Glossary

Term	Definition
Concordance table	A table that summarizes where requirements are met within the Environmental Impact Statement.
Environmental Assessment	An assessment of potential environmental consequences of a project. The environmental assessment considers the existing environment where the Project is to be located (including, but not limited to, Indigenous and Local Knowledge), predicts potential effects to valued components of the environment, identifies mitigation measures used to limit the effects of the project on the local environment, classifies potential effects remaining after mitigation, and describes monitoring and follow-up programs.
Environmental Impact Statement	A document that contains the environmental assessment for a project, and can also include details on the project description, engagement, mitigation measures, residual and cumulative effects, accidents and malfunctions, and effects of the environment on the project.
Greenhouse gas	A gas in the Earth's atmosphere that absorbs and emits infrared radiation. The most common examples include carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O).
In situ recovery	A mining method that uses a water-based solution, fortified with mining reagents, to dissolve naturally occurring uranium from within a host rock, while the host rock remains in place (in-situ) below surface.

1 Project Introduction and Overview

The Wheeler River Project (the Project) is a proposed in situ recovery (ISR) uranium mine and processing plant in northern Saskatchewan, Canada (Figure 1-1). It is located in Saskatchewan's Athabasca Basin approximately 4 km west of Highway 914 (Figure 1-2). The approximate UTM coordinates of the property are 477,000E and 6,374,000N (NAD83, Zone 13). The Project is a joint venture between Denison Mines Corp. (Denison; 90%) and JCU (Canada) Exploration Company Ltd. (JCU; 10%). Denison is also a 50% owner of JCU, which means that Denison has an effective 95% ownership interest in the Project.

The Project falls within the boundaries of Treaty 10, the Nuhtsiye-kwi Benéne (Ancestral Lands) of English River First Nation, the traditional territory of the Kineepik Métis Local #9, the homeland of the Métis, and the Nuhenéné, the traditional territory of the Athabasca Denesųłiné. The Project is also located within the Northern Saskatchewan Administration District (Figure 1-3; Figure 1-4). The Northern Saskatchewan Administration District includes approximately 250,000 km^2 (44% of Saskatchewan's land area) and is home to approximately 36,000 people (3.2% of Saskatchewan's population; Statistics Canada 2022).

Figure 1-1: Wheeler River Project Location in Canada

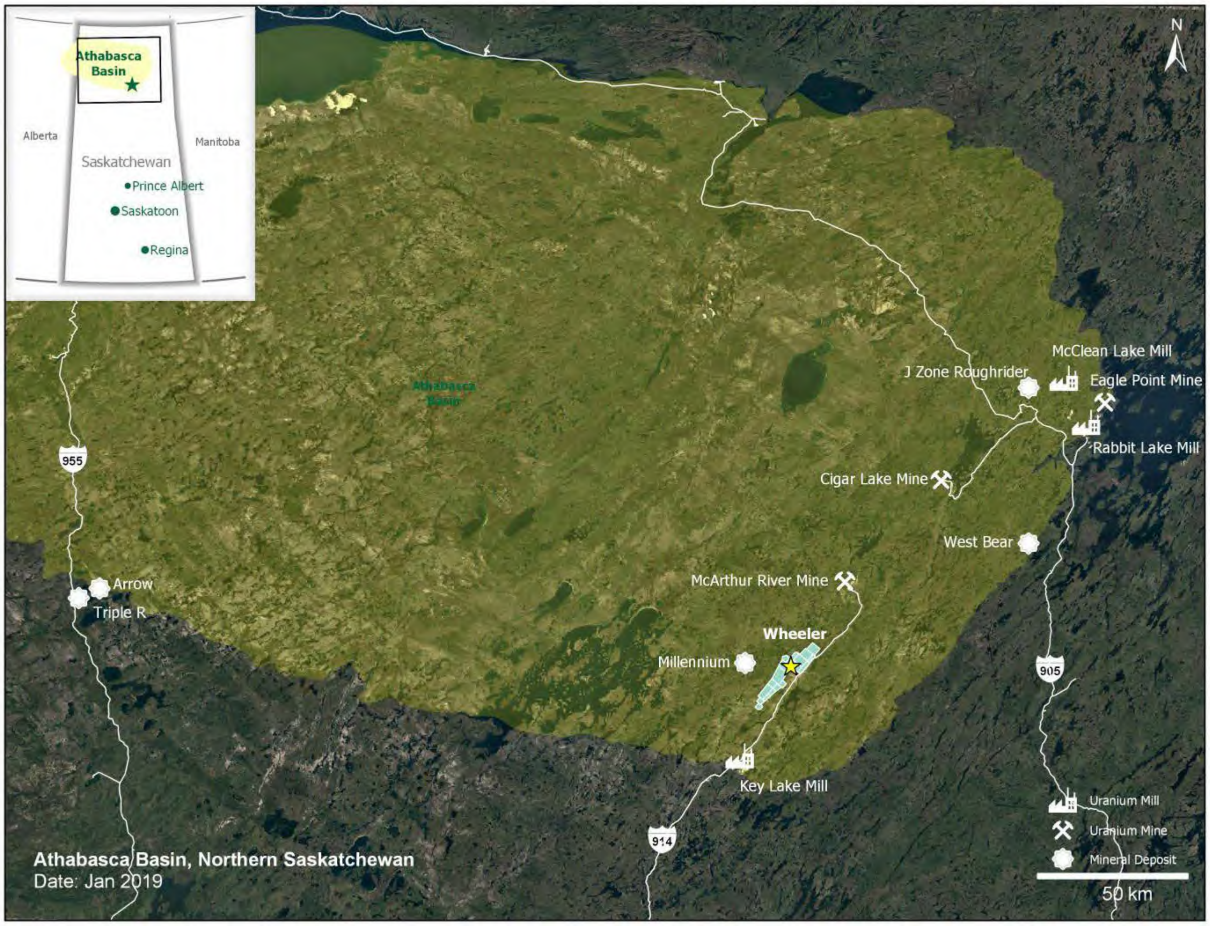

Figure 1-2: Wheeler River Project Location in the Athabasca Basin

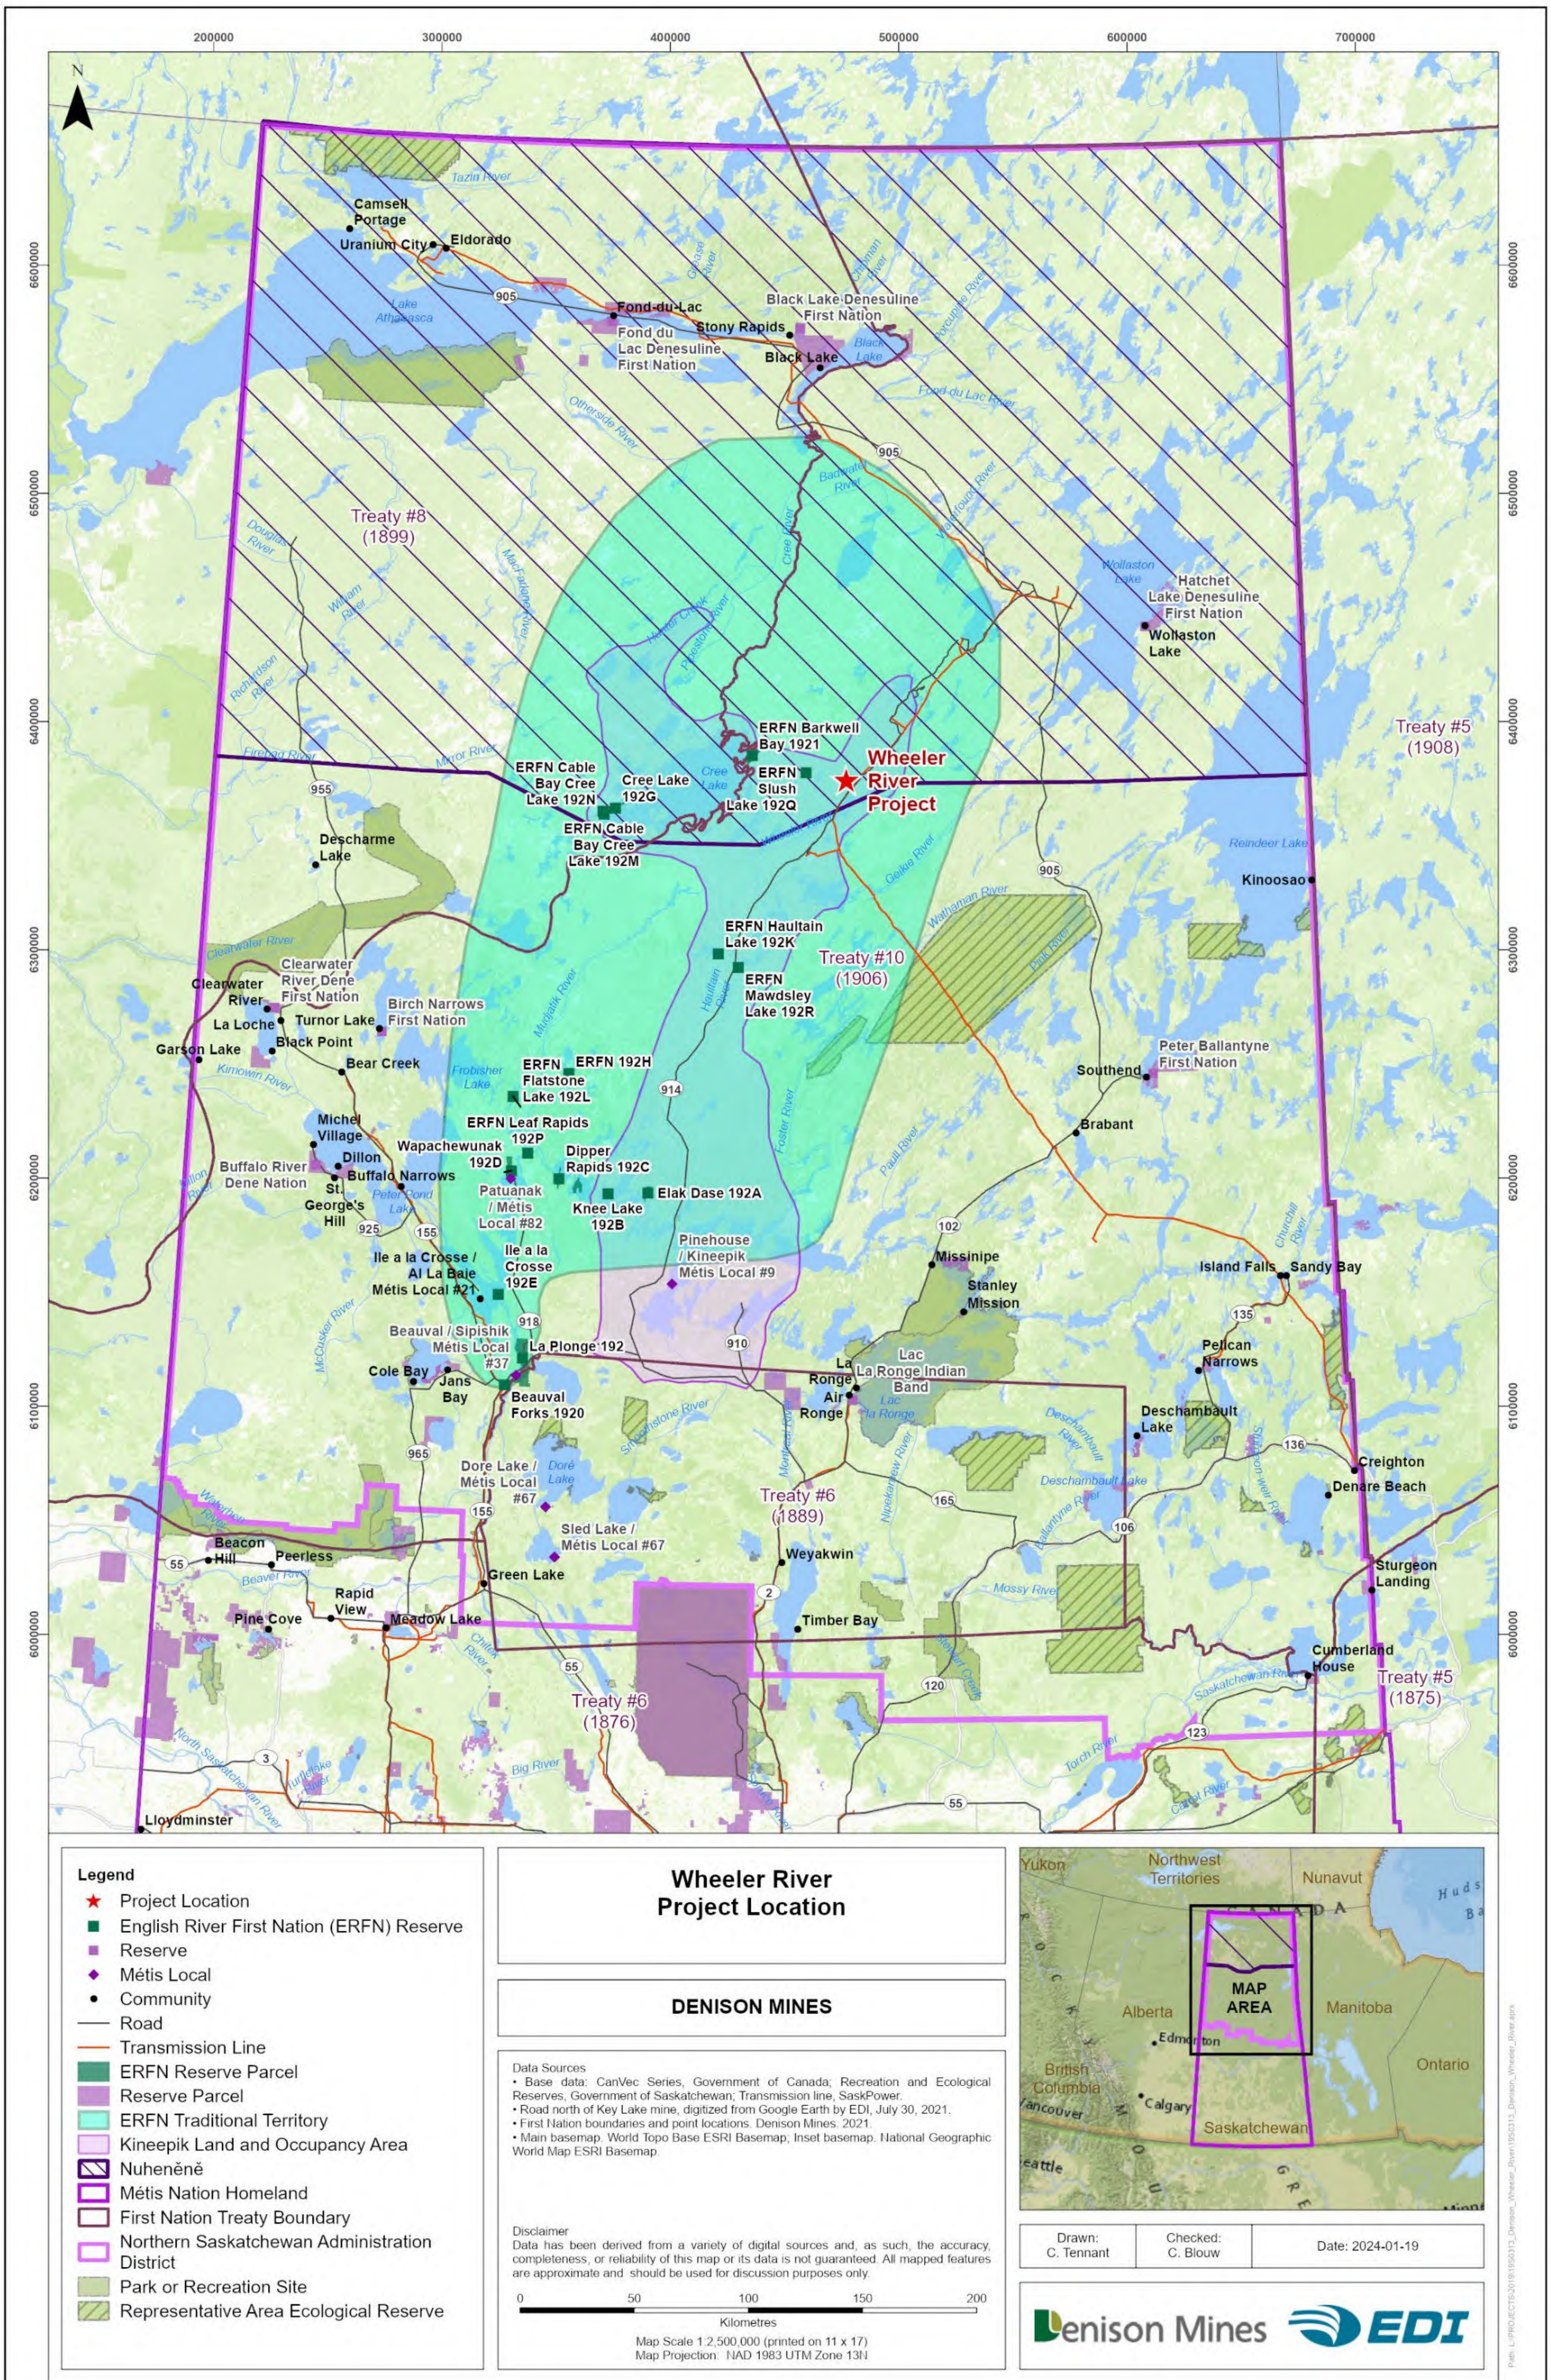

Figure 1-3: Wheeler River Project in Relation to Traditional Territories

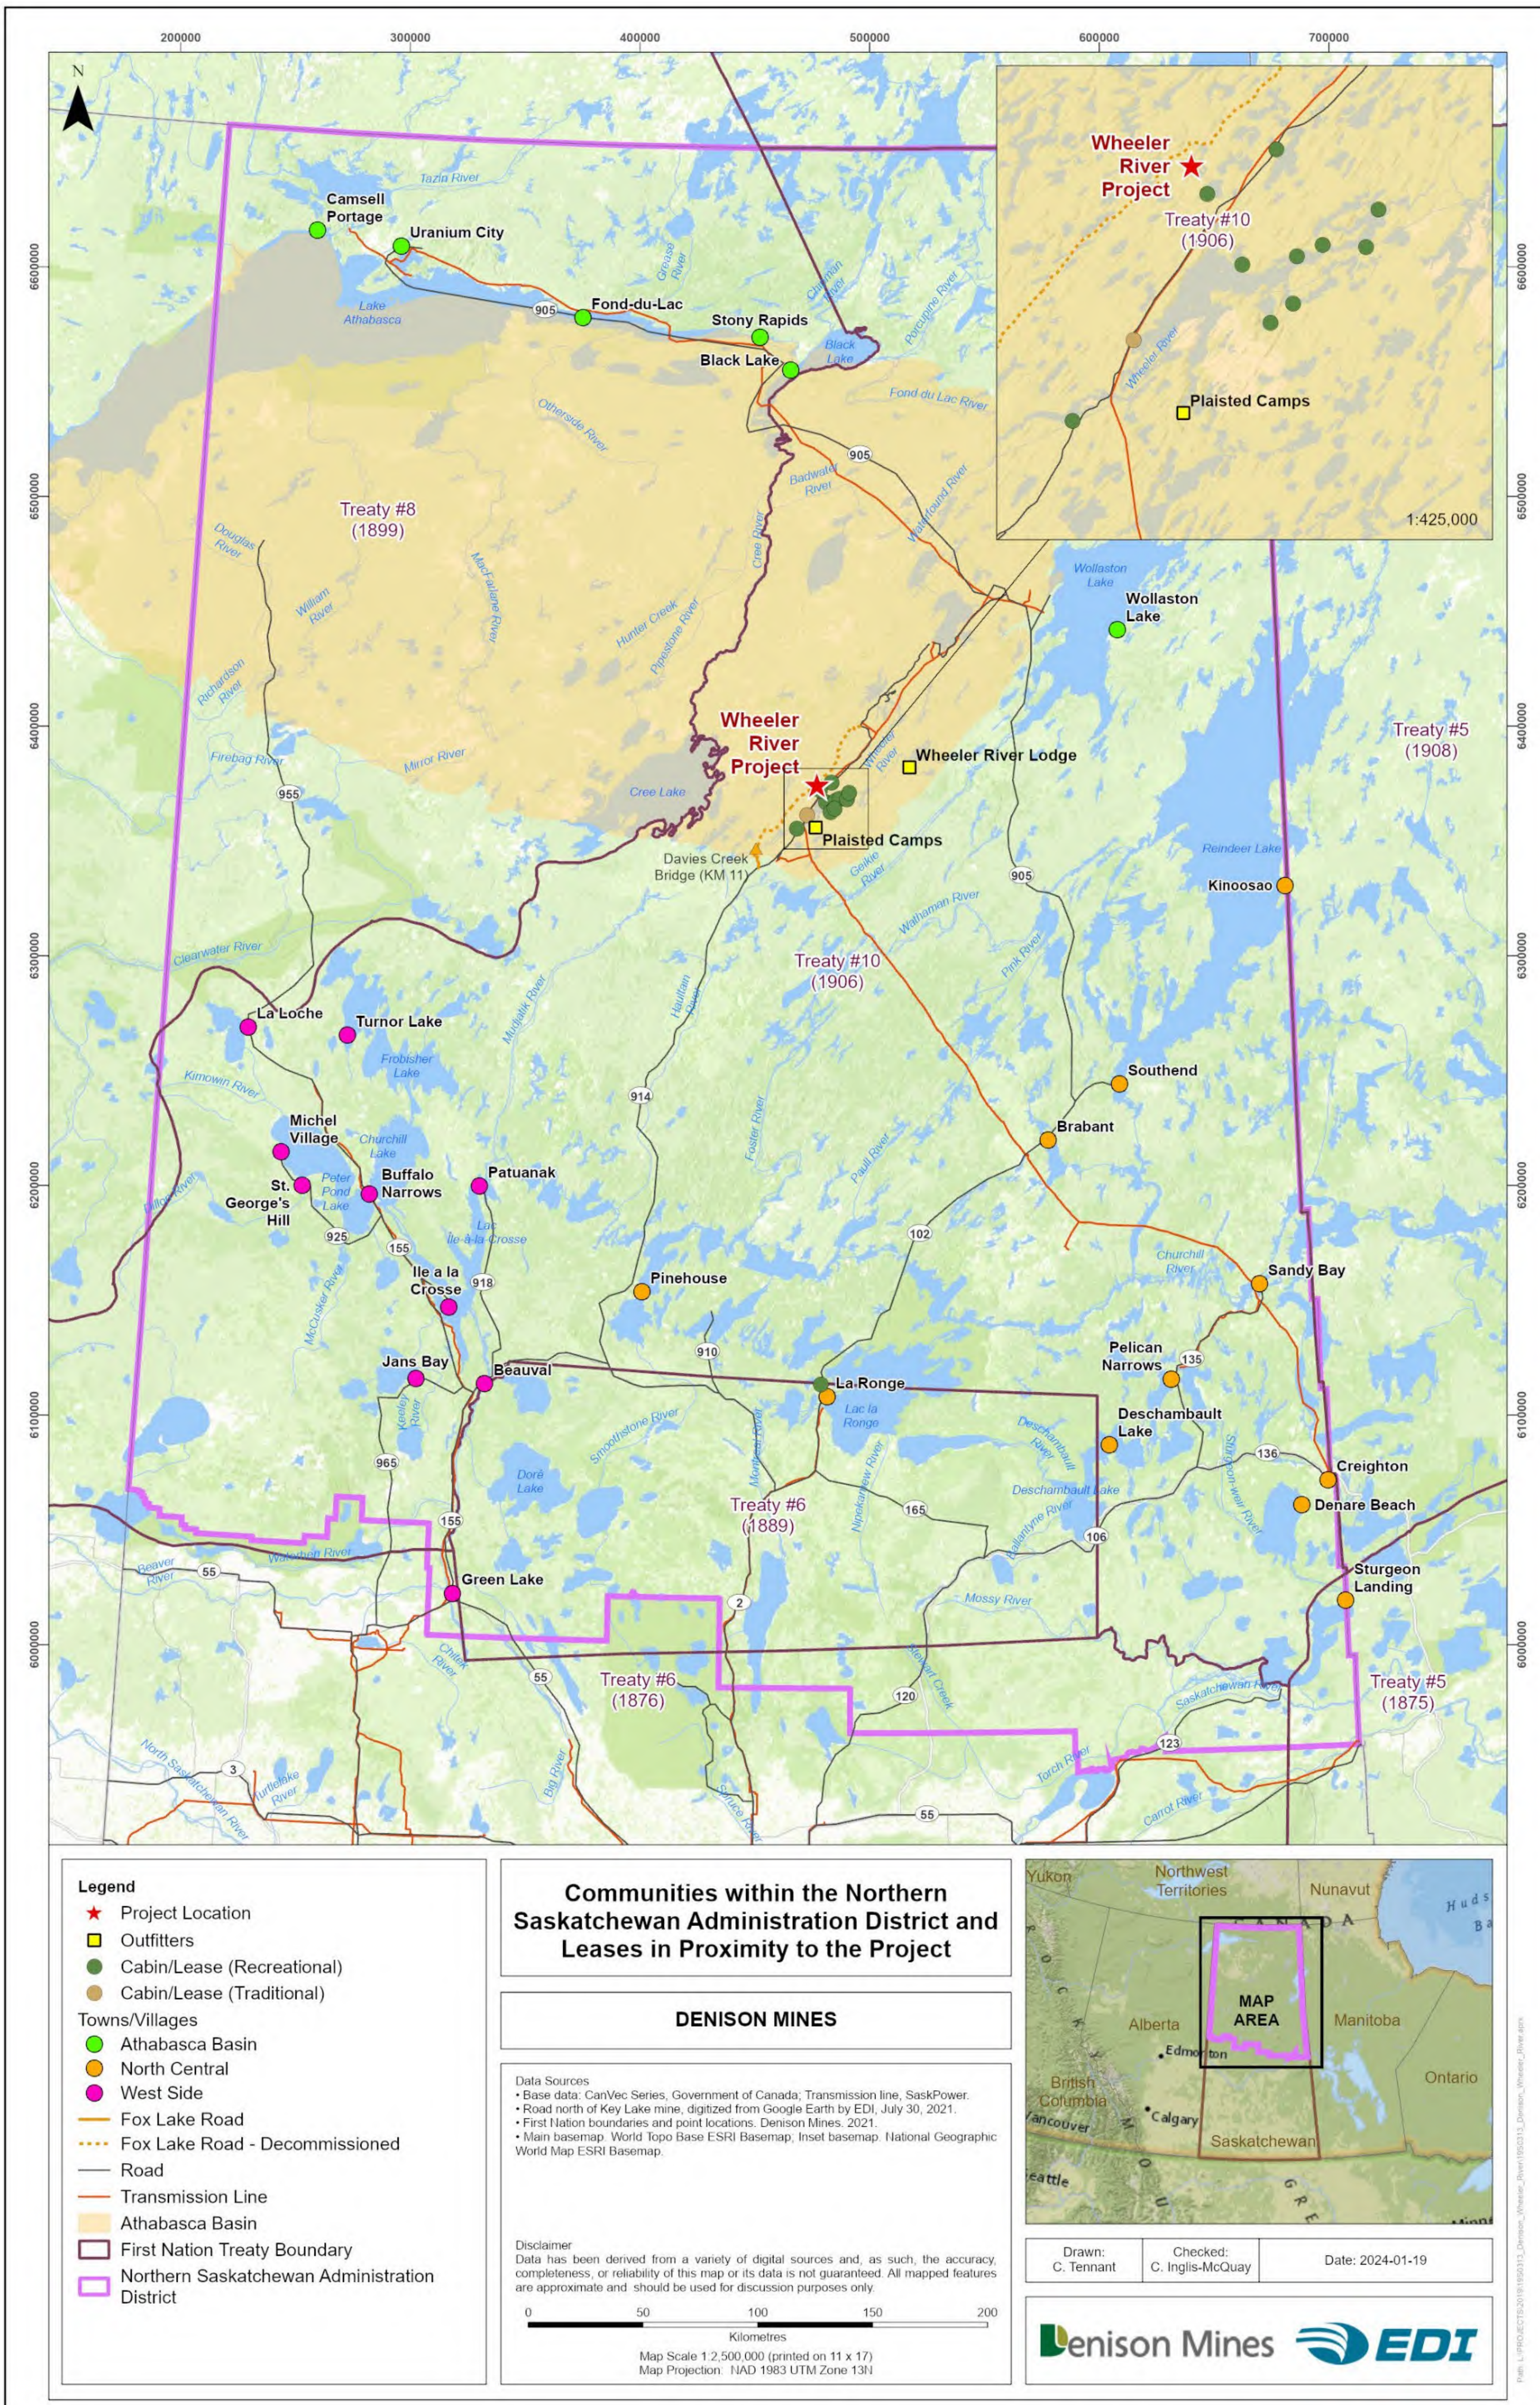

Figure 1-4: Communities within the Northern Saskatchewan Administration District and Leases in Proximity to the Project

No communities are located within the immediate proximity of the Wheeler River property (Figure 1-3 and Figure 1-4). Travelling by existing roads, the closest community to the Project is approximately 260 km away. Calculated using a straight line, the closest communities are approximately 150 km from the site and Saskatoon is 600 km south. The federal lands within a 100 km radius of the Wheeler River property are First Nation reserve land without permanent residences (Figure 1-3 and Table 1-1).

Table 1-1: Federal Lands in Proximity to the Project

Federal Land Type	Name	Distance from Project (km)
First Nation	English River First Nation Slush Lake Reserve No. 192Q	16
First Nation	English River Barkwell Bay Indian Reserve 192I	39
First Nation	English River First Nation Mawdsley Lake Reserve No. 192R	91
First Nation	English River Haultain Lake Indian Reserve 192K	94
First Nation	Cree Lake Indian Reserve 192G	98

The Project is located mid way between Cameco Corporation's Key Lake Operation (a uranium mill) and McArthur River Operation (a uranium mine; Figure 1-2). Ground access to the Project is along Highway 914. Access to the highway north of the Key Lake Operation is controlled at the Cameco Key Lake Operation gatehouse. Existing infrastructure in the area includes Highway 914, the provincial power line adjacent to the highway, and infrastructure for the Key Lake Operation and McArthur River Operation (Figure 1-2). Existing disturbances in the area are mainly from exploration activities, such as line cutting, drilling, and access routes (Section 1.1.2).

The main land use activities in the area by Indigenous and other land users are hunting, trapping, and fishing. There are recreational and traditional resource user leases nearby (Figure 1-4). The closest recreational lease is located approximately 2.5 km away. The closest traditional resource user lease is located approximately 12 km away.

The climate of the Project area is typical of the continental sub-arctic region of Canada and is characterized by extremely cold, dry winters and short summers. The Project's position near the centre of the continent, a relatively high latitude, and great distance from the moist and moderating influence of oceans results in temperatures that varying greatly between seasons. Daily mean temperatures are typically below freezing from January to April and again from October to December; temperature extremes in a year can range from -50°C to +35°C. The area is relatively dry with most of the annual precipitation falling in June, July, and August. During winter the snowpack is typically less than 1 m.

The Project is located in the Boreal Shield Ecozone and, more specifically, in the Wheeler River Upland Landscape Area of the Athabasca Plain Ecoregion (McLaughlan et al. 2010; Figure 1-5).

Topography is more subdued (low relief) in this ecoregion than elsewhere in the Canadian Shield due to flat-lying sandstone and almost continuous cover of sandy glacial deposits.

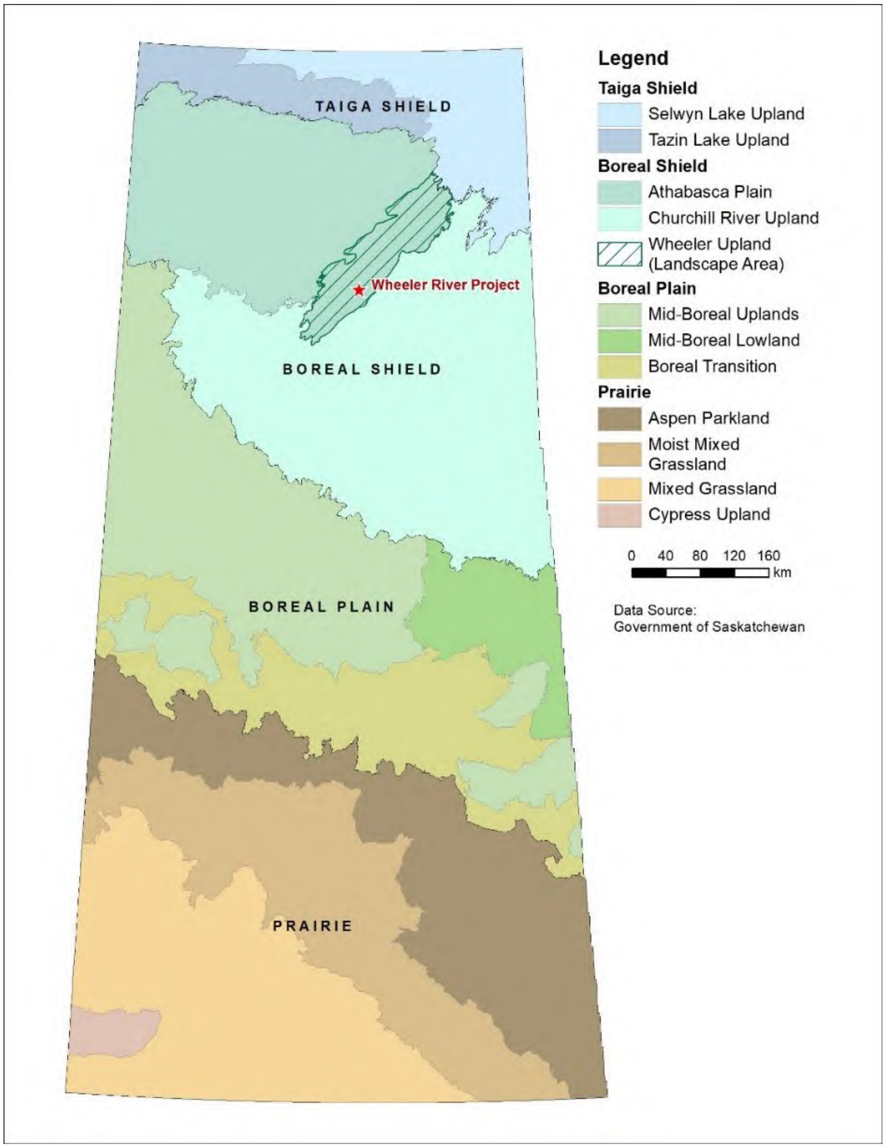

Figure 1-5: Project Location in the Boreal Shield Ecozone

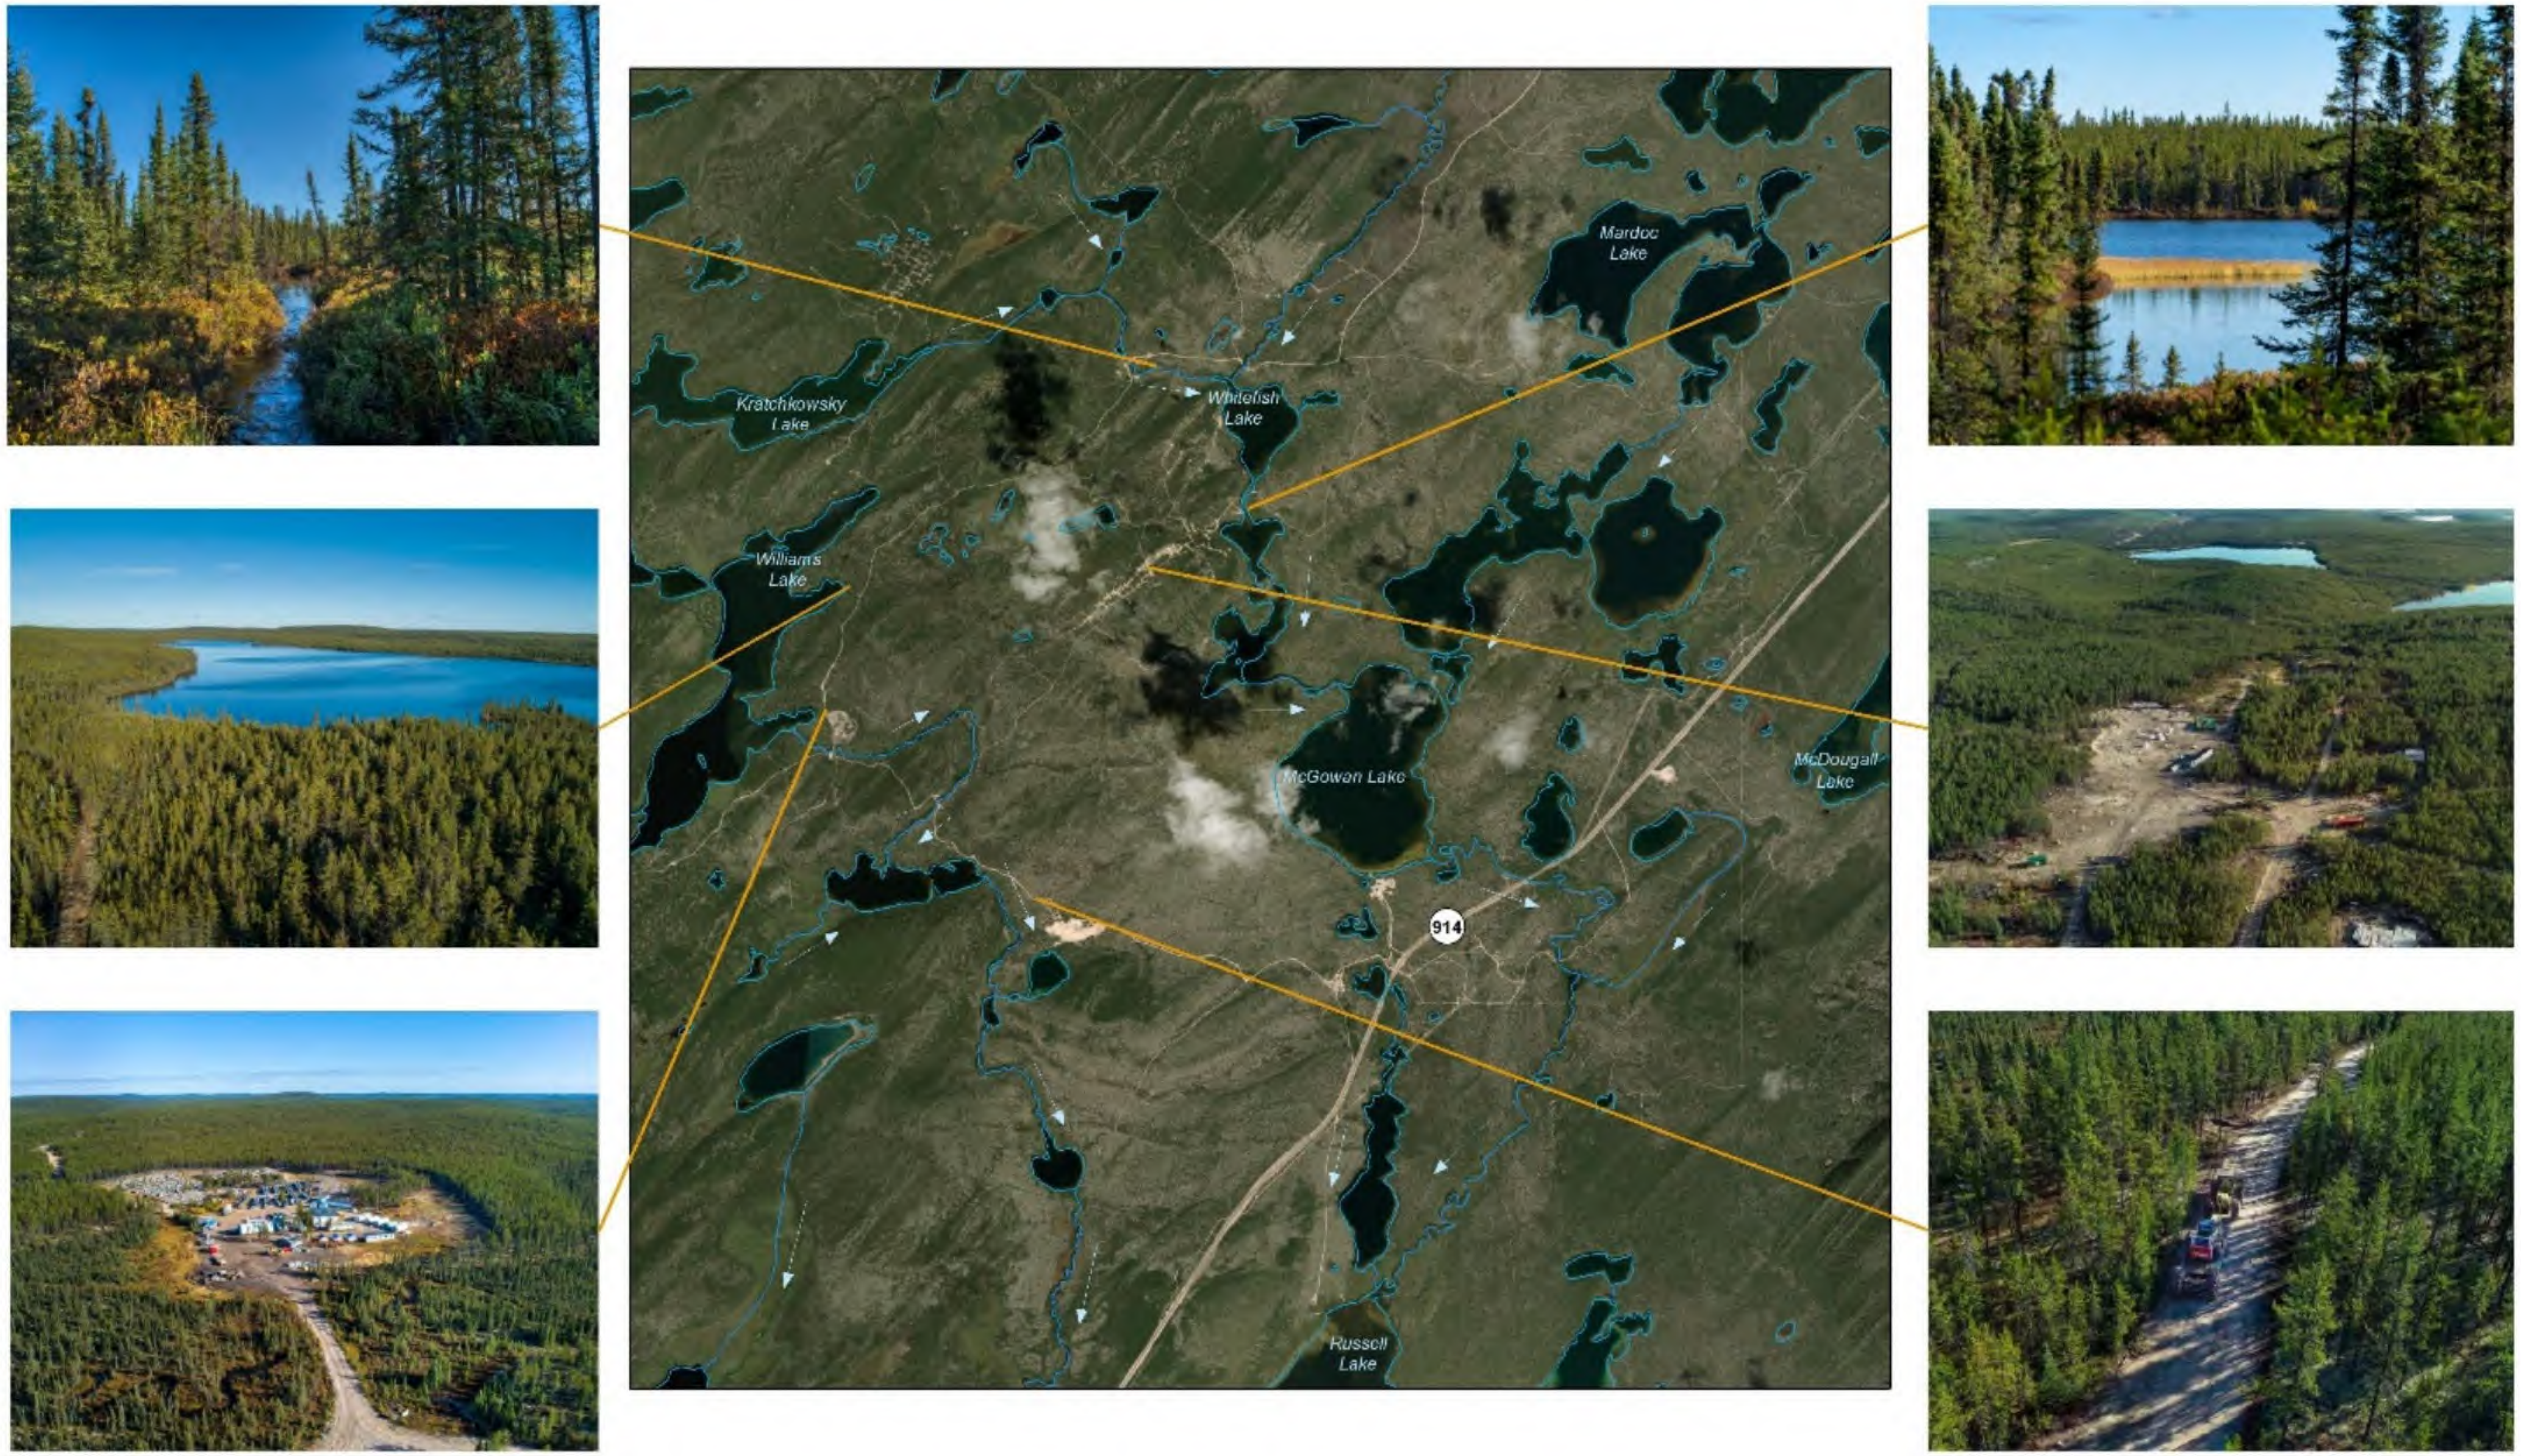
Open stands of jack pine and jack pine-black spruce forests dominate the drier upland areas with a thin ground cover of lichen and blueberry. Black spruce, and less commonly tamarack, are the dominant forest types in wetter lowland areas, including bogs and fens, where Labrador tea is a common ground cover. White spruce, aspen, balsam poplar, birch, and willow are less common. The Boreal Shield Ecozone experiences a largely natural fire regime that results in the most area burned per unit area and the highest proportion of very large fires (more than 50,000 ha) in the province (Parisien et al. 2004). Much of the vegetation in the area is in various stages of post-fire regeneration. Examples of terrestrial animals in the area include moose, woodland caribou, grey wolf, mink, marten, snowshoe hare, black bear, fox, and a variety of migratory and year-round resident birds such as ducks, grouse, songbirds, and raptors. Numerous lakes and streams are present in the Boreal Shield Ecozone. Water in the Project Area drains towards Russell Lake, the Wheeler River, and ultimately into Wollaston Lake (via the Geikie River). Examples of fish in the area include spottail shiner, slimy sculpin, white sucker, northern pike, lake whitefish, and walleye.

Figure 1-6 provides an overview of the current site conditions and the typical landscape near the Project.



Note: Clockwise from top right the photos taken in 2021 show: Whitefish Lake, the Phoenix deposit (with Whitefish Lake visible in the background), a section of the existing exploration access road, exploration camp facility, Williams Lake, and Kratchkowsky Creek flowing from Kratchkowsky Lake to Whitefish Lake.

Figure 1-6: Landscape Features and Current Site Conditions near the Project

1.1 Site History

The Wheeler River property was staked on July 6, 1977. Excluding the years 1990 to 1994, exploration activities, such as airborne and ground geophysical surveys, geochemical surveys, prospecting, and diamond drilling, have been carried out on the property from 1978 to present. Denison became the operator of the property in November 2004 and carried out property-wide airborne geophysical surveys in 2005. The Phoenix deposit was discovered by diamond drilling in 2008 with subsequent delineation completed over the next six years from 2008 to 2014.

1.1.1 Deposit and Geology

The Wheeler River property is located within the eastern margin of the Athabasca Basin of northern Saskatchewan and is host to the Phoenix and Gryphon uranium deposits. The Phoenix deposit is amenable to ISR mining and is the primary source of uranium expected to be mined by the ISR mining method, as evaluated in this Environmental Impact Statement (EIS). The Gryphon deposit is not amenable to ISR mining and, accordingly, is not included in the EIS evaluation. Like many other uranium deposits on the eastern portion of the Athabasca Basin (described in Jefferson et al. 2007), the Phoenix deposit is located at the base of the sandstones, just above the major unconformity that separates the sandstones and the underlying basement rock. This unconformity represents the period when the basement rock was exposed and subject to extensive weathering and erosion.

The Phoenix deposit is overlain and underlain by a natural barrier that has limited the release or movement of uranium and other chemicals associated with the mineralization in the deposit, outside of the ore body itself.

The Phoenix deposit is geologically situated at or above the unconformity between the Athabasca Basin sandstone and older basement rocks, approximately 400 m below the surface (Figure 1.1-1). To date, the Phoenix deposit has been estimated to contain a total of 70.2 million pounds of triuranium octoxide (U_3O_8) in indicated mineral resources, based on 166,400 tonnes of ore at an average grade of 19.14% U_3O_8. Globally, the Phoenix deposit ranks as the highest-grade undeveloped uranium deposit that has estimated resources over 50 million pounds U_3O_8.

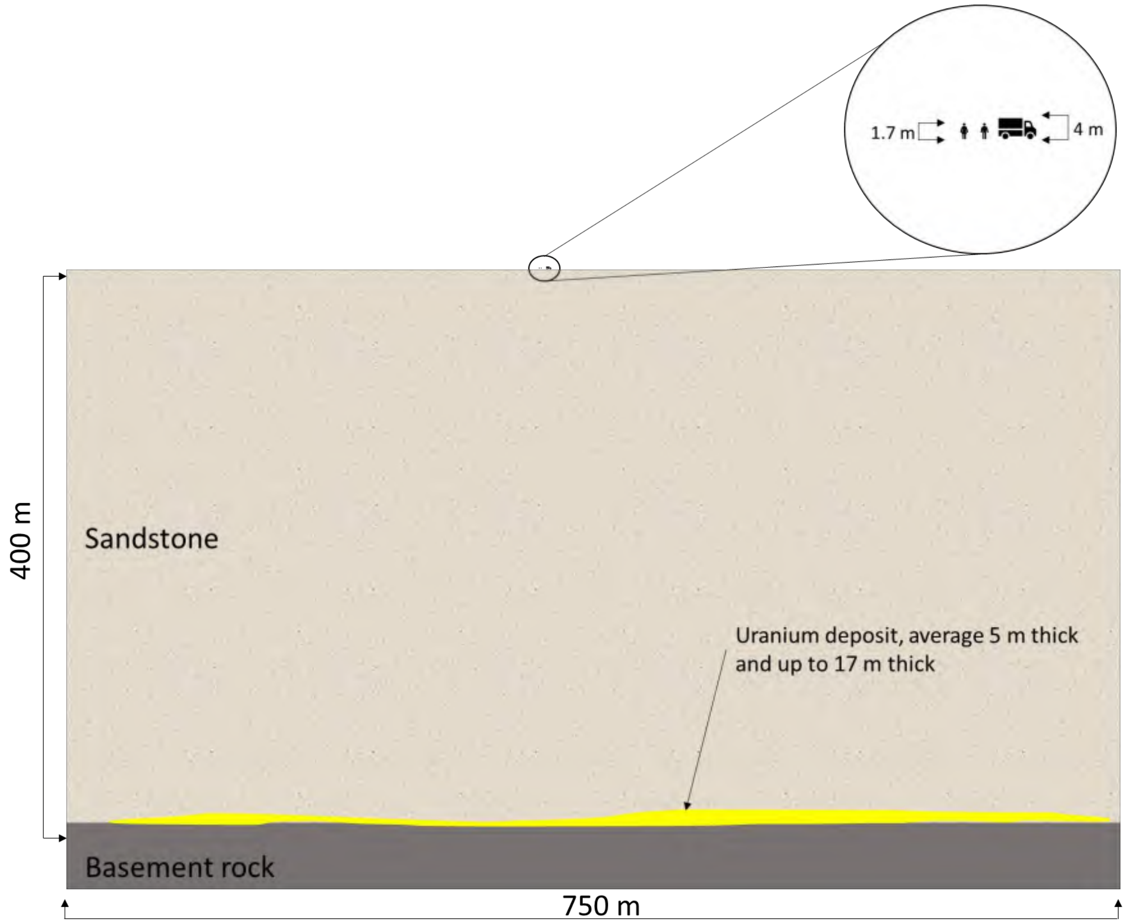


Figure 1.1-1: Uranium Deposit in Relation to People and Vehicles on the Surface

1.1.2 Current Site Conditions

Exploration field operations are currently conducted from Denison's on-site camp facilities, which are located approximately 3 km southwest of the Phoenix deposit. The camp provides accommodations for field staff using ATCO trailer units and tent facilities (Figure 1-6). Fuel and miscellaneous supplies are stored in existing warehouse and tank facilities at the camp. Drill core from exploration activities is also stored on site. The exploration site currently generates its own power by diesel generator. The camp and its activities are permitted through the Saskatchewan Ministry of Environment.

Denison maintains portions of the site roads (Figure 1-6) necessary to gain access to the camp facilities and to complete field activities. Maintenance includes installation of temporary water crossings (bridges) and general road maintenance to facilitate safe travel by either four-wheel-drive vehicle or all-terrain vehicle. In addition, several gravel and sand roads and drill trails provide access by either four-wheel-drive vehicle or all-terrain vehicle to the rest of the property. These roads are maintained only as necessary.

Outside of the Phoenix deposit (Figure 1-6) and exploration camp facility, various surface disturbances have occurred since commencement of exploration activities in 1978. Several ground geophysical survey grid lines transect the property uniformly, and approximately 750 exploration pads were cleared to accommodate diamond drill hole exploration programs. As a result of exploration activities, some areas of the property have been previously disturbed via vegetation removal to allow for access trails and drilling areas. Refer to Figure 1-6 for an overview of location the exploration camp and Phoenix deposit, along with other photos of the surrounding area.

1.2 Project Proponent

Denison is the operator of the Project and, as such, the proponent in all regulatory matters.

Denison is a publicly traded uranium exploration and development company with interests focused in the Athabasca Basin region of northern Saskatchewan. The company trades on the Toronto Stock Exchange and NYSE American exchange and is headquartered in Toronto, Ontario, with offices in Saskatoon, Saskatchewan, and Elliot Lake, Ontario.

1.2.1 History of Uranium Mining

Denison has a long legacy of uranium mining, with over 50 years of uranium mining experience (including predecessor companies) in Ontario, Saskatchewan, and the United States. In addition to an effective 95% ownership in the Project, Denison is part owner (22.5%) of the McClean Lake Joint Venture, which includes the operating McClean Lake uranium mill in northern Saskatchewan, and provides expert mine decommissioning and environmental services through its Closed Mines group.

Denison's history of uranium mining and unique expertise in the specialized sectors of uranium mine decommissioning and exploration, as well as its active involvement in the uranium sales and marketing business through its previous management of Uranium Participation Corporation (now the Sprott Physical Uranium Trust), have uniquely prepared the company to be a qualified proponent to develop and operate the Project.

Denison currently holds licences with the Canadian Nuclear Safety Commission (CNSC) for its decommissioned uranium mine sites in the Elliot Lake region, and for the areas within the Wheeler River Property as part of feasibility field testing (Federal Nuclear Substance and Radiation Device Licence). Additionally, Denison holds a permit to Operate a Pollutant Control Facility with the Province of Saskatchewan in connection with the feasibility field testing at Wheeler River. Denison's performance under its licences and permits exemplifies the company's commitment to the operation of its facilities in a manner that prioritizes safety, environmental protection, and sustainable development.

1.2.2 Governance Structure

As a TSX and NYSE American publicly listed company, Denison has developed a culture of rigorous governance and controls, which ensure that the Company's actions are properly deliberated, planned, implemented, and evaluated. Ultimate responsibility for the company's actions rests with Denison's Board of Directors, which is comprised of eight highly qualified professionals with varied experience and expertise in the fields of mine engineering, health and safety, sustainability, corporate securities law, finance, human resources, corporate commercial law, nuclear energy, and uranium marketing.

Board composition is regularly monitored by Denison's corporate governance and nominating committee to ensure that the Board is properly able to provide oversight of the company's management. A Technical Committee of the Board of Directors provides technical oversight for the advancement of Denison's projects and is comprised of Mr. Ron Hochstein (Chief Executive Officer [CEO] of Lundin Gold Inc. and previous Chief Operating Officer and CEO of Denison while the company operated the White Mesa Mill in Utah) and Mr. David Neuburger (previous Vice President, Mining Division for Cameco Corporation and past President of the Saskatchewan Mining Association). Mr. Hochstein and Mr. Neuburger are both Professional Engineers. Similarly, Denison's Audit Committee provides financial oversight and is chaired by Patricia Volker, an experienced Chartered Professional Accountant (CPA) and chartered accountant (CA), that has previously served as the Director of Standards Enforcement and the Director of Public Accounting for CPA Ontario, the self-regulating body for Ontario's CPAs.

The Board places a high value on the environment, corporate social responsibility, sustainability, and governance, recognizing the importance of understanding the impact of Denison's strategies and how such understanding can contribute to the long-term sustainability of the corporation's business, help identify and manage risk, and lead to transformative opportunities. Denison has completed a comprehensive Environment, Social and Governance report for 2021 (Denison 2022), which exemplifies the company's commitment to these business critical considerations. Additionally, Denison has adopted an industry-leading Indigenous Peoples Policy (Denison 2021), which recognizes the critical necessity of advancing reconciliation with Indigenous peoples in Canada and the important role of Canadian business in the reconciliation process.

Denison's President and CEO, Mr. David Cates, is responsible for oversight of the company's day-to-day operations consistent with the company's guiding policies and for facilitating reporting and engagement between management and the Board of Directors. Mr. Cates is a CPA and CA and holds a Master of Accounting degree from the University of Waterloo. Mr. Cates has extensive expertise in the Canadian and international uranium mining industry from nearly two decades of senior management and financial experience, and serves as a director on the board and executive committee (Finance Chair) of the Canadian Nuclear Association.

1.2.3 Management Structure

Denison’s current management structure is comprised of an executive leadership team and a management team, illustrated in the following organizational chart (Figure 1.2-1). The executive team provides overall direction on projects and expenditures to meet operational objectives. The management team executes operational directives set by the executive team. Ultimately, the collective team is governed by Denison’s Board of Directors.

David Cates – President and Chief Executive Officer

Mr. Cates is a CPA and CA and holds a Master of Accounting and Honours Bachelor of Arts degrees from the University of Waterloo. Mr. Cates has extensive expertise in the Canadian and international uranium mining industry from over a decade of senior management and financial experience in various roles with Denison. Mr. Cates was appointed President and CEO of Denison in 2015, having previously served as the company's Vice President, Finance and Tax and Chief Financial Officer. Prior to joining Denison in 2008, Mr. Cates held positions at Kinross Gold Corp. and Pricewaterhouse Coopers Limited Liability Partnership (PwC LLP). Mr. Cates also serves as a Director of Denison and is a Director of the Canadian Nuclear Association, SkyHarbour Resources Ltd. (TSX-V: SYH), and GoviEx Uranium Inc. (TSX-V: GXU). Both Skyharbour and GoviEx are engaged in uranium exploration and/or development.

Elizabeth Sidle – Vice President Finance and Chief Financial Officer

Ms. Sidle joined Denison in 2016 as Vice President Finance in September 2021 and was appointed to Chief Financial Officer in December 2023. Prior to joining Denison, she held various roles at Ernst & Young LLP, including serving in the firm's National Accounting and Assurance Group. Ms. Sidle has extensive experience in financial reporting under IFRS and has acquired substantial experience within the resource sector during her time with Denison and her exposure to multiple large Canadian mining companies while practicing in public accounting. Ms. Sidle is a CPA and CA and holds a Bachelor of Science degree from Queen's University and a Diploma in Accounting from Wilfred Laurier University.

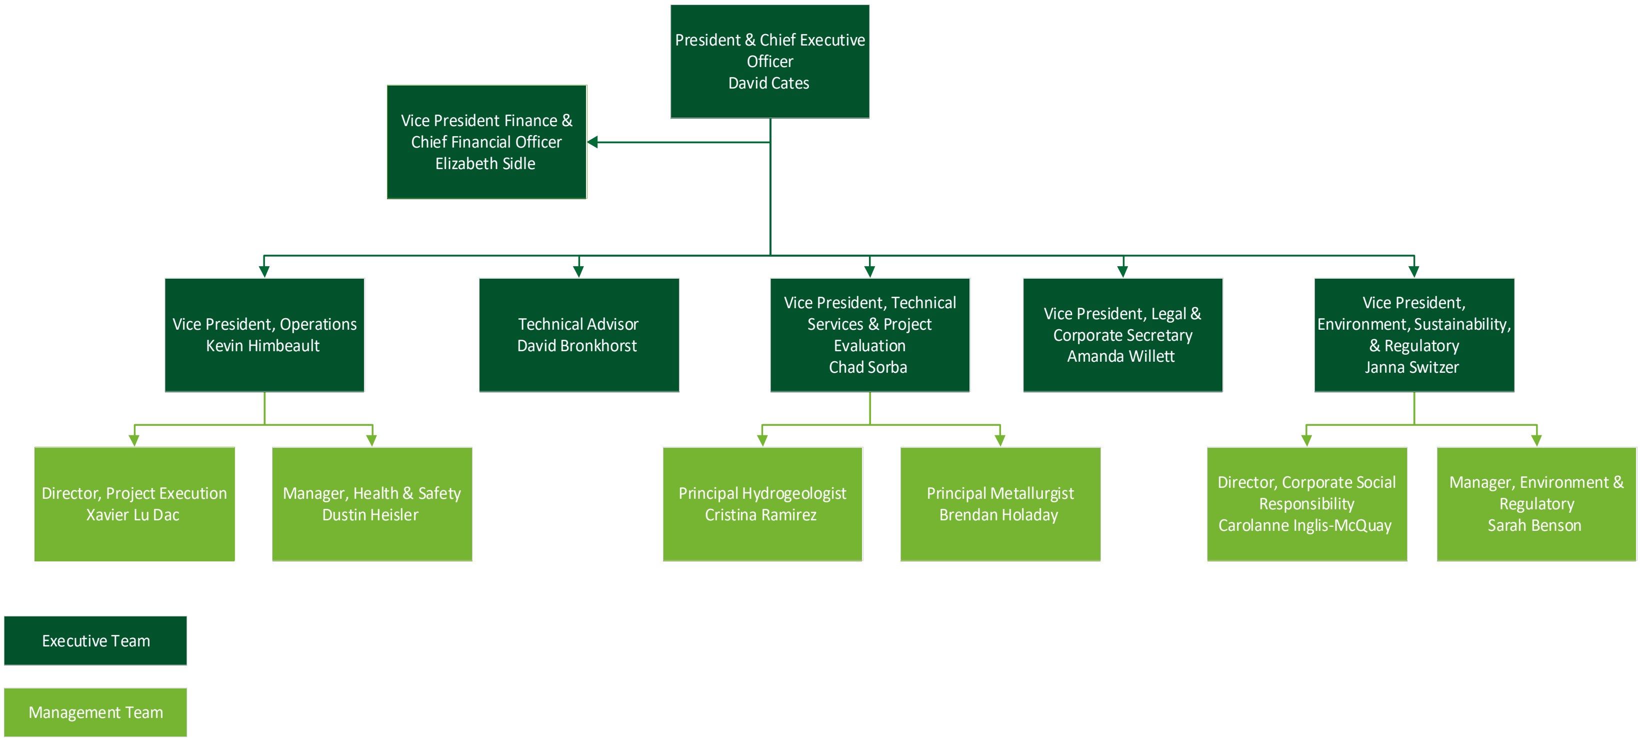

Figure 1.2-1: Denison Organizational Chart

David Bronkhorst – Technical Advisor

Mr. Bronkhorst is a seasoned mining executive with over 35 years of experience in base metals, gold, and uranium mining. Most recently, he held the position of Vice President, Mining, Projects and Technology at Cameco Corporation, which involved responsibilities for conventional mining operations in the Athabasca Basin region in northern Saskatchewan and ISR mining operations in the United States. During his 16-year career with Cameco Corporation, David also served as the General Manager at the Rabbit Lake Operation and the McArthur River Operation. Through his experience with Cameco Corporation's various mining operations, David has acquired unique senior-level expertise with both conventional and highly specialized uranium extraction techniques. David is a graduate of the Mining Engineering program at Queen's University and is a member of the Association of Professional Engineers in Saskatchewan. He has served as a director for the Saskatchewan Mining Association and continues to support the International Atomic Energy Agency as an expert in uranium extraction methods.

Kevin Himbeault – Vice President Operations

Mr. Himbeault has significant operational and regulatory experience, with over 25 years of diverse involvement in the mining industry through consulting and operations management. In previous roles, Mr. Himbeault has been responsible for substantial improvements in mining and processing facilities to ensure sustainability of operations, and has successfully facilitated environmental assessments (EAs) in both the uranium and diamond mining sectors. During his 18-year career with Cameco Corporation, Mr. Himbeault led the Key Lake Operation through multiple relicensing processes and spearheaded the development and approval of the EA for the Key Lake Extension Project. With over 14 years of direct experience at the Key Lake Operation, his responsibilities have included senior management leadership for plant operations (including uranium processing, site infrastructure services, maintenance, and recent automation initiatives) as well as oversight of the development of safety, health, quality, and radiation protection programs. Mr. Himbeault holds a Master of Science degree in Toxicology from the University of Saskatchewan.

Amanda Willet – Vice President Legal and Corporate Secretary

Ms. Willett joined Denison as Corporate Counsel and Corporate Secretary in 2016. Prior to joining Denison, Ms. Willett was a securities law associate at Blake, Cassels & Graydon LLP in Vancouver since 2011 and a corporate and securities law associate with Stikeman Elliott LLP in Toronto since 2008. Her practice focused on advising public and private companies on matters, including mergers and acquisitions, joint ventures, securities offerings, securities law and stock exchange compliance matters, and general corporate matters. She has been involved in a broad range of transactional and corporate governance work for companies listed on the TSX and the TSX Venture Exchange, with an emphasis on advising companies in the mining industry. Ms. Willett graduated from York University in 2007 with an LL.B. from Osgoode Hall Law School and a Master of Business

Administration degree from the Schulich School of Business. She is a member of both the Ontario and British Columbia Bars.

Janna Switzer – Vice President Environment, Sustainability and Regulatory

Ms. Switzer joined Denison in early 2020 to oversee the environment department and became the Vice President of Environment, Sustainability and Regulatory in January 2024. With over 20 years of experience in the resource industry, including 16 years in uranium mining and exploration, Ms. Switzer has developed substantial experience in EA, regulatory compliance, and community and regulatory relations. She led the EA for the Millennium Mine Project and the Rabbit Lake Tailings Extension with Cameco Corporation and, more recently, held the position of Senior Advisor of Communities and Social Performance with Rio Tinto Exploration before her role with Denison. Ms. Switzer holds a Bachelor of Science Degree from the University of Alberta, maintains her designation as a Project Management Professional and is a member of Métis Nation-Saskatchewan.

Chad Sorba – Vice President Technical Services and Evaluation

Mr. Sorba joined Denison in 2008 and became Vice President of Technical Services and Evaluation in January 2024. Mr. Sorba has over 16 years of experience in the mineral industry, including exploration geology, resource estimation, project development, and project evaluations. For the past 16 years, Mr. Sorba has held positions of increasing responsibility at Denison within its global portfolio of uranium exploration and development projects in North America, Africa, and Mongolia. Mr. Sorba has extensive experience in Saskatchewan's uranium industry through both majority-owned company projects as well as joint ventures. At Denison, Mr. Sorba was a significant contributor to the team that discovered, delineated, and developed the novel ISR mining methodology of over 130M lbs of mineral resources at the Project, including the Phoenix and Gryphon deposits. He has also co-authored NI 43-101 economic studies related to Denison's Midwest, Midwest A, and THT deposits.

Carolanne Inglis-McQuay – Director Corporate Social Responsibility

Ms. Inglis-McQuay joined Denison in 2019 as the Corporate Social Responsibility Manager and became the Director of Corporate Social Responsibility in January 2023. Prior to joining Denison, she held various roles at Orano Canada, including most recently as a Senior Advisor for Corporate Social Responsibility, where she was tasked with implementing company-wide systems for ensuring transparency in relation to key social metrics regarding the existing uranium mining operation. Ms. Inglis-McQuay has extensive experience in facilitating and leading negotiations with Indigenous communities in relation to a wide array of agreements. She also has more than 20 years of experience leading engagement activities with the public for complex mining projects, a career which began in Cambridge Bay, Nunavut. Ms. Inglis-McQuay holds a Bachelor of Arts from the University of Calgary.

Xavier Lu Dac – Director Project Execution

Mr. Lu Dac joined Denison in 2020 as a senior Project Engineer and became the Director of Project Execution in January 2023. Prior to joining Denison, he held various roles at the Mosaic Company where he worked in Surface Operations and Capital projects departments. Mr. Lu Dac has extensive experience in Engineering and Project Management from his prior roles held in mining, consulting, engineering, and equipment manufacturing. Mr. Lu Dac is a Professional Engineer in the Province of Saskatchewan and holds a Mechanical Engineering Degree from the University of Technology of Belfort Montbeliard, France, which he obtained in 2004.

Dustin Heisler – Safety Manager

Mr. Heisler joined Denison in 2021, bringing with him a wealth of knowledge from working in various manufacturing and mining industries. Prior to joining Denison, he most recently worked at the Suncor base plant in Fort McMurray for Worley Industrial Services, providing health and safety oversite in various divisions. His eight years in this role included advising Suncor and Worley on necessary improvements to their health and safety programs, ensuring compliance with regulatory requirements, incident investigation, and case management, and was the direct health and safety contact with the Suncor senior leadership team. Mr. Heisler's health and safety career began in the potash industry and continued with Occupational Health and Safety education at the University New Brunswick. In 2019, Mr. Heisler achieved the highest health and safety designation in Canada after successfully becoming a Canadian Registered Safety Professional.

Sarah Benson – Environment and Regulatory Manager

Ms. Benson joined Denison in early 2021 as Environmental and Regulatory Manager in Denison's Closed Mines division. This role has since expanded to include Denison's Saskatchewan projects. Prior to joining Denison, she was an Environmental Scientist at Orano Canada, for 14 years, providing technical support to both operating and decommissioned uranium mine sites and proposed projects in the areas of environmental monitoring, reporting, regulatory compliance, and licensing. Ms. Benson has developed substantial experience in environmental assessment, regulatory compliance and approvals and is knowledgeable in the application of provincial and federal environmental legislation, regulations, standards, and guidelines. She was part of the team that completed the final Cuff Lake Project assessment, advancing it to acceptance into the Saskatchewan Institutional Control Program before her role with Denison. Ms. Benson holds a Bachelor of Science Degree in Biology and a Master of Science degree in Toxicology, both from the University of Saskatchewan.

Cristina Ramirez – Principal Hydrogeologist

Ms. Ramirez joined Denison in 2023 as Principal Hydrogeologist. Prior to joining Denison, she has various roles in gold and copper open pit mining, including drilling programs, implementing the dewatering and groundwater control system of the mine site. She has 19 years expertise in groundwater mining management with hydrogeology model, well design, surface infrastructure and optimization during construction and operation with Barrick Gold, in Pueblo Viejo Mine and Inmet Mining in Cobre Las Cruces, include. Ms. Ramirez holds a Bachelor of Geology from Universidad de Huelva, a postgraduate in Groundwater from Universitat Politecnica de Catalunya, a Master of Business Administration degree from UQAM and also a Master of Occupational Hazard from Universidad Camilo Jose Cela.

Brendan Holaday - Principal Metallurgist

Mr. Holaday joined Denison in early 2022 as Senior Metallurgist and was appointed to Principal Metallurgist in January 2024. He has 15 years of experience in the uranium industry, and brings with him technical, operational, and industry specific knowledge to support the Denison team. Prior to joining Denison, he worked at Orano's McClean Lake Operation, and Cameco's Rabbit Lake Operation as a senior member of their on-site metallurgy teams. Mr. Holaday is a Professional Engineer registered with the Association of Professional Engineers and Geoscientists of Saskatchewan, and holds a Bachelor of Science degree in Chemical Engineering from the University of Saskatchewan which he obtained in 2009.

1.2.4 Key Contact Information

The primary contact for the purposes of the EIS for the Project is:

Janna Switzer
Vice President, Environment Sustainability and Regulatory
Denison Mines Corp.
345 4th Avenue South
Saskatoon, SK, Canada, S7K 1N3
Phone: (306) 652-8200
Fax: (306) 652-8202
Email: jswitzer@denisonmines.com

1.2.5 Environmental Impact Statement Preparation Team

Completing an EIS is a complex undertaking. This document was prepared by a team of Denison staff along with various consultants. Table 1.2-1 provides a list of key consultants and contributors who supported Denison with drafting EIS sections.

Table 1.2-1: Wheeler River Project Environmental Impact Statement – Consultants and Contributors

Wheeler River Project EIS Section		Consultant or Contributor
1	Project Introduction and Overview	Bennett Hain Consulting Ltd.
2	Project Description	Bennett Hain Consulting Ltd.
3	Indigenous and Local Knowledge	English River First Nation, InterGroup Consultants Ltd.
4	Engagement	InterGroup Consultants Ltd.
5	Approach and Methodology of the Assessment	EDI Environmental Dynamics Inc.

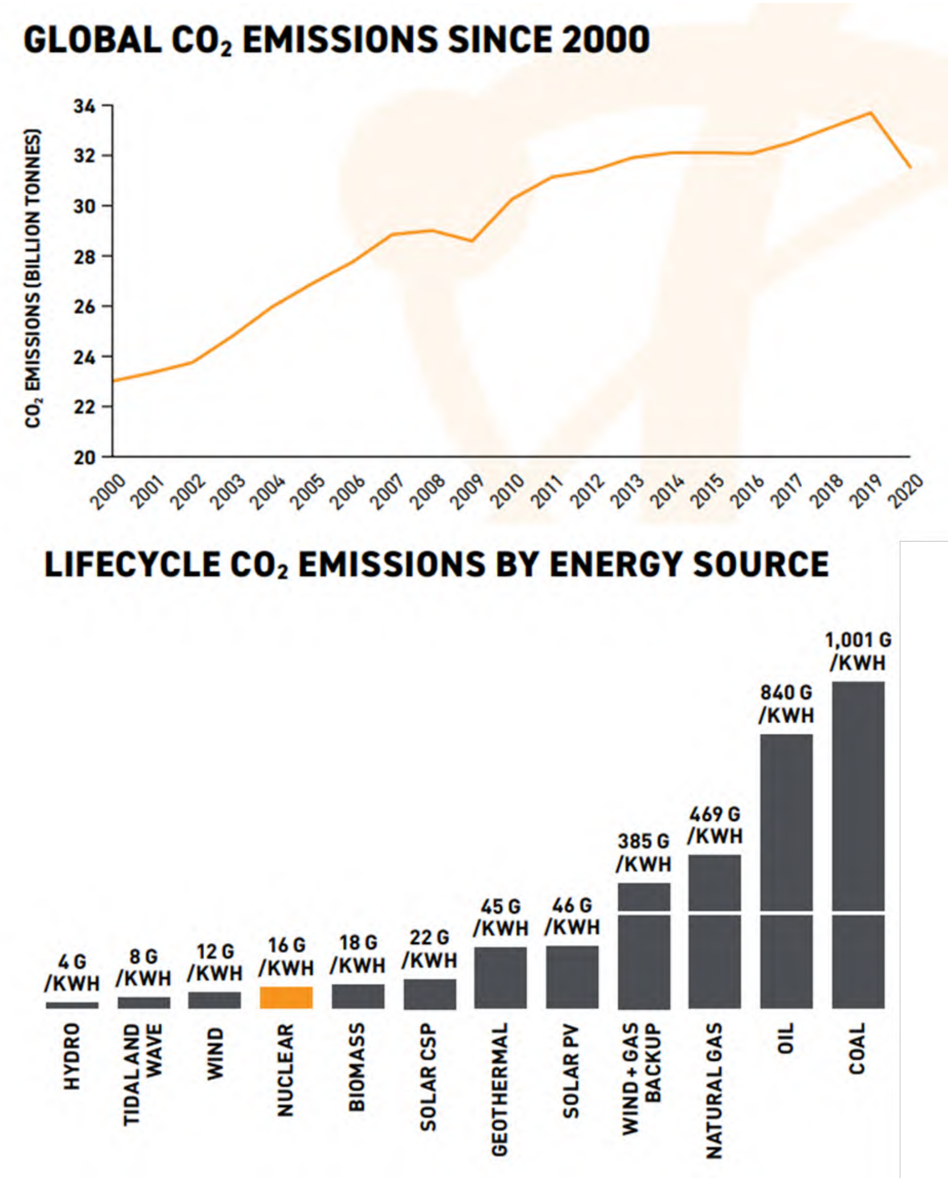
1.3 Need for and Purpose of the Project

The United Nations estimates that the world's population will grow from approximately 7.6 billion in 2017 to over 9.7 billion in 2050 (United Nations 2017), which is expected to substantially increase global electricity demand. Economic development in non-Organization for Economic Co-Operation and Development countries is rapidly shifting global electricity demands and generating more interest in new nuclear plant investments (MIT 2018). According to the International Atomic Energy Agency, high-case projections for nuclear generating capacity suggest that current global capacity could increase from 392 GWe in 2019 to 715 GWe in 2050 (IAEA 2020). At present, there are approximately 442 operable nuclear reactors worldwide, with an additional 51 reactors under construction, over 100 reactors on order or planned, and over 300 proposed reactors (Canadian Nuclear Association 2021).

Hand-in-hand with the rising demand for reliable and low-cost energy is the discussion surrounding greenhouse gas (GHG) emissions and climate change. Despite numerous environmental initiatives and on-going research, global climate change continues at an alarming rate. In 2019, global energy-related carbon dioxide (CO_2) emissions rose to 33.5 billion tonnes, the highest on record, which was approximately 45% above the total in 2000 (World Nuclear Association 2021; Canadian Nuclear Association 2021; Figure 1.3-1). One of the most influential energy sources available to combat the rise of CO_2 emissions is nuclear power. If all the world's coal and natural gas plants were replaced with low carbon nuclear, CO_2 emissions would be reduced by nearly 13 billion tonnes annually (Canadian Nuclear Association 2021).



Source: The Canadian Nuclear Association 2021

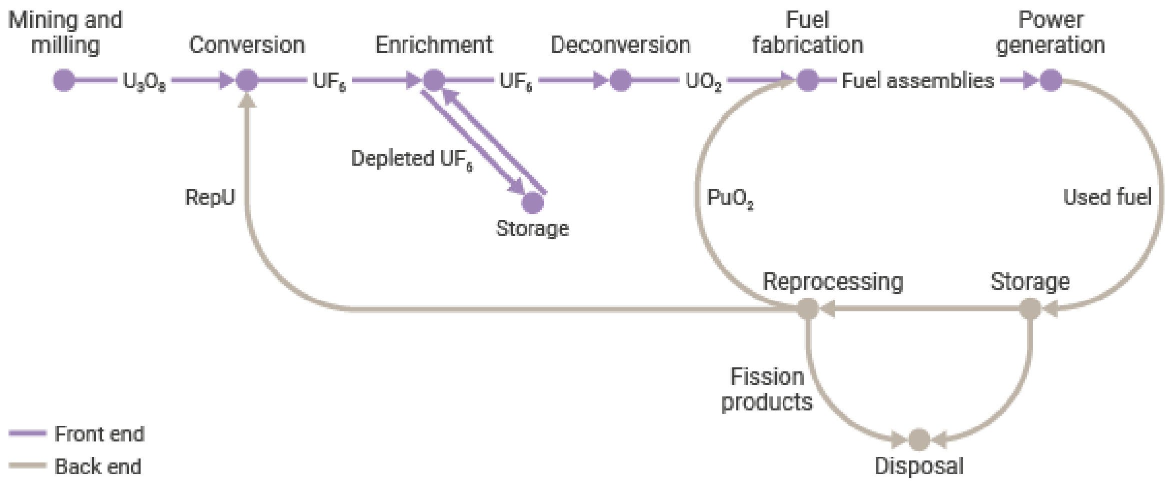
Figure 1.3-1: Global CO_2 Emissions Since 2000 and Lifecycle CO_2 Emissions by Energy Source

A recent report by the United Nations Intergovernmental Panel on Climate Change examined 89 climate change mitigation scenarios and concluded that achieving the 1.5°C target from the Paris Agreement will require an immediate reduction in global GHG emissions and an increase in nuclear power generation of approximately 2.5 times by 2050 (World Nuclear Association 2021). Without a significant contribution from nuclear energy, as the global power mix shifts to respond to climate change initiatives, the cost of achieving meaningful decarbonisation targets will steadily rise, or targets will simply go unmet. Nuclear energy is critical to global climate change objectives because of its unique combination of low carbon emissions, large scale, and high level of reliability.

Nuclear power is safe and reliable. The Canadian nuclear industry is one of the most closely monitored industries in the world. Major nuclear facilities are the most protected critical infrastructure in Canada. Not once has a nuclear incident caused a death in Canada and very few other industries have such a strong health and safety record. Canada's nuclear safety record is unmatched by any other industry in the world (Canadian Nuclear Association, 2022). It is one of the few reliable energy sources that can reduce greenhouse gas emissions. The world's current use of nuclear power already reduces emissions by about 2.5 billion tonnes of carbon dioxide each year by avoiding fossil fuels (World Nuclear Association 2022a).

According to Natural Resources Canada, 15% of Canada's electricity was provided by nuclear power in 2018 (Natural Resources Canada 2022). The nuclear industry in Canada directly and indirectly supports a total of 76,000 jobs, with a total impact on the Canadian gross domestic product of $17 billion per year (Canadian Nuclear Association 2021). Given the integral role it plays in the Canadian economy, the nuclear power industry has been, and will continue to be, a growth vehicle for economic and employment opportunities, an aid to rapidly increasing electricity demand, and a key contributor in the battle against the environmental effects associated with GHG emissions.

Mining of uranium is the first step in the nuclear fuel cycle (Figure 1.3-2), which ultimately concludes with the furnishing of nuclear fuel assemblies to nuclear power plants around the world for the generation of low-carbon and low-cost electricity. Accordingly, uranium mining is an essential component in the global battle against climate change and the shift towards the generation of low-carbon electricity. Lifecycle GHG emissions associated with nuclear power at 16 g CO_2e/KWh (Figure 1.3-1) include uranium mining and milling, which have been estimated to contribute 1.1g CO_2e/KWh (Parker et al. 2016) to the total lifecycle.



Source: World Nuclear Association 2022

Figure 1.3-2: The Nuclear Fuel Cycle

Presently, the annual global uranium supply is less than the annual global demand, and limited inventories have been accessed to make up the supply shortfall. In the upcoming decade, many new uranium mining projects will be required to meet the needs of existing global nuclear power plants, without considering additional demands from new plants (both conventional and emerging small modular reactor designs) and life extension of existing plants (World Nuclear Association 2022). In Canada, new build, small modular reactor projects are currently under consideration in New Brunswick, Ontario, and Saskatchewan.

The purpose of the Project is to construct and operate an ISR uranium mine and processing plant to provide a uranium supply necessary to meet existing and increasing global demand for nuclear power generation. Facilitating global growth in nuclear through environmentally sustainable uranium exports positions Canada and the Province of Saskatchewan to not only help Canada meet its climate change objectives, but to support numerous nations around the world to do the same.

The ISR mining method proposed for the Project has the potential to improve overall economics for smaller-scale uranium deposits while minimizing disturbance to the land and resources in the area. In situ recovery mining uses a water-based solution, fortified with mining reagents, to dissolve naturally occurring uranium from within a host rock, while the host rock remains in place (in situ) below the surface. This mining method can extract the uranium mineralization without physically removing the host rock for processing on the surface. Accordingly, the Project involves no underground or open pit mine workings, no heavy equipment is needed to excavate rocks, and people do not work underground. Taken together, ISR mining is an environmentally sustainable way to mine uranium. As minimal surface disturbance occurs, minimal waste rock is generated and no long-term placement of conventional tailings are produced.

While the ISR method has been used to mine uranium globally for many years, the Project aims to be the first application of this method of uranium mining in Canada. If successful, the Project will pioneer the use of the ISR method amongst the high-grade uranium deposits of the Athabasca Basin region in northern Saskatchewan, which could potentially unlock additional uranium deposits that are currently unsuitable for other mining methods or are uneconomic.

Canada is uniquely positioned to support global climate change initiatives. Canada is the second largest producer and fourth largest exporter of uranium in the world (Natural Resources Canada 2022). In 2019, approximately 75% of the uranium produced in Canada was exported for use in nuclear power throughout the world (Natural Resources Canada 2022). Canada has a rich history of involvement with nuclear power, uranium mining, and the technological advances that have been made within the industry since the early 1940s. Canada also has a mature regulatory regime for the nuclear industry, including uranium mining, which is globally recognized and respected.

The amount of uranium produced during the life of mine from the Wheeler project could supply power to 1,000,000 Canadian homes for 100 years (WNA, 2022, Stats Can, 2019). In addition, to supporting the reduction of GHG, the Project is expected to (1) contribute economically to Canada's nuclear energy industry and (2) provide positive benefits through employment and business opportunities to Indigenous and northern communities in Saskatchewan.

Denison recognizes the thriving culture and deep-rooted traditions of northern Saskatchewan communities and their aspirations of achieving economic growth and prosperity. Denison strives to achieve the development of the Project through positive partnerships with Communities of Interest, integrating information from Indigenous and non-Indigenous Interested Parties, and maintaining high standards for environmental protection and worker safety.

Overall, the world and Canada need uranium to meet the projected future needs of nuclear power generation, and the Project can provide a critical component in the nuclear fuel cycle while making a meaningful contribution to the Canadian economy and Saskatchewan's northern and Indigenous communities.

1.4 Structure of the Environmental Impact Statement

The EIS has been organized to facilitate navigation and readability. The main part of the document has been presented in four parts: Part I Introduction and Context, Part II Biophysical Environment Assessments, Part III Human Environment Assessments, and Part IV Integrated Topics and Summaries.

Within these four main parts, there are a total of 16 sections.

- Part I: Introduction and Context
  - Section 1 Project Introduction and Overview
  - Section 2 Project Description

  - Section 3 Indigenous and Local Knowledge
  - Section 4 Engagement
  - Section 5 Approach and Methodology of the Assessment
- Part II: Biophysical Environment Assessments
  - Section 6 Atmospheric and Acoustic Environment
  - Section 7 Geology and Groundwater
  - Section 8 Aquatic Environment
  - Section 9 Terrestrial Environment
- Part III: Human Environment Assessments
  - Section 10 Human Health
  - Section 11 Land and Resource Use
  - Section 12 Quality of Life
  - Section 13 Economics
- Part IV: Integrated Topics and Summaries
  - Section 14 Accidents and Malfunctions
  - Section 15 Effects of the Environment on the Project
  - Section 16 Assessment Summary and Conclusions

Supporting documents have been presented as appendices to the main document. Appendices include databases, baseline reports, technical reports, and concordance tables.

The structure of the EIS is presented graphically in Figure 1.4-1, with the list of appendices identified in Figure 1.4-2. The central biophysical and human environment assessments are shown in Figure 1.4-3.

Figure 1.4-1: Wheeler River Project Environmental Impact Statement Roadmap – Main Document

Part I: Introduction and Context

- Appendix 1-A Concordance Tables
- Appendix 2-A Engagement Database Summary – Project Description
- Appendix 2-B Project-related Traffic
- Appendix 2-C Alternative Means Assessment
- Appendix 3-A Ya'thi Néné Report

1.5 Project Summary

The proposed site layout for the Project is provided in Figure 1.5-1.

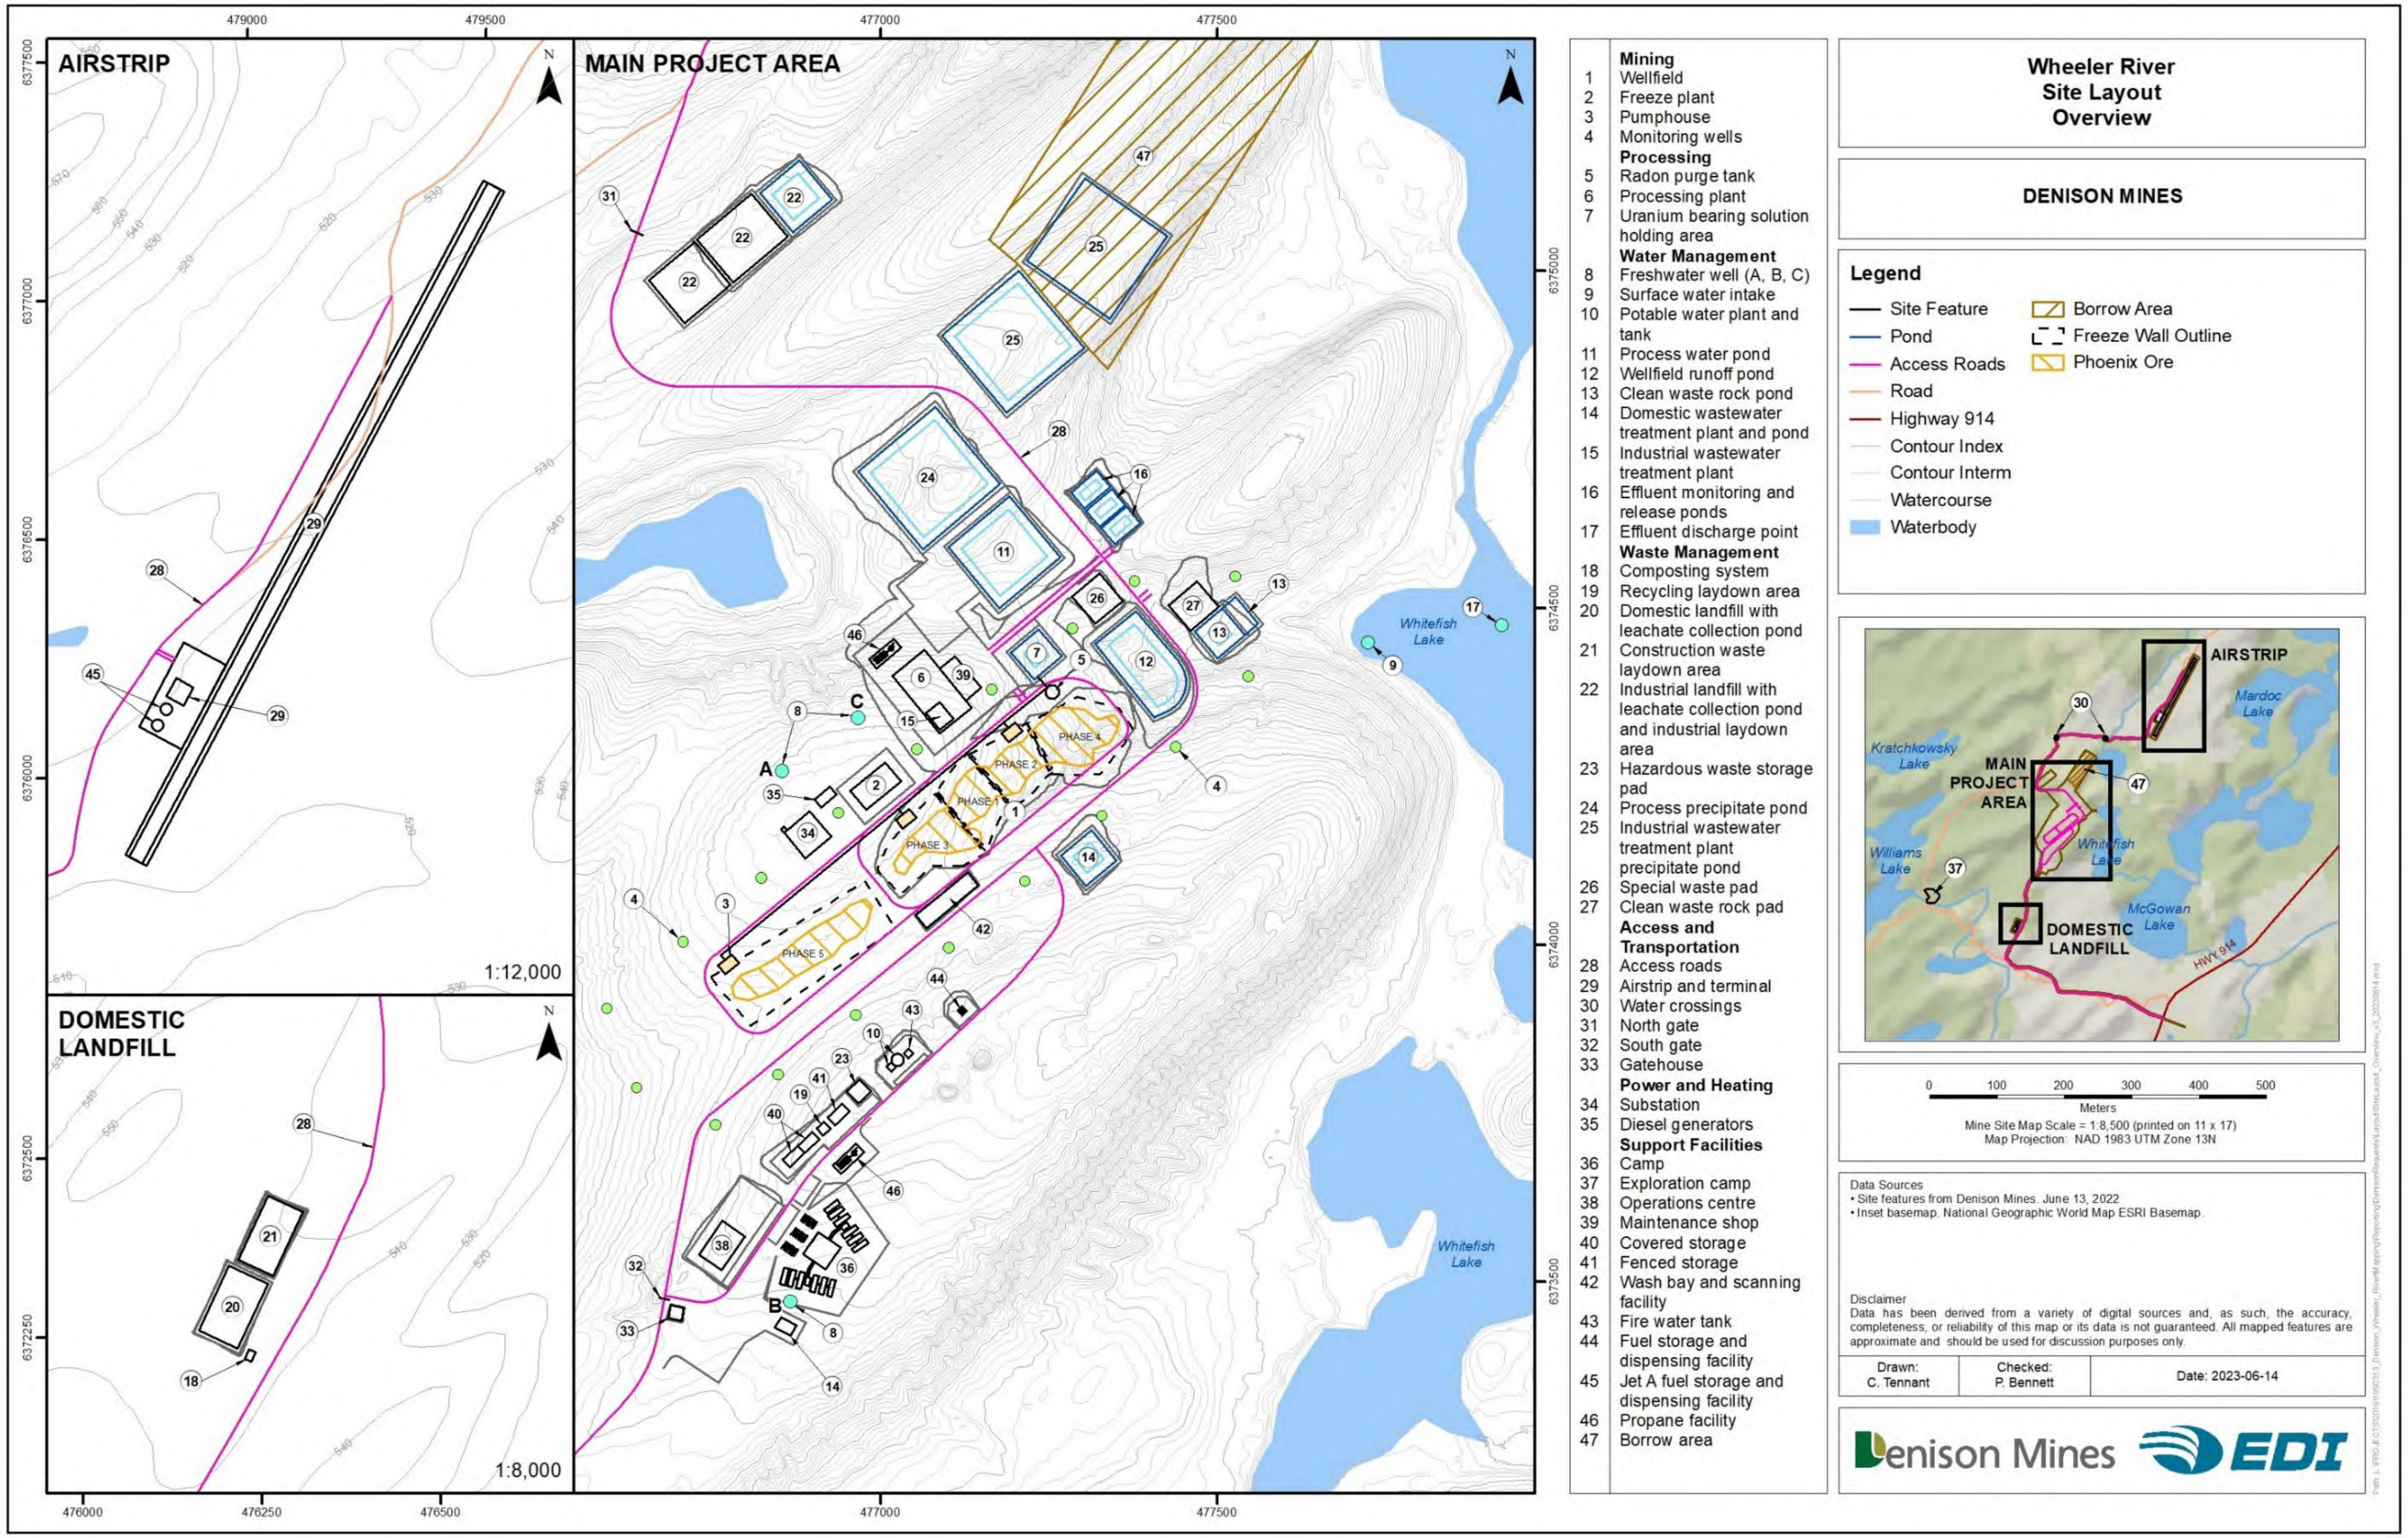

Figure 1.5-1: Wheeler River Project Proposed Site Layout

Briefly, Denison proposes to use the ISR method to mine uranium from the Phoenix uranium deposit. The deposit is a high-grade (average grade 19% uranium ore concentrate [i.e., U_3O_8]) with approximately 70.2 million pounds of U_3O_8. The ISR method involves drilling several wells and then circulating an acidic mining solution underground. The mining solution dissolves uranium, which is brought to the surface and run through a simple processing plant. The processing plant will remove precipitates from the solution and then process the solution to produce yellowcake. The yellowcake is a final, saleable product that is transported off site to customers.

Denison has bound the EA above the Phoenix deposit's indicated resources of 70.2 million pounds. It has been assumed that the Project will generate an annual average production of 9 million pounds of U_3O_8, with a potential annual peak production of 12 million pounds of U_3O_8, and Operation will last up to 15 years. The conservative EA case allows for overall total life of mine production of 135 million pounds of U_3O_8, which is expected to allow for the EA case to accommodate operational flexibility from one year to the next.

Various components and activities are required to support the ISR mining and processing activities. This includes infrastructure and systems for water management, waste management, site access and transportation, power, heating, and other support features, such as a camp.

1.6 Project Schedule

The total duration of the proposed Project is estimated to be approximately 38 years, which includes about 2 years for Construction, 15 years for Operation, five years for Decommissioning, and 15 years for Post-Decommissioning. A summary of the anticipated key activities for Construction, Operation, Decommissioning, and Post-Decommissioning are provided in Table 1.6-1.

Table 1.6-1: Key Activities for the Wheeler River Project

Phase and Year	Description of Activities
Construction Year 1 to 3	• Development of access roads and air strip • Site preparation and earthworks; clearing, levelling, and grading of the Project Area • Power generation – generators • Installation of main substation and distribution of power around site • Wellfield and freeze hole drilling; ground freezing • Batch plant operation (concrete); crusher at borrow area • Development of surface infrastructure (camp, operations centre, plants, ponds, pads, and support facilities) • Waste management (composting, domestic and industrial landfill operation, recycling) • Water management (including treatment and site runoff) • Groundwater supply • Surface water withdrawal • Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel) • On-site and off-site operation of vehicles and transport of materials • Air transportation for workers • Regulatory site inspections • Engagement – site visit from Interested Parties • Employment and expenditures

Phase and Year	Description of Activities
Operation Year 3 to 18	• Operation of the ISR wellfield • Wellfield and freeze wall drilling • Operation and expansion of freeze wall • Batch plant operation (grout and cement); crusher at borrow area • Expansion of pond and pads • Operation of the processing plant and production of uranium concentrate • Water withdrawal from groundwater or surface water body • Management of surface water (including seepage and site runoff) • Water treatment, both domestic and industrial • Water release to surface water body • Waste management (composting, domestic and industrial landfill operation, recycling) • Hazardous waste management (temporary storage, handling, and off-site transportation) • Storage and disposal of drill waste rock, process precipitates, and industrial wastewater treatment plant precipitates • On-site and off-site operation of vehicles and transport of materials • Power supply – primarily power from the grid, also generators and back-up generators • Package and transport of nuclear substances • Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel) • Air transportation for workers • Progressive decommissioning and reclamation • Regulatory site inspections • Engagement – site visit from Interested Parties • Employment and expenditures
Decommissioning Year 18 to 23	• Site water management, treatment, and release • Mining area remediation and thawing of freeze wall • Process water treatment and release • Closure of ISR and freeze wells and related infrastructure • Decontamination of surface facilities and injection, recovery, and monitoring wells • Asset removal (including site power transmission lines and electrical infrastructure) • Demolition and disposal of non-salvageable surface infrastructure and materials • Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and process plant area) • Power generation – generators • Waste management (composting and landfill operation) • Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal) • On-site and off-site operation of vehicles and transport of materials • Reclamation of disturbed areas • Regulatory site inspections • Engagement – site visit from Interested Parties • Employment and expenditures
Post-Decommissioning Year 23 to 38	• Environmental monitoring • Regulatory site inspections • Engagement – site visit from Interested Parties • Employment and expenditures

1.7 Regulatory Framework

The proposed Project is subject to both a federal and provincial EA process. This section provides an overview of the regulatory framework for the EIS. A detailed consideration of applicable legislation, guidelines, policies, standards, and codes is incorporated into each assessment.

The provincial and federal EA processes for the Project will be conducted in parallel. The Saskatchewan Ministry of Environment's Environmental Assessment and Stewardship Branch and the CNSC will cooperate in conducting a coordinated provincial-federal EA that will follow the spirit of the Canada-Saskatchewan Agreement on Environmental Assessment Cooperation (2005; Government of Canada 2016) to the extent possible. The agreement allows for cooperation in the assessment of projects that require regulation by both levels of government. The cooperation agreement allows for the production of a single EIS that meets the requirements of both levels of government, such that each level of government can make an independent decision on the approval of the EIS.

1.7.1 Provincial Legislation

Denison has conducted, prepared, and submitted this EIS for the Project to the Saskatchewan Ministry of Environment's Environmental Assessment and Stewardship Branch. This EIS meets the requirements outlined in the *Environmental Assessment Act* (Government of Saskatchewan 2018d). Ultimately, the Project will require issuance of a ministerial approval under Section 15 of the *Environmental Assessment Act* (Government of Saskatchewan 2018d) before proceeding to licensing and permitting.

Provincial acts and associated regulations applicable to the Project are summarized in the following list. This list is not exhaustive.

- *The Environmental Assessment Act* (Government of Saskatchewan 2018d)
- The *Environmental Management and Protection Act*, 2010 (Government of Saskatchewan 2018e)
  - The Mineral Industry Environmental Protection Regulations, 1996 (Government of Saskatchewan 1996)
  - The Hazardous Substances and Waste Dangerous Goods Regulations (Government of Saskatchewan 2000)
  - The Waterworks and Sewage Works Regulations (Government of Saskatchewan 2020f)
  - The Environmental Management and Protection (Saskatchewan Environmental Code Adoption) Regulations (Government of Saskatchewan 2021a)
- *The Wildlife Act, 1998* (Government of Saskatchewan 2020g)
  - The Wildlife Regulations, 1981 (Government of Saskatchewan 2022d)

- *The Wildlife Habitat Protection Act* (Government of Saskatchewan 2018h)
  - The Wildlife Habitat Lands Disposition and Alteration Regulations (Government of Saskatchewan 2001)
- *The Fisheries (Saskatchewan) Act*, 2020 (Government of Saskatchewan 2020b)
  - The Fisheries Regulations (Government of Saskatchewan 2022b)
- *The Forest Resources Management Act* (Government of Saskatchewan 2021b)
  - The Forest Resources Management (Saskatchewan Environmental Code Adoption) Regulations (Government of Saskatchewan 2021c)
  - The Forest Resources Management Regulations (Government of Saskatchewan 2020c)
- *The Natural Resources Act* (Government of Saskatchewan 2019e)
- *Wildfire Act* (Government of Saskatchewan 2019)
- *The Heritage Property Act* (Government of Saskatchewan 2019c)
- *The Provincial Lands Act, 2016* (Government of Saskatchewan 2019f)
- *The Saskatchewan Employment Act* (Government of Saskatchewan 2021h)
  - The Mines Regulations, 2018 (Government of Saskatchewan 2019d)
  - The Occupational Health and Safety Regulations, 2020 (Government of Saskatchewan 2021e)
  - The Radiation Health and Safety Regulations, 2005 (Government of Saskatchewan 2005)
- *The Reclaimed Industrial Sites Act* (Government of Saskatchewan 2018g)
  - The Reclaimed Industrial Sites Regulations (Government of Saskatchewan 2021g)
- *The Water Security Agency Act* (Government of Saskatchewan 2019g)
- *The Dangerous Goods Transportation Act* (Government of Saskatchewan 2018c)
  - The Dangerous Goods Transportation Regulations (Government of Saskatchewan 2002)

1.7.2 Federal Legislation

This EIS has been prepared to comply with the requirements of the *Canadian Environmental Assessment Act, 2012* (Government of Canada 2019a).

The proposed Project will include the construction, operation, and decommissioning of a uranium mine, processing plant, and supporting facilities on a site that is not within the boundaries of an existing licensed uranium mine or mill. As such, the Project is a designated project as set out in Section 31 of the Regulations Designating Physical Activities (Government of Canada 2014) and is therefore subject to a federal EA.

The CNSC is the federal authority responsible for the Project's EA. Federal acts and associated regulations applicable to the Project are summarized in the following list. This list is not exhaustive.

- *Fisheries Act* (Government of Canada 2019c)
  - Metal and Diamond Mining Effluent Regulations (Government of Canada 2022a)
- *Canadian Environmental Assessment Act* (Government of Canada 2019a)
  - Regulations Designating Physical Activities (Government of Canada 2014)
  - Prescribed Information for the Description of a Designated Project Regulations (Government of Canada 2019e)
- *Species at Risk Act* (Government of Canada 2022b)
- *Nuclear Safety and Control Act* (Government of Canada 2017c)
  - General Nuclear Safety and Control Regulations (Government of Canada 2015a)
  - Uranium Mines and Mills Regulations (Government of Canada 2017d)
  - Packaging and Transport of Nuclear Substances Regulations, 2015 (Government of Canada 2015b)
  - Radiation Protection Regulations (Government of Canada 2021b)
- *Migratory Birds Convention Act*, 1994 (Government of Canada 2017b)
- *Transportation of Dangerous Goods Act*, 1992 (Government of Canada 2019f)
  - Transportation of Dangerous Goods Regulations (Government of Canada 2021c)
- *Canadian Environmental Protection Act*, 1999 (Government of Canada 2021a)
  - Environmental Emergency Regulations, 2019 (Government of Canada 2019b)
- *Canada Wildlife Act* (Government of Canada 2017a)
- *Canadian Navigable Waters Act* (Government of Canada 2019d)

1.7.3 Guidelines, Policies, Standards, and Codes

In addition to regulatory requirements from federal and provincial acts and regulations, Denison has applied several guidelines, policies, standards, and codes to the Project while completing this EIS. The following list provides examples of guidelines, policies, standards, and codes that are applicable to the Project. This list is not exhaustive.

- Canadian Environmental Assessment Agency
  - Technical Guidance for Assessing Physical and Cultural Heritage or any Structure, Site or Thing that is of Historical, Archaeological, Paleontological or Architectural Significance under the *Canadian Environmental Assessment Act, 2012* (CEAA 2015c)
  - Addressing “Purpose of” and “Alternative Means” under the *Canadian Environmental Assessment Act, 2012* (CEAA 2015a)

  - Determining Whether a Designated Project is Likely to Cause Significant Adverse Environmental Effects under the *Canadian Environmental Assessment Act, 2012* (CEAA 2018)
  - Reference Guide Considering Aboriginal Traditional Knowledge in Environmental Assessments Conducted under the *Canadian Environmental Assessment Act, 2012* (CEAA 2015b)
- The Federal Policy on Wetland Conservation (Government of Canada 1991)
- Various CNSC regulatory documents, including:
  - REGDOC-2.9.1 Environmental Protection – Environmental Principles, Assessments and Protection Measures (CNSC 2020);
  - REGDOC-2.11-2 Waste Management – Decommissioning (CNSC 2021c);
  - REGDOC-3.1.2 Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills (CNSC 2018); and
  - REGDOC-3.2.2 Indigenous Engagement (CNSC 2019b).
- Generic Guidelines for the Preparation of an Environmental Impact Statement pursuant to the *Canadian Environmental Assessment Act, 2012* (CNSC 2021a)
- Various Canadian Standards Association standards, including:
  - N288.4-10 Environmental monitoring programs at Class I nuclear facilities and uranium mines and mills (CSA 2010);
  - N288.7-15 Groundwater protection programs at Class I nuclear facilities and uranium mines and mills (CSA 2015);
  - N286-12 Management system requirements for nuclear facilities (CSA 2012b);
  - N288.5-11 Effluent monitoring programs at Class I nuclear facilities and uranium mines and mills (CSA 2011);
  - N288.6-12 Environmental risk assessments at Class I nuclear facilities and uranium mines and mills (CSA 2012a); and
  - N294-19 Decommissioning of facilities containing nuclear substances (CSA 2019).
- Guidelines for Compost Quality (CCME 2005)
- Northern Mine Decommissioning and Reclamation Guidelines (Government of Saskatchewan 2008)
- Saskatchewan Environmental Code and attendant standards (Government of Saskatchewan 2022a)

1.7.4 Concordance Tables

Concordance tables linking the content of the EIS to specific requirements are provided in Appendix 1-A. Concordance tables have been generated between the EIS and the following documents:

- Generic Guidelines for the Preparation of an Environmental Impact Statement pursuant to the Canadian *Environmental Assessment Act*, 2012 (version: March 23, 2021; CNSC 2021a);
- Denison Mines Wheeler River Project Terms of Reference (Denison 2019).

1.7.5 Licensing and Permitting

The following list of permits, approvals, and licences are anticipated at different stages of the Project.

- Provincial EA approval
- Federal EA approval
- CNSC licences to:
  - prepare and construct the site
  - operate the site
  - decommission the site
  - abandon the site (release from licensing)
- Surface lease agreement
- Saskatchewan Heritage Conservation Branch approval
- Provincial forest product permit
- Saskatchewan Water Security Agency aquatic habitat protection permit
- Saskatchewan Water Security Agency permit to operate a waterworks
- Saskatchewan Water Security Agency permit to operate a sewage works
- Provincial approval to construct an approach to a highway
- Provincial approval to construct and operate a pollutant control facility
- Provincial approval to construct a hazardous substances and waste dangerous goods facility and store hazardous substances and waste dangerous goods
- Provincial approval to decommission a pollutant control facility
- Release from decommissioning and reclamation requirements
- Provincial acceptance of the decommissioned and reclaimed site into the Institutional Control Program

It is important to note that Denison is completing a sequential EA and licensing process for the Project.

While a preview of the permits, approvals, and licences required after the EA process is complete is important to consider and provides valuable context, detailed information needed to support licensing and permitting has not be included in the EIS. A summary of the main phases for the CNSC's licensing process and the Government of Saskatchewan's approval process is provided in Figure 1.7-1.

Abbreviations, Acronyms and Units

Abbreviation / Acronym	Definition
AADT	Annual Average Daily Traffic
ALARA	As Low As Reasonably Achievable
ATV	All-terrain vehicle
BATEA	best available technology economically achievable
CDP	conceptual decommissioning plan
COPC	constituent of potential concern
CNSC	Canadian Nuclear Safety Commission
CSA	Canadian Standards Association
DDP	Detailed decommissioning plan
Denison	Denison Mines Corp.
DWWTP	Domestic wastewater treatment plant
EA	Environment Assessment
ECCC	Environment and Climate Change Canada
EI	Emission Intensity
EIS	Environmental Impact Statement
EMS	Environmental Management System
ERFN	English River First Nation
GCL	Geosynthetic Clay Liner
GHG	Greenhouse gas
GM	Geomembrane
GWMP	Groundwater protection and groundwater monitoring plan
GWP	Global Warming Potential
HDPE	High-density polyethylene
HVAC	Heating, ventilation, air conditioning
IWWTP	Industrial Wastewater Treatment Plant
IPCC	Intergovernmental Panel on Climate Change
ISR	In situ recovery
IWWTP	Industrial Wastewater Treatment Plant
LSA	Local Study Area
MDMER	Metal and Diamond Mining Effluent Regulations
NIR	National Inventory Report
PAG	Potentially Acid Generating
PDP	Preliminary decommissioning plan
PEA	Preliminary economic assessment
PFS	Prefeasibility study

Abbreviation / Acronym	Definition
PMP	probable maximum precipitation
Project	Wheeler River Project
SACC	Strategic Assessment of Climate Change
SK MOE	Saskatchewan Ministry of the Environment
SRC	Saskatchewan Research Council
TAADT	Truck Annual Average Daily Traffic
UBS	Uranium bearing solution
VWP	Vibrating wire piezometers
WTP	Water treatment plant

Units	Definition
cm	centimeter
°C	degrees Celsius
g/L	gram per litre
ha	hectare
in	inch
km	kilometre
L	litre
L/day	litres per day
L/min	litre per minute
L/s	litres per second
m	metre
m^2	square metre
m^3	cubic metre
mg/L	milligram per litre
Mlbs	million pounds
Mlbs/year	million pounds per year
psi	pound per square inch
tonne	a metric unit of mass equal to a thousand kilogram

Glossary

Term	Definition
Active mining area	The active area within the broader mining area where focused in situ recovery mining will occur. The active mining area is effectively the ore zone, where the injection and recovery wells will be screened. The ore zone has an average thickness is 5 m, with a range of 2 to 17 m.
Basement rock	The foundation of thick, ancient rocks (e.g., metamorphic and igneous), which form the crust of continents. For the Wheeler River Project, it involves rock of low permeability located under the uranium ore deposit.
Bounding	Bounding in the context of environmental assessment refers to establishing the limits or boundaries within which the assessment will be conducted.
Brine solution	A solution of calcium chloride that will be circulated through the freeze holes to remove heat from the ground to create the freeze wall.
Clean waste rock	Waste rock generated as sandstone cuttings and core from drilling activities associated with well and freeze hole development that does not have uranium containing materials.
Climate Change	Refers to long-term shifts in temperatures and weather patterns and events.
Combustion	The act or instance of burning a fuel like natural gas to produce energy. For example, combustion is typically the process that powers automobile engines and power plant generators.
Diamond drilling	A form of core drilling which uses a rotary drill with a diamond drill bit attached in order to create precisely measured holes and obtain cores of rock samples.
Domestic Wastewater Treatment Plant	The wastewater facility for the treatment of domestic wastewater, i.e., greywater (e.g., water drained from sinks, showers, washing machines) and blackwater (i.e., sewage).
Dry (dries, or mine dry)	A mine dry is a change room which provide workers with a safe space to change and clean up before returning to their living quarters.
Environmental Assessment	An assessment of potential environmental consequences of a project. The environmental assessment considers the existing environment where the Project is to be located (including, but not limited to, Indigenous and Local Knowledge), predicts potential effects to valued components of the environment, identifies mitigation measures used to limit the effects of the project on the local environment, classifies potential effects remaining after mitigation, and describes monitoring and follow-up programs.
Environmental Impact Statement	A document that contains the environmental assessment for a project, and can also include details on the project description, engagement, mitigation measures, residual and cumulative effects, accidents and malfunctions, and effects of the environment on the project.
Freeze pipe	As it relates to the freeze wall, a pipe that is used to deliver the cold brine solution to the ground in a controlled manner to remove heat from the ground and create a freeze wall. The brine, warmed by the ground, is returned to the top of the freeze pipe in the gap between the injection tube and casing of the freeze pipe.
Freeze wall	A wall of frozen ground extending from surface down to basement rock. The freeze wall is used to limit groundwater movement into the vertical area in and above the mining area and, in conjunction with well design and hydraulic containment from pumping, contain solutions (mining solution and uranium bearing solution) within the mining area.
Geomembrane liner	A synthetic material with low permeability used to control or prevent the migration of a liquid or gas.
Geosynthetic clay liner	A liner made of geotextiles and bentonite to prevent the migration of a liquid or gas.

Term	Definition
Greenhouse gas	A gas in the Earth's atmosphere that absorbs and emits infrared radiation. The most common examples include carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O).
Industrial Wastewater Treatment Plant	The wastewater facility for the treatment of industrial wastewater, including wastewaters produced in the processing plant during uranium extraction and from other various sources (e.g., wash bay sump water, leachate from the industrial landfill, wellfield runoff pond).
Industrial Wastewater Treatment Plant Precipitates	Precipitates generated in stage 2 of the Industrial Wastewater Treatment Plant which are non-radioactive and planned to be decommissioned on site.
Injection tube	As it relates to the freeze wall, a tube in a freeze pipe that delivers cold brine solution to freeze the ground around the pipe.
Injection well	The well that delivers mining solution to the uranium ore deposit.
In situ recovery	A mining method that uses a water-based solution, fortified with mining reagents, to dissolve naturally occurring uranium from within a host rock, while the host rock remains in place (in situ) below surface.
Laydown	A laydown is an area on a construction site where tools, materials, equipment, and vehicles are stored temporarily when they are not in use.
Lixiviant	A chemical used to extract a particular element from ore. The lixiviant for the Project is referred to as mining solution.
Mining solution	An acidic solution prepared on site by adding reagents, such as sulphuric acid, hydrogen peroxide, and ferric sulphate, to water.
Mining area	Underground area where in situ recovery mining occurs and within which mining solutions are contained. The maximum extent of the mining area is roughly 90 m wide x 750 m long x 50 m high. This is the approximate wellfield width and length, with consideration for the maximum vertical migration of mining fluids above the ore zone.
Mud rotary drilling	A drilling technique that uses a rotating drill bit to grind rock as the drill bit advances and then uses drilling mud to transport the drill cuttings up to the ground surface.
Ore zone	Location of the economic portion of the deposit that is being mined
Permeable	The ability of a material to allow fluids or gases to pass through. Conversely, an impermeable material would not allow fluids and/or gases to pass through it.
Primary containment of mining solution	Primary containment of mining solutions is achieved through well design and operation. Each well will have double containment, wells will be constructed of materials resistant to the mining solution, wells will be pressure grouted from the ore zone to surface, wells will tested for mechanical integrity prior to commissioning to confirm an adequate seal from surface to the well screen at the mining area. Operational monitoring of pressure and flow will provide assurance of proper functioning of wells.
Process precipitate	Process precipitates are radioactive precipitates that contain economic concentrations of uranium and are generated in the process precipitate removal circuit in the processing plant and in stage 1 of the Industrial Wastewater Treatment Plant.
Processing plant	The processing plant will house the tanks and equipment to process the uranium bearing solution recovered from the in situ recovery wellfield into yellowcake.
Project area	The area within which the Project and all components/activities are located. It was developed by applying a buffer around the Project footprint and represents the area of maximum physical disturbance. This area is consistent throughout the environmental impact statement for all valued components and is 169.6 ha.
Project footprint	Anticipated, direct footprint of Project components. This area of direct physical disturbance is estimated to be 74.8 ha.

Term	Definition
Pumphouse	A pumphouse is a small building or container on the surface where pipes from injection and recovery wells in the wellfield are operated and mining solution flows are monitored.
Recovery well	The well that brings the uranium bearing solution from the mining area up to surface.
Secondary containment of mining solution	Secondary containment of mining solutions is via pumping and creating hydraulic gradients to control fluid movement.
Special waste	Includes mineralized core and cuttings from well development that have uranium containing materials.
Uranium bearing solution	Mining solution containing uranium that is extracted from the uranium ore deposit by way of the recovery wells and is then processed into yellowcake in the processing plant.
Tertiary containment of mining solution	Tertiary containment of mining solutions is proposed to be a freeze wall that extends from the surface to the basement rock, isolating the mining area from regional groundwater.
Wellfield	A group of injection and recovery wells, installed, and completed in the ore zone for in situ recovery mining.
Yellowcake	uranium ore concentrate or U_3O_8 (triuranium octoxide)

2 Project Description

Section 2 of the Environmental Impact Statement (EIS) describes the Wheeler River Project (the Project) as it is planned to proceed through Construction, Operation, Decommissioning, and Post-Decommissioning phases. This section provides a timeline for the Project and describes the anticipated Project components and activities. Project alternatives and ancillary projects are discussed. The Project information is presented at a level sufficient to provide confidence in the effects assessments, recognizing that the Project engineering is currently at a prefeasibility-feasibility level and Project design details will be refined over time through to the permitting and licensing phase.

2.1 Purpose of the Project

The purpose of the Project is to construct, operate, and decommission an in situ recovery (ISR) uranium mine and processing plant to provide uranium supply for the increasing demands for nuclear power generation. Denison's goal is to achieve this while continuing partnerships with communities of interest, integrating information from Indigenous and public Interested Parties, and maintaining high standards for environmental protection and worker safety.

2.2 Project Components

The following subsections describe the anticipated Project components. An overview of proposed Project components and site layout is provided in Figure 2.2-1.

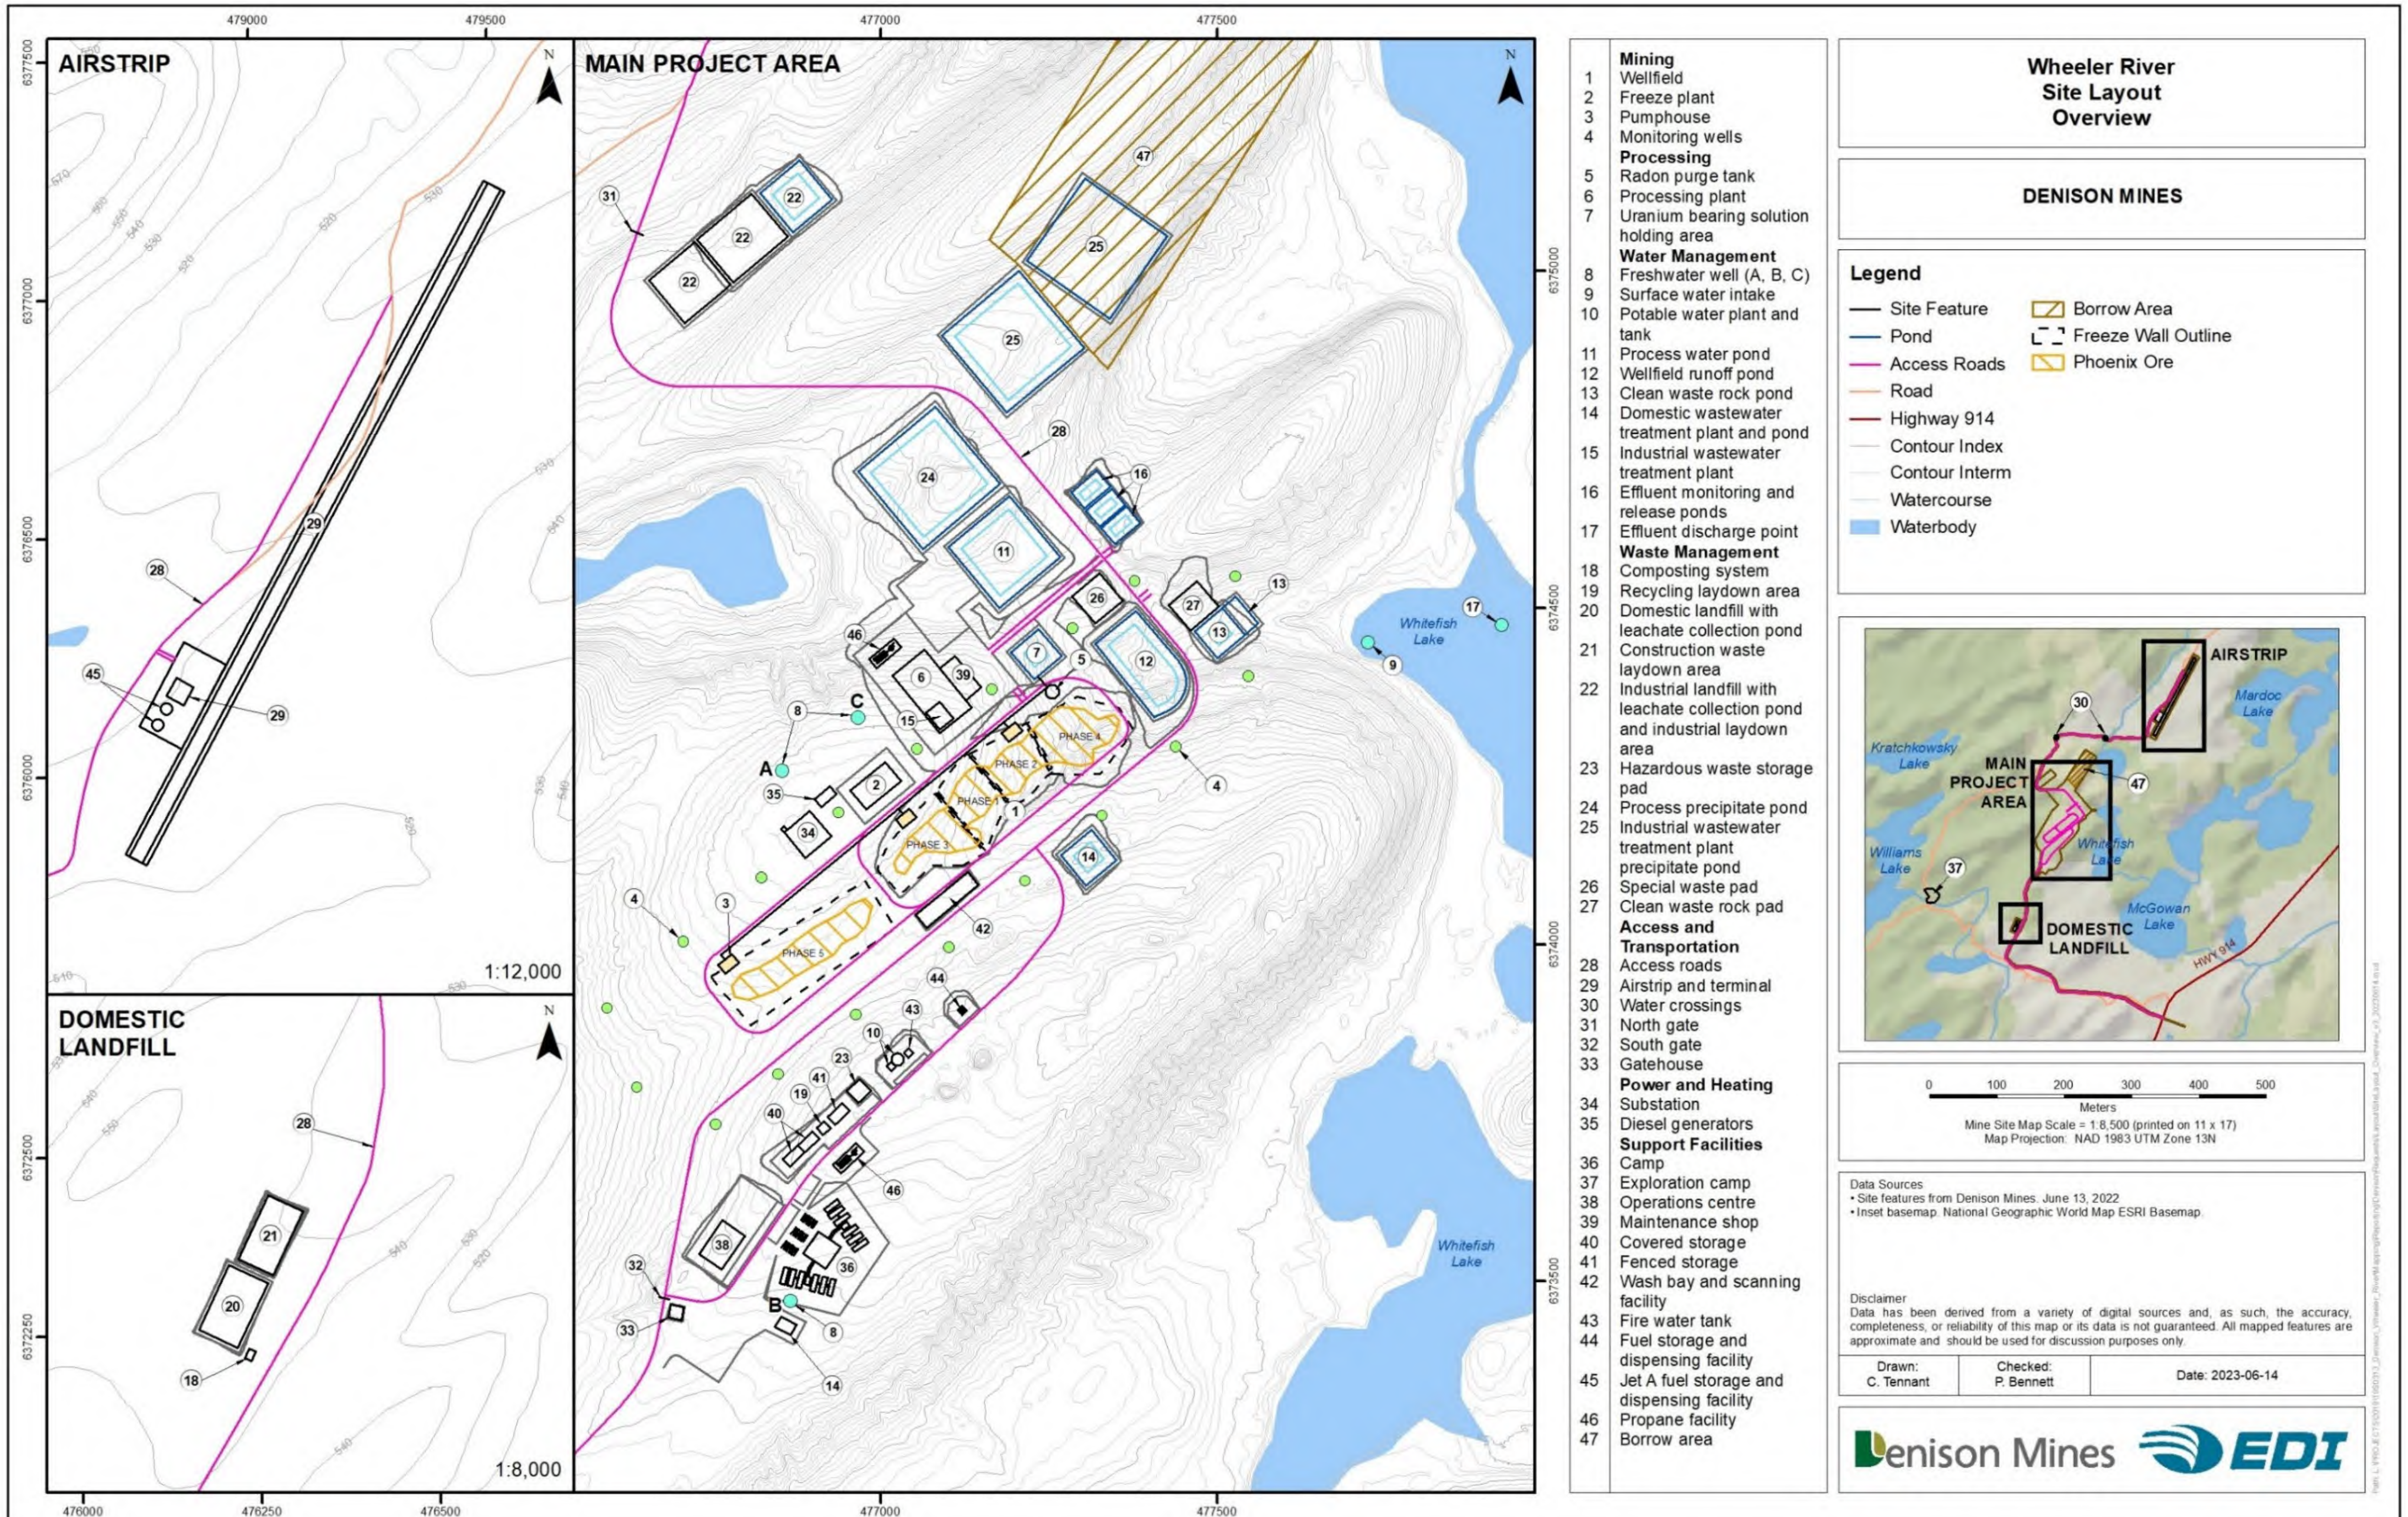

Figure 2.2-1: Wheeler River Project Proposed Site Layout

2.2.1 Mining

In situ recovery of uranium is the mining method proposed for the Project. An overview of the ISR process is provided in Figure 2.2-2 and the details will be provided in this section of the EIS. Figure 2.2-3 provides a to-scale image to illustrate the depth to the deposit (approximately 400 m) and length of wellfield (approximately 750 m) relative to the height of people and a typical transport truck on the ground surface.

Denison discussed potential mining methods early in the engagement process for the Project. In 2018, Denison organized a series of workshops with Communities of Interest and stakeholders. Given the history of uranium mining in northern Saskatchewan, there is a wealth of knowledge on various mining methods, and input was requested on which method would be best suited to efficiently and safely mine the Phoenix deposit. ISR mining for uranium is new to northern Saskatchewan and Canada. Because of this, some participants had reservations about ISR since it has not been previously used to mine uranium in the region. Other comments that the process reminded them of fracking, which carried a negative connotation (18-EN-VB-4.54[1]; see Section 2.2.1.4 for comparison of ISR to conventional oil and gas fracking). Some workshop participants were unsure how to evaluate the potential benefits and/or drawbacks of this mining method (18-EN-VILX-3.69). Other participants were confident in the method, saying they know it works in other countries, there are minimal waste streams, and the method is more economically feasible than other methods (18-EN-VILX-3.68). A participant in the Village of Beauval workshop preferred the small footprint and smaller environmental impacts of ISR compared to other methods (18-EN-VB-4.51). New opportunities are welcomed in the area, as they can support local businesses, provide training and learning opportunities, and keep money within the local economy (16-EN-MLA-109.26, 18-EN-VB-4.51).

[1] See Appendix 2-A for a summary of unique identification numbers from the Engagement Database referenced in this section.

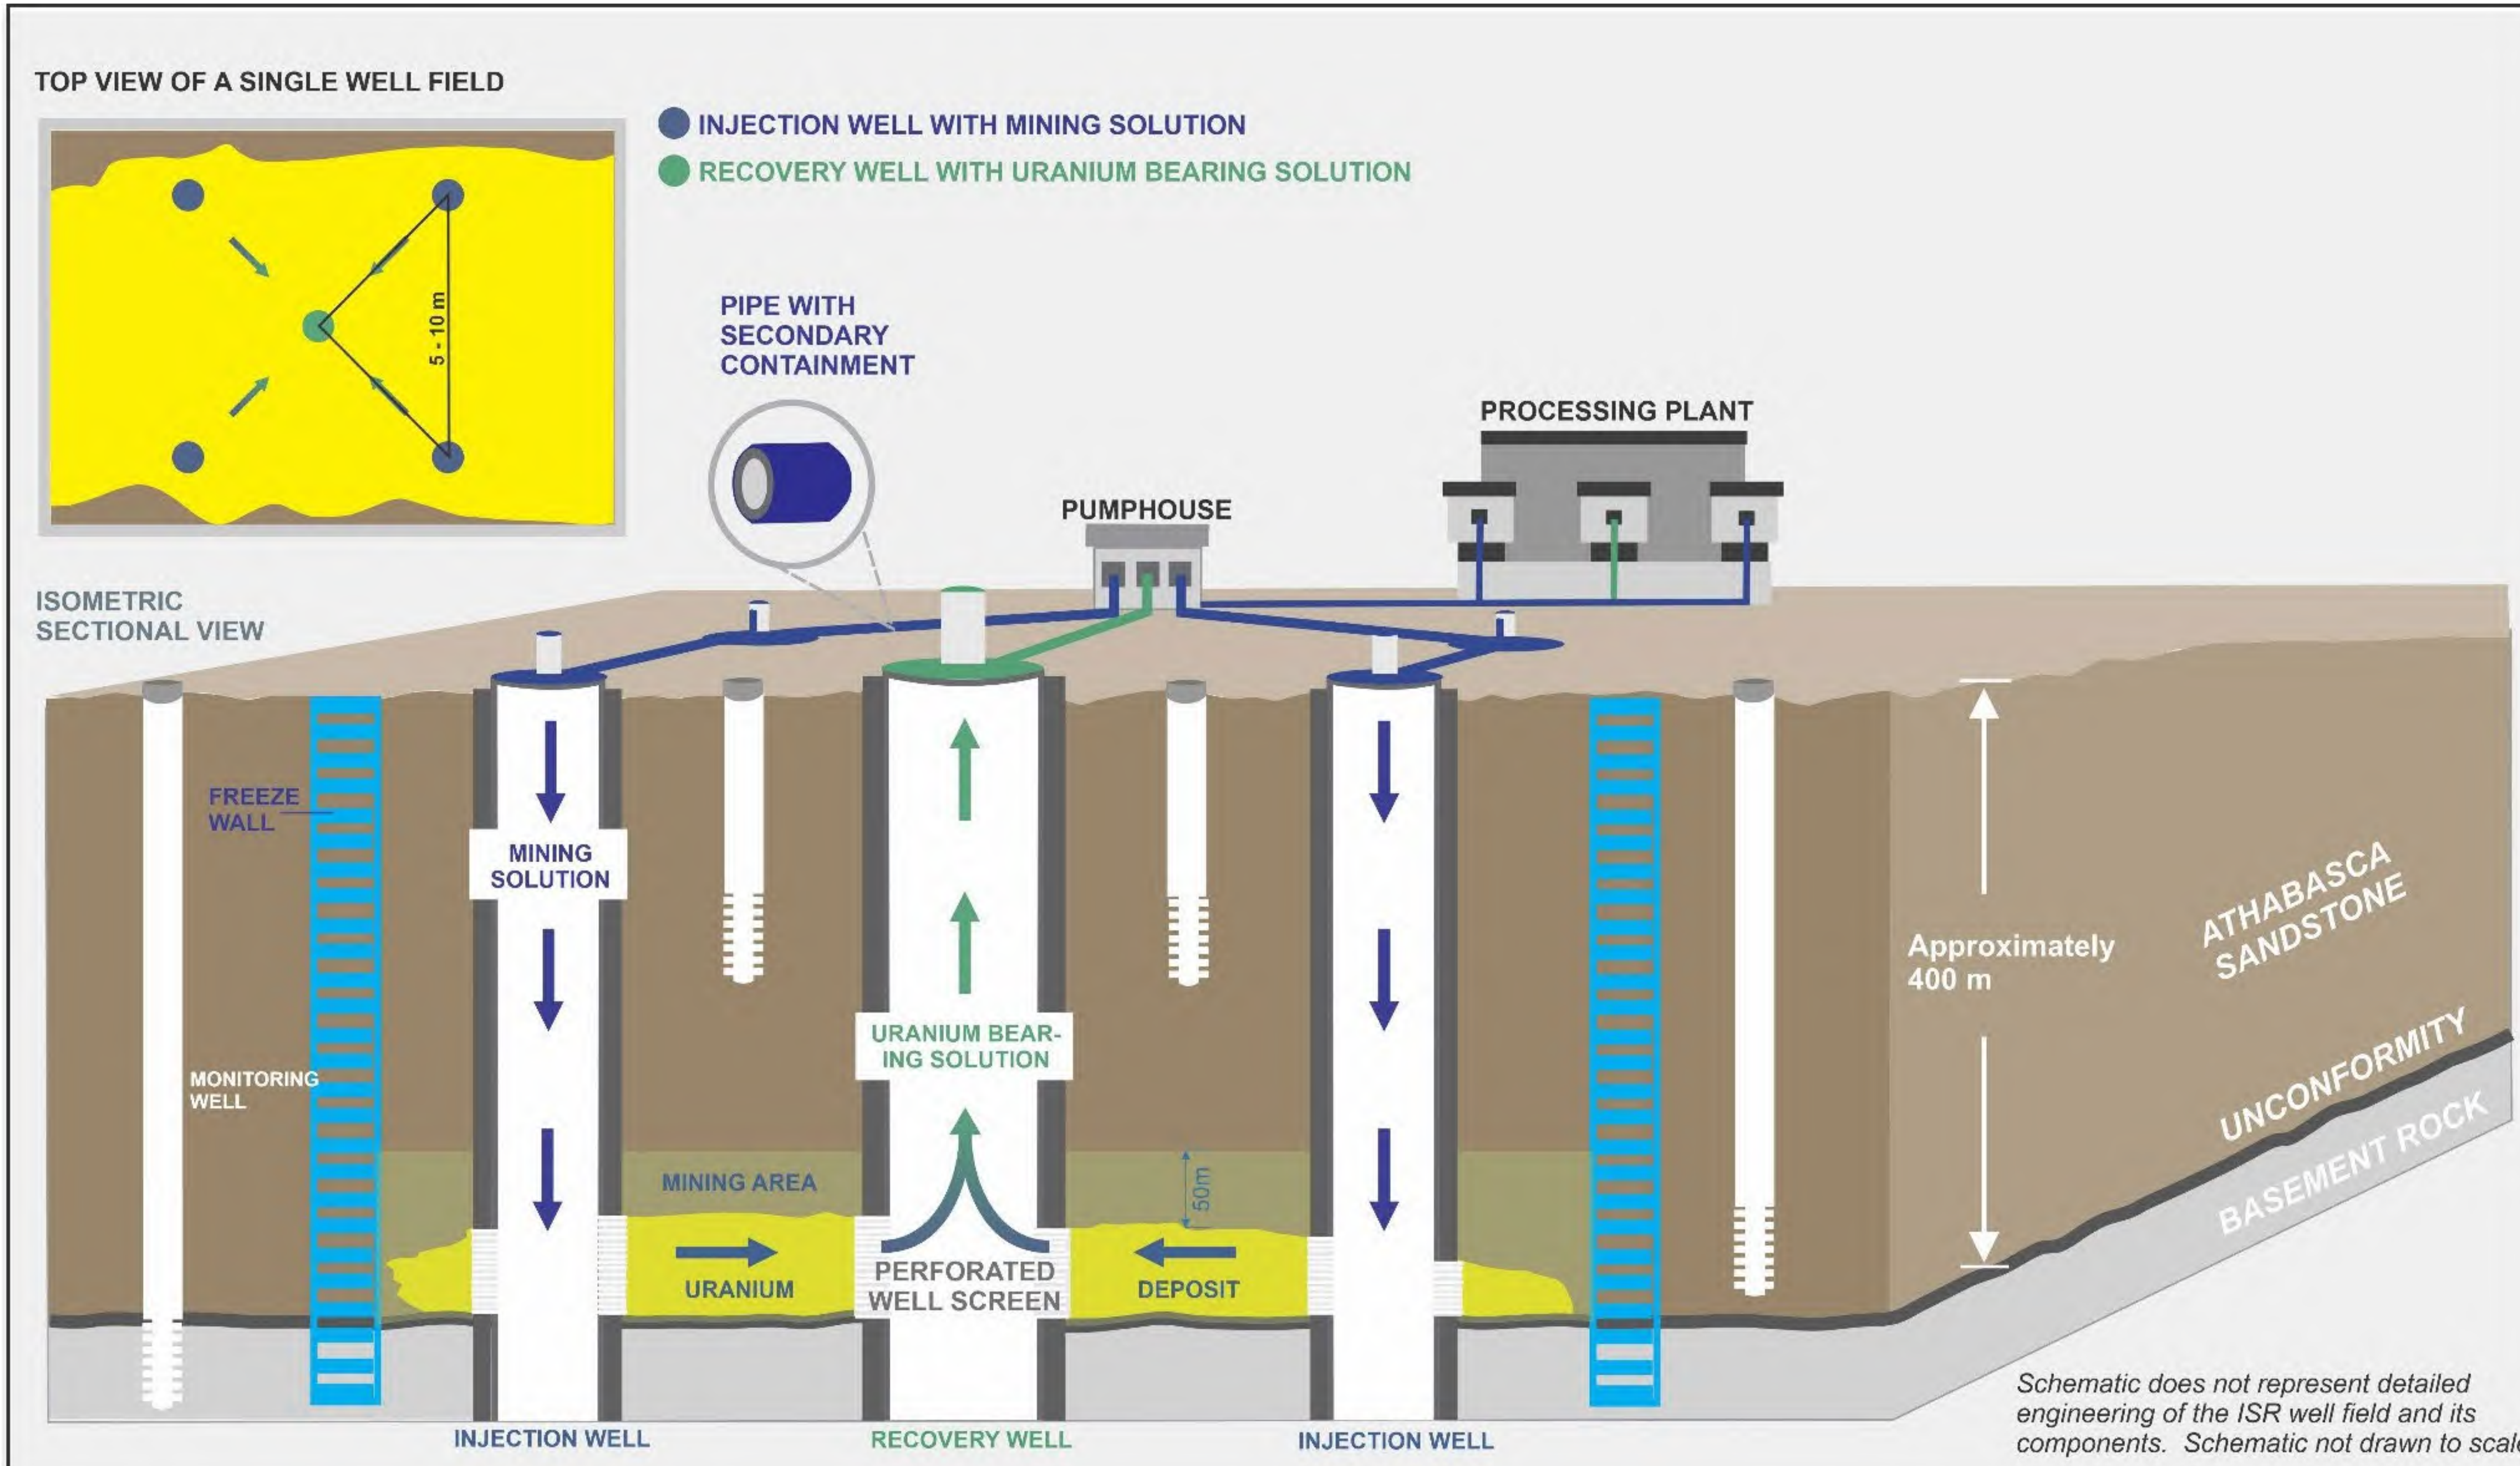

Figure 2.2-2: Overview of the In Situ Recovery Process

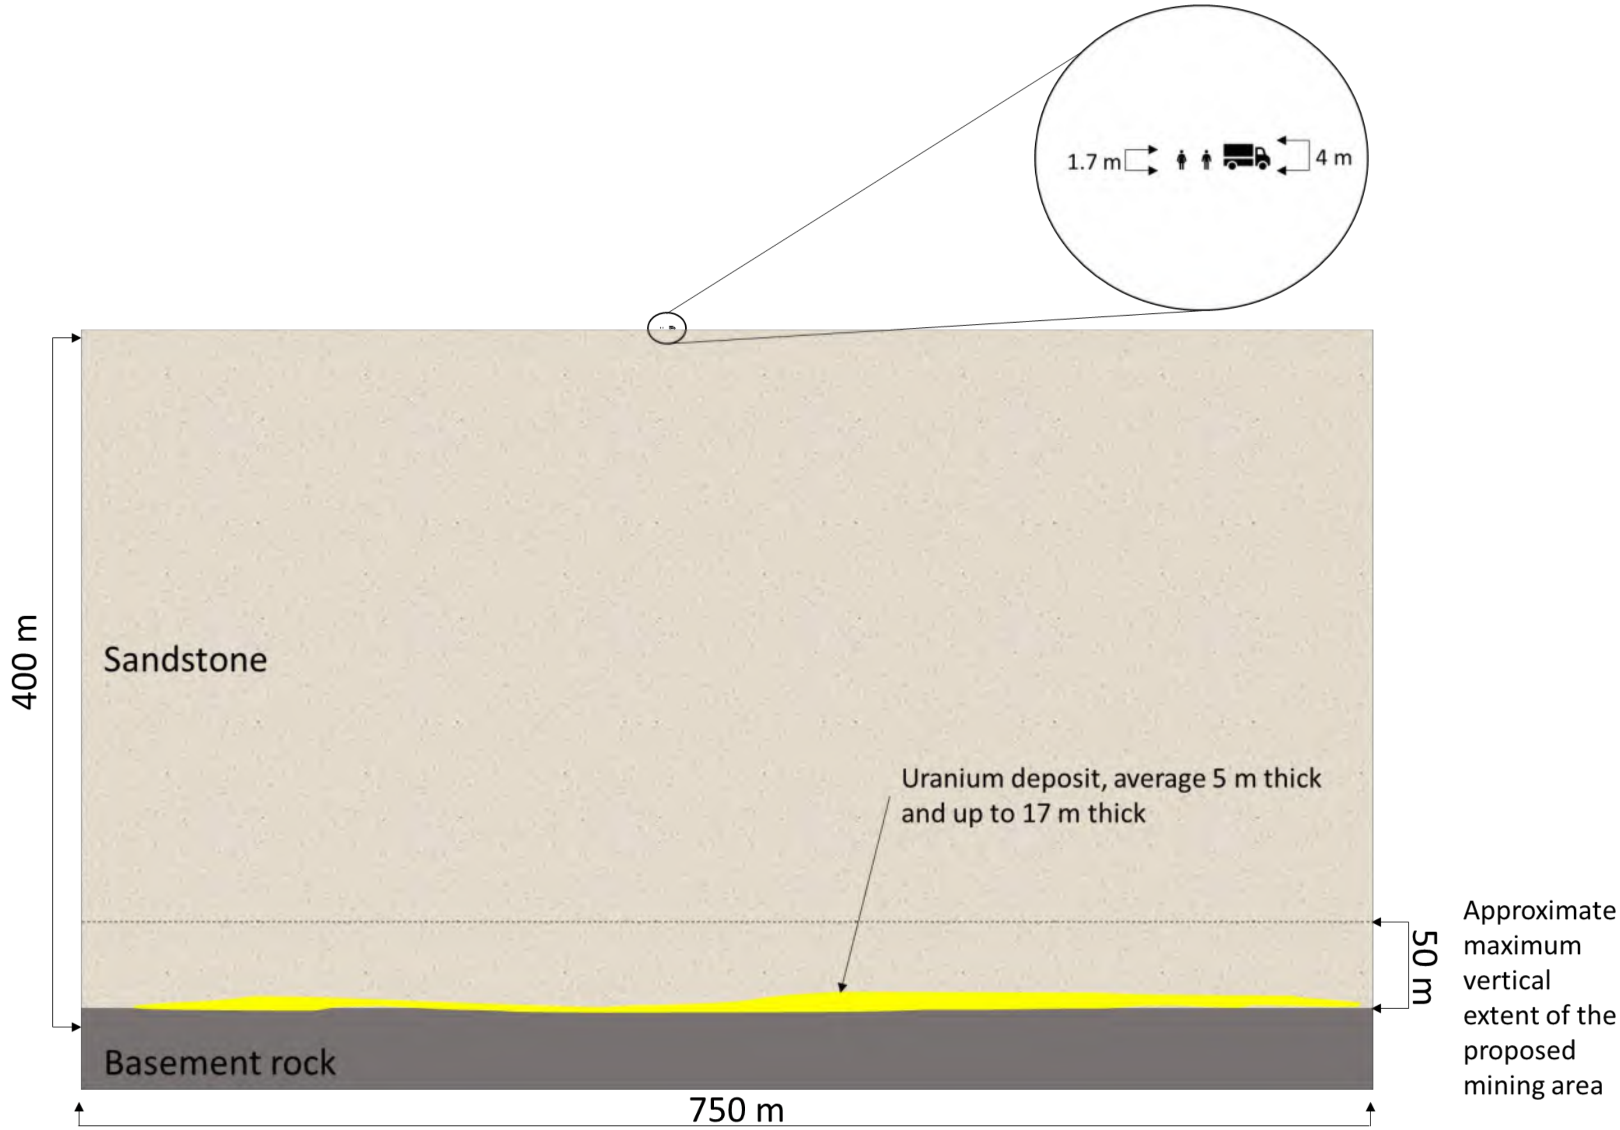

Figure 2.2-3: Approximate Depth to Deposit (400 m) and Length of Wellfield (750 m) Relative to People and Truck on Surface

The next subsection describes Project reserves and production. The general components of the mining process are presented in the subsequent sections and include an overview of drilling, freeze wall, wellfield, and the monitoring well network.

2.2.1.1 Reserves and Production

The Project proposes to use the ISR method to mine uranium from the Phoenix uranium deposit. The deposit is a high-grade (average grade 19% uranium ore concentrate [i.e., triuranium octoxide or U_3O_8]) with approximately 70.2 million pounds (Mlbs) of U_3O_8.

Denison has bound the environmental assessment above the deposit indicated resources of 70.2 Mlbs U_3O_8. The assessment basis for this EIS assumes an annual average production of 9 million pounds U_3O_8, with an annual peak production of 12 million pounds U_3O_8, over an operating period of 15 years. This conservative assessment basis provides operational flexibility from one year to the next and appropriately bounds the assessment of effects.

Note this is different than what was proposed in the Provincial Technical Proposal and Federal Project Description (Denison 2020), which suggested the EIS would evaluate an annual average production of 12 million pounds U_3O_8 over an operating period of 20 years. As reserve estimates and Project definition became refined over the intervening period, the need to assess this higher production was deemed unnecessary and unduly conservative.

2.2.1.2 Drilling

Well-established drilling techniques will be used to create the holes for the injection and recovery wells that make up the wellfield, the holes needed to create the freeze wall, and the holes for various monitoring wells. Considering this, an introduction to drilling techniques are provided here.

Two types of drilling have been successfully tested at the Project as part of Project development and exploration work: mud rotary drilling and diamond drilling. These two main drilling techniques are expected to be used for the ISR wellfield, groundwater monitoring well, and the freeze hole drilling required for the Project.

2.2.1.2.1 Mud Rotary Drilling

Mud rotary drilling is one of the most common methods of well drilling in Canada and may be used for the Project. Mud rotary drilling is generally used to develop larger diameter wells (greater than 7 inches or 17.78 cm) compared to diamond drilling. Mud rotary drilling may be used for installation of injection and recovery wells as the creation of a larger well will facilitate installation and operation of downhole equipment such as pumps.

A drilling bit is threaded onto drilling rods to be pushed down by the drilling rig to create a borehole for the well (Figure 2.2-4). The drilling rig rotates the rods and drilling bit, which grinds the rock, forming the borehole. The rock in the Project Area is sandstone. As the drilling bit grinds the rock, it creates drill cuttings, which are small pieces of the rock that have been broken down by the drilling bit. At the Project Area, the cuttings created are fine sand grains from the broken-up sandstone.

To remove the cuttings, mud must be circulated through the drilling pipe and out through nozzles in the drilling bit. The mud is a mixture of water, clay, and environmentally friendly polymers that clean out the cuttings and help to keep the drilling bit cool. The mud returns to surface on the outside of the drilling rods, carrying the fine sand grain particles with it. Once the mud returns to surface, it is collected by a hose line and run through a centrifuge to remove the solid sand grain cuttings and recover the liquid mud to be sent to the mud tank (Figure 2.2-4) to be reused (i.e., recirculated back down the drilling rods). Because the mud is reused, the volume of water required to drill the well is relatively small, even though the instantaneous flow rates are high through the drilling rods. Drilling a mud rotary well will require approximately 250 m^3 of water. The volume of clean sand grain cuttings produced for one mud rotary drilled well is approximately 16 m^3, or about 32 tonnes.

2.2.1.2.2 Diamond Drilling

Diamond drilling uses a hollow bit with a surface containing low quality diamonds. It produces a long cylinder of rock referred to as a core. Diamond drilling is the planned drilling method for installation of freeze holes and may also be used for some injection and recovery wells. This is the most common method of mineral exploration drilling in Saskatchewan and is also a common method of freeze hole drilling at northern Saskatchewan uranium mines. Diamond drilling methods can be used to create wells that are up to 5.5 inches or 13.97 cm in diameter.

A diamond-embedded coring bit is threaded on to drilling rods to be rotated and pushed down by the drilling rig to core a hole in the ground and recover solid pieces of rock (Figure 2.2-5). The drilling rig rotates the rods and drilling bit, cutting rock cores (Figure 2.2-5), which are then recovered and brought to surface. The volume of fine grain sand cuttings produced by the diamond drilling bit is very small because most of the sandstone rock is recovered intact (i.e., core).

To keep the diamond drilling bit cool and to remove sand cuttings from the bottom of the drilling bit, mud must be circulated through the drilling pipe and out through the bit. The mud is a mixture of water, bentonite clay, and environmentally friendly polymers. A single diamond drill hole will require approximately 400 m^3 of water. The flow rates of mud required for diamond drilling are much lower than the rates needed for mud rotary drilling, approximately $1/50^{th}$. Because of this, the mud does not make it back to surface and no fine grain sand cuttings are produced on surface. This also means that the drilling mud cannot be recirculated into the drilling rods and more water is required to create fresh mud. Cores can be saved and stored in core boxes for future study, or they can be placed on the clean waste rock pad if not required for further analysis. The volume of solid sandstone core produced for each hole is approximately 2.4 m^3, or about 6.2 tonnes.

2.2.1.3 Freeze Wall

ISR mines typically operate without freeze walls, as the containment of mining solution is achieved primarily through hydraulic control of the injected and recovered fluids and secondarily through the well design. Denison is proposing a freeze wall for tertiary containment of mining solution to support a defence in depth strategy as additional, site-specific data is obtained on hydraulic containment. The role of the freeze wall within the broader mining solution containment strategy is discussed in more detail in Section 2.2.1.4; and considered further in Section 2.3.1 Mine Plan (and see Figure 2.3-1).This subsection of the EIS is focused on outlining the steps required to establish the freeze wall.

Ground freezing technology is well established throughout the world. Its use in a mining environment was pioneered in Saskatchewan’s potash mining industry for shaft sinking activities, and later adapted for use in Saskatchewan’s uranium industry. Ground freezing to control and eliminate groundwater from entering the mining areas is a fundamental component of two existing Athabasca Basin underground uranium mines: Cameco Corporation’s McArthur River Operation and Cigar Lake Operation.

The freeze wall will be established by drilling vertical holes from surface to the basement rock (over 400 m below surface). The freeze holes will be spaced approximately 5 to 10 m apart. Over 300 freeze holes are estimated for the Project. The ground will be frozen from surface down to the low permeability basement rock to create a continuous wall around the mining area that is completely contained from the surrounding regional groundwater.

The drill holes for the freeze wall will be made using diamond drill methods. Once the drill holes have been installed, a chilled brine solution (e.g., calcium chloride brine) will be circulated through the cased holes to remove heat from the ground (Figure 2.2-6). A freeze pipe is comprised of an inner injection tube that delivers cold brine to its far end within a sealed steel casing. The brine then returns to the collar of the hole via the annular gap between the injection tube and the casing. Denison received this helpful perspective on the freeze technology during a presentation to high schools: “Isn’t it correct to say the brine is in a closed loop system? Like in an artificial ice rink? The brine doesn’t go into the environment? Is that correct?” (21-EN-YOUTH-445.6).

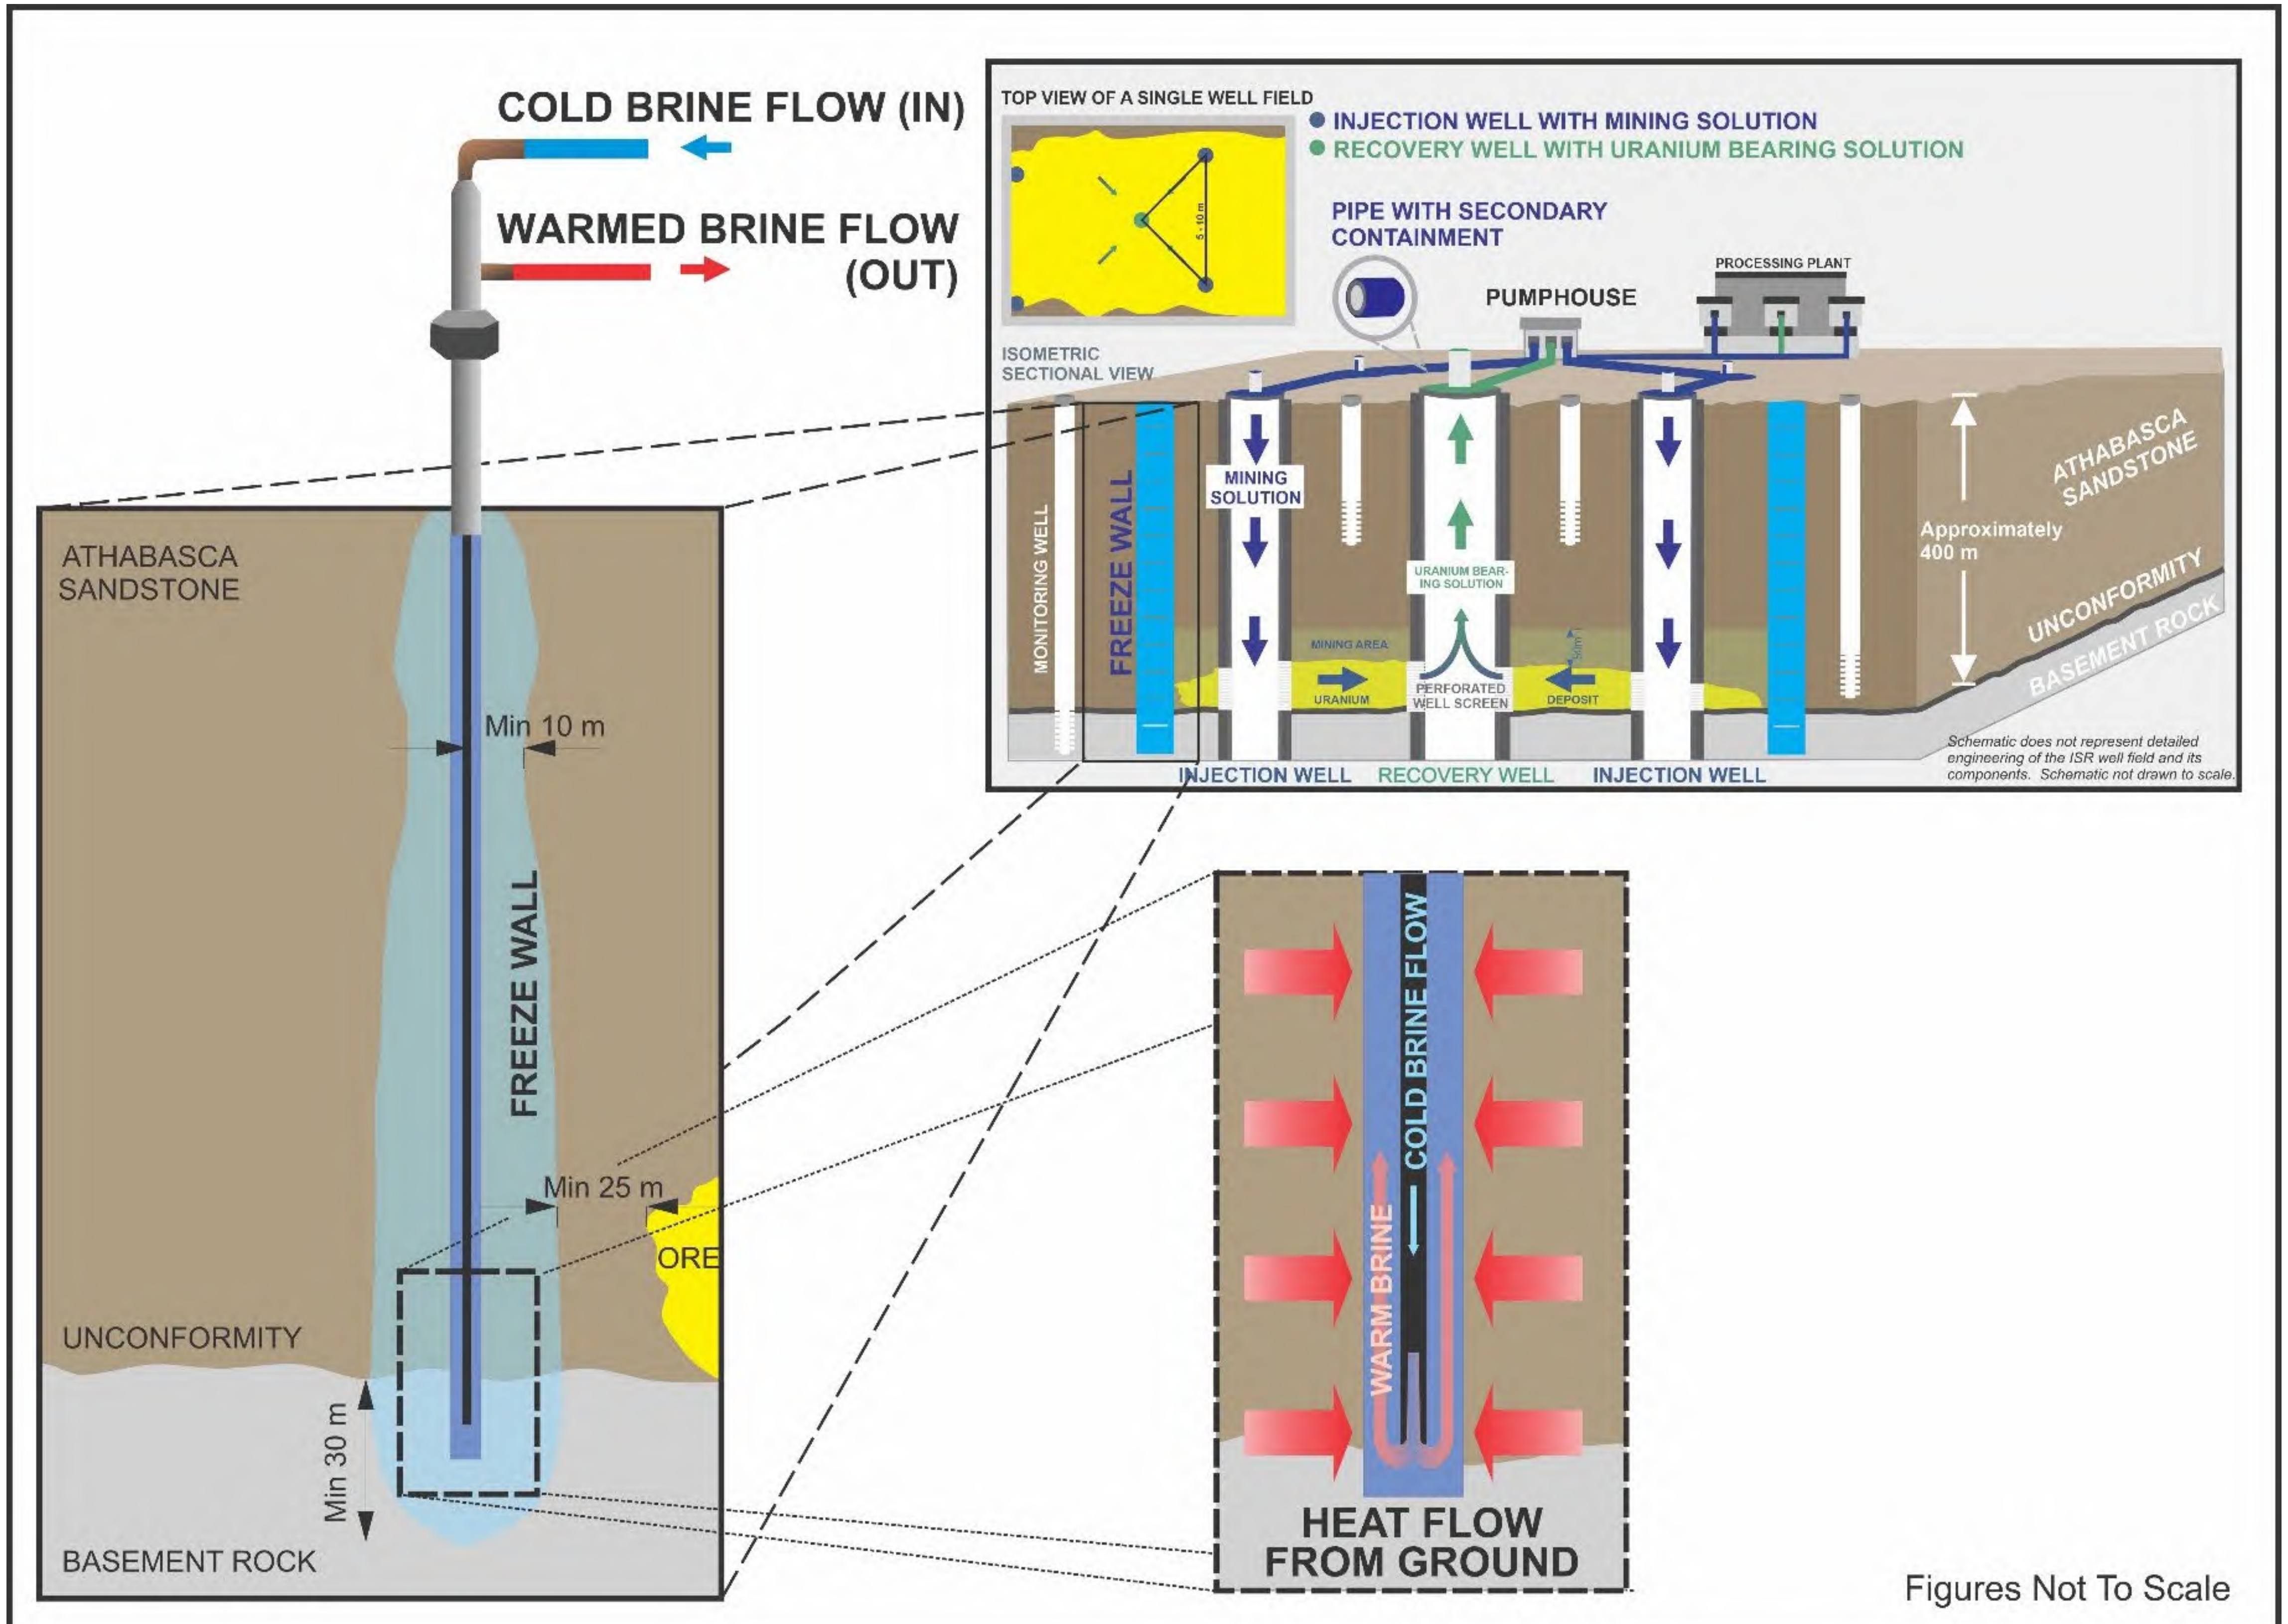

Figure 2.2-6: Illustration of Heat Transfer from Ground to Annular Flow in a Typical Freeze Pipe1

The three stages of ground freezing are column, closure, and wall (Figure 2.2-7). In the early weeks of freezing, initial closure is being established. Initial closure occurs when the frozen ground columns, growing around an individual freeze pipe, intersect with the adjacent pipes' frozen column; the hydraulic connection between the outside of the freeze circle and the inside is cut off; and the frozen columns around each pipe grow together and in thickness to create a wall. The freeze wall is expected to be several metres thick and will be developed around the uranium deposit to minimize freezing of the uranium deposit itself.

The thickness of the freeze wall is controlled by cycling the freeze system on and off once the desired thickness is achieved to prevent overgrowth or unwanted thawing. A monitoring network of continuous fiberoptic cables are installed in specific location both within and on the outside of the wall to monitor the freeze development and guide the freeze system cycling. This system proposed is solar powered and uploads data directly and live to a cloud service for data history and operational purposes.

Current plans are for the freeze wall to be a minimum of 10 m thick, be installed 25 m away from the uranium deposit, and extend 30 m into the basement rock (Figure 2.2-6).

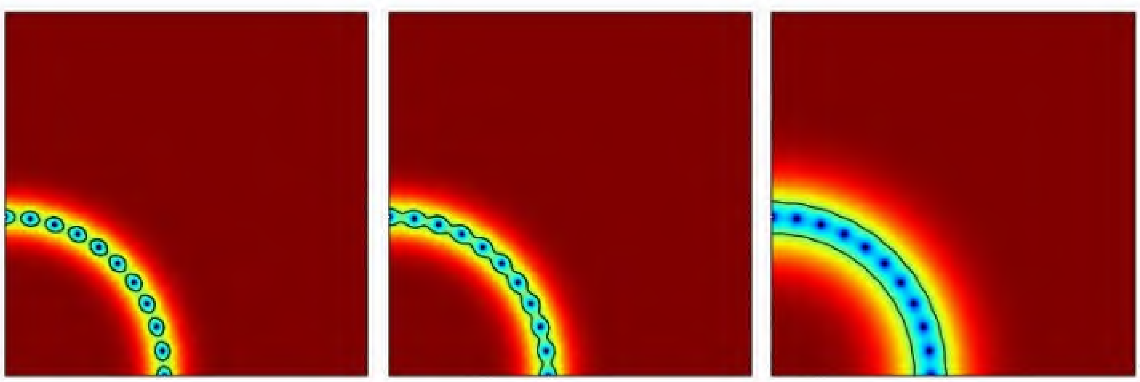

Figure 2.2-7: Stages of Ground Freezing: Column, Closure, and Wall

2.2.1.3.1 Freeze Plant

A freeze plant will be required on surface near the deposit where the freeze holes are collared (Figure 2.2-1). The freeze plant will be modular for easy installation and operation as more chiller units will be added as ground freezing needs increase. Each chiller unit produces about 300 tons of refrigeration and contains an ammonia compound compressor, which is run by a 1,000 horsepower motor. The brine distribution system is handled by a surface brine mixing tank that can move brine to the freeze holes at 300 m^3/hr. The freeze plant capacity is expected to be scaled up throughout the mining phases based on refrigeration requirements, from two chiller units at the start up to a total of six units. The approximate size of the freeze plant with six chiller units is 27 m x 64 m (i.e., under 1,800 m^2).

Piping will be required between freeze holes and the freeze plant. The piping is expected to be insulated polyethylene pipes joined by electrofusion. The piping will be installed in a poly-lined trench on wooden blockings.

The freeze plant will operate using electrical power from the grid, with back-up diesel generators (see Section 2.2.6 for Project power information). The freeze plant will be designed with ammonia safety in mind to monitor for and minimize risks to workers and the environment from potential ammonia leaks.

2.2.1.3.2 Freeze Wall Timeline

Modelling predicts that each section of the freeze wall will require approximately 12 months to be established. The freeze wall will be created in phases to support the mine plan (see Section 2.3.2).

After Decommissioning and remediation is complete (see Section 2.3.3), refrigeration will be turned off and the freeze wall will begin to melt. The removal of the freeze wall will allow groundwater to re-establish its original flow path through the area (22-EN-VB/ERFNLP-619.6). It will take a minimum of 12 months for the freeze wall to thaw, depending on how long the freeze wall was active and ground conditions encountered.

2.2.1.4 Wellfield for In Situ Recovery Mining

The ISR wellfield is a group of wells, installed, and completed in an area where uranium mineralization is present. The Project wellfield will consist of a combination of injection and recovery wells. In general, the arrangement is one recovery well in the centre surrounded by four injection wells. This is referred to as a five-spot pattern. At surface, the spacing between the recovery well and each injection well is anticipated to be approximately 5 to 10 m (Figure 2.2-1). With these configuration options, the wellfield is expected to include approximately 300 wells over an area measuring 90 m wide x 750 m long.

A variety of alternative arrangements or patterns of injection and recovery wells may be used and may include other vertical or horizontal arrangements. The final details of the wellfield design (e.g., pattern on surface, distance between wells, the orientation of wells, number of pumphouses) will be developed as Project engineering advances through engineering design stages. Additionally, continual improvement of the wellfield design will be ongoing throughout Operation.

2.2.1.4.1 Wellfield Installation

Figure 2.2-8 provides an overview of Denison's current conceptual injection and recovery well installation sequence based on current level of engineering. Specific details of well installation and design may change as the Project advances through engineering design stages.

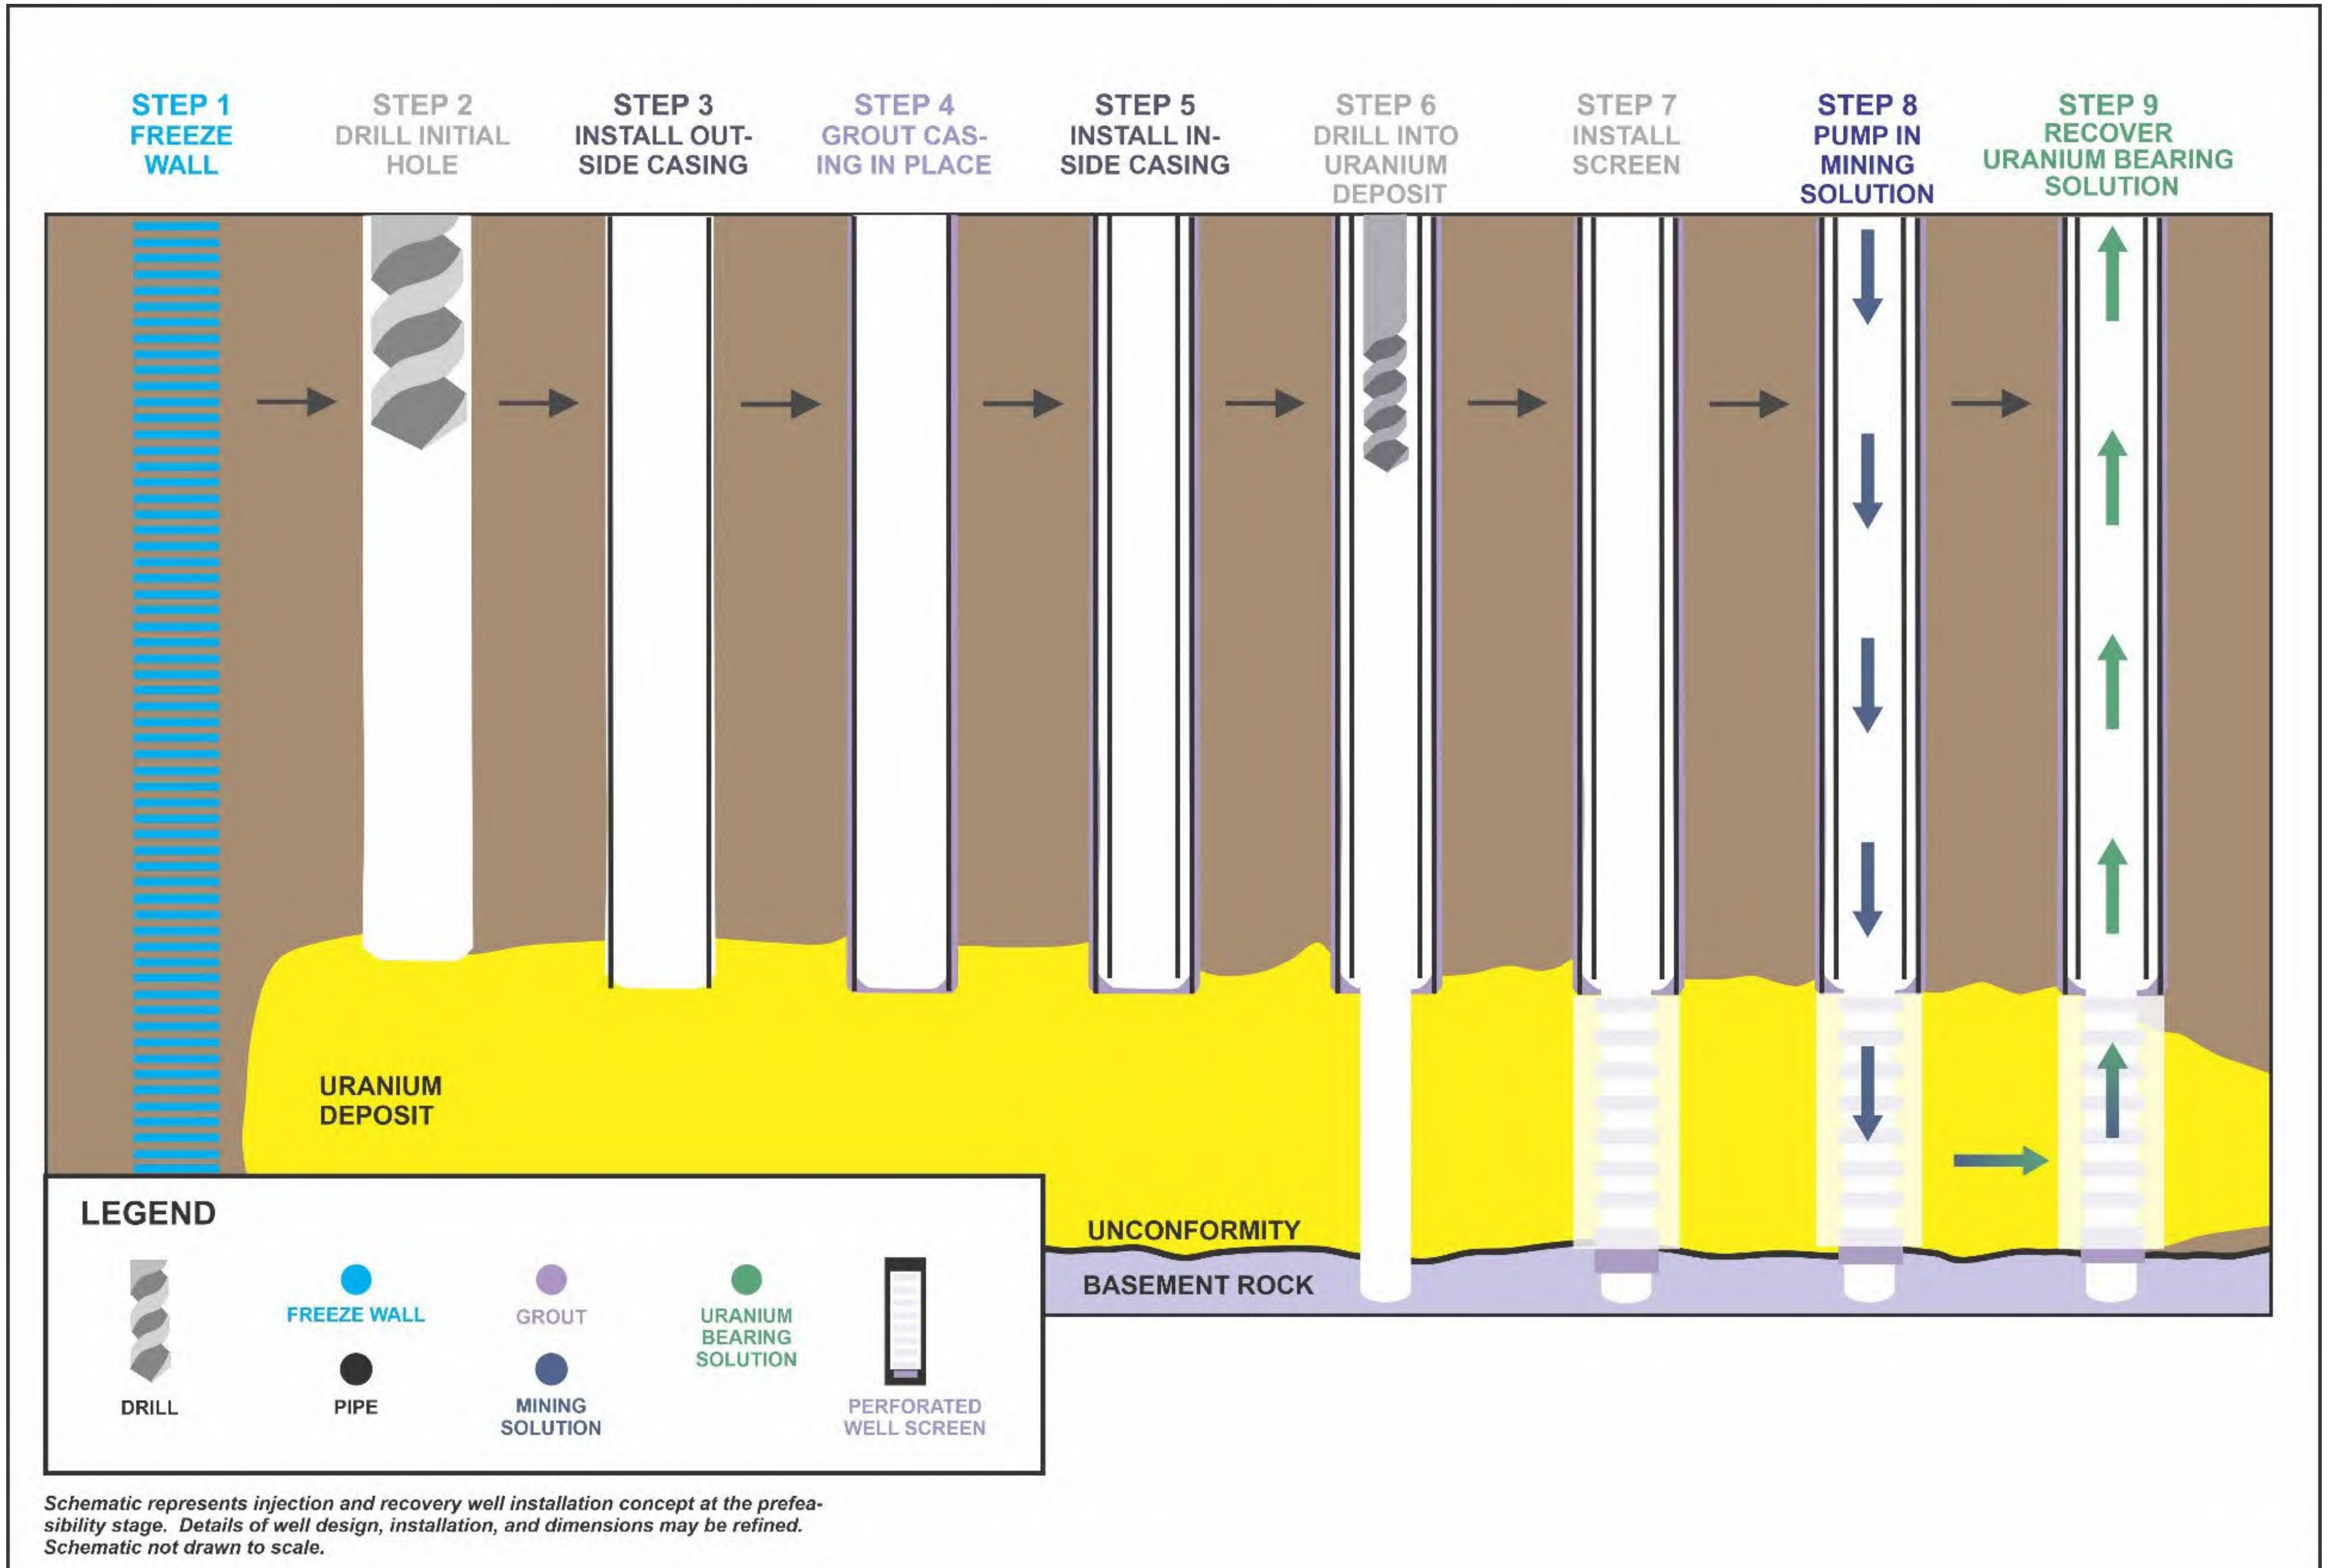

Figure 2.2-8: Proposed Injection and Recovery Well Installation Sequence

The method for drilling the wellfield injection and recover wells is anticipated to be mud rotary drilling. A mud rotary drill will be used to drill from surface to above the ore zone. The outside casing will be installed and grouted in place. Both grout and cement can be used for stabilizing casing during the well installation process. Generally, cement is used when a less viscous material is needed to flow through fine pore spaces and fractures and grout is used when a more viscous material is needed to flow through coarse pore spaces and stabilize the ground. Raw powdered cement and grout mix will be obtained from third party drill contractors and mixed on site within the batch plant tanks for use by drill rigs. The cement and grout process will be the same for both diamond drilling and mud rotary drilling.

Next, the inside casing will be installed inside the outside casing. This design provides secondary containment of mining solution (Section 2.2.1.4.2.2). The inside casing will be constructed of materials resistant to the mining solution. During a virtual presentation to the high school in English River on the Patuanak Reserve, students communicated the importance of avoiding groundwater contamination (21-EN-YOUTH-448.1). Denison then explained the various safeguards that have been incorporated, including the well design and installation process.

The casings will be made of materials resistant to the acidic mining solution and will need to meet other design ratings such as tensile strength and operating pressures. The outer casing may be constructed of fibreglass reinforced plastic or coated mild steel and the inner casing may be coated mild steel, fibreglass, or boreline flex hose.

A drill (diamond or mud rotary) will re-enter the hole and go through the ore zone, creating either a core or drill cuttings which contain uranium and will be recovered, brought to surface, and placed on the special waste rock pad. A perforated well screen will be installed at the ore zone interface. The well screen creates the interface where the mining solution from an injection well enters the ore zone and where the uranium bearing solution enters a recovery well.

The planned water sources for mud rotary drilling include, but are not limited to, freshwater (from a groundwater well or surface waterbody), treated effluent from the domestic or industrial wastewater treatment plant, and water collected at the clean waste rock pond.

After a well has been completed and before it is made operational a mechanical integrity test of the well casing will be completed to make sure the installation has been successful and the well is functioning as designed. Well casings that fail integrity tests will be repaired before the well is placed into service.

Figure 2.2-9 shows photographs of a typical ISR well at surface and a standard type of well cover.

Figure 2.2-9: Typical In Situ Recovery Well at Surface

2.2.1.4.2 Wellfield Operation

The acidic mining solution, injected from surface pumphouses via a series of injection wells, enters the mining area from well screens located at the base of the injection wells (Figure 2.2-2). Uranium is dissolved in place (i.e., in situ) as the mining solution travels from an injection well towards a recovery well (Figure 2.2-10). The mining solution now contains uranium and is referred to as uranium bearing solution (UBS). The UBS is pumped to surface by a recovery well (Figure 2.2-2).

Conceptually, based on an individual five-spot pattern (Figure 2.2-2), four injection wells could each inject mining solution at a rate of 7.5 L/minute and the central recovery well would recover uranium bearing solution UBS at 30 L/minute. In terms of pressures, ISR mining is planned at nominal pressures of 100 psi and intermittent pressures of up 250 psi. Denison has completed laboratory studies to replicate the ISR process. These studies used mineralized drill core from the Project and demonstrated that uranium can be consistently recovered. Laboratory studies found steady-state and average UBS head grades above 15 g/L.

Throughout mining, Denison plans to primarily control the mining solution within the mining area via pumping. To achieve an inward hydraulic gradient and control of solutions within the mining area, an area of lower pressure is created by a recovery well to continuously draw solution from areas of higher pressure (e.g., injection wells).

Figure 2.2-10: Wellfield Operation at the Mining Area

Operational parameters may include injection pressures, injection flow rates, and recovery flow rates. The flow rate in the wellfield pattern will be mainly determined by permeability, hydraulic head of the targeted mining area above the recovery well screens, and spacing between injection and recovery wells. Denison has successfully installed injection and recovery wells which passed mechanical integrity tests, and documented pressure and flow control during a tracer study completed in 2021 and the feasibility field test initiated in 2022.

As Denison advanced the Project as an ISR operation, it was common to receive questions about how the mining method compared to hydraulic fracturing or fracking, most commonly associated with the oil and gas industry. For instance, when mining options were presented at workshops in 2018, some members of the communities had reservations with ISR because it reminded them of fracking and fracking carried negative connotations (18-EN-VB-4.54). Conventional fracking pressures used in the oil and gas industry can vary; however, common pressures to induce fracturing can range up to 15,000 psi and require injection of fracking fluids of up to 16,000 liter per minute over periods of three to four days. Fracking fluids are comprised of a slurry of water, proppant (generally silica sand), and chemical additives to support and maintain the open fracture system after fracking is conducted. Conversely, ISR mining for the Project is planned at nominal pressures of 100 psi, intermittent pressures of up 250 psi, and average flow rates of 30 liters per minute within a recovery well. The ISR mining method proposed for the Project is markedly different than fracking. Looking at intermittent pressures alone, ISR pressures are anticipated to be 60 times lower than fracking pressures.

2.2.1.4.2.1. Primary Containment of Mining Solution – Wells

Primary means of mining solution containment involves the wells themselves. The well designs and operational monitoring of the wellfield will mitigate accidental release of mining solution or UBS in the sandstone above the mining area. Each well will have double containment: mining solution will travel inside an inner casing with the outer casing acting as secondary containment for the mining fluids. Denison received specific questions about well design and if a liner would be included in the wells (21-EN-FDLFN-570.16). As described earlier, wells will be constructed of materials resistant to the mining solution that meet well design specifications. Wells will be pressure grouted from the ore zone to surface and tested for mechanical integrity prior to commissioning to confirm an adequate seal from surface to the well screen at the mining area.

2.2.1.4.2.2. Secondary Containment of Mining Solution - Pumping

In existing ISR operations, mining solution containment is normally achieved through naturally impermeable geological layers (aquitards) or by artificially creating a drawdown of the water table by pumping. At the Project, the very low permeability basement rock below the uranium deposit serves as a natural aquitard; however, the sandstone hosting the uranium deposit is permeable and groundwater can flow horizontally through the deposit.

Hydrogeological studies and models completed show that mining solution within the mining area can primarily be controlled by maintaining an inward hydraulic gradient. The inward hydraulic gradient will be created by recovering more solution than is being injected. In general, the wellfield will operate to draw a minimum of 1% more solution out of the wellfield compared to solutions injected in. This will help avoid increased subsurface pressures from injection pressure build up within the deposit. Inward hydraulic gradient is controlled by instruments installed within the injection, recovery, and monitoring well networks to assess that lower pressures are always present at the recovery wells to produce the inward gradient. If pressures begin to increase within the active mining area or decrease outside of the active mining area, pumping and injection rates can be adjusted accordingly to re-establish the desired gradient. Perimeter pumping wells will be installed vertically, horizontally, and laterally surrounding the mining area both inside and outside the freeze wall with the ability to capture fluids by pumping when required and recycle solutions should the primary containment system not perform as expected. This combination of pumping creates a secondary means to contain mining solution within the mining area. In the case of an upset condition, such as pump failure, or scheduled pump maintenance when a given extraction well would be shut down purposefully, the fluids that would normally be recovered by a particular extraction well would then temporarily be recovered by one of the adjacent extraction wells within the larger extraction well network. When the upset conditions or scheduled maintenance have been completed, the "normal" mining solution recovery pattern would be restored to the original flow path. In this way, and by design, hydraulic containment is maintained at all times.

Groundwater modelling and flow path analysis calibrated to field conditions have evaluated upward solution migration and demonstrated that the maximum height that injected fluids will migrate upwards from the ore zone during active mining is likely between 11 to 13 m. For conservatism, a 50-m vertical zone above the deposit was included in the assessment as potentially disturbed by mining activities. This entire area is referred to as the mining area, although the active mining area is expected to be a smaller area within the broader mining area and is the area immediately within the ore zone. The ore zone has an average thickness is 5 m, with a range of 2 to 17 m.

2.2.1.4.2.3. Tertiary Containment of Mining Solution - Freeze Wall

As a tertiary means of containment for the mining area, the uranium deposit is proposed to be surrounded by freeze wall that extends from the surface to the basement rock, isolating the mining area from regional groundwater. The freeze wall design is discussed in Section 2.2.1.3. Current plans are for the freeze wall to be a minimum of 10 m thick, be installed 25 m away from the uranium deposit, and extend 30 m into the basement rock (Figure 2.2-6).

Using a tracer (salt dissolved in water), feasibility field tests conducted in 2021 showed hydraulic containment was achieved with pumping. For the purposes of the EIS, a freeze wall has been assumed to be in place. The need for tertiary containment of mining solution is an important area of technical study that Denison will advance through Project design and into Operation.

2.2.1.4.3 Permeability Enhancement

In situ recovery relies on fluid movement within the ore zone. Several permeability enhancement techniques have been considered for the Project to essentially enhance the existing fracture network to improve the uranium recovery. These techniques include mechanical, propellant, and hydraulic options. Denison may use permeability enhancement techniques on injection and recovery wells to increase hydraulic connectivity within the wellfield.

Mechanical permeability enhancement uses a downhole tool that produces clean flowpaths radially from an existing borehole into the ore zone (Figure 2.2-9 and Figure 2.2-11). The tool uses mechanical pressure excavation methods to drill ‘penetration tunnels’ out from the borehole. The resulting tunnels can be up to 1.8 m in length and 1.8 cm in diameter. Mechanical permeability enhancement methods can reach pressures up to 4,000 psi and occur intermittently over a 24-to-48-hour period pending the number of penetration tunnels drilled in a given well.

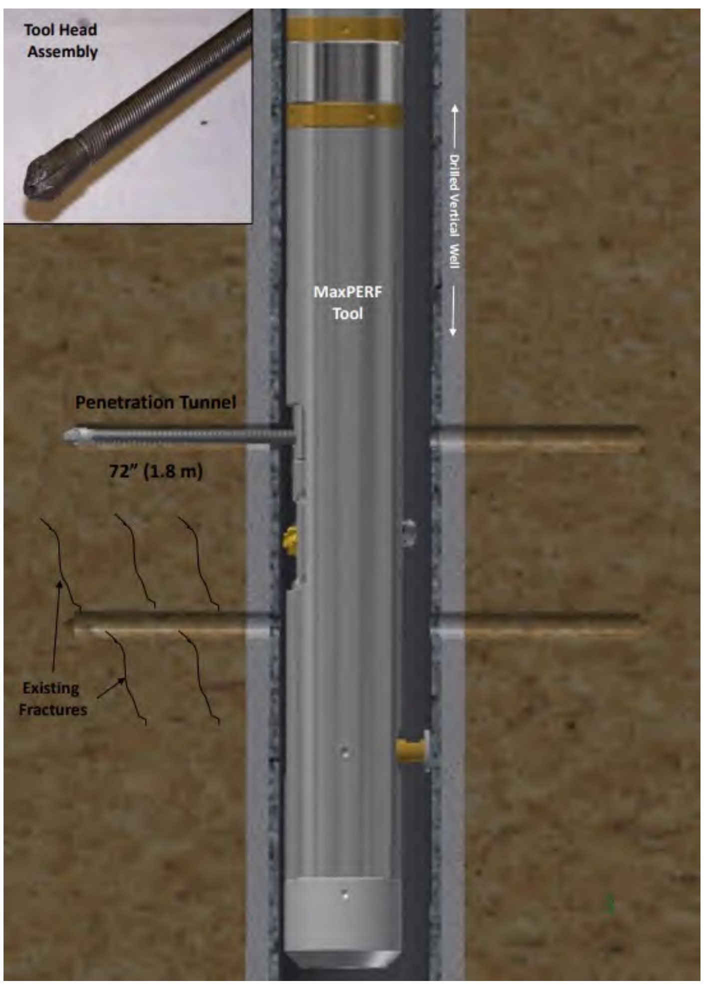

Figure 2.2-11: Example of Permeability Enhancement Technique - Mechanical Option

Propellant permeability enhancement methods are wireline-conveyed tools designed to perforate and stimulate well production using a controlled propellant. These may be progressively burning solid propellants or gas injection. The wireline tools effectively clean out restricted pathways within the well screen, well bore, and the geological formation and provide increased flow rates in the wells by intersecting and connecting to the naturally occurring fractures within the mining area.

Propellants used are typically classified as a low hazard explosive (S.1 special-purpose explosives, low hazard explosives, per *Explosive Regulations*, section 36). Propellants technically do not explode (like classic mine explosives which detonate) but rather burn through a process called deflagration. Deflagration means the material burns slower than the speed of sound, thus no shock waves are generated. Propellant permeability enhancement methods reach injection pressures of up to 8,000 psi and are near instantaneous over periods of milli seconds.

Hydraulic permeability enhancement is a technique involving the flushing of bedrock formations. The process involves injection of water into a wellbore to create access to existing fractures in the defined formations that may not have been previously connected to the main fracture network due to clays, sands, or other materials being present in the fractures themselves. After hydraulic permeability enhancement, mining solutions may flow more freely. Hydraulic enhancement can be used as a means of flushing or cleaning the well and formation in preparation for mining. Hydraulic permeability enhancement pressures can reach up to 250 psi with a consistent duration of 24 to 48 hrs. By comparison, conventional fracking pressures used in the oil and gas industry can range up to 15,000 psi and require injection of fracking fluids of up to 16,000 liter per minute over periods of three to four days. The pressures expected for hydraulic permeability enhancement are well below conventional fracking pressures.

2.2.1.4.4 Pumphouses

Based on the current designs for the Project, approximately three pumphouses will be required. A pumphouse is a small building or container on the surface where pipes from injection and recovery wells are operated and mining solution flows are monitored. See photos in Figure 2.2-12 for examples of components inside an operating ISR pumphouse in the USA.

Figure 2.2-12: Inside a Typical In Situ Recovery Pumphouse

Pumphouses will distribute the mining solution to the injection wells and collect the UBS from the recovery wells. Each pumphouse will be connected to two production pipelines. One of the pipelines will be used for receiving mining solution from the processing plant, and the other will be used for returning UBS back to the processing plant (Figure 2.2-1 and Figure 2.2-2). Each pumphouse will include a manifold, valves, flow meters, pressure meters, and instrumentation, as required, to fully operate, monitor, and control the process. Pumphouse control monitoring systems enable operators to individually adjust each recovery or injection well and allow for sampling. Operators can also use the master control system in the processing plant to remotely control pumphouse production lines.

Ventilation in the pumphouses will be designed with the as low as reasonably achievable (ALARA) principle in mind to provide sufficient worker protection from potential radon and radon progeny exposure. Monitoring systems will be in place to make sure these mitigation measures are meeting design specifications.

2.2.1.4.5 Wellfield Piping System

Pipes will transport the mining solution and UBS between the wellfield and the processing plant. The flow rates and pressures of the individual well lines will be monitored in the pumphouses. These data will be transmitted to the processing plant for remote monitoring through a master control system. Through the master control system, operators will be capable of controlling pumphouse production lines remotely.

Double-walled high-density polyethylene (HDPE), or equivalent, piping will be used in the wellfields. The lines from the processing plant, pumphouses, and individual well lines will be freeze protected and secured to minimize pipe movement. The lines will be designed to have secondary containment or catchment and have leak detection systems in place at key locations.

2.2.1.4.6 Mining Solution

The uranium at the Project is amenable to the same type of leach solution that is used to leach other Athabasca Basin uranium ores in mills: an acidic (i.e., low pH) solution. Communication of the constituents used in the mining solution is very import to the Communities of Interest. As described by an English River First Nation (ERFN) member and local trapper, "*Denison needs to be much more clear that the mining solution is acidic. This is really important. When I was here* [Wheeler River Project site] *in August everyone was talking about water and there was not much mention of acid*" (19-LK-ERFNTrap-134.261). A clear understanding of the constituents used in the mining solution is an important component of ongoing engagement work.

The acidic mining solution will be prepared on site by adding reagents, likely sulphuric acid, hydrogen peroxide, and ferric sulphate, to water. The concentration of reagents required for mining will be based on previous field and laboratory test work. At any one time, it is estimated that 3,500 m^3 of mining solution will be in use in the wellfield. The liquids will be mixed to achieve the optimal parameters for the mining solution, including pH and oxidation reduction potential.

The mining solution will be pumped underground to the uranium deposit via an injection well and recovered as uranium bearing solution (i.e., mining solution now containing uranium) through a series of recovery wells (Figure 2.2-1). Once UBS is recovered to surface, it will be pumped from the wellfield into the processing plant where uranium will be removed from the UBS (Section 2.2.2). The treated solution created can be refortified with reagents as required and pumped back into the mining area to maximize water recycling during the life of the mine. Water requirements to create the mining solution will be preferentially sourced from site runoff and recycled where possible; however, to be conservative, the assessment has included options for obtaining all required water from either a shallow groundwater well or a nearby lake (Whitefish Lake). No water recycle has been included in the water balances, although it is expected to occur.

2.2.1.5 Monitoring Well Network

Groundwater monitoring wells will be installed at various depths and locations in and around the wellfield. The monitoring wells have a variety of purposes including groundwater sample collection, measurement of groundwater levels, and detection of changes in pressure and temperature in the groundwater environment.

Small groundwater observation wells will be installed and screened at various depths, from shallow sandstone to basement rock. These are polyvinyl chloride-lined wells with a bentonite clay sealed annulus, sealed at surface with cap, and have secondary containment. These wells can be used to collect groundwater samples and can be fitted with pressure/temperature sensors.

Vibrating wire piezometers (VWP) have pressure/temperature sensors grouted in place at multiple levels. These VWPs provide real time data on pressure responses as an indicator for water movement within the formation and allow Denison to make informed decisions about groundwater movement and injection and recovery well performance.

The monitoring wells network consisting of observation wells and VWPs will be configured to demonstrate effective containment of mining solutions and liquid residues within the mining area and provide early warning of any excursions. Monitoring of groundwater pressures and quality will be conducted outside of the mining area. The mining area has been defined for this Project as inside the freeze wall and up to 50 m above the ore zone. Groundwater samples taken outside of the mining area during Operation are expected to be comparable to regional groundwater quality.

Regarding the freeze wall and freeze wall monitoring, the alignment of the freeze wall is located 25 m offset from the lateral extent of the recoverable ore and the freeze wall will grow in thickness both towards the ore and away from the ore. The freeze wall will solidify all liquid porewater and develop into a contiguous impermeable barrier many metres thick. Ground temperature monitoring will be installed through a series of continuous fiberoptic temperature and pressure wells from surface to the depth of impermeable basement rock below the unconformity. Such monitoring wells/systems will be installed on both the ore (inside) and non-ore (outside) sides of the freeze wall to confirm the thickness of frozen ground. There will be sufficient operational controls in place to verify that the freeze plant is operating, to measure the temperature in the ore zone, and to measure the temperature on opposite sides (inside and outside) of the freeze wall so that early detection of any upset conditions can be identified and addressed. Options for addressing issues include: lowering the temperature of the freeze system to draw more heat out; increasing the freeze coolant flow rates in freeze wells nearer to active ISR cells; and/or to adaptively manage the lixiviant injection and recovery rates in cells located nearest to the freeze wall.

2.2.1.6 ISR Mining-Related Inputs for the EIS

It is important to note that Denison is completing a sequential EA and licensing process for the Project (see Section 1). Detailed ISR mining related information needed to support licensing and permitting has not been included in the EIS; it will be provided to regulators as part of permitting and licensing.

For the EIS, an understanding of ISR design is needed to describe potential effects related to Project activities within the biophysical environment (EIS Part II, Section 6 to 9), human environment (EIS Part III Sections 10 to 13), and accidents and malfunction (Section 14) assessments. Denison used the ISR mine design and the 3D hydrogeology and contaminant transport numerical modelling of the injection and extraction wells to determine the potential interactions between mining activities and the environment. Two key outputs from the ISR mine design and 3D hydrogeology modelling work were used as inputs for the groundwater assessment (Section 7): 1) The extent of mining solution migration away from the injection and recovery well screens, as defined by the mining area (50m above the ore zone and within the freeze wall) and 2) groundwater quality of the mining area following remediation. Monitoring will be completed during operations and decommissioning to confirm these inputs.

Importantly, since the mine design includes the freeze wall, movement of mining solution is restricted and contained horizontally during operations. Wellfield pumping provides the hydraulic containment to keep mining solution within the 50 m mining area (see Section 2.2.1.4.2). During the operation phase, and under normal operational conditions there is no interaction between the mining zone and surface water or down gradient groundwater environments, and the groundwater assessment (Section 7) focuses on the post-decommissioning period following removal of the freeze wall, once the groundwater flow paths return to pre-mining conditions. During mining area remediation (see Section 2.3.3.1.1), the freeze wall will remain in place until decommissioning objectives are achieved. Refinement of the mining area decommissioning objectives and associated modelling will be done through updates to the Decommissioning Plan, and will be bounded by the objectives evaluated in the EIS.

2.2.2 Processing

The recovery of uranium from the UBS obtained in the wellfield will be undertaken in a two-stage precipitation process. The two-stage process creates a low-grade uranium precipitate and a concentrated uranium product known as yellowcake.

Denison’s processing plans are based on numerous metallurgical tests completed as part of engineering activities. A detailed metallurgical testing program was developed and implemented in collaboration with the Saskatchewan Research Council (SRC) under the supervision of several third-party consultants and Denison. Around 1,000 L of UBS was produced by leaching over 64 kg of core samples recovered from the Phoenix deposit and the UBS produced was tested using variations of several parameters to define the processing plant design and its components.

2.2.2.1 Processing Plant Components

The processing plant will house the tanks and equipment to process the UBS recovered from the ISR wellfield into yellowcake. The building will be constructed adjacent to the wellfield to minimize piping distances and is anticipated to be approximately 63,000 ft^2 (5,850 m^2) in size (Figure 2.2-1).

The processing plant will contain a control room, laboratory, and men's and women's dries (change rooms), laundry facilities, and maintenance shop. Bulk storage tanks for various process chemical will be located within a dedicated room within the processing plant. This includes tanks for the mining solution chemicals (e.g., sulfuric acid, iron sulphate, hydrogen peroxide), milling (e.g., magnesium hydroxide, hydrogen peroxide) and the water treatment (e.g., barium chloride, calcium hydroxide also known as lime. The industrial wastewater treatment plant (IWWTP) will be located inside the processing plant and is discussed further in Section 2.2.3.8.

The processing plant will be designed using engineering best practices, taking into account potential environmental and health and safety effects and mitigating interactions to the extent possible. For instance, the floor will be graded as required and sumps will be installed to collect spills. Ventilation in the processing plant will be designed to be consistent with the ALARA principle to provide sufficient worker protection. The heating, ventilation, air conditioning (HVAC) monitoring systems will be in place to confirm worker health and safety. Dust control equipment and good housekeeping practices throughout the processing plant will also form a critical component of the Radiation Protection Program developed for the Project. The processing plant exhaust, mainly from drying and packaging areas, will be cleaned with venturi scrubbers then directed through a stack and released outside of the building. The stack height will be designed based on results of air dispersion modelling to be an appropriate height for optimal dispersion; the air dispersion model assumed stacks were at 45 m above grade or approximately 22 m above the processing plant building.

2.2.2.2 Processing Steps

Refer to Figure 2.2-13 for an overview of the proposed processing plant design.

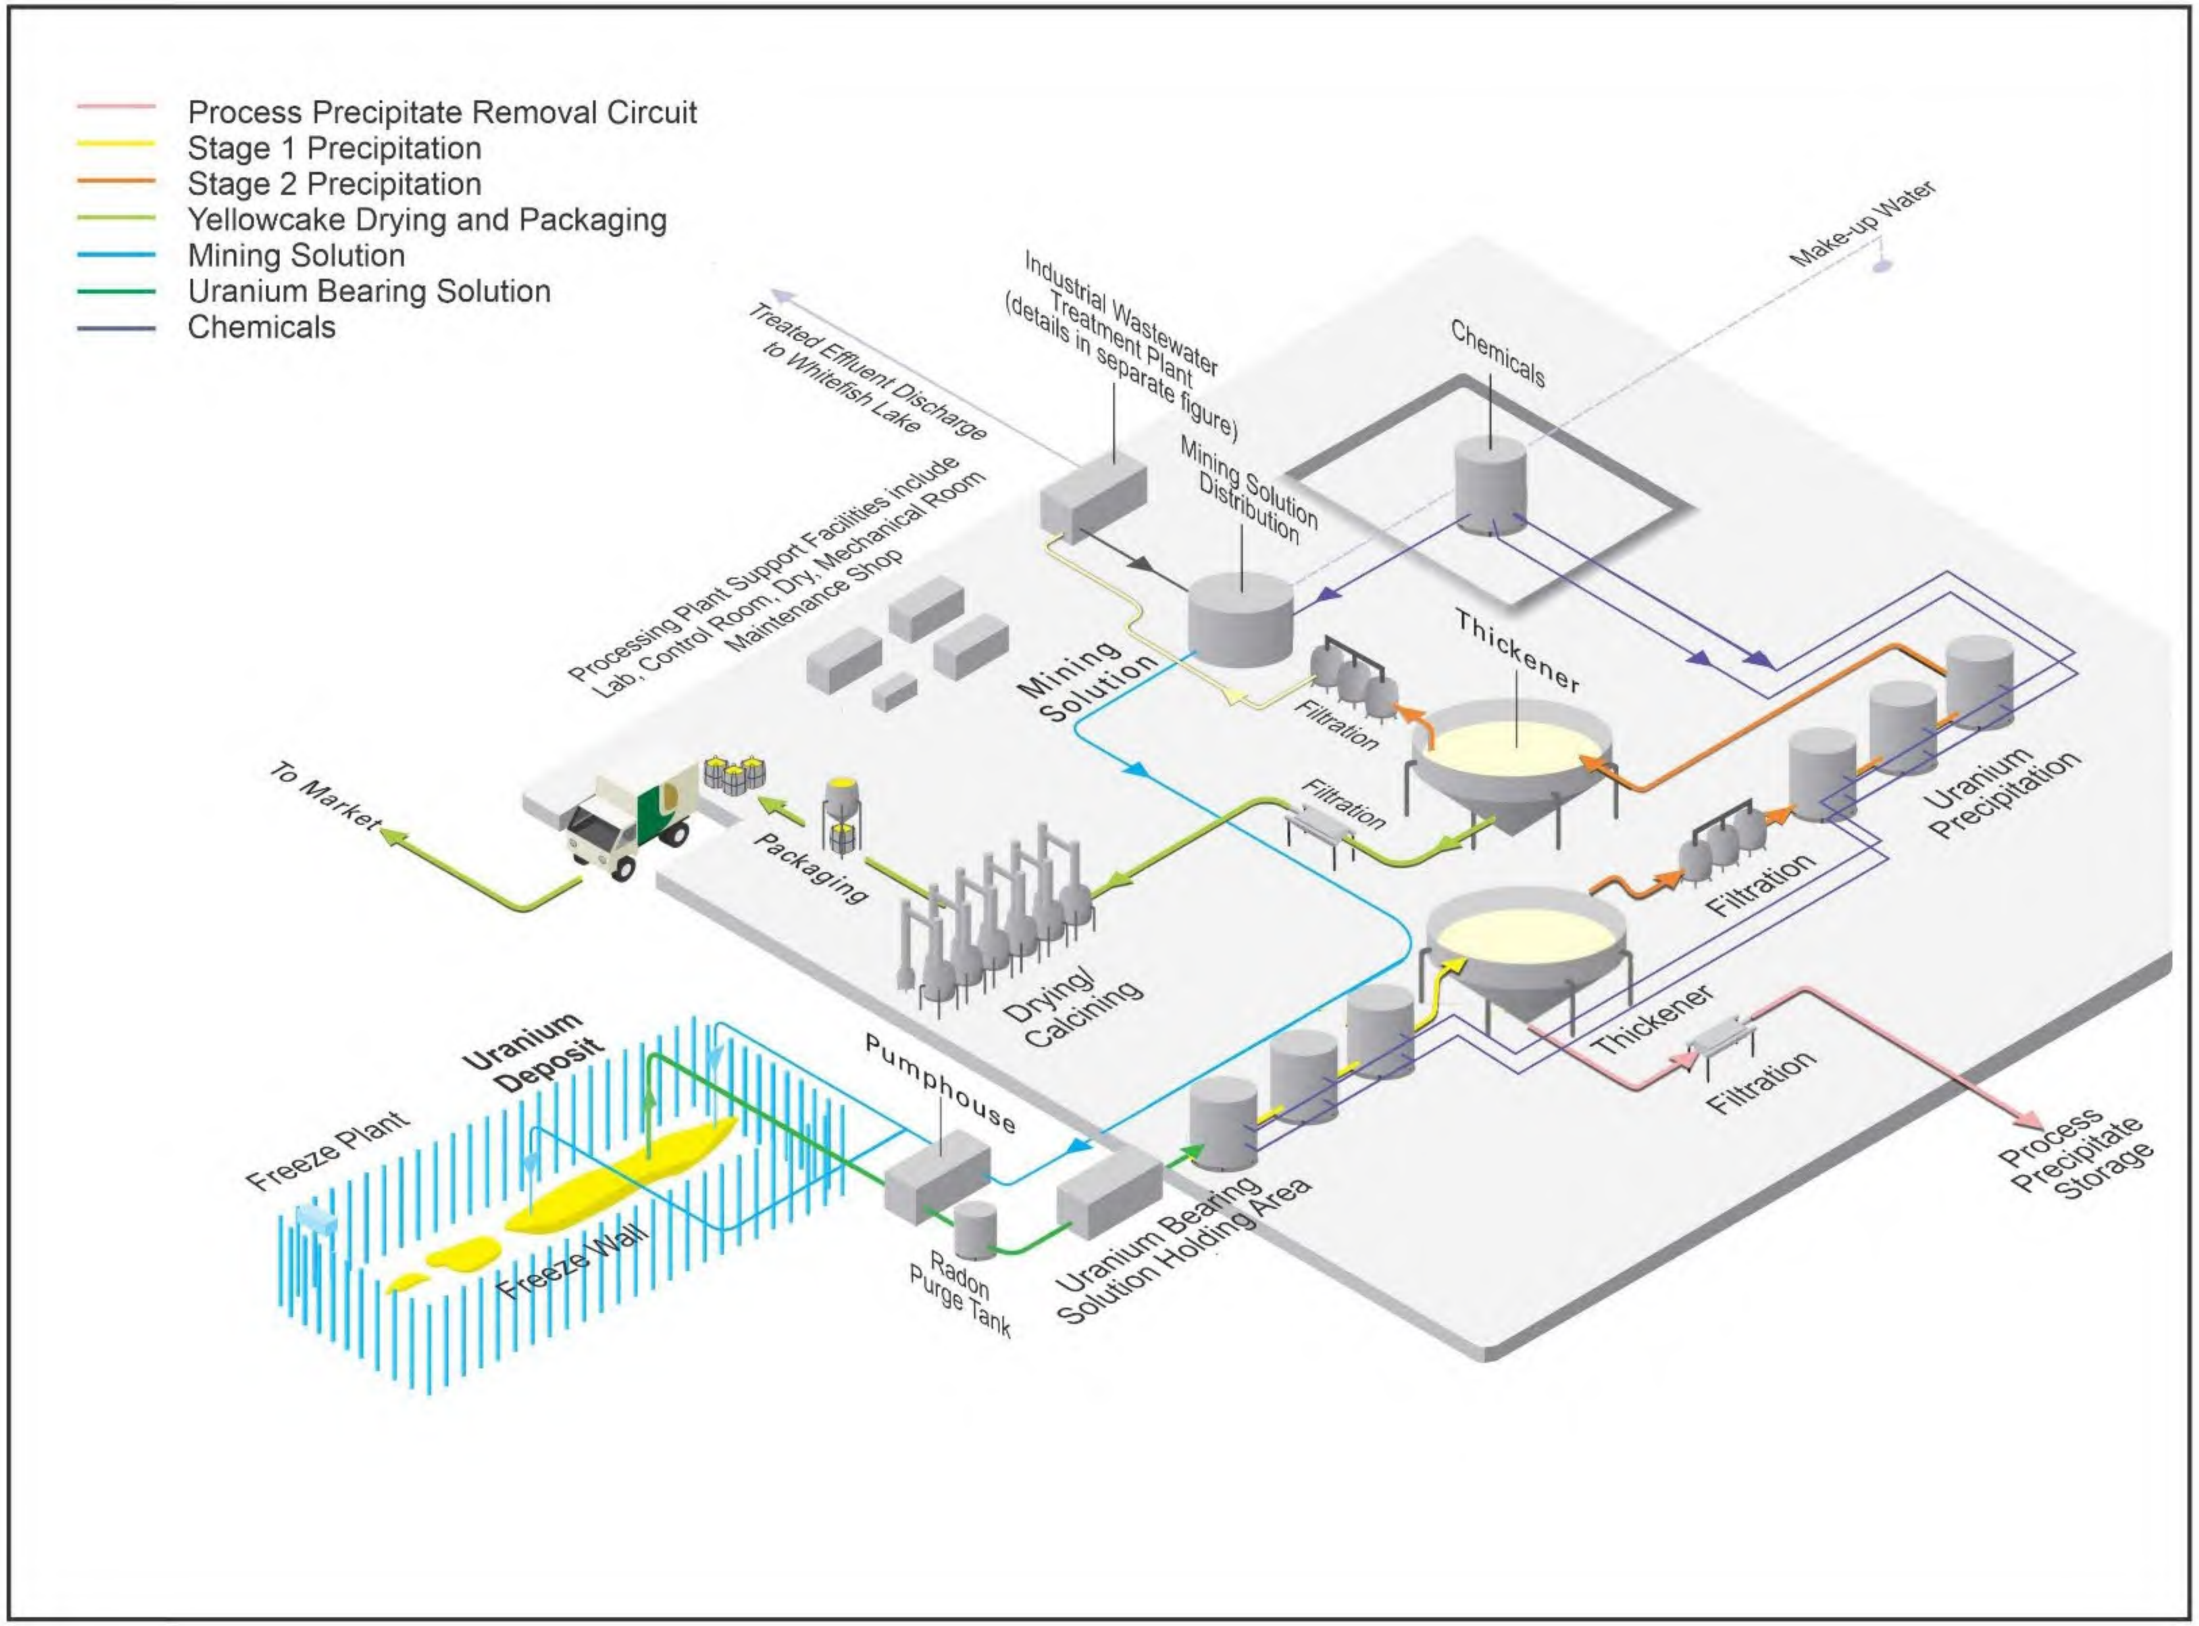

Figure 2.2-13: Processing Plant Overview

Chemicals, fresh water, and treated water from the IWWTP will be mixed to generate the mining solution that will be injected into the mining area and recovered as UBS.

The UBS will be pumped from the wellfield pumphouse(s) through the following areas and circuits that are adjacent to or inside of the processing plant.

2.2.2.2.1 Radon Purge Tank

When the uranium bearing solution comes to surface, radon gas will naturally move out of solution and into the atmosphere. To keep worker radiation exposure ALARA, a radon purge tank will be used to remove this initial volume of radon before the solution enters the processing plant. The radon purge tank will contain a mechanical ventilation system to facilitate the aeration of the solution and the removal of radon gas from the UBS to the air outside of the plant.

2.2.2.2.2 Uranium Bearing Solution Holding Area

The ISR mining and subsequent processing of uranium will not always occur at the same rates. Additionally, there will be times when parts of the processing plant are down for routine maintenance. For these reasons, Denison has incorporated a UBS holding area into the current design of the processing plant. It will be a controlled area where UBS can be safely stored on surface, prior to processing. The UBS holding area will be adjacent to the processing plant and under a fabric tension building system. The fabric tensioned roof will help to keep precipitation from entering the uranium bearing solution. The volume of the UBS holding area is anticipated to be 5,000 m^3. The area will be contained by a double composite liner system with leak detection (Figure 2.2-18). Options to use tanks instead of holding area will be evaluated as engineering advances.

2.2.2.2.3 Two-Stage Precipitation Process

The UBS from the holding tanks will be introduced into the processing plant based on target production rate requirements.

In Stage 1 precipitation reagents such as hydrogen peroxide, barium chloride, flocculant, and lime are added and the pH is increased through agitator tanks to remove process precipitates which are iron-hydroxides, associated metals, radium-226, and thorium-230. The process precipitates also contain low-grade uranium at approximately 2 to 3% grade. The process precipitates will be temporarily stored on site prior to sale and transportation to a licensed offsite facility for processing as part of Decommissioning. The overflow product from Stage 1 precipitation is a purified UBS that will be further processed in Stage 2 precipitation.

In Stage 2 precipitation, additional pH adjustments and flocculant additions are made to the solution, which is then allowed to settle and dewater as uranium oxides within the yellowcake precipitation thickener. This form of uranium concentrate is yellow, giving it the term yellowcake. The precipitated uranium will be transferred to the yellowcake drying and packaging area, and the overflow liquid solution will be filtered and transferred to the industrial wastewater treatment circuit.

2.2.2.2.4 Yellowcake Drying and Packaging

Following Stage 2 precipitation, the uranium solids are transferred from the thickener underflow to a filter system to further reduce the moisture content prior to drying. The removal of moisture is important to reduce the energy demand required for the drying process. The removed water is recycled to the precipitation circuit to recover any remaining uranium. The filtered uranium solids are transferred through an enclosed conveyor to the dryer where any remaining moisture will be evaporated. The exhaust air from the drying process is controlled through a scrubber system to remove particulates and moisture prior to release to the environment. Any water collected from the drying process will be condensed and reused in the plant for reagents preparation. Denison has assessed the use of low temperature dryers and calciners for the drying step in the processing plant. The low temperature dryer will be indirectly heated by electric power and outfitted with a venturi scrubber allowing separation of yellowcake dust from the process gas exhaust. The yellowcake slurry created in the venturi scrubber will be sent to the yellowcake thickener and the process off gas will be further cleaned using mist eliminators prior to be released to atmosphere through a stack. Calcining allows for additional removal of impurities from the produced yellowcake to meet certain purchasers' requirements. The calciner will be indirectly heated by propane, therefore the products of combustion will not be in direct contact with the products being calcined. The combustion products will consist of nitrogen, carbon dioxide, water, oxygen and minor amounts of CO and NOx. Low NOx burners will be used and no post-combustion control is expected. The process off gas created during the calcining of the product will be ducted through a venturi scrubber with mist eliminators allowing process off gas cleaning and recycling of slurry to the yellowcake thickener. Once the moisture is removed from the yellowcake product, the yellowcake is packaged into 55 gallon steel drums via gravity.

The yellowcake drying and packaging area will be outfitted with hygiene systems to capture dust generated during the material handling of the yellowcake product and sent to either the dryer or calciner venturi scrubbers. All equipment located after the dewatering of the yellowcake will be selected to provide minimal dust generation and outfitted with dust collection systems where required. The ventilation system in this area of the processing plant will also be adequately designed to provide safety of workers and control fugitive dust emissions. The packaging of the yellowcake into drums is planned to be automated so it requires minimal manual worker intervention other than moving the barrels full of yellowcake from the equipment offloading area by forklift to a truck loading area for shipment to customers. The yellowcake storage area will be located in an enclosed area with secondary containment outfitted with a sump to facilitate any cleaning when required.

2.2.2.2.5 Industrial Wastewater Treatment Plant

The IWWTP is located inside the processing plant building and is discussed in Section 2.2.3.8.

2.2.3 Water Management

Denison intends to recycle process water to the greatest extent possible, thereby reducing the demand for fresh water supply and volume of treated effluent. In an effort to develop a conservative assessment basis for the EA, the water recycle flows from the industrial wastewater treatment plant back into the processing plant and wellfield have not been incorporated into the estimates for freshwater withdrawal and treated effluent discharge.

An overview of the site water balance during Construction, Operation, and Decommissioning are provided in Figure 2.2-14, Figure 2.2-15, and Figure 2.2-16, respectively. These figures provide a summary of the water needs for certain Project activities, plans for water treatment (both potable and wastewater), and the general flow of managed water at the site. The estimated flows in the site water balances do not account for water recycle back into the processing plant and wellfield. This results in a conservative estimate of both freshwater withdrawal needs and treated effluent discharge rates. Water consumption rates, water supply locations, proposed water treatment practices, and water sampling locations were common questions during engagement meetings with communities where Project information was being shared (18-EN-VB-4.22) (22-EN-SUR-652.4).

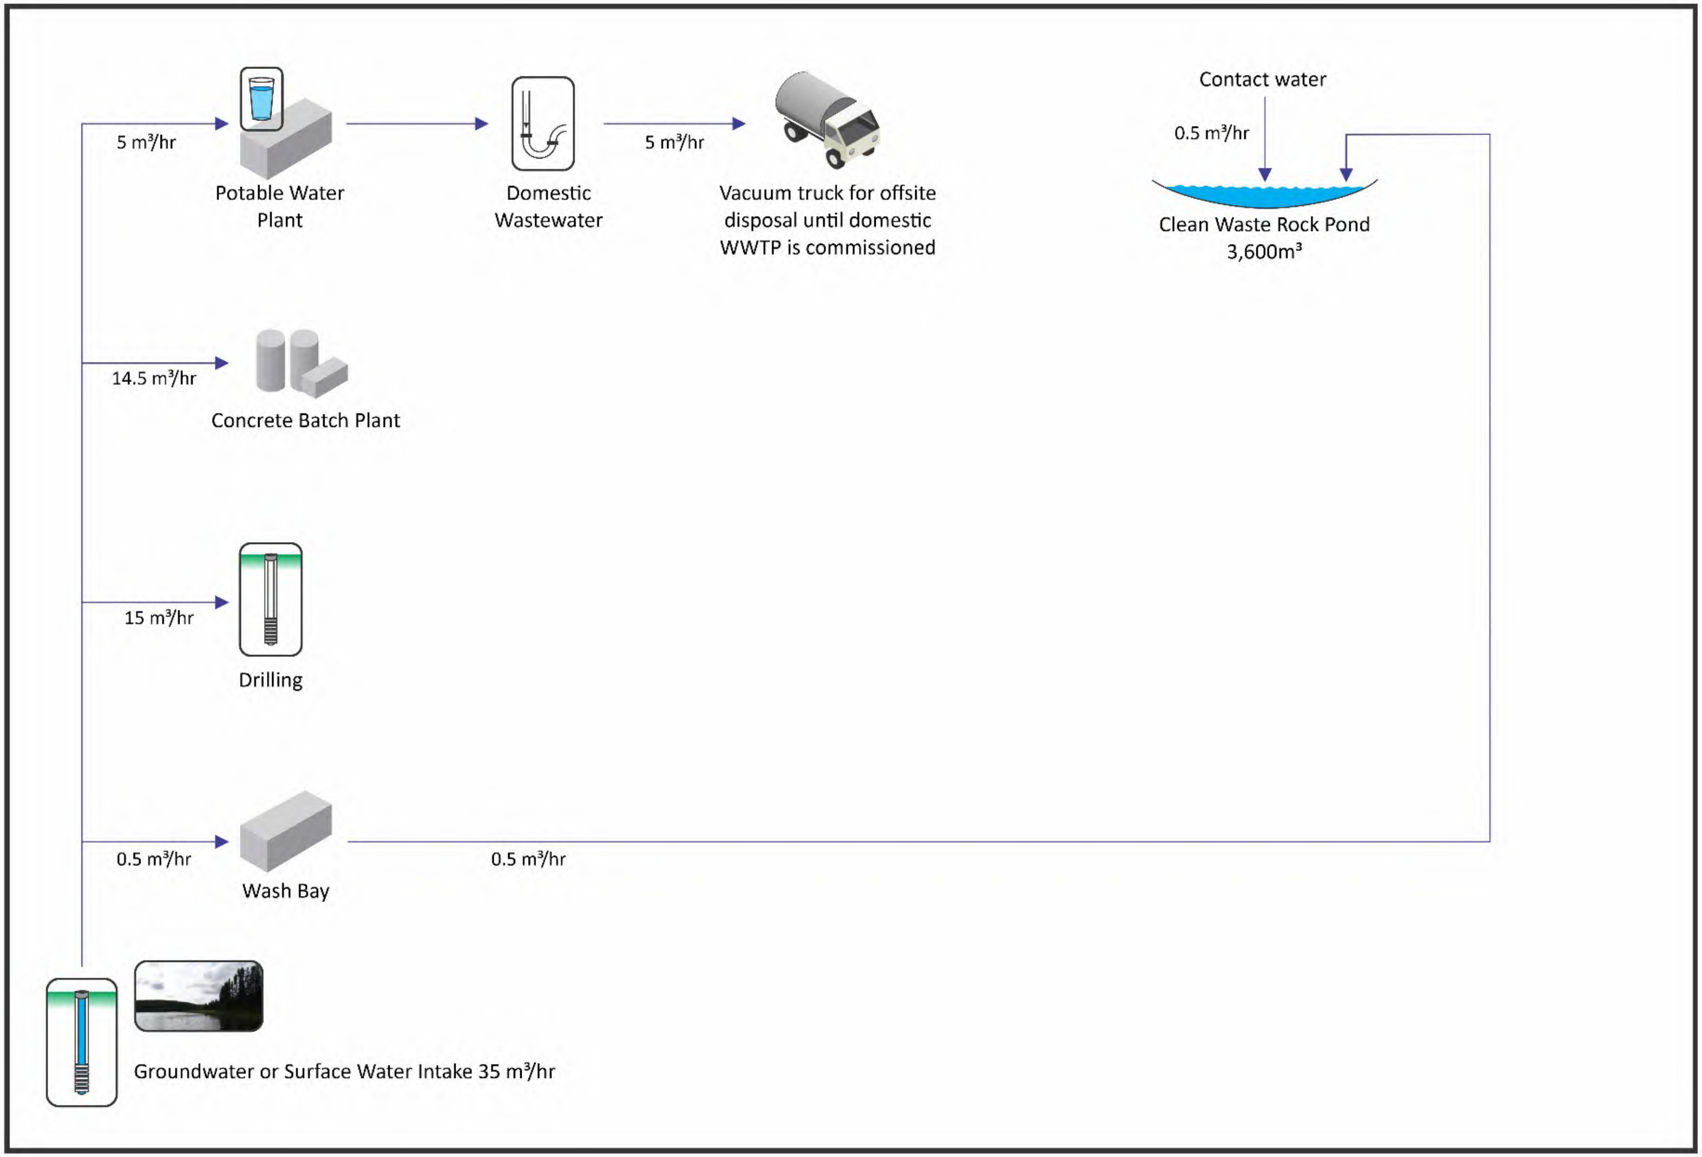

Figure 2.2-14: Construction Water Balance for the Project

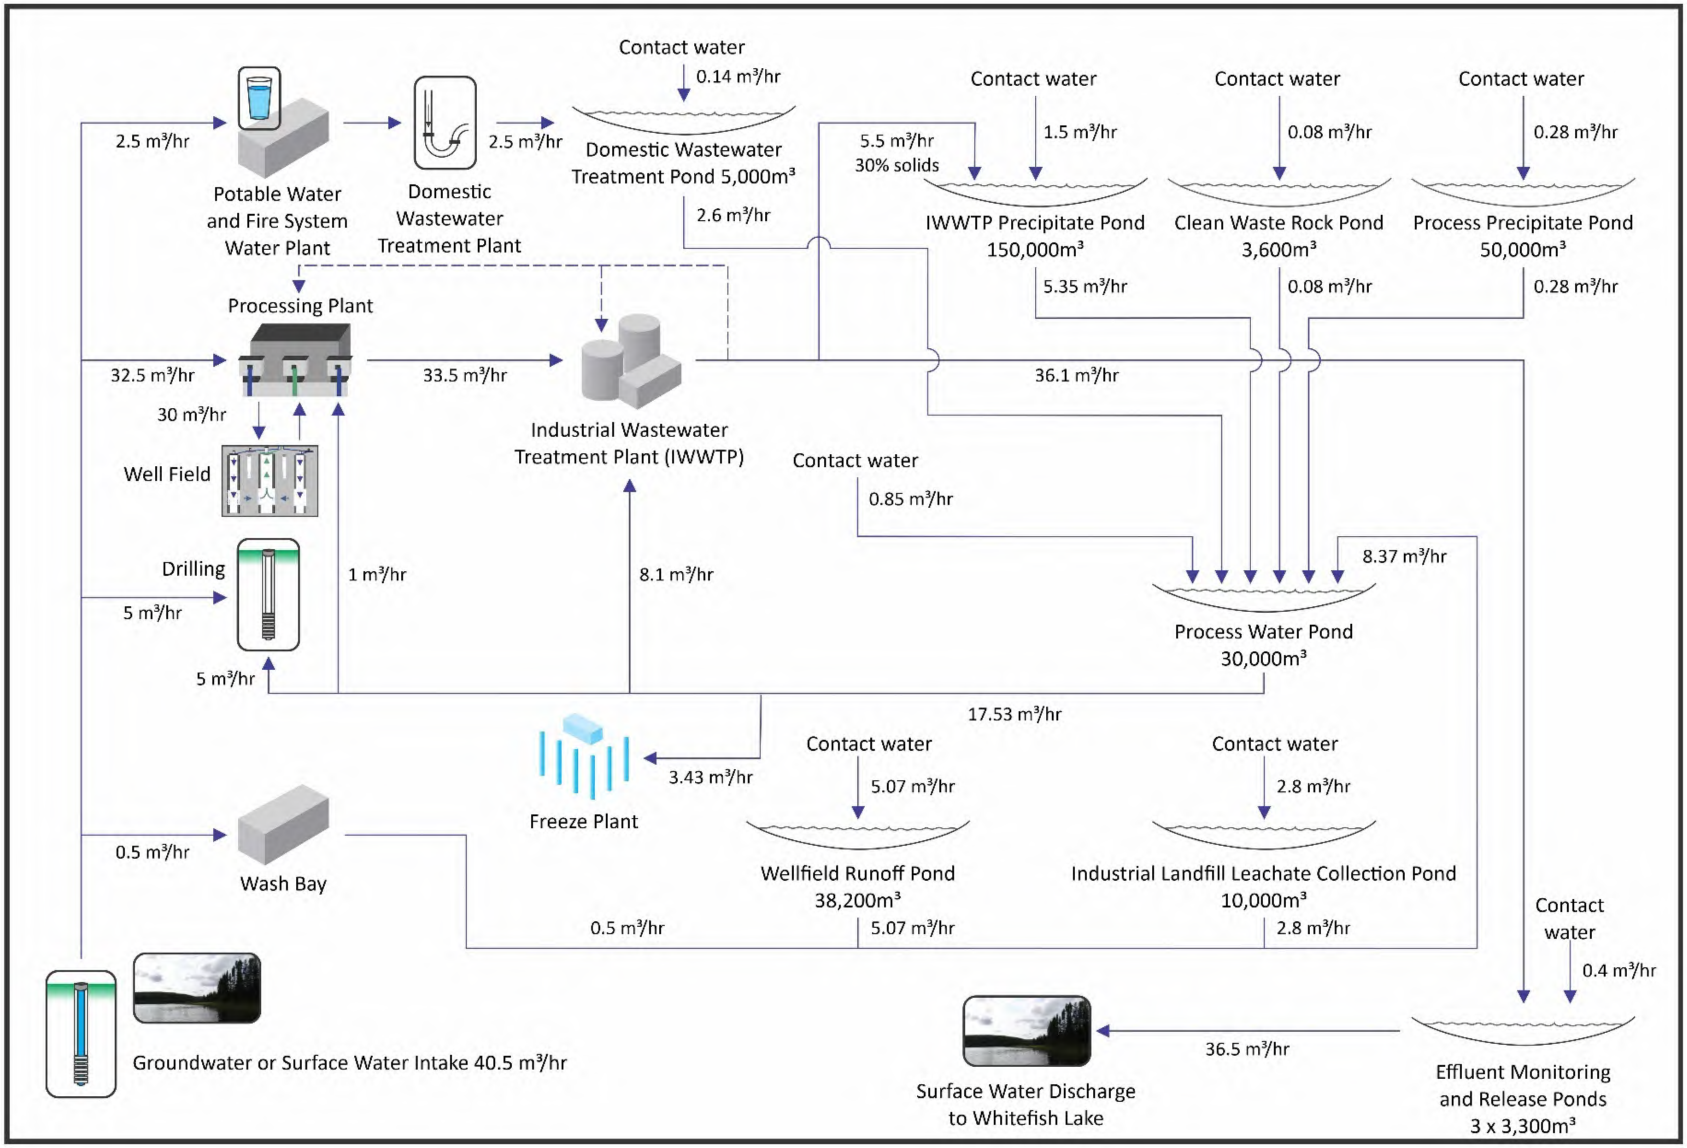

Figure 2.2-15: Operation Water Balance for the Project

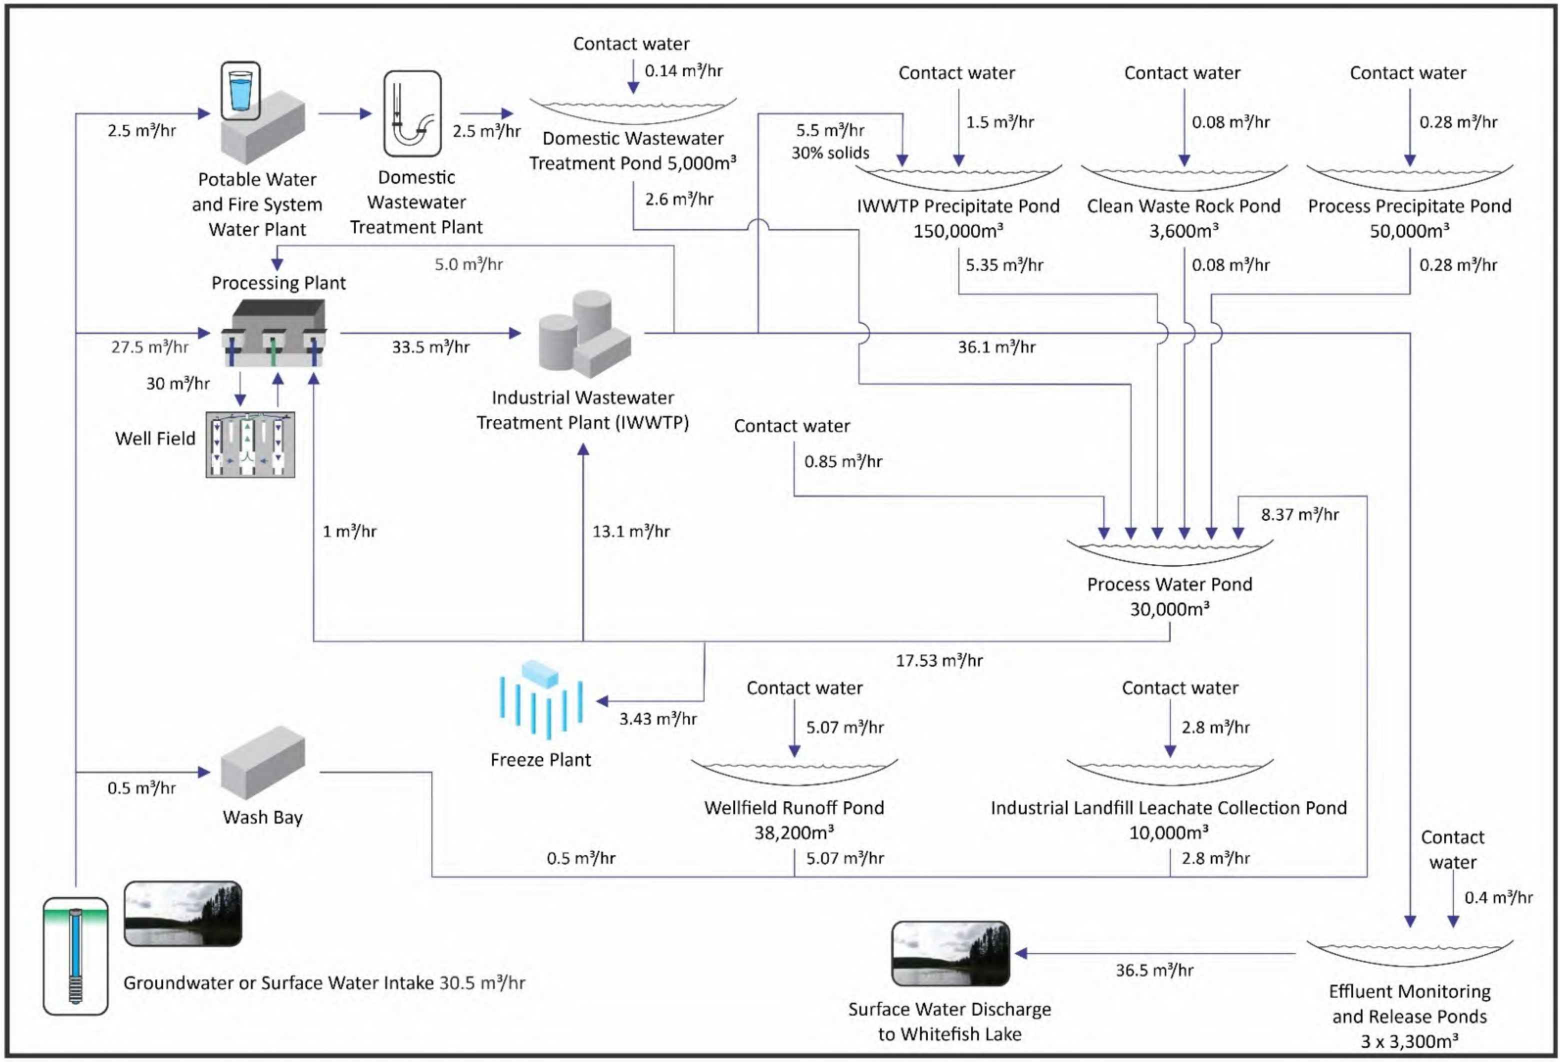

Note: the freshwater withdrawal rates used in the groundwater (Section 7) and surface water quantity (Section 8.1) assessments are higher than those shown here and were 35.5 m^3/hour

Figure 2.2-16: Decommissioning Water Balance for the Project

2.2.3.1 Site Drainage

Clean, non-contact runoff will be diverted around Project components where possible. Contact water, including, for example, runoff from the wellfield and around the processing plant, will be collected in various ponds and eventually routed through the IWWTP for treatment prior to release to Whitefish Lake. Figure 2.2-17 provides an overview of the potential site drainage plan with flow directions and culvert locations.

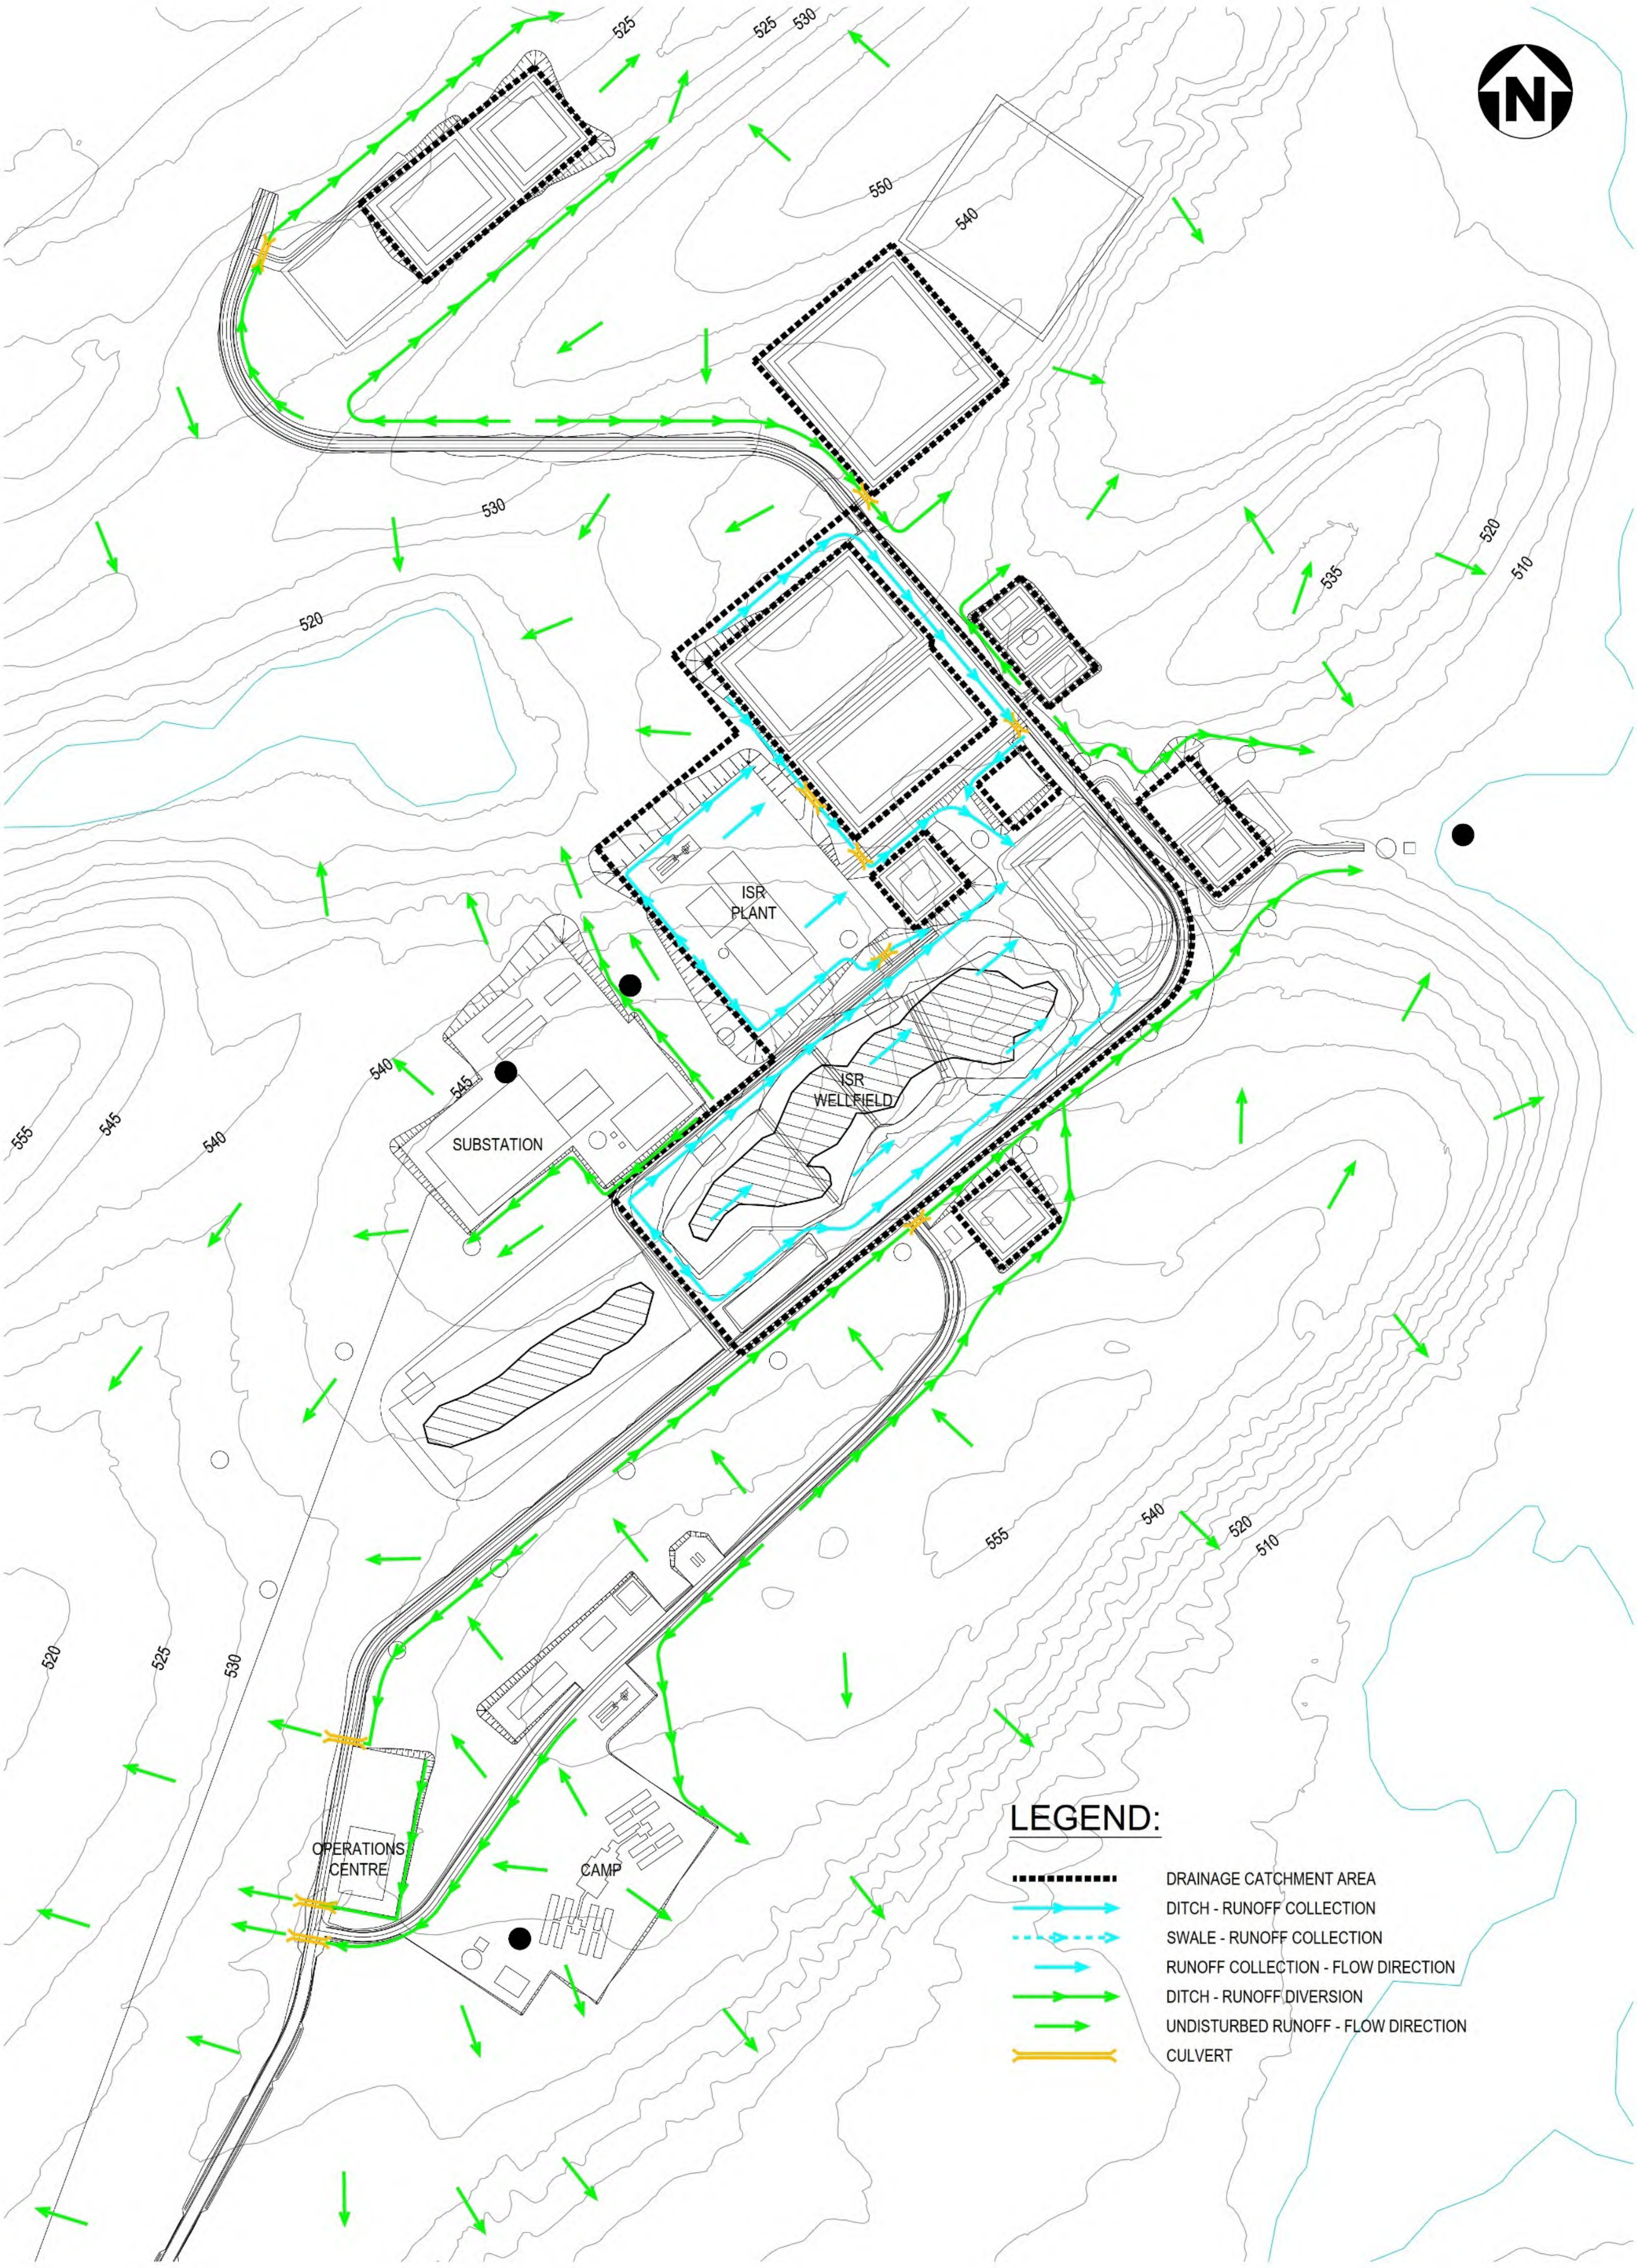

Figure 2.2-17: Site Drainage Plan with Flow Direction and Culvert Locations

2.2.3.2 Freshwater Supply and Distribution

A freshwater distribution system will be designed to provide fresh water for, the potable water treatment plant (WTP), the fire water system, the processing plant including mining solution preparation, the wash bay, drilling, and batch plant operation. Fresh water will likely be sourced from a shallow groundwater well(s); however, to be conservative, the freshwater withdrawal bounding case for this assessment was an assumed maximum water withdrawal of 40.5 m^3/hr from both a groundwater source and a surface water (Whitefish Lake) source for a total freshwater withdrawal of 81 m^3/hr for Project needs during Operation. The fresh water well(s) and surface water intake will be located, designed, installed, and operated according to applicable standards and best practices to minimize effects on the groundwater and surface water environments. Refer to Figure 2.2-1 for the proposed locations of freshwater wells A, B, and C and Section 7, Appendix 7-C for details.

Water usage and maximum water withdrawal was discussed during a virtual engagement meeting with the Ya'thi Nene Land and Resources Office and Leadership representing communities throughout the Athabasca Basin (21-EN-FDLFN-570.17). Denison intends to recycle process water to the greatest extent possible, thereby reducing the demand for fresh water supply. In an effort to develop a conservative assessment basis for the EA, the water recycle flows from the industrial wastewater treatment plant back into the processing plant and wellfield have not been incorporated into the estimates for freshwater withdrawal and treated effluent discharge.

2.2.3.3 Potable Water Treatment Plant and Distribution

Potable water will be generated on site by a prefabricated modularized potable water treatment plant (WTP) comprised of a treatment plant, a 2,000 L storage tank, and a bottle filling station.

Potable water will be piped to the camp, the fire water tank, the operations centre, and the processing plant to provide water for food preparation, hygienic usage, safety showers, eyewash stations and fire suppression requirements. Other locations, such as the airstrip terminal and satellite lunch trailers (during Construction), will receive bottled water as required.

Ultrafiltration or reverse osmosis with ultraviolet (UV) filtration are proposed for Potable water treatment. Chlorination will be needed prior to water distribution. Chemical requirements for the potable WTP will be standard and may include sodium hypochlorite, antiscalant, and bisulfite. The modular plant will be capable of all necessary processes and will contain required HVAC and lighting. The potable WTP will be placed on a concrete pad and will generate 2.5 m^3/hr (60,000 L/day) of potable water based on the assumed consumption rate of 200 people using 300 L per person per day.

2.2.3.4 Process Water Pond

A double-lined process water pond with leak detection has been designed to capture water from a variety of areas, including the process precipitate storage pad and special waste pad. During an open house information session with ERFN specific information regarding the process water pond were discussed to answer questions about the pond liners and concerns on groundwater contamination caused by potential breaches (22-EN-ERFN-618.17). Details on the liner system cross-section is provided in Figure 2.2-18. The pond will be designed to hold up to 30,000 m^3 of water and will be located next to the processing plant. The pond will be surrounded by a 2.0 m berm, have capacity for 0.5 m storage from a probable maximum precipitation (PMP) event estimated to be 493 mm, and allow for maintenance of 1.0 m of free board.

The pond will be able to receive water from all site ponds and monitoring wells. If required, water in this pond can be used directly in the processing plant or be directed to the IWWTP.

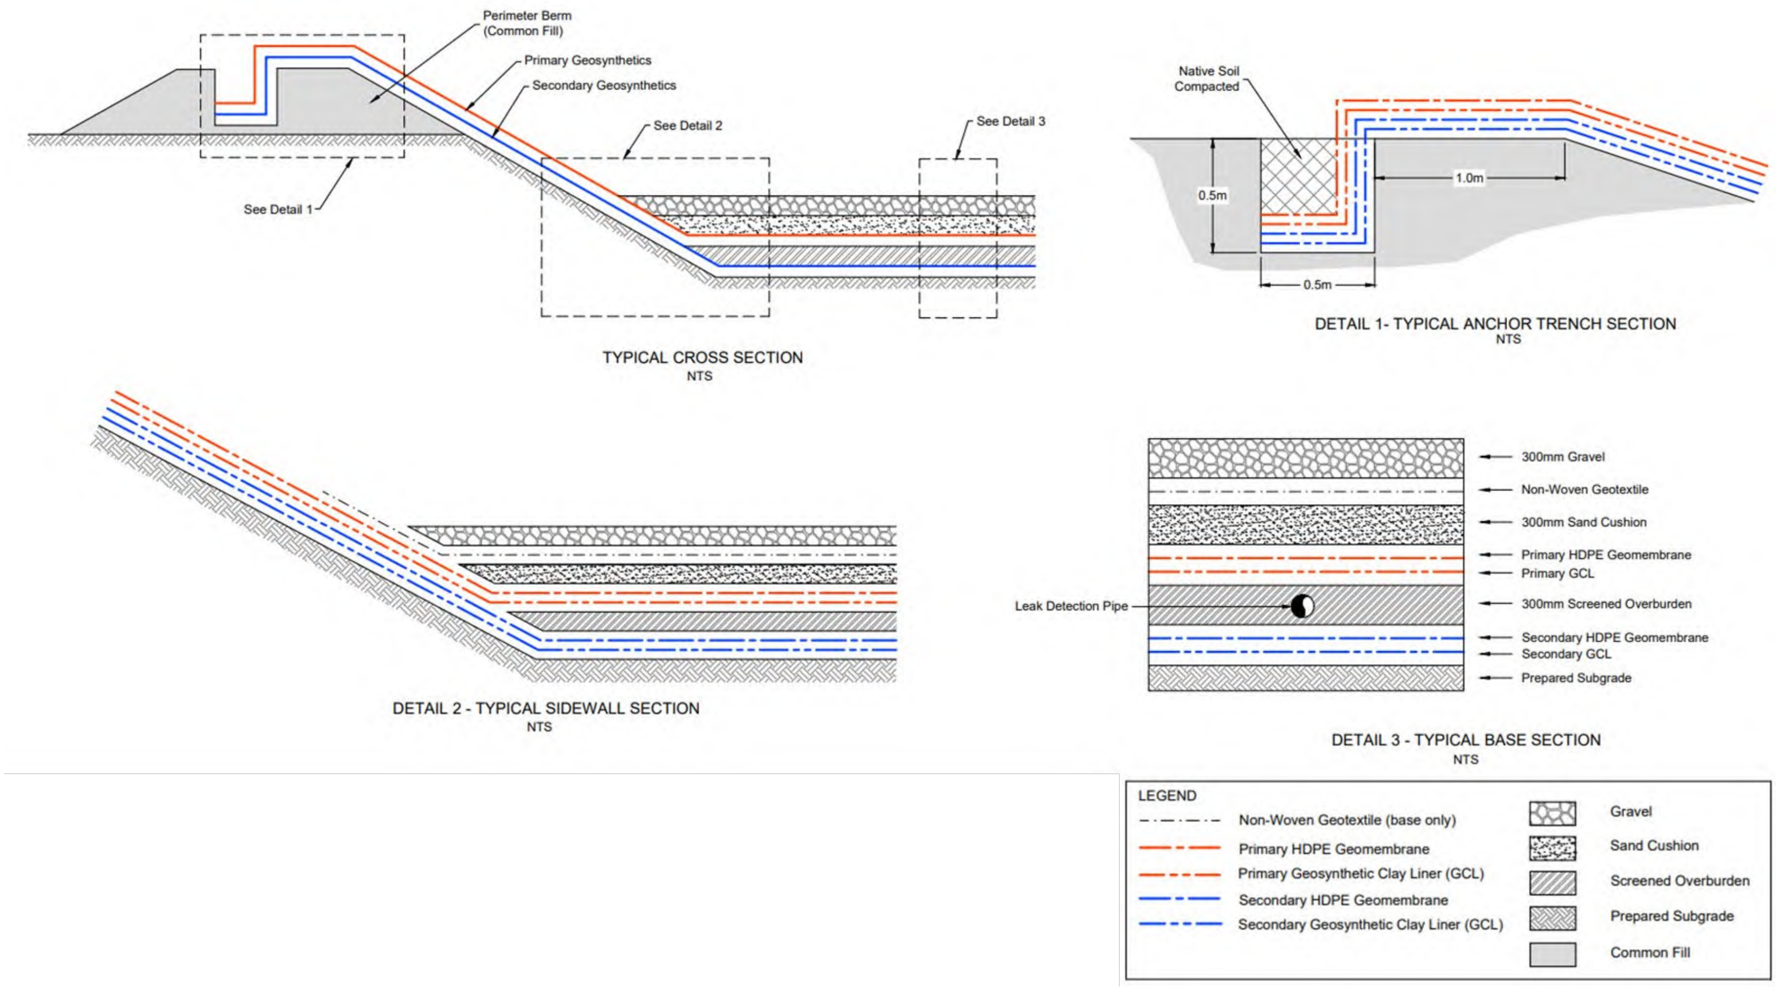

Figure 2.2-18: Pond Double Composite Liner System with Leak Detection Proposed for Uranium Bearing Solution Holding Area, Process Water Pond, Wellfield Runoff Pond, Landfill Leachate Collection Ponds, Process Precipitate Pond

2.2.3.5 Wellfield Runoff Pond

The wellfield runoff pond has been designed to capture runoff from the wellfield and the special waste pad. It will be designed to hold up to 38,200 m^3 of water and have a double composite liner system with leak detection (Figure 2.2-18).

The water in this pond will routed to the process water pond for recycle through the processing plant and eventual treatment at the IWWTP.

2.2.3.6 Clean Waste Rock Pond

A pond may be constructed beside the clean waste rock pad (Section 2.2.4.8) to collect runoff, if required. The pond would be a single geomembrane lined pond (Figure 2.2-26). Water collected in the clean waste rock pond would be routed to the process water pond.

2.2.3.7 Domestic Wastewater Treatment Plant and Pond

Greywater (e.g., water drained from sinks, showers, washing machines) and blackwater (i.e., sewage), collectively referred to as domestic wastewater, will be generated at the camp, processing plant, airstrip terminal, and the operations centre. Domestic wastewater was assumed to be generated at the rate of 300 L per person per day.

At the central facilities, such as the camp and processing plant, domestic wastewater will be piped directly to the on-site treatment domestic wastewater treatment plant (DWWTP). Sewage from facilities located away from the camp (airstrip terminal and satellite lunch trailers during Construction) will be collected in septic tanks and transported by a vacuum truck to the DWWTP.

The DWWTP will be a modular facility comprised of two heated and insulated units, a holding tank, ancillary filtration, ancillary treatment process equipment, and sludge handling system. A 5,000 m^3 pond with a composite liner system (Figure 2.2-19) will be designed to receive treated effluent from the DWWTP. This design is based on providing three months of capacity for 200 people generating 300 L of domestic wastewater per person per day.

Treated effluent from the DWWTP pond will be routed to the process water pond. Reject solids from the DWWTP will be collected, dewatered, and disposed of at an on-site landfill or in the site composting system.

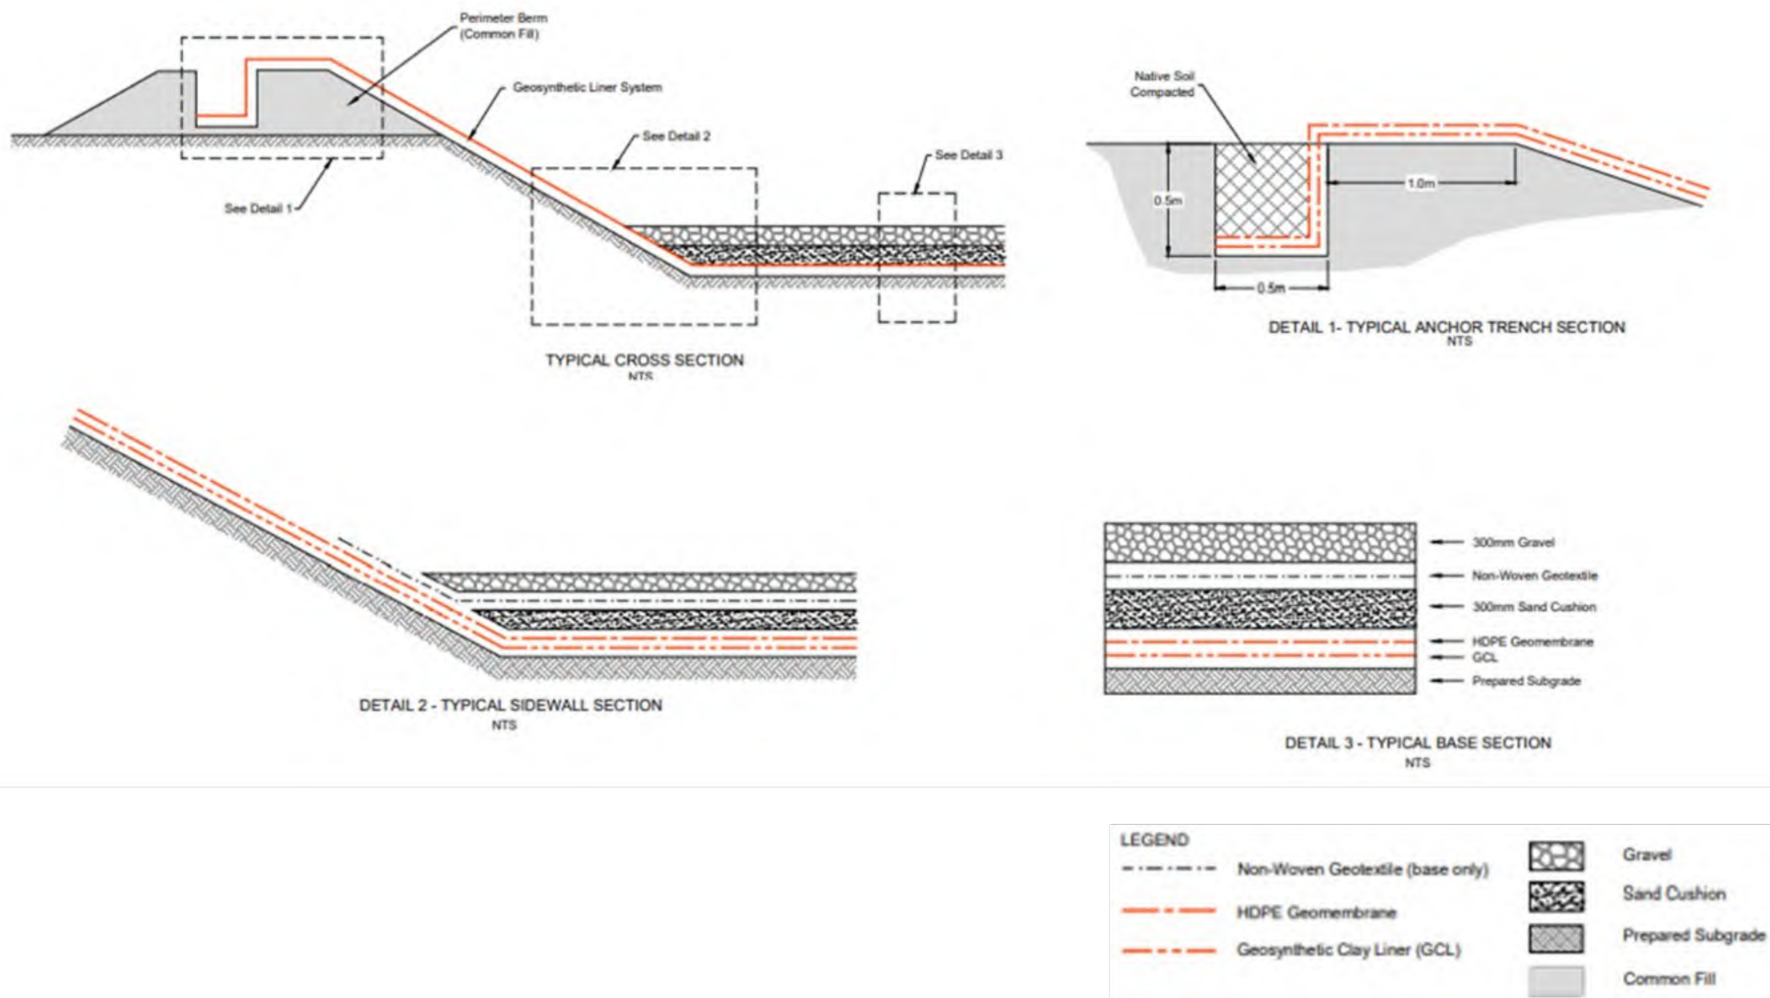

Figure 2.2-19: Pond Composite Liner System Proposed for Industrial Wastewater Treatment Plant Precipitate Pond, Effluent Monitoring and Release Ponds, Domestic Wastewater Treatment Plant Pond

2.2.3.8 Industrial Wastewater Treatment Plant

A metallurgical test program was completed at SRC to help define the IWWTP design and performance criteria. A three-stage IWWTP is proposed to treat contaminated waters produced during ISR process and other various sources (e.g., wash bay sump water, leachate from the industrial landfill, wellfield runoff pond), routed to the IWWTP through the process water pond (Figure 2.2-20). The three stages are: low pH treatment, high pH treatment, and neutralization. Water treatment will involve the addition of various chemicals, which may include sulphuric acid, barium chloride, flocculant, calcium hydroxide (also known as lime), sodium hydroxide, iron sulphate, and zero valent iron. The IWWTP will be located inside of the processing plant and anticipated to be designed to treat approximately 40 m^3/hr.

Stage 1: Low pH Treatment

The first water treatment step will precipitate the majority of remaining radioactive materials from the water. This will be achieved by reagent additions and pH adjustment through agitated tanks then through a clarifier. Over the life of mine an expected 10,000 m^3 of solids are expected to be produced and will be blended with the other radioactive solids in the process precipitates pond. Management of the process precipitates are discussed in Section 2.2.4.5.

Stage 2: High pH Treatment

The second step of the IWWTP will consist of removing remaining acidity from the solution by reagents and pH adjustment through agitated tanks then through a clarifier to allow for precipitation of the IWWTP precipitates. Over the life of mine, an expected 150,000 m^3 of IWWTP precipitates are expected to be produced and will be send to the IWWTP pond. The majority of the IWWTP precipitates are gypsum and these precipitates are not expected to be radioactive. Management of the IWWTP precipitates are discussed in Section 2.2.4.6.

Stage 3: Neutralization

The third step of the IWWTP is anticipated to further neutralize and improve the remaining water quality to allow for release to the environment (i.e., Whitefish Lake). This is proposed to be achieved with further pH adjustments through agitated tanks and a clarifier with negligible solids generation expected at this stage. Several additional technologies including ion exchange are being evaluated as part of an ongoing Best Available Technology Study to be complete as part of future permitting.

It is Denison's intent to incorporate treated water back into the mining water balance as make-up water in the processing plant and to generate mining solution, to the extent possible. Any excess treated water from the IWWTP will be pumped to the effluent monitoring and release ponds (Section 2.2.3.9). The recycle design helps reduce the volume of both freshwater and treated effluent, which were important topics coming out of engagement activities (18-EN-VB-4.40; 21-EN-VILX-443.24).

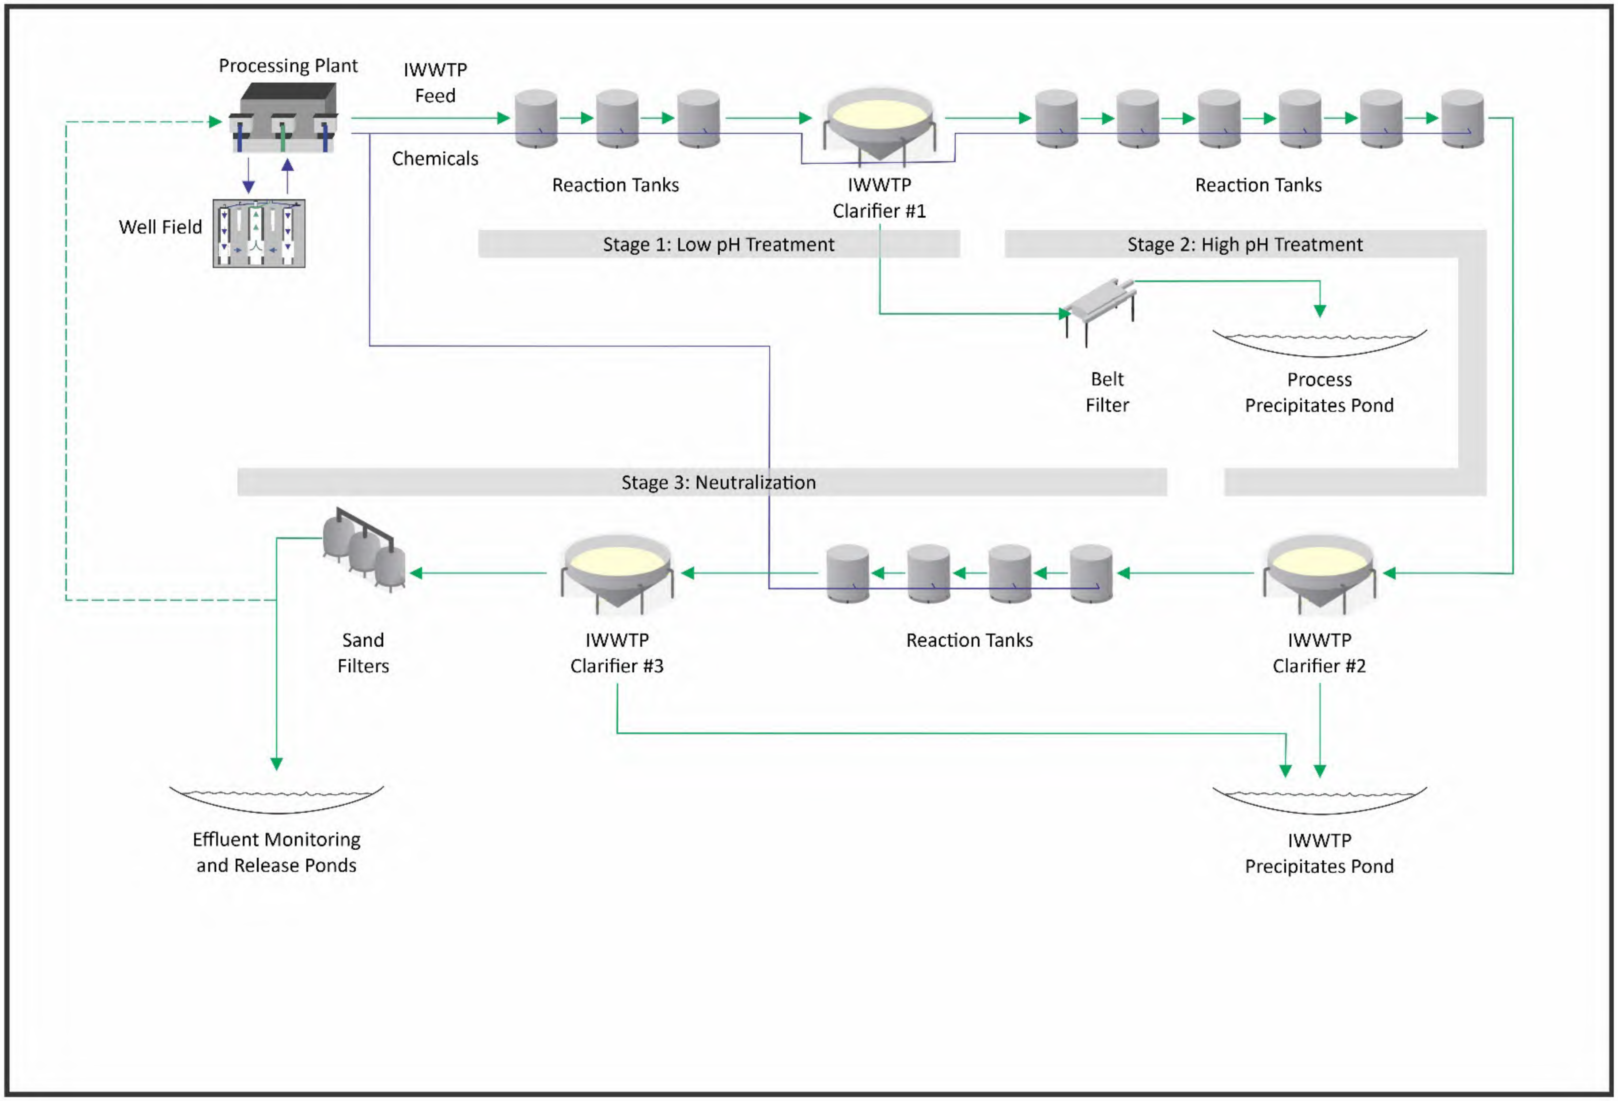

Figure 2.2-20: Three-Stage Industrial Wastewater Treatment Plant Circuits

2.2.3.9 Treated Effluent Monitoring and Release Ponds

Denison plans to construct and operate three treated effluent monitoring and release ponds (Figure 2.2-1). The effluent monitoring and release ponds will receive treated water from the IWWTP. As described earlier, there will be an option to recycle water from this pond back into the processing plant via the process water pond. Details of Denison's plans for effluent monitoring and release ponds were discussed during a virtual meeting with ERFN in response to questions like, "*Are there reservoirs for water treatment?*" (21-EN-ERFN-447.42).

Each of the three ponds will have capacity for 3,300 m^3 of water and a composite liner system (Figure 2.2-19). The ponds have been designed to hold effluent for a period of 80 hours for testing before discharge to the environment. Having three ponds allows for increased operational flexibility, as one pond can be undergoing maintenance when required. A minimum of two ponds are required to be operational at all times to make sure all effluent released to surface water meets federal and provincial discharge limits. Each pond will be operated with the following stages: 1) filling, 2) holding while awaiting quality confirmation; and 3) releasing to Whitefish Lake once water quality is confirmed to meet discharge limits.

Table 2.2-1 presents upper bound estimates of constituent concentrations in treated effluent. This representation of an upper bound effluent quality provides a conservative basis for the assessment of potential Project-related effects that is presented in subsequent sections of the EIS.

The effluent quality information developed for the purposes of the EIS was determined to be achievable through laboratory test results conducted by Denison at SRC. In the laboratory tests, effluent treatment feed solution was prepared by leaching drill core material from the Phoenix deposit. These solutions were further processed through the processing steps described previously (process precipitate removal and yellowcake precipitation) prior to effluent treatment testing. Effluent treatment tests incorporated three stages: low pH, high pH, and neutralization. A combination of reagents (sulfuric acid, lime, barium chloride, and iron sulfate) was used to facilitate precipitation of constituents within the solution. All liquids and solids were assayed to characterize the treatment process and confirm effluent quality targets.

During the EIS review process, the initial list of effluent quality parameters presented in the draft EIS was updated to address comments from the federal government to include, for example, Metal and Diamond Mining Effluent Regulations (MDMER) Schedule 4 and Schedule 5 parameters. These parameters were not initially included because they were not associated with the geology, mining method, and processing plant design. Denison fully understands its obligations with respect to the MDMER and will comply with the MDMER end of pipe effluent discharge criteria and other requirements of the regulation. Section 2 of the EIS is where the Project is described; the subsequent evaluation and assessment of effluent in the receiving environment is presented in EIS Section 8.2, including Table 8.2-10 near-field receiving water quality results and the associated appendix (Appendix 8-E). Additionally, comparison of effluent quality to water quality guidelines is not appropriate. Surface water quality guideline comparisons were completed in Section 8.2 following the process outlined there, in consideration of background water quality, effluent discharge rates, and under three flow scenarios.

With further reference to the upper bound effluent quality, it is noted that Denison intends to continue to refine effluent quality predictions to define a more accurate and precise representation of the expected final effluent as part of the best available technology economically achievable (BATEA) assessment and licensing/permitting phase of the Project. Nevertheless, the effluent quality predictions provided in the EIS serve to bound the assessment, and provide a conservative representation of risk to human health and the environment. The actual effluent quality will meet prescribed limits developed through licensing and permitting, as informed by the BATEA evaluation process and meeting the requirements of REGDOC-2.9.2.

Table 2.2-1: Upper Bound Industrial Wastewater Treatment Plant Effluent Quality

Parameter	Units	Proposed Effluent Quality [1]
General Chemistry, Nutrients and Anions		
Alkalinity [4]	mg/L	12.4
Ammonia as Nitrogen [4]	mg/L	3.9
Un-ionized ammonia [4]	mg/L	0.0129
Hardness [4]	mg/L	> 250
Conductivity (µS/cm) [4]	µS/cm	21.7
Nitrate (concentration in units of nitrogen) [4]	mg/L	<0.249
pH [4]	pH units	7
Phosphorus [4]	mg/L	0.01
Sulphate	mg/L	2600
Total Dissolved Solids	mg/L	6420
Temperature [4]	°C	16.5 [2]
Total Suspended Solids [4]	mg/L	6.0
Chloride	mg/L	600
Metals		
Aluminum [4]	mg/L	0.051
Arsenic	mg/L	0.006
Cadmium	mg/L	0.0018
Chromium	mg/L	0.025
Cobalt	mg/L	0.0027
Copper	mg/L	0.0222
Cyanide [4]	mg/L	NA

Parameter	Units	Proposed Effluent Quality [1]
Iron [4]	mg/L	0.0039
Lead [4]	mg/L	0.0003
Manganese [4]	mg/L	0.03
Mercury [4]	mg/L	<0.00001
Molybdenum	mg/L	2.5
Nickel [4]	mg/L	0.0138
Selenium	mg/L	0.0419
Strontium [4]	mg/L	1.68
Thallium [4]	mg/L	0.0006
Uranium	mg/L	0.057
Vanadium [4]	mg/L	0.059
Zinc	mg/L	0.042
Radiological		
Lead-210 (Bq/L)	Bq/L	0.419
Polonium-210 (Bq/L)	Bq/L	0.150
Radium-226 (Bq/L)	Bq/L	0.150
Thorium-230 (Bq/L)	Bq/L	0.900
Uranium-238 (Bq/L)	Bq/L	0.704 [3]
Uranium-234 (Bq/L)	Bq/L	0.704 [3]

Notes:

All parameters listed as total concentrations unless otherwise specified

1 The effluent quality presented here provides a bounding scenario of the basis of the assessment of Project effects. The actual effluent quality will meet prescribed limits developed through licensing and permitting, as informed by the BATEA.

2 Temperature was assumed to be 1.5°C above the background average annual temperature of 15°C

3 Estimated from uranium using the specific activity of 12356 Bq/g and assuming secular equilibrium between uranium-238 and uranium-234 (https://www.wise-uranium.org/rup.html)

4 Indicates parameter was added during EIS review to address comments from reviewers including those related to the MDMER and were not the initial focus of effluent characterization based on Project geology, mining, and processing methods

2.2.3.10 Treated Effluent Discharge

The treated effluent discharge line will run from the effluent monitoring and release ponds into Whitefish Lake (Figure 2.2-1). Effluent release into surface waters is of interest to Indigenous groups. Through a variety of engagement initiatives, Denison has become aware that treated effluent discharge is a topic of importance to Communities of Interest (18-EN-VPL-2.15) (18-EN-VB-4.51) (18-EN-ERFN-5.35) (18-EN-VPL-2.11) (18-EN-VPL-2.15). The effluent discharge line will be double walled with heat tracing to prevent operational issues with cold weather temperatures. A small trail will be constructed parallel to the line so it can be checked by Denison staff as part of routine inspections.

The discharge line will be located in a suitable area of the lake bottom to minimize disruption of fish habitat. A diffuser will be installed at the end of the line for effluent mixing within the lake. The assumed average effluent discharge rate for the EIS was 36.5 m^3/hr, with a maximum bounding scenario of 81 m^3/hr. Modelling of treated effluent discharge is provided in Appendix 10-A in Section 10.

In-water works will be limited to placement of the discharge and intake pipeline (if required, Section 2.2.3.2) infrastructure which will not expected to include any major works requiring excavation or substantial noise disturbance.

2.2.4 Waste Management

Conventional waste, radiologically contaminated waste, and hazardous waste will be managed at the Project. Denison is committed to conducting stringent waste characterization throughout the life of the Project. This includes physical, radiological, and chemical characterization to maintain accurate waste inventories and determine how wastes will be dispositioned through either re-use, recycling, temporary storage, or permanent disposal (on or off site). This includes clearance of material that meets unconditional release requirements and can be safely removed from site.

A waste management program will be developed for the Project to support licensing and permitting. The waste management program and associated plans developed to support licensing will be based on the 4 R’s: Reduce, Reuse, Recycle, and Recover, and will detail how each type of waste generated on site will be managed. Resources used to develop the waste management program will include, but are not limited to, the CNSC’s REGDOC-2.11 series, related Canadian Standards Association (CSA) standards, and the Hazardous Substances and Waste Dangerous Goods Regulations (Government of Saskatchewan 2000). The conceptual decommissioning plan for each waste stream or Project component, if applicable, is provided in Section 2.3.3.

Denison is proposing to design pond, pad, and landfill liners systems and develop appropriate performance monitoring (e.g., leak detection, groundwater monitoring) based on the characteristics of the material being stored. This will be discussed in more detail below, but broadly was as follows:

- Ponds or pads designed to temporarily or permanently store non-radioactive materials will be lined with a single geosynthetic composite liner system. This is a primary HDPE geomembrane (GM) over a Geosynthetic Clay Liner (GCL). The GCL will include a low permeable layer of bentonite clay. Examples of Project components proposed to have this type of liner include: the industrial wastewater treatment plant precipitate pond, hazardous waste storage pad, and effluent monitoring and release ponds.

- Ponds or pads designed to temporarily or permanently store potentially radioactive materials will be lined with a double geosynthetic composite liner system. This is a primary HDPE GM over a GCL and a secondary HDPE GM over an additional GCL. The GCL will include a low permeable layer of bentonite clay. In between the primary and secondary liners, a leak detection and collection system will also be installed. The selected design is the most robust currently known and offers a life of several hundred years with proper installation and maintenance. Examples of Project components proposed to have this type of liner include: wellfield runoff pond, process precipitate pond, landfill leachate collection ponds, process water pond, UBS holding area, and special waste pad.

Table 2.2-2 provides an overview of expected waste volumes throughout the life of the mine.

Table 2.2-2: Waste Predictions for Life of Mine and Description of Associated Waste Management Component

Waste				Associated On-site Waste Management Component (temporary storage or permanent disposal)				
Type	Volume (m^3)	Examples of Wastes	Disposal Method	Waste Management Component	Temporary (T) Storage or Permanent (P) Disposal	Volume (m^3) or Area (m^2)	Design Notes	Waste Management Component Liner Design Figure (if applicable)
Organic waste	2,170	Food waste, kitchen scraps	On-site composting	Brome composting system	P	n/a	Composting system with pad near domestic landfill for final curing.	n/a
Recyclables	8,000	Steel, cardboard, paper, plastic, common household recyclables	Off-site recycling	Recycling laydown area	T	n/a	Recycling laydown area with recycling bins will be located near the camp and operations centre. No liner system is planned.	n/a
Construction waste	7,000	Steel, wood, plastics, concrete	Temporary laydown area for construction wastes. Recyclables will taken off site and any nonrecyclable waste will be permanently disposed of in the domestic landfill, once constructed	Construction waste laydown area	T	7,000 m^3	Temporary laydown area to receive construction waste. Adjacent to the future domestic landfill. No liner system is planned.	Figure 2.2-23
Domestic waste	34,400	Wood, plastics	On-site disposal in domestic landfill	Domestic landfill with associated leachate collection pond	P	34,400 m^3	Domestic landfill will have a composite liner system with leachate collection. The leachate collection pond will have a double composite liner system with leak detection.	Landfill: Figure 2.2-21 Leachate collection pond: Figure 2.2-18
Radiologically and other contaminated waste	6,000	Radiologically contaminated material that can be cleaned to meet unconditional clearance level requirements	Cleaned on site and then sent off site for recycling or reuse	Industrial laydown area	T	2,500 m^2	Radiologically contaminated components can be cleaned via dry blasting, sand blasting, and/or high pressure washing at the industrial laydown area, adjacent to the industrial landfill. The laydown will be placed within the industrial landfill double lined area in close proximity to the industrial landfill leachate collection pond. Any wash water generated during cleaning will drain to the industrial landfill leachate collection pond.	Figure 2.2-22

Waste				Associated On-site Waste Management Component (temporary storage or permanent disposal)				
Type	**Volume (m^3)**	**Examples of Wastes**	**Disposal Method**	**Waste Management Component**	**Temporary (T) Storage or Permanent (P) Disposal**	**Volume (m^3) or Area (m^2)**	**Design Notes**	**Waste Management Component Liner Design Figure (if applicable)**
Radiologically and other contaminated waste	41,270	Radiologically contaminated material from operational activities that cannot be cleaned to pass radiological clearance, e.g., used wellfield piping, laboratory waste	On-site disposal in industrial landfill	Industrial landfill with associated leachate collection pond	P	100,000 m^3	Industrial landfill will have a double composite liner system with leak detection and leachate collection capabilities. The leachate collection pond will have a double composite liner system with leak detection.	Landfill: Figure 2.2-22 Leachate collection pond: Figure 2.2-18
Hazardous waste	1,900	Fuel, paint, used oil, chemicals	Off-site recycling or disposal	Hazardous waste storage pad	T	250 m^2	Hazardous waste storage pad will have a composite liner system.	Figure 2.2-24
Process precipitates	50,000	Iron/radium-226 precipitates	On-site temporary storage on process precipitate pond, followed by off-site processing and permanent disposal	Process precipitate pond	T	50,000 m^3	Process precipitate pond will be double lined with leak detection capabilities. Any runoff from the pad will be directed to the process water pond.	Figure 2.2-18
Industrial wastewater treatment plant (IWWTP) precipitates	150,000	Gypsum	On-site disposal in IWWTP precipitate ponds	IWWTP precipitate ponds	P	150,000 m^3	Ponds will have composite liner system. Water from the ponds will either be recycled through the processing plant via the process water pond, or routed to the effluent monitoring and release ponds.	Figure 2.2-19
Special waste rock	150	Mineralized drill cuttings produced during drilling	On-site temporary storage on special waste pad, followed by reprocessing in the processing plant or disposal off site	Special waste pad	T	2,500 m^2	Special waste pad will be constructed with a double composite liner system with leak detection capabilities. Any contact water coming off the special waste pad will be directed to the wellfield runoff pond.	Figure 2.2-25
Clean waste rock	7,800	Sandstone cuttings or core produced during drilling	On-site temporary storage on clean waste rock pad, used in construction as possible and balance decommissioned on site	Clean waste rock pad with associated pond	T/P	2,500 m^2	Clean waste rock pad will have a single geomembrane liner with protection. Adjacent pond will also have a single geomembrane lined with protection. Runoff will go to the process water pond, or effluent monitoring and release ponds.	Figure 2.2-26

2.2.4.1 Organic Waste

Denison is proposing to use a composter for disposal of organic waste which is anticipated to primarily be food waste. A contained and partially automated composter, such as the Brome composting system, is the preferred option. The composting system is expected to be in a seacan. After composting is complete, an outdoor curing phase will be required during summer months. Based on experience with the Brome composting system at other mine sites, the finished compost is not foreseen to be a wildlife attractant. Prior to any compost being used on site for remediation purposes, the compost will be tested to determine its suitability for unrestricted or restricted use based on the Canadian Council of Ministers of the Environment guidelines for compost quality (Canadian Council of Ministers of the Environment 2005).

2.2.4.2 Recyclables

Recyclable materials include steel, plastics, common household recyclables, cardboard, and paper.

The recycling laydown area with recycling bins will be located close to the camp and be accessible by trucks. Any recyclable material from the camp, operations centre, and airport terminal will go directly to the recycling bins at this laydown.

Recyclable material generated at the wellfield and processing plant that may have radiological contamination will be moved to the industrial laydown area, which will be located near the industrial landfill. Any suspect recyclables will be scanned prior to release to the recycling laydown. Any recyclables that do not meet radiological clearance criteria following reasonable cleaning efforts will be disposed of in the industrial landfill.

The emptying of the recycling bins will be managed through third-party waste management service providers. All recyclables will be shipped off site to approved recycling facilities. Adherence to the recycling program will be managed through training of all site personnel and oversight by Denison staff.

2.2.4.3 Landfills

Two waste landfills are included as part of the proposed Project. The design of these facilities is consistent with best management practices both at northern Saskatchewan mine sites and from comparable jurisdictions. The two landfills are the:

- Domestic Waste Landfill
- Industrial Waste Landfill

Laydown areas will be adjacent to each landfill to provide temporary areas for storing or staging material prior to cleaning and off-site disposal or on-site disposal. The design of these facilities is discussed in the sections below.

2.2.4.3.1 Domestic Landfill

Denison plans to construct, operate, monitor, and decommission a domestic landfill on site to manage non-recyclable, inert wastes. Examples of materials destined for the domestic landfill include wood, non-recyclable plastics, broken furniture, textiles, and non-recyclable items from the camp and operations centre.

The total volume of domestic waste to be received at the domestic landfill over the life of mine is approximately 34,400 m^3, which includes approximately 6,400 m^3 of waste during Construction and 4,000 m^3 of waste during Decommissioning.

The domestic landfill will have a composite liner system with leachate collection (Figure 2.2-21). The design consists of a HDPE liner directly over a GCL, with leachate collection system. The leachate collection pond associated with the domestic landfill will have a double composite liner system with leak detection (Figure 2.2-18). The leachate will be collected by vacuum truck and treated in the IWWTP.

The landfill will be fenced and the surface contoured to direct runoff away from the facility. The domestic landfill will require regular covering with clean soil to prevent wind borne litter leaving the landfill and to avoid attracting wildlife and birds. Performance of the domestic landfill and leachate containment system will be monitored through a network of groundwater monitoring wells, including at a minimum one upgradient and two downgradient wells.

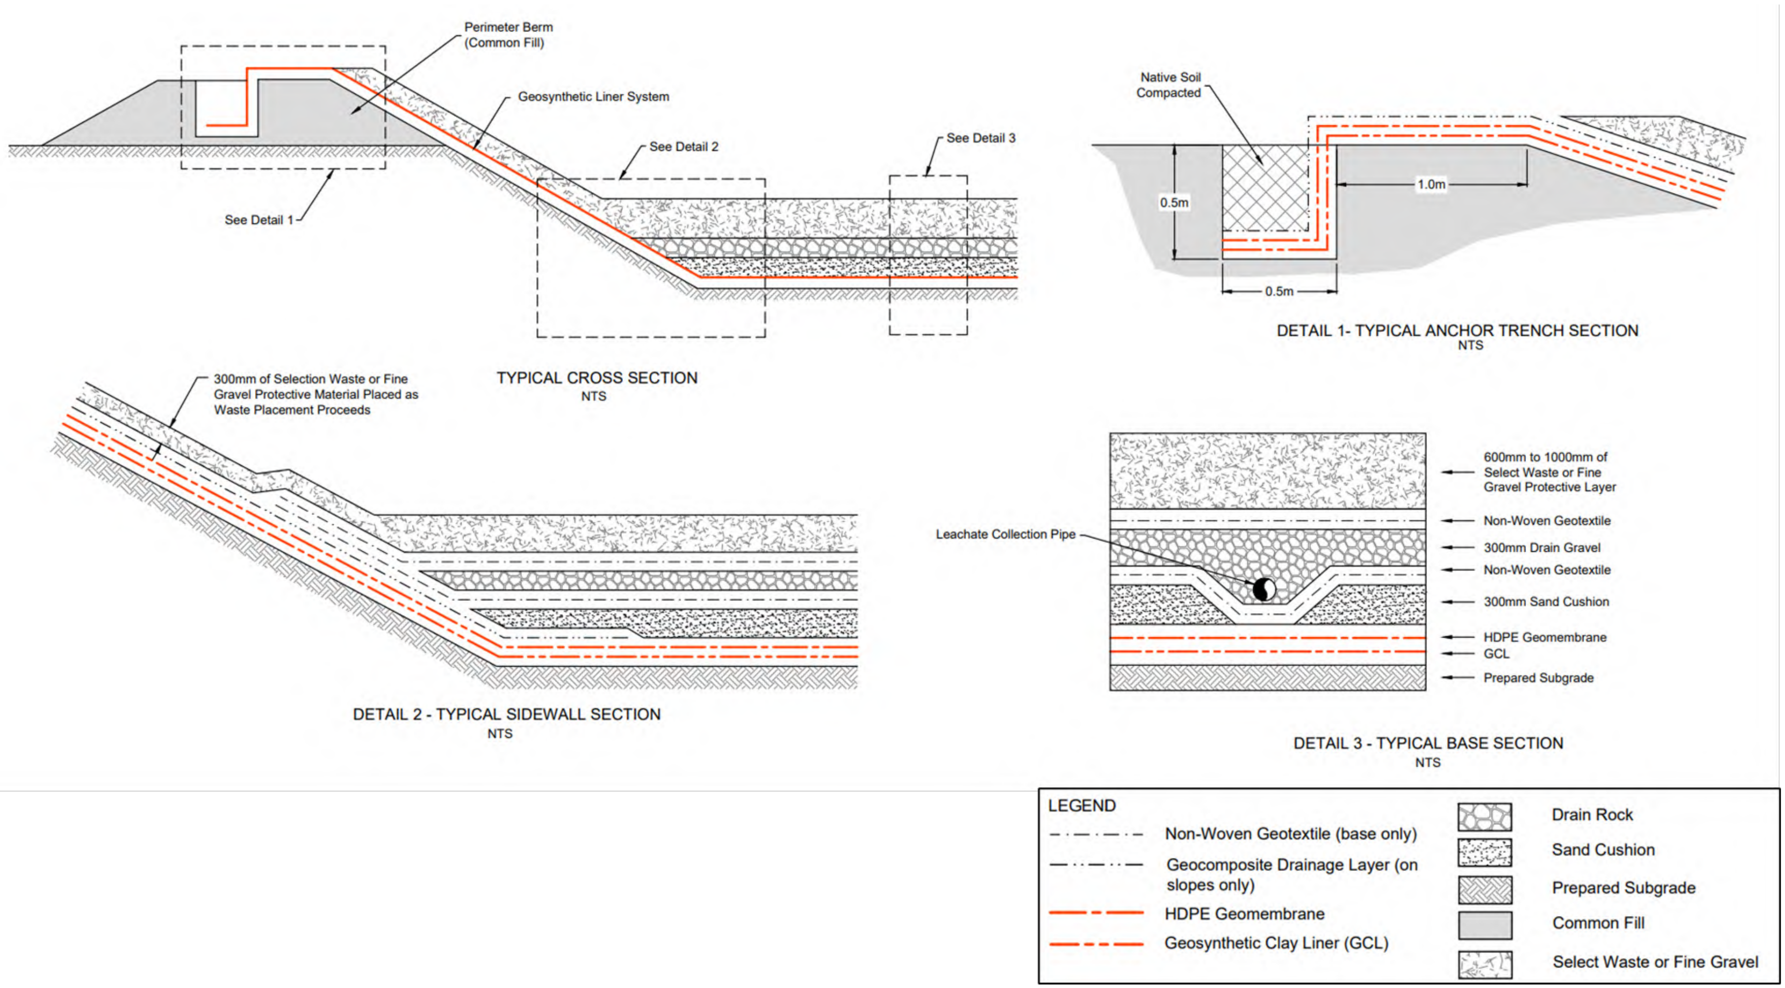

Figure 2.2-21: Domestic Landfill Composite Liner System with Leak Detection

2.2.4.3.2 Industrial Landfill

The industrial landfill will be designed to accept industrial wastes generated at site including waste with chemical and/or radiological contamination. It will initially be sized to be 50,000 m^3 with room to expand to 100,000 m^3 at Decommissioning to accept decommissioning wastes. There will be an associated leachate collection pond immediately north of the industrial landfill.

Radiologically contaminated material that can be cleaned (e.g., via dry blasting, sand blasting, and/or high pressure washing) at the industrial laydown area (see below) to meet unconditional clearance level requirements will then be sent off site for recycling or reuse (Table 2.2-2). Radiologically contaminated material from operational activities that cannot be cleaned to pass radiological clearance, e.g., used wellfield piping, laboratory waste, will be disposed of in the industrial landfill and classified as low level radioactive material. Radioactive waste in Canada is defined as any material (liquid, gaseous, or solid) that contains a radioactive nuclear substance, as defined in section 2 of the *Nuclear Safety and Control Act*, for which no further use is foreseen. Following a graded approach that is commensurate with risk, Denison has broadly characterized radioactive waste as being temporarily on site or permanently on site.

The double liner design proposed for the industrial landfill is shown on Figure 2.2-22. It consists of a double geosynthetic composite liner system including a primary HDPE GM over a GCL and a secondary HDPE GM over another GCL. A leak detection and collection system is planned to be installed between the primary and secondary geosynthetic composite liners. The GCL includes a layer of bentonite clay, which has very low permeability and very good longevity. This type of design is the most robust currently known and offers a life of several hundred years with proper installation and maintenance. Published information predicts a life of 446 years for a single properly selected and installed geomembrane (Koerner et al. 2011).

Leachate generated from the waste in the industrial landfill will be collected, removed, and sent to a leachate collection pond, located immediately north of the landfill. The leachate collection pond will have a double liner system with leak detection (Figure 2.2-18). Leachate will be pumped via dedicated piping from the collection pond to the process water pond. The landfill will be fenced, and the surface contoured to direct runoff away from the facility.

The industrial landfill will be designed to be several metres above the groundwater table to which will minimize any leachate infiltrating into the shallow groundwater system. Upon closure of the site, the industrial landfill will be covered with an engineered impermeable liner system to minimize infiltration of precipitation into the containment system.

Performance of the containment system will be monitored through a network of groundwater monitoring wells located around the industrial landfill.

Industrial Laydown Area

The industrial landfill will contain a 2,500 m^2 industrial laydown area where radiologically-contaminated components will be cleaned via dry blasting, sand blasting, and/or high pressure washing. The industrial laydown area will be placed within the footprint of the industrial landfill's double liner and in close proximity to the industrial landfill leachate collection pond. Any wash water generated during cleaning will be drained to the industrial landfill leachate collection pond and routed to the process water pond via dedicated piping. If, after cleaning, the material passes radiological clearance for off-site removal, it will be moved to the recycling laydown (if recyclable) or taken off site for re-use. If material on the laydown does not meet radiological clearance to remain inside the industrial landfill, it will be recleaned to remain inside the industrial landfill or disposed off site at an approved facility.

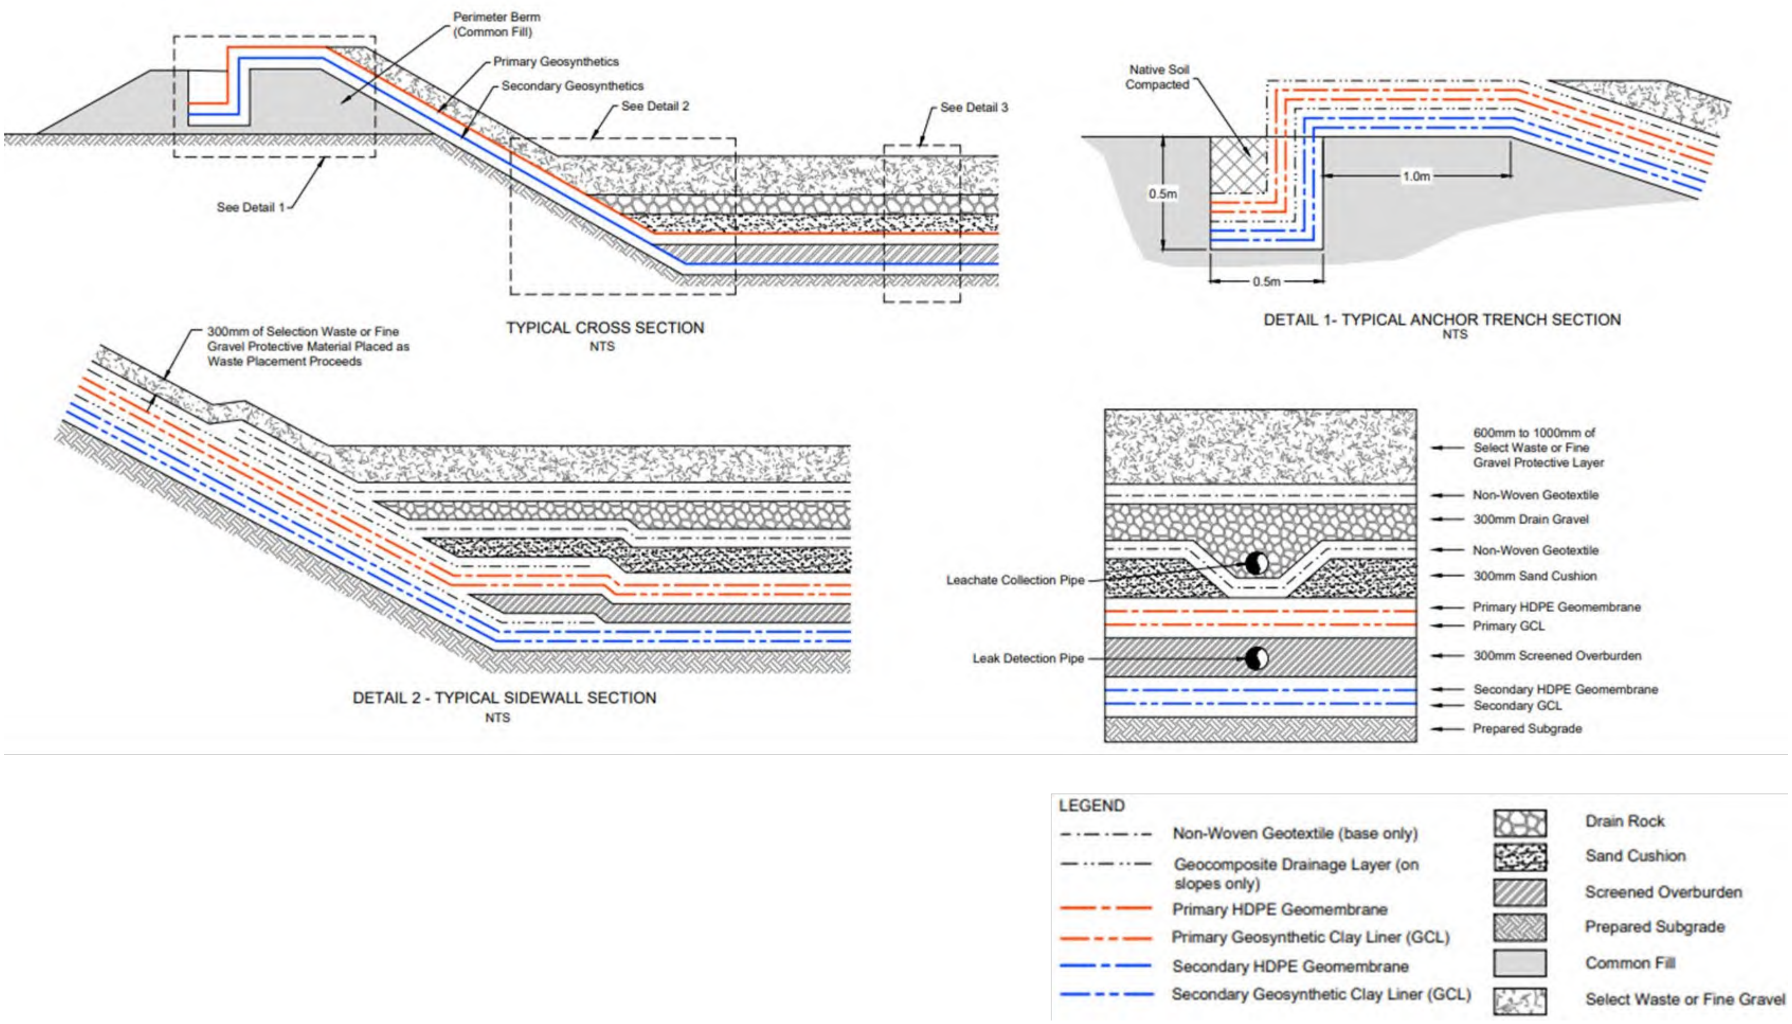

Figure 2.2-22: Industrial Landfill Double Composite Liner with Leachate Collection and Leak Detection

2.2.4.3.3 Construction Laydown Area

During Construction, Denison plans to create a laydown area next to the future domestic landfill to temporarily store construction waste. Examples of materials include clean wood, plastics, metal, and concrete. The construction laydown area will not be lined, but it will have a berm surrounding the area to minimize run-on and runoff. The base of this laydown will be scarified and recompacted prior to waste placement (Figure 2.2-23). This laydown will be monitored by the domestic landfill groundwater monitoring well network. Material stored here will be moved to the domestic landfill once it is constructed, or taken off site for recycling or reuse, as applicable.

2.2.4.4 Hazardous Waste Management

Denison identified a need to have a small (250 m^2) pad designated for temporary storage of hazardous waste such as paints, solvents, hydrocarbons, and used oil. The temporary storage pad will have a composite liner system (Figure 2.2-24). Hazardous wastes will be taken off site by waste management service providers for proper recycling as soon as practical.

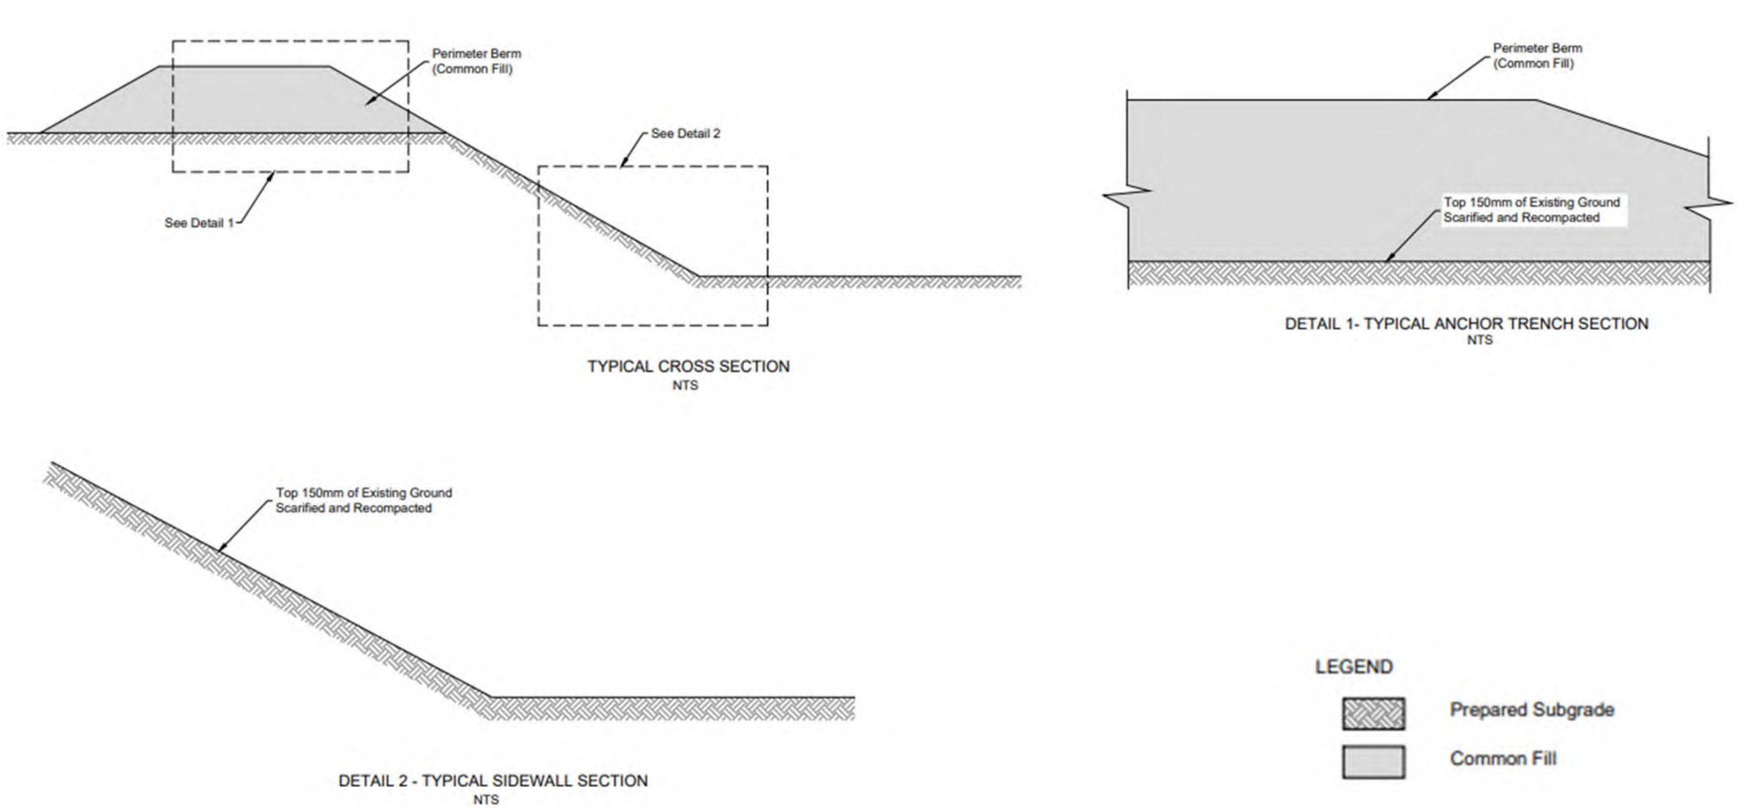

Figure 2.2-23: Construction Laydown Area

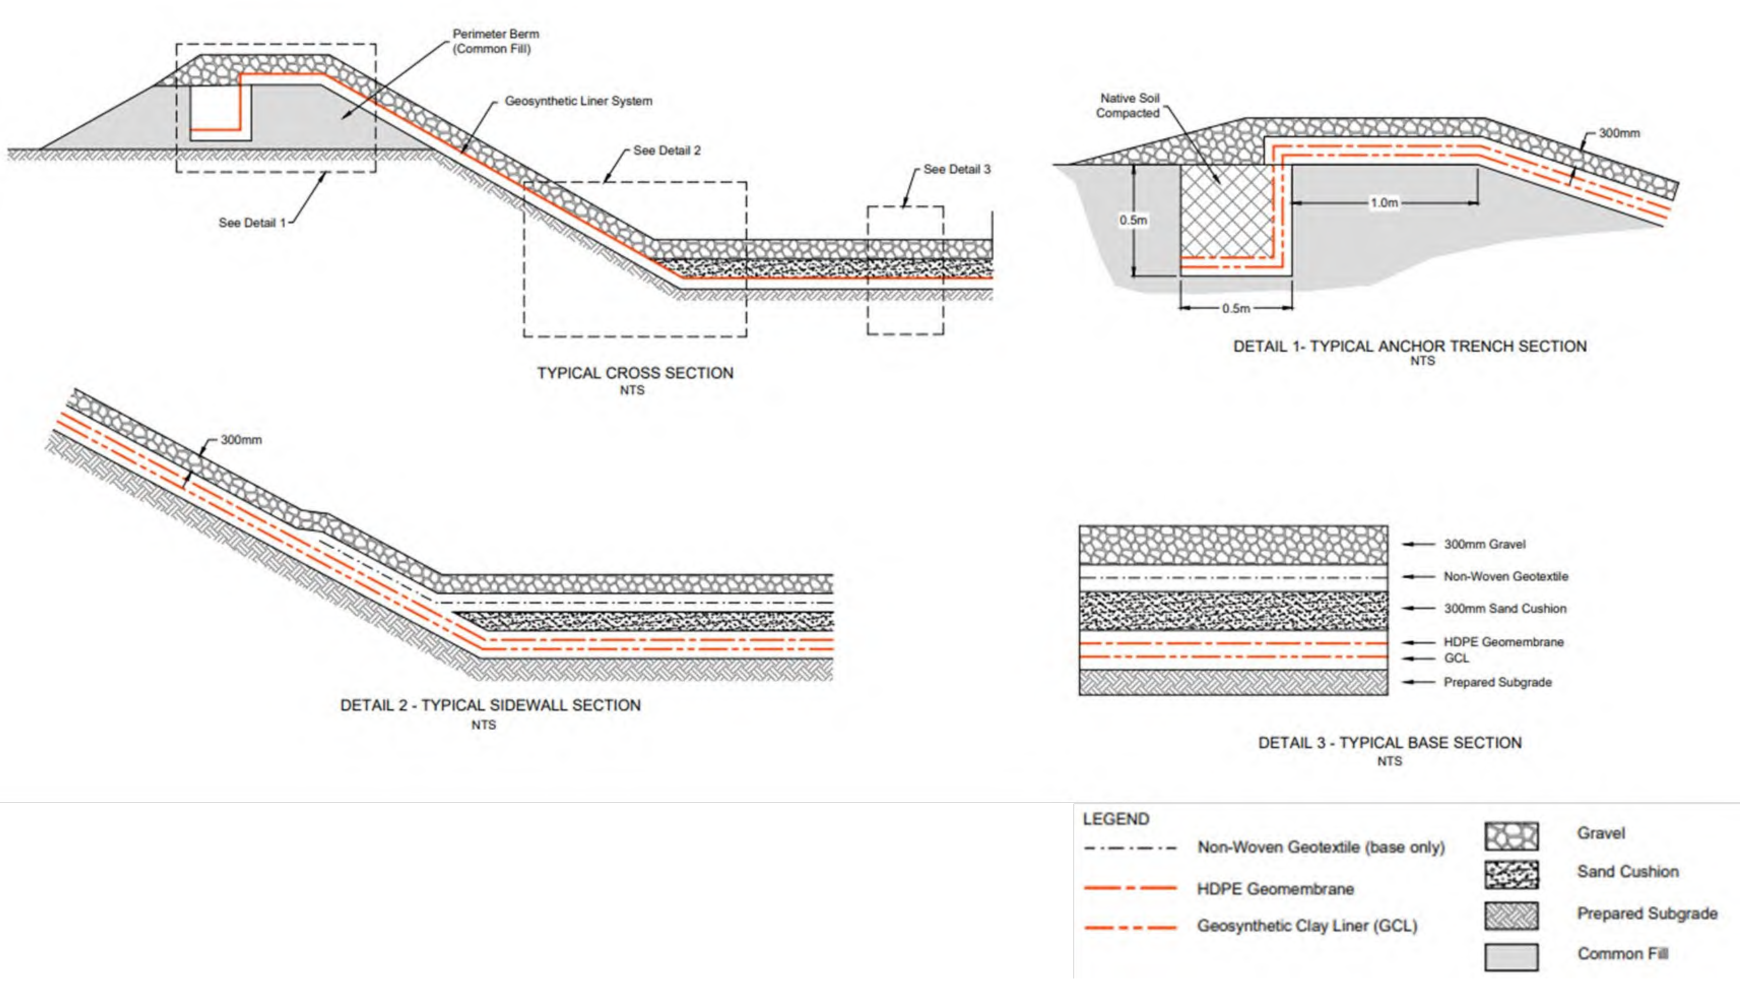

Figure 2.2-24: Pad Composite Liner System Proposed for the Hazardous Waste Storage Pad

2.2.4.5 Process Precipitate Pond

The precipitates generated in the processing plant (Section 2.2.2.2) will be transferred to the process precipitate pond. Any radioactive precipitates generated during the first stage of the IWWTP will also be directed to the process precipitate pond. The precipitates may be stored in totes inside the pond. This pond design will allow the precipitate totes to be stacked below ground level. The pond will be double lined with leak detection capabilities; refer to Figure 2.2-18. It will be designed to hold up to 50,000 m^3 of precipitates. Any runoff collected in the pond will be directed to the process water pond (Section 2.2.3.4) and recycled through the plant.

The metallurgical test work completed at SRC has also allowed Denison to estimate volumes of process precipitates that could be generated during the LOM confirming the 50,000 m^3 LOM volume allotted for the process precipitate pond is sufficient for the environmental assessment and provides a conservative assessment basis. In addition, metallurgical test program completed at SRC indicates that the process precipitates will contain approximately 2 to 3% uranium. This makes the process precipitates of economical value, allowing for sale and removal for processing at an off-site facility as part of Decommissioning. Transport of any radiological material off site during Decommissioning will adhere to the *Transportation of Dangerous Goods Regulations*.

Discussions surrounding mine waste management were discussed in detail during numerous community engagement meetings (21-EN-LLRIB-392.21). Denison communicated that the proposed ISR mining method for the Project will produce very minimal volumes of waste and detailed the steps by which waste streams will be managed (18-EN-VPL-2.49; 18-EN-VILX-3.68; 19-EN-YNLR-84.1; 21-EN-ERFN-447.40; 21-EN-YOUTH-448.7).

2.2.4.6 Industrial Wastewater Treatment Plant Precipitate Pond

The main precipitate generated in the IWWTP process is expected to be a non-radioactive, gypsum-type material (calcium sulphate mineral). Denison plans to manage these precipitates separately from the process precipitates because of the difference in their composition, particularly radioactivity.

The non-radioactive IWWTP precipitates will be transferred from the IWWTP to the IWWTP precipitate pond. The IWWTP precipitate pond will initially be sized to hold 50,000 m^3 with room for expansion to 150,000 m^3. The metallurgical test work completed at SRC has allowed Denison to characterize the precipitates composition and estimate volumes IWWTP precipitates that could be generated during the LOM confirming the 150,000 m^3 LOM volume allotted for the IWWTP precipitate pond size provides a conservative assessment basis.

The liner design proposed for the IWWTP precipitate pond is shown in Figure 2.2-19. It consists of a geosynthetic composite liner system including a primary HDPE GM over a GCL. The GCL includes a layer of bentonite clay, which has very low permeability and very good longevity. This type of design is the most robust currently known and offers a life of several hundred years with proper installation and maintenance. Published information predicts a life of 446 years for a single properly selected and installed geomembrane (Koerner et al. 2011). Water from the ponds will be recycled through the processing plant via the process water pond. The IWWTP precipitate pond will be installed several meters above the water table and will be decommissioned on site as the ponds will be covered with an impermeable liner during physical decommissioning.

2.2.4.7 Special Waste and Special Waste Pad

During Operation, the special waste pad is expected to contain special waste that is primarily mineralized core, cuttings from wellfield development, basement rock, and any waste rock determined to be potentially acid generating (PAG). Special waste from drilling activities is defined as uranium containing materials that cannot be disposed of in the clean waste pile, including PAG waste rock. Special waste will be determined by Denison geologists based on ore zone intersection expectations, probe reading taken during wellfield drilling activities, and results of systematic assays to characterize the acid generating potential of waste rock. Based on the current wellfield and freeze wall design, approximately 2,000 m^3 of special waste rock will be generated.

Denison will examine opportunities to reprocess the mineralized core and cuttings generated during wellfield development to recover uranium. This reprocessing may be done by placing the material in tanks with mining solution or placing the material underground into the mining area at the end of a well's production.

The special waste pad may be used to temporarily store other materials that may be radioactive (e.g., contaminated soil) prior to final disposal in the industrial landfill or a licensed off-site facility.

The special waste pad is estimated to be 2,500 m^2 in size and will be constructed with a double composite liner system with leak detection capabilities (Figure 2.2-25). Any contact water coming off the special waste pad will be directed to the wellfield runoff pond (Section 2.2.3.5).

2.2.4.8 Clean Waste Rock and Clean Waste Rock Pad

Clean waste rock (non-mineralized and non-potentially acid generating [PAG] rock) will be generated as sandstone cuttings and core from drilling activities. Based on the current wellfield and freeze wall design, approximately 7,800 m^3 of clean waste rock will be generated. Clean waste rock will be stored on a 2,500 m^2 single geomembrane liner (Figure 2.2-26) and can be used for road construction and/or concrete production. The clean waste rock will be assayed and tested for PAG during Operations to ensure the material can be reused when required. A pond may be constructed beside the pad to collect runoff, if required, and would also have a single geomembrane lined with protection (Figure 2.2-26).

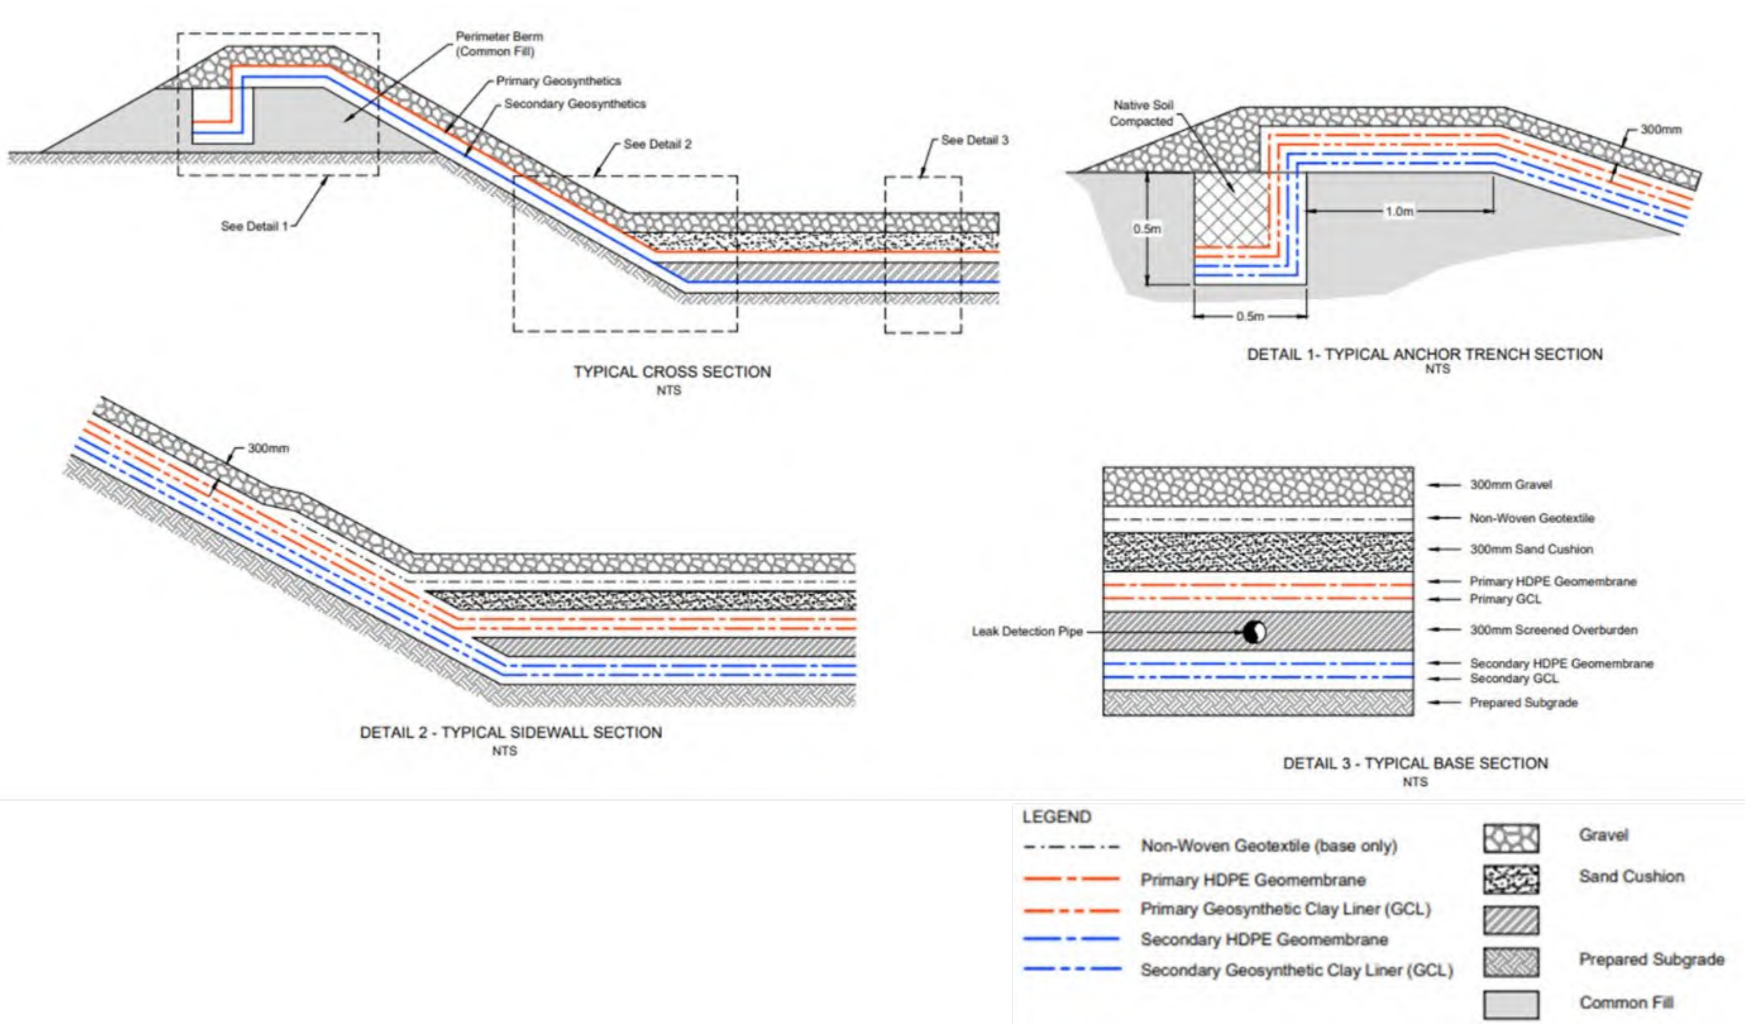

Figure 2.2-25: Pad Double Composite Liner System with Leak Detection Proposed for the Special Waste Pad

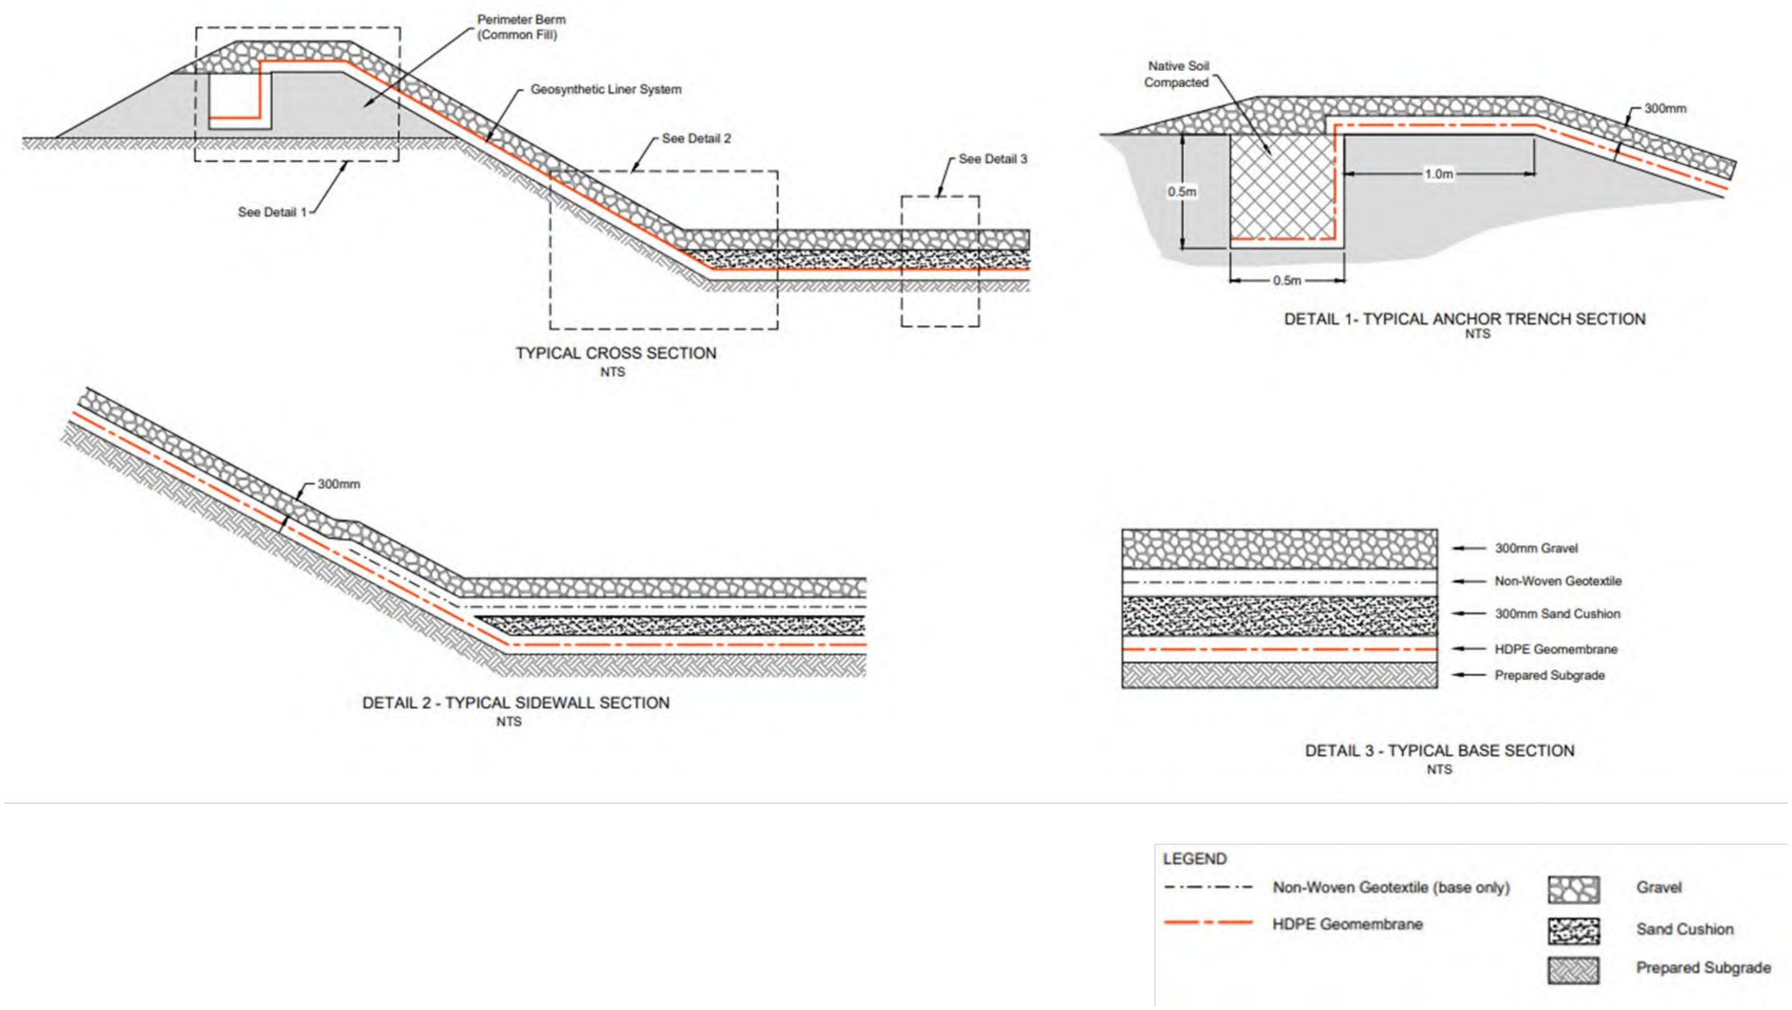

Figure 2.2-26: Single Geomembrane Liner Design Proposed for Clean Waste Rock Pad and Pond

2.2.5 Access and Transportation

2.2.5.1 Roads

Mainland access to the site will be from Highway 914. A 7-km section of road will be constructed from the highway to the Project site and a 5-km long road will also be constructed from the Project site to the airstrip (Figure 2.2-1); the total road length is 12 km. Additional site roads will include a service loop to the camp and a short service road to the runoff pond and the potential treated effluent discharge point. Many of the proposed roads will be developed along previously disturbed areas, including roads currently used for exploration activities, thereby minimizing terrestrial habitat disturbance.

Two water crossings will be installed along the road from the Project site to the airstrip. Access routes to the airstrip and proposed safeguards to support site safety were discussed in detail with ERFN (21-EN-ERFN-473.4) (21-EN-ERFN-473.7). The crossings will be designed, constructed, and maintained to avoid causing harm to fish and fish habitat and will be clear span bridges. The approximate locations of the proposed water crossings are provided in Figure 2.2-27.

During a meeting with ERFN, Denison provided a detailed discussion on the need for restrictions through the Project site for safety reasons, and where those proposed restrictions would be (i.e., gate houses). The locations of the north and south security gates are shown in Figure 2.2-1. Generally, ERFN agreed with the concepts of check points in key areas of safety concern, provided that Members could access areas that were not subject to the need for restrictions (21-EN-ERFN-473.4). Denison confirmed the importance of providing access to the greatest degree possible for ERFN and other Indigenous people, while respecting the need for safety for all in the area.

During engagement activities, comments and concerns were raised regarding access including for example:

> "*If the gate at Key Lake is removed or the road is redesigned to go around Key Lake allowing unimpeded access to the north, there would be lots of concerns about the increase in the number of people coming north into this area*" (19-LK-ERFNTrap-134.230).
>
> "*I am concerned with how Denison will access their mine on the same road as Cameco uses from the Key Lake mine to McArthur. Presently, Cameco has gates which restrict access to that section of road. If these gates are to be removed or altered by Denison so that everyone has access to the section of road between Key Lake and McArthur that would be disastrous to the region. The theft, vandalism and crime would increase astronomically and the region would lose its remoteness, tranquility and quality of fishing and a lot more*" (20-LK-LEASESUR-267.62).

The Project does not propose any changes to the current access to Highway 914 north of Cameco's Key Lake Operation gate.

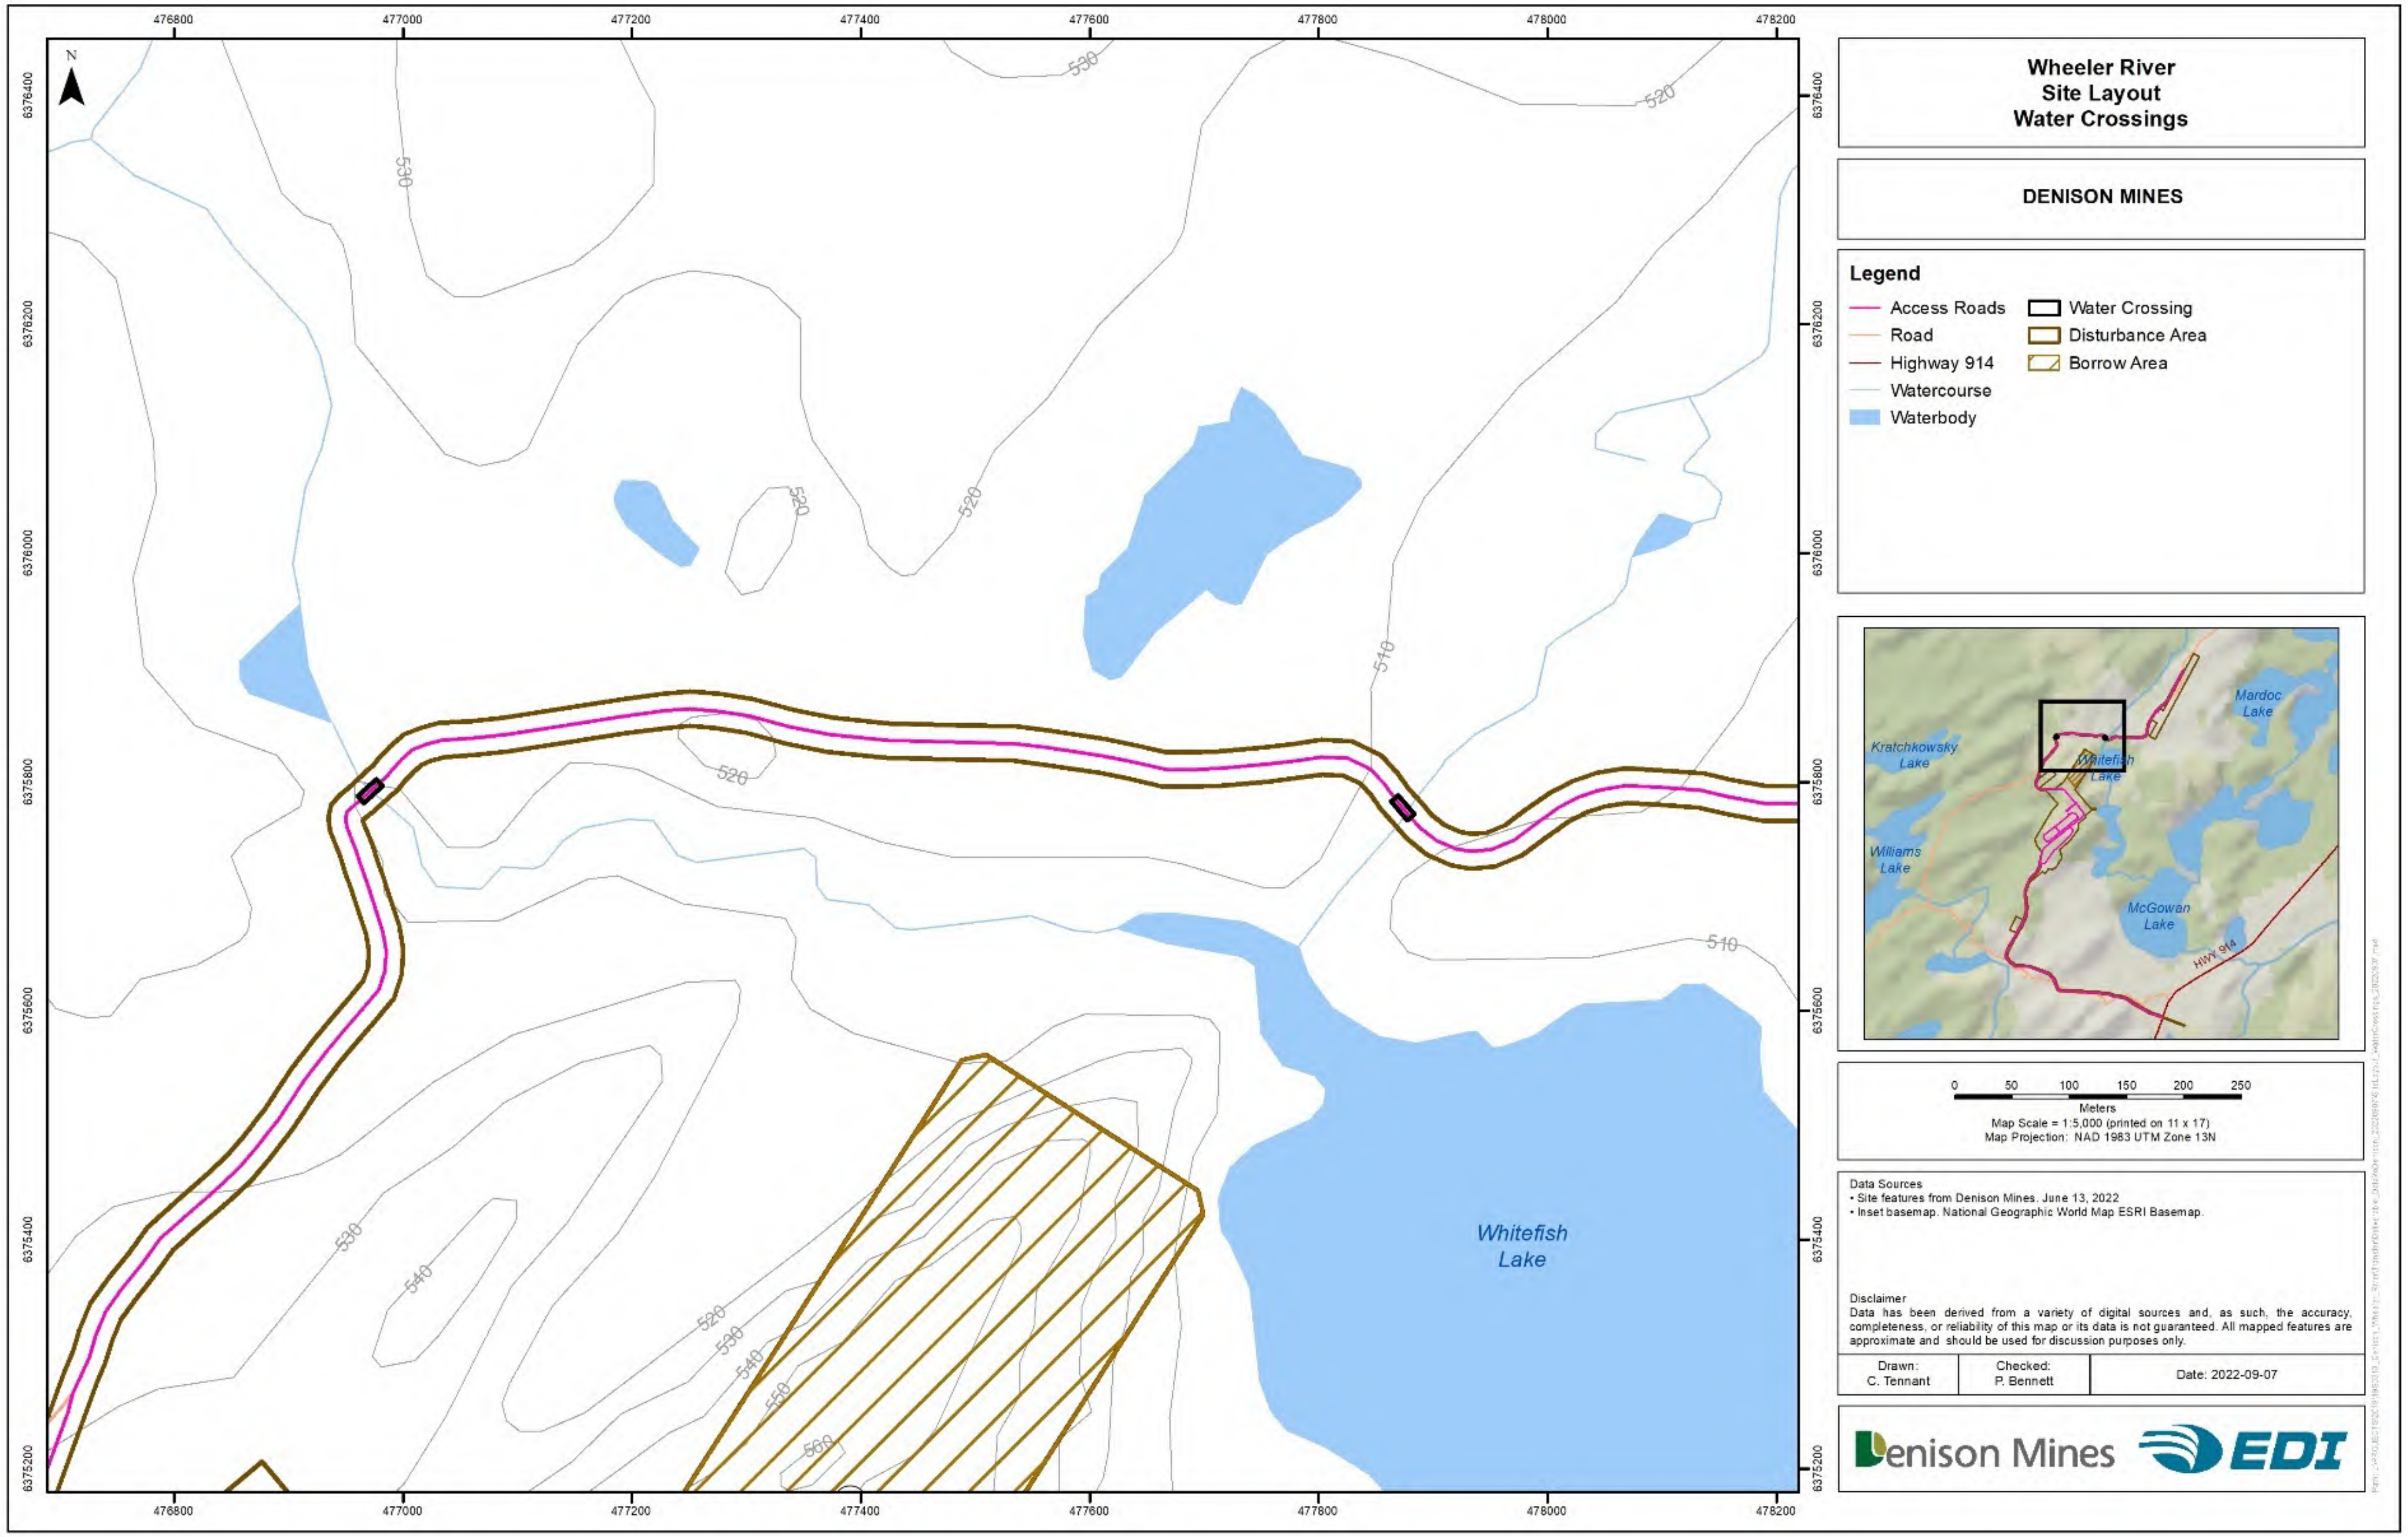

Figure 2.2-27: Water Crossings Associated with the Project

2.2.5.2 Traffic

Estimates of traffic are provided by Saskatchewan Ministry of Highways by road segments and are broken down by total traffic and truck traffic. Truck traffic, reported as Truck Annual Average Daily Traffic (TAADT), is a subset of all traffic, which is reported as Annual Average Daily Traffic (AADT).

An estimate of the Project-related traffic during Construction and Operation is available in Table 2.2-3 and details are provided in Appendix 2-B.

The Project-related traffic is associated with transportation of required supplies such as equipment, materials, reagents, food, and fuel.

Table 2.2-3: Estimated Project-related Traffic During Construction and Operation

Phase	Truck Annual Average Daily Traffic	Annual Average Daily Traffic
Construction	14	22
Operation	18	18

Note: These traffic volumes assume travel to site and return occur on the same day.

2.2.5.3 Air Strip and Terminal

The Project is proposed as a fly in-fly out operation. As such, the Project will require an airstrip to bring personnel to and from the site. A 1,600-m long airstrip is proposed to be positioned in a natural and relatively flat valley to the northeast of the Project site (Figure 2.2-1). The magnetic headings are 03/21. The runway has been designed to accommodate the aircraft presently used by existing mining operations in northern Saskatchewan to transport personnel into and out of site. The approach line to the airstrip from the southwest clears the Project surface facilities by 500 m.

An airstrip terminal building and two double-walled Jet A fuel tanks, to provide site service to aircraft as required, will be constructed near the airstrip. All fueling and de-icing activities will occur in specifically designed areas to collect any hydrocarbons and de-icing fluids. Collected waters will be characterized and brought to the Project site for treatment, shipped off site to an approved facility or released to environment if water quality allows. For the EA, a small diesel generator, to power the airstrip and terminal and provide terminal building services, communications, and runway lighting, was assessed. Bottled water will be supplied to the terminal. Domestic wastewater generated at the terminal will be collected in septic tanks and transported by a vacuum truck to the DWWTP.

2.2.5.4 Site Security

Road access to the property will be controlled by both a north and south security gate (Figure 2.2-1). The main, south gate will be located close to the operations centre and staffed as required. A weigh scale will be installed and will allow for verifying incoming and outgoing loads. The north gate is a simple gate and will not be staffed.

Hazardous areas will be fenced for the health and safety of the public.

2.2.6 Power

2.2.6.1 Primary Power Supply

Electrical service to the Project will be provided via an approximate 5-km extension tap from the existing 138 kV overhead transmission line that runs along Highway 914. Optimization of the precise line route will be completed as the Project advances and will likely follow the access road alignment.

Power transmission to the site (e.g., assessment, obtaining necessary permits, and construction) will be led by SaskPower and is not considered part of this Project (refer to Section 2.4).

An electrical substation will be built on site (Figure 2.2-1). Distribution will include a combination of overhead and underground lines. Site infrastructure anticipated to draw power from the provincial power grid includes the freeze plant, processing plant, industrial landfill, camp, and operations centre.

The airstrip and terminal will not be connected to the substation; a small diesel generator will be used to provide terminal building services, communications, and runway lighting.

2.2.6.2 Back-up Power Supply

Based on historical data provided by SaskPower, the outage rate of the existing line is approximately six outages per year. To provide electrical service during times of utility outages, diesel generators will be installed to service the site and maintain essential functions. The generators will be used to maintain power to the processing plant and the camp, as well as to maintain other essential services as required.

2.2.7 Support Facilities

2.2.7.1 Camp

Located southwest of the wellfield, the proposed camp or accommodations facility is anticipated to be a turnkey building manufactured off site and assembled and commissioned on site. The building’s design will be sized to accommodate a peak load of about 190 individuals during Operation; however, due to its modularized design, additional modules can be easily installed should additional beds be required in the future.

The camp will include a central services complex with:

- kitchen with food preparation area and serving area;
- dining room;
- camp office;
- commissary;
- recreation area; and

- exercise facilities.

The building will be heated with propane and connected to all utilities for potable water, electricity, and sewage management.

2.2.7.2 Operations Centre

The operations centre is planned to be a standalone, multi-functional building that will serve the administrative needs of the site.

The operations centre will have offices, meeting rooms, a boardroom, washrooms, lunchroom, small change areas (the main dries will be located in the processing plant), a nursing station with a waiting area, space for storing emergency response equipment and supplies, environment department storage area, and services rooms. Adequate parking will be available, including a dedicated area for emergency response vehicles.

2.2.7.3 Covered and Fenced Storage

Warehousing activities are planned to be completed inside a covered area, along with a fenced storage area, located east of the operations centre (Figure 2.2-1).

2.2.7.4 Wash Bay and Radiological Clearance Scanning Area

A wash bay will be available to clean items, equipment, and vehicles that may have been in contact with potential contaminants. The wash bay area will have an impermeable floor and a lined water collection sump. Rinse water from the wash bay sump will be routed to the wellfield runoff pond or directly to the process water pond. Items that are too large for the wash bay can be cleaned at the industrial landfill laydown area.

Radiological scanning will be located near the wash bay and will confirm clearance criteria are met for any items, equipment, or vehicles leaving the site.

2.2.7.5 Fire Water System

The on-site fire water system will include a 500 m^3 fire water tank, to meet National Fire Protection Association requirements. The fire water system location is shown in Figure 2.2-1 and will include two electric fire water pumps, and a back-up diesel fire water pump for on-site fire suppression needs.

2.2.7.6 Hazardous Substances Management for Support Facilities

Hazardous substances associated with support facilities include fuel, paint, used oil, and chemicals. These hazardous substances will be managed in a safe and secure manner in line with Safety Data Sheets, permit conditions, and applicable regulations such as the *Hazardous Substances and Waste Dangerous Goods Regulations*. Denison will maintain an up-to-date record of the various hazardous substances on site and will maintain Safety Data Sheets and appropriate procedures for spill management, handling, and clean up in an accessible location. Communities of Interest want assurance that appropriate emergency response plans (with specific focus on spill response) will be developed for the Project (18-EN-VILX-3.33) (21-EN-VPL-444.25). Denison will identify and reduce the potential for accidents and emergency situations, and implement emergency response plans that will protect the health and safety of its workers, contractors, the public and the environment.

Denison identified a need to have a small (250 m^2) pad designated for temporary storage of hazardous waste such as paints, solvents, hydrocarbons, and used oil. The temporary storage pad will have a composite liner system (Figure 2.2-24). Hazardous wastes will be taken off site by waste management service providers for proper recycling as soon as practical.

No fuels, oils, or other hazardous substances will be stored within 100 m of any water body. No equipment maintenance or re-fuelling will be conducted within 100 m of a water body.

2.2.7.6.1 Fuel Storage and Dispensing Facility

Because the site's primary power supply will be the provincial electrical grid, fuel consumption at the Project may be limited to diesel for mud rotary and diamond drill rigs, fuel for auxiliary vehicles (i.e., all-terrain vehicles [ATVs] and snowmobiles), miscellaneous equipment (i.e., portable pumps), back-up power supply, and freight and personnel transportation to site. This will reduce Project fuel consumption and minimize direct greenhouse gas emissions.

Jet A fuel for airplanes will be stored in tanks at the airstrip and managed by Denison, although the dispensing is the responsibility of the air carrier. Emissions associated with use of Jet A fuel are not included in the air dispersion model for the Project and the emissions are considered Scope 3 for Denison.

Tanker trucks will deliver diesel, gasoline, and Jet A fuel to the site on an as-needed basis. Fuels will be stored in approved, above-ground, 25,000 L double-walled storage tank(s) equipped with secondary containment in accordance with provincial regulations and standards. Fuel storage and distribution infrastructure will be constructed and operated in accordance with applicable legislation requirements (e.g., *Hazardous Substances and Waste Dangerous Goods Regulations*). Stationary equipment will be fuelled with a fuel-dispensing truck.

The anticipated greenhouse gas emissions associated with the Project are included in Section 2.5.

2.2.7.6.2 Propane Storage Areas

Propane may be used as a primary or back-up means to support the calciner or dryer, mining solution heating, comfort heat for buildings, and camp kitchen.

The propane storage will be sized to meet the needs of the site activities and will feature a storage tank (assumed to be 30,000 Unites States water gallons [uswg]), vaporizers, a propane bottle fill station, and a propane bottle weigh station. Propane will be delivered to site on an as-needed basis. The anticipated greenhouse gas emissions for this Project component are included in Section 2.5.

2.2.7.6.3 Other Hazardous Substances

Chemicals required for water treatment, ISR mining, and processing constitute the ‘other’ hazardous substances anticipated for use at the Project.

Sulfuric acid, iron sulphate, hydrogen peroxide, magnesium hydroxide, barium chloride, calcium hydroxide (lime), sodium hydroxide, and flocculant are the main chemicals anticipated to be used in mining, processing, and water treatment (Table 2.2-4). Bulk storage tanks for these chemicals will be located inside the processing plant, in a separate room from the processing equipment. The storage tanks will sit inside appropriately designed and sized concrete secondary containment basins. The secondary containment basin for each applicable chemical system will be physically separated from the containment basins for other chemical systems.

The various lubricants and coolants required for regular maintenance of equipment will be stored on site in the maintenance shop and processing plant. Each one of these materials will be stored, handled, recycled or disposed of in an appropriate manner and meet the requirements of the *Hazardous Substances and Waste Dangerous Goods Regulations*.

Table 2.2-4: Planned Chemical Use for the Project

Chemical	Planned Use at the Project						Dedicated Storage Tank Within Processing Plant
	Mining Solution	Processing		Industrial and Domestic Water Treatment (Operation and Decommissioning)	Remediation Solution (Decommissioning)	Freeze Plant	
		Stage 1 Precipitation	Stage 2 Precipitation				
Ammonia						✓	
Barium chloride		✓		✓			✓
Flocculant		✓	✓	✓			✓
Hydrogen peroxide	✓	✓	✓				✓
Iron sulphate	✓			✓			✓
Lime (calcium hydroxide)		✓		✓			✓
Magnesium hydroxide			✓				✓
Sodium bicarbonate					✓		
Sodium hydroxide		✓			✓		✓
Sulphuric acid	✓			✓			✓
Zero valent iron				✓			

2.2.7.7 Borrow Area

A borrow area is planned for an area northeast of the processing plant. The borrow material or overburden will be used in Construction for roads, airstrip, and pads. The borrow material will also be used in the batch plant for concrete production needs (e.g., foundations) during Construction. Borrow material may be needed during Operation for ongoing maintenance of various Project components. During Decommissioning, borrow material will be needed for fill and cover material.

2.2.8 Project Area

The total footprint of Project components (infrastructure footprint) is anticipated to be 74.8 ha. By applying a buffer around these components, the maximum footprint of the Project was estimated to be 169.6 ha (Figure 2.2-28). This spatial area with the buffer is referred to as the Project Area in the biophysical and human environment assessments of the EIS. The decision to assume a larger area of disturbance than is anticipated contributes to Denison's goal to have a conservative assessment basis in the EA.

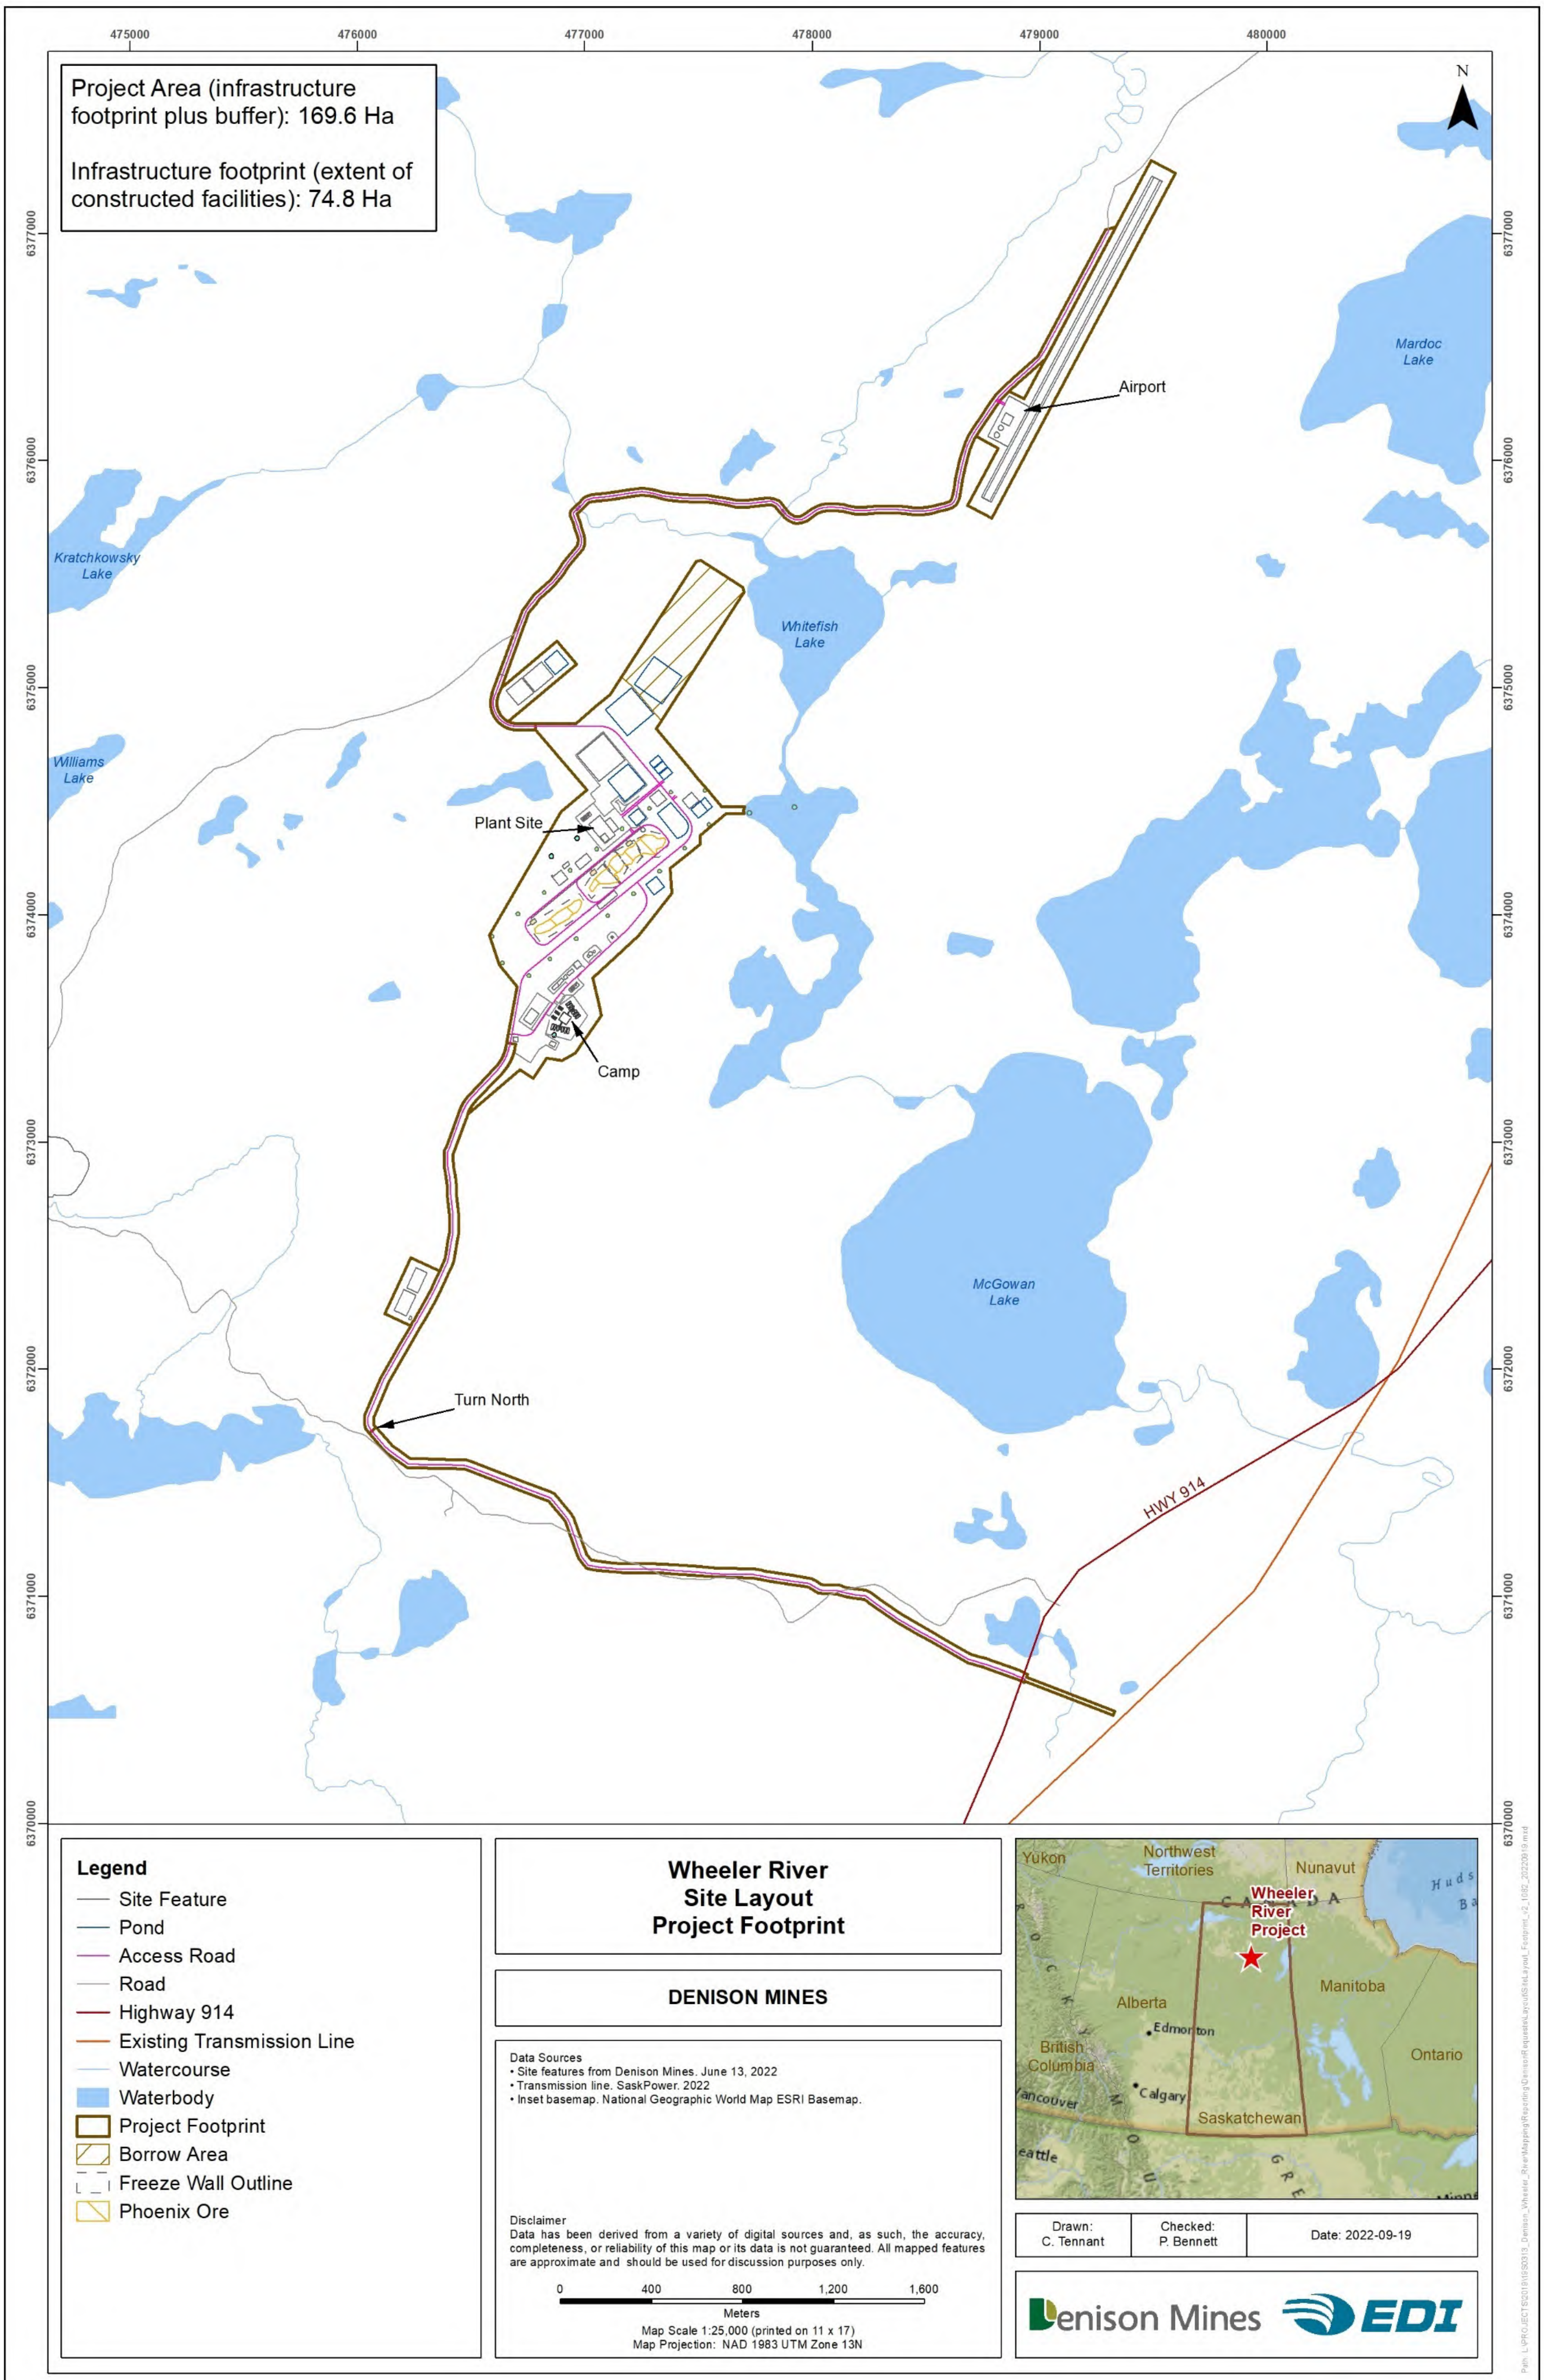

Figure 2.2-28: Project Area

2.3 Project Activities

A summary of the anticipated key activities for Construction, Operation, Decommissioning and Post-Decommissioning of the Project are provided in Table 2.3-1.

Table 2.3-1: Key Activities for the Wheeler River Project

Phase and Year	Description of Activities	
Construction Year 1 to 3	• Development of access roads and air strip • Site preparation and earthworks; clearing, leveling and grading of the Project Area. • Power generation – generators • Installation of main substation and distribution of power around site • Wellfield and freeze hole drilling; ground freezing • Batch plant operation (concrete); crusher at borrow area • Development of surface infrastructure (camp, operations centre, plants, ponds, pads and support facilities) • Waste management (composting, domestic and industrial landfill operation, recycling)	• Water management (including treatment and site run-off) • Groundwater supply • Surface water withdrawal • Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel) • On-site and off-site operation of vehicles and transport of materials • Air transportation for workers • Regulatory site inspections • Engagement - site visit from Interested Parties • Employment and expenditures
Operation Year 3 to 18	• Operation of the ISR wellfield • Wellfield and freeze wall drilling • Operation and expansion of freeze wall • Batch plant operation (grout and cement); crusher at borrow area • Expansion of pond and pads • Operation of the processing plant and production of uranium concentrate • Water withdrawal from groundwater or surface water body • Management of surface water (including seepage and site run-off) • Water treatment, both domestic and industrial • Water release to surface water body • Waste management (composting, domestic and industrial landfill operation, recycling) • Hazardous waste management (temporary storage, handling, and off-site transportation)	• Storage and disposal of drill waste rock, process precipitates and industrial wastewater treatment plant precipitates • On-site and off-site operation of vehicles and transport of materials • Power supply – primarily power from the grid, also generators and back-up generators • Package and transport of nuclear substances • Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel) • Air transportation for workers • Progressive decommissioning and reclamation • Regulatory site inspections • Engagement - site visit from Interested Parties • Employment and expenditures
Decommissioning Year 18 to 23	• Site water management, treatment and release • Mining area remediation and thawing of freeze wall	• Power generation – generators • Waste management (composting and landfill operation)

Phase and Year	Description of Activities	
	• Process water treatment and release • Closure of ISR and freeze wells and related infrastructure • Decontamination of surface facilities and injection, recovery and monitoring wells • Asset removal (including site power transmission lines and electrical infrastructure) • Demolition and disposal of non-salvageable surface infrastructure and materials • Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and processing plant area)	• Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal) • On-site and off-site operation of vehicles and transport of materials • Reclamation of disturbed areas • Regulatory site inspections • Engagement - site visit from Interested Parties • Employment and expenditures
Post-Decommissioning Year 23 to 38	• Environmental monitoring • Regulatory site inspections	• Engagement - site visit from Interested Parties • Employment and expenditures

2.3.1 Construction

Construction activities will follow industry best management practices to minimize effects of the Project on the environment and keep risks to workers as low as reasonably achievable.

The sequence for Construction activities will occur in a logical manner based on Project execution plans. As one example, Denison will prioritize bringing power into the site, allowing the freeze plant operation to start early in the construction process and the Phase 1 freeze wall can be established.

2.3.1.1 Pre-Construction Activities

2.3.1.1.1 Mineral Surface Lease Agreement

Before constructing any permanent surface facilities, Denison must obtain a mineral surface lease agreement. A mineral surface lease agreement is the legal authorization for a mining company to occupy Crown land. Surface leases are coordinated through the Ministry of Government Relations, Northern Engagement Branch and the Saskatchewan Ministry of Environment (SK MOE), Lands Branch, with input from other ministries or branches as required. Issuance of a surface lease agreement is tied to the successful outcome of the provincial EA process.

2.3.1.1.2 Licensing and Permitting

Denison will require various licences and permits prior to initiating construction. This includes, but is not limited to, a licence to prepare site and construct from the CNSC, an approval to construct a pollutant control facility from SK MOE, and permit to construct a facility to handle hazardous substances or waste dangerous goods from SK MOE.

2.3.1.1.3 Pre-Clearance Surveys

Prior to commencing any site clearing during the nesting season, bird nest surveys will be conducted. Should the Project footprint change, additional surveys may be required for rare plants and/or heritage resources.

A baseline radiological scan of the Project footprint will be conducted to provide a benchmark for future remediation efforts.

2.3.1.2 Construction Camp

During early stages of Construction, the existing Project exploration camp will be used by Denison staff and contractors. Additional, temporary sleeper units may be brought to the camp area, as required. Installation of the new permanent camp will be prioritized in the construction sequence to add capacity. Domestic wastewater generated at the new camp will have to disposed of off site using a vacuum truck, until the permanent infrastructure, including the DWWTP, is online.

2.3.1.3 Site Preparation and Earthworks

Site clearing and other works that involve disturbance of vegetation and/or soil will be conducted outside of the nesting season, whenever practicable. The Heritage Resources Management Plan (Appendix 11-B in Section 11) will be followed should any archeological sites be discovered.

Clearing and leveling of the surface facilities will be contracted out to a suitable contractor. Topsoil and brush will be stockpiled on site for future use during reclamation; the location of the topsoil stockpile will be determined closer to Construction.

Construction of foundations and general earthworks will be required for various Project components. Construction of roads, foundations, pads, ponds, and the airstrip will be initiated during site preparation. Suitable construction fill material will be sourced from a proposed borrow area and any suitable clean sandstone generated during freeze wall and well drilling (Section 2.2.7.7). It is estimated that 11,000 m^3 of subgrade fill will be needed.

Temporary security checkpoints will be established early in the site preparation phase.

Construction activities are expected to be completed without the use of explosives for blasting.

2.3.1.4 Wellfield

Denison has been drilling on the property since 2004; this experience and knowledge will be applied to the drilling of the freeze and wellfield holes. Suitably qualified and experienced contractors will be overseen by Denison personnel to complete drilling activities.

Ground freezing requires the establishment of a pattern of freeze wells, refrigeration units, and corresponding electrical and mechanical services. Freeze well drilling, using diamond drilling methods, will be initiated as early as possible. The freeze plant chiller units will arrive at site and be physically installed and used when the appropriate tie-ins to the site power distribution system are complete.

Holes for wellfield injection and recovery wells may be drilled using techniques described in Section 2.2.1.2 and well installation will proceed as described in Section 2.2.1.4.

Pump tests will be completed in the wellfield as part of wellfield commissioning to confirm the hydraulic connectivity in the mining area.

2.3.1.5 Processing Plant

While the processing plant is likely the most complex construction activity for the Project, it is relatively simple when compared to other full-service uranium mills, as there are a limited number of vessels and minimal piping. Most of the equipment and materials inside the plant are small in size, enabling the shipment of tanks and other vessels pre-assembled, with current engineering activities focusing on modularization. Processing plant construction will begin immediately following earthworks at the site. After foundations are completed, building construction can begin.

A short commissioning period for the processing plant begins post-construction, prior to first uranium production and receipt of operating licences and permits.

2.3.1.6 Water Management

Construction, installation, and commissioning of the water management components, described in Section 2.2.3, will proceed in a logical sequence. This includes components for groundwater and/or surface water withdrawal, treated effluent release, various ponds, the potable WTP, the DWWTP, the IWWTP in the processing plant, and piping between facilities.

For surface water withdrawal and treated effluent release to Whitefish Lake the works proposed in and around water will be conducted to avoid fish habitat, be of short duration, of a small spatial scale, and constructable during appropriate timing windows.

Water management of runoff during Construction will follow industry best management practices for erosion control.

2.3.1.7 Waste Management

Construction of various waste management Project components (e.g., ponds, pads, landfills) required for operations, as outlined in Section 2.2.4, will be completed.

Waste generated during Construction will be recycled off site to the extent possible. Any remaining wastes will be temporarily piled or stored in laydown areas and placed in the appropriate landfill once construction of the landfills are complete.

2.3.1.8 Access and Transportation

Construction of the site roads will proceed in a logical fashion, with the initial priority on completing the access road connection to Highway 914. Following construction of the main access road corridor, the remaining site roads and the airstrip will be constructed. This includes installation of two stream crossings. Information received from several engagement meetings with local communities informed the selection of the proposed access road alignment (21-EN-YOUTH-445.11).

Transportation of staff and deliveries of supplies to the Project will be ongoing throughout Construction. Transportation will be by ground until the airstrip and terminal are completed.

2.3.1.9 Power

Until electrical power is available, power for Construction activities will be from diesel generators.

The main substation will be installed early in the Construction phase. A powerline will be constructed from the existing provincial power line adjacent to Highway 914 into the new substation; this will be completed by SaskPower. Overhead and underground distribution lines around site will be installed as required to provide electricity for Project needs.

Diesel generators needed for primary and back-up power during Operation will also be installed during Construction.

2.3.1.10 Support Facilities

Other surface infrastructure including the camp, operations centre, the airstrip terminal building will be constructed. With the exception of the operations centre and processing plant, all buildings are expected to be pre-fabricated buildings to reduce costs and simplify construction activities.

The operations centre is planned to be completed ahead of commissioning. This will allow the operations team to conduct activities in a suitable building. The camp is to be completed in a similar time frame, along with basic services, such as communications and fire systems.

A batch plant will be used during Construction to create concrete. Concrete will be required for construction of foundations and containment walls in select surface infrastructure.

2.3.1.11 Commissioning

Commissioning of the Project facilities is expected to be supported by engineering and/or supply vendors, along with the assistance of the construction team. This will help to make sure the constructed facilities adhere to the designs and specifications set forth.

2.3.1.12 Construction Management

Project and construction management during the capital development phase of the Project will be managed by a small, dedicated Project management team. During Construction, Denison will provide general and administrative services to operate the site and support the contractors (e.g., room and board, flights, general supplies, freight haulage). It is expected that a mix of employees, contractors, and engineering service providers will support site construction efforts.

2.3.2 Operation

Operation of the Project is planned to last up to 15 years. Denison anticipates operating the site with mine employees and a limited number of external contractors. Denison will require a licence to operate from the CNSC and an approval to operate a pollutant control facility from SK MOE.

The Operation phase is generally focused on operating the Project components that were presented in Section 2.2. As such, the operational activities for the Project include, but are not limited to:

- operation of the ISR wellfield;
- wellfield drilling as the mining phases advance;
- operation and expansion of the freeze wall as the mining phases advance;
- operation of the processing plant and production of uranium concentrate at an average production rate of 9 Mlbs U_3O_8/year and a peak production rate of up to 12 Mlbs U_3O_8/year;
- water management, including management of seepage and site-runoff, freshwater withdrawal, potable water treatment and distribution, domestic and industrial wastewater treatment, managing contact water, effluent monitoring, and discharge of tested water to a Whitefish Lake that meets discharge limits;
- waste management, including management of organic waste, recyclables, domestic and industrial landfills, hazardous wastes, mining wastes, and processing wastes;
- maintenance activities at the wellfield, processing plant, roads, airstrip, and other support facilities;
- environmental monitoring as outlined in the Environmental Management System;
- package and transport of nuclear substances;
- reporting to regulators;
- engagement with local Indigenous and non-Indigenous communities; and
- systems for maintaining site security.

2.3.2.1 Mine Plan

Denison is proposing a five-phase approach to mining at the Project (Figure 2.3-1). Each phase is intended to target a specific area of the deposit and reduces the upfront capital expenditure requirements and initial ground freezing requirements. Development of the freeze wall is also planned to occur in phases, with a limited initial freeze wall, and new mining phases brought on throughout the mine life by expanding the extent of the freeze wall. The freeze wall will be used to partition off each mining phase. The frozen cross walls (see isometric view in Figure 2.3-1) may be thawed as the freeze wall expands to accommodate subsequent phases. The outer freeze wall will remain in place until mining is complete and through to Decommissioning until remediation is completed. The plan, longitudinal, and isometric views of the five mine phases and the proposed freeze wall are shown in Figure 2.3-1.

Mine sequencing and scheduling is based on confidence levels of potentially mineable resources based on a number of factors including geology, hydrogeology, and mineral resources. Table 2.3-2 below illustrates a conceptual mine plan based on mining phases with larger reserves allocated to earlier phases. As noted in Section 2.2.1.1, Denison has bound the EA above the deposit indicated resources to provide operational flexibility from one year to the next and appropriately bound the assessment of effects.

Table 2.3-2: Conceptual Mine Plan for the Project

Mine Phase	Production (Mlbs)

2.3.3 Decommissioning

This subsection outlines a conceptual decommissioning plan (CDP) to support the EA for the Project. Denison's decommissioning commitment is to return the land back to the Province of Saskatchewan for unrestricted surface land use post-closure. The CDP outlines how radiological, physical, and chemical risks will be managed during Decommissioning so no unreasonable risks remain. Denison will prioritize passive versus active controls to reduce long-term risk.

Additional decommissioning details will be provided in the preliminary decommissioning plan (PDP), which will submitted to regulators as part of Project licensing and permitting. The PDP will be prepared considering provincial, federal, and international documents relevant to decommissioning and reclamation. Examples of key reference documents for development of the PDP are CNSC's REGDOC-2.11.2, Decommissioning (CNSC 2021a) and the SK MOE's Northern Mine Decommissioning and Reclamation Guideline (SK MOE 2008). The PDP will include an associated estimate for the decommissioning costs and Denison will provide financial assurance to confirm the identified decommissioning activities can be completed as planned.

Prior to executing Decommissioning activities, Denison shall prepare and submit a detailed decommissioning plan (DDP) to regulators for acceptance, which builds on the preliminary decommissioning plan.

Broadly, the CDP outlines physical decommissioning activities, followed by reclamation. Decommissioning is expected to take approximately 5 years.

The three main physical decommissioning activities include:

- mining area remediation;
- asset removal; and
- decontamination, demolition, and disposal.

Physical decommissioning activities are followed by reclamation.

Progressive decommissioning and reclamation will be completed throughout the life of the Project, whenever feasible, and reported to the regulatory agencies as part of the annual reporting requirements throughout Operation. Progressive decommissioning activities will focus on the decontamination, demolition, and disposal of unused buildings and infrastructure, as well as the removal of unused equipment and machinery. Reclamation of inactive areas will take place when these areas become available.

Closure of the entire Project will be completed in accordance with provincial and federal regulations and guidance documents with the fundamental considerations being to confirm physical and chemical stability of the site to protect human health and the environment. The importance of successful decommissioning was raised frequently in engagement activities, including for example:

> *Who is responsible for restoring the environment?* (21-EN-ERFN-447.33)
>
> *Who is responsible for cleaning up contaminants?* (21-EN-ERFN-447.34)
>
> *What happens if the environment gets contaminated? How can you restore it to its original state?* (21-EN-ERFN-447.35)

2.3.3.1 Physical Decommissioning

2.3.3.1.1 Mining Area Remediation

The objective of mining area remediation is to restore the groundwater within the confines of the freeze wall to reach an acceptable remediation target, prior to turning off the freeze wall.

As discussed in Section 2.2.1.4, during Operation, mining solutions will be contained within the mining area that has been defined as inside the freeze walls and up to 50 m vertically from the ore zone. This will be confirmed during Operation by a robust groundwater monitoring network comprised of numerous wells located at various vertical depth horizons above the ore zone (both within and outside of the freeze walls).

Remediation of the mining area will involve injecting water into the mining area via injection wells and recovering groundwater through the recovery wells, similar to how mining was conducted during Operation. Reagents such as sodium bicarbonate and sodium hydroxide (Table 2.2-4) may be added to the injected water to accelerate groundwater quality recovery. Produced water will be processed through the processing plant until non-economic uranium concentrations are observed. Non-economic produced waters will be treated and mixed with fresh water for continued circulation in the mining area. Water treatment and treated effluent discharge release will continue during the Decommissioning phase (Figure 2.2-16). Information obtained during Operation from the wellfield, such as flow rates, will inform the remediation plans and rates.

Mining area remediation will continue until recovered water reaches and is demonstrated to be stabilized (maintained) at acceptable mining area decommissioning objectives (Table 2.3-3). Meeting the acceptable mining area decommissioning objectives will be based on statistically demonstrating that the water quality meets acceptable target values with associated levels of uncertainty (i.e., central tendency and 95% confidence intervals) and is stable over sufficient time for there to be confidence that conditions will not change.

The mining area decommissioning objectives have been developed through groundwater modelling work and are achievable based on metallurgical testing. Metallurgical testing, including column tests and core flooding tests, have been undertaken at SRC to understand the anticipated evolution of groundwater hydrochemistry as groundwater quality in the mining is restored. Numerical groundwater modelling was applied to evaluate the fate and transport of the groundwater in the remediated mining area (see Section 9 and Section 10). Groundwater flow and geochemical reactive transport modelling were applied to help understand the migration and attenuation of remediated groundwater from the mining area toward Whitefish Lake, the primary surface water receptor. Refinement of the mining area decommissioning objectives will continue as the Project progresses. The final acceptable mining area decommissioning objectives will be developed prior to initiation of groundwater remediation, as part of the DDP.

Once the mining area decommissioning objectives have been met, the perimeter freeze wall will be turned off and allowed to thaw. This will allow the eventual re-establishment of the pre-operational groundwater flow regime in the former mining area.

Table 2.3-3: Mining Area Decommissioning Objectives

Parameter	Units	Restored Solution
pH		4.3
Aluminum	mg/L	7
Arsenic	mg/L	0.06
Cadmium	mg/L	0.015
Cobalt	mg/L	2
Chromium	mg/L	0.05
Copper	mg/L	0.17
Iron	mg/L	100
Molybdenum	mg/L	0.1
Nickel	mg/L	9.7
Lead	mg/L	3.1
Sulphate	mg/L	703
Selenium	mg/L	0.08
Zinc	mg/L	1.4
Uranium	mg/L	100
Vanadium	mg/L	0.51
^{226}Radium	Bq/L	2.00E+02

2.3.3.1.2 Asset Removal

Salvageable machinery, equipment, and other materials at the Project site will be dismantled, decontaminated, and taken off site for resale or recycling. Remaining items will either be managed at a facility licenced to manage radioactive wastes or disposed of in the industrial landfill.

Process precipitates temporarily stored at the process precipitate pond during Operation will be transported off site to an approved facility for reprocessing and permanent disposal.

Any mineralized core or drill cuttings remaining on the special waste pad at Decommissioning will be trucked off site to an approved facility for reprocessing and permanent disposal.

2.3.3.1.3 Decontamination, Demolition, and Disposal

Surface facilities, together with injection, recovery, and monitoring wells, will be systematically surveyed and decontaminated as necessary. Decontamination can include cleaning via dry blasting, sand blasting, and/or high pressure washing. Surplus chemicals and other hazardous materials will be removed and stored in designated temporary storage facilities. Sumps will be cleaned. Hazardous materials will be disposed of at approved off-site facilities. Radiologically contaminated material will be disposed of on site in accordance with licence conditions.

Empty tanks will be removed from the sites and sold as scrap or reused. Otherwise, they will be transported to an approved waste management facility. Fuel tanks will be managed by a contractor licenced to handle these types of tanks. Any remaining fuel and tanks will be removed by the contractor from the site. Any waste hauled off site will be disposed of at appropriate licenced facilities.

Permanent structures that remain after asset removal will require demolition. Most process equipment and non-supporting structures will be removed from buildings prior to demolition and the buildings will be demolished.

During demolition, an initial wash of the structures to be demolished will be required along with dust control using water. The requirement and duration of misting will be determined on a case-by-case basis.

A review prior to the start of demolition will identify areas requiring additional procedures. Where possible, dust generating materials will be removed prior to demolition. Appropriate personal protective equipment and personnel decontamination procedures will be employed.

Valuable recyclable materials will be separated and processed for transport and sale concurrent with demolition. Excavators equipped with grapples will sort the recyclable products from the non-recyclables. Shears will be used to size recyclables for shipping and sale. Cleaning procedures of recyclables will be integrated into demolition, as necessary.

Concrete foundations will be left in place. Any portions of concrete foundations remaining above grade will be levelled and rebar will be cut-off at grade. Large slabs will be perforated on a 2-m grid to permit drainage. Concrete slabs will be covered with 0.5 m of development rock or locally stockpiled till.

The demolition process will produce:

- saleable recyclable materials (e.g., steel, stainless steel, copper, steel sections, and sheet metal);
- hazardous materials, including contaminated material that cannot be decontaminated;

- roofing materials and insulation;
- wood;
- concrete; and
- contaminated soils.

Saleable recyclable materials will also be transported off site as scrap or recycled.

Hazardous materials will be handled and disposed of in accordance with the appropriate regulations and good practice. Where possible, chemicals will be mixed to produce a neutral solution and disposed of in an approved manner at site. Hazardous materials, such as spent chemicals (that cannot be managed on site), waste oil, and sludges, will be disposed of off site at licenced facilities.

Non-hazardous waste materials, such as roofing materials, insulation, wood, co-mingled concrete, and light steel (i.e., hand railings), may be disposed of on site or off site in a licensed landfill. Soil testing will be conducted in any areas of known contamination and/or potential spills, including areas around chemical, fuel, and explosive storage areas. Testing will be conducted according to industry standard procedures and compared to provincial and federal soil standards.

Closure of the ISR wellfield and associated infrastructure will require the following activities:

- decommissioning of all injection and recovery wells: a plug will be placed at the base of the casing to provide containment from the bottom of the well. The lower 50 m within the casing will be grouted with a bentonite clay-cement blend and further capped at this level with an additional plug. The well casings will be cut off about 1 m below the current ground surface and a cement–grout plug will be placed immediately over top of the casing near surface to inhibit water flow down the outside of the casing. The ground surface will then be built up by about 0.5 m with a combination of low permeability material and/or local fill amended with 5% bentonite to reduce hydraulic conductivity. These mounds will be graded away from each former well, to make sure no standing water accumulates immediately above the casings. Wellheads will also be removed as part of the decommissioning process prior to abandonment.
- removal, decontamination, and disposal of all surface piping;
- decontamination and removal of the pumphouses;
- decontamination, removal, and/or disposal of the processing plant;
- thawing of the freeze wall and decommissioning of all freeze pipes and the freeze plant. The freeze holes will be decommissioned in the same manner as the ISR wellfield injection and recovery wells. The freeze pipes, which will be located inside the freeze holes, will simply be unthreaded and removed from site after the freeze wall is no longer required; and
- placement of waste in the industrial landfill or an off-site licensed facility.

Demolition and disposal of remaining infrastructure components involves the decommissioning and removal of components such as power transmission lines and electrical infrastructure, water pipelines, and water treatment plants. Ponds will be decommissioned once they are no longer required for water management. Any contaminated liners will be removed and hauled to an approved landfill or disposed of in the industrial landfill.

The industrial landfill will have an engineered impermeable cover installed to limit water infiltration into the industrial wastes. Similarly, the material in the IWWTP precipitate pond will be covered and decommissioned in place. The industrial landfill will be designed to have two HDPE geomembrane liner over two Geosynthetic Clay Liner and the IWWTP precipitate pond will be designed to have a single HDPE geomembrane liner over a Geosynthetic Clay Liner. A single liner system is expected to remain in place for over 400 years (Koerner et al. 2011). Further reducing the potential for groundwater movement through the liner, the industrial landfill and IWWTP will be installed several meters above the water table. The physical location of the industrial landfill and IWWTP precipitate pond along with the impermeable cover and liner design will reduce the likelihood of any infiltration post decommissioning.

2.3.3.2 Reclamation

Once the asset removal, decontamination, demolition, and disposal are completed, and the site has been cleared and leveled, reclamation activities, including replanting, will take place. Currently this would largely be jack pines, but the mix of plants will depend on location and available species. This reclamation will be monitored for a period until it is deemed self-sustaining and viable wildlife habitat.

Future discussions will be held with Indigenous and general public Interested Parties to determine the amount of access to the area they wish to maintain in the future (post-decommissioning). Based on results of these discussions, transportation corridors associated with the Project site that are no longer needed will be graded and scarified to promote natural revegetation. Access roads or trails required for post-closure monitoring or deemed useful by Interested Parties may be left to facilitate continued access. Access to the site may be restricted by gates and/or berms.

Laydown areas will be scarified, covered with 0.5 to 1.0 m of stockpiled overburden, and vegetated with native, self-sustaining species. The footprints of other infrastructure, such as the camp, will be scarified and vegetated with native, self-sustaining species as required. The topsoil and brush stockpiled during pre-construction activities will be used during reclamation.

Lessons learned from progressive decommissioning and any site-specific reclamation studies will be incorporated into the detailed reclamation design. Additionally, information from other northern Saskatchewan mine sites will be examined to help Denison select the reclamation tools, including revegetation options, that will contribute towards decommissioning success.

2.3.4 Post-Decommissioning

Post-Decommissioning extends from the end of physical decommissioning until transfer of the site into the provincial Institutional Control Program (Government of Saskatchewan 2009) or direct release of the land back to the Crown. This phase of the Project is expected to last fifteen years.

Following Decommissioning, physical, chemical, and biological monitoring of the site will be conducted to confirm that the site is chemically and physically stable. The importance of this phase of the Project is clear based on questions and comments from engagement activities, such as o*nce the mine is closed how will the community know that the environment is restored*? (21-EN-ERFN-447.36) and *is the environment monitored after the closure of the mine? Who monitors it?* (21-EN-VILX-443.17). The Post-Decommissioning monitoring program will be designed and conducted in accordance with the provincial and federal regulations and licence conditions. The monitoring program will be conducted until the site-specific decommissioning and reclamation objectives for the Project are met. Monitoring reports will be developed and submitted to both the provincial and federal regulators, in accordance with licence conditions.

2.4 Ancillary Projects

SaskPower proposes to tap the existing I3P 138 kV line near Highway 914 and build approximately 4.5 km of new 138 kV line from the I3P tap to the Project site. SaskPower will be responsible for conducting activities such as line routing, environmental studies, and permitting, public consultation, and engineering design work as applicable to the load interconnection.

2.5 Greenhouse Gas Emissions

The Government of Canada requires that greenhouse gas (GHG) emissions be assessed in support of any project seeking federal approval. Concerns related to climate change were raised during engagement and consultation activities completed by Denison. It should be noted that these concerns pertain to climate change rather than GHG emissions specifically, although these are closely related topics. The concerns included observations of climate-related changes that have been noticed by the English River First Nation (e.g., depth of permafrost; 16-EN-ERFN-100.17) and observations by the English River First Nation Trapper who provided local knowledge in support of the EIS (19-LK-ERFNTrap-134.232 to 19-LK-ERFNTrap-134.235). In addition, the Village of Pinehouse Lake posed questions regarding the potential effects of the Project on climate change (21-EN-VPL-444-4 and 21-EN-VPL-444.18).

Environment and Climate Change Canada (ECCC) has developed the *Strategic Assessment of Climate Change* (SACC) report (ECCC 2020) to assist proponents in developing GHG emissions estimates in a consistent manner. The SACC report defines the information that must be submitted, including quantification of direct GHG emissions (e.g., combustion sources) and GHG emissions from acquired energy (e.g., energy purchased from a third party such as provincial hydro providers). To assist in the quantification of GHG emissions, and to provide consistency across all projects, ECCC has developed the *Draft Technical Guide Related to the Strategic Assessment of Climate Change* (SACC guide; ECCC 2021a). The SACC guide was applied in the quantification of GHG emissions for the Project in this assessment.

The GHGs that are included in emissions reporting include carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O), which are reported on an annual basis. The SACC guide identifies the *National Inventory Report* (NIR; ECCC 2021b) as the primary source of emission factors that are to be used in the calculation of these releases, based on fuel consumption for combustion sources. Combustion sources are the main source of direct GHG emissions anticipated at the Project, with a minor contribution from the loss of a carbon sink associated with the development of the Project Area during the first year of Construction. In addition to direct emissions, ECCC requires that emissions associated with the generation of electricity required to power the Project also be accounted for in the emissions inventory, where the emissions are being generated by a third party (i.e., provincial provider such as SaskPower). Emission factors for this calculation are provided in the SACC guide (ECCC 2021a).

In addition to individual reporting of GHGs (i.e., CO_2, N_2O, and CH_4), emissions of GHGs are reported as CO_2 equivalent (CO_2e), which is a normalized unit used to describe a mixture of GHGs in terms of the relative radiative forcing of CO_2 for each component of the mixture. These CO_2e emissions are calculated using Global Warming Potential (GWP) factors, which are identified in the NIR (ECCC 2021b) as being consistent with those applied in the Fourth Synthesis report from the Intergovernmental Panel on Climate Change (IPCC; Pachauri and Reisinger 2008). Nitrous oxide has a GWP of 298, meaning that the calculated N_2O emissions in tonnes are to be multiplied by 298 to determine the CO_2e emission (i.e., one tonne of N_2O is equivalent to 298 tonnes of CO_2 in terms of warming potential). The GWP for methane is 25 (ECCC 2021b) and is applied in the same manner.

Project activities involve the use of combustion equipment such as on-road mobile equipment (e.g., trucks, vans), off-road mobile equipment (e.g., dozers, loaders), and stationary equipment (e.g., generators, propane heaters). Airstrip and road development, as well as site clearing activities during Construction, were also included in the analysis as they contribute to the conversion of land use from vegetated to developed (i.e., existing biomass removed).

Information from the *Prefeasibility Study Report for the Wheeler River Uranium Project* (Denison 2018) pertaining to projected vehicle usage and associated equipment fuel consumption, as well as projected fuel consumption required for propane heating and operation of the generators, was used to calculate the annual fuel volumes anticipated for each source type and Project phase (i.e., Construction, Operation, and Decommissioning). No GHG emissions are associated with Post-Decommissioning.

Per the SACC guide, the emission factors from the NIR were applied, specifically from Table A6.1-14 for on- and off-road mobile combustion sources, from Table A6.1-5 for generators, and from

Table A6.1-4 for propane heating (ECCC 2021b). For combustion sources, the annual fuel estimates for each source were multiplied by the appropriate emission factors (provided in units of g/L) to estimate the associated emissions. The detailed combustion emissions calculations are provided in the *Climate Baseline and Greenhouse Gas Emissions Report* that has been prepared for the Project (Appendix 6-C in Section 6).

The SACC guide specifies that carbon emissions associated with changing land use characteristics are to be included in the GHG inventory (ECCC 2021a). For the Project, these emissions are associated with the 169.6 ha representing the Project Area (or disturbed area), which are currently vegetated and will be cleared and developed during Project activities. The carbon stock associated with the removed vegetation will be calculated and converted to GHG emissions in CO_2e. The SACC guide recommends procedures from the NIR and the *Guidelines for National Greenhouse Gas Inventories, Volume 4* (IPCC guidelines; Eggleston et al. 2006). The current vegetative cover of the Project Area was characterized based on information included in Section 9.2 of this EIS. According to Table 9.2-5 in Section 9, vegetation in the Local Study Area (i.e., LSA for Vegetation and Ecosystems) primarily consists of low and tall shrubs, young forest, and mature forest. These vegetation types make up approximately 90% of the LSA, and it was assumed that the full Project Area was similarly vegetated. The ratio of the area of forested lands and shrub-covered lands in the LSA was applied to the 169.6 ha that comprise the Project Area for the purposes of the calculation, and default values for the typical above-ground mass of the boreal plains in Saskatchewan from the SACC report were applied (ECCC 2021a). The typical carbon content of the above-ground mass was referenced from the IPCC guidelines for conifer-type vegetation in boreal areas (IPCC 2006). The calculation assumed that all living biomass in the removed material would be instantly oxidized (ECCC 2021a). The detailed combustion emissions calculations are provided in the *Climate Baseline and Greenhouse Gas Emissions Report* that has been prepared for the Project (Appendix 6-C in Section 6).

The contribution of acquired energy to the total GHG emissions associated with the Project were calculated using Emission Intensity (EI) projections (in tonnes CO_2e/GWh) from Annex C of the SACC report (ECCC 2021a), in conjunction with the estimated annual power requirement for the Project from the *Prefeasibility Study Report for the Wheeler River Uranium Project* (Denison 2018). The total emissions associated with acquired energy were then calculated by multiplying the EI by the power requirement. This is expected to be a conservative calculation as the maximum EI value was applied, which is expected to trend downward over time due to policy decisions and technology improvements (ECCC 2021a), and most of the energy being used by the Project is expected to be produced at the SaskPower Island Falls Plant, which is a hydroelectric plant with no associated GHG emissions. The detailed combustion emissions calculations are provided in the *Climate Baseline and Greenhouse Gas Emissions Report* that has been prepared for the Project (Appendix 6-C in Section 6).

The calculated annual GHG emissions for the Project are provided in Table 2.5-1. These are maximum bounding total annual emissions for each Project phase.

Table 2.5-1: Summary of Predicted Greenhouse Gas Emissions

Scenario	Annual Greenhouse Gas (GHG) Emissions (tonnes/year)			
	CO_2	CH_4	N_2O	CO_2e
Direct GHG Emissions (Combustion, Land Use Change)				
Construction	30,767	0	1	31,039
Operation	11,752	0	1	12,002
Decommissioning	24,794	0	1	25,019
Post-Decommissioning	0	0	0	0
Acquired GHG Emissions (Purchase of Electrical Power)				
Construction	-	-	-	0
Operation	-	-	-	18,700
Decommissioning	-	-	-	0
Post-Decommissioning	-	-	-	0
Total GHG Emissions (Direct and Acquired)				
Construction	-	-	-	31,039
Operation	-	-	-	30,702
Decommissioning	-	-	-	25,019
Post-Decommissioning	-	-	-	0

Notes: CO_2 = carbon dioxide; CH_4 = methane; N_2O = nitrous oxide; CO_2e = CO_2 equivalent.
The annualized GHG intensity during operations is estimated at 7.5 tonnes of CO2e / tonnes of U_3O_8.

Assessment of upstream GHGs under the SACC guide are required for projects that are likely to exceed the upstream threshold of 500 kt of CO_2e per year. The upstream GHG emissions for the Project are expected to be well below this threshold. Parker et al. (2016) identified that for uranium mining and milling in Canada, direct emission and acquired energy are the main contributors to total GHG emissions compared to other value chain (including upstream) emissions. The total emissions estimated above for the Project are less than 31.1 kt of CO_2e per year, and based on Parker et al. (2016) it is assumed that 1. the upstream GHG emissions would be well below the annual total GHG emissions and 2. the upstream GHG emissions would be well below the SACC 500 kt of CO_2e per year threshold. Additionally, the CNSC (2017) guidance for assessing total GHG production from nuclear facilities follows a cradle-to-grave analysis that starts with mining and milling. The Project represents the start of the cycle and the emissions estimated here would be considered the most upstream in the cycle. Under this guidance, an assessment of upstream emissions would not be applicable.

Based on the predicted emissions, the Project will likely be required to report annually through the federal Greenhouse Gas Reporting Program. Facilities are required to report if annual emissions are over 10,000 tonnes of CO_2e and the information is collected under section 46 of the *Canadian Environment Protection Act*.

To provide context for the predicted emissions, the anticipated GHGs generated from the Project were compared to the nation- and province-wide GHG emissions. The average annual nation-wide GHG emissions (2010 to 2019) were 719 Mt CO_2e (ECCC 2021c). The average annual province-wide GHG emissions (2014 to 2019) were 75.2 Mt CO_2e. By contrast, the total annual emissions predicted for the Project were 0.031 Mt CO_2e for Construction, 0.031 Mt CO_2e for Operation, and 0.025 Mt CO_2e for Decommissioning. These amounts represent less than 0.0043% of the nation-wide annual average, and less than 0.041% of the province-wide annual average. The 2020 greenhouse gas emissions from large facilities (emitting over 10,000 tonnes of CO_2e on an annual basis) are shown in Figure 2.5-1.

As additional context, the emissions associated with uranium mining and processing are part of the low GHG lifecycle emissions for nuclear power. Considering CO_2e emissions by energy source, lifecycle emissions for nuclear power are approximately 16 g CO_2e/KWh versus coal at 1,001 g CO_2e/KWh and oil at 840 g CO_2e/KWh (Figure 1.3-1 in Section 1). The lifecycle GHG emissions associated with nuclear power at 16 g CO_2e/KWh include uranium mining and milling, which have been estimated separately to contribute 1.1 g CO_2e/KWh (Parker et al. 2016) to the total.

Denison will look for opportunities to optimize energy management and improve the energy intensity of the Project where practical. Examples of potential opportunities include:

- Heat recovery loops for comfort heating.
  - Freeze plant glycol loops heat recycle for processing plant heat and comfort heating. GHG emissions estimates above incorporate propane heating for processing plant heat and comfort heating.
- Investigate or source electric powered drills. GHG emissions estimates above includes fuel-powered drills.

Figure 2.5-1: Greenhouse Gas Emissions from Large Facilities, 2020

2.6 Project Schedule

Following successful completion of the EA process and securing the required licences, permits, and approvals, the total duration of the Project is proposed to be 38 years including approximately 2 years of Construction, 15 years of Operation, 5 years for Decommissioning, and 15 years for Post-Decommissioning. The proposed Project schedule and milestones are summarized in Table 2.6-1.

Table 2.6-1: Project Conceptual Development Schedule

Project Activity	Duration (Years)	Year
Construction	2	1 to 3
Operation	15	3 to 18
Decommissioning (does not include progressive decommissioning during operations)	5	18 to 23
Post-Decommissioning	15	23 to 38
Release from licence and transfer back to Crown land or into Provincial Institutional Control Program	Event	Event

2.7 Project Benefits

Approximately 300 workers are expected to be required during the two-year Construction period. Each component of Construction will require workers with different types of skills and training depending on the task (e.g., road construction, wellfield drilling, erection of buildings, connection to services). During Operation, about 180 people will be employed annually to operate the wellfield and processing plant, and provide various supporting activities such as security, camp operations, operation of the water treatment and potable water plants, environmental monitoring, and maintenance of roads, equipment, and buildings.

Denison will concentrate initial and sustained efforts for employment and training initiatives for the Project with its Communities of Interest. Best efforts will be made to make sure employment is maximized within the Communities of Interest and beyond that, with Indigenous people and Residents of Saskatchewan's North. Denison will work with the leadership of the Communities of Interest to assist in determining appropriate hiring practices during all phases of the Project. In 2018, Residents of Saskatchewan's North made up approximately 47% of the total workforce in northern Saskatchewan mines (Government of Saskatchewan, Ministry of Government Relations. 2019).

Positions expected throughout Construction and Operation of the Project include supervisory and management positions, trade positions, professional and technical positions, and labour positions (with a Grade 12 requirement and in-house training programs). Training for various positions is offered through Saskatchewan Indian Institute of Technologies, Saskatchewan Polytechnic, and other institutes in northern Saskatchewan. Specific training for the Project will be developed on an identified needs basis.

The need for goods and services during Construction, Operation, and Decommissioning will generate business opportunities throughout the life of the Project. In response to the demand for northern Saskatchewan based services, northern, Indigenous-owned businesses have grown to meet a broad range of supplies and services required by the mining industry. Examples of anticipated operating goods and services include catering, housekeeping, food, freight, and bulk materials such as fuel, propane, and reagents. The total annual operating costs for the Project are expected to be approximately $39 million. Total direct and sustaining capital costs for the Project are expected to be approximately $387 million.

As outlined in Denison’s Indigenous Peoples Policy, Denison recognizes the critical necessity of advancing reconciliation with Indigenous peoples in Canada and the important role of Canadian business in the reconciliation process. Denison is committed to providing Indigenous people and businesses with sustainable economic opportunities and benefits and sharing the economic benefits of Denison's business activities (Denison Mines 2022).

Denison has established a procurement approach that requires the procurement of all goods and services for the Project to first consider businesses based within the Communities of Interest prior to looking elsewhere in northern Saskatchewan, southern Saskatchewan, and/or outside of Saskatchewan. Throughout all phases of the Project, Denison will prioritize procurement efforts within the immediate vicinity and region.

Programs and actions focused on producing socio-economic benefits for Communities of Interest have been initiated (Section 13.4 in Section 13). It is Denison’s intent to leverage its early work and existing relationships with Communities of Interest to expand current socio-economic commitments, where possible. Denison will make sure that appropriate socio-economic considerations are made in the Province’s Saskatchewan Surface Lease Agreement and any other arrangements, as appropriate.

2.8 Project Design Features

Various Project design features have been proposed that serve to eliminate, reduce, or control potential Project effects on the biophysical and human environments through all Project phases. Additional VC-specific mitigation measures are proposed in Sections 6 through 13. Examples of Project design features are provided here:

- The Project footprint and Project Area (i.e., the area of maximum physical disturbance) have been reduced to the extent practicable, to minimize habitat loss and alteration, as well as noise propagation.

- Much of the proposed Project footprint will be developed within previously disturbed areas, including roads currently used for exploration activities, thereby minimizing additional habitat disturbance.
- Restrict all construction activities to the approved Construction footprint.
- Site clearing and other works that involve disturbance of vegetation and/or soil will be completed during least-risk timing windows for wildlife and birds to avoid disturbance during sensitive time periods, whenever practicable.
- Cleared brush and soil will be stockpiled when possible, to be used in progressive reclamation.
- Implement erosion and sediment controls during Construction.
- Ponds will be designed maintain a minimum freeboard of at least 1.0 m to allow for continued functioning during a probable maximum precipitation (PMP) event.
- Processing plant exhaust from drying and packaging areas will be directed through a venturi scrubber prior to release outside of the building.
- The height of the processing plant stack will be based on results of air dispersion modelling to be an appropriate height for optimal dispersion.
- Various aspects of the processing plant design incorporate best practices for worker protection including grading floors towards sumps for spill collection, having appropriate ventilation rates, and monitoring systems in place to make sure these mitigation measures are meeting design specifications.
- Bulk storage tanks for processing and water treatment will be located inside the processing plant, in a separate room from the processing equipment. The storage tanks will sit inside appropriately designed and sized concrete secondary containment basins. The secondary containment basin for each applicable chemical system will be physically separated from the containment basins for other chemical systems.
- Ventilation in the pumphouses will be designed with the ALARA principle in mind to provide sufficient worker protection from potential radon and radon progeny exposure. Monitoring systems will be in place to make sure these mitigation measures are meeting design specifications.
- Design liners and develop appropriate performance monitoring (e.g., leak detection, groundwater monitoring) based on the characteristics of the material being stored:
  - Ponds or pads designed to temporarily or permanently store non-radioactive materials will be lined with a single geosynthetic composite liner system. This is a primary HDPE GM over a GCL. The GCL will include a low permeable layer of bentonite clay. Examples of Project components proposed to have this type of liner include: the industrial wastewater treatment plant precipitate pond, hazardous waste storage pad, and effluent monitoring and release ponds.

   - Ponds or pads designed to temporarily or permanently store potentially radioactive materials will be lined with a double geosynthetic composite liner system. This is a primary HDPE GM over a GCL and a secondary HDPE GM over an additional GCL. The GCL will include a low permeable layer of bentonite clay. In between the primary and secondary liners, a leak detection and collection system will also be installed. The selected design is the most robust currently known and offers a life of several hundred years with proper installation and maintenance. Examples of Project components proposed to have this type of liner include: wellfield runoff pond, process precipitate pond, landfill leachate collection ponds, process water pond, UBS holding area, and special waste pad.
- Fuel storage and distribution infrastructure will be constructed in accordance with applicable legislation requirements.
- Fuels will be stored in approved, above-ground, double-walled storage tank(s) equipped with secondary containment in accordance with provincial regulations and standards.
- Stationary and mobile equipment will be fueled with a fuel-dispensing truck.
- A minimum 100 m distance from any waterbody will be maintained for fuel storage, refueling activities, or equipment servicing.
- Hazardous substances will be managed in a safe and secure manner in line with Safety Data Sheets, permit conditions, and applicable regulations. Denison will maintain an up-to-date record of the various hazardous substances on site and will maintain Safety Data Sheets and appropriate procedures for spill management, handling, and clean up in an accessible location.
- Clean, non-contact runoff will be diverted around Project components where possible. Contact water, including, for example, runoff from the wellfield and around the processing plant, will be collected in various ponds and eventually routed through the IWWTP for treatment prior to release to Whitefish Lake.
- The fresh water well(s) and surface water intake will be located, designed, installed, and operated according to applicable standards and best practices to minimize effects on the groundwater and surface water environments.
- The Project will adhere to treated effluent discharge limits as stipulated in operating approvals and by regulations and for protection of aquatic life and receptors associate with the water exposure pathway.
- Battery-powered light vehicles and mobile equipment, and an AC powered dual rotary drill for ISR wellfield development instead of a traditional diesel-powered unit will be employed where practical to reduce air emissions and noise levels and improve energy efficiency.
- Project components including equipment and machinery will regularly maintained and inspected to make sure they are in good working order.
- Speed limits will be implemented on site roads for worker safety, to minimize generation of road dust, and to protect wildlife.

- Containment and control of mining solution and uranium bearing solution in the ground in general, and the mining area in particular, will use three layers of protection:
  1. well design and operation – well will have secondary containment, be made of material resistant to mining solution, pressure grouted from the ore zone to surface, and tested for mechanical integrity prior to commissioning to confirm an adequate seal from surface to the well screen at the mining area. Operational monitoring of pressure and flow will provide assurance that the wells are functioning properly.
  2. pumping – operation of the injection and recovery wells will be done in a way to maintain an inward hydraulic gradient to keep mining solutions no more than 50 m above the well screened area in the ore zone. Perimeter pumping wells will be installed vertically, horizontally, and laterally surrounding the mining area both inside and outside the freeze wall with the ability to capture fluids by pumping when required and recycle solutions should the primary containment system not perform as expected.
  3. freeze wall – a freeze wall around the mining area, extending from the surface to the basement rock isolating the mining area from regional groundwater. The freeze wall is expected to be a minimum of 10 m thick, be installed 25 m away from the uranium deposit, and extend 30 m into the basement rock.

  Data from the groundwater monitoring network installed in and around the wellfield and freeze wall will make sure these mitigation measures are meeting design specifications.
- Well casing integrity will be monitored in a rigorous fashion, thereby allowing Denison to respond to any steel casing failures in a timely manner.
  - A network of monitoring wells installed within the freeze wall area will be equipped with pressure instrumentation for the determination of the vertical strain/stresses placed on the formation. This monitoring network is designed to detect if these strains may be approaching their acceptable levels prior to failure. The injection and recovery wells will also be equipped with continuous monitoring devices for pressure and temperature that can detect a breach in the well casing if one were to occur. This data will be transmitted to the processing plant for remote monitoring through a master control system. Through the master control system, operators will be capable of controlling pumphouse production lines remotely. Wellfield monitoring will facilitate detection of any issues with the injection and recovery wells. As a further preventative measure, annual mechanical integrity testing is conducted on the wells to ensure their containment and compliancy. Active monitoring will allow for operational shutdown if a scenario is approaching a failure mode.
- Double-walled (HDPE), or equivalent, piping will be used for the wellfield surface piping system and the piping will be freeze protected and secured to minimize movement. Surface pipelines

will be designed to have secondary containment or catchment and have leak detection systems in place at key locations.

- Denison is committed to conducting stringent waste characterization throughout the life of the Project. This includes physical, radiological, and chemical characterization to maintain accurate waste inventories and determine how wastes will be dispositioned through either re-use, recycling, temporary storage, or permanent disposal (on or off site). This includes clearance of material that meets unconditional release requirements and can be safely removed from site.
- During Operation, progressive decommissioning and reclamation activities will be completed where possible, and the progress and success of these activities will be assessed annually.
- At Decommissioning, areas requiring additional control (potentially the industrial landfill and IWWTP precipitate pond) will be covered with an engineered impermeable liner system to limit infiltration of precipitation into the containment system.
- Denison's decommissioning commitment is to return the land back to the Province of Saskatchewan for unrestricted surface land use post-closure. The CDP outlines how radiological, physical, and chemical risks will be managed during Decommissioning so no unreasonable risks remain. Denison will prioritize passive versus active controls to reduce long-term risk. Additional decommissioning details will be provided in the PDP, which will submitted to regulators as part of Project licensing and permitting. Prior to executing Decommissioning activities, Denison shall prepare and submit a DDP to regulators for acceptance, which builds on the preliminary decommissioning plan.

Additional opportunities for improving the Project health, safety, and environmental performance through Project design will be completed as the Project engineering advances. The Project feasibility work is underway, with a focus on design for safety. The intent of designing for safety is to eliminate a hazard completely or to reduce its magnitude sufficiently to eliminate the need for elaborate safety systems (engineered controls) and procedures (administrative controls). Furthermore, this hazard elimination or reduction is accomplished by means that are inherent in the design and, thus, permanent and inseparable from it. The implementation of the design for safety is achieved by application of the following principles by the whole team performing engineering design or planning the construction and/or commissioning work:

- Eliminate – Remove hazardous materials, processes, and activities.
- Minimize – Use smaller quantities of hazardous substances, minimize the number of hazardous activities or process/equipment items.
- Substitute – Replace a hazardous material with one that is less hazardous; substitute a hazardous activity for one that is less hazardous.
- Moderate – Minimize the effect of a release of hazardous material or energy by changing the layout or facilities, adopting less hazardous operating conditions or a less hazardous form of a material, or by reducing the number of people exposed.

- Simplify – Design facilities to eliminate unnecessary complexity, thus minimizing causes of hazards and human errors.

2.9 Management System

Denison is undertaking sequential EA and licensing processes with the CNSC. As such, a detailed management system based on the CNSC's safety and control areas and focused on anticipated compliance verification criteria will be developed over the upcoming months to support licensing activities. It is expected that Denison's management system will be governed by corporate policies, described in programs, and detailed in plans, and will naturally mature as the Project advances.

For the EIS, the Environmental Management System (EMS) framework is provided here to support review of the assessment and provide confidence in the various biophysical and human environment assessments and overall conclusions.

2.9.1 Environmental Management System Framework

The EMS for the Project forms a critical component of the overall management system for the Project. While the overall management system forms the common basis upon which all Project activities would be implemented, the EMS provides the specific commitments to, and framework for, defining the practices and procedures to establish and confirm protection of the environment, as well as the health and safety of workers and the public. Denison will develop the EMS as the Project proceeds through licensing and permitting.

Denison will develop an EMS for the Project consistent with the principals set out by CAN/CSA ISO 14001, *Environmental Management Systems – Requirements with Guidance for Use,* with consideration to applicable provincial and federal requirements and consideration of other guidance as may be deemed appropriate.

In general terms, the EMS is a framework that provides the means to pro-actively manage environmental risks and opportunities. The EMS provides processes, procedures, policies, assigned roles and responsibilities, and considers continual monitoring and improvement of organizational structures and practices. Within the specific context of the Project, the EMS provides an overall perspective on how potentially adverse effects would be minimized and managed over the Project life. In addition, the EMS establishes expectations (and associated mechanisms) for contractors and sub-contractors to comply with environmental commitments and policies including auditing and enforcement programs.

Denison is responsible for, and committed to, providing sufficient resources to: develop and implement the EMS to meet statutory/regulatory requirements; meet its corporate expectations with respect to environment performance; meet the expectations of its interested party partners, including Indigenous communities, with respect to environment performance; and fulfill any commitments made through the EA process and beyond through all Project phases.

For additional reference, the EMS would describe Denison's environmental policies, and the measures and procedures that would be implemented to manage environmental risk. The documentation would include considerations of organizational structure (including roles and responsibilities) that would facilitate the planning and resources needed for developing, implementing, and maintaining policies and practices associated with environmental protection. Key considerations that would be addressed by the EMS include:

- identifying and managing environmental risks associated with Project components, facilities and activities;
- the identification, implementation and maintenance of pollution control activities and technologies;
- monitoring of water and air releases;
- monitoring of constituents of potential concern and for their potential effects in the environment;
- performance monitoring, non-conformance, and contingency planning; and
- communication and distribution of information.

2.9.1.1 Environment, Health, Safety and Sustainability Policy and Objectives

Denison’s corporate Environment, Health, Safety and Sustainability Policy is as follows:

Denison is committed to the operation of its facilities in a manner that puts the safety of its workers, its contractors, its community, the environment, and the principles of sustainable development above all else. Whenever issues of safety conflict with other corporate objectives, safety shall be the first consideration. Accordingly, Denison is committed to the following principles:

- building and operating facilities in compliance with all applicable laws and regulations of the jurisdictions in which it operates;
- adopting and adhering to standards that are protective of both human health and the environment at all of its facilities;
- establishing goals and objectives that would encourage the ongoing development of a sound program of sustainability in the communities that it operates in;
- approaching sustainability and engagement activities with the utmost respect for Indigenous communities, Indigenous Rights, and Indigenous Knowledge; and
- keeping radiation, health and safety hazards, and environmental risks as low as reasonably achievable.

In support of these principles, Denison shall endeavour to:

- establish and maintain clearly defined Environmental Management System to guide its operations in accordance with the foregoing principles;
- provide adequate resources and appropriate staffing to implement its health, safety, environmental, sustainability and engagement programs;
- make sure its employees and contractors are properly trained in the implementation of its Environmental Management Systems and in compliance with applicable laws and regulations;
- institute regular monitoring programs to identify risks to its workers, contractors, Indigenous Rights holders, the public, or the environment, and to confirm compliance with regulatory requirements;
- set objectives and targets in an effort to continually improve its management and performance of health, safety, environmental, sustainability and engagement programs;
- identify and reduce the potential for accidents and emergency situations, and implement emergency response plans that will protect the health and safety of its workers, contractors, the public and the environment;
- conduct regular audits to assess and confirm compliance with this policy;
- develop processes for preventing non-conformance with this policy and adopting corrective actions; and
- require regular reporting to its Board of Directors regarding compliance with this policy.

This policy has been adopted by, and its implementation is the responsibility of, the Board of Directors of Denison. The Board of Directors holds all levels of management and all employees responsible for compliance with this policy within their areas of responsibility.

2.9.1.2 Implementation of the Environmental Management System – Roles and Responsibilities

As indicated, Denison is responsible for, and committed to, providing sufficient resources to develop and implement the EMS for the Project.

The Board of Directors of Denison (the Board) has established an Environment, Health, Safety and Sustainability Committee (the Committee) to assist the Board in fulfilling its oversight responsibilities with respect to the Corporation’s commitment to environmentally sound and sustainable business practices. The mandate of the Committee is to oversee the development and implementation of policies and best practices relating to environment, health, safety, and sustainability issues in compliance with applicable laws, regulations, and policies in the jurisdictions in which Denison carries on business.

The following responsibilities of the Board are delegated to the Committee:

- periodically review and report to the Board on Denison policies related to worker health and safety; environmental and permitting matters; climate change; engagement with communities and Indigenous peoples; remediation activities and tailings facility management; and emergency response plans (collectively "Sustainability Matters");

- receive reports from management on significant Sustainability Matters;
- review with management, as they relate to Sustainability Matters: (i) the risk identification, assessment, and management systems; (ii) activities taken to monitor and mitigate risks; and (iii) the resources allocated to address such risks;
- review with management long term strategies and plans with respect to Sustainability Matters;
- review and monitor the effectiveness of policies, and systems necessary for compliance with policies, related to Sustainability Matters, with the specific direction to bring any material noncompliance with the policies to the attention of the Board in a timely fashion;
- receive regular updates from management regarding compliance with environment, health, and safety legislation, licenses, the policies and systems in place to monitor such compliance;
- report and, where appropriate, make recommendations to the Board; and
- perform such other duties as may be assigned to the Committee by the Board, from time to time.

As the EMS for the Project is developed, the responsibilities of all levels of employees (senior managers, managers, staff), as well as contractors, will defined and clearly communicated.

2.9.1.3 Environmental Management System Components – Programs and Plans

The programs and plans within the EMS are essential to implement the design and mitigation measures that have been identified in the EIS, to measure environmental performance and the effectiveness of the design and mitigation (control) measures, and to provide the information necessary for Denison to foster a culture of continuous improvement as it concerns environmental considerations.

Programs and plans that would be established within the overall umbrella of the EMS are highlighted below. Please note that the specific titles of the programs and plans provided here and their organization within the broader management system may change as the Project advances. Additionally, the details associated with these programs and plans would be developed with the EMS as the Project proceeds through licensing and permitting.

2.9.1.3.1 Environmental Protection Program

An Environmental Protection Program would be established to provide an overarching framework for key environmental monitoring and management plans and to ensure a means to demonstrate compliance with applicable environmental regulatory requirements and other performance targets that Denison may set. The program would be developed in a manner that aligns with the ISO 14001 EMS Standard, as follows:

- Planning
  - Identification and determination of significance of those environmental aspects associated with Denison's activities.
  - Establishment of environmental objectives and targets.
  - Development of appropriate plans and/or programs to achieve the objectives and targets.
- Implementation and Operation
  - Defining and documenting appropriate roles and responsibilities.
  - Establishment and maintenance of operational controls over environmental aspects.
- Checking and Corrective Action
  - Monitoring to verify environmental performance and compliance.
  - Maintaining non-conformance and corrective and preventative action procedures.
- Management Review
  - Periodic review by Denison's management to ensure the on-going suitability, adequacy and effectiveness of the EMS.

Aspects of the Environmental Protection Program are discussed further below. For context, a discussion of management of monitoring of Project emissions is provided, emissions being one of the primary means by which Project activities interact with the environment. Subsequently, select plans that would fall within the umbrella of the Environmental Protection Program are highlighted.

Management and Monitoring of Emissions

A procedure document would be developed to guide the management of emissions from the Project. The procedure would define the key requirements, responsibilities, and processes for the management of radioactive and non-radioactive emissions. The procedure would be developed in accordance with relevant guidance such as REGDOC-2.9.2, *Controlling Releases to the Environment* (CNSC 2021b) and CSA Standard N288.17, Establishing and Implementing Action Levels for Releases to the Environment from Nuclear Facilities (CSA 2017).

The procedure document would expand on regulatory requirements for the effective management of these emissions, and involves the following activities:

- identification and assessment of emission pathways;
- control and treatment of emissions;
- operational control monitoring; and
- emissions verification monitoring.

Identification and assessment of emission pathways involves identifying routes by which radioactive and non-radioactive constituents are likely to be emitted to the environment. The type and quantities of these constituents to be emitted are characterized, and subsequently assessed for the likelihood of exceeding regulatory and internal emissions limits, the magnitude and likelihood of effects to the public, the potential for adverse effects to the environment, and the potential for public concern.

Control and treatment of emissions includes identifying mitigation to prevent, reduce, or limit release of emissions to the environment. Preventive maintenance programs are implemented to reduce the likelihood of system failures, and appropriate systems are in place to provide timely warning in the event of a failure or degradation of control and treatment systems. Operational control monitoring is completed to evaluate whether emission control systems are functioning as intended.

Emissions verification monitoring is intended to verify that emissions are below regulatory limits and includes measuring or estimating substances being released into the environment by the Site. An emissions verification monitoring program is established for the monitoring of radioactive and non-radioactive emissions.

Environmental monitoring is performed to assist in determining the effect of emissions in the environment surrounding a site or facility and consists of measuring or estimating substances present in the environment.

Liquid Effluent Monitoring Plan

The liquid effluent monitoring plan would consider emissions to surface water environments from Project activities and facilities. The liquid effluent monitoring plan would describe sampling locations, frequencies and constituents. Data generated from the liquid effluent monitoring plan would serve various purposes, such as to measure quantities of materials released via this pathway to the environment, demonstrate compliance with statutory limits or internal action levels, assess performance of emissions control systems, contribute to the understanding of the potential influence of the Project's liquid emissions on the environment.

The liquid effluent monitoring plan would be informed by existing local and traditional knowledge, ongoing engagement activities with interested parties, information generated by development of EIS and its supporting documents, relevant guidance (such as REGDOC-2.9.1, Environmental Protection: Environmental Principles, Assessments and Protection Measures, Version 1.2 [CNSC 2020] and CSA Standard N288.5-11, *Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mine and Mills* [CSA 2011]), the Metal and Diamond Mine Effluent Regulations, licenses, approvals, and permits.

Air Emissions Monitoring Plan

The air emissions monitoring plan would consider emissions to the atmosphere from Project activities and facilities. The air emissions monitoring plan would describe sampling locations, frequencies and constituents. Data generated from the air emissions monitoring plan would serve various purposes, such as to measure quantities of materials released via this pathway to the environment, demonstrate compliance with statutory limits or internal action levels, assess performance of emissions control systems, contribute to the understanding of the potential influence of the Project's air emissions on the environment.

The liquid effluent monitoring plan would be informed by existing local and traditional knowledge, ongoing engagement activities with interested parties, information generated by development of EIS and its supporting documents, as well as relevant guidance such as that provided by the Saskatchewan Environmental Code.

Groundwater Monitoring Plan

Given the nature of the ISR mining method that will be employed by the Project groundwater monitoring is an important consideration. The groundwater monitoring plan would be developed in consideration of how Project facilities and activities could interact with the groundwater environment and groundwater users to define monitoring needs (locations, frequencies and constituents). Data generated from the groundwater monitoring plan would serve various purposes, such as to assess performance and the controls associated with the ISR process, demonstrate compliance with internal action levels, assess performance of emissions control systems, and contribute to the understanding of the potential influence of the Project on the groundwater environment. The groundwater monitoring program would demonstrate, during each Project phase, that:

- excursions are not occurring; if excursions do occur, an early warning/timely signal will be provided of when and where they are occurring such that appropriate further evaluation and actions can be undertaken;
- commitments made in the EA are being achieved; and
- protection of groundwater end use/receiving environment is being achieved.

The groundwater monitoring plan would be informed by existing local and traditional knowledge, ongoing engagement activities with interested parties, information generated by development of EIS and its supporting documents, relevant guidance, such as CSA Standard N288.7-15, *Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mine and Mills* (CSA 2015) as well as any applicable licenses, approvals, and permits.

Environmental Monitoring Plan

The environmental monitoring plan would consider the potential effects of Project emissions on the environment, focussing on downgradient or downstream areas and receptors. The environmental monitoring plan would describe sampling locations, frequencies, and measurement endpoints. Data generated from the environmental monitoring plan would serve various purposes, such as to measure the accumulation of Project-associated materials released to the environment, verify predictions made in the EIS (e.g., ERA), demonstrate compliance with statutory limits or internal action levels, contribute to the understanding of the potential influence of the Project's emissions on the environment, including risks to human health and biota.

The environmental monitoring plan would be informed by existing local and traditional knowledge, ongoing engagement activities with interested parties, information generated by development of EIS and its supporting documents, relevant guidance, such as REGDOC-2.9.1, *Environmental Protection: Environmental Principles, Assessments and Protection Measures* (CNSC 2020) and CSA Standard N288.4-19, *Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mine and Mills* (CSA 2019), the Metal and Diamond Mine Effluent Regulations and as well as any applicable licenses, approvals, and permits.

Woodland Caribou Management Plan

A woodland caribou management plan would be developed to address wildlife-specific mitigation measures based on proven and accepted mitigation following standard industry guidelines and best management practices. The plan would provide guidance to avoid or minimize interaction of the Project on woodland caribou and their habitat and include monitoring and follow-up programs, as appropriate. It would be in place during all phases of the Project and would be subject to ongoing review and revision as required. If monitoring identifies a need for additional or revised mitigation measures, a process of adaptive management (as described in the plan) would be triggered. A woodland caribou management plan for the Project would be consistent with the management goals of the SK-1 Boreal Shield Woodland Caribou Management Unit.

2.9.1.3.2 Radiation Protection Program

A Radiation Protection Program would be designed and implemented so that Denison complies with, or exceeds, the level of radiation safety that is required by the relevant regulations pursuant to the *Nuclear Safety and Control Act* and Denison's Health and Safety Policy.

Activities within the program would include:

- implementing a radiation code of practice;
- measuring and monitoring radiation on an ongoing basis; and
- reporting radiation testing results to regulators.

2.9.1.3.3 *Waste Management Program*

The Waste Management Program would include requirements and processes to ensure that Denison's activities that involve planning for, handling, transporting, processing, storage, and disposal of wastes are performed in a manner that complies with applicable regulatory and licence requirements and protects workers, the public, and the environment.

The Waste Management Program would include identification of waste inventory and the characteristics of the waste (radiological and hazardous non-radiological), waste segregation waste packaging and transfer requirements, and the plan for storage or disposal of the wastes. The Waste Management Program will detail the plans for waste rock segregation based on mineralized content and acid generating potential.

2.9.1.3.4 *Occupational Health and Safety Program*

The Occupational Health and Safety Program would be designed to provide for the protection of workers and public health and safety in relation to Denison's activities. Denison and its contactors would meet all applicable health and safety legislative requirements, provincially and federally. All activities related to the Project would be compliant with relevant legislation and would include:

- promoting employee participation in the development and implementation of safety and health programs and procedures;
- maintaining records, and reporting and investigating safety incidents;
- providing effective management and integration of contractors; and
- providing training to employees so that they can perform their tasks safely and identify potential hazards.

2.9.1.3.5 *Emergency Preparedness and Response Program*

The Emergency Preparedness and Response Program would identify how the Project will prepare for and addresses emergencies that may affect the health and safety of persons, the environment, and the protection of property. The objectives of the program would include the following:

- identification of accidents and emergencies and the actions and responsibilities in the event of an emergency;
- Project requirements for emergency response equipment and personnel;
- internal incident command structure to effectively manage complex, lengthy, and large scale emergencies;
- required communications with external emergency services, statutory bodies, and public, Indigenous groups, and regulatory agencies;
- development of appropriate emergency procedures; and
- assurance of availability of vital information during an emergency.

Emergency Preparedness and Response Program would be developed consistent with guidance provided by CNSC in REGDOC-2.10.1, *Nuclear Emergency Preparedness and Response* (CNSC 2016).

2.9.1.3.6 Fire Protection Program

The Fire Protection Program would be developed to ensure appropriate fire protection management in consideration of fire hazard and risk analyses and demonstration of compliance to applicable fire protection codes and standards.

2.9.1.3.7 Transportation of Dangerous Goods Program

The Transportation of Dangerous Goods Program would be intended to provide for the safe transport of dangerous goods by conforming to all applicable laws, regulations, company policies and procedures. The Transportation of Dangerous Goods Program applies to all modes of transport and all locations where Denison assumes care and control of the materials.

2.9.1.3.8 Personnel Training and Performance Management Program

A Personnel Training and Performance Management Program would be developed to ensure all Project related personnel are fully equipped to effectively implement their work functions, in particular consideration of how job function may affect the environment, including worker and public health, within the context of the EMS. Measurement of performance provides the means to Denison to foster a culture of continuous improvement.

2.9.1.3.9 Contractor Performance Management Program

The Contractor Performance Management Program would be developed to manage contract development, implementation, and administration for maximizing performance and managing risk over the life cycle of a contract.

2.9.1.3.10 Site Security Program

A site Security Program would be developed. The objective of the Site Security Program would be to provide security to the site, in compliance with *Nuclear Safety and Control Act* legislation and federal government security policy, as applicable.

2.9.1.3.11 Quality Assurance Program

The Quality Assurance Program would be developed to provide an overarching risk management framework within the EMS and contribute to the goal of continuous improvement.

2.9.1.3.12 Public Information Program

Although this program would not likely be within the EMS, it would be in the Project's broader management system and has been included here for information purposes. The CNSC REGDOC-3.2.1, *Public Information and Disclosure* (CNSC 2018) sets out requirements and guidance for public information and disclosure for licensees and applicants of Class I and Class II nuclear facilities, and uranium mines and mills, for all lifecycle phases. The primary goal of the public information program, as it relates to the licensed activities, is to ensure that information related to the health, safety and security of persons and the environment, and other issues associated with the lifecycle of nuclear facilities are effectively communicated to the public. Denison would meet all requirements set out in this REGDOC, including the development of an appropriate public information program and disclosure protocol.

2.10 Project Alternatives

2.10.1 Purpose of the Project

As outlined in Section 1.3 and Section 2.1, the purpose of the Project is to construct, operate, and decommission an ISR uranium mine and processing plant to provide uranium supply for the increasing demands for nuclear power generation. The purpose of the designated project under the *Canadian Environmental Assessment Act* (Government of Canada 2019) is defined as the rationale or reasons for which the designated project would be carried out from the proponent's perspective (Canadian Environmental Assessment Agency 2015). The purpose of the Project in this context incorporates Denison's perspective as a uranium exploration and development company.

Denison has identified that there is current and future market demand for uranium, the primary raw material for nuclear fuel generation. Presently, the annual global uranium supply is less than the annual global demand, and limited inventories have been accessed to make up the supply shortfall. In the upcoming decade, new uranium mining projects will be required to meet the needs of existing global nuclear power plants, without considering additional demands from new plants (both conventional and emerging small modular reactor designs) and life extension of existing plants (World Nuclear Association 2022). Development of the Project provides an opportunity for Denison to contribute to this increased demand and lessen the gap between annual global uranium supply and annual global demand.

One way the Project contributes to broader policies is that the product contributes to zero-carbon nuclear power generation. This supply of uranium for the purpose of power generation meaningfully contributes to initiatives focussed on decarbonization at various levels of government and in the private sector. For instance, the Government of Canada is committed to reducing Canada's emissions by 40 to 45% from 2005 levels by 2030 and putting Canada on a path to reach net-zero emissions by 2050. The *Canadian Net-Zero Emissions Accountability Act* (Government of Canada 2021) establishes in law Canada's emissions reduction target of net-zero emissions by 2050. In the private sector, the voluntary Net-Zero Challenge encourages businesses to develop and implement credible and effective plans to transition their facilities and operations to net-zero emissions by 2050.

Other opportunities that the Project can provide are socio-economic in nature. Meaningful opportunity would be generated by the Project, including, but not limited to, training opportunities, direct and indirect job creation and business opportunities, increased household income, increased national gross domestic product, and increased tax revenue for governments.

The Project is located in the Athabasca Basin that is recognized globally as a leading region for uranium mining. The Project will operate within a very politically stable jurisdiction with a strong regulatory framework. This provides assurance that the Project can be developed in such a way to achieve a high level of performance from health, safety, and environment perspectives, while generating socio-economic opportunities.

In consideration of the above, the purpose of the Project from Denison's perspective is multi-faceted: the Project can address gaps in annual global uranium supply and the use of uranium in nuclear power plants can contribute to net-zero goals, and this can be achieved while making a meaningful contribution to the Canadian economy.

2.10.2 Alternatives Means Assessment

Denison first evaluated production potential from the Project in 2010. Since that time, the Project has undergone significant design and review stages and has naturally evolved into the Project described and assessed in this EIS. Appendix 2-C provides details related to the alternative means assessment framework employed and the results of the alternatives assessment for key Project components and activities; this section of the EIS provides a summary of Appendix 2-C.

Alternative means are the various ways Denison considered to implement Project components and activities. During the planning process, it is common to consider various means by which to fulfill a specific aspect of the Project.

A systematic assessment of these alternatives was used to select preferred alternatives that are carried forward as Project design elements in a manner consistent with Canadian Environmental Assessment Agency's operational policy statement (Canadian Environmental Assessment Agency 2015). These preferred alternatives ultimately become the basis upon which potential Project-related effects are evaluated in the EIS. The preferred alternatives have been presented in the preceding section of this Project Description. The documentation of this systematic alternative assessment provides transparency and traceability with respect to decision making on Project design. It also documents how input received by Indigenous groups and other Interested Parties has been considered in the design/planning process.

The alternative means assessment has been carried out in a stepwise fashion as follows (Figure 2.10-1):

1. Identification of Alternative Means: Project components for which alternate means were considered are identified;
2. Consideration of Technical Feasibility, Economic Feasibility, and Land Use Factors: the technical and economic feasibility of these alternate means is considered along with a specific screening for land use intensity and importance. Only alternate means that are

deemed technically feasible, economically feasible, and passed the land use screening are carried forward in the evaluation.

3. Potential Residual Effects Associated the Alternative Means: the potential residual effects of each alternative, in consideration of mitigation, are described; and,
4. Evaluation of Alternative Means: a comparative evaluation of alternative means that considers the potential residual effects for each alternative relative to various assessment criteria and indicators.

A description of the above four steps along with an example from Appendix 2-C (for Mining - Method) is provided in the following sections.

2.10.2.1 Identification of Alternative Means

Several Project components and activities had alternate means or options considered:

- Mining
  - Method
  - Freeze design for tertiary containment of mining solution
  - Permeability enhancement
  - Mining solution
- Processing
  - Location of processing
  - On-site processing method
- Water management
  - Freshwater supply
  - Drinking water
  - Treated effluent discharge location
  - Treated effluent discharge location to surface water
- Waste management
  - Organic waste disposal
  - Process precipitate management
  - Domestic waste disposal
- Access and transportation
  - Access road alignment
  - Stream crossing structures
  - Worker transportation

- Power
  - Primary power supply
- Support facilities
  - Camp location optimization

For each Project component or activities listed above, a variety of options were considered. For example, the options considered under Mining – Method included:

- Option 1: Open pit
- Option 2: Jet boring
- Option 3: Surface boring
- Option 4: Micro tunnel boring
- Option 5: ISR

2.10.2.2 Consideration of Technical Feasibility, Economic Feasibility, and Land Use Factors

Alternative means considered in an EIS must be technically and economically feasible (CEAA 2015).

Denison integrated an additional category at this early stage in the alternative means assessment framework: land use screening. Although technical feasibility can include land use considerations, Denison opted to include land use separately to provide greater transparency on the approach taken and also in recognition of the importance of local land use that has been communicated by interested parties. In conjunction with screening for technical and economic feasibility, an initial evaluation was conducted to review Indigenous and other land use in the area to identify alternative means that may interact with areas of high land use intensity or areas of cultural importance (e.g., known gravesites). Consideration was given to information made available to Denison in the early stages of project planning. Note that subsequent, additional consideration of engagement information, including Indigenous and other land and resource use is completed at later stages in the alternatives means assessment framework (Section 2.10.2.4). The purpose of considering land use information at this stage was to identify land use that could compromise the feasibility of the Project and screen an alternative means out from additional evaluation.

For each Project component or activity, a consideration of the technical, economic, and land use characteristics of each alternative was considered. The purpose of this step in the alternative means assessment framework is to identify feasible alternatives for further assessment and to eliminate those alternative means that are not considered to be feasible from a technical, economic, or land use lens. Only those alternatives that are deemed technically and/or economically feasible and avoided interaction with areas of high intensity or high importance land use, are carried forward for further assessment.

For example, at this step in the alternative means assessment framework Option 1 Open pit mining (under Mining – Method) was screened out due to economic factors. For Mining – Methods, the remaining four options were carried forward for further assessment.

2.10.2.3 Potential Residual Effects Associated the Alternative Means

For all alternative means carried forward from the previous step, the expected residual effects following application of mitigation measures were considered. This step in the alternative means assessment framework identifies the potential residual effects which are then brought forward to the evaluation of alternative means. Again, as an example, the information related to Mining - Method (from Appendix 2-C, Table 4) is summarized here in Table 2.10-1.

2.10.2.4 Evaluation of Alternative Means

Detailed comparative evaluations of alternative means is presented in Appendix 2-C, Table 6 to Table 22. These evaluations considered the relative residual effects of each of the technical and economically feasible alternatives for each of the evaluation criteria identified in Table 2.10-2 (same as Table 5 from Appendix 2-C), following the application of mitigation measures (described in Appendix 2-C Table 4).

By way of example (refer to Appendix 2-C for details), a detailed evaluation of Mining – Method from Appendix 2-C has been provided here as Table 2.10-3.

Based on the above alternative means assessment process, a preferred alternative means for each respective Project component or activity evaluated was selected. Rationale for the selection based on the comparative evaluation of alternatives is provided in Appendix 2-C including input received by Indigenous groups and other Interested Parties.

For reference, the alternative means assessment is conducted at a screening level, appropriate for the stage of the Project when the alternatives were considered. The assessment considered both quantitative (where possible) and qualitative information as available. The comparative evaluation identified more preferred versus less preferred alternatives. The preferred alternative(s) was selected and evaluated in much greater detail in the EA. A summary of the alternative means carried forward into the EA is provided in Table 2.10-4**.**

2.10.3 Summary of Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Alternative Means Assessment

As described above, Indigenous Knowledge, local knowledge, and engagement has influenced the alternative means assessment, specifically in step 2 (Consideration of Technical Feasibility, Economic Feasibility, and Land Use Factors) and step 4 (Evaluation of Alternative Means) of the alternative means assessment framework.

Alternative means considered in an EIS must be technically and economically feasible (CEAA 2015). Denison opted to integrate an additional category at this early stage in the alternative means assessment framework: land use screening. Denison included land use separately to provide greater transparency on the approach taken and also in recognition of the importance of local land use that has been communicated by Interested Parties. At this step in the alternative means assessment framework, an option for treated effluent discharge location was eliminated due to land use screening in conjunction with technical considerations.

Denison's specific engagement initiatives on Project alternatives are outlined in Appendix 2-C for the 1) mining method, 2) freeze design for tertiary containment of mining solution, 3) treated effluent discharge location to surface water, and 4) access road alignment. In addition to these targeted engagement sessions, information gathered more broadly during engagement was also considered in Project alternatives through the consideration of general concerns or statements. The comparative evaluation of alternative means includes specific input received from Indigenous groups and other Interested Parties that contributed to the selection of the preferred option, when applicable. Refer to the row titled *Input received from Interested Parties* in Table 2.10-3 below for an example of how engagement influenced the selection of mining method.

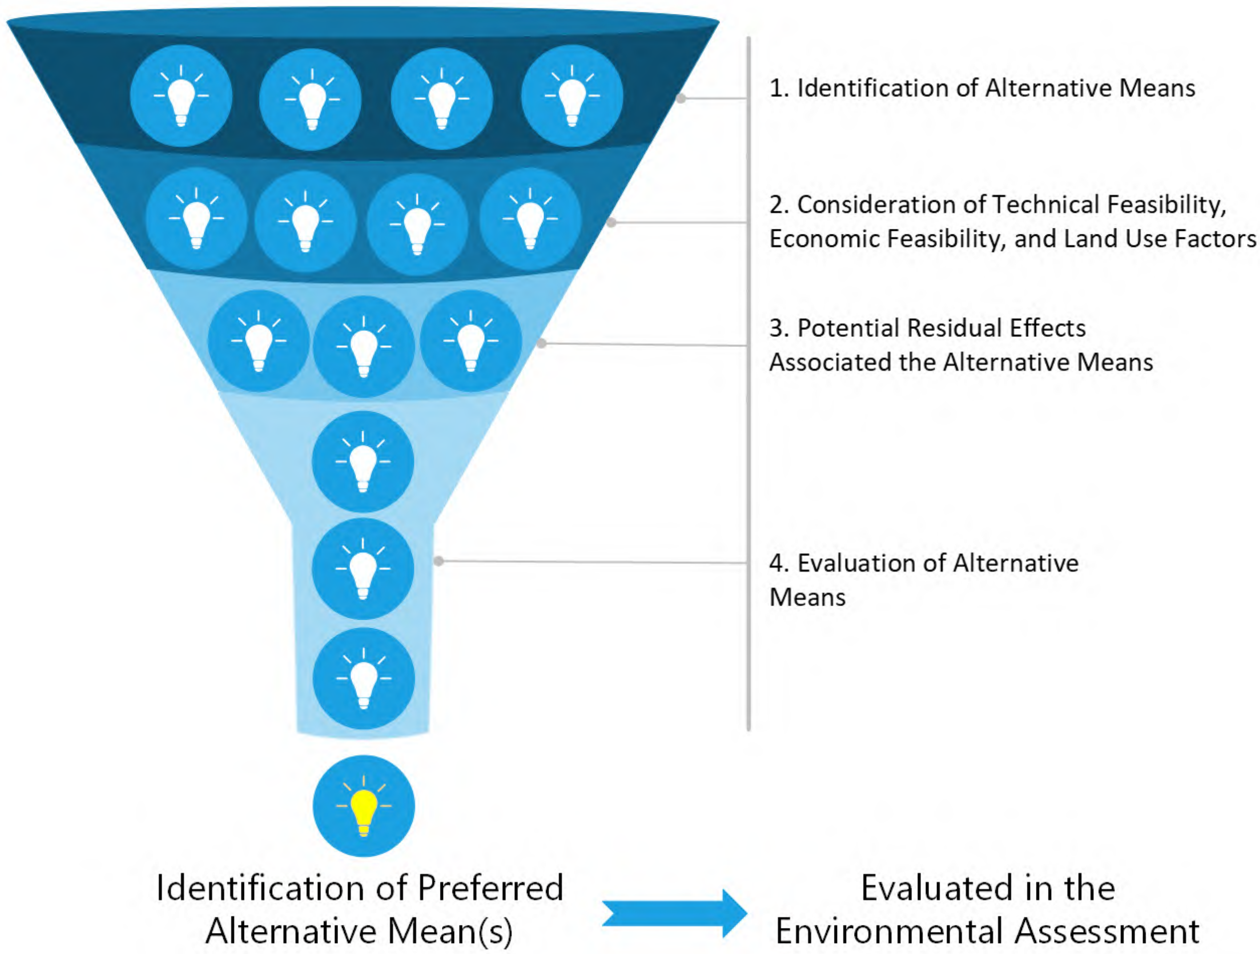

Figure 2.10-1: Alternative Means Assessment Framework for the Project

Table 2.10-1: Mitigation Measures and Residual Effects for Mining - Method (Excerpt from Appendix 2-C Table 4)

Project Component		Alternative Means Carried Through after Screening for Technical, Economic, and Land Use Factors	Mitigation Measures	Residual Effects
Mining	Method	Option 2: Jet Boring	Through design and monitoring, make sure emissions from ventilation meet applicable air quality emissions criteria Any water associated with workings and mining activities meets applicable discharge quality criteria prior to release Limit any surface development to extent practical and avoid areas of significance Follow best management practices and standards for waste characterization and management, containment of hazardous material, liner designs, fuel management	Effects to local geology by development of underground workings Effects on local vegetation, soil, bird, and wildlife habitat as a result of clearing required to develop surface infrastructure to support mining Effects on air quality via emissions from ventilation of underground workings Effects on groundwater quantity and flow paths based on need to dewatering underground mine workings Effects to surface water quality and surface water related receptors whereby mine water is released to local surface water features
		Option 3: Surface Boring	Through design and monitoring, make sure emissions from ventilation meet applicable air quality emissions criteria Any water associated with workings and mining activities meets applicable discharge quality criteria prior to release Limit any surface development to extent practical and avoid areas of significance Follow best management practices and standards for waste characterization and management, containment of hazardous material, liner designs, fuel management	Effects to local geology by development of underground workings Effects on local vegetation, soil, bird, and wildlife habitat as a result of clearing required to develop surface infrastructure to support mining Effects on air quality via emissions from ventilation of underground workings Effects on groundwater quantity and flow paths based on need to dewatering underground mine workings Effects to surface water quality and surface water related receptors whereby mine water is released to local surface water features
		Option 4: Micro Tunnel Boring	Through design and monitoring, make sure emissions from ventilation meet applicable air quality emissions criteria Any water associated with workings and mining activities meets applicable discharge quality criteria prior to release Limit any surface development to extent practical and avoid areas of significance Follow best management practices and standards for waste characterization and management, containment of hazardous material, liner designs, fuel management	Effects to local geology by development of underground workings Effects on local vegetation, soil, bird, and wildlife habitat as a result of clearing required to develop surface infrastructure to support mining Effects on air quality via emissions from ventilation of underground workings Effects on groundwater quantity and flow paths based on need to dewatering underground mine workings Effects to surface water quality and surface water-related receptors whereby mine water is released to local surface water features

Project Component		Alternative Means Carried Through after Screening for Technical, Economic, and Land Use Factors	Mitigation Measures	Residual Effects
		Option 5: ISR	Through design and monitoring, make sure emissions from ventilation meet applicable air quality emissions criteria Any water associated with workings and mining activities meets applicable discharge quality criteria prior to release Limit any surface development to extent practical and avoid areas of significance Follow best management practices and standards for waste characterization and management, containment of hazardous material, liner designs, fuel management	Effects to local geology by development of ISR mining area Effects on local vegetation, soil, bird, and wildlife habitat as a result of clearing required to develop surface infrastructure to support ISR mining Effects on groundwater quantity and flow paths based on development of ISR wellfield (injection and recovery well systems) Effects on groundwater quality by introduction of ISR mining solutions to the mining area Effects to surface water quality and surface water related receptors whereby mine water is released to local surface water features

Table 2.10-2: Detailed Alternatives Means Assessment Evaluation Criteria and Metrics (same as Table 5 in Appendix 2-C)

Criteria	Section	Valued Component	Indicator	Metric
Biophysical Environment	Atmospheric and Acoustic Environment	Air quality	Changes in air quality, including concentrations of dust, combustion products, uranium, metals and/or radionuclides	Alternatives that minimize changes in air quality and effects on ecological and human receptors are preferred.
		Noise	Changes in sound levels	Alternatives that minimize the increase in sound levels, and subsequent effects on wildlife and human receptors, are preferred.
	Geology and Groundwater	Geology	Changes in geology	Alternatives that avoid or minimize effects on geology are preferred
		Groundwater quantity	Changes in groundwater levels, groundwater flow patterns, and discharge rates to local surface water bodies	Alternatives that minimize interaction with groundwater quantity are preferred.
		Groundwater quality	Changes in concentrations of physical and chemical parameters in groundwater with consideration of discharge to local surface water bodies	Alternatives that minimize changes in groundwater quality, in the context of groundwater discharge to surface water bodies, are preferred.
	Aquatic Environment	Surface Water Quantity	Changes in surface water quantity through water taking, surface water discharge, and project overprinting of drainage areas (footprints)	Alternatives that minimize Project footprint, as well as surface water intake and release to surface water bodies, are preferred.
		Surface Water Quality	Changes in physical and chemical parameters of surface water quality can result from discharge of treated effluent to surface water bodies and land disturbance and clearing can mobilize solids into the aquatic environment	Alternatives that minimize Project footprint and changes in surface water quality and effects on fish, and other ecological receptors, are preferred.
		Fish and Fish Habitat	Changes in fish and fish habitat may develop from Project overprinting of fish habitat (habitat alteration or loss), changes in surface water quantity, surface water quality (physical and chemical parameters), sediment quality, or benthic invertebrates	Alternatives that minimize interaction with fish and fish habitat are preferred.
		Sediment Quality	Changes in sediment quality mainly from discharge of treated effluent to surface water bodies	Alternatives that minimize effects on sediment quality are preferred.
		Benthic Invertebrates	Changes in benthic invertebrate communities and quality from uptake of chemical parameters	Alternatives that minimize effects on benthic invertebrates are preferred.
		Fish Health	Changes in fish health mainly from discharge of treated effluent to surface water bodies	Alternatives that minimize effects on fish health are preferred.

Criteria	Section	Valued Component	Indicator	Metric
	Terrestrial Environment	Terrain	Changes to terrain	Alternatives that minimize interaction with terrain are preferred.
		Soil	Changes in soil quantity or quality	Alternatives that minimize loss or alteration of soil quantity, and minimize changes in soil quality, are preferred.
		Organic matter/peat	Loss of organic matter/peat	Alternatives that minimize loss or alteration of organic matter/peat are preferred.
		Vegetation and Ecosystems	Change in areal extent of vegetation habitat types and ecosystems	Alternatives that minimize loss vegetation and ecosystems are preferred.
		Listed Plant Species	Change in number of listed plant species	Alternatives that minimize direct and indirect effects on listed plant species are preferred.
		Wetlands	Change in areal extent of wetlands	Alternatives that minimize loss or alteration of wetlands are preferred.
		Ungulates	Changes in ungulate habitat (loss and/or alteration) and indirect or direct mortality of individuals	Alternatives that minimize ungulate habitat loss or alteration and minimize ungulate mortality are preferred.
		Furbearers	Changes in furbearer habitat (loss and/or alteration) and indirect or direct mortality of individuals	Alternatives that minimize furbearer habitat loss or alteration and minimize furbearer mortality are preferred.
		Woodland caribou	Changes in woodland caribou habitat (loss and/or alteration) and indirect or direct mortality of individuals	Alternatives that minimize woodland caribou habitat loss or alteration and minimize woodland caribou mortality are preferred.
		Raptors	Changes in raptor habitat (loss and/or alteration) and indirect or direct mortality of individuals	Alternatives that minimize raptor habitat loss or alteration and minimize raptor mortality are preferred.
		Migratory breeding birds	Changes in migratory breeding bird habitat (loss and/or alteration) and indirect or direct mortality of individuals	Alternatives that minimize migratory breeding bird habitat loss or alteration and minimize migratory breeding bird mortality are preferred.
		Bird species at risk	Changes in bird species at risk habitat (loss and/or alteration) and indirect or direct mortality of individuals	Alternatives that minimize bird species at risk habitat loss or alteration and minimize bird species at risk mortality are preferred.
Human Environment	Human Health	Human Health	Changes in human health from exposure to non-radiological and radiological constituents in air, water, and food	Alternatives that minimize negative changes in human health are preferred.
		Worker Health	Worker conventional health and safety and radiation exposure	Alternatives that reduce conventional health and safety risks and radiation exposure are preferred.

Criteria	Section	Valued Component	Indicator	Metric
	Land and Resource Use	Indigenous Land and Resource Use	Changes in the area of land available for Indigenous land and resource use, as well as resource availability, and perceived suitability of land and resources for safe use	Alternatives that minimize negative changes in Indigenous land and resource use are preferred.
		Other Land and Resource Use	Changes in the area of land available for non-Indigenous land and resource use, as well as resource availability, and perceived suitability of land and resources for safe use	Alternatives that minimize negative changes in other land and resource use are preferred.
		Heritage Resources	Change in the number of known archaeological resources	Alternatives that minimize direct or indirect alteration or loss of archaeological resources are preferred
	Quality of Life	Cultural Expression	Changes to knowledge transmission and traditional diet, including perceived changes in the suitability and safety of resources that support a traditional diet	Alternatives that minimize direct or indirect adverse effects on cultural expression are preferred.
		Community Well-being	Change in income of local workers and community cohesion	Alternatives that minimize direct or indirect adverse effects on community well-being are preferred.
		Infrastructure and Services	Changes in traffic, community infrastructure and services	Alternatives that minimize direct or indirect adverse effects on infrastructure and services are preferred.
	Economics	Economy	Changes in participation in the traditional economy	Alternatives that minimize direct or indirect adverse effects on economy are preferred.
Other Evaluation Factors				
Criteria			**Metric**	
Technical Factors	Complexity of design, construction, operation, and decommissioning		Simple or straightforward designs, construction techniques, and operational procedures based on tested and proven technologies are preferred. Alternatives that are more amenable to decommissioning and/or reclamation are preferred.	
Cost Factors	Capital, operating, and decommissioning costs		Lower capital costs are preferred to reduce the pre-production costs and influence the project economic viability. Lower operational costs are preferred to maintain project economics. Lower decommissioning costs are preferred to reduce long term liabilities	

Table 2.10-3: Mining – Methods - Alternative Means Assessment (same as Table 6 in Appendix 2-C)

Table Criteria	Section	Valued Component	Option 2: Jet Boring	Option 3: Surface Boring	Option 4: Micro Tunnel Boring	Option 5: ISR
Biophysical	Atmospheric and Acoustic Environment	Air quality	Less preferred option. Air quality on surface would be influenced by slurry handling, radon gas, radioactive dust in vent exhaust, dust from surface stockpiles including clean waste rock. Air quality in the mine workings would be managed with ventilation.	More preferred option. Size of mine rock stockpiles and their influence on air quality would be similar to Option 5. Changes in concentrations of radon in air from well development would be similar to option 5.	Less preferred option. Air quality in the mine workings would be managed with ventilation. Air quality on surface would be influenced by hoisted cuttings or slurry, radon gas, radioactive dust in vent exhaust, dust from surface stockpiles including clean waste rock.	More preferred option. Size of mine rock stockpiles and their influence on air quality would be similar to Option 3. Changes in concentrations of radon in air from well development would be similar to option 3.
		Noise	No appreciable difference was identified among the alternatives for changes in noise. Continual noise from surface ventilation fans and noise from mobile equipment. Similar to Option 4.	No appreciable difference was identified among the alternatives for changes in noise. No fans, noise from production drilling from surface includes compressors and mobile equipment would be continual.	No appreciable difference was identified among the alternatives for changes in noise. Continual noise from surface ventilation fans and noise from mobile equipment. Similar to Option 2.	No appreciable difference was identified among the alternatives for changes in noise. No fans, noise from surface drilling equipment includes compressors and mobile equipment would be intermittent as drilling is done only as required.
	Geology and Groundwater	Geology	Less preferred option for changes to geology, compared to options 3 and 5.	More preferred option for geology compared to options 2 and 4 since this is a surface method requiring less excavation.	Less preferred option for changes to geology, compared to options 3 and 5.	More preferred option for geology compared to options 2 and 4 since this is a surface method requiring less excavation.
		Groundwater quantity	Less preferred compared to option 3. Volume of groundwater management during mining would be similar to Option 4.	Preferred option with smallest interaction on groundwater quantity compared to options 2, 4 and 5.	Less preferred compared to option 3. Volume of groundwater management during mining would be similar to Option 4.	Less preferred compared to option 3. Use of ground freezing temporarily interacts with groundwater flow during operations.
		Groundwater quality	No appreciable difference was identified among the alternatives for changes to groundwater quality. Groundwater quality would interact with mine workings in a limited way due to groundwater management during mining.	No appreciable difference was identified among the alternatives for changes to groundwater quality.	No appreciable difference was identified among the alternatives for changes to groundwater quality. Groundwater quality would interact with mine workings in a limited way due to groundwater management during mining.	No appreciable difference was identified among the alternatives for changes to groundwater quality. Mining area remediation during decommissioning would mitigate effects on groundwater quality.
	Aquatic Environment	Surface Water Quantity Surface Water Quality Fish and Fish Habitat	Less preferred than options 3 and 5. The volume of water requiring treatment and release would be high, because of the groundwater	More preferred option compared to options 2 and 4. The volume of water needed treatment and release to a surface waterbody would be	Less preferred than options 3 and 5. The volume of water requiring treatment and release would be high, because of the groundwater	More preferred option compared to options 2 and 4. The volume of water needed treatment and release to a surface waterbody would be minimal,

Table Criteria	Section	Valued Component	Option 2: Jet Boring	Option 3: Surface Boring	Option 4: Micro Tunnel Boring	Option 5: ISR
		Sediment Quality Benthic Invertebrates Fish Health	management required for mine development. This could result in a larger effect on the aquatic environment. Quality of treated effluent expected to the similar among all four options.	minimal, and as such, this option would have a smaller effect on the aquatic environment. Quality of treated effluent expected to the similar among all four options.	management required for mine development. This could result in a larger effect on the aquatic environment. Quality of treated effluent expected to the similar among all four options.	and as such, this option would have a smaller effect on the aquatic environment. Quality of treated effluent expected to the similar among all four options.
	Terrestrial Environment	Terrain Soil Organic matter/peat Vegetation and Ecosystems Listed Plant Species Wetlands Ungulates Furbearers Woodland caribou Raptors Migratory breeding birds Bird species at risk	This option is less preferred as it may result in a greater potential effect (loss) of terrain, soil, organic matter/peat, vegetation, listed plant species, wetlands and related loss and alteration of wildlife habitat. Largest amount of disturbance due to underground waste rock creating stockpiles of acid generating, contaminated and clean waste rock. Footprint estimated to be similar to Option 4 and double the total disturbance of Option 5.	Direct surface footprint/mining disturbance expected to be the second lowest of the four options. This option is more preferred than option 2 and 4, similar to option 5 with regard to potential effects on the terrestrial environment.	This option is less preferred as it may result in a greater potential effect (loss) of terrain, soil, organic matter/peat, vegetation, listed plant species, wetlands and related loss and alteration of wildlife habitat. Largest amount of disturbance due to underground waste rock creating stockpiles of acid generating, contaminated and clean waste rock. Footprint estimated to be similar to Option 2 and double the total disturbance of Option 5.	Direct surface footprint/mining disturbance expected to be the lowest of the four options. This option is more preferred than option 2 and 4, similar to option 3 with regard to potential effects on the terrestrial environment.
Human Environment	Human Health	Human Health	Less preferred. Potential exposure to non-radiological and radiological constituents in air, water, and food may be higher with this option compared to options 3 and 5 due to 1. changes in air quality from mine rock, slurry handling, and mine ventilation and 2. larger volume of treated effluent release to the aquatic environment.	More preferred compared to option 2 and 4 due to smaller changes in air quality and smaller volume of treated effluent release	Less preferred. Potential exposure to non-radiological and radiological constituents in air, water, and food may be higher with this option compared to options 3 and 5 due to 1. changes in air quality from mine rock, slurry handling, and mine ventilation and 2. larger volume of treated effluent release to the aquatic environment.	More preferred compared to option 2 and 4 due to smaller changes in air quality and smaller volume of treated effluent release
		Worker Health	No appreciable difference was identified between alternatives	No appreciable difference was identified between alternatives	No appreciable difference was identified between alternatives	No appreciable difference was identified between alternatives

Table Criteria	Section	Valued Component	Option 2: Jet Boring	Option 3: Surface Boring	Option 4: Micro Tunnel Boring	Option 5: ISR
			because with application of mitigation measures and monitoring, all options would protect worker health and maintain radiation exposure within limits for nuclear workers. Within this context, underground work is higher risk than surface due to confined working area with heavy equipment underground and higher contaminates in underground atmosphere compared to open air conditions on surface.	because with application of mitigation measures and monitoring, all options would protect worker health and maintain radiation exposure within limits for nuclear workers. Surface operation with specialized surface equipment to drill horizontal cavities at ore depth. Physical ore cuttings will need to be rehandled on surface to either slurry for wet transport or dewater for dry transport increasing dose relative to Option 5 (which has a fraction of the drill cuttings to handle). Good conventional H&S as there is minimal mobile surface equipment.	because with application of mitigation measures and monitoring, all options would protect worker health and maintain radiation exposure within limits for nuclear workers. Within this context, this option has potentially the highest dose as workers will have greater potential exposure to radiation while servicing equipment that is working within the ore zone. Underground work is higher risk than surface due to confined working area with heavy equipment underground and higher contaminates in underground atmosphere compared to open air conditions on surface.	because with application of mitigation measures and monitoring, all options would protect worker health and maintain radiation exposure within limits for nuclear workers. Lowest dose of the four mining options evaluated in terms of dose associated with drill cuttings. The main contributor to worker dose would be radon associated with drilling the ISR wells. Surface piping of UBS, pumphouses, and well maintenance will also be a source of dose during pipeline repairs and inspection of equipment.
	Land and Resource Use	Indigenous Land and Resource Use	Less preferred compared to options 3 and 5 because of larger potential changes in resource availability linked to: 1. Larger footprint (changes to terrestrial environment) and 2. Higher volume of treated effluent (changes to aquatic environment). For all options, the area immediately around the mining activity would not be available for Indigenous land and resource use activities during operations for safety reasons. Perceived suitability of land and resources for safe use expected to be similar for all options.	More preferred compared to options 2 and 4 because of smaller potential changes in resource availability linked to: 1. smaller footprint (and changes to terrestrial environment) and 2. lower volume of treated effluent (and changes to aquatic environment). For all options, the area immediately around the mining activity would not be available for Indigenous land and resource use activities during operations for safety reasons. Perceived suitability of land and resources for safe use expected to be similar for all options.	Less preferred compared to options 3 and 5 because of larger potential changes in resource availability linked to: 1. Larger footprint (changes to terrestrial environment) and 2. 			the area immediately around the mining activity would not be available for Indigenous land and resource use activities during operations for safety reasons. Perceived suitability of land and resources for safe use expected to be similar for all options.	environment). For all options, the area immediately around the mining activity would not be available for Indigenous land and resource use activities during operations for safety reasons. Perceived suitability of land and resources for safe use expected to be similar for all options.	the area immediately around the mining activity would not be available for Indigenous land and resource use activities during operations for safety reasons. Perceived suitability of land and resources for safe use expected to be similar for all options.	volume of treated effluent (changes to aquatic environment). For all options, the area immediately around the mining activity would not be available for Indigenous land and resource use activities during operations for safety reasons. Perceived suitability of land and resources for safe use expected to be similar for all options.
		Heritage Resources	Less preferred compared to options 3 and 5. Larger area of surface disturbance increases potential interaction with archaeological resources.	More preferred compared to options 2 and 4. Smaller area of surface disturbance reduces potential interaction with archaeological resources.	Less preferred compared to options 3 and 5. Larger area of surface disturbance increases potential interaction with archaeological resources.	More preferred compared to options 2 and 4. Smaller area of surface disturbance reduces potential interaction with archaeological resources.
	Quality of Life	Cultural Expression	No appreciable difference was identified between alternatives for changes to knowledge transmission and traditional diet, including perceived changes in the suitability and safety of resources that support a traditional diet.			
		Community Well-being	No appreciable difference was identified between alternatives for change in income of local workers and community cohesion.			
		Infrastructure and Services	No appreciable difference was identified between alternatives for changes in traffic, community infrastructure and services.			
	Economics	Economy	No appreciable difference was identified between alternatives for changes in participation in the traditional economy.			

Technical Factors	Complexity of design, construction, operation, and decommissioning	Potential advantages: technology currently in use in Canadian uranium industry; mine layouts do not require development at or above the unconformity; remote system – safe for radiological risks. Potential technical weaknesses: Long duration development timeline; low production rate with limited ability to increase; currently used at only one mine with limited experience outside of that operation; may require extensive research and development; high technical risk including	Potential advantages: technology in widespread use in oil and gas industry; reduced safety and environmental risks with elimination of underground excavations; completely remote system – safe for radiological risks; reduced number of employees on site; short timeframe to production (weeks); good production rate with scalability; similar technique under evaluation in Canadian uranium industry (Orano's SABRE mining method).	Potential advantages: technology in widespread use in civil / municipal applications; remote system – safe for radiological risks under normal operating conditions; self-supported tunnels, thus risk of ground failure or inflow in tunnels reduced; simple concept and operation, variety of knowledgeable contractors/personnel; moderate production rate (approximately 4M lbs/yr per machine); ability to apply multiple units (scalability).	Potential advantages: technology in widespread use in international uranium operations (USA, Kazakhstan, Australia); reduced safety and environmental risks with elimination of underground excavations; completely remote system – safe for radiological risks; reduced number of employees on site; short timeframe to production (months); reduced technical risk with majority of remaining risks tested during feasibility stage; toll milling not required.

		underground operating risks, inflow risk, design and operating risk; may require bulk freezing approach versus perimeter freeze design as assumed in the PEA. This would increase freeze cost and time significantly.	Potential technical weaknesses: Drilling accuracy is paramount and needs additional testing; not currently in use in Canadian uranium industry.	Potential technical weaknesses: Recovery of ore may be limited to 90% at best due to configuration of the tunnels; congested working space in the launch stations; not currently in use in Canadian uranium industry.	Potential technical weaknesses: Not currently in use in Canadian uranium industry; mining solution permeability requires additional testing to increase confidence; low production rate – based on production rate at US operations (future testing may allow for higher production rates).
Cost Factors	Capital, operating, and decommissioning costs	Option 2 has high operating cost relative to the grade of the ore body, high capital costs and long duration development timeline, although the technology is in use at an existing uranium operation in Canada.	Option 3 has low capital and operating costs compared to jet boring.	Option 4 has the lowest ore recovery and high capital costs and long duration development timeline. Technology is commonly used in civil engineering.	Option 5 has low capital and operating costs. The technology is in widespread use at international uranium operations. ISR mining operations often have comparatively low capital and operating costs, as well as shorter timelines to first production and greater flexibility to allow production to be scaled to meet market demands.

Input received from Interested Parties:

Denison discussed potential mining methods early in the engagement process. As part of the engagement program for the Project, Denison organized a series of in-person workshops with Indigenous and non-Indigenous communities of interest (COI) and other Interested Parties in 2018. The workshops gathered community and student input in relation to potential mining methods for the Phoenix deposit. Given the history of uranium mining in the Athabasca Basin, there is a wealth of knowledge on various mining methods, and Denison sought input for which method would be best suited to efficiently and safety mining the Phoenix deposit.

The following mining methods were evaluated for effectiveness in mining the Phoenix deposit at the Project: Jet Boring, Surface Boring, Micro Tunnel Boring and In Situ Recovery. There was no specific engagement data collected related to surface boring or micro tunnel boring. Workshop participants noted that while jet boring was a relatively well-known method of mining, the high economic costs may make it undesirable for the Phoenix deposit (18-EN-VPL-2.38) (18-EN-ERFN-5.44). ISR mining is new to northern Saskatchewan and Canada. Some workshop participants were unsure how to evaluate the potential benefits and/or drawbacks of this mining method (18-EN-VILX-3.69), however other participants were confident in the method, saying they know it works in other locations, there are minimal waste streams, and method is more economically feasible than other methods (18-EN-VILX-3.68). A participant in the Village of Beauval workshop preferred the small footprint and lesser environmental impacts of ISR and viewed this method as a new opportunity for northern Saskatchewan (18-EN-VB-4.51). New opportunities are welcomed in the area, as they can support local businesses, provide training and learning opportunities, and keep money within the local economy (16-EN-MLA-109.26).

Selected alternative for mining method = Option 5: ISR

Rationale: Mining methods were evaluated through an increasingly rigorous process and considered factors such as: safety, environment, production rates, capital costs, operating costs, schedule, operational flexibility, and risk. The top four mining methods considered for the Phoenix deposit were: jet boring, surface boring, micro tunnel boring, and ISR. Independent preliminary economic assessment or class 5 level assessments were completed on each of these four options in 2017. The parameters evaluated included safety, environmental impacts, radiological safety, capital cost, operating cost, development timeframe, production rate, economic results (net present value, internal rate of return), regulatory risk, technology risk, equipment and contractor availability, and operating flexibility; this information has been summarized above in the alternatives means assessment cells. In addition, workshops were held in local Indigenous and non-Indigenous communities to capture community input into the selection of a preferred mining method once the options were narrowed down. Ultimately, based on the alternatives evaluated and feedback from Communities of Interest, Denison included the ISR method in the prefeasibility study (PFS; Denison 2018) and this mining method was selected as the basis for the EA.

Less Preferred	Neutral	More preferred

Table 2.10-4: Summary of Alternative Means Carried Forward into the Environmental Assessment

Project Component		Reference to Detailed Alternative Means Assessment Table in Appendix 2-C	Alternative Means						
			Option 1	Option 2	Option 3	Option 4	Option 5	Option 6	Option 7

Glossary

Term	Definition
Indigenous Community of Interest	A community whose traditional land or potential or established Aboriginal and/ or Treaty rights are in proximity to the Project or has existing transportation infrastructure that would be used by the Project. An Indigenous Community of Interest is more likely to experience impacts from the Project.
Indigenous community	An Indigenous community with a potential interest in the Project, including any Indigenous community identified by a Regulatory Agency as having a potential interest in the Project.
Indigenous Knowledge	Indigenous Knowledge is also known as Aboriginal Traditional Knowledge and Traditional Ecological Knowledge. Generally, Aboriginal Traditional Knowledge is considered as a body of knowledge built up by a group of people through generations of living in close contact with nature. Aboriginal Traditional Knowledge is cumulative and dynamic. It builds upon the historic experiences of a people and adapts to social, economic, environmental, spiritual and political change.
Indigenous people	Section 35 of the *Constitution Act, 1867* defines the term "Aboriginal peoples of Canada" as referring to the First Nation, Inuit and Métis peoples of Canada. The term "Indigenous" is used interchangeably with "Aboriginal".
Local Knowledge	Specialized knowledge developed through long-term association, interaction, and cumulative experience.

3 Indigenous and Local Knowledge

Each Indigenous community/organization defines Indigenous Knowledge (IK[1]) in their own way. Although no universally accepted definition of IK exists, an understanding of the key features and defining characteristics of IK is offered by Indigenous communities and in the literature. Canadian Environmental Assessment Agency (CEAA) (2015)[2] provides the following definition of IK:

> *"Generally, ATK [Aboriginal Traditional Knowledge] is considered as a body of knowledge built up by a group of people through generations of living in close contact with nature. ATK is cumulative and dynamic. It builds upon the historic experiences of a people and adapts to social, economic, environmental, spiritual and political change."*

Indigenous Knowledge also can be understood as the unique and collective knowledge of Indigenous peoples that may include, but is not limited to, the environmental, cultural, economic, political, and spiritual conditions of a community or region (CEAA 2015). This knowledge is passed down orally from generation to generation by Elders and is best understood in an Indigenous language to not lose any meaning through translation. Indigenous Knowledge has been developed by Indigenous groups after generations of living in close contact with the land and, fundamentally, this knowledge holds respect for each other and the earth.

Local knowledge (LK) is defined as specialized knowledge developed through long-term association, interaction, and cumulative experience (IAAC 2020). It is context-specific and unique. Local knowledge can be held by individuals, organizations, or communities. Local knowledge holders can be Indigenous or non-Indigenous (IAAC 2021). The information held does not need to be validated and vetted through processes commonly applied in the collection of IK, which is considered as community-held and shared knowledge.

This section primarily focusses on IK, but also includes LK where applicable. This section discusses the value of IK in Environmental Assessment (EA), the regulatory environment, IK and LK sources, and the approach to IK taken in the EA.

3.1 The Value of Indigenous Knowledge in Environmental Assessment Practice

Indigenous Knowledge plays an important role in the environmental assessment of major projects in Canada, with the understanding that different types of knowledge and diverse perspectives are needed to obtain a full understanding of the existing conditions in which a project is proposed, the potential effects of a project, and the significance of those effects, especially to Indigenous Peoples (BC EAO 2020).

[1] Also known as Aboriginal Traditional Knowledge or ATK and Traditional Ecological Knowledge or TEK.
[2] The Canadian Environmental Assessment Agency of Canada is now the Impact Assessment Agency of Canada.

Inclusion of Indigenous Knowledge strengthens all stages of EA in the following ways (MVEIRB 2005; BC EAO 2020):

- makes sure the perspectives and concerns of Indigenous peoples are heard;
- provides information, including historical information, that may not have been available through other sources;
- leads to better decisions, including improved project design and stronger mitigation measures;
- identifies and defines valued components; and
- identifies potential project effects to be included in the Environmental Impact Statement (EIS).

As part of 2022 engagement activities for English River First Nation, Beauval, and Pinehouse, Denison prepared a survey that asked a series of questions relating to the results of the environmental assessment. Responses indicated that Denison could learn from people regarding how to reduce the effects of the project to the environment and that the Indigenous voice should be included in monitoring plans.

3.2 Regulatory Context

The Wheeler River Project (the Project) is subject to both provincial and federal EAs, under the *Saskatchewan Environmental Assessment Act* (SEAA) and the *Canadian Environmental Assessment Act* (Government of Canada 2019a). The Canadian Nuclear Security Commission (CNSC) is Canada's nuclear regulator, responsible for regulating the use of nuclear energy and materials to protect health, safety, security, and the environment (CNSC 2018). Both the provincial and federal regulatory context is described in the following subsections.

3.2.1 Provincial Regulatory Context

The SEAA does not specifically define or require IK; however, provincial policy documents provide further guidance to the consideration of traditional knowledge, a term sometimes used interchangeably with IK.

The Government of Saskatchewan’s (2014a) technical proposal guidelines state that:

> *“Proponents should actively solicit input from the general public in the area and from other individuals or groups that may have an interest in the project and utilize their traditional and local environmental knowledge where appropriate. These groups may include community associations, municipal governments, regional planning agencies, First Nations and Métis communities, businesses, recreational users, and non-government organizations.”*

The Government of Saskatchewan's (2014b) guidance on consultation with First Nations and Métis in Saskatchewan EAs states:

> *"Proponents are encouraged to incorporate relevant ecological, traditional, or other knowledge in the presentation of information within the EIS. Common methods for working with First Nations and Métis communities to gather and present such information include conducting project-specific traditional knowledge and/or land use studies. Information-gathering exercises should be undertaken prior to submitting an EIS to ensure all relevant information is included."*

3.2.2 Federal Regulatory Context

Requirements for IK under federal legislation and regulation are described under:

- The *Canadian Environmental Assessment Act, 2012* (Government of Canada 2019a) S. 19 (3), Community knowledge and Aboriginal traditional knowledge:
  - The environmental assessment of a designated project may take into account community knowledge and Aboriginal traditional knowledge.
- Under the CNSC's Regulatory Document, 3.2.2 Aboriginal Engagement (CNSC 2016):
  - Indigenous Knowledge may help to identify potential impacts from the activity described in the licence application on traditional land use, treaty rights, Indigenous rights, and culturally important sites, including archeological sites. Gathering of IK must be approached respectfully, in collaboration with the Indigenous group, and with the understanding that the IK may be sensitive or proprietary. Indigenous Knowledge must be understood in the context of the Indigenous group's world view.

The Canadian Environmental Assessment Agency's reference guide (CEAA 2015) on considering Aboriginal traditional knowledge for EAs conducted under the *Canadian Environmental Assessment Act*, *2012* recommends implementing the following general principles:

- Work with the community.
- Seek prior informed consent.
- Access IK with the support of the community.
- Respect intellectual property rights.
- Collect IK in collaboration with the community.
- Bring IK and western knowledge together.

3.3 Indigenous Knowledge Approach

3.3.1 Guiding Principles for the Inclusion of Indigenous Knowledge

Broadly, Denison Mines Corp. (Denison) has committed to working with Indigenous communities in a spirit of mutual respect and cooperation. Denison's Indigenous Peoples Policy reflects the company's belief that reconciliation is advanced through collaboration with Indigenous peoples and communities to build long-lasting, respectful, trusting, and mutually beneficial relationships (Denison 2021). Denison's Indigenous Peoples Policy was developed based on the company's experiences with, and feedback and guidance from, Indigenous communities with whom the company is engaged. This approach makes sure that the policy captures a mutual vision for reconciliation and one that is best advanced through action (Denison 2021). The policy was developed to be consistent with the standards and principles in The United Nations Declaration on the Rights of Indigenous Peoples (UN 2007) and the Call to Action 92 (Business and Reconciliation) from Canada's Truth and Reconciliation Commission (TRC 2015).

3.3.2 Respecting Community Protocols and Procedures for Indigenous Knowledge

Access to IK is a privilege and must be respected. Prior to sharing and collecting IK, current local protocols and procedures developed by the Indigenous Community of Interest ("Indigenous COI") for the management of IK must be understood and followed. Consideration was also given to consent processes directed by the community to approve what information becomes publicly accessible and included in the EIS. For all sources of IK, guidance was sought on how specifically the knowledge should be treated and respected through a funding agreement process. To date, Denison has received permission to use and reproduce English River First Nation (ERFN) land use mapping located in the Project Terms of Reference (Denison 2019). Denison also has received permission to use two ERFN summary documents of a health and socioeconomic study (ERFN and SVS 2022a) and a Traditional Knowledge study (ERFN and SVS 2022b) as per 'Permitted Purposes' defined in an ERFN/Denison Participation and Funding Agreement. Denison fully funded both studies.

The Kineepik Métis Local #9 of Pinehouse has provided permission (Denison 2019) to use Geographic Information System (GIS) data collected as part of 2011 and 2018 use and occupancy studies (Tobias and Associates 2018a). Denison funded 75% of the 2018 land use and occupancy study. To protect the privacy of the IK, new maps have not been generated from the GIS points; instead, a generalized map has been used in Section 11.1 Indigenous Land and Resource Use.

The MN-S entered into a capacity funding agreement with Denison to produce a Métis Knowledge Study, which was provided to Denison in October 2023. Information sharing protocols were included in the agreement consistent with MN-S expectations on confidentiality. This included protocols for any disclosure of traditional land use or traditional knowledge information with other parties.

In March 2022, the Ya'thi Néné Lands and Resources Office (YNLR) transmitted their report entitled An Exploration of Recorded Athabasca Denesųłiné Traditional Knowledge, Land Use and Occupancy Information in the Vicinity of Denison Mines Wheeler River Project (YNLR 2022) and expressed support for inclusion in the report in the EIS. This report, funded by Denison, focused primarily on the Athabasca Denesųłiné First Nations including Hatchet Lake, Black Lake, and Fond du Lac. Indigenous Knowledge and LK within this report, as well as publicly available information, has been integrated into the EIS with focus on the Athabasca Denesųłiné communities. This report is an amalgamation of known information from YNLR and was not collected explicitly for the purposes of the Project and, as such, should be interpreted with caution. At the YNLR's request, the March 2022 report is included as an appendix to the EIS (See Appendix 3-A).

3.4 Indigenous and Local Knowledge Sources

3.4.1 Identifying Indigenous Knowledge Holders

An important initial step in the development of the EIS was to identify IK holders. The step is linked to how Indigenous communities were identified in the context of Project-related engagement. Section 4 Engagement describes how "Interested Parties" were identified and the process for selection. Broadly, Interested Parties are defined as any person or organization that can affect, be affected by, perceive itself to be affected by, or is interested in a decision or activity related to the Project (Section 4.3).

In identifying Indigenous communities as Interested Parties, three sub-groups were identified:

- **Indigenous Community of Interest (Indigenous COI)**: a community whose traditional land or potential or established Aboriginal and/ or Treaty rights are in proximity to the Project or has existing transportation infrastructure that would be used by the Project. An Indigenous COI is more likely to experience impacts from the Project.
- **Indigenous Community**: an Indigenous community with a potential interest in the Project, including any Indigenous community identified by a Regulatory Agency as having a potential interest in the Project.
- **Indigenous Organization**: an organization that is owned, operated, or delegated to represent Indigenous Communities in connection with the Project.

With respect to the identification of IK holders, the Indigenous COI formed the basis of where IK was explicitly sought by Denison, although Indigenous Organizations also offer relevant sources of information.

Figure 3.4-1 displays the Project location relative to the Indigenous COIs: the ERFN at Patuanak, the Métis Local #82 of Patuanak, the Kineepik Métis Local #9 of Pinehouse, and the Sipishik Métis Local #37 of Beauval. Other Indigenous communities include the Dore/Sled Lake Métis Local #67, the A La Baie Métis Local #21, Birch Narrows Dene Nation, Buffalo River Dene Nation, Lac La Ronge

Indian Band, and the Athabasca Denesųłiné First Nation communities including Fond du Lac First Nation, Black Lake First Nation, and Hatchet Lake First Nation. Indigenous organizations (not shown on map) include the Métis Nation- Saskatchewan, who has been delegated the Duty to Consult for a number of Métis locals (see Section 4), and the YNLR, who represent the Athabasca Denesųłiné First Nations.

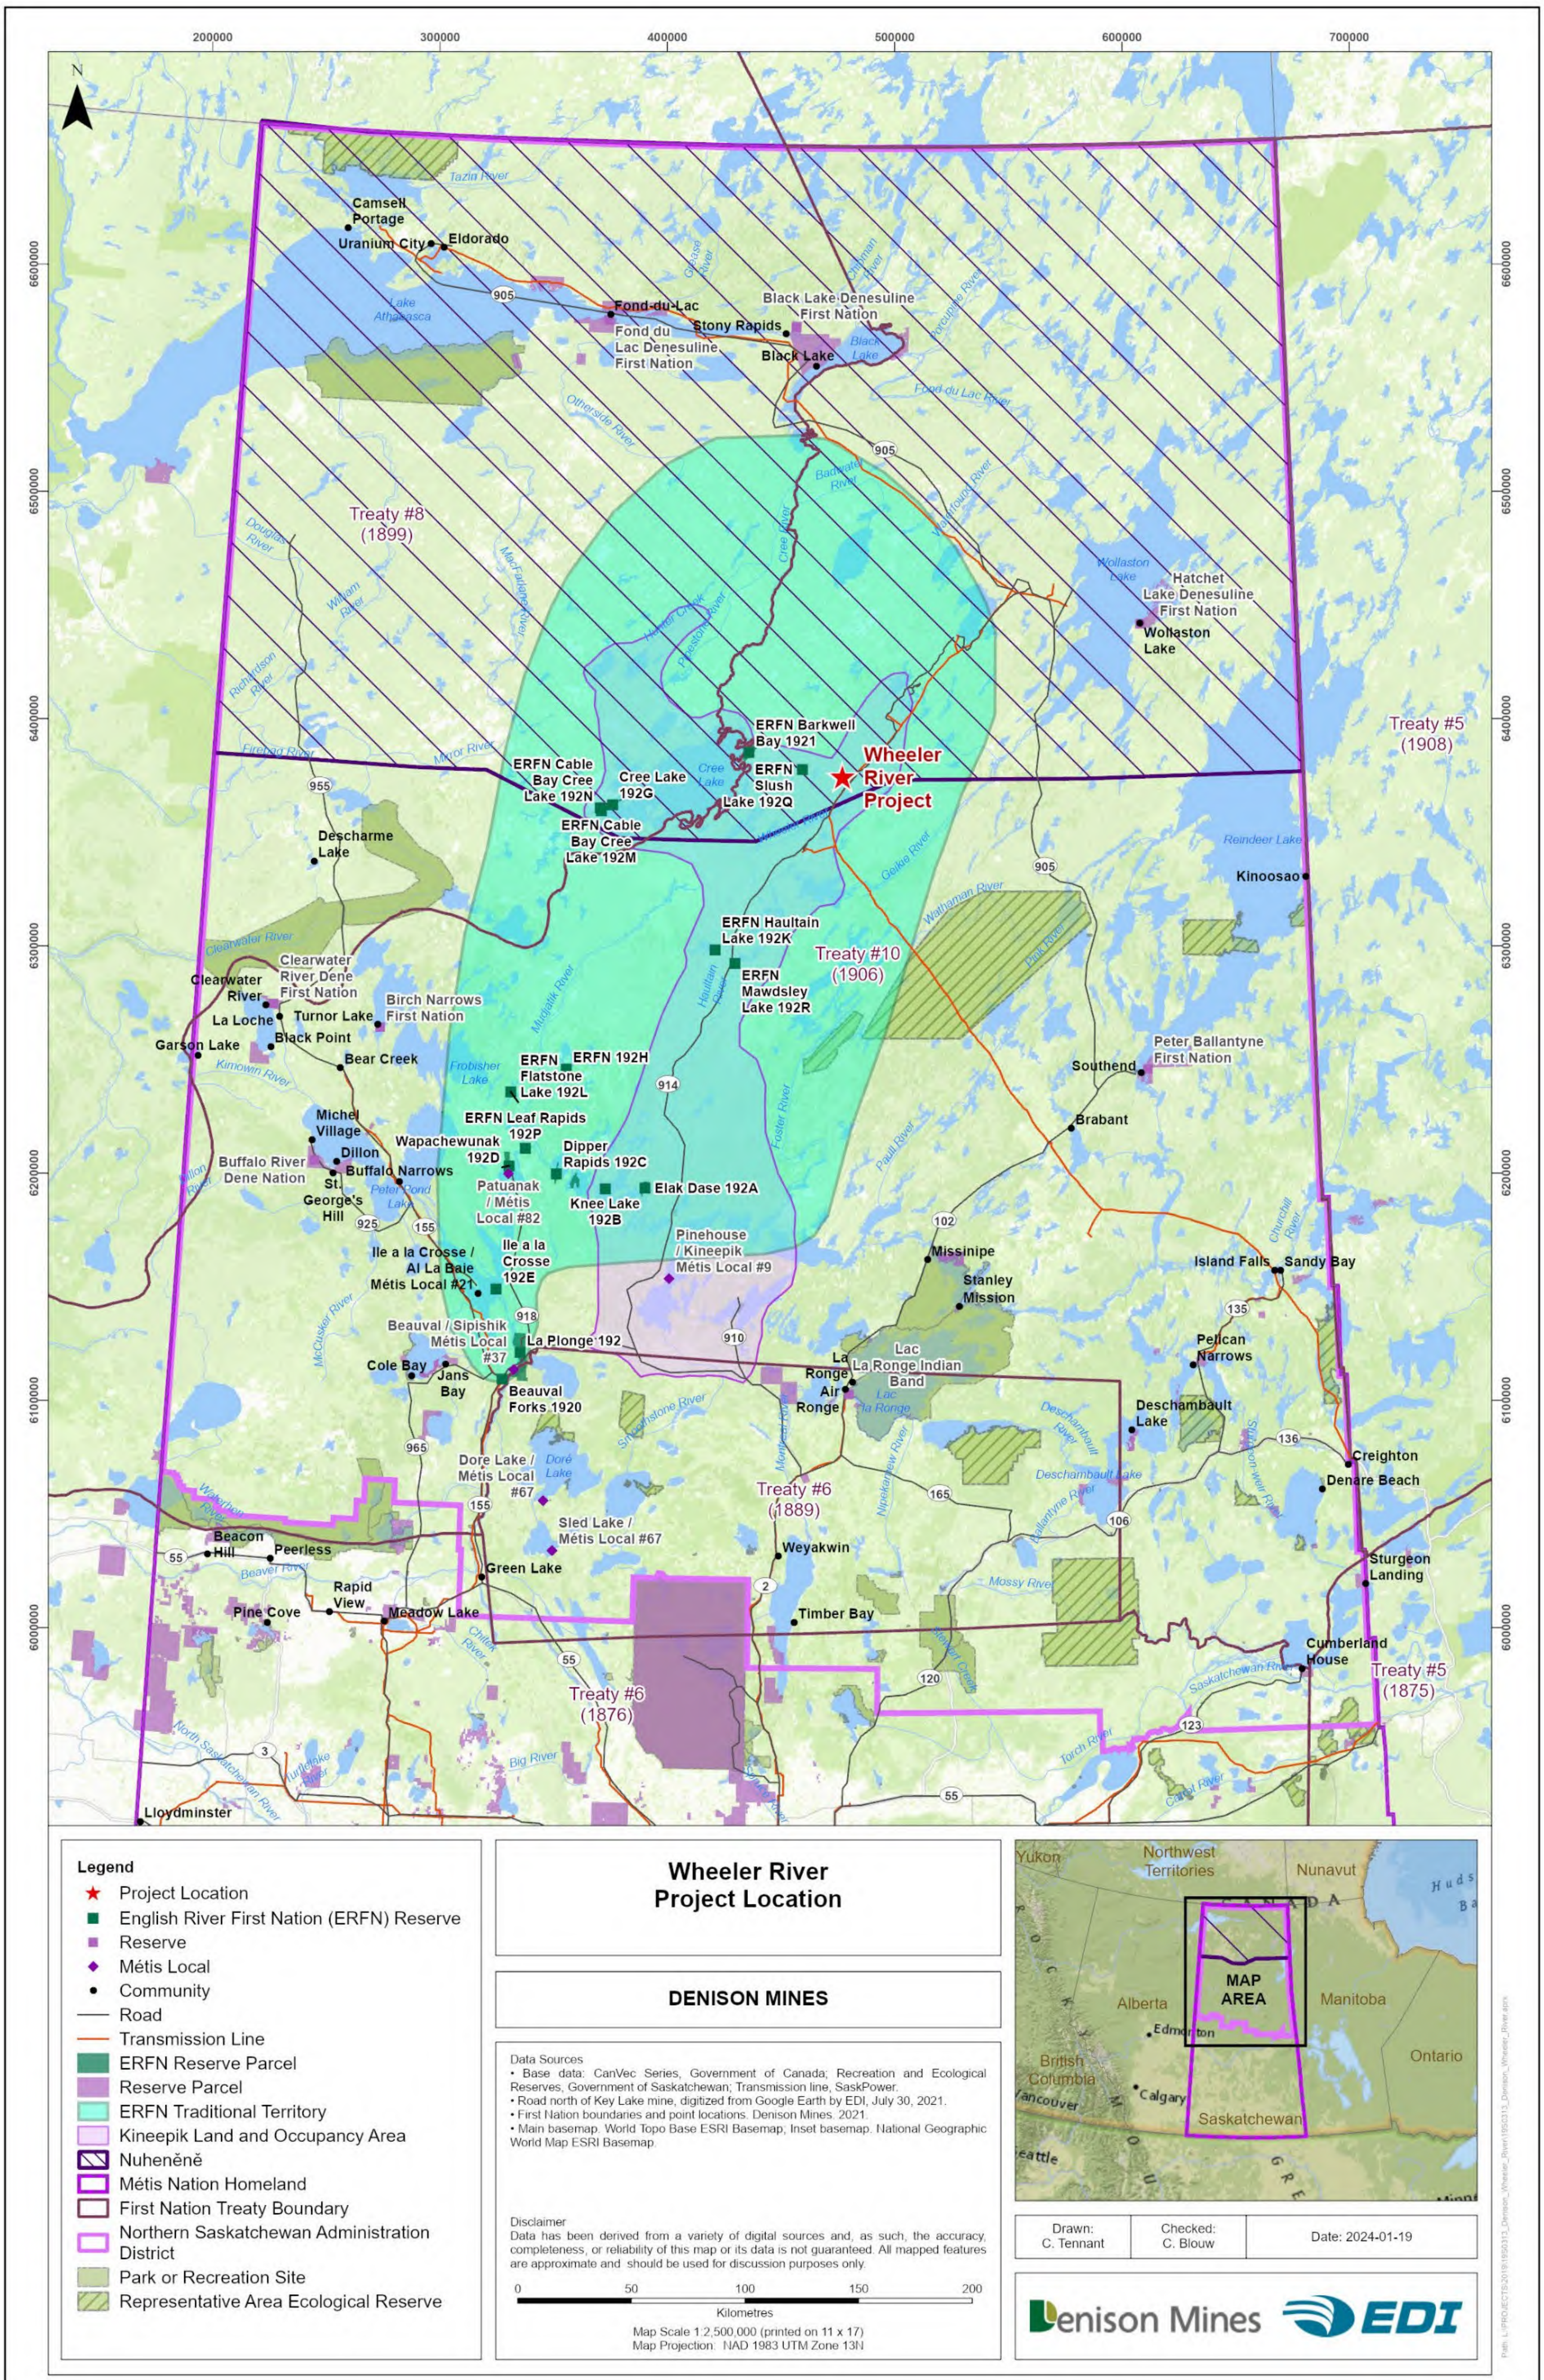

Figure 3.4-1: Overview of Project Location Relative to Communities

3.4.2 Sources of Indigenous Knowledge

Denison is supporting several processes to aid community-led collection of IK. These processes are at different stages of completion. Denison will continue to consider and integrate results from any forthcoming materials provided by communities as it advances the EIS process.

3.4.2.1 English River First Nation at Patuanak

The English River First Nation is a Denesųłiné community, comprised of both Denesųłiné and Cree people, with ancestral lands (*nuhtsiyw-kwi-Benéne*) stretching from the Churchill River to Wapata Lake in northern Saskatchewan.

> *"The ERFN name originates from the English River area, which was inhabited by the Poplar House people for periods during the year. Most of the families that now live at the Wapachewunak Reserve traditionally lived along the Churchill River system at Primeau Lake, Knee Lake, Dipper Lake and/or Cree Lake to the north (Canada North Environmental Services, 2017). Summers were spent primarily fishing along the river system. For the rest of the year, family units would spread out through the northern forests for trapping and subsistence hunting. Commonly used winter trapping areas included Haultain Lake, Costigan Lake, Foster Lake, and the area between Cree Lake and the Churchill River (Jarvenpa, 1980)"* (ERFN and SVS 2022a).

English River First Nation provided a land use map dated 2017 for Denison to gain an understanding of the extent and distribution of land use in the Project area. This map is published in the Project Terms of Reference (TOR; Denison 2019). To supplement the mapping information, funding was provided to ERFN to write their own independent contribution to the EIS, with assistance from Shared Value Solutions. English River First Nation produced a draft Traditional Knowledge Study and Health and Socio-Economic Study Results document that was split and finalized into two summary reports: 1) Wheeler River Project – Summary of Health and Socio-Economic Study Results (ERFN and SVS 2022a); and 2) Wheeler River Project - Summary of Traditional Knowledge Study Results (ERFN and SVS 2022b). The studies collectively documented baseline land use and socio-economic conditions and identified Project-related concerns and opportunities.

The first report summarizes results from sixteen interviews that were conducted for the health and socio-economic section (ERFN and SVS 2022a). The second study, i.e., the traditional knowledge study, conducted, analyzed, and presented results from 21 land use interviews, which provided both IK and LK (ERFN and SVS 2022b). The Traditional Knowledge study included maps of ERFN ecological knowledge features, personal harvesting sites, commercial harvesting sites, and occupancy sites. The Traditional Knowledge component also considered data collected with ERFN Elders in the 1980s and an analysis to look at the cumulative effects of industry on ERFN traditional territory.

3.4.2.2 Kineepik Métis at Pinehouse

The Kineepik Métis "*are considered Woodland Cree, Woodland Dene and Woodland Métis, although historical documents indicate that the member of (the Kineepik Métis Local) came from a diverse range of Métis, First Nations, and other backgrounds. The Northern Village of Pinehouse is located within the digitally mapped traditional territory of Indigenous people of Kineepik Métis Local. (They) have used these lands surrounding Missinippi (Churchill River) watershed for gathering food, shelter, and material supplies since time immemorial.*" (KML 2022).

In 2018, the Kineepik Métis Local #9 at Pinehouse (KML) approached Denison to support a land use mapping initiative in the Project area. The 2018 study builds on the land use mapping completed in 2011 by extending the spatial boundaries (Tobias and Associates 2018a). Methods used in the 2018 data collection are documented in Tobias and Associates (2018b) and results represent input from 128 respondents in 2011 and 55 respondents in 2018. The 2011 study area focussed on the community and environs north to George Lake and the 2018 study area focussed on the area north of and contiguous with the 2011 study area (from George Lake to north of Cree Lake Including the Project area). The essential methodology remained consistent for both iterations (Tobias and Associates 2018b). The Tobias and Associates (2018b) methods report indicates that collectively, the results from the 2011 and 2018 surveys represent the contemporary land base of Pinehouse residents determined "*primarily by locations where residents procure fish, birds, mammals and plant resources for direct family consumption*". A verification meeting was held in late 2018 to make sure no geographic data gaps existed and that the results speak for the whole community.

In 2022, the Kineepik Métis Local #9 (KML 2022) prepared a document to voice their perspectives on Project valued components and to provide a record for EIS development. Based on 12 community engagement sessions and review of the land use maps described above, the Kineepik Métis explained their unique social, cultural and historical context, expressed a general consensus of support for the Project, and described issues and concerns. The Kineepik Métis indicated that they regard Denison's engagement approach as a best practice process, which has surpassed any previous engagement protocols experienced before (KML 2022). As a result, the community is looking forward to continuing the engagement process with Denison and working collaboratively through any issues and concerns (KML 2022). Additional IK and LK was drawn from Kineepik Métis Local #9's *Response to the Environment Impact Assessment for the proposed Ministry of Highways 914 Extension Project* which, while expressing concerns about the proposed highway, also identified IK and LK priorities and concerns within the community (KML and NVP 2022).

3.4.2.3 Métis Nation - Saskatchewan

The Métis Nation - Saskatchewan represents the province's Métis citizens, with the Métis Nation Legislative Assembly as their governing authority. *"The Métis emerged as a distinct people/Nation in the historic Northwest during the course of the 18th & 19th centuries prior to Canada becoming a formal nation state. While the initial offspring of these unions were individuals who possessed* *mixed ancestry, the gradual establishment of distinct Métis communities, outside of First Nations and European cultures and settlements, as well as the subsequent inter-marriages between Métis women and Métis men, resulted in the genesis of a new Indigenous people – the Métis. The definition of Métis as adopted by Métis Nation–Saskatchewan is: 'a person who self identifies as Métis, is of historic Métis Nation ancestry, is distinct from other Aboriginal peoples, and is accepted by the Métis Nation'"* (Métis Nation – Saskatchewan not dated).

In recognition of the MN-S' potential interests in the Project, Denison and MN-S entered a capacity funding agreement to produce a Métis Knowledge Study.

In October 2023, the MN-S submit *The Wheeler River Project: Métis Knowledge Study Report* (MN-S and Two Worlds Consulting 2023) to Denison. The Métis knowledge summarized therein included secondary literature approved for use by the MN-S and primary information collected during interviews with nine Métis citizens from Northern Region 1 (NR1) and Northern Region 3 (NR3), exclusive of information from the KML at Pinehouse who formally revoked its delegated Duty to Consult from the MN-S.

The study included an introduction; a description of the Métis in Saskatchewan; the methodology for the study; Métis knowledge; Métis ways of knowing, doing and living; and findings and recommendations relative to the Project (MN-S and Two Worlds Consulting 2023). The study occurred in three phases: planning, engagement, and reporting. After a kick-off meeting with the MN-S and NR1 and NR3 locals to introduce the Project, an in-person community-based workshop with MN-S was held to develop the overall methodology, schedule, mapping templates, and interview guides. The draft interview guide was reviewed in that process, and customized to MN-S preferences. The interview guide followed a semi-structured approach to encourage information sharing.

Nine Métis advisors were selected for interviews if they met the criteria of having lived in NR1 and/or NR3, previously worked in NR1 and/or NR3, and/or had strong kinship ties to NR1 and/or NR3 and were able to share Metis knowledge learned through oral history. The spatial boundaries were based on the Northern Saskatchewan Administrative District, which encompassed NR1 and NR3. The draft EIS was updated to include Métis knowledge where relevant to the Valued Components (VCs) assessed.

3.4.2.4 Athabasca Denesųłiné Communities

The communities of Black Lake, Fond du Lac, and Hatchet Lake Denesųłiné First Nations are collectively referred to as the Athabasca Denesųłiné. *"Fur traders originally referred to the Denesųłine as the Northern Indians and later as the Caribou Eaters or Ethen-eldeli (Smith 1981, Elias 2003, Usher 1990, Bone et al. 1973). (They) have also been called Chipewyan; a name (they) found offensive since it was given to (them) by (their) traditional enemies, the Cree. In recent times, (they) have moved away from both terminologies, preferring the term Denesųłine, meaning 'the Real or*

Genuine People'. This is the term (their) ancestors used to define themselves." (YNLR 2022). The project is located within the Nuhenéné, traditional territory of the Athabasca Denesųłiné.

The Ya'thi Néné Lands and Resources Office is the point of contact for, and representative of, the Athabasca Denesųłiné communities of Black Lake, Fond du Lac, and Hatchet Lake Denesųłiné First Nations, as well as the northern hamlets/settlements of Stony Rapids, Wollaston Lake, Uranium City, and Camsell Portage. The YNLR provided their report, named *An Exploration of Recorded Athabasca Denesųłiné Traditional Knowledge, Land Use and Occupancy Information in the Vicinity of Denison Mines Wheeler River Project*. This report summarized traditional knowledge and land use and occupancy information collected for various other projects and initiatives, documenting Athabasca Denesųłiné use in the Project area, although it was not considered a site-specific study. The Athabasca Denesųłiné have participated in many traditional knowledge studies since the 1970s and the study provided to Denison uses these existing datasets to document traditional knowledge, land use, and occupancy near the Project with the goal of supporting the regulatory process. The study documents the importance of caribou to the Athabasca Denesųłiné, their history, and maps showing land use and occupancy sites and traditional knowledge within the Nuhenéné, traditional territory of Athabasca Denesųłine. Athabasca Denesųłiné land use is further described in Section 11.

3.4.3 Local Knowledge Sources

The sources of LK used in the EIS included Indigenous resource users who provided information outside of a community-led IK process, key person interviews (KPIs), and engagement events.

One key source of LK was an ERFN trapper, whose primary residence was in the Project area. This ERFN trapper was the primary Indigenous land user in the Project area year-round and had years of experience fishing and trapping for both food and commercial purposes, hunting and travelling throughout the Project area, and this individual possessed long-term observations of the natural environment. Unfortunately, prior to the time of filing the EIS, the ERFN trapper passed away.

Additional LK was sourced through KPIs and engagement activities (see Section 4) with people that have specific knowledge and/or expertise. For example, KPIs may be conducted with outfitters to learn LK about the use of lands for harvest and recreation; school principals and day care directors to identify LK about infrastructure and services available to local communities; and local community administrators / councillors to gather information on economic characteristics such as employment and training. Engagement activities that provide LK include site visits, letters and email correspondence, phone calls, surveys, and workshops. Records of LK are recorded in the Engagement Database and are cited throughout the EIS.

3.4.4 Indigenous Knowledge Values and Worldviews

Indigenous Knowledge is generated by millennia of experience in natural resource management and environmental decision-making practice (Eckert et al. 2020). Indigenous Knowledge systems, therefore, make valuable contributions to and improve the rigor of EA (Government of Canada 2019b). It should be noted that IK systems are not homogenous or universal because they are grounded in the local history and experience of different Indigenous groups. As noted previously, communities determine the content and the degree to which IK is shared.

The ERFN, the Kineepik Métis Local #9 of Pinehouse, and the Athabasca Denesųłiné, have shared some of their key values and worldviews to inform the EA process for the Project. For example, maintaining the health of both the ecological world and the human world is a guiding principle in many of ERFN's teachings (ERFN and SVS 2022a). Through extensive experience on the land, IK of fish spawning areas, mammal habitat, important waterways, and wildlife migration corridors is held by ERFN members in the Project area and throughout the ERFN traditional territory, Nuhtsiye-Kwi Benene (ERFN and SVS 2022b). The land, in turn, takes care of the people.... "*it's like our plate; it gives us everything. The land gives us the food that we need, it gives us the clothing that we need, it gives us the heartbeat that we need."* (ERFN and SVS 2022b). On the connectivity between people and the land, an ERFN member stated: *"Water is seen as a source of life, a part of every living being, and an interconnected network that flows through everything.*" (ERFN and SVS 2022b).

English River First Nation also point out differences for conceptions of land between IK and western knowledge systems. English River First Nation explained that to understand the sociological and cultural context of ERFN, western knowledge holders are encouraged to avoid considering land as *terra nullius*, or as empty space available for extraction or development (ERFN and SVS 2022a). They state that bridging cultures requires understanding how these cultural conceptions differ (ERFN and SVS 2022a).

Transmission of knowledge is important to cultural continuity. The ERFN explain that *"Dene and Cree cultures are oral-based knowledge systems",* meaning that the language is the primary way through which their teachings (e.g., values, stories, history, relationships with land, and governance decisions) are passed on from generation to generation. As a result, several cultural and language revitalization programs are underway in the community (ERFN and SVS 2022a).

The Kineepik Métis' land and occupancy area, within which the proposed Project is situated, has been used by the people for gathering food, shelter, and material supplies since time immemorial (KML 2022). Land use is not only for securing food; Kineepik Métis hunt and gather for cultural, language, and identity purposes as well (KML 2022).

The Kineepik Métis Local #9 of Pinehouse have indicated the importance of language in the transmission on knowledge (KML and NVP 2022). The efforts to revitalize language and culture has had momentum for over a decade at Pinehouse and is moving towards an organic beginning of self-governance (KML and NVP 2022).

> *"Being the nearest community south of the uranium mining operation (the Kineepik Métis Local #9) have worked with the uranium industry for many years, formalizing partnerships with Cameco Corporation and Orano Canada in 2012 with a collaboration agreement. These relationships have allowed (Kineepik Métis Local #9) to understand the impacts stemming from projects throughout their lifecycle from (their) unique Indigenous lens"* (KML and NVP 2022).

The Kineepik Métis have completed their cultural calendar, which is comprised of the current annual traditional activities (KML 2022). This process includes the seasonal changes and adjustments of cultural activities within those changes, which include celebrations of cultural events that bring pride to community members (KML 2022).

The Kineepik Métis Local #9 also reflect on interconnectedness of language, cultural and land stewardship:

> *"While industrial development created employment and business opportunities it has also exerted extreme pressure to confirm to western cultural practices. This pressure creates an erosion of language and cultural practices… the loss of language included the loss of cultural understanding – as we lose our language, we lose our connection to the land. We lose our ability to communicate with our elders. Once the connection to the land is lost, then the spirit of conservation and concern for how the ecosystems are defined by our elders is also lost. The is the very nature of diversity as we the Indigenous peoples have know then land for time immemorial, the connection is irreplaceable, authentic, and inherent."* (KML and NVP 2022).

Similarly, the Athabasca Denesųłiné note the interconnection among people and the land, explaining that Athabasca Denesųłiné "*culture, history and way of life are interwoven with the movements and the health of the Beverly, Ahiak and Qamanijuaq barren-ground caribou herds. We are so intrinsically tied that it is often stated that the Caribou are Dene; Dene are caribou*" (YNLR 2022). As the "lifeblood" of the Athabasca Denesųłiné, the range of caribou—which fluctuates due to natural cycles, climate change, forest fires, industrial development, and other factors—defines the extent of their traditional territory (YNLR 2022).

The Wheeler River Project: Métis Knowledge Study Report explained that kinship relationships, and the relationship to the land, are paramount to their culture:

> "*These kinship relationships between our communities and families, as well as those with our extended First Nations relation, are vital to our success as a community. As such, our traditions are often a blend of Michif, Cree, and Dene spirituality, as well as*

> *the Christian traditions. This blend forms a foundational piece of our understanding of our role in the world and in our communities and families."* (MN-S and Two World Consulting 2023).

Michif is a distinct language, combining French and Cree, and evolved from communication between the Indigenous mothers and European fathers, although Métis spoke many Indigenous languages through intermarriage among regions. Storytelling and oral histories are a time-honoured concept, with stories retold year after year, with each telling allowing listened "*to understand things differently while they age(d) and gain(ed) experience*" (MN-S and Two Worlds Consulting 2023).

Similarly, Métis artistic expression is a blend of Indigenous and European styles, reflective of the regional differences and communities from which individuals came:

> *"Beadwork, embroidery, and quillwork showcase intricate patterns and motifs that tell stories of cultural intersections and shared histories. Métis artisans often incorporate natural materials like porcupine quills, moose hair, and birch bark into their creations, highlighting a deep connection to the land*" (MN-S and Two Worlds Consulting 2023).

3.4.5 Interweaving Indigenous Knowledge and Western Scientific Knowledge

In the context of contemporary decision-making, Denison recognizes that IK systems offer an alternative source of knowledge, often complementary to western science (Eckert et al. 2020). Inclusion of IK alongside western scientific knowledge should be considered through all phases of an effects assessment. This not only addresses regulatory expectations, but also recognizes the value IK adds to project planning, the completion of the EIS, and throughout the lifespan of the Project. The degree to which each community has contributed may vary because they decide what IK and LK they want to share, how it should be collected, and how it should be included in the EA process.

3.4.6 Addressing Divergence Between Indigenous Knowledge and Western Scientific Knowledge Systems

In response to instances where IK and western science diverge, Denison has established principles to address and resolve potential disagreements. These principles are outlined in more detail in Section 4 as part of the Engagement plan; however, action to resolve diverging perspectives begins when concerns are raised about the EA process, the Project, or its potential impacts. Denison seeks to:

- collaborate with IK holders in developing potential solutions to those concerns;
- where necessary, adjust the initial plans for the Project to reduce potential impacts and accommodate Rights and interests; and

- make active and good-faith efforts to resolve all material issues in the above-identified fashion.

Using this approach, Denison seeks mutually acceptable agreement where western science and IK diverge. This not only addresses regulatory expectations, but also recognizes the value IK adds to Project planning including greater knowledge about the environment, understanding of potential impacts of the development, identifying mitigation, and the significance of those impacts.

In cases where IK and western scientific disagreement cannot be resolved, EIS authors were instructed to note the divergence in the limitations at the beginning of each discipline section as well as in the concluding sections that discuss confidence in the assessment determinations and how this has been addressed in the proposed mitigation and monitoring.

Discrepancies among IK and western scientific information provide an opportunity for Denison to take a precautionary approach. Examples of concrete actions to address uncertainty in cases where IK and LK have differing conclusions on predicted Project effects include addressing uncertainty through monitoring and follow-up programs and communicating results of those monitoring and follow-up programs to demonstrate they have been responsive to the IK shared.

3.4.7 Integrating Indigenous Knowledge, Local Knowledge and Engagement into the Environmental Impact Statement

Denison has recorded and stored information regarding IK, LK and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers. These numbers are referenced throughout the EIS, but particularly in Parts II and III, to indicate where specific information from the database has been integrated into the assessment

Within each section of Part II and Part III are subsections titled “Influence of Indigenous Knowledge, Local Knowledge and Engagement on the Assessment”. Within these subsections are summary tables that provide additional details related to each one of the unique identification numbers referred to in that section.

3.4.8 Lands Taken Up from an Indigenous Perspective

Cumulative effects assessment is important to Indigenous communities in general because incremental effects to the environment can weaken resource economies, affect important resources such as plants, fish, and wildlife, affect rights-based and cultural activities, and affect both the health of wildlife and humans (Indigenous Centre for Cumulative Effects 2021). Indigenous people have had a long-term and close connection to lands and waters since time immemorial and have been keenly observant of changes over an extended period. For that reason, Indigenous peoples are best positioned to understand how cumulative effects from development and other activities impact their lands, resources, and communities (Indigenous Centre for Cumulative Effects 2020).

Indigenous perspectives can be complementary to the CEA for the Project, and Denison acknowledges the important relationship of the Indigenous COI to the lands and waters. "*Active land users from Indigenous communities are often quite aware of changes that have happened to the environment over time. This information can be useful to proponents in understanding the baseline conditions of their Project Study Area*" (ERFN and SVS 2022b). Throughout the EA process, Denison has gathered and brought Indigenous Knowledge together with western science to make a better Project (e.g., evaluating and considering the Ecological Knowledge Features and Concerns) (ERFN and SVS 2022b).

In addition to Project-related engagement outcomes, the Indigenous COI of ERFN and the KML have shared their Indigenous Knowledge on past, present, and predicted cumulative effects through the following sources:

- *Wheeler River Project – Summary of Health and Socio-Economic Study Results* (ERFN and SVS 2022a);
- *Wheeler River Project - Summary of Traditional Knowledge Study Results* (ERFN and SVS 2022b);
- *Kineepik Valued Ecosystem Components – KML Pre-statement for Denison EIS* (KML and NVP 2022); and
- *Response to the Environment Impact Assessment For the proposed Ministry of Highways 914 Extension Project* (KML and Limnos Environmental 2022).

Should additional information become available from ERFN, KML, or from the Métis Nation Saskatchewan, this information will be considered as it becomes available.

English River First Nation Perspectives on Cumulative Impacts

English River First Nation explained their own history and experience of colonial effects, including residential schools, language loss, their resilience, and their steps towards recovery (ERFN and SVS 2022a). They described the importance of and efforts towards reconnecting to the lands and waters after past developments in their territory and overcoming uncertainty about how these cumulative effects may have affected the health of the resources they consume (ERFN and SVS 2022a).

As part of their Traditional Knowledge study, ERFN members were asked to reflect on how their traditional territory had changed over time (ERFN and SVS 2022b). An Elder spoke about the change that the highway brought. The Elder described different time periods beginning when the road reached the community, followed by its expansion across the Churchill River, and north to facilitate access to existing uranium mines and mills. The Elder noted,

> "*Well, basically we were in an isolated community before the roads came in… we had used the rivers and the lake systems for our transportation…I would say 30 to 40 years that has changed dramatically, in terms of the road access to these areas, roads*

> *being built because of corporations and because of development…would say the early 1980s, there was an abundance of moose, an abundance of caribou, on the Haultain area, but with the road coming in, there has been more people taking the moose, taking the caribou. Also, more people starting to settle in that area, in terms of cabins, and so on and so forth, which are not the English River First Nation members"* (ERFN and SVS 2022b).

Past mining activities also have brought in local roads and trails, cutlines, and clearing for exploration that disturb wildlife habitat and movements (ERFN and SVS 2022b). The operation of heavy equipment also has disrupted wildlife. One ERFN member explained:

> "*The whole area is sensitive now, with all the things that are going on. It's disturbing the environment; the environment has been disrupted. So, the animals, the birds, and the fish are all affected, especially where there's mining activity. Because of that, animals tend to move away. So, they're not around because of all the activities that are going on*" (ERFN and SVS 2022b).

Waste from previous developments and disturbances from exploration activities are still visible and generate concerns for the health and well-being of ERFN members (ERFN and SVS 2022b).

English River First Nation used a mapping analysis known as "lands taken up" to examine cumulative changes to the land base over time. The approach subtracted disturbed lands (i.e., those affected by human influence, such as settlement, infrastructure, mining, forestry, and other industrial activities, as well as environmental changes such as forest fire and climate change) from Nuhtsiye-kwi Benene (ERFN territory) to illustrate the remaining areas of intact forests, that is, lands that remain available for ERFN land use. Results illustrated disturbances along Highway 914 between Mawdsley Lake and the Key Lake gate and further north along the Key Lake – McArthur Falls haul road between the Key Lake gate and the Project. This area "*is an important gathering place for the ERFN community, where ancestors have passed on knowledge of fishing, trapping, hunting, plant harvesting areas, historical sites, and routes for travel that continue to be used today*" (ERFN and SVS 2022b). Given the importance of this area, ERFN stress the importance of minimizing further effects that fragment the landscape going forward (ERFN and SVS 2022b).

Kineepik Métis Local Perspectives on Cumulative Impacts

The KML have cared for their lands from time immemorial and describe their connection to the land as "*irreplaceable, authentic, and inherent*". Colonization events eroded cultural practices and language in the community (KML and NVP 2022). Based on being the nearest community south of the uranium mining and having partnered with Cameo Corporation, KML noted they have a unique perspective on the cumulative effects of uranium mining (KML and Limnos Environmental 2022). Historical activities are an important consideration for the community, who noted:

> *"We have issues on cumulative impacts from historical legacy exploration and mining practices. Not specific to Denison, Cameco or Orano our land users have often found remnants of past poor exploration practices that are now affecting our continued land use. The abandoned camps and industrial waste left with no community known program for clean up are the most significant of these remnants"* (KML and NVP 2022).

Similarly,

> *"Current regulation of hunting, fishing, tourism, resources development and increase human traffic will affect and limit our ability to practice our protected rights. KML request further study on how current provincial regulations including opportunity for co-management so lessen the impacts from this project"* (KML and NVP 2022).

The KML also note the relationship of these activities to their ability to be on the land:

> *"While one project or mining operation does not materially affect our land use practices. The substantial and growing projects and mineral exploration activity severely limits our ability to practice continued and use for the region north of Haultain River. KML land users' limitation are leading to complete exclusion of the area for food sovereignty. As an example of this our hunting practices currently use high powered rifles to engage with big game including moose, bear, deer, and caribou in the area. With the significant and growing numbers of projects we do not know how we can continue to practice this method of food gathering in a safe method"* (KML and NVP 2022).

The community is concerned with the increased traffic on the road and would like better information on safety processes for community members and maintenance plans for the road (KML and Limnos Environmental 2022). With respect to the Project, the KML note that the Project alone is not expected to cause any material effect on land use, but future expansion of exploration activities and the Highway 914 extension project may cumulatively change access to resource harvesting locations and, therefore, food supply (KML and NVP 2022).

The KML noted that Denison provides "*best in class engagement practices*" and look forward to solving concerns and finding opportunities to increase community capacity in areas such as emergency response and waste management (KML and NVP 2022).

The MN-S (MN-S and Two Worlds Consulting 2023) describe some of the factors that have contributed to cumulative changes to land and resource use across their homeland including:

- imposed government programs and policies, such as the establishment of the Treaties; the game laws and fishing restrictions created by the federal and provincial governments; and the creation of the Primrose Lake Air Weapons Range;

- changes to wildlife behaviour, particularly changes to woodland caribou behaviour as a result of habitat loss, climate change, and other environmental changes;
- settler relationships and access to land and resource use over time (e.g., non-Indigenous purchase of cabins in northern Saskatchewan); and
- development activities, including various on-going uranium operations; access roads and highways; creation of campgrounds and recreation areas; presences of lodges, outfitters, and tourism; hydroelectric and transmission facilities; and abandoned mines.

The Metis Knowledge Study acknowledges that the extraction of natural resources (e.g., minerals, timber) contributes to both economic opportunities and environmental challenges, and the need to strike a balance to promote their economic interests while safeguarding the environment (MN-S and Two World Consulting 2023).

How Indigenous Perspectives Influenced the Cumulative Effects Assessment

For the purposes of this EIS, "*cumulative impacts can include environmental, socio-cultural, or economic changes that are caused by a combination of natural or human activities*" (ERFN and SVS 2022b). For the Project CEA, all residual effects, regardless of significance, are considered in each of the respective CEA for each VC. In determining potential cumulative effects, the CEA considers whether residual adverse effects of the Project on a given VC will overlap spatially and temporally with the same residual adverse effects on the VC resulting from other past, present, and reasonably foreseeable projects or activities.

Denison recognizes that Indigenous Knowledge systems offer an alternative source of knowledge, often complementary to western science (Eckert et al. 2020). The CEA for the Project follows standard methodology as per provincial (e.g., Guidelines for an Environmental Assessment under the [Saskatchewan] *Environmental Assessment Act*, 1980; Government of Saskatchewan 2022) and federal guidance (e.g., Assessing Cumulative Environmental Effects under the *Canadian Environmental Assessment Act*, 2012; Government of Canada 2019a). Among the sources of information to consider, the federal guidance notes the importance of *"Aboriginal traditional knowledge, community knowledge and scientific knowledge, or simply an expression of concern regarding potential cumulative effects to a particular VC"* (Government of Canada 2019). All sources of information were considered by discipline leads as described in this EIS section and Section 4 Engagement. The CEA for all VCs completed for the Project incorporated, as appropriate, the characterization of activities/events that have shaped the existing environment and continue to influence the VCs used for the EIS.

Much of the information shared by the Indigenous COI reflects upon their experience with past industry and other colonial factors that have shaped the existing environment, combined with their knowledge and understanding of the resources that support each communities' continued ability to express their Indigenous and Treaty Rights. Denison has considered and presented this information throughout the EIS consistent with federal guidance, which notes:

> *"Where a cumulative effects assessment gathers information useful to understanding the historical context of past impacts on Aboriginal rights, practitioners should keep in mind that, in the context of consultation and accommodation, such information will also help in understanding potential impacts to Aboriginal rights"* (Government of Canada 2019).

3.5 Summary of Indigenous Knowledge and Local Knowledge in the Environmental Assessment

3.5.1 Indigenous Knowledge in the Environmental Impact Statement

During the EIS, inclusion of IK provided greater knowledge about the environment and understanding of potential effects of the Project and the significance of those effects. Table 3.5-1 contains a record of how IK has been interwoven into the existing environment and effects assessment sections in Parts II and III of the EIS. The information is sorted according to discipline and detailed for each relevant aspect of the assessment.

Table 3.5-1: How Indigenous Knowledge was Incorporated into Existing Environment and Effects Assessment Sections

Discipline	Aspect Influenced	Section(s)	How Indigenous Knowledge was Incorporated	Source of Indigenous Knowledge (Community)
Groundwater	Project Design	7.2	Comments associated with concerns to groundwater quality, changes in water levels and quantity, and discharge to the environment were significant and these were considered within the context of community interest in the groundwater remaining supportive of surface water quality and discharge quantity and impacts to groundwater levels and quality. To this end, groundwater management, monitoring, mitigation, and evaluation of groundwater impacts are important to maintaining groundwater levels and water quality within the Local Study Area (LSA) and Regional Study Area (RSA).	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
	Assessment	7.4	Indigenous Knowledge was valuable to understand the concern of water levels and impacts to fish and fisheries.	English River First Nation
	Mitigation	7.5	Specific concerns over the impacts from mining.	Kineepik Métis Local #9 and Northern Village of Pinehouse
	Monitoring and Follow Up	7.8	Specific concerns with respect to understanding the local hydrogeological setting. The information in the reports was valuable to understand the need for a robust monitoring program pre-mining that takes into account water levels in the local aquifers.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
Aquatic Environment	Project Design	8.2.2	Environmental advantages of the in situ recovery (ISR) mining at Phoenix and the potential to avoid discharges into surface waters were noted.	Kineepik Métis Local #9 and Northern Village of Pinehouse
	Existing Environment	8.3.2, 8.3.3	Indigenous Knowledge was used to determine traditional land activities that regularly occur in the area, such as fishing and navigation (boating). Indigenous Knowledge identified two camps (ERFN Culture Camp and the Kineepik Métis [Pinehouse] camp) of particular importance to local Indigenous residents.	English River First Nation Athabasca Denesųłiné First Nations and Communities
			Indigenous Knowledge was also important for determining traditional food consumption in the Project area, especially in terms of frequency and diet composition. The ERFN Country Foods Study was used to determine the traditional food diet.	English River First Nation

Discipline	Aspect Influenced	Section(s)	How Indigenous Knowledge was Incorporated	Source of Indigenous Knowledge (Community)
	Assessment	8.3.2, 8.3.4	Indigenous Knowledge provided confirmation and additional information in identifying fish presence/absence and critical life history use habitats in the LSA.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
Terrestrial Environment - Ungulates, Furbearers, and Woodland Caribou	Existing Environment	9.3.3.1, 9.3.3.2, 9.3.3.3	Indigenous Knowledge improved understanding of species' habitat and diet preferences, calving areas, population trends, and local harvest.	English River First Nation Athabasca Denesųłiné First Nations and Communities
	Assessment	9.3.6, 9.3.7	Indigenous Knowledge improved and confirmed knowledge was considered in the residual effects assessment and the cumulative effects assessment (CEA), including site access and noise disturbance.	English River First Nation Athabasca Denesųłiné First Nations and Communities
Terrestrial Environment – Raptors, Migratory Breeding Birds, and Bird Species at Risk	Existing Environment	9.4.3.1.2, 9.4.3.2.2, 9.4.3.3.2	Indigenous Knowledge improved understanding of species' distribution and regional population trends.	English River First Nation
	Assessment	9.4.6.3.2, 9.4.7	Indigenous Knowledge was considered in the residual effects assessment and the CEA. Concerns about decreasing numbers in some species and increased access to the area were incorporated into the CEA.	English River First Nation
Human Health and Ecological Risk Assessment	Existing Environment	10.1.3	Indigenous Knowledge was used to determine traditional land activities that regularly occur in the area, such as fishing, hunting, trapping, and gathering. Indigenous Knowledge identified two camps (ERFN Culture Camp and the Kineepik Métis [Pinehouse] camp) of particular importance to local Indigenous residents. Indigenous Knowledge was also important for determining traditional food consumption in the Project area, especially in terms of frequency and diet composition. The ERFN Country Foods Study was used to determine the traditional food diet. IK from ERFN indicated that they have a strong connection to the land and the importance of the natural environment.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Athabasca Denesųłiné First Nations and Communities
Heritage Resources	Existing Environment	11.3.3	Indigenous Knowledge was used to confirm that the Project area contained cultural resources.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse

Discipline	Aspect Influenced	Section(s)	How Indigenous Knowledge was Incorporated	Source of Indigenous Knowledge (Community)
Indigenous Land and Resource Use (ILRU)	Assessment Approach	11.1.2	The social, cultural, and economic value of ILRU and future goals for the continuation of ILRU was communicated. Indigenous Knowledge provided an understanding that overall health and well-being is derived from both the consumption of resources and the practice of harvesting them, which contributed to the selection of Key Indicators. Indigenous Knowledge indicated that the communities needed to have confidence in the ISR mining approach so this was included within the assessment and follow-up engagement designed.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Athabasca Denesųłiné First Nations and Communities Métis Nation Saskatchewan
	Existing Environment	11.1.3.2	Indigenous Knowledge described the connection to the land for Indigenous peoples including: • the gifts of shelter and medicines that the land provides; • the meaning and value of water; • how respect is taught and passed on to future generations; and/or • a growing desire to reconnect with the land and waters and continue traditional activities. The importance of specific resources for hunting, fishing, trapping and gathering was explained including their relative importance to diet.	English River First Nation Athabasca Denesųłiné First Nations and Communities Métis Nation Saskatchewan
	Assessment	11.1.4	Specific concerns were communicated. These included: • change in the abundance of animals; • air quality; • workforce fishing levels; • noise; • potential for accidental release of pollution; • the safety of drinking water downstream of the treated effluent discharge pipe; and • the ISR mining method and its safety for animals and human health. These concerns were then incorporated into the assessment to determine the nature of the potential effect.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan

Discipline	Aspect Influenced	Section(s)	How Indigenous Knowledge was Incorporated	Source of Indigenous Knowledge (Community)
Other Land and Resource Use (OLRU)	Existing Environment	11.2.3	Historic trapping and trapping trails were described, which provided context for the boundaries of the traditional territory. Commercial fishing history was described and mapped including the species harvested, the seasons, and the timeframe that commercial fishing was undertaken.	English River First Nation Métis Nation Saskatchewan
	Assessment	11.2.4	The locations where commercial fishing and commercial trapping were considered in relation to potential Project effects.	English River First Nation Métis Nation Saskatchewan
Cultural Expression	Assessment Approach	12.1.2	Indigenous Knowledge confirmed the key indicators for community well-being and that residents in the LSA benefit from the employment and business opportunities that come with resource development projects.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan
	Existing Environment	12.1.3	Indigenous Knowledge was used to describe the key indicators: information pertaining to knowledge transmission (inclusive of language), land-based cultural programs, land-based programming and supports, and travel routes and habitation; and traditional diet, which supports social bonds within families and communities.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan
	Assessment	12.1.4.2	Indigenous Knowledge contributed to the characterization of changes to: • participation in cultural practices and subsequent knowledge transmission as a result of employment (e.g., time spent away from community because of the worker rotation schedule); • location of cultural practices to support knowledge transmission because of restricted access or avoidance of areas; • change in availability of country foods that support a traditional diet because of restricted access to or avoidance of hunting, fishing, trapping, and gathering areas; and • change in perceived suitability of country foods that are part of a traditional diet.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan

Discipline	Aspect Influenced	Section(s)	How Indigenous Knowledge was Incorporated	Source of Indigenous Knowledge (Community)
	Mitigation	12.1.5	Indigenous Knowledge informed mitigation for cultural expression such as: • working with Indigenous communities to understand their important harvest times and cultural camps to support Indigenous employees in taking time off to participate in such events; and • measures protective of Indigenous land and resource use.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
Community Well-Being	Assessment Approach	12.2.2	Indigenous Knowledge verified and confirmed the key indicators for community well-being and that residents in the LSA benefit from the employment and business opportunities that come with resource development projects.	Kineepik Métis Local #9 and Northern Village of Pinehouse
	Existing Environment	12.2.3.1, 12.2.3.2, 12.2.3.3	Indigenous Knowledge confirmed and verified information for the existing environment, including: • challenges and barriers to seeking post-secondary education, employment, and other economic opportunities; • youth access to education and employment as a priority; • the importance of traditional activities including for mental health and well-being, spiritual health, and cultural identity; and • social values and kinship rooted in relationships to the land and their importance to social cohesion.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan
	Assessment	12.2.4.2.1, 12.2.4.2.2, 12.2.4.2.3	Indigenous Knowledge confirmed and verified information for the assessment of Community Well-being, including: • the challenges and barriers of the remote location of LSA communities such as access a lack of economic opportunities and employment; • new projects (i.e., mining industry) are seen as a benefit for LSA communities including for employment and business opportunities; and • the importance of having Elders on site at resource development projects to continue to play a role as a knowledge holders, connection to family and culture, and to provide cultural programming.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan

Discipline	Aspect Influenced	Section(s)	How Indigenous Knowledge was Incorporated	Source of Indigenous Knowledge (Community)
	Mitigation	12.2.5	Indigenous Knowledge informed and confirmed mitigations for Community Well-being, including: • the need for pick-up point; • a no alcohol and drug policy on site; and • the need for culturally sensitive employment policies that support the Indigenous workforce, such as an Elder representative to provide cultural programming or minimizing Project activity during key cultural events.	(Informed through existing environment and assessment) English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
Infrastructure and Services	Assessment Approach	12.3.2, 12.3.3.1	Indigenous Knowledge verified and confirmed the key indicators for Infrastructure and Services.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
	Existing Environment	12.3.3.2.1, 12.3.3.3.1, 12.3.3.3.2	Indigenous Knowledge verified and confirmed information for the existing environment, including: • highway descriptions (Highway 914 and 165) and Key Lake gatehouse access; • education infrastructure and programming; • health facility services, providers, and programming; • social services and programming; and • recreational infrastructure and services.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
	Assessment	12.3.4.2.1, 12.3.4.2.2	Indigenous Knowledge confirmed and verified information for the assessment of Infrastructure and Services, including: • concerns for increased truck traffic and truck traffic incidents as a result of the Project; • a need for better information on transportation safety processes; and • concerns for becoming a through road community that could further dilute community and emergency services currently in place.	Kineepik Métis Local #9 and Northern Village of Pinehouse
	Mitigation	12.3.5	Indigenous Knowledge informed and enhanced mitigations for Infrastructure and Services, including the need for an Environment and Culture Monitor and the need for an on-site Elder to provide culturally relevant programming and support.	(Informed through existing environment and assessment) English River First Nation

Discipline	Aspect Influenced	Section(s)	How Indigenous Knowledge was Incorporated	Source of Indigenous Knowledge (Community)
Economy	Assessment Approach	13.1.1, 13.1.2, 13.1.4	Indigenous Knowledge confirmed and verified the key indicators for economy and confirmed and verified the economic aspects of the Project that could be challenging or cause concern for members, including that jobs and employment should be prioritized for Indigenous communities.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan
	Existing Environment	13.1.1, 13.1.2, 13.1.4, 13.2, 13.2.1, 13.2.3, 13.2.4	Indigenous Knowledge confirmed and verified information for the existing environment, including • challenges and barriers to seeking post-secondary education, employment, and other economic opportunities (including barriers associated to the remote location of communities and costs and time commitments for education and training); • the need to prioritize Indigenous communities for employment and contracting opportunities; • that youth access to education and employment is a priority including that previous resource development projects have encouraged younger generations to graduate and advance careers; • that limited employment opportunities currently exist (including job advancement) for Indigenous communities and its residents; and • the importance of the traditional economy to communities and its residents.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan
	Assessment	13.3.2	Indigenous Knowledge confirmed and verified information for the assessment of Economy, including: • the importance of the traditional economy to the economic well-being of community members; • the positive impacts resource development has brought in terms of training and employment to Indigenous communities (including through Des Nedhe and PBN Construction); • that employment opportunities have encouraged younger generations to graduate and advance careers; and • that consensus exists among community members that the Project will benefit the community through employment opportunities and local community owned business and contracting opportunities.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Métis Nation Saskatchewan

Discipline	Aspect Influenced	Section(s)	How Indigenous Knowledge was Incorporated	Source of Indigenous Knowledge (Community)
	Mitigation	13.4	Indigenous Knowledge informed mitigation and enhancement measures for Economy, including: • the need for agreements with Indigenous communities to reflect community interests and objectives relative to Project opportunities; • workforce development plans to prioritize Indigenous and non-Indigenous communities in the LSA in terms of employment and training opportunities and hiring practices during all phases of the Project; and • the establishment of a procurement approach prioritizing businesses within LSA communities throughout all phases of the Project.	(Informed through existing environment and assessment) English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
Accidents and Malfunctions	Assessment	14.4, 14.6.7	Incorporated traffic related accident scenario along the transportation route at cultural camp locations identified in IK.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse

3.5.2 Local Knowledge in the Environmental Impact Statement

During the EIS, inclusion of LK provides greater knowledge about the environment and understanding of potential effects of the development and the significance of those effects. Table 3.5-2 contains a record of how LK has been interwoven into the existing environment and effects assessment sections. The information is sorted according to each discipline and detailed for each relevant aspect of the assessment.

Table 3.5-2: How Local Knowledge was Incorporated into Existing Environment and Effects Assessment Sections

Discipline	Aspect Influenced	Section(s)	How Local Knowledge was Incorporated	Sources of Local Knowledge
Noise	Assessment	6.2.4	As the concern was related to leased property, all leases in the study area were assumed to have a cabin and were included in the assessment.	Lease Survey
	Mitigation	6.2.5	While no exceedances of the guideline limits were predicted at any of the lease properties, mitigation measures were outlined to assist in controlling noise during construction and operations as there was a predicted increase in sound level during construction that may be noticeable.	Lease Survey
	Monitoring	6.2.8	A follow-up noise monitoring program will be completed as an outcome of the analysis to confirm that the sound levels at the nearest leased property is within the guideline limits.	Lease Survey
Groundwater	Assessment Approach	7.2	Local Knowledge was used to inform the use of groundwater in the area and the groundwater to surface water interactions. It was important to understand the use of water and protection of the aquifer system to surface water bodies.	ERFN Trapper
	Existing Environment	7.3	Study evaluation to confirm appropriate baseline groundwater monitoring.	ERFN Trapper
	Monitoring	7.8	Local Knowledge was used to inform and confirm the monitoring of groundwater quality in pre-operational and post-operational phases of the Project.	ERFN Trapper
Aquatic Environment	Existing Environment	8.3.2, 8.3.3, 8.3.4	Local Knowledge was used to determine traditional land use activities that regularly occur in the area. Specifically, LK for the fish and fish habitat assessment was generally gathered through consultation with a local fisher/trapper. Consultations with the ERFN Trapper provided confirmation and additional information in identifying fish presence/absence and critical life history use habitats in the LSA. Confirmation of fish and fish habitat information through follow-up consultation. Consultations with the ERFN Trapper provided confirmation and additional information in identifying fish presence/absence and critical life history use habitats in the LSA.	ERFN Trapper
Terrestrial Environment – Vegetation and Ecosystems	Existing Environment	9.2.3.1.1	Included cultural plant use references.	ERFN Trapper Lease Survey
	Assessment	9.2.4.2.1, 9.2.4.2.2, 9.2.4.2.1	Included reference to desire for progressive reclamation.	ERFN Trapper Lease Survey

Discipline	Aspect Influenced	Section(s)	How Local Knowledge was Incorporated	Sources of Local Knowledge
Terrestrial Environment - Ungulates, Furbearers, and Woodland Caribou	Existing Environment	9.3.3.1, 9.3.3.2, 9.3.3.3	Improved understanding of species' habitat and diet preferences. Confirmed species population trends. Improved information on local harvest.	ERFN Trapper
	Assessment	9.3.6, 9.3.7	Improved and confirmed local knowledge was considered in the residual effects assessment and the CEA. Concerns about increased access were incorporated into the CEA.	ERFN Trapper
Terrestrial Environment - Raptors, Migratory Breeding Birds, and Bird Species at Risk	Existing Environment	9.4.3.2.2, 9.4.3.3.2	Improved understanding of species' distribution and regional population trends.	ERFN Trapper
	Assessment	9.4.6. 9.4.7	Improved knowledge that was considered in the residual effects assessment and the CEA. Concerns about decreasing numbers in some species and increased access to the area were incorporated into the CEA.	ERFN Trapper
Human Health and Ecological Risk Assessment	Existing Environment	10.1.3	Local Knowledge was used to determine traditional land use activities that regularly occur in the area such as fishing, hunting, trapping, and gathering. Specifically, LK for the human health and safety assessment was generally gathered through consultation with a local fisher/trapper.	ERFN Trapper KPI Program 2018
	Assessment	10.1.4	Information gathered during consultation with local community members was used to determine residency characteristics for the recreational fisher/hunter/firewood gatherer and the fisher/trapper receptors; specifically, the location of cabins and hunting/fishing areas near Denison mine and the length of time spent in the Project area versus the reference area. Consultation with the ERFN Trapper was also helpful in determining local traditional food diet composition and the proportion of traditional foods in the diet.	KPI Program 2019 ERFN Trapper
			The Lease Holder survey was used to determine the locations of a few operational cabins near the Project area and their uses. It also confirmed that traditional activities such as fishing and hunting are regularly occurring activities in the Project area.	Lease Survey

Discipline	Aspect Influenced	Section(s)	How Local Knowledge was Incorporated	Sources of Local Knowledge
Heritage Resources	Existing Environment	11.3.1.1, 11.3.3	Local Knowledge confirmed that the Project area could have cultural/heritage resources as the area is the traditional territory of three separate Indigenous groups.	English River First Nation Ya'thi Néné Land and Resources Office Kineepik Métis Local #9 and Village of Pinehouse Lake Lease Survey
Indigenous Land and Resource Use (ILRU)	Existing Environment	11.1.3.1 11.1.3.2	The traditional territories boundaries and seasonal travel routes were shared and mapped for use in the assessment and to provide an understanding of historic and contemporary land use places and areas. Travel on local waterbodies, overland trails, and cabins were described and mapped, which helped understand any potential effects on navigation, travel, cabins or campsites. Resources harvested through hunting, fishing, trapping and gathering were mapped and described to provide an understanding of the extent, frequency, and importance of this land use. Important cultural and sacred gathering spots were described and the importance of cultural camps for the continuation of culture was explained so that any changes to these features could be assessed.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse Athabasca Denesųłiné
	Assessment	11.1.4, 11.1.4.5	The ERFN Trapper provided perspectives on how the Project may affect ERFN Trapper's land use. Provided concerns about potential changes to water quality at treated effluent discharge location, and the ability to drink surface water untreated in proximity to the Project. Asked about accidents and malfunctions including failure of freeze wall and follow up explanation was provided to explain that the freeze wall takes an extended period of time to thaw. Provided perspectives and details about concerns with respect to increases in traffic associated with Project activities.	ERFN Trapper English River First Nation Kineepik Métis Local Northern Village of Pinehouse
	Mitigation	11.1.5.3	Provided concerns about ISR mining (new to Canada) and perceived benefits (no mill, tailings, and better overall environmentally). Planned follow-up was developed to conduct further engagement about the ISR technology.	English River First Nation, Lodge owner, Northern Village of Pinehouse

Discipline	Aspect Influenced	Section(s)	How Local Knowledge was Incorporated	Sources of Local Knowledge
	Cumulative Effects	11.1.7	Expressed concerns about future interactions that ILRU could have with the Highway 914 extension project and traditional use.	English River First Nation Kineepik Métis Local #9 and Northern Village of Pinehouse
Other Land and Resource Use (OLRU)	Assessment Approach	11.2.1.1 11.2.1.2	The selection of OLRU as a Valued Component and its Key Indicators was supported by engagement with communities.	English River First Nation, Northern Village of Pinehouse, Northern Village of Beauval
	Existing Environment	11.2.3.2 11.2.3.4	The ERFN provided a multi-generational history of trapping that informed the Commercial Trapping section. The value of species for income was explained. The ERFN provided information about their participation in the lodge and outfitting industry which provided perspectives on the resource economy. Travel on local waterbodies, overland trails, and cabins were described and mapped, which helped understand any potential effects on navigation, travel, cabins or campsites. Specific concerns related to commercial activities were incorporated into the assessment to determine the nature of the potential effect.	English River First Nation
		11.2.3.3.1	Locations where commercial fishing was conducted by residents provided understanding of the potential for effects on commercial fishing.	English River First Nation Ya'thi Néné Land and Resources Office
	Assessment	11.2.4.4	The ERFN provided information on how management of trapping on Fur blocks N-18 and N-16 is conducted, which enabled appropriate consideration of mitigation options.	English River First Nation
		11.2.4.5.1	Provided an understanding of concerns with respect to air quality.	English River First Nation
		11.2.4.5	Provided perspectives and details about concerns with respect to increases in traffic associated with Project activities Provided concerns about the potential for workforce fishing and how this fishing may interact with the local environment around the cabin.	Kineepik Métis Local #9 Cabin Owner
		11.2.4.5	Provide concerns about ISR mining (new to Canada) and perceived benefits (no mill, tailings, and better overall environmentally). Planned follow-up was developed to conduct further engagement about the ISR technology.	English River First Nation, Lodge owner, Northern Village of Pinehouse

Discipline	Aspect Influenced	Section(s)	How Local Knowledge was Incorporated	Sources of Local Knowledge
		11.2.4.5	Provided concerns about potential changes to water quality at treated effluent discharge location (LA-5).	Cabin Owner
		11.2.4.5	Asked about accidents and malfunctions including failure of freeze wall and follow up explanation was provided to explain that the freeze wall takes an extended period of time to thaw.	English River First Nation Northern Village of Pinehouse
	Cumulative Effects	11.2.7	Concerns were raised about increased access into the OLRU LSA by interactions with the Highway 914 extension project and the bypass of the Key Lake gate.	Lodge Owner, Cabin Owners, ERFN Trapper Kineepik Métis Local #9 and Northern Village of Pinehouse
Community Well-Being	Existing Environment	12.2.3.1, 12.2.3.3	Local Knowledge confirmed and verified information for the existing environment, including: • the importance of family, kinship, and community for LSA community cohesion; • concerns of family members and community members working for a resource development project being taken out of community for periods at a time (such as commuter rotation); • the benefits of resource development projects on the local economy including increased income and employment opportunities; and • that the main policing issues in Beauval and Pinehouse Lake include offences related to drugs and alcohol.	KPI Program 2021-2022
	Assessment	12.2.4.2.3, 12.2.4.2.1, 12.2.4.2.3	Local Knowledge confirmed and verified information for the assessment of Community Well-being, including: • factors that influence migration decisions include access to employment, income, and education; • concerns of family members and community members working for a resource development project being taken out of community for periods at a time (such as commuter rotation); • the benefits of resource development projects on the local economy including increased income and employment opportunities; and • concern for the potential adverse effects from increased income on workers, their families, and communities such as those related to drug and alcohol use and addictions.	KPI Program 2021-2022

Discipline	Aspect Influenced	Section(s)	How Local Knowledge was Incorporated	Sources of Local Knowledge
	Mitigation	12.2.5	Local Knowledge informed and enhanced mitigations for Community Well-being, including the need for pick-up points to reduce hardship on employees and a no alcohol and drug policy on site.	(Informed through existing environment and assessment) KPI Program 2021-2022
Infrastructure and Services	Existing Environment	12.3.3.2.1, 12.3.3.3.1	Local Knowledge verified and confirmed information for the existing environment, including: highway descriptions (Highway 914 and 165) and Key Lake gatehouse access.	KPI Program 2021-2022
	Assessment	12.3.4.2.1, 12.3.4.2.2	Local Knowledge verified and confirmed the understanding of individuals and communities' key interests and concerns related to Project truck traffic and community infrastructure and services, including an understanding of social services and health services gaps for Beauval and Pinehouse Lake.	KPI Program 2021-2022 Lease Survey
Economy	Existing Environment	13.2.3	Local Knowledge, through an ERFN Trapper, confirmed and verified information for the existing environment, including information on the traditional economy in and near the LSA, such as wildlife and fish species population and distribution and hunting, fishing, and trapping.	ERFN Trapper
	Assessment	13.3.2	Local Knowledge, through an ERFN Trapper, verified and enhanced information on the traditional economy in and near the LSA.	ERFN Trapper

Glossary

Term	Definition
Duty to Consult	First Nations, Inuit and Métis peoples in Canada have unique rights that are guaranteed under section 35 of the Constitution Act, 1982. Section 35 recognizes and affirms the existing Aboriginal and treaty rights of Indigenous peoples. As a way to protect these rights, the doctrine of the duty to consult and, where appropriate, accommodate Indigenous groups, was developed by Canadian courts.
Indigenous Community of Interest	A community whose traditional land or potential or established Aboriginal and/ or Treaty rights are in proximity to the Project or has existing transportation infrastructure that would be used by the Project. An Indigenous Community of Interest is more likely to experience impacts from the Project.
Indigenous Community	An Indigenous community with a potential interest in the Project, including any Indigenous community identified by a Regulatory Agency as having a potential interest in the Project.
Indigenous Knowledge	Indigenous Knowledge is also known as Aboriginal Traditional Knowledge and Traditional Ecological Knowledge. Generally, Aboriginal Traditional Knowledge is considered as a body of knowledge built up by a group of people through generations of living in close contact with nature. Aboriginal Traditional Knowledge is cumulative and dynamic. It builds upon the historic experiences of a people and adapts to social, economic, environmental, spiritual and political change.
Indigenous Organization	An operation or organization that is owned and/or operated by an Indigenous Community or group of Indigenous Communities or has been delegated the right to represent an Indigenous Community or group of Indigenous Communities in connection with the Project.
Indigenous People	Section 35 of the *Constitution Act, 1867* defines the term “Aboriginal peoples of Canada” as referring to the First Nation, Inuit and Métis peoples of Canada. The term “Indigenous” is used interchangeably with “Aboriginal”.
Interested Party	Any person or organization that can affect, be affected by, perceive itself to be affected by, or is interested in a decision or activity related to the Project.
Local Knowledge	Specialized knowledge developed through long-term association, interaction, and cumulative experience.
Non-Indigenous Community of Interest	A municipality or other non-Indigenous community located near the existing transportation infrastructure utilized by the Project. A Non-Indigenous COI may experience efforts by Denison to offer employment, training, and business opportunities in connection with the Project and therefore may experience positive socioeconomic impacts as a result of the Project.
Northern Saskatchewan Administration District	The Northern Saskatchewan Administration District is defined in the province of Saskatchewan’s *Northern Municipalities Act, 2010.* The Northern Saskatchewan Administration District includes approximately 250,000 square kilometres (about 44% of Saskatchewan’s land area) but is home to only 38,000 people or less than 4% of the province’s population. Residents of the Northern Saskatchewan Administration District live in over 40 communities, which include incorporated municipalities (towns, villages, hamlets and settlements – most of which self-identify as Métis communities), First Nation reserves, and unincorporated areas. More than 80% of people who live in the Northern Saskatchewan Administration District self-identify as Indigenous.
Valued Components	Valued Components are aspects of the biophysical and human environments that may be affected (adversely or positively) by the Project. The value of a component not only relates to its role in the environment, but also the value people place on it.

4 Engagement

4.1 Introduction

Denison Mines Corp. (Denison) understands the importance of engaging with Indigenous communities and organizations, the general public, and regulatory agencies, collectively referred to as Interested Parties. Since 2016, Denison has engaged with Interested Parties to develop meaningful relationships so a collaborative approach to the Wheeler River Project (the Project) can take place. Denison has developed and implemented a Project engagement plan to guide and structure engagement activities. This section will describe the engagement requirements and activities undertaken by Denison regarding the Project up to January 2024. The activities have been designed to comply with regulatory requirements detailed in Section 4.1.1.

4.1.1 Regulatory Context

The Project is subject to both federal and provincial Environmental Assessment (EA) processes under the *Canadian Environmental Assessment Act, 2012* (CEAA 2012; Government of Canada 2019) and *The Environmental Assessment Act* (Government of Saskatchewan 2018). Requirements for engagement under each regulatory process include the following guidance documentation:

- Canadian Nuclear Safety Commission (CNSC) requirements (under CEAA 2012 assessment):
  - P*ublic and Indigenous Engagement – Public Information and Disclosure* (CNSC 2018). Licensees and licence applicants of uranium mines and mills, Class I and applicable Class II nuclear facilities shall develop and implement a public information program that includes a disclosure protocol. The public information program and its disclosure protocol shall be commensurate with the public's perception of risk and the level of public interest in the licensed activities, which may be influenced by the complexity of the nuclear facility's lifecycle and activities, and the risks to public health and safety and the environment perceived to be associated with the facility and activities.
  - *Public and Indigenous Engagement – Indigenous Engagement* (CNSC 2022). The CNSC identifies requirements for CNSC licensees, with respect to Indigenous engagement. It also provides guidance and information on conducting Indigenous engagement activities. The CNSC has the responsibility for fulfilling its legal duty to consult, and where appropriate, accommodate Indigenous peoples when its decisions may have an effect on potential or established Indigenous and/or treaty rights. This includes the requirement to complete an Indigenous Engagement Report (IER). This report must include a list of Indigenous groups identified for engagement, summary of engagement activities conducted to date, a description of planned Indigenous engagement activities, and a proposed schedule for reporting to the CNSC.

  - *Guidance on Indigenous Engagement for Proposed Projects undergoing Environmental Assessments under CEAA 2012* (CNSC 2021). The guidance document is intended to assist the proponent in preparing Indigenous documentation that will satisfy CNSC's requirements for undergoing an EA under CEAA 2012. The document includes a description of what is expected in the Environmental Impact Statement (EIS) and the IER, CNSC's requirements for the key steps in the EA process (draft and final EIS submissions), and details on how the proponent must demonstrate they have conducted adequate or complete Indigenous engagement (including instructions related to engagement methods, topics, and recording of Indigenous engagement (i.e., a record of engagement and a summary of issues and concerns by Indigenous groups).
  - *Generic Guidelines for the Preparation of an Environmental Impact Statement, pursuant to the CEAA 2012* (CNSC 2016). These guidelines summarize the requirements of CEAA 2012 for public participation and Indigenous engagement. The purpose of these guidelines is to ensure opportunities for meaningful public and Indigenous peoples participation during an EA and to provide the public and Indigenous peoples with opportunities to participate in the EA. Meaningful public and Indigenous participation is best achieved when all parties have a clear understanding of the proposed project as early as possible in the review process. The proponent is required to provide current information about the project to the public and Indigenous peoples and especially to the communities likely to be most affected by the project (CNSC 2016).
- Saskatchewan requirements:
  - *First Nation and Métis Consultation Policy Framework* (Government of Saskatchewan 2010). The Government of Saskatchewan's Duty to Consult Policy states that consultation with First Nations and rights-bearing Métis communities is required prior to any decisions that may affect Treaty Rights, Aboriginal Rights, and traditional uses of land and resources. The Duty to Consult Policy is in place to advance reconciliation and promote certainty for Saskatchewan residents, including First Nations and Métis.
  - Proponent's Guide: Consultation with First Nations and Métis in Saskatchewan Environmental Impact Assessment – Guidelines for Engaging and Consulting with First Nations and Métis Communities in Relation to Environmental Assessment in Saskatchewan (Government of Saskatchewan 2014). This document provides direction for project proponents on the Ministry of Environment's requirements for consultation with First Nations and Métis is outlined in this Government of Saskatchewan's Proponents Guide. Engagement must be carried out by the proponent during all stages of the EA. The Duty to Consult process aims to make sure all pertinent information received during engagement activities will be incorporated in the EA, the engagement process is well-documented for the Ministry to assess if the proponent fulfilled engagement requirements, and any potential

effects to Indigenous rights and traditional uses and resources have been documented and mitigated as to the best of the proponent's abilities.

- *Proponent Handbook – Voluntary Engagement with First Nations and Métis Communities to Inform Government's Duty to Consult Process* (Government of Saskatchewan 2013). The Government of Saskatchewan has a Duty to Consult with First Nations and Métis communities when there is a possibility of effects to Treaty and Aboriginal rights, or Traditional uses of lands and resources, resulting from a decision or action.
- *Guidelines for the Terms of Reference and Environmental Impacts Statement* (Government of Saskatchewan 2021). This guideline provides information to assist proponents in developing a term of reference and EIS for a proposed project determined to be a development pursuant to Section 2(d) of *The Environmental Assessment Act* (Government of Saskatchewan 2018). The guidelines outline the staged process a proponent must follow, general EIS requirements, advice on confidentiality, and how the province and federal governments cooperate in the EA process. Template guides are provided for the terms of reference and the EIS, including information related to engagement.

4.1.2 Denison's Indigenous Peoples Policy and Investment and Sustainability Philosophy

In 2021, Denison announced the adoption of an Indigenous Peoples Policy (IPP). The IPP reflects Denison's recognition of the important role of Canadian business in the process of reconciliation with Indigenous peoples in Canada and outlines Denison's commitment to take action towards advancing reconciliation. The IPP was developed based on Denison's experiences with, as well as feedback and guidance received from, Indigenous communities with whom Denison is actively engaged. This approach was designed to make sure the IPP appropriately captures a mutual vision for reconciliation. The IPP identifies five key areas of action that will support the ongoing development of a continuously evolving Reconciliation Action Plan (RAP): Engagement; Empowerment; Environment; Employment; and Education. Through the RAP, Denison is striving to interweave the principles of reconciliation throughout all areas of the company's operations (Denison 2021a).

Development of the Project will require significant capital expenditures and will represent a considerable investment. Similar to other mine sites, the development of the Project will carry significant risks (including technical and non-technical risks). During the evaluation and assessment phase, Denison will evaluate these risks, amongst others, and determine the extent to which the Project justifies the required capital investment. Denison will always weigh the investment risks related to its ability to generate a competitive economic return for its shareholders.

Denison is committed to operating the Project in a fully sustainable manner, considering not only the maintenance of high standards of safety and environmental compliance, but also financial discipline. Denison envisions a project that provides maximal benefits to employees, potentially affected communities, business partners, and Denison shareholders. This commitment will require the partnership and support of all parties with interests in, or related to, the Project.

4.2 Engagement Approach

Denison understands the importance of engaging with local and Indigenous communities, residents, businesses, organizations, land users and the various regulatory authorities. Since 2016, Denison has been engaging with Interested Parties to support the development of positive relationships and a mutual commitment to collaboration. Interested Parties are further categorized into three broad groups, each with several sub-categories (more fully described in Sections 4.3 and 4.4):

- Indigenous Groups
  - Indigenous Communities of Interest (COI)
  - Other Indigenous Communities
  - Indigenous Organizations
- General Public
  - Non-Indigenous COI
  - Other Non-Indigenous Communities
  - Nearby Land Users
  - Organizations
- Regulatory Agencies

A list of the Interested Parties for the Project can be found in Figure 4.2-1.

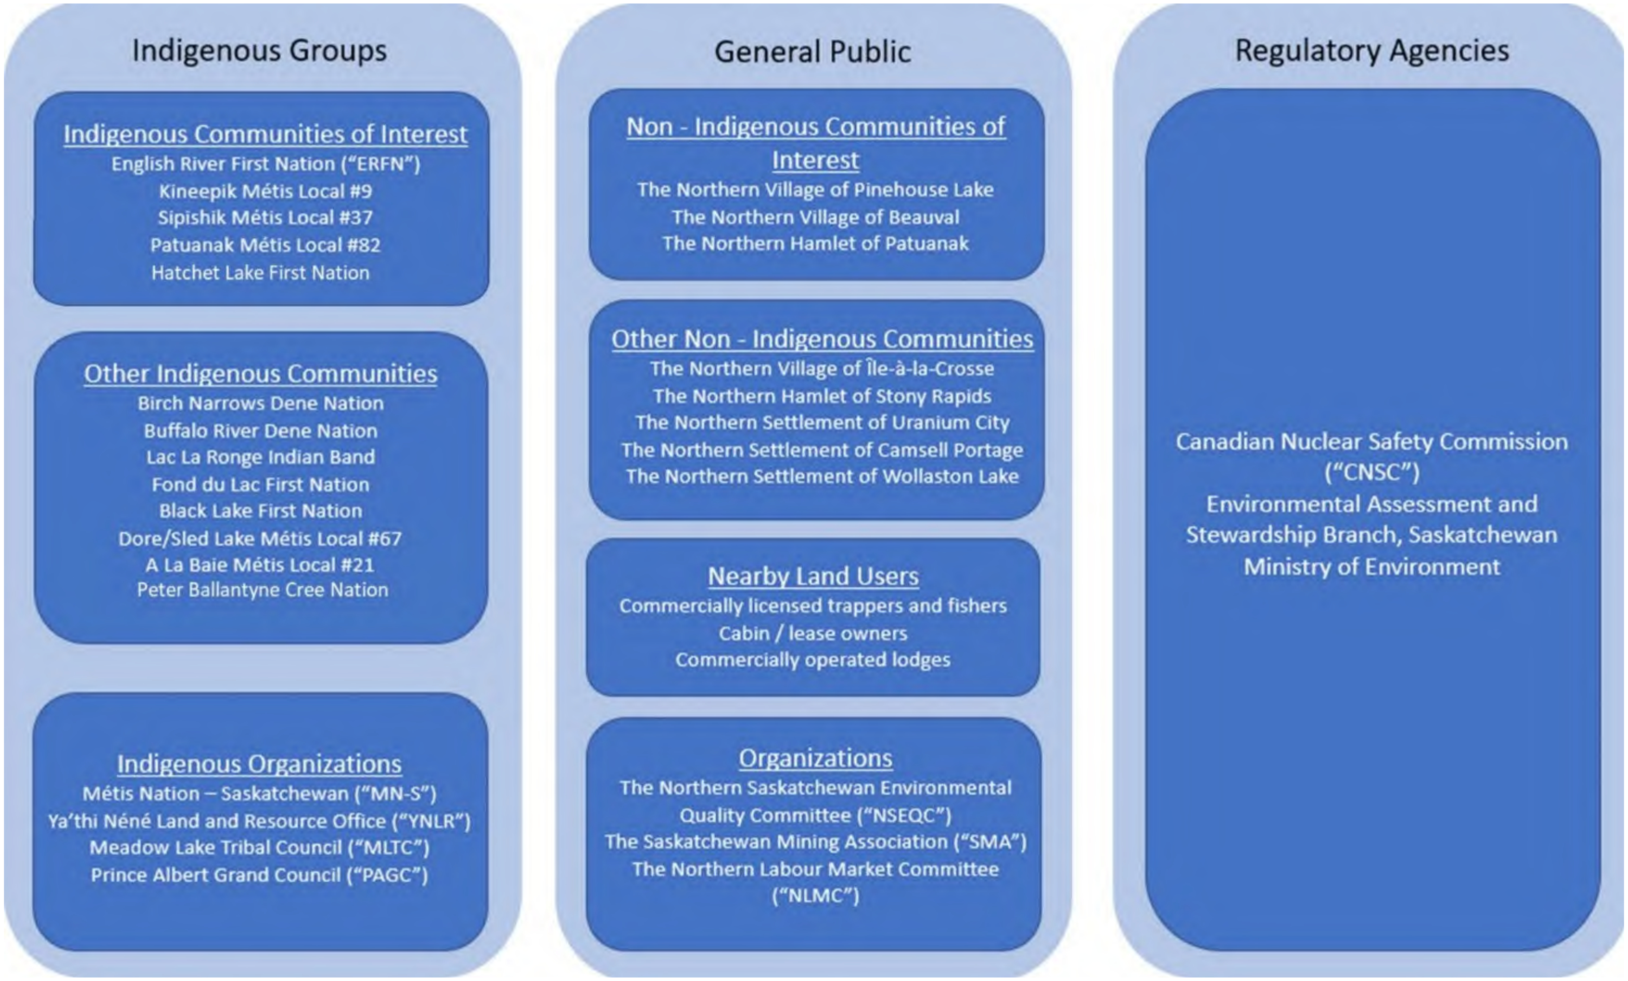

Figure 4.2-1: Interested Parties for the Project[1,2]

---

[1] The MN-S holds the delegated Duty to Consult for Dore/Sled Lake Métis Local #67 and A La Baie Métis Local # 21, SML, and PML.

[2] Engagement activities with the Athabasca Basin First Nations and Communities (Fond du Lac, Black Lake, Hatchet Lake, Stony Rapids, Camsell Portage, Uranium City and Wollaston Lake) occur through YNLR.

Denison's engagement activities with Interested Parties have been designed to meet their expectations while complying with both federal and provincial regulatory legislation. Engagement is defined as the sharing and gathering of project-related information from Interested Parties, and the collaboration with Interested Parties in a good faith effort with the goal of developing mutually acceptable resolutions to issues identified. The development of relationships with Interested Parties is a fundamental determinant of the Project's success. Denison has outlined the following key principles to develop positive relationships through engaging with Interested Parties:

1. Conduct engagement in a variety of ways, venues, and make every effort to identify and include all Interested Parties using an iterative process.
2. Undertake the development of a relationship between Denison and the Interested Party.
3. Provide meaningful and relevant information about the Project in a culturally appropriate format and language that is easily understood by each specific group – which respects local traditions, timeframes, and the decision-making processes of each entity.
4. Based on information shared between Denison and the Interested Party, seek information about their interests; listen to the information shared; and aim to understand their perspectives and priorities.
5. Consider how the interests of Interested Parties interact with Denison's and the Project.
6. Integrate the perspectives and interests of Interested Parties in decision-making about the Project, where appropriate, including the process for assessing the Project.
7. Where concerns are raised about the process, the Project, or its potential effects, collaborate with Interested Parties in developing potential solutions to those concerns.
8. Where necessary, adjust the initial plans for the Project to reduce potential effects and accommodate Rights and interests.
9. Make active and good-faith efforts to resolve all material issues in the above-identified fashion.
10. Commence development of the Project (if appropriate and permitted) in a manner that respects interests.

Denison has further identified key objectives respecting Indigenous engagement associated with the Project:

- Build and maintain authentic relationships based on a foundation of trust, good faith, and transparency.
- Create a respectful dialogue process that promotes communication and collaboration among Denison and Indigenous communities, in a timely and accurate fashion.
- Understand how the proposed development of the Project may affect the interests of Indigenous peoples (including Indigenous and/or Treaty Rights), and work with Indigenous

peoples to avoid, mitigate, or otherwise address effects, while also collaborating to maximize potential positive effects.

Engagement activities for the Project can and will evolve over time, as information is gathered that is pertinent to Denison's understanding of the Interested Parties and their relationship to, and interest in, the Project.

4.2.1 Engagement Methods

Denison has applied a variety of methods to support engagement activities throughout the engagement process and used different methods with various groups depending on requirements and preferences of the process. Engagement methods have included in-person, remote (audio only, virtual, and digital), and print. These methods were aligned with key Project phases:

- pre-Project description (April 2016 to May 2019);
- post-Project description (July 2019 to October 2022);
- environmental assessment outcomes and relationship to licensing/approvals (October 2022 to January 2024) and
- future activities (following final EIS submission).

Engagement methods were reviewed in March 2020 in response to the initial wave of the COVID-19 pandemic. Activities that included direct in-person interaction, such as site visits, were not possible in 2020 and 2021 and necessitated a shift to remote-style engagement methods.

Workshops/Information Sessions: Denison hosted these types of engagement on the overall Project and the EA. Topics included general Project information, potential effects associated with Project activities, alternatives/options assessment, identification of Valued Components (VCs), preliminary effects assessment, and mitigation.

Site Visits: Denison coordinated and hosted site visits at the Project location (generally in the summer months).

Meetings: Various types of meetings, with Indigenous and non-Indigenous members, were held to learn about the Project, meet Denison and its team, and provide an opportunity to ask questions. Meetings with leadership of Indigenous and non-Indigenous communities also occurred. The purpose of the various meetings was to provide opportunities for sharing of information and to solicit feedback.

Virtual Meetings/Presentations: Denison adapted to the COVID-19 pandemic by hosting virtual community meetings and/or presentations.

Presentations: Denison made presentations to various groups and organizations to share information and seek feedback.

Letters: These were distributed at key junctures in the process to inform recipients of pertinent Project information and the EA process (including identifying what stage the Project was at).

Project Website: Denison created a Project website to provide ongoing and updated online information about the Project and the EA process, including key milestone events and engagement activities. The Project website provided another avenue for receiving feedback about the Project, including the ability to submit email comments, questions, and information requests directly through the Project website.

Online or Mailed Survey Questionnaire: Due to the COVID-19 pandemic, Denison used an online survey with select key Interested Party groups to receive input on VCs and baseline land and resource user information. Online surveys were advertised to the Indigenous COI and the non-Indigenous COI; a mailed survey was sent to Nearby Land Users.

Supporting Media and Tools: Denison has used local community radio stations, digital and social media, and print media to help reach a variety of audiences.

4.2.2 Engagement Recording

For each of the engagement methods described in Section 4.2.1, any perspectives that were shared by an Interested Party were recorded and consolidated into a single Engagement Database for the Project. Individual comments/questions and responses were recorded and coded into the database by one Denison staff person to provide quality control and continuity.

After this process was completed, the Engagement Database was used to generate unique reports for subject matter specialists to support EA activities. Each comment, question, or statement and response was assigned a unique identification number (e.g., 21-EN-SUR-446.52) so that individual statements could be properly referenced in the assessment documentation. As evidenced throughout the EIS, specific engagement data have been highlighted where the information shared with Denison has been informative to the EA process. This can be seen through the reference to the unique identification number, coupled with supporting materials found in Appendix 4-A.

4.3 Engagement with Indigenous Groups

Denison is committed to conducting meaningful engagement with Indigenous communities and organizations potentially affected by the Project, and to maintain relationships with these communities and organizations throughout all phases of the Project.

The approach to engagement has considered relevant guidance, specifically *Public and Indigenous Engagement – Indigenous Engagement* (CNSC 2022), *Proponent's Guide: Consultation with First Nations and Métis in Saskatchewan Environmental Impact Assessment – Guidelines for Engaging and Consulting with First Nations and Métis Communities in Relation to Environmental Assessment in Saskatchewan* (Government of Saskatchewan 2014), *Considering Aboriginal Traditional*

Knowledge in Environmental Assessments Conducted Under the Canadian Environmental Assessment Act, 2012 (Government of Canada 2015).

The submission of the proposed Project to the Federal and Provincial regulatory agencies to obtain environmental impact assessment approvals has triggered the Crown's Duty to Consult (both Federal and Provincial) with potentially affected Indigenous communities. Denison is committed to supporting the Crown in carrying out its Duty to Consult obligations. Specifically, as directed by the Province of Saskatchewan, Denison has been assigned various procedural aspects of Saskatchewan Ministry of Environment's (SK MOE) consultation process in the development of the EIS. For this Project, the CNSC has not delegated any procedural aspects of the Duty to Consult to Denison (Denison 2022). Denison remains committed to providing CNSC, along with the Province of Saskatchewan, information that may inform the CNSC analysis of its Duty to Consult in connection with the EA process.

Indigenous people's have a unique relationship with the environment, and importantly, Indigenous and Treaty Rights, which must be fully respected during the process of Project development, Construction, Operation, and Decommissioning. To this end, Denison's objectives with respect to Indigenous engagement associated with the Project are as follows:

- build and maintain authentic relationships built on trust and transparency;
- create a respectful dialogue process that promotes communication between Denison and Indigenous communities and organizations, in a timely and accurate fashion; and
- understand how the proposed development of the Project may affect the ability of Indigenous peoples to exercise collective Indigenous/Treaty Rights.

4.3.1 Engagement with Identified Indigenous Communities and Organizations, and Supporting Criteria

The Northern Administration District (NAD) of Saskatchewan (northern Saskatchewan) includes approximately half of Saskatchewan's land area, but less than four per cent of the province's population (Government of Saskatchewan n.d.). Northern Saskatchewan is approximately 250,000 square kilometres, or about 44% of Saskatchewan's area and is home to about 38,000 people (Statistics Canada 2017) living in approximately 45 communities, which include incorporated municipalities (such as towns, villages, hamlets, and settlements), First Nation reserves, and unincorporated areas. More than 80% of people who live in northern Saskatchewan self-identify as Indigenous. Within the NAD, the communities are roughly divided between the three regions: the Athabasca Basin region, the North Central region, and the West Side region. Figure 4.3-1 illustrates where these NAD communities are in relation to the Project. Figure 4.3-2 illustrates where identified Indigenous communities and organizations are located in relation to the Project.

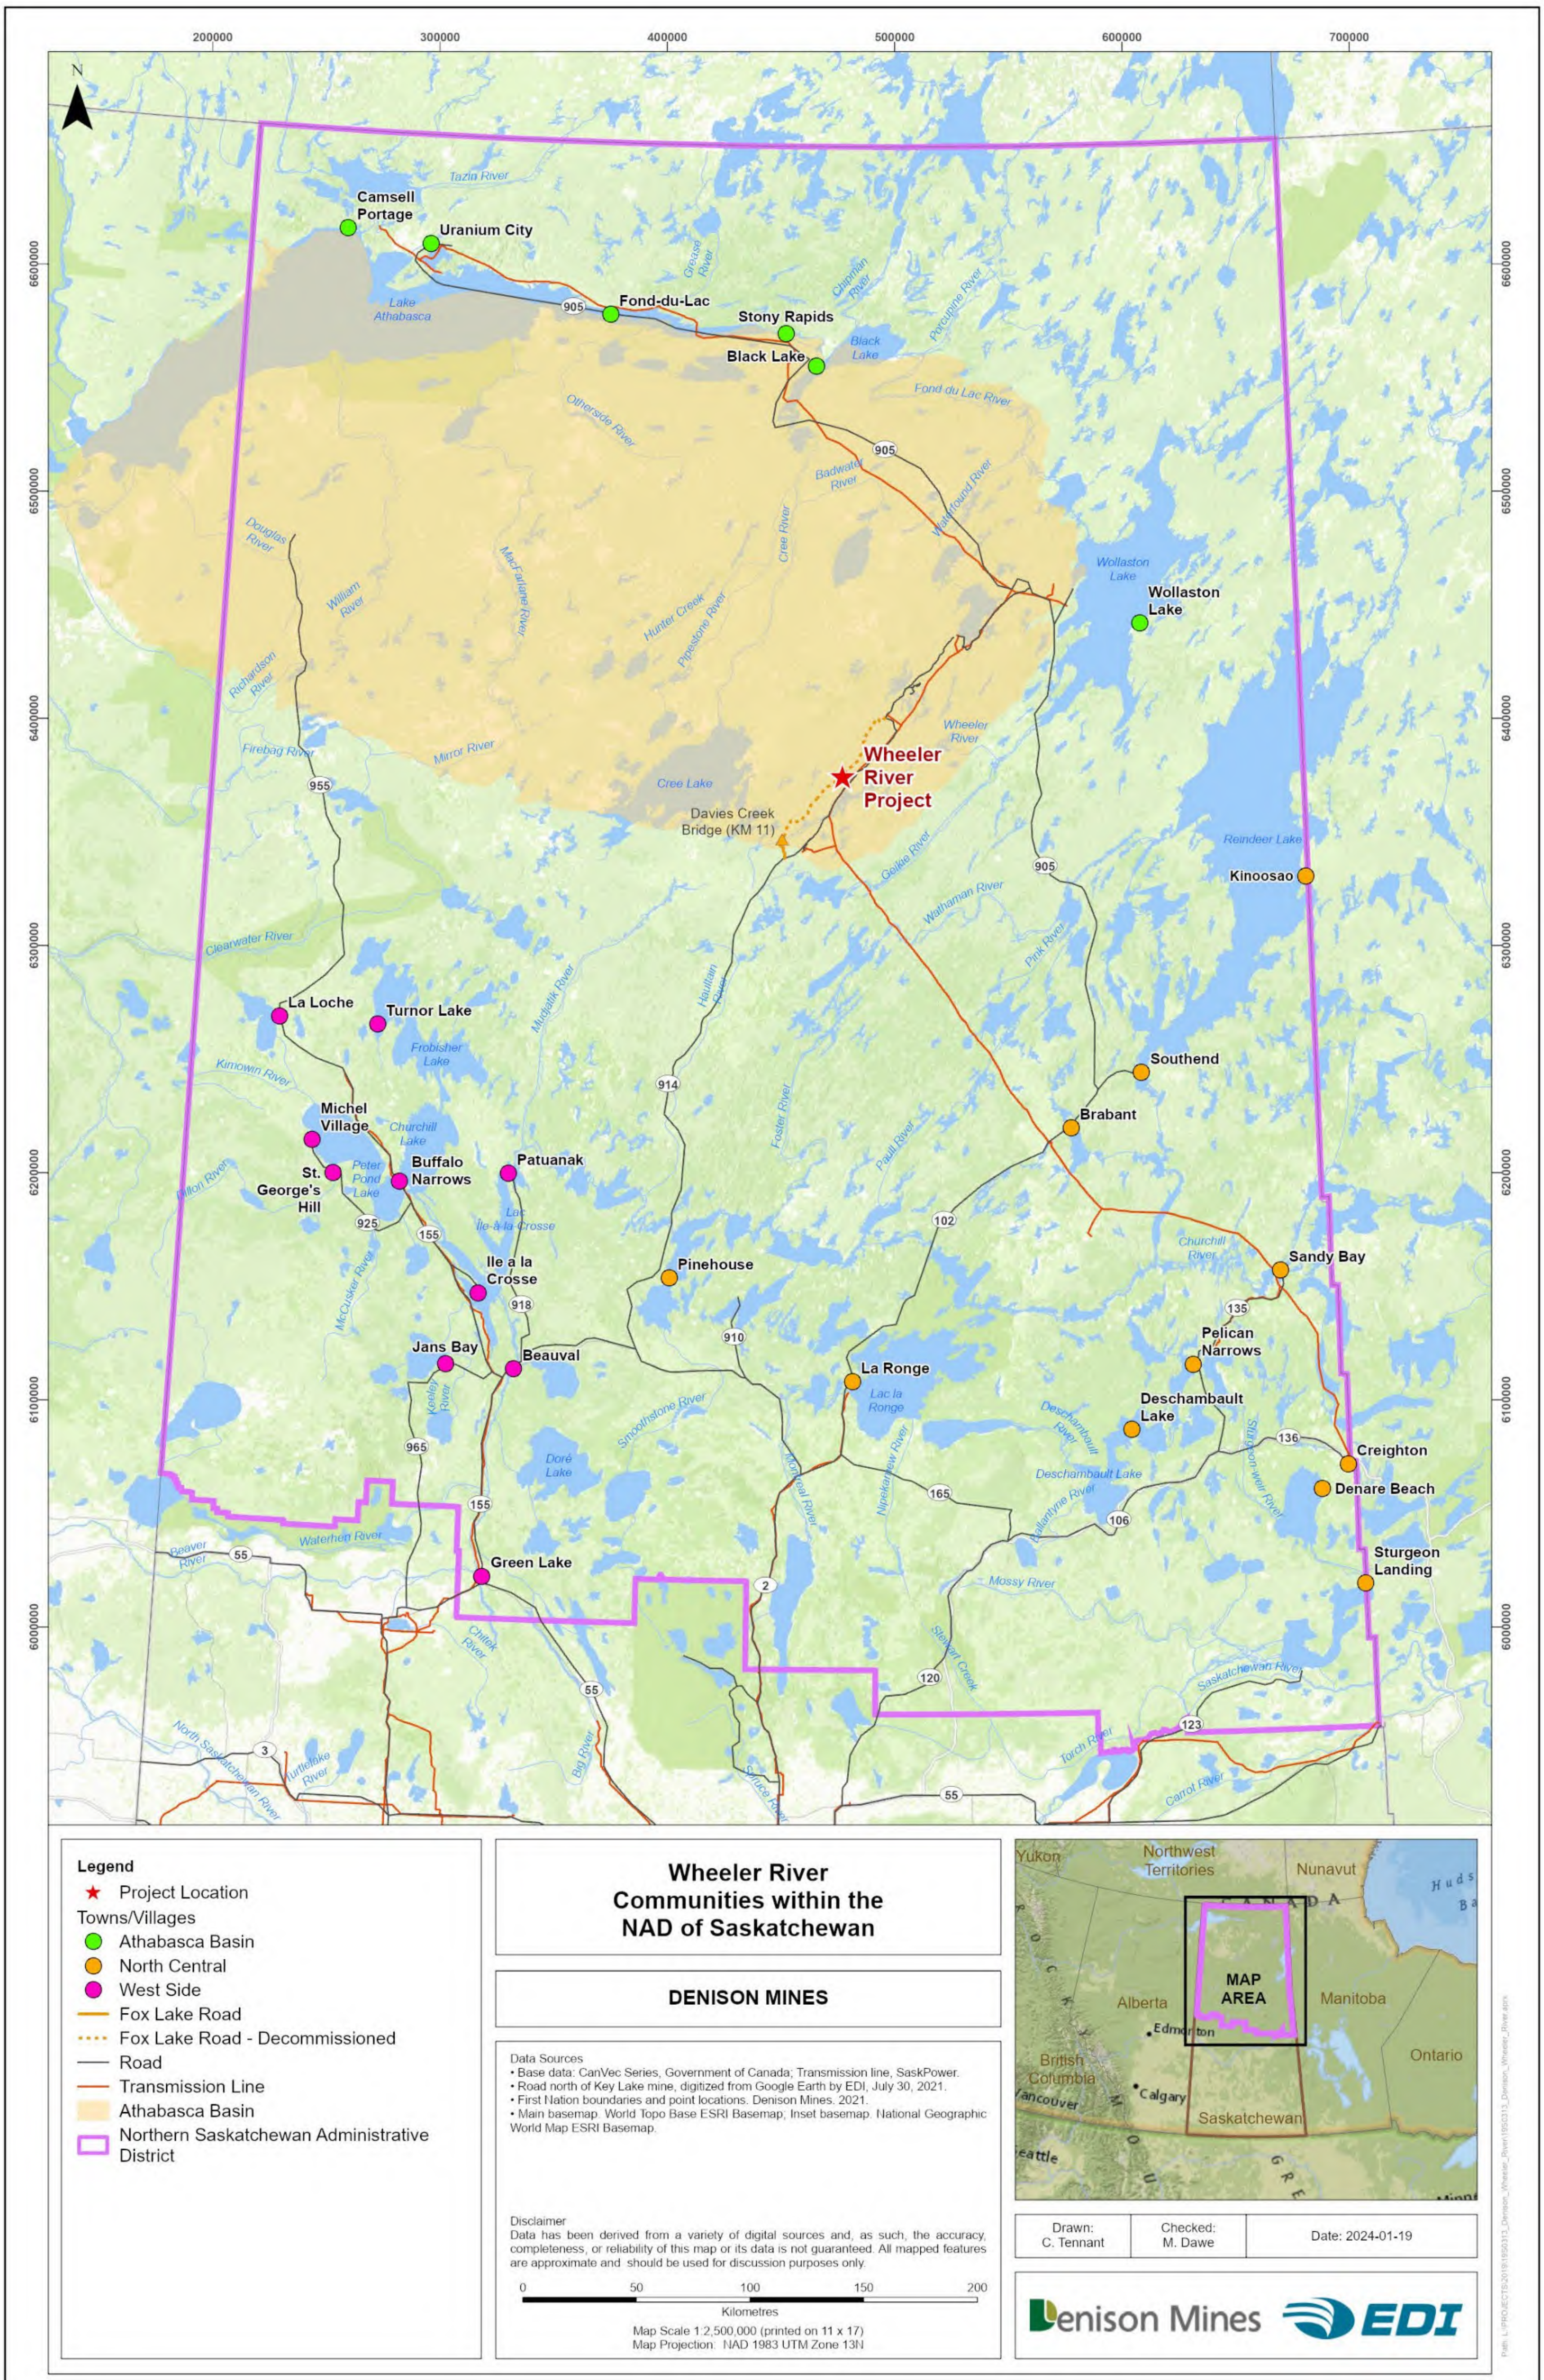

Figure 4.3-1: Communities within the Northern Administration District of Saskatchewan

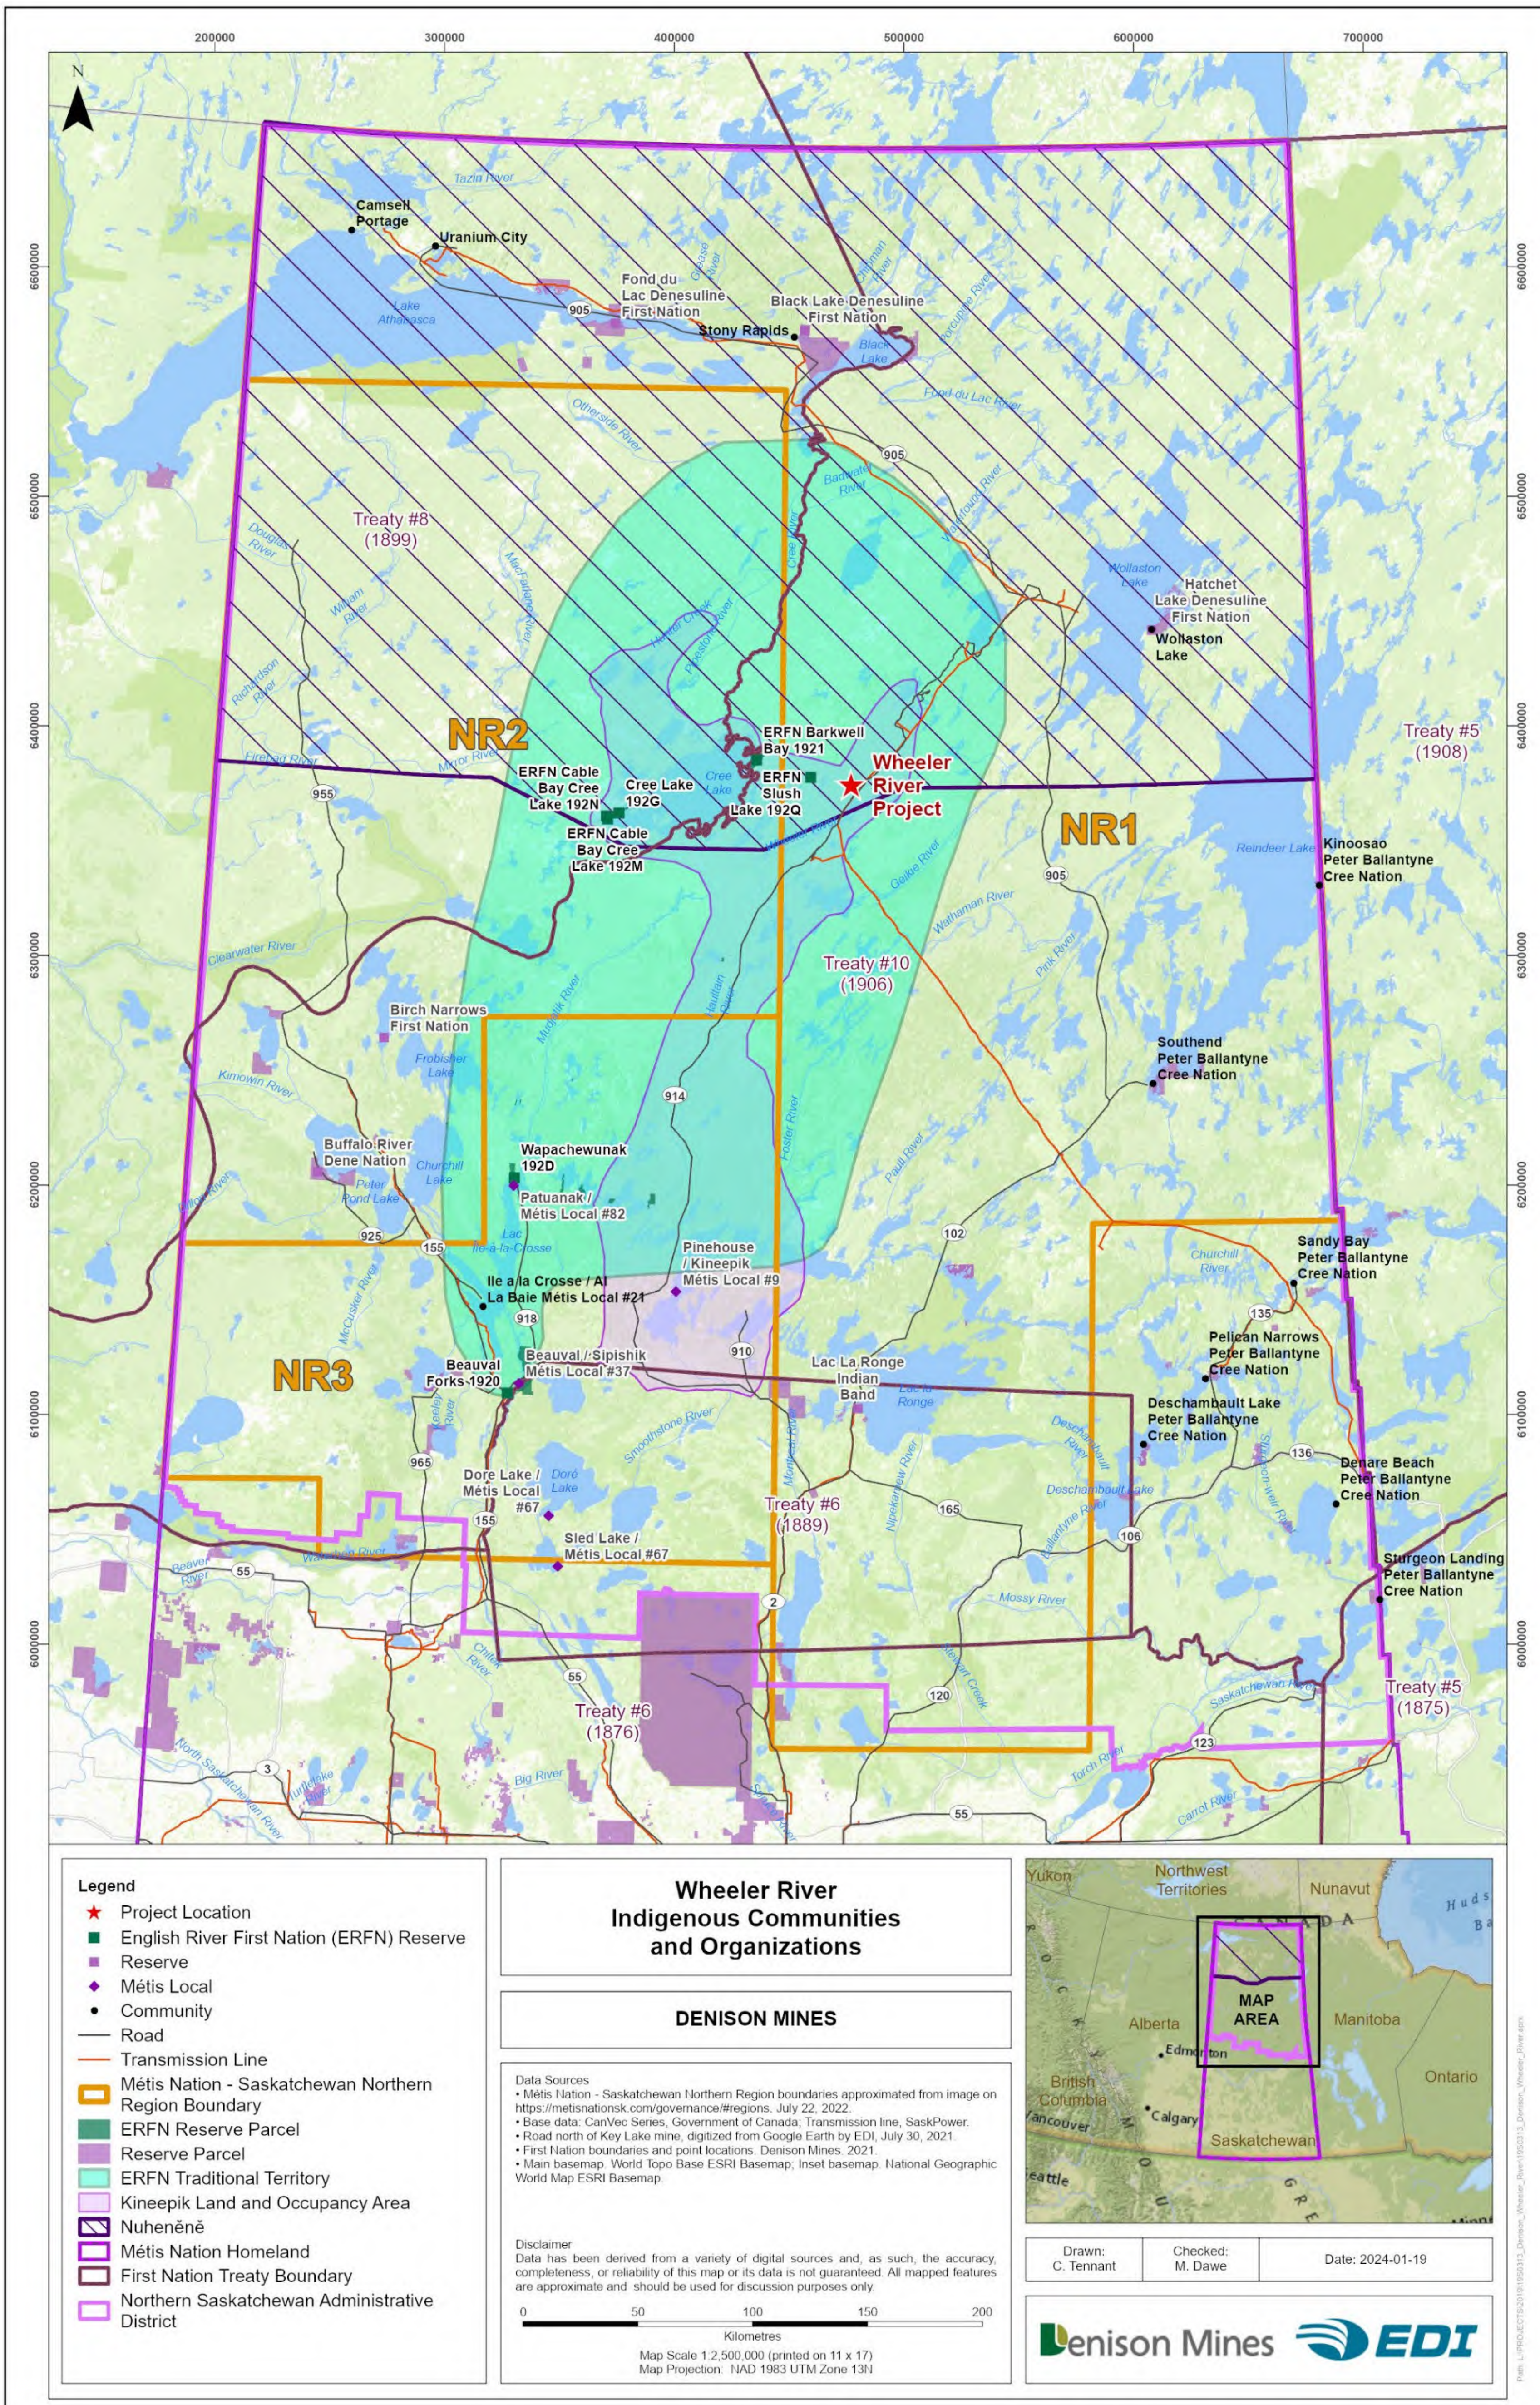

Figure 4.3-2: Identified Indigenous Communities and Organizations in Relation to the Project

Consistent with the history associated with other uranium mining projects located within the NAD, Denison recognizes that many Indigenous communities within the NAD typically have an interest in uranium activities, but that an approach based on appropriate criteria to determine those included in the engagement program is required.

No populated Indigenous communities occur in close proximity to the Project site. Calculated using a straight line, the closest Indigenous communities are approximately 150 km from the site. Travelling by existing roads, the closest Indigenous community to the Project is approximately 260 km away.

The following criteria have been used to appropriately evaluate Indigenous communities located in the NAD that would be engaged by Denison:

- Treaty 10 signatory (Treaty in which the Project is located);
- potential or established Indigenous and/or Treaty Rights within the Project Area;
- geographic proximity of community and/or reserve land to the Project site;
- known traditional territory in and around the Project site;
- history of relationship with operating companies, the CNSC, and the Province in relation to other projects located near the Project (McArthur River, Key Lake, Millennium); and
- the potential for collective exercising of Indigenous and/or Treaty Rights in proximity to the Project.

The results of the initial assessment using these criteria determined that English River First Nation (ERFN), Kineepik Métis Local #9 (KML), the Sipishik Métis Local #37 (SML), and the A La Baie Métis Local #21 (ALBML) would form part of Denison's initial focus for Indigenous engagement activities (see Table 4.3-1). These initial Indigenous groups were discussed with representatives of the SK MOE and the CNSC. The Patuanak Métis Local #82 (PML) was added after those discussions based on further evaluation. As more information has been gained since the onset of engagement activities in 2016 regarding the various traditional land use and areas of occupancy by Indigenous groups around the Project, the list has been modified accordingly, including with respect to the reclassification of ALBML, and the addition of Hatchet Lake First Nation (HLFN). Engagement details with the current four Indigenous COI, as set out below, are included in Section 4.3.2.

Table 4.3-1: Indigenous Communities of Interest and Focus of Engagement Activities

Indigenous Communities of Interest	Brief Description of Rationale Criteria
English River First Nation	• Treaty 10 signatory. • Potential or established Indigenous/Treaty Rights within the Project Area. • Geographic proximity of community and/or reserve land to the Project site (Slush Lake reserve approximately 16 km away; Barkwell Bay reserve 39 km away; community of Patuanak 229 km away in straight line). • Known traditional territory in and around the Project site, including travel routes. • History of relationship with operating companies, the CNSC and the Province in relation to other projects located near the Project (McArthur River, Key Lake, Millennium). • Potential for collective exercising of Indigenous/Treaty Rights in proximity to the Project.
Kineepik Métis Local #9	• Potential or established Indigenous/Treaty Rights within the Project Area. • Geographic proximity of community and/or reserve land to the Project site (233 km away). • Known traditional territory in and around the Project site, including travel routes. • History of relationship with operating companies, the CNSC and the Province in relation to other projects located near the Project (McArthur River, Key Lake, Millennium). • Potential for collective exercising of Indigenous/Treaty Rights in proximity to the Project.
Sipishik Métis Local #37	• Potential or established Indigenous/Treaty Rights within the Project Area. • Known traditional territory in and around the Project site, including travel routes. • Familial ties through the ERFN Membership and La Plonge reserve (immediately adjacent to Beauval). • Potential for collective exercising of Indigenous/Treaty Rights in proximity to the Project.
Patuanak Métis Local #82	• Potential or established Indigenous/Treaty Rights within the Project Area. • Known traditional territory in and around the Project site, including travel routes. • Familial ties through the ERFN Membership and Wapachewunak 192D reserve (immediately adjacent to Patuanak). • Potential for collective exercising of Indigenous/Treaty Rights in proximity to the Project.
Hatchet Lake First Nation	• Treaty 10 signatory. • Potential or established Indigenous/Treaty Rights within the Project Area. • Geographic proximity of community and/or reserve land to the Project site (150 km) • Known traditional territory in and around the Project site. • Potential for collective exercising of Indigenous/Treaty Rights in proximity to the Project.

Denison has recognized other nearby Indigenous communities exist with a potential interest in the Project, including Indigenous communities that have been identified by a Regulatory Agency as having a potential interest in the Project. These Other Indigenous Communities have been identified to include Birch Narrows Dene Nation (BNDN), Buffalo River Dene Nation (BRDN), Lac La Ronge Indian Band (LLRIB), Fond du Lac First Nation, Black Lake First Nation, Dore/Sled Lake Métis Local #67, ALBML, and Peter Ballantyne Cree Nation (PBCN). Engagement details with these nine Other Indigenous Communities are included in Section 4.3.3.

Indigenous Organizations

Indigenous organizations can provide a single point of contact for Denison to share information more broadly to a wide variety of Indigenous communities and their leadership regarding project information, and company information. In many cases, these Indigenous organizations have been delegated the right to represent an Indigenous community or group of Indigenous communities in connection with the Project. These organizations can also provide specific information regarding their members, interests their members may have, and opportunities for Denison to work collaboratively together on various initiatives.

Denison has identified four Indigenous Organizations: the Métis Nation – Saskatchewan (MN-S); Ya'thi Néné Lands and Resource Office (YNLR); Meadow Lake Tribal Council (MLTC); and Prince Albert Grand Council (PAGC).

Métis Nation-Saskatchewan

As the elected government of the Métis people of Saskatchewan, the MN-S plays an important role related to engagement activities. The MN-S is currently structured with a President, an Executive, a Provincial Métis Council, Regional Directors, and Local Presidents.

The Project is located within Métis Northern Region 1 in Saskatchewan. However, several key Métis communities with whom Denison is engaging are located in Métis Northern Region 3.

The MN-S website states that "*consultations must be with the Métis government structures that are elected and supported by the Métis people*." (MN-S n.d.c.)

Engagement with MN-S is captured under Section 4.3.4.1.

Ya'thi Néné Lands and Resource Office

The YNLR was created as a not-for-profit organization to be the single point of contact between industry, government and the local Athabasca communities of Hatchet Lake First Nation, Black Lake First Nation, Fond du Lac First Nation, Camsell Portage, Stony Rapids, Uranium City, and Wollaston Post. Hatchet Lake First Nation is a Treaty 10 signatory.

The Project is located within the Nuhenéné (the Athabasca Denesųłiné territory). Engagement with YNLR is captured under Section 4.3.4.2.

Meadow Lake Tribal Council

According to the MLTC website "*the [MLTC] began in 1981 when the First Nations of Northwest Saskatchewan united to form the Meadow Lake District Chiefs Joint Venture. The Meadow Lake District Chiefs became officially known as the Meadow Lake Tribal Council in 1996*" (MLTC n.d.a). Meadow Lake Tribal Council represents nine Cree and Dene nations: BNDN, BRDN, Canoe Lake Cree Nation, Clearwater River Dene Nation, ERFN, Flying Dust First Nation, Makwa Sahgaiehcan First Nation, Ministikwan Lake Cree Nation, and Waterhen Lake First Nation. Meadow Lake Tribal

Council is an advocate for program delivery and services in the nine participating Nations. The Indigenous communities that overlap with the Project and are members of MLTC are BNDN, BRDN, and ERFN. Engagement with MLTC is captured under Section 4.3.4.3.

Prince Albert Grand Council

According to the Prince Albert Grand Council (PAGC) website, the Grand Council's history dates back to the 1960s when "*the twelve Chiefs of the Prince Albert District formed a political alliance, to collectively work together on common issues, which was formalized under the Charter of the Federation of Saskatchewan Indians*" (PAGC n.d.) In 1993, the name was changed to PAGC. The 12 Nations that make up PAGC are: Black Lake Denesuline Nation, Cumberland House, Fond du Lac First Nation, Hatchet Lake First Nation, James Smith Cree Nation, LLRIB, Montreal Lake Cree Nation, Peter Ballantyne Cree Nation, Red Earth Cree Nation, Shoal Lake Cree Nation, Sturgeon Lake First Nation, and Wahpetan Dakota Nation. The Indigenous communities that overlap with the Project and are members of PAGC include Black Lake Denesuline Nation, Fond du Lac First Nation, Hatchet Lake First Nation, and LLRIB. Engagement with PAGC is captured under Section 4.3.4.3.

4.3.2 Engagement with Indigenous Communities of Interest

As described in Section 4.3.1, the Indigenous COI were determined to be:

- English River First Nation;
- Kineepik Métis Local #9;
- Sipishik Métis Local #37;
- Patuanak Métis Local #82; and
- Hatchet Lake First Nation.

4.3.2.1 Engagement with English River First Nation

English River First Nation is a Denesųłiné community with ancestral lands (*nuhtsiyw-kwi-Benéne*) stretching from the Churchill River to Wapata Lake in northern Saskatchewan.

> "*The ERFN name originates from the English River area, which was inhabited by the Poplar House people for periods during the year. Most of the families that now live at the Wapachewunak Reserve traditionally lived along the Churchill River system at Primeau Lake, Knee Lake, Dipper Lake and/or Cree Lake to the north (Canada North Environmental Services, 2017). Summers were spent primarily fishing along the river system. For the rest of the year, family units would spread out through the northern forests for trapping and subsistence hunting. Commonly used winter trapping areas included Haultain Lake, Costigan Lake, Foster Lake, and the area between Cree Lake and the Churchill River (Jarvenpa, 1980).*" (ERFN and SVS 2022a)

English River First Nation is a signatory to Treaty 10. English River First Nation's reserves are approximately 16 km from the Project (Slush Lake reserve); 39 km from the Project (Barkwell Bay reserve); and 229 km away (Wapachuanak Reserve, the main residential reserve for ERFN). The ERFN also has a reserve at La Plonge.

Figure 4.3-2 illustrates where communities are in relation to the Project, both in terms of direct linear distance and travel distance.

4.3.2.1.1 History of Interactions

Since 2016, Denison has engaged with members of the ERFN in various ways. A comprehensive listing of engagement activities between Denison and ERFN, including a brief description of the purpose or activity and outcome where appropriate, is included in the IER.

4.3.2.1.2 Agreements Relative to the Environmental Assessment Process

To formalize Denison's commitment to ERFN, a Memorandum of Understanding (MOU) was signed between Denison and ERFN in 2018. This non-binding MOU formalized the intent to work together in a spirit of mutual respect to cooperate to collectively identify practical means by which to avoid, mitigate, or otherwise address potential effects of the Project upon the exercise of Indigenous Rights, Treaty Rights, and interests.

In 2021, Denison and ERFN built upon the 2018 MOU and signed a Participation and Funding Agreement and Letter of Intent, which outlined a mutually agreeable framework and applicable funding arrangements to facilitate ERFN's participation and engagement in the EA process for the Project—including ERFN's contribution to Denison's understanding of the Project in a holistic way that respected ERFN's rights and interests (Denison 2021b). As a result, several additional activities have been undertaken between ERFN and Denison, which are further described in Section 4.3.2.1.3.

In 2023, ERFN and Denison concluded an Agreement in respect of the Project that provides, among other matters, various procedural and substantive commitments by Denison to ERFN and the support and consent of ERFN for the development and operation of the Project in a sustainable manner which respects ERFN's inherent, Aboriginal and Treaty rights, advances reconciliation with Indigenous peoples, and provides economic opportunities and other benefits to ERFN.

4.3.2.1.3 Key Engagement Activities

During the engagement activities undertaken with ERFN, several key engagement activities have played a significant role in relation to the EA process. The main forms of engagement included meetings with Chief and Council, community meetings, a workshop on early infrastructure options (2018), a site visit (2019), virtual presentations and meetings on VCs (2021), two online surveys (2021 and 2022), and a meeting and information session on preliminary effects and mitigation (2022). Also in 2021, Denison met with the newly formed ERFN's Nuhtsiye-kwi Benéne (Ancestral Lands Committee) for specific input into the Project. As noted in Section 4.2.1, due to the COVID-19 pandemic, engagement switched to virtual meetings in 2021. In mid-2022, appropriate engagement activities moved back to in-person.

The following text describes several the key engagement activities in more detail. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1.

Engagement Focus: Pre-Project Description - April 2016 to May 2019

Introductory Meeting – July 7, 2016: This was the inaugural meeting between members of the senior management team of Denison and the Chief of ERFN. General discussion occurred pertaining to direct employment, business opportunities, and overall planning for a meeting to occur in the community of Patuanak, for later in the month. For more specifics about this activity, please see Appendix 4-A, ROC #99.

Introductory Meeting – July 27, 2016: This was the inaugural meeting between the senior management team of Denison and ERFN Members of Wapachewunak. About 30 Members were in attendance, along with the Chief and several ERFN Councillors. Much of the meeting focussed on clarifying the nature of Denison's activities, including the Project, the interest in an agreement for the Nation in relation to any project, the interest in employment and business opportunities, the interest in protection of the environment from exploration and Project activities, questions in relation to the nuclear industry in general, and the general sharing of information pertaining to knowledge of land and wildlife in and around the Project. For more specifics about this activity, please see Appendix 4-A, ROC #100.

Workshop – May 3, 2018: In collaboration with the Chief of ERFN, Denison hosted a workshop with several individuals representing a variety of entities within ERFN Patuanak. The focus of this engagement activity was to obtain feedback on three alternatives/options for the proposed Project: the road alignment from Highway 914 into the Project Area; the potential treated effluent discharge location; and the mining method options. The meeting had been rescheduled several times and the attendance was minimal. The Chief attended this meeting. General questions were asked regarding the various alternatives and options, and points of clarification pertaining to aspects of the Project. Please See Section 2 Project Description for more details. For more specifics about this activity, please see Appendix 4-A, ROC #5.

Engagement Focus: Post-Project Description – July 2019 to October 2022

The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project.

In August 2019, Denison hosted a site tour at the Project location over two separate days. Day one was a tour comprising a wide variety of Interested Parties, and included an ERFN Member. Day two was a tour with the ERFN Chief, Elders and a local ERFN Trapper. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. During these site visits, ERFN commented on or queried about:

- the importance of Denison respecting their traditional territory and making sure benefits flow to ERFN;
- the proposed in situ recovery (ISR) mining method (pressures, makeup of mining solution);
- the proposed freezing method (potential concern to groundwater, understanding of the drilling process);
- the important of working with ERFN harvesters and land users;
- the nature of the 2019 in-field test;
- effects of the proposed Project on air emissions; and
- reclamation activities.

For additional details about this activity, please see Appendix 4-A, ROC#1 and ROC #140.

Engagement efforts were temporarily suspended in March 2020 as a result of the COVID-19 pandemic. As noted in Section 4.2.1, due to the COVID-19 pandemic, engagement switched to virtual meetings in 2021. In mid-2022, appropriate engagement activities moved back to in-person.

Meetings - March 31, 2021: Denison hosted three virtual meetings with ERFN including with Chief and Council, with the St. Louis School (high school students), as well as a virtual meeting for ERFN Members living on the Patuanak reserve, La Plonge reserve and urban members.

The focus of these engagement activities was to provide information about the Project to the ERFN members, present a preliminary list of VCs that Denison had identified as part of the EA process, and provide an opportunity for members to provide feedback on the proposed list of VCs, and ask questions about Project components of interest or concern to them. For more specifics about these activities, please see Appendix 4-A, ROC #447, 448 & 456.

The virtual meeting was advertised on the radio and social media, and posters were placed in community buildings. The Zoom platform was used for the meeting, which was also broadcasted live through the La Plonge radio station (93.1FM). At least 24 Zoom accounts were used to attend the presentation, although it is possible that more than one person viewed the presentation from each account.

The ERFN Members meeting was held live on March 31, 2021, by Zoom. Topics covered during the presentation include the following:

- Denison company introduction and key staff members;
- introduction to regulators;
- location of the Project;

- ISR mining at the Project, including the recent change in the Project design from freeze dome technology to a freeze wall containment method;
- employment opportunities;
- EA; and
- VCs.

Meeting participants were encouraged to complete Denison's online survey in relation to the VCs considered important to ERFN Members. Following the presentation, Denison answered questions submitted through the online chat function.

Key themes that emerged from the questions posed at the ERFN meetings, which indicated either interests or concerns, are summarized below:

- Participants wanted to understand more about the ISR mining method, how it is different from other mines in the area, if this method creates tailings or other wastes, how the freeze wall works, what happens to the mining solution, and the potential effects of this method on the environment.
- Questions were also asked about the reclamation process at the Project, such as what would happen to the mining cavity and the wells once mining was completed.
- Participants wanted to know more about potential effects to the environment including effects to wildlife; effects specifically to moose and caribou populations during Construction of the mine; reclamation of the mine; issues surrounding potential contamination and clean-up; and effects to groundwater and surface water near the Project.
- Participants wanted to know if they would be able to view the EIS before the public hearings start.
- Participants asked questions about hiring practices, specifically if local companies and community members be given priority for contracts and employment.
- Questions were also asked about training; would Denison pay for training for specific jobs and would this training be transferrable to other jobs?
- Several participants raised concerns about the use of online engagement. They explained that engaging with Elders was very important and that engaging through technology is hard for some members, especially without a translator.
- Participants wanted to know what kind of benefits the community would receive from the Project, specifically collaboration agreements.
- Questions were asked about access to the land around the Project and statements were made regarding the importance that those who use land for traditional purposes continue to be able to pursue this.

Denison provided a report back to ERFN regarding what was heard by Denison during the engagement activities. This report was shared in hard copy form (sent to the ERFN Patuanak and La Plonge offices), shared with ERFN for posting to an ERFN website, posted on the Denison website (www.wheelerriverproject.ca), and a video was made by Denison for those who prefer oral communications, also on the Denison website. For additional details about this activity, please see Appendix 4-A, #447.

Online Survey**:** During and following the ERFN meeting(s), members were invited to provide feedback on VCs through an online survey. The purpose of the survey was to seek feedback on the importance of the VCs to members, and identify interests or concerns related to the Project, providing an additional mean by which feedback could be provided to Denison. Members who were unable to attend the presentation were also encouraged to provide feedback through the survey. The survey was marketed to members using Facebook and radio advertisements.

The survey was open for feedback from March 31 to April 9, 2021, for 10 days. A total of 23 responses were received, and 20 of these were considered complete, for an 87% rate of survey completion.

The survey included reach and marketing questions about how respondents heard about the survey and if they attended a presentation. This information helped Denison to determine which event marketing efforts were most effective.

The survey also asked respondents to disclose voluntary demographic information, such as age, primary residence, and identity, to help Denison determine if there were large demographic groups whose perspectives were not represented in the results.

Following the reach and marketing and demographic questions, the survey included questions specific to the preliminary list of VCs. These questions were followed by the opportunity for respondents to share their thoughts on opportunities and challenges related to the Project.

Demographics

A total of 21 respondents disclosed their age range. Most survey respondents (76%) were between the ages of 35 and 64, compared to 19% who were between the ages of 16 and 34.

A total of 20 respondents disclosed information about Indigenous identity. The majority (95%) of respondents identified as First Nations. The remaining respondents identified as non-Indigenous (5%). No respondents identified as Métis, or non-status.

A total of 21 participants disclosed where they live for most of the year. Most respondents live in English River (43%), followed by Patuanak (29%), and members who lived in urban areas (14%). The remaining members lived in La Plonge (5%; n=1) and “other” communities (9%; n=2).

Valued Components

A total of 26 interconnected VCs were proposed to respondents. Respondents were asked to select from the list which VCs they felt were important for Denison to research further as part of the EA. A total of 19 respondents identified VCs that were important to them. One respondent indicated that all the VCs were both important and not important to them. Another respondent had contradictory responses. Such responses were not included in the analysis.

While all 26 VCs were identified as important by at least one respondent, the following were identified as important by more than half of the respondents:

- traditional land and resource use;
- surface water;
- fish;
- groundwater quality;
- air quality;
- employment;
- community well-being;
- vegetation; and
- fish habitat and aquatic plants.

The VCs identified as important by the greatest number of respondents included traditional land and resource use (selected by 72% of respondents) and surface water, which was selected by 67% of respondents.

In response to why they felt the VCs they selected were important, the following themes emerged from the responses received.

- Respondents selected VCs they felt were vital to the well-being of the environment.
- Respondents selected VCs they felt would protect their traditional territory for future generations and would allow their traditional livelihood to continue.
- Others selected VCs related to employment opportunities and explained that there are not many opportunities in northern Saskatchewan.

The theme of protecting the land to allow future generations to continue traditional lifeways stood out as particularly important to respondents.

Six respondents identified VCs they felt were missing from the preliminary list and should be added including:

- knowledge of resource management;

- traditional food;
- consultation;
- the longevity of the land;
- working relationships (particularly between ERFN and Denison); and
- joint ventures.

Traditional food, the longevity of the land (sustainability) and joint ventures were well captured by VCs already considered by Denison. Knowledge of resource management, consultation, and working relationships have been considered by Denison as items to focus on in terms of the relationship between Denison and ERFN and regular information sharing.

The complete list of VCs included in this EIS is available in Section 5.3.1 in Section 5 Approach and Methodology of the Assessment.

Opportunities and Challenges

Respondents were asked, based on what they knew so far about the Project, to share the aspects of the Project that they felt could benefit or work well for the community. A total of 17 people responded to this question.

Some of the unique or specific opportunities mentioned included the following items:

- training opportunities;
- employment opportunities;
- opportunities for local companies (TRON and Des Nedhe);
- the possibility of royalties for the community;
- increased communications (quarterly) would be beneficial to the community, possibly through a community liaison; and
- the potential for community development and a collaborative agreement.

One respondent believed that "*no aspect of the project is beneficial to the community as it will harm the earth.*"

Respondents were then asked what aspects of the Project they felt would be challenging or cause concern for their community. Themes that emerged from the 26 responses received included the following:

- potential effects from ISR mining including the use of acid, and the possibility of residual uranium leaking into the groundwater after the freeze wall has been removed;
- storage and shipping of yellowcake and other harmful substances is a concern;

- the potential effect of the Project on the environment, including on wildlife in the area around the Project;
- potential negative effects to community health;
- concern that Elders are not being consulted as most of the engagement has been through online means and without a translator;
- concerns around long-term effects on the land and the potential for this to negatively affect traditional lifeways; and
- the need for consistent communication and updates to make sure Denison is accountable and is conducting the Project with integrity and respect.

None of these themes stood out as more prevalent than others.

Questions and Comments

Respondents were asked if they had any questions for Denison and if there was anything else they wanted Denison to know related to the Project. Several questions were posed relating to local training and employment opportunities. A comment was made that people from northern Saskatchewan should be given priority in hiring and business opportunities.

Other questions related to Project design details, such as how Denison will make sure residual uranium will not leak into the environment.

Finally, some respondents noted the importance of engaging in non- electronic/technological ways to make sure the voices of Elders are heard. They also noted that it will be essential to have a translator. Additionally, one respondent noted that it would be helpful to have a community office for the Project. For additional details about this activity, please see Appendix 4-A, ROC #456.

Meetings (Chief and Council and Patuanak & La Plonge Open Houses) - May 30 and May 31, 2022: On May 30 and May 31, 2022, engagement activities were undertaken at the ERFN Patuanak reserve at the Band Hall (May 30) and ERFN La Plonge reserve at the Silver Building (May 31). The ERFN La Plonge meeting was originally intended to occur at the Beauval Community Centre, but owing to a set of community circumstances, was moved to the La Plonge Reserve Silver Building. The change in venue was communicated via radio the day of the event. The focus of these engagement activities was to share the preliminary findings of the EA, proposed mitigation measures, and preliminary conclusions of the EIS, and to facilitate dialogue related to this information.

Engagement activities were conducted as a focused meetings with Chief and Council and as general open houses. Date and location of open house meetings were advertised on local radio stations, Facebook pages, TV channels, and posters. During the open houses members were able to complete a survey, in hard copy or digital format, to express their opinions. Comments and questions were also captured by Denison in a record-keeping notebook, and transcribed following the event.

To communicate EA findings and Projects details, Denison created and displayed three models and 15 informational poster boards. The three models depicted: 1) the uranium ore body and projected, below ground, extraction infrastructure; 2) the Project site surface with associated infrastructure; and 3) A 1:294 scale map of the area surrounding the Project site. The 15 informational poster boards presented EA findings in relation to VCs identified as important during previous rounds of engagement activities, as well as detail on technologies, regulatory processes, and procedures.

Chief and Council Leadership Meeting – May 30, 2022**:** The leadership meeting was held in ERFN Patuanak on May 30, 2022, with the Chief and Council. Denison provided an overview of the Project that included information on Project specifics, current status, predicted timeline, and preliminary EA findings.

The dialogue between Denison and ERFN Chief and Council highlighted several themes that primarily centered around the biophysical environment, socio-economic elements, and general technical inquires. A general concern for environmental integrity was expressed, including mention of climate change, potential seismic activity, and monitoring as it relates to uranium decay. Inquiries relating to employment, training, and community benefits were made. Representatives from the CNSC and SK MOE were present. For additional details about this activity, please see Appendix 4-A, ROC #621.

Open House in Patuanak (ERFN Reserve) - May 30, 2022**:** The open house was held at the ERFN Patuanak Band Hall, with members of the Hamlet of Patuanak welcomed to attend. A total of 31 attendees signed the sign-in sheet. Several individuals chose not to sign in, making the attendance at the ERFN Patuanak open house higher than implied by the sign-in sheet. Dialogue during the open house was largely in the form of attendees seeking clarity. The inquiries of attendees highlighted a general concern for the biophysical environment. Comments relating to ground subsistence, water quality, and environmental integrity were recurrently expressed. Questions surrounding Project specifics were often expressed in relation to concern for the biophysical environment. Multiple questions additionally related to socio-economic matters. Attendees expressed comments and inquiries relating to employment, training, accessibility, and benefit agreements. The basis of all socio-economic related dialogue appeared to highlight general focus on community and community member well-being. For additional details about this activity, please see Appendix 4-A, ROC #618.

Open House in La Plonge (ERFN Reserve) - May 31, 2022**:** The open house in La Plonge was held at the Silver Building. The ERFN La Plonge members and residents of Beauval and surrounding area were welcomed to attend. A total of 14 attendees signed the sign-in sheet. Several individuals chose not to sign in, making the attendance at the La Plonge open house higher than implied by the sign-in sheet. Spatial restraints led Denison to display only 7 poster boards. Brochures containing all poster board imagery and information were distributed, accommodating for the absent poster board information.

Dialogue during the open house expressed regard for groundwater and geology. Community members asked questions relating to methodology, inquiring as to effects of Project specifics on characteristics of groundwater and geology. Additional questions predominantly pertained to Project specific information. For additional details about this activity, please see Appendix 4-A, ROC #619.

Online Survey**:** During and following the ERFN meeting(s), attendees were invited to provide feedback on preliminary effects, mitigation, and monitoring through an online survey. Denison created a survey, available in hardcopy and digital formats during each open house and in digital format for two weeks following open house meetings.

Ten survey respondents indicated that they were from ERFN, with six stating that their primary residence was ERFN Patuanak and four stating their primary residence was ERFN La Plonge, and all self-identifying as First Nation. Seven survey respondents indicated that they were within the age range of 35 to 64 years old, two indicated that they were 65 years or more, and one indicated that they were within the 16 to 34 age cohort. Five survey respondents selected the "Other" category to indicate how they heard of the survey, three selected "Word of Mouth," one selected "Facebook," and one selected "Radio".

The survey was comprised of four core questions:

1. Are there any topics of particular concern that Denison needs to pay special attention to?
2. Are there any things missing that Denison should consider to reduce the effects of the Project to the environment?
3. Are there any topics that you would like to see included in monitoring plans?
4. What additional information would be helpful for you to understand the Project and its potential impacts to people and the environment?

When asked the question **"Are there any topics of particular concern that Denison needs to pay special attention to?"** responses predominantly centered around the biophysical environment. This was expressed in several ways, with three responses having some mention of the general environment, one response more specifically referencing cumulative effects through mention of climate change and the vulnerability of northern environments, and one response expressing concern over groundwater quality. Remaining topics expressed by survey respondents in relation to question one were varied, though still relate to a consideration for community context. Employment was mentioned in two instances, traditional land and resource use in two instances, community politics in one instance, and community concerns in one instance. The remaining two responses expressed that there was no topics of concern they felt afforded special attention.

When asked the question **“Are there any things missing that Denison should consider to reduce the effects of the Project to the environment?”** five survey respondents indicated that they felt there was nothing missing. Two survey respondents referenced the environment: one by simply referencing the environment, and the other by referencing the potential effect of exploration on various characteristics of the biophysical environment. While these responses did not relate to the survey question, they emphasized that maintenance of environmental integrity is important. One respondent stated, “Environmental jobs,” in response to this survey question. One survey respondent left the answer incomplete.

When asked the question **“Are there any topics that you would like to see included in the monitoring plan?”** many respondents provided unrelated responses. Of the responses that related to the survey question, one stressed the inclusion of long-term monitoring and surface water. These responses reference environmental jobs and general environmental plans. One response asked how the uranium was discovered, and another requested that ERFN communities be declared as Denison’s priority Indigenous community in relation to the Project. Two responses stressed Indigenous considerations, one stating that they would like to see Indigenous voices be part of the monitoring plan and the other stating that they would like community Elders to be liaison workers. One survey response emphasized mental health.

When asked the question **“What additional information would be helpful for you to understand the Project and its potential impacts to people and the environment?”** three respondents indicated that they did not require any additional information. Three survey responses specifically and directly related to the survey question. One respondent referenced the accessibility of information, stating that it would be helpful to provide explanations in Dene. One survey respondent suggested a community liaison worker to communicate the most current information. One survey respondent suggested to increase the number of infographics. The respondents provided unrelated answers on training and employment, family history and non-specific environmental effects, and questions regarding community benefits. One survey respondent indicated it would be helpful to have a better understanding of the environment.

The survey results were shared with the EIS discipline leads for consideration, where appropriate, in their assessments. In a few instances, the recommendations provided by survey respondents are considered as part of ongoing discussions Denison and ERFN are having, such as the need for Indigenous representation in environmental monitoring and the consideration of Elders/community members as liaisons between Denison and the Nation. For additional details about this activity, please see Appendix 4-A, ROC #652.

Engagement Focus: Environmental Assessment and Relationship to Licensing / Approvals – October 2022 to Present

Site Tour – June 22, 2023: On June 22, 2023, Denison hosted ERFN at the Project to provide an overview of the work done to date on the Project, including the 2022 and 2023 Feasibility Field

Tests in support of the Project. During the site tour, an overview of the overall Project was provided, including the environmental assessment outcomes and next steps for licensing / approvals. Twenty-five ERFN Members were in attendance, including several youth and elders. The site visit opened with the Wheeler River Project site being blessed by two Elders from the ERFN.

The focus of the following engagement activities was to share the findings of the EA, mitigation measures, monitoring, significance, cumulative effects, the conclusions of the EIS, and the relationship between the environmental assessment and the ultimate licensing / approvals process for the Project.

During October 2023, ERFN held an election for Chief and Council, and as such, it was requested by ERFN that Denison not undertake in-community engagement activities.

Meeting – December 13, 2023: On December 13, 2023, Denison and the newly-elected ERFN Chief and Council held a meeting in which the details of the Project were shared, including the status of the regulatory process and next steps.

Workshop – March 15, 2024: On March 15, 2024, Denison hosted a workshop in Saskatoon with 22 members of English River First Nation, as well as ERFN's environmental advisor, and 6 Denison staff members in attendance. The workshop focus was to provide details associated with the environmental assessment outcomes and the relationship to licensing/approvals and to facilitate discussion and receive feedback pertinent to these topics. Information was shared through presentation slides and information handouts. For additional details about this activity, please see Appendix 4-A, ROC #1087.

Future Engagement Activities

Denison and ERFN have an agreed-upon process to regularly engage about ongoing matters related to the Project and the associated regulatory approval process. Denison expects to continue working with ERFN, throughout the remainder of the environment assessment and approval process and into the licensing process, to coordinate engagement activities in relation to topics of interest in relation to the Project.

4.3.2.1.4 Engagement Activities Associated with ERFN-Specific Processes

As noted in Section 4.3.2.1.2, Denison entered into a Participation and Funding Agreement and Letter of Intent with ERFN in relation to the EA process in 2021. As a result, ERFN and Denison have developed some engagement activities specific to ERFN, funded by Denison:

1. Early information-sharing occurred between Denison and ERFN pertaining to the scope development of various activities in relation to various components of the EA:
    a. Denison was invited to review proposed interview questions for the studies to be undertaken by ERFN in relation to socioeconomics/health and wellness.

b. The ERFN was invited to review scoping materials for socioeconomic/health and wellness in relation to the assessment methodology proposed by Denison. In response to specific feedback from ERFN, Denison undertook a full assessment on a new Key Indicator called Traditional Economy. See Section 13 Economics.

c. The ERFN was invited to review the proposed Table of Contents and structure for the EIS in relation how they expected ERFN-authored information to be included into the EIS; the ERFN provided comments relative to this pertaining to various sections of the EIS. Denison shared the information with the discipline leads for consideration, where appropriate, in the respective sections of the EIS.

d. The ERFN was invited to review the proposed scope for Cumulative Effects in relation how ERFN's view of cumulative effects in ERFN's traditional territory. The ERFN provided direction to Denison that the ERFN perspective in relation to cumulative effects would include a 'lands taken up' map incorporated into the forthcoming ERFN-prepared Traditional Knowledge (TK) study (see next point for additional details).

2. Preparation of ERFN-authored reports on topics determined as important by ERFN in relation to the Project:

   a. The ERFN prepared their own independent contribution to the EIS, with assistance from Shared Value Solutions. The information from the following two reports has been shared with Denison to contribute and inform the EA:

      i. The Wheeler River Project – Summary of Health and Socio-Economic Study Results report summarizes results from 16 interviews that were conducted for the health and socio-economic topics (ERFN and SVS 2022a).

      ii. The Wheeler River Project – Summary of Traditional Knowledge Study Results (ERFN and SVS 2022b) presented results from 21 land use interviews, which provided both TK and Local Knowledge (LK) (ERFN and SVS 2022b). The TK study included maps of ERFN ecological knowledge features, personal harvesting sites, commercial harvesting sites, and occupancy sites. The TK component also considered data collected with ERFN Elders in the 1980s and consideration of the cumulative nature of industry in ERFN traditional territory.

The information in the EIS with respect to the knowledge and information by and about ERFN is substantially based on the information contained in these two reports. Please see Table 3.5-1 in Section 3 Indigenous and Local Knowledge for more information.

3. Review by ERFN of EIS information prior to filing draft EIS with Regulators:

   a. Denison shared EIS information (in the forms of specific sections of the EIS) with ERFN prior to filing the draft EIS with the Regulators, to provide ERFN an opportunity to review information made in reference to ERFN, including that information provided to Denison in the reports authored by ERFN, as identified above. The sections shared with ERFN were:

i. Section 3 Indigenous and Local Knowledge;
ii. Section 11 Land and Resource Use;
iii. Section 12 Quality of Life;
iv. Section 13 Economics; and
v. Section 16 Assessment Summary and Conclusions.

During this pre-review, ERFN expressed a variety of concerns to Denison regarding:

- the geographic boundaries of the Local Study Area and Regional Study Area;
- the level of information included in the EIS relating to ERFN's Indigenous Knowledge (IK) and traditional land use activities;
- the potential effects of uranium mining and the Project and how this concern may influence certain members to be averse to using lands or resources near the Project site; and
- employment and business opportunities for ERFN and its members.

Denison addressed these concerns in a response letter to ERFN in early October 2022, which included a disposition table responding to each specific concern identified by ERFN. As necessary, Denison has also addressed ERFN's concerns in the relevant sections of the EIS.

Nuhtsiye-kwi Benéne Committee (Ancestral Lands Committee)

In 2021, in response to ERFN's interest in the establishment of a specific committee in relation to Denison activities and the Project, ERFN and Denison established the Nuhtsiye-kwi Benéne Committee (Ancestral Lands Committee), supported by Denison. As declared by one of the participants, during the inaugural meeting, the purpose of the Nuhtsiye-kwi Benéne Committee is "*to let Denison know how we feel, giving a voice to the people in a community in a respectful way, share information – two-way sharing.*"

Over 2021, the Nuhtsiye-kwi Benéne Committee held three meetings.

Inaugural Meeting – April 22, 2021: During this inaugural meeting of the Nuhtsiye-kwi Benéne Committee, the focus was developing the purpose, vision and expectations of the Nuhtsiye-kwi Benéne Committee. General discussion occurred about the history and use of the land, and the perspectives of ERFN regarding activity that has occurred in their traditional territory. Brief discussion occurred regarding Project design considerations that would enable safe access to and around the Project site for ERFN and non-ERFN members; Denison committed to providing more details about this at the following meeting. For additional details about this activity, please see Appendix 4-A, ROC #458.

Project Site Access, Subsidence, Linear Feature Reclamation Pilot Program – June 15, 2021: During this meeting, Denison and ERFN shared information between each other regarding a number of topics related to the Project.

Denison provided a detailed discussion on the need for restrictions through the Project site for safety reasons, and where those proposed restrictions would be (i.e., gate houses). Generally, ERFN agreed with the concepts of check points in key areas of safety concern, provided that Members could access areas that were not subject to the need for restrictions (see Section 2 for more information). Denison confirmed the importance of providing access to the greatest degree possible for ERFN and other Indigenous people, while respecting the need for safety for all in the area.

At the request of ERFN, Denison also provided a detailed discussion on the potential for subsidence (i.e., surface disturbance involving the gradual sinking of land due to underground activities, such as mining). Denison had commissioned a report on the potential for this and provided the results from the third-party expert. The ERFN expressed satisfaction at the information that was provided in relation to their concerns (see Section 7 Geology and Groundwater and Section 9 Terrestrial Environment for additional information about the potential for subsidence).

Denison also provided an overview of a pilot program being undertaken with respect to mitigation of *existing* cut lines in relation to reduction of predation of ungulates (i.e., moose, caribou) by wolves. General information was shared between the groups regarding knowledge pertaining to use of the area by ungulates in relation to the cut lines, and forest fire areas. While the pilot project was not related to the EA for the Project, some of the information shared by ERFN in relation to these elements have been incorporated into an understanding of the existing environment (see Section 9 for more information). For additional details about this activity, please see Appendix 4-A, ROC #473.

Exploration Activities, Update on the Project, Heritage Management Protocols – October 14, 2021: During this meeting, Denison provided ERFN with an overview of general exploration activities, and an update on the Project and the plans for 2021 and 2022 activities. In response to a request from ERFN, Denison presented information on the heritage assessment done for the Project and the proposed plans for responding to the identification of a heritage artifact. In this context, heritage refers to archaeological and palaeontological (precontact) items. As part of the discussion regarding the finding of artifacts, Denison committed to including a consultation element with ERFN in the Heritage Management Plan, should an artifact be found during the development of the Project (see Section 11.3 in Section 11 for more information). For additional details about this activity, please see Appendix 4-A, ROC #591.

4.3.2.1.5 English River First Nation Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, the public was invited to comment on the draft EIS by the CNSC.

On Feb 22, 2023, ERFN submitted public comments on the draft EIS to the CNSC (Government of Canada 2024).

The initial ERFN public comments on the draft EIS totaled 271 technical comments. In working with ERFN and its support team, this initial list was discussed, prioritized, and summarized into 15 key areas of concern to be addressed prior to finalizing the EIS, and those areas that can be addressed in later stages of the various approvals processes. On August 18, 2023, ERFN provided Denison with specific questions in relation to these 15 key areas of concern, with a request for Denison to respond to the summary of the issues (see Appendix 4-A, ROC #968). On November 1, 2023, Denison provided ERFN with a technical memo providing responses to the summary of main issues as requested by ERFN (see Appendix 4-A, ROC #987). On November 28, 2023, Denison was notified by ERFN that ERFN had reviewed Denison's responses to their main issues and areas of concern, and were satisfied with the level of response provided by Denison at this stage of project planning (see Appendix 4-A, ROC #1007).

4.3.2.1.6 English River First Nation Consent for the Project

On September 27, 2023, ERFN provided a letter to the CNSC and the Province of Saskatchewan a letter that outlined ERFN's consent for the Project, subject to Denison materially fulfilling its commitments to ERFN. The letter further noted ERFN's intent to participate in the ongoing regulatory approval processes for the Project in a manner consistent with agreement between the two parties.

4.3.2.1.7 English River First Nation Key Interests, Issues and Concerns

A summary of key interests, issues and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA 2012; they can be reflective of *general* areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.3.2.2 Engagement with Kineepik Métis Local #9

Pinehouse is the community in which KML generally resides. The Kineepik Métis "*are considered Woodland Cree, Woodland Dene and Woodland Métis, although historical documents indicate that the member of (the Kineepik Métis Local) came from a diverse range of Métis, First Nations, and other backgrounds. The Northern Village of Pinehouse is located within the digitally mapped traditional territory of Indigenous people of Kineepik Métis Local. (They) have used these lands surrounding Missinippi (Churchill River) watershed for gathering food, shelter, and material supplies since time immemorial.*" (KML 2022).

Figure 4.3-2 illustrates where KML is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, KML is located 230 km away from the Project. In terms of travel distance by existing transportation routes, KML is located 270 km away from the Project.

4.3.2.2.1 History of Interactions

Since 2016, Denison has been engaging with KML in a variety of ways. "*As of 2011, KML has a population of 1,600 people, of which 1,400 live on the [Northern Village of Pinehouse] municipality and 200 living either in other jurisdictions or on the land surrounding the community*" (KML 2022). In some instances, the elected officials of Métis Locals are also elected members of the municipality and, therefore, represent both their Indigenous community as well as their municipality. As a result, during the onset of engagement activities in 2016, the entities of KML and the Village of Pinehouse Lake had some overlap between each other.

In 2019, the KML delegated their Duty to Consult for the Project to the MN-S. Clear distinction between the Métis leadership and Citizens, and the Village leadership and residents was, therefore, necessary to make sure the MN-S was able to appropriately provide the representation of the Métis of KML, per the delegated Duty to Consult. As a result, Denison distinguished its engagement efforts between MN-S, on behalf of KML, and the general public of the Village of Pinehouse, with no intended overlap in relation to Métis interests.

In 2021, the KML revoked their delegated Duty to Consult to the MN-S. Denison re-engaged the KML directly in respect of the Project.

A comprehensive listing of engagement activities between Denison and KML, including a brief description of the purpose or activity and outcome where appropriate, is included in the IER.

4.3.2.2.2 Agreements Relative to the Environmental Assessment Process

To formalize Denison's commitment to KML, a MOU was signed by Denison, KML, and the Village of Pinehouse Lake in 2017. The signing of this MOU with both KML and the Village of Pinehouse Lake reflected the perspective of KML and the Village of Pinehouse Lake to represent both municipal residents and the Métis Citizens co-operatively. This non-binding MOU formalized the intent to work together in a spirit of mutual respect to cooperate to collectively identify practical means by which to avoid, mitigate, or otherwise address potential effects of the Project upon the exercise of the Indigenous Rights, Treaty Rights, and interests.

In 2018, Denison, the KML, and the Village of Pinehouse Lake signed an addendum to the original MOU whereby Denison committed to financially supporting an initiative to undertake a second phase of land use and occupancy mapping representing the KML and the Village of Pinehouse Lake. This work was subsequently undertaken in 2018 and shared with Denison for use in documents in relation to regulatory proceedings associated with its activities, including the Project.

In 2019, the KML delegated their Duty to Consult for the Project to the MN-S. Thereafter, as directed, Denison engaged with MN-S on behalf of KML (and other Métis Locals who likewise delegated their Duty to Consult to MN-S).

In 2021, the KML revoked their delegated Duty to Consult to the MN-S. Denison re-engaged the KML directly in respect of the Project while continuing to engage separately with the general public of the Village of Pinehouse Lake.

In 2022, Denison and the KML built upon the 2017 MOU and signed a Participation Agreement and associated Letter Agreement, which outlined a mutually agreeable framework and applicable funding arrangements to facilitate KML's participation and engagement in the EA process for the Project—including KML's contribution to Denison's environmental understanding of the Project in a holistic way that respected KML's rights and interests. As a result, several additional activities have been undertaken between KML and Denison, which are further described in Section 4.3.2.2.3.

In July 2024, KML and Denison concluded an Agreement in respect of the Project that provides, among other matters, various procedural and substantive commitments by Denison to KML and the support and consent of KML for the development and operation of the Project in a sustainable manner, which respects KML's inherent Aboriginal rights, advances reconciliation with Indigenous peoples, and provides economic opportunities and other benefits to KML.

4.3.2.2.3 Key Engagement Activities

During the engagement activities undertaken with KML, several key engagement activities took place that have played a meaningful role in relation to the EA process. The main forms of engagement included meetings with leadership, community meetings, a workshop on early infrastructure options (2018), a site visit (2019), a meeting coordinated by the MN-S (2019), one online survey (2022), and a meeting and information session on preliminary effects and mitigation (2022). As noted in Section 4.2.1, due to the COVID-19 pandemic, engagement switched to virtual meetings in 2021. In mid-2022, appropriate engagement activities moved back to in-person. The following text describes several the key engagement activities. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1.

Engagement Focus: Pre-Project Description - April 2016 to May 2019

Meeting – September 7, 2016: Introductory meeting in Village of Pinehouse Lake: This was the inaugural meeting between the senior management team of Denison and members of KML. About 20 individuals were in attendance, along with the President of KML. Much of the meeting focussed on clarifying the nature of Denison's activities, including the Project and related exploration activities, the interest in employment and business opportunities, the interest in protection of the environment from exploration and Project activities, including consideration of cumulative effects, and questions in relation to the nuclear industry in general and the market related to uranium. For additional details about this activity, please see Appendix 4-A, ROC #105.

Workshop – January 16, 2018: Denison hosted a workshop with grade 11 and 12 students, plus a number of community members. The focus of the workshop was to obtain feedback on three alternatives/options for the proposed Project: the road alignment from Highway 914 into the Project Area; the potential treated effluent discharge location; and the mining method options.

The focus of this engagement activity was to obtain feedback on three alternatives/options for the proposed Project: the road alignment from Highway 914 into the Project Area; the potential treated effluent discharge location; and the mining method options. For additional information about this activity, please see Appendix 4-A, ROC #2. General questions were asked regarding the various alternatives and options, and points of clarification pertaining to aspects of the Project. Feedback was collected on the various options and has been incorporated into the final design for road alignment, and the treated effluent discharge location. Please see Section 2 for more details. For additional details about this activity, please see Appendix 4-A, ROC #2.

Engagement Focus: Post-Project Description – July 2019 to October 2022

Site Tour - August 23, 2019: In August 2019, Denison hosted a site tour at the Project location. Attending the site tour was the President of KML and the Executive Director of the KML. The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project.

The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Representatives from the CNSC and SK MOE were present. For more information about this activity, please see Appendix 4-A, ROC #1.

Meeting – November 5, 2019: Denison hosted a meeting with the MN-S President, the Northern Region 3 President, legal counsel, some administrators, and several Local Presidents and representatives, including KML in attendance. This engagement activity was coordinated with the MN-S, in response to the delegated Duty to Consult from several Métis Locals as of November

2019. The focus was to provide an overview of the Project and discuss Métis interests in the Project. See Section 4.3.4.1.3 for a detailed discussion on this meeting. For additional details about this activity, please see Appendix 4-A, ROC #62.

Engagement efforts were temporarily suspended in March 2020 as a result of the COVID-19 pandemic. As noted in Section 4.2.1, due to the COVID-19 pandemic, engagement switched to virtual meetings in 2021. In mid-2022, appropriate engagement activities moved back to in-person.

During this period, Denison engaged with MN-S on behalf of KML (and other Métis Locals who likewise delegated their Duty to Consult to MN-S). See Section 4.3.4.1.3 for a detailed discussion of this engagement.

Meetings (Leadership and Open House in the Village of Pinehouse Lake) – June 1, 2022:

On June 1, 2022, engagement activities were undertaken in collaboration with KML to occur in the Village of Pinehouse Lake, in the Village Hall. The focus of these engagement activities was to share the preliminary findings of the EA, proposed mitigation measures and preliminary conclusions of the EIS, and to facilitate dialogue related to this information. The structure and layout of the meeting was jointly established between Denison and KML. Engagement activities were conducted as a focused leadership meeting with KML representatives and the Village of Pinehouse representatives (at their joint request), and as a general open house. Date and location of open house meetings were advertised on local radio stations, Facebook pages, TV channels, and posters. During the open house, members were able to complete a survey, in hard copy or digital format, to express their opinions. Comments and questions were also captured by Denison in a record-keeping notebook, and transcribed following the event.

To communicate EA findings and Projects details, Denison created and displayed three models and 15 informational poster boards. The three models depicted: 1) the uranium ore body and projected, below ground, extraction infrastructure; 2) the Project site surface with associated infrastructure; and 3) a 1:294 scale map of the area surrounding the Project site. The 15 informational poster boards presented EA findings in relation to VCs identified as important during previous rounds of engagement activities, as well as detail on technologies, regulatory processes, and procedures.

KML and Village of Pinehouse Leadership Meeting – June 1, 2022: The leadership meeting was held in at the Pinehouse Lake gas bar on June 1, 2022, with invited representatives of KML and the Village of Pinehouse Lake. Denison provided an overview of the Project that included information on Project specifics, current status, predicted timeline, and preliminary EA findings.

The dialogue between Denison and the leadership related to Project specifics, including inquiries about the dimensions of the ore body and freeze wall. Questions surrounding employment and training were also expressed. A need for a culturally sensitive training model was communicated. This bridged to discussion of the reduced footprint of the Project translating to fewer employment opportunities. Leadership expressed a desire for appropriate training for community residents to adequately compete as Project related jobs become available. Representatives from the CNSC and SK MOE were present. For more information about this activity, please see Appendix 4-A, ROC #623.

Open House in Village of Pinehouse Lake – June 1, 2022: As mentioned previously, the open house was co-planned between Denison and KML. The open house was held at the Pinehouse Community Centre, welcoming members of the surrounding area. A total of 52 attendees signed the sign-in sheet. Some individuals chose not to sign in, making the attendance at the Pinehouse open house slightly higher than recorded by the sign-in sheet. Through open house dialogue, community members expressed a general interest in the Project and Project-specific information. Questions such as "How does ISR mining work?" and "How does calcium chloride (CaCl) cool and freeze the ground?" illustrate this interest. Other questions, while primarily geared toward gaining clarity on Project specifics, suggest consideration for mitigation measures, human health, and the biophysical environment. Examples of this include questions such as "Where will the drinking water [for the camp] come from?" and inquiries over potential effects of work schedules on worker health. Representatives from the CNSC and SK MOE were present. For additional details about this activity, please see Appendix 4-A, ROC #620.

Online Survey: During and following the meeting(s), attendees were invited to provide feedback on preliminary effects, mitigation, and monitoring through an online survey. Denison created a survey, available in hardcopy and digital formats during each open house and available in digital format for two weeks following the open house. The survey was comprised of four core questions:

1. Are there any topics of particular concern that Denison needs to pay special attention to?
2. Are there any things missing that Denison should consider to reduce the effects of the Project to the environment?
3. Are there any topics that you would like to see included in monitoring plans?
4. What additional information would be helpful for you to understand the Project and its potential impacts to people and the environment?

The 25 survey respondents indicated that they were from Pinehouse, with 15 self-identifying as Métis, nine as First Nation, and one as Indigenous without further specification. Survey respondents primarily heard of the survey through word of mouth, indicated by 10 survey respondents. Five survey respondents indicated that they heard of the survey through Facebook, and five indicated they heard of the survey through "other" means. Three respondents heard of the survey through posters, and two through radio. Most survey respondents were in the 35 to 64 age cohort, indicated in 16 instances. Five respondents indicated that they were in the 16 to34 cohort and four indicated that they were in the 65+ age cohort.

When asked the question **“Are there any topics of particular concern that Denison needs to pay special attention to?”** five respondents provided incomplete answers. Six survey respondents expressed that they had no concerns, with statements ranging from variations of the word “no” to positive statements such as “*I think Denison covered all the main topics very well*.” Five respondents emphasized employment and training, one of which framed this emphasis in a northern context. Five survey respondents highlighted a concern for the environment; responses included: one focused on water quality; two environmental restoration; one on the general environment; and one on mining source water treatment and runoff, presumably as it relates to the environment. One response expressed a concern over recycling. The remaining responses touched on a variety of topics. One survey respondent supplied a community benefits inquiry. Accessibility of the Project site and Project buildings was a concern for another respondent. Concern over the potential for future Covid-19 restrictions and possible vaccination requirements was expressed, though this response may be extended to include pandemic planning in general.

When asked the question **“Are there any things missing that Denison should consider to reduce the effects of the Project to the environment?”** 10 survey respondents indicated that they felt that was nothing missing. These responses, again, ranged from “no” to positive commentary such as “*No- work at Denison Mine couple shifts, like the safe orientated culture and respect of land and native people that live near the mine sites*.” One additional survey response stated “*May in the future*.” This may express no concern and/or a desire for forward planning. One survey respondent directly referenced forward planning in addition to stressing the importance of wildlife, and caribou habitat management. Waste management was referenced by one respondent, emphasizing recycling and providing the suggestion of recycling paper. One survey respondent emphasized air quality, while another inquired “*Are these surface pipes [spill] ready at all times*?” One survey response suggested the inclusion of LK and TK, suggesting Denison “*learn from the people around this project*.” One survey respondent expressed concern for land users and wanted it to be affirmed that mining methods were safe. Seven survey respondents provided incomplete responses.

When asked the question **“Are there any topics that you would like to see included in the monitoring plans?”** five respondents supplied incomplete answers and nine indicated that there was nothing additional that they felt needed to be considered. Several responses did not relate to the survey question; two suggested a focus on local employment opportunities, one inquired about water quality as per human consumption and treatment, one requested more local meetings, one inquired about double plated pipes and spill readiness, one stated that someone was required to teach safety, and one requested more project context. Responses related to the survey question related to water quality, with one response simply stating water sampling and the other emphasizing monitoring of aquatic environments as well as budgeting appropriately for long-term monitoring. Similarly, another survey respondent stated “future-wise”, potentially referring to long-term monitoring or incorporating topics into the monitoring plan in a future context. One survey response indicated they would like to see ongoing reporting on Project Operation.

When asked the question **“What additional information would be helpful for you to understand the Project and its potential impacts to people and the environment?”** six indicated that no additional information was needed and five provided incomplete responses. Several survey respondents provided unrelated suggestions to this survey question. Forming mutually beneficial agreements was suggested through the response “*Always explain the motto ‘help us help you.”*. Two respondents focused on opportunities for youth, one in terms of employment and the other in terms of scholarships, and one survey respondent emphasized general opportunity for future employment. One survey respondent suggested employment considerations for people with disabilities. Waste management was focused on, with one survey respondent suggesting an increase in practice of recycling as well as questioning water quality and sampling. One respondent suggested Elder representation in decision making. Responses that related to the survey question generally suggested a need for high level information including Project timeline, more information on environmental effects, water quality changes from Project Operation, and general Project site information including potential jobs and tasks. The importance of ongoing dialogue was emphasized in responses that suggested continued transparency and regular community meetings.

Most of the information shared with Denison regarding the above questions on the survey are suitably captured and addressed by Denison as part of the current work on the EA and the Project in general. In a few instances, the recommendations in relation to sharing of information in the future, such as with respect to environmental monitoring and employment opportunities, will be carried through into ongoing discussions between Denison and KML. For additional details about this activity, please see Appendix 4-A, ROC #652.

Engagement Focus: Environmental Assessment and Relationship to Licensing / Approvals – October 2022 to Present

Site Tour – June 14, 2023*:* On June 14, 2023, Denison hosted KML at the Project site to provide an overview of the work done to date on the Project, including the 2022 and 2023 Feasibility Field Test in support of the Project. During the site tour, an overview of the overall Project was provided, including the environmental assessment outcomes and next steps for licensing / approvals. Twenty-one KML representatives were in attendance, including several youth and elders.

Meetings (Land User and Open House) – October 24, 2023: On October 24, 2023, engagement activities were undertaken in collaboration with KML in the Village of Pinehouse Lake at the Village Hall.

The focus of these engagement activities was to share the findings of the EA, mitigation measures, monitoring, significance, cumulative effects, the conclusions of the EIS, and the relationship between the environmental assessment and the ultimate licensing / approvals process for the Project.

The structure and layout of the meeting was jointly established between Denison and KML. Engagement activities were conducted as a focused leadership meeting with KML land users, and as a general open house with a specified time period for an overview presentation. The date and location of open house meetings were advertised on local radio stations, Facebook pages, TV channels, and posters. Comments and questions were also captured by Denison in a record-keeping notebook, and transcribed following the event.

To communicate EA findings, Project details and the relationship to the licensing / approvals process, Denison displayed three models and 6 informational poster boards. The three models depicted: 1) the uranium ore body and projected below ground and extraction infrastructure; 2) the Project site surface with associated infrastructure; and 3) a 1:294 scale map of the area surrounding the Project site. The 6 informational poster boards presented EA findings and related licensing / approvals actions in relation to VCs identified as important during previous rounds of engagement activities.

KML Land User Meeting – October 24, 2023: The KML land user meeting was held in at the Village Hall on October 24, 2023, from 1pm to 3pm. The purpose of this meeting was to share information about the Project, with a particular focus on the flow of information from the environmental assessment into licensing, permits, and commitments. The event was planned and invitations extended as part of the process in place led by KML. Information boards and area models were displayed and information booklets were provided. Denison prepared a formal presentation, and a translator was present to translate as needed. The Canadian Nuclear Safety Commission and the Saskatchewan Ministry of Environment were invited by Denison and were in attendance.

For more information about this activity, please see Appendix 4-A, ROC #979

Open House in Village of Pinehouse Lake – October 24, 2023: In coordination with KML, Denison hosted an open house event in the Northern Village of Pinehouse to share information about the Project, with a particular focus on the flow of information from the environmental assessment into licensing, permits, and commitments. Denison advertised the event with social media posts and posters around the community. In addition to members of KML, 48 residents were recorded as in attendance. Information boards and area models were displayed and information booklets were provided. Denison prepared a formal presentation, and a translator was present to translate as needed. The Canadian Nuclear Safety Commission and the Saskatchewan Ministry of Environment were invited by Denison and were in attendance. For additional details about this activity, please see Appendix 4-A, ROC #978.

Site Tour (Student) – May 7, 2024: In coordination with Kineepik Métis Local, Denison hosted a site tour at the Wheeler River Project for Pinehouse high school students.

Meeting (Land User) – May 8, 2024: In coordination with Kineepik Métis Local, Denison hosted a land user meeting at the Pinehouse Village Hall. The focus of the meeting was to share updates on the Wheeler River Project, answer land user questions, facilitate discussion, and provide information on Project stage and licensing progression. The event was planned and invitations extended as part of the process in place led by KML. Denison prepared a presentation and distributed informational handouts to attendees. The meeting was attended by 38 land users and 4 KML staff. For additional details about this activity, please see Appendix 4-A, ROC #1088.

Future Engagement Activities

Denison and KML have an agreed-upon process to regularly engage about ongoing matters related to the Project and the associated regulatory approval process. Denison expects to continue working with KML throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities in relation to topics of interest to them in relation to the Project.

4.3.2.2.4 Engagement Activities Associated with KML-Specific Processes

As noted in Section 4.3.2.2.2, Denison entered into an MOU with KML and Addendum in 2017 and 2018, along with a Participation Agreement in 2022. As a result, KML and Denison have developed engagement activities specific to KML, funded by Denison:

1. Land Use and Occupancy Mapping

In 2018, the KML at Pinehouse approached Denison to support a land use mapping initiative in the Project Area. The 2018 study builds on the land use mapping completed in 2011 by extending the spatial boundaries (Tobias and Associates 2018a). Methods used in the 2018 data collection are documented in Tobias and Associates (2018b) and results represent input from 128 respondents in 2011 and 55 respondents in 2018. The Tobias and Associates (2018b) methods report indicates that, collectively, the results from the 2011 and 2018 surveys represent the contemporary land base of Pinehouse residents determined "*primarily by locations where residents procure fish, birds, mammals and plant resources for direct family consumption*". A verification meeting was held in late 2018 to make sure no geographic data gaps existed and that the results speak for the whole community.

This occupancy and land use data have been incorporated into the EIS. Please see Table 3.5-2 in Section 3.

2. KML Valued Ecosystem Components:

In 2022, the KML prepared a report (KML 2022) to voice their perspectives on Project valued ecosystem components. An initial draft was provided to Denison in April 2022 and a final report was provided in June 2022. Based on 12 community engagement sessions and review of the land use maps described above, the Kineepik Métis explained their unique social, cultural and historical context, expressed general support for the Project, and described issues and concerns. (KML 2022).

This report was used throughout the EIS, where appropriate. Please see Table 3.5-1 in Section 3.

Kineepik Métis Local #9 Public Comments on the Draft Environmental Impact Statement and Related Processes: An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On Feb 17, 2023, KML submitted public comments on the draft EIS to the CNSC (Government of Canada 2024), consisting of 11 technical comments.

On June 11, 2023, following work undertaken together since receipt of the February 17, 2023, public comments, Denison provided KML with an updated table of issues, concerns and interests capturing engagement efforts over the years for both KML and the NVP – including Denison's responses to those issues, concerns, and interests, as associated with the Project draft EIS. KML provided feedback and stated that they were satisfied with the updated table, including Denison's responses to the issues, concerns, and interests (see ROC #917).

On November 22, 2023, Denison provided KML with specific responses to KML's February 17, 2023, public comments (see Appendix 4-A, ROC #970). On December 5, 2023, KML confirmed to Denison that Denison's responses to the February 17, 2023, public comments had resolved KML's comments / concerns on the draft EIS and the Project (see Appendix 4-A, ROC #1027).

4.3.2.2.5 Kineepik Métis Local #9 Consent for the Project

On August 1, 2024, KML provided a letter to the CNSC and the Province of Saskatchewan that outlined KML's consent for the Project, subject to Denison materially fulfilling its commitments to KML. The letter further noted KML's intent to participate in the ongoing regulatory approval processes for the Project in a manner consistent with the agreement between the two parties.

4.3.2.2.6 Kineepik Métis Local #9 Key Interests, Issues and Concerns

A summary of key interests, issues, and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA - they can be reflective of *general* areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction. Additional information on key issues and concerns raised from the Northern Village of Pinehouse (NVP) can be found in Appendix 4-B.

4.3.2.3 Engagement with Sipishik Métis Local #37

Beauval is the community in which SML residents generally reside. Beauval—"Beautiful Valley"—is located in northern Saskatchewan overlooking the picturesque Beaver River Valley, providing a striking view of the river and surrounding nature. The community has a proud history of culture, language, and heritage. In history, Beauval was a trading post location along the Churchill River trade route for the Hudson's Bay Company; this route is still traveled via canoe by history buffs and avid outdoorsman for the pristine scenes and memorable nature experience with historic influence. The trail to Fort Black was an early access route from Beauval to neighboring Île-à-la-Crosse for early settlers, trappers and fishers. The historical significance of this trail to the livelihood of the community in the past adds to the rich history of the Métis heritage and culture of Beauval, Saskatchewan (MN-S n.d.a).

Figure 4.3-2 illustrates where SML is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, SML is located 295 km away from the Project. In terms of travel distance by existing transportation routes, SML is located 375 km away from the Project.

4.3.2.3.1 History of Interactions

Since 2016, Denison has been engaging with SML in a variety of ways. The Northern Village of Beauval (NVB), and many of the community members residing in Beauval, self-identify as Métis. In some instances, the elected officials of Métis Locals are also elected members of the municipality and, therefore, represent both their Indigenous community as well as their municipality. As a result, during the onset of engagement activities in 2016, the entities of SML and the Village of Beauval had some overlap.

In 2019, the SML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing SML in respect of engagement with Denison for the Project. Clear distinction between the Métis leadership and Citizens, and the Village leadership and residents was, therefore, necessary to make sure the MN-S was able to appropriately provide the representation of the Métis of SML, per the delegated Duty to Consult. As a result, Denison focussed engagement efforts exclusively toward the general public of the Village of Beauval onwards from this point, with no intended overlap in relation to Métis interests.

A comprehensive listing of engagement activities between Denison and SML, including a brief description of the purpose or activity and outcome where appropriate, is included in the IER.

4.3.2.3.2 Agreements Relative to the Environmental Assessment Process

To formalize Denison's commitment to SML, a MOU was signed by Denison, SML and the Village of Beauval in 2018. The signing of this MOU with both SML and the Village of Beauval reflected the perspective of SML and the Village of Beauval to represent both municipal residents and the Métis Citizens co-operatively. This non-binding MOU formalized the intent to work together in a spirit of mutual respect to cooperate to collectively identify practical means by which to avoid, mitigate, or otherwise address potential effects of the Project upon the exercise of the Indigenous Rights, Treaty Rights, and interests, to the extent they are identified in relation to the Project.

In 2019, SML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing SML in respect of engagement with Denison for the Project.

4.3.2.3.3 Key Engagement Activities

During the engagement activities undertaken with SML, the main forms of engagement included meetings with leadership, a community meeting, a workshop on early infrastructure options (2018), and a site visit (2019) and a meeting coordinated by the MN-S (2019). These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1.

Engagement Focus: Pre-Project Description - April 2016 to May 2019

Introductory Meeting in the Village of Beauval - December 6, 2016: This was the inaugural meeting between the senior management team of Denison and various entities associated with SML and the Village of Beauval. Much of the meeting focussed on clarifying the nature of Denison's activities, including the Project and related exploration activities, the interest in employment and business opportunities, opportunities and considerations for the long-term, and questions in relation to the nuclear industry in general and the market related to uranium. For more information about this activity, please see Appendix 4-A, ROC #107.

Workshop – January 18, 2018: Denison hosted a workshop with several community members. The focus of the workshop was to obtain feedback on three alternatives/options for the proposed Project: the road alignment from Highway 914 into the Project Area; the potential treated effluent discharge location; and the mining method options. General questions were asked regarding the various alternatives and options, and points of clarification pertaining to aspects of the Project. Feedback was collected on the various options and has been incorporated into the final design for road alignment, and the treated effluent discharge location. Please see Section 2 for more details. For additional details about this activity, please see Appendix 4-A, ROC #4.

Engagement Focus: Post-Project Description – July 2019 to October 2022

Site Tour – August 23, 2019: In August 2019, Denison hosted a site tour at the Project location. The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project. Attending the site tour was the Vice President of SML. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Representatives from the CNSC and SK MOE were present. For more information about this activity, please see Appendix 4-A, ROC #1.

Meeting – November 15, 2019: Denison hosted a meeting with the MN-S President, the Northern Region 3 President, legal counsel, some administrators, and several Local Presidents and representatives, including SML in attendance. This engagement activity was coordinated with the MN-S, in response to the delegated Duty to Consult from several Métis Locals as of October 2019. The focus was to provide an overview of the Project and discuss Métis interests in the Project.

See Section 4.3.4.1.3 for a detailed discussion on this meeting. For more specifics about this activity, please see Appendix 4-A, ROC #62.

In 2019, SML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing SML in respect of engagement with Denison for the Project. For details on Denison's engagement with MN-S, see Section 4.3.4.1.

Future Engagement Activities

Denison expects to continue working with the SML, through the MN-S 2024, throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities in relation to topics of interest in relation to the Project, in accordance with an agreed-upon process.

4.3.2.3.4 Sipishik Métis Local #37 Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On March 3, 2023, the MN-S submitted public comments on the draft EIS to the CNSC (Government of Canada 2024). As SML delegated their duty to consult to the MN-S, engagement on issues related to the environmental assessment are now represented by the MN-S.

On December 1, 2023, following work undertaken with the MN-S since receipt of the March 3, 2023, public comments, Denison provided responses to the MN-S' public comments made on the draft EIS (please see Appendix 4-A, ROC #973).

During this same time period, Denison and the MN-S met regularly to discuss the advancement of the Métis Knowledge Study and to discuss items in relation to the development of a MN-S defined process for engagement on the Project, including in relation to the resolution of the MN-S public comments and general issues and concerns. One of the key areas of concern raised by the MN-S was the inclusion of information obtained as a result of the completion of the Métis Knowledge Study into the EIS. The Métis Knowledge Study was received by Denison on October 24, 2023, and Denison has integrated relevant information from the Study into the EIS accordingly.

In July 2023, Denison and the MN-S began discussions pertaining to the development of a Joint Working Group process in relation to engagement with the MN-S about the Project. As of June 30, 2024, Denison and the MN-S had tentatively agreed to amendments to the existing Capacity Funding Agreement in support of this mutually agreeable engagement process, with the amendments awaiting final approval as part of a process defined by MN-S.

Following further discussions between Denison and the MN-S during August 2024, MN-S outlined an additional process that MN-S desired take place between Denison and the MN-S, to occur in parallel to the earlier discussed mutually agreeable engagement process. It is Denison's understanding that the commencement of these parallel processes is expected to occur in the coming months.

For more information about the work undertaken with the MN-S, please see Section 4.3.4.1.

4.3.2.3.5 Sipishik Métis Local #37 Key Interests, Issues and Concerns

A summary of key interests, issues, and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction. As SML delegated their duty to consult to the MN-S in late 2019, the table is representative to the timeframe prior to the delegation of the duty to consult by the SML to the MN-S.

Additional information on key issues and concerns raised from the NVB can be found in Appendix 4-B.

4.3.2.4 Engagement with Patuanak Métis Local #82

Patuanak is the community in which PML generally resides. As of the June 2022, there were 14 registered Citizens associated with PML. Patuanak is a community in northern Saskatchewan, Canada. It is the administrative headquarters of the ERFN reserve near Churchill River and the north end of Lac Île-à-la-Crosse. In Dene, it sounds similar to Boni Cheri (Bëghą́ɲch'ërë). The community consists of the Northern Hamlet of Patuanak with 64 residents governed by a Mayor and three Councillors and the adjoining Wapachewunak 192D reserve of the English River Dene Nation with 482 residents (Canada Census 2011). Patuanak is about 92 km (57 miles) north of Beauval at the end of Highway 918.

Figure 4.3-2 illustrates where Patuanak is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, PML is located 230 km away from the Project. In terms of travel distance by existing transportation routes, PML is located 460 km away from the Project.

4.3.2.4.1 History of Interactions

Before 2019, Denison undertook engagement activities in the Patuanak area (including with PML) more broadly through work done in relation to the ERFN Wapachewunak reserve, consistent with the strong interconnections in the area. In mid-2019, Denison was advised by the Province of Saskatchewan of the interest of PML in relation to the Project. As a result, beginning June 2019, Denison began engaging directly with PML. This included sending correspondence to PML about the Project description, having informal discussions pertaining to their interests in the Project, and hosting a site visit (2019) and a meeting jointly coordinated by the MN-S (2019).

In 2019, the PML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing PML in respect of engagement with Denison for the Project. Since then, Denison has been engaging with MN-S on behalf of PML and other Métis Locals. For details of this engagement, see Section 4.3.4.1. The following section summarizes engagement activities that occurred with Denison and PML in 2019. Appendix 4-A includes further details pertaining to all these interactions. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1.

4.3.2.4.2 Key Engagement Activities

<u>**Engagement Focus: Pre-Project Description - April 2016 to May 2019**</u>

Site Tour – August 23, 2019: In August 2019, Denison hosted a site tour at the Project location. The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project.

Attending the site tour was the President of PML. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Representatives from the CNSC and SK MOE were present.

For more information about this activity, please see Appendix 4-A, ROC #1.

Meeting – November 5, 2019: Denison hosted a meeting with the MN-S President, the Northern Region 3 President, legal counsel, some administrators, and several Local Presidents and representatives, including PML in attendance. This engagement activity was coordinated with the MN-S in response to the delegated Duty to Consult from several Métis Locals as of November 2019. The focus was to provide an overview of the Project and discuss Métis interests in the Project.

See Section 4.3.4.1.3 for a detailed discussion on this meeting. For more specifics about this activity, please see Appendix 4-A, ROC #62.

In 2019, PML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing PML in respect of engagement with Denison for the Project. For details on Denison's engagement with MN-S, see Section 4.3.4.1.

Future Engagement Activities

Denison expects to continue working with the PML, through the MN-S, throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities in relation to topics of interest in relation to the Project in accordance with an agreed-upon process.

4.3.2.4.3 Patuanak Métis Local Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On March 3, 2023, the MN-S submitted public comments on the draft EIS to the CNSC (Government of Canada 2024). As PML delegated their duty to consult to the MN-S, engagement on issues related to the environmental assessment are now represented by the MN-S.

On December 1, 2023, following work undertaken with the MN-S since receipt of the March 3, 2023, public comments, Denison provided responses to the MN-S' public comments made on the draft EIS (please see Appendix 4-A, ROC #973).

During this same time period, Denison and the MN-S met regularly to discuss the advancement of the Métis Knowledge Study and to discuss items in relation to the development of a MN-S defined process for engagement on the Project, including in relation to the resolution of the MN-S public comments and general issues and concerns. One of the key areas of concern raised by the MN-S was the inclusion of information obtained as a result of the completion of the Métis Knowledge Study into the EIS. The Métis Knowledge Study was received by Denison on October 24, 2023, and Denison has integrated relevant information from the Study into the EIS accordingly.

In July 2023, Denison and the MN-S began discussions pertaining to the development of a Joint Working Group process in relation to engagement with the MN-S about the Project. As of June 30, 2024, Denison and the MN-S had tentatively agreed to amendments to the existing Capacity

Funding Agreement in support of this mutually agreeable engagement process, with the amendments awaiting final approval as part of a process defined by MN-S.

Following further discussions between Denison and the MN-S during August 2024, MN-S outlined an additional process that MN-S desired take place between Denison and the MN-S, to occur in parallel to the earlier discussed mutually agreeable engagement process. It is Denison's understanding that the commencement of these parallel processes is expected to occur in the coming months.

For more information about the work undertaken with the MN-S, please see Section 4.3.4.1.

4.3.2.4.4 Patuanak Métis Local Key Interests, Issues and Concerns

A summary of key interests, issues, and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues, or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of *general* areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction. As PML delegated their duty to consult to the MN-S in late 2019, the table is representative to the timeframe prior to the delegation of the duty to consult by the PML to the MN-S.

4.3.2.5 Engagement with Hatchet Lake First Nation

On March 18, 2019, YNLR sent a letter to Denison directing Denison to undertake engagement and communication solely with YNLR for the purposes of any activities requiring approval actions from the Athabasca Denesųłiné, such as the EA for the Project. The letter explicitly stated:

> "*Please be advised that in relation to all new and ongoing mining, milling, exploration, forestry, road building and other industrial and non-industrial developments and activities for which a federal or provincial licensing permit, regulatory process, environmental assessment or other approval is required the sole point of contact for Black Lake First Nation, Fond du Lac First Nation, Hatchet Lake First Nation, Stony Rapids, Wollaston Lake, Camsell Portage and Uranium City is to be the Ya'thi Néné Lands and Resource Office. Accordingly, we direct you to communicate solely with Ya'thi Néné Lands and Resource Office in all related matters and our staff will be in direct contact with the First Nations and Municipal communities as it relates to activities in the Athabasca Basin and the Athabasca First Nations traditional territory.*"

As a result, Denison's engagement activities with the Hatchet Lake First Nation have been undertaken through engagement activities with the YNLR. Please see Section 4.3.4.2 for a full discussion on these activities.

Hatchet Lake First Nation is a signatory to Treaty 10. Figure 4.3-1 illustrates where the communities are in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Hatchet Lake First Nation is located 150 km away from the Project. In terms of travel distance by existing transportation routes Hatchet Lake First Nation is located 945 km away from the Project.

4.3.3 Engagement with Other Indigenous Communities

As noted in Section 4.3.1, engagement with Other Indigenous Communities focused on Indigenous community with a potential interest in the Project, which may include any Indigenous community identified by a Regulatory Agency as having a potential interest in the Project.

As described in Section 4.3.1, these Other Indigenous Communities include the following:

- Fond du Lac First Nation;
- Black Lake First Nation;
- Birch Narrows Dene Nation;
- Buffalo River Dene Nation;
- Lac La Ronge Indian Band;
- A La Baie Métis Local;
- Dore/Sled Lake Métis Local #67; and
- Peter Ballantyne Cree Nation.

4.3.3.1 Engagement with Fond du Lac First Nation and Black Lake First Nation

On March 18, 2019, YNLR sent a letter to Denison directing Denison to undertake engagement and communication solely with YNLR for the purposes of any activities requiring approval actions from the Athabasca Denesųłiné, such as the EA for the Project. The letter explicitly stated:

> "*Please be advised that in relation to all new and ongoing mining, milling, exploration, forestry, road building and other industrial and non-industrial developments and activities for which a federal or provincial licensing permit, regulatory process, environmental assessment or other approval is required the sole point of contact for Black Lake First Nation, Fond du Lac First Nation, Hatchet Lake First Nation, Stony Rapids, Wollaston Lake, Camsell Portage and Uranium City is to be the Ya'thi Néné Lands and Resource Office. Accordingly, we direct you to communicate solely with Ya'thi Néné Lands and Resource Office in all related matters and our staff will be in direct contact with the First Nations and Municipal communities as it relates to activities in the Athabasca Basin and the Athabasca First Nations traditional territory.*"

As a result, Denison's engagement activities with the Fond du Lac First Nation and Black Lake First Nation have been undertaken through engagement activities with the YNLR. Please see Section 4.3.4.2 for a full discussion on these activities.

Black Lake First Nation is a signatory to Treaty 8. Fond du Lac First Nation is a signatory to Treaty 8. Figure 4.3-1 illustrates where the communities are in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Black Lake First Nation is located 180 km away from the Project. In terms of travel distance by existing transportation routes Black Lake First Nation is located 1130 km away from the Project. In terms of direct linear distance, Fond du Lac First Nation is located 230 km away from the Project. In terms of travel distance by existing transportation routes Fond du Lac First Nation is more than 1,200 km away, a portion of which is only accessible via winter road.

4.3.3.2 Engagement with Birch Narrows Dene Nation

Birch Narrows Dene Nation has territory at three (3) sites: 1) Turnor Lake 193B with 296.7 hectares (733 acres) 56.4726°N 108.6869°W, which adjoins the Northern Hamlet of Turnor Lake; 2) Churchill Lake 193A with 159.8 hectares (395 acres), which contains the historic site of Clear Lake 56.1408°N 108.2072°W at the junction of Churchill Lake and Frobisher Lake; 3) Turnor Lake 194 with 2,445.9 hectares (6,044 acres) 55.9353°N 108.8450°W, which is on Peter Pond Lake east of Dillon (MLTC n.d.a).

Birch Narrows Dene Nation is a signatory to Treaty 10. Figure 4.3-2 illustrates where the community is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, BNDN is located 230 km away from the Project. In terms of travel distance by existing transportation routes BNDN is located 570 km away from the Project.

4.3.3.2.1 History of Interactions

With respect to the Project, BNDN was identified by the CNSC in 2019 as potentially interested in the Project. Since 2019, Denison has shared information with BNDN about the Project, with offers to meet and share information between each other about the Project and potential Treaty Rights in relation to the Project. Engagement efforts were temporarily suspended in March 2020 as a result of the COVID-19 pandemic.

In May 2021, BNDN informed the CNSC that they were interested in being consulted by the Crown. This correspondence was copied to Denison, following which Denison offered to meet with BNDN to provide information in relation to the Project. Denison did not receive a response from BNDN to this offer. In May 2022 a BNDN Councillor connected with Denison seeking information about the Project and Denison provided them all information that was requested.

On October 27, 2022, BNDN sent a letter to Denison accepting Denison's earlier offers to meet regarding the Project. The letter further identified that BNDN was concerned about the potential impacts to water, wildlife, and medicines from the Project and requested Denison enter into a process agreement between Denison and BNDN.

On November 11, 2022, Denison responded to BNDN’s October 27, 2022, letter. Denison identified its willingness to meet with BNDN to provide an overview of the Project to better understand BNDN’s interests in relation to the Project, before entering into a process agreement with BNDN.

Over the course of the next few months, Denison and BNDN worked together to establish a mutually agreeable time that would work for a meeting.

Meeting – February 14, 2023: On February 14, 2023, Denison and BNDN met in person, whereby Denison provided an overview of the Project and the related environmental assessment, the valued components for the Project, the Project technologies, and the schedule. During the meeting, several clarification questions were asked of Denison with respect to the Project. During the meeting BNDN stated that Denison was in the traditional territory of BNDN and had land use information in relation to the Project, and BNDN would share the information with Denison provided that Denison entered into a confidentiality agreement with BNDN. Denison indicated its willingness to do so, and reiterated its interest in receiving information from BNDN regarding BNDN activities in and around the Project(see Appendix 4-A, ROC #851).

Following the February 14, 2023, meeting, Denison and BNDN connected about the request from BNDN to enter into a confidentiality agreement in order for Denison to receive the traditional territory information and land use data pertinent to the Project. BNDN also requested that Denison fund a process to develop a Project agreement. On April 25, 2023, Denison provided BNDN with a draft confidentiality agreement for their review and consideration. To date, a confidentiality agreement has not been entered into between the parties.

Meeting – May 10, 2023: On May 10, 2023, Denison and BNDN met virtually to discuss next steps with respect to the Project. Denison reiterated its interest in receiving BNDN information in respect of BNDN uses of the land in and around Wheeler prior to making a determination about entering into further agreements with BNDN. BNDN suggested that the information that could be shared would be limited because Denison was not providing funding in respect of the existing information. On May 11, 2023, Denison provided BNDN a copy of the meeting notes from May 10, 2023, and they were confirmed as received.

Meeting – July 31, 2023: On July 31, 2023, Denison met with BNDN to discuss next steps and moving forward to resolve BNDN’s concerns raised about the Project. A course of action was recommended, which involved Denison responding to the March 3, 2023, public comments from BNDN, as well as providing a high-level summary of the broader potential impacts to people and the environment. See below for more information about these next steps.

Future Engagement Activities

Denison will continue to ensure BNDN is informed about the progression of the Project, and will be responsive to BNDN's future interests in the Project.

4.3.3.2.2 *Birch Narrows Dene Nation Public Comments on Draft Environmental Impact Statement and Related Processes*

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators, and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On March 3, 2023, BNDN provided public comments on the draft EIS for the Project (Government of Canada 2024), consisting of 88 technical comments. On November 29, 2023, following work undertaken with BNDN since receipt of the March 3, 2023, public comments (as described above), Denison provided responses to the BNDN public comments made on the draft EIS (please see Appendix 4-A, ROC #972).

On January 18, 2024, BNDN sent correspondence to Denison advising that Denison's responses to BNDN's public comments on the EIS had been deemed adequate, and that BNDN looked forward to receiving information about the progress of the Project in the future (please see Appendix 4-A, ROC #1036).

Denison will continue to ensure BNDN is informed about the progression of the Project, and will be responsive to BNDN's future interests in the Project.

4.3.3.2.3 *Birch Narrows Dene Nation Key Interests, Issues, and Concerns*

A summary of key interests, issues, and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or, concerns are not always related to environmental effects as defined by CEAA 2012 (they can be reflective of *general* areas of interest in relation to the Project more broadly). Where appropriate, the table aims to provide clarity with respect to this distinction.

4.3.3.3 Engagement with Buffalo River Dene Nation

Dillon is a village in the boreal forest of northern Saskatchewan, Canada. It is located on the western shore of Peter Pond Lake at the mouth of the Dillon River. The village is the administrative headquarters of the BRDN and is accessed by Highway 925 from Highway 155 (MLTC n.d.b).

The North West Company had a post near Dillon in 1790. It was called Lac des Boeufs Post (Buffalo Lake Post). In 1932 the name of the village of Buffalo River was officially changed to Dillon, the name of the river was changed from Buffalo River to Dillon River, and Buffalo Lake was renamed Peter Pond Lake.

Buffalo River Dene Nation is a signatory to Treaty 10. Figure 4.3-2 illustrates where the community is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, BRDN is located 285 km away from the Project. In terms of travel distance by existing transportation routes BRDN is located 540 km away from the Project.

4.3.3.3.1 History of Interactions

With respect to the Project, BRDN was identified by the CNSC in 2019 as having a potential interest in the Project. Since 2019, Denison has shared information with BRDN about the Project, with offers to meet and share information between each other about the Project and potential Treaty Rights in relation to the Project. Engagement efforts were temporarily suspended, along with the EA, in March 2020 as a result of the COVID-19 pandemic. In 2021, Denison advised BRDN about the EA restart. As of June 2024, Denison has not received any engagement from BRDN to Denison expressing interests, issues, or concern.

Denison remains willing to engage with BRDN regarding the Project to the extent BRDN expresses interest in doing so.

4.3.3.4 Engagement with Lac La Ronge Indian Band

Located in north-central Saskatchewan, the LLRIB is the largest First Nation in Saskatchewan, and one of the 10 largest in Canada, with a population of 11,602, as of March 31, 2022. The LLRIB reserve lands extend from rich farmlands in central Saskatchewan, all the way north through the boreal forest to the mighty Churchill River and beyond. The central administration office for LLRIB is located in La Ronge, 241 km north of Prince Albert, on the edge of the Pre-Cambrian Shield. (Lac La Ronge Indian Band, n.d.)

The LLRIB is a signatory to Treaty 6. LLRIB has several reserves, such as Hall Lake, Stanley Mission, Grandmothers' Bay and others. The administrative centre for the LLRIB is located adjacent to La Ronge and Air Ronge. Figure 4.3-2 illustrates where this LLRIB reserve is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, this location is 265 km away from the Project. In terms of travel distance by existing transportation routes, this location is 480 km away from the Project.

4.3.3.4.1 History of Interactions

With respect to the Project, engagement with the LLRIB started in December 2019 when they were informed about the Project and expressed an interest in learning more. A presentation was made at a meeting to the LLRIB Lands and Resources Sub-committee in February 2020. Notification of the temporary suspension of the EA in March 2020 as a result of the COVID-19 pandemic was communicated, as well as status updates later in 2020 and the restart of the EA in January 2021.

In early 2023, the LLRIB contacted the CNSC about the Project. As an outcome of this contact, LLRIB requested the shapefiles for the Project from Denison.

In February 2023 Denison and LLRIB discussed LLRIB's interest in the Project, including in relation to LLRIB's trapping activities in the area. Denison clarified to LLRIB that the Project is located in the ERFN N-18 furblock, and outside the LLRIB Traditionally Occupied Territory available publicly online. Denison committed to attending a LLRIB Lands and Resources Board meeting at a time that was mutually convenient.

On August 30, 2023, Denison attended, both in person and virtually, the LLRIB Land and Resources Board meeting to provide an update on the Project and provided information in response to issues raised by LLRIB during the public review of the draft EIS for the Wheeler River Project (see Appendix 4-A, ROC #956).

On June 12, 2024, Denison met with the Lac La Ronge Lands and Resource Board for an in-person meeting in Saskatoon, for the purpose of providing Wheeler River Project updates, as requested by LLRIB, to support the resolution of LLRIB's comments made of the draft EIS.

Future Engagement Activities

Denison will continue to make sure LLRIB is informed about the progression of the Project and will be responsive to LLRIB's future interests in the Project.

4.3.3.4.2 Lac La Ronge Indian Band Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by the federal regulators, and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022.On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On February 9, 2023, LLRIB submitted public comments on the draft EIS to the CNSC (Government of Canada 2024).

On November 4, 2023, following work undertaken with LLRIB since receipt of the February 9, 2023, public comments (as described above), Denison provided responses to the LLRIB public comments made on the draft EIS (please see Appendix 4-A, ROC #986).

On June 12, 2024, Denison met with the Lac La Ronge Lands and Resource Board for an in-person meeting in Saskatoon, for the purpose of providing Wheeler River Project updates, as requested by LLRIB, to support the resolution of LLRIB's comments made on the draft EIS. In this meeting, the LLRIB indicated that the Project was located within the boundaries specified in the Misinipiy Integrated Land Use Plan.

On June 12, 2024, following the meeting between the Lac La Ronge Lands and Resource Board and Denison, LLRIB provided Denison with a copy of the Misinipiy Integrated Land Use Plan (2012). Please see Appendix 4-A, ROC #1107.

On June 18, 2024, in response to the Misinipiy Integrated Land Use Plan (2012) provided to Denison by LLRIB following their recent meeting, Denison responded confirming this information was used throughout the planning of the Wheeler River Project. Denison provided a georeferenced map showing Denison's properties fall outside both the Misinipiy Planning Area, and the Lac La Ronge Indian Band Traditionally Occupied Territory, as depicted in the Misinipiy Integrated Land Use Plan (2012). Denison informed the LLRIB that, should activities fall within the area defined in the shared map, Denison would proactively reach out to the LLRIB for discussions. Please see Appendix 4-A, ROC #1108.

On June 18, 2024, following receipt of the georeferenced map provided by Denison, the LLRIB responded indicating that Misinipiy Integrated Land Use Plan (2012) had not been reviewed or amended since it was finalized in 2012, and that LLRIB's boundaries have been updated internally and that LLRIB considers the Wheeler River Project to be within their traditional territory, and therefore wishes to enter into an agreement with Denison. Please see Appendix 4-A, ROC #1109.

On June 28, 2024, Denison replied to the LLRIB, outlining the process Denison follows in relation to formal agreements. Denison reiterated their commitment to continuing efforts in responding positively to areas of interest identified by LLRIB in relation to business development/community investment. Please see Appendix 4-A, ROC#1113.

4.3.3.4.3 Lac La Ronge Indian Band Key Interests, Issues and Concerns

A summary of key interests, issues and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues, or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of *general* areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.3.3.5 Engagement with A La Baie Métis Local #21

A La Baie Métis Local #21 is situated within the Community of Île-à-la-Crosse. The Community of Île-à-la-Crosse was designated as a National Historic Site in 1954 by the Federal Environment Minister on the advice of the Historic Sites and Monuments Board of Canada. Additionally, the entire community is considered a historical Métis community, and as such, contains a strong Métis identity throughout (Sakitawak Conservation n.d.a).

Île-à-la-Crosse is the birthplace of Louis Riel Sr. and is the gravesite of Sr. Marguerite Riel (the sister of Louis Riel). In countless history books and maps, the community of Île-à-la-Crosse is duly noted for its historical significance in settling this entire area. Sakitawak is the Cree name for Île-à-la-Crosse, which means “where the rivers meet” (MN-S n.d.c). Recently, the Sakitawak Conservation Project commenced, which is mandated to protect habitats of vulnerable species, advance Indigenous ways of life, identify knowledge systems, and implement stewardship activities. The first area identified for this work is the N-14 Furblock (Sakitawak Conservation n.d.b).

Figure 4.3-2 illustrates where Île-à-la-Crosse is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Île-à-la-Crosse is located 275 km away from the Project. In terms of travel distance by existing transportation routes Île-à-la-Crosse is located 460 km away from the Project.

4.3.3.5.1 History of Interactions

Since 2016, Denison has been engaging with ALBML. The type and frequency of engagement has reflected an evolving understanding of ALBML’s traditional activities and land use, including in the region of the Project. The Northern Village of Île-à-la-Crosse, and many of the community members residing in Île-à-la-Crosse, self-identify as Métis. In some instances, the elected officials of Métis Locals are also elected members of the municipality and, therefore, represent both their Indigenous community as well as their municipality. As a result, during the onset of engagement activities in 2016, there was overlap in engagement with the entities of ALBML and the Village of Île-à-la-Crosse.

In 2019, the ALBML delegated their Duty to Consult for the Project to the MN-S. Clear distinction between the Métis leadership and Citizens, and the Village leadership and residents was, therefore, necessary to make sure the MN-S was able to appropriately provide the representation of the Métis of ALBML, per the delegated Duty to Consult. As a result, Denison distinguished its engagement efforts between MN-S, on behalf of ALBML, and the general public of the Village of Île-à-la-Crosse, with no intended overlap in relation to Métis interests.

From 2019 onwards, the MN-S has been representing ALBML in respect of engagement with Denison for the Project.

For details on Denison’s engagement with MN-S, see Section 4.3.4.1.

4.3.3.5.2 Agreements Relative to the Environmental Assessment Process

A MOU was signed by Denison, ALBML and the Village of Île-à-la-Crosse in 2018. The signing of this MOU with both ALBML and the Village of Île-à-la-Crosse reflected the perspective of ALBML and the Village of Île-à-la-Crosse to represent both municipal residents and the Métis Citizens co-operatively. This non-binding MOU formalized the intent to work together in a spirit of mutual respect to cooperate to collectively identify practical means by which to avoid, mitigate, or otherwise address potential effects of the Project upon the exercise of the Indigenous Rights, Treaty Rights, and interests, to the extent they are identified in relation to the Project.

In 2019, ALBML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing ALBML in respect of engagement with Denison for the Project.

4.3.3.5.3 Key Engagement Activities

During the engagement activities undertaken with ALBML, several key engagement activities took place that have played a meaningful role in relation to the EA process. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1. The main forms of engagement included meetings with leadership, a community meeting, a workshop on early infrastructure options (2018), a site visit (2019) and a meeting coordinated by the MN-S. Considerable engagement has also occurred between Denison and MN-S on behalf of ALBML and other Métis Locals, as described in Section 4.3.4.1.

Engagement Focus: Pre-Project Description - April 2016 to May 2019

Introductory meeting – December 7, 2016: This was the inaugural meeting between the senior management team of Denison and various entities associated with ALBML and the Village of Île-à-la-Crosse. The meeting focussed on clarifying the nature of Denison's activities, including the Project and related exploration activities, the interest in employment, business and training opportunities, reclamation requirements, agreement negotiation considerations, investment possibilities, environmental sampling and monitoring, and questions in relation to the nuclear industry in general and market related to uranium. For more specifics about this activity, please see Appendix 4-A, ROC #109.

Workshop – January 17, 2018: Denison hosted a workshop with many community members and students. The focus of the workshop was to obtain feedback on three alternatives/options for the proposed Project: the road alignment from Highway 914 into the Project Area; the potential treated effluent discharge location; and the mining method options. The workshop opened and concluded with questions pertaining to Denison and the Project, comments on the importance of training, agreement negotiations and other general items.

General questions were asked regarding the various alternatives and options, and points of clarification pertaining to aspects of the Project. Feedback was collected on the various options and has been incorporated into the final design for road alignment, and the treated effluent discharge location. Please see Section 2 for more details. For more information about this activity, please see Appendix 4-A, ROC #3.

Engagement Focus: Post-Project Description – July 2019 to October 2022

Site Tour – August 23, 2019: In August 2019, Denison hosted a site tour at the Project location. The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project.

Attending the site tour was the President of ALBML. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Representatives from the CNSC and SK MOE were present.

For additional details about this activity, please see Appendix 4-A, ROC #1.

Meeting – November 5, 2019: Denison hosted a meeting with the MN-S President, the Northern Region 3 President, legal counsel, some administrators, and several Local Presidents and representatives, including ALBML in attendance. This engagement activity was coordinated with the MN-S, in response to the delegated Duty to Consult from several Métis Locals as of November 2019. The focus was to provide an overview of the Project and discuss Métis interests in the Project. See Section 4.3.4.1.3 for a detailed discussion on this meeting. For more information about this activity, please see Appendix 4-A, ROC #62.

In 2019, ALBML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing ALBML in respect of engagement with Denison for the Project. For details on Denison's engagement with MN-S, see Section 4.3.4.1.

Future Engagement Activities

Denison expects to continue working with the ALBML, through the MN-S, throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities in relation to topics of interest in relation to the Project, in accordance with an agreed upon process.

4.3.3.5.4 A La Baie Métis Local #21 Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators, and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On March 3, 2023, the MN-S submitted public comments on the draft EIS to the CNSC (Government of Canada 2024). As ALBML delegated their duty to consult to the MN-S, engagement on issues related to the environmental assessment are now represented by the MN-S. On December 1, 2023, following work undertaken with the MN-S since receipt of the March 3, 2023, public comments, Denison provided responses to the MN-S' public comments made on the draft EIS (please see ROC #973).

On December 1, 2023, following work undertaken with the MN-S since receipt of the March 3, 2023, public comments, Denison provided responses to the MN-S' public comments made on the draft EIS (please see Appendix 4-A, ROC #973).

During this same time period, Denison and the MN-S met regularly to discuss the advancement of the Métis Knowledge Study and to discuss items in relation to the development of a MN-S defined process for engagement on the Project, including in relation to the resolution of the MN-S public comments and general issues and concerns. One of the key areas of concern raised by the MN-S was the inclusion of information obtained as a result of the completion of the Métis Knowledge Study into the EIS. The Métis Knowledge Study was received by Denison on October 24, 2023, and Denison has integrated relevant information from the Study into the EIS accordingly.

In July 2023, Denison and the MN-S began discussions pertaining to the development of a Joint Working Group process in relation to engagement with the MN-S about the Project. As of June 30, 2024, Denison and the MN-S had tentatively agreed to amendments to the existing Capacity Funding Agreement in support of this mutually agreeable engagement process, with the amendments awaiting final approval as part of a process defined by MN-S.

Following further discussions between Denison and the MN-S during August 2024, MN-S outlined an additional process that MN-S desired take place between Denison and the MN-S, to occur in parallel to the earlier discussed mutually agreeable engagement process. It is Denison's understanding that the commencement of these parallel processes is expected to occur in the coming months.

For more information about the work undertaken with the MN-S, please see Section 4.3.4.1.

4.3.3.5.5 A La Baie Métis Local #21 Key Interests, Issues and Concerns

A summary of key interests, issues and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction. As ALBML delegated their duty to consult to the MN-S in late 2019, the table is representative to the timeframe prior to the delegation of the duty to consult by the ALBML to the MN-S.

4.3.3.6 Dore/Sled Lake Métis Local #67

In November 2019, when Denison was advised by the MN-S that a number of Métis Locals had delegated to MN-S the Duty to Consult for the Project, Dore/Sled Lake Métis Local #67 was one of the Locals. As such, the MN-S has held the Duty to Consult for Dore/Sled Lake Métis Local #67 since that time and Denison has been engaging through the MN-S for the Project.

Figure 4.3-2 illustrates where the communities are in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Sled Lake is located 363 km away from the Project. In terms of travel distance by existing transportation routes, Sled Lake is located 537 km away from the Project. In terms of direct linear distance, Dore Lake is located 344 km away from the Project. In terms of travel by existing transportation routes, Dore Lake is located 590 km away from the Project.

4.3.3.6.6 Key Engagement Activities

Engagement Focus: Post-Project Description – July 2019 to October 2022

Meeting – November 5, 2019: Denison hosted a meeting with the MN-S President, the Northern Region 3 President, legal counsel, some administrators, and several Local Presidents and representatives. This engagement activity was coordinated with the MN-S, in response to the delegated Duty to Consult from several Métis Locals as of November 2019. The focus was to provide an overview of the Project and discuss Métis interests in the Project.

The President of Dore/Sled Lake Métis Local #67 was in attendance. For more specifics about this activity, please see Appendix 4-A, ROC #62.

In 2019, Dore/Sled Lake Métis Local #67 delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing Dore/Sled Lake Métis Local in respect of engagement with Denison for the Project. For details on Denison's engagement with MN-S, see Section 4.3.4.1.

Future Engagement Activities

Denison expects to continue working with the Dore/Sled Lake Métis Local through the MN-S, throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities in relation to topics of interest in relation to the Project in accordance with an agreed-upon process.

4.3.3.6.7 Dore/Sled Lake Métis Local Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators, and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On March 3, 2023, the MN-S submitted public comments on the draft EIS to the CNSC (Government of Canada 2024). As Dore/Sled Lake Métis Local #67 delegated their duty to consult to the MN-S, engagement on issues related to the environmental assessment are now represented by the MN-S.

On December 1, 2023, following work undertaken with the MN-S since receipt of the March 3, 2023, public comments, Denison provided responses to the MN-S' public comments made on the draft EIS (please see Appendix 4-A, ROC #973).

During this same time period, Denison and the MN-S met regularly to discuss the advancement of the Métis Knowledge Study and to discuss items in relation to the development of a MN-S defined process for engagement on the Project, including in relation to the resolution of the MN-S public comments and general issues and concerns. One of the key areas of concern raised by the MN-S was the inclusion of information obtained as a result of the completion of the Métis Knowledge Study into the EIS. The Métis Knowledge Study was received by Denison on October 24, 2023, and Denison has integrated relevant information from the Study into the EIS accordingly.

In July 2023, Denison and the MN-S began discussions pertaining to the development of a Joint Working Group process in relation to engagement with the MN-S about the Project. As of June 30, 2024, Denison and the MN-S had tentatively agreed to amendments to the existing Capacity Funding Agreement in support of this mutually agreeable engagement process, with the amendments awaiting final approval as part of a process defined by MN-S.

Following further discussions between Denison and the MN-S during August 2024, MN-S outlined an additional process that MN-S desired take place between Denison and the MN-S, to occur in parallel to the earlier discussed mutually agreeable engagement process. It is Denison's understanding that the commencement of these parallel processes is expected to occur in the coming months.

For more information about the work undertaken with the MN-S, please see Section 4.3.4.1.

4.3.3.7 Peter Ballantyne Cree Nation

The Peter Ballantyne Cree Nation (PBCN) is a Woodland Cree First Nation in northern Saskatchewan consisting of eight communities: Denare Beach, Deschambault Lake, Kinoosao, Pelican Narrows, Prince Albert, Sandy Bay, Southend and Sturgeon Landing. The Peter Ballantyne Cree Nation are called Assin'skowitiniwak or Rocky Cree. Assin'skowitiniwak means "people of the rocky area".

PBCN is a signatory to Treaty 6. Figure 4.3-2 illustrates where the communities are in relation to the Project, both in terms of direct linear distance and travel distance. PBCN is comprised of eight communities, including Amisk Lake (Denare Beach), Deschaumbault Lake, Kinoosao, Pelican Narrows, Prince Albert, Sandy Bay, Southend, and Sturgeon Landing (PBCN 2024). In terms of direct linear distance and travel distance by existing transportation routes, the following information is provided: Amisk Lake (Denare Beach)(direct linear distance = 375 km; travel distance by existing transportation routes = 750 km), Deschambault Lake (direct linear distance = 310 km; travel distance by existing transportation routes = 650 km), Kinoosao (direct linear distance = 200 km; travel distance by existing transportation routes = 1,520 km), Pelican Narrows (direct linear distance = 296 km; travel distance by existing transportation routes = 715 km), Prince Albert (direct linear distance = 485 km; travel distance by existing transportation routes = 615 km), Sandy Bay (direct linear distance = 287 km; travel distance by existing transportation routes = 785 km), Southend (direct linear distance = 180 km; travel distance by existing transportation routes = 700 km), Sturgeon Landing (direct linear distance = 425 km; travel distance by existing transportation routes = 850 km).

4.3.3.7.1 History of Interactions

With respect to the Project, Denison was contacted by PBCN on March 6, 2023, notifying Denison of their interest in the Project. In this initial contact, PBCN provided Denison a draft traditional territory map dated February 8, 2023, which differed from that information published on their website, and showed a portion of the property associated with the Project within the PBCN traditional territory.

As a result of this initial contact, Denison and PBCN planned for an initial introductory meeting about the Project. This introductory meeting occurred on May 15, 2023. During this meeting, PBCN expressed its interest to Denison about entering into agreement with them in support of engagement activities on the Project. PBCN also identified its perspective that the Project may adversely affect PBCN's Aboriginal and / or Treaty rights. As a result, Denison requested PBCN provide Denison with information about activities in and around the Project area (Appendix 4-A, ROC #907).

Denison and PBCN planned for an additional meeting whereby Denison would provide an overview of the Project and responses to PBCN's public comments on the draft EIS and related concerns, and PBCN would provide information regarding PBCN activities in and around the Project area. Denison and PBCN agreed on Denison providing capacity funding in support of this engagement activity. This meeting was held on September 20, 2023. During this meeting, Denison provided an overview of the Project and responded to questions of clarifications related to the Project activities. PBCN also provided an overview of the PBCN history and relationship to Reindeer Lake, from Hatchet Lake to Pelican Narrows. As well, PBCN noted that Denison is in the traditional territory of PBCN. During this meeting, Denison requested information about specific PBCN land uses in and around the

Project in order to better understand the potential for adverse impacts to PBCN rights. In response to this, PBCN noted that the Director of Lands and Resources, who was prepared to speak to this information, was unable to attend due to illness.

PBCN also provided an overview of their Land and Resources Committee (LRC) and the process designed by the LRC to engage with industry and participate in the regulatory process, which has been delegated to them by the Chief and Council of PBCN. It was noted that part of this process is to ensure that projects and potential impacts are understood, and PBCN is engaged throughout the process, which also includes undertaking commercial conversations with PBCN in relation to understanding impacts and sharing of benefits. In response to this, Denison restated its perspective that in order to consider such arrangements it would need to have clearer information about the potential for the Project to adversely impact PBCN rights.

Due to time constraints, Denison was unable to complete the presentation developed in response to PBCN public comments on the EIS. In the correspondence follow-up to the meeting provided on October 10, 2023, Denison provided PBCN with the presentation related to the Project overview, the presentation prepared in response to the PBCN public comments on the draft EIS, a set of meeting notes referencing key points made by both parties, and some follow-up information in relation to PBCN concerns about the potential for adverse impacts to water quality and the relationship to PBCN communities, along with transparency regarding monitoring for the Project. For more details, please see Appendix 4-A, ROC #977.

On October 20, 2023, PBCN sent a letter to Denison following up on the September 20, 2023, meeting and to Denison's October 10, 2023, correspondence. In this letter, PBCN articulated how PBCN members shared the important link between community wellness and the natural environment, and the importance of PBCN Members to exercise their treaty and Aboriginal rights. PBCN restated that the Project is within the PBCN traditional territory and will have potential environmental and socio-economic impacts, and thus have related impacts to PBCN's Aboriginal and treaty rights. This letter noted that PBCN was in contact with the federal and provincial regulators to explain PBCN's treaty and Aboriginal rights. PBCN also reiterated its perspective that PBCN lacked the capacity needed to support PBCN's engagement with respect to the Project.

On November 22, 2023, Denison responded to PBCN's letter of October 20, 2023. Denison reiterated its interest to continued engagement with PBCN on the Project, and restated its request to receive information pertaining to PBCN's specific interests and land use activities in the Project area that would be adversely impacted by the Project. Denison also provided an overview of its history with the Wheeler River property since 2004, outlining the information used to date to identify those Indigenous communities who may be impacted by the Project, such as the wildlife and fur block management administrative areas, existing traditional land use information made available through Key Lake and McArthur River public review processes, anticipated transportation routes, and anticipated impacts to water and publicly available information about Indigenous Nations' traditional territories.

On December 12, 2023, PBCN responded to Denison's letter of November 22, 2023. PBCN requested that discussions commence regarding capacity funding from Denison to support PBCN's engagement with Denison on the Project and to complete a PBCN-specific traditional land and resources use study and report for the Project. PBCN highlighted that, during the September 20, 2023, meeting between PBCN and Denison, members of the Lands and Resources Committee shared information with Denison about uses in and around the Project area, demonstrating PBCN's concerns regarding the potential impacts of the Project on PBCN's Aboriginal and treaty rights and interests.

On January 10, 2024, Denison responded to PBCN's correspondence from December 12, 2023. In that correspondence Denison provided a history of engagement activities that had occurred between PBCN since interest was expressed by PBCN in the Project, along with a response from Denison with respect to the PBCN concerns regarding potential water contamination to Reindeer Lake, the main waterbody in proximity to Southend, SK. Denison also responded to PBCN's concerns regarding cumulative effects and provided some information in relation to the methodology undertaken by Denison in respect of cumulative effects related to water. Denison also stated that in order for it to undertake deeper engagement than has occurred to date with PBCN, Denison would appreciate receiving information about how the Project will adversely impact PBCN land uses and rights, and without such information, was unable to determine that a traditional land and resources use study and report for the Project was warranted.

A comprehensive listing of engagement activities between Denison and PBCN, including a brief description of the purpose or activity and outcome where appropriate, is included in the IER.

Future Engagement Activities

Denison has indicated its willingness to engage with PBCN about the Project and will continue to do so, provided mutually agreeable circumstances for such engagement can occur.

4.3.3.7.2 Peter Ballantyne Cree Nation Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by the federal regulators, and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from

January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On March 3, 2023, PBCN submitted public comments on the draft EIS to the CNSC (Government of Canada 2024).

As noted earlier in the section, Denison and PBCN met on May 15, 2023, to hold an introductory meeting between the parties. On September 20, 2023, another meeting was held in which it was planned that Denison would respond to the March 3, 2023, PBCN public comments on the draft EIS. Due to time constraints, this did not occur. As a follow up to the meeting, Denison provided those responses to PBCN in written form.

Since that time, Denison has offered to further discuss the responses to the public comments made on the draft EIS with PBCN. As recent as January 10, 2024, Denison has indicated its willingness to engage with PBCN about the Project and PBCN issues and concerns, and expects efforts to be undertaken in the future in this regard, provided that mutually agreeable circumstances for such engagement can be reached.

4.3.3.7.3 Peter Ballantyne Cree Nation Key Interests, Issues and Concerns

A summary of key interests, issues and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.3.4 Engagement with Indigenous Organizations

4.3.4.1 Métis Nation – Saskatchewan

As the elected government of the Métis people of Saskatchewan, the MN-S plays an important role related to engagement activities. The MN-S is currently structured with a President, an Executive, a Provincial Métis Council, Regional Directors, and Local Presidents. The MN-S website states that '*consultations must be with the Métis government structures that are elected and supported by the Métis people*' (MN-S n.d.b). The Project is located within Métis Region 1; however, there are Métis Locals in the general area of interest from Northern Region 3. Figure 4.3-2 illustrates where these Métis Locals and Regions are in relation to the Project.

In November 2019, Denison was advised by the MN-S that Kineepik Métis Local 9 (Pinehouse), A La Baie Métis Local 21, Sipishik Métis Local 37 (Île-à-la-Crosse), Métis Local 67 (Dore Lake and Sled Lake), and Patuanak Métis Local 82 (Patuanak) had delegated to MN-S the Duty to Consult for the Project, and also advised that MN-S would provide direction regarding engagement activities with Northern Region 1, Northern Region 3 and any other entities of the MN-S. Since then, Denison has been following the request of the MN-S in this regard. In November 2021, Denison was informed that KML had revoked its delegation of the Duty to Consult to the MN-S that it had previously provided in November 2019. As of June 2022, the MN-S have been formally delegated the Duty to Consult for the Project by Sipishik Métis Local 37 (Beauval), A La Baie Métis Local 21 (Île-à-la-Crosse), Patuanak Métis Local 82 (Patuanak) and Local 67 (Dore Lake and Sled Lake).

4.3.4.1.1 *History of Interactions*

Since Denison's initial connection with the MN-S about the Project in June 2019, the main focus of the activities between the parties has been on the development of appropriate processes, deliverables, and budgets desired by MN-S to support its meaningful participation in the EA process, including the representation of those Métis Locals who have delegated the Duty to Consult to MN-S.

Throughout the engagement, Denison has repeatedly and consistently affirmed its interest in MN-S participation and the incorporation of Métis knowledge into the EIS, in addition to the information and input that has already been gathered with KML.

A comprehensive listing of engagement activities between Denison and MN-S, including a brief description of the purpose or activity and outcome where appropriate, is included in the IER.

4.3.4.1.2 *Agreements Relative to the Environmental Assessment Process*

Since being advised by the MN-S in October 2019 that a number of Métis Locals had delegated to the MN-S the Duty to Consult for the Project, Denison has been engaged in extensive ongoing discussions with the MN-S with the goal of reaching agreement regarding the EA process and MN-S' participation in it.

In recognition of the MN-S' potential interests in the Project, the parties have specifically agreed to a process between each other that will be funded by Denison and undertaken on behalf of the MN-S in connection with the EA of the Project: a Métis Knowledge Study, meetings to focus on VCs and preliminary effects, and regular meetings and associated costs for hosting such meetings.

A capacity funding agreement was signed relative to the above process with the MN-S in October 2022. As part of this agreement, Denison agreed to fully fund a Métis Knowledge Study. Denison received the Métis Knowledge Study from the MN-S on October 24, 2023, and has integrated relevant information from the Study into the EIS. For more information about the Métis Knowledge Study, please see Section 3 of the EIS.

On February 17, 2023, based on a request by the MN-S, Denison and the MN-S entered into an amendment to the Capacity Funding Agreement to provide additional funding to further support the MN-S technical review on the draft EIS.

In July 2023, Denison and the MN-S began discussions pertaining to the development of a Joint Working Group process in relation to engagement with the MN-S about the Project. As of June 30, 2024, Denison and the MN-S had tentatively agreed to amendments to the existing Capacity Funding Agreement in support of this mutually agreeable engagement process, with the amendments awaiting final approval as part of a process defined by MN-S.

Following further discussions between Denison and the MN-S during August 2024, MN-S outlined an additional process that MN-S desired take place between Denison and the MN-S, to occur in parallel to the earlier discussed mutually agreeable engagement process. It is Denison's understanding that the commencement of these parallel processes is expected to occur in the coming months.

4.3.4.1.3 Key Engagement Activities

During the engagement activities undertaken with MN-S, two engagement activities of note took place. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1. The following describes the activities in more detail.

Engagement Focus: Post-Project Description – July 2019 to October 2022

Site Tour – August 23, 2019: In August 2019, Denison hosted a site tour at the Project location. The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project.

Attending the site tour were the President of the MN-S, the President of MN-S Region 3, and a number of Métis Local Presidents and/or representatives, including the President and Executive Director of the KML, the Vice President of the SML, the President of PML, and the President of the ALBML. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Representatives from the CNSC and SK MOE were present.

Specific questions were raised by the MN-S representatives in relation to:

- confirmation that Denison was following the engagement protocols and direction set out by the MN-S in relation to the Regions and the Locals;
- queries regarding general Project particulars, such as waste management, wastewater, radiation monitoring and management, and the composition of the mining solution to be used, and the nature of this solution in relation to the grade of the ore; and
- confirmation that Denison will be using local contractors for the Project.

For more specifics about this activity, please see Appendix 4-A, ROC #1.

Meeting – November 5, 2019: In response to the delegated Duty to Consult from a number of Métis Locals provided in November 2019, Denison hosted a meeting with the MN-S President, the Northern Region 3 President, legal counsel, some administrators, and several Local Presidents and representatives, including from the KML, the SML, the ALBML, and the PML. The focus was to provide an overview of the Project and discuss Métis interests in the Project.

The MN-S noted that they are focused on supporting the Locals, and finding capacity within the organization to support efforts going forward with Denison.

The MN-S noted that they provided direction to legal counsel to seek an exploration agreement with Denison.

Questions were asked regarding location of Denison sites and focused interests, what would occur should the Project change ownership with a potential Impact Benefit Agreement and the relationship developed between Denison and MN-S, costs assessment of the Project, the relationship of share price and community investment expenditures, and the challenges related to securing business opportunities at sites for smaller communities.

Technical questions were asked regarding the ISR mining method: employment related to the ISR operation; the potential for other deposits in the Athabasca Basin to be mined using ISR; clarification that ISR is not the same as fracking, as fracking uses very high pressures to break the rock apart; the consequence of various types of accidents that could occur, such as a pumping or injection well breaking, the volume of acid required and requirement for transportation of the acid; and the transportation requirements for yellowcake.

Logistical questions were asked regarding the potential future mining of the Gryphon deposit, which is not part of the Project assessed herein. These questions were focused on the location for milling of Gryphon ore and whether the road connection between McArthur River and Cigar Lake would be part of the Gryphon project, if it were to proceed in the future.

Questions related to the environment and protection of people were asked, such as those focused on water sampling conducted to date, methodology of dealing with treated effluent, environmental monitoring in general, the interest of the Métis regarding transparent environmental monitoring data and access to such data, and understanding the potential for radiation doses from the operation.

The MN-S identified their interest in understanding the IK collected for the Project (from KML), if Denison was conducting additional work in this area, and if Denison would consider doing so. Denison indicated that IK, including land use data, is an integral part of the EIS development, and expects to receive direction from the MN-S on this topic as the process moves forward.

Discussion occurred regarding the concern about racism occurring at sites, include the Project exploration site, and how to make sure all people are treated with respect at the working sites, now and in the future. It was mutually expressed that the MN-S and Denison have a shared interest towards making sure values of respect are embedded into the Project development.

The MN-S identified that the land in which the Project is located is subject to a land claim, the resources within the land claim area are claimed by the Métis, and removal of the resources claimed by the Métis must result in a portion of the revenue going back to the Métis. The MN-S has a desire to create a legacy and generate wealth for its people.

For more information about this activity, please see Appendix 4-A, ROC #62.

Engagement Focus: Environmental Assessment Outcomes and Relationship to Licensing / Approvals – October 2022 to Present

Meetings – February 11and February 12, 2023: In February 2023 the MN-S coordinated meetings with the leadership of NR1 and NR3 separately, in order to support the MN-S' efforts towards processing the Métis Knowledge Study and contributions toward the MN-S' public comments on the draft EIS.

Subsequently, on February 11, 2023, Denison met with MN-S and NR1 leadership along with Two Worlds Consulting, the CNSC, and the Government of Saskatchewan. On February 12, 2023, Denison met with MN-S and NR3 leadership along with Two Worlds Consulting, the CNSC, and the Government of Saskatchewan. In both meetings, Denison presented an overview of the Project, the environmental assessment process, the valued components, and the environmental assessment outcomes. Generally, during both meetings, numerous questions were asked about the Project and the technical elements of the Project. There was also discussion about the importance of transparency with respect to environmental monitoring outcomes and ensuring that opportunities are available for Métis people beyond entry level positions. It is Denison's understanding that the MN-S utilized the engagement discussions to inform their contributions toward the MN-S' public comments on the draft EIS. For more information about this activity, please see Appendix 4-A, ROC #824 and ROC #835.

Future Engagement Activities

Denison expects to continue working with the MN-S, throughout the remainder of the environmental assessment process and into the licensing process, to coordinate engagement activities in relation to their topics of interest related to the Project, in accordance with an agreed-upon process.

4.3.4.1.4 Métis Nation – Saskatchewan Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators, and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On March 3, 2023, the MN-S submitted public comments on the draft EIS to the CNSC (Government of Canada 2024), which comprised 125 technical comments.

On December 1, 2023, following work undertaken with the MN-S since receipt of the March 3, 2023, public comments, Denison provided responses to the MN-S' public comments made on the draft EIS (please see Appendix 4-A, ROC #973).

During this same time period, Denison and the MN-S have met regularly to discuss the advancement of the Métis Knowledge Study and to discuss items in relation to the development of a MN-S defined process for engagement on the Project, including in relation to the resolution of the MN-S public comments and general issues and concerns. One of the key areas of concern raised by the MN-S was the inclusion of information obtained as a result of the completion of the Métis Knowledge Study into the EIS. The Métis Knowledge Study was received by Denison on October 24, 2023, and Denison has integrated relevant information from the Study into the EIS accordingly.

In July 2023, Denison and the MN-S began discussions pertaining to the development of a Joint Working Group process in relation to engagement with the MN-S about the Project. As of June 30, 2024, Denison and the MN-S had tentatively agreed to amendments to the existing Capacity Funding Agreement in support of this mutually agreeable engagement process, with the amendments awaiting final approval as part of a process defined by MN-S.

Following further discussions between Denison and the MN-S during August 2024, MN-S outlined an additional process that MN-S desired take place between Denison and the MN-S, to occur in parallel to the earlier discussed mutually agreeable engagement process. It is Denison's understanding that the commencement of these parallel processes is expected to occur in the coming months.

4.3.4.1.5 Métis Nation – Saskatchewan Key Interests, Issues and Concerns

A summary of key interests, issues and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA (they can be reflective of general areas of interest in relation to the Project more broadly). Where appropriate, the table aims to provide clarity with respect to this distinction.

4.3.4.2 Ya'thi Néné Lands and Resources Office

The YNLR was created as a not-for-profit organization to be the single point of contact between industry, government, and the local Athabasca communities of Hatchet Lake First Nation, Black

Lake First Nation, Fond du Lac First Nation, Camsell Portage, Stony Rapids, Uranium City, and Wollaston Post. As outlined on their website, their mission is to protect the lands and waters of the Athabasca Basin for the long-term benefit of its Denesųłiné First Nations and Athabasca communities, guided by their knowledge, traditions, and ambitions, while being a respected partner in relations with industries, governments, and organizations who seek to develop the Athabasca Basin's resources (YNLR n.d.).

In March 2019, Denison was notified by the YNLR that the Indigenous communities within the local Athabasca communities identified above were interested in the Project and that YNLR held the Duty to Consult from these communities. Prior to this, Denison followed the previously accepted approach by the CNSC and Province of Saskatchewan to engage with the Athabasca Basin communities (Indigenous and non-Indigenous communities) in relation to activities occurring in the northern part of the Athabasca Basin region (from Cigar Lake and north). The YNLR was also identified by the CNSC as having interests in the Project.

The Project Is located within the Nuhenéné (the Athabasca Denesųłiné territory) and, as such, Denison has engaged with YNLR to better understand the traditional land use activities that are currently being undertaken in the Project Area by the member Indigenous communities of YNLR.

As stated above, YNLR directed Denison to undertake engagement and communication solely with YNLR for the purposes of any activities requiring approval actions, such as an EA for the Project. As such, engagement activities undertaken with YNLR are, therefore, considered representative of the Indigenous communities of Hatchet Lake First Nation, Black Lake First Nation and Fond du Lac First Nation (unless otherwise specified), and the municipal non-Indigenous communities of Uranium City, Stony Rapids, Camsell Portage and Wollaston Lake.

4.3.4.2.1 History of Interactions

Since Denison's initial connection with the YNLR about the Project in March 2019, Denison has been engaging with YNLR in a variety of ways. A comprehensive listing of engagement activities between Denison and YNLR, including a brief description of the purpose or activity and outcome where appropriate, is included in the IER.

4.3.4.2.2 Agreements Relative to the Environmental Assessment Process

The Project is located within the Nuhenéné (the Athabasca Denesųłiné territory). As such, Denison entered into two letter agreements with YNLR in 2021 to support the YNLR's participation in the EA process for the Project:

1. A Letter Agreement outlining arrangements for Denison and YNLR to mutually plan and coordinate appropriate engagement activities in relation to the Project, with Denison fully funding the activities.
2. A Letter Agreement outlining a mutually agreeable process by which the YNLR would author a report for Denison to consider and include, as appropriate, into the EIS. This included a process

by which the YNLR would also pre-review the pertinent sections of the EIS in relation to their authored report to comment in respect of Denison's inclusion of the YNLR-authored materials.

As a result, several additional activities have been undertaken between Denison and YNLR, including YNLR's pre-review of pertinent sections of the EIS, which are further described below in Section 4.3.4.2.4.

4.3.4.2.3 Key Engagement Activities

During the engagement activities undertaken with YNLR, the main forms of engagement included meetings with YNLR leadership (including representation of various Chiefs, Councillors and municipal leaders), an online survey (2021), a virtual meeting targeted toward all of the YNLR communities, and an in-person series of community meetings. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1.

The following describes the key engagement activities in more detail.

Engagement Focus: Post-Project Description – July 2019 to October 2022

Meeting – October 3, 2019: This meeting was the inaugural meeting between members of the senior management team of Denison and the leadership of the YNLR, including the administration of YNLR, three Chiefs each from Black Lake, Fond du Lac and Hatchet Lake, two Councillors each from Hatchet Lake and Black Lake, Board Directors of the YNLR and advisors and support team to the YNLR. Attendees asked questions on the following topics to Denison:

1. the nature of the mining solution and containment methods for the mining solution, including contingency measures if excursions occur outside of freeze dome;
2. details regarding the freeze concept;
3. details regarding groundwater in the area and number and location of the monitoring wells;
4. details on the type of ore body (grade, impurities, percentage recovered);
5. lifespan of the Project and opportunities for employment, training and business;
6. quality of treated effluent;
7. use of ISR methodology and relationship to other deposits in the area, such as Midwest; and
8. specific comments pertaining to Treaty and/or Indigenous Rights in or around the Project.

For additional details about this activity, please see Appendix 4-A, ROC #78.

Meetings (Leadership and Virtual) – September 29, 2021: On September 29, 2021, Denison hosted virtual meetings with YNLR including with leadership and staff members of the YNLR, two Chiefs each from Fond du Lac and Hatchet Lake, two Councillors each from Black Lake and Hatchet Lake and four municipal leaders each from Uranium City, Camsell Portage, Stony Rapids and Wollaston

Lake, as well as hosted a virtual meeting for community members from all the YNLR-represented communities. These meetings were planned in collaboration with the YNLR. The focus of these engagement activities was to provide information about the Project to the YNLR leadership and community members, present a preliminary list of VCs that Denison had identified as part of the EA process, provide an opportunity for members to give feedback on the proposed list of VCs, and ask questions about Project components of interest or concern to them.

The topics covered during the presentations at the meeting included the following:

- Denison company introduction and key staff members;
- introduction to regulators;
- location of the Project;
- ISR mining, in general;
- ISR mining at the Project, including the recent change in the Project design from freeze dome technology to a freeze wall containment method;
- past work undertaken by Denison on options analysis;
- employment opportunities;
- EA; and
- VCs.

Leadership Meeting – September 29, 2021: Denison hosted the leadership meeting over Zoom. There were 20 leadership participants, including with leadership and staff members of the YNLR, two Chiefs each from Fond du Lac and Hatchet Lake, two Councillors each from Black Lake and Hatchet Lake and four municipal leaders each from Uranium City, Camsell Portage, Stony Rapids and Wollaston Lake:

Questions and comments focussed on:

- the importance of engagement with the Athabasca Denesų̨łiné;
- opportunities from the Project;
- access through the Key Lake Gate;
- general agreement comments (in relation to other Collaboration Agreements, exploration agreements);
- technical questions pertaining to the mining method including the amount of water to be used, treatment;
- use of the method in other locations;
- managing the potential effects to the land; and

- training opportunities.

For more information about this activity, please see Appendix 4-A, ROC #570.

Virtual Meeting – September 29, 2021: Denison hosted the virtual community presentation over Zoom. The virtual meeting was advertised on the radio and social media, and posters were placed in community buildings. Denison delivered a presentation over Zoom. Athabasca Basin community members were invited to ask questions during the presentation, share their thoughts through a survey questionnaire, or email Denison directly with feedback. At least nine Zoom accounts were used to attend the presentation; however, more than one person may have viewed the presentation from each account. Throughout the meeting, Denison encouraged attendees to share their questions in the Zoom chat feature. Attendees did not post any questions in the chat during the meeting. The Provincial regulator was in attendance. For additional details about this activity, please see Appendix 4-A, ROC #571.

Online Survey**:** During and following the YNLR meeting(s), members were invited to provide feedback on VCs through an online survey. The purpose of the survey was to seek feedback on the importance of the VCs to members, and identify interests or concerns related to the Project, providing an additional means by which feedback could be provided to Denison. Those who were unable to attend the presentation were also encouraged to provide feedback through the survey. The survey was marketed using Facebook and radio advertisements.

The survey was open for feedback from September 29 until October 10, 2021. No responses from Athabasca Basin residents were received during this time.

Engagement Focus: Environmental Assessment Outcomes and Relationship to Licensing / Approvals – October 2022 to Present

Meetings – January 23 to January 25, 2023: In January 2023 a series of community meetings were jointly coordinated with the YNLR and Denison, during which information was shared about the Project. In addition to providing an overview on exploration activities and the recently signed Exploration Agreement, Denison also provided an update to community members pertaining to the Wheeler River Project. Live translations were carried out throughout the presentation. The presentation pertained to Project components, Project technologies, Project schedule, the regulatory process, and the environmental impact assessment process and outcomes. Booklets were available for community members to take home that included, but were not limited to, detail on Project components, Project technologies, regulatory process, Project schedule and the EIS including valued components, significance findings, monitoring, and mitigation. A one-page summary on the WRP was available for community members to take home in English, Cree, and Dene. The in-person meetings were as follows:

January 23, 2023 (evening): Black Lake First Nation (Please see Appendix 4-A, ROC #823)

January 24, 2023 (daytime): Uranium City (Please see Appendix 4-A, ROC #842)

January 24, 2023 (evening): Fond du Lac First Nation (Please see Appendix 4-A, ROC #845)

January 25, 2023 (evening): Hatchet Lake First Nation (Please see Appendix 4-A, ROC #846)

Site Tour – November 2, 2023: In accordance with a previous commitment to the YNLR, Denison worked with the YNLR to coordinate a site visit to the Project in 2023. On September 15, 2023, Denison and the YNLR representatives attempted to fly to the Project site to undertake the site visit, but due to poor visibility, were unable to complete this activity. Subsequently, on November 2, 2023, Denison and the YNLR successfully visited the Project site. An overview of the work done to date on the Project was provided, including the 2022 and 2023 Feasibility Field Test in support of the Project.

Meeting - February 22, 2024: In support of resolution of issues raised by the YNLR on the draft EIS for the Project, Denison and the YNLR held an in-person technical meeting focused on cumulative effects, with both Denison's and YNLR's technical experts in attendance. Both YNLR and Denison provided presentations centered around cumulative effects, and YNLR provided an overview on environmental monitoring and management with reference to Denison's responses to YNLR comments on the environmental impact statement for the Wheeler River Project.

Athabasca Basin Community Meetings – June 10 to June 13, 2024: In June 2024, Denison and the YNLR collaboratively facilitated a series of in person meetings for Athabasca communities. In addition to Denison's and the YNLR's participation in these meetings, members of the Saskatchewan Ministry of Environment were also in attendance. The CNSC was also invited but, due to a conflict with other commitments, was unable to attend.

In advance of these meetings, Denison and the YNLR met virtually for discussion at regular intervals for the purpose of discussing logistics and planning. Through this process, engagement materials were developed by Denison that incorporated YNLR feedback.

At the recommendation of the YNLR, engagement focused largely on introducing the in situ recovery mining method at a conceptual level. Specifics pertaining to the Wheeler River Project were then shared with community members and included Project stage, Project components, and mitigation and monitoring, and future employment and business opportunities. This information was shared through PowerPoint presentation and accompanying hardcopy booklets. Live translations were carried out throughout the presentations and associated dialogue, and a one-page summary of the Wheeler River Project was available, in hard copy, in English, Cree, and Dene. Presentations were additionally conducted by the YNLR and the Saskatchewan Ministry of Environment.

The in-person meetings and associated themes central to discussion are as follows:

Stony Rapids Community Meeting – July 10, 2024 (afternoon): Throughout the Stony Rapids Community Meeting, the most prominent and recurrent theme expressed by attendees related to socio-economic wellbeing and was often expressed in terms of economic benefits such as employment, training, and business opportunities. The importance of providing youth with opportunities for training and employment relative to the mining industry was expressed. Attendees emphasized the importance of developing relationships to further socio-economic benefits. In addition to highlighting employment, training, and business opportunities, attendees expressed the need for improved infrastructure, emphasizing the poor quality of the road connecting Stony Rapids to Points North.

During this community meeting, questions were asked specific to Project technology and Project components. Some attendees expressed support of the small Project footprint and the low impact mining method, while others emphasized hesitancy based on expressed perspectives related to the sharing of benefits. Attendees additionally stressed the importance of ongoing communication and information sharing. It was indicated by one attendee that trapping is impacting by the onset of surrounding exploration activities. Please see Appendix 4-A, ROC #1102 for more information on this meeting.

Black Lake First Nation Community Meeting – June 10, 2024 (evening): During the Black Lake Community Meeting, attendees asked Project specific questions following the presentation provided by Denison such as the life of the Wheeler River Mine, the depth of the Phoenix ore body, and clarifications surrounding the leaching process as part of the in situ recovery mining method. Dialogue that followed these questions centred around employment and training opportunities, with attendees placing emphasis on enabling community members to obtain and retain meaningful employment. The importance of training opportunities was highlighted. Please see Appendix 4-A, ROC #1103 for more information on this meeting.

Uranium City Community Meeting with Camsell Portage Attending Virtually – June 11, 2024 (evening): During the Uranium City Community Meeting, dialogue was primarily related to Project technologies and notably centred around freeze wall technology. Attendees sought information on the freeze wall through questions such as, “Are the freeze walls keyed into the basement rock?” and, “How thick is the freeze wall once it's in place?” Similarly, attendees sought clarity on processes by which groundwater is protected. This was shown through questions relating to groundwater remediation, monitoring wells, and the potential for mining fluid to migrate outside of the mining area. Please see Appendix 4-A, ROC #1104 for more information on this meeting.

Fond du Lac First Nation Community Meeting – June 12, 2024 (canceled): Denison was informed by the YNLR on June 7, 2024, of the cancellation of the community meeting in Fond du Lac, owing to unforeseen circumstances.

Hatchet Lake First Nation Community Meeting – June 13, 2024 (evening): Dialogue that occurred throughout the Hatchet Lake First Nation Community Meeting centred largely around the mining area, particularly with respect to containment and the freeze wall. This was emphasized through questions such as, “Will those chemicals be able to escape out of the freeze wall?” Similarly, attendees looked to confirm the freeze wall timeline in relation to a phased approach to mining through questions such as, “Mining will be done in phases. What do you do with the freeze wall when you move on to future phases?” and, “Will the freeze walls of earlier phases stay frozen while later phases are mined? In the long run will anything escape to the environment?” A common theme can be inferred from this dialogue: the potential impacts associated with the ISR mining process and related mitigation and contingency measures. By asking for clarification on the potential for an accidental release should the freeze wall fail and expressing a consideration of remediation, attendees emphasized a regard for subsurface impacts in both short terms and long-term contexts, evidenced by the questions: “How will you protect against radiation from escaping the leaching area?”

While the primary point of emphasis throughout the Hatchet Lake First Nation Community meeting related to the subsurface environment, additional topics were discussed as guided by questions and comments expressed by attendees: i) Attendees asked questions and shared thoughts about engagement processes, ii) Attendees asked questions and shared thoughts about the impacts of sulfuric acid on vegetation, iii) Attendees shared thoughts about impacts to the fishing economy as a result of reporting, iv) Attendees looked to confirm that Denison would have a water treatment plant, v) Attendees shared thoughts about water quality requirements per federal and provincial legislation in the context of fishing and food industry standards, vi) Attendees asked questions about Project components, vii) One attendee referenced the Project footprint, stating that, “[The] small footprint of the project is ok, but the community looks at the new disturbance along with a lot of other activities that are happening on the landscape. Cumulatively, the footprint of mining is not small to communities.” Please see Appendix 4-A, ROC #1105 for more information on this meeting.

Future Engagement Activities

Denison expects to continue working with the YNLR, throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities in relation to topics of interest in relation to the Project.

4.3.4.2.4 Engagement Activities Associated with Ya’thi Néné Lands and Resources Office-Specific Processes

As noted in Section 4.3.4.2.2, Denison entered into two Letter Agreements with the YNLR in relation to the Project in 2021 to provide capacity support to enable YNLR to contribute to the EIS. As a result of the Letter Agreements, YNLR and Denison have developed engagement activities specific to YNLR, funded by Denison:

1. In March 2022, the YNLR transmitted and expressed support for inclusion in the EIS of their report entitled *An Exploration of Recorded Athabasca Denesųłiné Traditional Knowledge, Land Use and Occupancy Information in the Vicinity of Denison Mines Wheeler River Project* (see Appendix 3-A in Section 3). This report, funded by Denison, focused primarily on the Athabasca Denesųłiné First Nations, including Hatchet Lake, Black Lake, and Fond du Lac. Indigenous

Knowledge and LK within this report, as well as publicly available information, has been integrated into the EIS with focus on the Athabasca Denesųłiné communities. This report is an amalgamation of known information from YNLR and was not collected explicitly for the purposes of the Project and, as such, should be interpreted with caution.

These reports have contributed to the information Denison is presenting in the EIS with respect to the knowledge and information by and about YNLR. Please see Table 3.5-1 in Section 3 for more information.

2. Review by YNLR of EIS information prior to filing draft EIS with Regulators.
   a. Denison shared EIS information (in the forms of specific sections of the EIS) with YNLR prior to filing the draft EIS with the Regulators, to provide YNLR an opportunity to review information made in reference to YNLR, including that information provided to Denison in the report authored by YNLR, as identified above. As a result, the sections shared with YNLR were:
      i. Section 3 Indigenous and Local Knowledge; and
      ii. Section 11 Land and Resource Use.

During this pre-review, YNLR expressed concern regarding the classification of the Athabasca Denesųłiné First Nations (specifically Hatchet Lake First Nation) as Indigenous Communities rather than Indigenous Communities of Interest. Denison responded to this concern in a letter to YNLR in early October 2022, which also included a disposition table responding to each specific concern identified by YNLR. As necessary, Denison has also addressed these other concerns in the relevant sections of the EIS.

4.3.4.2.5 Ya'thi Néné Lands and Resources Office Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators, and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022. On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On March 4, 2023, the YNLR submitted public comments on the draft EIS to the CNSC (Government of Canada 2024), which comprised 64 technical comments.

On July 18, 2023, Denison and the YNLR met to discuss the YNLR’s public comments on the draft EIS.

On July 20, 2023, the YNLR sent Denison a letter outlining the YNLR’s preferred approach for Denison to respond to the YNLR’s public comments on the draft EIS, which was that they wished to have Denison provide a written response to all items raised in the public comments on the draft EIS (see Appendix 4-A, ROC #920).

On November 23, 2023, following work undertaken with the YNLR since receipt of the July 20, 2023, letter to Denison from the YNLR, Denison responded to YNLR’s public comments made on the draft EIS (see Appendix 4-A, ROC #971).

On February 2, 2024, following Denison’s response to YNLR’s public comments made on the draft EIS, in advance of the technical meeting between Denison and the YNLR in support of resolution of issues raised by the YNLR on the draft EIS for the Project, YNLR provided a letter to Denison outlining their perspective on the status of comments (see Appendix 4-A, ROC #1044).

On February 22, 2024, in support of resolution of issues raised by the YNLR on the draft EIS for the Project, Denison and the YNLR held an in person technical meeting focused on cumulative effects, with both Denison's and YNLR's technical experts in attendance. Both YNLR and Denison provided presentations centered around cumulative effect methodology, and YNLR provided an overview on environmental monitoring and management with reference to Denison's responses to YNLR comments on the environmental impact statement for the Wheeler River Project.

On February 23, 2024, following their recent technical meeting, Denison emailed the YNLR and provided to YNLR copies of: i) the meeting agenda, ii) Denison's presentation, iii) The Caribou Management Framework that was filed with the revised draft environmental impact statement for the Wheeler River Project, iv) the WRP draft EIS Section 16- Summary of Monitoring & Follow-up Programs for Wheeler River, and v) Denison's commitments register updated as of filing of the draft EIS on February 10, 2024 (see Appendix 4-A, ROC #1081).

On March 13, 2024, the YNLR provided additional comments on Denison’s November 23, 2023, EIS responses. The YNLR indicated that Denison’s initial November 23, 2023, responses on pages 19 to 39 dealt with woodland caribou, cumulative effects, and other terrestrial matters and as such they were addressed in the February 22, 2024, meeting with Denison and representatives from Ecometrix (see Appendix 4-A, ROC #1084).

On April 5, 2024, Denison provided responses to YNLR’s March 13, 2024, comments and indicated that Denison would consider YNLR’s comments resolved in instances where no follow up comment has been provided. This correspondence from Denison outlined a number of specific commitments from Denison in respect of the draft EIS comments made and the further March 13, 2024, comments. (see Appendix 4-A, ROC#1085).

On April 30, 2024, Denison requested an update on the status of comment resolution from Ya'thi Néné Lands and Resource Board, following a recent meeting between Denison and the YNLR in which a number of items were discussed (see Appendix 4-A, ROC #1089)

On June 19, 2024, the YNLR provided a letter to update Denison on the status of YNLR comments made on the draft EIS for the Wheeler River Project following measures taken in pursuit of comment resolution to date. YNLR indicated that they do not consider any of their concerns expressed in their February 2, 2024, and March 13, 2024, letter to be resolved (see Appendix 4-A, ROC #1110).

On June 28, 2024, Denison provided a response to the YNLR, clarifying Denison's position on the various endeavours undertaken in pursuit of comment resolution, and seeking clarity from the YNLR in relation to the process by which YNLR desires to have undertaken in order to move forward toward the resolution of outstanding concerns. This correspondence reiterated several commitments made by Denison in response to the concerns and requests made by the YNLR over the entirety of the public review process for the Project (see Appendix 4-A, ROC #1112).

Denison expects to continue working with the YNLR to coordinate engagement activities related to their topics of interest related to the Project.

4.3.4.2.6 Ya'thi Néné Lands and Resources Office Key Interests, Issues and Concerns

A summary of key interests, issues and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.3.4.3 Meadow Lake Tribal Council and Prince Albert Grand Council

As noted in the introduction to this section, Denison corresponded with MLTC and PAGC to keep them informed of key project stages. As interactions were few, they have been grouped together in this subsection.

In 2019, MLTC and PAGC were identified by the CNSC as potentially having an interest in the Project. As a result, Denison sent correspondence to them in 2019 with information about the Project; in March 2020 informing them of the temporary suspension of the EA; and in January 2021 about the Project Restart. As of January 2024, Denison has not been contacted by either Council in respect of the Project.

On March 5, 2023, the PAGC submitted public comments on the draft EIS to the CNSC (Government of Canada 2024). Due to an administrative error, Denison was unaware these comments had been submitted to the CNSC. Upon realization of this situation, Denison provided a direct response to the PAGC comments.

On June 6, 2024, Denison responded to the PAGC's public comments on the draft EIS (Please see Appendix 4-A, ROC #1099).

4.4 Engagement with the General Public

As noted in Section 4.2, Denison determined that engagement with the General Public would focus on four groups:

- Non-Indigenous COI;
- Other Non-Indigenous Communities;
- Nearby Land Users; and
- Organizations.

The rationale for inclusion of these groups to receive engagement is as follows: A municipality or non-Indigenous COI community located near the existing transportation infrastructure used by the Project may experience efforts by Denison to offer employment, training, and business opportunities in connection with the Project and, therefore, may experience socioeconomic effects from the Project. Nearby Land Users such as commercial trappers or fishers, cabin/lease owners, or commercially operated lodges in the vicinity of the Project have the potential to experience effects from the Project. Several relevant groups or organizations represent various interests relevant to the Project. Each of these groups are discussed in Sections 4.4.1, 4.4.2, and 4.4.3.

4.4.1 Engagement with Non-Indigenous Communities of Interest

Engagement with Non-Indigenous COI included the following:

- Northern Village of Pinehouse;
- Northern Village of Beauval; and
- Northern Hamlet of Patuanak.

4.4.1.1 Engagement with the Northern Village of Pinehouse

The NVP has a history dating back to the times of the North West Company and the Hudson's Bay Company. The 1906 Canada Census used the name Serpent Lake on the Churchill River to describe the community. A townsite was established in the 1940s and a Roman Catholic church (St. Dominic) was built in 1944, followed by a store, and in 1948 a school. In 1954, the community was renamed Pinehouse Lake. Pinehouse was originally named Snake Lake (kinêpiko-sâkahikam in Cree) and Elders still use this name in reference to the community. Although officially named Pinehouse, numerous official sources including the official road map of Saskatchewan issued by the province, identify the community by the name Pinehouse Lake. Eighty houses were built between 1967 and

1980 and Pinehouse Lake was connected to the power grid in 1984, replacing a diesel generator set up around 1970. The first road to the community was built from Highway 2 in 1977 (Pinehouse Lake n.d.).

Figure 4.3-1 illustrates where NVP is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, NVP is located 230 km away from the Project. In terms of travel distance by existing transportation routes NVP is located 270 km away from the Project.

4.4.1.1.1 History of Interactions

Since 2016, Denison has been engaging with the NVP in a variety of ways. In some instances, the elected members of the municipality are also officials of Métis Locals and, therefore, represent both their municipality as well as their Indigenous community. As a result, during the onset of engagement activities in 2016, the entities of KML and the Village of Pinehouse Lake had some overlap. In 2019, the KML delegated their Duty to Consult for the Project to the MN-S. Clear distinction between the Métis leadership and Citizens, and the NVP leadership and residents was, therefore, necessary to make sure the MN-S was able to appropriately provide the representation of the Métis of KML, per the delegated Duty to Consult. As a result, Denison distinguished its engagement efforts between MN-S, on behalf of KML, and the general public of the Village of Pinehouse, with no intended overlap in relation to Métis interests.

4.4.1.1.2 Agreements Relative to the Environmental Assessment Process

A MOU was signed between Denison, KML and the NVP in 2017. The signing of this MOU with both KML and the NVP reflected the perspective of KML and the NVP to represent both municipal residents and the Métis Citizens co-operatively. This non-binding MOU formalized the intent to work together in a spirit of mutual respect to cooperate to collectively identify practical means by which to avoid, mitigate, or otherwise address potential effects of the Project upon the exercise of the Indigenous Rights, Treaty Rights, and interests.

In 2018, Denison, the KML and the NVP signed an addendum to the original MOU whereby Denison committed to financially supporting an initiative to undertake a second phase of land use and occupancy mapping representing the KML and the NVP. This work was subsequently undertaken in 2018 and shared with Denison for use in documents in relation to regulatory proceedings associated with its activities, including the Project.

In 2019, the KML delegated their Duty to Consult for the Project to the MN-S. Thereafter, as directed, Denison engaged with MN-S on behalf of KML (and other Métis Locals which likewise delegated their Duty to Consult to MN-S).

In 2021, the KML revoked their delegated Duty to Consult to the MN-S. Denison re-engaged the KML directly in respect of the Project while continuing to engage separately with the general public of the NVP.

In 2022, Denison, KML/NVP built upon the 2017 MOU and signed a Participation Agreement and associated Letter Agreement, which outlined a mutually agreeable framework and applicable funding arrangements to facilitate KML's/NVP's participation and engagement in the EA process for the Project—including KML's/NVP's contribution to Denison's environmental understanding of the Project in a holistic way that respected KML's rights and interests. As a result, several additional activities have been undertaken between KML/ NVP and Denison, which are further described in Section 4.3.2.2.3 and Section 4.4.1.1.3.

In July 2024, KML and the NVP and Denison concluded an Agreement in respect of the Project that provides, among other matters, various procedural and substantive commitments by Denison to KML/NVP and the support and consent of KML/NVP for the development and operation of the Project in a sustainable manner which respects KML's inherent Aboriginal rights, advances reconciliation with Indigenous peoples, and provides economic opportunities and other benefits to KML/NVP.

4.4.1.1.3 Key Engagement Activities

During the engagement activities undertaken with the NVP, several key engagement activities took place that have played a meaningful role in relation to the EA process. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1. The main forms of engagement included meetings with leadership, community meetings, a workshop on early infrastructure options (2018), a site visit (2019), two online surveys (2021 and 2022), and a meeting and information session on preliminary effects and mitigation (2022). As noted in Section 4.2.1, due to the COVID-19 pandemic, engagement switched to virtual meetings in 2021. In mid-2022, appropriate engagement activities moved back to in-person. The following text describes several of the key engagement activities.

Engagement Focus: Pre-Project Description - April 2016 to May 2019

Introductory meeting in the NVP – September 7, 2016: This was the inaugural meeting between the senior management team of Denison and residents of the NVP. About 20 individuals were in attendance, along with the Mayor of the NVP. Much of the meeting focussed on clarifying the nature of Denison's activities, including the Project and related exploration activities, the interest in employment and business opportunities, the interest in protection of the environment from exploration and Project activities, including consideration of cumulative effects, and questions in relation to the nuclear industry in general and the market related to uranium. For more information about this activity, please see Appendix 4-A, ROC #105.

Workshop – January 16, 2018: Denison hosted a workshop with grade 11 and 12 students, plus a number of community members. The focus of the workshop was to obtain feedback on three alternatives/options for the proposed Project: the road alignment from Highway 914 into the Project Area; the potential treated effluent discharge location; and the mining method options. General questions were asked regarding the various alternatives and options, and points of clarification pertaining to aspects of the Project. Feedback was collected on the various options and has been incorporated into the final design for road alignment, and the treated effluent discharge location. Please see Section 2 for more details. For more specifics about this activity, please see Appendix 4-A, ROC #2.

Engagement Focus: Post-Project Description – July 2019 to October 2022

The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project.

In August 2019, Denison hosted a site tour at the Project location. Attending the site tour was the Mayor of the NVP. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Representatives from the CNSC and SK MOE were present. For more specifics about this activity, please see Appendix 4-A, ROC #1.

Meetings – February 11, 2021: On February 11, 2021, Denison hosted virtual meetings with the leadership of the NVP, as well as virtual meeting for the residents of the NVP. The focus of these engagement activities was to provide information about the Project to the NVP and residents, present a preliminary list of VCs that Denison had identified as part of the EA process, and provide an opportunity for members to provide feedback on the proposed list of VCs, and ask questions about Project components of interest or concern to them.

During the leadership meeting with the NVP, Denison confirmed it was acceptable to continue hosting the virtual meeting for the residents of the NVP, given concerns raised by the MN-S related to the Métis nature of the NVP. The leadership of the NVP confirmed it was acceptable to host the virtual meeting for the residents. Denison confirmed to MN-S that it respected the delegation of the Duty to Consult to MN-S by the Métis Locals. As a result, the purpose of these community meetings was to seek feedback with respect to the Project from the general public residing in Beauval, and not to gather information about the distinct interests of the Métis regarding the Project. The virtual meeting for residents was advertised on the radio and social media, and posters were placed in community buildings. The Zoom platform was used, but the meeting was also broadcasted live through CFNK-FM 89.9. At least 52 Zoom accounts were used to attend the presentation, although it is possible that more than one person viewed the presentation from each account. Representatives from the CNSC and the Province of Saskatchewan were present during both virtual meetings.

Topics covered during the virtual presentations include the following:

- Denison company introduction and key staff members;
- introduction to regulators;
- location of the Project;

- ISR mining, in general;
- ISR mining at the Project, including the recent change in the Project design from freeze dome technology to a freeze wall containment method;
- employment opportunities;
- EA; and
- VCs.

Meeting participants were encouraged to complete Denison's online survey in relation to the VCs considered important to residents of the NVP. Following the presentation, Denison answered questions that were put into the online chat function.

Key themes that emerged from the questions posed at the NVP meetings, which indicated either interests or concerns, are summarized as follows:

- the ISR mining method, including volumes of water used and evidence regarding the efficacy of the freeze wall techniques and its potential to affect the environment;
- the reclamation process at the Project, and Denison's interest in working together with the NVP regarding baseline information and expectations, also in relation to climate change;
- emergency response measures in relation to the transportation of the chemicals used in the mining process, protection of the Churchill River in respect of a potential spill, involvement of the NVP in emergency planning; and
- economic opportunities, including job opportunities, training opportunities, business opportunities and community liaison concepts.

For additional details about this activity, please see Appendix 4-A, ROC #440 and ROC #444.

Denison provided a report to the NVP regarding what was heard by Denison during the engagement activities. This report was shared in hard copy form (sent to the NVP Office), shared with the NVP for posting to a website, posted on the Denison website (www.wheelerriverproject.ca) and a video was made by Denison for those who prefer oral communications, also on the Denison website.

Online Survey**:** During and following the NVP meeting(s), attendees were invited to provide feedback on VCs through an online survey. The purpose of the survey was to seek feedback on the importance of the VCs to members, and identify interests or concerns related to the Project, providing an additional mean by which feedback could be provided to Denison. People who were unable to attend the presentation were also encouraged to provide feedback through the survey. The survey was marketed to members using Facebook and radio advertisements.

The survey was open for feedback from February 9 to 23, 2021, for a total of 14 days. Twenty responses were received, with 100% rate of survey completion.

The survey included reach and marketing questions about how respondents heard about the survey and if they attended a presentation. This information helped Denison to determine which event marketing efforts were most effective.

The survey also asked respondents to disclose voluntary demographic information such as age, primary residence, and identity, to help Denison determine if there were large demographic groups whose perspectives were not represented in the results.

Following the reach and marketing and demographic questions, the survey included questions specific to the preliminary list of VCs. These questions were followed by the opportunity for respondents to share their thoughts on opportunities and challenges related to the Project.

Demographics

Most survey respondents (70%) were between the ages of 35 and 64, compared to 30% who were between the ages of 16 to 34, and none who identified as age 65 or older. Most respondents self-identified as Indigenous peoples, with the majority (40%) of people identifying as Métis, 30% identifying as First Nations, 10% identifying as non-status, and 5% identifying as Indigenous but did not indicate a specific group. Additionally, 10% of respondents did not self-identify as Aboriginal and 5% preferred not to answer.

Valued Components

A total of 26 interconnected VCs were proposed to respondents. Respondents were asked to select from the list which VCs they felt were important for Denison to research further as part of the EA. While all 26 VCs were identified as important by at least one respondent, the following environmental components were identified as important to more than half of respondents:

- traditional land and resource use;
- air quality;
- fish;
- groundwater quality;
- employment;
- surface water;
- fish habitat and aquatic plants;
- local economy;
- public safety; and
- birds.

The importance of traditional land and resource use, the potential for environmental effects, and local employment and business opportunities were echoed in the questions asked by those who attended the virtual presentation. Respondents explained that these VCs are important to them because they are most at risk of disturbance, most important to the well-being and survival of all humans, and they are components that are increasing in value. Respondents also noted the importance of jobs and new opportunities for community members. Respondents from Pinehouse and area felt that the following VCs were missing and important so should be added to the list:

- housing; and
- community participation.

Just over 25% of respondents identified VCs that they felt were not important to study further. These VCs included:

- noise level;
- outfitting;
- birds;
- industry use;
- heritage resources; and
- ungulates.

Of these, noise level was the only VC that was selected as not important more often than it was identified as important.

The complete list of VCs included in this EIS is available in Section 5.3.1 in Section 5.

<u>Opportunities and Challenges</u>

Respondents were asked, based on what they knew so far about the Project, to share the aspects of the Project that they felt could benefit or work well for the community.

Some of the unique or specific opportunities mentioned included the following items:

- training opportunities;
- increased employment;
  - potential for jobs in Pinehouse that could benefit community members who can't work away from home;
- potential for funding to the community;
- potential for collaborative agreements;
- potential for Denison to form a partnership with the community; and

- an increase in opportunities for community improvement and participation.

Respondents were then asked what aspects of the Project they felt would be challenging or cause concern for their community. Responses included:

- the potential to interrupt wildlife and traditional land users access to the land;
- the potential for mining activities to affect the environment and displace wildlife;
- being asked to choose between the land and the economic opportunities;
- an increase in traffic affecting road quality;
- the transportation of dangerous chemicals to and from the Project;
- the potential for the contamination of the environment;
- concerns about the transport of dangerous chemicals; and
- the possibility that residents won't be able to take advantage of the opportunities presented to them by the project due to existing social issues like the lack of housing.

For more information about this activity, please see Appendix 4-A, ROC #446.

Engagement Focus: Post-Project Description – July 2019 to October 2022

Meetings – June 1, 2022: On June 1, 2022, engagement activities were undertaken in collaboration with KML to occur in the Village of Pinehouse Lake, in the Village Hall and be open to KML members and the NVP residents. The structure and layout of the meeting was jointly established between Denison and KML. The focus of these engagement activities was to share the preliminary findings of the EA, proposed mitigation measures, preliminary conclusions of the EIS, and to facilitate dialogue related to this information.

Engagement activities were conducted as a focused leadership meeting with KML representatives and the Village of Pinehouse representatives (at their joint request), and as a general open house. Date and location of the open house meeting was advertised on local radio stations, Facebook pages, TV channels, and posters. During the open house, attendees were able to complete a survey, in hard copy or digital format, to express their opinions. Comments and questions were also captured by Denison in a record-keeping notebook and transcribed following the event.

To communicate EA findings and Projects details, Denison created and displayed three models and 15 informational poster boards. The three models depicted: 1) the uranium ore body and projected, below ground, extraction infrastructure; 2) the Project site surface with associated infrastructure; and 3) a 1:294 scale map of the area surrounding the Project site. The 15 informational poster boards presented EA findings in relation to VCs identified as important during previous rounds of engagement activities, as well as detail on technologies, regulatory processes, and procedures.

KML and Village of Pinehouse Leadership Meeting – June 1, 2022: The leadership meeting was held in at the Pinehouse Lake gas bar on June 1, 2022, with invited representatives of KML and the Village of Pinehouse Lake. Denison provided an overview of the Project that included information on project specifics, current status, predicted timeline, and preliminary EA findings.

The dialogue between Denison and the leadership related to Project specifics, including inquiries about the dimensions of the ore body and freeze wall. Questions surrounding employment and training were also expressed. A need for a culturally sensitive training model was expressed. This bridged to discussion of the reduced footprint of the Project translating to fewer employment opportunities. Leadership expressed a desire for appropriate training for community residents to adequately compete as Project related jobs become available. Representatives from the CNSC and SK MOE were present. For more information about this activity, please see Appendix 4-A, ROC #623.

Open House in Village of Pinehouse Lake – June 1, 2022: The open house was co-planned between Denison and the KML. The open house was held at the Pinehouse Community Centre, welcoming members of the surrounding area. A total of 52 attendees signed the sign-in sheet. Some individuals chose not to sign in, making the attendance at the Pinehouse open house slightly higher than recorded by the sign-in sheet. Through dialogue at the open house, community members expressed a general interest in the Project and Project-specific information. Questions such as "*How does ISR mining work?"* and "*How does calcium chloride (CaCl) cool and freeze the ground?*" illustrate this interest. Other questions, while primarily geared toward gaining clarity on Project details, suggest consideration for mitigation measures, human health, and the biophysical environment. Examples of this include questions such as "*Where will the drinking water [for the camp] come from?*" and inquiries over potential effects of work schedules on worker health. Representatives from the CNSC and SK MOE were present. For more information about this activity, please see Appendix 4-A, ROC #620.

Online Survey: During and following the meeting(s), attendees were invited to provide feedback on preliminary effects, mitigation, and monitoring through an online survey. Denison created a survey, available in hardcopy and digital formats during each open house and available in digital format for two weeks following the open house. The survey was comprised of four core questions:

1. Are there any topics of particular concern that Denison needs to pay special attention to?
2. Are there any things missing that Denison should consider to reduce the effects of the Project to the environment?
3. Are there any topics that you would like to see included in monitoring plans?
4. What additional information would be helpful for you to understand the Project and its potential impacts to people and the environment?

The 25 survey respondents indicated that they were from Pinehouse, with 15 self-identifying as Métis, nine as First Nation, and one as Indigenous without further specification. Survey respondents primarily heard of the survey through word of mouth, indicated by 10 survey respondents. Five survey respondents indicated that they heard of the survey through Facebook, and five indicated they heard of the survey through "other" means. Three respondents heard of the survey through posters, and two through radio. Most survey respondents were in the 35 to 64 age cohort, indicated in 16 instances. Five respondents indicated that they were in the 16 to 34 cohort and four indicated that they were in the 65+ age cohort.

When asked the question **"Are there any topics of particular concern that Denison needs to pay special attention to?"** five respondents provided incomplete answers. Six survey respondents expressed that they had no concerns, with statements ranging from variations of the word "no" to positive statements such as "*I think Denison covered all the main topics very well*." Five respondents emphasized employment and training, one of which framed this emphasis in a northern context. Five survey respondents highlighted a concern for the environment; one of these responses focused on water quality, two on environmental restorations, one on the general environment, and one on mining source water treatment and runoff, presumably as it relates to the environment. One response expressed a concern over recycling. The remaining responses touched on a variety of topics. One survey respondent supplied a community benefits inquiry. Accessibility of the Project site and Project buildings was a concern for another respondent. Concern over the potential for future Covid-19 restrictions and possible vaccination requirement was expressed, though this response may be extended to include pandemic planning in general.

When asked the question **"Are there any things missing that Denison should consider to reduce the effects of the Project to the environment?"** 10 survey respondents indicated that they felt nothing was missing. These responses, ranged from "no" to positive commentary such as "*No- work at Denison Mine couple shifts, like the safe orientated culture and respect of land and native people that live near the mine sites*." One additional survey response stated "*May in the future*." This may express no concern and/or a desire for forward planning. One survey respondent directly referenced forward planning in addition to stressing the importance of wildlife, and caribou habitat management. Waste management was referenced by one respondent emphasizing recycling and providing the suggestion of recycling paper. One survey respondent emphasized air quality, while another inquired "*Are these surface pipes [spill] ready at all times*?" One survey response suggested the inclusion of LK and TK, suggesting Denison "learn from the people around this project." One survey respondent expressed concern for land users and wanted it to be affirmed that mining methods were safe. Seven survey respondents provided incomplete responses.

When asked the question **"Are there any topics that you would like to see included in the monitoring plans?"** five respondents supplied incomplete answers and nine indicated that there was nothing additional they felt needed to be considered. Several responses did not relate to the survey question: two suggested a focus on local employment opportunities; one inquired about water quality as per human consumption and treatment; one requested more local meetings; one inquired about double plated pipes and spill readiness; one stated that someone to teach safety was required; and one requested more Project context. Responses related to the survey question related to water quality, with one response simply stating water sampling and the other emphasizing monitoring of aquatic environments as well as budgeting appropriately for long-term monitoring. Similarly, another survey respondent stated "*future-wise*", potentially referring to long-term monitoring or incorporating topics into the monitoring plan in a future context. One survey response indicated they would like to see ongoing reporting on Project Operation.

When asked the question **"What additional information would be helpful for you to understand the Project and its potential impacts to people and the environment?"** six indicated that no additional information was needed and five provided incomplete responses. Several survey respondents provided unrelated suggestions to this survey question. Forming mutually beneficial agreements was suggested through the response "Always explain the motto 'help us help you."". Two respondents focused on opportunities for youth, one in terms of employment and the other in terms of scholarships. One survey respondent emphasized general opportunity for future employment, while another suggested employment considerations for people with disabilities. Waste management was focused on, with one survey respondent suggesting an increase in practice of recycling as well as questioning water quality and sampling. One respondent suggested Elder representation in decision making. Responses that related to the survey question generally suggested a need for high level information including Project timeline, more information on environmental effects, water quality changes from Project Operation, and general Project site information including potential jobs and tasks. The importance of ongoing dialogue was emphasized in responses that suggested continued transparency and regular community meetings.

Most of the information shared with Denison regarding the survey questions has been captured and addressed by Denison as part of the current work on the EA and the Project, in general. In a few instances, the recommendations in relation to sharing of information in the future, such as with respect to environmental monitoring and employment opportunities will be carried through into ongoing discussions between Denison and KML. For additional details about this activity, please see Appendix 4-A, ROC #652.

Engagement Focus: Environmental Assessment Outcomes and Relationship to Licensing / Approvals – October 2022 to Present

Open House – October 24, 2023: On October 24, 2023, engagement activities were undertaken in collaboration with KML to occur in the Village of Pinehouse Lake, in the Village Hall. This collaboration includes general residents of the NVP, in addition to KML Citizens. The focus of these engagement activities was to share the findings of the EA, mitigation measures, monitoring, significance, cumulative effects, the conclusions of the EIS, and the relationship between the environmental assessment and the ultimate licensing / approvals process for the Project.

The structure and layout of the meeting was jointly established between Denison and KML. Engagement activities were conducted as a focused leadership meeting with KML land users, and as a general open house with a specified time period for an overview presentation. The date and location of open house meetings were advertised on local radio stations, Facebook pages, TV channels, and posters. Comments and questions were also captured by Denison in a record-keeping notebook, and transcribed following the event.

To communicate EA findings, Project details, and the relationship to the licensing / approvals process, Denison displayed three models and 6 informational poster boards. The three models depicted: 1) the uranium ore body and projected, below ground, extraction infrastructure; 2) the Project site surface with associated infrastructure; and 3) a 1:294 scale map of the area surrounding the Project site. The 6 informational poster boards presented EA findings and related licensing / approvals actions in relation to VCs identified as important during previous rounds of engagement activities.

***Open House in Village of Pinehouse Lake – October 24, 2023*:** In coordination with KML, Denison hosted an open house event in the Northern Village of Pinehouse to share information about the Project, with a particular focus on the flow of information from the environmental assessment into licensing, permits, and commitments. Denison advertised the event with social media posts and posters around the community. In addition to members of KML, 48 residents were recorded as in attendance. Information boards and area models were displayed, information booklets were provided. Denison prepared a formal presentation, and a translator was present to translate as needed. The Canadian Nuclear Safety Commission and the Saskatchewan Ministry of Environment were invited by Denison and were in attendance. For additional details about this activity, please see Appendix 4-A, ROC #978.

Site Tour (Student) – May 7, 2024: In coordination with Kineepik Métis Local, Denison Mines hosted a site tour at the Wheeler River Project for Pinehouse high school students.

Meeting (Land User) – May 8, 2024: In coordination with Kineepik Métis Local, Denison hosted a land user meeting at the Pinehouse Village Hall. The focus of the meeting was to share updates on the Wheeler River Project, to answer land user questions, to facilitate discussion, and to provide information on Project stage and licensing progression. The event was planned and invitations extended as part of the process in place led by KML. Denison prepared a presentation and distributed informational handouts to attendees. The meeting was attended by 38 land users and 4 KML staff. For additional details about this activity, please see Appendix 4-A, ROC #1088.

Future Engagement Activities

Denison and KML/NVP have an agreed-upon process to regularly engage about ongoing matters related to the Project and the associated regulatory approval process. KML leads this process but also includes the NVP. Denison expects to continue working with KML/NVP, throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities in relation to topics of interest to them in relation to the Project.

4.4.1.1.4 Northern Village of Pinehouse Public Comments on Draft Environmental Impact Statement and Related Processes

An important part of the engagement of Interested Parties for the Project is facilitated by federal regulators, and occurs vis-à-vis a public review of the draft EIS. During this public review of the draft EIS, Interested Parties can submit their views in writing on the adequacy of the information presented in the EIS, as measured against appropriate guidance materials, and on the technical merit of the information presented in the EIS.

The CNSC offered participant funding to assist Indigenous peoples, members of the public, and stakeholders in the review of the draft EIS. This participant funding offering was available from January 10, 2022, to March 14, 2022.

On November 21, 2022, public comments were invited on the draft EIS by the CNSC.

On Feb 17, 2023, KML submitted public comments on the draft EIS to the CNSC (Government of Canada 2024), consisting of 11 technical comments.

On June 11, 2023, following work undertaken together since receipt of the February 17, 2023, public comments, Denison provided KML with an updated table of issues, concerns and interests capturing engagement efforts over the years for both KML and the NVP – including Denison’s responses to those issues, concerns and interests, as associated with the Project draft EIS. KML provided feedback and stated that they were satisfied with updated table, including Denison’s responses to the issues, concerns, and interests (see Appendix 4-A, ROC #917).

On November 22, 2023, Denison provided KML with specific responses to KML’s February 17, 2023, public comments (see Appendix 4-A, ROC #970). On December 5, 2023, KML confirmed to Denison that Denison’s responses to the February 17, 2023, public comments had resolved KML’s comments / concerns on the draft EIS and the Project (see Appendix 4-A, ROC #1027).

4.4.1.1.5 Northern Village of Pinehouse Support for the Project

On August 1, 2024, KML/NVP provided a letter to the CNSC and the Province of Saskatchewan that outlined NVP’s specific support for the Project, subject to Denison materially fulfilling its commitments to KML/NVP. The letter further noted KML/NVP’s intent to participate in the ongoing regulatory approval processes for the Project in a manner consistent with the agreement between the two parties.

4.4.1.1.6 Northern Village of Pinehouse Key Interests, Issues and Concerns

A summary of key interests, issues and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-B. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.4.1.2 Engagement with the Northern Village of Beauval

Beauval—"Beautiful Valley”"—is located in Northern Saskatchewan overlooking the lovely Beaver River Valley providing a striking view of the river and surrounding nature. The Beaver River offers world-class pickerel fishing, and nearby lakes stocked with abundant Trout and Northern Pike makes Beauval an ideal destination for anglers. The community has a proud history of culture, language, and heritage. In history, Beauval was a trading post location along the Churchill River trade route for the Hudson’s Bay Company, this route is still travelled via canoe by history buffs and avid outdoors people for the pristine scenes and memorable nature experience with historic influence (Village of Beauval n.d.).

Figure 4.3-1 illustrates where Beauval is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Beauval is located 295 km away from the Project. In terms of travel distance by existing transportation routes Beauval is located 375 km away from the Project.

4.4.1.2.1 History of Interactions

Since 2016, Denison has been engaging with the NVB in a variety of ways. In some instances, the elected members of the municipality are also officials of Métis Locals and, therefore, represent both their municipality as well as their Indigenous community. As a result, during the onset of engagement activities in 2016, the entities of SML and the NVB had some overlap between each other. In 2019, the SML delegated their Duty to Consult for the Project to the MN-S. Clear distinction between the Métis leadership and Citizens, and the NVP leadership and residents was, therefore, necessary to make sure the MN-S was able to appropriately provide the representation of the Métis of KML, per the delegated Duty to Consult. As a result, Denison distinguished its engagement efforts between MN-S, on behalf of SML, and the general public of the NVB, with no intended overlap in relation to Métis interests.

4.4.1.2.2 Agreements Relative to the Environmental Assessment Process

To formalize Denison’s commitment to SML, a MOU was signed between Denison, SML and the NVB in 2018. The signing of this MOU with both SML and the NVB reflected the perspective of SML and the NVB to represent both municipal residents and the Métis co-operatively. This non-binding

MOU formalized the intent to work together in a spirit of mutual respect to cooperate to collectively identify practical means by which to avoid, mitigate, or otherwise address potential effects of the Project upon the exercise of the Indigenous Rights, Treaty Rights, and interests, to the extent they are identified in relation to the Project.

In 2019, SML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing SML in respect of engagement with Denison for the Project.

In March 2024, an Agreement was concluded in respect of the Wheeler River Project between Denison and Northern Village of Beauval, along with of Île-à-la Crosse, Jans Bay, and Cole Bay, that provides, among other matters, various commitments by Denison to these four communities and includes specific support of the Northern Village of Beauval, Île-à-la Crosse, Jans Bay, and Cole Bay for the development and operation of the Project.

4.4.1.2.3 Key Engagement Activities

During the engagement activities undertaken with the NVB, several key engagement activities took place that have played a meaningful role in the EA process. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1. The main forms of engagement included meetings with leadership, community meetings, a workshop on early infrastructure options (2018), a site visit (2019), two online surveys (2021 and 2022), and a meeting and information session on preliminary effects and mitigation (2022). As noted in Section 4.2.1, due to the COVID-19 pandemic, engagement switched to virtual meetings in 2021. In mid-2022, appropriate engagement activities moved back to in-person. The following text describes several of the key engagement activities.

Engagement Focus: Pre-Project Description - April 2016 to May 2019

Introductory Meeting in the NVB – December 6, 2016: This was the inaugural meeting between the senior management team of Denison and various entities associated with SML and the Village of Beauval. Much of the meeting focussed on clarifying the nature of Denison's activities, including the Project and related exploration activities, the interest in employment and business opportunities, opportunities and considerations for the long-term, and questions in relation to the nuclear industry in general and the market related to uranium. For more information about this activity, please see Appendix 4-A, ROC #107.

Workshop – January 18, 2018: Denison hosted a workshop with a number of community members. The focus of the workshop was to obtain feedback on three alternatives/options for the proposed Project: the road alignment from Highway 914 into the Project Area; the potential treated effluent discharge location; and the mining method options. General questions were asked regarding the various alternatives and options, and points of clarification pertaining to aspects of the Project. Feedback was collected on the various options and has been incorporated into the final design for road alignment, and the treated effluent discharge location. Please see Section 2 for more details. For more information about this activity, please see Appendix 4-A, ROC #4.

Engagement Focus: Post-Project Description – July 2019 to October 2022

The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project.

In August 2019, Denison hosted a site tour at the Project location. Attending the site tour was the Mayor of the NVB. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Representatives from the CNSC and SK MOE were present. For additional details about this activity, please see Appendix 4-A, ROC #1.

Meeting – February 9, 2021: On February 9, 2021, Denison hosted a virtual meeting for the residents of the NVB. The virtual meeting for residents was advertised on the radio and social media, and posters were placed in community buildings. The focus of these engagement activities was to provide information about the Project to the NVB and residents, present a preliminary list of VCs that Denison had identified as part of the EA process, provide an opportunity for members to provide feedback on the proposed list of VCs, and ask questions about Project components of interest or concern to them. The Zoom platform was used, but the meeting was also broadcasted live through Beauval's radio station (94.1). At least 15 Zoom accounts were used to attend the presentation, although it is possible that more than one person viewed the presentation from each account. Representatives from the CNSC and the Province of Saskatchewan were present during both virtual meetings.

Topics covered during the virtual presentations include the following:

- Denison company introduction and key staff members;
- introduction to regulators;
- location of the Project;
- ISR mining, in general;
- ISR mining at the Project, including the recent change in the Project design from freeze dome technology to a freeze wall containment method;
- employment opportunities;
- EA; and
- VCs.

Meeting participants were encouraged to complete Denison's online survey in relation to the VCs considered important to residents of the NVB. Following the presentation, Denison answered questions that were put into the online chat function.

Key themes that emerged from the questions posed at the NVB meeting, which indicated either interests or concerns, are summarized as follows:

- the length of the EA process;
- the processing of the uranium into product and the quality of the uranium ore body; and
- training opportunities with northern training institutions.

For additional information about this activity, please see Appendix 4-A, ROC #442.

Denison provided a report to the NVB regarding what was heard by Denison during the engagement activities. This report was shared in hard copy form (sent to the NVB Office), shared with the NVB for posting to a website, posted on the Denison website (www.wheelerriverproject.ca) and a video was made by Denison for those who prefer oral communications, also on the Denison website.

Online Survey: During and following the NVB meeting, attendees were invited to provide feedback on VCs through an online survey. The purpose of the survey was to seek feedback on the importance of the VCs to members, and identify interests or concerns related to the Project, providing an additional mean by which feedback could be provided to Denison. People who were unable to attend the presentation were also encouraged to provide feedback through the survey. The survey was marketed to members using Facebook and radio advertisements.

The survey was open for feedback from February 9 to 23, 2021, for a total of 14 days. A total of 10 responses were received, with 100% rate of survey completion.

The survey included reach and marketing questions about how respondents heard about the survey and if they attended a presentation. This information helped Denison to determine which event marketing efforts were most effective.

The survey also asked respondents to disclose voluntary demographic information such as age, primary residence, and identity, to help Denison determine if there were large demographic groups whose perspectives were not represented in the results.

Following the reach and marketing and demographic questions, the survey included questions specific to the preliminary list of VCs. These questions were followed by the opportunity for respondents to share their thoughts on opportunities and challenges related to the Project.

<u>Demographics</u>

Most survey respondents (70%) were between the ages of 16 and 34, compared to 30% who were between the ages of 35 and 64, and none who identified as age 65 or older. All respondents self-identified as Indigenous peoples, with the majority (60%) of people identifying as Métis, and 40% identifying as First Nations people.

<u>Valued Components</u>

A total of 26 interconnected VCs were proposed to respondents. Respondents were asked to select from the list which VCs they felt were important for Denison to research further as part of the EA. While all 26 VCs were identified as important by at least one respondent, the following environmental components were identified as important to more than half of respondents:

- local economy;
- employment;
- training;
- traditional land and resource use;
- birds;
- fish;
- air quality;
- fish habitat and aquatic plants;
- soil;
- surface water; and
- groundwater quality.

The importance of local economy, jobs, training, and the need for environmental monitoring were echoed in the questions asked by those who attended the virtual presentation. Respondents explained that these VCs are important to them because they do not want the land to be damaged and feel that these components are important to the well-being of life on the planet.

Respondents from Beauval and area did not identify any VC that were important to them but missing from the list.

A total of 80% of respondents identified VCs that were not important to study further. Most VCs selected as not important were only selected as such by two or fewer respondents. The VCs considered not important included:

- noise level;
- fish;
- infrastructure and services;
- business activity;
- soil;
- surface water;
- heritage resources;

- furbearers; and
- industry uses.

The number of respondents who indicated that noise levels and outfitting tourism were not important was greater than the number who felt they were important. For all other VCs, more respondents felt they were important than not important.

The complete list of VCs included in this EIS is available in Section 5.3.1 in Section 5.

Opportunities and Challenges

Respondents were asked, based on what they knew so far about the Project, to share the aspects of the Project that they felt could benefit or work well for the community.

Some of the unique or specific opportunities mentioned included the following items:

- training opportunities;
- increased employment and reduced unemployment;
- employee transportation to site from communities;
- the possibility of a legacy fund for the impacted communities; and
- the possibility of a collaboration agreement between Beauval and Denison.

Respondents were then asked what aspects of the Project they felt would be challenging or cause concern for their community. Responses included:

- environmental monitoring;
- mistrust between community members and regulatory bodies and industry;
- the importance to have an outside, impartial body conducting monitoring to ensure that the results can be trusted by the community;
- effects to mental health due to the development of the land;
- potential damage to the land as many people still lie off the land; and
- community safety with an increase in traffic.

For additional details about this activity, please see Appendix 4-A, ROC #446.

Meetings (Mayor and Council and Open House Meetings) – May 31, 2022: On May 31, 2022, engagement activities were undertaken in the Beauval area, at the ERFN La Plonge reserve at the Silver Building. The focus of these engagement activities was to share the preliminary findings of the EA, proposed mitigation measures, preliminary conclusions of the EIS, and to facilitate dialogue related to this information.

This meeting originally was planned to occur at the Beauval Community Centre, but owing to a set of community circumstances, was moved to the La Plonge Reserve Silver Building the day of the event. The change in venue was communicated via radio.

Mayor and Council Meeting – May 31, 2022: Engagement activities were conducted as a focused meeting with the Mayor and Council and as a general open house. Date and location of the open house meeting was advertised on local radio stations, Facebook pages, TV channels, and posters. During the open house, attendees were able to complete a survey, in hard copy or digital format, to express their opinions. Comments and questions were also captured by Denison in a record-keeping notebook and transcribed following the event.

To communicate EA findings and Projects details, Denison created and displayed three models and 15 informational poster boards. The three models depicted: 1) the uranium ore body and projected, below ground, extraction infrastructure; 2) the Project site surface with associated infrastructure; and 3) a 1:294 scale map of the area surrounding the Project site. The 15 informational poster boards presented EA findings in relation to VCs identified as important during previous rounds of engagement activities, as well as detail on technologies, regulatory processes, and procedures. For more information about this activity, please see Appendix 4-A, ROC #619.

Open House in Beauval Region – May 31, 2022: The open house in La Plonge was held at the Silver Building. The ERFN La Plonge members and residents of Beauval and the surrounding area were invited to attend. Fourteen attendees signed the sign-in sheet. Several individuals chose not to sign in, making the attendance at the La Plonge open house higher than implied by the sign-in sheet. Spatial restraints led Denison to display only 7 poster boards. Brochures containing all poster board imagery and information were distributed, accommodating for the absent poster board information.

Dialogue during the open house expressed regard for groundwater and geology. Community members asked questions relating to methodology, inquiring as to effects of Project specifics on characteristics of groundwater and geology. Additional questions predominantly pertained to Project-specific information. For additional details about this activity, please see Appendix 4-A, ROC #619.

Online Survey: During and following this meeting, attendees were invited to provide feedback on preliminary effects, mitigation, and monitoring through an online survey. Denison created a survey, available in hardcopy and digital formats during each open house and available in digital format for two weeks following the open house. No responses were received by those identifying as residents of Beauval. For more information about this activity, please see Appendix 4-A, ROC #652.

Engagement Focus: Environmental Assessment Outcomes and Relationship to Licensing / Approvals – October 2022 to Present

Meeting – October 23, 2023: On October 23, 2023, Denison hosted a meeting with the leadership of the Northern Village of Beauval. The focus of these engagement activities was to share the findings of the EA, mitigation measures, monitoring, significance, cumulative effects, the conclusions of the EIS, and the relationship between the environmental assessment and the ultimate licensing / approvals process for the Project. See Appendix 4-A, ROC #981 for more information.

Open House – October 23, 2023: On October 23, 2023, Denison hosted an open house event in the Northern Village of Beauval to share information about the Wheeler River Project. The focus of these engagement activities was to share the findings of the EA, mitigation measures, monitoring, significance, cumulative effects, the conclusions of the EIS, and the relationship between the environmental assessment and the ultimate licensing / approvals process for the Project. Denison advertised the event with social media posts and posters around the community. 24 attendees signed the sign in sheet. Information boards and area models were displayed, information booklets were provided, Denison staff were available to answer questions, and a translator was present to translate as needed. The CNSC and the Saskatchewan Ministry of Environment were invited by Denison and were in attendance.

To communicate EA findings, Project details and the relationship to the licensing / approvals process, Denison displayed three models and 6 informational poster boards. The three models depicted: 1) the uranium ore body and projected, below ground, extraction infrastructure; 2) the Project site surface with associated infrastructure; and 3) a 1:294 scale map of the area surrounding the Project site. The 6 informational poster boards presented EA findings and related licensing / approvals actions in relation to VCs identified as important during previous rounds of engagement activities. See Appendix 4-A, ROC #957 for more information.

Future Engagement

Denison expects to continue working with the NVB, throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities related to their topics of interest related to the Project.

4.4.1.2.4 Northern Village of Beauval Support for the Project

In March 2024, an Agreement was concluded in respect of the Wheeler River Project between Denison and Northern Village of Beauval, along with of Île-à-la Crosse, Jans Bay, and Cole Bay, that provides, among other matters, various commitments by Denison to these four communities and includes specific support of the Northern Village of Beauval, Île-à-la Crosse, Jans Bay, and Cole Bay for the development and operation of the Project.

4.4.1.2.5 Northern Village of Beauval Key Interests, Issues and Concerns

A summary of key interests, issues, and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-C. It is important to note that areas of identified interest, issues, or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.4.1.3 Engagement with the Northern Hamlet of Patuanak

The Northern Hamlet of Patuanak is a community in northern Saskatchewan, Canada. The community consists of the Northern Hamlet of Patuanak with residents governed by a Mayor and three Councillors. Patuanak is about 92 km (57 miles) north of Beauval at the end of Highway 918 (Planning for Growth Northern Saskatchewan n.d.a).

Figure 4.3-1 illustrates where Patuanak is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Patuanak is located 230 km away from the Project. In terms of travel distance by existing transportation routes Patuanak is located 460 km away from the Project.

4.4.1.3.1 History of Interactions

Up until 2019, Denison was undertaking engagement activities in the Patuanak area more broadly through work done in relation to the ERFN Wapachewunak reserve, consistent with ERFN's strong interconnections in the area. In mid-2019, Denison was advised by the Hamlet of Patuanak of its distinct interest in the Project. As a result, beginning in June 2019, Denison began engaging directly with the Hamlet of Patuanak. This included sending correspondence to the Hamlet of Patuanak about the Project description, the Project postponement, and the Project EA restart, as well as offering for their participation in a site visit (2019) and offers to participate in virtual and in-person meetings. To date, the Hamlet of Patuanak has not responded to the engagement efforts initiated by Denison, but Denison continues to make offers to engage with the Hamlet of Patuanak as they wish to do so.

4.4.2 Engagement with Other Non-Indigenous Communities

Engagement with Other Non-Indigenous Communities included the following:

- Northern Village of Île-à-la-Crosse;
- Northern Hamlet of Stony Rapids;
- Northern Hamlet of Uranium City;
- Northern Hamlet of Camsell Portage; and

- Northern Settlement of Wollaston Lake.

4.4.2.1 Engagement with the Northern Village of Île-à-la-Crosse

The Northern Village of Île-à-la Crosse (NVILX) is located in north-central Saskatchewan at the base of a peninsula extending into Lac Île-à-la Crosse. The village is the second oldest community in northern Saskatchewan, established in 1776. In 1846, Roman Catholic Missionaries arrived and constructed the Chateau St. Jean Mission and a neighbouring school. The Sisters of Charity of the Roman Catholic Church was initiated soon after and still plays a prominent role within the community. This strong Métis community is the birthplace of Louis Riel Sr. and was home to Sister Margaret Riel, sister of Louis Riel. The Village has a population of 1,425 (2021 Census) and prominent Aboriginal architect Douglas Cardinal designed Rossignol Elementary School (Planning for Growth Northern Saskatchewan n.d.b).

Figure 4.3-1 illustrates where Île-à-la Crosse is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Île-à-la-Crosse is located 275 km away from the Project. In terms of travel distance by existing transportation routes Île-à-la-Crosse is located 460 km away from the Project.

4.4.2.1.1 History of Interactions

Since 2016, Denison has been engaging with the NVILX in a variety of ways. In some instances, the elected members of the municipality are also officials of Métis Locals and, therefore, represent both their municipality as well as their Indigenous community. As a result, during the onset of engagement activities in 2016, the entities of ALBML and the NVILX had some overlap. In 2019, the ALBML delegated their Duty to Consult for the Project to the MN-S. Clear distinction between the Métis leadership and Citizens, and the NVP leadership and residents was, therefore, necessary to make sure the MN-S was able to appropriately provide the representation of the Métis of ALBML, per the delegated Duty to Consult. As a result, Denison distinguished its engagement efforts between MN-S, on behalf of ALBML, and the general public of the NVILX, with no intended overlap in relation to Métis interests.

4.4.2.1.2 Agreements Relative to the Environmental Assessment Process

A MOU was signed by Denison, ALBML and the NVILX in 2018. The signing of this MOU with both ALBML and the NVILX reflected the perspective of ALBML and the NVILX to represent both municipal residents and the Métis co-operatively. This non-binding MOU formalized the intent to work together in a spirit of mutual respect to cooperate to collectively identify practical means by which to avoid, mitigate, or otherwise address potential effects of the Project upon the exercise of the Indigenous Rights, Treaty Rights, and interests, to the extent they are identified in relation to the Project.

In 2019, ALBML delegated their Duty to Consult for the Project to the MN-S. From 2019, the MN-S has been representing ALBML in respect of engagement with Denison for the Project.

In March 2024, an Agreement was concluded in respect of the Wheeler River Project between Denison and Île-à-la Crosse, along with the Northern Village of Beauval, Jans Bay, and Cole Bay, that provides, among other matters, various commitments by Denison to these four communities and includes specific support of Île-à-la Crosse, the Northern Village of Beauval, Jans Bay, and Cole Bay for the development and operation of the Project.

4.4.2.1.3 Key Engagement Activities

During the engagement activities undertaken with the NVILX, several key engagement activities took place that have played a meaningful role in relation to the EA process. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1. The main forms of engagement included meetings with leadership, community meetings, a workshop on early infrastructure options (2018), a site visit (2019), and one online survey (2021). An open house for the general public was planned to be hosted in 2022 on preliminary effects and mitigation, but due to concerns identified by MN-S about hosting a public open house in a community with a significant Métis population, this meeting was postponed by Denison. Denison looks forward to rescheduling the meeting in collaboration with the MN-S. As noted in Section 4.2.1, due to the COVID-19 pandemic, engagement switched to virtual meetings in 2021. In mid-2022, appropriate engagement activities moved back to in-person. The following text describes several of the key engagement activities in more detail.

Engagement Focus: Pre-Project Description - April 2016 to May 2019

Introductory Meeting – December 7, 2016: This was the inaugural meeting between the senior management team of Denison and various entities associated with ALBML and the NVILX . The meeting focussed on clarifying the nature of Denison's activities, including the Project and related exploration activities, the interest in employment, business and training opportunities, reclamation requirements, agreement negotiation considerations, investment possibilities, environmental sampling and monitoring, and questions in relation to the nuclear industry in general and the market related to uranium. For more information about this activity, please see Appendix 4-A, ROC #109.

Workshop – January 17, 2018: Denison hosted a workshop with many community members and students. The focus of the workshop was to obtain feedback on three alternatives/options for the proposed Project: the road alignment from Highway 914 into the Project Area; the potential treated effluent discharge location; and the mining method options. The workshop opened and concluded with questions pertaining to Denison and the Project, comments on the importance of training, agreement negotiations, and other general items.

General questions were asked regarding the various alternatives and options, and points of clarification pertaining to aspects of the Project. Feedback was collected on the various options and has been incorporated into the final design for road alignment, and the treated effluent discharge location. Please see Section 2 for more details. For additional details about this activity, please see Appendix 4-A, ROC #3.

Engagement Focus: Post-Project Description – July 2019 to October 2022

Site Tour – August 23, 2019: In August 2019, Denison hosted a site tour at the Project location. The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project. Attending the site tour was the Mayor of the NVILX and a Councillor of the NVILX. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Representatives from the CNSC and SK MOE were present. For more information about this activity, please see Appendix 4-A, ROC #1.

Meetings – February 10, 2021: On February 10, 2021, Denison hosted virtual meetings with the leadership of the NVILX, as well as virtual meeting for the residents of the NVILX. The focus of these engagement activities was to provide information about the Project to the NVILX and residents, present a preliminary list of VCs that Denison had identified as part of the EA process, provide an opportunity for members to give feedback on the proposed list of VCs, and ask questions about Project components of interest or concern to them.

During the leadership meeting with the NVILX, Denison confirmed it was acceptable to continue hosting the virtual meeting for the residents of the NVILX, given concerns raised by the MN-S related to the Métis nature of the NVILX. The leadership of the NVILX confirmed it was acceptable to host the virtual meeting for the residents. The virtual meeting for residents was advertised on the radio and social media, and posters were placed in community buildings. The Zoom platform was used, but the meeting was also broadcasted live through 92.5 FM. At least 34 Zoom accounts were used to attend the presentation, although it is possible that more than one person viewed the presentation from each account. Representatives from the CNSC and the Province of Saskatchewan were present during both virtual meetings.

Topics covered during the virtual presentations include the following:

- Denison company introduction and key staff members;
- introduction to regulators;
- location of the Project;
- ISR mining, in general;
- ISR mining at the Project, including the recent change in the Project design from freeze dome technology to a freeze wall containment method;
- employment opportunities;
- EA; and

- VCs.

Meeting participants were encouraged to complete Denison's online survey in relation to the VCs considered important to residents of the NVILX. Following the presentation, Denison answered questions that were put into the online chat function.

Key themes that emerged from the questions posed at the NVILX meetings, which indicated either interests or concerns, are summarized as follows:

- the ISR mining method, the length of the Project, the novelty of ISR for uranium mining in Canada, the processing of the uranium bearing solution, water treatment processes;
- monitoring during mining operations and closure monitoring, monitoring of groundwater in relation to the freeze wall;
- critical habitats in relation to the potential effects of the Project;
- transportation issues, such as the need for an airstrip and the trucking routes for uranium ore concentrate;
- economic opportunities, including job opportunities, training opportunities, business opportunities; and
- considerations of revenue sharing.

For more specifics about this activity, please see Appendix 4-A, ROC #443.

Denison provided a report to the NVILX regarding what was heard by Denison during the engagement activities. This report was shared in hard copy form (sent to the NVILX Office), shared with the NVILX for posting to a website, posted on the Denison website (www.wheelerriverproject.ca) and a video was made by Denison for those who prefer oral communications, also on the Denison website.

Online Survey: During and following the NVILX meeting(s), attendees were invited to provide feedback on VCs through an online survey. The purpose of the survey was to seek feedback on the importance of the VCs to members, and identify interests or concerns related to the Project, providing an additional mean by which feedback could be provided to Denison. People who were unable to attend the presentation were also encouraged to provide feedback through the survey. The survey was marketed to members using Facebook and radio advertisements.

The survey was open for feedback from February 9 to 23, 2021, for a total of 14 days. Thirty responses were received.

The survey included reach and marketing questions about how respondents heard about the survey and if they attended a presentation. This information helped Denison to determine which event marketing efforts were most effective.

The survey also asked respondents to disclose voluntary demographic information such as age, primary residence, and identity, to help Denison determine if there were large demographic groups whose perspectives were not represented in the results.

Following the reach and marketing and demographic questions, the survey included questions specific to the preliminary list of VCs. These questions were followed by the opportunity for respondents to share their thoughts on opportunities and challenges related to the Project.

Demographics

Most survey respondents (67%) were between the ages of 16 and 34, compared to 30% who were between the ages of 35 and 64, and 3% who identified as age 65 or older. Most respondents self-identified as Indigenous peoples with the majority (60%) of people identifying as Métis, 17% identifying as First Nations people, and 7% identifying as Indigenous but preferring not to specify. The remaining respondents identified as non-Indigenous (10%) or preferred not to answer (7%).

Valued Components

A total of 26 interconnected VCs were proposed to respondents. Respondents were asked to select from the list which VCs they felt were important for Denison to research further as part of the EA. While all 26 VCs were identified as important by at least one respondent, the following environmental components were identified as important to more than half of respondents:

- traditional land and resource use;
- air quality;
- employment;
- local economy; and
- training.

The importance of local economy, jobs, training and the need for environmental monitoring were echoed in the questions asked by those who attended the virtual presentation. Respondents explained that these VCs are important to them because they help to build for future community health and growth, promote the importance of valuing and protecting the earth and Indigenous cultural practices and beliefs, and encourage strong local economies and employment opportunities for northerners.

Respondents from Île-à-la-Crosse felt that the following VCs were missing and should be added to the list:

- housing; and
- community participation.

Fewer than 50% of respondents identified VCs that were not important to study further. These VCs included:

- noise level;
- employment;
- outfitting;
- business activity;
- soil;
- training;
- traditional land and resources use;
- infrastructure and services;
- vegetation; and
- birds.

Of these, noise level was the only VC that was selected as not important more often than it was identified as important.

The complete list of VCs included in this EIS is available in Section 5.3.1 in Section 5.

Opportunities and Challenges

Respondents were asked, based on what they knew so far about the Project, to share the aspects of the Project that they felt could benefit or work well for the community.

Some of the unique or specific opportunities mentioned included the following items:

- training and education opportunities;
- employment opportunities for skilled local people at all intervals throughout the life of the mine;
- donations to school groups;
- potential for a northern company to complete environmental monitoring;
- business partnerships or involvement opportunities;
- opportunity for joint ventures; and
- potential for communities in the north to work together.

Respondents were then asked what aspects of the Project they felt would be challenging or cause concern for their community. Responses included:

- issues that arise after the mines close, including decline in employment and mental health concerns;
- potential effects to the environment;
- potential political issues and communities not able to work in partnership;
- a lack of transparency in terms of environmental effects;
- potential for spills, pollution, and water contamination and lack of transparency about these occurrences;
- safe transportation of uranium; and
- lack of education about potential benefits of the uranium industry for the community.

For more information about this activity, please see Appendix 4-A, ROC #446.

Engagement Focus: Environmental Assessment Outcomes and Relationship to Licensing / Approvals – October 2022 to Present

Meeting - October 25, 2023: On October 25, 2023, Denison hosted a meeting with the leadership of the NVILX to share information about the Wheeler River Project. The focus of these engagement activities was to share the findings of the EA, mitigation measures, monitoring, significance, cumulative effects, the conclusions of the EIS, and the relationship between the environmental assessment and the ultimate licensing / approvals process for the Project. A strong focus of the meeting by the NVILX leadership was about industry signing formal agreements with Indigenous communities and the municipalities not being included.

Open House – October 25, 2023: On October 25, 2023, Denison hosted an open house event in the NVILX to share information about the Wheeler River Project. The focus of these engagement activities was to share the findings of the EA, mitigation measures, monitoring, significance, cumulative effects, the conclusions of the EIS, and the relationship between the environmental assessment and the ultimate licensing / approvals process for the Project. Denison advertised the event with social media posts and posters around the community. Information boards and area models were displayed, information booklets were provided, Denison staff were available to answer questions, and a translator was present to translate as needed. The CNSC and the Saskatchewan Ministry of Environment were invited by Denison and were in attendance.

To communicate EA findings, Project details and the relationship to the licensing / approvals process, Denison displayed three models and 6 informational poster boards. The three models depicted: 1) the uranium ore body and projected, below ground, extraction infrastructure; 2) the Project site surface with associated infrastructure; and 3) a 1:294 scale map of the area surrounding the Project site. The 6 informational poster boards presented EA findings and related licensing / approvals actions in relation to VCs identified as important during previous rounds of engagement activities.

Please see Appendix 4-A, ROC #1034 for more details about this engagement activity.

Future Engagement

Denison expects to continue working work with the NVILX, throughout the remainder of the environmental assessment and approval process and into the licensing process, to coordinate engagement activities in relation to their topics of interest related to the Project.

4.4.2.1.4 *Northern Village of Île-à-la-Crosse Support for the Project*

In March 2024, an Agreement was concluded in respect of the Wheeler River Project between Denison and Île-à-la Crosse, along with the Northern Village of Beauval, Jans Bay, and Cole Bay, that provides, among other matters, various commitments by Denison to these four communities and includes specific support of Île-à-la Crosse, the Northern Village of Beauval, Jans Bay, and Cole Bay for the development and operation of the Project.

4.4.2.1.5 *Northern Village of Île-à-la-Crosse Key Interests, Issues and Concerns*

A summary of key interests, issues and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-C. It is important to note that areas of identified interest, issues, or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.4.2.2 Engagement with the Northern Hamlet of Stony Rapids

The Northern Hamlet of Stony Rapids is a non-Indigenous community that participated in engagement with Denison through YNLR. Please see Section 4.3.4.2 for additional information on engagement.

Figure 4.3-1 illustrates where Stony Rapids is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Stony Rapids is located 195 km away from the Project. In terms of travel distance by existing transportation routes Stony Rapids is located 1,145 km away from the Project.

4.4.2.3 Engagement with the Northern Settlement of Uranium City

The Northern Settlement of Uranium City is a non-Indigenous community that participated in engagement with Denison through YNLR. Please see Section 4.3.4.2 for additional information on engagement.

Figure 4.3-1 illustrates where Uranium City is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Uranium City is located 295 km away from the Project. In terms of travel distance by existing transportation routes Uranium City is more than 1,200 km away, a portion of which is only accessible via winter road.

4.4.2.4 Engagement with the Northern Settlement of Camsell Portage

The Northern Settlement of Camsell Portage is a non-Indigenous community that participated in engagement with Denison through YNLR. Please see Section 4.3.4.2 for additional information on engagement.

Figure 4.3-1 illustrates where Camsell Portage is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Camsell Portage is located 325 km away from the Project. In terms of travel distance by existing transportation routes Camsell Portage is more than 1,200 km away, a portion of which is only accessible via winter road.

4.4.2.5 Engagement with the Northern Settlement of Wollaston Lake

The Northern Settlement of Wollaston Lake is a non-Indigenous community that participated in engagement with Denison through YNLR. Please see Section 4.3.4.2 for additional information on engagement.

Figure 4.3-1 illustrates where Wollaston Lake is in relation to the Project, both in terms of direct linear distance and travel distance. In terms of direct linear distance, Wollaston Lake is located 160 km away from the Project. In terms of travel distance by existing transportation routes, Wollaston Lake is located 945 km away from the Project, a portion of which is only accessible via winter road.

4.4.3 Engagement with Nearby Land Users

As part of engagement with the category of the General Public, Denison identified three types of Nearby Land Users who have the potential to experience effects from the Project, including:

- commercially licensed trappers and fishers; and
- cabin/lease owners and commercially operated lodges.

Figure 4.4-1 illustrates where cabin, lease owners, and commercially operated lodges are located.

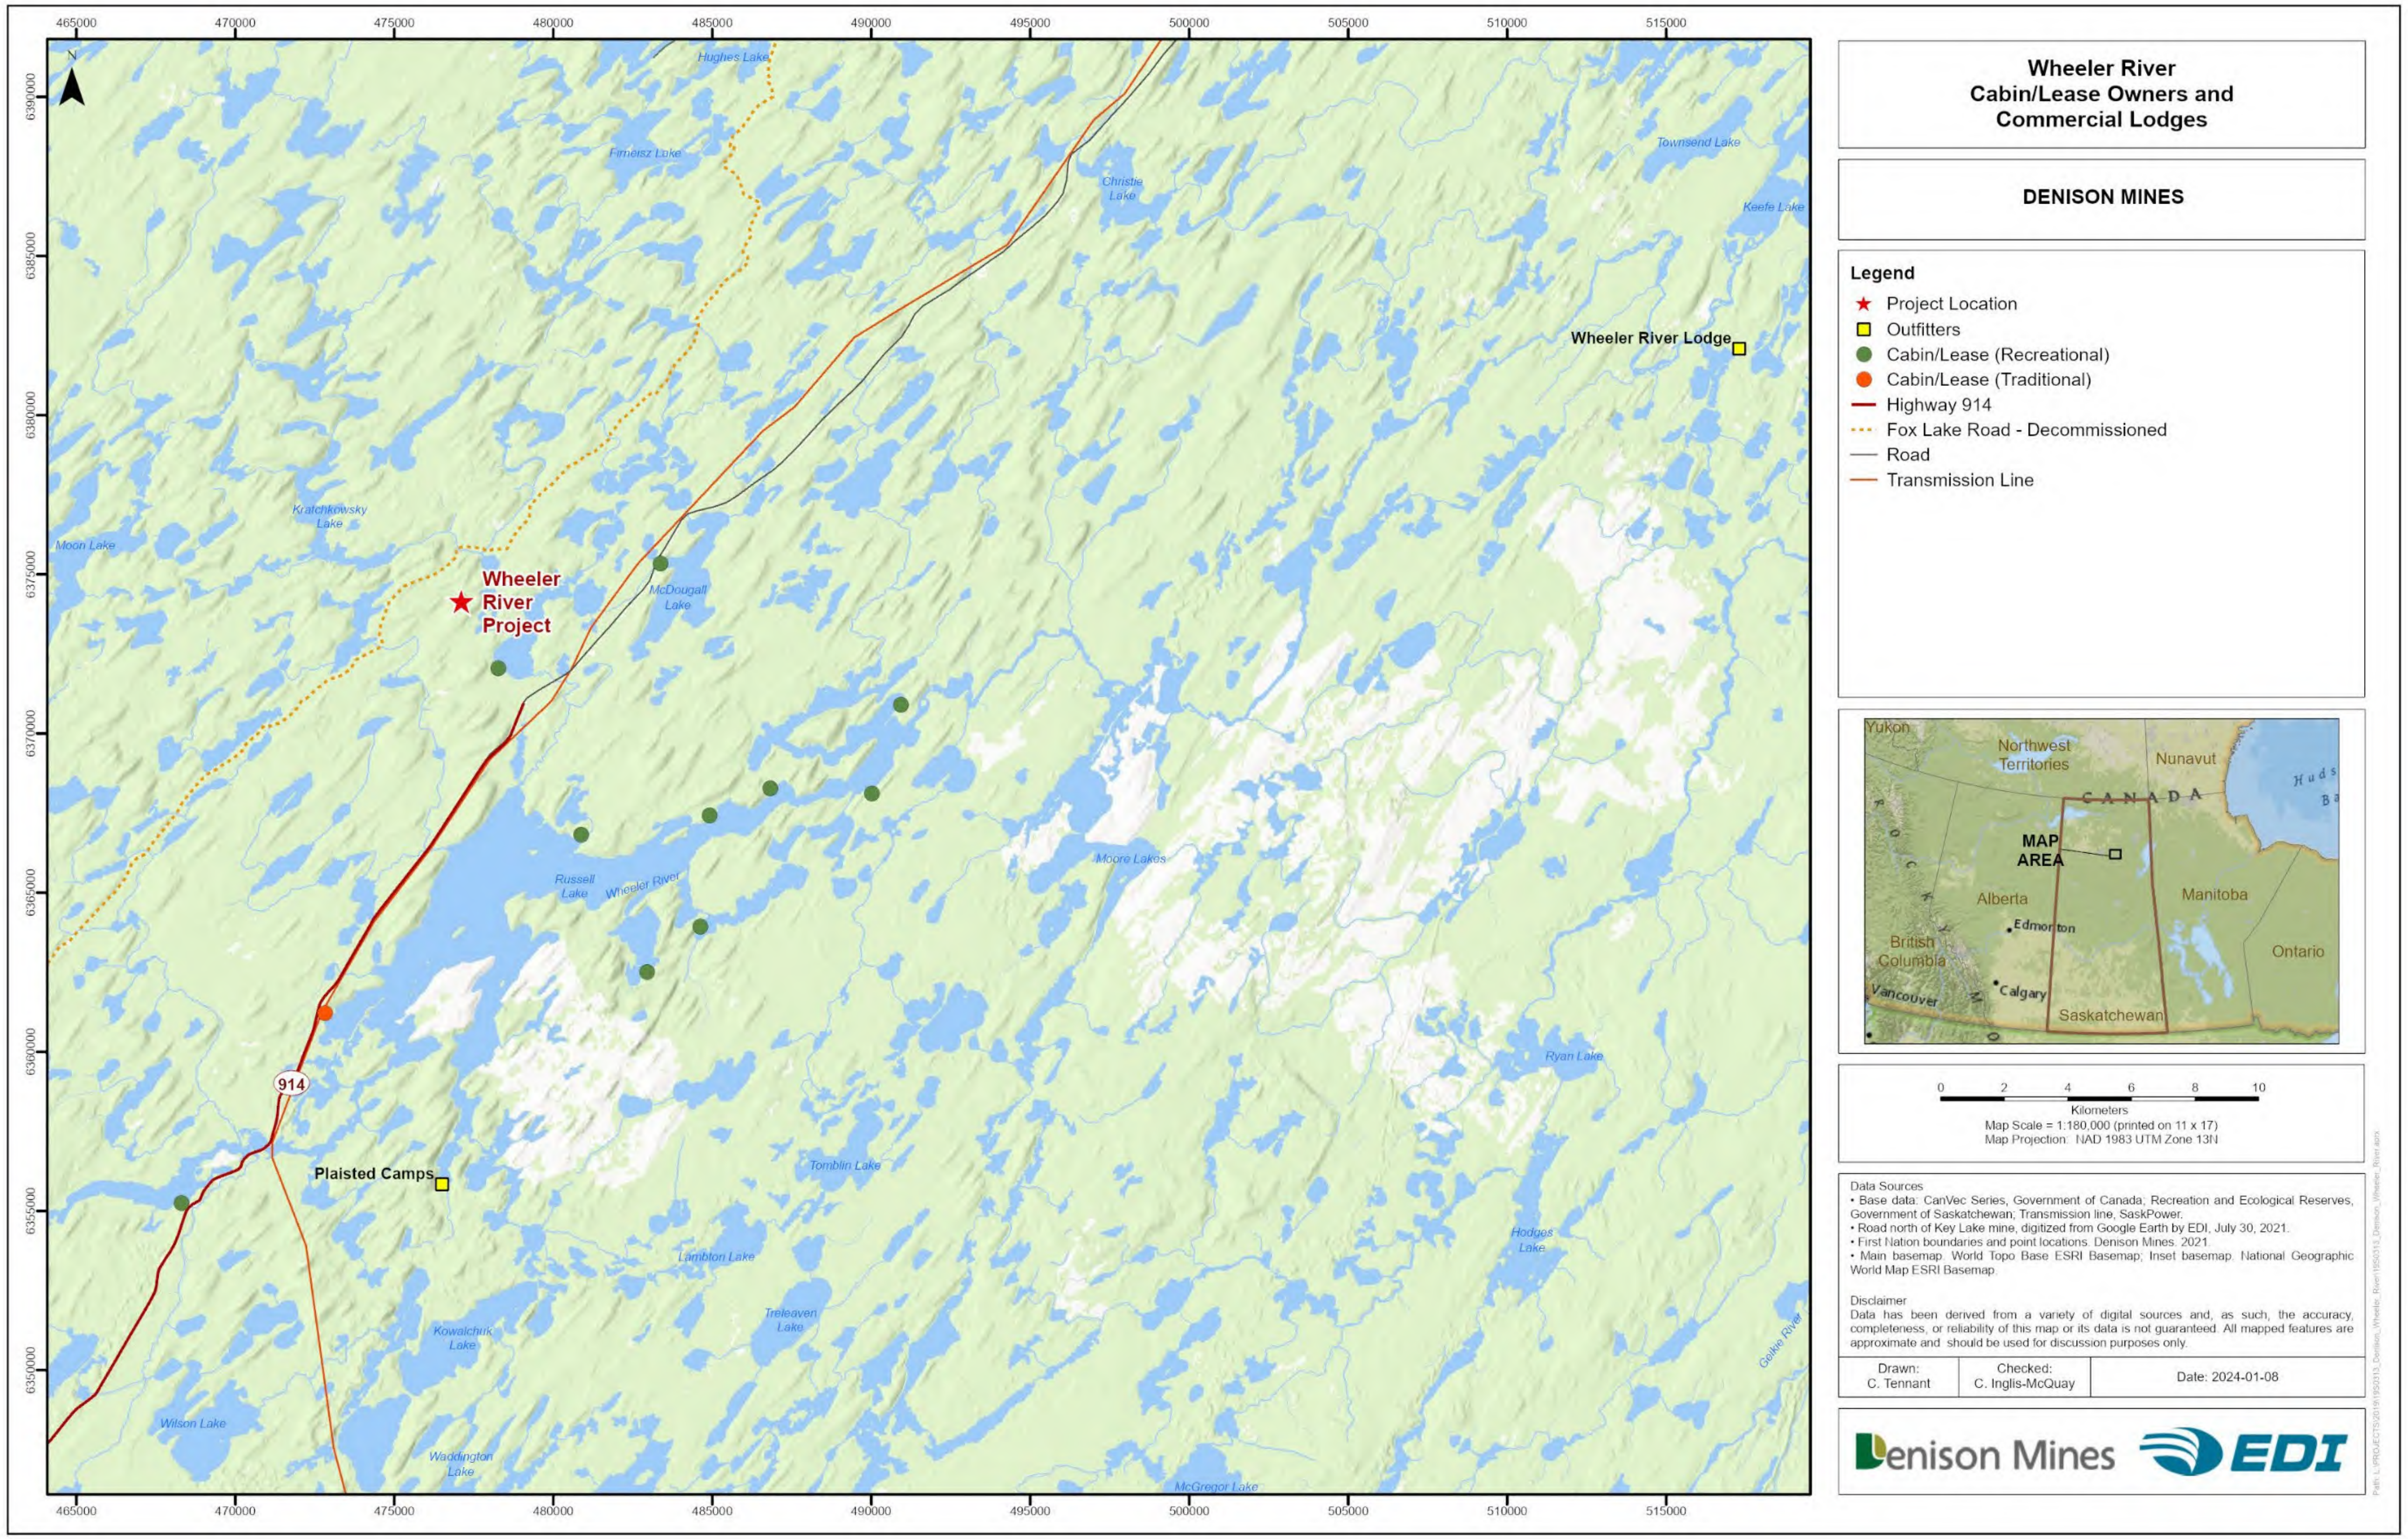

Figure 4.4-1: Cabin/Lease Owners and Commercial Lodges Near the Project

4.4.3.1 Engagement with Commercially Licensed Trappers and Fishers

For the Project, Denison engaged regularly with one commercially licensed trapper and fisher (who was also a member of ERFN; referred to herein as the ERFN Trapper) in relation to the Project. Denison worked closely with this individual to gather detailed land and resource use information. The individual maintained a main cabin on the Wheeler River and secondary cabins on Russell Lake, Philips Lake, and a family cabin on Creek Lake. Unfortunately, prior to the time of filing the EIS, the ERFN Trapper passed away.

Denison has also shared information with the Chairperson of the N-18/N-16 furblock, as the representative responsible for the commercial trapping activities within these two furblocks.

4.4.3.1.1 History of Interactions

Throughout regular exploration activities in the area where the Project occurs, Denison had been regularly engaging with the ERFN Trapper on various matters. With the onset of the filing of the Project Description in 2019, Denison and the ERFN Trapper shifted engagement activities toward the Project and sharing of information on between the ERFN Trapper and Denison in respect of the ERFN Trapper's specific information about the area in which the Project is located, key concerns, and feedback on pilot activities in relation to mitigation planning. This resulted in several key engagement activities, the outcomes of which have informed several components of the EIS. These key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1.

4.4.3.1.2 Key Engagement Activities

Engagement Focus: Pre-Project Description - April 2016 to May 2019

The focus of this engagement activity was to provide an in-field opportunity to understand the proposed Project and the various elements associated with the Project.

During a tour with the ERFN Chief and Elders, the ERFN Trapper was included. The tour involved an initial presentation regarding the Project, followed by travel around the Project site to the various locations for the proposed elements of the Project. Over the course of the site visits, the ERFN Trapper made comments or queried about:

- the proposed ISR mining method (makeup of mining solution); and
- the general effect of the Project on the surrounding lands.

For more information about this activity, please see Appendix 4-A, ROC #140.

Engagement Focus: Post-Project Description – July 2019 to October 2022

Denison and the ERFN Trapper undertook a full-day on-site interview in order for Denison to receive input and land knowledge about the existing environment, and also in relation to general questions and/or concerns the ERFN Trapper might have regarding the Project. Notes from this interview were finalized and approved for use on January 2, 2020. The interview findings were subsequently shared with all discipline leads and have been included throughout the EIS and more prominently in Sections 9 and 11. Please see Appendix 4-A ROC#134 for more details.

In 2021, Denison sought feedback from the ERFN Trapper on a multi-year test program to test options for the Project in relation to mitigation of linear features. While this test program is not formally considered part of the EA as it is intended as a test to support future potential programming, Denison considered it important to make sure the ERFN Trapper was suitably informed about the program to provide feedback and guidance to Denison's team. General concerns were noted about cutlines, and corridors being used by wolves to gain better access to caribou were identified. Later that summer, the ERFN Trapper was provided an opportunity to see the test program in place and again provided feedback to Denison regarding the measures installed. Noted concerns were the aesthetic issue with mounding of earth to block linear features and recommended alternatives. These concerns have been considered as part of the overall test plan, in terms of including criteria to determine successful mitigation strategies that consider community and local land user concerns. Please see Appendix 4-A ROC#506 and ROC#516 for more details.

4.4.3.1.3 Nearby Land Users (Commercially Licensed Trappers and Fishers) Key Interests, Issues and Concerns

A summary of key interests, issues, and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-C. It is important to note that areas of identified interest, issues or concerns are not always related to environmental effects as defined by CEAA 2012 (they can be reflective of general areas of interest in relation to the Project more broadly). Where appropriate, the table aims to provide clarity with respect to this distinction.

4.4.3.2 Engagement with Cabin/Lease Owners and Commercially Operated Lodges

Denison regularly shares information with and seeks feedback from several cabin/lease owners and a commercially operated lodge. These Nearby Land Users are generally defined as those within a 20-km radius to the Project site.

Figure 4.4-1 illustrates where cabin/lease owners and commercially operated lodges are in relation to the Project, both in terms of direct linear distance and travel distance. The figure shows that there are ten known recreational cabin/lease owners, one known traditional cabin/lease owner, and two known commercial lodges within a 20 km radius of the Project site.

4.4.3.2.1 History of Interactions

With the onset of the filing of the Project Description in 2019, Denison commenced engagement activities with the cabin/lease owners and the commercially operated lodge. This included sharing information about the Project description, the pause of the EA, the EA restart, and importantly, seeking feedback from these Interested Parties in respect of their interests in the Project. Key engagement activities were supported by ongoing engagement methods including, but not limited to, those outlined in Section 4.2.1. A survey was conducted in January 2020 when Denison sent known local cabin/lodge leaseholders a survey in the mail to be completed regarding their interests in the Project. Since then, update information has been sent to this group of Interested Parties.

4.4.3.2.2 Key Engagement Activities

One of the key engagement activities undertaken with the cabin/lease owners and the commercially operated lodge occurred in January 2020 when Denison sent known local cabin/lodge leaseholders a survey in the mail to be completed regarding their interests in the Project. Denison received six responses from the survey (five cabin/lease owners and one commercially operated lodge), which has informed Denison's understanding of leaseholder uses in the area and interests regarding elements to be assessed as part of the EA. A copy of the survey sent to cabin owners in January 2020 can be found in Appendix 4-A as ROC #267.

The five cabin/leaseholders in the area that responded to the survey noted they have been leaseholders of their property for less than 5 years (n=1), 5 to 10 years (n=2), 10 to 15 years (n=1) and over 15 years (n=1). Use of these cabins ranges from 4 to 5 times per year (n=3) to more than five years (n=2). Users generally spend between 2 to 5 weeks (n=2) or 5 to10 weeks (n=3) using their facilities. The cabins are located between 5 and 20 km away from the Project site, and users travel across the landscape to conduct their various activities in a range of 5 to 10 km (n=1) and over 10 km (n=4). Cabins are used for a variety of activities, with all respondents using it for fishing, enjoying nature, and family time; three users noted the additional use for ATVing and boating, hunting, and trapping; and one user noted the additional use for plant harvesting/collecting and accessing cultural sites.

According to the owner of Wheeler River Lodge, the lodge and land in the area are used for recreational and commercial fishing, hunting, and trapping, ATVing and boating, enjoying nature, and family time. The owner expressed concerns over potential Project effects to these activities.

As Appendix 4-C indicates, the issue of maintaining the gated access at Key Lake is important to four of the five respondents of the cabin/lease owners due to concerns over vandalism to property and infrastructure if more users were granted access to the area. Another concern was effects to overall land and resource use, especially hunting, fishing, ATVing, and boating (four of the five cabin/lease holders), with one respondent also commenting on the concern over hunting and fishing pressure by Project staff. Concern was also noted (by three of the five respondents) about increased traffic, particularly on Highway 914. Conflicts with outfitter and cabin owners were noted by all five cabin/lease owners.

Similar to the other Nearby Land Users, maintaining the existing controlled access at Key Lake was a recurring concern for the Wheeler River Lodge owner. Having the gatehouse removed would increase access to the area, opening it up to increased use, and potential vandalism/theft to his property and belongings. The increased access would then put increased pressure on fishing, hunting and other outdoor recreation activities in the area, potentially affecting his lodge business (see Appendix 4-C). Conflicts with outfitters and cabin owners was also noted.

The Wheeler River Lodge owner expressed a concern that the name of lodge and the Project are similar, and resulting in searches on the internet confusing and/or concerning potential future clients about the proximity of a new mining operation in relation to his lodge—with the potential for loss of business.

4.4.3.2.3 Nearby Land Users (Cabin/Lease Owners and Commercial Lodge Owners) Key Interests, Issues and Concerns

A summary of key interests, issues, and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-C. It is important to note that areas of identified interest, issues, or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.4.3.3 Engagement with Organizations

Denison identified three organizations to engage with, as part of the General Public:

- Northern Saskatchewan Environmental Quality Committee (NSEQC);
- Saskatchewan Mining Association; and
- Northern Labour Market Committee.

Generally, Denison engages with these organizations on an as-requested basis, providing presentations and/or information requested. It is expected that as the Project continues to advance through the regulatory process, more engagement will occur with these, and other, organizations as they identify their interest to Denison.

As of Q2, 2022, Denison had provided two presentations to the NSEQC (2017 and 2022), one presentation to the Northern Labour Market Committee, and several presentations to the Saskatchewan Mining Association various forums and meetings over the years.

4.4.3.3.1 Key Issues and Concerns

A summary of key interests, issues, and concerns gathered throughout the course of engagement for the Project, including any formal submissions made through the regulatory process, are identified in Appendix 4-C. It is important to note that areas of identified interest, issues, or concerns are not always related to environmental effects as defined by CEAA 2012 (the regime under which the Project is undergoing regulatory assessment) - they can be reflective of general areas of interest in relation to the Project more broadly. Where appropriate, the table aims to provide clarity with respect to this distinction.

4.5 Engagement with Regulatory Agencies

The Project will undergo a joint provincial-federal EA process led by SK MOE's Environmental Assessment and Stewardship Branch and the CNSC. As government entities were involved in the assessment and regulatory process, engagement included both organizations, starting with meetings in 2018 prior to the submission of the Technical Proposal and Project Description to provide agency staff with information on the Project and the regulatory submission plans.

Denison carried out proactive and early engagement to align the process with existing guidance documents, with CNSC and SK MOE staff. Engagement was initiated during completion of prefeasibility engineering and early collection of environmental baseline data in early 2018. Meeting held in late 2018 were intended to serve as pre- engagement meetings for submission of the Technical Proposal and Project Description. Denison provided a Project overview, sought guidance, and addressed questions before submission of the Technical Proposal and Project Description.

Regular engagement activities continued throughout the EA development phase from 2019 through 2024. Table 4.5-1 outlines the engagement activities that took place between 2018 up until the submission of the Final EIS.

Table 4.5-1: Engagement Activities with Regulatory Agencies

Date	Organization	Engagement Type	Purpose
February 14, 2018	Canadian Nuclear Safety Commission (CNSC) – Uranium Mines and Mills Division (UMMD)	Meeting	Introduced Denison and the Project; provided an overview of the Project from the Preliminary Economic Assessment and scope for the Prefeasibility Study, which is underway; discussion and Q&A.
March 1, 2018	SK MOE	Meeting	Introduced Denison and the Project; provided an overview of the Project from the Preliminary Economic Assessment and scope for the Prefeasibility Study, which is underway; discussion and Q&A.
April 25, 2018	CNSC	Meeting	Introduced Denison and the Project; provided an overview of the Project from the Preliminary Economic Assessment and scope for the Prefeasibility Study, which is underway; discussion and Q&A.
November 13, 2018	CNSC	Meeting	Denison provided a Project update, including an overview of the Prefeasibility Study and the Project scope for the Project Description; answered any questions about the Project. Denison advised on plans to submit a Project Description in 2019; the group discussed plans for the regulatory process moving forward.

Date	Organization	Engagement Type	Purpose
November 21, 2018	SK MOE	Meeting	Denison provided a Project update, including an overview of the Prefeasibility Study and the Project scope for the Technical Proposal. Denison advised on plans to submit a Technical Proposal in 2019; the group discussed plans for the regulatory process moving forward.
December 3, 2018	SK MOE – Mines and Mills	Meeting	Denison provided a Project update, including an overview of the Prefeasibility Study and the Project scope for the Technical Proposal. Denison advised on plans to submit a Technical Proposal in 2019; the group discussed plans for the regulatory process moving forward.
February 19, 2019	SK MOE, CNSC	Submission	Denison filed the Technical Proposal and Project Description to initiate the EA process under the Saskatchewan *Environmental Assessment Act* and the CEAA 2012.
March 7, 2019	SK MOE	Submission	Denison submitted the Wheeler River Terms of Reference to the Province of Saskatchewan as a requirement of the provincial EA process.
May 1, 2019	CNSC	Meeting	Denison and the CNSC held a meeting to discuss Denison's responses to CNSC comments on the Project Description and the Aboriginal Engagement Report.
May 15, 2019	SK MOE, CNSC	Submission	Denison filed the revised Technical Proposal and Project Description, revised Terms of Reference, and Indigenous Engagement Report.
June 19, 2019	CNSC	Meeting	Denison presented on the recommended approach to engagement for the Project EA.
August 7, 2019	SK MOE, CNSC	Meeting	Denison presented an overview of engagement conducted and planned for the Project EA.
August 23, 2019	SK MOE, CNSC	Site tour	Denison hosted the MN-S President, MN-S Minister of Environment/MN-S Region 3 President, and the Presidents of the Métis Locals at the Project site for a site tour and to discuss the Project, along with representatives from the CNSC and SK MOE.
January 22, 2020	CNSC	Information Letter	Denison provided the CNSC with the draft Wheeler River Engagement Plan for consideration.
March 19, 2020	SK MOE, CNSC	Notification Letter	Denison filed a notice of suspension of the Wheeler River EA, citing significant social and economic disruption that emerged because of the COVID-19 pandemic, and the Company's commitment to ensure employee safety, support public health efforts to limit transmission of COVID-19, and exercise prudent financial discipline.
July 7, 2020	CNSC	Meeting	Denison provided a general update on 2020 activities pertaining to the Wheeler River exploration program.
July 16, 2020	SK MOE	Meeting	Denison provided a general update on 2020 activities pertaining to the Wheeler River exploration program.
September 30, 2020	SK MOE, CNSC	Meeting	Denison presented information on the trade-off study conducted for the Wheeler River freeze wall design.

Date	Organization	Engagement Type	Purpose
November 12, 2020	SK MOE, CNSC	Notification	Denison filed a notification letter of the plans to restart the Wheeler River EA in January 2021.
December 22, 2022	SK MOE, CNSC	Submission	Denison filed an updated Technical Proposal and Project Description to reflect the change in freeze wall design.
January 15, 2021	SK MOE, CNSC	Meeting	Monthly discussions provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
February 17, 2021	SK MOE, CNSC	Meeting	Monthly discussions provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
March 9, 2021	SK MOE, CNSC	Meeting	Monthly discussions provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
April 14, 2021	SK MOE, CNSC	Meeting	Monthly discussions provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
April 23, 2021	CNSC	Meeting	Discussion regarding federal participant funding for review of the EA.
May 19, 2021	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
May 20, 2021	CNSC	Meeting	Discussion regarding engagement records to be filed with the draft EIS.
June 16, 2021	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
July 27, 2021	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
August 11, 2021	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
September 17, 2021	SK MOE, CNSC	Technical Meeting	Denison's assessment team provided a presentation to members and provincial and federal technical reviewers, including an overview of the atmospheric modelling for the Wheeler River EA.
October 12, 2021	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
November 8, 2021	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
December 7, 2021	CNSC, Environment and Climate Change Canada	Technical Meeting	Denison's assessment team provided a presentation to several members of the federal EIS technical review team, including an overview of the atmospheric modelling for the Wheeler River EA.
December 13, 2021	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
January 17, 2022	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
January 22, 2022	SK MOE, Saskatchewan Ministry of Energy and Resources	Meeting	Introduction to Denison, the supporting Saskatchewan team, and the objectives and near-term deliverables for the Project.
January 26, 2022	SK MOE, CNSC	Meeting	Denison provided a presentation on the 2022 plans for the Feasibility Field Test and how the information from the test work will inform future regulatory submissions and engineering design.
February 1, 2022	SK MOE, CNSC, Natural Resources Canada, Water Security	Technical Meeting	Denison's assessment team provided a presentation to several members of the federal EIS technical review team, including an overview of the groundwater modelling for the Wheeler River EA.

Date	Organization	Engagement Type	Purpose
	Agency, Environment and Climate Change Canada		
February 14, 2022	SK MOE, CNSC	Meeting	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
March 14, 2022	SK MOE, CNSC	Meeting	
April 11, 2022	SK MOE, CNSC	Meeting	
May 9, 2022	SK MOE, CNSC	Meeting	
June 13, 2022	SK MOE, CNSC	Meeting	
July 7, 2022	SK MOE, CNSC	Meeting	
August 8, 2022	SK MOE, CNSC	Meeting	
September 29, 2022	SK MOE, CNSC	Site Tour	Denison hosted representatives from the SK MOE and CNSC at the Project site to present details on the scope of the Project as presented in the draft EIS and to tour the proposed Project location. The site tour took place during the active 2022 Advanced Exploration Feasibility Field Test.
October 21, 2022	SK MOE, CNSC	Submission	Denison filed the Wheeler River Project draft EIS.
November 25, 2022	CNSC, ECCC, NRCan, Fisheries and Oceans Canada (DFO), Health Canada, Transport Canada, ERFN	Technical Meeting	Denison's assessment team provided an overview of the draft EIS and its key findings to the Federal-Indigenous Review Team (FIRT) to kick-off their 90-day technical review of the Wheeler River Project draft EIS.
2023 (monthly meetings throughout the year)	SK MOE, CNSC	Meetings	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
January 11, 2023	CNSC, NRCan, DFO, ECCC	Technical Meeting	Denison's assessment team presented information on the geology and groundwater assessments in the draft EIS to the FIRT and responded to questions. This meeting was in support of the FIRT's technical review of the draft EIS.
January 12, 2023	SK MOE		Denison receives provincial technical review comments (TRCs) on the draft EIS.
January 16, 2023	CNSC, Health Canada, ECCC	Technical Meeting	Denison's assessment team presented information on the accidents and malfunctions assessment in the draft EIS to the FIRT and responded to questions. This meeting was in support of the FIRT's technical review of the draft EIS.
January 27, 2023	CNSC, ECCC	Technical Meeting	Denison's assessment team presented information on meteorology in the draft EIS to the FIRT and responded to questions. This meeting was in support of the FIRT's technical review of the draft EIS.
March 20, 2023	CNSC		Denison receives FIRT information requirements (IRs) on the draft EIS.

Date	Organization	Engagement Type	Purpose
April 6, 2023	CNSC, ECCC	Technical Meeting	Denison's assessment team met with key individuals on the FIRT following receipt of the draft EIS information requirements (IRs) on March 20, 2023. This meeting's purpose was to discuss a subset of the seven IRs where the FIRT identified that a technical discussion was required; specifically, IR-223 and IR-224 related to freeze wall integrity and post decommissioning seismic events.
April 19, 2023	CNSC, ECCC	Technical Meeting	Denison's assessment team met with key individuals on the FIRT following receipt of the draft EIS IR on March 20, 2023. This meeting's purpose was to discuss a subset of the seven IRs where the FIRT identified that a technical discussion was required; specifically, ECCC's comment IR-10 related to freeze wall design and integrity.
April 19, 2023	CNSC, ECCC	Technical Meeting	Denison's assessment team met with key individuals on the FIRT following receipt of the draft EIS IRs on March 20, 2023. This meeting's purpose was to discuss a subset of the seven IRs where the FIRT identified that a technical discussion was required; specifically, IRs-103, -104, -235, -236 from ECCC related to precipitation under current and future climate scenarios, hydrology, and probable maximum precipitation.
April 20, 2023	CNSC, ECCC	Technical Meeting	Denison's assessment team met with key individuals on the FIRT following receipt of the draft EIS IRs on March 20, 2023. This meeting's purpose was to discuss IRs related to woodland caribou (IRs-137, -143, -144, -145, -148, -149, -152, -156, -157), species at risk (IRs-131, -132, -142, -158, -161, -174), and data granularity/baseline data available in the context of EIS approach and assumptions (IRs-143,-144, -145, -152, -159, -160, -163, -164).
April 20, 2023	CNSC	Information Session	Denison's Wheeler River Project team met with representatives from CNSC's Regulatory Operations Branch, Technical Support Branch and the Regulatory Affairs Branch. The meeting purpose was to provide the CSNC with an overview of the Project components, a summary of Project engagement activities and to discuss areas of regulatory uncertainty.
May 18, 2023	SK MOE	Technical Meeting	Denison's assessment team met with SK MOE (Environmental Assessment Branch staff and Resource Management Division staff) to present and discuss Denison's framework for a conceptual Caribou Mitigation Plan.
June 1, 2023	SK MOE	Submission	Denison submits responses to provincial TRCs on the draft EIS.
June 5, 2023	SK MOE	Technical Meeting	Denison's assessment team and SK MOE (Environmental Assessment Branch staff and Resource Management Division staff) discuss the Project's conceptual Caribou Mitigation Plan.
June 19 and 20, 2023	CNSC	Site tour	Denison hosted representatives from the CNSC at the Project site to discuss the Project and tour the proposed Project location.
July 14, 2023	CNSC	Submission	Denison submits responses to FIRT IRs on the draft EIS.

Date	Organization	Engagement Type	Purpose
July 26, 2023	SK MOE		Denison receives results of provincial review of Denison's TRC responses (i.e., second round of TRCs on the draft EIS).
August 18, 2023	CNSC	Submission	Denison re-submits responses to the FIRT IRs to address the CNSC's feedback on their completeness check.
September 14, 2023	SK MOE	Submission	Denison submits responses to second round of provincial TRCs.
October 17, 2023	SK MOE	Technical Meeting	SK MOE provides Denison with an overview of the caribou habitat offset calculator.
October 26, 2023	SK MOE	Technical Meeting	SK MOE provides Denison with results of the caribou habitat offset calculator which incorporates initial Wheeler River Project footprints and activities in the calculation
October 31, 2023	SK MOE		SK MOE provides notification to Denison that the ministry is satisfied with the TRC responses provided and proposed updates to the draft EIS.
December 5, 2023	CNSC		Denison receives results of FIRT review of Denison's IR responses (i.e., second round of FIRT comments on the draft EIS, aka round 2 IRs).
December 11, 2023	CNSC	Meeting	Path forward and confirmation on process for Denison to address second round of IRs to meet requirements under CEAA 2012 and for the FIRT to draw conclusions on the EA process.
2024 (monthly meetings throughout the year)	SK MOE, CNSC	Meetings	Monthly discussion provided updates on the progress of the EA, including technical details, regulatory requirements, and engagement.
January 4, 2024	SK MOE	Technical Meeting	SK MOE provides an update to Denison on the caribou habitat offset calculation framework and expectations for the offset at the EA stage.
February 10, 2024	CNSC	Submission	Denison submits responses to FIRT round 2 IRs on the draft EIS, along with Version 1 of the Commitments Register, the revised draft EIS, and the Indigenous Engagement Report updated to January 2024.
May 24, 2024	CNSC		Denison receives draft of the FIRT's review of Denison's responses to Round 2 IRs (i.e., round 3 IRs).
May 31, 2024	CNSC		Denison receives updated draft of the FIRT's review of Denison's responses to Round 2 IRs (i.e., round 3 IRs).
June 5, 2024	CNSC, HC, ECCC	Technical Meeting	Denison's assessment team met with key individuals on the FIRT following receipt of the draft round 3 IRs, specifically IR-100, IR-190, IR-198-R1, IR-107, and IR-110.
June 6, 2024	CNSC, ECCC	Technical Meeting	Denison's assessment team met with key individuals on the FIRT following receipt of the draft round 3 IRs, specifically IR-89 and IR-89-R1, IR-115 and IR-115-R1, IR-124 and IR-124-R1, IR-126, IR-134 and IR-134-R1, IR-142, IR-159, IR-167-R1, IR-170, IR-174, IR-194, IR-197, IR-149, IR-149-R1A, IR-149-R1B, and IR-157.
June 14, 2024	CNSC, ECCC	Technical Meeting	Denison's assessment team met with key individuals on the FIRT following receipt of the draft round 3 IRs, specifically IR-12, IR-12-

Date	Organization	Engagement Type	Purpose
			R1A and IR-12-R1B, IR-18, IR-101, IR-108 and IR-108-R1, IR-113 and IR-113-R1, IR-114, IR-193, IR-195, and IR-103.
June 18, 2024	CNSC	Site visit	Denison hosted representatives from the CNSC at the Project site to discuss the Project and tour the proposed Project location.
June 21, 2024	SK MOE	Technical Meeting	Discussion with SK MOE on the caribou habitat offset framework.
June 27 to July 9, 2024	CNSC	Submissions	Denison submits responses to all FIRT round 3 IRs, on an IR-by-IR basis.
July 11, 2024	CNSC	Submission	Denison submits responses to FIRT round 3 Advice Comments.
July 17, 2024	CNSC	Submission	Denison submits the Indigenous Engagement Report updated to July 10, 2024.
July 17, 2024	CNSC	Submission	Denison submits responses to Public Comments.

The intent of engagement with regulatory staff was to share relevant information on the progress and scope of the EA, Project components, and methodologies used to technically assess the effects on the biophysical and human environments. Denison facilitated several presentations focused on the specific technical assessment methods, with federal and provincial technical experts in attendance. These presentations allowed for the technical experts to learn about the Project scope and modelling approaches to assess effects on the receiving environment.

Regulatory agencies were also provided with the opportunity to attend Denison's engagement activities with other Interested Parties (either virtually or in-person), primarily with Denison's Indigenous and non-Indigenous COI. Over the course of the assessment, the regulatory agencies attended most or all of Denison's key engagement activities with Interested Parties in 2019 (i.e., site visit), 2021 (i.e., virtual meetings), 2022, 2023, and 2024 (i.e., in-person meetings). Denison plans to continue engagement activities going forward.

4.6 Influence of Engagement on the Assessment

The interests, issues, and concerns shared as a result of engagement activities have meaningfully informed the Project and the EA process. This includes valuable perspectives that were provided and influenced the Project, the selection of VCs, identification and consideration of potential effects, as well as mitigation and monitoring of effects.

Details about how information received from each interested party is documented in Section 4.3 (Indigenous Groups), and Section 4.4 (General Public).

Specific information on how engagement activities have influenced the assessment process for each VC is provided in the following:

- Section 6 Atmospheric and Acoustic Environment:
  - Section 6.1.2 for Air Quality; and

- Section 6.2.2 for Noise.
- Section 7 Geology and Groundwater, Section 7.2.
- Section 8 Aquatic Environment:
- Section 8.1.2 for Surface Water Quantity;
- Section 8.2.2 for Surface Water Quality;
- Section 8.3.2 for Fish and Fish Habitat;
- Section 8.4.2 for Sediment Quality and Benthic Invertebrates; and
- Section 8.5.2 for Fish Health.
- Section 9 Terrestrial Environment:
- Section 9.1.2 for Terrain, Soil, and Organic Matter/Peat;
- Section 9.2.2 for Vegetation and Ecosystems;
- Section 9.3.2 for Ungulates, Furbearers, and Woodland Caribou; and
- Section 9.4.2 for Raptors, Migratory Breeding Birds, and Bird Species at Risk.
- Section 10 Human Health, Section 10.1.2.
- Section 11 Land and Resource Use:
- Section 11.1.2 for Indigenous Land and Resource Use;
- Section 11.2.2 for Other Land and Resource Use; and
- Section 11.3.2 for Heritage Resources.
- Section 12 Quality of Life:
- Section 12.1.2 for Cultural Expression;
- Section 12.2.2 for Community Well-being; and
- Section 12.3.2 for Infrastructure and Services.
- Section 13 Economics, Section 13.1.4.

4.7 Future Engagement Activities

Denison believes that the development of positive and effective working relationships with Interested Parties will not conclude with the completion of the assessment and licensing process. Denison believes that there is considerable value in sustaining opportunities for engagement with Indigenous communities and organizations, the general public, and regulatory agencies. Denison is committed to ongoing engagement throughout the entire Project lifespan.

4.7.1 Future Indigenous Engagement Activities

With Denison's adoption of the IPP in 2021, the commitment to take action towards advancing reconciliation with Indigenous peoples in Canada and the identified action plan focus areas of engagement, empowerment, environment, employment and education, reflect a commitment to implementation of the continuously evolving RAP. Ongoing and meaningful engagement is one of the foundational action areas that Denison is committed to interweave the principles of reconciliation throughout all areas of operations.

Just as the Project engagement process has evolved to date, specific activities will be identified in discussion with Indigenous Interested Parties to make sure they align with specific areas of interest or concern. This may include some of the following:

- follow-up to specific feedback received on the EIS and identified areas of concern or questions;
- benefit agreements and implementation working groups;
- monitoring (environment or other); and
- any other items of interest.

For each Indigenous Community of Interest, Other Indigenous Community, or Indigenous Organization, future engagement activities are described in those relevant sections.

4.7.2 Future Public Engagement Activities

Engagement activities involving the General Public Interested Parties will continue after the submission of the EIS and completion of the EA process. Denison believes that there is considerable value in ongoing opportunities for discussion. Specific activities will be developed in discussion with interested public parties to ensure, among other things, potential effects continue to be minimized and Project benefits have opportunity to be maximized.

Denison expects that opportunities to share information on Project status and receive information on issues and concerns will include activities that focus on communication (website, newsletters) and direct interaction (e.g., workshops, youth/elder sessions, meetings with community leadership, ongoing discussion with resource harvesters) would be reasonable initial activities to implement.

Where appropriate, Denison has described any future engagement for the General Public, in those relevant sections.

4.7.3 Future Regulatory Engagement Activities

Regulatory engagement activities following submission of the EIS can be expected to occur to review initial EA results, respond to questions and concerns that may be identified, and identify and consider regulatory or assessment areas of interest that had not been previously defined or addressed.

Engagement with regulatory agencies is expected to continue throughout the lifespan of the Project to confirm regulatory requirements are adequately fulfilled.

km^2	square kilometre
m	metre
m^2	square metre
m^3/s	cubic metre per second
mg/kg	milligram per kilogram
mg/L	milligram per litre

Glossary

Term	Definition
Cumulative effect	A cumulative effect occurs when a residual adverse effect of the Project on a given valued component overlaps spatially and/or temporally with the same residual adverse effects on the valued component from other past, present, and reasonably foreseeable projects or activities.
Environmental Assessment	An assessment of potential environmental consequences of a project. The environmental assessment considers the existing environment where the Project is to be located (including, but not limited to, Indigenous and Local Knowledge), predicts potential effects to valued components of the environment, identifies mitigation measures used to limit the effects of the project on the local environment, classifies potential effects remaining after mitigation, and describes monitoring and follow-up programs.
Environmental Impact Statement	A document that contains the environmental assessment for a project, and can also include details on the project description, engagement, mitigation measures, residual and cumulative effects, accidents and malfunctions, and effects of the environment on the project.
Follow-up program	A follow-up programs addresses uncertainties identified during the environmental assessment process (e.g., to verify predictions made during the environmental assessment; determine the effectiveness of proposed and implemented mitigation measures) and to determine if and when to implement adaptive management measures.
Indigenous Knowledge	The unique and collective knowledge of Indigenous peoples that may include, but is not limited to, the environmental, cultural, economic, political, and spiritual conditions of a community or region.
Intermediate Valued Component	Intermediate Valued Components (VCs) are VCs that are fully characterized in the residual effect evaluation, with significance determination completed on related, receptor VCs. The intermediate VCs in this assessment are: Air Quality, Noise, Geology, Groundwater Quality, Groundwater Quantity, Surface Water Quantity, Surface Water Quality, and Sediment Quality.
Key indicator	An important component or aspect of a valued component that is expected to be affected (changed) as a result of the Project.
Local Knowledge	Specialized knowledge developed through long-term association, interaction, and cumulative experience.
Local Study Area	The area that surrounds the Project Area where both direct and indirect effects resulting from Project activities can be reasonably measured.
Measurable parameter	A parameter or metric associated with a key indicator that can be used to detect and measure Project-related changes.
Mitigation/Mitigation Measure	Mitigation is the elimination, reduction, or control of the adverse effects of the Project and includes restitution for any damage to a valued component caused by such effects through replacement, reclamation, compensation, or any other means. Mitigation measures refer to Project-specific mitigation and can include, but are not limited to, engineering design features and responses, best management practices, management plans, emergency response programs, and training.
Monitoring program	A monitoring program is designed to meet regulatory requirements (e.g., permit or license conditions), and/or to demonstrate compliance with environmental commitments made in the Environmental Impact Statement.
Project Area	The area within which the Project and all components/activities are located (i.e., the Project footprint with an applied buffer; the area of maximum physical disturbance).

Term	Definition
Receptor Valued Component	Receptor Valued Components (VCs) are generally biological or integrated assessment endpoints. A change in an intermediate VC may lead to an effect on a receptor VC.
Regional Study Area	The area that surrounds and includes the LSA, established to assess the potential, largely indirect effects of the Project in a regional context.
Residual effect	The potential adverse effect of the Project on a valued component after mitigation measures have been considered.
Valued Component	Aspects of the biophysical and human environments that will likely be affected (adversely or positively) by the Project. The valued components selected reflect identified scientific, Local Knowledge, Indigenous Knowledge, and community interests.

5 Approach and Methodology of the Assessment

5.1 Introduction

This Environmental Impact Statement (EIS) addresses the recommended guidelines and legislated requirements, pursuant to *The Environmental Assessment Act* (Government of Saskatchewan 2018) and the *Canadian Environmental Assessment Act*, 2012 (Government of Canada 2019b). Denison considers the Environmental Assessment (EA) to be a planning and decision-making tool that assesses the potential effects of the Project in a careful and precautionary manner, including appropriate engagement with Indigenous communities and communities of interest, so that mitigation can be designed and applied to support of the approval of the Project by the appropriate regulators (i.e., Saskatchewan Ministry of Environment [SK MOE] and the Canadian Nuclear Safety Commission [CNSC]). As such, the EA is a process for identifying the Project's potential interactions with the biophysical and human environment, predicting potential adverse effects, identifying mitigation measures, and evaluating residual and cumulative effects remaining after mitigation. The EA also outlines the proposed efforts for monitoring and reporting to verify compliance with the terms and conditions of approval and the follow-up to assess the accuracy and effectiveness of predictions and mitigation measures presented in the EA.

This section presents the approach and methodology used to identify and assess the effects that are likely to occur as a result of the Project. The methods used are current, proven, and accepted EA approaches and best practices and have been developed and used to provide a thorough and rigorous analysis, while presenting the assessment results in a clear, concise, and well-organized manner. Indigenous Knowledge (IK) and Local Knowledge (LK) of the existing biophysical and human environments and potential effects have been integrally incorporated throughout this EIS.

The EA aspect of this EIS involves predicting and evaluating the likely adverse effects of the Project, which are generally defined as changes the Project is likely to cause in the biophysical and human environments. The EA approach involves 'overlaying' the Project onto the existing environment, and then considering the proposed mitigation, to identify and describe whether, how, and to what degree components of the environment are likely to change after application of the mitigation measures (i.e., residual effects), and evaluating the change (Figure 5.1-1).

The key elements of the EA involve:

- defining the scope of the assessment in terms of Valued Components (VCs), selected Key Indicators (KIs) for each VC, Measurable Parameters (MPs), and the spatial and temporal boundaries for the assessment;
- identifying the influence of IK, LK, and engagement on the assessment;
- describing the existing environment for each VC;
- determining which Project components and/or activities interact with the VCs;

- determining potential Project effects and applicable mitigation measures (e.g., design features) and operational methods that will be used to avoid or limit adverse effects resulting from the construction, operation, decommissioning, and reclamation activities of the Project;
- completing a residual effects evaluation (e.g., characterizing anticipated adverse effects remaining after implementing appropriate mitigation);
- determining the significance, when applicable, of the identified adverse residual effects;
- identifying cumulative effects, i.e., the spatial and/or temporal overlapping of residual Project effects with the same residual effects resulting from other past, present, and reasonably foreseeable projects or activities (including characterization of cumulative effects and significance determination);
- describing monitoring and follow-up programs that will be completed; and
- summarizing, in plain language, the main points of the assessment, including potential residual and cumulative effects to the VC/KI from the Project and relevant mitigation, monitoring and follow-up.

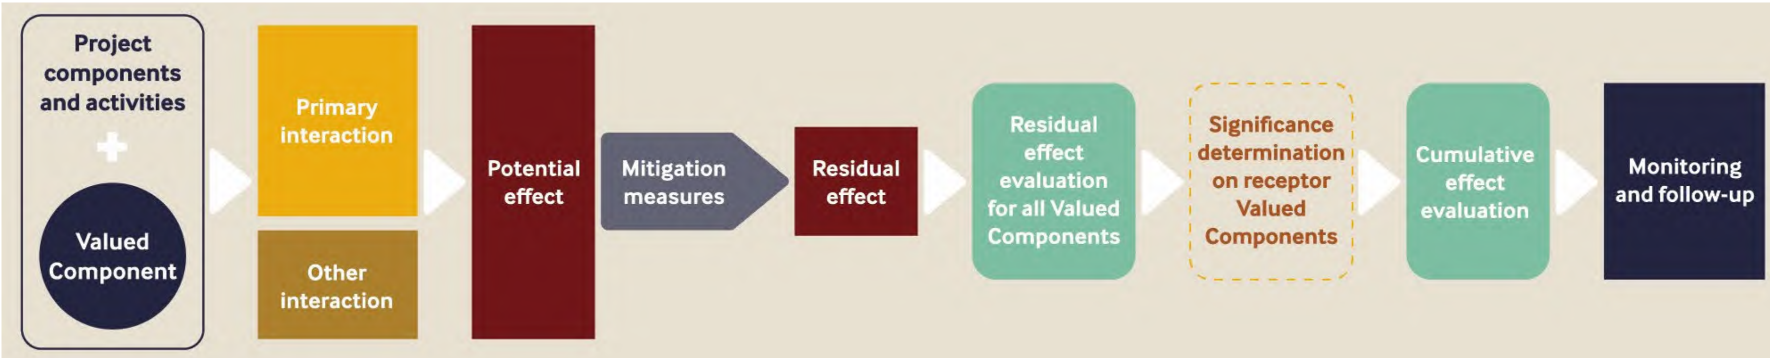

Figure 5.1-1: Environmental Assessment Process for the Wheeler River Project

5.2 Areas of Assessment

The EA for the Project is made up of two broad areas of assessment (Figure 5.2-1): the biophysical environment (Part II of the EIS) and the human environment (Part III of the EIS). The biophysical environment has been organized into the following sub-categories:

- atmospheric and acoustic environment;
- geology and groundwater;
- aquatic environment; and
- terrestrial environment.

The human environment has been organized into the following sub-categories:

- human health;
- land and resource use;
- quality of life; and
- economics.

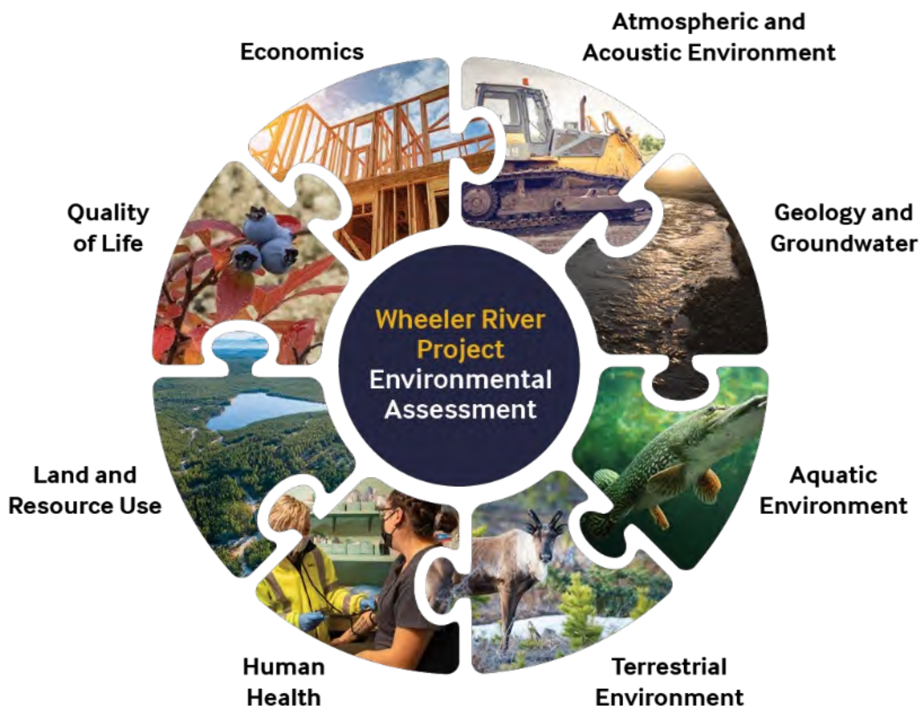

Figure 5.2-1: Biophysical and Human Environment Assessments for the Wheeler River Project Environmental Assessment

Part IV of the EIS contains integrated topics and summaries including:

- accidents and malfunctions;
- effects of the environment on the project;
- assessment summary and conclusions, which contains appendices summarizing:
  - potential residual effects;
  - potential cumulative effects; and
  - monitoring and follow-up programs.

5.3 Scope of the Assessment

5.3.1 Valued Components Selection

As per standard, accepted EA practice, this EA is organized by and focused on VCs. The VCs are aspects of the biophysical and human environments that will likely be affected (adversely or positively) by the Project. The VCs reflect identified scientific, LK and IK, and community interests regarding the Project and its potential effects and are typically identified early in the EA process as a result of questions and concerns raised through engagement with government departments and agencies, Indigenous and community groups, and the general public.

Initial direction and input into VC selection were obtained through discussions with Indigenous groups, government agencies, and the public. Denison reviewed and considered this input to develop a VC list that reflects the key environmental, socio-economic, heritage, and human health components and interests to focus the detailed assessment for the EA.

The VC list provided in the Terms of Reference (Denison 2019) was evaluated, consolidated, and organized to allow for the logical assessment of Project effects, and is presented in Table 5.3-1. Some of the initial VCs outlined in the Terms of Reference have been addressed as KIs, discussed in the subsequent subsections. Each VC-specific section in Parts II and III of this EIS expands on the rationale for VC inclusion provided herein.

As shown in Figure 5.1-1, all VCs selected for this EA go through a thorough residual effect evaluation. The VCs selected for this assessment were further identified as being either intermediate or receptor VCs. A change in an intermediate VC may lead to an effect on a receptor VC. Receptor VCs are generally biological or integrated assessment endpoints. The intermediate VCs in this EA are: Air Quality, Noise, Geology, Groundwater Quality, Groundwater Quantity, Surface Water Quantity, Surface Water Quality, and Sediment Quality. Significance determination is not completed on intermediate VCs, but integrated into the residual effect evaluation, residual effect characterization, and significance determination for related receptor VCs.

Table 5.3-1: Valued Components and Rationale for Their Inclusion in the Environmental Assessment

Valued Component	Rationale
Biophysical Environment	
Atmospheric and Acoustic	
Air Quality	Project-related air emissions could reduce the air quality, resulting in implications for human health and well-being as well as the aquatic and terrestrial environments (receptor VCs).
Noise	Project activities may result in increased noise levels above ambient conditions that may cause temporary disturbance to local land users or wildlife (receptor VCs), which could result in temporary avoidance of the area and other behavioural responses.
Geology and Groundwater	
Geology	Project activities may alter underlying surficial geological material through terrain destabilization and accelerated erosion, which may affect the land use and economic activity in proximity to the Project and may also affect biological functions in proximity to the Project.
Groundwater Quality	Project activities may result in a change to the quality of groundwater, which may in turn influence surface water quality, resulting in public concern and non-compliance with regulations or permit conditions.
Groundwater Quantity	Project activities may result in a change to the quantity of groundwater, which may in influence surface water quantity, resulting in public concern and non-compliance with regulations or permit conditions.
Aquatic Environment	
Surface Water Quantity	Project activities may result in a change to existing surface drainage patterns resulting in change in surface water flows and/or levels. Such changes have the potential to influence water quality, biodiversity, and biological function. Surface water quantity change may affect Indigenous values, public concern, non-compliance with regulations or permit conditions.
Surface Water Quality	Changes to Surface Water Quality have the potential to affect biodiversity and biological function through direct exposure and indirect food chain influences and the cultural values of Indigenous groups, the public, non-compliance with regulations or permit conditions
Sediment Quality	Project activities may alter sediment quality. Potential changes in sediment particle size, chemistry, and distribution within the aquatic environment, may in turn, influence biodiversity and biological function in the aquatic environment (specifically for benthic invertebrates and fish). Such effects are of interest with respect to cultural values of Indigenous groups, the public, and other stakeholders.
Benthic Invertebrates	Project activities may result in changes to benthic invertebrates as a receptor through changes to surface water quality and sediment quality. Benthic invertebrates are of ecological importance for aquatic environments and therefore with respect to cultural values of Indigenous groups, the public, and other stakeholders.
Fish and Fish Habitat	Project activities may result in a change to fish and fish habitat thereby affecting the ecological function of the aquatic environment, cultural values of Indigenous peoples, Interested Parties and other

Valued Component	Rationale
	stakeholders. Assessment of Fish and Fish Habitat as a VC is consistent with regulatory requirements (e.g., *Fisheries Act* [Government of Canada 2019c]).
Fish Health	Project activities may result in a change to fish health (through chemical/radiological exposure) via changes to surface water quality and sediment quality. Changes to fish health may affect cultural values of Indigenous peoples and result in public concern non-compliance with regulatory requirements (e.g., *Fisheries Act* [Government of Canada 2019c]) or permit conditions.
Terrestrial Environment	
Terrain	Project activities may alter the topography and may affect the land use and economic activity in proximity to the Project and may also affect biological functions in proximity to the Project.
Organic Matter/Peat	Project activities may alter the availability of organic matter/peat, which may affect the land use, economic activity, and biological functions in proximity to the Project.
Soil Quantity	Project activities may alter soil quantities, as well as increase the potential for erosion and sediment transport; all of which may affect the land use, economic activity, and biological functions in proximity to the Project.
Soil Quality	Project activities may alter the soil quality, as well as increase the potential for erosion and sediment transport; all of which may affect the land use, economic activity, and biological functions in proximity to the Project.
Vegetation and Ecosystems	Project activities may affect vegetation communities and ecosystems, which may result in effects on ecosystem integrity, function, biodiversity and how the area in proximity to the Project is used by wildlife and land users.
Listed Plant Species	Project activities may affect listed plant species, which contribute to biodiversity and are of provincial and/or federal management concern.
Wetlands	Project activities may affect wetland habitats, which contribute to biodiversity, maintenance of hydrology, nutrient cycling, water quality, and carbon storage. Wetlands also provide habitat for listed plant species and wildlife. These effects may also result in non-compliance with regulatory requirements or permit conditions (e.g., Aquatic Habitat Protection Permit).
Ungulates	Project activities and infrastructure may affect ungulate populations resulting in non-compliance with permit conditions and requirements (e.g., *The Wildlife Act, 1998* [Government of Saskatchewan 2020]).
Furbearers	Project activities and infrastructure may affect local furbearer populations, including species at risk, resulting in non-compliance with permit conditions requirements (e.g., *Species at Risk Act* [SARA; Government of Canada 2022], *The Wildlife Act, 1998* [Government of Saskatchewan 2020]).

Valued Component	Rationale
Woodland Caribou	Project activities and infrastructure may affect woodland caribou populations, resulting in non-compliance with permit conditions requirements (e.g., SARA [Government of Canada 2022], *The Wildlife Act, 1998* [Government of Saskatchewan 2020]).
Raptors	Project activities and infrastructure may affect raptor populations (specifically disturbance and/or destruction of eggs, young, and adults) resulting in non-compliance with regulatory requirements (e.g., *Saskatchewan Activity Restriction Guidelines for Sensitive Species* [Government of Saskatchewan 2017], *Wildlife Act* [Saskatchewan]).
Migratory Breeding Birds	Project activities and infrastructure may affect migratory breeding bird populations (specifically disturbance and/or destruction of eggs, young, and adults) resulting in non-compliance with regulatory requirements (e.g., SARA [Government of Canada 2022], *Migratory Birds Convention Act, 1994* [Government of Canada 2017], *Saskatchewan Activity Restriction Guidelines for Sensitive Species* [Government of Saskatchewan 2017], *The Wildlife Act, 1998* [Government of Saskatchewan 2020]).
Bird Species at Risk	Project activities and infrastructure may affect bird species at risk (specifically disturbance and/or destruction of eggs, young, and adults) resulting in non-compliance with regulatory requirements (e.g., SARA [Government of Canada 2022], *Migratory Birds Convention Act, 1994* [Government of Canada 2017], *Saskatchewan Activity Restriction Guidelines for Sensitive Species* [Government of Saskatchewan 2017], *The Wildlife Act, 1998* [Government of Saskatchewan 2020]).
Human Environment	
Human and Worker Health	
Human Health	Project activities and by-products could affect the health and safety of local community members, and land users.
Worker Health and Safety	Project activities and by-products could affect the health and safety of Project employees and contractors.
Land and Resource Use	
Indigenous Land and Resource Use	Project activities may alter the relative abundance of moose, woodland caribou, waterbirds and waterfowl, and upland game birds, which are important for subsistence harvesting. Project activities may alter safe access and navigation to resource harvest areas and the availability of supporting infrastructure such as cabins and camping sites, which are important to the continuation of traditional land and resource. Project activities can affect traditional land and resource use aesthetics and the perceived suitability of resources and resource harvest areas.
Other Land and Resource Use	Project activities may alter the relative abundance and distribution of Walleye, Northern Pike, moose, and furbearers (particularly pine marten), which are important species for recreational and commercial fishing, recreational hunting, or commercial trapping. Project activities may alter safe access and navigation to resource harvest areas and the availability of supporting infrastructure such as cabins and camping sites, which are important to the continuation of other land and resource. Project activities may also alter the continued ability to participate in and

Valued Component	Rationale
	maintain access to recreational activities provided by parks and protected areas, lodge and outfitting services, and ecotourism. Project activities can affect other land and resource use aesthetics and the perceived suitability of resources and resource harvest areas.
Heritage Resources	Project activities may alter the number of archaeological resources.
Quality of Life	
Cultural Expression	Project activities may affect opportunities for knowledge transmission on the land. This includes effects on language and land-based activities (such as hunting and gathering, travel, habitation, ceremonies, and cultural camps) where knowledge transmission occurs. Project activities may affect harvesting country foods (i.e., traditional foods), which support social bonds within families and communities and maintain cultural identities and traditional food systems.
Community Well-being	Project activities may change population and demographics if in/out migration results from people seeking employment opportunities. Project activities may change income of local workers through participation in employment and/or contracting activities. Project activities may lead to a change in community cohesion through a change in income and participation in a worker rotation system.
Infrastructure and Services	Project activities may increase traffic. Project activities may affect demands on local infrastructure and services. Project activities may affect demands on emergency services.
Economics	
Economy	The Project may affect current income levels and/or revenues to the local and provincial economies. The Project may affect current employment, training, and educational opportunities. The Project may affect current business levels and opportunities that would affect local communities and potentially provincial market sectors.

5.3.2 Key Indicators and Measurable Parameters

To provide focus and analytical rigour to the EA, the effects assessment for each VC identifies relevant KIs and associated MPs, as applicable. These are defined as follows:

- **Key Indicator**: an important component or aspect of the VC that is expected to be affected (changed) as a result of the Project. The KIs may comprise subsets or a guild of the VC (e.g., Soil Quality VC – Chemical Soil Properties KI), certain aspects of the VC that may be affected by the Project and/or which have a particular importance (e.g., Raptor VC – Bald Eagle and Osprey KIs;

Indigenous Land and Resource Use VC – Resource Availability KI), and/or that can serve as indicators of potential effects on the VC.

- **Measurable Parameter**: a parameter or metric associated with the KI that can be used to detect and measure Project-related changes (e.g., amount of habitat altered, change in levels of contaminants of concern, or change in regional unemployment rates).

The VCs, KIs, and their associated MPs are identified and listed as outlined in Table 5.3-2 and form the basis for the subsequent VC-specific assessment.

Table 5.3-2: Valued Components, Key Indicators, and Measurable Parameters

Valued Component Category	Valued Component	Key Indicator	Measurable Parameter
Biophysical Environment			
Atmospheric and Acoustic	Air Quality	Levels of dust, combustion products, uranium, metals, and/or radionuclides	Change in concentrations and deposition rates of total suspended particulate (TSP), inhalable particulate matter (PM_{10}), respirable particulate matter ($PM_{2.5}$), nitrogen dioxide (NO_2), sulphur dioxide (SO_2), carbon monoxide (CO), uranium, metals, and radionuclides compared to the most appropriate air quality criteria.
	Noise	Noise levels	Change in sound pressure levels (Ldn, Ld, and Ln), measured in decibels, over ambient noise. Changes in % highly annoyed.
Geology and Groundwater	Geology	Surficial geology	Amounts of removed underlying surficial geological material through terrain destabilization and accelerated erosion.
	Groundwater Quality	Constituent concentrations in groundwater	Change in level of constituents of concern and water parameters within the surface waterbodies relative to baseline conditions.
	Groundwater Quantity	Water levels in local and regional aquifers	Percentage loss or change of groundwater volume.
Aquatic Environment	Surface Water Quantity	Surface water flow and/or levels	Percentage loss or change of surface water flow and/or level (e.g., change in water level [m], mean monthly discharge [m^3/s], 5th percentile monthly discharge [m^3/s]).
	Surface Water Quality	Change in surface water quality from baseline concentrations	Change in the concentration of constituents that are directly related to Project activities as measured as a mass of a chemical per unit volume in water (e.g., mg/L)
	Sediment Quality	Sediment quantity and physical quality (particle size) from baseline conditions	Change in the quantity of solids deposited on aquatic sediments directly related to the Project.
		Change in sediment quality (chemical) from baseline concentrations	Change in the concentration of constituents in aquatic sediments directly related to Project activities.
	Benthic Invertebrates	Change in available aquatic habitat from baseline conditions	Aerial extent (m^2 or ha) of overprinted aquatic habitat.

Valued Component Category	Valued Component	Key Indicator	Measurable Parameter
		Change in sediment quality (chemical) from baseline concentrations	Change in the concentration of constituents in aquatic sediments directly related to Project activities, which may affect benthic invertebrate communities.
		Change to water levels or flows from baseline conditions	Changes in water levels (m) or percent changes to flow conditions (%).
	Fish and Fish Habitat	Change to water levels or flows from baseline conditions	Changes in water levels (m) or percent changes to flow conditions (%).
		Change in available aquatic habitat from baseline conditions	Aerial extent (m^2 or ha) of overprinted aquatic habitat.
		Change in surface water quality from baseline conditions	Change in the concentration of constituents that are directly related to Project activities, measured as a mass of a chemical per unit volume in water (e.g., mg/L).
	Fish Health	Change in surface water quality from baseline conditions	Change in the concentration of constituents that are directly related to Project activities, measured as a mass of a chemical per unit volume in water (e.g., mg/L).
		Change in sediment quality from baseline conditions	Introduction of constituents into the sediments of waterbodies as a result of the Project that are of a magnitude to negatively affect aquatic biota associated with the waterbodies.
		Change in fish tissue constituents of potential concern (COPC) concentrations from baseline conditions	Change in the concentration of constituents that are directly related to Project activities, measured as a mass of a chemical per unit mass in fish tissue (e.g., mg/kg).
Terrestrial Environment	Terrain	Terrain morphology	Change in slope grade, aspect. Change in topographical contours and drainage pattern.
		Terrain stability	Change in the stability of landform attributes. Increase in erosion potential; acceleration of erosional processes.
	Soil Quantity	Soil quantity	Change (i.e., net loss) of soil volume.
	Soil Quality	Physical and chemical soil properties	Change (i.e., degradation) in soil physical properties (particle size/texture, structure, and aggregation). Change in chemical properties (essential and non-essential metals).
	Organic Matter/Peat	Organic matter/peat	Change (i.e., net loss) in percentage of area extent of organic matter as a result of Project activities.
	Vegetation and Ecosystems	Vegetation abundance	Change in areal extent of habitat types.
		Constituent concentrations in vegetation	Change in level of constituents of concern in plant tissue.

Valued Component Category	Valued Component	Key Indicator	Measurable Parameter
	Listed Plant Species	Listed Plant Species	Change in number of known listed plant occurrences.
	Wetlands	Wetlands	Change in areal extent of wetlands.
	Ungulates	Moose (*Alces alces*)	Amount of habitat (km^2) (not necessarily occupied) that may be altered or lost relative to its availability in the Regional Study Area (RSA). The number of moose mortalities directly or indirectly attributable to the Project.
	Furbearers	Wolverine (*Gulo gulo*)	Amount of habitat (km^2) (not necessarily occupied) that may be altered or lost relative to its availability in the RSA. The number of wolverine mortalities directly or indirectly attributable to the Project.
		Pine marten (*Martes americana*)	Amount of habitat (km^2) (not necessarily occupied) that may be altered or lost relative to its availability in the RSA. The number of pine marten mortalities directly or indirectly attributable to the Project.
		Mink (*Neovison vison*)	Amount of habitat (km^2) (not necessarily occupied) that may be altered or lost relative to its availability in the RSA. The number of mink mortalities directly or indirectly attributable to the Project.
		Muskrat (*Ondatra zibethicus*)	Amount of habitat (km^2) (not necessarily occupied) that may be altered or lost relative to its availability in the RSA. The number of muskrat mortalities directly or indirectly attributable to the Project.
	Woodland Caribou	Woodland caribou (*Rangifer tarandus caribou*)	Amount of habitat (km^2) (not necessarily occupied) that may be altered or lost relative to its availability in the RSA. The number of woodland caribou mortalities directly or indirectly attributable to the Project.
	Raptors	Bald Eagle (*Haliaeetus leucocephalus*)	Percentage of Bald Eagle habitat altered/lost directly or indirectly as a result of Project activities. The number of Bald Eagle mortalities directly or indirectly attributable to the Project.
		Osprey (*Pandion haliaetus*)	Percentage of Osprey habitat altered/lost directly or indirectly as a result of Project activities. The number of Osprey mortalities directly or indirectly attributable to the Project.

Valued Component Category	Valued Component	Key Indicator	Measurable Parameter
	Migratory Breeding Birds	Waterbirds and waterfowl	Percentage of habitat for waterbirds and waterfowl altered/lost directly or indirectly as a result of Project activities. The number of waterbirds and waterfowl mortalities directly or indirectly attributable to the Project.
		Upland game birds	Percentage of habitat for upland game birds altered/lost directly or indirectly as a result of Project activities. The number of upland game bird mortalities directly or indirectly attributable to the Project
		Migratory songbirds	Percentage of habitat for migratory songbirds altered/lost directly or indirectly as a result of Project activities. The number of songbird mortalities directly or indirectly attributable to the Project.
	Bird Species at Risk	Common Nighthawk (*Chordeiles minor*)	Percentage of habitat for Common Nighthawk altered/lost directly or indirectly as a result of Project activities. The number of Common Nighthawk mortalities directly or indirectly attributable to the Project.
		Short-eared Owl (*Asio flammeus*)	Percentage of habitat for Short-eared Owl altered/lost directly or indirectly as a result of Project activities. The number of Short-eared Owl mortalities directly or indirectly attributable to the Project.
		Yellow Rail (*Coturnicops noveboracensis*)	Percentage of habitat for Yellow Rail altered/lost directly or indirectly as a result of Project activities. The number of Yellow Rail mortalities directly or indirectly attributable to the Project.
		Rusty Blackbird (*Euphagus carolinus*)	Percentage of habitat for Rusty Blackbird altered/lost directly or indirectly as a result of Project activities. The number of rusty blackbird mortalities directly or indirectly attributable to the Project
		Olive-sided Flycatcher (*Contopus cooperi*)	Percentage of habitat for Olive-sided Flycatcher altered/lost directly or indirectly as a result of Project activities. The number of Olive-sided Flycatcher mortalities directly or indirectly attributable to the Project
Human Environment			
Human Health	Human Health	Public health	Evaluation of risk of exposure to COPC through use of hazard quotient, incremental lifetime cancer risk, or radiation dose.
	Worker Health and Safety	Worker health	Change in risk of exposure to COPC. Radiological exposure and dose.

Valued Component Category	Valued Component	Key Indicator	Measurable Parameter
Land and Resource Use	Indigenous Land and Resource Use	Resource availability for harvesting subsistence resources	Change in relative abundance and distribution of fish wildlife, fish, and plant species. Change in the suitability of wildlife, fish, and plants for human consumption.
		Land/waters available for traditional practices	Change in lands available to conduct traditional harvesting, such as lands and waters altered/lost as a result of Project activities. Change in opportunities for traditional land use, including access, navigation, and occupation sites
		Perceived suitability of land and resources therein	Change in aesthetics of the land/water use experience. Change in perceived suitability of land/water for resource use. Change in quality of resources for consumption.
	Other Land and Resource Use	Resource availability for commercial and recreational harvests	Change in relative abundance and distribution of fish species. Change in relative abundance and distribution of wildlife species. Change to the health of the resources. Change in continued opportunities for commercial and recreational resource use.
		Land/waters available to conduct commercial and recreational harvests	Change in the area and accessibility of areas for commercial or recreational uses, such as cabins, tourism, guided outfitting, protected areas, mining, and forestry that is altered/lost because of Project activities. Changes in availability/accessibility of waterways.
		Perceived suitability of lands and resources therein	Change in aesthetic experience (with consideration of traffic, noise, air quality, modification of the wilderness experience). Change in perceived suitability of resources for safe use.
	Heritage Resources	Archaeological sites	Change in the number of known archaeological resources directly or indirectly altered/lost as a result of Project activities.
Quality of Life	Cultural Expression	Knowledge transmission	Changes to cultural practices that support knowledge transmission. Changes in the location of cultural practices that support knowledge transmission
		Traditional diet	Changes in availability of country foods included in a traditional diet. Changes in the perceived suitability and safety of country foods in a traditional diet.
	Community Well-being	Population and demographics	Change in population and demographics.
		Income of local workers	Change in income of local workers.

Valued Component Category	Valued Component	Key Indicator	Measurable Parameter
		Community cohesion	Change in community cohesion as understood by community members through Key Person Interviews.
	Infrastructure and Services	Traffic	Change in traffic volumes and types and risk of accident.
		Community infrastructure and services	Change in access to and capacity of community infrastructure and services. Change in emergency services capacity.
Economics	Economy	Employment and training	The number of Project-related employment opportunities. The number of Project-related training, and educational opportunities. Proportion of Project-related employment opportunities offered and attained by residents in the Local Study Area (LSA). Proportion of Project-related training and educational opportunities offered and attained by residents in the LSA.
		Income	Total wages and salaries paid by Denison and direct contractors on the Project. Changes in income levels of residents in the LSA communities (personal and household).
		Traditional economy	The change in LSA residents participating in the traditional economy due to the Project.
		Business opportunities	The total expenditures of northern Saskatchewan businesses contracted by the Project and procurement agreements and policies in place with Indigenous and northern businesses.
		Government revenues	Changes to provincial royalties and resource surcharges due to the Project. Changes to federal and provincial corporate income tax due to the Project. Change to federal and provincial direct employment income tax due to the Project.

5.3.3 Spatial Boundaries

Spatial boundaries for the EA are defined for each VC, based on the extent of the anticipated Project-related effects (i.e., direct and indirect) on the VC. When determining the spatial boundaries, the following information was considered, as appropriate and available:

- IK, LK, and engagement;
- information on current land and resource use by Indigenous groups;

- other pertinent ecological, technical, social, and cultural considerations (e.g., watersheds, ecozones);
- input from federal and provincial regulators and the public; and
- professional expertise of Denison and the EIS third party consultants.

The study areas for this EA are identified for each VC according to the following definitions:

- **Project Area:** the area within which the Project and all components/activities are located (i.e., the Project footprint; the area of maximum physical disturbance). This area is not VC-specific, but consistent throughout the EA.
- **Local Study Area (LSA):** the area that surrounds the Project Area where both direct and indirect effects resulting from Project activities can be reasonably measured. The LSA is established to assess the potential, largely direct effects of the Project and represents the extent to which there is a reasonable potential for the Project or Project-related activities to interact with and potentially adversely effect the VC.
- **Regional Study Area (RSA):** the area that surrounds and includes the LSA, established to assess the potential, largely indirect effects of the Project in a regional context. The RSA is large enough to capture the extent of potential effects (i.e., zone of influence) on a VC and defines the area within which cumulative effects may occur (i.e., cumulative effects assessment [CEA] boundary).

The Project Area is presented in Figure 5.3-1. The VC-specific LSAs and RSAs are presented in their respective sections of the EIS.

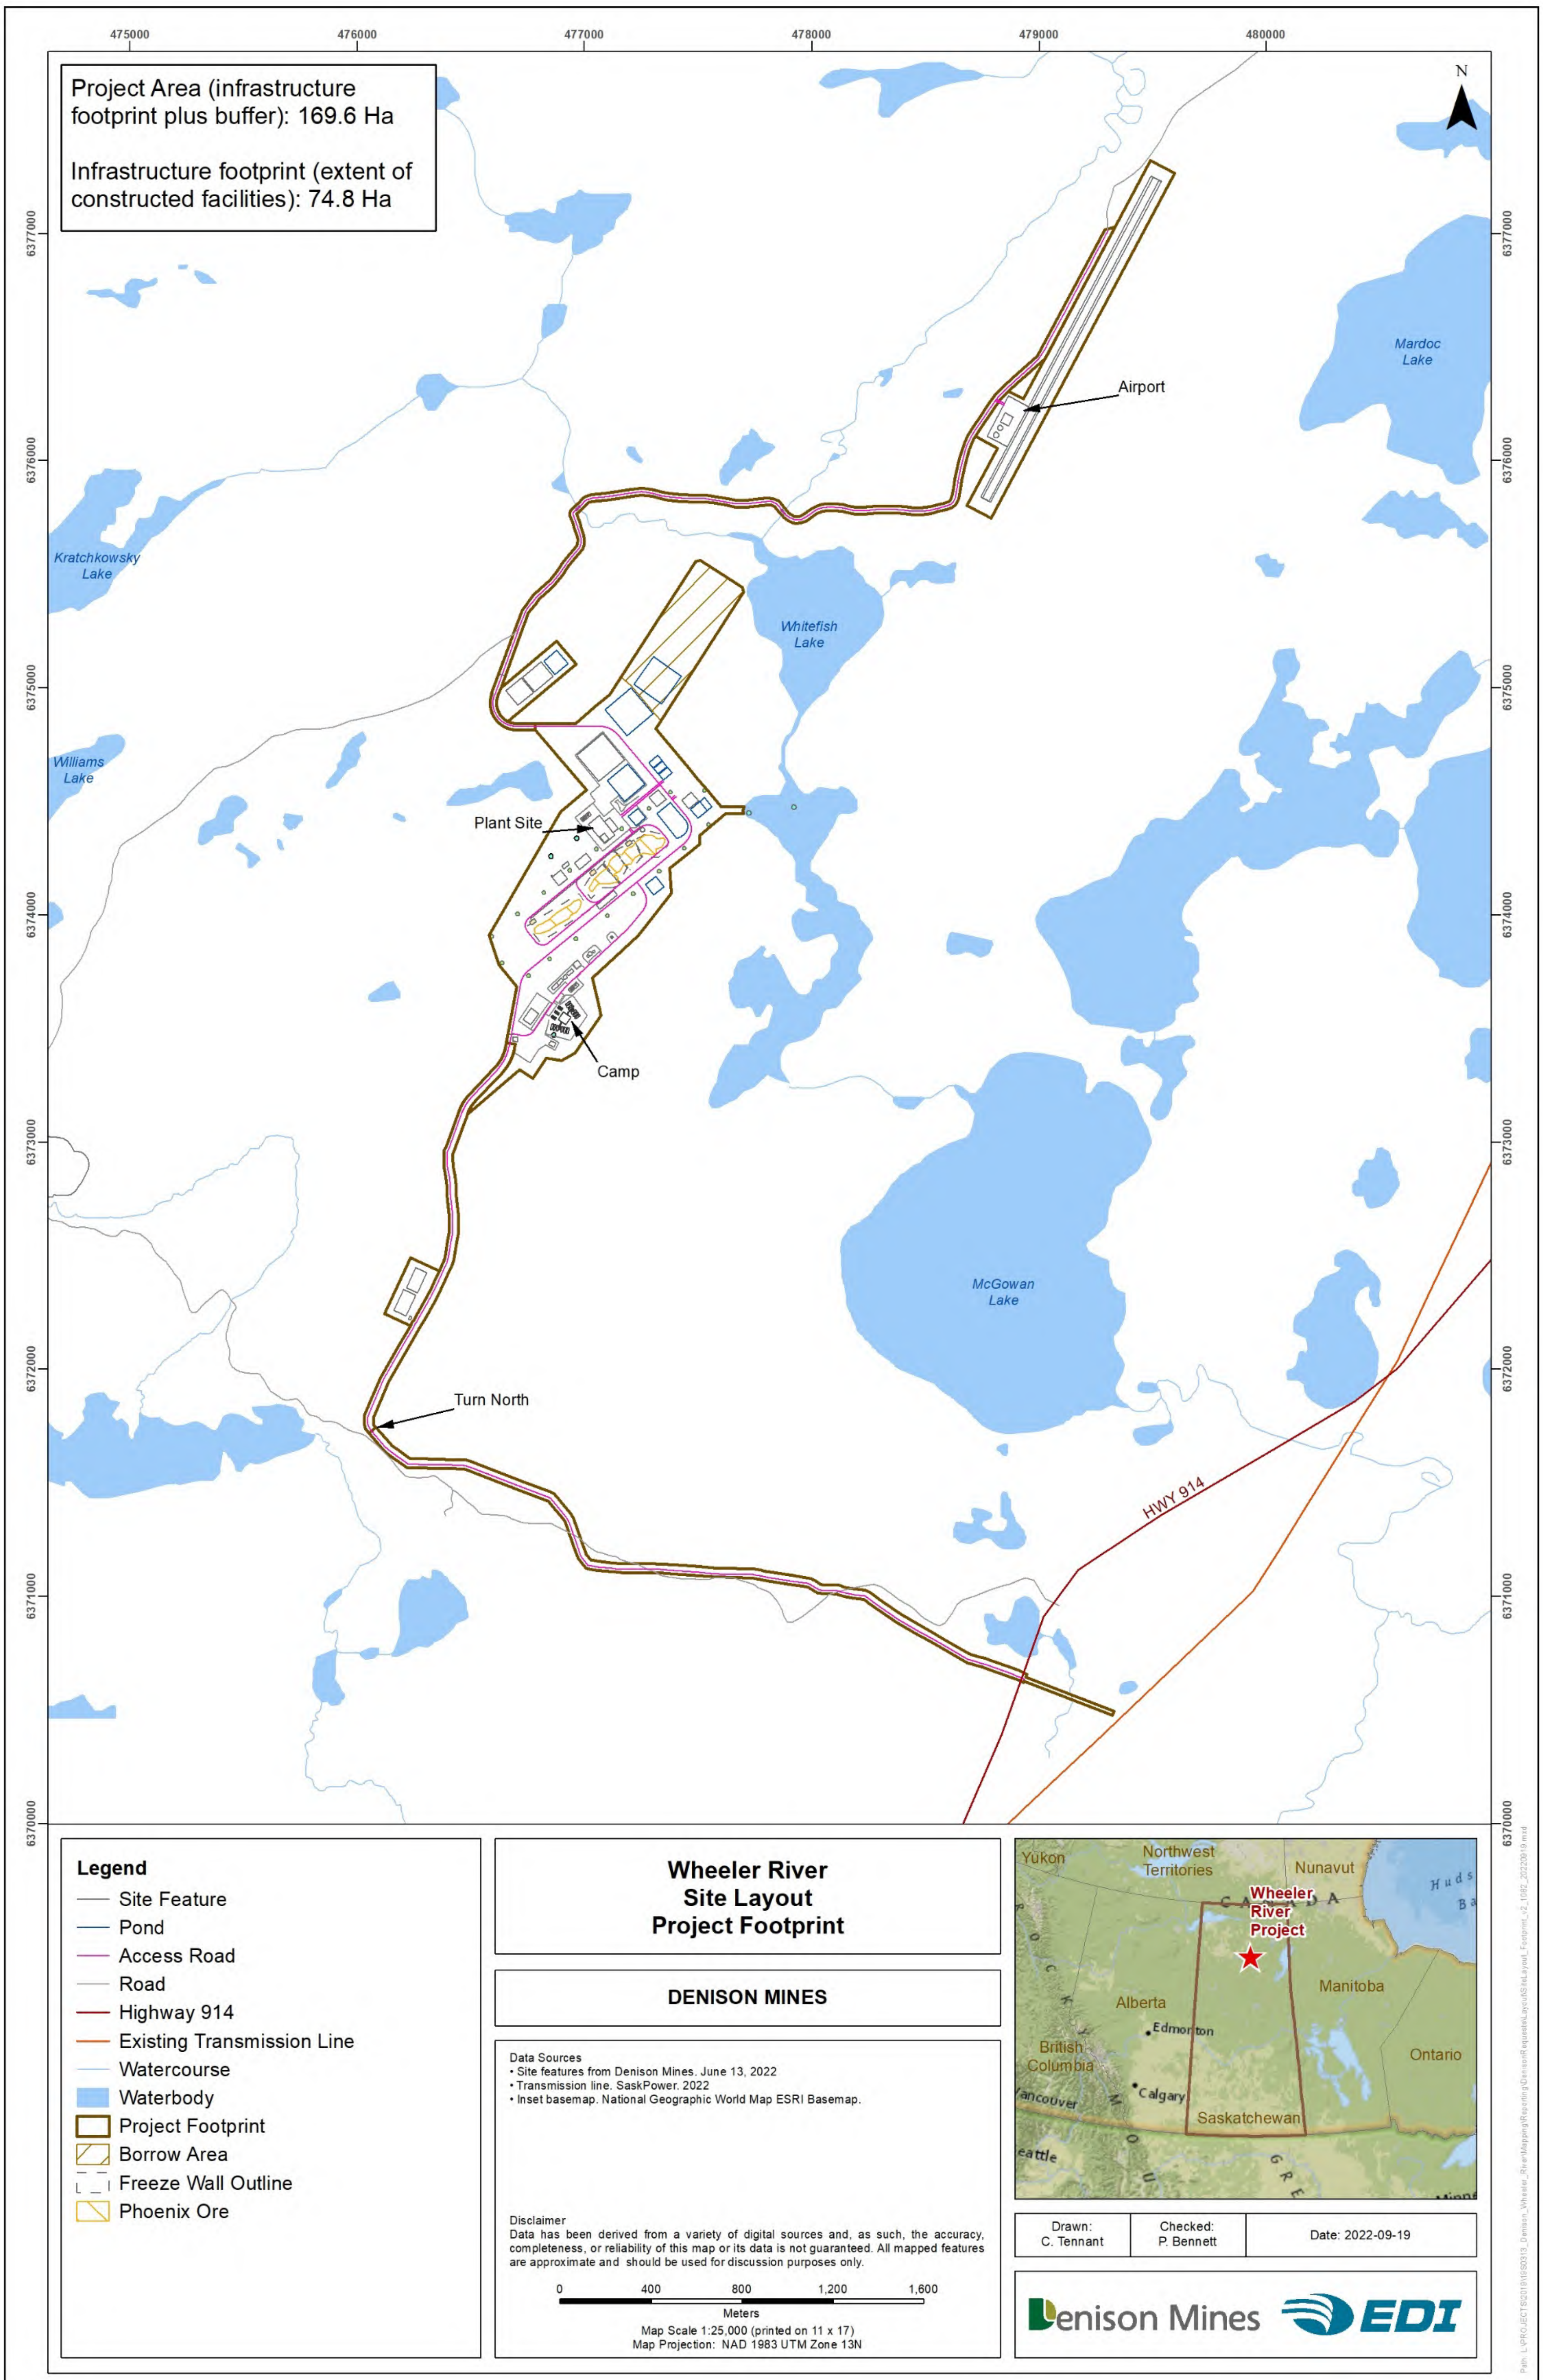

Figure 5.3-1: Project Area for the Wheeler River Project

5.3.4 Temporal Boundaries

The temporal boundaries for the EA represent the timeframes that the Project is expected to interact with and potentially affect the VCs, and as appropriate, reflect seasonal and annual variations or biophysical constraints related to a VC. Temporal boundaries are based on the different phases of the Project, Construction (including site preparation), Operation, Decommissioning, and Post-Decommissioning as described in Table 5.3-3.

Table 5.3-3: Temporal Boundaries for the Environmental Assessment

Phase and Year	Description of Activities	
Construction Year 1 to 3	• Development of access roads and air strip • Site preparation and earthworks; clearing, levelling, and grading of the Project Area • Power generation – generators • Installation of main substation and distribution of power around site • Wellfield and freeze hole drilling; ground freezing • Batch plant operation (concrete); crusher at borrow area • Development of surface infrastructure (camp, operations centre, plants, ponds, pads, and support facilities) • Waste management (composting, domestic and industrial landfill operation, recycling)	• Water management (including treatment and site runoff) • Groundwater supply • Surface water withdrawal • Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel) • On-site and off-site operation of vehicles and transport of materials • Air transportation for workers • Regulatory site inspections • Engagement – site visit from Interested Parties • Employment and expenditures
Operation Year 3 to 18	• Operation of the in situ recovery (ISR) wellfield • Wellfield and freeze wall drilling • Operation and expansion of freeze wall • Batch plant operation (grout and cement) crusher at borrow area • Expansion of pond and pads • Operation of the processing plant and production of uranium concentrate • Water withdrawal from groundwater or surface water body • Management of surface water (including seepage and site runoff) • Water treatment, both domestic and industrial • Water release to surface water body • Waste management (composting, domestic and industrial landfill operation, recycling)	• Hazardous waste management (temporary storage, handling, and off-site transportation) Storage and disposal of drill waste rock, process precipitates, and industrial wastewater treatment plant precipitates • On-site and off-site operation of vehicles and transport of materials • Power supply – primarily power from the grid, also generators and back-up generators • Package and transport of nuclear substances • Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel) • Air transportation for workers • Progressive decommissioning and reclamation • Regulatory site inspections • Engagement - site visit from Interested Parties • Employment and expenditures

Phase and Year	Description of Activities	
Decommissioning Year 18 to 23	• Site water management, treatment, and release • Mining horizon remediation and thawing of freeze wall • Process water treatment and release • Closure of ISR and freeze wells and related infrastructure • Decontamination of surface facilities and injection, recovery, and monitoring wells • Asset removal (including site power transmission lines and electrical infrastructure) • Demolition and disposal of non-salvageable surface infrastructure and materials	• Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and process plant area) • Power generation – generators • Waste management (composting and landfill operation) • Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal) • On-site and off-site operation of vehicles and transport of materials • Reclamation of disturbed areas • Regulatory site inspections • Engagement – site visit from Interested Parties • Employment and expenditures
Post-Decommissioning Year 23 to 38	• Environmental monitoring • Regulatory site inspections	• Engagement – site visit from Interested Parties • Employment and expenditures

5.4 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

At its broadest level, IK can be understood as the unique and collective knowledge of Indigenous peoples, which may include, but is not limited to the environmental, cultural, economic, political, and spiritual conditions of a community or region. The results of IK collection influence the assessment by guiding the development and refinement of primary data collection, providing context for interpretation of secondary data, and providing context for the baseline.

The category of LK for the Project applies only to the information provided by Bobby John, a member of the English River First Nation (ERFN) who previously resided is in the Project Area. Local knowledge is considered as specialized knowledge developed through long-term association, interaction, and cumulative experience. It is context-specific and unique. As the information is held by an individual, it cannot be validated and vetted through processes commonly applied in the collection of IK, which is considered as community-held and shared knowledge.

In this EIS, IK and LK are viewed as complementary and influential alongside western science to produce a full understanding of the potential effects of the Project, whether measurable or perceived. Both forms of information have been given full and fair consideration. Each VC-specific section in Parts II and III of the EIS contains a subsection that outlines the influence of IK, LK, and engagement on the assessment. Indigenous Knowledge and LK quotes and citations have been included to provide readers the information considered as the Project advanced throughout the effect assessment process.

Denison recognizes the importance of engaging with local and Indigenous communities, residents, businesses, organizations, land users and the various regulatory authorities, collectively referred to as Interested Parties. Since 2016, Denison has been engaging with these Interested Parties to support the development of positive relationships and a mutual commitment to collaboration. Broadly speaking, Denison has grouped Interested Parties into three categories:

- Indigenous (Communities/Organizations);
- general public; and
- regulatory agencies.

Specific guidance on inclusion of IK, LK, and engagement in the assessment is provided in Section 3 Indigenous and Local Knowledge and Section 4 Engagement. A summary table listing where IK, LK, and engagement have been considered is included, when applicable, as an appendix in each relevant EIS section.

5.5 Existing Environment

The existing environment section for each VC (and, where applicable, KI) establishes the current conditions and setting (i.e., considers past and current anthropogenic and natural disturbances) for each KI for the assessment of Project-related effects. The information is provided at an overview level for the RSA and in more detail for the LSA. The level of detail provided for each study area is sufficient to allow potential Project effects to be identified and understood.

Existing conditions are based on available information and are accompanied by supporting information including:

- federal, provincial, Indigenous, and local government jurisdictions, mandates, agreements, and interests of specific relevance to the VC/KI;
- an overview of the data sources, and desktop and baseline studies conducted for the Project, with reference to appendices as appropriate;
- a brief description of the quality and reliability of the baseline data and their applicability for the purpose used, including any uncertainty or gaps;
- natural and human caused trends that are presently affecting baseline conditions, including an explanation of if and how other projects and activities have or are currently affecting the VC/KI;
- available IK, LK, and results of engagement activities of specific relevance to the particular VC/KI, subject to any confidentiality constraints that may apply; and
- scientific and other information, such as published literature, databases, remote sensing imagery and data, monitoring programs, and previous EAs or associated technical reports.

5.6 Assessment of Project-related Effects

In this EA, each VC is evaluated consistently by first identifying potential interactions between the Project and each VC (and, where applicable KIs), then identifying and describing potential Project effects, and finally, assessing the changes due to the Project (i.e., considering residual effects after mitigation) and their significance for receptor VCs. In a next step, the results of the residual effects characterizations for all KIs for a VC are summarized (i.e., rolled-up) to determine the significance of those effects on the receptor VC. The significance is typically related to the sustainability or integrity of the KI/VC at the regional level.

All residual effects (independent of significance, or designation as intermediate or receptor VC) are further assessed in a CEA. The CEA considers whether residual adverse effects of the Project on a given VC will overlap spatially and/or temporally with the same residual adverse effects on the VC resulting from other past, present, and reasonably foreseeable projects or activities (see Section 5.9).

5.6.1 Potential Interactions Between the Project and Valued Components/Key Indicators

This subsection within each VC-specific section identifies which Project activity potentially interacts with which VC/KI. Interactions are determined by providing Project information to third party experts who use their knowledge and experience to conduct a qualitative ranking. Interactions between the Project and VC consider feedback through engagement with Communities of Interest. Potential interactions in the summary table are ranked as:

- **Primary Interaction** (✓): Project activity is expected to interact with the VC/KI, which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.
- **Other Interaction** (✓)**:** Project activity is expected to interact with the VC/KI. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects.
- **No Interaction:** Project activity is not expected to interact with the VC/KI, no adverse effects are expected, and a rationale is provided for not considering this potential interaction further.

Potential interactions between key Project activities and the VCs are summarized by Project phase in Table 5.6-1 and Table 5.6-2, with a check mark with grey highlight (✓) indicating a primary interaction and a check mark (✓) indicating an 'other' interaction. No check mark means no interaction is anticipated. Each VC-specific section contains its own summary table relating to VCs and KIs.

Environmental monitoring			✓	✓		✓		✓	
Regulatory site inspections									
Engagement – site visit from Interested Parties									
Employment and expenditures[1]							✓	✓	✓

1 Project employment and expenditures are generated by most Project activities and components throughout the phases of the Project. Hence, Project employment and expenditures have been added into the table as a separate row for each Project phase instead of acknowledging these individually by component or activity.

2 Operational activities include maintenance.

5.6.2 Potential Project-related Effects

Based on the anticipated Project – VC/KI interactions, this section of each VC-specific assessment describes the potential Project-related effects (i.e., changes to the MPs that result from the Project), by Project phase. It provides an overview of what is known and understood about the potential effects of this type of Project and other similar projects on the VC/KI. This includes relevant information and findings from the literature; input from IK, LK, and engagement; reported monitoring results of other similar projects; and/or professional knowledge and experience. In short, this section presents what is known about whether and how the Project is expected to affect the VC/KI.

5.7 Mitigation Measures

Mitigation in this EA is defined as the elimination, reduction, or control of the adverse effects of the Project and includes restitution for any damage to the VC caused by such effects through replacement, reclamation, compensation, or any other means. Mitigation measures refer to Project-specific mitigation and can include, but are not limited to, engineering design features and responses, best management practices, management plans, emergency response programs, and training. The rationale for and effectiveness of the proposed mitigation measures are discussed, as appropriate, and evaluated. Available data, survey and study results, and detailed mitigation measures that demonstrate a particular emphasis on avoidance of effects are included here. From there, and with this base of general mitigation and optimization in place, the assessment identifies and proposes additional VC-specific mitigation measures as required and appropriate.

Following identification of potential effects for each VC/KI, a pragmatic and transparent approach was taken to describe mitigation measures to either avoid or minimize effects, including:

- project design options;
- best management practices;
- environment, health and safety management plans, programs, and procedures;
- employee training programs and procedures;
- emergency response programs and procedures; and
- compensation, where appropriate and discussed with Denison.

5.8 Residual Effects Evaluation

The residual effects evaluation in each VC-specific section describes the likely residual effects of the Project on the VC/KI. Residual effects are effects that remain after the implementation of all mitigation measures and management plans and are the expected consequences of the Project on the VC and, where applicable, KI. For each KI of the VC, each residual effect is assessed in the context of the Project activities that will occur within each Project phase. Each residual effect is then characterized based on the combined predicted residual effect for all Project phases.

5.8.1 Definitions for Residual Effects Characterization and Significance

5.8.1.1 Residual Effects Characteristics

Table 5.8-1 summarizes the criteria used for characterizing residual effects, although the specific definitions and ratings for some characteristics may be developed on a VC-specific basis and presented in each VC-specific section.

Table 5.8-1: Effect Characteristics Considered When Evaluating Residual Effects for each Valued Component/Key Indicator

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Negative effect or effect is not desirable. **Positive** – Beneficial effect or effect is desirable.
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low** – Minimal amount of change relative to the range of existing variation. **Moderate** – Moderate amount of change relative to the range of existing variation. **High** – High amount of change relative to the range of existing variation.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area. **Local** – Effect is limited to the VC LSA. **Regional** – Effect extends beyond the VC LSA into the VC RSA. **Beyond Regional** – Effect extends beyond VC RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals. **Frequent** – Effect occurs many times on a regular basis. **Continuous** – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions. **Partially Reversible** – A residual effect that partially diminishes to baseline conditions. **Irreversible** – A residual effect that will not diminish to baseline conditions.
Context	Receptor VC - The extent to which the VC or KI has been affected by past and present environmental and socio-economic processes and conditions, its potential sensitivity to the Project-related residual effect, and its	**Low** – VC/KI has high resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a lack of historic and ongoing anthropogenic or natural disturbance. No listed species present. **Moderate** – VC/KI has moderate resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or an intermediate level of historic or ongoing anthropogenic or natural disturbance with the capacity to assimilate more change. Presence of listed species.

Residual Effect Characteristic	Definition	Rating
	ability to recover from that effect (i.e., resilience)	**High** – VC/KI has weak resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a high level of historic or ongoing anthropogenic or natural disturbance. Presence of SARA-listed species.
	Intermediate VC- describes how the residual effect evaluation is carried forward to significance determination for receptor VCs.	
Likelihood	Likelihood that the residual effect will occur including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

5.8.1.2 Significance and Confidence

5.8.1.2.1 Significance

Significant effects are those adverse effects that will cause a change in the VC/KI that will alter its status or integrity beyond an acceptable level. A residual effect that does not meet the aforementioned criteria is considered **not significant**. Significance definitions, based on this approach, are developed on a VC-specific basis, or on a KI-specific basis as applicable.

Significance is determined for receptor VCs that represent assessment endpoints (e.g., Fish Health; Ungulates, Furbearers, and Woodland Caribou). The results of the residual effects evaluation for intermediate VCs (i.e., Air Quality, Noise, Geology, Groundwater Quality, Groundwater Quantity, Surface Water Quantity, Surface Water Quality, and Sediment Quality) feed into receptor VCs and they do not have significance determinations of their own.

5.8.1.2.2 Confidence

In this EA, the precautionary approach to the evaluation of potential effects was adopted, recognizing areas of uncertainty and uses conservative assumptions and approaches within the assessment process. Areas of uncertainty in the process and in predictions for each VC are identified and discussed in each VC-specific section, or on a KI-specific basis as applicable.

Confidence predictions are defined as low, moderate, or high. Where a high degree of uncertainty regarding a residual adverse effect is evident, the confidence level may be low. A high level of confidence is assigned to predictions that have direct, site-specific quantitative data to support the predictions. Low or moderate degrees of uncertainty are manageable through monitoring and follow-up programs to confirm the absence, presence, and extent of residual adverse effects.

5.8.2 Residual Effects Evaluation

This subsection first provides an overview of the analytical methods used to conduct the EA for the VC/KI. It includes a general description of the information and methods that have been used to characterize the existing (baseline) conditions, as well as the manner that this information and the Project Description were used to predict the likely adverse effects of the Project on the VC (by KI and MP), using a combination of quantitative and qualitative methods, as appropriate.

The residual effects are described for each of the KIs by discussing how the Project is expected to change the MP, considering the mitigation measures discussed earlier in the VC-specific section. This discussion frames and informs the characterization of each residual effect (i.e., through change in the MP). Additional details are provided for each of the characteristics, augmenting the information related to the rationale provided for the ratings.

5.8.3 Summary of Project-related Residual Adverse Effects on the Valued Components

This part of each VC-specific section provides a summary of characterizations and significance of the residual effects on the KIs, to determine the significance of the resulting total effect on the receptor VC. The significance definition used for the residual effects on the KIs is also used for the prediction of significance of the effects on the receptor VC. Residual effects of the Project are summarized in Section 16 Assessment Summary and Conclusions. All residual effects, regardless of significance, are considered in the CEA (see Section 5.9).

5.9 Cumulative Effects

The CEA considers whether residual adverse effects of the Project on a given VC will overlap spatially and/or temporally with the same residual adverse effects on the VC resulting from other past, present, and reasonably foreseeable projects or activities. The CEA follows standard methodology as per provincial (e.g., *Guidelines for an Environmental Assessment* [Government of Saskatchewan 2022]) and federal guidance (e.g., *Assessing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012* [Government of Canada 2019a]). The methodology for the CEA is discussed in subsequent subsections. Cumulative effects are presented within each VC-specific section of the EIS and are summarized within Section 16.

5.9.1 Cumulative Effects Assessment Process

For residual effects to be considered in the CEA for the Project, the following criteria had to be met:

- potential exists for a residual adverse effect of the Project on a VC;
- the residual adverse effect can be demonstrated to act cumulatively with the residual adverse effects from other projects or activities on the same VC;
- other projects or activities must have been, or are expected to be, carried out in the reasonably foreseeable future; and,
- the cumulative effect is likely to occur.

The approach for assessing cumulative effects considers both the current conditions (which include changes caused by past development, projects, and activities, and are, therefore, considered in the baseline condition of the VC) and the identified reasonably foreseeable future projects and/or activities. The steps of the CEA for each VC are:

1. Determine the spatial boundaries for the CEA, which is VC specific, and typically the RSA for the VC.
2. Determine the project inclusion list of all other past, present, and reasonably foreseeable projects and/or activities that are expected to have adverse residual effects that extend into the VC RSA.
3. Consider all Project-related residual effects that were identified during the effects assessment for each VC, regardless of significance.
4. Identify the potential for interaction (i.e., must overlap spatially and temporally) of the Project-related residual effects with those of other projects and activities identified in Step 2 above.
5. Identify and describe the cumulative effects, and if practical, identify technically and economically feasible mitigation measures (i.e., in addition to those already identified to mitigate potential Project effects) to avoid, reduce, or otherwise mitigate the predicted cumulative effects.
6. Qualitatively assess and evaluate (i.e., characterize) the cumulative effects with respect to the likely nature and degree of change from the existing (baseline) environment as a result of the Project's residual effects in combination with the residual effects of other relevant future projects and activities.
7. Determine the significance of the cumulative effect using characterization criteria as defined for the residual effects evaluation.

5.9.2 Identification of Present or Reasonably Foreseeable Projects and Activities

Projects and activities that are considered reasonably foreseeable and may be a source of residual effects that could interact with residual effects of the Project were identified through a literature review, database review (e.g., Saskatchewan – EA Projects), discussion with Indigenous groups, discussion with local communities and review by the EIS team and Denison. Projects and activities were included in the CEA based on the following criteria:

- projects or activities that have been built or conducted for which the residual effects overlap spatially and temporally with those of the Project and are expected to continue (i.e., they are certain); and
- projects that are either proposed (e.g., are in the publicly available review process) or have been approved to be built, but are not yet built, for which the residual effects overlap spatially and temporally with those of the Project (i.e., they are reasonably foreseeable).

A preliminary list of projects and activities for potential consideration in the VC-specific CEA for the Project are listed in Table 5.9-1. Their general locations and boundaries (where available) are shown in Figure 5.9-1. The inclusion list generally includes:

- exploration and mining activities;
- Indigenous and other land use activities;
- lodges/outfitters and tourist/recreational activities;
- infrastructure use and maintenance activities; and
- others, as appropriate.

A subset of these projects and activities were assessed for each VC, subject to their overlap with the residual Project effects on each VC within the cumulative effects study area, which is typically based on the RSA for each VC. The projects and activities expected to have residual effects that overlap with the residual effects of the Project for each VC are described in the respective VC-specific sections in Parts II and III of this EIS. Note that the projects and activities listed in Table 5.9-1 include those presented in the main Map Area of Figure 5.9-1, which does not include the entire RSA for the Human Environment (i.e., Land and Resource Use, Quality of Life, and Economics) that is illustrated in the side bar of Figure 5.9-1. However, relevant projects and activities associated with VCs for the Human Environment have been assessed in Section 11, Section 12, and Section 13 of Part III of the EIS.

Table 5.9-1: Projects and Activities for Consideration in the Cumulative Effects Assessment for the Valued Components

Description	Project/Land Use Type	Activity
Cameco Key Lake Operation	Existing Mines and Mills	Exploration and mining activities
Cameco McArthur River Operation	Existing Mines and Mills	Exploration and mining activities
Cameco Cigar Lake Mine	Existing Mines and Mills	Exploration and mining activities
Courtenay Lake	Campground/Recreation Site	Tourist/recreational activities
Geikie River	Campground/Recreation Site	Tourist/recreational activities
Wollaston Lake (Hidden Bay)	Campground/Recreation Site	Tourist/recreational activities
Cree Lake Winter Road	Completed Road	Infrastructure use and maintenance activities
Davies Creek Bridge	Completed Road	Infrastructure use and maintenance activities
Fox Lake Road	Completed Road	Infrastructure use and maintenance activities
Key Lake Road	Completed Road	Infrastructure use and maintenance activities
MacFarlane Lake Winter Road	Completed Road	Infrastructure use and maintenance activities
Thin Creek Bridge	Completed Road	Infrastructure use and maintenance activities
Waterbury Lake Local Access Road	Completed Road	Infrastructure use and maintenance activities
Highway 914 All Weather Road	Future Road	Infrastructure use and maintenance activities
Beaver Lodge Fly-Inn Co. Ltd.	Outfitter	Lodges/outfitters
Broken Arrow Lodge	Outfitter	Lodges/outfitters
Costigan Lake Lodge	Outfitter	Lodges/outfitters

Description	Project/Land Use Type	Activity
Cree Lake Lodge	Outfitter	Lodges/outfitters
Johnson River Camp	Outfitter	Lodges/outfitters
Mawdsley Lake Fishing Lodge	Outfitter	Lodges/outfitters
Plaisted Camps	Outfitter	Lodges/outfitters
Wheeler River Lodge	Outfitter	Lodges/outfitters
Wilderness Family Outfitters	Outfitter	Lodges/outfitters
Pink Lake	Ecological Reserve (provincially designated protected area[1])	Tourist/recreational activities
Treaty #8	Indigenous Land/Treaty	Indigenous and other land use activities
Treaty #10	Indigenous Land/Treaty	Indigenous and other land use activities
Cree Lake I.R	Indigenous Land/Treaty	Indigenous and other land use activities
English River First Nation Barkwell Bay Reserve Land	Indigenous Land/Treaty	Indigenous and other land use activities
English River Haultain Lake I.R.	Indigenous Land/Treaty	Indigenous and other land use activities

1 No new industrial activities are permitted; continued use for Indigenous and recreational land use activities.

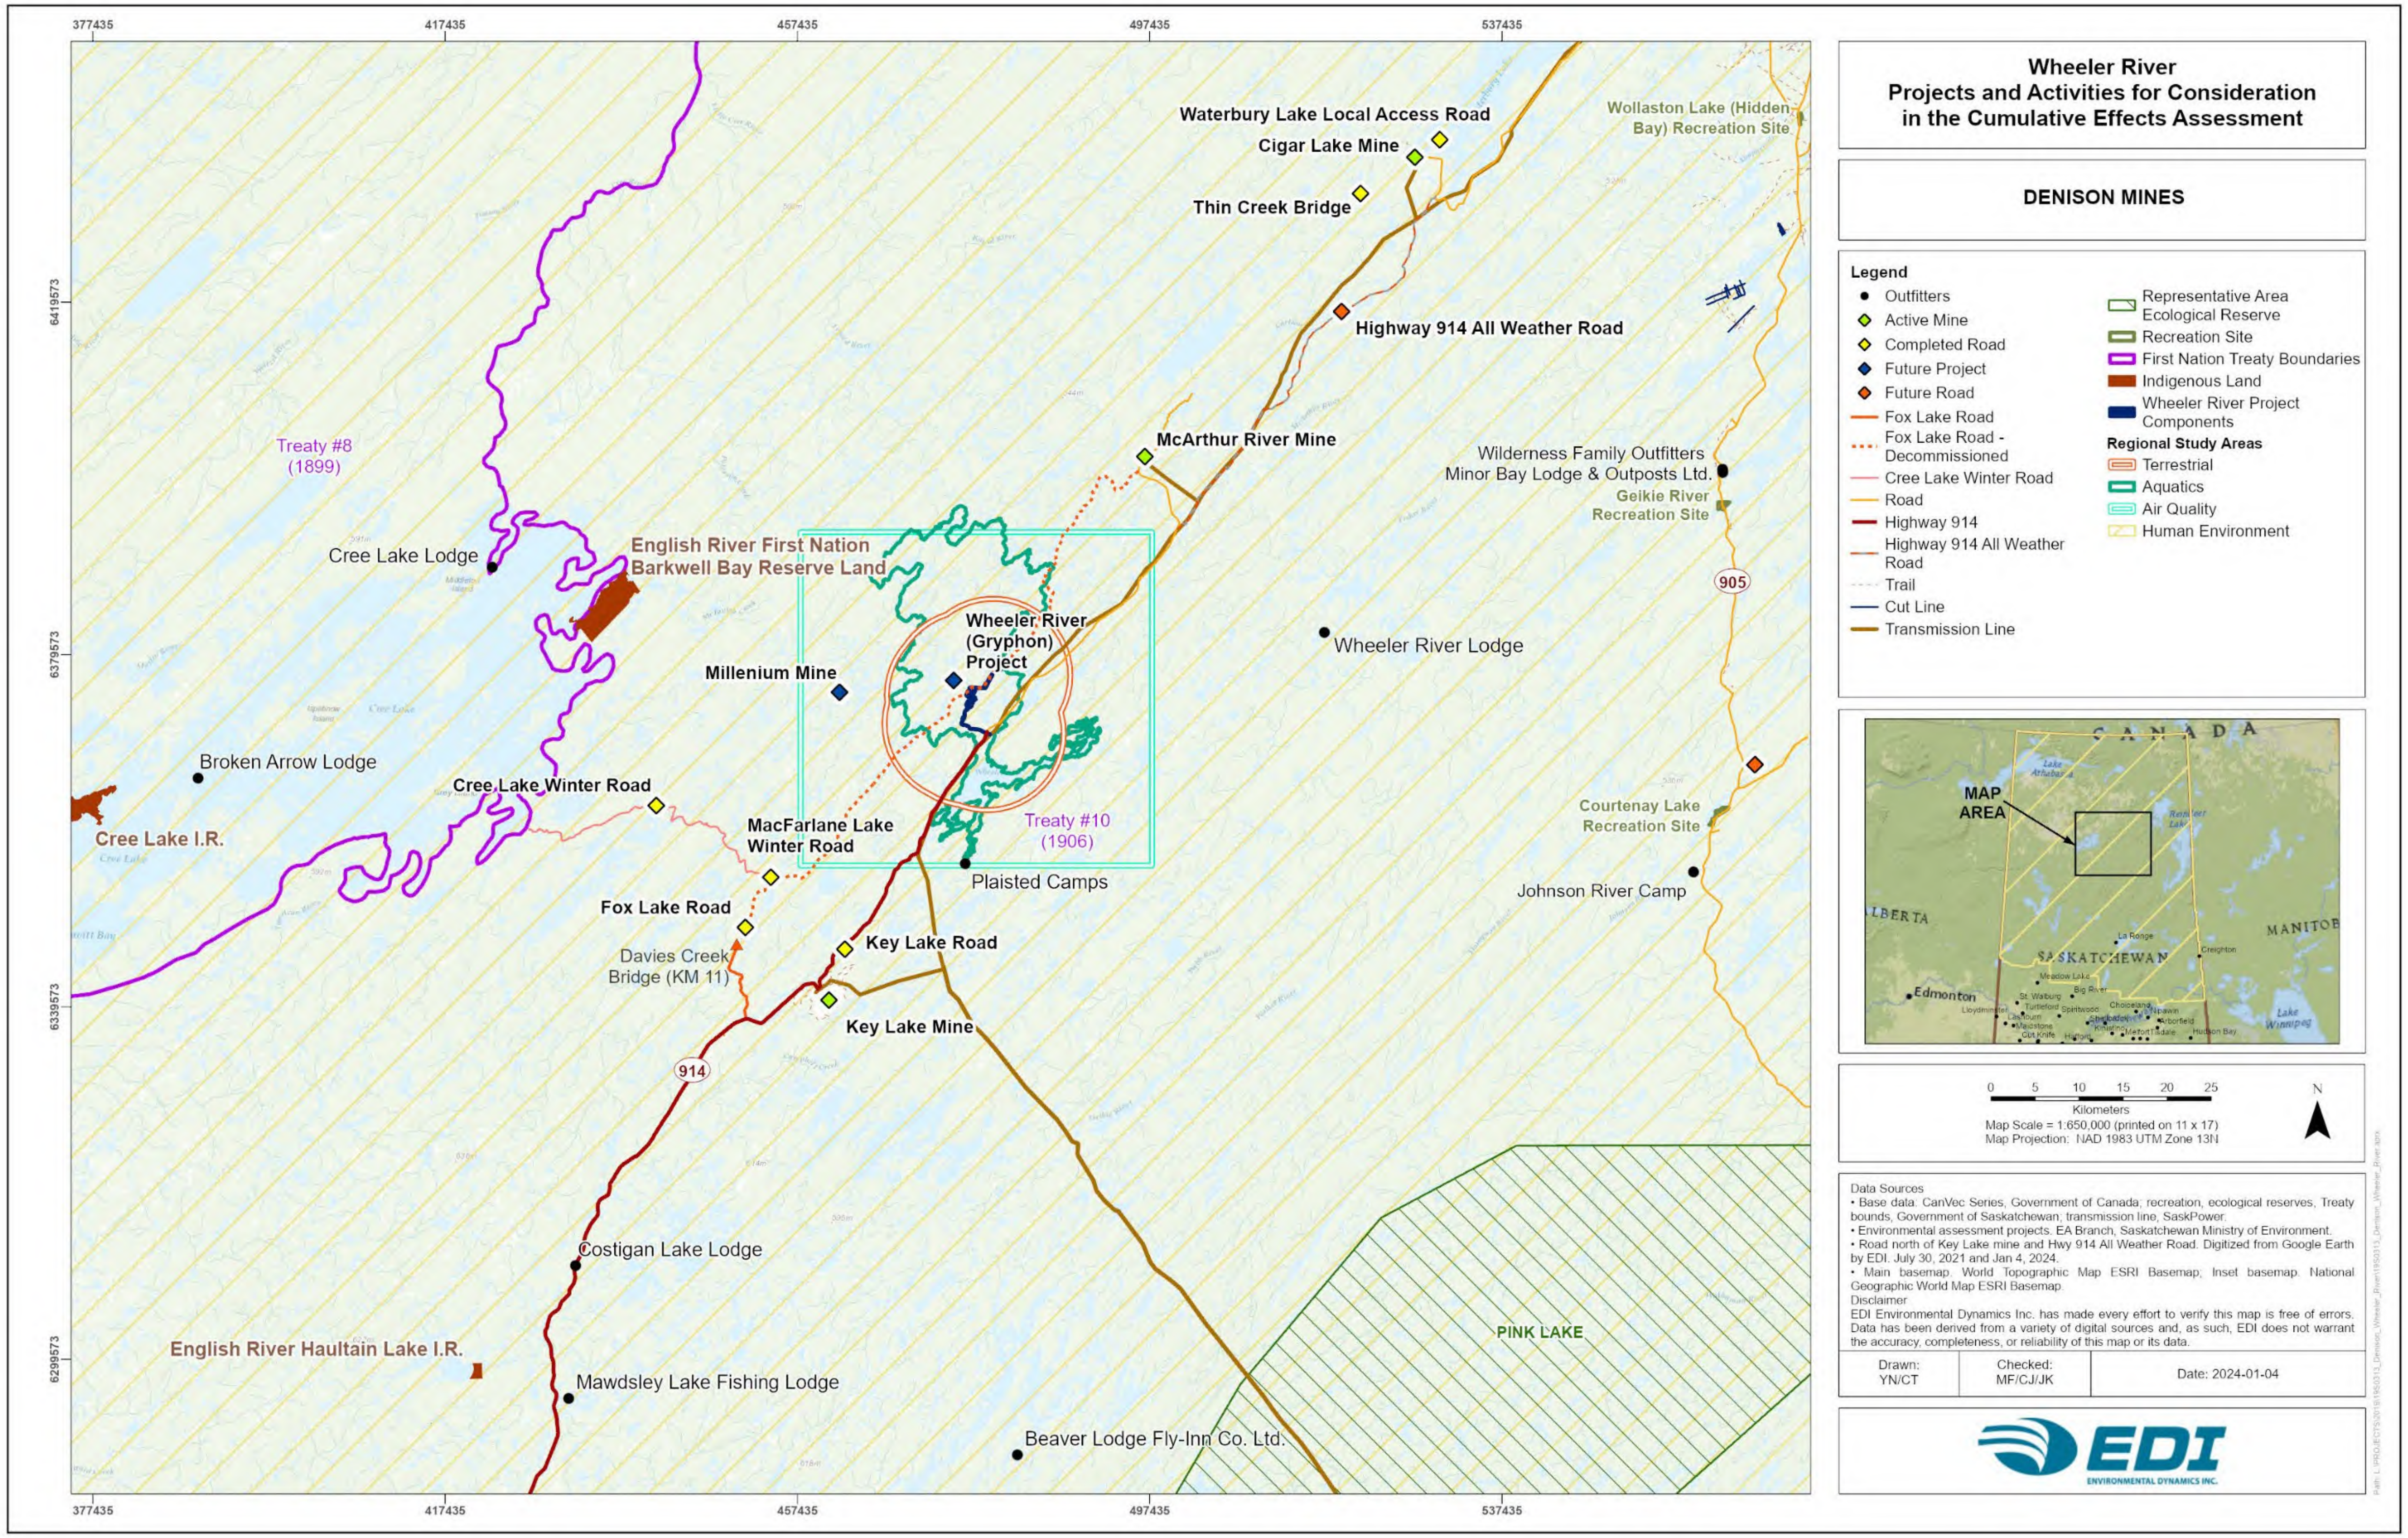

Figure 5.9-1: Projects and Activities for Consideration in the Cumulative Effects Assessment for the Valued Components

5.9.2.1 Description of Present or Reasonably Foreseeable Projects and Activities

According to the Canadian Environmental Assessment Agency's (CEAA's) Interim Technical Guidance (CEAA 2018), a future project (or physical activity) could be considered reasonably foreseeable based on the following criteria:

- The intent to proceed is officially announced by a proponent.
- The project or activity is under regulatory review (i.e., the application is in process).
- The submission for regulatory review is imminent.
- The project or activity is identified in a publicly available development plan that is approved or for which approval is anticipated (e.g., a wastewater treatment plant in a city's long term development plan).
- The physical activity supports—or is consistent with—the long-term economic or financial assumptions and engineering assumptions made for the project's planning purposes.
- A physical activity is required in order for the project to proceed (e.g., rail or port transportation facilities, or a transmission line).
- The economic feasibility of the project is contingent upon the future development.
- The completion of the project would facilitate or enable the future development.

Residual effects from the Project on a given VC have the potential to interact cumulatively with the residual effects from the present or reasonably foreseeable projects and/or activities on the same VC if they overlap spatially and temporally. The following provides a general description of the projects and/or activities presented in Table 5.9-1 and Figure 5.9-1 that have the potential to act cumulatively with the Project. These have been categorized by activity as well as by Project/land use type.

5.9.2.1.1 Exploration and Mining Activities

Historic anthropogenic disturbance such as seismic activity, drilling, and access creation in support of past exploration and mining activities, and future exploration activities have occurred within the Athabasca Basin since the 1940s when uranium was first discovered in the region. Uranium is the predominant ore most actively mined in this region because of the high-grade deposits that are present. The following provides a summary of the active operations that may be considered as part of the CEA.

Existing Mines and Mills

Cameco Key Lake Operation

The Key Lake site included two uranium ore bodies, Gaertner and Deilmann, discovered in 1975 and 1976. Mining was conducted between 1983 and 1997 and milling began in 1983. Since 2000, uranium ore is transported from the McArthur River Operation to Key Lake for milling. The mill is located approximately 570 kilometres north of Saskatoon, Saskatchewan. The Key Lake Operation is located 35 km southwest of the Project. The site is accessible by both aircraft and via Highway 914 (Cameco 2013). In 2018, sustained low uranium prices resulted in a decision to curtail production for the foreseeable future and place the operation into safe care and maintenance. On February 9, 2022, Cameco announced plans for the operation's gradual return to production.

Cameco McArthur River Operation

Cameco discovered the McArthur River ore body in 1988. Construction of the McArthur River Operation began in 1997, with mining beginning in 2000. The McArthur River Operation consists of an underground mine with underground production workings, an ore handling system, and surficial facilities. The ore is trucked to the Key Lake mill for processing and the tailings disposed of at the Deilmann pit tailings management facility. The McArthur River Operation is located 35 km northeast of the Project. The site is accessible by both aircraft and Highway 914. In 2018, sustained low uranium prices resulted in a decision to curtail production for the foreseeable future and place the operation into safe care and maintenance. On February 9, 2022, Cameco announced plans for the operation's gradual return to production.

Cigar Lake Mine

Commercial operation of Cameco's Cigar Lake Mine began in May 2015. Infrastructure at this mine includes an underground mine with ore processing and load out, surficial facilities, as well as a freezing plant and associated freeze pads. The ore from the mine is processed at the McClean Lake mill operated by Orano. The Cigar Lake Mine is located 85 km northeast of the Project.

5.9.2.1.2 Infrastructure Use and Maintenance Activities

Completed Roads

Existing infrastructure considered as part of the CEA include the Highway 914, as well as winter roads (e.g., Cree Lake Winter Road, Fox Lake Road, MacFarlane Lake Winter Road), mine access and haul roads (e.g., Key Lake Road), as well as exploration roads and trails (e.g., Waterbury Lake Local Access Road). It is anticipated that these will be continuously used during the lifetime of the Project and may require varying levels of maintenance. Maintenance activities may include vegetation management for safety and line-of-sight, road grading and gravelling, improvement of surface water management infrastructure (e.g., culvert replacement and recontouring of ditches and drainages), and other repairs.

Future Roads

Highway 914 Extension (All Weather Road)

Highway 914 is presently gated at the Key Lake Operation, which restricts public access to the northeast. The Ministry of Highways and Infrastructure proposes to extend Highway 914 by approximately 51 km (Stantec 2021). The extension is between a point on the existing road near the Cameco McArthur River Operation and Highway 905, approximately 8 km southeast of the

Cameco Cigar Lake mine site. This project also includes a 13.5 km bypass around the McArthur River mine surface lease. Development of the highway extension would provide a secondary route for vehicles travelling to and from the north (with the current access provided by Highway 905). The extension would also provide an efficient travel route for traffic to access mines and exploration sites operated by industry stakeholders in northern Saskatchewan. The EIS for the proposed extension was submitted to the Saskatchewan Environmental Assessment Branch in 2021 (Stantec 2021); construction of the extension has not started but this project was included in the CEA as being reasonably foreseeable.

5.9.2.1.3 Lodges/Outfitters and Tourist/Recreational Activities

Lodges and Outfitter Camps

The majority of hunting and/or fishing lodges and/or camps located near the Project in northern Saskatchewan are fly-in establishments only, whereas the Johnson River Camp, Mawdsley Lake Fishing Lodge, and Thompson's Resort are accessible by road. Some outfitters offer moose and/or bear hunting. Sport fish such as Northern Pike, Walleye, and Lake Trout are most commonly sought after by anglers at all locations.

Plaisted Camps and Wheeler River Lodge are located 15 km and 34 km, respectively, from the Project. Both outfitters are relatively small, with a main lodge for meals, and offering two to three smaller cabins as accommodation. The Plaisted Camp is a fishing only camp, whereas the Wheeler River Lodge offers fly-in fishing and guided bear hunting.

Campground and Recreational Sites

The Courtney Lake Recreational Site and Geikie River Recreational Site are located 85 km and 88 km, respectively, from the Project, with the Wollaston Lake (Hidden Bay) further away and north of the Geikie River site. These sites typically consist of day use areas, although Courtney Lake and Geikie River have amenities and facilities for overnight stays.

Ecological Reserves

The Pink Lake Representative Area Ecological Reserve is part of the Saskatchewan's Representative Areas Network that was launched in 1997 to conserve representative or unique examples of landscapes across Saskatchewan. The Pink Lake Ecological Reserve, located 75 km from the Project, is Saskatchewan's largest provincially-designated protected area of approximately 3,660 km^2. Although this ecological reserve is situated in relatively remote location, users may access the areas for recreational or other land use purposes.

5.9.2.1.4 *Indigenous and Other Land Use Activities*

The CEA has included consideration of numerous First Nations Reserves in proximity to the Project. Many of the closer reserve lands do not have permanent residences (e.g., ERFN Barkwell Bay). Refer to Section 5.9.3 for information on past, present, and predicted cumulative effects from ERFN and the Kineepik Métis Local #9 at Pinehouse.

5.9.2.2 Projects Deemed Not Reasonably Foreseeable

In addition to the projects listed in Table 5.9-1, two other mining projects located in proximity to the Project were also evaluated to see if they met the criteria to be considered reasonably foreseeable projects (as outlined in Section 5.9.2.1).

- **Cameco Millennium Mine:** Located approximately 15 km west of the Project, the Millennium Mine is a proposed underground uranium mine that is awaiting approval as part of a joint Federal-Provincial EA and approval process. Product from the Millennium mine will be transported to the Key Lake mill via a new haul road that will be constructed that will join with the McArthur River-Key Lake haul road. Construction was initially anticipated to begin in 2014; however, the timeline for project initiation has been pending corporate decision to proceed since 2012 (Cameco 2012). As part of the provincial-federal EA process and rigorous licensing process under the CNSC, a joint provincial-federal EIS was initiated in 2009 and the EIS was submitted in 2013. In December 2013, the Saskatchewan Minister of Environment provided Ministerial Approval for the project under Section 15(1)(a) of *The Environmental Assessment Act* (Government of Saskatchewan 2018). However, the federal part the EA and licensing was not completed. In May 2014, Cameco informed the CNSC that it did not wish to proceed with licensing of the Millennium Mine Project at that time, due to current economic conditions (https://www.ceaa-acee.gc.ca/050/evaluations/document/99381). If, at a later date, Cameco requests the CNSC to consider the application for a licence for the Millennium Mine, the EA will be re-opened and completed at that time.
- **Wheeler River (Gryphon) Project:** Future development of the Gryphon deposit is proposed as an underground mining operation, using a conventional long hole mining approach with processing of ore off site at the McClean Lake mill. Development of the Gryphon deposit as an underground mine was evaluated at the prefeasibility level in 2018, but has not advanced to feasibility study or EA. Denison has not announced an intent to proceed with the development of the Gryphon deposit.

Based on the information available, neither the Millennium mine nor the mining of the Gryphon deposit are reasonably foreseeable based on the CEAA's Interim Technical Guidance (CEAA 2018).

5.9.3 Lands Taken From an Indigenous Perspective

Cumulative effects assessment is important to Indigenous communities in general because incremental effects to the environment can weaken resource economies, affect important resources such as plants, fish, and wildlife, affect rights-based and cultural activities, and affect both the health of wildlife and humans (Indigenous Centre for Cumulative Effects 2021). Indigenous perspectives can be complementary to the CEA for the Project, and Denison acknowledges the important relationship of the Indigenous Communities of Interest to the lands and waters. The Indigenous Communities of Interest of ERFN and the Kineepik Métis Local #9 at Pinehouse (KML) have shared their Indigenous Knowledge on past, present, and predicted cumulative effects through the following sources:

- *Wheeler River Project – Summary of Health and Socio-Economic Study Results* (ERFN and SVS 2022a);
- *Wheeler River Project - Summary of Traditional Knowledge Study Results* (ERFN and SVS 2022b);
- *Kineepik Valued Ecosystem Components – KML Pre-statement for Denison EIS* (KML and NVP 2022); and
- *Response to the Environment Impact Assessment For the proposed Ministry of Highways 914 Extension Project* (KML and Limnos Environmental 2022).

These perspectives on cumulative effects have been summarized in Section 3.4.8 of Section 3. Denison and the Communities of Interest agreed on the high value of this contribution being part of the EIS.

5.9.4 Potential Cumulative Effects

For each VC, baseline conditions (as outlined in the EIS sections for the VC) represent past and present projects/activities including all associated disturbances. In addition to current disturbances, there is a likelihood of cumulative effects as a result of the residual Project effects (as identified in VC section of the EIS) overlapping with residual effects of a variety of reasonably foreseeable projects and activities in the VC-specific spatial boundaries for the CEA, typically the RSA.

For those projects that warranted additional consideration/analysis for a specific VC, the likely cumulative effects were described, and a qualitative assessment provided. All Project-related residual effects that were identified during the Project EA for each VC were considered and the potential for interaction of the Project-related residual effects with those residual effects of identified future projects and activities was described.

5.9.5 Additional Mitigation Measures

If applicable and appropriate, additional measures to mitigate the cumulative effects, in addition to Project-related mitigation measures outlined specifically for each VC, were described. Measures may include technically and economically feasible mitigation measures to avoid, reduce, or otherwise mitigate the predicted cumulative effects.

5.9.6 Cumulative Effects Characterization and Determination of Significance

Residual cumulative effects with respect to the likely nature and degree of change from the existing (baseline) environment, resulting from the Project's residual effects in combination with the residual effects of the identified future projects and activities, were qualitatively evaluated. The assessment was completed using the characterizations introduced in the residual effects assessment of Project effects on the VC (see Section 5.8.1) by Project Phase. In addition, significance and level of confidence of each cumulative effect were assessed using the characterization criteria as defined for the residual Project effects assessment (see Section 5.8.1).

5.9.7 Cumulative Effects Assessment Summary

A summary table of the overall results of the CEA is provided in Appendix 16-B of Section 16, including the additional mitigation measures to be implemented to eliminate, reduce, or control adverse cumulative effects that may occur due to interactions with other projects and activities as it relates to the VC.

5.9.8 Environmental Monitoring and Follow-up for Cumulative Effects

When applicable, VC-specific CEA sections contain a discussion of any proposed environmental monitoring and/or follow-up programs. Focusing on areas of identified uncertainty, the need for and scope of monitoring and follow-up programs as required were described to verify the accuracy of the cumulative effects predictions, and the value of proposed additional mitigation measures. Additional details on monitoring and follow-up are provided in Section 5.10.

5.9.9 Climate Change Considerations

Within the CEA of applicable VC-specific sections, a subsection has been included that provides a brief discussion on how climate change has been considered. Climate change has been included in the cumulative effects section because it is an external force that can influence the potential effects of the Project. For details on climate change in the context of the Project, please refer to Section 15 Effects of the Environment on the Project.

5.10 Monitoring and Follow-up

Each VC-specific section includes a discussion of any proposed monitoring and/or follow-up programs for each VC, by KI or MP as appropriate. Appendix 16-C of Section 16 provides a summary of monitoring and follow-up programs mentioned in the EIS.

For the purposes of this EIS, monitoring and follow-up are defined as follows:

- Monitoring programs are designed to meet regulatory requirements (e.g., permit or license conditions), and/or to demonstrate compliance with environmental commitments made in the EIS.
- Follow-up programs are those that are proposed to address any uncertainties identified during the EA process (e.g., to verify predictions made during the EA; determine the effectiveness of proposed and implemented mitigation measures) and to determine if and when to implement adaptive management measures.

Monitoring requirements will be directed by the provincial or federal regulators and as requested by Indigenous groups during the Project licensing process and will include requirements related to scheduling, sampling design, frequency, and reporting. Monitoring programs can include, as appropriate:

- objectives of the monitoring program and a schedule for collection of the monitoring data required to meet these objectives;
- sampling design, methodology, selection of the subjects and indicators to be monitored, and their selection criteria;
- frequency, duration, and geographic extent of monitoring, and justification for the extent;
- application of the principles of adaptive environmental management;
- reporting and response mechanisms, including criteria for initiating a response and procedures;
- approaches and methods for monitoring the cumulative effects of the Project with existing and future developments in the Project area;
- integration of monitoring results with other aspects of the Project including adjustments to operating procedures and refinement of mitigation measures;
- experience gained from previous and existing monitoring programs;
- advisory roles of independent experts, government agencies, communities, holders of IK and LK, and renewable resource users;
- procedures to assess the effectiveness of monitoring and follow-up programs, mitigation measures and recovery programs for areas disturbed by the Project; and
- information plans to describe the results of monitoring to Interested Parties.

Denison has committed to working with the regulators, Indigenous groups and other Interested Parties to finalize the details of many of the monitoring and follow-up programs outlined in this EIS. Additional information on this topic is included in each VC-specific section, when appropriate.

Denison continues to improve its approach based on experience gained in the construction and operation of various projects. If unforeseen adverse effects are identified during any of the monitoring or follow-up programs, Denison will, as per its ongoing adaptive management process, adjust the existing mitigation measures or, if necessary, develop new mitigation or other measures to address those effects. This could result in Denison refining or modifying the design and implementation of management plans, mitigation measures, and Project operations, with the final approach selected depending on the issue identified.

5.11 Valued Component Specific Summary

Each VC-specific section contains a final, brief summary written in plain language. This summary provides a high-level overview of the main points of the assessment, including potential residual and cumulative effects to the VC/KI from the Project and relevant mitigation, monitoring, and follow-up.

5.12 Accidents and Malfunctions Assessment

An assessment of potential accident and malfunction scenarios associated with the Project was undertaken and is detailed in Section 14 Accidents and Malfunctions of the EIS, as well as in the accidents and malfunctions Technical Supporting Document (see Appendix 14-A; Ecometrix 2022).

For the purpose of the assessment, accidents and malfunctions refer to events or conditions that are not part of any activity or normal operation of the Project as proposed by Denison. This is consistent with the definition of an accident as described in REGDOC-3.6 (CNSC 2022). The assessment was carried out in alignment with federal (CNSC 2020) and provincial (Government of Saskatchewan 2014a, 2014b) guidance, as well as recent EA practices in consideration of proposed uranium mining developments in the Athabasca Basin.

The objective of the assessment was to evaluate the potential effects to human health or the biophysical environment resulting from radiological and conventional accidents and malfunctions in consideration of proposed environmental protection measures. The assessment considered all Project phases focusing on the Project site, the Project site access road and specific off-site locations along the Project-related transportation route (i.e., provincial highway system) of interest to local Indigenous peoples.

The assessment of accidents and malfunctions employed a risk assessment approach to characterize the potential effects of non-routine events on human health and/or the biophysical environment. Residual effects (i.e., effects that cannot be mitigated) for accidents and malfunctions and transportation-related events were defined in terms of risk, which can be characterized based on the likelihood of the postulated event and the effect or severity of the potential effects on human health or the biophysical environment. The assessment involved initially identifying a comprehensive list of Project-specific hazard scenarios, which represent physical situations with the potential to harm human health or the biophysical environment. This initial list was then screened qualitatively based on likelihood and consequence to determine overall risk level using a risk matrix approach. Bounding scenarios were then selected from this initial list of hazard scenarios. The subsequent analysis focused on evaluating the hypothetical effects associated with each bounding scenario. A revised risk evaluation that considered the results of the detailed assessment was then completed for each bounding scenario.

5.13 Effects of the Environment on the Project

The environmental setting in which the Project is located can affect the design, construction, operation, and decommissioning of the Project. Section 15 provides information on the interaction of these environmental considerations with the Project. The potential effect on the Project is evaluated, activities sensitive to these potential effects are discussed, and the mitigation and contingency plans and designs are presented.

Several steps were taken to identify and evaluate potential effects of natural hazards on the Project:

- identifying and describing the existing environmental conditions relating to natural hazards that may affect the Project;
- describing the implications that a natural hazard may have on the performance and environmental consequences of the Project; and
- selecting appropriate mitigation measures to address reasonable risks through the adaptive management process.

A natural hazard is considered to have a potential effect on the Project if it could result in one or more of the following:

- modification to the Project design;
- harm to Project personnel or the public;
- substantial delay in construction (i.e., more than one season);
- interruption in the mining process (i.e., more than one week);
- damage to Project infrastructure;
- threat to public safety; and
- damage to infrastructure to the extent that repair is not economically or technically feasible.

Natural hazards that either affected Project design or have the potential to affect Project Construction, Operation, and Decommissioning include:

- seismic events (e.g., earthquakes);
- forest fires;
- extreme weather short-term events (i.e., major precipitation events and drought; atypically high or low temperatures; atypically high winds); and
- climate change (long-term changes).

Historical data and published literature were used to characterize the natural hazards that may affect the Project. Predictions were used to characterize potential changes associated with climate change.

Project design features and mitigation measures were described to inform how potential effects of the environment on the Project would be prevented, minimized, or managed. This approach demonstrates Denison's due diligence in identifying the potential risks from the environment to assist with the planning, design, construction, operation, monitoring, and eventual decommissioning of the Project to reduce overall adverse effects. As part of this process, the existing environmental setting and potential environmental conditions and scenarios that may collectively affect the Project were considered so that suitable and practical mitigation measures could be evaluated and implemented during the various phases of the Project.

5.14 Concordance Tables

Concordance tables linking the content of the EIS to specific regulatory requirements are provide in Appendix 1-A of Section 1.

Abbreviations, Acronyms and Units

Abbreviation / Acronym	Definition
AAQC	Ambient air quality criteria
AER	Alberta Energy Regulator
AERMOD	American Meteorological Society/Environmental Protection Agency Regulatory Model
ARM	Ambient Ratio Method
CAAQS	Canadian Ambient Air Quality Standards
CCME	Canadian Council of Ministers of the Environment
CLMC	Cigar Lake Mining Corporation
CNSC	Canadian Nuclear Safety Commission
CO	Carbon monoxide
CO_2	Carbon dioxide
COPC	Constituent of potential concern
EA	Environmental assessment
ECCC	Environment and Climate Change Canada
EIS	Environmental Impact Statement
HA	Highly annoyed
ISR	In situ recovery
KI	Key indicator
Ldn	day-night level
LSA	Local Study Area
MECP	Ministry of Environment, Conservation and Parks (Ontario)
MP	Measurable parameter
NO_2	Nitrogen dioxide
NO_x	Nitrogen oxide
$PM_{2.5}$	Respirable particulate matter
PM_{10}	Inhalable particulate matter
PSL	Permissible sound level
RCP	Representative concentration pathway
RSA	Regional Study Area
SAAQS	Saskatchewan Ambient Air Quality Standards
SO_2	Sulphur dioxide
TSP	Total suspended particulate
VC	Valued component
WRF-NMM	Weather Research Forecast Non-Hydrostatic Mesoscale Model

Units	Definition
°C	degrees Celsius
Bq/m^3	becquerels per cubic metre
d/y	days per year
dB	decibels
dBA	decibels A
ft	foot
h/y	hours per year
ha	hectare
kHz	kilohertz
km	kilometre
kW	kilowatt
m	metre
mg/cm^2/30-days	milligram per squared centimetre per 30 days
mm	millimetre
mSv	millisievert
MW	Megawatt
ppb	parts per billion
$\mu g/m^3$	microgram per cubic metre

Glossary

Term	Definition
A-weighted decibel (dBA), or A-weighting	"A-weighted decibels" are *decibels* that have been adjusted to approximate the relative sensitivity of the normal human ear to different frequencies (pitches) of sound. *Decibels* are direct measures of atmospheric pressure across a range of frequencies (low pitch to high pitch); however, the human hearing mechanism is not equally sensitive to all frequencies. Application of *A-weighting* reduces the contribution of sound at frequencies that humans are not particularly sensitive to (e.g., very low and very high pitches).
Ambient air	Ambient air is the natural state of the air at a particular time and place out of doors. Often used interchangeably with "outdoor air."
Ambient ratio method	The ambient ratio method is a method used to convert concentrations of nitrogen oxide (NOx) to nitrogen dioxide (NO_2). It uses an empirical NO_2/NOx ratio to estimate NO_2 concentrations.
AP-42	AP-42 is the United States Environmental Protection Agency's (US EPA) primary compilation of emission factors and supporting information for various air pollution source categories. It is collectively known as the "AP-42, Compilation of Air Pollutant Emission Factors".
CALMET	A diagnostic, three-dimensional meteorological model used in conjunction with CALPUFF.
CALPUFF	An advanced, three-dimensional, non-steady-state puff air quality dispersion model for assessing the transport of contaminants in the atmosphere.
Carbon monoxide (CO)	A colourless, odourless, tasteless, and flammable gas, produced by burning fuel, such as natural gas. It consists of one carbon atom and one oxygen atom.
Climate	The typical, long-term weather pattern of a geographical location or area (usually, 30 years).
Combustion	The act or instance of burning a fuel like natural gas to produce energy. For example, combustion is typically the process that powers automobile engines and power plant generators.
Concentration (Air)	With respect to air quality, it refers to the amount of a particular contaminant within a given volume of air. Typically, in units of micrograms per cubic meter ($\mu g/m^3$).
Constituent of potential concern	For air quality, a contaminant for which measurable concentrations in the atmosphere can be used to describe the condition or quality of the air.
Day-night level (L_{dn})	The "day-night sound level", or L_{dn}, is a 24-hour *energy equivalent sound level* in which the night-time sound levels (occurring between 22:00 and 07:00) have been adjusted by +10 dB, in order to account for people being generally more sensitive to sounds that occur at night.
Daytime sound level (Ld)	The "daytime sound level", or Ld, is the *energy equivalent sound level* calculated over the 15-hour period from 07:00 to 22:00.
Decibel (dB)	A "decibel" is used to describe the magnitude of *sound pressure levels* relative to the threshold of human hearing (20 µPa). A *sound pressure level* in decibels is defined as twenty times the (base 10) logarithm of the ratio of the sound pressure (P, in units of Pascals) to the reference pressure (Pr, being the threshold of human hearing, or 20 µPa). Expressed as an equation, $dB = 20\log(P/Pr)$.
Dispersion Model (Air)	A group of mathematical relationships used to simulate on a computer the transport, dispersion, transformation of contaminants emitted into the air.
Dustfall or Dust Deposition	The amount of dust particles or particulate matter in the air that falls to an area on the ground, primarily due to gravitational settling.

Term	Definition
Emission Factor	A mathematical relationship used to estimate of the release rate of a contaminant to the atmosphere by a given source.
Energy equivalent sound level	The "Energy equivalent sound level", or Leq, is the constant sound level which would result in exposure to the same total A-weighted energy as would the specified time-varying sound if the constant sound level persisted over an equal time interval.
Fugitive dust	Dust particles or particulate matter that are introduced into the air through open sources and not discharged through a confined air stream like an exhaust stack. Examples of fugitive dust sources include unpaved roads and stockpile wind erosion.
Gamma radiation	Penetrating electromagnetic radiation emitted from an atom's nucleus. Also called gamma rays.
High-Volume Air Sample (Hi-Vol)	An instrument used to measure the amount of particulate matter (TSP, PM_{10}, or $PM_{2.5}$) in ambient air.
Incremental concentration	The concentration of an air contaminant in the atmosphere above a baseline air concentration. Used to measure the contribution of a project to overall air quality.
Meteorology	The science of the atmosphere and its direct effects upon the Earth's surface. Meteorology is especially concerned with how atmospheric conditions affect the weather.
Night-time sound level (Ln)	The "night-time sound level", or Ln, is the *energy equivalent sound level* calculated over the 9-hour period from 22:00 to 07:00.
Nitrogen oxides (NOx)	A general term pertaining to compounds of nitric oxide (NO), nitrogen dioxide (NO_2) and other oxides of nitrogen. Nitrogen oxides are typically created during combustion processes and are major contributors to smog formation and acid deposition.
Nitrogen dioxide (NO_2)	A highly reactive gas having a characteristic reddish-brown colour and strong odour. The main anthropogenic (i.e., man-made) source of NO_2 is fossil fuel combustion. It consists of one nitrogen atom and two oxygen atoms.
Particulate matter of 10 microns or less (PM_{10})	Tiny subdivisions of solid particles suspended in the atmosphere, with diameters that are generally 10 micrometers or less. Also known as inhalable particulate matter.
Particulate matter of 2.5 microns or less ($PM_{2.5}$)	Tiny subdivisions of solid particles suspended in the atmosphere, with diameters that are generally 2.5 micrometers or less. Also known as respirable particulate matter.
Percent Highly Annoyed (%HA)	The "percent highly annoyed", or %HA, is a measure of the percentage of people in a community that are typically annoyed by sounds at given levels. The %HA value is calculated using the *day-night level*, using an equation that is based on a dose-response curve developed from socio-acoustic studies that related increasing community noise levels with an associated increasing percentage of the community that is reported to be 'highly annoyed' by the noise as it rises.
Permissible Sound Level (PSL)	The "Permissible sound level (PSL)" is a sound level limit adopted by the Alberta Energy Regulator (AER) for assessment of industrial noise. PSLs are defined for the daytime period (see "Daytime sound level (Ld)") and night-time period (see "Night-time sound level (Ln)") and are applicable at sensitive receptor locations. These are *energy equivalent sound levels* (see "Energy equivalent sound level (Leq)").
Radionuclide	A material with an unstable atomic nucleus that spontaneously decays or disintegrates, producing radiation. Nuclei are distinguished by their mass and atomic number.
Sound level	"Sound level" generally refers to an A-weighted *sound pressure level* (see "Sound pressure level" and "A-weighted decibel (dBA)").
Sound power level	"Sound power" is a measure of sound energy and is associated with a source of noise. Sound power quantifies the sound output produced by a source of noise (e.g., an engine), and is presented in units of decibels, using a standard reference power level of 10^{-12} Watts.

Term	Definition
Sound pressure level	“Sound pressure” is the instantaneous difference between the actual pressure and the barometric pressure at a given location (e.g., a dwelling). Sound pressure levels are typically expressed in *decibels*.
Sulphur dioxide (SO_2)	A strong smelling, colourless gas that is formed by the combustion of fossil fuels. SO_2 and other sulphur oxides also contribute to the problem of acid deposition. It consists of one sulphur atom and two oxygen atoms.
Total suspended particulate	Airborne particulate matter with an upper size limit of approximately 100 micrometers (µm) in diameter.
Weather Research Forecast Non-Hydrostatic Mesoscale Model (WRF-NMM)	WRF-NMM is a state-of-the-art numerical weather prediction model used for research and operational forecasting purposes.

6 Atmospheric and Acoustic Environment

Section 6 of the Environmental Impact Statement (EIS) for the Wheeler River Project (the Project) is focused on the Atmospheric and Acoustic Environment. The integrated biophysical and human environment assessment approach is illustrated in Figure 6-1. As a guide for EIS reviewers, Figure 6-2 provides a preview of the Valued Components (VC) associated with the assessments completed in this section of the EIS.

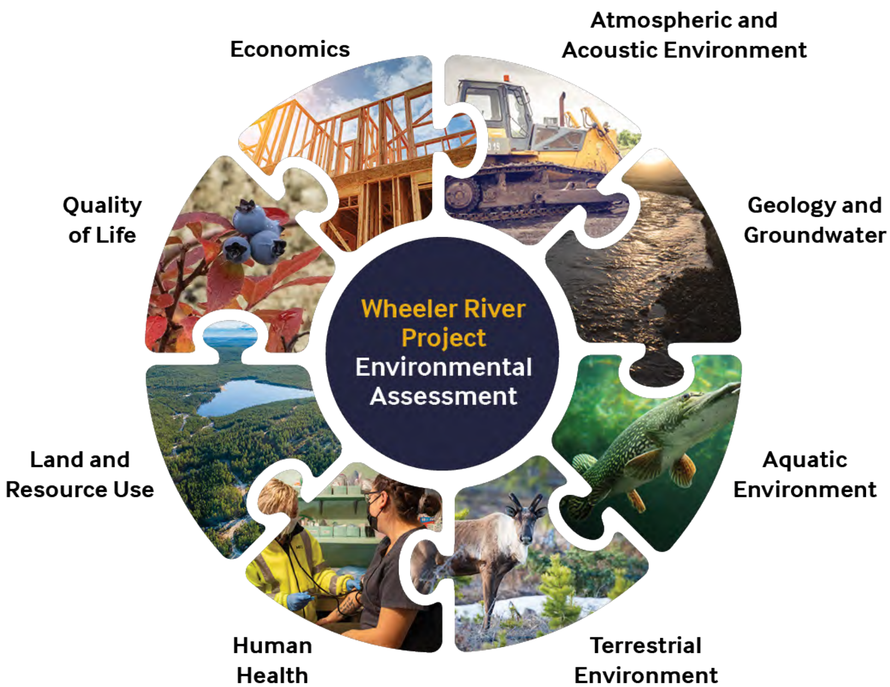

Figure 6-1: Biophysical and Human Environment Assessments for the Wheeler River Project Environmental Assessment

Figure 6-2: Atmospheric and Acoustic Environment - Valued Components

6.1 Air Quality

This section of the EIS addresses the potential for the Project to affect existing air quality in the vicinity of the Project Area. The Project will introduce new emissions sources to the area, which in turn will change the ambient air environment. Changes to the ambient air environment may affect Indigenous groups and the public. Existing air quality conditions in the Project Area have been established through field studies and a literature review, and predictions have been completed as part of this assessment using dispersion modelling to evaluate how the anticipated Project activities may change existing air quality conditions, and what the effect of these changes may be on people and the biophysical environment, such as soil and vegetation quality.

Air emission sources associated with the Project include unpaved road surfaces, site clearing and construction activities, fuel combustion (e.g., power generators, diesel-powered mobile equipment), wellfield and freeze hole drilling, operation of the in situ recovery (ISR) wellfield, operation of the ISR processing plant, and storage and disposal of drill waste rock and process precipitates. Potential effects related to air quality were identified using thresholds set by federal and provincial authorities pertaining to predicted concentrations in air of the identified constituents of potential concern (COPC). For instance, at the federal level, the Canadian Council of Ministers of the Environment (CCME) has developed the Canadian Ambient Air Quality Standards

(CAAQS), which have been adopted by Environment and Climate Change Canada (ECCC). Similarly, at the provincial level, the Government of Saskatchewan has developed a series of Saskatchewan Ambient Air Quality Standards (SAAQS) for application on industrial sites operating in the province.

This section of the EIS addresses potential Project-related effects on the Air Quality VC and is comprised of the following information:

- scope of the assessment;
- summary of existing conditions;
- identification and description of potential interactions between the Project and the Air Quality VC;
- identification and description of mitigation measures and monitoring activities to eliminate reduce, or control the potential adverse Project-related effects on the Air Quality VC;
- characterization of potential Project-related residual effects (i.e., after mitigation), including determination of significance and level of confidence in the predictions; and
- identification and characterization of cumulative effects.

Figure 6.1-1 is a graphic representation of the assessment process used in this EIS.

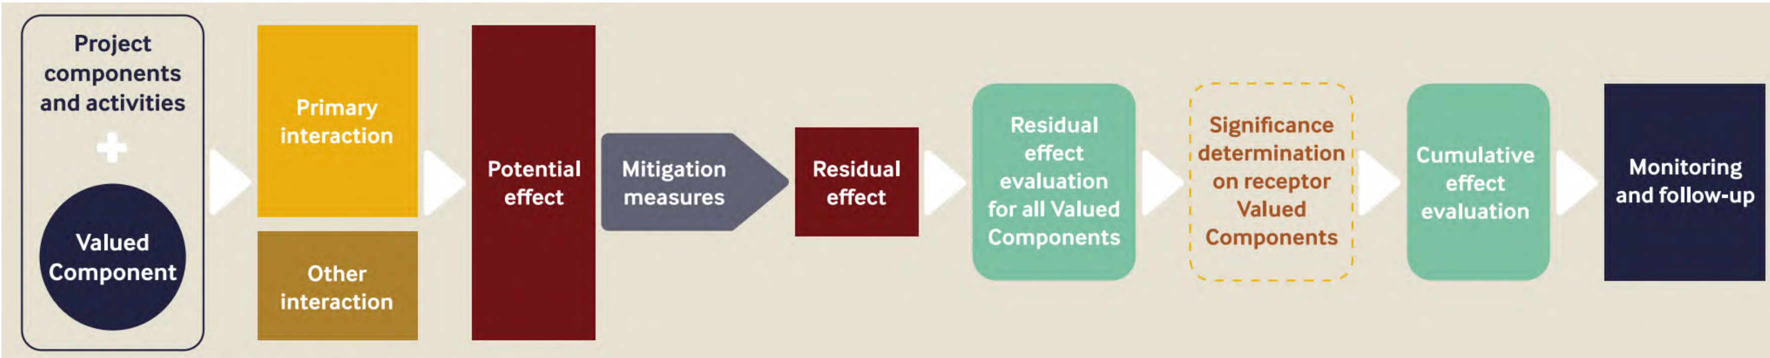

Figure 6.1-1: Environmental Assessment Process for the Wheeler River Project

6.1.1 Scope of the Assessment

6.1.1.1 Valued Component Selection

The process and rationale for the selection of VCs and establishment of Key Indicators (KIs) and associated measurable parameters (MPs) is described in Section 5 Approach and Methodology of the Assessment. Air Quality was selected as a VC based on the likelihood of Project-related activities to interact with and change the ambient air environment. Since changes to Air Quality could in turn lead to effects on other VCs selected for assessment Air Quality was identified as an intermediate VC (i.e., does not have an assessment endpoint). The significance of potential effects of Project-related changes to ambient air quality on the terrestrial environment, human health, and land use are discussed in Section 9 Terrestrial Environment, Section 10 Human Health, and Section 11 Land and Resource Use, respectively. Figure 6.1-2 is a graphic representation of the main linkages among the Air Quality VC and other VCs, illustrating the flow of assessment information from the Air Quality VC.

As stated in REGDOC-2.9.1 (CNSC 2016), Project-related emissions of radionuclide and non-radionuclide COPC to air pose a potential risk to human health and non-human biota receptors, and potential effects on ambient air quality should be assessed in the context of an EA. Indicators of effects on ambient air quality include air quality standards or criteria established by the CCME (CCME 2022) and the Government of Saskatchewan (Government of Saskatchewan 2014). The KIs and MPs derived to assist in the assessment of Air Quality are discussed in Section 6.1.1.2.

Due to the association of air quality with potential human health considerations, and the possibility of effects on the aquatic and terrestrial environments, Air Quality has been included as a VC in other EAs of similar scope that have been completed in the area. For example, the assessment of potential air quality effects associated with the Cameco Millennium Project are discussed in Annex L of the EIS document (Cameco 2013).

The Saskatchewan Ministry of Environment (SK MOE) has developed the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a) to assist proponents in conducting air dispersion modelling assessments in a consistent manner. The guideline defines the recommended approach for dispersion modelling assessments in Saskatchewan, including model selection, emission source characterization, and the determination of compliance criteria to apply. To assist in the quantification of emissions for this EIS, published emission factors and industry guidance documents were followed.

In addition to the regulatory requirement to include Air Quality as a VC in an EA, concerns relating to air quality were raised during engagement and consultation activities completed by Denison Mines Corp. (Denison). The concerns included the effects of the Project on Air Quality (19-EN-ERFN-140.27) and how the Project may affect the health of humans and wildlife (21-EN-ERFNSUR-456.21 and 21-EN-ERFNSUR-456.22). Significance determination is not completed on intermediate VCs, but integrated into the residual effect evaluation, residual effect characterization, and significance determination for related receptor VCs. As such, the discussion of Air Quality effects specific to the aquatic environment, terrestrial environment, and human health due to changes in Air Quality is part of the assessments included in Section 8, Section 9, and Section 10, respectively.

Figure 6.1-2: Integrated Assessment Approach - Key Connections between Air Quality and Other Valued Components

6.1.1.2 Key Indicators and Measurable Parameters

The KIs and associated MPs for the Air Quality VC are summarized in Table 6.1-1. The MPs are discussed further following the summary table.

Table 6.1-1: Key Indicators and Measurable Parameters for Air Quality

Key Indicator	Rationale for Key Indicator	Measurable Parameter
Levels of dust, combustion products, uranium, metals, and/or radon.	• Project activities will introduce new sources of air emissions to the area. • The existing air quality environment is characterized by low ambient levels of dustfall, NO_2, SO_2, and radon, and therefore susceptible to the introduction of new industrial air sources. • Air quality may be reduced, resulting in effects on the terrestrial environment and human health. • Air quality has been historically addressed for other mining projects in northern Saskatchewan.	Change in concentrations and deposition rates of total suspended particulate (TSP), inhalable particulate matter (PM_{10}), respirable particulate matter ($PM_{2.5}$), nitrogen dioxide (NO_2), sulphur dioxide (SO_2), carbon monoxide (CO), uranium, metals, acrolein and radon compared to the most appropriate air quality criteria.

The COPC identified for the Air Quality VC include total suspended particulate matter (TSP), inhalable particulate matter (PM_{10}), respirable (fine) particulate matter ($PM_{2.5}$), carbon monoxide (CO), sulphur dioxide (SO_2), nitrogen dioxide (NO_2), uranium, arsenic, cadmium, chromium, cobalt, copper, lead, molybdenum, nickel, selenium, vanadium, zinc, and radon gas. Acrolein emissions from diesel combustion were also evaluated using a quantitative screening analysis (detailed in Appendix 6-A) but were determined to be negligible and not considered a COPC. Emissions to air for each COPC were estimated and predictive modelling was used to estimate changes in COPC concentrations and deposition rates.

The primary source of emission factors that was used in the calculation of non-radiological COPC releases was the US EPA AP-42 database (US EPA 1995). Unpaved surfaces such as site roads are anticipated to be the main source of dust emissions from the Project, with a minor contribution from process emissions during Operation. Fuel combustion from mobile and stationary equipment is expected to be the main source of combustion gases from the Project, including CO, SO_2, and NO_2. The main sources of uranium and radon are related Operation and include the ISR processing plant and operation of the ISR wellfield, respectively. Emissions of radiological COPC were estimated using guidance from the United States Nuclear Regulatory Commission (US NRC 2003) and available engineering data for the Project. A detailed discussion of the methods applied to derive the emission rates for use in this assessment are provided in Appendix 6-A.

Except for radon, model predictions of COPC concentrations and depositions were added to background levels and compared to ambient air quality standards and criteria where available. The standards and criteria applied in this assessment are discussed in the following sections. Where federal and provincial criteria differed, the most stringent standards and criteria were adopted for the assessment of Project-related effects. The discussion of background levels is provided in Section 6.1.3.

6.1.1.2.1 Federal Assessment Criteria

The Project will be expected to demonstrate compliance with the CCME CAAQS (CCME 2022), which include the COPC of $PM_{2.5}$, SO_2, and NO_2. The CAAQS are presented in terms of the averaging period they are applicable to, and the values decrease in future years to reflect emission reduction targets. The CAAQS are presented in Table 6.1-2.

Table 6.1-2: Canadian Ambient Air Quality Standards

Constituents of Potential Concern	Averaging Time	Numerical Value		
		2015	2020	2025
Fine particulate matter ($PM_{2.5}$)	24-hour [1]	28 µg/m^3	27 µg/m^3	-
	Annual [2]	10 µg/m^3	8.8 µg/m^3	-
Sulphur dioxide (SO_2)	1-hour [3]	-	183.4 µg/m^3 (70 ppb)	170.3 µg/m^3 (65 ppb)
	Annual [4]	-	13.1 µg/m^3 (5 ppb)	10.5 µg/m^3 (4 ppb)
Nitrogen dioxide (NO_2)	1-hour [5]	-	112.8 µg/m^3 (60 ppb)	79 µg/m^3 (42 ppb)
	Annual [4]	-	32.0 µg/m^3 (17 ppb)	22.6 µg/m^3 (12 ppb)

Notes:

[1] 3-year average of the annual 98th percentile of the daily 24-hour average concentrations.

[2] 3-year average of the annual average of the daily 24-hour concentrations.

[3] 3-year average of the annual 99th percentile of the daily maximum 1-hour average concentrations.

[4] The average over a single year of all 1-hour average concentrations.

[5] 3-year average of the annual 98th percentile of the daily maximum 1-hour average concentrations.

6.1.1.2.2 Provincial Assessment Criteria

On June 1, 2015, the Government of Saskatchewan enacted the *Saskatchewan Environmental Code* (the Code; Government of Saskatchewan 2014) under *The Environmental Management and Protection Act, 2010* (Government of Saskatchewan 2018). The Industrial Source (Air Quality) Chapter of the Code provided updated provincial ambient air quality standards for TSP, NO_2, SO_2, and CO, and added standards for PM_{10}, and $PM_{2.5}$. The SAAQS applied in this assessment are presented in Table 6.1-3.

Table 6.1-3: Saskatchewan Ambient Air Quality Standards

Constituents of Potential Concern	Average Concentration for Applicable Time Period (µg/m³)			
	1-hour	8-hour	24-hour	Annual
Particulate matter ($PM_{2.5}$)	-		28[1]	10
Particulate matter (PM_{10})	-	-	50	-
Total suspended particulates (TSP)	-	-	100	60[2]
Nitrogen dioxide (NO_2)	300 (159 ppb)	-	200 (106 ppb)	45[3] (24 ppb)
Sulphur dioxide (SO_2)	450 (172 ppb)	-	125 (48 ppb)	20[3] (8 ppb)
Carbon monoxide (CO)	15,000 (13,000 ppb)	6,000 (5,000 ppb)	-	-

Notes:

1 3-year average of the annual 98th percentile of the daily 24-hour average concentrations.

2 Geometric means.

3 Arithmetic means.

While there are no SAAQS for dust deposition (i.e., dustfall), the *Air Monitoring Guideline for Saskatchewan* (SK MOE 2012b) provides a guideline level of 2 mg/cm^2/30-days, which was applied in the assessment.

6.1.1.2.3 Other Guidelines and Standards

Saskatchewan does not currently have published air quality standards or criteria that apply to uranium or other metals. As a result, criteria for these COPC were adopted from the Ontario ambient air quality criteria (AAQC) list, which is maintained by the Ontario Ministry of Environment, Conservation and Parks (Ontario MECP 2020). Notably, the Ontario AAQC for metals are based on a variety of time-averaging periods (e.g., 24-hour, annual). These AAQC are summarized with the applicable averaging periods in Table 6.1-4.

Table 6.1-4: Ontario Ambient Air Quality Criteria for Metals

Constituents of Potential Concern	Ontario Ambient Air Quality Criteria (µg/m³)		
	24-hour	30-day	Annual
Arsenic (As)	0.3	-	-
Cadmium (Cd)	0.025	-	0.005
Chromium (Cr) [1]	0.5	-	-
Cobalt (Co)	0.1	-	-
Copper (Cu)	50	-	-
Lead (Pb)	0.5	0.2	-
Molybdenum (Mo)	120	-	-
Nickel (Ni) as PM_{10} [2]	0.1	-	0.02
Nickel (Ni) as SPM [3]	0.2	-	0.04
Selenium (Se)	10	-	-
Uranium (U) in PM_{10} [2]	0.15	-	0.03
Uranium (U) in SPM [3]	0.3	-	0.06
Vanadium (Vn)	2	-	-
Zinc (Zn)	120	-	-

Notes:

1 Ambient air quality criteria is for metallic, divalent, and trivalent forms of chromium compounds.

2 PM_{10} = inhalable particulate matter.

3 SPM = suspended particulate matter, an equivalent term to total suspended particulates (TSP).

Historically, the Radiation Protection Regulations (CNSC 2000) from the Canadian Nuclear Safety Commission (CNSC) recommended a guideline value of 60 Bq/m^3 for incremental average annual radon concentrations. This guideline was derived from an action level of 600 Bq/m^3 corresponding to a dose of 10 mSv per year inside of a dwelling (ICRP 1993). This value was divided by 10 to arrive at a concentration of 60 Bq/m^3 corresponding to an annual effective dose of 1 mSv per year for a member of the public. In 2009, the International Commission on Radiological Protection revised its Statement on Radon (ICRP 2009) and changed the action level from 600 Bq/m^3 to 300 Bq/m^3. Using the same logic, a radon guideline of 30 Bq/m^3 was derived, which is within the range of background radon concentrations reported by the CNSC (CNSC 2018) in northern Saskatchewan (<7.4 to 25 Bq/m^3) and does not allow for additional exposure pathways. As a result, background radon concentrations were used instead of 60 Bq/m^3 as an indicator of the magnitude of predicted radon concentrations from the Project.

6.1.1.2.4 *Summary of Assessment Criteria*

A summary of the criteria applied in the Air Quality assessment is provided in Table 6.1-5. While many of the COPC criteria in Table 6.1-5 are health-based, they are intended to evaluate the potential effects of the Project on Air Quality and are not necessarily intended to assess potential risks to the aquatic environment, terrestrial environment, or human health. Instead, predicted COPC concentrations and deposition rates derived from the air dispersion model were used by the assessors in Sections 8, 9, and 10 to determine the potential effects of air COPC on the aquatic, terrestrial, and human environments, considering all pathways of exposure. Furthermore, refined dose estimates were completed by the assessors of human health and worker health using predictions of radon from the air dispersion model (see Section 10).

For simplicity and to facilitate a conservative assessment, a single criterion and time-averaging period were selected for each COPC based on the most stringent criteria or standard presented in the preceding sections. As per the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a), the Project criteria applied to the maximum predicted value for each time-averaging period at receptors located outside of the Property Boundary, after allowing for the removal of meteorological anomalies[1].

It should be noted that the Ontario criteria for uranium in PM_{10} were conservatively selected as the Project criteria. At this time, the particle size information for the main source of uranium emissions (the ISR plant stacks) is not known; however, the literature suggests that the particle size distribution for yellowcake is 80% less than PM_{10} (US EPA 1980).

Emissions of nitrogen oxides (NO_x) from combustion sources are comprised of nitric oxide (NO) and small amounts of NO_2. Over time, NO is converted to NO_2 through a series of chemical reactions in the atmosphere. Since the CAAQS and SAAQS are based on NO_2, a conversion must be applied to the NO_x predictions to estimate the NO_2 content. For this assessment, the Ambient Ratio Method (ARM), as described in the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a), was applied. The ARM assumes a default NO_2/NO_x conversion ratio of 70%. The SK MOE considers this method to be conservative for the estimation of NO_2 emissions.

[1] As per the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a), predicted concentrations at ground level can be high due to extreme, rare, and transient meteorological conditions. Thus, the eight highest 1-hour predictions and the single highest 24-hour prediction at each receptor can be discarded according to this method.

Table 6.1-5: Criteria for the Assessment of Potential Air Quality Effects

Constituents of Potential Concern	Averaging Period	Criteria	Units	Jurisdiction
Total suspended particulates (TSP)	24-hour	100	µg/m³	Saskatchewan
	Annual	60	µg/m³	Saskatchewan
Particulate matter (PM_{10})	24-hour	50	µg/m³	Saskatchewan
Particulate matter ($PM_{2.5}$)	24-hour	27	µg/m³	Federal
	Annual	8.8	µg/m³	Federal
Dustfall	30-day	2	mg/cm²/30-days	Saskatchewan
Carbon monoxide (CO)	1-hour	15,000	µg/m³	Saskatchewan
	8-hour	6,000	µg/m³	Saskatchewan
Sulphur dioxide (SO_2)	1-hour	170	µg/m³	Federal
	24-hour	125	µg/m³	Saskatchewan
	Annual	10	µg/m³	Federal
Nitrogen dioxide (NO_2)	1-hour	79	µg/m³	Federal
	24-hour	200	µg/m³	Saskatchewan
	Annual	23	µg/m³	Federal
Arsenic (As)	24-hour	0.3	µg/m³	Ontario
Cadmium (Cd)	24-hour	0.025	µg/m³	Ontario
	Annual	0.005	µg/m³	Ontario
Cobalt (Co)	24-hour	0.1	µg/m³	Ontario
Chromium (Cr)	24-hour	0.5	µg/m³	Ontario
Copper (Cu)	24-hour	50	µg/m³	Ontario
Molybdenum (Mo)	24-hour	120	µg/m³	Ontario
Nickel (Ni)	24-hour	0.2	µg/m³	Ontario
	Annual	0.04	µg/m³	Ontario
Lead (Pb)	24-hour	0.5	µg/m³	Ontario
	30-day	0.2	µg/m³	Ontario
Selenium (Se)	24-hour	10	µg/m³	Ontario
Uranium (in PM_{10})	24-hour	0.15	µg/m³	Ontario
	Annual	0.03	µg/m³	Ontario
Vanadium (Vn)	24-hour	2	µg/m³	Ontario

6.1.1.3 Spatial and Temporal Boundaries

The areas used to assess the effects of the Project on the Air Quality VC are shown on Figure 6.1-3 and in the following bullets:

- **Project Area**: the area within which the Project and all components/activities will be located (i.e., the area of maximum physical disturbance).
- **Air Quality Property Boundary (Property Boundary)**: the area within which there will be limited to no public access, and the air quality effects criteria will apply in accordance with the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a).
- **Air Quality Local Study Area (LSA)**: the area surrounding the Project Area where direct and indirect Project-related effects will be reasonably measured. The Air Quality LSA was generally established to assess the potential, largely direct effects of the Project on Air Quality, and represents the extent within which there is a reasonable potential for the Project to interact with and potentially adversely effect the Air Quality VC.

  The LSA for the Air Quality VC was delineated in consideration of the locations of sensitive land uses of interest for the assessors of other VCs (e.g., Human Health), and professional experience regarding potential air quality effects from mining operations. The Air Quality LSA includes lands within 10 km of the Project Area.
- **Air Quality Regional Study Area (RSA)**: the area surrounding the Air Quality LSA. The Air Quality RSA was established to assess the potential, largely indirect effects of the Project on Air Quality in a regional context. The Air Quality RSA is large enough to capture the extent of potential effects (i.e., zone of influence) on the Air Quality VC and defines the area within which cumulative effects may occur (i.e., cumulative effects assessment boundary). The Air Quality RSA was established 10 km from the Air Quality LSA based on proximity to other nearby projects that may have COPC that overlap with, and thereby interact cumulatively with, the effects of the Project on Air Quality.

Temporal boundaries in the context of the Air Quality assessment have a two-fold meaning. The assessment accounted for (1) time periods when an effect is expected to occur in relation to specific Project phases and activities, and (2) time periods that the prediction of Air Quality effects are applicable to. The latter is largely driven by the MPs identified in Table 6.1-1 and subsequent air quality criteria presented in Table 6.1-5. The time periods over which air dispersion model predictions apply include 1-hour, 24-hour, 30-day, and annual averaging periods. In keeping with these requirements, the Project assessment scenarios for Air Quality were evaluated in two parts:

- a short-term emissions inventory was developed for each scenario to capture the maximum 1-hour and 24-hour operating conditions and production rates for the various Project activities; and

- a long-term or annual emissions inventory was developed for each scenario to reflect the average operating conditions and production rates for the various Project activities.

Air dispersion modelling requires meteorological data as an input, which is also timebound. In accordance with the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a), a minimum of one year of site-specific meteorological data is required for dispersion modelling. For the assessment, a one-year meteorological dataset was created in consultation with SK MOE for the year 2016 and used to run the air dispersion model (detailed information on this process is provided in Appendix 6-A). The maximum predicted air concentrations for each time-averaging period were then extracted from the modelling results and compared to the applicable air quality criteria.

Regarding the overall timeline of the Project and the associated phases and activities, these were established in accordance with the summary provided in Table 5.3-3 in Section 5. This assessment included an evaluation of the Construction, Operation, and Decommissioning phases of the Project. The Post-Decommissioning phase consists generally of environmental monitoring. A detailed discussion of the assessment scenarios and the associated sources and emissions is provided in Appendix 6-A.

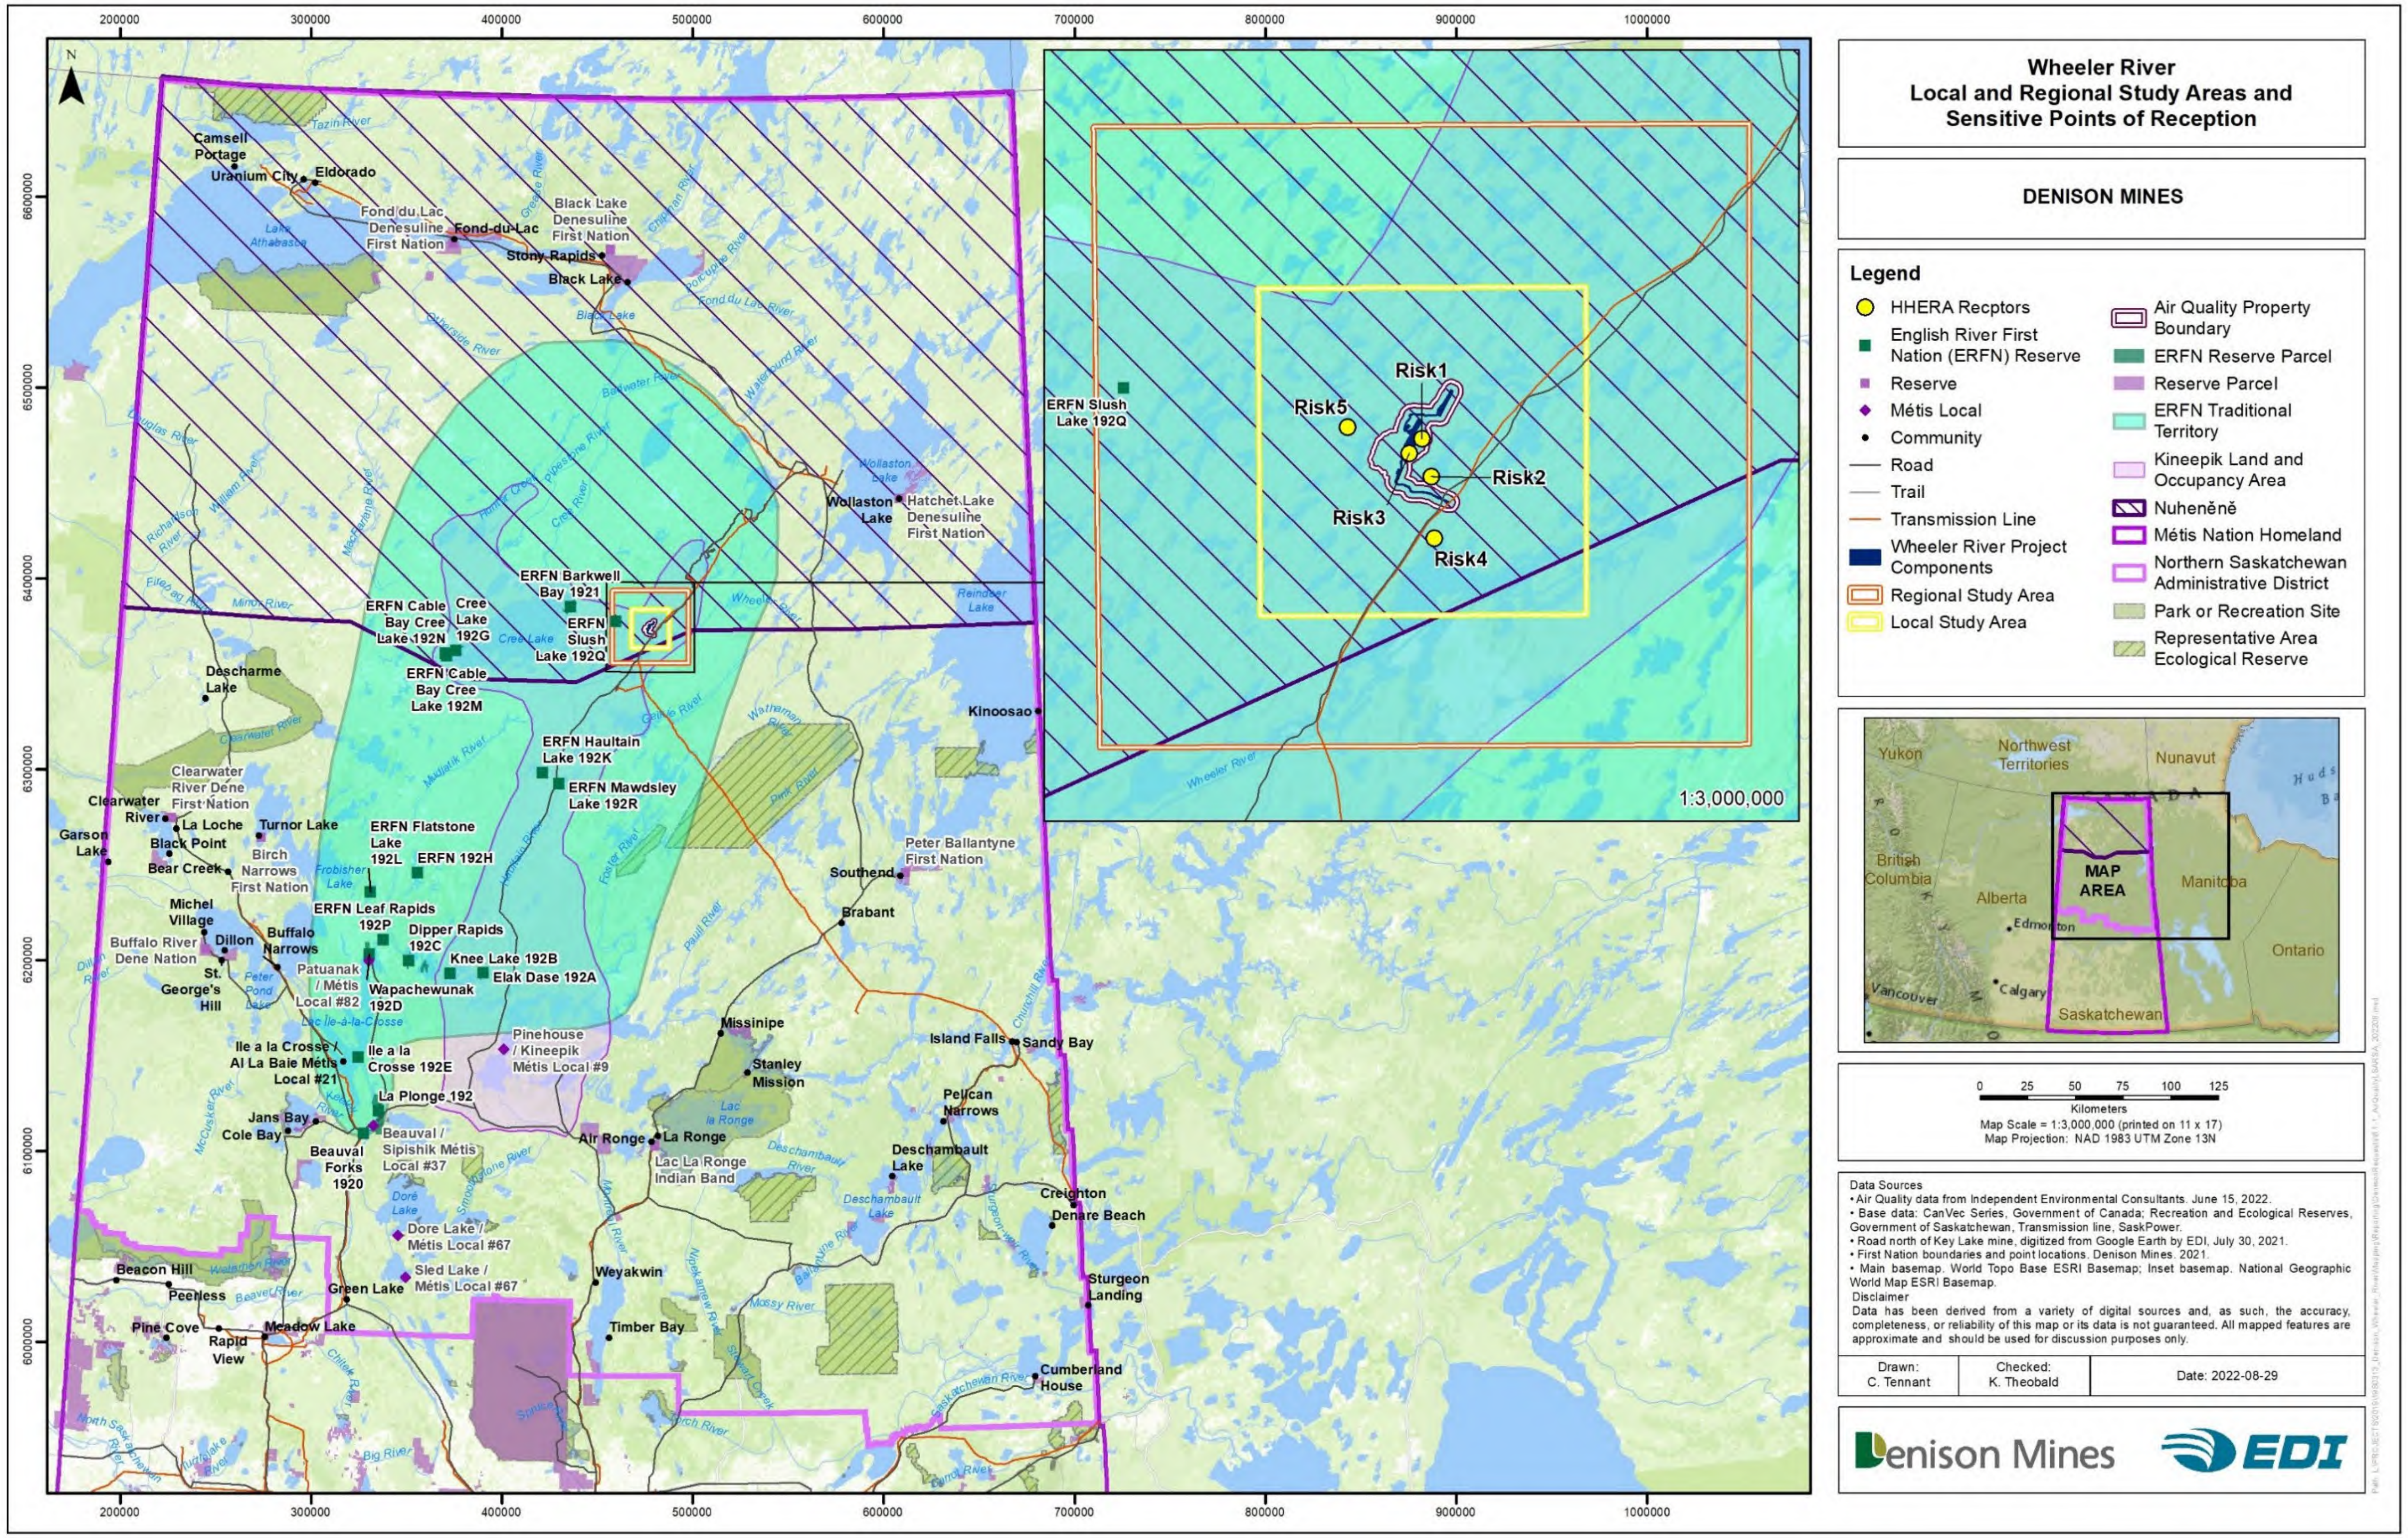

Figure 6.1-3: Local and Regional Study Areas and Sensitive Points of Reception for the Air Quality Valued Component

6.1.2 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

Lands within the study areas are currently being used, or have historically been used, for traditional purposes by the Indigenous communities that lay claim to the traditional territories that include the Project Area. These traditional uses include hunting, fishing, trapping, and harvesting of native plants for food and medicinal purposes. The process for selecting points of reception relating to air quality that represent these locations was primarily informed by local knowledge, as imparted to Denison in the form of traditional land use maps from the English River First Nation and Pinehouse Kineepik Métis, with permission to use this information in the EIS.

Denison has recorded and stored information regarding Indigenous Knowledge, Local Knowledge and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers (e.g., 21 EN-ERFNSUR-456.21). These numbers are referenced throughout the EIS, but particularly in Parts II and III, to indicate where specific information from the database has been integrated into the assessment. Appendix 6-B provides a summary of unique identification numbers referenced within Section 6.1.

During engagement activities, concern was raised regarding the effects of the Project on the health of humans and wildlife (21-EN-ERFNSUR-456.21 and 21-EN-ERFNSUR-456.22). Specific points of reception for the Human Health and Ecological Risk Assessment (Appendix 10-A in Section 10) and the worker health assessment were included in the predictive modelling. A map depicting the location of sensitive receptor locations used in the model is provided in Figure 6.1-3.

6.1.3 Existing Environment

6.1.3.1 Climate

The Project Area is located within the Athabasca Plain ecoregion of the Boreal Shield ecozone, specifically in the cold and snowy forest zone of northern Saskatchewan. The climate of the Project area is typical of the continental sub-arctic region as characterized by extremely cold, dry winters and brief, cool and moist summers.

The nearest Environment and Climate Change Canada (ECCC) meteorological station to the Project site is located approximately 32 km away at Key Lake. Data from this station were used to characterize the existing climate conditions for the period 2011 to 2020. ECCC also provides 30-year climate normals for Key Lake, with the 1981-2010 dataset being the most recently available. The following sections provide a brief overview of existing climate conditions. Additional details about the existing climate are provided in the Climate Baseline and Greenhouse Gas Emissions Report in Appendix 6-C.

6.1.3.1.1 Temperature

The annual average temperature at Key Lake for the 2011 to 2020 period was -2.6° Celsius (C) and the daily average temperatures were less than or equal to 0°C between October and April. The coldest month on average was January, with a daily mean temperature of -21.1°C, while July was the warmest month with a daily mean temperature of 16.4°C. Temperature data for the 2011 to 2020 period is comparable to 30-year climate normals. The average annual temperature for the 1981 to 2010 period was -2.3°C, with the warmest daily temperatures in July (16.3°C) and the coldest in January (-22.3°C).

6.1.3.1.2 Precipitation

The average annual amount of total precipitation recorded at Key Lake for the period of 2011 to 2020 was 456 mm, which is comparable to the climate normals data, which has an average annual total precipitation value of 483 mm. For the 2011 to 2020 period, the greatest amount precipitation in a 24-hour period was 45.9 mm, which fell as rain on August 8^{th}, 2020. For the climate normals, the maximum 24-hour precipitation event was 72 mm, which fell as rain on July 12^{th}, 1998. The average number of days with measurable precipitation for the 2011 to 2020 period was 132 days, compared to 149 days for the climate normals period.

6.1.3.1.3 Wind

Hourly wind data for Key Lake were analysed for the 2011 to 2020 period to determine the frequencies of wind direction and average wind speed. The results are presented as wind roses in Appendix 6-C. The wind roses show that wind blows predominantly from the west (about 10% of the time), followed by south and east directions. The average wind speed is approximately 3.5 m/s. Wind data are not available for the climate normals period for comparison.

6.1.3.2 Air Quality

In accordance with the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a), modelled concentrations of COPC must be added to ambient background concentrations before being compared to applicable air quality criteria. "Background" is defined by the SK MOE in the guideline as the "*portion of the ambient concentration due to both natural and anthropogenic sources, which are other than the source(s) being evaluated*" (SK MOE 2012a). Baseline air quality measurements completed by Denison and regional data available from the SK MOE and neighbouring uranium mines in northern Saskatchewan were used to characterize baseline air quality for the Project.

As per Table 6.1-1, the only KI associated with the Air Quality VC pertains to levels of dust, combustion products, uranium, metals, and/or radionuclides. Existing air quality in the vicinity of the Project Area was characterized via a baseline monitoring program, which commenced in 2016. Due to the remote nature of the Project site and no access to power for monitoring equipment, baseline air quality was measured using passive approaches. The SK MOE approves of passive monitoring methods at remote sites where access to power is not possible (SK MOE 2012b). The baseline monitoring program included particulate matter (in the form of dustfall), NO_2, SO_2, radon, and external gamma. The baseline monitoring locations are shown in Figure 6.1-4. Additional details on monitoring program design, including detailed equipment descriptions, are provided in the *Baseline Air Quality Monitoring Report* in Appendix 6-D.

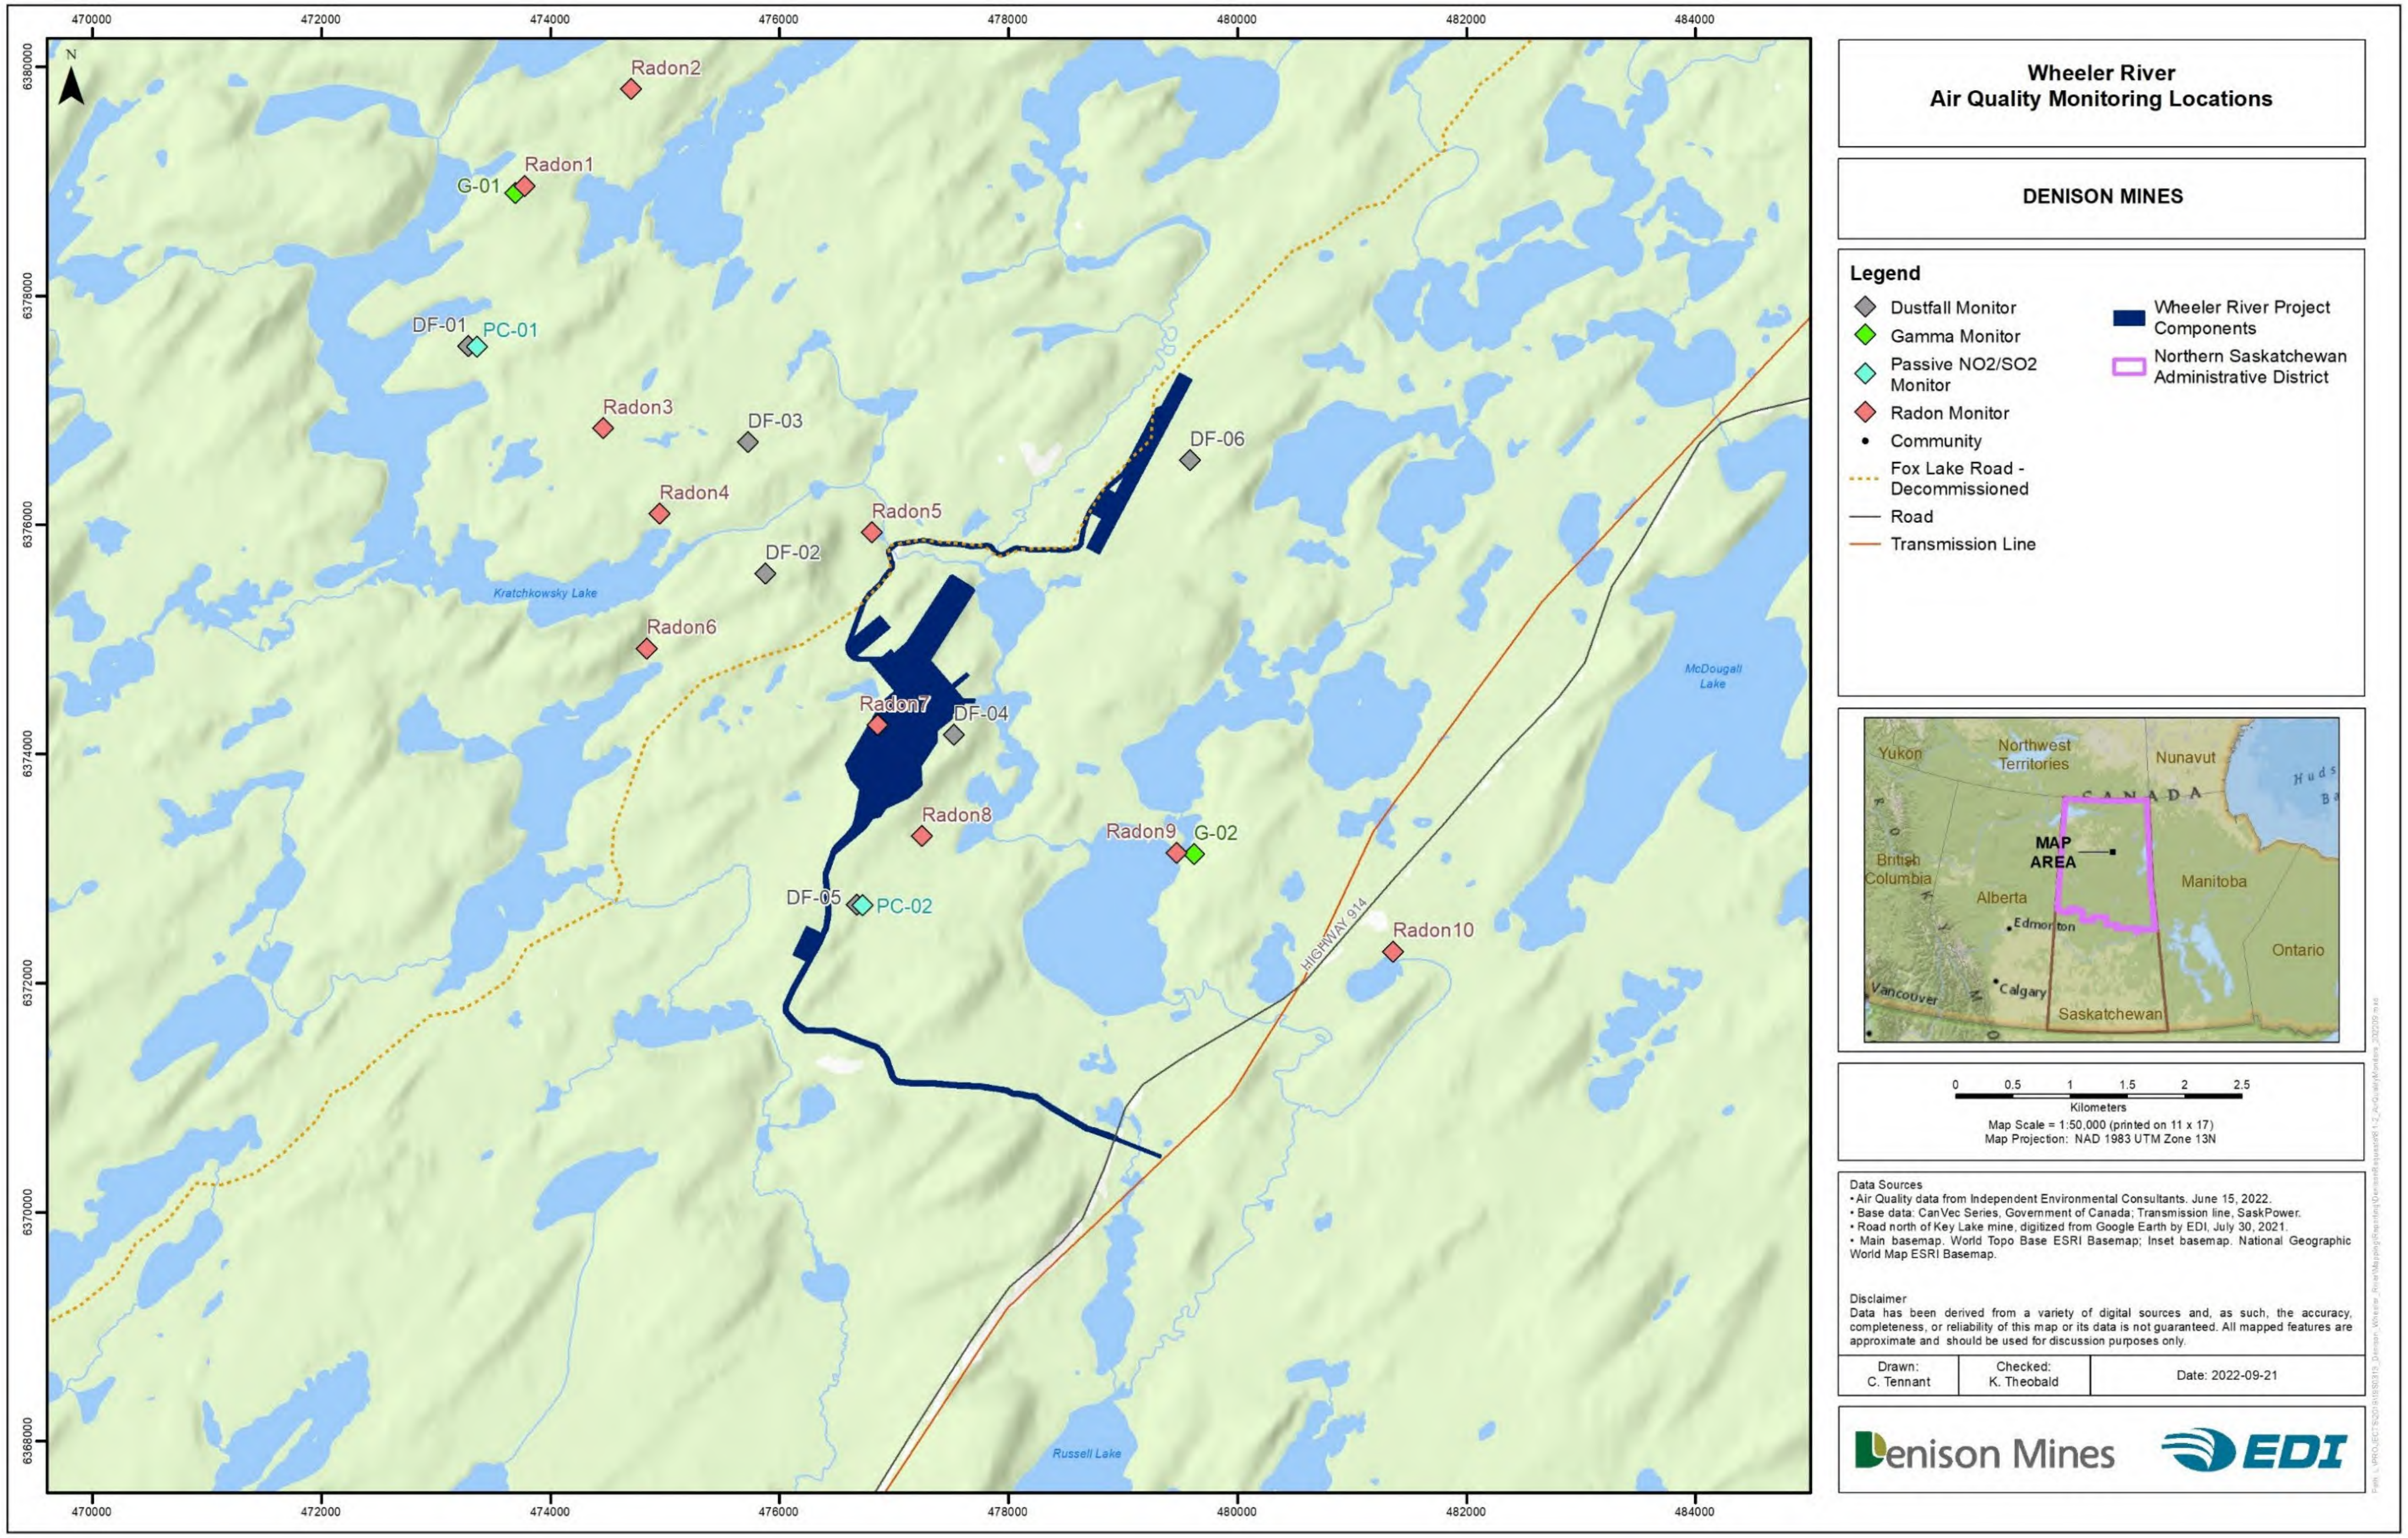

Figure 6.1-4: Air Quality Monitoring Locations

6.1.3.2.1 Particulate Matter

Particulate monitoring was included in the baseline monitoring program as settleable particulates (or dustfall), with measurements completed in accordance with ASTM Standard D1739:1998 (ASTM International 1998) and procedures from the British Columbia Environmental Lab Manual (BC MOE 2015). Dustfall monitoring commenced in 2018 and continued through 2021 for a total of nine campaigns, with samples being collected in duplicate at six locations (Figure 6.1-4).

As would be expected in a natural, undisturbed environment, the average and maximum levels of settleable particulates were well below the guideline of 2 mg/cm²/30-days from Table 6.1-5. The maximum dustfall amount from the various campaigns was 0.91 mg/cm²/30-days, which represents approximately 46% of the SK MOE guideline for settleable particulates. The average detectable dustfall across all locations and campaigns was 0.13 mg/cm³/30-days, or 6.5% of the guideline. A summary of the dustfall results is provided in Table 6.1-6.

Table 6.1-6: Summary of Total Dustfall Monitoring Results

Parameter	Unit	Monitoring Location					
		DF-01	DF-02	DF-03	DF-04	DF-05	DF-06
No. of samples	#	18	18	18	18	18	16
No. less than detection	#	9	7	10	5	6	5
Average detectable	mg/cm²/30-day	0.16	0.17	0.09	0.10	0.18	0.08
Maximum	mg/cm²/30-day	0.56	0.91	0.14	0.26	0.77	0.17
Minimum	mg/cm²/30-day	0.03	0.03	0.03	0.03	0.03	0.03
Average	mg/cm²/30-day	0.10	0.12	0.06	0.08	0.13	0.06

A metals analysis was completed on the dustfall samples collected during the September 2021 and October 2021 campaigns. Most of the metals included in the analysis were not present at detectable levels. The metals that were generally detectable in one or both campaigns included aluminum, barium, calcium, copper, iron, lead, magnesium, manganese, phosphorous, potassium, silicon, sodium, strontium, and uranium. A summary of the detectable metals included as air quality COPC, provided as a percentage by mass of fixed (i.e., insoluble) dustfall, is provided in Table 6.1-7.

Table 6.1-7: Detectable Metals as a Percentage of Fixed Dustfall

Constituents of Potential Concern	Average Composition (%)	Maximum Composition (%)
Arsenic (As)	0.0015	0.0015
Cadmium (Cd)	0.0006	0.0007
Chromium (Cr)	0.0012	0.0015
Cobalt (Co)	0.0057	0.0072
Copper (Cu)	0.0136	0.0359
Lead (Pb)	0.0013	0.0018
Molybdenum (Mo)	0.0058	0.0100
Nickel (Ni)	0.0057	0.0072
Selenium (Se)	0.0115	0.0145
Uranium (U)	0.0004	0.0012
Vanadium (Vn)	0.0115	0.0145
Zinc (Zn)	0.0420	0.0560

6.1.3.2.2 Nitrogen Dioxide and Sulphur Dioxide

Baseline concentrations of NO_2 and SO_2 were measured at two locations using passive samplers (Figure 6.1-4). The air concentrations represent the average concentration for the deployment period (typically around 30 days) and are not directly comparable to the criteria identified in Table 6.1-5. To facilitate a comparison of the measured levels to the criteria, a conservative approach to adjusting the averaging period from Section 9.1.1 of the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a) was applied to the data. It should be noted that the resulting concentrations still represent averages for the denoted period and should not be taken as maximum levels. The results in Table 6.1-8 (PC-01) and Table 6.1-9 (PC-02) show that average baseline levels of NO_2 and SO_2 are low and well below the applicable criteria, as would be expected for the remote location of the Project.

Table 6.1-8: Summary of Baseline Nitrogen Dioxide and Sulphur Dioxide Monitoring Results at PC-01

Parameter	Unit	Nitrogen Dioxide Concentration				Sulphur Dioxide Concentration			
		Period	Annual	24-hour	1-hour	Period	Annual	24-hour	1-hour
Measurement period	days	32	-	-	-	32	-	-	-
No. of samples	#	20	-	-	-	18	-	-	-
No. less than detection	#	18	-	-	-	10	-	-	-
Average detectable	µg/m³	0.28	0.15	0.76	1.8	0.33	0.17	0.88	2.1
Maximum detectable	µg/m³	0.38	0.19	0.99	2.4	0.52	0.27	1.4	3.4
Minimum	µg/m³	0.19	0.09	0.45	1.1	0.26	0.12	0.63	1.5
Weighted average	µg/m³	0.20	0.10	0.52	1.3	0.29	0.15	0.77	1.9

Table 6.1-9: Summary of Baseline Nitrogen Dioxide and Sulphur Dioxide Monitoring Results at PC-02

Parameter	Unit	Nitrogen Dioxide Concentration				Sulphur Dioxide Concentration			
		Period	Annual	24-hour	1-hour	Period	Annual	24-hour	1-hour
Measurement period	days	31.2	-	-	-	31.2	-	-	-
No. of samples	#	20	-	-	-	18	-	-	-
No. less than detection	#	18	-	-	-	17	-	-	-
Average detectable	µg/m³	0.28	0.13	0.67	1.6	0.52	0.27	1.4	3.5
Maximum detectable	µg/m³	0.38	0.17	0.90	2.2	0.79	0.39	2.1	5.0
Minimum	µg/m³	0.19	0.09	0.45	1.1	0.26	0.12	0.63	1.5
Weighted average	µg/m³	0.20	0.10	0.51	1.3	0.30	0.15	0.79	1.9

6.1.3.2.3 Radon

Monitoring of baseline radon levels, using alpha-track etch monitors, has been occurring at ten locations around the Project Area since 2016 (Figure 6.1-4). A statistical summary of the data collected at each location is provided in Table 6.1-10.

The maximum radon levels at the monitoring locations ranged from 9 Bq/m^3 at Radon 10 to 23 Bq/m^3 at Radon 6 and 7. Radon 6 and 7 are located towards the west side of the Project Area, between the Phoenix and Gryphon deposits, while Radon 10 is located furthest to the southeast of the Project Area, next to Highway 914. The *Regulatory Oversight Report for Uranium Mines and Mills in Canada* (CNSC 2018) states that the regional baseline in northern Saskatchewan is less than 7.4 Bq/m^3 to 25 Bq/m^3. All results from the baseline monitoring program are within this range.

Table 6.1-10: Summary of Baseline Radon Monitoring

Location	Number of Samples	Number Less Than Detection	Average Detectable (Bq/m^3)	Maximum Detectable (Bq/m^3)	Minimum (Bq/m^3)	Weighted Average (Bq/m^3)	Detectable Range (Bq/m^3)
Radon 1	26	17	4.8 ± 3.3	9 ± 3	< 3	5.0	0 to 13
Radon 2	26	17	4.7 ± 3.0	8 ± 3	< 3	4.8	0 to 11
Radon 3	32	17	4.6 ± 2.8	9 ± 3	< 2	4.6	0 to 12
Radon 4	31	17	3.9 ± 2.9	10 ± 3	< 3	4.4	0 to 13
Radon 5	30	13	5.1 ± 2.8	12 ± 4	< 3	5.2	0 to 15
Radon 6	32	18	5.9 ± 3.1	19 ± 4	< 3	5.1	0 to 23
Radon 7	32	18	6.2 ±3.1	19 ± 4	< 3	5.7	0 to 23
Radon 8	32	21	4.0 ± 3.2	5 ± 5	< 3	4.3	0 to 10
Radon 9	31	22	5.0 ± 3.1	9 ± 4	< 3	4.5	0 to 13
Radon 10	30	16	3.8 ± 2.8	6 ± 3	< 3	3.9	0 to 9

6.1.3.2.4 External Gamma

Long-term baseline gamma doses were assessed at two locations using Landauer InLight® optically stimulated luminescence dosimeters (Figure 6.1-4). Due to the nature of the dosimeters, sample collection involved several transit and deploy controls to calculate the final net gamma exposure results from the gross dose of the dosimeters deployed in the field. The adjustment from a gross dose to a net dose resulted in negative values in some instances. This indicates that the baseline gamma at the Project site is very low. The results of the baseline gamma monitoring are provided in Table 6.1-11.

Table 6.1-11: Summary of Baseline External Gamma Monitoring

Location ID	Start Date (YYYY-MM-DD)	End Date (YYYY-MM-DD)	Exposure Days	Exposure (mSv)	
				Gross	Net
G-01	2019-09-25	2019-11-14	50	0.252	0.008
	2020-07-25	2020-11-03	101	Destroyed in field by wildlife	
	2021-03-11	2021-06-08	89	0.469	-0.139
	2021-06-08	2021-09-21	105	0.31	-0.129
G-02	2019-09-26	2019-11-14	49	0.22	-0.024
	2020-07-24	2020-11-03	102	0.218	-0.098
	2021-02-17	2021-06-08	111	0.289	-0.06
	2021-06-08	2021-09-22	106	0.242	-0.197

6.1.3.2.5 Saskatchewan Ministry of Environment Regional Air Quality Data

The SK MOE has collected data from a series of monitoring stations that can be used to represent regional background air quality (SK MOE 2012a). Table 6.1-12 presents the available 1-hour, 24-hour, and annual regional background concentrations of PM_{10}, $PM_{2.5}$, CO, NO_2, and SO_2 for the northern air dispersion modelling zone. The SK MOE provides 99th and 90th percentiles of measured 1-hour or 24-hour concentrations; however, for refined assessments such as this one, the 90th percentile values should be considered. For COPC with annual standards, the 50th percentile should be used. Note that the SK MOE reports that the background concentrations of SO_2 are zero for all averaging periods.

No SK MOE regional background concentrations exist for TSP or annual PM_{10}. However, according to Brook et al. (1997), PM_{10} is on average close to 50% of TSP and $PM_{2.5}$ is approximately 50% of PM_{10}. Therefore, annual background concentrations for TSP and PM_{10} can be estimated by multiplying the SK MOE regional background concentration for annual $PM_{2.5}$ by four and two, respectively. Similarly, a background concentration for 24-hour TSP can be estimated by multiplying the SK MOE regional background concentration for 24-hour PM_{10} by two.

Table 6.1-12: Saskatchewan Ministry of Environment Regional Background Concentrations

Constituents of Potential Concern	Saskatchewan Ministry of Environment Regional Background (µg/m³)[1] (Northern Zone)			
	1-hour	8-hour	24-hour	Annual
Total suspended particulates (TSP)	-	-	46.2[2]	12.4[3]
Particulate matter (PM_{10})	-	-	23.1	6.2[3]
Particulate matter ($PM_{2.5}$)	-	-	6.5	3.1
Nitrogen dioxide (NO_2)	11.3	-	9.4	3.8
Sulphur dioxide (SO_2 [4])	0.0	-	0.0	0.0
Carbon monoxide (CO)	575	575	-	-

Notes:

1 From Table B-1 of the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a).

2 Calculated assuming 24-hour TSP = 2 x PM_{10}, as suggested by Brook et al. (1997).

3 Calculated assuming annual PM_{10} = 2 x $PM_{2.5}$ and TSP = 4 x $PM_{2.5}$, as suggested by Brook et al. (1997).

4 90th percentile regional background concentrations for SO_2 are reported as zero in the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a).

6.1.3.2.6 Reference Data from Other Operations

Cameco Corporation's Key Lake operation is located approximately 35 km south of the Project and monitors uranium, arsenic, and nickel using High Volume air samplers (Hi-Vols). Twenty-four-hour TSP samples are collected at five Hi-Vol stations located around the site on a one-in-six-day cycle, and a quarterly composite is used to analyze uranium, arsenic, and nickel (Cameco 2018). Since the camp Hi-Vol is approximately located upwind of the main operation, it was considered as a reference station for the purposes of characterizing baseline air quality. Data for the camp Hi-Vol are presented in Table 6.1-13.

Table 6.1-13: Key Lake Uranium, Arsenic, and Nickel Measurements at the Camp High Volume Air Samplers, 2009 to 2018

Constituents of Potential Concern	24-Hour Concentration (µg/m³)										
	2018	2017	2016	2015	2014	2013	2012	2011	2010	2009	Avg.
Uranium (U)	0.0005	0.0004	0.0005	0.0007	0.0002	0.0005	0.0006	0.0008	0.0006	0.0010	0.0006
Arsenic (As)	0.0005	0.0002	0.0005	0.0011	0.0012	0.0005	0.0005	0.0003	0.0011	0.0007	0.0007
Nickel (Ni)	0.0002	0.0003	0.0004	0.0005	0.0004	0.0003	0.0003	0.0005	0.0004	0.0002	0.0004

Prior to construction of the Cigar Lake Operation, the Cigar Lake Mining Corporation (CLMC) measured ambient concentrations of TSP and metals using Hi-Vols from 1989 to 2003 (Cameco 2004). Total suspended particulates were measured on a one-in-six-day cycle, and select metals (i.e., arsenic, nickel, lead, zine, copper, and selenium) and uranium were measured quarterly. The geometric means of this data set are presented in Table 6.1-14. The historic geometric mean for TSP was 8.8 µg/m³, which is lower than the regional background concentration of 12.4 µg/m³ estimated using SK MOE data. This suggests that the SK MOE regional background concentrations of particulate matter may be an overestimate of actual background concentrations. This is likely caused by the fact that the SK MOE regional background value is based on the La Loche monitoring station, which is located near anthropogenic sources, while the Project is in a remote area removed from anthropogenic sources.

Table 6.1-14: Baseline Air Quality Data for the 2004 Cigar Lake Environmental Assessment Study Report

Constituents of Potential Concern	Annual Geometric Mean[1] (µg/m³)	Constituents of Potential Concern	Annual Geometric Mean[1] (µg/m³)
Total suspended particulates (TSP)	8.8	Molybdenum (Mo)	nd[2]
Arsenic (As)	0.0005	Nickel (Ni)	0.0014
Cadmium (Cd)	nd	Selenium (Se)	0.000154
Cobalt (Co)	nd	Uranium (U)	0.0003
Chromium (Cr)	nd	Vanadium (Vn)	nd
Copper (Cu)	0.063	Zinc (Zn)	0.216
Lead (Pb)	0.0031	-	-

Notes:

1 Geometric means, as reported in Appendix A, Table A4.1 of 2004 Environmental Assessment Study Report (Cameco 2004).

2 nd = no data.

6.1.3.2.7 Adopted Background Concentrations

The background air quality data discussed in the previous sections were used to develop reasonable and conservative background concentrations for TSP, PM_{10}, $PM_{2.5}$, dustfall, CO, NO_2, SO_2, uranium, and metals, which are presented in Table 6.1-15.

The Saskatchewan Air Quality Modelling Guideline (SK MOE 2012a) requires that background concentration data be added to air model predictions using an accepted set of data. Following the SK MOE requirements, the regional SK MOE data presented in Table 6.1-12 were conservatively used to represent background concentrations of TSP, PM_{10}, $PM_{2.5}$, CO, SO_2, and NO_2. In the absence of SK MOE data, Key Lake data were selected to represent background concentrations of uranium, arsenic, and nickel. For copper, lead, selenium, and zinc, the Cigar Lake data in Table 6.1-14 were used.

For the remaining metals (i.e., cadmium, cobalt, chromium, molybdenum, and vanadium), the average compositions from recent dustfall data (Table 6.1-7) were conservatively applied to the background concentrations of TSP. For example, the 24-hour background concentration of cadmium is 0.0006% x 46.2 µg/m³, or 0.00028 µg/m³. Since the data set for dustfall was limited to two samples, Key Lake and Cigar Lake data were favoured over dustfall data.

For dustfall, the lowest arithmetic average of measured concentrations across all monitoring stations was used to represent background levels; therefore, the adopted background dustfall level is 0.06 mg/cm²/30-day.

As described in Section 6.1.3.2.5, the SK MOE regional data is considered conservative. While this data set has been adopted for the purposes of modelling and evaluating worst-case COPC concentrations in air, future measurement programs and air quality modelling for the Project will be evaluated using alternative data sets that are more recent and representative of baseline conditions in northern Saskatchewan (i.e., Buffalo Narrows monitoring station).

Table 6.1-15: Summary of Adopted Constituents of Potential Concern Background Concentrations

Constituents of Potential Concern	Period	Background Concentration (µg/m³)	Constituents of Potential Concern	Period	Background Concentration (µg/m³)
Total suspended particulates (TSP)	24-hour	46.2	Chromium (Cr)	24-hour[1]	5.54E-04
	Annual	12.4		Annual	1.49E-04
Particulate matter (PM_{10})	24-hour	23.1	Copper (Cu)	24-hour[1]	3.29E-01
Particulate matter ($PM_{2.5}$)	24-hour	6.5		Annual	6.30E-02
	Annual	3.1	Molybdenum (Mo)	24-hour[1]	2.68E-03
Dustfall	30-day	0.06 mg/cm²/30-day		Annual	7.19E-04
Carbon monoxide (CO)	1-hour	575	Nickel (Ni)	24-hour[1]	2.00E-03
	8-hour	575		Annual	4.00E-04
Sulphur dioxide (SO_2)	1-hour	0.0	Lead (Pb)	24-hour[1]	1.62E-02
	24-hour	0.0		30-day[1]	6.24E-03

Constituents of Potential Concern	Period	Background Concentration (µg/m³)	Constituents of Potential Concern	Period	Background Concentration (µg/m³)
	Annual	0.0		Annual	3.10E-03
Nitrogen dioxide (NO_2)	1-hour	11.3	Selenium (Se)	24-hour[1]	8.03E-04
	24-hour	9.4		Annual	1.54E-04
	Annual	3.8	Uranium (U)	24-hour[1]	3.00E-03
Arsenic (As)	24-hour[1]	3.00E-03		Annual	6.00E-04
	Annual	7.00E-04	Vanadium (Vn)	24-hour[1]	5.31E-03
Cadmium (Cd)	24-hour[1]	2.77E-04		Annual	1.43E-03
	Annual	7.44E-05	Zinc (Zn)	24-hour[1]	1.13
Cobalt (Co)	24-hour[1]	2.63E-03		Annual	0.22
	Annual	7.07E-04			

Notes:

1 Concentrations derived using the conversion methodology based on Section 9.1.1 of the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a)

6.1.4 Assessment of Project-Related Effects

6.1.4.1 Potential Interactions Between the Project and Valued Component / Key Indicators

Potential Project-related interactions with the Air Quality VC and its associated KI are summarized by Project phase in Table 6.1-16. Potential interactions in the summary table are ranked as:

- Primary Interaction (✓): Project activity is expected to interact with the VC/KI, which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.
- Other Interaction (✓): Project activity is expected to interact with the VC/KI. While the interaction is further considered in the effect assessment, it is not expected to be a primary contributor to potential adverse effects.
- No Interaction: Project activity is not expected to interact with the VC/KI, no adverse effects are expected, and rationale is provided for not considering this potential interaction further.

The potential interactions identified in Table 6.1-16 are addressed further in the subsections following the table.

Table 6.1-16: Potential Project Interactions for Air Quality

Project Phase/Activity	Air Quality Levels of Dust, Combustion Products, Uranium, Metals, and/or Radionuclides
Construction Activities	
Development of access roads and air strip	✓
Site preparation and earthworks; clearing, levelling, and grading of the Project Area	✓
Power generation – generators	✓
Installation of main substation and distribution of power around site	✓
Wellfield and freeze hole drilling; ground freezing	✓
Batch plant operation (concrete); crusher at borrow area	✓
Development of surface infrastructure (camp, operations centre, plants, ponds, pads, and support facilities)	✓
Waste management (composting, domestic and industrial landfill operation, recycling)	✓
Water management (including treatment and site runoff)	
Groundwater supply	
Surface water withdrawal	
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
On-site and off-site operation of vehicles and transport of materials	✓
Air transportation for workers	✓
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Operation Activities	
Operation of the ISR wellfield	✓
Wellfield and freeze wall drilling	✓
Operation and expansion of freeze wall	
Batch plant operation (grout and cement); crusher in borrow area	✓
Expansion of pond and pads	✓
Operation of the processing plant and production of uranium concentrate	✓
Water withdrawal from groundwater or surface water body	
Management of surface water (including seepage and site runoff)	
Water treatment, both domestic and industrial	
Water release to surface water body	
Waste management (composting, domestic and industrial landfill operation, recycling)	✓
Hazardous waste management (temporary storage, handling, and off-site transportation)	✓
Storage and disposal of drill waste rock, process precipitates, and industrial wastewater treatment plant precipitates	✓
On-site and off-site operation of vehicles and transport of materials	✓

Project Phase/Activity	Air Quality
	Levels of Dust, Combustion Products, Uranium, Metals, and/or Radionuclides
Power supply – primarily power from the grid, also generators and back-up generators	✓
Package and transport of nuclear substances	✓
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
Air transportation for workers	✓
Progressive decommissioning and reclamation	✓
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Decommissioning Activities	
Site water management, treatment, and release	
Mining horizon remediation and thawing of freeze wall	✓
Process water treatment and release	
Closure of ISR and freeze wells and related infrastructure	✓
Decontamination of surface facilities and injection, recovery, and monitoring wells	✓
Asset removal (including site power transmission lines and electrical infrastructure)	✓
Demolition and disposal of non-salvageable surface infrastructure and materials	✓
Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and process plant area)	✓
Generators	✓
Waste management (composting and landfill operation)	✓
Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal)	✓
On-site and off-site operation of vehicles and transport of materials	✓
Reclamation of disturbed areas	✓
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Post-Decommissioning Activities	
Environmental monitoring	
Regulatory site inspections	
Engagement – site visit from Interested Parties	

The information on activities associated with each phase of the Project shown in Table 6.1-16 was used to develop assessment scenarios for use in predictive modelling. The scenarios were developed based on the year with the maximum activity occurring in each phase. As noted previously, the Air Quality assessment included an evaluation of the Construction, Operation, and

Decommissioning phases of the Project. Post-Decommissioning consists generally of environmental monitoring.

The Construction scenario was based on the first year of construction as this involves the most equipment operating at the site, including construction of surface facilities, wellfield drill mobilizations, drilling of freeze holes and ISR wells, and development of the borrow area and landfills. Construction activities will be supported by a concrete batch plant and crusher, and power to the site during this stage will be provided by two (2) 1.1 MW generator sets and two (2) 450 kW generator sets. In addition, there will be regular truck trips to the site for delivering construction materials and site supplies (e.g., food, fuel).

The conservative Operation scenario was based on activities being completed in the late stages of Operation, with work being completed in Phase 5 of the deposit. Wellfield drilling would continue, and the ISR processing plant was assumed to be operating at maximum capacity. While the site will be powered from the provincial grid at this stage, the power generators were assumed to be operating under emergency conditions as a worst-case scenario, as the Air Quality assessment considers a maximum 1-hour and day (24-hour) of operations. Regular truck traffic will continue for provision of materials and supplies, and shipping of yellowcake will commence.

The Decommissioning scenario was based on remediation activities occurring at contaminated areas, including the ISR wellfield, pads, ponds, and process plant area. Power to the site during this stage will be provided by generator sets, and on- and off-site operation of vehicles and transport of materials will continue.

The specific emissions sources associated with each of the above activities that were included in the assessment of Project-related effects are summarized in Appendix 6-A. The discussion of sources therein also includes detailed information on the derivation of emission rates for use in predictive modelling.

6.1.4.2 Potential Project-Related Effects

The propagation of air emissions from Project activities associated with Construction, Operation, and Decommissioning was predicted using version 7 of the CALMET/CALPUFF modelling package (Exponent 2015). CALPUFF is an advanced three-dimensional (3D) dispersion model that can handle complex terrain and multiple emissions sources from facilities and activities located over large study areas. While the *Saskatchewan Air Quality Modelling Guideline* identifies that the **A**merican Meteorological Society/**E**nvironmental Protection Agency **R**egulatory **Mod**el (AERMOD) should be used for most assessments in Saskatchewan, Section 3.3 of the guideline does allow for the use of more sophisticated models, including CALPUFF, where justified (SK MOE 2012a). In consultation with the SK MOE, CALPUFF was selected for the Air Quality assessment primarily for its ability to model long range transport in the large RSA, along with its wet and dry removal processes and chemical transformation algorithms that are needed to generate inputs for the human health assessment. Consultations with the SK MOE regarding the use and setup of CALMET/CALPUFF began in December 2019 (Fudge 2019), with follow-up correspondences regarding CALMET in March 2020 (IEC 2020) and April/May 2021 (Fudge 2021a, b, IEC 2021). In August 2021, SK MOE staff also completed a review of the CALPUFF model input files (Fudge 2021c).

To overcome the limited meteorological record in the Project study areas, a prognostic meteorological data set was developed. Specifically, data outputs from the Weather Research Forecast Non-Hydrostatic Mesoscale Model were combined with surface observations from Key Lake Airport in CALMET to develop a one-year meteorological data set for the 2016 calendar year. Details of the CALMET modelling are provided in Appendix 6-A.

A scaled 3D representation of the Project and its surroundings were constructed in CALPUFF using digital terrain mapping and information on the planned building layouts and sources. The identified sources were parameterized in the CALPUFF model using either area sources, volume sources, or point sources, the details of which are provided in Appendix 6-A. Similarly, the identified sensitive points of reception were included in the model, as shown in Figure 6.1-3. In addition to the sensitive points of reception, a nested receptor grid was established for the study areas, meeting the minimum requirements of the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a).

Conservative air emission inventories were developed for each Project phase where Project-environment interactions are expected, including Construction, Operation, and Decommissioning (Table 6.1-16). Emission rates for the identified air sources were generally established using published emission factors and engineering calculations. The inputs for the calculations were derived from available information from the prefeasibility study (Denison 2018), other engineering studies, or test work for the Project. Where Project-specific information was not available, values based on recommended defaults or professional judgement were used. Additional details regarding the air emissions inventory and source configuration are provided in Appendix 6-A.

Using the CALMET data set, a CALPUFF model run was executed to determine the COPC concentrations and deposition rates at each receptor location associated with each modelled phase of the Project. Except for radon, the predictions were added to baseline air quality levels and compared to the available standards summarized in Table 6.1-5 at receptors located outside the Property Boundary. The predictions are also evaluated in the aquatic environment, terrestrial environment, and human health assessments in Section 8, Section 9, and Section 10, respectively.

There were no predicted exceedances of the criteria for dustfall, $PM_{2.5}$, CO, SO_2, arsenic, cadmium, chromium, cobalt, copper, lead, molybdenum, nickel, lead, selenium, vanadium, and zinc for any of the modelled Project phases. Similarly, the annual criteria for TSP, NO_2, cadmium, nickel, and uranium, and the 24-hour criteria for NO_2, were not exceeded for any of the modelled Project phases. In all modelled phases of the Project, annual average radon concentrations at receptors beyond the Property Boundary are expected to be indiscernible from background levels.

Concentrations of 24-hour TSP and PM_{10} were predicted to exceed the air quality criteria at receptors located outside of the Property Boundary in all modelled phases of the Project. The highest off-property (i.e., beyond the Property Boundary) concentrations of particulate matter were predicted during Construction at a receptor near Highway 914, with the highest overall concentrations at 313% of the TSP criterion of 100 $\mu g/m^3$ and 232% of the PM_{10} criterion of 50 $\mu g/m^3$.

For all modelled phases of the Project, 1-hour NO_2 concentrations were predicted to exceed the Project criterion of 79 $\mu g/m^3$ at off-property receptors, reflecting worst-case operations of the stand-by diesel generators. The maximum off-property concentrations of 1-hour NO_2 concentrations were similar between the modelled phases, having predictions that were 224% (Construction) and 225% (Operation and Decommissioning) of the criterion.

Twenty-four-hour uranium concentrations were predicted to exceed the criterion of 0.15 $\mu g/m^3$ at off-property receptors during Operation only, reflecting worst-case operations of ISR stacks. The highest 24-hour uranium concentration was predicted to be 148% of the criterion at the maximum off-property receptor.

6.1.4.2.1 Potential Effect 1: 24-hour Total Suspended Particulate Exceedances

Concentrations of 24-hour TSP were predicted to exceed the criterion of 100 $\mu g/m^3$ during Construction, Operation, and Decommissioning, up to a maximum of 313% of the criterion during Construction. An analysis of exceedances showed that 24-hour TSP concentrations exceed the criterion 28% of the time during Construction, 21% of the time during Operation, and 0.5% of the time during Decommissioning at the maximum off-property receptor. The analysis also showed that exceedances do not extend beyond 200 m from the Property Boundary in any of the modelled Project phases. Exceedances are attributable to fugitive dust from general construction activities (e.g., earthworks) and unpaved road dust during Construction and Operation. The 24-hour TSP exceedance plots are presented in Figure 50, 52 and 54 of Appendix 6-A.

6.1.4.2.2 Potential Effect 2: 24-hour Particulate Matter (PM_{10}) Exceedances

Concentrations of 24-hour PM_{10} were predicted to exceed the criterion of 50 $\mu g/m^3$ at off-property receptors during Construction and Operation, up to a maximum of 232% of the criterion during Construction. An analysis of exceedances showed that 24-hour PM_{10} concentrations exceed the criterion 17% of the time during Construction and 12% of the time during Operation at the maximum off-property receptor, which occurs on the Property Boundary. The analysis also showed that exceedances do not extend beyond 300 m from the Property Boundary in any of the modelled Project phases. Exceedances are attributable to fugitive dust from general construction activities (e.g., earthworks) and unpaved road dust during Construction and Operation. The 24-hour PM_{10} exceedance plots are presented in Figure 51 and 53 of Appendix 6-A.

6.1.4.2.3 Potential Effect 3: 1-hour Nitrogen Dioxide Exceedances

Concentrations of 1-hour NO_2 were predicted to exceed the criterion of 79 µg/m³ at off-property receptors during Construction, Operation, and Decommissioning, up to a maximum of 225% of the criterion during Operation and Decommissioning. An analysis of exceedances showed that 1-hour NO_2 concentrations exceed the criterion less than 1% of the time during any of the modelled Project phases at the maximum off-property receptor, which occurs on the Property Boundary. The analysis also showed that exceedances do not extend beyond 1 km from the Property Boundary in any of the modelled Project phases. Exceedances are attributable to the use of diesel generators. The standby diesel generators were included in the Operation and Decommissioning modelling as a worst-case scenario; however, the standard operating condition of the site will be to operate using power from the provincial grid during these Project phases. The 1-hour NO_2 exceedance plots are presented in Figure 55 and 56 of Appendix 6-A.

6.1.4.2.4 Potential Effect 4: 24-hour Uranium Exceedances

Concentrations of 24-hour uranium were predicted to exceed the criterion of 0.15 µg/m³ at off-property receptors during Operation only, up to a maximum of 148% of the criterion. An analysis of exceedances showed that 24-hour uranium concentrations exceed the criterion less than 0.5% of the time at the maximum off-property receptor, which occurs on the Property Boundary. The analysis also showed that exceedances do not extend beyond 400 m from the Property Boundary. Exceedances are attributable to uranium emissions from the ISR plant stacks during Operation. The 24-hour uranium concentration and exceedance plots are presented in Figure 32 and 57 of Appendix 6-A.

6.1.5 Mitigation Measures

Strategies to reduce the likelihood and magnitude of the predicted Project-related effects on the Air Quality VC include emission controls and utilizing planning measures to counter the conditions that contribute to the predicted effects. Some mitigation measures have been incorporated into the Project plans and carried through the Air Quality assessment. These mitigation measures include the following:

- applying water at least twice per day to unpaved roads and surfaces;
- limiting equipment and vehicle speeds along the access road and site roads to <40 km/h;
- equipping the dryer, calciner, and hygiene exhausts with scrubber systems;
- making sure the dryer, calciner, and hygiene exhaust stacks are at least two times the building height to eliminate building downwash effects; and
- collecting and venting radon gas from wellfield operations (including test phases) through a radon surge tank equipped with a vertical stack at least 15 feet (4.5 m) above grade.

The success of these measures was estimated via modelling, and the results are discussed in the following section.

Additional mitigation measures beyond those incorporated in the predictive modelling include:

- creating and implementing an Environmental Management System (EMS) to address air quality monitoring, including the application of water or chemical dust suppressants to control fugitive dust, in addition to other operational strategies to assist in dust control;
- planning vehicle and equipment routes to minimize travel distances, where possible; and
- employing standard operating procedures and completing regular inspections of equipment machinery to make sure it is in good working order.

6.1.6 Residual Effects Evaluation

After application of the proposed mitigation measures in the predictive model, exceedances of the air quality criteria remain at receptors located beyond the Property Boundary. The residual effects are summarized in Table 6.1-17. Characterization of the residual effects are discussed in the Section 6.1.6.1.

Table 6.1-17: Summary of Residual Effects for the Air Quality Valued Component

Constituents of Potential Concern	Averaging Period	Criteria	Construction			Operation			Decommissioning		
			Max. Off-Property Conc.	% Of Criteria	Exceed.	Max. Off-Property Conc.	% Of Criteria	Exceed.	Max. Off-Property Conc.	% Of Criteria	Exceed.
Total suspended particulates (TSP)	24-hour	100 µg/m³	313.3 µg/m³	313%	104 d/y	281.2 µg/m³	281%	80 d/y	114.8 µg/m³	115%	2 d/y
Particulate matter (PM_{10})	24-hour	50 µg/m³	116.2 µg/m³	232%	61 d/y	103.8 µg/m³	208%	42 d/y	n/a	n/a	n/a
Nitrogen dioxide (NO_2)	1-hour	79 µg/m³	176.5 µg/m³	223%	28 h/y	177.7 µg/m³	225%	28 h/y	177.7 µg/m³	225%	25 h/y
Uranium (U)	24-hour	0.15 µg/m³	n/a	n/a	n/a	0.22 µg/m³	148%	3 d/y	n/a	n/a	n/a

Notes:

d/y – days per year; h/y – hours per year; n/a – not applicable; Max. = maximum; Conc. = concentration

6.1.6.1 Residual Effects Characterization

General definitions of the residual effects characteristics are provided in Table 5.8-1 in Section 5. Residual effects characteristics specific to Air Quality are defined in Table 6.1-18.

Table 6.1-18: Air Quality – Definitions of Effect Characteristics Considered When Determining the Significance of Residual Effects

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Negative effect or effect is not desirable. **Positive** – Beneficial effect or effect is desirable.
Magnitude	The magnitude of predicted COPC concentrations relative to air quality criteria.	**Low** – Less than 125% of the air quality criteria. **Moderate** – Between 125% and 150% of the air quality criteria. **High** – More than 150% of the air quality criteria.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Air Quality Property Boundary and the Project Area. **Local** – Effect is limited to the Air Quality LSA. **Regional** – Effect extends beyond the Air Quality LSA into the Air Quality RSA. **Beyond Regional** – Effect extends beyond the Air Quality RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs less than 10% of the time. **Sporadic** – Effect occurs between 10% and 50% of the time. **Frequent** – Effect occurs more than 50% of the time. **Continuous** – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions. **Partially Reversible** – A residual effect that partially diminishes to baseline conditions. **Irreversible** – A residual effect that will not diminish to baseline conditions.
Context	Since Air Quality is an intermediate VC, the context is best defined in the significance determination of the receptor VCs including various VCs in the Terrestrial Environment, Indigenous Land and Resource Use, and Other Land and Resources Use assessments.	
Likelihood	Likelihood that the residual effect will occur, including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

The residual effects criteria defined in Table 6.1-18 have been applied to the scenarios with residual effects that were identified in Table 6.1-17, and include the following:

- Construction, Operation, and Decommissioning – exceedances of the 24-hour TSP criterion (Table 6.1-19, Table 6.1-20, and Table 6.1-21);
- Construction and Operation – exceedances of the 24-hour PM_{10} criterion (Table 6.1-22 and Table 6.1-23);
- Construction, Operation, and Decommissioning – exceedances of the 1-hour NO_2 criterion (Table 6.1-24, Table 6.1-25, and Table 6.1-26); and
- Operation – exceedances of the 24-hour uranium criterion (Table 6.1-27).

Table 6.1-19: Air Quality – Summary of the Characteristics Ratings for Residual Effect 1 (Construction, 24-hour TSP Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	High	The predicted concentration is more than 150% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Short-term	The increase is related to Construction.
Frequency	Sporadic	The frequency of exceedances is between 10% and 50%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline levels as construction activities cease.
Context	Context is described for receptor VCs	
Likelihood	Likely	There is a moderate to high probability that the residual effect will occur.

Table 6.1-20: Air Quality – Summary of the Characteristics Ratings for Residual Effect 2 (Operation, 24-hour TSP Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	High	The predicted concentration is more than 150% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Medium-term	The increase is related to Operation.
Frequency	Sporadic	The frequency of exceedances is between 10% and 50%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline as sources cease to operate.
Context	Context is described for receptor VCs	
Likelihood	Unlikely	There are limited sources of fugitive dust during Operation. The primary source of dust (i.e., unpaved roads) can be effectively managed through operational controls.

Table 6.1-21: Air Quality – Summary of the Characteristics Ratings for Residual Effect 3 (Decommissioning, 24-hour TSP Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	Low	The predicted concentration is between 100% and 125% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Medium-term	The increase is related to Decommissioning.
Frequency	Infrequent	The frequency of exceedances is less than 10%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline as sources cease to operate.
Context	Context is described for receptor VCs	
Likelihood	Likely	There is a moderate probability that the residual effect will occur.

Table 6.1-22: Air Quality – Summary of the Characteristics Ratings for Residual Effect 4 (Construction, 24-hour PM_{10} Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	High	The predicted concentration is more than 150% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Short-term	The increase is related to Construction.
Frequency	Sporadic	The frequency of exceedances is between 10% and 50%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline as construction activities cease.
Context	Context is described for receptor VCs	
Likelihood	Likely	There is a moderate to high probability that the residual effect will occur.

Table 6.1-23: Air Quality – Summary of the Characteristics Ratings for Residual Effect 5 (Operation, 24-hour PM_{10} Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	High	The predicted concentration is more than 150% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Medium-term	The increase is related to Operation.
Frequency	Sporadic	The frequency of exceedances is between 10% and 50%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline as sources cease to operate.
Context	Context is described for receptor VCs	
Likelihood	Unlikely	There are limited sources of fugitive dust during Operation. The primary source of dust (i.e., unpaved roads) can be effectively managed through operational controls.

Table 6.1-24: Air Quality – Summary of the Characteristics Ratings for Residual Effect 6 (Construction, 1-hour NO_2 Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	High	The predicted concentration is more than 150% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Short-term	The increase is related to Construction.
Frequency	Infrequent	The frequency of exceedances is less than 10%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline as construction activities cease.
Context	Context is described for receptor VCs	
Likelihood	Unlikely	The NO_x to NO_2 conversion method applied is conservative for a 1-hour averaging period.

Table 6.1-25: Air Quality – Summary of the Characteristics Ratings for Residual Effect 7 (Operation, 1-hour NO_2 Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	High	The predicted concentration is more than 150% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Medium-term	The increase is related to Operation.
Frequency	Infrequent	The frequency of exceedances is less than 10%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline as sources cease to operate.
Context	Context is described for receptor VCs	
Likelihood	Unlikely	The NO_x to NO_2 conversion method applied is conservative for a 1-hour averaging period. The effect is associated with use of the generators, which will only be used in an emergency scenario.

Table 6.1-26: Air Quality – Summary of the Characteristics Ratings for Residual Effect 8 (Decommissioning, 1-hour NO_2 Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	High	The predicted concentration is more than 150% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Medium-term	The increase is related to Decommissioning.
Frequency	Infrequent	The frequency of exceedances is less than 10%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline as decommissioning activities cease.
Context	Context is described for receptor VCs	
Likelihood	Unlikely	The NO_x to NO_2 conversion method applied is conservative for a 1-hour averaging period.

Table 6.1-27: Air Quality – Summary of the Characteristics Ratings for Residual Effect 9 (Operation, 24-hour Uranium Exceedances)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased air quality concentrations are considered an undesirable effect.
Magnitude	Moderate	The predicted concentration is between 125% and 150% of the air quality criterion.
Geographic Extent	Local	The receptors are in the Air Quality LSA.
Duration	Medium-term	The increase is related to Operation.
Frequency	Infrequent	The frequency of exceedances is less than 10%.
Reversibility	Fully Reversible	Air quality concentrations are expected to return to baseline as sources cease to operate.
Context	Context is described for receptor VCs	
Likelihood	Likely	There is a moderate probability that the residual effect will occur.

6.1.6.2 Significance and Confidence

6.1.6.2.1 Significance

Significance is determined for receptor VCs that represent assessment endpoints for Air Quality (e.g., Vegetation and Ecosystems, Human Health, Indigenous Land and Resource Use, and Other Land and Resource Use). Since Air Quality feeds into these other assessment endpoints, the results of the residual effects characterizations for Air Quality do not have significance determinations of their own. See Sections 9, 10, and 11.

6.1.6.2.2 Confidence

To have confidence that the predictions completed in support of the Air Quality assessment will bound the actual observed conditions upon Project commencement, a series of conservative assumptions were implemented at each stage of the assessment. It should be noted that air dispersion models are generally considered accurate to within a factor of two. This would indicate that if all emissions sources were characterized accurately, and the model conditions reflected actual conditions (e.g., meteorology, source parameterization), then the model predictions would be within ± 2 of a measured level at the point of prediction. To have confidence in the bounding of the predictions for this assessment, the air emissions and configuration of modelled sources were set with conservatism. The assumptions to facilitate a conservative assessment are summarized in the following bullets:

- The assessment scenarios considered all activities occurring concurrently at their individual maximum rates of production.
- Where Project-specific variables were not known (e.g., material silt content), the upper range of suggested defaults from emissions quantification guidance were used.
- If a range of values were provided for Project-specific variables (e.g., stack emission estimates), the maximum value was used.
- The dimensions and initial dispersion parameters (i.e., sigma values) for area and volume sources were limited where source-specific information was not readily available.
- Conservative regional background concentrations from the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a) and based on the La Loche monitoring station were used for particulate matter, NO_2, SO_2, and CO. The La Loche monitoring station is located near anthropogenic sources, while the Project is in a remote area removed from anthropogenic sources.
- The ARM, a methodology recognized as conservative (SK MOE 2012a), was used to convert NO_x to NO_2 concentrations.
- A single criterion was selected for each air quality COPC and time-averaging period based on the most stringent criteria or standard presented in Section 6.1.1.2.

- A gap analysis memo/model inputs summary was prepared for review by Denison prior to modelling, to make sure that the source list was reflective of current Project plans and that the modelling reflected the worst-case operating scenario for each phase.

Details regarding the air emissions calculations, as well as the detailed model configuration, are provided in Appendix 6-A.

6.1.6.3 Summary of Project-Related Residual Adverse Effects on Air Quality

Residual effects were predicted at receptors located beyond the Property Boundary for 24-hour concentrations of TSP, PM_{10}, and uranium, and 1-hour concentrations of NO_2. The effects during Construction were short-term (less than three years), while the effects during Operation and Decommissioning were medium-term. Twenty-four-hour TSP and PM_{10} exceedances during Construction and Operation were sporadic; however, the residual effects during Operation were considered unlikely. During Decommissioning, 24-hour TSP exceedances were infrequent. Exceedances of the 24-hour uranium criterion during Operation and the 1-hour NO_2 criterion during Construction, Operation, and Decommissioning were also infrequent. In general, in all Project phases, the residual effects were limited in geographic extent and mostly infrequent.

6.1.7 Cumulative Effects

The Project site will be accessed from Highway 914 by a proposed access road. Highway 914 is approximately 3.4 km (direct) from the developed Project site, or approximately 5 km by the proposed access road. The Cameco McArthur River Operation and Key Lake sites are currently in Care and Maintenance mode; therefore, there is currently no truck traffic between the sites on Highway 914. When these sites were to become operational again, there is potential for a cumulative effect at sensitive locations near the highway. Based on data from the Millennium EIS (Cameco 2013), which are summarized in a Traffic Volumes Memorandum prepared by Denison (Appendix 2-B in Section 2 Project Description), the average daily traffic between Key Lake and the Project site is expected to increase by 23% during Construction and 30% during Operation due to the Project. A 5-km portion of Highway 914 from the access road and south towards Key Lake was included in the air dispersion model and emissions from traffic associated with the Project were considered (see Appendix 6-A). While traffic associated with Cameo Operations was not modelled, conservative regional background concentrations from the *Saskatchewan Air Quality Modelling Guideline* (SK MOE 2012a) and the La Loche monitoring station were used for particulate matter, NO_2, SO_2, and CO (see Section 6.1.3.2.5 and Appendix 6-A). The La Loche monitoring station is located near anthropogenic sources, while the Project is in a remote area removed from anthropogenic sources. Accordingly, emissions to air from traffic associated with Cameco's operations are captured by the regional background concentrations used in the air dispersion model and are considered in the assessment of Project-related effects discussed in Section 6.1.4.

6.1.7.1 Climate Change Considerations

Changes to the climate during the lifetime of the Project have the potential to affect meteorological parameters that govern dispersion, and therefore, ambient concentrations and deposition rates of COPC. As discussed in Section 15.5.2, future climate conditions over the life of the Project will include warmer, snowier winters, and longer, hotter summers. There is also an increased trend in total and extreme precipitation events, although there is uncertainty with projected precipitation and whether it could affect the Project.

Increased precipitation may decrease suspended particulate matter (and its adsorbed constituents) in ambient air via two pathways: 1) increased precipitation could wash out or remove suspended particulate from the air; and 2) increased precipitation could suppress emissions of fugitive dust from unpaved surfaces and storage areas. An increase in temperature would reduce the difference between in-stack temperature and ambient air temperature, leading to a decrease in buoyant flux and dispersion from point sources like the ISR plant stacks. However, the initial dispersion for most of the stacks at the Project is driven by momentum flux (i.e., the flow rate) and is unlikely to be sensitive to an increase in ambient air temperature. An increase in ambient temperature during the summer months without an increase in precipitation could also lead to drier conditions and increased emissions of fugitive dust. However, this type of condition could be effectively managed through air quality monitoring (Section 6.1.8 and Section 16).

6.1.8 Monitoring and Follow-up

To confirm the residual effects of the Project on Air Quality and demonstrate compliance with provincial ambient air quality standards, an adaptive air quality management program will be implemented. The air quality management program will contain various plans which will be finalized during permitting and licensing. The plans within the air quality management program will incorporate mitigation measures and monitoring requirements directed by provincial and federal regulators and by Indigenous groups and other Interested Parties as requested.

The air quality management plan will outline operational procedures and controls used to control fugitive emissions of particulate matter from unpaved roads, open areas, and material stockpiles and will also address community complaints and response procedures. An air quality monitoring plan will be designed to evaluate the effectiveness of these measures.

The air quality monitoring plan will detail the monitoring objectives, sampling design, methods and quality assurance and control requirements. The air quality monitoring plan will be an extension of the ongoing baseline monitoring program for the Project and will include the following:

- TSP;
- dustfall;
- uranium, select metals, and radionuclides in TSP and/or dustfall;
- passive NO_2; and

- radon.

The air quality monitoring plan will also define sampling requirements and methods for the processing plant stacks.

6.1.9 Air Quality Summary

Air Quality was selected as a VC because of the likelihood of Project-related activities to emit COPC and change ambient air quality. Air Quality is also important to human and ecological health and was raised as a concern during the engagement and consultation process. Indicators of Air Quality include levels of particulate matter (including adsorbed radionuclide and non-radionuclide constituents), combustion products, and radon compared to provincial and federal air quality criteria. Predicted COPC levels are also evaluated by the assessors of the aquatic environment, terrestrial environment, and human health.

The Air Quality assessment is spatially bound by the Project Area, the Project Boundary, the Air Quality LSA, and the Air Quality RSA. The Project Area is the area of maximum physical disturbance, while the Project Boundary is the boundary at which the air quality criteria apply. The Air Quality LSA is where direct Project effects can be expected and is within 10 km of the Project Area. The Air Quality RSA is where indirect or cumulative effects may potentially occur and extends 10 km from the Air Quality LSA. The assessment considered the Construction, Operation, and Decommissioning phases of the Project, where Project-environment interactions are expected.

The existing environment is typical of a remote northern setting with the baseline monitoring program measuring low levels of dust, NO_2, and SO_2. Baseline levels of radon are also low and within the regional baseline for northern Saskatchewan, which is less than 7.4 Bq/m^3 to 25 Bq/m^3 (CNSC 2018).

For each Project phase, emissions of COPC were estimated using industry-standard methodologies, such as published emission factors. Constituents of potential concern concentrations were predicted using the CALPUFF model and compared to criteria derived from provincial and federal standards, including from the SK MOE and the CCME. In the absence of provincial and federal standards, criteria from the Ontario Ministry of Environment, Conservation and Parks were used.

Residual effects were predicted at receptors located beyond the Property Boundary for 24-hour concentrations of TSP, PM_{10}, and uranium, and 1-hour concentrations of NO_2 during at least one Project phase. Overall, predicted residual effects were limited in geographic extent and mostly infrequent. Twenty-four-hour TSP and PM_{10} exceedances during Construction and Operation were sporadic; however, the residual effects during Construction were short-term and unlikely for Operation. During Decommissioning, 24-hour TSP exceedances were infrequent. Exceedances of the 24-hour uranium criterion during Operation and the 1-hour NO_2 criterion during all three phases were also infrequent.

To confirm the residual effects of the Project on Air Quality and demonstrate compliance with provincial ambient air quality standards, an adaptive air quality management program will be implemented during permitting and licensing. The EMS will evaluate the effectiveness of the air quality monitoring.

6.2 Noise

This subsection addresses the potential for the Project to affect the existing sound environment in the vicinity of the Project. The Project Area is currently characterized by low ambient sound levels that are primarily attributable to sounds of nature, as would be expected for a remote location. The Project will introduce new sound sources into this environment, which will change the nature of the environment through the introduction of anthropogenic sounds associated with industrial activity, resulting in a localized increase in sound levels.

Noise sources associated with the Project include site clearing activities, construction of facilities, use of power generators, diesel-powered mobile equipment, drilling in the wellfield, on-site traffic and air traffic, chilling equipment associated with the freeze plant, and various equipment associated with the ISR process (e.g., pumps). Potential effects related to noise occur when sound levels are audible above background conditions at noise-sensitive locations or increase by a noticeable amount. Health Canada provides guidance for the assessment of noise during EAs, which includes recommended criteria for use in assessing the significance of the predicted sound levels and sound level increases at noise-sensitive locations (Health Canada 2017). Health Canada uses annoyance with sound as an indicator for potential effects on human health.

This section of the EIS addresses potential Project-related effects on the Noise VC and is comprised of the following information:

- scope of the assessment;
- summary of existing conditions;
- identification and description of potential interactions between the Project and the Noise VC;
- identification and description of mitigation measures and monitoring activities to eliminate, reduce, or control the potential adverse Project-related effects on the Noise VC;
- characterization of potential Project-related residual effects (i.e., after mitigation), including determination of significance and level of confidence in the predictions; and
- identification and characterization of cumulative effects.

Figure 6.2-1 is a graphic representation of the assessment process used in this EIS.

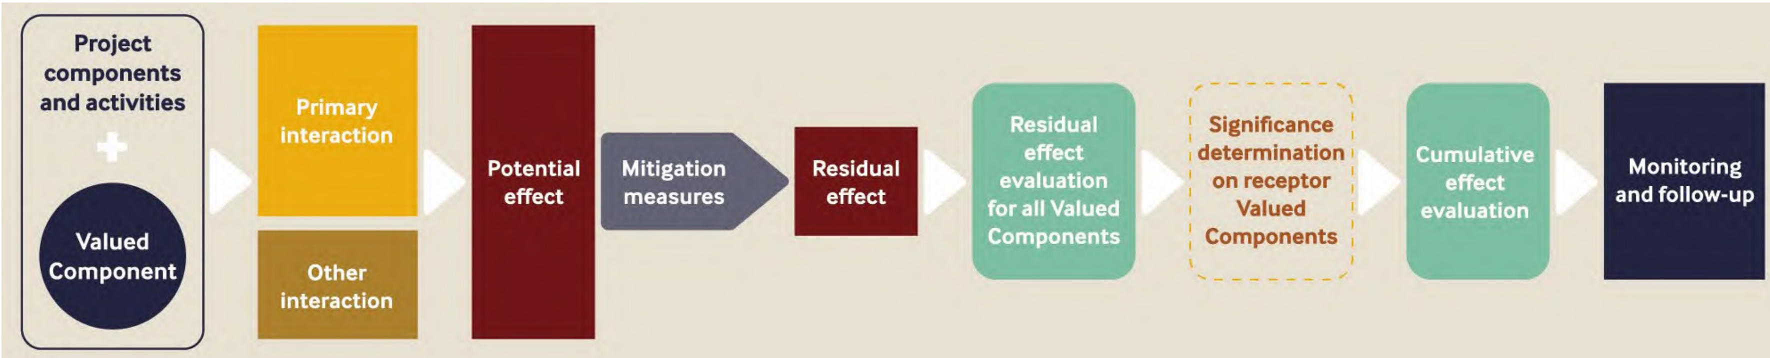

Figure 6.2-1: Environmental Assessment Process Used in This Environmental Impact Statement

6.2.1 Scope of the Assessment

6.2.1.1 Valued Component Selection

The process and rationale for the selection of VCs and establishment of KIs and associated MPs is described in Section 5. Noise was selected as a VC in general based on the likelihood of Project-related activities to interact with and change the existing sound environment. Any change to the existing sound environment in the vicinity of the Project has the potential to affect Indigenous groups and the public in terms of creating nuisance noise that may affect human health, and to change animal behaviours as related to hunting activity. The potential effects of Project-related changes to noise levels on the Ungulates, Furbearers, and Woodland Caribou VC are discussed in Section 9.3. The discussion in this section is focused on potential effects on humans. Figure 6.2-2 is a graphic representation of the main linkages among the Noise VC and other VCs, illustrating the flow of assessment information from the Noise VC.

Health Canada identifies that project-related changes to environmental noise carry a potential risk to human health (Health Canada 2017), and therefore recommends that noise be assessed in the context of an EA. According to Health Canada, indicators of effects on human health due to noise exposure include sleep disturbance and prolonged periods of high annoyance, which may in turn lead to health effects associated with cardiovascular health, mental health, and accidents (Health Canada 2017). The KIs and MPs derived from the Health Canada guidelines to assist in the assessment of Noise are discussed in Section 6.2.1.2.

Due to the association of noise with potential human health considerations, and the possibility of changes to noise levels influencing terrestrial wildlife behaviour (and the nature of use of traditional hunting grounds by Indigenous groups), Noise has been included as a VC in other EAs of similar scope that have been completed in the area. For example, the assessment of potential noise effects associated with the Cameco Millennium Project are discussed in Annex L of the EIS document (Cameco 2013).

While Saskatchewan does not currently have provincial guidance related to the assessment of potential noise effects associated with industry, other Canadian provinces, such as Ontario and Alberta, do maintain provincial noise assessment guidelines, which tend to pertain to environmental noise effects rather than health-specific effects (i.e., keeping the noise contribution of individual facilities below absolute thresholds that are based on the project setting). Based on professional experience, the SK MOE has considered the *Alberta Directive 038* (AER 2013) as a suitable stand in for provincial guidance. The Alberta Energy Regulator (AER) Directive involves establishing a permissible sound level (PSL) specific to the nearest identified sensitive receptor locations to the facility, and then using predictive modelling to evaluate whether the project under assessment is below the PSL. The PSL and project contributions are discussed as KIs and MPs in Section 6.2.1.2.

In addition to the scientific and regulatory rationale, and historic precedent for including Noise as a VC in other nearby projects of similar scope, concerns related to noise were also raised during engagement and consultation activities completed by Denison. The concerns included the audibility of Project-related noise at leased properties (20-LK-LEASE-328.10) and how noise may affect animal populations (21-EN-ERFN-447-45). As noted previously, significance determination is not completed on intermediate VCs, but integrated into the residual effect evaluation, residual effect characterization, and significance determination for related receptor VCs. The significance determination of Noise effects specific to the Ungulate, Furbearer, and Woodland Caribou VCs due to changes in noise level is part of the terrestrial environment assessment (Section 9.3).

Figure 6.2-2: Integrated Assessment Approach - Key Connections between Noise and Other Valued Components

6.2.1.2 Key Indicators and Measurable Parameters

The KIs and associated MPs for the Noise VC are summarized in Table 6.2-1. The MPs are further discussed in the following sub-sections.

Table 6.2-1: Key Indicators and Measurable Parameters for Noise

Key Indicator	Rationale for Key Indicator	Measurable Parameter
Noise Levels	• Project activities will introduce new sources of noise to the area. • The existing sound environment is characterized by very low ambient sound levels and is therefore sensitive to the introduction of new industrial noise sources. • The difference between the ambient noise levels with and without the Project, as well as the predicted noise levels with the Project operating, can be used to evaluate the potential response of those exposed. • Change in noise levels has historically been addressed for other mining projects in northern Saskatchewan.	MP 1: Total day-night level (Ldn). MP 2: Change in percentage of persons highly annoyed (%HA). MP 3: Daytime sound level (Ld). MP 4: Nighttime sound level (Ln). MP 5: Change in Ld and Ln.

6.2.1.2.1 Federal Guidance

The assessment of noise effects in support of EAs for projects designated under the *Canadian Environmental Assessment Act, 2012* (Government of Canada 2019) are to be completed in accordance with the Health Canada publication *Guidance for Evaluating Human Health Impacts in Environmental Assessment: Noise* (Health Canada 2017). Health Canada's preferred methodology for the assessment of noise effects has been developed for the assessment of human health endpoints—the methodology is not intended for application to occupational exposure, or to the assessment of wildlife or ecosystems.

The Health Canada assessment approach is premised on community reaction to noise being a potential indicator of adverse health, and one of the most common community reactions is annoyance. The use of annoyance as an indicator of health effects relies on annoyance levels being correlated with sound levels. To achieve this, Health Canada relies on the results of socio-acoustic studies, which have demonstrated a link between increasing community noise levels and an associated increasing percentage of the community that is reported to be 'highly annoyed' by the noise as it rises. These studies have resulted in a dose-response curve that relates sound levels to 'percentage highly annoyed' (i.e., percentage of persons that are typically annoyed by sounds at the corresponding levels). This dose-response curve is the basis for the assessment of effects under the Health Canada approach.

The sound level metric that is applied in the assessment approach preferred by Health Canada is the 'day-night level' or Ldn (Health Canada 2017). This is a normalized sound level in which the sounds that occur during nighttime hours (22:00 to 07:00) are penalized by +10 dBA. This nighttime penalty is to account for people generally being more sensitive to sounds that occur at night; therefore, nighttime sounds are artificially raised. The Ldn that exists in a community before a project is implemented is determined through monitoring, modelling, and the dose-response relationship, which corresponds with an indication of the 'percentage of persons highly annoyed' by sounds at that level (or %HA). The future sound level with a project in place and operating is then estimated through modelling, and this contribution is added to the baseline sound level that previously existed in the community. This future Ldn also corresponds to a %HA value. Health Canada stipulates that a project should not cause the future sound level in a community to exceed an Ldn of 75 dBA (MP 1), and the %HA in a community should not increase from baseline conditions by more than 6.5% (MP 2).

Based on the aforementioned information, there are two Health Canada criteria for noise effect assessments: an absolute criterion (Ldn not to exceed 75 dBA) and a relative criterion (increase in %HA less than 6.5%). Both criteria are to be met for a project to be considered compliant. If either criteria are not met, then the effects of the project are considered severe and noise mitigation measures must be investigated. Furthermore, in quiet, rural areas where there is anticipated to be higher sensitivity to noise, Health Canada recommends that the baseline and predicted future Ldn sound levels be adjusted by +10 dBA prior to calculating the %HA values (and change in %HA), as this produces a greater change in %HA than would otherwise have occurred (Health Canada 2017).

6.2.1.2.2 Provincial Guidance

As mentioned previously, provincial guidance from Alberta was used as surrogate provincial criteria since there is currently no provincial environmental noise guidance for Saskatchewan. The AER Directive (AER 2013) outlines a comprehensive methodology for assessing sound levels from industrial facilities, including establishing sound level criteria and outlining requirements for quantitative predictions through calculations or detailed modelling. It should be noted that the AER Directive is not applicable to construction activities; however, it does include recommendations consider when planning construction. While the AER Directive is not strictly applicable to construction, the criteria have been applied in this assessment due to construction being a multi-year project.

The procedure outlined in the AER Directive involves the evaluation of daytime (07:00 to 22:00) and nighttime (22:00 to 07:00) periods. The daytime and nighttime sound levels considered in the AER Directive are measured or predicted sound pressure levels that were used to describe the baseline and future conditions with the Project in place. The procedure begins with the development of PSLs for the daytime and nighttime periods, which are the criteria by which the Project is assessed. The PSLs consider a basic sound level (provided in the AER Directive based on the project setting), a series of adjustments related to the specifics of the operation (e.g., duration, schedule), and the measured conditions at the site, if available. The PSLs for this assessment were established at 40 dBA for daytime hours and 36 dBA for nighttime hours.

The AER Directive requires acoustic modelling be completed to predict the sound effects of a project under conservative operating conditions. Minimum acceptable modelling parameters are outlined in Section 3.5.1 of the AER Directive and include requirements to account for geometric spreading of sound, barrier effects, atmospheric absorption, ground attenuation, and wind speed/direction. Source parameters must account for location, sound output, and intermittency, where applicable. Modelling is to be based on accepted international standards, such as International Organization for Standardization (ISO) 9613-2 (ISO 1996). The model adopted for this Project, as discussed in Section 6.2.4, is Cadna-A from DataKustik GmbH (DataKustik 2020), which meets all the preceding requirements.

Regarding Construction, the recommendations in the AER Directive include limiting construction activity to daytime hours (07:00 to 22:00), scheduling significant noise-causing activities and notifying residents of the schedule, making use of mufflers for combustion equipment, and using on-site buildings to shield construction noise from nearby residences.

6.2.1.2.3 Change in Subjective Loudness

It should be noted that, while the sound levels may comply with various criteria discussed in the preceding sections, given the Project setting and low ambient sound levels, the increase in sound level due to the Project may still be noticeable and potentially objectionable. As such, additional criteria have been adopted for the assessment for use in characterizing the degree to which the Ld and Ln may change from baseline conditions. These are summarized in Table 6.2-2.

Table 6.2-2: Criteria for the Assessment of Residual Noise Effects

Sound Level Increment	Change in Subjective Loudness	Effects Rating
Up to 3 dBA	Not perceptible	Marginal to none
3 to 5 dBA	Perceptible	Low
5 to 10 dBA	Almost twice as loud	Moderate
Greater than 10 dBA	More than twice as loud	High

An increase in sound level of less than 3 dBA is not typically perceptible to the human ear (Cowan 1994); therefore, an exceedance of less than 3 dBA is considered to be a marginal effect. Sound level increases greater than 3 dBA up to 5 dBA are perceptible but generally not considered to be intrusive; therefore, a low effect rating is assigned. In general, every 10 dBA increase in sound level results in a doubling of the perceived loudness (Cowan 1994). In other words, if the sound level in an environment were to increase by 10 dBA, the environment would seem twice as loud as before to a listener in that environment. An increase in sound level of 20 dBA would result in the environment seeming four times as loud as before. Increases in sound level above 5 dBA are associated with higher potential for complaints and are therefore assigned a moderate (increment above 5 dBA) or high (increment above 10 dBA) effect rating.

6.2.1.3 Spatial and Temporal Boundaries

The areas used to assess the effects of the Project on the Noise VC are shown on Figure 6.2-3 and described in the following bullets.

- **Project Area**: the area within which the Project and all components/activities are located (i.e., the area of maximum physical disturbance). The Project Area is considered to be a conservative estimate of the area of direct disturbance effects on the Noise VC in this assessment.
- **Noise LSA**: the area that surrounds the Project Area where both direct and indirect effects resulting from Project activities can be reasonably measured. The Noise LSA is generally established to assess the potential, largely direct effects of the Project, and represents the extent to which there is a reasonable potential for the Project or Project-related activities to interact with and potentially adversely affect the Noise VC.

  The LSA for the Noise VC was set in consideration of the nearest sensitive land uses and professional experience regarding noise propagation from mining operations. At typical mining operations, noise returns to ambient levels at 3 to 5 km from the site. As there are sensitive receptors beyond this distance in this assessment, the Noise LSA was extended to include the lands within 10 km of the Project Area for a more fulsome assessment.
- **Noise RSA**: the area that surrounds the Noise LSA, established to assess the potential, largely indirect effects of the Project in a regional context. The Noise RSA defines the area within which cumulative effects may occur. As noise is not typically considered a regional issue, the Noise RSA has been established simply as the area outside of the Noise LSA for the purposes of identifying proximity to other northern projects.

Temporal boundaries in the context of the Noise assessment have a two-fold meaning. The assessment accounted for temporal boundaries in terms of when an effect is expected to occur in relation to specific Project phases and activities, and also in terms of the time periods that the prediction of noise effects are applicable to. The latter is largely driven by the MPs that have been identified in Table 6.2-1 and subsequent discussion. The Health Canada assessment approach focuses on activities being completed within a 24-hour period, while the assessment of the Ld and Ln necessitate the consideration of a daytime (15-hour) and nighttime (9-hour) period. Regarding the overall timeline of the Project and the associated phases and activities, these were established in accordance with the summary that has been provided in Table 5.3-3 in Section 5.

6.2.2 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

Denison has recorded and stored information regarding Indigenous Knowledge, Local Knowledge, and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers (e.g., 20-LK-LEASE-328.10). Appendix 6-B provides a summary of unique identification numbers referenced within Section 6.2.

During engagement activities, concern was raised regarding audibility of noise at leased properties (20-LK-LEASE-328.10). There are several lease areas in the vicinity of the Project site, and it has been assumed that each of these contain cabins for purposes of this assessment. As such, these locations have been included as points of reception in the model if they are located within the Noise LSA. A map depicting the location of sensitive receptor locations used in this assessment is provided in Figure 6.2-4. A brief description of the sensitive noise receptors is also provided in Table 6.2-3.

Table 6.2-3: Sensitive Noise Receptors

ID	Description
300601	Leased property – recreational lease, assumed to contain a rustic cabin
301493	Leased property – recreational lease, assumed to contain a rustic cabin
302424	Leased property – recreational lease, assumed to contain a rustic cabin
302586	Leased property – recreational lease, known to contain a rustic cabin
302955	Leased property – recreational lease, assumed to contain a rustic cabin
303010	Leased property – recreational lease, assumed to contain a rustic cabin
303069	Leased property – recreational lease, assumed to contain a rustic cabin
303109	Leased property – recreational lease, assumed to contain a rustic cabin
303238	Leased property – recreational lease, assumed to contain a rustic cabin
602377	Leased property – traditional land use lease, known to include a rustic cabin
Risk1	Risk – ecological receptor on-site
Risk2	Risk - human: seasonal resident at McGowan Lake (leased property #300601). This receptor is at the same location as the recreational fisher/hunter in the Human Health Risk Assessment (EIS Section 10)
Risk3	Risk - human: camp worker
Risk4	Risk - human: seasonal resident at Russell Lake. This receptor is at the same location as fisher/trapper, recreational fisher/hunter and seasonal resident in the Human Health Risk Assessment (EIS Section 10)
Risk5	Risk - reference receptor location

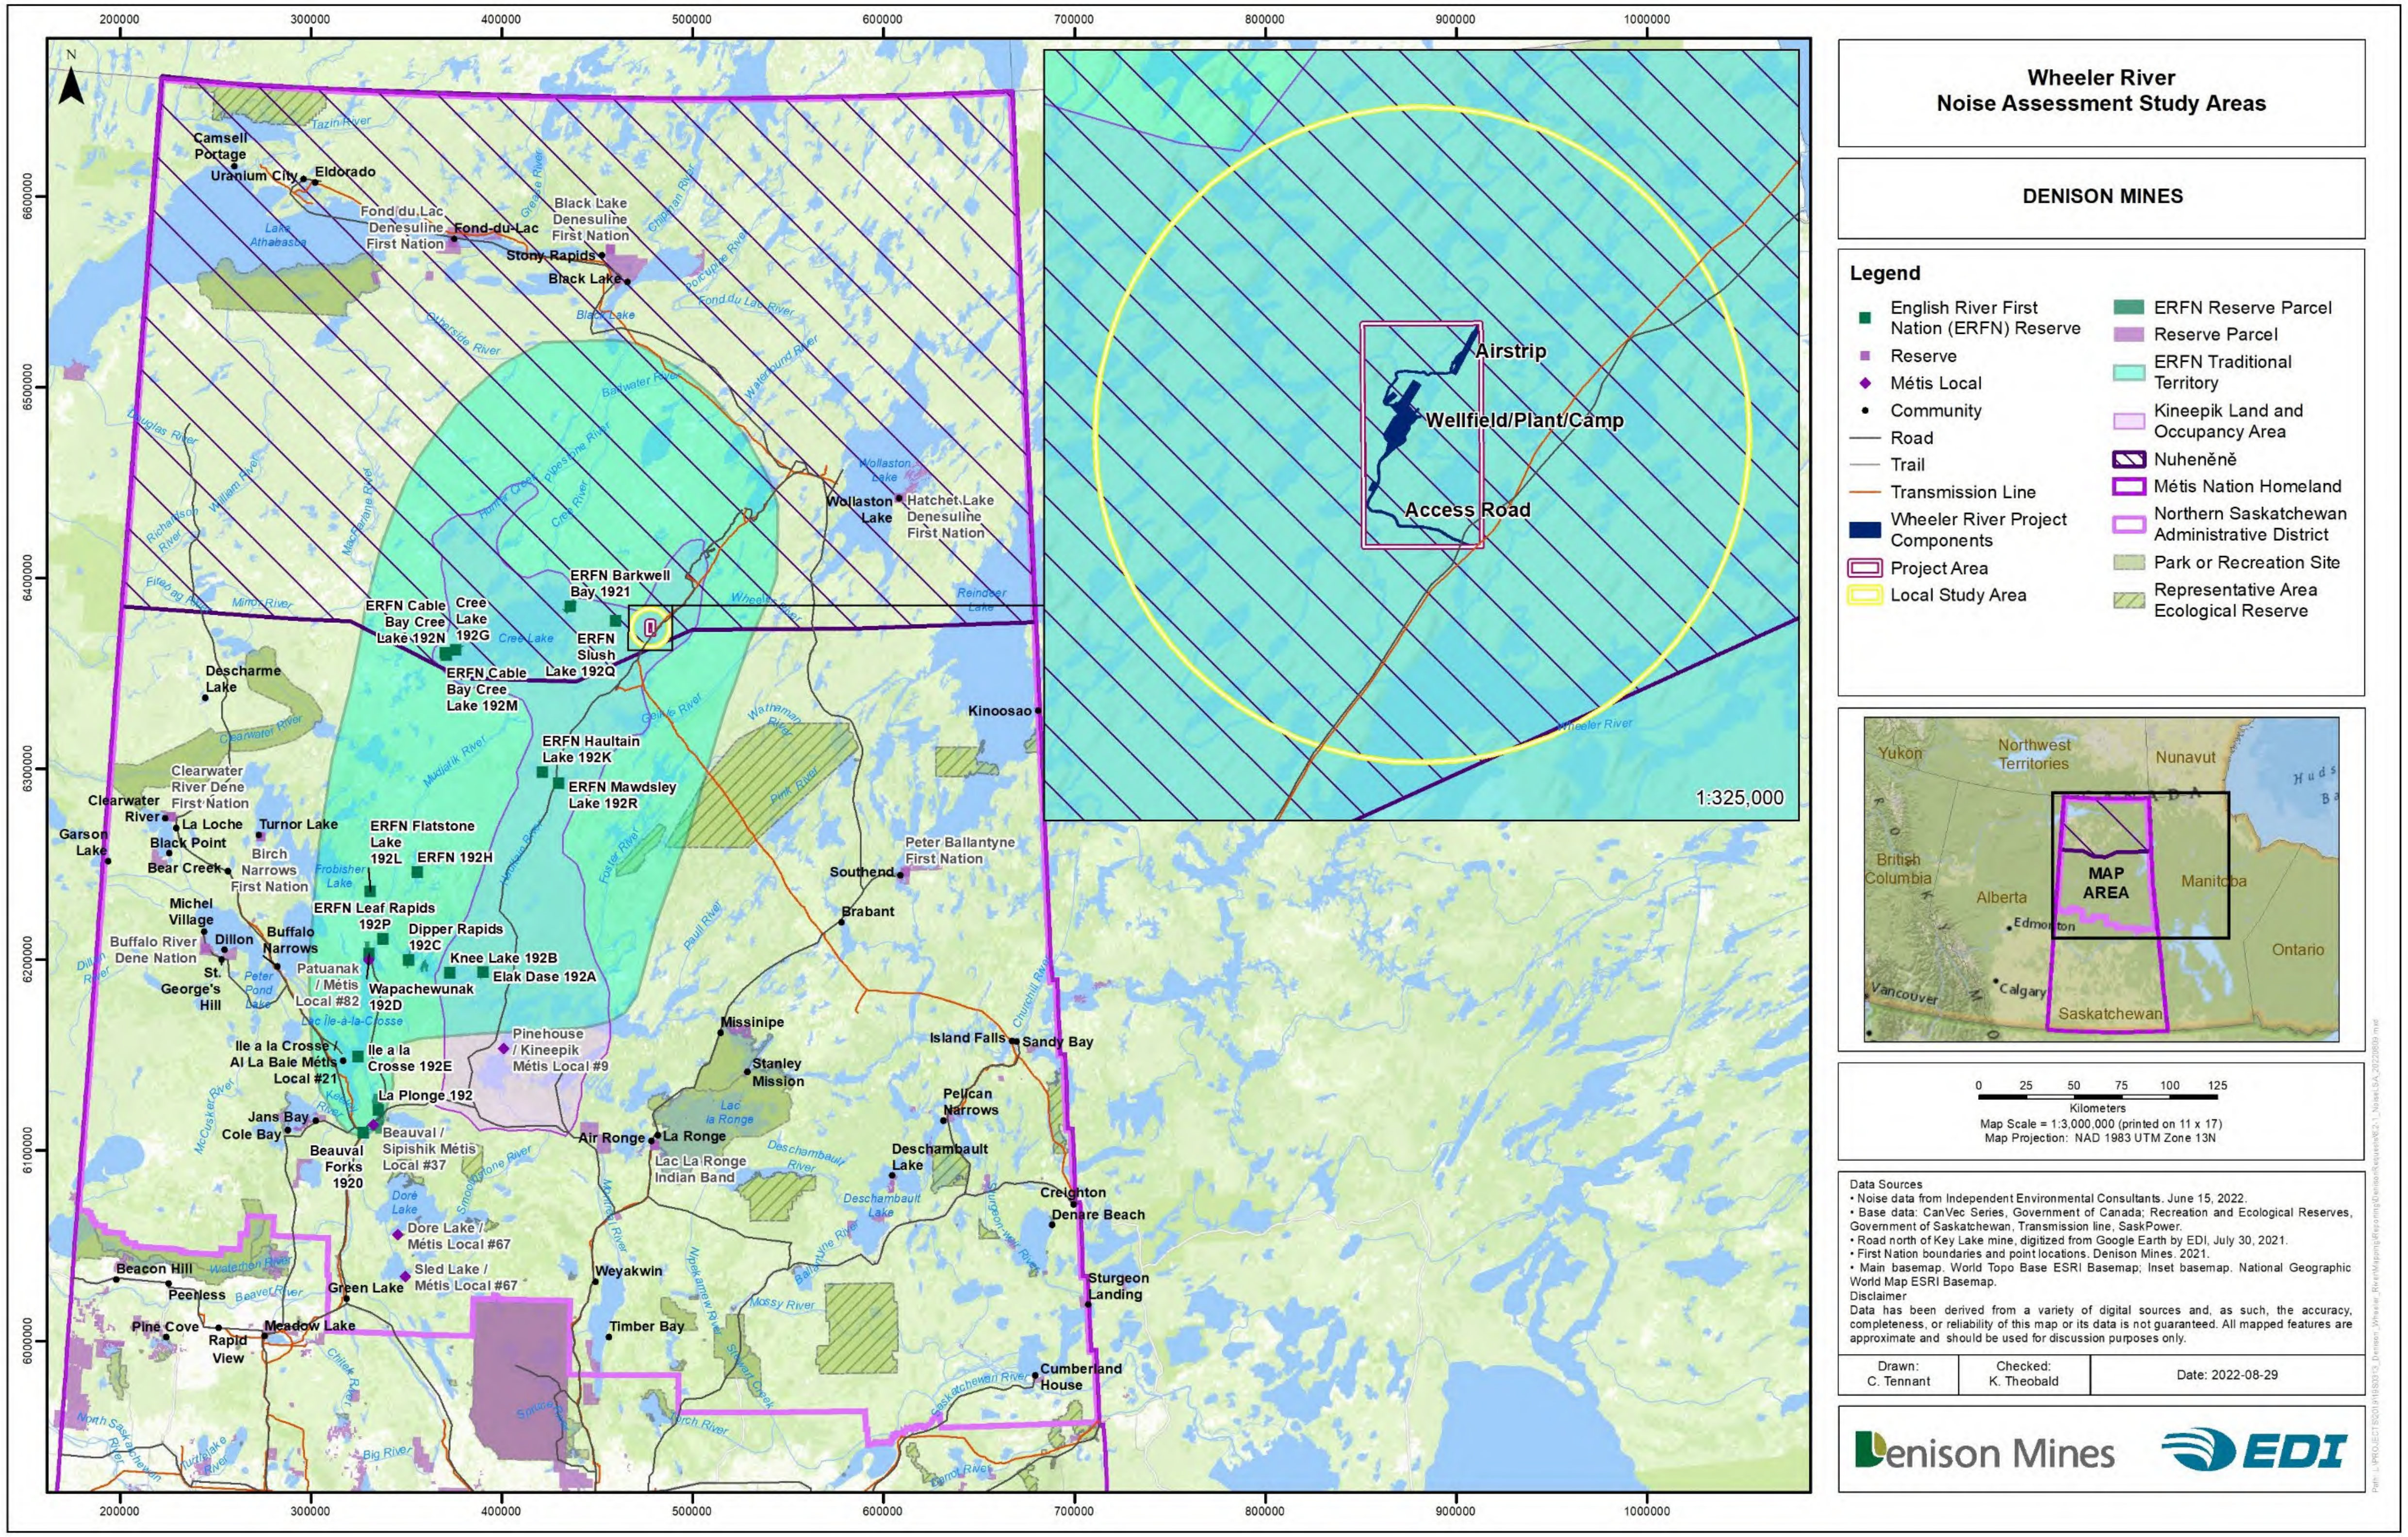

Figure 6.2-3: Noise Assessment Study Areas

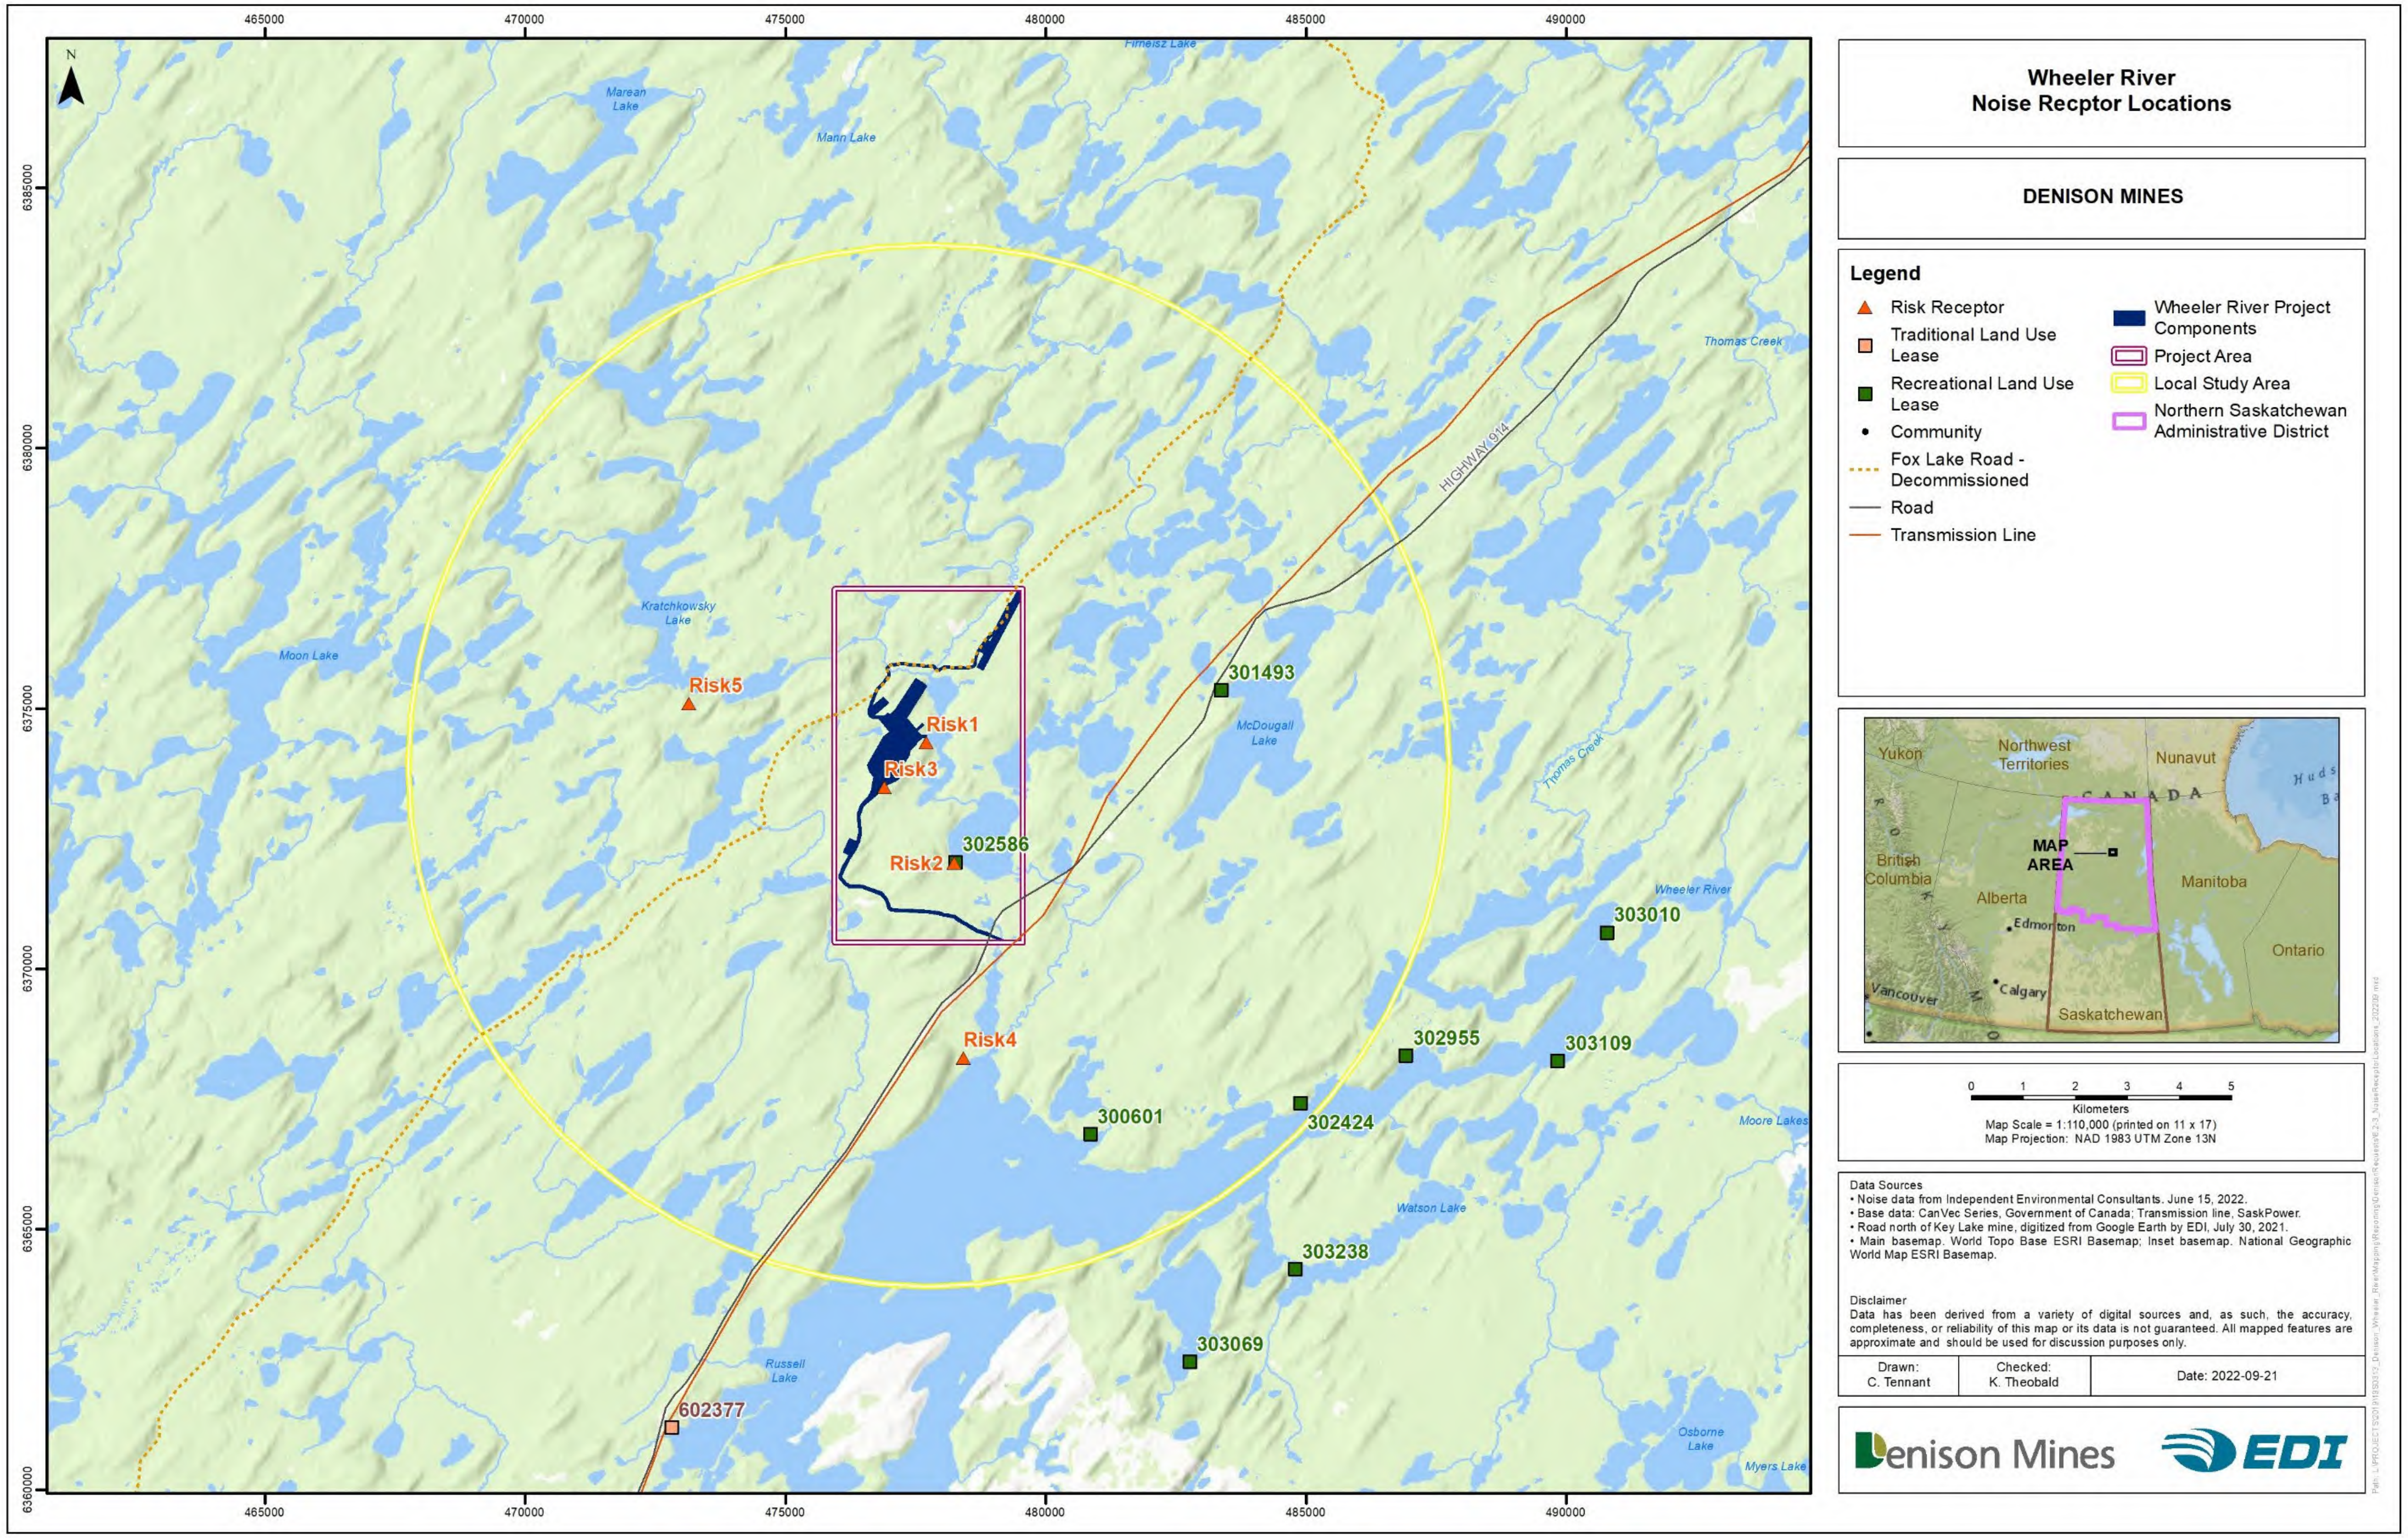

Figure 6.2-4: Sensitive Noise Receptors

6.2.3 Existing Environment

6.2.3.1 Baseline Noise Measurement Program

As per Table 6.2-1, the only KI associated with the Noise VC pertains to noise levels (i.e., sound pressure levels), which are considered both as absolute levels and in relation to existing levels in the assessment of effects. The existing sound environment in the vicinity of the Project Area was characterized via a noise measurement program, which was completed in May 2021. In accordance with Health Canada guidance, the measurement program was designed based on ISO Standard 1996-2:2007 (ISO 2007).

Per ISO requirements, the baseline measurement program was completed using a Class 1 sound level meter system (inclusive of calibrator), outfitted with a wind shield, and with all components calibrated to a traceable national standard (e.g., National Institute of Standards and Technology) within one year of use in the program. The sound level measurement system used in the program was a Larson Davis SoundExpert® LxT outfitted with environmental protection, including a wind screen, bird spikes, and desiccant chamber to control humidity in the pre-amplifier. The calibration device was a Class 1 Larson Davis CAL200, and calibration checks took place before and after the measurement program at 1 kHz (114 dB).

The program was completed over approximately one week (from May 5 to 13, 2021). In accordance with industry best practices and instrument manufacturer recommendations, the hourly meteorological conditions that occurred over the course of the measurement program were summarized with the measurement data, and any measurement data associated with unrepresentative conditions (e.g., precipitation, high gusting winds) were removed from the data set prior to summarization. The meteorological boundary conditions applied in the assessment are summarized in Table 6.2-4. Meteorological data for the noise measurement period were collected from the ECCC station located at the Key Lake site, approximately 32 km from the Project site, as an on-site meteorological station has not yet been established for the Project site. The parameters from Table 6.2-4 were summarized for the monitoring period and time synched with the noise measurement data. Measurement data corresponding with any hours for which one or more of the meteorological parameters was outside of the associated boundary condition were flagged and removed from the data set. The resulting data set was then carried forward to the analysis of the background sound conditions. Out of the approximately 187 hours of measurement data, only 14 hours (or 7.5%) of the data were discarded as a result of being outside of the established acceptable meteorological boundary conditions.

Table 6.2-4: Meteorological Boundary Conditions for Noise Monitoring

Parameter	Lower Limit	Upper Limit
Temperature[1]	-10°C	+39°C
Relative Humidity [1]	25%	90%
Precipitation[2]	Any amount of precipitation is unacceptable	
Wind Speed[2]	N/A	20 km/h

Notes:

1 Instrument manufacturer (Larson Davis) operating parameters (Larson Davis 2020).

2 Industry best practices.

Baseline sound level monitoring was completed at two locations, as shown on Figure 6.2-5. The sound level meters used in the baseline program at the Project site were in open outdoor spaces with no reflecting surfaces and were considered to be free-field measurements. The microphones were mounted on tripods (approximately 1.5 m above ground) to limit the influence of ground reflections. The locations of ongoing Denison exploration work were taken into consideration during planning, and monitoring locations were selected to be as far from these operations as possible while still being accessible by site personnel. It should be noted that there has been no hauling of ore from Cameco McArthur River to Key Lake along Highway 914 since 2017; therefore, baseline sound levels do not include traffic along Highway 914.

Sound levels were measured on a continuous 15-minute interval over the full measurement period (May 5 to 13, 2021) to provide an opportunity to flag and review any anomalous data within each 1-hour period (e.g., potential presence of wildlife). These sound levels were then summed to hourly levels for comparison to the meteorological data, unrepresentative data were removed as described above, and data were summed to Ld and Ln values for each day of measurement. These values were then used to calculate an Ldn for each day.

Upon return to collect the sound level meters, it was found that the measurements at NO-01 had been interrupted by a wildlife encounter. The tripod was found on its side and the bird spikes were bent and windscreen damaged. Upon inspection of the data, it appeared that the wildlife encounter occurred early in the program, on May 5 at approximately 20:45. As such, the full dataset from NO-01 was disregarded in the analysis. The validated sound levels measured at NO-02 are summarized in Table 6.2-5.

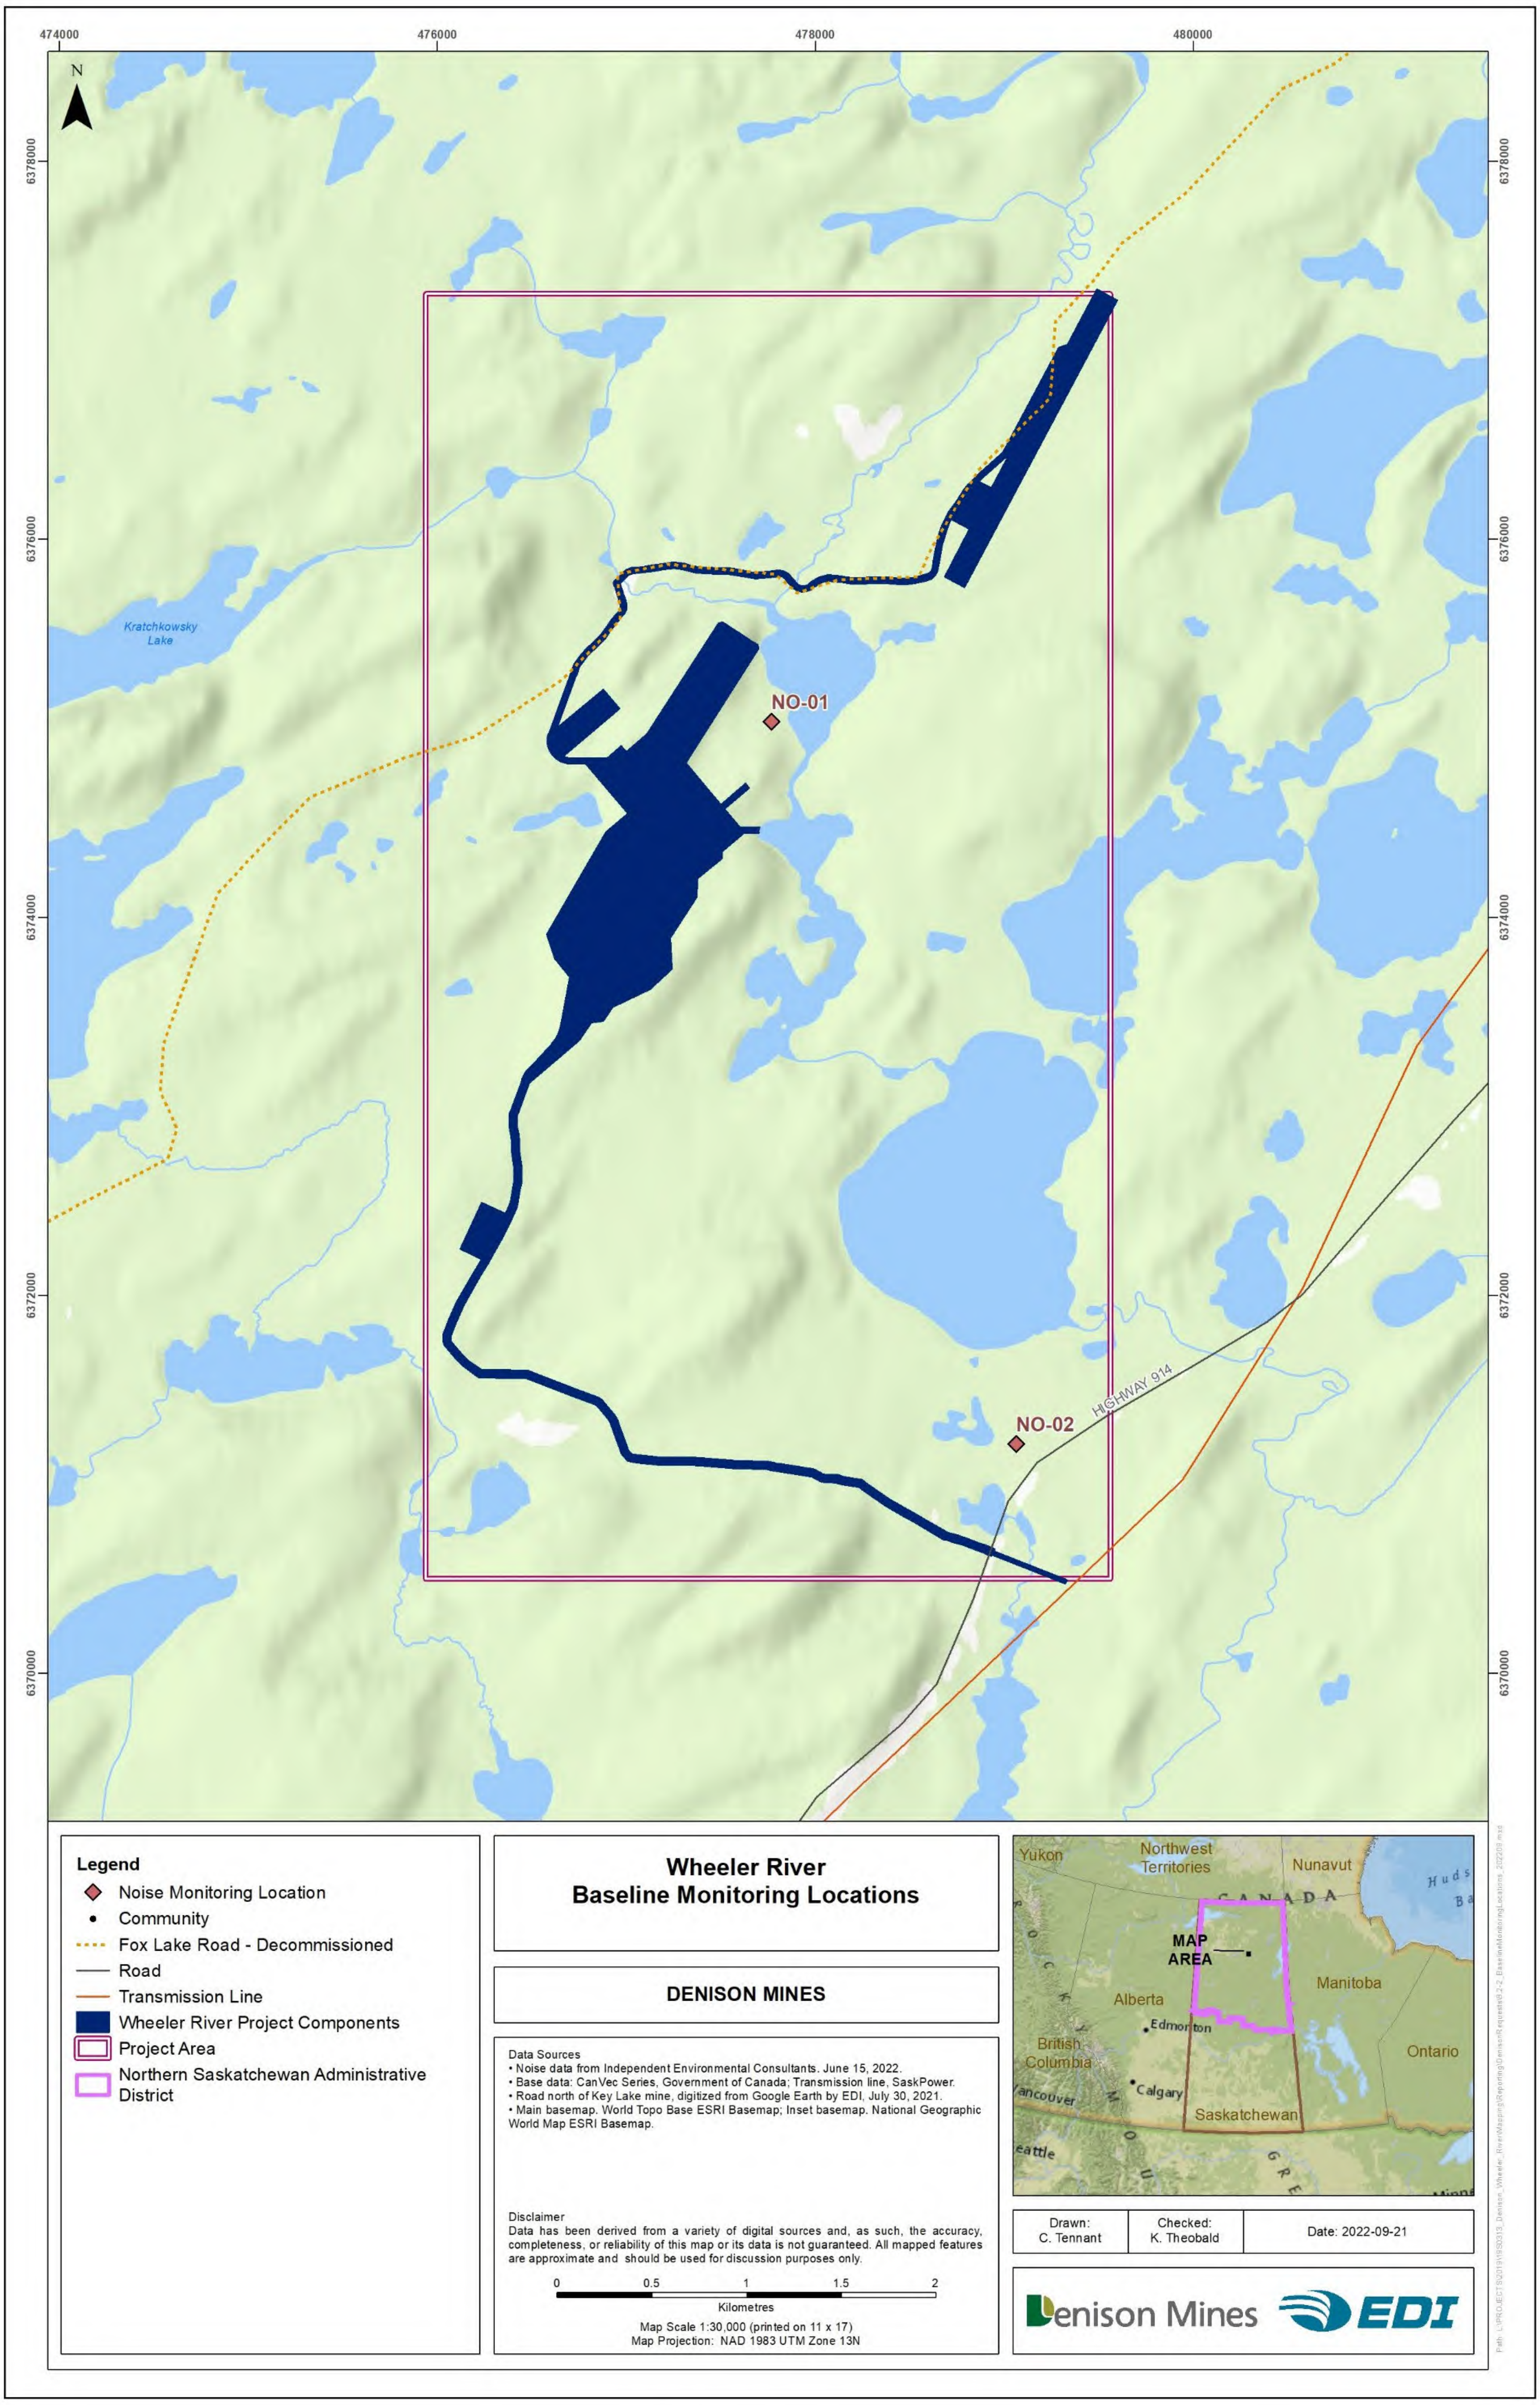

Figure 6.2-5: Baseline Monitoring Locations for Noise

Table 6.2-5: Ambient Noise Measurement Data (NO-02)

Date	Ld (15-hour, dBA)	Ln (9-hour, dBA)	Ldn (24-hour, dBA)
05-May-21	30.9	29.7	34.8
06-May-21	30.3	32.2	38.4
07-May-21	32.7	30.2	37.1
08-May-21	31.4	30.7	37.2
09-May-21	29.6	36.5	42.4
10-May-21	28.2	29.9	36.1
11-May-21	32.5	31.7	38.2
12-May-21	29.8	29.8	36.2
Average	**30.7**	**31.3**	**37.6**

6.2.3.2 Baseline Measurement Program Results as Sound Level Criteria

Both the federal and provincial guidelines adopted for this assessment (Section 6.2.1.2) consider the actual baseline conditions as a factor in the development of the applicable criteria. The Health Canada assessment approach uses the Ldn to calculate a corresponding baseline %HA for use in the assessment. An Ldn of 37.6 dBA corresponds with a %HA of 0.43%. If the baseline Ldn is increased by 10 dBA to account for the heightened expectation of quiet in a remote area, per Health Canada guidelines (Health Canada 2017), the resulting value of 47.6 dBA corresponds with a %HA value of 1.6%.

In terms of the provincial guidance, the AER Directive identifies that the starting points for determining sound level criteria in a remote area are 50 dBA during daytime and 40 dBA during nighttime (basic sound levels). These may be adjusted based on ambient monitoring data, and the results in Table 6.2-5 indicate that background sound levels during the daytime and nighttime were each approximately 31 dBA (actual sound levels). The adjustments were calculated based on the difference between the basic sound levels and actual sound levels. The differences of 19 dBA (day) and 9 dBA (night) result in adjustments of -10 dBA (day) and -4 dBA (night), indicating that the final criteria (or PSL) are 40 dBA (day) and 36 dBA (night).

6.2.4 Assessment of Project-Related Effects

6.2.4.1 Potential Interactions Between the Project and Valued Component / Key Indicators

Potential Project-related interactions with the Noise VC and its associated KI are summarized by Project phase in Table 6.2-6, with a grey highlighted check mark (✔) indicating a primary interaction, and a check mark (✓) indicating another interaction. Potential interactions in the summary table are ranked as:

- **Primary Interaction** (✓): Project activity is expected to interact with the VC/KI, which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.
- **Other Interaction (✓):** Project activity is expected to interact with the VC/KI. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects.
- **No Interaction:** Project activity is not expected to interact with the VC/KI, no adverse effects are expected, and a rationale is provided for not considering this potential interaction further.

The potential interactions identified in Table 6.2-6 are addressed further following the table.

Table 6.2-6: Potential Project Interactions for Noise

Project Phase/Activity	Noise
	Noise Levels
Construction Activities	
Development of access roads and air strip	✓
Site preparation and earthworks; clearing, levelling, and grading of the Project Area	✓
Power generation – generators	✓ (primary)
Installation of main substation and distribution of power around site	
Wellfield and freeze hole drilling; ground freezing	✓ (primary)
Batch plant operation (concrete); crusher at borrow area	✓ (primary)
Development of surface infrastructure (camp, operations centre, plants, ponds, pads, and support facilities)	✓
Waste management (composting, domestic and industrial landfill operation, recycling)	
Water management (including treatment and site runoff)	
Groundwater supply	
Surface water withdrawal	
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
On-site and off-site operation of vehicles and transport of materials	✓
Air transportation for workers	✓
Regulatory site inspections	
Engagement – site visit from Interested Parties	

Project Phase/Activity	Noise
	Noise Levels
Operation Activities	
Operation of the ISR wellfield	✓
Wellfield and freeze wall drilling	✓
Operation and expansion of freeze wall	✓
Batch plant operation (grout and cement); crusher in borrow area	✓
Expansion of pond and pads	
Operation of the processing plant and production of uranium concentrate	
Water withdrawal from groundwater or surface water body	
Management of surface water (including seepage and site runoff)	
Water treatment, both domestic and industrial	
Water release to surface water body	
Waste management (composting, domestic and industrial landfill operation, recycling)	
Hazardous waste management (temporary storage, handling, and off-site transportation)	
Storage and disposal of drill waste rock, process precipitates, and industrial wastewater treatment plant precipitates	✓
On-site and off-site operation of vehicles and transport of materials	✓
Power supply – primarily power from the grid, also generators and back-up generators	✓
Package and transport of nuclear substances	✓
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
Air transportation for workers	✓
Progressive decommissioning and reclamation	
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Decommissioning Activities	
Site water management, treatment, and release	
Mining horizon remediation and thawing of freeze wall	
Process water treatment and release	
Closure of ISR and freeze wells and related infrastructure	
Decontamination of surface facilities and injection, recovery, and monitoring wells	
Asset removal (including site power transmission lines and electrical infrastructure)	✓
Demolition and disposal of non-salvageable surface infrastructure and materials	✓

Project Phase/Activity	Noise
	Noise Levels
Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and process plant area)	
Generators	✓
Waste management (composting and landfill operation)	
Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal)	
On-site and off-site operation of vehicles and transport of materials	✓
Reclamation of disturbed areas	
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Post-Decommissioning Activities	
Environmental monitoring	
Regulatory site inspections	
Engagement – Site visit from Interested Parties	

It should be noted that the assessment of noise effects included only Construction and Operation activities as Decommissioning and Post-Decommissioning activities would be effectively bounded by these phases in terms of the potential to cause an effect.

The information on activities associated with each phase of the Project shown in Table 6.2-6 was used to develop assessment scenarios for use in predictive modelling. The scenarios were developed based on the year with the maximum activity occurring in each phase.

The Construction scenario was based on the first year of construction as this involves the most equipment operating at the site, including construction of surface facilities, wellfield drill mobilizations, drilling of freeze holes and ISR wells, and partial operation of the freeze plant. Construction activities will be supported by a concrete batch plant and crusher, and power to the site during this stage will be provided by two (2) 1.1 MW generator sets and two (2) 450 kW generator sets. In addition, there will be regular truck trips to the site for delivering construction materials and site supplies (e.g., food, fuel). This scenario also included air traffic for personnel changes.

The Operation scenario was based on activities being completed in the late stages of Operation, with work being completed in Phase 5 of the deposit. Well drilling would continue, and the freeze plant was assumed to be operating at maximum capacity. While the site will be powered from the provincial grid at this stage, the power generators were assumed to be operating under emergency conditions as a worst-case scenario. Regular truck traffic will continue for provision of wellfield materials, process supplies, food, and fuel, and shipping of yellowcake material will commence. This scenario also included air traffic for personnel changes.

The specific noise sources associated with each of the above activities that were included in the assessment of noise effects are summarized in Appendix 6-E. The discussion of sources therein also includes detailed information on the derivation of source sound power levels for use in predictive modelling.

6.2.4.2 Potential Project-Related Effects

The propagation of sound from the Project associated with Construction and Operation was predicted using the software package Cadna-A from DataKustik GmbH (DataKustik 2020), which is based on the industry standard calculation method described in ISO Standard 9613-2 (ISO 1996). Air traffic was also assessed within the same Cadna-A model using a module for Cadna-A (DataKustik 2013) that implements the Integrated Noise Model developed by the Federal Aviation Administration in the United States. Sound power levels for the identified sources were generally established using manufacturer specifications, historic measurement data from similar sites, or engineering calculation methods referenced from scientific literature. The inputs for the calculations were derived from available manufacturer specifications and the operating parameters outlined on the equipment lists supporting the prefeasibility study (Denison 2018). Details regarding source characterization are provided in Appendix 6-E.

A scaled 3D representation of the facility and its surroundings was constructed in the model using digital terrain mapping and information on the planned building, road, and airstrip layouts. The model space was then populated with the identified noise sources and the associated sound power levels. Sensitive points of reception within the Noise LSA, including locations of interest to the Human Health and Ecological Risk Assessment and the aforementioned leased properties, were plotted at the provided coordinates as shown in Figure 6.2-4. The model was then run to calculate sound levels associated with each source active in each Project phase at each of the identified points of reception, and these were compared to the baseline levels discussed in Section 6.2.3 and/or the sound level limits summarized in Section 6.2.1.2. Additional details regarding the model configuration are provided in Appendix 6-E.

6.2.4.2.1 Potential Effect 1: Ldn and Increase in %HA

The first potential effect relates to the parameters associated with the Health Canada guidelines. There were found to be no predicted exceedances of the Health Canada limits for either of the modelled scenarios (Construction or Operation). The maximum predicted total Ldn was 42.3 dBA during Construction (Figure 8 in Appendix 6-E) and 40.4 dBA during Operation (Figure 10 in Appendix 6-E), which are well below the criterion of 75 dBA. Both were predicted at the property identified as 302586/Risk2, which is a seasonal cabin where recreational activities such as fishing may occur for a few weeks each summer located southeast of the Project Area at the south end of

McGowan Lake (Figure 6.2-4). When adjusted by +10 dBA and converted to %HA, and then compared to the adjusted baseline %HA, the predicted change in %HA at this location was +1.3% and +0.7% for Construction and Operation, respectively. These are each below the criterion of +6.5%. Contour plots depicting the %Ha are presented in Figures 9 and 11 in Appendix 6-E.

6.2.4.2.2 Potential Effect 2: Daytime and Nighttime Sound Levels

The second potential effect is associated with the provincial guideline under which daytime and nighttime sound levels were assessed and compared to the PSLs discussed in Section 6.2.1.2 and established based on the baseline conditions discussed in Section 6.2.3.2.

The daytime sound levels were not predicted to exceed the PSL of 40 dBA at any of the identified receptors in either scenario. The maximum predicted daytime sound levels were predicted at the property identified as 302586/Risk2 and were 35.8 dBA during Construction and 34.1 dBA during Operation. The increase in sound level at this location was found to be primarily attributable to drilling activity in the wellfield, concrete batching, and movement of trucks on the access road.

The nighttime sound levels were not predicted to exceed the PSL of 36 dBA at any of the identified receptors during Construction or Operation. As with the daytime sound levels, the maximum predicted nighttime sound levels were predicted at the property identified as 302586/Risk2. The predictions at this location were 35.9 dBA and 34.0 dBA for Construction and Operation, respectively. Detailed contour plots are presented in Figures 12-15 in Appendix 6-E.

As these are not impulse or tonal sources, no adjustments were made to the source sound levels. The crusher was modelled at its maximum sound output, while the diesel-powered equipment (e.g., dozers, drill rigs) were adjusted for partial operation over the respective daytime and nighttime periods. To account for potential issues resulting from equipment operating at maximum levels (as opposed to daytime and nighttime averages), the models were run with the partial operation adjustments removed, for comparison to the Health Canada recommended criteria value of 45 dBA Lmax at night. The predictions at the nearest human receptors did not exceed 45 dBA Lmax for either Construction or Operation.

6.2.4.2.3 Potential Effect 3: Change in Ld and Ln

In terms of incremental increases in sound level over the baseline conditions, it was found that the maximum increase was during Construction in the daytime hours at location 302586/Risk2 and was in the order of +5.1 dBA. In relation to the criteria in Table 6.2-2, an increase of greater than 5 dBA is considered a moderate effect. The nighttime increase of +4.6 dBA during Construction is considered a *Low* effect in accordance with Table 6.2-2. The increase in sound levels at this location was primarily due to construction activity in the wellfield, concrete batching and associated activity, and truck movements along the access road from Highway 914. During Operation, the maximum increase in sound level was predicted at 302586/Risk2 in the order of +3.4 dBA during the day and

+2.7 dBA during the night. These are associated with low and marginal effect ratings in accordance with Table 6.2-2. The increase in sound at this location is primarily due to wellfield activity, truck movements on the access road from Highway 914, and the operation of the two emergency generators (included as a worst-case scenario, not part of the standard operating condition). Detailed contour plots are presented in Figures 12-15 in Appendix 6-E.

6.2.5 Mitigation Measures

Strategies to reduce the likelihood and magnitude of the predicted effects include source elimination and utilizing planning measures to counter the conditions that contributed to the predicted effects. Mitigation measures to be applied during both Construction and Operation include:

- not using the concrete batching plant and crusher during nighttime hours, where possible;
- locating the concrete batching operation as far away from sensitive locations as possible;
- directing the generator discharge openings away from sensitive locations;
- making use of available on-site obstructions to control sound exposure at sensitive areas (i.e., locate sources behind buildings); and
- collecting sound level measurements from the identified sources once they are operating and determining whether the actual effect is lower than that which was modelled.

6.2.6 Residual Effects Evaluation

The results of the assessment of potential effects indicated that there were no predicted exceedances of the federal or provincial noise criteria (first and second potential effects). The increases in sound level (third potential effect) result in a moderate effect at one receptor during Construction in the daytime hours, which based on Table 6.2-2 may be perceptible and potentially objectionable. As a conservative measure, this has been carried forward as a residual effect. Characterization of the residual effects are discussed in the following section.

6.2.6.1 Residual Effects Characterization

General definitions of the residual effects characteristics are provided in Table 5.8-1 in Section 5. Residual effects characteristics specific to the Noise VC are defined in Table 6.2-7.

Table 6.2-7: Noise – Definitions of Effect Characteristics Considered When Determining the Significance of Residual Effects

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Negative effect or effect is not desirable. **Positive** – Beneficial effect or effect is desirable.
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low** – Minimal amount of change relative to the range of existing variation. **Moderate** – Moderate amount of change relative to the range of existing variation. **High** – High amount of change relative to the range of existing variation.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area. **Local** – Effect is limited to the Noise LSA. **Regional** – Effect extends beyond the Noise LSA into the Noise RSA. **Beyond Regional** – Effect extends beyond the Noise RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals. **Frequent** – Effect occurs many times on a regular basis. **Continuous** – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions. **Partially Reversible** – A residual effect that partially diminishes to baseline conditions. **Irreversible** – A residual effect that will not diminish to baseline conditions.
Context	Since Noise is an intermediate VC, the context is best defined in the significance determination of the receptor VCs including various VCs in the Terrestrial Environment, Indigenous Land and Resource Use, and Other Land and Resources Use assessments.	
Likelihood	Likelihood that the residual effect will occur, including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

The residual effects criteria defined in Table 6.2-7 have been applied to the change in sound level during daytime Construction hours, which was the only scenario with a residual effect. An assessment of the residual effect is summarized in Table 6.2-8.

Table 6.2-8: Noise – Summary of the Characteristics Ratings for Residual Effect 1 (Construction, Daytime Increase over Baseline)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Increased noise is considered an undesirable effect.
Magnitude	Moderate	The predicted increase is greater than 5 dBA but less than 10 dBA.
Geographic Extent	Local	The receptor is located in the Noise LSA.
Duration	Short-term	The increase of greater than 5 dBA is only related to Construction.
Frequency	Frequent	The increase during the daytime is related to sources that operate continuously (drilling, generators, concrete batching, truck movements).
Reversibility	Fully Reversible	Sound levels are expected to return to baseline as sources cease to operate.
Context	Context is described for receptor VCs	
Likelihood	Likely	Sound levels are associated with equipment that is likely to operate on a continuous basis.

6.2.6.2 Significance and Confidence

6.2.6.2.1 Significance

As discussed in Section 5.8.1.2.1, significance is determined for VCs that represent assessment endpoints (e.g., Ungulates, Furbearers, Woodland Caribou, Indigenous Land and Resource Use, Other Land and Resource Use). Since the results of the Noise assessment feed into these other assessment endpoints, the results of the residual effects characterization for Noise do not have significance determinations of their own. See Sections 9 and 11.

6.2.6.2.2 Confidence

To have confidence that the predictions completed in support of this assessment will bound the actual observed conditions upon Project commencement, a series of conservative assumptions were implemented at each stage of the assessment. It should be noted that the ISO 9613-2 method that the predictive model implemented for sound propagation indicates that the estimated accuracy of the predictions is ±3 dB (ISO 1996). This would indicate that if all sources were characterized accurately, and the model conditions reflected actual conditions (e.g., meteorology, reflective parameters), then the model predictions would be within 3 dB of a measured level at the point of prediction. To have confidence in the bounding of the predictions for this assessment, the source sound level inputs and model configuration were set with conservatism. The assumptions to facilitate a conservative assessment are summarized in the following bullets:

- Sound power levels for mechanical equipment were calculated from literature based on the rated power for each source in the equipment list developed for the prefeasibility study (Denison 2018). To remain conservative, the rated powers for sources such as pumps and motors were doubled.
- Sound power levels for mobile construction equipment were calculated from literature using the maximum rated power for the associated expected manufacturer model.
- Generators were modelled at the maximum rated power levels, whereas they are actually likely to operate at partial load.
- The assessment scenarios account for all associated equipment running simultaneously and continuously (except for inherently intermittent sources such as vehicle trips).
- A gap analysis memo/model inputs summary was prepared for review by Denison prior to modelling, to make sure that the source list was reflective of current Project plans and that the modelling reflected the worst-case operating scenario for each phase.
- Modelling was completed using the temperature and relative humidity settings that resulted in the highest predicted sound levels. As per the model defaults, all receptors were treated as being downwind regardless of actual location relative to Project activities.

Details regarding the source sound levels and calculations, as well as the detailed model configuration, are provided in Appendix 6-E.

6.2.6.3 Summary of Project-Related Residual Adverse Effects on Noise

Residual effects were predicted at one location (i.e., the cabin at 302586/Risk2). The effect was limited to daytime hours during Construction, where daytime sound levels were predicted to increase by +5.1 dBA, resulting in a moderate effect. It should be noted that the federal and provincial criteria were not exceeded at this receptor location, nor at any other receptor location included in the assessment. Effects during Construction were predicted to be short-term (less than three years). The mitigation measures discussed in Section 6.2.5 are expected to assist in reducing the likelihood of this effect occurring.

6.2.7 Cumulative Effects

The Project Area will be accessed from Highway 914 by a proposed access road. Highway 914 is approximately 3.4 km (direct) from the developed Project site, or approximately 5 km by the proposed access road. The Cameco McArthur River Operation and Key Lake sites are currently in Care and Maintenance mode; therefore, there is currently no truck traffic between the sites on Highway 914. When these sites are to become operational again, there is potential for a cumulative effect at sensitive locations near the highway. Based on traffic volumes documented as part of the Millennium Project EA and summarized in a memo prepared by Denison (Denison 2022), the estimated daily truck traffic on Highway 914 when McArthur River and Key Lake are operating is approximately 58 trucks per day. A model was prepared that estimated the contributing sound levels of this amount of traffic on Highway 914 at each of the sensitive receptors included in the assessment. At location 302586/Risk2 (where the maximum effect of the Project was predicted), the predicted Ldn due to truck traffic was 18.3 dBA, which would not change the predicted sound levels when added on a logarithmic basis and therefore not change the assessment results based on the Health Canada guidelines. Similarly, the predicted daytime and nighttime levels at 302586/Risk2 due to anticipated Cameco truck traffic were each 11.9 dBA, which would also not change the predicted sound levels when added on a logarithmic basis, and therefore not change the assessment results based on the provincial guidance.

There are two leased properties that are closer to Highway 914 than 302586/Risk2: 301493 (125 m) and 602377 (240 m). The contributions from the Project at these locations were well below background (i.e., not expected to change the background noise levels). The increases in sound level at these locations (or any of the other locations included in the assessment) due to the addition of Cameco traffic to the model did not result in any exceedances of the federal or provincial guidelines, and incremental increases remain in the marginal to low range.

6.2.7.1 Climate Change Considerations

The generation of noise is not generally considered to be a factor that inherently or directly influences climate change. That said, climatological factors may influence the propagation of noise, and may also change the nature of operations. For instance, if temperatures warm, then cooling equipment (and electricity generation required to run it) may run longer and under greater loads, resulting in greater sound levels over longer periods. In terms of propagation, meteorological conditions such as temperature and relative humidity may influence the propagation of sound. The modelling was completed using a combination that generally results in the most conservative predictions (low temperature and high humidity). Temperature inversions are another climate-related occurrence that may affect noise propagation as temperature inversions act to refract sound waves that would otherwise disperse in the atmosphere back to the ground, resulting in further propagation. If climate change were to increase the frequency of temperature inversions, then sound levels from Operation would be expected to travel further; however, it should be noted that the modelling for this assessment accounts for moderate temperature inversions in the predictions and further assumes all receptors are downwind. Lastly, it should also be noted that sources of noise are often associated with sources of air emissions, which may then affect climate change depending on the releases. Climate change considerations related to Air Quality are discussed in Section 6.1.7.1.

6.2.8 Monitoring and Follow-up

An EMS will be implemented and include noise management and monitoring plans to confirm that the Project is compliant with the federal and provincial guidelines that have been adopted for this assessment during both Construction and Operation. Noise monitoring will be similar in nature to baseline monitoring that was completed in support of this assessment and will be completed twice per year to capture seasonal variability. The monitoring program will incorporate requirements directed by provincial and federal regulators and will seek and include input from Indigenous groups and other Interested Parties as requested.

The monitoring program will be developed in accordance with the following outline, provided as required by the EIS Guidelines. Prior to the commencement of the first routine noise monitoring campaign during Construction, Indigenous Groups and other Interested Parties will be notified of the monitoring schedule and planned locations. Initially, the proposed locations will be the same locations as were used in the baseline program for direct comparison of the data to the baseline conditions. These locations may be revised or expanded upon to include other locations based on feedback received. At the same time, Indigenous Groups and other Interested Parties will also be notified of how noise complaints may be registered. If a noise complaint is received, the associated monitoring would then take place at the location of the complainant.

Upon receiving a noise complaint, the responsible Denison environmental staff will implement a complaints response and resolution process, documented using a complaints management form.

The information to be recorded during the registration of the complaint will include the name and contact details of the complainant, the nature of the complaint, a description of the possible source(s) at the site associated with the complaint. Sound levels will then be monitored at the location of the complainant according to the description below, and a recommended action will be identified within two days with a timeline for implementation. Follow-up with the complainant will then take place to ensure that the issue has been resolved and follow-up monitoring will be completed where appropriate. Once the complainant is satisfied that that the issue has been resolved, the complaint will be formally closed out and a summary report will be completed by Denison and kept on file.

Routine and complaints-based noise monitoring will utilize the same methods as the baseline monitoring program, as described in Section 6.2.3. Sound levels will be monitored on a continuous basis using a calibrated Class 1 sound level meter and data logger, calibrated to a National Institute of Standards and Technology traceable standard within one year of its use in the program, and field calibrated using a Class 1 acoustic calibrator. The sound level meters log sound levels on a minimum one-hour basis (and logged on the hour for direct comparison to site meteorological data). At a minimum, the parameters to be logged include the energy equivalent sound level (Leq) and statistical parameters (Lmin, Lmax, L10, L50 and L90) logged on a continuous basis, and the Ldn logged on a 24-hour basis (midnight to midnight). The collected data will be compared with hourly meteorological data collected on-site for purposes of validation. The same validation parameters as outlined in Table 6.2-3 will be used. Any data collected under unrepresentative conditions will be discarded prior to analysis. For routine monitoring, the programs will be of a minimum one-week duration. For complaints-based monitoring, the duration will be set based on the nature of the complaint.

6.2.9 Noise Summary

Noise was selected as a VC in general based on the likelihood of Project-related activities to interact with and change the existing sound environment. Any change to the existing sound environment in the vicinity of the Project has the potential to affect Indigenous groups and the public in terms of creating nuisance noise that may affect human health and change animal behaviours as related to hunting activity. The assessment of Noise included a baseline monitoring program to establish existing conditions and the use of predictive models to assess how the Project may change the sound environment from existing conditions. The predicted changes to the sound environment were then assessed against federal and provincial guidelines to determine if the effects of the Project were significant and if mitigation measures were required.

Federal and provincial guidance documents include procedures for predicting the effects of a project, including the specific parameters to be assessed (e.g., 24-hour sound levels, daytime sound levels, nighttime sound levels, and measures of community annoyance) and thresholds for each parameter to be used to assess the effects. For instance, Health Canada uses a 24-hour sound level metric and a change in sound level between existing and future conditions to evaluate the effects of a project. The guidelines also identify the appropriate means of assessing project-related sound levels, which include predictions using internationally recognized software. The software used for these predictions was Cadna-A from DataKustik GmbH, which is based on ISO Standard 9613-2, being the industry standard for industrial noise predictions.

Sources associated with the Project were identified using information detailing the process description and feasibility studies developed to identify equipment requirements. Sound levels were conservatively calculated using engineering calculation approaches, manufacturer data, or measurement data for similar sources at similar sites. The site infrastructure and sources were input in the model and sound levels were predicted at sensitive locations, including leased properties and locations of interest to the Human Health and Ecological Risk Assessment. The predicted sound levels were then compared to the baseline sound levels and the thresholds from the guidance documents.

The predicted sound levels were below the threshold values from the federal and provincial guidelines at all receptor locations, indicating that additional mitigation measures would not be required. The closest sensitive location to the Project is a cabin identified as leased property 302506. While the predicted sound levels were less than the guideline values, the increase from baseline was predicted to be noticeable. Therefore, as a conservative approach, this effect was carried forward as a residual effect and mitigation measures and follow-up monitoring were recommended.

Abbreviations, Acronyms, and Units

Abbreviation / Acronym	Definition
COPC	Constituent of potential concern
CSM	Conceptual Site Model
Denison	Denison Mines Corp.
EA	Environmental assessment
EC	Electrical conductivity
EIS	Environmental Impact Statement
GWMP	Groundwater Monitoring Plan
IK	Indigenous Knowledge
ISR	In situ recovery
KI	Key Indicator
LK	Local Knowledge
LSA	Local Study Area
MF	Manitou Falls
MP	Measurable Parameter
ORP	Oxidation-Reduction Potential
Project	Wheeler River Project
RSA	Regional Study Area
VC	Valued Component
VWP	Vibrating wire piezometer

Units	Definition
%	percent
cm	centimetre
km	kilometre
km^2	square kilometre
L/s	litre per second
m	metre
masl	metres above sea level
mbgs	metres below ground surface
m^3	cubic metre
m/s	metre per second
m^3/hr	cubic metre per hour
m^3/s	cubic metre per second
mg/L	milligram per litre
µS/cm	microsiemen per centimetre

Glossary

Term	Definition
Adsorption	The retention of atoms, ions, or molecules onto the surface of another substance.
Advection	Process by which a solute is transported in groundwater and moves at the same velocity.
Alluvial (material, deposit, sediment, fan)	Unconsolidated material deposited in a sorted or semi-sorted condition by a stream or other body of running water, in a stream bed, floodplain, delta or at the base of a mountain slope as a fan.
Aquifer	Rocks or unconsolidated sediments that are capable of yielding a significant amount of water to a well or a spring.
Aquifer Test	A test which involves adding to or discharging from a well, measured quantities of water, and recording the resulting changes in head in the aquifer (during and after addition/withdrawal). Examples are slug tests, bail tests, and pumping tests.
Aquitard	A geologic formation that may contain groundwater but is not capable of transmitting significant quantities of groundwater under normal hydraulic gradients. In some situations, aquitards may function as confining beds.
Attenuation, Attenuate	The reduction or removal of groundwater constituents by the sum of all physical, chemical, and biological factors acting upon the groundwater. In geophysical terms, it refers to a reduction in energy or amplitude caused by the physical characteristics of a transmitting system.
Average Linear Groundwater Velocity	The velocity of groundwater moving through porous rock or sediment. It is the time required for the water to move from A to B divided by the linear distance from A to B.
Background concentration	The amount of a substance typically found in the air, water, or soil from non-site related activities.
Base Flow	The sustained low flow in a stream. Generally base flow is the inflow of groundwater to the stream.
Bedrock	A general term referring to rock that underlies unconsolidated material.
Borehole	A hole drilled or bored into the earth, and into which casing, screen, etc. may be installed to construct a well.
Borrow Pit	An excavated area where soil, sand, or gravel has been dug up for use elsewhere.
Boundary Condition	A specified numerical condition (e.g., specified water level or rate of flow in, or out, of a model) at a location within a mathematical model. Process variables are primarily computed (i.e., simulated) for nodes without boundary conditions.
Bounding	Bounding in the context of environmental assessment refers to establishing the limits or boundaries within which the assessment will be conducted. In this Section (Geology and Groundwater), the term bounding has been used specifically to establish the range, or upper or lower limit(s) (as specified), of values considered conservative and appropriate for the assessment based on available information in the literature and Project/site-specific testing (metallurgical, hydrogeological, etc.,).
Calibration	The process of matching a model simulation with observed data. Typically, one or more model parameters are varied within reasonable limits until a suitable match is obtained.
Characterization	A determination of the approximate concentration range of compounds of interest used to choose the appropriate analytical protocol. Also applied to refer to conceptualization of hydrogeologic conditions.
Conceptual (Site) Model	The idealization of a hydrogeological system which acts as a basis of further evaluation (e.g., mathematical model). The conceptual model includes assumptions on the hydrostratigraphy, material properties, dimensionality and governing processes.

Term	Definition
Confined Aquifer	A fully saturated aquifer overlain by a confining layer. The potentiometric surface (i.e., hydraulic head) of the water in a confined aquifer is at an elevation that is equal to or higher than the base of the overlying confining layer. Pumping wells in a confined aquifer lower the potentiometric surface which forms a cone of depression, but the saturated media remains saturated.
Connectivity	The degree to which a fracture network is connected. When defined statistically, fracture connectivity can be used to generate many different fracture network realizations for use in groundwater flow and mass transport models.
Conservative	A dissolved substance which moves as fast as water in the groundwater system and is not prone to attenuation beyond that occurring by diffusion and/or dispersion.
Consolidated	Naturally occurring geologic material that has been lithified and so has strength and resists disintegration.
Constituent	A component of a system or group (e.g., an ion within a suite of ions dissolved in groundwater).
Containment	The process of enclosing or containing hazardous substances in a structure, typically in a pond or lagoon, to prevent the migration of Constituents of Potential Concern into the environment.
COPC	Constituents of Potential Concern. Any physical, chemical, biological, or radiological substance in air, soil or water that could increase a concentration above background or baseline conditions.
Core	A continuous columnar sample of subsurface material extracted from a borehole. Such a sample preserves the features of the sampled material.
Corehole	The hole in the earth that remains after rock core has been collected. The corehole may naturally collapse when in unconsolidated deposits or remain open in solid rock environments.
(Drill) Cuttings	The rock fragments, sand grains, etc. produced at the drill bit by the drilling action and circulated to the surface in the drilling fluid where they can be sampled.
Decay	The gradual reduction in the magnitude of a quantity.
Density	The amount of mass per unit volume.
Desorption	Process of removing a sorbed substance by reversing adsorption or absorption.
Discharge	The rate of flow at a given time, measured as volume per unit time.
Discharge Area/Zone	An area in which there is upward groundwater flow in the subsurface. Groundwater flows toward the surface in a discharge area and may escape as a spring, seep, or baseflow, or by evaporation and transpiration.
Dispersion	The process by which a substance or chemical spreads and dilutes in flowing groundwater or soil gas.
Dissolution, Dissolve	Process of dissolving a solid to form ions or molecules uniformly distributed in water or another solvent.
Domain	In modelling, the segment of the subsurface being considered. It is defined by its boundaries and interior geometry (based on its hydrostratigraphy), and its material properties (porosity, hydraulic conductivity, etc.).
Downgradient	A downward hydrologic slope that causes groundwater to move toward lower elevations. Therefore, wells downgradient of a contaminated groundwater source are prone to receiving pollutants.
Drainage Pattern	The arrangement of natural stream courses in an area, in plan view. It depends on local geologic/geomorphologic features and history.

Term	Definition
Drawdown	A lowering of the water table of an unconfined aquifer or the potentiometric surface of a confined aquifer caused by pumping of groundwater from wells. The vertical distance between the original water level and the new water level.
Drumlin	Irish term for a small hill. Consists of glacial drift shaped by ice action into a 'hog- back', which is oval in plan and has its long axis pointing in the direction of ice movement. Drumlins often occur in groups.
Effective Porosity	The amount of interconnected pore space through which fluids can pass. Effective porosity is usually less than total porosity because some dead-end pores may be occupied by static fluid.
Esker	A narrow long ridge like form comprised mainly of gravel and sand. These stratified glacio-fluvial deposits were formed in a stream bed flowing inside the ice of a glacier generally at the glacier bottom. The glacio- fluvial deposits were then left in place after the ice melted.
Fate	The immediate or ultimate change in a chemical typically brought about by chemical or biological reaction.
Fault/Fault Zones	A fracture or zone of fractures along which there has been a displacement of the sides relative to one another and parallel to the fracture.
Finite Element (Model, Code)	An advanced numerical technique for solving partial differential equations, most useful for hydrogeological sites with complex geometry. As with finite difference models, a finite element model solves the hydrogeological system over a grid of many subregions, or elements.
Fluid Flux	The volume of flow movement through a unit cross-sectional area per unit of time due to a hydraulic gradient. Mass flux is the rate of movement of mass through a unit cross-sectional area per unit time in response to a concentration gradient or some advective force.
Fracture	A break in a rock formation as a result of structural stresses (e.g. faults, joints, shears). If they are open, fractures may provide pathways for fluid movement.
Geology	The science that deals with the earth's physical structure and substance, its history, and the processes that act on it.
Geomorphology	Geomorphology is the science dealing with the origin and evolution of landforms.
Glaciofluvial (Deposits)	Deposits related to the joint action of glaciers and meltwater streams.
Gradient	The rate of change in value of a physical or chemical parameter per unit change in position. For example, hydraulic gradient is equal to the difference in hydraulic head measured at two points (usually wells) divided by the distance separating the two points. The dimensions of head and distance are both lengths, therefore the gradient is expressed as a dimensionless ratio (L/L). A concentration gradient refers to the difference in concentration between two points and would have units of concentration over distance.
Groundwater	Underground water that fills pores in soils or openings in rocks to the point of saturation. In aquifers, groundwater occurs in sufficient quantities for use as drinking and irrigation water and other industrial purposes.
Groundwater Flow	Movement of water through openings in sediment and rock within the saturated zone.
Groundwater modeling/Model	A conceptual, mathematical, or physical system intended to represent a real system. A model's behaviour is used to understand processes in the physical system to which it is analogous.
Groundwater Plume	Constituents of Potential Concern (COPC) which dissolve into a groundwater system and are moved down gradient. The area of the aquifer containing the degraded water which resulted from the migration of a COPC is called a plume.
Groundwater Quality Assessment	The process of analyzing the chemical characteristics of groundwater to determine whether any hazardous materials exist.
Groundwater Table	That surface below which rock, gravel, sand or other material is saturated. It is the surface of a body of unconfined groundwater at which the pressure is atmospheric.

Term	Definition
Grout	A watery mixture of cement (and commonly bentonite) without aggregate that is used to seal the annular space around well casings to prevent infiltration of water or short-circuiting of vapor flow.
Heavy Metals	Metallic elements, some of which are required in trace concentrations for plant and/or animal nutrition, but which become toxic at higher concentrations (e.g., lead, copper).
Heterogeneity	The part of the subsurface that is different in some property (hydraulic conductivity, for example).
Heterogeneous	Composed of non-uniform constituents whose material properties vary in space. All geological material is heterogeneous, but the property of interest (porosity, for example) may be sufficiently uniform for the material to be treated as homogeneous in terms of that property.
Hydraulic Conductivity	A measure of the ability of a fluid to flow through a porous medium determined by the size and shape of the pore spaces in the medium and their degree of interconnection and also by the viscosity of the fluid. Hydraulic conductivity can be expressed as the volume of fluid that will move in unit time under a unit hydraulic gradient through a unit area measured at right angles to the direction of flow.
Hydraulic Gradient	The change in water level with distance. The concept is applicable to groundwater or surface water.
Hydraulic Head	Height above a datum plane (such as mean sea level) of the column of water that can be supported by the hydraulic pressure at a given point in a groundwater system. Equal to the distance between the water level in a well and the datum plane.
Hydrogeological Conceptual Model	A representation, often simplified and perhaps conceptual, of the hydrogeological flow system. The aspects important for the site are emphasized. See also model.
Hydrogeology	The study of groundwater, with particular emphasis on the chemistry and movement of water. The branch of geology concerned with water occurring underground or on the surface of the earth.
Hydrologic Cycle	The continued circulation of water between the ocean, atmosphere and land is called the hydrologic cycle.
Hydrostratigraphic Unit	A formation, part of a formation, or a group of formations which have similar hydrologic characteristics.
Igneous Rock	A rock or mineral which solidified from molten or partly molten material i.e., from a magma.
In situ	In its original place; unmoved; unexcavated; remaining in the subsurface.
Infiltration	The movement of water or other liquid down through soil from precipitation (rain or snow) or from application of wastewater to the land surface.
Lacustrine	Formed in, produced by or pertaining to a lake.
Landfill	A disposal facility where waste is placed in. Sanitary landfills are disposal sites for non-hazardous solid wastes. Secure landfills are disposal sites for hazardous waste. They are designed to minimize the chance of release of hazardous substances into the environment.
Leach, Leaching	The process by which soluble chemical components are dissolved and carried through soil by water or some other percolating liquid.
Leachate	A solution produced by the percolation of liquid through soil or solid waste, and the dissolution of certain constituents in the water.
Leachate Collection System	A system that gathers liquid that has leaked into a landfill or other waste disposal area and pumps it to the surface for treatment.
Lithology, Lithologic	A system for the description of rocks, with respect to mineral composition and texture.

Term	Definition
Mapping	Locating geological, chemical or geophysical information in space (as opposed to time, which is monitoring). The results are usually summarized of maps.
Mass Flux	Like fluid flux, but the mass of a chemical dissolved in groundwater which moves through a specified cross-sectional area per unit time.
Matrix	The solid framework of a porous medium. In fractured rock, matrix refers to the unfractured rock.
Migration	The movement of chemicals, bacteria, gases, etc. in flowing water or vapour in the subsurface.
Mineralogy	The study of minerals; formation, composition, properties, classification and occurrence.
Mineralization (context: uranium ore)	The process of formation and distribution of uranium minerals within a (uranium) ore body
Mineralization (context: groundwater)	The outcome of mineral dissolution in water. The extent of mineral dissolution is expressed as the total dissolved solids (TDS) in water, including groundwater.
Mitigation	Actions taken to improve site conditions by limiting, reducing, or controlling toxicity and sources.
Monitoring	Observing the change in a geophysical, hydrogeological or geochemical measurement with time.
Monitoring Wells	Special wells drilled at specific locations within, or surrounding, a hazardous waste site where groundwater can be sampled at selected depths and studied to obtain such information as the direction in which groundwater flows and the types and amounts of contaminants present.
Non-Unique	In geophysical interpretation and mathematical modelling, a problem for which two or more subsurface models, or parameter distributions, satisfy the observation data equally well.
Ore deposit	The economic portion of the uranium mineralize area that is being mined
Organic Compound	Substances containing carbon, with the exception of carbon dioxide (CO2) and carbonates (e.g., calcium carbonate, CaCO3).
Outwash (Deposits)	Stratified drift deposited by meltwater streams flowing away from melting ice.
Overburden	The layer of fragmented and unconsolidated material including loose soil, silt, sand and gravel overlying bedrock, which has been either transported from elsewhere or formed in place.
Oxidation-Reduction (redox)	A chemical reaction consisting of two half-reactions; an oxidation reaction in which a substance loses or donates electrons, and a reduction reaction in which a substance gains or accepts electrons. Redox reactions are always coupled because free electrons cannot exist in solution and electrons must be conserved.
Packer	A device placed in a well or borehole to isolate or seal a section at a certain level.
Paleoweathered	A weathering profile of a vertical assemblage of weathering zones (subsurface zones of bedrock alteration differing physically, chemically, or mineralogically from adjacent zones) as compared to the unaltered bedrock.
Partitioning	Chemical equilibrium condition where a chemical's concentration is apportioned between two different phases according to the partition coefficient, which is the ratio of a chemical's concentration in one phase to its concentration in the other phase.
Permeability	A qualitative description of the relative ease with which rock, soil, or sediment will transmit a fluid (liquid or gas). Often used as a synonym for hydraulic conductivity or coefficient of permeability.
pH	A measure of the acidity of a solution. pH is equal to the negative logarithm of the concentration of hydrogen ions in a solution. A pH of 7 is neutral. Values less than 7 are acidic, and values greater than 7 are basic.

Term	Definition
Phase	A homogeneous, physically distinct portion of the subsurface. For example, groundwater, soil gas.
Piezometer	A non-pumping well, generally of small diameter, which is used to measure the elevation of the water table or potentiometric surface. A piezometer generally has a short well screen and the water level within the casing is considered to be representative of the potentiometric surface at that particular depth in the aquifer.
Piezometer Nest	A set of two or more piezometers set in close proximity to one another but screened at different depths. This allows for determination of vertical flow gradients or differences in water chemistry with depth.
Plume	Constituents of potential concern dissolved in groundwater or vapour originating from a specific source and influenced by certain factors such as local groundwater or soil vapour flow patterns and character of the aquifer. The zone of impacts that exhibits dissolved-phase constituents at concentrations above some specified concentration level, such as background or baseline conditions.
Pore (Space)	An opening, void or interstice in a soil or rock mass.
Porosity	The ratio of the volume of pore spaces in a rock or sediment to the total volume of the rock or sediment.
Porosity, Primary	The pore spaces which were created at the time of deposition of a soil or rock unit.
Porosity, Secondary	The pore spaces which were created after the time of deposition of a soil or rock unit (e.g. fractures, solution channels).
Precipitation	a) Formation of solids out of dissolved constituents; it is caused by a change in conditions (e.g. temperature) b) Water that falls to the ground surface from the atmosphere as rain, snow, hail, sleet, etc..
Pumping Test	An aquifer test in which a well is pumped for a certain period of time and the change in hydraulic head in observation wells is recorded. It is used to determine the capacity of a well and hydraulic characteristics of the aquifer.
Radionuclide	A material with an unstable atomic nucleus that spontaneously decays or disintegrates, producing radiation. Nuclei are distinguished by their mass and atomic number.
Recharge	Addition of water to the groundwater system by natural or artificial processes.
Recharge Area/Zone	Area in the aquifer where there are downward components of hydraulic head. In this area, infiltration travels downward into the deeper sections of the aquifer.
Recovery	The rise in static water level in a well, after discharge from that well or a nearby well has ended.
Redox	Short for oxidation-reduction.
Reducing (Conditions)	Geochemical conditions favouring reduction reactions (e.g., SO4- conversion to H2S). Indicated by the occurrence of reduced forms of iron (Fe2+) and other species.
Residual	The amount of a pollutant remaining in the environment after a natural or technological process has taken place, e.g., the sludge remaining after initial wastewater treatment, or particulates remaining in the air after the air passes through a scrubbing or other process. This term can also be used in numerical modelling studies to refer to the difference between a simulated and observed value (e.g., water level).
Retardation, Retard	Retention of certain Constituents of Potential Concern in the subsurface due to one or more physical, chemical, or biological factors. Also known as attenuation.
Rock quality designation (RQD)	A standard technique in the mining industry for the qualitative and quantitative assessment of rock quality and degree of jointing, fracturing, and shearing in a rock mass.
(Overland) Runoff	That part of precipitation flowing overland to surface streams.

Term	Definition
Sample	A portion of material to be analyzed that is contained in single or multiple containers and identified by a unique sample number.
Saturated (Zone)	Portion of the subsurface environment in which all voids are ideally filled with water under pressure greater than atmospheric. The water table is the top of the saturated zone in an unconfined aquifer.
Sediment	The layer of soil, sand and minerals at the bottom of surface waters, such as streams, lakes and rivers that absorbs Constituents of Potential Concern.
Sensitivity Analysis	After a model is calibrated, a sensitivity analysis is often completed to address the sensitivity of the simulation result to specific input parameters. A sensitivity analysis is useful in determining additional field data requirements and for identifying non-uniqueness.
Solute	A substance dissolved in a solution.
Sorption	Process by which some material leaves the fluid phase and associates with the solid phase. The chemicals associated with the solid phase are sorbed.
Sorptive Retardation	The slowing of a chemical's migration in groundwater or soil vapour due to interaction (sorption/desorption) with the subsurface solids.
Source	A source is generally a mass of residual mass above background or baseline conditions located below ground surface, often below the water table.
Specific Conductance	The ability of a cubic centimeter of water to conduct electricity; depends on the quantity of ionized minerals in it. Measured in microohms per centimeter.
Static Water Level	The level of water in a well that is not being influenced by groundwater withdrawals. The distance to water in a well is measured with respect to some datum, usually the top of the well casing or ground level.
Storativity	The volume of water released from or taken into storage per unit surface area of aquifer, per unit change in head. Also known as storage coefficient.
Stratigraphy	The study of original succession (stratigraphic sequence) and age of unconsolidated materials and rock strata, dealing with their form, distribution, lithologic composition, fossil content, as well as geophysical and geochemical properties.
Surface Water	The portion of water which appears on the land surface; oceans, lakes, rivers, etc.
Surficial (deposits, materials, sediments)	Deposits overlying bedrock and consisting of soil, silt, sand, gravel and other unconsolidated materials.
Terrain Morphology	A stretch of land, especially with regard to its physical features.
Till	Consists of a generally unconsolidated, unsorted, unstratified heterogeneous mixture of clay, silt, sand, gravel and boulders of different sizes and shapes. Till is deposited directly by and underneath glacial ice without subsequent reworking by meltwater.
Topography	The relief and form of the land.
Total Dissolved Solids (TDS)	Concentration of TDS in groundwater expressed in milligrams per litre (mg/L), is found by evaporating a measured volume of filtered sample to dryness and weighing this dry solid residue.
Trace (element)	Any chemical (element) present in minute quantities in soil or water.
Transient	Occurring when the system is still changing with time; i.e., a steady state has not been attained. Most groundwater flow systems are transient, not steady state.
Travel Time	The time it takes (for example) Constituents of Potential Concern to travel from the source to a particular point downgradient.

Term	Definition
Uncertainty	The estimated quantity by which an observed or calculated value may depart from the true value. In numerical models, parameter uncertainty refers to the variance of a parameter from the baseline estimate.
Unconfined	Conditions in which the upper surface of the zone of saturation forms a water table under atmospheric pressure.
Unconfined Aquifer	An aquifer in which there are no confining beds between the capillary fringe and land surface, and where the top of the saturated zone (the water table) is at atmospheric pressure.
Unconsolidated Deposits	Deposits overlying bedrock and consisting of soil, silt, sand, gravel and other material which have either been formed in place or have been transported in from elsewhere.
Unconsolidated Material	Naturally occurring geologic material that has not been lithified into cohesive rock.
Unsaturated Zone	The zone between the land surface and the water table. It includes the root zone intermediate zone, and capillary fringe. The pore spaces contain water, as well as air and other gases at less than atmospheric pressure.
Upgradient	In the direction opposite of groundwater flow. An upgradient are that defines areas from which water would flow toward a contaminated area and, therefore, are not prone to impacts by the movement of groundwater.
Validation	Before a mathematical modelling code can be accepted for use, it must be validated, or proven to realistically simulate the processes for which it was designed. Validation is usually completed by comparing model results against a controlled laboratory or field scale experiment.
Water Balance (Hydrologic Budget)	A record of the outflow from, inflow to, and storage in a hydrologic unit like an aquifer, drainage basin etc.
Water Table	Upper surface of a zone of saturation, where that surface is not formed by a confining unit; water pressure in the porous medium is equal to atmospheric pressure (the phreatic surface). The surface between the vadose zone and the groundwater; that surface of a body of unconfined groundwater at which the pressure is equal to that of the atmosphere.
Watershed	The land area that drains into a stream or other water body.
Weathering	The process during which a complex compound is reduced to its simpler component parts, transported via physical processes, or biodegraded over time.
Well Collar	The height of the top of the casing above the ground surface

7 Geology and Groundwater

Section 7 of the Environmental Impact Statement (EIS) for the Wheeler River Project (the Project) is focused on Geology and Groundwater. The integrated biophysical and human environment assessment approach is illustrated in Figure 7-1. As a guide for EIS reviewers, Figure 7-2 provides a preview of the Valued Components (VCs) associated with the assessments completed in this section of the EIS.

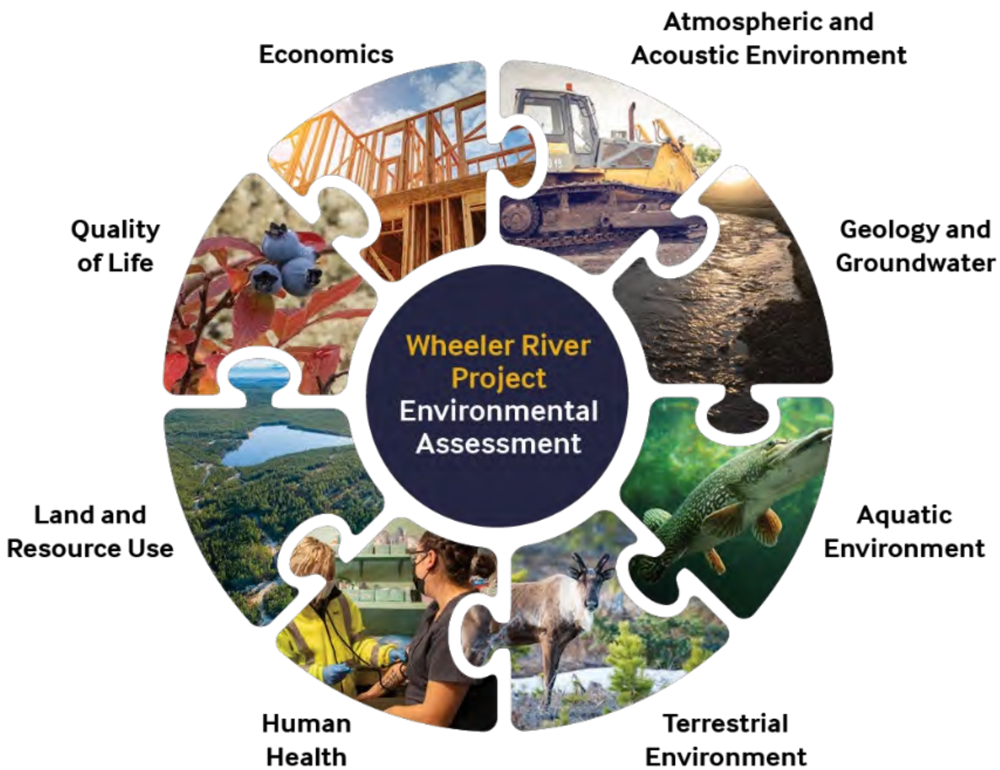

Figure 7-1: Biophysical and Human Environment Assessments for the Wheeler River Project Environmental Assessment

Figure 7-2: Geology and Groundwater – Valued Components

This subsection addresses the potential effects of the Project on the Geology and Groundwater VCs. The Geology and Groundwater VCs are treated together given their close relationship. This approach permits the description of existing and potential future conditions in sufficient detail to enable potential Project VC interactions and effects to be identified, understood, and evaluated.

The following are discussed herein as part of the environmental assessment (EA):

- scope of the assessment;
- influence of Indigenous Knowledge (IK), Local Knowledge (LK), and engagement on the assessment;
- summary of existing conditions relevant to the Geology and Groundwater VCs;
- identification and description of potential interactions between the Project and the Geology and Groundwater VCs;
- identification and description of mitigation measures applicable to the Geology and Groundwater VCs to eliminate, reduce, or control the potential adverse Project-related effects;
- identification of predicted Project-related residual effects on the Geology and Groundwater VCs after mitigation;
- characterization of the level of confidence in the predictions; and

- identification of potential cumulative effects.

Consistent with Section 5 Approach and Methodology of the Assessment, the Geology and Groundwater VCs are considered intermediate VCs, which means they are pathways or linkages to effects on receptor VCs. While a fulsome discussion and interpretation of residual effects on the Geology and Groundwater VCs is provided in this section, the determination of significance of these residual effects is considered within the report sections to which the VCs are linked.

Figure 7-3 is a graphic representation of the assessment process used in this EIS. As shown in Figure 7-3, all VCs selected for this EA went through a thorough residual effect evaluation. Since a change in an intermediate VC may lead to an effect on a receptor VC, significance determination is not completed on intermediate VCs, but integrated into the residual effect evaluation, residual effect characterization, and significance determination for related receptor VCs.

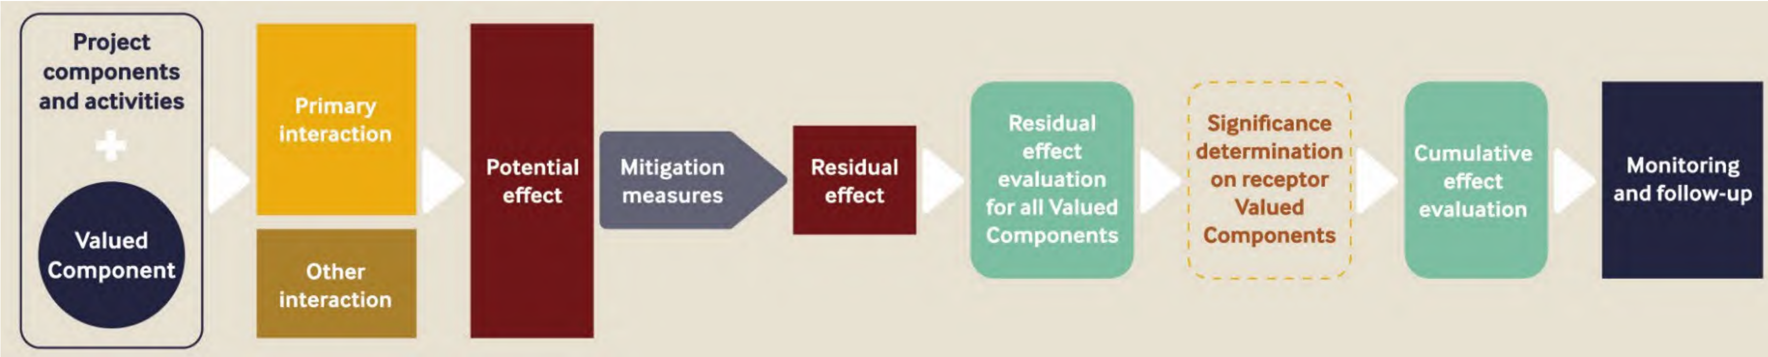

Figure 7-3: Environmental Assessment Process for the Wheeler River Project

7.1 Scope of the Assessment

Geology includes bedrock, soils, and geomorphology (i.e., the study of physical features on the earth and their relationship to underlying geological structures). Groundwater includes groundwater quantity and quality. The Geology and Groundwater assessment follows the overall EA approach and methods described in Section 5 and seeks to understand and characterize the potential residual effects of the Project and any foreseeable developments on the local geological environment and the chemical and physical groundwater environment and associated Geology and Groundwater VCs. Terrain and soil stability and groundwater quality and quantity are aspects of the environment that may be altered by the proposed Project.

This subsection describes the Geology and Groundwater components (i.e., groundwater quality and quantity) in the Project Area and evaluates potential interactions between the Geology and Groundwater VCs and proposed Project components and activities. These include mine contact with groundwater and potential discharge to local waterbodies during Operation, Decommissioning, and Post-Decommissioning. Linkages to other components of the environment include the following VCs: Section 8 Aquatic Environment, Section 9 Terrestrial Environment, Section 10 Human Health, and Section 11 Land and Resource Use.

The scope of the assessment of potential Project-related effects on the Geology and Groundwater VCs was guided by various federal and provincial laws, regulations, policies, and guidelines protecting groundwater quantity and quality in Canada and Saskatchewan, in addition to engagement with the public and Indigenous communities, IK, and LK. These inputs have informed:

- the scope of the assessment;
- the understanding of potential effects and pathways between the Project and groundwater quantity and quality during Construction, Operation, Decommissioning, and Post-Decommissioning;
- Measurable Parameters (MPs) to be used to quantify the potential effects of the Project on groundwater quantity and quality;
- the spatial and temporal boundaries of the assessment; and
- the approach for characterizing and determining the significance of the residual effects.

7.1.1 Valued Component Selection

Valued Components refer to environmental features that may be affected by a Project and have been identified as a VC of the local environment by the proponent, government agencies, Indigenous peoples, the scientific community, and/or the public. For this assessment, the shallow and deeper groundwaters are not considered to be a potable water source currently nor in the future within the Local Study Area (LSA; defined in Section 7.1.3.1), as detailed in Section 7.1.1.1.

Geology is recognized as an important component of the environment that may be affected by the Project. Changes to Geology could in turn lead to effects on other VCs selected for assessment. Acknowledging that changes to Geology are important aspects of the natural and human environment, Geology was referred to as an intermediate VC (i.e., does not have an assessment endpoint). Changes to this intermediate VC were evaluated to facilitate assessment of Project interactions, with links to other disciplines for inclusion in their assessments, including Sections 9 and 11.

Groundwater is an integral component of the hydrologic cycle and is considered an important environmental component and pathway (intermediate VC) to the receptor Surface Water Quantity and Surface Water Quality VCs. Groundwater was selected as a VC for assessment because it is important in maintaining ecological habitats through its influence on the surface water quantity (hydrology) and surface water quality of surface waterbodies, including wetlands. Indigenous Knowledge and engagement activities clearly identified the importance Interested Parties place on groundwater as a pathway to surface water, and the associated potential for changes in groundwater inputs to surface water to influence fish and fish habitat, sediment quality, benthic invertebrates, vegetation, wildlife, human health, and Indigenous land and resource use (Section 7.2).

Within the LSA, the Groundwater VC was considered an intermediate VC as it is a pathway to the aquatic environment. As an intermediate VC, the Groundwater VC does not undergo a significance determination.

As supported by comments and concerns provided by Interested Parties and informed by IK, maintaining groundwater quality and quantity is important for maintenance of surface water quality and health and the shared value of water and its life-sustaining properties (see Section 7.2). The rationale for the selection of the Geology and Groundwater VCs is summarized in Table 7.1-1. Linkages to other discipline assessments that consider potential effects of the Project on Geology and Groundwater are also provided. Figure 7.1-1, Figure 7.1-2, and Figure 7.1-3 are graphic representations of the main linkages among the Geology and Groundwater VCs and other VCs, illustrating the flow of assessment information from the Geology and Groundwater VCs.

Table 7.1-1: Valued Components and Rationale for Selection

Valued Component	Rationale for Selection	Discipline Assessments where Effects on Geology and Groundwater are Considered
Geology	Characteristics of Geology are recognized as fundamental components of the environment that may be affected by the Project. Changes to the local terrain and surface geomorphology could in turn lead to potential effects on other VCs selected for assessment. Components of Geology are important aspects of the natural and human environment. This VC is referred to as an intermediate VC (i.e., does not have an assessment endpoint).	Section 7 Geology and Groundwater Section 9 Terrestrial Environment
Groundwater: Quantity and Quality	Characteristics of Groundwater, and specifically groundwater quantity and quality, are important components that interact with other VCs (e.g., Section 8). If changed by Project activities, these characteristics of the Groundwater VC could affect terrestrial and aquatic biodiversity, as an example.	Section 7 Geology and Groundwater Section 8 Aquatic Environment Section 9 Terrestrial Environment Section 10 Human Health Section 11 Land and Resource Use

Figure 7.1-1: Integrated Assessment Approach – Key Connections between Geology and Other Valued Components

Figure 7.1-2: Integrated Assessment Approach – Key Connections between Groundwater Quantity and Other Valued Components

Figure 7.1-3: Integrated Assessment Approach – Key Connections between Groundwater Quality and Other Valued Components

7.1.1.1 Consideration of Groundwater as a Potable Water Source

The Groundwater VC was not considered a local potable water source. Groundwater is not currently used for domestic purposes based on the following information:

- A single domestic use well is listed in the Government of Saskatchewan, Water Security Agency, Water Well Information Database (WSA 2022) within a 100 km radius of the Project Area. This is a (shallow) well drilled by Cameco Corporation in 1969 to a depth of approximately 72 m bgs, installed in sand. There is also a shallow drinking water well at the existing Project camp, located over 2 km southwest of the Phoenix deposit. There are no records in the database of groundwater wells for non-industrial use (i.e., being used by residents in the area as a potable water source). During Operation, water treated in the potable water treatment plant for use as potable water for the Project may be sourced from shallow groundwater within the LSA (Section 2 Project Description).

- Groundwater use for potable water has not been documented throughout Denison Mines Corp.'s (Denison's) public engagement process.
- Existing water quality in the deep groundwater beneath the Phoenix area is characterized by several groundwater constituents exceeding drinking water guidelines (Appendix 7-A).

7.1.2 Key Indicators and Measurable Parameters

The assessment of Geology focused on potential changes to the surface topography or geomorphology of the Project Area and LSA.

The assessment of Groundwater focused on predicting changes in groundwater flow patterns, groundwater table elevations, and concentrations of selected constituents of potential concern (COPCs) that could affect local surface water. To provide focus, the potential effects assessment for Geology and Groundwater identified relevant Key Indicators (KIs) and MPs. These are defined as follows:

- **Key Indicator**: an important component or aspect of the VC that is expected to be affected (changed) as a result of the Project; and
- **Measurable Parameter**: a parameter or metric associated with the KI that can be used to detect and measure Project-related changes (e.g., change in levels of COPCs).

Table 7.1-2 summarizes the KIs and associated MPs for the Geology and Groundwater VCs. The KIs and MPs were selected based on professional judgement, understanding of the Project, similar EAs for mining projects in Canada, and comments provided during engagement activities with Interested Parties and IK (Section 7.2). The analysis of changes in KI values for Geology and Groundwater were provided to other disciplines for inclusion in their assessment (Table 7.1-2).

Table 7.1-2: Key Indicators and Measurable Parameters for the Geology and Groundwater Valued Components

Key Indicator	Rationale for Key Indicator	Measurable Parameter
Terrain Morphology and Stability *Changes to surface topography and potential subsidence	In situ recovery (ISR) operations could result in localized subsidence at ground surfaces associated with extraction of rock mass within the active mining area (approximately 400 m bgs).	Vertical displacement (i.e., subsidence at ground surface). The standard units used to describe the surface topography and the measure of subsidence are metres above sea level (masl).
Groundwater Quantity *Groundwater flow patterns and discharge rates to local surface water *Groundwater elevation changes	Project activities could result in local and temporal changes in groundwater recharge and changes to groundwater levels and flow. As a pathway to surface water, changes in groundwater levels and natural flow patterns could affect discharges to local surface waterbodies.	Shallow and deep static groundwater levels measured at monitoring locations (masl), resulting in a measurable reduction in baseflow to surface waterbodies (L/s).
Groundwater Quality *Groundwater quality with a focus on groundwater discharge to local surface waterbodies (i.e., Whitefish Lake)	Project activities could result in local and temporal changes in groundwater quality in the deep and shallow groundwater as a result of typical mining operations. As a pathway to surface water, potential changes in groundwater quality from Project activites could affect the quality of groundwater discharging to local surface waterbodies.	Values of physical (temperature) and chemical parameters in groundwater (e.g., pH units or concentrations in mg/L or µg/L) screened in relation to risk-based surface water environmental quality criteria (where available).

7.1.3 Spatial and Temporal Boundaries

7.1.3.1 Spatial Boundaries

The spatial boundaries selected for the Geology and Groundwater assessment were chosen to allow for a full description of existing conditions in sufficient detail to enable potential Project-VC interactions and potential effects to be identified, evaluated, and assessed. This included understanding and assessing the contribution of the Project to cumulative effects. The spatial boundaries for the assessment of the Geology and Groundwater VCs are the same and consisted of an LSA and a RSA, as summarized in Table 7.1-3. The spatial boundaries are:

- **Project Area**: the area within which the Project and all components/activities are located (i.e., the Project footprint; the area of maximum physical disturbance). This area is not VC-specific but is consistent throughout the EA for all VCs.
  - The Project Area is considered in the evaluation of surface topography subsidence associated with the Geology VC. The overall Project Area and Operation have been designed to limit disturbance to the natural geological environment outside of the immediate mining area, and subsidence assessments at this level are required to capture potential local effects.

- **Local Study Area (LSA)**: The LSA is established to assess the potential, largely direct effects of the Project and represents the extent to which there is a reasonable potential for the Project or Project-related activities to interact with and potentially adversely affect the VCs.
  - The boundaries of the LSA were selected in consideration of the Project footprint, mining phases, depth of the in situ recovery (ISR) mining area, site engineering processes, and the spatial extent of potential direct effects of the Project on the VCs, including discharge of groundwater to surface waterbodies. The LSA includes the Project Area and portions of the Icelander River and Williams Lake drainage areas. Specifically, the LSA is bounded by Whitefish Lake and adjacent surface waterbodies to be consistent with the LSA of the aquatic disciplines (e.g., Surface Water Quantity, Surface Water Quality), as shown in Figure 7.1-4.
- **Regional Study Area (RSA)**: the area that surrounds and includes the LSA, established to assess the potential, largely indirect effects of the Project in a regional context. The RSA is large enough to capture the extent of potential effects (i.e., zone of influence) on a VC and defines the area within which cumulative effects may occur (i.e., cumulative effects assessment boundary).
  - The spatial extent was developed to reflect potential groundwater discharge locations within the regional watershed area in which the Project Area is located, and is the RSA defined for the Aquatic Environment (Figure 8.2-3 in Section 8).

Table 7.1-3: Spatial Boundaries for the Geology and Groundwater Valued Components

Study Area	Area	Description/Rationale
Local Study Area	173 ha (17.3 km²)	• Defines the expected extent of the direct and indirect effects from the Project. • Centered on the Phoenix Deposit (see Figure 7.1-4). • Extends 1.5 to 2.5 km in all directions until a surface waterbody is reached: ○ West: William Lake; ○ North: Kratchkowsky Lake; ○ Northeast: northern portion of Whitefish Lake (LA-6); ○ Southeast: McGowan Lake and LA-2; and ○ Southwest: LB-2. • Extends 2 km south of the mine to represent potential groundwater flowing toward Russell Lake. • Provides local context for evaluating groundwater quality and quantity changes and assessing potential residual effects.
Regional Study Area	Approximately 100 km radius surrounding the Project Area (7,850 km²)	• Is the RSA defined for the Aquatic Environment (i.e., Icelander River and William Lake drainage areas), and was defined as such to reflect potential groundwater discharge locations within the regional watershed area in which the Project Area is located.

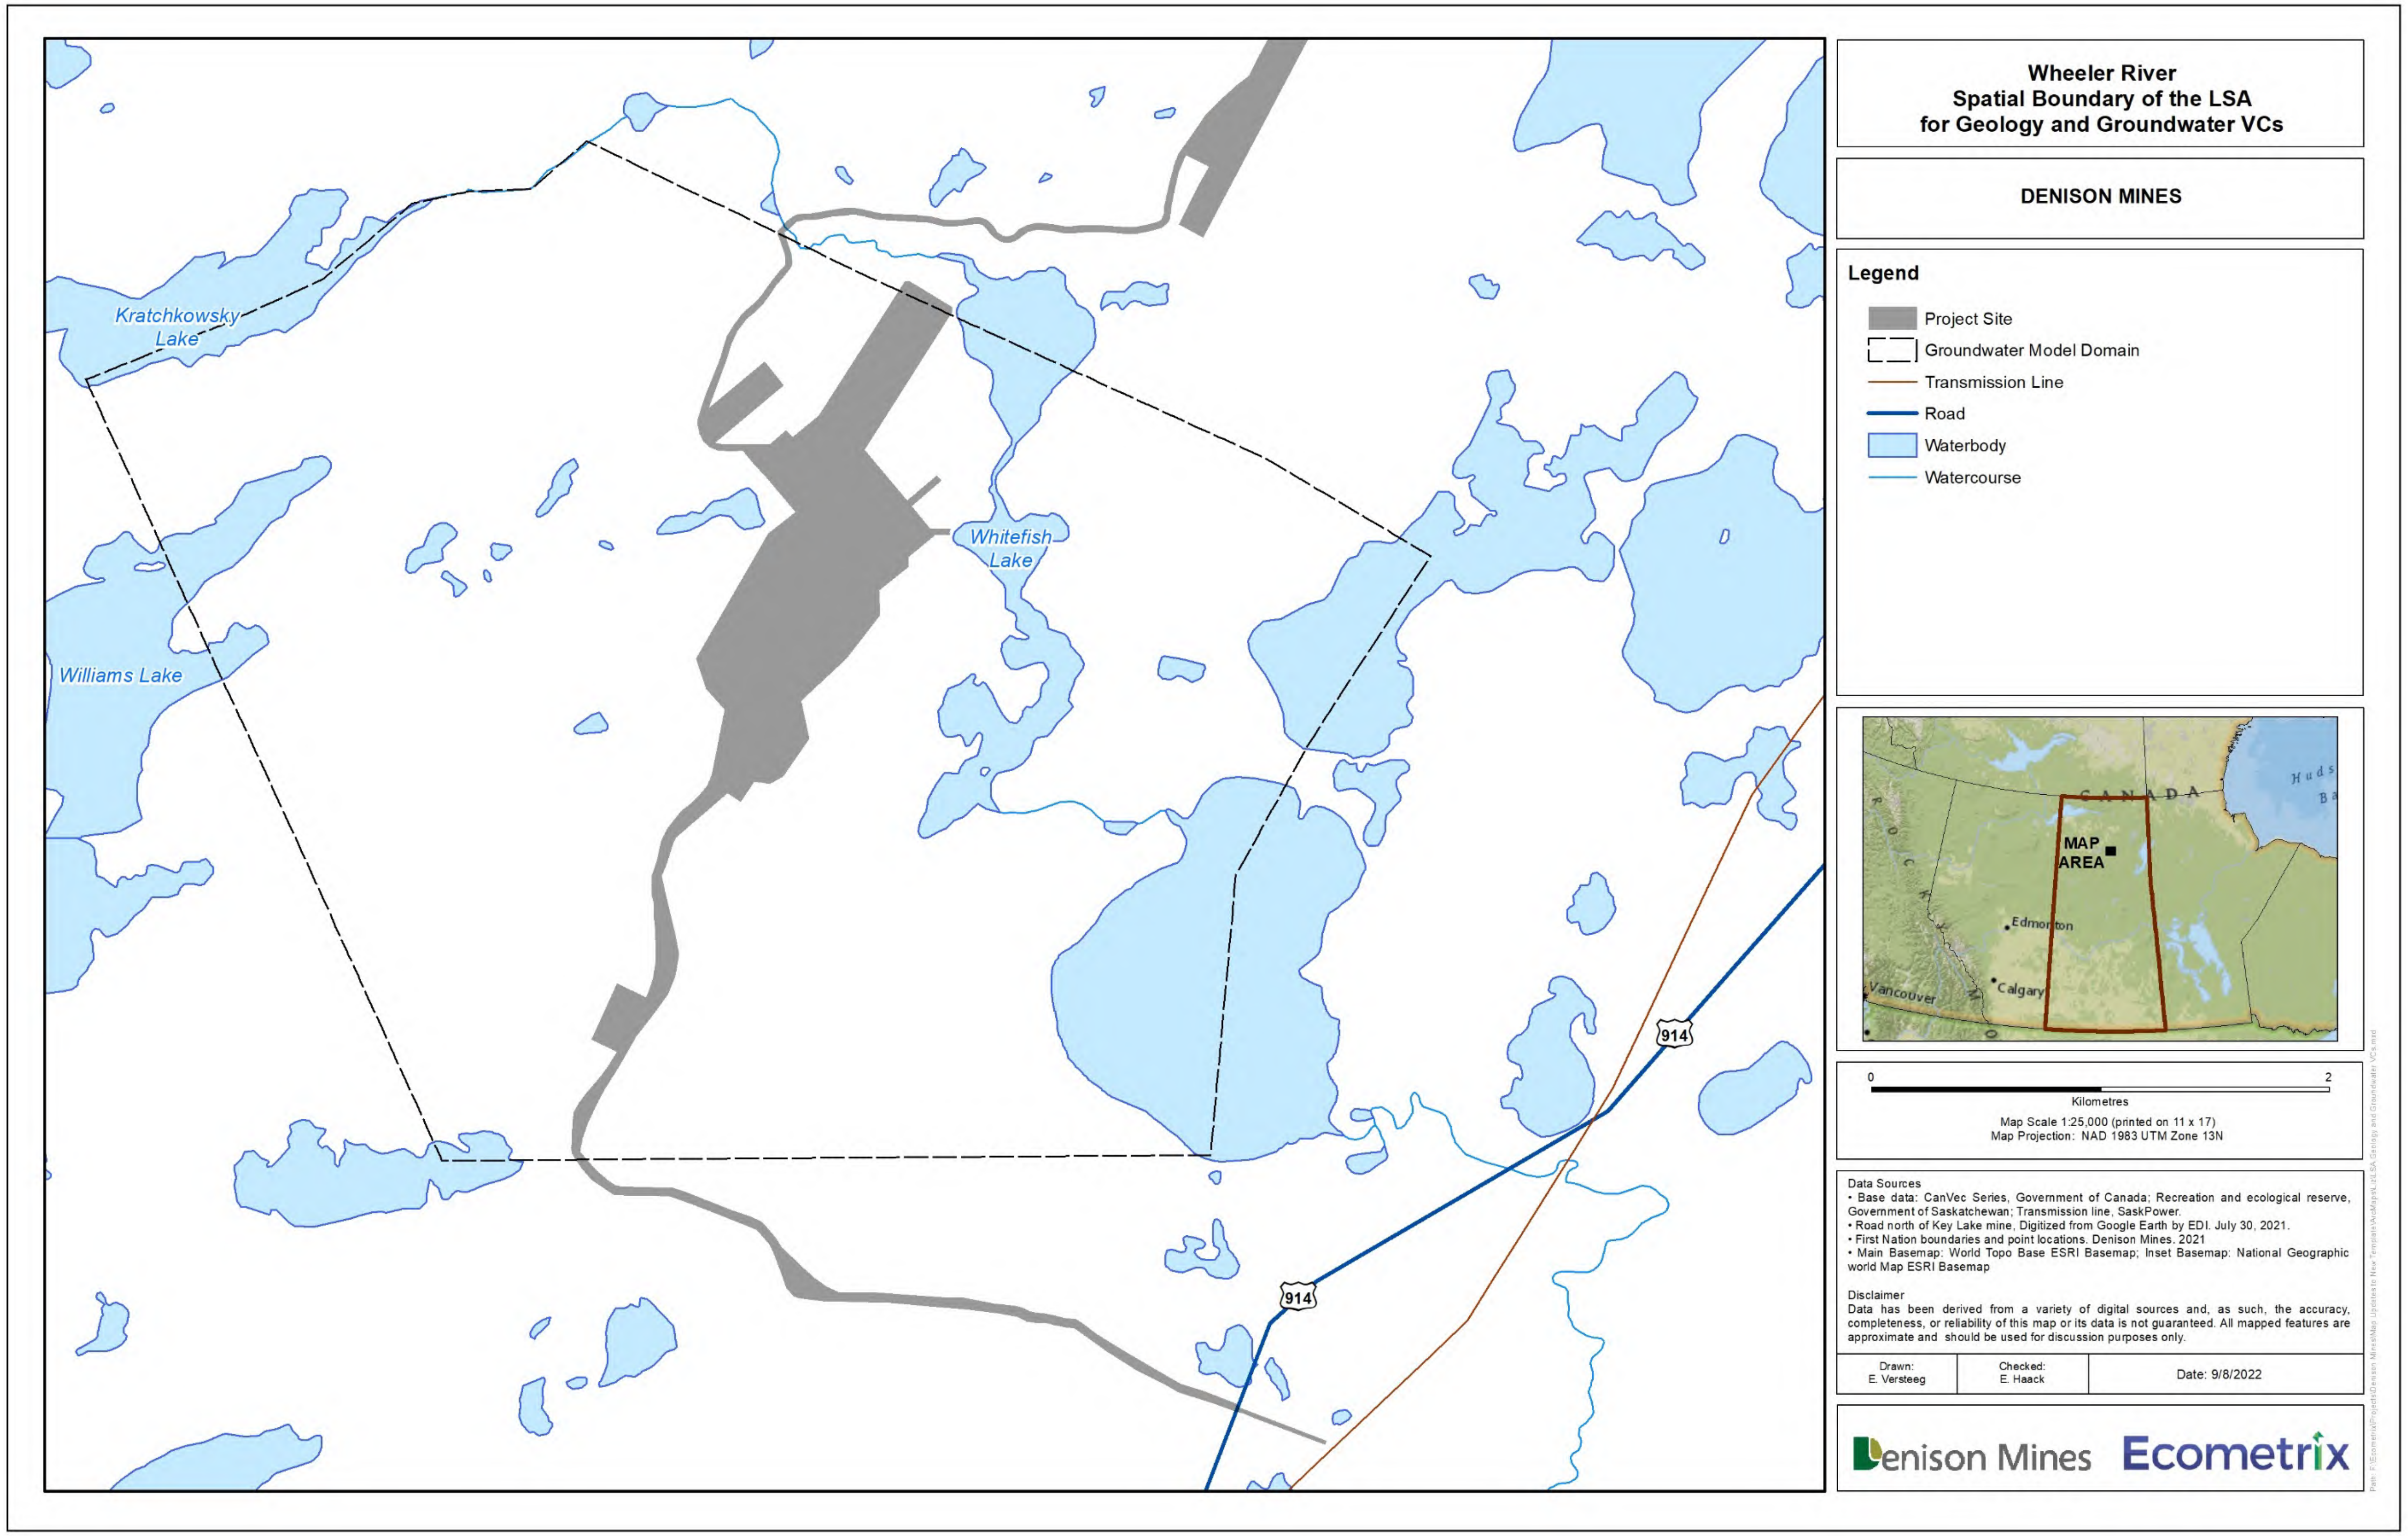

Figure 7.1-4: Spatial Boundary of the Local Study Area for the Geology and Groundwater Valued Components

7.1.3.2 Temporal Boundaries

The temporal boundaries represent the timeframes that the Project is expected to interact with and potentially affect the Geology and Groundwater VCs and, as appropriate, reflect seasonal and annual variations or biophysical constraints related to a VC. Temporal boundaries are based on the different phases of the Project, as described in the following list and in Section 2. The temporal boundaries of the Geology and Groundwater assessment considered all phases of the Project, including:

- Construction (Year 1 to 3);
- Operation (Year 3 to 18);
- Decommissioning (Year 18 to 23); and
- Post-Decommissioning (Year 23 to 38).

The temporal scope of the assessment for Geology and Groundwater also includes a 'future centuries' period following Post-Decommissioning that is unique and applied only to the Groundwater VC. The 'future centuries' temporal scope of the assessment for Groundwater considers the period for which the highest COPC concentrations in groundwater are predicted to interact with surface water based on groundwater modeling described in Appendix 7-C. Due to the relatively long travel time (relatively low groundwater velocities) between the mining area (Section 7.6.2.2.3) and the surface water environment where groundwater/surface water interactions are expected, as well as the potential for chemical reactions along the groundwater flow pathway, a 'future centuries' scenario was deemed appropriate to fully assess potential future effects beyond the Project timeline (i.e., 0 to 38 years). The 'future centuries' temporal scope was also developed in recognition of the concerns raised by Interested Parties through the engagement process around the potential for the Project to influence water quality into the future[1].

7.2 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

At its broadest level, IK can be understood as the unique and collective knowledge of Indigenous peoples that may include, but is not limited to, the environmental, cultural, economic, political, and spiritual conditions of a community or region. In this subsection, IK and LK are viewed as complementary and influential alongside western science to produce a full understanding of the potential effects of the Project, whether measurable or perceived. Both forms of information have been given full and fair consideration. Engagement is defined as the sharing and gathering of project-related information from Interested Parties, and the collaboration with Interested Parties in a good faith effort with the goal of developing mutually acceptable resolutions (Section 4.2 in

[1] 18-EN-ERFN-5.4, 18-EN-ERFN-5.72, and ERFN and SVS 2022.

Section 4 Engagement). Since 2016, Denison has been engaging with Interested Parties (i.e., local and Indigenous communities, residents, businesses, organizations, land users, and various regulatory authorities) to support the development of positive relationships and a mutual commitment to collaboration.

Denison has recorded and stored information regarding IK, LK, and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers (e.g., 18-EN-VILX-3.103). These numbers are referenced throughout the EIS, but particularly in Parts II and III, to indicate where specific information from the database has been integrated into the assessment. Appendix 7-B provides a summary of unique identification numbers referenced within Section 7. The available LK data in support of the assessment did not specifically address Geology or Groundwater. Indigenous Knowledge addressing Geology or Groundwater came from two sources (i.e., ERFN and SVS 2022; KML and NVP 2022). Indigenous Knowledge quotes and citations from engagement activities were included herein to provide readers with the information considered as the Project advanced throughout the EA process.

Several questions from Interested Parties reflected their interest in understanding more about the groundwater system and how it is sampled, generally[2].

> "*Are there aquifers in the area*?" (20-EN-VILX-343.2).
>
> "*How do you sample streams underground*" (18-EN-VILX-3.103).

Interested Parties had questions, comments, or concerns regarding:

- how baseline information was collected and existing groundwater conditions[3];
- how ISR mining may influence:
  - terrain (i.e., subsidence at ground surface; 21-EN-ERFN-473.8);
  - groundwater flow conditions, including water levels and groundwater discharge quantity to surface waterbodies (18-EN-VB-4.37); and
  - groundwater quality, and that the influence may not be observed for some time[4]; and
- mitigation measures, plans, and monitoring for groundwater protection[5].

[2] 18-EN-VILX-3.103, 18-EN-VPL02.53, 20-EN-VILX-343.2, and 21-EN-ERFN-447.19.

[3] 16-EN-VPL-105.5, 17-EN-NSEQC-112.6, and 18-EN-VILX-3.105.

[4] 18-EN-VILX-3.32, 18-EN-VB-4.38, 18-EN-ERFN-5.72, 18-EN-ERFN-5.4, 19-EN-ERFN-140.25, 21-EN-BNFN-479.7, and 21-EN-ERFNSUR-456.24.

[5] 16-EN-VILX-109.29, 18-EN-VPL-2.33, 18-EN-VPL-2.57, 19-EN-ERFN-140.28, 19-EN-ML37-62.9, 19-EN-ML82-62.21, 21-EN-ERFN-458.12, 21-EN-ERFN-474.1, 21-EN-LLRIB-392.5, 21-EN-SUR-446.92, 21-EN-VILX-443.17, and 21-EN-VILX-443.19.

Examples include:

> "*Ground freezing would reduce the amount of water that is needed to be discharged*" (18-EN-VB-4.37).

> "*In that area there are moose calving areas, whitefish spawning areas – a lot of creeks, inlets and outlets. The drilling – as a former driller back in the 80s, for water wells and diamond drilling – it may not impact underground hydrology right away but maybe 15-20 years down the road. Even the pH of the water changes with time with things that are happening. The ecosystem becomes disrupted. Those are some of the things we wanted to express*" (18-EN-ERFN-5.4).

> "*What happens when the freeze wall melts? Will there be monitoring of ground water during this*?" (21-EN-VILX-443.19).

Concerns on these same themes occurred in IK. An example includes:

> "*The community requires confidence that when incidence occurs with these mining methods there are plans in place to recover solutions that could impact groundwater quality. With so many Indigenous nations under boil water advisory coupled with water security becoming a real phenomenon, it is imperative that we understand the protection of water process implicitly*" (KML and NVP 2022).

The comments from both IK and the engagement record were considered within the context of community interest in the groundwater remaining supportive of surface water quality and health. The shared value of water and its life-sustaining properties is understood through the IK, LK, and engagement data related to the Surface Water Quality VC (Section 8).

> "*The lands and waters, we are definitely connected as peoples of English River. If we don't have the lands, we are not connected. If we don't have the water... Water is life to us*" (ERFN and SVS 2022).

Indigenous Knowledge and engagement activities clearly identified the importance placed on groundwater as a pathway to surface water by Interested Parties and the associated potential for changes in groundwater inputs to surface water to influence fish and fish habitat, sediment quality, vegetation, wildlife, human health, and Indigenous land and resource use. Examples include:

> "*Changes to the environment, including declines in water quality and water levels and increase in habitat damage from wildlife*" (ERFN and SVS 2022).

> "*Water Levels: Concern that water usage from the prospective mine could affect lake and river levels thereby having impacts on the fish and fishery*" (ERFN and SVS 2022).

This affirms the need to include Geology and Groundwater as VCs and intermediate VCs to the aquatic environment in the EA, to help inform the assessment of surface water quality and human health. Based on the IK and engagement activities, it is understood that additional detail is expected with respect to the potential effects of the Project on Geology and Groundwater, and this section of the EIS is responsive to that expectation. Specific ways in which data from IK and engagement activities influenced the Geology and Groundwater assessment are detailed in the following subsections.

Baseline Conditions and Conceptual Site Model

Substantive effort on Denison's part since 2006 has been directed towards developing an extensive database of existing (baseline) geological and groundwater conditions, providing Interested Parties the confidence that the subsurface environment for the Project is understood. The baseline assessment is provided in Appendix 7-A.

Project Interactions and Mitigation

Indigenous Knowledge and feedback from the community were used to inform scoping for Project interactions, pathway analysis, and mitigative strategies and approaches. Specific mitigation strategies to protect the Geology and Groundwater VCs were developed at the beginning of the Project, including a limited construction footprint and the use of a freeze wall system to reduce the potential for groundwater and surface water interactions.

Site Monitoring and Management

Information and feedback by the community during engagement was considered in the development of monitoring activities during Operation, Decommissioning, and Post-Decommissioning. As part of mining operations, detailed monitoring activities will be completed to assess the performance of various components of the Project associated with engineering mining designs, subsidence, and infrastructure designs to protect the Geology VC within the Project Area and LSA. Groundwater management, monitoring, and mitigation, and evaluation of groundwater effects, were considered important to maintaining groundwater levels and water quality within the Project Area and LSA.

7.3 Existing Environment

A Baseline Geology and Hydrogeology Report (see Appendix 7-A) was prepared as part of the EIS submission and describes the existing environment for the Project. The Baseline Geology and Hydrogeology Report builds on the Phoenix deposit geological model developed by Denison (Denison 2022a), which uses geological and numerical modelling functionalities in Leapfrog Geo™ 2021.2. The model includes lithology, structure, and alteration models from field data collected over more than 16 years of exploration activities.

The outcome of the Baseline Geology and Hydrogeology Report was the development of a robust hydrogeological Conceptual Site Model (CSM). The CSM provided the basis for development of a numerical groundwater flow and transport model for the baseline and Post-Decommissioning phases, which will be used over the life of the Project to inform groundwater conditions and the establishment of Decommissioning objectives (see Section 7.6.1).

The methodology used to characterize existing conditions is provided in Appendix 7-A and is summarized in the following subsections. Characterization of existing conditions relied upon information from regional studies (pertaining to the Athabasca Basin, and including (not exclusively) Sibbald et al. 1976; Macdonald 1980; AECL 1994; Ramaekers and Catuneanu 2004; Campell 2007; Harvey and Bethune 2007; Yeo and Delaney 2007; Cameco 2012a; Ng et al. 2013; Power 2014; Alexandre 2020; Bosman and Ramaekers 2015) and Project-specific information. Project-specific information was extensive and included the following:

- A database of geologic, geochemical, and geotechnical data for the Project, representing data collected over 16 years of exploration activities and more than 300 drill holes. The database contains a wide range of data for most of the exploration drill hole locations, including major lithologies and various geotechnical fields (e.g., estimates of rock quality designation, fracture intensity, core recovery percentages, and alteration).
- Composite samples collected from core material every 5 to 20 m through the Athabasca Supergroup Sandstones and discrete samples collected every 0.5 m within and proximal to the ore zone for bulk geochemical composition (elemental analysis). Clay mineralogy was determined from the bulk geochemical composition of the samples (elemental analysis) using a normative clay calculation. Mineralogy was further evaluated in a subset of location and depth intervals by infrared mineral analysis (i.e., PIMA) and/or petrography.
- Matrix permeability, hydraulic conductivity, porosity, and dry density values determined from permeameter data (Scibek 2019; Denison 2022b).
- Hydrogeological assessments, including packer tests and pumping and injection tests (Golder Associates 2014; Petrotek 2020; Petrotek 2021; Petrotek 2022; borehole testing by Denison analyzed by Ecometrix as part of Appendix 7-A).
- Groundwater quality from 26 single-interval groundwater monitoring wells, each sampled on one to three occasions from 2019 to 2021 following well development. Samples were submitted for general chemistry, dissolved metals, trace elements, and radionuclide analyses to the Saskatchewan Research Council Environmental Analytical Laboratory, and for tritium to A.E. Lalonde AMS Laboratory (University of Ottawa).
- Water level elevations in wells and open holes (390 water levels recorded in over 150 open hole core holes). Manual water levels were recorded on sampling events in the monitoring wells and pressure transducers provided continuous water level elevation data for several groundwater wells.

7.3.1 Physical Geography

Ground surface topography regionally has been shaped by glacial and fluvial processes active for over tens of thousands of years. The most important associated topographic features in the region are the northeast to southwest trending drumlins and eskers that are separated by lowland areas of well drained glaciofluvial outwash sands and gravels, and poorly drained till plains with associated muskeg/wetlands. The ground surface elevation in the area, including and immediately surrounding the Project Area, varies from a high of approximately 600 masl located between the Phoenix and Gryphon deposits, to a low of 494 masl at McGowan Lake in the southeast (Figure 7.3-1). Ground surface topography (locally) overlying the Phoenix deposit ranges from 520 to 550 masl (Figure 7.3-1).

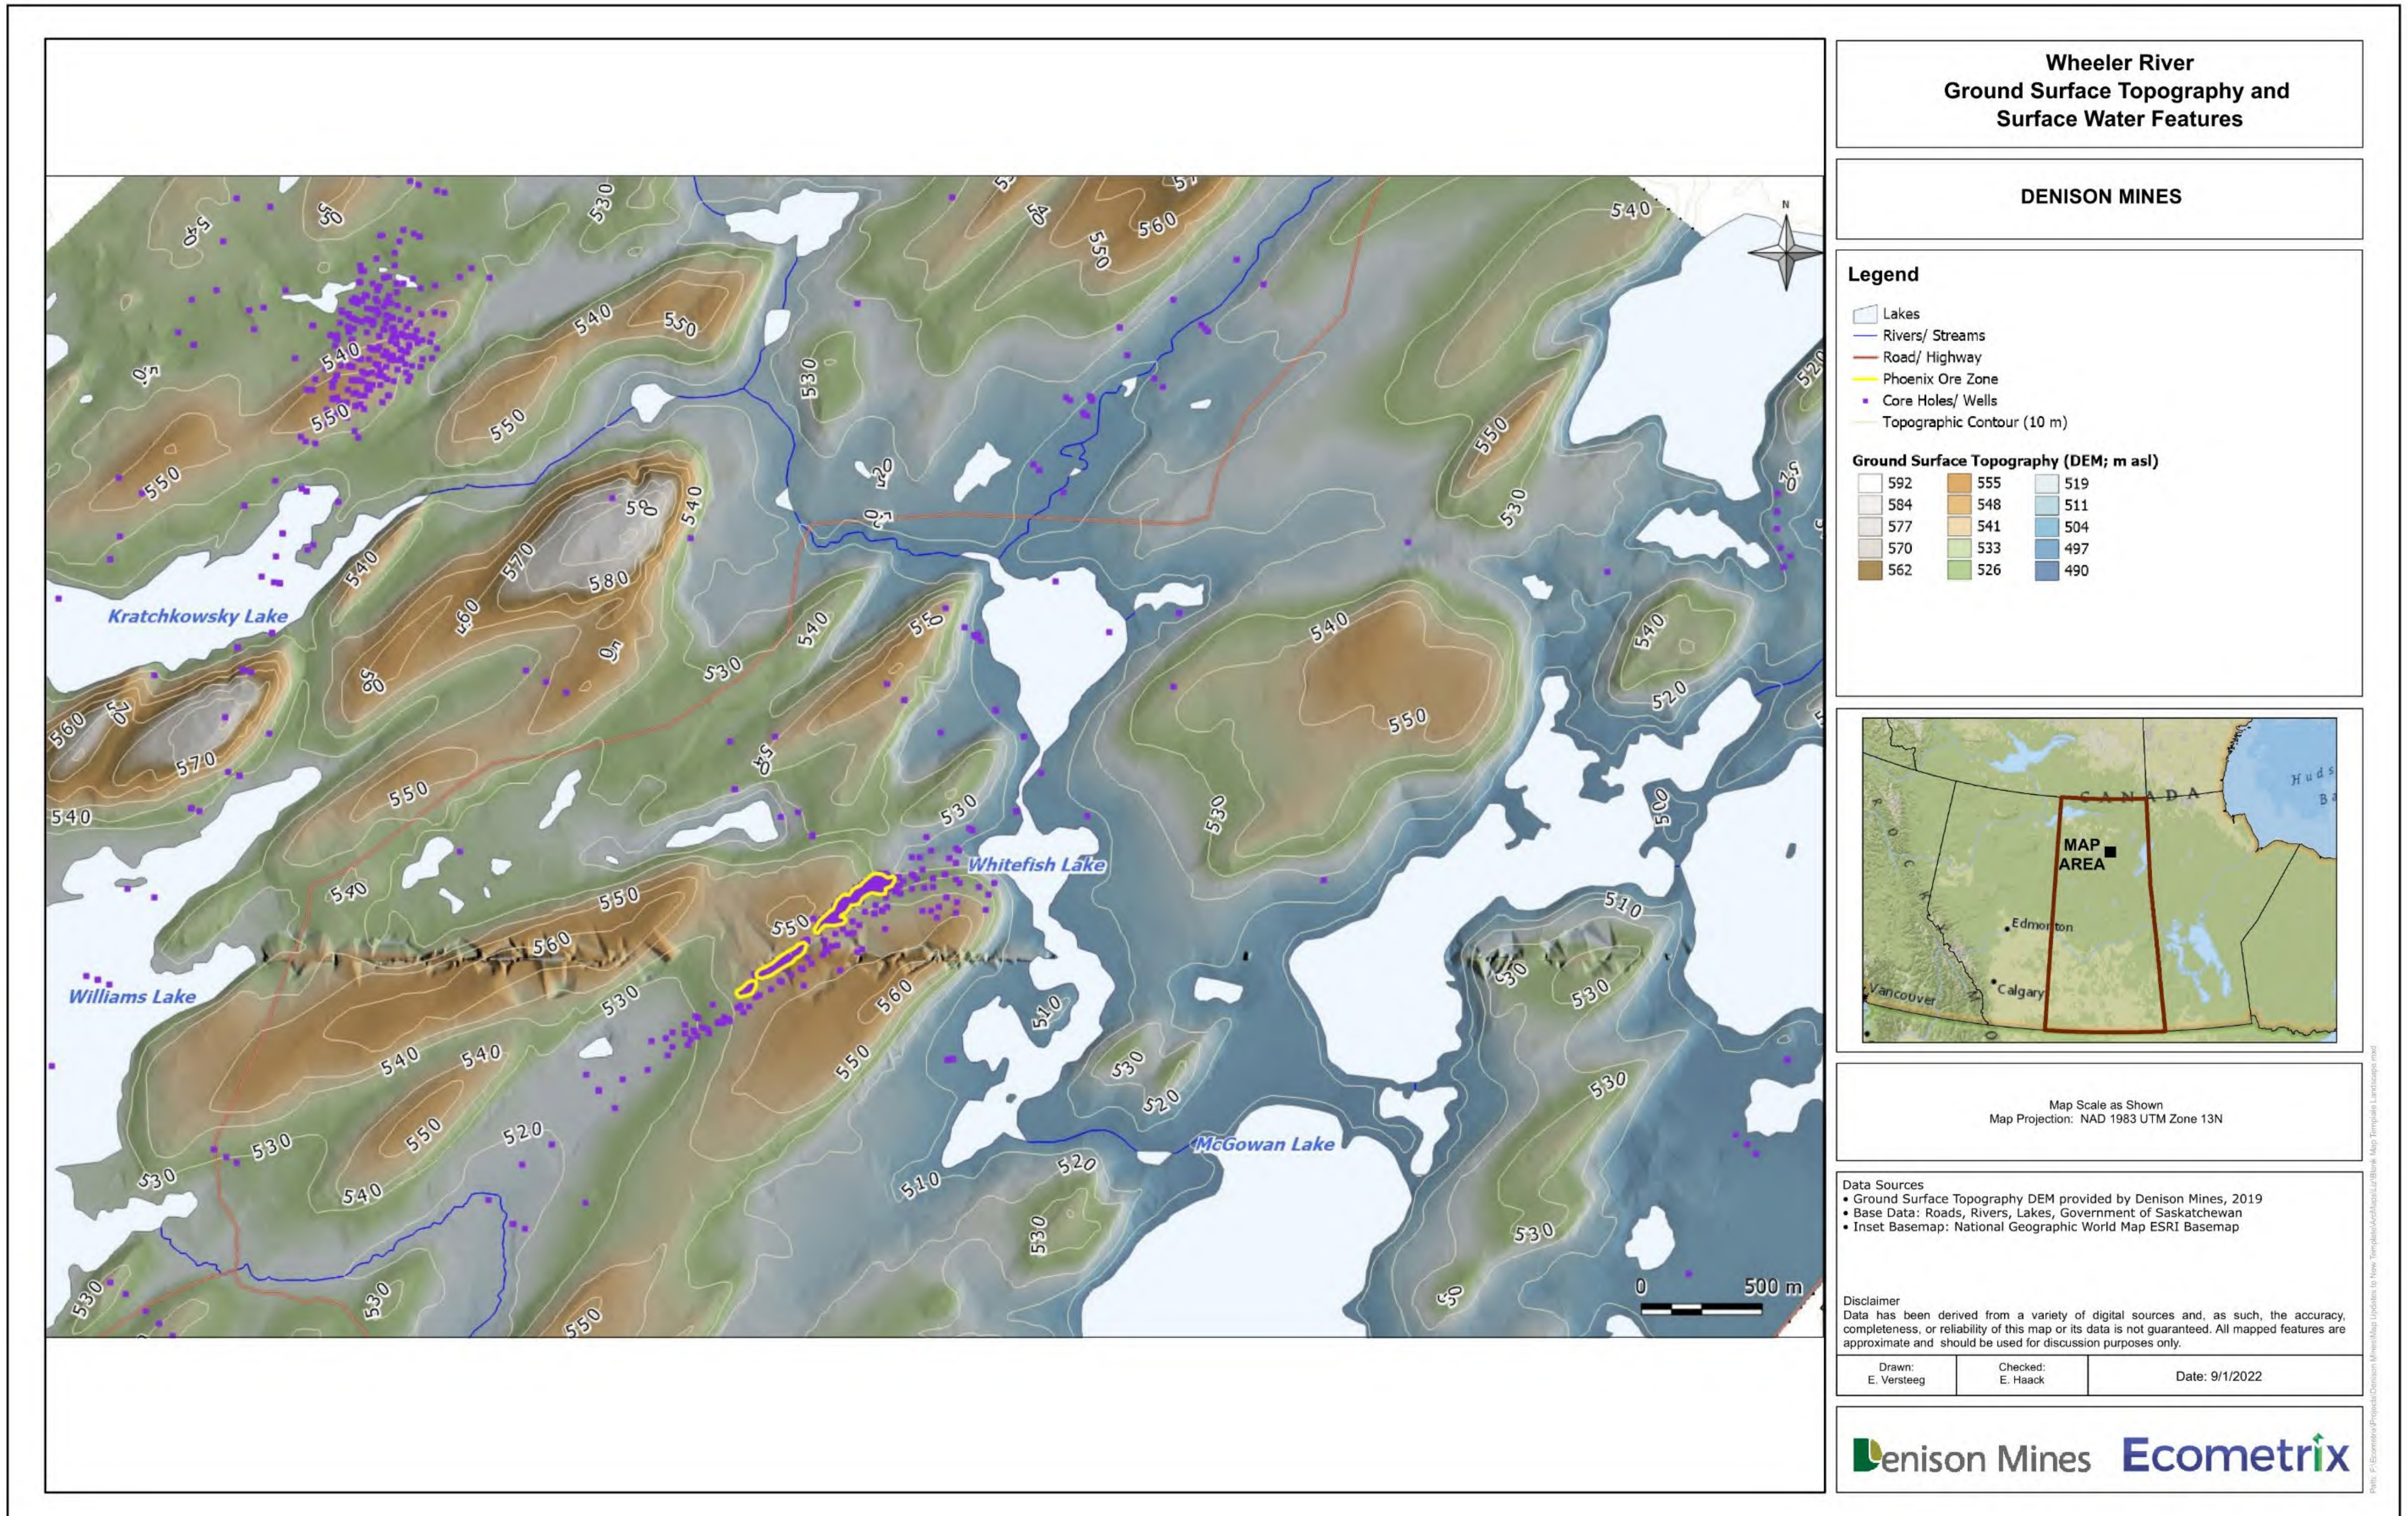

Figure 7.3-1: Ground Surface Topography and Surface Water Features

7.3.2 Geological Setting

The Wheeler River uranium deposit is located on the eastern margin of the Athabasca Basin in northern Saskatchewan. Like other uranium deposits on the eastern margin of the Athabasca Basin (described in Jefferson et al. 2007), the Phoenix deposit is located at the base of the sandstones and conglomerates of the Athabasca Supergroup (Bosman and Ramaekers 2015), just above the major unconformity that separates the sandstones and the underlying granitic gneisses and other basement rocks of the Wollaston Group (Yeo and Delaney 2007; Figure 7.3-2). This unconformity represents a period when the basement rock was exposed and subject to extensive weathering and erosion. The elevation at the top of the unconformity within the Phoenix area ranges from a high of approximately 310 masl to a low of 120 masl.

There are uncertainties associated with the depositional models for the ore zone, but a plausible model suggests there was ductile faulting and subsequent weathering and erosion of the various basement rock lithologies. These faults were reactivated after the deposition of the Athabasca Supergroup sandstones along weak graphite-rich ductile shear zones. At the Phoenix site, this included the WS Shear zone and the Hanging Wall Shear zone (Arseneau and Revering 2010). Uranium (VI) (i.e., hexavalent uranium, U^{6+})-bearing and oxidizing basinal fluids within the sandstone reacted with reducing fluids in the basement, resulting in uranium (VI) being reduced to uranium (IV) (i.e., tetravalent uranium, U^{4+}), and uraninite being precipitated (Alexandre 2020).

The Phoenix deposit is overlain and underlain by a natural barrier unit or halo that has limited the release or subsurface migration of uranium, and other chemical constituents associated with the ore zone, outside of the ore body itself. This natural barrier zone has limited the migration of chemical constituents in groundwater for more than 1 billion years. This inference - regarding the natural barrier unit's role to limit migration of chemical constituents away from the ore zone – is the authors' professional opinions on the present-day conditions which includes persistence of the ore body over geologic time and differences in groundwater chemistries within and outside the ore body. The information reviewed and used to formulate this inference is presented in detail in Appendix 7-A. The barrier units include the Upper and Lower Clay Zones, and Sulphide Cemented zones shown in Figure 7.3-3.

A summary of the geologic characterization present in the LSA, from basement rock to overburden, is provided in the following subsections. By way of introducing the geologic setting, the interpreted lithologic surfaces for the LSA are shown in cross section in Figure 7.3-4. The ore zone position just above the unconformity and the associated natural barrier units are shown schematically in Figure 7.3-3. Shown in Figure 7.3-2 is that the Phoenix ore bodies are long and narrow (approximately 25 to 50 m wide), directly overlie or are near a graphitic pelite unit of the basement rock, and are associated with the WS Shear zone. The lithologic units in the LSA are also summarized in Table 7.3-1 in Section 7.3.3.

7.3.2.1 Basement Rock

Basement rocks beneath the Phoenix deposits are Paleoproterozoic-aged metasedimentary, metavolcanics, pegmatites, gneisses and schists (Figure 7.3-2). The basement rocks have undergone several periods of alteration following their original deposition, which influenced the hydrogeological setting. These include:

- metamorphism;
- alteration post-metamorphism (less than 1800 Ma) and prior to deposition of the Athabasca Supergroup sandstones (1700 Ma; Adlahka, 2021; Toma et al., 2022);
- paleoweathering on the bedrock surface prior to subsidence and basin formation; and
- hydrothermal alteration associated with uranium ore mineralization. The most intense areas of hydrothermal alteration occur alongside the highest-grade mineralization, and alteration decreases (and eventually disappears) in all directions with distance away from the ore zone (Macdonald 1980; Wilson 1986; Harvey and Bethune 2007).

Faults within the basement rocks trend in a northeast-southwest direction. Following this trend, the WS Shear zone is a reverse fault that has a 55-degree (northeast to southwest) azimuth and a 55-degree dip to the southeast (Figure 7.3-2). There are also several west-east trending cross faults that lie roughly perpendicular to the WS Shear zone and propagate through the ore zone and basement rocks.

A quartzite ridge occurs north of the Phoenix deposit. "Quartzite ridges" are topographic features of the sub-Athabasca unconformity surface (Li et al., 2015). They are an alteration facies resulting from pre-Athabasca Supergroup basement silicification, that cause relief at the unconformity surface of up to 200 m (Card, 2014). A quartzite ridge occurs west of the Pheonix deposit and has a southwest-northeast trend, which parallels the Phoenix deposit. The elevation at the top of the unconformity within the Phoenix area is approximately 310 m asl along the quartzite ridge, in comparison to an elevation of approximately 150 m asl at the Phoenix deposit (Appendix 7-A). The quartzite ridge is interpreted as a low permeability zone that acts as a barrier to fluid flow, and played a role in controlling alteration patterns and mineralization (Card, 2014; Li et al., 2015).

7.3.2.2 Ore Deposit

As introduced above, the uranium ore deposit lies proximal to the unconformity between the basement rocks and the overlying Athabasca sandstone. The Phoenix ore bodies are long and narrow (approximately 25 to 50 m wide) and are located within or near a graphitic pelite unit. Hydrothermal alteration associated with the ore zone is a discontinuous envelope of clay alteration and a sulphide-cemented rock zone that extends into the overlying sandstone and the underlying basement (Figure 7.3-3). This black, clay-rich zone is approximately 3 m thick on average and locally hydraulically isolates the ore zone from the overlying sandstones and underlying weathered basement rock. The ore zone has complex mineralogy, including uraninite (Fe, Pb, Cu, Zn) sulfides, nickel arsenides, aluminum phosphate sulphate minerals, oxide, carbonate, and clay minerals and quartz.

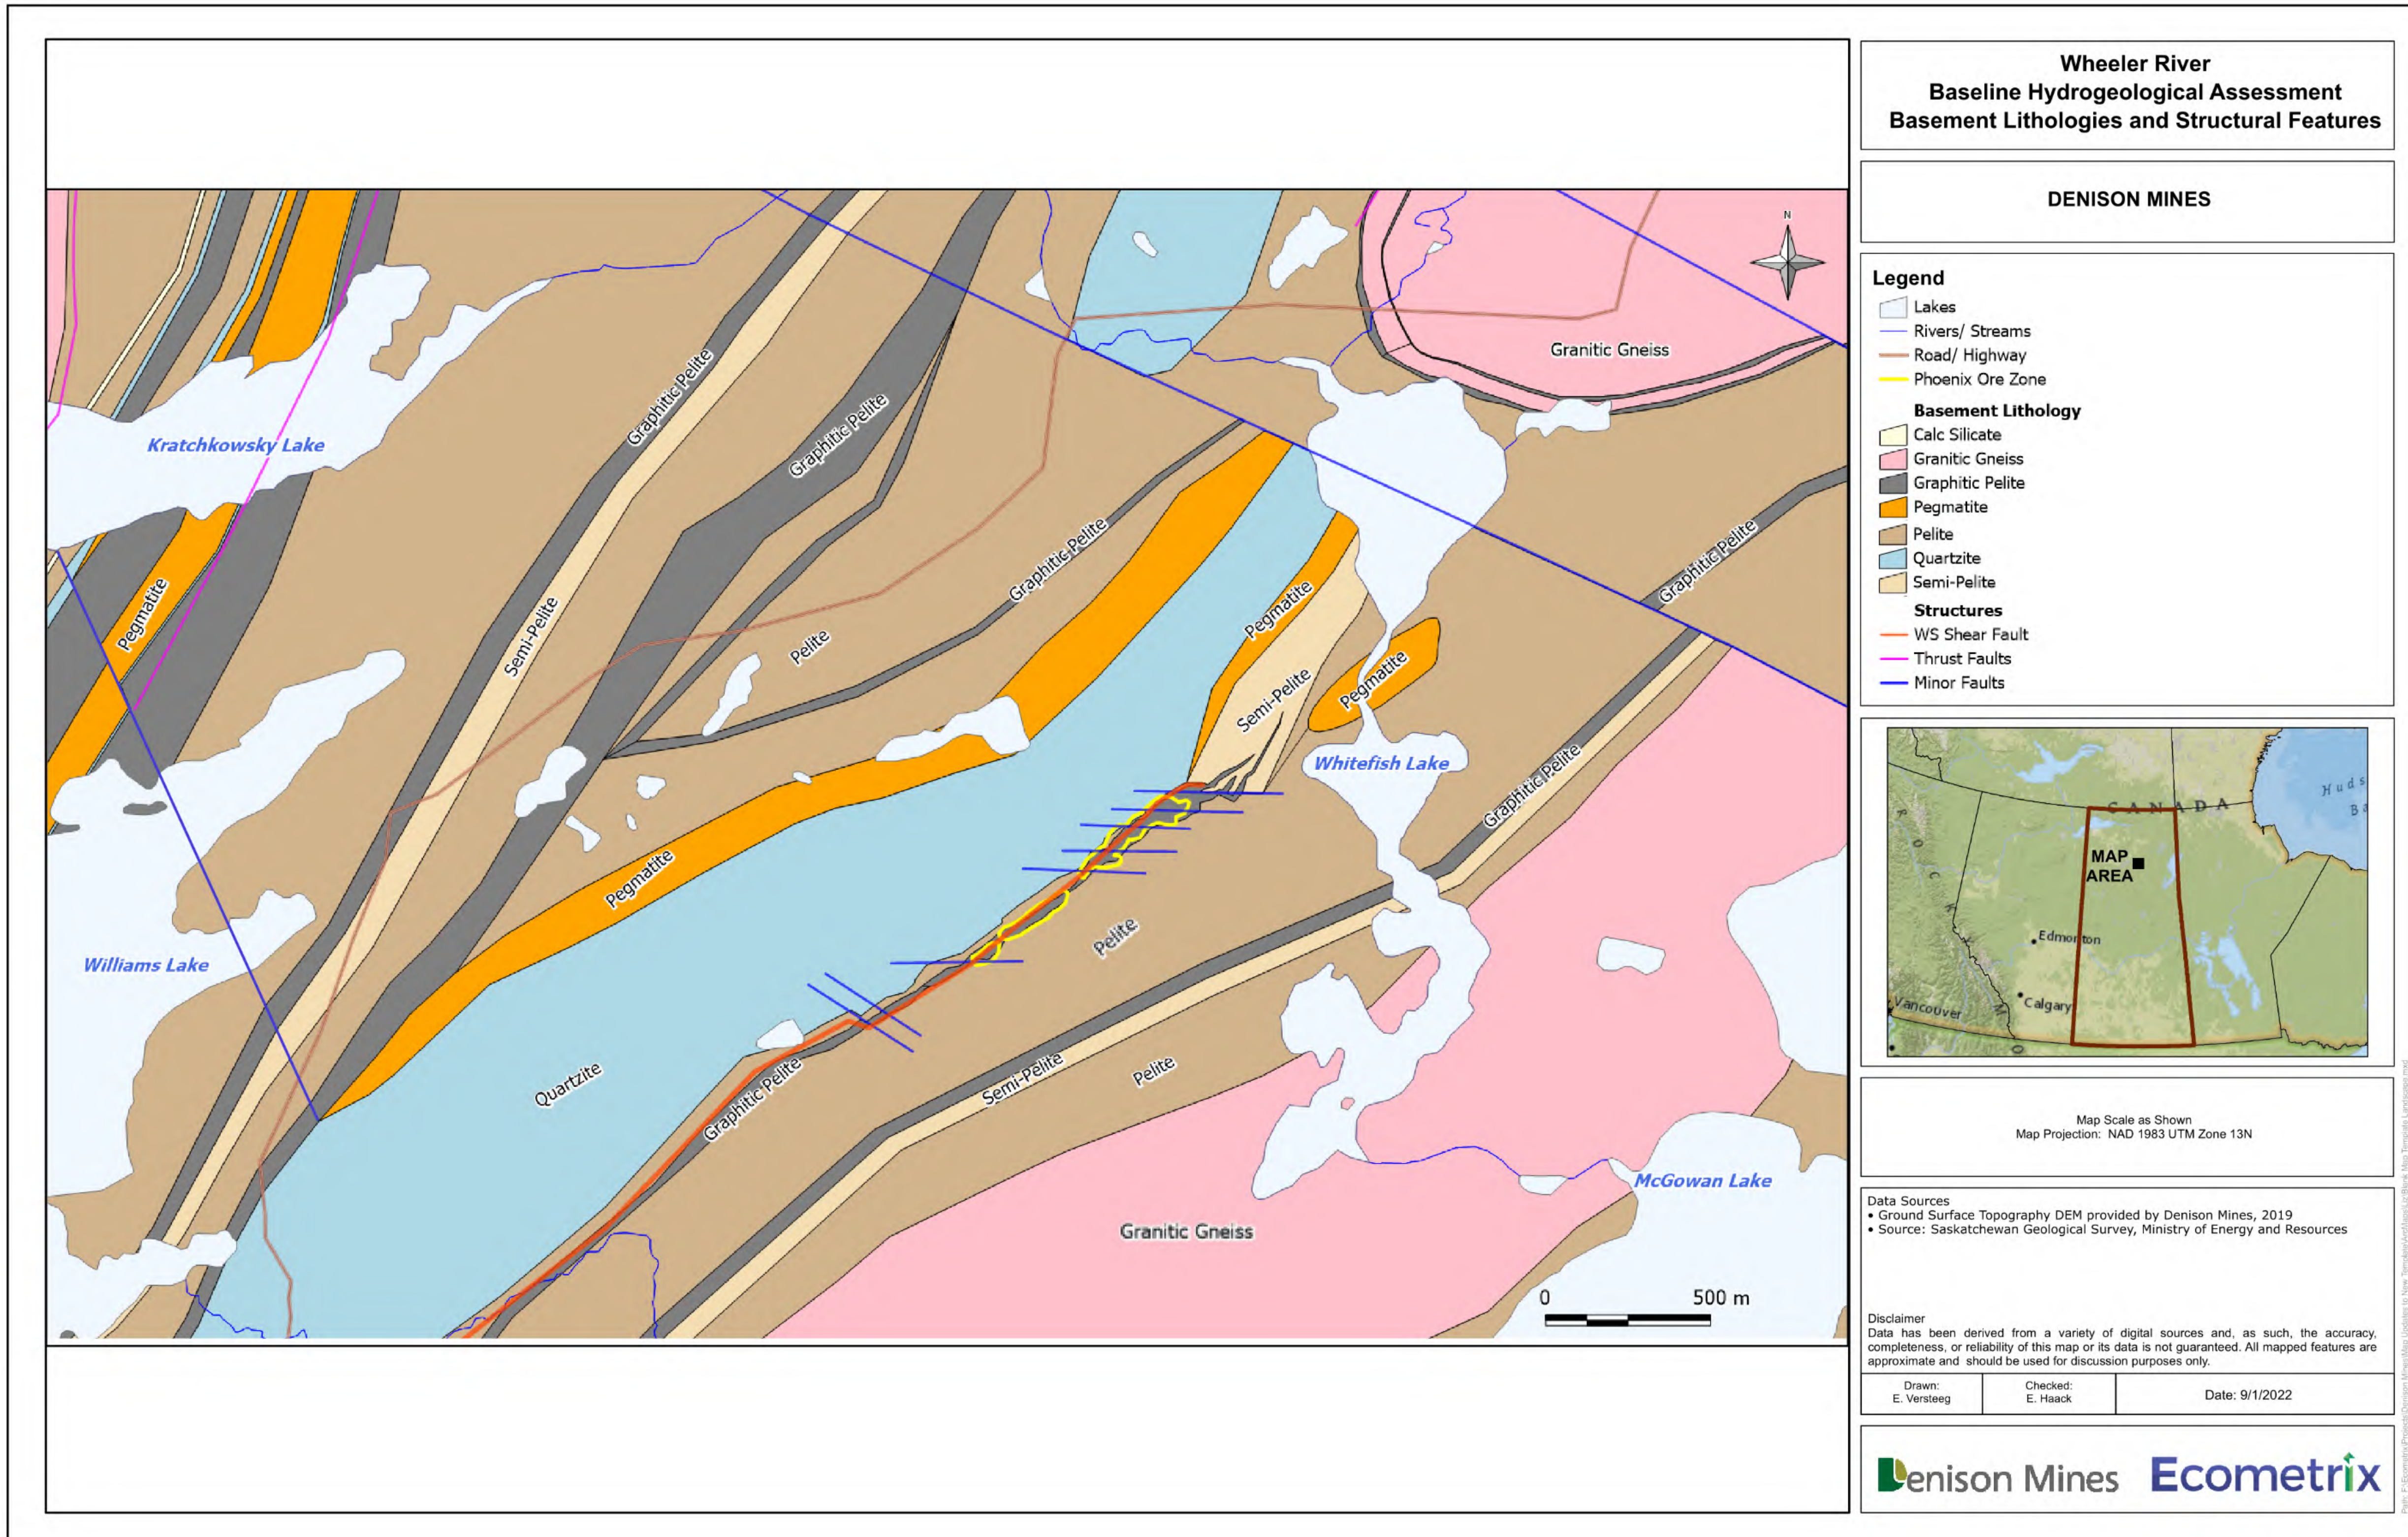

Figure 7.3-2: Basement Lithologies and Structural Features

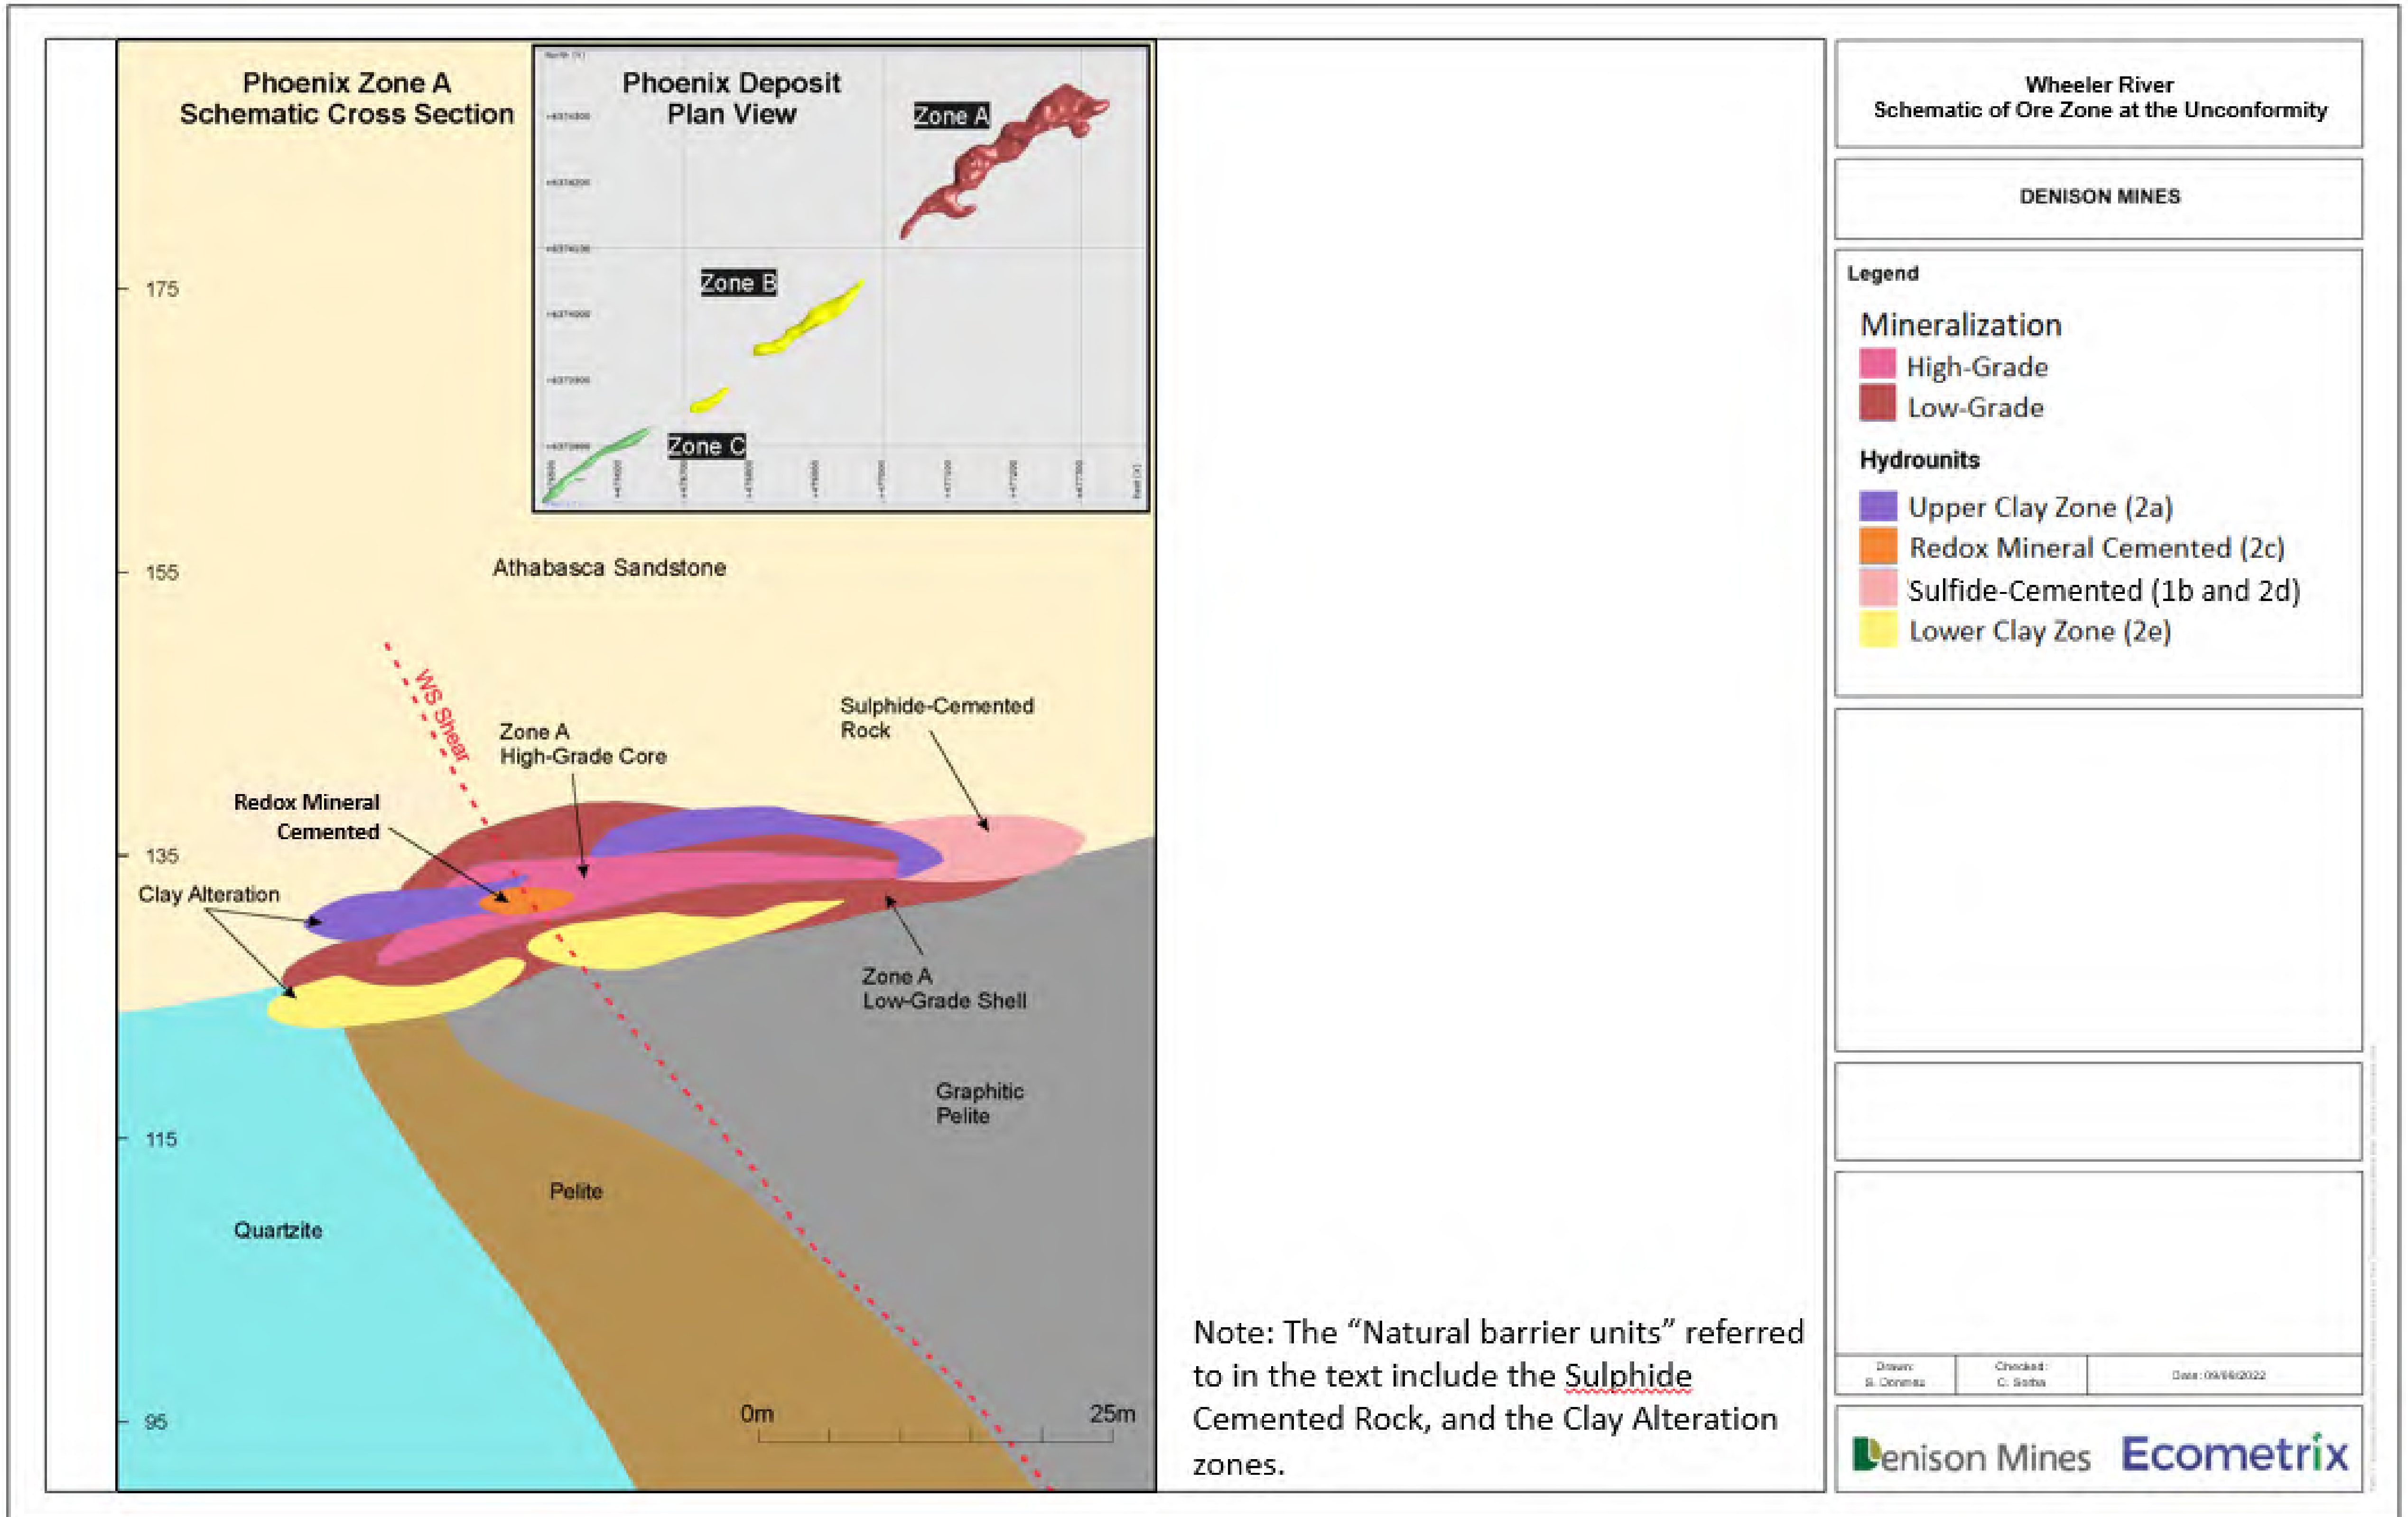

Figure 7.3-3: Schematic of the Ore Zone at the Unconformity

7.3.2.3 Athabasca Supergroup Sandstones and Conglomerates

Overlying the basement rock are Proterozoic-aged consolidated sandstones and conglomerates of the Athabasca Supergroup that were deposited 1.5 to 1.74 billion years ago (Creaser and Stasiuk 2007). These sedimentary rocks are horizontally bedded and were deposited in an intracontinental sedimentary basin initially marked by alluvial fans, braided rivers, and possibly shallow marine or lacustrine to eolian environments (Ramaekers and Catuneanu 2004; Ramaekers 1990).

The Athabasca Supergroup sandstones are subdivided into formations within the Manitou Falls Group (MF), (Bosman and Ramaekers, 2015). From shallowest to deepest, the MF Group present in the LSA includes the MFd (Dunlop Formation), MFc (Collins Formation), MFb (Bird Formation), and the MFa (Read Formation (Figure 7.3-4). The Read Formation is abbreviated as MFa in this report, and as MFr in Bosman and Ramaekers (2015); both abbreviations refer to the same formation. The MFa (Read Formation) underlies the MFb but is not present across the entire LSA as it pinches out against the quartzite ridge north of the Phoenix deposit. The sandstones are differentiated by their proportions of conglomerate beds and presence of clay intraclasts (Ramaekers et al. 2007). The Read Formation of the Manitou Falls Group hosts most of the uranium mineralization associated with the Phoenix deposit; some mineralization lies within the underlying paleoweathered basement (Figure 7.3-3). The Athabasca Supergroup sandstones consist almost entirely of quartz (Ramaekers 1990) and any detrital feldspar that was present was altered to clay minerals, such as kaolinite and illite, during the 200-million-year long period of diagenesis that impacted the Athabasca Basin (Sibbald et al. 1976; Hoeve and Quirt 1984). The Athabasca Supergroup sandstones are relatively iron-rich (median iron oxide [Fe_2O_3] concentrations of 0.24% in unmineralized samples [Alexandre 2020] and Project-specific information) and are characterized by thoroughly oxidized redbed sequences (Jefferson et al. 2007). Some portions of the MF Group including the upper portions of the Read Formation were silicified during diagenesis, whereby quartz cement sealed the sandstone's primary porosity (Alexandre 2020; Ng et al. 2013) and effectively reduced groundwater flow through the sandstone matrix and made it prone to brittle fracturing.

Regionally, sub-basin scale hydrothermal alteration halos have been recognized to be spatially associated with unconformity-type deposits. The alteration halo associated with the Pheonix deposit is of the 'egress type' (as defined by Jefferson et al. 2007), in that it extends primarily outwards and upwards into the Athabasca Supergroup sandstones and is interpreted to have resulted when hydrothermal fluid and gases were released along the shear zone and propagated along zones of weakness in the rock, including fractured and faulted bedrock. Hydrothermal alteration and desilicification occurs in the area overlying and east of the Phoenix deposit to Whitefish Lake, particularly in the Athabasca Supergroup sandstones above the WS Shear zone and associated splays. This zone of desilicification, enhanced fracture frequency, and elevated friability is interpreted to be the result of the merging of two different tectonic stress fields in the area

(Quantec Geoscience 2014). The matrix desilicification has effectively resulted in completely to partially unconsolidated sands. The Desilicified Zone, delineated by cores logged as having very low rock quality designation values, high fracture intensity, and high friability, is shown in Figure 7.3-5.

The sandstones have also been faulted and fractured, which affects the movement of groundwater through these units. Faults in the sandstone represent reactivated brittle basement faults along the northeast-southwest trending WS Shear zone, or responses to volume adjustments in the sandstone during hydrothermal alteration and mineralization.

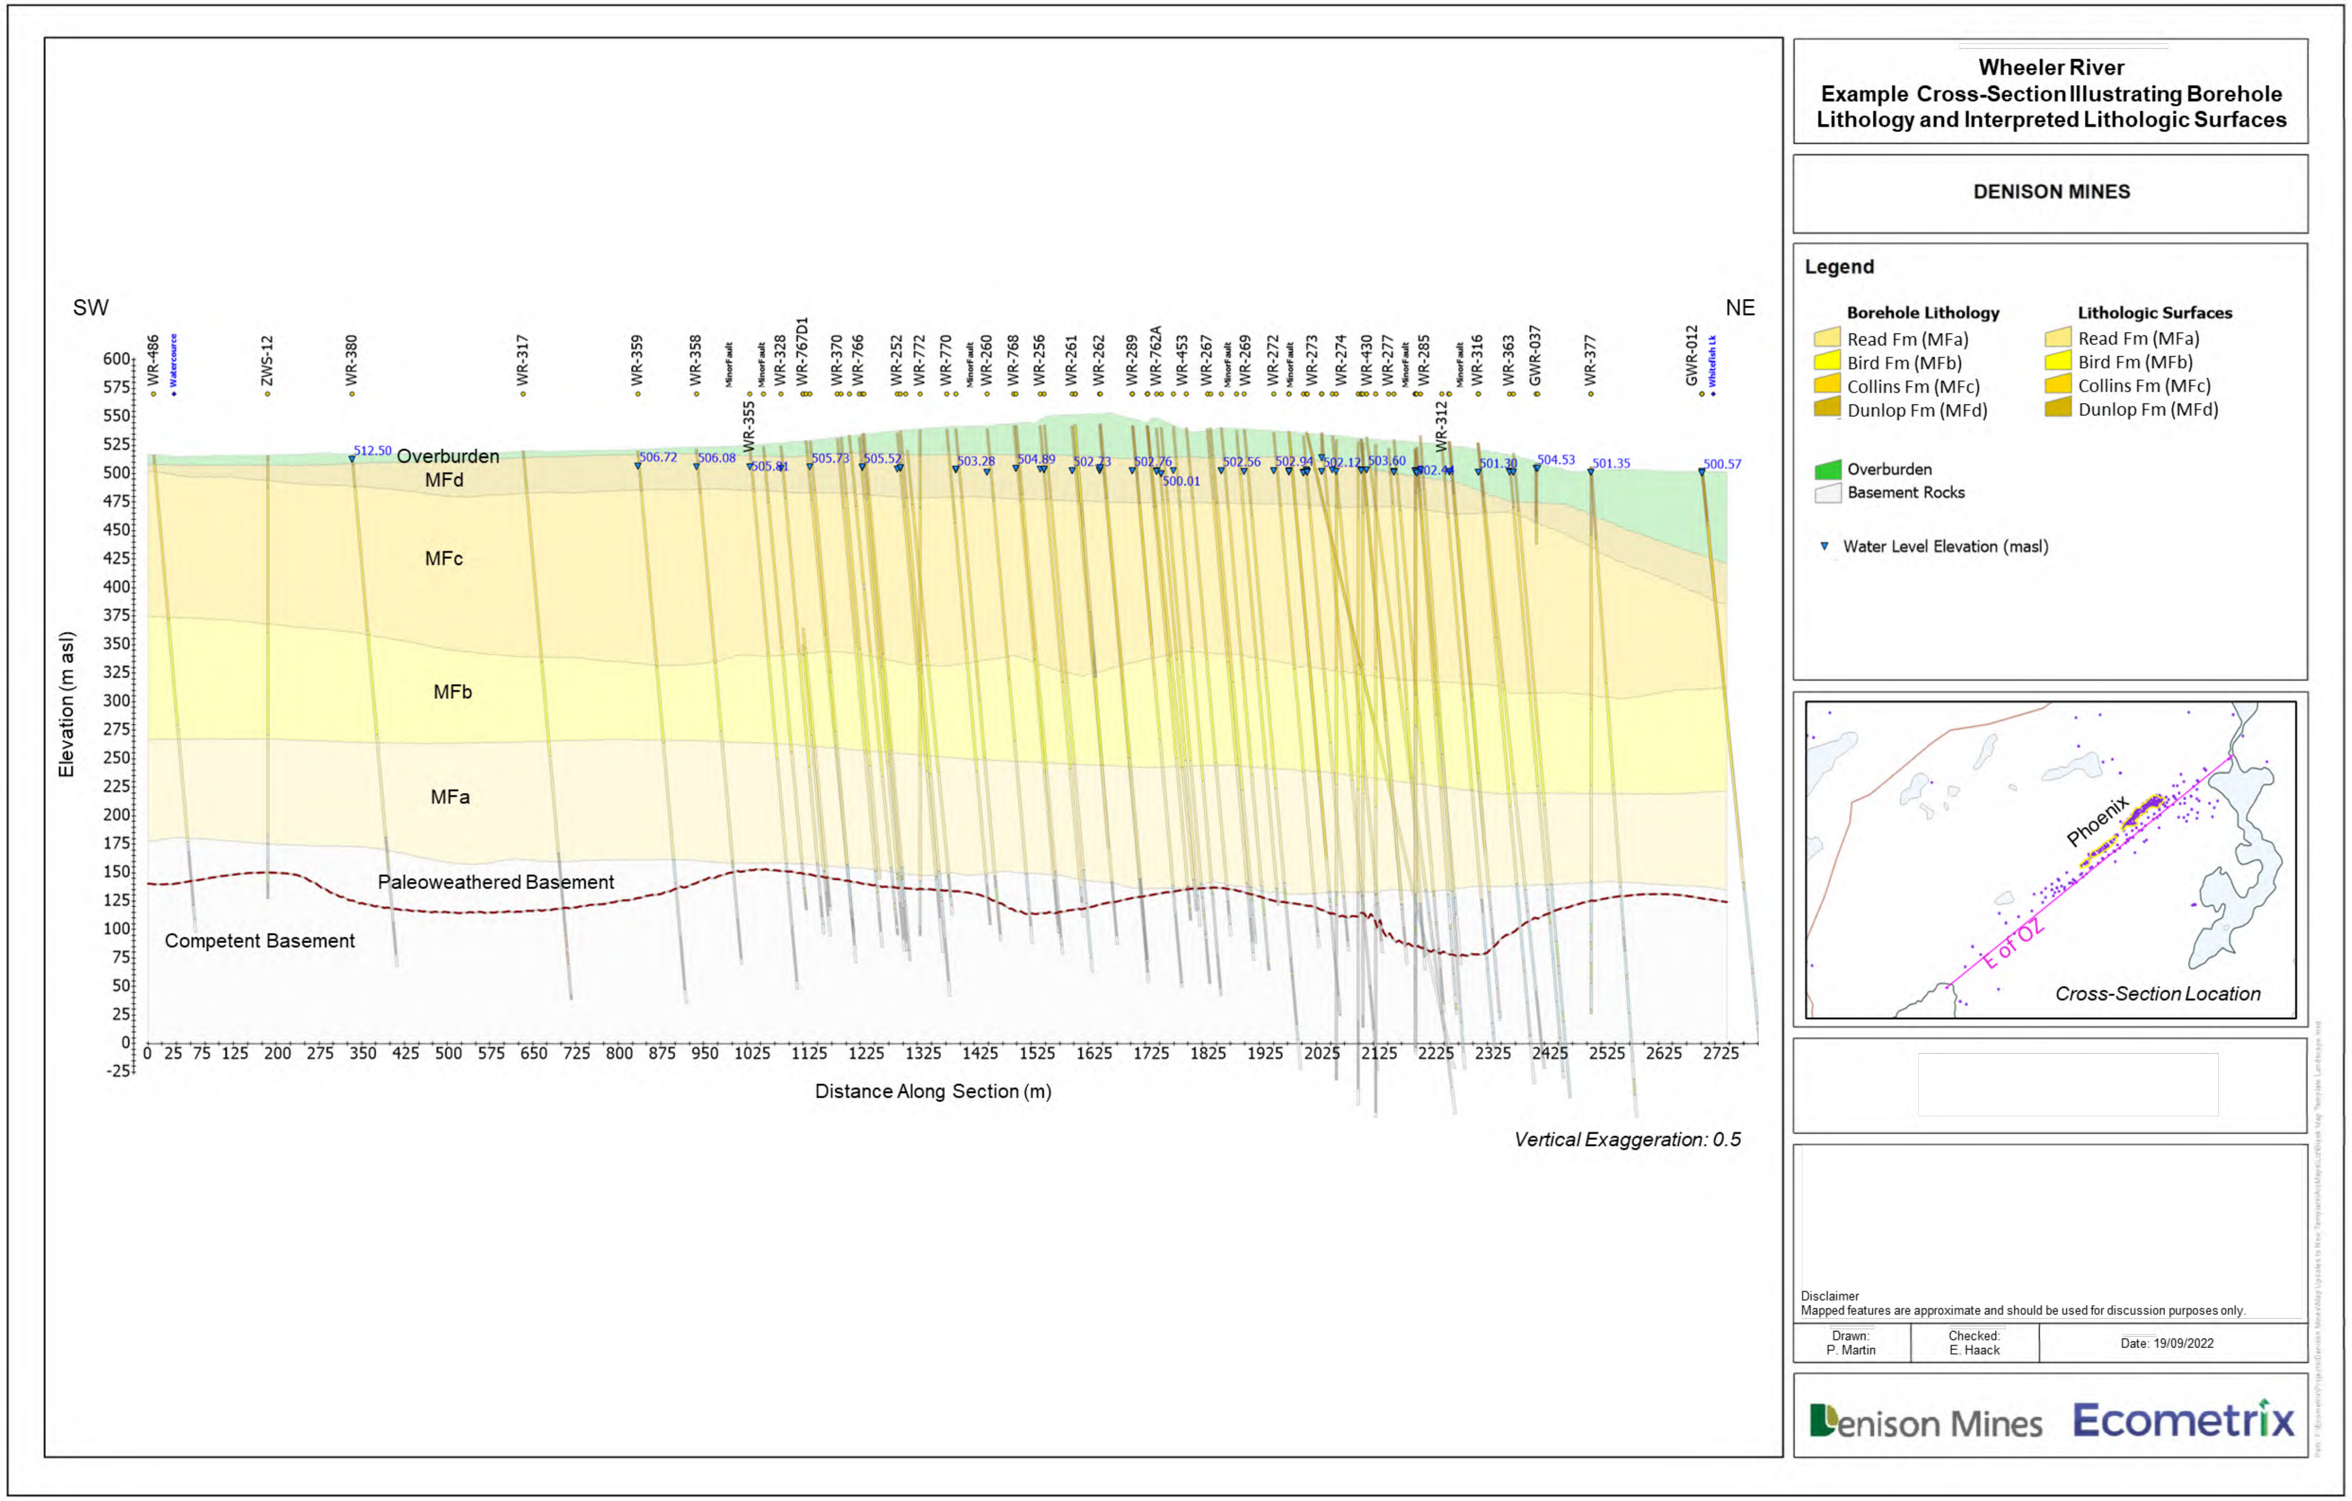

Figure 7.3-4: An Example Cross-section Illustrating Borehole Lithology and Interpreted Lithologic Surfaces

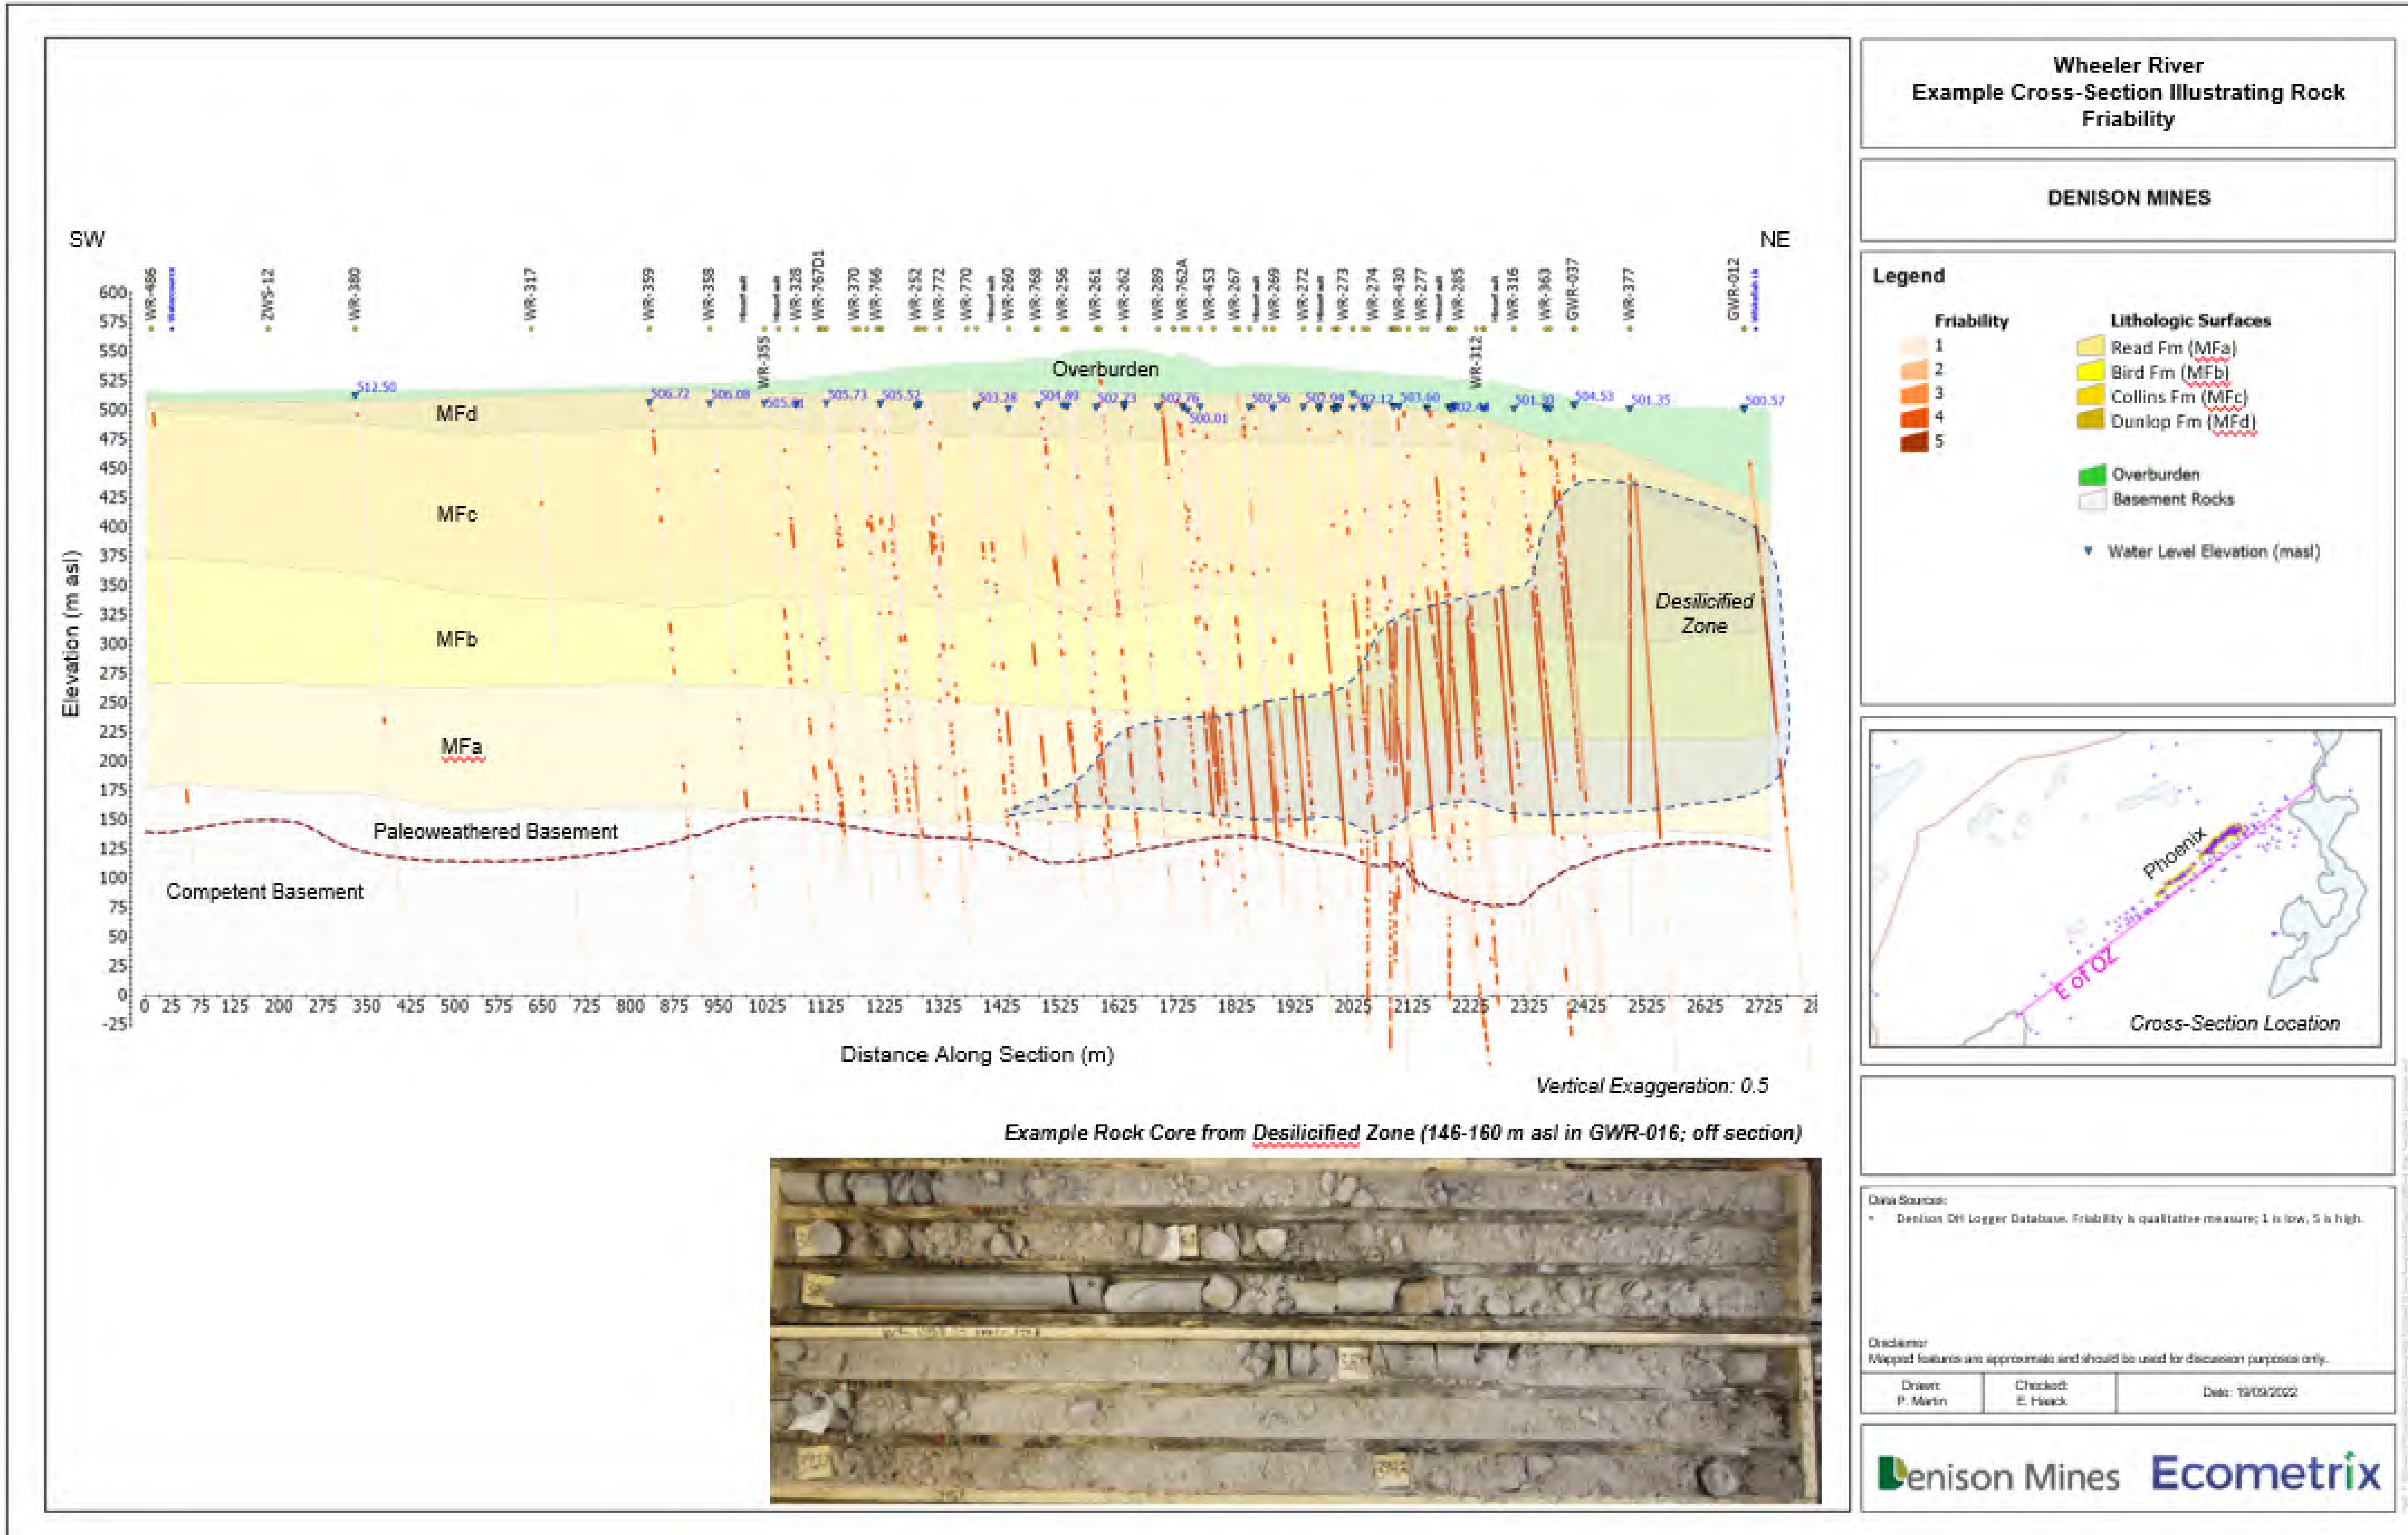

Figure 7.3-5: Example Cross-section Illustrating Rock Friability

7.3.2.4 Overburden

The regional geomorphology is typical of the Athabasca Plain Region and is dominated by landforms associated with continental glaciation, such as drumlins, eskers, outwash plains, and till plains (Figure 7.3-6). Drumlins and eskers present in the region trend in a northeast to southwest direction and form topographic highs on the landscape. Drumlins rise over 50 m above the surrounding land surface in some areas regionally, including the drumlin lying between the Phoenix and Gryphon deposits (Figure 7.3-6).

Based on regional-scale 1:250,000 mapping (Figure 7.3-6 and descriptions from borehole logs that describe surficial sediments, the surface deposits in the region consist predominantly of outwash sand and glacial till with organic and alluvial sediments (Power 2014; Campbell 2007; Schreiner 1984). In the LSA, data from corehole logging indicate overburden thickness ranges from less than a few metres on low-lying areas to over 100 m in the northwestern reaches of Whitefish Lake where weathering and glacial erosion of the sandstone bedrock formed a bedrock valley or 'trough' (as shown in the far northeast extent of the cross section in Figure 7.3-4).

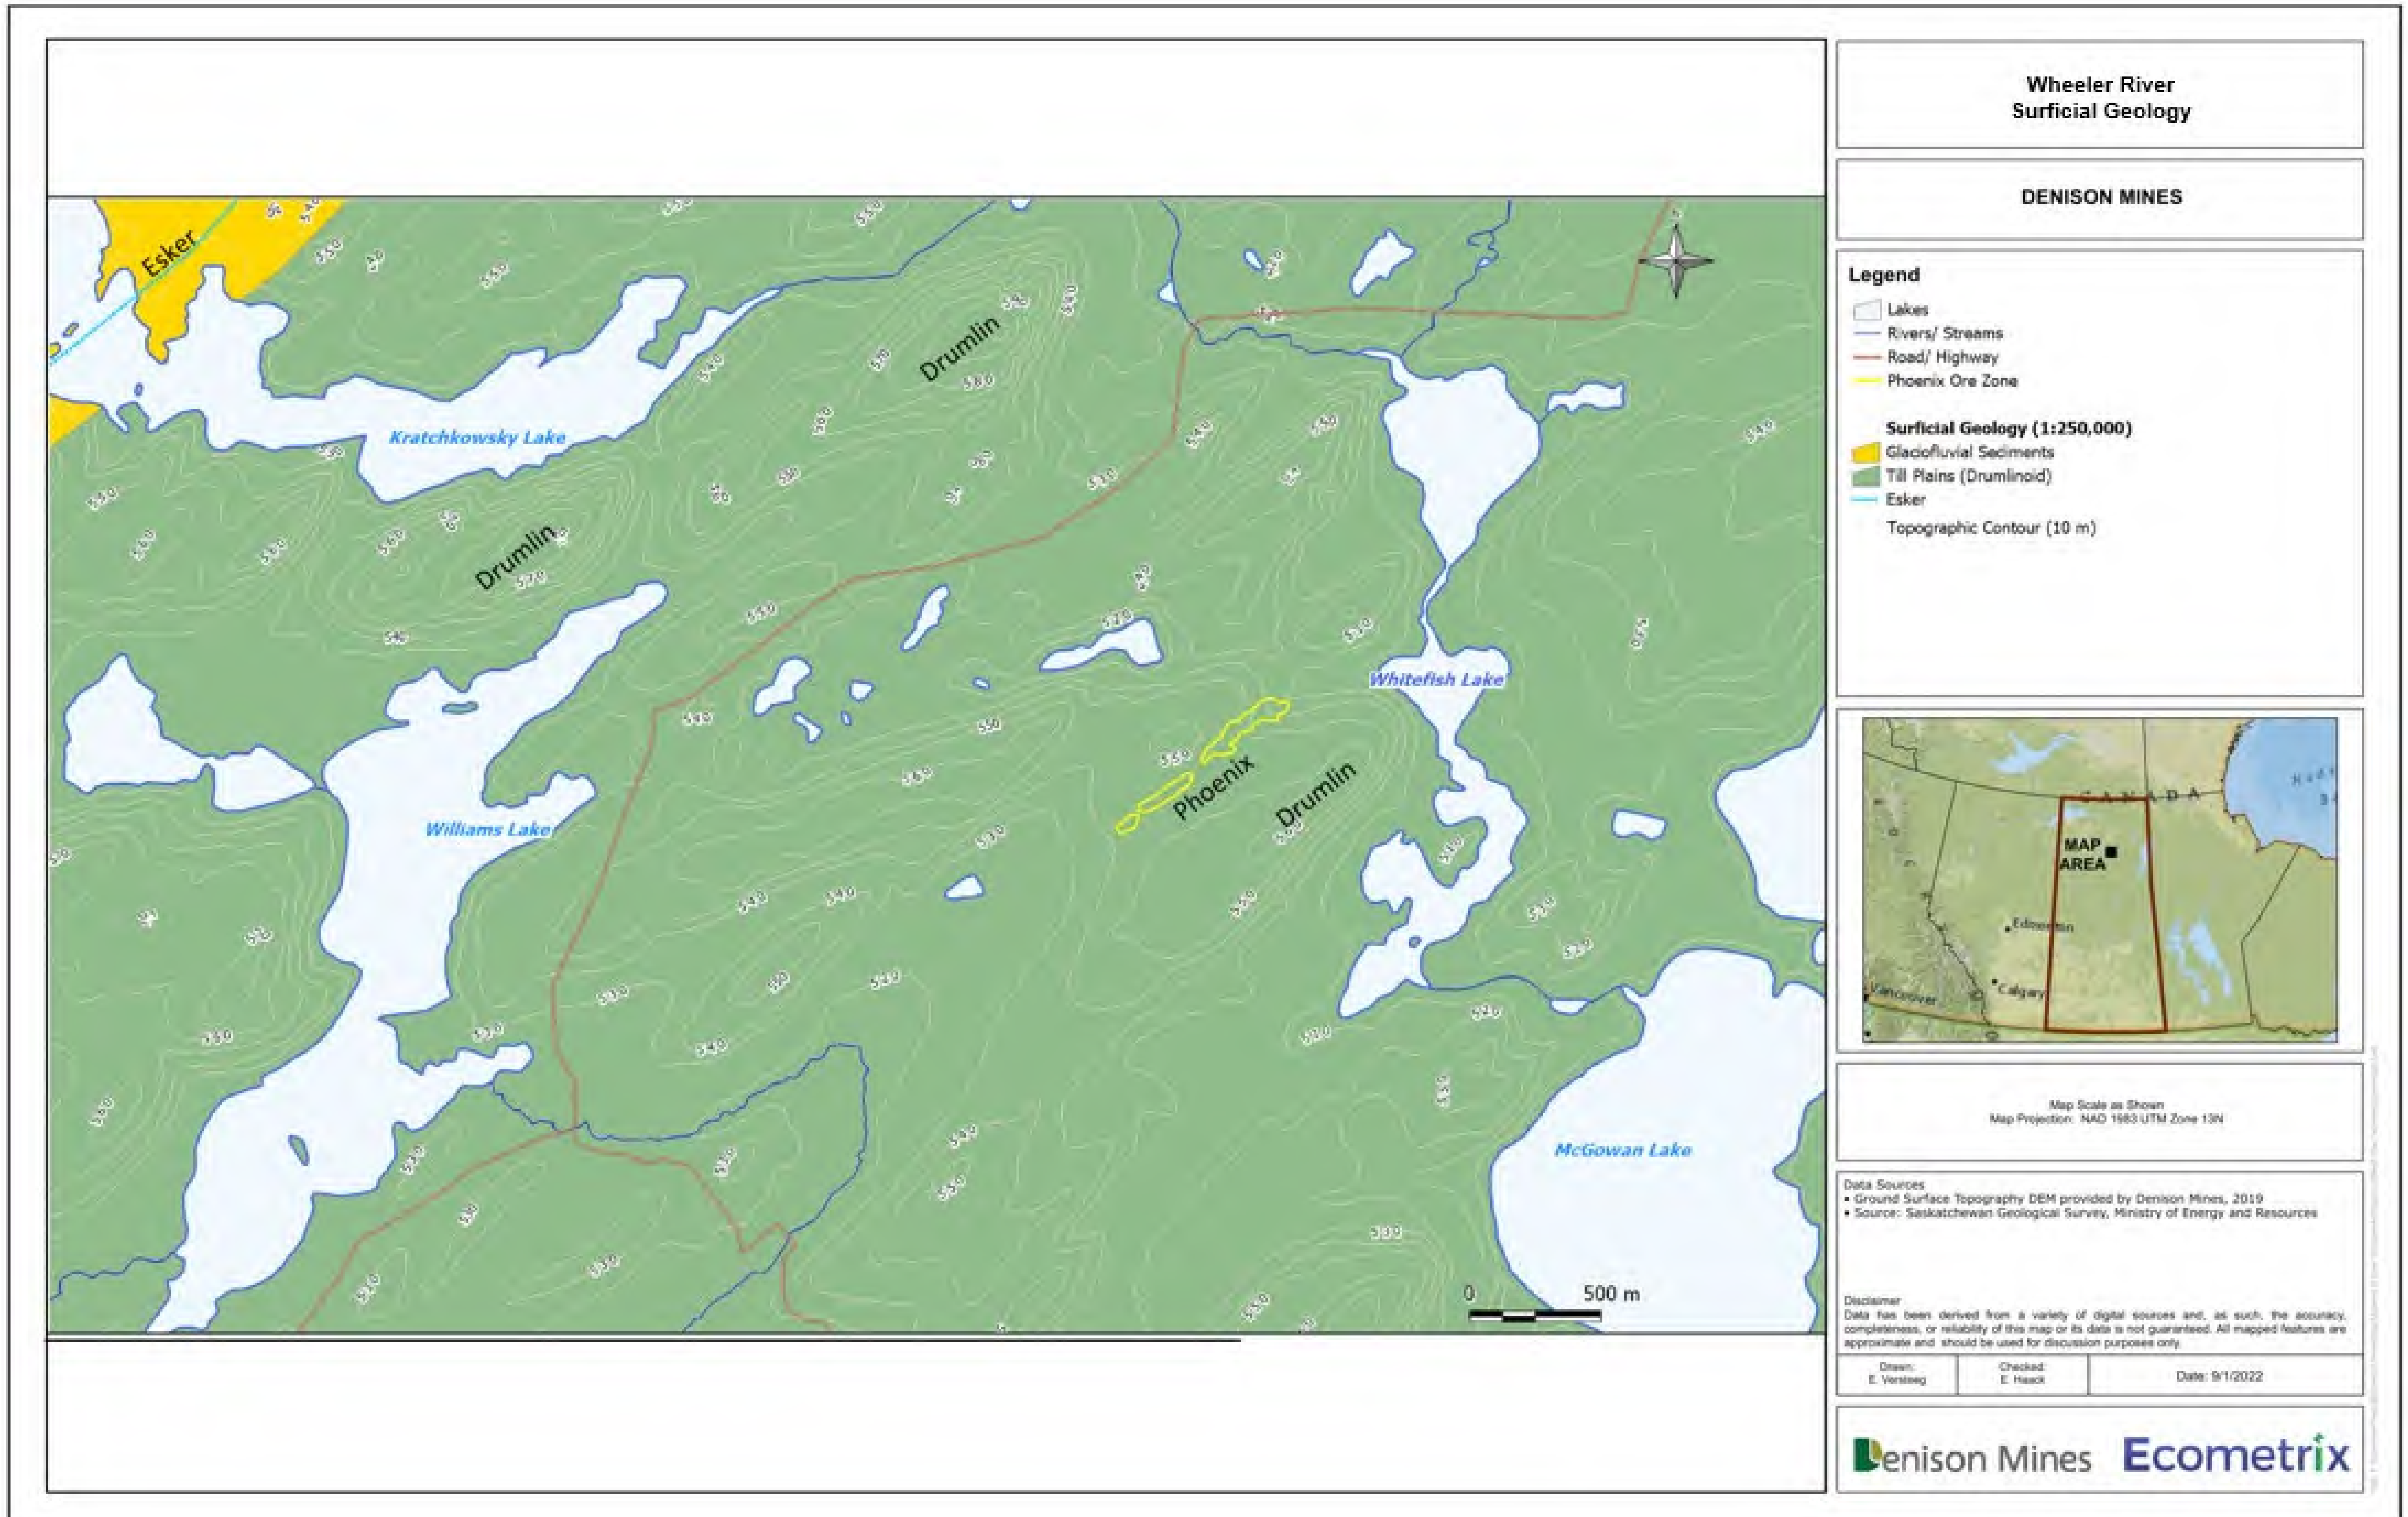

Figure 7.3-6: Surficial Geology

7.3.3 Hydrogeological Setting

Hydrostratigraphic units can be derived from stratigraphic or lithologic units based on their general hydrogeologic properties. Units that can transmit reasonable volumes of water are referred to as aquifers, while units that do not readily transmit water are referred to as aquitards. As the hydraulic conductivity in fractured rock settings is generally dominated by secondary porosity features such as faults and fractures, the hydrostratigraphic units do not necessarily align with lithologic, geologic, or stratigraphic boundaries. In addition, geologic or stratigraphic units that have similar hydrogeologic properties are often grouped together to form hydrostratigraphic units.

Nine hydrostratigraphic units were defined within the LSA. These are summarized in relation to subsurface geology (lithological units) in Table 7.3-1, and pictorially in the hydrogeological CSM, presented as Figure 7.3-7.

Figure 7.3-7: Hydrogeological Conceptual Site Model

7.3.3.1 Aquifer Properties

Methodologically, the combination of the fracture frequency and normative clay content features is interpreted to have the greatest influence on the observed hydraulic conductivity trends in the area surrounding the Phoenix deposit. The degree of fracturing results in the potential capability to transmit water, and thus have zones of enhanced hydraulic conductivity. This potential enhancement of hydraulic conductivity is counteracted where sufficient clay content is present, as the clays in the rock tend to infill and seal the available fractures.

Hydraulic conductivity, porosity, and storage values of the hydrostratigraphic units in the LSA are summarized in Table 7.3-2.

Table 7.3-2: Summary of Hydrostratigraphic Unit Properties

Hydrostratigraphic Units	Field-Based Hydraulic Conductivity (m/s)		Effective Porosity (%)	Storage[2]
	Range	Geomean[1]		
Overburden Aquifer/Aquitard	3×10^{-6} and 2×10^{-4}	-	25% (sand); 18% (till)	20% (Sy)
Upper Sandstone Aquifer	4×10^{-7} to 1×10^{-4}	3.7×10^{-6}	1 to 5%	1×10^{-5} (Ss)
Intermediate Bedrock Aquitard	1×10^{-10} to 3.8×10^{-6}	8.4×10^{-9}	1 to 10%	
Desilicified Zone	1×10^{-6} to 2×10^{-5}	4.8×10^{-6}		
Lower Sandstone Aquifer	7.8×10^{-8} to 3×10^{-5}	2.2×10^{-6}		
Upper and Lower Barrier Zone Aquitard (clay cap and sulphide-cemented rock)	Hydraulic tests have not been completed on these units as they are relatively thin in comparison to overlying/underlying units.[3]			1×10^{-6} (Ss)
Ore Zone Aquifer				
Basement Aquitard	1.1×10^{-11} to 1.1×10^{-5}	4.8×10^{-9}		

Notes

1 A geomean value was not calculated for the Overburden Aquifer/Aquitard or the Upper and Lower Barrier zone as only two measurements were available for each unit.

2 Sy values expressed as a percent of total volume. Ss values expressed in units of 1/m.

3 Screened intervals of the wells often intercept the ore zone and upper or lower barrier zones. Elevated hydraulic conductivity values were interpreted to reflect the ore zone aquifer and lower values reflect the barrier zone aquitard.

Overburden is generally sand-rich with minor silt and clay content, resulting in an aquifer that ranges from high to moderate hydraulic conductivity.

Aquifer zones within sandstone result from fractured zones (presumably associated with faulting) and areas of lower clay content. The Upper Sandstone Aquifer is comprised of fine- to medium-grained sandstone that has a very low (less than 3%) normative clay content. The Intermediate Sandstone Aquitard is comprised of competent fractured sandstone that has normative clay contents that vary from 4 to 10%. Like the Upper Sandstone Aquifer, groundwater flow within this unit is controlled by fracture spacing, orientation, connectivity, and aperture thickness; however, the normative clay content in this hydrostratigraphic unit is conceptualized to reduce or seal the fracture apertures and their connectivity and, in turn, reduce the hydraulic conductivity of the unit. Denison staff noted that fractures observed in cores drilled in the MFb B and MFc units often had red hematite smearing or clay that appears to have healed once open fractures (Sorba 2021). The Lower Sandstone Aquifer is comprised of fractured and faulted sandstone that overlies the basement rock units. This unit has a consistently low normative clay content (less than 4%).

Hydraulic conductivity values for the Desilicified Zone are expected to vary depending on the alteration and local extent of friability of the sandstone, but in general, higher hydraulic conductivity values are expected, as shown in Table 7.3-2.

The hydraulic properties within the Basement Aquitard unit vary as the properties are dependent on the fracture or fault properties. The highest hydraulic conductivity values are expected along the primary fault zones, including the WS Shear zone where the rock is more fractured. Lower hydraulic conductivity values are observed in most portions of the Basement Aquitards where the basement rocks are competent and fracture frequency is low.

7.3.3.2 Groundwater Flow Systems

As presented in Figure 7.3-7, groundwater flow in the LSA is conceptualized to occur in two groundwater flow regimes. The uppermost flow system is unconfined and includes groundwater flow through the overburden and Upper Sandstone Aquifer. The lower, semi-regional system is confined by the Intermediate Sandstone Aquitard and includes flow through the Lower Sandstone Aquifer and (locally) in the Ore Zone Aquifer.

Horizontal groundwater flow in the deeper, semi-regional flow system is generally directed from the west to the east and southeast, as interpreted by water level and groundwater quality observations (Figure 7.3-8). Groundwater flow within the Overburden and Upper Sandstone Aquifer is influenced by ground surface topography and surface water features (Figure 7.3-9). Flow in the upper groundwater flow regime is derived from recharge in the local area, whereas groundwater flow within the semi-regional groundwater flow system is derived from a combination of regional groundwater flow from upgradient sources and vertical flow through the Intermediate Sandstone Aquitard. Vertical gradients are interpreted to be directed downward in areas west of the Phoenix deposit and upward beneath the surface waterbodies, such as Whitefish and Williams lakes.

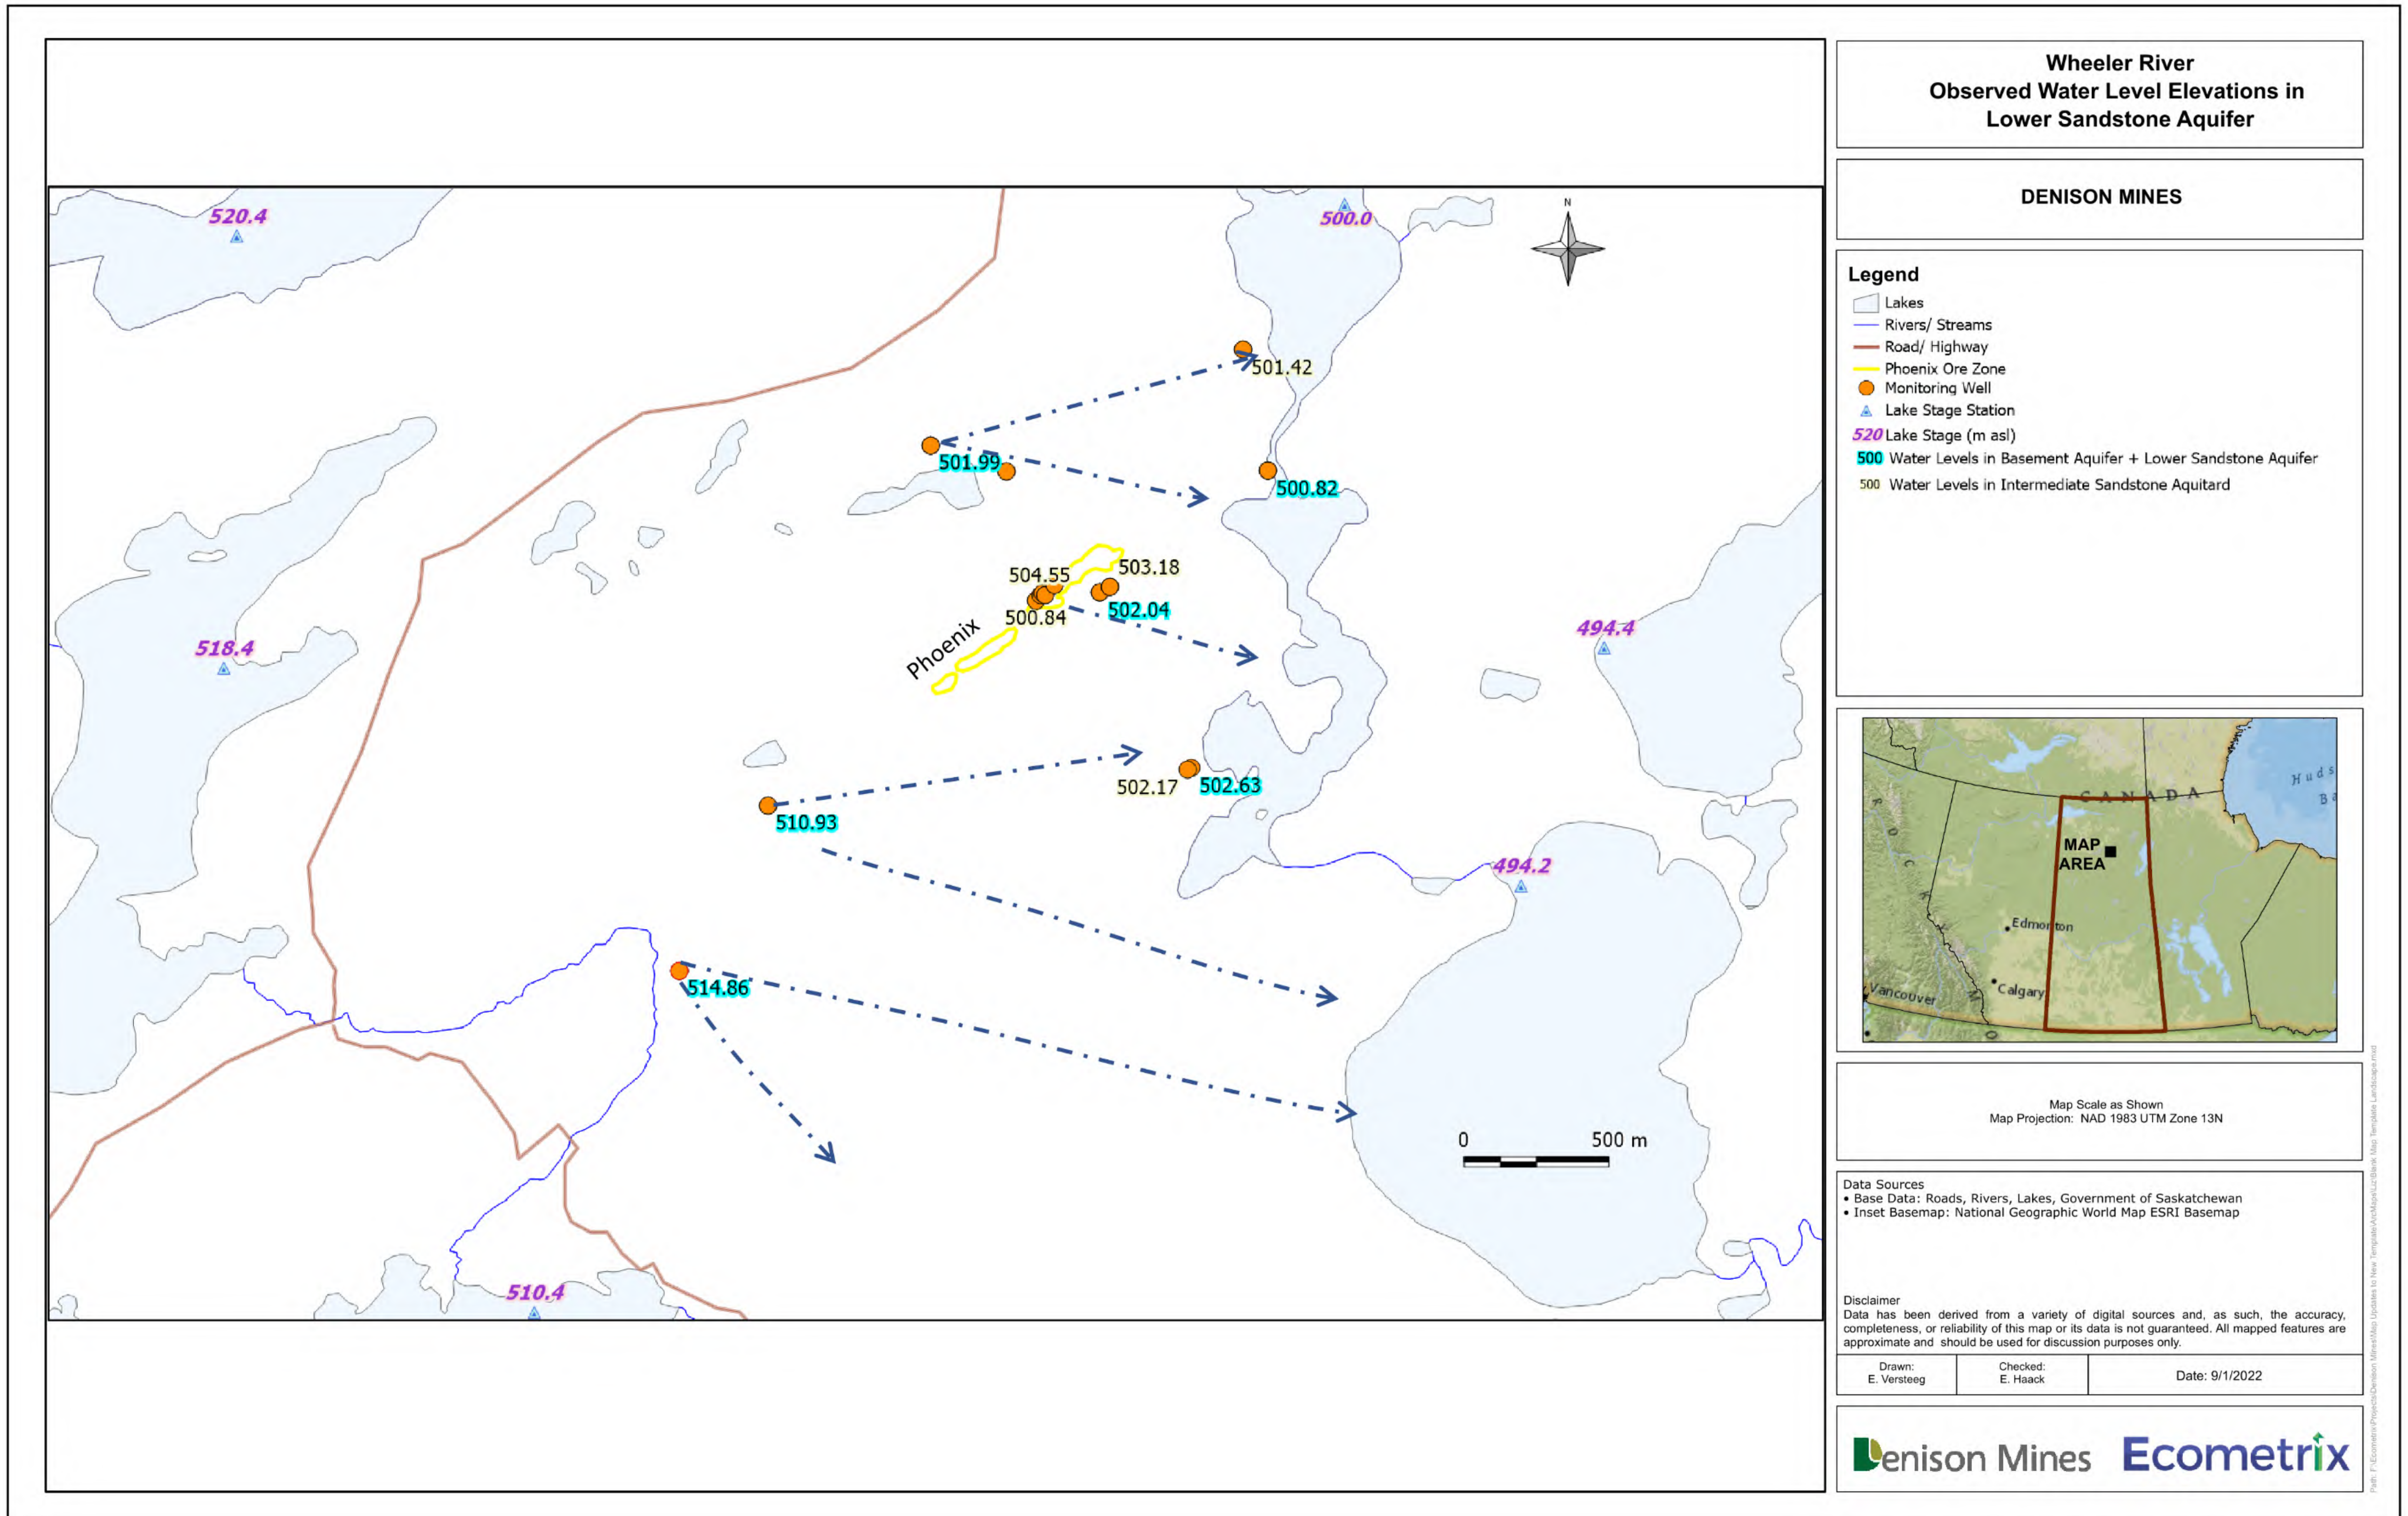

Figure 7.3-8: Observed Water Level Elevations in the Lower Sandstone Aquifer

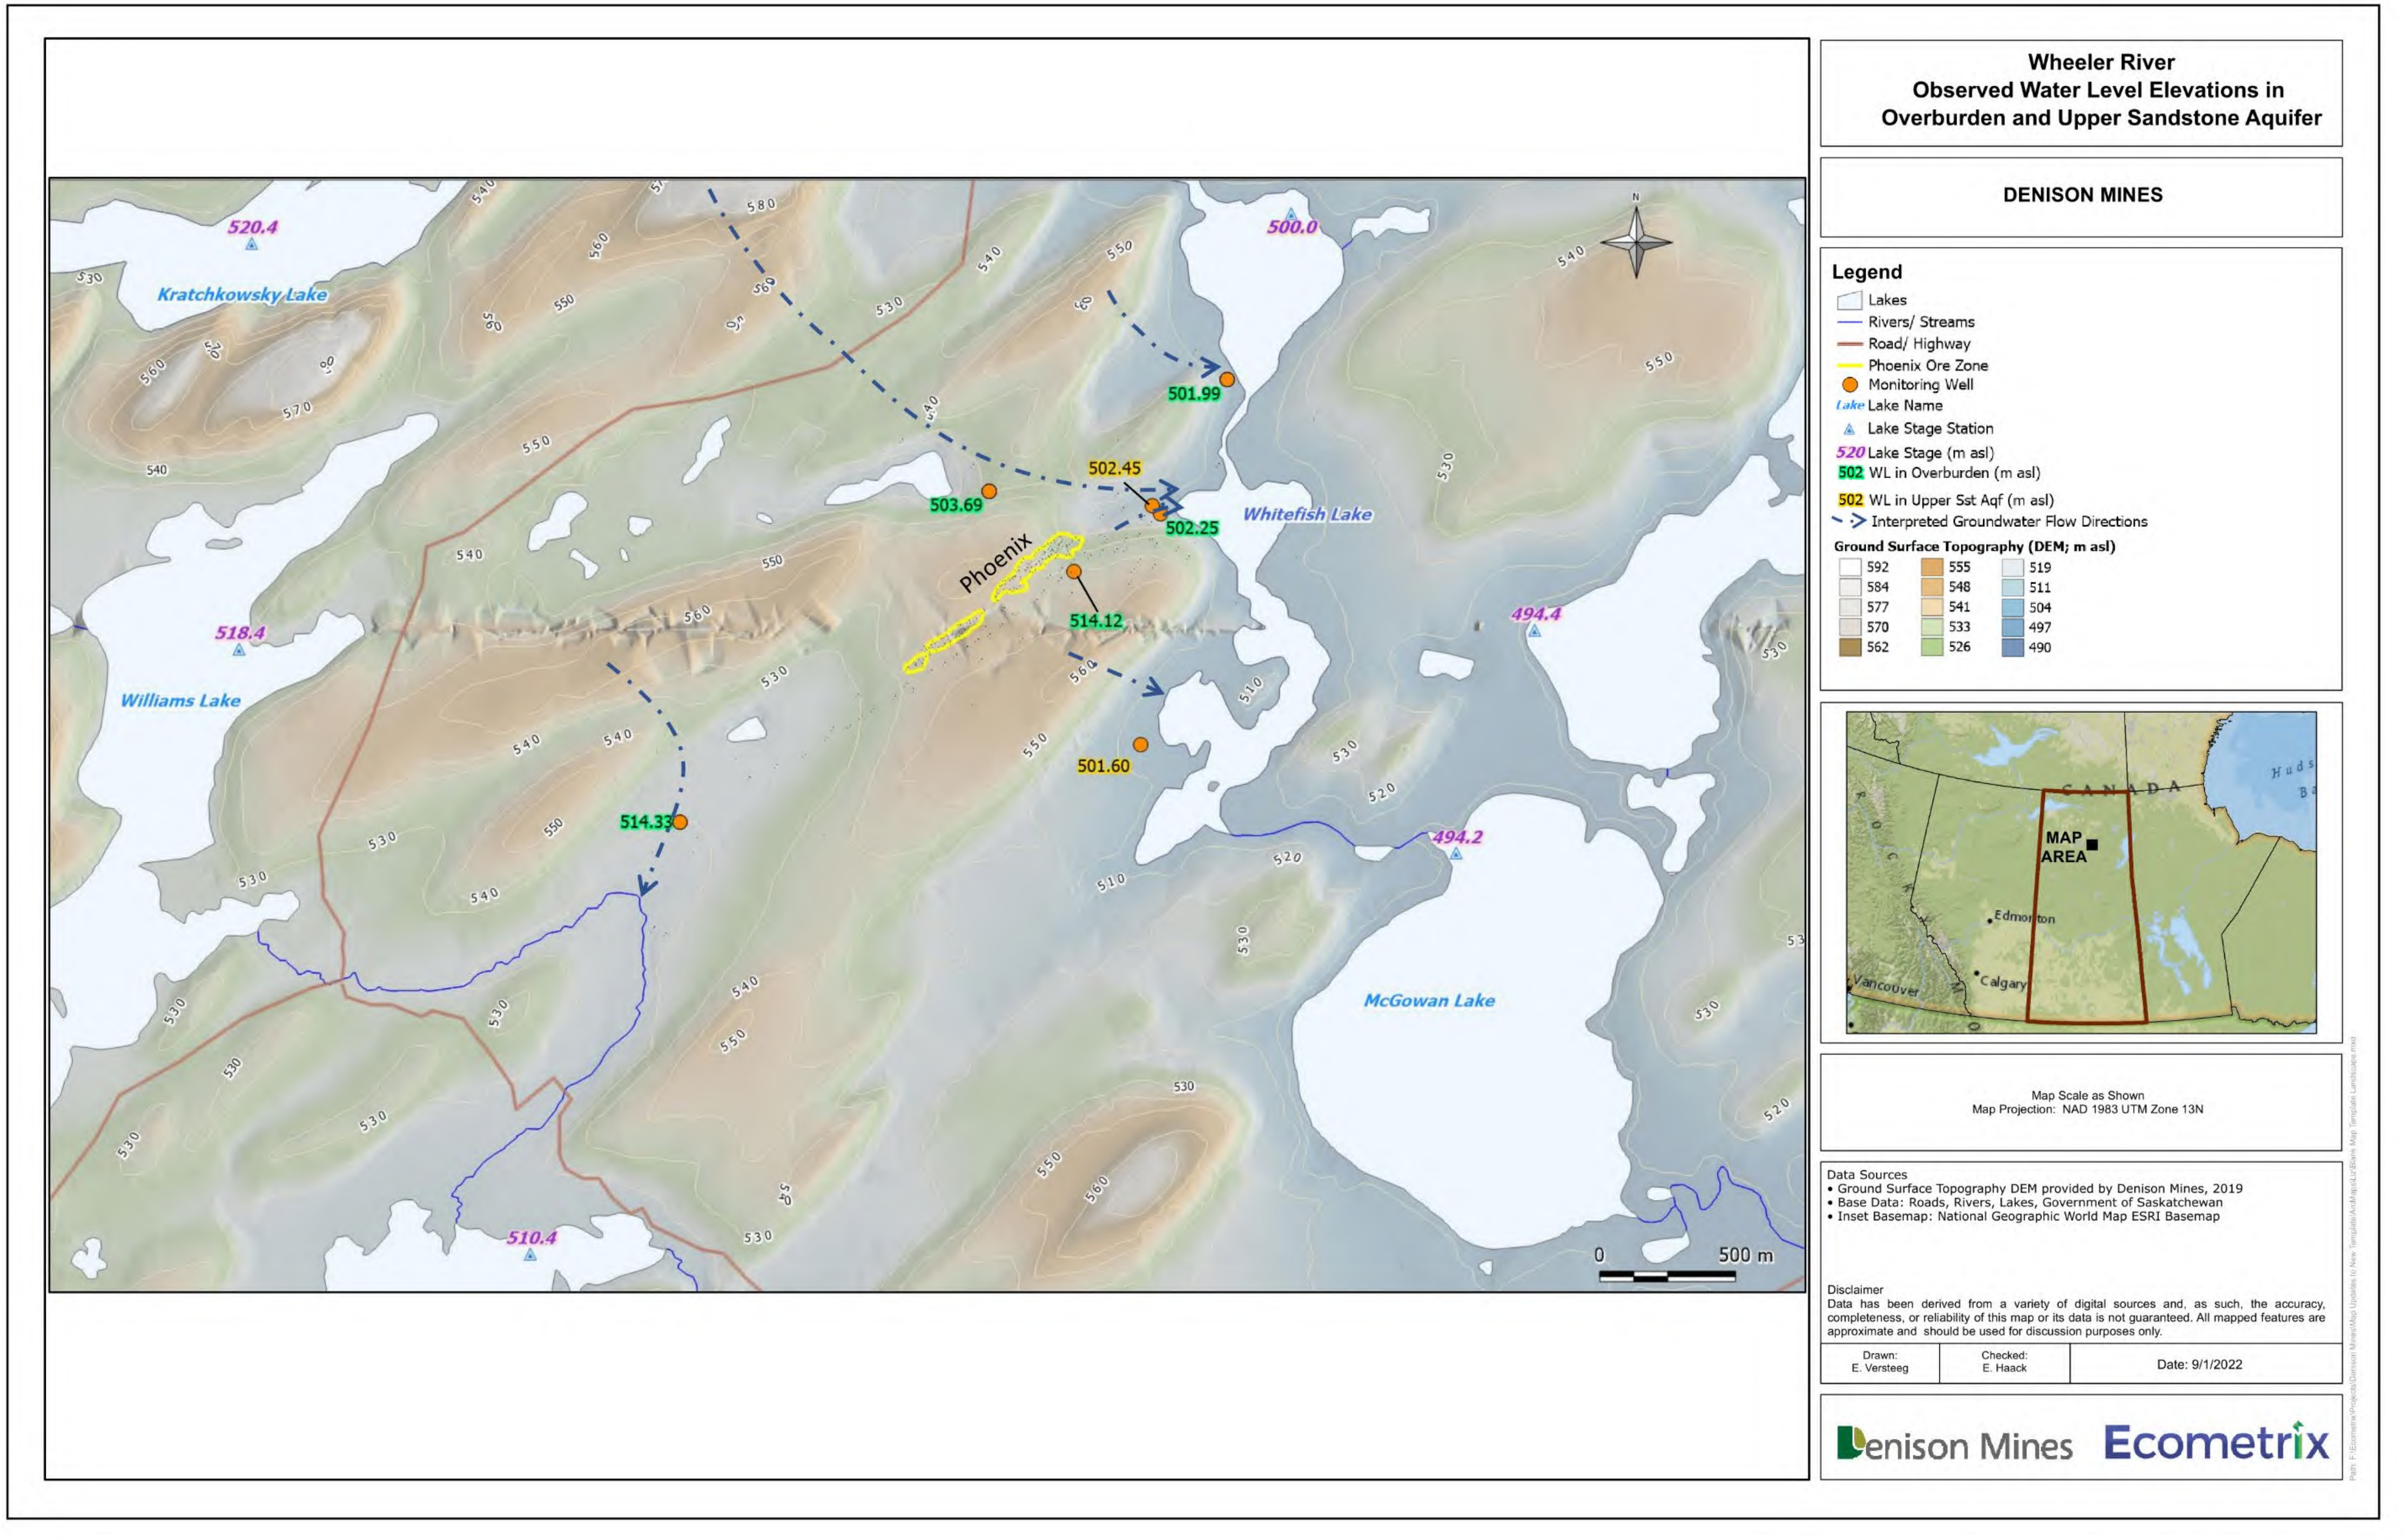

Figure 7.3-9: Observed Water Level Elevations in the Overburden and Upper Sandstone Aquifer

7.3.3.2.1 *Groundwater Recharge and Discharge*

Groundwater recharge occurs across much of the LSA, and after infiltrating to the water table, flows toward the local streams and surrounding lakes where it discharges to the surface. Recharge from the Local Flow System to the Lower Sandstone Aquifer is conceptualized to occur along fault zones (see Section 7.3.3.2.2) and where downward gradients are present.

Within the LSA, shallow groundwater in the Overburden and Upper Sandstone Aquifer is conceptualized to discharge into Whitefish Lake, which is located approximately 500 m east of the deposit and has a lake level of approximately 500 masl (Figure 7.3-9). Other major lakes in the area include Kratchkowsky Lake and Williams Lake, located west of the Phoenix deposit, which have lake levels of 520 and 518 masl, respectively (Figure 7.3-9). McGowan Lake, located southeast of Whitefish Lake and 2 km from the Phoenix deposit, has a lake elevation of 494 masl (6 m lower than Whitefish Lake), while Russell Lake, located 6 km south of the deposit, has a lake elevation of 488 masl.

The elevations observed in water levels between the Phoenix deposit and Whitefish Lake consistently exhibit an upward hydraulic gradient from the Lower Sandstone Aquifer (and ore zone) into Whitefish Lake (Figure 7.3-8) through the Desilicified Zone in the Intermediate Sandstone Aquitard. It is interpreted that the elevated hydraulic conductivity value represented by the Desilicified Zone creates a preferential pathway for water to discharge into Whitefish Lake, rather than continuing to stay in the Lower Sandstone Aquifer and discharge to Russell Lake. It is possible that some deeper regional flow within the Upper Sandstone Aquifer may discharge to Russell Lake south of the Phoenix site. However, despite the fact there is hydraulic potential for groundwater in the Lower Sandstone Aquifer to discharge to Russell or McGowan lakes, the Intermediate Sandstone Aquitard acts to hydraulically separate the Lower Sandstone Aquifer from the overlying Upper Sandstone Aquifer and the local groundwater flow regime in the Russell Lake and McGowan Lake areas.

Discharge to streamflow measurements have been shown to consistently increase from above Whitefish Lake to below McGowan Lake. Similarly, discharge to streamflow measurements along the drainage course west of the Phoenix deposit were measured to increase from upstream areas to the outlet at McGowan Lake. Low flow discharge per unit area is estimated to be approximately 125 mm/yr. This suggests that local groundwater discharge is sustaining streamflow even during low precipitation periods.

7.3.3.2.2 *Hydraulic Influence of Fault Zones and Drill Holes*

<u>Fault Zones</u>

Vertical fracture or fault zones that hydraulically connect the Local (upper) and Semi-Regional (lower) groundwater flow regimes are present throughout the Athabasca Basin (Ramaekers 1981; Kotzer and Kyser 1990; Sibbald et al. 1990). The distribution of monitoring wells outside of the

Phoenix ore zone area makes it difficult to identify these features with confidence, but these features may exist between data points.

Water level trends throughout the region surrounding the Phoenix deposit are largely consistent across the area (Figure 7.3-8, Figure 7.3-9, and Appendix 7-A). Large scale faults that extend from ground surface through the sandstone into the top of basement rock were not evident in the core; however, water levels in the deep sandstone and basement rocks in the areas west of the Phoenix ore zone are higher than those in the ore zone. For example, it is interpreted that the WS Shear zone (fault) may extend to ground surface and act as a preferential pathway for water to flow quickly from surface into the Lower Sandstone Aquifer. This interpretation is supported by groundwater quality within the Lower Sandstone Aquifer southwest of the Phoenix deposit (see Section 7.3.3.3).

Drill Holes

Exploration boreholes drilled in the Phoenix area, where left partially plugged to protect surficial aquifers, have the potential to provide preferential flow paths between the Overburden and Upper and Lower Sandstone Aquifers. Exploration holes were reportedly grouted approximately 10 to 20 m above and below the ore zone, resulting in open holes remaining throughout the overlying materials. These portions of the open holes may act as open conduits for groundwater flow through the 400 m of Athabasca Supergroup Sandstone. During Operation, select exploration boreholes will be re-utilized for narrow diameter injection wells that will be developed with monitoring devices for the determination of excursions and water levels. Exploration boreholes not selected for the use of narrow injection wells will be grouted to surface to seal off any remaining conduit.

Currently, these boreholes may be influencing the local vertical gradients observed in monitoring wells close to the Phoenix deposit, but as all observation wells local to the ore zone are screened at considerable depth (i.e., over 200 m), it is difficult to understand the potential influence of these open holes. These pathways will be considered during the planning and design of the groundwater monitoring plan (GWMP).

7.3.3.3 Baseline Groundwater Chemistry

The network of single interval groundwater monitoring wells in the LSA is shown in Figure 7.3-10. The GWR (‘Groundwater, Regional’) series wells were installed in all lateral directions around the ore zone and, for the most part, were advanced in groups of three. The groups of three wells targeted each of the local and regional groundwater flow zones, including: a) the Overburden and Upper Sandstone Aquifers (overburden, MFd, and upper MFc); b) the Intermediate Sandstone Aquitard (lower MFc and upper MFb); and c) the Lower Sandstone Aquifer (lower MFb and MFa). These groups of wells are referred to as ‘clusters’.

One monitoring well, GWR-031, is installed across the ore zone and Paleoweathered zone. Groundwater quality from this well is considered most reflective of Paleoweathered zone hydrochemistry of all the wells installed in the study area. Monitoring wells installed within or across the ore zone include GWR-032, GWR-038. GWR-039, GWR-040, GWR-041, and GWR-042.

Monitoring well GWR-004 was installed in the Basement Aquifer in Phase 3 of the Phoenix deposit, but due to the small drill/core size, cannot support sampling. An attempt was made to sample the basement rock as part of the Gryphon Shaft Pilot Hole Drill Support Program (SRK Consulting 2018a). Due to low permeability and groundwater recovery, it was not possible to collect a sample from the basement rock. Groundwater quality for the basement rock is available from information available from Cigar Lake (AECL 1994) and the *Millennium Project Environmental Impact Statement: Annex D, Regional Geology and Hydrogeology* (Cameco 2012a).

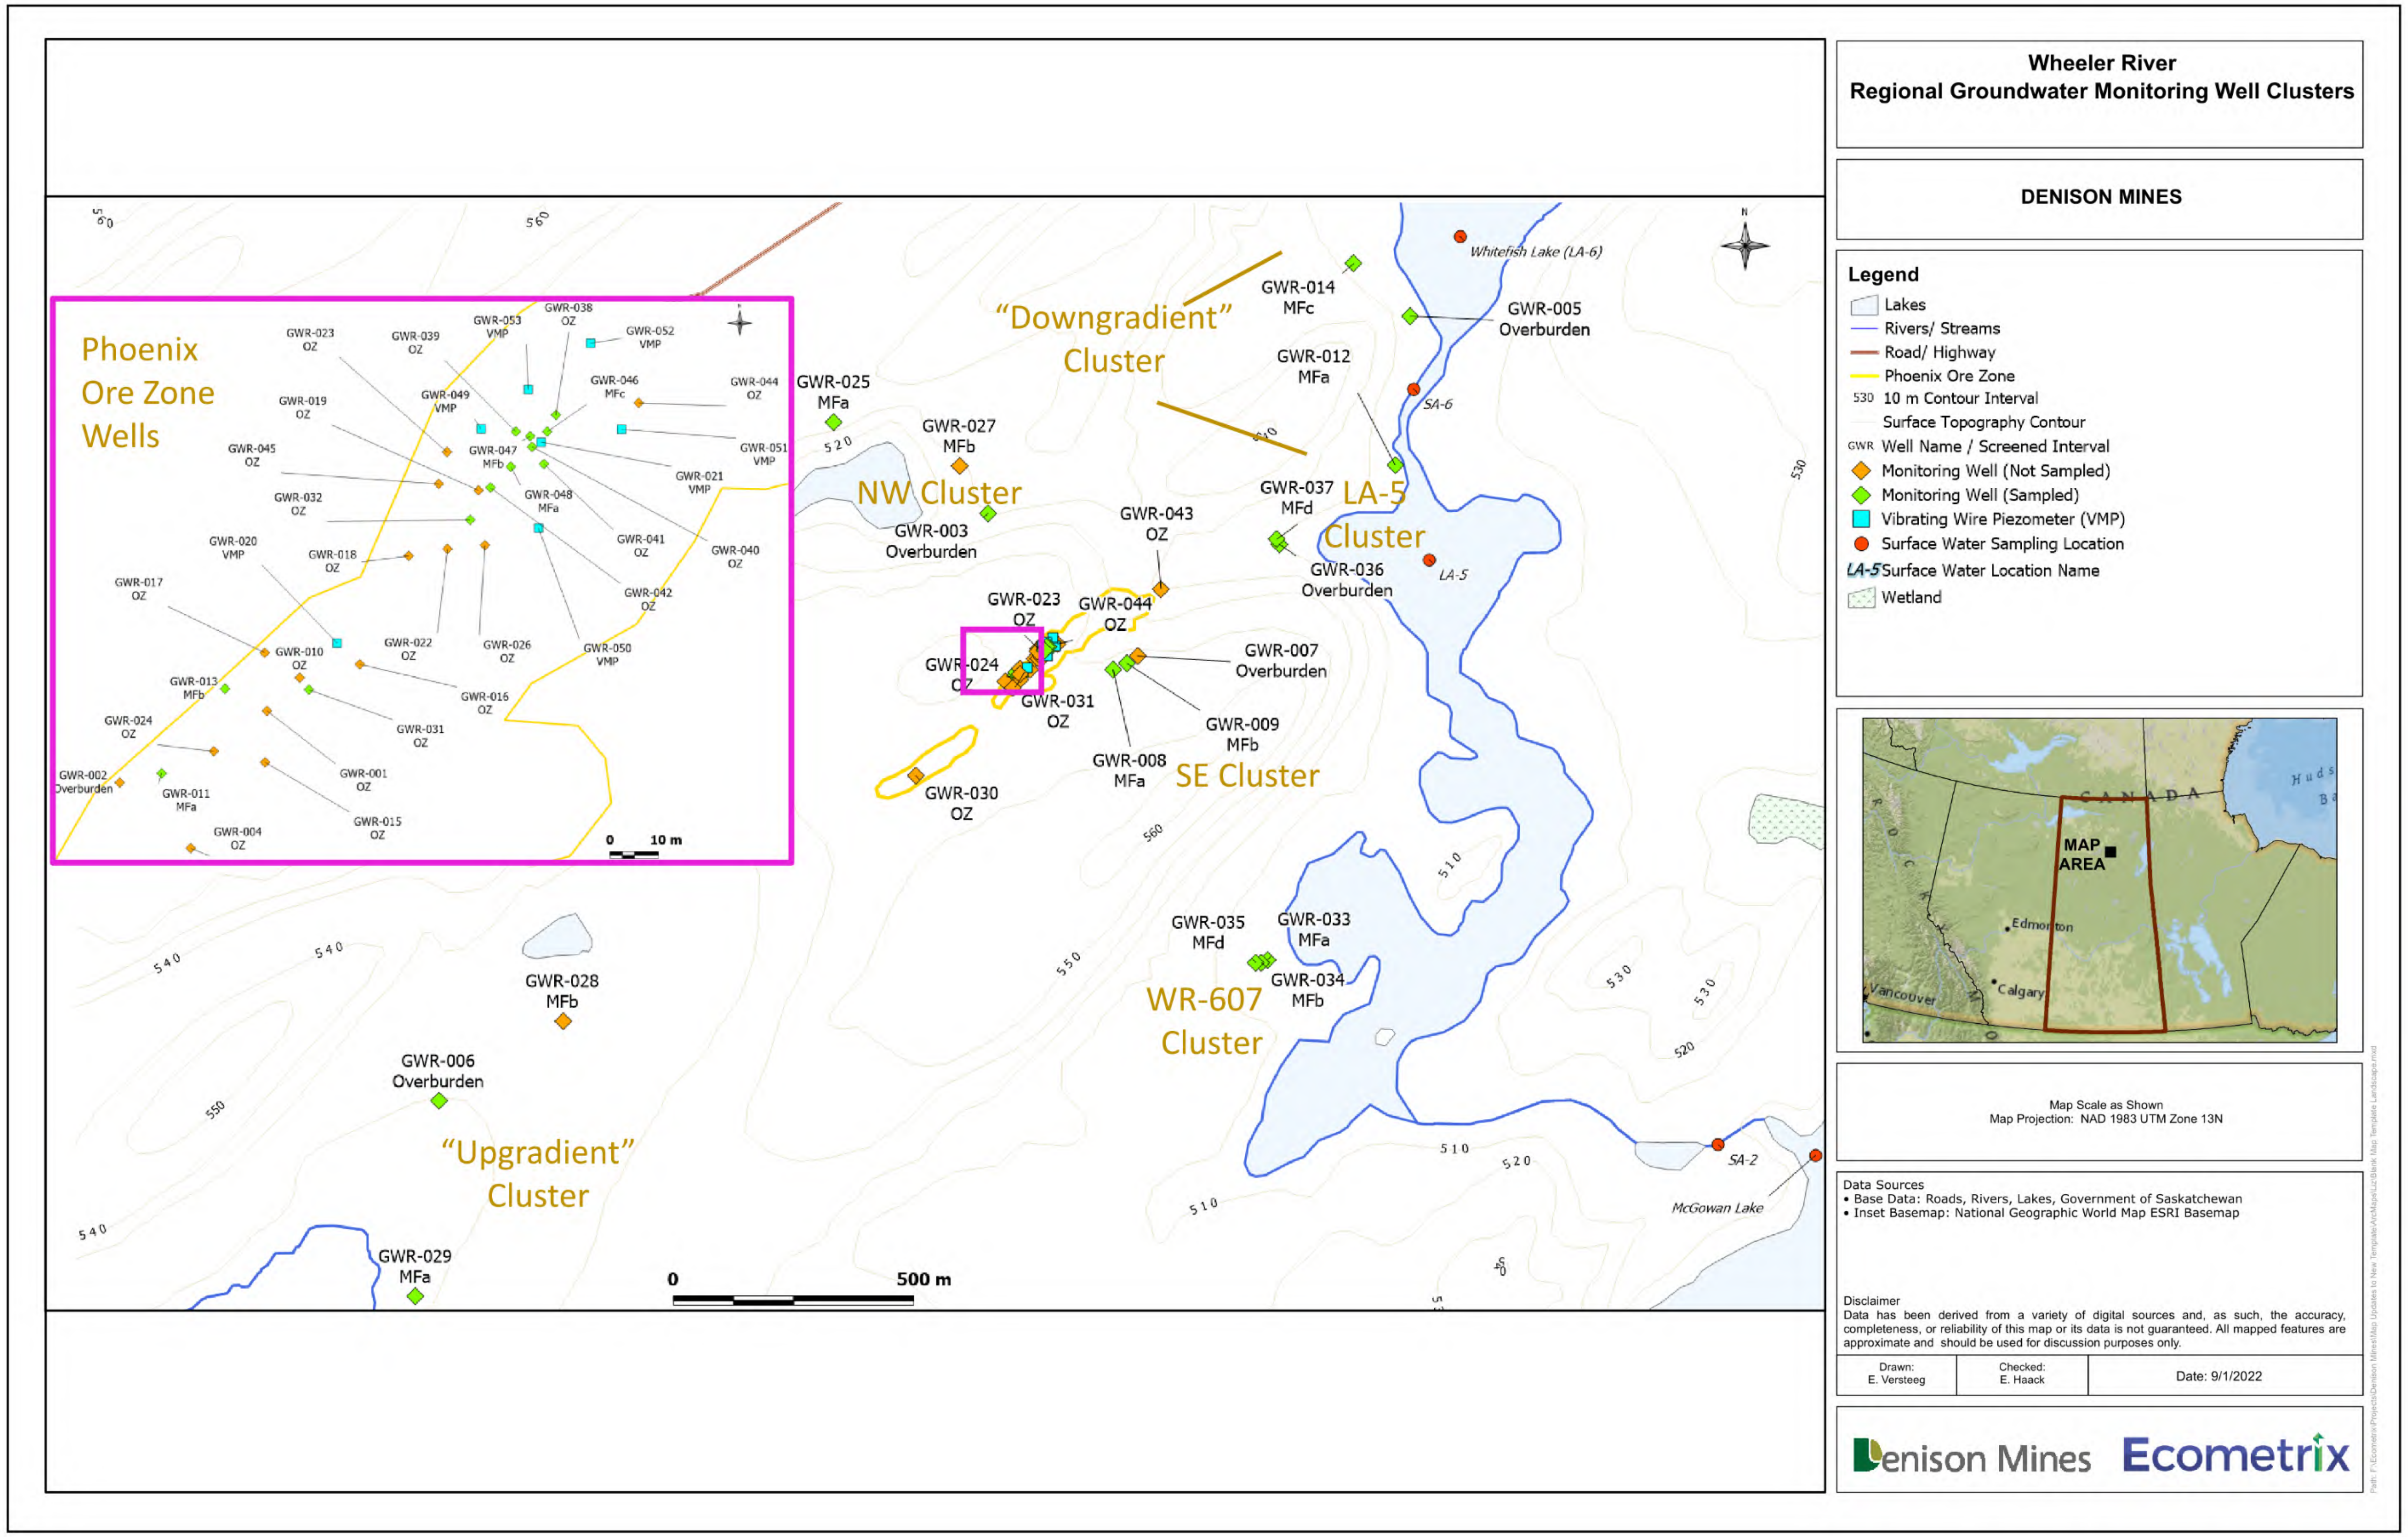

Figure 7.3-10: Regional Groundwater Monitoring Well Clusters

Tabulated groundwater quality measured within the LSA is provided in Appendix 7-A. Groundwater across hydrostratigraphic units is generally characterized by low mineralization (i.e., total dissolved solids concentrations less than 1,000 mg/L). Concentrations of radiological constituents and a small number of heavy metals and trace elements measured in groundwater associated with the uranium deposit in the Phoenix area are generally orders of magnitude lower in overlying hydrostratigraphic units and surface water than they are in the ore zone groundwater samples, as demonstrated for uranium concentrations spatially in Figure 7.3-11. This is evidence of a very low mass flux of these constituents from the ore zone and a discontinuous barrier zone aquitard that envelopes the ore zone over time.

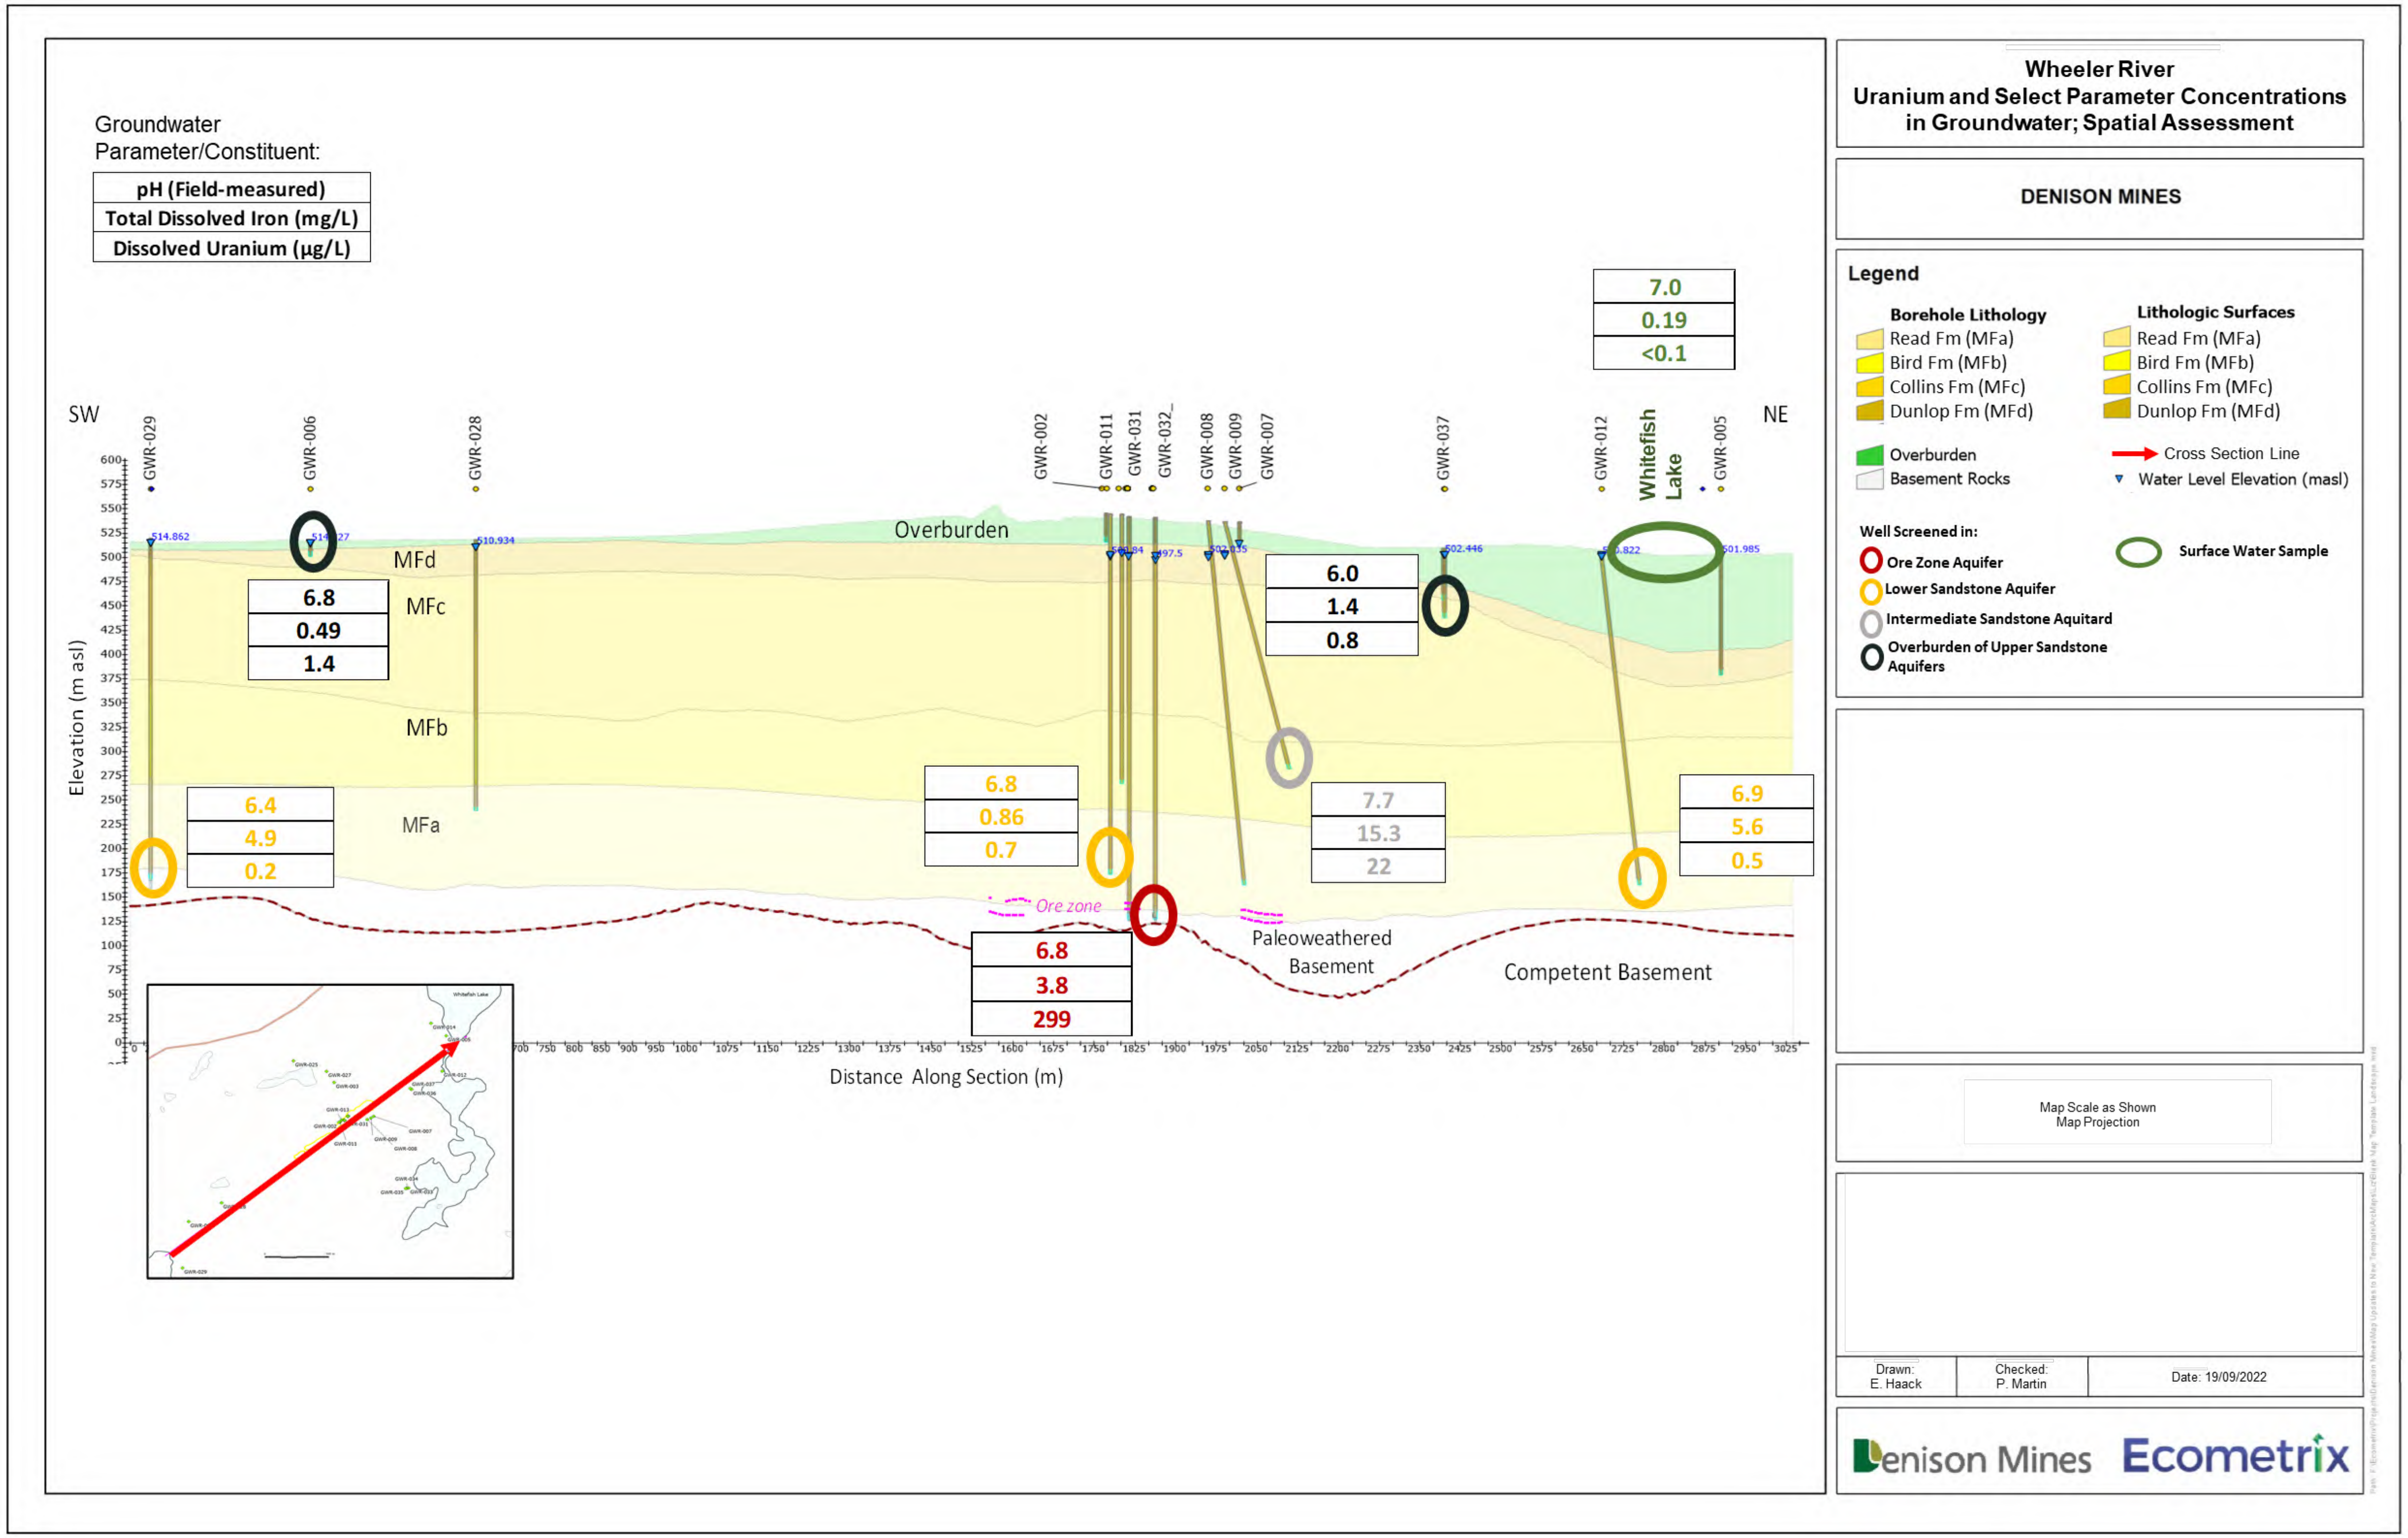

Figure 7.3-11: Uranium and Select Parameter Concentrations in Groundwater – Spatial Assessment

The groundwater chemistry measured supports the presence of a Local Flow System, Intermediate Sandstone Aquitard, and Lower Sandstone Aquifer in the study area. The chemistry of groundwater in the Local Flow System is that of recharge water with a relatively low pH (due to contact with organic matter in the upper soil profile) that has become mineralized through dissolution of quartz, feldspars, kaolinite, and illite. The chemistry of groundwater in the Intermediate Sandstone Aquitard is similar to the Local Flow System in terms of major ion composition, but a longer residence time in the aquitard has led to more extensive mineral dissolution and higher mineralization with a similar hydrochemical type. Higher relative variability in concentrations of groundwater constituents measured in monitoring wells from the Intermediate Sandstone Aquitard may reflect the localized influence of desilicification on the flow conditions, and consequently on groundwater quality conditions.

The Lower Sandstone Aquifer is characterized spatially by two types of groundwater. The first groundwater type is most like that observed in the Local Flow System. This reflects hydraulically active fractures and fault systems that allow fresh recharge water to penetrate and mix with deeper waters in the aquifer. The second type of groundwater is within the zone of thermal alteration around the ozone and has relatively high mineralization, thought to be the result of dissolution of remnant halide salts present on grain boundaries and in intragranular pores within the rock matrix at depth in the Athabasca Sandstones.

Groundwater quality results suggest that connectivity between the Upper Sandstone Aquifer and Intermediate Sandstone Aquitard is limited. Desilicification of these formations to the northeast of the ore zone may affect interconnectivity of these units on a localized scale. Although limited in number of samples available, groundwater quality in the Paleoweathered zone for the Project assessment suggests a distinct geochemical environment from that of the overlying Athabasca Sandstone hydrostratigraphic units.

7.4 Assessment of Project-related Effects

This subsection describes the process by which interactions between Project components and activities and the Geology and Groundwater VCs were identified and evaluated. A Project interaction analysis was used to focus the assessment on key interactions between the Project and the environment. The key interactions were evaluated to determine the significance of potential residual effects on the VCs.

Primary pathways that may lead to residual effects after incorporation of mitigation are further characterized in subsequent subsections of the assessment, as required. As such, the discussion of Project-related interactions and mitigation measures (Sections 7.4.1, 7.4.2, and 7.5) helps to focus the remainder of the assessment on those interactions (i.e., effects pathways) likely to result in residual adverse effects.

7.4.1 Potential Project-Valued Component Interactions

Potential Project-related interactions with the Geology and Groundwater VCs are summarized by Project phase in Table 7.4-1 and Table 7.4-2, respectively. Potential interactions in the summary tables were ranked in accordance with the following categories using professional judgement, understanding of the Project, recent EAs for mining projects in Canada, and comments provided during engagement:

- **Primary Interaction** (✓): The pathway is likely to result in an environmental change relative to the base case and/or guideline values that could contribute to residual effects on Geology and/or Groundwater VCs.
- **Other Interaction** (✓): Project activity is expected to interact with the Geology and/or Groundwater VCs. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects. The interaction has the potential to result in a measurable minor environmental change but would have a negligible residual effect on Geology and/or Groundwater relative to base case and/or guideline values. Such pathways are not expected to contribute cumulatively to other Project effects or to the effects of other previous, existing, or reasonably foreseeable developments to cause a significant effect.
- **No Interaction**: Project activity is not expected to interact with the Geology or Groundwater VCs due to environmental design features or mitigation. The Project activity would not be expected to result in a measurable environmental change relative to base case values and therefore would have no residual effects on Geology and/or Groundwater.

Table 7.4-1: Potential Project Interactions for the Geology Valued Component

Project Phase/Activity	Key Indicator #1 Terrain/Subsidence
Construction Activities	
Development of access roads and air strip	
Site preparation and earthworks; clearing, levelling, and grading of the Project Area	
Power generation – generators	
Installation of main substation and distribution of power around site	
Wellfield and freeze hole drilling; ground freezing	
Batch plant operation (concrete); crusher at borrow area	
Development of surface infrastructure (camp, operations centre, plants, ponds, pads, and support facilities)	
Waste management (composting, domestic and industrial landfill operation, recycling)	
Water management (including treatment and site runoff)	
Groundwater supply	
Surface water withdrawal	

Project Phase/Activity	Key Indicator #1 Terrain/Subsidence
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
On-site and off-site operation of vehicles and transport of materials	
Air transportation for workers	
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Operation Activities	
Operation of the ISR wellfield	✓
Wellfield and freeze wall drilling	✓
Operation and expansion of freeze wall	✓
Batch plant operation (grout and cement); crusher in borrow area	
Expansion of pond and pads	
Operation of the processing plant and production of uranium concentrate	
Water withdrawal from groundwater or surface waterbody	
Management of surface water (including seepage and site runoff)	
Water treatment, both domestic and industrial	
Water release to surface waterbody	
Waste management (composting, domestic and industrial landfill operation, recycling)	
Hazardous waste management (temporary storage, handling, and off-site transportation)	
Storage and disposal of drill waste rock, process precipitates, and industrial wastewater treatment plant precipitates	
On-site and off-site operation of vehicles and transport of materials	
Power supply – primarily power from the grid, also generators and back-up generators	
Package and transport of nuclear substances	
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
Air transportation for workers	
Progressive decommissioning and reclamation	
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Decommissioning Activities	
Site water management, treatment, and release	
Mining horizon remediation and thawing of freeze wall	
Process water treatment and release	
Closure of ISR and freeze wells and related infrastructure	
Decontamination of surface facilities and injection, recovery, and monitoring wells	
Asset removal (including site power transmission lines and electrical infrastructure)	

Project Phase/Activity	Key Indicator #1 Terrain/Subsidence
Demolition and disposal of non-salvageable surface infrastructure and materials	
Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and process plant area)	
Generators	
Waste management (composting and landfill operation)	
Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal)	
On-site and off-site operation of vehicles and transport of materials	
Reclamation of disturbed areas	
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Post-Decommissioning Activities	
Environmental monitoring	
Regulatory site inspections	
Engagement – Site visit from Interested Parties	

A check mark ✓ indicates an 'other' interaction and a grey check mark (✓) indicates a primary interaction.

Table 7.4-2: Potential Project Interactions for the Groundwater Valued Component

Project Phase/Activity	Groundwater Valued Component	
	Key Indicator #1 Groundwater Quantity	Key Indicator #2 Groundwater Quality
Construction Activities		
Development of access roads and air strip		
Site preparation and earthworks; clearing, levelling, and grading of the Project Area	✓	
Power generation – generators		
Installation of main substation and distribution of power around site		
Wellfield and freeze hole drilling; ground freezing	✓	✓
Batch plant operation (concrete); crusher at borrow area		
Development of surface infrastructure (camp, operations centre, plants, ponds, pads, and support facilities)	✓	
Waste management (composting, domestic and industrial landfill operation, recycling)		
Water management (including treatment and site runoff)		✓
Groundwater supply	✓	
Surface water withdrawal		
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)		

Project Phase/Activity	Groundwater Valued Component	
	Key Indicator #1 Groundwater Quantity	Key Indicator #2 Groundwater Quality
On-site and off-site operation of vehicles and transport of materials		
Air transportation for workers		
Regulatory site inspections		
Engagement – site visit from Interested Parties		
Operation Activities		
Operation of the ISR wellfield	✓	✓
Wellfield and freeze wall drilling	✓	✓
Operation and expansion of freeze wall	✓	✓
Batch plant operation (grout and cement); crusher in borrow area		
Expansion of pond and pads	✓	✓
Operation of the processing plant and production of uranium concentrate		✓
Water withdrawal from groundwater or surface waterbody	✓	
Management of surface water (including seepage and site runoff)	✓	✓
Water treatment, both domestic and industrial		✓
Water release to surface waterbody		
Waste management (composting, domestic and industrial landfill operation, recycling)		✓
Hazardous waste management (temporary storage, handling, and off-site transportation)		✓
Storage and disposal of drill waste rock, process precipitates, and industrial wastewater treatment plant precipitates		✓
On-site and off-site operation of vehicles and transport of materials		
Power supply – primarily power from the grid, also generators and back-up generators		
Package and transport of nuclear substances		
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)		
Air transportation for workers		
Progressive decommissioning and reclamation		
Regulatory site inspections		
Engagement – site visit from Interested Parties		
Decommissioning Activities		
Site water management, treatment, and release	✓	✓
Mining horizon remediation and thawing of freeze wall	✓	✓
Process water treatment and release	✓	✓
Closure of ISR and freeze wells and related infrastructure	✓	✓

Project Phase/Activity	Groundwater Valued Component	
	Key Indicator #1 Groundwater Quantity	Key Indicator #2 Groundwater Quality
Decontamination of surface facilities and injection, recovery, and monitoring wells		✓
Asset removal (including site power transmission lines and electrical infrastructure)		
Demolition and disposal of non-salvageable surface infrastructure and materials		
Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and process plant area)	✓	✓
Generators		
Waste management (composting and landfill operation)		✓
Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal)		
On-site and off-site operation of vehicles and transport of materials		
Reclamation of disturbed areas	✓	
Regulatory site inspections		
Engagement – site visit from Interested Parties		
Post-Decommissioning Activities		
Environmental monitoring	✓	✓
Regulatory site inspections		
Engagement – Site visit from Interested Parties		

A check mark ✓ indicates an 'other' interaction and a grey check mark (✓) indicates a primary interaction.

7.4.2 Potential Project-related Effects

Based on the anticipated Project interactions analysis summarized in Table 7.4-1 and Table 7.4-2, key interactions and potential effects that warrant further assessment were identified. These potential effects have a greater potential to result in an adverse residual effect or to be a concern to Indigenous peoples, governments, or the public. The following subsections provide an overview of what is known and understood about the potential effects. Understanding of the potential effects is based on professional judgement, understanding of the Project, similar EAs for mining projects in Canada, and comments provided during engagement.

Project interactions determined as "No Interaction" were not carried forward for further assessment for one or more of the following reasons:

- the Project activities do not interact with the Geology or Groundwater VCs (e.g., on-site and off-site operation of vehicles and transport of materials);
- the Project activities are managed under another discipline (e.g., Aquatic Environment); and/or

- the Project activities are deemed to be a part of routine operations or expected activities with best management practices or health and safety plans (e.g., asset removal [including site power transmission lines and electrical infrastructure]).

The primary potential effect from the Project on the Geology VC is changes to soil terrain and stability during Operation. The primary potential effect from the Project on the Groundwater VC is changes to groundwater quantity and quality during Construction, Operation, Decommissioning, and Post-Decommissioning associated with mining activities and following remediation of the mining area. For clarity throughout this section, the definition of the mining area provided in Section 2 is summarized herein. The mining area includes:

- the ‘active mining area’, which is the target ore zone;
- a zone extending between 11 and 13 m above the active mining area that represents the maximum vertical height over which the injected mining fluids will migrate upwards from the ore zone during active mining; and
- a zone extending 50 m vertically upwards from the active mining area (that incorporates the active mining area and the 11 to 13 m zone defined in the previous bullet) that was selected to account for potential upset conditions.

Denison has committed to containing mining solutions within the mining area. Residual effects associated with the mining area have been shown through groundwater modelling simulations to be confined to the LSA (see Section 7.6).

Primary pathways that may result in changes to the environment and one or more associated measurement indicator(s) and that have the potential to cause a greater than negligible effect on the Geology and Groundwater VCs were evaluated and carried forward to the mitigation measures discussion (Section 7.5) and, if warranted, to the residual effects evaluation (Section 7.6).

The Project components, activities, and expected interactions with the Geology and Groundwater VCs are presented in Table 7.4-3. Detailed descriptions and evaluations of the key potential effects that were identified as having primary or other interactions with the Project are presented in the following subsections.

Table 7.4-3: Potential Project-related Effects by Project Phase for the Geology and Groundwater Valued Components

Project Activity	Potential Effect within the Local Study Area	Project Interactions[1]
Construction		
Site preparation, site clearing, and grading Development of surface facilities Wellfield and freeze hole drilling; ground freezing Groundwater withdrawal(s) for water supply	Construction of the surface facilities and site preparation for the Project may physically alter groundwater recharge rates, groundwater levels, and flow conditions within the shallow hydrostratigraphic units to surface water receptors. Groundwater withdrawal for water for construction purposes may cause changes to the groundwater system within the shallow hydrostratigraphic units.	EX Groundwater Quantity
Refuelling of equipment and general site construction activities	Spills or leaks from Construction may cause changes to the shallow groundwater quality.	EX Groundwater Quality
Operation		
Operation of the ISR wellfield Operation and expansion of freeze walls Landfills, ponds, waste management, contaminated waste storage, septic fields Surface storage and disposal of waste rock and plant precipitates.	Operation of the ISR wellfield may result in subsidence of the ground surface in the area of the well field, associated with extraction of rock mass (ore) at significant depth (approximately 400 m) below ground.	EX Terrain Morphology and Stability
	Groundwater withdrawals for water during Operation may cause changes to the groundwater system within the shallow hydrostratigraphic units. Mining and freeze wall operation may physically alter groundwater levels and flows within the shallow hydrostratigraphic units and, to a lesser degree, within the deeper hydrostratigraphic units.	EX Groundwater Quantity
	Mining may affect shallow groundwater quality in the wellfield area and deep groundwater quality within the LSA. This would include issues with potential excursions or migration of mining fluids and uranium-bearing solution through earlier exploration drill holes in the LSA that have been partially plugged to protect surficial aquifers. Spills, leaks, leachate from ponds, and landfills may cause changes to shallow groundwater quality.	EX Groundwater Quality
Decommission and Post-Decommissioning		
Landfills, ponds, waste management, contaminated waste storage Mining area remediation and thawing of freeze wall Environmental monitoring	Groundwater withdrawal(s) for water for Decommissioning may cause changes to the groundwater system within the shallow hydrostratigraphic units.	EX Groundwater Quantity
	Most surface facilities are to be decommissioned and materials removed from the Project Area (Section 2). Spills, leaks, and leachate from the industrial landfill and the Industrial Wastewater Treatment Plant precipitate pond may cause changes to shallow groundwater quality. Remediation of the mining area and migration of dissolved COPC concentrations in remediated groundwater during Decommissioning and Post-Decommissioning, respectively, may affect shallow and deep groundwater quality.	EX Groundwater Quality

Project Activity	Potential Effect within the Local Study Area	Project Interactions[1]
Future Centuries		
A period following Post-Decommissioning that is unique and applied only to the Groundwater VC. This temporal scope subtends the period over which the highest concentrations of COPC dissolved in groundwater are predicted to interact with the Surface Water Quality VC.	Long-term potential (i.e., hundreds to thousands of years) for COPCs dissolved in remediated groundwater to migrate along the natural groundwater flow path from the mining area, which is predicted to be eastward within the deeper groundwater units and then upward through the Desilicified Zone toward Whitefish Lake. The potential effect is migration of COPCs dissolved in groundwater from the mining area to proximal surface waterbodies.	P Surface Water Quality VC

1 P = Primary Interaction; EX = 'Other' Expected Interaction.

7.4.2.1 Potential Effect #1: Groundwater Quantity – Construction to Decommissioning (General Activities)

Construction of surface facilities, site preparation, site operations, and Project-related water demands over the life of the Project have the potential to physically alter groundwater levels and flow within the shallow hydrostratigraphic units. A detailed study was completed to evaluate baseline groundwater flow to local surface water receptors (e.g., Whitefish Lake) using a robust dataset of available hydrology and hydrogeology information for the Project and the predictive numerical groundwater model (Appendix 7-C).

The KI for this assessment was groundwater flow and discharge to Whitefish Lake, the most susceptible local receptor. The MP for this assessment was baseflow to surface waterbodies (L/s). The potential effect on groundwater levels and baseflow to local surface water receptors was completed using the calibrated numerical groundwater model and the water demands calculated for all phases of the Project.

<u>Baseline Pre-mining Groundwater Baseflow and Water Balance</u>

The calibrated groundwater model (Appendix 7-C) was used to evaluate the regional groundwater budget (Table 7.4-4). The groundwater budget is presented for steady-state, pre-mining conditions and, as such, represents what is expected to occur within a typical year.

Most of the inflow is simulated in the model to occur as groundwater recharge, which is supplied through annual precipitation (i.e., infiltration of rainfall, runoff, and snowmelt). Additional inflow is provided via some of the natural ponds within the LSA (e.g., near GWR-025 and further west toward the Gryphon deposit) and from deep regional groundwater flow within the Lower Sandstone Aquifer, which enters the model near Kratchkowsky (north) and Williams (west) lakes. Deep regional groundwater flow is estimated to be a relatively minor part of the groundwater flow budget, as deep inflows account for less than 1% of the total inflow into the LSA. Similarly, deep regional outflow south toward Russell Lake is estimated to be negligible (0.2%).

Most water leaving in the model is simulated to exit as groundwater discharge (seepage) to surface waterbodies. Such groundwater discharge supports stream baseflow in otherwise dry conditions. Most groundwater discharge occurs to the lakes; the distribution of discharge to the various lakes is presented in Table 7.4-5. Whitefish Lake is simulated to receive 55% of the groundwater flowing through the model domain, with smaller amounts discharging to lakes in the southeast (McGowan Lake and LA-2) and southwest (LB2 and the river between Williams Lake and LB-2). Katchkowsky and Williams lakes receive relatively small amounts of the groundwater recharged within the model domain.

Table 7.4-4: Regional Water Budget (Average Annual Rates)

Element	Water In (m^3/d)	Water Out (m^3/d)	Comment
Groundwater Recharge from Precipitation	6,365		Inflow at Ground Surface
Interaction with Lakes	510	6,903	Inflow/Outflow at Ground Surface
North Inflow	22		Lateral Inflow to Lower Sandstone Aquifer
South Outflow		15	Lateral Outflow from Lower Sandstone Aquifer toward Russell Lake
West Inflow	21		Lateral Inflow to Lower Sandstone Aquifer
Sum	6,918	6,918	

Table 7.4-5: Groundwater Discharge to Surface Waterbodies

Element	Water In (m^3/d)	Water Out (m^3/d)	Percentage (%) of Groundwater Recharge that Discharges to Surface Features in the LSA
Whitefish Lake		3,517	55%
McGowan Lake and LA-2		1,938	30%
Kratchkowsky Lake and Williams Lake		445	7%
LB-2 and Inflowing River		1,003	16%
Interior Ponds	510		8%
Sum	510	6,903	

As indicated by the regional water budget, most of the groundwater flow through the model domain occurs within the shallow portions of the model domain (i.e., the Overburden and Upper Sandstone Aquifer). Additional sub-domain water budgeting suggests that 99% of groundwater flow occurs through the Upper Sandstone and Overburden deposits, extending from the groundwater recharge areas to discharge areas at the respective lakes and rivers. Similarly, it was calculated that flow from the Lower Sandstone Aquifer, up through the Desilicified Zone, accounts for less than 1% of the groundwater discharge to Whitefish Lake. This suggests that any deep groundwater discharge from the vicinity of the ore zone will be a small proportion of the groundwater received within Whitefish Lake.

Groundwater discharge to Whitefish Lake is estimated to be 40 L/s (3,456 m^3/d or 0.04 m^3/s), which is a small component (approximately 3%) of the average surface flow through the lake (average of 1.4 m^3/s). The component of groundwater discharge from the Lower Sandstone Aquifer is 1% of the total groundwater discharge, or 0.03% of the total flow through Whitefish Lake. At low flow conditions (7Q10; provided in Appendix 8-B in Section 8 [2011–2019 Baseline Hydrology Summary Report – Wheeler River Project, Denison Mines]), the estimated surface flow through Whitefish Lake is 0.81 m^3/s, indicating that the portion of deep groundwater discharge could reach a maximum level of 0.05% ($4x10^{-4}$ m^3/s) of the flow through Whitefish Lake.

Evaluation of Groundwater Conditions During Mine Operations

An overview of the site water balances during Construction, Operation, and Decommissioning is provided in Table 7.4-6, as referenced in Section 2. This table provides a summary of the water needs for certain Project activities, planned water treatment (both potable and wastewater), and the general flow of managed water at the site.

Table 7.4-6: Site Water Balance

Category	Source/Destination	Phase			EIS Bounding Scenario
		Construction (Year 1 to 3)	Operation (Year 3 to 18)	Decommissioning (Year 18 to 23)	
Water Taking	Groundwater Source	20 m^3/hr	31.3 m^3/hr	35.5 m^3/hr	40.5 m^3/hr
	Surface Water Feature(s)	20 m^3/hr	31.3 m^3/hr	35.5 m^3/hr	40.5 m^3/hr
	Onsite Runoff Collection	1 m^3/hr	1 m^3/hr	1 m^3/hr	n/a
	Onsite Storage Facility	10,000 m^3	252,763 m^3	252,763 m^3	n/a
Water Discharge	Underground Water Discharge	0	0	0	
	Surface Water Feature(s)	6.5 m^3/hr	36.5 m^3/hr	36.5 m^3/hr	81 m^3/hr
	Onsite Storage Facility	10,000 m^3	252,763 m^3	252,763 m^3	n/a

Designed mining operations include the use of groundwater for several purposes, including to supply domestic water use within the camp and make-up water to the ISR plant, and to support the wash bay and drilling activities. Numerical modelling was applied to evaluate changes in groundwater flow conditions during Operation. Pumping demand in the model was estimated to be the following:

- 20 m^3/hr (5.6 L/s) during Construction (Year 1 to 3) to support drilling activities and development of the freeze wall;
- 31.3 m^3/hr (8.7 L/s) during Operation (Year 3 to 18); and
- 35.5 m^3/hr (9.9 L/s) during Decommissioning.

Other changes to groundwater flow conditions were incorporated into the model. Recharge is anticipated to be reduced (estimated at 50%) within the freeze wall area but enhanced over the footprint/area of the borrow pit (20%). Groundwater inflow from the septic effluent pond is estimated at 2.5 m^3/hr (0.7 L/s). The reduced hydraulic conductivity associated with the planned vertical freeze walls was incorporated within the groundwater model simulations.

The pumping demand and changes to recharge were incorporated into a transient simulation performed using the calibrated groundwater flow model. The model simulation was started 10 years prior to mining, such that changes due to mining were introduced mid-simulation. The simulation was continued for more than 50 years to include the entire period of ISR mining and subsequent flushing of the ore zone.

Figure 7.4-1 illustrates the predicted change in groundwater level elevations due to planned groundwater pumping. Pumping is planned from three wells located outside of but proximal to the ISR wellfield and installed in the Upper Sandstone Aquifer (Well A, Well B, and Well C). The expected drawdown ranges from a maximum value of 9 m for Well B (reached during Decommissioning when pumping rates are highest) to a minimum value of 2.4 m for Well C (reached during Decommissioning). The predicted drawdown is proportional to the estimated local hydraulic conductivity. Pumping ceases during Post-Decommissioning and groundwater levels are predicted to return to baseline (pre-mining) levels approximately nine years later (i.e., at year 34 of the life of the Project; Figure 7.4-1).

Figure 7.4-2 illustrates the predicted changes to average streamflow through Whitefish Lake over the life of the Project. Groundwater discharge to Whitefish Lake is predicted to be reduced by as much as 25% (from 41 to 31 L/s) during Decommissioning. During Construction and Operation, groundwater discharge is predicted to be reduced to a lesser extent (approximately 10% during Construction; up to approximately 17% during Operation). Groundwater discharge to Whitefish Lake is predicted to begin to recover to baseline (pre-mining) conditions during the early years of Post-Decommissioning when pumping has ceased. Recovery of groundwater discharge to Whitefish Lake is predicted to reach 90% four years into Post-Decommissioning. Full recovery of groundwater discharge to Whitefish Lake (to pre-mining levels) is asymptotically approached and predicted to be achieved nine years into Post-Decommissioning (i.e., at year 23 of the life of the Project). However, because groundwater discharge to Whitefish Lake is a small component of the flow through the lake (average flow estimated as 1.41 m^3/s or 1,410 L/s), the change in water quantity within Whitefish Lake during all Project phases is predicted to be negligible and too small to measure.

Consequently, the potential effect on water quantity in Whitefish Lake is expected to be of low magnitude over a moderate length of time. This outcome is considered likely as Project water use is small relative to surface flow through Whitefish Lake, which has been measured over the years of streamflow monitoring (2011 to 2019; Appendix 8-B in Section 8).

The water demand and water balance evaluations, along with standard mitigation measures (Section 7.5), suggest that the potential effect on water quantity at surface water discharge zones (e.g., Whitefish Lake) is expected to be negligible. Therefore, this potential effect is not expected to be a primary contributor to potential residual effects following the application of proposed mitigation measures (Section 7.5).

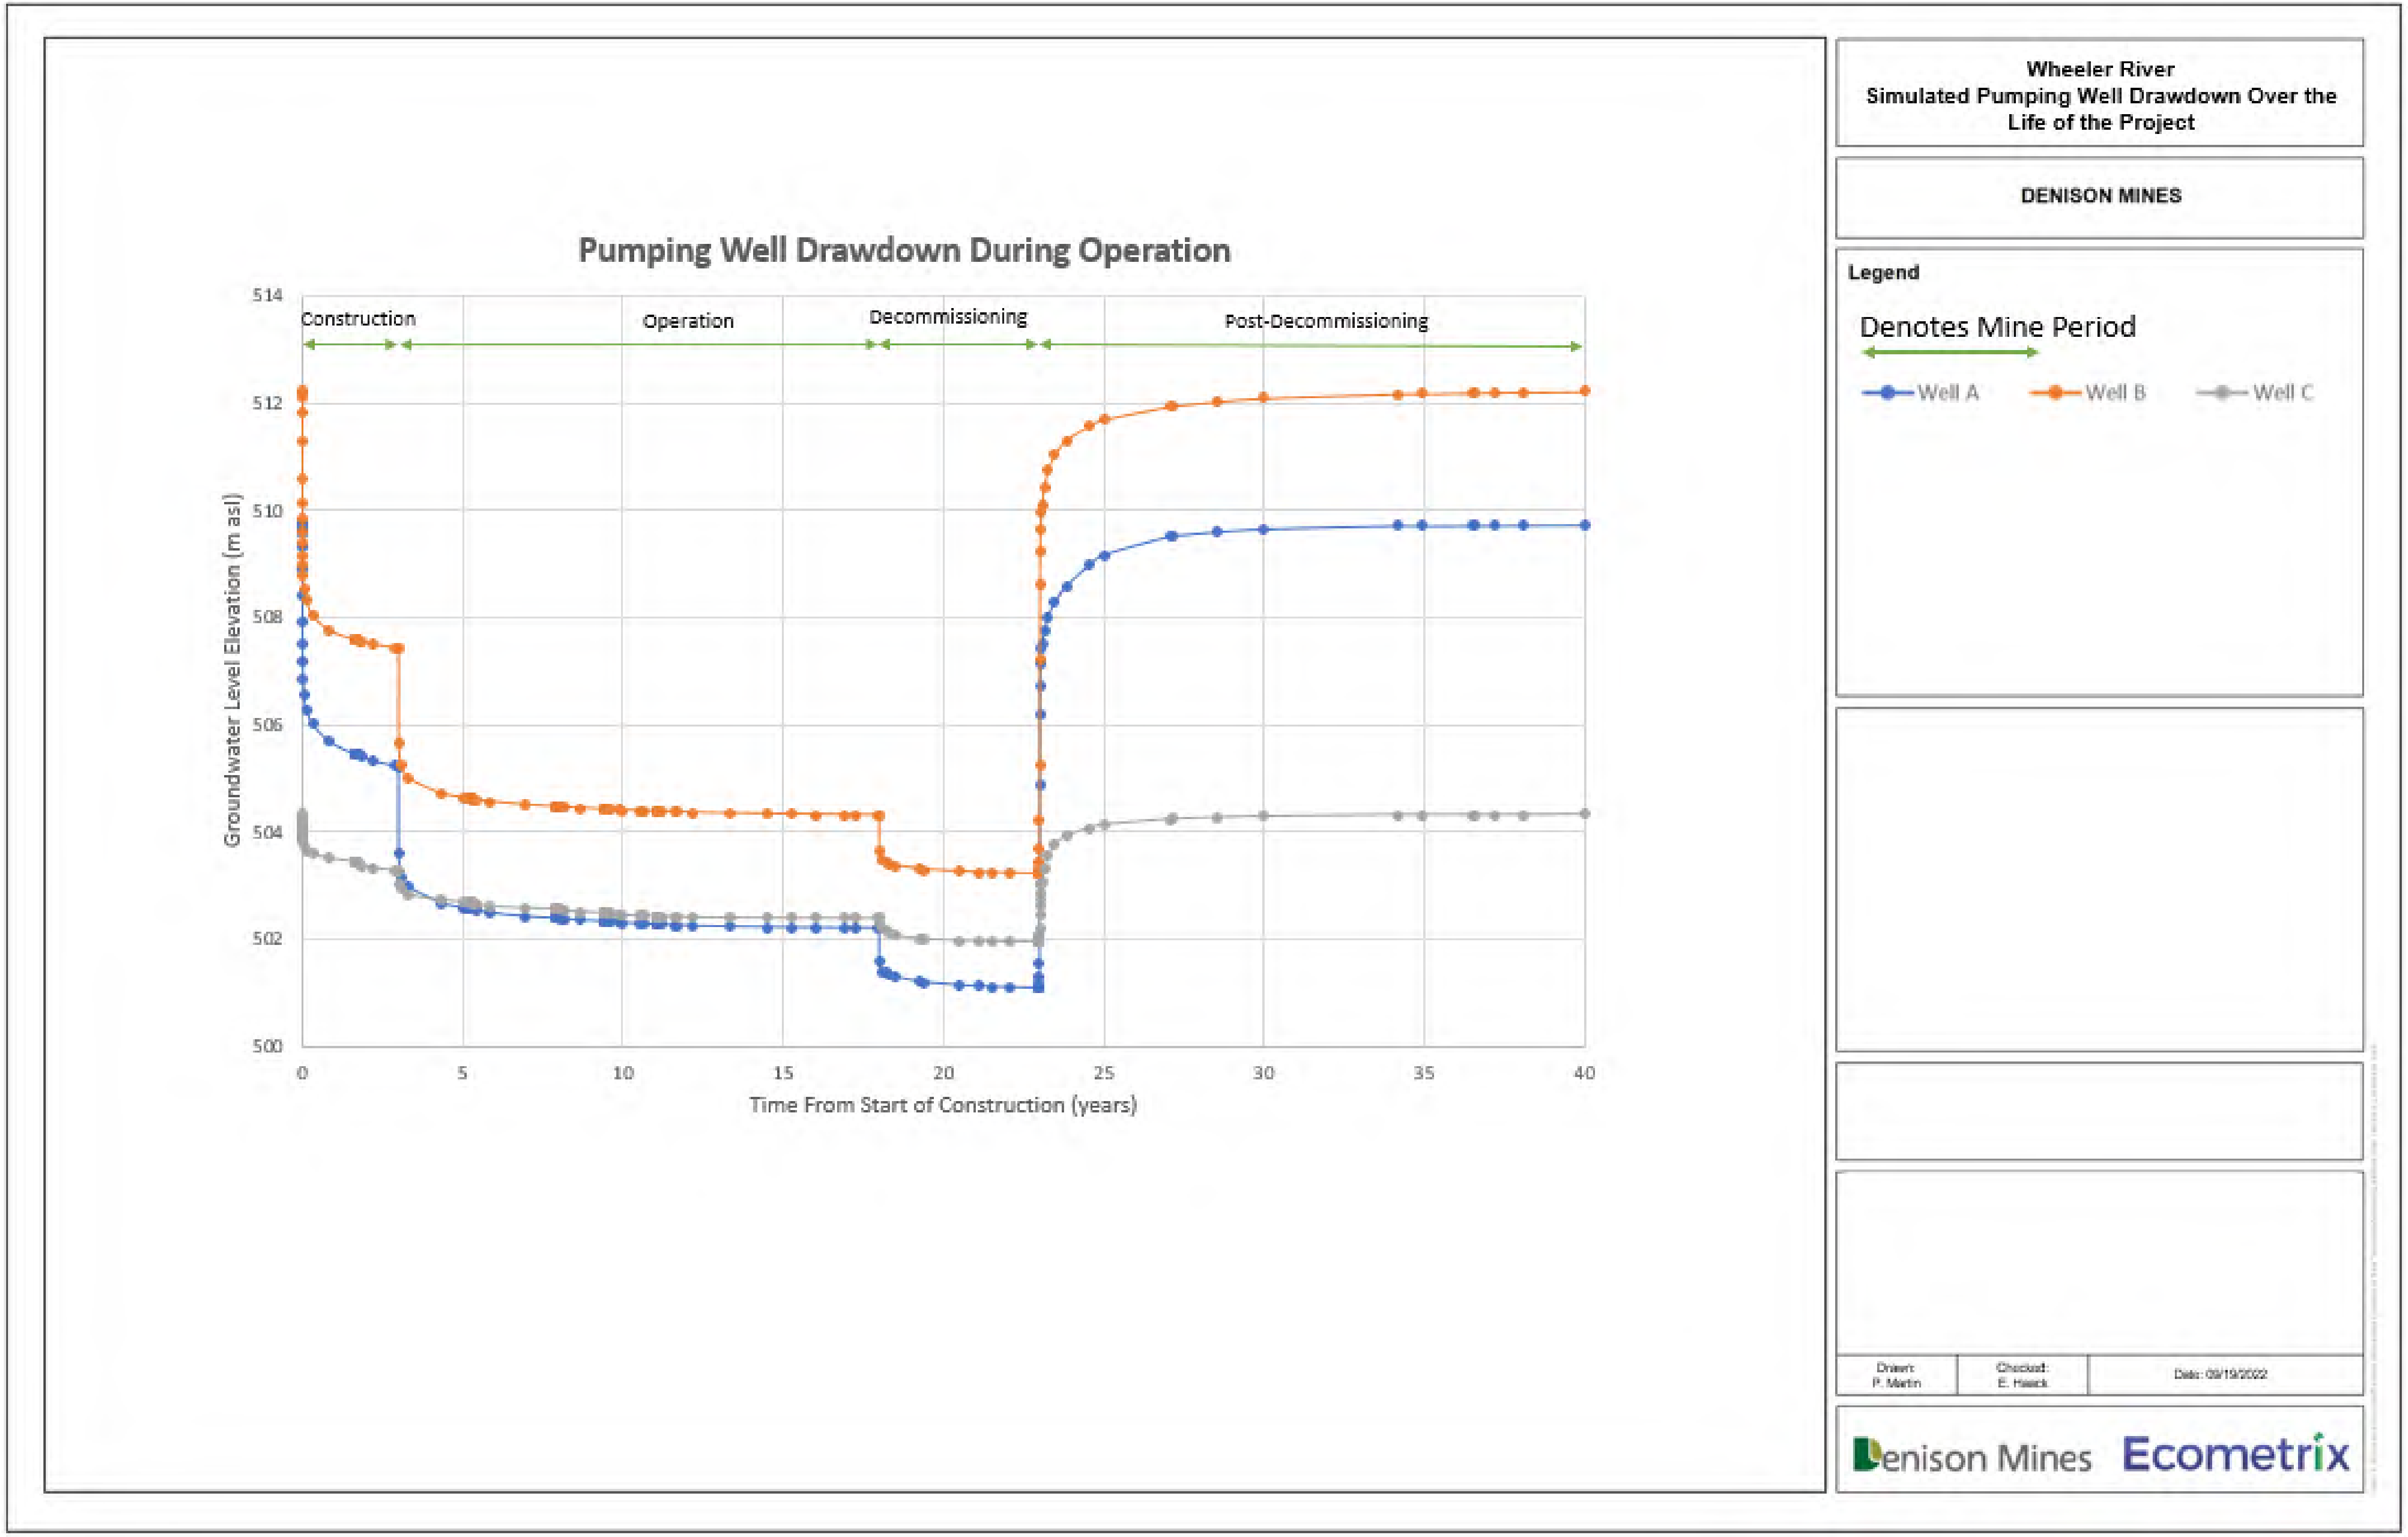

Figure 7.4-1: Simulated Pumping Well Drawdown Over the Life of the Project

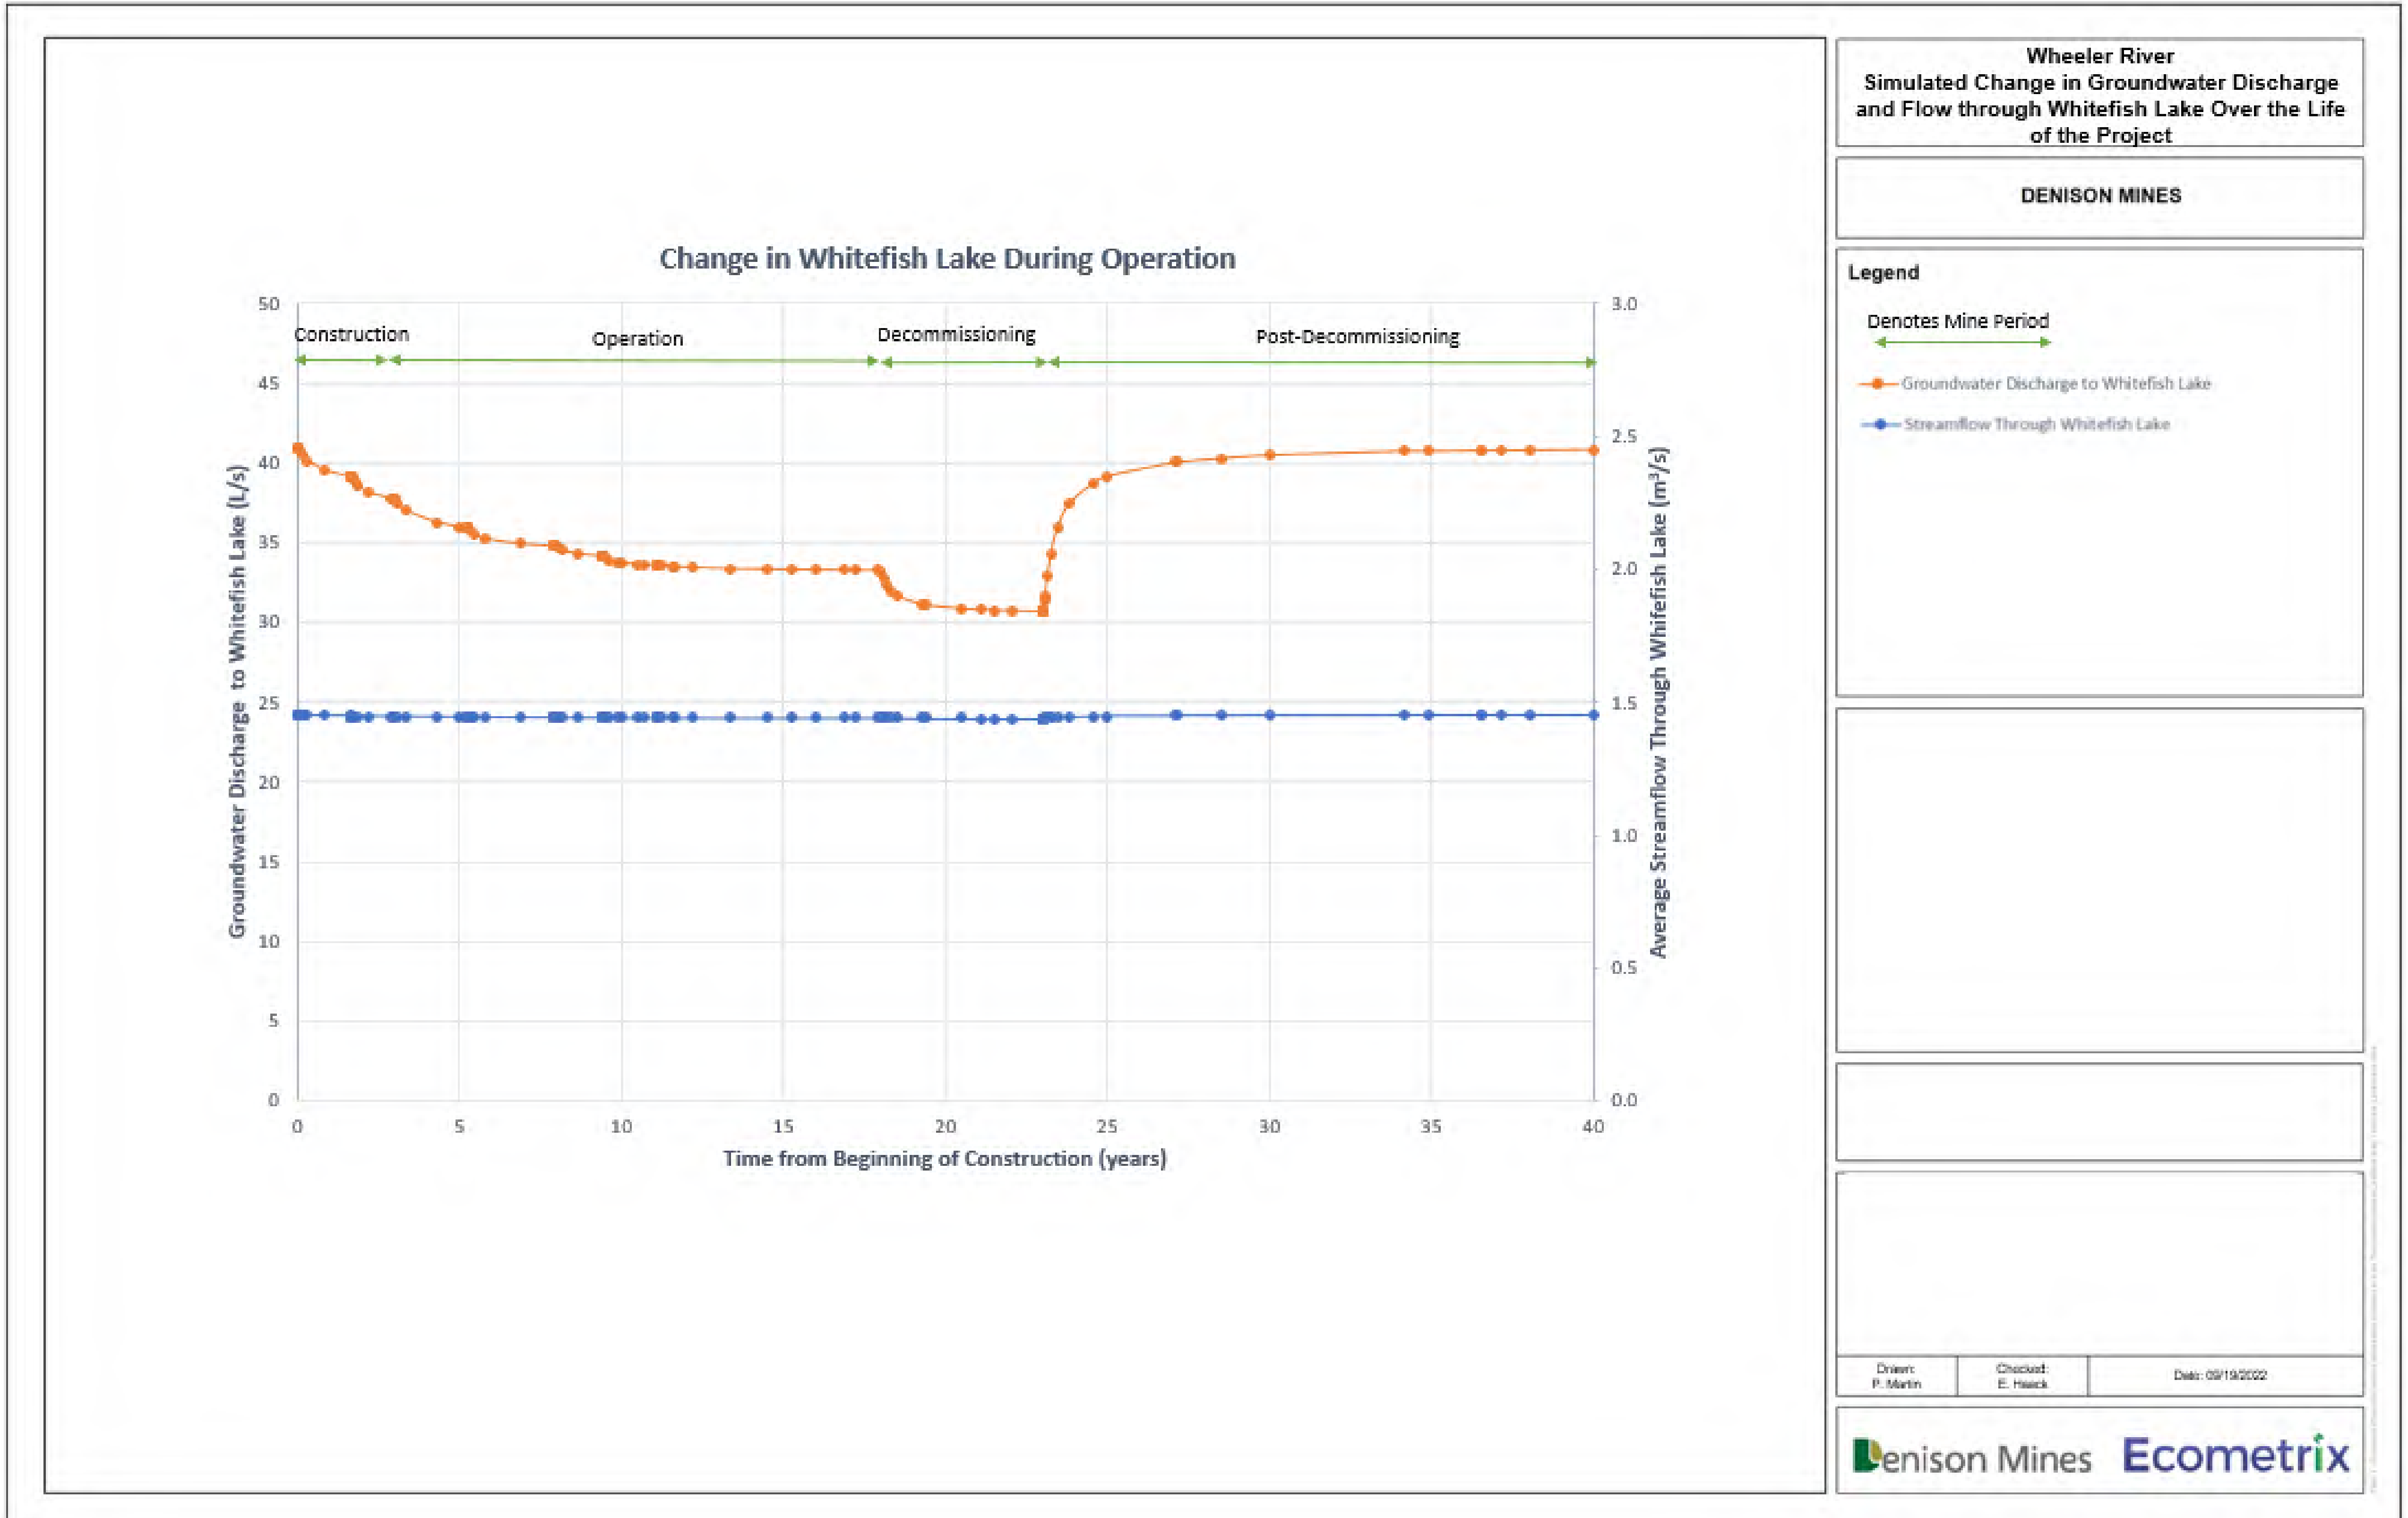

Figure 7.4-2: Simulated Change in Groundwater Discharge and Flow through Whitefish Lake Over the Life of the Project

7.4.2.2 Potential Effect #2: Terrain Morphology and Stability – Operation

One component of the geologic assessment focused on subsidence at ground surface associated with extraction of rock mass (ore) at significant depth (approximately 400 m) below ground, from within the active mining area. Geological conditions in terms of rock and mineral composition stratigraphy (i.e., how geological materials are arranged in sequence with depth/spatially) and structural components (i.e., faulting and fracturing) are well understood based on Project-specific and regional information (Section 7.3 and Appendix 7-A).

Maintaining the stability of the rock matrix while leaching rock (ore) mass is critical for protecting the overlying aquifers, preventing substantial surface disturbance, safeguarding casing integrity, and mitigating plug-off of the remaining ore as well as mining extraction efficiently. To aid in advancing the Project, a study was undertaken to evaluate the geomechanical stability of rock mass within the Phoenix deposit, overlying sandstones, and underlying basement rock following ore extraction with ISR and including the presence of the proposed freeze wall. The geomechanical study (RESPEC, 2024) is presented as Appendix K of Appendix 7-A. Specifically, a full-scale 3D model of northeast extent of the ore zone, and specifically the northern half-length of Zone A shown in Figure 7.3-3, was developed to evaluate stress redistribution in the case of failure of remnant rock from rock mass removal. Average material properties were assumed for hydrostratigraphic units in the Pheonix deposit and surrounding rock, including hydrostratigraphic units shown in Figure 7.3-3. In the numerical model, instantaneous and random rock removal representing 30% by volume and 3% by volume for the high-grade ore zone and low-grade ore zone, respectively, was assumed.

Quantified in the model was the competency of the remnant rock based on the predicted stress field and the potential for tensile fracturing of the rock. The modelling results indicated that the highest predicted failure volumes in remnant rock are associated with the ore zone (41%), but that predicted failure volumes decrease substantively to 8-26% in the immediately surrounding clay zones, and are very limited (0.02%) in the overlying sandstones, including within the desilicified zone, and underlying bedrock. In addition, no (0%) failure was predicted within the freeze wall itself. Importantly, associated vertical displacement of host rock into the mined cavity is predicted to be limited to values of no more than 49 cm in the ore zone and decrease to 0-7 cm only 4-5 m from the low-grade ore zone. Overall, predicted failure conditions are limited to 5-8 m of the extent of the low-grade ore zone and there is limited potential instability in the freeze wall.

Subsidence at ground surface from displacement of host rock was predicted to be negligible. The average vertical displacement at ground surface is 2.5 mm.

The assessment evaluated what is considered the 'worst-case' scenario from a stability perspective. The model evaluated post-extraction stability as a single mass loss event across the entire active mining area. In reality, the mining area will be mined in phases and the phased approach is anticipated to lessen potential effect(s) on geological stability. In alignment with the modelling approach, the potential Project-related effect of subsidence was assumed to occur, essentially instantaneously, upon termination of mining (i.e., at the end of Operation). The modelling work is considered to provide a worst-case bounding scenario: if subsidence were to occur during the Project phases or in the years following mining, the extent of vertical displacement is not expected to exceed that predicted in the modelling.

The potential for subsidence related to changes in fluid balance within the freeze wall during Operation was also considered. The freeze wall will provide hydraulic containment between the internal wellfield and the external regional groundwater system with each well pattern maintaining a 1.7% 'bleed' to maintain hydraulic gradients towards recovery wells. This results in an isolated hydrogeological environment within the freeze wall, separate from the regional groundwater system but considered an unconfined aquifer within the freeze wall, being open to atmosphere. The "extra" water pumped (i.e., the water pumped in excess of injection) will be derived from stored groundwater within the sandstone units above the ore zone, and from the underlying paleoweathered zone, within each phase of Operation that is surrounded by freeze walls. The volume of stored water was estimated using the calibrated groundwater flow model (Appendix 7-C), which contains 3D volumes for the saturated soil and rock within each of the walled phases, including appropriate porosity values. These volumes of stored water were compared to the volume pumped within each phase of operation, over the expected period of extraction based on the mining plan. The stored volume of water was calculated to be 3.4 (Phase 1) to 9.7 (Phase 4) times the estimated excess pumped volume. In other words, there is ample stored water within each walled phase to supply the excess pumped volume. The excess pumping creates a hydraulic gradient toward the ore zone within each walled phase, which will help to avoid vertical spreading of the UBS during operations. If monitoring during operations indicates water levels are falling quicker than anticipated, additional water could be added within the walled phase, within the Upper Sandstone Aquifer.

Given the above, a fluid balance (or flow rate balance) was conducted as part of wellfield planning to inform Feasibility Study production rates within the mining zone contained within the confines of the freeze wall. Freeze studies concluded a no flow boundary once closure of the freeze wall is established along the perimeter of the mining area. Additional modelling within the mining area, including groundwater (FEFLOW) and production (Goldsim) modelling, were applied and although a net increase in volume is anticipated over the life of mine, a net draw is maintained on a well pattern basis to maintain 'bleed' and inward hydraulic gradient during active mining operations. To maintain fluid balance and not draw down the water table in the overlying sandstone units, additional sources of water from groundwater wells outside the freeze wall will be injected inside of the freeze wall as part of normal drilling operations during wellfield development and will be accounted for in the balance. This ensures potential for subsidence related to water table drawdown in the upper sandstone units is mitigated. Operating parameters rely on a relative net water balance for successful operations and would not support a significant drawdown of the water table owing to ground subsidence concern.

Beyond subsidence, changes in hydraulic conductivity localized to the mining area and anticipated to be associated with ISR mining were incorporated as part of the assessment of potential effects on groundwater quantity and quality (Section 7.6.2.2.3).

Monitoring will be undertaken to evaluate any vertical displacement at ground surface and the monitoring program will include a contingency plan, as described in Section 7.8.1. Therefore, this potential effect is not expected to be a primary contributor to potential residual effects following application of the proposed mitigation measures.

7.4.2.3 Potential Effect #3: Groundwater Quality – Construction (General Activities)

During Construction, refuelling and general fuel handling will be required as part of routine site operations. Spills or leaks from these activities may cause changes to shallow groundwater quality in discrete and localized areas. Figure 2.2-1 in Section 2 shows the Project layout with the location of the fuel storage and general fuel handling areas delineated. As provided, the potential source areas are located within a discrete and defined area of the site.

Specific Project designs, best practices, and standard mitigation measures (Section 7.5) will be employed to eliminate, reduce, or control such activities during Operation. As such, this potential effect is not expected to be a primary contributor to potential residual effects following application of proposed mitigation measures.

7.4.2.4 Potential Effect #4: Groundwater Quality – Operation (In Situ Recovery Mining and Surface Facilities)

Routine operation of ISR mining may affect shallow and deep groundwater quality within the Project Area and LSA. Groundwater quality within the mining area is expected to change because of direct contact with the mining solution during Operation.

Mining solution and uranium-bearing solution may enter groundwater outside of the mining area and freeze wall via accidents or malfunctions. Examples of accidents and malfunctions include well damage and release outside of the mining chamber and adverse effect(s) to groundwater from the surface via spills at the pumphouses or leaks along the pipelines (Section 14 Accidents and Malfunctions).

Shallow groundwater quality may be changed via accidents and malfunctions related to spills or leaks from waste pads and ponds, spills of hazardous substances (e.g., reagents and fuels), leaks from water treatment plant ponds, and leaching from the landfill (accidents and malfunctions are considered in Section 14). Figure 2.2-1 in Section 2 shows the Project layout with the location of the ponds, pads, and landfills, along with general construction details (e.g., double lining system with leak detection and collection), delineated. Details regarding the functions of the surface facilities, including their sizes and liner systems, are provided in Section 2. A summary is also provided in Table 7.4-7.

Within the broader context of terrain stability, it is noted that natural seismic activity in Northern Saskatchewan is quite rare with no significant events in recorded history (refer to Section 15.2 Seismic Events).

Mining induced seismicity has been of interest for some time, with mining-induced seismicity reported in Canadian hard-rock mines since the 1920s (Hudyma et al, 2017) and the first formal Canadian research on the problem starting in the 1930s (Hedley, 1992). Hasegawa et al. (1989) and Ortlepp (1992) describe several mechanisms by which induced seismicity may be capable of occurring in relation to underground (excavation based) mining; though, those mechanisms generally relate to discrete, large-scale rockmass failures whereas more than 90% of seismic events can be categorized as micro seismic events with moment magnitude < 0 (Hudyma, 2008).

In Saskatchewan, investigations of inducted seismic have been completed in association with potash mining and uranium operations. Sedghizadeh et al. (2023) applied statistical methods to investigate the nature of micro seismicity in a potash mine. Clustering analysis of micro seismicity indicated that the majority of events could be treated as independent background events mostly driven by underground mining operations; however, there is some clustering of seismicity and the formation of limited aftershock sequences of the “burst-type” (i.e., those that have only one parent event and many children). For example, with respect to uranium mining (Barghwal and van der Baan) investigated the source mechanisms and possible causes of micro seismicity recorded in an underground Uranium mine for a period of one month in January 2011. The events occurred near the main working level at 480 m depth and show some temporal correlation with the daily rate of rock removal. The study concluded the observed micro seismicity occurred due to reactivation of pre-existing faults that were favourably oriented in the static stress state created by the extensive horizontal tunnel network and due to dynamic stress due to rock crushing activities.

Despite the above noted link between seismicity and conventional hard-rock mining techniques / operations, as well as compared to high pressure liquid injection processes, the potential for mining-induced seismicity from the nature of the ISR mining that is proposed by the Project is interpreted as being quite low, given that the mechanisms that are purported to create or induce seismicity will not occur. Nevertheless, potential for mining-induced events for the Project that could be postulated to occur as the result of a few sources are discussed below for completeness: 1) collapse of cavity voids from leaching, 2) hydraulic fracturing, and 3) use of permeability enhancement techniques.

1. Collapse of cavity voids. To clarify, the portion of the deposit being mined is never truly a void (as in a large empty underground cavern); rather, what remains will be a honeycomb textured environment with water filled interstices. The mined area is filled with a fluid at all times, whether it be a mining solution, groundwater, or the neutralizing solution. This is different from a more traditional underground operation such as Cigar Lake where there is physical excavation of the orebody, leaving a temporary air-filled space. Although the uranium ore is high-grade by global standards it is not entirely massive in nature. As such, the uranium will be leached in a 'honeycomb' texture leaving behind a structure of partial intact rock mass with the remaining area being filled by fluid. This retains the pressure balance of the mining zone with the adjacent water-saturated rock masses. In terms of void

space creation and collapse of the overlying strata, modelling has demonstrated that only 0.05% by volume of desilicified material immediately overlies the ore zone and would be subject to collapse (Appendix 7-C, Attachment K). This low volume and percentage are determined to not be of significant seismic concern.

2. Hydraulic fracturing. EIS Section 2.2.1.4.2 Wellfield Operation provides a comparison of ISR mining pressures to conventional fracking pressures used in the oil and gas industry. Conventional fracking pressures used in the oil and gas industry can vary; however, common pressures to induce fracturing can range up to 15,000 psi and require injection of fracking fluids of up to 16,000 liter per minute over periods of three to four days. Fracking fluids are comprised of a slurry of water, proppant (generally silica sand), and chemical additives to support and maintain the open fracture system after fracking is conducted. Conversely, ISR mining for the Project is planned at nominal pressures of 100 psi, intermittent pressures of up 250 psi, and average flow rates of 30 liters per minute within a recovery well. The ISR mining method proposed for the Project is markedly different than fracking. For example, looking at intermittent pressures alone, ISR pressures are anticipated to be 60 times lower than fracking pressures.

3. Permeability enhancement techniques. EIS Section 2.2.1.4.3 Permeability Enhancement outlines the three types of techniques being considered for the Project: mechanical, Propellant, and hydraulic options. Propellants are classified as a low hazard explosive (S.1 special-purpose explosives, low hazard explosives, per Explosive Regulations, section 36). Propellants technically do not explode (like classic mine explosives which detonate) but rather burn through a process called deflagration. Deflagration means the material burns slower than the speed of sound, thus no shock waves are generated. Propellant permeability enhancement methods reach injection pressures of up to 8,000 psi and are near instantaneous over periods of milli seconds. Neither ISR mining or permeability enhancement is expected to produce mining-induced seismicity.

Under normal operating conditions there is no expected mining-induced seismicity. See also Bounding Scenario 4 Failure of the Freeze Wall in Section 14.

Specific Project designs, best practices, and standard mitigative measures, such as liners and pumping to control fluid movement (outlined in Table 7.4-7 and Section 7.5), will be employed to eliminate, reduce, or control potential Project-related effects on shallow groundwater. Potential Project-related effects from ISR mining will be mitigated via operation of the freeze wall and other measures as outlined in Section 7.5. As such, these potential Project-related effects are not expected to be a primary contributor to potential residual effects following application of the proposed mitigation measures.

Table 7.4-7: Surface Facilities that May Contribute Constituents of Potential Concern to Groundwater

Facility #	Structure	Function	Construction
11	Process Water Pond	Captures water from a variety of areas, including the process precipitate storage pad and special waste pad.	Double composite liner systems with leak detection.
12	Wellfield Runoff Pond	Captures runoff from the wellfield and the special waste pad.	Double composite liner systems with leak detection.
13	Clean Waste Rock Pond	May be constructed beside the clean waste rock pad to collect runoff, as required.	Single geomembrane liner with protection.
14	Domestic Wastewater Treatment Plant and Pond	Receives water from the Domestic Wastewater Treatment Plant.	Composite liner system.
16	Effluent Monitoring and Release Ponds, and Treated Effluent Discharge Line	Receives treated water primarily from the Domestic Wastewater Treatment Plant and the Industrial Wastewater Treatment Plant. Option to recycle water from these ponds back into the processing plant via the process water pond. The treated effluent discharge line runs from the effluent monitoring and release ponds into Whitefish Lake.	Composite liner system. Discharge line double walled with heat tracing. Trail along length of discharge line allowing visual inspection.
20	Domestic Waste Landfill with Leachate Collection Pond	Accepts materials, including wood, non-recyclable plastics, broken furniture, textiles, and non-recyclable items from the camp and operations centre.	Composite liner system with leachate collection. Pond is double composite liner system with leak detection.
21	Construction Waste Laydown Area	Located next to the future domestic landfill. Temporary storage of leftover construction materials.	Not lined. Base soil compacted. Bermed to prevent run on and run off.
22	Industrial Waste Landfill with Leachate Collection Pond and Industrial Laydown Area	Accepts industrial wastes generated at site, including waste with chemical and/or low-level (as defined by the Canadian Nuclear Safety Commission) radiological waste contamination.	Double composite liner system with leak detection between the composite liners and a leachate collection system above the primary (or upper) composite liner. Leachate pond has double liner system with leak detection.
23	Hazardous Waste Storage Pad	Denison identified a need to have a small (250 m^2) pad designated for temporary storage of hazardous waste such as paints, solvents, hydrocarbons, and used oil.	Composite liner system.
24	Process Precipitate Pond	Receives radioactive process precipitates.	Double liner system with leak detection capabilities.
25	Industrial Wastewater Treatment Plant Precipitate Pond	Receives non-radioactive industrial wastewater treatment plant precipitates.	Composite liner system.

Facility #	Structure	Function	Construction
26	Special Waste Pad	Expected to contain primarily mineralized core and cuttings from wellfield development.	Double composite liner system with leak detection capabilities.
27	Clean Waste Rock Pad	Receives clean waste rock, generated as sandstone cuttings and core from drilling activities.	Single geomembrane liner with protection.
42	Wash Bay and Scanning facility	Area to clean items, equipment, and vehicles that may have been in contact with potential contaminants.	May have a single geomembrane liner with protection. Perimeter berms and a lined sump for collection.

7.4.2.5 Potential Effect #5: Groundwater Quality – Decommissioning (In Situ Recovery Mining and Surface Facilities)

Groundwater quality in the mining area will be remediated during Decommissioning to meet acceptable levels (Section 2). These acceptable levels are the Decommissioning objectives, also referred to as the remediation targets (Section 2), and are described further in Section 7.6.2.1. The freeze wall functions as tertiary containment and when utilized, will remain in place until it can be demonstrated that groundwater quality in the mining area meets these objectives, after which time thawing of the freeze wall will occur. This will allow the eventual re-establishment of the pre-operational groundwater flow regime in the LSA.

Similar to Potential Effect #4 (Section 7.4.2.4), Decommissioning of the ISR wellfield may affect shallow and deep groundwater quality proximal to the mining area within the LSA. This potential effect is expected to be localized and at a depth associated with groundwater in and proximal to the mining area.

Most surface facilities will be decommissioned and removed during Decommissioning (Section 2). While the facilities remain and during Decommissioning, shallow groundwater quality may be changed by accidents and malfunctions related to leachate leaks from waste pads and ponds, spills of hazardous substances (e.g., reagents and fuels), leaks from water treatment plant ponds, and leaching from the landfill.

The potential Project-related effects during Decommissioning are not expected to be a primary contributor to potential residual effects following application of the mitigation measures outlined in Section 7.5.

7.4.2.6 Potential Effect #6: Groundwater Quality – Post-Decommissioning and Future Centuries

There is the potential for COPCs dissolved in groundwater following the remediation process in the mining area during Decommissioning to migrate in groundwater as part of natural groundwater flow conditions in the subsurface within the LSA. The ‘future centuries’ period has been defined as part of the assessment for the Groundwater VC and includes the period over which groundwater quality downgradient of the mining area, potentially affected by dissolved COPC concentrations, may ultimately discharge to proximal surface water sources. The ‘future centuries’ period has been defined as hundreds to thousands of years, reflecting the relatively low groundwater velocities of the hydrostratigraphic units between the ISR mining area and the receiving environment (Whitefish Lake), and the difference in dissolved COPC behaviour along the groundwater flow path.

A rigorous numerical model was used as a predictive tool for careful evaluation of groundwater flow and spatial temporal behaviour of residual mass of COPCs dissolved in groundwater following thawing of the freeze wall. The model and results are summarized in Section 7.6.2 and presented in Appendix 7-C. The model is founded on proven scientific principles and processes (e.g., groundwater flow, contaminant transport, and geochemical reaction processes) that allowed future conditions to be evaluated.

The results of the numerical model support the conclusion that following implementation of appropriate mitigation during Decommissioning, the potential effect of the Project on the Groundwater VC is not expected to result in a potential residual effect. Dissolved COPC concentrations migrating from the remediated mining area to Whitefish Lake (i.e., the local surface water receptor) are expected to remain below values that would result in an environmental risk (Section 7.6.2).

7.5 Mitigation Measures

Following the identification of potential Project-related effects (Section 7.4), the next step in the evaluation was the development of environmental design features and mitigation measures that could be incorporated into the Project. Mitigation is defined as the elimination, reduction, or control of the potential adverse effects of the Project and may include measures associated with compensation of effects that cannot be mitigated by other means. Environmental design features and mitigation measures were developed through an iterative process between the Project's engineering and environmental teams, supplemented with input from Project-specific or regional engagement with other parties. The environmental design features and mitigation measures were selected considering their effectiveness for implementation and maintenance, and their appropriateness within the context of the identified potential Project-related effects.

Table 7.5-1 provides a summary of the mitigation measures for the Geology and Groundwater VCs related to the six key potential Project-related effects (Section 7.4.2). The mitigation measures refer to Project-specific mitigation and include, but are not limited to, engineering design features and responses, best management practices, management plans, and training.

Table 7.5-1: Summary of the Mitigation Measures Based on Project Phases for the Geology and Groundwater Valued Components

Valued Component	Key Indicators	Measurable Parameters	Project Activities Resulting in Primary Interactions	Project Phase	Mitigation Measures
Geology	Terrain morphology and stability	Vertical displacement (i.e., subsidence at ground surface) (m).	In situ recovery operations affecting subsidence at ground surface associated with consolidation of rock mass (ore) at significant depth (approximately 400 m) below ground.	Operation	Incorporation of specific Project design components and practices, including: • subsidence at ground surface within the wellfield is expected to be on the ~2-3 mm level and is beyond the range of current Lidar technology (with resolution of 10 cm). Injection and recovery wells will be collared at surface and surveyed regularly to monitor for any changes in collar height over time.
Groundwater	Groundwater quantity 1. Groundwater flow patterns and discharge rates to local surface water. 2. Groundwater elevation changes.	Change in shallow and deep groundwater levels measured in monitoring wells (m) and baseflow to surface waterbodies (L/s).	Site preparation, site clearing, and grading. Development of surface infrastructure. Ground freezing. Water supply and surface water releases.	Construction to Decommissioning	Incorporation of specific Project design components and practices, including: • limiting the construction footprint (i.e., Project Area) to the extent possible to reduce the potential for reductions in groundwater recharge and limit the number of watersheds overprinted by the Project Area; • designing the Project to limit water use and enhance water recycling; and • implementing water management best practices to reduce site runoff and recharge to aquifers. In addition, commitment to follow-up on ongoing hydrogeological evaluations, as well as monitoring and adaptive management, including: • groundwater elevations in the groundwater well network; and • water elevations of surface waters within the LSA.
	Groundwater quality Focus on changes to groundwater discharge to local surface waterbodies (i.e., Whitefish Lake).	Changes in concentrations of physical and chemical parameters in groundwater (mg/L or µg/L) compared to appropriate risk-based surface water environmental quality criteria.	Water management. Fuel management and refuelling of equipment and general site construction activities.	Construction	• Incorporate best management practices to avoid effects on groundwater from hazardous substances, including those outlined in Section 2. No fuels, oils, or other hazardous substances will be stored within 100 m of any waterbody and no equipment maintenance or re-fuelling will be conducted within 100 m of a waterbody. • Develop environment management plans, programs, and procedures to provide consistent and responsible practices. • Make sure employee training programs and procedures are in place.
	Groundwater quality Focus on changes to groundwater discharge to local surface waterbodies (i.e., Whitefish Lake).	Changes in concentrations of physical and chemical parameters in groundwater (mg/L or µg/L) compared to appropriate risk-based surface water environmental quality criteria.	In situ recovery operations affecting groundwater, in particular concentrations of COPCs dissolved in groundwater.	Operation	Incorporation of specific Project design components, including: • establishment of the freeze wall before mining operations to hydraulically isolate the mining area from the surrounding groundwater environment; • creation of hydraulic controls that will limit vertical migration to the zone 50 m above the ore zone within the freeze wall; • design injection and recovery wells to have secondary containment; • recognize option to drill additional wells to recover mining solution excursions; • design pipelines to have secondary containment or catchment; • establishment of a leak detection system for wells and pipelines; • implementation of a groundwater monitoring well network within and surrounding the outer perimeter of the freeze wall, and a groundwater monitoring (quantity and quality) plan; • development of contingency plans, including drilling additional wells into any potentially contaminated areas for recovery of the mining solution back to surface; and • development of contingency plans to respond to excursions.

	Groundwater quality
	Focus on changes to groundwater discharge to local surface waterbodies (i.e., Whitefish Lake).
		Changes in concentrations of physical and chemical parameters in groundwater (mg/L or µg/L) compared to appropriate risk-based surface water environmental quality criteria.	Site infrastructure (e.g., landfills and pads) affecting groundwater, in particular concentrations of COPCs dissolved in groundwater.	Operation	Incorporation of Project design components, including:
					• design landfill and pads with geomembrane liner protective systems and double liner systems with leak detection and leachate collection systems appropriate for the materials stored;
					• store hazardous substances in approved storage areas with secondary containment, as required; and
					• implement appropriate monitoring and management plans, including:
					  ○ a groundwater monitoring well network and GWMP for surface facilities;
					  ○ environment, health, and safety management plans, programs, and procedures;
					  ○ waste management plans, programs, and procedures; and
					  ○ employee training programs and procedures.

Valued Component	Key Indicators	Measurable Parameters	Project Activities Resulting in Primary Interactions	Project Phase	Mitigation Measures
	<u>Groundwater quality</u> Focus on changes to groundwater discharge to local surface waterbodies (i.e., Whitefish Lake).	Changes in concentrations of physical and chemical parameters in groundwater (mg/L or µg/L) compared to appropriate risk-based surface water environmental quality criteria.	Migration of COPCs dissolved in groundwater along the groundwater flow path from the mining area to the receiving environment (Whitefish Lake) at concentrations outside of those predicted to not pose an environmental risk through numerical modelling.	Decommissioning	Incorporation of Project design components, including: • mining area remediation during Decommissioning – water will be injected into the mining area via injection wells and then recovered through the recovery wells to flush residual COPC mass in groundwater; • continued groundwater remediation until appropriate levels (i.e., Decommissioning objectives), protective of the environment over the long term (i.e., ‘future centuries’ period), are achieved; • implement groundwater monitoring (quantity and quality) within and exterior to the former freeze wall and along the groundwater flow path to demonstrate that groundwater conditions are aligned with those bounded by the modelling predictions, and, as such, are protective of the receiving environment; and • develop contingency plans, including drilling additional wells into potentially contaminated areas for recovery of the mining solution back to surface.

7.6 Residual Effects Evaluation

7.6.1 Life of Mine (0 to 38 years)

Given the incorporation of mitigation measures outlined in Section 7.5, no residual effects to the Geology and Groundwater VCs were predicted during the life of the Project (i.e., 0 to 38 years). The proposed design features and mitigation measures are considered effective and protective within the context of the identified Project-related effects.

7.6.2 Future Centuries Period

The temporal scope of the assessment for the Groundwater VC included consideration of a 'future centuries' period. The potential for residual effects during this period is a consequence of dissolved-phase COPC mass in groundwater within the mining area following Decommissioning. Residual COPC mass is derived from mobilization of elements/compounds from the (natural) minerals during mining and, in some cases, from chemicals in the mining solution.

Remediation of groundwater during Decommissioning is a mitigation measure. Numerical modelling was used as a tool to establish Decommissioning objectives in terms of concentrations of COPCs in groundwater, such that the Surface Water Quality VC is protected.

7.6.2.1 Decommissioning Objectives

The process of groundwater remediation in the mining area during Decommissioning is described in Section 2. It involves circulation of water (with or without addition of chemical reagents to accelerate groundwater quality recovery) through the mining area until it can be demonstrated that recovered water has reached and been stabilized at groundwater quality Decommissioning objectives.

Metallurgical testing, including column tests and core flooding tests, have been undertaken at the Saskatchewan Research Council to understand the anticipated evolution of groundwater hydrochemistry as groundwater quality in the mineralized zone is restored. Details on the metallurgical testing are provided in Appendix F of Appendix 7-C. The constituents with concentrations that were outside of the range of values observed for baseline conditions in the leachate during metallurgical testing reflect the mineralogy of the ore zone and the mining fluids. The mining fluids are expected to be made up of sulfuric acid, iron sulphate, and hydrogen peroxide (Section 2). Groundwater constituents identified as COPCs associated with mining of the ore zone include:

- pH;
- sulfate and chloride;
- uranium, iron, aluminum, and heavy metals/trace elements (i.e., As, Cd, Co, Cu, Cr, Pb, Mo, Ni, Se, V, and Zn); and

- radionuclides (i.e., 226Ra, 230Th, 210Pb, and 210Po).

Although not a chemical parameter, metallurgical testing has indicated that temperature in the active mining area during Operation is expected to exceed that of ambient groundwater by 10°C or more. Thus, temperature is included as a measurable parameter for groundwater for the Project. Electrical conductivity is included as a measurable parameter but not as a COPC for the Project, as a bulk indicator of water quality. Further, existing redox conditions in the ore zone are strongly reducing. Strongly oxidizing conditions need to be created for oxidation of U(IV) in uraninite to U(VI) and solubilization of uranium. Measurement of oxidation-reduction potential (ORP) is also suggested as a, for the most part, qualitative indicator of groundwater conditions – meaning, not as a COPC but as a measurable parameter with respect to groundwater quality for the Project.

The leachate chemistries used to conceptualize remediated groundwater quality for input into the reactive transport model were primarily from two coreflood tests: Coreflood#2B and Coreflood#3C. In the coreflood tests, core flushing was done using groundwater and amended with sodium hydroxide (1.5 g/L; Coreflood #2B) or bicarbonate (150 to 1,500 mg/L $NaHCO_3$; Coreflood #3C). 'Restored Solution #1' and 'Restored Solution #2' were developed to represent the bounding scenarios for groundwater quality evaluated in the reactive transport model, to assess the potential for environmental effects following remediation of the ore zone. Details on the development of the chemistry of the restored solutions from the metallurgical testing is provided in Appendix F of Appendix 7-C. The hydrochemistry of Restored Solution #1, which has a lower pH and generally higher COPC concentrations, is provided in Table 2.3-3 of Section 2 and was largely the focus of numerical modelling in support of the EIS (Appendix 7-C). The hydrochemistry of Restored Solution #2 is provided in Appendix 7-C.

As introduced in Section 7.4.2, the mining area is made up on three different zones, including the active mining area, the anticipated maximum extent of upward migration of mining fluids (11 to 13 m above the active mining area), and potential upset conditions (50 m above the active mining area). Within the 3D reactive transport model, the mining area was conceptualized as two zones in terms of water quality following remediation. These two zones are shown in Figure 7.6-1. Both zones are limited laterally by the freeze wall. The first zone was assumed to have water quality equivalent to Restored Solutions #1 or #2 and extends from the base of the paleoweathered zone through to the anticipated maximum extent of upward migration of the mining fluids. This maximum upward extent was conservatively assumed to be 15 m overlying the active mining area, compared to the 11 to 13 m that is expected. Solution #1 (pH 4.3) has a lower pH and, generally, higher COPC concentrations compared to Solution #2 (pH 6.1); as such, it is considered to potentially pose a higher risk to the receiving environment and was the focus of 3D reactive modelling.

A second zone, extending between 15 and 50 m above the active mining area was defined as having water quality equivalent to mixing of Restored Solutions #1 or #2 by 50% with groundwater of baseline quality. For the Project, as with other ISR projects, it is anticipated that there will be a certain degree of outward migration (horizontal and vertical) of the oxidizing solution beyond the boundary of the wells/production area. This was recognized in identifying the potential upset conditions as 50 m above the ore zone (Section 7.4.2). Outward migration of fluids from the active mining area is a result of normal hydrodynamic behaviour, and the area affected outside of the ISR injection and recovery well pattern is often referred to as the 'flare' (IAEA 2001). Inclusion of the 'flare' in predictive numerical modelling has precedence in ISR projects, related both to ISR performance (e.g., Cameco 2012b) and the fate and transport modelling downgradient of the ore zone (e.g., Johnson et al. 2016).

It has been concluded through 3D reactive transport (Appendix 7-C) and environmental risk assessment (Appendix 10-A in Section 10) that water quality that achieves concentrations for COPCs equivalent to that of Restored Solution #1 does not pose an environmental risk (Section 7.6.2.2.4) and Section 10.1.4.2.3 in Section 10). Decommissioning objectives (Section 2.3.3.1.1 in Section 2) have thus been proposed as water quality achieving that of Restored Solution #1.

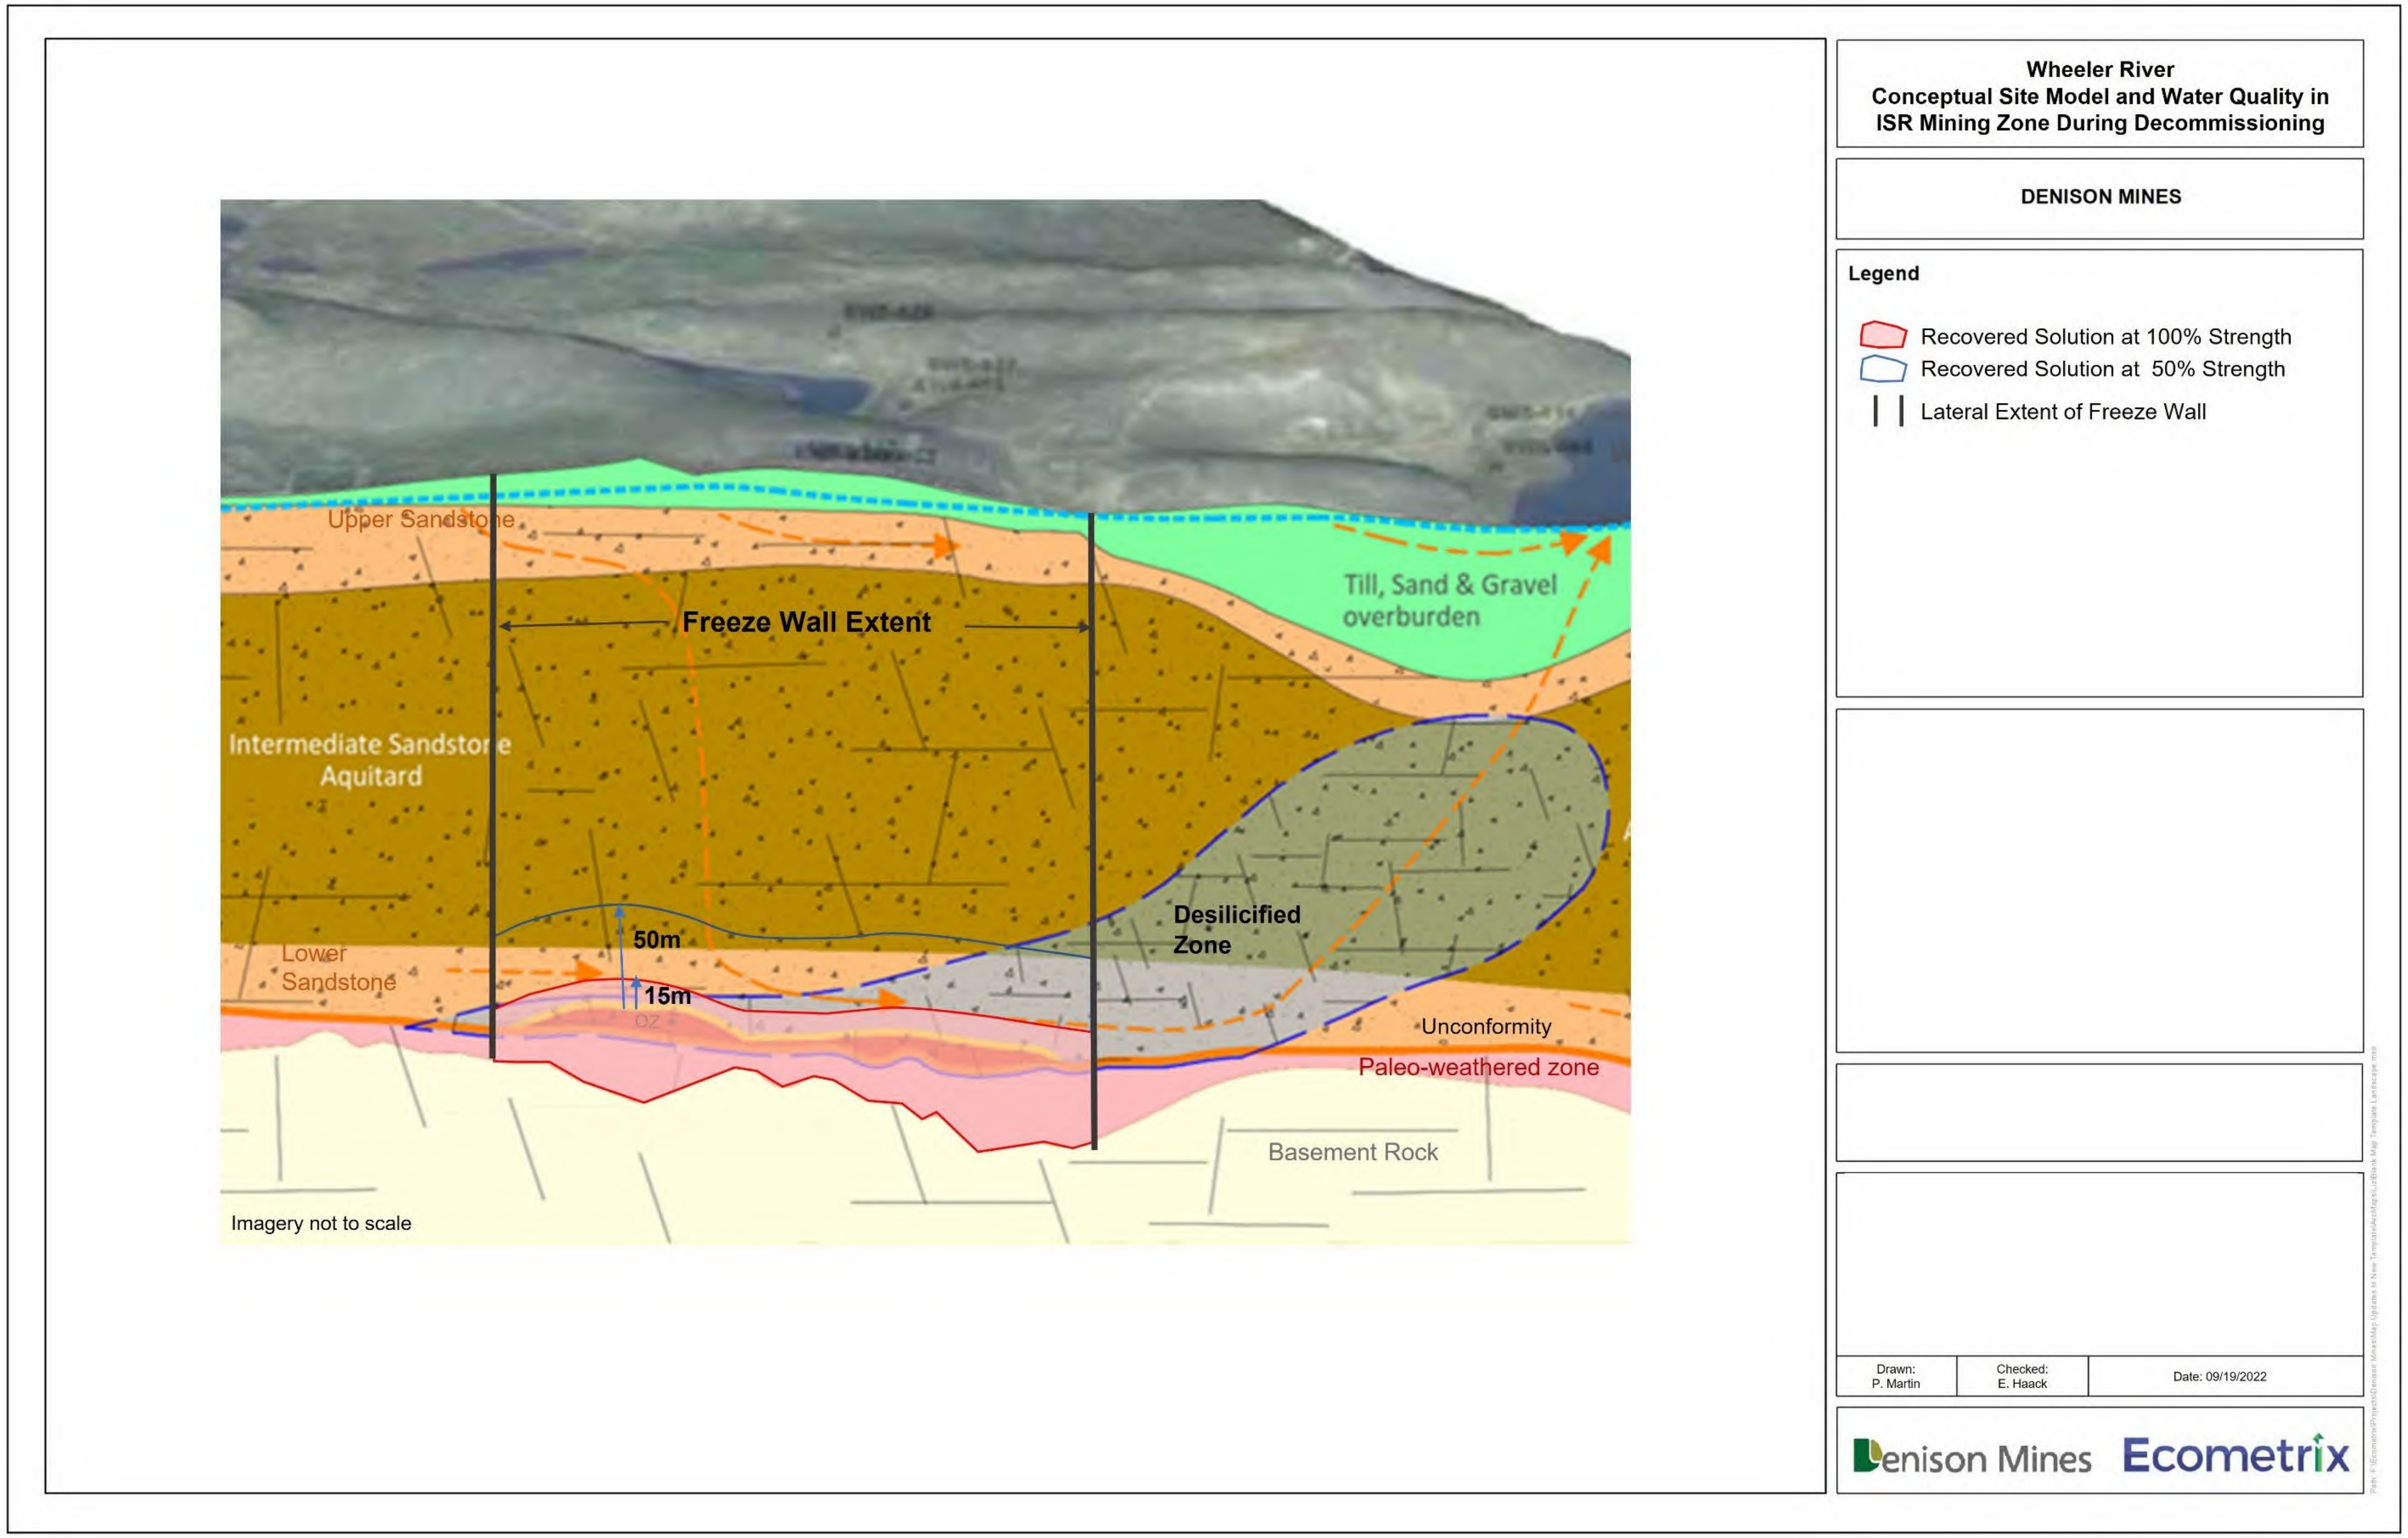

Figure 7.6-1: Conceptual Site Model and Water Quality in the In Situ Recovery Mining Area During Decommissioning

7.6.2.2 Numerical Model

A report has been prepared providing the details of the numerical modelling used to support the EA and the development of the Decommissioning objectives (Appendix 7-C). The following subsections are a summary of what is presented in that report. As such, reference will not be given explicitly to Appendix 7-C from this point forward.

Groundwater flow and geochemical reactive transport modelling were applied to help understand the migration and attenuation of COPCs from the mining area toward Whitefish Lake, the primary surface water receptor (Section 7.6.2.2.2).

There were five steps in the numerical modelling:

1) development of a calibrated 3D groundwater flow model for the LSA for existing/baseline conditions. This model is described in more detail in Section 7.6.2.2.1 and was the basis for evaluating changes in groundwater quantity during Operation (presented in Section 7.4.2.1);
2) modification of the 3D groundwater flow model as required to reflect post-Operation changes to the subsurface (Section 7.6.2.2.3);
3) identification of key geochemical reactions for dissolved groundwater constituents along the groundwater flow path (Appendix 7-C);
4) development of the 3D geochemical reactive transport model (Section 7.6.2.2.3); and
5) demonstration that the Decommissioning objectives are protective of the Surface Water Quality VC. This was done by comparing groundwater quality discharging at Whitefish Lake with screening groundwater quality criteria, and provision of water quality information for further assessment of potential environmental risks (Section 10).

7.6.2.2.1 3D Groundwater Flow

The first stage of numerical modelling was the development of a 3D groundwater flow model for the LSA. The model was calibrated to observed water level and stream baseflow data. Beyond the statistical match achieved between observed and simulated conditions, the groundwater flow patterns in the calibrated groundwater flow model were consistent with the CSM presented in Figure 7.3-7.

The 3D groundwater flow model for the LSA was built using FEFLOW (Diersch 2014). The FEFLOW code offers the flexibility to represent complex spatial features at surface and within the subsurface and can represent saturated and unsaturated flow and transport. The modelling code was applied without any modifications to the processes simulated in the code.

The FEFLOW code is a finite element code whereby the model area (domain) is subdivided horizontally and vertically into a set of triangular prisms called elements that represent a unit of porous media. Each element has specified hydraulic properties, such as hydraulic conductivity and storage values, that are assigned. The FEFLOW code simulates the flow of groundwater using the properties assigned within the elements and water level elevations (hydraulic heads) at known locations, such as surface water features like lakes and rivers.

Groundwater flow observed and simulated in the calibrated groundwater model travelled eastward within the Lower Sandstone Aquifer before moving upward through the Desilicified Zone in the Athabasca Sandstone and overlying overburden deposits toward Whitefish Lake. The Desilicified Zone is better described as a porous media rather than a fractured rock environment and it facilitates the connection between the Upper and Lower groundwater flow systems in the area east of the Phoenix deposit. From a water budget perspective, the calibrated groundwater flow model was used to identify that groundwater discharge to Whitefish Lake is primarily through the Upper Aquifer (overburden and upper sandstone aquifer), with a lesser component flowing from the Lower Sandstone Aquifer through the Desilicified Zone into the base of Whitefish Lake near its eastern shore.

The flow patterns for groundwater discharging to Whitefish Lake are illustrated in plan and cross-section view in Figure 7.6-2, based on backward-tracking particles that were started at the orange dots and tracked backward in time toward their source area. Particle traces illustrate that while Whitefish Lake receives groundwater from all directions, most groundwater starts in areas west of Whitefish Lake. Review of the cross-section illustrates that most of the groundwater flow to Whitefish Lake is sourced from waters flowing through the Upper Sandstone Aquifer and Overburden units, with a lesser contribution flowing from the Lower Sandstone Aquifer through the Desilicified Zone. Downward gradients from the Upper Sandstone Aquifer are found near the western (i.e., upgradient) edge of the Desilicified Zone where flow from the Upper Sandstone Aquifer expands to flow through the permeable Desilicified Zone; the gradient transitions to upward beneath Whitefish Lake. Similarly, slight upward flow paths from the Lower Sandstone Aquifer are experienced near the western (i.e., upgradient) edge of the Desilicified Zone, where flow through the Lower Sandstone Aquifer extends vertically to flow into the overlying Desilicified Zone.

The colours on the particle traces in Figure 7.6-2 illustrate that groundwater discharging to Whitefish Lake through the Upper Sandstone Aquifer requires less than 50 years of travel time for groundwater recharge near the Phoenix site; groundwater recharge west of the Phoenix site would require 50 to 500 years (i.e., groundwater discharge to Whitefish Lake was generated from precipitation hundreds of years earlier). Groundwater travel time from the Lower Sandstone Aquifer through the Desilicified Zone to Whitefish Lake requires 250 to 400 years of travel time.

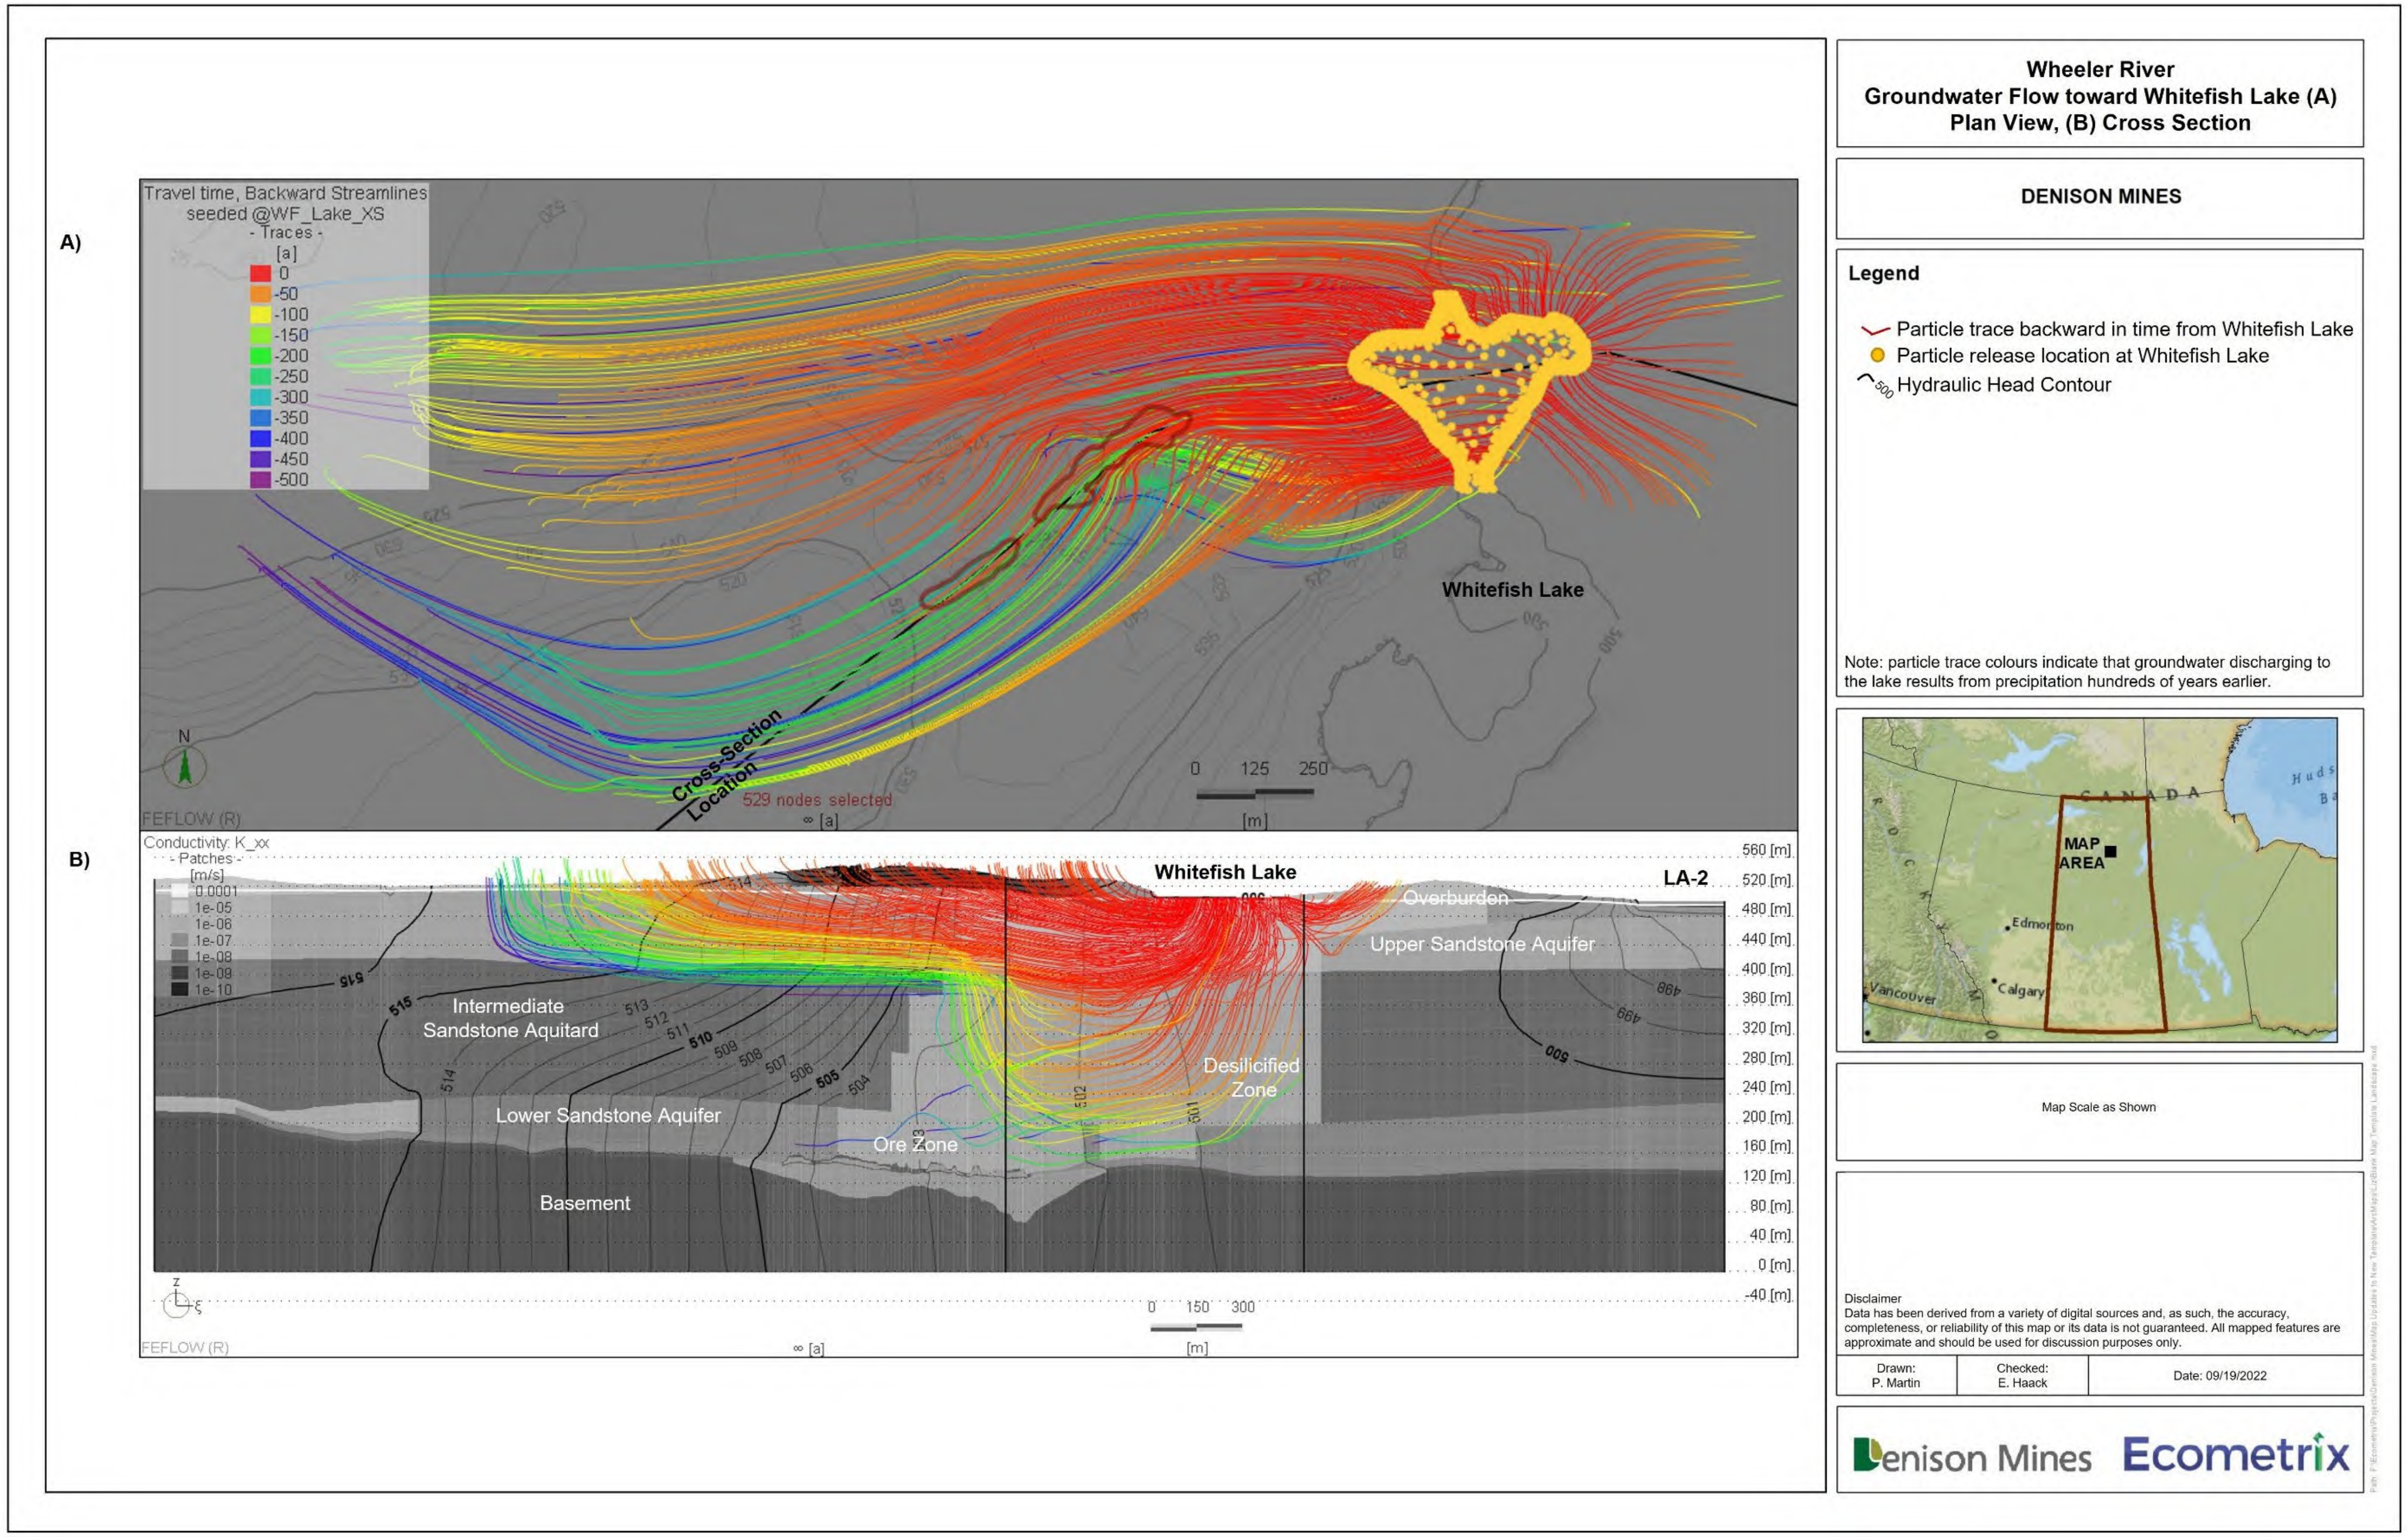

Figure 7.6-2: Groundwater Flow Toward Whitefish Lake – (A) Plan View, (B) Cross Section

7.6.2.2.2 Evaluation of Potential Receiving Bodies

Important during groundwater modelling was gaining an understanding of where groundwater flowing through the mining area will ultimately discharge. Boundary conditions applied in the model, as illustrated in Figure 7.6-3 and Figure 7.6-4, show that within the model, groundwater is permitted to exit/leave the domain at any of the surface lakes or flow further south toward Russell Lake.

Identification of potential receiving bodies involved review of available groundwater level, streamflow, and stream or lake level elevation data. The potential hydraulic gradients and flow rates were also evaluated to identify the potential for groundwater to migrate from the ore zone to each potential receiving body. The observed (and calibrated) groundwater flow patterns identified a primarily west to east groundwater flow direction in the Phoenix ore zone that suggests surface waterbodies east of the site are the most likely downgradient receiving bodies. Waterbodies located east of the ore zone include Whitefish Lake (500 m east), McGowan Lake (2 km southeast), and an unnamed lake (LA-2) east of McGowan Lake (1.9 km east). Russell Lake, located 6 km south of the ore zone (Figure 7.6-3), was also considered a potential regional discharge location.

Hydraulic gradients were estimated in the model based on water level differences between the ore zone and each potential surface water receptor. In addition, calculations of potential groundwater flow rates to each surface water receptor were evaluated for a range of interpreted hydraulic conductivity values. Estimated hydraulic gradients toward McGowan Lake and Lake LA-2 were 50% larger than the gradient toward Whitefish Lake. However, the groundwater flow rate through the Desilicified Zone, where a relatively high hydraulic conductivity is conservatively interpreted to exist, is estimated to be more than ten times greater than other areas where the intermediate sandstone aquitard is unaltered. As a result, the groundwater flow rate potential is estimated to be highest (i.e., by an order of magnitude or more) toward Whitefish Lake than any other surface waterbody in the area. Groundwater flow potential toward Russell Lake is the lowest of any surface water feature evaluated.

The implication of this interpretation is that the primary potential receiving body of COPCs in groundwater associated with the mining area is Whitefish Lake. The potential for groundwater to flow from the ore zone and discharge at other waterbodies in the area is interpreted to be significantly lower than the potential for discharge into Whitefish Lake. Groundwater discharge to Whitefish Lake is also most conservative from a predictive perspective as groundwater flow and discharge into other nearby surface waterbodies, such as McGowan or Russell Lakes, would predict lower concentrations due to greater dispersion along those longer flow paths.

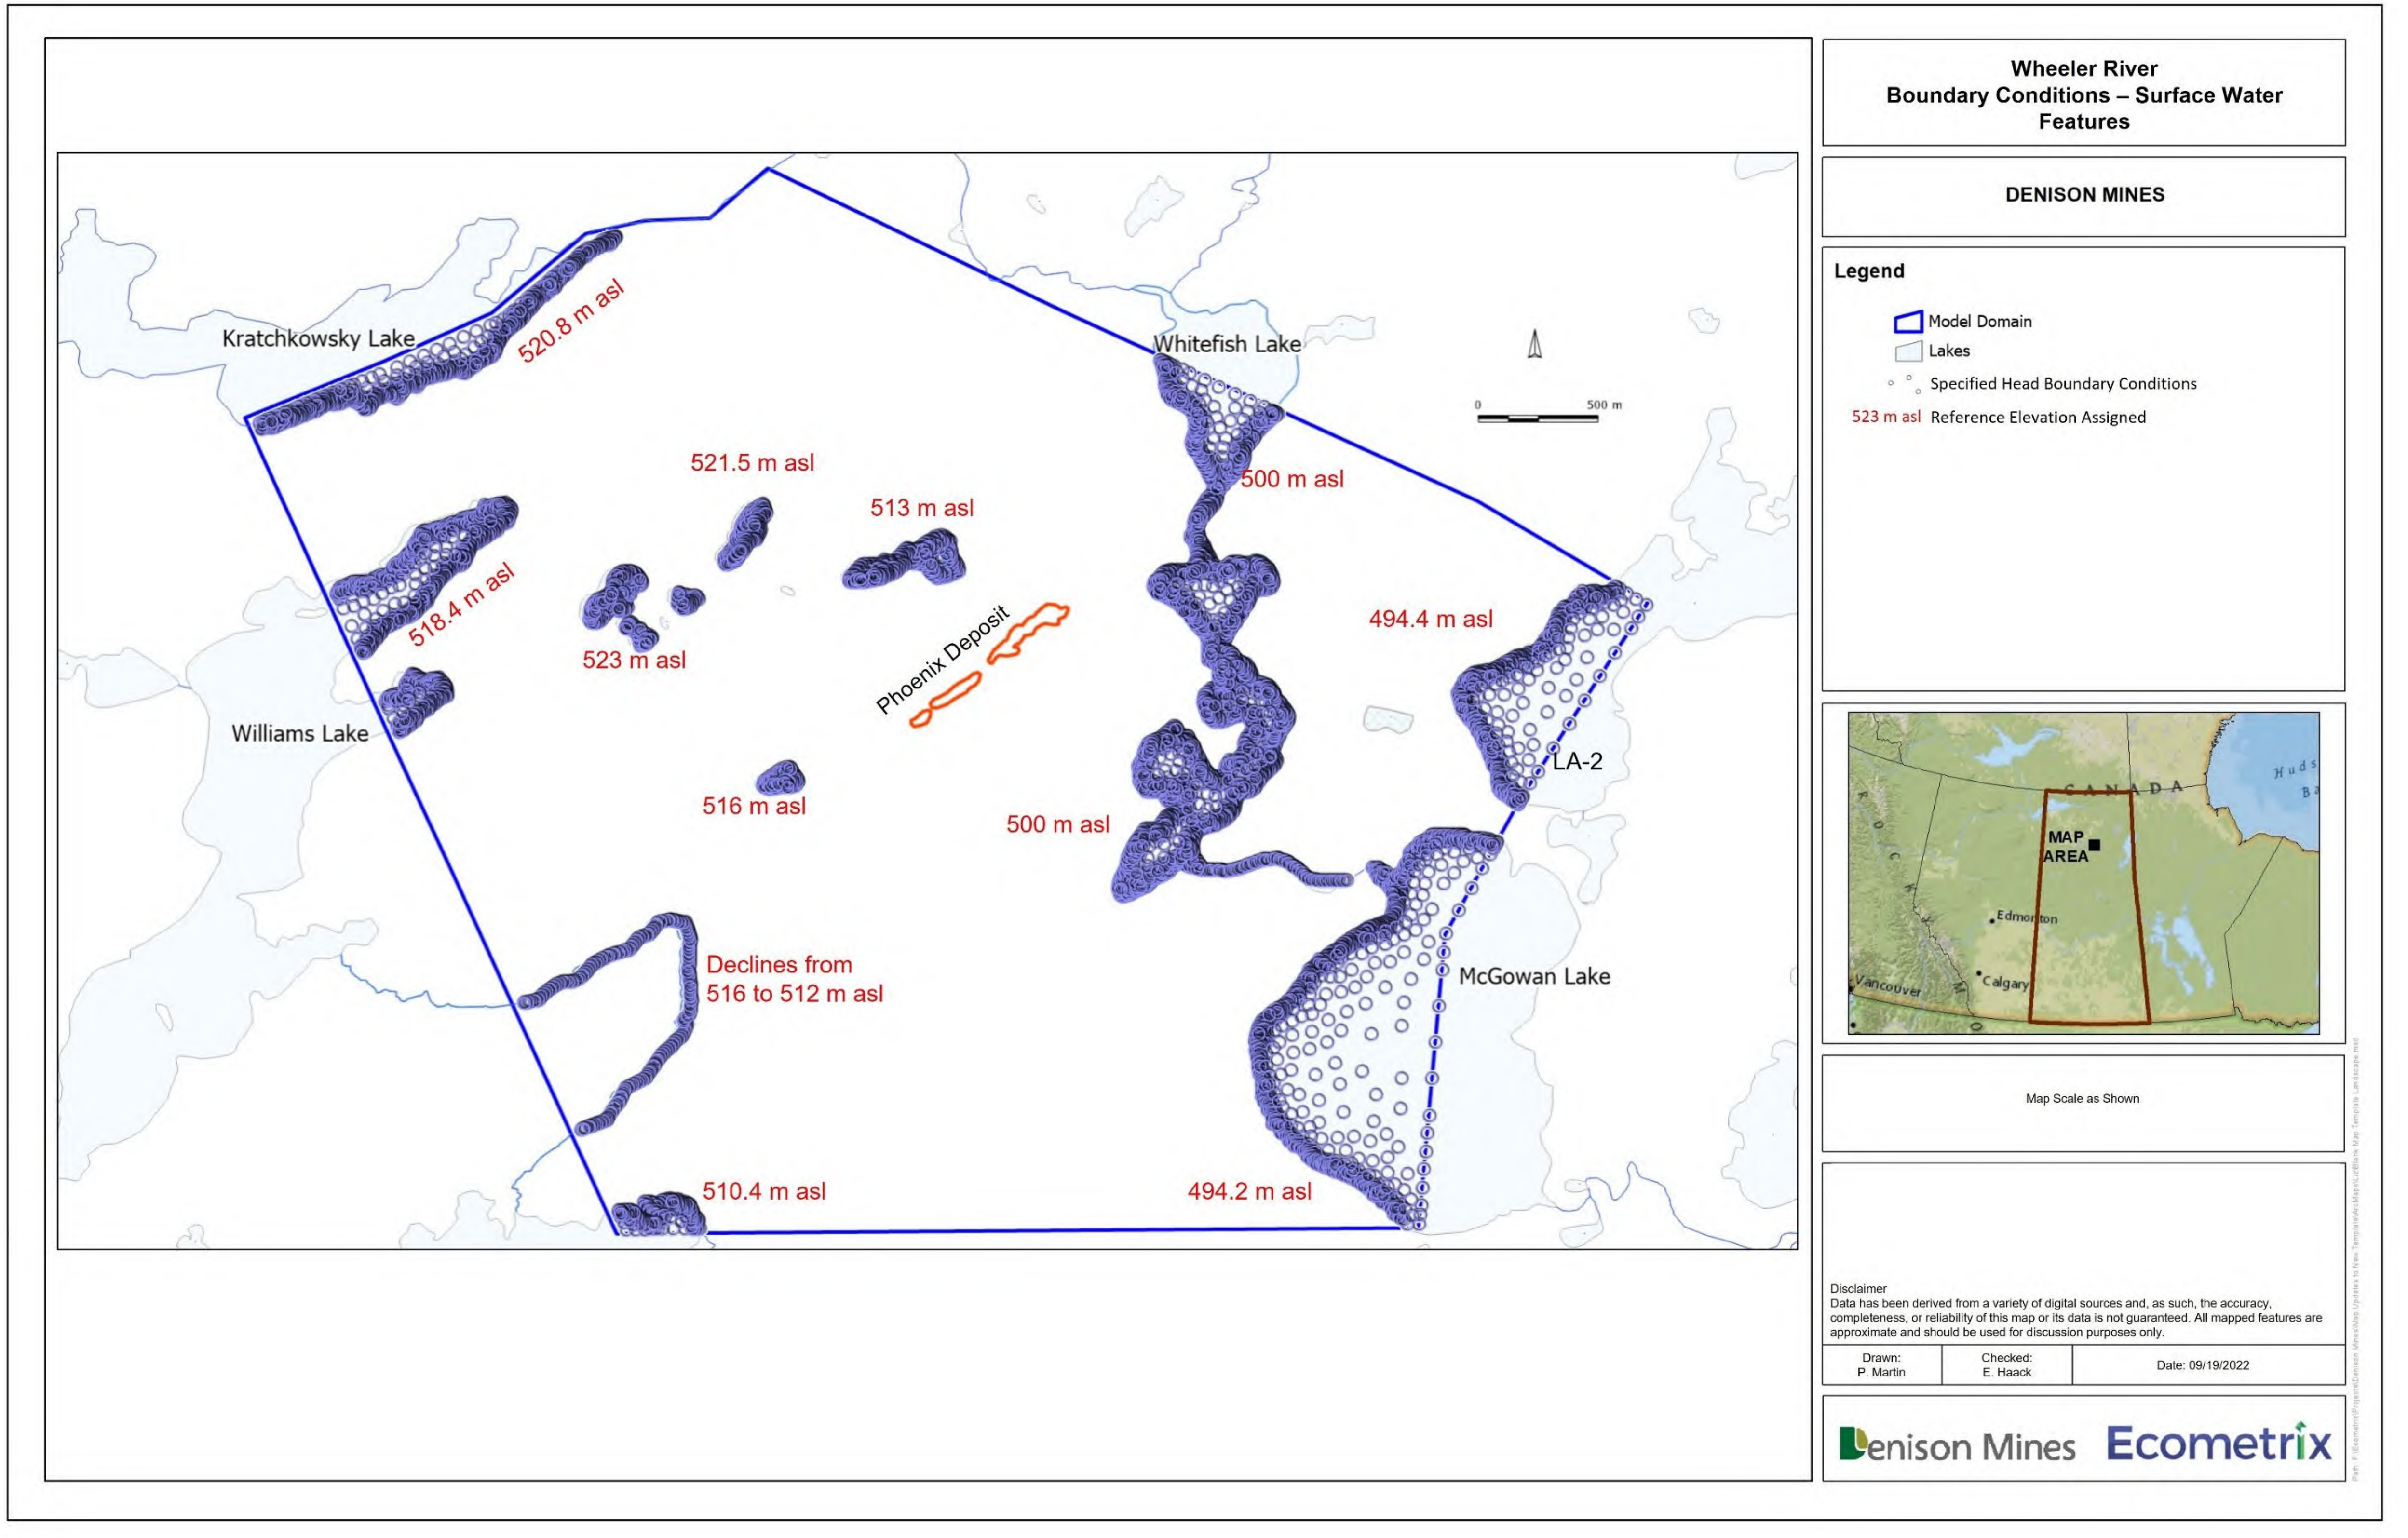

Figure 7.6-3: Boundary Conditions – Surface Water Features

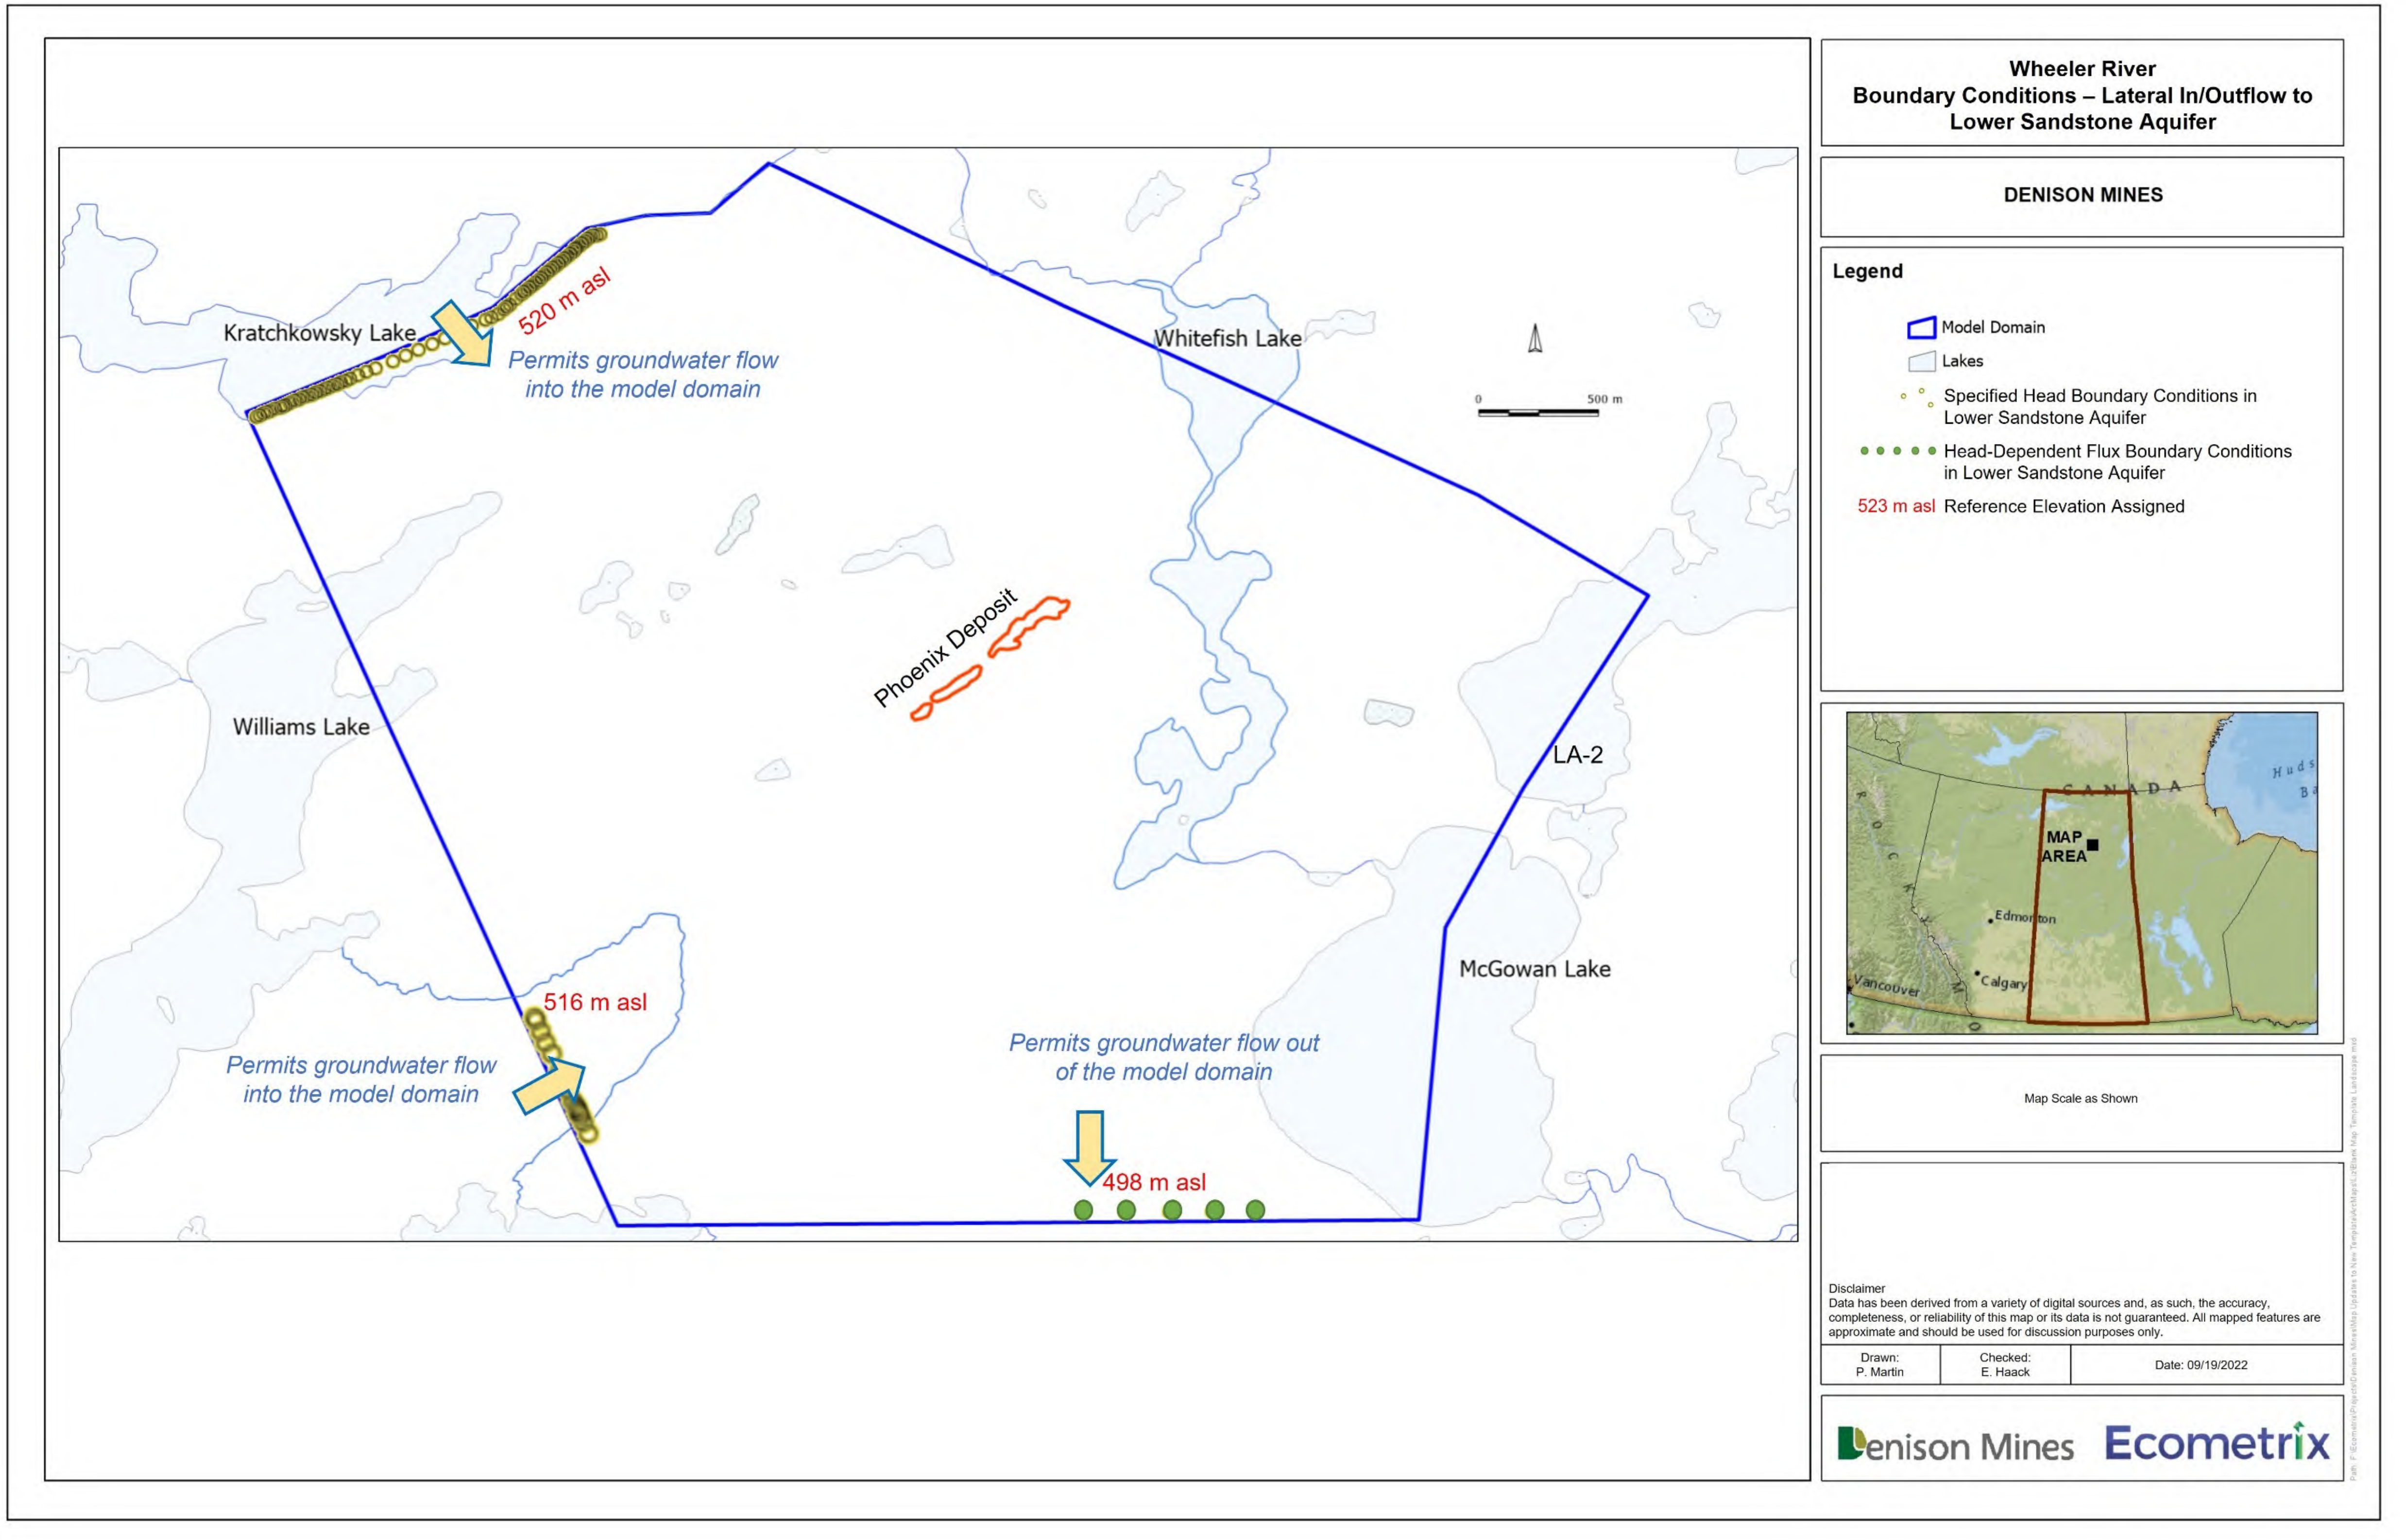

Figure 7.6-4: Boundary Conditions – Lateral In/Outflow to the Lower Sandstone Aquifer

7.6.2.2.3 *Evaluation of Geochemical Reactive Transport*

3D Geochemical Reactive Transport Model

Reactive transport modelling required integrating multi-component, time-varying flow and transport simulations using FEFLOW's simulator with the chemical processes that affect the migration of COPCs along the groundwater flow path. To incorporate the chemical processes, the piChem 'plug-in' option available with the FEFLOW software was used. PiChem (Wissmeier 2016) facilitates the linkage of geochemical reactions simulated using the geochemical code PHREEQC (Parkhurst and Appelo 2013). Reactive transport is simulated using an operator splitting technique, wherein solute transport and geochemical reactions are carried out within the model sequentially in each calculation step.

The computational requirements of a 3D geochemical reactive transport model with multiple constituents far exceeded what was practically achievable within the regional-scale 3D model. As such, a smaller 3D model domain was developed to carry out reactive transport modelling. The 3D sub-domain model for reactive transport modelling is shown in relation to the LSA in Figure 7.6-5. Particle traces showing the groundwater flow path from the mining area to the discharge zone/area in Whitefish Lake in the 3D reactive transport model are shown in Figure 7.6-6.

Changes to hydrogeological conditions within the mining area due to ore extraction were considered during development of the 3D sub-domain model. Dissolution of ore within the active mining area is expected to enhance the interconnected pore space, and thereby enhance (increase) the hydraulic conductivity. As such, one key difference between the sub-domain model input parameters and those assigned in the 3D Regional Model was the assignment of the properties associated with the Upper Barrier Aquitard Zone, the Ore Zone, and the Lower Barrier Aquitard Zones. As there is uranium mineralization contained within the Upper and Lower Barrier Zones, these zones are expected to be removed during Project operations and, as such, the hydraulic conductivity values representing these units were replaced with elevated hydraulic conductivity values relative to those assigned in the regional-scale base case model. Specifically, a hydraulic conductivity value of $5x10^{-6}$ m/s was assigned to represent the area where the uranium mineralization will be removed as part of Project operations. This value ($5x10^{-6}$ m/s) is a factor of five greater than the value assumed for the ore zone in the 3D Regional Model and conservatively simulates that the Upper and Lower Barrier Zones no longer result in effective barriers for mineral transport from the ore zone.

One-dimensional Geochemical Analysis

Chemical processes that may affect COPC concentrations in groundwater reaching Whitefish Lake were evaluated using a 1D reactive transport model. This was done because of the practicality and relative ease (i.e., much less extensive computational demands) of modelling in 1D with PHREEQC in comparison to 3D reactive transport modelling.

Geochemical modelling was used to simulate the behaviour of the COPCs associated with groundwater in the mining area Post-Decommissioning and to support an understanding of:

- which constituents in the Ore Zone restored solution are likely to undergo reactions along the groundwater transport pathway, such as interactions with the solid phase that result in their removal from the solution phase; and
- how these reactions will affect timelines and concentrations of constituents observed in groundwater at the base of the primary receiving body (i.e., Whitefish Lake).

Use of thermodynamic geochemical models for such purposes is precedented for ISR projects (e.g., Johnson et al. 2016; Lagneau et al. 2019; Reimus et al. 2019; de Boissezon et al. 2020). The model was developed using site-specific data for mineralogical assemblages, as well as truthing the conceptualized interactions to measured concentrations of the constituents in the solid phase. The simulations evaluated included the following:

- Sorption (adsorption and ion exchange) of COPCs to reactive sites associated with mineral surfaces – The mineral surfaces selected from available Project information and relevant literature were goethite, clay minerals, and quartz. The sorption process represents the partitioning of a fraction of COPCs dissolved in groundwater to the solid phase through binding at mineral surface(s) chemically (i.e., a new chemical bond is formed) or through ion exchange/electrostatic interactions (i.e., the dissolved constituent is attracted to the mineral surface based on opposite charge). The affinity of a COPC to bind to a mineral surface is specific to the COPC, the surface properties, the concentration of the dissolved COPC, and the composition of the solution phase overall. Constituents of potential concern that are similar in chemical nature (like many cationic metals, for example) compete for binding sites. Sorption was modeled as reversible, meaning constituents were allowed to sorb and desorb to achieve thermodynamic equilibrium conditions. Because minerals found throughout the subsurface are known to provide important sorbing potential, sorption was considered to some extent in all model runs.
- Redox – The influence of redox conditions and potential redox transformations of key constituents was also evaluated. This included transformation of uranium and iron. Groundwater in the hydrostratigraphic units in the LSA is largely anoxic but there is some evidence for the presence of oxygenated conditions within the upper aquifers (within the overburden materials and Upper Sandstone Aquifer). For iron, the potential for oxidation of ferric iron to ferrous iron (Fe(II) to Fe(III)) and subsequent precipitation of iron oxide minerals under oxygenated conditions in the upper hydrostratigraphic units was evaluated because these reactions influence pH. For uranium, the potential for dissolved U(VI) in groundwater from the mining area to be reduced to U(IV) and immobilized as uraninite in association with pyrite present in hydrothermally altered sediments at depth (within the Lower Sandstone Aquifer and Intermediate Sandstone Aquitard) was evaluated.

- Solubility Control – The potential for the precipitation of uranyl (U(VI)) mineral phases and other mineral phases to control the solution-phase concentrations of uranium and other COPCs.
- pH of the plume – Inclusion of proton sorption to, and subsequent desorption from, clays within the mining area. The pH of Solution #1 is acidic (pH 4.3). Assuming equilibrium of the clays with the pH results in protons that are desorbed as circumneutral pH groundwater flows through the mining area during Post-Decommissioning and the 'future centuries' period. This results in the groundwater plume from the mining area being acidic over a longer period of time.

Radioactive decay of radionuclides along the groundwater flow path was not included in the final 3D reactive transport simulations. This was a conservative approach.

Through the 1D evaluation process, sorption to quartz, iron-containing minerals (goethite), and clay minerals (illite) were identified as being an important process for COPC transport and, as such, these processes were carried forward into the 3D reactive transport model. Precipitation of COPCs as solid phases was also carried forward for a subset of COPCs (i.e., Ra, Ba, Al, and, in some simulations, Fe). Redox transformations of U(VI) and Fe(II) were also carried forward for further evaluation in the 3D model.

3D Model Simulations

It is the complexity of groundwater flow conditions and chemical processes previously described in the subsurface that necessitated the use of a sophisticated approach (i.e., PiChem) for the assessment of the 'future centuries' period. This approach was considered necessary to achieve realistic simulation of COPC transport and fate.

The 3D geochemical reactive transport model simulations were run for thousands to tens-of-thousands of years after thawing of the freeze wall (i.e., Post-Decommissioning and beyond). Simulations of up to 100,000 years were performed to make sure that desorption, ion exchange, and other processes reached a stable equilibrium and would not yield additional mass available for transport. However, for base case simulations, the dissolved uranium mass was reduced 90% within the first 5,000 years, and a steady-state uranium plume was achieved within the first 10,000 years. By 25,000 years, the dissolved mass was reduced to 1% of the decommissioning restored solution mass. Some simulations were extended to and beyond 50,000 years (base case simulation was 60,000 years) because that timeframe was required to reduce peak plume concentrations for uranium to 1/100th the initial conditions; note that the plume is most persistent within the low conductivity paleoweathered bedrock. Beyond 60,000 years, where peak concentrations are 1/100th the source concentration, the potential for a continued groundwater plume from the mining area is all but eliminated and conditions have returned to baseline conditions.

Multiple model simulations were run to evaluate the sensitivity of the results (sensitivity analysis) to uncertainties in the model inputs and assumptions. A 'base case' was developed that reflected sorption to mineral phases, with mineral phase concentrations being aligned with the central tendency of measured values. The following uncertainties were evaluated and are reflected in Table 7.6-1:

- (Scenario 1): COPC concentrations at the Decommissioning objectives (i.e., Solution #1) assumed over the whole of the mining area, versus 50% concentrations in the upper portion of the mining area. This extends the source zone vertically; the lateral extent is physically constrained by the freeze walls. This scenario effectively simulates an increase in the total mass of the source.
- (Scenario 2): Proton sorption to clays in the ore zone. As described previously, proton desorption from clays results in a plume of lower pH for a longer period. Because COPC sorption is affected by the pH of the solution, potential effects of lower pH conditions in the plume on migration behaviour of the COPC was important to evaluate.
- (Scenario 3): Transport simulation time was extended to 100,000 years following cessation of mining to evaluate the potential that desorption, ion exchange, and other processes could yield additional mass available for transport.
- (Scenarios 4, 5, 6): Increased hydraulic conductivity values in portions of the flow path between the mining area and Whitefish Lake, and specifically in the Lower Sandstone Aquifer and altered (desilicified) portion of the Intermediate Sandstone Aquitard.
- (Scenario 7): Increased hydraulic conductivity in the active mining area. Higher hydraulic conductivity within the ore zone, representing the potential that the ore zone may have an enhanced flow through rate and thus create a greater mass flux leaving the ore zone.
- (Scenario 8): Higher hydraulic conductivity along the WS Shear within the paleoweathered zone. The WS Shear is interpreted to have an enhanced fracture zone (damaged zone) surrounding the fault plane, with the frequency and apertures of fractures decreasing exponentially away from the fault plane (i.e., typical interpretation for fracturing surrounding a fault). The enhanced fracturing along the WS shear is only expected to be relevant within the paleoweathered portion of the subsurface as the overlying sediments have been desilicified, and thus are more like porous media than fractured media.
- (Scenario 9): Increased hydraulic conductivity along exploration coreholes where grout was only placed in the 15 m above the Ore Zone. The overlying coreholes were simulated to have enhanced hydraulic conductivity through the Intermediate Sandstone Aquitard (Figure 2-6 in Appendix 7-C).
- (Scenario 10): The number of available sorption sites on the mineral surfaces was reduced to $1/10^{th}$ the base case to reflect the potential that the solids in the system will have fewer available sites than what is described/assumed in the literature, for reasons such as particle

size, mineral phase, etc. Consequently, the potential for dissolved mass to adsorb (and thus have transport retarded) was reduced.

- (Scenario 11): Reduction in the number of available reaction sites to 1/10th the base case, as in Scenario 10, but with the full suite of constituents.
- (Scenario 12): The Lower Sandstone Aquifer has relatively low clay and iron concentrations in relation to the overlying hydrostratigraphic units. These minerals were removed altogether from this zone to evaluate the influence on COPC migration.
- (Scenario 13): The longitudinal and transverse dispersivity were reduced by a factor of two to reduce the potential dispersion of the plume along the flow path to values of 5 m and 2.5 m, respectively. This has the effect of increasing the peak concentration along the dominant flow paths.
- (Scenario 14): Oxygenated conditions may be encountered in the upper flow zone. Oxidation of ferrous iron from the mining area to ferric iron and subsequent oxidation to goethite was allowed, and the effect on pH and COPC behaviour was evaluated.
- (Scenario 15): The groundwater is largely anoxic and pyrite is present in the zone of thermal alteration in the Lower Sandstone Aquifer. The potential for U(VI) reduction linked to pyrite oxidation was explored. In this scenario, no sorption was assumed in the Lower Sandstone Aquifer for U(VI) or other COPCs.

In Scenarios 3, 4, and 5, the values for increased hydraulic conductivities in the Lower Sandstone Aquifer and Desilicified Zone of the Intermediate Sandstone Aquitard were developed using a robust uncertainty analysis (i.e., Parameter ESTimation utility, PEST++ IES; Doherty 2015, 2018; White 2018; White et al. 2020). This approach was used in recognition that model calibration is non-unique and that a range of parameter combinations should be evaluated to understand potential environmental predictions.

Results with respect to peak concentration of COPCs in groundwater discharging to Whitefish Lake are summarized in Table 7.6-1, for the multiple model simulations introduced above. Concentrations in groundwater discharging at Whitefish Lake are not simulated to vary appreciably from baseline conditions for the base case or in any of the scenarios that, overall, evaluate the sensitivity of the model predictions to a range of subsurface conditions. Changes in water quality are gradual and will result in an evolution of the groundwater quality reaching Whitefish Lake.

The potential Project-related effect was evaluated in two phases. Concentrations of COPCs in groundwater discharging at the lake were compared to available generic guidelines for the protection of freshwater aquatic life, which were used as groundwater quality screening criteria. The groundwater quality screening criteria are summarized in Table 7.6-1 and the sources of the criteria are provided in Appendix 7-C. COPC concentrations overwhelmingly met the screening guidelines across the scenarios evaluated, including those that were least conservative with respect to attenuation of COPC concentrations. However, to further evaluate potential Project-related effects during the ‘future centuries’ period (mass flux of COPC), inputs from groundwater were evaluated in the ERA using the IMPACT model. This is presented in Section 10.1.4.2.3 in Section 10.

For the COPCs identified in the effluent, the predicted mass flux from groundwater into Whitefish Lake starting 200 years after the Project phases during the ‘future centuries’ period was added into the IMPACT model to predict the water and sediment concentrations over time at the exposed locations. As shown in the ERA (Appendix 10-A in Section 10), predicted water and sediment concentrations at all locations are expected to be below water and sediment quality guidelines. Even though the water and sediment concentrations of COPCs are below their respective guidelines, dose and risk predictions for human receptors were performed using the IMPACT model as part of the ERA to understand what the predicted effects might be during ‘future centuries’ for the same COPCs as during the Project phases. During ‘future centuries’, a permanent resident was included on the former mine site instead of a camp worker. There were no predicted risks to human receptors for all non-carcinogens evaluated during the ‘future centuries’ period, and the cancer risk from arsenic was not predicted to exceed the negligible cancer risk level for any of the receptors assessed during ‘future centuries’ (Section 10.1.6.1.4 in Section 10). Further, the radiation dose estimate was below the public dose limit; thus, no discernable health effects are anticipated due to exposure of the permanent resident receptor to releases from the Project.

Project-related effects from the long-term transport of groundwater solutes to Whitefish Lake during the ‘future centuries’ period were modelled (Appendix 10-A in Section 10) and evaluated with respect to the Surface Water Quality VC (Section 8.2.4.2.5 in Section 8). No residual effects were identified.

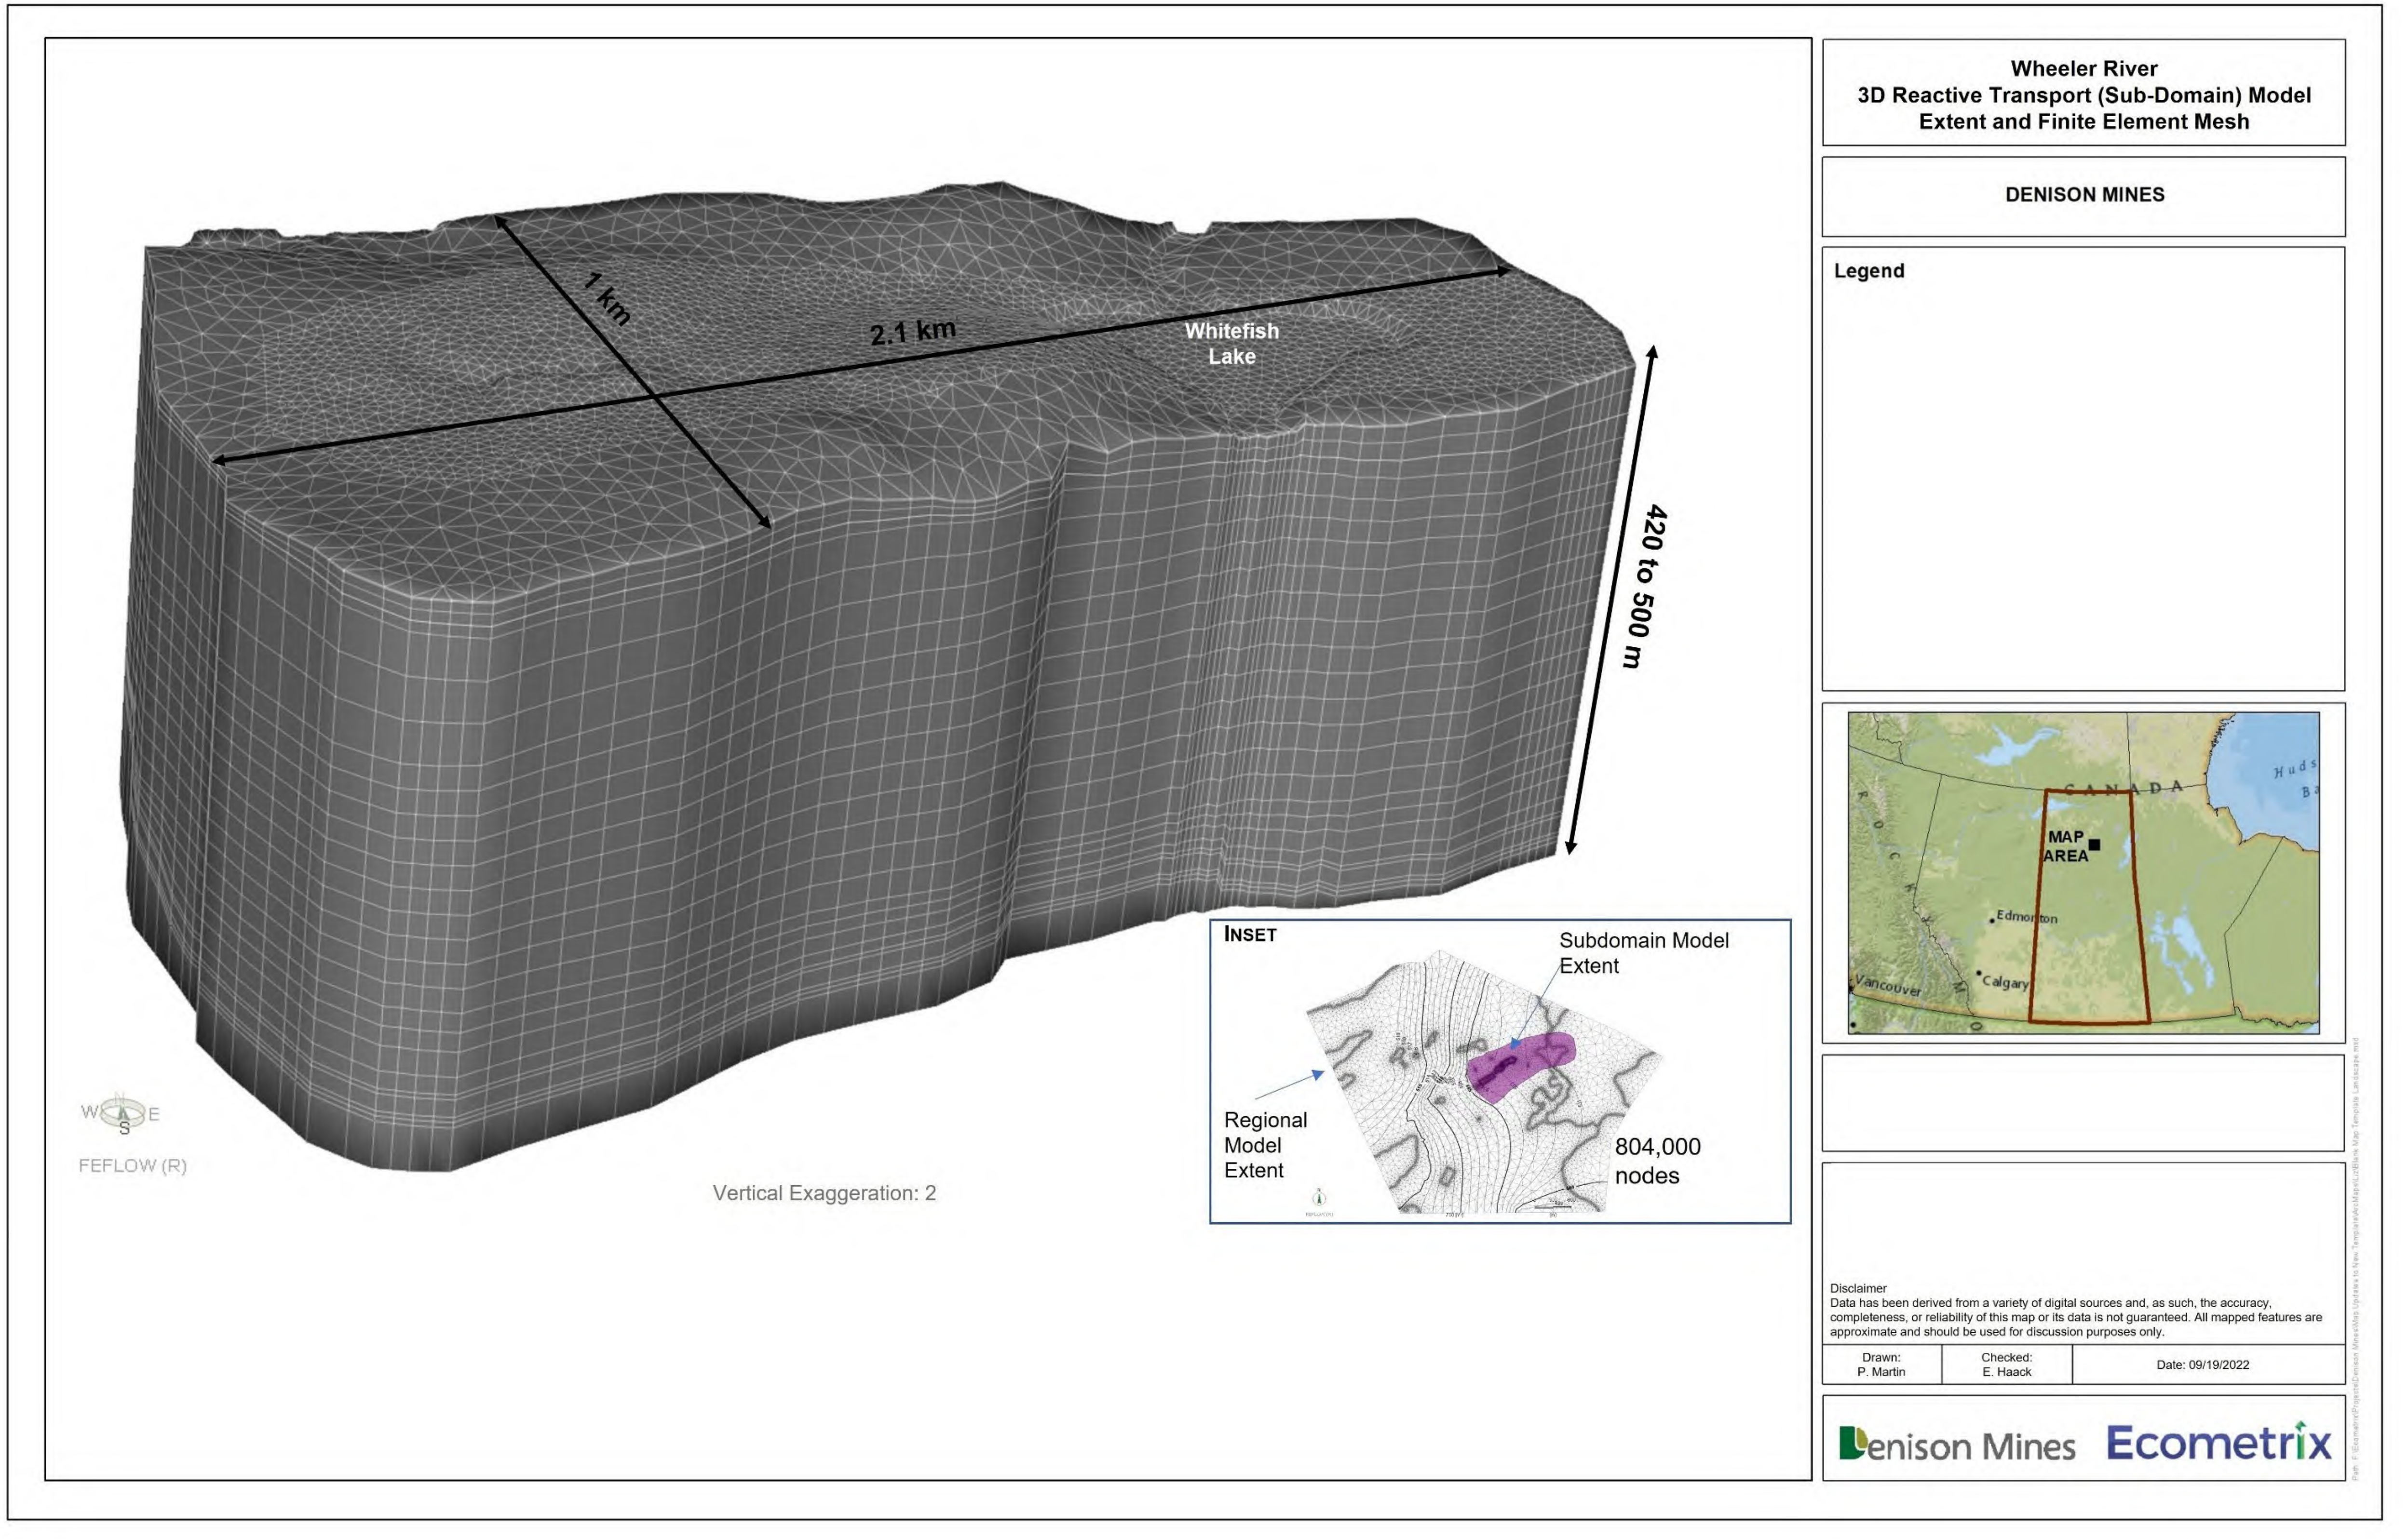

Figure 7.6-5: 3D Reactive Transport (Sub-Domain) Model Extent and Finite Element Mesh

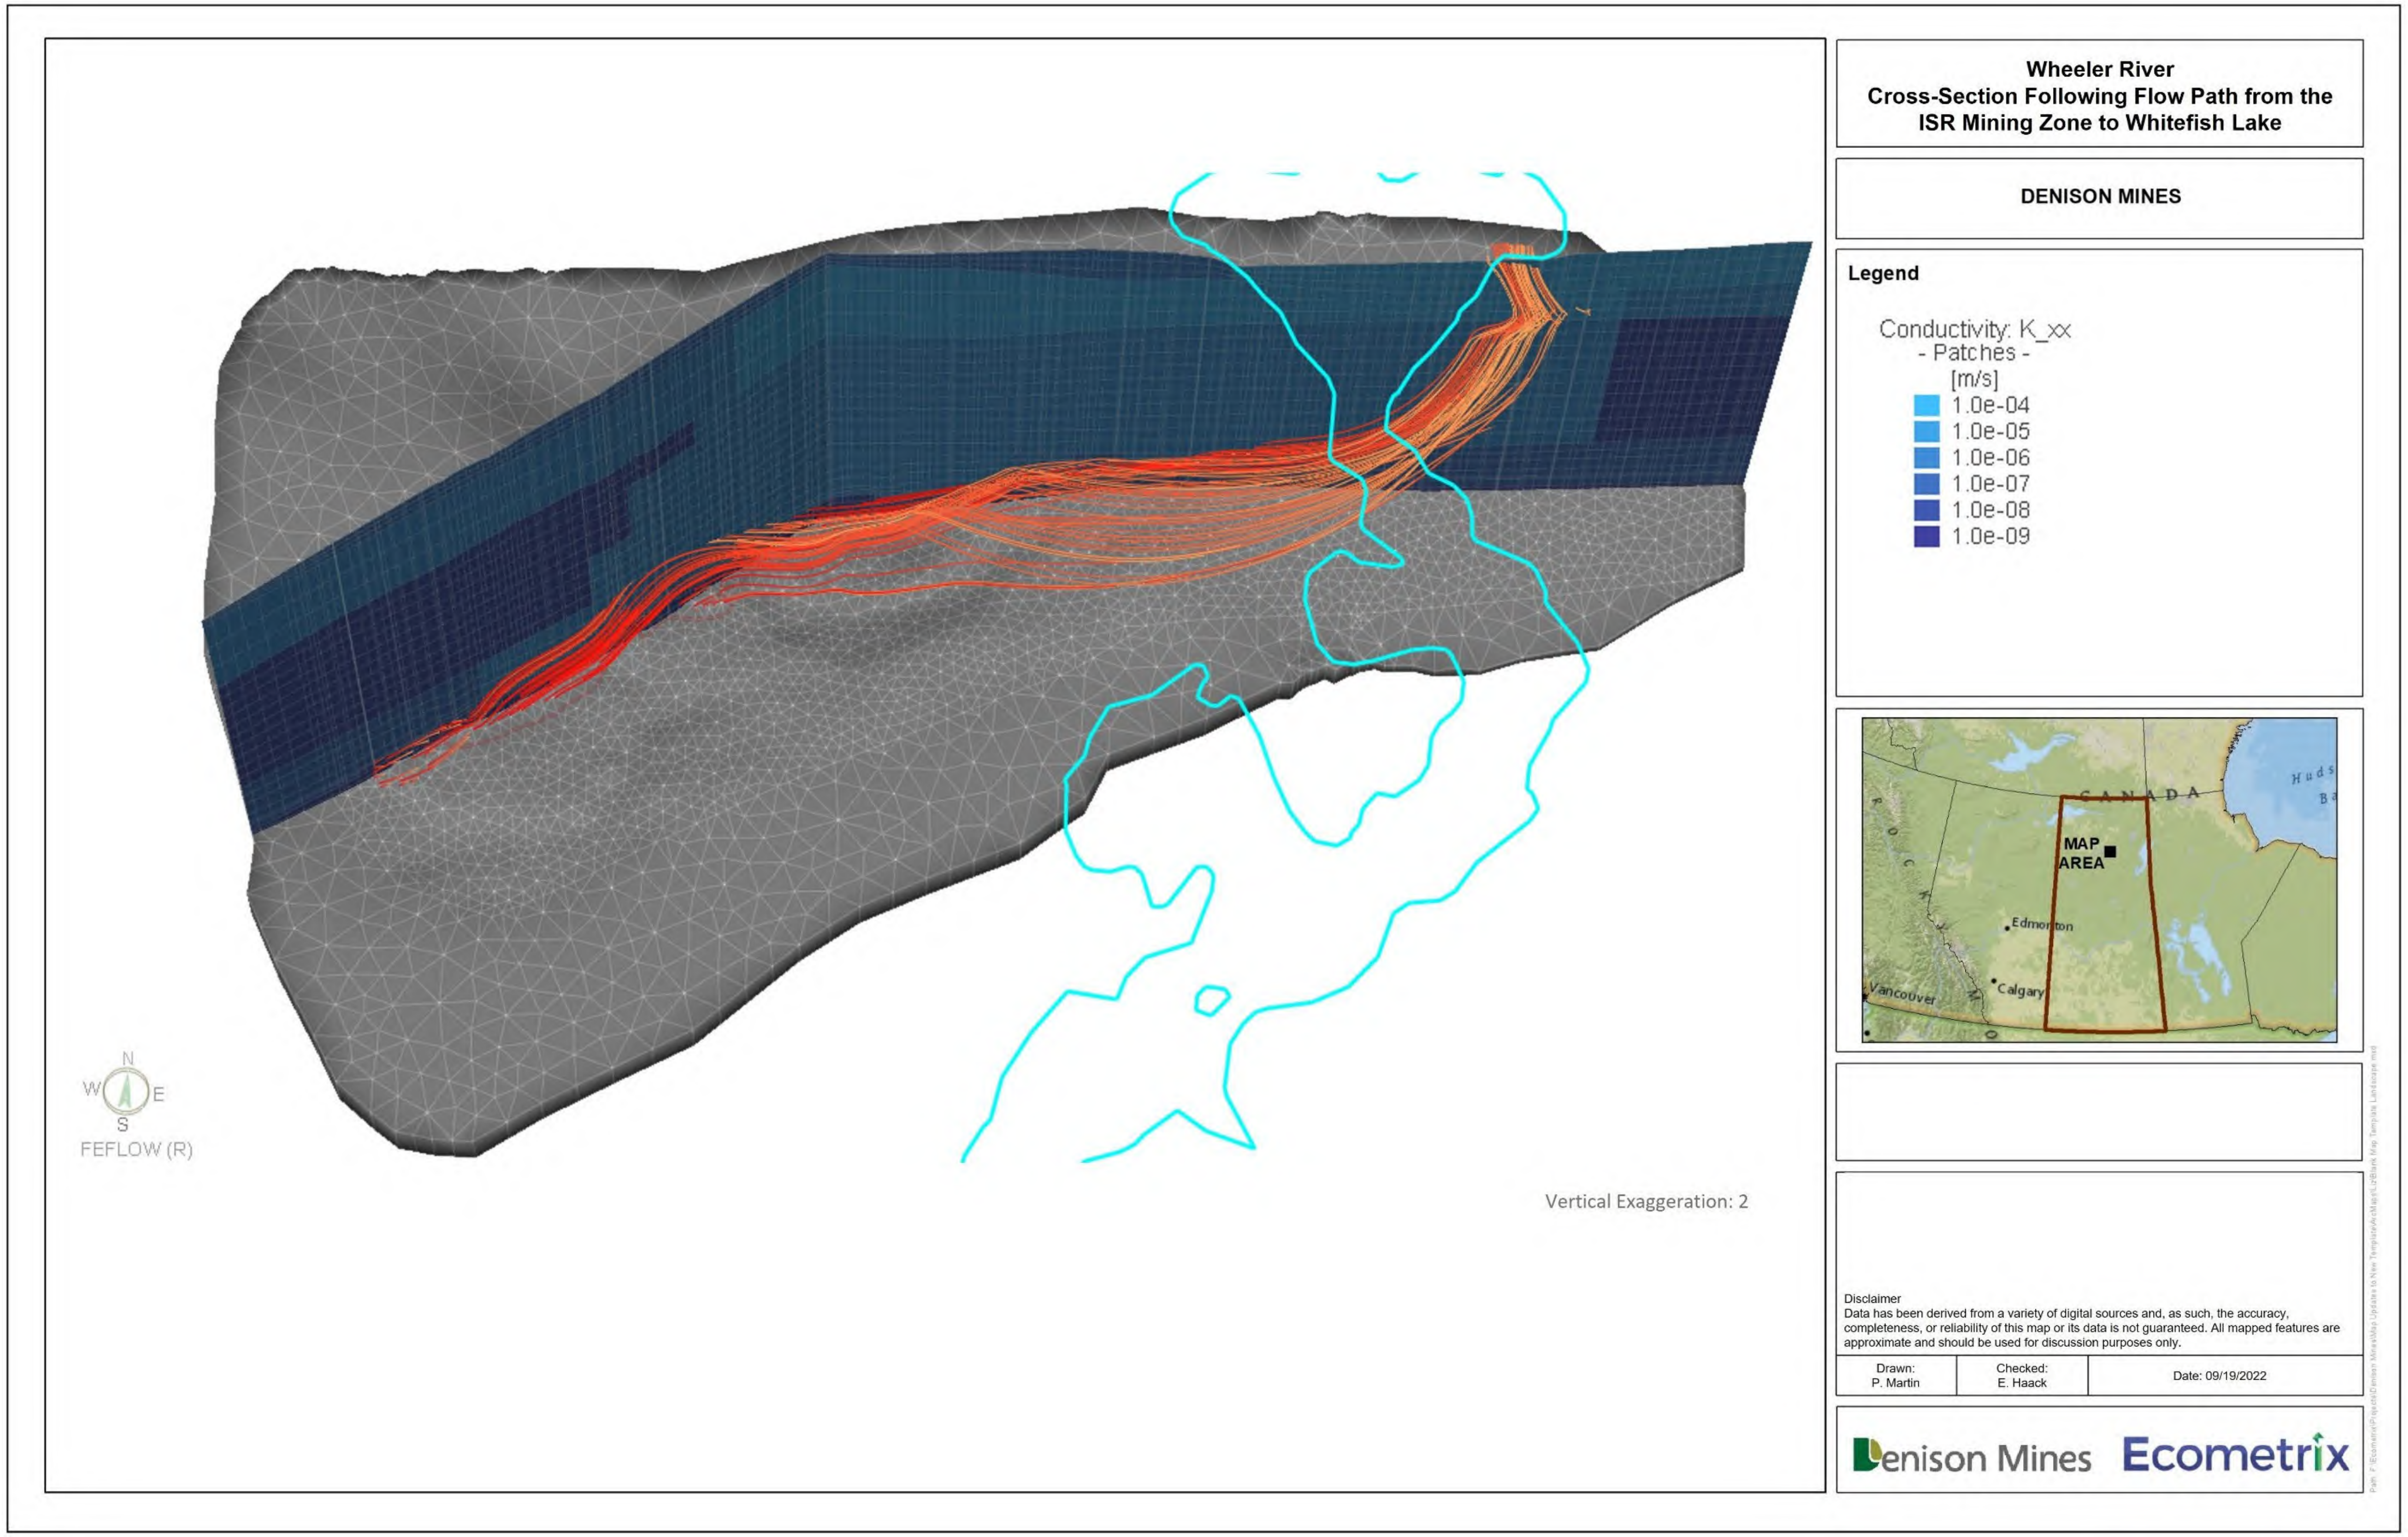

Figure 7.6-6: Cross-section Following Flow Path from the In Situ Recovery Mining Area to Whitefish Lake

Plume Behaviour – Base Case Scenario

Predicted transport of dissolved COPCs was generally found to follow anticipated flow paths with additional spreading due to dispersion. Dispersion reduces the concentrations as time progresses in the model and the dissolved plume spreads, resulting in lower concentrations of COPCs in groundwater reaching Whitefish Lake than those in the remediated mining area (Section 7.6.2.1). This is shown in Figure 7.6-7 for chloride. Chloride is a COPC that acts conservatively in groundwater, meaning that due to its chemical nature, its behaviour will be affected by dispersion and advection but not by chemical reactions with other groundwater constituents or the solid matrix along the groundwater flow path. Chloride and other COPCs that behave conservatively (including sulphate) are simulated to reach their peak concentration in the lake in approximately 400 years; this is consistent with the early arrival particle traces illustrated in Figure 7.6-6.

The area simulated to be a source of contaminant mass Post-Decommissioning includes the Ore Zone, the overlying Lower Sandstone Aquifer (i.e., 50 m above the Ore Zone), and the underlying Paleoweathered bedrock (Section 7.6.2.1). As indicated in Figure 7.6-7, elevated concentrations of even conservative COPCs persist within the Paleoweathered zone due to its lower hydraulic conductivity (i.e., it takes longer for COPCs to be flushed out of this zone).

Several types of chemical reactions can affect the concentrations of COPC along the groundwater flow path. Chemical reactions that can act to retard the velocity of groundwater plumes relative to the average linear velocity of groundwater (i.e., advection) and/or attenuate COPC concentrations in groundwater include precipitation as a mineral phase, sorption, and redox transformation (and subsequent precipitation and/or sorption). Other processes, like radioactive decay and ingrowth, can affect concentrations of radiological constituents along the groundwater flow path.

The transformation of mass from the dissolved to the sorbed state is illustrated in Figure 7.6-8 through Figure 7.6-11. Selenium and uranium are elements that have very different affinities for sorption to the mineral phases in the subsurface across the LSA. Selenium shows a low affinity for the solid phase and selenium migration to Whitefish Lake is retarded to a limited extent in comparison to chloride (conservative constituent) (Figure 7.6-8 and Figure 7.6-9). Concentrations of selenium in groundwater are attenuated primarily from dispersion, as for chloride.

Uranium is very strongly sorbed to the mineral phases. Because of this, migration is very strongly retarded and uranium in the dissolved phase is not predicted to reach Whitefish Lake in 50,000 years or beyond (Figure 7.6-10 and Figure 7.6-11). The distance that the dissolved uranium plume migrates is limited by the adsorption reactions and dispersion. The uranium plume is simulated to grow modestly over the first 5,000 years of the simulation but then start to retract (i.e., shrink) during later times as the source concentration (i.e., dissolved uranium concentrations in remediated groundwater in the mining area) is depleted. Depletion of the source concentration occurs as background water carrying lower uranium (and other constituent) concentrations flows through the source area.

For the uncertainty scenario with lower dispersivity, exceedances of the groundwater quality screening criteria for cobalt (Co) and selenium (Se) were simulated to occur. The exceedances for these two elements represent dissolved concentrations in groundwater 1.2 and 1.1 times their respective groundwater quality screening criteria. Figure 7.6-12 provides an example of the portion of Whitefish Lake which could receive concentrations greater than the groundwater quality screening criteria (in this case for selenium). Note that as the portion of the lake with potential to experience concentrations above the groundwater quality screening criteria is small, the mass flux entering the lake would is simulated to be relatively unchanged from background conditions. The simulated concentrations reaching the base of Whitefish Lake would be further readily reduced during mixing within the lake (Appendix 10-A in Section 10).

By accounting for flow, transport, and chemical reactions, the simulated plumes of dissolved COPCs emanating from the Ore Zone were found to reach a maximum extent within the Lower Sandstone Aquifer and the deeper part of the Desilicified Zone after 5,000 to 10,000 years (depending on the COPC).

7.6.2.2.4 Summary of Residual Effects Evaluation

The concentrations and mass loadings of COPCs associated with mining activities reaching Whitefish Lake were simulated to be modest variations from the background concentrations, as shown in Figure 7.6-13 and Figure 7.6-14, respectively. Sulphate is predicted to experience the largest change in concentration at Whitefish Lake, rising from 3 to 12 mg/L (i.e., a factor of four); however, this change in concentration is anticipated to occur over a small portion of the lake and thus results in a mass flux increase of 14%. For most of the constituents, the mass flux to Whitefish Lake raises by less than 5%. As such, the variations predicted to occur at Whitefish Lake are considered modest.

Consequently, future concentrations of COPCs at Whitefish Lake were simulated to be similar to background concentrations. Under the base case scenario (i.e., the best estimate of what will occur), exceedances of groundwater quality screening criteria were only predicted for iron, manganese, and pH. Predicted concentrations/values for these parameters were within baseline concentrations observed in the LSA; iron and manganese concentrations in groundwater are naturally elevated and pH values in groundwater range naturally down to approximately pH 6.

Groundwater monitoring will be completed over the life of the Project to assess trends and compliance with model predictions (Section 7.8).

Results of the residual effect evaluation are provided in the following residual effects characteristic definition and rating summary tables for Geology (Table 7.6-2 and Table 7.6-3), Groundwater Quantity (Table 7.6-4 and Table 7.6-5), and Groundwater Quality (Table 7.6-6 and Table 7.6-7) VCs.

Table 7.6-2: Geology – Definitions for Residual Effect Characteristics

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Negative effect or effect is not desirable.
		Positive – Beneficial effect or effect is desirable.
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low** – Minimal amount of change relative to the range of existing variation.
		Moderate – Moderate amount of change relative to the range of existing variation.
		High – High amount of change relative to the range of existing variation.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area.
		Local – Effect is limited to the VC LSA.
		Regional – Effect extends beyond the VC LSA into the VC RSA.
		Beyond Regional – Effect extends beyond VC RSA.

Residual Effect Characteristic	Definition	Rating
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only).
		Medium-term – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning).
		Long-term – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals.
		Frequent – Effect occurs many times on a regular basis.
		Continuous – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions
		Partially Reversible – A residual effect that partially diminishes to baseline conditions
		Irreversible – A residual effect that will not diminish to baseline conditions
Context	Since Geology is an intermediate VC, the context is best defined in the significance determination of the receptor VCs, specifically Terrain.	
Likelihood	Likelihood that the residual effect will occur including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur.
		Unlikely – A low probability that the residual effect will occur.

Table 7.6-3: Geology – Summary of the Residual Effect Characteristics Ratings

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	The possible effect is subsidence, and thus a vertical displacement of soil at ground surface. This is a negative or undesirable effect.
Magnitude	Low	The extent of subsidence is expected to be limited in terms of vertical displacement, to a maximum of 2-3 mm at ground surface. This degree of change is negligible and is likely within the range of ground surface elevation change/disturbance associated with other routine operations at surface.
Geographic Extent	Project Area	The geographic extent of subsidence is expected to be localized to a small portion of the Project Area.
Duration	Long-term	The time period of subsidence was modelled as a single mass loss event. However, the period of subsidence, if it occurs, may extend over a longer period of time, and would extend beyond the lifetime of the Project.
Frequency	Continuous	Subsidence at ground surface, once it occurs, will be continuous.

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Reversibility	Partially Reversible	Subsidence can be integrated with the surrounding natural environment through site reclamation.
Context	Context is described for receptor VCs, being Terrain.	
Likelihood	Likely	Although modelled to be negligible in magnitude, it is likely that subsidence will occur through the course of the Project. The likelihood is expected to be mitigated/lessened by the mining approach whereby mass is removed/ore extracted in multiple phases (versus a single mass loss event in the active mining zone, as modelled).

Table 7.6-4: Groundwater Quantity – Definitions for Residual Effect Characteristics

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Negative effect or effect is not desirable. **Positive** – Beneficial effect or effect is desirable.
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low** – Minimal amount of change relative to the range of existing variation. Defined as a less than 10% change in groundwater discharge (L/s). **Moderate** – Moderate amount of change relative to the range of existing variation. Defined as a change in groundwater discharge (L/s) more than 10% but less than 25%. **High** – High amount of change relative to the range of existing variation. Defined as a change in groundwater discharge (L/s) greater or equal to 25%.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area. **Local** – Effect is limited to the VC LSA. **Regional** – Effect extends beyond the VC LSA into the VC RSA. **Beyond Regional** – Effect extends beyond VC RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals. **Frequent** – Effect occurs many times on a regular basis. **Continuous** – Effect occurs continuously.

Residual Effect Characteristic	Definition	Rating
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions **Partially Reversible** – A residual effect that partially diminishes to baseline conditions **Irreversible** – A residual effect that will not diminish to baseline conditions
Context	Since Groundwater Quantity is an intermediate VC, the context is best defined in the significance determination of the receptor VCs including various VCs in the Aquatic Environment.	
Likelihood	Likelihood that the residual effect will occur including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

Table 7.6-5: Groundwater Quantity – Summary of the Residual Effect Characteristics Ratings

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Groundwater quantity characterized at discharge to Whitefish Lake (LA-5) will be reduced, primarily as a result of water taking and anticipated changes in groundwater recharge, during Construction, Operation and Decommissioning.
Magnitude	Moderate to High	Groundwater discharge is expected to be reduced by as much as 25% in Whitefish Lake during Decommissioning. Discharge is expected to be reduced to a lesser extent during Construction (10%) and Operation (20%).
Geographic Extent	Local	The geographic extent of changes in groundwater quantity is expected to be localized to a Whitefish Lake in the LSA.
Duration	Medium-term	Discharge flows to Whitefish Lake are expected to be most affected (reduced) during Decommissioning. Recovery to baseline (pre-mining) conditions is expected during the early years of Post-Decommissioning (by year 9) when pumping has ceased.
Frequency	Continuous	The effect is expected to occur from Construction through Operation into Decommissioning, and is predicted to revert to baseline conditions by year 9 of Post-Decommissioning.
Reversibility	Fully Reversible	The effect is fully reversible upon cessation of pumping.
Context	Context is described for the Surface Water Quantity VC. Because groundwater discharge to Whitefish Lake is a small component of water flow through the lake, the change in overall water quantity within the lake during all Project phases is predicted to be too small to measure.	
Likelihood	Likely	Changes to groundwater quantity (discharge to Whitefish Lake) are likely to occur due to water taking for Project activities and changes in groundwater recharge in the Project Area.

Table 7.6-6: Groundwater Quality – Definitions for Residual Effect Characteristics

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Negative effect or effect is not desirable. **Positive** – Beneficial effect or effect is desirable.
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low –** A measurable change that is not within the variability of baseline conditions but below groundwater quality screening criteria. The criteria are a compilation of generic guidelines for the protection of aquatic life for constituents of potential concern in groundwater discharging to Whitefish Lake for the Project. **Moderate** – A measurable change that is not within the variability of baseline conditions and not within groundwater quality screening criteria; therefore, it could have an adverse effect on water uses in the LSA. **High** – A measurable change that is not within the variability of baseline conditions and is substantively outside of groundwater quality screening criteria; therefore, it is likely to have an adverse effect on water uses in the LSA.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area. **Local** – Effect is limited to the VC LSA. **Regional** – Effect extends beyond the VC LSA into the VC RSA. **Beyond Regional** – Effect extends beyond VC RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals. **Frequent** – Effect occurs many times on a regular basis. **Continuous** – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions **Partially Reversible** – A residual effect that partially diminishes to baseline conditions **Irreversible** – A residual effect that will not diminish to baseline conditions
Context	Since Groundwater Quality is an intermediate VC, the context is best defined in the significance determination of the receptor VCs including various VCs in the Aquatic Environment and the Human Health VC.	
Likelihood	Likelihood that the residual effect will occur including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

Table 7.6-7: Groundwater Quality – Summary of the Residual Effect Characteristics Ratings

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	The Project will cause a change in concentrations of constituents in groundwater, measured as a mass of chemical per unit volume in water (e.g., mg/L). Groundwater quality in the subsurface within the LSA will be changed following the remediation process in the mining area. Groundwater constituents within the remediated groundwater will migrate away from the mining area during a period beginning at Post-Decommissioning. This migration will extend toward Whitefish Lake (the receiving environment) over hundreds to thousands of years ('future centuries') because of the relatively low groundwater velocities between the mining area and Whitefish Lake. Some constituents will require even more time for this migration as they are strongly held back (retarded) in the subsurface relative to the groundwater flow velocity due to interaction with the naturally existing minerals along the flow path. Dispersion (spreading) of constituents along the flow path will reduce constituent concentrations significantly throughout the groundwater migration period.
Magnitude	Low	Under the base case, there were no exceedances of groundwater quality screening criteria except those constituents that are naturally outside of criteria. Under highly conservative sensitivity analysis scenarios, minor exceedances (≤ 1.2 times the groundwater quality screening criteria) occurred for two of the constituents evaluated; because these exceedances were limited to one highly conservative scenario, exceedances are considered unlikely.
Geographic Extent	Local	The geographic extent of the residual effects is predicted to be local as effects are predicted to be confined to a small portion of the waterbody immediately adjacent to the Project (i.e., Whitefish Lake).
Duration	Long-term	In the 'future centuries' period following the remediation process in the mining area, there is the potential for COPCs dissolved in groundwater to migrate as part of natural groundwater flow conditions in the subsurface. Such migration will occur over hundreds to thousands of years.
Frequency	Continuous	Changes to groundwater quality are anticipated over the 'future centuries' period and will require hundreds to thousands of years to migrate through the sub-surface to a receiving water body. As such the effects are considered continuous during that period.
Reversibility	Irreversible	Although the changes to groundwater quality may be reversible within the future centuries period, they are considered irreversible in the context of the EIS.
Context	Context is described for surface water VCs as they will be the receptor of effected groundwater in the future centuries. The significance of the residual effect was evaluated further in the ERA (Section 10) and no risks to the Human Health VC were identified from inputs of constituents of potential concern to Whitefish Lake. No residual effects were identified with respect to the Surface Water Quality VC (Section 8).	
Likelihood	Likely	It is expected that a change in groundwater quality will occur.

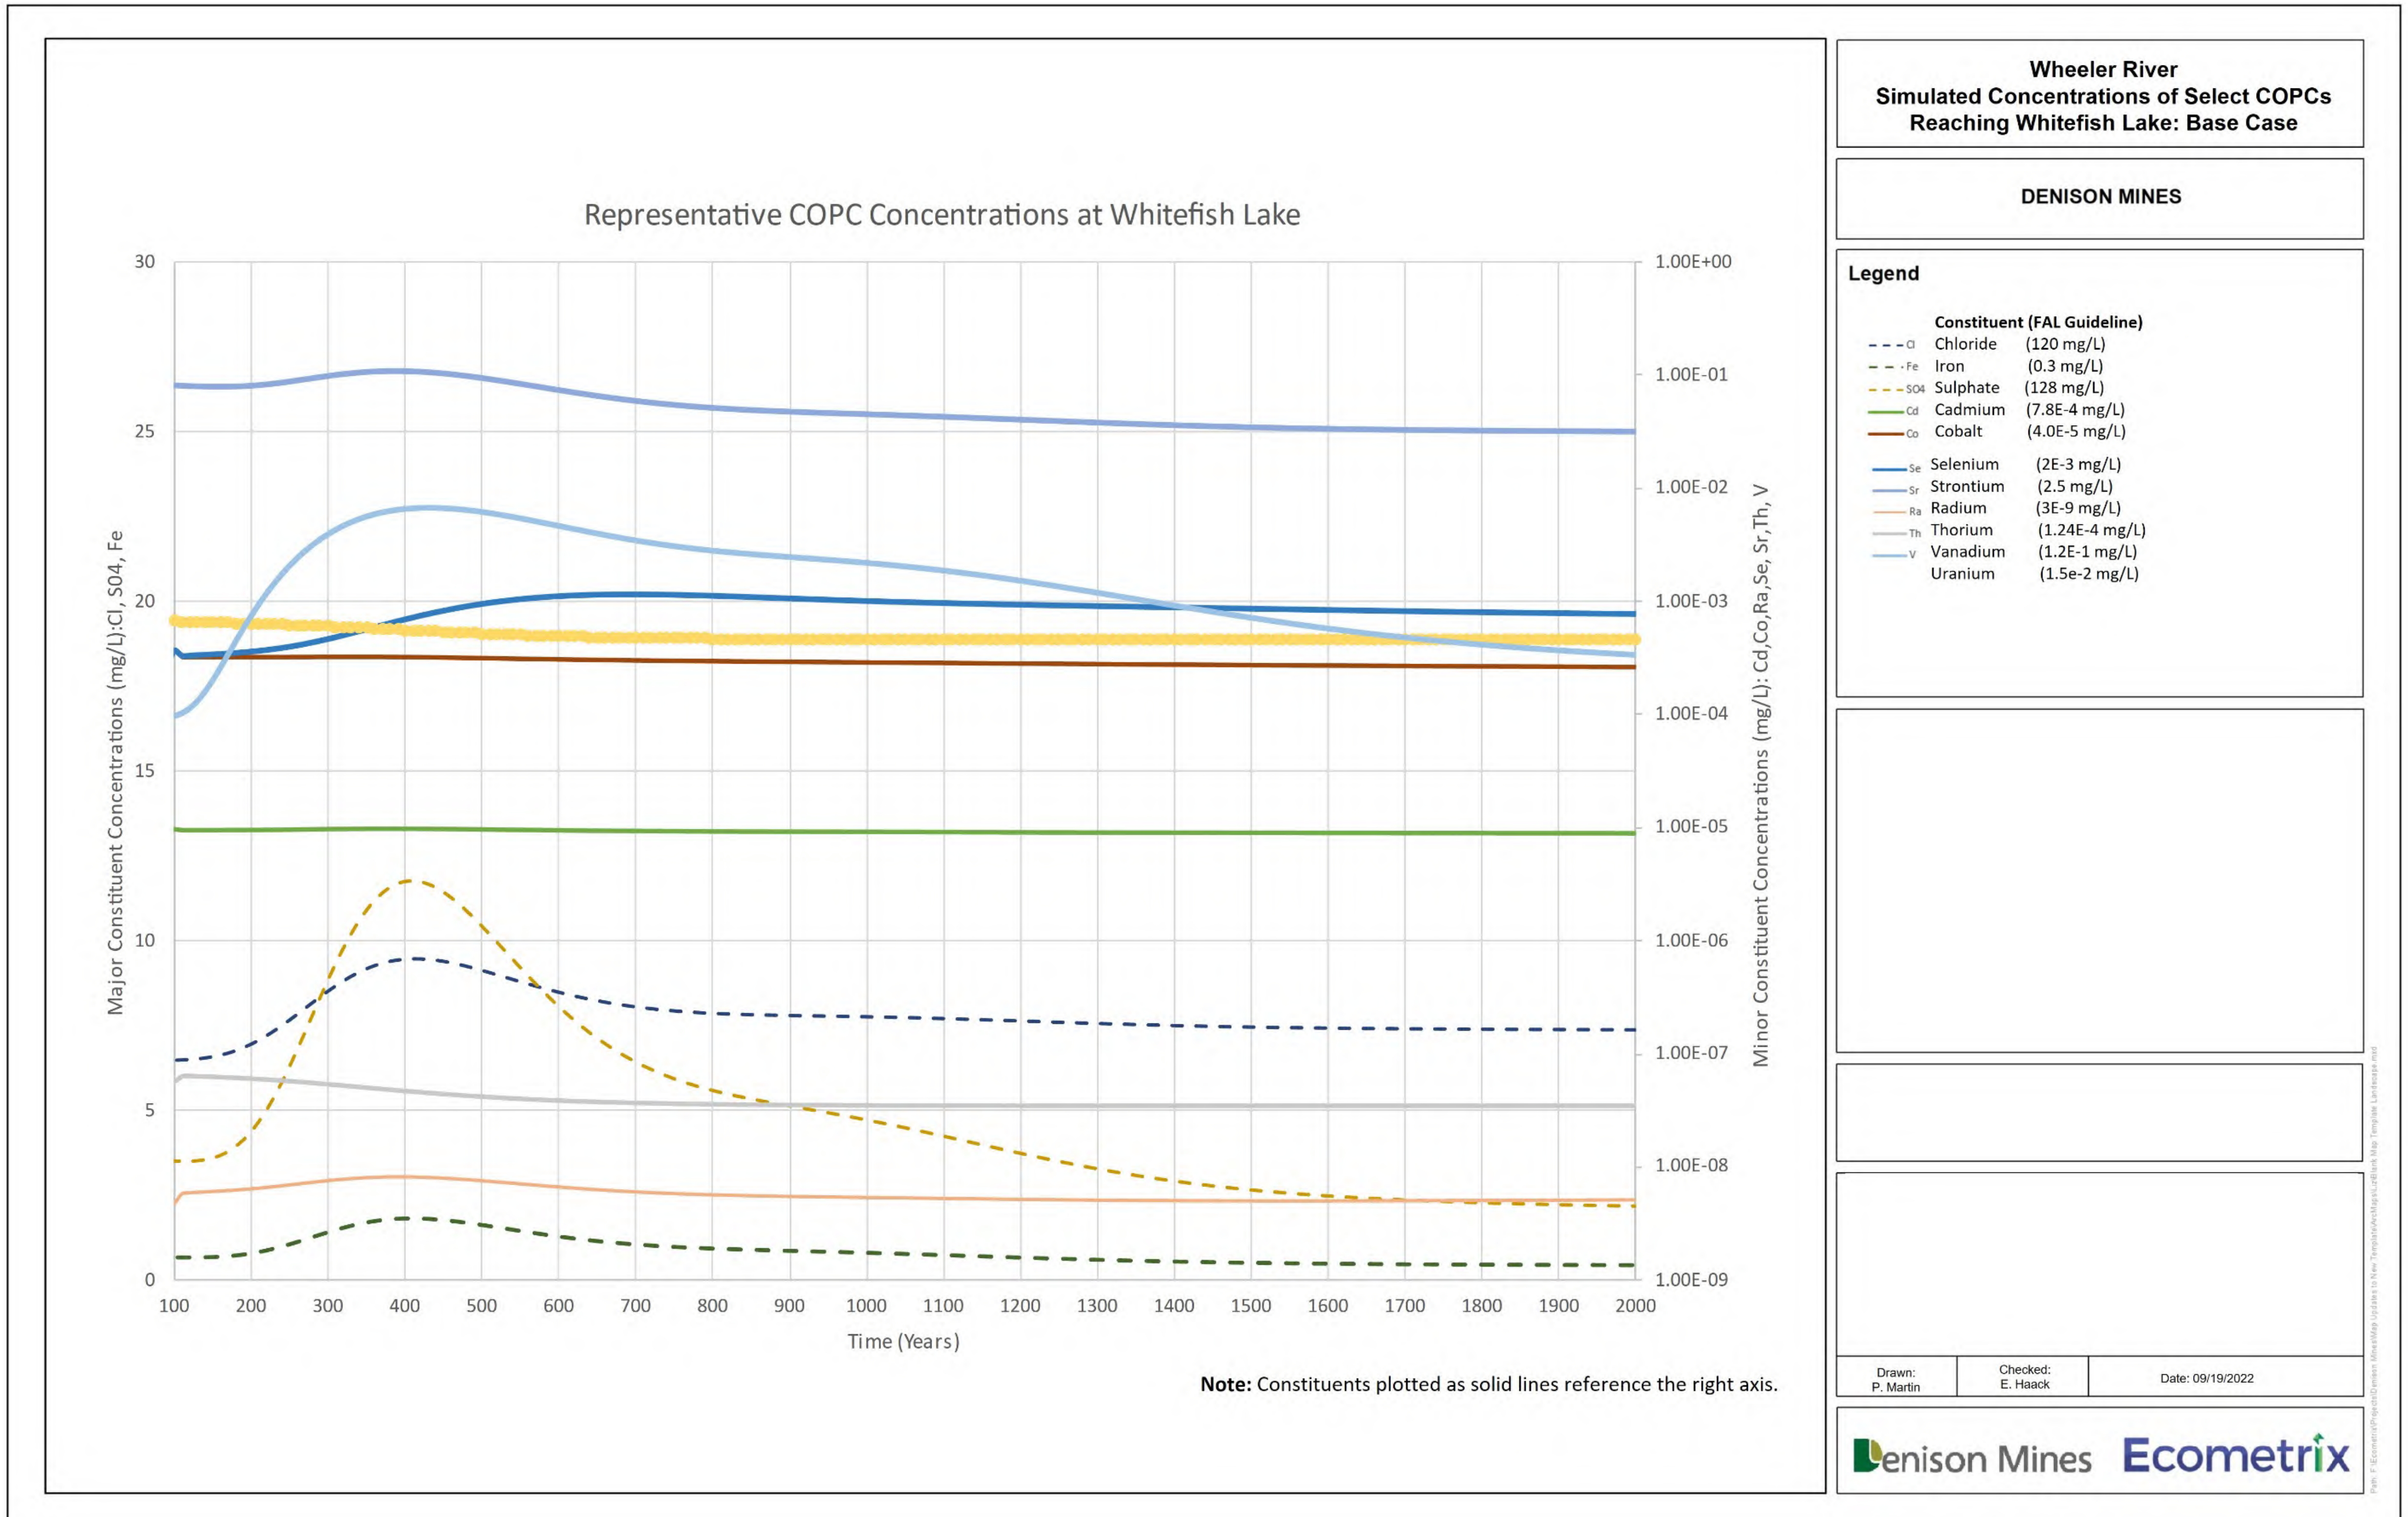

Figure 7.6-13: Simulated Concentrations of Select Constituents of Potential Concern Reaching Whitefish Lake – Base Case

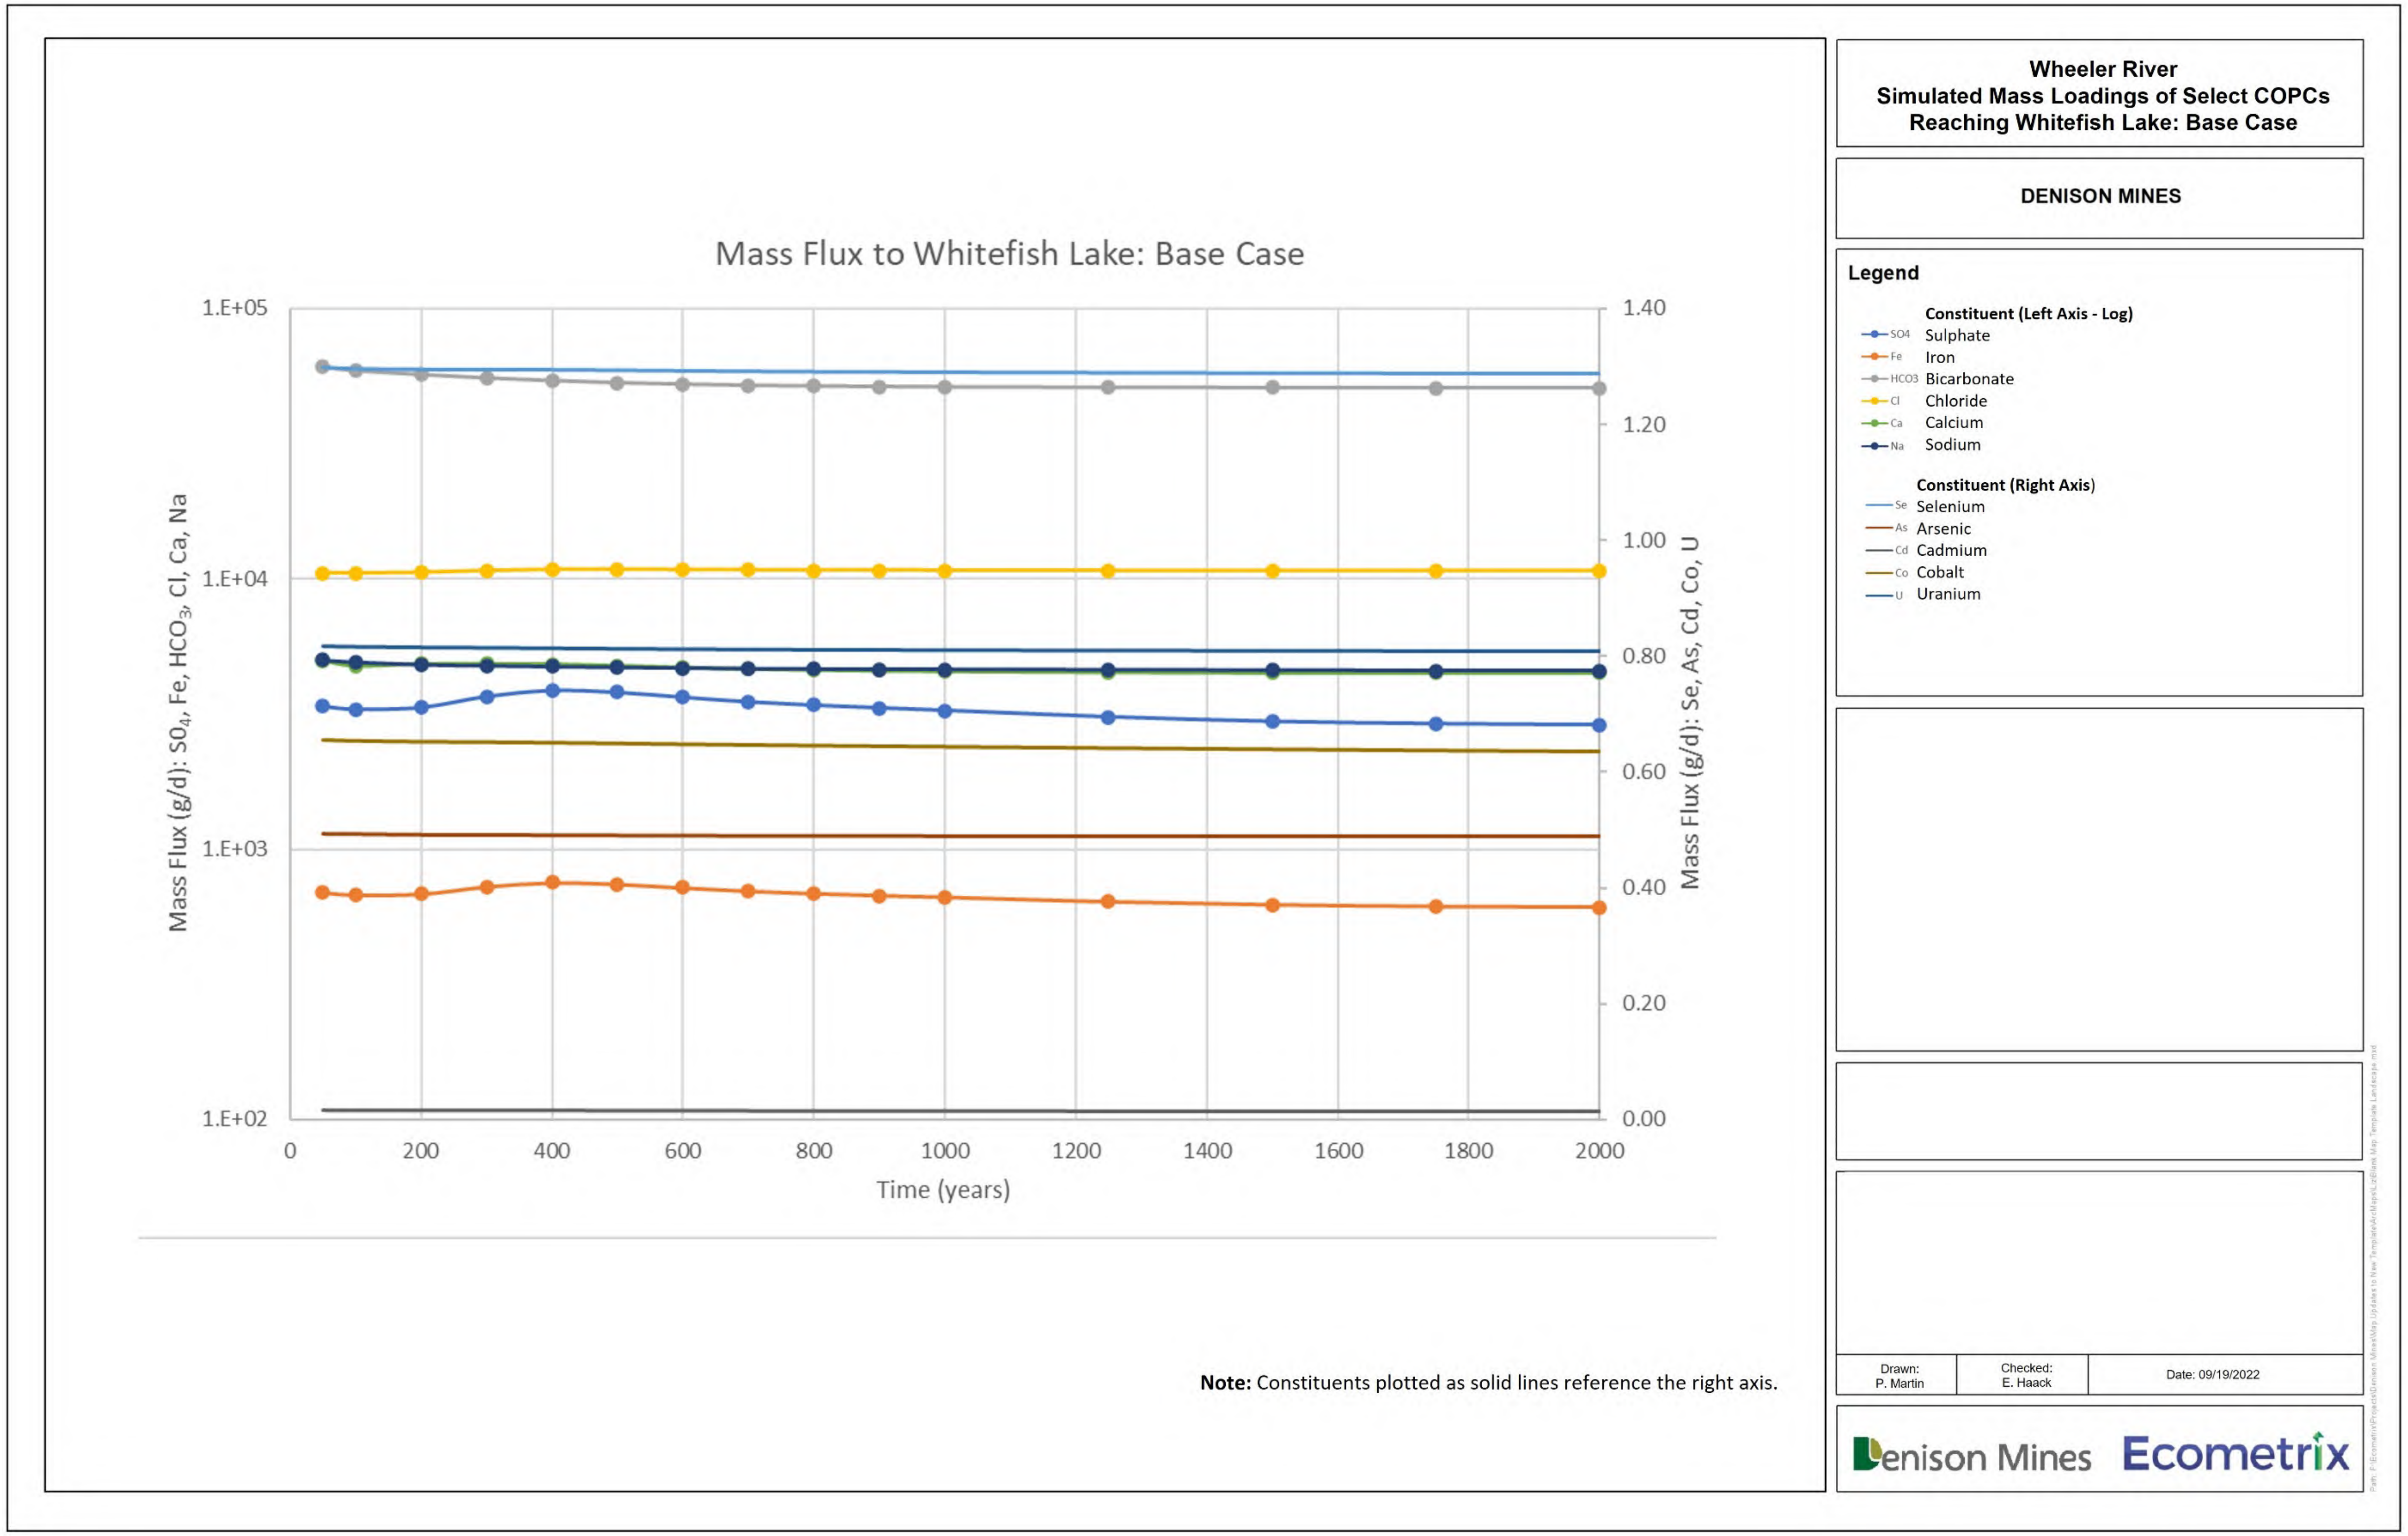

Figure 7.6-14: Simulated Mass Loading of Select Constituents of Potential Concern Reaching Whitefish Lake – Base Case

7.6.2.3 Significance and Confidence

Numerical models are approximations of the real-world environment and generalizations are necessary to take a complex hydrogeologic system and bring it into the numerical model. As such, there is inherent uncertainty associated with groundwater flow and reactive transport modelling presented in the previous sections and Appendix 7-C.

Despite the inherent uncertainty, confidence in the simulated hydrogeologic conditions is provided by the following:

- Model calibration that fits all data to within a tolerance of 2 m, with calibration residuals randomly distributed within the area of interest. The model calibration also includes simulated flow rates through the model that are consistent with observed baseflow estimates. The model calibration was achieved with relatively minor deviation from the conceptualized model parameters. These considerations together illustrate that the model developed provides an excellent representation of observed hydrogeologic conditions.
- A model parameter uncertainty assessment was completed to generate alternative calibrated parameter distributions. The parameter sets with higher hydraulic conductivity values, which are expected to produce higher flow velocities, were carried forward and used to evaluate prediction uncertainty regarding COPC concentrations reaching Whitefish Lake.
- Fifteen uncertainty scenarios were developed to test the implication of assumptions regarding the source condition, hydrogeologic conductivity along the flow path, transport parameter, and geochemical reactions on predicted concentrations reaching Whitefish Lake. All scenarios produced similar COPC plume transport and peak concentrations arriving at Whitefish Lake.

Together, the abovementioned factors provide confidence that the predicted outcomes (i.e., COPC concentrations reaching Whitefish Lake) are representative. The uncertainty analysis provides an understanding of how different the results could be should parameters differ from the best estimate parameters. All simulations indicate that the natural hydrogeologic environment has a high capacity for attenuating concentrations of COPCs from the mining area post-decommissioning.

Despite this confidence, groundwater monitoring planned for during Operation, Decommissioning, and Post-Decommissioning will be used to guide adaptive management. The model predictions will be updated if monitoring data indicate conditions meaningfully different from those simulated and/or if new information becomes available that might affect modelling assumptions. Management approaches will be updated as required to safeguard the environment.

Regarding significance determination, Geology, Groundwater Quality, and Groundwater Quantity are intermediate VCs and the significance of any associated residual effects are assessed within the context as a pathway to effects on receptor VCs. A change in an intermediate VC may lead to an effect on a receptor VC. Receptor VCs are generally biological or integrated assessment endpoints. Significance determination is not completed on intermediate VCs, but integrated into the residual effect evaluation, residual effect characterization, and significance determination for related receptor VCs. The receptor VCs for Geology are Terrain, and the receptor VCs for Groundwater Quality and Groundwater Quantity are carried into the aquatic environment through various VCs.

7.7 Cumulative Effects

The cumulative effects assessment considers whether the residual adverse effects of the Project on the Geology and Groundwater VCs will overlap spatially and/or temporally with the same kind of residual adverse effects on the VC resulting from other past, present, and reasonably foreseeable projects and activities

Existing and reasonably foreseeable projects within the Wheeler River system that have been considered for potential to interact with the Geology and Groundwater VCs include the following existing mines and mills: Cameco Cigar Lake Mine, Cameco Key Lake Operation, and Cameco McArthur River Operation.

No cumulative effects are expected for the Geology VC as a result of the Project. Subsidence is expected to be limited in terms of vertical displacement, if detectable, and localized to a small portion of the Project Area that does not spatially overlap with other project footprints. The Geology VC is not considered further under cumulative effects.

No significant residual effects were determined for the Groundwater VC (quantity) as a result of the Project. Changes to surface water levels and flows are expected to be well below criteria identifying a residual effect during all phases of the Project. Furthermore, Project-related interactions are predicted to be limited spatially and temporally. Spatially, the interactions of the Project with the Surface Water Quantity VC are highly localized to the LSA, and specifically to Whitefish Lake (LA-5), and is not further propagated downstream of this immediate area. Project-related interactions do not extend beyond the LSA into the RSA. This is due to the small footprint of the Project and relatively small change in groundwater discharge, which results in a very small change in surface water levels in Whitefish Lake during all Project phases.

Project residual effects on the Groundwater VC (quality) relate to changes (increases) in constituent concentrations in groundwater during all Project phases, and the associated change in loadings of these constituents to local receiving environments. Such changes are predicted to be negligible to low in magnitude and limited to the LSA. For example, during Construction, there are no activities expected to interact with the Groundwater VC (quality). During Operation, engineering measures will be in place to mitigate any changes to water quality. Following Decommissioning and the restoration of groundwater flow patterns that are similar to pre-mining conditions, changes to groundwater, limited to the LSA, do not extend to the RSA.

The Project is situated approximately 35 km (straight distance) northeast of the Key Lake Operation, 35 km southwest of the McArthur River Operation, and 85 km southwest of the Cigar

Lake Mine. These projects do not spatially overlap with the Project LSA and are not further considered under cumulative effects.

7.7.1 Climate Change Considerations

Climate change was evaluated qualitatively for the Geology and Groundwater VCs. Climate change is not anticipated to affect subsidence; therefore, the Geology VC is not anticipated to be affected. With regards to the Groundwater VC, climate change may affect the overall hydrological water balance for the Project. As discussed in Section 8.1.3.3 in Section 8, several parameters influence the water balance for the Project, including mean annual temperature, surface wind speed, total precipitation, and snow depth. Mean annual temperature and surface wind speed affect evaporation while total precipitation and snow depth affect local runoff. In a scenario of increased precipitation and decreased or constant evaporation, climate change may result in greater flows in the Wheeler River drainage system (see Section 8.1.7.6 in Section 8) and increased recharge to groundwater. The 3D hydrogeological model for the LSA shows 99% of local recharge remains within the shallow groundwater system (Potential Effect #1: Groundwater Quantity – Construction to Decommissioning (General Activities 7.4.2.1). The consequences would be increased discharge to Whitefish Lake, combined with an increase in available water inputs to the lake from additional precipitation, and subsequent runoff with more water available for dilution. Groundwater quality discharging to Whitefish Lake would be similar or improved under this climate change scenario compared to the EA case.

Quantification of the effects of climate change were not specifically addressed because the case of reduced groundwater recharge (i.e., the most relevant parameter which could change within the groundwater flow system), and thus a lower driving force for transport, was considered less conservative than the scenarios tested.

Overall, the cumulative effects on the Groundwater VC from climate change are predicted to be minimal.

7.8 Monitoring and Follow-up

For the purposes of this EIS, monitoring and follow-up are defined as follows:

- monitoring programs are designed to meet regulatory requirements (e.g., permit or license conditions) and/or to demonstrate compliance with environmental commitments made in the EIS; and
- follow-up programs are designed to address any uncertainties identified during the EA process (e.g., to verify predictions made during the EIS; to determine the effectiveness of proposed and implemented mitigation measures) and to determine if and when to implement adaptive management measures.

7.8.1 Monitoring of Surface Terrain

Subsidence at ground surface within the wellfield will be evaluated from Construction through to Decommissioning by monitoring the elevation of collars (top of pipe) for wells within the wellfield.

Additional details include the following:

Initial wellfield construction primarily consisting of earthworks to level the pertinent wellfield phases will be guided by Lidar surveys to provide a consistent datum prior to the installation of any well type (monitoring, injection, recovery, freeze) within the wellfield.

The subsequent installation of any well type is located on a ‘easting’ and ‘northing’ basis guided by a differential global positioning system (DGPS) with accuracy of within 5 cm. Although DGPS systems can measure a point in the vertical or ‘Y’ direction with a comparable level of accuracy to the ‘X’ and ‘Y’, the vertical datum of any installed well will be further validated by use of stadia rods, which have accuracy to within 5 mm.

The top of collar elevation of all newly installed wells will be measured to a known datum located off the wellfield. As part of annual inspections well collar elevations will be measured on a regular basis and recorded relative to the prior years’ measurements to determine the degree (if any) subsidence occurring within the well itself that may be attributable to sloughing or shifting of a well at depth. Measurements of the well collar elevations are a surveying industry standard tool for determination of any vertical movement within a well itself.

Satellite system’s such as InSAR may be utilized to complement the stadia rod measurements on an as needed basis; however, due to the negligible subsidence (<10 mm) anticipated the system is envisioned to have its limitations with emphasis and reliance placed on site specific measurements.

The proposed monitoring program, as conceptually described above, will be documented more formally as part of the overall operations management program prior to establishment of the well field. The monitoring program will include a contingency plan whose objective would be to facilitate the timely identification of, and response(s) to, potentially emerging conditions whereby routine monitoring data indicate performance is not meeting expectations (e.g., levels of subsidence are outside the range of expectations). The contingency plan conceptually would identify performance objectives, key performance indicators and measurement endpoints, triggers that would describe conditions, when met, where a response is required and a tiered-response plan in which an emerging issue would be confirmed (or not), with successive levels of response, including investigation of cause and risk, investigation of strategies to mitigate risk and implementation of preferred risk mitigation.

7.8.2 Groundwater Monitoring

The Project has the potential to directly (through the ISR process) or indirectly influence groundwater quality and/or quantity near the Project Area. Groundwater conditions will be monitored extensively prior to, during, and post Operation. A detailed Groundwater Protection and Groundwater Monitoring Plan will be provided for the Project. The GWMP will be informed by the understanding of existing groundwater conditions at the Project Area (Appendix 7-A), the reactive transport modelling of groundwater COPCs associated with the restored mining area (Appendix 7-C), and the commitments made within the Geology and Groundwater section of the EIS.

Groundwater protection and groundwater monitoring programs are mandatory components of the CSA N288.7:15 standard *Groundwater protection programs at Class I nuclear facilities and uranium mines and mills* (CSA 2015). The GWMP is a 'living document' that will be adapted and updated as required to achieve the level of environmental protection committed to in the EIS, over the life of the Project.

The requirements of the GWMP are to demonstrate, during each Project phase, that:

- excursions are not occurring; if excursions do occur, an early warning/timely signal will be provided of when and where they are occurring such that appropriate further evaluation and actions can be undertaken;
- commitments made in the EA are being achieved; and
- protection of groundwater end use/receiving environment is being achieved.

The groundwater well monitoring network and sampling plan will be flexible and adapted at each stage to identify any changes in groundwater quality and quantity associated with mining activities in a timely fashion. The spatial pattern of monitoring wells (i.e., well locations and density) and the sampling schedule will reflect the spatial and temporal distribution of COPCs, guided by anticipated operational conditions and by the range of constituent behaviours identified in the site-specific COPC fate and transport modelling. The monitoring system will be designed at each phase of the Project to provide adequate coverage of all hydrostratigraphic units.

The chemical and physical constituents to be monitored in groundwater include the COPCs provided in Section 7.6.2.1. Other major ion constituents of groundwater are also recommended (e.g., total alkalinity, bicarbonate, carbonate, sodium, magnesium, potassium, and calcium). Additional COPCs identified in association with surface facilities are nitrogen species (i.e., ammonium, nitrate, and nitrite) and volatile organic compounds.

Not all COPCs will be measured in groundwater at all sampling locations or during each sampling event. Higher priority will be given to some parameters that are KIs of site activity-related changes in water quality. Constituents to be considered as key performance indicators in groundwater are listed in the following bullets. The first three may be considered for continuous measurement.

- Hydraulic response – The mining fluids are injected at operating pressures that exceed ambient subsurface pressures. Changes in hydraulic head (or the hydraulic response) is a very sensitive measure to changes in pressure. A hydraulic response would be interpreted to indicate fluid movement between the mining chamber and the observation point and may indicate that an excursion has occurred.
- Temperature – Ambient groundwater temperatures in the Lower Sandstone Aquifer are expected to be less than 10°C. The temperature of the mining fluids is expected to exceed these temperatures to some extent (on the order of 10°C) due to reactions between the ore and the fluids. An increase in temperature may indicate that an excursion has occurred.
- EC – The mining fluids have high total dissolved solids and associated EC/specific conductance. The specific conductance of the mining fluids is expected to exceed 15,000 µS/cm, whereas the maximum specific conductance in groundwater in the overlying Lower Sandstone Aquifer is approximately 1,000 µS/cm (Appendix 7-A). An increase in EC may indicate an excursion has occurred.
- pH – The mining fluids are expected to have a pH less than 2. Groundwater pH values are circumneutral (pH ranges from 6.3 to 7.5). A change in pH to more acidic values (less than 6) may indicate an excursion has occurred.
- ORP – The mining fluids are expected to have an ORP that is very oxidizing (greater than 400 mV). The groundwater is anoxic and has ORP values that are typically less than 150 mV. An increase in ORP may indicate an excursion has occurred.
- Sulphate – The primary chemical in the injected fluids is sulfuric acid. During metallurgical testing completed for the Project to date, sulphate concentrations in the leachate exceeded 40,000 mg/L. Concentrations of sulphate in groundwater may be influenced by interactions with other groundwater/mining fluid constituents; however, elevated concentrations of sulphate may indicate an excursion has occurred.
- Dissolved uranium – Mobilized uranium in the injected fluids may reach concentration orders of magnitude higher than in groundwater. Should an excursion occur, it is important to understand the associated dissolved uranium concentration.

One additional parameter, chloride, has been included as a key parameter. It is possible that mobilized chloride concentrations are higher in the injected fluids than in groundwater; however, this is not the primary intent of including this parameter in the routine monitoring. Rather, calcium chloride brine makes up fluids that maintain the freeze wall. Thus, a change in the concentration of chloride - and EC - may indicate that a loss of freezing capacity has occurred in the freeze wall, representing an excursion, and delineate the extent of brine migration. However, loss of freezing is considered as an accident and malfunction, and loss of freezing is expected to be signaled much earlier by operational monitoring (e.g., pressure changes in the cooling circuit) than through monitoring of water quality.

In addition to the above parameters, tritium concentrations will also be measured in groundwater to further analyze the potential to age groundwater in the subsurface.

The list of parameters being analyzed at any given location and time will be rationalized in the GWMP for each Project phase and each Project area (e.g., surface facilities versus mining area versus freeze wall perimeter).

7.8.2.1 Surface Facilities

Excursions associated with surface facilities are changes in groundwater flow conditions or groundwater quality that represent Project design failure. Such failures include spills, leaks, or uncontrolled leachate from ponds and landfills that may cause changes to the shallow groundwater flow conditions and/or groundwater quality.

A groundwater monitoring network will be developed to monitor groundwater conditions upgradient, on the perimeter, and downgradient of the surface facilities outlined in Table 7.4-7. Surface facilities do not extend more than approximately 4 metres below ground surface (mbgs); thus, groundwater wells associated with the surface facilities will be shallow wells installed for the most part in the overburden materials. The monitoring well network can be built up over time in alignment with construction and operation of the facilities. Sufficient time will be given prior to Operation to collect baseline samples at each location. Because baseline conditions in shallow groundwater have been established (Appendix 7-A), the objective of collecting baseline samples from wells in the surface infrastructure groundwater monitoring well network is to confirm that conditions are aligned with those understood from baseline conditions. Samples collected from the surface facilities groundwater monitoring wells prior to Operation should be collected on two occasions, and preferably in two seasons.

During Operation, groundwater will be monitored across the monitoring network and samples submitted to an accredited laboratory for analysis of the full suite of COPCs or for KI parameters. Sampling frequency will be at least semi annually, and may be more frequent in wells surrounding specific facilities.

During Decommissioning, shallow monitoring wells associated with decommissioned surface facilities will be abandoned in accordance with provincial well abandonment legislation. Facilities retained on site, and their decommissioned configurations, include:

- the industrial landfill containing low-level (as defined by the Canadian Nuclear Safety Commission) radiological waste contamination, which will have an engineered cover installed to limit water infiltration into the industrial wastes; and
- the material (primarily gypsum) in the Industrial Wastewater Treatment Plant precipitate pond, which will be covered and decommissioned in place.

Monitoring wells upgradient, on the perimeter, and downgradient of these facilities will be retained to demonstrate chemical stability of groundwater surrounding and downgradient of these facilities after the covers have been placed. Groundwater quality associated with these facilities will have been sampled relatively extensively during Operation. Thus, there will be a good understanding of the chemical stability prior to cover placement. It is expected that long-term chemical stability, post cover placement, will be demonstrated in two to three years of sampling on a seasonal (spring, summer, fall/winter) basis. Monitoring of these wells may extend into early Post-Decommissioning.

Response to potential excursions will follow the Excursion Contingency Plan provided in Section 7.8.2.3.

7.8.2.2 In Situ Recovery Mining area

7.8.2.2.1 Pre-Construction and Construction

The groundwater monitoring network for the Operation phase will be installed during pre-construction and Construction. Existing monitoring wells will be used as much as possible, but it is anticipated that several new wells will be installed to meet monitoring needs. During pre-construction and Construction, existing/baseline conditions will be established in each well under pre-Operation conditions. As such, data collected are supplemental to the baseline conditions understood for the Project (Appendix 7-A). Supplemental data are anticipated to include:

- additional spatial coverage of baseline conditions within the active mining area; and
- additional data for water quality within the Desilicified Zone Aquifer.

A follow-up study is recommended to supplement the available data on hydraulic conductivity in the Desilicified Zone. Pumping tests, minimally 48-hours long, are recommended in wells on the freeze wall perimeter that are completed within desilicified sediments of the Lower Sandstone Aquifer and Intermediate Sandstone Aquitard. Additional commitments related to the Desilicified Zone include:

- assessment of vertical hydraulic conductivity;
- quantification of horizonal and vertical flow gradients; and
- identification and mapping of any structures with the potential to influence groundwater flow in the DSZ, such as fractures/fault zones.

7.8.2.2.2 Operation

The groundwater monitoring network during Operation will focus on groundwater conditions within and on the outside perimeter of the freeze wall, and evaluation of changes in groundwater quality including detection of excursions from potential loss of freezing capacity. The monitoring well network within and surrounding the freeze wall is shown at a conceptual level in Figure 7.8-1.

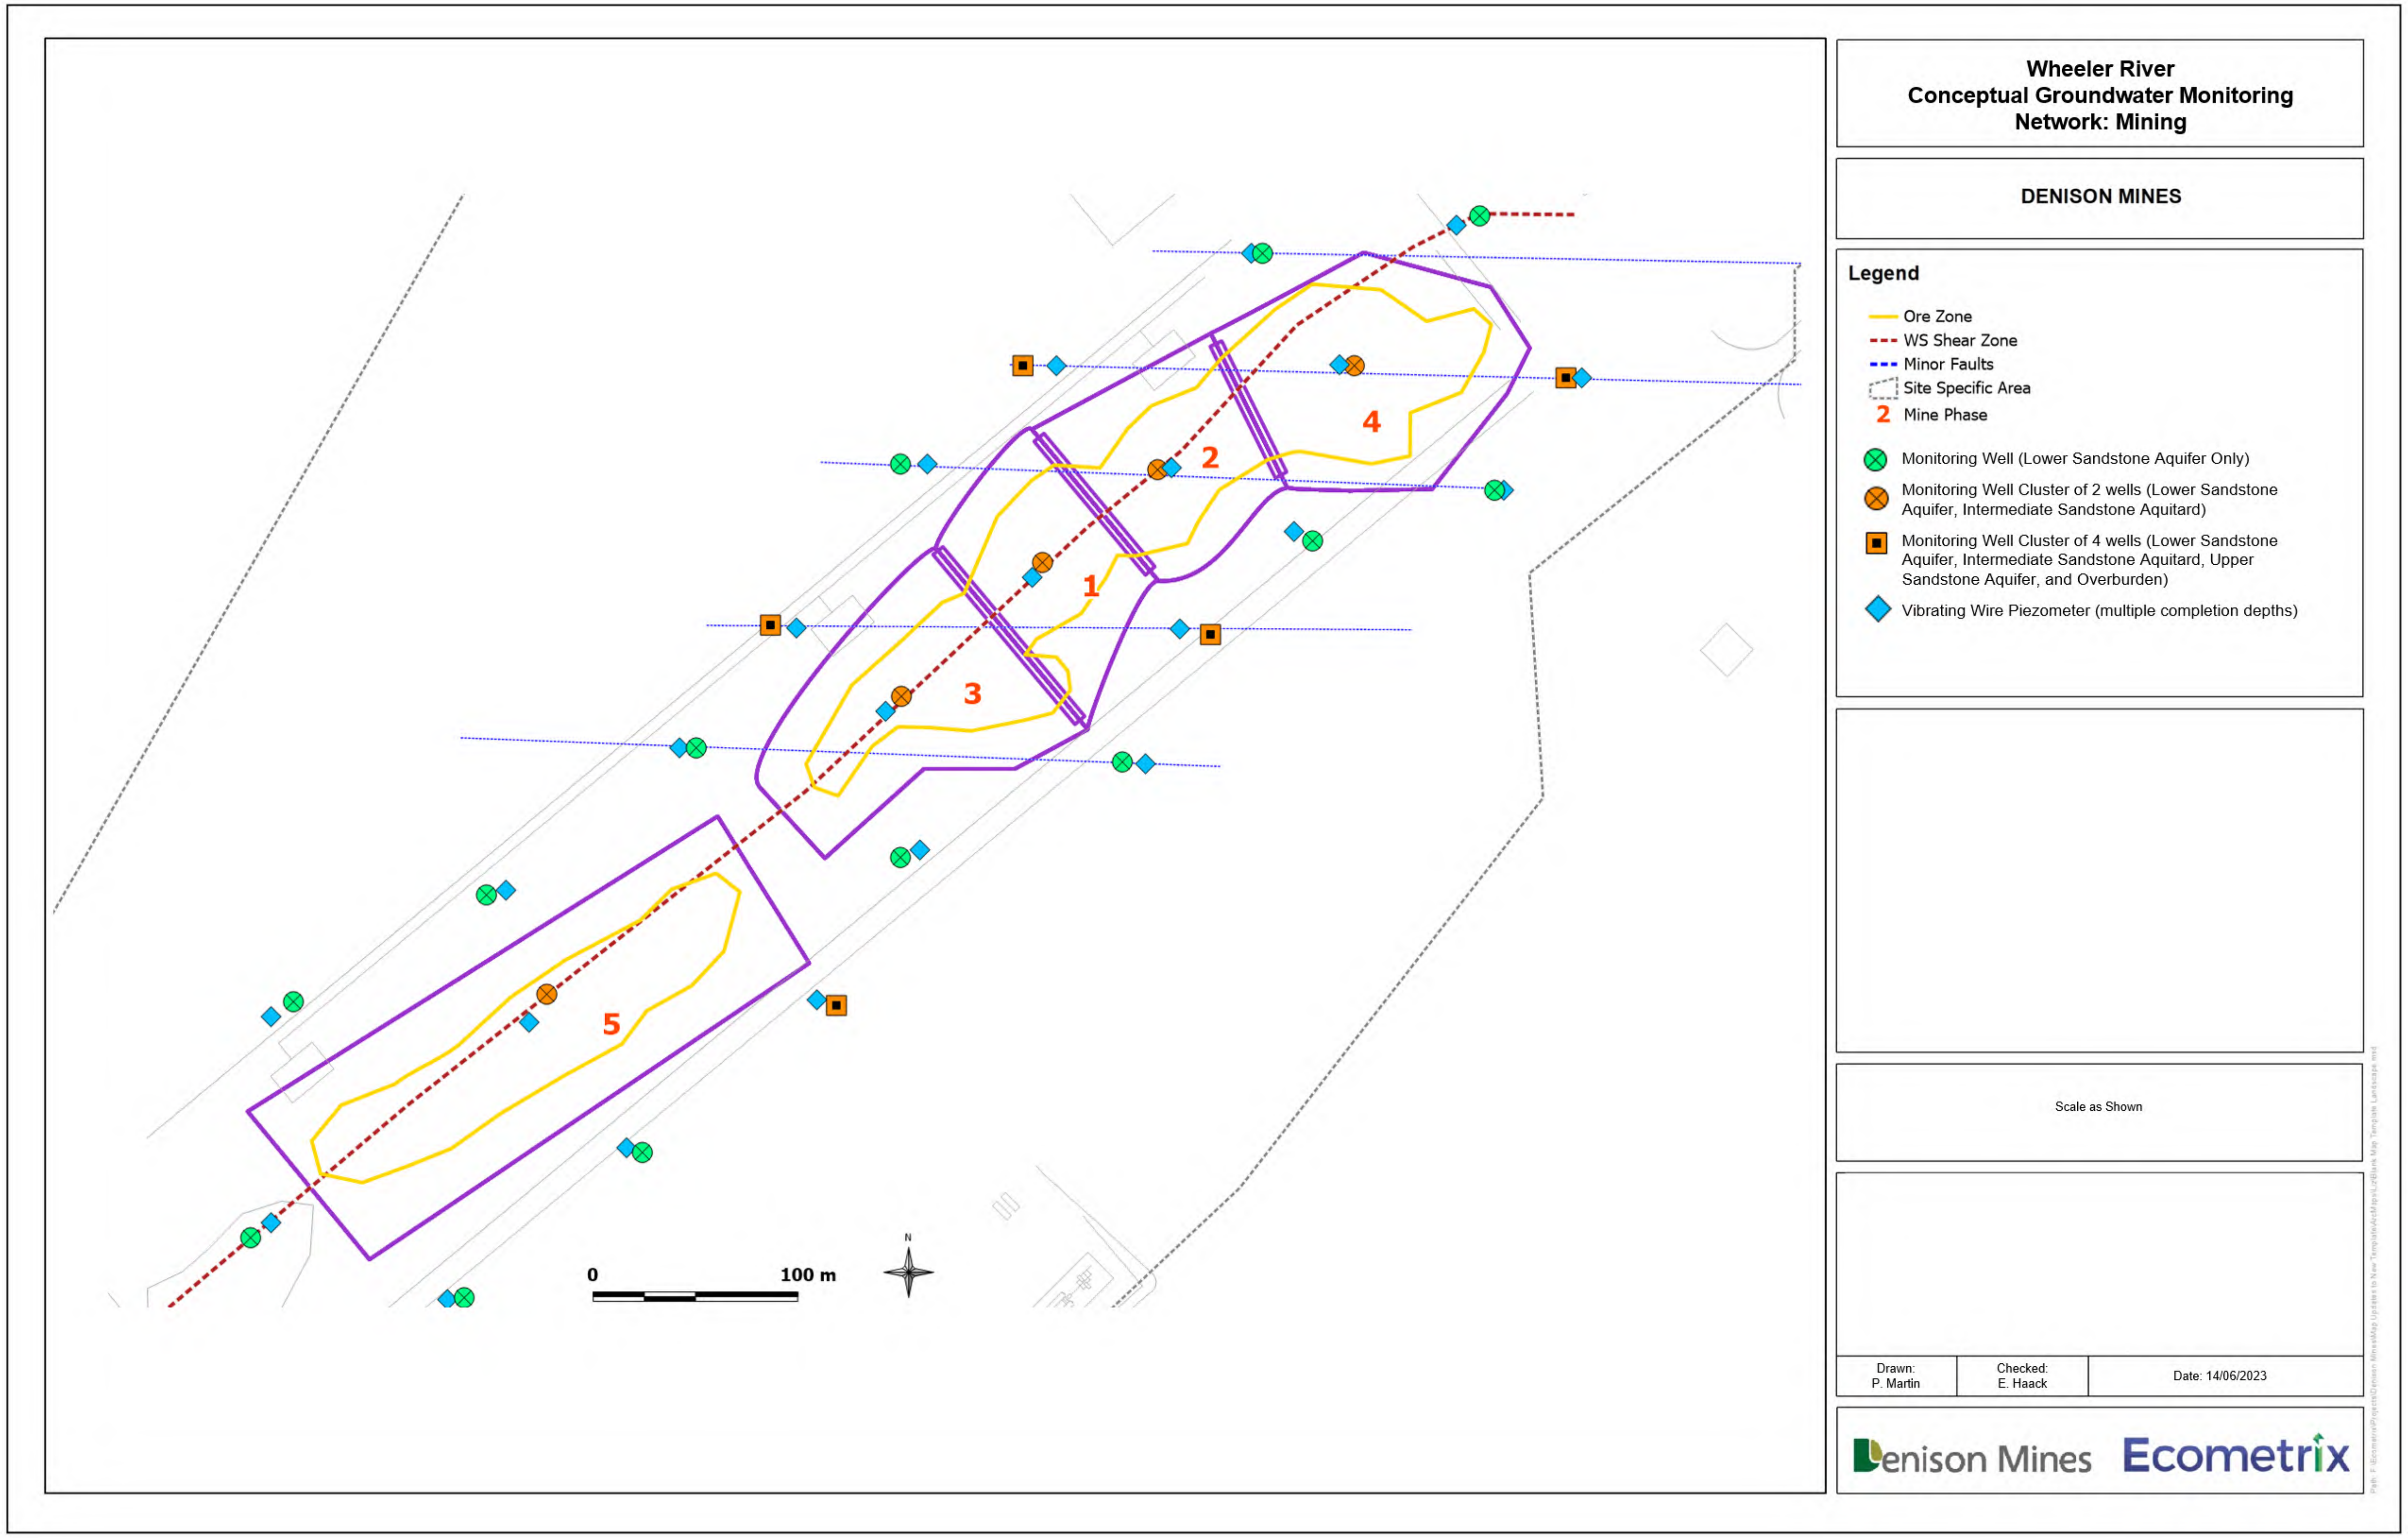

Figure 7.8-1: Conceptual Groundwater Monitoring Network – Mining

Positioning of wells for the conceptual groundwater monitoring network within and surrounding the freeze wall during the Project phases will reflect precedent from other ISR mining projects (NRC 1997, 2006; Mackin et al. 2001), which includes one well per 1.2 to 2 ha (1 ha = 10,000 m^2) within the mining area. A frequency of one well per Project phase, as shown in Figure 7.8-1, is aligned with this and results in a greater number of wells than the precedent. The maximum spacing between monitoring wells around the freeze wall perimeter will be no more than 125 m (as proposed) and will not exceed 150 m.

The wells around the perimeter of the freeze wall will be positioned 20 m from the expected outside perimeter of the freeze wall. This distance was selected because:

- a response to changes in water quality from the mining area/freeze wall in the perimeter wells will be dependent on the effective porosity but is reasonably expected to occur within 8 to 10 years (this estimation reflects the geomean hydraulic conductivity of the Lower Sandstone Aquifer and Desilicified Zone [i.e., 2.2×10^{-6} m/s and 4.8×10^{-6} m/s, respectively; Appendix 7-A]); and
- it is as close to the freeze wall as is considered advisable to represent undisturbed/ambient conditions.

The conceptual monitoring network consists of four types of installations:

- vibrating wire piezometers (VWP);
- multi-level wells or well nests/clusters of four groundwater monitoring wells;
- multi-level wells or well nests/clusters of two groundwater monitoring wells; and
- single interval groundwater monitoring wells.

Around the outside perimeter of the freeze wall, monitoring wells will generally target the Lower Sandstone Aquifer (single interval groundwater monitoring wells) as this is the most likely unit through which mobilized COPCs may migrate laterally from the mining area. In all monitoring locations, monitoring/sampling wells will be coupled with adjacent vibrating wire piezometers. The VWPs are intended to provide early warning of potential excursions by signaling any pressure changes outside the freeze wall. Adjacent to each mining Phase, the monitoring well plan also includes a cluster of four monitoring wells, wherein multiple elevations will be monitored at discrete intervals to observe any changes vertically above or below the elevations of the active mining area.

Within the footprint of each Project phase, vertical sets of wells (i.e., well clusters) and VWPs will be utilized to monitor vertical pressure changes and potential upward COPC migration. Vibrating wire piezometers will be designed to have multiple completions with depth to monitor pressure variability between the active mining area and the overlying strata.

The proposed monitoring network does not include wells installed within the ore zone within the basement aquitard, including the upper paleoweathered zone. The underlying basement rock has very low hydraulic conductivity (Table 7.3-2) that will act to limit the downward vertical migration, but severely limit the capacity of the rock to yield water for sampling. Despite the low hydraulic conductivity, the fluids injected during mining are characterized by a high density and specific gravity (greater than sea water) and have the potential to migrate downward to the base of the paleoweathered zone. Vibrating wire piezometers will delineate the pressure front in the aquitard. Should the potential for an excursion be identified through monitoring of the pressures, the process for excursions (Section 7.8.2.3) will be followed.

Per the monitoring wells and VWPs proposed in the mining area and the freeze wall perimeter are, for the most part, located along the WS Shear zone or minor faults. The placement of these wells along these features will make sure that changes in groundwater flow conditions and water quality along possible preferential pathways are being monitored.

Sampling will focus on KI parameters. Some key parameters, including hydraulic response, temperature, and EC, have been selected for continuous measurement. The VWPs measure hydraulic response and temperature. Electrical conductivity probes are proposed to be deployed at least within a subset of wells within the freeze wall and on the freeze wall perimeter. Groundwater samples will be collected at least monthly and semi-annually in the wells within the freeze wall and on the freeze wall perimeter, respectively.

7.8.2.2.3 Decommissioning

The focus of the groundwater monitoring network during Decommissioning is demonstrating groundwater remediation within the mining area to meet Decommissioning objectives and continued monitoring on the outside perimeter of the freeze wall. The groundwater monitoring network inside the freeze wall during Decommissioning has been developed conceptually and is shown in Figure 7.8-2. Outside of the freeze wall, the network of freeze wall perimeter wells and the sampling schedule will be similar to that established during Operation.

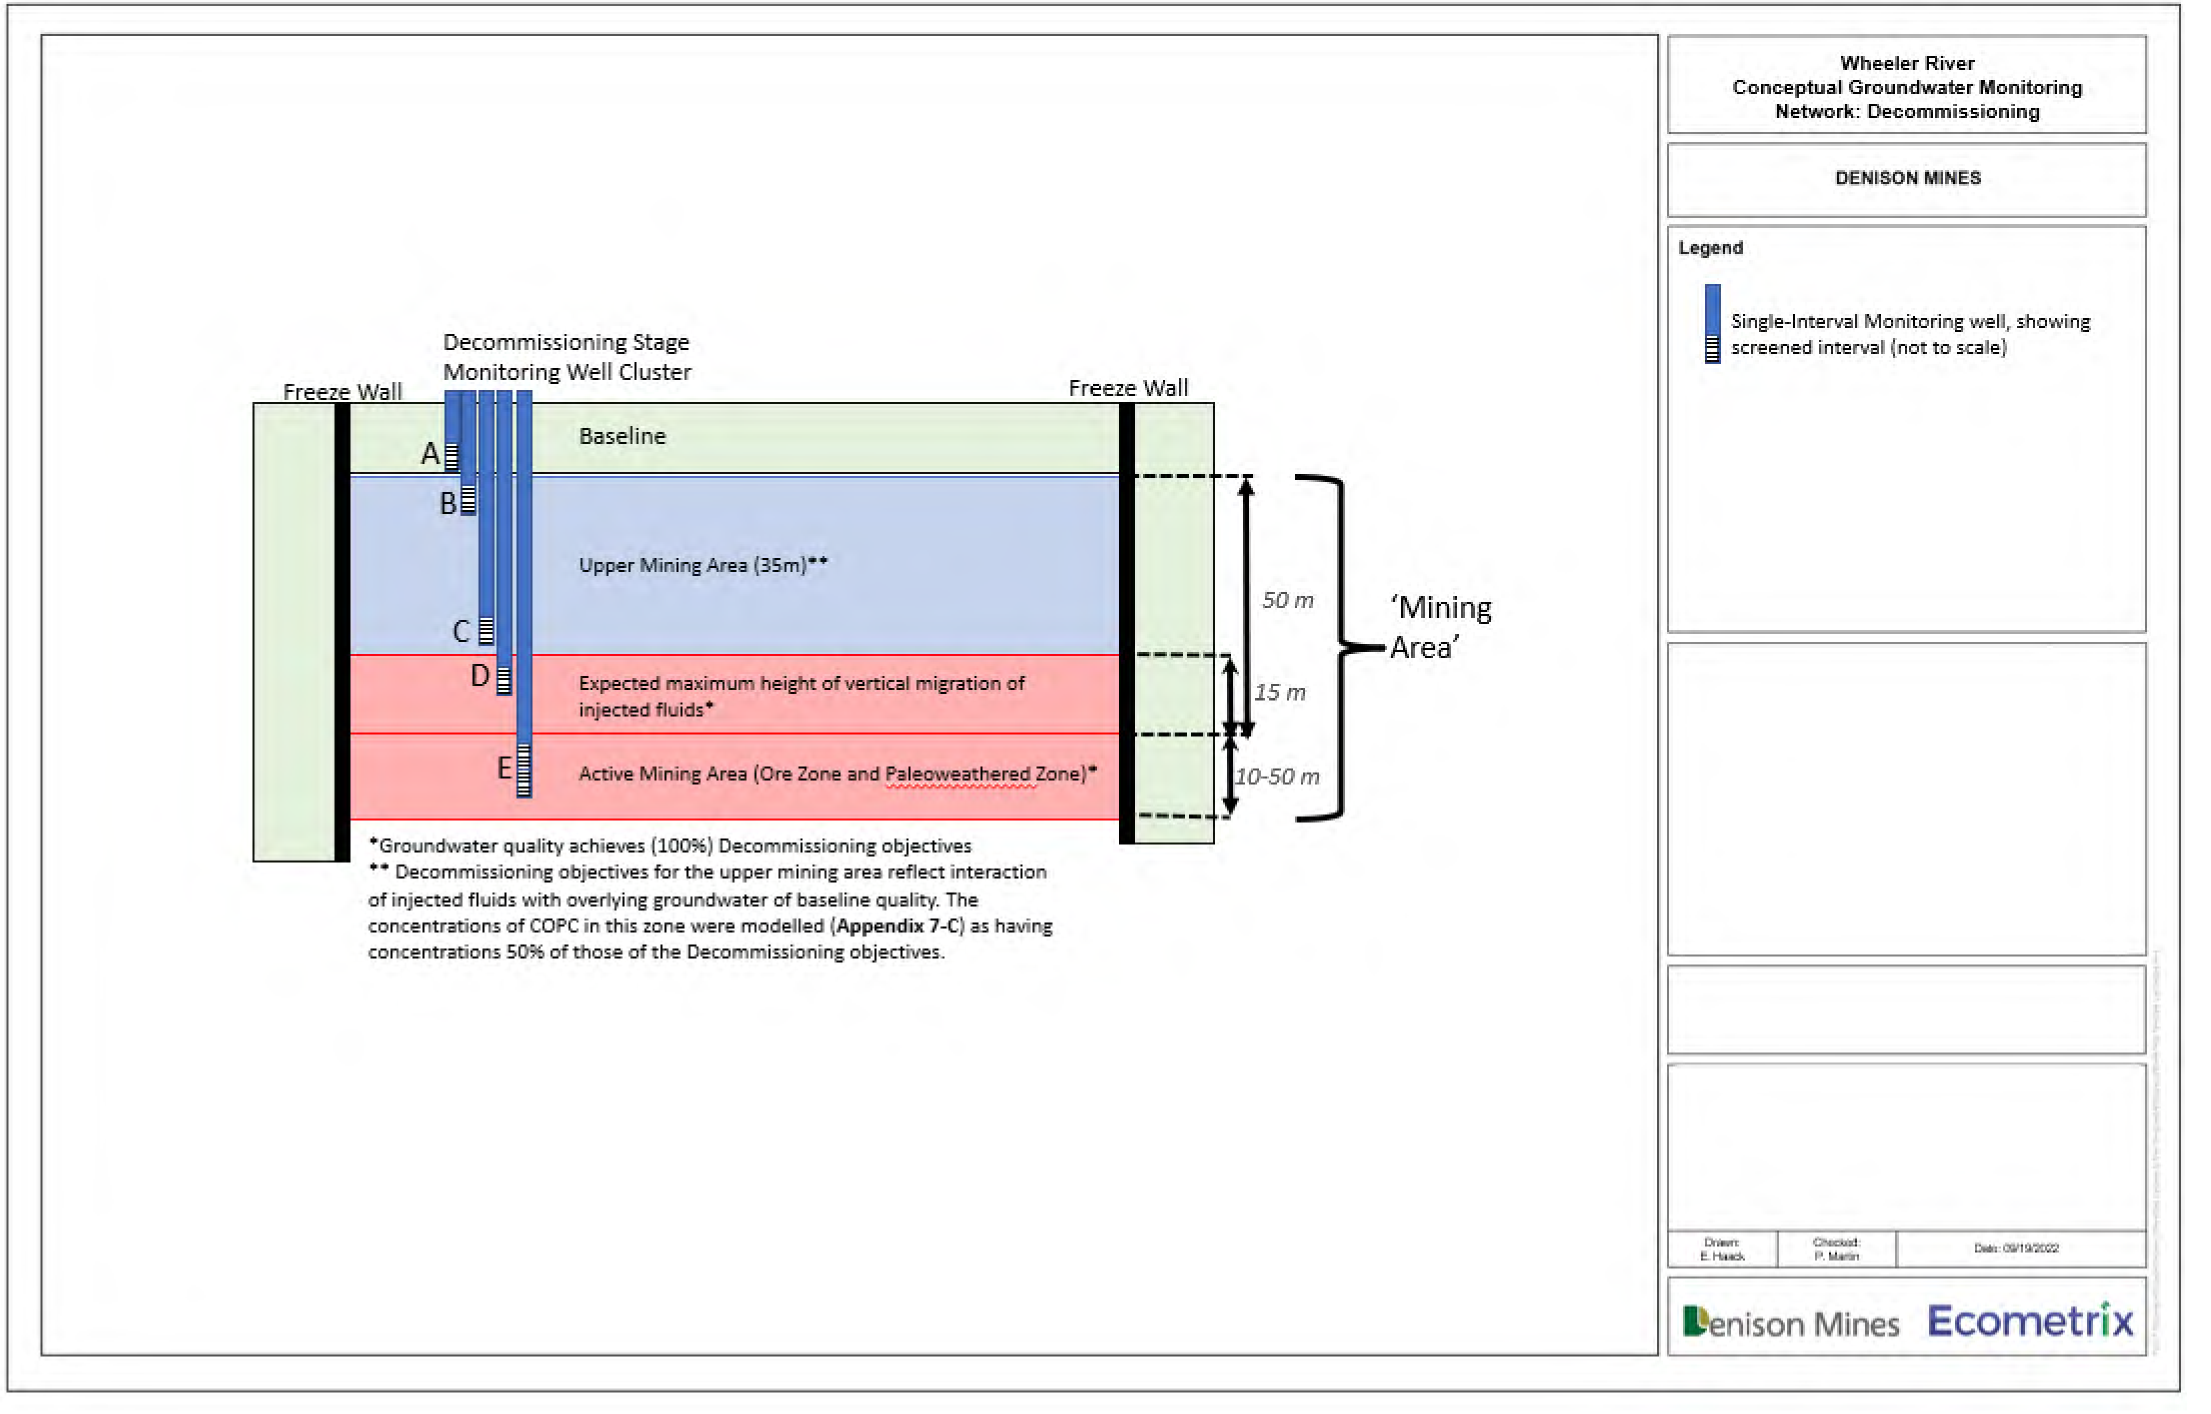

Figure 7.8-2: Conceptual Groundwater Monitoring Network – Decommissioning

At least five to seven multi-well clusters are proposed across the mined area (Figure 7.8-2). Sampling will include KI parameters or the full suite of COPCs at different times in the remediation process.

Within the freeze wall, two wells will be positioned within the active mining area to monitor conditions towards the base (well 'E') and towards the upper extent of the active mining area (well 'D'). Two wells will be positioned within the upper mining area towards the base (well 'C') and the upper extent of the zone (well 'B'). A well will also be positioned immediately above the upper mining area (well 'A') to confirm baseline water quality above the mining area.

Sampling of water quality of the water produced in the active mining area over the entire remediation process will be frequent (at least weekly) to allow the remedial approach to be adapted as required on a spatial-temporal basis. Sampling of the wells in the upper mining area and overlying Athabasca Sandstones will be seasonally during the first three years of Decommissioning and potentially more frequent during the later two years of Decommissioning to demonstrate chemical stability.

Groundwater quality is not expected to be uniform across the monitoring wells installed in the same area; for example, groundwater quality in 'D' wells across the mining area will not be uniform. As such, meeting the acceptable Decommissioning objectives will be based on statistically demonstrating that the water quality in each zone meets acceptable target values with associated levels of uncertainty (i.e., central tendency and 95% confidence intervals) and is stable over sufficient time for there to be confidence that conditions will not change.

Where possible, groundwater monitoring wells installed above the ore zone during Operation will be used for monitoring during Decommissioning. New wells will be installed as needed.

7.8.2.2.4 Post-Decommissioning

After groundwater remediation within the mining area has been completed, the freeze wall will be turned off and allowed to thaw. This will allow the eventual re-establishment of the pre-operational groundwater flow regime in the former mining area. The post-decommissioning period will extend from the end of physical decommissioning until transfer of the site into the provincial Institutional Control Program (Government of Saskatchewan 2009) or direct release of the land back to the Crown.

The primary objectives during Post-Decommissioning are to demonstrate that:

- the pre-operational flow conditions have been re-established; and
- chemical stability has been achieved.

During Post-Decommissioning, the monitoring well network will be developed (within and outside the freeze wall) and will require an augmented well network beyond the outer perimeter of the freeze wall. The highest density of wells will continue to be within the mining area, reflecting the extensive monitoring in that area during Decommissioning. The density of the freeze wall perimeter wells may need to be augmented to increase the number of clusters/multi-levels, such that there is adequate coverage of the Intermediate Sandstone Aquitard. Furthermore, a small number of additional clusters will be required in the inferred downgradient direction (i.e., to the northeast) beyond the freeze wall perimeter wells. These wells will be completed primarily in desilicified sediments of the Lower Sandstone Aquifer and Intermediate Sandstone Aquitard.

To the southwest of the freeze wall perimeter wells and further downgradient to the northeast, there will be a zone of intermediate density wells where well clusters will be positioned no more than 200 m apart along the predicted plume path, and plume delineation wells will be offset from that path in both directions. Numerical groundwater modelling simulations (Appendix 7-C) suggest that lateral migration will be limited, such that monitoring 100 m beyond the plume path will be sufficient to delineate the plume. In the upgradient direction, well clusters in the intermediate density zone will be completed in the Lower Sandstone Aquifer and Intermediate Sandstone Aquitard. In the downgradient direction, well clusters will be completed in desilicified sediments of the Lower Sandstone Aquifer and Intermediate Sandstone Aquitard, and in the Upper Sandstone and Overburden Aquifers.

Further southwest and beyond Whitefish Lake in the downgradient (northeast) direction will be low density (regional) groundwater monitoring zones. Existing regional (GWR-series) wells will be used where possible. Well clusters will monitor the Lower Sandstone Aquifer, Intermediate Sandstone Aquitard, Upper Sandstone Aquifer, and Overburden Aquifer. Well clusters will be positioned to delineate any influence of mining activities on water quality.

The groundwater constituents being measured and the frequency of sampling of wells in the Post-Decommissioning groundwater network will be identified in future iterations of the GWMP. Over the life of the Project, predictions of the assimilative capacity of the subsurface and associated migration potential for COPCs will be refined through updated reactive transport modelling. These will guide the specific details of the Post-Decommissioning GWMP.

7.8.2.3 Excursion Contingency Plan

The overall objective of the Excursion Contingency Plan as part of the GWMP is to facilitate the timely identification of, and response(s) to, potentially emerging conditions (excursions) whereby routine monitoring data indicate environmental performance is not meeting expectations.

During each mining stage, excursions signal that performance expectations are not being met.

- Mining and Decommissioning Stages:
  - Excursions are signaled by a change in water quality in specific wells compared to baseline conditions. These include wells on the perimeter and downgradient of surface facilities, the freeze wall perimeter wells, and wells within the freeze wall overlying the mining area.

  - A change in water quality is defined as an upward trend in a COPC concentration (or KI value) over a meaningful period above that statistically established as the background or baseline concentration. The upward trend is identified based on a suitable statistical test, such as the Mann Kendall Test.
- Post-Decommissioning Stage:
  - Excursion are signaled by a change in water quality that is outside of that bounded by modelling predictions.
    - The model predictions spatiotemporally bound COPC concentrations in the subsurface that do not pose a risk to the receiving environment. Water quality that is outside of this bounding is defined as representing a material increase over a meaningful period compared to the predicted values either in rate of change or magnitude of change of COPC concentrations.

In the previous statements, a meaningful period refers to an appropriate number of sampling intervals. The number of sampling intervals defining a trend above control limits (baseline conditions or modelling predictions) that is considered appropriate will depend on the frequency of sampling and the location of the wells, and will be defined in the GWMP.

An excursion, signaled in the manner previously described, triggers a response. The response plan is tiered and involves confirmation of an excursion with successive levels of response, including:

- investigation of cause and risk;
- investigation of strategies to mitigate risk; and
- implementation of preferred risk mitigation.

The GWMP will provide details regarding the aforementioned investigative and mitigative actions. The actions are summarized in the following levels:

Level 1 – Confirmation of Validity of the Sample Results

In Level 1, the objective is to confirm the validity of the results signaling the excursion. This will be done through review of QA/QC information that was collected coincident with the results signaling the excursion. These data are assessed to determine whether there are issues with the sample result, such that the result is considered to be accurate or not. The laboratory would also be consulted in order to confirm the accuracy of reporting.

In instances where sample results are validated, Level 2 actions are implemented; conversely, if the data cannot be validated, it may be appropriate to re-sample and increase sampling frequency to confirm the results, or to end the inquiry and return to routine sampling.

For reference, validation of the results for individual sampling events will be carried out upon receipt of those data since follow-up activities associated with validation may be time sensitive, and also to make sure that implementation of Level 2 actions, when appropriate, is done in a timely manner. Such follow-up activities could include, beyond confirmation of sampling and laboratory QA/QC, the re-analysis of samples by the laboratory or re-sampling.

Level 2 – Investigation of Cause and Risk

An investigation to confirm that the observations signalling an excursion are related to Project activities and to determine the potential cause will be initiated. The investigation could take many forms but ultimately the investigation should identify a causal mechanism to confirm that the sample results are related to mining activities or surface facilities. In addition, consideration of the results within a temporal context will be undertaken to understand the extent to which future change might be expected. Such an analysis supports the assessment of risk, as described below.

Risk associated with the confirmed Excursion Contingency Plan trigger should be described. Risk in this context is risk to surface water quality and biota. The characterization of risk is meant to contribute to decision making for next steps, with respect to both scope and timing.

The nature of the Level 2 response is likely to vary depending on the result and level of investigation required; as such, the response times may vary (e.g., one to several months) but will be conducted in a timely manner. By way of example, in the instance that the investigation process identifies that the trigger exceedance is in fact site-related, follow up would be appropriate (see Level 3). Alternatively, enhanced monitoring or targeted studies could be recommended to reduce uncertainties, or in the case that the trigger exceedance is not site-related, it may be appropriate to return to routine monitoring.

Level 3 – Development of Strategies for Mitigation

Alternatives to mitigate the identified trigger exceedance will be considered. Mitigation measures associated with the protection of groundwater quality and quantity are outlined in Section 7.5. Other mitigation measures, likely to be primarily focused on reduction of constituent loadings and/or concentrations reporting to the environment, may also be developed and implemented. It is expected that the effectiveness of any mitigation alternative under consideration will be assessed quantitatively (to the extent possible), and that the assessment will include predictions about the degree of risk reduction expected. Criteria should be developed to assist in the selection of the preferred alternative.

The response time for a Level 3 response will be agreed upon in collaboration with appropriate stakeholders, including all applicable government ministries and regulatory authorities.

Level 4 – Implementation of a Preferred Mitigation Strategy

A plan to implement a preferred mitigation strategy would be developed in consultation with regulatory authorities and Interested Parties, as appropriate, pending the outcomes of Levels 1 to 3 of the Response Plan. Any regulatory permits/approvals that may be required will be obtained and any stakeholder and/or Indigenous consultation obligations will be fulfilled.

Monitoring plans will be developed to track the environmental response in relation to the implementation of the preferred mitigation strategy. In many cases, the monitoring needed to track environmental response following mitigation will already be in place as part of routine monitoring programs. In some cases, minor revisions to routine monitoring programs may be required, whereas in other cases, it may not be possible to adequately assess the success of abatement actions through routine monitoring. In these cases, additional special studies will be needed. The details of these special studies will be documented.

The response time for a Level 4 response will be agreed upon in collaboration with appropriate stakeholders, including all applicable government ministries and regulatory authorities.

7.9 Geology and Groundwater Summary

This subsection of the EIS was completed to understand and characterize the potential residual effects of the Project and foreseeable developments on the physical aspects of the Geology and Groundwater VCs. The spatial and temporal boundaries for the Geology and Groundwater VCs were similar and were chosen as they permitted the description of existing and potential future conditions in sufficient detail to allow potential Project-VC interactions and potential effects to be identified, understood, and evaluated.

Geology

Geology includes bedrock, soils, and geomorphology (i.e., the study of physical features on the earth and their relationship to underlying geological structures). The Geology VC is recognized as an important component of the environment that may be affected by the Project, and changes to Geology could in turn lead to effects on other VCs selected for assessment. For example, terrain morphology dictates landscape function, such as surface drainage patterns, and reflects the underlying surficial (geological) materials. Changes to terrain morphology can affect and use economic activity and biological functions in proximity to the Project.

Acknowledging that changes to Geology are important aspects of the natural and human environment, the Geology VC was referred to as an intermediate VC (i.e., it does not have an assessment endpoint). Changes to this intermediate VC were evaluated to facilitate the assessment of Project interactions with links to other disciplines for inclusion in their assessments, including Groundwater, Terrestrial Environment, and Land and Resource Use.

Geological conditions, in terms of rock and mineral composition stratigraphy (i.e., how geological materials are arranged in sequence with depth/spatially) and structural components (i.e., faulting and fracturing), are well understood based on Project-specific and regional information. The overall Project Area and Operation have been designed to limit disturbance to the natural geological environment outside of the immediate mining area. One component of the Geology VC assessment focused on subsidence at ground surface associated with consolidation of rock mass (ore) at significant depth (approximately 400 m) below ground, from within the mining chamber. The assessment predicted negligible change in ground elevation of 2-3 mm within a discrete and localized area of the Project Area. This minor change is likely not to be measurable and is likely within the bounds of other routine operational surface disturbances. Beyond subsidence, changes in hydraulic conductivity localized to the mining area anticipated to be associated with ISR mining were evaluated as part of the assessment of potential effects on groundwater quantity and quality (Section 7.6.2.2.3).

As part of mining operations, detailed monitoring activities will be completed to assess the performance of various components of the Project associated with engineering mining designs, subsidence, performance, and infrastructure designs to protect the Geology VC. Subsidence at ground surface within the wellfield will be evaluated from Construction through to Decommissioning by monitoring the elevation of collars (top of pipe) for wells within the wellfield. Monitoring will be undertaken to evaluate any vertical displacement at ground surface, and the monitoring program will include a contingency plan should conditions with respect to subsidence not meet expectations (e.g., levels of subsidence are outside of range of expectations) (Section 7.8.1).

Groundwater

Groundwater is an integral component of the hydrologic cycle and is considered an important environmental component and pathway to the Surface Water Quality VC. Groundwater was selected as a VC for assessment because it is important in maintaining ecological habitats through its influence on the hydrology and water quality of surface waterbodies, including wetlands. Indigenous Knowledge and engagement activities clearly identified the importance Interested Parties place on groundwater as a pathway to surface water, and the associated potential for changes in groundwater inputs to surface water to influence fish and fish habitat, sediment quality, vegetation, wildlife, human health, and Indigenous land and resource use (Section 7.2). Groundwater includes domestic, commercial, and industrial water supplies, and the groundwater component of freshwater ecosystems, including stream flow, wetlands, and surface waterbodies. As supported by comments and concerns provided by Interested Parties and informed by IK, maintaining groundwater quality and quantity is important for maintenance of surface water quality and health and the shared value of water and its life sustaining properties (see Section 7.2).

Within the LSA, the Groundwater VC was considered an intermediate VC as it is a pathway to the aquatic environment. As an intermediate VC, the Groundwater VC does not have an assessment endpoint.

The overall Project Area and Operation have been designed to limit disturbance to the natural groundwater environment outside of the immediate mining area. Specific and standard mitigation measures will be employed to eliminate, reduce, or control the potential residual effects of the Project on groundwater quantity and quality and protect discharges to local surface waterbodies. Examples of mitigation measures include the use of liners and effluent collection systems at landfills and pads; the establishment of freeze walls before mining operations to hydraulically isolate the mining area; and remediation of groundwater quality within the mining area during Decommissioning to appropriate levels (i.e., Decommissioning objectives).

To carefully evaluate how residual mass of COPCs dissolved in groundwater may interact with the environment after remediation of groundwater in the mining area, a rigorous numerical model of groundwater flow and chemical COPC behaviour along the groundwater flow path was used as a predictive tool. The model is founded on proven scientific principles and processes (e.g., groundwater flow, contaminant transport, and geochemical reaction processes) and allowed future conditions to be evaluated. The results of the numerical model support the conclusion that with the implementation of appropriate mitigation, the potential effects of the Project on the Groundwater VC are not expected to cause adverse residual effects. Dissolved COPCs are predicted to migrate varying extents along the groundwater path between the mining area and Whitefish Lake, with constituents that do not interact with the solid matrix predicted to arrive within approximately 400 years. Concentrations of COPCs were predicted to remain at levels that would not result in environmental risk.

Over the life of the Project, groundwater quantity and quality monitoring activities will be completed to assess the performance of various components of the Project associated with engineering mining designs and performance and infrastructure designs to protect the Groundwater VC. A groundwater monitoring plan, including an Excursion Contingency Plan, and measures for adaptive management will be implemented for the Project.

Roadmap

This roadmap of the Wheeler River Project Environmental Impact Statement (EIS) has been provided to summarize the main document sections and appendices of the EIS.

Wheeler River Project
Environmental Impact Statement

Executive Summary

PART I: INTRODUCTION AND CONTEXT
- Section 1: Project Introduction and Overview
- Section 2: Project Description
- Section 3: Indigenous and Local Knowledge
- Section 4: Engagement
- Section 5: Approach and Methodology of the Assessment

PART II: BIOPHYSICAL ENVIRONMENTAL ASSESSMENTS
- Section 6: Atmospheric and Acoustic Environment
- Section 7: Geology and Groundwater
- Section 8: Aquatic Environment
- Section 9: Terrestrial Environment

PART III: HUMAN ENVIRONMENT ASSESSMENTS
- Section 10: Human Health
- Section 11: Land and Resource Use
- Section 12: Quality of Life
- Section 13: Economics

PART IV: INTEGRATED TOPICS AND SUMMARY
- Section 14: Accidents and Malfunctions
- Section 15: Effects of the Environment on the Project
- Section 16: Assessment Summary and Conclusions

µg/g	microgram per gram
µm	micrometre
µs/cm	microsiemen per centimetre
y	year

Glossary

Term	Definition
Bathymetry	Measurement of the depth of water in rivers, lakes, or oceans.
Beach seine	A net deployed by hand or boat that, when retrieved, forms a tightening “U” that corrals fish to a common point.
Bedload movement	Granular particles at the sediment-water interface that are moved if the flow velocity is great enough to overcome gravity and resistance.
Benthic invertebrates	Organisms that lack an internal skeleton and inhabit the bottom of a waterbody, either on or in the sediment.
Braided streams	Multiple channels that branch and merge to form a characteristic braided pattern.
Canopy cover	Percentage of a study area shaded by riparian vegetation.
Effluent	Liquid waste discharged into a waterway.
Electrofishing	A fishing technique that produces a current of electricity at a set voltage between a submerged anode and cathode. This current generates an electric field and attracts fish; when fish enter the field, they become temporarily stunned.
Flat	Calm, level, or a slow-flowing water channel.
Gill net	A panel of vertical netting that traps fish.
Hydrology	Study of the distribution and movement of water.
Instream cover	Sheltered areas in a stream that could provide protection or refuge to aquatic organisms.
Macrophyte	A plant, typically aquatic, that is large enough to be seen by the naked eye.
Major earthworks	Engineering works created through processing parts of the earth’s surface (excluding ore extraction) that causes major disturbance to the land, or to the bed or subsoil under water.
Minnow traps	Small fish traps, usually composed of a mesh box or cylinder with two funnel-shaped entrances at either end.
Mixing Zone	An area of water contiguous to a point source or definable non-point source where the water quality does not comply with one or more of the Water Quality Objectives.
Overprinting	When a project is constructed on or over existing terrestrial or aquatic habitat.
Plankton	A diverse group of organisms that exist suspended in marine or freshwaters and are incapable of swimming against the current.
Pool	Deeper and wider area of a stream with a slower rate of flow.
Riffle	A shallow area in a stream with fast flowing water over rocks.
Riparian	Area located at the junction between land and a natural watercourse.
Run	Deep, faster flowing stream water with little to no turbulence.
Stream gradient	The slope of a stream’s channel measured by the vertical drop of a stream over a horizontal distance.
Thermocline	Thin but distinct layer between the warmer mixed surface water and the cooler deep water below.
Total Suspended Solid	Undissolved suspended particles, typically greater than 2 microns, in a water sample.
Voucher specimen	Preserved specimen serving as a record of and organism.
WGS84 datum	The World Geodetic System 1984 is a datum featuring coordinates that change over time.
Young-of-year	All fish of a species in a population that are less than one year of age.
Zone of influence	Spatial area receiving water flow within which some degradation or water quality or use impairment is anticipated to occur as a result of discharge.

8 Aquatic Environment

Section 8 of the Environmental Impact Statement (EIS) for the Wheeler River Project (the Project) is focused on the Aquatic Environment. The integrated biophysical and human environment assessment approach is illustrated in Figure 8-1. As a guide for EIS reviewers, Figure 8-2 provides a preview of the Valued Components (VC) associated with the assessments completed in this section of the EIS.

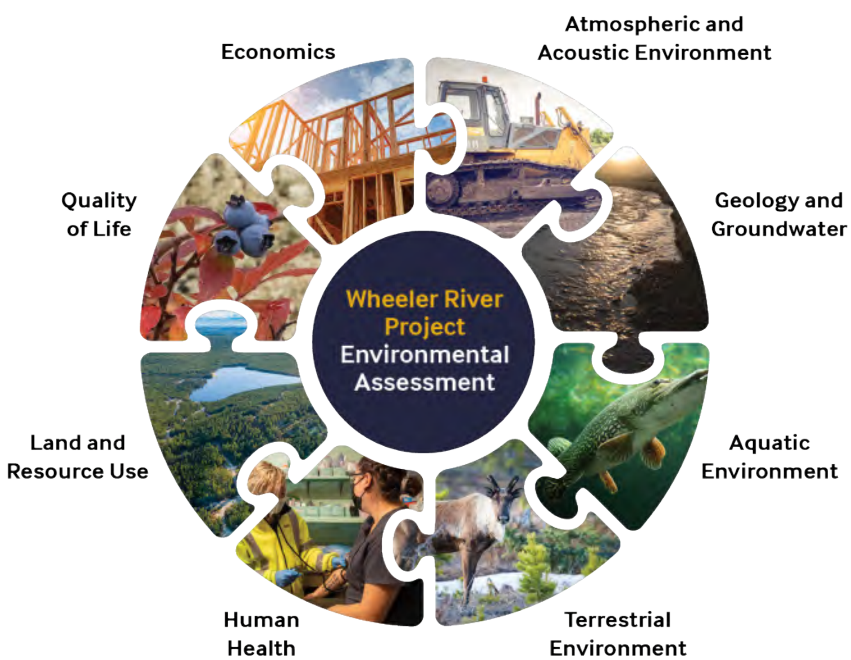

Figure 8-1: Biophysical and Human Environment Assessments for the Wheeler River Project Environmental Assessment

Figure 8-2: Aquatic Environment – Valued Components

8.1 Surface Water Quantity

This section addresses the potential effects of the Project on Surface Water Quantity (i.e., surface water hydrology) as a VC. The following are discussed herein as part of the environmental assessment EA:

- scope of the assessment;
- summary of existing conditions relevant to the Surface Water Quantity VC;
- identification and description of potential interactions between the Project and the Surface Water Quantity VC;
- identification and description of mitigation measures applicable to the Surface Water Quantity VC to eliminate, reduce, or control the potential adverse Project-related effects;
- identification and characterization of predicted Project-related residual effects on the Surface Water Quantity VC after mitigation;
- characterization of significance and assignment of the level of confidence in the predictions; and
- identification and characterization of potential cumulative effects.

Figure 8.1-1 is a graphic representation of the assessment process used in this EIS.

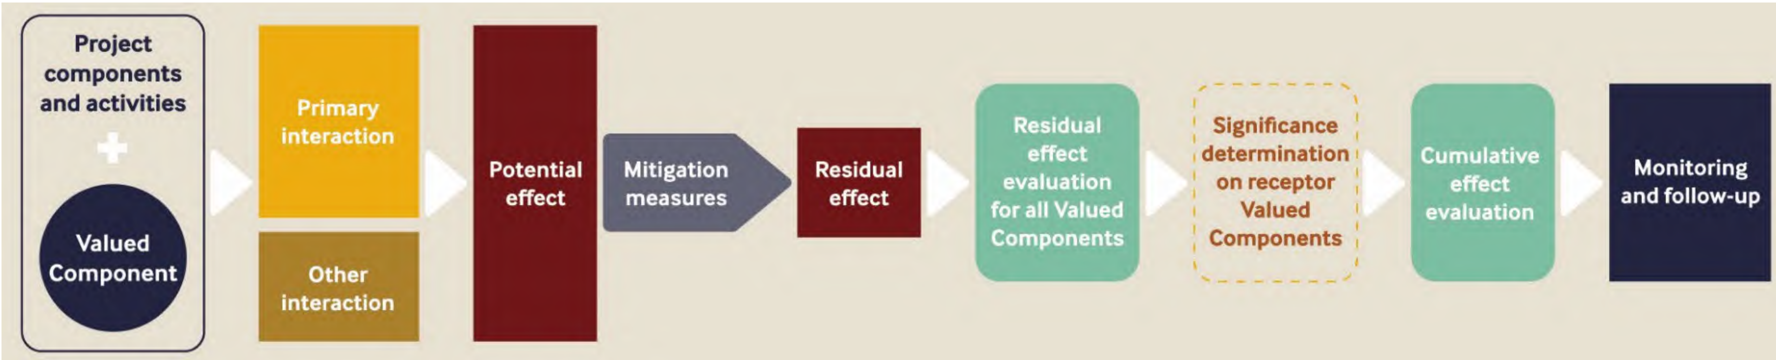

Figure 8.1-1: Environmental Assessment Process for the Wheeler River Project

8.1.1 Scope of the Assessment

The purpose of this assessment is to assess potential changes to hydrological conditions (as represented by the Surface Water Quantity VC) for all Project phases at the Project, local, and regional study areas scales. The Surface Water Quantity VC concerns hydrological parameters of interest, including flow regimes and water levels in watercourses and waterbodies within defined study areas. Key considerations of the assessment are associated with how Project activities such as, but not limited to, water taking activities, water discharges, and changes to drainage patterns could result in changes to hydrological conditions.

8.1.1.1 Valued Component Selection

The process and rationale for selection of VCs and establishment of Key Indicators (KIs) and associated Measurable Parameters (MPs) is described in Section 5 Approach and Methodology of the Assessment. Section 5.8.1.1 defines intermediate VCs and receptor VCs. This section addresses the Surface Water Quantity (hydrology) VC which is identified as an intermediate VC as it represents a physical medium and pathway of influence to biological and ecological receptor VCs. This section addresses the Surface Water Quantity VC, which was selected for inclusion as Project activities have the potential to affect existing surface drainage patterns. Potential changes to water, from both a quantity and quality perspective, are key considerations within the EA process, as demonstrated by previous uranium mining development proposals in the Athabasca Basin, and draw a high level of concern from Interested Parties (see Section 8.1.2). Changes to existing surface drainage patterns are directly and indirectly linked to several VCs and have the potential to influence water quality, biodiversity, and biological function (i.e., Fish and Fish Habitat, Benthic Invertebrates) and the cultural values of Indigenous groups, the public, and other stakeholders. In this context, Surface Water Quantity is interrelated or linked, to varying extents, to other VCs that are considered in this effects assessment, including:

Intermediate Valued Components

Surface Water Quality: Surface water flow volumes and periodicity directly influence the interface of waterbodies with their riparian zones (inundation) and the available assimilative capacity of water features, which can directly influence Surface Water Quality.

Groundwater Quantity and Groundwater Quality: Surface hydrology can influence hydrologic connectivity with groundwater sources, and vice versa.

Receptor Valued Components

Terrestrial Environment: Surface water interacts with various VCs to shape ecosystem form, function, and biodiversity, including Vegetation and Ecosystems and Wetlands (i.e., riparian and wetland vegetation); Terrain, Soils, Organic Matter/Peat; Ungulates, Furbearers and Woodland Caribou as well as Raptors, Migratory Breeding Birds, and Bird Species at Risk.

Fish and Fish Habitat: Surface water flows (i.e., water level [depth] and velocity) directly influence fish life histories and behaviours (i.e., spawning, migration, and overwintering) and food availability and health (i.e., benthic invertebrates, zooplankton, and phytoplankton).

Land and Resource Use: Indigenous Land and Resource Use and Other Land and Resource Use are influenced by seasonal flow regimes of surface waters and water levels with respect to navigation and fish harvest.

Figure 8.1-2 is a graphic representation of the main linkages among the Surface Water Quantity VC and other VCs, illustrating the flow of assessment information into and from the Surface Water Quantity VC.

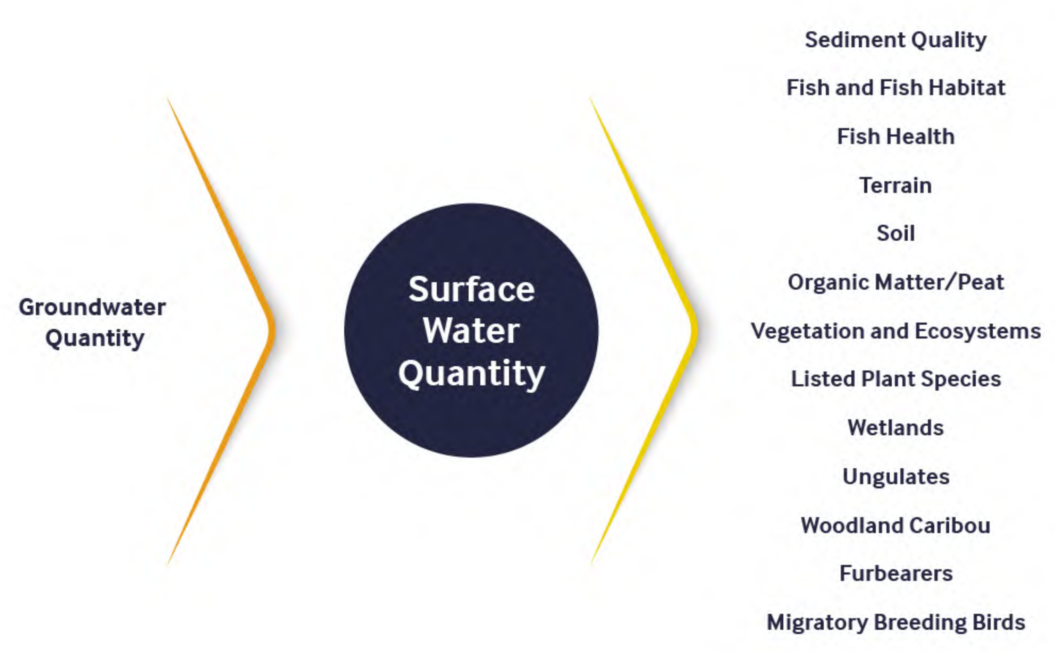

Figure 8.1-2: Integrated Assessment Approach - Key Connections between Surface Water Quantity and Other Valued Components

8.1.1.2 Key Indicators and Measurable Parameters

Key Indicators of change for the Surface Water Quantity VC include hydrometric metrics of surface water discharge (flow) and water level. Assessment of potential changes to discharge is investigated at average conditions and low flow conditions (i.e., the 5th percentile condition flow). The KIs and MPs for the Surface Water Quantity VC are summarized in Table 8.1-1.

Table 8.1-1: Key Indicators and Measurable Parameters for Surface Water Quantity

Key Indicator	Rationale for Key Indicator	Measurable Parameter
Water level	Assesses the change in water level of waterbodies as a function of Project development. Water level is important as it is tied to discharge, water taking, and/or redistribution of natural flow patterns and is directly measurable in lake environments. Maintenance of water levels facilitates continued habitat for aquatic biota and navigation for resource users.	Water level in metres
Average monthly discharge (flow) (m^3/s)	Project activities will result in changes to the local hydrology. A reduction or increase in flows may result due to the elimination or redirection of subwatershed area and through Project water management (i.e., water taking, storage and effluent discharge). Changes to the average monthly discharge represents the typical effect that may be realized.	Percentage change to average condition flow (%)
5^{th} percentile monthly discharge (flow) (m^3/s)	Project activities will result in changes to the local hydrology. A reduction or increase in flows may result due to the elimination or redirection of subwatershed area and through Project water management (i.e., water taking, storage and effluent discharge). Changes to the low flow monthly discharge represents the bounding effect that may be realized with respect to environmental flows.	Percentage change to 5^{th} percentile condition flow (%)

8.1.1.3 Spatial and Temporal Boundaries

Generic considerations associated with the establishment of the spatial boundaries of the assessment are described in Section 5.3.3 in Section 5. As it pertains to the Surface Water Quantity VC, the following is noted.

- The **Project Area** is the direct footprint of the Project. The Project Area represents the area within which Project activities and components may occur and, as such, represents the area within which direct physical disturbance may occur as a result of the Project, either temporary or permanent (i.e., the area of maximum physical disturbance). This area is not VC-specific, but consistent throughout the EIS for all VCs.
- The **Local Study Area (LSA)** is the area that surrounds the Project Area where both direct and indirect effects resulting from Project activities can be reasonably measured. The LSA was established to assess the potential, largely direct effects of the Project and represents the extent to which there is a reasonable potential for the Project or Project-related activities to interact with and potentially adversely affect the VC. For the Surface Water Quantity VC, the LSA was derived from watershed boundaries within proximity of the Project Area, including portions of watersheds that overlap the Project site, as well as areas directly downstream that may be influenced by the Project site or effluent discharge/water withdrawal effects (Figure 8.1-3). The subwatersheds within the LSA are presented in Figure 8.1-4. This area was selected based on important waterbodies (notably Whitefish and McGowan Lakes) downstream of the Project where effects may occur through all Project phases. The LSA extends from those waterbodies down to their inflows to Russell Lake. The downstream extent

of the Surface Water Quantity LSA is at the confluence with Russell Lake. This location was chosen since, cumulatively, the drainage areas associated with the subwatersheds in the LSA represent a very small portion of the larger Russell Lake watershed at that node., As such, the potential for Project-specific effects on the Surface Water Quantity VC can be assessed within this area.

- The **Regional Study Area (RSA)** is the area that surrounds and includes the LSA, and was established to assess the potential, largely indirect effects of the Project, as well as other activities, in a regional context. The RSA is large enough to capture the extent of potential effects (i.e., zone of influence) on a VC and defines the area within which cumulative effects may occur (i.e., cumulative effects assessment boundary). The RSA for the Surface Water Quantity VC is bounded by the regional watershed area in which the Project Area is located. The RSA for this assessment is based on the whole watershed within which the Project is located and extends downstream to include Russell Lake (Figure 8.1-3).

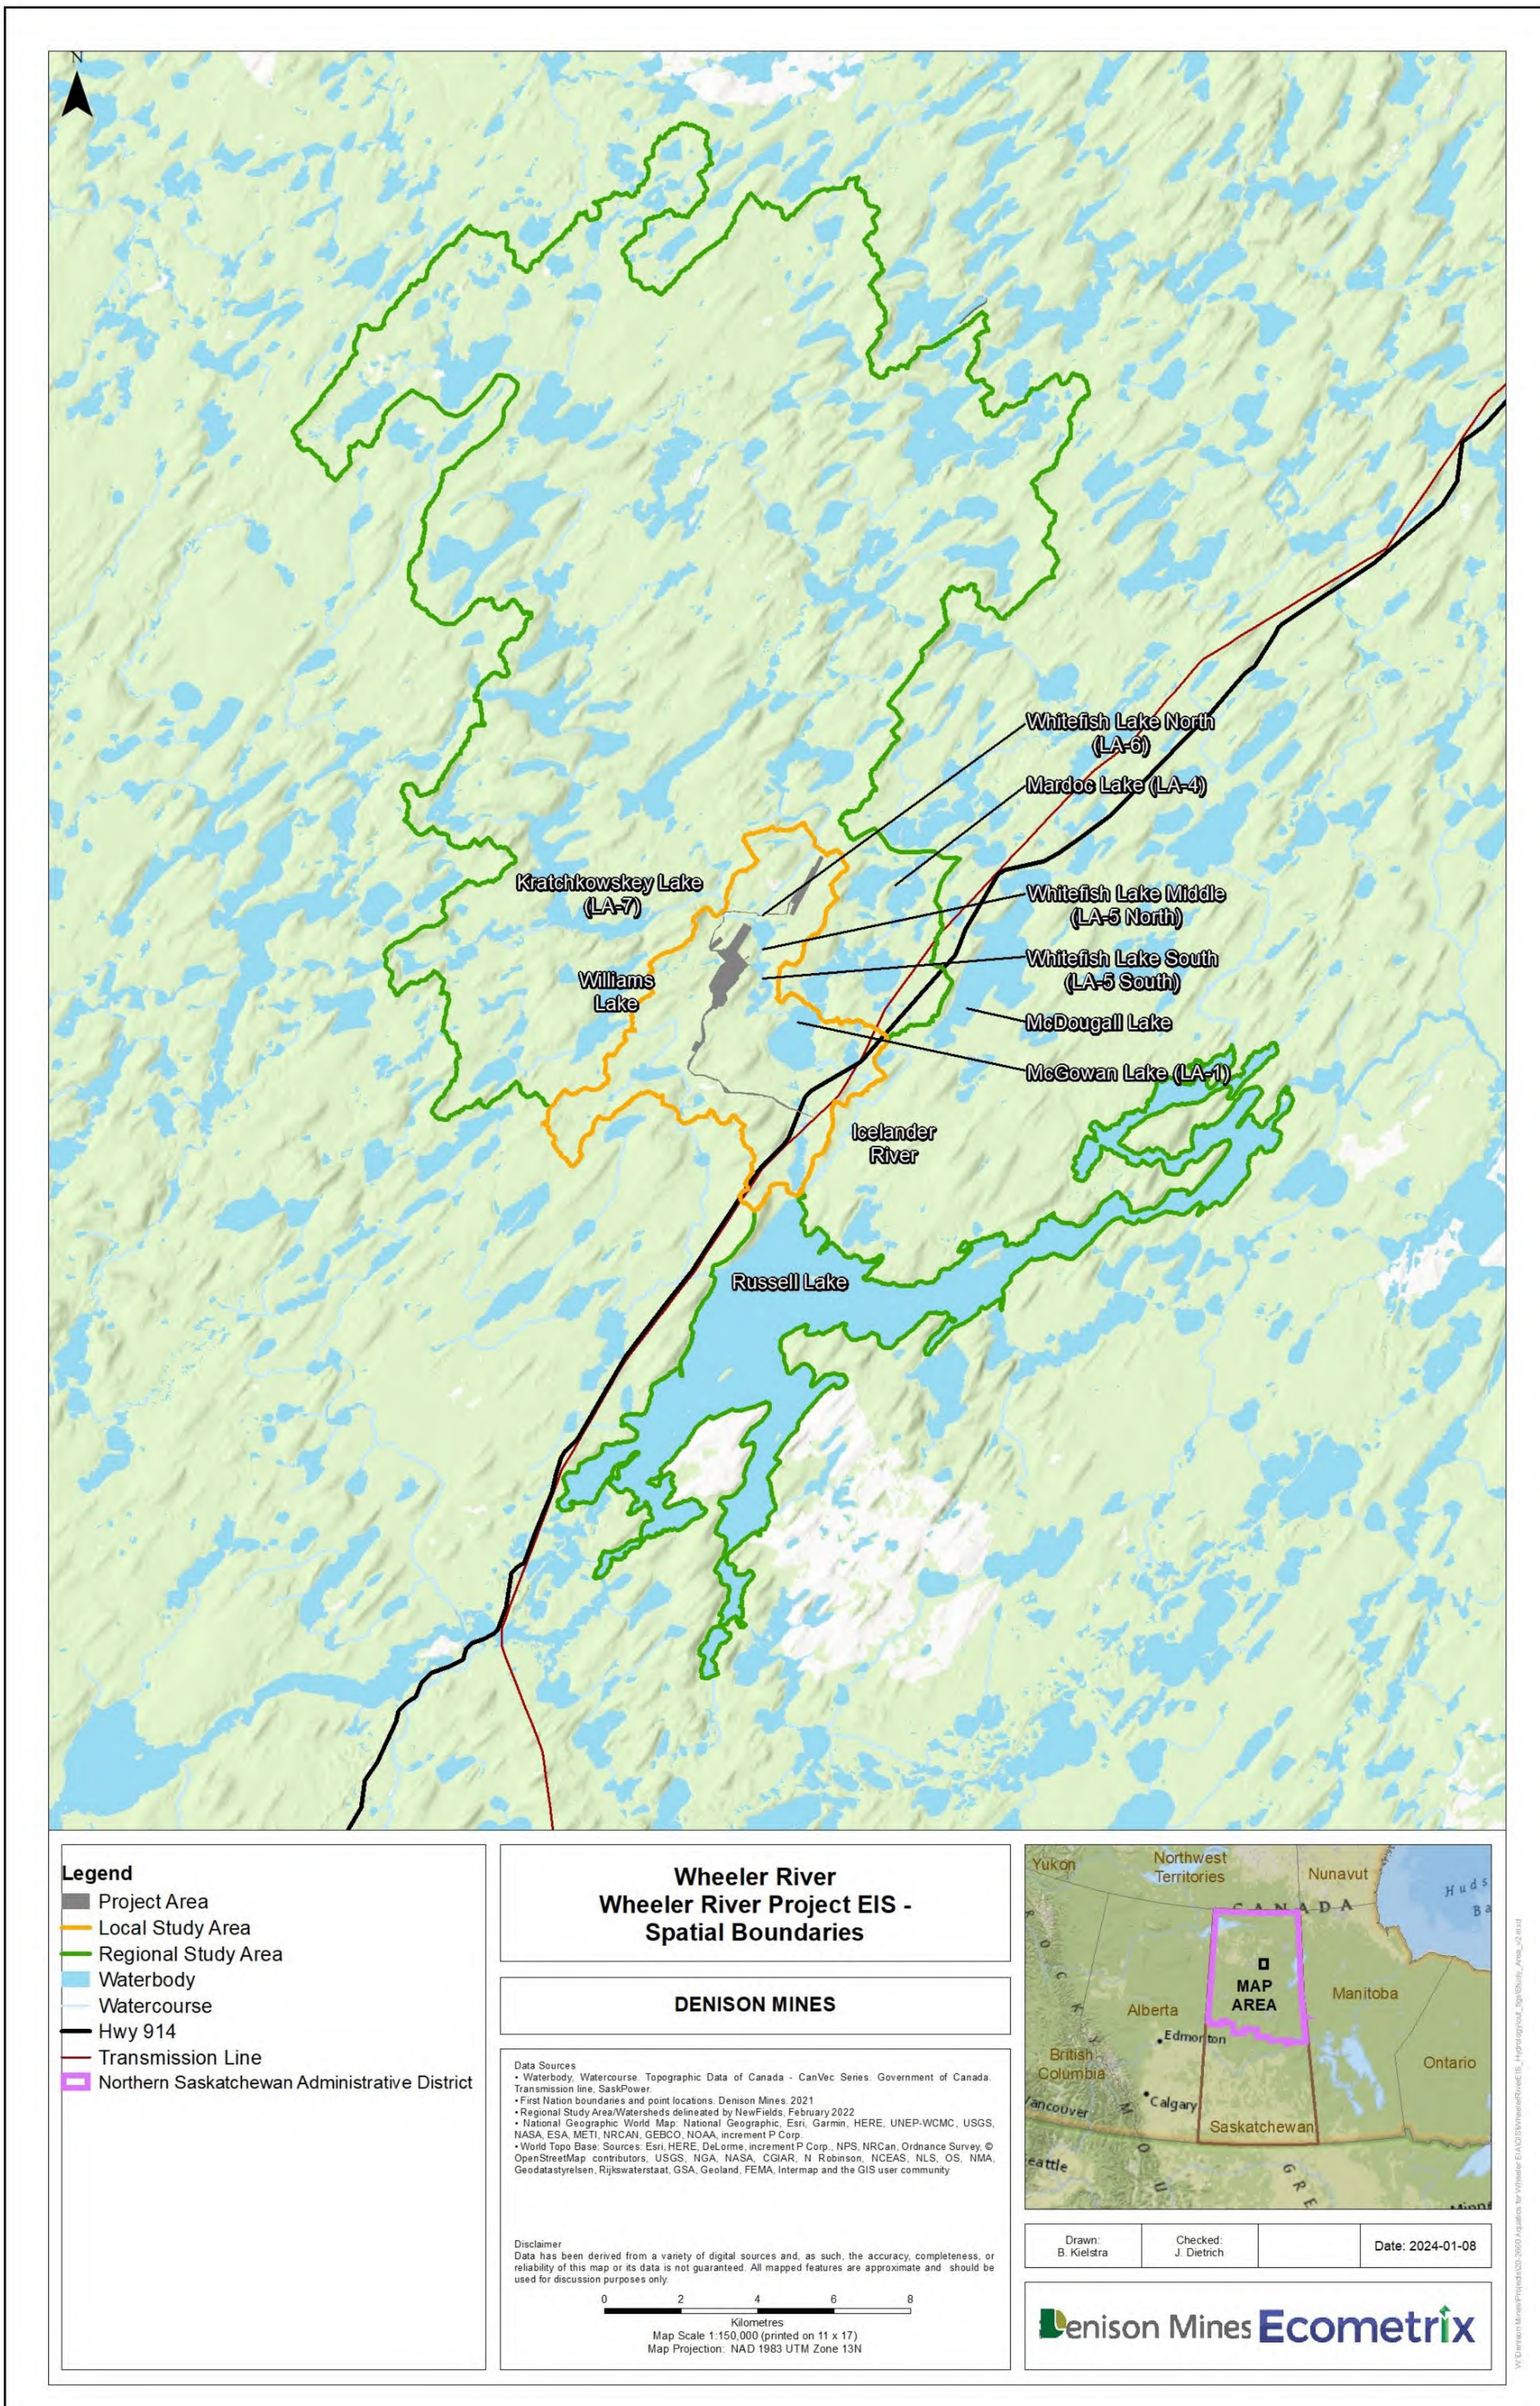

Figure 8.1-3: Study Area Boundaries

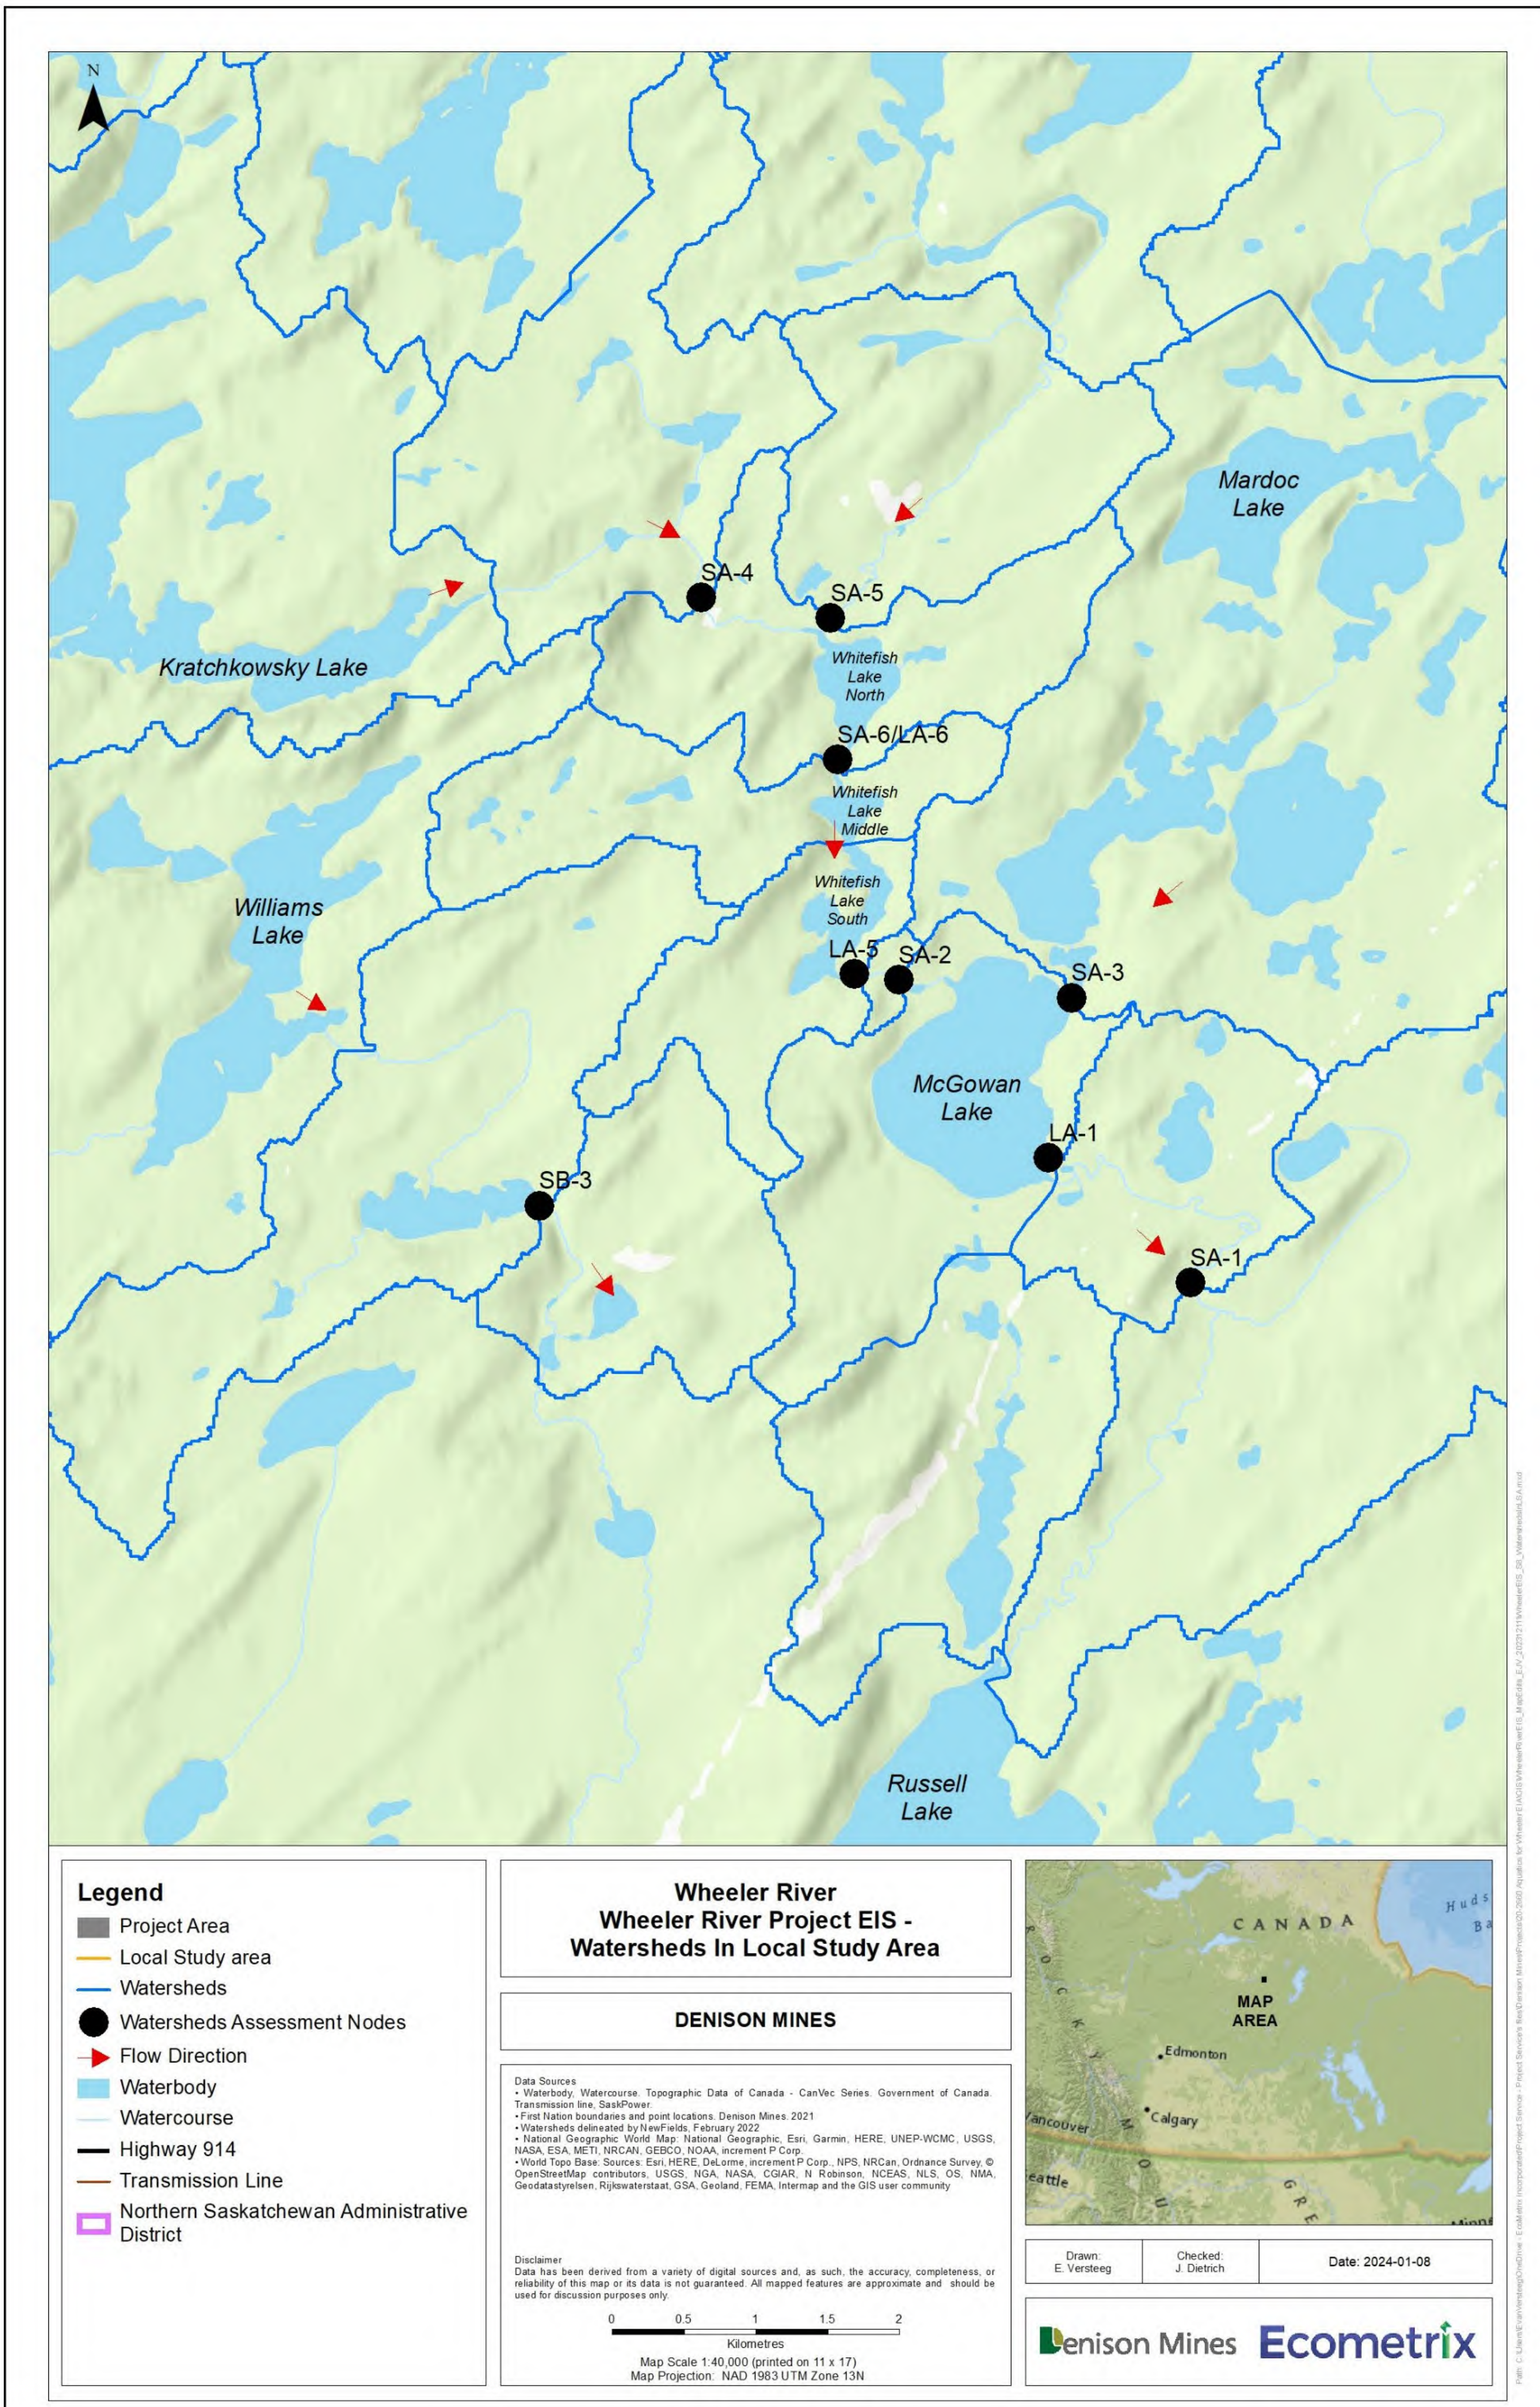

Figure 8.1-4: Watersheds Within the Local Study Area

Temporal boundaries for the EIS are defined in Table 5.3-3 in Section 5.3.4. The temporal boundaries applicable to and considered in the EIS include the following Project phases:

- Construction (Year 1 to 3);
- Operation (Year 3 to 18);
- Decommissioning (Year 18 to 23); and
- Post-Decommissioning (Year 23 to 38).

Additionally, a "future centuries" scenario is considered to assess the potential effects post-restoration (i.e., beyond the Project timeline of 0-38 years) and to reflect the time period over which the highest constituent concentrations in groundwater are predicted to migrate towards and interact with surface water.

This period represents the time where the highest constituent concentrations in groundwater are predicted to interact with surface water based on groundwater modeling. In this context, the future centuries scenario is considered with respect to the interaction of groundwater migration from the Project site and its potential influence on surface water in local water bodies. The future centuries projection encompasses the long-term period during which slow migration of groundwater from the Phoenix Ore Zone area to the surface water environment is anticipated and constitutes a bounding scenario of maximum concentrations of constituents of potential concern (COPC).

8.1.2 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

At its broadest level, Indigenous Knowledge (IK) can be understood as the unique and collective knowledge of Indigenous peoples that may include, but is not limited to, the environmental, cultural, economic, political, and spiritual conditions of a community or region. In this section, IK and Local Knowledge (LK) are viewed as complementary and influential alongside western science to produce a full understanding of the potential effects of the Project, whether measurable or perceived. Both forms of information have been given full and fair consideration.

Denison Mines Corp. (Denison) has recorded and stored information regarding IK, LK and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers (e.g., 21-EN-BNFN-479.6). These numbers are referenced throughout the EIS, but particularly in Parts II and III, to indicate where specific information from the database has been integrated into the assessment. Appendix 8-A provides a summary of unique identification numbers referenced within Section 8.1.

Indigenous Knowledge and LK quotes and citations were included herein to provide readers with the information considered as the Project advanced throughout the EA process. Since 2016, Denison has been engaging with Interested Parties (i.e., local and Indigenous communities, residents, businesses, organizations, land users, and various regulatory authorities) to support the development of positive relationships and a mutual commitment to collaboration.

The influence of IK, LK, and engagement on the assessment of the Surface Water Quantity VC has first and foremost shaped the shared value of water and its life-sustaining properties.

> *"The lands and waters, we are definitely connected as peoples of English River. If we don't have the lands, we are not connected. If we don't have the water... Water is life to us"* (ERFN and SVS 2022).

Comments associated with water management and discharge to the environment were not directly specific to potential effects on Surface Water Quantity[1]; however, these were considered within the context of community interest regarding surface waters remaining supportive of natural function for biota and existing and future water uses. To this end, Project-related water management is important to maintaining surface water hydrology within the LSA.

Based on engagement (21-EN-BNFN-479.6), it is understood that additional detail is expected with respect to the potential effects of the Project on Surface Water Quantity because Denison proposes to discharge effluent into the local environment and take water from the local environment to support uranium bearing solution processing. This section directly meets this request.

Comments from Indigenous peoples regarding the potential role of climate change are further acknowledged in this assessment as a result of engagement (21-EN-VPL-444.3 and 21-EN-VPL-444.4).

8.1.3 Existing Environment

Denison initiated baseline hydrological monitoring in 2011, which has continued up to the present. Data are reported in Appendix 8-B for the period 2011 to 2019. The baseline flow record is robust and the duration of monitoring is sufficient to establish long-term streamflow trends at the Project site through relationships to long-term operating hydrometric gauging stations in the same watershed. As such, these records can be used to estimate long-term potential effects for the temporal phases and spatial study areas for the Project.

Baseline monitoring for the Project included streamflow monitoring, lake level monitoring, and installation of stage dataloggers at various locations throughout two main watersheds (identified as Watersheds A and B) reporting to Russell Lake (Appendix 8-B). Hydrometric monitoring at the Project site has been carried out by several organizations since 2011. Recently, the focus of each program has shifted to Watershed A stations, predominantly in the vicinity of the Project site. Hydrometric monitoring at streamflow stations has included measurement of stream discharge and water levels, and maintenance of in-stream dataloggers. The discussion of methodology used to develop baseline hydrologic characterization is provided in Appendix 8-B.

[1] 19-EN-MN-SR3-1.2, 19-EN-ML82-1.3, 19-EN-MOE-1.4, 18-EN-VILX-3.33, 18-EN-VILX-3.35, 18-EN-VILX-3.39, and 18-EN-VILX-3.84.

Critical locations of interest for this assessment include the following nodes, which are coincident with baseline monitoring stations and/or watersheds of interest for the assessment (Table 8.1-2; Figure 8.1-4). The assessment nodes represent the collective watershed.

- SA-1 – Streamflow monitoring station on the stream colloquially known as the Icelander River, which is located downstream of LA-1 (McGowan Lake).
- SA-2 – Streamflow monitoring station situated downstream of the outflow from LA-5 (Whitefish Lake) and upstream of the inflow to LA-1 (McGowan Lake).
- SA-3 – Streamflow monitoring station situated upstream of the inflow to LA-1 (McGowan Lake).
- SA-4 – Streamflow monitoring station situated upstream of the inflow to LA-6 (Unnamed Lake).
- SA-5 – Streamflow monitoring station situated upstream of the inflow to LA-6 (Unnamed Lake).
- SA-6 – Stream flow monitoring station situated downstream of the outflow from LA-6 (Whitefish Lake North) and upstream of the inflow to LA-5 (Whitefish Lake South).
- LA-6 – Lake level monitoring station at LA-6 (Whitefish Lake North).
- SB-3 – South Project drainage basin flowing to Russell Lake.
- LA-1 – McGowan Lake.
- LA-5 – Whitefish Lake South.

Gross drainage areas for the above-mentioned locations are presented in Table 8.1-2.

Table 8.1-2: Drainage Areas for Assessment Nodes

Location	Description	Gross Drainage Area (km^2)
SA-1	Icelander River flowing from McGowan Lake	280.6
SA-2	Inflow to McGowan Lake from Whitefish Lake	257.4
SA-3	Inflow to McGowan Lake	15.5
SA-4	Inflow to LA-6 (Unnamed Lake) from Kratchkowski Lake	80.5
SA-5	Inflow to LA-6	167.3
SA-6/LA-6	Flow from LA-6 to Whitefish Lake	251.7
SB-3	Southern Project drainage basin flowing to Russell Lake	24.9
LA-1	McGowan Lake	277.5
LA-5	Whitefish Lake	257.2

Notes:

Gross drainage is the total area of the watershed that would generate runoff to a contributing point.

8.1.3.1 Baseline Stream Flow

Available baseline streamflow data for the Project covered a sufficient time period to support the assessment. To make sure seasonable variability in hydrology was adequately captured as part of the dataset used to assess potential effects, an additional step in data preparation was undertaken to fill in seasonal gaps in the long-term record. This was accomplished by additional modelling (pro-rating) using a known continuous data source. Environment and Climate Change Canada operates hydrometric gauging stations across the country, including one station located approximately 32 km downstream of the Project (i.e., the Project Area and RSA lie within the watershed at this gauge). Environment and Climate Change Canada monitors flow rates on the Wheeler River below Russell Lake (station 06DA005) and has reported historical data from 1973 to 2019 (ECCC 2021). Data prior to 1977 have frequent missing records and were not used for this assessment. Daily average discharge data from station 06DA005 were used, extending from 1977 to 2019, for modelling purposes.

Extending the discharge records from station 06DA005 to other assessment nodes required correlation through unit area runoff relationships or same day discharge best fit correlation. The methodology used is discussed in Appendix II of Appendix 8-C-B. The extended discharge records for each station were then processed to obtain monthly average discharge for each assessment node for the purposes of the effect assessment for the Project. These data are presented in Appendix 8-B, with summary statistics presented in Table 8.1-3.

Table 8.1-3: Summary of Hydrological Statistics for Project Relevant Nodes

Station	Gross Drainage Area (km²)	Statistic	Jan	Feb	Mar	Apr	May	Jun	July	Aug	Sep	Oct	Nov	Dec	Monthly Average	Monthly Average Yield (m³/s/km²)

8.1.3.2 Low Flow Statistics

Low flow assessment statistics are important for gaining an understanding of the bounding scenario for effluent discharge (i.e., low flow scenario water quality modelling) when a proposed discharge is anticipated for a Project (Section 8.2). The statistic required for the assessment, as required by the Saskatchewan Water Security Agency, is the seven-day average 1:10 year low flow return period (7Q10). This assessment requires tabulation of flow data series into one-week intervals, with summary statistics of the low flow return periods generated from the Log Pearson III analysis. The 7Q10 estimates are presented in Table 8.1-4 for assessment nodes LA-1 and LA 5.

Table 8.1-4: 7Q10 Estimated Discharge

Assessment Node	7Q10 Low Flow Rate (m^3/s)
LA-1	0.874
LA-5 (upstream)	0.626
LA-5 (downstream)	0.810

8.1.3.3 Climate Change

8.1.3.3.1 Water Balance Influenced Parameters

Climate change is recognized as a growing issue facing future developments. The Canadian Centre for Climate Services provides an online tool that identifies potential changes to mean annual temperature, surface wind speed, total precipitation, and snow depth, among other parameters, based on location and timeframes within Canada (CCCS 2021). The four aforementioned parameters influence the water balance at the Project, with mean annual temperature and surface wind speed affecting evaporation, and total precipitation and snow depth affecting local runoff. The climate change parameter estimates presented in Table 8.1-5 are based on projected time intervals and emission scenarios referred to as representative concentration pathways (RCPs), as well as the predicted change referenced to the average of the period 1986 to 2005. The RCP scenarios represent projected plausible emissions based on potential future anthropogenic activity.

Table 8.1-5: Climate Change Parameter Estimates

Parameter	Units	Time Period	Emission Scenario Representative Concentration Pathway (RCP)		
			Low (RCP 2.6)	Moderate (RCP 4.5)	High (RCP 8.5)
Mean Temperature	°C	2021–2040	+1.3	+1.4	+1.6
		2041–2060	+1.7	+2.3	+3.2
		2061–2080	+1.7	+2.8	+4.8
		2081–2100	+1.7	+3.1	+6.2
Surface Wind Speed	% change	2021–2040	-1.4	-1.3	-1.2

Parameter	Units	Time Period	Emission Scenario Representative Concentration Pathway (RCP)		
			Low (RCP 2.6)	Moderate (RCP 4.5)	High (RCP 8.5)
		2041–2060	-0.9	-1.3	-2.6
		2061–2080	-1.3	-0.9	-2.8
		2081–2100	-1.4	-1.6	-2.6
Total Precipitation	% change	2021–2040	+3.6	+2.7	+5.0
		2041–2060	+5.7	+7.3	+8.1
		2061–2080	+5.3	+8.0	+9.4
		2081–2100	+5.7	+7.9	+10.7
Snow Depth	% change	2021–2040	-9.0	-7.1	-9.7
		2041–2060	-7.6	-11.8	-16.0
		2061–2080	-7.5	-14.3	-30.5
		2081–2100	-12.0	-19.5	-38.6

8.1.3.4 Climate Change Influenced Extreme Events

8.1.3.4.1 Intensity Duration Frequency Events

Intensity duration frequency (IDF) curves are used to estimate the size of water management structures around a site. Typically, the 1:100 year, 24-hour precipitation event is the design event used in analyses for water management. Intensity duration frequency curves are often specific to climate monitoring stations; however, the online tool IDF_CC Tool 5.0 developed by the Institute for Catastrophic Loss Reduction (2021) is available for presentation of IDF curves at ungauged locations and includes the ability to estimate future IDF curve values under influences of climate change.

Baseline IDF curve data (Table 8.1-6) are based on a gridded data set extracted from the online tool. The climate change influenced IDF curve data (Table 8.1-7) are based on the time window of 2020 to 2050 under a climate condition scenario yielding the largest magnitude storm fall. The 1:100 year, 24-hour return period rainfall events for the baseline and climate change influenced IDF curves are 79.9 mm and 88.6 mm, respectively (Appendix 8-C).

Table 8.1-6: Baseline of Intensity Duration Frequency Curve Data

Duration	Return Period (Years)						
	2	5	10	20	25	50	100
5 minutes	4.3	6.7	8.8	11.5	12.4	16	20.7
10 minutes	6.4	9.8	12.8	16.7	17.9	23	29.3

24 hours	41.3	54.3	63	70.7	72.8	81	88.6

8.1.3.4.2 Probable Maximum Precipitation Events

The probable maximum precipitation (PMP) event is a design standard value for an extreme rainfall event. The PMP event does not have an estimated return period but is instead based on the theoretical maximum amount of water that a storm could produce based on the maximum persisting dew point (Atmospheric Environment Branch 1999). An assessment completed by the Atmospheric Environment Branch (1999) indicated that a trend in the maximum persisting dew point was not shifting appreciably; however, no formal analysis of projected climate change effects has been completed. Based on data presented by the Atmospheric Environment Branch (1999), the estimated PMP event for the Project is 489.3 mm (Appendix 8-C).

8.1.4 Assessment of Project-related Effects

8.1.4.1 Potential Interactions Between the Project and Valued Component / Key Indicators

The Project will require the construction, operation, and decommissioning of several components (as described in Section 2 Project Description). Potential interactions between Project activities and the Surface Water Quantity VC are summarized by Project phase in Table 8.1-8 and are categorized as:

- Primary Interaction (✓): Project activity is expected to interact with the VC/KI, which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.
- Other Interaction (✓): Project activity is expected to interact with the VC/KI. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects.
- No Interaction**:** Project activity is not expected to interact with the VC/KI, no adverse effects are expected, and a rationale is provided for not considering this potential interaction further.

Based on professional judgment and understanding of the nature of Project activities and their sequencing, the Project activity list was reviewed and the type of interactions determined. Potential Project-related effects are then discussed in Section 8.1.4.2. Primary Project activities with the potential for adverse effects on Surface Water Quantity (i.e., flagged as 'Primary Interactions') are expected to involve surface land clearing, major earthworks, surface/grading preparations, changes to land cover, water management feature construction and operation, and water taking and effluent discharge. Other Project activities (i.e., flagged as 'Other Interaction') refer to those activities that may be associated with hydrogeological influences on local waterbodies and are expected to be secondary contributors to potential adverse effects. The remaining activities (e.g., power generation and supply) were deemed to have no interaction and were not carried forward in the assessment as they are not expected to result in detectable changes in the MPs associated with Surface Water Quantity. Activities during Post-Decommissioning (e.g., site inspections; monitoring and on-site engagement with Interested Parties) were deemed to have no interaction because they do not involve any land clearing, surface preparations, or major earthworks.

Table 8.1-8: Potential Project Interactions for Surface Water Quantity

Project Phase/Activity	Surface Water Quantity
Construction Activities	
Development of access roads and air strip	✓
Site preparation and earthworks; clearing, levelling, and grading of the Project Area	✓
Power generation – generators	
Installation of main substation and distribution of power around site	
Wellfield and freeze hole drilling; ground freezing	✓
Batch plant operation (concrete); crusher at borrow area	
Development of surface infrastructure (camp, operations centre, plants, ponds, pads, and support facilities)	✓
Waste management (composting, domestic and industrial landfill operation, recycling)	

Project Phase/Activity	Surface Water Quantity
Water management (including treatment and site runoff)	✓
Groundwater supply	✓
Surface water withdrawal	✓
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
On-site and off-site operation of vehicles and transport of materials	
Air transportation for workers	
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Operation Activities	
Operation of the in situ recovery (ISR) wellfield	✓
Wellfield and freeze wall drilling	✓
Operation and expansion of freeze wall	✓
Batch plant operation (grout and cement); crusher in borrow area	
Expansion of pond and pads	✓
Operation of the processing plant and production of uranium concentrate	✓
Water withdrawal from groundwater or surface waterbody	✓
Management of surface water (including seepage and site runoff)	✓
Water treatment, both domestic and industrial	✓
Water release to surface waterbody	✓
Waste management (composting, domestic and industrial landfill operation, recycling)	
Hazardous waste management (temporary storage, handling, and off-site transportation)	
Storage and disposal of drill waste rock, process precipitates, and industrial wastewater treatment plant precipitates	
On-site and off-site operation of vehicles and transport of materials	
Power supply – primarily power from the grid, also generators and back-up generators	
Package and transport of nuclear substances	
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
Air transportation for workers	
Progressive decommissioning and reclamation	✓
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Decommissioning Activities	
Site water management, treatment, and release	✓
Mining horizon remediation and thawing of freeze wall	✓
Process water treatment and release	✓
Closure of ISR and freeze wells and related infrastructure	✓

Project Phase/Activity	Surface Water Quantity
Decontamination of surface facilities and injection, recovery, and monitoring wells	✓
Asset removal (including site power transmission lines and electrical infrastructure)	
Demolition and disposal of non-salvageable surface infrastructure and materials	
Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and process plant area)	✓
Generators	
Waste management (composting and landfill operation)	
Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal)	
On-site and off-site operation of vehicles and transport of materials	
Reclamation of disturbed areas	✓
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Post-Decommissioning Activities	
Environmental monitoring	
Regulatory site inspections	
Engagement – site visit from Interested Parties	

Interactions between the Project and Surface Water Quantity during the future centuries phase were considered an indirect (secondary) interaction associated with changes in groundwater migration from the restored mining horizon to the surface water environment.

8.1.4.2 Potential Project-related Effects

Denison does not intend to include constant freshwater withdrawal or effluent discharge throughout Operation; however, for the purpose of assessing the scenario of greatest potential effects, the Project was assessed as having a continuous freshwater withdrawal rate of 40.5 m^3/hr and a continuous effluent discharge rate of 36.5 m^3/hr. The withdrawal and discharge rates were assessed independently, despite withdrawal from and discharge to being associated with the same waterbody, to exaggerate the projected effects. In addition, the withdrawal and discharge rates were assessed cumulatively with the Project Area and estimated changes to groundwater contributions through different temporal phases of the Project.

Flows and water levels under pre-development conditions were used as the baseline against which Project-related changes during Construction, Operation, Decommissioning, and Post-Decommissioning were assessed. Pre-disturbance watershed areas are presented in Table 8.1-2. Expected changes to these watersheds were estimated for subsequent phases of the Project (Table 8.1-9). Changes in watershed areas will be primarily a result of construction of mine infrastructure and implementation of the Surface Water Management Program. Two scenarios were considered separately for water withdrawal and treated effluent discharge to LA-5, relevant to Operation and Decommissioning. Changes in monthly and annual streamflow rates were projected based on effects predicted for assessment nodes SA-1, SA-2, SA-6/LA-6, LA-1, LA-5, and SB-3. Changes in flow rates were assessed for the mean and 5th percentile low flow statistics. These statistics were selected as being most representative of potential effects given the relatively small withdrawal/discharge rates with respect to baseline flow rates in the area. The Project is expected to have the greatest effect on baseline flow rates during very low flow conditions. It was noted that these low flow conditions have not been observed in the measured record. Groundwater received in LA-5 under natural conditions and estimates of the changes to this contribution were evaluated for Operation and Decommissioning. The following sections discuss each Project-related effect.

Table 8.1-9: Project Effect Scenarios

Temporal Stages	Scenario Number	Project Influence
Construction	1	Fully developed Project Area
Operation and Decommissioning with water withdrawal	2	Fully developed Project Area Freshwater withdrawal from LA-5 Change in groundwater contribution to LA-5
Operation and Decommissioning with effluent discharge	3	Fully developed Project Area Effluent discharge to LA-5 Change in groundwater contribution to LA-5

8.1.4.2.1 Project Overprinting of Drainage Areas

Construction

For the purpose of this assessment, the full measure of site clearing, grading, and infrastructure construction and commissioning was assumed (175 ha). Please note this value was obtained from Denison early in the assessment process. Subsequent revisions to the site layout has further reduced this footprint to (169.6 ha) and as such, this analysis is overly conservative. As such, the total overprinted area by the Project, including access roads and the airstrip, were assessed with respect to changes in functional drainage areas that would have reported to surface water features in the LSA. The overprinting of the landscape by the Project Area will directly change the surface drainage patterns in the area. This will occur via physical change in the landscape and as a result of redirection of surface flows to catchment features (ponds) for the purpose of water collection for mine processing and site water balance.

The Project Area consists of an access road from Highway 914 that extends northwest to the main facilities and northeast to the proposed airstrip. The road and airstrip were not considered to affect hydrology materially. Both may potentially redirect some flow and have a small influence on the timing of concentration of runoff and infiltration rates; however, in general, they are anticipated to have a very small influence and are not expected to change runoff volumes at assessment nodes. Project facilities will influence runoff to assessment nodes as Denison intends to collect all runoff local to Project facilities, reuse where possible, and treat and discharge this water Whitefish Lake (LA-5). The assessment nodes affected by the Project Area are presented in Table 8.1-10.

Table 8.1-10: Site Footprint Effects

Affected Assessment Node	Decrease in Drainage Area (km²)	% of Drainage Area (km²)
SA-5	0.273	0.2
SA-6	0.566	0.2
SB-3	0.214	0.9

Analysis of the Project effects during Construction with a fully developed Project Area indicated that waterbodies LA-1, LA-5, and LA-6 were within affected assessment nodes for the Project. In all cases, the reduction in surface water flow at each hydrology node is expected to be less than 1% of baseline (Table 8.1-11) based on the reduced surface drainage area reporting to the local waterbodies because of Project land use and infrastructure.

Operation

A loss of functional drainage area reporting to local waterbodies, as realized during Construction, is expected during Operation. Collection of surface drainage in on-site storage and treatment ponds will reduce surface drainage to local waterbodies which report to the Icelander River thereby effecting surface water quantity. If considering Scenario 1, which is exclusive of water taking and discharge, the reduction in surface water flow at each hydrology node is expected to be less than 1% of baseline (Table 8.1-11).

Decommissioning/Post-Decommissioning

Decommissioning of the Project is intended to create a safe, stable, and self-sustaining landscape. This will include remediation of on-site storage and effluent ponds and re-establishment of drainage patterns to local surface waterbodies.

Reclamation activities involving earthworks (i.e., cut/fill, infilling/backfilling, and re-grading/recontouring) and other landscape preparations may result in similar Project-related effects previously described, but to a lesser extent. Project-related effects may include discrete/isolated slope failures, minimal surface subsidence (specific to the area above the mining area), and changes in surface drainage patterns. Areas with exposed/unconsolidated surficial materials will constitute roughness coefficients that are not reflective of naturalized conditions until vegetation re-establishment.

In all cases, the reduction in surface water flow at each hydrology node is expected to be less than 1% of baseline (Table 8.1-11) based on the reduced surface drainage area reporting to the local waterbodies because of Project land use and infrastructure. Surface water flows are expected to move toward pre-development levels following Decommissioning and Post-Decommissioning.

8.1.4.2.2 Surface Water Taking

Site water management is described in Section 2, with water block flow diagrams for each phase of the Project provided in Figure 2.2-14, Figure 2.2-15, and Figure 2.2-16. It is important to note that Denison plans to recycle process water to the greatest extent possible, thereby reducing both the demand for freshwater supply and the need for discharge to the receiving water environment.

Construction

Water taking is expected to occur from both groundwater and surface water sources during construction at a volume of 35 m^3/hr to support activities such as operation of the concrete batch plant, wash station, drilling activities, and the potable water plant (Figure 2.2-14 in Section 2). The main source of water taking for operation of the mine and to maintain water balance will be from groundwater sources. However, to supplement these volumes, surface water taking from Whitefish Lake (LA-5) was considered as part of the Surface Water Quantity assessment. As the total volume of water taking from surface water is expected to be lower during Construction (35 m^3/hr) compared to Operations (40.5 m^3/hr), discussion of impacts of surface water taking for the bounding scenario (Operation) is provided below.

Operation

Water taking is expected to occur from both groundwater and surface water sources during Operation. Groundwater taking may have an indirect effect on surface water quantity during phases of maximum taking for the purposes of ISR mining.

The main source of water taking for operation of the mine and to maintain water balance may be from groundwater sources. However, to supplement these volumes and to provide a conservative assessment of potential effects, surface water taking from Whitefish Lake (LA-5) at a rate of 40.5 m^3/hr was considered as part of the Surface Water Quantity assessment.

Potential hydrogeological effects are discussed in more detail in Section 7 Geology and Groundwater. However, Whitefish Lake (LA-5) was estimated under baseline conditions to receive 40 L/s from groundwater sources. Modelling for the Project estimated a decrease in this input to 36 L/s during Operation and Decommissioning. As such, this slight reduction in baseflow contribution to LA-5 was incorporated into the estimates of flow reduction at that node (LA-5).

In all cases, the reduction in surface water flow at each hydrology node was less than 3% of baseline (Table 8.1-12) based on the reduced surface drainage area reporting to the local waterbodies because of Project land use and infrastructure. Under natural conditions studied during the baseline survey period (2011 to 2019), the difference between the minimum and maximum water levels at LSA lakes was typically in the order of 0.4 m (Ecometrix 2020). The potential Project-related change in water level in LA-1 (McGowan Lake), LA-5 (Whitefish Lake), and LA-6 (Unnamed Lake) was estimated from the difference in flow rates between the baseline and affected scenarios (Appendix 8-B). For LA-1, the largest predicted change in water level was

0.0037 m under average conditions for May and June during withdrawal. At LA-5, the largest predicted change in water level in a withdrawal scenario was -0.0041 m during March of the 5th percentile dataset. All expected water level effects on other lakes within the vicinity of the Project, including LA-6, were expected to be negligible, with magnitudes also in the sub-centimeter range.

Decommissioning/Post-Decommissioning

Water taking from groundwater and surface water sources is expected through some portion of Decommissioning during remediation of the ore zone well field and treatment prior to discharge to surface waterbodies. The expected volume of water taking will be similar during the Decommissioning (35.5 m^3/hr) period as during Construction (35 m^3/hr) and Operation (40.5 m^3/hr). The water balance during this phase will be consistent with the cessation of drilling and ore extraction followed by mining area remediation, and finally the gradual thawing of the freeze wall (Figure 2.2-16 in Section 2).During this phase, water taking will mainly be used by the processing plant and wellfield remediation and to support the potable water plant and wash bay. The assessment of the potential impacts of water taking described above for Operation remains consistent for the Decommissioning phase. Groundwater and surface water flows will move toward pre-development levels following in Post-Decommissioning.

Table 8.1-12: Scenario 2 – Operation and Decommissioning – Water Withdrawal – Effects on Surface Water Quantity

8.1.4.2.3 Surface Water Discharge

Construction

Discharge to the environment is not expected during Construction. Site contact water will be collected and held in the Clean Waste Rock Pond (Figure 2.2-14 in Section 2). Therefore, potential effects of discharge on the Surface Water Quantity VC are not expected because there is no planned discharge during this phase of the Project.

Operation

Discharge to the surface water environment is expected during Operation. For the purpose of this assessment, a continuous discharge was assumed into Whitefish Lake (LA-5) (Table 8.1-13). As a result, this Scenario (3) indicated a potential increase in surface water flow and water levels to LA-5. During a discharge scenario, the maximum predicted change in water level was 0.0032 m in March of the 5th percentile dataset. All expected water level effects on other lakes within the vicinity of the Project, including LA-6, were expected to have negligible effects, with magnitudes also in the sub-centimeter range.

Decommissioning/Post-Decommissioning

Discharge to the aquatic environment of Whitefish Lake during some portion of Decommissioning is expected. Effluent rates during this phase (36.5 m^3/hr) are expected to be the same as during Operation. Therefore, the analysis of potential effects on the Surface Water Quantity VC during Operation provided above and summarized in Table 8.1-13 is considered the bounding scenario for Decommissioning as well. Surface water flows will move toward pre-development levels in Post-Decommissioning.

Table 8.1-13: Scenario 3 – Operation and Decommissioning – Effluent Discharge – Effects on Surface Water Quantity

8.1.4.2.4 Future Centuries

During the future centuries phase, remediation works will be completed and the site naturalized, thereby restoring drainage patterns to report to surface waterbodies. Water taking or discharge will have ceased for several hundred years. Groundwater contributions to baseflow in local waterbodies, including Whitefish Lake, are expected to have rebounded to pre-development levels; therefore, effects on future centuries with respect to Surface Water Quantity are expected to be undetectable. After remediation has been completed, thawing of the freeze wall will occur. This will allow the eventual re-establishment of the pre-operational groundwater flow regime in the former mining area. The groundwater levels and discharge volumes to Whitefish Lake will return to baseline condition nine years into Post-Decommissioning and is projected to stabilize moving forward (Figure 7.4-2 in Section 7).

8.1.5 Mitigation Measures

The mitigation measures presented in the following bullets are proposed to avoid or reduce Project-related effects on Surface Water Quantity.

- Limit and stage the construction footprint (i.e., Project Area).
- Maintain existing drainage patterns with the use of culverts, where applicable.
- Maintain access roads by periodically regrading and ditching to improve water flow, reduce erosion, and manage vegetation growth.
- Inspect culverts periodically. Remove accumulated material and debris upstream and downstream of the culverts to prevent erosion, flooding, habitat damage, property damage, and mobilization of sediment.
- Attenuate peak discharges and augment baseflows to the environment using Project water storage features (i.e., runoff, process water, contact water, monitoring/effluent ponds).
- Recycle contact water for use as process water.
- Recycle process water for re-use.

8.1.6 Residual Effects Evaluation

8.1.6.1 Residual Effects Characterization

General definitions of the residual effect characteristics are provided in Section 5.8. A residual effect on Surface Water Quantity is defined as a measurable change in the flow or water levels relative to baseline. Residual effect characteristics specific to Surface Water Quality are defined in Table 8.1-14.

Table 8.1-14: Surface Water Quantity – Definitions of Effect Characteristics Considered When Determining the Significance of Residual Effects

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Effect moves measurable parameters (flow or water level) in a direction detrimental to water quantity relative to baseline conditions. A Project-caused increase in surface water levels and flows during flooding, or a decrease in surface water flow below environmental flow requirements. **Positive** – Effect moves measurable parameters (flow or water level) in a direction beneficial to water quantity relative to baseline conditions. A Project-caused reduction in flooding events and related peak-flows/surface water levels resulting from flooding events.
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low** – A Project-related change in hydrology (flows or levels) compared to baseline conditions, but where the change is <5% from baseline conditions. **Moderate** – A Project-related change in hydrology (flows or levels) compared to baseline conditions, but where the change is >5% from baseline conditions. **High** – A Project-related change in hydrology (flows or levels) that results in surface water levels and flows above existing flood maximums or a change in the surface water quantity within a watercourse that is less than the environmental flow threshold, which may affect aquatic ecosystems.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area. **Local** – Effect is limited to the Surface Water Quantity LSA. **Regional** – Effect extends beyond the Surface Water Quantity LSA into the Surface Water Quantity RSA. **Beyond Regional** – Effect extends beyond the Surface Water Quantity RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals. **Frequent** – Effect occurs many times on a regular basis. **Continuous** – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions. **Partially Reversible** – A residual effect that partially diminishes to baseline conditions. **Irreversible** – A residual effect that will not diminish to baseline conditions.
Context	The extent to which the VC or KI has been affected by past and present environmental and socio-economic processes and conditions, its potential sensitivity to the Project-related residual effect, and its ability to recover	**Low** – VC/KI has high resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a lack of historic and ongoing anthropogenic or natural disturbance. **Moderate** – VC/KI has moderate resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or an intermediate level of historic or ongoing anthropogenic or natural disturbance with the capacity to assimilate more change. **High** – VC/KI has weak resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or

Residual Effect Characteristic	Definition	Rating
	from that effect (i.e., resilience).	ecosystem, and/or a high level of historic or ongoing anthropogenic or natural disturbance.
Likelihood	Likelihood that the residual effect will occur, including consideration of the likelihood that the mitigation will be successful.	**Likely** – There is a moderate to high probability that the residual effect will occur. **Unlikely** – There is a low probability that the residual effect will occur.

Flows and water levels in lakes and rivers within the LSA will realize some adverse change (reduction) as a result of overprinting drainage areas reporting specifically to Whitefish Lake and water taking from this same waterbody. However, under all scenarios, including under low flow (5th percentile), the reduction in flow is expected to be less than 3% and, therefore, below the criteria for magnitude of 5%. This would be considered a low impact to existing environmental flows. Furthermore, the maximum predicted reduction in lake water levels was 0.0032 m at LA-5. All anticipated water level effects on other lakes within the vicinity of the Project, including LA-6, are expected to have negligible effects, with magnitudes also in the sub-centimeter range. As natural fluctuations in lake water levels were approximately 0.4 m from 2011 to 2019, Project-related changes are not expected to be of a magnitude to compromise the Surface Water Quantity VC.

Effects on surface water flows and levels are predicted to be localized to the subwatersheds within proximity to the mine, specifically Whitefish Lake, yet they are expected to occur over the course of the Project. However, the effects are expected to be fully reversible following Decommissioning as natural drainage patterns will be restored. A summary of residual effect ratings is provided in Table 8.1-15.

Table 8.1-15: Surface Water Quantity – Summary of the Characteristics Ratings for Residual Effects

Residual Effect Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Water quantity (flow and level) will be reduced in Whitefish Lake (LA-5) as a result of the overprinting of its reporting drainage area by mine infrastructure and through site water balance. Water taking has an additional potential to reduce water levels in Whitefish Lake.
Magnitude	Low	Under all scenarios, the Project-related change in hydrology (flows or levels) compared to baseline conditions is predicted to be <5% of baseline conditions, and generally <3%.
Geographic Extent	Local	The effects are expected to be limited to the LSA, specifically the lakes within proximity to the Project site (i.e., LA-5, LA-6, and LA-1).
Duration	Medium-term	The effects are expected to last between 3 to 38 years (i.e., effects expected during Construction through to the end of Post-Decommissioning).

Residual Effect Characteristic	Rating	Summary Rationale for Rating
Frequency	Continuous	Although the mine is unlikely to require water taking on a continuous basis, this scenario was assessed as the bounding scenario and, as such, was considered to be a continuous effect.
Reversibility	Fully Reversible	Surface water hydrology is expected to return to pre-development levels following Post-Decommissioning.
Context	Moderate	Surface water flow regimes are variable and it is this variability that provides for morphological form to be maintained and for ecological reliance (i.e., riparian inundation, aquatic biota movement and migration, ecological life process success). Some change to environmental flows is tolerated by hydrological systems.
Likelihood	Unlikely	Due to the localized nature and low magnitude of the predicted effects on surface water hydrology, the likelihood of an effect is considered to be very low.

8.1.6.2 Confidence in Assessment

As Surface Water Quantity is considered an intermediate VC, the significance of any associated residual effects is assessed within the context as a pathway to effects on receptor VCs. These receptor VCs include Fish and Fish Habitat (Section 8.3) and Sediment Quality and Benthic Invertebrates (Section 8.4). Determinations of significance of residual effects are provided in these sections.

The confidence in the assessment of predicted effects on hydrology is quite high due to available hydrological data for the LSA. Uncertainty is minimal with the assumptions that water withdrawal and discharge scenarios presented herein represent the bounding case and hydrogeological modelling projections are not changed. The low potential water withdrawal and discharge magnitudes proposed by Denison for the Project are predicted to result in negligible effects on the receiving environment within the LSA. The RSA was not assessed due to the much larger drainage area at the outlet of Russell Lake and greater attenuation of the signal of expected effects. All projected influences on streamflow from the Project are within +/- 5% of baseline conditions on a monthly average basis, with the largest influence occurring during withdrawal at a magnitude of -3.1%. Lake levels are anticipated to have a similarly negligible effect, with expected changes to water levels in LA-1 and LA-5 being less than 0.01 m.

8.1.6.3 Summary of Project-related Residual Adverse Effects on Surface Water Quantity

Since Surface Water Quantity is an intermediate VC, the results of residual effect characterizations for Surface Water Quantity do not have significance determinations of their own. Determinations of significance of residual adverse effects related to Surface Water Quantity are provided in association with receptor VCs in Sections 8.3, 8.4, and 8.5 (Fish and Fish Habitat, Sediment Quality and Benthic Invertebrates and Fish Health, respectively).

8.1.7 Cumulative Effects

The spatial and temporal boundaries of the Project specific to the Surface Water Quantity VC are provided in Section 8.1.1.3. A description of the methods used in assessing cumulative effects is provided in Section 5.9.

Project-related interactions are predicted to be limited both spatially and temporally. Spatially, interactions between the Project and Surface Water Quantity are predicted to be highly localized to Whitefish Lake South (LA-5) with no further propagation downstream of this immediate area. This is due to the small footprint of the Project, the relatively small volume of water that may be taken from surface waters, and the limited interaction between groundwater and surface waterbodies (i.e., Whitefish Lake) during all Project phases.

Existing projects within the Wheeler River Watershed have been considered for potential to interact with the Surface Water Quantity VC for the Project. These include reasonably foreseeable projects that are described in Section 5.9.

Projects with the potential to interact with the Surface Water Quantity VC for the Project include three existing mines and mills (i.e., Cameco Cigar Lake Mine, Cameco Key Lake Operation, and Cameco McArthur River Operation).

The Project is situated approximately 35 km northeast of the Cameco Key Lake Operation and 35 km southwest of the Cameco McArthur River Operation. The Project is located approximately 85 km southwest of the Cameco Cigar Lake Mine. These projects do not overlap spatially with the LSA of the Project and are, therefore, not further considered in the cumulative effects assessment.

8.1.7.1 Additional Mitigation Measures

Additional mitigation measures were not warranted as no potential cumulative effects were identified for the Surface Water Quantity VC.

8.1.7.2 Cumulative Effects Characterization and Determination of Significance

A determination of significance was not warranted as no potential cumulative effects were identified for the Surface Water Quantity VC.

8.1.7.3 Cumulative Effects Assessment Summary

No cumulative effects were identified for the Surface Water Quantity VC as no project and/or activity that may be considered as reasonably foreseeable overlaps with the defined RSA.

8.1.7.4 Environmental Monitoring and Follow-Up

Additional monitoring and follow-up were not warranted as no potential cumulative effects were identified for the Surface Water Quantity VC.

8.1.7.5 Climate Change Considerations

As discussed in Section 8.1.3.3, climate change is projected to increase precipitation in the vicinity of the Project. Though this will result in an increase of runoff in the LSA, the potential implications to evaporative effects are unknown. Evaporation, being a function of air temperature, wind speed, relative humidity, and radiation, may have a small increase given that air temperature may increase by as much as 6.2% (Table 8.1-5), though wind speed may similarly decrease by 2.6% in the same RCP scenario. Relative humidity is a representation of the ratio of actual to saturated vapour pressure and both are a function of temperature as well as vapour phase water in the air. Without a complete projected dataset for all parameters, as well as an accepted model, it is difficult to estimate the response of evaporation to these climatic influences.

Augmenting the data in an existing dataset did not yield a consistent shift in evaporation, which indicates the relationship is dynamic (Appendix 10-B). Any noted change between the datasets resulted in a change in evaporation rates of less than 5%. As such, given the small influence of evaporation and the variable range of predicted changes in precipitation and snow depth, the effects of climate change on the water balance are discussed qualitatively based on the four scenarios described in Section 8.1.4.2. The four projections for climate change scenarios are:

1. mean precipitation static and increased evaporation – this projection would result in a marginal decrease in flow rates from the Project;
2. increased precipitation and evaporation – this projection would at least partially cancel out, with either increased or decreased flow rates from the Project;
3. mean precipitation static and decreased evaporation – this projection would result in increased flow rates from the Project; and
4. increased precipitation and decreased evaporation – this projection would also result in increased flow rates from the Project.

Of the four potential climate change scenarios, only projections 1 and 2 have the potential to result in a condition where flow rates decrease as a result of climate change. Any decrease in flow rates due to climate change would likely be marginal and not statistically detectable as a result of projections 1 and 2. This is typically due to the already highly variable climate in Saskatchewan. Appreciable changes to the timing and magnitude of snow depth have the potential to alter current flow rates but are still unlikely to have substantial influence from the Project.

Extreme events are expected to change due to climate change. Qualitatively, climate change is expected to increase the frequency and magnitude of such events. Though the potential maximum PMP is not expected to increase as it is limited by the persistent dew point, the magnitude of the 1:100 year, 24-hour storm is expected to increase from 77.9 to 88.6 mm (approximately 10%). This may require consideration for greater storage and conveyance capacity for Project water management infrastructure.

8.1.8 Monitoring and Follow-up

For the purposes of this EIS, monitoring and follow-up are defined as follows:

- monitoring programs are designed to meet regulatory requirements (e.g., permit or license conditions) and/or to demonstrate compliance with environmental commitments made in the EIS; and
- follow-up programs are those that are proposed to address any uncertainties identified during the EA process (e.g., to verify predictions made during the EA; determine the effectiveness of proposed and implemented mitigation measures) and to determine if and when to implement adaptive management measures.

As no significant residual effects were identified and uncertainty was low with respect to the assessment of Project effects on Surface Water Quantity, a follow-up program is not required. However, it is suggested that continued hydrologic monitoring is important to provide Project phase information to monitor predictions and support effluent discharge permitting and approvals (i.e., meet approvals for continued surface water quality levels).

The long-term hydrological monitoring study at the Project site has been in place since 2011. The program should remain consistent to allow for the continued establishment of long-term streamflow trends at the site through relationships to long-term operating hydrometric gauging stations in the same watershed.

Monitoring should continue to include the following:

- streamflow monitoring;
- lake level monitoring; and
- installation of stage dataloggers.

Monitoring stations should continue to survey at locations throughout key catchment areas. Hydrometric monitoring at streamflow stations should include measurement of stream discharge and water level survey and maintenance of in-stream dataloggers.

8.1.9 Surface Water Quantity Summary

Denison initiated hydrometric baseline monitoring in 2011, which has continued up to the present at various locations throughout the LSA. Streamflow records at existing stations provide an understanding of the range of flows during open water conditions, including snowmelt runoff, rainfall response to storm events, and late summer low flow periods. Winter data are not available at most stations due to a lack of winter field monitoring programs. Long-term flow records with winter discharge are available from a Water Survey of Canada hydrometric monitoring station located downstream of Russell Lake on the Wheeler River (station 06DA005). Flow records from station 06DA005 have been extended to the assessment nodes at the Project either through correlation or unit area runoff analysis.

Assessment node LA-5 (Whitefish Lake) is located immediately downstream of the outlet of the lake adjacent to the main Project facilities. The extended flow record estimated for this node indicates mean annual flows ranging from 0.867 to 2.990 m^3/s, with an average flow of 1.409 m^3/s. The projected withdrawal and discharge rates proposed for the Project are the largest influence on the hydrological effects of the Project; however, the largest predicted change in streamflow rate is -3.1% at the LA-5 and SA-2 nodes (immediately downstream of the Project) during Operation and Decommissioning, as projected against the 5th percentile low flow dataset in March. Lake levels are expected to deviate less than ±0.01 m due to all Project influences. All Project influences on the environment are expected to return to baseline conditions during Post-Decommissioning.

Following mitigation through design and water management, Project-related effects on Surface Water Quantity are predicted to be **not significant**. The low potential water withdrawal and discharge magnitudes proposed by Denison for the Project are expected to result in no significant residual effects on the receiving environment within the LSA.

Some influence as a result of climate change is expected; however, predicted scenarios do not indicate an exacerbation of potential effects on the Surface Water Quantity of LSA waterbodies as a result of the Project.

Critical locations for monitoring should include the following nodes to remain consistent with the current long-term dataset.

- SA-1 – Streamflow monitoring station on the stream colloquially known as the Icelander River, which is located downstream of LA-1 (McGowan Lake).
- SA-2 – Streamflow monitoring station situated downstream of the outflow from LA-5 (Whitefish Lake) and upstream of the inflow to LA-1 (McGowan Lake).
- SA-3 – Streamflow monitoring station situated upstream of the inflow to LA-1 (McGowan Lake).
- SA-4 – Streamflow monitoring station situated upstream of the inflow to LA-6 (Unnamed Lake).
- SA-5 – Streamflow monitoring station situated upstream of the inflow to LA-6 (Unnamed Lake).
- SA-6 – Stream flow monitoring station situated downstream of the outflow from LA-6 (Whitefish Lake North) and upstream of the inflow to LA-5 (Whitefish Lake South).
- LA-6 – Lake level monitoring station at LA-6 (Whitefish Lake North).
- SB-3 – South Project drainage basin flowing to Russell Lake.
- LA-1 – McGowan Lake.
- LA-5 – Whitefish Lake South.

No cumulative effects were identified for the Surface Water Quantity VC as there are no projects and/or activities that may be considered as reasonably foreseeable that overlap with the defined RSA for this VC.

Changes in precipitation volumes, periodicity, and extreme events are plausible based on predictive models; however, any decrease in flow rates due to climate change would likely be marginal and not statistically detectable.

8.2 Surface Water Quality

This subsection addresses the potential effects of the Project on the Surface Water Quality VC. The following are discussed herein as part of the EA:

- scope of the assessment;
- summary of existing conditions relevant to the Surface Water Quality VC;
- identification and description of potential interactions between the Project and the Surface Water Quality VC;
- identification and description of mitigation measures applicable to the Surface Water Quality VC to eliminate, reduce, or control the potential adverse Project-related effects;
- identification and characterization of predicted Project-related residual effects on the Surface Water Quality VC after mitigation;
- characterization of significance and assignment of the level of confidence in the predictions; and
- identification and characterization of potential cumulative effects.

Figure 8.2-1 is a graphic representation of the assessment process used in this EIS.

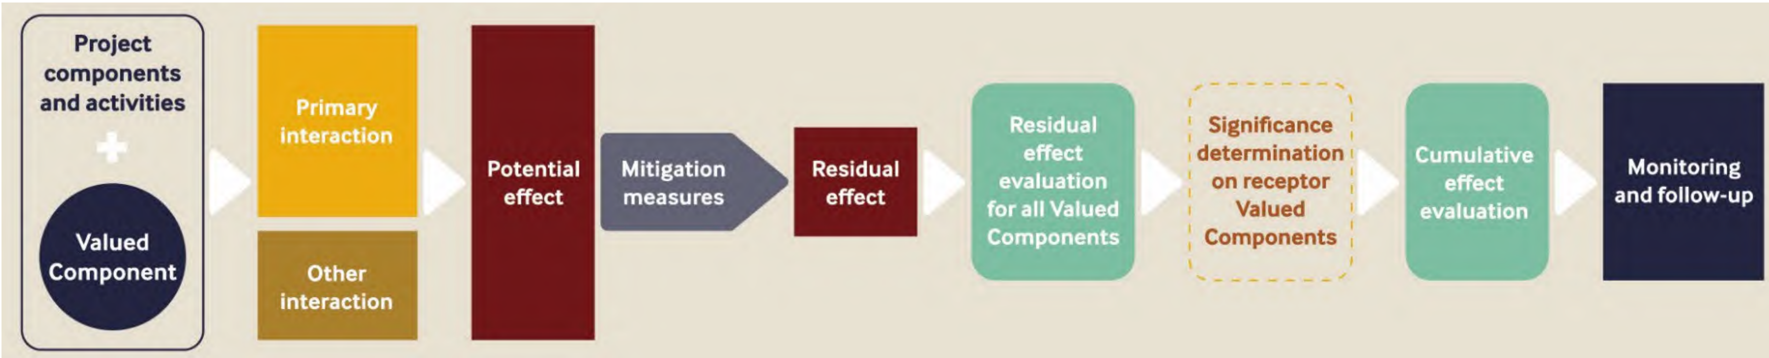

Figure 8.2-1: Environmental Assessment Process for the Wheeler River Project

8.2.1 Scope of the Assessment

The purpose of this assessment is to assess potential changes to Surface Water Quality in consideration of all Project phases at the Project, local, and regional study areas scales. Surface water quality pathways that are of interest are associated with site clearing and the potential for erosion-driven mobilization of suspended sediment, groundwater interactions with surface water features, and effluent discharge to the natural environment.

8.2.1.1 Valued Component Selection

The process and rationale for selection of VCs and establishment of KIs and associated MPs is described in Section 5. Section 5.8.1.1 defines intermediate VCs and receptor VCs. This section addresses the Surface Water Quality VC which is identified as an intermediate VC as it represents a physicochemical medium and pathway of influence to biological and ecological receptor VCs. The Surface Water Quality VC was selected for inclusion as Project activities have the potential to affect erosion-driven mobilization of suspended sediment, groundwater interactions with surface water features, and effluent discharge to the natural environment. Potential changes to water, from both a quantity and quality perspective, are key considerations within the EA process, as demonstrated by previous uranium mining development proposals in the Athabasca Basin, and draw a high level of concern from Interested Parties (see Section 8.2.2). Changes to Surface Water Quality have the potential to affect biodiversity and biological function through direct exposure and indirect food chain influences (i.e., aquatic sediments, fish and fish habitat, and benthic invertebrates), and the cultural values of Indigenous groups, the public, and other stakeholders. In this context, Surface Water Quality is interrelated or linked, to varying extents as an intermediate VC, to other intermediate and receptor VCs that are considered in this EIS, including:

Intermediate Valued Components

Surface Water Quantity: Surface water flow volumes and periodicity directly influence water quality in a waterbody. Natural and seasonal changes in precipitation, and therefore Surface Water Quantity, are directly related to Surface Water Quality. Project changes to surface drainage patterns, site water balance, and effluent discharge may influence Surface Water Quantity, which in turn may influence the assimilative capacity of receiving waters.

Groundwater Quality and Quantity: The quantity and quality of groundwater reporting to surface water through hydrologic connections can influence the water quality in surface waterbodies.

Receptor Valued Components

Terrestrial Environment: Surface water interacts with various VCs to shape ecosystem form, function, and biodiversity, including Vegetation and Ecosystems and Wetlands (i.e., riparian and wetland vegetation); Terrain, Soils, Organic Matter/Peat; Ungulates, Furbearers and Woodland

Caribou as well as Raptors, Migratory Breeding Birds, and Bird Species at Risk. Surface water quality is directly linked to terrestrial biota health through habitat and as a watering source.

Sediment Quality: Surface water and groundwater interface directly with the sediments of aquatic environments and the quality of this water directly influences the quality of the sediments. Aquatic sediments that fish, invertebrates, and microbes inhabit are the medium responsible for their ability to carry out some proportion of their life processes. An alteration to Surface Water and Groundwater Quality in the aquatic environment can affect Sediment Quality.

Fish and Fish Habitat, and Benthic Invertebrates: The water that fish and benthic invertebrates inhabit is the medium responsible for their ability to carry out their life processes. An alteration to Surface Water Quality in the aquatic environment can directly affect Fish and Fish Habitat, and Benthic Invertebrates.

Land and Resource Use: Indigenous Land and Resource Use and Other Land and Resource Use are influenced by Surface Water Quality as resource users use aquatic and terrestrial flora and fauna.

Human Health: Consideration is given to people drinking surface water as part of the Human Assessment.

Based on the above and the assessment approach described in Section 5, the Surface Water Quality VC is considered an intermediate VC. The assessment of the Surface Water Quality VC provides a full evaluation of residual effects with the determination of significance completed on receptor VCs such as Sediment Quality, Benthic Invertebrates, Fish and Fish Habitat, Fish Health, and Human Health.

Figure 8.2-2 is a graphic representation of the main linkages among the Surface Water Quality VC and other VCs, illustrating the flow of assessment information into and from the Surface Water Quality VC.

Figure 8.2-2: Integrated Assessment Approach - Key Connections between Surface Water Quality and Other Valued Components

8.2.1.2 Key Indicators and Measurable Parameters

The KI for this VC is any potential change in surface water quality from baseline conditions (e.g., a change in the concentration or level of a constituent in water that interacts with the Project). The rationale and MPs for the Surface Water Quality VC are provided in Table 8.2-1.

Table 8.2-1: Key Indicators and Measurable Parameters for Surface Water Quality

Key Indicator	Rationale for Key Indicator	Measurable Parameter
Change in surface water quality from baseline concentrations	Introduction of constituents into receiving waterbodies as a result of the Project that are of a magnitude to negatively affect aquatic and non-aquatic biota associated with those waterbodies and/or water uses in the study area.	Change in the concentration of constituents that are directly related to Project activities as measured as a mass of a chemical per unit volume in water (e.g., mg/L).

8.2.1.3 Spatial and Temporal Boundaries

Generic considerations associated with the establishment of the spatial boundaries of the assessment are described in Section 5.3.3. As it pertains to the Surface Water Quality VC, the following is noted.

- The **Project Area** is the direct footprint of the Project. The Project Area represents the area within which Project activities and components may occur and, as such, represents the area within which direct physical disturbance may occur as a result of the Project, either temporary or permanent (i.e., the Project footprint; the area of maximum physical disturbance). This area is not VC-specific, but consistent throughout the EIS for all VCs.

- The **LSA** is the area that surrounds the Project Area where both direct and indirect effects resulting from Project activities can be reasonably measured. The LSA was established to assess the potential, largely direct effects of the Project and represents the extent to which there is a reasonable potential for the Project or Project-related activities to interact with and potentially adversely affect the VC. For the Surface Water Quality VC, the LSA was derived from watershed boundaries within proximity of the Project Area, including portions of watersheds that overlap the Project site, as well as areas directly downstream that may be influenced by the Project site or effluent discharge. The subwatersheds within the LSA are presented in Figure 8.1-3. This area was selected based on important waterbodies (notably Whitefish and McGowan lakes) downstream of the Project where effects may occur through all temporal phases. The LSA extends from those waterbodies down to their inflows to Russell Lake.
- The **RSA** is the area that surrounds and includes the LSA, and was established to assess the potential, largely indirect effects of the Project, as well as other activities, in a regional context. The RSA is large enough to capture the extent of potential effects (i.e., zone of influence) on a VC and defines the area within which cumulative effects may occur (i.e., cumulative effects assessment boundary). The RSA for the Surface Water Quality VC is bounded by the regional watershed area in which the Project Area is located. The RSA for this assessment is based on the whole watershed within which the Project is located and extends downstream to include Russell Lake (Figure 8.2-3).

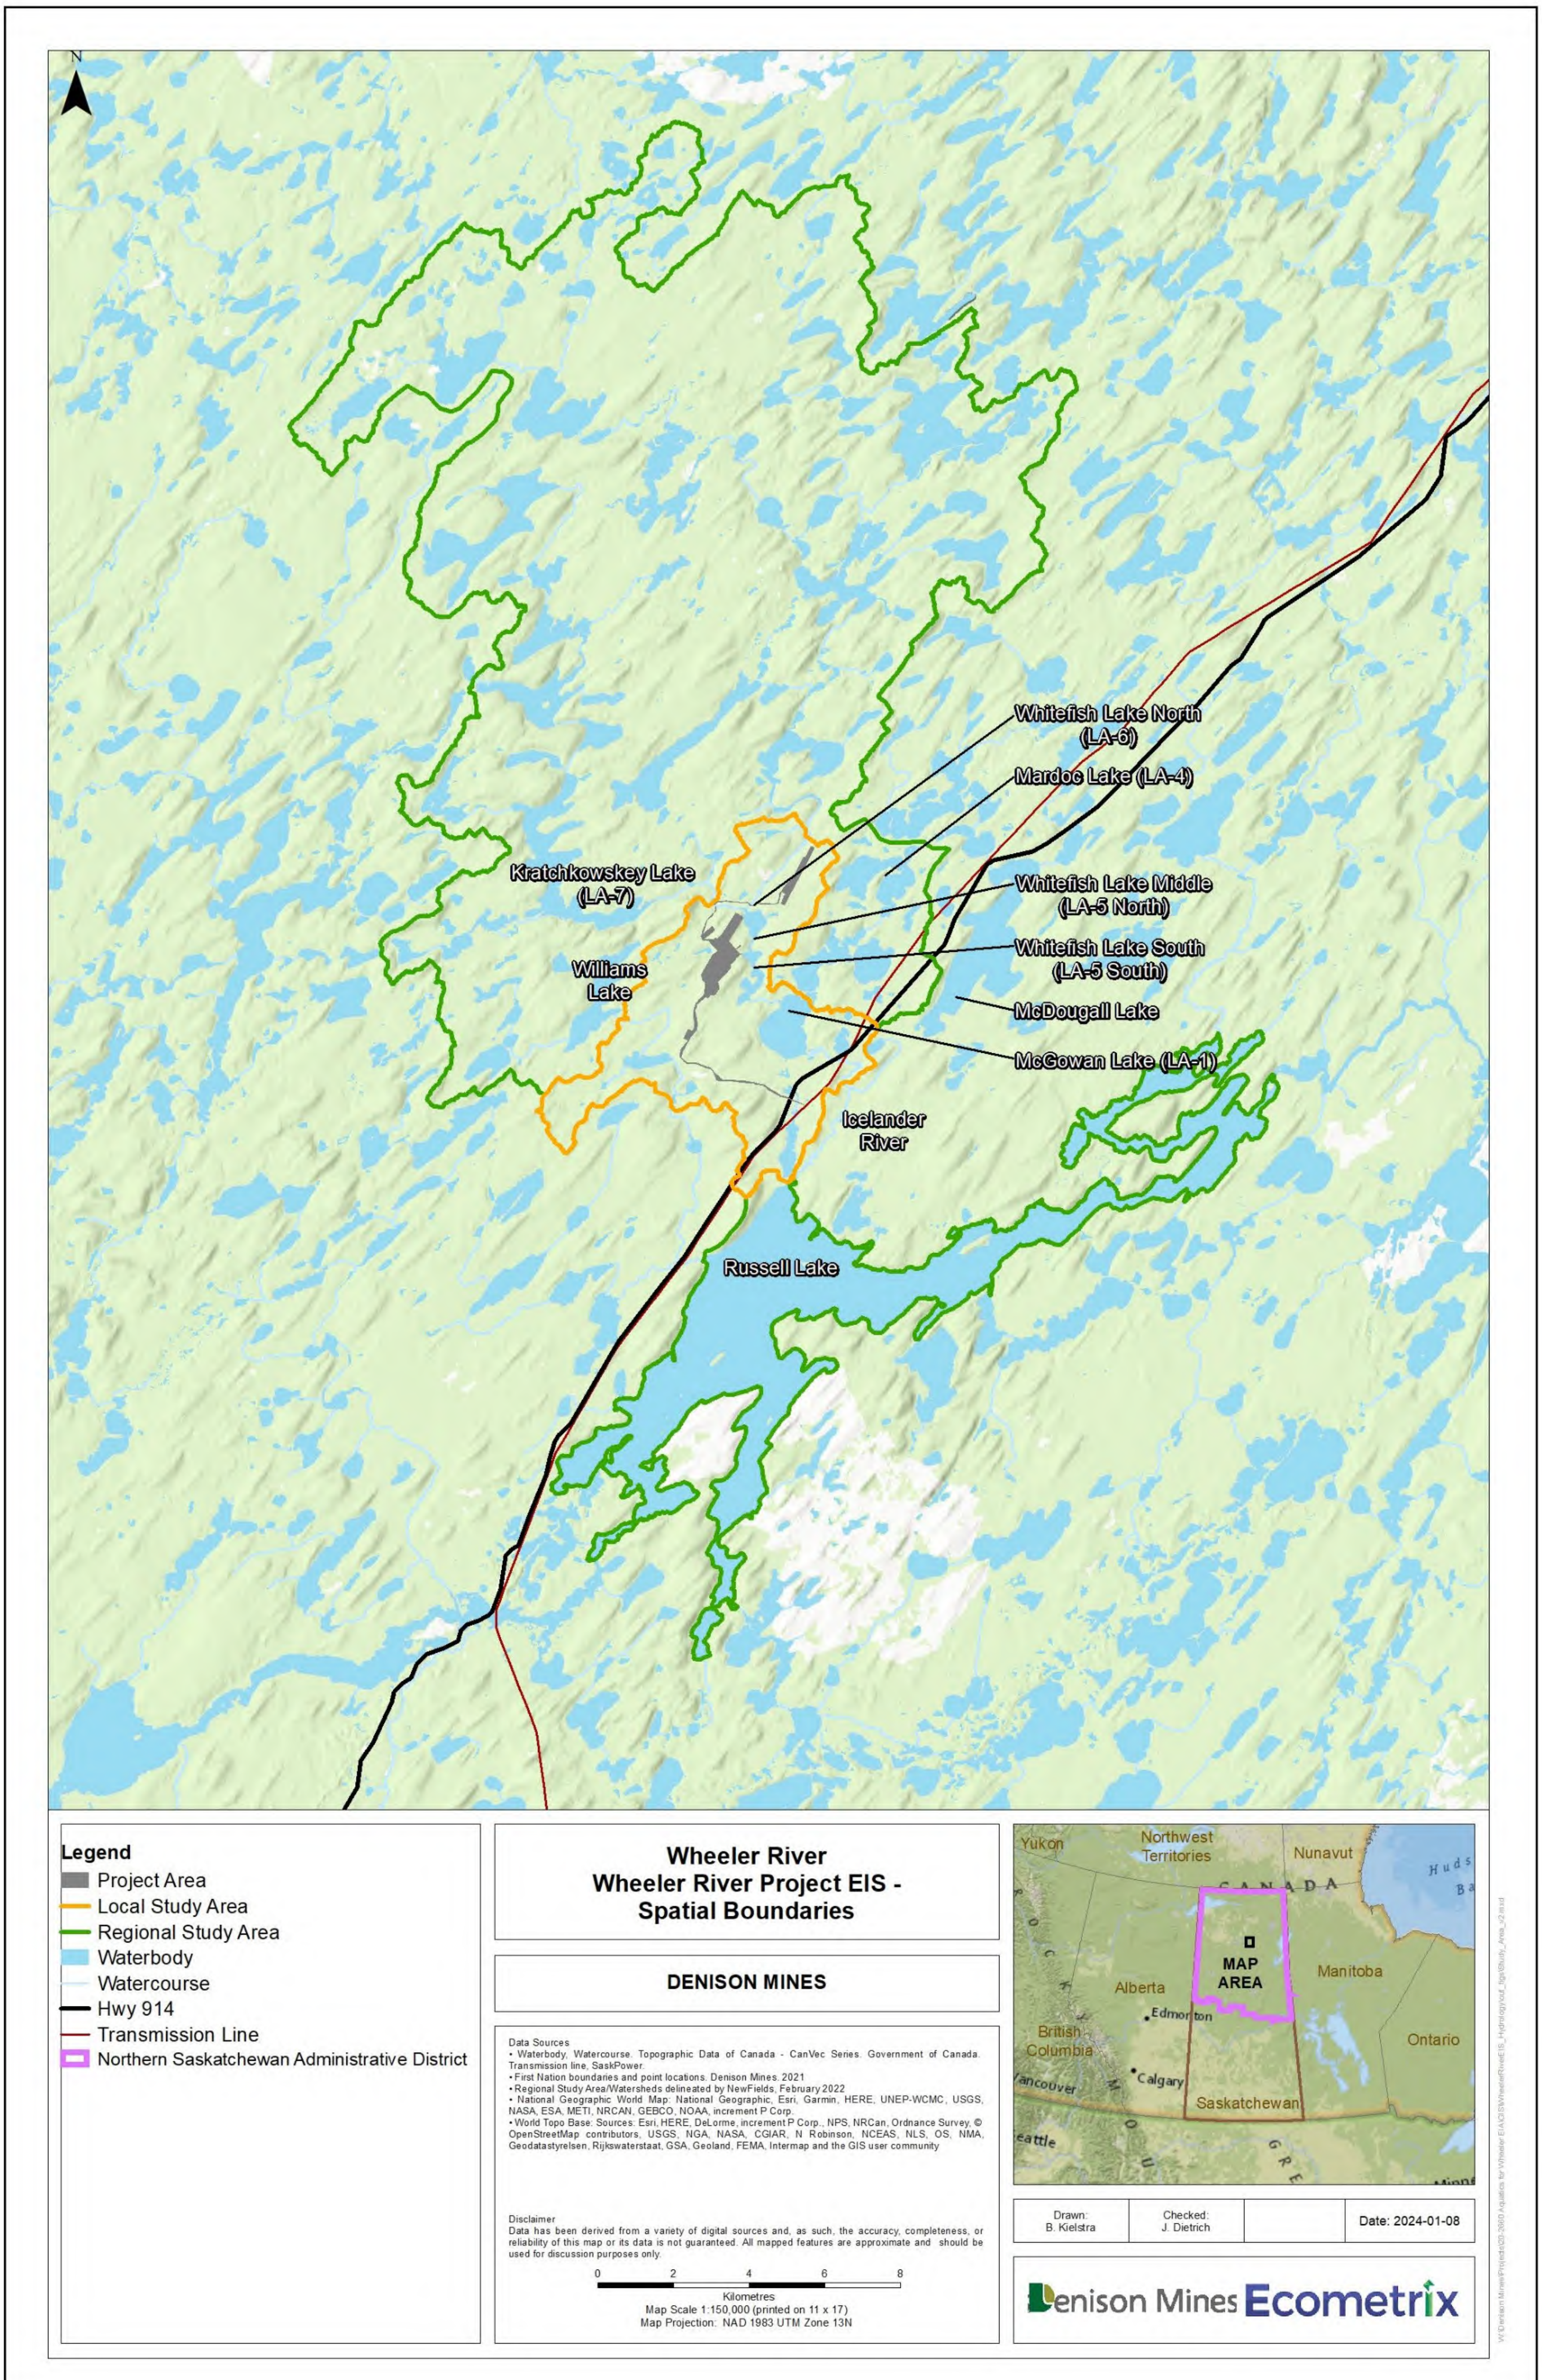

Figure 8.2-3: Spatial Boundaries for the Surface Water Quality Valued Component

Temporal boundaries for the EIS are defined in Table 5.3-3 in Section 5.3.4. The temporal boundaries applicable to and considered in the EIS include the following Project phases:

- Construction (Year 1 to 3);
- Operation (Year 3 to 18);
- Decommissioning (Year 18 to 23); and
- Post-Decommissioning (Year 23 to 38).

Additionally, a "future centuries" scenario is considered to assess the potential effects post-restoration (i.e., beyond the Project timeline of 0-38 years) and to reflect the time period over which the highest constituent concentrations in groundwater are predicted to migrate towards and interact with surface water.

This period represents the time where the highest constituent concentrations in groundwater are predicted to interact with surface water based on groundwater modeling. In this context, the future centuries scenario is considered with respect to the interaction of groundwater migration from the Project site and its potential influence on surface water in local water bodies. The future centuries projection encompasses the long-term period during which slow migration of groundwater from the Phoenix Ore Zone area to the surface water environment is anticipated and constitutes a bounding scenario of maximum concentrations of COPC.

8.2.2 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

At its broadest level, IK can be understood as the unique and collective knowledge of Indigenous peoples that may include, but is not limited to, the environmental, cultural, economic, political, and spiritual conditions of a community or region. In this section, IK and LK are viewed as complementary and influential alongside western science to produce a full understanding of the potential effects of the Project, whether measurable or perceived. Both forms of information have been given full and fair consideration.

Denison has recorded and stored information regarding IK, LK and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers (e.g., 18-EN-ERFN-5.68). These numbers are referenced throughout the EIS, but particularly in Parts II and III, to indicate where specific information from the database has been integrated into the assessment. Appendix 8-A provides a summary of unique identification numbers referenced within Section 8.2.

Indigenous Knowledge and LK quotes and citations were included herein to provide readers with the information considered as the Project advanced throughout the EA process. Since 2016, Denison has been engaging with Interested Parties (i.e., local and Indigenous communities, residents, businesses, organizations, land users, and various regulatory authorities) to support the development of positive relationships and a mutual commitment to collaboration.

The history of resource sharing was described in sharing, such as:

> *"The biggest body of water to be impacted is Russell Lake – "Big Poor Fish Lake" in Dené. A lot of Scandinavians and Norwegians went up there in the 1930s and partnered with First Nations in that territory"* (18-EN-ERFN-5.68).

The influence of IK, LK, and engagement on the assessment of the Surface Water Quality VC has first and foremost shaped the shared value of water and its life-sustaining properties.

> *"The lands and waters, we are definitely connected as peoples of English River. If we don't have the lands, we are not connected. If we don't have the water... Water is life to us"* (ERFN and SVS 2022).

Comments associated with water management and discharge to the environment were significant in the engagement record[2], and these were considered within the context of community interest regarding surface waters remaining supportive of natural function for biota. To this end, Project-related water management and treatment are important to maintaining surface water quality within the LSA and RSA.

Indigenous peoples and LK holders were clear in their interest regarding current levels of constituents in the aquatic ecosystem and the potential for adverse changes resulting from the Project. For example:

> *"How many lakes have you tested? Is there mercury?"* (19-EN-ML21-62.34);
>
> *"Russell is one lake where I commercially fish. How will this effluent impact the water quality, fish health? Will I be able to sell fish from here? If there is going to water pollution, I just want to know"* (19-LK-ERFNTrap-134.255);
>
> *"How are you going to protect the water quality? We are concerned about mercury in fish, other animals, etc. Is there mercury or arsenic in the uranium solution?"* (21-EN-LLRIB-392.15); and
>
> *"What is the plan for storing and cleaning the water and where does it flow? What is the impact of ISR mining on water quality?"* (21-EN-VILX-443.25).

Indigenous Knowledge and LK clearly identify the importance of water quality to local community members, plants, wildlife, and fish. This affirms the necessity to include Surface Water Quality as a VC in the EA Based on engagement, it is understood that additional detail is expected with respect to the potential effects of the Project on Surface Water Quality, and this section of the EIS is responsive to that expectation.

[2] 19-EN-MN-SR3-1.2, 19-EN-ML82-1.3, 19-EN-MOE-1.4, 18-EN-VILX-3.33, 18-EN-VILX-3.35, 18-EN-VILX-3.39, and 18-EN-VILX-3.84.

8.2.3 Existing Environment

Sampling of the aquatic environment for water quality and biota was conducted from 2014 to 2019. Detailed accounts of the methods and results of these field surveys are provided in Ecometrix (2020) and further discussed from an ecological risk perspective in the *Environmental Risk Assessment for Wheeler River* (see Appendix 10-A in Section 10).

8.2.3.1 Methodology and Metrics

Surface water quality was sampled during 2016, 2018, and 2019 at lakes and watercourses within the LSA and RSA (Figure 8.2-4 and Appendix 8-D). Sampling at lakes and ponds included the measurement of both physical and chemical parameters obtained in situ during field surveys and by laboratory analysis. Field measurements at each station included:

- conductivity;
- pH;
- temperature;
- dissolved oxygen (DO); and
- water clarity.

A depth profile of these parameters was recorded in each lake at its deepest location, as identified during bathymetric investigations. Conductivity, pH, temperature, and DO were measured at 1 m intervals from the surface to the bottom of the water column. Water clarity at the lake profile location was assessed by measuring the secchi disk depth.

Laboratory analysis of samples collected during baseline collections included the following:

- pH and conductivity;
- total suspended solids (TSS) and total dissolved solids (TDS);
- alkalinity, acidity, and hardness;
- nutrients (total and dissolved phosphorus, ammonia, and total kjeldahl nitrogen);
- total metals; and
- radionuclides.

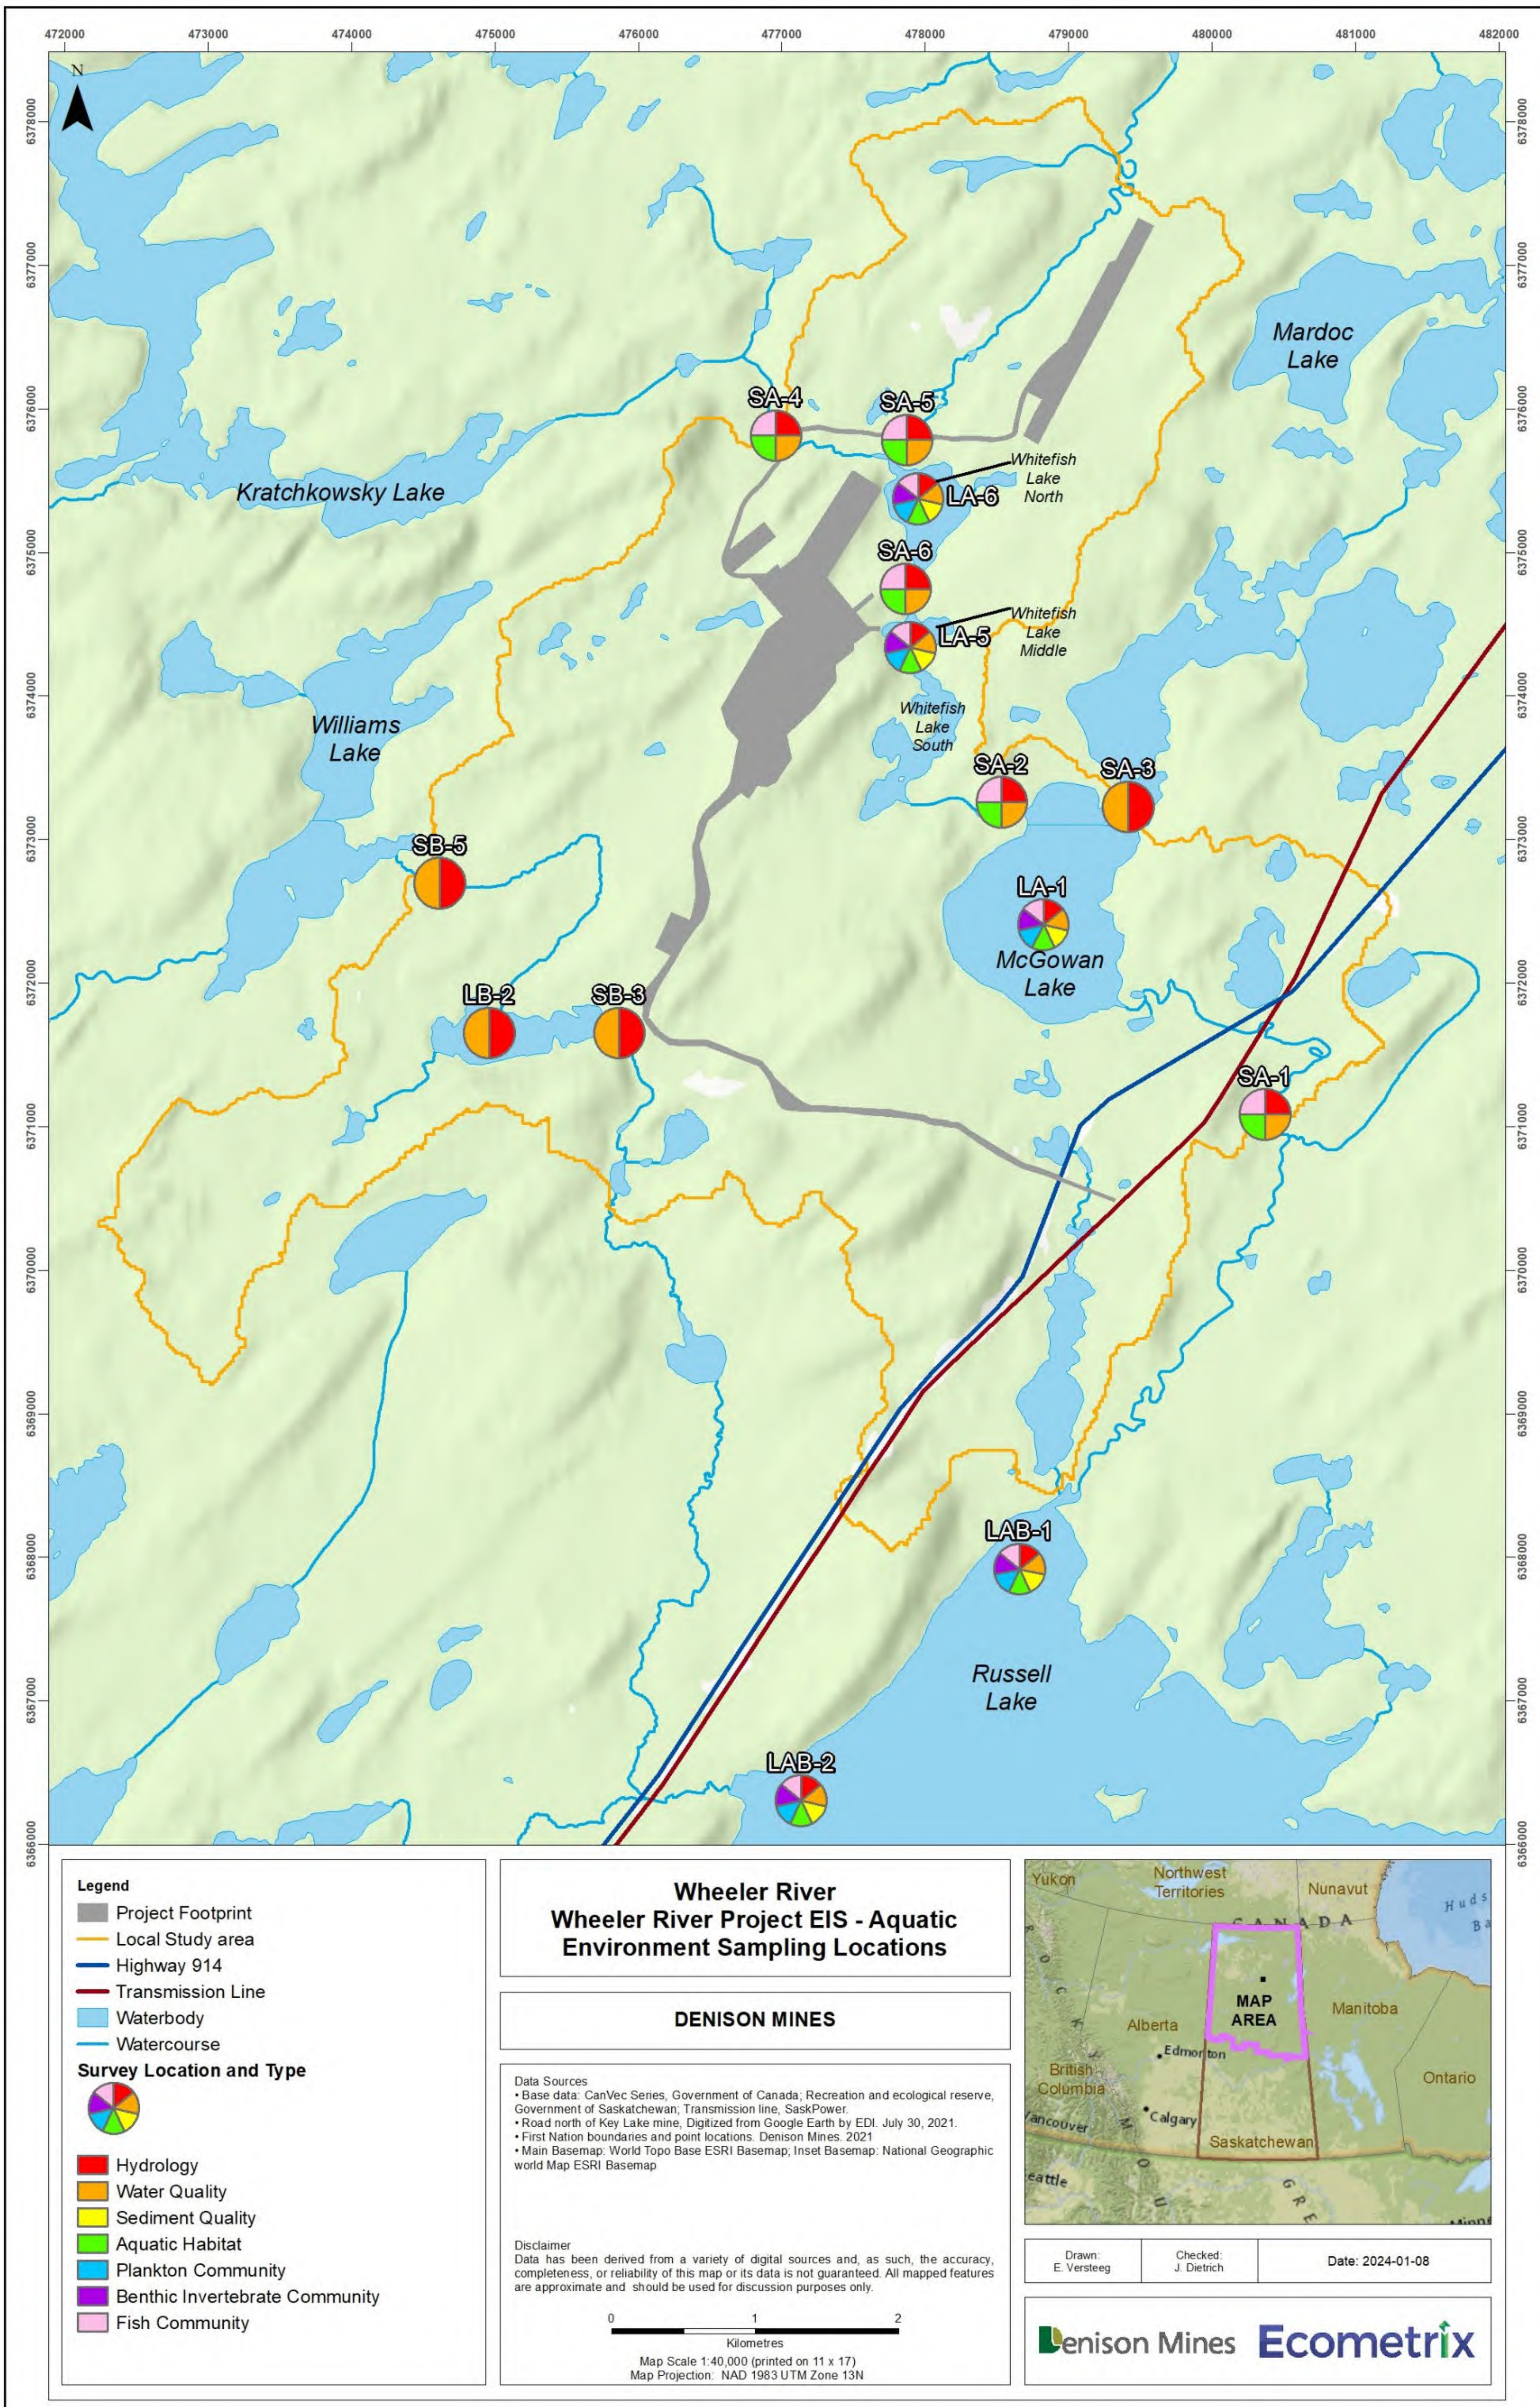

Figure 8.2-4: Water Quality, Biota, and Sediment Sampling Locations (2016 to 2018)

For each sampling location, a single surface water sample was collected for laboratory analysis from near the surface using a beta bottle. At stations where a distinct thermocline was observed at the time of the field sampling program (i.e., the water column was not well mixed), a second water sample was collected from below the thermocline using a beta bottle. Quality assurance samples (i.e., field blank, trip blank, and field duplicates) were collected as part of the sampling program. Sampling locations were georeferenced. Water samples were analyzed by Saskatchewan Research Council Environmental Analytical Laboratories (Saskatoon, Saskatchewan), a Canadian Association for Laboratory Accreditation Inc. certified laboratory, for the full series of constituents. Samples were analyzed with method detection limits at or below Saskatchewan Environmental Quality Guidelines (SEQG) Saskatchewan Surface Water Quality Objectives (SSWQO) and Canadian Council of Ministers of the Environment (CCME) Canadian Water Quality Guidelines (CWQG) for the Protection of Aquatic Life for each parameter. Surface water chemistry was also measured in situ at all stream stations and was consistent with those measured at lakes (Figure 8.2-4).

8.2.3.2 Sample Locations

Locations of interest for this assessment include the following nodes that are coincident with baseline monitoring stations and/or watersheds of interest to the assessment (Table 8.2-2; Figure 8.2-4). Surface water quality was sampled at these stations along with other study components, as listed below.

- SA-1 – Fish community and habitat survey location on the stream colloquially known as the Icelander River, which is located downstream of LA-1 (McGowan Lake).
- SA-2 – Fish community and habitat survey location situated downstream of the outflow from LA-5 (Whitefish Lake South) and upstream of the inflow to LA-1 (McGowan Lake).
- SA-3 – Hydrology and water quality survey location situated in a small channel upstream of LA-1 (McGowan Lake) and downstream of LA-2.
- SA-4 – Fish community and habitat survey location situated upstream of the inflow to LA-6 (Whitefish Lake North).
- SA-5 – Fish community and habitat survey location situated upstream of the inflow to LA-6 (Whitefish Lake North).
- SA-6 – Fish community and habitat survey location situated downstream of the outflow from LA-6 (Whitefish Lake North) and upstream of the inflow to LA-5 (Whitefish Lake South).
- SB-3 – Hydrology and water quality survey location situated upstream of LB-1, in the outlet of LB-2.
- SB-5 – Hydrology and water quality survey location situated upstream of LB-2, near the outlet of LB-3 (Williams Lake).
- LAB – Russell Lake.
- LB-2. – Unnamed Lake

- LA-1 – McGowan Lake.
- LA-5 – Whitefish Lake South.
- LA-6 – Whitefish Lake North.

8.2.3.3 Existing Surface Water Quality

Summary statistics of existing surface water quality for lakes and watercourses are provided in Table 8.2-2 and Table 8.2-3. Percent occurrence of water quality concentrations not meeting provincial or federal benchmarks during baseline are provided in Table 8.2-4. Additional detail is provided in Appendix 8-D.

For parameters where water quality guidelines were available, most were below their respective guidelines at all sampling locations. Cases where constituent concentrations exceeded guidelines are detailed in Table 8.2-2. Generally, at least one sample from each waterbody within the LSA contained aluminum concentrations that exceeded the SEQG. In some cases, such as waterbodies LB-2 and SB-3, all water samples exhibited aluminum concentrations higher than the SEQG. There were also several instances where water pH was below the lower threshold of the CCME CWQG for the Protection of Aquatic Life, such as samples from Whitefish Lake North, SA-1, SA-3, SA-5, SA-6, SB-3, and SB-5 (Table 8.2-4). Other metals that had higher concentrations than their guidelines included lead, iron, copper, and cadmium, though in these cases, the maximum concentration was only marginally above the guideline value and for copper the detection limit (0.0002 mg/L) is equal to the long-term guideline.

Table 8.2-2: Baseline Surface Water Quality in Local Study Area Lakes and Russell Lake

Parameter	Units	Short-term Benchmark			Long-term Benchmark			McGowan Lake (LA-1)			Whitefish Lake South (LA-5)			Whitefish Lake North (LA-6)

Notes:

All parameters listed as total concentrations unless otherwise specified.

Saskatchewan Water Quality Objectives, SEQG on-line (https://envrbrportal.crmp.saskatchewan.ca/seqg-search/), SEQG for the protection of aquatic life were selected, based on total concentrations.

Bold numbers indicate exceedance of a long-term criterion.

Bold and italicized indicate exceedance of the short-term criterion and long-term criterion.

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Temperature - Maximum Weekly Average Temperature: Thermal additions to receiving waters should be such that the maximum weekly average temperature is not exceeded. Short-term Exposure to Extreme Temperature: Thermal additions to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect the important species.

pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).

(1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.
(2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf).
(3) Based on water hardness of >0 to <5.3 mg/L (Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
(4) Based on water hardness >0 to <17 mg/L.
(5) Guideline specific to Chromium VI for conservative comparison to baseline water quality.

(6) Based on hardness of 5.26 mg/L (Short-term equation is ($e^{\{0.979123[\ln(hardness)]-8.64497\}}$)*1000 (SEGQ via AEP 1996b).
(7) Federal Water Quality Guideline for Copper Biotic Ligand Model (BLM) Tool and User Manual, (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6).
(8) Short Term Guideline is based on dissolved manganese. Benchmark = exp(0.878[ln(hardness)] + 4.76) where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO3 equivalents in mg/L. (Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
(9) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L.
(10) Framework provides Trigger Ranges for Total Phosphorus (µg/L) - guideline for oligotrophic waterbody 4 - 10 µg/L.
(11) Guideline is based on dissolved zinc.
(12) Short term guideline is based on Benchmark = exp(0.833[ln(hardness mg·L-1)] + 0.240[ln(DOC mg·L-1)] + 0.526). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
(13) Long term guideline is based on CWQG = exp(0.947[ln(hardness mg·L-1)] - 0.815[pH] + 0.398[ln(DOC mg·L-1)] + 4.625). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
(14) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L.

Notes

All parameters listed as total concentrations unless otherwise specified.

Saskatchewan Water Quality Objectives, SEQG on-line (https://envrbrportal.crmp.saskatchewan.ca/seqg-search/), SEQG for the protection of aquatic life were selected, based on total concentrations.

Bold numbers indicate exceedance of a long-term criterion.

Bold and italicized indicate exceedance of the short-term criterion and long-term criterion.

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Temperature - Maximum Weekly Average Temperature: Thermal additions to receiving waters should be such that the maximum weekly average temperature is not exceeded. Short-term Exposure to Extreme Temperature: Thermal additions to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect the important species.

A pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).

(1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.

(2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf).
(3) Based on water hardness of >0 to <5.3 mg/L (Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
(4) Based on water hardness >0 to <17 mg/L.
(5) Guideline specific to Chromium VI for conservative comparison to baseline water quality.
(6) Based on hardness of 5.26 mg/L (Short-term equation is ($e^{\{0.979123[\ln(hardness)]-8.64497\}}$)*1000 (SEGQ via AEP 1996b).
(7) Federal Water Quality Guideline for Copper Biotic Ligand Model (BLM) Tool and User Manual, (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 [95th percentile of LA-5 and LA-6]).
(8) Short Term Guideline is based on dissolved manganese. Benchmark = exp(0.878[ln(hardness)] + 4.76) where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO3 equivalents in mg/L. (Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
(9) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L.
(10) Framework provides Trigger Ranges for Total Phosphorus (µg/L) - guideline for oligotrophic waterbody 4 - 10 µg/L.
(11) Guideline is based on dissolved zinc.
(12) Short term guideline is based on Benchmark = exp(0.833[ln(hardness mg·L-1)] + 0.240[ln(DOC mg·L-1)] + 0.526). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
(13) Long term guideline is based on CWQG = exp(0.947[ln(hardness mg·L-1)] - 0.815[pH] + 0.398[ln(DOC mg·L-1)] + 4.625). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
(14) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L.

Table 8.2-4: Summary of Constituents from Baseline Surface Water Quality Sampling of Waterbodies within the Local Study Area that Exceed Guideline Values

Location	Parameter	Percent of Samples Not Meeting Guideline	Max Value (mg/L)	Guideline Reference	Guideline Value

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

8.2.4 Assessment of Project-related Effects

8.2.4.1 Potential Interactions Between the Project and Valued Component / Key Indicators

The Project will require the construction, operation, and decommissioning of several components (as described in Section 2). Potential interactions between Project activities and Surface Water Quality are summarized by Project phase in Table 8.2-5 and are ranked as:

- Primary Interaction (✓): Project activity is expected to interact with the VC/KI, which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.
- Other interaction (✓): Project activity is expected to interact with the VC/KI. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects.
- No Interaction: Project activity is not expected to interact with the VC/KI, no adverse effects are expected, and a rationale is provided for not considering this potential interaction further.

Based on professional judgment and understanding of the nature of Project activities and their sequencing, the Project activity list was reviewed and the type of interactions determined. Potential Project-related effects are then discussed in Section 8.2.4.2. Primary Project activities with the potential for adverse effects on Surface Water Quality (i.e., flagged as 'Primary Interactions') are expected to involve surface land clearing, major earthworks, surface/grading preparations, changes to land cover, water management feature construction and function, and water taking and effluent discharge. Other Project activities (i.e., flagged as 'Other Interactions') refer to those activities that may be associated with hydrogeological influences on local waterbodies and are expected to be secondary contributors to potential adverse effects. The remaining activities (e.g., power generation and supply) were deemed to have no interaction and were not carried forward in the assessment as they are not expected to result in detectable changes in the MPs associated with Surface Water Quality. Activities during Post-Decommissioning (e.g., site inspections; monitoring and on-site engagement with Interested Parties) were deemed to have no interaction because they do not involve any land clearing, surface preparations, or major earthworks.

Table 8.2-5: Potential Project Interactions for Surface Water Quality

Project Phase/Activity	Surface Water Quality
Construction Activities	
Development of access roads and air strip	✓
Site preparation and earthworks; clearing, levelling, and grading of the Project Area	✓
Power generation – generators	
Installation of main substation and distribution of power around site	
Wellfield and freeze hole drilling; ground freezing	✓

Project Phase/Activity	Surface Water Quality
Batch plant operation (concrete); crusher at borrow area	
Development of surface infrastructure (camp, operations centre, plants, ponds, pads, and support facilities)	✓
Waste management (composting, domestic and industrial landfill operation, recycling)	✓
Water management (including treatment and site runoff)	✓
Groundwater supply	✓
Surface water withdrawal	✓
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
On-site and off-site operation of vehicles and transport of materials	✓
Air transportation for workers	
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Operation Activities	
Operation of the ISR wellfield	✓
Wellfield and freeze wall drilling	✓
Operation and expansion of freeze wall	✓
Batch plant operation (grout and cement); crusher in borrow area	
Expansion of pond and pads	✓
Operation of the processing plant and production of uranium concentrate	✓
Water withdrawal from groundwater or surface waterbody	✓
Management of surface water (including seepage and site runoff)	✓
Water treatment, both domestic and industrial	✓
Water release to surface waterbody	✓
Waste management (composting, domestic and industrial landfill operation, recycling)	✓
Hazardous waste management (temporary storage, handling, and off-site transportation)	
Storage and disposal of drill waste rock, process precipitates, and industrial wastewater treatment plant precipitates	✓
On-site and off-site operation of vehicles and transport of materials	✓
Power supply – primarily power from the grid, also generators and back-up generators	
Package and transport of nuclear substances	
Fuel management (e.g., propane for comfort heating; vehicle and aircraft fuel)	
Air transportation for workers	
Progressive decommissioning and reclamation	✓
Regulatory site inspections	
Engagement – site visit from Interested Parties	

Project Phase/Activity	Surface Water Quality
Decommissioning Activities	
Site water management, treatment, and release	✓
Mining horizon remediation and thawing of freeze wall	✓
Process water treatment and release	✓
Closure of ISR and freeze wells and related infrastructure	✓
Decontamination of surface facilities and injection, recovery, and monitoring wells	✓
Asset removal (including site power transmission lines and electrical infrastructure)	
Demolition and disposal of non-salvageable surface infrastructure and materials	✓
Remediation of contaminated areas (wellfield, pads, ponds, domestic wastewater treatment location, and process plant area)	✓
Generators	
Waste management (composting and landfill operation)	✓
Decommissioning of landfills; hazardous materials management (temporary storage and off-site disposal)	✓
On-site and off-site operation of vehicles and transport of materials	
Reclamation of disturbed areas	✓
Regulatory site inspections	
Engagement – site visit from Interested Parties	
Post-Decommissioning Activities	
Environmental monitoring	
Regulatory site inspections	
Engagement – site visit from Interested Parties	

Interactions between the Project and Surface Water Quality during the future centuries phase were considered indirect (secondary) interactions associated with changes in groundwater migration from the restored area source to the surface water environment. Such interactions and their potential for residual effects are discussed in Section 8.2.4.2.5.

8.2.4.1.1 Site Water Management

Site water management is described in Section 2, with water block flow diagrams for each phase of the Project provided in Figure 2.2-14, Figure 2.2-15, and Figure 2.2-16. It is important to note that Denison plans to recycle process water to the greatest extent possible, thereby reducing the demand for freshwater supply and reducing the need for discharge to the receiving water environment.

Construction

Groundwater or surface water taking will be used to support the concrete batch plant, wash station, drilling activities, and the potable water plant (Figure 2.2-14 in Section 2). Domestic wastewater will be disposed of via vacuum truck at a licenced disposal location until the Industrial Wastewater Treatment Plant (IWWTP) is commissioned. Site contact water will be directed to the Clean Waste Rock Pond, which will be built to hold this water through Construction without the need for discharge to the natural environment.

Operation

During Operation (Figure 2.2-15 in Section 2), site contact water will be collected at the following locations:

- Domestic Wastewater Pond;
- IWWTP Precipitate Pond;
- Clean Waste Rock Pond;
- Process Precipitate Pond;
- Process Water Pond;
- Industrial Landfill Leachate Collection Pond; and
- Wellfield Runoff Pond.

Most of the collected contact water will be directed to the Process Water Pond and the Wellfield Runoff Pond, which will store water for use during ISR drilling (i.e., recycled). Other site runoff collection needs will be examined and identified as part of detailed design and permitting. Any excess water not required during the ISR process will be directed to the IWWTP.

The IWWTP will be designed to treat contaminated water removed during the ISR process (e.g., backwash of sand filters, bleed solution), runoff collected from the waste pad, and other contact water, such as water from the wash bay and process sumps. The IWWTP will be located inside of the processing plant.

Treated water from the IWWTP will be pumped to the three Effluent Monitoring and Release Ponds (each 3,300 m^3). These ponds will be designed to hold effluent for 72 hours for testing before discharge to the environment.

Treated water in the Effluent Monitoring and Release Ponds will be monitored prior to release Whitefish Lake. The treated effluent discharge line will be heated and have secondary containment in place.

The conceptual design for the diffuser used in the assessment of potential effects consisted of a diffuser line with three evenly spaced nozzles, with each nozzle approximately 0.07 m in diameter. The diffuser line is located approximately 115 m offshore from the north shoreline and 440 m from the west shoreline, in approximately 3 m of water. The diffuser extends from a single pipe, which reaches a ‘T’ that extends parallel to the north shoreline (Figure 8.2-5 and Appendix 8-E). The exact design configuration will be optimized as required during the engineering design and permitting phase to facilitate optimal performance of the diffuser specific to site conditions.

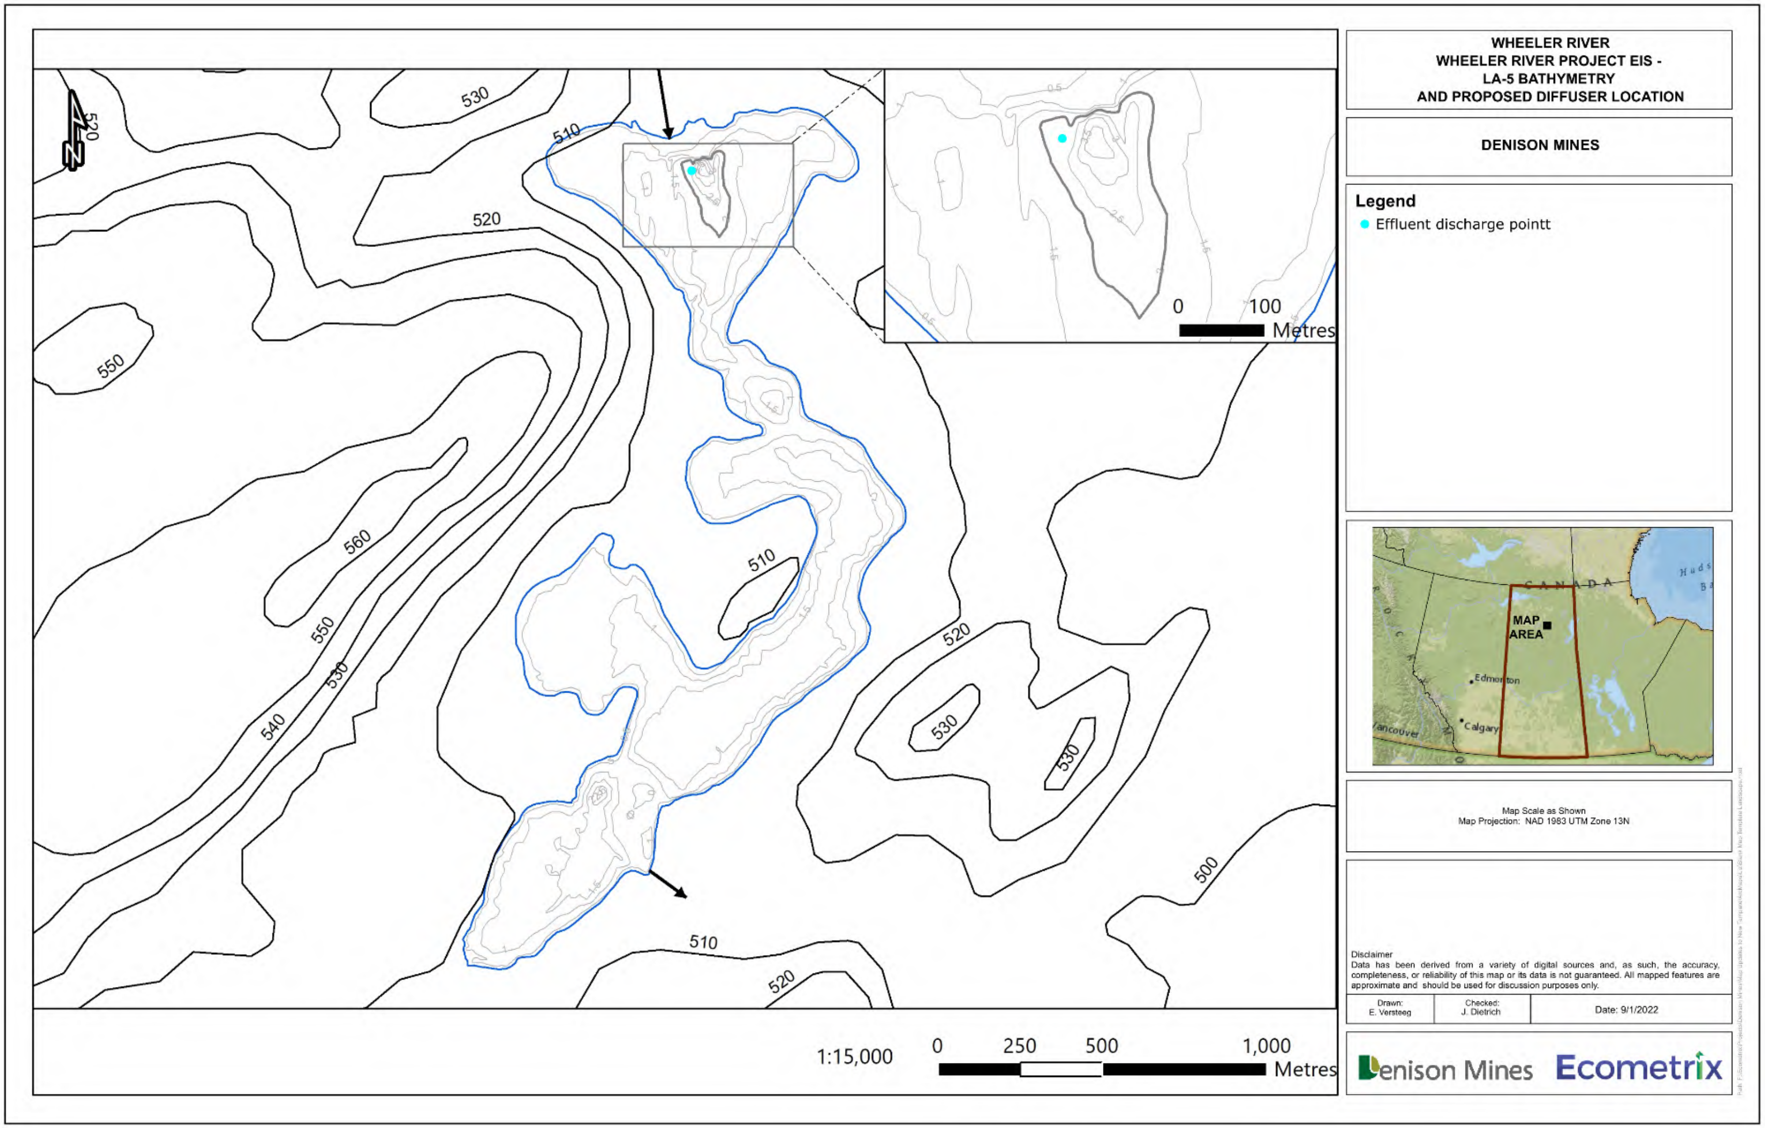

Figure 8.2-5: LA-5 Bathymetry and Proposed Diffuser Location

Decommissioning and Post-Decommissioning

The water balance during this phase will be consistent with the cessation of drilling and ore extraction followed by mining area remediation, and finally the gradual thawing of the freeze wall (Figure 2.2-16 in Section 2). Recycling of water through the ore zone from the IWWTP will continue to make sure contact and wellfield water meet water quality objectives prior to discharge to the environment through the Effluent and Monitoring Release Ponds. It is expected that discharge will cease at the end of physical decommissioning, which includes mining are remediation, decontamination, asset removal, and demolition and disposal.

8.2.4.2 Potential Project-related Effects

Project activities may interact with Surface Water Quality during all Project phases. In general, the interactions can be characterized as being primarily associated with controlled, routine discharges from the Project site. During Construction, the primary effect pathway relates to the mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. During Operation and Decommissioning, excess water from the effluent monitoring ponds will be released to the environment. Routine discharge of this sort will be directed to Whitefish Lake only. Direct discharge of treated effluent to the natural environment has the potential to change surface water constituent concentrations and temperature. Decommissioning will involve the restoration of natural site drainage to the Whitefish Lake receiver and, similar to Construction, has the potential to increase the mobilization of suspended solids into natural surface waters. The following sections discuss each predicted residual effect.

8.2.4.2.1 Mobilization of Suspended Materials

Construction

The primary effect pathway during Construction relates to the mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. According to the site water balance (Figure 2.2-14 in Section 2), there is no planned discharge to Whitefish Lake during Construction. The mobilization of suspended material into natural surface water features is readily mitigatable by virtue of the mine development plan and through the implementation of standard water management and sediment control practices. Water management infrastructure (e.g., collection ditches, ponds, pumping, stations), as well as various aspects of the water management and sediment control management systems, will be put into place coincident with the initiation of construction activities. Waters (e.g., runoff) associated with areas under development will be collected and stored within management infrastructure (e.g., Clean Waste Rock Pond; Figure 2.2-14 in Section 2). In the event that releases into the natural environment are necessary, they would only occur once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). No downstream effects on local surface waters are expected.

Operation

During Operation, mobilization of suspended materials will be managed through the development of water management infrastructure and the Surface Water Management Program. Releases to the natural environment of contact water will be directed through the applicable collection ponds, IWWTP, and Effluent Monitoring and Release Ponds. Discharge will only occur once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). Management of TSS levels in the final discharge will be implemented to make sure discharge quality can be maintained consistently. As necessary, Denison may employ active means (e.g., filtering), if required, to achieve low TSS levels in discharge, in addition to passive means such as settling and clarification in the IWWTP to manage TSS in the effluent stream to low levels. No downstream effects on local surface waters are expected.

Decommissioning

During Decommissioning, the site wide management system will continue to operate such that Denison will maintain control of the site aspect affected water through the IWWTP. Surface drainage during decommissioning activities will continue to be directed to the collection ponds, IWWTP, and Effluent Monitoring and Release Ponds to facilitate the control of suspended solids and achieve low TSS levels in the discharge.

8.2.4.2.2 Controlled Discharge

Construction

Discharge to the environment is not expected during Construction. Site contact water will be collected and held in the Clean Waste Rock Pond (Figure 2.2-14 in Section 2). Therefore, potential effects of discharge on the Surface Water Quality VC are not expected.

Operation

Denison does not intend to include constant freshwater withdrawal or effluent discharge throughout Operation; however, for the purpose of assessing the scenario of greatest potential effects, the Project was assessed as having a continuous freshwater withdrawal rate of 40.5 m^3/hr and a continuous effluent discharge rate of 36.5 m^3/hr. The withdrawal and discharge rates were assessed independently, despite withdrawal from and discharge to being associated with the same waterbody, to exaggerate the predicted effects. In addition, they were assessed cumulatively with the Project site and estimated changes to groundwater contributions through different temporal phases of the Project.

The approach to assessing Project-related effects on the Surface Water Quality VC was conservative for the following reasons:

- The assessment was based on a continuous (year-round) discharge rate at an expected average effluent discharge of 0.0101 m^3/s (or 36.5 m^3/hr) throughout Construction, Operation, and

Decommissioning despite the likelihood that effluent discharge is not expected to be continuous and is anticipated to only discharge when the site water balance requires such, based on water storage capabilities. Water storage capability of the Effluent Monitoring and Release Ponds has been designed to enable contingency in water storage (i.e., three ponds of 3,300 m^3 capacity each).

- Ninety-fifth percentile (95%) concentrations of constituents at baseline condition were used in modelling potential effects.
- The water quality analysis was conducted for each of the low flow scenarios (i.e., 7Q10 low flow, monthly low flow, and monthly average flow) for the receiving water environment.

Flows and water levels under pre-development conditions were used as the baseline against which Project-related changes during Construction, Operation, Decommissioning and Post-Decommissioning were assessed. The assessment of Surface Water Quantity supporting the Surface Water Quality VC is provided in Section 8.2.4.2. Groundwater is received in LA-5 (Whitefish Lake South) under natural conditions and estimates of the changes to this contribution are evaluated for Operation and Decommissioning. An analysis of the potential effects on the Surface Water Quality VC during Operation is provided in Sections 8.2.4.2.3 and 8.2.4.2.4.

Decommissioning and Post-Decommissioning

Discharge to the aquatic environment of Whitefish Lake during some portion of Decommissioning is expected. Effluent rates during this phase are expected to be less than during Operation. Effluent water quality is also expected to have lower levels of COPC compared to Operation. Therefore, the analysis of potential effects on the Surface Water Quality VC during Operation provided in Sections 8.2.4.2.3 and 8.2.4.2.4 is considered the bounding scenario for Decommissioning as well.

8.2.4.2.3 Near-Field Water Quality Model

A near-field water quality model was used to predict the potential change in constituent concentrations and the near-field mixing zone as a result of effluent discharge to the LA-5 portion of Whitefish Lake (Figure 8.2-5) (Appendix 8-E). The analysis is detailed further in Appendix 10-A and Appendix A of Appendix 10-A). To assess constituent concentrations within LA-5, information about local inflow rates, site discharge rates, background receiver water quality, and predicted effluent discharge water quality was required.

A hydrological assessment of the LSA was conducted by NewFields Canada (Appendix 8-C) and a water quality assessment, including identifying applicable screening concentrations, was conducted by Ecometrix (Appendix 8-E).

The effluent from the Project site is predicted to discharge to Whitefish Lake North (LA-5) through an engineered, offshore, submerged, multiport diffuser, designed to maximize the mixing potential and reduce the spatial extent of the mixing zone (as described above) (Appendix 8-E). Upon discharge, the effluent flows within the lake current, both downstream and offshore, are expected to gradually mix across the lake until fully mixed. Key definitions of terms related to this section are provided below.

- **Mixing zone**: An area of water contiguous to a point source or definable non-point source where water quality does not comply with one or more of the water quality guideline concentrations.
- **Edge of the mixing zone**: The point within the constituent plume at which water quality objectives are met.
- **Well mixed**: The point in which the water column is completely mixed (i.e., no vertical or horizontal concentration gradients exist) and no further dilution occurs.

For the purpose of calculating water quality predictions within LA-5, an expected average effluent discharge rate of 0.0101 m^3/s (or 36.5 m^3/hr) was considered. Furthermore, it was assumed that discharge from the Project site remains constant throughout the year; however, this is unlikely and therefore provides a conservative approach.

To assess the variability in inflow rates to LA-5, three flow scenarios were considered to determine effects on LA-5 water quality. These flow scenarios are summarized below with monthly average flow rates summarized in Table 8.2-6 and model input flow rates summarized in Table 8.2-7.

- **7Q10 low flow**: The 7Q10 low flow scenario was defined as "the lowest flow averaged over a period of seven consecutive days that can be statistically expected to occur once every 10 climatic years". This flow condition was used to assess concentrations under an extreme low flow event.
- **Monthly low flow**: The monthly low flow scenario was calculated from historical flow monitoring data collected via the Water Survey of Canada on the Wheeler River (Station 06DA005, 57°28'40"N, 104°59'50"W). A drainage area of 3,030 km^2 was used to estimate average monthly flows in the north basin of LA-5. The monthly low flow into LA-5 occurred in March and was calculated as 1.04 m^3/s.
- **Monthly average flow**: The monthly average flow scenario was calculated from historical flow monitoring data collected via the Water Survey of Canada on the Wheeler River (Station 06DA005, 57°28'40"N, 104°59'50"W). A drainage area of 3,030 km^2 was used to estimate annual average flows in the north basin of LA-5. The monthly average flow into LA-5 was calculated as 1.40 m^3/s.

Table 8.2-6: Monthly Average Baseline Flow Rates to LA-5

Month	Baseline Flow Rate (m^3/s)
January	1.14
February	1.08
March	1.04
April	1.21

Month	Baseline Flow Rate (m^3/s)

June	1.94
July	1.63
August	1.43
September	1.38
October	1.45
November	1.36
December	1.19
Annual	**1.40**

Table 8.2-7: Estimated Flow Rates to LA-5

Flow Parameter	Estimated Flow Rate (m^3/s)
Discharge Rate	0.0101
7Q10 Low Flow	0.616
Monthly Low Flow	1.04
Monthly Average Flow	1.40

Surface water quality criteria for the receiving environment were obtained from existing federal and Saskatchewan provincial guidelines. The most restrictive of either the Saskatchewan provincial (SEQG) or federal (CCME and/or FEQG) guidelines for the protection of aquatic life were used for the screening criteria. Where there was no screening criterion provided by the province of Saskatchewan or federal government, an appropriate and available criteria from another jurisdiction was used as an alternative. In some instances, screening concentrations for select parameters were adjusted for hardness, dissolved organic carbon, and pH. For a complete description on screening values, see Appendix A of Appendix 10-A in Section 10 Human Health. The following is noted for reference.

For molybdenum, the Saskatchewan Water Security Agency published an updated water quality objective for the protection of aquatic life based on current understanding of aquatic toxicity of molybdenum to freshwater aquatic organisms (WSA 2017). This water quality objective of 31 mg/L was adopted for the Project for the protection of aquatic life in preference over the CCME water quality objective of 0.073 mg/L. For the protection of human health through the drinking water pathway, a value of 0.07 mg/L was used from the World Heath Organization (WHO 2017).

Background water quality was defined by 95th percentile concentrations for constituents in LA-5, as taken from the baseline data collected. The 95th percentile generates a conservative baseline for water quality assessment.

A summary of background water quality and screening level criteria are provided in Table 8.2-8. Screening level values represent the most restrictive criteria for the protection of aquatic life.

Table 8.2-8: Summary of Background Water Quality Screening Criteria

Parameter	Units	Short-term Screening Criteria (background hardness)	Short-term Screening Criteria (Hardness induced [>250 mg/L])	Source	Note	Long-term Screening Criteria (background hardness)	Long-term Screening Criteria with Toxicity Modifier Applied (induced hardness)	Source	Note

Notes:

Induced hardness was considered to be >250 mg/L unless otherwise specified.

All parameters listed as total concentrations unless otherwise specified.

Saskatchewan Water Quality Objectives, SEQG on-line (https://envrbrportal.crmp.saskatchewan.ca/seqg-search/), SEQG for the protection of aquatic life were selected, based on total concentrations.

Bold numbers indicate exceedance of long-term criteria.

Bold and italicized indicate exceedance of short-term criteria and long-term criteria.

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life; CCME – Canadian Council of Ministers of the Environment; HC – Health Canada; BC MOE – British Columbia Ministry of the Environment; FEQG – Federal Environmental Quality Guidelines; MDMER – Metal and Diamond Mining Effluent Regulations; DOC – Dissolved organic carbon; TDS – Total dissolved solids; TSS – Total suspended solids.

Narrative – Temperature - Maximum Weekly Average Temperature: Thermal additions to receiving waters should be such that the maximum weekly average temperature is not exceeded. Short-term Exposure to Extreme Temperature: Thermal additions to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect the important species.

(1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.
(2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf).
(3) Cadmium criteria based on water hardness of >0 to <5.3 mg/L (Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
(4) Guideline specific to Chromium VI for conservative comparison to baseline water quality.
(5) Based on hardness of 5.26 mg/L (Short-term equation is (e{0.979123[ln(hardness)]-8.64497})*1000 (SEGQ via AEP 1996b).
(6) Federal Water Quality Guideline for Copper using the Biotic Ligand Model (BLM) Tool and User Manual is 0.0002 mg/L using site-specific background hardness of 5.26 mg/L, DOC of 2.24 mg/L, and pH of 6.61 (95th percentile of LA-5 and LA-6) and 0.0005 mg/L using conditions expected during operations including hardness of 9 mg/L, DOC of 2.24, and pH of 7.
(7) Short term guideline is based on dissolved manganese. Benchmark = exp(0.878[ln(hardness)] + 4.76) where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO3 equivalents in mg/L. (Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
(8) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L.
(9) Framework provides Trigger Ranges for Total Phosphorus (µg/L) - guideline for oligotrophic waterbody 4 - 10 µg/L.
(10) Guideline is based on dissolved zinc.
(11) Short term guideline is based on Benchmark = exp(0.833[ln(hardness mg·L-1)] + 0.240[ln(DOC mg·L-1)] + 0.526). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
(12) Long term guideline is based on CWQG = exp(0.947[ln(hardness mg·L-1)] - 0.815[pH] + 0.398[ln(DOC mg·L-1)] + 4.625). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
(13) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L.
(14) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt. Based on equation and hardness of 250 mg/L for equation of FWQG = exp{(0.414[ln(hardness)] – 1.887}.

Predicted maximum effluent concentrations during Operations of constituents of interest are provided in Table 8.2-9.

Table 8.2-9: Predicted Effluent Water Quality

Constituent	Unit	Predicted Discharge Concentrations (Max Expected)

(1) Hardness value provided here is not the expected hardness in effluent, but was selected as a concentration at which to evaluate a high hardness condition at the edge of the mixing zone for interpretation of modelled results against water quality guidelines.

Using these inputs, water quality was estimated for the near-field mixing zone under the three flow scenarios (i.e., 7Q10 low flow, monthly low flow, and monthly average flow). The results of this analysis are provided in Table 8.2-10.

Parameters where the available assimilative capacity is less than the max predicted discharge concentration when screening criteria subject to background water quality include sulphate, copper, chromium, molybdenum, and selenium. For chromium and selenium, the assessment was influenced by datapoints with values below the detection limit.

For the screening criteria subject to induced (by effluent) water quality these parameters include chromium, copper, molybdenum, and selenium. For chromium and selenium, the assessment was influenced by datapoints with values below the detection limit.

Parameters whose available assimilative capacity exceed short term criteria listed in Table 8.2-10 for both sets of screening criteria include chloride, cadmium, copper, manganese, uranium, and zinc.

Note that although cyanide is a parameter identified in Schedule 4 of the MDMER, it was not considered in the above assessment due to the lack of background cyanide concentration in the receiver. Furthermore, cyanide will not be present in the effluent as it is not part of the mining process.

Notes:

Induced hardness was considered to be >250 mg/L unless otherwise specified.

All parameters listed as total concentrations unless otherwise specified.

Saskatchewan Water Quality Objectives, SEQG on-line (https://envrbrportal.crmp.saskatchewan.ca/seqg-search/), SEQG for the protection of aquatic life were selected, based on total concentrations.

Bold numbers indicate exceedance of long-term criteria based on background hardness.

Underlined numbers indicate exceedance of long-term criteria based on induced hardness.

Italicized numbers indicate exceedance of short-term criteria

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CCME – Canadian Council of Ministers of the Environment.

HC – Health Canada.

BC MOE – British Columbia Ministry of the Environment.

FEQG – Federal Environmental Quality Guidelines.

MDMER – Metal and Diamond Mining Effluent Regulations

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TSS – Total suspended solids.

Narrative – Temperature - Maximum Weekly Average Temperature: Thermal additions to receiving waters should be such that the maximum weekly average temperature is not exceeded. Short-term Exposure to Extreme Temperature: Thermal additions to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect the important species.

A pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).

(1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.
(2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf).
(3) Cadmium criteria based on water hardness of >0 to <5.3 mg/L (Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
(4) Guideline specific to Chromium VI for conservative comparison to baseline water quality.
(5) Based on hardness of 5.26 mg/L (Short-term equation is ($e^{\{0.979123[\ln(hardness)]-8.64497\}}$)*1000 (SEGQ via AEP 1996b).
(6) Federal Water Quality Guideline for Copper using the Biotic Ligand Model (BLM) Tool and User Manual is 0.0002 mg/L using site-specific background hardness of 5.26 mg/L, DOC of 2.24 mg/L, and pH of 6.61 (95^{th} percentile of LA-5 and LA-6) and 0.0005 mg/L using conditions expected during operations including hardness of 9 mg/L, DOC of 2.24, and pH of 7.
(7) Short Term Guideline is based on dissolved manganese. Benchmark = exp(0.878[ln(hardness)] + 4.76) where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO3 equivalents in mg/L. (Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
(8) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L.

(9) Framework provides Trigger Ranges for Total Phosphorus (µg/L) - guideline for oligotrophic waterbody 4 - 10 µg/L.

(10) Guideline is based on dissolved zinc.

(11) Short term guideline is based on Benchmark = exp(0.833[ln(hardness mg·L-1)] + 0.240[ln(DOC mg·L-1)] + 0.526). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.

(12) Long term guideline is based on CWQG = exp(0.947[ln(hardness mg·L-1)] - 0.815[pH] + 0.398[ln(DOC mg·L-1)] + 4.625). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.

(13) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L.

(14) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt. Based on equation and hardness of 250 mg/L for equation of FWQG = exp{(0.414[ln(hardness)] – 1.887}.

(15) Hardness value provided here is not the expected hardness in effluent, but was selected as a concentration at which to evaluate a high hardness condition at the edge of the mixing zone for interpretation of modelled results against water quality guidelines.

In addition to concentration predictions, a preliminary mixing zone assessment was conducted for the discharge of effluent to LA-5. This preliminary mixing zone assessment predicts the extent/size of the area for which constituent water quality guidelines may be exceeded relative to the screening level criteria within LA-5 (Table 8.2-10). Simulations were carried out to assess the size of the mixing zone under different flow scenarios. To assess the size of a mixing zone within a lake, Cornell Mixing Zone Expert System (CORMIX) was used. CORMIX (Jirka and Akar, 1991) is a US EPA-supported mixing zone model and decision support system for environmental impact assessment of regulatory mixing zones resulting from continuous point source discharges. The model uses local current velocities around the diffuser rather than volumetric flow rates. For this investigation, current velocities near the diffuser were estimated by converting Icelander River (from LA-6 to LA-5) volumetric flow rates to current speeds using the cross-sectional area of the river. This characterization of current speed near the diffuser is appropriate since the current diffuser design is placed near the mouth of the river. To assess variability in river flow rates, current velocity estimates were made by considering the minimum, average, and maximum flow rates through the mouth of the river. Current velocities used in the mixing zone assessment are summarized in Table 8.2-11.

Table 8.2-11: Estimated Current Velocities Near the Diffuser

Flow Condition	Current Velocity (m/s)
Minimum	0.1
Average	0.23
Maximum	0.297

The extent of the mixing zone for concentrations predicted for the minimum, average, and maximum current velocities are provided in Table 8.2-12. Under all flow scenarios, the size of the mixing zone for all constituents remains less than 5 m^3.

Table 8.2-12: Size of the Mixing Zone Under Various Flow Conditions

Current Velocity (m/s)	Mixing Zone Distance (m)		
	7Q10 Low Flow	Monthly Low Flow	Monthly Average Flow
0.1	4.2	0.7	0.5
0.23	0.8	0.1	0.05

[3] We note that in response to the EIS review process and specifically comment Round 4 IR-114, the hardness induced guideline for Cu (hardness 9 mg/L, pH 7, DOC 2.24, temperature 13C) was include in Table 8.2-10, and this hardness was in relation to interpreting the well mixed results, which are downstream of the mixing zone. Using the expected parameters at the edge of the mixing zone (hardness 250 mg/L, pH 7, DOC 2.24, temperature 13C), the size of the mixing zone for copper remains less than 5 m.

0.297	0.5	0.1	0.05

Notes:
Under all flow conditions, all constituents meet screening concentrations within the mixing zone.

Under a conservative assessment, effluent discharge from the monitoring/effluent ponds is expected to occur year-round. Since effluent is stored in on-site ponds, it is anticipated that during the summer months, effluent temperatures and lake temperatures will be subject to the same ambient conditions. Furthermore, the receiving waterbody has a maximum depth of 4 m and therefore, is not expected to be stratified throughout the year with respect to temperature. As a result, the receiving environment is expected to have a similar water temperature to that of the discharged effluent. However, during winter, the ponds may be maintained at a slightly increased water temperature (compared to lake temperature) to prevent freezing.

It was assumed that the effluent temperature during winter would be approximately 5°C, while the ice-covered lake would have a temperature of 3 to 4°C. This results in a temperature differential of 1 to 2°C at end of pipe, leading to a slight temperature increase of the well-mixed (beyond the extend of the mixing zone) portion of LA-5 by approximately 0.2°C. Qualitatively, this suggests that there is a low thermal affect on the well-mixed portion of LA-5, a low thermal affect within the small mixing zone, and a low temporal occurrence (the largest temperature difference occurring under ice).

8.2.4.2.4 Regional Surface Water Quality Model

A regional surface water quality model was used to predict the effects on Surface Water Quality within Whitefish Lake. The model also served to support the human health and ecological risk assessments for the Project. Full details of the methodology in model inputs, model assumptions, and screening of COPC for surface water are provided in Appendix A of Appendix 10-A in Section 10.

The screening involved a conservative process of comparing the reasonable upper bound treated effluent quality against the selected water quality guidelines protective of human and ecological health Appendix A of Appendix 10-A. The reasonable upper bound treated effluent was derived using information available from pilot tests conducted by Denison, as well as derived effluent quality based on not exceeding water and sediment quality guidelines in the middle part of Whitefish Lake.

Surface water quality modeling was completed using IMPACT version 5.6.0. IMPACT is consistent with the COPC transport equations outlined in CSA N288.1-20 (CSA Group 2020). The modeling is discussed in detail in the *IMPACT Model Report for the Wheeler River Project* (Appendix A of Appendix 10-A). Waterbodies from Whitefish Lake to the Russell Lake inlet were modelled in IMPACT to assess the effects of the Project on the downstream environment. This included the following distinct water polygons: Whitefish Lake Middle, Whitefish Lake South, McGowan Lake, and Russell Lake. Kratchkowsky Lake and Whitefish Lake North were modelled as reference locations.

Model inputs, including hydrology, background water quality, effluent quality and discharge volume, and the screening level criteria, were consistent with those presented in Table 8.2-8 and Table 8.2-9**.**

Surface water quality modelling included predicting water and sediment concentrations in Whitefish Lake, the lake to which treated effluent will be released, as well as locations farther downstream. The geometric mean of measured water concentrations from baseline studies performed between 2011 and 2019 (Ecometrix 2020) was selected as the water baseline concentration for constituents that had measured data over the detection limit. Sediment baseline concentrations were predicted from surface water concentrations using the partitioning coefficients (Kd), which consist of regional published values that have been calibrated on similar sites in northern Saskatchewan and have been checked against measured data for the Wheeler River. In the case of constituents for which most or all measured concentrations in water were under the detection limit, but sediment concentration measurements were over the detection limit, the baseline water concentration was calculated from the geometric mean of the sediment measurements using the Kds (Section 3.3.2 in Appendix A of Appendix 10-A in Section 10).

When the treated effluent is released to Whitefish Lake South (LA-5), surface water concentrations were predicted using IMPACT according to the equations outlined in the IMPACT model (Section 2.2.2 in Appendix A of Appendix 10-A). The predicted maximum concentrations of COPC in water are shown in Table 8.2-13. With the exception of copper where baseline concentrations exceed the FEQG (due to the copper analytical detection limit being equal to the FEQG) and the guideline does not consider conditions expected during operations, there are no predicted exceedances of water quality guidelines for any of the COPC during Construction, Operation, or Decommissioning.

8.2.4.2.5 Long-Term Transport of Groundwater Solutes to Whitefish Lake in Future Centuries

During the 'future centuries' phase as described in Section 8.2.1.3, remediation works will be completed, and the site naturalized, thereby restoring drainage patterns to report to surface waterbodies. As indicated in Section 7 of the EIS, groundwater plumes may develop from residual mass remaining post mining based on bench-scale lab tests of core flushing, and numerical modelling of reactive fate and transport.

Groundwater flow and reactive transport of dissolved constituents were modelled using three-dimensional modelling whereby the reactions were computed using PHREEQC and the transport was computed using FEFLOW (Ecometrix 2022). Groundwater flow observed, and simulated in the calibrated groundwater model, travels eastward from the mining zone within the Lower Sandstone Aquifer before moving upward through the Desilicified Zone in the Athabasca Sandstone and overlying overburden deposits toward Whitefish Lake. Modelled transport of dissolved constituents along the groundwater flow path allowed for interactions of the dissolved constituents with the geologic media through which they are flowing. Due to the relatively low groundwater velocities between the mining zone and Whitefish Lake and chemical reactions along the groundwater flow pathway, the "Future Centuries" scenario spans 100s to 1000s of years.

The results of the numerical modelling, as provided in Section 7 and Appendix 10-A in Section 10, support the conclusion that with the implementation of appropriate mitigation during the decommissioning and restoration phase of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect to surface water. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future from the deep Ore Zone to Whitefish Lake remain below fresh water environmental quality criteria in Whitefish Lake.

For the COPC identified in the effluent, the predicted mass flux from groundwater into Whitefish Lake starting 200 years after the Project phases during the future centuries was added into the IMPACT model to predict the surface water concentrations over time at the exposed locations (see Table 8.2-14). As shown in the Environmental Risk Assessment (ERA; Appendix 10-A in Section 10), predicted surface water concentrations at all locations are expected to be below water guidelines for the protection of aquatic life, except for copper where baseline concentrations exceed the FEQG (due to the copper analytical detection limit being equal to the FEQG) and an incremental increase in concentration is predicted such that the predicted copper concentration (0.0006 mg/L) would be greater than the FEQG of 0.0002 mg/L under baseline conditions, indicating a slight increased level of risk to the most sensitive aquatic biota.

Table 8.2-14: Maximum Concentration of Surface Water Constituents of Potential Concern in Surface Water During Future Centuries

Constituent	Unit	Kratchkowsky Lake (LA-7)	Whitefish Lake North (LA-6)	Whitefish Lake Middle (LA-5 North)	Whitefish Lake South (LA-5 South)	McGowan Lake (LA-1)	Icelander River	Russell Lake Inlet	Long-term Screening Concentration	Source of Screening Concentration	Notes

Notes:

All parameters listed as total concentrations unless otherwise specified

Saskatchewan Water Quality Objectives, SEQG on-line (https://envrbrportal.crmp.saskatchewan.ca/seqg-search/), SEQG for the protection of aquatic life were selected, based on total concentrations

Bold numbers indicate exceedance of long-term criteria

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CCME – Canadian Council of Ministers of the Environment.

HC – Health Canada.

BC MOE – British Columbia Ministry of the Environment.

FEQG – Federal Environmental Quality Guidelines.

MDMER – Metal and Diamond Mining Effluent Regulations.

DOC – Dissolved organic carbon.

TSS – Total suspended solids.

A pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).

(1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.
(2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf).
(3) Guideline specific to Chromium VI for conservative comparison to baseline water quality.

(4) Federal Water Quality Guideline for Copper Biotic Ligand Model (BLM) Tool and User Manual (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 [95th percentile of LA-5 and LA-6]).

(5) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L.

(6) Framework provides Trigger Ranges for Total Phosphorus (µg/L) - guideline for oligotrophic waterbody 4 - 10 µg/L.

(7) Long term guideline is based on CWQG = exp(0.947[ln(hardness mg·L-1)] - 0.815[pH] + 0.398[ln(DOC mg·L-1)] + 4.625). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.

(8) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L.

(9) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt. Based on equation and hardness of 250 mg/L for equation of FWQG = exp{(0.414[ln(hardness)] – 1.887}.

(10) "NC" means not calculated/estimated in the IMPACT model during future centuries. Nitrate is not a COPC associated with ISR mining for the Project and was not included in the groundwater source term to Whitefish Lake developed through geochemical reactive transport modelling (Section 7, Appendix 7-C). Nitrate concentrations are low in the groundwater environment and in metallurgical testing informing the groundwater reactive transport model (Section 7, Appendix 7-C). As such, nitrate concentrations are expected to remain at baseline conditions in surface water bodies in the future centuries. Alkalinity was included in the geochemical reactive transport model but not in the IMPACT modelling. As such, the maximum alkalinity concentration (mg/L as $CaCO_3$) during future centuries was calculated outside of IMPACT using the same equations/approach presented in Section 10 (Appendix A of Appendix 10-A) and the mass flux of alkalinity from the geochemical reactive transport model (Reported as "C" in Table 4-4 of Appendix 7-C). The maximum concentration calculated (8.1 mg/L) is within the range or alkalinity values measured in the south part of Whitefish Lake (3-13 mg/L; Table 8.2-2) and represents an increase of approximately 5.2% over the mean baseline value of 7.7 mg/L in the south part of Whitefish Lake (Table 8.2-2). Alkalinity values in the other lakes were not calculated because they are expected to remain at baseline levels during future centuries.

8.2.5 Mitigation Measures

To mitigate adverse effects on Surface Water Quality, Denison will implement the following mitigation measures.

- Develop and implement a Surface Water Management Program that provides an integrated framework to manage water quality, including provision for water management practices for each of the primary site aspects, as well as areas of the Project site where contact water is expected.
- Maximize the recycle and reuse of process water to reduce freshwater intake and release to Whitefish Lake.
- Design the discharge diffuser/outfall to provide effective mixing and dilution and discharge flows that do not detrimentally affect sediments.
- Develop site-specific effluent treatment to treat COPC to appropriate release limits in accordance with provincial standards and licence/permit conditions.
- Discharge effluent under a scenario that will meet provincial and federal discharge criteria as identified through permitting. Scenarios may include:
  - discharging at a fixed rate while maintaining an appropriate minimum dilution ratio (i.e., discharge when able to meet the required dilution ratio and cease discharge during periods when unable to meet the necessary dilution ratio);
  - discharging under a variable waste load allocation (i.e., discharge an appropriate effluent volume based on flow in the receiver to maintain minimum dilution ratio); and
  - managing discharge via a hybrid of these (i.e., discharge effluent at a fixed rate to maintain the required dilution ratio, but the fixed rate can be varied on a seasonal basis based on flow).
- Collect and monitor contact water to determine whether treatment is required prior to release to the environment to inform optimal levels of treatment.
- Maintain the water management system in place during decommissioning until such time that water quality is suitable to release to the environment.
- Monitor and manage effluent, including contingency for effluent treatment as may be required, so that water discharge objectives are achieved as defined by applicable provincial and federal regulatory instruments.
- Design and implement an Environmental Code of Practice that defines action levels and appropriate steps to be taken to mitigate elevated concentrations of chemical and radiological constituents in treated effluent discharge to acceptable levels.

- Implement Project-specific monitoring programs (e.g., effluent monitoring plan, environmental monitoring plan) that include monitoring treated effluent, surface water and sediment quality, and applying adaptive management, if necessary.
- Work with the associated communities to develop and implement the Project-specific monitoring programs and a framework to share the results for the purpose of assessing the performance of the water management system.
- Develop and implement a decommissioning and reclamation plan to decommission and transfer the site to the province under the Institutional Control Program.

8.2.6 Residual Effects Evaluation

8.2.6.1 Residual Effects Characterization

This section describes the likely residual effects of the Project on the VC of Surface Water Quality and its associated KI. Residual effects are effects that remain after the implementation of mitigation measures and management strategies and are the expected consequences of the Project. The approach to assessing residual Project effects on the Surface Water Quality VC follows the methodology outlined in Section 5.8 in Section 5. For each VC and associated KI, each residual effect is characterized in the context of the Project activities that will occur within each Project phase. A residual effect on Surface Water Quality is defined as a measurable change in the concentration of a water quality parameter (or parameters) that exceeds relevant water quality assessment benchmarks that represent concentrations that are protective of aquatic biota and water uses in watercourse and waterbodies that receive mine-affected drainage. Residual effect characteristics specific to Surface Water Quality are defined in Table 8.2-15 and summarized in Table 8.2-16. A reminder that Surface Water Quality is an intermediate VC and as such, the rating of residual effects as being not significant or significant is completed for the receptor VCs and KIs.

Construction

The primary potential water quality change associated with Construction is the mobilization of suspended material into natural surface water features as a result of land clearing activities and road crossing construction. According to the site water balance (Figure 2.2-14 in Section 2), there is no planned discharge to Whitefish Lake during Construction. However, the potential influence of such discharge, if it were to occur, would be bounded by the analysis of water quality in Whitefish Lake during Operation.

Mobilization of suspended solids into natural surface water features is readily mitigatable by virtue of the mine development plan and through the implementation of standard water management and sediment control practices. Water management infrastructure (e.g., collection pads, ponds, pumping stations), as well as various aspects of the water management and sediment control management systems, will be put into place coincident with the initiation of construction activities. Runoff associated with areas under development will be collected and either stored within management infrastructure (e.g., water management ponds) or potentially released into natural surface water features once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). No downstream effects on local surface waters are expected.

Operation

During Operation, the primary potential water quality effect from the Project is the discharge of excess water from the site water management system to Whitefish Lake (LA-5). Discharge to Whitefish Lake South has the potential to change the concentrations of water quality constituents from background.

For planning purposes, a continuous (year-round) discharge at an expected average effluent discharge rate of 0.0101 m^3/s (or 36.5 m^3/hr) was used during Operation, despite the likelihood that effluent discharge will not be continuous, and Denison will only discharge when the site water balance requires (based on water storage capabilities). The water storage capability of the Effluent Monitoring and Release Ponds has been designed to enable contingency in water storage (i.e., three ponds of 3,300 m^3 capacity).

No other routine mine-related discharges to other receiving environments are proposed during Operation. Water management infrastructure will collect and divert all site aspect influenced water (often referred to as contact water), as well as water associated with the ISR process, through the IWWTP. Any excess water not required during the ISR process will be directed to the WTP. Treated water from the WTP will be pumped to the Effluent Monitoring and Release Ponds.

Treated water in the Effluent Monitoring Ponds will be monitored prior to release to Whitefish Lake. The treated effluent discharge line will be heated and have secondary containment in place.

Based on pilot tests completed for the IWWTP to date, sulphate, chromium, molybdenum, TSS, and selenium have been identified as having potential management needs. However, for each of these parameters, the estimated discharge concentrations provided herein are conservative in nature with a contingency factor of 1 to 3 times incorporated for conservancy. Additionally, the effluent discharge concentrations for these parameters do not consider any further physical or chemical mechanisms that may occur in the effluent/monitoring ponds prior to discharge to the environment. As such, concentrations of these parameters have the potential to be lower than presented. Despite further reduction in constituent effluent concentrations, the near-field and regional surface water quality models predict concentrations of these parameters in the receiving environment below criteria for the protection of aquatic biota and human health within a short distance of the diffuser. One exception is copper where incremental increase in concentration is predicted such that the predicted copper concentration (~0.0007 to 0.0008 mg/L) would be greater than the FEQG of 0.0002 mg/L under baseline conditions, indicating a slight increased level of risk to the most sensitive aquatic biota.

Local Indigenous communities have expressed direct concern with respect to mercury. Mercury has not been identified as a COPC for the Project as it is currently not present in the receiving environment (i.e., background condition) at detectable concentrations and will not be produced as part of the mine process, and, therefore, not discharged to the aquatic environment. However, it is understood that potential nutrient enrichment-related effects are possible and can be linked to increases in mercury in the environment.

As described above, the site-wide water management strategy involves care and control of all site aspect influenced water and no discharge is proposed beyond that to Whitefish Lake. In practice, it may be necessary at times to manage runoff from disturbed areas that are either outside the water management system or are yet to be integrated into the water management system. In these cases, the areas would be isolated and specific water and sediment control management practices would be implemented to make sure that any water released to natural surface water drainages would be suitable for release and that water quality in these natural surface water drainages would be protected.

Decommissioning/Post-Decommissioning

Following the cessation of mining operations, discharge to Whitefish Lake will cease. Water quality in Whitefish Lake is expected to return to background, pre-mining conditions at that time.

The site-wide water management system will continue to operate such that Denison will remain in control of site aspect affected water via the IWWTP. At that time, water (runoff) from the ISR wellfield, and contact water from the developed portion of the Project site (e.g., contaminated runoff pond, landfill pond, process water pond), will continue to be collected and diverted to the IWWTP. From the IWWTP, the water will be directed back to the ISR wellfield to be pumped as clean water to ground or pumped to the Effluent Monitoring and Release Ponds for monitoring prior to discharge to LA-5. Following Decommissioning, piping infrastructure will be removed and discharge to surface water will cease.

Table 8.2-15: Surface Water Quality – Definitions of Effect Characteristics Considered When Determining the Significance of Residual Effects

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Effect moves measurable parameters in a direction detrimental to surface water quality. An increase in constituent concentrations in comparison to baseline conditions and trends. **Positive** – Effect moves measurable parameters in a direction beneficial to surface water quality. An improvement in water quality in comparison to baseline conditions and trends.
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low** – A measurable change that is not within the variability of baseline conditions but below relevant water quality objectives and criteria. **Moderate** – A measurable change that is not within the variability of baseline conditions and not within applicable guidelines, legislated

Residual Effect Characteristic	Definition	Rating
		requirements, and/or federal and provincial management objectives; therefore, it could have an adverse effect on water uses in the LSA. **High** – A measurable change that is not within the variability of baseline conditions and not within applicable guidelines, legislated requirements, and/or federal and provincial management objectives; therefore, it is likely to have an adverse effect on water uses in the LSA, with the effect extending beyond the LSA.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area. **Local** – Effect is limited to the Surface Water Quality LSA. **Regional** – Effect extends beyond the Surface Water Quality LSA into the Surface water Quality RSA. **Beyond Regional** – Effect extends beyond the Surface Water Quality RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals. **Frequent** – Effect occurs many times on a regular basis. **Continuous** – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions. **Partially Reversible** – A residual effect that partially diminishes to baseline conditions. **Irreversible** – A residual effect that will not diminish to baseline conditions.
Context	The extent to which the VC or KI has been affected by past and present environmental and socio-economic processes and conditions, its potential sensitivity to the Project-related residual effect, and its ability to recover from that effect (i.e., resilience).	**Low** – VC/KI has high resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a lack of historic and ongoing anthropogenic or natural disturbance. **Moderate** – VC/KI has moderate resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or an intermediate level of historic or ongoing anthropogenic or natural disturbance with the capacity to assimilate more change. **High** – VC/KI has weak resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a high level of historic or ongoing anthropogenic or natural disturbance.
Likelihood	Likelihood that the residual effect will occur, including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

Table 8.2-16: Surface Water Quality – Summary of the Characteristics Ratings for Residual Effects

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	The Project, and specifically the discharge of effluent to the natural environment, will cause a change in the concentration of constituents, measured as a mass of a chemical per unit volume in water (e.g., mg/L). Surface water quality in the local receiving environment will be adversely affected by effluent discharge to the environment.
Magnitude	Moderate	The magnitude of the residual effects associated with the Project is predicted to be low overall as the vast majority of constituents that may be introduced as part of Project activities are expected to remain below criteria for the protection of aquatic life and human health. However, with the exceedance of the Cu FEQG and in response to Round 4 IR-114, the overall rating was conservatively changed to moderate, even though the copper values in the EIS have been overpredicted in the models for a number of reasons including the fact that the baseline water quality analytical detection limit for copper was equal to the Cu FEQG.
Geographic Extent	Local	The geographic extent of the residual effects is predicted to be local as effects are expected to be confined to the immediate waterbody adjacent to the Project (i.e., Whitefish Lake) and the estimated mixing zone is less than 5 m, implementing an effluent discharge configuration that promotes mixing.
Duration	Long-term	Effects are expected to last between 3 to 38 years (i.e., effects expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuous	For the purposes of this EIS in identifying the conservative scenario, effluent discharge has been considered as continuous during Operation and Decommissioning.
Reversibility	Fully Reversible	Surface water quality is expected to return to pre-development levels following Post-Decommissioning as Project-related sources will cease to operate.
Context	Low	The Surface Water Quality VC is resilient in the context of this assessment as COPC meet protective criteria at the extreme low water scenario. Therefore, under applicable mitigative measures and average flow conditions, the contextual resilience of the aquatic system to respond to change is considered to be great.
Likelihood	Likely	There is a high probability that a change in water quality from background condition will occur.

8.2.6.2 Confidence of Assessment

As Surface Water Quality is considered an intermediate VC, the significance of any associated residual effects is assessed within the context as a pathway to effects on receptor VCs. These receptor VCs include Fish and Fish Habitat (Section 8.3), and Sediment Quality and Benthic Invertebrates (Section 8.4) and Fish Health (Section 8.5). Determinations of significance of residual adverse effects are provided in these sections which include surface water quality as a KI of potential residual effects.

The prediction confidence with respect to Surface Water Quality is high as the mobilization of sediment can be readily mitigated, making the effects prediction relative to this effect pathway easily understood.

Potential effects on Surface Water Quality as a result of Project discharges to local receiving environments were assessed by way of numerical modeling. These predictions are generally considered conservative in nature because the assumptions on which they are based are conservative. For example:

- The assessment is based on a continuous (year-round) discharge at an expected average effluent discharge rate of 0.0101 m^3/s (or 36.5 m^3/hr) throughout Construction, Operation, and Decommissioning, despite the likelihood that effluent discharge will not be continuous and Denison will only discharge when the site water balance requires, based on water storage capabilities.
- Constituents in effluent discharge have been estimated conservatively. Presented discharge concentrations provided herein include contingency factors of 1 to 3 times incorporated to facilitate conservancy.
- Baseline water quality is defined by the 95th percentile concentrations of individual constituents. Such an assumption is conservative as it constrains the assimilative capacity associated with the receiving environment. By definition, the assimilative capacity of a receiving environment is equal to the incremental difference between the existing baseline condition and the assessment benchmark (i.e., water quality criterion) on which the evaluation is based. Use of the 95th percentile concentration, rather than a measure of central tendency (i.e., 50th percentile, geomean), means that the incremental change in a given constituent concentration can be assimilated by the receiving environment, whereby use of the receiving environment is projected to be relatively small in magnitude.
- Water quality predictions did not consider physical or chemical processes that may attenuate concentrations in the receiving environment. An example of such a process would be partitioning of constituents from the water column to Whitefish Lake sediments. No attempt has been made to adjust water quality predictions to account for this portioning, despite using this relationship to consider the potential effects of discharge on Sediment Quality.

Due to the conservative nature of the assumptions on which the numerical assumptions are based, a high degree of confidence can be assumed.

8.2.6.3 Summary of Project-related Residual Adverse Effects on Surface Water Quality

Since Surface Water Quality is an intermediate VC, the results of residual effect characterizations for Surface Water Quality do not have significance determinations of their own. Determinations of significance of residual adverse effects related to Surface Water Quality are provided in association with receptor VCs in Sections 8.3, 8.4, and 8.5 (Fish and Fish Habitat, Sediment Quality and Benthic Invertebrates, and Fish Health, respectively).

8.2.7 Cumulative Effects

Existing projects within the Wheeler River Watershed have been considered for potential to interact with the Surface Water Quality VC for the Project. These include reasonably foreseeable projects that are described in Section 5.9.

The Cameco Key Lake Operation has the potential to interact with the Surface Water Quality VC for the Project (Figure 5.9.1). The site has been in operation since 1983. In 2018, sustained low uranium prices resulted in a decision to curtail production for the foreseeable future and place the operation into safe care and maintenance. On February 9, 2022, Cameco announced plans for the operation's gradual return to production. Cameco's Key Lake Operation will overlap spatially and temporally with the Project.

The Project is situated approximately 35 km northeast of the Key Lake Operation and both are located in watersheds that ultimately report to Russell Lake. Releases to the aquatic environment from the Key Lake Operation are received by the David Creek, McDonald Creek, and Outlet Creek drainages. These three drainages join the Wheeler River, which then flows to Russell Lake (Cameco 2020). Therefore a potential spatial overlap was identified for the Project and the Key Lake Operation and further assessed or cumulative effects.

The assessment of cumulative effects on the Surface Water Quality VC considered releases from the Project and the Key Lake Operation during all phases of the Project. The key Project component contributing to potential cumulative effects is the discharge of treated effluent to the aquatic environment during Operation and Decommissioning which may interact with Cameco's current releases to water including treated water released to David Creek drainage, treated groundwater and diverted surface water to the McDonald Creek drainage (Cameco 2020).

Temporal overlap of the Key Lake Operation and the Project will also occur during 'future centuries' as described as 'post-decommissioning phase' in the Key Lake Extension Project EIS (Cameco 2020). There is potential for increased contaminant transport via groundwater to surface water during the long-term, post-decommissioning phase (i.e., 10,000 years after operations cease and the site has been reclaimed) for the Key Lake Operation. The long-term storage of tailings at a higher elevation has the potential to influence contaminants in the groundwater and incrementally add to the effect on surface water quality in the Outlet Creek Drainage.

Operation and Decommissioning

The assessment of cumulative effects on the aquatic environment considered releases from the Key Lake Operation and proposed Project during all phases of the Project. The primary Key Lake Operation component contributing to potential cumulative effects is the placement of tailings to a higher elevation in the Deilmann Tailings Management Facility (DTMF). The increased loadings from the DTMF are anticipated to result in an incremental (i.e., existing conditions plus the Project) increase of concentrations of COPCs in the aquatic environment (Cameco 2013). The spatial extent of any significant adverse effects on the aquatic environment from the Key Lake Operation were anticipated to be localized and not to extend to the Wheeler River and Russell Lake during any phase of the Project (Cameco 2013). The 2010 Status of the Environment report for the Key Lake Operation identified that no adverse effects to individual fish or fish populations are present in the Wheeler River (EcoMetrix 2010 as cited in Cameco 2020).

Potential Project residual effects on surface water quality relate to changes (increases) in constituent concentrations that are related to the controlled discharge of Project site waters into local receiving environments (Whitefish Lake). Such changes are predicted to be negligible to low in magnitude and limited to the LSA. For example, during Construction, no discharge from the Project site is planned. During Operation, treated effluent will be discharged to Whitefish Lake. The Whitefish Lake discharge will be the only routine discharge location during Operation. Water quality in Whitefish Lake and, by extension, downstream of Whitefish Lake will meet appropriate benchmarks for the protection of aquatic life in consideration of a small mixing zone in the lake. Following Decommissioning and the restoration of drainage patterns that are similar to pre-mining conditions, water quality is expected to meet appropriate benchmarks for the protection of aquatic life in Whitefish Lake and downstream. This includes Russell Lake of which the Icelander River system is associated.

In consideration of the above discussion, effects on the aquatic environment due to changes in surface water quality from the Key Lake Operation are not anticipated to spatially overlap with those from the Project and therefore a cumulative effect is not expected.

Future Centuries

The 2013 Key Lake ERA indicated that during the 10,000-year post-decommissioning period, predicted exposure levels may affect lower trophic level aquatic biota on a population or community level within some isolated lakes in the SSA, but adverse effects on the ecology of the Outlet Creek drainage, and therefore further downstream were not expected during the post-decommissioning phase (Cameco 2013). The results of the 2020 ERA for the Key Lake Operation were consistent with the findings from the 2013 ERA in that there were limited significant risks posed to aquatic receptors situated in the area surrounding the Operation, but not to areas farther downstream. The 2020 ERA concluded that environmental health in the vicinity of the Key Lake Operation will remain protected (Cameco 2020).

The results of the numerical modelling for the Project, as provided in Section 7 and Appendix 10-A in Section 10, support the conclusion that with the implementation of appropriate mitigation during the decommissioning and mining area remediation phase of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect to surface water. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future ("Future Centuries") from the mining area to Whitefish Lake will be localized to that waterbody and remain below fresh water environmental quality criteria. As such, impacts to downstream portions of the drainage including Russell Lake are not expected.

In consideration of the above discussion, effects on the aquatic environment due to changes in surface water quality from the Key Lake Operation are not anticipated to spatially overlap with those from the Project and therefore a cumulative effect is not expected.

8.2.7.1 Additional Mitigation Measures

Additional mitigation measures not warranted as no potential cumulative effects were identified for this VC.

8.2.7.2 Cumulative Effects Characterization and Determination of Significance

A determination of significance is not warranted as no potential cumulative effects were identified for this VC.

8.2.7.3 Cumulative Effects Assessment Summary

Surface water impacts on the aquatic environment from the Key Lake Operation are expected to remain localized and not extend to the Wheeler River system or Russell Lake. Likewise, impacts on surface water quality from the Project are expected to remain localized (Whitefish Lake) and not extend to Russell Lake. Effects on the aquatic environment due to changes in surface water quality associated with the Key Lake Operation are not anticipated to spatially overlap with those from the Project during operation/decommissioning or during “future centuries” and therefore a cumulative effect is not expected.

8.2.7.4 Climate Change Considerations

As discussed in Section 8.1.7.5**,** the frequency and magnitude of extreme precipitation events has the potential to change water levels and flows in the RSA. Changes to the periodicity and frequency of flood and drought conditions has the potential to vary the interaction of the watersheds with their floodplains and subsequently the nutrient and mineral inputs and concentrations. Changes in water quality during storms, snowmelt, and periods of elevated air temperature or drought can cause conditions that exceed thresholds of ecosystem tolerance thereby leading to changes in water-quality. Surface water quantity changes are likely first to occur during episodes of climate-induced stress, and in ecosystems where the factors controlling water quality are sensitive to climate variability. Climate changes over the life of the project (i.e., 35 to 40 years) will be monitored by default as part of environmental monitoring programs and the influence of such on Surface Water Quality, Sediment Quality and Fish Health will require adaptive management to mitigate any potential effects of the mine that may be exacerbated by climate related changes in the aquatic environment.

8.2.8 Monitoring and Follow-up

For the purposes of this EIS, monitoring and follow-up are defined as follows:

- monitoring programs are designed to meet regulatory requirements (e.g., permit or license conditions) and/or to demonstrate compliance with environmental commitments made in the EIS; and
- follow-up programs are those that are proposed to address any uncertainties identified during the EA process (e.g., to verify predictions made during the EA; determine the effectiveness of proposed and implemented mitigation measures) and to determine if and when to implement adaptive management measures.

Monitoring and follow-up are proposed for the Surface Water Quality VC to verify the accuracy of the predicted effects and the effectiveness of the proposed mitigation measures. The surface water quality monitoring program should be considered in conjunction with the surface water quantity (hydrology) monitoring program.

The surface water quality monitoring and follow-up program will have the following objectives:

- collecting and recording surface water quality to confirm that source and receiving water quality predictions are consistent with those presented in the EIS; and
- monitoring to confirm the effluent and receiving water quality meet applicable regulation criteria.

The monitoring and follow-up program will include measurement of water quality parameters to meet regulatory criteria (i.e., provincial discharge permits, Metal and Diamond Mining Effluent Regulations [MDMER; Government of Canada 2022] and CSA N288.4-19 (CSA Group 2019). At a minimum, this will include collection of non-radiological parameters (e.g., metals, nutrients, hardness, temperature, pH, TDS, TSS, and sulphate) and radiological parameters.

Monitoring will occur within the collection ponds, specifically the Effluent Monitoring and Release Ponds and the receiving water (Whitefish Lake). Water quality monitoring in the natural environment will occur at the point of discharge (near-field) at LA-5 (Whitefish Lake South), at an upstream reference location (Whitefish Lake North [LA-6]) and at downstream locations (far-field locations). The far-field monitoring locations will be located in Whitefish Lake South (LA-5) prior to its discharge to McGowan Lake (LA-1).

Constituent concentrations will be compared to the values used in the EIS and to applicable regulatory criteria or objectives.

Specific monitoring and follow-up plans for the Surface Water Quality VC will be prepared to refine and finalize the approach and specific metrics following consultation with Indigenous groups, other stakeholders, and relevant federal and provincial agencies with interest in the development and implementation of this VC-specific program.

8.2.9 Surface Water Quality Summary

The Project Area is in primarily undisturbed area of the boreal forest and the existing water quality in the LSA lakes and rivers is indicative of a low level of disturbance. In general water quality parameters were below criteria for the protection of aquatic life, yet several constituents had concentrations higher than guidelines including aluminum, lead, iron, copper, and cadmium. Though in these cases, the maximum concentration was only marginally above the guideline value. The waters within the local and regional study areas sustains aquatic life and supports resource users and Indigenous peoples. Changes to surface water quality have the potential to influence biodiversity and biological function through direct exposure and indirect food chain influence (i.e., aquatic sediments, fish and fish habitat, and benthic invertebrates) and cultural values of Indigenous groups, the public and other stakeholders.

Project activities may interact with surface water quality in all Project phases. In general, the interactions can be characterized as being primarily associated with controlled, routine discharges from the site. During site preparation and construction, the primary effect pathway relates to the mobilization of suspended material into natural surface water features as the result of land disturbance and clearing. During operations and closure phases, excess water from the effluent monitoring ponds will be released to the environment. Routine discharge of this sort will be directed to Whitefish Lake only. Direct discharge of treated effluent to the natural environment has the potential to change surface water constituent concentrations and temperature. Potential effects to water quality as the result of project discharges to local receiving environments were assessed by way of conservative numerical modeling.

Modelling results support the conclusion that with the implementation of appropriate mitigation during the decommissioning and restoration phase of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect to surface water through construction, operation, decommissioning of the future centuries period. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future from the deep Ore Zone to Whitefish Lake remain below fresh water environmental quality criteria in Whitefish Lake

To minimize residual effects of the Project on surface water quality, Denison will develop and implement a Surface Water Management Program that provides an integrated framework to manage water quality that includes provision for water management practices for each of the primary site aspects, as well as areas of the site where there is contact water. Water management will include maximizing the recycle and reuse of contact and process water to reduce freshwater intake and release to Whitefish Lake. They will also design discharge diffuser/outfall to provide effective mixing and dilution and to provide discharge flows that do not detrimentally impact water quality. Denison will develop site-specific effluent treatment to treat effluent to appropriate release limits in accordance with provincial standards and licence/permit conditions.

Residual adverse effects are expected to surface water quality due to the mobilization of solids and effluent discharge to Whitefish Lake. With the implementation of appropriate design criteria for site water management, design criteria for effluent discharge pipeline and diffuser, meeting provincial and federal criteria for discharge criteria, and as needed mine water treatment, the residual effects of the Project on surface water quality can be mitigated. Assessment of the significance of changes in water quality are assessed through the appropriate biological receptor VCs.

Monitoring programs are recommended for confirming the effectiveness of mitigation measures and predictions made in the assessment and will include measurement of radiological and non-radiological water quality parameters to meet regulatory criteria. Monitoring will occur within the collection ponds, and the receiving water (Whitefish Lake). Specific follow-up and monitoring plans will be prepared to refine and finalize approach in consultation with Indigenous groups, other stakeholders, and relevant federal and provincial agencies with interest in the development and implementation of this VC specific program.

8.3 Fish and Fish Habitat

This section addresses the potential effects of the Project on the Fish and Fish Habitat VC. The following are discussed herein as part of the EA:

- scope of the assessment;
- summary of existing conditions relevant to the VCs;
- identification and description of potential interactions between the Project and the VCs;
- identification and description of mitigation measures applicable to the VCs to eliminate, reduce, or control the potential adverse Project-related effects;
- identification and characterization of predicted Project-related residual effects on the VCs after mitigation;
- characterization of significance and assignment of the level of confidence in the predictions; and
- identification and characterization of potential cumulative effects.

Figure 8.3-1 is a graphic representation of the assessment process used in this EIS.

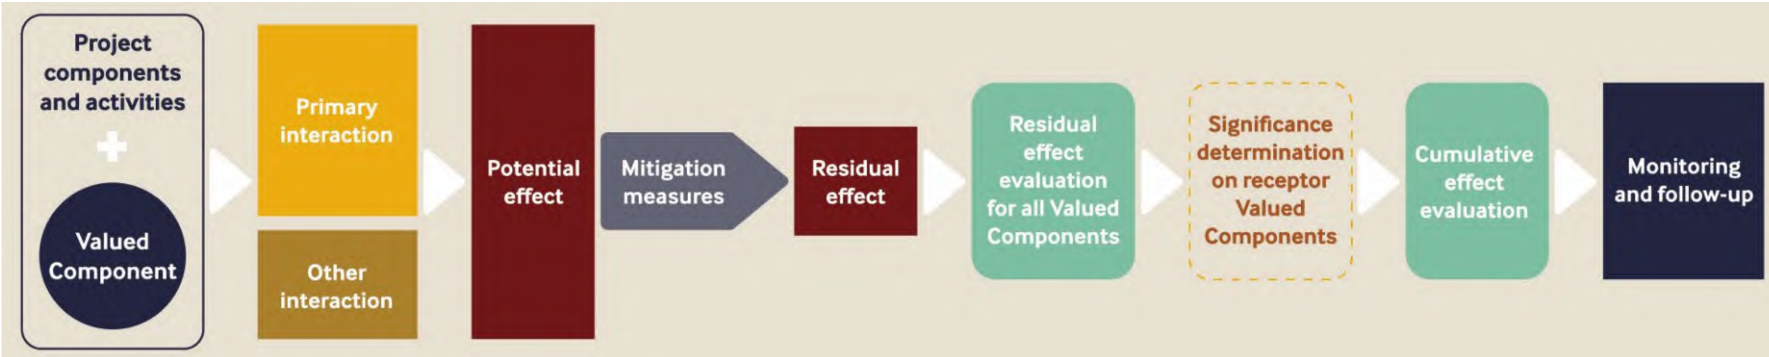

Figure 8.3-1: Environmental Assessment Process for the Wheeler River Project

8.3.1 Scope of the Assessment

The purpose of this assessment is to assess potential changes to fish and fish habitat (as represented by the Fish and Fish Habitat VC) in consideration of all phases of the Project at the Project Area, local, and regional study area scales. Pathways affecting Fish and Fish Habitat are directly associated with potential changes to the Surface Water Quantity (hydrology), Surface Water Quality, Sediment Quality, and Benthic Invertebrates VCs. Changes to hydrology, water quality, sediment quality, and benthic invertebrate communities may directly affect fish habitat and fish food resources. Fish and Fish Habitat is inclusive of wetland features within the LSA and for the purposes of this assessment the Fish and Fish Habitat VC should be considered in tandem with the Wetlands VC which is further discussed in Section 9. The Wetlands VC is further assessed as part of Appendix 8-F and the results of that assessment are incorporated in this section. Wetland habitats are variable with respect to their ability to hold water and the duration which a wetland holds a specific depth of water provides some level of classification (along with soils, sediment and vegetative communities). For the purposes of this assessment, wetlands which are inundated throughout the majority of the year have been considered as "waterbodies". Those that are variable in their period of inundation or are complex with respect to their groundwater/surface water interface (fens, bogs, etc.) are considered as wetland features herein.

The assessment approach reflects these connections within the aquatic environment, as the significance determination for the Surface Water Quantity and Surface Water Quality VCs was conducted at the receptor VC level (i.e., Fish and Fish Habitat Fish Health, Sediment Quality and Benthic Invertebrate VCs). Pathways that are of interest include those associated with site clearing and the potential for erosion-driven mobilization of suspended sediment into local surface waters (including surrounding wetlands); groundwater interactions with surface water features; the establishment of new subwatershed boundaries and the resulting effects on effluent discharge to the receiving environment; and the potential overprinting of fish habitat and wetlands by Project infrastructure. Secondary effects on fish communities within the vicinity of the Project resulting from an increase in access to fish-bearing waters are also considered as part of this assessment.

8.3.1.1 Valued Component Selection

The protection and management of fish and fish habitats are of high importance and regulated via federal and provincial legislation. An assessment of the pathways of effects and potential residual effects on Fish and Fish Habitat is a requirement of federal agency guidelines for completion of the EIS (see the concordance table in Section 1 Project Introduction and Overview). The regulatory framework associated with the Fish and Fish Habitat VC is described in Section 1. *The Fisheries (Saskatchewan) Act, 2020* (Government of Saskatchewan 2020) and the modernized federal *Fisheries Act* (Government of Canada 2019), and by extension the MDMER (Government of Canada 2022), provide regulation of development activities within and adjacent to waters frequented by fish.

The modernized federal *Fisheries Act* provides two core prohibitions related to fish and fish habitat protection: a prohibition against persons carrying out works, undertakings, or activities that result in the death of fish by means other than fishing (subsection 34.4(1)), and a prohibition against persons carrying out works, undertakings, or activities that result in the harmful alteration, disruption, or destruction (HADD) of fish habitat (subsection 35(1)) (Government of Canada 2019). The modernized federal *Fisheries Act* includes a more comprehensive definition of fish habitat under subsection 2(1): "water frequented by fish and any other areas on which fish depend directly or indirectly to carry out their life processes" (Government of Canada 2019). The types of areas that can directly or indirectly support life processes include, but are not limited to, spawning grounds and nursery, rearing, food supply, and migration areas.

The modernized federal *Fisheries Act* also includes a prohibition against the deposit of deleterious substances of any type in water frequented by fish (subsection 36(3)) (Government of Canada 2019), which is administered by Environment and Climate Change Canada. When death of fish or a HADD of fish habitat cannot be avoided or mitigated, an authorization under subsections 34.4(2) and 35(2), respectively, may be provided by the Minister of Fisheries and Oceans with the provision of appropriate offsetting of residual adverse effects. Factors that may be taken into account by the Minister when considering approval of an authorization include, but are not limited to, the following:

- contribution to the productivity of relevant fisheries by the fish or fish habitat that is likely to be affected;
- fisheries management objectives;
- whether there are measures and standards to avoid the death of fish or mitigate the extent of death or offset death, or to avoid, mitigate, or offset the HADD of fish habitat;
- whether any measures and standards to offset the HADD of fish habitat give priority to the restoration of degraded fish habitat;
- Traditional Knowledge of Indigenous peoples that has been provided to the Minister; and
- any other factor that the Minister considers relevant.

In support of the modernized federal *Fisheries Act*, the Department of Fisheries and Oceans (DFO) has published updated policy statement and guidance documents and interim standards and codes of practice. These include, but are not limited to, the following:

- *Fish and Fish Habitat Protection Policy Statement* (DFO 2019a);
- *Policy for Applying Measures to Offset Adverse Effects on Fish and Fish Habitat Under the Fisheries Act* (DFO 2019b); and
- *Framework for Assessing the Ecological Flow Requirements to Support Fisheries in Canada* (DFO 2013).

The first two documents replace the previous policy with regards to fish and fish habitat protection and offsetting measures associated with the former version of the *Fisheries Act*.

Under a memorandum of understanding, DFO relies on the Canadian Nuclear Safety Commission to take on responsibilities for the assessment and monitoring of project-related effects on fish for Class I nuclear facilities and uranium mines and mills, including species listed under the *Species at Risk Act*, and to make recommendations to DFO related to authorizations under the *Fisheries Act*. As such, the Canadian Nuclear Safety Commission will be responsible for review of the potential effects of the Project on Fish and Fish Habitat.

The Metal Mining Effluent Regulations included under Section 36 of the *Fisheries Act* were amended in 2018 and are now known as the MDMER. The MDMER are administered by Environment and Climate Change Canada. The MDMER authorize the deposit of effluent in waters frequented by fish. The regulations form the basis of the federal mine effluent standards (among other requirements) by defining authorized limits for releasing selected deleterious substances outlined in the regulation (Schedule 4), including pH, arsenic, copper, cyanide, lead, nickel, zinc, suspended solids, and radium 226. The MDMER specify requirements for carrying out effluent sampling, reporting, and environmental effects monitoring. The MDMER also provide for authorization of mine waste disposal to waters frequented by fish (under Schedule 2) when certain conditions are met, including compensation (MDMER term similar to offsetting). The requirements of a compensation plan are provided under subsection 27.1 of the MDMER.

The process and rationale for the selection of VCs and the establishment of KIs and associated MPs are described in Section 5. Potential changes to water quantity and quality are key considerations within the EA process, as demonstrated by previous uranium mining development proposals in the Athabasca Basin, that draw a high level of concern from Interested Parties (see Sections 8.1.2 and 8.2.2). Changes to surface water quality have the potential to influence sediment particle size, chemistry, and distribution within the aquatic environment, which in turn may influence biodiversity and biological function of fish habitat and fish food resources. Such effects are of interest with respect to the cultural values of Indigenous groups, the public, and other stakeholders. In this context, the Fish and Fish Habitat VC is interrelated or linked, to varying extents, to other VCs that are considered in this EIS, including:

Intermediate Valued Components

Surface Water Quantity: Surface water flow volumes and periodicity directly influence the availability of the medium on which fish depend to sustain life. Changes in flow volumes can affect multiple life stages of fish species and influence fish movement. Changes in Surface Water Quantity can also affect drainage system water quality, bedload movement, and sediment deposition. Natural and seasonal changes in precipitation, and therefore Surface Water Quantity, are directly related to Surface Water Quality, Sediment Quality characteristics, and Benthic Invertebrate distribution, and, therefore, Fish and Fish Habitat.

Surface Water Quality: Changes in Surface Water Quality, and by extension Sediment Quality, constitute a direct change in Fish Habitat, which may affect fish and their forage base.

Groundwater Quantity and Quality: The quantity and quality of groundwater reporting to surface water through hydrologic connections can influence the water quality of surface waterbodies. Partitioning of chemicals from surface waters to sediments may further affect fish habitat and fish communities.

Receptor Valued Components

Terrestrial Environment: Fish and their habitat as a food resource and habitat medium, respectively, for terrestrial fauna are linked to the function and biodiversity of the terrestrial environment.

Sediment Quality: The sediment that fish and their food resources inhabit to carry out their life processes is a component of fish habitat. Aquatic sediments are inferred as part of the definition of fish habitat under subsection 2(1) of the *Fisheries Act* (Government of Canada 2019). Alterations to Sediment Quality or Benthic Invertebrate communities in an aquatic environment can directly affect Fish and Fish Habitat.

Benthic Invertebrates: Fish rely directly on Benthic Invertebrates during part or all of their life cycle (depending on species). Changes to benthic invertebrate communities affect the ecological integrity of the aquatic environment, including fish communities.

Fish Health: Health of fish within the aquatic environment is directly linked to the viability of fish populations. Changes to fish habitat via intermediate VCs can affect the ability for such habitat to support Fish Health and, ultimately, fish communities and populations.

Land and Resource Use: Indigenous and Other Land and Resource Use are influenced by Sediment Quality and Benthic Invertebrates as they contribute to the function and biodiversity of terrestrial and aquatic flora and fauna and, subsequently, their use as natural resources by communities.

Figure 8.3-2 is a graphic representation of the main linkages among the Fish and Fish Habitat VC and other VCs, illustrating the flow of assessment information into and from the Fish and Fish Habitat VC.

Figure 8.3-2: Integrated Assessment Approach - Key Connections between Fish and Fish Habitat and Other Valued Components

8.3.1.2 Key Indicators and Measurable Parameters

The KIs for the Fish and Fish Habitat VC include potential changes in surface water quantity, surface water quality, and available fish habitat from baseline conditions. The rationale for each KI and associated MPs is summarized in Table 8.3-1. Key indicators and measurable parameters associated with wetlands as fish habitat are further detailed in Appendix 8-F and Section 9.

Table 8.3-1: Key Indicators and Measurable Parameters for Fish and Fish Habitat

Valued Component	Key Indicator	Rationale for Key Indicator	Measurable Parameters
Fish and Fish Habitat	Change to water levels or flows from baseline conditions	Project activities are expected to result in changes to local hydrology. A reduction or increase in flows may result due to the elimination or redirection of subwatershed area and through Project water management (i.e., water taking, storage, and effluent discharge). These changes in flow to the aquatic environment may alter stream flows or lake levels required for fish mobility and productivity during all life stages.	Changes in water levels (m) or percent changes to flow conditions (%).
	Change in available fish habitat from baseline conditions	Overprinting of fish habitat by Project infrastructure may affect fish and fish habitat by: • fish mortality/death of fish by means other than fishing (subsection 34.4 of the *Fisheries Act*); and • direct physical HADD of fish habitat (subsection 35(1) of the *Fisheries Act*). Work in or around water may cause direct mortality of fish, which are protected under subsection 34.4(1) of the *Fisheries Act.* A HADD of fish habitat may occur as a result of physical alteration or loss of in-water and/or riparian habitat through the development of the Project	Aerial extent (m^2 or ha) of overprinted aquatic habitat.

Valued Component	Key Indicator	Rationale for Key Indicator	Measurable Parameters
		site, including the potential creation of barriers to fish passage.	
	Change in surface water quality from baseline conditions	Changes in water quality are regulated (subsection 36(1) of the *Fisheries Act* and the MDMER). Changes that may occur as a result of the Project include: • mobilization of solids into local watersheds; and • deposition of deleterious substances into the receiving environment as a result of mine effluent and/or surface runoff.	Change in the concentration of constituents that are directly related to Project activities, measured as a mass of a chemical per unit volume in water (e.g., mg/L).

8.3.1.3 Spatial and Temporal Boundaries

Generic considerations associated with the establishment of the spatial boundaries of the assessment are described in Section 5.3.3 in Section 5. As it pertains to the Fish and Fish Habitat VC, the following is noted:

- The **Project Area** is the direct footprint of the Project. The Project Area represents the area within which Project activities and components may occur and, as such, represents the area within which direct physical disturbance may occur as a result of the Project, either temporary or permanent. (i.e., the area of maximum physical disturbance). This area is not VC-specific, but consistent throughout the EIS for all VCs.
- The **LSA** is the area that surrounds the Project Area where both direct and indirect effects resulting from Project activities can be reasonably measured. The LSA was established to assess the potential, largely direct effects of the Project, and represents the extent to which there is a reasonable potential for the Project or Project-related activities to interact with and potentially adversely affect the VC. For the Fish and Fish Habitat VC, the LSA was derived from watershed boundaries within proximity of the Project Area, including portions of watersheds that overlap the Project site, as well as areas directly downstream that may be influenced by the Project site or effluent discharge. The subwatersheds within the LSA are presented in Figure 8.3-3. This area was selected based on important waterbodies (notably Whitefish and McGowan lakes) downstream of the Project where effects may occur through all Project phases. The LSA extends from those waterbodies down to their inflows to Russell Lake.
- The **RSA** is the area that surrounds and includes the LSA, and was established to assess the potential, largely indirect effects of the Project, as well as other activities, in a regional context. The RSA is large enough to capture the extent of potential effects (i.e., zone of influence) on a VC and defines the area within which cumulative effects may occur (i.e., cumulative effects assessment boundary). The RSA for the Fish and Fish Habitat VC is bounded by the regional watershed area within which the Project Area is located and extends downstream to include Russell Lake (Figure 8.3-3).

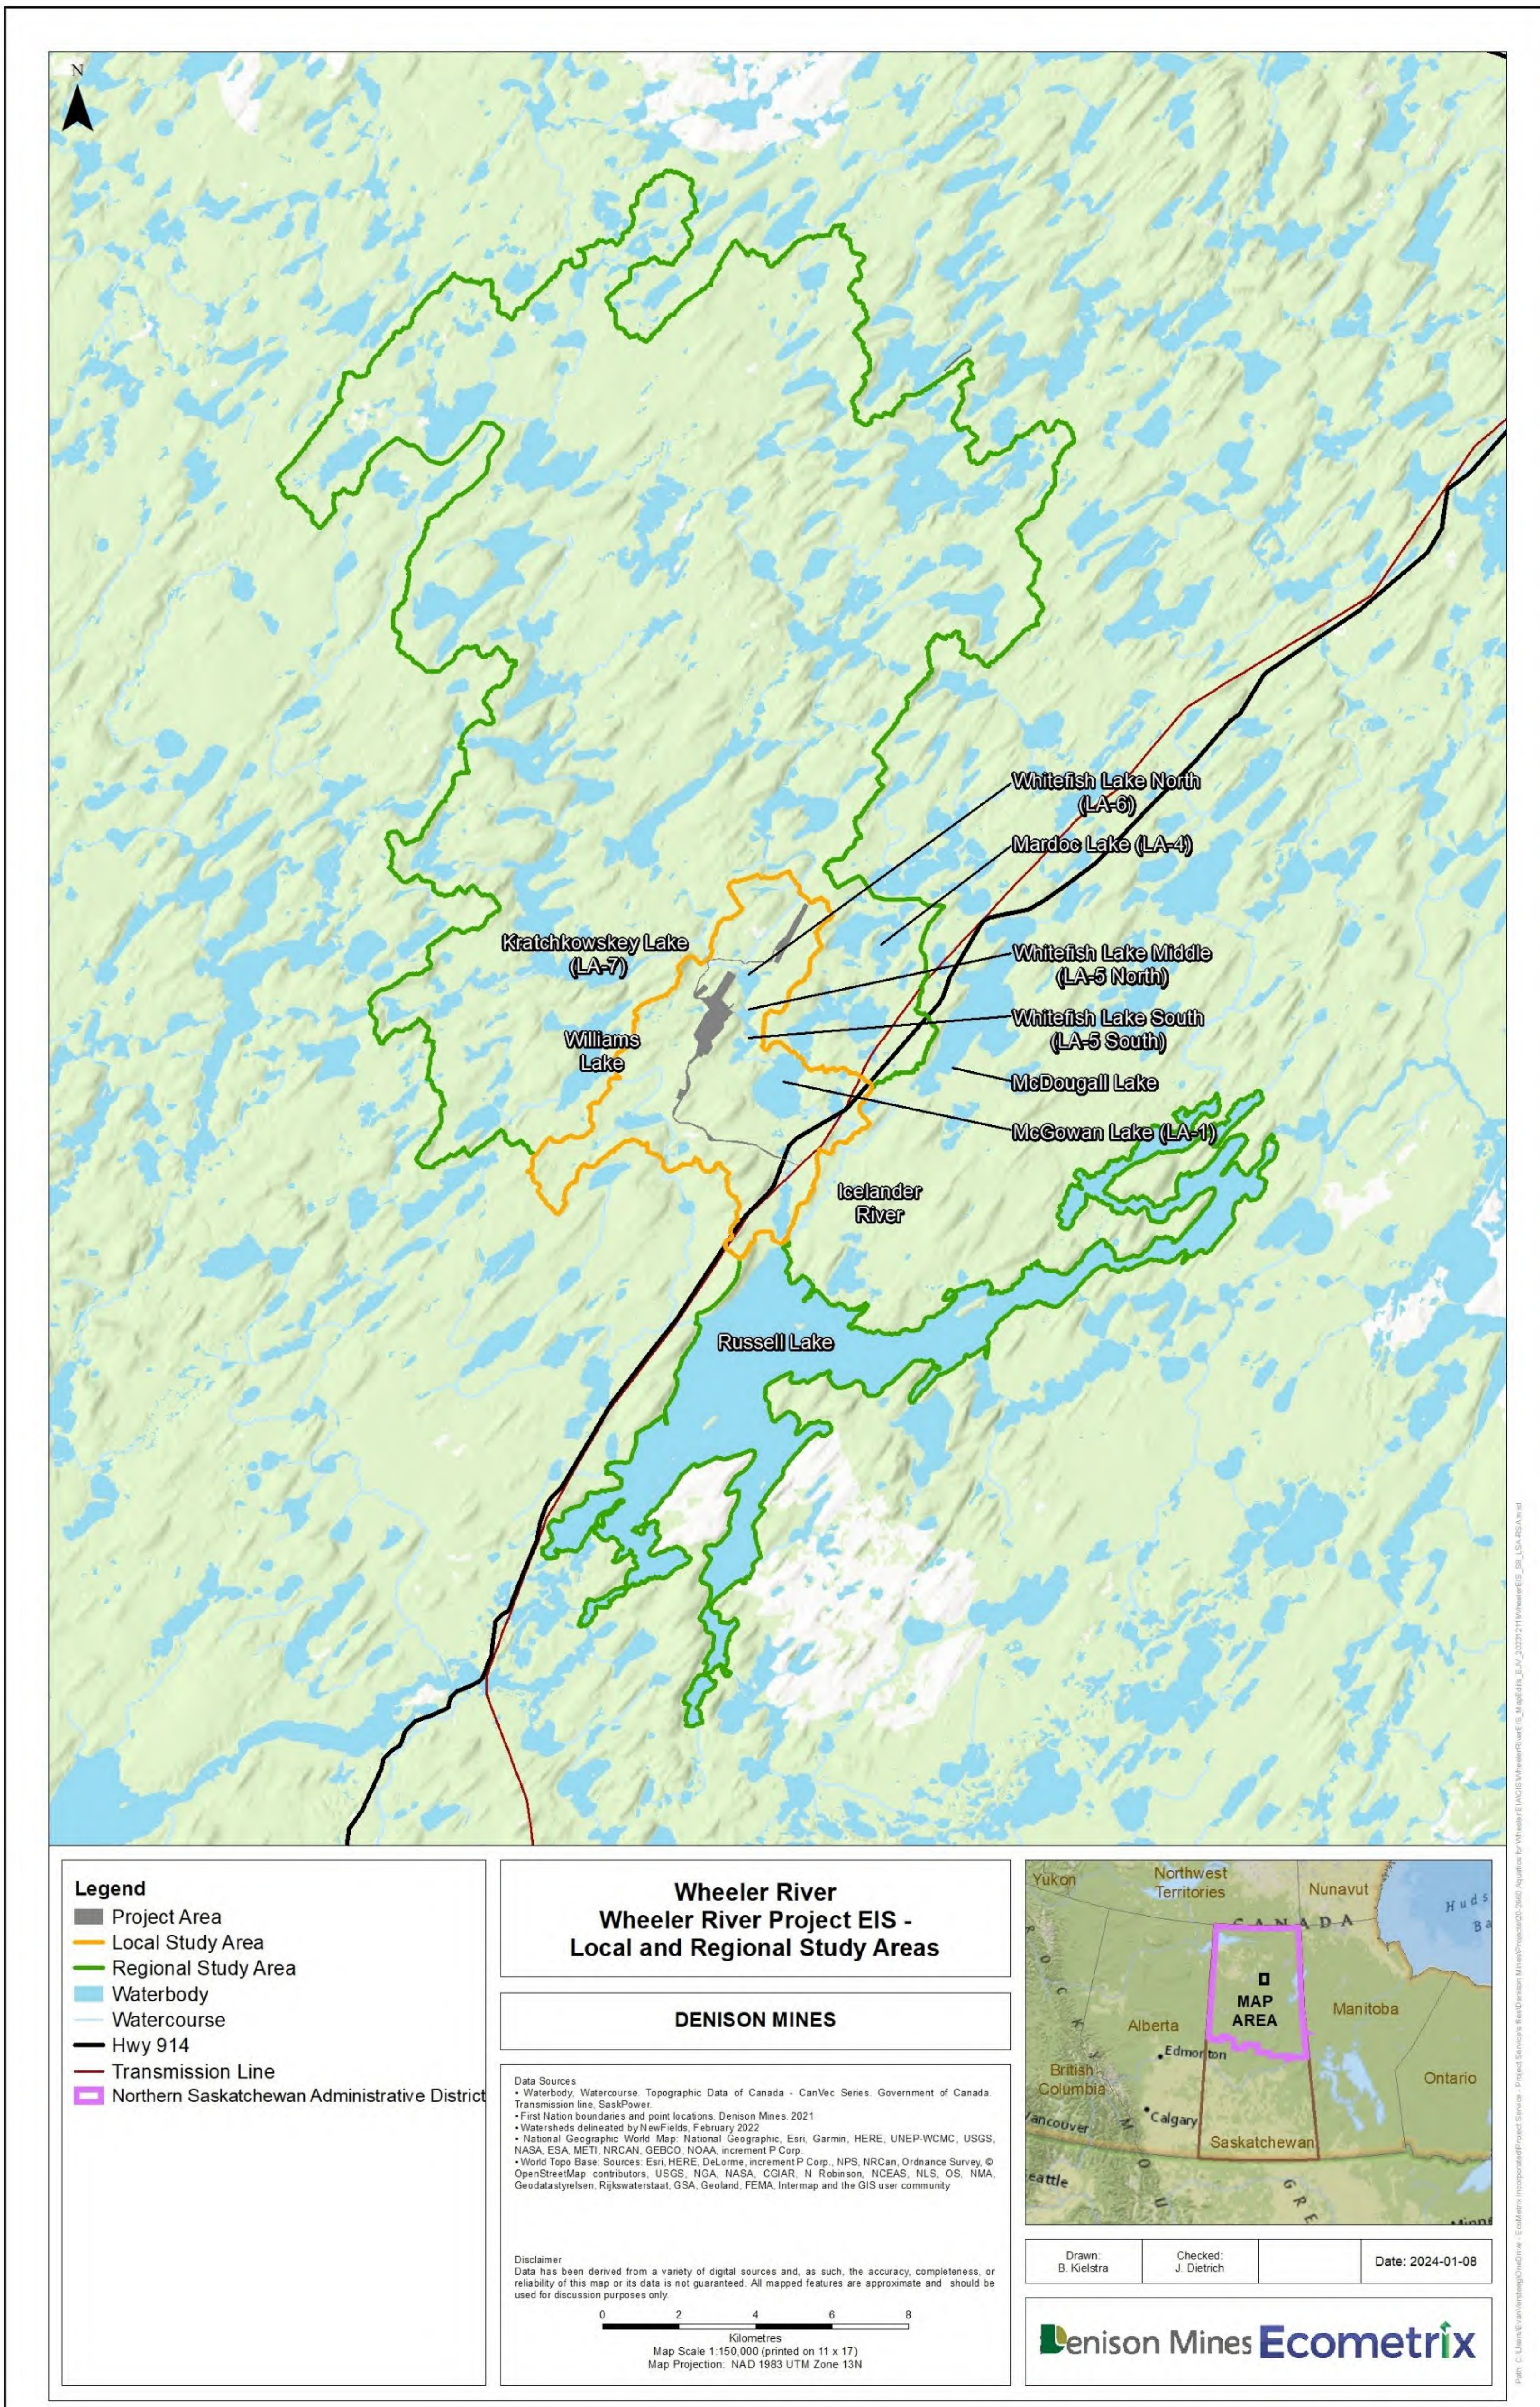

Figure 8.3-3: Spatial Boundaries for the Fish and Fish Habitat Valued Component

Temporal boundaries for the EIS are defined in Table 5.3.3 in Section 5. The temporal boundaries applicable to and considered in the EIS include the following Project phases:

- Construction (Year 1 to 3);
- Operation (Year 3 to 18);
- Decommissioning (Year 18 to 23); and
- Post-Decommissioning (Year 23 to 38).

Additionally, a 'future centuries' scenario is considered to assess the potential effects post-restoration (i.e., beyond the Project timeline of 0 to 38 years) and to reflect the time period over which the highest constituent concentrations in groundwater are predicted to migrate towards and interact with surface water (based on groundwater modeling). In this context, the future centuries scenario is considered with respect to the interaction of groundwater migration from the Project site and its potential influence on surface water in local waterbodies. The future centuries scenario prediction encompasses the long-term period during which slow migration of groundwater from the Phoenix Ore Zone area to the surface water environment is anticipated, and constitutes a bounding scenario of maximum concentrations of COPC.

8.3.2 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

At its broadest level, IK can be understood as the unique and collective knowledge of Indigenous peoples that may include, but is not limited to, the environmental, cultural, economic, political, and spiritual conditions of a community or region. In this section, IK and LK are viewed as complementary and influential alongside western science to produce a full understanding of the potential effects of the Project, whether measurable or perceived. Both forms of information have been given full and fair consideration.

Denison has recorded and stored information regarding IK, LK, and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers (e.g., 18-EN-ERFN-5.68). These numbers are referenced throughout the EIS, but particularly in Parts II and III, to indicate where specific information from the database has been integrated into the assessment. Appendix 8-A provides a summary of unique identification numbers referenced within Section 8.3.

Indigenous Knowledge and LK quotes and citations were included in this section to provide readers with the information considered as the Project advanced throughout the EA process. Since 2016, Denison has engaged with Interested Parties (i.e., local and Indigenous communities, residents, businesses, organizations, land users, and various regulatory authorities) to support the development of positive relationships and a mutual commitment to collaboration.

The history of resource sharing between Indigenous peoples and Europeans in the Project RSA indicates the importance of natural resources to all peoples. Such partnerships were described during engagement with English River First Nation:

> "*The biggest body of water to be impacted is Russell Lake – "Big Poor Fish Lake" in Dené. A lot of Scandinavians and Norwegians went up there in the 1930s and partnered with First Nations in that territory*" (18-EN-ERFN-5.68).

The influence of IK, LK, and engagement on the assessment of the Fish and Fish Habitat VC has first and foremost shaped the shared value of water and its life-sustaining properties.

> "*The lands and waters, we are definitely connected as peoples of English River. If we don't have the lands, we are not connected. If we don't have the water... Water is life to us*" (ERFN and SVS 2022).

Comments associated with water management and discharge to the environment were significant in the engagement record[4], and these were considered within the context of community interest regarding surface waters remaining supportive of natural function for biota. To this end, Project-related water management and treatment are important to maintaining surface water quality and sediment quality within the LSA and RSA.

Indigenous peoples and LK holders were clear in their interest regarding current levels of constituents in the aquatic ecosystem and the potential for adverse changes resulting from the Project. For example:

> *"What is the plan for storing and cleaning the water and where does it flow? What is the impact of ISR mining on water quality?"* (21-EN-VILX-443.25).

This affirms the necessity to assess water quality and sediment quality as they inform assessments for benthic invertebrates, fish and fish habitat, human health, and Indigenous land and resource use components.

Indigenous peoples and LK holders were also interested in the potential for overfishing [from the mine and people accessing the area] (20-LK-LEASESUR-267.66).

Consultations with a local harvester provided confirmation and additional information in identifying fish presence/absence, and critical life history use habitats, within the LSA (Local Harvester Knowledge GIS Shapefiles). Information was reviewed by the local harvester to ensure accuracy, for example:

> *"Northern pike spawning area in creek south of Williams Lake (Figure 4) and in areas identified in Figure 5. Lake whitefish spawn in creeks/rivers. Trout spawning areas in*

[4] 19-EN-MN-SR3-1.2, 19-EN-ML82-1.3, 19-EN-MOE-1.4, 18-EN-VILX-3.33, 18-EN-VILX-3.35, 18-EN-VILX-3.39, and 18-EN-VILX-3.84.

> *Russell Lake: one south of LAB area (Figure 5); around island and rocky shoals to both north and south of island (Figure 4)*" (19-LK-ERFNTrap-134.72).

This quote speaks to figures previously used for engagement purposes and since represented in Figure 8.3-4.

Furthermore, mapping that was provided by Indigenous groups with respect to land and resource use were consulted when assessing potential impacts (i.e., KML and NVP 2022; ERFN and SVS 2022; YNLR 2022).

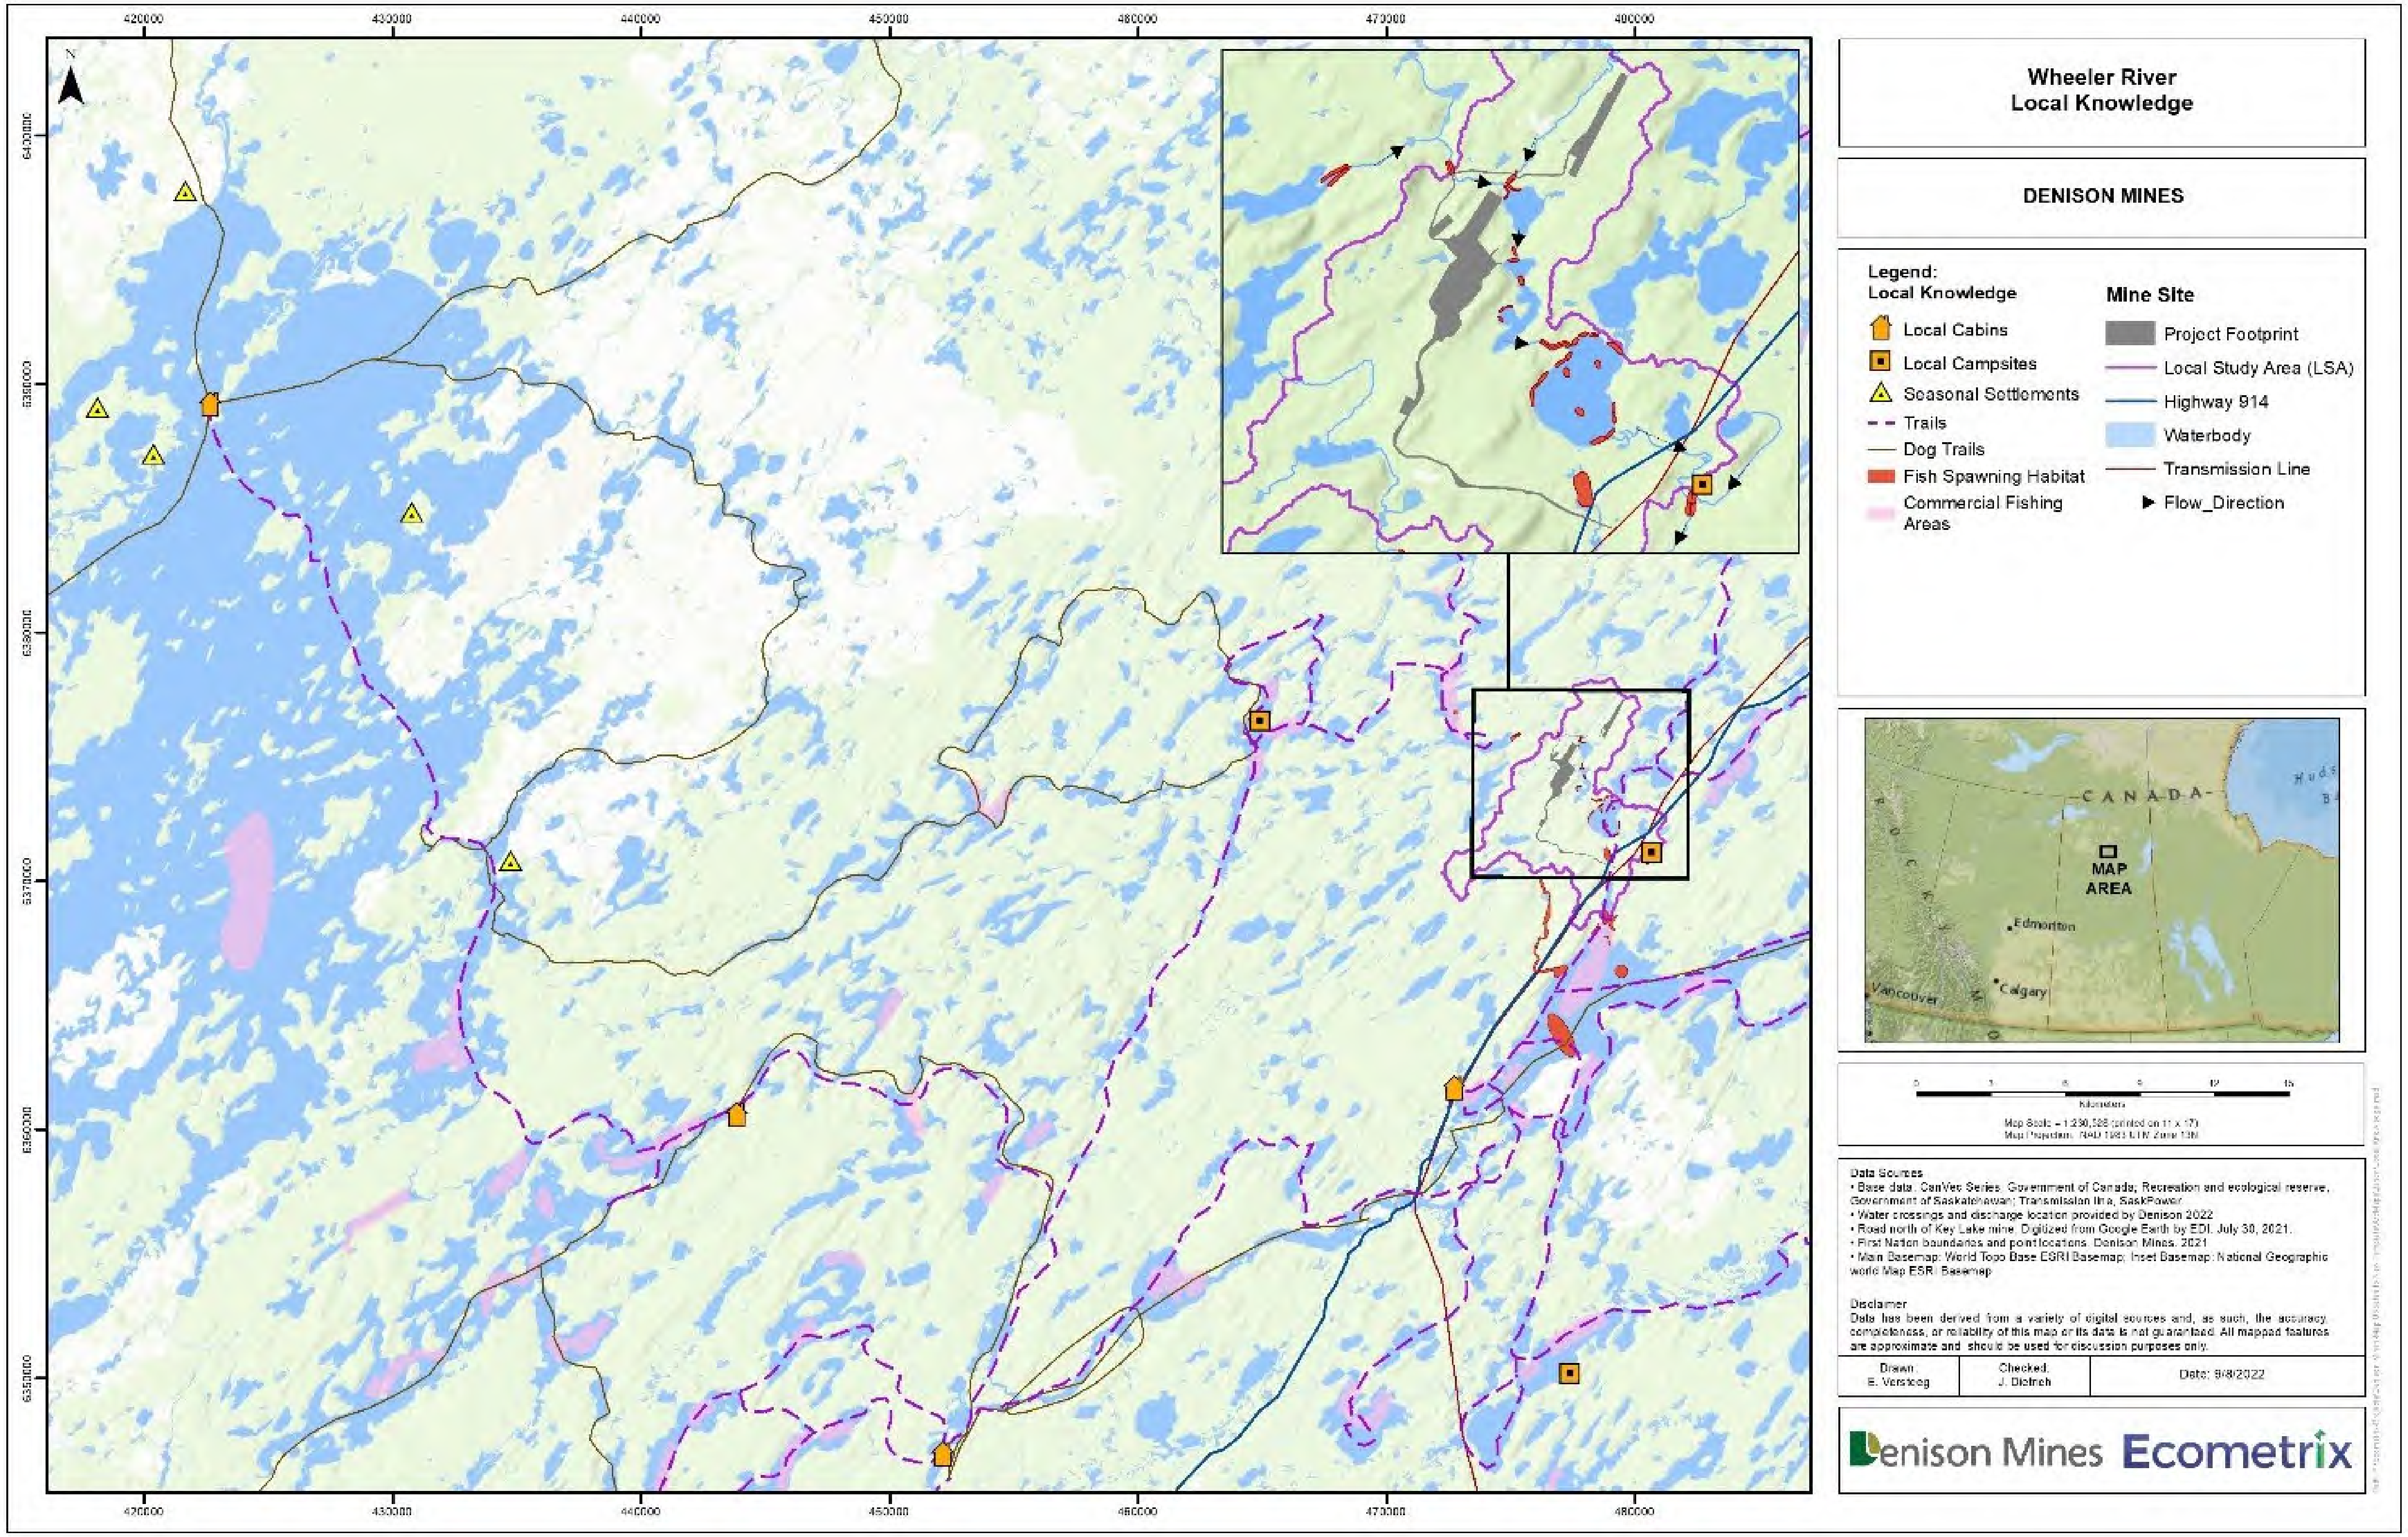

Figure 8.3-4: Local Harvester Knowledge in the Regional Study Area

8.3.3 Existing Environment

Details pertaining to existing conditions related to Surface Water Quantity (Section 8.1), Surface Water Quality, (Section 8.2), Sediment Quality and Benthic Invertebrates (Section 8.4), Fish Health (Section 8.5), Groundwater (Section 7) and Wetlands (Section 9) that are relevant to the Fish and Fish Habitat VC, as together they describe aquatic environment conditions, are presented elsewhere in the EIS. In this subsection, fish community and fish habitat data collected as part of the baseline aquatic environment program are summarized. These data have not been presented previously in this EIS but are relevant to the consideration of the Fish and Fish Habitat VC. Detailed information regarding fish and fish habitat baseline data collection and analyses are provided in Appendix 8-D. Additional baseline information pertaining to wetlands is provided in Appendix 8-F.

Baseline fish and fish habitat surveys for the Project were performed in a combination of lentic (lakes and ponds) and lotic (streams and rivers) environments. Aquatic habitat surveys were undertaken in September 2016, coincident with biological sampling (fish and benthos) that was conducted at that time, and included the collection of bathymetric and water quality data, as well as observations of physical shoreline and lake/pond/stream substrate features, and aquatic vegetation, fish, and benthic communities.

Critical locations of interest for this assessment include the following nodes, which are coincident with baseline monitoring stations and/or watersheds of interest for the assessment (Figure 8.3-5):

- SA-1 – Fish community and habitat survey location on the stream colloquially known as the Icelander River, which is located downstream of LA-1 (McGowan Lake);
- SA-2 – Fish community and habitat survey location situated downstream of the outflow from LA-5 (Whitefish Lake South) and upstream of the inflow to LA-1 (McGowan Lake);
- SA-4 – Fish community and habitat survey location situated upstream of the inflow to LA-6 (Whitefish Lake North), colloquially known as Kratchkowsky Creek;
- SA-5 – Fish community and habitat survey location situated upstream of the inflow to LA-6 (Whitefish Lake North), colloquially known as Hart Creek;
- SA-6 – Fish community and habitat survey location situated downstream of the outflow from LA-6 (Whitefish Lake North) and upstream of the inflow to LA-5 (Whitefish Lake South);
- LA-1 – McGowan Lake;
- LA-5 – Whitefish Lake South; and
- LA-6 – Whitefish Lake North.

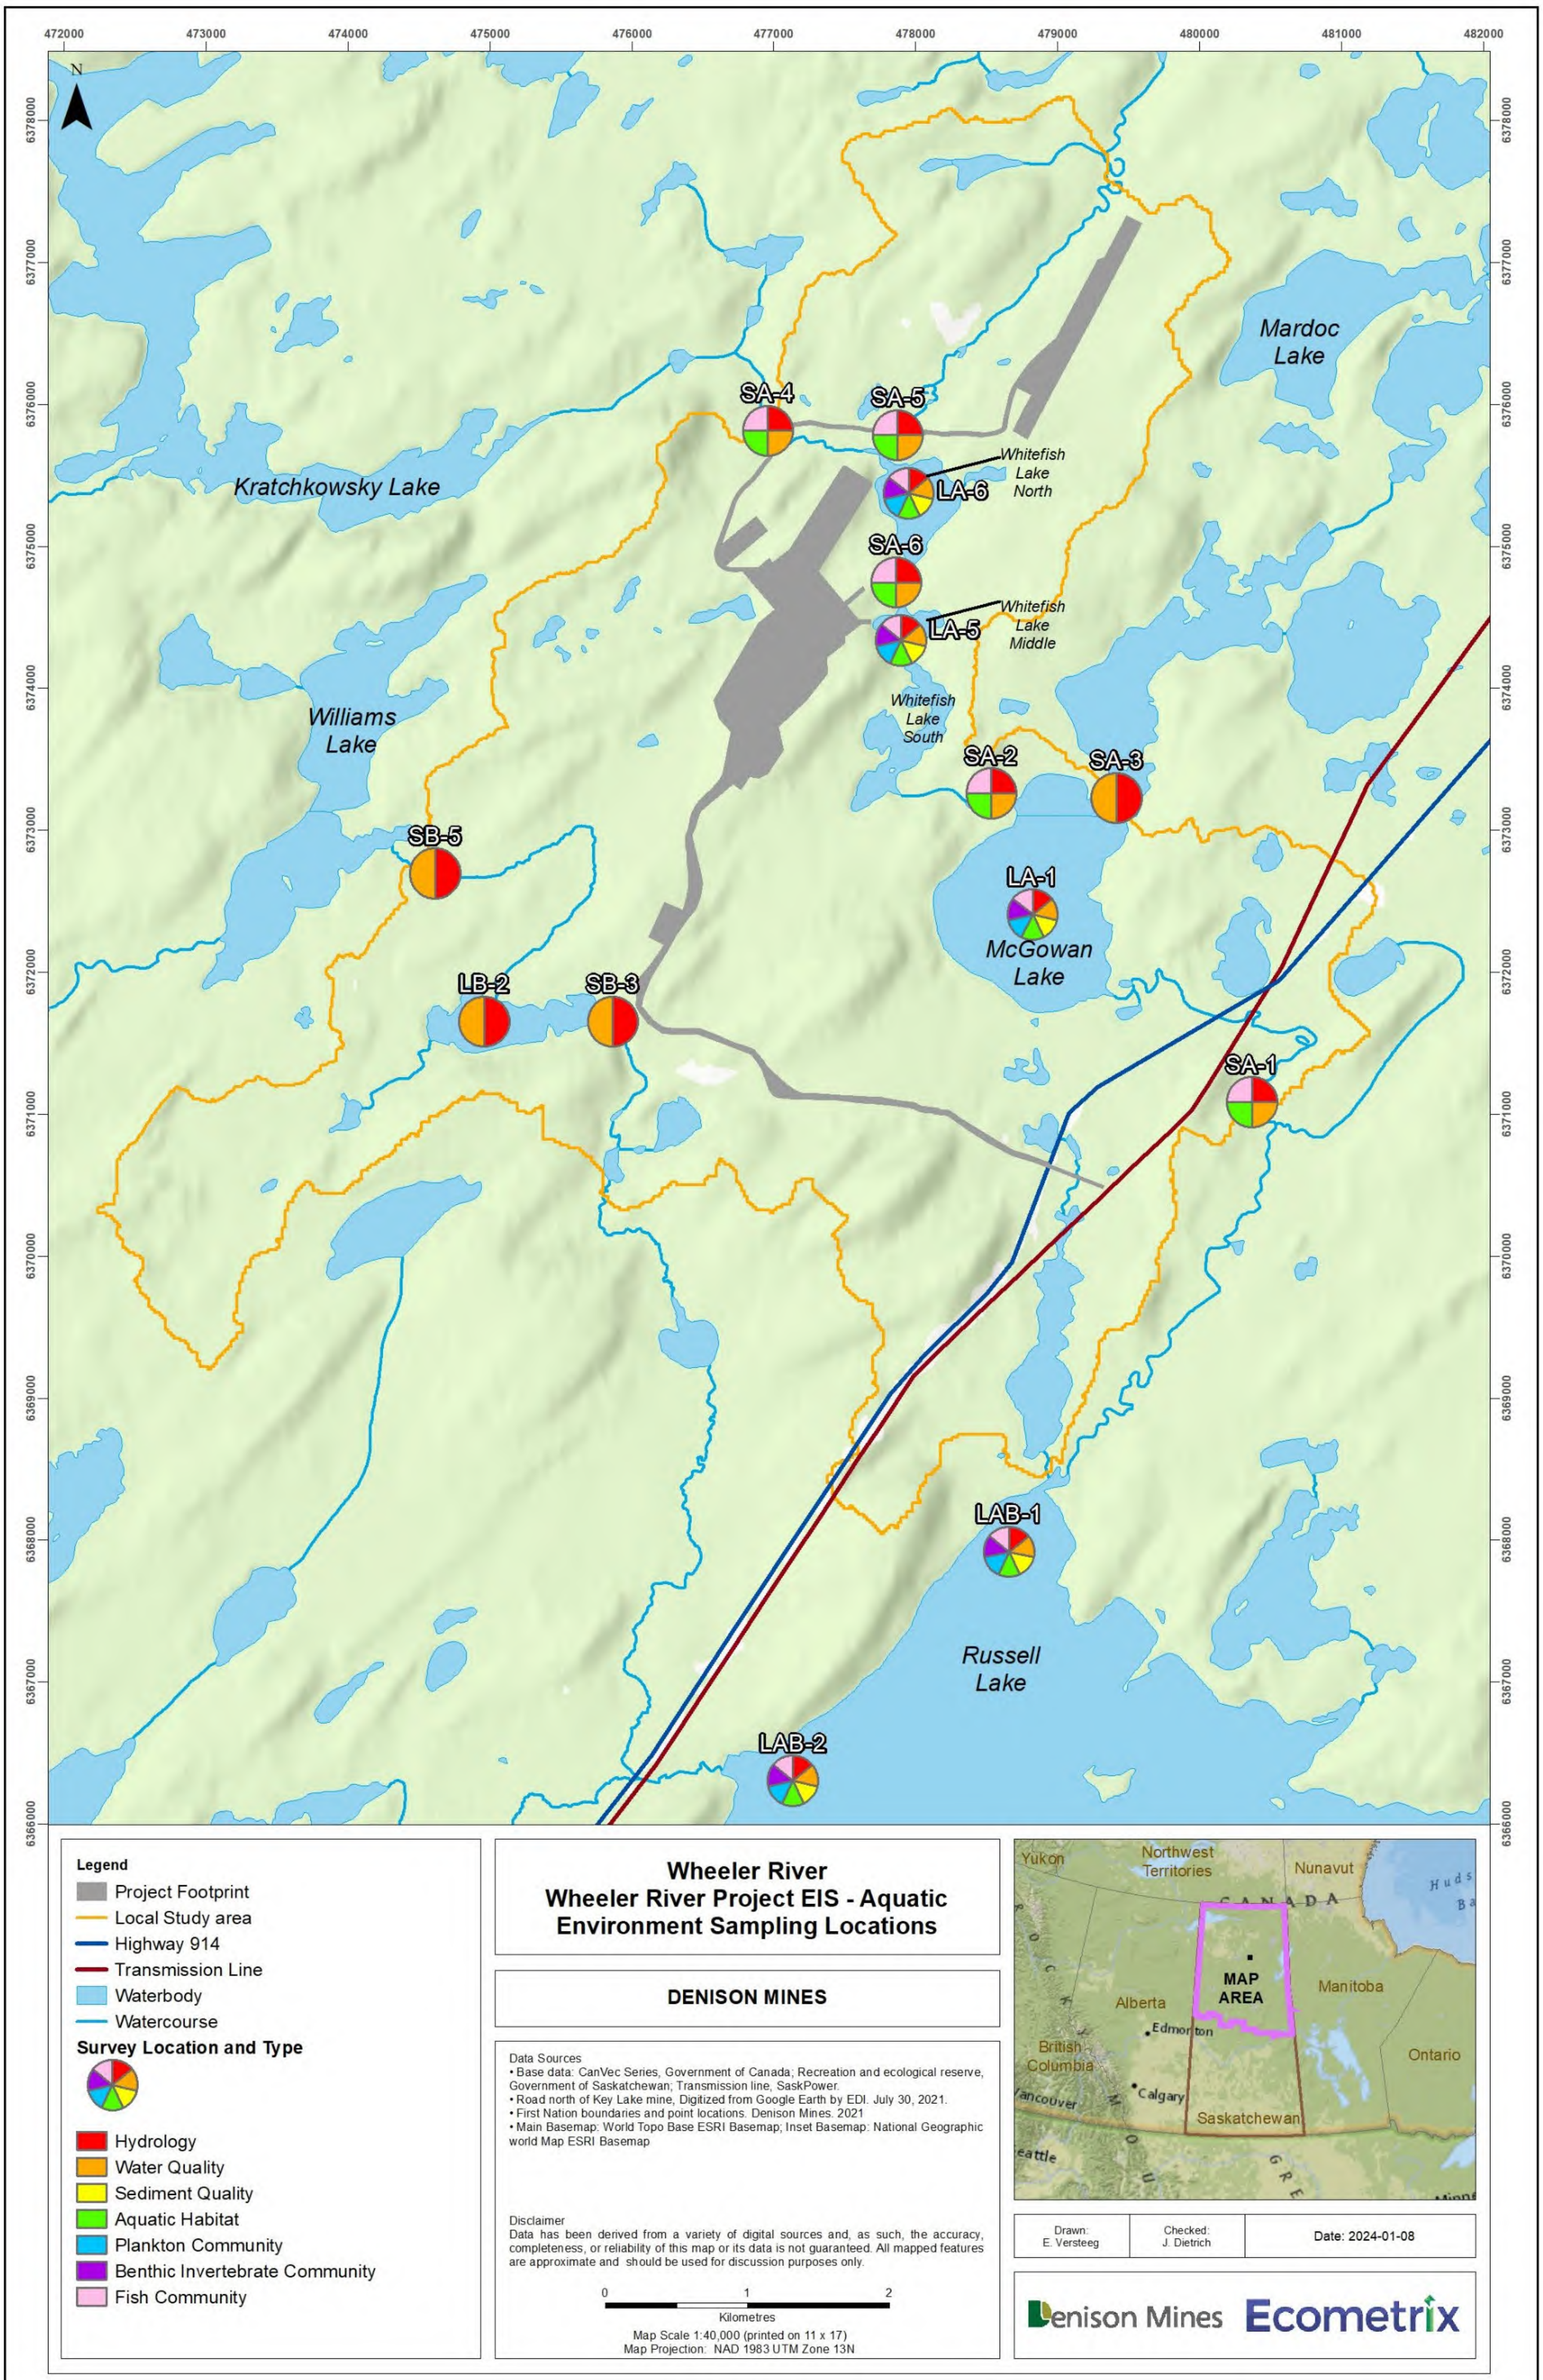

Figure 8.3-5: Water Quality, Biota, and Sediment Sampling Locations (2016 to 2018)

8.3.3.1 Methodology and Metrics

Fish Habitat

At lake and pond locations, aquatic habitat data collected included bathymetry, adjacent land uses and terrain, aquatic, riparian, and adjacent vegetation, and shoreline features, including locations and descriptions of inlets and outlets and substrate characterization. The distribution of aquatic macrophyte species in lake locations was documented, with distinction being made between emergent, floating, and submergent communities. Photographic documentation demonstrating the nature of the aquatic habitats present within the subject waterbodies was obtained and is provided in Appendix 8-C.

At stream locations, aquatic habitat characterization involved the assessment of physical, biological, and chemical characteristics. Recorded data included mean channel width, depth, and flow velocity, bank stability, stream morphology (i.e., pool, riffle, run, and flat), stream gradient, channel type, canopy cover, instream cover, and substrate type. Additional notes were collected on the surrounding terrain characteristics, dominant terrestrial vegetation, dominant aquatic vegetation, adjacent land use, amount of sediment overlaying substrates, and the amount of algae overlaying substrates. Weather conditions, including recent and current precipitation, air temperature, and cloud cover, were recorded. Finally, water colour and clarity were noted, as well as qualitative observations of benthic invertebrates encountered during fish surveys (Appendix 8-C).

Fish Communities

In the lakes and ponds, deeper areas offshore were fished with short duration (i.e., 4 to 8 hour) gill net sets. Where a distinct thermocline was evident (e.g., Kratchkowsky Lake), gill nets were set above and below the thermocline. Gill nets comprised varying mesh sizes such that all types of fish and age classes present could be collected. Nearshore fish collections were conducted by beach seines and/or minnow traps. Gear location coordinates were obtained with a GPS, and coordinates were recorded at each sampling station and expressed as degrees, minutes, and seconds (i.e., dd mm ss; WGS84 datum). Fish were identified to species and assigned an age class (i.e., young-of-year, juvenile, or adult). Length (to nearest mm) and weight (to nearest 0.01 kg) were measured for all fish at each location. All fish, live or dead, were returned to the same waterbody in which they were captured, with the exception of specimens retained for fish tissue chemical analysis (see Section 8.5).

In streams, the fish community was surveyed using a backpack electrofisher (Smith-Root Model LR-24) and dip net. Up to 300 m of stream were fished at the selected locations and captured fish were retained in a 25 L pail until the completion of electrofishing within the reach. With the exception of voucher specimens retained as a condition of the scientific collection permit, all fish were released to the same waterbody in which they were captured. Additional data were recorded, including date, time, location (i.e., coordinates, map datum), electrofisher settings (i.e., frequency and volts), fishing effort (seconds), reach length, mean width, and water temperature. Data were recorded on Fish Collection Forms (Appendix 8-C).

Large-bodied fish spawning surveys were undertaken during the fall of 2016 and spring of 2017 at selected lake and stream locations to determine the utilization of these areas for spawning. The fall survey was conducted during a period in which it was expected that fall spawners would be sexually mature and active. The spring survey was timed to take place shortly after ice-out, a period when spring spawning was expected to be underway. Fishing activities were conducted in a manner to maximize data collection and minimize incidental fish mortalities (i.e., visual when possible). If spawning activity was not directly observed, attempts to capture fish were undertaken to assess sexual condition (degree of ripeness) using the most effective method(s) for the habitat present (e.g., electrofishing, angling, gill netting, or seining). Gill nets were employed as seine nets to capture large-bodied fish observed at stream stations during the spring spawning survey. Captured fish were identified to species, sexed (if possible for live fish), assigned to an age class (i.e., juvenile, adult), assessed for spawning condition (i.e., immature, green [early or late development], ripe, partially spent, spent), measured (length to nearest mm, weight to nearest g), and released. Aging structures were collected, and sex was determined and sexual condition was verified from incidental mortalities. All live fish were returned to the same waterbody they were captured in.

A summary of fishing techniques employed by waterbody is provided in Table 8.3-2.

Table 8.3-2: Summary of Fish Survey Methods within the Local Study Area

Capture Methods	Lake and Pond Sample Stations			Stream Sample Stations				
	McGowan Lake (LA-1)	Whitefish Lake South (LA-5)	Whitefish Lake North (LA-6)	SA-1	SA-2	SA-4	SA-5	SA-6
Angling	X	X	X	X	-	-	-	-

Visual	X	X	X	-	-	X	X	X

X Indicates that the species was either captured or observed.

\- Indicates that the species was neither captured nor observed.

8.3.3.2 Key Baseline Results and Existing Conditions

Existing fish habitat for each waterbody and watercourse within the LSA is summarized in Table 8.3-3. Results from habitat surveys completed for the aquatic environment baseline study, detailed descriptions of the areas surveyed, including representative photographs and tables summarizing habitat conditions within each waterbody and watercourse, are provided in Appendix 8-C.

Shoreline vegetation at most lakes primarily consisted of shrubs and black spruce with upland jack pine forests. The shoreline generally consisted of rocks with overhanging shrubs, transitioning from small boulders and cobbles to a sand or silty bottom, with patches of sandy beach and sparse emergent or submergent aquatic vegetation. The shoreline near the LA-9 lake inlet and outlet consisted of bog habitat. At some lakes submerged tree trunks were found in localized areas near shore. Typical nearshore substrates included boulders, cobbles, sand, and organic matter. Shoreline slopes ranged from shallow to steep with the presence of old and active erosional areas. Cover types for aquatic biota included emergent and submergent vegetation, interstitial spaces in coarse substrate, overhanging vegetation, and woody debris. Ponds supported emergent, submergent, and floating aquatic macrophyte beds along much of the nearshore area.

Stream habitats surveyed as part of the baseline study included 2nd and 3rd order streams in the Icelander River basin and the Williams Lake drainage. Stream channels were generally stable and portions of the channels within the reaches surveyed were braided, meandering, straight, or ponded.

Stream gradients within the reaches surveyed were high to low and characterized by riffles, runs, or pools, with some flats. No barriers to fish migration were observed.

A summary of fish habitat within lakes and rivers within the LSA is provided in Table 8.3-3 and Table 8.3-4.

Presence or absence of fish in the subwatersheds of the LSA is summarized in Table 8.3-5 and Figure 8.3-6 and Figure 8.3-7. These include a number of large-bodied species (i.e., Northern Pike [*Esox lucius*], White Sucker [*Catostomus commersonii*], Longnose Sucker [*Catostomus catostomus*], Artic Graying [*Thymallus arcticus*], Walleye [*Sander vitreus*], Lake Trout [*Salvelinus namaycush*], Lake Whitefish [*Coregonus clupeaformis*], and Burbot [*Lota lota*]), as well as small-bodied forage fish species (i.e., Ninespine Stickleback [*Pungitius pungitius*], Slimy Sculpin [*Cottus cognatus*], Spottail Shiner [*Notropis hudsonius*], and Yellow Perch [*Perca flavescens*]). Fish captured during baseline field studies showed no gross abnormalities.

As barriers to fish movement were not identified, the absence of a species in lake or river habitats does not necessarily confirm that the species does not inhabit that area; rather, that the species was not actively captured, or the area is not characteristic of preferred habitat for the species.

Fish spawning habitat for several species was confirmed in the LSA, both through LK and confirmatory field reconnaissance. This habitat is summarized in Table 8.3-3 and Table 8.3-4 and Figure 8.3-8**,** Figure 8.3-9**,** and Figure 8.3-10. Known spawning habitat occurs for Northern Pike, White Sucker, Longnose Sucker, Artic Graying, Walleye, Lake Trout, and Lake Whitefish in the LSA and Russell Lake, as well as upstream of the Project in the Icelander River system.

No species at risk were identified as part of baseline assessments or through engagement with LK or IK holders.

8.3.4 Assessment of Project-related Effects

8.3.4.1 Potential Interactions Between the Project and Valued Component/Key Indicators

The Project will require the construction, operation, and decommissioning of several components (as described in Section 2). Potential interactions between Project activities and the Fish and Fish Habitat VC are summarized by Project phase in Table 8.3-6 and are ranked as:

- Primary Interaction (✓): Project activity is expected to interact with the VC/KI, which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.
- Other Interaction (✓): Project activity is expected to interact with the VC/KI. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects.
- No Interaction: Project activity is not expected to interact with the VC/KI, no adverse effects are expected, and a rationale is provided for not considering this potential interaction further.

Based on professional judgment and understanding of the nature of Project activities and their sequencing, the Project activity list was reviewed and the type of other interactions determined. Potential Project-related effects are discussed in Section 8.3.4.2. Primary Project activities with the potential for adverse effects on the Fish and Fish Habitat VC (i.e., flagged as 'primary interactions') are expected to involve surface land clearing, major earthworks, surface/grading preparations, changes to land cover, water management feature construction and operation, and water taking and effluent discharge. Other Project activities (i.e., flagged as 'other interactions') refer to those activities that may be associated with hydrogeological influence on local waterbodies and are expected to be secondary contributors to potential adverse effects. The remaining activities (e.g., power generation and supply) were deemed to have no interaction and were not carried forward in the assessment as they are not expected to result in detectable changes in the MPs associated with the Fish and Fish Habitat VC (which is inclusive of wetlands). Activities during Post-Decommissioning (e.g., site inspections; monitoring and on-site engagement with Interested Parties) were deemed to have no interaction because they do not involve any land clearing, surface preparations, or major earthworks.

8.3.4.2 Potential Project-related Effects

Project activities may interact with the Fish and Fish Habitat VC during all Project phases. In general, the interactions can be characterized as being primarily associated with controlled, routine discharges from the site. During Construction, the primary effect pathway relates to the mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. During Operation and Decommissioning, excess water from the effluent monitoring ponds will be released to the environment. Routine discharge of this sort will be directed to Whitefish Lake only. Direct discharge of treated effluent to the natural environment has the potential to change surface water constituent concentrations, which may be partitioned to sediments, potentially affecting fish communities and fish habitat via exposure. Post-Decommissioning will involve the restoration of natural site drainage to the Whitefish Lake receiver. Similar to Construction, Decommissioning and Post-Decommissioning activities have the potential to increase the mobilization of suspended solids into natural surface waters (including wetland features), increasing the potential for sedimentation of benthic invertebrate habitat. The following sections discuss each Project-related effect.

8.3.4.2.1 Mobilization of Suspended Materials

Construction

The primary effect pathway during Construction relates to the mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. According to the site water balance (Figure 2.2-14 in Section 2), there is no planned discharge to Whitefish Lake during Construction. The mobilization of suspended material into natural surface water features is readily mitigatable by virtue of the mine development plan and through the implementation of standard water management and sediment control practices. Water management infrastructure (e.g., collection ditches, ponds, pumping stations) and various aspects of the water management and sediment control management systems will be put into place coincident with the initiation of construction activities. Waters (e.g., runoff) associated with areas under development will be collected and stored within management infrastructure (e.g., clean waste rock pond, see Figure 2.2-14 in Section 2). In the event that releases to the natural environment are necessary, they would only occur once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). No downstream effects on surface waterbodies, wetland natural sediments, or fish and fish habitat are expected.

Operation

During Operation, mobilization of suspended materials will be managed through the development and operation of water management infrastructure and implementation of surface water management through the Surface Water Management Program. Releases of contact water to the natural environment will be directed through applicable collection ponds, the IWWTP, and the Effluent Monitoring and Release Ponds. Discharge will only occur once it is safe to do so (i.e., suspended solids levels in the water would be at acceptable levels). Denison may employ active means (e.g., filtering), if required, to achieve low TSS levels in discharge, in addition to passive means, such as settling and clarification in the IWWTP to manage TSS in the effluent stream to low levels. No downstream effects on surface waters, natural sediments, fish and fish habitat including wetlands are expected.

Decommissioning and Post-Decommissioning

During Decommissioning and Post-Decommissioning, the site-wide water management system will continue to operate such that Denison will maintain control of the site aspect affected water through the IWWTP. Surface drainage during Decommissioning activities will continue to be directed to the system of collection ponds, the IWWTP, and the Effluent Monitoring and Release Ponds to facilitate the control of suspended solids and achieve low TSS levels in the discharge, thereby minimizing any potential for adverse changes to water quality, sediment quality, and fish and fish habitat (including wetlands).

8.3.4.2.2 Overprinting of Fish Habitat

For the purposes of this assessment the bogs and fens within the area can be assumed to provide supporting fish habitat to the adjacent lake and river water bodies in the vicinity of the LSA. Overprinting of fish habitat is only expected as a result of construction and commissioning of the effluent discharge/intake pipeline and diffuser at Whitefish Lake. The discharge pipeline and diffuser will terminate at an engineered, offshore, submerged, multiport diffuser, which will be designed to maximize the mixing potential and reduce the spatial extent of the mixing zone (as described in Section 8.2.4.1.1). Negligible aquatic habitat loss is predicted in Whitefish Lake due to the installation of a discharge pipeline and diffuser configuration. The total area of the lake substrate that would be overprinted by the pipeline is expected to be approximately 135 m^2, which will constitute less than 0.05% of the lake's surface area and, therefore, is not expected to require an Authorization under the *Fisheries Act*. The discharge point will be at a depth of approximately 3 m offshore so as not to interfere with known, nearshore Northern Pike spawning habitat in the vicinity. The exact design configuration will be optimized as required during the engineering design and permitting phase to facilitate optimal performance of the diffuser specific to site conditions. However, under the conceptual design (i.e., diffuser line with three evenly spaced nozzles, with each nozzle approximately 0.07 m in diameter, approximately 115 m offshore from the north shoreline of LA-5, at a depth of approximately 3 m [Appendix 8-E]) and maximum effluent discharge concentrations (as listed in Table 8.2-9 in Section 8.2.4.2.3 and Appendix 8-E), it is estimated that the extent of the mixing zone will be less than 5 m.

The pipeline and diffuser structure will remain in place during Operation and Decommissioning while the site-wide water management system continues to operate, such that Denison will maintain control of the site process and contact water through the IWWTP. The effects on Fish and Fish Habitat are expected to be confined to this area throughout the duration of the Project, but will be returned to pre-construction character following removal of the infrastructure, establishment of natural sediment distribution patterns in the lake, and recolonization of food resources (i.e., benthic invertebrates).

Two water crossings will be installed along the road from the Project site to the airstrip (see Figure 2.2-27 in Section 2 and Figure 8.3-8).

- At the airstrip access road west crossing, Kratchkowsky Creek. The crossing will be over a segment of the western sub-basin of the Icelander River drainage (downstream of Kratchkowsky Lake, LA-7).
- At the airstrip access road east crossing. The crossing will be over a segment of the northern sub-basin of the Icelander River drainage (downstream of LA-9). This creek has been previously referred to as Hart Creek.

The road crossings will be built in locations where crossings previously existed. The previous crossings were decommissioned by Cameco Corporation in 2015. The new crossing structures are proposed to be clear span solutions without in-water supports or buttresses. Vegetation removal, fill, and grading will be required only to the extent necessary to prepare footings for the bridge, which will remain above the high-water mark. Heavy construction equipment will be needed to prepare footing areas for concrete. Laydown areas will be kept adjacent to the roadway and above the flood-prone area. Crossings will be pre-assembled in the laydown area and lifted into place.

It is expected that the works proposed in and around water as part of the Project can be either conducted to avoid fish habitat or conducted over a short duration, at a small spatial scale, and during appropriate timing windows. As such, the proposed works are not expected to constitute a HADD under subsections 34(1) and 35(2) of the *Fisheries Act.*

Construction, operation, and maintenance of the airstrip access road crossings have the potential to increase access for recreational resource users to adjacent waterbodies. The phase of greatest impact due to fishing pressure on local fish populations is expected to occur during Construction when the peak in onsite workers occurs, followed by Operation and, to a lesser extent, Decommissioning (Section 11.3 in Section 11 Land and Resource Use).

Investigation of the potential overprinting of wetland features as a result of the Project it is evident that wetland loss is avoidable. The interaction of the Project with wetlands is isolated to those areas where stream crossings for access roads and hydro-line connections are proposed (Figure 3).

With the use of single span bridges and implementation of best management practices, direct wetland disturbance associated with the crossings of Kratchkowsky Creek and Hart Creek is expected to be avoided. It should be noted that SaskPower proposes to tap the existing I3P 138 kV line near Highway 914 and build approximately 4.5 km of new 138 kV line from the I3P tap to the Project site. SaskPower will be responsible for conducting activities such as line routing, environmental studies, and permitting, public consultation, and engineering design work as applicable to the load interconnection. As such, wetland disturbance related to the SaskPower Hydro Corridor is expected to be addressed through the SaskPower permitting process. (Appendix 8-F).

8.3.4.2.3 Controlled Discharge to Receiving Environments

Construction

Discharge to the environment is not expected during Construction. Site contact water will be collected and held in the Clean Waste Rock Pond (Figure 2.2-14 in Section 2). Therefore, potential effects of discharge on the Fish and Fish Habitat VC are not expected.

Operation

Denison does not intend to include constant freshwater withdrawal or effluent discharge throughout Operation; however, for the purpose of assessing the scenario of greatest potential effects, the Project was assessed as having a continuous freshwater withdrawal rate of 40.5 m^3/hr and a continuous effluent discharge rate of 36.5 m^3/hr (Figure 2.2-15 in Section 2).

With respect to the discharge of treated effluent, the Fish and Fish Habitat VC was assessed as an ecological receptor as part of the *Wheeler River Environmental Risk Assessment* (Appendix 10-A in Section 10). The potential effects on Fish and Fish Habitat were assessed based on pathways through surface water quality for both radiological and non-radiological constituents.

The estimation of potential changes in surface water quality as a result of effluent discharge to the environment is discussed in Sections 8.2.4.2.2, 8.2.4.2.3, and 8.2.4.2.4. These subsections discuss the methods, assumptions, and results of predictive models used to assess the potential effects on the receiving environment in the LSA.

The near-field analysis (Section 8.2.4.2.3) identified that under all flow regime scenarios (i.e., 7Q10, monthly low, and monthly average), constituents are expected to be well mixed within LA-5 yet parameters where the available assimilative capacity is less than the max predicted discharge concentration when screening criteria subject to background water quality include sulphate, chromium, molybdenum, and selenium. For chromium and selenium, the assessment was influenced by datapoints with values below the detection limit. However, these are conservative estimates which are not yet based on BATEA (Table 8.2-10 and Appendix 8-E). Additionally, the extent of the mixing zone in Whitefish Lake is estimated to be less than 5 m under average flow scenarios assessed (Table 8.2-11 and Appendix 8-E).

A regional surface water quality model was used to predict effects on surface water quality within Whitefish Lake outside the initial mixing zone (Section 8.2.4.2.4). When the treated effluent is released to Whitefish Lake (LA-5), surface water concentrations were predicted using IMPACT according to the equations outlined in the IMPACT model (Appendix 10-A in Section 10). The predicted maximum concentrations of COPC in water are summarized in Table 8.2-13. With the exception of copper where baseline concentrations exceed the FEQG (due to the copper analytical detection limit being equal to the FEQG) and the guideline does not consider conditions expected during operations, there are no predicted exceedances of water quality guidelines were identified for any of the COPC during Construction, Operation, or Decommissioning.

Other than LA-5 (Whitefish Lake) no other controlled discharge will occur to the natural environment and no wetlands will be impacted as a result (Appendix 8-F).

Decommissioning and Post-Decommissioning

Discharge to the aquatic environment of Whitefish Lake during some portion of Decommissioning is expected. Effluent rates during Decommissioning are expected to be less than during Operation. The effluent is also expected to have lower levels of COPC compared to Operation. Therefore, the analysis of the potential effects on the Fish and Fish Habitat VC via surface water quality pathways during Operation provided in Section 8.3.4.2.3 is considered the bounding scenario for Decommissioning as well.

8.3.4.2.4 Change in Water Levels and Flow

As detailed in Section 8.1, the projected withdrawal and discharge rates proposed for the Project are the largest influence on the hydrological effects of the Project. The largest predicted change in streamflow rate is -3.1% at the LA-5 and SA-2 nodes (immediately downstream of the Project) during Operation and Decommissioning, as projected against the 5^{th} percentile low flow dataset in March. Lake and wetland levels are expected to deviate less than ±0.01 m due to all Project influences. All Project influences on the environment are expected to return to baseline conditions during Post-Decommissioning. These changes are within the range of fluctuation of environmental flows and water levels and are unlikely to affect fish passage or life history environmental cues.

8.3.4.2.5 Long-Term Transport of Groundwater Solutes to Whitefish Lake in Future Centuries

During the ‘future centuries’ scenario as described in Section 8.3.1.3, remediation works will be completed and the site naturalized, thereby restoring drainage patterns to report to surface waterbodies. As indicated in Section 7, groundwater plumes may develop from residual mass remaining post-mining based on bench-scale lab tests of core flushing, and numerical modelling of reactive fate and transport.

Groundwater flow and reactive transport of dissolved constituents were modelled using three-dimensional modelling, whereby the reactions were computed using PHREEQC and transport was computed using FEFLOW (Appendix 9-C). Groundwater flow observed and simulated in the calibrated groundwater model travelled eastward from the mining zone within the Lower Sandstone Aquifer before moving upward through the Desilicified Zone in the Athabasca Sandstone and overlying overburden deposits toward Whitefish Lake. Modelled transport of dissolved constituents along the groundwater flow path allowed for interactions of the dissolved constituents with the geologic media through which they were flowing. Due to the relatively low groundwater velocities between the mining zone and Whitefish Lake, and chemical reactions along the groundwater flow pathway, the 'future centuries' scenario spans hundreds to thousands of years.

Although the precise location of the groundwater discharge to the surface is somewhat uncertain, the groundwater transport scenarios that have been evaluated (Appendix 7-C of the EIS) to date suggest groundwater discharge impacted from mining will most likely be relegated to Whitefish Lake. The discharge to Whitefish Lake is generally predicted to occur along the eastern shore of the lake, as this is interpreted to be the eastern edge of the underlying desilicified zone. The Labrador Tea Shrubby Bog habitat located on the eastern shore of Whitefish Lake may be in the zone of influence of groundwater discharge, yet chemically will remain below freshwater environmental quality criteria. Groundwater impacts to other surrounding wetlands will be negligible as groundwater is not predicted to discharge within any area beyond the central portion of Whitefish Lake. (Appendix 8-F).

The results of the numerical modelling (as provided in Section 7 and Appendix 10-A in Section 10) support the conclusion that with the implementation of appropriate mitigation during the decommissioning and restoration phases of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect on surface water. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future from the deep Ore Zone to Whitefish Lake are expected to remain below fresh water environmental quality criteria in Whitefish Lake.

For the COPC identified in the effluent, the predicted mass flux from groundwater (Table 8.3-7) into Whitefish Lake starting 200 years after the Project phases during the future centuries scenario was added into the IMPACT model to predict the surface water concentrations over time at the exposed locations. As shown in the *Wheeler River Environmental Risk Assessment* (Appendix 10-A in Section 10), predicted surface water concentrations at all locations are expected to be below water guidelines for the protection of aquatic life, except for copper where baseline concentrations exceed the FEQG (due to the copper analytical detection limit being equal to the FEQG). An incremental increase in concentration is predicted such that the predicted copper concentration (~0.0006 mg/L) would be greater than the FEQG of 0.0002 mg/L under baseline conditions, indicating a slight increased level of risk to the most sensitive aquatic biota.

Table 8.3-7: Summary of Predicted Mass Flux of Constituents of Potential Concern in Groundwater During the Future Centuries Scenario

Mass Flux (mg/s or Bq/s)									
Year After Project Phases	200	300	400	500	600	700	800	900	1000
General Chemistry (mg/s)									
Chloride	1.26E+02	1.28E+02	1.29E+02	1.29E+02	1.29E+02	1.29E+02	1.29E+02	1.28E+02	1.28E+02

Notes:

1 Estimated from uranium using the specific activity of 12,356 Bq/g and assuming secular equilibrium between uranium-238 and uranium-234.

2 Unit conversion from mg/s to Bq/s using the specific activity of 7.47E+08 Bq/g, which was calculated from its half-life of 77,000 y.

3 Unit conversion from mg/s to Bq/s using the specific activity of 3.66E+10 Bq/g, which was calculated from its half-life of 1,600 y.

4 Assuming equilibrium between radium-226 and lead-210 due to the long half-life of radium-226.

5 Calculated from lead-210 assuming transient equilibrium between lead-210 and polonium-210.

8.3.5 Mitigation Measures

Measures to mitigate adverse effects on the Fish and Fish Habitat VC are consistent with those to mitigate adverse effects on the Surface Water Quantity, Surface Water Quality, Sediment Quality and Benthic Invertebrates, and Fish Health VCs. These measures are repeated in this section for completeness, with additional measures added as applicable to the Fish and Fish Habitat VC.

- Avoid more sensitive habitats (spawning, nursery and overwintering habitats to the extent practicable.
- Maintain existing drainage patterns with the use of culverts, where applicable.
- Maintain access roads by periodically re-grading and ditching to improve water flow, reduce erosion, and manage vegetation growth.
- Inspect culverts periodically. Remove accumulated material and debris upstream and downstream of the culverts to prevent erosion, flooding, habitat damage, property damage, and mobilization of sediment.
- Attenuate peak discharges and augment baseflows to the environment through the use of Project water storage features (i.e., runoff, process water, contact water, monitoring/effluent ponds).
- Develop and implement a Surface Water Management Program that provides an integrated framework to manage water quality and includes provision for water management practices for each of the primary site aspects, as well as areas of the site where there is contact water.
- Maximize the recycle and re-use of process water to reduce freshwater intake and release to Whitefish Lake.
- Design the discharge diffuser/outfall to have the smallest footprint possible while still providing effective mixing and dilution and discharge flows that do not detrimentally affect sediments.
- Adhere, as applicable, to the *Interim Code of Practice: End-of-Pipe Fish Protection Screens for Small Water Intakes in Freshwater* (DFO 2020a).
- Adhere, as applicable, to the *Interim Code of Practice for Temporary Cofferdams and Diversion Channels* (DFO 2020b).
- Adhere, as applicable, to the *Interim Code of Practice for Temporary Stream Crossings* (DFO 2020c).
- Plan in-water works, undertakings, or activities to respect timing windows to protect fish and fish habitat, including their eggs, juveniles, spawning adults, the organisms upon which they feed, and the areas where they migrate. In-water works should be deferred based on the specific waterbody and known species that inhabit the waterbody (*Saskatchewan Restricted Activity Timing Windows for the Protection of Fish and Fish Habitat* [DFO 2020d]).
  - Spring spawning species (northern Saskatchewan) – avoid work between May 1 and July 15.
  - Fall spawning species (northern Saskatchewan – Lake Trout present) – avoid work between September 1 and July 15).
  - Fall spawning species (northern Saskatchewan – Lake Trout absent) – avoid work between October 1 and July 15).
- Where possible, conduct instream work during periods of low flow (e.g., summer or winter) to further reduce risk to fish.

- In discussion with responsible authorities, prepare a fish salvage plan to relocate fish prior to in-water works.
- Design treated effluent discharge or freshwater intake infrastructure to prevent entrainment or impingement of fish.
- Implement an erosion and sediment control plan for the site to reduce potential sedimentation of waterbodies and potential lethal affects to fish, larvae, and eggs. Ensure erosion and sedimentation measures are maintained as applicable throughout the duration of the Project.
- Develop site-specific effluent treatment to treat COPC to appropriate release limits in accordance with provincial standards and licence/permit conditions.
- Discharge effluent under a scenario that will meet provincial and federal discharge criteria, as identified through permitting. Scenarios may include:
  - discharging at a fixed rate while maintaining an appropriate minimum dilution ratio (i.e., discharge when able to meet the required dilution ratio and cease discharge during periods when unable to meet the necessary dilution ratio);
  - discharging under a variable waste load allocation (i.e., discharge an appropriate effluent volume based on flow in the receiver to maintain a minimum dilution ratio); and
  - managing discharge via a hybrid of the two previous options (i.e., discharge effluent at a fixed rate to maintain the required dilution ratio, but the fixed rate is varied on a seasonal basis based on flow).
- Collect and monitor contact water to determine whether treatment is required prior to release to the environment. This will inform optimal levels of treatment.
- Maintain the water management system in place during Decommissioning until such time that water quality is suitable to release to the environment.
- Monitor and manage effluent, including contingency for effluent treatment as may be required, so that water discharge objectives are achieved, as defined by applicable provincial and federal regulatory instruments.
- Design and implement an environmental code of practice that defines actions levels and appropriate steps to mitigate elevated concentrations of chemical and radiological constituents in treated effluent discharge to acceptable levels.
- Workforce members will be transported to/from site via a fly-in/fly-out rotation and will, therefore, not use ground travel options during shift changes, which will eliminate fishing on local lakes during commutes to/from the site and during time off work. Denison site vehicles will not be available for recreational purposes. While at the Project site and off duty, workers may opt to fish local waterbodies. To protect sustainable use of resources, only catch and release of fish will be encouraged, and fish storage or cooking facilities will not be provided.

- Implement Project-specific monitoring programs (e.g., effluent monitoring plan, environmental monitoring plan) that include monitoring treated effluent, surface water, and sediment quality and applying adaptive management if necessary.
- Work with the associated communities to develop and implement the Project-specific monitoring programs and a framework to share the results for the purpose of assessing the performance of the water management system.
- Develop and implement a decommissioning and reclamation plan to decommission and transfer the site to the Province of Saskatchewan under the Institutional Control Program.

Additional mitigation measures are presented in Appendix 8-F with respect to mitigating potential effects to wetlands as they relate to providing fish habitat. Wherever possible, wetlands will be avoided through Project design and instituting proper buffers.

8.3.6 Residual Effects Evaluation

8.3.6.1 Residual Effects Characterization

This section describes the likely residual effects of the Project on the VC of Fish and Fish Habitat and its associated KIs. Residual effects are effects that remain after the implementation of mitigation measures and management strategies and are the expected consequences of the Project. The approach to assessing residual Project effects on the Fish and Fish Habitat VC follows the methodology outlined in Section 5.8 in Section 5. For each VC and associated KI, each residual effect is characterized in the context of the Project activities that will occur within each Project phase. A residual adverse effect on the Fish and Fish Habitat VC is defined as a measurable change in the concentrations of a surface water quality parameter(s) that exceed relevant water quality assessment benchmarks that represent concentrations that are protective of aquatic biota and water uses in watercourse and waterbodies that receive mine-affected drainage. Additionally, a change in water level or flow greater than 5% from baseline environmental flows, and a change in available fish habitat, are also considered residual adverse effects on Fish and Fish Habitat. Residual effect characteristics specific to Fish and Fish Habitat are defined in Table 8.3-8.

Construction

The primary potential change in the Fish and Fish Habitat VC associated with Construction is related to the mobilization of suspended material into natural surface water features as a result of land clearing activities and road crossing construction. According to the site water balance (Figure 2.2-14 in Section 2), there is no planned discharge to Whitefish Lake during Construction. However, the potential influence of such discharge, if it were to occur, would be bounded by the analysis of water quality in Whitefish Lake during Operation.

Mobilization of suspended material into natural surface water features is readily mitigatable by virtue of the mine development plan and through the implementation of standard water management and sediment control practices. Water management infrastructure (e.g., collection pads, ponds, pumping stations), as well as various aspects of the water management and sediment control management systems, will be put into place coincident with the initiation of construction activities. Runoff associated with areas under development will be collected and either stored within management infrastructure (e.g., water management ponds) or potentially released into natural surface water features once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). No downstream effects on local sediment quality or benthic invertebrate communities are expected.

Negligible aquatic habitat loss is predicted in Whitefish Lake due to the installation of a discharge pipeline and diffuser configuration. The total area of the lake substrate that would be overprinted by the pipeline is expected to be approximately 135 m^2, which will constitute less than 0.05% of the lake's surface area.

Two road crossings will be built in locations where crossings previously existed. The previous crossing were decommissioned by Cameco Corporation in 2015. The new crossing will be constructed as clear span bridges, thereby avoiding in-water works, and standard mitigations will be undertaken to minimize potential effects on Fish and Fish Habitat.

It is expected that the works proposed in and around water as part of the Project can be either conducted to avoid fish habitat or conducted over a short duration, at a small spatial scale, and during appropriate timing windows. As such, the proposed works are not expected to constitute a HADD under subsection 34(1) or 35(2) of the *Fisheries Act.*

Construction, operation, and maintenance of the airstrip access road crossings have the potential to increase access for recreational resource users to adjacent waterbodies. The phase of greatest impact due to fishing pressure on local fish populations is expected to occur during Construction when the peak in onsite workers occurs. Given the mitigations, increased pressure on resources is expected to be limited due to a lack of transportation to fishing locations beyond walking distance and a prohibition on firearms/hunting. Given that fishing on LA-5 has not been documented, and the effect is expected to be of low magnitude, changes in fish abundance or distribution are not expected to be detectable to Indigenous land users.

Operation

During Operation, the primary potential water quality effect from the Project is the discharge of excess water from the site water management system to Whitefish Lake (Figure 2.2-14 in Section 2). Discharge to Whitefish Lake has the potential to change the concentrations of water and sediment quality constituents from background and, therefore, affect fish through direct exposure, as well as via secondary pathways.

For planning purposes, a continuous (year-round) discharge at an expected average effluent rate of 0.0101 m^3/s (36.5 m^3/hr) has been used to characterize Operation, despite the likelihood that effluent discharge will not be continuous and will only discharge when the site water balance requires, based on water storage capabilities. The water storage capability of the Effluent Monitoring and Release Ponds has been designed to enable contingency in water storage (i.e., three ponds of 3,300 m^3 capacity).

No other routine mine-related discharges to other receiving environments are proposed during Operation. Water management infrastructure will collect and divert all site process and contact water, as well as water associated with the ISR process, through the site IWWTP. Any excess water not required for the ISR process will be directed to the IWWTP. Treated water from the IWWTP will be pumped to the Effluent Monitoring and Release Ponds.

Parameters where the available assimilative capacity is less than the maximum predicted discharge concentration when screening criteria subject to background water quality include sulphate, chromium, molybdenum, and selenium. For chromium and selenium, the assessment was influenced by datapoints with values below the detection limit. However, these are conservative estimates which are not yet based on BATEA. Treated water in the Effluent Monitoring and Release Ponds will be monitored prior to release to Whitefish Lake. The treated effluent discharge line will be heated and have secondary containment in place. Estimated total hazard quotients (HQs) for all COPCs, with the exception of copper, for all aquatic biota are predicted to remain below the HQ benchmark of 1. HQs for copper remain below 1 for forage fish. HQs slightly exceed 1 for benthic invertebrates (all locations) and predatory fish (Whitefish Lake Middle and South) under baseline conditions (for hardness and pH). Under site operational conditions during periods of treated effluent discharge, the HQs for copper are below 1 for all locations and aquatic biota. These results indicate an acceptable level of risk via the direct exposure pathway to the receptors (Appendix 10-A in Section 10).

Local Indigenous communities have expressed direct concern with respect to mercury. Mercury has not been identified as a COPC for the Project as it is currently not present in the receiving environment (i.e., background condition) at detectable concentrations and will not be produced as part of the mine process; therefore, it will not be discharged to the aquatic environment.

As described above, the site-wide water management strategy involves care and control of all site process and contact water, and no discharge is proposed beyond that to Whitefish Lake. In practice, it may be necessary at times to manage runoff from disturbed areas that are either outside the water management system or are yet to be integrated into the water management system. In these cases, the areas would be isolated and specific water and sediment control management practices would be implemented to make sure any water released to natural surface water drainages is suitable for release such that the water quality in these natural surface water drainages is protected.

Changes in surface water levels (±0.01 m) and flows (maximum of -3.1% occurring at the LA-5 and SA-2 nodes during Operation) are expected to be less than the variation of natural environmental flows. As such, these changes are not expected to have a significant effect on sediment movement and/or benthic invertebrate habitats.

The effluent pipeline and diffuser will be operational during Operation and continue to constitute a less than 0.05% overprint of the receiving lake's (i.e., Whitefish Lake South) surface area.

Decommissioning/Post-Decommissioning

Following the cessation of mining operations, discharge to Whitefish Lake will continue until the end of Decommissioning upon which it will cease. Water quality in Whitefish Lake is expected to return to pre-mining conditions following Decommissioning.

The site-wide water management system will continue to operate during Decommissioning such that Denison will remain in control of site aspect affected water via the IWWTP. At that time, water (runoff) from the ISR wellfield, and contact water from the developed portion of the site (e.g., contaminated runoff pond, landfill pond, process water pond), will continue to be collected and diverted to the IWWTP. From the IWWTP, the water will be directed back to the ISR wellfield to be pumped as clean water to ground or pumped to the Effluent Monitoring and Release Ponds for monitoring prior to discharge to Whitefish Lake.

Following Decommissioning, piping infrastructure will be removed and discharge to surface water will cease. Therefore, effects on sediment quality and the benthic invertebrate community are bounded by the Operation scenario. Partitioning of COPC from surface waters to sediment will cease and any changes to sediment will be monitored during Decommissioning.

Residual effect characteristics specific to the Fish and Fish Habitat VC are defined in Table 8.3-8 with evaluation of residual effects provided in Table 8.3-9, Table 8.3-10, Table 8.3-11.

Table 8.3-8: Fish and Fish Habitat – Definitions of Effect Characteristics Considered When Determining the Significance of Residual Effects

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Effect moves MPs in a direction detrimental to Fish and Fish Habitat that may affect ecological integrity (i.e., fish populations). *Water Quantity* – Effect moves MPs (flow or water level) in a direction detrimental to water quantity relative to baseline conditions. A Project-related increase in surface water flows and levels during flooding, or a decrease in surface water flow below environmental flow requirements. *Water Quality* – An increase in constituent concentrations attributable to the Project in comparison to baseline conditions and trends. *Fish Habitat* – A physical loss of available fish habitat (aerial extent) in comparison to baseline conditions. **Positive** – Effect moves MPs in a direction beneficial to Fish and Fish Habitat. An improvement in water quality in comparison to baseline conditions and trends or an increase in the aerial extent of fish habitat.
Magnitude	The amount of change in a MP relative to baseline conditions.	**Low** – A measurable change that is not within the variability of baseline conditions but below relevant water quality objectives and criteria. A Project-related change in hydrology (flows or levels) compared to baseline

Residual Effect Characteristic	Definition	Rating
		conditions, but where the change is <5% from baseline conditions, or a small measurable change in habitat (ha). **Moderate** – A measurable change in habitat area (ha). A measurable change in water quality that is not within the variability of baseline conditions and not within applicable guidelines, legislated requirements, and/or federal and provincial management objectives. A Project-related change in hydrology (flows or levels) compared to baseline conditions, but where the change is >5% from baseline conditions, and could, therefore, have an adverse effect on Fish and Fish Habitat within the LSA. **High** – A measurable change in habitat area (ha), monthly flows (>10%), or lake surface elevation (m) in a waterbody or watercourse that is greater than the range of natural variability and large enough that fish can no longer rely on this habitat to carry out one or more of their life processes. A measurable change in water quality that is not within the variability of baseline conditions and not within applicable guidelines, legislated requirements, and/or federal and provincial management objectives and is likely to have an adverse effect on Fish and Fish Habitat within the LSA, with the effect extending beyond the LSA.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is expected to be limited to the Project Area. **Local** – Effect is expected to be limited to the Fish and Fish Habitat LSA. **Regional** – Effect is expected to extend beyond the Fish and Fish Habitat LSA into the Fish and Fish Habitat RSA. **Beyond Regional** – Effect is expected to extend beyond the Fish and Fish Habitat RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect predicted to happen during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect predicted to happen from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect predicted to extend beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect expected to occur several times at sporadic intervals. Effect not expected to occur during critical life stages (e.g., outside of the fish migration, spawning, and nursery [larval] stages). **Frequent** – Effect expected to occur many times on a regular basis. Effect may occur during a lower sensitive period of a critical life stage; for many species, this is the start (e.g., during early phases of the migration period). **Continuous** – Effect expected to occur continuously and, therefore, during critical life stages (e.g., the fish migration, spawning, and nursery [larval] stages).
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that is expected to diminish to baseline conditions. **Partially Reversible** – A residual effect that is expected to partially diminish to baseline conditions. **Irreversible** – A residual effect that is not expected to diminish to baseline conditions.
Context	The extent to which the VC or KI has been affected by past and present environmental and socio-economic processes and conditions, its potential sensitivity to the Project-	**Low** – VC/KI is predicted to have a high resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a lack of historic and ongoing anthropogenic or natural disturbance. **Moderate** – VC/KI is predicted to have a moderate resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or an intermediate level of

Residual Effect Characteristic	Definition	Rating
	related residual effect, and its ability to recover from that effect (i.e., resilience).	historic or ongoing anthropogenic or natural disturbance with the capacity to assimilate more change. **High** – VC/KI is predicted to have a weak resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a high level of historic or ongoing anthropogenic or natural disturbance.
Likelihood	Likelihood that the residual effect will occur, including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

Table 8.3-9: Fish and Fish Habitat – Summary of the Residual Effect Characteristics for Surface Water Quality

Residual Effect Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	The Project (specifically the discharge of effluent to the natural environment) will cause a change in the concentration of constituents, as measured as a mass of a chemical per unit volume in water (e.g., mg/L). Surface water quality in the local receiving environment will be adversely affected by effluent discharge to the aquatic environment, thereby providing a pathway to adversely affect Fish and Fish Habitat.
Magnitude	Moderate	The magnitude of the residual effect is predicted to be low overall as the vast majority of constituents that may be introduced as part of Project activities are expected to remain below criteria for the protection of aquatic life and human health. However, with the exceedance of the Cu FEQG and in response to Round 4 IR-114, the overall rating was conservatively changed to moderate. We note that the copper values in the EIS have been overpredicted in the models for a number of reasons including the fact that the baseline water quality analytical detection limit for copper was equal to the Cu FEQG. Additionally under site operational conditions (hardness and pH) during periods of treated effluent discharge, HQs for all COPCs for all aquatic biota are predicted to remain below the HQ benchmark of 1, indicating an acceptable level of risk via the direct exposure pathway to the receptors.
Geographic Extent	Local	The geographic extent of the residual effect is predicted to be confined to the immediate waterbody adjacent to the Project (i.e., Whitefish Lake). The estimated mixing zone is less than 5 m, implementing an effluent discharge configuration that promotes mixing.
Duration	Long-term	The residual effect is expected to last between 3 to 38 years (i.e., effect expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuous	For the purposes of this EIS, a conservative scenario was identified, with effluent discharge being considered as continuous during Operation and Decommissioning.
Reversibility	Fully reversible	Surface water quality is expected to return to pre-development levels following Post-Decommissioning as Project-related sources will cease to operate.
Context	Low	Fish health is expected to be resilient to changes in surface water quality in the context of this assessment, as COPC meet protective criteria even at the extreme low water scenario. Therefore, under applicable mitigative measures and average flow conditions, the contextual resilience of the aquatic system to respond to change is considered to be great.

Residual Effect Characteristic	Rating	Summary Rationale for Rating
Likelihood	Likely	A high probability exists that a change in water quality from background conditions will occur.

Table 8.3-10: Fish and Fish Habitat – Summary of the Residual Effect Characteristics for Change in Fish Habitat

Residual Effect Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	A reduction of fish habitat by 135 m^2 is expected due to the construction of pipeline and diffuser infrastructure at LA-5.
Magnitude	Low	The magnitude of the residual effect is predicted to be low. The change in available benthic invertebrate habitat by the overprinting of substrates in LA-5 constitutes less than 0.05% of the surface area of the waterbody.
Geographic Extent	Local	The residual effect is expected to be limited to the LSA, specifically a small portion of LA-5.
Duration	Medium-term	The residual effect is expected to last between 3 to 38 years (i.e., effect expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuously	Although the mine is unlikely to require water taking on a continuous basis, this has been assessed as a bounding scenario and, as such, must be considered as a continuous effect.
Reversibility	Fully reversible	Following decommissioning and removal of the pipeline and diffuser, the available habitat will be restored to natural conditions.
Context	Low	The Fish and Fish Habitat VC is expected to have a high resiliency with respect to physical disturbance in the context of a small, localized area being altered or disturbed. It is not expected that the ecological integrity of the areas adjacent to the infrastructure will be affected and, as such, will provide for sources of re-distribution and recolonization following Post-Decommissioning.
Likelihood	Likely	The infrastructure associated with the pipeline and diffuser are likely to affect the localized area for which they overprint.

Table 8.3-11: Fish and Fish Habitat – Summary of the Residual Effect Characteristics for Change in Surface Water Quantity (Hydrology)

Residual Effect Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Water quantity (flow and level) will be reduced in LA-5 as a result of the overprinting of its reporting drainage area by mine infrastructure and through site water balance. Water taking has an additional potential to reduce water levels in LA-5.
Magnitude	Low	The magnitude of the residual effect is predicted to be low. Under all scenarios, the Project-related change in hydrology (flows or levels) compared to baseline conditions is less than 5% of baseline conditions, and generally less than 3%.
Geographic Extent	Local	The residual effect is expected to be limited to the LSA, specifically the lakes within proximity to the Project site (i.e., LA-5, LA-6, and LA-1).
Duration	Moderate	The residual effect is expected to last between 3 to 38 years (i.e., effect expected during Construction through to the end of Post-Decommissioning).

Residual Effect Characteristic	Rating	Summary Rationale for Rating
Frequency	Continuously	Although the mine is unlikely to require water taking on a continuous basis, this has been assessed as a bounding scenario and, as such, must be considered as a continuous effect.
Reversibility	Fully reversible	Surface water hydrology is expected to return to pre-development levels following Post-Decommissioning.
Context	Moderate	Surface water flow regimes are variable, and it is this variability that provides for morphological form to be maintained and for ecological reliance (i.e., fish habitat, fish movement, and life-cycle success). Some change to environmental flows is tolerated by fish populations.
Likelihood	Low	Due to the localized nature and low magnitude of the effect on surface water hydrology, the likelihood of an effect is considered to be very low; therefore, the likelihood of an effect on Fish and Fish Habitat is expected to be low.

8.3.6.2 Significance and Confidence

The significance of the residual effect is rated as **not significant** or **significant**, based on the following:

Not significant – a residual effect that is not expected to result in a change to a VC/KI that would alter its population viability or persistence beyond an acceptable level (e.g., where it is not sustainable or is unavailable to contribute to biodiversity and ecosystem function).

Significant – a residual effect that is expected to result in a change to a VC/KI that would alter its population viability or persistence beyond an acceptable level (e.g., where it is not sustainable or is unavailable to contribute to biodiversity and ecosystem function).

The threshold for significance for the Fish and Fish Habitat VC relates to predicted changes in the concentrations of water quality parameters, where changes could result in exceedances of relevant water quality benchmarks that are protective of aquatic biota in waterbodies that receive mine-affected drainage. The threshold for significance for Fish and Fish Habitat also includes predicted changes in surface water flows greater than baseline environmental flows and direct habitat loss.

The significance of the residual effects on the Fish and Fish Habitat VC has been deemed **not significant.** Following mitigation, the residual effects are not expected to cause a change in Fish and Fish Habitat (or associated KIs) to the extent that they might alter the ecological integrity of the VC in the LSA beyond an acceptable level.

The predicted confidence with respect to the Fish and Fish Habitat VC is high as the mobilization of suspended materials can be readily mitigated, making the effects prediction relative to this effect pathway easily understood.

Confidence in the assessment of predicted effects on water levels or flow is quite high due to available hydrological data for the LSA. Uncertainty is minimal with the assumptions that the water withdrawal and discharge scenarios presented herein represent the bounding case, and hydrogeological modelling projections are not changed (Section 8.1).

Potential effects on water quality as a result of Project discharges to local receiving environments were assessed by way of numerical modeling. These predictions are generally considered conservative in nature because the assumptions on which they are based are conservative. For example:

- The assessment is based on a continuous (year-round) discharge at an expected average effluent rate of 0.0101 m^3/s (36.5 m^3/hr) throughout Construction, Operation, and Decommissioning, despite the likelihood that effluent discharge will not be continuous and will only discharge when site water balance requires, based on water storage capabilities.
- The constituents in effluent discharge have been estimated conservatively. Presented discharge concentrations provided herein include contingency factors of one to three times.
- Baseline water quality is defined by the 95th percentile concentrations of individual constituents. Such an assumption is conservative as it constrains the assimilative capacity associated with the receiving environment. By definition, the assimilative capacity of a receiving environment is equal to the incremental difference between the existing baseline condition and the assessment benchmark (i.e., water quality criterion) on which the evaluation is based. Use of the 95th percentile concentration, rather than a measure of central tendency (i.e., 50th percentile, geomean), means that the incremental change in a given constituent concentration that can be assimilated by the receiving environment (whereby use of the receiving environment is protected) is relatively small in magnitude.

Due to the conservative nature of the assumptions on which the numerical assumptions are based, a high degree of confidence can be assumed.

8.3.6.3 Summary of Project-related Residual Adverse Effects on Fish and Fish Habitat

Residual adverse effects on Fish and Fish Habitat are expected to occur during Construction, Operation, and Decommissioning through pathways previously identified. A summary of the Project-related residual effects on Fish and Fish Habitat is provided in Table 8.3-12.

Table 8.3-12: Project-related Residual Effects on Fish and Fish Habitat

Residual Effect	Residual Effect Characterization									
	Project Phase	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Context	Likelihood	Significance Determination
Change in Water Quality	C, O, D	A	M	L	LT	C	FR	L	L	NS
Change in Aquatic Habitat (Area)	C, O, D	A	L	L	MT	C	FR	L	L	NS
Change in Water Level or Flow	C, O, D	A	L	L	MT	C	FR	M	L	NS

Notes:

Project Phase: Construction (C), Operation (O), Decommissioning (D)
Direction: Adverse (A), Positive (P)
Magnitude: Low (L), Moderate (M), High (H)
Geographic Extent: Project Area (PA), Local (L), Regional (R), Beyond Regional (BR)
Duration: Short-term (ST), Medium-term (MT), Long-term (LT)
Frequency: Infrequent (I), Frequent (F), Continuous (C)
Reversibility: Reversible (FR), Partially Reversible (PR), Irreversible (I)
Context: Low (L), Moderate (M), High (H)
Likelihood: Unlikely (U), Likely (L)
Significance: Not Significant (NS), Significant (S)

8.3.7 Cumulative Effects

The spatial and temporal boundaries of the Project specific to the Fish and Fish Habitat VC are provided in Section 8.3.1.3. A description of the methods used in assessing cumulative effects is provided in Section 5.9 in Section 5. Cumulative effects associated with changes to wetlands are further discussed in Section 9.2.7 in Section 9.

8.3.7.1 Potential Cumulative Effects

Existing projects within the Wheeler River system have been considered for their potential to interact with the Fish and Fish Habitat VC for the Project. These include reasonably foreseeable projects that are listed in Section 5.9.

The Cameco Key Lake Operation has the potential to interact with the Fish and Fish Habitat VC for the Project (Figure 5.9.1) via the surface water quality pathway. The site has been in operation since 1983. In 2018, sustained low uranium prices resulted in a decision to curtail production for the foreseeable future and place the operation into safe care and maintenance. On February 9, 2022, Cameco announced plans for the operation's gradual return to production. Cameco's Key Lake Operation will overlap spatially and temporally with the Project.

The Project is situated approximately 35 km northeast of the Key Lake Operation and both are located in watersheds that ultimately report to Russell Lake. Releases to the aquatic environment from the Key Lake Operation are received by the David Creek, McDonald Creek, and Outlet Creek drainages. These three drainages join the Wheeler River, which then flows to Russell Lake (Cameco 2020). Therefore, a potential spatial overlap was identified for the Project and the Key Lake Operation and further assessed or cumulative effects.

The assessment of cumulative effects on the Surface Water Quality VC considered releases from the Project and the Key Lake Operation during all phases of the Project. The key Project component contributing to potential cumulative effects is the discharge of treated effluent to the aquatic environment during Operation and Decommissioning which may interact with Cameco's current releases to water including treated water released to David Creek drainage, treated groundwater and diverted surface water to the McDonald Creek drainage (Cameco 2020).

The key potential cumulative effect pathway as it concerns the Fish and Fish Habitat VC is the surface water exposure pathway. The assessment of potential cumulative effects on the Fish and Fish Habitat VC considered releases to surface water from the Project and the Key Lake Operation during all phases of the Project.

Temporal overlap of the Key Lake Operation and the Project will also occur during 'future centuries' as described as 'post-decommissioning phase' in the Key Lake Extension Project EIS (Cameco 2020). There is potential for increased contaminant transport via groundwater to surface water during the long-term, post-decommissioning phase (i.e., 10,000 years after operations cease and the site has been reclaimed) for the Key Lake Operation. The long-term storage of tailings at a higher elevation has the potential to influence contaminants in the groundwater and incrementally add to the effect on surface water quality in the Outlet Creek Drainage.

Operation and Decommissioning

The assessment of cumulative effects on the aquatic environment considered releases from the Key Lake Operation and proposed Project during all phases of the Project. The primary Key Lake

Operation component contributing to potential cumulative effects is the placement of tailings to a higher elevation in the Deilmann Tailings Management Facility (DTMF). The increased loadings from the DTMF are anticipated to result in an incremental (i.e., existing conditions plus the Project) increase of concentrations of COPCs in the aquatic environment (Cameco 2013). The spatial extent of any significant adverse effects on the aquatic environment from the Key Lake Operation were anticipated to be localized and not to extend to the Wheeler River and Russell Lake during any phase of the Project (Cameco 2013). The 2010 Status of the Environment report for the Key Lake Operation identified that no adverse effects to individual fish or fish populations are present in the Wheeler River (EcoMetrix 2010 as cited in Cameco 2020).

Potential Project residual effects on surface water quality relate to changes (increases) in constituent concentrations that are related to the controlled discharge of Project site waters into local receiving environments (Whitefish Lake). Such changes are predicted to be negligible to low in magnitude and limited to the LSA. For example, during Construction, no discharge from the Project site is planned. During Operation, treated effluent will be discharged to Whitefish Lake. The Whitefish Lake discharge will be the only routine discharge location during Operation. Water quality and sediment quality in Whitefish Lake and, by extension, sediment quality downstream of Whitefish Lake, are expected to meet appropriate benchmarks for the protection of aquatic life in consideration of a small mixing zone in the lake, which is anticipated to remain within tolerable HQs for fish. Following Decommissioning and the restoration of drainage patterns that are similar to pre-mining conditions, water quality is expected to meet appropriate benchmarks for the protection of aquatic life in Whitefish Lake and downstream. This includes Russell Lake of which the Icelander River system is associated.

In consideration of the above discussion, effects on the aquatic environment due to changes in surface water quality from the Key Lake Operation are not anticipated to spatially overlap with those from the Project and therefore a cumulative effect is not expected.

Future Centuries

The 2013 Key Lake ERA indicated that during the 10,000-year post-decommissioning period, predicted exposure levels may affect lower trophic level aquatic biota on a population or community level within some isolated lakes in the SSA, but adverse effects on the ecology of the Outlet Creek drainage, and therefore further downstream were not expected during the post-decommissioning phase (Cameco 2013). The results of the 2020 ERA for the Key Lake Operation were consistent with the findings from the 2013 ERA in that there were limited significant risks posed to aquatic receptors situated in the area surrounding the Operation, but not to areas farther downstream. The 2020 ERA concluded that environmental health in the vicinity of the Key Lake Operation will remain protected (Cameco 2020).

The results of the numerical modelling for the Project, as provided in Section 7 and Appendix 10-A in Section 10, support the conclusion that with the implementation of appropriate mitigation during the decommissioning and mining area remediation phase of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect to surface water or fish. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future ("Future Centuries") from the mining area to Whitefish Lake will be localized to that waterbody and remain below fresh water environmental quality criteria. As such, impacts to downstream portions of the drainage and fish and fish habitat therein and including Russell Lake are not expected.

In consideration of the above discussion, effects on the aquatic environment due to changes in surface water quality from the Key Lake Operation are not anticipated to spatially overlap with those from the Project and therefore a cumulative effect is not expected.

8.3.7.2 Additional Mitigation Measures

Additional mitigation measures are not warranted as no cumulative effects are expected on the Fish and Fish Habitat VC.

8.3.7.3 Cumulative Effects Characterization and Determination of Significance

A determination of significance is not warranted as no cumulative effects are expected on the Fish and Fish Habitat VC.

8.3.7.4 Cumulative Effects Assessment Summary

Effects to Fish and Fish Habitat VC due to changes in surface water quality from the Key Lake Operation are expected to remain localized and not extend to the Wheeler River system or Russell Lake. Likewise, impacts on surface water quality from the Project are expected to remain localized (Whitefish Lake) and not extend to Russell Lake. Effects on the aquatic environment due to changes in surface water quality associated with the Key Lake Operation are not anticipated to spatially overlap with those from the Project during operation/decommissioning or during "future centuries" and therefore a cumulative effect is not expected.

8.3.7.5 Environmental Monitoring and Follow-up

Specific monitoring and follow-up for Fish and Fish Habitat related to cumulative effects is not warranted as no cumulative effects are expected on the Fish and Fish Health VC. Monitoring and follow-up specific to the Project is detailed in Section 8.3.8.

8.3.7.6 Climate Change Considerations

As discussed in Section 8.1.7.5, the frequency and magnitude of extreme precipitation events have the potential to change water levels and flows in the RSA, which may affect water quality, sediment transport, deposition, and, therefore, fish habitat. Changes to average and upper and lower bounds of ambient temperatures may also affect aquatic habitat, which in turn may affect fish and their food resources. Climate change over the life of the Project (i.e., 35 to 40 years) will be monitored as part of the Project's environmental monitoring programs, and influences on water quality, sediment quality, benthic invertebrates, and fish and fish habitat will require adaptive management to mitigate any potential effects of the Project that may be exacerbated by climate-related changes on the aquatic environment.

8.3.8 Monitoring and Follow-up

For the purposes of this EIS, monitoring and follow-up are defined as follows:

- monitoring programs are designed to meet regulatory requirements (e.g., permit or license conditions) and/or to demonstrate compliance with environmental commitments made in the EIS; and
- follow-up programs are designed to address any uncertainties identified during the EA process (e.g., to verify predictions made during the EA; determine the effectiveness of proposed and implemented mitigation measures) and to determine if and when to implement adaptive management measures.

Monitoring and follow-up are proposed for the Fish and Fish Habitat VC to verify the accuracy of the predicted effects and the effectiveness of the proposed mitigation measures. The fish and fish habitat monitoring program should be considered in conjunction with the surface water quantity (hydrology) (Section 8.1.8), surface water quality (Section 8.2.8), sediment quality and benthic invertebrates (Section 8.4.8), and fish health (Section 8.5.8) monitoring programs as it is specifically tied to these monitoring programs from the perspective of pathways of effects. Specifically, monitoring of water quality in the effluent monitoring ponds and other catchment ponds prior to discharge to the environment will be important to provide context to further evaluate Project-related effects on Fish and Fish Habitat in the receiving water environment (i.e., Whitefish Lake).

The fish and fish habitat monitoring and follow-up program will have the following objectives:

- collecting and recording surface water quality data to confirm that source and receiving water quality predictions for mobilization of solids are consistent with those presented in the EIS;
- monitoring to confirm that effluent and receiving water quality meet applicable regulation criteria;
- monitoring changes in fish communities/populations within the Project LSA; and
- monitoring changes in physical fish habitat within the receiving environment of LA-5.

Fish and fish habitat monitoring will occur in tandem with water quality, sediment quality, benthic invertebrate, and fish health sampling. Sampling locations will be co-located to facilitate comparison to water quantity, water quality, and sediment quality characteristics.

Changes in fish communities/populations will be assessed through comparison of Construction, Operation, and Decommissioning results to pre-development conditions, as well as through contemporaneous comparison of “exposure area” versus “reference area” data. In this context an “exposure area” is an area downstream of potential mine influence and a “reference area” is an area outside of potential mine influence. Where possible, the reference area would be located in the same drainage, upstream of mine influence where conditions closely mimic those downstream as is possible and where there is no, or reduced likelihood that exposure and reference fish populations can co-mingle. Fish and fish habitat monitoring will include collection of metrics associated with species presence, abundance, and life history parameters (e.g., survival, condition, growth) to meet applicable agency guidance (i.e., MDMER and CSA N288.4-19 [CSA Group 2019]).

Specific monitoring and follow-up plans for the Fish and Fish Habitat VC will be prepared to refine and finalize the approach and specific metrics following consultation with Indigenous groups, other stakeholders, and relevant federal and provincial agencies with interest in the development and implementation of this VC-specific program

8.3.9 Fish and Fish Habitat Summary

The Fish and Fish Habitat VC was selected for inclusion in the assessment as Project activities have the potential to cause erosion-driven mobilization of suspended sediment. Project activities are also expected to discharge effluent to the natural environment, overprint fish habitat, and locally increase access to fisheries resources throughout multiple phases of the Project. Furthermore, inclusion of the Fish and Fish Habitat VC is vital due to its importance to Indigenous peoples from a cultural and subsistence perspective.

Fish and fish habitat surveys were completed in the LSA and RSA for identified river, stream, and lake features that support a variety of fish species, including Lake Trout, Lake Whitefish, Northern Pike, Walleye, Yellow Perch, Arctic Grayling, and several sucker and forage fish species. With the help of IK, LK, and in-field surveys, critical spawning and nursery habitats for keystone species were identified and summarized for the LSA, specifically for Whitefish Lake and Russell Lake. Baseline conditions for the Fish and Fish Habitat VC were assessed in conjunction with baseline information specific to the Surface Water Quantity and Surface Water Quality VCs due to the interconnected nature of these VCs.

Project activities may interact with the Fish and Fish Habitat VC including wetlands during all Project phases. In general, the interactions were characterized as being primarily associated with controlled, routine discharges from the site and mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. During Operation and Decommissioning, excess water from the effluent monitoring ponds will be released to the environment. Routine discharge of this sort will be directed to Whitefish Lake only. Changes in surface water quality due to effluent discharge may affect the water chemistry and temperature of Whitefish Lake. The installation of the pipeline and diffuser structure will result in the overprinting of a small proportion of the Whitefish Lake substrate (less than 0.05%). No other alteration, disruption, or destruction of aquatic habitat in the LSA is expected. Changes in fish populations resulting from increased fishing pressure following improved accessibility due to the development of access roads are possible.

To minimize the residual effects of the Project on the Fish and Fish Habitat and Wetlands VCs, Denison will develop and implement a Surface Water Management Program that includes an integrated framework to manage water quality and water management practices for each of the primary site aspects and areas of the site where contact water is expected. This plan will include the collection and monitoring of contact water to determine whether treatment is required prior to release to the environment, which will inform optimal levels of treatment. This plan will also include the monitoring and management of effluent, including contingency for effluent treatment as may be required so that water discharge objectives are achieved as defined by applicable provincial and federal regulatory instruments. These measures are expected to mitigate effects associated with mobilization of solids and changes to water and sediment quality that may affect the Fish and Fish Habitat VC. Denison will design the discharge diffuser/outfall to have the smallest footprint possible while still providing effective mixing and dilution such that discharge flows do not detrimentally affect fish lifecycle processes.

Construction of the access road will involve the installation of two stream crossings. These stream crossings are located at the historical watercourse crossings along the proposed airstrip access road. These crossings will be constructed as clear-span bridges, and their mitigative design will provide for protection of the Fish and Fish Habitat and Wetlands VCs. A lack of transportation to fishing areas will minimize the geographic extent of any workforce fishing, and a lack of facilities to store or cook fish will limit the quantity of harvest.

The assessment predicted residual effects on the Fish and Fish Habitat VC due to change in water quality (including temperature), change in sediment quality, change in aquatic habitat (aerial extent), and change in fish harvest. However, with the implementation of appropriate mitigation measures, the predicted residual effects were characterized as low magnitude, localized, and fully reversible, and are, therefore, anticipated to be **not significant**.

Potential residual effects from releases of treated mine water or from potential releases associated with solids mobilization from the Project Area are expected to be spatially limited to LA-5 (Whitefish Lake) and are not expected to extend downstream to the Wheeler River. Alteration of fish habitat is expected to be localized and of small spatial extent. No interactions with existing and reasonably foreseeable activities are expected over the Project timeline; therefore, no cumulative effects are expected on Fish and Fish Habitat.

Monitoring for the Fish and Fish Habitat VC including wetland features will occur to verify the accuracy of the predicted effects and the effectiveness of the proposed mitigation measures. Effluent and receiving water quality monitoring will be conducted as per federal and provincial regulations and will include radiological and non-radiological parameters. Monitoring of the biological environment will be undertaken to meet federal and provincial regulations (e.g., MDMER environmental effects monitoring program) and will occur in consultation with Indigenous groups. Monitoring of worker habits in relation to fisheries resources may be applicable to allow for adaptive management of the Fish and Fish Habitat VC.

8.4 Sediment Quality and Benthic Invertebrates

This section addresses the potential effects of the Project on the Sediment Quality and Benthic Invertebrates VCs. The following are discussed herein as part of the EA:

- scope of the assessment;
- summary of existing conditions relevant to the VCs;
- identification and description of potential interactions between the Project and the VCs;
- identification and description of mitigation measures applicable to the VCs to eliminate, reduce, or control the potential adverse Project-related effects;
- identification and characterization of predicted Project-related residual effects on the VCs after mitigation;
- characterization of significance and assignment of the level of confidence in the predictions; and
- identification and characterization of potential cumulative effects.

Figure 8.4-1 is a graphic representation of the assessment process used in this EIS.

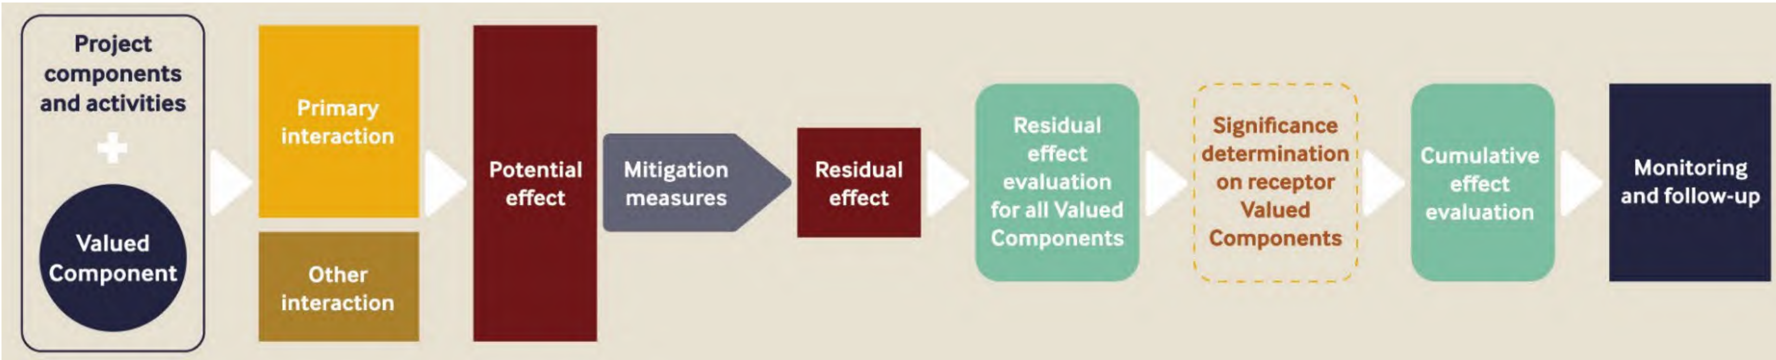

Figure 8.4-1: Environmental Assessment Process for the Wheeler River Project

8.4.1 Scope of the Assessment

The purpose of this assessment is to assess potential changes to sediment quality and benthic invertebrate communities (as represented by the Sediment Quality and Benthic Invertebrates VCs) in consideration of all Project phases at the Project, local, and regional study area scales. Pathways affecting Sediment Quality and Benthic Invertebrates are directly associated with potential changes to the Surface Water Quantity (hydrology) and Surface Water Quality VCs. Changes to flow and water quality may directly or indirectly affect how constituents partition sediments. Similarly, benthic invertebrates may be directly or indirectly affected by changes to flow and water quality, as well as changes to sediment quality arising thereof. The assessment approach reflects these connections within the aquatic environment, as the significance determination for Surface Water Quality and Water Quantity VCs are conducted at the Sediment Quality and Benthic Invertebrate VCs and also the Fish Health, and Fish and Fish Habitat VCs. Pathways that are of interest include those associated with site clearing and the potential for erosion-driven mobilization of suspended sediment into local surface waters, groundwater interactions with surface water features, and effluent discharge to the receiving environment.

8.4.1.1 Valued Component Selection

The process and rationale for the selection of VCs and the establishment of KIs and associated MPs is described in Section 5. This section addresses Sediment Quality and Benthic Invertebrates together as they are directly associated with one another. Benthic sediments are the medium benthic invertebrates inhabit for all or a considerable portion of their life cycles, and benthic sediments provide a forage base for benthic invertebrates. The physical and chemical attributes of benthic sediments directly influence benthic invertebrate community distribution, diversity, abundance, and health. The Sediment Quality and Benthic Invertebrates VCs were selected for inclusion as it has the potential to be affected by Project-related activities that result in erosion-driven mobilization of suspended sediment, groundwater interactions with surface water features, and effluent discharge to the natural environment. Potential changes to water quantity and quality are key considerations within the EA process, as demonstrated by previous uranium mining development proposals in the Athabasca Basin, that draw a high level of concern from Interested Parties (see Section 8.1.2 and 8.2.2). Changes to surface water quality have the potential to influence sediment particle size, chemistry, and distribution within the aquatic environment, which in turn may influence biodiversity and biological function. Such effects are of interest with respect to cultural values of Indigenous groups, the public, and other stakeholders. In this context, the

Sediment Quality and Benthic Invertebrates VCs are interrelated or linked, to varying extents, to other VCs that are considered in this EIS, including:

Intermediate Valued Components

Surface Water Quantity: Surface water flow volumes and periodicity directly influence water quality, bedload movement, and sediment deposition in a waterbody. Natural and seasonal changes in precipitation, and therefore water quantity, are directly related to water quality, sediment characteristics, and benthic invertebrate distribution. Project changes to surface drainage patterns, site water balance, and effluent discharge may influence water quantity, which in turn may influence the assimilative capacity of receiving waters, the movement of sediment, and available habitat for benthic invertebrates.

Surface Water Quality: Surface water quality can affect the concentrations of constituents in sediments and may directly affect the distribution, abundance, and health of benthic invertebrates through direct exposure.

Groundwater Quantity and Quality: The quantity and quality of groundwater reporting to surface water through hydrologic connections can influence the Surface Water Quality of surface waterbodies. Partitioning of chemicals from surface waters to sediments may further affect benthic invertebrate habitat and communities.

Receptor Valued Components

Terrestrial Environment: Sediment as a habitat medium and benthic invertebrates as a food resource for terrestrial fauna are linked to the function and biodiversity of the terrestrial environment.

Fish and Fish Habitat: The sediment that benthic invertebrates inhabit is the medium responsible for their ability to carry out their life processes. Benthic invertebrates provide an important forage base for fish species. Aquatic sediments are inferred as part of the definition of fish habitat under subsection 2(1) of the *Fisheries Act, 1985* (Government of Canada 2019). Alterations to Sediment Quality or Benthic Invertebrate communities in an aquatic environment can directly affect Fish and Fish Habitat.

Fish Health: Sediment act as a habitat medium and benthic invertebrates as a food resources and, therefore, have the potential to be taken up by fish through processes such as respiration, ingestion, and absorption. As such, they can directly affect the receptor VC of Fish Health.

Land and Resource Use: Indigenous Land and Resource Use and Other Land and Resource Use are influenced by Sediment Quality and Benthic Invertebrates as they contribute to the function and biodiversity of terrestrial and aquatic flora and fauna and, subsequently, their use as natural resources by communities.

Figure 8.4-2 and Figure 8.4-3 are graphic representations of the main linkages among the Sediment Quality and Benthic Invertebrates VCs and other VCs, illustrating the flow of assessment information into and from the Sediment Quality and Benthic Invertebrates VCs.

Figure 8.4-2: Integrated Assessment Approach - Key Connections between Sediment Quality and Other Valued Components

Figure 8.4-3: Integrated Assessment Approach - Key Connections between Benthic Invertebrates and Other Valued Components

8.4.1.2 Key Indicators and Measurable Parameters

The KIs for the Sediment Quality and Benthic Invertebrates VCs are any potential changes in sediment quality (e.g., a change in the concentration or level of a constituent in sediment) or benthic invertebrate community structure and/or abundance (e.g., changes in the amount of available habitat and the quality of that habitat) from baseline conditions. The rationale and MPs for the Sediment Quality and Benthic Invertebrates VCs are provided in Table 8.4-1.

Table 8.4-1: Key Indicators and Measurable Parameters for Sediment Quality and Benthic Invertebrates

Valued Component	Key Indicator	Rationale for Key Indicator	Measurable Parameters
Sediment Quality	Sediment quantity and physical quality (particle size) from baseline conditions	Introduction of depositional solids (sedimentation) into the sediments of waterbodies as a result of the Project that are of magnitude to negatively affect aquatic biota, non-aquatic biota, or other potential uses of those waterbodies.	Change in the quantity of solids deposited on aquatic sediments directly related to the Project.
	Change in sediment quality (chemical) from baseline concentrations	Introduction of constituents into the sediments of waterbodies as a result of the Project that are of magnitude to negatively affect aquatic biota, non-aquatic biota, or other potential uses of those waterbodies.	Change in the concentration of constituents in aquatic sediments directly related to Project activities.
Benthic Invertebrates	Change in available aquatic habitat from baseline conditions	The quantitative estimation of the areal extent of fish habitat that is affected (disturbed or overprinted) by Project infrastructure (direct loss of benthic invertebrate habitat).	Aerial extent (m^2 or ha) of overprinted aquatic habitat.
	Change in sediment quality (chemical) from baseline concentrations	Introduction of constituents into the sediments of waterbodies as a result of the Project that are of magnitude to negatively affect aquatic biota of those waterbodies.	Change in the concentration of constituents in aquatic sediments directly related to Project activities, which may affect benthic invertebrate communities.
	Change to water levels or flows from baseline conditions	Project activities will result in changes to the local hydrology. A reduction or increase in flows may result due to the elimination or redirection of subwatershed area and through Project water management (i.e., water taking, storage and effluent discharge). Changes to water levels or flow may affect sediment transport and influence benthic invertebrate community structure and abundance.	Changes in water levels (m) or percent changes to flow conditions (%).

8.4.1.3 Spatial and Temporal Boundaries

Generic considerations associated with the establishment of the spatial boundaries of the assessment are described in Section 5.3.3. As it pertains to the Sediment Quality and Benthic Invertebrates VCs, the following is noted.

- The **Project Area** is the direct footprint of the Project. The Project Area represents the area within which Project activities and components may occur and, as such, represents the area within which direct physical disturbance may occur as a result of the Project, either temporary or permanent (i.e., the area of maximum physical disturbance). This area is not VC-specific, but consistent throughout the EIS for all VCs.

- The **LSA** is the area that surrounds the Project Area where both direct and indirect effects resulting from Project activities can be reasonably measured. The LSA was established to assess the potential, largely direct effects of the Project and represents the extent to which there is a reasonable potential for Project-related activities to interact with and potentially adversely affect the VC. For the Sediment Quality and Benthic Invertebrates VCs, the LSA was derived from watershed boundaries within proximity of the Project Area, including portions of watersheds that overlap the Project site, as well as areas directly downstream that may be influenced by the Project site or effluent discharge. The subwatersheds within the LSA are presented in Figure 8.4-4. This area was selected based on important waterbodies (notably Whitefish and McGowan lakes) downstream of the Project where effects may occur through all Project phases. The LSA extends from those waterbodies down to their inflows to Russell Lake.
- The **RSA** is the area that surrounds and includes the LSA and was established to assess the potential, largely indirect effects of the Project, as well as other activities, in a regional context. The RSA is large enough to capture the extent of potential effects (i.e., zone of influence) on a VC and defines the area within which cumulative effects may occur (i.e., cumulative effects assessment boundary). The RSA for the Sediment Quality and Benthic Invertebrates VCs is bounded by the regional watershed area within which the Project Area is located. The RSA for this assessment is based on the whole watershed within which the Project is located and extends downstream to include Russell Lake (Figure 8.4-4).

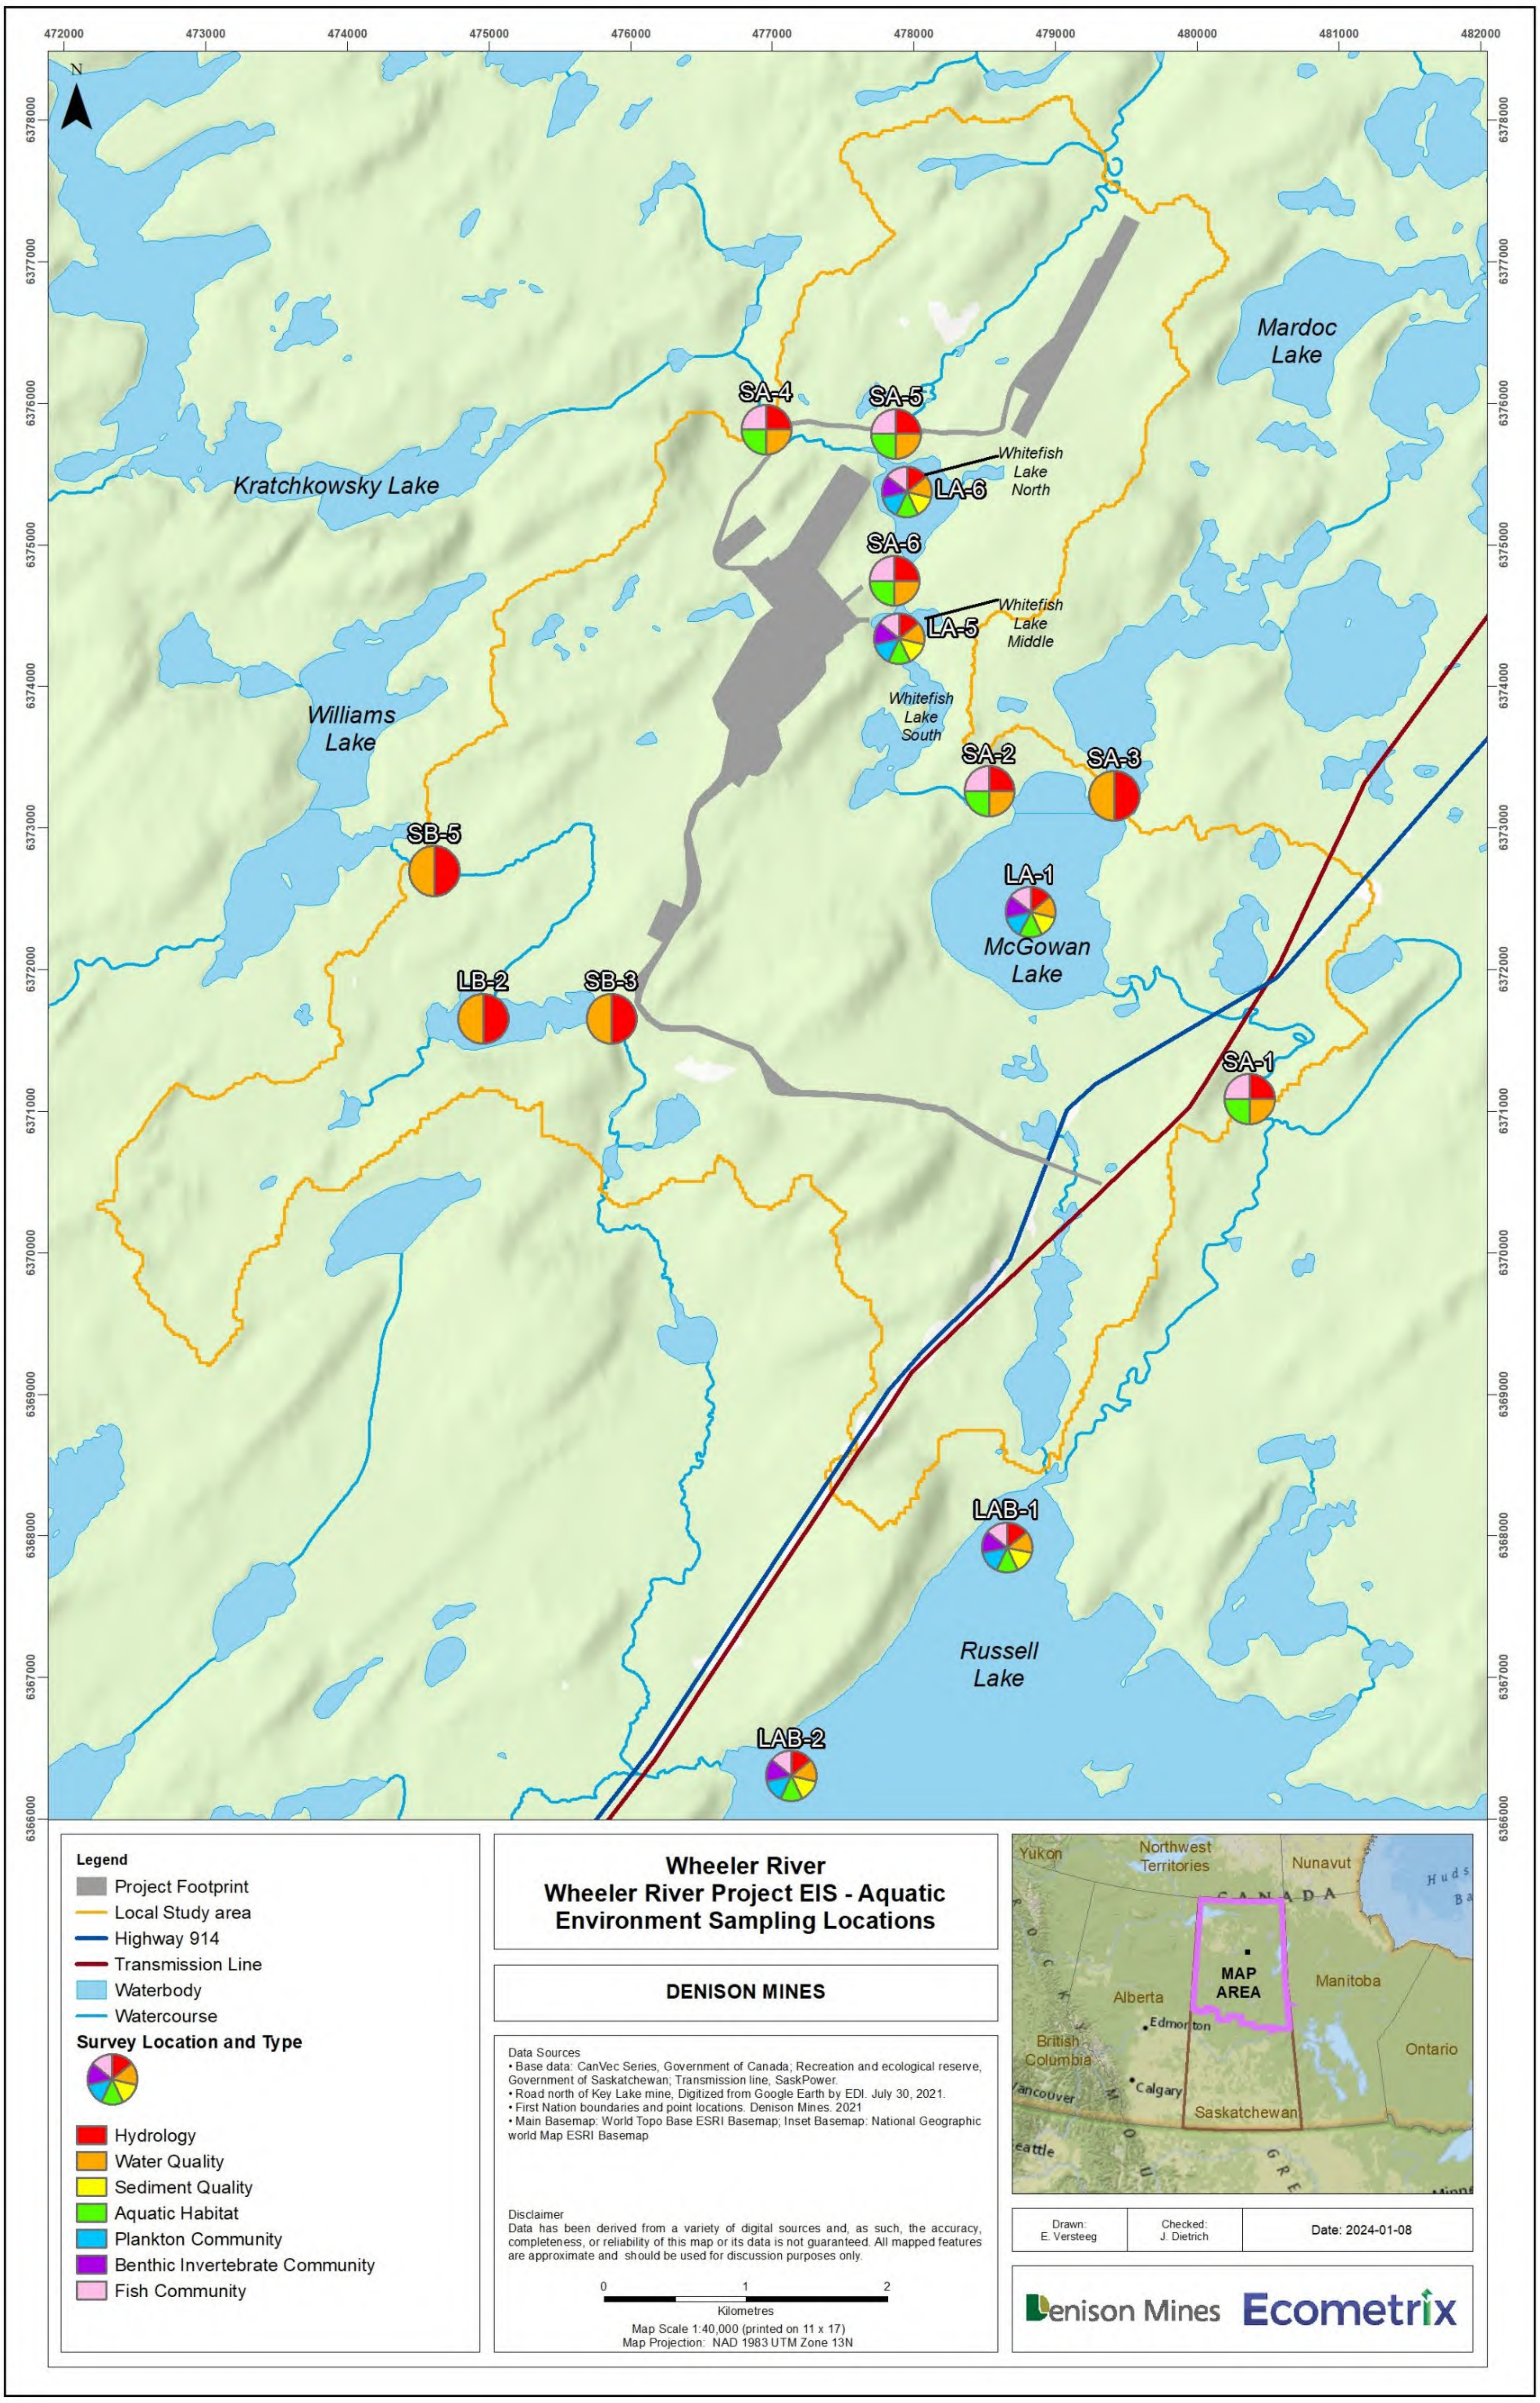

Figure 8.4-4: Spatial Boundaries for the Sediment Quality and Benthic Invertebrates Valued Components

Temporal boundaries for the EIS are defined in Table 5.3-3 in Section 5.3.4. The temporal boundaries applicable to and considered in the EIS include the following Project phases:

- Construction (Year 1 to 3);
- Operation (Year 3 to 18);
- Decommissioning (Year 18 to 23); and
- Post-Decommissioning (Year 23 to 38).

Additionally, a “future centuries” scenario is considered to assess the potential effects post-restoration (i.e., beyond the Project timeline of 0-38 years) and to reflect the time period over which the highest constituent concentrations in groundwater are predicted to migrate towards and interact with surface water.

This period represents the time where the highest constituent concentrations in groundwater are predicted to interact with surface water based on groundwater modeling. In this context, the future centuries scenario is considered with respect to the interaction of groundwater migration from the Project site and its potential influence on surface water in local water bodies. The future centuries projection encompasses the long-term period during which slow migration of groundwater from the Phoenix Ore Zone area to the surface water environment is anticipated and constitutes a bounding scenario of maximum concentrations of COPC.

8.4.2 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

The influence of IK, LK, and engagement on the Sediment Quality and Benthic Invertebrates VCs is consistent with that provided in Sections 8.1.2 and 8.2.2 (i.e., the value placed on the waterbodies and watercourses within the RSA is directly associated with the inclusive value placed on the Sediment Quality and Benthic Invertebrates VCs as parts of the aquatic environment). The intrinsic understanding and importance of aquatic environment systems to the environmental, cultural, economic, political, and spiritual conditions of Indigenous peoples were consistently reflected in the information they shared through the engagement process. In this section, IK and LK are viewed as complementary and influential alongside western science to produce a full understanding of the potential effects of the Project, whether measurable or perceived. Both forms of information have been given full and fair consideration.

The influence of IK, LK, and engagement on the assessment of the Surface Water Quantity and Quality VCs, and by extension the Sediment Quality and Benthic Invertebrates VCs, has first and foremost shaped the shared value of the aquatic environment and its life-sustaining properties.

> *“The lands and waters, we are definitely connected as peoples of English River. If we don't have the lands, we are not connected. If we don't have the water... Water is life to us”* (ERFN and SVS 2022).

Comments associated with water management and discharge to the environment were significant in the engagement record[5], and these were considered within the context of community interest regarding surface waters remaining supportive of natural function for biota. To this end, Project-related water management and treatment are important to maintaining Surface Water Quality and Sediment Quality within the LSA and RSA.

Indigenous peoples and LK holders were clear in their interest regarding current levels of constituents in the aquatic ecosystem and the potential for adverse changes resulting from the Project. For example:

> *"What is the plan for storing and cleaning the water and where does it flow? What is the impact of ISR mining on water quality?"* (21-EN-VILX-443.25).

This affirms the necessity to assess water quality and sediment quality as they inform assessments for the VCs of Benthic Invertebrates, Fish and Fish Habitat, Human Health, and Indigenous Land and Resource Use.

Denison has recorded and stored information regarding IK, LK and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers (e.g., 21-EN-VILX-443.25). These numbers are referenced throughout the EIS, but particularly in Parts II and III, to indicate where specific information from the database has been integrated into the assessment. Appendix 8-A provides a summary of unique identification numbers referenced within Section 8.4.

8.4.3 Existing Environment

8.4.3.1 Methodology and Metrics

Sediment samples for physical and chemical characterization were collected in 2016 coincident with benthic invertebrate sampling in depositional environments of selected lakes. Three replicate sediment samples were collected from each lake. Sampling location coordinates were obtained with a global positioning system. Coordinates were recorded at each sampling station and expressed as degrees, minutes, and seconds (i.e., dd mm ss; WGS84 datum).

Wherever possible, surficial sediment samples were collected by coring. The surficial sediment (top 6 cm) of each core was sectioned into 2 cm increments, with the 0 to 2 cm fraction sent for analysis. A minimum of three sectioned core samples were composited at each sampling location to ensure sufficient material for analysis. Where coring was not possible due to the nature of the sediments, surficial sediment samples were collected using a petit Ponar grab, and the top 0 to 2 cm was carefully collected manually for analysis.

[5] 19-EN-MN-SR3-1.2, 19-EN-ML82-1.3, 19-EN-MOE-1.4, 18-EN-VILX-3.33, 18-EN-VILX-3.35, 18-EN-VILX-3.39, and 18-EN-VILX-3.84.

Sediments were stored in large Ziploc bags labelled with the date, depth fraction, and sample location. Excess air was removed from the bags, and the bags were kept in coolers until delivery to the Project camp where they were kept refrigerated or frozen. Samples were analyzed for the full series of chemical constituents, including:

- total organic carbon (TOC);
- nutrients (nitrogen, total kjeldahl nitrogen, and phosphorus);
- total metals (acid extractable by inductively coupled plasma); and
- grain size.

The specific parameters of interest for this assessment included grain size, TOC, phosphorus, lead, selenium, and arsenic. Sediment grain size classification followed the Wentworth scale for geometric grain size, where particles less than 4 µm are classified as clay, particles between 4 to 62 µm are classified as silt, particles between 63 to 2,000 µm are classified as sand, and particles larger than 2,000 µm are classified as gravel.

Benthic macroinvertebrate samples were collected from selected lakes for taxonomic analysis in 2016. As noted, samples were collected at the same locations from which sediment quality samples were collected. Supporting environmental/limnology measurements, including pH, water temperature, conductivity, secchi depth, and general sediment descriptions, were recorded at each location. Sampling location coordinates were obtained with a global positioning system, and coordinates were recorded at each sampling station and expressed as degrees, minutes, and seconds (i.e., dd mm ss; WGS84 datum). Detailed benthic invertebrate collection data are provided in Ecometrix (2020).

Three to five replicate samples were collected at each location, with each replicate sample comprised of a three-grab composite. Samples were collected using a petite Ponar, sieved through a 500 µm mesh, and preserved in labelled (date, sampling area) containers with 10% buffered formalin in the field. Collected samples were kept at ambient temperature until delivery to the taxonomic laboratory. Benthic invertebrate samples were processed according to standard protocols based on recommendations in Environment Canada (2012), the details of which are provided in Ecometrix (2020).

Benthic invertebrates were identified to genus for most samples. Damaged organisms and early instar invertebrates were identified to the lowest level possible (generally to family). The most common taxa were distinguishable based on gross morphology and only required a few slide mounts (five to ten) for verification. Organisms that required detailed microscopic examination for identification (i.e., Chironomidae and Oligocheata) were mounted on microscope slides using appropriate medium. All rare or less commonly occurring taxa were mounted on microscope slides for identification. Identifications were made using recognized taxonomic keys. The following benthic invertebrate community metrics were calculated:

- total invertebrate density (i.e., number of individuals per m^2);
- invertebrate richness (i.e., number of unique families);
- Simpson's Diversity (D);
- Bray-Curtis Dissimilarity Index (B-C);
- Simpson's Evenness (E);
- relative and absolute density of invertebrate taxa groups based on their feeding strategy (i.e., functional feeding groups);
- density of major invertebrate taxonomic groups (i.e., sum of individuals within each group); and
- relative density of major invertebrate taxonomic groups (i.e., proportion of individuals within each group relative to the total).

Benthic invertebrate tissue samples were collected for analysis of metals and radionuclides at selected locations in September 2016. Composite samples of multiple organisms of a common order were collected for each of the selected waterbodies. Sufficient fresh weight tissue samples of abundant macroinvertebrates were collected to ensure sufficient mass for dry weight tissue analysis. Caddisfly larvae were collected from McGowan Lake (LA-1), Whitefish Lake South (LA-5), Whitefish Lake North (LA-6), and Russell Lake (LAB-1 and LAB-2). For caddisflies, only larvae tissue was retained for analyses; casings were manually removed and discarded. Tissue samples were collected in re-sealable plastic bags and frozen until delivery to the analytical laboratory.

8.4.3.2 Key Baseline Results and Existing Conditions

Critical locations of interest for this assessment are displayed on Figure 8.4-5 and include McGowan Lake, Whitefish Lake South, and Whitefish Lake North. These locations represent lakes within the LSA that may potentially be affected by the Project. Sediment grain size results for these locations are summarized in Table 8.4-2, and sediment chemical composition results are summarized in Table 8.4-3. Detailed sediment results are provided in Ecometrix (2020). Benthic invertebrate community data are summarized in Table 8.4-4 and benthic invertebrate tissue chemistry data are summarized in Table 8.4-5.

8.4.3.2.1 Grain Size

In all three waterbodies, clay-sized fractions made up the largest proportion of the sediment (Table 8.4-2). For McGowan Lake and Whitefish Lake North, silt was the next largest proportion followed by sand. In Whitefish Lake South, sand made up the second largest proportion followed by silt. None of the samples from any of the three lakes contained gravel.

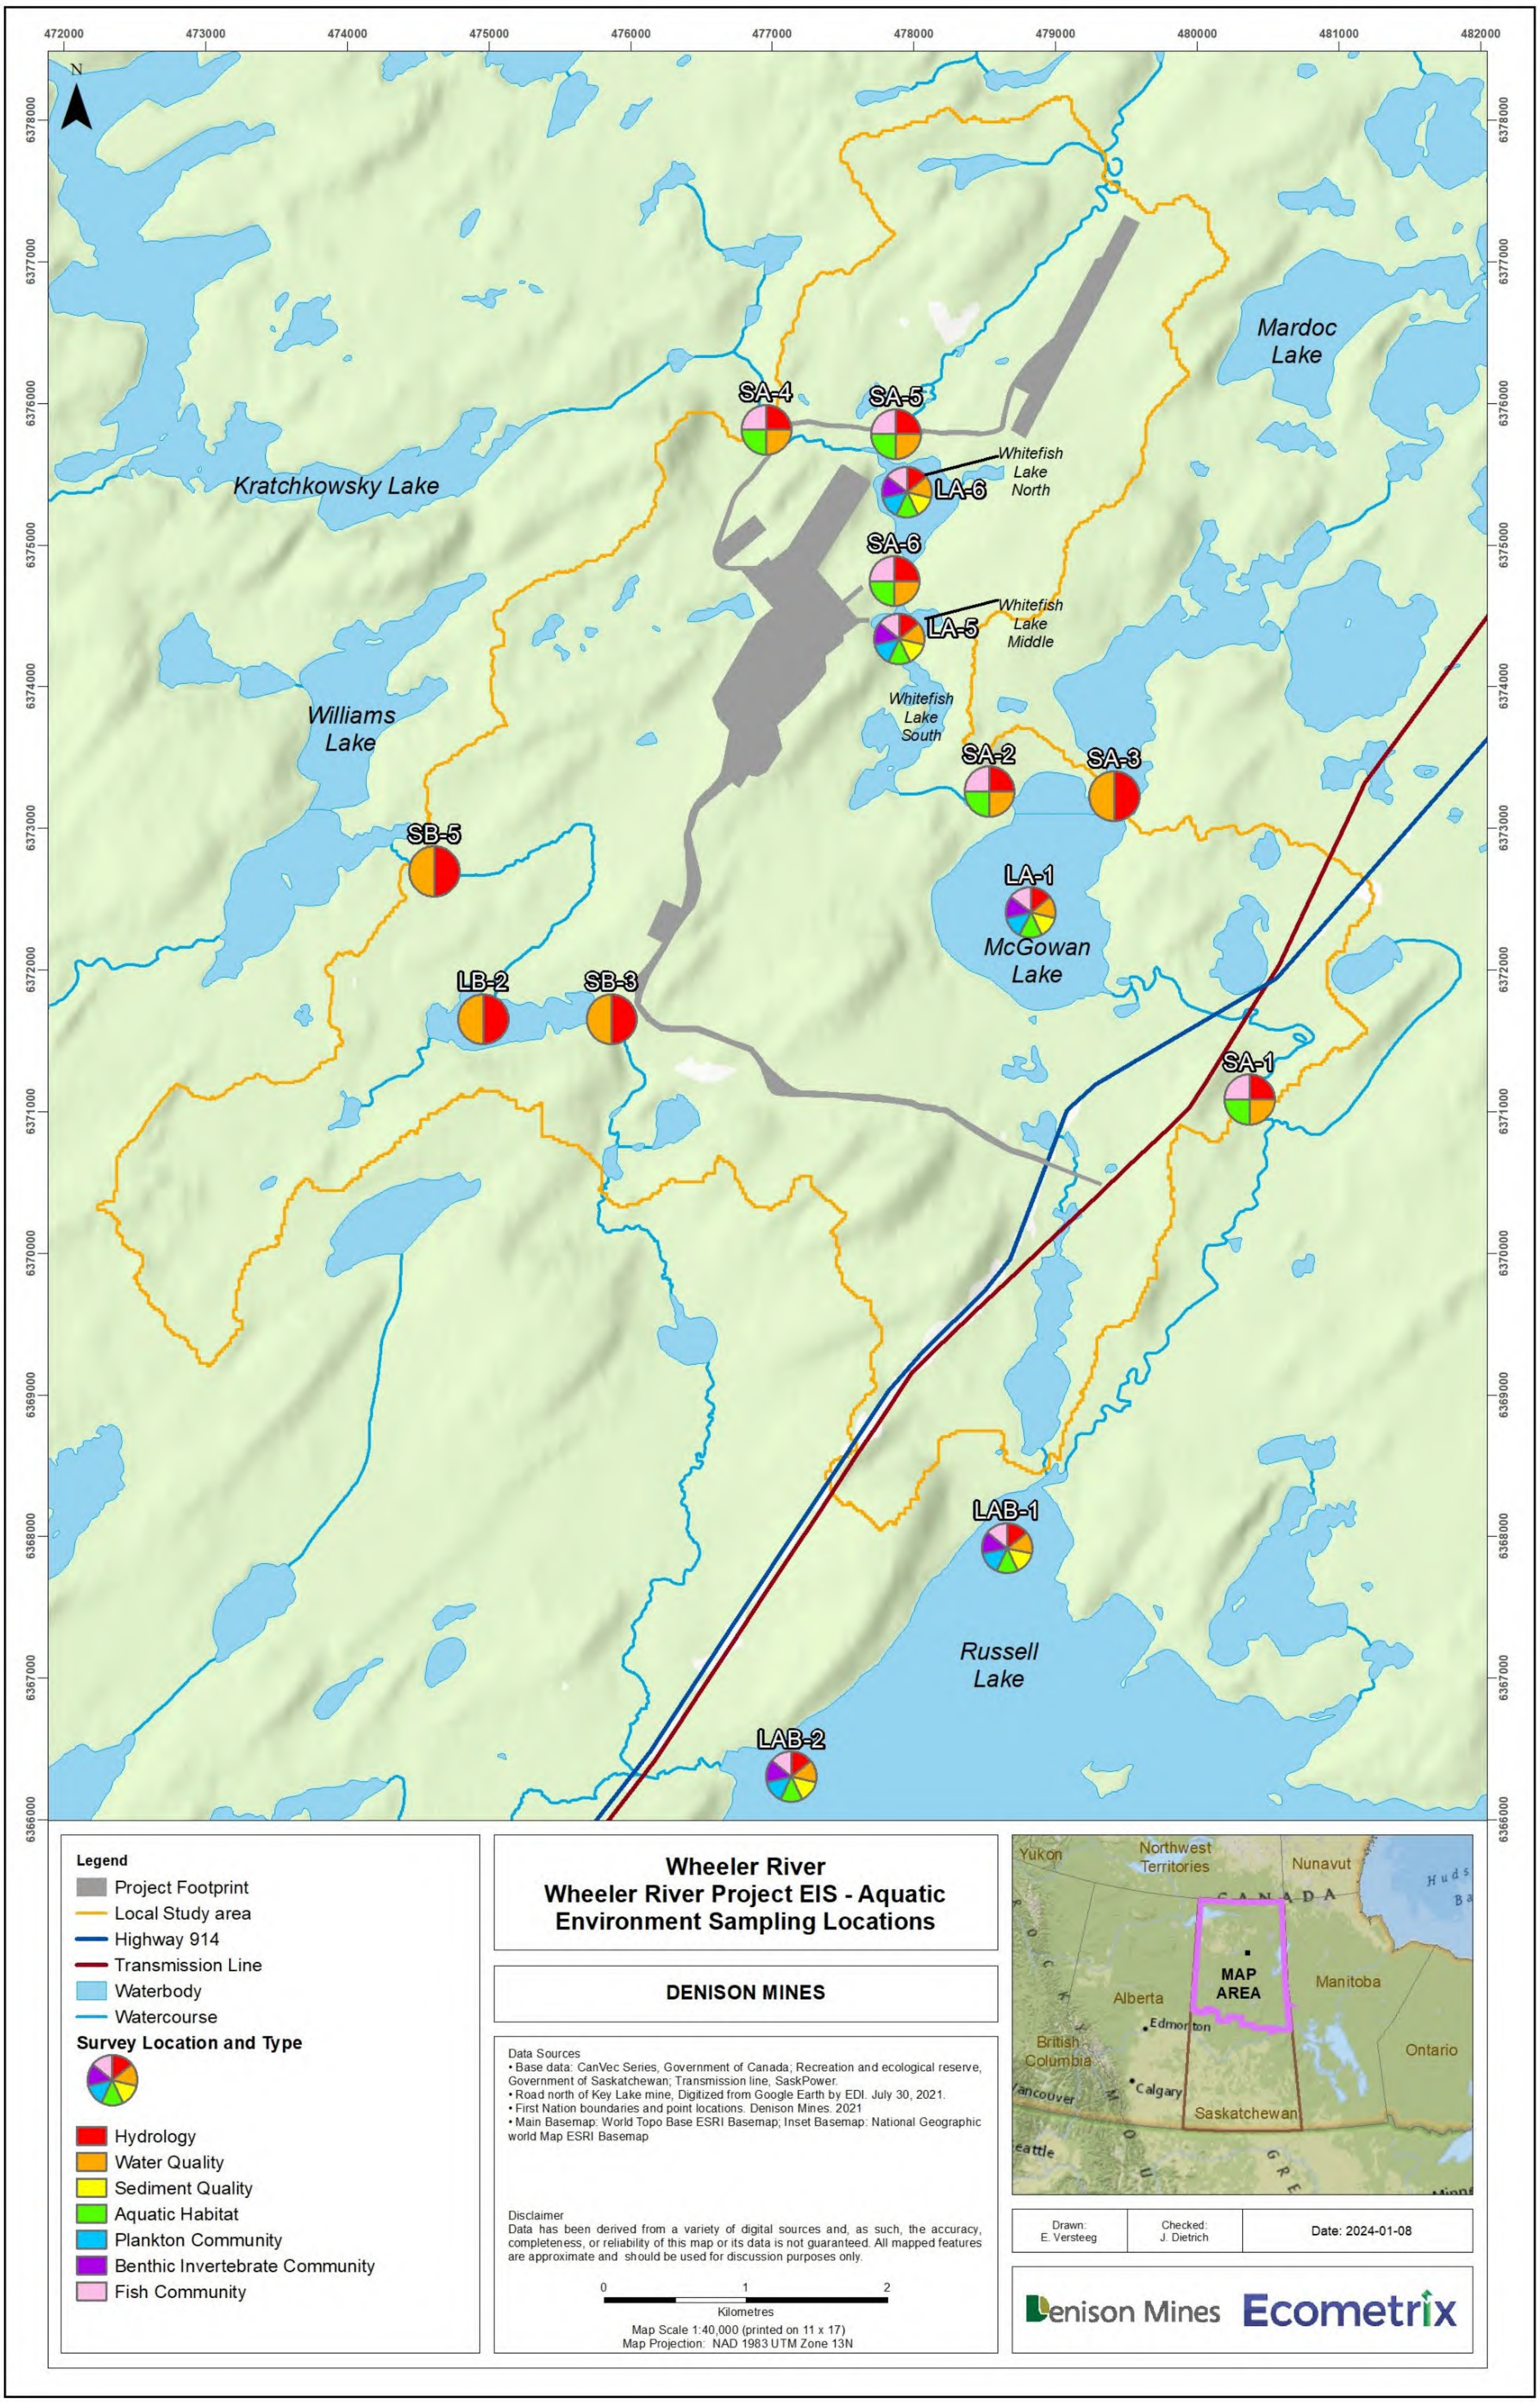

Figure 8.4-5: Water Quality, Biota, and Sediment Sampling Locations (2016 to 2018)

Table 8.4-2: Summary of Baseline Benthic Sediment Soil Classification Results for Select Lakes Within the Local Study Area

Sample Area	Soil Classification	n	Max	Min	Mean	SD
McGowan Lake (LA-1)	Gravel	3	0.0%	0.0%	0.0%	0.0
	Sand	3	0.3%	0.1%	0.2%	0.1
	Silt	3	21.6%	17.7%	20.0%	2.0
	Clay	3	82.2%	78.2%	79.8%	2.1
Whitefish Lake South (LA-5)	Gravel	5	0.0%	0.0%	0.0%	0.0
	Sand	5	77.2%	0.1%	30.8%	40.3
	Silt	5	21.7%	12.8%	17.7%	3.7
	Clay	5	82.0%	10.0%	51.4%	36.9
Whitefish Lake North (LA-6)	Gravel	5	0.0%	0.0%	0.0%	0.0
	Sand	5	12.0%	0.4%	4.0%	4.9
	Silt	5	41.8%	20.8%	27.8%	8.7
	Clay	5	78.8%	46.2%	68.2%	13.6
Russell Lake (LAB-1)	Gravel	3	0.0%	0.0%	0.0%	0.0%
	Sand	3	2.8%	0.3%	1.2%	1.3%
	Silt	3	26.8%	22.0%	24.9%	2.4%
	Clay	3	77.8%	70.4%	73.8%	3.7%

Notes:

n = number of samples; max = maximum; min = minimum; SD = standard deviation.

8.4.3.2.2 Total Organic Carbon

Average TOC was similar between McGowan Lake and Whitefish Lake North at 16% and 17.4%, respectively (Table 8.4-3). Whitefish Lake South had the lowest TOC at 10.6%. Notably, both the lowest (0.4%) and highest (18.8%) sample values came from Whitefish Lake South, indicating a higher degree of spatial heterogeneity of TOC deposition within that lake.

8.4.3.2.3 Metals

Average sediment phosphorus concentrations were nearly identical between McGowan Lake and Whitefish Lake North (1,233 ug/g and 1,232 ug/g, respectively) (Table 8.4-3). Phosphorus levels in Whitefish Lake South were significantly lower than the other lakes at 796 ug/g. Similar to TOC, samples from Whitefish Lake South contained both the lowest (50 ug/g) and highest (1,600 ug/g) levels of phosphorus of all three lakes. Average sediment lead concentrations were highest in McGowan Lake (8.9 ug/g) followed by Whitefish Lake North (7.8 ug/g) and Whitefish Lake South (4.8 ug/g). Whitefish Lake South had the lowest average sediment arsenic concentrations at 2.5 ug/g, while arsenic levels in Whitefish Lake North and McGowan Lake were 3.6 ug/g and 5.3 ug/g, respectively. Out of all metals and nutrients that were examined in the sediment samples, Whitefish Lake South contained the lowest average concentrations out of the three lakes, except for iron and sodium. Thorium isotopes (228, 230, and 232) were below the detection limit (0.02 ug/g) in every sample from all three lakes.

For parameters where sediment quality guidelines are available, all constituent concentrations were at or below their respective reference value, interim sediment quality guideline, or lowest effect level in each of the lakes.

Notes

Chemical analysis is reported on a dry weight basis; **bold** value exceeds REF/ISQG; shaded value exceeds NE2/PEL

REF and NE2 values from Burnett-Seidel and Liber (2013). REF = Reference, NE2 = No Effect Level based on benthic invertebrate abundance, richness and evenness

ISQG and PEL values from Canadian Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life (CCME 2024b). ISQG = Interim Sediment Quality Guideline, PEL = Probable Effects Level.

Chemical analysis is reported on a dry weight basis; **bold** value exceeds LEL; shaded value exceeds SEL

LEL and SEL values from Thompson *et al*. (2005). LEL = Lowest Effect Level, SEL = Severe Effect Level

8.4.3.2.4 Benthic Invertebrate Community

Taxa dominance varied between sampled lakes in the Icelander River system. The most dominant taxa in order abundance in McGowan Lake (LA-1) were chironomids (44%), phantom midges (33%) and water fleas (11%). In Whitefish Lake North (LA-6) these were water fleas (65%) and chironomids (16%). While in Whitefish Lake South (LA-5) the proportions of dominant taxa were water fleas (55%) and chironomids (20%). Russell Lake was dominated by chironomids at both LAB-1 and LAB-2 (59% and 75%), respectively. Secondary dominant taxa found at LAB-1 and LAB-2 were Naidid worms (19%) and rust flies (13%), respectively (Table 8.4-4).

McGowan Lake had the most diverse benthic invertebrate community (D = 0.76) with a family richness of 12. Whitefish Lake South had similar diversity (D = 0.76) while Whitefish Lake North was the least diverse (D = 0.65). While relatively lower in richness than the other sample areas, McGowan Lake had the highest Simpson's Evenness score (E = 0.44), where a score of 0 indicates that one family comprises all of the density, and a score of 1 indicates that all families are equally abundant. Whitefish Lake South had the highest taxonomic richness at 22 families but was less even (E = 0.23). Whitefish Lake North was the least even (E = 0.18) of the three sample areas with a mean family richness of 17. McGowan Lake had a higher B-C index, where a score of 0 indicates sample stations have identical community structure, and a score of 1 indicates sample stations have completely dissimilar community structure. The higher B-C score, along with higher diversity and evenness, indicate that McGowan Lake is likely the most sensitive of the three lakes to environmental stressors, followed by Whitefish Lake South and Whitefish Lake North.

Table 8.4-4: Summary of Benthic Invertebrate Endpoints for Lakes Within the Local Study Area

Sample Area	Mean Simpson's Diversity	Mean Simpson's Evenness	Mean Family Richness	Mean Density (Individuals per m^2)	Bray-Curtis Dissimilarity	Dominant Taxa
McGowan Lake (LA-1)	0.76	0.44	12	981	0.50	Chironomids 44% Phantom Midges 33% Water Fleas 11%
Whitefish Lake South (LA-5)	0.73	0.23	22	9,597	0.39	Water Fleas 55% Chironomids 20%
Whitefish Lake North (LA-6)	0.65	0.18	17	10,163	0.37	Water Fleas 65% Chironomids 16%
Russell Lake (LAB-1)	0.85	0.34	16	3,505	0.71	Chironomids 59% Naidid Worms 19%
Russell Lake (LAB-2)	0.82	0.25	21	5,295	0.87	Chironomids 75% Rust Flies 13%

Notes:

Bray-Curtis calculations for Whitefish Lake South and Whitefish Lake North used mean of condition values from the small lakes (i.e., LA-5 and LA-6) while calculations for McGowan Lake used mean of condition values from the large lakes (i.e., LA-1, LA-7, LA-7A, LA-8, LA-9, LAB-1, and LAB-2.

8.4.3.2.5 Benthic Invertebrate Chemistry

Radionuclide and metal concentrations for caddisfly larvae collected from McGowan Lake, Whitefish Lake South, Whitefish Lake North, and Russell Lake are presented in Table 8.4-5.

Table 8.4-5: Baseline Benthic Invertebrate Chemistry for Lakes within the Local Study Area

Notes:

- Results are for one sample per lake assessed.
- Samples were collected between September 18 and 21, 2016.
- Results are on a dry weight basis.

8.4.4 Assessment of Project-related Effects

8.4.4.1 Potential Interactions Between the Project and Valued Component / Key Indicators

The Project will require the construction, operation, and decommissioning of several components (as described in Section 2). Potential interactions between Project activities and the Sediment Quality and Benthic Invertebrates VCs are summarized by Project Phase in Table 8.4-6 and are ranked as:

- Primary Interaction (✓): Project activity is expected to interact with the VC / KI, which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.
- Other Interaction (✓): Project activity is expected to interact with the VC / KI. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects.
- No Interaction: Project activity is not expected to interact with the VC/KI, no adverse effects are expected, and a rationale is provided for not considering this potential interaction further.

Based on professional judgment and understanding of the nature of Project activities and their sequencing, the Project activity list was reviewed and the type of interactions determined. Potential Project-related effects are then discussed in Section 8.4.4.2. Primary Project activities with the potential for adverse effects on Sediment Quality and Benthic Invertebrates (i.e., flagged as 'Primary Interactions') are expected to involve surface land clearing, major earthworks, surface/grading preparations, changes to land cover, water management feature construction and operation, and water taking and effluent discharge. Other Project activities (i.e., flagged as 'Other Interactions') refer to those activities that may be associated with hydrogeological influence to local waterbodies and are expected to be secondary contributors to potential adverse effects. The remaining activities (e.g., power generation and supply) were deemed to have no interaction and were not carried forward in the assessment as they are not expected to result in detectable changes in the MPs associated with Sediment Quality and Benthic Invertebrates. Activities during Post-Decommissioning (e.g., site inspections; monitoring and on-site engagement with Interested Parties) were deemed to have no interaction because they do not involve any land clearing, surface preparations, or major earthworks.

Table 8.4-6: Potential Project Interactions for Sediment Quality and Benthic Invertebrates

Interactions between the Project and Sediment Quality and Benthic Invertebrates during the future centuries phase would be considered an indirect (secondary) interaction associated with changes in groundwater migration from the restored mining theater to the surface water environment. Such interactions and their potential for residual effects are discussed in Section 8.4.4.2.5.

8.4.4.2 Potential Project-related Effects

Project activities may interact with Sediment Quality and Benthic Invertebrates during all Project phases. In general, the interactions can be characterized as being primarily associated with controlled, routine discharges from the site. During Construction, the primary effect pathway relates to the mobilization of suspended material into natural surface water features as the result of land disturbance and clearing. During Operation and Decommissioning, excess water from the effluent monitoring ponds will be released to the environment. Routine discharge of this sort will be directed to Whitefish Lake only. Direct discharge of treated effluent to the natural environment has the potential to change surface water constituent concentrations, which may be partitioned to sediments, potentially affecting benthic invertebrate communities via exposure. Post-Decommissioning will involve the restoration of natural site drainage to the Whitefish Lake receiver. Similar to Construction, Decommissioning and Post-Decommissioning activities have the potential to increase the mobilization of suspended solids into natural surface waters, increasing the potential for sedimentation of benthic invertebrate habitat. The following sections discuss each Project-related effect.

8.4.4.2.1 *Mobilization of Suspended Materials*

Construction

The primary effect pathway during Construction relates to the mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. According to the site water balance (Figure 2.2-14 in Section 2), there is no planned discharge to Whitefish Lake during Construction. The mitigation of potential mobilization of suspended material into natural surface water features is readily mitigatable by virtue of the mine development plan and through the implementation of standard water management and sediment control practices. Water management infrastructure (e.g., collection ditches, ponds, pumping, stations), as well as various aspects of the water management and sediment control management systems, will be put into place coincident with the initiation of construction activities. Waters (e.g., runoff) associated with areas under development will be collected and stored within management infrastructure (e.g., clean waste rock pond, Figure 2.2-14 in Section 2). In the event that releases into the natural environment are necessary, they would only occur once it is safe to do so (i.e., suspended solids levels in the water would be at acceptable levels). No downstream effects on surface waters, natural sediments, or benthic invertebrate habitats are expected.

Operation

During Operation, mobilization of suspended materials will be managed through the water management infrastructure and the Surface Water Management Program. Releases of contact water to the natural environment will be directed through the applicable collection ponds, IWWTP, and Effluent Monitoring and Release Ponds. Discharge will only occur once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). Management of TSS levels in the final discharge will be implemented to make sure discharge quality can be maintained consistently to avoid effects on sediment quantity and quality and benthic invertebrates. As necessary, Denison may employ active means (e.g., filtering), if required, to achieve low TSS levels in discharge, in addition to passive means such as settling and clarification in the IWWTP to manage TSS in the effluent stream to low levels. No downstream effects on surface waters, natural sediments, and benthic invertebrate habitats are expected.

Decommissioning

During Decommissioning, the site-wide water management system will continue to operate such that Denison will maintain control of the site process and contact water through the IWWTP. Surface drainage during Decommissioning activities will continue to be directed to the system of collection ponds, IWWTP, and Effluent Monitoring and Release Ponds to control suspended solids and achieve low TSS levels in the discharge, minimizing any potential for sedimentation of existing benthic habitat.

8.4.4.2.2 Overprinting of Aquatic Habitat

Overprinting of aquatic habitat is only expected as a result of construction and commissioning of the effluent discharge/intake pipeline and diffuser at Whitefish Lake. The discharge pipeline and diffuser will terminate at an engineered, offshore, submerged, multiport diffuser, which will be designed to maximize the mixing potential and reduce the spatial extent of the mixing zone (as described in Section 8.2.4.1.1). Negligible aquatic habitat loss is predicted in Whitefish Lake due to the installation of a discharge pipeline and diffuser configuration. The total area of the lake substrate that would be overprinted by the pipeline is expected to be approximately 135 m^2, which will constitute less than 0.05% of the lake's surface area. The structure will remain in place during Operation and Decommissioning while the site-wide water management system continues to operate such that Denison will maintain control of the site process and contact water through the IWWTP. The effects on benthic invertebrates and their physical habitat (sediments) will be confined to this area throughout the duration of the Project but will be returned to pre-construction character following removal of the infrastructure, establishment of natural sediment distribution patterns in the lake, and recolonization of benthic invertebrates.

8.4.4.2.3 Controlled Discharge to Receiving Environments

Construction

Discharge to the environment is not expected during Construction. Site contact water will be collected and held in the clean waste rock pond (Figure 2.2-14 in Section 2). Therefore, potential effects of discharge on the Sediment Quality and Benthic Invertebrates VCs are not expected.

Operation

Denison does not intend to include constant freshwater withdrawal or effluent discharge throughout Operation; however, for the purposes of assessing the scenario of greatest potential effects, the Project has been assessed as having a continuous freshwater withdrawal rate of 40.5 m^3/hr and a continuous effluent discharge rate of 36.5 m^3/hr.

Benthic invertebrates were assessed as an ecological receptor as part of the *Wheeler River Environmental Risk Assessment* (Appendix 10-A in Section 10). The effects on Benthic Invertebrates were assessed based on pathways through Surface Water Quality and Sediment Quality (radiological and non-radiological constituents).

Surface water and sediment quality modeling were completed using IMPACT version 5.6.0., which is consistent with the COPC transport equations outlined in CSA N288.1-20 (CSA Group 2020). The modeling is discussed in detail in the *IMPACT Model Report for the Wheeler River Project* (Appendix A of Appendix 10-A in Section 10). Waterbodies from Whitefish Lake to the Russell Lake inlet were modelled in IMPACT to assess the effects of the Project on the downstream environment. This included the following distinct water polygons: Whitefish Lake Middle, Whitefish Lake South, McGowan Lake, and Russell Lake. Kratchkowsky Lake and Whitefish Lake North were modelled as reference locations. Surface water quality modelling included predicting water and sediment concentrations in Whitefish Lake (the lake to which treated effluent will be released), as well as locations farther downstream. The geometric mean of measured water concentrations from baseline studies performed between 2011 and 2019 (Ecometrix 2020) was selected as the water baseline concentration for constituents that had measured data over the detection limit. Sediment baseline concentrations were predicted from surface water concentrations using the partitioning coefficients (Kd), which consist of regional published values that have been calibrated on similar sites in northern Saskatchewan and checked against Wheeler River measurement data. The estimated effluent concentrations of COPC are presented in Table 8.2-9 (Section 8.2.4.2.3).

Predicted maximum concentrations of constituents of interest in sediment were compared against sediment quality guidelines for the protection of aquatic life and other relevant screening values. Sediment quality screening values were selected based on the following of sources:

- reference (REF) and no-effect (NE2) sediment quality values from Burnett-Seidel and Liber (2013);
- lowest effect levels and severe effect levels from Thompson et al. (2005); and
- Canadian interim sediment quality guidelines and probable effect levels from the Canadian Council of Ministers of the Environment (1999).

Sediment screening (Table 8.4-7) focused on COPC identified during surface water screening as exceeding screening values, and on other constituents of interest from other uranium mining and milling operations. Based on a comparison of maximum predicted sediment quality in Whitefish Lake against the REF values from Burnett-Seidel and Liber (2013), molybdenum and selenium were predicted to exceed the REF values; however, they are not predicted to exceed the NE2 values. Molybdenum and selenium were already identified as COPC based on the surface water screening, and are assessed further in the quantitative environmental risk assessment, considering both water and sediment concentrations.

There is no sediment screening value for cobalt; however, cobalt has already been identified as a COPC in surface water. As such, it will be subject to further quantitative assessment in the environmental risk assessment, considering both water and sediment concentrations.

Predicted concentrations of most COPC did not exceed sediment quality guidelines; however, molybdenum and selenium exceeded REF values from Burnett-Seidel and Liber (2013), but not NE2 values (Appendix 10-A in Section 10). As such, these constituents were carried forward as part of the ecological risk assessment. The ecological risk assessment estimated dose and risk to representative aquatic receptors, including benthic invertebrates, during all Project phases, and included the pathway through Surface Water Quality and Sediment Quality. The potential for ecological effects was assessed by comparing exposure levels to toxicological benchmarks, and characterized quantitatively in terms of total HQs. A total HQ greater than 1 indicates adverse effects may be possible for a given ecological receptor and further investigation is warranted.

As discussed in Section 8.3.6.1, based on water concentrations, the estimated total HQs for all COPCs for aquatic biota are predicted to remain below the HQ benchmark of 1 (Table 8.4-8), with the exception of HQs for copper that are predicted to exceed 1 for benthic invertebrates (at reference and exposure locations) under baseline conditions (for hardness and pH). Under site operational conditions during periods of treated effluent discharge, the HQs for copper are below 1 for all downstream exposure locations for benthic invertebrates.

There were no predicted exceedances of the 9.6 mGy/d radiation dose benchmark for aquatic biota during any Project phase (Appendix 10-A).

Table 8.4-7: Maximum Concentration of Surface Water Constituents of Potential Concern in Sediment

Location	Maximum Concentration of COPCs During Project Phases

Decommissioning and Post-Decommissioning

Discharge to the aquatic environment of Whitefish Lake during Decommissioning is expected. Effluent rates during this phase are expected to be less than during Operation. Effluent water quality is also expected to have lower levels of COPC compared to Operation. Therefore, the analysis of potential effects on the Surface Water Quality VC during Operation (provided in Section 8.2.4.2) is considered in the bounding scenario for Decommissioning due to the influence of surface water quality on sediment quality and benthic invertebrates. There are no expected effects on sediment quality as a result of effluent discharge.

8.4.4.2.4 Changes in Water Levels and Flow

As detailed in Section 8.1, the projected withdrawal and discharge rates proposed for the Project are the largest influence on the hydrological effects of the Project. The largest predicted change in streamflow rate is -3.1% at the LA-5 and SA 2 nodes (immediately downstream of the Project) during Operation and Decommissioning, as projected against the 5th percentile low flow dataset in March. Lake levels are expected to deviate less than ±0.01 m due to all Project influences. All Project influences on the environment are expected to return to baseline conditions during Post-Decommissioning. These changes are within the range of fluctuation of environmental flows and water levels and are unlikely to affect the distribution of sediments as habitat for benthic invertebrates in the LSA.

8.4.4.2.5 Long-Term Transport of Groundwater Solutes to Whitefish Lake in Future Centuries

During the ‘future centuries’ phase as described in Section 8.4.1.3, remediation works will be completed, and the site naturalized, thereby restoring drainage patterns to report to surface waterbodies. As indicated in Section 7 of the EIS, groundwater plumes may develop from residual mass remaining post mining based on bench-scale lab tests of core flushing, and numerical modelling of reactive fate and transport.

Groundwater flow and reactive transport of dissolved constituents were modelled using three-dimensional modelling whereby the reactions were computed using PHREEQC and the transport was computed using FEFLOW (Ecometrix 2022). Groundwater flow observed, and simulated in the calibrated groundwater model, travels eastward from the mining zone within the Lower Sandstone Aquifer before moving upward through the Desilicified Zone in the Athabasca Sandstone and overlying overburden deposits toward Whitefish Lake. Modelled transport of dissolved constituents along the groundwater flow path allowed for interactions of the dissolved constituents with the geologic media through which they are flowing. Due to the relatively low groundwater velocities between the mining zone and Whitefish Lake and chemical reactions along the groundwater flow pathway, the “Future Centuries” scenario spans 100s to 1000s of years.

The results of the numerical modelling, as provided in Section 7 and Appendix 10-A in Section 10, support the conclusion that with the implementation of appropriate mitigation during the decommissioning and restoration phase of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect to surface water. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future from the deep Ore Zone to Whitefish Lake remain below fresh water environmental quality criteria in Whitefish Lake.

For the COPC identified in the effluent, the predicted mass flux from groundwater into Whitefish Lake starting 200 years after the Project phases during the future centuries was added into the IMPACT model to predict the surface water concentrations over time at the exposed locations (see Table 8.4-9). As shown in the ERA (Appendix 10-A in Section 10), predicted surface water concentrations at all locations are expected to be below water guidelines for the protection of aquatic life, with the exception of copper which will return to baseline concentrations; however exceed the baseline copper FEQG.

Table 8.4-9: Maximum Concentration of Surface Water Constituents of Potential Concern in Surface Water During Future Centuries

Constituent	Unit	Kratchkowsky Lake (LA-7)	Whitefish Lake North (LA-6)	Whitefish Lake Middle (LA-5 North)	Whitefish Lake South (LA-5 South)	McGowan Lake (LA-1)	Icelander River	Russell Lake Inlet	Long-term Screening Concentration	Source of Screening Concentration	Notes

Notes:

All parameters listed as total concentrations unless otherwise specified

Saskatchewan Water Quality Objectives, SEQG on-line (https://envrbrportal.crmp.saskatchewan.ca/seqg-search/), SEQG for the protection of aquatic life were selected, based on total concentrations

Bold numbers indicate exceedance of long-term criteria

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CCME – Canadian Council of Ministers of the Environment.

HC – Health Canada.

BC MOE – British Columbia Ministry of the Environment.

FEQG – Federal Environmental Quality Guidelines.

MDMER – Metal and Diamond Mining Effluent Regulations.

DOC – Dissolved organic carbon.

TSS – Total suspended solids.

A pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).

(11) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.

(12) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf).

(13) Guideline specific to Chromium VI for conservative comparison to baseline water quality.

(14) Federal Water Quality Guideline for Copper Biotic Ligand Model (BLM) Tool and User Manual (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 [95th percentile of LA-5 and LA-6]).

(15) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L.

(16) Framework provides Trigger Ranges for Total Phosphorus (µg/L) - guideline for oligotrophic waterbody 4 - 10 µg/L.

(17) Long term guideline is based on CWQG = exp(0.947[ln(hardness mg·L-1)] - 0.815[pH] + 0.398[ln(DOC mg·L-1)] + 4.625). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.

(18) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L.

(19) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt. Based on equation and hardness of 250 mg/L for equation of FWQG = exp{(0.414[ln(hardness)] – 1.887}.

(20) "NC" means not calculated/estimated in the IMPACT model during future centuries. Nitrate is not a COPC associated with ISR mining for the Project and was not included in the groundwater source term to Whitefish Lake developed through geochemical reactive transport modelling (Section 7, Appendix 7-C). Nitrate concentrations are low in the groundwater environment and in metallurgical testing informing the groundwater reactive transport model (Section 7, Appendix 7-C). As such, nitrate concentrations are expected to remain at baseline conditions in surface water bodies in the future centuries. Alkalinity was included in the geochemical reactive transport model but not in the IMPACT modelling. As such, the maximum alkalinity concentration (mg/L as $CaCO_3$) during future centuries was calculated outside of IMPACT using the same equations/approach presented in Section 10 (Appendix A of Appendix 10-A) and the mass flux of alkalinity from the geochemical reactive transport model (Reported as "C" in Table 4-4 of Appendix 7-C). The maximum concentration calculated (8.1 mg/L) is within the range or alkalinity values measured in the south part of Whitefish Lake (3-13 mg/L; Table 8.2-2) and represents an increase of approximately 5.2% over the mean baseline value of 7.7 mg/L in the south part of Whitefish Lake (Table 8.2-2). Alkalinity values in the other lakes were not calculated because they are expected to remain at baseline levels during future centuries.

8.4.5 Mitigation Measures

Measures to mitigate adverse effects on Sediment Quality and Benthic Invertebrates are consistent with those to mitigate adverse effects on Surface Water Quantity and Quality. These measures are repeated in this section for completeness.

- Maintain existing drainage patterns with the use of culverts, where applicable.
- Maintain access roads by periodically regrading and ditching to improve water flow, reduce erosion, and manage vegetation growth.
- Inspect culverts periodically. Remove accumulated material and debris upstream and downstream of the culverts to prevent erosion, flooding, habitat damage, property damage, and mobilization of sediment.
- Attenuate peak discharges and augment baseflows to the environment through the use of Project water storage features (i.e., runoff, process water, contact water, monitoring/effluent ponds).
- Develop and implement a Surface Water Management Program that provides an integrated framework to manage water quality and includes provision for water management practices for each of the primary site aspects, as well as areas of the site where there is contact water.
- Maximize the recycle and reuse of process water to reduce freshwater intake and release to Whitefish Lake.
- Design the discharge diffuser/outfall to have the smallest footprint possible while still providing effective mixing and dilution and discharge flows that do not detrimentally affect sediments.
- Develop site-specific effluent treatment to treat COPC to appropriate release limits in accordance with provincial standards and licence/permit conditions.
- Discharge effluent under a scenario that will meet provincial and federal discharge criteria, as identified through permitting. Scenarios may include:
  - discharging at a fixed rate while maintaining an appropriate minimum dilution ratio (i.e., discharge when able to meet the required dilution ratio and cease discharge during periods when unable to meet the necessary dilution ratio);
  - discharging under a variable waste load allocation (i.e., discharge an appropriate effluent volume based on flow in the receiver to maintain minimum dilution ratio); and
  - managing discharge via a hybrid of the two previous options (i.e., discharge effluent at a fixed rate to maintain the required dilution ratio, but the fixed rate is varied on a seasonal basis based on flow).
- Collect and monitor contact water to determine whether treatment is required prior to release to the environment. This will inform optimal levels of treatment.

- Maintain the water management system in place during decommissioning until such time that water quality is suitable to release to the environment.
- Monitor and manage effluent, including contingency for effluent treatment as may be required, so that water discharge objectives are achieved, as defined by applicable provincial and federal regulatory instruments.
- Design and implement an Environmental Code of Practice that defines actions levels and appropriate steps to mitigate elevated concentrations of chemical and radiological constituents in treated effluent discharge to acceptable levels.
- Implement Project-specific monitoring programs (e.g., effluent monitoring plan, environmental monitoring plan) that include monitoring treated effluent, surface water, and sediment quality and applying adaptive management if necessary.
- Work with the associated communities to develop and implement the Project-specific monitoring programs and a framework to share the results for the purpose of assessing the performance of the water management system.
- Develop and implement a decommissioning and reclamation plan to decommission and transfer the site to the province under the Institutional Control Program.

8.4.6 Residual Effects Evaluation

8.4.6.1 Residual Effects Characterization

This section describes the likely residual effects of the Project on the VCs of Sediment Quality and Benthic Invertebrates and their associated KIs. Residual effects are effects that remain after the implementation of mitigation measures and management strategies and are the expected consequences of the Project. The approach to assessing residual Project effects on the Sediment Quality and Benthic Invertebrates VCs follows the methodology outlined in Section 5.8 in Section 5. For each VC and associated KI, each residual effect is characterized in the context of the Project activities that will occur within each Project phase. A residual adverse effect on Sediment Quality is defined as a measurable change in the concentrations of a sediment quality parameter (or parameters) that exceed relevant water quality assessment benchmarks that represent concentrations that are protective of aquatic biota and water uses in watercourse and waterbodies that receive mine-affected drainage. A residual effect is also identified as a change in the sediment quantity and physical quality (grain size) from background (i.e., an increase in sedimentation). These changes also characterize a residual effect for benthic invertebrates. Additionally, a change in water level or flow from baseline and a change in available benthic invertebrate habitat are also considered residual effects on Benthic Invertebrates. Residual effects characteristics specific to Sediment Quality are defined in Table 8.4-10.

<u>Construction</u>

The primary potential change in sediment quality or benthic invertebrate habitat associated with Construction is the mobilization of suspended material into natural surface water features as a result of land clearing activities and road crossing construction. According to the site water balance (Figure 2.2-14 in Section 2), there is no planned discharge to Whitefish Lake during Construction. However, the potential influence of such discharge, if it were to occur, would be bounded by the analysis of water quality in Whitefish Lake during Operation.

Mobilization of suspended material into natural surface water features is readily mitigatable by virtue of the mine development plan and through the implementation of standard water management and sediment control practices. Water management infrastructure (e.g., collection pads, ponds, pumping stations), as well as various aspects of the water management and sediment control management systems, will be put into place coincident with the initiation of construction activities. Runoff associated with areas under development will be collected and either stored within management infrastructure (e.g., water management ponds) or potentially released into natural surface water features once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). No downstream effects on local sediment quality or benthic invertebrate communities are expected.

Operation

During Operation, the primary potential water quality effect from the Project is the discharge of excess water from the site water management system to Whitefish Lake (Figure 2.2-14 in Section 2). Discharge to Whitefish Lake has the potential to change the concentrations of sediment quality constituents from background and, therefore, affect benthic invertebrate habitat and communities.

For planning purposes, a continuous (year-round) discharge at an expected average effluent rate of 0.0101 m^3/s (36.5 m^3/hr) is expected throughout Operation, despite the likelihood that effluent discharge will not be continuous and will only discharge when the site water balance requires, based on water storage capabilities. The water storage capability of the Effluent Monitoring and Release Ponds has been designed to enable contingency in water storage (i.e., three ponds of 3,300 m^3 capacity).

No other routine mine-related discharges to other receiving environments are proposed during Operation. Water management infrastructure will collect and divert all site process and contact water, as well as water associated with the ISR process, through the site IWWTP. Any excess water not required during the ISR process will be directed to the IWWTP. Treated water from the WTP will be pumped to the Effluent Monitoring and Release Ponds.

Treated water in the Effluent Monitoring and Release Ponds will be monitored prior to release to Whitefish Lake. The treated effluent discharge line will be heated and have secondary containment in place.

Predicted changes in sediment quality for molybdenum and selenium are above background and most conservative screening criteria.

However, estimated total HQs for all COPC with the exception of copper, for all ecological receptors are predicted to remain below the HQ benchmark of 1. HQs for copper exceed the HQ of 1 for benthic invertebrates (all locations) and predatory fish (Whitefish Lake Middle and South) under baseline conditions (for hardness and pH). Under site operational conditions during periods of effluent discharge, the HQs for copper are below 1 for all downstream exposure locations for all aquatic biota (Appendix 10A, Section 6.3.2).

Local Indigenous communities have expressed direct concern with respect to mercury. Mercury has not been identified as a COPC for the Project as it is currently not present in the receiving environment (i.e., background condition) at detectable concentrations and will not be produced as part of the mine process; therefore, it will not be discharged to the aquatic environment. However, it is understood that potential nutrient enrichment-related effects are possible and can be linked to increases in mercury in the environment.

As described above, the Surface Water Management Program involves care and control of all site process and contact water and no discharge is proposed beyond that to Whitefish Lake. In practice, it may be necessary at times to manage runoff from disturbed areas that are either outside the water management system or are yet to be integrated into the water management system. In these cases, the areas would be isolated and specific water and sediment control management practices would be implemented to make sure any water released to natural surface water drainages is suitable for release such that the water quality in these natural surface water drainages is protected.

Changes in surface water levels (±0.01 m) and flows (maximum of -3.1% occurring at the LA-5 and SA 2 nodes during Operation) are expected to be less than the variation of natural environmental flows. As such, these changes are not expected to have a significant effect on sediment movement and/or benthic invertebrate habitats.

The overprinting of a small portion (less than 0.05%) of the LA-5 surface area by the effluent discharge pipeline and diffuser is not anticipated to constitute a major loss in benthic invertebrate habitat for the lake. Following installation of the diffuser, recolonization of the benthic invertebrate community is expected to occur. The conceptual design of the diffuser is anticipated to minimize any velocity-related effects on benthic invertebrates. Direction of discharge (nozzles) and velocities are expected to avoid any scour of sediment within the near-field discharge area.

Decommissioning / Post-Decommissioning

Following the cessation of mining operations, discharge to Whitefish Lake will cease. Water quality in Whitefish Lake is expected to return to pre-mining conditions at that time.

The site-wide water management system will continue to operate such that Denison will remain in control of site aspect affected water via the IWWTP. At that time, water (runoff) from the ISR wellfield, and contact water from the developed portion of the site (e.g., contaminated runoff pond, landfill pond, process water pond), will continue to be collected and diverted to the IWWTP. From the IWWTP, the water will be directed back to the ISR wellfield to be pumped as clean water to ground or pumped to the Effluent Monitoring and Release Ponds for monitoring prior to discharge to Whitefish Lake. Following Decommissioning, piping infrastructure will be removed and discharge to surface water will cease. Therefore, effects on sediment quality and the benthic invertebrate community are bounded by the Operation scenario. Partitioning of COPC from surface waters to sediment will cease and any changes to sediment will be monitored during Decommissioning.

Residual effects characteristics specific to the Sediment Quality and Benthic Invertebrates VCs are defined in Table 8.4-10 with evaluation of residual effects provided in Table 8.4-11, Table 8.4-12, Table 8.4-13 and Table 8.4-14.

Table 8.4-10: Sediment Quality and Benthic Invertebrates – Definitions of Effect Characteristics Considered When Determining the Significance of Residual Effects

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Effect moves measurable parameters in a direction detrimental to sediment quality or benthic invertebrates. *Sediment Physical Quality* – A change in grain size or particle size distribution that is attributable to the mine in comparison to baseline conditions and trends. *Sediment Chemical Quality* – An increase in constituent concentrations attributable to the mine in comparison to baseline conditions and trends. *Benthic Invertebrate Habitat* – a physical loss of available benthic invertebrate habitat (area of benthic substrate) in comparison to baseline condition and/or changes in waterbody flow or water levels that reduce the availability or detrimentally alter the characteristics of benthic invertebrate habitat. **Positive** – Effect moves measurable parameters in a direction beneficial to sediment quality and/or benthic invertebrate habitat quantity or quality. An improvement in sediment quality in comparison to baseline conditions and trends.
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low** – A measurable change that is not within the variability of baseline conditions but below relevant sediment quality objectives and criteria. **Moderate** – A measurable change that is not within the variability of baseline conditions and not within applicable guidelines, legislated requirements, and/or federal and provincial management objectives, and could therefore have an adverse effect on sediment quality and/or benthic invertebrates in the LSA. **High** – A measurable change that is not within the variability of baseline conditions and not within applicable guidelines, legislated requirements, and/or federal and provincial management objectives, and is likely to have an adverse effect on sediment quality and/or benthic invertebrates in the LSA, with the effect extending beyond the LSA.

Residual Effect Characteristic	Definition	Rating
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area. **Local** – Effect is limited to the Sediment Quality and Benthic Invertebrates LSA. **Regional** – Effect extends beyond the Sediment Quality and Benthic Invertebrates LSA into the Sediment Quality and Benthic Invertebrates RSA. **Beyond Regional** – Effect extends beyond the Sediment Quality and Benthic Invertebrates RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals. **Frequent** – Effect occurs many times on a regular basis. **Continuous** – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions. **Partially Reversible** – A residual effect that partially diminishes to baseline conditions. **Irreversible** – A residual effect that will not diminish to baseline conditions.
Context	The extent to which the VC or KI has been affected by past and present environmental and socio-economic processes and conditions, its potential sensitivity to the Project-related residual effect, and its ability to recover from that effect (i.e., resilience).	**Low** – VC/KI has high resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a lack of historic and ongoing anthropogenic or natural disturbance. **Moderate** – VC/KI has moderate resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or an intermediate level of historic or ongoing anthropogenic or natural disturbance with the capacity to assimilate more change. **High** – VC/KI has weak resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a high level of historic or ongoing anthropogenic or natural disturbance.
Likelihood	Likelihood that the residual effect will occur, including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

Table 8.4-11: Sediment Quality and Benthic Invertebrates – Summary of the Characteristics Ratings for Sediment Quantity and Physical Quality (Particle Size)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	There is a potential through all Project phases for mobilization of solids into the natural environment, which may adversely affect the benthic sediment character and, therefore, the habitat of benthic invertebrates.

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Magnitude	Low	Using design-based mitigation through water balance and best practices or erosion and sediment control planning, the potential for an increase of suspended solids to the natural environment is predicted to be low.
Geographic Extent	Local	The effects are expected to be limited to the waterbodies (LA-5) and stream crossings associated with the Project Area and the discharge location at LA-5, which is in the LSA.
Duration	Medium-term	The effects are expected to last for the duration of the Project through to Post-Decommissioning
Frequency	Continuous	Although mobilization of suspended materials will occur at the greatest magnitude during Construction, a much smaller continuous source is considered as part of effluent discharge to LA-5.
Reversibility	Fully Reversible	Following cessation of discharge to the natural environment and reclamation of the site during Post-Decommissioning, the potential for mobilization of suspended materials to the natural environment is expected to stop and the natural processes associated with sediment mobilization and deposition are then expected to characterize the benthic environment within the LSA.
Context	Moderate	The physical characteristics of the benthic environment are resilient and typically managed by environmental flows, water depths, and ice scour.
Likelihood	Unlikely	There is a low probability of the residual effect following proper implementation of the erosion and sediment control plan and design-based water management and water treatment prior to discharge to the environment.

Table 8.4-12: Sediment Quality and Benthic Invertebrates – Summary of the Characteristics Ratings for Sediment Quality (Chemical)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	The Project (specifically the discharge of effluent to the natural environment) will cause a change in the concentration of constituents, which may be partitioned to sediment in the receiving water. Sediment quality in the local receiving environment will be adversely affected by effluent discharge to the environment.
Magnitude	Low	The magnitude of the residual effects associated with the Project are expected to be low as constituents that may be introduced as part of Project activities are anticipated to remain below criteria for the protection of aquatic life, or below risk HQs.
Geographic Extent	Local	The geographic extent of the residual effects is predicted to be local as effects are anticipated to be confined to the immediate waterbody adjacent to the Project (Whitefish Lake) and the estimated mixing zone is less than 5 m, facilitating an effluent discharge configuration that promotes mixing.
Duration	Long-term	Effects are expected to last between 3 to 38 years (i.e., effects expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuous	For the purposes of this EIS and identifying the conservative scenario, effluent discharge has been considered as continuous during Operation and Decommissioning.

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Reversibility	Fully Reversible	Sediment quality is expected to return to pre-development levels following Post-Decommissioning as Project-related sources will cease to operate.
Context	Low	The Sediment Quality and Benthic Invertebrates VCs are resilient in the context of this assessment as COPC meet protective criteria under the bounding scenario. Therefore, under applicable mitigative measures and average flow conditions, the contextual resilience of the aquatic system to respond to change is considered to be great.
Likelihood	Likely	There is a high probability that a change in sediment quality from background conditions will occur.

Table 8.4-13: Sediment Quality and Benthic Invertebrates – Summary of the Characteristics Ratings for Benthic Invertebrates – Change in Aquatic Habitat (Area)

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	A reduction of benthic invertebrate habitat by 135 m^2 is expected due to the construction of pipeline and diffuser infrastructure at LA-5.
Magnitude	Low	The change in available benthic invertebrate habitat by the overprinting of substrates in LA-5 constitutes less than 0.05% of the surface area of the waterbody.
Geographic Extent	Local	The effects are expected to be limited to the LSA, specifically a small portion of LA-5.
Duration	Medium-term	The effects are expected to last between 3 to 38 years (i.e., effects expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuous	Although the mine is unlikely to require water taking on a continuous basis, this has been assessed as a bounding scenario and, as such, must be considered as a continuous effect.
Reversibility	Fully Reversible	Following decommissioning and removal of the pipeline and diffuser, the available habitat will be restored to natural conditions due to lake currents and sediment transport dynamics.
Context	Low	The Sediment Quality and Benthic Invertebrates VCs have a high resiliency with respect to physical disturbance in the context of a small, localized area being altered or disturbed. It is not expected that the ecological integrity of the areas adjacent to the infrastructure will be affected and, as such, will provide for sources of re-distribution and recolonization following Post-Decommissioning.
Likelihood	Likely	The infrastructure associated with the pipeline and diffuser are likely to affect the localized area for which they overprint.

Table 8.4-14: Sediment Quality and Benthic Invertebrates – Summary of the Characteristics Ratings for Benthic Invertebrates – Change in Water Level or Flow

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	Water quantity (flow and level) will be reduced in LA-5 as a result of the overprinting of its reporting drainage area by mine infrastructure and through site water balance. Water taking has an additional potential to reduce water levels in LA-5.
Magnitude	Low	Under all scenarios, the Project-related change in hydrology (flows or levels) compared to baseline conditions, is less than 5% of baseline conditions, and generally less than 3%.
Geographic Extent	Local	The effects are expected to be limited to the LSA, specifically the lakes within close proximity to the Project site (i.e., LA-5, LA-6, and LA-1)
Duration	Medium-term	The effects are expected to last between 3 to 38 years (i.e., effects expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuous	Although the mine is unlikely to require water taking on a continuous basis, this has been assessed as a bounding scenario and, as such, must be considered as a continuous effect.

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Reversibility	Fully Reversible	Surface water hydrology is expected to return to pre-development levels following Post-Decommissioning.
Context	Moderate	Surface water flow regimes are variable, and it is this variability that provides for morphological form to be maintained and for ecological reliance (i.e., benthic invertebrate habitat, movement, and life-cycle success). Some change to environmental flows is tolerated by benthic invertebrate communities.
Likelihood	Low	Due to the localized nature and low magnitude of the effect on surface water hydrology, the likelihood of an effect is considered to be very low; therefore, the likelihood of an effect on benthic invertebrates is low.

8.4.6.2 Significance and Confidence

The significance of the residual effect is rated as **not significant** or **significant**, based on the following:

Not significant – a residual effect that is not expected to result in a change to a VC/KI that would alter its population viability or persistence beyond an acceptable level (e.g., where it is not sustainable or is unavailable to contribute to biodiversity and ecosystem function).

Significant – a residual effect that is expected to result in a change to a VC/KI that would alter its population viability or persistence beyond an acceptable level (e.g., where it is not sustainable or is unavailable to contribute to biodiversity and ecosystem function).

The significance of the residual effects on the Sediment Quality and Benthic Invertebrates VCs has been deemed **not significant.** The residual effects are not expected to cause a change in sediment quality and/or benthic invertebrate communities (or their KIs) to the extent that it will alter the ecological integrity of the VCs in the LSA beyond an acceptable level.

The prediction confidence with respect to Sediment Quality and Benthic Invertebrates is high as the mobilization of sediment can be readily mitigated, making the effects prediction relative to this effect pathway easily understood.

Confidence in the assessment of predicted effects on water levels or flow is quite high due to available hydrological data for the LSA. Uncertainty is minimal with the assumptions that the water withdrawal and discharge scenarios presented herein represent the bounding case, and hydrogeological modelling projections are not changed (Section 8.1).

Potential effects on Sediment Quality as a result of Project discharges to local receiving environments were assessed by way of numerical modeling. These predictions are generally considered conservative in nature because the assumptions on which they are based are conservative. For example:

- The assessment is based on a continuous (year-round) discharge at an expected average effluent rate of 0.0101 m^3/s (36.5 m^3/hr) throughout Construction, Operation, and

Decommissioning, despite the likelihood that effluent discharge will not be continuous and will only discharge when site water balance requires, based on water storage capabilities.

- The constituents in effluent discharge have been estimated conservatively. Presented discharge concentrations provided herein include contingency factors of one to three times.
- Baseline water quality and sediment quality are defined by the 95th percentile concentrations of individual constituents. Such an assumption is conservative as it constrains the assimilative capacity associated with the receiving environment. By definition, the assimilative capacity of a receiving environment is equal to the incremental difference between the existing baseline condition and the assessment benchmark (i.e., water quality criterion) on which the evaluation is based. Use of the 95th percentile concentration, rather than a measure of central tendency (i.e., 50th percentile, geomean), means that the incremental change in a given constituent concentration that can be assimilated by the receiving environment, whereby use of the receiving environment is protected, is relatively small in magnitude.

Due to the conservative nature of the assumptions on which the numerical assumptions are based, a high degree of confidence can be assumed.

8.4.6.3 Summary of Project-related Residual Adverse Effects on Sediment Quality and Benthic Invertebrates.

Residual adverse effects on Sediment Quality and Benthic Invertebrates are expected to occur during Construction, Operation, and Decommissioning through pathways previously identified. A summary of sediment quality and benthic invertebrate residual environmental effects that are likely to occur as a result of the Project, and their significance, is provided in Table 8.4-15.

Table 8.4-15: Project Residual Effects on Sediment Quality and Benthic Invertebrates

Residual Effect	Residual Effects Characterization									
	Project Phase	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Context	Likelihood	Significance Determination

8.4.7 Cumulative Effects

The spatial and temporal boundaries of the Project specific to the Sediment Quality and Benthic Invertebrate VCs are provided in Section 8.4.1.3. A description of the methods used in assessing cumulative effects is provided in Section 5.9.

8.4.7.1 Potential Cumulative Effects

Existing projects within the Wheeler River system have been considered for their potential to interact with the Sediment Quality and Benthic Invertebrates VCs for the Project. These include reasonably foreseeable projects that are described in Section 5.9.

The key potential cumulative effect pathway as it concerns the Sediment Quality and Benthic Invertebrate VCs is the surface water exposure pathway. The assessment of cumulative effects on the Sediment Quality and Benthic Invertebrate VCs considered surface water releases and partitioning to sediments from the Project and the Key Lake Operation during all phases of the Project. The key Project component contributing to potential cumulative effects is the discharge of treated effluent to the aquatic environment during Operation and Decommissioning which may interact with Cameco's current releases to water including treated water released to David Creek drainage, treated groundwater and diverted surface water to the McDonald Creek drainage (Cameco 2020).

Temporal overlap of the Key Lake Operation and the Project will also occur during 'future centuries' as described as 'post-decommissioning phase' in the Key Lake Extension Project EIS (Cameco 2020). There is potential for increased contaminant transport via groundwater to surface water during the long-term, post-decommissioning phase (i.e., 10,000 years after operations cease and the site has been reclaimed) for the Key Lake Operation. The long-term storage of tailings at a higher elevation has the potential to influence contaminants in the groundwater and incrementally add to the effect on surface water quality in the Outlet Creek Drainage.

Operation and Decommissioning

The assessment of cumulative effects on the aquatic environment considered releases from the Key Lake Operation and proposed Project during all phases of the Project. The primary Key Lake Operation component contributing to potential cumulative effects is the placement of tailings to a higher elevation in the Deilmann Tailings Management Facility (DTMF). The increased loadings from the DTMF are anticipated to result in an incremental (i.e., existing conditions plus the Project) increase of concentrations of COPCs in the aquatic environment (Cameco 2013). The spatial extent of any significant adverse effects on the aquatic environment from the Key Lake Operation were anticipated to be localized and not to extend to the Wheeler River and Russell Lake during any phase of the Project (Cameco 2013). The 2010 Status of the Environment report for the Key Lake Operation identified that no adverse effects to individual fish or fish populations are present in the Wheeler River (EcoMetrix 2010 as cited in Cameco 2020).

Potential Project residual effects on surface water quality relate to changes (increases) in constituent concentrations that are related to the controlled discharge of Project site waters into local receiving environments (Whitefish Lake). Such changes are predicted to be negligible to low in magnitude and limited to the LSA. For example, during Construction, no discharge from the Project site is planned. During Operation, treated effluent will be discharged to Whitefish Lake. The Whitefish Lake discharge will be the only routine discharge location during Operation. Water quality in Whitefish Lake and, by extension, downstream of Whitefish Lake will meet appropriate benchmarks for the protection of aquatic life in consideration of a small mixing zone in the lake. Benthic invertebrates were assessed as an ecological receptor as part of the *Wheeler River Environmental Risk Assessment* (Appendix 10-A in Section 10). The effects on Benthic Invertebrates were assessed based on pathways through Surface Water Quality and Sediment Quality (radiological and non-radiological constituents). No significant adverse effects on aquatic populations or communities (including benthic invertebrates) as a result of releases from the Project are predicted during the Project phases. All estimated total HQs for all COPC for all ecological receptors are predicted to remain below the HQ benchmark of 1 (Table 8.4-8) with the exception of copper (Section 10, Appendix 10A, Section 6.3.2). HQs for copper exceed the HQ of 1 under baseline conditions for benthic invertebrates (all locations) and predatory fish (Whitefish Lake Middle and South). Under site operational conditions during periods of treated effluent discharge, the HQs for copper are below 1 for all aquatic biota.

There were no predicted exceedances of the 9.6 mGy/d radiation dose benchmark for aquatic biota during any Project phase (Appendix 10-A). Following Decommissioning and the restoration of drainage patterns that are similar to pre-mining conditions, water quality is expected to meet appropriate benchmarks for the protection of aquatic life in Whitefish Lake and downstream. This includes Russell Lake of which the Icelander River system is associated.

In consideration of the above discussion, effects on the aquatic environment due to changes in surface water quality from the Key Lake Operation are not anticipated to spatially overlap with those from the Project and therefore a cumulative effect is not expected.

Future Centuries

The 2013 Key Lake ERA indicated that during the 10,000-year post-decommissioning period, predicted exposure levels may affect lower trophic level aquatic biota on a population or community level within some isolated lakes in the SSA, but adverse effects on the ecology of the Outlet Creek drainage, and therefore further downstream were not expected during the post-decommissioning phase (Cameco 2013). The results of the 2020 ERA for the Key Lake Operation were consistent with the findings from the 2013 ERA in that there were limited significant risks posed to aquatic receptors situated in the area surrounding the Operation, but not to areas farther downstream. The 2020 ERA concluded that environmental health in the vicinity of the Key Lake Operation will remain protected (Cameco 2020).

The results of the numerical modelling for the Project, as provided in Section 7 and Appendix 10-A in Section 10, support the conclusion that with the implementation of appropriate mitigation during the decommissioning and mining area remediation phase of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect to surface water or aquatic sediments. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future (“Future Centuries”) from the mining area to Whitefish Lake will be localized to that waterbody and remain below fresh water environmental quality criteria. As such, impacts to downstream portions of the drainage including Russell Lake are not expected.

In consideration of the above discussion, effects on the aquatic environment due to changes in surface water quality from the Key Lake Operation are not anticipated to spatially overlap with those from the Project and therefore a cumulative effect is not expected.

8.4.7.2 Additional Mitigation Measures

Additional mitigation measures are not warranted as no potential cumulative effects were identified for the Sediment Quality and Benthic Invertebrates VCs.

8.4.7.3 Cumulative Effects Characterization and Determination of Significance

A determination of significance is not warranted as no potential cumulative effects were identified for the Sediment Quality and Benthic Invertebrates VCs.

8.4.7.4 Cumulative Effects Assessment Summary

Impacts on the aquatic environment (including sediment quality and benthic invertebrates) via the surface water quality pathway from the Key Lake Operation are expected to remain localized and not extend to the Wheeler River system or Russell Lake. Likewise, impacts on sediment quality and benthic invertebrates via the surface water pathway from the Project are expected to remain localized (Whitefish Lake) and not extend to Russell Lake. Effects on the aquatic environment due to changes in surface water quality associated with the Key Lake Operation are not anticipated to spatially overlap with those from the Project during operation/decommissioning or during "future centuries" and therefore a cumulative effect is not expected.

8.4.7.5 Environmental Monitoring and Follow-up

Specific monitoring and follow-up for Sediment Quality and Benthic Invertebrates related to cumulative effects is not warranted as no cumulative effects were identified for the Sediment Quality and Benthic Invertebrates VCs. Monitoring and follow-up specific to the Project is detailed in Section 8.4.8.

8.4.7.6 Climate Change Considerations

As discussed in Section 8.1.7.5, the frequency and magnitude of extreme precipitation events have the potential to change water levels and flows in the RSA, which may affect sediment transport, deposition and therefore benthic invertebrate habitat. Changes to average and upper and lower bounds of ambient temperatures may also affect aquatic habitat, which in turn may affect benthic invertebrate communities. Climate change over the life of the Project (i.e., 35 to 40 years) will be monitored as part of the Project's environmental monitoring programs, and influences on water quality, sediment quality, and benthic invertebrates will require adaptive management to mitigate any potential effects of the Project that may be exacerbated by climate-related changes on the aquatic environment.

8.4.8 Monitoring and Follow-up

For the purposes of this EIS, monitoring and follow-up are defined as follows:

- monitoring programs are designed to meet regulatory requirements (e.g., permit or license conditions) and/or to demonstrate compliance with environmental commitments made in the EIS; and
- follow-up programs are those that are proposed to address any uncertainties identified during the EA process (e.g., to verify predictions made during the EA; to determine the effectiveness of proposed and implemented mitigation measures) and to determine if and when to implement adaptive management measures.

Monitoring and follow-up are proposed for the Sediment Quality and Benthic Invertebrates VCs to verify the accuracy of the predicted effects and effectiveness of proposed mitigation measures. The sediment quality and benthic invertebrate monitoring program should be considered in conjunction with the surface water quantity (hydrology) (Section 8.1.8) and surface water quality (Section 8.2.8) monitoring programs as sediment quality and benthic invertebrate are specifically tied to surface water quantity and quality from the perspective of pathways of effects. Specifically, monitoring of TSS in the effluent monitoring ponds and other catchment ponds prior to discharge to the environment will be important to provide context to further evaluate Project-related effects on sediment and benthic invertebrate communities in the receiving water environment (i.e., Whitefish Lake).

The sediment quality and benthic invertebrate monitoring and follow-up program will have the following objectives:

- collecting and recording surface water quality to confirm that source and receiving water quality predictions for mobilization of solids are consistent with those presented in the EIS;
- monitoring to confirm that effluent and receiver sediment quality meet applicable regulation criteria; and
- monitoring benthic invertebrate community structure and abundance in the near-field discharge area to assess any changes that may be attributable to the Project.

The monitoring and follow-up program will include measurement of sediment quality parameters to meet regulatory criteria (i.e., provincial discharge permits, MDMER [Government of Canada 2022], and CSA N288.4-19 [CSA Group 2019]). At a minimum, this will include collection of non-radiological parameters (e.g., metals, nutrients, pH, and sulphate), radiological parameters, and physical characteristics (grain size).

Benthic invertebrate community monitoring will include the collection of samples following regulatory guidance (Government of Canada 2022) on proper collection and analysis to detect change in biota assemblages. This will include reasonable replication over a geographic area.

Metrics assessed will be associated with benthic invertebrate community diversity, evenness, density, taxa richness, and similarity indices.

Sediment and benthic invertebrate monitoring will occur in tandem and sampling locations will be co-located to facilitate comparison of benthic invertebrate community metrics with sediment quality characteristics.

Sediment and benthic invertebrate monitoring in the natural environment will occur at the point of discharge in Whitefish Lake South (near-field), at an upstream reference location (Whitefish Lake North), and at downstream locations (far-field). The far-field monitoring locations will be located in Whitefish Lake South prior to its discharge to McGowan Lake.

Constituent concentrations will be compared to the values used in the EIS and to applicable regulatory criteria or objectives.

Specific monitoring and follow-up plans for the Sediment Quality and Benthic Invertebrates VCs will be prepared to refine and finalize the approach and specific metrics following consultation with Indigenous groups, other stakeholders, and relevant federal and provincial agencies with interest in the development and implementation of this VC-specific program.

8.4.9 Sediment Quality and Benthic Invertebrates Summary

The Sediment Quality and Benthic Invertebrates VCs were selected for inclusion as Project activities have the potential to affect them via erosion-driven mobilization of suspended sediment, groundwater interactions with surface water features, and effluent discharge to the natural environment throughout all phases of development.

Baseline sediment quality surveys confirmed that the waterbodies in the LSA (i.e., McGowan Lake, Whitefish Lake North, and Whitefish Lake South) were dominated by clay substrates with silt and sand being present in lesser proportions. Sediment-metal concentrations in these waterbodies were variable. For parameters where sediment quality guidelines are available, all constituent concentrations were at or below their respective reference criteria or guidelines for the protection of aquatic life.

Benthic invertebrate communities were characteristic of depositional lake habitats (i.e., chironomids, midges, water fleas, and worms) in McGowan Lake and Whitefish Lake. Overall, diversity of the benthic invertebrate communities was highest in McGowan Lake followed by Whitefish Lake South and Whitefish Lake North.

The physical and chemical attributes of aquatic sediments directly influence benthic invertebrate community distribution, diversity, abundance, and health. Potential changes to water, from both a quantity and quality perspective, are key considerations within the EA process, as demonstrated by previous uranium mining development proposals in the Athabasca Basin, and draw a high level of concern from Interested Parties. Changes to surface water quality have the potential to influence sediment particle size and the chemistry and distribution within the aquatic environment, resulting in changes to biodiversity and biological function. Such effects are of interest with respect to the cultural values of Indigenous groups, the public, and other stakeholders.

Project activities may interact with Sediment Quality and Benthic Invertebrates during all Project phases. In general, the interactions can be characterized as being primarily associated with controlled, routine discharges from the site and mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. During Operation and Decommissioning, excess water from the effluent monitoring ponds will be released to the environment. Routine discharge of this sort will be directed to Whitefish Lake only. The reduction in surface drainage reporting to Whitefish Lake due to Project development may change water levels and flows in the receiving water, thereby influencing the depositional properties of the lake and the benthic invertebrates there. The installation of the pipeline and diffuser structure will result in the overprinting of a small proportion of the Whitefish Lake benthic substrate (less than 0.05%).

To minimize the residual effects of the Project on Sediment Quality and Benthic Invertebrates, Denison will develop and implement a Surface Water Management Program that provides an integrated framework to manage water quality and includes provision for water management practices for each of the primary site aspects, as well as areas of the site where there is contact water. This will include the collection and monitoring of contact water to determine whether treatment is required prior to release to the environment, which will inform optimal levels of treatment. This will also include the monitoring and management of effluent, including contingency for effluent treatment as may be required, so that water discharge objectives are achieved as defined by applicable provincial and federal regulatory instruments. This will mitigate effects associated with the mobilization of solids and changes to sediment quality that may affect benthic invertebrates. Denison will design the discharge diffuser/outfall to have the smallest footprint possible while still providing effective mixing and dilution such that discharge flows do not detrimentally affect sediments.

The assessment predicted residual effects on Sediment Quality and Benthic Invertebrates due to change in sediment quantity and physical quality (particle size), change in sediment quality (chemical), change in aquatic habitat (area), and change in water level or flow. However, with the implementation of appropriate mitigation measures and the effects being characterized as low magnitude, localized, and fully reversible, the residual effects on Sediment Quality and Benthic Invertebrates are predicted to be **not significant**.

Monitoring and follow-up are recommended for the Sediment Quality and Benthic Invertebrates VCs to verify the accuracy of the predicted effects and effectiveness of proposed mitigation measures. The sediment quality and benthic invertebrate monitoring program should be considered in conjunction with the surface water quantity (hydrology) (Section 8.1.8) and surface water quality (Section 8.2.8) monitoring programs as sediment quality and benthic invertebrates are specifically tied to surface water quantity and quality from the perspective of pathways of effects. Specifically, monitoring of TSS in the effluent monitoring ponds and other catchment ponds prior to discharge to the environment will be important to provide context to further evaluate Project-related effects on sediment and benthic invertebrate communities in the receiving water environment (Whitefish Lake).

8.5 Fish Health

This subsection addresses the potential effects of the Project on the Fish Health VC. The following are discussed herein as part of the EA:

- scope of the assessment;
- summary of existing conditions relevant to the Fish Health VC;
- identification and description of potential interactions between the Project and the Fish Health VC;
- identification and description of mitigation measures applicable to the Fish Health VC to eliminate, reduce, or control the potential adverse Project-related effects;
- identification and characterization of predicted Project-related residual effects on the Fish Health VC after mitigation;
- characterization of significance and assignment of the level of confidence in the predictions; and
- identification and characterization of potential cumulative effects.

Figure 8.5-1 is a graphic representation of the assessment process used in this EIS.

For reference, and as discussed in Section 8.5.1, the Fish Health VC is closely linked to, and follows directly from, the assessment of environmental pathways whereby fish could be exposed to Project-related emissions that could in turn affect their health. Health effects on fish due to exposure to chemicals in the environment are well established and such considerations form the basis of biological monitoring programs that are mandated through the MDMER (Government of Canada 2022).

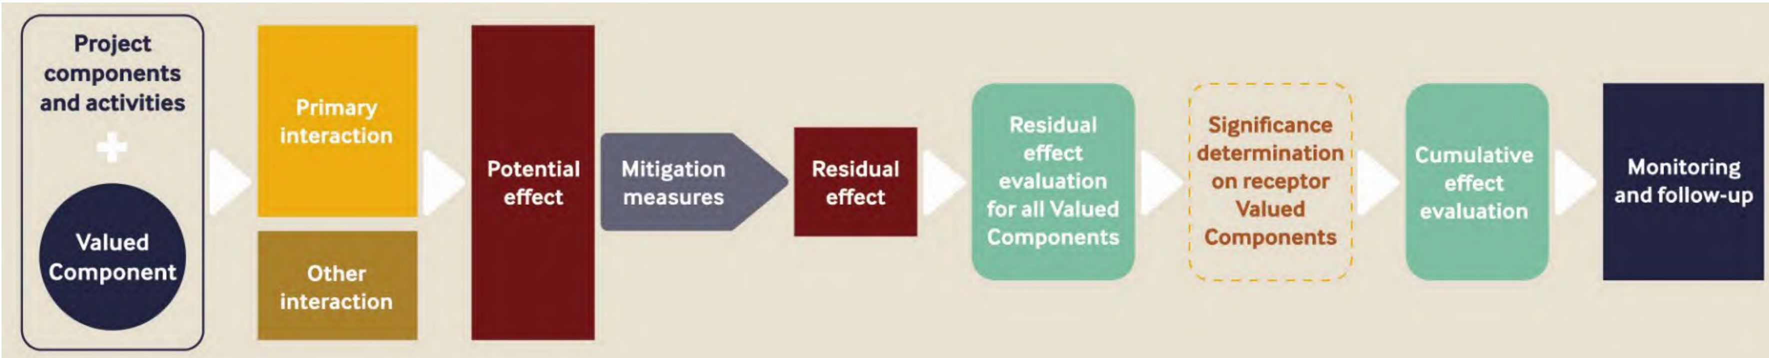

Figure 8.5-1: Environmental Assessment Process for the Wheeler River Project

8.5.1 Scope of the Assessment

The purpose of this assessment is to assess potential changes to Fish Health for all Project phases at the Project, local, and regional study areas scales. Pathways affecting Fish Health are directly associated with potential changes to intermediate VCs of Surface Water Quality and Sediment Quality. Fish rely on surface water and sediment as direct habitat within which they complete their life processes. These media sustain fish physiological processes and provide food sources (e.g., benthic invertebrates). Fish may be directly exposed to COPC in the aquatic environment, and COPC have the potential to be taken up by fish through processes such as respiration, ingestion, and absorption. As such, surface water and sediment quality, and changes thereof, can directly affect the receptor VC of fish health. Project-specific interactions with the Fish Health VC include those associated with potential changes to surface water and sediment quality, including site clearing and the potential for erosion-driven mobilization of suspended sediment into local surface waters; groundwater interactions with surface water features whereby constituents in groundwater are introduced to the surface water environment; and effluent discharge to the receiving environment whereby constituents in effluent are introduced to the receiving environment. The assessments of these pathways are considered in detail in other sections of this EIS and are summarized in this section as needed to support the assessment of Project-related effects on the Fish Health VC.

8.5.1.1 Valued Component Selection

The process and rationale for selection of VCs and establishment of KIs and associated MPs is described in Section 5. This section addresses the Fish Health VC. Changes to surface water quality and sediment quality have the potential to influence biodiversity and biological function through direct exposure and indirect food chain influences (i.e., fish health), and the cultural values of Indigenous groups, the public, and other stakeholders. In this context, Fish Health is interrelated or linked, to varying extents, to other VCs that are considered in this EIS, including:

Intermediate Valued Components:

Surface Water Quantity: Surface water flow volumes and periodicity directly influence water quality, bedload movement, and sediment deposition in a waterbody. Natural and seasonal changes in precipitation, and therefore water quantity, are directly related to water quality, sediment characteristics, and benthic invertebrate distribution. Project-related changes to surface drainage patterns, site water balance, and effluent discharge may influence water quantity, which in turn may influence the assimilative capacity of receiving waters, the movement of sediment, and sediment quality and invertebrates, which characterize the habitat and forage base of fish. Surface water Quantity may also influence the integrity of the aquatic ecosystem and, therefore, Fish Health.

Surface Water Quality: Surface Water Quality may affect the concentrations of constituents in sediments and the fish forage base, and consequently the bioaccumulation of COPC in fish tissues.

Groundwater Quantity and Quality: The quantity and quality of groundwater reporting to surface water through hydrologic connections may influence water quality in surface waterbodies and partitioning through sediments, and consequently the bioaccumulation of COPC in fish tissues.

Receptor Valued Components

Terrestrial Environment: Fish are a food resource for terrestrial fauna; therefore, Fish Health is linked to the function, biodiversity, and health of the terrestrial environment.

Fish and Fish Habitat: Fish habitat, as defined in subsection 2(1) of the *Fisheries Act* (Government of Canada 2019), includes all waters frequented by fish and any other areas upon which fish depend directly or indirectly to carry out their life processes. The types of areas that can directly or indirectly support life processes include, but are not limited to, spawning grounds, nursery habitats, rearing habitats, food supply areas, and migration areas. Alteration of Fish and Fish habitat through changes to Surface Water Quality and/or Sediment Quality may affect Fish Health.

Land and Resource Use: Indigenous Land and Resource Use and Other Land and Resource Use are influenced by Fish Health, and, specifically, concentrations of COPC in fish tissues that might influence harvest and consumption, particularly if guidelines are exceeded.

Figure 8.5-2 is a graphic representation of the main linkages among the Fish Health VC and other VCs, illustrating the flow of assessment information into and from the Fish Health VC.

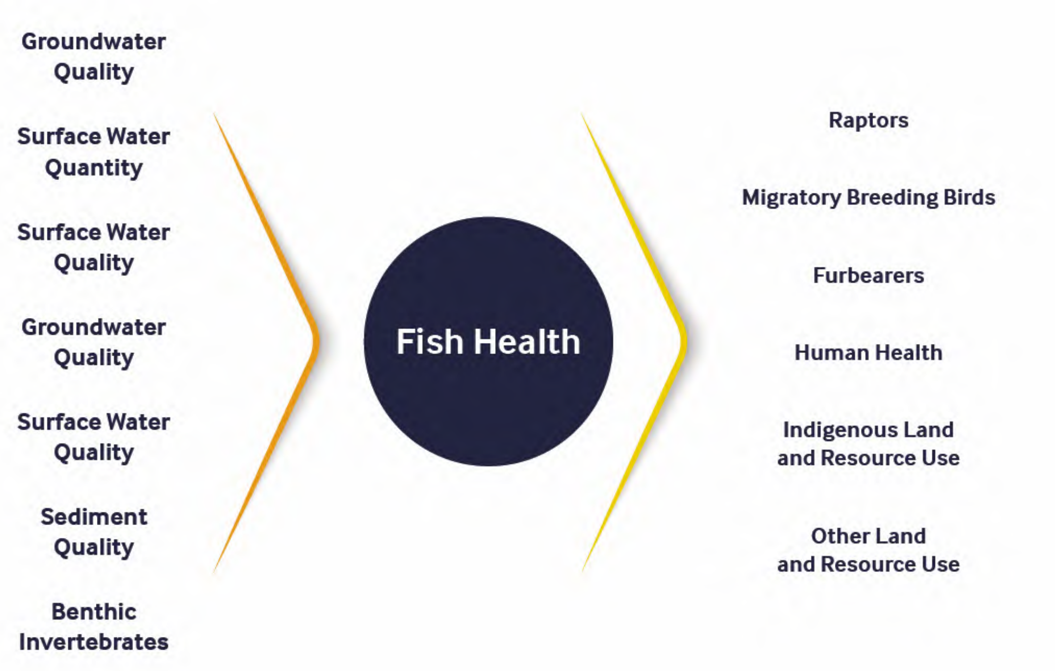

Figure 8.5-2: Integrated Assessment Approach - Key Connections between Fish Health and Other Valued Components

8.5.1.2 Key Indicators and Measurable Parameters

The KIs for the Fish Health VC include potential changes in surface water quality, sediment quality, and fish tissue COPC concentrations from baseline conditions. The rationale for each KI and the associated MPs are summarized in Table 8.5-1.

Table 8.5-1: Key Indicators and Measurable Parameters for the Fish Health Valued Component

Key Indicator	Rationale for Key Indicator	Measurable Parameter
Change in surface water quality from baseline conditions	Introduction of constituents into receiving waterbodies as a result of the Project that are of a magnitude to adversely affect aquatic biota associated with the waterbodies.	Change in the concentration of constituents that are directly related to Project activities, measured as a mass of a chemical per unit volume in water (e.g., mg/L).
Change in sediment quality from baseline conditions	Change in sediment quality as a result of the Project that is of a magnitude to adversely affect aquatic biota associated with the waterbody.	Introduction of constituents into the sediments of waterbodies as a result of the Project that are of a magnitude to negatively affect aquatic biota associated with the waterbodies.
Change in fish tissue COPC concentrations from baseline conditions	Introduction of constituents into receiving waterbodies (surface water and sediments) as a result of the Project that are of a magnitude to adversely affect aquatic biota associated with the waterbodies.	Change in the concentration of constituents that are directly related to Project activities, measured as a mass of a chemical per unit mass in fish tissue (e.g., mg/kg).

8.5.1.3 Spatial and Temporal Boundaries

Generic considerations associated with the establishment of the spatial boundaries of the assessment are described in Section 5.3.3. As it pertains to the Fish Health VC, the following is noted.

- The **Project Area** is the direct footprint of the Project. The Project Area represents the area within which Project activities and components may occur and, as such, represents the area within which direct physical disturbance may occur as a result of the Project, either temporary or permanent. (i.e., the area of maximum physical disturbance). This area is not VC-specific, but consistent throughout the EIS for all VCs.
- The **LSA** is the area that surrounds the Project Area where both direct and indirect effects resulting from Project activities can be reasonably measured. The LSA was established to assess the potential, largely direct effects of the Project and represents the extent to which there is a reasonable potential for the Project or Project-related activities to interact with and potentially adversely affect the VC. For the Fish Health VC, the LSA was derived from watershed boundaries within proximity of the Project Area, including portions of watersheds that overlap the Project site, as well as areas directly downstream that may be influenced by the Project site or effluent discharge. The subwatersheds within the LSA are presented in Figure 8.5-3. This area was selected based on important waterbodies (notably Whitefish and McGowan lakes)

downstream of the Project where effects may occur through all Project phases. The LSA extends from those waterbodies down to their inflows to Russell Lake.

- The **RSA** is the area that surrounds and includes the LSA, and was established to assess the potential, largely indirect effects of the Project, as well as other activities, in a regional context. The RSA is large enough to capture the extent of potential effects (i.e., zone of influence) on a VC and defines the area within which cumulative effects may occur (i.e., cumulative effects assessment boundary). The RSA for the Fish Health VC is bounded by the regional watershed area in which the Project Area is located. The RSA for this assessment is based on the whole watershed within which the Project is located and extends downstream to include Russell Lake (Figure 8.5-3).

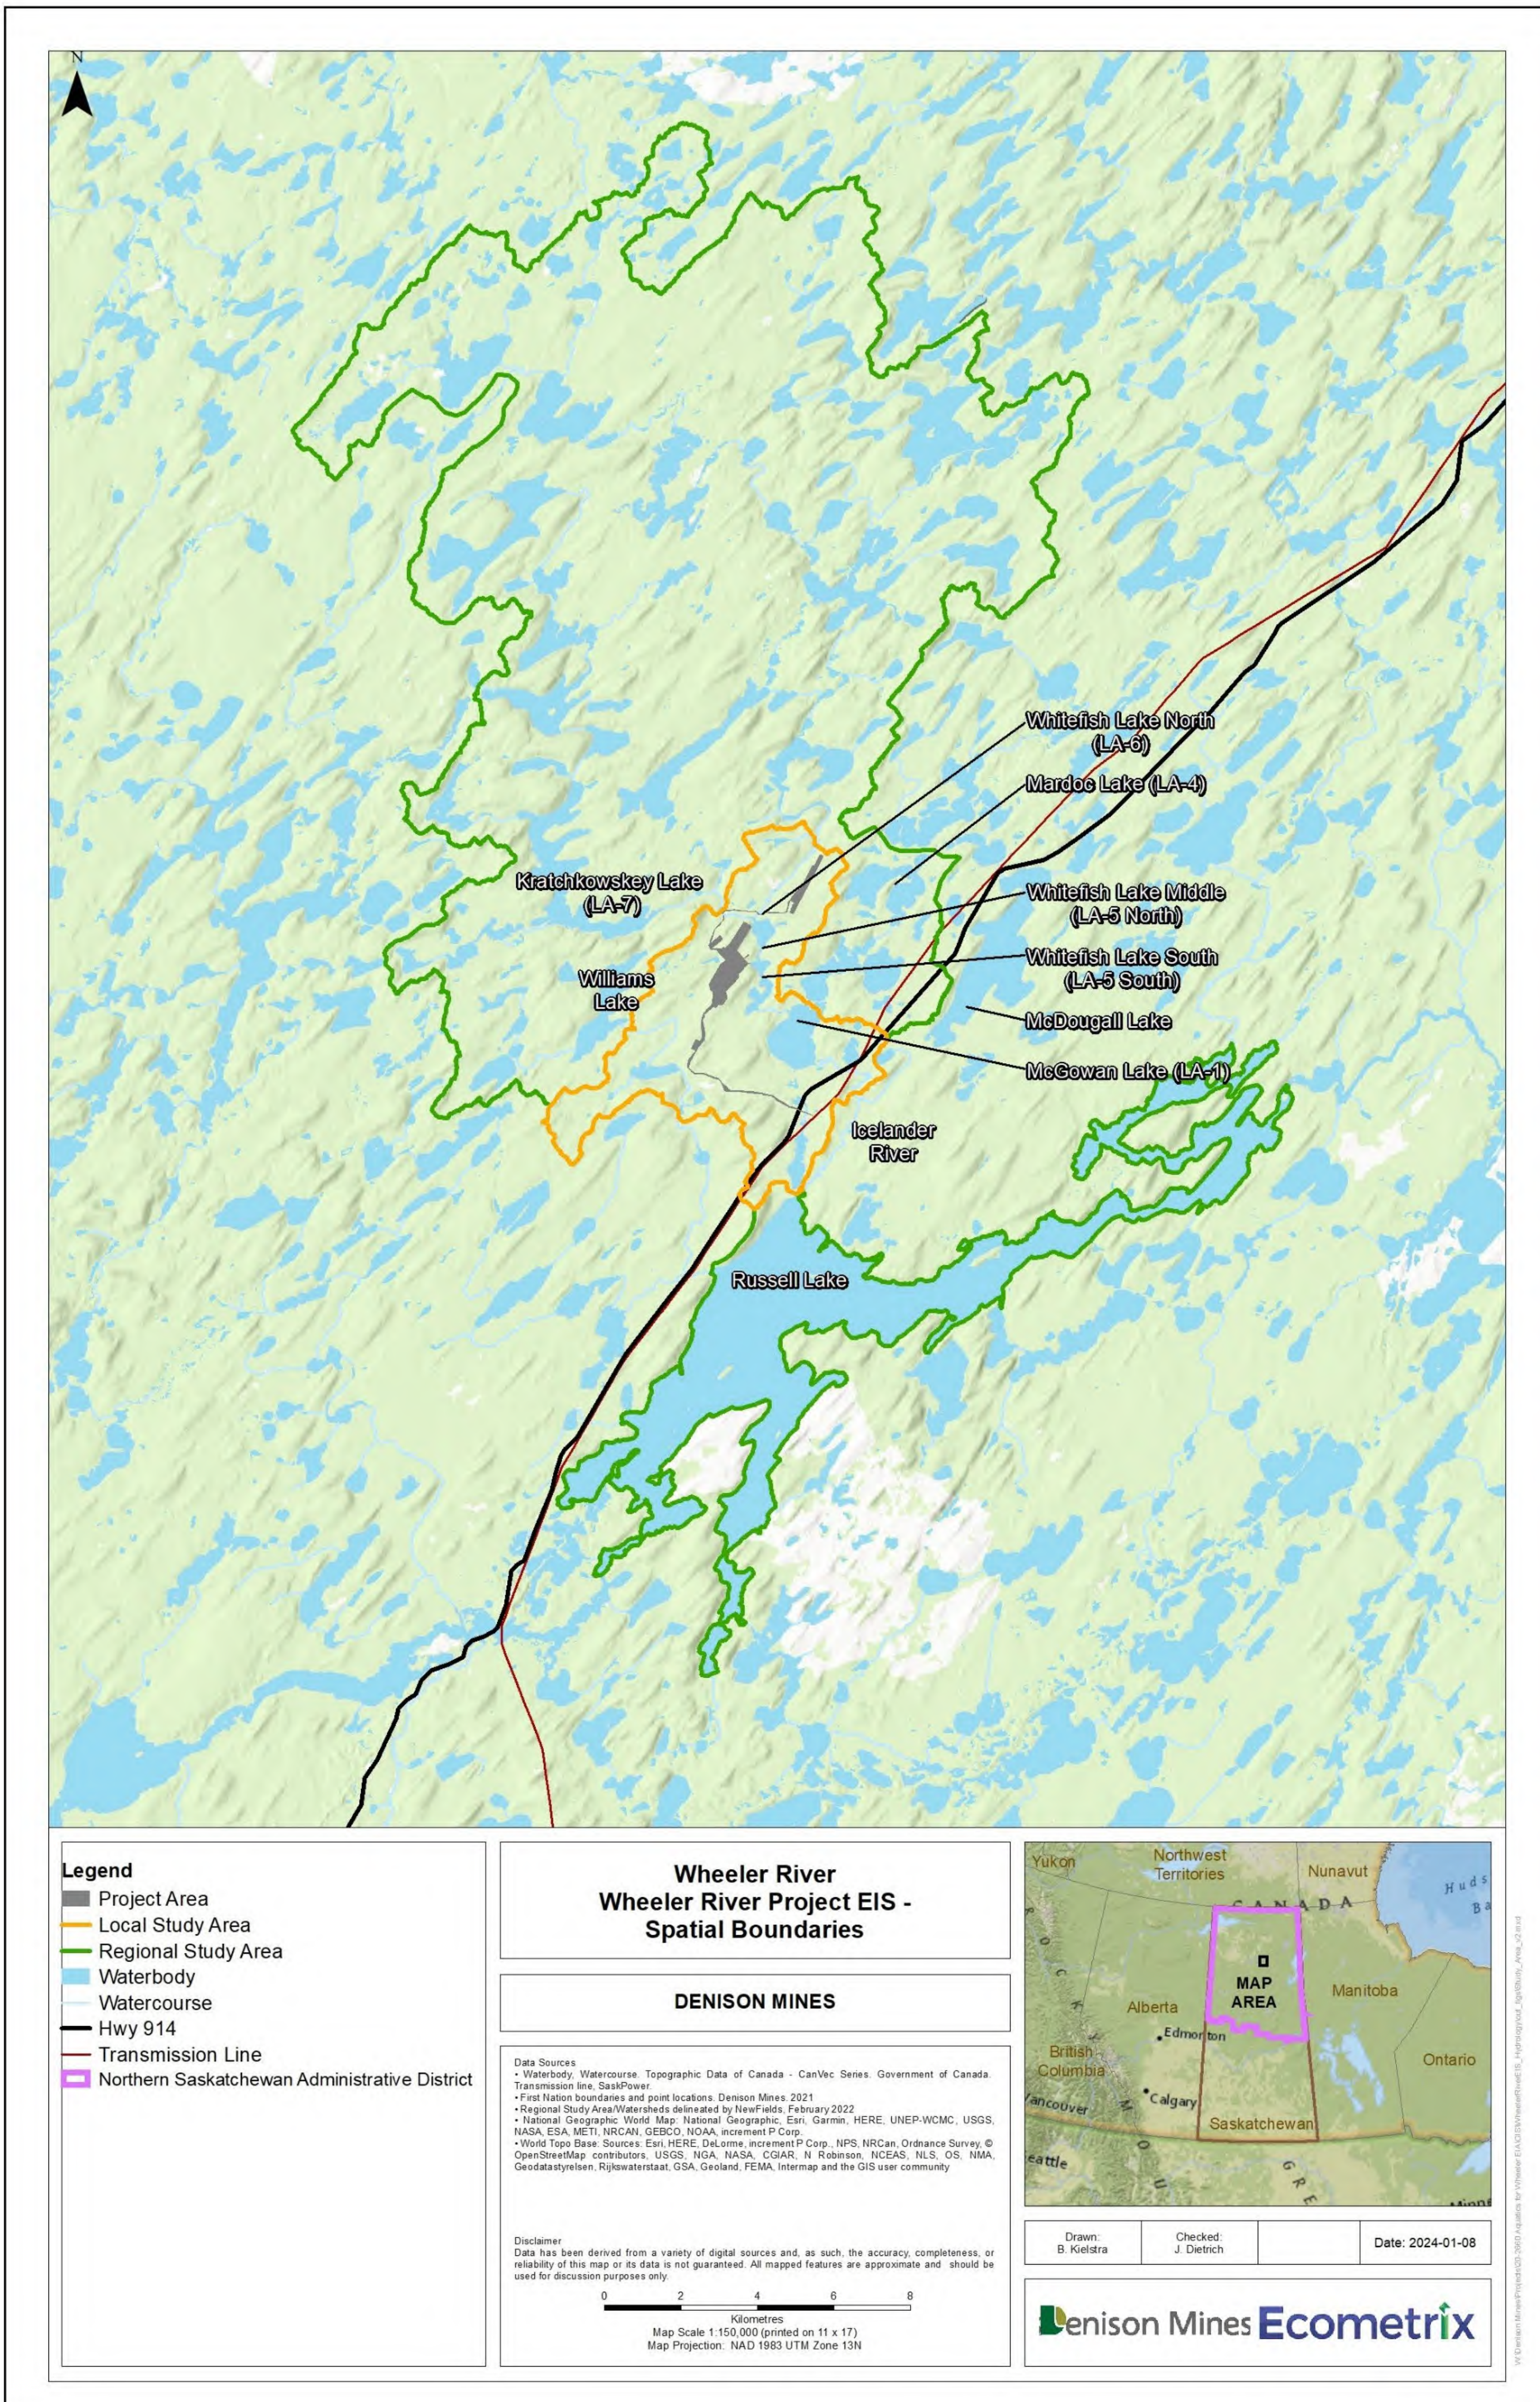

Figure 8.5-3: Spatial Boundaries for the Fish Health Valued Component

Temporal boundaries for the EIS are defined in Table 5.3-3 in Section 5.3.4. The temporal boundaries applicable to and considered in the EIS include the following Project phases:

- Construction (Year 1 to 3);
- Operation (Year 3 to 18);
- Decommissioning (Year 18 to 23); and
- Post-Decommissioning (Year 23 to 38).

Additionally, a "future centuries" scenario is considered to assess the potential effects post-restoration (i.e., beyond the Project timeline of 0-38 years) and to reflect the time period over which the highest constituent concentrations in groundwater are predicted to migrate towards and interact with surface water.

This period represents the time where the highest constituent concentrations in groundwater are predicted to interact with surface water based on groundwater modeling. In this context, the future centuries scenario is considered with respect to the interaction of groundwater migration from the Project site and its potential influence on surface water in local water bodies. The future centuries projection encompasses the long-term period during which slow migration of groundwater from the Phoenix Ore Zone area to the surface water environment is anticipated and constitutes a bounding scenario of maximum concentrations of COPC.

8.5.2 Influence of Indigenous Knowledge, Local Knowledge, and Engagement on the Assessment

At its broadest level, IK can be understood as the unique and collective knowledge of Indigenous peoples that may include, but is not limited to, the environmental, cultural, economic, political, and spiritual conditions of a community or region. In this section, IK and LK are viewed as complementary and influential alongside western science to produce a full understanding of the potential effects of the Project, whether measurable or perceived. Both forms of information have been given full and fair consideration.

Denison has recorded and stored information regarding IK, LK and engagement activities in an Engagement Database. Within the database, records are given unique identification numbers (e.g., 18-EN-ERFN-5.68). These numbers are referenced throughout the EIS, but particularly in Parts II and III, to indicate where specific information from the database has been integrated into the assessment. Appendix 8-A provides a summary of unique identification numbers referenced within Section 8.5.

Indigenous Knowledge and LK quotes and citations were included in this section to provide readers with the information considered as the Project advanced throughout the EA process. Since 2016, Denison has engaged with Interested Parties (i.e., local and Indigenous communities, residents, businesses, organizations, land users, and various regulatory authorities) to support the development of positive relationships and a mutual commitment to collaboration.

The history of resource sharing between Indigenous Peoples and Europeans in the Project RSA indicates the importance of natural resources to all peoples. Such partnerships were described during engagement with English River First Nation:

> "*The biggest body of water to be impacted is Russell Lake – "Big Poor Fish Lake" in Dené. A lot of Scandinavians and Norwegians went up there in the 1930s and partnered with First Nations in that territory*" (18-EN-ERFN-5.68).

The influence of IK, LK, and engagement on the assessment of the Fish Health VC has first and foremost shaped the shared value of water and its life-sustaining properties.

> "*The lands and waters, we are definitely connected as peoples of English River. If we don't have the lands, we are not connected. If we don't have the water... Water is life to us*" (ERFN and SVS 2022).

Comments associated with water management and discharge to the environment were significant in the engagement record[6], and these were considered within the context of community interest regarding surface waters remaining supportive of natural function for biota. To this end, Project-related water management and treatment are important to maintaining surface water quality within the LSA and RSA.

Indigenous peoples and LK holders were clear in their interest in the current levels of constituents in the aquatic ecosystem and the potential for adverse changes resulting from the Project, for example:

> "*How many lakes have you tested? Is there mercury?*" (19-EN-ML21-62.34).
>
> "*Russell is one lake where I commercially fish. How will this effluent impact the water quality, fish health? Will I be able to sell fish from here? If there is going to water pollution, I just want to know*" (19-LK-ERFNTrap-134.255).
>
> "*How are you going to protect the water quality? We are concerned about mercury in fish, other animals, etc. Is there mercury or arsenic in the uranium solution?"* (21-EN-LLRIB-392.15).
>
> "What is the plan for storing and cleaning the water and where does it flow? What is the impact of ISR mining on water quality? "(21-EN-VILX-443.25).

[6] 19-EN-MN-SR3-1.2, 19-EN-ML82-1.3, 19-EN-MOE-1.4, 18-EN-VILX-3.33, 18-EN-VILX-3.35, 18-EN-VILX-3.39, and 18-EN-VILX-3.84.

Indigenous peoples shared their interest regarding the effects that changes to water quality may have on fish health. As an example the ERFN Trapper shared that:

> *"Russell is one lake where I commercially fish. How will this effluent impact the water quality, fish health? Will I be able to sell fish from here? If there is going to water pollution, I just want to know"* (19-LK-ERFNTrap-134.255).

Indigenous Knowledge and LK clearly identified the importance of water quality to local community members, plants, wildlife, and fish health. This affirms the necessity to include Fish Health as a VC in the EIS. It is understood based on engagement that additional detail is expected with respect to the potential effects of the Project on surface water quality and Fish Health, and this section of the EIS is responsive to that expectation.

8.5.3 Existing Environment

Details pertaining to existing conditions related to Surface Water Quantity (Section 8.1), Surface Water Quality, (Section 8.2), Fish and Fish Habitat (Section 8.3), Sediment Quality and Benthic Invertebrates (Section 8.4), and Groundwater (Section 7) that are relevant to the Fish Health VC, as together they describe aquatic environment conditions, are presented elsewhere in the EIS. In this subsection, fish tissue chemistry data collected as part of the baseline aquatic environment program are summarized. These data have not been presented previously in this EIS but are relevant to the consideration of the Fish Heath VC. Detailed information regarding fish tissue data collection and analyses are provided in Ecometrix (2020).

Fish tissue (i.e., flesh and bone) samples were analyzed by SRC Environmental Analytical Laboratories (Saskatoon, Saskatchewan) for the full series of constituents. Fifteen samples collected in September 2016 were destroyed at the laboratory during an ashing oven malfunction prior to radionuclide analyses. Additional fish tissue samples collected in May and June 2017 were analyzed for radionuclides and trace metals to compensate for these lost samples.

During the fish community assessment, five samples from a predator species (i.e., Northern Pike [*Esox lucius*]) and five samples from a forage species (i.e., White Sucker [*Catostomus commersonii*]) were collected at each sampling location for analysis of metals and radionuclides. In most cases, each sample was comprised of a single fish; however, to make sure that a sufficient volume of tissue was retained for analysis, some samples were comprised of two or three fish. Lengths, weights, and ages of fish comprising the samples are provided by Ecometrix (2020). Fish were gutted at the location where they were collected, and remains were returned to the waterbody. Flesh was removed from the bone either at the sampling location or at the camp the same day as capture. Flesh and bones were stored separately in individual Ziploc bags labelled with the date, sampling location, fish species, specimen number, and an indication of whether the sample contained 'flesh' or 'bone'. The samples were then frozen until delivery to the analytical laboratory. Constituent concentrations in fish tissues were determined based on the 'raw weight' and were compared to relevant guideline values. Guideline values for constituents in fish tissue are available for mercury (Health Canada 2007) and selenium (BC MOE 2014; US EPA 2021. Health Canada's total mercury guidelines of 0.5 µg/g wet weight (ww) is a human health risk-based maximum permissible concentration applied to most species of commercially sold fish. The BC MOE selenium guideline of 4 µg/g dry weight (dw) and the US EPA selenium guideline of 11.3 µg/g dw for fish muscle provide fish tissue concentrations that are protective of the health of freshwater aquatic life.

Critical locations of interest for this assessment include the following nodes, which are coincident with baseline monitoring stations and/or watersheds of interest for the assessment (Figure 8.5-4; Table 8.5-2).

- SA-1 – Fish community and habitat survey location on the stream colloquially known as the Icelander River, which is located downstream of LA-1 (McGowan Lake).
- SA-2 – Fish community and habitat survey location situated downstream of the outflow from LA-5 (Whitefish Lake) and upstream of the inflow to LA-1 (McGowan Lake).
- SA-4 – Fish community and habitat survey location situated upstream of the inflow to LA-6 (Unnamed Lake).
- SA-5 – Fish community and habitat survey location situated upstream of the inflow to LA-6 (Unnamed Lake).
- SA-6 – Fish community and habitat survey location situated downstream of the outflow from LA-6 (Whitefish Lake North) and upstream of the inflow to LA-5 (Whitefish Lake South).
- LA-1 – McGowan Lake.
- LA-5 – Whitefish Lake South.
- LA-6 – Whitefish Lake North.

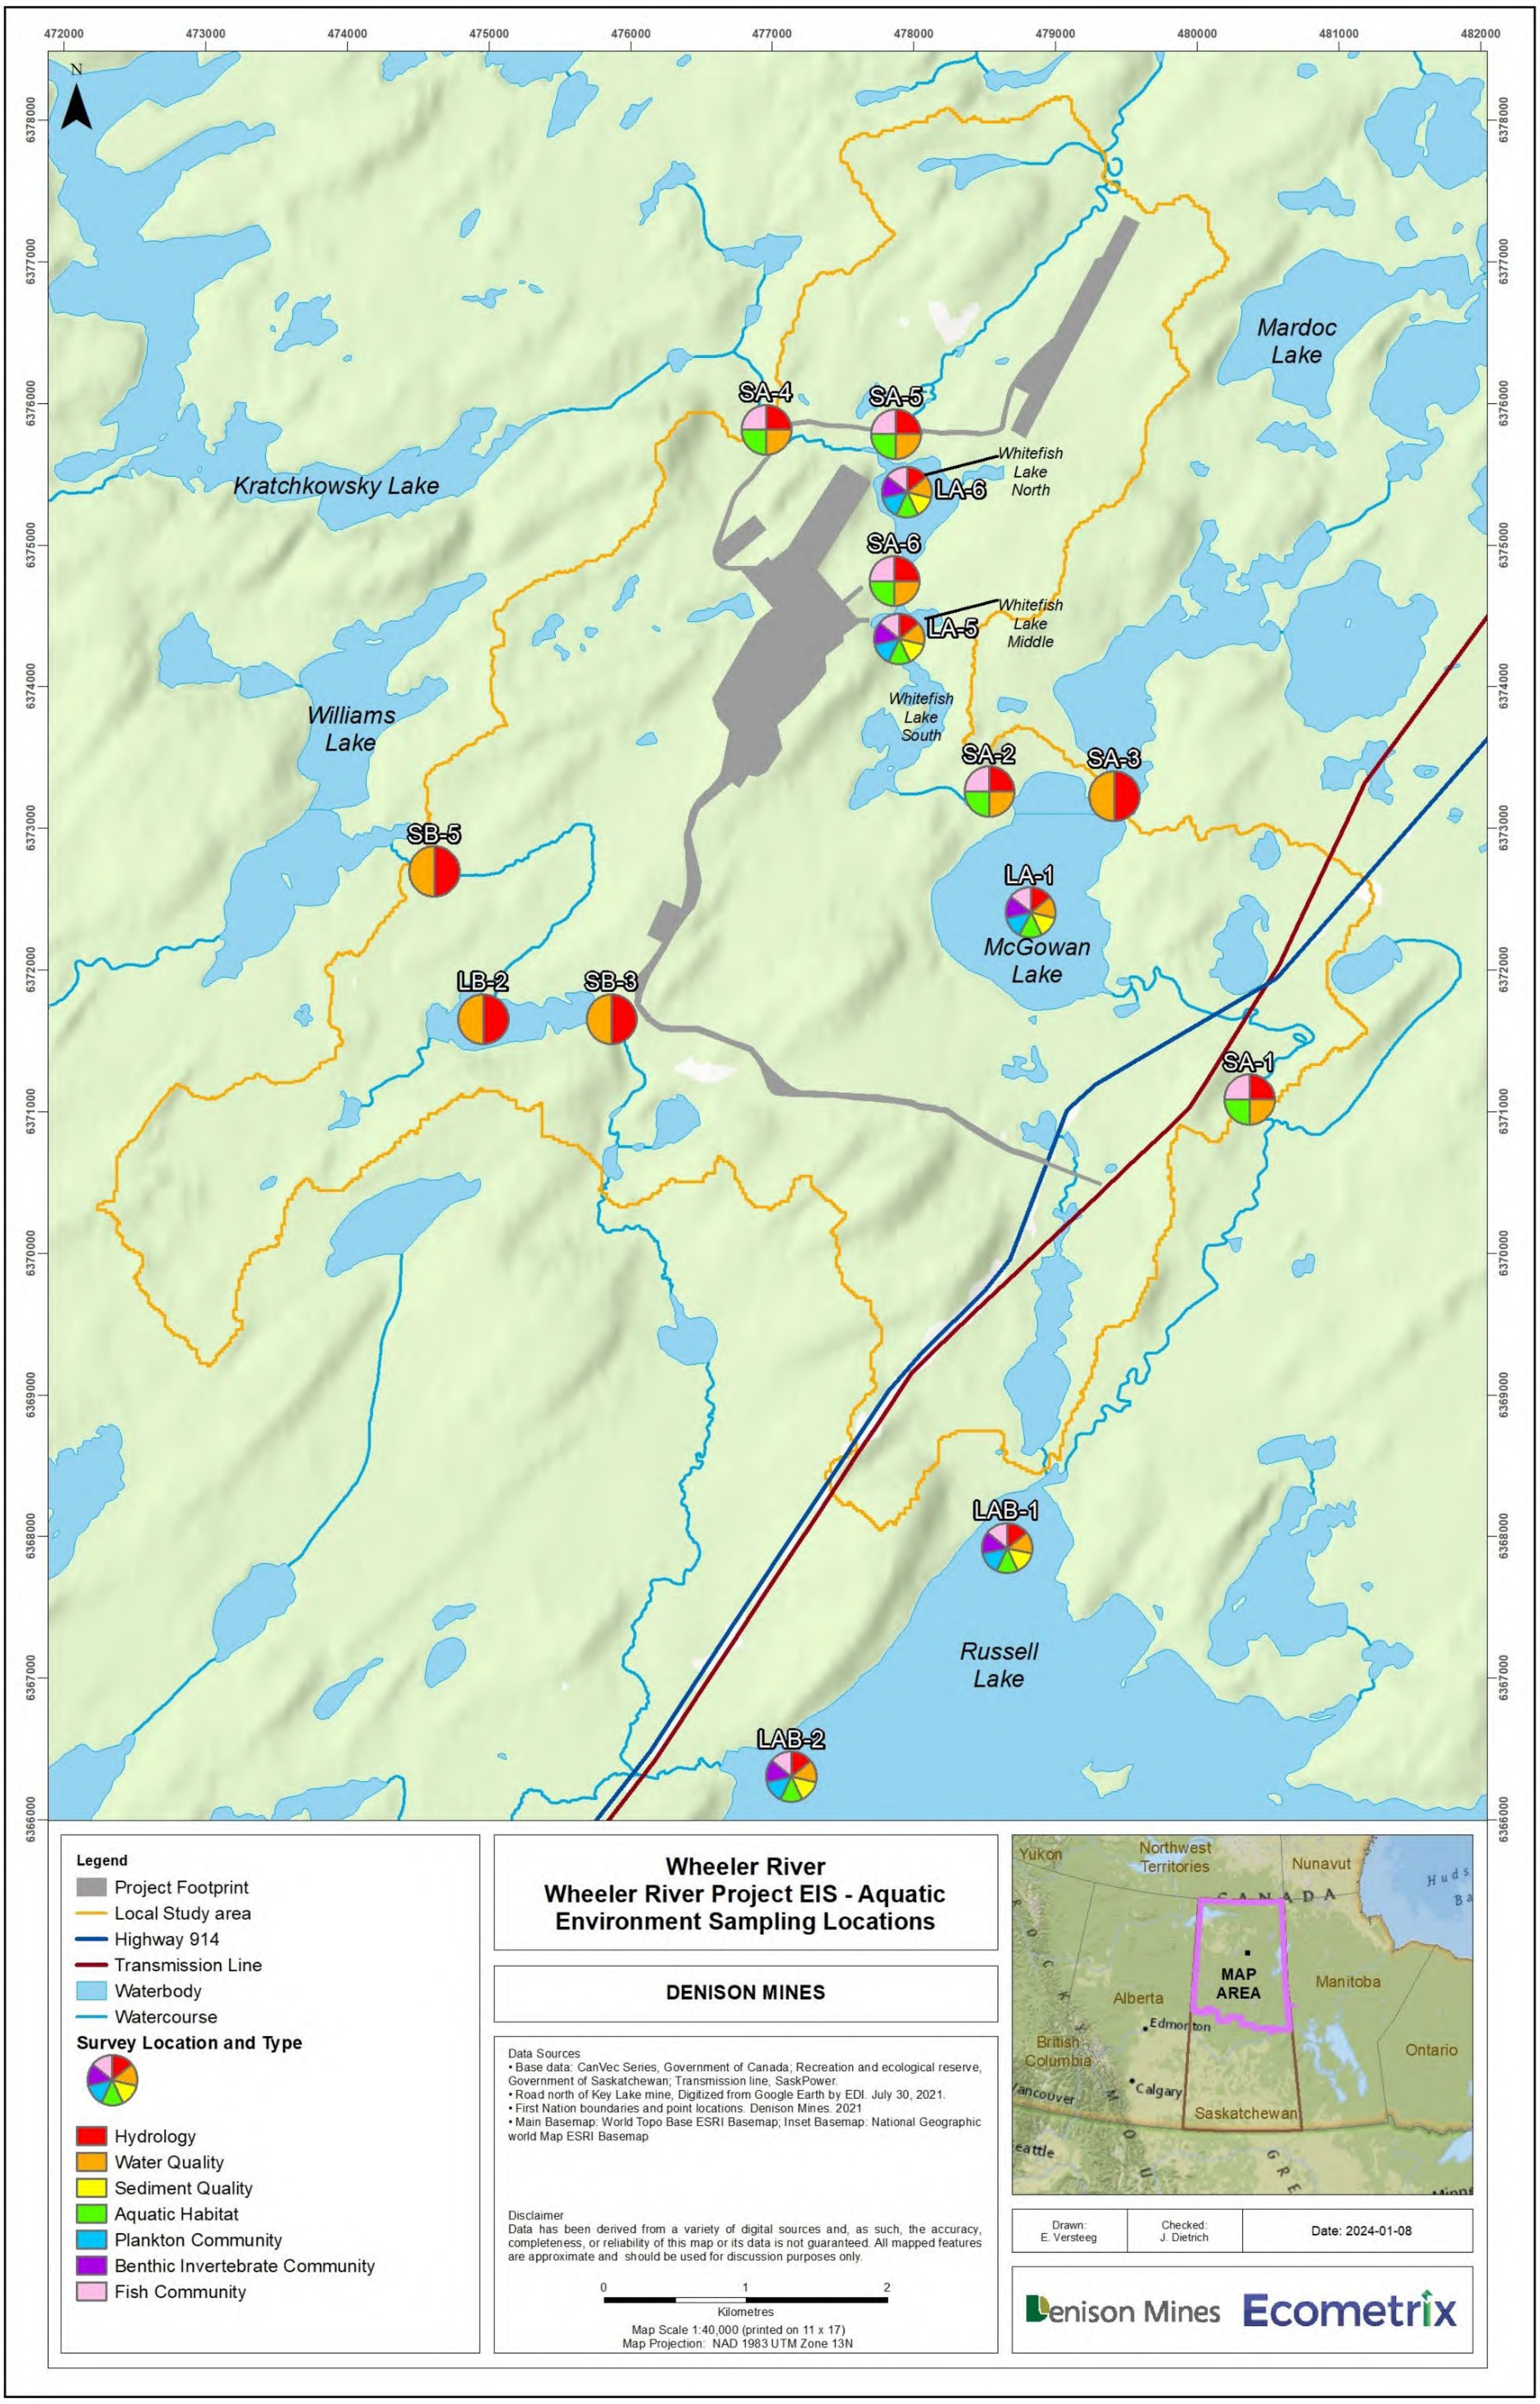

Figure 8.5-4: Water Quality, Biota, and Sediment Sampling Locations (2016 to 2018)

Fish bone and tissue samples for Northern Pike and White Sucker collected from McGowan Lake (LA-1), Whitefish Lake South (LA-5), Whitefish Lake North (LA-6), Kratchkowsky Lake (LA-7), and Russell Lake (LAB) were sent for chemical analysis. Summary results are presented in Table 8.5-2 for critical locations of interest within the LSA (i.e., McGowan Lake, Whitefish Lake North, and Whitefish Lake South), as well as for Russell Lake, which is the receiving waterbody. Detailed results, including additional constituents that were tested for and their summary stats, are provided in Ecometrix (2020).

In McGowan Lake, mean total mercury concentrations in Northern Pike (mean 0.17 ug/g ww) and White Sucker (mean 0.038 ug/g ww) tissue were below the Health Canada guideline of 0.5 ug/g ww. Mercury concentrations were higher in Northern Pike than in White Sucker, reflecting bioaccumulation through the aquatic food chain. Selenium concentrations in Northern Pike (mean 1.00 ug/g dw) and White Sucker (mean 1.29 ug/g dw) tissues were below the BC MOE and US EPA guidelines of 4 µg/g dw and 11.3 µg/g dw, respectively.

In Whitefish Lake South, total mercury concentrations in Northern Pike (mean 0.16 µg/g ww) and White Sucker (mean 0.045 µg/g ww) tissue were below the Health Canada guideline of 0.5 µg/g ww. Total mercury concentrations were higher in Northern Pike than in White Sucker, reflecting bioaccumulation through the aquatic food chain. Selenium concentrations in Northern Pike (mean 0.81 µg/g dw) and White Sucker (mean 1.03 µg/g dw) tissue were below the BC MOE and US EPA guidelines of 4 µg/g dw and 11.3 µg/g dw, respectively.

In Whitefish Lake North, total mercury concentrations in Northern Pike (mean 0.19 µg/g ww) and White Sucker (mean 0.04 µg/g ww) tissue were below the Health Canada guideline of 0.5 µg/g ww. Mercury concentrations were higher in Northern Pike than in White Sucker, reflecting bioaccumulation through the aquatic food chain. Selenium concentrations in Northern Pike (mean 0.92 µg/g dw) and White Sucker (mean 0.97 µg/g dw) tissue were below the BC MOE and US EPA guidelines of 4 µg/g dw and 11.3 µg/g dw, respectively.

In Russell Lake, total mercury concentrations in Northern Pike (mean 0.27 µg/g ww) and White Sucker (mean 0.027 µg/g ww) tissue were below the Health Canada guideline of 0.5 µg/g ww. Total mercury concentrations were higher in Northern Pike than in White Sucker, reflecting bioaccumulation through the aquatic food chain. Selenium concentrations in Northern Pike (mean 1.62 µg/g dw) and White Sucker (mean 2.15 µg/g dw) tissue were below the BC MOE and US EPA guidelines of 4 µg/g dw and 11.3 µg/g dw, respectively.

When selenium concentrations in fish are compared to the recently published ECCC FEQG (2022), fish concentrations are below the whole body and egg-ovary guidelines at all locations.

Table 8.5-2: Baseline Fish Tissue Chemistry Summary Values for Waterbodies Within the Local Study Area and Russell Lake

Parameter	Statistic	McGowan Lake (LA-1)				Whitefish Lake South (LA-5)				Whitefish Lake North (LA-6)				Russell Lake (LAB)			
		Northern Pike		White Sucker		Northern Pike		White Sucker		Northern Pike		White Sucker		Northern Pike		White Sucker	
		Bone	Tissue	Bone	Tissue	Bone	Tissue	Bone	Tissue	Bone	Tissue	Bone	Tissue	Bone	Tissue	Bone	Tissue

8.5.4 Assessment of Project-related Effects

8.5.4.1 Potential Interactions Between the Project and Valued Component / Key Indicators

The Project will require the construction, operation, and decommissioning of several components (as described in Section 2). Potential interactions between Project activities and the Fish Health VC are summarized by Project phase in Table 8.5-3 and are ranked as:

- Primary Interaction (✓): Project activity is expected to interact with the VC/KI, which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.
- Other Interaction (✓): Project activity is expected to interact with the VC/KI. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects.
- Project activity is not expected to interact with the VC/KI, no adverse effects are expected, and a rationale is provided for not considering this potential interaction further.

Based on professional judgment and understanding of the nature of Project activities and their sequencing, the Project activity list was reviewed to determine the type of interactions. Potential Project-related effects are discussed in Section 8.5.4.2. Primary Project activities with the potential for adverse effects on Fish Health (i.e., flagged as 'Primary Interactions') are expected to involve surface land clearing, major earthworks, surface/grading preparations, changes to land cover, water management feature construction and function, and water taking and effluent discharge. Other Project activities (i.e., flagged as 'Other interactions') refer to those activities that may be associated with hydrogeological influences on local waterbodies and are expected to be secondary contributors to potential adverse effects. The remaining activities (e.g., power generation and supply) were deemed to have no interaction and was not carried forward in the assessment as they are not expected to result in detectable changes in the MPs associated with Fish Health. Activities during Post-Decommissioning (e.g., site inspections; monitoring and on-site engagement with Interested Parties) were deemed to have no interaction because they do not involve any land clearing, surface preparations, or major earthworks.

Table 8.5-3: Potential Project Interactions for Fish Health

8.5.4.2 Potential Project-related Effects

Potential Project-related effects on Fish Health are directly related to changes in surface water quality and are assessed on this basis. Project activities may interact with surface water quality and, therefore, fish health during all Project phases. In general, the interactions can be characterized as being primarily associated with controlled, routine discharges from the Project site. During site preparation and construction, the primary effect pathway relates to the mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. During Operation and Decommissioning, excess water from the effluent monitoring ponds will be released to the environment. Routine discharge of this sort will be directed to Whitefish Lake only. Direct discharge of treated effluent to the natural environment has the potential to change surface water constituent concentrations. Constituents of potential concern in the aquatic environment have the potential to be taken up by fish through fish life functions (i.e., respiration, ingestion, and absorption). Decommissioning will involve the restoration of natural site drainage to the Whitefish Lake receiver and, similar to Construction, Decommissioning activities have the potential to increase the mobilization of suspended solids into natural surface waters. The following sections discuss each predicted effect.

8.5.4.2.1 Mobilization of Suspended Materials

Construction

The primary effect pathway during Construction relates to the mobilization of suspended material into natural surface water features as a result of land disturbance and clearing. According to the site water balance (Figure 2.2-14 in Section 2), there is no planned discharge to Whitefish Lake during Construction. The mobilization of suspended material into natural surface water features is readily mitigatable by virtue of the mine development plan and through the implementation of standard water management and sediment control practices. Water management infrastructure (e.g., collection ditches, ponds, pumping stations) and various aspects of the water management and sediment control management systems will be put into place coincident with the initiation of construction activities. Waters (e.g., runoff) associated with areas under development will be collected and stored within management infrastructure (e.g., clean waste rock pond, Figure 2.2-14 in Section 2). In the event that releases to the natural environment are necessary, they will only occur once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). No downstream effects on surface waters, natural sediments, or fish health are expected.

Operation

During Operation, mobilization of suspended materials will be managed through the development and operation of water management infrastructure and implementation of the Surface Water Management Program. Releases of contact water to the natural environment will be directed through applicable collection ponds, IWWTP, and Effluent Monitoring and Release Ponds. Discharge will only occur once it is safe to do so (i.e., suspended solids levels in the water would be at acceptable levels). Denison may employ active means (e.g., filtering), if required, to achieve low TSS levels in discharge, in addition to passive means, such as settling and clarification in the IWWTP to manage TSS in the effluent stream to low levels. No downstream effects on surface waters, natural sediments, or fish health are expected.

Decommissioning and Post-Decommissioning

During Decommissioning and Post-Decommissioning, the site-wide management system will continue to operate such that Denison will maintain control of the site aspect affected water through the IWWTP. Surface drainage during Decommissioning activities will continue to be directed to the system of collection ponds, IWWTP, and Effluent Monitoring and Release Ponds to facilitate the control of suspended solids and achieve low TSS levels in the discharge, thereby minimizing any potential for adverse changes to water quality, sediment quality, sedimentation, fish health.

8.5.4.2.2 Controlled Discharge to Receiving Environments

Construction

Discharge to the environment is not expected during Construction. Site contact water will be collected and held in the Clean Waste Rock Pond (Figure 2.2-14 in Section 2). Therefore, potential effects of discharge on the Fish Health VC are not expected.

Operation

Denison does not intend to include constant freshwater withdrawal or effluent discharge throughout Operation; however, for the purpose of assessing the scenario of greatest potential effects, the Project was assessed as having a continuous freshwater withdrawal rate of 40.5 m^3/hr and a continuous effluent discharge rate of 36.5 m^3/hr (Figure 2.2-15 in Section 2).

Fish Health was assessed as an ecological receptor as part of the *Wheeler River Environmental Risk Assessment* (Appendix 10-A in Section 10). The potential effects on Fish Health were assessed based on pathways through surface water quality and sediment quality for both radiological and non-radiological constituents.

Surface water and sediment quality modeling were completed using IMPACT™ version 5.6.0. The IMPACT™ programming code is consistent with the COPC transport equations outlined in CSA N288.1-20 (CSA Group 2020). The modeling is discussed in detail in the *IMPACT™ Model Report for the Wheeler River Project* (Appendix A of Appendix 10-A of Section 10). Waterbodies from Whitefish Lake to the Russell Lake inlet were modelled in IMPACT™ to assess the effects of the Project on the downstream environment, including the following distinct water polygons: Whitefish Lake Middle, Whitefish Lake South, McGowan Lake, and Russell Lake. Kratchkowsky Lake and Whitefish Lake North were modelled as reference locations. The geometric mean of measured water concentrations from baseline studies performed between 2011 and 2019 (Ecometrix 2019) were selected as the baseline concentrations for constituents that had measured data over the detection limit. Sediment baseline concentrations were predicted from surface water concentrations using the partitioning coefficients that are based on regional published values that have been calibrated at similar sites in northern Saskatchewan and were checked against data collected for the Project. The assessment of potential Project emissions (effluent) on water quality was based on estimated effluent concentrations of COPC as presented in Table 8.2-9 (Section 8.2.4.2.3).

Surface Water Quality

The estimation of potential changes in surface water quality as a result of effluent discharge to the environment are discussed in Sections 8.2.4.2.2, 8.2.4.2.3, and 8.2.4.2.4. These subsections discuss the methods, assumptions, and results of predictive models used to assess the potential effects on the receiving environment in the LSA.

The near-field analysis (Section 8.2.4.2.3) identified that under all flow regime scenarios (i.e., 7Q10, monthly low, and monthly average), constituents are expected to be well mixed within LA-5 and below the most restrictive criteria for the protection of aquatic life (Table 8.2-10; Appendix 8-E). Under induced water quality criteria chromium, copper, molybdenum, and selenium do not meet criteria for the protection of aquatic life, but these are conservative estimates and not yet based on BATEA. Additionally, the extent of the mixing zone in Whitefish Lake is estimated to be less than 5 m under all flow scenarios assessed (Table 8.2-11).

A regional surface water quality model was used to predict effects on surface water quality within Whitefish Lake outside the initial mixing zone (Section 8.2.4.2.4). When the treated effluent is released to Whitefish Lake (LA-5), surface water concentrations were predicted using IMPACT according to the equations outlined in the IMPACT model (Section 2.2.2 in Appendix A of Appendix 10-A in Section 10). The predicted maximum concentrations of COPC in water are summarized in Table 8.2-13. No predicted exceedances of water quality guidelines were identified for any of the COPC during Construction, Operation, or Decommissioning, with the exception of copper where baseline concentrations exceed the FEQG (due to the copper analytical detection limit being equal to the FEQG) and the guideline does not consider conditions expected during operations.

Sediment Quality

Sediment quality predictive modeling was completed using IMPACT version 5.6.0. IMPACT is consistent with the COPC transport equations outlined in CSA N288.1-20 (CSA Group 2020). The modeling is discussed in detail in the *IMPACT Model Report for the Wheeler River Project* (Appendix A of Appendix 10-A in Section 10). The geographic area assessed was consistent with the area identified for surface water quality. The results of this modelling are discussed in Section 8.4.4.2.3. Sediment baseline concentrations were predicted from surface water concentrations using the partitioning coefficients, which consist of regional published values that have been calibrated on similar sites in northern Saskatchewan and have been checked against data collected for the Project. Predicted concentrations of most COPC did not exceed sediment quality guidelines; however, molybdenum and selenium exceeded reference level values, but not no-effect (NE2) level as developed by Burnett-Seidel and Liber (2013) for application at Saskatchewan uranium operations (Appendix 10-A).

The Ecological Risk Assessment (Appendix 10-A) estimated dose and risk to representative aquatic receptors, including fish, during all Project phases, including the pathway through water quality and sediment quality. The potential for ecological effects was assessed by comparing exposure levels to toxicological benchmarks, and the potential effects were characterized quantitatively in terms of total HQs. A total HQ greater than one indicates adverse effects may be possible for a given ecological receptor and further investigation is warranted.

Risk to Fish Health

No significant adverse effects on aquatic populations or communities (including fish) as a result of releases from the Project were predicted during the Project phases. Estimated total HQs for all COPC for all ecological receptors were predicted to remain below the HQ benchmark of 1 (Table 8.5-4) with the exception of copper. Under baseline conditions (for hardness and pH), HQs for copper exceed the HQ of 1 for benthic invertebrates (all locations) and predatory fish (Whitefish Lake Middle and South). Under site operational conditions during periods of treated effluent discharge, the HQs for copper are below 1 (Section 10, Appendix 10A, Section 6.3.2).

An HQ is not typically calculated for radiological risk; however, a comparison of the total radiological dose (baseline plus Project) against the ecological dose benchmarks is presented as part of the Ecological Risk Assessment (Appendix 10-A).

There were no predicted exceedances of the 9.6 mGy/d radiation dose benchmark for aquatic biota in the Project area, LSA, or RSA during any phase of the Project. This includes Whitefish Lake, McGowan Lake, and Russell Lake as exposure locations, as well as Kratchkowsky Lake as a reference location. All predicted doses were predicted to be well below the radiation dose benchmarks (Appendix 10-A).

Table 8.5-4: Estimated Non-radiological Total Risk to Fish Ecological Receptors

Fish Tissues

The recommended US EPA criterion for selenium in fish tissue (i.e., 11.3 mg/kg dw muscle; US EPA 2021) was used for large-bodied fish included in this assessment (i.e., Northern Pike and White Sucker). To compare against predicted selenium fish tissue concentrations that are in ww, the criterion needed to be adjusted from a dw to a ww basis based on the moisture content of the fish tissue collected. The dw to ww ratio of 0.25 to 1.0 from CSA N288.1-20 (CSA Group 2020) was used to convert the selenium criterion to a fresh weight (fw) basis (Appendix 10-A in Section 10).

Fish Tissue Criterion (mg/kg fw) = Fish Tissue Criterion (mg/kg dw) * 0.25 (kg dw/kg fw)

Therefore, the recommended criterion for selenium in fish tissue on a fw basis is 2.83 mg/kg ww muscle. The concentration of selenium in fish tissue is predicted to increase during Operation to an upper bound selenium concentration of 1.49 mg/kg (ww) for Northern Pike and 2.28 mg/kg (ww) for White Sucker; both of these vales are below the US EPA criterion for selenium. Following cessation of effluent discharge to the aquatic environment, selenium concentrations in fish tissues are predicted to return to background condition (Figure 8.5-5).

For other COPC assessments of risk to fish health (including molybdenum), a toxicity reference value was used. Toxicity reference values for aquatic biota, such as fish, are based on water concentrations. An HQ was used to provide a quantitative estimate of overall risk to fish health. For fish, the HQs were estimated as the ratio between the water concentration and the fish toxicity reference value. The predicted HQs for fish were less than one for all COPC during all phases of the Project (Table 8.5-4 and Appendix 10-A in Section 10) with the exception of copper (Section 10, Appendix 10A, Section 6.3.2). HQs for copper exceed the HQ of 1 under baseline conditions for predatory fish in Whitefish Lake Middle and South. Under site operational conditions during periods of treated effluent discharge, the HQs for copper are below 1(Section 10, Appendix 10A, Section 6.3.2). Risk to fish health is not expected.

Local Indigenous communities have expressed direct concern with respect to mercury. Mercury has not been identified as a COPC for the Project as it is currently not present in the receiving environment (i.e., background condition) at detectable concentrations and will not be produced as part of the mine process and therefore, not discharged to the aquatic environment. However, it is understood that potential nutrient enrichment-related effects are possible and can be linked to increases in mercury in the environment. Denison notes that there is potential for increased methylmercury production in the receiving environment under a certain combination of factors to which the Project may contribute, such as increased nutrient levels in the environment; and will undertake monitoring or total mercury and methylmercury in the aquatic environment over the life of the Project. Further details of such monitoring are provided in Section 8.5.8.

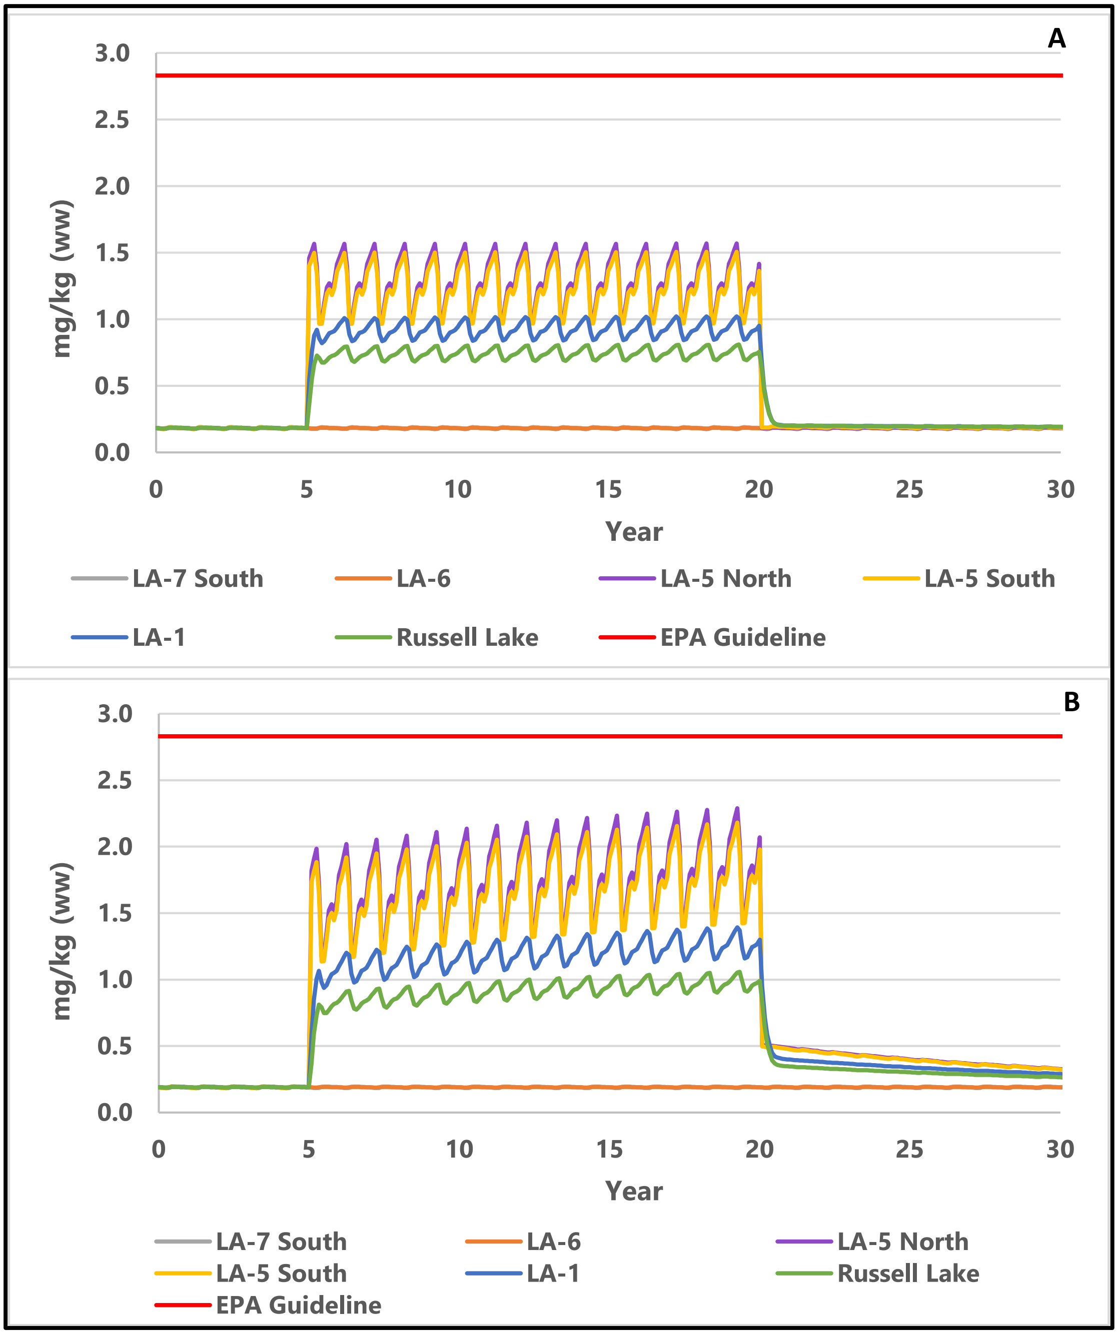

Figure 8.5-5: Predicted Selenium Concentrations in Fish Tissues Against Criterion for Key Indictor Species (A) Northern Pike (B) White Sucker

Decommissioning and Post-Decommissioning

Discharge to the aquatic environment of Whitefish Lake during some portion of Decommissioning is expected. Effluent rates during Decommissioning are expected to be less than during Operation. Effluent water quality is also expected to have lower levels of COPC compared to Operation. Therefore, the analysis of the potential effects on the Fish Health VC via surface water quality and sediment quality pathways during Operation provided in Section 8.5.4.2.2 is considered the bounding scenario for Decommissioning as well. No effects on sediment quality are expected as a result of effluent discharge.

8.5.4.2.3 Long-Term Transport of Groundwater Solutes to Whitefish Lake in Future Centuries

During the 'future centuries' phase as described in Section 8.5.1.3, remediation works will be completed, and the site naturalized, thereby restoring drainage patterns to report to surface waterbodies. As indicated in Section 7 of the EIS, groundwater plumes may develop from residual mass remaining post mining based on bench-scale lab tests of core flushing, and numerical modelling of reactive fate and transport.

Groundwater flow and reactive transport of dissolved constituents were modelled using three-dimensional modelling whereby the reactions were computed using PHREEQC and the transport was computed using FEFLOW (Ecometrix 2022). Groundwater flow observed, and simulated in the calibrated groundwater model, travels eastward from the mining zone within the Lower Sandstone Aquifer before moving upward through the Desilicified Zone in the Athabasca Sandstone and overlying overburden deposits toward Whitefish Lake. Modelled transport of dissolved constituents along the groundwater flow path allowed for interactions of the dissolved constituents with the geologic media through which they are flowing. Due to the relatively low groundwater velocities between the mining zone and Whitefish Lake and chemical reactions along the groundwater flow pathway, the "Future Centuries" scenario spans 100s to 1000s of years.

The results of the numerical modelling, as provided in Section 7 and Appendix 10-A in Section 10, support the conclusion that with the implementation of appropriate mitigation during the decommissioning and restoration phase of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect to surface water. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future from the deep Ore Zone to Whitefish Lake remain below fresh water environmental quality criteria in Whitefish Lake.

For the COPC identified in the effluent, the predicted mass flux from groundwater into Whitefish Lake starting 200 years after the Project phases during the future centuries was added into the IMPACT model to predict the surficial sediment concentrations over time at the exposed locations (see Table 8.5-5). As shown in the ERA (Appendix 10-A in Section 10), predicted surface water concentrations at all locations are expected to be below water guidelines for the protection of aquatic life, except for copper where incremental increase in concentration is predicted such that the predicted copper concentration (0.0006 mg/L) would be greater than the FEQG of 0.0002 mg/L under baseline conditions, indicating a slight increased level of risk to the most sensitive aquatic biota.

Table 8.5-5: Predicted Maximum Concentrations of Sediment Constituents of Potential Concern during Future Centuries

Constituent	Unit	Kratchkowsky Lake (LA-7)	Whitefish Lake North (LA-6)	Whitefish Lake Middle (LA-5 North)	Whitefish Lake South (LA-5 South)	McGowan Lake (LA-1)	Russell Lake Inlet	Sediment Quality Guidelines

								REF	NE2	LEL	SEL	ISQG	PEL
Aluminum	mg/kg(dw)	Monitoring required in effluent under MDMER Schedule 5 - no criteria stipulated under this regulation											
Iron	mg/kg(dw)	Monitoring required in effluent under MDMER Schedule 5 - no criteria stipulated under this regulation											
Thallium	mg/kg(dw)	Monitoring required in effluent under MDMER Schedule 5 - no criteria stipulated under this regulation											
Manganese	mg/kg(dw)	Monitoring required in effluent under MDMER Schedule 5 - no criteria stipulated under this regulation											
Phosphorus	mg/kg(dw)	Monitoring required in effluent under MDMER Schedule 5 - no criteria stipulated under this regulation											

Note:

Bolded values indicate exceedance of the CCME ISQG

Estimated total HQs for all COPC for fish tissues during the ‘future centuries’ phase were predicted to be lower than those predicted for the period of mine life (i.e., construction through to post-decommissioning) and therefore below the HQ benchmark of 1 (Appendix 10-A in Section 10).

The concentration of selenium in fish tissue during the ‘future centuries’ phase is predicted to remain below 0.26 mg/kg ww muscle for both Northern Pike and White Sucker, which is well below the recommended criterion for selenium in fish tissue on a fresh weight basis of 2.83 mg/kg ww muscle (Appendix 10-A). Therefore, risk to fish health during this phase is not expected.

8.5.5 Mitigation Measures

Measures to mitigate adverse effects on Fish Health are consistent with those to mitigate adverse effects on Surface Water Quality and Sediment Quality. These mitigation measures are repeated in this section for completeness. To mitigate adverse effects on the Fish Health VC, Denison will implement the following mitigation measures.

- Inspect culverts periodically. Remove accumulated material and debris upstream and downstream of the culverts to prevent erosion, flooding, habitat damage, property damage, and mobilization of sediment.
- Develop and implement a Surface Water Management Program that provides an integrated framework to manage water quality, including provision for water management practices for each of the primary site aspects, as well as areas of the Project site where contact is expected.
- Maximize the recycle and reuse of process water to reduce freshwater intake and release to Whitefish Lake.
- Design the discharge diffuser/outfall to provide the smallest footprint possible while still achieving effective mixing and dilution, and to provide discharge flows that do not adversely effect sediments.
- Develop site-specific effluent treatment to treat COPC to appropriate release limits in accordance with provincial standards and licence/permit conditions.
- Discharge effluent under a scenario that will meet provincial and federal discharge criteria identified through permitting. Scenarios may include:
  - discharging at a fixed rate while maintaining an appropriate minimum dilution ratio (i.e., discharge when able to meet the required dilution ratio and cease discharge during periods when unable to meet the necessary dilution ratio);
  - discharging under a variable waste load allocation (i.e., discharge at an appropriate effluent volume based on flow in the receiver to maintain a minimum dilution ratio); and
  - managing discharge via a hybrid of the two previous scenarios (i.e., discharge effluent at a fixed rate to maintain the required dilution ratio, but the fixed rate can be varied on a seasonal basis based on flow).

- Collect and monitor contact water to determine whether treatment is required prior to release to the environment to inform optimal levels of treatment.
- Maintain the water management system during Decommissioning until such time that water quality is suitable to release to the environment.
- Monitor and manage effluent, including contingency for effluent treatment as may be required, so that water discharge objectives are achieved as defined by applicable provincial and federal regulatory instruments.
- Design and implement an environmental code of practice that defines action levels and appropriate steps to be taken to mitigate elevated concentrations of chemical and radiological constituents in treated effluent discharge to acceptable levels.
- Implement Project-specific monitoring programs (e.g., effluent monitoring plan, environmental monitoring plan) that include monitoring treated effluent, surface water, sediment quality, and fish tissue contaminant concentrations and applying adaptive management, if necessary.
- Work with the associated communities to develop and implement the Project-specific monitoring programs and a framework to share the results for the purpose of assessing the performance of the water management system.
- Develop and implement a decommissioning and reclamation plan to decommission and transfer the site to the province under the Institutional Control Program.

8.5.6 Residual Effects Evaluation

8.5.6.1 Residual Effects Characterization

General definitions of the residual effects characteristics are provided in Section 5.8. Residual effects characteristics specific to Fish Health are defined in Table 8.5-6 with evaluation of residual effects provided in Table 8.5-7, Table 8.5-8, and Table 8.5-9.

Table 8.5-6: Fish Health – Definitions of Effect Characteristics Considered When Determining the Significance of Residual Effects

Residual Effect Characteristic	Definition	Rating
Direction	Identifies whether the residual effect will be adverse or positive.	**Adverse** – Effect moves measurable parameters in a direction detrimental to fish health. *Water Quality* – An increase in constituent concentrations attributable to the Project in comparison to baseline conditions and trends. *Sediment Chemical Quality* – An increase in constituent concentrations attributable to the Project in comparison to baseline conditions and trends. *Fish Tissue Concentrations* – An increase in constituent concentrations attributable to the Project in comparison to baseline conditions and trends. **Positive** – Effect moves measurable parameters in a direction beneficial to fish health. An improvement in fish health in comparison to baseline conditions and trends.

Residual Effect Characteristic	Definition	Rating
Magnitude	The amount of change in a measurable parameter relative to baseline conditions.	**Low** – A measurable change that is not within the variability of baseline conditions but is below relevant sediment quality objectives and criteria. **Moderate** – A measurable change that is not within the variability of baseline conditions or within applicable guidelines, legislated requirements, and/or federal and provincial management objectives; therefore, the change could have an adverse effect on Fish Health in the LSA. **High** – A measurable change that is not within the variability of baseline conditions or within applicable guidelines, legislated requirement, and/or federal and provincial management objectives; therefore, the change is likely to have an adverse effect on Fish Health in the LSA, with the effect extending beyond the LSA.
Geographic Extent	The geographic area within which the residual effect is expected to occur.	**Project Area** – Effect is limited to the Project Area. **Local** – Effect is limited to the Fish Health LSA. **Regional** – Effect extends beyond the Fish Health LSA into the Fish Health RSA. **Beyond Regional** – Effect extends beyond the Fish Health RSA.
Duration	Length of time over which the residual effect is expected to persist.	**Short-term** – Less than 3 years (i.e., effect happens during Construction only). **Medium-term** – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning). **Long-term** – More than 38 years (i.e., effect extends beyond Post-Decommissioning).
Frequency	How often the residual effect is expected to occur.	**Infrequent** – Effect occurs several times at sporadic intervals. **Frequent** – Effect occurs many times on a regular basis. **Continuous** – Effect occurs continuously.
Reversibility	Whether or not the residual effect can be reversed once the activity causing the residual effect ceases.	**Fully Reversible** – A residual effect that diminishes to baseline conditions. **Partially Reversible** – A residual effect that partially diminishes to baseline conditions. **Irreversible** – A residual effect that will not diminish to baseline conditions.
Context	The extent to which the VC or KI has been affected by past and present environmental and socio-economic processes and conditions, its potential sensitivity to the Project-related residual effect, and its ability to recover from that effect (i.e., resilience).	**Low** – VC/KI has high resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a lack of historic and ongoing anthropogenic or natural disturbance. **Moderate** – VC/KI has moderate resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or an intermediate level of historic or ongoing anthropogenic or natural disturbance with the capacity to assimilate more change. **High** – VC/KI has weak resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a high level of historic or ongoing anthropogenic or natural disturbance.
Likelihood	Likelihood that the residual effect will occur, including consideration of the likelihood that the mitigation will be successful.	**Likely** – A moderate to high probability that the residual effect will occur. **Unlikely** – A low probability that the residual effect will occur.

Table 8.5-7: Fish Health – Summary of the Characteristics Ratings in Relation to Water Quality

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	The Project, and specifically the discharge of effluent to the natural environment, will cause a change in the concentration of constituents, as measured as a mass of a chemical per unit volume in water (e.g., mg/L). Surface water quality in the local receiving environment will be adversely affected by effluent discharge to the aquatic environment, thereby providing a pathway to adversely affect fish health.
Magnitude	Moderate	The magnitude of the residual effects associated with the Project is predicted to be low overall as the vast majority of constituents that may be introduced as part of Project activities are expected to remain below criteria for the protection of aquatic life and human health. However, with the exceedance of the Cu FEQG and in response to Round 4 IR-114, the overall rating was conservatively changed to moderate, even though the copper values in the EIS have been overpredicted in the models for a number of reasons including the fact that the baseline water quality analytical detection limit for copper was equal to the Cu FEQG.
Geographic Extent	Local	The geographic extent of the residual effects is predicted to be confined to the immediate waterbody adjacent to the Project (i.e., Whitefish Lake). The estimated mixing zone is less than 5 m, implementing an effluent discharge configuration that promotes mixing.
Duration	Long-term	Effects are expected to last between 3 to 38 years (i.e., effects expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuous	For the purposes of this EIS, a conservative scenario was identified, with effluent discharge being considered as continuous during Operation and Decommissioning.
Reversibility	Fully Reversible	Surface water quality is expected to return to pre-development levels following Post-Decommissioning as Project-related sources will cease to operate.
Context	Low	Fish health is expected to be resilient to changes in surface water quality in the context of this assessment as COPC meet protective criteria even at the extreme low water scenario. Therefore, under applicable mitigative measures and average flow conditions, the contextual resilience of the aquatic system to respond to change is considered to be great.
Likelihood	Likely	A high probability exists that a change in water quality from background conditions will occur.

Table 8.5-8: Fish Health – Summary of the Characteristics Ratings in Relation to Sediment Quality

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	The Project, and specifically the discharge of effluent to the natural environment, will cause a change in the concentration of constituents, which may be partitioned to sediment in the receiving water. Sediment quality in the local receiving environment will be adversely affected by effluent discharge to the environment, which may in turn affect fish health.
Magnitude	Low	The magnitude of the residual effects associated with the Project is predicted to be low as constituents that may be introduced as part of Project activities are expected to remain below criteria for the protection of aquatic life or below risk HQs.

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Geographic Extent	Local	The geographic extent of the residual effects is predicted to be confined to the immediate waterbody adjacent to the Project (i.e., Whitefish Lake). The estimated mixing zone is less than 5 m, implementing an effluent discharge configuration that promotes mixing.
Duration	Long-term	Effects are expected to last between 3 to 38 years (i.e., effects expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuous	For the purposes of this EIS, a conservative scenario was identified, with effluent discharge being considered as continuous during Operation and Decommissioning.
Reversibility	Fully Reversible	Sediment quality is expected to return to pre-development levels following Post-Decommissioning as Project-related sources will cease to operate.
Context	Low	Fish health is expected to be resilient to changes in sediment quality in the context of this assessment as COPC meet protective criteria even at the extreme low water scenario. Therefore, under applicable mitigative measures and average flow conditions, the contextual resilience of the aquatic system to respond to change is considered to be great.
Likelihood	Likely	A high probability exists that a change in sediment quality from background conditions will occur.

Table 8.5-9: Fish Health – Summary of the Characteristics Ratings in Relation to Fish Tissue Concentrations

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Direction	Adverse	The Project, and specifically the discharge of effluent to the natural environment, has the potential to change the concentration of constituents in fish tissues though ingestion, respiration, and absorption pathways.
Magnitude	Low	The magnitude of the residual effects associated with the Project is predicted to be low as constituents that may be introduced as part of Project activities are expected to remain below criteria for the protection of aquatic life or below risk HQs.
Geographic Extent	Local	The geographic extent of the residual effects is predicted to be confined to the immediate waterbody adjacent to the Project (i.e., Whitefish Lake). The estimated mixing zone is less than 5 m, implementing an effluent discharge configuration that promotes mixing.
Duration	Long-term	Effects are expected to last between 3 to 38 years (i.e., effects expected during Construction through to the end of Post-Decommissioning).
Frequency	Continuous	For the purposes of this EIS, a conservative scenario was identified, with effluent discharge being considered as continuous during Operation and Decommissioning.
Reversibility	Fully Reversible	Water quality and sediment quality are expected to return to pre-development levels following Post-Decommissioning as Project-related sources will cease to operate. As a result, exposure to COPC by fish will cease, reversing the potential for uptake of these constituents to fish tissues.
Context	Low	Fish health is expected to be resilient to changes in fish tissue concentrations in the context of this assessment as COPC meet protective criteria even at the extreme low water scenario.

Residual Effects Characteristic	Rating	Summary Rationale for Rating
Likelihood	Likely	A high probability exists that a change in COPC concentrations in fish tissue from background condition will occur.

8.5.6.2 Significance and Confidence in the Assessment

The characterization of residual effects is based on the review of existing conditions, the assessment of Project-related effects and proposed mitigation measures and management strategies, other relevant scientific information, IK, and the professional judgment of the EA team.

The significance of the residual effect is rated as **not significant** or **significant**, based on the following:

Not significant – a residual effect that is not expected to result in a change to a VC/KI that would alter its population viability or persistence beyond an acceptable level (e.g., where it is not sustainable or is unavailable to contribute to biodiversity and ecosystem function).

Significant – a residual effect that is expected to result in a change to a VC/KI that would alter its population viability or persistence beyond an acceptable level (e.g., where it is not sustainable or is unavailable to contribute to biodiversity and ecosystem function).

The threshold for significance for the Fish Health VC relates to predicted changes in the concentrations of water quality parameters, sediment quality parameters, and/or fish tissue concentrations of COPC, whereby the changes could result in exceedances of relevant water quality, sediment quality, or fish tissue assessment benchmarks. These benchmarks represent concentrations that are protective of aquatic biota in waterbodies that receive mine-affected drainage.

With the proposed mitigation and environmental protection measures outlined in Section 8.5.5, the residual effects of the Project on Fish Health are predicted to be **not significant**. This determination is supported by the fact that the predicted changes in water quality, sediment quality, and fish tissue concentrations are not expected to result in exceedances of assessment benchmarks in the LSA.

Potential effects on Fish Health as a result of Project discharges to local receiving environments were assessed by way of numerical modeling. These predictions are generally considered conservative in nature because the assumptions on which they are based are conservative. For example:

- The assessment was based on a continuous (year round) discharge at an expected average effluent discharge rate of 0.0101 m^3/s (or 36.5 m^3/hr) throughout Construction, Operation, and Decommissioning despite the likelihood that effluent discharge will not be continuous and

Denison will only discharge when site water balance requires, based on water storage capabilities.

- Constituents in effluent discharge were estimated conservatively. Presented discharge concentrations provided herein include contingency factors of one to three times to facilitate conservancy.
- Baseline water quality and sediment quality were defined by the 95th percentile concentrations of individual constituents. Such an assumption is conservative as it constrains the assimilative capacity associated with the receiving environment. By definition, the assimilative capacity of a receiving environment is equal to the incremental difference between the existing baseline condition and the assessment benchmark (i.e., water quality criterion) on which the evaluation is based. Use of the 95th percentile concentration, rather than a measure of central tendency (i.e., 50th percentile, geomean), means that the incremental change for a given constituent concentration that can be assimilated by the receiving environment is relatively small in magnitude.
- Water quality predictions did not consider physical or chemical processes that may attenuate concentrations in the receiving environment. An example of such a process would be partitioning of constituents from the water column to Whitefish Lake sediments. No attempt was made to adjust water quality predictions to account for this portioning, despite using this relationship to consider the potential effects of discharge on sediment quality.

Due to the conservative nature of the assumptions on which the numerical assumptions were based, a high degree of confidence was assumed.

8.5.6.3 Summary of Project-related Residual Adverse Effects on Fish Health

Residual adverse effects on Fish Health are expected to occur during Construction, Operation, and Decommissioning through pathways previously identified. A summary of fish health residual environmental effects that are likely to occur as a result of the Project, and their significance, is provided in Table 8.5-10.

Table 8.5-10: Project Residual Effects on Fish Health

Residual Effect	Residual Effects Characterization									
	Project Phase	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Context	Likelihood	Significance Determination
Change in Water Quality	C, O, D	A	M	LSA	LT	CF	FR	L	L	NS
Change in Sediment Quality	C, O, D	A	L	LSA	LT	CF	FR	L	L	NS

Residual Effect	Residual Effects Characterization									
	Project Phase	Direction	Magnitude	Geographic Extent	Duration	Frequency	Reversibility	Context	Likelihood	Significance Determination
Change in Fish Tissue Concentrations	C, O, D	A	L	LSA	LT	CF	FR	L	L	NS

Notes:

Project Phase:	Construction (C), Operation (O), Decommissioning (D)
Direction:	Adverse (A), Positive (P)
Magnitude:	Low (L), Moderate (M), High (H)
Geographic Extent:	Project Area (PA), Local (LSA), Regional (RSA), Beyond Regional (Beyond RSA)
Duration:	Short-term (ST), Medium-term (MT), Long-term (LT)
Frequency:	Infrequent (IF), Frequent (FF), Continuous (CF)
Reversibility:	Reversible (FR), Partially Reversible (PR), Irreversible (IR)
Context:	Low (L), Moderate (M), High (H)
Likelihood:	Unlikely (U), Likely (L)
Significance:	Not Significant (NS), Significant (S)

8.5.7 Cumulative Effects

The spatial and temporal boundaries of the Project specific to the Fish Health VC are provided in Section 8.5.1.3. A description of the methods used in assessing cumulative effects is provided in Section 5.9.

8.5.7.1 Potential Cumulative Effects

Existing projects within the Wheeler River Watershed have been considered for potential to interact with the Surface Water Quality VC for the Project. These include reasonably foreseeable projects that are described in Section 5.9.

The Cameco Key Lake Operation has the potential to interact with the Fish Health VC for the Project (Figure 5.9.1) via the surface water pathway. The site has been in operation since 1983. In 2018, sustained low uranium prices resulted in a decision to curtail production for the foreseeable future and place the operation into safe care and maintenance. On February 9, 2022, Cameco announced plans for the operation's gradual return to production. Cameco's Key Lake Operation will overlap spatially and temporally with the Project.

The Project is situated approximately 35 km northeast of the Key Lake Operation and both are located in watersheds that ultimately report to Russell Lake. Releases to the aquatic environment from the Key Lake Operation are received by the David Creek, McDonald Creek, and Outlet Creek drainages. These three drainages join the Wheeler River, which then flows to Russell Lake (Cameco

2020). Therefore, a potential spatial overlap was identified for the Project and the Key Lake Operation and further assessed or cumulative effects.

The key potential cumulative effect pathway as it concerns the Fish Health VC is the surface water exposure pathway. The assessment of cumulative effects on the Fish Health VC considered surface water releases and partitioning to sediments from the Project and the Key Lake Operation during all phases of the Project. The key Project component contributing to potential cumulative effects is the discharge of treated effluent to the aquatic environment during Operation and Decommissioning which may interact with Cameco's current releases to water including treated water released to David Creek drainage, treated groundwater and diverted surface water to the McDonald Creek drainage (Cameco 2020).

Temporal overlap of the Key Lake Operation and the Project will also occur during 'future centuries' as described as 'post-decommissioning phase' in the Key Lake Extension Project EIS (Cameco 2020). There is potential for increased contaminant transport via groundwater to surface water during the long-term, post-decommissioning phase (i.e., 10,000 years after operations cease and the site has been reclaimed) for the Key Lake Operation. The long-term storage of tailings at a higher elevation has the potential to influence contaminants in the groundwater and incrementally add to the effect on surface water quality in the Outlet Creek Drainage.

Operation and Decommissioning

The assessment of cumulative effects on the aquatic environment considered releases from the Key Lake Operation and proposed Project during all phases of the Project. The primary Key Lake Operation component contributing to potential cumulative effects is the placement of tailings to a higher elevation in the Deilmann Tailings Management Facility (DTMF). The increased loadings from the DTMF are anticipated to result in an incremental (i.e., existing conditions plus the Project) increase of concentrations of COPCs in the aquatic environment (Cameco 2013). The spatial extent of any significant adverse effects on the aquatic environment from the Key Lake Operation were anticipated to be localized and not to extend to the Wheeler River and Russell Lake during any phase of the Project (Cameco 2013). The 2010 Status of the Environment report for the Key Lake Operation identified that no adverse effects to individual fish or fish populations are present in the Wheeler River (EcoMetrix 2010 as cited in Cameco 2020).

Potential Project residual effects on the Fish Health VC are primarily related to controlled discharge of site water into local receiving environments during all Project phases. Such changes are predicted to be negligible to low in magnitude and limited to the LSA. For example, during Construction, no discharge from the Project site is planned. During Operation, treated effluent will be discharged to Whitefish Lake. The Whitefish Lake discharge will be the only routine discharge location during Operation. Water quality in Whitefish Lake and, by extension, downstream of Whitefish Lake will meet appropriate benchmarks for the protection of aquatic life in consideration of a small mixing zone in the lake, which will remain within tolerable HQs for fish health. Changes to fish tissue concentrations in the LSA are also predicted to remain within or near existing levels and are not predicted to be associated with effects on Fish Health. Selenium levels in fish tissues in Russell Lake during operation will remain well below the EPA recommended criterion (less than 1.25 mg/kg ww and 2.83 mg/kg ww muscle, respectively). Following cessation of effluent discharge to the aquatic environment, selenium concentrations in fish tissues are predicted to return to background condition (Figure 8.5-5). Following Decommissioning and the restoration of drainage patterns that are similar to pre-mining conditions, water quality and sediment quality are expected to meet appropriate benchmarks for the protection of aquatic life in Whitefish Lake and downstream. This includes Russell Lake, of which the Icelander River system is associated.

In consideration of the above discussion, effects on the Fish Health VC due to changes in surface water quality from the Key Lake Operation are not anticipated to spatially overlap with those from the Project and therefore a cumulative effect is not expected.

Future Centuries

The 2013 Key Lake ERA indicated that during the 10,000-year post-decommissioning period, predicted exposure levels may affect lower trophic level aquatic biota on a population or community level within some isolated lakes in the SSA, but adverse effects on the ecology of the Outlet Creek drainage, and therefore further downstream were not expected during the post-decommissioning phase (Cameco 2013). The results of the 2020 ERA for the Key Lake Operation were consistent with the findings from the 2013 ERA in that there were limited significant risks posed to aquatic receptors situated in the area surrounding the Operation, but not to areas farther downstream. The 2020 ERA concluded that environmental health in the vicinity of the Key Lake Operation will remain protected (Cameco 2020).

The results of the numerical modelling for the Project, as provided in Section 7 and Appendix 10-A in Section 10, support the conclusion that with the implementation of appropriate mitigation during the decommissioning and mining area remediation phase of the Project, the residual effects of the Project on the intermediate Groundwater VC will not result in an adverse effect to surface water. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future (“Future Centuries”) from the mining area to Whitefish Lake will be localized to that waterbody and remain below fresh water environmental quality criteria. As such, impacts to fish health in downstream portions of the drainage including Russell Lake are not expected.

In consideration of the above discussion, effects on fish health due to changes in surface water quality from the Key Lake Operation are not anticipated to spatially overlap with those from the Project and therefore a cumulative effect is not expected.

8.5.7.2 Additional Mitigation Measures

Additional mitigation measures are not warranted as no potential cumulative effects were identified for the Fish Health VC.

8.5.7.3 Cumulative Effects Characterization and Determination of Significance

A determination of significance is not warranted as no potential cumulative effects were identified for the Fish Health VC.

8.5.7.4 Cumulative Effects Assessment Summary

Effects on the aquatic environment and specifically the Fish Health VC due to changes in surface water quality or sediment quality from the Key Lake Operation are expected to remain localized and not extend to the Wheeler River system or Russell Lake. Likewise, impacts on surface water quality from the Project are expected to remain localized (Whitefish Lake) and not extend to Russell Lake. Effects on the aquatic environment due to changes in surface water quality associated with the Key Lake Operation are not anticipated to spatially overlap with those from the Project during operation/decommissioning or during "future centuries" and therefore a cumulative effect is not expected.

8.5.7.5 Environmental Monitoring and Follow-Up

Specific monitoring and follow-up for Fish Health related to cumulative effects are not needed as no cumulative effects were identified for this VC. Monitoring and follow-up specific to the Project for the Fish Health VC are detailed below in Section 8.5.8.

8.5.7.6 Climate Change Considerations

As discussed in Section 8.1.7.5, the frequency and magnitude of extreme precipitation events have the potential to change water levels and flows in the Project RSA, which may affect water quality, sediment transport, fish habitat and, subsequently, fish health. Changes to average and upper and lower bounds of ambient temperatures may also affect Fish and Fish Habitat, which in turn may affect Fish Health. Climate change over the life of the Project (i.e., 35 to 40 years) will be monitored as part of the Project's environmental monitoring programs, and influences on Water Quality, Sediment Quality, and Fish Health will require adaptive management to mitigate any potential effects of the Project that may be exacerbated by climate-related changes on the aquatic environment.

8.5.8 Monitoring and Follow-Up

For the purposes of this EIS, monitoring and follow-up are defined as follows:

- monitoring programs are designed to meet regulatory requirements (e.g., permit or license conditions) and/or to demonstrate compliance with environmental commitments made in the EIS; and
- follow-up programs are designed to address any uncertainties identified during the EA process (e.g., to verify predictions made during the EA; determine the effectiveness of proposed and implemented mitigation measures) and to determine if and when to implement adaptive management measures.

Monitoring and follow-up are proposed for the Fish Health VC to verify the accuracy of the predicted effects and the effectiveness of the proposed mitigation measures. The fish health monitoring program should be considered in conjunction with the surface water quality monitoring (Section 8.2.8), fish and fish habitat monitoring (Section 8.3.8), and sediment and benthic invertebrate monitoring (Section 8.4.8) programs as it is specifically tied to these monitoring programs from the perspective of pathways of effects. Specifically, monitoring of water quality in the effluent monitoring ponds and other catchment ponds prior to discharge to the environment will be important to provide context to further evaluate Project-related effects on Fish Health in the receiving water environment (i.e., Whitefish Lake).

The fish health monitoring and follow-up program will have the following objectives:

- collecting and recording surface water quality to confirm that source and receiving water; quality predictions for mobilization of solids are consistent with those presented in the EIS;
- monitoring to confirm that effluent and receiving water quality meet applicable regulation criteria; and,
- monitoring changes in fish tissue concentrations of COPC that may be attributable to the Project.

The monitoring and follow-up program will include measurements of fish health for comparison to baseline data and regulatory criteria (i.e., Canadian Tissue Residue Guidelines for the Protection of Wildlife Consumers of Aquatic Biota [e.g., CCME 2000], MDMER [Government of Canada 2022], CSA N288.4-19 (CSA Group 2019), and applicable United States Environmental Protection Agency criteria (e.g., US EPA 2021). At a minimum, this will include collection of representative fish species from multiple trophic levels and size classes to investigate the bioaccumulation potential of non-radiological (e.g., molybdenum, selenium, total mercury, methylmercury and other metals) and radiological parameters. Fish will also be assessed for their general health condition through assessment of condition and growth metrics consistent with those described in current or updated MDMER EEM technical guidance (e.g., Environment Canada 2012).

Local Indigenous communities have expressed direct concern with respect to mercury. Mercury has not been identified as a COPC for the Project as it is currently not present in the receiving environment (i.e., background condition) at detectable concentrations and will not be produced as part of the mine process and therefore, not discharged to the aquatic environment. However, it is understood that potential nutrient enrichment-related effects are possible and can be linked to increases in mercury in the environment. Denison notes that there is potential for increased methylmercury production in the receiving environment under a certain combination of factors to which the Project may contribute, such as increased nutrient levels in the environment. Denison commits to monitoring mercury and methylmercury in the aquatic environment over the life of the Project to determine the potential changes in mercury concentrations in fish tissue over time. As the Project advances and operational monitoring is underway, Denison will assess health risks from fish consumption by comparing fish tissue data collected during operation from the monitoring program against applicable human health risk-based maximum permissible concentrations.

Fish Health monitoring will occur in tandem with Surface Water Quality, Sediment Quality, Benthic Invertebrate and Fish and Fish Habitat sampling. Sampling locations will be co-located to facilitate comparison to water quality and sediment quality characteristics.

Sediment and benthic invertebrate monitoring in the natural environment will occur at an upstream reference location (i.e., LA-6 – Whitefish Lake North), at a downstream near-field location close to the point of discharge (i.e., LA-5 – Whitefish Lake South), and at downstream far-field locations (i.e., in LA-5 – Whitefish Lake South prior to its discharge to LA-1 – McGowan Lake).

The assessment will also include comparison of fish tissue COPC concentrations between a pre-mining period (i.e., before) and the Construction, Operation, and Decommissioning period (i.e., after). It is recognized that additional collection of pre-mining fish tissue concentrations in Whitefish Lake and a reference area are needed.

Specific monitoring and follow-up plans for the Fish Health VC will be prepared to refine and finalize the approach and specific metrics following consultation with Indigenous groups, other stakeholders, and relevant federal and provincial agencies with interest in the development and implementation of this VC-specific program.

8.5.9 Fish Health Summary

The Fish Health VC was selected for inclusion as effluent discharge to the natural environment has the potential to affect fish health. Furthermore, inclusion of the Fish Health VC is vital due to its importance to Indigenous peoples from a cultural and subsistence perspective. Contaminants of concern in fish may include heavy metals, including mercury. Concentrations of mercury and selenium in fish tissues collected during baseline studies were below guidelines that are protective of human health and freshwater aquatic life.

The main Project activity that may affect Fish Health is the release of treated effluent to Whitefish Lake. Changes in surface water quality and sediment quality have the potential to affect Fish Health in the receiving environment.

To minimize Project-related residual effects on Fish Health, Denison will develop and implement a Surface Water Management Program that provides an integrated framework to manage water quality, including provision for water management practices for each of the primary site aspects and areas of the site where contact water is expected. This will include the collection and monitoring of contact water to determine whether treatment is required prior to release to the environment, which will inform optimal levels of treatment. This will also include the monitoring and management of effluent, including contingency for effluent treatment as may be required, so that water discharge objectives are achieved as defined by applicable provincial and federal regulatory instruments. Measures in the Surface Water Management Program are expected to mitigate effects associated with changes to water and sediment quality that may affect Fish Health.

The assessment predicted residual effects on Fish Health due to treated effluent discharge. It should be noted that predicted effects do not include mercury-related effects. Identified residual effects are associated with changes in surface water quality and sediment quality; however, the changes are expected to remain well below levels that may affect Fish Health. Considering this, and following the implementation of appropriate mitigation measures, the residual effects of the Project on Fish Health are predicted to be **not significant**.

A fish health monitoring program is recommended for confirming the effectiveness of the proposed mitigation measures and the predications made in the EIS. The monitoring program will consist of the collection of multiple fish species to assess changes in fish tissue COPC, including mercury and selenium.

Roadmap

This roadmap of the Wheeler River Project Environmental Impact Statement (EIS) has been provided to summarize the main document sections and appendices of the EIS.

Wheeler River Project
Environmental Impact Statement

Executive Summary

PART I: INTRODUCTION AND CONTEXT	PART II: BIOPHYSICAL ENVIRONMENTAL ASSESSMENTS	PART III: HUMAN ENVIRONMENT ASSESSMENTS	PART IV: INTEGRATED TOPICS AND SUMMARY
Section 1: Project Introduction and Overview	Section 6: Atmospheric and Acoustic Environment	Section 10: Human Health	Section 14: Accidents and Malfunctions
Section 2: Project Description	Section 7: Geology and Groundwater	Section 11: Land and Resource Use	Section 15: Effects of the Environment on the Project
Section 3: Indigenous and Local Knowledge	Section 8: Aquatic Environment	Section 12: Quality of Life	Section 16: Assessment Summary and Conclusions
Section 4: Engagement	Section 9: Terrestrial Environment	Section 13: Economics	
Section 5: Approach and Methodology of the Assessment
