System and Equipment Functions**

###### **10.3.1.1.1 Normal Functions (Non-Safety Category)**

The CFD continuously operates during all modes of normal power plant operation, including startup and shutdown, receiving untreated condensate from, and supplying treated condensate to, the CFS. The CFD carries out the following functions:

1. Continuously removes dissolved and suspended solids and corrosion products from the condensate and from drains returned to the condenser hotwell, to limit accumulation of corrosion products. The series of filters and demineralizers through which FW is processed target the achievement of water chemistry requirements specified in Reference 10.3.1-2, Electric Power Research Institute, "BWRVIP-190 Revision 1: BWR Vessel and Internals Project," Volume 1, 2014, or most current version.
2. Removes impurities entering the power cycle due to condenser circulating water leaks as required to permit continued power operation within specified water quality limits as long as such condenser leaks are small. Continued operation with minor condenser circulating water leaks is controlled by site-specific chemistry threshold values.
3. Maintains the Condensate Storage Tank (CST) water quality as required for condensate makeup and miscellaneous condensate supporting services.
4. The CFD limits the entry of dissolved solids into the FW system in the event of large condenser leaks, such as a tube break, to permit a reasonable amount of time for orderly plant shutdown.
5. The CFD flow controls and bypass are arranged such that the condensate system flow is uninterrupted even in the presence of a single failure.
6. The CFD filters and removes ionic impurities from the Reactor Water Cleanup System (CUW) (Chapter 9A, Subsection 9A.2.2).

###### **10.3.1.1.2 Normal Functions (Safety Category)**

The system does not perform any Safety Category functions during normal conditions.

###### **10.3.1.1.3 Off-Normal Functions (Non-Safety Category)**

The CFD continuously operates during all modes of off-normal power plant operation, including turbine trip, low reactor load, and condenser leakage.

The CFD bypass can be used during startup and normal operations, in the event of an Anticipated Operational Occurrence resulting in a disruption of CFS flow through the CFD. The CFD bypass will remain open until the CFD flow is returned to normal, or the plant is brought to an orderly shutdown.

The CFD is not required to operate during or after a design basis event.

#### **10.3.1.1.4 Off-Normal Functions (Safety Category)**

The system does not perform any Safety Category functions during off-normal conditions.

#### **10.3.1.2 Safety Design Bases**

The CFD does not perform, ensure, or support any Safety Category function, and thus, has no safety design bases. The CFD is Non-Safety Class (SCN) and is categorized as Non-Nuclear Seismic.

The CFD is not required to operate during or after a design basis event. The design of the CFD meets CNSC requirements specified in REGDOC-2.5.2 Section 6.1 (Reference 10.3.1-1) as it relates to design for Defence-in-Depth and Section 7.1 as it relates to classification of SSC.

#### **10.3.1.3 Description**

Refer to Figure 10.3.1-1 which depicts the CFD.

CFD equipment, valves, and instrumentation are located within the Radwaste Building.

The CFD includes three (3) filter vessels, each rated at 50% of total FW flow with high efficiency backwash type filter elements arranged in parallel, complete with valves, piping, instrumentation, and filter backwash equipment. The condensate demineralizers include three (3) demineralizer vessels, each rated at 50% of total FW flow arranged in parallel, complete with valves, piping, controls, and instrumentation.

The CFD has connections to auxiliary skids and tanks to assist in tasks required to clean the condensate filters and replace spent resin in the condensate demineralizers. A fresh resin hopper is used to feed the demineralizer.

The CST transfer pumps will provide adequate pressure and condensate flow to transport resin to and from the demineralizers. The capability exists to wash resin injected into the condensate demineralizer prior to placing the demineralizer into standby mode.

The CFD is capable of handling the normal condensate flow while maintaining the required water quality.

Demineralizer influent and effluent conductivities are monitored by the Process Radiation and Environmental Monitoring System (PREMS) (Chapter 11, Section 11.5) to determine condenser leakage and resin exhaustion, respectively.

Total throughput capacity for each demineralizer and filter vessel is monitored. Flow rates of demineralizers and filters in-service are monitored and controlled.

Initial resin rinse for the mixed resins is performed in the offline condensate demineralizer tank. Rinse water is supplied from the Liquid Waste Management System (LWM) (Chapter 11, Section 11.2) CST and drained to the EFS (Chapter 9A, Subsection 9A.4.2).

Individual air-operated bypass valves are provided for both the condensate filters and condensate demineralizers. Each bypass valve is capable of handling full condensate flow.

Each bypass system includes a single automatic bypass valve with two manual isolating valves. These manual valves are used to isolate the automatic valve from the CFS.

Provisions are included to permit cleaning and replacement of the ion exchange resin. To perform the addition of new resins to the condensate demineralizers, one fresh resin hopper is included in the CFD design.

#### **10.3.1.3.1 Component Description**

The following paragraphs provide information that pertains to the major CFD components. Table 10.3.1-1 contains a summary of CFD components:

- **Condensate Filters**

The CFD includes backwash type high efficiency filters. The filters and vessels are designed to meet the requirements of ASME Boiler and Pressure Vessel Code (BPVC), Section VIII, Division 1 (Reference 10.3.1-3). The condensate filters receive condensate from the CFS and assist in purifying by filtering out suspended solids that have entered the condensate stream.

Filter vessels are constructed of corrosion resistant stainless steel or epoxy coated carbon steel.

- **Condensate Demineralizers**

Demineralizer vessels are constructed of corrosion resistant steel or lined with corrosion resistant material. The demineralizers are designed to meet the requirements of ASME BPVC, Section VIII, Division 1 (Reference 10.3.1-3). The mixed bed type condensate demineralizers receive condensate water from the CFS after being filtered by the condensate filters. The demineralizers assist in treating the condensate water by removing iron, copper, silica, and suspended solids.

- **Resin Traps**

The CFD includes resin trap housings located downstream of the condensate demineralizers. A resin trap is installed downstream of each demineralizer vessel to preclude gross resin leakage into the power cycle in case of vessel resin screen failure.

The resin traps are constructed of corrosion resistant stainless steel resin baskets.

- **Condensate Filter Bypass Valve**

A condensate filter bypass valve is provided for use during startup and in an off-normal condition until the condensate flow is returned to normal or the plant is brought to an orderly shutdown.

The condensate filter bypass valve is constructed of corrosion resistant stainless steel.

- **Condensate Demineralizer Bypass Valve**

A condensate demineralizer bypass valve is provided for use during startup and in an off-normal condition until the condensate flow is returned to normal or the plant is brought to an orderly shutdown.

The condensate demineralizer bypass valve is constructed of corrosion resistant stainless steel.

- **Air Surge Tank**

An air surge tank is provided in the CFD as a means of transporting spent resin from the condensate demineralizer drain to the Solid Waste Management System (SWM) (Chapter 11, Section 11.4) spent resin tanks. The air surge tank can also provide air for backwashing the filters when needed. The air surge tank receives air from the Plant Pneumatics System (Chapter 9A, Subsection 9A.4.1). The air surge tank is designed to meet the requirements of ASME BPVC, Section VIII, Division 1 (Reference 10.3.1-3).

- Fresh Resin Addition Hopper

The fresh resin addition hopper provides a location for storage of fresh resin before injection into a condensate demineralizer vessel.

The resin addition hopper is constructed of corrosion resistant stainless steel.

- Piping and Valves

The piping is designed to meet the requirements of ASME B31.1 for power piping (Reference 10.3.1-4) and B31.3 for process piping (Reference 10.3.1-5).

Isolation valves are provided on the inlet and outlet of each condensate filter vessel and each demineralizer vessel to allow the vessel to be out of service for backwashing, resin transfer or vessel maintenance.

Pressure taps between the automatic valve and the downstream isolation valve are used as test connections to indicate whether one of the valves is leaking.

#### **10.3.1.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials specifically through material chemistry, heat treatment, contamination, and material processes controls. CFD components are constructed of stainless steel or lined with corrosion resistant materials as applicable.

#### **10.3.1.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.3.1-2 for system interfaces.

#### **10.3.1.6 System and Equipment Operation**

The CFD is capable of performing its system functions as described in Section 10.3.1 during the modes of operation described below.

##### ***10.3.1.6.1 Normal Operational Concept***

##### **Plant Startup Mode**

The CFD is used during plant startup to clean up the condensate, and to minimize the time required to achieve low power operation of the unit. The CFD provides high purity water to the CFS. The CFS provides recirculation flow paths to assist in cleaning the condenser hotwell and facilitate achieving the desired condensate water chemistry prior to sending FW to the reactor.

##### **Plant Normal Operation Mode**

The CFD operates continuously and provides the required reactor FW quality.

The CFD is designed to operate with two online demineralizers and two online filters. Demineralizers are sequenced as necessary to prevent resin channeling. The filters are sized to allow full-load operation with one filter out of service. Each filter is capable of handling approximately 50% of normal condensate flow.

During normal operation, the condensate pump discharge is routed through the CFD. The condensate enters the filters, which removes filterable solids. The effluent from the filters passes through mixed bed ion exchange demineralizers, which are also piped in parallel (one on standby) and where removal of dissolved impurities is accomplished. Effluent from the CFD is returned to the CFS.

During normal operation the CFD is capable of completing typical resin and filter maintenance activities, including backwashing, receiving fresh resin, resin transfer, discharging exhausted resin, placing a standby filter or demineralizer into service, and removing an operating filter or demineralizer from service.

### **CFD System Bypass**

The design includes bypass facilities capable of bypassing condensate flow around the CFD to provide continuous short-term condensate flow in the event of a condition within CFD which prevents treatment of the entire condensate flow. The CFD bypass can also be used during CFS startup of the condensate pumps.

Independent bypass valves are supplied for both the condensate filters and condensate demineralizers. The filter bypass valve automatically opens based upon differential pressure across the filters. The filter bypass valve is capable of passing full condensate flow. The demineralizer bypass valve opens automatically based upon the differential pressure across the demineralizers. The demineralizer bypass valve is capable of passing full condensate flow. The demineralizer bypass valve will open upon high temperature upstream of the CFD system to prevent damage to the resin media.

### **Plant Shutdown**

The CFD is not required to be in-service during unit shutdown.

#### ***10.3.1.6.2 Off-Normal Operational Concept***

### **Turbine Trip**

During and following a turbine trip, the CFD operates continuously and provides treated condensate to the CFS.

### **Reactor Low Load**

The CFD operates continuously and provides treated condensate to the CFS under low load conditions.

### **Condenser Tube Leak**

The CFD limits the entry of dissolved solids into the CFS and, in the event of a tube break, allows a reasonable amount of time for orderly plant shutdown.

#### **10.3.1.7 Instrumentation and Control**

The following defines some Instrumentation and Controls (I&Cs) required for system operation and control. Most operations are through the MCR and the following indications, alarms and controls are provided but are not limited to the items below.

Differential pressure transmitters are provided to monitor pressure drop across:

- The effluent and inlet filter vessel headers
- Individual filter vessels
- Effluent and inlet demineralizer vessel headers
- Individual demineralizer vessel
- Each demineralizer resin trap

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

Flow transmitters are provided to monitor flow through:

- Each filter
- Each demineralizer vessel
- The demineralizer sluice water supply header
- The combined influent header of the condensate filters
- The combined influent header of the demineralizers

Temperature elements and transmitters are provided to monitor:

- The CFD inlet temperature
- The demineralizer sluice supply header temperature

Pressure transmitters are provided to monitor pressure of:

- The filter backwash water supply header
- Air supply header to the air surge tank
- Combined effluent header of demineralizers
- Service air supply header for resin transfer

The following defines the basic controls required for system operation and control.

The MCR is equipped with the appropriate instruments and controls to allow an operator the ability to perform the following operations as directed by procedure:

- Monitor filters and demineralizers in normal operation
- Control the filters and demineralizers in their various operating modes
- Remove a saturated filter from service
- Clean up the isolated filter by backwashing and place it back in operation
- Remove an exhausted demineralizer from service and replace it with a standby unit
- Transfer the resin inventory of the isolated demineralizer vessel into the spent resin tank for disposal
- Wash resin within an isolated demineralizer via slow water washing
- Transfer the fresh resin to any isolated demineralizer vessel

Interlocks are provided for the following:

- To prevent feed into a demineralizer with a high differential pressure across the demineralizer inlet isolation valve
- To prevent high temperature feed to demineralizers
- To open the bypass in case of high differential pressure across the condensate filters or demineralizers
- To prevent sending waste backwash water from the filter to the SWM if the SWM is unavailable

Conditions for the condensate filters are alarmed in the MCR:

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

- High influent conductivity (monitored by PRM)
- High differential pressure across condensate filter system
- High differential pressure across individual condensate filters

Conditions for the condensate demineralizers are alarmed in the MCR:

- CFD influent temperature high
- High differential pressure across condensate demineralizer system
- High conductivity at the outlet of each demineralizer vessel (monitored by PRM)
- High conductivity at the common effluent from the demineralizers (monitored by PRM)
- High differential pressure across each demineralizer
- High differential pressure across each demineralizer effluent resin trap

The following signals for the condensate filters are monitored in the MCR:

- Condensate filter status
- Condensate filters common inlet conductivity (monitored by PRM)
- Individual condensate filter flow and totalization
- Differential pressure across condensate filters
- Condensate filter combined effluent flow

The following signals for the demineralizers are monitored in the MCR.

- Condensate demineralizer status
- Condensate demineralizer flow and totalization
- Condensate demineralizer system differential pressure
- Condensate demineralizer vessel differential pressure
- Differential pressure across resin trap
- CFD inlet header temperature
- Condensate demineralizer effluent conductivity (monitored by PRM)
- Condensate demineralizers combined effluent conductivity (monitored by PRM)

#### **10.3.1.8 Monitoring, Inspection, Testing, and Maintenance**

Section 10.3.1.7 identifies some conductivity measurements that are monitored by PRM.

Pre-operational tests are performed on the CFD to ensure operability, reliability, and integrity of the system. Each filter and demineralizer vessel can be isolated during normal plant operation to permit testing and maintenance. Filters can be backwashed remotely.

Isolation valves are provided on the inlet and outlet of each condensate demineralizer vessel to allow the vessel to be out of service for backwashing, resin transfer, or vessel maintenance. CFD capacity is designed to allow full power operation with one condensate filter or demineralizer out of service for maintenance.

The equipment and components of the CFD are designed for ease of inspection and maintenance during plant operation. Routine testing of the CFD is conducted in accordance with normal power plant requirements for demonstrating system and component operability and integrity.

The CFD design provides equipment removal paths and personnel access for maintenance. Shielding is provided to protect personnel from the concentration of radioactive material (activated corrosion products and fission products that are carried over from the reactor) in filters, demineralizers and other CFD equipment.

#### **10.3.1.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states.

Shielding is provided to protect personnel from the concentration of radioactive material (activated corrosion products and fission products that are carried over from the reactor) in filters, demineralizers and other CFD equipment.

#### **10.3.1.10 Performance and Safety Evaluation**

The CFD is capable of performing its system functions during the modes described in Subsection 10.3.1.6. The CFD does not perform any Safety Category functions during normal and off-normal conditions and therefore does not require a safety evaluation.

NON-PROPRIETARY INFORMATION

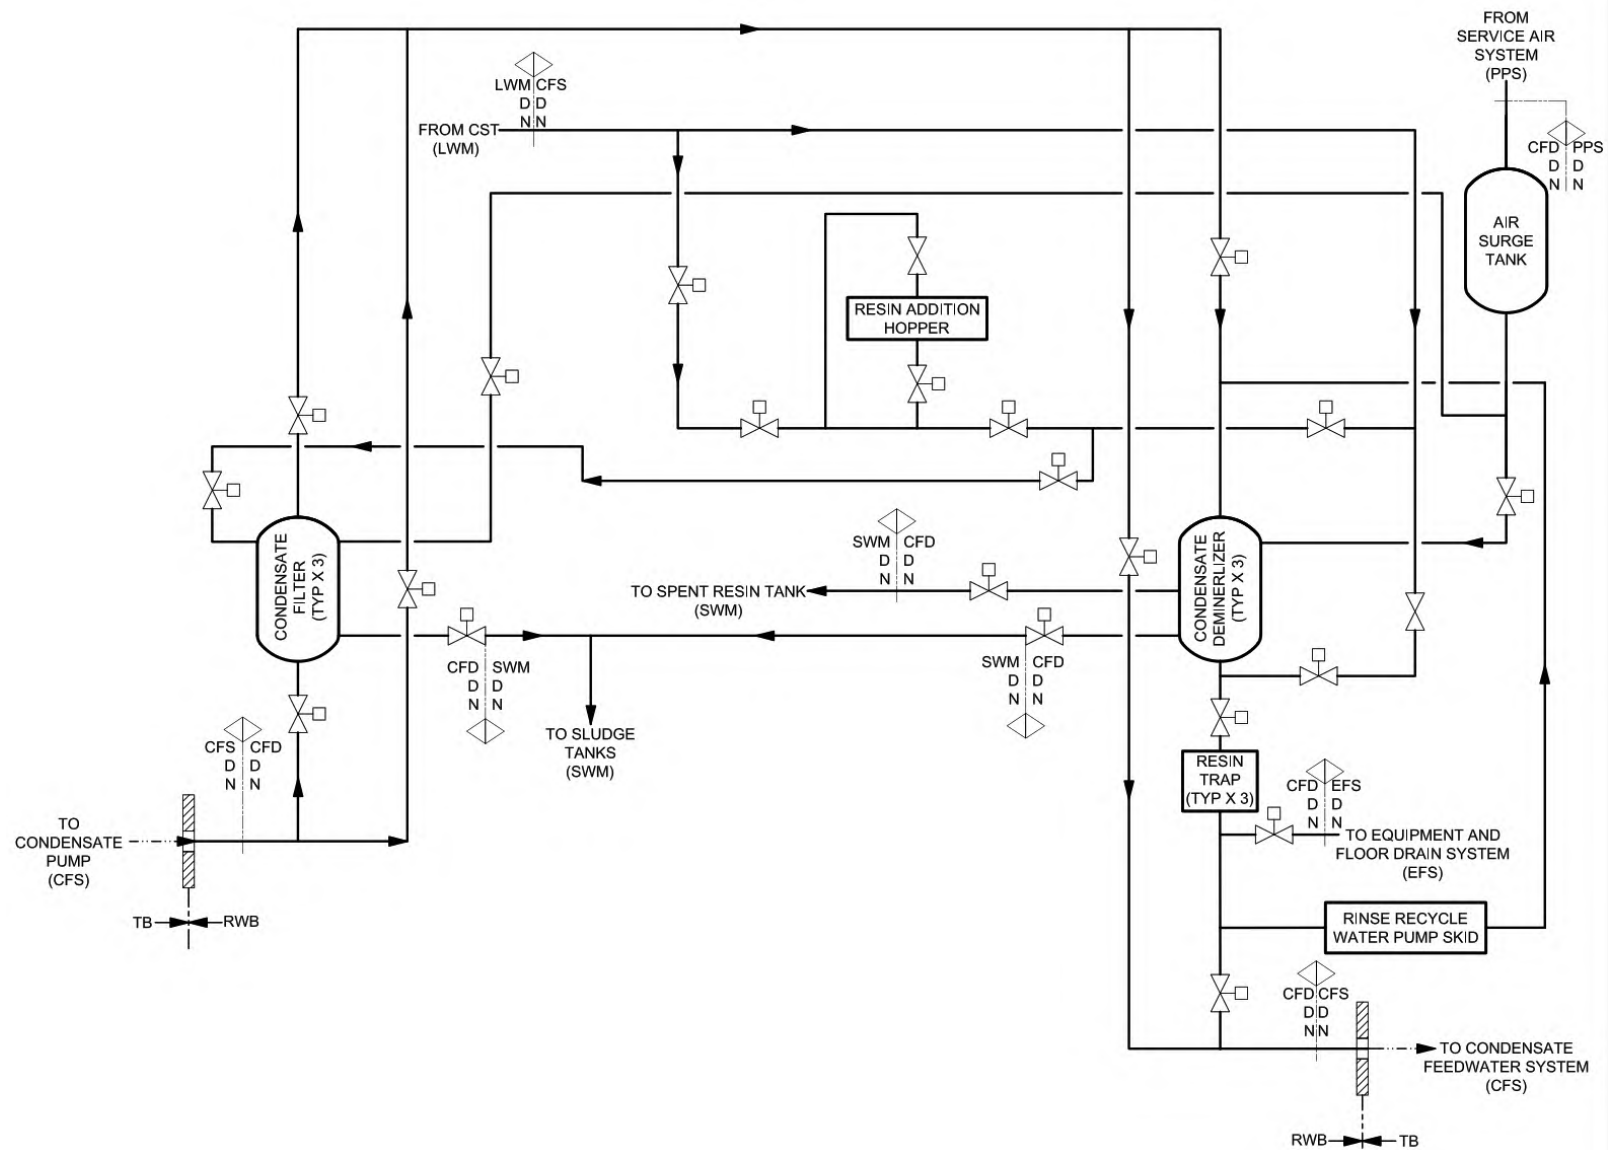

Figure 10.3.1-1: Condensate Filters and Demineralizer System

### **10.3.2 Condensate and Feedwater Heating System**

The condensate portion of the CFS is designed to pump condensate from the main condenser hotwell through the CFD and three stages of LP FW heating to the suction side of the reactor feed pumps. The FW portion of CFS is designed to pump FW through three stages of HP FW heating and deliver the FW to the reactor inlet nozzles.

#### **10.3.2.1 System and Equipment Functions**

##### **10.3.2.1.1 Normal Functions (Non-Safety Category)**

The CFS provides the following Non-Safety Category functions during normal conditions:

1. Provides vent paths for vapor and non-condensables in the closed FW heaters

##### **10.3.2.1.2 Normal Functions (Safety Category)**

The CFS provides the following Safety Category functions during normal conditions:

1. Supplies subcooled FW to the NBS to maintain the operating reactor water level band in the RPV whenever the condenser is available to reject decay heat.
2. Controls the steam demand to the 6th stage FW heater to automatically control the final FW temperature. This includes measuring final FW temperature.
3. Raises the temperature of the FW through FW heaters.
4. Provides normal and alternative drain paths for condensed steam in the FW heaters.
5. Supplies condensate to the Control Rod Drive (CRD) system.

##### **10.3.2.1.3 Off-Normal Functions (Non-Safety Category)**

The CFS does not provide any Non-Safety Category functions during off-normal conditions.

##### **10.3.2.1.4 Off-Normal Functions (Safety Category)**

The CFS provides the following Safety Category functions during off-normal conditions:

1. CFS provides the capability to measure FW pressure.
2. CFS provides the capability to modulate the flow of FW to the reactor for the purpose of reactor level control, based on signals from I&C systems.
3. Continues to supply condensate water following a single condensate pump trip.
4. Continues to supply FW following a single FW pump trip.
5. CFS provides the capability to monitor the operational status of the condensate and FW pumps.
6. CFS FW pump in standby will start when signaled to do so by I&C systems.
7. CFS provides the sensors to measure final FW temperature.
8. CFS provides the sensors to detect a FW line break outside containment.
9. CFS provides containment and system isolation of CFS piping penetrating the primary containment and will close when demanded from the SC1 I&C System or SC2 and SC3 I&C System.
10. CFS provides the capability to measure FW flowrate.

### **10.3.2.2 Safety Design Bases**

The CFS system is primarily SC3. The CFS provides for closure of the containment isolation valves (CIV)s and system isolation valves when signaled to do so as discussed in Section 10.3.2.1. The containment isolation components, system isolation components, leak detection components, and flow measuring devices are SC1. Containment isolation is provided in accordance with REGDOC-2.5.2 Section 8.6.6 (Reference 10.3.2-1).

Codes and standards related to pressure boundary and seismic classification are identified in the component descriptions in Subsection 10.3.2.3.1 as applicable.

The standby condensate and FW pumps will start when signaled to do so by the SC2 and SC3 Instrument and Control System. In support of this function, the CFS provides the capability to monitor the operational status of the FW pumps.

The CFS modulates FW flow to the vessel to control reactor vessel level.

The CFS provides for measurement of FW flow to provide input to the SC1 Instrument and Control System.

CFS measures final FW temperature and pressure and provides this information to the SC2 and SC3 Instrument and Control System.

CFS provides sensors to detect a FW line break outside containment.

CFS provides containment isolation of CFS piping penetrating the primary containment and will close when signaled to do so from the SC1 Instrument and Control System.

CFS provides system isolation of CFS piping penetrating the primary containment and will close when signaled to do so from the SC1 Instrument and Control System.

### **10.3.2.3 Description**

Figure 10.3.2-1 and Figure 10.3.2-2 depict the CFS flow diagrams. Figure 10.3.2-3 and Figure 10.3.2-4 depict CFS heaters and vents associated with the CFS.

The CFS is located in the TB, Reactor Building and Containment. During normal operation, the CFS provides a continuous supply of purified condensate water to the NBS (Chapter 5) at the required temperature, pressure, and flowrate.

The CFS consists of two (2) 100% capacity condensate pumps, three (3) LP FW heaters arranged series, one (1) Low Flow Control Valve, two (2) 100% capacity reactor FW pumps, three (3) HP FW heaters arranged in series, bypass valves around LP Heaters No. 1 and No. 2 and HP FW heater, piping, valves, and instrumentation.

A condensate pump discharge header connects the CFS to the CFD (Subsection 10.3.1). The CFS provides cooling to the CUW (Chapter 9A, Subsection 9A.2.2) heat exchanger, SJAЕ intercondensers, TGSS condenser, and offgas condenser. The CFS provides condensate water to the condenser hood spray, CRD pumps, and the CST for high level control in the condenser. A recirculation line to the main condenser is equipped with a control valve that connects to the auxiliary condensate loop downstream of the TGSS condenser is provided to ensure condensate minimum flow and auxiliary condenser cooling.

Downstream of the auxiliary condensate loop, FW heaters are provided for condensate and FW temperature control. Condensate pumps and FW pumps are provided to meet rated pressure and flowrate entering the NBS. The condensate pump minimum flow/short cycle cleanup line provides water inventory control during multiple operating modes, in addition to the minimum flow and cleanup functions.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

The shell side of the FW heaters drain in a cascading order from FW Heater No. 6 to FW Heater No. 1.

The final stage HP FW heater (No. 6) accommodates final FW temperature control during power operation and power maneuvering. It comes in-service gradually from 70-90% power. The final stage HP FW heater is fully in-service to raise FW temperature when power is above 90% to increase stability margins.

The main FW line also connects to the long cycle cleanup recirculation path line back to the main condenser.

A final FW strainer is installed to minimize debris entry into the NBS. The strainer is placed downstream of FW Heater No. 6 and upstream of the FW measurement devices. Downstream of the HP FW heaters, the FW line divides into two (2) FW lines that pass through the containment via a system and CIV. Inside containment, each of these lines splits again into a total of four (4) lines that connect to the reactor via the NBS FW reactor isolation valves.

The SDC (Chapter 9A, Subsection 9A.2.3) return lines connect to the FW lines upstream of the outboard CIVs. SDC uses the CFS containment penetrations to reduce the total number of containment penetrations.

The CFS design follows recommended practices for prevention of water damage to steam turbines and prevention of excessive corrosion/erosion damage due to flashing liquid flow (Subsection 10.2.3.3). The system capacity allows for continuous long-term power plant operation with either an HP FW heater or LP FW heater out of service.

#### **10.3.2.3.1 Component Description**

The following paragraphs provides descriptive information specific to the major equipment in the CFS. Table 10.3.2-1 summarizes major components in the CFS.

#### **Condensate Pumps**

The CFS consists of two (2) 100% capacity condensate pumps.

The condensate pumps are located below the normal water level of the main condenser hotwell to ensure the pump suction remains flooded. Each condensate pump has an individual suction line and is equipped with an anti-vortex device. A permanent suction strainer is provided on the suction of the condensate pumps to remove larger debris from the condensate to protect the pumps.

A condensate pump discharge header connects the CFS to the CFD (Subsection 10.3.1).

#### **Low Pressure Feedwater Heaters**

The stage 1 and 2 duplex LP FW heaters are located within each condenser neck.

LP FW Heaters No. 1, No. 2, and No. 3 are closed FW heater types, designed in accordance with ASME BPVC, Section VIII, Division 1 (Reference 10.3.2-2), and the Heat Exchange Institute Standards.

The FW heater tubes and tubesheets are corrosion resistant stainless steel. Tube to tubesheet joints are welded. The FW heater internal vent piping is also constructed of corrosion resistant stainless steel. The FW heater shell material considers the effects of corrosion product metals to minimize deposits on fuel.

FW Heater No. 3 is designed for 100% of the plant condensate flow and duty. FW Heater No. 1 and No. 2 are designed for 50% of the plant condensate flow and duty.

### **High Pressure Feedwater Heaters**

Three (3) HP FW heaters are provided. The HP FW heaters are horizontal U-tube type heat exchangers with integral drain cooler. Each HP FW heater is designed for 100% of the plant FW flow.

The FW heater tubes and tubesheets are corrosion resistant stainless steel. Tube to tubesheet joints are welded. The FW heater internal vent piping is also constructed of corrosion resistant stainless steel. The FW heater shell material considers the effects of corrosion product metals to minimize deposits on fuel.

The FW heaters are designed in accordance with ASME BPVC, Section VIII, Division 1 (Reference 10.3.2-2), and Heat Exchange Institute Standards.

Downstream of the HP FW heaters, the FW line divides into two (2) FW lines that pass through the containment via a system and CIV. Inside containment, each of these lines splits again into a total of four (4) lines that connect to the reactor via the NBS FW reactor isolation valves. The main FW line also connects to the long cycle cleanup recirculation path line back to the main condenser.

### **Feedwater Pumps**

Two (2) FW pumps, driven by an electrical motor and powered by an Adjustable Speed Drive, are sized for 100% of the total rated FW flow, plus margin for control. One (1) pump is in operation while the other is on standby.

The FW pumps are located on grade elevation of the TB.

A bypass is provided around the FW pumps to permit FW supply to the reactor during early startup using only the condensate pumps as well as during preparation for outage leakage tests. During startup, a Low Flow Control Valve is used to control the RPV level.

### **Piping and Valves**

The CFS CIVs and piping are SC1 and are designed to ASME BPVC, Section III, Class 2 (Reference 10.3.2-3).

To ensure containment integrity at the primary vessel containment penetrations, the containment piping and isolation valves, and the CFS piping upstream of the CIVs to and including the system isolation valves are designed to Seismic Category A; Boiler and Pressure Vessel Code, Section III, Division 1-Subsection NCD; and Quality Group B requirements.

The CFS piping upstream of the system isolation valves is designed SC1, ASME Section III, Class 2 up to and including the seismic restraint upstream from the system isolation valve. The CFS piping upstream from the seismic restraint, located upstream of the system isolation valve, is classified as SC3, Quality Group D, Non-Nuclear Seismic Category, and designed to meet the requirements of ASME Code for Pressure Piping B31.1, Power Piping (Reference 10.3.2-4).

The CFS piping and valves are constructed of corrosion resistant stainless steel.

The low flow level control valve is capable of controlling condensate flow smoothly at low power levels.

The layout of the CFS and the characteristics of the valves is such that water hammer loads are below the reactor design limits. The design of the CFS complies with NUREG-0927 (Reference 10.3.2-5).

The normal and alternate drain control valves on the shell side of the FW heaters are located to minimize flashing upstream of the control valve under any load or drain flow condition and materials are selected to be compatible with any flashing conditions.

Refer to Chapter 3, Section 3.9 for information pertaining to equipment qualification of BWRX-300 SSC.

#### **10.3.2.4 Materials**

The CFS is designed to avoid FAC damage. The design and layout of the piping system considers the effects on the piping material of fluid velocity, bend location and the location of flash points. The selection of piping layout, velocity and material is based on successful operating experience.

#### **10.3.2.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.3.2-2 for system interfaces.

#### **10.3.2.6 System and Equipment Operation**

##### ***10.3.2.6.1 Normal Operational Concept***

##### **Startup Mode**

The CFS is started by first placing the condensate portion of the system in service. Condensate is sent through the CFD and then returned to the main condenser through the condensate pump minimum flow recirculation line for short cycle cleanup.

The CFD is aligned in the bypass mode and the condensate pump minimum flow control valve is opened. The condensate pumps are started and the CFD is placed in-service before the CFD bypass valve is closed. The minimum flow bypass valve modulates as the proper flow rates and pressure drops are established in the CFD. Condensate from the condenser hotwell is recirculated through the auxiliary condensate loop and min flow/cleanup line until the required water quality is achieved. Condensate may be recirculated through the short cycle cleanup line to establish condensate quality in the hotwell.

When the required condensate quality has been achieved, flow is directed through the LP and HP FW heaters and associated piping by establishing flow through the long cycle cleanup line.

A bypass is provided around the FW pumps to permit FW supply to the reactor during early startup using only the condensate pumps as well as during preparation for outage leakage tests. During startup, a Low Flow Control Valve is used to control the RPV level.

FW pumps may be started when the required condensate purity levels are reached, and adequate pressure is provided to the FW pump suction. FW flows through the HP FW heaters and back to the condenser through the FW pump recirculation valve in long path cleanup mode.

The FW cleanup flowpath is used to recycle the condensate and FW through the CFD before admission to the reactor core.

Normal and alternate drain line control valves modulate as required to maintain water levels in the closed FW heaters based on the signals from the corresponding level transmitters.

##### **Recirculation/Cleanup Mode**

The CFS is designed to enable the entire condensate and FW water volume (including the hotwell and LP & HP FW heaters) to be recirculated via the CFD before plant startup, ensuring proper water quality before admission to the reactor.

The CFS cleanup process is carried out using the condensate pumps to clean the condensate subsystem and using the FW pumps operating at lower speed to clean the FW subsystem.

The water inventory in the CST may also be cleaned by circulating through the hotwell using the hotwell makeup and condensate reject lines.

### **Normal Plant Operation**

The CFS is normally operated with one (1) condensate pump operating and one (1) on standby and one (1) FW pump operating and one (1) on standby. All LP and HP FW heater isolation valves are normally open. The LP FW heaters bypass valves and the HP FW heaters bypass valves are normally closed.

During power operation, reactor vessel water level is controlled by the Reactor Level Control System (RLC) (Chapter 7, Subsection 7.3.3.2). At higher powers, typically above 25%, RLC controls FW flow and thus reactor water level by adjusting FW pump speed. At lower powers the RLC controls the position of the Low Flow Control Valve based on target reactor water level.

The CFS continuously drains the condensed HP and LP extraction steam in a cascading setup from FW Heater No. 6 to FW heaters 1 A/B and then the condenser hotwell. Normal and alternate drain line control valves will maintain water level in each HP and LP FW heater based on the signal from the corresponding level transmitters.

The CFS continuously vents vapor and non-condensables from the closed FW heaters to the main condenser.

#### **10.3.2.6.2 Off-Normal Operational Concept**

### **Condensate Pump Trip**

The CFS is normally operated with one condensate pump operating and one on standby. In the event of a condensate pump trip, the standby pump starts to continue supplying condensate to the FW pump suction and RPV. The CFS has built-in logic to immediately start the standby pump to minimize the system transients to the system and RPV.

### **Feedwater Pump Trip**

The CFS is normally operated with one FW pump operating and one on standby. In the event of a FW pump trip, the standby pump starts to continue supplying FW to the RPV. The CFS has built-in logic to immediately start the standby pump to minimize the transients to the system and RPV.

### **One LP or HP Feedwater Heater Out of Service or Isolated**

The CFS can be operated with one LP FW heater or one HP FW heater out of service by closing the FW heater inlet and outlet isolation air-operated valves and opening the air-operated FW heater bypass valve. The FW heater bypass valve is fully opened prior to isolation of one of the LP FW heaters or HP FW heaters.

The Extraction Steam System (Subsection 10.2.3.11) HP or LP extraction isolation valves for the affected heater close, the non-return valves for the affected heater (release to close), and the extraction steam drain isolation valves for the affected heater open, providing a path to the main condenser. The Extraction Steam System supplies steam to Heaters No. 1 A/B through Heater No. 5.

The steam supply for Heater No. 6 is from the MS subsystem (Section 10.4). When the heater is out of the service, the steam supply isolation valve closes and the steam drain isolation valves open, providing a path to the main condenser.

The CFS provides signals indicating that valves are closed to the SC2 and SC3 I&C System to provide automatic reactor power reduction upon isolation of one of the LP FW heaters or HP FW heaters.

### **10.3.2.7 Instrumentation and Control**

This section describes some I&Cs required for system operation and control.

Instrumentation is provided to verify condensate and FW pumps, as well as FW heater performance. Provisions include instrumentation to provide input to the plant heat balance.

Differential pressure transmitters are provided to monitor the following parameters:

1. LP and HP FW heater differential pressure
2. Differential pressure across the FW Low Flow Control Valve

Flow transmitters are provided to monitor the following parameters:

1. The discharge flow in the condensate pump header. The measurement is used to modulate the valve on the minimum flow/short cycle cleanup line. It is also used to trip the pump when flow through the pump is below a preset value.
2. Flow is measured at each main FW pump discharge and each main FW pump minimum flow recirculation line. This allows for measurement of the total FW flow from each pump.
3. The FW supply line to the reactor water flow. The measurement is used to determine the FW supply to the reactor. The signals from the flow transmitter are used by the FW Control System to control reactor level by adjusting the FW pump speed.

Pressure transmitters are provided to monitor the following parameters:

1. Suction and discharge pressure of each condensate pump
2. Pressure at the inlet of the auxiliary condensate loop.
3. The suction pressure and discharge pressure of each FW pump. The suction flow pressure measurement is also used to control the corresponding pump minimum flow control valve and to alarm and trip the pump when the pressure is below a preset minimum value
4. Pressure for the FW supply line to the reactor (each branch)
5. Normal drain outlets of the closed FW heaters
6. FW heater shell pressure.

Temperature is monitored in the following system locations:

1. Each Condensate pump suction and discharge
2. Each FW heater inlet and outlet line
3. FW temperature in each FW line to the reactor. These temperature measurements are provided in each FW line to the reactor to determine the reactor FW inlet temperature and to monitor the temperature difference. These temperature measurements are also used as part of the control scheme to control the final FW temperature

Vibration transducers and monitoring equipment are provided for the condensate pumps and FW pumps in accordance with API 670 (Reference 10.3.2-6). Vibration level control limits are in accordance with API 610 (Reference 10.3.2-7).

#### **10.3.2.8 Monitoring, Inspection, Testing, and Maintenance**

The equipment and components of the CFS are designed to support inspection and maintenance activities.

Routine testing of the CFS is conducted in accordance with normal power plant requirements for demonstrating system and component operability and integrity. Suitable access and/or remote functions to permit in-service testing and inspection of the FW piping are provided. ISI accessibility is provided by appropriate arrangement of piping and major equipment.

For the portion of the system that is ASME Class 2, accessible arrangement of vents and drains in the system comply with ASME Code Section XI (Reference 10.3.2-8) requirements for the performance of ISI and testing for assessing operational readiness.

CFS piping and valves for the containment penetrations are tested in accordance with 10 CFR 50, Appendix J and REGDOC-2.5.2 (Reference 10.3.2-1). Test and vent connections are provided at the CIVs to validate local leak rate limits.

#### **10.3.2.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states.

#### **10.3.2.10 Performance and Safety Evaluation**

The CFS is capable of performing its design functions as presented in Subsection 10.3.2.1, during the modes of operation when the system is intended to function. To ensure containment integrity at the Steel-plate Composite Containment Vessel penetrations, the CIVs, and piping are designed to Seismic Categories A and B respectively; and to the requirements of the ASME BPVC, Section III, Division 1-Subsection NCD.

## **10.4 Main Steam System**

The MS is a subsystem of the NBS. This section describes the MS subsystem from the non-safety ASME B31.1 piping interface with the ASME BPVC, Section III, Class 2 piping downstream of the SC1 Seismic Interface Restraint (SIR), to the TSVs (Subsection 10.2.3.1), the TBVs, the MSL drains, and other load isolation/maintenance valves. The lines to these loads, all connecting branch lines up to and including their respective isolation valves, and all associated piping supports are also part of the MS subsystem.

Information pertaining to the MS subsystem from the outboard side of the outboard MS Reactor Isolation Valves up to and including the SIR is addressed in Chapter 5.

### **10.4.1 System and Equipment Functions**

The system and equipment functions associated with the MS subsystem are identified below.

#### **10.4.1.1 Normal Functions (Non-Safety Category)**

The MS subsystem described in this section performs the following Non-Safety Category functions:

1. As a subsystem of the NBS, it contributes to the ability to produce the steam flow capacity and conditions to the main turbine for electric power production.
2. As a subsystem of the NBS, it contributes to the transport of steam generated in the RPV to the main turbine for electric power production in Mode 1.

#### **10.4.1.2 Normal Functions (Safety Category)**

The MS subsystem described in this section does not perform any Safety Category functions during normal conditions.

#### **10.4.1.3 Off-Normal Functions (Non-Safety Category)**

The MS subsystem described in this section does not perform any Non-Safety Category functions during off-normal conditions.

#### **10.4.1.4 Off-Normal Functions (Safety Category)**

The MS subsystem described in this section does not perform any Safety Category functions during off-normal conditions.

### **10.4.2 Safety Design Bases**

The design of the MS System meets CNSC requirements specified in REGDOC-2.5.2 Section 8.3 as it relates to the steam lines, Section 6.1 (Reference 10.4-1) as it relates to design for Defence-in-Depth and Chapter 7, Section 7.1 as it relates to classification of SSC.

### **10.4.3 Description**

Figure 10.4-1 depicts the MS subsystem.

This section describes the portion of the MS subsystem located downstream of the ASME BPVC, Section III, Class 2 piping interface with the ASME B31.1 piping. Two MSLs are routed to the TSVs, the equalizing header, and the MSL drains.

The MS equalizing header is designed to be located as close as practical to the TSVs and at least as large in diameter as a single main steam line. The MS equalizing header supplies high pressure steam via branch piping to the TBVs, the MSR, the FW Heater No. 6, and the TASS.

The MSL drains drain condensate from the MSLs to the main condenser during startup, low power operation, normal power operation, and shutdown. A reduction in power below 40% Rated

Thermal Power (RTP) results in the automatic opening of drain line valves, thereby establishing drain flow to the main condenser.

Subsections 10.7.6 and 10.2.6 provide information related to RPC during startup and normal operation respectively. In addition, Chapter 6, Subsection 6.2.2 provides information pertaining to overpressure protection.

#### **10.4.3.1 Component Description**

##### **10.4.3.1.1 Main Steam Lines**

MSLs are designed to mitigate acoustic loads generated as a result of NBS and interfacing system configuration such that their impact on system functional capabilities and material condition is acceptable.

The MS piping in the TB is designed to ASME B31.1 (Reference 10.4-2), Non-Nuclear Seismic Category requirements including all the connecting branch lines up to the various steam loads including their respective isolation valves.

The MS subsystem piping has a design pressure of 10.342 MPaA (1500 psig) and design temperature of 314.4°C (598°F). It is sized to limit steam velocities at full power steady-state operating conditions (to limit the effects of flashing, noise, vibration, water/steam hammer, and erosion).

The MS system is designed so that the pressure drop through the piping at 100% RTP condition does not exceed the minimum and maximum limits.

NBS is designed so that the pressure downstream of the outboard MSCIV is equal to or greater than the pressure specified for standard plant operating conditions with 10% margin.

##### **10.4.3.1.2 Main Steam Line Drains**

The MS drain lines provide the ability to drain the condensate from the MSL to the condenser in a controlled manner during startup, lower power operation (approximately 40% RTP for the bypass drain valves), normal power operation, and shutdown.

Drains are at low points or catch-points to drain condensate back to the main condenser.

The drain line isolation valves on MSL drain lines fail open. The drain lines contain an orifice and an in-line strainer.

#### **10.4.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components, corrodents and mitigating the degradation of materials specifically from corrosion (as applicable) through material chemistry, heat treatment, contamination, and material processes controls.

#### **10.4.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.4-1 for system interfaces.

#### **10.4.6 System and Equipment Operation**

Chapter 5, Subsection 5.3.3 describes NBS operations. The subsections below focus on operations of the MS subsystem in each of the facility modes.

##### **10.4.6.1 Initial Configuration (Pre-Startup)**

System configuration is established per plant procedures.

#### **10.4.6.2 System Startup**

Chapter 5, Subsection 5.3.4.2 describes NBS startup. The MSL drains remain open to approximately 40% RTP to remove excess moisture carryover during NBS startup operations.

#### **10.4.6.3 Normal Operations**

Chapter 5, Subsection 5.3.4.3 describes normal operations of the NBS system. During normal operations, the MS subsystem continues to transport steam generated in the RPV that passed through containment from the RPV nozzles through the MS Reactor Isolation Valves and MSCIVs to provide the steam power needed to drive the main turbine. Steam is directed through the open maintenance block valves to the MSR, FW Heater No. 6, and TASS. MSL drain line valves open and close as a function of the level of condensed steam in the drain pot up to about 40% power where they are closed.

During power operation, the NBS also vents non-condensable gases generated in the RPV through the RPV head vent to the MS piping.

#### **10.4.6.4 Off-Normal Operations**

Chapter 5, Subsection 5.3.4.4 describes planned and unplanned transients for the NBS system. Transients that lead to reductions in power to 40% or less result in automatic opening of the drain line valves to the main condenser.

Unplanned transients are listed in the fault list described in Chapter 3, Appendix 3A.

#### **10.4.6.5 System Shutdown**

Chapter 5, Subsection 5.3.4.5 describes NBS system shutdown consisting of hot shutdown, stable shutdown, and cold shutdown. Normally, the reactor design is to be cooled down from the hot shutdown condition by opening one or more TBVs to direct steam to the main condenser. Opening of a TBV reduces pressure in the reactor and the steam lines. The reactor coolant is flashed to steam, which flows through the MSLs and the TBVs and ultimately to the main condenser.

The MS drain lines provide the ability to drain the condensate from the MS lines to the condenser in a controlled manner during startup, lower power operation (approximately 40% nuclear boiler rated for the drain valves), normal power operation, and shutdown.

#### **10.4.7 Instrumentation and Controls**

The I&Cs for the MS subsystem within the NBS described in Chapter 5 consists of the following:

1. Chapter 7, Subsection 7.3.3 describes the I&Cs for the RPC system.
2. The TB contains MSL leak detection instrumentation. This instrumentation is designed to fail-safe as the TB is a Non-Nuclear Seismic structure.
3. The MSL drain isolation valves have control logic interlocked to support automatic plant startup and shutdown operation.
4. Pressure transmitters are provided and located on the MSLs near the equalizing header in the TB to monitor steam line parameters.

#### **10.4.8 Monitoring, Inspection, Testing, and Maintenance**

Piping and components are inspected and tested in accordance with the requirements of ASME B31.1 (Reference 10.4-2). Areas requiring inspections are provided with access spaces/routes and with removable and reusable insulation coverings.

The MS equalizing header arrangement upstream of the TSVs allows for online testing.

#### **10.4.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states.

#### **10.4.10 Performance and Safety Evaluation**

Components and piping for the MS subsystem described in this section are designed in accordance with the ASME B31.1 code (Reference 10.4-2). MSLs are designed to ensure there are no negative interactions between lines. This ensures that the MS subsystem can accommodate operational stresses resulting from static and dynamic loads, including water (steam) hammer and includes provisions to limit water entrainment. Operating and maintenance procedures include adequate precautions to minimize the potential for water (steam) hammer.

The break of a MSL does not result in offsite radiation exposures in excess of the site limits as discussed in Chapter 15, Subsection 15.5.9.2.1.

NON-PROPRIETARY INFORMATION

**Table 10.4-1: Main Steam System Subsystem Interfaces**

Interface System	Interface Description	Interface Boundary
Non-Safety Instrumentation and Control System	The Non-Safety DCIS along with plant automation functions provide a distributed control and instrumentation data communication network to support non-safety portion of MS subsystem.	Interface is at the Non-Safety DCIS termination cabinet
Process Radiation and Environmental Monitoring System	In the event of a large steam line pipe break outside containment, the plant's PREMS is designed to continuously monitor to detect such an occurrence.	PREMS Termination Cabinets
Condensate and Feedwater Heating System	MS subsystem provides 32.54 kg/s (0.2583 Mlbm/hr) steam from the MSLs to the FW Heater No. 6.	NBS block valve to CFS piping to FW Heater No. 6
Main Turbine Equipment	The NBS supplies steam to the main turbine during power operation and transients such as load variations.	MSL to TSVs connection
Main Turbine Equipment	The Equalizing Header is sized so as to permit the performance of a full close test at 90% power of one of the main TSVs during operation without imposing a severe pressure load transient on the reactor vessel internals.	MSL to TSVs connection
Moisture Separator Reheater System	MS supplies 21.62 kg/s (0.1716 Mlbm/hr) of steam for the MSR System.	NBS block valve to MSR piping to MSR
Turbine Bypass System	MS supplies steam to the TBVs via piping between the equalizing header and the TBVs.	MSL piping to TBV A and TBV B
Main Condenser and Auxiliaries	During startup and up to approximately 40% power operation, the main condenser via the MS drain lines receives steam, steam condensate, and non-condensable gases from the RPV and MSLs.	NBS block valve to MCA piping to condenser & NBS block valve to MCA piping to condenser

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

Interface System	Interface Description	Interface Boundary
Non-Safety Electrical Distribution System	The Non-Safety Electrical Distribution System provides power to the SCN valves in the MS subsystem. These valves are all located in the TB.	The interface point will be the electrical terminations of the power cables at the valve actuator
Equipment and Floor Drain System	The EFS provides sumps or drain tanks to the NBS system.	Interface is the connection from the NBS to the EFS in the TB
Turbine Building Structure	The TB provides the necessary space and structural support for the NBS MSLs and MS drain lines and components.	Interfaces are the pipe support attachments to the TB structures

The diagram illustrates the main steam system (MSS) configuration. It features two parallel steam generators, each with its own set of control valves and instrumentation. The system is connected to a common main steam header, which then branches out to various components including the RB and TB systems, the STEAM TUNNEL, and the main steam header itself. Key components include:
 

- Steam Generators:** Two parallel units, each with a main steam drain (MS DRN) and a main steam header connection.
- Valves:** MS DRN, TSV A, TSV B, and various control valves (e.g., TBP, TBV A, TBV B).
- Pumps and Flow Control:** NBS (Normal Boiling System), MCA (Main Control Actuator), and EFS (Emergency Flow Stop).
- Sensors:** Temperature (T) and Pressure (P) sensors.
- Connections:** Connections to the RB and TB systems, the STEAM TUNNEL, and the main steam header.

10-70

## **10.5 Main Condenser and Auxiliaries System**

The MCA System is the heat sink for the power generation and normal reactor cooldown and plant startup activities. The MCA System consists of the main condenser, two SJAE skids, and two condenser vacuum pump skids as well as associated piping, valves, instrumentation, and controls.

### **10.5.1 System and Equipment Functions**

The MCA performs the function listed below during normal and off-normal conditions.

#### **10.5.1.1 Normal Functions (Non-Safety Category)**

The MCA provides the following Non-Safety Category functions during normal conditions:

1. The MCA System provides a main condenser with interfaces to other systems as needed to condense steam exhaust from the main turbine and main turbine bypass.
2. The main condenser includes a reservoir (hotwell) in which the condensate is collected as a suction source for the condensate pumps.
3. The main condenser collects equipment drains, vents, and relief valve discharges from other plant equipment.
4. The condenser vacuum pumps draw a vacuum and remove non-condensable gases from the condenser shell during startup.

#### **10.5.1.2 Normal Functions (Safety Category)**

The MCA provides the following Safety Category functions during normal conditions:

1. The MCA provides the capability to measure main condenser vacuum (pressure).
2. The MCA provides the heat sink to condense reactor steam or drainage from the FW heaters and other steam supply users.
3. The SJAE draws a vacuum and removes non-condensable gases from the condenser shell.
4. The MCA provides a condensate supply to the condensate pump suction.

#### **10.5.1.3 Off-Normal Functions (Non-Safety Category)**

The system does not perform any Non-Safety Category functions during off-normal conditions.

#### **10.5.1.4 Off-Normal Functions (Safety Category)**

The system does not perform any Safety Category functions during off-normal conditions.

### **10.5.2 Safety Design Bases**

The safety design bases for the MCA include the items listed below. Codes and standards related to pressure boundary are identified in the component descriptions in Subsection 10.5.3.1 as applicable. MCA System equipment is categorized as Non-Nuclear Seismic.

**SC2 Requirements:**

1. As part of Defense Line (DL) 4a, the MCA has the capability to measure main condenser vacuum (pressure) to initiate a scram when the mode switch is in the RUN position, due to low condenser vacuum.

**SC3 Requirements:**

1. As part of DL2, the MCA provides the capability to measure main condenser pressure to initiate TBV closure, due to low condenser vacuum.
2. The MCA provides the heat sink to condense reactor steam or drainage from the FW heaters and other steam supply users.
3. The SJAЕ draws a vacuum and removes non-condensable gases from the condenser shell.
4. The MCA provides a condensate supply to the condensate pump suction.

The MCA is not required to operate during or after a design basis event. The design of the MCA meets CNSC requirements specified in REGDOC-2.5.2 Section 6.1 (Reference 10.5-1) as it relates to design for Defence-in-Depth and Section 7.1 as it relates to classification of SSC.

### **10.5.3 Description**

The main condenser is a single-pressure, two-shell, unit. Each shell is located beneath its respective LP turbine. The two condenser shells operate at similar pressures and drain to hotwells that are cross connected. Circulating water flows through each of the two single-pass tube bundles to condense the turbine exhaust steam into the hotwells. The main condenser receives and condenses turbine exhaust steam and turbine bypass steam during all modes of operation. The main condenser provides hold-up for N16 decay, and supplies condensate to the condensate pumps. The main condenser also serves as a collection point for other steam cycle miscellaneous drains, vents, and relief valve discharges.

Two 100% capacity SJAEs are used to maintain the turbine backpressure and remove non-condensable gases from the main condenser. Non-condensable gases extracted from the condenser are exhausted to the Offgas System.

During startup, two condenser vacuum pumps draw the initial condenser vacuum and exhaust the gases to the TB Heating, Ventilation, and Air Conditioning (Chapter 9A, Subsection 9A.5.4).

Refer to Chapter 3, Section 3.9 for information pertaining to equipment qualification of BWRX-300 SSC.

#### **10.5.3.1 Component Description**

The following paragraphs provides information that pertains to the major MCA components.

##### **10.5.3.1.1 Main Condenser**

The main condenser is located in the TB. The main condenser has two shells each mounted beneath and connected to a LP turbine by an expansion joint. The condenser is designed in accordance with the Heat Exchange Institute Standard for Steam Surface Condensers.

Vacuum breaker(s) are provided to break the vacuum and maintain atmospheric pressure within the condenser during shutdown. Connections are provided on each condenser shell to allow for the removal of air and other non-condensable gases.

The main condenser provides connections for the condensate pump minimum recirculation flow lines. The condenser hotwell receives makeup water from the CST. Excess water volume in the

condenser hotwell is drawn off by the condensate pumps and transferred to the CST. The hotwells of the two condenser shells are interconnected. The condensate pumps take suction from one of the hotwells.

Corrosion resistant alloys are used for condenser components exposed to steam or condensate where particularly severe duty is expected. The condenser tubes are titanium or stainless steel and the tubesheets are made of a compatible material.

Connections are provided to allow draining and cleaning of the condenser hotwell during plant shutdown.

The shielded area and controlled access for the main condenser is provided to protect personnel from radiation.

LP turbine exhaust steam, turbine bypass steam, and other miscellaneous power cycle drains, and vents are routed to the main condenser.

#### **10.5.3.1.2 Condenser Vacuum Pumps**

Two vacuum pumps are used as rapid evacuators to remove the air from the condenser shells and associated turbine, creating the initial vacuum which allows the startup of the plant. The vacuum pumps are used up to 5% reactor power before transfer to the SJAEs, due to the potential for H<sub>2</sub> concentration limits being reached.

The vacuum pumps can also run during shutdown when adequate steam is not available to operate the SJAEs.

A check valve is provided on each vacuum pump skid to prevent reverse flow, thereby preserving the condenser vacuum when the vacuum pump stops.

#### **10.5.3.1.3 Steam Jet Air Ejectors**

The SJAEs are sized in accordance with the "Venting Equipment Capacity" of Heat Exchange Institute's Standards for Steam Surface Condensers. Additionally, radiolytic oxygen and hydrogen entrained in the main condenser is removed by SJAEs.

The SJAEs function by using MS through the Turbine Auxiliary Steam System. The motive steam that condenses in the steam jet air ejector intercondenser flows through the loop seal to the condenser. The second stage air ejector is non-condensing. The air ejectors provide adequate motive force for the Offgas System (Chapter 11, Section 11.3.).

The steam supply to the second stage SJAEs ensures adequate dilution of hydrogen (less than 4% by volume) and prevent the non-condensable gases from reaching the flammable limit of hydrogen.

#### **10.5.3.1.4 Piping and Valves**

Any sections of pipe that may carry potentially explosive mixtures of hydrogen and oxygen are designed to contain the explosion.

All other piping is designed in accordance with ASME B31.1, Power Piping (Reference 10.5-2).

Valves exposed to higher hydrogen/oxygen mixture have bellows stem seals, double stem seals, or equivalent.

### **10.5.4 Materials**

Material and process control requirements for the BWRX-300 components ensure the reliability of plant operations through its design life by minimizing irradiation of the plant components,

corrodents and mitigating the degradation of materials specifically from corrosion (as applicable) through material chemistry, heat treatment, contamination, and material processes controls.

### **10.5.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.5-1 for system interfaces.

### **10.5.6 System and Equipment Operation**

The MCA is designed to operate during all modes of normal power plant operation and startup. The general operating logic for each of the operating modes is provided.

#### **10.5.6.1 Normal Operational Concept**

##### ***10.5.6.1.1 Normal Startup/Shutdown Mode***

The main condenser hotwell is filled from the CST, if drained, to the normal water level by automatic control of the normal and emergency makeup valves.

Prior to placing the condenser vacuum pumps in operation, the seal water separator is filled to the normal level and cooling water is flowing through the tube side of the seal water heat exchanger.

The condenser vacuum pumps are started to evacuate air from the condenser before the TGSS is placed into operation and the expansion joint seal water trough has been filled, if provided. The condenser vacuum pumps shut off automatically if abnormal levels of radioactivity are detected in the MSL and/or TB vent stack. Refer to Subsection 10.2.3 for information pertaining to TGSS.

Upon establishing a sufficient initial vacuum in the condenser, the condenser vacuum pumps remain in-service and hold the partial vacuum until motive steam is available for use by an SJAE skid. Steam flows from the NBS through the TASS to the SJAE.

Prior to placing an SJAE skid into operation, condensate is flowing through the tube side of the associated SJAE intercondenser.

The main condenser is also used to deaerate the reactor before criticality.

The Circulating Water System (CWS) is in operation prior to admitting any high energy fluids into the main condenser. Refer to Section 10.8 for information related to the CWS.

The condenser hotwell and its level control system are designed to accommodate the reactor vessel inventory shrink and swell associated with pressurization/de-pressurization during normal startups and shutdowns.

The main condenser acts as a heat sink in the initial phase of reactor cooldown during a normal plant shutdown.

Condenser vacuum breaker(s) are opened, slowing the turbine during shutdown.

##### ***10.5.6.1.2 Normal Operation***

The main condenser condenses the LP turbine exhaust steam, stores condensate, acts as a condensate surge volume, and supplies condensate to the condensate pumps. The main condenser also accepts vents and drains discharge from various points in the cycle.

SJAE units removes air in-leakage and radiolytic gases from the condenser shells, and in conjunction with the CWS, maintains a vacuum in the condenser shells.

### **10.5.6.2 Off-Normal Operational Concept**

#### **10.5.6.2.1 Transient Operation**

The main condenser hotwell acts as surge volume in the following events:

1. Tube failure of FW heaters, SJAE intercondensers, MSRs, and other miscellaneous heat exchangers.
2. High-water level in the FW heaters and reheater drain tanks
3. Relief valve discharge for system overpressure protection as well as condensate from the MSLs through their drain subsystem

The condenser accepts steam and drains from various points in the turbine cycle, including those that require steam dumps during turbine generator load rejection.

The condenser hotwell receives overboard flow from the Shutdown Cooling System (SDC) (described in Chapter 9, Subsection 9A.2.3) during reactor heatup. The CUW can overboard to the LWM Chapter 11, Section 11.2) or MCA depending on radiation monitoring. The primary flow path is to MCA with the option for diverting to LWM.

#### **10.5.6.2.2 Load Rejection**

The main condenser accepts up to 25% rated steam flow via the TBS (Chapter 10, Section 10.7) in the event of a turbine trip or load reject.

There is enough condensate stored in the hotwell to allow operation of the condensate pump(s) during this transient.

#### **10.5.6.2.3 High Condenser Backpressure**

The pressure in the condenser may rise during normal operation due to low circulating water flow, high circulating water temperature, or high condenser duty. In any case, as condenser pressure increases above normal levels, an alarm annunciates. A further increase in pressure to the turbine trip limit results in a turbine trip. As pressure increases further beyond an established condenser limit, the turbine steam bypass valves are inhibited from opening and if open, they close to prevent overpressurization of the condenser shell. If the pressure continues to increase, the MSCIVs close.

The SJAE skid on standby may be brought online if a high absolute pressure exists in the condenser.

#### **10.5.6.2.4 Loss-of-Offsite Power**

The main condenser accommodates the turbine bypass flow for at least six seconds following a trip of the circulating water pumps due to a loss of preferred power without exceeding the TBV isolation pressure setpoint in the condenser.

### **10.5.7 Instrumentation and Control**

The MCA provides the instrumentation to control and monitor (indicate and alarm) system operation. Package (skid) instrumentation is provided to verify vacuum pumps and steam jet air ejector performance in addition to normal operation and control. Instrumentation is included and installed to provide an accurate plant heat balance.

#### **10.5.7.1 Instrumentation**

Major system parameters, i.e., hotwell levels; and process flow rate, pressures, and temperatures are indicated and alarmed as required to provide operational information and performance assessment.

#### **10.5.7.2 Controls**

The MCA is operated and controlled from the MCR. Major system control functions, i.e., hotwell level, SJAE performance, and valve positioning logics, are based on system operating parameters.

#### **10.5.8 Monitoring, Inspection, Testing and Maintenance**

The equipment and components of the MCA are designed for easy inspection and maintenance with the intent to reduce or eliminate radiation exposure potential. Routine testing of the MCA is conducted in accordance with normal power plant requirements for demonstrating system and component operability and integrity.

#### **10.5.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states.

#### **10.5.10 Performance and Safety Evaluation**

The MCA is capable of performing its Safety Category normal functions as presented in Subsection 10.5.1. The MCA does not perform any Safety Category off-normal functions.

The MCA is capable of measuring main condenser vacuum (pressure) to meet Safety Category 2 and Safety Category 3 requirements. The system also provides a heat sink, removes non-condensable gases from the condenser shell and supplies condensate to meet Safety Category 3 requirements listed in Subsection 10.5.2.

**Figure 10.5-1: Main Condenser and Auxiliaries System**

## **10.6 Moisture Separator Reheater**

The MSR is composed of one moisture separator reheater, three drain tanks and the piping from the HP turbine exhaust (cold reheat) to the MSR, from the MSR to LP turbines (hot reheat) inlet, piping up to the intermediate stop valves and intercept valves as well as piping and valves from MSL equalizing header for 2nd stage reheating. The MSR has one stage of moisture separation and two stages of reheating.

### **10.6.1 System and Equipment Functions**

The MSR System performs the following functions during normal and off-normal conditions.

#### **10.6.1.1 Normal Functions (Non-Safety Category)**

The MSR System performs a Non-Safety Category normal function to reheat HP turbine exhaust prior to use by the LP turbines (TBD).

#### **10.6.1.2 Normal Functions (Safety Category)**

The MSR System provides the following Safety Category functions during normal conditions:

1. The MSR System repositions level control valves, for both normal and alternative flow paths, based on signals from I&C systems, to drain condensed steam from the moisture separator reheater drain tanks.
2. The MSR System provides hot condensate for FW heating.
3. The MSR System provides indication of Moisture Separator Reheater Drain Tank water level.

#### **10.6.1.3 Off-Normal Functions (Non-Safety Category)**

The MSR System does not provide any Non-Safety Category functions during off-normal conditions.

#### **10.6.1.4 Off-Normal Functions (Safety Category)**

The MSR System does not provide any Safety Category functions during off-normal conditions.

### **10.6.2 Safety Design Bases**

The MSR is categorized as Non-Nuclear Seismic. The MSR routes hot condensate from the MSR to FW heaters numbered 3, 4, and 5 as a Safety Category function as well as provides indication of Moisture Separator Reheater Drain Tank water level. Additionally, the system provides an alternate drain path from the MSR drain tanks to the condenser. These Safety Category functions serve to maintain reactor parameters within normal ranges during normal operations.

The design of the MSR meets CNSC requirements specified in REGDOC-2.5.2 Section 6.1 (Reference 10.6-1) as it relates to design for Defence-in-Depth and Section 7.1 as it relates to classification of SSC.

### **10.6.3 Description**

Figure 10.6-1 depicts the MSR. The MSR is located in the TB. The MSR reheats the HP turbine exhaust and then directs the reheated steam into the LP turbine. The purpose of this system is to dry and reheat the expanded steam from the HP turbine exhaust (cold reheat steam) to improve the cycle efficiency and reduce liquid impingement erosion and FAC in the LP turbines.

The MSR is protected by a safety relief valve that ensure that it is not overpressurized under the most adverse operating conditions associated with the turbine generator operations. The relief valve is located on the shell of the MSR with an outlet discharging to the condenser.

Steam from the HP turbine exhaust (cold reheat steam) enters the bottom of the MSR where steam separators remove entrained moisture before passing the steam to the reheater sections. Heating steam to the first stage of reheat in the MSR is supplied by the Extraction Steam Subsystem. Refer to Subsections 10.2.3 and 10.2.3.1.5 for additional information pertaining to the Extraction Steam Subsystem. The second stage reheating steam to the MSR is supplied by the MS subsystem (Section 10.4). Hot reheat steam is supplied to the two LP turbines through the reheat intermediate stop and intercept valves, which are located upstream of the LP turbines inlet nozzles.

Removed moisture is drained to the drain tank. Steam condensed from the reheater stages of the MSR is also drained to drain tanks. FAC resistant materials are used for all components exposed to wet steam or flashing liquid flow where significant erosion could occur. The degree of FAC resistance of the material is consistent with the temperature, moisture content and velocity of the wet steam to which the component is exposed.

Provisions are made to evacuate and purge all reheater tube bundles prior to pressurization to minimize distortion when heating steam is admitted to the tube bundle.

Drains are provided at the low points in the cold and hot reheat piping. These drains are placed as close to the turbine as possible and are designed in accordance with ASME TDP-2 (Reference 10.6-2). Two valves are provided in series in each drain line. The upstream valve is air-operated (fail open). This drain valve is located as close as possible to the drain pot to minimize the amount of water trapped upstream from the closed valve. The second valve is manually operated.

A power operated non-return valve and control valve is installed in the supply piping to the first stage reheater.

A control valve is installed in the supply piping to the second stage reheater tube bundle. A control valve is installed upstream of this valve and a manual valve downstream. Piping containing a control valve is installed to bypass the control valve station.

All horizontal runs of the cold reheat steam, hot reheat steam, and first and second stage reheating steam is sloped toward the MSR for drainage where appropriate.

The routing of the small-bore miscellaneous drain piping is designed to slope downward in the direction of the flow.

Refer to Chapter 3, Section 3.9 for information pertaining to equipment qualification of BWRX-300 SSC.

### **10.6.3.1 Component Description**

The following paragraphs describe the major components of the MSR.

#### **10.6.3.1.1 Moisture Separator Reheaters**

The MSR has one stage of moisture separation and two stages of reheating.

The MSR has cylindrical, horizontal, combined moisture separator shells with steam separators and closed U-tube reheater tube bundles. Steam separators are made of stainless steel and are adequately supported to resist aerodynamic, fluid elastic or any other type of vibration. Analyses supported by testing is performed to ensure good flow distribution to the inlet face of the moisture separator to maximize effectiveness and to eliminate the possibility of structural damage from locally high steam velocities.

The MSR is designed in accordance with ASME BPVC, Section VIII, Division 1, (Reference 10.6-3) Unfired Pressure Vessels, and Thermal Exchanger Manufacturers Association Standards.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

The reheater tube supports are designed and spaced to prevent wear or damage due to aerodynamic, fluid elastic or any other type of vibration of the reheater tubing.

Layup provisions which are appropriate for the MSR materials are provided. Tube side layup is performed with treated water, nitrogen, or dry clean air according to paragraph 304 of ASME NQA-1 (Reference 10.6-4). Shell side layup is performed with treated water or dry clean air.

The MSR is protected by a safety relief valve to prevent overpressurization.

The relief valve is located on the shell of the MSR with outlets discharging to the condenser.

#### **10.6.3.1.2 MSR Drain Tanks**

The MSR includes three drain tanks; one for the moisture separation stage, one for the first stage of reheat, and one for the second stage of reheat.

The drain tanks are designed in accordance with ASME BPVC, Section VIII, Division 1.

Moisture separator drain tank piping is designed to handle two-phase flow.

#### **10.6.3.1.3 Piping and Valves**

MSR piping is designed to the requirements of ASME B31.1, Power Piping (Reference 10.6-3) as applicable.

A power operated non-return valve and control valve is located in the supply piping to first stage reheater tube bundle for isolation purposes.

An air-operated control valve is located in the MS supply piping to each second stage reheater tube bundle to modulate the steam flow. A control valve is located upstream of this valve and a manual valve is located downstream for isolation purposes. Piping containing a control valve is provided to bypass the control valve in the event it is unavailable.

Steam shutoff, and control valves have both automatic and manual control to regulate the second stage reheater temperature. Manual control includes the capability to manually open and close the shut-off valve and position the control valve.

#### **10.6.3.1.4 Drains**

Each moisture separator and reheater tube bundle has its own separate drain system.

Moisture separator drains are sized for self-venting gravity downflow into the moisture separator drain tanks to allow the system to vent properly during plant operating conditions. In addition, a separate vent is taken from above the water level in each drain tank back to the moisture separator to avoid any possibility of lock-up during plant operating conditions.

#### **10.6.3.1.5 Vents**

Venting and/or other arrangements are provided to ensure the continuous removal of non-condensable gases from the reheater tube bundle and also ensure the steady removal of condensate from the reheater tubes with minimum subcooling. Thermal-hydraulic instabilities in the reheater tube bundle is minimized to such an extent no short or long-term operational or reliability problems occur. Vent piping has no low points and is sloped to ensure adequate drainage.

### **10.6.4 Materials**

Material and equipment selection for the MSR is based on the range of normal environmental conditions that may exist at the location of the system equipment and components.

FAC resistant materials is used for components exposed to wet steam or flashing liquid flow where significant erosion could occur. The degree of FAC resistance of the material is consistent with the temperature, moisture content and velocity of the wet steam to which the component is exposed.

#### **10.6.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.6-1 for MSR interfaces.

#### **10.6.6 System and Equipment Operation**

The MSR is designed to operate during modes of normal power plant operation, including startup and shutdown. The general operating logic for each of the operating modes is provided below.

##### ***10.6.6.1.1 Normal Operational Concept***

The MSR receives steam from the HP turbine exhaust. Moisture is removed and the steam is reheated for use in the LP turbine.

HP turbine extraction steam is directed through open isolation valves to the first stage reheater.

MS is directed through open control valves to the second stage reheater. The second stage heating medium is HP steam supplied by the MS subsystem as discussed in Subsection 10.6.3. This steam supply is regulated by flow control valves to control the temperature of the steam at the outlet of the MSRs.

##### **10.6.6.2 Off-Normal Operational Concept**

###### ***10.6.6.2.1 Turbine Trip***

Upon a turbine trip, the first stage reheater isolation valve and the second stage reheater control valve close, and the cold reheat drains open. Hot reheat steam is isolated by closing the intermediate stop valve and intercept valves. The MSR is isolated and condensate is drained from the MSR.

###### ***10.6.6.2.2 Load Following***

The MSR accommodates load following with CRD operation between 100% and 50% of rated power with ramp rates up to  $\pm 0.5\%$  per minute. The design accommodates approximately 20,805 equivalent daily load following cycles. Refer to Subsection 10.2.2 for information pertaining to load following.

###### ***10.6.6.2.3 System Startup***

During startup, the main turbine stop and control valves, first stage reheater isolation valve, and second stage reheater control valve are closed. As the main turbine stop and control valves begin to open allowing steam to be admitted to the turbine, cold reheat steam enters the MSR. The first stage reheater isolation valve is opened allowing HP extraction steam to enter the first stage reheater. The second stage reheater control valve is slowly opened to increase the hot reheat temperature at which point the second stage reheater control valve is fully open.

###### ***10.6.6.2.4 Turbine Shutdown***

The main turbine stop and control valves remain open and the MSR continues to receive cold reheat steam from the HP exhaust and supply hot reheat steam to the LP turbine until the main turbine falls below the manufacturer's specified kW output. At this point, the main turbine stop and control valves, the first stage reheater isolation valves, and the second stage reheater control valves are closed.

### **10.6.7 Instrumentation and Control**

Instruments are designed to withstand or be protected from transient pressures and flow resulting from the transitions between the various modes of system operation.

All instruments, excluding welded-in flow nozzles, are removable for servicing without cutting pipes or grinding welds.

Instrument scale, size and style is selected in compliance with Human Factors Engineering requirements (Chapter 18). The scale graduations are consistent with the required accuracy and range of the measurement.

#### **10.6.7.1 Special Features**

The MSR loop contains sufficient instrumentation to:

- Monitor and maintain appropriate heating steam flow for proper reheater operation
- Monitor and operate drain pot drain valves
- Verify reheater heat transfer quality
- Initiate turbine trip upon two-out-of-three coincident logic for high-water level in the moisture separator section of the MSR (Turbine Water Induction Prevention requirement)
- Provide necessary status indication of key valves and annunciation of abnormal conditions during operation

#### **10.6.7.2 Instrumentation**

The instrument features of the MSR System are as follows:

1. The moisture separator section is equipped with triple redundant level instruments mounted on cross connected independently valved bridles. The instruments initiate turbine trip based on high moisture separator water level.
2. Both the cold reheat steam and hot reheat steam piping is equipped with triple redundant pressure instrumentation and redundant temperature instrumentation.
3. The steam supply piping to the reheaters is also equipped with pressure and temperature instrumentation, and flow instrumentation to detect tube leaks.
4. MSR is equipped with differential pressure transmitters to measure the pressure drop across the MSR.
5. Each cold reheat and hot reheat drain line is equipped with temperature instrumentation.

The MSR includes the sensors recommended in ASME PTC 12.4.

Refer to Chapter 7 for information pertaining to triple redundancy.

#### **10.6.7.3 Control**

Key control features of the MSR are included below. This system is automatically controlled.

Manual initiation and shutdown of the System is provided from the MCR.

Cold reheat drain valves manually open and close from the MCR. The cold reheat drain valves are fail open valves that auto open when level instruments in their respective drain pots give a high or high-high level signal, turbine trip, load rejection, or drain group open signal and auto close on drain group close signal.

Hot reheat drain pot air-operated drain valves manually open and close from the MCR. The hot reheat drain valves are fail open valves that auto open when level instruments in their respective drain pots give a high or high-high level signal and auto close on drain group close signal.

The control valve in the supply piping to the first stage reheater tube bundle automatically and manually opens and closes from the MCR. No temperature control is carried out for first stage heating steam. Flow rate and steam conditions are dependent upon the heat and mass balance of the HP turbine.

The control valve located in the MS supply piping to the second stage reheater tube bundle automatically and manually opens and closes from the MCR and is designed to fail closed. The NBS control valve upstream of the MSR control valve is designed to open manually from the MCR.

The following primary MSR displays, and alarms are provided:

- Main Control Console Displays
  - Heating steam flow, pressure, and temperature
  - Reheat steam pressure and temperature
  - Valve positions
- MCR Alarms
  - Drain pot high or high-high level
  - High level in the moisture separator section

#### **10.6.8 Monitoring, Inspection, Testing, and Maintenance**

Routine testing of the MSR is conducted in accordance with plant requirements for demonstrating system and component operability and integrity. Routine testing includes inspection for liquid impingement erosion and heat exchanger tube integrity inspections per applicable codes and standards.

The equipment and components of the MSR are designed for easy inspection and maintenance during shutdown/refueling.

The MSR is directly accessible by the TB crane. Lift capability and space is provided to permit removal and replacement of an entire MSR as well as tube bundles without requiring the removal of any other major component or large size piping.

Tube bundle replacement does not require removal of permanent walls, major piping, or cables trays. Adequate space is provided for laydown of replacement MSR tube bundles and associated equipment. MSR tube bundle pull fixtures are specifically designed for each location.

Flow restriction orifices are located to allow ease of access for replacement.

#### **10.6.9 Radiological Aspects**

Chapter 12, Section 12.1 provides information pertaining to occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states.

#### **10.6.10 Performance and Safety Evaluation**

The MSR is designed to operate during modes of normal power plant operation, including startup and shutdown.

The Safety Category functions associated with the MSR provide:

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

- A route for hot condensate from the MSR to FW Heaters No. 3, 4, and 5
- An alternative drain path from the MSR drain tanks to the condenser
- Indication of MSR Drain Tank water level

These Safety Category functions serve to maintain reactor parameters within normal ranges during normal operations.

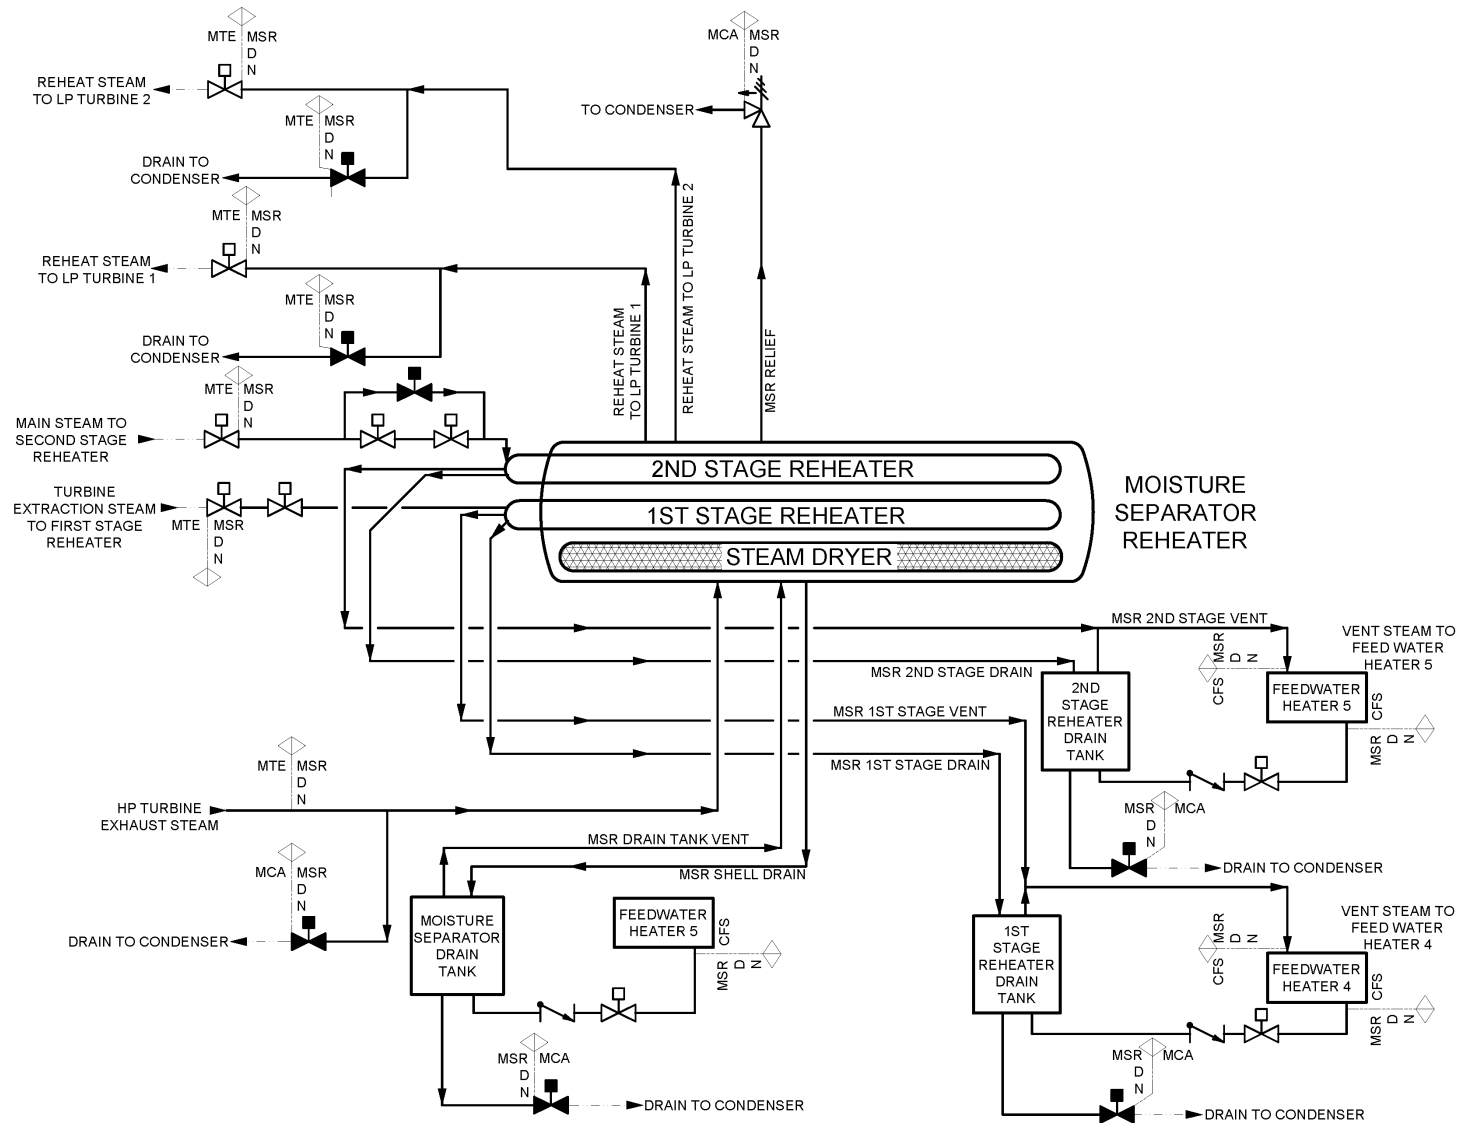

Figure 10.6-1: Moisture Separator Reheater System

## **10.7 Turbine Auxiliary Systems**

This section describes the TBS. The TBS takes excess steam from the NBS (Chapter 5), expands the steam to lower pressure, then uses spargers to deliver the steam to the condenser (Subsection 10.5.1).

### **10.7.1 System and Equipment Functions**

#### **10.7.1.1 Normal Functions (Non-Safety Category)**

The TBS does not perform any Non-Safety Category functions during normal conditions.

#### **10.7.1.2 Normal Functions (Safety Category)**

The TBS performs the following Safety Category functions during normal conditions:

- Reposition the TBVs to control reactor dome pressure in Modes 1 (Power Operation) and 2 (Startup)
- Remove decay heat from the reactor and discharge to the main condenser in Modes 3 (Hot Shutdown) and 4 (Stable Shutdown)

#### **10.7.1.3 Off-Normal Functions (Non-Safety Category)**

The TBS does not perform any Non-Safety Category functions during off-normal conditions.

#### **10.7.1.4 Off-Normal Functions (Safety Category)**

The TBS has three Safety Category functions during off-normal conditions:

- Control reactor dome pressure using the TBVs based on signals from I&C systems in Modes 1 (Power Operation) and 2 (Startup).
- TBVs will fast open in response to a turbine trip when demanded by I&C systems in Mode 1 (Power Operation).
- TBVs will close on high main condenser pressure when demanded by the I&C system in Modes 1 (Power Operation) and 2 (Startup).

### **10.7.2 Safety Design Bases**

The TBS is designed to operate in modes of normal power plant operation and startup. The TBVs open as required to maintain reactor pressure following a load reduction or load rejection or whenever the turbine is not able to flow the steam demanded by the RPC. As part of DL2 the TBVs receive a signal from the SC2 and SC3 I&Cs System to open and close when signaled to do so.

The design of the TBS meets CNSC requirements specified in REGDOC-2.5.2 Section 6.2 (Reference 10.7-1) as it relates to maintaining the plant in a normal operational state.

### **10.7.3 Description**

Figure 10.7-1 depicts the TBS. The TBS is located in the TB and is comprised of the following:

1. Two TBVs
2. TBV hydraulic actuators, hydraulic accumulators, supply and drain piping, servo valves, solenoid valves, check valves, and position transmitters
3. Piping, fittings, instruments, and valves from the inlet connections of the TBV to the sparger connections at the main condenser

Two TBVs receive steam from the NBS piping connected to equalization header and discharge the steam to the main condenser.

Threaded and flanged connections are not used except where required to permit component removal for maintenance.

The TBVs have accumulators, which allow for limited operation of TBV upon electrical power failure. In the event power is lost to the hydraulic pumps but is still available to the control system, the hydraulic actuation system is capable of either cycling the valves open and closed three times or opening the valves for a minimum time of six seconds and then re-closing them under the direction of the RPC. In the event electrical power is lost to the control system (regardless of whether the hydraulic unit has power or not), the valves automatically close and remain closed.

The TBVs have sufficient capacity and transient response capability to permit generator synchronization with the power grid without a pressure transient resulting in an excessive power excursion or reactor water level perturbations.

The TBV has sufficient capacity and transient response capability to permit stable operation of the automatic pressure control of the reactor and to permit controlled cooldown of the plant to the point where the SDC can be placed in service.

The total rated turbine bypass capacity is 25% of the nuclear boiler rated steam flow at rated turbine inlet pressure.

The TBS is designed such that no failure of a single component can disable more than 50% of the installed bypass capacity

#### **10.7.3.1 Component Description**

##### **10.7.3.1.1 Turbine Bypass Valves**

Two (2) TBVs are provided. Each TBV is a control valve operated by a hydraulic actuator. The actuator is equipped with a spring which is capable of shutting the valve against the design steam pressure. The TBVs are capable of modulating steam flow to meet system requirements.

Individual TBVs are designed to fail closed upon loss of control power or loss of hydraulic pressure to their operators. Individual TBV hydraulic accumulators have the capability to stroke the valves with HPU failure and meet opening time and duration requirements. The accumulators in combination with hydraulic check valves ensure that no single hydraulic failure disables more than 50% of the TBVs. The accumulator hydraulic supply is also designed to ensure that upon LOOP or station auxiliary power, TBVs can still be opened for a minimum time of six (6) seconds and re-close.

American National Standards Institute (ANSI FCI 70-2) Class V leakage class is specified for bypass valves to minimize wire drawing and other damage to the valve caused by leakage across the seat.

##### **10.7.3.1.2 Turbine Bypass System Piping**

TBS piping is designed to ASME B31.1, Non-Nuclear Seismic requirements (Reference 10.7-2) as applicable.

Piping supports are designed for water-filled line loads under static loading conditions that may be encountered in plant operations. In addition, provisions are made for conveniently supporting (e.g., by pinning hangers) the dead weight loads imposed during hydrostatic testing.

The MS piping from the equalization header slopes upward to the TBV inlets and the discharge piping downstream of the TBVs slopes downward to the main condenser with a slope of at least

1/100 of run with no low points. Suitable low point drains are provided by the NBS to prevent excessive moisture from accumulating upstream of the TBVs.

Spargers distribute the steam within the main condenser as required.

#### **10.7.4 Materials**

Material and equipment selection for the TBS is based on the range of normal environmental conditions that exist at the location of the system's equipment and components.

#### **10.7.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.7-1 for TBS interfaces.

#### **10.7.6 System and Equipment Operation**

The TBS is designed to operate in all modes of normal power plant operation and startup.

##### **10.7.6.1 Normal Operational Concept**

###### **10.7.6.1.1 Startup Mode**

During startup, the turbine stop and control valves are initially closed. The RPC opens the TBVs as required, bypassing steam to the main condenser, to control reactor pressure allowing the reactor to operate to a rated condition and to minimize pressure transients in the reactor during initial steam admission to the turbine. As steam is admitted to the turbine, the TBVs close as required to maintain reactor pressure.

###### **10.7.6.1.2 Normal Operation**

During normal operation, the TBVs are maintained in the closed position.

The TBVs open as required to maintain reactor pressure following a load reduction or load rejection. The TBS is capable of accommodating a <25% load rejection with the TBVs modulating as required to maintain reactor pressure and support operation of the turbine under reduced load.

###### **10.7.6.1.3 System Shutdown**

The TBVs initially open upon turbine trip, then modulate as required to maintain reactor pressure. During shutdown, reactor power is reduced by rod insertion at specified rates and sequences. The turbine stop and control valves remain open until the main turbine power falls below the manufacturer's specified kW output limit. At this point, the turbine stop and control valves close, and the TBVs open and modulate as required to control steam pressure.

#### **10.7.7 Instrumentation and Control**

The TBVs open in response to redundant bypass demand signals received from the SC2 and SC3 I&C System (Chapter 7) whenever the actual steam pressure exceeds the preset steam pressure by a preset amount. This occurs when the amount of steam generated by the reactor cannot be entirely used by the turbine. The number of TBVs required to open for bypass operation is determined by the SC2 and SC3 I&C System, and the TBVs modulate as required in response to changes in the bypass demand, discharging steam to the main condenser.

The following signals are monitored in the MCR:

- Temperature in each bypass line for bypass steam leakage detection
- Valve position indication for each TBV
- TBV operable status and annunciation of any signals that cause the valves to become inoperable

Three SC3 valve open/close sensors are provided by the SC2 and SC3 I&C System and installed at each TBV detects the 10% open position and provides valve status to the SC2 and SC3 I&C System reactor protection logic. These position sensors are fail-safe such that they cannot prevent actuation of the reactor protection function.

SC3 valve position transmitters are provided and installed at each TBV. These valve position transmitter signals are used to perform input voting as applicable and are used for the reactor pressure controller of the SC2 and SC3 I&C System DCIS. The TBV operational status are used for monitoring functions in SCN Non-Safety I&C System DCIS.

Temperature elements installed in each TBV discharge pipe near the main condenser inlet provides temperature signals to the RPC for bypass steam leakage detection.

Triply redundant bypass valve position transmitters installed at each TBV provide valve position signals to the RPC.

Control and monitoring of the TBS is accomplished by the RPC and the logic contained therein.

Triply redundant servo valves and fast-acting solenoid valves provide hydraulic actuation of the TBVs upon receiving demand signals from the RPC.

The RPC determines bypass operating conditions and setpoints which require fast opening of the TBVs and provides the corresponding demand signals to the TBS.

Automatic and manual control of the TBS is provided. TBV controls, including manual initiation and shutdown, are located in the MCR to facilitate system operation.

#### **10.7.8 Monitoring, Inspection, Testing, and Maintenance**

The equipment and components of the TBV are designed for ease of inspection and maintenance. The TBVs are oriented to facilitate maintenance activities. Routine testing of the TBV is conducted in accordance with normal power plant requirements for demonstrating system and component operability and integrity. Periodic inspections are performed on a rotating basis within a preventive maintenance program in accordance with manufacturer's recommendations. Testing is in accordance with ASME OM Code.

#### **10.7.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states.

#### **10.7.10 Performance and Safety Evaluation**

The TBS is designed to operate in all modes of normal power plant operation and startup. As part of DL2, the TBVs receive a signal from the RPC to open and close when signaled to do so.

1. The TBVs are capable of modulating steam flow to meet system requirements.
2. The TBVs are designed to fail closed upon loss of control power or loss of hydraulic pressure to their operators.
3. The TBV hydraulic accumulators have the capability to stroke the valves with hydraulic power and meet opening time and duration requirements after loss of power to the EHC pumps.
4. The accumulators in combination with hydraulic check valves ensure that no single hydraulic failure disables more than 50% of the TBVs.

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

5. The accumulator hydraulic supply is also designed to ensure that upon LOOP or station auxiliary power, TBVs can still be opened for the minimum time and re-closed.

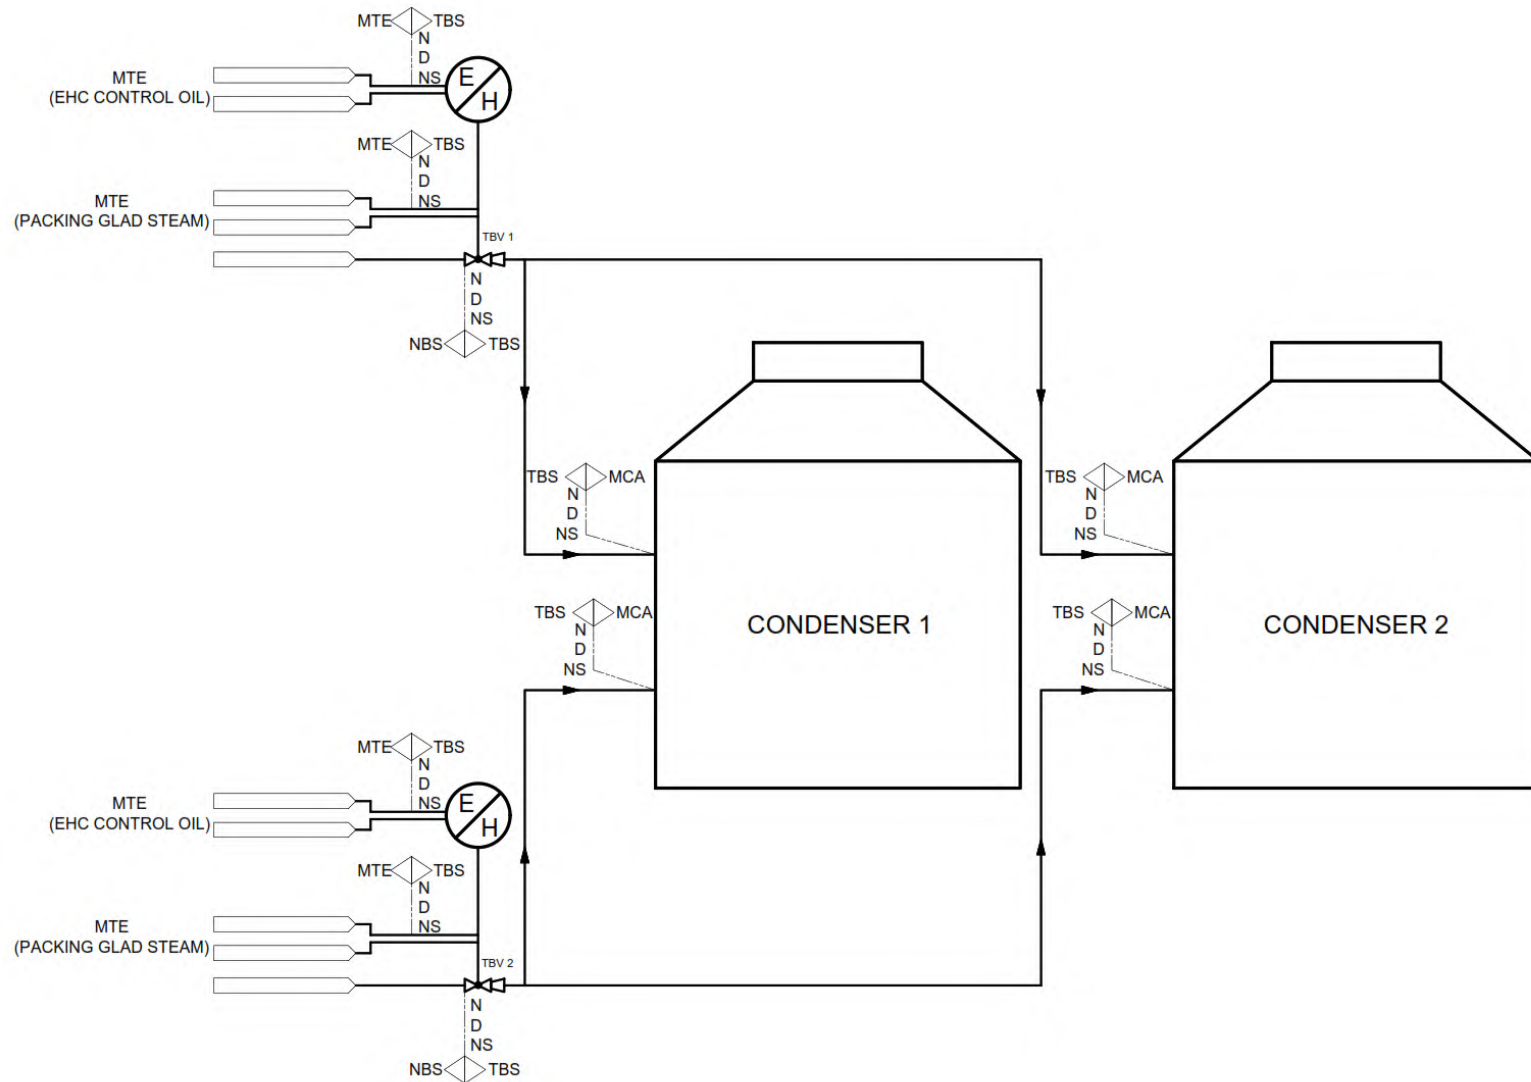

Figure 10.7-1: Turbine Bypass System Interfaces

## **10.8 Circulating Water System**

The CWS has two subsystems, the main condenser supply and the PCW supply. The main condenser supply uses 2x50% pumps to provide cooling water to the MCA (Subsection 10.5.1) during all modes of condenser heat removal. The plant cooling water supply uses 2x100% pumps to provide cooling water to the PCW (Chapter 9, Subsection 9A.2.1) heat exchangers for all normal and abnormal operating modes. All CWS pumps are located in bays in the intake structure of the Normal Heat Sink (NHS) (Chapter 9, Subsection 9A.2.5).

### **10.8.1 System and Equipment Functions**

The CWS performs the functions listed below during normal and off-normal conditions.

#### **10.8.1.1 Normal Functions (Non-Safety Category)**

The CWS performs the following Non-Safety Category functions during normal conditions:

- Removes accumulated air and other gases from the water boxes through water box vents
- Provides the means to drain the condenser supply and return water boxes

#### **10.8.1.2 Normal Functions (Safety Category)**

The CWS performs the following Safety Category functions during normal conditions:

- Provides means to reject heat from the MCA to the environment through the NHS
- Provides means to reject heat from the PCW heat exchangers to the environment through the NHS

#### **10.8.1.3 Off-Normal Functions (Non-Safety Category)**

The system does not perform any Non-Safety Category functions during off-normal conditions.

#### **10.8.1.4 Off-Normal Functions (Safety Category)**

The CWS continues to provide its Safety Category functions during off-normal conditions. Upon a Loss-of-Offsite Power (LOOP), the NHS continues to provide a cooling water source and heat rejection functions to support CWS interface with PCW. The two PCW supply pumps are powered from the diesel generators via the SC3 Electrical Distribution System, during a LOOP.

### **10.8.2 Safety Design Bases**

The safety design bases for the CWS are included below. Codes and standards related to pressure boundary are identified in the component descriptions in Subsection 10.8.3.1 as applicable. CWS system equipment is categorized as Non-Nuclear Seismic.

SC3 Requirements:

- As part of DL2, the CWS has an integral support function to cool PCW.
- The CWS provides a means to reject heat from the MCA to the environment through the NHS.

The design of the CWS meets CNSC requirements specified in REGDOC-2.5.2 Section 8.7 (Reference 10.8-1) as it relates to heat transfer to an ultimate heat sink.

### **10.8.3 Description**

Figure 10.8-1 depicts the CWS. The CWS is a recirculating system that supplies cooling water to the main condenser from the NHS. The circulating water pumps located in the intake structure of the NHS, take suction from the intake basin and discharge through a common underground

NEDO-33960 REVISION 0  
NON-PROPRIETARY INFORMATION

pipe. In the TB, the piping comes above grade and routes into the tube side of the main condenser to act as the cooling flow for condensing main turbine exhaust steam. Circulating water exiting the main condenser is piped back underground to the NHS.

A hot circulating water return line is also provided to recycle water returning from the condenser in cold weather conditions as required to prevent freezing in the NHS intake area and moderate cold water into the condenser to improve turbine performance. The CWS includes water box vents to help fill the condenser water boxes during startup and remove accumulated air and other gases from the water boxes during normal operation.

The PCW (Chapter 9, Subsection 9A.2.1) circulating water pumps are redundant and can provide water to the PCW heat exchanger at all times. During normal operation only one PCW heat exchanger is in-service, and the corresponding plant cooling water supply pump is used to provide cooling. During a plant shutdown, both PCW heat exchangers and PCW supply pumps can be in-service to facilitate a plant shutdown. With the loss of a PCW supply pump the plant shutdown may take longer due to the reduction in heat removal. In the event of a LOOP, the PCW portion of CWS is powered by the standby diesel generators to provide continuous cooling support to PCW.

The CWS drains the condenser water boxes via the water box drain pump. The CWS is designed for continuous operation and to provide sufficient circulating water to the condenser to support full power operation.

The CWS must be in operation before any steam or high energy sources are routed into the condenser. The CWS supplies cooling water at a flow rate that allows the steam entering the condenser the ability to condense.

A CWS pump may be taken out of service if the remaining pump is capable of supplying sufficient circulating water to cool the main condenser when operating at reduced load or the circulating water temperature is low enough.

The CWS, together with the NHS, provide circulating water to the main condenser in support of rated turbine generator power or greater operation. The CWS and NHS also supply circulating water to the main condenser sufficient to support 100% reactor power operation when operating up to 2% exceedance temperatures of the normal heat sink.

The PCW supply pump(s) must be in operation before any cooling water is required by the PCW. Only one pump is required to be in operation at a time to provide sufficient cooling capacity.

The PCW supply pumps provide sufficient cooling water to meet the performance requirements of the heat exchangers within the PCW. The PCW supply pumps are 100% capacity pumps. One pump can remain in standby while the operating pump provides the required cooling water flow.

Measure(s) are applied to control macrofouling (e.g., from zebra mussels) of the circulating cooling water systems.

Refer to Chapter 3, Section 3.9 for information pertaining to equipment qualification of BWRX-300 SSC.

#### **10.8.3.1 Component Description**

The following paragraphs describe major equipment items that comprise the CWS.

##### **10.8.3.1.1 Circulating Water Pumps**

The circulating water pumps are 50% capacity pumps. The pumps are arranged in parallel with suction from the NHS intake basin. There are two individual pump discharge lines and they combine into one circulating water supply line to the main condenser.

#### **10.8.3.1.2 Plant Cooling Water Supply Pumps**

The PCW supply pumps are 100% capacity pumps. These pumps take suction from the NHS intake basin.

The individual PCW supply pump discharge lines supply the independent PCW heat exchangers.

#### **10.8.3.1.3 Water Box Drain Pump**

The water box drain pump is sized to drain the CWS piping, pumps, and condenser water boxes. The water box drain pump discharge is routed to the CWS piping downstream of the condenser discharge isolation valves.

#### **10.8.3.1.4 Piping and Valves**

The CWS piping of 600 mm (24 in) nominal diameter and smaller is designed to meet the requirements of ASME B31.1, Power Piping (Reference 10.8-2). The piping with a nominal diameter of 650 mm (26 in) and larger is designed in accordance with American Water Works Association (AWWA) standards.

Valves installed at the discharge of the circulating water pumps are the motor-operated butterfly type. In the event of a trip of a circulating water pump, the closing characteristics of these valves limit the water hammer pressure to limits that are acceptable by the piping system.

All major CWS valves are operable by remote controls located in the MCR.

Underground piping from the circulating water pumps to the main condenser is made of a corrosion resistant material.

Pipe coating, lining, and cathodic protection is provided as appropriate based on-site specific conditions.

#### **10.8.3.1.5 Condenser Water Boxes**

The main condenser water boxes are constructed of carbon steel. The exterior surfaces are coated as appropriate based upon site-specific conditions.

The water box vacuum breakers open automatically to prevent excessive pressure transients caused by multiple circulating water pump trips.

Cathodic protection may be provided to protect the water boxes based on-site specific conditions.

### **10.8.4 Materials**

Material and equipment selection for the CWS is based on the range of environmental conditions that exist at the plant location.

### **10.8.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.8-1 for CWS interfaces with other systems.

### **10.8.6 System and Equipment Operation**

The CWS is designed for continuous operating for the following plant operating modes:

1. Normal operation
2. Off-normal operation

#### **10.8.6.1 Normal Operational Concept**

With two 50% capacity circulating water pumps in operation one of the two operating pumps may be manually stopped only if stopping the pump does not cause a trip of the turbine because of

HP in the condenser and that the pressure loss in the condenser with only one pump in operation is enough for the correct operation of its cleaning system. To accomplish this, power may need to be reduced to within the capacity of a single circulating water pump prior to stopping one pump.

Only one of two 100% capacity PCW pumps are in normal operation at a time with the other in standby. This does not preclude two pump operation under normal operations.

#### **10.8.6.2 Off-Normal Operational Concept**

The CWS is designed to maintain reactor operation during a turbine trip or a 25% load rejection, whereby 25% of the MS bypasses the turbine to the condenser.

##### ***10.8.6.2.1 Cold Weather Operation***

When required for cold weather operation, the system is designed to support cold weather startup by maintaining a minimum basin temperature. A hot-water recirculation line connects the piping downstream of the condenser with the intake forebay for use in maintaining the required intake temperature range.

Freeze protection is provided for above ground components that contain stagnant water.

##### ***10.8.6.2.2 Circulating Water Pump Trip***

If a circulating water pump trips, the associated pump discharge valve automatically closes to avoid water backflow. The trip of a circulating water pump alarms in the MCR. Tripping of the pump initiates a drop in power output and an increase in condenser back pressure due to an increase in circulating water temperature.

##### ***10.8.6.2.3 Plant Cooling Water Supply Pump Trip***

If a PCW supply pump trips, the backup pump auto starts and the process cooling water system will realign and put the associated heat exchanger in service. The trip of the pump alarms in the MCR.

##### ***10.8.6.2.4 Isolation of the Condenser Due to Tube Leak***

If a main condenser tube leak is detected, by changes in hotwell conductivity, the power output of the plant may need to be reduced to a value that accounts for the reduced cooling flow through the condenser tubes.

##### ***10.8.6.2.5 Flooding in the Turbine Building***

In the event that two of the three level transmitters in the condenser area detect a high-water level, a trip signal is sent to the circulating water pumps thereby tripping the pumps and the unit.

##### ***10.8.6.2.6 Isolation of the PCW System Due to High Radiation Levels***

In the event of high radiation levels detected downstream of either of the PCW heat exchangers, a signal is sent to the valves downstream of the heat exchangers. The valves close to prevent contaminated water from reaching the NHS.

#### **10.8.7 Instrumentation and Control**

The CWS provides the instrumentation to control and monitor (indicate and alarm) system operation.

##### **10.8.7.1 Instrumentation**

Major system parameters, i.e., forebay and water box levels; and process flow rate, pressures, and temperatures are indicated and alarmed as required to provide operational information and performance assessment.

#### **10.8.7.2 Control**

The CWS is operated and controlled from the MCR. Major system control functions, i.e., pump start/stop and valve positioning logics, are based on system operating parameters. For example, high radiation levels downstream of each PCW heat exchanger result in valve closure.

#### **10.8.8 Monitoring, Inspection, Testing, and Maintenance**

Routine testing of the CWS is conducted in accordance with normal power plant requirements for assuring component operability and integrity.

Equipment and components of the CWS are designed for ease of inspection and maintenance during plant operation. The CWS is provided with a water box drain pump with capability to drain the main condenser water boxes. Condenser inlet and outlet isolation block valves are provided to allow for isolation of condenser tube bundles for maintenance.

Each circulating water pump discharge has the ability to be individually isolated for service and maintenance. Manholes are provided for maintenance and cleaning of the circulating water piping and condenser water boxes.

#### **10.8.9 Radiological Aspects**

Chapter 12, Subsection 12.1.5.4 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states.

#### **10.8.10 Performance and Safety Evaluation**

The CWS has two subsystems, the main condenser supply and the PCW supply. The CWS is capable of performing its Safety Category normal and off-normal functions as presented in Subsection 10.8.1. The CWS is capable of meeting its Safety Category 3 requirements.

The CWS provides sufficient circulating water to the main condenser to support full power operation. A pump may be taken out of service if the remaining pump is capable of supplying sufficient circulating water to cool the main condenser when operating at reduced load.

The PCW cooling water supply pumps are redundant and provide water to the PCW heat exchangers to remove PCW heat loads. The PCW cooling water supply pumps are powered by the standby diesel generators in the event of a LOOP to provide continuous cooling support to PCW. The PCW heat exchanger discharge is monitored to ensure the water returning to the NHS is free of radionuclides. High radiation levels would result in isolation of the discharge by automatic valve closure.

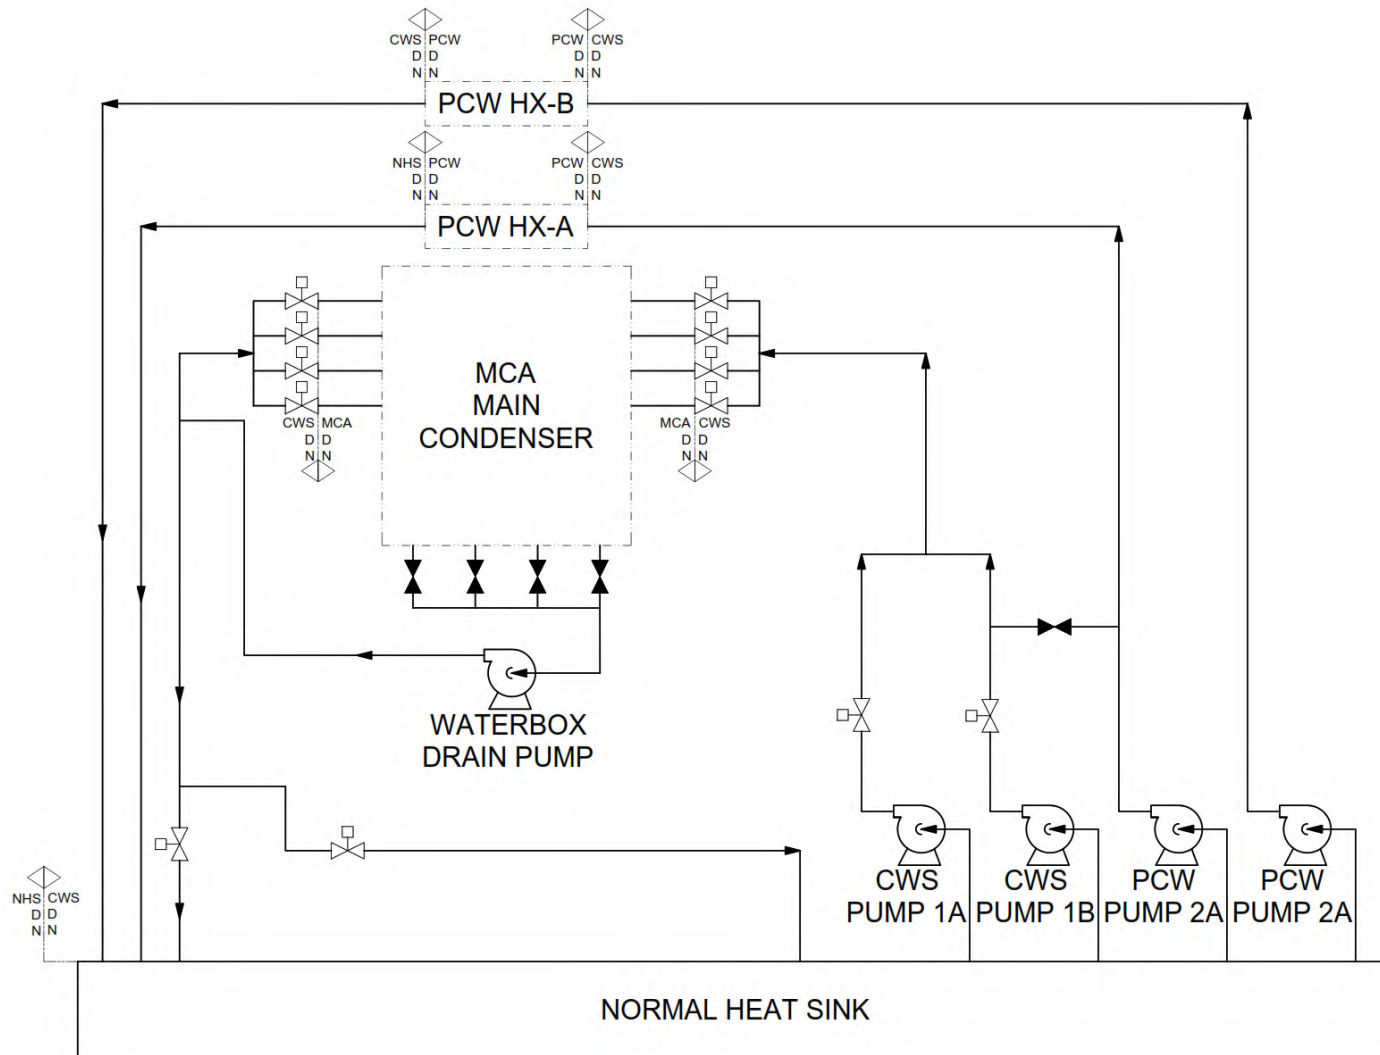

Figure 10.8-1: Circulating Water System

## **10.9 Generator and Exciter**

The Generator and Exciter System converts the rotational energy of the BWRX-300 turbine into electrical power that is transmitted to the Non-Safety Electrical Distribution System and utility power grid. The generator consists of a synchronous electric generator (including rotor, stator, and stator frame), collector, generator shaft seals, generator bearings, generator heat exchangers, neutral grounding resistor and associated neutral grounding transformer, potential transformers, current transformers, surge protection, generator protection panel and relaying (shared with Non-Safety Electrical Distribution System), the generator field winding, and instrumentation. Additionally, this system includes the Generator Excitation System that consists of a field exciter and Automatic Voltage Regulator that function to provide rated output voltage.

### **10.9.1 System and Equipment Functions**

#### **10.9.1.1 Normal Functions (Non-Safety Category)**

The function of the generator is to convert rotational energy produced by the main turbine into electrical power.

The function of the generator neutral grounding equipment is to provide protection for the generator in the event of a ground fault.

The Generator Excitation System does not perform any Non-Safety Category functions during normal conditions.

#### **10.9.1.2 Normal Functions (Safety Category)**

The functions of the generator exciter, in conjunction with the voltage regulator, are:

1. To supply direct current to the generator field winding to control the voltage and reactive volt-ampere output of the generator during all modes of power generation.
2. To operate in conjunction with the TGCS for synchronization during startup.
3. To operate in conjunction with the TGCS for power factor control during normal operation.
4. To operate in conjunction with the TGCS during shutdown.

The generator and exciter can initiate transients up to a scram.

#### **10.9.1.3 Off-Normal Functions (Non-Safety Category)**

This system does not perform any Non-Safety Category functions during off-normal conditions.

#### **10.9.1.4 Off-Normal Functions (Safety Category)**

This system does not perform any Safety Category functions during off-normal conditions.

### **10.9.2 Safety Design Bases**

The system has SC3 SSC and the neutral grounding transformer and resistor are SCN. The system is categorized as Non-Nuclear Seismic.

The generator provides input signals of system operating parameters to DCIS for monitoring.

The generator is able to withstand a sudden three-phase short circuit at the output terminals of the generator under a worst-case condition of the generator operating at full rated load, at rated power factor overexcited and up to the fabrication ratings of the machine.

Instrumentation is provided to monitor the operating parameters of the generator and excitation system over its anticipated ranges of normal and abnormal performance to facilitate plant operation and ensure safety.

The design of the MTE System meets CNSC requirements specified in REGDOC-2.5.2 Section 8.3.3 as it relates to providing provisions for overspeed protection, minimization of missiles due to a turbine break-up and inspection and testing (Reference 10.9-1). Minimization of potential missile impacts is also afforded through the favorable perpendicular orientation of the reactor to the turbine.

### **10.9.3 Description**

The generator produces its rated electrical output power at rated torque produced by the turbine and design condenser vacuum conditions.

The Generator and Exciter System provides electricity to be distributed to the grid via the isophase bus ducts and the generator step up transformer in Mode 1 and to the station loads via the Unit Auxiliary Transformer.

The generator operates at a 300 MW rating at 21 kV not more than five percent above or below rated voltage with a rated speed of 3600 rpm. The generator, exciter and generator control system are designed to be capable of responding to grid frequency changes.

The generator stator frame is fabricated of steel and is designed such that no damaging frame vibration occurs during normal operation and transients. The Generator Excitation System static exciter supplies and controls the direct current for the field winding of the generator and controls the voltage and reactive volt-ampere output of the generator. The DC current is supplied by a 250Vdc uninterruptible control power source. The neutral grounding is composed of a neutral grounding transformer with a secondary resistor and a current transformer dedicated to the stator earth fault protection. The Automatic Voltage Regulator monitors and adjusts the field excitation to maintain the output voltage within the specified range.

Refer to Chapter 3, Section 3.9 for information pertaining to equipment qualification of BWRX-300 SSC.

#### **10.9.3.1 Component Description**

##### **10.9.3.1.1 Generator**

The generator is capable of operating without air cooler cooling water flow at a level and duration determined by the manufacturer to not incur any damage. All the moving parts are provided with machine guards and barriers.

##### **10.9.3.1.2 Generator Exciter**

The generator exciter is designed to supply and control the direct current for the field winding of the generator and control the voltage and reactive volt-ampere output of the generator during normal plant operation and startup.

The power potential excitation transformer is protected by at least (and against):

- Transformer differential current
- Phase overcurrent
- Lightning strikes with appropriate surge protection and basic insulation level rating

##### **10.9.3.1.3 Automatic Voltage Regulator**

The voltage regulator, in conjunction with the generator exciter, maintains the output voltage of the generator at 21 kV +/- 5%.

#### **10.9.3.1.4 Neutral Ground Resistor**

The neutral grounding resistor is sized such that, in the event of a ground fault, the maximum current experienced by the neutral phase is between 3 and 25 amps.

#### **10.9.3.1.5 Neutral Ground Transformer**

The neutral grounding transformer in conjunction with the neutral grounding resistor, limits the maximum stator ground fault to between 3 and 25 amps.

#### **10.9.4 Materials**

Material and equipment selection for the Generator and Exciter System is based on the range of environmental conditions that exist at the plant location.

#### **10.9.5 Interfaces with Other Equipment or Systems**

Refer to Table 10.9-1 for information pertaining to Generator and Exciter System interfaces.

#### **10.9.6 System and Equipment Operation**

The generator is designed to operate during modes of normal power plant operation, including startup and shutdown activities. The generator is also designed to trip based on abnormal conditions. For all operating modes, automatic controls are provided for equipment and components to minimize operator action while ensuring optimum system performance. The system also operates in conjunction with the turbine auxiliary controller and generator auxiliary controller to perform system operations as needed.

##### **10.9.6.1 Startup**

The generator is controlled by the TGCS. The TGCS synchronizes the initial loading by:

- Matching turbine speed to the grid frequency
- Matching generator voltage to the grid
- Ensuring generator phase angle leads the grid phase angle
- Closing generator output breakers

##### **10.9.6.2 Normal Operation**

During normal operation, the TGCS controls the generator by operating in coordination with the Plant Automation System and RPC. During normal operation the TGCS utilizes the capabilities of the Automatic Voltage Regulator and the exciter to provide consistent generator output to the SCN Electrical Distribution System. The turbine and generator auxiliary controllers can also assist with the control of generator output as required.

##### **10.9.6.3 Off-Normal Operation**

During off-normal operation, the TGCS causes the generator to experience a load runback or trip of the generator, depending on the condition and the signals received from the Plant Automation System. These signals perform the following, based on conditions:

- Initiate runback or trip signals
- Provide signals for generator and switchyard breaker control, including tripping
- Runback the turbine generator to a safe operating condition based on input signals
- Provide automatic and manual controls to unload the unit during controlled shutdowns

## **10.9.7 Instrumentation and Control**

### **10.9.7.1 Instrumentation**

Instrumentation is provided to monitor the operating parameters of the generator and excitation system over anticipated ranges of normal and abnormal performance to facilitate plant operation and ensure safety.

Manual and automatic controls are provided to maintain generator parameters within prescribed operating ranges and, specifically, to control the voltage and reactive volt-ampere output of the generator.

The following alarms and trip signals are generated based on inputs provided to the DCIS:

- A. Stator winding fault
- B. Loss of excitation
- C. Negative phase sequence currents
- D. Stator overcurrent
- E. Stator overvoltage/undervoltage
- F. Loss of synchronism
- G. Journal bearing vibration high
- H. Reverse power (time delayed)
- I. Field overexcitation
- J. Under-frequency
- K. Neutral overvoltage
- L. Distance Backup Protection
- M. Inadvertent Energization
- N. Generator Vibration High
- O. Sequential Trip signals (Dry Contacts and Power Contacts)

Upon sensing any of the following abnormal generator conditions, an alarm is actuated in the MCR based on generator parameters that are provided to the DCIS:

- A. Rotor winding ground
- B. Stator winding temperatures
- C. Stator winding cooling coil outlet temperatures
- D. Journal bearing metal temperatures
- E. Shaft voltage
- F. Collector-ring cooling-air inlet and outlet temperatures
- G. Generator bushing temperatures
- H. Core-end or flux-shield temperatures
- I. Air cooler gas outlet temperature
- J. Core monitor conditions

- K. Generator voltage
- L. Generator frequency
- M. Generator output volts/hertz
- N. Excitation field ground
- O. DC Excitation potential

A zero (0) speed indication signal is supplied to reset the alarm for generator protection equipment or generator health monitoring equipment.

The following signals are sent from the static exciter to the generator protection panel:

- A. Generator voltage
- B. Generator DC excitation voltage
- C. Generator DC excitation current
- D. Volts/Hertz
- E. Power potential transformer lockout relay status
- F. Instantaneous DC current
- G. Bridge temperature
- H. Bridge AC phase angle
- I. Phase voltage

The power potential excitation transformer is protected by at least (and against) the following:

- A. Transformer differential current
- B. Phase overcurrent
- C. Lightning strikes with appropriate surge protection and basic insulation level rating

#### **10.9.7.2 Control**

As part of the Generator and Exciter System design, controls and protection signals are capable of being multiplexed based on interfacing system requirements. Fire Protection signals are provided to the Main Fire Alarm Panel and the DCIS and can be used in the coordination with other plant equipment and all cyber security requirements are followed.

The generator protection system design includes redundant instrumentation with a coincident logic trip system. Initiation devices for all trips have a separate set of contacts that can be used for DCIS monitoring. DCIS Human Machine Interface screen displays are provided for each trip initiating signal to identify the source of the trip signal.

#### **10.9.8 Monitoring, Inspection, Testing, and Maintenance**

The equipment and components of the generator are designed for ease of inspection and maintenance during plant operation. Generator and Exciter System components are arranged, sized, and selected to facilitate their replacement during a normal maintenance outage. Individual components are manufactured to standard sizes and gauges to the greatest extent possible.

Routine testing of the generator is conducted in accordance with normal power plant requirements for demonstrating system and component operability and integrity. An inspection of the generator is performed per the vendor's supplied maintenance and inspection requirements.

The Generator and Exciter System supports online inspection activities to the extent practical. Condition monitoring equipment and instrumentation is included where appropriate to ensure equipment performance and health is as desired. Maintenance can be performed online where redundant components can be bypassed or taken out of service one at a time without affecting plant operation.

#### **10.9.9 Radiological Aspects**

Chapter 12, Section 12.1 provides information pertaining to measures taken to ensure that occupational exposures arising from the operation or maintenance of the equipment or system are ALARA in operational states.

#### **10.9.10 Performance and Safety Evaluation**

The Generator and Exciter System is provided with sufficient I&C channels such that the system can continue operation in the event of the failure of a single instrumentation channel. The generator protection system design includes redundant instrumentation with a coincident logic trip system.

## **11.0 MANAGEMENT OF RADIOACTIVE WASTE**

This chapter describes the main sources of liquid, gaseous and solid radioactive waste including the radiological source term used in calculating liquid and airborne effluent. Also described are the radioactive waste processing systems (i.e., pre-treatment, treatment, and conditioning systems) as well as temporary waste storage located on the site. The design of the Structures, Systems and Components (SSC) provided for these purposes and the instrumentation provided to monitor for possible leaks of radioactive waste is described per Canadian Nuclear Safety Commission (CNSC) REGDOC-2.5.2, Section 8.11 (Reference 11.1-1).

The systems and equipment that monitor and sample the process and effluent streams to measure and control the discharge of radioactive materials generated in operational states and accident conditions are described.

The measures for the safe management of radioactive and hazardous waste of all types that will be generated throughout the lifetime of the plant as well as how these measures meet the relevant safety requirements including the measures taken for the safe management and disposal of this waste are described in OPG's Waste Management Program.

### **Sources of Waste**

Liquid radioactive waste is generated by cleanup of the reactor coolant, cleanup of the Spent Fuel Pool (SFP), and leakage from process streams. Leaked liquids are collected through floor drains, pump bed plate drains, and process drains in the Reactor Building (RB), Turbine Building (TB), Radwaste Building (RWB) and Plant Services Area. These waste sources are collected by drains and drain headers, routed by gravity drainage piping to a sump, and pumped to the Liquid Waste Management System (LWM) for processing.

Gaseous radioactive waste is generated as a result of activation of the reactor coolant during normal reactor operation, tramp uranium that may adhere to the outside of the fuel cladding during fabrication, and leakage of fission gas through miniscule defects in the fuel cladding.

Solid waste is created through plant operations, decontamination activities and through processing liquid radwaste. It includes the filter backwash sludges, reverse osmosis concentrates, charcoal media, and bead resins generated by the Fuel Pool Cooling and Cleanup (FPC), Isolation Condenser System Pool Cooling and Cleanup System (ICC), and Condensate Filters and Demineralizer (CFD) systems. Contaminated solids such as High Efficiency Particulate Air (HEPA) and cartridge filters, rags, plastic, paper, clothing, tools, and equipment are also disposed of in the Solid Waste Management System (SWM).

### **Waste Minimization**

The BWRX-300 is designed to minimize the generation of radioactive waste to the extent practicable as per CNSC REGDOC-2.5.2, Section 8.13.4 (Reference 11.1-1).

The BWRX-300 LWM is designed such that under normal conditions the need to release liquid effluent to the environment is minimized. LWM tanks are designed with significant holdup capacity and filtration skids are capable of filtering water to a sufficient quality for return to plant processes.

The Offgas System (OGS), described in Section 11.3, minimizes, and controls the release of radioactive material into the atmosphere by delaying and filtering the offgas process steam containing the radioactive isotopes so that gaseous effluent levels are below action levels calculated per CSA Group (CSA) N288.8 (Reference 11.1-2) ensuring prescribed limits for effluent releases cited in SOR/2000-203 (Reference 11.1-3) are not exceeded before discharge from the plant.

As discussed in Section 11.5, the Process and Effluent Monitoring System minimizes the generation of radioactive waste by directing continuous samples from radioactive processes back to the sampled process and by minimizing the amount of a sample that needs to be extracted, consistent with laboratory and sensitivity requirements.

### **Waste Storage**

Gaseous and liquid waste generated through normal plant processes are held up and filtered to a sufficient quality to allow for return to plant processes or released as described above. The design is such that there is no need for storage of gaseous or liquid waste external to the systems.

To the extent possible, discarded chemicals (including those classified as hazardous) are kept separate from solid radioactive waste. Section 11.4 discusses how solid waste is categorized, separated, and prepared for short term storage and eventual transport to an offsite facility.

### **11.1 Source Terms**

Two source terms are presented in this section. The first source term is a realistic model used to predict expected long-term average concentrations of radionuclides in the primary and secondary fluid streams. The second is a conservative design basis model that utilizes an established GEH fuel clad defect model, Reference 11.1-5.

The realistic model, which is based on available measured nuclide concentrations during normal operation at operating BWRs, is formulated as a standard for the American Nuclear Standard Source Term Specifications (ANSI) and American Nuclear Society (ANS) 18.1 (Reference 11.1-4) and is the source term model used to estimate liquid and gaseous effluent releases. The realistic model is referred to as the normal operation source term.

The second source term conservatively employs a GEH fuel clad defect model, Reference 11.1-5, serves as a basis for system and shielding requirements and is referred to as the design basis coolant source term.

#### **11.1.1 Coolant Radiation Concentrations**

##### **Normal Operation Coolant Source Term**

The normal operation BWRX-300 reactor water and steam radiation concentrations are based on Boiling Water Reactor (BWR) operating data reported in the ANSI/ANS-18.1 (Reference 11.1-4). This standard provides bases for estimating typical concentrations of the principal radionuclides that may be anticipated over the lifetime of a BWR. The source term data is based on the cumulative industry experience at operating BWR plants, and measurements at several stations. It therefore reflects the influence of a number of observations made during the transition period from operation with fuel of older designs to operation with fuel of current improved designs. The source terms specified in this section were obtained by applying the procedures of Reference 11.1-4 for estimation of typical source terms and adjusting the results, as appropriate, to assure conservative bases for design.

The BWRX-300 cleanup system configuration differs from the reference configuration in ANSI/ANS-18.1, and typical BWRs, since the CUW does not include any filtering media. The CFD performs all of the cleanup of the reactor coolant and is expected to filter the reactor coolant more efficiently than existing BWR systems employing a traditional reactor water cleanup system with a condensate demineralizer. The condensate filters include three filter vessels with high efficiency backwash-type filter elements arranged in parallel, and the condensate demineralizers include three demineralizer vessels arranged in parallel which significantly increases the residence time of the of the condensate and represents the best available technology economically achievable for the CFD.

A performance assumption is established at this stage of the design process that assumes the BWRX-300 CFD will provide coolant cleanup that is equivalent or better than existing BWRs that employ the use of traditional coolant cleanup systems. Thus, the ANSI/ANS-18.1 cleanup system removal efficiencies based on BWR operating data are used for the source terms presented here and must be validated when a CFD vendor is selected.

The information provided in this section defines the radioactive source terms in the reactor water and steam which serve as design bases for the gaseous, liquid, and solid radioactive waste management systems.

### **Design Basis Coolant Source Term**

The radionuclides included in the design basis source term are categorized as fission products or activation products. The lists do not necessarily include all radionuclides that may be detectable or theoretically predicted to be present. The principal nuclides identified in ANSI/ANS 18.1 are included because they are potentially significant with respect to one or more of the following criteria:

- Plant equipment design
- Shielding design
- Understanding system operation and performance
- Measurement practicability

#### **11.1.2 Fission Products**

##### **Normal Operation Noble Radiogas**

The BWRX-300 normal operation noble gas source term consists of the thirteen principle noble gas fission products as observed in steam flowing from the reactor vessel which are provided in the Radioactive Source Term Standard ANSI/ANS-18.1 (Reference 11.1-4). Concentrations in the reactor water are considered negligible under normal power operation because all of the gases released to the coolant are assumed to be rapidly transported out of the vessel with the steam and removed from the system with the other non-condensable gases in the main condenser. Due to the rapid removal of the gases, the expected relative mix of gases does not depend on the reactor design. The normal operation principle noble radiogas source terms are presented in Table 11.1 2b.

##### **Design Basis Noble Radiogas**

The design basis noble gas source terms are developed by normalizing the ANSI/ANS-18.1 normal operation noble gas source term mixture to a fuel release rate of 3,700 MBq/sec (100,000  $\mu$ Ci/sec) at 30 minutes decay. The noble radiogas source term rate after 30-minute decay has been used as a conventional measure of the fuel leakage rate, since it is conveniently measurable and was consistent with the nominal 30-minute offgas holdup system used on a number of early plants. A design basis noble gas release rate of 3700 MBq/s at 30-minute decay has historically been used for the design of the gaseous waste treatment systems in BWR plants (Reference 11.1-5) with satisfactory results. It was selected on the basis of operating experience with consideration given to several judgmental factors, including the implications to environmental releases, system contamination, and building air contamination. The design basis principle noble radiogas source terms are presented in Table 11.1-2a.

##### **Normal Operation Radioiodine**

The BWRX-300 normal operation radioiodine concentrations of the 5 principal radioiodines in reactor water and steam are determined by adjusting BWR Reference Plant radioiodine

NEDO-33961 REVISION 0  
NON-PROPRIETARY INFORMATION

concentrations using the methods in ANSI/ANS-18.1 and the BWRX-300 operating parameters in Table 11.1-4b.

### **Design Basis Radioiodine**

Historically, design basis radioiodine source terms for BWRs are normalized to an I-131 leak rate of 26 MBq/sec (700  $\mu$ Ci/sec) from the fuel (Reference 11.1-5). Experience indicates that I-131 leakage rates this high would only be approached during full power operation with multiple fuel cladding defects. It is not expected that full power operation would continue for any significant period of time with fuel cladding defects as severe as indicated by I-131 leakage in excess of 26 MBq/sec (700  $\mu$ Ci/sec).

The design basis reactor water radioiodine concentrations are developed by normalizing the ANSI/ANS-18.1 normal operation radioiodine concentrations to an I-131 leakage rate of 26 MBq/sec (700  $\mu$ Ci/sec) from the fuel (Reference 11.1-5) reported in Table 11.1-1. This provides a margin relative to the expected I-131 release rate shown in Table 11.1-1.

The design basis concentrations are presented in Table 11.1-4a.

### **Other Fission Products**

This category includes fission products other than noble gases and iodines and also includes transuranic nuclides. Some of the fission products are noble gas daughter products that are produced in the steam and condensate system. The only transuranic which is detectable in significant concentrations is Np-239.

The BWRX-300 normal operation concentrations for fission products other than noble gases and iodine in reactor water and steam are determined by adjusting BWR Reference Plant radioiodine concentrations using the methods in ANSI/ANS-18.1 and the BWRX-300 operating parameters in Table 11.1-3. In order to assure conservative design basis concentrations for the BWRX-300, the normal operation is normalized to the I-131 leakage rate from the fuel reported in Table 11.1-1.

The design basis reactor water concentrations are presented in Table 11.1-5a, and the normal operation concentrations reside in Table 11.1-5b.

### **11.1.3 Activation Products**

#### **11.1.3.1 Coolant Activation Products**

The coolant activation product of primary importance in BWRs is N-16. Based on the ANSI/ANS 18.1 (Reference 11.1-4) BWR Reference Plant and the BWRX-300 operating parameters, the N-16 levels of in steam leaving the reactor vessel for the plant without Hydrogen Water Chemistry system (HWC) is 1.78 MBq/gm (48  $\mu$ Ci/gm), and 9.25 MBq/gm (250  $\mu$ Ci/gm) with HWC. The BWRX-300 is expected to utilize HWC. This is treated as essentially independent of reactor design because both the production rate of N-16 and the steam flow rate from the vessel vary in direct proportion to reactor thermal power. For this reason, the same N-16 concentrations in reactor water and steam with HWC is used for both the normal operation and the design basis source terms.

It should be noted that a portion of the source term traditionally identified as "N-16" actually represents C-15. To the extent that C-15 is present, it is generally about ~0.55 MBq/gm (15  $\mu$ Ci/gm) or less. Historically, gross gamma dose rate measurements made to confirm the magnitude of the N-16 concentration have included responses to gamma rays from C-15. Use of the combined "N-16" source term in shielding design introduces additional conservatism because the C-15 component has a 2.45 second half-life, and therefore decays more rapidly with transport time through the system than N-16, which has a 7.1 second half-life.

The design basis N-16 concentrations in steam and reactor water are shown in Table 11.1-6. Reference 11.1-4 gives the reactor water concentration at the recirculation system. Because the BWRX-300 does not have an external recirculation loop, the reactor water concentration has been decay-corrected to the reactor core exit to obtain an estimated value shown in Table 11.1-1.

#### **11.1.3.2 Non-Coolant Activation Corrosion Products**

Radionuclides produced in the coolant by neutron activation of circulating impurities and by corrosion of irradiated system materials are classified as activated corrosion products. Typical reactor water concentrations for activated corrosion products are contained in the ANSI/ANS 18.1 BWR Reference Plant concentrations (Reference 11.1-4).

The BWRX-300 activated corrosion product concentrations are calculated by adjusting the BWR Reference Plant concentrations of non-coolant activation products to BWRX-300 conditions by using the methods in ANSI/ANS 18.1 and appropriate data from Table 11.1-3.

The BWRX-300 design basis concentrations of the activated corrosion products are not normalized using the fuel leakage model because they do not originate in the fuel but are rather produced by corrosion of irradiated system materials in the reactor and associated piping. Thus, the production of activated corrosion products is dependent on the inner surface area of the reactor and piping where gamma and neutron activation can occur, and the BWRX-300 has much less surface area than the large BWRs that provide the operating data bases for BWR Reference Plant concentrations.

The activated corrosion products concentrations in reactor water and steam are presented in Table 11.1-7. The Table 11.1-7 concentrations are used for both normal operation and design basis source terms.

#### **Tritium**

Tritium is produced by activation of naturally occurring deuterium in the primary coolant and, to a lesser extent, as a fission product in the fuel (Reference 11.1-6). The tritium is primarily present as tritiated oxide, T-O-H. Because tritium has a long half-life (12 years) and is not affected by cleanup processes in the system, the concentration is controlled by the rate of loss of water from the system by evaporation or leakage (Reference 11.1-4). Plant process water and steam have a common tritium concentration. The concentration reached depends on the actual water loss rate; however, Reference 11.1-4 specifies a typical concentration of 518 Bq/gm (0.014  $\mu$ Ci/gm) based on BWR operating data adjusted to account for liquid recycle. This value is applicable for the BWRX-300.

#### **Argon-41**

Argon-41 is produced in the reactor coolant as a consequence of neutron activation of naturally occurring Argon-40 in air that is entrained in the feedwater. The Argon-41 gas is carried out of the vessel with the steam and stripped from the system with the non-condensable gases in the main condenser. Observed Argon-41 levels are highly variable due to the variability in air in-leakage rates into the system. Reference 11.1-6 specifies a normal operation Argon-41 release rate from the vessel into the offgas treatment system of 1.5 MBq/sec (40  $\mu$ Ci/sec). This value is considered conservative as it bounds the available experimental database; this value is provided in Table 11.1-1..

#### **11.1.4 Radionuclide Concentration Adjustments**

In order to determine the estimated concentrations of radionuclides in the groups classified as iodines, other non-volatile fission products, and non-coolant activation products using the ANSI/ANS 18.1 Source Term Standard (Reference 11.1-4), it is necessary to apply appropriate

NEDO-33961 REVISION 0  
NON-PROPRIETARY INFORMATION

adjustment factors to the Reference Plant concentrations provided in the Standard, per the following equations.

Equilibrium concentrations in reactor water are assumed to satisfy the relationship:

$$C = \frac{S}{M(\lambda + R)}$$

where:

- C = radionuclide concentration
- S = radionuclide input rate to coolant
- M = reactor water mass
- $\lambda$  = radionuclide decay constant
- R = sum of removal rates of the radionuclide from the system.

Consequently, if the radionuclide input rate is taken to depend primarily on the reactor thermal power, the adjustment factors to be applied to the Reference Plant reactor water concentrations are given by:

(11.1-2)

$$\text{Adjustment Factor} = \frac{P M_r (\lambda + R_r)}{P_r M (\lambda + R)}$$

where the subscript "r" refers to the Reference Plant, P is the reactor thermal power and M,  $\lambda$ , and R are as defined above.

The removal rate from the system is the sum of the removal rates due to the CUW and the condensate demineralizer and is given by:

$$R = \frac{(FA \cdot NA) + (NC \cdot FS \cdot NS \cdot NB)}{WP} \quad (11.1-3)$$

where:

- FA = CUW flow rate
- NA = fraction of nuclide removed in CUW
- NC = ratio of CFD System flow rate to steam flow rate (=1 for BWRX-300)
- FS = steam flow rate
- NS = ratio of nuclide concentration in steam to concentration in water
- NB = fraction of nuclide removed by the CFD System
- WP = weight of water in the reactor vessel

The Reference Plant and BWRX-300 plant parameters and the nuclide-dependent removal rate parameters used for the BWRX-300 are shown in Table 11.1-3.

## **11.2 Systems for Management of Liquid Radioactive Waste**

### **11.2.1 System and Equipment Functions**

The purpose of the BWRX-300 LWM is to collect liquid radioactive waste generated as the result of normal operation, throughout the plant from the Equipment and Floor Drain System (EFS), separate and filter the waste, then return the filtered water to the Condensate Storage Tank (CST) for plant reuse.

#### **11.2.1.1 Normal Functions (Non-Safety Category)**

The LWM perform the following Non-Safety Category functions during normal conditions:

- The LWM collects potential radioactive liquid waste from plant areas via the EFS for processing and filtering, returning condensate quality water to the CST.
- The LWM also serves to transfer, hold, and filter the Reactor Well Pool volume of water when the reactor head bolts are required to be loosened or tightened during an outage. The Refueling Water Storage Tank (RWST) is used for this purpose.
- The LWM via the CST provides water during outages for under vessel washdown.

#### **11.2.1.2 Normal Functions (Safety Category)**

LWM is designed to perform the following Safety Category functions during normal conditions:

- The LWM provides Containment Isolation Valves (CIVs) on piping that penetrates the containment boundary. One manual, locked closed valve is provided on each side of the containment wall for isolation. The valves are locked closed during normal operations.
- The CST provides an alternate source of water for the Control Rod Drive (CRD) System if the Condensate and Feedwater System (CFS) is not available.

#### **11.2.1.3 Off-Normal Functions (Non-Safety Category)**

The LWM does not perform any non-safety category functions during off-normal conditions.

#### **11.2.1.4 Off-Normal Functions (Safety Category)**

The LWM has the capability to function under off-normal conditions providing a means to replenish the SFP following a Design Basis Accident (DBA). Additionally, the CST provides continuous water to purge the CRD when the CFS is not available.

### **11.2.2 Safety Design Bases**

The CIVs on piping that penetrates the containment boundary provide containment isolation in accordance with CNSC REGDOC-2.5.2 Section 8.6.6 (Reference 11.2-1). These valves are classified Safety Class (SC) 1 due to their Defense Line 3 Safety Category 1 Fundamental Safety Function (FSF) of maintaining containment during and following DBAs. The containment penetration piping and associated valves portion of LWM are classified as Seismic Category A as described in Chapter 3, Subsection 3.2.3.

LWM SSC other than the CIVs are classified SC3 for their Defense Line 2 role in confinement of radioactive materials during normal and off-normal operating conditions.

LWM is designed such that personnel exposures during system operation and maintenance are ALARA per CNSC REGDOC-2.5.2 Section 8.11 (Reference 11.2-1).

The LWM has the capability to process the maximum anticipated quantities of liquid waste without impairing the operation or availability of the plant during both normal and anticipated operational

NEDO-33961 REVISION 0  
NON-PROPRIETARY INFORMATION

occurrence conditions, satisfying the requirements of CNSC REGDOC-2.5.2 Section 8.11.1 (Reference 11.2-1) and CNSC REGDOC-2.11 (Reference 11.2-2).

In the LWM, radioactive contaminants are removed, and the bulk of the liquid is purified and either returned to the CST or discharged to the environment if the plant's overall water inventory does not permit recycling. The BWRX-300 is designed such that under normal conditions the need to release liquid effluent to the environment is minimized.

Discharges to the environment are monitored by the Process Radiation Monitoring Subsystem (PRM) as described in Section 11.5. The discharge line is automatically isolated upon receiving a signal from PRM to ensure that liquid releases to the environment are within prescribed limits per CNSC REGDOC-2.5.2, Section 8.11.1 (Reference 11.2-1), and that the release of radioactive liquid effluents is below the action limits calculated based on CSA-N288.1 (Reference 11.2-3) and CSA-N288.5 (Reference 11.2-4) and within source dose limits for effluent release cited in SOR/2000-203 (Reference 11.2-5).

### **11.2.3 Description**

The LWM consists of collection tanks, sample tanks, filtration skids, RWST, CST, and associated pumps, piping, and instrumentation. The LWM is illustrated in Figures 11.2-1 to 11.2-2.

#### **11.2.3.1 Equipment, Arrangement, and Location**

The collection tanks, sample tanks and their associated pumps are located in the RWB.

The LWM filtration skids are also located in the RWB. The filtration skids are equipped with shielding to minimize exposure to personnel during operation and routine maintenance.

The RWST and the tank discharge pumps are located in the TB. The Reactor Well Pool filter and the drain pumps are located in the RB.

The CST and associated pumps and valves are located in the TB. CST distribution piping is located throughout the Turbine Building, the RWB and RB.

#### **11.2.3.2 Major Components Description**

##### **11.2.3.2.1 Tanks**

Tanks are sized to accommodate the expected volumes of waste generated in the upstream systems that feed liquid waste into the LWM for processing.

Materials are chosen for the tanks for protection of the tanks from abrasion, wet/dry cycles, freeze/thaw cycles, chemicals, and corrosion. The tanks are provided with mixing eductors. These eductors provide for mixing of the tank's contents to maintain a representative, homogenous fluid sample, and to keep solids in suspension for removal during transfer of the tank's contents. The capability exists to sample all Radwaste tanks. LWM tanks are vented into the Heating, Ventilation and Air Conditioning (HVAC) system of the Radwaste Building. The vents are also large enough to accommodate the airflow associated with pumping down the tanks at a maximum flowrate. To prevent the uncontrolled transport of contamination through those systems, the vents are not hard piped to the HVAC system.

#### **Collection and Sample Tanks**

The collection and sample tanks are cylindrical stainless steel atmospheric tanks sized to accommodate the expected waste volumes generated during normal operation, anticipated operational occurrences, and outage water movement requirements.

### **Refueling Water Storage Tank**

The RWST is a cylindrical stainless steel atmospheric tank sized to accommodate the Reactor Well Pool volume.

### **Condensate Storage Tank**

The CST is a cylindrical stainless steel atmospheric tank located in the TB ground floor. The CST is designed with a reserved capacity to support CRD functions.

### **Pumps**

The LWM process pumps are constructed of materials suitable for their intended service. In the RWB, the pumps are located underneath the corresponding tank. Each tank has a dedicated pump. Pumps are cross tied for flexibility of operation.

### **Filtration Skids**

The filtration skids are designed to process radioactive liquid waste to condensate water quality requirements for plant reuse. The skids utilize filters to remove suspended solids and ion exchangers for removing dissolved ionic compounds. Additional components to increase water quality may also be included on the filtration skids. Exhausted resins and solid wastes are collected into the holdup tanks of the SWM for processing.

### **Piping and Valves**

The containment penetration piping and isolation valves are SC1 and are designed in accordance with American Society of Mechanical Engineers (ASME) Boiler and Pressure Vessel Code Section III Class 2 (Reference 11.2-6) and Seismic Category A. All other piping is SC3 and is designed in accordance with the requirements of ASME B31.3 (Reference 11.2-7). LWM piping material is austenitic stainless steel to minimize corrosion. The LWM piping is butt-welded to prevent crud traps. Drainage piping is designed such that the waste from the collection point to the EFS flows by gravity.

#### **11.2.4 Materials**

Material and equipment selection for the system components is based on a planned 60-year design life, with appropriate provisions for maintenance and replacement. Piping and tanks are stainless steel for corrosion resistance. Components which may require periodic replacement and/or maintenance prior to the end of plant life include, but are not limited to, electrical and electronics, O-rings, bearings, gaskets and seals, lubricants, valve disks, seats, and packing.

#### **11.2.5 Interfaces with Other Equipment or Systems**

Refer to Table 11.2-1 for a listing and brief description of the LWM interfaces with other systems.

#### **11.2.6 System and Equipment Operation**

##### **11.2.6.1 Normal Operation**

The LWM normally operates on a batch basis. Liquid radioactive waste is collected into the collection tanks located in the RWB via the EFS. The Shutdown Cooling System (SDC) and the CUW overboarding flow are also routed to the LWM tanks. The EFS, SDC and CUW are described in Chapter 9A.

The liquid from the collection tanks is piped to the filtration skids for batch processing. Each batch is sampled to determine the concentrations of suspended solids and other contaminants. The analysis is completed within the laboratory of the RWB. Processed liquid waste that meets effluent criteria for condensate quality, is pumped to the CST for reuse within the plant or discharged to the environment if the plant's overall water inventory does not permit recycling.

NEDO-33961 REVISION 0  
NON-PROPRIETARY INFORMATION

Discharges to the environment are monitored by PRM and are automatically isolated upon receiving a signal from PRM (See Section 11.5). A recycle line from the sample tanks allows the sampled effluents that do not meet water quality requirements to be reprocessed.

The LWM is equipped with filtration skids for processing liquid waste in batches. Skid-mounted processing equipment along with cross-connections and bypasses are provided to enable efficient waste processing capability and flexibility of operation.

Filters are backwashed periodically to maintain efficiency and resin is replaced when depleted. Backwash waste and spent resin are discharged to the Solid Waste Management System.

During normal operation, when the Main Condenser Hotwell reaches low water level, the CST provides makeup water to the Hotwell.

#### **11.2.6.2 Off-Normal Operation**

The LWM has the capability to function under off-normal conditions providing a means to replenish the SFP following a DBA. Additionally, the CST provides continuous water to purge the Control Rod Drive system when the CFS is not available.

#### **11.2.6.3 Shutdown Conditions**

During shutdown, the Reactor Pressure vessel (RPV) temperature will decrease and cause the water volume in the RPV to shrink. The CST provides the additional makeup water to maintain the normal water level in the RPV.

During refueling outage, when the CFS is not available, the CST provides a continuous purge flow to the CRD system. During leaktest, the CST provides the water to flood the RPV.

The RWST is used to hold the Reactor Well Pool volume when reactor head bolts need to be loosened or tightened during an outage. The piping between the Reactor Well Pool and RWST contains a filter to maintain water purity during movement activities. Water is sampled to ensure water quality meets requirements before being pumped back into the Reactor Well Pool.

During the shutdown/refueling/startup mode, the increases in plant water demand may require use of a supplemental water. That makeup water is fed to the CST by the Water, Gas, and Chemical Pads (WGC) system.

#### **11.2.7 Instrumentation and Control**

The LWM provides the instrumentation to control and monitor (indicate and alarm) system operation.

##### **11.2.7.1 Instrumentation**

The LWM is operated and monitored from the Main Control Room (MCR). Major system parameters, i.e., tank levels, process flow rates, filters, and filtration skids effluent conductivity, etc., are indicated and alarmed as required to provide operational information and performance assessment. PRM (discussed in Section 11.5) continuously monitors the discharge of radioactivity to the environs.

##### **11.2.7.2 Control**

The LWM is controlled and monitored from the MCR.

The CST makeup water supply control valve of the WGC system modulates on the basis of level transmitters monitoring water level in the CST to control the water level in the tank. It also can be initiated manually from the MCR.

The condensate transfer pumps have the capability to be initiated manually locally and from the MCR. One of the pumps is normally operated in standby mode. The standby pump automatically starts when the running pump trips or when system flow demand exceeds the capacity of the operating pump.

The Main Condenser Hotwell is provided with two flow paths for Hotwell makeup, a normal flow path and an emergency flow path. Both flow paths are equipped with control valves that modulate on the basis of water level in the Main Condenser Hotwell to control the level of water in the Hotwell. The emergency valve modulates when the normal path cannot meet demands. Both valves also can be initiated manually from the MCR.

The flow of the liquid waste to the collection tanks is controlled by the EFS sump redundant level transmitters. Level signals can be used to start and stop the sump pumps based on high and low settings. A high LWM tank level initiates a high-level alarm in the MCR for the affected tank. Closure of the tank's inlet valves can be controlled remotely from the MCR to prevent overflow.

The environmental discharge controls consist of a flow control valve and two isolation valves in series that automatically close upon receiving a signal from the PRM and initiates a high radiation alarm in the MCR to ensure that release of radioactive liquid effluents meets the limits prescribed in the Radiation Protection Regulations (Reference 11.2-5), action levels and operational targets for releases in accordance with CNSC REGDOC-2.5.2, Section 8.11 (Reference 11.2-1), and per guidance in CSA N288.8 (Reference 11.2-8).

#### **11.2.8 Monitoring, Inspection, Testing, and Maintenance**

Provisions are made for periodic inspection of major components to ensure capability and integrity of the systems. The system design provides adequate equipment removal paths and personnel access for replacement per General Arrangement Drawings. Adequate space is provided in the RWB for maintenance of the pumps and valves and instruments.

#### **11.2.9 Radiological Aspects**

##### **Normal Operating Conditions**

Chapter 20, Section 20.14 summarizes analysis performed to determine the annual average liquid effluent releases from the LWM for normal operating conditions (including Anticipated Operational Occurrences (AOO)), based on normal operation source terms in the reactor coolant and steam described in Subsection 11.1.2. The results are used as an input to calculation of public dose show that the BWRX-300 is below regulatory limits.

As was discussed earlier, accidental discharge and discharge above regulatory limits is prevented through detection by PRM and alarm of abnormal conditions and by administrative controls. The LWM is designed to automatically stop liquid discharge from the sample tanks upon receiving a signal from the PRM. Offsite radiation exposures on an annual average basis are within the limits of CSA-N288.1 (Reference 11.2-3) and CSA-N288.5 (Reference 11.2-4).

##### **Leaks from Liquid Waste Management System Components**

To prevent tank leakage from exiting the building, the collection and sample tanks are enclosed within a concrete wall barrier. In the case that a tank failure occurs, the concrete wall containment area will prevent LWM water from exiting the RWB.

The overflow pipes of the tanks that hold radioactive liquid are designed to run to the appropriate radioactive drain collection system, and the vents are designed to run to the building's ventilation exhaust system, but neither are hard connected to their respective drain or vent systems to prevent the uncontrolled transport of contamination through those systems.

### **11.2.10 Performance and Safety Evaluation**

The two manual isolation CIVs are locked closed, only opened during refueling Mode 6 and are administratively controlled.

The performance of the LWM to minimize liquid effluent releases during normal operation to within prescribed limits and action levels is described in the analysis in Chapter 20, Section 20.14.

### **11.3 System for Management of Gaseous Radioactive Waste**

#### **11.3.1 System and Equipment Functions**

The objective of the Offgas System (OGS) is to process and control the release of gaseous radioactive effluents to the site environs so as to maintain the exposure of persons in unrestricted areas to radioactive gaseous effluents ALARA per CNSC REGDOC-2.5.2, Section 8.11.2 (Reference 11.3-1).

#### **11.3.2 Normal Functions (Non-Safety Category)**

The OGS does not perform any non-safety category functions during normal conditions.

#### **11.3.3 Normal Functions (Safety Category)**

The OGS performs the following Safety Category 3 FSF:

- Recombine hydrogen and oxygen back into water vapor to route back to the main condenser to reduce the explosion potential in downstream process components
- Provide a hold up via carbon adsorption for fission product gases to reduce the radioactive dose in the effluent released from the plant to the environment to levels below regulatory dosage requirements

#### **11.3.4 Off-Normal Functions (Non-Safety Category)**

The OGS does not perform any Non-Safety Category functions during off-normal conditions.

#### **11.3.5 Off-Normal Functions (Safety Category)**

The Charcoal Vault is designed such that the first charcoal bed in the series may be bypassed, referred to as the "Guard Bed". In the event that condensation occurs in the first charcoal bed, the bed may be bypassed, allowing for effluent to flow through the remaining three Charcoal Beds without carrying moisture from the first charcoal bed, and maintaining holdup for the Kkryptons and xenons. Acceptable holdup times are provided by the remaining three beds such that normal operation may continue until maintenance is able to restore the Guard Bed to normal operating conditions

#### **11.3.6 Safety Design Bases**

The OGS is designed to meet CNSC REGDOC-2.5.2, Section 8.11.3 requirements for control of radioactive contaminants to the environment and for maintaining airborne radioactive contaminants within prescribed limits and ALARA during reactor power operation. The OGS is an SC3 system due to its support of Defense Line 2 FSF fuel cooling and confinement of radioactive materials during normal operation.

The portion of the OGS within the TB is seismically categorized as Non-Seismic, while the portion of the OGS housed within the RWB is classified as RW-IIa.

#### **11.3.7 Description**

##### **11.3.7.1 Summary System Description**

The OGS provides for holdup and decay of radioactive gases in the offgas from the Main Condenser and Auxiliaries system.

The OGS minimizes and controls the release of radioactive material into the atmosphere by delaying and filtering the offgas process steam containing the radioactive isotopes of krypton, xenon, iodine, hydrogen, nitrogen, and oxygen sufficiently to achieve adequate decay before discharge from the plant.

The OGS is comprised of the following components shown in Figure 11.3-1:

- "3-in-1" Offgas Recombiner unit, including Offgas Preheater section, Offgas Catalytic Recombiner section, and Offgas Condenser section
- Cooler Condenser and Moisture Separator
- Refrigeration Dryers (two)
- Gas Analyzer
- Offgas Reheater
- Charcoal Adsorber Vault with Charcoal Adsorber Beds (four)
- Charcoal Vault HVAC equipment
- Offgas HEPA Filter
- Piping and Valves
- Instrumentation and Control equipment

#### **11.3.7.2 Equipment, Arrangement, and Location**

Equipment for the OGS is located within the TB and the RWB. The primary effluent line of the OGS begins at the valve interface with the Main Condenser and Auxiliaries system at the exit of the Steam Jet Air Ejectors (SJAES) within the TB.

The following components of the OGS are housed in the TB:

- Entrance process piping
- Offgas Recombiner
- Cooler Condenser and Moisture Separator
- Refrigeration Dryers (two)
- Gas Analyzer

After exiting the Refrigeration Dryers, OGS process piping carries the offgas effluent from the TB to the RWB.

The following components of the OGS are housed in the RWB:

- Offgas Reheater
- Charcoal Vault, including four Charcoal Adsorber Tanks
- Offgas HEPA Filter

The OGS process ends with the transfer of the offgas effluent to the Continuous Air Plenum (CAP) of the Heating Ventilation and Cooling System prior to final release.

#### **11.3.7.3 Structures, Systems and Components**

Figure 11.3-2 provides a simplified single line diagram for the OGS. The subsystems, components and their functions are described in the following subsections.

##### ***11.3.7.3.1 Offgas Recombiner***

The Offgas Recombiner is a "3-in-1" vessel consisting of a Preheater section, Catalytic Recombiner section, and Offgas Condenser section. The purpose of the Offgas Recombiner is

to facilitate the catalytic recombination of radiolytic oxygen and hydrogen into water, which is ultimately condensed via a series of downstream cooling equipment and returned to the main condenser.

The Preheater Section is a tube-and-shell heat exchanger. The purpose of the Preheater section is to raise the temperature of the offgas so that the water content reaches a superheated state, ensuring that it is fully boiled and gaseous prior to entering the Catalytic Recombiner section. Effluent offgas from the SJAEs, consisting of steam, air, hydrogen, oxygen, and other trace radioactive gases, enters the Catalytic Recombiner section through the Preheater section and flows through the shell side. Steam from the Main Steam line flows through the tube side and is used to heat the offgas. The Main Steam is condensed from a saturated vapor state to a saturated liquid state. The condensed Main Steam water is drained and returned to the main condenser, while the superheated offgas flows to the Catalytic Recombiner section. The Preheater section contains a pressure relief line to the main condenser, temperature element, and condensed steam drain line to the main condenser with a steam trap.

The Catalytic Recombiner section uses a precious metal catalyst bed to cause the recombination of radiolytic oxygen and hydrogen gases into water. Temperature and heating elements maintain the catalyst environment to acceptable temperature and moisture levels prior and during operation. For maintenance, normally-closed drains are included. Offgas flows from the Catalytic Recombiner section into the Offgas Condenser section.

The Offgas Condenser section is a tube-and-shell heat exchanger. This component provides the first stage of condensation of both the dilution steam in the effluent mix along with the additional water vapor resulting from the recombination of the radiolytic gases. The offgas effluent enters the shell side of the heat exchanger. Condensate water from the CFS enters the tube side of the heat exchanger and is used to cool the offgas effluent. Condensate water passes through the Condenser Section and returns to the CFS. The condensed liquid water from the offgas is drained to the main condenser. The remaining gaseous offgas effluent flows forward to the Cooler Condenser. The Offgas Condenser section includes a pressure relief line to the main condenser, flow element to monitor offgas condensate flowing to the main condenser, and temperature elements to monitor the Feedwater Condensate and gaseous offgas leaving the Offgas Recombiner.

#### ***11.3.7.3.2 Cooler Condenser***

The Cooler Condenser Section is a tube-and-shell heat exchanger. This component provides the second stage of condensation of the offgas. The offgas effluent enters the shell side of the heat exchanger. Chilled water from the Chilled Water Equipment (CWE) enters the tube side of the heat exchanger and is used to cool the offgas effluent. Chilled water passes through the Cooler Condenser and returns to the CWE. As most moisture is condensed in the Offgas Recombiner Condenser section, the condensed liquid water from the Cooler Condenser is drained to local floor drains. The remaining gaseous offgas effluent flows forward to the Moisture Separator.

#### ***11.3.7.3.3 Moisture Separator***

The Moisture Separator is downstream of the Cooler Condenser. This is an in-line tank with a wire mesh or chevron screen-type media which serves to divert any moisture droplets remaining in the effluent stream to a drain.

#### ***11.3.7.3.4 Refrigeration Dryers***

The Refrigeration Dryers provide the final stage of cooling and condensation removal of the offgas effluent. Two dryers are provided in parallel, though only one is active at any given time. This is

to ensure that operation of the OGS may continue if one dryer needs maintenance. Condensed water is drained to local floor drains.

#### ***11.3.7.3.5 Offgas Reheater***

Downstream of the Dryers is the Reheater. This serves the function to raise the effluent flow stream temperature from the refrigeration dryers to the higher temperature of the charcoal in the Charcoal Vault to prevent moisture in the flow stream from condensing onto the charcoal due to the temperature difference between the flow stream and the charcoal. This component is composed of a series of electrical resistance heaters mounted onto the exterior of the effluent pipe just upstream from the Charcoal Vault.

#### ***11.3.7.3.6 Charcoal Adsorber Vault and Tanks***

The OGS Charcoal Vault is a shielded and isolated room in which radioactive isotopes are contained and held up to allow for decay prior to release. Charcoal Vault pressure is maintained slightly lower than atmospheric pressure relative to the general area pressure to mitigate the risk of noble gas leaks. The Charcoal Vault HVAC system maintains the ambient temperature of the vault at a constant temperature. Vault temperature is continuously monitored, and the HVAC system has a redundant train of heating and cooling equipment.

The Charcoal Beds consist of four vertical tanks of granulated activated charcoal designed to hold up the targeted krypton and xenon isotopes so as to reduce released effluent activity. These tanks (and their contained charcoal volume) are designed to provide the required holdup for targeted noble gas isotopes to meet site requirements for release below action levels calculated per CSA N288.8 (Reference 11.3-2) ensuring prescribed limits for effluent releases cited in SOR/2000-203 (Reference 11.3-3). This is done through the process of adsorption, by which the atoms of the krypton and xenon gases are held (by Van der Waal-type forces) to the surfaces of the charcoal granules long enough to delay their migration downstream. Multiple temperature elements monitor the temperatures within each tank. A Carbon Monoxide (CO) monitor is provided to detect combustion of the charcoal, and nitrogen may be injected into the vault piping to extinguish the fire if necessary.

The first charcoal bed, known as the Guard Bed, is configured to be bypassed if a problem manifests in it (e.g., high moisture or potential combustion issue) such that the system could operate on the latter three beds (for short periods of time). As this is the first bed to process the effluent, it is most susceptible to any issues caused by a malfunction of the upstream equipment. Bypassing the Guard Bed is acceptable for short periods of time until any issue with that bed (and associated equipment) can be remedied.

The offgas effluent flows through the Guard Bed, then through the other three beds, before moving forward to the final offgas HEPA Filter for release. The entire Charcoal Vault may also be bypassed during offgas startup or off-normal operation.

#### ***11.3.7.3.7 Offgas HEPA Filter***

Downstream from the Charcoal Beds is an in-line HEPA filter. This is a small filter contained in a tank which serves to pick up any fine pieces of charcoal and any other particulates which may pass downstream of the Charcoal Beds immediately prior to offgas release. Differential pressure across the filter is monitored to detect whether a buildup of particulate within the filter is occurring.

#### ***11.3.7.3.8 Gas Analysis Equipment***

Hydrogen and oxygen concentration and moisture content are monitored at the outlet of the Dryer. The annunciators of high hydrogen concentration and high/low oxygen concentration alarm are provided at the MCR, and also serve as an input to the Hydrogen Water Chemistry system to adjust the injection of hydrogen and oxygen as needed. CO monitoring is provided at the outlet

of the Charcoal Vault to detect for fire. Radioactivity level in the OGS is monitored at the outlet of the dryers and just prior to release, and high radioactivity level trips an alarm in the MCR.

#### **11.3.8 Materials**

Material and equipment selection for the OGS are based on a 60-year design life, with appropriate provisions for maintenance and replacement.

#### **11.3.9 Interfaces with Other Equipment or Systems**

The interface between the OGS and other systems is listed in Table 11.3-1.

#### **11.3.10 System and Equipment Operation**

##### **11.3.10.1 Normal Operation**

The primary functions of the OGS are most applicable when the reactor is operating at high power. Production of radiolytic H<sub>2</sub> and O<sub>2</sub>, and of radioactive noble gas isotopes, are minimal outside of Reactor Power Operation mode, and as such, the OGS is not required to be in operation during Reactor Startup, Shutdown, and Refueling modes. The OGS System Modes coinciding with Plant Operating Modes are listed in Table 11.3-2 and described below.

##### ***11.3.10.1.1 Initial Configuration (Pre-Startup) Mode C (Secured))***

The OGS is secured (inactive) during initial startup operations (0-5% reactor power), all shutdown modes, and refueling. Because the reactor is at very low or no power during these operating modes, and because these modes occur for a relatively short period of time, the OGS is not required to process radiolytic gases in the effluent stream, and so the OGS is bypassed. The Mechanical Vacuum Pump is active and drawing main condenser vacuum, and valves controlling effluent flow to the OGS are closed.

##### ***11.3.10.1.2 System Startup (Mode B)***

The Startup Operation Mode of the OGS occurs between the time that the SJAEs are placed into service (at around 5% reactor power) as the reactor power rises, until reactor power has reached 10% power. At the beginning of startup, the Catalytic Recombiner section heaters are activated to ensure a sufficiently high temperature is present when the offgas effluent begins to flow through the OGS. This mode begins when the Mechanical Vacuum Pump is secured (i.e., no longer drawing main condenser vacuum). Radiation levels (in the effluent flow stream) are relatively low at this time.

During Startup Operation Mode, the effluent stream flows through a bypass valve around the Charcoal Vault, then releases to the HVAC system. This is to prevent damage to the Charcoal Beds due to the increased air in-leakage rate during startup.

During OGS startup, there is little hydrogen and oxygen to recombine as radiolysis is directly dependent on (and directly proportional to) reactor power to drive the process. As such, there is little temperature rise seen in the Offgas Recombiner during this mode (due to the minimal heat added by the exothermal process of recombination). Likewise, leakage rates of radioactive isotopes (kryptons and xenons) into the offgas effluent are minimal at this stage.

##### ***11.3.10.1.3 Normal Operation (Mode A)***

The Normal Operation Mode of the OGS begins at or just beyond 10% reactor power, where main condenser vacuum is stable, much of the in-leakage has subsided, and higher levels of radiation (in the flow stream) are occurring due to the rise in noble gas release from the fuel in the form of xenons and kryptons. The flow of effluent is routed through all primary system components, including the Offgas Recombiner, Cooler Condenser, Moisture Separator, Refrigeration Dryer, Charcoal Vault and all Charcoal Tanks, and the Filter before being released.

During normal operation, radiolytic gas production varies linearly with thermal power.

During the beginning of the normal Mode of operation, the Catalytic Recombiner temperature steadily rises with reactor power up to 100% reactor power, at which point the Catalytic Recombiner temperature stabilizes.

One dryer is in-service, with the other on standby.

#### **11.3.10.2 Off-Normal Operation**

The Charcoal Vault is designed such that the first charcoal bed in the series (referred to as the "Guard Bed") may be bypassed. If condensation occurs in the first charcoal bed, the bed may be bypassed, allowing for effluent to flow through the remaining three Charcoal Beds preventing moisture passing from the first charcoal bed, and maintaining holdup for the kryptons and xenons. Acceptable holdup times are provided by the remaining three beds such that normal operation may continue until the Guard Bed is restored to normal operating conditions.

#### **11.3.10.3 System Shutdown**

OGS Shutdown operation essentially functions as a reversal of the startup operation. As the reactor powers down, the OGS will continue operating until the main condenser vacuum is switched to the Mechanical Vacuum Pump. When vacuum flow is no longer flowing through the OGS, a final purge flow from the Plant Pneumatic System (PPS) is sent through the OGS to eliminate any remaining gas in the piping. When the plant has reached SHUTDOWN operation mode, the OGS is secured.

#### **11.3.11 Instrumentation and Control**

##### **11.3.11.1 Minimum Offgas Flow Rate Control and Air Injection**

A minimum offgas flowrate is maintained at all times while there is flow through the Offgas Recombiner to support normal function of the Catalytic Recombiner.

Flow detectors continuously measure the minimum offgas flowrate and transmit a control signal upstream to the Main Condenser and Auxiliaries to inject additional air into the effluent flow if this minimum is not met.

##### **11.3.11.2 Instrumentation**

The following are the key instrumentation features of the OGS:

1. Temperature and pressure of noncondensable gases entering the Offgas Recombiner are continuously monitored in the MCR. These measurements are used to alarm on low gas temperature (which may impact the catalytic recombination operation) and high gas pressure (which may exceed the design pressure of the Offgas Recombiner vessel.).
2. Temperature of the offgas effluent stream is measured in the Preheater Section and at different locations within the Catalytic Recombiner section using temperature elements. These measurements are displayed in the MCR to assure that recombination is occurring. Low (Preheater Section) and high/low (Catalytic Recombiner section) temperatures generate alarms in the MCR.
3. Temperature of the offgas effluent stream is measured after the Offgas Condenser section with temperature elements to assure the effluent is cooled sufficiently to remove undesired moisture.
4. Temperature of the offgas effluent stream is measured after the Cooler Condenser with temperature elements to assure the effluent is cooled sufficiently to remove undesired moisture.

NEDO-33961 REVISION 0  
NON-PROPRIETARY INFORMATION

5. Offgas effluent flowrate downstream of the Offgas Recombiner and downstream of the Charcoal Adsorber Vault is continuously monitored to permit monitoring of fission gases from the reactor and calculation of offgas discharge to the vent and will permit calculation of the charcoal adsorber system performance.
6. Radiation levels at two sample points, one just downstream of the Refrigeration Dryers, and one just downstream of the Charcoal Vault, are monitored and are continuously displayed in the MCR. These measurements are used to alarm on high radiation levels.
7. Drain seal loops on the Offgas Condenser section are monitored using level transmitters that alarm in the MCR on low/high water level.
8. A CO monitor downstream of the first Charcoal Adsorber Tank (the Guard Bed) and another CO monitor downstream of the last charcoal adsorber are used to confirm the presence and cessation of charcoal combustion within the vessels.

### **11.3.11.3 Control**

Controls for the OGS are available in the MCR to facilitate system operation. System and component operating status, including the state of any bypasses or manual overrides, are provided at the control console. Manual initiation and shutdown of the OGS is provided from the control room.

OGS parameter indications are provided in the MCR. The indications available included but not limited to: Offgas Recombiner temperatures and flows, Dryer Outlet hydrogen and oxygen content, Charcoal Adsorber bed temperatures, and OGS release effluent radiation and flow rates.

OGS alarms are provided in the MCR based on specific setpoints for the Offgas Recombiner indications, Charcoal Adsorber bed temperatures, Hydrogen and Oxygen levels, and OGS Discharge Radiation levels.

### **11.3.12 Monitoring, Inspection, Testing, and Maintenance**

#### **11.3.12.1 Monitoring**

Regular sampling of the offgas is conducted for isotopic analysis of the offgas to ensure that the required limits for the annual average atmospheric dispersion factor are satisfied. This sample occurs on an established frequency, under normal operating conditions to ensure that the increase is not indicative of a sustained increase in the radioactivity rate. The frequency is established based on operating experience and is in addition to other instrumentation that continuously monitors the offgas. The sampling is not required to be performed until radioactive fission gases are present in the Main Condenser Offgas System at significant rates.

Individual component maintenance and inspection requirements will be provided in vendor specification documentation.

The design of the OGS components includes, where appropriate, any special tools or special facilities which are required to disassemble, assemble, or otherwise perform maintenance on those components.

#### **11.3.12.2 Accessibility for Maintenance**

Equipment will not normally be accessible for maintenance during system operation. All equipment is available during the plant outage. The following are exceptions:

1. The redundant refrigeration dryer is accessible for maintenance while inactive.
2. Control valving and hydrogen analyzers are accessible for maintenance during the out-of-service portion of their cycle.

3. Charcoal Vault air HVAC equipment is accessible for maintenance during plant operation.
4. The isolation valves in the nitrogen and air purge lines are accessible for maintenance from outside the Charcoal Vault and when operating the OGS.

#### **11.3.12.3 Surveillance Testing and In-Service Inspection Provisions**

Routine testing of the OGS is conducted in accordance with normal power plant requirements for demonstrating system and component operability and integrity.

The system has no requirements for In-Service Inspection.

#### **11.3.13 Radiological Aspects**

##### **Normal Operating Conditions**

Chapter 20, Section 20.13 summarizes analysis performed to determine the annual average gaseous effluent releases (including releases from the OGS) for long-term normal operation (including AOOs).

The OGS minimizes and controls the release of radioactive material into the atmosphere by delaying release of the offgas process stream initially containing radioactive isotopes of krypton, xenon, iodine, nitrogen, and oxygen. This delay, using activated charcoal adsorber beds, is sufficient to achieve adequate decay before the process offgas stream is discharged from the plant.

The gaseous effluent treatment systems are designed to limit the dose to offsite persons from routine station releases to significantly less than the limits in Radiation Protection Regulations (Reference 11.3-3) and below the action levels established per CSA N288.8 (Reference 11.3-2).

Charcoal Vault pressure is maintained slightly lower than atmospheric pressure relative to the general area pressure to mitigate the risk of noble gas leaks from the vault into the wider plant.

##### **OGS Leak or Failure**

The limiting BWRX-300 OGS failure is an inadvertent bypass of the charcoal delay beds. An evaluation was performed, and the resulting public dose consequences are well below the CNSC REGDOC-2.5.2, Section 4.2.1 (Reference 11.3-1) limits as shown in Table 11.3-3.

#### **11.3.14 Performance and Safety Evaluation**

The performance of the OGS to minimize gaseous effluent releases during normal operation to within prescribed limits and action levels is described in the analysis in Chapter 20, Section 20.13.

**Table 11.3-1: System Interfaces**

<b>Interfacing System</b>	<b>Interface Description</b>	<b>Interface Boundary</b>
Nuclear Boiler System (NBS)	Input: Reactor steam is provided to the OGS to heat the effluent entering the Preheater. Steam enters the OGS piping, enters the tube side of the Preheater is condensed to liquid, and is ultimately ejected to the MCA.	Boundary Air Operated Valve (AOV) is owned by NBS.
SC2 and SC3 Digital Control and Information System (DCIS)	NS DCIS receives/provides signals to S I&C equipment in the OGS.	Throughout the system.
Process Radiation Monitoring Subsystem (PRM)	Output: Offgas effluent are sampled and monitored by PRM downstream of dryers and prior to release to ensure offgas radiation content is below the acceptable release limit.	Release sample flow to Rad Monitoring. Post-dryer monitoring.
Condensate and Feedwater System (CFS)	Output: CFS reactor condensate water flows through the tube side of the Offgas Condenser. Effluent heat is rejected to the CFS condensate. CFS condensate water is returned to the CFS system piping after exiting the Offgas Condenser.	Piping immediately up to the fitting on the Offgas Condenser is owned by CFS. The boundary where condensate water returns from OGS to CFS.

NON-PROPRIETARY INFORMATION

Interfacing System	Interface Description	Interface Boundary
Main Condenser and Auxiliaries (MCA)	Input: Effluent gases (including air in-leakage and noncondensable gases) and dilution steam from the MCA SJAEs flow directly to OGS.	Boundary valve owned by MCA.
	Input: Air Injection. When additional air is required to maintain the minimum required flow of 0.17 sm <sup>3</sup> /min (6 scfm) through the Offgas Recombiner, air may be injected into the effluent line upstream of OGS within the boundaries of MCA.	Boundary valve owned by MCA. Additional air is injected directly into incoming effluent line.
	Output: Condensed water from Offgas Preheater tube side (originating from Main Steam) and from the Offgas Condenser shell side (originating from the dilution steam from the SJAEs) is drained to the main condenser.	Boundary to MCA is at the main condenser itself.
	Output: Flowrate of air into the Offgas Recombiner is monitored to ensure minimum required flow 0.17 sm <sup>3</sup> /min (6 scfm) is met. This flowrate is sent as a control signal to MCA to indicate if air injection is required.	Flow Indicator/transmitter located prior to entering Offgas Preheater.
Chilled Water Equipment (CWE)	Output: Chilled water is used to provide cooling to the Cooler Condenser and to the cooling coils in the Charcoal Vault HVAC system. Chilled water flows through the equipment then returns directly to CWE.	Boundary valves owned by CWE.
Plant Pneumatics System (PPS)	Input: Motive air for AOV valve control provided by the PPS.	At each valve.
	Input: Nitrogen flow to purge Charcoal Tanks during maintenance periods.	N <sub>2</sub> inlet within the Charcoal Vault.

NEDO-33961 REVISION 0  
NON-PROPRIETARY INFORMATION

Interfacing System	Interface Description	Interface Boundary
Hydrogen Water Chemistry	Input: Hydrogen Water Chemistry control.	Hydrogen Water Chemistry may inject additional hydrogen into the effluent flow upstream of OGS, to be recombined with oxygen into water in the Offgas Recombiner.
	Output: hydrogen and oxygen monitoring and control signal.	A Gas Analyzer in OGS will sample the flow downstream of the Refrigeration Dryers to monitor H <sub>2</sub> and O <sub>2</sub> content in the effluent flow, sending a signal to Hydrogen Water Chemistry if the detected gas content is above a set threshold.
SC2 and SC3 Electrical Distribution System	Input: Non-Safety Electrical Distribution System to provide power to non-safety category electrical loads in OGS system.	Interface to be located at local breaker.
Heating Ventilation and Cooling System	Output: Exhaust heat from Offgas equipment (Refrigeration Dryers and Charcoal Vault cooling), offgas effluent release.	TB HVAC, RWB HVAC.
Equipment and Floor Drain System (EFS)	Output: Water condensed from the effluent in the Cooler Condenser, through the Moisture Separator, and the Refrigeration Dryers are drained to EFS.	Cooler Condenser, Moisture Separator, and Refrigeration Dryer drain lines.
Turbine Building Structure	Input: OGS equipment is housed within TB.	TB interior.
Radwaste Building	Input: OGS Charcoal Vault and downstream equipment is housed within the RWB.	RWB interior.

**Figure 11.3-1: OGS Simplified Flow Diagram**

## **11.4 System for Management of Solid Radioactive Waste**

### **11.4.1 System and Equipment Functions**

The purpose of the SWM is to control, collect, handle, process, package and temporarily store solid waste generated by the plant prior to shipping the waste offsite.

#### **11.4.1.1 Normal Functions (Non-Safety Category)**

The SWM processes the LWM filtering skid spent resins and filter backwash, lab waste, oily sump waste, filter backwash sludges, reverse osmosis concentrates, charcoal media, and bead resins generated by the FPC, ICC, and CFD systems. Contaminated solids such as HEPA and cartridge filters, rags, plastic, paper, clothing, tools, and equipment are also disposed of in the SWM system.

The SWM is capable of receiving, processing, and dewatering the solid radioactive waste inputs for permanent offsite disposal in accordance with CSA N292.0 (Reference 11.4-1).

#### **11.4.1.2 Normal Functions (Safety Category)**

The SWM has no Safety Category function. There is no liquid plant discharge from the SWM. Failure of the system does not compromise any SC system or component, nor does it prevent shutdown of the plant. No interface with the SC electrical system exists.

#### **11.4.1.3 Off-Normal Functions (Non-Safety Category)**

The SWM does not perform any non-safety category functions during off-normal conditions.

#### **11.4.1.4 Off-Normal Functions (Safety Category)**

The SWM does not perform any safety category functions during off-normal conditions.

### **11.4.2 Safety Design Bases**

The SWM system has no Safety Category function. There is no liquid plant discharge from the SWM system. Failure of the system does not compromise any SC system or component, nor does it prevent shutdown of the plant. No interface with the SC electrical system exists.

### **11.4.3 Description**

The SWM is primarily located in the RWB with individual collection locations around the plant, and consists of the following functions:

- Spent Resin Processing
- Sludge Processing
- Solid Waste Storage

Figure 11.4-1 provides a simplified single line diagram for the SWM. The subsystems, components and their functions are described in the following subsections.

#### **11.4.3.1 Equipment, Arrangement, and Location**

The SWM major components, which include the spent resin tank, sludge tanks, high integrity containers (HICs) (containers designed or engineered for radioactive waste), dewatering pump, sludge transfer pumps, and spent resin transfer pump are all located in the RWB which has adequate space for on-site storage of the HICs, shielded filter containers, and drums. The HICs are also located in such a manner as to allow for easy installation and removal.

#### **11.4.3.2 Major Components**

The following sections describe the major components in the SWM.

#### ***11.4.3.2.1 Spent Resin Processing***

##### **Spent Resin Tank**

The spent resin tank is a cylindrical stainless steel atmospheric tank fitted with a liquid level sensor and transmitter to prevent overfilling of the tank. The spent resin tank is also fitted with an overflow connection at least the size of the largest tank inlet and installed below the tank vent and above the high-level alarm setpoint. The tank overflow line is routed to the EFS system. A mixing eductor is fitted to the tank to facilitate mixing of the heavier solids and liquid and prevent heavier solids from settling at the bottom of the tank.

Tank capacities were selected to provide sufficient storage capacity for waste generation at normal generation rates and to allow sufficient time for the decay of shorter-lived radionuclides before shipping to an offsite facility.

##### **Spent Resin Tank Transfer Pump**

The SWM is designed with pumping capable of transferring the spent resin from the spent resin tank to the HICs.

#### ***11.4.3.2.2 Sludge Processing***

The following pieces of equipment are designed to exclusively handle sludge.

##### **Sludge Tank**

The sludge tanks are cylindrical stainless steel atmospheric tanks fitted with liquid level sensors and transmitters to prevent overfilling of the tanks. The sludge tanks are also fitted with an overflow connection at least the size of the largest tank inlet and installed below the tank vent and above the high-level alarm setpoint. The tanks' overflow lines are routed to the EFS system. Mixing eductors are fitted to the tanks to facilitate the creation of a slurry prior to the sludge transfer to the HICs.

Tank capacities were selected to provide sufficient storage capacity for waste generation at normal generation rates and to allow sufficient time for the decay of shorter-lived radionuclides before shipping to an offsite facility.

##### **Sludge Tank Transfer Pump**

The SWM is designed with pumps capable of transferring the sludge from the sludge tanks to the HICs.

#### ***11.4.3.2.3 Solid Waste Storage***

The following pieces of equipment are design to dewater the spent resin coming from the spent resin tank and the collected sludge from the sludge tanks.

##### **High Integrity Containers**

The SWM is designed with HICs configured with dewatering internals which remove standing liquid to <1% by volume. Per CSA N292.0 (Reference 11.4-1) solid radioactive waste should contain as little free standing and corrosive liquid as practicable. The HICs are installed with level sensors, level transmitters, passive vents, and sample monitoring.

##### **Dewatering Pump**

The SWM is designed with a pump capable of removing water from the HICs.

## **Drum Evaporator**

The drum evaporator is loaded with a drum filled with solids from lab samples, LWM skid waste, and oily waste from EFS. The drum evaporator is capable of removing excess moisture, through evaporation, which is routed to the RWB ventilation system to elimination.

### **11.4.3.2.4 Piping and Valves**

The piping and valves associated with resin and sludge systems are corrosion resistant stainless steel designed to the requirements of ASME B31.3 (Reference 11.4-2). The valves minimize crud buildup by utilizing full port valves for transferring, and diaphragm style valves to control flow. Full port valves reduce the potential for solidification due to minimal flow restrictions, and diaphragm valves can handle slurry fluids without the potential of contaminating working parts of the valve. Bottom valves on slurry containing tanks are designed to be flush mounted to eliminate pockets.

### **11.4.4 Materials**

Material and equipment selection for the system components is based on a planned 60-year design life, with appropriate provisions for maintenance and replacement. Piping and tanks are stainless steel for corrosion resistance.

Components which may require periodic replacement and/or maintenance prior to the end of plant life include, but are not limited to, electrical and electronics, O-rings, bearings, gaskets and seals, lubricants, valve disks, seats, and packing.

### **11.4.5 Interfaces with Other Equipment or Systems**

Refer to Table 11.4-1 for a listing and brief description of the SWM interfaces with other systems.

### **11.4.6 System and Equipment Operation**

The SWM operates continuously during all normal operating modes of the plant. The SWM carries out the following functions:

- Continuously remove dissolved and suspended solids, corrosion products, and spent bead resin so they do not enter the floor and equipment drain system
- Store high activity spent resin for decay
- Dewater and package the waste for temporary on-site storage prior to shipping the waste offsite

#### **11.4.6.1 Spent Resin and Sludge Processing**

Spent bead resin slurry from the ICC, CFD, FPC and LWM systems is sent to the dedicated spent resin tank for collection and decay. When sufficient bead resins have been collected in the spent resin tank, resin is transferred to HICs for dewatering and eventual disposal.

The associated tanks, piping, pumps, and valves can be flushed using CST water to minimize trace solids and reduce dose in the system.

Filter and demineralizer backwash from the FPC and CFD systems is collected in the two sludge tanks to allow the solids to settle out. Backwash water from the high flow fine filtration filters and skids can also be routed to the SWM sludge tanks for processing and liquid removal. Once enough sludge has been collected, the sludge is transferred by the sludge tank transfer pumps to the HICs for dewatering and eventual disposal.

The spent resin and sludge tanks are sized to accommodate the expected volume of waste generated in the upstream systems that feed waste into the SWM for processing.

#### **11.4.6.2 Solid Waste Storage**

Dry solid wastes consist of air filters, miscellaneous paper, rags, etc., from contaminated areas; containment clothing, tools, and equipment parts that cannot be effectively decontaminated; and solid laboratory waste. These wastes are collected in containers located in appropriate areas throughout the plant, as dictated by volume of wastes generated during operation and maintenance. The filled containers are sealed and moved to controlled-access enclosed areas for temporary storage.

Most dry waste is expected to be sufficiently low in activity to permit temporary storage in an unshielded, cordoned-off area. Dry active waste is sorted and packaged in a suitably sized container that meets guidance in CSA 292.0 (Reference 11.4-1) for shipment to either a licensed offsite processor or for ultimate disposal. The dry waste is separated into three categories: non-contaminated wastes (clean), contaminated metal wastes, and the other wastes, i.e., clothing, plastics, HEPA filters, and other components. Non-contaminated (clean) materials identified during the sorting process can be removed for plant reuse or general debris disposal.

On-site storage space for packaged waste including the HICs, shielded filter containers, drums, and other shipping containers is provided in the RWB.

To the extent possible, discarded chemicals (including those classified as hazardous) will be kept out of the SWM. Waste is collected primarily in collection drums and sent offsite to an appropriately permitted vendor processor per CNSC REGDOC 2.11.1 (Reference 11.4-3).

Solids from lab samples, LWM skid waste, and oily waste from the EFS are collected in a drum and loaded in the drum evaporator. The drum evaporator removes excess moisture, through evaporation, which is routed to the RWB ventilation system for elimination.

#### **11.4.7 Instrumentation and Control**

##### **11.4.7.1 Instrumentation**

Level transmitters are provided on each tank for high-level indication and alarm to prevent overflow of the tanks and the HICs. As the HICs are intended to be removable, they come preinstalled with a level transmitter.

Other parameters indicated and alarmed in the MCR include pump pressures, discharge flows, remote valve positions, process mode, evaporator temperature and level.

##### **11.4.7.2 Control**

All operations, including system operating mode selection and transfer pump operation, can take place remotely through the MCR control panel. System interlocks prevent tank overflow and prevent simultaneous transfer of spent resin and sludge to the HICs. System logic includes a flushing cycle to clean the tanks and transfer lines of any residual particulates which are then transferred to the HICs for further dewatering. Flexibility in system operation exists to allow backflushing of filters into the empty sludge tank while the full sludge tank is being processed to the HICs. This flush consists of clean water addition from the CST. The addition of the flush water to the tanks assures complete mixing and forwarding of suspended solids minimizing the solids depositing within the transfer piping. Manual initiation is required to transfer the spent resin and sludge to the HICs.

#### **11.4.8 Monitoring, Inspection, Testing, and Maintenance**

Component specific maintenance procedures are outlined in the vendor manuals provided as part of each procurement package.

Isolation valves are provided for equipment, control valve, and piping circuit to facilitate maintenance and repair.

Tanks and pumps are arranged to provide adequate floor space and unobstructed clearance to permit monitoring, maintenance, and inspection of each unit.

The piping is routed to minimize the number of areas in the SWM requiring in-service inspection.

#### **11.4.9 Radiological Aspects**

SWM is designed to include shielding and controls sufficient to limit accessible general area radiation levels consistent with ALARA principle per CNSC REGDOC-2.7.1 (Reference 11.4-4) during normal processing. During filter media or waste container transfer operations, process system provisions for remote operation limit average worker radiation dose rates.

Isolation diaphragms are installed between all transmitters and the piping to avoid contaminating the instrument. Component selection is based upon the need for minimizing crud buildup.

There is no liquid plant discharge from the SWM. Failure of the system does not compromise any SC system or component, nor does it prevent shutdown of the plant. No interface with the SC electrical system exists.

#### **11.4.10 Performance and Safety Evaluation**

The SWM performs no Safety Category function.

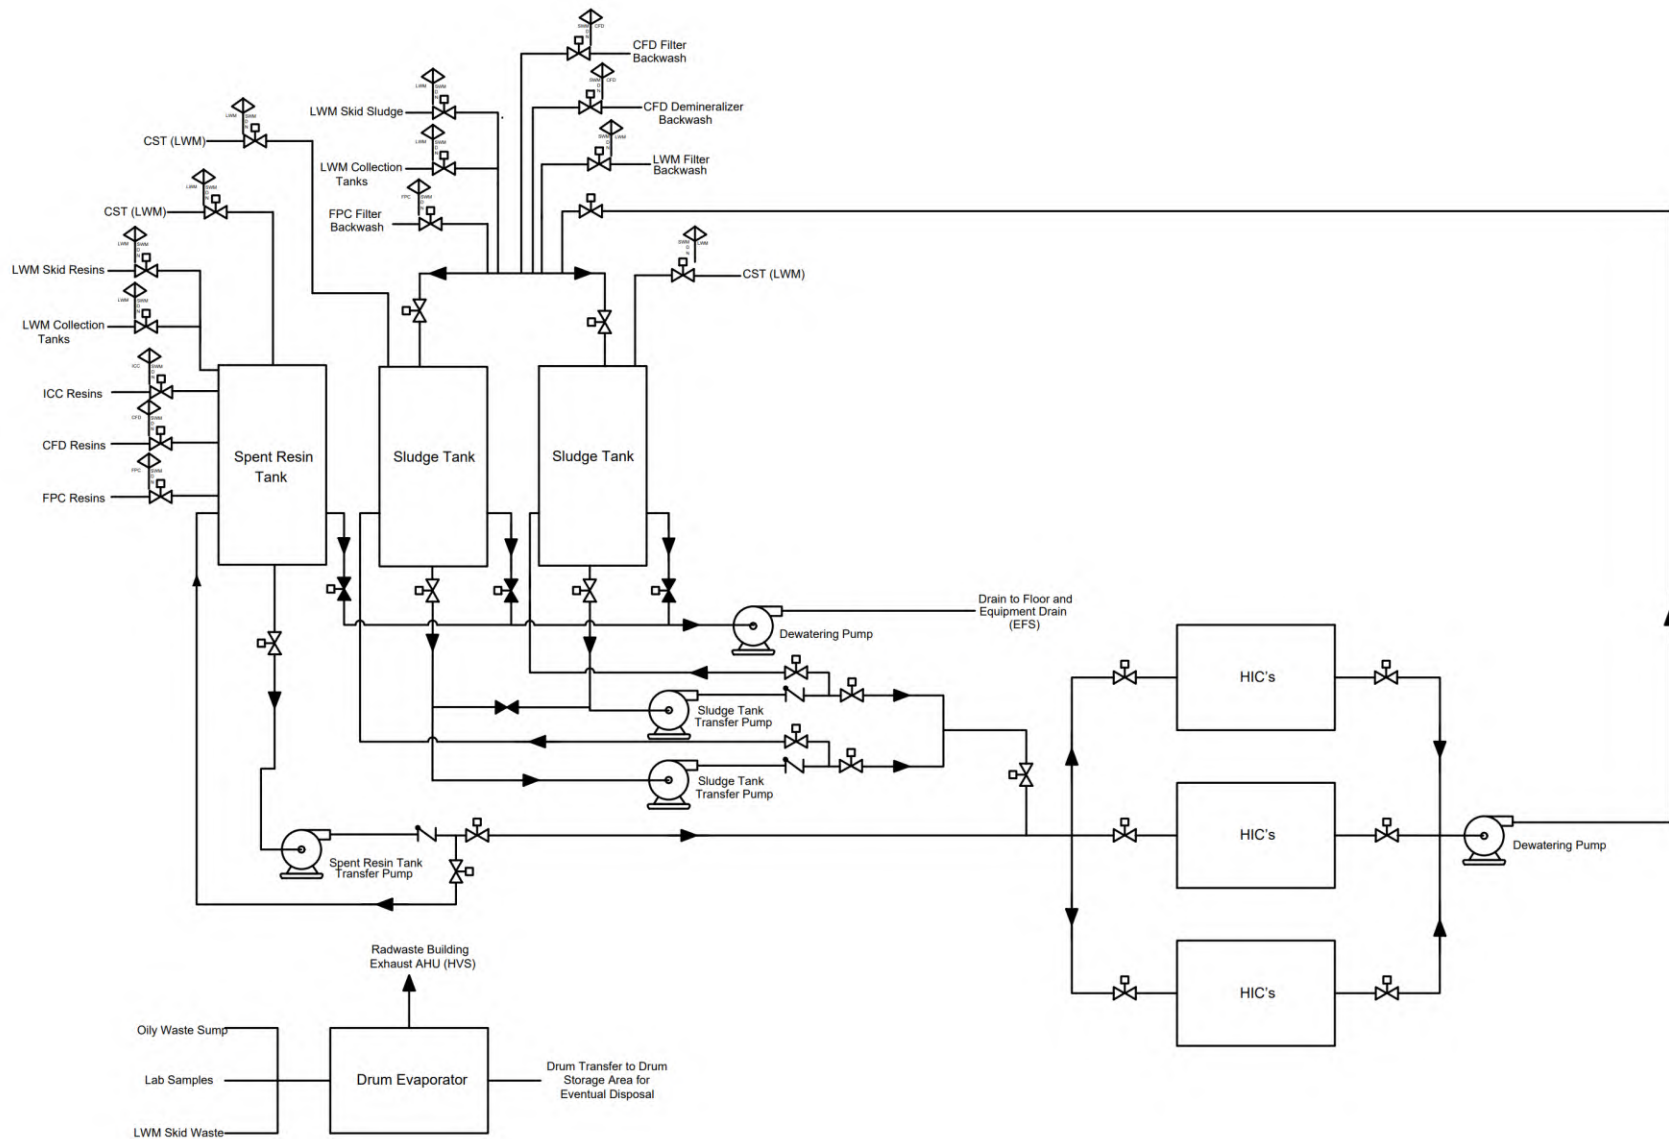

Figure 11.4-1: System Simplified Line Diagram

## **11.5 Process and Effluent Radiological Monitoring**

### **11.5.1 System and Equipment Functions**

The Process Radiation and Environmental Monitoring System (PREMS) for the BWRX-300 provides continuous and periodic monitoring to allow determination of the content of radioactive material in various gaseous, liquid process, and effluent streams.

PREMS also provides monitoring of other conditions such as oxygen and hydrogen concentrations in containment, HVAC contamination and toxic gas intake. PREMS includes a means to collect liquid and gaseous samples for analysis to support monitoring of plant processes.

PREMS consists of four subsystems as described below. The Process Radiation Monitoring subsystem is mostly relevant to process and effluent radiological monitoring with contributions from the other subsystems as discussed in detail in this Chapter. Detailed descriptions of the other subsystems of the PREMS are discussed in other PSAR chapters as indicated.

The PREMS includes the following subsystems:

- Process Radiation Monitoring Subsystem (PRM) – the purpose of the PRM is to determine the content of radioactive material in various gaseous and liquid process and effluent streams.
- Area Radiation Monitoring Subsystem (ARM) – the purpose of the ARM is to continuously measure, indicate and record gamma radiation levels at strategic locations throughout the plant, except for the containment areas, and initiates alarms in the MCR, Secondary Control Room (SCR), and locally to warn personnel. (Details of the ARM are found in Chapter 12, Subsection 12.3.14.)
- Containment Monitoring Subsystem (CMon) – the purpose of the CMon is to provide instrumentation to monitor multiple parameters inside containment. (Details of the CMon system are found in Chapter 12, Subsection 12.3.14.)
- Process Sampling Subsystem (PS) - The PS collects representative liquid and gaseous samples for analysis and provides the analytical information required for monitoring plant and equipment performance. (Details of the PS are found in Chapter 9A, Section 9A.3.1.).

#### **11.5.1.1 Normal Functions (Non-Safety Category)**

Radiation monitoring for plant operations provides personnel with sufficient warning to seek protection from radioactive material content in Non-Safety Category gaseous and liquid effluent, and process streams.

The following Non-Safety Category functions are monitored by this PRM instrumentation:

- Gaseous Effluent Streams:
  - Main Turbine Gland Seal Steam Condenser Exhaust
  - TB Normal HVAC Exhaust
  - TB Compartment Area HVAC Exhaust
  - TB Annex HVAC Exhaust
  - Radwaste Building HVAC Exhaust
- Gaseous Process Streams:
  - Offgas Pre-treatment

- Offgas Post-treatment
- Charcoal Vault Ventilation
- Liquid Process Streams:
  - CUW
  - Shut Down Cooling System

The following ARM area radiation monitors are provided:

- FPC Filter/Demineralizer
- Various locations in the Refueling Area
- Others based on plant layout

Other interfaces for the ARM include locations within:

- Reactor Building Structure
- Turbine Building Structure
- Control Building Structure
- Radwaste Building Structure

#### **11.5.1.2 Normal Functions (Safety Category)**

The following Safety Category functions are initiated by the PRM instrumentation:

- Main Steam Line (MSL) in the NBS downstream of the Containment Isolation Valves
- ICS leaking
- Liquid Radwaste Discharge
- CWS Discharge
- RB HVAC exhaust
- Stack
- Refuel Floor/Fuel Pool Area HVAC exhaust
- Containment Purge exhaust
- Control Room Habitability Area HVAC subsystem
- SCR HVAC

#### **11.5.1.3 Off-Normal Functions (Non-Safety Category)**

The off-normal non-safety category functions are generally the same as the normal non-safety category functions.

#### **11.5.1.4 Off-Normal Functions (Safety Category)**

The off-normal safety category functions initiated and monitored by the PRM instrumentation are the same as the normal safety category functions.

### **11.5.2 Safety Design Bases**

The PRM provides both Safety Category and Non-safety Category functions. The safety category functions include the environmental safety and radiation protection instrumentation functions to

initiate protective actions to limit the potential release of radioactive materials to the environment if major process/effluent stream radiation levels are exceeded. A second function is to provide plant personnel with alarms in support of personnel exposure prevention and potential environmental issues.

In accordance with CNSC REGDOC-2.5.2, Section 8.11 (Reference 11.5-1), liquid and gaseous radioactive release points/paths within the plant are identified and monitored by the PRM to ensure that planned radiological releases from both normal operation and waste management activities conform to the ALARA principle and are below prescribed limits. Action levels are established per CSA N288.8 (Reference 11.5-2) and monitored through the implementation of an Effluent Monitoring Program per CSA N288.5 (Reference 11.5-3). Details on the Effluent Monitoring Program are provided in Chapter 20, Section 20.11.2.

Radiation monitoring is provided during normal reactor operation, anticipated operational occurrences, and post-accident conditions.

### **11.5.3 Description**

The PRM provides radiation instrumentation required for:

- Environmental safety and protection
- Monitoring during plant operation

This instrumentation is provided in various plant locations for monitoring in various plant systems as described in Subsection 11.5.5.

### **11.5.4 Materials**

The materials selected for use in the system have been chosen to fulfill environmental requirements. Components and cables used in radioactive areas are qualified for the anticipated or calculated radiation conditions.

### **11.5.5 Interfaces with Other Equipment or Systems**

The PRM interfaces with other equipment and systems as a function of system operation. The interfaces are listed in Table 11.5-1 and summarized below.

#### **11.5.5.1 Nuclear Boiler System**

The PRM monitors the gamma radiation level of the steam transported by the Main Steam Lines (MSLs) in the MSL tunnel. The normal radiation level is produced primarily by coolant activation gases plus smaller quantities of fission gases being transported with the steam. The MSL radiation monitors consist of three instrument channels for each of the two main steam lines. Each channel consists of a local gamma-sensitive detector with instrumentation to transmit the data to the MCR and SCR.

The detectors are physically located near the MSLs just downstream of the outboard MSL isolation valves in the steam tunnel. These detectors are arranged so that they are capable of detecting significant increases in radiation levels in either of the MSLs in operation.

The PRM provides the detection signals to the DCIS that support decision logic for shutdown and isolation of the main turbine condenser mechanical vacuum pump and the SJAEs upon detection of high MSL radiation. Channel trips are annunciated in the MCR and SCR. The measurement range is selected to provide detection from normal background radiation at zero percent reactor power up to, and including, gross releases of fission products from reactor fuel into the reactor vessel and its subsequent transport to the MSLs.

#### **11.5.5.2 Isolation Condenser System**

The PRM provides radiation monitoring for the Isolation Condenser (IC) pool areas that are part of the ICC for monitoring the ICS system. The PRM will monitor the radiation from the exhaust of the air above each IC. Elevated radiation levels may indicate an ICS pressure boundary leakage. The radiation monitors will be placed above each inner pool, near the access hatch to facilitate easy access for maintenance. Any condenser leakage would release radionuclides into the atmosphere and the slightly positive pressure maintained inside the inner pool air space would force air through the ventilation space that will be monitored for radiation.

#### **11.5.5.3 Shutdown Cooling System**

The PRM provides a single gamma-sensitive radiation monitor located on the overboard line upstream of the SDC Supply Flow Element and provide alarm function only on a high radiation signal.

#### **11.5.5.4 Reactor Water Cleanup System**

The PRM provides a single gamma-sensitive radiation monitor that will be located between the CUW regenerative heat exchanger and the pressure reduction station and provide alarm function on a high radiation signal.

#### **11.5.5.5 Liquid Waste Management System**

The PRM provides a radiation monitor on the offsite discharge line from the LWM, with an automatic shutoff function that would terminate the discharge based on a determined setpoint in the radiation monitor.

#### **11.5.5.6 Offgas System**

The PRM provides radiation monitoring at various locations in the OGS.

##### ***11.5.5.6.1 Charcoal Vault Ventilation***

The ventilation of the Charcoal Vault is monitored for gamma radiation level, to detect charcoal tank leakage. A single instrument channel is used. The channel includes a gamma-sensitive detector and a radiation monitor. The detector is located outside the Charcoal Vault on the HVAC exhaust line from the vault. The radiation monitor is located adjacent to the ductwork.

##### ***11.5.5.6.2 Offgas Pre-treatment***

Radioactivity is monitored in the main turbine condenser offgas after it has passed through the offgas condenser and moisture separator/cooler. The single channel monitor detects the gross radiation level that is attributable to the fission gases that are produced in the reactor and then transported with steam through the turbine to the main turbine condenser.

A continuous sample is extracted from the offgas pipe, then passed through a sample chamber and a sample panel. Sample line flow is measured and indicated on the sample panel. A gamma-sensitive detector, positioned on the sample chamber, is connected to a local radiation monitor.

The radiation level reading can be directly correlated to the concentration of the noble gases in the sample chamber by obtaining a grab sample at the sample panel. The sample is then removed and analyzed with a multi-channel gamma pulse height analyzer to determine the concentration of the various noble gas radionuclides. A correlation between the observed activity and the monitor reading permits calibration of the monitor.

##### ***11.5.5.6.3 Offgas Post-treatment***

The OGS post-treatment stream is monitored for halogens, particulates, and noble gas releases during normal and accident conditions in the offgas piping downstream of the OGS charcoal

adsorbers and upstream of the OGS discharge valve. A continuous sample is extracted from the OGS piping, passed through an offgas post-treatment sampler for monitoring and sampling, and returned to the OGS piping. The sampler contains provisions for continuous gaseous, particulate and halogen radioactivity monitoring of the offgas post-treatment process. Automatic compensation for variation in main process flow is provided to maintain the sample panel flow proportional to the main flow. A local radiation monitor, connected to a gamma-beta sensitive radiation detector, analyzes, and visually displays the measured radiation level. The radiation monitor actuates MCR annunciators for operator response as discussed in Section 11.3.11.

#### **11.5.5.7 Main Turbine Equipment**

The PRM provides radiation monitoring for the Main Turbine Gland Seal Steam Condenser Exhaust flow path.

#### **11.5.5.8 Circulating Water System**

The PRM provides radiation monitoring CWS discharge to the NHS, with an automatic shutoff function that terminates the discharge based on a determined setpoint in the radiation monitor.

#### **11.5.5.9 Heating Ventilation and Cooling System**

##### ***11.5.5.9.1 Reactor Building Heating Ventilation and Cooling System***

The PRM and ARM provide monitoring in the fuel handling area of the RB. On a high radiation signal, RB supply and exhaust isolation dampers close. Supply and exhaust air handling units will de-energize.

The PRM provides three gamma-sensitive radiation monitors for each RB lower-level supply AHUs. Upon a high radiation signal, both RB lower-level supply AHUs de-energize and isolate, while the exhaust AHU will ramp down in flow. A high radiation signal causes an auto start of a SCR makeup AHU.

##### ***11.5.5.9.2 Control Building Heating Ventilation and Cooling***

The PRM provides an adequate number of gamma-sensitive radiation monitors commensurate with its SC for each Control Room Normal Supply AHUs. On a high radiation signal, both AHU inlet dampers close and de-energize, and an automatic swap over to the Control Room Envelope Emergency Filtration Units takes place.

The PRM provides an adequate number of gamma-sensitive radiation monitors, commensurate with its SC for each of the Control Room Envelope Emergency Filtration Units.

##### ***11.5.5.9.3 Turbine Building Heating Ventilation and Cooling***

The PRM and ARM provide general monitoring located in the TB. Upon receiving a high radiation signal from PRM, TB supply and exhaust isolation dampers close, and supply/exhaust AHUs de-energize. The planned monitoring is for noble gases, iodides, and particulates.

The TB Annex Exhaust AHU is also monitored. Upon a high radiation signal on the TB Annex Supply AHU, the respective inlet and exhaust dampers closes and the AHUs deenergizes.

The main Plant Vent Stack is located on the TB and is equipped with gamma-sensitive radiation monitor(s).

##### ***11.5.5.9.4 Radwaste Building Heating Ventilation and Cooling***

The PRM includes three radiation monitors on the combined AHU discharge duct and has no automatic actions on a high radiation signal.

#### **11.5.6 System and Equipment Operation**

During normal operations, the monitoring equipment is continuously in operation, or performing periodic monitoring as required, unless removed from service for maintenance. Sampling equipment operates continuously, periodically, or in the grab sample mode. There may be cases where the system with which the PRM interfaces is out of service, in which case the instrumentation allocated to that system will be taken out of service.

There are no generic startup protocols. Specific startup operation descriptions may be applicable to the host systems that interface with PREMS instrumentation.

The system performance requirements are generally the same for all operational modes.

#### **11.5.7 Instrumentation and Control**

PREMS instrumentation design is organized primarily by the Safety Category of the system functions that the instrumentation is supporting. PREMS provides monitoring only; there are no mitigating system functions controlled by PREMS. The PREMS may provide the primary detection in some cases or be a secondary avenue in other cases to collect instrumentation readings or signals from other systems for transmission to the DCIS.

##### **11.5.7.1 Instrumentation**

Each subsystem consists primarily of radiation detectors and transmitters. The sampling instrumentation primarily consists of grab samples which are analyzed to identify and quantify the specific radionuclides in effluents. The results from the sample analysis are used to establish relationships between the gross gamma monitor readings and concentrations or release rates of radionuclides in continuous effluent releases.

##### **11.5.7.2 Radiation Level Setpoints**

The derivation of trip setpoints for effluent and discharge radiation monitors are specified in plant operating procedures. Setpoints are established on the basis of discharge flow rates and the resulting offsite doses (as discussed in Chapter 20).

#### **11.5.8 Monitoring, Inspection, Testing, and Maintenance**

Maintenance includes servicing and replacement of defective components and adjustments as required. Periodic testing or calibration checks will be performed as part of the maintenance plan. If any work is performed that would affect the calibration of the instrument, a re-calibration is performed following the maintenance operation.

#### **11.5.9 Radiological Aspects**

The PREMS is comprised of subsystems that monitor liquid and gaseous effluents utilizing components designed and installed in various ways to minimize the possibility of contaminating non-radiological systems or components. To the extent possible, the system components and subsystems are constructed to avoid contamination due to leakage, spills, errors in valve lineup or other operating conditions as a result of interfacing with radioactive systems. These types of radiation monitoring components and subsystems are typically purely electrical in nature and do not physically interconnect with the radioactive systems they are monitoring. In addition, these PREMS subsystems do not interconnect with other non-radioactive systems, thereby eliminating the potential for transfer of radioactive material from a radioactive system to a non-radioactive system.

There are circumstances in the design of the PREMS subsystems where some interconnections to radioactive systems are necessary. In these cases, the additional subsystem interconnections to non-radioactive systems are limited to purge air, purge water and makeup water for filling loop

seals. The designs of these interconnections prevent contamination of the non-radioactive system or process due to leakage, spillage, valving errors, or other operating conditions.

PREMS is designed to minimize facility and environmental contamination, minimize the generation of radioactive waste, and facilitate decommissioning. These objectives are supported by the procedures for operation, and is controlled as follows:

- Minimizing contamination by:
  - Locating radiation detectors outside the process that they monitor, whenever feasible, to avoid the potential of coming in contact with a radioactive process
  - Providing atmospheric purging of the internal portion of air sampling skids as necessary
  - Providing the ability for liquid flushing of the internal portions of liquid sampling skids as necessary
  - Designing the interior portions of liquid and gaseous sampling chambers to minimize the plate out of radioactive material
  - Designing sample extraction points such that they minimize the potential for spillage and contamination of adjacent areas
- Facilitating decommissioning by providing equipment, where feasible, that reduces the need for decontamination during the removal and disposal of the equipment
- Minimizing the generation of radioactive waste by:
  - Directing continuous samples from radioactive processes back to the sampled process
  - Utilizing electronic devices that simulate radioactive sources, where compatible with the subsystem design, in order to minimize the use of radioactive sources
  - Minimizing the amount of a sample that needs to be extracted, consistent with laboratory and sensitivity requirements

#### **11.5.10 Performance and Safety Evaluation**

PREMS provides monitoring only; there are no mitigating system functions controlled by PREMS.

## **12.0 RADIATION PROTECTION**

Administrative programs and procedures, in conjunction with facility design, ensure that the occupational radiation exposure to personnel is kept As Low As Reasonably Achievable (ALARA). The systematic application of the ALARA principle during the design phase of the BWRX-300 establishes the basic design criteria observed to reducing occupational exposure during plant operation and maintenance, decommissioning and post-accident ALARA.

ALARA design requirements are established to improve the layout of enclosures, accesses, and exits from controlled areas of the plant structures that confine radioactive material. The design of plant Structures, Systems, and Components (SSCs) minimizes personnel exposure to radiation during operation, inspection, maintenance, or plant design modifications.

The ALARA design requirements keep radiation exposures ALARA during normal operation or Anticipated Operational Occurrences (AOOs) and planned radioactive material releases below regulatory limits. The ALARA design criteria includes provisions for mitigating the radiological consequences of design basis accidents in accordance with Canadian Nuclear Safety Commission (CNSC) REGDOC-2.5.2, Section 4.1.1 (Reference 12.1-1).

The plant design:

- Precludes the release of radioactive material to the public and the environment that exceeds the limits of applicable regulations for normal operations, transients, and accidents
- Minimizes personnel exposure
- Minimizes the generation of radioactive contamination and waste

### **12.1 Optimization of Protection and Safety**

#### **12.1.1 Design and Construction Policies**

ALARA is applied during the initial design of the plant and implemented via internal design reviews. The design is reviewed in detail for ALARA considerations and is reviewed, updated, and modified during the design phase to apply best practices operating experience. Engineers review the plant design and integrate the layout, shielding, ventilation and instrument monitoring designs with traffic control, security, access control, and health physics aspects to ensure the overall design maintains exposures ALARA.

All radioactive fluid pipe expected to contain significant radiation sources are designed with adequate shielding and properly routed to reduce personnel exposure. Operating Experiences (OPEX) from industry that includes the operating Boiling Water Reactor (BWR) fleet are continuously integrated during the design phase.

#### **12.1.2 Operational Policies**

The ALARA principle is applied during the operation of the BWRX-300 throughout the completion of the plant life cycle by implementing the Radiation Protection Program discussed in Section 12.7.

#### **12.1.3 Compliance With Standards for Radiation Protection to Ensure Occupational Exposures are ALARA**

The BWRX-300 plant is designed for Radiation Protection to comply with Government of Canada Radiation Protection Regulations (Reference 12.1-2) and to meet the requirements and guidance in CNSC REGDOC-2.7.1 (Reference 12.1-3). Additionally, guidance from International Atomic

Energy Agency (IAEA) international safety standards, and U.S. Nuclear Regulatory Commission (USNRC) guidance informs the design.

#### **12.1.4 Ensuring Occupation Radiation Exposures Remain ALARA**

The BWRX-300 design considers that the majority of station personnel radiation exposure of is received during:

- Maintenance
- Radwaste (RW) work
- In-service inspection
- Refueling
- Non-routine operations
- Decommissioning

The BWRX-300 SSC that contain, collect, store, process, or transport radioactive materials follow the ALARA principle.

The BWRX-300 is designed to meet requirements in REGDOC 2.5.2, Section 8.13 (Reference 12.1-1). REGDOC-2.7.1, Section 4.1 (Reference 12.1-3) provides measures for the application of ALARA with reference to international standards for facility, equipment, and instrumentation design features delineated in Section 12.3. Cited standards for implementing and for maintaining ALARA include IAEA NS-G-1.13 (Reference 12.1-4) and International Commission on Radiological Protection (ICRP) standards such as ICRP Publication 101(b), (Reference 12.1-5) and ICRP Publication 103, (Reference 12.1-6).

The Radiation Protection Program discussed in Section 12.7 is implemented in accordance with REGDOC 2.7.1 (Reference 12.1-3) to ensure that radiation exposures to personnel and the public are ALARA, and that personnel are qualified, trained and monitored to keep exposures ALARA.

#### **12.1.5 ALARA Design Considerations**

This section describes the methods and features incorporated into the design that keep exposures ALARA.

##### **12.1.5.1 General Design Considerations for ALARA Exposures**

Consistent with the recommendations of IAEA and ICRP standards, general design considerations and methods employed to maintain in-plant radiation exposures ALARA, have two objectives:

- Reducing the necessity for and amount of personnel time spent in radiation areas
- Reducing radiation levels in routinely occupied plant areas in the vicinity of plant equipment that require personnel attention

Equipment and facility designs are evaluated for maintaining exposures ALARA during plant operations. Plant operations include normal maintenance and repairs, refueling operations and fuel storage, in-service inspection and calibrations, radioactive waste handling and disposal, and decommissioning.

Descriptions of general design features that maintain doses ALARA during normal power and shutdown operations are provided in Section 12.3.

Features that assist in maintaining low occupational exposures during decommissioning include:

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

- Provisions for draining, flushing, and decontaminating equipment and piping
- Equipment design minimizes the radioactive material buildup and facilitates crud traps flushing
- Shielding protection during maintenance, repairs, or during decommissioning operations
- Provision for adequate space for movable shielding
- Separation of highly radioactive equipment from less radioactive equipment
- Provision for separate shielded compartments for adjacent items of radioactive equipment
- Provision for access hatches for the installation or removal of plant components
- Provision for the Reactor Water Cleanup (CUW) and Shutdown Cooling (SDC) System and the condensate demineralizer to minimize crud buildup

#### **12.1.5.2 BWRX-300 Design Considerations**

The following BWRX-300 design features minimize radioactive contamination:

1. Containment in areas where leaks and spills are likely to occur.
2. Leak detection capability to provide prompt detection SSC leakage.
3. Usage of leak detection methods (e.g., instrumentation, automated samplers) capable of early leak detection in areas difficult (inaccessible) to conduct regular inspections (such as the fuel pool), and buried, embedded, or subterranean piping) to avoid release of contamination. All BWRX-300 tanks containing radioactive fluids are within the Radwaste Building (RWB) that have cubicles and drain back into the radioactive liquid waste for processing.
4. Minimizing embedded piping, sumps, or buried equipment to facilitate decommissioning.
5. Removal or replacement of equipment or components during facility operation or decommissioning.
6. Minimizes the generation of radioactive contamination and waste during operation and decommissioning by reducing the volume of components and structures that become contaminated during plant operation.

#### **12.1.5.3 ALARA Equipment Design Considerations**

BWRX-300 engineering design procedures require the integration of international standards (including USNRC Regulatory Guide 8.8), and the radiation received for the component or system application.

##### ***12.1.5.3.1 Equipment Design Consideration to Limit Time Spent in Radiation Areas***

BWR fleet OPEX is factored into current designs. Equipment instrumentation and controls are accessible during normal and abnormal operating conditions. Equipment such as the CUW and the Fuel Pool Cooling and Cleanup System (FPC) are remotely operated, including backwashing and precoat operations.

Equipment design facilitates maintenance. Equipment such as the Isolation Condenser System (ICS) heat exchanger is designed with an excess of tubes in order to permit tube plugging, when necessary. Heat exchanger drains exist on the shell side. Some valves have stem cartridge-type packing that is easily replaced. Refueling tools come equipped with drainage and have smooth surfaces that reduces contamination. Vessel and piping insulation is easily removed.

The materials selected are chosen for operating conditions. Valves use stem packing to reduce leakage and maintenance.

#### **Equipment Design Consideration to Limit Component Radiation Levels**

Equipment and piping reduce the accumulation of radioactive materials in the equipment. The piping, where possible, is constructed of seamless pipe as a means to reduce radioactivity accumulation on seams. The filter demineralizers in the CUW and FPC systems are backwashed and flushed prior to maintenance.

Equipment is designed for limiting leaks or controlling fluid leaks include piping the released fluid to the sumps and using drip pans with drains piped to the floor drains.

The primary coolant system materials selected consist mainly of austenitic stainless steel, carbon steel and low alloy steel components.

The system design includes a CUW system on the reactor coolant. This system is designed to limit the radioactive isotopes in the coolant by processing the coolant in the plant Condensate Filters and Demineralizers System (CFD) for cleanup. The feedwater piping downstream of the CFD is stainless steel with low cobalt content. Zinc is injected into the system to aid in reducing dose rates from Co-60 deposition.

#### **12.1.5.4 Facility Layout General Design Considerations for Maintaining Radiation Exposures ALARA**

Facility general design considerations minimizing personnel time spent in radiation areas include:

- Locating equipment, instruments, and sampling stations, that require routine maintenance, calibration, operation, or inspection, for ease of access and minimum required occupancy time in radiation areas
- Laying out plant areas allowing remote or mechanical operation, service, monitoring, or inspection of highly radioactive equipment
- Providing, where practicable, transportation of equipment or components requiring service to a lower radiation area
- Minimizing radiation levels in plant access areas and vicinity of equipment

Facility general design considerations directed toward minimizing radiation levels in plant access areas and in the vicinity of equipment requiring personnel attention include:

- Separating radiation sources and occupied areas where practicable (e.g., pipes or ducts containing potentially high radioactive fluids not passing through occupied areas)
- Providing adequate shielding between radiation sources and access and service areas
- Locating equipment, instruments, and sampling sites in the lowest practicable radiation zone
- Providing central control panels permitting remote operation of Safety Class (SC) instrumentation and controls from the lowest radiation zone practicable
- Separating highly radioactive equipment from less radioactive equipment, instruments, and controls
- Providing adequate space for movable shielding for sources within the service area
- Providing and facilitating contamination control

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

- Providing service area decontamination
- Providing space for pumps and valves outside highly radioactive areas for maintenance and inspection
- Providing remotely operated centrifugal discharge and/or back-flushable filter systems for highly radioactive RW and cleanup systems
- Providing labyrinth entrances to radioactive pump, equipment, and valve rooms
- Providing adequate space in labyrinth entrances for easy access
- Maintaining ventilation airflow patterns from areas of lower radioactivity to areas of higher radioactivity

## **12.2 Sources of Radiation**

This section contains a qualitative description of radiation sources present in the BWRX-300 plant. These sources are identified based upon GEH BWR design evolution and fleet operations.

At this stage of the plant design, source strengths have not been calculated. The characterization of plant sources is limited to source descriptions. These sources are quantified in the Pre-Operational Safety Analysis Report (POSAR).

### **12.2.1 Contained and Immobile Sources of Radioactive Material**

#### **12.2.1.1 Containment Radiation Sources**

This section describes the significant radiation sources found inside the BWRX-300 containment. The calculated sources provided in the POSAR consist of those elements that contain significant quantities of radioactive elements. The radiation source does not include incidental contamination, such as sources in valves (deposition from corrosion), fission product species on component surfaces, or gamma sources emitted from pipes containing radioactive fluids. The Fine Motion Control Rod Drive (FMCRD) system provides the only other notable source of radiation in containment. The only significant source of post-operation radiation in containment is the reactor core and irradiated reactor internals.

#### **Reactor Vessel Core Sources**

A reactor vessel model and pertinent data necessary to calculate neutron and gamma fluxes inside and outside of the reactor core during normal operation is defined. Ex-core particle fluxes from the reactor core during operation calculations require a detailed analysis of neutron particle transport and using a deterministic solution to the Boltzmann equation or probabilistic modeling techniques. The primary source for the neutron and gamma fluxes outside the core is the fission process. Gammas are also created by the decay of fission products, and secondary gammas resulting from neutron absorption and scattering in structural materials, both inside and outside of the core. Nuclide cross-section libraries contain gamma production data for all of these sources. As a result, it is only necessary to define the neutron fission source in the core, and then perform a coupled neutron-gamma transport calculation.

After shutdown, the neutron fluxes are negligible, and N-16 activity quickly decays to zero. The most significant radiation source is the gammas resulting from fission product decay in the reactor core. Neutron and gamma fluxes inside and outside the reactor core during normal operation are provided in the POSAR that include neutron and gamma flux results, reactor vessel model definition, and all pertinent data used in the analysis for the reactor during operation and shutdown conditions.

#### *Physical Data*

A POSAR table presents the physical data required to form a model that provides sufficient regions to adequately represent the reactor. The in-core region is divided into a determined number of axial nodes, with one radial node per fuel bundle. A unique neutron fission source is determined for each of these nodes using the nodal cycle average power and exposure data. Water densities are determined at each of the determined planes for peripheral bundles and in-core bundles. A POSAR table provides nominal dimensions and material volume fractions for each boundary and region in the reactor model with core average data presented for the core. To describe the reactor core, thermal power, power density, core dimensions, core average material volume fractions, and cycle average reactor power distributions and exposures are provided. Reactor power distributions are given for both radial and axial distributions and represent cycle averages for an equilibrium cycle.

### *Core Boundary and Vessel Neutron Fluxes*

A POSAR table presents multigroup neutron fluxes at the representative location of the core boundary and at the vessel. The multigroup neutron fluxes and the fast neutron flux ( $E > 1$  MeV) at the peak elevation of the core boundary, vessel inside surface, and a determined thickness of the vessel are presented the POSAR. The uncertainty of the fast neutron flux at the vessel is estimated within a determined percentage. Normalized axial variations for the fast flux at the vessel inside surface are shown in another POSAR table.

### *Gamma Ray Source Energy Spectra*

The average gamma ray source energy spectra in both core and non-core regions is presented in a POSAR table. The energy spectrum in the core, bypass water, shroud, downcomer, and Reactor Pressure Vessel (RPV) is presented. This represents the average gamma ray energy released by energy group per unit volume of the region. The energy spectra in MeV per seconds per  $\text{cm}^3$  is used with the power distributions to obtain the source in any part of the core.

The gamma ray energy spectrum includes the fission gamma rays, the fission product gamma rays, and the gamma rays resulting from inelastic neutron scattering and neutron capture. The total gamma ray energy released in the core is estimated accurate within a conservative percentage.

### *Post-Operation Gamma Sources*

A gamma ray energy spectrum in MeV/sec per MW thermal in spent fuel as a function of time after operation is provided in a POSAR table. The data is prepared from the irradiation and decay calculation of a representative BWRX-300 fuel bundle average exposure. To obtain shutdown sources in the core, the gamma ray energy spectra are combined with the core thermal power and power distributions. Shutdown sources in a single fuel bundle is obtained by using the gamma ray energy spectra and the thermal power of the element during operation. Similar information suitable for the spent fuel pool fuel bundles with an average exposure is also provided in the POSAR.

### *Neutron and Gamma Ray Fluxes Outside the Vessel*

The maximum axial neutron and gamma ray fluxes outside the vessel is provided in the POSAR. The maximum axial flux occurs near the core midplane elevation where the maximum power density is located for the peripheral bundle. This elevation is determined using the data for the maximum axial neutron and gamma ray fluxes outside the vessel. The fluxes at this elevation represent the fluxes at the peak azimuth angle. The gamma ray calculations include gamma ray sources from regions inside the vessel and the vessel itself.

### **Control Rod Drive System Sources**

The Control Rod Drive (CRD) source term data is provided in the POSAR.

Historically, removal and replacement of CRDs is a significant contributor to occupational exposures. Improved maintainability associated with the FMCRDs design reduces personnel exposures compared to conventional BWR CRDs. The CRD system is comprised of three major elements: (a) the FMCRD mechanisms; (b) the Hydraulic Control Unit assemblies; and (c) the CRD hydraulic subsystem. The BWRX-300 CRD hydraulic subsystem supplies high-pressure demineralized water that is regulated and distributed to provide charging of the Hydraulic Control Unit scram accumulators and purge water flow to the FMCRDs. The CRD system is described in Section 4.5.

### **Reactor Startup Source**

The Cf-252 reactor startup source is shipped to the site in a special shielded cask. The source is transferred under water while in the cask and loaded into a stainless steel source holder. This is loaded into the reactor while remaining under water. The source and source holder are removed from the reactor during the first refueling outage and moved to a designated location in the fuel pool. Operations and Radiation Protection personnel determine placement and duration of residence for the Cf-252 source and holder in the fuel pool. The activity requirements for the reactor startup source are provided in the POSAR

#### **12.2.1.2 Reactor Building and Plant Services Area Radiation Sources**

The Reactor Building (RB) radiation source terms consist of significant quantities of radioactive elements from the fission source, but do not include sources due to incidental contamination such as sources in valves and pipes due to deposition of corrosion or fission products species on the surfaces of the components. Water radioactive source concentrations in the fuel pool are assumed as 1% of normal reactor water concentrations. The Plant Services Area includes the RB auxiliary bay where new and spent fuel enter and leave the RB. Source terms in the RB are identified in the POSAR.

### **Fuel Pool Cooling and Cleanup System**

The FPC system is designed to service the fuel pool, cask pit, and reactor cavity pool on a rotating basis. The activity in this system is the result of the accumulation of residual activity in each of these pools. The filters are backwashed and the backwash routed to the liquid RW systems for processing. Clean water connections are provided for this system to flush lines prior to switching between pools to prevent ancillary contamination between pools.

### **Fuel Pool**

The gamma source energy spectra from spent fuel in the fuel pool is significant; however, the spent fuel is submerged in water and shielding around the fuel pool is provided ALARA. Radiation source terms from the fuel pool is provided in the POSAR.

### **Reactor Building and Containment Post-Accident Radiation Source**

The BWRX-300 design limits potential radiation exposure from accidents to personnel and to the public in the plant using passive safety features, containment, and treatment of potential normal operation and accident sources. The following describes those features of the BWRX-300 germane to post-accident radiation sources in containment and the RB.

1. Containment is a nitrogen-inerted, Steel-Plate Composite Containment Vessel (SCCV) pressure boundary capable of containing all design basis accident sources with minimal leakage to the environment or other plant areas. The containment is provided with redundant passive cooling systems to ensure that this primary boundary does not exceed design criteria. Radioactive sources from the pressure vessel are adequately contained during design basis accidents and some beyond design basis accidents.
2. Surrounding the cylindrical containment, the BWRX-300 employs a RB that provides a secondary holdup volume to trap containment penetration and valve leakage. All major connections from containment (e.g., main steam, feedwater) include an isolation valve in the RB. Pipe ruptures within containment are mitigated by the RPV isolation valves for large and intermediate pipe ruptures, and the coolant released that becomes airborne is captured in the containment airspace. Any releases from potential ruptures outside of containment but inside the RB are isolated by the RPV isolation valves.

### **12.2.1.3 Turbine Building Source Terms**

Significant radioactive source terms in the BWRX-300 Turbine Building (TB) consist of those elements that contain significant quantities of radioactive materials. This does not include sources due to incidental contamination such as valves with corrosion deposition or fission products species on component surfaces. The following systems that may contain radioactive material sources are located in the TB.

#### **Reactor Water Cleanup System (CUW) Radiation Sources**

The CUW system is located in the TB in a shielded area containing other radioactive equipment and systems. Radioactive sources contained in the CUW result from component contamination by reactor water through the system and accumulation of radioisotopes removed from the water. Components for this system include a Regenerative Heat Exchanger (RHX), pressure reduction station, and valves. The RHX is fitted with decontamination ports. The CUW system does not have filters and demineralizer beds; however, the CFD provides all of the cleanup of the reactor coolant.

#### **Heating, Ventilation and Cooling System**

The Heating Ventilation and Cooling System (HVS) employs High Efficiency Particulate Air (HEPA) filters for use in the event of airborne contamination of the RB or controlled purge of containment. The HEPA filters, which can accumulate radioactive sources, are shielded to ensure the radiation zones are maintained ALARA in areas adjacent to the filter housings.

#### **Main Steam and Feedwater Lines**

All radioactive material in the main steam system results from radioactive sources carried over from the reactor core during plant operations. In most components carrying live steam, N-16 is the dominant source of radioactivity. Otherwise, under conditions where sufficient decay time has removed the N-16 source, noble radioactive gases become the dominant source term.

#### **Normal Operating Sources**

N-16 in the steam flow from the pressure vessel is the primary TB source of radioactivity. The N-16 source results in significant gamma shine from the main steam lines and steam bearing components. Other sources of radiation in the TB are the Offgas System (OGS) and CUW. The OGS consists of the recombiner, OGS condenser, and offgas charcoal tanks (located in the RWB), and the CUW includes an RHX, pressure reduction station, and various valves.

#### **Post-Accident Sources**

The TB contains no major post-accident sources of releasable radioactivity (discounting N-16 because of the short half-life) and potential releases are limited to liquid releases of low activity water. Two other sources exist that contain radioactive species, but in a form not amenable for release. The potential for accident releases from these two sources, the OGS, and the CUW system, is reduced due to heavy shielding and compartmentalizing of the components.

### **12.2.1.4 Radwaste Building Sources**

This subsection provides brief descriptions of the significant radioactive source terms found in the BWRX-300 RWB. These source terms consist of those elements that contain significant quantities of radioactive materials but do not include sources due to incidental contamination, such as sources in valve corrosion deposition or fission product species on the surfaces of the components.

## **Normal Operating Sources**

Major RWB components that contain radiation sources include liquid RW collection tanks, spent resin tanks, sludge tanks, liquid waste sample tanks, filtration equipment, and high integrity containers with solid waste. These contained sources will be quantified as the design progresses. These sources are based on the waste stream concentrations fed to the RW systems and represent sources for shielding calculations.

## **Post-Accident Sources**

Potential releases in the RWB are contained by isolating the RWB atmosphere and sealing any water releases in the building. The RWB is seismically designed, and the concrete tank areas are provided with sealant and steel liners to prevent any releases from high-activity areas.

### **12.2.2 Sources of Airborne Radioactive Material**

#### **12.2.2.1 Reactor Building**

The RB HVS is discussed in Subsection 9A.5.1. Subsection 12.2.1.3 discusses the radiation control aspects of the HVS.

#### **Normal Operation**

The main source of airborne activity in the RB is primary coolant leakage. The highest potential activity sources are in containment but pose no threat to plant personnel during normal operation.

The containment cooling system conditions and circulates air through the contaminated areas of the building. Flow is directed from the corridors (point of highest pressure) to the equipment alcove rooms, the rooms themselves, and finally to the external wall pipe chases and from the pipe chases back to the HVS.

Access into the containment is not permitted during normal operation. The ventilation system inside merely circulates the air, without filtering it. The only airflow out of containment into accessible areas is minor potential leakage through penetrations. During maintenance, the containment atmosphere is purged using the containment inerting system and replaced with clean air before access is permitted.

#### **Reactor Building Airborne Sources During Refueling**

BWR operating experience shows that airborne radioactivity is generated from the steam dryer and separator if their surfaces are allowed to dry. Other potential airborne sources occur during vessel head venting and fuel movement. The airborne radioactive material sources resulting from reactor vessel head removal are minimized by venting to the containment cooling system or to the main condenser prior to removal. The contribution to the airborne radioactivity due to the reactor vessel internals is minimized because they are wet and submerged.

Airborne radioactivity during refueling is similar or lower due to improved design features and OPEX incorporation. Experience shows that airborne radioactivity results from water in the reactor cavity exceeding 38°C (100°F) and flaking of cobalt dioxide (CoO<sub>2</sub>) from the steam dryer and separator if their surfaces are allowed to dry. Other potential airborne sources resulting from reactor vessel head and internals removal are determined from OPEX. OPEX shows that Iodine-131, Co-60, Mn-54, Nb-95, Zr-95, Ru-103, and Ce-144 are the major radioisotopes found with Ce-141, Cs-137, Co-58, and Cr-51 at lower concentrations.

To minimize airborne radioactivity, the following actions are specified:

- Maintain steam dryer and separator surfaces wet or covered
- Cool fuel pool through large heat capacity heat exchangers

- Fuel pool ventilation system designed to sweep the pool surface and prevent pool releases from mixing with the area atmosphere

### **Refueling Area of Reactor Building**

The refueling area is serviced by the containment cooling system, including radiation control aspects of the system is discussed in Chapter 9A, Subsection 9A.5.6.

The airborne activity source in the fuel pool area of the RB is in the spent fuel storage pool and equipment areas. The ventilation system is designed to sweep air from the fuel pool surface removing the major portion of potential airborne contamination. In addition, evaporation from the fuel pool is minimized by pool cooling.

The assumptions and parameters used to determine the airborne activity levels in the spent fuel storage pool and equipment areas, and the airborne concentrations are provided in the POSAR.

#### **12.2.2.2 Turbine Building Airborne Sources**

The main potential source of airborne radioactivity within the TB is leakage from valves on large steam pipes. The design provides for collection of this leakage and its transport back to the condenser. Therefore, noble gas airborne concentrations are negligible throughout the TB except for inside the Steam Jet Air Ejector (SJAE) cubicles. These areas are not normally occupied during operation, and the exhaust from these cubicles is exhausted to the environment after filtration eliminating the possibility of contamination of adjoining areas. Another airborne activity source is equipment leakage in the TB atmosphere.

#### **12.2.2.3 Radwaste Building Airborne Sources**

The RWB HVS is discussed in Chapter 9A, Subsection 9A.5.3.

RWB corridors and routine access operating areas do not have significant airborne radioactivity levels. Equipment cubicles are infrequently accessed and may contain low levels of airborne radioactivity, but design provisions minimize the release of radioactivity.

RWB tanks are filled from the top and as the water splashes into the tanks, dissolved and entrained radioactivity may become airborne. This activity is not released into the atmosphere in the rooms because the tank vents are connected directly to the building ventilation system. Pumps and valves for radioactive systems in the RWB are in separate compartments that are not normally accessed by operating personnel. The RWB ventilation design provides airflow from areas of low potential for airborne contamination to areas of increasing potential. This ensures that any leakage from RW pumps and valves is not directed into normally occupied areas of the building but exhausted from the building.

#### **12.2.2.4 Control Building Airborne Sources**

The Control Building (CB) HVS is discussed in Chapter 9, Subsection 9A.5.2. If the CB air intake radiation monitor setpoint is reached, the intake is isolated, and the system initiates the recirculation mode. The SCR is available if the MCR becomes uninhabitable. There are no contaminated areas in the CB.

#### **12.2.2.5 Plant Services Area**

The Plant Services Area (PLSA) contains the Reactor Auxiliary Bay where new and irradiated fuel is moved in and out of the reactor building.

### **12.2.3 Airborne Sources for Within the Plant**

The design keeps all radioactive material contained. Leaks from process systems, refueling, and decontamination may lead to airborne radioactivity. Equipment cubicles, corridors, and areas

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

routinely occupied by operating personnel do not contain significant airborne radioactivity sources and comply with the limits specified in SOR/2000-203 (Reference 12.2-2). Radioactive equipment that potentially leaks is installed in separate shielded compartments that are not routinely occupied.

In general, airflow within the building ventilation systems is from areas of low potential for airborne contamination to areas of increasing potential. Routinely occupied areas are maintained at low airborne radioactivity levels. OPEX data from operating BWRs corroborate the general lack of airborne activity in corridors and routinely occupied operating areas. Air samples and surface contamination swipe samples are performed to verify the absence of airborne and surface contamination.

Process leakage results in potential release of noble gases and other volatile fission products via ventilation systems. Leakage of fluids from the process system results in the release of radionuclides into plant buildings. In general, the noble radiogases remain airborne and are released to the atmosphere with little delay via ventilation exhaust ducts. Other radionuclides partition between air and water may plate-out on metal surfaces, concrete, and paint. Radioiodines are found in ventilation air as methyl iodide and as inorganic iodine (particulate, elemental, and hypoiodous acid forms).

### **12.3 Design Features for Radiation Protection**

The design features incorporated in the BWRX-300 are based on GEH BWR OPEX. The BWRX-300 ALARA design requirements incorporate the guidance of REGDOC-2.7.1 Radiation Protection (Reference 12.3-1).

#### **12.3.1 Facility and Equipment Design Features**

The BWRX-300 plant design features ensure plant personnel radiation exposures are ALARA. General design considerations and methods to maintain in-plant radiation exposures ALARA are:

- Minimizing the necessity for and amount of personnel time spent in radiation areas
- Minimizing radiation levels in routinely occupied plant areas in the vicinity of plant equipment that require personnel attention

The BWRX-300 is designed to ensure the radiation exposure to any nuclear energy worker is less than the limits specified in the SOR/2000-203 (Reference 12.3-2).

##### **12.3.1.1 Radiation Source Term Reduction**

Radiation source term reduction design considerations:

1. N-16 skyshine dose contribution is determined from N-16 activity in the vessel nozzle outlet steam based upon the hydrogen water chemistry.
2. Noble gas airborne concentrations are negligible throughout the TB except for inside the SJAE cubicles. The process air from these cubicles is exhausted to the environment after HEPA filtration and noble gas decay in activated carbon beds in the gaseous RW system reducing contamination in adjoining areas.
3. Minimizing airborne radioactivity includes:
  - a. Storing underwater the steam dryer, separator, and chimney during refueling operations
  - b. Cooling the RB pools with large heat capacity heat exchangers
  - c. Sweeping the spent fuel pool surface and preventing evaporative pool losses and gases from mixing with the area atmosphere using the FPC
4. Radioactive material is kept in containers to the extent possible.
5. Equipment cubicles, corridors, and areas routinely occupied by operating personnel do not contain significant airborne radioactivity sources. Radioactive equipment that potentially leaks is installed in separate shielded compartments.
6. Material selection minimizes the creation of activated corrosion products.
7. Zinc injection minimizes dose rate from Co-60 deposition.

#### **12.3.2 ALARA Design Guidelines for Mechanical System and Components**

This section describes the incorporation of the ALARA principle in the BWRX-300 systems and components design complying with REGDOC-2.7.1, Section 4.1 ALARA (Reference 12.3-1).

##### **12.3.2.1 General Mechanical Design Guidelines**

1. Shielding, remotely operated valves, and sample transporting casks reduce radiation exposure.

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

2. Equipment is designed for normal and abnormal operating conditions while maintaining radiation exposures ALARA.
3. Passive equipment is used where possible, thus minimizing worker exposure.
4. Process equipment that accumulates radiation sources from filtering process streams, such as the condensate and feedwater and the fuel pool cooling systems, are remotely operated, including backwashing operations.
5. Equipment facilitates maintenance.
6. Refueling tools have smooth surfaces and are easily drained to reduce contamination.
7. Vessel and piping insulation is easily removed and restored.
8. Equipment and piping minimize crud buildup and provide easy decontamination and maintenance.
9. Remotely operated mechanical devices are used to inspect the RPV body and nozzle welds.
10. In-Service Inspection (ISI) laydown space accommodates insulation removal.
11. These services are in close proximity to equipment facilitating maintenance and inspection:
  - a. Electrical outlets
  - b. Welding outlets
  - c. Condensate grade and/or demineralized water
  - d. Compressed air
  - e. Communications
12. For areas where the dose rate is 50  $\mu\text{Sv/hr}$  (5 mrem/hr) or higher where worker access is limited due to the radiation zone (as described in Section 12.6), or where equipment is removed for maintenance, the equipment design provides rapid removal using “plug in” or “quick disconnect” piping connections, electrical leads, instrumentation connections, and support linkages.
13. Passageways are provided for access ease where equipment is removed and replaced for maintenance by plant personnel wearing full Personnel Protective Equipment (PPE).

**12.3.2.1.1 Mechanical Components**

**Tanks**

1. Overflow pipes are connected to liquid radioactive waste drain system for processing. Vents run to the building ventilation exhaust system.
2. To facilitate decontamination, corrosion-resistant materials and linings prevent corrosion products buildup on the walls.
3. Walls or curbs and drains to the liquid radioactive waste system are provided around the tank for leakage collection. Room collection capacity is sized to contain the tank volume.
4. Spent resin, phase separator, and backwash tanks are located in enclosures free of flammable or combustible substances.
5. Bottom valves on slurry tanks are flush-mounted.

### **Heat Exchangers in Radioactive Service**

1. Tube and shell heat exchangers are designed with excess tubes accommodating tube plugging.
2. Where feasible, leakage from highly contaminated fluids is prevented from entering clean fluids by maintaining a higher pressure in the clean fluid sided.
3. Heat exchanger design allows for fluid drainage avoiding pooling that may lead to radioactive crud deposition.
4. Heat exchanger drains are hard piped to floor drains.
5. Cleaning connections are provided for condensate, demineralized water, and/or chemical solutions.

### **Piping**

1. Piping selection provides a service life equivalent to the design life of the plant, with corrosion and environmental condition allowances.
2. Contaminated piping systems are welded to the extent possible.
3. Piping in highly radioactive systems such as the spent fuel pool cooling system have butt-welded connections, rather than socket welds, reducing crud traps.
4. Radioactive piping is sized to produce turbulent flow to maintain solids suspension without plugging.
5. In systems where contamination settling can occur, the drains are placed on the side of the piping.
6. Systems that contain multiple pumps are placed in separate alcoves with piping routed into shielded pipe chases.
7. Radioactive piping minimizes plant personnel radiation exposure as follows:
  - a. Radioactive pipe routing in corridors is minimized
  - b. Shielded pipe trenches and pipe chases are used for routing high-activity pipes in low-level radiation areas
  - c. Separating radioactive and non-radioactive pipe routes for maintenance
  - d. Piping is arranged based upon SC, grouping of components, system operability, and maintenance access
  - e. Non-radioactive line systems are not run inside biologically shielded compartments except where needed to supply services inside the compartment
  - f. Piping configurations minimize the number of "dead legs" and low points to avoid radioactive crud and fluids accumulation
8. Systems are designed with vents and flushing lines reducing crud buildup.
9. Instrument lines, except those for the reactor vessel, are designed for backflushing and maintaining a clean fill in the sensing lines. The reactor vessel sensing lines are flushed with condensate from the instrument rack when the reactor is depressurized.
10. Piping conveying highly contaminated fluids is routed through shielded pipe chases and shielded cubicles. When these options are not feasible, the radioactive pressurized

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

process piping is sleeved embedded in concrete walls and floors. Embedded pipes connected to floor drains are butt-welded stainless steel.

11. Contaminated piping design facilitates cleaning and removal during decommissioning.
12. "Clean" services, such as compressed air and demineralized water are routed through shielded pipe chases.
13. Where piping penetrates walls the use of embedded piping is minimized facilitating system dismantling and plant decommissioning.
14. When radioactive and non-radioactive pipes are collocated, drain provisions are provided for removing radioactive fluids, and the valves are remotely controlled.
15. Piping penetrations through shield walls minimize the shine on surrounding areas.
16. Underground piping is installed for clean service only. If not possible, it is routed with a guard pipe, trench or tunnel for visual inspection and monitored leakage. Threaded and flanged connections are kept to a minimum. Other joints are welded or permanently bonded depending on the piping material.

#### **Ion Exchange and Activated Carbon Beds and Filters**

1. Filters in purification and cleaning systems are operated and cleaned remotely.
2. For purification systems, preparation, and resin changeout are performed remotely.
3. A mesh trapping resins or activated carbon particles is installed downstream of vessels.
4. Sampling points are installed at the inlet and outlet of, ion exchange vessels and activated carbon beds.
5. Cartridge-type filters or duplex filters with on-line exchangers are sized for one fuel cycle without changeout.

#### **Pumps and Valves in Radioactive Service**

1. Pumps located in radiation areas are designed with features to minimize maintenance time: quick-change cartridge-type seals, back pullout features that permit removal of the pump impeller, or mechanical seals without disassembly of attached piping.
2. Where two or more pumps conveying highly radioactive fluids are located adjacently, shielding is provided between them maintaining exposure levels ALARA. Pumps adjacent to other highly radioactive equipment are shielded to reduce personnel exposure.
3. Pump control instrumentation for process equipment is located outside high radiation areas in separate alcoves. Motor or pneumatic-operated valves or valve extension stems are used allowing operation.
4. Radioactive system pumps and valves are remotely controlled.
5. Pump casing drains are provided on radioactive systems and drained to the liquid radioactive waste system for processing.
6. Valves have cartridge-type packing that is easily replaced, or diaphragm valves or quarter-turn ball valves are used that do not require similar packing.
7. Instrumentation and valves in high radiation areas are remotely operated.
8. Straight-through valves are selected over those that exhibit flow discontinuities or internal crevices minimizing crud trapping.

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

9. Valves are placed in horizontal runs to facilitate dismantling.
10. For systems in high radiation areas, gasket materials are selected that inhibit degradation. Degradation mechanisms (i.e., stress corrosion, thermal aging, embrittlement, fatigue, thermal fatigue etc.) are considered during the material selection process.
11. Valves containing radioactive fluids are separated from “clean” services to reduce the radiation exposure from adjacent valves and piping.
12. Safety and relief valves and depressurization valves are designed with flange connections to allow whole valve removal.
13. Isolation valves are located so that fluid contained in dead branch-pipes is minimized.
14. Back seat valves are used reducing leaks through the packing when the valve is full open.
15. Pipe insulation around valves is easily removed.

### **Radioactive Drains**

1. For systems containing highly radioactive fluids, frequently used drains are hard piped to the nearest drain. An air gap exists between the system drain and the floor or equipment drain hub. For drains used less frequently, a drain connection with a valve is provided so plant personnel can connect a hose and direct the outflow to the nearest drain.
2. Sump vents are located near the room exhaust vent register to control airborne radioactivity released from sump discharges.
3. Sumps are stainless steel-lined reducing corrosion and providing easily decontaminated surfaces.
4. Pipes carrying fluid to radioactive drains and clean drains are separate and independent.
5. The high-activity level resin slurry drains are separated from other drains and the contents routed to liquid radioactive waste for subsequent treatment.
6. Drain lines are gravity-sloped.
7. Drain lines containing highly radioactive fluids are routed through pipe chases or shielded cubicles.
8. One piece floor drains minimizing possibility of liquid penetrating at embedment boundaries. Non-porous alternatives to grout such as epoxy are used for the installation of floor drains.
9. Drain lines contain traps that prevent the flow of radioactive gas from compartment to compartment.
10. The drains from rooms that house spent resin tanks, phase separator tanks, or demineralizer vessels are equipped with normally closed isolation valves.
11. Sumps are located at the lowest level of the buildings.

### **Sludge and Resin Systems**

System design and implementation prevent accumulating and retaining radioactive sludge and resins in transfer pipes by:

1. Pipe runs are reduced.
2. Low points and blind sections are avoided.
3. Appropriate pipe slope to support gravity flow is used.

4. Pipe flow restrictions are avoided.
5. Short 90° elbows are avoided and replaced by large-radius curved sections at least five times the diameter, or two 45° elbows spaced apart.
6. Whenever T connections are required, the main flow runs through the straight section. If the secondary flow is into the T, then the connection is made above the axis of the pipe. If the secondary flow is out of the T, then the connection is on the lateral connector side.

#### **12.3.2.1.2 Materials**

1. The reactor coolant system materials selected prevent corrosion product formation. Reactor internal components, except for the zircaloy in the reactor core, are stress corrosion-resistant stainless steels or other high alloy steels.
2. Carbon steel used in systems processing or storing reactor coolant or steam are low in nickel content and contain small amounts of cobalt impurity.
3. Main condenser tubes and closed loop cooling heat exchangers cooled by the plant cooling water tubes and their tube sheets are low-cobalt stainless steel or titanium alloys and low-cobalt materials.
4. Ni-Cr-Fe alloys such as Inconel 600 and Inconel X750 that have high nickel content, are used in some reactor vessel internal components. These materials are used in applications where special requirements (possessing specific thermal expansion characteristics along with adequate corrosion resistance) are necessary, and where no suitable alternative low-nickel material is available. Cobalt content in the Inconel X750 used in the fuel assemblies is limited to 0.05%.
5. The BWRX-300 limits the use of cobalt-bearing materials on moving components that are historically identified as major sources of reactor coolant contamination. Stellite is used for hard facing of components that must be extremely wear resistant. Use of high cobalt alloys such as Stellite is restricted to those applications where no satisfactory alternative material is available. Alternative materials (Colmonoy® and NOREM®) are used for some hard facings.
6. Control Blade Materials: All control rod materials are less than 0.03 weight percent cobalt. The average niobium content for the handle and absorber section, less boron carbide and hafnium, is less than 0.1 weight percent.
7. Non-stainless steel equipment has an adequate finish and is protected with a non-corrosive material aiding in decontamination for some applications.
8. For systems in contact with reactor coolant (pumps, valves, etc.), component materials are as degradation-mechanism resistant as possible. Degradation mechanisms (i.e., stress corrosion, thermal aging, embrittlement, fatigue, thermal fatigue etc.) are considered during the material selection process.
9. System components are made of materials that are qualified to withstand pressure, temperature, and radiation minimizing maintenance.
10. Pipes are designed for a 60-year life, based on the environmental conditions and corrosion preventing maintenance, unless documented otherwise (e.g., abrasive slurry lines). Pipes with less than a 60-year life are replaceable (i.e., not embedded in concrete).
11. Long-life materials that withstand the operating pressure, temperature and radiation are used for component joints and seals minimizing maintenance.

12. Heat exchangers are constructed of stainless steel or titanium tubes minimizing failure and reducing maintenance requirements.

### **12.3.2.2 Mechanical Systems, Equipment and Components Arrangements**

#### **12.3.2.2.1 Confinement of Systems**

1. Radioactive systems are isolated from non-radioactive systems by confining them in different enclosures. Adequate shielding is provided between both areas.
2. Clean systems (non-radioactive) are in areas with no radioactivity or with low background radioactivity levels.
3. Piping and pumps or systems that have components that are major sources of radiation are in separate cubicles to reduce exposure during maintenance.
4. The various redundancies of a radioactive system that are provided for the same function are in separate areas and shielded from each other.
5. As a consequence of normal steam and water leakage into containment, airborne radioactive contamination exists during normal operation. Containment atmosphere purging to the environment is via the containment purge system, that is routed and processed through HEPA filters then to the TB plant stack.

#### **12.3.2.2.2 Confinement of Equipment**

1. Radioactive system equipment with different radiation levels are in different rooms.
2. System equipment that accumulates or contains radioactive fluids (tanks, heat exchangers) are isolated from other equipment (pumps, valves) and located in different rooms.
3. System equipment that concentrates radionuclides (particulate filters, and demineralizers) are isolated from the rest of the equipment in the system and located in different rooms or shielded.

#### **12.3.2.2.3 Location of Components**

1. Radioactive piping is accessible and arranged allowing inspection and maintenance with minimum exposure to personnel.
2. The location of equipment is optimized to minimize the length of the radioactive fluid ducts between them.
3. Functionally different radioactive system components such as control valves and pumps that require frequent maintenance or inspection, are in different rooms, to avoid personnel exposure.
4. Radioactive equipment is located as far as practicable from personnel dwelling and passage areas.
5. Labyrinths are used in radioactive equipment room accesses so that personnel are not exposed directly in corridors or staircases. Double labyrinths are used to shield high intensity radiation sources. Sealed cubicles with hatches or shield doors are used to shield very high radiation sources.
6. Intense radiation source equipment rooms are arranged so that workers are not exposed to the source while in the room.
7. Rooms house piping associated with the functional system.

8. Radioactive pipes are run inside trenches or shielded pipe boxes whenever the run is through a low-level radiation area.
9. Radioactive pipes are grouped on the opposite side of the entrance to the room and away from components that require frequent maintenance.
10. Radioactive pipes are sloped unless there are drains or purges at low points.
11. Equipment startup, handling devices, and actuation mechanisms are in low activity areas.
12. Sampling equipment, instrumentation, and stations requiring routine attention (maintenance, calibration, actuation, reading or inspection) are in places that are easily and quickly accessible (next to the entrance to the enclosure) and in low activity areas.

#### **12.3.2.2.3 Auxiliary Spaces**

1. Remotely operated, back-flushable filter systems are provided for radioactive RW and cleanup systems.
2. The following auxiliary spaces prevent contamination dispersion:
  - a. Posted areas for storage of contaminated parts and equipment before they become decontaminated
  - b. Areas where equipment is decontaminated before repair. (e.g., the PLSA maintenance rooms that may be used for disassembling pumps, motors, etc.)
3. Decontamination areas have condensate quality water available to carry out preliminary decontamination of equipment segregated for repair.

#### **12.3.2.3 Minimization of Crud Buildup**

The crud buildup minimization facilitates decontamination and cleaning equipment, components, and contaminated areas, and minimizes airborne contamination dispersion.

Flushing provisions are made for equipment for minimizing crud buildup.

### **12.3.3 In-Service Maintenance and Inspection Provisions**

#### **12.3.3.1 Layout of Components, Space and Access Provisions**

The following provisions prevent or minimize radiation exposure:

1. Adequate means are provided to monitor and control access to medium and high-activity areas (These are radiation zones C to I, inclusive as described in 12.6).
2. Equipment and component laydown areas have adequate space for dismantling, repair, removal, and insulation restoration for inspection or maintenance. Adequate access is also provided for transporting failed and replacement components and maintenance tools.
3. The welds in the reactor cooling circuit and in the pipes connected to it requiring ISI are readily accessible.
4. Sufficient space is provided to store and use temporary shielding.

#### **12.3.3.2 Staircase and Platform Requirements**

The following design requirements minimize time spent in radiation areas:

1. Stairs are provided and stepladders or ladders are avoided.
2. Stairs are sized for wearing protective gear and carrying necessary tools.

3. Platforms and staircases used to access components requiring frequent inspection or maintenance are permanent structures sized with sufficient space and capacity to withstand the component size and weight and additional mobile shielding.

#### **12.3.3.3 Hoisting and Transport Mechanisms**

The following provisions limit the operations and exposure duration:

1. Space is available for installing and hoisting transport mechanisms such as cranes, hoists, monorails, hand rigging, and trolleys used during periodic inspection and maintenance. Monorail beams are permanently installed over heavy equipment (equipment weighing one metric ton or more).
2. Hoisting/transport mechanisms are provided to handle heavy equipment, component parts, slabs, and heavy removable structural elements.
3. Hoisting/transport mechanisms are provided to handle parts and components in decontamination areas, in contaminated storage areas and active workshops
4. Remotely operated electric hoists are used for tasks/equipment associated with general area dose rates in excess of 1 mSv/hr (100 mrem/hr) where access is limited to one hour per week (In alignment with radiation zone E as described in 12.6).
5. Embedments are provided, in walls, floors, and overhead facilities for special rigging that requires scheduled maintenance. The design load capacity is marked on each embedment.

#### **12.3.4 Room Leak-Tightness and Drain Provisions**

The following measures prevent contamination dispersion and radiation passing through holes in walls and structures:

##### **Leak-Tightness**

1. House equipment enclosures with large radioactive liquid volumes (tanks, heat exchangers, filters, etc.) are leak tight. Additionally, containment measures are provided to prevent dispersion in the event of liquid overflow (curbs, sloping floor drains).
2. Gaseous radioactive waste system is leak tight minimizing radioactive gases and potentially flammable hydrogen escape.
3. Penetrations in walls and structures separating enclosures and buildings are located and sealed to prevent fluid contamination if a break or leak develops.

##### **Drains**

1. Enclosures that contain equipment used to store radioactive liquids have drains for spills or failures.
2. Sample station effluents are returned to the process stream or to the liquid radioactive waste through a common return line.

#### **12.3.5 General Considerations of Systems that Process Radioactive Fluids**

##### **12.3.5.1 System Isolation**

1. When a contaminated or potentially contaminated system is connected to a clean (i.e., non-contaminated) system, provisions are implemented ensuring backflow cannot occur. Backflow prevention is provided by double isolation and double check valves that permit periodic sampling ensuring clean systems are not contaminated.

2. All contaminated or potentially contaminated systems are isolated from outside environment or otherwise equipped with isolation devices to control discharges.
3. Systems discharges to the environment are equipped with radiation monitoring devices to automatically isolate the discharge if high activity is detected. The high-activity setpoints for these systems are provided in the POSAR that ensure compliance to the (Darlington New Nuclear Project (DNNP) site derived release limits.

#### **12.3.5.2 Sealing of Radioactive Components and Leak Isolation**

1. Gaseous radioactive systems are sealed.
2. Equipment designs includes leak isolation, limiting leak devices, or controlling fluid leaks by piping to the sumps or using drip pans with drains piped to the floor drains.

#### **12.3.5.3 Corrosion Limitation Products**

1. Thermal cycle system corrosion is limited by using high quality, corrosion-resistant materials, and continuously controlling other properties via water chemistry.
2. Retention and elimination of corrosion products with the use of CFD are incorporated into the thermal cycle systems.
3. Features preventing flow discontinuities that lead to retention of corrosion products (crud traps) in the walls of the equipment and components are incorporated. Bends, branches, corners, dead legs, and low points are avoided in piping and piping layout. Mitigating engineering features are added where avoidance is not possible.
4. Backing rings and consumable inserts are not used in pipes containing radioactive materials.

#### **12.3.5.4 Activity Control and Monitoring Systems**

The activity control and monitoring criteria are described by system function.

##### **12.3.5.4.1 Process Sampling System**

Sample stations in the plant provide routine reactor water quality surveillance:

1. Local sampling points and sampling stations are in low radiation areas.
2. Fume hoods are used for airborne contamination control. Sample sinks, fume hoods, and glove boxes are constructed of polished stainless steel and/or plastic easing decontamination if a spill occurs.
3. Grab spouts are located above the sink reducing contaminating surrounding areas during the sampling process.
4. Radiation shielding is used for panels, local sampling boxes, cells, and racks to maintaining ALARA.
5. Sampling stations are closed system and the grab samples taken at the sampling stations have a chemical fume hood preventing operating personnel exposure. Constant air velocity is maintained through the working face of the hoods ensuring airborne contamination does not escape to the room under operating conditions.
6. A shut-off valve is placed in the sample lines immediately downstream of the sample nozzle, and sampling lines not continuously used during normal operations are drained-sloped to prevent crud pockets or areas of stagnant fluids.

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

7. If a sample cannot be returned to its original system, it is directed to the nearest appropriate drain.
8. Provisions are made for flushing pipes with demineralized water before the sample bottle is removed from the panel. Panel drains are drained to the appropriate drain system.
9. Means are provided for remote handling and shielded transport of sample bottles, when required.
10. Connections to containment airspace are provided facilitating atmospheric sampling for isotopic composition and hydrogen and oxygens concentrations in the event of an accident.

**12.3.5.4.2 Process Radiation and Environmental Monitoring System**

1. Gross beta-gamma activity is constantly monitored in the main steam line to detect potential increases in fuel leaks to the coolant.
2. Activity monitors are installed close to the interface barriers where clean fluids that serve to cool the contaminated process fluids might receive radioactive fluid leakage.
3. Activity monitors are installed to monitor and control system discharge. These systems are isolated upon high level detection.
4. Area radiation monitors are installed in:
  - a. Areas where doses may significantly increase either periodically or inadvertently
  - b. Areas where unauthorized or inadvertent movement of radioactive material may occur
  - c. Areas where leaks of radioactive material from process streams may occur
  - d. Areas where nuclear fuel is stored or handled, such as areas close to the refueling machine and close to the fuel pool
  - e. Areas frequently accessed for operation or maintenance requirements

To prevent radiation overexposure, to detect leaks, and to prevent high-activity discharge, the atmospheres of the rooms and stacks are monitored for particulates, noble gases, and iodine. Radiation monitor locations and descriptions for the plant are provided in Subsection 12.3.14 Monitoring of Individuals and Working Areas (Instrumentation for Radiation Levels and Airborne Radioactivity).

The Containment, TB, TB, PLSA, and RWB atmospheres are monitored for particulates, noble gases, and iodine:

- Laboratories are monitored continuously for noble gas and particulate activity levels, and periodically for iodine
- Atmosphere adjacent to personnel access hatches is monitored for particulates
- Buildings housing large equipment that store reactor coolant are continuously monitored for noble gases and particulates
- Buildings where radioactive waste is stored are continuously monitored for particulates
- Refueling machine atmosphere is continuously monitored for noble gases during refueling

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

- Particulates, via an iso-kinetic sampler, and noble gas activity levels are continuously monitored in the TB stack during normal and shutdown operations, and periodic surveillance

Activity monitoring systems detect and signal off-normal operating conditions for:

- High differential pressure in the sampling filters
- High and low air flow in the activity monitoring lines
- Malfunction of a blower or monitor
- Incorrect operation of valves

### **12.3.6 ALARA Structures Criteria**

This section delineates the main ALARA criteria provided in the BWRX-300 structural design.

#### **12.3.6.1 Building/Structure Specific Shielding Requirements**

1. Containment - The major shielding structures consist of containment walls and reactor shield wall (bioshield):
  - a. The reactor shield wall consists of shielding using the steel bricks and steel plate.
  - b. The containment outer wall is a steel concrete steel cylinder or steel bricks, that totally surrounds containment. A steel brick top slab covers containment.
  - c. The shielding for the RB maintains areas requiring regular daily access to dose rates less than 6  $\mu\text{Sv/hr}$  (0.6 mrem/hr).
  - d. All necessary shielding in the upper containment maintains dose ALARA during transfer of irradiated spent fuel assemblies.
  - e. Shielding or appropriate controls minimize dose rates if a fuel handling mishap results in dropping a fuel assembly across the reactor flange.
2. Penetrations through the containment wall are shielded reducing radiation streaming. Localized dose rates outside these penetrations are limited to less than 50  $\mu\text{Sv/hr}$  (5 mrem/hr). The penetrations through interior shield walls of the RB are shielded using a modified high-density silicone elastomer, or equivalent absorber, reducing radiation streaming. Penetrations are also located to minimize radiation streaming consequences into surrounding areas.
3. The CUW RHX is located in a shielded cubicle.
4. Demineralizer and filter units are in separate shielded cubicles. This arrangement allows maintenance of one unit while the other operates. The dose rate in the adjoining demineralizer cubicle from the operating unit is less than 250  $\mu\text{Sv/hr}$  (25 mrem/hr). Infrequent entry into the demineralizer cubicle is through shielded hatches. The bulk of the piping and valves for the demineralizers and filters are in an adjacent shielded valve gallery.

Backflushing and resin application of the demineralizers are controlled from an area where dose rates are less than 10  $\mu\text{Sv/hr}$  (1 mrem/hr).
5. Fuel Storage - The fuel storage pool ensures the dose rate around the pool area is less than 25  $\mu\text{Sv/hr}$  (2.5 mrem/hr).
6. Fuel Handling - Integral shielding installed on the refueling machine is equivalent to one foot of water. Refueling pool depth maintains less than 25  $\mu\text{Sv/hr}$  (2.5 mrem/hr) at the

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

water surface (per ANSI/ANS 57.1) during transit of a single grappled fuel bundle from/to the reactor vessel and the spent fuel racks.

7. The dose rate in the Main Control Room (MCR) is limited to a maximum threshold of 2  $\mu\text{Sv/hr}$  (0.2 mrem/hr) during normal reactor operating conditions. The outer walls of the CB are designed to attenuate radiation from within the RB and from possible airborne radiation surrounding the CB following beyond design basis event. The wall shielding limits the direct-shine exposure from all potential high radiation sources.
8. Noble gas airborne concentrations are expected to be negligible throughout the TB except near the SJAES. These components are placed in shielded cubicles that are not normally occupied during operation.
9. Facilities supporting responses to accidents and emergencies in accordance with REGDOC-2.5.2, Section 8.13.3 and REGDOC-2.10.1, Sections 5.2 and 5.7 are provided with radiological protection and monitoring equipment necessary to ensure that personnel radiation exposure during accident recovery does not exceed 50 mSv (5 rem).

#### **12.3.6.2 General Layout and Accesses**

1. Radiological protection layout follows the concept of separation into three distinct and isolable areas: uncontrolled access areas, controlled (limited) access areas, and uncontrolled areas.
2. The controlled access areas encompass all radioactive systems, equipment, components, and materials.
3. The buildings and areas that define the controlled access area are separated and/or have sufficient shielding to maintain dose rates in uncontrolled areas to less than 6  $\mu\text{Sv/hr}$  (0.6 mrem/hr.)
4. The routes between buildings of the controlled access area and their accessible rooms are short as possible, designed for easy passage, and run through low radiation areas.
5. All accessible rooms are easily reached from service corridors.
6. The accessible areas floor-ceiling height accommodates personnel transporting tools for inspections and maintenance.
7. Areas are provided for storing removable components and mobile shielding that do not hinder personnel passage and mobility.
8. Plant areas are arranged for service operations, monitoring or inspection of highly radioactive equipment that is carried out manually or remotely.
9. Easy escape routes are provided with appropriate signage posted.
10. Access to high radiation areas is posted and blocked by physical barriers.
11. Access to enclosures accommodates entry and exit of components and tools.
12. Properly sized access hatches are provided (e.g., installation or removal of plant components).
13. Equipment, instruments, and sampling stations that require routine maintenance, calibration, operation, or inspection, are located for ease of access and minimum occupancy time.
14. Highly radioactive equipment plant areas are laid out to allow remote or mechanical operation, service, monitoring, or inspection.

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

15. Transportation equipment (monorails, carts, hoists, etc.) is provided so that equipment is serviced in lower radiation areas.
16. Centralized control panels are provided permitting remote operation of all SC equipment from the lowest radiation zone practicable and are provided for SCN equipment.
17. Adequate space is provided for movable shielding for sources within the service area.
18. Means to control contamination and facilitate decontamination of contaminated areas are provided.
19. Space for pumps and valves not containing radioactive fluids are outside radioactive areas.
20. Pump configuration provides sufficient space for maintenance, including laydown space for disassembled piping, insulation, and components and for maintenance support features such as monorails and work platforms.
21. Personnel exposure is minimized during inspection and maintenance by locating equipment and instrumentation as far as possible from potential sources of high radiation.
22. The BWRX-300 plant does not contain underground pipelines that are directly buried in the ground (i.e., contained in concrete trenches/tunnels or concrete duct bank) or buried in masonry wall construction.
23. Penetrations through outer walls of the building containing radiation sources are sealed to prevent miscellaneous leaks into the environment.
24. Sloped floor drains are provided in shielded cubicles and other areas where spill potential exists limiting contamination.
25. Smooth, flat surfaces are used where radioactive spills could occur and expanded metal-type floor gratings are minimized.
26. The RW tank cubicles concrete is provided with a sealant and tank cubicle stainless steel liners to prevent any water releases to the environment.
27. The RB washdown bays are designed so that after the spent fuel cask is loaded on the transporter, potential surface contamination is monitored and decontaminated.
28. The washdown bays include the following:
  - a. Walls or curbs are located around areas of potential contaminated fluid leakage
  - b. Floor surfaces are sloped to drains, and sumps sized for maximum decontamination liquid flow rate
  - c. Concrete surfaces, including floor surfaces are protected with a non-porous coating
  - d. The decontamination fluid is processed through the liquid RW system
29. Health physics facilities and features administratively control:
  - a. Plant personnel activities limiting personnel exposure to radiation and radioactive materials ALARA, and within the guidelines of REGDOC-2.7.1
  - b. Effluent releases to maintain releases ALARA, and within the limits of CSA-N288.1, and the plant Operational Limits and Conditions (OLC)
  - c. Waste shipments meet applicable shipping and receipt material requirements at the storage or burial site

### **12.3.6.3 Walls, Structures and Shielding Elements**

1. The shielding requirements:
  - a. Limit radiation exposure to the public, workers, and the environment that are ALARA and comply with REGDOC-2.7.1, Section 4.4.1 (Reference 12.3-1) requirements
  - b. Limit radiation exposure to workers, in the event of an accident, to levels that are ALARA and consider the limits in ICRP Publication 103 (Reference 12.3-3)
  - c. Limit the radiation exposure of critical components assuring component performance and design life are not impaired
2. Shielding reduces radiation levels from N-16 sources in occupied areas during power operation.
3. Shine between joints of different shielding elements, especially removable blocks, are avoided preventing radiation passage.
4. Penetrations through shield walls are avoided reducing the number of streaming paths. Whenever penetrations are required through shield walls, they are located minimizing the effect on surrounding areas. Penetrations are located so that the radiation source cannot pass through the penetration. When this is not possible, an added order of radiation source reduction is provided.
5. The annular area between pipe and penetration sleeves and electrical penetrations are filled with shielding material reducing the streaming. Examples of the shielding materials used in these applications include modified high-density silicone elastomer (or equivalent), with a density comparable to concrete, and boron-loaded refractory-type material for applications requiring neutron as well as gamma shielding.
6. Whenever a penetration cannot be avoided and a simpler and more effective solution does not prevent the radiation passing through the penetration, a shielded enclosure is installed around the penetration as it exits the shield wall.
7. The maximum number of elements is fed through penetrations and openings minimizing the number of openings.
8. The number of openings between highly radioactive areas and accessible areas are minimized.
9. Equipment is located minimizing shielding requirements. Shielded labyrinth entrances are selected for radioactive pump, equipment, and valve rooms instead of shield doors and hatches. Adequate space is provided in labyrinth entrances for access.
10. All systems containing radioactivity are identified and shielded based on access and exposure level requirements for surrounding areas.
11. Provisions are made for shielding major radiation sources during ISI to reduce inspection personnel exposure. For example, steel platforms are provided for ISI of the RPV welds and associated piping.
12. Concrete used for shielding purposes is designed considering guidance in Regulatory Guide 1.69 (Reference 12.3-4). Where special circumstances dictate, steel, encapsulated lead, water, a modified high-density silicone elastomer, or a boron-laced refractory material is used.

13. Shielding thicknesses are selected reducing the aggregate dose rate from significant radiation sources in surrounding areas to values below the upper limit of the radiation zone specified in the zone maps.

#### **12.3.6.4 Pools Containing Radioactive Liquids**

1. The liner welds for all pools are equipped with a leak detection system.
2. The leak chase is grouped to different pool areas and leakage is directed to area drains. This allows both leak detection and determining where leaks originate. After construction is finished, each isolated pool is leak tested.

#### **12.3.6.5 Doors and Shield Walls**

1. Doors are installed to manage access to high radiation level areas. Additional measures such as radioactive signs or locks may be used.
2. The doors in shielding labyrinths are located at the entrance to the labyrinth.

#### **12.3.6.6 Coatings, Surface Finishes and Painting**

1. Epoxy-type wall and floor coverings are used providing smooth surfaces easing the decontamination. Smooth surfaces are applied to the walls and floors of the RB, TB, RWB, and TB Annex rooms containing equipment with liquid radioactive sources, floor drain areas, and washdown bays.
2. A non-porous surface paint and finish for easing decontamination is applied to room walls, floors, staircases, and platforms.
3. Protective coatings are qualified and capable of surviving a Design Basis Accident (DBA) without adversely affecting safety mitigating SSCs per guidance in Regulatory Guide 1.54 (Reference 12.3-5).
4. A contrasting undercoat color is included in the coating system for wear indication.

#### **12.3.7 ALARA Criteria for Electrical Instrumentation and Control Design**

The ALARA criteria are applied to the electrical and instrumentation design.

##### **12.3.7.1 Component Arrangement**

1. Motor control centers and system control panels are in low radiation level areas.
2. Motor-operated valves are controlled from low radiation level areas.
3. The cable trays and equipment layout does not hinder personnel passage.
4. The electrical motors connectors located in high radiation zones has quick disconnects simplifying repair and maintenance.
5. The RW piping gallery between the TB and the RW contains only SCN electrical cables that are separated from the RW piping by a minimum shielding of 20 cm (7.9 in).

##### **12.3.7.2 Lighting, Telephone and Loudspeaker System**

1. Lighting levels are suitable for surveillance and maintenance operations in radiation areas.
2. Multiple lighting fixtures prevent the immediate need to replace faulty bulbs in shielded cubicles.
3. Lighting fixtures are in easily accessible locations reducing exposure time during bulb replacement.

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

4. Light bulbs within containment, main steam tunnel, and refueling level of the RB containing mercury are not used due to mercury's neutron activation potential.
5. Radioactive areas rooms and corridors have emergency lighting and illuminated exit signs to indicate escape routes.
6. Alarms and the personal address system use uninterruptible power supplies.
7. The lighting equipment, communications, and loud-speakers location allows for maintenance with minimal radiation exposure.

#### **12.3.7.3 Instrumentation**

1. Instrumentation for equipment operation, control, and sampling is located in low-level areas (shielded rooms for valves, corridors, or control rooms) that are accessible during normal and off-normal operating conditions. Shielded valve galleries are provided for the CUW, FPC, and RW (e.g., spent resin tank) systems.
2. Sensing lines are routed from primary system taps avoiding placing transmitters or readout devices in high radiation areas. For example, reactor water level sensing instruments are located outside containment.
3. Instrument sensors requiring inspection, repair, or maintenance accessibility are located facilitating operations.
4. Instruments located in high radiation areas allow removal to low radiation areas for maintenance.
5. Transmitters and display instruments are in radiation zones A or B to the extent possible. The radiation levels in these zones are defined in Subsection 12.6.1.
6. Sampling instrumentation system design minimizes the required amount of radioactive fluid.
7. Radiation monitors located in high radiation areas have displays located in an adjacent low radiation areas and local visible and audible alarms.

#### **12.3.7.4 Materials**

Components and cables used in radioactive areas are qualified for the calculated radiation conditions.

### **12.3.8 System and Major Component Design Considerations**

#### **12.3.8.1 Main Condenser**

1. Main condenser hotwell provides a holdup for Main Steam Isolation Valve leakage.
2. During normal operation, the main condenser shells operate with a vacuum. Radioactive circulating water leakage to the atmosphere does not occur. Any air leakage is into the main condenser shell side.
3. Condensate is retained in the main condenser permitting radioactive decay before entering the condensate system.
4. Necessary shielding and controlled access for the main condenser is provided.

#### **12.3.8.2 Nuclear Boiler System**

1. Entry into the RB steam tunnel is through a controlled and shielded personnel access door that has a concrete labyrinth to attenuate radiation streaming from the adjoining steam lines. During reactor operation, the steam tunnel is controlled access.

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

2. Selected valves within the steam tunnel are provided with drains that are piped to drain sumps minimizing leakage into surrounding areas. Floor drains are provided within the steam tunnel minimizing contamination if a leak occurs.
3. Penetrations through the steam tunnel walls are minimized, reducing streaming paths. Penetrations through the steam tunnel walls are located exiting controlled access areas or in areas not aligned with the steam lines. A modified high-density silicone elastomer (or equivalent) is employed whenever possible for these penetrations reducing the available streaming area presented.
4. The steam tunnel shields the plant complex from N-16 gamma shine in the main steam lines. The steam tunnel walls provide shielding limiting the direct-shine exposure from the main steam lines at any point that are inhabited in areas adjacent to the steam tunnel to less than 50  $\mu\text{Sv/hr}$  (5 mrem/hr) during normal operations (controlled access area).

#### **12.3.8.3 Fuel Pool Cooling System**

1. The FPC system services the fuel pool, cask pit, and reactor cavity pool on a rotating basis. This system operates continuously removing generated heat, reducing pool evaporation, and reducing contamination.
2. The FPC system includes two independent filters and demineralizers that remove radioactive contamination from the fuel pool, cask pit, and reactor cavity pool. These units are the highest radiation level components in the system. Each unit is located in a concrete-shielded cubicle accessible through a shielded hatch.
3. Remotely backflushing the filters and demineralizers is possible. FPC system filters are backwashed into a receiving tank and routed to the liquid radioactive waste system.
4. Clean water connection flushing lines are provided for the FPC system prior to switching between pools preventing contamination between pools.
5. All processing FPC system valves (inlet, outlet, recycle, vent, and drain) on the filters and demineralizers are located outside the shielded cubicles in a separate shielded cubicle or area together with associated piping, headers, and instrumentation.
6. FPC system piping containing resin is sloped downward to the receiving system or tank.
7. All shielded FPC system components are consolidated in the same section of the RB. Personnel access to shielded system components is controlled. Shielding for the components reduces the radiation level to less than 10 mSv/hr (1000 mrem/hr) in adjacent areas where normal access is permitted.
8. FPC system operation is accomplished from the MCR, and local control panels located where radiation levels are less than 50  $\mu\text{Sv/hr}$  (5.0 mrem/hr), and controlled limited access is permitted.
9. The FPC system provides for the collecting, monitoring, and draining pool liner leaks from the fuel pool, cask pit, and reactor cavity pools to the Liquid Waste Management System.
10. The fuel pool is equipped with drainage paths for:
  - a. Preventing stagnant water buildup behind the liner plate
  - b. Preventing the uncontrolled loss of contaminated pool water
  - c. Providing liner leak detection and measurement

11. The fuel pool, cask pit, and reactor cavity pool is also equipped with stainless steel liners and leak detection drains. All leak detection drains permit free gravity drainage to a local building drain sump.

#### **12.3.8.4 Condensate Filters and Demineralizers System**

The Condensate Purification System (CPS) shields dose rates in uncontrolled areas less than 6  $\mu\text{Sv/hr}$  (0.6 mrem/hr). The CPS removes condensate system corrosion products and impurities resulting from condenser tube leakage, some radioactive material, activated corrosion products, and fission products carried over from the reactor.

#### **12.3.9 Radwaste Building**

Liquid and solid radioactive wastes generated during normal plant operations are transferred to the RWB for collection, holdup, and processing by Liquid Waste Management System (LWM) and the Solid Waste Management System (SWM).

1. LWM and SWM process subsystems include shielding and controls limiting accessible general area radiation levels to less than 10 mSv/hr (1000 mrem/hr). Transient radiation levels during filter media or waste container transfer operations may exceed these levels, but remote operation limits the average worker radiation dose to less than 150  $\mu\text{Sv/hr}$  (15 mrem/hr).
2. Design features minimizing occupational exposure include:
  - a. Remote pipe and equipment flushing
  - b. Remote viewing and handling equipment
  - c. Centralized sampling station minimizing exposure time
  - d. LWM and SWM tanks vent to RWB Heating, Ventilation, and Air Conditioning (HVAC) for processing
  - e. Radiation monitors with alarms provided both inside and outside RWB building liquid or solid RW processing rooms
3. Processing systems (pumps, valves, tanks, and skid-mounted process systems) are remotely operated from a central RWB control panel.
4. Remote operation for routine radioactive waste management system functions is performed from local RW control panel. This includes remote actuated valves for controlling process flow between process stations and permanently installed equipment.
5. The RWB process systems area accommodates modular shield walls that limits access and reduces radiation levels from waste processing equipment.
6. Dry active waste sorting, processing, and packaging operations are also performed in the RWB or TB Annex. Portable radiation detectors, portable shielding, and remote handling tools reduces radiation levels and occupational exposure.
7. Routine maintenance uses skid-mounted process systems for RW processing, reducing maintenance requirements for permanently installed systems.

##### **12.3.9.1 Liquid Waste Management System**

The LWM collects liquid wastes from floor drains, and other sources within the facility. Radioactive liquids generated during operation are segregated, collected, stored, and processed in the LWM.

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

1. Radioactive contaminants are removed, and the bulk of the liquid is purified and either returned to the Condensate Storage Tank (CST) or reprocessed. The BWRX-300 is designed as a zero liquid release plant under normal conditions.
2. LWM is divided into subsystems where liquid wastes are segregated and processed according to the impurity type and chemical content. Segregating liquid waste minimizes the total waste produced through efficient processing.
3. The calculated individual dose from the annual release of radioactive liquid effluents meets the DNNP action levels.
4. The liquid effluent release controls based upon the DNNP, action levels, and discharge limits are provided in the POSAR.
5. Liquid waste removed and concentrated in filter media, ion exchange resins, and other forms is further processed into the SWM.
6. Radioactive waste tanks effluents discharge near the tank room ventilation exhaust register. Baffle plates are used in tank vents preventing liquid and entrained solids splashing out. No hard connections to the ventilation system are used to avoid liquid or moisture propagation through the ventilation system damaging the HEPA filters.
7. The RW system has significant holdup capacity in waste collection tanks and sample tanks that allows for reprocessing and minimizes effluent releases to the environment.

#### **12.3.9.2 Solid Waste Management System**

1. Radioactive solid waste is segregated for wet and dry packaging minimize total waste stream and offsite shipment and storage.
2. SWM activities are controlled remotely at a local control panel. Remote controlled operations include movement of casks and liners, filter handling, resin transport, and movement or reconfiguration of RW processing skids.

#### **12.3.9.3 Offgas System**

1. The release of radioactive material into the atmosphere is minimized by the OGS. The OGS holds gas allowing for decay of the offgas stream that contain krypton, xenon, iodine, nitrogen, and oxygen isotopes.
2. The release of gaseous radioactive effluents to the environs maintains exposure in unrestricted areas ALARA according to action levels.
3. The gaseous effluent release controls based upon the DNNP action levels, action levels, and discharge limits are provided in the POSAR.
4. OGS equipment is selected, arranged, and shielded maintaining occupational exposure ALARA.
5. OGS contains a recombiner, condenser, and activated carbon beds.
6. OGS provides sufficient holdup until the required fraction of the radionuclides has decayed, and the daughter products are retained by the charcoal.

#### **12.3.10 Reactor Building Spent Fuel and Components**

The RB structural design provides flow resistance in contaminated areas that hold up radioactive releases from containment.

**Spent Fuel Storage Design Bases:** The fuel storage pool has capacity for five refueling cycles and a complete core offload as well as some highly radioactive waste (e.g., filters) assuring safety under normal and postulated accident conditions. These safety measures include:

- Periodic inspection and testing of components important to safety
- Radiation Protection shielding
- Containment, confinement, and filtering systems
- Residual heat removal capability that is reliable and testable
- Ensuring fuel storage coolant inventory under accident conditions

The design allows for:

- Controlling airborne release
- Preventing coolant inventory drainage below the acceptable depth through the use of drains, gates, and weirs
- Coolant flow to spent fuel racks
- Fuel pool liner leakage detection and confinement

#### **12.3.10.1 Reactor Water Cleanup System**

1. CUW system that is in contact with the reactor coolant system is constructed of corrosion-resistant materials. For system piping, smooth bends are used instead of welded fittings. At certain locations within the system, stainless steel pipes with electro-polished finish are used to reduce corrosion product buildup.
2. CUW components include an RHX, a pressure reduction station, and associated valves located inside the TB.
3. The shielded cubicle CUW valves and piping reduces radiation levels, but entry is not allowed during normal operation. Most CUW valves and piping are in a shielded valve gallery adjacent to the cubicle and are remotely operated.
4. Chemical cleaning and decontamination connections use condensate to flush piping and equipment for decontamination prior to RHX maintenance pressure reduction station, and associated valves.
5. HVAC system limits the spread of contaminants from these shielded CUW cubicles by maintaining negative pressure.
6. Personnel access to the CUW cubicles for component maintenance is controlled to minimize personnel exposure.

#### **12.3.10.2 Control Rod Drive System**

The FMCRD design allows removal of the motor unit, position indicator probe, separation indicator probe and lower component for maintenance during plant outages without disturbing the upper assembly of the drive.

#### **12.3.10.3 Containment**

1. Containment and other safety features limit accident radiological effects and release are within acceptable limits.

2. Containment air that is inerted with nitrogen during normal operation is purged (specifically purging N-16) before access is allowed during shutdown conditions. Containment access is not permitted during normal operation above 25% power.
3. Prior to removing the reactor vessel head, airborne radioactive material sources are removed by either the containment purge exhaust system or the main condenser.

#### **12.3.10.4 Containment Leak Detection and Isolation System**

For process lines that penetrate the containment, leakage detection and isolation is provided. The leakage detection instrumentation initiates alarms at established limits and isolates the affected system(s).

#### **12.3.10.5 Plant Cooling Water System**

Plant cooling water is supplied to for the following fire protection measures:

1. Fire suppression devices are provided for activated carbon beds and radioactive filter that ignite due to high inlet temperatures.
2. Fire protection barriers and fire detection protects decontamination areas and RW storage areas.
3. Fire protection hoses are in low radiation areas.

#### **12.3.10.6 Secondary Control Room**

1. SCR shielding design protects personnel from radiological conditions during normal operation. Shielding permits access and occupancy of the SCR following an event where the MCR becomes uninhabitable.
2. Habitability contingencies are provided for continued occupancy under accident, station blackout conditions, and severe accidents.

#### **12.3.11 Control Building**

1. The MCR shielding design is based upon protecting personnel from radiation resulting from the most limiting design basis accident. Shielding permits access and occupancy of the MCR to ensure plant personnel exposure following an accident does not exceed dose limits.
2. The MCR is shielded against normal sources of radiation. Habitability contingencies are provided for continued occupancy under design basis accident, station blackout conditions and Design Extension Conditions without core melt. Severe accidents require operators relocate to the secondary control room.
3. Safe occupancy of the MCR during abnormal conditions (AOOs, DBAs) is provided in the design.

#### **12.3.12 Decommissioning ALARA Considerations**

The following plant design features ensure the plant is operated and maintained ALARA. These features aid in facilitating ALARA exposures during decommissioning:

1. Shielding design protects workers during maintenance or repairs and decommissioning.
2. The RB, TB, RWB, and TB Annex design consists of entry doors from the outside and numerous cubicles with equipment hatches inside the buildings for large equipment removal to facilitate decommissioning.

3. The RW process systems located in the RWB are skid-mounted and facilitate decommissioning and ease of access, by allowing truck access, and skid loading/unloading.

### **12.3.13 Ventilation**

#### **12.3.13.1 General HVAC System ALARA Design Controls**

1. The following design objectives apply to building ventilation systems:
  - a. Systems ensure releases to the environment are ALARA.
  - b. Radionuclide air concentrations in accessible areas to personnel for normal plant surveillance and maintenance is below 10% of the derived air concentrations during normal power operation.
  - c. HVAC room concentration setpoints are determined ensuring airborne releases are ALARA and comply with the action levels in the POSAR.
2. The plant stack and the major streams feeding the stack are monitored by the PRM so that action is taken avoiding releases in excess of regulatory limits.
3. During normal operation purging, the containment exhausts air through the HVAC HEPA filter unit prior to stack discharge.
4. During an isolation event, if offsite or backup power is not available, outside air is supplied to MCR by Emergency Filter Unit (EFU) operation.
5. The EFUs are in closed areas preventing the spread of radioactive contamination and providing adequate space for maintenance activities. Before charcoal removal, radioactivity is allowed to decay to minimal levels.
6. The control room EFU ventilation systems filter unit operates during accident conditions providing pressurization and outside air.
7. The shielding wall thickness between the HVAC filter cubicles is sized so that the dose contribution in any cubicle does not exceed 250  $\mu\text{Sv/hr}$  (25 mrem/hr) under normal operation, ensuring filter maintenance exposure ALARA.

#### **12.3.13.2 Heating, Ventilation and Cooling Systems**

1. HVAC system limits airborne contamination by providing airflow patterns from areas of low contamination to higher contaminated areas. This is accomplished by creating negative pressure areas in contaminated cubicles maintaining air flow into each cubicle from the corridor area. The higher contaminated areas exhausts flow through the HEPA filters prior to the plant stack.
2. HVAC service in contaminated areas circulates air through the contaminated areas of the buildings in a once-through fashion. Flow is directed from corridors (point of highest pressure) to the equipment alcove rooms, to the area rooms, to air ducts, and finally to the exhaust ductwork for processing through HEPA filters.
3. The ventilation system in the fuel pool and equipment areas sweeps air from the fuel pool surface, removing the major portion of potential airborne contamination at the source.
4. The passage of ventilation ducts through walls and structures ensures the shielding efficiency is not reduced. HVAC duct penetrations used for exhaust are routed above personnel head height to minimize streaming effects to worker exposure. HVAC duct penetrations are in line of sight between radiation sources and occupied areas.

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

5. Major HVAC equipment (e.g., fans, coolers) is located in dedicated low radiation areas to minimize maintenance worker exposures.
6. Airflow from areas of lower contamination potential to areas of greater contamination potential are maintained using a negative pressure in the more contaminated area.
7. Buildings containing radioactive materials are equipped with radiological monitoring connections (sample ports) in the exhaust ductwork targeting radiological system leakages.
8. In areas where HVAC air emergency filtration is required, joints, corners, sharp bends, obstructions, and dampers where radioactive contamination accumulates are minimized.
9. Fume hoods or similar devices are installed in laboratories, sampling rooms, and component decontamination rooms.
10. HEPA and charcoal filters are installed in potentially contaminated exhaust pathways.
11. HVAC filters that are highly contaminated are shielded from one another and from personnel access areas to minimize exposure.
12. Isolation dampers are installed at fans, whenever flow needs segregation for repair and maintenance.
13. Remote actuation of redundant filter trains is provided for high-activity areas within the building.
14. HEPA filters are equipped with differential pressure detection and remote indication.
15. The MCR and SCR envelopes maintain overpressure.
16. HEPA filters are located close to the radioactive source.
17. Respiratory protection is provided in cases where high airborne contamination levels contaminants are not removed efficiently by the HVS.

**12.3.14 Monitoring of Individuals and Working Areas (Instrumentation for Radiation Levels and Airborne Radioactivity)**

The following Process Radiation and Environmental Monitoring System (PREMS) radiation monitoring subsystems are provided for monitoring area radiation and airborne radioactivity within the plant:

- Containment Monitoring Subsystem (CMon)
- Process Sampling Subsystem (PS)
- Process Radiation Monitoring Subsystem (PRM)
- Area Radiation Monitoring Subsystem (ARM)

Airborne radioactivity in effluent releases and ventilation air exhausts is continuously sampled and monitored by the PREMS for noble gases, air particulates and halogens. Airborne contamination is sampled and monitored at each stack, in the offgas releases, and in the ventilation exhaust from the RB, RWB and TB. Samples are periodically collected and analyzed for radioactivity. In addition to this instrumentation, portable air samplers are used to check for airborne radioactivity in work areas prior to entry where radiation levels have the potential to exceed the allowable limits.

#### **12.3.14.1 Containment Monitoring Subsystem**

The CMon provides instrumentation for monitoring the following conditions inside containment:

- Hydrogen and oxygen concentration
- Pressure
- Water level
- Temperature
- Relative humidity
- Area radiation
- Gross gamma radiation for fission products

Signals are provided to the appropriate Distributed Control and Information System according to safety category. The Distributed Control and Information System processes each signal for display in the MCR and SCR, actuation of audible and visual alarms, and initiation of response functions such as reactor scram, containment valve isolation, feedwater isolation and PAM.

Monitoring is provided during normal reactor operation, AOOs, and post-accident conditions.

#### **12.3.14.2 Process Sampling Subsystem**

PS collects liquid and gaseous samples for analysis. This analytical information is used to monitor plant and equipment performance. This process subsequently informs plant operations if changes to operating parameters are necessary in order to meet acceptance criteria. This subsystem functions during all plant operational modes. Continuously sampled flows are routed from select locations in the process streams to the sampling stations. The sample flows enter the sample stations where pressure, temperature, and flow adjustments are made as necessary. Grab sampling facilities and special monitoring are provided for select areas (e.g., liquid radioactive waste). Continuous samples are diverted to continuous monitoring equipment that transmits data to the plant computer. Alarms indicate off-normal conditions.

#### **12.3.14.3 Process Radiation Monitoring Subsystem**

Airborne radioactivity in effluent and ventilation air exhausts are continuously sampled and monitored for noble gases, air particulates, and halogens by the PRM. PRM samples and monitors airborne contamination at the stack, in OGS streams, and in the ventilation exhaust from the RB, RWB, and TB. Detection of high radiation levels are alarmed in the MCR. Sampling in the exhaust lines is continuously analyzed. PRM facilitates periodic sampling for analysis. In addition to this instrumentation, portable air samplers are used to check for airborne radioactivity in work areas prior to entry where radiation levels could exceed allowable limits. Detectors in the PRM subsystem provide measurement indication of airborne radiological conditions from occupied areas.

#### **12.3.14.4 Area Radiation Monitoring Subsystem**

The ARM continuously measures, indicates and records gamma radiation levels at strategic locations throughout the plant except within containment. Alarms are activated in the MCR and SCR, as well as in local areas to warn personnel to take appropriate protective measures.

ARM detectors are located upstream of the CB and SCR AHUs. These detectors indicate and alarm in the MCR and SCR and are used by plant personnel in conjunction with portable monitors to evaluate airborne radiological conditions in occupied areas.

#### ***12.3.14.4.1 Area Radiation Monitoring Subsystems Description***

Every ARM channel consists of a gamma-sensitive detector and a digital area radiation processor. All channels are provided with local visual and audible alarms and local readouts. Additional readouts and alarms are provided by local auxiliary units. The output signals from the detectors are digitized and multiplexed for transmission to digital radiation monitors for measurement and display. The radiation signals are transmitted to the process computer for recording. Each radiation monitoring channel has adjustable trip alarm circuits, one for high radiation and the other for downscale indication (loss of sensor input). Also, each area radiation monitor has a built-in self-check for gross failures and activates an alarm on a power failure or an inoperative monitor. Auxiliary units with local audible alarms are provided in selected local areas that immediately warn occupants. Each area radiation monitor is powered from an uninterruptible power source that is continuously available during loss of offsite power.

#### ***12.3.14.4.2 Area Radiation Monitoring Subsystems Detector Locations and Sensitivity***

The appropriate locations and monitoring ranges of each area radiation monitor is finalized in detailed design phase.

#### ***12.3.14.4.3 Area Radiation Monitoring Subsystems Design Parameters and Requirements***

Two high-range radiation channels are provided on the refueling floor and fuel pool area to monitor radiation from a design extension condition Fuel Handling Accident. The conservative Out of Core Criticality analysis provided in Subsection 15.5.9.3 demonstrates that a criticality alarm system is not necessary at the BWRX-300 DNNP. An Out of Core Criticality accident in the refueling area is practically eliminated due to physical impossibility and supporting operating procedures. Practical elimination of this event is consistent with BWRX-300 Safety Strategy, described in Chapter 3, Subsection 3.1.8.

Defense Line 1 design provisions and supporting operating procedures provide design and administrative controls that effectively manage factors that influence system reactivity and the criticality. Design factors that influence reactivity are enrichment, mass, moderation, geometry, reflection, interaction and spacing. Plant procedures prohibit the handling and storage of more fuel assemblies than have been determined to be safely subcritical at any one time and under the most adverse moderation conditions feasible by un-borated water. The amount of water moderator available for internal flooding is limited by the storage location structure design making any credible possibility of an Out of Core Criticality physically impossible. As a result, the need for a criticality alarm system is practically eliminated consistent with BWRX-300 Safety Strategy as described in Chapter 3, Subsection 3.1.8.

Both process radiation monitors and area radiation monitors are in the fuel storage and associated handling areas.

Process radiation monitor alarms and isolation are provided for fuel pool area ventilation. Area radiation monitors with visual and audible alarms is also provided.

Final alarm setpoints established in the field are based on sensor location, background radiation levels, expected radiation levels, and low occupational radiation exposures. The radiation alarm setpoint for each channel is set slightly above the background radiation level for the monitor location.

## **12.4 Shielding**

The permanent shielding analysis is completed during detailed design phase. The evaluation identifies those areas experiencing elevated dose rates during power and shutdown conditions and are not mitigated by structure or component design or location. The anticipated dose rates and frequency of access are included in analysis. Using these results, system interaction and structural/component loading analyses, permanent shielding is installed in target areas/components. Permanent shielding is preferred to temporary shielding.

### **12.4.1 General Design Guides**

The primary objective of radiation shielding is protecting operating personnel, and the general public from radiation emanating from the reactor, the power conversion systems, the RW process systems, and the auxiliary systems, while maintaining appropriate access for operation and maintenance in accordance with REGDOC-2.7.1, Sections 4.1 and 5.3 (Reference 12.4-1). Radiation shielding keeps radiation doses to equipment below levels where disabling radiation damage occurs.

The shielding requirements in the plant perform the following functions:

1. Limit, plant personnel, contractors and visitors, exposure ALARA and within guidance of ICRP Publication 103 (Reference 12.4-2) and CNSC SOR/2000-203 (Reference 12.4-3) limits
2. Limit personnel radiation exposure in the unlikely event of an accident to levels that are ALARA, conforming to the limits specified in REGDOC-2.5.2, Section 4.2.1 (Reference 12.4-4 and REGDOC-2.4.1, Section 4.3.2, (Reference 12.4-5) and ensuring the plant is maintained in a safe condition during and after an accident
3. Limit critical components radiation exposure within specified radiation tolerances assuring component performance and design life are not impaired

### **12.4.2 Design Description**

The following guidance is used in the BWRX-300 shielding design:

1. All systems containing radioactivity are identified and shielded based on access and exposure level requirements of surrounding areas. The radiation zone maps described in 12.6 indicate design radiation levels where equipment shielding contributes to achieving the dose rate in the area.
2. The source terms used in the shielding calculations are analyzed conservatively. Transient conditions, shutdown, and normal operating conditions are used ensuring a conservative source is used in the analysis. Shielding is based on design basis fission product concentrations in the coolant in addition to activation products. For components where N-16 is the major radiation source, a concentration based upon BWR fleet operating plant data is used.
3. Processing equipment is located as far as possible from personnel dwelling and passage areas minimizing shielding. Shielded labyrinths are used to eliminate radiation streaming through access ways from sources located in cubicles.
4. Penetrations through shield walls are shielded reducing radiation streaming through the penetrations. The approaches used to locate and shield penetrations are discussed in Subsection 12.3.6.
5. Wherever possible, radioactive piping is run in a manner minimizing plant personnel radiation exposure that includes:

NEDO-33962 REVISION 0  
NON-PROPRIETARY INFORMATION

- a. Minimizing radioactive pipe routing in corridors
  - b. Avoiding routing high-activity pipes through low radiation zones
  - c. Using shielded pipe trenches and pipe chases where routing of high-activity pipes in low-level areas cannot be avoided
  - d. Separating radioactive and non-radioactive pipes for maintenance
6. Maintaining acceptable levels at valve stations by using motor-operated or diaphragm valves. Minimizing worker radiation exposure by providing draining and flushing provisions in the valve design. Operator shielding is provided for manual valve applications using shield walls or valve stem extensions.
  7. Shielding is provided to permit access and occupancy of the MCR ensuring plant personnel exposure following an accident does not exceed the values set forth in REGDOC-2.5.2, Section 4.2.1 and REGDOC-2.4.1, Section 4.3.2 and supports compliance with REGDOC-2.5.2, Section 8.10.1.
  8. Provisions are made for shielding major radiation sources during ISI to reduce personnel exposure. Steel platforms are provided for ISI of the RPV nozzle welds and associated piping.
  9. The primary material used for shielding is concrete. Where special circumstances dictate, steel, lead, water, a modified high-density silicone elastomer, or a boron-laced refractory material is used.

#### **12.4.3 Shielding Method Design**

Radiation sources in various pieces of plant equipment are cited in Section 12.2. Shutdown conditions, such as fuel transfer operation, as well as accident conditions, such as a Loss-of-Coolant Accident (LOCA) or a Fuel Handling Accident, are considered in designing shielding for the plant.

The mathematical models used to represent a radiation source and associated equipment and shielding are established to ensure conservative calculation results. Depending on the versatility of the applicable computer program, various degrees of complexity for the actual physical situation are incorporated.

## **12.5 Dose Constraints and Dose Assessment**

This section describes the Radiation Protection philosophy, objectives, and requirements used throughout the plant design. Radiation Protection ensures:

1. Compliance with regulatory dose limits
2. Radiation exposure during normal plant operation is ALARA with social and economic factors taken into account
3. Cumulative plant worker doses average less than one person-Sv/year over the operating life of a single unit plant

### **12.5.1 Interfaces for Protecting People and the Environment**

#### **12.5.1.1 Radiation Protection Objectives**

During normal operation and AOOs, the Radiation Protection Program objectives are:

1. Radiation exposures are kept within regulatory limits
2. Radiation exposures are kept ALARA with social and economic factors taken into account

Adherence to the first objective is demonstrated by comparing the calculated dose consequences with the dose limits specified in SOR/2000-203 (Reference 12.5-1). The second objective of keeping exposures ALARA, is a cost/benefit design decision for reducing dose exposures. This is accomplished by following the:

SOR/2000-203 (Reference 12.5-1) and REGDOC-2.7.1 (Reference 12.5-2).

#### **12.5.1.2 Normal Operation Dose Limits and Action Levels**

SOR/2000-203 (Reference 12.5-1) states in part: "every licensee shall implement a Radiation Protection Program and shall, as part of that program, (a) keep the amount of exposure to radon progeny and the effective dose and the equivalent dose received by and committed to persons as low as is reasonably achievable, social, and economic factors being taken into account."

#### **Nuclear Energy Worker**

The CNSC effective dose limits for a nuclear energy worker is an average of 20 mSv effective dose per year over a five-year period (100 mSv over five consecutive years), with no single year exceeding 50 mSv effective dose.

#### **Members of the Public**

Per CNSC Radiation Protection Regulations, the effective dose limit for a member of the public is 1 mSv per year from all sources of radiation other than natural background and medical exposures.

#### **Action Levels**

Action levels for the Radiation Protection Program are developed considering the guidance from REGDOC-2.7.1 (Reference 12.5-2). Typical action levels include external or internal doses above the planned ambient external or airborne hazards that are greater than anticipated in the design, and contamination found at levels significantly greater than expected with the plant or released to the public domain. These action levels are developed and available as part of the licence to operate.

#### **12.5.1.3 Limiting Exposures**

The BWRX-300 design minimizes radiation exposure and is consistent with CNSC REGDOC-2.7.1 (Reference 12.5-2).

#### **12.5.1.4 Waste Management**

Management of radioactive solid, liquid, and gaseous waste produced annually and during the operating life of the station is minimized according to ALARA principles and practices. Radioactive waste streams are controlled to limit worker and public doses and comply with regulatory limits. See Chapter 11 for a description of RW management systems.

The BWRX-300 design ensures public exposure from all radionuclides in effluent streams is less than 1 mSv/year (100 mrem/year). The following design and operational practices ensure the plant operates within the action levels:

1. Controlled and monitored liquid and gaseous waste releases
2. Liquid and gaseous waste activity is measured and recorded prior to release
3. The waste management systems have a target dose of 50  $\mu$ Sv per year averaged over the plant lifetime at the exclusion area boundary (see REGDOC-2.7.1) (Reference 12.5-2)

#### **12.5.1.5 Radiation Monitoring**

Radiation monitoring includes:

1. Detecting failed fuel in the core
2. Measuring external radiation in plant locations where plant workers and equipment are present
3. Monitoring, tracking, and recording personnel dosimetry
4. Monitoring, alarming, and isolating airborne contaminants
5. Providing offsite monitoring for radioactive material in the environment
6. Providing a radiation laboratory for analyzing environmental and biological samples, and workers monitoring
7. Providing a calibration facility for all plant radiation monitors

In the event of a release, the monitoring system provides:

1. Data to characterize radiological conditions around the plant and assess the need for offsite action
2. Data on radiological plant conditions facilitating safe evacuation, if necessary.

#### **12.5.1.6 Radiation Exposure Control Program**

The exposure risk for each radioactive plant system or component is estimated as part of a Radiation Exposure Control Program. The Radiation Exposure Control Program estimates the exposures involved in the operation, maintenance, inspection, repair, replacement, or decommissioning of potentially contaminated equipment.

Exposure considerations for plant workers include:

1. Breakdown of system work activities
2. Number of operators required for each activity
3. Time taken for each activity
4. External radiation field and internal airborne hazards

BWR operating experience and BWR operating data is used to inform decisions about estimated exposures.

12.5-2 CNSC Regulatory Document REGDOC-2.7.1, "Radiation Protection."

## **12.6 Radiation Zones and Access Requirements**

Radiation zones are established in all areas as a function of access requirements and area radiation sources. These zones are shown on Figures 12.6-1 through 12.6-17.

All areas of the plant have at least two assigned radiation zone classifications. The first classification is based on normal operation radiation fields and the second classification is based on the normal shutdown radiation fields. Additional classifications are assigned for selected off-normal events, as appropriate.

Updated radiation zones, or radiation zone maps are provided in the POSAR based on the general arrangement drawings, that show the normal operation and normal shutdown radiation zone classifications.

All radiation areas or enclosures have labels to show their radiation zone class. Access to radiation zones is controlled with locked doors in the case of high radiation areas (radiation levels greater than 1 mSv/h (100 mrem/hr)) with clearly marked entrances and chain barriers and marked entrances.

Technology infrastructure systems supporting permanent and temporary functions include:

- Physical access controls for radiologically controlled and significant areas
- Radiation work permit change stations
- Supplemental ARM with portable devices
- Equipment radiation monitoring
- Integrated security access and radiologically controlled area access
- Leak detection systems

### **12.6.1 Radiation Zones**

The following classifications for radiation zones are used:

#### **12.6.1.1 Class A Radiation Zones**

Class A radiation zones are non-radiological controlled zones and have free access and unlimited stay time. The areas outside the controlled area, including electrical equipment rooms, MCR, SCR and administrative areas, are Class A radiation zones. The radiation dose rate in these areas are allowed a maximum of 6  $\mu$ Sv/h (0.6 mrem/h).

#### **12.6.1.2 Class B Radiation Zones**

Class B radiation zones have restricted access and unlimited occupation time. This zone corresponds to the corridors, staircases, control panel areas, and areas around rooms with radioactive material. These areas do not have radioactive equipment or components. The shielded walls guarantee worker safety. The radiation dose rate in these areas reach 10  $\mu$ Sv/h (1 mrem/h), and there is no radioactive or environmental contamination. Access to these areas is through designated entry control points, and rooms with a higher radiation zone class are accessed from these control points.

#### **12.6.1.3 Class C Radiation Zones**

Class C radiation zones have restricted access and occupation time limited to 20 h/wk. These zones are areas of frequent access, such as sampling stations and valve operating rooms. The dose rate in contact with the existing equipment is not greater than 50  $\mu$ Sv/h (5 mrem/h), and there is a possibility of radioactive and/or environmental radiation.

#### **12.6.1.4 Class D Radiation Zones**

Class D radiation zones have restricted access and occupation time is limited to 4 h/wk. These areas are infrequently accessed and are rooms for valves or equipment where the dose rate on contact is no greater than 250  $\mu\text{Sv/h}$  (25 mrem/h). There is a possibility of radioactive and/or environmental radiation.

#### **12.6.1.5 Class E Radiation Zones**

Class E radiation zones have restricted access and occupation time is limited to 1 h/wk. These are occasionally accessed for equipment actuation (pumps, valves, heat exchangers and tanks). The contact dose rate with equipment is no greater than 1000  $\mu\text{Sv/h}$  (100 mrem/h), but the radiation level may be reduced without significantly altering the plant operating mode. There is a possibility of radioactive and/or environmental radiation.

#### **12.6.1.6 Class F to J Radiation Zones**

Class F to J radiation zones are high radiation zones that are areas accessible to individuals where radiation levels external to the body could result in an individual receiving a dose equivalent in excess of 1 mSv (100 mrem) in one hour at 30 centimeters from the radiation source, or 30 centimeters from any surface that the radiation penetrates.

Access to Class F and higher zones is not permitted without specific authorization. This corresponds to equipment rooms that do not require attention for actuation, inspection, and/or maintenance, such as tanks, filters, and pipes with radiation levels greater than 1 mSv/h (100 mrem/h). Their radiation level cannot be reduced without significantly altering plant operation.

Typical non-accessible Class F to J, High and Very High radiation areas include the reactor vessel area, containment during power operation, the areas of the RB with numerous or large unshielded containment penetrations, the areas of spent fuel transfer whenever it is present, the fuel pool, the steam pipe tunnel during power operation, the FPC systems and the resin wash water collection tanks.

The relationship between radiation zone designations and accessibility requirements is presented in Table 12.6-1. The dose rate applicable for a particular zone is based on OPEX and represents design dose rates in a particular zone. They are not interpreted as the expected dose rates that would apply in all portions of that zone, for all types of work within that zone, or all instances of zone entry. BWR plants have been operating for several decades, and OPEX with similar design basis shows that only a small fraction of the permissible dose is received from radiation sources controlled by equipment layout, or the structural shielding provided. The BWRX-300 radiation zone approach accomplishes the ALARA objectives.

Access to areas in the plant is controlled and regulated by the given area zone. Areas with dose rates where an individual could receive a dose in excess of 1 mSv (100 mrem) in a period of one hour are locked and posted with "High Radiation Area" signs. Areas where an individual could receive a dose in excess of 5 Sv (500 rem) within a period of one hour at 1 meter from a radiation source, or 1 meter from any surface that the radiation penetrates are posted with "Very High Radiation Area" signs.

**Table 12.6-1: BWRX-300 Radiation Zone Classifications**

Zone	Dose Rate	Occupancy limit	Description
A	$\leq 6 \mu\text{Sv/h}$ (0.6 mrem/h)	40 hr/wk	Uncontrolled and unlimited access
B	$\leq 10 \mu\text{Sv/h}$ (1 mrem/h)	40 hr/wk	Controlled and unlimited access
C	$\leq 50 \mu\text{Sv/h}$ (5 mrem/h)	20 hr/wk	Controlled and limited access
D	$\leq 250 \mu\text{Sv/h}$ (25 mrem/h)	4 hr/wk	Controlled and limited access
E	$\leq 1 \text{ mSv/h}$ (100 mrem/h)	1 hr/wk	Controlled and limited access
F <sup>1</sup>	$\leq 10 \text{ mSv/h}$ (0.1 rem/h)	5 hr/year	Limited and controlled access with special authorization permit required
G <sup>1</sup>	$\leq 100 \text{ mSv/h}$ (10 rem/h)	30 min/year	(Same as Zone F above)
H <sup>1</sup>	$\leq 1 \text{ Sv/h}$ (100 rem/h)	No access	(Same as Zone F above)
I <sup>1</sup>	$\leq 5 \text{ Sv/h}$ (500 rem/h)	No access	(Same as Zone F above)
J <sup>2</sup>	$> 5 \text{ Sv/h}$ (500 rem/h)	No access	Limited and controlled access with special authorization permit required

(1) High radiation sources present. Limit and controlled access with special authorization permits required.

(2) Very High radiation sources present. Very limited and controlled access with special authorization permits required.

## **12.7 Radiation Protection Program**

The Radiation Protection Program is described in the Licence to Construct Application, Section 4.7, Radiation Protection, and is expected to be revised with the Licence to Operate application.

The Radiation Protection Program is consistent with the guidance set forth in CNSC REGDOC-2.7.1, "Radiation Protection" (Reference 12.7-1). The Radiation Protection Program consists of a series of procedures and programs that keep radiation exposure to workers and the public as low as reasonably achievable.

The Radiation Protection Program includes the following elements:

- Radiation protection organization, oversight, and administration
- Training and qualifications
- Process and procedures
- Radiation zones classification
- Program measures to limit exposure and dose
- Equipment and instrumentation
- Contamination control
- Emergency planning

**LIST OF TABLES**

None.

## **LIST OF FIGURES**

None.

## **13.0 CONDUCT OF OPERATIONS**

### **13.1 Organizational Structure of Operating Organization**

The prime responsibility for safety is assigned to OPG's operating organization. This responsibility includes covering all activities related to operation directly and indirectly and the supervision of activities of all other related groups, such as design, supply, manufacture and construction, employers, and contractors, as well as the operating organization itself. This responsibility is discharged in accordance with the management system.

This section contains information addressing the following:

1. Design principles used to develop the organizational structure (e.g., layers of hierarchy, length of decision-making chains, scope of managerial control, policy for use of contracted resources)
2. Description of relationships between organizations having significant interaction with information on how any potential effect on nuclear safety management (each relationship) is recognized and addressed
3. Organizational approach taken to ensure capabilities necessary to provide nuclear safety and ensure the integrity of the safety case, including how sufficient in-house core capability is retained to:
  - a. Manage the licenced facility and activities
  - b. Prevent over-reliance on contractors and degradation of in-house capabilities
  - c. Maintain subject matter expertise for all topics necessary for nuclear safety, including "informed (intelligent) customer" roles when expertise is contracted out
  - d. Be an "informed (intelligent) customer" for items or services procured
  - e. Ensure the organization maintains sufficient numbers of qualified workers and identifies nuclear safety-related positions and underpinning roles
  - f. Control organizational changes and maintain the organizational charts as evergreen documents
  - g. Set strategies to ensure the right resources are available at the right time with the right skills and experience to meet core capabilities at all stages of the facility lifecycle and provide for review of implementation and ongoing reviews
  - h. Describe how organizational aspects that lead to vulnerabilities are identified and mitigated (e.g., reliance on scarce or singular areas of expertise)
4. Organization control and how activities will not be subject to undue influence by other organizations
5. Description of how the resource strategy is proactively managed when project work is being implemented to ensure that the resource profiles and organizational arrangements remain fit for the purpose
6. Description of how contracted work is conducted to required levels of safety and quality from an organizational perspective.
  - a. Considerations to address:
    - i. Effective supply chain strategy for delivery of safety case requirements

- ii. “Informed (Intelligent) customer” capability for all work that may affect nuclear safety carried out by contractors or suppliers or their supply chain
- iii. Issuing specifications to contractors or suppliers that adequately describe the items or services, meet the safety case requirements, and identify the required level of Quality Assurance (QA)
- iv. Evaluation and confirmation before placing a contract with nuclear safety significance that the contractors and suppliers have the organizational, technical and project management capability, capacity, and culture to deliver the items or services

OPG manages organizational changes through a reviewed and approved change process.

### **13.1.1 Organizational Structure**

The BWRX-300 is a simple and safe design above traditional Boiling Water Reactors (BWR), requiring a smaller organization while still meeting the requirements of International Atomic Energy Agency (IAEA) Safety Guide NS-G-2.4, “The Operating Organization for Nuclear Power Plants” (Reference 13.6-1). The organizational structure framework is expected to be defined and included with the Licence to Operate application submission with all details, including roles and responsibilities, finalized and in place prior to receipt of the Licence to Operate.

Upper tier management staffing levels are expected to be similar to those at existing OPG facilities. For a single BWRX-300, it is expected that some roles are combined from traditional operating models and could change if additional units are built on the same site.

Staffing levels required to operate the BWRX-300 are expected to be defined based on the safety analysis (with consideration and integration of Human Factors Engineering (HFE)), Maintenance Program, and outage programs as they become better defined. Staff performing operations and maintenance are expected to be qualified as determined using training analysis, using assumptions and findings of HFE analyses. The minimum staffing level complement is expected to be determined in accordance with an analysis performed in accordance with the requirements of CNSC REGDOC-2.2.5, “Minimum Staffing Complement” (Reference 13.6-2).

The Plant Manager is expected to be accountable to OPG management, the Canadian Nuclear Safety Commission (CNSC), and the public to ensure the facility is operated and maintained with due diligence and in a manner consistent with the Power Reactor Operating Licence, and within the social licence objectives set by OPG.

The Operations and Maintenance Manager(s) ensure all aspects of the managed systems for operations and maintenance are implemented. The number of Operations and Maintenance Managers is expected to be defined as the staffing levels and programs are defined. For a single BWRX-300, we propose a single manager who was previously certified or licenced at a nuclear facility. The Maintenance Manager is not required to be previously certified or licenced at a nuclear facility.

The Shift Manager is accountable to ensure the facility is operated within its Operating Licence.

The site organization is augmented with support from the fleet organization, which includes the engineering component. The fleet organization program update framework is expected to be further defined as the design is progressed and included in the Licence to Operate application submission with all programs put in place prior to receipt of the Licence to Operate. Areas in the submission will include:

- Components and Equipment Surveillance

- Major Components
- Equipment Reliability
- Reactor Safety Program
- Aging Management (AM)
- Risk and Reliability
- Chemistry
- Welding
- Environmental Qualification
- Pressure Boundary

#### **13.1.2 Qualifications of Plant Personnel**

The Plant Manager and Operations Manager positions assigned to the BWRX-300 are expected to be filled by staff who have been previously certified or licenced at a nuclear power plant. This could include Small Modular Reactor, BWR, CANada Deuterium Uranium (CANDU), or Pressurized Water Reactor experience.

Qualifications are expected to be developed for each role in the organization according to the Systematic Approach to Training. Role documents defining specific job responsibilities are expected to be developed as appropriate based on the importance of the specific position.

## **13.2 Training**

### **13.2.1 General**

The BWRX-300 training program is developed using a Systematic Approach to Training process that complies with the prescribed regulatory training requirements of CNSC REGDOC-2.2.2, "Personnel Training" (Reference 13.6-3). The OPG personnel training programs ensure worker competence and qualification to perform the duties of their positions.

The OPG training system is developed and implemented to adhere to two fundamental principles:

1. Performance based training is focused on the essential knowledge, skills, and safety attributes required to meet the job requirements (derived from HFE task analysis) and nuclear safety specific needs throughout the lifecycle of the facility.
2. Systematically developed training is defined, produced, and maintained through an iterative and interactive series of steps, leading from the identification and satisfaction of a training requirement.

Training requirements are applied in a manner commensurate with risk. All training requirements apply, but associated training-related processes and procedures may vary based on the safety significance and complexity of the work being performed. The training systems/programs and requirements include:

1. Identification of the performance requirements of a specific job or duty area by conduct of a job task analysis
2. General worker training, initial job training, and continuing training based on a task analysis of the knowledge and skills required to perform each task and any attributes related to safety
3. Training designed, developed, and implemented to meet qualification requirements
4. Trainers meet and maintain documented qualification requirements
5. Formal evaluations used to confirm and document workers are qualified to perform their duties
6. Training change management process that systematically analyzes procedural, equipment, and job description changes (including operational experience feedback) that may require changes to tasks and lead to training modifications
7. Continuing training deemed necessary during the job and task analysis and training needs analyses processes
8. Periodic training program evaluations, with results incorporated into the training improvement process
9. Creation and maintenance of worker training and qualification records
10. Assurance that workers receive the level of training related to nuclear safety that corresponds to their employment and position duties; including, but not limited to radiation safety, conventional safety, fire safety, and on-site emergency arrangements

In addition, training programs are established for initial personnel certification and maintenance of regulatory certifications. Initial and continuing certification training programs are implemented in accordance with the principles of a Systematic Approach to Training.

Positions requiring regulatory certification are expected to be defined based on the technology needs and safety significance. Certification programs are expected to be developed as part of

the design process and only one certification program is required to meet the regulatory requirements.

### **13.2.2 Training Managed System Plan**

All training of personnel is expected to be designed, developed, and delivered using a Systematic Approach to Training.

A full-scope simulator, a replica of the Main Control Room panels, is expected to be utilized to train and qualify control room Operations staff. This approach allows the operators to interface with the simulated plant system in the Main Control Room environment.

#### **13.2.2.1 Minimum Staffing**

A minimum staff complement program is established to ensure sufficient numbers of qualified workers are present to meet regulatory and facility licence requirements during all credible events in the BWRX-300 safety analysis. The minimum complement staffing numbers are expected to be defined following completion of detailed design and safety analysis, and to be part of the Licence to Operate application submission.

The basis for the minimum staff complement is determined by a systematic staffing analysis as described in Chapter 18, Subsection 18.2.5. The analysis to determine the minimum staff complement considers:

1. Actions required in the facility and their timing for the full range of the most resource-intensive conditions
2. Resource-intensive initiating events and credible failures considered in the safety analysis report and the Probabilistic Safety Assessment (PSA) (with HFE considerations)
3. Operating strategies that define how the nuclear facility personnel respond to Anticipated Operational Occurrences (AOOs), Design Basis Accidents (DBAs), and emergencies
4. Required interactions among facility personnel for the purpose of diagnosing, planning, communicating, coordinating, and controlling AOOs, DBAs, and emergencies
5. Staffing demands required for the possible concurrent use of procedures related to AOOs, DBAs, and emergencies
6. Staffing demands required to monitor indicators, displays, and alarms and to promptly and effectively operate the facility's equipment controls using procedures related to AOOs, DBAs, and emergencies
7. Staffing demands required to perform tasks in field locations using procedures related to the events considered within the scope of the analysis
8. Staffing demands required for the successful completion of any important human actions using procedures related to the events considered within the scope of the analysis
9. Restrictions on the location of workers within the nuclear facility

The minimum staff complement requirements are validated to provide assurance that there are sufficient numbers of qualified workers available to operate the facility safely and respond to the most resource-intensive conditions at all times. Validation of the minimum staff complement is in accordance with the verification and validation processes described in CNSC REGDOC-2.5.1, "General Design Considerations: Human Factors" (Reference 13.6-4).

NEDO-33963 REVISION 0  
NON-PROPRIETARY INFORMATION

The minimum staffing requirements are expected to be formalized in a procedure that describes:

1. The specific number of staff to be present on-site, in the facility, and in the Main Control Room, and the composition of the minimum staff complement with reference to specific positions or qualifications
2. Modifications to minimum staff complement for different operational states and the specific number and composition of the minimum staff complement with reference to specific positions or qualifications for each operational state
3. Any specific restrictions on the location of individuals in the facility
4. Measures in place to monitor compliance with the minimum staff complement and to prevent non-compliance with the minimum staff complement
5. Specific actions to be taken to reduce the risk to the facility in the event of non-compliance with the minimum staff complement

### **13.3 Implementation of the Operational Safety Program**

#### **13.3.1 General Implementation**

The OPG Managed System is implemented under Nuclear Management System N-CHAR-AS-0002 (Reference 13.6-5). The system is implemented by a series of program documents which in turn define the required implementing procedures and standards. The Managed System is designed to be fully compliant with CSA Group (CSA) N286, "Managed System Requirements for Nuclear Facilities" (Reference 13.6-6). As such, all implementing procedures and standards ensure that all aspects of CSA N286 are fulfilled, as well as being fully compliant with all CNSC REGDOCs. The Managed System framework associated with BWRX-300 plant operation is expected to be outlined and included with the Licence to Operate application, with all programs finalized and in place prior to receipt of the Licence to Operate.

Changes to the Managed System are made in accordance with Nuclear Management System Administration, N-PROG-AS-0001 (Reference 13.6-7). Changes to the current charter (N-CHAR-AS-0002) (Reference 13.6-5) are expected to be required to accommodate BWRX-300 technology.

#### **13.3.2 Conduct of Operations**

This section addresses important operational issues relevant to safety throughout the lifetime of the plant and how the operating organization addresses identified issues adequately.

The OPG Nuclear Management System sets the standards for health, safety, environment, security, economics, and quality during facility design, construction, commissioning, and operation based on the authority of and a safety culture driven by the OPG Nuclear Safety Policy. The OPG Nuclear Management System promotes the safety culture by committing workers to adhere to the OPG Nuclear Management System, implementing practices that contribute to the excellence in worker performance, supporting workers in carrying out their tasks safely and successfully, and monitoring to improve the culture. The organizational structure implements the programs that make up the OPG Nuclear Management System with the Chief Nuclear Officer accountable for implementation and effectiveness of the OPG Nuclear Management System. The outline of the programs and standards utilized for operating the plant is expected to be included with the Licence to Operate application submission, with all program details and standards finalized prior to receipt of the Licence to Operate.

The OPG Nuclear Management System is based on a set of principles implemented in a graded approach consistent with CNSC REGDOC-2.1.1, "Management System" (Reference 13.6-8) and CSA N286 (Reference 13.6-6) guidelines.

##### **13.3.2.1 Safety Culture**

Consistent with CNSC REGDOC-2.1.2 "Management System: Safety Culture" (Reference 13.6-9), the safety culture is established, promoted, communicated, and fostered by Senior Management through the OPG Nuclear Safety Policy and OPG Nuclear Management System. The safety culture is applicable to all activities that affect the health and safety of workers, the public, and the environment in every phase of the facility life cycle.

The OPG Nuclear Management System is maintained in accordance with the requirements of CSA N286 (Reference 13.6-6).

The OPG Nuclear Management System meets the CNSC's Safety and Control Area principles and regulatory requirements necessary to protect health, safety, and the environment.

The safety culture is implemented, monitored, and periodically assessed consistent with CNSC REGDOC-2.1.2 (Reference 13.6-9) and CSA N286 (Reference 13.6-6) guidelines through

subordinate policies, programs, processes, and procedures that implement the varied administrative, maintenance, and operational aspects of facility operation. An established program, that summarizes OPG's internal and external processes used for oversight and assessment, tracks assessment action items and monitors various metrics that may reveal safety culture aspects (e.g., Operating Experience (OPEX), performance trends, condition reports, regulatory inspections). OPG's Human Performance and Performance Improvement programs also implement OPG expectations for understanding and promoting a strong safety culture.

A more detailed discussion of the OPG Nuclear Management System is provided in Chapter 17, Sections 17.1 and 17.2.

#### **13.3.2.2 Services and Equipment Acquisition/Receipt**

The OPG supply chain process is established and controlled. OPG supply chain services are responsible for establishing and maintaining an OPG nuclear approved supplier list. Periodic audits are performed to confirm the initial and ongoing acceptability of the supplier's management system. The OPG process/program describes methods used to originate, request, evaluate, qualify, and maintain qualification of suppliers of items and services required for QA programs or other OPG nuclear quality requirements.

Suppliers are assessed on their ability to meet purchasing requirements and have the organizational, technical and project management capability, capacity, and culture to deliver the item or service.

The supplier-customer relationship is monitored to ensure purchasing requirements are met. Monitoring includes the alignment of demand and supply signals between OPG and the supplier, a supplier/customer performance assessment, involvement of the supplier in customer demand planning, reporting requirements for delays or defects and supplier involvement in obsolescence and remediation. Monitoring results are used as input in determining the frequency and extent of inspection, verification, and audit activities. The audit program is established as part of the QA Program and is discussed further in Chapter 17, Sections 17.2 – 17.4.

OPG specifies the requirements for purchased expertise and equipment, provides work oversight, and technically reviews the output before, during, and after implementation. Contractors within the supply chain are also audited on a regular basis as part of the contractual agreements.

Components are checked when initially received to ensure the components are as ordered, undamaged, and are not fraudulent, counterfeit, or suspect. The components are subjected to more detailed inspection for acceptability prior to use. After receipt, the components are stored to protect against construction activities, physical and environmental damage, and deterioration.

#### **13.3.2.3 Fitness for Service**

The fitness for service safety and control area covers activities that affect the physical condition of Structures, Systems, and Components (SSC) to ensure adequacy and ability to perform their intended functions when required. Fitness for service is addressed in established programs that include Reliability, Maintenance, AM, Chemistry Control, Periodic Inspections, and In-Service Inspections.

Programmatic requirements addressing fitness for service span the full life cycle of the facility, beginning with inclusion in facility design decision-making and consideration during each phase (e.g., design, construction, commissioning, operation) of the facility's life. Requirements evolve as the facility ages and specific process requirements may vary based on the life cycle phase (e.g., construction versus operation).

NEDO-33963 REVISION 0  
NON-PROPRIETARY INFORMATION

Reliability is incorporated during facility design, consistent with the requirements of CNSC REGDOC-2.5.2, "Design of Reactor Facilities: Nuclear Power Plants" (Reference 13.6-10) and through the Reliability Program that complies with CNSC REGDOC-2.6.1, "Reliability Programs for Nuclear Power Plants" (Reference 13.6-11). The Reliability Program is implemented to ensure that systems function reliably in accordance with design and performance criteria. Although the Reliability Program focuses primarily on the facility operational phase, it applies to all phases of the facility life cycle. The Reliability Program includes:

- Identification and categorization of systems using a systematic process
- Identification of specific failure modes and specification of reliability targets
- Specification of minimum capability and performance level consistent with safety targets and regulatory requirements
- Provisions for information incorporation into maintenance programs
- Provisions for inspection, tests, modeling, and monitoring to assess reliability based on safety class
- Documentation of program activities, attributes, elements, results, and administration

The facility Maintenance Program establishes a maintenance strategy, based on the plant design and safety analysis, to ensure that SSC function as designed. The facility Maintenance Program is implemented by a maintenance organization, established consistent with CNSC REGDOC-2.6.2, "Maintenance Programs for Nuclear Power Plants" (Reference 13.6-12). A systematic approach is used to identify the SSC maintenance activities to be performed and the maintenance intervals.

The Maintenance Program describes the processes for planning, monitoring, scheduling, and executing maintenance work activities, including those maintenance activities performed during the construction and commissioning phases. Surveillances conducted as part of the Maintenance Program, including acceptance criteria, are addressed in Chapter 16, Sections 16.2 and 16.4, Operational Limits and Conditions.

An AM Program conforming to the requirements of CNSC REGDOC-2.5.2 (Reference 13.6-10) and CNSC REGDOC-2.6.3, "Aging Management" (Reference 13.6-13) is established to ensure the reliability and availability of the required SSC safety functions throughout the facility service life.

The effects of aging and wear are taken into consideration during the design of Safety Class SSC. The considerations include:

1. Design margin assessment that considers the known aging and wear mechanisms potential degradation in operational states, to include the effects of testing and maintenance
2. Provisions for monitoring, testing, sampling, and inspecting SSC to assess aging mechanisms and identify degradation that may occur during operation a result of aging and wear
3. Online monitoring to provide forewarning of degradation leading to failure and where failure could be safety significant

Details regarding AM design provisions are provided in Chapter 3, Subsection 3.1.12.

NEDO-33963 REVISION 0  
NON-PROPRIETARY INFORMATION

Chemistry Control policies and goals are established to:

- Preserve the integrity of SSC
- Minimize the effects of chemical impurities and corrosion on SSC
- Implement As Low as Reasonably Achievable to manage radioactive material buildup
- Limit release of chemicals and radioactive material to the environment

Chemistry Control governs the development and maintenance of chemistry procedures, specifications, and methods of control. Knowledgeable and trained staff are assigned to monitor for abnormal trends so that action can be taken to ensure operations within specified limits. Performance indicators are maintained to satisfy reporting requirements.

Included in Chemistry Control are requirements for:

- Data management (to include trending, evaluation, and reporting of analysis results and investigations)
- Chemistry surveillance program
- Chemistry specifications for systems
- Procedures for chemistry parameter selection, monitoring, analysis, and trending
- Procedures for operations involving chemistry processes and evaluation of results
- Operation and reference limits for chemistry parameters and associated action levels
- Chemical Control Program
  - Training (chemical hazards, labeling and storage)
  - Procedures for the storage and handling of chemicals
  - Approval, procurement, and receipt of chemicals
  - Listing of chemicals approved for site use and those that are precluded from site use or other classification
  - Administrative controls for controlling products in the workplace

The Chemistry and Chemical Control programs, as applicable to construction and commissioning, are described in Chapter 14, Subsection 14.2.4.

Periodic and in-service inspection and testing programs are established in conformance with CNSC REGDOC-2.5.2 (Reference 13.6-10) to confirm that service-induced degradation has not increased the likelihood of a failure of a barrier against the release of radioactive material.

Periodic and in-service inspection and testing are established for:

- Nuclear pressure boundary components
- Containment components
- Containment structures
- Safety-related structures
- Balance-of-plant pressure boundary Safety Class components or based on AM requirements

#### **13.3.2.4 Nuclear Material Packaging and Transport**

Processes and procedures are expected to be established that address the safe packaging, registration, and transport of nuclear substances to and from the facility as described in OPG's Radioactive Material Transportation Program. The program ensures shipping packages are designed and maintained to ensure protection and containment of the quantities of nuclear material transported. In addition, package certification, package testing, inspection, and maintenance are addressed within the program. This program is expected to be established prior to fuel delivery to the Darlington site, an activity which will be subject to separate licensing by CNSC, as the Licence to Construct scope does not include transport, import, possession, or storage of nuclear fuel.

#### **13.3.3 Maintenance, Surveillance, Inspection and Testing**

This section provides a description and justification of arrangements that the operating organization has in place to identify, control, plan, execute, audit, and review maintenance, inspection, and testing practices that influence reliability and affect nuclear safety.

SSC credited in the safety analysis are identified and periodically tested (surveilled) at a frequency related to the results of reliability analysis and operational experience to ensure that they will function as required. SSC performance that is inconsistent with assumptions in the safety analysis are identified. Following modification to SSC, the test requirements are re-evaluated. Defense Line 3 (Safety Category 1) SSCs credited in the deterministic safety analysis are addressed in the Operational Limits and Conditions (OLC) of Chapter 16 and the Defense Line 2 and 3 SSCs credited in the deterministic safety analysis are addressed in a program required by Chapter 16. Furthermore, additional SSCs credited in the probabilistic safety analysis will be addressed in the OLC if its failure is a significant contributor to Core Damage Frequency. This defence-in-depth approach provides reasonable assurance the consequences of postulated initiating events are bounded by Chapter 15 results and safety goals are met

SSC are maintained in accordance with a maintenance strategy defining the frequency and type of maintenance to be performed, taking into consideration the supplier recommendations, safety analysis, periodic inspection requirements, OPEX, cost benefit analysis, and service conditions. Maintenance activities are performed in accordance with approved procedures and practices. Preventive measures are employed to eliminate structural, system, and component damage or the contamination of systems with foreign material. In addition, predictive maintenance is performed based on plant monitoring system information. Maintenance includes the repair or replacement of malfunctioning SSC as needed to re-establish conformance with requirements.

A Maintenance Program is to be implemented consistent with the requirements of CNSC REGDOC-2.6.2 (Reference 13.6-12) to address:

1. Measures, policies, methods, and procedures providing direction for maintaining SSC capable of maintaining their functions as described in design documents and the safety analysis
2. Processes for planning, monitoring, scheduling, and executing work activities so SSC continue to meet design intent and remain fit for service in the presence of degrading mechanisms
3. Preventive maintenance activities, maintenance processes and record retention requirements, corrective maintenance, calibration of measuring and monitoring devices, SSC monitoring (activity optimization), outage management, work planning and scheduling, work execution, maintenance procedures, post-maintenance verification and testing and Maintenance Program assessment

4. Predictive maintenance based on plant monitoring system information
5. Surveillance program covering OLC, with surveillance frequencies based on a reliability analysis, a PSA, and previous OPEX, and that shows viability of inspection techniques to meet performance requirements while taking As Low as Reasonably Achievable into account
6. Approach taken to develop SSC surveillance program acceptance criteria
7. Assurance that the surveillance program is adequate to ensure the inclusion of all relevant aspects of the OLC
8. Timeline for the development of each program with milestones for development and implementation of each program and the processes followed
  - a. Results of each activity to be reviewed against acceptance criteria and with periodic reviews to ensure the program continues to meet objectives.

Multiple aspects of the surveillance, inspection, and testing program are addressed within OLC (Chapter 16, Section 16.4), to include:

1. Safety Class plant items that require monitoring to ensure they remain fit for their purpose and operation is within the operational limits for reliable and safe operation
2. How surveillance, maintenance and repair ensure OLC parameters remain within acceptable limits and systems/components are operable
3. Surveillance frequency basis on a reliability analysis, including where available, a PSA and a study of experience gained from previous surveillance results (in the absence of both, the surveillance is based on supplier recommendations)
4. System for ensuring testing is performed and confirmed within the timelines allowed

### **13.3.4 Core Management and Fuel Handling**

#### **13.3.4.1 Core Management**

The programs and procedures that govern the operational activities associated with BWRX-300 core management regarding fuel reliability are based on guidelines established by GEH, utilizing decades of experience with fuel from Global Nuclear Fuel. Fuel related design aspects, including operational, transient, and accident limits, are discussed in Chapter 4, Sections 4.2 and 4.4. The core/fuel management guidelines are implemented through operational methods implemented to mitigate and reduce duty related fuel performance risks.

In general, the BWRX-300 operational methods employ an approach of limiting the duration of low power periods and limiting the rate at which power is raised following prolonged operation at low power. When raising power, a combined approach of an unrestricted power increase to an established threshold or prior conditioned power envelope, followed by raising power to a final value at a defined, controlled, slow ramp rate, is used.

The operational practices are based on BWRX-300 operational experience:

1. An established exposure dependent Linear Heat Generation Rate threshold, below which no power maneuvering restrictions are applied with power increases above the threshold limited to a defined controlled rate
2. Power envelopes (conditioned power) established by the maintenance of specific power conditions sustained for a defined period

3. Defined power ramp rates for power increases above the more limiting of a Linear Heat Generation Rate threshold or the conditioning envelope value, performed at a defined, controlled ramp rate
4. Sequence exchange intervals established based on cycle exposure, that consider multiple factors, including fuel reliability
5. Threshold power levels established for fuel bundles or nodes with unusually long periods of low power operation (long control intervals), implemented on a case-by-case basis using industry OPEX best practices
6. Employing power envelopes best practices considering the BWR characteristics of top peaked axial power shapes at the end of fuel cycle and bottom peaked axial power shapes at the beginning of fuel cycle operation
7. Control rod exercising requirements
8. Barrier fuel risk mitigation
9. Established threshold values for fuel with high residence time in central portions of the core

Core Monitoring is a function of the plant computer system that provides three-dimensional core power monitoring to satisfy the requirements of CNSC REGDOC-2.5.2, Section 8.1 (Reference 13.6-10) to ensure the plant operates within the power distribution design basis. Core Monitoring provides confidence that the plant is operating in conformance to specified acceptable fuel design limits. Core Monitoring obtains instrumentation information from the C20 Distributed Control and Instrumentation System (refer to Chapter 7, Subsection 7.3.3.2), calculates thermal power limits, and provides estimates of power distributions. These estimates are calculated by the core simulator.

The Core Monitoring function acquires real-time reactor data from site plant data acquisition systems as necessary to define the reactor state for use by the core simulator. Core Monitoring can calculate the accumulated thermal and electrical energy produced by the plant from the beginning of an operating cycle. The Core Monitoring function is described further in Chapter 4, Subsection 4.6.8.

### **13.3.5 Aging Management and Long-Term Operation**

This section provides a description of an integrated AM Program that will meet the requirements of CNSC REGDOC-2.6.3 (Reference 13.6-13) and CNSC REGDOC-2.5.2, Section 7.17 (Reference 13.6-10). AM processes and plans ensure the reliability and availability of required safety functions of SSC throughout the service life of the facility (Lifecycle Management Plans). Periodic inspection or in-service inspection programs, as they relate to BWRX-300 aspects, are expected to be incorporated directly into AM programs.

AM is addressed during design within the design process. The design provisions for AM are discussed in more detail in Chapter 3, Section 3.1. Consideration is given to the feedback of OPEX. A systematic approach is taken during design to understand the aging of SSC to evaluate design features for aging prevention, monitoring, and mitigation. Mechanical, thermal, chemical, electrical, physical, biological, and radiation aspects are taken into consideration. SSC determined to have shorter service lives than the nominal design life are identified with AM strategies provided in the design documentation. The components that are identified with service lives less than the nominal design life also have replacement plans defined in the plant Maintenance Program, with associated monitoring requirements and provisions to permit their removal and replacement.

NEDO-33963 REVISION 0  
NON-PROPRIETARY INFORMATION

Aging effects under design basis conditions, including transient and postulated initiating event conditions, are also considered in equipment qualification programs.

The design information derived with these design aging considerations establish the baseline for the test data required to be collected and documented for AM Program monitoring and evaluation requirements.

Design documents also identify any special manufacturing or construction processes that are to be applied to prevent, mitigate, or eliminate known aging mechanisms. These provisions are necessary for specification in procurement documents.

The AM Program and processes are used to detect, assess, and manage deterioration of SSC as a result of aging effects such as irradiation, corrosion, erosion, fatigue, and other material degradation.

Descriptions of the following AM Program elements include:

- Organizational arrangements
- Data collection and record keeping
- Screening and selection process for AM
- Evaluations for AM
- Condition assessments
- SSC-specific AM plans
- Management of obsolescence
- Interfaces with other supporting programs
- Implementation of SSC-specific AM plans
- Review and improvement processes for the AM Program

An integrated AM Program ensures that availability and reliability of required safety functions throughout the facility's service life is established. The program requires AM activities to be implemented proactively throughout the life cycle of a nuclear facility in compliance with CNSC REGDOC-2.6.3 (Reference 13.6-13).

### **13.3.6 Control of Modifications**

This section addresses the method of identification for designing, planning, executing, controlling, testing, auditing, reviewing, and documenting modifications to the plant throughout its lifetime, consistent with the guidance provided in IAEA SSG-61, "Format and Content of the Safety Analysis Report for Nuclear Power Plants," (Reference 13.6-14). The modification control process covers all safety significant changes (permanent and temporary) made to SSC, OLC, plant procedures, and process software. The design and safety analysis is incorporated into the purchasing, construction, commissioning, operating, and maintenance documentation such that the as-built configuration of the facility is aligned with the design and safety analysis. Design authority configuration requirements, including the responsibilities and authority of organizations whose functions affect the configuration of the facility, including activities such as design, maintenance, construction, licensing, and procurement, are controlled through its Configuration Management System. A series of programs, including engineering change control, design management, and software, ensures plant configuration is controlled in a manner that is analyzed to be safe. Control of modifications and configuration management during construction and commissioning phases is discussed further in Chapter 14, Section 14.1.

The information provided includes descriptions of:

1. Modification control process for maintaining the design basis, taking into account new information, OPEX, safety analyses, resolution of safety issues, or correction of deficiencies
2. Description of how design changes are assessed, addressed, and accurately reflected in the safety analyses or record prior to implementation

The plant modification control process covers:

1. Changes made to plant systems and components, OLC, plant procedures and process software, taking into account the safety significance of the proposed modifications to allow them to be graded and referred to the CNSC when necessary
2. Changes to task performance requirements (task step alterations, expected outcomes, procedure level), personnel job role responsibilities or the operating organization
3. Records retention, and where necessary, revision documentation, procedures, instructions, and drawings to reflect the changes

#### **13.3.6.1 Configuration Management**

Configuration management is incorporated into purchasing, operating, and maintenance so that the as-built configuration of the facility aligns with the design and safety analysis in accordance with CSA N286 (Reference 13.6-6) and CSA N286.10, "Configuration Management for High Energy Facilities" (Reference 13.6-15). Configuration management is applied in a graded approach.

Configuration management during the construction and commissioning phases is described further in Chapter 14, Section 14.1.

Configuration management is not a stand-alone program. Configuration management plans are developed and integrated within the OPG Nuclear Management System (e.g., assessment, problem identification and resolution, training). From conception to the end of operations, configuration management ensures data generated during design, construction, and commissioning reflects the design basis and specified requirements are kept current in the design, as-built, and field change documentation.

The design basis and requirements for the BWRX-300, including safety analysis, are established and documented in accordance with CSA N286 (Reference 13.6-6) and are traceable to the respective SSC. Impacts of design changes are assessed, addressed, and when applicable, reflected in the safety analysis. Subsequent changes to the physical and operational configuration are maintained consistent with design requirements and configuration information throughout the operational life cycle. Where SSC requirements exceed functional design requirements (safety margin versus design margin), the process ensures safety margin is maintained for subsequent modifications. Physical assessments of SSC configuration are conducted as part of facility management.

Temporary and permanent changes are managed in accordance with the requirements of CSA N286 (Reference 13.6-6).

Configuration information, the types and sources of configuration information, and associated documentation are controlled and maintained in accordance with CSA N286 (Reference 13.6-6), with the status of changes identifiable. As-built information is turned over prior to commencement of operations (turnover) and subsequent as-built information is incorporated in a timely manner commensurate with the associated risk. The facility design basis is maintained following turnover

and commissioning by OPG to reflect new information, OPEX, safety analyses, and the resolution of safety issues or deficiency corrections.

Configuration deviations, when identified, are managed through the problem identification and resolution processes consistent with the requirements of CSA N286 (Reference 13.6-6). Deviations are immediately controlled (if required), documented, evaluated for significance, and the underlying cause assessed if deemed systemic and accepted. Problem resolutions are reviewed for effectiveness.

Configuration management objectives and concepts are addressed in the respective training programs, with the necessary links between configuration management and the training programs established and maintained.

Configuration information records and documents are maintained consistent with the requirements of CSA N286 (Reference 13.6-6).

#### **13.3.6.2 Engineering Change Control**

OPG engineering change control is an integrated management process that ensures the physical and operational configuration and documentation continue to conform to the design and licensing basis requirements.

Facility configuration is maintained from initial fuel load to the end of operating life through established programmatic configuration and change control processes that adhere to CSA N286 (Reference 13.6-6).

The change control process makes certain that safety limits, design basis, licensing basis, and normal operating margins are controlled under engineering change control to always ensure the facility is operated well within conditions analyzed to be safe. Additionally, this process ensures all changes, from minor parts substitution to safety-related modifications, are controlled to ensure the designed facility is operated with margin.

#### **13.3.6.3 Design Management**

The Design Management Program will specify requirements for the following two areas:

1. Management of prescribed activities appropriate for execution and control of required design, design support, and documentation for nuclear facilities and organizations in accordance with CSA N286 (Reference 13.6-6)
2. Processes for creating or modifying documentation required for controlling design bases and design outputs

A minimum set of documentation identifies and describes design bases, design output, and the design process.

#### **13.3.6.4 Software**

The Software Program complies with CSA N286 (Reference 13.6-6) and CSA N286.7 "Quality Assurance of Analytical, Scientific, and Design Computer Programs" (Reference 13.6-16), and applies to software classified as Real-Time Process Computing and Scientific, Engineering, and Safety Analysis Software and Software Engineering Tools. The program identifies the processes and overall requirements for classification of software and identifies governing standards for each software classification, defining requirements for software development, maintenance, procurement, qualification, use, and retirement.

### **13.3.7 Program for the Feedback of Operating Experience**

This section describes the program implemented for the feedback of OPEX. The OPEX Program ensures operational events and incidents occurring at the facility and other relevant facilities are captured or identified, recorded, notified, investigated internally, and used to incorporate lessons learned for the operation of the facility.

Relevant OPEX is considered for the BWRX-300 during design, construction, commissioning, operation, maintenance, and decommissioning. The design authority (GEH) establishes provisions for the incorporation of OPEX through Integrated Management Systems. The OPEX comes from a variety of sources, including direct input, GEH/Global Nuclear Fuel experience from operating the BWR and Advanced Boiling Water Reactor fleet, Institute of Nuclear Power Operations, Electric Power Research Institute, Boiling Water Reactor Owners' Group, U.S. Department of Energy, U.S. Nuclear Regulatory Commission, CANDU Owners Group, and CNSC. OPEX associated with the construction and commissioning phases is discussed in Chapter 14, Section 14.1.

Industry OPEX information is routinely made available to or distributed by GEH design and modifications personnel. The more important industry-wide issues are routinely addressed in CNSC Nuclear Incident Reports and U.S. Nuclear Regulatory Commission Generic Letters and Bulletins.

OPG has an established OPEX process for evaluating, integrating, accessing, and sharing OPEX information. The OPEX process addresses implementation of OPEX feedback during design activities and its continuance through the construction, commissioning, and operational phases of the facility life cycle, to include how events are identified, recorded, investigated, and reported; as well as how findings from the events are used to enhance safety performance.

### **13.3.8 Documents and Records**

This section addresses the programmatic provisions for creating, receiving, classifying, controlling, storing, retrieving, updating, revising, and deleting documents, records, and reports relevant to the operation of the facility over its lifetime in accordance with OPG-PROG-0001 "Information Management" (Reference 13.6-17).

Document and records program management is the responsibility of the operating organization.

OPG records management encompasses the control of documents and records with requirements addressed in the Controlled Document Management Program. The OPG process for the control of documents includes the development, validation, and approval of safety-related documents. Documents are available for use at the location where the work is to be performed. Changes to documents are documented and tracked. The OPG process for the control of records ensures that records are readable, complete, identifiable, traceable, retrievable, preserved, and retained as necessary.

Documents are controlled consistent with their intended use and consistent with CNSC REGDOC-2.1.1 (Reference 13.6-8) and CSA N286 (Reference 13.6-6).

The program document ensures that controlled documents include:

- Unique identification
- Defined format and presentation
- Identification of status
- Review for adequacy and approval

NEDO-33963 REVISION 0  
NON-PROPRIETARY INFORMATION

- Availability for use at the location where the work is performed or where the document is required for reference
- Prompt removal of obsolete documents for use

Records are:

- Readable
- Complete
- Identifiable
- Traceable to the related items and work
- Retrievable
- Preserved
- Retained as specified

Document management for the BWRX-300 is controlled under the QA Program during design. The QA Program includes document management aspects. The QA Program requirements during design of the BWRX-300 are established in NEDO-11209-A, "GE Hitachi Nuclear Energy Quality Assurance Program Description" (Reference 13.6-18). NEDO-11209-A includes requirements during design, addressing:

- Procurement document control
- Instructions, procedures, and drawings
- Document control
- Control of QA records

Document and records management is discussed with respect to the QA Program in Chapter 17, Section 17.2. Documents and records management during construction and commissioning is discussed in Chapter 14, Section 14.1.

### **13.3.9 Outages**

This section addresses the programmatic aspects of the conduct of periodic reactor shutdowns (outages).

The current reference cycle for DNNP BWRX-300 is based on a nominal 12-month fuel cycle. Different fuel cycle durations can be supported depending on the overall fuel reload strategy to be deployed on a cycle/multi-cycle specific basis.

Outage analysis does not address forced outages, but surveillance and maintenance activities that require the plant to be shut down are minimized to the extent possible, largely by enhanced system reliability achieved through design simplicity.

Outage planning, scheduling, and maintenance activities are managed consistent with the guidance provided in CNSC REGDOC-2.6.2 (Reference 13.6-12), and reporting requirements are consistent with the requirements of CNSC REGDOC-3.1.1, "Reporting Requirements for Nuclear Power Plants" (Reference 13.6-19).

The Work Management Program provides for the implementation of processes and procedures for the planning, scheduling, and execution of maintenance activities. Work planning is conducted at both the overall plant and individual job levels. The Outage Management Program establishes the criteria followed to confirm that planned outage and emergent work is completed satisfactorily.

NEDO-33963 REVISION 0  
NON-PROPRIETARY INFORMATION

In addition to procedures for routine outage maintenance activities, OPG maintains a forced outage plan for emergent conditions.

Outage plans are reviewed for nuclear safety, with work groups reviewing the plans within their area of responsibility and with specific consideration given to:

- Impact on operating units and systems
- Application of controls during infrequently performed tests and evolution to ensure the plant is maintained within the design basis
- Contingency plans for alternate measures to maintain safe shutdown
- Routine review to capture changes from the original plan impact assessment
- Outage OPEX

The cumulative effect of plant equipment taken out of service is taken into consideration to ensure there are no adverse effects on the performance of safety functions when planning and scheduling outage work. In addition, plans to remove equipment from service during an outage include measures to deal with the possible consequences of an event occurring while the equipment is out of service. Clear statements are made to identify when equipment is being taken out of service, to include the duration and impact of removing the equipment from service.

The outline of the Outage Management Program utilized for operating the plant is expected to be included with the Licence to Operate application, with all details finalized prior to receipt of the Licence to Operate.

### **13.4 Plant Procedures and Guidelines**

This section programmatically addresses the relevant documents used by plant staff to ensure that procedures and guidelines for normal operation, AOOs, and accident conditions are followed in the intended manner. Procedure development is a technical element of the BWRX-300 HFE program. The procedure development process is described in Chapter 18, Subsection 18.3.7.

#### **13.4.1 Administrative Procedures**

This section describes the administrative procedures that outline the essential elements of the administrative programs used by the operating organization to ensure the safe management of the plant. The processes to develop, approve, revise, and implement the procedures are described along with a list of the relevant procedures.

Administrative procedures contain adequate programmatic controls to provide an effective interface between organizational elements. This includes contractors or organizations providing support to the facility operating organization.

Procedure Writer's Guides promote standardization and the application of HFE usability principles to administrative procedures. Additional details are provided in Chapter 18, Subsection 18.3.7.

Procedural compliance with all administrative procedures ensures all regulatory requirements and standards are met. Procedural steps that implement these specific requirements are flagged with "bases" statements (e.g., [B-1] meaning refer to B-1 for the overriding regulatory and legal requirement). The "Content Authority" is accountable to ensure the administrative procedure meets applicable regulatory requirements and standards. The flagging of bases requirements ensures that regulatory and legal requirements are checked during the continuous improvement (revision) process.

Procedure maintenance and control of procedure updates are performed in accordance with OPG's QA Program processes.

The plant administrative procedures provide for the following:

- Establishment of a formal review and approval process
- Control of equipment, as necessary, to maintain personnel and reactor safety, and to avoid unauthorized operation of equipment
- Control of maintenance and modifications
- Temporary changes
- Temporary procedure issuance and control
- Special orders of a temporary or self-cancelling nature
- Standing orders to shift personnel, including the authority and responsibility of the control room staff
- Manipulation of controls and assignment of shift personnel to duty stations
- Shift relief and turnover procedures
- Fitness for Duty
- Working hour limitations
- Feedback of design, construction, and applicable important industry OPEX
- Shift Manager administrative duties

- Verification of correct performance of operational activities
- Vendor interface program that provides vendor information for SSC is incorporated into plant documentation
- Fire protection program implementation
- Process for implementing safety/security interface requirements

#### **13.4.2 Operating Procedures**

The facility is operated, monitored, and maintained within the safe operating envelope and in accordance with procedures that are consistent with the design. Operating procedures are established to provide for the safe conduct of BWRX-300 normal operations. Normal operation is operation within specified OLC, within one of the following plant operating modes (further defined in Chapter 16, Appendix 16A):

- Mode 1: Power Operation
- Mode 2: Startup
- Mode 3: Hot Shutdown
- Mode 4: Stable Shutdown
- Mode 5: Cold Shutdown
- Mode 6: Refueling

Procedure Writer's Guides promote standardization and the application of HFE usability principles to the operating procedures. Additional details are provided in Chapter 18, Subsection 18.3.7.

Normal, abnormal, unplanned, and emergency operating procedures are validated to be accurate and usable without any human error traps and verified to be consistent with the safe operating envelope.

Plant operations are performed in accordance with procedures, with use and adherence direction provided for the worker. Temporary procedures may be issued when existing permanent procedures are not applicable to the work being performed. Temporary procedures are periodically reviewed for applicability and cancelled when no longer required.

Operating procedures address:

- Normal operation
- Abnormal operation
- Emergency operation
- Refueling and outage planning
- Alarm response
- Maintenance, inspection, test, and surveillance
- Beyond design basis and severe accidents

The status of SSC is controlled with the following requirements:

- Status changes must be authorized
- Operational position of Safety Class devices is known and controlled

- Status of SSC under maintenance, inspection, or test is known
- Field equipment deficiencies are identified
- Placement and removal of tags on systems and components (e.g., caution tags, work protection tags, terminal point tags, and other similar tags) is controlled
- Plant status information is transferred during shift turnovers

### **13.4.3 Procedures and Guidelines for Operating the Plant During Accidents**

#### **13.4.3.1 Emergency Operating Procedures**

This section describes the programmatic approach followed to develop the Emergency Operating Procedures (EOPs) in accordance with CNSC REGDOC-2.3.2, "Operating Performance – Accident Management" (Reference 13.6-20), and procedure development that supports the operator when responding to anticipated and unanticipated events. EOPs are developed in accordance with CNSC REGDOC-2.5.2, Section 4.2.4 (Reference 13.6-10).

Emergency procedures are available for non-routine and emergency conditions that require immediate action. Emergency conditions addressed include unexpected radiological and non-radiological hazards, excessive emission of radiological and non-radiological liquid or gaseous effluent, fires, and natural disasters. Emergency procedures are kept in prominent, easily accessible locations. Emergency procedures are exercised in practice drills to ensure that requirements are met.

EOPs implement the strategies and measures employed in the integrated accident management plan and ensure that escalation of an accident is avoided, the accident progression is terminated, and fission product releases are kept to a minimum. The EOPs contain a set of information, instructions, and actions designed to prevent the escalation of an accident, mitigate its consequences, and bring the reactor to a safe and stable state. The development of these procedures takes into consideration the information available to the operating staff and conditions where some of the information may be incomplete with significant uncertainties. Also taken into consideration are long time periods to initiate and complete required actions, human and organizational performance, and the possibility of prolonged times to restore power.

All EOPs are developed in accordance with a systematic procedure development plan that considers HFE principles in both the actions required by the procedure and the design of the procedure itself. Procedure development is a technical element of the BWRX-300 HFE Program, as described in Chapter 18, Subsection 18.3.7.

#### **13.4.3.2 Guidelines for Accident Management**

This section describes the programmatic approach followed to develop accident management procedures and guidelines, including EOPs, Emergency Mitigating Equipment (EME) guidelines and Severe Accident Management Guidelines (SAMGs) in accordance with CNSC REGDOC-2.3.2 (Reference 13.6-20).

Accident management includes multiple components such as equipment and instrumentation, procedures and guidelines, and organizational accountabilities, and it interfaces with many programs established for a reactor facility. An adequate accident management plan ensures the ability to respond to any credible accident in order to prevent the escalation of the accident, mitigate the consequences of the accident, and achieve a long-term stable state after the accident.

Integrated accident management planning consists of a cohesive set of plans and arrangements undertaken to ensure:

NEDO-33963 REVISION 0  
NON-PROPRIETARY INFORMATION

1. Safety systems and the available SSC can be used to control the reactivity, cool the fuel, and contain the radioactive materials such that damage to the reactor vessel and harm to workers, public, and environment is prevented or mitigated
2. Personnel with responsibilities for accident management are adequately prepared to utilize the available resources, procedures, and guidelines to perform effective accident management actions and, when deemed necessary, to call for and interact with the emergency response teams

EOPs, EME guidelines, and SAMGs are developed and implemented to facilitate a licensee's capability to manage the AOOs, DBAs, and Beyond Design Basis Accidents, including Design Extension Conditions and severe accidents. These procedures are developed using a systematic approach in accordance with CNSC REGDOC-2.3.2 (Reference 13.6-20) and CNSC REGDOC-2.5.2, Sections 4.2.4, 7.9.3, 8.5, 8.10, and 9.3 (Reference 13.6-10).

The process of accident management planning will define and describe the following requirements:

- Specific goals of accident management
- Requirements of accident management
- Equipment and instrumentation
- Procedures and guidelines
- Organizational accountabilities

A timeline with milestones for the development, validation, and implementation of all operating procedures, EOPs, EME guidelines, and SAMGs for accident management is expected to be provided in the Licence to Operate application submission.

## **13.5 Nuclear Safety and Nuclear Security Interfaces**

### **13.5.1 General Nuclear Safety and Security**

The plans for physical protection of the facility are described in separate, confidential files. This section addresses how safety measures and nuclear security measures are designed and applied programmatically.

OPG, the operating organization, is responsible for managing the implementation of safety requirements and security requirements, with the primary objective of minimizing risk, through programs and processes established to ensure close cooperation between safety managers and security managers. The safety and security measures are designed and implemented through programs and processes in a complementary manner that do not compromise each other. Mechanisms are established within the programs to resolve any potential conflicts and to manage the safety-security interfaces.

### **13.5.2 Security**

The following security measures, in accordance with the Nuclear Safety Regulations (SOR/2000-209, "Nuclear Security Regulations" (Reference 13.6-28)) and consistent with the relevant guidance provided in CNSC REGDOC-2.12.1 Volume I, "High Security Facilities, Volume I: Nuclear Response Force" (Reference 13.6-21); CNSC REGDOC-2.12.1 Volume II, "High Security Facilities, Volume II: Criteria for Nuclear Security Systems and Devices" (Reference 13.6-22); and CNSC REGDOC-2.12.3, "Security of Nuclear Substances: Sealed Sources and Category I, II and III Nuclear Material" (Reference 13.6-23), are established for the prevention, detection, and response to unauthorized acts, criminal or intentional, that could directly or indirectly produce harmful site consequences:

- Site physical security
- Personnel security
- Information protection
- Document security
- Cyber security

Prescribed and security-sensitive information is only provided to persons with a valid security clearance and "need to know."

Public access to the site-controlled area is restricted by fencing and signage and with OPG Nuclear Security Officer patrols.

OPG maintains a security clearance program consistent with CNSC REGDOC-2.12.2, "Security: Site Access Security Clearance" (Reference 13.6-24). Staff and contractors requiring unescorted access to the site require a security clearance commensurate with activities performed or access required.

Threat risk assessment is performed as part of the Nuclear Security Program, with results taken into consideration in plan development and facility response. A Memorandum of Understanding exists with the Durham Regional Police Services and is maintained to provide for an off-site response to OPG facilities. The agreement(s) ensure that necessary resources are available to address design basis security events. The Memorandum ensures resources are available to address design basis security events in support of existing armed Nuclear Security. OPG periodically conducts drills and exercises that include integrated response with the off-site response force. Lessons learned from drills and exercises are implemented within the Security

Program. The Memorandum is subject to annual review and is revised to reflect existing security postures.

OPG's Cyber Security Program implements the OPG Cyber Security Policy. Information technology and industrial control systems are managed in a secure, vigilant, and resilient manner that minimizes cyber risks to information assets, renewable generation, and nuclear facilities. The Nuclear Cyber Security Program ensures secure operations of computer systems associated with the industrial control systems for OPG nuclear facilities. Cyber security is applied to plant systems, including those used to ensure safe operations and those which provide physical security of OPG nuclear facilities. The Nuclear Cyber Security Program complies with requirements of CSA N290.7, "Cyber Security for Nuclear Facilities" (Reference 13.6-25).

Nuclear Security Officers are selected, trained, and equipped in accordance with the applicable requirements of CNSC REGDOC-2.12.1 Volume I (Reference 13.6-21) and CNSC REGDOC-2.2.4, "Fitness for Duty, Volume III: Nuclear Security Officer Medical, Physical and Psychological Fitness" (Reference 13.6-26).

OPG has programs in place at existing operating nuclear facilities to facilitate compliance with applicable safeguard requirements and agreements. Measures related to site buildings and structures, operational parameters, and the flow and storage of nuclear material throughout the life cycle of the nuclear facility are described in the Environmental Impact Statement.

Details (prescribed information) of the Security Program are transmitted only by secure means consistent with OPG-STD-0030, "Protecting OPG's Information" (Reference 13.6-27) and SOR/2000-202, "General Nuclear Safety and Control Regulations," Sections 21-23, Prescribed Information (Reference 13.6-29).

Details providing security in design, which informs the Security Program, are provided in the Security Annex.

### **13.5.3 Physical Security**

The Nuclear Security Program is implemented by Nuclear Security, N-PROG-RA-0011, "Nuclear Security" (Reference 13.6-30) using a graded approach. The bulk of the program is classified and addressed separately.

### **13.5.4 Cyber Security**

The Cyber Security Program, OPG-PROG-0042 (Reference 13.6-31), procedures and controls ensure the following:

1. Ensure employees and contractors are in compliance with all applicable requirements of this Cyber Security Program
2. A culture of awareness is fostered to promote secure practices in the use of all digital technologies
3. Methods are established to monitor Information Technology and Operational Technology environments on an ongoing basis in order to detect and respond to threats that impact the confidentiality, integrity, and availability of OPG's assets
4. Strategies are in place to prepare for, respond to, and recover from cyber security incidents that impact OPG's reputation, energy production, and public and employee safety

### **13.5.5 Safeguards**

The Safeguards Program, N-PROG-RA-0015 (Reference 13.6-32) is compliant with Nuclear Safety and Control Act, June 2000; its associated General Regulations, and CNSC REGDOC-2.13.1, "Safeguards and Nuclear Material Accountancy" (Reference 13.6-33); and includes the following:

- Communication protocol between the IAEA, CNSC, and Ontario Power Generation, Nuclear
- Obligations to meet applicable regulatory requirements and requirements of associated safeguards procedures
- Reporting to meet applicable regulatory requirements and requirements of safeguards agreements

See the Safeguards Annex: Safeguards and Nuclear Material Accountancy for additional details.

## **14.0 PLANT CONSTRUCTION AND COMMISSIONING**

The purpose of Chapter 14, Plant Construction and Commissioning is to describe how OPG assures that the BWRX-300 will be suitable for service prior to entering the construction, commissioning, and operational stages.

### **14.1 Management System (Construction and Commissioning)**

The primary responsibility for safety and security is assigned to the operating organization or the constructor (depending on the project phase). This responsibility includes the supervision of activities of all other related groups, such as design, supply, manufacture, and construction, employers, and contractors, as well as the operating organization itself. This responsibility is discharged in accordance with the OPG management system.

Construction, commissioning, and related activities are developed and implemented under an OPG management system that meets the requirements of CSA Group (CSA) N286, "Management System Requirements for Nuclear Facilities" (Reference 14.4-1). The OPG Nuclear Management System sets the standards for health, safety, environment, security, economics, and quality during facility design, construction, and commissioning based on the authority of and a safety culture driven by the OPG Nuclear Safety Policy. The management system promotes a safety culture in which all workers adhere to the management system, implement practices that contribute to excellence in worker performance, supports workers in carrying out their tasks safely and successfully, and monitors to improve the culture.

Pending commercial agreement, OPG's contract model is expected to ensure integration and collaboration with GEH, the constructor, and vendors. As owner, OPG will have the responsibility to ensure ongoing and intrusive oversight for all phases of the facility development following the OPG management system. OPG will require the constructor to have its own management system compliant with applicable current standards. GEH and the constructor will qualify subcontractors to the appropriate quality level, commensurate with the risk that their activities pose to the facility.

The Quality Assurance (QA) Requirements documents align with the GEH internal procedures. The documents are utilized by the GEH team to communicate the OPG and project quality requirements to vendors and subcontractors.

All contractors fully support the QA requirements and implement the policies, philosophies, and practices. Each project professional has access to and is responsible for following the applicable governing documents and supporting program effectiveness through project audits, surveillance activities, and using the deviation and corrective action processes.

A Health, Safety and Environmental Plan is developed jointly by the OPG Health Safety and Environmental Manager and Site Manager, with input from the corporate Health, Safety and Environmental departments of GEH team members. The plan is consistent with the Ontario Occupational Health and Safety regulations and OPG Health, Safety and Environmental policies and programs.

The OPG Operations Program Management Plan details the requirements of the OPG Nuclear Operations Program. However, during BWRX-300 construction, OPG operations and maintenance are not required, thus associated operations and maintenance governance is not required. Commissioning prior to fuel load will be performed under the commissioning lead's (OPG or the constructor) managed system. The OPG Operations Program Management Plan is expected to be implemented prior to the Licence to Operate as a series of standards and procedures that ensure the safety of the public, environment, personnel, and equipment.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

OPG responsibilities cover all aspects related to the construction and commissioning of the facility. These responsibilities include the oversight of contracted activities as well as activities that are specifically performed by OPG to include:

1. Ownership of the safety case (including information provided by design authority, constructors, and contractors)
2. Confirmation that the facility is built in accordance with the design basis, regulatory requirements, and applicable codes and standards
3. Preparation and updating (management) of construction plan documents
4. Performance of inspections, tests, and verification of safety class Structures, Systems, and Components (SSC)
5. Evaluation of safety-significant inspection findings and associated reports to the Canadian Nuclear Safety Commission (CNSC)
6. Providing a point of contact for CNSC communications for all matters related to facility construction
7. Identification of jurisdictional boundaries and responsibilities where more than one regulatory body governs

During Darlington New Nuclear Project (DNNP) preparation, construction and operation phases, Operations team members use a graded approach (where the criteria and process used for grading is defined per the requirements of CSA N286 (Reference 14.4-1)), as applicable to the phase to support the following:

1. Developing and maintaining Operating Experience (OPEX), Risk Management and Significant OPEX Report programs
2. Work Protection
3. Operations Scoping and Assessment
4. Design Package Review and Approval
5. Work Plan Review and Approval
6. Support for commissioning and turnover of plant systems
7. Document Reviews and Governance Development and Revisions
8. Strategic Plans and Schedules Development and Reviews

The processes that comprise the management system and maintain objective evidence to demonstrate effective implementation of the management system are defined, documented, controlled, and maintained.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

This section specifically describes the management system and organizational arrangements for the transition from construction to commissioning to operation. The construction and commissioning phases overlap to the extent that the construction phase includes fuel-out equipment checks, referred to as “Check and Test,” and pre-commissioning. Construction, commissioning and related activities are developed using applicable management systems and associated implementing procedures and processes. This section also discusses the programmatic processes that address readiness for operation aspects important to the transition from construction to operation that will include:

1. The organization(s) and organizational structure(s)
2. Measures for assessing the suitability and effectiveness of the plan during all stages of the transition
3. Provisions for recruiting, training, assigning, and retaining the required numbers of workers/ staffing levels consistent with the schedules for implementation and workload
4. Policies, programs, and processes to manage key functions important to safety (i.e., operations, maintenance, and engineering) with a timeline and milestones for development
5. Document management (electronic or paper)
6. Configuration control
7. Transition or transfer of management systems (e.g., construction phase to commissioning phase) to include system and process turnovers
8. The applicability and point at which full implementation is considered complete and OPG assumes management control (in line with the transfer of SSC)

The OPG management system is further described in Chapter 17, Sections 17.1 and 17.2.

### **Organizational Structure and Operation**

The organizational structure implements the programs that make up the OPG management system with the Chief Nuclear Officer accountable for implementation and effectiveness of the nuclear management system. These programs address the following:

1. Organizational resource strategy addressing the quantity of resources and mix of disciplines and skills required as construction progresses through construction and commissioning
2. Description of how resource strategies are managed when project work is being implemented to ensure that the resource profiles and organizational arrangements remain fit for the purpose
3. Description of how contracted work (design, procurement and manufacturing, construction, pre-commissioning checks, and commissioning) is conducted to required levels of safety and quality from an organizational perspective. Considerations to address:
  - a. Evaluation and confirmation before placing a contract with nuclear safety significance that the contractors and suppliers have the organizational, technical and project management capability, capacity, and culture to deliver the items or services
4. The organizational arrangements for transition from construction to commissioning, to operation

### **Management Oversight (Construction/Commissioning)**

Accomplished through OPG's Nuclear Management System in compliance with CSA N286 (Reference 14.4-1) and OPG-PROG-0038, "Contract Management" (Reference 14.4-16), OPG ensures contracted design, procurement, construction, and commissioning work is carried out to the required level of safety and quality by:

- Establishing an effective commercial or supply chain strategy to enable delivery of safety case requirements
- Maintaining an informed (intelligent) customer capability for all work that may affect nuclear safety that is carried out on its behalf by any contractor
- Ensuring the contractor maintains an informed (intelligent) customer capability for all work carried out by the contractor's supply chain that may affect nuclear safety; for example, where a subcontractor may use its own supply chain to meet the needs of its customer, and will need to procure items or services appropriately
- Issuing specifications that adequately describe the items or services, meet the safety case requirements, and identify the required level of QA; some examples are:
  - Procurement specification
  - Commissioning specification
  - Design clarification
  - Codes and standards requirements
  - Description of any operational constraints
  - Review of the specifications and the results of the commissioning activities
  - Disposition and resolution of any design-related performance issues with the SSC, in accordance with a formal design change process for work with nuclear safety significance
  - Prior to contract placement, evaluating, and confirming that contractors and suppliers have the organizational, technical and project management capability, capacity and culture to deliver items or services to the specification
  - Ensuring suppliers have quality management arrangements that are appropriate and consistent with the safety significance of the procured items or services
  - Ensuring suppliers identify and categorize any deviations from specified requirements, and refer the deviations to the design authority and the authority having jurisdiction for assessment
  - Ensuring suitable arrangements to mitigate the risk of Counterfeit, Fraudulent and Suspect Items entering the supply chain
  - Ensuring arrangements are in place to capture and act on operational experience feedback from the safety case and supply chain management activities, sharing learning as appropriate within the organization and wider industry
  - Conducting effective oversight and assurance of the supply chain, including the acceptance of items or services for work with nuclear safety significance

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

Consistent with CNSC REGDOC-2.3.1, "Conduct of Licensed Activities: Construction and Commissioning Programs" (Reference 14.4-2), OPG has primary responsibility for the safety and security of construction and commissioning activities, including the work carried out on its behalf by contractors. OPG's oversight responsibilities cover aspects related to facility construction and commissioning.

Additional details of OPG's construction oversight activities and commissioning and turnover plan to address applicable CNSC REGDOC-2.3.1 (Reference 14.4-2) requirements is expected to be submitted in support of the Licence to Construct application via a Construction Management Plan and a Commissioning and Turnover Program Management Plan respectively.

OPG oversees construction of the facility in accordance with OPG's Project Management program. Design oversight is controlled in accordance with OPG's Nuclear Design program and commissioning is consistent with OPG's Nuclear Engineering Change Control program.

The OPG Nuclear Oversight Program periodically assesses the effectiveness of the management system. OPG is expected to provide ongoing and intrusive oversight during the design, construction, and commissioning phases. In addition, OPG requires the construction contractor to also have a management system that is compliant with the applicable standards. The OPG program includes independent audit, self-assessment, and a management review process conducted by OPG senior management. The audit program reviews programs within the management system, including programs that are maintained and implemented as a corporate responsibility. The frequency of audits and selection of program elements to be assessed are based on program risk assessment.

OPG oversight activities include the following:

- Oversight support from corporate Environmental, Safety, Health and Security group
- The Project Quality Manager provides oversight to supplier quality processes, including equipment quality and quality document packages
- The Supplier Quality Surveillance Manager provides oversight of shop inspection activities, inspection personnel for the project and duties of the Quality Control Coordinator
- Construction Management and startup management will have Site Manager and Project Manager oversight

Prior to construction start, interfaces between OPG and the CNSC and other regulatory authorities are defined, agreed upon and understood such that relevant performance issues that affect or have the potential to affect quality of construction and future operational safety of SSC are provided to the regulatory authorities.

NK054-PLAN-01210-00100 Sheet 0003, "Darlington New Nuclear Project Quality Program Management Plan" (Reference 14.4-17), addresses the quality requirements and takes authority from the Program Management Plan. Figure 14.1-1 provides a representation of the links between the OPG Nuclear Management System and the vendor quality systems. See Chapter 17, Section 17.3 for a detailed discussion of OPG quality management.

### **Security (Construction and Commissioning)**

Security measures consistent with the relevant guidance provided in CNSC REGDOC-2.12.1, “High Security Facilities, Volume II: Criteria for Nuclear Security Systems and Devices” (Reference 14.4-3) and CNSC REGDOC-2.12.3, “Security of Nuclear Substances: Sealed Sources and Category I, II, and III Nuclear Material” (Reference 14.4-4) are established during the construction and commissioning phases for the prevention, detection, and response to, criminal or intentional, unauthorized acts involving or directed at construction or commissioning activities and other intentional acts that could directly or indirectly produce harmful consequences:

- Site physical security
- Personnel security
- Information protection
- Document security
- Cyber security

The DNNP Site Security Plan, NK054-PLAN-61400-00001, “DNNP Site Security Plan” (Reference 14.4-18), defines the processes and procedures that are implemented to control and maintain overall security of the site. Defined roles, responsibilities and content of the security plan are determined by OPG and the constructor. The Site Security Plan is independent of the operating plant security.

The Nuclear Security Program provides for actions to protect SSC and deter conditions that impair site security during the construction and commissioning phases.

The security measures evolve during construction and commissioning commensurate with on-site conditions (e.g., turnover to operations, nuclear material on-site, etc.) with provisions for:

- Commercial loss control
- Access control of personnel, materials, and vehicles
- Scheduled and random patrols and inspections
- Screening (pre-employment and gate clearance) for access to work areas
- Physical barriers, fencing, surveillance and monitoring capability
- Cyber security controls to protect computer-based systems
- Response capability

Revisions to the Nuclear Security Program occur in a phased approach reflecting the stages of the project lifecycle from construction, commissioning, and operations to decommissioning. Nuclear security will increase when nuclear fuel is delivered to the site and further before the reactor is first operated. Measures are implemented appropriate for each phase of the project to ensure compliance with regulation and applicable codes and standards in addition to any measures required to protect personnel, information and physical assets against security risks identified in site-specific threat and risk assessments.

Prescribed and security sensitive information is only provided to persons with a valid security clearance and “need to know.”

Public access to the site-controlled area is restricted by fencing and signage with Security Officers patrolling on a regular basis. Additional security and access control measures are established or modified as appropriate for each phase of the project.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

OPG maintains a security clearance program consistent with CNSC REGDOC-2.12.2, "Security: Site Access Security Clearance" (Reference 14.4-5). Staff and contractors requiring unescorted access to the site require a security clearance commensurate with activities performed or access required. Clearance requirements will increase prior to delivery of nuclear fuel to the site.

Threat risk assessment is performed as part of the Nuclear Security Program with results taken into consideration in plan development and facility response. Agreements with offsite response forces are maintained that provide for an offsite response to OPG facilities. The agreement(s) ensure that necessary resources are available to address design basis security events. OPG periodically conducts drills and exercises that include integrated response with the offsite response force. Lessons learned from drills and exercises are implemented within the security program. Agreements are subject to annual review and are revised as necessary to reflect additional response needed during the various phases of the project.

Physical security measures focus primarily on-site access control with additional equipment, systems, and procedures implemented where required during the construction and commissioning phases.

OPG's Cyber Security Program implements the OPG Cyber Security Policy. Information technology and industrial control systems are managed in a secure, vigilant, and resilient manner that minimizes cyber risks to information assets, renewable generation, and nuclear facilities. The Nuclear Cyber Security Program ensures secure operations of computer systems associated with the industrial control systems for OPG nuclear facilities. Cyber security is applied to plant systems including those used to ensure safe operations and those which provide physical security of OPG nuclear facilities. The Nuclear Cyber Security Program complies with requirements of CSA N290.7, "Cyber Security for Nuclear Facilities" (Reference 14.4-6). Requirements for Cyber Security are documented and coordinated as part of the project contract.

Nuclear Security Officers are selected, trained, and equipped in accordance with the applicable requirements of CNSC REGDOC-2.12.1, "High Security Facilities, Volume I: Nuclear Response Force" (Reference 14.4-40) and CNSC REGDOC-2.2.4, "Fitness for Duty, Volume II; Managing Alcohol and Drug Use" (Reference 14.4-7).

Details (prescribed information) of the security program are transmitted only by secure means consistent with OPG-STD-0030, "Protecting OPG's Information" (Reference 14.4-19) and Section 21-23 of SOR/2000-202, "General Nuclear Safety and Control Regulations", "Prescribed Information" (Reference 14.4-8).

### **Safeguards (Construction and Commissioning)**

Access to the physical site and information about site buildings and structures, operational parameters, flow and storage of nuclear material, and the installation of safeguards surveillance and monitoring equipment is provided to the International Atomic Energy Agency consistent with the Canada-International Atomic Energy Agency safeguards agreement.

OPG has programs in place to facilitate compliance with all applicable safeguard requirements and agreements per CNSC REGDOC-2.13.1, "Safeguards and Nuclear Material Accountancy" (Reference 14.4-9). Measures related to site buildings and structures, operational parameters and the flow and storage of nuclear material throughout the lifecycle of the nuclear facility are described in the Environmental Impact Statement.

### **Training (Construction and Commissioning)**

Training programs consistent with CNSC REGDOC-2.2.2, "Personnel Training" (Reference 14.4-10) are established to ensure personnel engaged in construction and commissioning activities are provided with the necessary training and possess the qualifications and competence to perform assigned tasks effectively and safely. NK054-PLAN-01210-00100 Sheet 0007, "Darlington New Nuclear Project Training Program Management Plan" (Reference 14.4-20), under the authority of NK054-PLAN-01210-00008, "Darlington New Nuclear Project - Program Management Plan" (Reference 14.4-21), addresses the development and delivery of training for OPG staff and contract staff. The training programs are expected to evolve as construction progresses and the commissioning and operational phases are entered. Training is often integrated within specific programs or plans with links established and maintained with established training programs.

Vendors employing staff, supervisors, contractors, and subcontractors who are working on the project are responsible for the training and qualification of their staff in all training topic areas under the vendor's QA programs. OPG provides vendors with site-specific information where needed. Skilled Trades staff hold journeyman status and Certificate of Qualification as appropriate. Apprentices work under the accountability of a journeyman when performing tasks associated with the skilled trade.

Vendors maintain records of staff certifications, licences, training, and qualification and are available for OPG review on request. OPG Security personnel are trained under N-PROG-TR-0005, "Training" (Reference 14.4-22) including N-TQD-603-00001, "Nuclear Security Training and Qualification Description" (Reference 14.4-23).

Scheduling of OPG staff training for DNNP follow existing processes per N-PROC-TR-0044, "Training Demand, Scheduling, and Cancellation Process" (Reference 14.4-24) and align with staffing plans for the new station. Processing of results and maintenance of training records follow existing processes described in N-PROC-TR-0041, "TIMS II Administration" (Reference 14.4-25) and N-PROC-TR-0012, "Records and Documentation" (Reference 14.4-26).

Personnel engaged in construction activities are provided the training necessary to perform their assigned tasks effectively and safely. The training content is specific to the tasks performed and emphasize adherence to established programs, processes, and procedures to assure nuclear safety and, every person working at the site is responsible for safety.

The respective training for personnel engaged in commissioning activities to include:

- Commissioning organization and structure
- Commissioning procedures
- Reactor facility systems
- Conduct of testing and maintaining safe conditions
- Procedural and design changes
- Design process as it applies to configuration control and field changes
- Permanent and temporary modifications
- Work control and equipment isolation
- Interfaces of construction, design, and operation with commissioning

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

- Test limitation boundaries in mechanical, instrumentation and control and electrical systems
- Reporting incidents and deviations
- Commissioning methods and techniques
- Safety culture
- Nuclear safety, industrial safety, fire protection, emergency preparedness, radiation protection and security
- Industry OPEX and lessons learned
- Design criteria, technology and operational limits and conditions (or the equivalent) for the reactor facility
- Environmental protection and waste management of spent fuel and radioactive waste
- Full-scope simulator training of operators for reactor startup, regular operations, reactor shutdown and cool down and handling of various transients, including accidents

Training requirements will be implemented and maintained and will be consistent with the requirements pursuant to the phase of the project. When required, site personnel are initially provided general Site Orientation training which consists of topics that include fall prevention, confined space, aerial lifts, hazardous communication, ladder safety, excavation, and trenching. Additional training for specialized tasks is addressed on an individual need basis.

Documentation of employee certifications and education is recorded upon hiring by either OPG or vendors and contractors. Competencies, skills, and acquired knowledge is continuously monitored and documented.

Short term visitors to the site are provided with an orientation and overview of current site hazards. Visitors are required to provide written acknowledgment of the guidelines to be followed. Escorting of visitors will be used when conditions warrant additional oversight.

Minimum Staffing Complement is discussed in Chapter 13, Subsection 13.2.2.

### **Programs and Procedures (Construction and Commissioning)**

OPG's Nuclear Management System programs and a description of the specific programs associated with the safety culture elements of OPG's Management System are provided in Chapter 17, Subsections 17.1, 17.2 and 17.5 respectively.

Operating procedures developed for use during construction, installation and commissioning are developed under the same general guidelines as described for operating procedures developed for licensed operation of the facility with the exception that the primary focus of these operating procedures is directed to an evolving facility as it is constructed. Construction and commissioning phase operating procedures are established to provide for the safe conduct of operations and evolutions performed during these phases. The construction phase and commissioning phase procedures are primarily developed under procedure guidelines that are consistent with the requirements of CNSC REGDOC-1.1.2, "Licence Application Guide: Licence to Construct a Reactor Facility" (Reference 14.4-11).

The development, review, and approval of applicable procedures and programs, including necessary changes after approval, are governed by N-PROG-AS-0001, "Nuclear Management System Administration Program" (Reference 14.4-27), and implemented in accordance with OPG-PROG-0001, "Information Management" (Reference 14.4-28).

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

The schedule for development of plant operating procedures is based on completion of finalized design of SSC and later the complete plant site. Operating procedures are projected to be developed approximately 1 year prior to the start of pre-operational testing of systems. Plant operating procedures are used and tested to the extent practical during the pre-operational and startup testing. Technical procedures are developed under N-PROC-AS-0028, "Development, Review and Approval of Technical Procedures" (Reference 14.4-29). The plant simulator is expected to be used to validate specific operating scenarios.

Processes are established for the development and approval of test procedures that control the performance of tests and the review and approval of test results including the required actions to be taken when test results do not meet design requirements.

Processes are established for the development and approval of procedures for receipt inspection of fuel, fuel handling, fuel storage, initial fuel loading and initial criticality that include the protection and safety measures established for safe operation. Fuel receipt, storage, and initial core loading is controlled via procedure, which contains specific instructions and guidance to receive, handle, store, and load the fuel safely, correctly, and efficiently.

Out of core criticality is precluded by fuel storage design and the storage and handling procedure guidance.

Document and records program development and management during construction, commissioning and operation is the responsibility of the operating organization. Construction and commissioning phase documents and records are maintained during the applicable phase by the responsible organization (GEH, constructor, etc.) in an agreed upon form to facilitate their turnover to OPG. Document and records management is discussed further in Chapter 13, Subsection 13.3.8 and Chapter 17, Sections 17.2 to 17.4.

### **Operating Experience and Problem Identification (Construction and Commissioning)**

Relevant OPEX is considered for the BWRX-300 during the construction and commissioning phases. The design authority (GEH) establishes provisions for the incorporation of OPEX through integrated management systems. The OPEX comes from a variety of sources including direct input, GEH/GNF experience from the operating Boiling Water Reactor and Advanced Boiling Water Reactor fleet, Institute of Nuclear Power Operations, Electric Power Research Institute, Department of Energy, U.S. Nuclear Regulatory Commission, and CNSC. OPEX is also considered for use in test programs where special emphasis might be warranted. The constructor OPEX program is consistent with the OPG OPEX program and is implemented accordingly during construction planning and construction. OPG's problem identification and resolution process implements a program to take corrective action from facility events and has in place an established operating experience process that evaluates, integrates, accesses and shares OPEX information to prevent event recurrence and to initiate improvements. The problem identification and resolution program and OPEX programs are maintained consistent with CSA N286 (Reference 14.4-1). Problem identification and resolution requires that when problems arise; they are immediately controlled and documented if required, evaluated for significance and the underlying cause if deemed to be systemic or having an impact on business objectives, and accepted. The OPEX program for the operations phase is addressed in Chapter 13, Subsection 13.3.7.

Processes and programs are established for problem identification, resolution, and continual improvement during commissioning with expectations set for personnel to identify and report non-conformances. The GEH and construction problem and identification programs are consistent with the OPG program.

Based on construction lessons learned, measures are taken to mitigate the effects of adverse weather by construction means and methods addressed in the Construction Plan. Severe weather that may impact construction is also considered with measures to mitigate the impact and thus limit, but not prevent, effects to the Construction Program.

### **Nuclear Material Packaging and Transport (Construction and Commissioning)**

A Nuclear Material Packaging and Transport program, specifications, and procedures, established by the constructor, will be in place to cover all requirements for the construction and commissioning phases of the project. OPG/GEH is expected to ensure this constructor program meets CSA N286 (Reference 14.4-1) requirements.

Further details on the Nuclear Materials Packaging and Transport Program are provided in Chapter 13, Subsection 13.3.2.

This section does not include detailed information pertaining to operations. The information provided is intended to facilitate pre-commissioning checks and commissioning before fuel load and prepare for the transition to fuel-in commissioning and reactor operation upon receipt of a Licence to Operate.

### **Emergency Management and Fire Protection (Construction and Commissioning)**

Emergency management and Fire Protection for DNNP will adhere to the requirements of CNSC REGDOC-2.3.1 (Reference 14.4-2). All contract workers are required to complete mandatory emergency response training that outlines rules, notifications and required responses.

OPG developed the DNNP Nuclear Emergency Preparedness Plan. The plan provides a basis to document the concepts, roles, and resources required by OPG to implement and maintain its emergency response on the DNNP site to protect employees, visitors, and contractors in the event of a nuclear emergency originating from Darlington Nuclear Generating Station operations. See Chapter 19, Section 19.1 for further details.

Nuclear emergency response is based on the existing Darlington Nuclear Generating Station nuclear response requirements and CNSC REGDOC-2.10.1, "Nuclear Emergency Preparedness and Response" (Reference 14.4-12).

Emergency measures are routinely evaluated to ensure that they remain commensurate with on-site hazards.

#### **14.1.1 Configuration Control**

The design and safety analysis are incorporated into the purchasing, construction, commissioning, operating, and maintenance documentation such that the as-built configuration of the facility is aligned with the design and safety analysis. Design authority configuration requirements that include the responsibilities and authority of organizations whose functions affect the configuration of the facility, including activities such as design, maintenance, construction, licensing, and procurement are controlled through the configuration management process. OPG configuration management is an integrated management process that ensures the physical and operational configuration and documentation continue to conform to the design and licensing basis requirements. Configuration management during the construction phase is implemented through processes (design changes, field changes, etc.) agreed upon by GEH, constructor and OPG in consideration of the as-built documents to be turned over to OPG.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

Facility configuration is maintained from initial conception through established programmatic configuration and change control processes that adhere to CNSC REGDOC-2.3.1, Section 7 (Reference 14.4-2), CSA N286.10, "Configuration Management for High Energy Facilities" (Reference 14.4-13) and CSA N286 (Reference 14.4-1). The control of construction records is established at the beginning of the construction phase for schedule input.

Changes during the construction phase are processed to maintain conformance with design requirements, physical configuration, and configuration documentation with established arrangements between participating organizations for review, approval, and release, including notifications of field changes and non-conformance issues. Changes during the construction and commissioning phases are managed by the design authority with oversight and concurrence of OPG.

The design control process ensures engineering documents, calculations and detailed design drawings are generated and the corresponding GEH team, engineering service, or constructor procedure requirements for review, verification, and approval are completed. The design control procedures ensure appropriate reviews of manufacturers' drawings and data to ensure that the OPG requirements are incorporated in the plant design and documentation.

The construction contractor maintains detailed design control and engineering change notification procedures specific to their individual organization or implements procedures belonging to the organization responsible for the design. Selected construction contractors are required to demonstrate how their specific design control and engineering change procedures are compliant with CSA N286.10 (Reference 14.4-13).

Changes to the approved design are controlled, reviewed, and approved in the same manner as design review and verification. An engineering change notification, or equivalent, is used to provide interim notification of a change to be incorporated. Engineering Change Notifications are processed in accordance with the design change management process.

GEH also maintains an issue tracking system for change management during construction. Changes that may be the responsibility of OPG are submitted to OPG in accordance with the project contract.

#### **14.1.1.1 Facility Configuration**

Configuration management is incorporated into all aspects of purchasing, construction, and commissioning so the as-built configuration of the facility aligns with the design and safety analysis in accordance with CSA N286 (Reference 14.4-1) and CSA N286.10 (Reference 14.4-13).

Configuration information that describes, specifies, certifies SSC, or provides data or results created during construction are agreed to, planned, and processed to facilitate turnover for commissioning and operations. Control of construction records are established prior to beginning the Construction Program as part of construction schedule input. Visual documentation of the as-built condition is appropriate as part of configuration documentation, particularly in inaccessible areas or areas subject to radiation exposure.

#### **14.1.1.2 Change to Facility Configuration Information**

The design basis and requirements for the BWRX-300 including safety analysis is established and documented in accordance with CSA N286 (Reference 14.4-1) and is traceable to the respective SSC. Changes/modifications to the facility configuration during construction are processed and documented to maintain the facility design requirements, physical configuration, and the configuration information. Impacts of design changes are assessed, addressed and when applicable reflected in the safety analysis. Relevant configuration changes will be communicated to the CNSC in accordance with applicable licence conditions.

Temporary or permanent changes in design requirements, physical configuration and physical configuration information are configuration change mechanisms that include:

- Design changes
- Field changes
- Non-conformances
- Changes to as-built condition
- Changes to as-built test documentation
- Changes to inaugural inspection records
- Computer software changes
- Changes to records of maintenance history
- Temporary modifications and alterations

#### **Fitness for Service**

During the design and construction/procurement phases, equipment reliability requirements are addressed within the design authority's reliability program. During the startup and testing phase when transitioning from construction/commissioning to operation, equipment reliability requirements are addressed as a shared responsibility of the design authority (GEH) and OPG. The Equipment Reliability Programs of both organizations are consistent with CNSC REGDOC-2.6.1, "Reliability Programs for Nuclear Power Plants" (Reference 14.4-14).

The fitness for service safety and control area covers activities that affect the physical condition of SSC to ensure adequacy and ability to perform their intended function when required.

The Chemical Control Program establishes processes to control the use of chemicals throughout the facility during construction, commissioning, and operations.

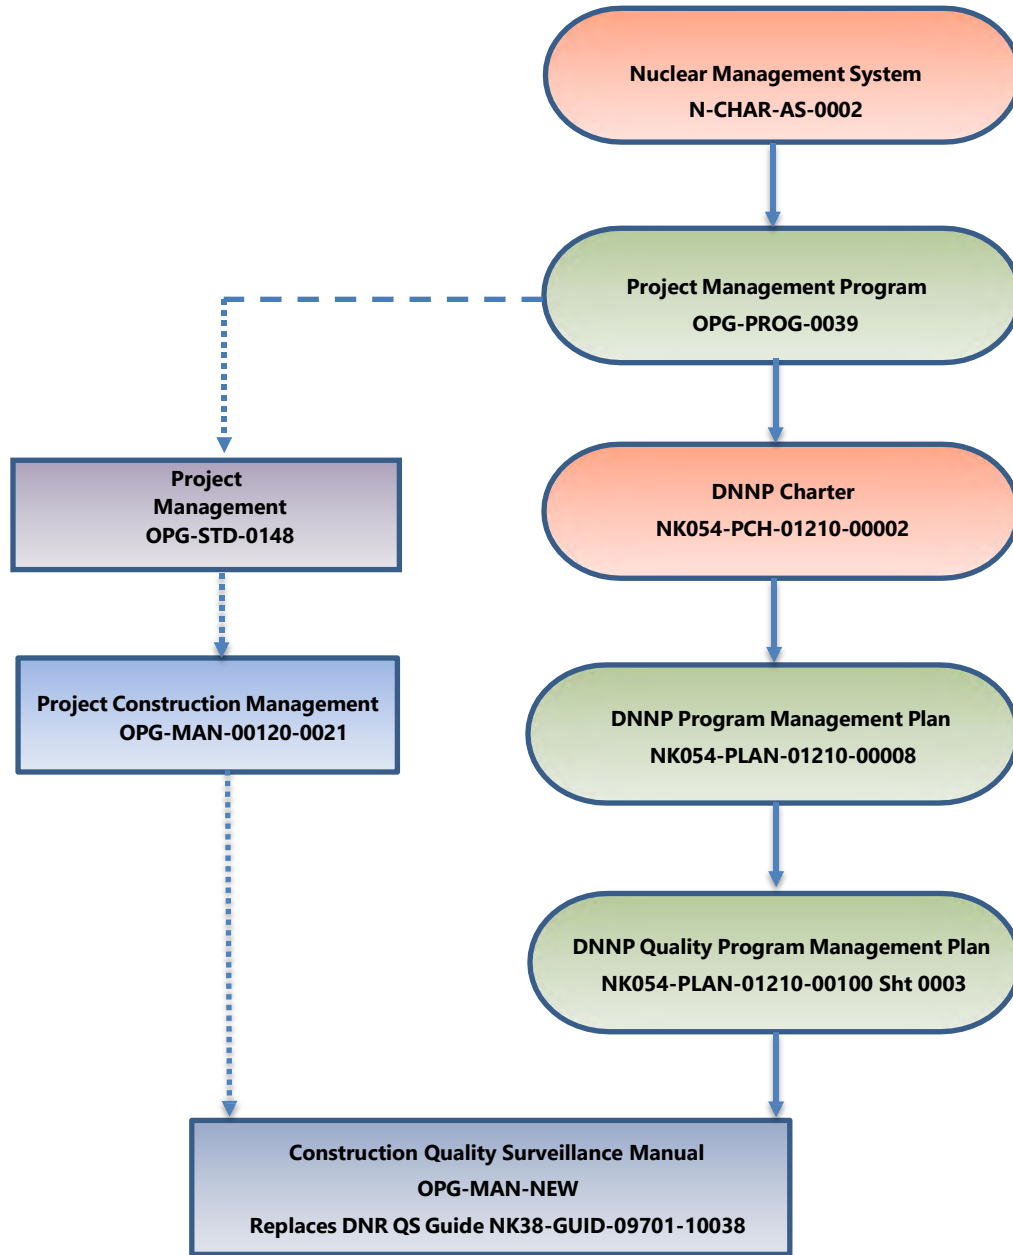

Figure 14.1-1: Quality Program Process Documents

## **14.2 Construction**

### **14.2.1 Organization**

#### **OPG Construction Team Organization**

The Construction Program Management Plan, NK054-PLAN-01210-00100 Sht. 00009, "Darlington New Nuclear Project Construction Program Management Plan" (Reference 14.4-30), provides guidance as well as the activities for the OPG construction oversight team engaged in the planning, construction, and commissioning of the BWRX-300. The Construction Program Management Plan aligns with Corporate, Nuclear, and business unit governance.

The construction organization performs independent risk-based observations focused primarily on High-Risk areas. This allows for proactive identification of areas for improvement that can be actioned to have corrective measures implemented.

Construction Management is the responsibility of the individual engineering service or Construction contractors. OPG Construction Managers, reporting to the OPG Director of Field Construction, support the Project Managers/Directors proactively with qualified and competent resources that have the experience required to execute effective oversight management. Effective communication both vertically and horizontally between the construction organization and the Project ensures alignment for field construction activities. Construction oversight is a project management function and is accomplished through OPG-PROG-0039, "Project Management" (Reference 14.4-31).

The typical OPG Construction Team organization consists of a Director of Construction, Construction Manager, Construction Supervisor, and Quality Officer.

Roles and accountabilities of the OPG Construction Team organization are described below:

#### **1. Project Director Construction Services**

The Director Construction Services is accountable for the oversight of the construction activities of the new nuclear plant. The Director interfaces with the General Contractor and Subcontractors to ensure project deliverables are met with due consideration for the site-specific safety and environmental regulations and requirements. The Director provides oversight of the General Contractor's compliance with the reviewed design and construction documents and the construction and installation methodology. The Director also provides oversight of the General Contractor's QA/Quality Control Program to ensure that regulatory and contractual requirements are met and that the work is performed by qualified staff.

The Director Construction Services also provides direction to the OPG Field Construction Managers on contractor observation in line with OPG-PROG-0039 (Reference 14.4-31) and ensures the Construction Manager is providing independent risk review of Major Projects to ensure vendors are ready to execute the work when scheduled.

2. Construction Manager

The Construction Manager reports to the Director of Construction Services and provides a point of accountability for implementation of the construction project, ensuring that all aspects of the DNNP work program are executed in accordance with expectations for safety, cost, schedule, and quality.

The Construction Manager provides leadership, strategic direction, support to assigned Construction planning and execution personnel and ensures that the engineering service vendor, and other vendors and subcontractors, deployed on the project executes the work to the schedule and consistent with the terms and conditions of the contract. This manager also ensures that the engineering service vendor performs work safely, effectively and in a manner consistent with OPG's policies, procedures, safety values and objectives.

3. Construction Supervisor

The Construction Supervisor reports to the Construction Manager and is required to support early design reviews at the onset of detailed design. Planning personnel are co-located with the engineering service vendor team to engage collaboratively, be efficient and effective in the design review and planning phases, assist with the development of the project plans, and support the engineering service construction execution planning efforts.

4. Quality Officer

The Quality Officer has the following responsibilities:

- a. Prepares Quality Surveillance Plans that inform the assessment of vendor compliance to quality programs, plans, and processes
- b. Conducts specified surveillance and records observations in an electronic observation repository
- c. Reports metrics and trends based on the observations and identifies adverse quality non-conformance trends and Significant Quality Events to the Senior Manager Assurance and the appropriate Project Manager
- d. Recommends strategies and corrective actions for quality issue resolution
- e. Ensures configuration management by surveillance of documents
- f. Prepares Quality Final reports for each major project

**Consortium Construction Team Organization**

The planned project structure that is being defined in the Project Contract Model (Chapter 17, Subsection 17.2.1.1) will result in a consortium or alliance involving OPG (owner), GEH (developer), a constructor and an architect engineer.

Subject to the final terms of the model, at the consortium level, key decision-making and high-level project leadership will be undertaken by a Project Leadership Team and an Executive Leadership Team. The team will consist of a Project Director from each member organization.

For construction leadership, the constructor will be under the overall direction and leadership of a Project Director. Project Managers and potentially reporting Directors will be accountable to the Project Director.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

Construction Leadership will roll down from the Project Managers, who are accountable for specific scopes or bundles, to the Construction Team, led by a Construction Manager and General Superintendent. The hierarchy will cascade down through discipline superintendents, General Forepersons, Forepersons, and ultimately tradespersons.

The construction field staff organization consists of a project site manager, Project Manager, general superintendent (Construction Manager), trade discipline superintendent, project controls lead, technical services lead, quality lead, health, safety and environmental lead, field office lead, general office administration, subcontracts coordinator, materials lead, and trade general foremen.

1. The project site manager is the senior site leader responsible for total project site construction performance including safety, costs, schedule, quality, and project status. The project site manager oversees operations of project personnel and maintains relationships with clients, engineers, and subcontractors.
2. The Project Manager is responsible for project performance including safety, costs, schedule, and project status. The Project Manager assists the project site manager with project management, project controls and reporting and acts in his/her place during the project site manager's turn around rotations.
3. The general superintendent(s) (Construction Manager), who manages all field construction on the project and is responsible for all field aspects of the project's budget, schedule, safety, resources and general performance, reports to the project site manager.
4. The trade discipline superintendents report directly to the general superintendent(s).
5. The project controls lead (or manager) reports to the project site manager. The project controls lead has overall responsibility to ensure that all project controls systems as related to cost control, progress monitoring, planning, and scheduling, and document control are implemented and delivered successfully.
6. The technical services lead, whose responsibilities include workforce planning, job site coordination, translating the interpretation of drawings, and specification into work instructions, reports to the project site manager. The technical services lead assists the general superintendent and project site manager in the management and coordination of the technical and administrative requirements of a project.
7. The quality lead reports to the project site manager and supervises the quality inspectors assigned to the project.
8. The Health, Safety and Environmental lead reports to the district Safety Manager and project Site Manager. This lead works closely with the OPG Construction Manager and provides the necessary expertise to ensure the construction effort complies with all GEH, or constructor, OPG, federal, provincial, and local jurisdictional authorities and project safety and loss prevention requirements.
9. The field office lead, reports to the project site manager and provides accounting, payroll, and project administrative expertise to support the construction and accounting teams for the project.
10. The general office administration is responsible for project office security, project office policies and procedures, systems and technology requirements for the project, and office equipment, office supplies, and furniture needs.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

11. The subcontracts coordinator formulates, negotiates, and executes subcontracts in accordance with the procurement/materials management process and the requirements for subcontract close-out.
12. The materials lead (or manager) develops and implements the project materials management system in alignment with the Materials Management Plan and looks after the development of project materials coordinators.
13. The trade forepersons report to a trade general foreperson(s) and trade superintendent and are responsible for directing and leading crews of hourly workers (trades) including all aspects of the crew's work including safety, quality, planning, production, look-ahead and measurement of performance (typically earned value and schedule adherence).

Terms and titles used above related to staffing positions may be revised during the project life cycle. Some roles will be combined during project ramp-up and ramp-down. The titles and roles listed represent the core construction functions to be performed by the construction organization.

The Construction Manager draws on the support available from within the full GEH team for advice and assistance, particularly when approaching new situations or when issues arise during implementation.

The construction management staffing schedule defines the GEH field team personnel by title, forecasted dispatch and departure dates, and location of work. De-staffing/demobilizing is forecasted within the staffing plan.

Trade labour for the project consists of a significant number of employees from the engineering service/constructor firm(s) and their affiliated Trade Unions, their subcontractors, and suppliers, and OPG that are local residents with the intent to maximize the amount of local content in the local community and province of Ontario. Applicable labour laws, including provincial and federal regulations are adhered to.

Prime, partner and subcontractor roles for construction are identified in the Construction Plan along with the identification of construction contracts that may start out in or remain under OPG control. The roles are subject to change as construction progresses. GEH is responsible for the majority of the small modular reactor engineering and related procurement while the engineering service/constructor manages the majority of on-site work and procurement of balance of plant materials.

During construction, the construction organization installs and erects plant equipment and performs construction and installation testing, typically via inspection and test plans. As construction and installation testing is completed and construction completions are declared, equipment and systems are ready for the execution of the pre-operational and startup testing by the licensee's operating organization. To ensure a smooth transition from the construction organization to the operating organization the licensee will have a commissioning organization.

A construction to procurement interface, described in the Construction Plan, is established to ensure that procurement requirements adequately capture construction plan input for skids, modules, shipping condition, instruction manuals, etc. The engineering service has established interface arrangements with the procurement team, GEH, key suppliers (e.g., steam turbine generator), and key subcontractors to develop construction plan input and convey it into procurement requirements.

## **Construction Management**

OPG is responsible for the identification of the health and safety, environmental, and other requirements applicable to construction activities and the communication of relevant requirements to all parties. The relevant requirements are taken into account and implemented via the established OPG management practices and controls.

The construction organization, in general, consists of the design authority, the engineering service, constructor, and various equipment vendors and subcontractors performing construction activities under OPG oversight.

The plan for the project setup, identifying OPG as "owner only" during construction, will be confirmed by the Contractor Owner Interface document which is currently in progress. OPG is highly involved with project execution from the start of the project through the end of the warranty period. OPG is expected to have multiple team members on-site during project execution.

Interface arrangements between OPG, the CNSC and other regulatory authorities are established and documented in the DNNP Licensing Program Management Plan NK054-PLAN-01210-00100 Sheet 00008, "Darlington New Nuclear Project - Licensing Program Management Plan" (Reference 14.4-32).

The satisfaction of contractor and subcontractor contractual obligations are ensured via processes and procedures developed in conformance with the OPG management system. OPG maintains oversight activity records and provides reports to the CNSC of any relevant contractor performance that has affected, or has the potential to affect, the quality of construction and future operational safety.

OPG oversight of contractor activities is addressed in the Construction Project Assurance Program Management Plans and includes:

- Qualitative and quantitative measures to monitor conformance and trending
- Proactive measures that monitor contractor performance
- Reactive measures to trend contractor performance
- Monitoring management system/QA program effectiveness
- Retention of relevant information and reports of contractor performance that has affected, or potentially affected, the quality of construction and future operational safety

The OPG Construction Organization facilitates construction activities in line with OPG-PROG-0039 (Reference 14.4-31), with the details provided in OPG-STD-0148, "Project Management" (Reference 14.4-33), OPG-MAN-00120-0021, "Project Construction Management" (Reference 14.4-34) and N-INS-00120-10008, "Nuclear Contractor Safety Management Process" (Reference 14.4-35). OPG Field Construction conducts activities to create alignment, as well as cover accountabilities and legal requirements under the Occupational Health and Safety Act as supervisors of the work when OPG is the constructor. This alignment ensures a strong relationship is maintained between the Project and vendors while work is being performed in the field.

The OPG Construction Organization performs both scheduled and emergent independent risk-based field observations of the vendor's conduct in specific field focused activities.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

Look-Ahead Teams review Project readiness including Comprehensive Work Packages, Task instructions, foreign material exclusion planning, inspection and test plans, Work Plans, assessing details including tasks for all activities, sequencing, task durations, Materials, Safe Work Plans, Lift Plans/Lift Classification, Approvals, Work Perimetry, Resources, Field Walk downs, Permits and Potential schedule impacts.

Work stoppage events pose significant risks to the project cost and schedule. To mitigate these risks, strategies are implemented for event management and event recovery. An event reporting protocol is provided to aid in corrective action(s) and development of recovery plans to reduce the impacts to the project and the site.

Weekly progress reports for construction and monthly progress reports for the project that summarize the performance and status of the project are expected to be issued. The specific content of the reports is expected to be outlined in the project contract.

A Project Controls calendar is used to define detailed dates for status reports issued throughout the project.

Periodic meetings are scheduled and conducted by the Startup Manager that consist of a review/status update of the overall schedule, system turnovers, punch lists, startup progress, startup activities for the upcoming work period, and operator training programs.

The monthly progress report summarizing the performance and status of the project is issued to OPG prior to the monthly meeting. The meeting attendees include the Project Manager, Assistant Project Manager, Project Field Manager, Original Equipment Manufacturer Startup Managers, and other applicable key personnel as may be required based on project phase.

OPG and the GEH team conduct monthly meetings for the purpose of reviewing the work scope progress, progress reports, health plan, environmental plan, safety plan, quality program, and adherence to the project schedule.

The Initial Test Program consists of a series of tests categorized as Construction Testing ("Test and Check"), Pre-operational Testing, and Startup Testing. A startup planning meeting for construction testing, pre-operational testing, and startup testing is expected to be performed.

A performance test meeting is conducted at least 120 days before commencement of the first performance test to finalize the initial coordination of the various tests. The meeting attendees include the Project Manager, Assistant Project Manager, Project Field Manager, Original Equipment Manufacturer Startup Manager, and other key personnel.

Engagement of the GEH team, OPG, and key subcontractors and vendors regularly occurs in the form of project execution planning workshops throughout the project life cycle.

The OPG oversight requirements are extended to contractor obligations to ensure its subcontractors meet their respective obligations.

Constructability workshops are held to finalize coordination between early site works subcontracted by OPG and construction. The workshops are continued throughout the project life cycle as detailed information becomes available.

A lesson learned/OPEX process is utilized through all phases of project execution. The constructability program addresses the lessons learned and implements as applicable. During construction, the team documents significant engineering, process, or construction lessons learned as they occur or, at a minimum, monthly. The appropriate lessons learned are collected and documented in the project files.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

The constructor has an approved American Society of Mechanical Engineers (ASME) Quality Program for design, fabrication, construction, and assembly of materials, systems, components, and parts governed by the ASME Boiler and Pressure Vessel Codes and National Board Inspection Code.

The constructor has appropriate ASME/National Board Inspection Code stamps and certificates necessary for the work to be performed to include S, A, U and PP, U2 & R Certificate Holder to design, fabricate, and assemble power boilers, pressure vessels, and power piping which conform to the requirements of ASME Boiler and Pressure Vessel Code, Section I, "Power Boilers", Section VIII, Division 1, "Pressure Vessels," Section VIII, Division 2, "Pressure Vessels, Alternative Rules" and ASME B31.1, "Power Piping" and the ability to perform alterations and repairs to the National Board Inspection Code and per applicable jurisdictional requirements.

For nuclear work, the constructor has appropriate ASME/National Board Inspection Code stamps and certificates necessary for the work to be performed to include N, NA, NPT, NS, CC and NR Certificate Holder to design, fabricate, and assemble components, containment, and piping which conform to the requirements of ASME Boiler and Pressure Vessel Code, Section III Division 1 and ASME Section III Division 2 and the ability to perform alterations and repairs to the National Board Inspection Code and per applicable jurisdictional requirements.

For nuclear work, the engineering service/constructor performing the work has the ASME N, NA, NPT, and NS stamps applicable to the work performed.

All members of the project management and supervision team are required to be familiar with project specifications and the contract (through self-reading or training). Construction inspection and test plans are based on design requirements and project specifications, contract requirements, local, state/provincial, and national code requirements, and specific vendor or manufacturer recommendations. These documents are distributed and discussed with the project team for a clear communication and understanding of all requirements, roles and responsibilities, and inspection points (Hold, Witness, Review). These documents are communicated to the workforce by use of installation work packages to ensure that the elements of the field quality control are applied.

Prior to the start of construction, quality requirements are identified for each work activity and planned into the work to invoke necessary in-process verification steps and controls for quality and to ensure compliance with the contract and other associated requirements. A "Work Plan" process is utilized to select methods of construction, verify material, review safety and quality concerns, and provide required quality documentation. The following is an example of some of the elements reflected in work packages with respect to quality

- Construction Inspection Test Plans
- Inspection and Test Records
- Acceptance Criteria
- Specification Tolerances

Where deviations are anticipated or required, they are managed and approved in accordance with project team approved manuals or procedures and stored in project files. If the management team has determined that it is necessary to deviate from governing documents, a formal request for deviation must be approved by the process owner before an alternate process occurs.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

Whenever non-conformances in materials, systems, components, parts, services, or workmanship are identified, assigned quality personnel (e.g., Project Quality Manager, Site Quality Manager, or Site Engineer) are notified. Non-conformances are documented, tracked, with disposition determined in accordance with approved procedures and stored in project files.

The GEH corrective action program is used for identifying improvement opportunities and other conditions adverse to quality. Corrective actions are focused on eliminating causes of the nonconformities to avoid recurrence. Refer to the approved GEH team quality manuals or similar manuals for Construction.

GEH formal audits are performed during construction to ensure the following processes and activities are effectively implemented in accordance with the governing requirements:

- Project Management
- General Construction and Site Infrastructure
- Document and Project Control
- Requisitions and Subcontracts
- Material Control
- Quality Control
- Welding and Non-Destructive Examination
- Civil Works
- Structural Steel Erection
- Boiler and Pressure Vessel Assembly
- Equipment Installation (Static and Rotating)
- Piping and Pipe Support Fabrication and Installation
- Electrical Construction
- Instrumentation and Controls
- System Turnover and Completion

During construction, official project correspondence, memoranda, calculations, drawings, procurement specifications, design specifications, stress reports, test reports, manufacturers' material certifications, manufacturers' drawings, and similar project records are considered controlled project documents. Project and quality records are controlled in accordance with quality management system requirements. Sensitive and safeguards information receive special handling as determined by GEH, OPG, Canadian, and United States requirements (as applicable).

Site documentation is maintained on-site and in the document management system. Document control administration (e.g., managing inflow and filing of documents) may be managed from the corporate (home) office. Site access to document files is controlled through the document management system.

Drawings are issued in accordance with the agreed-to project policies and procedures. Drawings are transmitted electronically, and hard copies are produced at the project site only on an as needed basis. Hard copy drawings are controlled in accordance with the project quality requirements.

Shop drawings are reviewed by the engineering and Construction Team before being released for fabrication.

Issued construction drawings are managed by the field engineering manager using the same system used by Engineering, including the revision process.

An audit process is implemented by the field whereby the drawings that are in the field are reviewed for correct revisions. The process is managed electronically, including workflow process verifications of the correct version being used.

Work packages without as-built redlines are not accepted as complete. The redline drawings are maintained in the document management system and copied to engineering. The drawings are retrievable from the document management system. As-built drawings associated with ASME Class 1, 2, or 3 piping and associated supports are processed into an engineering workflow for ASME Code Reconciliation.

#### **14.2.2 Existing Facility Effects**

The effects of hazards to or from near site facilities are considered in the assessment of safety and security during construction. The consequences of potential contamination (nuclear or hazardous substances) from a construction site to operating units and from an operating site to the construction sites are considered and assessed in Chapter 2, Sections 2.2, 2.4 and 2.8. The consideration includes an impact assessment of the cumulative environmental discharges of all facilities on the site.

Emergency response planning and response is discussed in Chapter 19.

The responsibilities of relevant licensees and construction organizations for safety and security are agreed upon before the start of construction activities with close communication established between the parties.

The boundaries of physical, system, controlled areas, security access and clean zones are identified for adjacent installations or with common buildings or services. If existing nuclear installation resources are used (e.g., water, electric power, or security), clear interfaces and limitations are defined so that the operating units and related facilities are not jeopardized.

Procedures are established that require an endorsement of a change of status for common buildings or services before construction work plans are put in place.

#### **14.2.3 Construction Readiness Review**

Prior to the beginning of construction, the readiness of contractors to proceed is ensured by a construction readiness review consistent with CNSC REGDOC-2.3.1 (Reference 14.4-2). The construction readiness review verifies:

- Management systems are in place
- Adequate planning has been conducted
- Procedures and training are completed as necessary
- Construction hazards have been adequately evaluated with control measures identified
- Environmental controls are in place consistent with assessed risks and potential or planned impacts

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

The construction readiness review assesses the following areas:

- Regulatory requirements
  - Satisfaction of all applicable regulatory requirements and all required permits (federal, provincial, and municipal) obtained.
- Management system
  - Key construction positions are established with related organizational roles and responsibilities known with the project sufficiently staffed to oversee construction.
  - Management systems are in place to monitor performance against the project baseline.
- Design completion
  - Design is sufficiently complete to allow the construction readiness review verification steps listed above to be undertaken. Incomplete areas are identified, and schedules established for completion.
- Information technology
  - Alignment and interoperability of hardware, software, information communications and the information technology environment for communications with contractors.
- Construction procedures
  - Contractor and subcontractor procedures used for completion of the facility construction in accordance with applicable regulations, design, and contract requirements.
- Materials management
  - Process for construction activities, including the acquisition of materials, delivery, inspection, packaging, storage requirements and waste management from materials receipt.
- Health, safety and environmental assurance
  - Capability of the constructor to manage a safe project that includes safety management system key requirements, specific plans and procedures related to industrial health and safety, industrial hygiene, and environmental controls. Verification that contractors have a completed project safety and health plan and environmental management plan.
- Project control
  - Adequacy of project controls that ensure adherence to the performance baseline and the systems or processes relied on for monitoring and controlling the project.
- Construction execution plan
  - Specific construction activities and the qualified personnel and procedures in place to accomplish the work; to include general construction topics such as site preparedness and work sequencing.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

- Training and qualification
  - Training and qualification of personnel responsible for construction activities to encompass the general training required for site access and specific training necessary to perform planned work activities.
- Work planning
  - Work processes are controlled by approved instructions, procedures, design documents, technical standards, or hazard controls appropriate for the task performed.
  - The organization of work and whether systems are in place and sufficiently mature to support the development of work packages or processes.
- Constructability
  - Design specifications, drawings, site conditions and construction schedule are reviewed by the construction organization and deemed practicable and efficient.
- Field engineering
  - Readiness explicit to construction of specific facility systems in accordance with the approved design, taking into account field observation feedback that may impact design.
  - Field staff in place to support construction with technical guidance and oversight and ensure adherence to the design requirements.
- Infrastructure
  - Support systems including required electricity, gas and water supply, fire protection, temporary offices and sanitation facilities, protection of SSC after installation (including environmental qualification requirements).
- QA
  - Verification of an approved QA plan to address construction and procurement activities.
- Labour management
  - Labour management necessary to successfully execute the project and ensure the adequacy of the local labour force to support the project.
- Construction tools and equipment
  - Availability and operability of tools and equipment necessary to support construction activities and ensuring the equipment meets jurisdictional requirements.

Construction of SSC is established and controlled using generally accepted construction and project management practices in accordance with the design documents. Construction activities are controlled in accordance with design drawings, specifications, and procedures that include:

- Prerequisites
- Precautions to be observed
- Installation requirements
- Sequential actions to be followed, including coordinating construction and verification activities

- Inspection and test plans
- Special equipment and procedures required for installation
- Specific document reference
- Data report forms and records
- Reviews and approvals
- Housekeeping requirements
- Foreign material exclusion requirements

#### **14.2.4 Construction Program**

The Construction Program, accepted by OPG, establishes the planning, scheduling and construction sequencing. Hold and witness points are identified with provisions for interested parties such as engineers, architects, inspectors and CNSC staff. Right of access to facilities and records for witness points or audit by the CNSC is assured.

Items with long lead times, on-site manufacturing, modular assembly, and testing are identified with provisions to ensure construction sequencing is not adversely affected. Any differences between purchasing requirements, the licence to construct design basis and as-built items are evaluated, reconciled, and reported to the authorized inspection agencies and the CNSC. Long lead items for the BWRX-300 construction include, but are not limited to:

- Reactor Pressure Vessel
- Hydraulic Control Units
- Fine Motion Control Rod Drives
- Steam Turbine Generator Set
- Reactor Pressure Vessel Internals – Large
- Main Output Transformer
- Steel Bricks™

Measures addressed in the Construction Program are in place that define OPG's contract management and oversight responsibilities. Contractors maintain a defined management system that is compliant with the current standards. OPG's oversight ensures that the required quality, health, safety, and security of the public and workers, and protection of the environment are maintained. OPG maintains records of contractor oversight activities and reports contractor performance that affects or has the potential to affect the quality of construction and future operational safety to regulators.

The Maintenance Program describes the processes for planning, monitoring, scheduling, and executing maintenance work activities performed during the construction and commissioning phases. During construction and commissioning (prior to fuel load) the maintenance, surveillance and in-service testing of components and systems will be managed by the design authority with the oversight and concurrence of OPG. This section describes the activities during construction and commissioning to ensure that maintenance, surveillance, inspection, and testing can be carried out effectively when the facility enters the operating phase.

The Maintenance Program (operations phase) is discussed in Chapter 13, Section 13.3.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

A chemistry control program, specifications, or procedures, established by the constructor, is expected to be in place to cover the requirements/aspects for the construction and commissioning phases of the project. The Chemistry Control Program establishes processes used to control contaminants to maintain system integrity during construction and commissioning.

Included in the constructor Chemistry Control Program are requirements for:

- Chemistry controls under layup conditions
- Chemistry control requirements during fabrication (provided in procurement/material specifications)
- Procedures for chemistry parameter selection, monitoring, and trending during layup and prior to startup

And the following Chemical Control Program requirements:

- Administrative controls for controlling products in the workplace
- Training
- Procedures for the storage and handling of chemicals
- Approval, procurement, and receipt of chemicals
- Listing of chemicals approved for site use, those that are precluded from site use and specifics on usage

The constructor is expected to use a quality management system planned and developed in compliance with contract requirements consistent with CSA N286 (Reference 14.4-1).

The OPG organization has oversight responsibility for Chemistry and Chemical Control Programs during the construction and commissioning phases.

The Chemistry and Chemical Control Programs, as applicable to post commissioning are described in Chapter 13, Subsection 13.3.2.

#### **14.2.4.1 Construction Plan**

The BWRX-300 design philosophy of “simplicity” and “designed for constructability” enables it to be constructed and commissioned in a short period of time.

Construction Plan details are expected to be provided in the OPG/constructor Construction Management Plan to outline compliance with CNSC REGDOC-2.3.1 (Reference 14.4-2).

#### **14.2.4.2 Planning, Scheduling, and Construction Sequence**

The project schedule utilizes the Critical Path Method technique for scheduling. The project schedule is developed in accordance with OPG and GEH standards and the project contract.

The construction Level 1 – Project Management Plan schedule provides a full set of activities and milestones with a goal of providing up to 300 MWe (nominal) to the grid by the end of 2028.

In addition, to the Level 1 plan a Level 2 – Construction, Mechanical Completion, and System Turnover Plan and a Level 3 – Engineering and Procurement Plan are developed. The project contract is expected to outline the process for modifying the Level 2 plan schedule requiring mutual agreement to modify the dates.

The Level 1 schedule is updated upon the notice to proceed and maintained monthly throughout the execution of the project.

The Level 3 schedule is routinely updated and reviewed for engineering and procurement, and also for construction and startup phase work. The progress reporting plan is aligned with OPG schedule management practices.

Overall schedule performance reporting is performed monthly with some specified weekly reporting requirements and daily updates to the schedule during construction for visibility of critical path activities.

The sequence of construction is described in the approved Construction Plan and associated schedules.

#### **14.2.4.3 Procurement and Receipt of Materials**

Processes and procedures are established to ensure equipment supplied is manufactured under a QA program that includes inspection for proper fabrication, cleanliness, calibration, and verification of operability. These processes and procedures are applicable to the construction and commissioning phases and as applicable, are continued in the operating phase within the QA program.

The Project Procurement Plan and Procurement Manual establish the purchasing process for the construction phase.

Procurement packages consisting of commercial and technical sections with any required drawing manifests are assembled into a procurement package in accordance with approved procurement processes that is reviewed by the team prior to release. OPG is provided a copy of the bid issue technical specifications. The product technical specifications establish the specific product requirements. Instructions for packaging are provided within the purchase order that describe the protection necessary during handling and transportation. If packaging and handling requirements are specified by contract, compliance is verified upon supplier notification that the material is ready for shipment. Material and equipment are categorized using a ranking system according to the consequence of failure and the probability of failure (relative risk) to determine which materials or equipment is subject to baseline assessment. The categorization uses a Level 1, 2, 3, or 4 ranking system. Criticality assessments consider the following as a minimum:

1. Consequence of equipment failure (including safety considerations, operational significance, economic significance, etc.)
2. Probable occurrence of failure
3. Complexity of the design, manufacturing process, and installation (including considerations for first of a kind designs)

Criticality ratings are established as Levels 1 and 2 (High), Level 3 (Medium), and Level 4 (low). The criticality rating is based on evaluation in five major categories: 1) plant operation, 2) financial consequences, 3) safety factors, 4) schedule (component failure), and 5) design complexity/proven technology. Risk assessment is performed on newly created specifications using a risk-based criticality assessment.

The criticality rating of the component or material sets the level of inspection requirement during manufacture.

Level 4 – Inspections may not be required or are limited to a final inspection and review of the documentation as needed to satisfy purchase specification requirements (final visual and dimensional inspection, review of testing results, positive material identification, and review of vendor data and documentation).

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

Level 3 – In addition to Level 4 inspection considerations, an order review with the vendor may be done at the initial visit. Limited event-driven, in-process inspection points may be established to satisfy purchase specification requirements (e.g., initial fit-up inspection, verification of welder qualifications, review of non-destructive examination requirements, witness testing, final visual and dimensional inspections, and review of vendor data).

Level 2 – In addition to Level 3 and Level 4 considerations, the inspector's initial visit includes a detailed order review with the vendor and may include a pre-fabrication meeting. Designated witness and hold points are established in the vendor's Quality Plan/Supplier Inspection Test Plan. Level 2 inspections require multiple, event-driven, in-process inspections. The inspection process may include progressive in-process inspections up to and including dimensional checks, visual examinations, witnessing of functional or performance testing, final acceptance, and pre-shipment inspection.

Level 1 – In addition to Level 2, 3, and 4 considerations, an initial pre-fabrication meeting with formal notification may be required. Designated witness and hold points at key manufacturing points are established in the vendor's Quality Plan/Supplier Inspection Test Plan. Intensive, event-driven visits up to and including establishment of a resident inspector may be required. The inspection process may include comprehensive, progressive in-process inspections, including dimensional checks, visual examinations, witnessing of functional or performance testing, final acceptance, and pre-shipment inspection. Sub-supplied components may require inspection prior to incorporation into the final product; inspections may be required at sub-supplier fabrication locations.

Surveillance activities are planned, monitored, performed, and reported in accordance with purchase order requirements or as deemed necessary by project management.

Procurement category inspection test plans are created and maintained by qualified personnel as needed in accordance with specification baseline supplier history, equipment use, consequence of potential failure, and supplier inspection test plans.

Components receive an initial on-site "receipt inspection" to ensure the components are as ordered, have not been damaged, and that the components are not fraudulent, counterfeit or suspect. Before acceptance for use, the component is further inspected to confirm:

- Correct configuration
- Correct identification and markings
- Manufacturing and assembly documentation (including deviations) is provided
- Associated Inspection records/certificates are traceable
- Source verification release notes for components and documentation are available, if required
- Protective covers and seals are intact
- Coatings and preservatives are not damaged
- No physical damage
- Cleanliness codes and design requirements are met
- Desiccants and inert gas blankets, where relevant, are not compromised
- Receipt inspection and detected manufacturing non-conformances to be corrected on-site are recorded.

Controls are established to prevent the inadvertent installation or use of safety class components.

Processes and procedures are established to ensure that equipment supplied is manufactured under a QA program that includes inspection for proper fabrication, cleanliness, calibration, and verification of operability.

#### **14.2.4.4 Protection of Structures, Systems, and Components**

Procurement procedures document the requirements associated with maintenance and conformity of materials and equipment during on-site fabrication and the construction cycle until turnover to OPG. Preservation requirements are specified by the parties responsible for conducting the preservation and are also defined in supplier submittals.

Measures are established to protect safety class SSC from construction activities that include:

1. Preventive and corrective maintenance requirements, as required by the design, until operational programs are initiated
2. Fabrication/manufacturing, construction, and installation process requirements that do not adversely affect ageing performance
3. Periodic monitoring of environmental conditions requirements that may apply
4. Housekeeping, cleanliness, and foreign material exclusion requirements to protect sensitive mechanical, electrical and control equipment from internal and external contamination

The following equipment protections controls are established:

1. Environmental condition limits for temperature, pressure, humidity, dust, dirt, airborne salt, wind, and electromagnetic conditions as determined by the component or system design criteria
2. Foreign material exclusion measures that prevent the introduction of outside materials, debris, tools, and components where the pose a health and safety hazard or environment impact
3. Protection requirements for installed components from personnel traffic, weather, adjacent construction activity or temporary structures
4. Implementation of system specific requirements and cleaning methods
5. Compatibility requirements for cleaning methods and materials with the components being cleaned to include cleanliness requirements before installation
6. Chemistry requirements for layup, cleaning, flushing, and conditioning of piping systems and components
7. Requirements for the removal of waste material and consumables generated during construction after completion of work

Any temporary use of safety class SSC requires authorization, and the use must perform within the component's designed safety conditions.

#### **14.2.4.5 Storage**

Components are stored in accordance with design and manufacturer guidance with the following considerations:

- Cleanliness and housekeeping practices
- Fire protection requirements
- Protective coatings, preservatives, cover and sleeves
- Physical damage prevention
- Environmental control
- Preventive maintenance requirements and in-storage maintenance
- Security against theft, vandalism, and unauthorized use or alteration
- Shelf life
- Component identification

A storage log is maintained by the engineering service/constructor that documents the proper storage and maintenance of equipment and materials to ensure compliance with contract and vendor recommendation requirements. The storage logs are periodically inspected to verify the records are being properly kept. In addition, the equipment and materials are periodically inspected to ensure that preventive maintenance is being performed. Safety Data Sheets are forwarded to the site Safety Manager for retention.

#### **14.2.4.6 On-site Manufacturing and Testing**

On-site manufacturing is located where it will not affect construction activity or safety class SSC. On-site manufacturing includes (as applicable):

- Concrete strength testing
- Rebar assembly
- Pipe spool fabrication
- Modular assemblies including Steel Bricks™
- Other on-site activities that facilitate construction

Rules and procedures are established for on-site testing to ensure that industry codes and standards are met. On-site testing to include (as applicable):

- Concrete mix
- Concrete strength
- Welded joint quality
- Process instrumentation

### **14.2.5 Work Turnover**

#### **14.2.5.1 Turnover During Construction**

Construction testing commences with the completion, or partial completion, of system/component installation and terminates at pre-operational testing for the respective system/component. The specifics of construction testing are defined in the installation specifications or in the documentation provided by the major equipment suppliers. The purpose is to demonstrate that components and systems are correctly installed, calibrated to ensure accuracy, and operational, that is ready for the application of energy. These tests may include, but are not limited to, flushing and cleaning, hydrostatic testing, initial calibration of instrumentation, checks of electrical wiring and equipment, valve testing, and initial energization and operation of equipment and systems. Completion of construction testing assures systems are ready for pre-operational testing. When construction testing is completed, also referred to as "check and test," equipment and systems are turned over to the Test Group for pre-operational testing. Pre-operational testing carries out a series of tests to demonstrate that the equipment and plant operating capacity, performance, and reliability are within the prescribed limits.

Process and procedures are established to control and coordinate the turnover of completed work and associated configuration information during construction. Transfer requirements and responsibilities are documented including with access control for safety class SSC and the associated work area established and implemented for the transfer. The SSC and work areas, as well the facility configuration information, are confirmed and verified. Deficiencies are addressed prior to turnover with work or corrective actions required to be performed by the previous owner, authorized by the current owner.

#### **14.2.5.2 Turnover to Operations/Commissioning**

Processes and procedures are established that control and coordinate the turnover of work, structures, equipment, and systems when completed and the associated configuration documentation. The transfer requirements and responsibilities are documented. Procedures are in place for the transfer and ownership of SSC and the reactor facility from the design authority, construction organization and non-OPG commissioning staff to the OPG startup and operating organization.

As construction test activities are completed, equipment and systems are turned over to the Test Group for Pre-operational and Startup Test Programs.

Turnover of SSC from one organization to another is conducted as follows:

1. One organization is designated as the lead organization and ensures that all responsibilities and limits of authority are clearly established, documented, and communicated.
2. Boundaries between SSC are clearly identified in the field and on documents.
3. System status is defined.
4. Prior to acceptance, workers perform walk downs to the extent necessary on the SSC that are being turned over to ensure that they are in the state defined in the turnover documentation but not necessarily ready for operation.
5. Incomplete items, exceptions, and completion schedules are identified and listed for resolution prior to final acceptance.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

The processes and procedures controlling turnover include the following aspects:

1. Review of the facility configuration information relating to SSC, and areas by the party turning over the work and the party receiving it for completeness and accuracy
2. Performance of tests to ensure the SSC have been manufactured, constructed, and installed to confirm to design specifications
3. Identification and assessment of any remaining non-conformances or incomplete components, to ensure there is no safety implication during commissioning activities
4. Development of inaugural or baseline inspection data for systems or components for comparative purposes for in-service inspection
5. Agreement upon, planning, and scheduling of any outstanding work
6. Identification of termination points of the boundaries of turned over SSC (or parts thereof) in turnover documentation with associated required configuration
7. Inspection of turned over components and associated records and documents
8. Verification of compatibility with information and communication technology systems when turning over electronic documents and records
9. Documentation of the turnover of responsibilities including transition of maintenance
10. Establishment and turnover of approved as-built plans together with adequate and precise plant configuration details
11. Marking and tagging of all SSC turned over

Equipment belonging to Construction is governed by Construction's managed system.

Turnover from construction to commissioning is accomplished via Construction Completion Declarations. The acceptance of a Construction Completion Declaration is a prerequisite for allowing commissioning by Operations, where required, to proceed. Commissioning is the process during which an SSC is tested and verified per design requirements. Operations is the plant configuration after successful commissioning and acceptance/turnover of the SSC and is where the SSC is used/operated in accordance with operating requirements.

Prior to first system turnover, Operations establishes the Controlling Authority. Computer software for equipment status monitoring is used by the Controlling Authority to track ownership of systems turned over to Operations and all terminal points with Construction along with the status of each component. Field demarcation is also used to identify equipment turned over to Operations. Following turnover to Operations, equipment may only be operated with Operations approval and must be operated by qualified staff.

During the design phase, formal design authority rests with the organization (GEH) that has overall responsibility for the design. Prior to fuel load, this authority is transferred to OPG.

Processes and procedures are established that control and coordinate the turnover of work, structures, equipment, and systems when completed and the associated configuration documentation. The transfer requirements and responsibilities are documented. Procedures are in place for the transfer and ownership of SSC and the reactor facility from the design authority, construction organization and non-OPG commissioning staff to the OPG operating organization.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

Prior to fuel-in-core testing, all SSC important to safety are under the control of OPG Operations. OPG maintains responsibility for safety and security at all times during the transfer. The transfer of SSC is documented, and all commissioning records are turned over to the OPG records management program to be retained for the lifetime of the facility.

Any equipment turned over to Operations may only be operated with specific Operations approval and must be operated and maintained by qualified staff using approved procedures. Any equipment belonging to Construction will be governed by Construction's managed system.

The above transition principle applies to the entire managed system including design authority. For systems turned over to Operations, the OPG management system will apply.

### **14.3 Commissioning**

#### **14.3.1 Organization**

The commissioning organization plans, organizes, coordinates, and maintains the status of deliverables associated with the turnover of the new facility. The commissioning organization is a multi-disciplinary team with individuals from the various organizations including construction contractor(s), GEH, equipment vendors, licensee, and others.

##### **14.3.1.1 Roles and Accountability**

The following is a generic overview of the roles and responsibilities of key individuals associated with the Commissioning Program:

1. Director Operations and Maintenance

The licensee's Director Operations and Maintenance is responsible for the implementation of the Commissioning Program. The Director Operations and Maintenance accepts responsibility of transferred systems and ensures their safe operation and maintenance.

2. Manager Turnover and Commissioning

The licensee's Manager Turnover and Commissioning reports to the Director Operations and Maintenance. The Manager Turnover and Commissioning is responsible for creating the organization that will oversee the turnover and commissioning of the new facility and for providing direction to that organization. The Manager Turnover and Commissioning is responsible for ensuring a smooth transition from the construction organization to the operating organization.

#### **14.3.2 Commissioning Management**

OPG is responsible for the identification of the health and safety, environmental, and other requirements applicable to commissioning activities and the communication of relevant requirements to all parties. The relevant requirements are considered and implemented via the established OPG management practices and controls.

The authorities and responsibilities of individuals and groups performing commissioning activities are clearly specified and delegated. The operating organization is responsible for the quality of construction activities, providing commissioning activity completion data (comprehensive baseline data and documentation) and providing qualified operations personnel for the commissioning process.

During and following commissioning, OPG is responsible for the following aspects, directly or as part of OPG's oversight responsibilities:

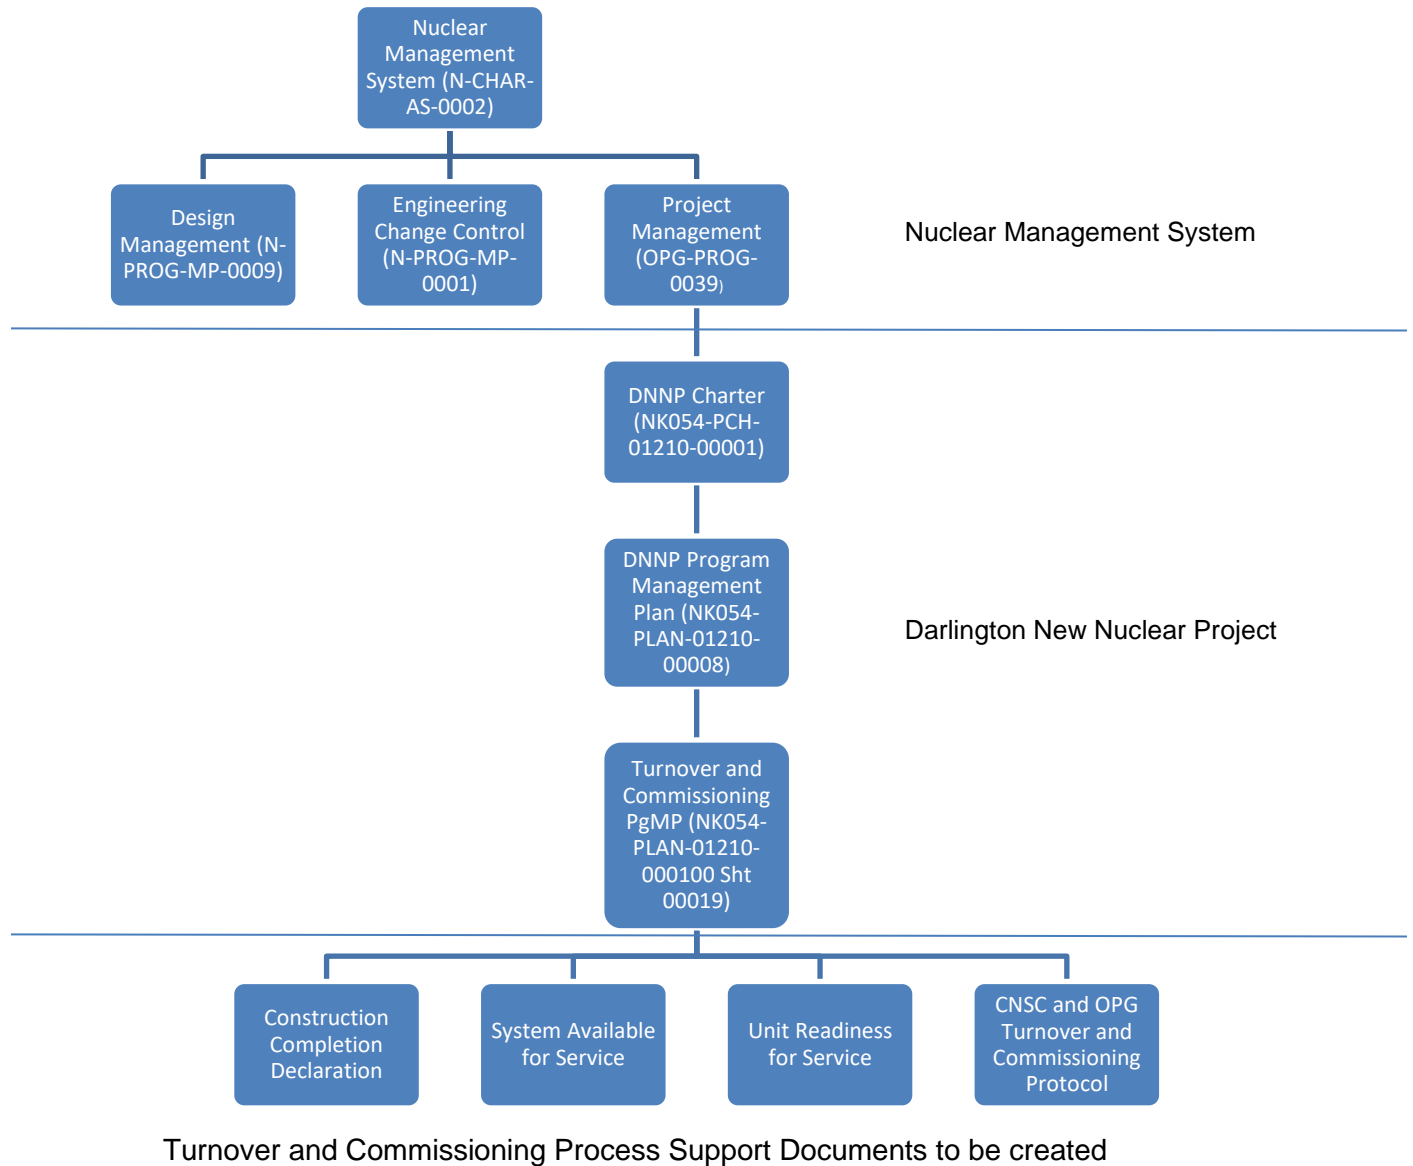

1. SSC have been constructed as per design and QA requirements are satisfied
2. SSC are tested to provide assurance that the reactor facility has been properly designed, constructed, and is ready for safe operation
3. SSC operation in accordance with the assumptions and intent of the Commissioning Program with respect to the operating limits and conditions that apply to each testing phase
4. Management, operation and maintenance of facility, systems, and components with sufficient numbers of qualified workers

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

5. Transferred systems compliance with the specified performance, design intent, and safety case
6. Documented specification of the responsibilities of other participants (designers, manufacturers, constructors, and supporting technical organizations)

The "Darlington New Nuclear Turnover and Commissioning Program Management Plan," NK054-PLAN-01210-000100 Sheet 0019 (Reference 14.4-36), describes the processes, procedures, and organization used to manage the turnover and commissioning of the facility. The program implements the applicable aspects of the OPG Nuclear Management System and is consistent with the guidance of CSA N286 (Reference 14.4-1) and CNSC REGDOC-2.3.1 (Reference 14.4-2). The framework of the plan is described in Figure 14.3.2-1.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

**Figure 14.3.2-1: Turnover and Commissioning Program Management Plan Framework**

Interface arrangements and communication between OPG, commissioning organization, operations, the CNSC and other organizational groups (construction, design, contractors, etc.) performing work are established, documented, and controlled based on collaborative agreements among OPG, GEH and the constructor with construction and commissioning OPEX taken into consideration.

Processes and procedures are established for the reporting and analysis of abnormal events, human errors, and near misses with input from OPEX incorporated as part of the procedure development. Experiences are fed back into commissioning and operating personnel training programs and considerations addressed with respect to needed changes to the design and related documents.

Turnover and Commissioning Program performance indicators are established and monitored in accordance with the Darlington New Nuclear Project Turnover and Commissioning Program Management Plan.

### **14.3.3 Commissioning Program**

The Commissioning Program covers the range of activities from completion of installation work to reactor power ascension to 100%. The Commissioning Program covers the integrated plant and all SSC consistent with CNSC REGDOC-2.3.1 (Reference 14.4-2). SSC are tested to provide assurance that the facility has been properly designed and constructed and is ready for safe operation. Commissioning is accomplished in accordance with the OPG Nuclear Operations Program and NK054-PLAN-01210-000100 Sheet 0019 (Reference 14.4-36).

The Commissioning Program:

1. Defines clear responsibilities for commissioning activities and oversight
2. Is structured such that objectives and methods of testing are understood to allow management control and coordination
3. Outlines testing performed to ensure that SSC are built as designed and meets the safety analysis requirements
4. Verifies safety analysis assumptions, satisfaction of design requirements and the presence of adequate safety and operating margins
5. Ensures tests are only conducted if the reactor facility remains with the range of assumptions made in the safety analysis and the licensing basis remains valid
6. Includes the provision of temporary equipment and utilities that may be controlled by temporary modifications
7. Identifies security systems to be commissioned before nuclear fuel or material is brought on-site
8. Documents test results and identifies any impact on or changes made to the facility design
9. Validates operating and emergency procedures
10. Ensures integrated system validation of control rooms and control areas
11. Ensures a schedule including milestones and regulatory hold points, and test results to be submitted for review are identified and communicated to the CNSC

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

The process for commissioning SSC is established and controlled to confirm that the design and safety analysis requirements are met prior to placing them in service. During commissioning of SSC, they are operated and maintained within the safe operating envelope and in accordance with documentation consistent with the design. A system of permits, tags, or equivalent controls are in place to support safe operation to include the marking of the boundary of commissioning, construction, and operational activities.

SSC are commissioned in accordance with written specifications and work procedures that clearly identify the test objectives, required performance data, acceptance criteria and prerequisites for commissioning. Interface agreements between GEH and OPG define the required types of commissioning documentation and the accountability as to which party prepares, reviews, and approves the different types of documents. The interface agreements will be managed as per OPG's Design Management program, N-PROG-MP-0009, "Design Management," (Reference 14.4-37).

The management of the regulatory interface between the CNSC and OPG is described in the Licensing Program Management Plan, NK054-PLAN-01210-00100 Sheet 00008 (Reference 14.4-32).

Commissioning documentation is verified for design conformity and commissioning results are reviewed and confirmed to be acceptable. Commissioning results are incorporated into operating documentation as appropriate. Commissioning work procedures describe the specific commissioning activities and contain:

- Precautions relative to the activities to be performed
- Back-out provisions to place the nuclear power plant in a safe condition for all anticipated risks to plant and workers
- Identification of characteristics to be inspected or tested and the conditions to be controlled
- Sequential actions to be followed, including coordinating construction, commissioning, operations
- Verification activities, and hold points to be used
- Acceptance criteria to be used
- Special equipment requirements to be used
- Data to be collected

Operating organization functions are demonstrated as part of the Commissioning Program. The demonstrated functions include:

- Management
- Personnel Training
- Radiation Protection Program
- Waste Management
- Records Management
- Fire Safety
- Physical Protection
- Emergency Plan

The administrative controls of the Commissioning Program are described in NK054-PLAN-01210-000100 Sheet 0019 (Reference 14.4-36).

In addition to GEH experience related to the commissioning and startup of new nuclear power plants, the plant OPEX from organizations such as the World Association of Nuclear Operators, Institute of Nuclear Power Operations, and Electric Power Research Institute is reviewed and applied to the development of the initial Commissioning Program of the BWRX-300.

Startup testing begins with fuel load and continues until the commercial operation milestone is met.

#### **14.3.4 Commissioning Tests**

Significant testing for commissioning is performed at the completion of construction activities to ensure that each SSC works individually and as integrated within its respective system(s). Prior to fuel load, each component and system of the BWRX-300 is tested to confirm that it will perform properly during operations. Once individual systems are tested, integrated system testing is performed with testing results evaluated for acceptability.

The activities performed in commissioning may be divided into the following categories:

1. Construction and installation testing to ensure that SSC have been manufactured, constructed, and installed according to design specifications
2. Pre-operational testing of systems prior to fuel load to confirm the operability, availability, and performance of SSC that ensure safety with fuel in the core
3. Startup testing, including initial fuel loading, subcriticality tests, initial criticality tests, low power tests, and power ascension tests to confirm reactor behavior

Testing is the core activity of the Commissioning Program and is sufficiently comprehensive to demonstrate that the facility can operate in the modes for which it has been designed. Tests necessary to demonstrate operability, safety and safety-related functions are fully performed. Where tests cannot be fully performed, documentation and the result of any alternative testing performed, is provided to demonstrate how safety and design intent has been achieved.

Brief descriptions are expected to be developed for all the commissioning tests conducted during the initial Commissioning Program, with emphasis on safety systems and safety features that are relied on for the following:

1. Safe shutdown and cool down of the plant in operational states and accident conditions
2. Conformance with Operational Limits and Conditions that will be established by the technical specifications
3. Prevention or mitigation of the consequences of anticipated operational occurrences and accident conditions

The summary of commissioning tests is expected to be included with the Licence to Operate application submission with details of all specific testing, finalized and in place prior to receipt of the Licence to Operate.

NEDO-33964 REVISION 0  
NON-PROPRIETARY INFORMATION

Testing is performed under realistic operating conditions, as practicable, and confirms any analytical validations. Proposed operating and maintenance procedures are validated to the extent practicable with participation of suitably trained and qualified operations and technical staff personnel. Operating and test procedures are verified for technical accuracy and validated to ensure usability with the installed equipment and control systems. Verification and validation is performed to the extent possible prior to fuel handling operations on-site and continued during the duration of the commissioning phase. Verification and validation is also used for overall operation procedures.

Processes are also in place for performing trial use of emergency procedures during commissioning testing.

The testing is sufficiently comprehensive to provide the reference data that characterize the SSC and provides information retained to ensure plant safety and evaluation in subsequent safety reviews.

Acceptance criteria for commissioning tests are defined by test procedure and the technical basis for the criteria is documented prior to conducting the tests. When analytical tools are used for testing, the testing and criteria are consistent with CSA N286.7, "Quality Assurance of Analytical, Scientific, and Design Computer Programs" (Reference 14.4-15).

Reviewed and approved arrangements for work control, modification control, and configuration control are established that meet the conditions of the commissioning tests. Commissioning testing is performed in accordance with procedures that have been reviewed, verified, and approved by OPG. The design authority provides the administrative controls that are used to develop, review, and approve individual test procedures, coordination with organizations involved in the test program, participation of facility operational and technical staff, and the review, evaluation, and approval of test results. Acceptance criteria for commissioning activities necessary to provide reasonable assurance that the as-built facility will conform to the approved plant design and applicable regulations are provided by the design authority.

Test results are reviewed by the commissioning organization and all deviations are resolved and operating restraints are identified and documented. Formal reports are prepared and approved by the commissioning and design organizations. Modifications to test procedures must be authorized by means of an approved process by the design authority that controls the change to documentation.

#### **14.3.5 Test Phases**

Commissioning and associated testing occurs in four basic phases with hold points to ensure the prerequisites are complete and required approvals obtained prior to transitioning from one phase to another. Hold points are controlled by the Director Operations and Maintenance, identified in the schedule, and require regulatory approval.

Criteria for the release of a hold point is addressed in the readiness for operation review. Written confirmation for hold points is provided to the CNSC that identifies the following:

1. Completion of project commitments tied to the hold point
2. Confirmation that all required system functions for safe operation beyond the hold point are available
3. Other information as appropriate

Testing is performed in a logical progressive sequence consistent with the guidance provided in CNSC REGDOC-2.3.1 (Reference 14.4-2). Review of test results for each stage is completed before commissioning continues to the next stage.

Specific testing is addressed in commissioning testing procedures. The Commissioning Program establishes the tests necessary to demonstrate the as-built, as installed plant satisfies the approved design, meets the requirements of the safety analysis report, and the plant can be operated in accordance with the operational limits and conditions.

Testing is performed in four basic phases:

- Prior to fuel load
- Prior to leaving reactor guaranteed shutdown state
- Approach to critical and low-power testing
- High power testing

#### **14.3.6 Structures, Systems, and Components and Facility Transfer**

Turnover and commissioning follow the OPG Corporate, and Nuclear Governance as described in:

- N-CHAR-AS-0002, Nuclear Management System (Reference 14.4-38)
- OPG-PROG-0039, Project Management (Reference 14.4-31)
- N-PROG-MP-0001, Engineering Change Control (Reference 14.4-39)
- N-PROG-MP-0009, Design Management (Reference 14.4-37)

Procedures are expected to be established for the transfer and ownership of SSC and the reactor facility to the OPG operating organization with detailed process steps including a description of the responsibilities and authorities of the parties involved. OPG is responsible for safety and security at all times during the transfer. The transfer of SSC is documented with all commissioning records turned over to the OPG operating organization records management program for life of the reactor facility retention.

Upon completion of the Commissioning Program, records relating to commissioning procedures and test data are transferred to the licensee's approved information management system with the appropriate retention schedule applied. Documentation is transferred in system packages over a reasonable time dependent on how responsibilities for testing are assigned and to allow a comprehensive review of every package.

0	All	Initial Release

### ACRONYM LIST

Acronym	Explanation
AAZ	Automatic Action Zone
AC	Alternating Current
ACRW	All Control Rod Withdrawal at Power
ALWR	Advanced Light Water Reactor
ANS	American Nuclear Society
ANSI	American National Standards Institute
AOO	Anticipated Operational Occurrence
ASME	American Society of Mechanical Engineers
AST	Alternative Source Term
ATLM	Automatic Thermal Limit Monitor
BDBA	Beyond Design Basis Accident
BE	Best Estimate
BIS	Boron Injection System
BL-AOO	Baseline Abnormal Operational Occurrence
BL-DBA	Baseline Design Basis Accident
BL-DSA	Baseline Deterministic Safety Analysis
BOP	Balance of Plant
BWR	Boiling Water Reactor
CAFTA	Computer Aided Fault Tree Analysis
CANDU	CANada Deuterium Uranium
CB	Control Building
CCDP	Conditional Core Damage Probability
CCF	Common Cause Failure
CDF	Core Damage Frequency
CET	Containment Event Tree
CIV	Containment Isolation Valve
CN-DBA	Conservative Design Basis Accident
CN-DSA	Conservative Deterministic Safety Analysis
CNSC	Canadian Nuclear Safety Commission
CPR	Critical Power Ratio
CRD	Control Rod Drive

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
CRDA	Control Rod Drop Accident
CRDM	Control Rod Drive Motor
CSA	CSA Group
CSAU	Code Scaling, Applicability, and Uncertainty
CUW	Reactor Water Cleanup System
CWS	Circulating Water System
DBA	Design Basis Accident
DCF	Dose Conversion Factor
DCIS	Distributed Control and Information System
DEC	Design Extension Condition
DF	Decontamination Factor
DL	Defense Line
D-in-D	Defence-in-Depth
DNGS	Darlington Nuclear Generating Station
DNNP	Darlington New Nuclear Project
DSA	Deterministic Safety Analysis
EAB	Exclusion Area Boundary
ECCS	Emergency Core Cooling System
EHE	External Hazard Evaluation
EOC	End of Cycle
EOP	Emergency Operating Procedure
EOR	End of Rated Cycle
EPRI	Electric Power Research Institute
ESBWR	Economic Simplified Boiling Water Reactor
EX-DBA	Extended Design Basis Accident
EX-DEC	Extended Design Extension Condition
EX-DSA	Extended Deterministic Safety Analysis
FFHE	Functional Failure Hazard Evaluation
FHA	Fuel Handling Accident
FLEX	Diverse and Flexible Coping Strategy
FMCRD	Fine Motion Control Rod Drive
FMEA	Failure Modes and Effects Analysis

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
FSF	Fundamental Safety Function
FV	Fussell-Vesely
FW	Feedwater
FWCIV	Feedwater Containment Isolation Valve
FWFI	Feedwater Flow Increase
FWPT	Feedwater Pump Trip
GEH	GE Hitachi Nuclear Energy
HCU	Hydraulic Control Unit
HEP	Human Error Probabilities
HFE	Human Factors Engineering
HOHE	Human Operation Hazard Evaluation
HRA	Human Reliability Analysis
HVAC	Heating, Ventilation, and Air Conditioning
I&C	Instrumentation and Control
IAEA	International Atomic Energy Agency
ICRW	Inadvertent Control Rod Withdrawal at Power – Single Rod
ICS	Isolation Condenser System
IE	Initiating Event
IHE	Internal Hazard Evaluation
IR	Inventory Reduction
LFWH	Loss of Feedwater Heating
LOCA	Loss-of-Coolant Accident
LOPP	Loss-of-Preferred Power
LPSD	Low Power Shutdown
LPZ	Low Population Zone
LRF	Large Release Frequency
LR-TT	Load Reduction – Turbine Trip
MAAP	Modular Accident Analysis Program
MCC	Motor Control Center
MCCI	Molten Core Concrete Interaction
MCPR	Minimum Critical Power Ratio
MCR	Main Control Room

NON-PROPRIETARY INFORMATION

<b>Acronym</b>	<b>Explanation</b>
MCS	Minimal Cutset
MOC	Middle of Cycle
MRBM	Multi-Channel Rod Block Monitor
MS	Main Steam
MSCIV	Main Steam Containment Isolation Valve
MSL	Main Steam Line
MSRIV	Main Steam Reactor Isolation Valve
NBS	Nuclear Boiler System
NBR	Nuclear Boiler Rated
NPP	Nuclear Power Plant
OBE	Operating-Basis Earthquake
ODE	Ordinary Differential Equation
OLC	Operational Limits and Conditions
OLMCPR	Operating Limit Minimum Critical Power Ratio
OCC	Out Of Core Criticality
OPEX	Operating Experience
OPG	Ontario Power Generation
PA	Postulated Accident
PCCS	Passive Containment Cooling System
PCT	Peak Cladding Temperature
PCW	Plant Cooling Water System
PI-AOO	Pressure Increase- Abnormal Operational Occurrence
PIE	Postulated Initiating Event
PIRT	Phenomena Identification and Ranking Table
POS	Plant Operating State
PPS	Plant Pneumatics System
PRA	Probability Risk Assessment
PSA	Probabilistic Safety Assessment
PSAR	Preliminary Safety Analysis Report
PSIG	Pounds per Square Inch Gauge
PWR	Pressurized Water Reactor
QHO	Quantitative Health Objectives

## 15.0 SAFETY ANALYSIS

This chapter includes the following safety analyses complying with the requirements of CNSC REGDOC-1.1.2, Section 4.4.1, Draft Version 2 (Reference 15.1-1):

- Hazards Analysis
- Deterministic Safety Analysis (DSA)
- Probabilistic Safety Assessment (PSA)

The safety analysis primary objective is demonstrating that the Fundamental Safety Functions (FSFs) (see Chapter 3, Subsection 3.1.5) are effective in:

- Controlling reactivity
- Removing heat from the fuel (reactor or fuel pool)
- Confining radioactive materials
  - Shielding against radiation
  - Controlling operational discharges
  - Limiting accidental releases

The BWRX-300 design basis is achieved through an iterative safety process. The design is implemented to meet defined safety objectives that are confirmed via the safety analyses. Results of the safety analyses provide feedback to the design. If indicated by the results, the design may be modified until safety objectives are met.

This chapter documents the safety objective and the safety analyses approach, description and results performed for the BWRX-300 design. The DSA and the PSA are conducted in compliance with CNSC REGDOC-2.4.1 (Reference 15.1-2), and CNSC REGDOC-2.4.2 (Reference 15.1-3), respectively. The content of Chapter 15 is structured as follows:

Section 15.1 General Considerations of the BWRX-300 Safety Analyses:

- Safety Analysis Objectives, Scope, and Approach
- Analysis of Hazards – Scope and Approach
- Analysis of Design Basis Conditions - Scope and Approach
- Analysis of Design Extension Conditions Without Core Damage Scope and Approach
- Analysis of Beyond Design Basis Accidents (BDBAs) with Core Damage (Severe Accident)- Scope and Approach

Section 15.2 Identification, Categorization, and Grouping of Postulated Initiating Events and Accident Scenarios discusses:

- Development of categorizing events according to their frequencies
- Grouping of events according to their types
- Selection of the bounding events for each group type

Section 15.3 Safety Objectives and Acceptance Criteria discusses:

- Safety objectives based upon the safety strategy

NEDO-33965 REVISION 0  
NON-PROPRIETARY INFORMATION

- Associated acceptance criteria for Anticipated Operational Occurrences (AOOs), Design Basis Accidents (DBAs) and safety goals

Section 15.4 Human Actions discusses:

- General Considerations
- Human Actions considered in the DSA
- Human Actions considered in the PSA

Section 15.5 Deterministic Safety Analysis discusses:

- Safety margins in the safety analysis (Subsection 15.5.1)
- Analysis of normal operations (Subsection 15.5.2)
- Analysis of AOOs (Subsection 15.5.3)
- Analysis of DBAs (Subsection 15.5.4)
- Analysis of Design Extension Conditions (DECs) without core damage (Subsection 15.5.5)
- Analysis of DECs with core damage (Subsection 15.5.6)
- Analysis of PIEs and accident scenarios associated with the fuel pool (Subsection 15.5.7)
- Analysis of fuel handling events (Subsection 15.5.8)
- Analysis of radioactive release from a system or component outside containment Loss-of-Coolant-Accidents (LOCA) outside containment (Subsection 15.5.9)
- Analysis of internal and external hazards (Subsection 15.5.10)

Section 15.6 Probabilistic Safety Assessment discusses:

- General approach to the PSA (Subsection 15.6.1)
- Results of the Level 1 PSA (Subsection 15.6.2)
- Results of the Level 2 PSA (Subsection 15.6.3)

Section 15.7 Summary Results of the Safety Analyses discusses:

- Analysis results of normal operation (Subsection 15.7.1)
- Analysis results of AOOs and DBAs (Subsection 15.7.2)
- Analysis results of DECs without core damage (Subsection 15.7.3)
- Analysis results of DECs with core damage (Subsection 15.7.4)
- Analysis results of fuel pool events (Subsection 15.7.5)
- Analysis results of fuel handling events (Subsection 15.7.6)
- Analysis results of radioactive releases from LOCAs outside containment (Subsection 15.7.7)
- Analysis results of internal and external hazards (Subsection 15.7.8)
- Analysis results of the PSA (Subsection 15.7.9)

Appendix 15A discusses reference source term for conditions that are practically eliminated.

Appendix 15B discusses complementary design features for mitigating DEC's.

Chapter 15 documents the analysis and results from the BWRX-300 plant safety analyses.

### **15.1 General Considerations of the BWRX-300 Safety Analyses**

The BWRX-300 safety strategy framework integrates the Defense Lines (DLs) provided by the implementation of the Defence-in-Depth (D-in-D) concept (defined in CNSC REGDOC-2.5.2, Section 4.3.1 (Reference 15.1-4) with the safety analyses. The D-in-D concept uses insights gained from operating experience and deterministic and risk-informed and performance-based analyses.

Chapter 3 defines the safety strategy framework implementation process shown on Figure 3.1-2. Design features, functions, and practices are organized into DLs that protect the integrity of the physical barriers against the radioactive releases. Safety analyses are performed that demonstrate the effectiveness of the Structures, Systems, and Components (SSCs) necessary to perform the functions assigned in various DLs that are credited to mitigate the Postulated Initiating Events (PIEs). The SSCs necessary to achieve the DL safety functions are described in Chapters 4 through 8. The PIEs analyzed are identified and selected through the systematic process of fault evaluation described in Section 15.2.

The safety analyses prove that the plant design meets the underlying safety objectives and acceptance criteria for event mitigation and confirms that the applicable regulatory safety objectives are met.

#### **15.1.1 Safety Analysis Objectives, Scope, and Approach**

The general Nuclear Safety Objectives in Chapter 3, Subsection 3.1.1 are demonstrated by the results from the safety analyses. Chapter 3, Figure 3.1-2 presents a graphical representation of the safety analysis performed according to the BWRX-300 safety strategy framework that includes:

- Hazards Analysis
- Deterministic Safety Analysis (DSA)
- Probabilistic Safety Assessment (PSA)

The Hazard Analysis consists of four types of hazard evaluations described in Subsection 15.1.2. The main objectives of the hazard evaluations are the identification of potential PIEs and confirmation that the plant design effectively responds to credible internal and external hazards.

The safety analysis objectives include:

- Demonstrating the design meets the acceptance criteria established following a graded approach for each plant state. The graded approach application may lead to acceptance criteria more restrictive for events with higher occurrence probability.
- Deriving and confirming Operational Limits and Conditions (OLCs) for normal operation
- Establishing and validating accident management procedures and guidelines

The safety analysis scope includes the plant states described in Chapter 3, Subsection 3.1.3 and illustrated in Figure 3.1-1. The plant states are consistent with CNSC REGDOC-2.5.2, Section 7.3 and includes:

- Normal operation
- AOOs

- DBAs
- BDBAs

The subset of BDBA or DECAs may occur without core damage or with core damage.

The hazards analysis consists of four types of hazard evaluations described in Subsection 15.1.3. The hazards evaluation main objective is the identifying potential PIEs and demonstrating the plant design effectively responds to credible internal and external hazards.

The BWRX-300 DSA uses a layered analysis approach that includes three types of DSA evaluations:

- Baseline – deterministic safety analysis (BL-DSA)
- Conservative – DSA (CN-DSA)
- Extended – deterministic safety analysis (EX-DSA)

This approach addresses initiating and mitigating DL function failures in a more systematic and structured manner than past approaches.

These DSA acceptance criteria are discussed in Section 15.3. The DSA results are compared against the applicable plant state acceptance criteria and dose limits specified in Subsection 15.3.1.

The PSA is performed to complement the DSA. PSA estimates the overall risk presented by the facility that is compared to the regulatory safety goals specified in Subsection 15.3.2. The PSA is presented in Section 15.6.

### **15.1.2 Analysis of Hazards**

An initial step in performing the safety analysis is a systematic hazards evaluation. The BWRX-300 Safety Strategy process described in Chapter 3, Subsection 3.1.6.4 identifies four types of hazard evaluations for the complete range of operational modes (full power, low power, load following, shutdown and refueling) that produces a comprehensive set of PIEs:

- Functional Failure Hazard Evaluation (FFHE)
- External Hazard Evaluation (EHE) – addressed in Chapters 3, 6, Sections 3.3, 6.5, respectively
- Internal Hazard Evaluation (IHE) Chapter 3, Section 3.4, Chapter 6, Section 6.5, Chapter 9A, Section 9A.6
- Human Operation Hazard Evaluation (HOHE)

The hazard evaluations include any consequential failure that occurs because of the PIE. They also address all sources of radioactivity (e.g., spent fuel, fuel being handled) in addition to the reactor core itself.

Each hazard evaluation identifies any potential challenges to an FSF.

#### **15.1.2.1 Functional Failure Hazard Evaluation**

The FFHE identifies failures of plant systems or equipment with potential to cause a challenge to an FSF. These hazards are identified in Failure Modes and Effect Analyses (FMEAs) performed on the plant systems.

The FFHE is limited to random single failures and to CCFs. The system FMEAs are reviewed to identify failures that cause challenges to FSFs. A consolidated list of failures from all system FMEAs is generated and organized.

The functional failure hazard potential PIE sources are organized by quantitative frequency, using the frequency ranges defined in the Safety Strategy.

#### **15.1.2.2 External Hazard Evaluation**

The EHE includes natural and human-induced hazards that originate from a source that is not under control of the nuclear power plant licence holder. The EHE addresses individual hazard sources and combinations of sources:

- Natural external hazards include earthquakes, droughts, floods, high winds, tornadoes, tsunami, and extreme meteorological conditions
- Human-induced external hazards include toxic gas releases, aircraft crashes, or ship collisions

External events are site-specific and are specified in the site evaluation provided in Chapter 2.

Once the external hazards are identified, the BWRX-300 structures are designed to withstand these external hazards, and the resulting protection is described in Chapter 9B. Human-induced external hazards such as toxic gas and aircraft impacts are provided in Chapter 6, Section 6.5 for control room habitability.

The sources of external hazard or combinations are organized by quantitative frequency as potential PIEs evaluated in the fault evaluation (see Chapter 3, Section 3.3). Malevolent acts are addressed in the Security Annex.

#### **15.1.2.3 Internal Hazard Evaluation**

The IHE identifies conditions originating within the boundaries of the site and with potential to lead to an unplanned plant transient. The internal hazard condition does not directly challenge an FSF, but the effects of the hazard may cause equipment failures. These equipment failures are then evaluated in the deterministic and probabilistic safety analyses.

Internal hazards include:

- Fires (discussed in Chapter 9A, Section 9A.6)
- Explosions, missiles from rotating or pressurized equipment (discussed in Chapter 3, Section 3.4)
- Collapse of structures/falling objects (discussed in Chapter 9B)
- Pipe whip, jet effects, and flooding (discussed in Chapter 3, Section 3.6)

The IHE addresses both individual hazard sources and combinations of sources.

The sources of internal hazard or combinations are organized by quantitative frequency as potential PIEs and evaluated in the fault evaluation (see Chapter 3, Section 3.4).

#### **15.1.2.4 Human Operation Hazard Evaluation**

The HOHE identifies erroneous decisions or human action(s) that lead to an unplanned plant transient. Human operations hazards, typically involve unplanned changes to plant equipment status by equipment operators or maintenance personnel.

Many human operations hazards produce the same effects as corresponding equipment failures and the effects of these are included in the FFHE described in Subsection 15.1.3.1. The HOHE

is limited to a single erroneous act that may lead to multiple system responses. The HOHE focuses on identifying unique hazards such as an operator initiating a group command on multiple actuators that is beyond what is considered in a single failure analysis of a particular system.

The sources of HOHE or combinations are organized by quantitative frequency as potential PIEs and evaluated in the fault evaluation (see Section 15.5).

### 15.1.3 Analysis of Design Basis Conditions

The BWRX-300 design basis conditions are normal operations, AOOs and DBAs described below:

1. **Normal Operation** is operation within specified OLCs (see Chapter 16) and includes the full range of plant operating modes (Chapter 1, Section 1.8.). The objective of the normal operation safety analysis is to demonstrate that DL1 measures are effective in preventing abnormal operations and failures, thus meeting radiological requirements.
2. **AOOs** are deviations from normal operation that are expected to occur at least once during the operating lifetime of the reactor facility. The objective of the AOO safety analysis is to demonstrate that DL2 functions are effective for most AOO PIEs in meeting the applicable acceptance criteria.
3. **DBAs** conditions are identified as deviations from normal operations that are less frequent and more severe than AOOs. An objective of DBA safety analysis is to demonstrate that DL3 functions are effective in mitigating events and meeting the applicable acceptance criteria.

Acceptance criteria applicable to the DSA for each plant state is discussed in Subsection 15.3.1. The response to AOOs and DBAs is achieved by SSCs specifically designed to mitigate these events and are assigned DL2 and DL3 functions (Chapter 3, Subsection 3.1.6.2).

The DSA results for design basis conditions in Section 15.7 demonstrate that the requirements of CNSC REGDOC-2.4.1 are met.

### 15.1.4 Analysis of Design Extension Conditions Without Core Damage

DECs are a subset of BDBAs. DECs are postulated accident conditions that are less frequent than DBAs. DECs may occur with or without core damage.

DSA is performed for DECs without core damage demonstrating that releases of radioactive material are kept within acceptable limits and support the PSA determination of no core damage.

DEC analysis include:

- Multiple failures defined as complex sequences identified in the Level 1 PSA or as a PIE with a Common Cause Failure (CCF)
- AOO and DBAs with postulated failures of DL2 and DL3 functions analyzed in EX-DSA. For these events, the DBA acceptance criteria are used as screening criteria to the evaluation of core damage
- Low frequency events
- Non-reactor fault sequences (fuel pool accidents) are analyzed in Level 1 PSA

The results of the DSA for DECs without core damage are discussed in Section 15.7. The analysis of DECs with core damage are addressed in the Level 2 PSA described in Subsection 15.6.4.

#### **15.1.5 Analysis of Beyond Design Basis Accidents with Core Damage (Severe Accident)**

These are referred to as Severe Accidents (SA) and involve a catastrophic failure, core damage, and fission product release. A SA is generally considered to begin with the onset of core damage. To the extent that core damage is not practically eliminated, representative DECAs with core damage are postulated to provide inputs for the containment design and safety features ensuring containment functionality. This set of accidents is considered in the design of corresponding safety features for DECAs and represents a set of bounding cases. Accident scenarios considered for practical elimination are described in Appendix 15A.

Severe accident sequences are selected that identify representative core damage scenarios and corresponding plant damage states that are used as the basis for performing the Severe Accident Analysis (SAA). The scope of SA scenario selection corresponds to sequences involving significant core damage that could lead to a containment breach and radioactive release analyzed in the Level 2 PSA in Section 15.6. The selected SA scenarios are included in a fault evaluation.

The SAA goal is to provide input to accident management for terminating the progression of core damage, maintaining containment integrity as long as possible, and minimizing on-site and offsite radioactive material releases. Halting core damage progress prevents Reactor Pressure Vessel (RPV) failure.

The response to SAs considers the use of safety and non-safety, permanent and temporary systems and equipment that are beyond their originally intended functions.

Consistent with SSR 2/1, Paragraph 2.11 (Reference 15.3-3), practical elimination is applied to events or sequences of events leading to or involving core damage (a severe accident) where confinement of radioactive materials cannot be reasonably achieved. Event sequences that are either physically impossible or extremely unlikely to occur are considered for practical elimination.

The practical elimination demonstration is performed with accident conditions and phenomena knowledge and is substantiated by relevant evidence (see Appendix 15A Reference Source Term for Conditions That Are Practically Eliminated).

## **15.2 Identification, Categorization and Grouping of Postulated Initiating Events and Accident Scenarios**

A fundamental element of the safety analyses is the identification and selection of PIEs that is achieved through systematic process of fault evaluation. The fault evaluation objective includes:
