The WR-1 Phase 1 decommissioning waste material was stored in Buildings 432 and 433 in the WMA. Approximately 96% of the WR-1 Phase 1 decommissioning waste stored in Buildings 432 and 433 had been processed by the end of 2016. One oversized crate along with five asbestos crates remain in Building 433 at the end of 2021. Through 2021, work to characterize the contents of B431, B432 and B433 occurred. This effort will continue in 2022 with off site shipping planned.

The marine container used for storing sealed sources that was transferred from Building 430 in the WMA to the Standpipes Protected Area to meet revised security regulations from the CNSC in 2015, remained in place through 2021. Sources are still held pending future dispositioning.

The process to convert Low Level Waste Bunker #6 to the Intermediate-Level Liquid Waste Treatment Centre, Building 202, began in 2021. Work consisted of removal of waste that had been temporarily returned to the bunker due to restrictions in work crews and shipments related to the COVID-19 Pandemic. Once the waste was removed, interior surveys were conducted in preparation for the next phases of work in 2022.

Removal of waste from Low Level Waste Bunker #5 began in 2021. The waste removal is a component of the decommissioning effort for the WMA, and will extend into 2022.

The Waste Transshipment Area outside the northern perimeter of the WMA had its footprint extended and pad upgraded to improve areas of formerly soft ground. The Waste Transshipment Area allows for holding shipments of waste that are ready to be shipped. The larger area will support the planned pace of waste extraction from the WMA.

In 2021, the Waste Transshipment Area also provided access through a west gate in that area to allow for construction of a road along the west side of the WMA. Pads off the west side of that road will host transformers and generators to provide Class IV and Class III power to waste extraction and processing equipment to be installed in the WMA. A non-active organic material laydown area was established on the north end stub of the west road to allow for an area for organic material from the development of the Waste Transshipment Area pad improvement and west road to be retained.

A replacement section of the north fence running from the west side of Building 923 to the east edge of the Recoverable Surface Staging and Storage Area was installed. This fence included an expanded width north gate to allow shipping containers to be transported without having to

raise them above the fence. The fence replacement was done to correct fence sections that were leaning outwards.

On the south side of the WMA, a new well nest was installed to the south of the south road. This well nest was installed to provide groundwater measurements outside of the zone of influence of the work conducted at the WMA. The previous wells fulfilling this role are now too close to the Protected Area expansion to be considered outside the zone of influence and will be used as part of the monitoring network for that area.

A bedrock well was installed to the west of the WMA-CCSF. This provided improved coverage at depth to monitor for potential contaminant migration.

D.4 Equipment Performance, Planned Maintenance Testing and Inspections

During 2021, the bunkers and other structures in the WMA remained fit for service. Building 923 and Low Level Waste Bunker #6 were removed from operations pending their conversion to the Cask Loading Facility and Intermediate Level Liquid Waste Treatment Centre respectively. Building 421 continued to operate as a waste examination and re-packaging area, making use of the Temporary Ventilated Enclosure.

Medium-Level Waste Bunker 4 did not have new waste placed in 2021 and remains ~70% full. Medium-Level Waste Bunker 6 is ~60% full; however it is not accepting waste due to water ingress issues. Medium-Level Waste Bunker 7 is ~86% full with one placement occurring. The percentage full values are estimates only. Road transportable totes of liquid waste remain in the heated Building 430 pending future processing. Building 431 contains historic waste which is in the process of being characterized and packaged. Building 432 and Building 433 also contain various historic wastes and wastes held in various stages of characterization and repacking operations.

A small seepage of an oily substance first noted in 2020 was again noted at the central gasket, near the south wall base of LLW Bunker 1. The substance was sampled in 2020 and found to contain oil and likely degraded liquid organic. The volume was small in 2020 and remained so in 2021. Seepage again only occurred during hot weather, and as weather cooled the seepage stopped. The area will continue to be monitored. The bunker is slated for remediation of its waste in the next few years.

The Soil Storage Compound remained empty of stored waste soil bags. There are three empty standpipes in the standpipe area.

In-service storage facilities were inspected for water ingress during routine waste emplacement operations. Filled storage facilities with accessible drainage sumps were inspected monthly during the summer months, when water ingress is most likely. Caulking of the roofs of all the WMA Quonset buildings with waterproof sealant was completed in 2010 resulting in reduced indications of water ingress during rainy weather. Re-caulking was done in 2014 and again in 2018 and 2021.

In 2015, shallow wells were installed beside each of the Medium/Intermediate Level Bunkers. These near field wells have been sampled annually. Results are discussed in Section D.2.1 under "Intermediate - Level Waste Bunkers Near Field Wells", and indicates limited migration of tritium beside the ILW bunkers, in particular ILW Bunker 3. There is no evidence that would lead CNL to conclude there is currently any significant contaminant migration pathway from the ILW Bunkers.

Compliance monitoring in the WMA and CCSF perimeter ditches have only found limited levels of contaminants, below drinking water guidelines, suggesting the waste storage structures and natural barriers of low permeability clay soil and upwards groundwater flow are performing as expected. In 2021, the weather was extremely dry and spring melt similarly limited to surface water in ditches was limited to a single set of measurements on one date in May.

As required by Section 8 of the Facility Authorization [59], most routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, however, two tests, both on transformers were not completed in 2021. Monthly housekeeping and fire prevention inspections were completed. An annual inspection of WL WMA concrete bunkers was conducted, in accordance with the Periodic Inspection Plan [16], and is further discussed in Section 6.

D.5 Wastes Generated

Solid radioactive waste was generated in the WMA as part of routine operations. This was mostly bagged waste generated from routine operations.

See Section 11.1 Waste Management Program for summaries of the volume of radioactive solid waste generated in the Waste Management Area in 2021.

Liquid radioactive waste was generated in the WMA as part of routine operations.

In 2021, approximately 564 L of water was removed from ILW Bunker 4, 863 L of water was removed from ILW Bunker 6 and approximately 114 L of water was removed from ILW Bunker 7. Low Level Waste Bunker 1 had 8 L from the west sump and 227 L from the east sump removed, and Low Level Waste Bunker 2 had 84 L from the west sump and 202 L from the removed from the east sump. The sumps are pumped out by Site and Nuclear Operations personnel using a WMA tanker with pump rig. The water collected in the tanker is later transferred to double walled totes. There totes are retained pending future processing.

The Building 923 sump tank and the Soil Storage Compound were both sampled as required and their water found not to be active in all cases. Water was directed to the WMA ditches. No other storage facilities and collection sumps at the WMA required pumping.

D.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the WMA as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection. There are no liquid effluents generated from this facility.

Appendix E Auxiliary Operation Facilities

E.1 Operations

The Auxiliary Operating Facilities are operated under the WL Site Licence [1].

There were no changes in the staffing for the operating staff responsible for the auxiliary facilities in 2021. There were no organizational changes.

No program changes were made for the auxiliary facilities in 2021. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

Research and Development Facilities Complex (Building 300)

Building 300 was the primary research laboratory for the site, housing a wide range of nuclear R&D programs. The building comprised an area of ~17,000 m^2 and was built in seven stages from 1964 to 1982. The building contained 68 laboratories as well as numerous offices. The south end high-bay area contained experimental activities that required large areas and significant headroom; RD-14M and RD-17 experimental loops were located in the South High Bay.

The research program in the Stage 6 (RD-14M) area was completed in 2018, and operational shutdown was started. The operational shutdown, decontamination, and decommissioning of the remainder of the building was completed in 2015. The demolition of Stages 4 and 7 was completed in 2016. The demolition of Stage 6 was completed in 2019.

During 2021, WL Site and Nuclear Operation’s staff and user groups in Building 300 carried out routine operations which included:

- Non-radiological laundry activities.
- Respirator fit test / maintenance activities.
- Ongoing CNL Nuclear Engineering & Systems Analysis R&D activities.
- Cleanup activities associated with decommissioning.
- Routine building and system maintenance; and
- Surveillance to ensure compliance with the site licence.

Health and Safety Facilities (Buildings 402 and 305)

Building 402 has three floors comprising an area of ~2,162 m^2, housing WL dosimetry services and Environmental Management laboratories. The CNL facilities in Building 402 include a whole-body counting facility, TLD readers, environmental laboratories, and a Cs-137 Gamma Calibrator.

Environmental and Dosimetry services continued to operate in Building 402 until 2021 May.

In 2021, routine operations were carried out and supervised by Site and Nuclear Operations personnel. Operational cleanout of Buildings 402 and 305 continued and demolition of Building 402 started in 2021 November. Demolition of the building worked around the Whole Body Counter which was scheduled to move in early 2022.

E.2 Facility Changes

All facility changes were performed using the Engineering Change Control procedure [13]. The environmental and Dosimetry services were moved to Building 300. Building 402 was completely isolated and rendered cold and dark in 2021 July.

E.3 Equipment Performance, Planned Maintenance Testing and Inspections

All maintenance and non-routine work in these facilities that may affect the safe operation of facilities, systems, and laboratories, or that may present a hazard to the general public are conducted in accordance with CNL's work permit system.

All routine maintenance for systems required to be operational was carried out, and all equipment tests and inspections were completed up until Building 402 went cold and dark.

E.4 Wastes Generated

There were minimal amounts of radioactive and/or hazardous wastes generated in the facilities as part of routine operations.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the facilities in 2021.

Building 300 generated 0.0 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2021.

Building 402 generated 0.8 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2021.

After processing at the Waste Handling Area, all waste was shipped to the WMA for storage.

See Table 86 for a summary of solid wastes for the last five years.

Table 86: Low-Level Solid Waste Generation – Buildings 300, 402,411

	2017	2018	2019	2020	2021
Building 300 (m^3)	14.7	4.5	0.4	0.3	0.0
Building 402 (m^3)	2.8	1	0.7	0.2	0.8
Building 411 (m^3)	355.1	7.6**	0.2**	0.0	0.0

* Volume prior to compaction, all compactable waste is consolidated at the Waste Handling Area.

** Legacy waste processed in 2018 for Building 411 that was decommissioned in 2017.

There was no liquid radioactive and/or hazardous waste generated in 2021 in this facility.

RESEARCH AND DEVELOPMENT (BUILDING 300) LOW-LEVEL LIQUID WASTE SYSTEM

Radioactive LLLW flows from the SF and Building 300 to the low-level liquid waste collection tanks, in Building 300 Room B-33. An accurate determination of the individual SF or Building 300 contribution cannot be made as both locations flow into these common tanks. The

sources of water from Building 300 are limited and the major contributor is the radiological decontamination service facilities in the IFTF.

During 2021, 78.3 m^3 of low-level liquid was processed through the Building 300 LLLWTS. Table 87 shows the historical volumes of LLLW processed through the Building 300 LLLWTS and also the total volume of Building 300 and Building 100 LLLW processed.

Table 87 - Historical Records of Low-Level Liquid Waste Processed

	2017	2018	2019	2020	2021
Total Combined Low-Level Waste Liquid Processed (m^3)[a]	172.3[b]	131.5[c]	189.3[c]	107	88.2
Low-Level Waste Liquid Processed in Building 300 (m^3)[d]	46	123	186.5	99	78.3

a All low-level liquid waste processed in Active Liquid Waste Treatment Centre for 2014-2016. This total includes laundry and decontamination and ALWTC facilities for 2014 and 2015. For 2016 the total is Building 100 and Building 300 and ALWTC. After 2017 all low-level liquid waste is processed in Building 100 and Building 300.

b This includes 126 m^3 of low-level liquid waste that was processed through the Active Liquid Waste Treatment Centre in Building 200.

c All Low-Level Liquid Waste processed through the low-level liquid waste treatment systems in Building 100 and Building 300.

d Building 300 LLLWTS came online in 2017 July.

The total activities given below are the combination of the Shielded Facilities, Building 300, and Building 100 active liquid effluents produced.

As determined by total-beta analysis, the beta radioactivity content in the effluent releases to the Outfall from the holding tanks at the Building 300 and Building 100 LLLWTS during 2021 was 0.01 GBq, compared with 0.01 GBq released during 2020. The maximum release in a month during the year was 0.001 GBq which is a small fraction of the administrative level of 0.48 GBq per month. This level conservatively assumes that all of the activity is due to Cs-137, which is the most restrictive isotope of those present, or potentially present.

As determined by total-alpha analysis, the alpha radioactivity content in effluent releases to the outfall was 0.001 GBq for 2021 compared with 0.001 GBq released during 2020. The maximum release in a month during the year was 1.4E-04 GBq which is a small fraction of the administrative level of 0.56 GBq per month. This level conservatively assumed that all the activity is due to Am-241 which is the most restrictive isotope of those expected to be present in this waste stream.

Table 88 provides a summary of the total activity released for both the Building 100 and Building 300 LLLWTS. Annual Release Limit values for radionuclides in liquid effluents for WL are based on the DRL [30]. These values were revised in 2016. An error was discovered in Table 88, note “d” in previous years’ reports. The alpha DRL was listed as 1.11×10^1 GBq/month, and should have read 1.11 GBq/month. The annual release limits for alpha were calculated using the correct value for DRL. The % of monthly DRL for alpha was calculated using the wrong DRL value. This made the % of monthly DRL for alpha a factor of 10 lower than the true value.

Observed levels of alpha in WL's LLLW active releases are sufficiently low that even with this correction, levels are well below the DRL. This correction was made for the 2021 values.

Table 88 – Building 100 and Building 300 LLLWTS Radioactive Releases

Radionuclide	Total 2021 Effluent (GBq)	Annual Release Limit[a] (GBq/a)	Total 2021 Effluent as a % of Annual Release Limit	Peak Release	
				Max. Monthly Release (GBq)	% of[b] Monthly DRL
Total (Total-Beta Analysis) [c]	0.01	–	–	0.001	–
Sr-90	1.02×10^{-3}	1.56×10^{2}	0.76×10^{-3}	2.18×10^{-4}	1.87×10^{-3}
Cs-137	3.74×10^{-3}	1.39×10^{2}	2.69×10^{-3}	5.95×10^{-4}	5.12×10^{-3}
Total Alpha (As Pu-239 Equivalent) [d]	0.86×10^{-3}	1.33×10^{1}	6.46×10^{-3}	1.35 x 10-4	1.22×10^{-2}
Historical Data Total Effluent (GBq)					
	2017[e]	2018[e]	2019[e]	2020[e]	2021
Total (Total-Beta Analysis) [c]	0.04	0.02	0.01	0.01	0.01

a The annual release limit is calculated by multiplying the DRL by 12.

b DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The beta particulate emitters are considered to be Cs-137, the most restrictive isotope of those identified or potentially present. The DRL is 1.16×10^{1} GBq/month [30].

c A total beta analysis results in a conservative (higher) estimate of the total amount of activity, which is more accurately determined by measuring the individual radionuclides by radiochemical or gamma spectrometry methods.

d DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The alpha particulate emitters are considered to be Pu-239, the most restrictive isotope of those identified or potentially present. The DRL is 1.11 GBq/month [30].

e Year's 2014 to 2016 effluent was all processed in ALWTC. 2017 effluent was processed in ALWTC and Building 300 LLWTS. From 2018 on, all effluent was processed in Buildings 300 and 100 LLWTS.

E.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from these facilities. Radioactive wastewater generated in Building 300 was pumped to the LLLWTS in Building 300 Room B-33.

Any liquid and/or gaseous releases from the facilities are provided and discussed in Section 9, Environmental Protection.

Appendix F WR-1 Facility

F.1 Operations

Activities in Whiteshell Reactor 1 (WR-1) were conducted under the WL site licence [1] from the CNSC, in accordance with the requirements of *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64]. The status of the WR-1 facility in its shut down, de-fuelled, and partially decommissioned state is described in *The WR-1 Reactor Phase 1 Decommissioning Project Interim End-State Report - Facility Description* [65]. The facility is monitored and maintained as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64].

Routine operations in the WR-1 facility, as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64], were carried out by the five (four and one trainee) Site and Nuclear Operations Technologists assigned to Building 100. Throughout the course of 2021, the number of Building 100 staff dropped to three (two and one trainee) with plans to hire additional staff. Building 100 continued to maintain the minimum staffing requirements outlined in the Facility Authorization [64]. Staffing was maintained at levels to provide the needed operational and safety support.

In 2018, approximately 20 m^3 of low concentration (3.4 E06 Bq/L) tritiated water was found in the thermoshield and bioshield cooling systems. This water is still in the systems, awaiting a decision on how to remove this water as the systems were not designed to be drained. Investigation is also ongoing to determine what the impact would be if this water is left in situ as part of the proposed in situ disposal of WR-1.

No program changes were made for WR-1 in 2021. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

F.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [13].

F.3 Equipment Performance, Planned Maintenance Testing and Inspections

During 2021, the operations status of WR-1 remained unchanged. There were no changes to the reactor’s equipment.

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence. All Monthly housekeeping and fire prevention inspections were completed.

F.4 Wastes Generated

Solid Radioactive and/or Hazardous Wastes

See Section 11.1 Waste Management Program for summaries of the volume of any volume of radioactive solid and/or liquid waste generated in WR-1 in 2021.

Solid radioactive waste was generated in the facility as part of routine operations. This consisted of mainly operational supplies such as Tyvek suits.

During 2021, 1.5 m^3 of low-level radioactive compactable waste and no non-compactible waste were generated from Building 100/WR-1 operations and sent to the Waste Handling Area for compaction.

There were no new hazardous solid wastes generated from Building 100/WR 1.

Liquid Radioactive and/or Hazardous Wastes

Liquid radioactive and no hazardous waste was generated in the facility as part of routine operations.

During 2021, 9.9 m^3 of low-level radioactive liquid waste was generated from Building 100/ WR-1 operations, the majority from the WR-1 sumps. Appendix E has more information on the liquid waste processed. There were no hazardous liquid wastes generated from this facility.

F.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the facility as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection.

Appendix G Non-Nuclear Facilities

G.1 Operations

The WL non-nuclear facilities status and changes for 2021 are as noted in Table 89.

Table 89: Operating Summary of Non-Nuclear Facilities

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
303	Containment Test Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed
304	Waste Clearance Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed
306	Waste Clearance Facility	Removed in 2016	None	None	Buildings & Lands D&D Project Personnel	Building removed, pad retained, End-State Report to be completed
308	Large Scale Vented Combustion Test Facility	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
309	Large Scale Vented Combustion Test Facility -Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
310	Large Scale Vented Combustion Test Facility -Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
311	Large Scale Vented Combustion Test Facility Hydrogen Storage	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
401	Security, Reception, Firehall and Security Monitoring Room	Operational	None	None	All Site/Visitors	No change
405	Lunchroom/Offices (formerly the Library)	Operational	None	None	All Site/Visitors	No change
408	Stores	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
409	Cold Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
412	Offices/Machine Shop	Operational	None	None	All Site/Visitors	No change
413	Quonset: Cold Storage	Shut down	None	None	Security and Common Services	Preparing for demolition

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
414	Controlled Area 2 Entrance	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
415	Warm Storage	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
416	Heated Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
418	Active Area Storage	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
420	Cold Garage	Shut down	None	None	Transportation, Security and Stores	Preparing for demolition
422	Outfall Monitoring Station	Operational	None	None	Environmental Monitoring and Maintenance	No change
424	WR-1 Organic Monitoring Building	Removed in 2020 l	None	None	Facilities	Building removed,, End-State Report to be completed
426	Quonset: Cold Storage	Shut down	None	None	Utility	Preparing for demolition
427	Cold Mechanical Storage	Removed in 2016	None	None	Facilities	Building removed, pad retained, End-state Report to be completed
428	Cold Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
429	Quonset: Cold Storage	Shut down	None	None	Maintenance	Preparing for demolition
505	Fire/Security Training (formerly R&D Lab)	Removed in 2016	None	None	Environmental	The building and pad were previously decommissioned, 3 environmental monitoring wells have been installed
531	Asbestos/PCB Storage	Operational	None	None	Facilities	No change
540	Modular Office Complex	Operational	None	New	Facilities	Modular Trailer office complex installed in parking lot
543	Dosimetry Building	Under Construction	None	New	Facilities	Start of construction 2021 To be completed 2022

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
570	Hazardous Chemical Storage	Operational	None	None	Facilities, Waste Management	Relocated from Building 402 to near Building 300 Shielded Facilities. Placed back in Operation.
597	Portable Boiler Building 1	Out of Operation	None	None	Powerhouse Operators and Maintenance	Taken out of Service due to shutdown of Building 200
598	Portable Boiler Building 2	Operational	None	None	Powerhouse Operators and Maintenance	No change
902	Pump House	Operational	None	None	Powerhouse Operators and Maintenance	No change

904	Fire Protection Water System	Operational	None	None	Powerhouse Operators and Maintenance	No change
905	Process Water System	Operational	None	None	Powerhouse Operators and Maintenance	No change
906	Storm Drainage System	Operational	None	None	Maintenance	No change
907	Sewage Lift Station and Lagoons	Operational	None	None	Powerhouse Operators and Maintenance	No change
911	Powerhouse	Operational	None	None	Powerhouse Operators and Maintenance	No change
913	Main Substation (Owned by MB Hydro)	Operational	None	None	Manitoba Hy dro	No change
914	Main Power Distribution	Operational	None	None	Powerhouse Operators and Maintenance	No change
916	Communications System	Operational	None	None	Security and Maintenance	No change
917	Supervisory Control and Alarm	Operational	None	None	Security and Maintenance	No change

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
918	Clarified Water System	Shut Down Mid-1980s	None	None	Powerhouse Operators and Maintenance	No change
921	Access Tunnel	Operational	None	None	All Site/Visitors	No change

[a] Security personnel perform regular patrols of all site buildings

There were no policy, program or procedural changes for the non-nuclear facilities in 2021. There were no changes in organization in 2021.

In 2021, the Facility continued to maintain the minimum staffing requirements to provide the needed operational and safety support.

G.2 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [13].

G.3 Equipment Performance, Planned Maintenance Testing and Inspections

Systems and equipment for all the non-nuclear facilities, including any safety-related systems, performed as designed and required during 2021 with the exception of Compressed Air Systems where one of the three compressors was not operational (awaiting parts). In addition, issues with some gas detection systems were part of the missed preventive maintenance activities that was reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence.

Routine maintenance was carried out, and equipment tests and inspection were completed in 2021 with no significant results.

G.4 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the non-nuclear facilities as part of routine operations.

G.5 Effluents Released

There were no radioactive and/or hazardous effluents (gaseous or liquid) released into the environment from the facilities as part of routine operations.

There was 1.15E+09 L of effluent released from buildings Building 422 (Outfall Monitoring Station) and 0 L of effluent released from Building 907 (Sewage Lift Station and Lagoons) as there was no lagoon release in 2021.

Landfill Dugout Water Monitoring

The WL landfill is surrounded by six dugouts where surface water collects. These dugouts are sampled as part of the ongoing operational control monitoring for the facility. In 2021, the precipitation was low over the year (395 mm) and the dugouts had low water levels during the summer sampling period. The location of the dugouts are shown in Figure 14. Dugout 22 is used as the Control and is about 300 m away from the landfill to the north-northeast, and would not be affected by facility operations.

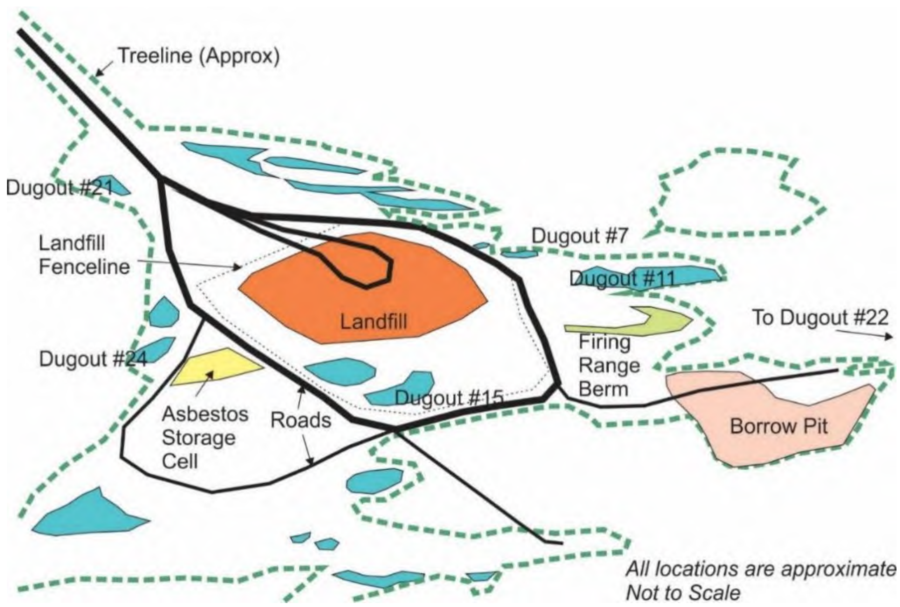

Figure 14: WL Landfill Area Showing Approximate Locations of Monitored Dugouts

The results from the sample analysis for alpha and beta from these dugouts are provided in Table 90 and Table 91 respectively. All alpha results for 2021 were at the detection limits, and are below the drinking water screening level of 0.50 Bq/L. All beta results for 2021 were near the detection limits, and are below the drinking water screening level of 1.0 Bq/L. Both alpha and beta results for 2021 are consistent with previous results obtained from 2016 to 2020.

Table 90: Gross Alpha Results from the Landfill Dugouts

Sample	Gross Alpha (Bq/L)					
Location	2016	2017	2018	2019	2020	2021
Dugout #7	< 0.14	< 0.17	< 0.17	0.07	<0.05	<0.05

Low levels of tritium (9 Bq/L) were detected in one of the landfill wells (water table) starting in 2011. Its appearance in the groundwater resulted in initiation of the surface (dugout) water measurement of tritium. Tritium has been detected in landfill Dugout 15 for the past eight years, and a low value was noted in Dugout 24 in 2011, 2012, 2016, and although a higher amount was noted in 2018 (76 Bq/L), the value returned to background in 2019 and remained there through 2021. The higher tritium level in Dugout 15 was 93 Bq/L, approximately one-half of that measured in 2019 (212 Bq/L). All results are well below drinking water limits of 7,000 Bq/L. The other dugouts do not appear to contain tritium, as levels comparable to blank samples analyzed from 2013 to 2021 that contain < 5 Bq/L of tritium were recorded. Tritium results from the landfill dugouts are shown in Table 92.

Table 92: Results from the Landfill Dugouts

Sample	Tritium (Bq/L)					
Location	2016	2017	2018	2019	2020	2021

Dugout #24	5.5	< 4	76	< 4	< 4	< 5

NA sample not available

When initially detected in the dugouts, it was assumed that it was possible that tritium emissions from the WR-1 Building 100 deposited in the ponds surrounding the landfill, and was subsequently drawn in to the water table. After consideration, it was determined that the most likely source of tritium is the landfill. The presence of above background tritium in only a few dugouts cannot be explained by air borne deposition. The highest tritium activities are found in the dugouts and wells in closest proximity to the landfill. Due to its 10 m height, the landfill has

a higher hydraulic head than the local terrain, including the asbestos storage cell, and thus will be more likely to contribute leached contaminants to the shallow ground water system. Due to local groundwater flow directions (toward the south and southwest), Dugouts 15 and 24 are more likely to receive contaminants from the migration of water from the landfill. As the landfill had been in operation for over 50 years, the potential for a historic error in placement is greater for the landfill than the adjacent asbestos storage cell.

The water testing conducted in 2018 included Sr-90 and Tc-99, two potentially mobile radionuclides. In 2018, near detection levels of Sr-90 were noted in Dugout 21 and near detection limit levels of Tc-99 were noted in Dugouts 21 and 24. In 2019, only Sr-90 was tested, and was found to be at the detection limit. In 2020, both Sr-90 and Tc-99 were again measured. Sr-90 was at the detection limit and Tc-99 was not detected. In 2021 (Table 93), no Sr-90 analysis was conducted as per the instructions provided to lab to only analyze if gross Beta exceeded 5 Bq/L. Tc-99 was again below the detection limit. The water from these dugouts and wells is not used for human consumption. All results were below drinking water limits of 5 Bq/L for Sr-90 and 200 Bq/L for Tc-99.

Table 93: Sr-90 and Tc-99 Results from the landfill Dugouts in 2021

Sample Location	(Bq/L)	
	Sr-90	Tc-99
Dugout #7	NA	ND
Dugout #11	NA	ND
Dugout #15	NA	ND
Dugout #21	NA	ND
Dugout #22	NA	ND
Dugout #24	NA	ND

NA – No Analysis Gross Beta below analysis trigger limit.
ND – Non Detect

The water from the dugouts was also tested for a suite of non-radiological parameters including total metals, mercury, nitrate + nitrite, sulphate, chloride, sodium, potassium, calcium, magnesium, sulphur, total ammonia (N), phosphorus, phenols and volatile organics (including benzene, toluene, ethylbenzene and xylene). Elevated levels of boron were detected in Dugout #15, a continuation of results from 2017 onwards (Table 94). The value in 2021 remained under the Drinking Water Guideline for Boron (5,000 µg/L). Dugout #24 showed 431 µg/L in 2021, all other dugouts showed values below detection limits.

Table 94: Boron Results from the Landfill Dugout #15

Sample Location	(µg/L)				
	2017	2018	2019	2020	2021
Dugout #15	1630	5460	8460	2040	3760

Molybdenum remained at detection limits from 2020 through 2021. In 2021, Manganese remained higher than drinking water guidelines of 50 µg/L in Dugout #15 (509 µg/L). No other parameters were detected at concentrations of concern.

Groundwater results will be discussed in the annual Environmental Monitoring report [29]. Sediment sampling of one of the dugouts was conducted as part of the Environmental Assessment Follow-up Program and will be reported in [28].

Landfill Dugout Sediment Monitoring

Sediment sampling of the dugouts was conducted in 2017 as part of the Environmental Assessment Follow-up Program. The analysis of the sediment included a full suite of metals, mercury, lead, PCBs and for radioactivity, including Sr-90. There were elevated levels of molybdenum in the surface sediment of one dugout (Dugout 24) and no other contaminants of potential concern noted. Molybdenum can be found naturally in the environment (minerals containing iron, bismuth, or copper) as well as being a component of man-made items such as filaments, X-ray tubes, screens, grids for radios, spark plugs, contacts, induction heating elements, and/or part of a waste stream from man-made processes (burning of fossil fuels). The source of the molybdenum is being investigated as part of the assessment of the Landfill prior to closure. Monitoring of the sediments in the dugouts around the landfill is planned to continue every 5 years (from 2017) as well as annual monitoring of the water, as such no sediment sampling was conducted in 2021.

Further investigation will be conducted during the eventual closure of the landfill and will also be reported in the Environmental Assessment Follow-up Program [28].

Landfill Radiological Monitoring

Annual radiological monitoring of the landfill surface is performed as a confirmatory measure. The results show readings consistent with background levels at the landfill fence line. Table 95 provides a five year listing of survey results at the top of the landfill. For some years monitoring was performed at the base of the pile, and more recently monitoring was performed around the perimeter of the fenced area of the landfill.

Table 95: Landfill Radiological Monitoring

1. Introduction

The National Pollutant Release Inventory (NPRI) is Canada's legislated, publicly accessible inventory of pollutant releases, disposals and recycling. Sections 46–53 of the *Canadian Environmental Protection Act*, *1999* (CEPA 1999) contain information-gathering provisions that allow the Minister of the Environment to require reporting of information on substances. The provisions also require the Minister to establish and publish a national inventory of releases and transfers of pollutants. These provisions under CEPA 1999 form the primary legislative basis for the NPRI. The NPRI reporting requirements for the 2012 and 2013 reporting years were published in the *Notice with respect to substances in the National Pollutant Release Inventory for 2012 and 2013* in the *Canada Gazette*, Part I, on December 29, 2012.

NPRI information is a major starting point for identifying and monitoring sources of pollution in Canada, and in developing indicators for the quality of our air, land and water. The NPRI helps determine if regulatory or other action is necessary to ensure reductions, and if so, the form that action should take. The NPRI provides Canadians with annual information on industrial, institutional, commercial and other releases and transfers in their communities.

This guide is designed to assist facility owners and operators in understanding the NPRI reporting requirements, and in determining if they are required to report to the NPRI. It provides a general overview of the reporting requirements for all NPRI substances, and provides information on additional guidance materials that address specific sectors, activities and substances.

2. Reporting Deadline and Changes to Reporting Requirements

2.1 Reporting Deadline

Reporting is mandatory for facilities that meet the requirements of the NPRI Notice published in the *Canada Gazette*, Part I.

The deadline for reporting to the NPRI for the 2012 calendar year is June 1, 2013. Because June 1, 2013, is a Saturday, reports for 2012 will be considered on time if they are submitted by **Monday, June 3, 2013**.

The deadline for reporting to the NPRI for the 2013 calendar year is June 1, 2014. Because June 1, 2014, is a Sunday, reports for 2013 will be considered on time if they are submitted by **Monday, June 2, 2014**.

Facilities that are required to report to other jurisdictions (for example, reporting under the Ontario *Toxics Reduction Act, 2009*) are advised to verify the correct reporting deadlines with those jurisdictions.

2.2 Changes to the Reporting Requirements for 2012 and 2013

2.2.1 No Changes to Reporting Requirements

There are no substantive changes to the reporting requirements for 2012 and 2013.

2.2.2 Gazette Notice Multi-Year Format

NPRI reporting requirements have been published annually in the *Canada Gazette*, Part I since the program was established. In the past, each Notice applied to a single calendar year (with the exception of the *Notice with respect to tailings and waste rock reporting under the National Pollutant Release Inventory for 2006 to 2008*). On December 29, 2012, a single Notice was published in the *Canada Gazette* that contains the reporting requirements for two years: 2012 and 2013. Because the notice applies to two years, the requirements described in this Guide also apply to the 2012 and 2013 calendar years.

Note that each year must be considered individually when determining if thresholds are met and if reporting is required. Quantities of substances that are released, disposed of and recycled should be reported for each separate year, by each reporting deadline indicated above.

3. General Information and Reporting Requirements

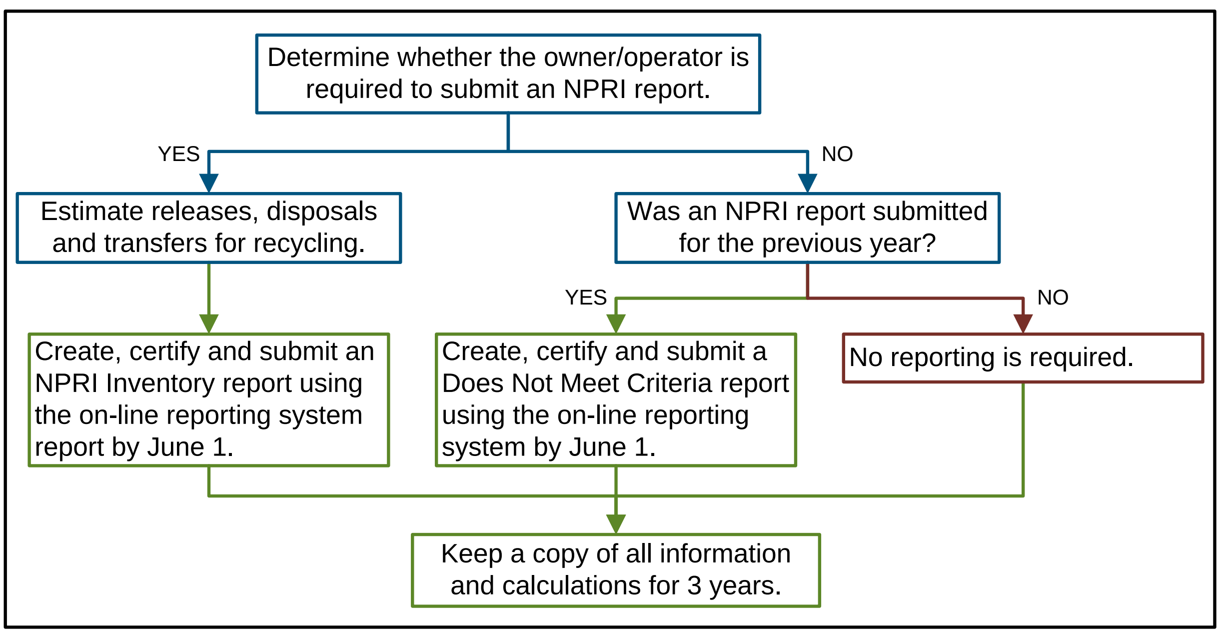
3.1 Introduction

This section summarizes the process for reporting to the NPRI, describes the legal basis for the NPRI, provides an overview of the NPRI reporting requirements, provides definitions of terms that are used throughout the Guide, and describes the information to be reported that applies to more than one group of substances. This section also provides information on additional resources that are available to assist in determining if a report is required for a facility, and on the methods for estimating quantities of releases, disposals and transfers for recycling. Details on reporting requirements and information to be reported that are specific to Parts 1 through 5 substances are presented in sections 4 through 9.

3.2 Process for Reporting to the National Pollutant Release Inventory

The NPRI reporting process is outlined in Figure 1. An NPRI report can be created and submitted to Environment Canada using the on-line reporting system, available through the NPRI website at www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=F6300E68-1. Step-by-step instructions on the process of creating and submitting a report are available in the on-line reporting system.

Figure 1. Process for Reporting to the National Pollutant Release Inventory



3.3 The *Canada Gazette* Notice – The Legal Basis for the National Pollutant Release Inventory

The legal basis for the NPRI is the *Notice with respect to substances in the National Pollutant Release Inventory for 2012 and 2013* published in the *Canada Gazette*, Part I (hereafter referred to as "the Notice"). The Notice is published under the authority of subsection 46(1) of CEPA 1999, and specifies that any person who owned or operated a facility during the 2012 or 2013 calendar years, under the conditions prescribed in the Notice, must provide certain information to the Minister of the Environment by the reporting deadline for that calendar year.

The owner or operator of that facility as of December 31st of a given year is required to report to the NPRI, whether or not the ownership of a facility changes during the calendar year. If operations at a facility are terminated during the calendar year, it is the last owner or operator of the facility that is required to report.

Companies that meet reporting requirements but fail to report, fail to report on time, or knowingly submit false or misleading information, face penalties as listed under sections 272 and 273 of CEPA 1999. Facilities that did not meet the reporting criteria or were exempt from reporting in previous years should review their status to determine whether they are required to report for the current reporting year.

The Notice encompasses a wide range of substances and groups of substances, reporting criteria and requirements. It is divided into four schedules with several parts in each, as described in Table 1. For the complete list of NPRI substances, consult the NPRI website at www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=E2BFC2DB-1.

Table 1. Overview of the National Pollutant Release Inventory *Canada Gazette* Notice

Schedule	Part	Contents
1 – List of Substances	1	Lists 237 substances and groups of substances and is divided into Groups A and B, based on thresholds and information to be reported (referred to as Part 1A and Part 1B substances)
	2	Lists 29 individual polycyclic aromatic hydrocarbons (PAHs)
	3	Lists 7 dioxins, 10 furans and hexachlorobenzene (HCB)
	4	Lists 7 criteria air contaminants (CACs)
	5	Lists 75 selected volatile organic compounds (VOCs) and groups of VOCs with additional reporting requirements (speciated VOCs)
2 – Definitions	n/a	Provides definitions of the terms used in the Notice
3 – Reporting Criteria	General	General reporting criteria, including the reporting deadline, the employee threshold, and exclusions and exemptions
	1	Criteria for substances listed in Schedule 1, Part 1
	2	Criteria for the PAHs listed in Schedule 1, Part 2
	3	Criteria for dioxins, furans and HCB listed in Schedule 1, Part 3
	4	Criteria for CACs listed in Schedule 1, Part 4
	5	Criteria for speciated VOCs listed in Schedule 1, Part 5

Schedule	Part	Contents
4 – Information to be Reported	General	General information required to be reported and manner of reporting
	Facility Information	Information to be reported on the facility, including name, identification codes, contacts and activities
	1	Information to be reported for substances listed in Schedule 1, Part 1
	2	Information to be reported for PAHs listed in Schedule 1, Part 2
	3	Information to be reported for dioxins, furans and HCB listed in Schedule 1, Part 3
	4	Information to be reported for CACs listed in Schedule 1, Part 4
	5	Information to be reported for speciated VOCs listed in Schedule 1, Part 5

3.4 Overview of the National Pollutant Release Inventory Reporting Requirements

This section provides a brief overview of what facilities are required to report and the reporting thresholds, which are described in detail in Sections 4 through 9 of this Guide. In general, an NPRI report is required for any facility:

- where employees work a total of ≥ 20 000 hours (the employee threshold) (see section 3.6.1);
- where specified activities to which the employee threshold does not apply take place (see section 3.6.2);
- where the employee threshold is not met, but the reporting criteria for CACs are met; or
- that is a pipeline installation (defined in section 3.5.1)

and that meets any of the other reporting criteria (e.g., mass, concentration or activity thresholds).

The groups of substances have various thresholds (e.g., mass, concentration, activity, etc.) that are specified in Schedule 3 of the Notice. The thresholds are summarized in Table 2.

Table 2. Overview of National Pollutant Release Inventory Reporting Thresholds

Part	Substances	Mass Threshold	Thresholds
1A	• 230 substances and groups of substances	10 tonnes	**TOTAL** quantity of a substance: • manufactured, processed or otherwise used at a concentration by weight of ≥ 1%, **plus** • incidentally manufactured, processed or otherwise used as a by-product at any concentration, **plus** • contained in tailings disposed of during the calendar year at any concentration, **plus** • contained in waste rock disposed of during the calendar year at a concentration by weight of ≥ 1%
1B	• Mercury	5 kilograms	**TOTAL** quantities of mercury at any concentration: • manufactured, processed or otherwise used, **plus** • incidentally manufactured, processed or otherwise used as a by-product, **plus** • contained in tailings disposed of during the calendar year, **plus** • contained in waste rock disposed of during the calendar year

Part	Substances	Mass Threshold	Thresholds
1B	• Cadmium	5 kilograms	**TOTAL** of the quantity of a substance: • manufactured, processed or otherwise used at a concentration by weight of ≥ 0.1%, **plus** • incidentally manufactured, processed or otherwise used as a by-product at any concentration, **plus** • contained in tailings disposed of during the calendar year at any concentration, **plus** • contained in waste rock disposed of during the calendar year at any concentration
	• Arsenic • Hexavalent chromium • Lead • Tetraethyl lead	50 kilograms	
	• Selenium	100 kg	**TOTAL** of the quantity of selenium: • manufactured, processed or otherwise used at a concentration by weight of ≥ 0.000005%, **plus** • incidentally manufactured, processed or otherwise used as a by-product at any concentration, **plus** • contained in tailings disposed of during the calendar year at any concentration, **plus** • contained in waste rock disposed of during the calendar year at any concentration
2	• 29 polycyclic aromatic hydrocarbons (PAHs)	50 kilograms	**TOTAL** of the quantities of PAHs at any concentration: • incidentally manufactured and released, disposed of or transferred for recycling, **plus** • contained in tailings disposed of during the calendar year
		Any quantity	Where wood preservation using creosote takes place, reporting is mandatory regardless of quantities or concentrations.
3	• 7 dioxins • 10 furans • Hexachlorobenzene (HCB)	Any quantity	Where specified activities take place, reporting is mandatory regardless of quantities or concentrations.
4	• Carbon monoxide • Nitrogen oxides • Sulphur dioxide • Total particulate matter	20 tonnes	Quantity released to air (no concentration threshold applies)
	• Volatile organic compounds (VOCs)	10 tonnes	
	• Particulate matter ≤ 10 micrometres (PM_{10})	0.5 tonnes	
	• Particulate matter ≤ 2.5 micrometres ($PM_{2.5}$)	0.3 tonnes	
5	• 75 speciated VOCs (individual VOCs, isomer groups and other groups and mixtures)	1 tonne	Quantity released to air, provided that ≥ 10 tonnes of total VOCs are released to air (no concentration threshold applies)

3.5 Definitions

A comprehensive glossary of terms and expressions used by the NPRI is available on the NPRI website at www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=9264E929-1. The following sections provide definitions for some of the most common terms and expressions.

3.5.1 Facilities

The term "facility" refers to a contiguous facility, a portable facility, a pipeline installation or an offshore installation, as defined below. The reporting requirements for Part 1 substances apply to contiguous facilities and offshore installations. The requirements for Parts 2 and 3 substances apply to contiguous, portable and offshore facilities. Parts 4 and 5 substance requirements apply to all four types of facilities: contiguous, portable, pipeline and offshore.

Contiguous facility

A contiguous facility is defined as all buildings, equipment, structures and stationary items that are located on a single site, or on contiguous sites or adjacent sites, that are owned or operated by the same person and that function as a single integrated site, including wastewater collection systems that release treated or untreated wastewater into surface waters.

Portable facility

A portable facility is defined as portable polychlorinated biphenyl (PCB) destruction equipment, portable asphalt plants and portable concrete batching plants. The definition applies where the facility can be entirely relocated for operation.

Pipeline installation

A pipeline installation is defined as a collection of equipment, situated at a single site, used in the operation of a natural gas transmission or distribution pipeline. This definition includes pipeline compressor and storage stations along pipelines used to transport both raw and processed natural gas. Pipeline installations are subject only to the reporting criteria for CACs (Part 4 substances) and speciated VOCs (Part 5 substances).

Offshore installation

An offshore installation is defined as an offshore drilling unit, production platform or ship, or subsea installation that is related to the exploitation of oil or natural gas and that is attached or anchored to the continental shelf of Canada or within Canada's exclusive economic zone.

3.5.2 Reporting Thresholds

Manufacture

The term "manufacture" means to produce, prepare or compound an NPRI substance. It also includes the incidental production of an NPRI substance as a by-product.

Examples of manufacture

The production of chlorine dioxide by a chemical plant is an example of manufacturing. The production of hydrochloric acid during the manufacture of chlorofluorocarbons is an example of the incidental manufacture of hydrochloric acid.

Process

The term "process" means the preparation of an NPRI substance, after its manufacture, for distribution in commerce. Processing includes the preparation of a substance with or without changes in physical state or chemical form. The term also applies to the processing of a mixture or formulation that contains an NPRI substance as one component, the processing of articles (see below for the definition of article), and the processing of a substance as a by-product.

Examples of process

The use of chlorine to manufacture hypochloric acid (not an NPRI substance) is an example of processing of chlorine. The use of toluene and xylene to blend paint solvent mixtures is an example of processing without changes in chemical form.

Other use or otherwise used

The terms "other use" and "otherwise used" mean any use, disposal or release of an NPRI substance that does not fall under the definitions of manufacture or process. This includes the use of the substance as a chemical processing aid, manufacturing aid or some other ancillary use, and the other use of by-products. Certain uses of substances are excluded. These are listed in Table 4 below.

Example of other use

The use of trichloroethylene in the maintenance of manufacturing and process equipment is considered an other use of that substance.

By-product

Before the by-product requirements were created, large-volume, low-concentration releases and disposals were not being reported to the NPRI because of the concentration thresholds for Part 1 substances. The by-product requirements were created to ensure that these releases and disposals are reported since the overall quantities of by-products can be significant, even though their concentration may be low.

The term "by-product" refers to the quantity of an NPRI Part 1 substance that is ***incidentally*** **manufactured, processed or otherwise used** at the facility **at any concentration**, and **released to the environment or disposed of**. The quantity of a substance that is recycled or that remains in the final product is not considered to be a by-product for the purpose of the NPRI threshold calculation.

In general, if a quantity of a substance is ***intentionally*** **manufactured, processed or otherwise used** at a facility, then that quantity of the substance is **not a by-product**, even if it is unintentionally manufactured, processed or otherwise used at another step in the process.

The quantity of a substance that is a by-product must be included in the calculation of the reporting threshold, regardless of concentration. The by-product requirements only apply to Part 1 substances and are only used for the purpose of determining whether or not the mass threshold for a substance has been met.

Examples of by-products

Hydrogen fluoride is incidentally manufactured and released during aluminum smelting. Therefore, the hydrogen fluoride is a by-product and must be included in the calculation of the reporting threshold, regardless of concentration.

Manganese and nickel are incidentally present in coal and are therefore by-products of the coal combustion process. During combustion, a portion of these metals is concentrated in the ash, which is disposed of, and a portion of the metals is released in stack emissions. The weight of the metal released from the stack and in the ash sent for disposal must be included in the calculation of the reporting threshold, regardless of concentration.

Metal cuttings, sent for disposal, contain alloyed chromium and nickel at a concentration of less than 1%. The chromium and nickel are essential components of the alloy; therefore they are not incidentally processed and are not considered to be by-products. Therefore, the chromium and nickel in the metal cuttings do not need to be included in the calculation of the reporting threshold, because the substances are present at a concentration less than the concentration threshold of 1%.

Article

An "article" is defined as a manufactured item that does not release an NPRI substance when it undergoes processing or other use. When articles are processed or otherwise used, and there are no releases, or the releases are recycled with due care, the NPRI substances in that article do not need to be included in the threshold calculation.

Exercising due care means that the facility generated less than one kilogram of a Part 1A substance as waste during the year. There is no quantitative measure of due care in recycling Part 1B substances, because even minimal releases of these substances can cause significant adverse effects and can reasonably be expected to contribute to exceeding their low thresholds. Therefore, if an article containing a Part 1B substance is processed or otherwise used and there are releases, the Part 1B substance in the article must be included in the threshold calculation.

Examples of articles

In an instance where a metal reclamation facility accepts spent lead-acid batteries for recycling, and the batteries are broken into pieces in a hammer mill and their parts (sulphuric acid, lead and plastic) are subsequently reclaimed, the batteries lose their article status, because they are broken apart during the recycling process. The metal reclamation facility is now required to report any NPRI substances from these batteries if the thresholds are met.

A sealed glass bulb containing mercury used in a leveling switch meets the definition of an article. However, the quantity of mercury in the switch must be included in a facility's calculation of the reporting threshold if the item loses its article status (e.g., the bulb is broken during waste management operations, thus allowing a release of mercury). As long as the bulbs remain intact, they are considered articles and are therefore not included in calculating the reporting threshold.

Tailings

The term "tailings" is defined as the waste material, which may or may not be mixed with water, that remains after processing of ore or mined materials, in order to extract marketable components such as metals, minerals or bitumen. This can include ground rock material, sand, clay, process chemicals or residual metals, minerals or bitumen, petroleum coke (petcoke) and sulphur.

Waste rock

"Waste rock" is rock that is removed in the mining process to provide access to the ore, and is not further processed during the reporting year. Waste rock does not include unconsolidated overburden, which is defined as unconsolidated materials overlying the ore (or bitumen) deposit, including, but not limited to, soil, glacial deposits, sand and sediment.

3.5.3 Releases, Disposals and Transfers

On-site releases

An on-site release is a discharge of a substance to the environment within the physical boundaries of the facility. This includes:

- emissions to air: discharges through a stack, vent or other point of release, losses from storage and handling of materials, fugitive emissions (releases that cannot be captured and releases that are unintentional), spills and accidental releases, other non-point releases, and road dust (particulate matter only);
- releases to surface waters: direct discharges, spills and leaks, but not including discharges to municipal wastewater treatment plants (which are reported under off-site transfers for treatment); and
- releases to land: spills, leaks and other releases.

On-site disposals

On-site disposals include the following:

- total quantities of substances sent for final disposal to landfill, land application or underground injection on the facility site; and
- net quantities of substances that are moved into an on-site area where tailings or waste rock are discarded or stored and further managed to reduce or prevent releases.

Off-site disposals

Off-site disposals include total quantities that are transferred off the facility site to:

- landfill, land application or underground injection;
- storage prior to final disposal;
- treatment prior to final disposal (see below); and
- an area where tailings or waste rock are discarded or stored and further managed to reduce or prevent releases.

Off-site transfers for treatment prior to final disposal

A substance may be transferred to a location off the facility site for treatment prior to final disposal. Treatment processes include:

- physical treatment (e.g., drying, evaporation, encapsulation or vitrification);
- chemical treatment (e.g., precipitation, stabilization or neutralization);
- biological treatment (e.g., bio-oxidation);
- incineration or thermal treatment, where energy is not recovered; and
- treatment at a municipal sewage treatment plant.

Off-site transfers for recycling and energy recovery

A substance may be transferred to a location off the facility site for recycling and energy recovery. Recycling refers to activities that keep a material or a component of the material from becoming a waste destined for final disposal. Ten types of recycling operations are identified:

- energy recovery
- recovery of solvents
- recovery of organic substances (not solvents)
- recovery of metals and metal compounds
- recovery of inorganic materials (not metals)
- recovery of acids or bases
- recovery of catalysts
- recovery of pollution abatement residues
- refining or reuse of used oil
- other recovery, reuse or recycling activities

3.6 Facilities to Which the NPRI Reporting Requirements Apply

The NPRI reporting requirements apply to a facility:

- where the employee threshold is met (see section 3.6.1);
- where activities to which the employee threshold does not apply take place (see section 3.6.2);
- where the employee threshold is not met, but the reporting criteria for Part 4 substances are met; or
- that is a pipeline installation (defined in section 3.5.1)

and that meets any of the other reporting criteria (e.g., mass and concentration thresholds).

3.6.1 Employee Threshold

Facilities where the employees work a total of 20 000 hours or more during the calendar year (the employee threshold) are required to report to the NPRI, if the thresholds for at least one substance are met, or if an activity-based threshold is met. The employee threshold depends on the number of hours worked by all employees at the facility during the calendar year. This includes:

- all hours worked by individuals employed at the facility, including students, part-time and term employees;
- all hours worked by the owner(s) who performed work on-site at the facility;

- all hours worked by a person, such as a contractor, who performed work at the facility that is related to the operations of the facility; and
- all paid vacation and sick leave.

The employee threshold must be met by most facilities before they need to consider reporting for Parts 1 through 3 substances, unless activities to which the employee threshold does not apply (see section 3.6.2) take place at the facility.

3.6.2 Activities to Which the Employee Threshold Does Not Apply

If one or more of the activities listed in Table 3 take place at the facility, the owner/operator of the facility must report to the NPRI, regardless of the number of hours worked by employees (provided that other reporting criteria, such as mass and concentration thresholds [see Table 2], are also met). The employee threshold does not apply to these activities because they release significant quantities of NPRI substances to the environment, while not necessarily meeting the employee threshold. Descriptions of these activities are provided below.

In addition to the activities listed in Table 3, the employee threshold does not apply to facilities where stationary combustion equipment is operated, for the purposes of reporting Part 4 and 5 substances. Facilities that operate stationary combustion equipment must report for Parts 4 and 5 substances regardless of employee hours, provided the release thresholds are met.

Table 3. Activities to Which the Employee Threshold Does Not Apply

Activity
Non-hazardous solid waste incineration of ≥ 26 tonnes of waste, including, but not limited to, conical burners and beehive burners
Biomedical or hospital waste incineration of ≥ 26 tonnes of waste
Hazardous waste incineration
Sewage sludge incineration
Wood preservation (using heat or pressure treatment, or both)
Terminal operations
Discharge of treated or untreated wastewater from a wastewater collection system discharging an average of ≥ 10 000 m^3/day into surface waters
Operations at pits or quarries where production is ≥ 500 000 tonnes

Incineration

A waste incinerator is a device, mechanism or structure constructed primarily to thermally treat (e.g., combust or pyrolyze) waste for the purpose of reducing its volume, or destroying hazardous chemicals or pathogens present in the waste. This includes facilities where waste heat is recovered as a by-product from the exhaust gases of an incinerator (e.g., energy-from-waste incinerators), conical burners and beehive burners. This does not include industrial processes where fuel derived from waste is fired as an energy source, such as industrial boilers. For example, if bark, wood chips or other wood waste is used as fuel to fire a boiler, these activities are not considered energy-from-waste incinerators.

Non-hazardous solid waste incineration

Non-hazardous solid waste is any solid waste, regardless of origin, that, if not incinerated, might normally be disposed of in a non-secure manner (e.g., at a sanitary landfill site). It includes clean wood waste (i.e., waste from woodworking or forest product operations, including bark, where the wood waste has not been treated with preservative chemicals or decorative coatings), and residential and other municipal wastes.

Biomedical or hospital waste incineration

Biomedical or hospital waste is waste that is generated by:

- human or animal health-care facilities;
- medical or veterinary research and testing establishments;
- health-care teaching establishments;
- clinical testing or research laboratories; and
- facilities involved in the production or testing of vaccines.

Biomedical or hospital waste includes human anatomical waste, animal waste, microbiology laboratory waste, human blood and body fluid waste, and waste sharps. It does not include waste that is from animal husbandry, is household in origin, or is controlled in accordance with the *Health of Animals Act*. Household wastes or wastes that are generated in food production, general building maintenance and office administration activities of those facilities to which this definition applies are considered to be non-hazardous waste, not biomedical or hospital waste. For more information, consult www.ccme.ca/assets/pdf/pn_1060_e.pdf.

Hazardous waste incineration

Hazardous waste includes wastes that are potentially hazardous to human health and/or the environment because of their nature and quantity, and that require special handling techniques. They are defined by taking into account the hazard criteria established under the *Transportation of Dangerous Goods Regulations* (www.tc.gc.ca/eng/tdg/clear-tofc-211.htm) as well as wastes and materials specifically listed in the Schedules of the *Export and Import of Hazardous Waste and Hazardous Recyclable Material Regulations* (www.ec.gc.ca/lcpe-cepa/eng/regulations/detailReg.cfm?intReg=84). This includes hazardous waste incinerated in a mobile incinerator temporarily located at a facility.

Sewage sludge incineration

Sludge is a semi-liquid mass removed from a liquid flow of wastes. Sewage sludge is sludge from a facility treating wastewater from a sewer system. The drying of sludge to reduce water content is part of the incineration stage.

Wood preservation

Wood preservation is the use of a preservative for the preservation of wood by means of heat or pressure treatment, or both, and includes the manufacture, blending or reformulation of wood preservatives for that purpose. For more information, consult the *Guidance for Wood Preservation Facilities Reporting to the NPRI*, available at www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=29B3E589-1.

Terminal operations

Terminal operations are either (i) the use of storage tanks and associated equipment at a site used to store or transfer crude oil, artificial crude or intermediates of fuel products into or out of a pipeline; or (ii) the operating activities of a primary distribution installation, normally equipped with floating roof tanks, that receives gasoline by pipeline, railcar, marine vessel or directly from a refinery. Terminal operations do not include bulk plants or service stations.

Wastewater collection systems

A wastewater facility is a wastewater collection system that discharges treated or untreated wastewater into surface waters. Therefore, a wastewater system includes both the collection components (a system of sewers and/or ditches that convey sanitary or combined sewage for a community) and treatment components (a plant or process location that accepts collection-system flows for the purposes of removing substances from the wastewater). For more information, consult the *NPRI Guidance Manual for the Wastewater Sector*, available at www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=86E3D932-1, and *Identification of Wastewater Treatment System Configuration and Process Characteristics*, available at www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=57FBBE31-1.

Pits and quarries

A pit is an excavation that is open to the air, and any associated infrastructure, that is operated for the purpose of extracting sand, clay, marl, earth, shale, gravel, unconsolidated rock or other unconsolidated materials, but not bitumen.

A quarry is an excavation that is open to the air, and any associated infrastructure, that is operated for the purpose of working, recovering or extracting limestone, sandstone, dolostone, marble, granite or other consolidated rock.

For more information on reporting for pits and quarries, consult *Pits and Quarries Guidance*, available at www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=A9C1EE34-1.

3.7 Exemptions and Exclusions

3.7.1 Facilities Exempt from All NPRI Reporting Requirements

Two types of facilities are exempt from reporting to the NPRI:

- facilities used exclusively for oil and gas exploration or the drilling of oil and gas wells; these are the only types of oil and gas facilities exempt from reporting to the NPRI; and
- pits and quarries where annual production is < 500 000 tonnes.

3.7.2 Exclusions for All Substances

The quantity of a substance contained in any item listed in Table 4 should not be included when calculating and reporting releases, disposals or transfers for recycling. In addition, vehicle emissions (not including unpaved road dust) should not be considered when calculating the thresholds and when reporting releases, disposals or transfers for recycling. A vehicle is any mobile equipment that is capable of self-propulsion, including fleet vehicles and earth-moving equipment (e.g., loaders, dump trucks, forklifts, excavators and bulldozers).

Table 4. Items Not Considered when Reporting to the National Pollutant Release Inventory

Articles that are processed or otherwise used(1)
Materials used as structural components of the facility (buildings and other fixed structures), but not process equipment
Materials used in janitorial or facility grounds maintenance(2)
Materials used for personal use by employees or other persons
Intake water or intake air, such as water used for process cooling or air used either as compressed air or for combustion

(1) See section 3.5.2 for the definition of an article.

(2) This includes NPRI substances contained in fertilizers and pesticides used for grounds maintenance, and cleaning agents used for maintaining facility cleanliness. The maintenance of process equipment (e.g., cleaning manufacturing equipment with a solvent) is not excluded.

3.7.3 Activities Exempt from Reporting for Parts 1-3 Substances

The threshold calculation for a substance must exclude the quantity of a substance that is manufactured, processed or otherwise used in the activities listed in Table 5. In cases where a facility met the reporting criteria for a substance based on sources other than those listed in Table 5, the quantity of that specific substance from any exempt activities should also not be included when reporting releases, disposals or transfers for recycling to the NPRI.

A facility is exempt from reporting Parts 1 through 3 substances if the only source or use of that substance is from one or more of the activities listed in Table 5. Note, however, that these facilities are not exempt from reporting releases of Parts 4 and 5 substances from stationary combustion equipment.

Table 5. Activities Not Considered when Reporting Parts 1, 2 and 3 Substances

Education or training of students (for example, universities, colleges and schools)
Research or testing
Maintenance and repair of vehicles (automobiles, trucks, locomotives, rail cars, ships or aircraft), except painting and stripping of vehicles or their components, or the rebuilding or remanufacturing of vehicle components(1)
Distribution, storage or retail sale of fuels, except as part of terminal operations(2)
Wholesale or retail sale of articles or products that contain the substance
Retail sale of the substance
Growing, harvesting or management of renewable natural resources
The practice of dentistry

(1) Substances used for activities involving routine, scheduled and preventative maintenance of vehicles are exempt (e.g., repair, cleaning, replacement of lubricants/fluids). However, substances used in the painting or stripping of vehicles or vehicle components are subject to reporting. There is no exemption for activities that involve the removal, breakdown and total reconstruction of vehicle components (e.g., engines, landing gear, traction motors) using recovered or new parts, such that the rebuilt component is reinstalled or sold as an as-new replacement.

(2) See section 3.5.2 for the definition of "terminal operations." The exemption for distribution, storage or sale of fuels does not include terminal operations.

3.7.4 Exclusions for Tailings and Waste Rock

Tailings and waste rock are defined in section 3.5.2. The following sections describe the exclusions for stable/inert constituents of tailings, unconsolidated overburden and inert waste rock. These exclusions apply only to substances **contained in** tailings and waste rock. If a substance is **released to air or water from** tailings or waste rock (e.g., in airborne dust or as effluent), the quantity of the substance released must then be included in threshold calculations.

Stable/inert constituents of tailings

Substances contained in certain materials in tailings should be excluded from threshold calculations and reporting (e.g., sand grains from bitumen mines or in-situ production of bitumen). In order to be excluded, these materials must:

- be inert,
- be inorganic, and
- not have been crushed or otherwise physically or chemically altered.

The exclusion applies only to the components of tailings that meet the above three criteria (i.e., if part of the tailings stream met the criteria, only that portion of the tailings would be excluded, and the remainder of the tailings would be included).

Unconsolidated overburden

Substances contained in unconsolidated overburden should be excluded from threshold calculations and reporting. Unconsolidated overburden is unconsolidated materials overlying the ore or bitumen deposit, including, but not limited to, soil, glacial deposits, sand and sediment.

Inert waste rock

Substances contained in inert or clean waste rock should be excluded from threshold calculations and reporting. Inert waste rock is defined as waste rock that:

- is inert or clean according to a federal or provincial operating permit; or
- has a sulphur concentration of $\leq 0.2\%$; or
- has a sulphur concentration of $> 0.2\%$, and the ratio of neutralizing potential to acid-generating potential is $\geq 3:1$.

There is one exception to the exclusion for inert or clean waste rock: even if waste rock is inert or clean as defined above, the quantity of arsenic in waste rock cannot be excluded if the concentration of arsenic is > 12 milligrams per kilogram of waste rock.

3.8 Methods of Estimation

Estimates of the quantity of a substance that is manufactured, processed or otherwise used, and of the quantity that is released, disposed of or transferred for recycling, may be based on one of the following methods:

- Continuous emission monitoring systems
- Predictive emission monitoring

- Source testing
- Mass balance
- Site-specific emission factor
- Published emission factor
- Engineering estimates

A description of these methods is provided in the following sections. Examples using these estimation methods can be found in the *NPRI Toolbox* (www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=65A75CDF-1).

Information on releases, disposals and transfers for recycling needs to be reported if the owner/operator possesses the information or may reasonably be expected to have access to the information. The Notice specifies that if emissions are already monitored or measured under provincial or federal legislation or a municipal bylaw, those measurements must be used to report to the NPRI. If emissions are not monitored or measured under provincial or federal legislation or a municipal bylaw, reasonable efforts must still be undertaken to gather information on releases, disposals and transfers of a substance. What is "reasonable" depends on individual circumstances, but may include additional monitoring for NPRI substances.

In deciding whether additional efforts should be undertaken to generate new information for the purposes of NPRI reporting, the following factors, among others, should be considered:

- the health and environmental risks posed by a substance, including whether the substance has been declared toxic under CEPA 1999;
- the relative contribution of the industrial sector to releases, disposals and transfers for recycling of a substance in Canada;
- the relative contribution of the facility to releases, disposals and transfers for recycling of a substance in Canada; and
- the cost of additional monitoring.

Environment Canada is developing more detailed guidance that will outline suggested estimation methods, and will be recommending their use as they become available. For more information, consult the *NPRI Toolbox*.

3.8.1 Continuous Emission Monitoring Systems

Continuous emission monitoring systems (CEMS) record emissions over an extended and uninterrupted period. Once the concentration of a substance and the flow rate have been determined, emission rates can be calculated by multiplying the concentration by the discharge flow rate or volumetric stack gas flow rate. Annual emissions of the substance can then be estimated by multiplying the concentration by the annual flow rate of the discharged effluent or the gases in the stack or duct.

3.8.2 Predictive Emission Monitoring

Predictive emission monitoring (PEM) is based on developing a correlation between substance emission rates and process parameters (e.g., fuel usage, steam production, furnace temperature). PEM may be considered a hybrid of continuous monitoring, emission factors and stack tests. A correlation test must first be performed to determine the relationship between emission rates and process parameters. Emissions can then be calculated or predicted using process parameters to predict emission rates based on the results of the initial source test.

3.8.3 Source Testing

Source testing involves collecting a sample of the emission or effluent, then determining the concentration of one or more substances in the sample. The concentration of the substance(s) of interest is then multiplied by the volumetric flow rate to determine the quantity of the substance(s) emitted over time. Source testing of air emissions generally involves inserting a sampling probe into the stack or duct to collect a volume of exhaust effluent isokinetically. The substances collected in or on various media are subsequently analyzed. For liquid effluents, grab samples or 24-hour composite samples are extracted from the effluent stream.

3.8.4 Mass Balance

Mass balance involves applying the law of conservation of mass to a facility, process or piece of equipment. If there is no accumulation, all the materials that go into the system must come out. Releases are determined from the differences in input, output, accumulation and depletion of a substance. The general equation for a mass balance is:

$M_{in} = M_{out} + M_{accumulated/depleted}$

Where:

M_{in} = Mass of compound in the raw material feed

M_{out} = Mass of compound in the finished product and released to air, land and water

($M_{out} = M_{product} + M_{emitted}$)

$M_{accumulated/depleted}$ = Mass of compound accumulated or depleted in the system

The reliability of release estimates based on mass balances is dependent on the source type considered. Mass balance methods may be preferred for some releases, such as solvent use and loss. However, this method may not be suitable for many other sources, such as cases where chemical transformation of input streams occurs.

3.8.5 Site-Specific and Published Emission Factors

Generally, emission factors relate the quantity of substances emitted from a source to a common activity associated with those emissions. Emission factors may be published or developed by facilities using emission testing data and source-activity information. For a particular piece of equipment, specific emission factors may be available from the manufacturer or sales centre. The basic equations for determining emissions from emission factors are as follows:

$E_x = BQ \times CEF_x$ or

$$E_x = BQ \times EF_x \times \frac{100 - CE_x}{100}$$

Where:

E_x = Emission of substance x (kg or other unit of mass)

BQ = Activity rate or base quantity (base quantity unit)

CEF_x = Controlled emission factors of substance x (kg/BQ [dependent on any control devices installed])
EF_x = Uncontrolled emission factors of substance x (kg/BQ)
CE_x = Overall emission control efficiency of substance x (%)

3.8.6 Engineering Estimates

In many cases, sound engineering assessment is the most appropriate approach to determining process factors and base quantity values. Releases can be estimated from engineering principles and judgement by using knowledge of the chemical and physical processes involved, the design features of the source, and an understanding of the applicable physical and chemical laws. The reliability of these estimates depends on the complexity of the process and the level of understanding of its physical and chemical properties. To apply an engineering assessment method, follow these four basic principles:

1. Review all data pertaining to the specific source and to the industrial sector in general.
2. Use this data to provide gross approximations—and refine the approximations using sound engineering principles as data become available, in order to provide more accurate estimations.
3. Whenever possible, use alternate methods of calculation to cross-check each level of approximation.
4. Employ good record keeping.

3.8.7 Method Detection Limit

In NPRI reporting, there are several situations in which the issue of measurements below the method detection limit (MDL) arises. The MDL is the smallest concentration of the substance under analysis (i.e., the analyte) that produces an instrumental response and that meets all analyte detection and identification criteria of a specified test method. An indication that a reportable substance is below the MDL is not equivalent to stating that the substance is not present. If it is known that the substance is present, a concentration equivalent to half of the MDL should be used.

In a year where multiple measurements of the concentration of a substance in a given process stream are all below the MDL, and there is no other reason to believe that the substance is present, it can be assumed that the concentration of the substance in that process stream is zero.

In a year where multiple measurements are taken, and some measurements indicate that the concentration is above the MDL and some indicate that it is below the MDL, there is reason to assume that the substance is present. Therefore, a value of half the MDL should be used for those measurements where the concentration is below the MDL.

3.9 Sources of Information

Information required to perform threshold calculations and to estimate releases, disposals and transfers for recycling of NPRI substances is available from a variety of sources, including Environment Canada, the U.S. Environmental Protection Agency (EPA) and industry associations. These resources are described in the following sections. Useful information can also be found in Material Safety Data Sheets, and in permits and certificates of approval.

3.9.1 Environment Canada Guidance Documents and Tools

NPRI Toolbox

The *NPRI Toolbox* (www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=65A75CDF-1) provides a number of tools:

- General Guidance
- General Information on Emission Factors and Emission Estimation Techniques
- Useful Equations and Conversion Factors
- Example Calculations
- Software
- Information on Fuel Combustion and Fugitive Emission Sources
- Sector-Specific Information
- Miscellaneous Resources and Other Relevant Links

The sections on fuel combustion and fugitive emission sources and the sector-specific pages of the *NPRI Toolbox* include links to calculation spreadsheets developed for specific activities and sectors. When information (such as production quantities or fuel used) is entered, these spreadsheets will automatically calculate releases of NPRI substances.

Guidance documents

In addition to this guide, Environment Canada has developed several substance-, activity- and sector-specific guidance documents to assist in reporting to the NPRI. Table 6 lists these documents and their Internet addresses.

Table 6. Environment Canada Guidance Documents

3.9.2 U.S. Environmental Protection Agency Guidance Documents and Tools

The U.S. EPA has published numerous documents and software programs that can be used to assist facilities; these are described in Table 7.

Table 7. U.S. Environmental Protection Agency Guidance Documents and Tools

Guidance Document/Tool	Description	Internet Address
AP 42, Fifth Edition – *Compilation of Air Pollutant Emission Factors, Volume 1: Stationary Point and Area Sources*	Primary compilation of the U.S. EPA's emission factor information, containing emission factors and process information for more than 200 air pollution source categories	www.epa.gov/ttn/chief/ap42/index.html
Guidance Documents for reporting to the Toxics Release Inventory	Industry/process-specific and substance-specific guidance manuals to help estimate releases for reporting to the Toxics Release Inventory, which provide useful information for NPRI reporters	www.epa.gov/tri/guide_docs/index.htm
Locating and Estimating Documents	Compilations of available information on substances and sources of emissions	www.epa.gov/ttn/chief/le/index.html
Landfill Gas Emissions Model	Tool that can be used to estimate emission rates for non-methane organic compounds and individual air pollutants from municipal solid waste landfills	www.epa.gov/ttn/catc/products.html#software
PM Calculator	Contains information that allows the estimation of particulate matter fractions from total particulate matter	www.epa.gov/ttn/chief/tools/pm_calculator_condensibles.zip
SPECIATE	Repository of total organic compound and particulate matter speciation profiles for air pollution sources	www.epa.gov/ttn/chief/software/speciate/index.html
TANKS	Program that estimates volatile organic compound and hazardous air pollutant emissions from fixed- and floating-roof storage tanks	www.epa.gov/ttn/chief/software/tanks/index.html
WATER9	Program for estimating air emissions of individual waste constituents in wastewater collection, storage, treatment and disposal facilities	www.epa.gov/ttn/chief/software/water/water9_3/index.html
WebFIRE	The online Factor Information Retrieval (FIRE) database, which contains information on air emissions factors	http://cfpub.epa.gov/webfire/

3.9.3 Industry Association Guidance

Table 8 lists the industry association guidance available through the *NPRI Toolbox*.

Table 8. Industry Association Guidance Documents

Sector(s)	Association	Guidance
Mining; base metal smelting; iron ore pellets; potash mining	Mining Association of Canada	• *Reporting to the National Pollutant Release Inventory, An Interpretation Guide*
Chemicals manufacturing	Canadian Chemical Producers Association	• *NERM Reporting Guide* • *Guideline for Quantifying Emissions from Chemical Facilities* • *Source Characterization Guidelines – Primary Particulate Matter and Particulate Precursor Emission Estimation Methodologies for Chemical Production Facilities*
Upstream oil and gas; oil sands; natural gas transmission, distribution and storage	Canadian Association of Petroleum Producers	• *NPRI Guide – A Recommended Approach to Completing the National Pollutant Release Inventory for the Upstream Oil and Gas Industry* • *National Pollutant Release Inventory VOC Speciation Calculator* • *NPRI Guide – CAPP VOC Speciation Calculator*
Petroleum refining; petroleum product terminals	Canadian Petroleum Products Institute	• *Code of Practice for Developing an Emission Inventory for Refineries and Terminals, Revision 12*
Wastewater	Canadian Water and Wastewater Association	• *National Pollutant Release Inventory and Municipal Wastewater Services – Reporting Guidance For Small To Medium Wastewater Facilities*

3.10 General Information to Be Reported

3.10.1 Contact Information

For each of the following, the name, position, mailing address, telephone number and email address must be provided:

- *Technical contact*: the person who prepared the report and who will be able to answer any questions pertaining to its contents. All correspondence from Environment Canada regarding the NPRI will be sent to the technical contact if no coordinator (see below) is identified.
- *Public contact* (if any): the person responsible for answering any questions from the public concerning the report. This name will appear on the NPRI website as the contact for the facility. If a public contact is not identified, the name of the coordinator, or technical contact if no coordinator is identified, will appear instead.
- *Coordinator* (if any): the person who is responsible for preparing and submitting NPRI reports for more than one facility for the same company. The coordinator is responsible for answering any questions concerning all of the NPRI reports he/she filed. All NPRI correspondence from Environment Canada will be sent to the coordinator, if one is identified.
- *Certifying official*: the person who is legally responsible for the contents of the NPRI report. The certifying official is usually the owner or operator, or a company official authorized to act on his/her behalf.

- *Independent contractor* (if any): if an independent contractor prepared the report, contact information must be provided, including the name of the contracting company.

It is important that contact and ownership information be kept up-to-date using the online reporting system or by contacting Environment Canada, if:

- there is a change in the name, address, telephone number or email address of the contacts identified for the facility; or
- there is a change in the owner or operator of a facility.

3.10.2 Facility Information

Table 9 summarizes the general information that must be provided for all facilities that report to the NPRI. Other facility information may also be required, depending on the type of facility and the substances reported.

Table 9. Facility Information Required to Be Reported to the National Pollutant Release Inventory

Type of Information	Information to Be Reported
Facility name and location	• name of the facility • address of the physical location of the facility (e.g., a civic address, a legal land description, or just a description if no other type of physical address is applicable [e.g., for an offshore installation]) • latitude and longitude coordinates of the facility if the facility is reporting for the first time or if the facility is portable
Employees	• number of full-time employees
Organization (company)	• legal and trade name of the facility's company • mailing address • Dun & Bradstreet (D-U-N-S) Number(1) • federal business number(2)
Parent companies (if any)	• legal names of any Canadian parent companies • civic addresses of the parent companies • D-U-N-S Numbers(1) of the parent companies • federal business numbers(2) of the parent companies
NPRI identification number	• unique identifier provided by Environment Canada and used for reporting to the NPRI
North American Industry Classification System (NAICS) Code(3)	• 6-digit NAICS Canada code of the facility
Pollution prevention plan	• whether and why a pollution prevention plan was prepared • whether an existing pollution prevention plan was updated • whether the plan addressed substances, energy conservation or water conservation

(1) A Dun & Bradstreet (D-U-N-S) number is a unique nine-digit identification number for a single business entity.

(2) A federal business number is a nine-digit registration number issued by the Canada Revenue Agency (CRA) to Canadian businesses that register for one or more of the following: corporate income tax; importer/exporter account number; payroll deductions; or goods and services tax. This number can be found on all forms issued to a business by the CRA. The first nine digits that appear on these forms is the federal business number.

(3) NAICS is an industry classification system developed by the statistical agencies of Canada, Mexico and the United States. For more information, see the Statistics Canada website: www.statcan.gc.ca/concepts/industry-industrie-eng.htm.

3.11 Other Requirements

3.11.1 Statement of Certification

A Statement of Certification (SOC) must be electronically signed and submitted with the NPRI report using the on-line reporting system. The certifying official should verify that the information submitted is true, complete and accurate, and acknowledge that the data will be made public. The certifying official is legally responsible for the contents of the NPRI report.

3.11.2 Record Keeping

Pursuant to subsection 46(8) of CEPA 1999, the owner/operator of a facility is required to retain copies of all information on which their report is based, including any calculations, measurements and other related data, for a period of three years. This information must be kept at the facility or at the principal place of business in Canada of the owner/operator of the facility to which the information relates, for a period of three years.

4. Reporting for Part 1A Substances – Core Substances

Part 1A lists 230 substances and groups of substances of concern, most of which have been listed on the NPRI since its inception. These substances are commonly referred to as the "core substances," and comprise the majority of the NPRI substance list. For the complete list of NPRI substances, consult the NPRI website at www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=E2BFC2DB-1.

4.1 Reporting Criteria for Part 1A Substances

In general, any person who owns or operates a contiguous facility or offshore installation must submit an NPRI report for a Part 1A substance if both of the following criteria are met:

1. employees work a total of ≥ 20 000 hours, or activities to which the employee threshold does not apply (see Table 3) take place at the facility, and
2. the **total quantity** of the Part 1A substance
    - o manufactured, processed or otherwise used at a concentration (by weight) of 1% or more, **plus**
    - o incidentally manufactured, processed or otherwise used as a by-product at any concentration, **plus**
    - o contained in tailings disposed of during the calendar year at any concentration, **plus**
    - o contained in waste rock disposed of during the calendar year that is not clean or inert (see section 3.7.4) at a concentration (by weight) of 1% or more

   is ≥ 10 tonnes.

Figure 2 illustrates the steps for determining if a report is required for Part 1A substances.

4.1.1 Part 1A Substance Qualifiers

Some Part 1A substances and groups of substances are qualified in terms of their specific physical or chemical form, state or particle size. The qualifiers, described in Table 10, determine whether a report will be required for a given substance.

Figure 2. Reporting for Part 1A Substances

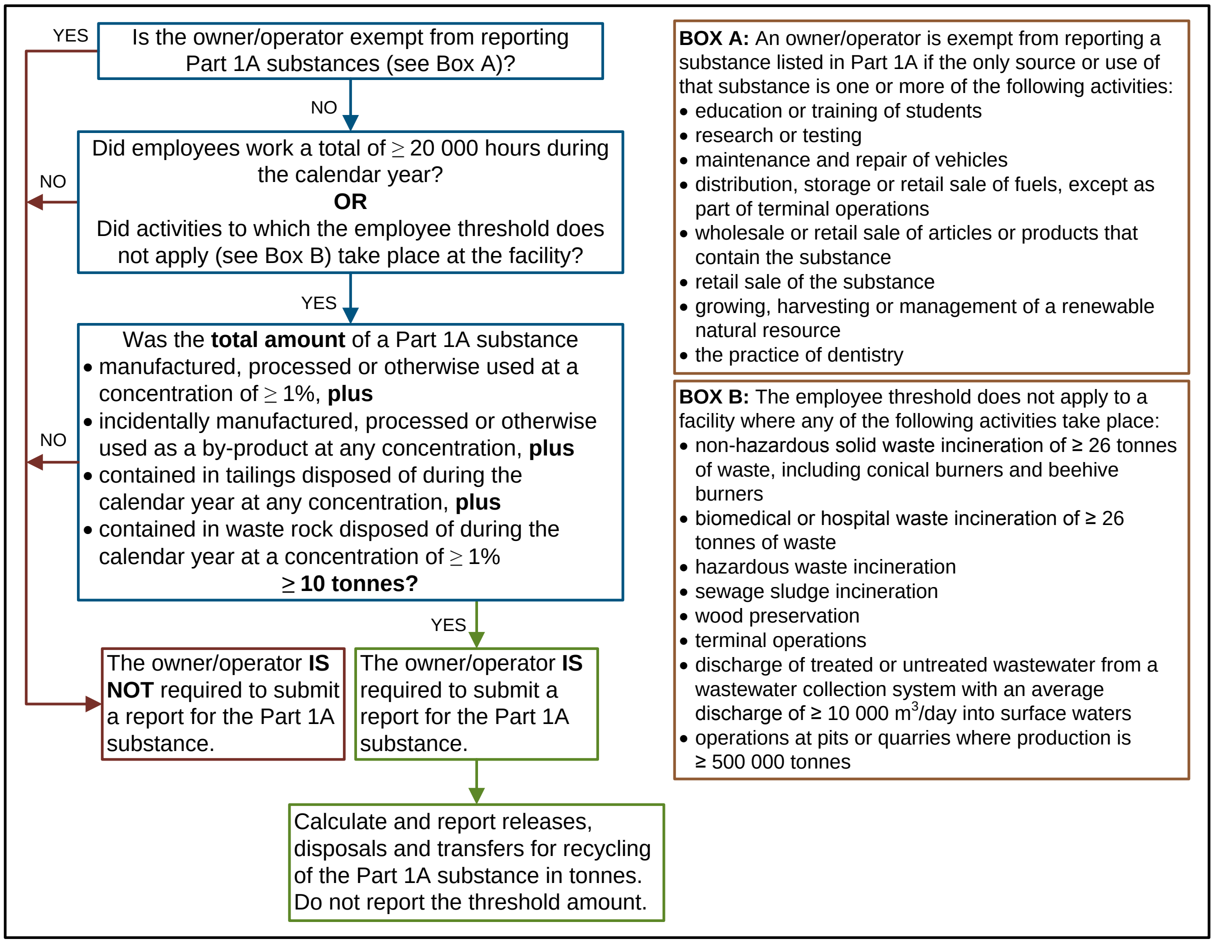

Table 10. Qualifiers for Part 1A Substances

Substance Qualifier	Substance(s) to Which the Qualifier Applies	Description
all isomers	cresol (CAS RN 1319-77-3), HCFC-122 (41834-16-6), HCFC-123 (34077-87-7), HCFC-124 (63938-10-3), and xylene (1330-20-7)	Total of all isomers reported as an aggregate of the individual isomers
and its compounds	antimony, cobalt, copper, manganese, nickel and zinc	The pure metal and the equivalent weight of the metal in any compound, alloy or mixture must be reported as the equivalent weight of the metal itself.
	chromium	Pure chromium and chromium contained in any compound, alloy or mixture must be reported as the equivalent weight of chromium, excluding hexavalent chromium and its compounds.
	vanadium (7440-62-2)	Pure vanadium and vanadium in any compound or mixture must be reported as the equivalent weight of vanadium. Do not include vanadium contained in an alloy.
and its salts	acrylic acid (79-10-7), aniline (62-53-3), chloroacetic acid (79-11-8), cresol (1319-77-3), 2,4-diaminotoluene (95-80-7), 2,4-dichlorophenol (120-83-2), diethanolamine (111-42-2), N,N-dimethylaniline (121-69-7), 4,6-dinitro-*o*-cresol (534-52-1), hydrazine (302-01-2), hydroquinone (123-31-9), Michler's ketone (90-94-8), nitrilotriacetic acid (139-13-9), *p*-nitrophenol (100-02-7), peracetic acid (79-21-0), phenol (108-95-2), *p*-phenylenediamine (106-50-3), *o*-phenylphenol (90-43-7), pyridine (110-86-1), and quinoline (91-22-5)	Weak acids and bases are listed with this qualifier. Although the CAS RN that appears on the NPRI list is specific to the acid or base, all salts of these substances must be reported as an equivalent weight of the acid or base.
expressed as hydrogen sulphide	total reduced sulphur (TRS)	Total of hydrogen sulphide (7783-06-4), carbon disulphide (75-15-0), carbonyl sulphide (463-58-1), dimethyl sulphide (75-18-3), methyl mercaptan (74-93-1), and dimethyl disulphide (624-92-0), expressed as hydrogen sulphide
fibrous forms only	aluminum oxide (1344-28-1)	Fibrous refers to a synthetic form of aluminum oxide that is processed to produce strands or filaments. This includes the form of aluminum oxide found in brake linings, but excludes the more common granular, powdered or fumed forms of alumina.
friable form only	asbestos (1332-21-4)	Only asbestos that is brittle and readily crumbled (i.e., friable) should be reported.
fume or dust only	aluminum (7429-90-5)	Include dry forms of aluminum only, with particle diameters of 0.001-1 micrometre for fumes and 1-100 micrometres for dust.
in solution at a pH of 6.0 or more	nitrate ion	This distinguishes nitrate ion in neutral or basic solution from nitric acid (pH of less than 6.0). If nitric acid is neutralized to a pH of 6.0 or greater, report for both nitric acid (7697-37-2) and nitrate ion in solution.
ionic	cyanides	Includes the salts of hydrogen cyanide, but excludes organocyanides, nitriles and organometallic cyanide compounds.
mixed isomers	dinitrotoluene (25321-14-6) and toluenediisocyanate (26471-62-5)	Total of all isomers occurring in mixtures.
total	ammonia	Total of ammonia (NH_3) (7664-41-7) and the ammonium ion (NH_4^+) (14798-03-9) in solution, expressed as ammonia
	phosphorus	Total of all phosphorus, not including yellow or white phosphorus (7723-14-0)
yellow or white only	phosphorus	Total of the yellow and white allotropes of elemental phosphorus only

4.2 Calculating the Reporting Threshold for Part 1A Substances

When calculating the 10-tonne reporting threshold, include the quantity of a Part 1A substance that is:

- manufactured, processed or otherwise used at a concentration equal to or greater than 1% by weight;
- a by-product, at any concentration, released on-site to the environment or disposed of on- or off-site;
- contained in tailings disposed of during the calendar year, at any concentration; and
- contained in waste rock that is not inert and that is disposed of during the calendar year at a concentration equal to or greater than 1% by weight.

Do not include quantities of a Part 1A substance contained in any of the sources that should not be considered, as listed in Table 4.

Since a substance may undergo many processes in a facility, care should be taken not to double-count process streams when calculating the reporting threshold.

A quantity of a substance that is transferred off-site for recycling and returned to the facility should be treated as the equivalent of newly purchased material. A quantity of a substance that is recycled on-site and re-introduced to a process stream (e.g., substances in ore processing water that are recycled back into the process from tailings) should be included in the threshold calculation only once.

The total quantity of a Part 1A substance manufactured, processed or otherwise used at concentrations greater than or equal to 1%, at any time or in any part of the facility, must be included when calculating the 10-tonne reporting threshold. For example, the quantity of a substance received by a facility at 30% concentration and then diluted to less than 1% for use, is included in the threshold calculation. A substance received at the facility at less than 1% and subsequently concentrated to 5% would also be included in the threshold calculation.

Facilities that repackage or transfer Part 1A substances between containers need only consider the quantity of the substance repackaged or transferred.

If only a range of concentrations is available for a substance present in a mixture, contact the supplier of the substance for more detailed information. If no additional information is available, use the average of the range for threshold determinations.

4.2.1 Example of Calculating the Reporting Threshold for Part 1A Substances

Table 11 illustrates the calculation of the reporting threshold. In the example, a facility has several processes in which a Part 1A substance is manufactured, processed or otherwise used. The substance is also released as a by-product and is contained in tailings and waste rock.

This example assumes that the employee threshold is met, or an activity to which the employee threshold does not apply takes place at the facility. In this case, a report is required for this substance, because the total quantity of the Part 1A substance manufactured, processed, otherwise used, and contained in tailings and waste rock at the facility exceeded 10 tonnes, as explained below.

Table 11. Example of a Threshold Calculation for Part 1A Substances

Material/Process Containing the Substance	Total Weight of Material Containing the Substance (Tonnes)	Concentration/Equivalent Weight of the Substance in Material/Process (Percent)	Net Weight of the Substance to Include in Threshold Calculation (Tonnes)
1. Compound material in process stream A	150	5	7.5
2. Raw material in process B	2	100	2.0
3. Raw material in process C	45	0.20	n/a
4. By-product released from process D	10 000	0.01	1.0
5. Tailings	24 000 000	0.00001	2.4
6. Waste rock	20 000 000	0.00002	n/a
7. **TOTAL**			**12.9**

1. In process A, the Part 1A substance is present at 5% concentration (or equivalent weight for metallic compounds) and is included in the threshold calculation.
2. In process B, the raw material added to the process is a pure substance. It is included in the threshold calculation, regardless of any subsequent dilution in the process.
3. The weight of the substance in the raw material used in process C is not included in the threshold calculation because the concentration is less than 1%. Note that, as a report is required in this example, the releases, disposals and transfers for recycling from all processes, including process C, are required to be reported, regardless of concentration and regardless of whether or not the quantity is used the threshold calculation.
4. The weight of the substance produced and released from process D is included in the calculation because it is a by-product, and the concentration threshold does not apply.
5. The weight of the substance contained in tailings is included in the threshold calculation because there is no concentration threshold for tailings.
6. The weight of the substance contained in waste rock is not included in the threshold calculation, because the concentration of the substance in the waste rock is less than 1%. The weight of the substance in the waste rock would also not be included when calculating disposals of the substance, because the concentration is less than 1%.
7. The total is the value that must be compared to the 10-tonne reporting threshold. This value is only used to determine that a report is required for the Part 1A substance. A subsequent calculation must be done to obtain the actual value of releases, disposals, and transfers for recycling that must be reported.

4.3 Calculating Releases, Disposals and Transfers for Recycling of Part 1A Substances

If the reporting threshold for a Part 1A substance is met (as discussed in section 4.2), a subsequent calculation is required to determine the quantities of that substance that are released, disposed of and transferred for recycling. If the reporting threshold is met, **all releases, disposals and transfers for recycling of that substance must be reported, regardless of their concentration or quantity and regardless of whether or not the quantity is used in the threshold calculation**. The only exception to this is for disposals of Part 1A substances in waste rock where the substance is at a concentration of less than 1%. In the case of waste rock, the 1% concentration threshold for Part 1A substances applies to both the threshold calculation and disposal calculation.

4.4 Reporting Releases, Disposals and Transfers for Recycling of Part 1A Substances

All releases, disposals and transfers for recycling of Part 1A substances must be reported in tonnes.

Note that even if on-site releases, disposals or off-site transfers for recycling are zero, a report must be submitted for a Part 1A substance, once the 10-tonne reporting threshold has been met.

5. Reporting for Part 1B Substances – Alternate Threshold Substances

Part 1B substances may have significant environmental and human health impacts at relatively low levels. Because minimal releases of Part 1B substances may result in significant adverse effects, the reporting thresholds for Part 1B substances are lower than those for Part 1A substances. As such, these substances are commonly referred to as the "alternate threshold substances."

5.1 Reporting Criteria for Part 1B Substances

In general, any person who owns or operates a contiguous facility or an offshore installation must submit a report for a Part 1B substance if both of the following criteria are met:

1. employees work a total of ≥ 20 000 hours, or activities to which the employee threshold does not apply (see Table 3) take place at the facility, and
2. the **total quantity** of the Part 1B substance
    - manufactured, processed or otherwise used at or above the concentration specified in Table 12, **plus**
    - incidentally manufactured, processed or otherwise used as a by-product at any concentration, **plus**
    - contained in tailings at any concentration, **plus**
    - contained in waste rock that is not inert and that is disposed of, at any concentration (see section 3.7.4)

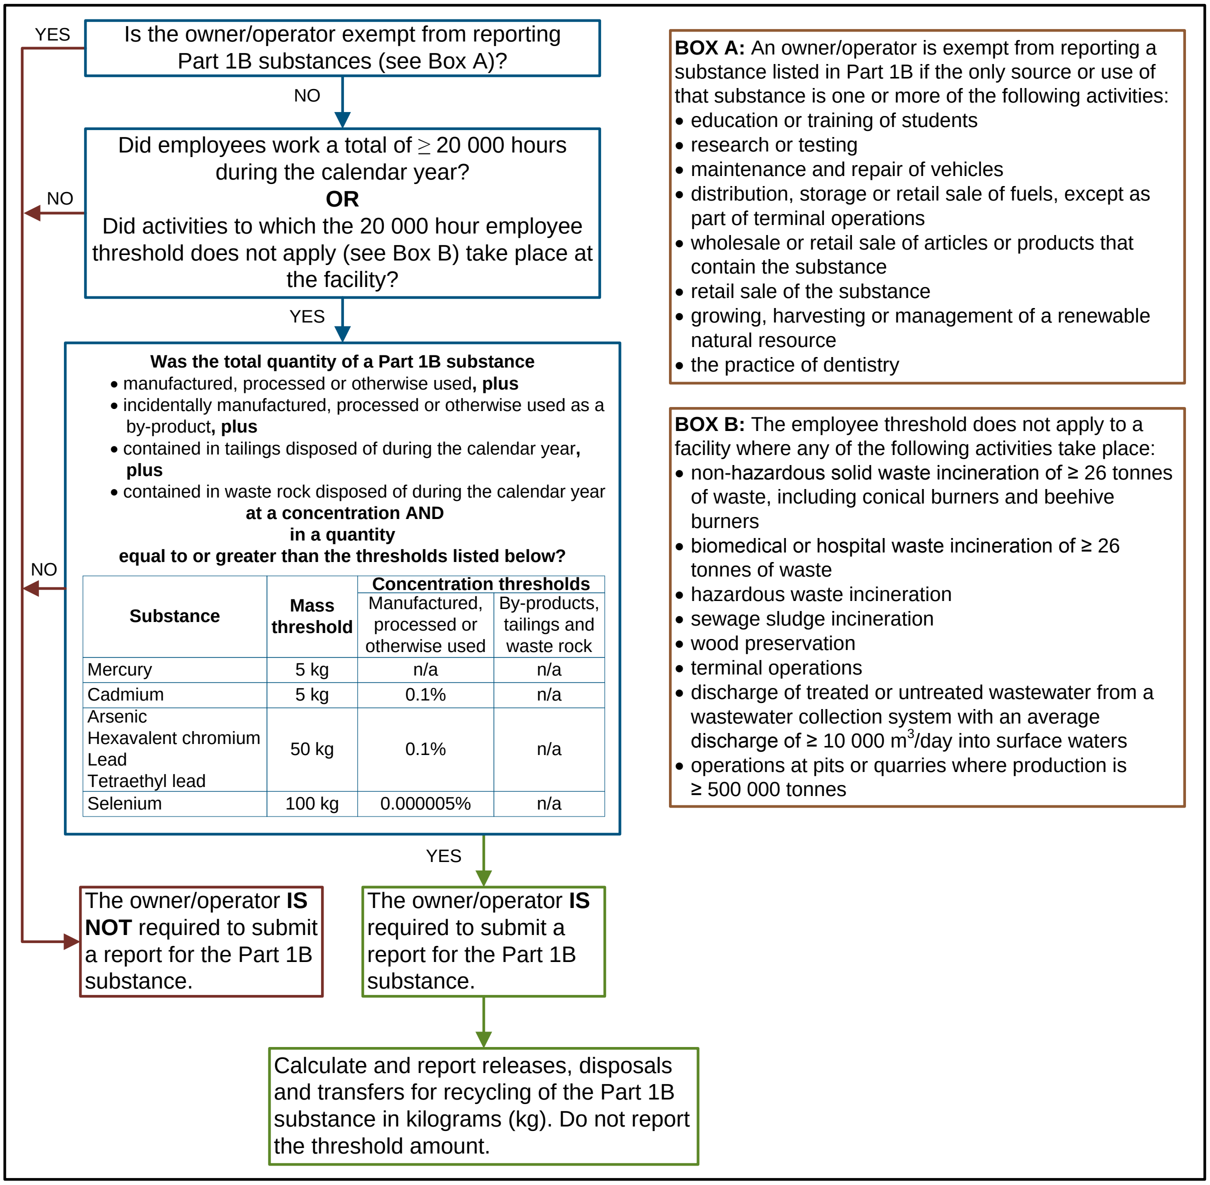
    is greater than or equal to the mass threshold specified in Table 12.

Figure 3 illustrates the steps for determining if a report for Part 1B substances is required.

Table 12. Concentration and Mass Thresholds for Part 1B Substances

Substance	Occurrence of the Substance	Concentration Threshold (by Weight)	Mass Threshold (kg)
Mercury	manufactured, processed or otherwise used	any concentration	5
	incidentally manufactured, processed or otherwise used		
	contained in tailings disposed of during the calendar year		
	contained in waste rock disposed of during the calendar year		
Cadmium	manufactured, processed or otherwise used	0.1% or more	5
	incidentally manufactured, processed or otherwise used	any concentration	
	contained in tailings disposed of during the calendar year		
	contained in waste rock disposed of during the calendar year		
Arsenic Hexavalent chromium Lead Tetraethyl lead	manufactured, processed or otherwise used	0.1% or more	50
	incidentally manufactured, processed or otherwise used	any concentration	
	contained in tailings disposed of during the calendar year		
	contained in waste rock disposed of during the calendar year		
Selenium	manufactured, processed or otherwise used	0.000005% or more	100
	incidentally manufactured, processed or otherwise used	any concentration	
	contained in tailings disposed of during the calendar year		
	contained in waste rock disposed of during the calendar year		

Figure 3. Reporting for Part 1B Substances



5.1.1 Part 1B Substance Qualifiers

Mercury, cadmium, arsenic, hexavalent chromium, lead and selenium are listed with the qualifier "and its compounds." The pure element and any compound, alloy or mixture of any Part 1B substance must be reported as the equivalent weight of the metal itself. For example, if potassium dichromate ($K_2Cr_2O_7$, molecular weight = 294 grams per mole [g/mol]) is used, only the mass contribution of hexavalent chromium (2 × 52 g/mol) in $K_2Cr_2O_7$ should be included in the threshold calculation for hexavalent chromium.

Note that lead has an additional qualifier: the lead contribution from tetraethyl lead, stainless steel, brass and bronze alloys should be excluded from threshold calculations for lead. Tetraethyl lead should be treated as a separate substance. If the criteria are met, separate reports should be submitted for lead (and its compounds) and tetraethyl lead, with the reporting criteria applied to each substance separately.

5.2 Calculating the Reporting Threshold for Part 1B Substances

When calculating the reporting threshold, include the quantity of a Part 1B substance that is:

- manufactured, processed or otherwise used at a concentration equal to or greater than the concentration threshold (if any) specified in Table 12;
- a by-product, at any concentration, released on-site to the environment or disposed of on- or off-site;
- contained in tailings disposed of during the calendar year, at any concentration; and
- contained in waste rock that is not inert and that is disposed of during the calendar year, at any concentration.

Do not include quantities of a Part 1B substance contained in any of the sources that should not be considered, as listed in Table 4.

As noted previously, quantities of substances disposed of in inert or clean waste rock do not need to be included in threshold calculations. However, the quantity of arsenic contained in inert or clean waste rock can be excluded only if the concentration of arsenic is < 12 mg/kg of waste rock.

5.3 Calculating Releases, Disposals and Transfers for Recycling of Part 1B Substances

If the reporting threshold for a Part 1B substance is met (as discussed in section 5.2), a subsequent calculation is required to determine the quantities of that substance that are released, disposed of and transferred for recycling. If the reporting threshold is met, **all releases, disposals and transfers for recycling of that substance must be reported, regardless of their concentration or quantity and regardless of whether or not the quantity is used in the threshold calculation**.

5.4 Reporting Releases, Disposals and Transfers for Recycling of Part 1B Substances

All releases, disposals and transfers for recycling of Part 1B substances must be reported in kilograms (kg).

Note that even if on-site releases, disposals or off-site transfers for recycling are zero, a report must be submitted for a Part 1B substance once the mass reporting threshold has been met.

6. Reporting for Part 2 Substances – Polycyclic Aromatic Hydrocarbons

Polycyclic aromatic hydrocarbons (PAHs) may be used as commercial chemicals, incidentally manufactured in certain industrial processes, or contained in tailings. There are 29 PAHs listed in Part 2 of the NPRI substance list. For a list of these PAHs, consult the NPRI website: www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=E2BFC2DB-1.

6.1 Reporting Criteria for Part 2 Substances

With the exception of facilities where wood preservation using creosote takes place (see below), reporting for PAHs is based on the quantities of PAHs that are released, disposed of or transferred for recycling as a result of incidental manufacture or from the generation of tailings. A person who owns or operates a contiguous facility, a portable facility, or an offshore installation must submit reports for PAHs if both of the following criteria are met:

1. employees work a total of ≥ 20 000 hours, or activities to which the employee threshold does not apply (listed in Table 3) take place at the facility; and
2. the sum of all PAHs released, disposed of or transferred off-site for recycling as a result of incidental manufacture and/or as a result of the generation of tailings is ≥ 50 kg.

Wood preservation facilities using creosote must report for Part 2 substances, regardless of quantities and regardless of the number of hours worked by employees. See section 3.6.2 and the *Guidance for Wood Preservation Facilities Reporting to the NPRI* (www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=29B3E589-1) for more information.

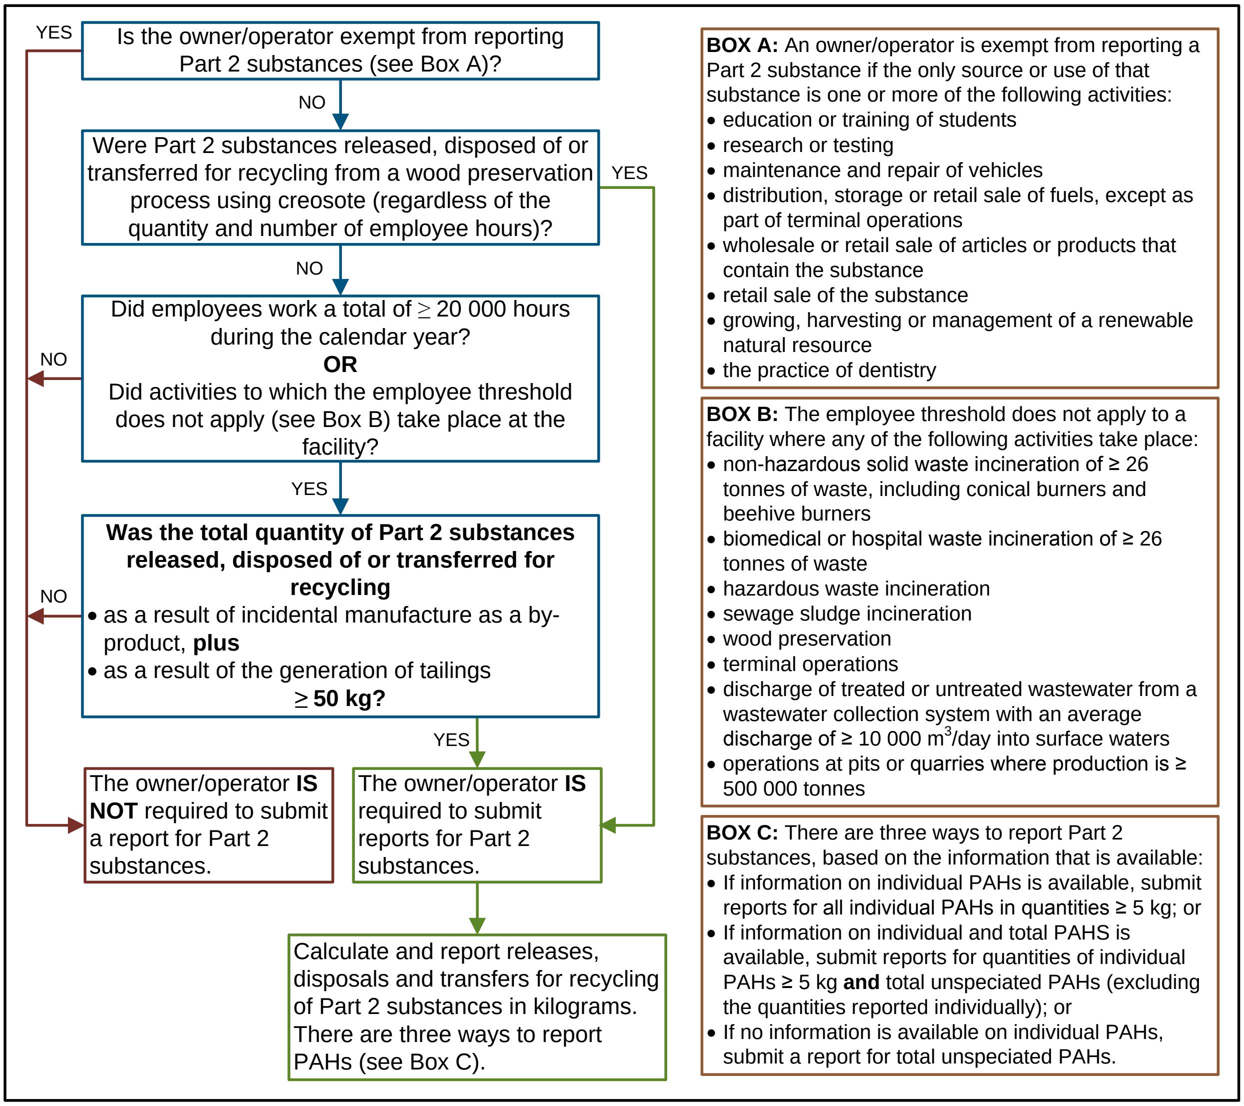
Figure 4 illustrates the steps for determining if reports for Part 2 substances are required, and, if so, what information must be reported.

6.2 Calculating the Reporting Threshold for Part 2 Substances

The sum of the quantities of individual PAHs incidentally manufactured and/or contained in tailings disposed of during the calendar year should be compared to the 50 kg threshold. In some cases, only information on unspeciated PAHs may be available, or a combination of information on individual and unspeciated PAHs may be available. Add the quantities of each individual PAH and the quantity of unspeciated PAHs to determine if the 50 kg reporting threshold is met.

Do not include anthracene (CAS RN 120-12-7) and naphthalene (CAS RN 91-20-3) when determining the reporting threshold for PAHs. Although anthracene and naphthalene are PAHs, they are NPRI Part 1A substances. Therefore, they are subject to Part 1A reporting requirements.

Figure 4. Reporting for Part 2 Substances



6.3 Reporting Releases, Disposals and Transfers for Recycling of Part 2 Substances

All releases, disposals and transfers for recycling of Part 2 substances must be reported in kilograms.

Releases, disposals and transfers for recycling must be reported for the individual PAHs, even though the 50 kg threshold applies to the aggregate total of all 29 PAHs. Depending on the information that is available, there are three ways to report PAHs (illustrated in Figure 4 and summarized in Table 13). If the 50 kg threshold is met, or if wood preservation using creosote takes place at the facility, and information on releases, disposals and transfers for recycling for individual PAHs is available, those PAHs that are incidentally manufactured and released, disposed of or transferred for recycling in quantities ≥ 5 kg must be reported individually.

If only a combination of information on individual and total PAHs is available, quantities of individual PAHs in quantities ≥ 5 kg and quantities of "total unspeciated PAHs" should both be reported. If the only available information is for total PAHs, total unspeciated PAHs should be reported.

Note that total unspeciated PAHs does not mean the sum of the 29 individual PAHs. In order to avoid double-counting when reporting both individual and total unspeciated PAHs, the quantities of individual PAHs that are reported separately should not be included in the quantity reported for total unspeciated PAHs. In addition, do not include release, disposal and transfer for recycling quantities of the two PAHs listed in Part 1A (anthracene and naphthalene) when reporting for total PAHs.

Facilities using creosote for wood preservation must report for PAHs regardless of the quantity of PAHs released, disposed of or transferred for recycling or the number of hours worked by employees. Depending on the information available to the facility, reports can be submitted for: individual PAHs released, disposed of or transferred for recycling in quantities ≥ 5 kg; a combination of individual PAHs in quantities ≥ 5 kg and total PAHs; or total PAHs.

Table 13. How to Report Polycyclic Aromatic Hydrocarbons

Type of information available	Comparison to thresholds	What to report
Quantities of individual PAHs	• Add quantities of individual PAHs • If the total is ≥ 50 kg, reporting is required	• Report quantities of individual PAHs that are incidentally manufactured and released, disposed of or transferred for recycling in quantities ≥ 5 kg • Quantities of individual PAHs that are < 5 kg are not required to be reported
Combination of quantities of individual PAHs and quantity of total PAHs	• Add quantities of total unspeciated PAHs and any individual PAHs that are not already included in the total unspeciated PAHs • If the total is ≥ 50 kg, reporting is required	• Report quantities of individual PAHs that are ≥ 5 kg, **and** • Report total unspeciated PAHs (not including quantities of individually reported PAHs) • Quantities of individual PAHs that are < 5 kg are not required to be reported
Quantity of total PAHs	• If total PAHs are ≥ 50 kg, reporting is required	• Report total unspeciated PAHs

7. Reporting for Part 3 Substances – Dioxins, Furans and Hexachlorobenzene

Polychlorinated dibenzo-p-dioxins (PCDDs or dioxins), polychlorinated dibenzofurans (PCDFs or furans) and hexachlorobenzene (HCB) are released primarily as by-products of industrial and combustion processes; they are also found as contaminants in certain pesticides or chlorinated solvents. HCB may also be found as a contaminant in the wood preservative pentachlorophenol (PCP). These substances are toxic under CEPA 1999, and are slated for virtual elimination.

HCB and 17 dioxin and furan congeners are listed in Part 3. For a list of these congeners, consult the NPRI website: www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=E2BFC2DB-1.

7.1 Reporting Criteria for Part 3 Substances

Reporting for dioxins, furans and HCB is mandatory for a contiguous facility, a portable facility or an offshore installation where the activities specified in Table 14 take place, regardless of quantity or concentration. These activities are described in sections 3.6.2, 7.1.1 and 7.1.2. The employee threshold applies to some of these activities, but does not apply to others, as indicated in Table 14. For those activities to which the employee threshold applies, both criteria must be met (i.e., the activity must take place, and the employee threshold must be met). For activities to which the employee threshold does not apply, reporting for dioxins, furans and HCB is mandatory, regardless of the number of hours worked by employees.

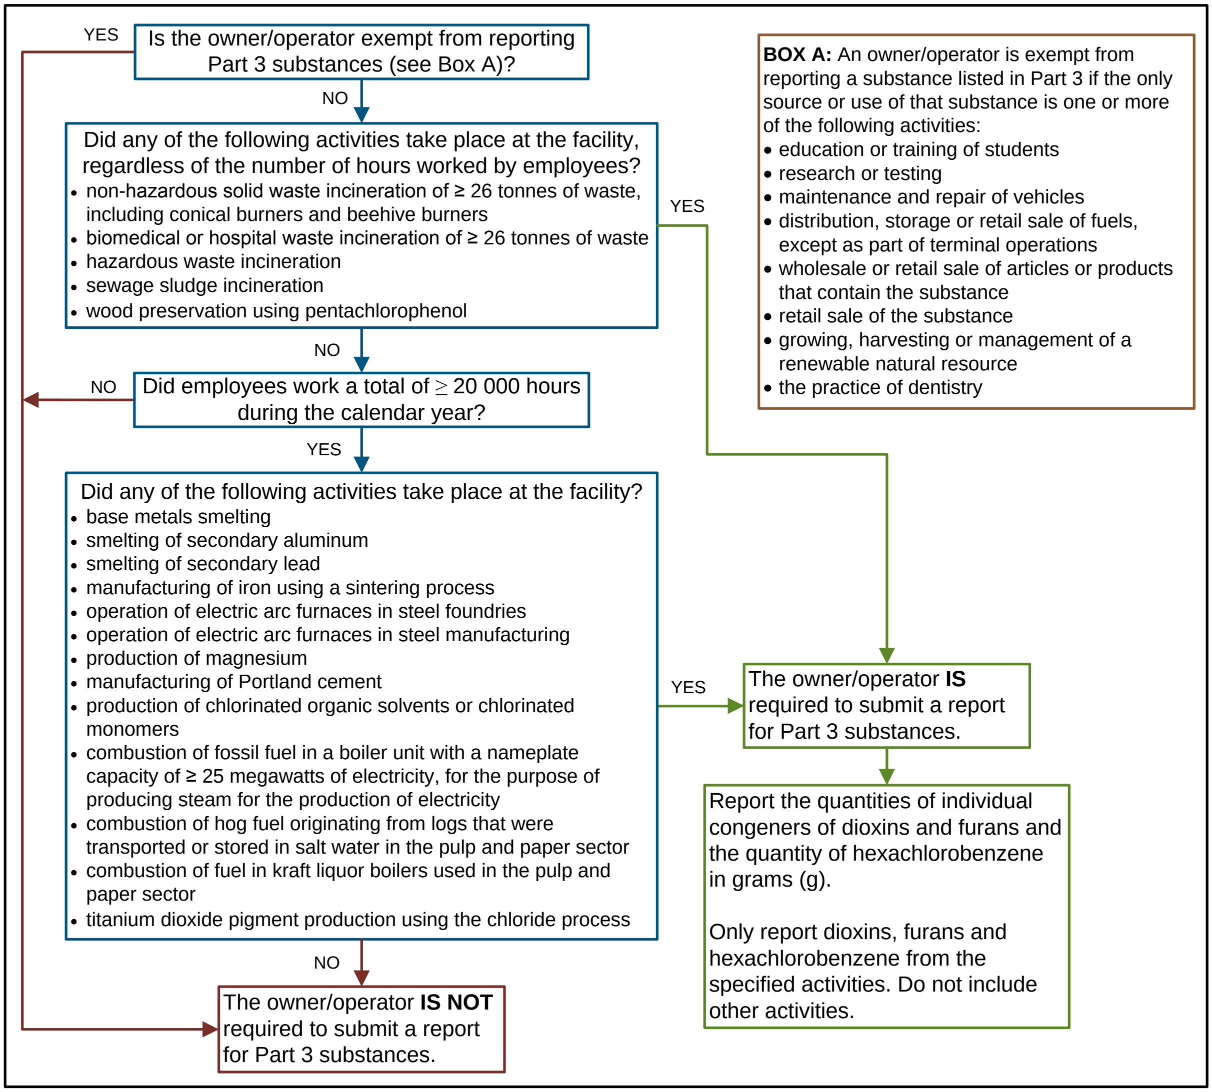
Table 14. Activities for Which Reports on Dioxins, Furans and Hexachlorobenzene Are Required

Employee Threshold	Activity
Employee threshold does not apply	non-hazardous solid waste incineration of ≥ 26 tonnes of waste, including conical burners and beehive burners
	biomedical or hospital waste incineration of ≥ 26 tonnes of waste
	hazardous waste incineration
	sewage sludge incineration
	wood preservation using pentachlorophenol
Employee threshold applies	base metals smelting (copper, lead, nickel or zinc only)
	smelting of secondary aluminum
	smelting of secondary lead
	manufacturing of iron using a sintering process
	operation of electric arc furnaces in steel foundries
	operation of electric arc furnaces in steel manufacturing
	production of magnesium
	manufacturing of Portland cement
	production of chlorinated organic solvents or chlorinated monomers
	combustion of fossil fuel in a boiler unit, with a nameplate capacity of ≥ 25 megawatts of electricity, for the purpose of producing steam for the production of electricity
	combustion of hog fuel originating from logs that were transported or stored in salt water in the pulp and paper sector
	combustion of fuel in kraft liquor boilers used in the pulp and paper sector
	titanium dioxide pigment production using the chloride process

Only those quantities of dioxins, furans and HCB that result from the activities listed in Table 14 need to be reported. Quantities of Part 3 substances that result from other activities do not need to be reported.

Figure 5 illustrates the steps for determining if a report for Part 3 substances is required, and, if so, what information must be reported.

Figure 5. Reporting for Part 3 Substances



7.1.1 Activities for Which Part 3 Substances Must Be Reported, Regardless of Employee Hours

The activities to which the employee threshold does not apply (see Table 14) are described in section 3.6.2. Wood preservation activities are also described in section 3.6.2. However, only wood preservation using PCP triggers mandatory reporting of Part 3 substances. PCP, by its chemical structure, is a close surrogate to HCB. PCP is derived from HCB by substituting one of HCB's six chloro-substituents with a hydroxyl group. Given its chemical similarity to HCB and that its manufacturing ingredients contain the precursors for dioxin and furan production (i.e., chlorinated aromatics), the manufacture of PCP often results in the incidental manufacture of HCB, dioxins and furans.

7.1.2 Activities for Which Part 3 Substances Must Be Reported if the Employee Threshold Is Met

The following sections describe the activities listed in Table 14 to which the employee threshold applies.

Smelting

Smelting is the melting of raw or scrap materials to produce metal for further processing into metal products. The smelting process is typically accompanied by a chemical change in which impurities are removed.

Base metals smelting

"Base metals" refer to copper, lead, nickel or zinc. Base metals smelting does not include smelting of aluminum, secondary lead or any other metals.

Smelting of secondary aluminum

"Secondary aluminum" refers to aluminum-bearing scrap or materials. Secondary aluminum smelting involves pre-cleaning and smelting, both of which may produce emissions of dioxins and furans.

Smelting of secondary lead

"Secondary lead" refers to lead-bearing scrap or materials, other than lead-bearing concentrates derived from a mining operation. Facilities engaged in smelting of lead-bearing concentrates derived from a mining operation are considered to be base metal smelters.

Manufacturing of iron using a sintering process

"Sintering" means to cause something to become a coherent mass by heating without melting, or the growth of contact area between two or more initially distinct particles at temperatures below the melting point but above one half of the melting point (in Kelvin). In sintering operations, dioxins and furans may be formed as by-products during high-temperature decomposition or combustion of raw materials containing chlorine and organic compounds.

Operation of electric arc furnaces in steel foundries and in steel manufacturing

In an electric arc furnace, material is heated by an electric arc. Dioxins, furans and HCB may be formed as by-products during high-temperature decomposition or combustion of raw materials containing chlorine and organic compounds.

Production of magnesium

Production of magnesium from magnesium chloride by electrolysis may result in the generation of dioxins, furans and HCB.

Manufacturing of Portland cement

Portland cement is a fine greyish powder consisting of four basic materials: lime, silica, alumina and iron compounds. Cement production involves heating the raw materials to a very high temperature in a rotating kiln to induce chemical reactions that produce a fused material called clinker. The cement clinker is further ground into a fine powder, and then mixed with gypsum to form Portland cement.

Production of chlorinated organic solvents or chlorinated monomers

This activity is limited to the intentional manufacturing of chlorinated organic solvents or chlorinated monomers, and does not include coincidental production.

Combustion of fossil fuel in a boiler unit, with a nameplate capacity of ≥ 25 megawatts of electricity, for the purpose of producing steam for the production of electricity

This activity includes fossil fuel combustion at electric power generation utilities and large industrial facilities co-generating electric power using waste heat from industrial processes. Fossil fuel is fuel that is in a solid or liquid state at standard temperature and pressure, such as coal, petroleum or any liquid or solid fuel derivatives. It does not include natural gas or other fuels that are gases at ambient pressure and temperature. Fuel combustion in diesel generators is not included in this activity.

Combustion of hog fuel originating from logs that were transported or stored in salt water in the pulp and paper sector

Pulp and paper boilers burning salt-laden wood are unique to British Columbia. Dioxins and furans are emitted from the burning of salt-contaminated hog fuel. Chlorine is absorbed by the bark of logs transported and stored in salt water. The bark stripped from logs is ground up with other waste wood to produce hog fuel, which is used as boiler fuel to produce heat and electrical energy.

Combustion of fuel in kraft liquor boilers used in the pulp and paper sector

A kraft liquor boiler burns black liquor, composed mostly of lignin, which is the residue from the digester in a kraft (sulphate) pulping process. The boiler recovers chemical products from the combusted black liquor, which are later recycled. It also produces steam, which is used in mill process operations.

Titanium dioxide pigment production using the chloride process

This activity is limited to titanium dioxide pigment manufactured by the chloride process, not the sulphate process.

7.2 Reporting Releases, Disposals and Transfers for Recycling of Part 3 Substances

The information that needs to be reported for Part 3 substances depends on the method used to determine the quantities released, disposed of and transferred for recycling. There are three possible scenarios:

- quantities are determined using CEMS, PEM or source testing;
- quantities are estimated using other methods; or
- no information is available.

To determine if a report is required, the quantities determined using CEMS, PEM or source testing must be compared to the level of quantification (LoQ). LoQ is defined in CEPA 1999 as "the lowest concentration that can be accurately measured using sensitive but routine sampling and analytical methods." Table 15 lists estimated LoQs for dioxins, furans and HCB, determined by Environment Canada for gases, liquids and solids.

Table 15. Estimated Level of Quantification for Dioxins, Furans and Hexachlorobenzene

Material State	Estimated Level of Quantification	
	Dioxins and furans(1)	Hexachlorobenzene
Gaseous(2)	32 picograms (pg) toxic equivalents (TEQ)/m^3	6 nanograms (ng)/m^3
Liquid(3)	20 pg TEQ/L	70 ng/L
Solid(4)	9 pg TEQ/g	2 ng/g

(1) See section 7.2.1 for an explanation of toxic equivalents (TEQ).

(2) Environment Canada, 1999. Use these values to determine whether concentrations in releases to air from stacks and other sources are above, equal to or below the LoQ.

(3) The LoQ for concentrations of dioxins and furans in liquids was extrapolated from the effective LoQ for 2,3,7,8-TCDD in the *Pulp and Paper Mill Effluent Chlorinated Dioxins and Furans Regulations*. Use 70 ng/L as the estimated LoQ for concentrations of HCB in liquids (Environment Canada, 1997).

(4) Environment Canada, 2000. Use these values to determine whether concentrations of dioxins and furans or HCB in solid materials are above, equal to or below the LoQ. Incinerator bottom ash, pollution-abatement residues and sludge are examples of solid materials containing dioxins and furans or HCB.

Measured concentrations must be compared to the appropriate LoQ indicated in Table 15 for each type of release, disposal and site transfer for recycling. If measured quantities are greater than or equal to the LoQ, the quantities must be reported. If measured quantities are less than the LoQ, reporting the quantities is optional.

If quantities of dioxins, furans and HCB are estimated using mass balance, emission factors or engineering estimates, the quantities that are released, disposed of or transferred for recycling do not need to be compared to an LoQ, and must be reported.

Table 16 summarizes the information that should be reported for Part 3 substances, depending on the method of estimation and the comparison to the LoQ. Figure 6 illustrates the steps for determining the information that should be reported for Part 3 substances.

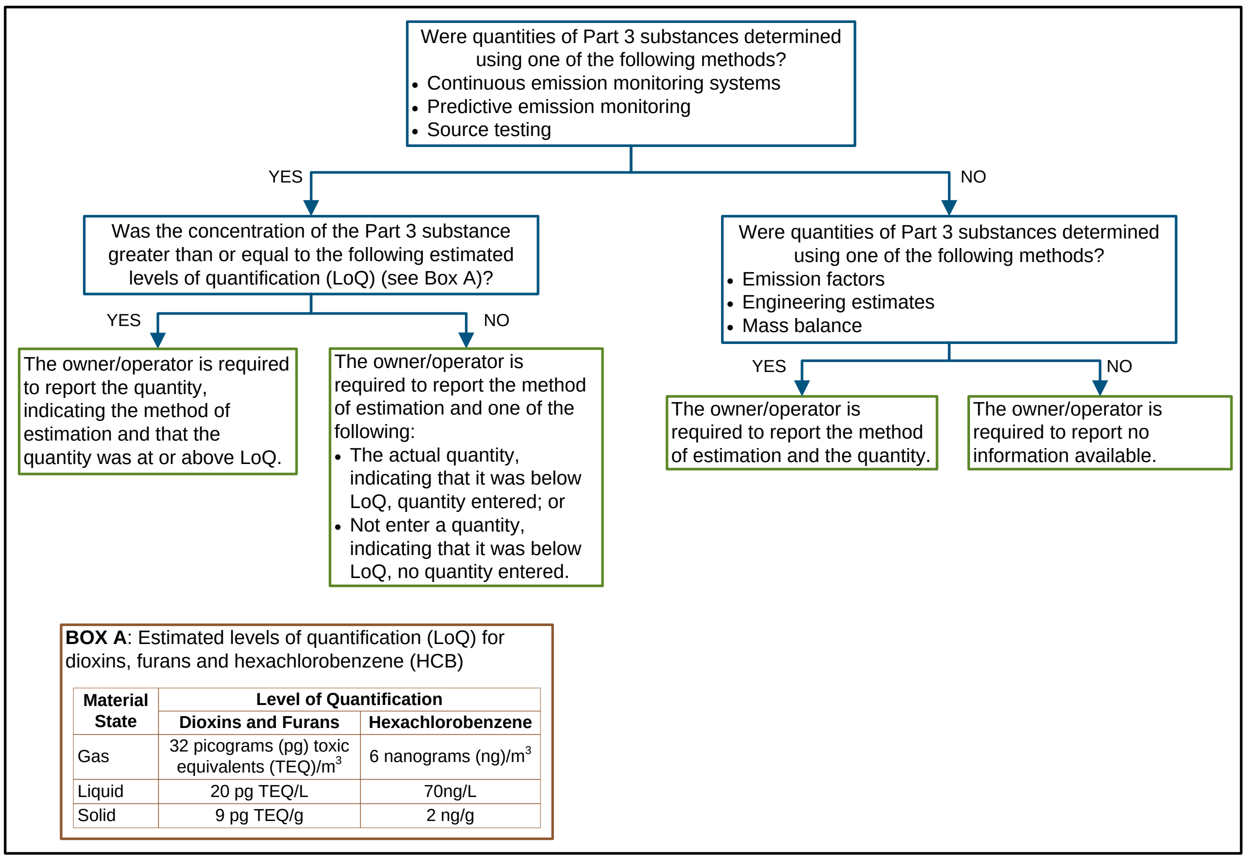
Table 16. How to Report Dioxins, Furans and Hexachlorobenzene

Method of Estimation	Comparison to Level of Quantification (LoQ)	What Must be Reported
CEMS, PEM or source testing	at or above LoQ	Report the quantity, and report that the quantity is at or above the LoQ.(1)
CEMS, PEM or source testing	below LoQ	Report that the quantity is below the LoQ. The quantity can also be reported, but this is optional when it is below the LoQ.(1)
Mass balance	n/a	Report the quantity.
Site-specific emission factor or published emission factor	n/a	Report the quantity.
Engineering estimate	n/a	Report the quantity.
No information available	n/a	Report that no information is available.(2)

(1) Use the "Help" link in the on-line reporting system to determine what detail codes are used to indicate whether the quantity is at, above or below the LoQ.

(2) "No information available" is an option under "Basis of Estimate" in the on-line reporting system, which can be selected for Part 3 substances only.

Figure 6. How to Report Dioxins, Furans and Hexachlorobenzene



Material State	Level of Quantification	
	Dioxins and Furans	Hexachlorobenzene
Gas	32 picograms (pg) toxic equivalents (TEQ)/m^3	6 nanograms (ng)/m^3
Liquid	20 pg TEQ/L	70ng/L
Solid	9 pg TEQ/g	2 ng/g

7.2.1 Reporting for Individual or Total Dioxins and Furans

Information on individual congeners of dioxins and furans must be reported if it is available. If the only information available is for total dioxins and furans, the total must be reported as toxic equivalents (TEQ).

Dioxins and furans are often found in complex mixtures, typically at extremely low concentrations, making it difficult to determine the cumulative toxicity of the mixture. Accordingly, toxic equivalency factors (TEFs) have been assigned to each dioxin and furan congener as weighting factors. These TEFs are assigned relative to the toxicity of 2,3,7,8-TCDD, the most toxic congener.

The TEFs listed in Table 17 should be used. To calculate TEQ, multiply the concentration (or quantity) of an individual congener by its respective TEF. For example, 1,2,3,4,7,8-HxCDF has a TEF of 0.1, and a sample concentration of 30 ng/kg 1,2,3,4,7,8-HxCDF is therefore equal to 3 ng TEQ/kg.

Table 17. Toxic Equivalency Factors for Dioxins and Furans

Congener	Abbreviation	CAS RN	Toxic Equivalency Factor
2,3,7,8-Tetrachlorodibenzo-p-dioxin	2,3,7,8-TCDD	1746-01-6	1
1,2,3,7,8-Pentachlorodibenzo-p-dioxin	1,2,3,7,8-PeCDD	40321-76-4	0.5
1,2,3,4,7,8-Hexachlorodibenzo-p-dioxin	1,2,3,4,7,8-HxCDD	39227-28-6	0.1
1,2,3,6,7,8-Hexachlorodibenzo-p-dioxin	1,2,3,6,7,8-HxCDD	57653-85-7	0.1
1,2,3,7,8,9-Hexachlorodibenzo-p-dioxin	1,2,3,7,8,9-HxCDD	19408-74-3	0.1
1,2,3,4,6,7,8-Heptachlorodibenzo-p-dioxin	1,2,3,4,6,7,8-HpCDD	35822-46-9	0.01
Octachlorodibenzo-p-dioxin	OCDD	3268-87-9	0.001
2,3,7,8-Tetrachlorodibenzofuran	2,3,7,8-TCDF	51207-31-9	0.1
2,3,4,7,8-Pentachlorodibenzofuran	2,3,4,7,8-PeCDF	57117-31-4	0.5
1,2,3,7,8-Pentachlorodibenzofuran	1,2,3,7,8-PeCDF	57117-41-6	0.05
1,2,3,4,7,8-Hexachlorodibenzofuran	1,2,3,4,7,8-HxCDF	70648-26-9	0.1
1,2,3,7,8,9-Hexachlorodibenzofuran	1,2,3,7,8,9-HxCDF	72918-21-9	0.1
1,2,3,6,7,8-Hexachlorodibenzofuran	1,2,3,6,7,8-HxCDF	57117-44-9	0.1
2,3,4,6,7,8-Hexachlorodibenzofuran	2,3,4,6,7,8-HxCDF	60851-34-5	0.1
1,2,3,4,6,7,8-Heptachlorodibenzofuran	1,2,3,4,6,7,8-HpCDF	67562-39-4	0.01
1,2,3,4,7,8,9-Heptachlorodibenzofuran	1,2,3,4,7,8,9-HpCDF	55673-89-7	0.01
Octachlorodibenzofuran	OCDF	39001-02-0	0.001

8. Reporting for Part 4 Substances – Criteria Air Contaminants

Air issues such as smog and acid rain result from the presence of, and interactions between, a group of pollutants known as criteria air contaminants (CACs) and related pollutants. There are seven CACs listed in Part 4 (see Table 18).

8.1 Reporting Criteria for Part 4 Substances

In contrast to the majority of NPRI substances, the thresholds for CAC emissions are based on the quantity released to air, rather than the quantity manufactured, processed and otherwise used. In general, any person who owns or operates a facility must submit a report to the NPRI for a Part 4 substance if the following criteria are met:

- employees work a total of ≥ 20 000 hours, or
- activities to which the employee threshold does not apply (see Table 3) take place at the facility, or
- employees work a total of < 20 000 hours, and stationary combustion equipment is operated at the facility, or
- the facility is a pipeline installation where stationary combustion equipment is operated (see section 3.5 for the definition of a pipeline installation)

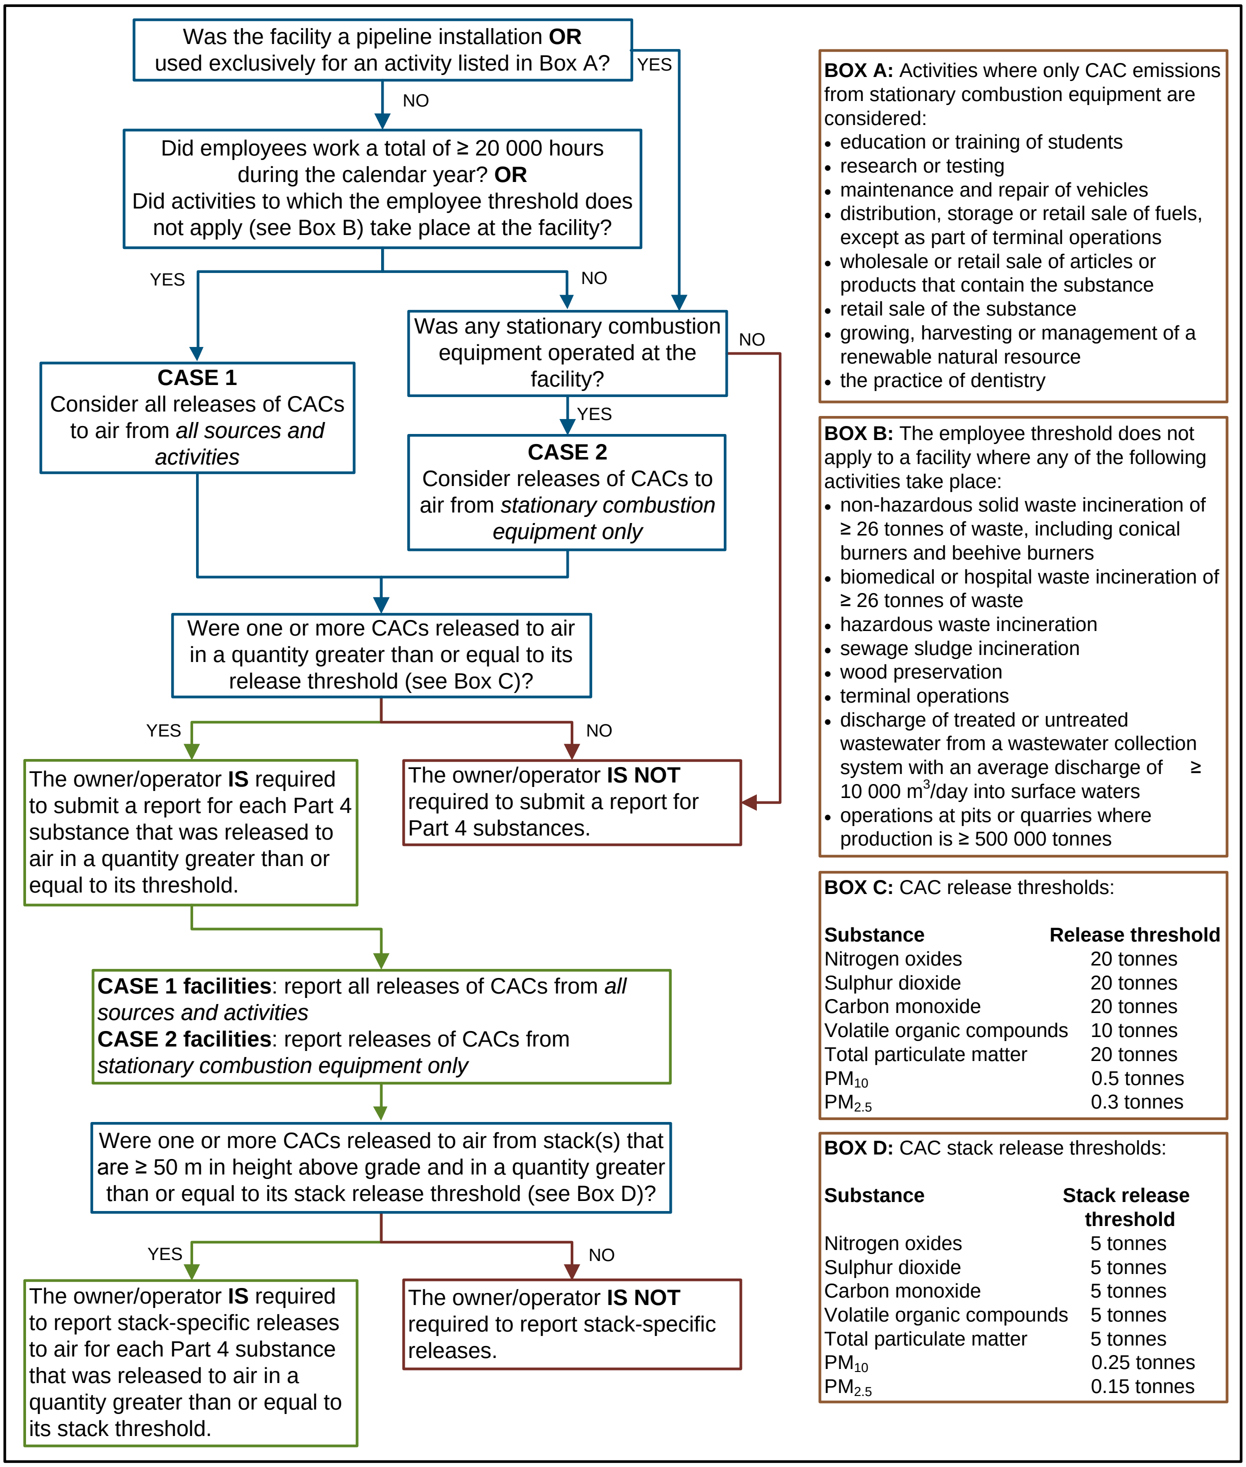
and the total quantity of the Part 4 substance released to air is greater than or equal to the release threshold specified in Table 18.

Table 18. Release Thresholds for Criteria Air Contaminants

Criteria Air Contaminant	Release Threshold (tonnes)
Nitrogen oxides (expressed as nitrogen dioxide)	20
Sulphur dioxide	
Carbon monoxide	
Total particulate matter	
Volatile organic compounds	10
Particulate matter with a diameter less than or equal to 10 micrometres (PM_{10})	0.5
Particulate matter with a diameter less than or equal to 2.5 micrometres ($PM_{2.5}$)	0.3

Figure 7 illustrates the steps for determining if a report for Part 4 substances is required, and, if so, what information must be reported. For further information on CACs and their reporting criteria, refer to the *Criteria Air Contaminants (CACs) Technical Source Guide for Reporting to the National Pollutant Release Inventory* (www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=3B695DF5-1) and the *Supplementary Guide for Reporting Criteria Air Contaminants (CACs) to the National Pollutant Release Inventory* (www.ec.gc.ca/Publications/default.asp?lang=En&xml=4A2D4BB8-BFA0-4129-A5A3-DBA372BD3B32).

Figure 7. Reporting for Part 4 Substances



8.1.1 Part 4 Substance Qualifiers

The following sections provide information on what should be included and excluded when reporting releases of CACs.

Nitrogen oxides

Nitrogen oxides (NO_x) include nitric oxide (NO) and nitrogen dioxide (NO_2). Since NO_x is a mixture, both NO and NO_2 must be expressed on an NO_2-equivalent basis before the individual quantities are combined for the total NO_x release. Do not include nitrous oxide (N_2O) when calculating NO_x releases.

Sulphur dioxide

Sulphur dioxide (SO_2) is part of the sulphur oxide (SO_x) family of gases. However, reporting to the NPRI is only required for SO_2, not SO_x. Therefore, the quantity of the other gases in the SO_x family, (i.e., sulphite, sulphur trioxide [SO_3] and sulphate [SO_4]) released should not be considered when calculating SO_2 releases.

Particulate matter

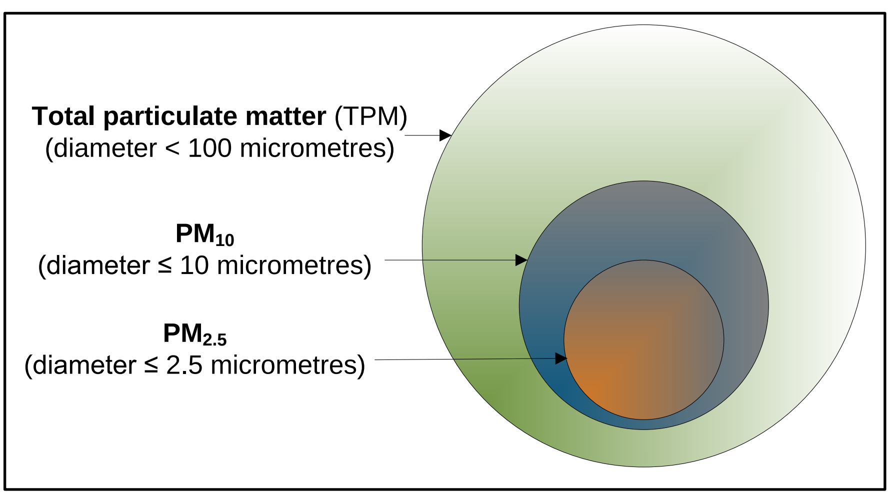
Three size fractions of particulate matter (PM) are required to be reported to the NPRI:

- total PM with a diameter less than 100 micrometres (TPM)
- PM with a diameter less than or equal to 10 micrometres (PM_{10})
- PM with a diameter less than or equal to 2.5 micrometres ($PM_{2.5}$)

As shown in Figure 8, the TPM fraction includes PM_{10} and $PM_{2.5}$, while PM_{10} includes $PM_{2.5}$. It is therefore impossible for $PM_{2.5}$ or PM_{10} releases to exceed TPM releases. It is also impossible for $PM_{2.5}$ releases to exceed PM_{10} releases.

TPM, PM_{10} and $PM_{2.5}$ emissions must be reported on a dry basis. Only filterable PM is reportable to the NPRI; condensable PM should not be included in release calculations.

Figure 8. Particulate Matter Size Fractions



Volatile organic compounds

Volatile organic compounds (VOCs) are an aggregate grouping of more than 1000 organic substances that readily volatilize and undergo photochemical reactions in the atmosphere.

VOCs should be reported as the total quantity of VOCs that participate in atmospheric photochemical reactions. Do not include any of the substances that are specified as exclusions in section 65 of Schedule 1 of the *Toxic Substances List* established under CEPA 1999 (for the list of excluded substances, see www.ec.gc.ca/lcpe-cepa/default.asp?lang=En&n=0DA2924D-1&wsdoc=4ABEFFC8-5BEC-B57A-F4BF-11069545E434).

In addition, it is important to note the following:

- Approximately 100 VOCs are listed individually in Part 1A. Individual reports must be submitted for each of these VOCs that meet the Part 1A criteria (based on quantities manufactured, processed or otherwise used). Regardless of whether the Part 1A criteria are met, any releases to air of these substances must also be included in threshold calculations for Part 4 VOCs, along with all other VOCs emitted.
- When calculating Part 4 total VOCs, include any substance that meets the CEPA 1999 definition of VOC, even if it is not listed separately in Part 1 or Part 5.
- Base the VOC emissions on the total mass of all VOC substances emitted annually.
- In addition to total VOCs, facilities may be required to report additional information on speciated VOCs listed in Part 5 (see section 9 for more information).
- Total organic compounds (TOCs) and VOCs do not have the same definition. All VOCs can be considered TOCs; however, not all TOCs are considered VOCs.

8.2 Calculating Releases of Part 4 Substances

Table 19 lists some of the most common sources of CAC emissions, with a brief description of each. For more information on these sources of CACs, consult the CAC guidance documents in the *NPRI Toolbox* (www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=65A75CDF-1).

There are two possible scenarios that must be considered to determine which sources of CAC emissions must be included in threshold calculations. In Case 1, all CAC emission sources at the facility must be included in calculations. In Case 2, only the releases from the stationary combustion equipment at the facility should be included. Each case is described below.

Case 1: Facilities that must consider CAC emissions from all sources

All sources of CAC emissions must be considered when calculating releases (excluding the sources listed in Table 4), if:

- the facility is a contiguous facility, portable facility or offshore installation at which employees work $\geq$ 20 000 hours; or
- any of the activities to which the employee threshold does not apply (see Table 3) take place at the facility, regardless of the hours worked by employees.

Case 2: Facilities that must consider CAC emissions from stationary combustion equipment only

When calculating releases of Part 4 substances, facilities must consider only emissions from stationary combustion equipment if:

- employees work < 20 000 hours; or
- the only activities that take place at the facility are those listed in Table 5; or
- the facility is a pipeline installation.

A facility that is exempt from reporting Parts 1-3 substances (see section 3.7.3) may still be required to report releases of CACs from stationary combustion equipment.

Table 19. Common Sources of Criteria Air Contaminant Emissions

Source	Description
Abrasive blasting	Abrasive blasting is the process of cleaning or texturing materials with an abrasive material, such as sand, coal and smelter slag, as well as mineral, metallic or synthetic abrasives. The blasting process itself is a source of PM emissions, especially PM_{10} and $PM_{2.5}$.
Equipment leaks	Equipment connections, joints and interfaces can be the source of gaseous and liquid releases. If the equipment is handling a gaseous stream containing a CAC, the gaseous leak would result in a fugitive CAC release. Depending on the properties of a liquid (such as vapour pressure, temperature and pressure), a liquid release may also result in a fugitive CAC release.
External combustion equipment	This comprises any equipment with a combustion process that occurs at atmospheric pressure and with excess air, including heaters, furnaces, incinerators, boilers, flares, combustion chambers, external combustion engines such as steam engines and Stirling engines, steam/electric generating plants, and other commercial units.
Fermenting	The process of fermentation involves the use of yeast, bacteria, enzymes, etc., to break down complex organic compounds. Many industries use fermentation, including the production of bread, spirits, pharmaceuticals, fuel, beer and wine, as well as environmental bioremediation processes.
Internal combustion equipment	This comprises any equipment with a combustion process that occurs in a confined space and above atmospheric pressure, including gas turbines, natural-gas-fired reciprocating engines, gasoline and diesel industrial engines, and large, stationary diesel and dual-fuel engines.
Loading and unloading	Fugitive CAC emissions can result from the loading and unloading of vehicles or containers. If the material being transferred is a liquid, the resulting emissions would likely be in the form of VOCs. If the material is a solid, the resulting emissions would likely be in the form of PM.
Painting	VOCs are released from paint during its application and drying. This category includes, but is not limited to, the painting of vehicles, furniture, storage tanks and any other painted product. $PM_{2.5}$ may also be emitted if paint is applied by pulverization.
Printing	VOCs are released from fixers, developers and solvents used during printing processes.
Road dust	TPM, PM_{10} and $PM_{2.5}$ releases from road dust caused by vehicular traffic on unpaved roads within facility boundaries are required to be included in release calculations, when travel on these roads is ≥ 10 000 vehicle kilometres travelled per year.
Solvent use	Solvent use includes, but is not limited to, solvent degreasing, waste solvent reclamation, product formulation and commercial solvent use. Many solvents contain VOCs that are released during storage, through evaporation.
Stationary combustion equipment	This comprises any combustion equipment that needs to be stationary to function or operate properly, or is not capable of self-propulsion, including both internal and external combustion equipment.
Storage piles	Handling storage piles generates PM emissions. Pile moisture content, wind speed and proportion of aggregate fines all influence total emissions from a storage pile.
Storage tanks	These comprise any storage tanks containing fuels, solvents, hydrocarbons, paints and other solutions that contain VOCs. This includes fixed roof, external floating roof, domed external floating roof, internal floating roof, variable vapour space and pressure storage tanks.

Possible exclusion for Case 2 facilities

A facility that meets the Case 2 criteria is **not** required to submit reports for CACs, if all the following criteria are met:

- CACs are released to air only from stationary external combustion equipment; and
- the cumulative nameplate capacity of all stationary external combustion equipment is less than 10 million BTUs/hour (10.55 million kJ/hour); and
- the only type of fuel combusted in that equipment is commercial-grade natural gas, liquefied petroleum gas, Number 1 or 2 fuel oil, or any combination thereof.

This exclusion does not apply if any other fuels are burned in the stationary external combustion equipment.

8.3 Reporting Releases of Part 4 Substances

If the reporting criteria are met for a Part 4 substance, the releases to air of that substance must be reported in tonnes. Case 1 facilities must report all releases from all sources. Case 2 facilities should only report releases from stationary combustion equipment.

Stack-specific releases to air may also need to be reported for each stack ≥ 50 metres (m) above grade, if the stack-specific release threshold specified in Table 20 is met. The following information about each stack must also be reported: height above grade, equivalent diameter, average exit velocity and average exit temperature.

Table 20. Stack-Specific Release Thresholds for Criteria Air Contaminants

Criteria Air Contaminant	Stack Release Threshold (Tonnes)
Nitrogen oxides (expressed as nitrogen dioxide)	5
Sulphur dioxide	
Carbon monoxide	
Volatile organic compounds	
Total particulate matter	
Particulate matter with a diameter less than or equal to 10 micrometres (PM_{10})	0.25
Particulate matter with a diameter less than or equal to 2.5 micrometres ($PM_{2.5}$)	0.15

Example of stack-specific CAC reporting

A facility releases 25 tonnes of NO_x to air from the whole facility. The facility has a stack that is 55 m above grade and that emitted 7 tonnes of NO_x. The following must be reported:

- 25 tonnes of NO_x must be first reported for total NO_x releases (NO_x has a total release threshold of 20 tonnes); and
- 7 tonnes of NO_x must be reported under the stacks requirement (NO_x has a stack release threshold of 5 tonnes).

9. Reporting for Part 5 Substances – Speciated Volatile Organic Compounds

Part 5 lists 75 VOCs in three groups (individual substances, isomer groups, and other groups and mixtures), which are subject to additional reporting requirements. These VOCs are collectively referred to as "speciated VOCs." For a list of the speciated VOCs listed in Part 5, consult the NPRI website: www.ec.gc.ca/inrp-npri/default.asp?lang=En&n=E2BFC2DB-1.

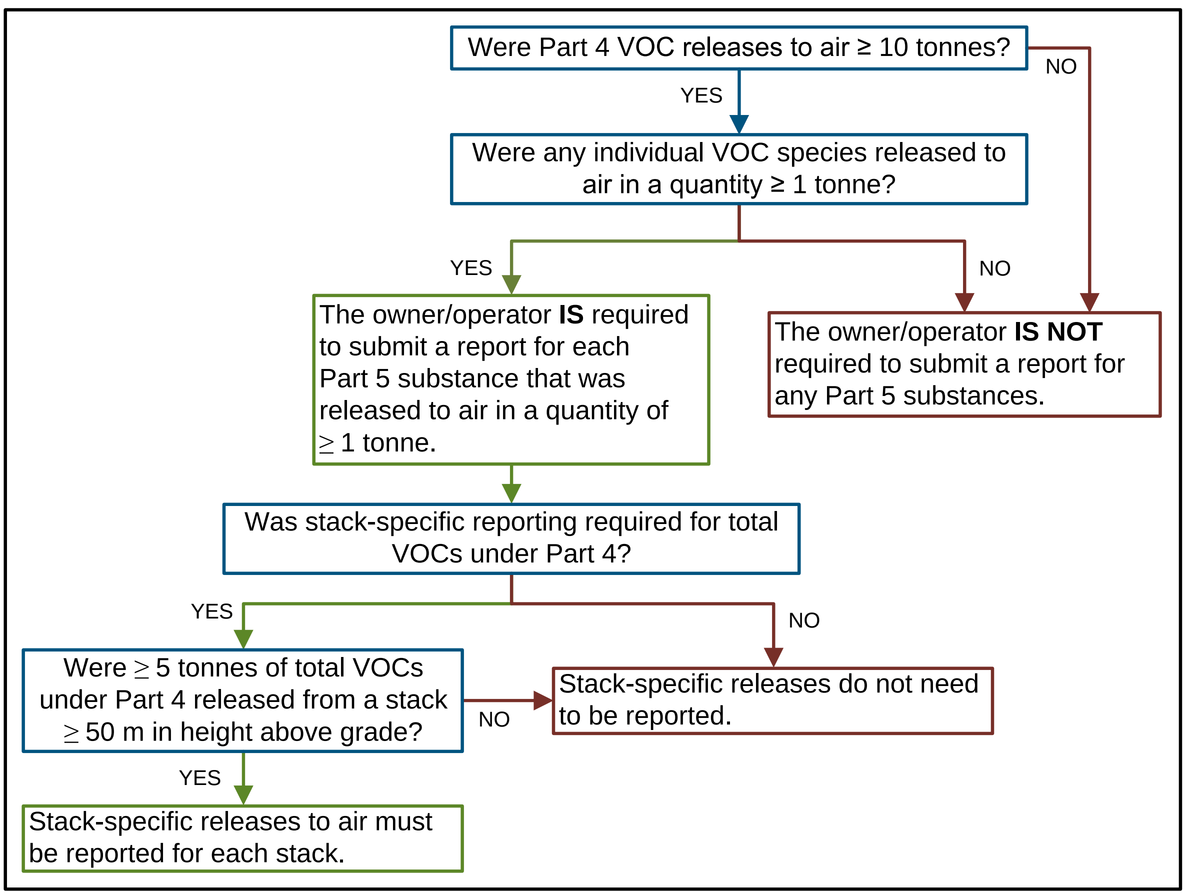
9.1 Reporting Criteria for Part 5 Substances

Like Part 4 substances, speciated VOCs must be reported based on quantities released to air. In general, any person who owns or operates a facility must submit a report to the NPRI for a Part 5 substance if both of the following criteria are met:

- Part 4 total VOCs released to air are ≥ 10 tonnes, and
- the total quantity of the Part 5 substance released to air is ≥ 1 tonne.

Figure 9 illustrates the steps for determining if a report for Part 5 substances is required, and, if so, what information must be reported.

Figure 9. Reporting for Part 5 Substances



9.1.1 Part 5 Substance Qualifiers

Some Part 5 substances and groups of substances are qualified in terms of what needs to be included when calculating releases. The qualifiers, described in Table 21, determine whether a report will be required for a given substance.

Table 21. Part 5 Substance Qualifiers

Substance Qualifier	Substance(s) to Which the Qualifier Applies	Description
and its salts	aniline (CAS RN 62-53-3)	Aniline and all salts of aniline must be reported as an equivalent weight of the acid or base.
all isomers	anthraquinone, butane, butene (25167-67-3), cycloheptane, cyclohexene, cyclooctane, decane, dihydronaphthalene, dodecane, heptane, hexene (25264-93-1), methylindan (27133-93-3), nonane, octane, pentane, pentene, terpenes (68956-56-9) and xylene (1330-20-7)	Total of all isomers reported as an aggregate of the individual isomers
	hexane	Total of all isomers reported as an aggregate of the individual isomers, excluding n-hexane (110-54-3)
	trimethylbenzene (25551-13-7)	Total of 1,2,3-trimethylbenzene (526-73-8) and 1,3,5-trimethylbenzene (108-67-8) Excludes 1,2,4-trimethylbenzene (95-63-6)

9.2 Calculating Releases of Part 5 Substances

There are two scenarios that must be considered to determine what sources of VOC emissions must be included in threshold calculations for Part 5 substances.

Case 1: Facilities that must consider all sources of VOC emissions

All sources of VOC emissions must be considered when calculating releases (excluding the sources listed in Table 4), if:

- the facility is a contiguous facility, portable facility or offshore installation at which employees work ≥ 20 000 hours; or
- any of the activities to which the employee threshold does not apply (see Table 3) take place at the facility, regardless of the hours worked by employees.

Case 2: Facilities that must consider VOC emissions from stationary combustion equipment only

Only VOC emissions from stationary combustion equipment must be considered when calculating releases if:

- employees work <20 000 hours; or
- the only activities that take place at the facility are those listed in Table 5; or
- the facility is a pipeline installation.

9.3 Reporting Releases of Part 5 Substances

If the reporting criteria are met for a Part 5 substance, the releases to air of that substance must be reported. Part 5 substances must be reported in tonnes. Stack-specific releases to air may also need to be reported for each stack ≥ 50 m above grade if both of the following criteria are met:

- stack-specific reporting is required for total VOCs under Part 4; and
- 5 tonnes or more of total VOCs under Part 4 are released to air from the stack.

Example of stack-specific speciated VOC reporting

A facility emits 28 tonnes of VOCs to air, 7 tonnes of which are emitted from a stack 65 m above grade. The remaining 21 tonnes are from storage/handling, fugitive releases, spills and other non-point sources. Three tonnes of styrene are released to air, 0.4 tonnes of which are from the 65 m stack. The following must be reported:

Part 4 (total VOCs)

- 28 tonnes of total VOCs must be reported under Part 4 (total VOCs have a release threshold of 20 tonnes)
- 7 tonnes of total VOCs must be reported for the facility's stack under Part 4 (total VOCs have a stack-specific release threshold of 5 tonnes)

Part 5 (speciated VOCs)

- 3 tonnes of styrene must be reported under Part 5 (speciated VOCs have a release threshold of 1 tonne)
- 0.4 tonnes of styrene must be reported for the facility's stack (speciated VOCs must be attributed to stack if the speciated VOC meets the facility-wide 1 tonne threshold, and the Part 4 VOC stack release threshold of 5 tonnes is met)
- the remaining 2.6 tonnes of styrene must be reported as being released from "other sources"

1. Purpose

The Whiteshell Laboratories (WL) Emergency Response Plan was created to support operations at the WL site to prepare for, respond to, and recover from emergency situations that are beyond the day-to-day operations of on-site emergency response services. This plan adheres to the industry standard of a four-pillared approach to emergency management. These pillars are:

- Prevention and Mitigation;
- Preparedness;
- Response; and
- Recovery.

This plan is designed to be an All-Hazards plan. This means that while specific high-risk events may receive additional planning rigor, the approaches and methodologies used are designed to build procedures and processes that can be applied to any emergency. The ultimate objectives of this plan, and the WL Emergency Preparedness (EmP) program, are to:

- Protect the public from the nuclear legacy of the site during the decommissioning process;
- Protect CNL employees and contractors;
- Protect the environment; and
- Protect the reputations and interests of both CNL and AECL through timely responses and quick recovery times.

2. Scope

This plan conforms to the requirements of the Company Wide Emergency Preparedness Program Requirements Document [1]. This plan is not restricted to radiological emergencies. Response to incidents that can be handled without invoking this site wide emergency plan are covered in the Fire Protection Program Description Document [2], the ESO Standard Operating Guidelines [3] and the Radiation Protection (RP) Program Requirements Document [4].

The Site-Wide Emergency Procedure [5] and corresponding quick reference tools were created to provide employees on site with instructions to follow during specific emergencies that support this plan, and those listed above.

This plan is designed to guide responses to any emergency at the WL site, which includes the controlled and supervised areas of the main campus, the Waste Management Area (WMA), and the Concrete Canister Storage Facility (CCSF). The plan includes a description of the site, a general description of the resources available to manage an emergency of either radiological or non-radiological nature, and a summary of the responsibilities and actions of various groups or individual employees.

This plan also provides an overview of the interactions between WL's EmP staff and supporting provincial and municipal emergency organisations and their plans.

3. Abbreviations

CCSF	Concrete Canister Storage Facility
CMT	Crisis Management Team
CNSC	Canadian Nuclear Safety Commission
EOC	Emergency Operations Centre
ESO	Emergency Services Operations
IC	Incident Commander
ICP	Incident Command Post
LGD	Local Government District
MB EMO	Manitoba Emergency Measures Organisations
OIC	Officer in Charge
PSC	Public Safety Canada
RP	Radiation Protection
SRC	Safety Review Committee
WL	Whiteshell Laboratories
WMA	Waste Management Area

4. Site Description

4.1 Location

WL is located in the Local Government District of Pinawa, along the Winnipeg River between Lac du Bonnet and Seven Sisters Falls (see Figure 1). The site is about 85 km east northeast of Winnipeg, and is accessible by all-weather highways. WL is served by Provincial Trunk Highway 211 which connects to Provincial Highway 11, on the west side of the Winnipeg River, with the community of Pinawa, 13 km east of the site.

This region is located in the Canadian Shield which is heavily forested, and near the northeastern boundary of the plains area of eastern Manitoba which is dominated by agricultural land. The site is located alongside the Winnipeg River but is well above present flood levels.

The seismology, meteorology, and population of WL and the surrounding areas are described in Appendix A.

4.2 WL Facilities

The main WL facilities from which radioactive material could be released to the environment following an accident or emergency event are:

1. The Shielded Facilities - a shielded research facility designed for remote examination of radioactive materials (primarily mixed fission products (Cs 137, Sr 90, Am 241) and activation products (Co 60, Nb 94). This facility has 12 hot-cells, six are operational and 6 are partially decommissioned.
2. The Waste Management Area - used for storing radioactive materials and some chemical wastes. This location will become very active over the life of the decommissioning project as waste is recovered, packaged, and shipped from site.
3. The Concrete Canister Storage Facility which consists of 16 canisters containing primarily mixed fission products and activation products - Th, U, and Pu.
4. The WR 1 Research Reactor - shutdown since 1985, defueled and partially dismantled 60 MW(t) organic cooled, heavy water moderated reactor (primarily activated reactor components, mixed fission products, activation products, and tritium).

For each of the facilities listed above, the current Source Term document [6] provides information on: the amount of radioactivity contained in a given facility; the most extreme accident scenario; and the amount of radioactivity that could be released as a consequence of the most extreme accident scenario. None of these have a potential for off-site impacts at this time.

There are many buildings and facilities on the WL site in which hazardous chemicals are handled under controlled conditions. The inventories involved are typically small enough that the consequences of an accidental release would be localized to the affected building or area.

A few facilities have inventories (e.g. quantities of liquid chlorine or petroleum products) large enough that a major release or involvement in a fire could impact a large portion of the site or have possible minor off site consequences.

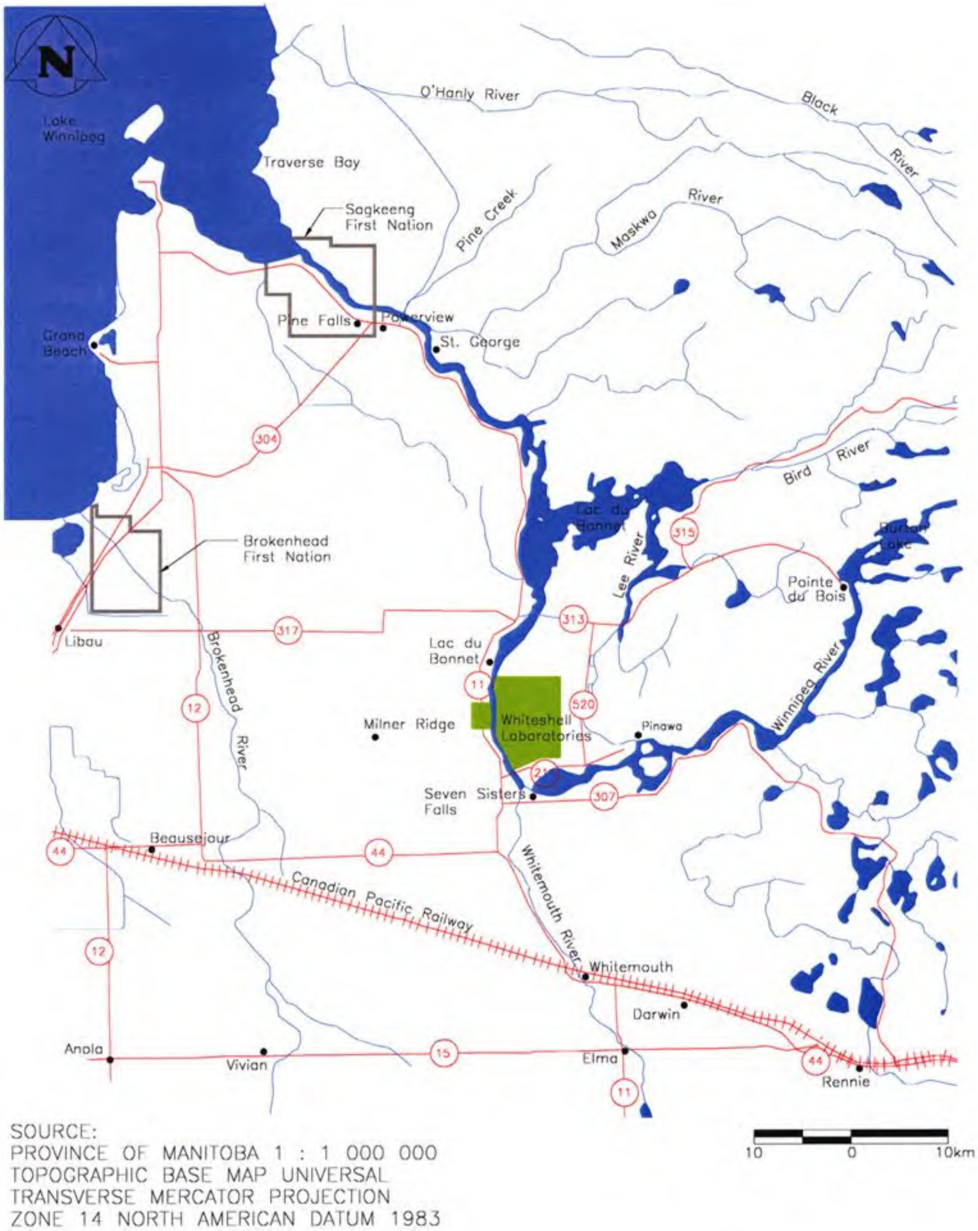

Figure 1: Map Showing Whiteshell Laboratories and Surrounding Area

5. Hazard/Vulnerability Analysis

5.1 Radiological Source Terms

5.1.1 Radiological Airborne Source Term

The Whiteshell Laboratories Source Term [6] documents the current radiological source terms for relevant nuclear buildings and locations of interest in WL, and the calculation of on-site and off-site radiation doses to individuals from postulated accidental airborne radiological releases, for both rare and extremely rare accident scenarios. The nuclear facilities at WL which are of radiological concern for accidental airborne contamination releases are the Shielded Facilities (Hot Cells and the Waste Handling Area), Waste Management Area, and WR-1 reactor. Bounding accidents (maximum worst case scenarios) are a fire involving radioactive material in the Shielded Facilities and WMA and a deflagration event occurring during remediation of an irradiated fuel bearing standpipe in the WMA.

For all exposure situations, the majority of the dose occurs within the first hour of the release due to inhalation as the radioactive plume passes the receptor location and is due primarily to inhalation of released actinide radionuclides. Fission products contribute to longer term exposure through ground shine of deposited contamination on the ground.

The most significant potential accidental radiological release is a deflagration event occurring in an irradiated fuel bearing standpipe [6][1]. The maximum calculated adult dose at the WMA site ranges from 0.81 mSv for a rare accident, to 81 mSv for an extremely rare accident. The rare accident dose is below the rare event dose risk criteria of 5 mSv that would warrant the provision of a stay-in. The extremely rare accident dose exceeds the stay-in dose risk criteria for extremely rare events of 50 mSv. The maximum adult dose at the boundary of the site ranges from 0.03 mSv (rare accident) and 3 mSv (extremely rare accident) both below the stay-in dose risk criteria. The maximum off-site adult dose8 for local residences in the vicinity of CNL property ranges from 3.2 x 10-2 mSv (rare accident) to 0.76 mSv (extremely rare accident) and the calculated maximum dose to local towns ranges from 2.1 x 10-3 mSv (rare accident) to 0.21 mSv (extremely rare accident). These off-site doses are below the stay-in dose risk criteria.

The event capable of causing the maximum calculated dose for an adult on the WL main site campus is a fire in the Shielded Facilities. The maximum dose ranges from 2.8 x 10-3 mSv (rare accident) to 0.95 mSv (extremely rare accident). Maximum off-site adult dose ranges from 9.0 x 10-5 mSv (rare accident) to 3.0 x 10-2 mSv (extremely rare) for local residences and from 2.8 x 10-5 mSv (rare accident) to 9.4 x 10-3 mSv (extremely rare) for local towns. All these doses are below the stay-in dose risk criteria. The calculated doses from an accidental release of tritium from WR-1 are about 100 times lower for on-site doses and 36 to 50 times lower for off-site doses compared to the dose from a Shielded Facility fire rare accident.

[1] See Table 20 of Reference [6] for dose acceptance criteria for accidents, including definitions of “rare” and “extremely rare” accidents.

5.1.2 Off-Hours Nuclear Emergencies

A Hazard and Operability study was carried out at WL [7] to ensure that the removal of trained nuclear operators from off shift operation would still result in an adequate response to emergency situations. The study was conducted to identify the potential emergency situations requiring specific nuclear operator off shift response and additional response required by other expert groups. Facilities were selected on the basis of highest inventory of radionuclides and/or hazardous chemicals or conventional hazards such as high temperature/pressure processes.

5.2 Analysis of Potential Emergencies at WL

A Hazard Impact and Risk Assessment (HIRA) [8] was created for WL in 2017 (last updated in 2022) and forms the basis for EmP planning activities. The HIRA rates the risk of potential emergency situations at WL based on a probability x impact matrix (Table 5-1). This sorted the hazards into four hazard categories; Low, Moderate, High, and Severe. The WL results of this process can be seen in Table 5-2.

Table 1: Hazard Impact and Risk Assessment Matrix

Impact	5	5	10	15	20	25
	4	4	8	12	16	20
	3	3	6	9	12	15
	2	2	4	6	8	10
	1	1	2	3	4	5
		1	2	3	4	5
		Probability				

Table 2: Summary of 2022 WL HIRA

Hazard	Score	Classification
Wildland Fire	9	Moderate
Physical Security Intrusion	8	Moderate
On-site Dangerous Goods Incident (Non-RAM)	8	Moderate
Pandemic	8	Moderate
Severe Weather (Snow)	6	Moderate
Severe Weather (Thunderstorm)	6	Moderate
Severe Weather (Tornado)	5	Moderate
Off-site RAM Transportation Accident	4	Moderate
Bulk Propane Systems	4	Moderate
Standpipes – Localised Fire	4	Moderate
Dam Failure (Flooding)	4	Moderate
Concrete Canister Storage Facility – Canister Breach	4	Moderate
Potential Bunker Leak/Spill During Pumping	4	Low
Emissions to River from D&D Activities	4	Low
Cask Loading Facility – Localised Fire	4	Low
Bldg. 300 Shielded Facilities – Ventilation Failure	4	Low
WMA – Localised Fire	3	Low
Bldg. 300 Shielded Facilities – Hot Cell Fire	3	Low
Bldg. 100 WR-1 Facility – Localized Fire	3	Low
Lagoon Breach	3	Low
Flooding	3	Low
Bldg. 902/903 – Chlorine Gas Release	3	Low
Earthquake	3	Low
On-site RAM Transportation Accident	2	Low

6. Supporting Plans and Policies

6.1 CNL Company-Wide Policies

The company-wide Emergency Preparedness Program Requirements Document [1] describes the EmP program for CNL. It defines specific responsibilities and objectives for the program. The company-wide Emergency Preparedness Program Description Document [9] provides direction to related program documentation and provides an overview of the program. The company-wide Crisis Management Field Instruction Document [10] would also be activated in the event of a crisis that actively threatens, or has significant potential to threaten, the corporation as a whole and whose resolution extends beyond the control of routine management policies and procedures. The Crisis Management documents focus on CNL senior management activities and communications during a crisis. EmP also deals with the health, safety and protection of employees, the public, and the environment as described in the Health & Safety Policy [11] and the Environment Policy [12].

6.2 Whiteshell Procedures/Plans

WL EmP maintains multiple procedures and plans that support the safety of staff and the Whiteshell mandate. All WL staff have been issued a Site-Wide Emergency Procedure Flipbook that describes the required action of all personnel in the event of specific emergencies. All project work at WL is performed under a project specific emergency procedure, called a Green Bordered Placard, which is reviewed by project staff weekly and posted at key location in the project area. The Emergency Operations Centre (EOC) staff operate under a procedure which provides direction on notification, activation, operation, and deactivation of the EOC [13]. General site staff, EOC staff, and other staff or groups with emergency responsibilities are tested and evaluated according to the WL 5 Year Exercise Plan [14] which is a five year guideline from which the annual exercise schedule is created.

6.3 Other Related Plans

The Federal Nuclear Emergency Plan [15] outlines the procedures to be followed by the Government of Canada in dealing with nuclear emergencies that may affect the health and safety of Canadians and that may have radiological safety implications outside Canada. The Federal Nuclear Emergency Plan is issued under the authority of Health Canada.

The Manitoba Emergency Plan [16] provides a mechanism for ensuring a prompt and coordinated response by the Government of Manitoba to any emergency or disaster within provincial jurisdiction, or in support of a municipality that has requested provincial assistance.

The Local Government District (LGD) of Pinawa Emergency Plan [17] provides a description of the response of the LGD of Pinawa to emergency events and the responsibilities of the LGD staff.

7. General Organisation

7.1 Internal Organisations

During emergency events an augmented organisational structure will be implemented to both support the emergency response and coordinate between normal day-to-day and emergency operations. This augmented structure is based on the Incident Command System (ICS) so that it can be seamlessly integrated with other local and provincial response groups. The WL emergency structure is shown in Figure 7-1.

The EOC operates with a minimum complement of six positions, but can expand to 13 unique functions to meet the dynamic needs of the emergency. As a result the EOC maintains two teams of 13 staff members that can be called upon during emergencies, with an additional staff member identified for each position as an alternate. A detailed description of the emergency response organization and training requirements is given in the Whiteshell Emergency Operations Centre Operating Procedure WL-508730-PRO-559 [13].

The normal WL reporting structure will stay the same for most employees during an emergency. The EOC will set up a parallel structure to the normal organisational structure and draw upon resources as required to respond to an emergency at WL. When there is an emergency at the WL site, employees are expected to obey all emergency signals and/or directions provided (e.g., site wide signals, PA and radio announcements). In the absence of any signals or announcements employees are expected to continue with their planned activities for the day.

7.1.1 Emergency Authority

The WL EOC Commanders are authorised by the CEO to operate with full executive authority over all WL Site resources during an emergency event. WL employees need to respond quickly to any request for information, supplies, or resources that come from the EOC. The EOC Commander, or their designate, have the authority to directly enter into service agreements and purchase goods that are urgently required to resolve the emergency situation.

When the EOC is supporting mutual aid agreements or other external emergencies AND when the level of CNL support provided will impact WL operations THEN the EOC Commander will obtain a final decision from the CNL Crisis Management Team on the extent of the CNL support to be provided. No support will be provided that impacts WL’s ability to maintain a safe site. Placing the site in a safe state and suspending site operations to better support an offsite emergency is a consideration that the Crisis Management Team may consider.

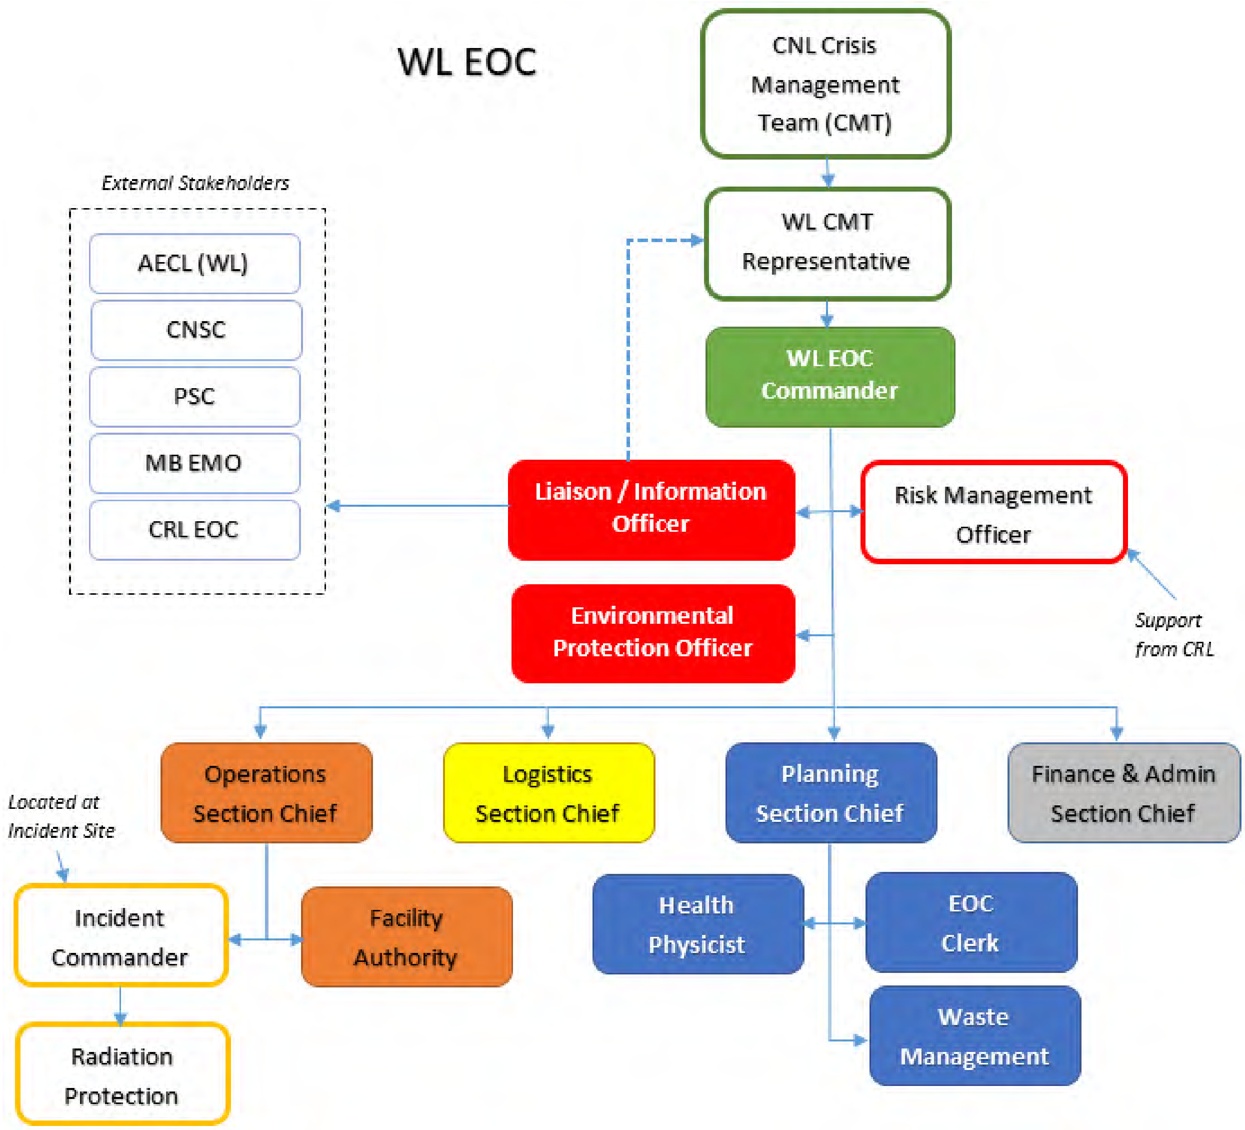

Figure 2: Internal Organisation

7.2 External Organisation

There are several external organizations that would potentially need to be engaged or informed of an emergency at WL. Interactions with these groups is the main responsibility of the Liaison Officer in the WL EOC. Depending on the nature of the emergency, some, or all, of the following federal, provincial, and local groups could need notification.

7.2.1 Federal

Canadian Nuclear Safety Commission (CNSC) - The CNSC is the regulatory body that issues the licence for CNL to operate or decommission the nuclear facilities at WL. The EOC must inform the CNSC of any event causing an emergency and it must keep the CNSC informed of the status of the emergency, as defined in this plan. In the event of being informed of an emergency condition at WL, the CNSC would initiate the current CNSC Emergency Response Plan.

Public Safety Canada (PSC) - PSC is the federal organization responsible for the coordination of federal assistance to Manitoba Emergency Measures Organization (MB EMO) and to federal departments (including CNL) in the event of an emergency. The procedures are documented in the Federal Emergency Response Plan [18]. Once PSC receives a call from AECL/CNL informing them that WL is in a state of emergency, they will inform all federal agencies to be prepared in case assistance is required. PSC utilizes a duty officer that can be contacted 24 hours a day.

Health Canada – Health Canada is the federal organization responsible for the Federal Nuclear Emergency Response Plan. They may be called in by MB EMO, PSC or CNL directly.

7.2.2 Provincial

Manitoba Emergency Measures Organization (MB EMO) – MB EMO is the provincial organization responsible for emergency preparedness and response in Manitoba. It is responsible for putting into effect all actions necessary to manage the off-site situation associated with an emergency. MB EMO may request assistance from the Federal Government as outlined in the Federal Nuclear Emergency Plan [15]. Once MB EMO receives a call from CNL informing them that WL is in a state of emergency, they will inform relevant provincial agencies and local municipalities of the emergency condition. MB EMO utilizes a duty officer that can be contacted 24 hours a day.

During events that originate on-site at WL, but could affect off-site locations, CNL will make the initial evaluation of the emergency condition. Once CNL has evaluated the situation sufficiently to understand the implications to public safety, the EOC will report the event along with public safety recommendations to MB EMO. MB EMO will inform and alert provincial departments, agencies, and municipal authorities, and take appropriate action to coordinate the provincial and municipal government emergency responses.

The EOC will maintain regular contact with MB EMO in an effort to keep the province and the local communities up to speed on the emergency situation and resulting hazard conditions. The CNSC will be included in off-site updates to ensure consistency of information until the emergency is resolved. CNL's Crisis Management Team (CMT) is responsible for providing public information, representing CNL to the Media, and coordinating messaging with external stakeholders.

Manitoba Sustainable Development – Sustainable Development is the lead agency for radiological emergencies that occur off-site, in the province of Manitoba [19]. In the event of a radiological emergency that originates off-site and does not involve CNL material, WL may be called upon to provide support and assistance. MB EMO has the authority to activate the WL Emergency Response Plan if they declare a provincial State of Local Emergency. WL Staff would provide support with CNL management consensus and approval.

7.2.3 Local

At the local level, the following response groups may need to be kept informed of emergency situations as they evolve. At this local level, many of these groups will also be invited to participate in emergency exercises for the mutual benefit of WL and the local community or response group.

LGD of Pinawa, the RM and Town of Lac Du Bonnet, and the RM of Whitemouth – Each of these communities shares a border with the WL site, or is very close to the WL site. Each has an assigned Emergency Coordinator who is responsible for the community level emergency preparedness and response activities for their communities. These communities are responsible for managing any off site situations associated with a non-radiological emergency. The LGD may request assistance from the MB EMO, as per the Manitoba Emergency Management Act.

Local Volunteer Fire Departments – The local volunteer fire departments are expected to automatically respond to all emergencies within their jurisdiction. For the LGD of Pinawa's fire department this does not include emergencies occurring on WL land. The LGD of Pinawa Fire Department does have a mutual assistance response agreement with CNL for the WL site which means the fire department will respond to emergencies on WL land if requested to do so by WL ESO. Joint exercises are conducted between Pinawa Fire Department and the WL Fire Fighters to practice integration of personnel, communications and equipment.

Local RCMP Detachment – The local RCMP detachment is based out of Lac Du Bonnet, although they maintain a part-time presence in the LGD of Pinawa. The RCMP will initially be notified of an emergency at WL by ESO. The RCMP is the primary response force for armed active threats and suspicious packages at WL and they will deploy resources to support incidents on-site. Should the emergency situation escalate to have an impact off site, the RCMP will take their directions from the LGD or provincial authorities as described in their own emergency plans.

Regional Emergency Medical Services (EMS) – The regional EMS, Interlake Eastman Regional Health Authority, serves the area around the WL site, and the site itself. ESO responders will handle immediate care while EMS is on-route to site. Once on-site, the patient is either transported to EMS or EMS is escorted to the patient, depending on injuries.

7.3 CNL

CNL Sites – Intra-site communication and coordination of emergency events is the primary responsibility of the Crisis Management Team (CMT). WL representation on the CMT is handled by the Site Head, Deputy Site Head, and Director of ESH&Q. Through the CMT, other CNL sites will be informed of any emergencies at WL. These sites are available to offer assistance as required. The requests for assistance shall be made by the EOC, through the CMT.

The WL CMT members will coordinate with the CRL Corporate Communications team to manage media and public relations issues during any crisis or event. In the absence of dedicated communications staff at WL, the Liaison Officer in the EOC will provide support to the CMT members and corporate communications.

7.4 General Staff and Resources

All WL employees participate in a site orientation on their first day on-site. This orientation includes an introduction to WL emergency signals and the corresponding expected actions, the use and location of the emergency procedures, and the location of muster points (assembly points). During this orientation, new employees are issued a copy of the Site-Wide Emergency Procedure Flipbook. After the site orientation, the first day on-site also includes a Radiation Protection (RP) component, where staff are informed of the signals and responses associated with various radiological emergencies. They are instructed on basic radiation theory which provides them with a basic understanding of the radiation safety techniques and practices followed at WL.

Employees are instructed to inform their managers if they have, or develop, any special assistance requirements associated with building or site-level evacuations. The manager is then responsible to inform WL ESO of any special needs and also to assign a 'buddy' style system of accountability within their branch to support the staff member in an emergency.

While all WL employees receive a minimum orientation to radiological safety (group 4 training), some employees specialise in radiation hazard control and/or environmental hazard control. These staff are tremendous resources during emergency events. When equipped with the correct instrumentation these staff can provide information on any release of radioactive material extending beyond controlled areas, and determine whether radioactive material exposure has occurred. Details of this instrumentation and dosimetry process can be found in the Radiation Protection program documentation.

Procedures to minimize and control radiological and non-radiological exposure to personnel are documented in the Radiation Protection Program Requirements Document [4] which governs dose protection and measurement under normal and emergency situations. Facilities are available on-site to analyze radiological material samples. The main analytical equipment on-site is kept at or beyond 100 metres distance from the main source of radioactivity on-site. Sufficient portable equipment also exists for backup of radiological measurements, if required.

Training requirements (including training program development) for emergency and non-emergency personnel are identified in the Emergency Preparedness Requirements Document [1].

WL ESO personnel are on-site and available 24/7/365 to provide emergency response or support services.

The Pinawa hospital is equipped to provide medical backup in the event of an emergency. Physicians, nurses, and analytical services are available. WL relies on provincial Emergency Medical Services for advanced in-field medical care and transportation of injured personnel.

CNL maintains personnel and equipment to respond to on and off site transportation accidents involving hazardous materials including, but not limited to radioactive materials, that belong to CNL or their mutual aid partners. Details for off-site responses are specified in the Transportation Accidents Involving Hazardous/Dangerous Goods [20].

8. Roles and Responsibilities

8.1 Emergency Operations Centre Commander

The EOC Commander is responsible for the overall management of an incident, including the incident site, the EOC staff and facility, the unaffected portion of the WL site, and all assigned resources. The EOC Commander guides strategic-level emergency management functions, and provides necessary resources to the Incident Commander through the various EOC functions. The EOC Commander does not direct tactical-level response operations, but instead provides high-level strategic guidance to operations personnel.

8.2 Incident Commander

The Incident Commander (IC) is the person in charge of the Incident Command Post and the emergency scene. The IC is responsible for tactical management of the incident and takes command of all resources assigned to the site to effect rescue, to control the incident, and to deal with the immediate situation at the location of the emergency. At WL, the senior ESO Lieutenant on shift will be the IC by default until the EOC declares the event over or assigns a new IC. When the EOC is activated, the IC reports to the Operations Section Chief in the EOC. If the EOC is not activated, the IC reports to their normal Line Manager.

8.3 WL Emergency Preparedness Program Manager

The EmP Program Manager at WL, in consultation with applicable response groups and facility personnel, ensures that the emergency plan and the related EmP documents are reviewed, updated, and tested as required. The Program Manager is responsible for overseeing the following activities at WL:

- Development of WL emergency plans for the site;
- Development of WL emergency procedures;
- Liaising with the Canadian Nuclear Safety Commission on WL Emergency Preparedness issues at the direction of the Functional Support Manager;
- Liaising with emergency planning and response partners at the local, provincial, and federal levels;
- Ensuring all EOC equipment is inspected and maintained in a state of readiness;
- Development and delivery of emergency exercises to evaluate the effectiveness of WL emergency procedures and evaluate the emergency response capability at WL; and
- Assessing the effectiveness of exercises and drills in preparing WL employees for emergencies.

8.4 Building Superintendents/Facility Managers

The Building Superintendent/Facility Manager, as defined in the Responsibility for Facilities and the Safety of Operations at the Whiteshell Laboratories document [21], is the person responsible for a specific building or area, and the development and maintenance of any building system-specific emergency procedures. The Building Superintendent/Facility Manager is also responsible for informing WL EmP when there are changes to the facility's use or overall hazard profile.

8.5 Officer in Charge

The Officer in Charge (OIC) is a role that is only filled in the event of an emergency occurrence. All WL employees receive adequate training in the site's emergency response procedures to be able to assume the role of the event OIC in an emergency. The first employee, or the most senior employee if in a group, to reach the muster point shall assume the role of the event OIC. There will only be one OIC at each muster point.

Using the provided OIC checklists (located at the muster points) the event OIC is responsible for collecting situation specific details from the other building occupants and providing that information to the Incident Commander. The OIC then coordinates the building occupant's movements while they are evacuated from the facility. Details on this role can be found in the Whiteshell Site-Wide Emergency Procedure [5].

8.6 Line Managers

All Line Managers are responsible for ensuring that employees under their supervision receive adequate training in their responsibilities under the EmP Program, and for making sure that any emergency equipment their branch is responsible for is kept in a state of readiness.

8.7 Response Groups

8.7.1 The Crisis Management Team

The Crisis Management Team (CMT) enables organisational resiliency, through effective management of CNL's communications and interactions with its employees, the public, media, regulators, shareholders, and other stakeholders, to maintain its credibility, reputation, and ability to carry on/recover business and routine operations, in the face of a crisis.

During an emergency event resulting in the activation of a CNL EOC, the CMT has an oversight and support function that does not implement emergency actions during the emergency response. The CMT is intended to compliment the EOC by focusing on the business impacts resulting from the event, the required business communications for the event, and planning for the recovery and resumption of affected business units.

The CMT is also accountable for assessing any crisis that could result in disruption to CNL critical business functions, and, as required, implementing business continuity plans and strategies [10].

8.7.2 The Emergency Operations Centre

During an emergency, the EOC coordinates organisational emergency management functions by providing guidance, support, and resources to the Incident Commander and the unaffected portion of the site. The EOC is responsible for strategic-level decision-making, and does not directly control field assets; instead the EOC determines operational objectives and leaves tactical decision-making to the Incident Commander. The EOC also coordinates with external agencies, and with CNL's Crisis Management Team. Another function of the EOC is to begin recovery operations, ultimately facilitating the transition from emergency operations back to day-to-day operations.

All EOC staff are required to maintain position logs which track directions given, requests received, decisions made, and actions taken. The maintenance of position logs creates continuity for the EOC functions during shift changes and supports the master events log that is displayed in the EOC, keeping all EOC staff on target. The master events log is a function of the Planning Section in the EOC. Position logs are collected and retained at the end of the emergency. More details on the EOC's function and individual EOC positions can be found in the WL EOC Procedure [13] or the EOC position binders located in the EOC (Room 2-13 in Building 401).

8.7.3 The Incident Command Post

The Incident Command Post (ICP) is a temporary 'facility' where the Incident Commander and their team will gather to coordinate the tactical operations in response to the emergency. For WL, the Incident Command Team on-site will function as the Operations Section for the EOC, with most other functions being facilitated by the EOC. Unless otherwise approved by the EOC, the Incident Commander will always be the Senior Lieutenant on shift for WL Emergency Services Operations (ESO).

The Incident Commander is responsible for determining the point at which an emergency has grown enough to require activation of the EOC. The EOC and Incident Command Post remain in communication throughout the duration of the event.

8.7.4 Radiation Protections

The RP Branch is responsible for supporting the EOC and the ICP in matters of radiological safety. RP provides Health Physics support at the scene, including dosimetry and radiological surveying. It also coordinates and communicates with the event OIC(s) to ensure that emergency procedures are being followed in responding to radiological emergencies. RP also provides: assistance in radiation monitoring and contamination control; monitoring of hazardous environments on-site (including radioactive contamination in the air); and personal protective equipment and emergency decontamination supplies. These supplies undergo regular inspections and maintenance.

8.7.5 Emergency Services Operations

ESO provides firefighting, security, and first aid services as required through the presence of the Nuclear Security Officers and/or Firefighters. Emergency response equipment is available on-site and routinely inspected and maintained by ESO.

Depending on the nature of the event, the WL site main gate may be closed with no one being allowed to enter or exit the site until the All Clear signal (a series of intermittent blasts on the site whistle) is given or a site-wide evacuation is called. The exception would be admittance of resources coming to assist in the emergency response.

In all emergencies at WL the ESO On-Duty Shift Senior Lieutenant is the default IC. ESO personnel will take responsibility for establishing an ICP at the incident site. The IC may establish Unified Command at the incident site if they feel this is warranted, but may not relinquish command of the site without approval of the WL EOC. The IC is responsible for directing emergency response actions until the emergency is terminated, or until they are relieved by the EOC Commander.

The IC may initiate an EOC activation at any point they feel it is necessary. Once the EOC is activated the IC will report to the Operations Section Chief in the EOC. If the Operations Section Chief is not activated they report directly to the EOC Commander. The IC must make effective use of subject matter experts available on-site as required to respond to the emergency.

In the event of an emergency condition in which there is no clearly defined incident scene, the EOC will coordinate emergency response actions.

8.7.6 Corporate Communications

During an emergency situation, Corporate Communications (located at CRL) provides communications support to the CMT and the WL EOC. Corporate Communications will manage conventional and social media and will work with CMT to appoint and prepare a CNL spokesperson, whether at WL or CRL.

The WL CMT representative will be the primary point of contact for the CMT and Corporate Communications staff in CRL. If the WL CMT representative is unavailable or needs assistance, the WL EOC’s Liaison Officer will support as required, collecting data and arranging media interactions on-site, etc.

8.8 Response Group Interactions

An essential feature of the emergency plan is cooperation between those engaged in the operation of facilities and those providing a specialized emergency response service. In the early stages of an emergency, it is critical that all necessary actions be taken in a timely manner and that the IC has access to expert advice from resource units such as RP and Facility Operations.

It may be that an emergency condition exists where there is no clearly defined scene or accident site and, therefore, no obvious location to set up an ICP. In such a situation, ESO would coordinate the initial emergency response actions from the Security Monitoring Room (SMR) until such time as the EOC could be activated. The EOC Commander in the EOC would then take direct control of the emergency, using the On-Duty ESO Shift Supervisor to augment the EOC Operations Section.

9. Emergency Alerting System

9.1 Emergency Signals

The WL site has the ability to alert staff and contractors of hazardous events on-site through a series of alarms and signals. Staff can be advised to stay-in, hold and secure, evacuate a building or the site, or that an event has passed and it is all clear. Alerting is accomplished through the PA system which broadcasts the appropriate tone and a follow up message with information and instructions for staff. The same capability exists at the Waste Management Area (WMA).

Alerting of staff outdoors is accomplished through the combined use of emergency response vehicle sirens, portable radios, and air horns (used at demolition sites). These signals serve to alert staff to the presence of an emergency and move them to a location where they can get more information. Due to the significantly reduced risk for a stay-in at the main campus [6], this has been determined to be adequate for the task of alerting those staff working outdoors. An external speaker provides notification to staff working in the WMA. As there is a risk of a stay-in occurring at the standpipe facility [6], the external speaker will be maintained as the primary alerting system until the risk to workers has decreased to an acceptable level.

9.2 Call Outs

Some of the EOC, RP and Operations staff are expected to be on call at all times. WL maintains two methods of communicating with these staff. The primary method is a secure internet-based notification system with pre-scripted messages and defined target groups. This system is used for emergency call-outs of staff as well as for monthly and quarterly drills. The system is tested twice a day by ESO. The secondary system that is used is a manual phone/email call-out process, also managed by ESO.

On-call staff are expected to keep their CNL-issued alerting devices charged and within earshot. For maximum effectiveness, EOC staff provide personal contact information (email and phone), in addition to their CNL-issued contact information, for the call-out system. EOC staff are expected to be able to respond to the site within 120 minutes of receiving a notification when they are on call. It is expected that the EOC can be staffed to a functional level within 90 minutes of the initial notification. Until the EOC is operational the Senior Lieutenant on shift is responsible for the entire site and all emergency response actions.

In the event of an incident requiring activation of the emergency alerting system, the SMR will initiate contact with the emergency response staff appropriate to the incident.

10. Activating the Plan

10.1 Implementation of the Plan

The emergency plan may be implemented in part or in whole when an emergency or a disaster has occurred or threatens to occur. While specific activation triggers are captured in the SMR Response Flowcharts and the WL EOC procedure [13], there may be situations that arise that don't conform easily to the flowcharts. In these rare occasions, the decision to activate the EOC can be made directly by the ESO Senior Lieutenant, or in collaboration with the EOC Commander and EOC Planning Section Chief. The notification system is set up with a pre-scripted notification that pulls all three positions into a teleconference call to facilitate rapid information sharing and decision making.

The plan is initiated with the activation of the WL EOC. The EOC is activated during operating hours by an announcement of a stay in over the site wide public address (PA) system, or direct communication with EOC staff. The stay in may be initiated by any employee on-site by calling Emergency Services Operations at local 88.

During all phases of an emergency or exercise event, it is important to communicate information clearly and succinctly. It is especially critical to ensure that all personnel understand whether the event is real or simulated. Emergency notification of staff is conducted via emergency signals on-site and/or with verbal announcements over the PA and radio systems. In the event of a failure of these systems, site-wide emails would be used or physically sending runners to other occupied buildings would be a last resort.

Implementation of the plan can be broken down into on-site and off-site situations.

10.1.1 Action by Employees Discovering Emergency Conditions

Emergency procedures are developed for the WL site, taking the form of site-wide emergency procedures which cover the whole site, or Green Bordered Placards which are for specific hazards not addressed by the site wide procedure. These procedures provide direction to employees on how to deal with the variety of events that can occur on-site.

The Site-Wide Emergency Procedure is available online and is also posted on the EmP Blue Boards, situated at the entrances of all the occupied buildings on-site. The specific actions for each emergency type have also been extracted from the procedure and published in a quick reference flipbook with a magnet on the back. Each employee on-site has been issued a copy of the flipbook to place in an area of convenience for them. They are also posted in most un-occupied buildings and in various common areas around the site. The magnet on them is to make them easy to 'post' without the risk of them being buried and lost so they can be quickly accessed when needed.

Green Bordered Placards are used to augment the Site-Wide Emergency Procedure (and flipbooks) when unusual hazards are present. Sometimes a job will have inherent risks based on the activities or will create hazardous conditions in an area that need to be addressed (ex:

entrapment hazard). In these cases, the process created for dealing with these hazards will be documented in a Green Bordered Placard.

Any employee who discovers an emergency condition at WL shall report the nature and location of the emergency to the Security Monitoring Room by one of the following three methods.

- Using a WL landline, dial '88'
- Using a WL radio, switch to the '401 SMR' talkgroup and call for "401 Control"
- Using a cell phone, call the site at (204) 753-2311, then dial ext. 62223 or wait on the line and ask for the SMR.

At that time the SMR will follow their own emergency procedures and flowcharts to respond to the emergency event. Additional steps for employees to take are posted in the Site-Wide Emergency Procedure [5] and the quick reference flipbooks.

10.1.2 Action by Emergency Services Operations Staff

Upon being notified of an emergency event, the SMR Operator will follow the appropriate emergency response flowchart as per protocol. ESO resources will also be dispatched based on flowcharts, procedures, and fire pre-plans. WL ESO will then respond in a manner that is in alignment with their roles and responsibilities as defined in their various operating procedures, and are not covered by this plan. As a general rule, WL ESO will take action to stop the emergency event, or mitigate the effects of the emergency when it is safe for them to do so.

10.2 Off-Site Emergency Response

It is important to appreciate that CNL jurisdiction covers only the WL site and CNL products that are in transit. Surveillance work outside of the area is, however, a routine operational procedure for WL and this surveillance would be continued during an emergency.

According to the current Source Term document there are no probable operational or material handling scenarios at the WL site that would lead to an off-site emergency. It is still necessary to retain emergency response capabilities for off-site radiological emergencies. In the unlikely event that something should occur, MB EMO will be responsible for putting into effect all actions necessary to manage the off-site situation. The WL EOC has the responsibility to ensure that MB EMO receives adequate information upon which to base its actions.

The most probable WL-based scenario with off-site implications would be a motor vehicle accident involving CNL owned radioactive materials being shipped to an alternate storage location. A separate procedure exists for responding to these sorts of events [20].

10.2.1 Monitoring Estimation of Dose

While there are no credible scenarios that would result in off-site radiation doses, WL is committed to ensuring this is evaluated and confirmed for every situation that poses a risk. Monitoring for assessing radiological hazards and doses would include:

1. Airborne releases measured by stack monitors.
2. Releases to the Winnipeg River measured by the outfall sampling system.
3. Radiation fields measured in the area of concern.
4. Airborne and surface contamination measured in the area of concern.
5. Sampling and radiochemical analysis of river water.

Rough estimates of the doses would then be made by comparison of some of the above listed field data with appropriate Derived Release Limits [22]. As described in Section 5, the postulated releases from a realistic worst case event are significantly less than that which would require countermeasures to avert doses to individuals off site.

10.3 Concept of Emergency Operations

The WL EOC operational model is based on the Incident Command System (ICS) principles. The basic operational process is made up of multiple operational periods, which are cyclical in nature. This process ensures the same consistent steps are used (plan, do, check, act) to ensure an effective response and recovery process.

Emergency management also follows a predictable path that repeats after each emergency event. These phases, known as the pillars of emergency management, are:

- Prevention/Mitigation – Once a hazard risk has been identified, the initial goal is to make it impossible for the risk to occur. If the risk cannot be prevented altogether, the goal changes to reducing the impacts of the risk when it does occur.
- Preparedness – This is the process of preparing for the residual risk (risk that cannot be prevented or mitigated), by having response plans and training for responses. These plans include identifying personnel, equipment, and supplies that will be needed to respond to emergency impacts when the hazard occurs. Exercising and evaluating plans and personnel is a major component of this phase. Most of emergency management work is conducted in this phase.
- Response – When the emergency occurs, this is the phase where all the preparedness plans/processes are implemented. This is the shortest phase of emergency management, though it receives the majority of attention and resources.
- Recovery – Almost as soon as the response phase has begun, elements of the recovery planning are implemented. As more of the response concludes, more effort is placed on recovery. Restoring the facility, business function, or site to 'normal' is the goal of the recovery phase. The WL EOC procedure [13] has more information of recovery planning at WL.

As stated above, the EmP program spends most of its time and resources in the preparedness phase of an emergency, constantly updating plans to reflect lessons learned from exercises and industry changes. Once an emergency occurs, the process of response begins, followed closely by recovery. After the event, lessons are captured and used to enhance prevention and mitigation efforts and EmP moves back into an ever-improving preparedness phase.

More details on the WL EOC operating model can be found in the EOC Procedure [13].

10.4 Termination of the Emergency

An emergency may only be terminated in part or in whole by the EOC Commander, or designate, following the advice of the EOC.

When conditions are no longer considered dangerous to life and health, the EOC Commander will inform Emergency Services Operations to initiate the All Clear signal. This is a series of intermittent blasts on the Site Whistle (lasting for 3 minutes) accompanied by an announcement on the site wide PA and radio system.

The EOC shall remain in control of the emergency site as the operations shift from response to recovery. The EOC Commander will consult with the Site Head and management team on a recommended course of recovery. Once recovery operations are sufficiently underway, the EOC will transition its workload and tasks over to the appropriate day-to-day staff and structure. Once this transition is complete, the EOC can be closed, collecting all records and filing appropriate after-action reports.

In some cases, re-entry to the site and its facilities may be restricted to prevent personal injury or contamination. This process is managed by the EOC and communicated to all WL staff as needed.

10.5 EOC Exercises and Training

Exercises shall be planned, conducted, and evaluated in accordance with the requirements listed in the Emergency Preparedness Program Requirements Document [1].

EOC exercises are planned in a five year program as outlined in the WL 5 Year Exercise Plan [14]. Based off of this plan, the WL EmP Program annually prepares a more detailed 12-month schedule. Exercises shall be conducted to train and test the emergency response groups, and to test the adequacy of the procedures. Exercises shall demonstrate the capability of WL's response teams in simulated emergency conditions with on-site impact. Outside organizations (e.g., Pinawa Hospital, RCMP, LGD of Pinawa, and MB EMO) may be invited to participate as appropriate.

Training requirements for emergency personnel are identified in the Emergency Preparedness Program Requirements Document [1]. All WL EOC team members and alternates should have a minimum training of EOC Essentials (or equivalent approved by the WL EmP Program Manager) to be provided to them within 18 months of being assigned to the EOC team. Core EOC members (and their alternates) are also provided an additional three days of training that focuses on the EOC Operations, Planning, and Logistics functions.

10.6 WL Emergency Plan Document Revision Procedure

The WL EmP Program Manager will ensure a formal review of the Emergency Plan is completed every five years. EmP Program documents shall be prepared, revised, and controlled in accordance with the Emergency Preparedness Program Requirements Document [1].

11. Glossary

Crisis: A crisis may be defined as any abnormal situation that actually threatens, or has significant potential to threaten, the assets and/or image of the Corporation and whose resolution extends clearly beyond the control of routine management policies and procedures.

Crisis Management Team (CMT): The CMT is the senior management group, supported by communications staff, which are the public face of the organisation during a crisis. The team is responsible for working with the media during a crisis and supporting the EOC's of the various CNL sites.

Emergency: An emergency, as defined within 900-508730-PRD-001, is a condition calling for immediate response, beyond the scope of normal operating procedures, and which activates the site or facility emergency response organization. An emergency is, or has the potential to become, life threatening and/or a danger to the environment.

Emergency Operations Centre (EOC): The members of the EOC are responsible for the management of the Whiteshell Laboratories during an emergency. The EOC is used to support the Incident Commander and the site emergency operations, balancing those needs with the needs of the rest of the WL Site. The members recommend off site action and maintain communications with municipal, provincial and federal agencies.

Emergency Preparedness: The state of readiness to implement emergency procedures and exceptional measures necessary to mitigate the effects of an emergency, including the organization, resources and communication processes to carry out these measures and to make the status of the situation known to on site and off site personnel.

Evacuation: An evacuation means all but essential services personnel leave the site. The Evacuation signal is a sustained note, accompanied by an announcement over the site wide public address system.

Hazard: A physical condition with potential for injury to human health or safety, damage to property, damage to the environment, threatens nuclear safety or a combination of these elements.

Incident Command Post (ICP): The ICP is responsible for the management of resources at the scene of the emergency. The centre is normally set up as close to the scene of the emergency as is reasonably safe. The ICP is managed by the Incident Commander who coordinates with the EOC as required.

Incident Command System (ICS): A scalable and adaptable system used by first responders and industry across most of North America to manage emergency situations.

Initial Notification Group: The group responsible for the off hours activation of the EOC. The group consists of both EOC Commanders, and both EOC Planning Section Chiefs.

Response Groups: Response Groups are branches, sections or logistical groups that may be required to provide assistance to either the EOC or the ICP. These centres include, but are not limited to, Radiation Protection Branch, Environmental Monitoring, Emergency Services Operations, Engineering and the Officers in Charge and Emergency Stewards.

Risk: The likelihood of a specific, significant consequence occurring within a specified period or in specified circumstances. Risk is calculated as: (potential impact of the event) x (probability of occurrence) = Risk.

Site: The property and facilities of the Whiteshell Laboratories and the surrounding area owned by CNL.

Appendix A Seismicity, Meteorology and Population

Seismicity

WL is situated in seismic zone 0. Seismic activity at WL has been recorded and analyzed by Natural Resources Canada since the installation of a short period vertical seismograph near WL in 1978 [A-1]. This station and others in the Canadian Shield are estimated to have the capability to locate seismic events down to a threshold magnitude of 2.5 on the Richter scale. Based upon a review of historical earthquake records and recent monitoring data, the southern two thirds of Manitoba appear to be aseismic at current detection levels [A-2].

Meteorology

The climate of the Whiteshell area is between a temperate continental and boreal climate, and so conditions vary from extreme cold in winter to extreme heat in summer. The record low temperature for WL is -47.8°C (1966 February) and the record high temperature is 37.5°C (1995 June). Thirty two years of records show that January is the coldest month and July is the warmest, with monthly mean temperatures of 16.6°C and 19.3°C, respectively (see Table 3) [A-3].

Table 3: Monthly Mean Temperatures (°C) at Whiteshell Laboratories (1981 - 2010)

January	February	March	April	May	June
-16.6	-13.2	-5.7	3.9	11.2	16.4
July	**August**	**September**	**October**	**November**	**December**
19.3	18.2	12.3	5.1	-4.5	-13.1

The average annual precipitation is 578 mm, and most of this occurs as showers in the summer season. The greatest recorded 24 hour rainfall at WL was 168 mm (1973 June).

Winter snowfall averages 113 cm at WL [A-3]. The greatest 24 hour snowfall on record is 48.0 cm (1997 April). Snow on the ground is usually continuous from early November to mid-April, and the depth reaches a peak of about 45 cm in February or March.

The Winnipeg River system usually freezes up in early December. Spring break up and clearing of ice from the river occurs in April.

The wind direction frequency has a double peak (Figure 3), one in the north northwest and one in the south southeast direction [A-4]. These winds are approximately parallel to the Winnipeg River valley at this location. The average wind speed is 9.3 km/h, considerably less than the long term average of 18.6 km/h at Winnipeg. This difference can be largely attributed to the measurements of wind speed 10 m above ground at Winnipeg airport, and 6 m above ground at WL; there is also the effect of the boreal forest at WL compared to the grassland around Winnipeg and the pavement at Winnipeg airport. Spring is generally the windiest season with an average wind speed of 10.1 km/h.

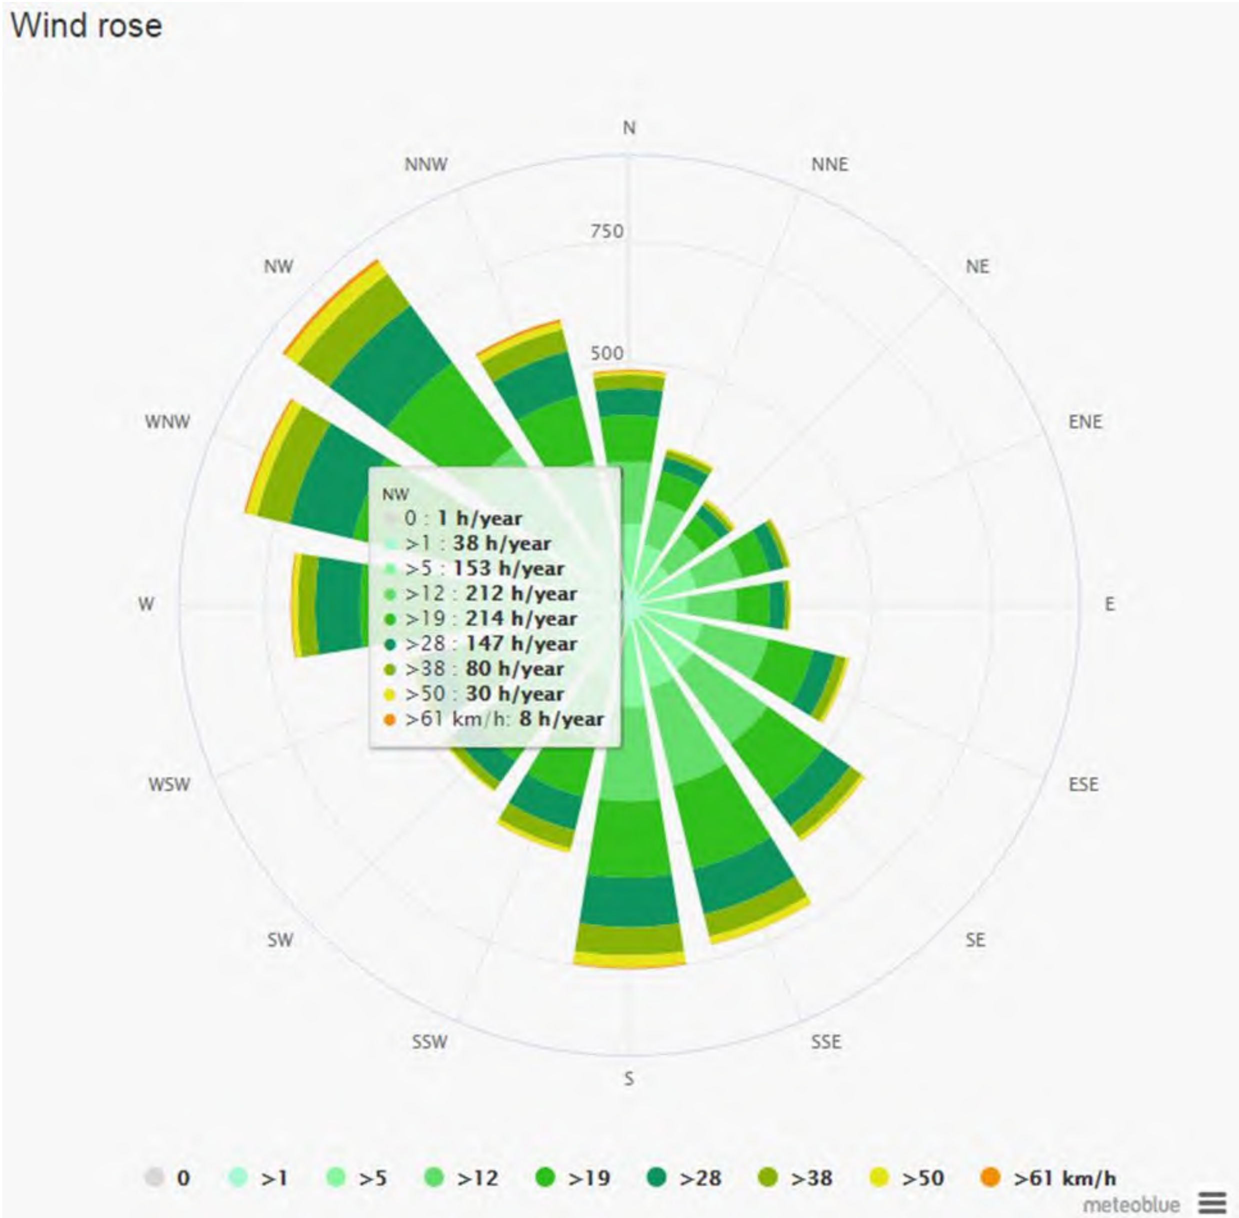

Figure 3: Wind Direction Frequency Distribution at WL

Thunderstorm activity reaches a peak in summer and significant hail has occurred twice in the last 20 years. Although tornadoes are relatively rare in the boreal forest, they have caused extensive damage to southern Manitoba communities on occasion. The most severe tornado damage occurred in 1978 when at least two tornadoes passed through southern Manitoba near WL, and another in 2006. Environment Canada statistics indicate that there were an average of 9.6 tornado strikes per year in Manitoba. Although the tornado frequency is highest in the southwest corner, tornadoes do appear in eastern portions as well.

Distribution of Population

The area surrounding WL is sparsely populated. The nearest population centres are Lac du Bonnet (population approximately 2800, located 8.6 km north), Pinawa (population approximately 1500, located 13.4 km west-southwest), Awanipark (population less than 100, located 3.5 km south of the main campus), River Hills (population less than 100, located 11.8 km south) and Seven Sisters (population less than 100, located 8.9 km south-southeast).

Notice of Violation (Corporation)

Date of notice: October 13, 2023
AMP number: 2023-AMP-04

Violation committed by:	**Amount of penalty:**
Canadian Nuclear Laboratories Ltd.	**$ 14,860**

Violation

Failure to comply with a condition of a licence in violation of 48(c) of the *Nuclear Safety and Control Act.*

Specifically, Canadian Nuclear Laboratories Ltd.'s Nuclear Research and Test Establishment Decommissioning Licence, NTREDL-W5-8.00/2024, condition 10.2 states that: *"The licensee shall implement and maintain a fire protection program."* Section 10.2 of the associated the Licence Condition Handbook NRTEDL-LCH-08.00/2024, provides criteria used to verify that licence condition 10.2 is being met, and provides amongst other criteria, that Canadian Nuclear Laboratories Ltd. comply with CSA 393:13, *Fire protection for facilities that process, handle, or store nuclear substances.*

Relevant facts

I, Kavita Murthy, Director General of the Nuclear Cycle and Facilities and designated officer authorized by the Canadian Nuclear Safety Commission (CNSC) to issue notices of violations, believe on reasonable grounds that Canadian Nuclear Laboratories Ltd. committed the above violation. The facts relevant to the violation and the penalty calculation are as follows:

1 Canadian Nuclear Laboratories Ltd., located at 286 Plant Road Chalk River, Ontario, holds a CNSC issued licence (NTREDL-W5-8.00/2024) to operate and decommission the Whiteshell Laboratories located in Pinawa, Manitoba.

2 Condition 10.2 states that: *"The licensee shall implement and maintain a fire protection program."* Section 10.2 of the associated the Licence Condition Handbook NRTEDL-LCH-08.00/2024, provides criteria used to verify that licence condition 10.2 is being met, and provides amongst other criteria, that Canadian Nuclear Laboratories Ltd. comply with CSA 393:13, *Fire protection for facilities that process, handle, or store nuclear substances*.

   a. Clause 11.5.5.2 of CSA 393:13 states that *"All fire response team members will receive firefighter training to a level response commiserate with the facilities hazards as* *determined by the needs analysis, as well as training in site design, including nuclear facility layout, major systems, and nuclear safety features, at levels appropriate for their specific response roles."*

b. Clause 11.5.8.3 of CSA 393:13 states that *"All personal protective clothing and equipment shall be maintained in a state of readiness at all times."*

c. Clause 10.11.1 of CSA 393:13 outlines how fire protective equipment is to be inspected, tested, maintained, and operated.

3 On April 27, 2023, Canadian Nuclear Laboratories Ltd. reported, in accordance with REGDOC-3.1.2, that Whiteshell Laboratories lacked properly trained and equipped fire response staff, and that this had a direct impact on the ability to maintain minimum complement for the fire brigade at the Whiteshell Laboratories site. Additional deficiencies with the training and equipment of firefighters, as well as the maintenance of fire protective equipment were subsequently identified.

a. Canadian Nuclear Laboratories Ltd. conducted an assessment of thirty-eight (38) of a total forty-eight (48) shift firefighters which determined that only twenty (20) of these thirty-eight (38) firefighters were adequately qualified.

b. Canadian Nuclear Laboratories Ltd. identified bunker gear that were missing pieces or expired, and deficiencies with self contained breathing apparatuses.

c. For some building fire protection equipment (e.g., fire extinguishers, detectors, and sprinklers), the required inspection testing and maintenance could not be confirmed by Canadian Nuclear Laboratories Ltd.

4 On April 30, 2023, Whiteshell Laboratories received spare equipment from Chalk River Laboratories.

5 On May 1, 2023, Canadian Nuclear Laboratories Ltd. sent a rotation of four Chalk River Laboratories firefighters to Whiteshell Laboratories to supplement minimum complement and assume response duties to better enable Whiteshell Laboratories shift staff to continue further assessments and training.

6 On May 4, 2023, Canadian Nuclear Laboratories Ltd. determined that Incident Commander training was incomplete for eight (8) Whiteshell Laboratories Emergency Services Organization staff. Chalk River Laboratories firefighters that were complementing the shifts had the required training but had not been assigned the Incident Commander role.

7 On May 5, 2023, and May 12, 2023, Canadian Nuclear Laboratories Ltd. conducted training sessions to qualify the necessary number of personnel to perform the role of Incident Commander.

8 On May 8, 2023, CNSC staff held a focused technical meeting (virtually) with Canadian Nuclear Laboratories Ltd. to discuss the preliminary event report, Canadian Nuclear Laboratories Ltd.'s immediate measures, any impacts on Chalk River Laboratories' fire response capabilities as a result of providing support to Whiteshell Laboratories, the next steps and timelines for action completions. This meeting focused on fire response and fire response equipment and did not include any discussion on deficiencies in fire protective equipment (as this was unknown at the time).

9 On May 15, 2023, a CNSC Designated Officer issued a request under subsection 12(2) of the *General Nuclear Safety and Control Regulations* for Canadian Nuclear Laboratories Ltd. to take specific actions to identify and address the cause of the programmatic failure of the fire protection program at Whiteshell Laboratories.

10 On May 19, 2023, Canadian Nuclear Laboratories Ltd. provided a detailed event report. The detailed event report identified deficiencies with facility fire protective systems. This was inconsistent with statements in the preliminary event report that these fire protective systems *"…have been verified through a records check to be functioning correctly or are up-to-date."*

11 On May 30, 2023, CNSC staff conducted a visit to the Whiteshell Laboratories site. During the site visit:

a. Canadian Nuclear Laboratories Ltd. stated that annual servicing and hydrostatic testing of fire extinguishers were not performed. As a result, Canadian Nuclear Laboratories Ltd. replaced all fire extinguishers on site. This was confirmed by CNSC staff during the site walkdown.

b. Canadian Nuclear Laboratories Ltd. stated that the fire pumps that supply the water for the fire hydrants did not meet the National Fire Protection Association (NFPA) requirements. Also, seven (7) fire hydrants were out of service. CNSC staff observed that Canadian Nuclear Laboratories Ltd. had pre-deployed 4" Hi Volume fire hoses from operable hydrants to non-functional ones as a compensatory measure.

c. A number of emergency lights were out of service, as they were not tested as per the NFPA standards. CNSC staff observed that signs were posted indicating this non-compliance and flashlights were on hand for staff to use upon entry.

d. The fixed suppression system for the hot cell facility was also out of service.

e. CNSC staff confirmed the implementation of newly acquired bunker gear and associated personal protective equipment for the fire fighters.

f. In order to demonstrate the qualification of the fire fighters at Whiteshell Laboratories, Canadian Nuclear Laboratories Ltd. was requested to provide training records. Upon review of the records, CNSC observed that several of these records were not dated, had incorrect dates, or had incomplete information. Following the site visit Canadian Nuclear Laboratories Ltd. provided training records with these corrections.

12 On August 21, 2023, while preparing for a CNSC inspection, Canadian Nuclear Laboratories Ltd. determined it did not have records of a pre-employment medical assessment for ten (10) firefighters hired between July 17, 2023 and August 21, 2023.

13 On August 22, 2023, CNSC staff conducted a reactive inspection of Whiteshell Laboratories.

14 On August 23, 2023 while preparing to submit all firefighter annual medical assessment records as requested by CNSC staff during the inspection, it was discovered that eight (8) annual medical assessments for existing Whiteshell Laboratories firefighters had lapsed during the months of July and August.

15 On August 24, CNSC staff issued a preliminary facts and findings report for the reactive inspection of Whiteshell Laboratories. In addition to the deficiencies with firefighter medical assessments, this report identified inappropriate storage of combustibles, incorrect colour-coding of a fire hydrant, improper maintenance and identification of fire separations, and out-of-date pre-fire plans.

Whereas it is understood that the complete implementation of the corrective actions require time, the non-compliances identified in August 2023 indicate that Canadian Nuclear Laboratories Ltd.'s oversight of its fire safety program continues to be deficient and Canadian Nuclear Laboratories Ltd. is not complying with the requirements in its management system. Based on my review of this matter, I am of the opinion that an administrative monetary penalty will deter recurrence of the above violation and promote future compliance with CNSC regulatory requirements. In consideration of the seven factors in section 5 of the *Administrative Monetary Penalties Regulations (Canadian Nuclear Safety Commission),* the amount of the penalty was determined based on the following relevant facts:

1. Compliance history: Assessed score = 1

Deficiencies in the fire safety program, including the issue of training and qualifying staff, and maintaining complete records was identified in April 2023. For staff hired as recently as July 2023, likely as a result of the previously identified deficiencies, it is reasonable to expect that Canadian Nuclear Laboratories Ltd. would have ensured that all records were up to date and current. It is also expected that annual qualifications of existing firefighters would not be permitted to lapse given the current focus on these requirements.

2. Intention or negligence: Assessed score = 2

Negligence was demonstrated in Canadian Nuclear Laboratories Ltd.'s failure to adequately maintain records of these qualifications. At this point there is no information which would indicate an explicit intention to commit this violation.

3. Actual or potential harm: Assessed score = 1

This non-compliance with implementation of a fire protection program could have had a potential impact on the health and safety of persons or on the environment as Canadian Nuclear Laboratories Ltd. was not able to sustain an effective fire response capability at Whiteshell Laboratories. Regulatory dose and release limits are expected to be met for postulated fire scenarios without crediting manual suppression activities. However, manual intervention is credited to meet the goals of CSA 393:13 to mitigate, recover and terminate a fire event, thus minimizing risk to persons, the environment, and conservation of radioactive material. Medical examination records indicate fitness to perform duty and not having these records could have resulted in an unfit person being responsible for fire safety.

4. Competitive or economic benefit: Assessed score = 0

There was no competitive or economic benefit to Canadian Nuclear Laboratories Ltd. as a result of its non-compliance.

5. Efforts to mitigate or reverse effects: Assessed score = 0

Canadian Nuclear Laboratories has made reasonable effort to mitigate the effects of the non-compliance by arranging medical assessments for the Whiteshell Laboratories firefighters that were lacking them.

6. Assistance to Commission: Assessed score = 0

Canadian Nuclear Laboratories Ltd. provided all reasonable assistance to the CNSC throughout this issue.

7. Attention of Commission: Assessed score = 0

Canadian Nuclear Laboratories Ltd. identified the initial non-compliance and initiated mitigating measures prior to involvement of the CNSC. However, the ongoing non-compliances regarding medical assessments of firefighters were only identified as a result of a CNSC inspection.

Penalty calculation:

(See *Administrative Monetary Penalties Regulations (Canadian Nuclear Safety Commission)* SOR/2013-139)

(a) **Category of violation**

Category A ☐ Category B ☐ **Category C** ☒

	[total] =	**13,860**
	+ $ 1000 [minimum for the category] =	**14860**

[(1)]29 being the maximum value of regulatory significance

To request a review

As a person subject to an administrative monetary penalty, you have the right to request a review of the amount of the penalty or the facts of the violation, or both. Your request must be made in writing indicating the reasons why you are requesting a review and providing supporting information.

If you choose to request a review, you must do so in writing by November 15, 2023 to:

Canadian Nuclear Safety Commission
c/o Denis Saumure
Commission Registrar
P.O. Box 1046, Station B
Ottawa, ON K1P 5S9

Fax: (613) 995-5086
Telephone: (613) 282-9537
Email: registry.greffe@ccsn-ccsn.gc.ca

Payment

You may pay this administrative monetary penalty by sending a cheque to:

> Receiver General for Canada
> c/o Canadian Nuclear Safety Commission
> Finance Division
> P.O. Box 1046, Station B
> Ottawa, ON K1P 5S9

For other payment methods and further instructions, please refer to the attached notice of payment due.

Should you neither pay the penalty nor exercise your right to a review, you will be considered as having committed the violation and will be liable to the penalty set out herein.

e-Doc 5756806 (WORD)
e-Doc 5961001 (PDF)

Summary

This CMD presents information about the following matter of regulatory interest with respect to Canadian Nuclear Laboratories:

- Canadian Nuclear Laboratories application for the Nuclear Research and Test Establishment Decommissioning Licence for the Whiteshell Laboratories

CNSC staff recommend the Commission take the following actions:

- Renew the Whiteshell Laboratories licence from January 1, 2020 to December 31, 2029.
- Delegate authority as set out in section 4.7 of this CMD.

The following items are attached:

- The proposed licence, NRTEDL-W5-08.06/2029
- The draft Licence Conditions Handbook
- The current licence, NRTEDL-W5-08.05/2019
- The Environmental Protection Review report

Résumé

Le présent CMD présente de l’information sur un ensemble de questions d’ordre réglementaire concernant les Laboratoires Nucléaires Canadiens (LNC) :

- La demande de Laboratoires Nucléaires Canadiens visant à renouveler le permis de déclassement de l’établissement de recherche et d’essais nucléaires pour les Laboratoires de Whiteshell

La Commission pourrait considérer prendre les mesures suivantes :

- Renouveler le permis pour les Laboratoires de Whiteshell du 1er janvier 2020 au 31 décembre 2029.
- Accepter la délégation des pouvoirs telle qu’elle est établie à la section 4.7 du présent CMD

Les pièces suivantes sont jointes :

- Le permis proposé, NRTEDL-W5-08.06/2029
- L’ébauche du Manuel des conditions de permis
- Le permis actuel, NRTEDL-W5-08.05/2019
- Le Rapport d’examen de la protection de l’environnement

Signed/signé le

EXECUTIVE SUMMARY

The current Whiteshell Laboratories (WL) licence, NRTEDL-W5-08.05/2019, is valid until December 31, 2019. Canadian Nuclear Laboratories (CNL) has applied to renew the licence for a period of 10 years, until December 31, 2029.

The purpose of this Commission Member Document (CMD) is to provide the results of CNSC staff's assessment of the CNL application, including conclusions and recommendations to inform the Commission decision on the licence renewal. In their assessment of the application, CNSC staff reviewed all 14 safety and control areas (SCAs) and took the licensee's past performance into consideration.

Based on this assessment, CNSC staff conclude that CNL has made and will continue to make adequate provisions for the protection of the environment and the health and safety of persons, and that there will be no adverse effects on the health and safety of persons or the environment as a result of the decommissioning of WL.

This conclusion is supported by CNSC staff's Environmental Protection Review (EPR) report for the WL site. The EPR report is attached to this CMD.

The matter before the Commission in this CMD **does not include in situ decommissioning (ISD)** of the WR-1 reactor. ISD of WR-1 is currently undergoing an environmental assessment under the Canadian Environmental Assessment Act (CEAA), 2012. This will be presented to the Commission at a separate public hearing. ISD of WR-1 is out of scope of this licence consideration.

The public, Indigenous groups and other stakeholders were invited to participate in the regulatory licence renewal process. To enable their participation, up to $50,000 was made available through the CNSC Participant Funding Program (PFP).

This CMD has two parts. Part one presents CNSC staff's review and assessment of CNL's licence application and a summary of CNL's performance in the operation of WL since 2008. Part two presents CNSC staff's proposed licence and licence conditions handbook (LCH).

Referenced documents in this CMD are available to the public upon request.

PART ONE

This Commission Member Document (CMD) is presented in two parts.

Part One includes:

[1] An overview of the matter being presented;

[2] Overall conclusions and overall recommendations;

[3] General discussion pertaining to the safety and control areas (SCAs) that are relevant to this submission;

[4] Discussion about other matters of regulatory interest; and

[5] Addenda material that complements items 1 through 4.

Part Two provides all available information pertaining directly to the current and proposed licence.

1. OVERVIEW

1.1 Background

CNL is authorized to decommission the Whiteshell Laboratories (WL), comprising both nuclear and non-nuclear facilities under a CNSC issued Nuclear Research and Test Establishment Decommissioning Licence NRTEDL-08.05/2019[1].

The WL site is located approximately 100 km northeast of Winnipeg near the town of Pinawa, Manitoba. Figure 1 illustrates the WL site location in relation to surrounding communities. The WL site encompasses an area of 4,375 hectares and includes facilities such as the Whiteshell Reactor (WR-1), the shielded facilities, the radioactive waste management facilities and structures, the concrete canister storage area and various research laboratories and support buildings. The WL site was operated by Atomic Energy of Canada Limited (AECL) as a nuclear research facility for approximately 40 years. During this time WR-1 operated for a period of 20 years under an operating licence issued by the Atomic Energy Control Board. In 2002 AECL applied for and was granted a decommissioning licence. In October 2014, the Commission approved the transfer of the licence from AECL to CNL. CNL remains the current licensee.

Figure 1: Location of WL (source Google)

Since 2002, significant decommissioning progress has been made with activities including: demolition of redundant buildings, phased decommissioning of the main research building, severing or redirecting services where necessary, construction of new enabling facilities, repurposing of buildings to support decommissioning and initiating subsurface investigations into the conditions of various containment structures inside the waste management area. An aerial view the WL site can be seen in figure 2.

Figure 2: Aerial view of WL in 2018 (Source: CNL)

Licensing History

The decommissioning licence was first issued by the Commission in November 2002 for a six-year period. This was followed by the Commission renewing the licence in December 2008 for a ten-year period. Licence amendments were approved by the Commission in 2010 and 2012 to reflect requested changes in report submission dates, reference documents and action levels. In October 2014, the Commission approved the transfer of all AECL licences, including the Whiteshell licence, to the Canadian Nuclear Laboratories. In January 2016, the Commission approved an administrative licence amendment that revised the licence to the standardized format with an associated LCH. In March 2018, the WL licence was renewed by the Commission for a 1-year term until December 2019. Details of the 2018 one year licence renewal are provided below.

CNL's 2018 Licensing Request

In September 2017, CNL submitted an application to renew the WL decommissioning licence for a 10-year period. With this application, CNL submitted a proposal for the in-situ decommissioning (ISD) of the WR-1 reactor. CNL's proposal to conduct ISD of the WR-1 reactor was a change from the original decommissioning approach of dismantlement and triggered the requirement for an environmental assessment (EA) under the Canadian Environmental Assessment Act (CEAA), 2012 [2].

As part of the CEAA 2012 process, a draft environmental impact statement (EIS) for the proposed ISD of the WR-1 reactor was submitted by CNL and made available to the public for comment. CNL determined that additional time was needed to address the large number of comments raised by the public, Indigenous groups, Métis communities and regulators in relation to the draft EIS that was developed in support of the EA. Note that this EA, and the associated licensing request for the ISD of WR-1, is not part of the current licence application.

Consequently, on March 13, 2018, CNL requested that the Commission renew their existing licence for a one-year period ending December 31, 2019, under the same terms and conditions as the previous licence. This short-term renewal request was granted by the Commission on August 1, 2018 with no changes to the terms, conditions or licensed activities.

The current decommissioning licence includes a decommissioning strategy for the WL site that was previously accepted by the Commission in 2002 and does not authorize the ISD of WR-1. The proposed ISD of WR-1 is out of scope of this licence application and safety case. CNL must seek separate Commission authorization for the newly proposed decommissioning strategy for WR-1.

Current Relicensing Request

CNL's current decommissioning licence NRTEDL-W5-8.05/2019 remains valid until December 31, 2019. On November 15, 2018 CNL requested a 10 year renewal of the WL licence in order to continue on-going decommissioning activities and provide adequate time to complete the safety case for the ISD of the WR-1 reactor. The matter before the Commission in this CMD does not include ISD of WR-1. The proposed ISD of WR-1 is out of scope of this licence consideration.

Reporting on Licensee Performance

CNSC staff conduct ongoing regulatory oversight and compliance verification activities at the WL site. Regular updates on licensee performance and project status have and will continue to be brought to the Commissions' attention via regulatory oversight reports (RORs) at public meetings. In relation to interim reporting, CNSC staff have kept the Commission informed of the status of decommissioning activities in 2012 (interim status report) [3], 2014 (annual performance report) [4], 2016 (status report) [5], and in 2018 (progress update) [6]. This CMD builds on the information provided in those documents. CNSC staff will next update the Commission on the status of CNL's performance at the WL site in a ROR to be presented to the Commission at a public hearing in November 2019. This ROR will discuss CNL's performance at all its licensed facilities.

1.2 Highlights

The purpose of this CMD is to provide the Commission with the results of CNSC staff's assessment on CNL's application for renewing the WL site licence. This CMD provides CNSC staff's conclusions and recommendations to inform the

Commission decision on the licence application. CNSC staff's assessment of the application takes into consideration the results of CNSC staff's compliance verification activities, CNL's operational performance history and information submitted by CNL in support of the application.

CNSC staff have prepared a proposed licence that uses the standard format and incorporates the standard licence conditions applicable to the WL site.

CNSC staff typically present supporting information for the previous licence period in submissions regarding licence applications. In this case, since the previous licence period was only 12 months, CNSC staff have provided supporting information dating back to 2009 for more meaningful trending for the Commission.

This CMD provides a summary of CNSC staff's review of all safety and control areas (SCAs).

1.3 Overall Conclusions

CNSC staff have concluded the following with respect to paragraphs 24(4)(a) and (b) of the *Nuclear Safety and Control Act* (NSCA) [7], in that the licensee:

1. Is qualified to carry out the activity authorized by the licence.
2. Will, in carrying out that activity, make adequate provision for the protection of the environment, the health and safety of persons and the maintenance of national security and measures required to implement international obligations to which Canada has agreed.

1.4 Overall Recommendations

CNSC staff recommend the following:

1. accept CNSC staff's conclusions and exercise the Commission's authority under the NSCA [7] to renew the CNL licence of the Whiteshell Laboratories from January 1, 2020 to December 31, 2029
2. authorize the delegation of authority as set out in subsection 4.7 of this CMD

2. MATTERS FOR CONSIDERATION

2.1 Environmental Protection Review Report

CNSC staff have determined that this licence application request is not on the designated project list under the *Canadian Environmental Assessment Act, 2012* and therefore does not trigger an EA under CEAA 2012. Addendum D of this CMD provides an Environmental Protection Review Report under the NSCA and its Regulations. The EPR is a science-based environmental technical assessment by CNSC staff of CNL's application for renewal of the decommissioning licence for the WL site. CNSC staff conclude that the licensee has, and will, continue to make adequate provision for the protection of the environment and health of persons.

2.2 Relevant Safety and Control Areas (SCAs)

The functional areas of any licensed facility or activity consist of a standard set of safety and control areas (SCAs). Each SCA is comprised of "specific areas" of regulatory interest; however, the applicable specific areas associated with each SCA vary between facility types. See Addendum C, "Safety and Control Framework", for further information about SCAs.

In the following table, the rating level for each SCA relevant to the WL site is indicated. The rating indicates the overall compliance with regulatory requirements (refer to Addendum A, "Rating Levels").

Functional Area	Safety and Control Area	Rating Level[1]
Management	Management System	SA
	Human Performance Management	SA
	Operating Performance	SA
Facility and Equipment	Safety Analysis	SA
	Physical Design	SA
	Fitness for Service	SA
Core Control Processes	Radiation Protection	SA
	Conventional Health and Safety	SA
	Environmental Protection	SA
	Emergency Management and Fire Protection	SA
	Waste Management	SA
	Security	BE
	Safeguards and Non-Proliferation	SA
	Packaging and Transport	SA

Each SCA is discussed in detail in Section 3, *General Assessment of SCAs*.

[1] FS = Fully Satisfactory, SA = Satisfactory, and BE = Below Expectations

2.3 Other Matters of Regulatory Interest

The following table identifies other matters that are relevant to this CMD.

OTHER MATTERS OF REGULATORY INTEREST	
Area	**Relevant to this CMD?**
Aboriginal Consultation	Yes
Other Consultation	Yes
Cost Recovery	Yes
Financial Guarantees	Yes
Improvement Plans and Significant Future Activities	Yes
Licensee's Public Information Program	Yes
Nuclear Liability Insurance	Yes

The relevant "other matters" of regulatory interest are discussed in section 4.

2.4 Regulatory and Technical Basis

The regulatory and technical basis for the matters discussed in this CMD are provided in Addendum B to this document.

3. GENERAL ASSESSMENT OF SCAS

The relevant specific areas that comprise the SCAs for the WL site are identified in Addendum C, section C.2.

3.1 Management System

The Management System SCA covers the framework that establishes the processes and programs required to ensure an organization achieves its safety objectives, continuously monitors its performance against these objectives, and fosters a healthy safety culture.

The specific areas that comprise this SCA at the WL site include:

- Management system
- Organization
- Performance assessment, improvement and management review
- Operating experience (OPEX) - (no significant observations to report)
- Change management - (no significant observations to report)
- Configuration management - (no significant observations to report)
- Records management - (no significant observations to report)
- Management of contractors - (no significant observations to report)

3.1.1 Trends

The following table indicates the overall rating trends for the Management System over the current licensing period:

TRENDS FOR MANAGEMENT SYSTEM				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments				
The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. The licensee has maintained a management system in accordance with CNSC requirements over this licensing period. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories.				

3.1.2 Discussion

In order to meet CNSC requirements for this specific area, the licensee must implement and maintain the management system requirements set out in Canada Standards Association (CSA) standard N286-12, *Management system requirements for nuclear facilities*. The management system brings together, in a planned and integrated manner, the processes necessary to satisfy the requirements that must be met to safely carry out the licensed activity. During the current licensing period, CNL has implemented and maintained a management system at the WL site.

CNSC staff performed a desktop review of CNL's implementation of their management system program at the WL site, and conclude that the program meets all applicable regulatory requirements and CNSC expectations. In addition, CNSC staff have reviewed CNL's updates to the WL Decommissioning Quality Assurance Plan. In each update to the document, CNSC staff comments were resolved satisfactorily by CNL. All inspection findings from the previous licensing period have been closed to CNSC staff's satisfaction by the licensee.

3.1.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.1.3.1 Past Performance

Management System

During the licensing period under review, CNL has provided CNSC staff with updates to their management system. The major update in this time period was the adoption of the CSA N286-12 standard requirements. This update applied to all CNL sites, as CNL made the decision to integrate management system requirements into one CNL-wide program.

CNL sites, such as WL, have developed Quality Assurance Plans to describe site-specific aspects of the CNL management system and the site-specific functions, responsibilities and authorities. Other changes described in the management system updates submitted included reorganizing the company document structure and format and also changes in responsibilities. CNSC staff confirmed that the WL Decommissioning Quality Assurance Plan incorporates all the requirements necessary to meet the CSA N286-12 standard.

CNSC staff verify elements of CNL's management system during all inspections conducted on the site. This is done through CNSC staff review of CNL's records, verification of the licensee's implementation of document control, training program and general maintenance of the programs relevant to the safe and secure conduct of the licensed activities.

Overall, the WL management system continues to meet CNSC requirements.

Organization

WL is owned and was historically operated by AECL, a federal crown corporation. In 2013 the Government of Canada announced its decision to engage a private-sector contractor to manage operations at WL under a government owned-contractor operated (Go-Co) business model [8]. CNL was established as a wholly-owned subsidiary of AECL in 2014. AECL applied to the Canadian Nuclear Safety Commission, under subsection 24(2) of the Nuclear Safety and Control Act, to transfer five licences to CNL. Based on its consideration of the matter, following a hearing held on October 22, 2014 the Commission concluded that CNL met the conditions of subsection 24(4) of the NSCA and approved the transfer of the licences. CNL then assumed responsibility for the day-to-day operations of WL.

In 2015, the management of CNL was contracted to Canadian National Energy Alliance (CNEA), completing the transition to the Go-Co model [9].

Under the Go-Co arrangement, AECL retains ownership of all the assets of WL while CNL remains the licensee with a CNEA-selected executive team. AECL's role is now focused on the oversight of the Go-Co contract to ensure CNL's performance meets the government objectives for the contract.

As part of the Go-Co transformation management, CNL created new:

- corporate profile, mission, vision and values,
- governance model/Board of Directors/Executive Team,
- organization structure, and
- roles, responsibilities, accountabilities and authorities.

CNSC staff confirmed that CNL has appropriately documented the changes to the CNL organization. CNSC staff have no concerns regarding the changes to the CNL organization and have confirmed CNL's organization is suitable to ensure continued safe operation and compliance with regulatory requirements.

Performance assessment, improvement and management review

CSA N286-12 requires that problems are identified, controlled, documented and resolved by the nuclear facility operator. CNL documents issues and opportunities for improvement through a problem identification and resolution mechanism referred to as ImpAct.

CNSC staff verify ImpAct initiation, routing, trending, approval, and effectiveness by performing routine desktop reviews of ImpAct reports. Field verification of the completion of followup actions, where appropriate, are integrated into site inspection activities. As a result of these reviews CNSC staff conclude that CNL continues to meet CNSC regulatory requirements in this area.

3.1.3.2 Regulatory Focus

CNSC staff will verify the implementation of the revised WL Decommissioning Quality Assurance Manual during compliance activities.

CNSC staff will continue to monitor CNL's performance in this SCA through regulatory oversight activities including onsite inspections and desktop reviews of relevant program documentation to ensure WL continues to meet applicable regulatory documents, codes and standards for the upcoming proposed 10-year licence period.

3.1.3.3 Proposed Improvements

CNL has stated that they will implement the revised WL Decommissioning Quality Assurance Plan that was recently accepted by CNSC staff. CNL will also implement a continuous improvement program to ensure that the integrated management system enables effective and efficient management of the company.

3.1.4 Conclusion

There are no challenges with CNL's implementation of this SCA.

Based on CNSC staff's assessments of CNL's application, supporting documents, and correction of inspection findings, CNSC staff conclude the licensee continues to maintain an effective management system in accordance with regulatory requirements.

3.1.5 Recommendation

One licence condition is included in the proposed licence for this SCA. Licence condition 1.1 requires CNL to implement and maintain a management system. Compliance verification criteria for this licence condition are included in the draft LCH.

3.2 Human Performance Management

The Human Performance Management SCA covers activities that enable effective human performance through the development and implementation of processes that ensure a sufficient number of licensee personnel are in all relevant job areas and have the necessary knowledge, skills, procedures, and tools in place to safely carry out their duties

The specific areas that comprise this SCA at the WL site include:

- Human performance program
- Personnel training
- Fitness for duty

3.2.1 Trends

The following table indicates the overall rating trends for the Human Performance Management over the current licensing period:

TRENDS FOR HUMAN PERFORMANCE MANAGEMENT				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. The licensee has maintained a human performance management program in accordance with CNSC requirements over this licensing period. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories.				

3.2.2 Discussion

CNL is required to implement and maintain a human performance program in order to ensure a sufficient number of qualified workers are available in all relevant job areas, and they have the necessary knowledge, skills, procedures and tools in place to safely carry out their duties. Compliance inspections conducted by CNSC staff during the current licensing period included verifications of the training records of staff in safety-related positions and a general verification of the licensee's maintenance of a complement of competent and knowledgeable workforce. CNSC staff conclude that programs related to CNL's Human Performance Management activities at WL have met applicable regulatory requirements and CNSC expectations.

3.2.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.2.3.1 Past Performance

Human Performance Program

For the past few years, CNL has been transitioning to a new management system structure. As part of that work, they have been developing corporate-level program documents applicable to all activities at CNL sites.

The main elements of the corporate Performance Assurance Program at CNL are as follows:

- Operating Experience (OPEX) and Corrective Action Program (CAP),
- Assessment,
- Human Performance,
- Continual Improvement, and
- Performance Measures and Analysis.

The six elements of the Human Performance Program are operationalized through the application and use of:

- Event Free Day Reset,
- Event Free Tools,
- Observation and Coaching,
- Operational Decision-Making,
- Safety Culture Assessment, and
- Dynamic Learning Activities.

The suite of management system documents relevant to human performance include Procedures, Management Control Procedures (MCP), Operating Instructions, and other documents that will be used to manage and support human performance.

Though CNL is still in the process of updating its management system documents, a review of the top two governing documents for the Performance Assurance Program has been completed by CNSC staff. Staff comments will be communicated to CNL, and follow-up will be performed on CNL's response. CNSC staff comments represent opportunities for improvement, and do not raise any impediments for the renewal of the WL site licence.

Personnel Training

CNL is required by the *General Nuclear Safety and Control Regulations* to ensure there are a sufficient number of properly trained and qualified workers to safely conduct the licensed activities. REGDOC 2.2.2, *Personnel Training* provides additional requirements. CNL has incorporated the requirements of REGDOC 2.2.2 in to their corporate-wide training program.

Compliance inspections conducted by CNSC staff during the current licensing period included verifications of training records. These reviews showed that training records were maintained and that CNL employees were provided appropriate training.

Fitness for Duty

In 2017, CNL provided the CNSC with a gap analysis and implementation plan for REGDOC-2.2.4, *Fitness for Duty: Managing Worker Fatigue* (Fatigue), and in 2018, a gap analysis and implementation plan for REGDOC-2.2.4, *Fitness for Duty, Volume II: Managing Alcohol and Drug Use* (Alcohol and Drug), with the purpose of providing the measures by which CNL will meet the requirements of REGDOC-2.2.4.

For Vol I of the REGDOC (Fatigue), CNL has indicated that they have revised scheduling requirements to meet REGDOC-2.2.4.

For Vol II (Alcohol and Drug), CNL has proposed timelines of July 2019 for implementation of all program and testing requirements of this REGDOC except random testing. A date has yet to be determined for implementation of random testing. Licensees have requested that their implementation dates for this REGDOC be delayed to allow discussion of industry-proposed amendments regarding the use of oral fluid testing. CNSC staff have agreed to this delay and are assessing the industry-proposed amendments. Should the REGDOC be amended, the revised draft will be subject to Commission approval at a future date.

3.2.3.2 Regulatory Focus

CNSC staff will focus on monitoring the implementation of the requirements of REGDOC 2.2.4.

A few refinements to licensee program documentation has been identified by CNSC staff. Once responses to those recommendations have been made, CNSC staff will be able to determine appropriate compliance activities. As stated in section 3.2.3.1, CNSC staff comments do not raise any impediments for the renewal of the WL site licence.

3.2.3.3 Proposed Improvements

CNL plans to implement the requirements of REGDOC 2.2.4 volumes I and II.

CNSC staff will continue to monitor CNL's performance in this SCA through regulatory oversight activities including onsite inspections and reviews of relevant program documentation.

3.2.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

Based on CNSC staff assessments of CNL's application, supporting documents and past performance, CNSC staff conclude that CNL continues to implement and maintain an effective human performance program for WL in accordance with regulatory requirements.

3.2.5 Recommendation

Two licence conditions are included in the proposed licence for this SCA. Licence condition 2.1 requires CNL to implement and maintain a human performance program, and condition 2.2 requires CNL to implement and maintain a training program. Compliance verification criteria for the two licence conditions are included in the draft LCH.

3.3 Operating Performance

The Operating Performance SCA includes an overall review of the conduct of the licensed activities and the activities that enable effective performance.

The specific areas that comprise this SCA at the WL site include:

- Conduct of licensed activity
- Procedures
- Reporting and trending

3.3.1 Trends

The following table indicates the overall rating trends for the Operating Performance over the current licensing period:

TRENDS FOR OPERATING PERFORMANCE				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments				
The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. The licensee has maintained an operating program in accordance with CNSC requirements over this licensing period. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories.				

3.3.2 Discussion

CNL is required by the Class I Nuclear Facilities Regulations to ensure measures, policies, methods and procedures for safely operating and maintaining the nuclear facility are in place. Verification of the licensee's compliance with the requirements of this SCA are an integral part of all of CNSC's compliance activities ranging from desktop reviews of reports, documents and events to site inspections. CNSC staff confirm that CNL has implemented and maintains an effective Operating Program in order to ensure licensed activities are performed safely and in compliance with regulatory requirements. CNSC staff conclude that CNL's Operating Performance at the WL site met all applicable regulatory requirements and CNSC staff's expectations. CNSC staff are satisfied that licensed activities at the WL site are conducted in a safe manner.

3.3.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.3.3.1 Past Performance

Conduct of Licensed Activity

Nuclear facilities at the WL site are governed by CNL's Facility Authorization and facility-specific Conduct of Operations documents, which indicate the operational limits and conditions for the various facilities. Facilities in permanent safe shutdown state or undergoing active decommissioning are governed by storage-with-surveillance plans or decommissioning plans, respectively. These governing documents prescribe how each facility is operated and maintained to ensure nuclear safety and that the risk to the public remains low.

CNSC staff carried out many verification activities since 2009 on CNL's operations across the WL site and found that overall, all nuclear facilities at the WL site have been operating safely. As CNL transitions to its new management system structure, operating procedures and instructions are being revised to align to the new format.

In accordance with the current LCH, CNL continues to provide information regarding the operating performance of nuclear facilities at the WL site in annual reports submitted to CNSC staff. CNSC staff evaluate the information provided in these reports to ensure CNL remains in compliance with regulatory requirements.

Procedures

CNL's Management System consists of high level documentation supported by lower level procedures. CNL maintains a comprehensive suite of procedures across all programs and facilities at the WL site. Since 2009, CNL has continually updated the facility-specific procedures as needed to support ongoing process improvements at the WL site.

CNSC staff review procedure level documents as part of ongoing compliance verification activities. Based on these reviews, CNSC staff conclude that the changes made to CNL's procedures were carried out in accordance with CNL's change control process and there were no significant changes to operating documentation that could have affected the safe operation of the facilities at the WL site.

Reporting and Trending

Detailed requirements for reporting unplanned situations or events at the WL site to the CNSC are included in the WL LCH. CNL has complied with the requirements for submission of these reports since 2009.

Events reported to the CNSC by CNL are presented in table 1.

Table 1: Reportable Events for the WL Site (2009-2018)

Year	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
Total	6	24	10	5	4	5	0	5	4	0

CNSC staff review all reported events to identify if there are any regulatory concerns and report significant events to the Commission at public meetings of the Commission. There were no event initial reports (EIR) related to the WL site presented to the Commission since 2009.

CNL also submits annual reports on compliance monitoring and operating performance of facilities at the WL site, as required by licence condition 5.1 of the current licence. CNSC staff reviewed these reports and no significant regulatory issues were identified during the review.

3.3.3.2 Regulatory Focus

CNSC staff continue to monitor CNL's performance in this SCA through regulatory oversight activities including onsite inspections and desktop reviews of relevant program documentation.

CNSC staff will focus compliance verification activities on operational activities at the WL site. As the licensee's activities on the WL site continues its steady shift towards decommissioning and demolition activities and the transport of waste offsite, CNSC staff's compliance activities will focus on verification of the safe conduct of these activities.

3.3.3.3 Proposed Improvements

The regulatory document REGDOC-3.1.2, *"Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills* is referenced in the proposed WL LCH. This document sets out requirements and guidance for reports and notifications that licensees must submit to the CNSC. This REGDOC outlines the types of reports that are required to be submitted to the CNSC, and the applicable timeframe for reporting.

3.3.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

Based on CNSC staff assessments of CNL's application, supporting documents and past performance, CNSC staff conclude that CNL continues to implement and maintain an effective operating program for the WL site in accordance with regulatory requirements.

3.3.5 Recommendation

Two licence conditions are included in the proposed licence for this SCA. Licence condition 3.1 requires CNL to implement and maintain an operating program, which includes a set of operating limits. Licence condition 3.2 requires CNL to implement and maintain a program for reporting to the Commission or a person authorized by the Commission. The recommended delegation of authority for licence condition 3.2 is detailed in section 4.7 of this CMD. Compliance verification criteria for both licence conditions are included in the draft LCH.

3.4 Safety Analysis

The Safety Analysis SCA covers maintenance of the safety analysis that supports the overall safety case for the facility. Safety analysis is a systematic evaluation of the potential hazards associated with the conduct of a proposed activity or facility and considers the effectiveness of preventative measures and strategies in reducing the effects of such hazards.

The specific areas that comprise this SCA at the WL site includes:

- Deterministic safety analysis
- Hazard analysis
- Criticality safety

3.4.1 Trends

The following table indicates the overall rating trends for the Safety Analysis over the current licensing period:

TRENDS FOR SAFETY ANALYSIS				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. The licensee has over this licensing period maintained a safety analysis program in accordance with CNSC requirements. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories.				

3.4.2 Discussion

CNL is required by the Class I Nuclear Facilities Regulations to prepare formal Safety Analysis Reports (SAR) for Class I nuclear facilities. CNL has implemented a safety analysis program that ensures systematic evaluation of the potential hazards associated with the conduct of a proposed activity or facility and to consider the effectiveness of preventative measures and strategies in reducing the effects of such hazards.

CNSC staff note that the scope, content and detail of the safety analysis for the WL site is not the same as for an operating nuclear power reactor. There is no operating reactor on site and there are no activities related to fissionable material on this site, other than storage of low-risk irradiated fuel. The CNSC applies a graded approach to safety analysis, commensurate with the level of risk of the facility.

CNSC staff conducted desktop reviews of CNL's safety analysis documentation and conclude that CNL's Safety Analysis at the WL site met applicable regulatory requirements and CNSC expectations.

3.4.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.4.3.1 Past Performance

Deterministic Safety Analysis

CNL maintains SARs for all Class I nuclear facilities at the WL site.

CNL updates the SARs over time as operational requirements change. Updates are carried out in accordance with the requirements of the licensing basis. When CNL updates the SARs, they are provided to CNSC staff for review. CNSC staff monitors changes in the SAR to ensure continued compliance with the licensing basis.

Criticality Safety

There remain no activities associated with fissionable material at the WL site, other than storage of used fuel in the Concrete Canister Storage Facility (CCSF) and the waste management area's standpipes, which CNL and CNSC staff consider to be low risk. CNSC staff continue to monitor any changes to the risk that result from activities to remediate the standpipes and CCSF.

CNL is required to implement and maintain a nuclear criticality safety program compliant with RD-327, *Nuclear Criticality Safety*. The nuclear criticality safety program at CNL is a corporate-wide program, and is used at both the WL and CRL sites. CNL has developed a suite of nuclear criticality safety program documents acceptable to CNSC staff. CNL maintains and updates its criticality safety documents (CSD). CNSC staff reviewed changes to the CSDs as they were updated by CNL. Based on the reviews, CNSC staff concluded that CNL continues to make changes and updates to CSDs that are consistent with CNSC regulatory requirements.

Hazard Analysis

CNL carried out code compliance reviews and Fire Hazard Analysis for the WL site facilities in accordance with CSA-N393, *Fire protection for facilities that process, handle, or store nuclear substances*. These reviews are discussed in section 3.5.3, Fire Protection Program, of this CMD.

3.4.3.2 Regulatory Focus

CNSC staff continue to monitor CNL's performance in this SCA through regulatory oversight activities including onsite inspections and desktop reviews of relevant program documentation, new and/or revised safety analyses and criticality safety documents.

3.4.3.3 Proposed Improvements

CNL is required to continually update its safety analyses to reflect the current operational state of all facilities on site.

3.4.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

Based on CNSC staff assessments of CNL's application, supporting documents and past performance, CNSC staff conclude that CNL continues to implement and maintain a Safety Analysis program at the WL site in accordance with regulatory requirements.

3.4.5 Recommendation

Two licence conditions are included in the proposed licence for this SCA. Licence condition 4.1 requires CNL to implement and maintain a safety analysis program. Licence condition 4.2 requires CNL to implement and maintain a nuclear criticality safety program. Compliance verification criteria for both licence conditions are included in the draft LCH.

3.5 Physical Design

This SCA relates to activities that impact on the ability of systems, components and structures to meet and maintain their design basis given new information arising over time and taking changes in the external environment into account.

Given that the WL site is undergoing decommissioning, there is very little activity on physical design.

The specific areas that comprise this SCA at the WL site include:

- Design governance
- Site characterization - (no significant observations to report)
- Facility design
- Structure design - (no significant observations to report)
- System design - (no significant observations to report)
- Component design - (no significant observations to report)

3.5.1 Trends

The following table indicates the overall rating trends for the Physical Design over the current licensing period:

TRENDS FOR PHYSICAL DESIGN				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories. CNSC staff conclude that CNL's Physical Design performance meets regulatory requirements.				

3.5.2 Discussion

CNL is required to implement and maintain a design program so that design of facilities is managed using a well-defined systematic approach. Implementing and maintaining a design program confirms that safety-related structures, systems and components (SSC), and any modifications to them, continue to meet their design basis taking new information and changes in the external environment into account. It also confirms that SSCs continue to be able to perform their safety functions under all facility conditions. An important cross-cutting element of a design program is design basis management.

CNSC staff confirm that CNL has implemented and maintained a design program to ensure the ability of systems, structures and components to meet and maintain their design basis. CNSC staff conclude that CNL's physical design measures at the WL site meet all applicable regulatory requirements and CNSC expectations.

3.5.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.5.3.1 Past Performance

Design governance

Fire Protection Program

CNL's Fire Protection Program at the WL site identifies how protection from fire is achieved through planned, coordinated and controlled activities to reduce the risk to the health and safety of persons and to the environment from a fire. CNL continues to maintain its fire protection program in accordance with the current licence and associated LCH, the National Building Code, the National Fire Code [10] and CSA standards. During the current licence period, CNSC and CNL fire protection staff at the WL site held meetings to discuss the progress of projects, and any other programmatic matters or subjects of interest. CNSC staff conclude that the fire protection program at the WL site meets regulatory requirements and the WL site is performing satisfactorily.

CNL carried out fire protection assessments, which include code compliance reviews (CCR) and Fire Hazard Analysis (FHA), for the WL site facilities in accordance with the CSA-N393 standard, as well as key standards referenced herein, such as the National Building Code of Canada, National Fire Code of Canada, associated NFPA standards etc.

CNL has submitted to CNSC staff their CCR which demonstrates that they are in compliance with the programmatic and operational requirements of the CSA standard. The opportunities for improvement identified as part of the self-assessment were also provided to CNSC. CNSC staff assessed CNL's CCR and conclude that the findings from the CNL CCRs are not considered to be risk significant and CNL's proposed modifications will increase the safety margin of the facility with respect to fire protection.

CNSC staff conducted two inspections at WL in 2012 & 2018 which included a review of compliance with the regulatory requirements on fire protection. Seven actions were raised as a result of the 2012 inspection. These actions addressed: the storage of combustible materials, damage to fire doors, obstruction of sprinkler discharge and fire alarm system upgrades. CNSC staff have confirmed that all actions have been adequately addressed by CNL. As a result of an inspection conducted in May 2018 CNSC staff recommended that CNL ensure all legacy safety-related equipment that are no longer in use be clearly labelled and/or made inaccessible to workers in order to prevent workers from trying to use such equipment in the case of an accident or emergency. CNSC staff verified CNL's implementation of this recommendation during two subsequent inspections conducted in October 2018 and June 2019.

Pressure Boundary Program

During the current licence period, CNL updated and revised their Pressure Boundary Quality Assurance Manual WL-508140-QAM-001 and associated pressure boundary procedure. CNSC staff reviewed the information submitted by CNL and concluded the pressure boundary systems at the WL site meet regulatory requirements.

Facility Design

CNL constructed some new facilities to support the on-going decommissioning activities at the WL site. CNSC staff reviewed elements related to the design of facilities and the FHA prior to the operation of new facilities. These new facilities were not related to ISD of WR-1. CNSC staff reviewed and assessed CNL's application of appropriate sets of codes and design standards for the new facilities. Reviews carried out by CNSC staff included the design of:

- Shielded Modular Above-Ground Storage Building, and
- Soil Storage Compound

CNSC staff concluded CNL met regulatory requirements related to the design of its facilities, and the operation of these new facilities remained within the design basis.

During the next licence period, CNL plans to design and construct facilities for the remediation of the Standpipes and Intermediate Level Waste Bunkers. Standpipes are vertical, in-ground storage structures, located within the WL WMA which provide storage for ILW or HLW waste packages. One hundred seventy-one (171) standpipes were constructed within the WMA. CNL expects that these structures will be emptied of their contents and removed during the next licence period. CNL will construct a number of supporting facilities for the removal, characterization, packaging, and shipment of the ILW and HLW waste from the Standpipes and Intermediate Level Waste Bunkers. CNSC staff will review the design of these facilities prior to their operation.

3.5.3.2 Regulatory Focus

CNSC staff continue to monitor CNL's performance in this SCA at the WL site through regulatory oversight activities including onsite inspections and desktop reviews of relevant program documentation, and review of designs for new or modified facilities.

3.5.3.3 Proposed Improvements

CNL is required to update the pressure boundary procedure WLD-508140-PRO-001, *Whiteshell Laboratories Code Classification and Design Registration of Pressure-Retaining Systems/Components* (part of Pressure boundary program) to include the decommissioning of pressure boundary systems/components.

CNSC staff continue to review the design of facilities prior to the operation of new facilities at the WL site. This will include a review of the standpipe and intermediate bunker remediation facility design.

3.5.4 Conclusion

There are no challenges with CNL's implementation of this SCA.

Based on CNSC staff assessments of CNL's application, supporting documents and past performance, CNSC staff conclude that CNL continues to implement and maintain programs for pressure boundary and design at the WL site in accordance with regulatory requirements.

3.5.5 Recommendation

Two licence conditions are included in the proposed licence for this SCA. Licence condition 5.1 requires CNL to implement and maintain a design program. Licence condition 5.2 requires CNL to implement and maintain a pressure boundary program. Compliance verification criteria for both licence conditions are included in the draft LCH.

3.6 Fitness for Service

The fitness for service SCA covers activities that impact the physical condition of structures, systems and components to ensure that they remain effective over time. This area includes programs that verify all equipment is available to perform its intended design function when called upon to do so.

The specific areas that comprise this SCA at the WL site include:

- Maintenance
- Structural integrity

3.6.1 Trends

The following table indicates the overall rating trends for the Fitness for Service over the current licensing period:

TRENDS FOR FITNESS FOR SERVICE				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4].				

The licensee has over this licensing period maintained a fitness for service program in accordance with CNSC requirements. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories.

3.6.2 Discussion

CNL is required to implement and maintain a fitness for service program to cover activities that impact on the physical condition of systems, components and structures to ensure that they remain effective over time.

Elements of the fitness for service program requirements are incorporated into CNSC inspections carried on at the site, with CNSC inspectors verifying that: in-service inspections of safety related structures are carried out by CNL as required, safety related equipment is maintained in good working order and ,where required, components are appropriately calibrated and are tested at the requisite frequency. The fitness for service program at the WL site focuses on in-service inspections of the concrete bunkers in the Waste Management Area (WMA).

3.6.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.6.3.1 Past Performance

Maintenance

As part of their management system, CNL is required by CSA N286-12 to have processes in place to maintain systems, structures and components (SSCs). CNSC staff reviewed CNL's governing documents for the conduct of maintenance at the WL site and concluded that the program meets regulatory requirements.

CNSC staff have found that SSCs observed during CNSC inspections were well-maintained. Based on CNSC inspection results and reviews conducted of CNL submitted information, CNSC staff conclude that CNL has met and will continue to meet the regulatory requirements related to this specific area.

Structural Integrity

CNL is required to conduct annual inspections of the WL WMA concrete bunkers in accordance with the Periodic Inspection Plan (PIP), and report the results annually to CNSC staff.

Additionally, CNL performs quarterly inspections of the Concrete Canister Storage Facility (CCSF). These CCSF inspections have shown no significant cracking or spallation.

In October 2018 CNSC staff performed an inspection on CNL's Waste Management Program at the WL site, during which CNSC staff confirmed that the CCSF inspections had been performed by CNL at the required frequency, and that actions were identified by CNL to correct any deficiencies. CNSC staff also visually inspected the CCFS canisters and found them to be in good condition.

Based on CNSC staff inspections and reviews of the PIP and CCSF inspection reports submitted by CNL, CNSC staff conclude that CNL has met and will continue to meet the regulatory requirements related to this specific area.

3.6.3.2 Regulatory Focus

CNSC staff continue to maintain oversight of the fitness for service program until the facilities are decommissioned.

CNSC staff continue to monitor CNL's performance in this SCA through regulatory oversight activities including onsite inspections and desktop reviews of relevant program documentation.

3.6.3.3 Proposed Improvements

No improvements within this SCA are proposed.

3.6.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

Based on CNSC staff assessments of CNL's application, supporting documents and past performance, CNSC staff conclude that CNL continues to implement and maintain effective fitness for service programs at the WL site in accordance with regulatory requirements.

3.6.5 Recommendation

One licence condition is included in the proposed licence for this SCA. Licence condition 6.1 requires CNL to implement and maintain a fitness for service program. Compliance verification criteria for this licence condition are included in the draft LCH

3.7 Radiation Protection

The radiation protection SCA covers the implementation of a radiation protection program in accordance with the *Radiation Protection Regulations*. The program must ensure that contamination levels and radiation doses received by individuals are monitored, controlled and maintained As Low As Reasonable Achievable (ALARA).

The specific areas that comprise this SCA at the WL site include:

- Application of ALARA
- Worker dose control
- Radiation protection program performance
- Radiological hazard control
- Estimated dose to public

3.7.1 Trends

The following table indicates the overall rating trends for the Radiation Protection over the current licensing period:

3.7.2 Discussion

During the current licensing period, CNL has implemented and maintained a Radiation Protection (RP) program at the WL site that protected the health and safety of persons and ensured occupational exposures are below regulatory dose limits and maintained ALARA. From 2009-2018 the average effective doses to workers at WL has remained very low, typically less than 10% of the 1 mSv annual dose limit for members of the public.

CNSC staff conclude that CNL's implementation of their RP program at the WL site meets all applicable regulatory requirements and CNSC expectations. CNSC staff are satisfied that licensed activities at the WL site are conducted in a safe manner.

3.7.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.7.3.1 Past Performance

CNSC staff's assessment of performance considers indicators such as: monitoring of performance data, event reviews and results of inspection.

Application of ALARA

CNL has a documented ALARA program that identifies the methods and processes in place at the WL site to control dose and minimize exposures. This program integrates ALARA into design, planning, management and control of radiological activities. The ALARA program is based on current industry best practices and operating experience.

CNL's application of ALARA within the RP program includes management commitment and oversight, personnel qualification and training, provision of design features to optimize exposure, provision of protective equipment and clothing, ALARA assessments and reviews for higher risk radiological activities.

Radiological work assessments and radiological work plans/procedures are prepared and used to provide assurance that work activities at the WL site will be consistent with the ALARA principle and provide effective control to prevent unplanned exposures. These documents incorporate radiological control hold and back-out points, individual and collective dose estimates, and control measures to ensure worker safety.

CNSC staff are satisfied with the implementation of CNL's RP program at the WL site and conclude that the program meets all applicable regulatory requirements and expectations related to the application of ALARA.

Worker Dose Control

The *Radiation Protection Regulations* require that all licensees implement a RP program to control the occupational doses received by persons.

The RP program at the WL site has been effectively implemented to ensure doses received by workers are monitored, controlled and maintained well below regulatory limits.

CNL operates a CNSC licensed dosimetry service to monitor, assess, records and report doses received by employees and contractors as a result of licensed activities at the WL site. The RP program includes the criteria and procedures necessary to provide assurance that licensed dosimetry will be provided in accordance with regulatory requirements for all potential hazard types. The implementation of the RP program relating to personal dosimetry meets regulatory requirements.

At the WL site, all workers (e.g. full time workers, contractors) that have a reasonable probability of receiving an occupational dose greater than 1 mSv/year are identified as Nuclear Energy Workers (NEWs) in accordance with RP program criteria.

During the period from 2009 to 2018, no person received an exposure that exceeded the annual dose limit of 50 mSv/year for a NEW:

- The maximum annual individual effective dose[2] received by a NEW over this period was 1.7 mSv (approximately 3.3% of the 50 mSv annual effective dose limit).
- The maximum equivalent dose[3] to the skin received by a NEW over this period was 4.1 mSv (approximately 0.8% of the annual 500 mSv equivalent dose limit for the skin).
- The maximum equivalent dose to the skin of the hands and feet received by a NEW over this period was 36.7 mSv (approximately 7.3% of the annual 500 mSv equivalent dose limit for the hands and feet).

Figure 3 illustrates the distribution of annual effective dose to workers at the WL site for the years 2009 – 2018.

Figure 4 illustrates the average and maximum effective doses to WL workers for the years 2009 – 2018. Average effective doses to workers remained very low

[2] Effective dose is a measure of the total detriment, or risk, due to an exposure to ionizing radiation. It is calculated by multiplying the equivalent dose of radiation received by and committed to each organ or tissue by the weighting factor for that tissue/organ and then summing the products.

[3] The equivalent dose is a measure of detriment to an organ or tissue. It is calculated by multiplying the absorbed dose of radiation by its radiation weighting factor (radiation type specific). It is designed to reflect the amount of detriment caused regardless of the type of radiation.

throughout the licensing period, typically less than 10% of the 1 mSv annual dose limit for members of the public.

The average and maximum effective and equivalent doses, along with the effective dose distribution data demonstrate that CNL is maintaining effective control over worker exposures at the WL site.

Figure 3: Effective dose distribution to CNL-WL workers from 2009 to 2018

	Number of Workers Monitored	≤ 1 mSv	> 1 - 2 mSv	> 2 - 5 mSv	> 5 - 10 mSv	> 10 - 20 mSv	> 20 - 50 mSv	> 50 mSv
2009	781	779	2	0	0	0	0	0
2010	798	798	0	0	0	0	0	0
2011	771	770	1	0	0	0	0	0
2012	746	744	2	0	0	0	0	0
2013	846	846	0	0	0	0	0	0
2014	797	797	0	0	0	0	0	0
2015	753	753	0	0	0	0	0	0
2016	659	659	0	0	0	0	0	0
2017	607	606	1	0	0	0	0	0
2018	595	583	12	0	0	0	0	0

Figure 4: Average and maximum effective doses to CNL-WL workers from 2009 to 2018

	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
Average	0.1	0.0	0.0	0.1	0.0	0.0	0.0	0.0	0.0	0.1
Maximum	1.4	0.9	1.1	1.1	0.8	0.7	0.4	0.4	1.4	1.7

*Average doses are calculated values rounded to the nearest tenth of a mSv (e.g. 0.0 mSv denotes from 0.00 mSv to 0.04 mSv).

Table 2: Dose to the skin of the hands and feet to CNL-WL's workers from 2009 to 2018

Dose Statistic	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	Annual Regulatory Dose Limit for a NEW
Average extremity dose (mSv)	1.2	0.4	0.4	1.0	0.2	0.4	0.1	0.1	1.5	5.0	500 mSv/yr
Maximum extremity dose (mSv)	6.2	1.8	1.9	4.3	0.7	1.3	0.7	0.1	11.4	36.7	

Table 3: Skin doses to CNL-WL's workers from 2009 to 2018

Dose Statistic	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	Annual Regulatory Dose Limit for a NEW
Average skin dose (mSv)	0.1	0.0	0.0	0.1	0.0	0.0	0.0	0.0	0.1	0.1	500 mSv/yr
Maximum skin dose (mSv)	4.1	1.2	1.2	4.0	1.3	1.6	0.7	0.4	2.9	3.7	

CNSC staff are satisfied with the implementation of CNL's RP program at the WL site, and confirm that the program meets all applicable regulatory requirements and expectations related to worker dose control

Radiation Protection Program Performance

CNL has effectively implemented the RP program at the WL site. This program satisfies the requirements of the *Radiation Protection Regulations* and includes a number of performance indicators to continuously monitor RP program performance.

In 2016, CNL began revising RP documentation in order to reflect and support the radiological activities performed at all CNL sites and to harmonize it with CNL's revised company-wide management system.

CNL has established action levels for effective dose, equivalent dose (for skin and the skin on the hands and feet), internal exposure and skin exposure due to a skin contamination event. If any of the action levels are reached or exceeded, CNL must notify CNSC staff and conduct an investigation of the circumstances so that corrective actions can be taken well before a regulatory dose limit is exceeded.

RP program inspections were conducted by CNSC staff throughout the licensing period. Findings from these inspections confirmed compliance with regulatory requirements. Findings of a non-compliant nature were non-safety significant and corrected in a timely manner. Currently there are no open findings of regulatory non-compliance in the RP SCA.

CNSC staff are satisfied with the implementation of the RP program at the WL site. The program meets regulatory requirements and adequate oversight is being applied by the licensee to monitor the implementation and the performance of the RP program

Radiological Hazard Control

CNL continued to maintain and implement RP program requirements for contamination monitoring and control at all of their facilities at the WL site.

CNL’s RP program ensures there are adequate measures in place to monitor and control radiological hazards. This includes, but is not limited to: contamination control, radiation dose rate control, and airborne monitoring and control.

Contamination control at the WL site ensures contamination is prevented from leaving radiologically controlled areas, and the spread of contamination within these areas is minimized. This is achieved by establishing radiological zones with prescribed contamination limits, classifying areas according to their radiation hazard potential, restricting access to authorized personnel, ensuring each radiological area is posted, routine monitoring of workplaces for contamination, minimizing contamination levels, and monitoring personnel and material prior to leaving contaminated or potentially contaminated areas. During CNSC staff inspections of the site, inspectors have regularly verified the effectiveness of the licensee’s program of radiological zone control.

Based on CNSC staff’s assessments through inspection observations and record reviews, radiological hazards continued to be effectively controlled at the WL site.

Estimated Dose to the Public

There was no significant dose to the public during the previous licence period. Data on the maximum effective dose to a member of the public for the last 5 years is provide in Table 4.

Table 4: Maximum effective dose to a member of the public, CNL-WL, 2014-18

Dose data	2014	2015	2016	2017	2018	Regulatory dose limit
Maximum effective dose mSv)	1.4E-03	4.2E-05	7.5E-05	4.8E-05	3.6E-05	1 mSv/year

3.7.3.2 Regulatory Focus

Since 2009, CNL focused on monitoring and improving the RP program documentation. CNSC staff will continue to evaluate the processes used by CNL to verify that the protection of the workers is optimized and that the radiological exposures remain ALARA. As CNL updates the RP program, CNSC staff conduct desktop reviews to ensure the requirements of the *Radiation Protection Regulations* continue to be met.

3.7.3.3 Proposed Improvements

CNL is in the process of revising some of the Action Levels for use at the WL site. These new Action Levels will be subject to CNSC staff review and acceptance. The revision of the Action Levels was initiated in 2017 in accordance with the guidance in section 9.1, Radiation Protection, of the current LCH. The licensee is expected to conduct a documented review and, if necessary, revise Action Levels at least once per licence period in order to validate their effectiveness. The results of such reviews should be provided to the CNSC. CNL has had a productive on-going dialog with CNSC staff on the justification for the proposed revisions to the Action Levels. CNSC staff are confident that the new Action Levels s will be in effect prior to the end of the current licence period.

CNSC staff will continue to monitor CNL's performance in this SCA through regulatory oversight activities including onsite inspections and reviews of relevant program documentation.

3.7.4 Conclusion

There are no challenges with CNL's adherence with the RP regulations and CNL's implementation of RP requirements under this SCA.

Based on CNSC staff assessments of CNL's application, supporting documents and past performance, CNSC staff conclude that CNL continues to implement and maintain an effective radiation protection program at the WL site in accordance with regulatory requirements.

3.7.5 Recommendation

One licence condition is included in the proposed licence for this SCA. Licence condition 7.1 requires CNL to implement and maintain a radiation protection program, which includes a set of action levels. When the licensee becomes aware that an action level has been reached, the licensee shall notify the Commission within seven days. Compliance verification criteria for this licence condition are included in the draft LCH.

3.8 Conventional Health and Safety

The Conventional Health and Safety SCA relates to the implementation of a program to manage workplace safety hazards and to protect workers.

The specific areas that comprise this SCA at the WL site include:

- Performance
- Practices
- Awareness

3.8.1 Trends

The following table indicates the overall rating trends for the Conventional Health and Safety over the current licensing period:

TRENDS FOR CONVENTIONAL HEALTH AND SAFETY				
Overall Compliance Ratings				
2014	2015	2016	2017	2018
SA	SA	SA	SA	SA
Comments The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories. CNSC staff conclude that CNL's Conventional Health and Safety performance meets regulatory requirements.				

3.8.2 Discussion

CNL has implemented and maintains a conventional health and safety program to manage workplace safety hazards and to protect personnel and equipment. The nature of the activities related to decommissioning, dismantlement and demolition of redundant structures at the WL site make conventional health and safety an important program, for this site.

CNSC staff on inspection routinely observe workers' compliance with requirements related to proper use of personal protective equipment (PPE), use of proper signage and barriers and the general state of work sites. CNSC staff conclude that CNL's Conventional Health and Safety SCA at the WL site met all applicable regulatory requirements and CNSC expectations.

3.8.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.8.3.1 Past Performance

Practices

In addition to the NSCA [7] and its associated regulations, CNL's activities must comply with Part II: *Occupational Health and Safety* of the *Canada Labour Code* [11], its *Canada Occupational Health and Safety Regulations*, and other applicable federal and provincial health and safety acts and regulations.

CNL's occupational health and safety program applies to all work performed by CNL employees, and to work performed by others on sites and work places controlled by CNL.

CNSC staff verified CNL safety practices during compliance inspections. CNSC staff are satisfied with CNL's performance at the WL site in the aspects related to conventional health and safety.

Awareness

CNL actively promotes conventional health and safety through the provision of information, training, instructions, and supervision. Employees are encouraged to participate, and to report concerns (e.g., unsafe conditions, non-compliances, or events) in order to identify hazards and ensure measures are put in place to prevent injury and illness.

On May 30, 2019 CNL conducted a company-wide full day Safety Stand Down. The Safety Stand Down was dedicated to raising safety awareness, strengthening work practices, and taking immediate action to address emergent safety issues, in effort to improve CNL's performance related to industrial safety. CNSC staff were present as observers at the Safety Stand Down event. In addition to the all-day event in May, CNL has held company-wide themed meetings in response to incidents at any of the CNL sites to increase awareness and incorporate lessons learned. CNSC staff routinely monitor these meetings, and as needed, follow up on corrective actions during inspections.

Since 2009, CNL improved aspects of the conventional health and safety program based on industry best practices and the results of internal focused audits, self-assessments, effectiveness reviews and health and safety inspections.

The findings from these reviews, audits, inspections and self-assessments resulted in internal actions being raised to improve site wide health and safety performance. These internal actions focused on continuing to increase awareness of occupational hazards and the potential for injury to workers, as well as on methodologies to reduce the frequency of occurrence.

CNSC staff monitors CNL employee reports of safety concerns through the initiation of ImpActs as stated in section 3.1.3.1. CNSC staff are satisfied with CNL's promotion of health and safety awareness at WL.

Performance

The key performance indicators for conventional health and safety are the number of recordable lost-time injuries (RLTI) that occur per year, RLTI severity and RLTI frequency. An RLTI is defined as an injury that takes place at work, and results in the worker being unable to return to work and carry out their duties for a period of time. The RLTI frequency and RLTI severity are both based on 100 full time workers (100 FTE = 200,000 hours worked).

$$RLTI\ frequency = 200{,}000\ hrs\ X\ \frac{\#\ of\ lost\ time\ injuries}{person\ hours\ worked}$$

$$RLTI\ severity = 200{,}000\ hrs\ X\ \frac{\#\ of\ working\ days\ lost}{person\ hours\ worked}$$

Data on RLTI, RLTI Frequency and RLTI Severity since 2009 is included in table 5 below.

Table 5: Recordable lost-time injuries (RLTI), frequency and severity at WL

Year	RLTIs	RLTI Frequency	RLTI Severity
2009	5	1.6	8.5
2010	7	2.0	12.2
2011	8	2.1	13.1
2012	5	1.2	9.2
2013	7	1.6	14.4
2014	4	0.90	12.2
2015	0	0	0
2016	1	0.29	1.46
2017	3	0.86	7.67
2018	1	0.28	1.45

3.8.3.2 Regulatory Focus

CNSC staff continue to monitor CNL's performance in this SCA through regulatory oversight activities including onsite inspections and desktop reviews of relevant program documentation.

CNSC staff continue to focus regulatory oversight in this area as decommissioning and demolition activities are planned by CNL. As the CNL occupational health and safety program is updated, CNSC staff conduct desktop reviews to ensure regulatory requirements continue to be met.

3.8.3.3 Proposed Improvements

No improvements to this SCA are proposed.

3.8.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

Based on CNSC staff assessments of CNL's application, supporting documents and past performance, CNSC staff conclude that CNL continues to implement and maintain an effective conventional health and safety program at the WL site in accordance with regulatory requirements.

3.8.5 Recommendation

One licence condition is included in the proposed licence for this SCA. Licence condition 8.1 requires CNL to implement and maintain a conventional health and safety program. Compliance verification criteria for this licence condition are included in the draft LCH.

3.9 Environmental Protection

The Environmental Protection SCA covers programs that identify, control and monitor all releases of radioactive and hazardous substances and effects on the environment from facilities or as the result of licensed activities.

The specific areas that comprise this SCA at the WL site include:

- Effluent and emissions control (releases)
- Environmental management system (EMS)
- Assessment and monitoring
- Protection of the public
- Environmental risk assessment

3.9.1 Trends

The following table indicates the overall rating trends for the Environmental Protection over the current licensing period:

TRENDS FOR ENVIRONMENTAL PROTECTION				
Overall Compliance Ratings				
2014	2015	2016	2017	2018
SA	SA	SA	SA	SA
Comments				
The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. Performance levels for Environmental Protection SCA have been consistent from year to year, with satisfactory ratings given from 2009 to 2018. CNSC staff conclude that CNL's Environmental Protection performance meets regulatory requirements.				

3.9.2 Discussion

CNL submitted its Integrated Environmental Monitoring Program as the framework for its Environmental Protection Program (EnvP) at the WL site [12]. The basis for the program is the WL Comprehensive Study Report (CSR) [13] conducted in 2001 and the WL Site's Dose Model [14]. These two assessments generated conclusions which were used to design and update the monitoring program, as well as any recommendations for further work required to adequately determine WL's environmental risk.

CNL's Integrated Environmental Monitoring Program achieves three main tasks:

- Direct release monitoring
- Contaminant pathways monitoring and
- Biological effects monitoring as applicable to all individual monitoring

The Integrated Environmental Monitoring Program aligns with the principles of the associated CSA Standards and consists of the following three distinct programs:

- the Effluent Verification Monitoring Program (EVMP)
- the Environmental Monitoring Program (EMP)
- the Groundwater Monitoring Program (GWMP)

The WL Radiological and Non-radiological EMP, EVMP and GWMP are being revised to comply with CSA Standards N288.4-10 and N288.5-11. CNL has committed to the following implementation dates to update their EVMP and EMP to be in compliance with these CSA standards:

- CSA N288.4-10, Environmental monitoring programs at Class I nuclear facilities and uranium mines and mills, by January 01, 2020
- CSA N288.5-11, Effluent monitoring programs at Class I nuclear facilities and uranium mines and mills, by January 01, 2020
- CSA N288.7-15, Groundwater protection programs at Class I nuclear facilities and uranium mines and mills, by January 01, 2020

CNL has established Derived Release Limits (DRLs) [14] and action levels [15], at the WL site, to ensure that the releases of radionuclides from the facility's operations would not exceed the established regulatory limit of 1 mSv/yr and the public and environment are protected.

To complement ongoing compliance activities, the CNSC has implemented its Independent Environmental Monitoring Program (IEMP). The IEMP results around the WL site indicate that the public and the environment in the vicinity of WL are protected. The IEMP report for the WL site is published on the CNSC's website *http://www.nuclearsafety.gc.ca/eng/resources/maps-of-nuclear-facilities/iemp/whiteshell.cfm*. Additional information on the IEMP is presented in Addendum D, Environmental Protection Review Report, of this CMD.

3.9.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.9.3.1 Past Performance

Effluent and emissions control (releases)

CNL has implemented and maintained an EVMP at the WL site. CNL's EVMP provides details on WL's radioactive and non-radioactive release monitoring including the decision for the need and development of the program, as well as identifying the rationale behind the current monitoring schedule. The EVMP also provides the WL site specific details on the execution of the program.

As per CNSC reporting requirements in the current LCH, CNL provides its EVMP results through the issuance of the annual report, to confirm compliance with the applicable regulations. CNSC staff review of CNL's EVMP monitoring results [16 to 33] for WL for the licence period of 2009 to 2018, indicates that releases were below regulatory limits. The minimum and maximum weekly releases are included in tables 6 and 7.

Table 6: The weekly releases to water from the WL site operations

Parameter	Releases (range Min & Max) (*Bq/wk*)	Release limits (*Bq/wk*)	
		2009-2015	2016*-2018
Cs-137	1.22E+00-1.30E+07	2.41E+11	1.16E+10
Sr-90	3.30E+06 -1.3E+07	1.46E+12	1.3E+10
Gross Alpha Particulates	2.90E+06 -9.50E+06	2.8E+11	1.1E+09

** = Release limits were revised in 2016 to meet CSA N288.1-08*

Table 7: The weekly releases to air from the WL site operations

Parameter	Releases (range Min & Max) (*Bq/wk*)	Release limits (*Bq/wk*)	
		2009- 2015	2016*-2018
Tritium	4.00E+08-3.66E+09	7.64E+14	1.65E+14
Gross Beta Particulates (Cs-137)	4.31E+03 -1.5E+04	1.19E+10	6.92E+09
Gross Alpha Particulates (Pu-239)	1.70E+03 - 2.20E+03	7.6E+14	1.73E+09

** = Release limits were revised in 2016 to meet CSA N288.1-08*

Based on review and assessment of the EVMP results [16 to 33] presented in CNL's reports, CNSC staff conclude that the EVMP currently in place for the WL site continues to protect the public and the environment.

Environmental Management System (EMS)

CNL has established and implemented an Environmental Management System (EMS) for the WL site that meets CNSC requirements outlined in REGDOC 2.9.1, *Environmental Principles, Assessment and Protection Measures*. The EMS assesses environmental risks associated with its nuclear activities to ensure these activities are conducted in a way that prevents or mitigates adverse environmental effects. CNL's EMS has been registered to International Standards Organization (ISO) 14001:2004 Standard, Environmental Management Systems – Requirements with Guidance for Use.

Assessment and Monitoring

CNL has implemented a radiological environmental monitoring procedure that defines the requirements, responsibilities and process for radiological environmental monitoring at the WL site and in the surrounding areas. This procedure is in accordance with general requirements for radiological effluent and environmental monitoring of Management, Monitoring of Emissions and Environmental Monitoring Programs.

The purpose of CNL's environmental monitoring procedure is to:

- Measure contaminants in surrounding environmental media including ground water of the facility or site.
- Determine the impacts of the site or facility operation on people and the environment.
- Verify the effectiveness of emission controls and the adequacy of effluent monitoring.

CNL provides its environmental monitoring results through the issuance of the annual report. The annual report is reviewed by CNSC staff to confirm compliance with the applicable regulation. CNSC staff review of environmental monitoring results [16 to 33] for the licence period of 2009 to 2018, indicate that:

- Monitoring of potential atmospheric effluent exposure pathways did not indicate any significant dose contributions from the operations of the WL site.
- Radioactive contaminants in Winnipeg River water remained below allowable levels defined in the Canadian Drinking Water Guidelines [42].
- The groundwater monitoring program has demonstrated that there is no significant radioactive parameters (gross beta, gross alpha, tritium and uranium) migration from the waste management facilities.

This procedure follows and is consistent with CSA-N288.4-M90. CNL has committed to implement the new CSA standards N288.4-10 and N288.7-15 by January 01, 2020.

CNSC staff review of EMP monitoring results [16 to 33] for the licence period of 2009 to 2018, indicate that total estimated doses due to radioactivity in WL effluents were in the range of 4.8 x 10-5 mSv/yr and 1.8 x 10-3 mSv/yr (liquid pathway) and 2.0 x 10-6 and 8.0 x 10-6 mSv/yr (airborne pathway). This indicates that the releases of radionuclides in the environment resulted in a low level of dose to the public. The estimated maximum effective radiation dose to the public from WL's operations continues to be well below the regulatory dose limit of 1 mSv/yr. The detailed results of public dose are presented in section 3.7, Radiation Protection, of this CMD.

Based on review and assessment of the environmental monitoring results [16 to 33] presented in CNL's reports, CNSC staff conclude that the EVMP currently in place for WL continues to protect the public and the environment.

Protection of the public

This specific area within the Environmental Protection SCA is related to ensuring that members of the public are not exposed to "unreasonable" risk with respect to hazardous substances discharged from the nuclear facilities.

CNSC staff conducted a review of EVMP non-radiological monitoring results [16 to 33] for the licence period of 2009 to 2018, which indicated that:

- Starting in 2013 with the conversion from centralized, fuel oil heating operations to localized electrical or propane heating (and the continuing shut down and demolition of site buildings), non-radiological emissions to air (greenhouse gases) dropped significantly. Overall airborne emission remained below the National Pollutant Release Inventory (NPRI) reporting threshold except for particulate matter (PM10 & 2.5) which was reported to NPRI.
- Liquid effluents non-radiological monitoring results have been consistent over the licence period and in general remained below the monthly CNL internal guidelines for chemical substances in liquid effluents.

Greenhouse gas (GHG) emissions from the WL site include carbon dioxide, methane and nitrous oxide. Emissions are primarily from the burning of propane, the use of diesel generators, the on-site transportation fleet, the on-site landfill and open-pit wood burning. They are measured in CO2 equivalent tonnes which is a measure used to compare between gases that have different Global Warming Potential (GWP).

The GHG emissions from the site have had a decreasing trend (from 8056 tonnes/yr in 2011 to 1678 tonnes/yr in 2018), which CNL has attributed to the decrease in fuel required to heat the site as buildings are decommissioned and elimination of the use of Number 2 Fuel in 2013, which was historically the greatest contributor of GHG emissions at the WL site. Table 8 provides the total estimated annual greenhouse gas emissions from the WL site.

Table 8: Total estimated annual greenhouse gas emissions from the WL site (2011-2018)

Year	2011	2012	2013	2014	2015	2016	2017	2018
Greenhouse Gas (CO_2e tonnes/yr)*	8,056	6,310	4,260	1,940	1,957	1,883	1,873	1,678

* CO_2e tonnes: A unit of measure used to compare between greenhouse gases with different Global Warming Potentials. For example, the Global Warming Potentials for methane is 25. This means that emissions of one metric ton of methane are equivalent to emissions of 25 metric tons of CO_2. In 2013, the GWP for methane and nitrous oxide were changed from 21 to 25 and 310 to 298 respectively under the Canadian Environmental Protection Act Notice with Respect to Reporting of Greenhouse Gases for 2013.

Environmental risk assessment

From the perspective of environmental risk assessment (ERA), CNSC staff have reviewed the CSR and the follow-up monitoring results as well as safety reports submitted annually for the Whiteshell Laboratories Decommissioning Project. The CSR concluded that the decommissioning project is not likely to cause significant adverse environmental effects taking into account the mitigation measures implemented by the licensee.

As part of future decommissioning activities, an updated ERA for the lagoon and landfill areas of the WL site is currently underway. CNSC staff will review this assessment, when submitted.

As required under CNL's licence, a series of annual safety reports were submitted for the WL site. CNSC staff review of these reports indicate that radiation levels and radioactive contamination from operations at the site resulted in radiation doses to members of the public below regulatory limits and guidelines.

Monitoring of pathways for exposure to potential liquid effluent(s) from operational and decommissioning activities at the WL site indicated very small contributions to downstream concentrations of radionuclides (Cs-137) in fish in the Winnipeg River. Similarly, radioactive contaminants in the Winnipeg River were well below the Canadian drinking water guidelines. Dose to members of the public from liquid effluents at WL was calculated to be 4.8 X 10-5 mSv/yr.

Levels of radioactivity in groundwater, soil and vegetation in the vicinity of the WL site indicated that there was no significant migration of radioactive contamination from the waste management facilities at the WL site.

Sampling and analysis of groundwater from the waste management areas and the lagoon and landfill areas for non-radiological parameters (chromium, copper, iron, lead, zinc, arsenic, mercury, nitrate, nitrite, ammonia, chloride, volatile organic compounds and HB-40) indicated that concentrations of these substances were either below their respective limits of detection or were below guideline values.

Furthermore, monitoring of pathways for exposure to atmospheric emissions did not indicate any measurable dose contributions above background levels from operational and decommissioning activities at the WL site. Airborne contaminants that were monitored included ambient gamma, gross beta, gross alpha, Sr-90, Cs-137, and K-40. Airborne emissions were negligible, with an estimated public dose of 2 X 10-6 mSv/yr.

For non-human biota, dose modelling for aquatic species (fish, clams) and measured radionuclide concentrations in incidental animal road kill (deer, grouse) indicated dose levels below United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) benchmarks.

Finally, results of the CNSC's IEMP reported in 2018 indicated that there is no human health impact expected in the vicinity of the WL site. This sampling campaign included air, water, soil, sediment, vegetation and food stuffs (fish, vegetables, etc.) taken from publically accessible areas near the WL site and analyzed for a range of radiological contaminants such as gross alpha, gross beta, tritium, Cs-137, and Co-60. The detailed results of the IEMP are presented in Addendum D, Environmental Protection Review Report.

Based on the available information from the CSR, and the follow-up monitoring results as well as safety reports submitted annually for the site and the CNSC IEMP, CNSC staff conclude that risk to human health and the environment can be characterized as low, with an overall trend that indicates stable performance of the WL site.

3.9.3.2 Regulatory Focus

CNSC staff will continue to monitor CNL's performance in the Environmental Protection SCA through regulatory oversight activities including onsite inspections and desktop reviews of relevant environmental protection program documentations.

CNSC staff will review the ERA for the lagoon and landfill sites at the WL site, once they are submitted by CNL. It is also expected that CNL will conduct a site-wide ERA in accordance with REGDOC-2.9.1-2017 and the CSA Standard N288.6-12 *Environmental Risk Assessment at Class I Nuclear Facilities and Uranium Mines and Mills* during the next licensing period.

3.9.3.3 Proposed Improvements

CNL has noted that over the next licence period, through the implementation of the following standards/regulatory requirements, they expect to achieve, improvements in the WL Environmental Protection Program:

- REGDOC-2.9.1 (2017), Environmental Principles, Assessment and Protection Measures, version 1.1, section 4.6;

- CSA N288.4-10 (R2015), Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills;
- CSA N288.5-11 (R2016), Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills;
- CSA N288.6-12 (R2017), Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills;
- CSA N288.7-15, Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills; and
- CSA N288.8-17, Establishing and Implementing Action Levels for Releases to the Environment from Nuclear Facilities,
- The federal requirements for the total residual chlorine in wastewater come into force in 2021 for CNL's lagoon. WL will continue to adjust the site's chlorination practices to meet and exceed the new requirements.

CNSC staff have accepted CNL's plan and schedule for the implementation of these standards, and through regular program updates, CNSC staff track and monitor licensee's compliance with its commitments. There are no concerns with licensee's implementation schedule.

3.9.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

Based on the CNSC staff assessments of CNL's safety and control measures at the WL site regarding the specific areas of the Environmental Protection SCA and upon review of CNL's licensing applications, supporting documentation and past performance, CNSC staff conclude that there are no significant concerns related to the protection of the public and the environment. CNL continues to maintain and implement an environmental protection program at WL in accordance with CNSC requirements.

3.9.5 Recommendation

One licence condition is included in the proposed licence for this SCA. Licence condition 9.1 requires CNL to implement and maintain an environmental protection program, which includes a set of action levels. When the licensee becomes aware that an action level has been reached, the licensee shall notify the Commission within seven days. Compliance verification criteria for this licence condition are included in the draft LCH.

CNSC staff will include the following in the Environmental Protection section of the draft LCH; "The licensee shall conduct an updated site-wide environmental risk assessment (ERA) in accordance with the CSA Standard N288.6-12 *Environmental Risk Assessment at Class I Nuclear Facilities and Uranium Mines and Mills* taking into account current conditions at the WL site".

3.10 Emergency Management and Fire Protection

The Emergency Management and Fire Protection SCA covers emergency plans and emergency preparedness programs that exist for emergencies and for non-routine conditions.

The specific areas that comprise this SCA at the WL site include:

- Conventional emergency preparedness and response;
- Nuclear emergency preparedness and response; and
- Fire emergency preparedness and response.

3.10.1 Trends

The following table indicates the overall rating trends for the Emergency Management and Fire Protection over the current licensing period:

TRENDS FOR EMERGENCY MANAGEMENT AND FIRE PROTECTION				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories. CNSC staff conclude CNL's Emergency Management and Fire Protection performance meets regulatory requirements.				

3.10.2 Discussion

The current licence requires CNL to implement and maintain an emergency preparedness program and a fire protection program. The approach to Emergency Preparedness and Fire Protection for the WL site is based on a combination of detailed planning and hazard identification and risk assessments at all facilities. This is complemented by drills and emergency exercises conducted in partnership with the emergency response teams in local municipalities. CNSC staff have assessed that the WL site continues to meet regulatory requirements and is performing satisfactorily with respect to this SCA.

3.10.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.10.3.1 Past Performance

CNL completes drills and exercises annually at the WL site, in accordance with the WL five-year drill and exercise plan. Drill and exercise topics include fires, active threats, hazardous goods events (e.g., PCBs, chlorine, fuel), radiation events, and transportation accidents involving radiological materials. The drill and exercise plan was revised during the previous licence period to reflect the current status of the site.

Nuclear Emergency Preparedness and Response

CNL is required to implement to requirements of REGDOC 2.10.1, *Nuclear Emergency Preparedness and Response*. REGDOC 2.10.1 has been incorporated into CNL's corporate-wide emergency preparedness program, as well as the WL site emergency procedures. To evaluate the emergency preparedness of a licensee, CNSC staff assess the licensee emergency plan and preparedness program as well as the results of emergency exercises. Emergency preparedness at the WL site is governed by the CNL document WL-508730-ERP-001, *Whiteshell Laboratories Emergency Response Plan*. The WL Site Emergency Response Plan includes, but is not limited to, radiological emergencies and outlines the interfaces with the Manitoba Emergency Plan.

Fire Emergency Preparedness and Response

The CNL Fire Protection program documentation identifies how fire response is achieved on the site. A gap analysis was performed in 2016 by CNL against the operational requirements of CSA-N393, *Fire Protection for Facilities that Process, Handle, or Store Nuclear Substances*, as requested by the CNSC. A corrective action plan to address the gaps identified was developed and implemented. This corrective action plan was reviewed and assessed by CNSC staff through a desktop review and found to be acceptable. The implementation of this corrective action plan is complete and will be verified by CNSC staff during upcoming inspections.

CNL has a multi-disciplinary emergency response force on site at WL and mutual aid partners (Pinawa and Lac Du Bonnet fire departments) off site.

CNSC staff confirm that the fire response program at the WL site meets regulatory requirements.

Conventional Emergency Preparedness and Response

CNL continues to maintain effective conventional emergency response programs. Emergency response personnel are available on site 24 hours a day to respond to any type of emergency. Training and equipment continue to be maintained for medical response, hazardous materials and other conventional hazards that may be present. CNSC staff conclude CNL's conventional emergency response programs meet regulatory requirements.

3.10.3.2 Regulatory Focus

CNSC staff continue to monitor CNL emergency response programs and their performance in drills and exercises to ensure continuous learning and improvement, and ensure that CNL's emergency response capabilities are maintained.

CNSC staff continue to focus on the site emergency plan during regular compliance activities to ensure the plan remains scalable and flexible to respond to any emergency at site and reflects changing infrastructure at site.

3.10.3.3 Proposed Improvements

No additional changes are proposed for this SCA.

3.10.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

CNL has sufficient provisions in place for emergency preparedness and response capability that would mitigate the effects of accidental releases of nuclear substances and hazardous substances on the environment and the health and safety of persons. CNSC staff are satisfied that CNL has made sufficient preparations to respond to any emergency that may arise on the WL site.

Based on CNSC staff assessment, CNSC staff conclude that CNL emergency management and fire protection programs meet regulatory requirements.

3.10.5 Recommendation

Two licence conditions are included in the proposed licence for this SCA. Licence condition 10.1 requires CNL to implement and maintain an emergency preparedness program. Licence condition 10.2 requires CNL to implement and maintain a fire protection program. Compliance verification criteria for both licence conditions are included in the draft LCH.

3.11 Waste Management

The Waste Management SCA covers internal waste-related programs that form part of the facility's operations up to the point where the waste is removed from the facility to a separate waste management facility. This SCA also covers the planning for decommissioning.

The specific areas that comprise this SCA at the WL site includes:

- Waste characterization

- Waste minimization
- Waste management practices
- Decommissioning plans

3.11.1 Trends

The following table indicates the overall rating trends for the Waste Management over the current licensing period:

TRENDS FOR WASTE MANAGEMENT				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments				
The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. CNL continues to be rated SA for their waste management performance at the Whiteshell Laboratories. CNSC staff conclude CNL's Waste Management performance meets performance objectives and applicable regulatory requirements.				

3.11.2 Discussion

The Waste Management SCA includes a waste management program and a plan for the decommissioning of the WL site. CNL has implemented and maintains a waste management program that documents the activities to control the safe management of radioactive waste during all steps of its management. CNL prepared a program overview decommissioning plan that describes the decommissioning strategy and final end-state planned. CNL has also implemented and maintains a decommissioning program.

The singular focus of CNL at the WL site has been decommissioning and demolition of redundant structures on the site, all of which generate waste; waste management is therefore an area of primary focus of CNSC's regulatory activities. CNSC staff have evaluated CNL's compliance through oversight activities such as desktop reviews and compliance inspections. CNSC staff conclude that CNL's Waste Management SCA at the WL site meets all applicable regulatory requirements.

CNSC staff recommendations related to this SCA did not consider the proposed ISD of WR1 reactor. Any proposed activities specifically related to the proposed ISD of WR1 are out of scope of this application and will potentially be considered by the commission in a separate hearing.

3.11.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.11.3.1 Past Performance

Under CNL's waste management program at the WL site, wastes are generated from operational activities and decommissioning projects. Associated with their waste management program, CNL is segregating, packaging, storing and reusing or recycling radioactive, hazardous and conventional wastes. Waste management and decommissioning activities at the WL site were presented to the Commission most recently in the progress update (CMD 18-M30) [5], and the status update (CMD 16-M12) [6]. The following describes updates since these reports were presented.

Waste Characterization and Waste Minimization

CNL maintains a waste management program to control and minimize the volume for all waste streams of waste generated from licensed activities. Waste generated at the WL site are radiologically screened and segregated at the source as either "Likely Clean" or "Radiological Contaminated". Likely Clean waste is monitored for radiological clearance. If the waste is confirmed clean (i.e. not radiologically contaminated), the waste is either dispositioned for reuse or recycling where possible, or disposed of in the WL landfill or transferred to an appropriate storage or process facility for hazardous material. Radiologically contaminated waste is decontaminated to meet clearance criteria where feasible or characterized and sent to the Waste Management Area (WMA) for processing or storage.

CNSC staff confirmed through on-site inspections that CNL continues to characterize waste at the various steps in the management of radioactive waste to meet acceptance criteria of the receiver. CNSC staff verify licensee compliance with waste segregation and labelling requirements at the WL site as a standard part of site inspections.

Waste Management Practices

The WMA provides processing and storage facilities for radioactive waste. It consists of the Shielded Modular Above Ground Storage (SMAGS) building, bunkers and Quonset buildings used to store low-level waste (LLW) and intermediate-level waste (ILW) generated from WL decommissioning activities. CNL conducts projects to re-characterize radioactive waste as necessary, and to assess waste conditions, environmental conditions and potential environmental impacts. CNL performs inspections of WMA to confirm waste is stored in a safe manner.

CNL is executing the decommissioning of the WMA in accordance with detailed decommissioning plans. This work includes improving access to the area, reducing and repackaging existing waste, and preparing facilities to be decommissioned. The detailed decommissioning plans include the proposed waste management practices and are evaluated and approved by CNSC staff. Following the completion of decommissioning of a building or a location on site, the licensee is required to submit a post-decommissioning report called the end-state report to the CNSC. This report is reviewed by CNSC staff to verify licensee's compliance with the approved plans.

Some of the WL decommissioning activities that have been conducted by CNL at the WMA since the last update to the Commission (CMD 18-M30 [5]) are listed below:

- On-going preparation for the extraction of waste from the ILW bunkers and standpipes. This work began in 2017 and includes the design/construction of systems for remediating these facilities (60% design complete).
- The completion of the construction work for expansion of the protected area in the WMA that surrounds the standpipes. This is required to allow space for the extraction of wastes noted above. The expanded protected area encompasses the standpipes and the ILW bunkers.
- Completion of the development of a modular workspace complex at the entrance of the WMA to control and coordinate worker access to the WMA.
- In 2017, CNL completed waste segregation and repackaging. Since 2016, most WR-1 and some other WMA wastes have been sorted and repackaged, in order to reduce fire loading in storage buildings and to reduce waste volumes. Repackaged wastes have been placed into steel containers and transferred to storage in the SMAGS building.
- Completion of the shipment to CRL of over sixty Cs-137 and Cf-252 sources and approximately 1500 m^3 of soil waste from the former Experimental Cesium Pond.

CNSC staff have evaluated CNL's compliance through oversight activities such as desktop reviews and compliance inspections. CNSC staff are satisfied that CNL is carrying out waste management practices and decommissioning work in accordance with the licensing basis.

Decommissioning Plans

CNL is planning, preparing for, executing and completing decommissioning activities, in accordance with detailed decommissioning plans.

The WL site is undergoing decommissioning in a staged manner. CNL's planning for decommissioning includes all nuclear and non-nuclear facilities at the site and these decommissioning plans are submitted to the CNSC as separate volumes. 12 Volumes are planned for the entire decommissioning of the WL site. Volume 1 is the program overview document which describes the overall decommissioning strategy of the site and a general overview of individual facilities. The subsequent volumes are submitted to CNSC as separate decommissioning plans for each facility on the WL site. Not all volumes of the detailed decommissioning plan have been developed, as they are developed when so required by CNL.

As stated in the previous section, since the last licensing renewal in 2009 CNL has progressed with decommissioning at the WL site.

3.11.3.2 Regulatory Focus

CNSC staff will continue to carry out verification activities as CNL conducts decommissioning activities at the WL site. CNSC staff will continue to monitor

CNL's performance in this SCA through compliance verification activities including onsite inspections, desktop reviews of relevant program documentation. This SCA will remain an area of focus in the next licensing period, as CNL continues to pursue decommissioning activities generating radioactive waste that must be stored and managed at the WL site until a final solution is determined.

3.11.3.3 Proposed Improvements

To better align with the current regulatory requirements and standards, CNL is updating their Volume 1 Program Overview DDP to align with CSA N294-09, *Decommissioning of Facilities Containing Nuclear Substances* and CNSC Regulatory Document, G-219, *Decommissioning Planning for Licensed Activities*.

3.11.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

Based on CNSC staff assessment of CNL's application, supporting documents and past performance, CNSC staff conclude that CNL continues to implement and maintain an effective waste management program at the WL site in accordance with regulatory requirements.

3.11.5 Recommendation

Two licence conditions are included in the proposed licence for this SCA. Licence condition 11.1 requires CNL to implement and maintain a waste management program. Licence condition 11.2 requires CNL to maintain a decommissioning plan. Compliance verification criteria for both licence conditions are included in the draft LCH.

3.12 Security

The Security SCA covers the programs required to implement and support the security requirements stipulated in the regulations, the licence, orders, or expectations for the facility or activity.

The specific areas that comprise this SCA at the WL site include:

- Facilities and equipment
- Response arrangements
- Security practices
- Drills and exercises

3.12.1 Trends

The following table indicates the overall rating trends for the Security over the current licensing period:

TRENDS FOR SECURITY				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	BE
Comments				
The ratings for the time period of 2009 and 2010 were SA for each year. The rating for 2011 was FS. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both FS. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. During 2018, CNSC staff identified a deficiency in the security arrangements at the WL site. These issues have been the subject of enforcement actions, including an Order against CNL, and have led CNSC staff to evaluate CNL's 2018 performance in the SCA of Security at the WL site as 'below expectations' (BE).				

3.12.2 Discussion

The information supporting the performance rating will be presented to the Commission in a separate classified document (CMD 19-H4.A). During 2018, CNSC staff identified a deficiency in the security arrangements at the WL site. These issues have been the subject of enforcement actions, including an Order against CNL, and have led CNSC staff to evaluate CNL's 2018 performance in the SCA of Security at the WL site as 'below expectations' (BE). CNL has proposed corrective actions that are acceptable to CNSC staff. CNSC staff continue to monitor implementation of these corrective actions.

3.12.3 Recommendation

One licence condition is included in the proposed licence for this SCA. Licence condition 12.1 requires CNL to implement and maintain a security program. Compliance verification criteria for this licence condition are included in the draft LCH.

3.13 Safeguards and Non-Proliferation

The Safeguards and Non-Proliferation SCA covers the programs and activities required for the successful implementation of the obligations arising from the Canada/International Atomic Energy Agency (IAEA) safeguards agreements as well as other measures arising from the Treaty on the Non-Proliferation of

Nuclear Weapons (NPT). This SCA comprises a safeguards program and a non-proliferation program.

The scope of the non-proliferation program for the WL site is limited to the tracking and reporting of foreign obligations and origins of nuclear material. This tracking and reporting assists the CNSC in the implementation of Canada's bilateral Nuclear Cooperation Agreements with other countries. The import and export of controlled nuclear substances, equipment and information identified in the *Nuclear Non-proliferation Import and Export Control Regulations* require separate authorization from the CNSC, consistent with section 3(2) of the *General Nuclear Safety and Control Regulations*.

The specific areas that comprise this SCA at the WL site includes:

- Nuclear material accountancy and control
- Access and assistance to the IAEA
- Operational and design information
- Safeguards equipment, containment and surveillance

3.13.1 Trends

The following table indicates the overall rating trends for the Safeguards and Non-Proliferation over the current licensing period:

TRENDS FOR SAFEGUARDS AND NON-PROLIFERATION				
Overall Compliance Ratings				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments The ratings for the time period of 2009 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. This SCA has been rated SA each year over the licensing period. Non-Proliferation was added to this SCA in 2012. Compliance ratings from 2008-2011 are for the former Safeguards-only SCA. CNSC staff conclude that CNL's Safeguards and Non-Proliferation performance meet regulatory requirements.				

3.13.2 Discussion

CNL has an effective safeguards program that conforms to measures required by the CNSC to meet Canada's international safeguards obligations as well as other measures arising from the *Treaty on the Non-Proliferation of Nuclear Weapons*.

The CNSC regulatory mandate includes ensuring conformity with measures required to implement Canada's international obligations on the peaceful uses of nuclear energy. Pursuant to the *Treaty on the Non-Proliferation of Nuclear Weapons*, Canada has entered into a Comprehensive Safeguards Agreement and Additional Protocol with the IAEA (hereafter, the safeguards agreements). The objective of the Canada/IAEA safeguards agreements is for the IAEA to provide annual assurance to Canada and to the international community that all declared nuclear material is in peaceful, non-explosive uses and that there is no indication of undeclared material.

The CNSC provides the mechanism, through the *Nuclear Safety and Control Act*, the regulations and a licence condition, for the IAEA to implement the safeguards agreements. Conditions for the application of IAEA safeguards are contained in the licence, and the criteria in order to meet the conditions are contained in the LCH.

3.13.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections. The compliance rating takes into consideration the CNSC staff assessment in all specific areas included for the WL site within this SCA. IAEA and CNSC's safeguards activities at the WL site were presented to the Commission most recently in the Interim Status Report on the Progress of Decommissioning activities (CMD 12-M47) , and the CNSC staff report on the performance of CNL sites for 2013 (CMD 14-M79), the following describes updates since these reports were presented.

3.13.3.1 Past Performance

Nuclear Material Accountancy and Control

During the licensing periods under review, CNL provided the CNSC and IAEA with all reports and information necessary to comply with the safeguards regulatory requirements, including those related to nuclear material accounting and reporting. Reports are now submitted electronically through the CNSC's Nuclear Materials Accountancy Reporting (NMAR) portal. NMAR was fully implemented in 2016.

Access and Assistance to the IAEA

CNL continues to grant access and assistance to the IAEA for inspection activities at the WL site. Details of the IAEA inspections can be found in the following table:

Table 9: IAEA inspection activities

Year	SNRI	PIV	DIV	Total
2014	1	0	1	2
2015	0	1	1	2
2016	0	0	1	1
2017	0	0	0	0
2018	0	0	1	1
Total Inspections				6

SNRI - Short Notice Random Inspection

PIV - Physical Inventory Verification

DIV - Design Information Verification

The IAEA indicated that the results from their inspection activities at the WL site were satisfactory and no actions were requested from CNL.

Operational and Design Information

During the licensing period, CNL submitted annual Operational Programs and quarterly updates as required. These documents provide a forward-looking plan of CNL's activities which assists the IAEA in planning inspections.

CNL has also provided timely annual Additional Protocol submissions to CNSC staff which include a description of each building on the WL site, the scale of its operations, and future plans for nuclear fuel research and development activities

Safeguards Equipment, Containment and Surveillance

CNL continues to provide assistance to the IAEA for the installation and maintenance of IAEA's containment measures at the WL site. During the licensing period, the IAEA performed a technical visit at the WL site to identify locations to install equipment which will become part of the equipment-based safeguards approach once CNL begins shipping out nuclear material from the WL site.

Overall, CNL programs for safeguards and non-proliferation at the WL site continued to meet CNSC requirements and expectations.

3.13.3.2 Regulatory Focus

CNSC staff will continue to monitor CNL's performance through participation in IAEA inspections, evaluations independent of the IAEA, and ongoing assessments of compliance with the various reporting requirements.

3.13.3.3 Proposed Improvements

The regulatory document REGDOC-2.13.1, *Safeguards and Nuclear Material Accountancy*, is referenced in the proposed WL LCH. This document sets out requirements and guidance for safeguards programs for applicants and licensees who possess nuclear material, operate a uranium and/or thorium mine, carry out specified types of nuclear fuel-cycle related research and development work, and/or carry out specified types of nuclear-related manufacturing activities. The REGDOC-2.13.1 supersedes RD-336, which only sets out requirements and guidance for accounting and reporting of nuclear material.

3.13.4 Conclusion

There are no challenges with CNL's implementation of this SCA.

CNSC staff have assessed CNL documentation and analyses under the Safeguards and Non-Proliferation SCA, and have found them to be acceptable and compliant with regulatory requirements.

3.13.5 Recommendation

One licence condition is included in the proposed licence for this SCA. Licence condition 13.1 requires CNL to implement and maintain a safeguards program. Compliance verification criteria for this licence condition are included in the draft LCH.

3.14 Packaging and Transport

The Packaging and Transport SCA covers the safe packaging and transport of nuclear substances to and from the licensed facility.

The specific areas that comprise this SCA at the WL site include:

- Package design and maintenance;
- Packaging and transport; and
- Registration for use.

3.14.1 Trends

The following table indicates the overall rating trends for the Packaging and Transport over the current licensing period:

TRENDS FOR PACKAGING AND TRANSPORT				
OVERALL COMPLIANCE RATINGS				
2014	**2015**	**2016**	**2017**	**2018**
SA	SA	SA	SA	SA
Comments				
The ratings for the period of 2008 to 2011 were SA for each year. These were reported in the CMD 12-M47, *Interim Status Report on the Progress of Decommissioning Activities at Whiteshell Laboratories* [3]. The ratings for 2012 and 2013 were both SA. These were reported in CMD 14-M79, *Annual Performance Report AECL's Nuclear Sites and Projects: 2013* [4]. CNL continues to be rated SA in this SCA at the Whiteshell Laboratories. CNSC staff conclude that CNL's Packaging and Transport program ensures compliance with the regulations.				

3.14.2 Discussion

CNSC regulates the transport of nuclear substances through a series of safety-centred regulatory requirements covering the entire journey of a shipment, from the time it is initially packaged to arrival at its destination.

Regulatory control of packaging and transport of nuclear substances is generally exerted through:

- certifying of packages used for transporting nuclear substances
- registering users of the certified packaging
- licensing the transport of nuclear substances
- issuing licences for the import and export of nuclear substances

Requirements for licensing vary depending on the type of nuclear substance being transported, and the origin and destination of the shipment. The type of package required depends on the nuclear substance being transported and its quantity, and the mode of transportation being used. To be certified by the CNSC, packages must meet stringent performance criteria for shielding, containment, ability to withstand impacts, and ability to withstand heat. Safety during transport relies heavily on the design of the transport package.

Package designs are combined with additional regulatory controls, including labelling, placarding, quality assurance and maintenance records, allowing nuclear substances to be carried safely in all modes of transport such as road, rail, air and sea transportation. This philosophy is universally accepted for transport and has guided the development of the International Atomic Energy Agency (IAEA) and Canadian Nuclear Safety Commission (CNSC) regulations on the packaging and transport of nuclear substances. All nuclear substances are transported in packages that are selected based on the nature, form and quantity or activity of the nuclear substance. There are general design requirements that apply to all package types to ensure that they can be handled safely and easily, secured properly and are able to withstand routine conditions of transport.

CNL has developed and implemented a packaging and transport program to ensure compliance with the *Packaging and Transport of Nuclear Substances Regulations*, *2015* and the *Transportation of Dangerous Goods Regulations* for all shipments to and from the WL site. This program covers elements of package design, package maintenance, and the registration for use of certified packages as required by the regulations. CNSC's compliance activities in this SCA have included desktop reviews of the companywide corporate program as well as inspections at both the WL site and at CNL's Chalk River Laboratories site, which is the primary destination for nuclear substances transported from the WL site. There are no concerns with CNL's implementation of its packaging and transport program.

3.14.3 Summary

A summary of the licensee's past performance, challenges and proposed improvements are presented in the following subsections.

3.14.3.1 Past Performance

CNL has developed and implemented a packaging and transport program that ensures compliance with the *Packaging and Transport of Nuclear Substances Regulations, 2015* and the *Transportation of Dangerous Goods Regulations* for all shipments leaving their sites, including WL. CNL's packaging and transport program also covers elements of package design and maintenance as well as the registration for use of certified packages as required by the regulations.

The *Packaging and Transport of Nuclear Substances Regulations, 2015* apply to the packaging and transport of nuclear substances, including the design, production, use, inspection, maintenance and repair of packages, and the preparation, consigning, handling, loading, carriage and unloading of packages.

CNL is required to have appropriate training for personnel involved in the handling, offering for transport and transport of dangerous goods at their facility, and is required to issue a training certificate to those workers in accordance with the *Transportation of Dangerous Goods Regulations*. During inspections, CNSC inspectors verify that licensee personnel involved in transport hold valid training certificates.

There were no events reported under the *Packaging and Transport of Nuclear Substances Regulations, 2015* for consignments transported from the WL site.

The transportation of nuclear substances has been a frequent and routine activity at the WL site during the current licence period. In 2018 alone, 303 radioactive transport packages were safely sent offsite [43]. This included the transportation of 1,333.8 m³ of low-level waste and 7.9 m³ intermediate-level waste to CRL.

CNL's packaging and transport program is corporate-wide. In 2019, CNSC staff conducted packaging and transport inspections at both the Chalk River Laboratories (which receives shipments from the WL site) and at the WL site itself. CNSC staff were satisfied that CNL's packaging and transport program ensures compliance with the regulations.

3.14.3.2 Regulatory Focus

CNSC staff will continue to monitor and evaluate CNL's performance in this SCA through regulatory oversight activities including inspections and reviews of compliance reports and other licensee submissions. This SCA will remain an area of focus in the next licensing period, as CNL develops a final long-term solution to the radioactive waste stored and generated at the WL site.

3.14.3.3 Proposed Improvements

No improvements within this SCA are proposed.

3.14.4 Conclusion

There are no challenges to with CNL's implementation of this SCA.

Based on CNSC staff assessments of the licence renewal application, supporting documents and past performance, CNSC staff conclude that CNL's packaging and transport program is effectively implemented at the WL site and ensures compliance with the *Packaging and Transport of Nuclear Substances Regulations, 2015* and the *Transportation of Dangerous Goods Regulations*.

3.14.5 Recommendation

One licence condition is included in the proposed licence for this SCA. Licence condition 14.1 requires CNL to implement and maintain a packaging and transport program. Compliance verification criteria for this licence condition is included in the draft LCH.

4. OTHER MATTERS OF REGULATORY INTEREST

4.1 Indigenous Consultation and Engagement

The common law duty to consult with Indigenous groups applies when the Crown contemplates actions that may adversely impact potential or established Indigenous and/or treaty rights. The CNSC ensures that all of its licensing decisions under the NSCA [7] uphold the honour of the Crown and consider Indigenous peoples' potential or established Indigenous and/or treaty rights pursuant to section 35 of the Constitution Act, 1982 [44].

4.1.1 Discussion

CNSC staff have identified the First Nation and Métis groups who may have an interest in the proposed relicensing of CNL's decommissioning activities at Whiteshell Laboratories in Pinawa, Manitoba. These groups include the Sagkeeng Anicinabe, Brokenhead Ojibway Nation, Black River First Nation, Hollow Water First Nation, Manitoba Metis Federation, Northwest Angle No.33, Shoal Lake #40 First Nation, Iskatewizaagegan #39 Independent First Nation, Wabaseemoong Independent Nations, and Grand Council of Treaty 3.

These groups were identified due to the proximity of their communities, treaty areas and/or traditional territories to the WL site, or due to previously expressed interest in being kept informed of CNSC licensed activities occurring in or proximal to their traditional territories.

CNSC staff sent letters of notification for this proceeding in January 2019 to the Indigenous groups identified above, providing information regarding the proposed licence renewal application, the availability of participant funding to facilitate participation in the hearing process, and details on how to participate in the Commission's public hearing process. Follow-up phone calls were conducted with the identified groups in March 2019 to ensure they had received the letters and to answer any questions about the regulatory process and how to get involved in the Commission proceedings.

CNSC REGDOC-3.2.2 *Indigenous Engagement*, published in February 2016, sets out requirements and guidance for licensees whose proposed projects may raise the Crown's duty to consult. While the CNSC cannot delegate its obligation, it can delegate procedural aspects of the consultation process to licensees. The information collected and measures proposed by licensees to avoid, mitigate or offset adverse impacts from the proposed licence renewal may be used by CNSC staff in meeting its consultation obligations.

Based on the information received and reviewed, CNSC staff determined that CNL's continuation of decommissioning operations at the WL site will not result in novel impacts. All proposed decommissioning activities under this license will occur in the existing project footprint and there is a low probability of emissions or waste being produced that could adversely impact the surrounding environment. This licence renewal application is not anticipated to result in adverse impacts on any potential or established Indigenous and/or treaty rights.

Therefore, CNSC staff are of the opinion that the decision on the licence renewal for CNL's WL decommissioning activities does not raise the duty to consult.

4.1.2 Conclusion

This licence application by CNL does not raise a duty to consult, therefore the guidance set out in CNSC REGDOC-3.2.2 pertaining to formal engagement do not apply. However, CNSC staff encourage CNL to continue to engage with interested Indigenous communities on the licence application and on-going activities of interest to the communities.

The CNSC ensures that all of its licensing decisions under the NSCA [7] uphold the honour of the Crown and consider the broader interests of Indigenous peoples who exercise Indigenous and/or treaty rights within proximity to the licensed activities or facilities. On this basis CNSC staff continue to pursue an approach of meaningful Indigenous engagement integrated into the licence application review and hearing process.

Indigenous groups (Sagkeeng Anicinabe and the Manitoba Metis Federation) have provided the CNSC with Indigenous Knowledge (IK) studies pertaining to the WL site and the proposed WR1 in-situ decommissioning project.

For more information regarding these IK studies, please see the Environmental Protection Review Report (appendix D).

4.2 Other Consultation

The CNSC made available up to $50,000 through its PFP to Indigenous peoples, members of the public and stakeholders in providing value-added information to the Commission through informed and topic-specific interventions. This funding was offered to review CNL's application and associated documents and to prepare for and participate in the Commission's public hearing.

4.2.1 Discussion

The deadline for applications was May 10, 2019. A Funding Review Committee (FRC), independent from CNSC staff, reviewed the funding applications received, and made recommendations on the allocation of funding to eligible applicants. Based on recommendations from the FRC, the CNSC awarded participants up to 63,299.50 in funding to the following recipients, who are required to submit a written intervention and make an oral presentation at the Commission's public hearing in October 2019:

- Canadian Environmental Law Association
- Concerned Citizens of Renfrew County
- Northwatch
- Sagkeeng First Nation
- Manitoba Metis Federation

4.2.2 Conclusion

The CNSC continues to actively promote ongoing communication and dissemination of regulatory and scientific information through social media channels, webinars, outreach in the local communities and postings on the CNSC web site. The CNSC has various mechanisms and processes such as the PFP and mail outs to encourage the public to participate in the Commission's public hearing, as described above. The CNSC has offered assistance to interested members of the public, Indigenous groups, and other stakeholders, through the PFP, to prepare for and participate in the Commission's public hearing.

4.3 Cost Recovery

A Class I licensed nuclear facility is subject to the requirements of Part 2 of the CNSC *Cost Recovery Fees Regulations* (CRFR). CNSC staff have concluded that CNL is compliant with the CNSC's CRFR for the WL site.

4.3.1 Discussion

Through review of CNSC records, CNSC staff have determined that CNL is in good standing with respect to CRFR requirements for the WL site. CNL has paid their cost recovery fees in full.

4.3.2 Conclusion

CNSC staff confirm that CNL is in good standing with respect to CRFR requirements for the WL site.

4.4 Financial Guarantees

The WL licence requires CNL to maintain in effect a financial guarantee for decommissioning of the WL site that is acceptable to the Commission. CNSC Regulatory Guides G-219, *Decommissioning Planning for Licensed Activities* and G-206, *Financial Guarantees for Decommissioning of Licensed Activities* provides guidance on calculating the financial guarantees.

4.4.1 Discussion

With respect to a financial guarantee required by the paragraph 3(1)(l) of the *General Nuclear Safety and Control Regulations* (GNSCR), CNSC Regulatory Document, G-206, *Financial Guarantees for the Decommissioning of Licensed Activities*, (2000) states that an expressed commitment from a federal or provincial government is an acceptable form of financial guarantee.

This commitment was last expressed to the CNSC in a letter from the Federal Minister of Natural Resources to Dr. Binder dated July 31, 2015 [45]. This letter states that AECL will retain ownership of the lands, assets and liabilities associated with CNL's licences, including the Whiteshell Licence, and states that the liabilities of AECL are the liabilities of Her Majesty in Right of Canada.

4.4.2 Conclusion

CNSC staff confirm that a financial guarantees in a format that meets G-206 requirements is in place for the WL site.

4.5 Licensee Public Information Program

A public information and disclosure program (PIDP) is a regulatory requirement for licence applicants. CNSC document RD/GD-99.3 *Public Information and Disclosure*, sets out the requirements for public information and disclosure. The primary goal of the program, as it relates to the licensed activities, is to ensure that information related to the health, safety and security of persons and the environment, and other issues associated with the lifecycle of nuclear facilities are effectively communicated to the public.

This information promotes transparency and improves the public's understanding of the licensed activities and operations. The program includes a commitment to and protocol for ongoing, timely communication of information related to the licensed facility during the course of the licence period.

CNSC expectations of a licensee's public information program and disclosure protocol are commensurate with the level of risk of the facility and the level of public interest in the licensed activities. The program and protocol may be further influenced by the complexity of the nuclear facility's lifecycle and activities, and the risks to public health and safety and the environment perceived to be associated with the facility and activities.

4.5.1 Discussion

The WL licence requires CNL to implement and maintain a PIDP. CNSC staff have reviewed CNL's PIDP and determined that it:

- identifies clear goals and measurable objectives in terms of dissemination of information to targeted audiences
- is available to the public and is posted on the licensee's web site
- targets multiple audiences such as local residents, elected and government representatives, media, business leaders, youth, interest groups, and community organizations
- provides contact information for members of the public who want to obtain additional information

CNL presents their public outreach and Indigenous engagement activities to CNSC staff each month at regularly scheduled meetings. CNSC staff have attended a sample of CNL outreach activities, including the WL Public Liaison committee meetings and the Whiteshell Site Open House.

CNSC staff will continue to monitor CNL's compliance with CNSC RD/GD-99.3 and ongoing implementation of the PIDP.

4.5.2 Conclusion

CNSC staff conclude that CNL's PIDP meets the regulatory requirements of RD/GD-99.3 *Public Information and Disclosure*. CNSC staff continue to oversee CNL's implementation of the PIDP to ensure that CNL meets its obligations regarding dissemination and notifying the public and Indigenous communities on its licensed activities. CNSC staff have also communicated with CNL to refine and update the PIDP on a regular basis to meet the changing information needs of their target audiences.

4.6 Nuclear Liability Insurance

The WL site is currently designated, pursuant to section 7 of the *Nuclear Liability and Compensation Act* (NLCA) [46], as a nuclear installation in Item 17 of the Schedule (Section 2) of the *Nuclear Liability and Compensation Regulations* (NLCR) [47].

4.6.1 Discussion

The WL site contains several facilities which are authorized to contain nuclear material as defined in the NLCA. These facilities fall under various risk categories, as defined in paragraph 4(1) of the NLCR, and are listed in Column 4 of Item 17 in the Schedule.

Because the Concrete Canister Storage Facility is a “Nuclear Fuel Waste Management Facility”, it is the facility in this list with the highest risk. As a result, the WL site falls under the “Nuclear Fuel Waste Management Facility Class” pursuant to paragraph 4(2) of the NLCR, and the operator’s liability amount is prescribed at $13 million pursuant to paragraph 5(c) of the NLCR.

4.6.2 Conclusion

CNL has maintained nuclear liability insurance for WL under the *Nuclear Liability Act* [46] and continues to maintain nuclear liability insurance under the *Nuclear Liability and Compensation Act* (NLCA) [47] which came into force on January 1, 2017.

4.7 Delegation of Authority

The Commission may include in a licence any condition it considers necessary for the purposes of the NSCA. The Commission may delegate authority to CNSC staff with respect to the administration of licence conditions, or portions thereof.

There is one proposed licence condition in the proposed licence that contains the phrase “the Commission or a person authorized by the Commission”: LC 3.2 Operating Performance.

Licence condition 3.2 states “The licensee shall implement and maintain a program for reporting to the Commission or a person authorized by the Commission.”

CNSC staff recommend the Commission delegate its authority for the purposes described in the above licence conditions to the following staff:

- Director, Canadian Nuclear Laboratories Regulatory Program Division
- Director General, Directorate of Nuclear Cycles and Facilities Regulation
- Executive Vice-President and Chief Regulatory Operations Officer, Regulatory Operations Branch

5. OVERALL CONCLUSIONS AND RECOMMENDATIONS

CNSC staff have concluded the following with respect to paragraphs 24(4)(a) and (b) of the *Nuclear Safety and Control Act* (NSCA) [7], in that CNL:

1. is qualified to carry out the activities authorized by the licence; and
2. will in carrying out the licensed activities, has made, and will continue to make adequate provision for the protection of the environment, the health and safety of persons and the maintenance of national security and measures required to implement international obligations to which Canada has agreed.

Therefore, CNSC staff recommend that the Commission:

1. accept CNSC staff's conclusions and exercise its authority under the NSCA [7] to renew the licence to authorize Canadian Nuclear Laboratories to continue to decommission the Whiteshell Laboratories from January 1, 2020 to December 31, 2029
2. authorize the delegation of authority as set out in subsection 4.7 of this CMD

GLOSSARY

For definitions of terms used in this document, see REGDOC-3.6 Glossary of CNSC Terminology, which includes terms and definitions used in the *Nuclear Safety and Control Act* (NSCA) [7] and the regulations made under it, and in CNSC regulatory documents and other publications. REGDOC-3.6 is provided for reference and information.

A. RATING LEVELS

Fully Satisfactory (FS)

Safety and control measures implemented by the licensee are highly effective. In addition, compliance with regulatory requirements is fully satisfactory, and compliance within the safety and control area (SCA) or specific area exceeds requirements and CNSC expectations. Overall, compliance is stable or improving, and any problems or issues that arise are promptly addressed.

Satisfactory (SA)

Safety and control measures implemented by the licensee are sufficiently effective. In addition, compliance with regulatory requirements is satisfactory. Compliance within the SCA meets requirements and CNSC expectations. Any deviation is minor and any issues are considered to pose a low risk to the achievement of regulatory objectives and CNSC expectations. Appropriate improvements are planned.

Below Expectations (BE)

Safety and control measures implemented by the licensee are marginally ineffective. In addition, compliance with regulatory requirements falls below expectations. Compliance within the SCA deviates from requirements or CNSC expectations to the extent that there is a moderate risk of ultimate failure to comply. Improvements are required to address identified weaknesses. The licensee is taking appropriate corrective action.

Unacceptable (UA)

Safety and control measures implemented by the licensee are significantly ineffective. In addition, compliance with regulatory requirements is unacceptable and is seriously compromised. Compliance within the SCA is significantly below requirements or CNSC expectations, or there is evidence of overall non-compliance. Without corrective action, there is a high probability that the deficiencies will lead to unreasonable risk. Issues are not being addressed effectively, no appropriate corrective measures have been taken and no alternative plan of action has been provided. Immediate action is required.

B. BASIS FOR THE RECOMMENDATION(S)

B.1 Regulatory Basis

The recommendations presented in this CMD are based on compliance objectives and expectations associated with the relevant SCAs and other matters. The regulatory basis for the matters that are relevant to this CMD are as follows.

Management System

- It is a requirement of the *Class I Nuclear Facilities Regulations* under paragraph 3(d) that an application for a licence for a Class I nuclear facility shall contain the proposed management system for the activity to be licensed, including measures to promote and support safety culture.
- The *General Nuclear Safety and Control Regulations* require that an application for a licence shall contain, under the following paragraph:
    - 3(1)(k), the applicant's organizational management structure insofar as it may bear on the applicant's compliance with the NSCA [7] and the Regulations made under the NSCA, including the internal allocation of functions, responsibilities and authority.
    - 15(a), the persons who have the authority to act for them (the applicant/licensee) in their dealings with the Commission.
    - 15(b), the names and position titles of the persons who are responsible for the management and control of the licensed activity and the nuclear substance, nuclear facility, prescribed equipment or prescribed information encompassed by the licence.

Human Performance Management

- It is a requirement of the *General Nuclear Safety and Control Regulations* under section 12, that the licensee shall:
    - 12(1)(a), ensure the presence of a sufficient number of qualified workers to carry on the licensed activity safely and in accordance with the NCSA, the Regulations made under the NSCA [7], and the licence.
    - 12(1)(b), train the workers to carry on the licensed activity in accordance with the NSCA, the Regulations made under the NSCA, and the licence.
    - 12(1)(e), require that every person at the site of the licensed activity to use equipment, devices, clothing, and procedures in accordance with the NSCA, the Regulations made under the NSCA, and the licence.
- It is a requirement of the *Class I Nuclear Facilities Regulations* under paragraph 3(d.1) that a licence application contain the proposed human performance program for the activity to be licensed, including measures to ensure workers' fitness for duty.
- It is a requirement of the *Class I Nuclear Facilities Regulations* under paragraph 6(m) that a licence application contain information on the proposed responsibilities, qualification requirements, and training program for workers including the procedures for the requalification of workers.

- It is a requirement of the *Class I Nuclear Facilities Regulations* under paragraph 6(n) that a licence application contain information on the results that have been achieved in implementing the program for recruiting, training, and qualifying workers in respect of the operation and maintenance of the nuclear facility.

Operating Performance

- Paragraph 6(d) of the *Class I Nuclear Facilities Regulations* requires that an application for a licence to operate a Class I nuclear facility contains the proposed measures, policies, methods and procedures for operating and maintaining the nuclear facility.
- Subsection 24(5) of the *Nuclear Safety and Control Act* (NSCA) [7] states that the licence may contain any term or condition that the Commission considers necessary for the purpose of the NSCA.

Safety Analysis

- 3(1)(i) of the *General Nuclear Safety and Control Regulations* requires that an application for a licence shall contain a description and the results of any test, analysis, or calculation performed to substantiate the information included in the application.
- It is a requirement of the *Class I Nuclear Facilities Regulations* that an application for a licence to operate a Class I nuclear facility shall contain the following information under paragraph:
  - 6(c), a final safety analysis report demonstrating the adequacy of the design of the nuclear facility.
  - 6(h), the effects on the environment and the health and safety of persons that may result from the operation and decommissioning of the nuclear facility, and the measures that will be taken to prevent or mitigate those effects.

Physical Design

- Paragraph 3(1)(d) of the *General Nuclear Safety and Control Regulations* requires that an application for a licence shall contain a description of any nuclear facility, prescribed equipment, or prescribed information to be encompassed by the licence.
- Other requirements set out in paragraphs 3(a), 3(b), 6(a) and 6(b) of the *Class I Nuclear Facilities Regulations* require more specific information to be submitted in the licence application related to the site and design of the facility and the final safety analysis report.
- Paragraphs 6(c) and 6(d) of the *Class I Nuclear Facilities Regulations* require that an application for a licence contain a final safety analysis report demonstrating the adequacy of the design of the facility and proposed measures, policies, methods, and procedures for operating and maintaining the facility.

Fitness for Service

- It is a requirement of the *Class I Nuclear Facilities Regulations* under paragraph 6(d) that an application for a licence to operate a Class I nuclear facility contain the proposed measures, policies, methods, and procedures for operating and maintaining the nuclear facility.

Radiation Protection

- The *General Nuclear Safety and Control Regulations* require, under subsection 3(1) that a licence application contain the following information under paragraph:
  - 3(1)(e), the proposed measures to ensure compliance with the *Radiation Protection Regulations*.
  - 3(1)(f), any proposed action level for the purpose of section 6 of the *Radiation Protection Regulations*.
- The *Radiation Protection Regulations* require, under sections 4 to 6 that the licensee implements a radiation protection program, ascertain and record doses, and take the required actions in the case that an action level has been reached.
- The *Class I Nuclear Facilities Regulations* require that an application for a licence to operate a Class I nuclear facility contain the following information under paragraph:
  - 6(e), the proposed procedures for handling, storing, loading, and transporting nuclear substances and hazardous substances.
  - 6(h), the effects on the environment and the health and safety of persons that may result from the operation and decommissioning of the nuclear facility, and the measure that will be taken to prevent or mitigate those effects.

Conventional Health and Safety

- It is a requirement of the C*lass I Nuclear Facilities Regulations* under paragraph 3(f) that an application for a licence in respect of a Class I nuclear facility, other than a licence to abandon, shall contain the proposed worker health and safety policies and procedures.
- The WL's activities and operations must comply with the *Canada Labour Code* [11], *Part II: Occupational Health and Safety*.

Environmental Protection

- The *General Nuclear Safety and Control Regulations*, under paragraphs 12(1)(c) and (f) require that each licensee take all reasonable precautions to protect the environment and the health and safety of persons, and to control the release of radioactive nuclear substances and hazardous substances within the site of the licensed activity and into the environment.
- The *Radiation Protection Regulations* prescribe the dose limit for the general public, which under subsection 1(3) is 1mSv per calendar year.
- In addition, Sections 3 and 6 of the *Class I Nuclear Facilities Regulations* must be met by the applicant. The application for a licence shall contain under paragraph:

- □ 3(e), the name, form, characteristics, and quantity of any hazardous substances that may be on the site while the activity to be licensed is carried on.
- □ 3(g), the proposed environmental protection policies and procedures.
- □ 3(h), the proposed effluent and environmental monitoring programs.
- □ 6(e), the proposed procedures for handling, storing, loading, and transporting nuclear substances and hazardous substances.
- □ 6(h), the effects on the environment and the health and safety of persons that may result from the operation and decommissioning of the nuclear facility, and the measures that will be taken to prevent or mitigate those effects.
- □ 6(i), the proposed location of points of release, the proposed maximum quantities and concentrations, and the anticipated volume and flow rate of releases of nuclear substances and hazardous substances into the environment, including their physical, chemical, and radiological characteristics.
- □ 6(j), the proposed measures to control releases of nuclear substances and hazardous substances into the environment.

Emergency Management and Fire Protection

- 12(1)(c) of the *General Nuclear Safety and Control Regulations* states that every licensee shall "take all reasonable precautions to protect the environment and the health and safety of persons and to maintain the security of nuclear facilities, and of nuclear substances".
- 12(1)(f) of the *General Nuclear Safety and Control Regulations* states that every licensee shall "take all reasonable precautions to control the release of radioactive nuclear substances or hazardous substances within the site of the licensed activity and into the environment of the licensed activity…".
- It is a requirement of the *Class I Nuclear Facilities Regulations* under paragraph 6(k) that a licence application contain information on the licensee's proposed measures to prevent or mitigate the effects of accidental releases of nuclear substances and hazardous substances on the environment, the health and safety of persons and the maintenance of national security, including measures to:
  - □ Assist offsite authorities in planning and preparing to limit the effects of an accidental release.
  - □ Notify offsite authorities of an accidental release or the imminence of an accidental release.
  - □ Report information to offsite authorities during and after an accidental release.
  - □ Assist offsite authorities in dealing with the effects of an accidental release.
  - □ Test the implementation of the measures to prevent or mitigate the effects of an accidental release.

Waste Management

- It is a requirement of the *General Nuclear Safety and Control Regulations* under paragraph 3(1)(j) that an application for a licence include the name, origin, quantity, form, and volume of any radioactive waste or hazardous waste that may result from the activity to be licensed, including waste that may be stored, managed, processed, or disposed of at the site of the activity to be licensed, and the proposed method for managing and disposing of that waste.

Security

- Paragraph 3(1)(e) of the *General Nuclear Safety and Control Regulations* requires that an application for a licence contains the proposed measures to ensure compliance with the *Radiation Protection Regulations*, the *Nuclear Security Regulations* and the *Packaging and Transport of Nuclear Substances Regulations, 2015*.
- Paragraph 12(1)(c) of the *General Nuclear Safety and Control Regulations* requires the licensee to take all reasonable precautions to protect the environment and the health and safety of persons and to maintain the security of nuclear facilities and of nuclear substances.
- Paragraph 6(k) of the *Class I Nuclear Facilities Regulations* requires that an application for a licence to operate a Class I nuclear facility contains the proposed measures to prevent or mitigate the effects of accidental releases of nuclear substances and hazardous substances to the environment, the health and safety of persons and the maintenance of national security.
- Paragraph 2(a) of Part 1 of *Nuclear Security Regulations* states that Part 1 applies to Category I, II or III nuclear material.
- Subsection 24(5) of the *Nuclear Safety and Control Act* (NSCA) [7] states that the licence may contain any term or condition that the Commission considers necessary for the purpose of the NSCA.

Safeguards and Non-Proliferation

- Subsection 24(5) of the *Nuclear Safety and Control Act* (NSCA) states that the licence may contain any term or condition that the Commission considers necessary for the purpose of the NSCA.
- Paragraph 12(1)(i) of the *General Nuclear Safety and Control Regulations* requires the licensee to take all necessary measures to facilitate Canada’s compliance with any applicable safeguard agreement.
- Paragraph 6(f) of the *Class I Nuclear Facilities Regulations* requires that an application for a licence to operate a Class I nuclear facility contains the proposed measures to facilitate Canada’s compliance with any applicable safeguards agreement. The applicable safeguards agreements are:
    - *Agreement Between the Government of Canada and the International Atomic Energy Agency for the Application of Safeguards in Connection with the Treaty on the Non-Proliferation of Nuclear Weapons* (INFCIRC/164); and

- □ *Protocol Additional to the Agreement Between Canada and the International Atomic Energy Agency for the Application of Safeguards in Connection with the Treaty on the Non-Proliferation of Nuclear Weapons* (INFCIRC/164/Add. 1).

Packaging and Transport

- CNL is required to comply with the *Packaging and Transport of Nuclear Substances Regulations, 2015*, and Transport Canada's *Transportation of Dangerous Goods Regulations*.

Cost Recovery

- Paragraph 24(2)(*c*) of the *Nuclear Safety and Control Act* requires that a licence application is accompanied by the prescribed fee.
- The *Canadian Nuclear Safety Commission Cost Recovery Fees Regulations* (CRFR) set out the specific requirements based on the activities to be licensed.

Financial Guarantee

- The *General Nuclear Safety and Control Regulations* requires under paragraph 3(1)(l) that a licence application contains a description of any proposed financial guarantee relating to the activity to be licensed.

Licensee Public Information Program

- It is a requirement of the *Class I Nuclear Facilities Regulations* under paragraph 3(j) that an application for a licence in respect of a Class I nuclear facility, other than a licence to abandon, shall contain information on the licensee's public information program.

B.2 Technical Basis

The technical basis for the recommendations presented in this CMD are as follows. The following CNSC regulatory documents and CSA standards are relevant to WL.

Management System

- CSA N286 *Management system requirements for nuclear facilities*
- REGDOC-2.1.2 *Management System: Safety Culture*
- CSA N286.0.1 *Commentary on N286-12, Management system requirements for nuclear facilities*

Human Performance Management

- REGDOC-2.2.4 *Fitness for Duty: Managing Worker Fatigue*
- RD-363 *Nuclear Security Officer Medical, Physical, and Psychological Fitness*
- REGDOC-2.2.4 *Fitness for Duty, Volume II: Managing Alcohol and Drug Use, version 2*
- G-323 *Ensuring Presence of Sufficient Qualified Staff at Class I Nuclear Facilities: Minimum Staff Complement*
- REGDOC-2.2.2 *Personnel Training, version 2*

Operating Performance

- REGDOC-3.1.2 *Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills*

Safety Analysis

- IAEA SSR-4 *Safety of Nuclear Fuel Cycling Facilities*
- IAEA TECDOC-1267 *Procedures for Conducting Probabilistic Safety Assessment for Non-reactor Nuclear Facilities*
- IAEA GSR Part 4, Rev. 1 *Safety Assessment for Facilities and Activities*
- RD-327 *Nuclear Criticality Safety*
- REGDOC 2.4.3 *Nuclear Criticality Safety*
- GD-327 *Guidance for Nuclear Criticality Safety*

Physical Design

- NFPA-801 *Standard for Fire Protection for Facilities Handling Radioactive Materials*
- CSA-N393 *Fire Protection for Facilities that Process, Handle, or Store Nuclear Substances*
- *National Fire Code of Canada*
- *National Building Code of Canada*
- G-276 *Human Factors Engineering Program Plans*
- G-278 *Human Factors Verification and Validation Plans*
- CSA N285.0 *General requirements for pressure-retaining system and components in CANDU nuclear power plants*
- CSA B51 *Boiler, Pressure Vessel and Pressure Piping Code*
- CSA N285.0.1 *Commentary on CSA N285.0-12, General requirements for pressure-retaining systems and components in CANDU nuclear power plants*

Fitness for Service

- REGDOC-2.6.3 *Aging Management*
- REGDOC-2.6.2 *Maintenance Programs for Nuclear Power Plants*

Radiation Protection

- G-129, Rev. 1 *Keeping Radiation Exposures and Doses "As Low as Reasonably Achievable* (ALARA)*"*
- G-228 *Developing and Using Action Levels*
- G-91 *Ascertaining and Recording Radiation Doses to Individuals*
- GD-150 *Designing and Implementing a Bioassay Program*

Conventional Health and Safety

- None provided

Environmental Protection

- REGDOC-2.9.1 *Environmental Principles, Assessments and Protection Measures, version 1.1*
- CSA N288.4 *Environmental monitoring programs at Class I nuclear facilities and uranium mines and mills*
- CSA N288.5 *Effluent monitoring programs at Class I nuclear facilities and uranium mines and mills*
- CSA N288.6 *Environmental risk assessment at Class I nuclear facilities and uranium mines and mills*
- CSA N288.7 *Groundwater protection programs at Class I nuclear facilities and uranium mines and mills*
- CSA N288.8 *Establishing and implementing action levels to control releases to the environment from nuclear facilities*
- CSA N288.1 *Guidelines for calculating derived release limits for radioactive material in airborne and liquid effluents for normal operation of nuclear facilities*
- CSA N288.2 *Guidelines for calculating the radiological consequences to the public of a release of airborne radioactive material for nuclear reactor accidents*

Emergency Management and Fire Protection

- REGDOC-2.10.1 *Nuclear Emergency Preparedness and Response, Version 2*
- CSA N1600 *General requirements for nuclear emergency management programs*
- *Canadian Guidelines for Intervention During a Nuclear Emergency*
- *Canadian Guidelines for the Restriction of Radioactively Contaminated Food and Water Following a Nuclear Emergency*
- CSA-N393*Fire protection for Facilities that Process, Handle, or Store Nuclear Substances*
- *National Fire Code of Canada*
- *National Building Code of Canada*

Waste Management

- CSA N292.0 *General principles for the management of radioactive waste and irradiated fuel*
- CSA N292.2 *Interim dry storage of irradiated fuel*
- CSA N292.3 *Management of low- and intermediate-level radioactive waste*
- CSA N292.6 *Long-term management of radioactive waste and irradiated fuel*
- REGDOC-2.11.1 *Waste Management, Volume III: Assessing the Long-Term Safety of Radioactive Waste Management*

- CSA N292.5 *Guideline for the exemption or clearance from regulatory control of materials that contain, or potentially contain, nuclear substances*
- CSA N294*Decommissioning of Facilities Containing Nuclear Substances*
- G-219 *Decommissioning Planning for Licensed Activities*

Security

- REGDOC-2.12.1 *High-Security Facilities, Volume II: Criteria for Nuclear Security Systems and Devices*
- REGDOC-2.12.2 *Site Access Security Clearance*
- REGDOC-2.12.3 *Security of Nuclear Substances: Sealed Sources*
- CSA N290.7 *Cyber-security for nuclear power plants and small reactor facilities*
- G-208 *Transportation Security Plans for Category I, II or III Nuclear Material*
- G-274 *Security Programs for Category I or II Nuclear Material or Certain Nuclear Facilities*

Safeguards and Non-proliferation

- REGDOC-2.13.1 *Safeguards and Nuclear Material Accountancy*

Packaging and Transport

- IAEA SSR-6 *Regulations for the Safe Transport of Radioactive Material (2012 Edition)*
- RD-364 *Joint Canada-United States Guide for Approval of Type B(U) and Fissile Material Transportation Packages*
- REGDOC-2.14.1 *Information Incorporated by Reference in Canada's Packaging and Transport of Nuclear Substances Regulations, 2015*

C. SAFETY AND CONTROL AREA FRAMEWORK

C.1 Safety and Control Areas Defined

The safety and control areas identified in section 2.2, and discussed in summary in sections 3.1 through 3.14 are comprised of specific areas of regulatory interest which vary between facility types.

The following table provides a high-level definition of each SCA. The specific areas within each SCA are to be identified by the CMD preparation team in the respective areas within section 3 of this CMD

SAFETY AND CONTROL AREA FRAMEWORK		
Functional Area	**Safety and Control Area**	**Definition**
Management	Management System	Covers the framework which establishes the processes and programs required to ensure an organization achieves its safety objectives and continuously monitors its performance against these objectives and fostering a healthy safety culture.
	Human Performance Management	Covers activities that enable effective human performance through the development and implementation of processes that ensure that licensee staff is sufficient in number in all relevant job areas and that licensee staff have the necessary knowledge, skills, procedures and tools in place to safely carry out their duties.
	Operating Performance	This includes an overall review of the conduct of the licensed activities and the activities that enable effective performance.
Facility and Equipment	Safety Analysis	Maintenance of the safety analysis that supports that overall safety case for the facility. Safety analysis is a systematic evaluation of the potential hazards associated with the conduct of a proposed activity or facility and considers the effectiveness of preventative measures and strategies in reducing the effects of such hazards.
	Physical Design	Relates to activities that impact on the ability of systems, components and structures to meet and maintain their design basis given new information arising over time and taking changes in the external environment into account.
	Fitness for Service	Covers activities that impact on the physical condition of systems, components and structures to ensure that they remain effective over time. This includes programs that ensure all equipment is available to perform its intended design function when called upon to do so.

SAFETY AND CONTROL AREA FRAMEWORK		
Functional Area	**Safety and Control Area**	**Definition**
Core Control Processes	Radiation Protection	Covers the implementation of a radiation protection program in accordance with the RP Regulations. This program must ensure that contamination and radiation doses received are monitored and controlled.
	Conventional Health and Safety	Covers the implementation of a program to manage workplace safety hazards and to protect personnel and equipment.
	Environmental Protection	Covers programs that identify, control and monitor all releases of radioactive and hazardous substances and effects on the environment from facilities or as the result of licensed activities.
	Emergency Management and Fire Protection	Covers emergency plans and emergency preparedness programs which exist for emergencies and for non-routine conditions. This also includes any results of exercise participation.
	Waste Management	Covers internal waste-related programs which form part of the facility’s operations up to the point where the waste is removed from the facility to a separate waste management facility. Also covers the planning for decommissioning.
	Security	Covers the programs required to implement and support the security requirements stipulated in the regulations, in their licence, in orders, or in expectations for their facility or activity.
	Safeguards and Non-Proliferation	Covers the programs and activities required for the successful implementation of the obligations arising from the Canada/IAEA safeguards agreements as well as all other measures arising from the *Treaty on the Non-Proliferation of Nuclear Weapons*.
	Packaging and Transport	Programs that cover the safe packaging and transport of nuclear substances and radiation devices to and from the licensed facility.

C.2 Specific Areas for this Facility Type

The following table identifies the specific areas that comprise each SCA for the Whiteshell Laboratories site:

SPECIFIC AREAS FOR THIS FACILITY TYPE		
Functional Area	**Safety and Control Area**	**Specific Areas**
Management	Management System	▪ Management System ▪ Organization ▪ Performance Assessment, Improvement and Management Review ▪ Operating Experience (OPEX) ▪ Change Management ▪ Configuration Management ▪ Records Management ▪ Management of Contractors
	Human Performance Management	▪ Human Performance Programs ▪ Personnel Training ▪ Fitness for Duty
	Operating Performance	▪ Conduct of Licensed Activity ▪ Procedures ▪ Reporting and Trending
Facility and Equipment	Safety Analysis	▪ Deterministic Safety Analysis ▪ Hazard Analysis ▪ Criticality Safety
	Physical Design	▪ Design Governance ▪ Site Characterization ▪ Facility Design ▪ Structure Design ▪ System Design ▪ Components Design
	Fitness for Service	▪ Maintenance ▪ Structural Integrity

SPECIFIC AREAS FOR THIS FACILITY TYPE		
Functional Area	**Safety and Control Area**	**Specific Areas**
Core Control Processes	Radiation Protection	▪ Application of ALARA ▪ Worker Dose Control ▪ Radiation Protection Program Performance ▪ Radiological Hazard Control ▪ Estimated Dose to Public
	Conventional Health and Safety	▪ Performance ▪ Practices ▪ Awareness
	Environmental Protection	▪ Effluent and Emissions Control (releases) ▪ Environmental Management System (EMS) ▪ Assessment and Monitoring ▪ Protection to the Public ▪ Environmental Risk Assessment
	Emergency Management and Fire Protection	▪ Conventional Emergency Preparedness and Response ▪ Nuclear Emergency Preparedness and Response ▪ Fire Emergency Preparedness and Response
	Waste Management	▪ Waste Characterization ▪ Waste Minimization ▪ Waste Management Practices ▪ Decommissioning Plans
	Security	▪ Facilities and Equipment ▪ Response Arrangements ▪ Security Practices ▪ Drills and Exercises

SPECIFIC AREAS FOR THIS FACILITY TYPE		
Functional Area	**Safety and Control Area**	**Specific Areas**
	Safeguards and Non-Proliferation	▪ Nuclear Material Accountancy and Control ▪ Access and Assistance to the IAEA ▪ Operational and Design Information ▪ Safeguards Equipment, Containment and Surveillance
	Packaging and Transport	▪ Package Design and Maintenance ▪ Packaging and Transport ▪ Registration for Use

REVISION HISTORY

The following table identifies the revision history of this document.

Revision number	Change	Summary of changes	Date
000	Initial release	N/A	
001			

-

EXECUTIVE SUMMARY

The Canadian Nuclear Safety Commission (CNSC) conducts Environmental Protection Reviews (EPRs) for all licence applications with potential environmental interactions, in accordance with its mandate under the *Nuclear Safety and Control Act* (NSCA), to ensure the protection of the environment and the health of persons. An EPR is a science-based environmental technical assessment by CNSC staff as set out in the NSCA. The fulfillment of other aspects of the CNSC's mandate, such as safety and security, are met through other regulatory oversight activities.

This EPR Report was written by CNSC staff for the Commission, Indigenous peoples and the public. It describes the scientific, evidence-based findings from CNSC staff review of the application by Canadian Nuclear Laboratories (CNL) to renew the Whiteshell Laboratories (WL) Nuclear Research and Test Establishment Decommissioning Licence NRTEDL-W5-8.05/2019. The licence application proposes the continued operations of the WL site over a period of 10 years, from January 1, 2020 to December 31, 2029. During this licensing period, CNL is proposing to continue the decommissioning activities planned for the WL site, including the decommissioning of the Concrete Canister Storage Facility, Waste Management Area, Shielded Facilities and other remaining buildings and infrastructure.

This EPR Report does not consider CNL's proposed *In Situ* Decommissioning of the Whiteshell Reactor #1 (WR-1) Project, which is undergoing a separate regulatory review process under both the *Canadian Environmental Assessment Act, 2012* and the NSCA. Hence, the proposed *in situ* strategy to decommission the WR-1 facility is outside the scope of this licence renewal.

The CNSC's EPR Report can be read as a stand-alone document that focuses on items that are of current public and regulatory interest such as releases of radiological and hazardous substances to the receiving environment, as well as effects on valued ecosystem components and species at risk, during ongoing operations and decommissioning activities.

This EPR Report includes CNSC staff's assessment of the documents submitted in support of the licence application, as well as but not limited to, the following:

- predictions of radionuclides and hazardous substances in the receiving environment, as presented in the 2001 Comprehensive Study Report (CSR) for the Whiteshell Laboratories Decommissioning Project, previously accepted by the Commission
- CNSC staff verification that environmental monitoring data reported by CNL are within those predicted in the 2001 CSR
- CNL's environmental monitoring and reporting requirements including:
    - Annual Compliance Monitoring Reports
    - Progress Reports on the Environmental Assessment Follow-Up Program for WL
- the results of CNSC's Independent Environmental Monitoring Program
- the results from other regional monitoring programs and/or health studies completed by other levels of government in proximity to the WL site
- the results of the Manitoba Metis Federation's Indigenous knowledge study submitted to the CNSC

The information provided in this EPR Report supports the environmental protection conclusions made by CNSC staff in CMD 19-H4 that CNL has made, and will continue to make adequate provision for the protection of the environment, the health and safety of persons as decommissioning activities continue.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

1.0 INTRODUCTION

1.1 Purpose

The purpose of this Environmental Protection Review (EPR) is to report the outcome of Canadian Nuclear Safety Commission (CNSC) staff review of licensing and environmental compliance activities conducted under the *Nuclear Safety and Control Act* (NSCA). This review serves to assess whether Canadian Nuclear Laboratories (CNL) has made, and will continue to make, adequate provisions to protect the environment and health and safety of persons at the WL site.

This EPR Report presents information that supports CNSC staff's recommendations in CMD 19-H4 regarding the proposed licence renewal of the Whiteshell Laboratories (WL) Nuclear Research and Test Establishment Decommissioning Licence, NRTEDL-W5-8.05/2019, as it pertains to environmental protection. CNL has requested to renew the licence for a period of 10 years, from January 1, 2020 to December 31, 2029 [1]. The current licence expires on December 31, 2019 [2].

This EPR Report does not consider CNL's proposed *In Situ* Decommissioning of the Whiteshell Reactor #1 (WR-1) Project, which is undergoing a separate regulatory review process under both the *Canadian Environmental Assessment Act, 2012* and the NSCA. Hence, the proposed *in situ* strategy to decommission the WR-1 facility is outside the scope of this licence renewal.

CNSC staff assess the health of persons and the environment at every phase of a project and its activities, and throughout all phases of a facility's lifecycle. EPR Reports are prepared to provide science-based transparent information to the public and that supports staff's recommendations to the Commission. The fulfillment of other aspects of the CNSC's mandate, such as safety and security, are met through other regulatory oversight activities that are outside the scope of this report.

This EPR Report is based on information submitted by CNL, compliance and technical assessment activities completed by the CNSC staff, and independent verification activities, including the following:

- regulatory oversight (section 2.0)
- CNSC staff review of the WL decommissioning strategy and program overview [3] (section 1.2)
- CNSC staff review of CNL's Environmental Assessment (EA) Follow-Up Program (FUP) (section 2.2) [4]
- CNSC staff review of CNL's Annual Compliance Monitoring Reports (formerly referred to as Annual Safety Reports) [5 to 33], and other supplementary documents provided by CNL in support of the 2019 Application for Renewal [34 to 35]
- Independent Environmental Monitoring Program (IEMP) results (section 4.0) [36]
- health studies and other regional monitoring programs in proximity to the WL site (sections 5.0 and 6.0)
- an Indigenous knowledge (IK) study submitted by the Manitoba Metis Federation (MMF) [37 to 38], which focused on the *In Situ* Decommissioning of the WR-1 Project but also

provided relevant information on the Indigenous perspectives of the impact of the WL site on MMF Citizens (section 7.0)

A review has been conducted for all environmental components related to the project, but only a selection of topics related to environmental performance of the facility are presented in detail in this report. These were selected based on licensing requirements, as well as those that have historically been of interest to the Commission, Indigenous peoples and the public.

This EPR Report can be read as a stand-alone document that focuses on topics related to the environmental performance of the facility include emissions (atmospheric releases) and liquid releases to the environment, their potential transfer through key environmental pathways and associated potential exposures and or effects on valued ecosystem components including human and non-human biota. The focus is on nuclear and hazardous substances associated with WL site activities, with additional information provided on other substances of public and/or regulatory interest such as greenhouse gas (GHG) emissions. CNSC staff also present information on any relevant regional environmental or health monitoring or studies conducted by the CNSC (i.e., IEMP) or other levels of government.

Additionally, the IK study produced by MMF, while produced for the proposed *In Situ* Decommissioning of the WR-1 Project, identified a number of site-wide valued components (VCs) of significance to their rights, culture and interests, in and around the WL site. Indigenous perspectives and cultural context enhance the CNSC's understanding of potential impacts of projects, strengthening the rigour of project reviews and regulatory oversight. This information was considered in this review, and is presented in later sections of this report.

1.2 Project Background

This section of the report provides general information on the WL site. This includes a description of the site location and a basic history of the WL site activities and licensing. More detailed information is provided with respect to the proposed decommissioning strategy for the WL facility and activities completed over the previous licensing period, followed by information on activities planned for the proposed licence period.

This information is intended to provide context for later sections of this report, which discuss completed and ongoing decommissioning activities.

1.2.1 Site Description

The WL site is located in Pinawa, Manitoba, approximately 100 kilometres (km) northeast of Winnipeg, on the shore of the Winnipeg River. Historically owned and operated by Atomic Energy Canada Limited (AECL) and comprised of 4,375 hectares of land, the WL site was established in the 1960s in order to conduct nuclear research activities.

The WL site was commissioned in 1964 and operated for approximately 40 years under a Nuclear Research and Test Establishment Operating Licence (NRTEOL) [39]. CNL took over management of the WL site in 2015, and although AECL remains the site owner, operations are managed by CNL under a government-owned, contractor-operated ("Go-Co") model.

See figures 1.1 and 1.2, for maps of the site location.

Figure 1.1: Overview of site and surrounding features (figure adapted from Whiteshell Reactor #1 EIS figure 1.0-1) [40]

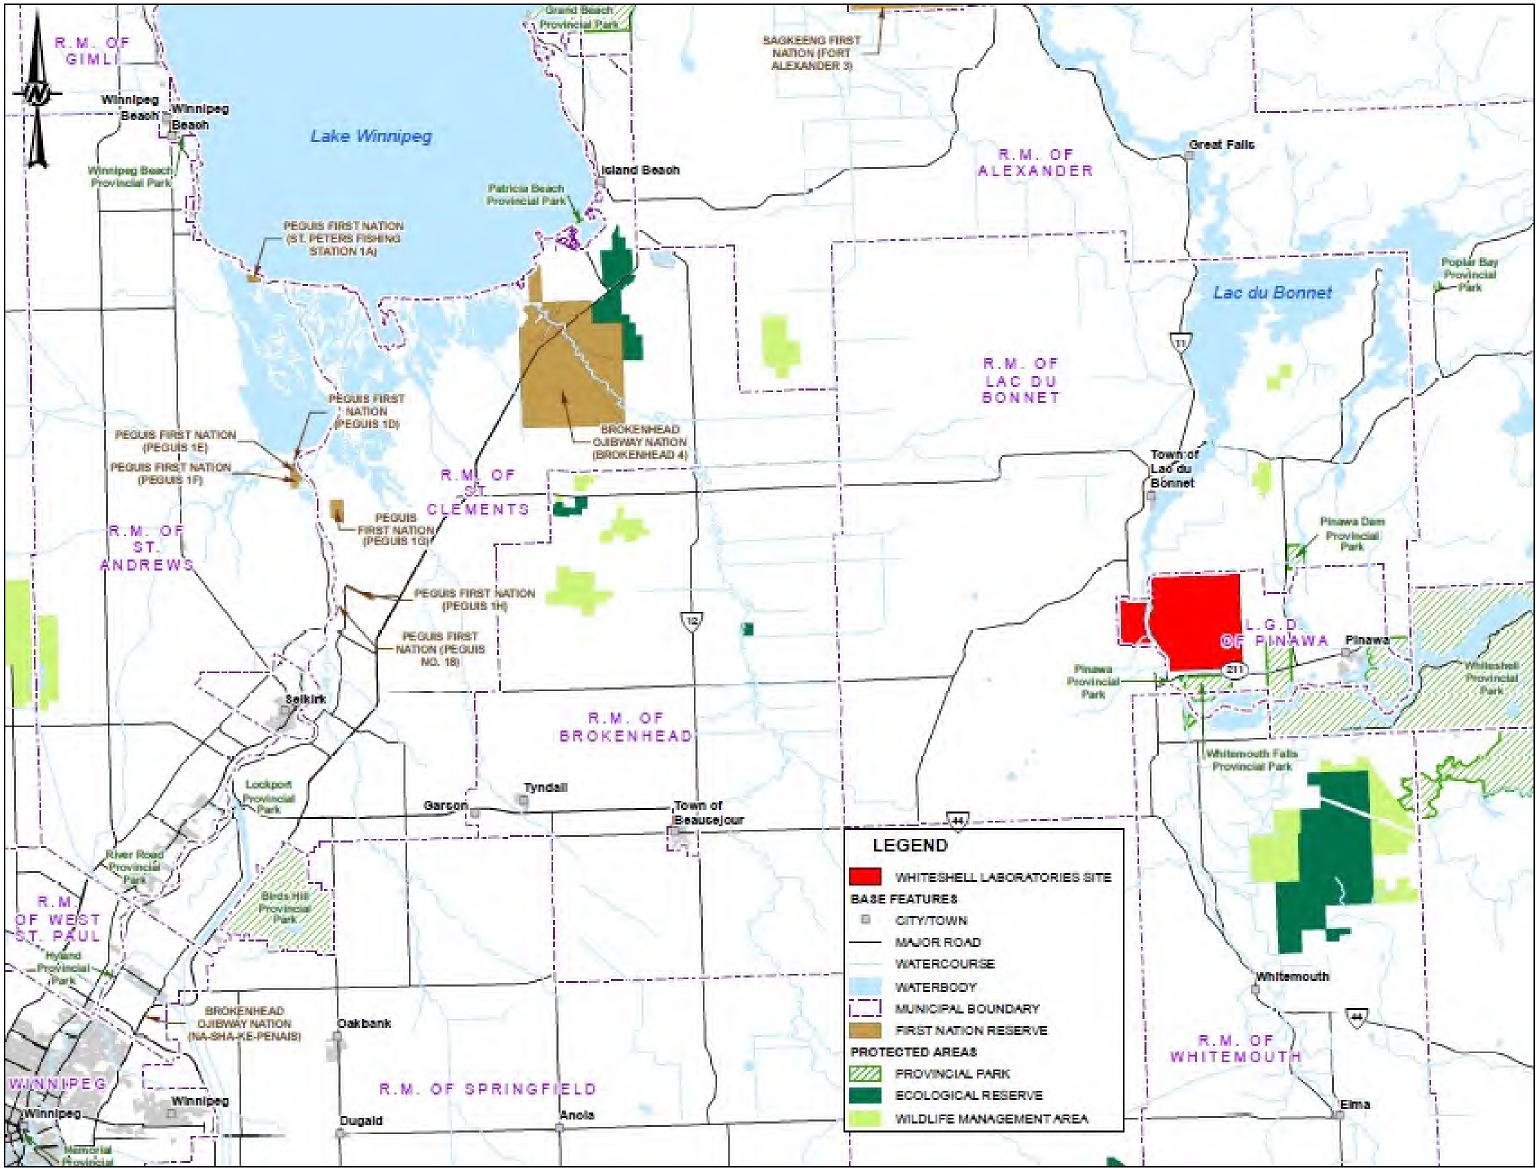

Figure 1.2: Aerial view of the WL site, including WMA, Inactive Landfill, Lagoon, and Main Campus relative to the Winnipeg River (figure adapted from WR-1 EIS figure 1.0-2) [40]

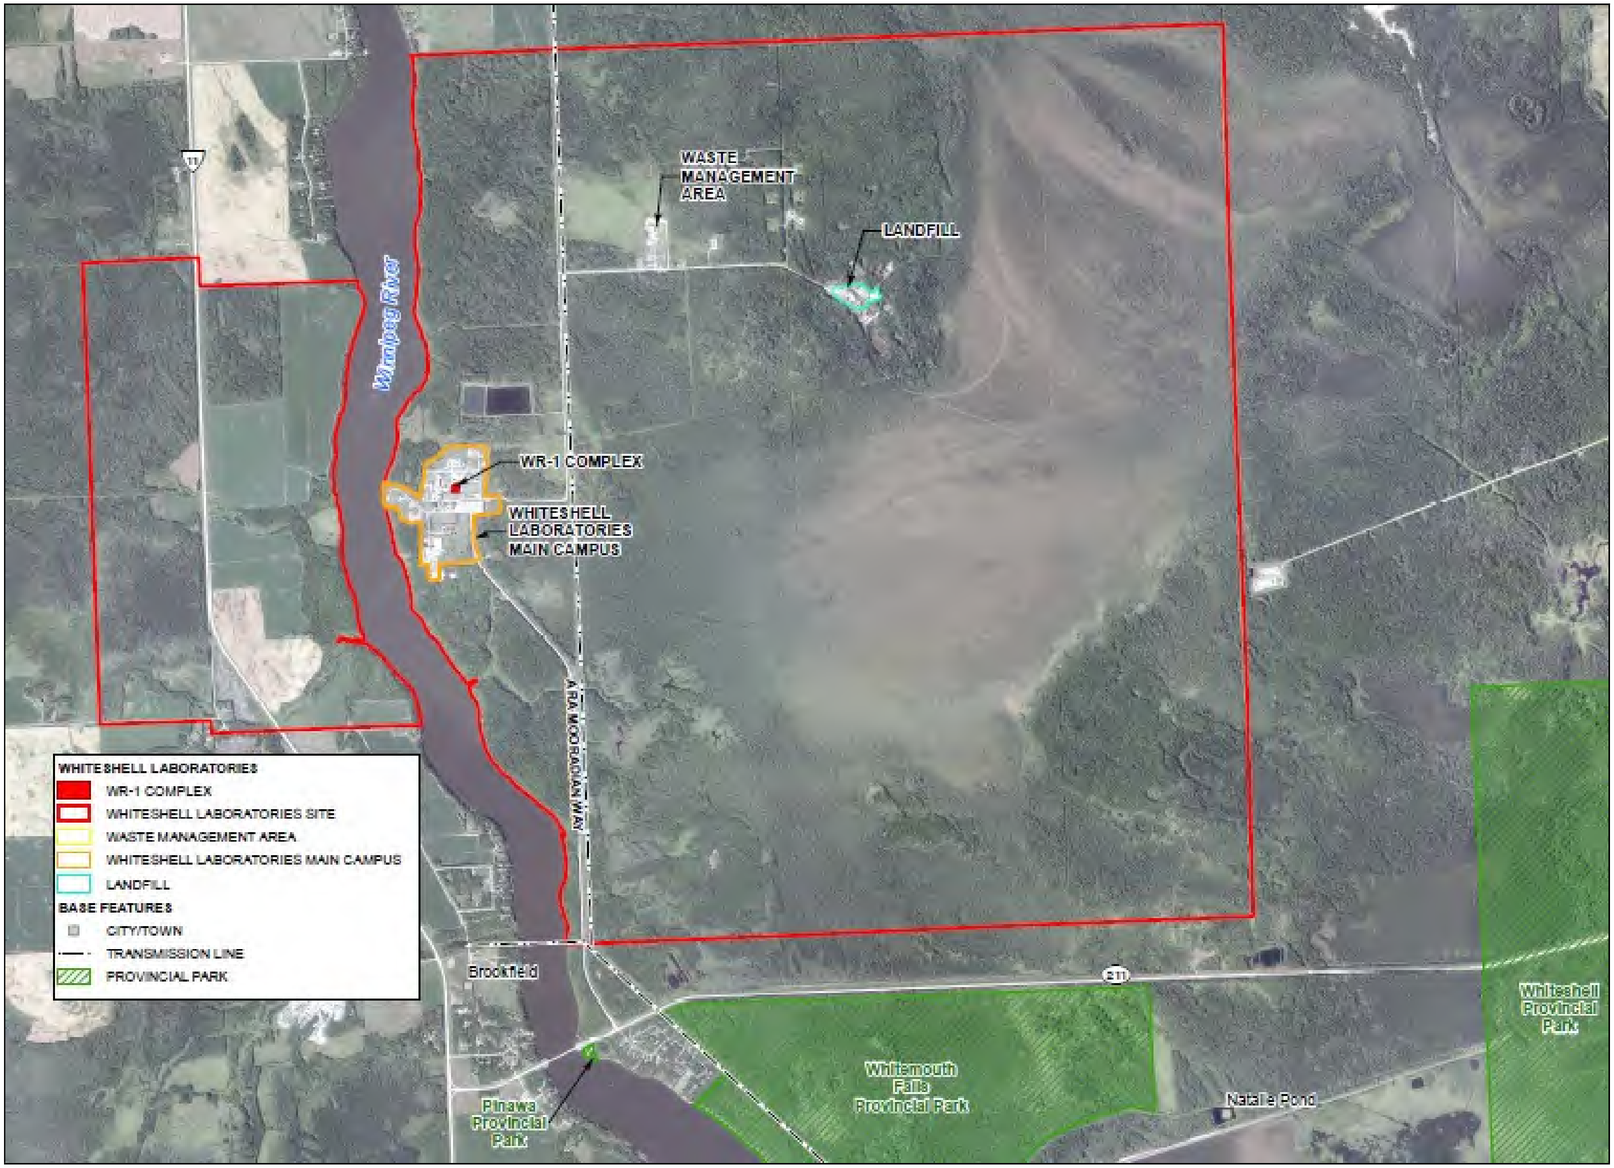

The following is a description of the buildings and infrastructure that were originally located on the WL site along with their purpose [41]:

- **Active Liquid Waste Treatment Center (ALWTC), Building (B) 200**: Historically used for receiving low-level liquid waste effluent (transferred from WR-1, Research laboratories in B300, and laundry / decontamination via underground piping), as well as processing and solidification of medium-level liquid waste (concentrating waste steam originating from the Shielded Facility (SF) building), which was eventually transported to and stored in the Waste Management Area (WMA).
- **Concrete Canister Storage Facility (CCSF)**: Used as part of the Concrete Canister Fuel Storage Program in order to demonstrate dry storage as a feasible alternative to water pool storage for irradiated reactor fuel, and eventually to store remaining used fuel from the WR-1.
- **Decontamination Centre, B411**: Used to provide decontamination services for equipment and tools, including laundry services for radioactively contaminated clothing.
- **Neutron Generator Facility, B300**: Originally located in the Research and Development Complex, this facility was used in the development of methods for the assay of fissile and fertile materials in reactor fuels and components, and eventually fast neutron activation analysis.
- **Sewage Lagoon**[1]: The Lagoon is comprised of a primary settling pond and a secondary pond (connected via a culvert), an outlet and a sewage lift station (B907), constructed of low permeability clay embankments placed on a prepared clay surface. The Lagoon was historically used to receive liquid wastes from lavatories, showers and non-active drains. It is located just north of the main laboratory site.
- **Shielded Facility (SF), B300**: Also located in the Research and Development Complex and comprised of the Hot Cells facility, the SF was used to provide shielded, remote handling facilities in support of the CANDU Reactor Safety research programs and other activities involving radioactive materials. The Immobilized Fuel Test Facilities were used for experiments involving radioactive materials, in support of the Canadian Nuclear Fuel Waste Management and CANDU Reactor Safety research programs.
- **Van de Graff Accelerator Facility, B300 (four rooms)**: This facility housed the accelerator, a target room and a control room. The Van de Graff Accelerator operated from 1970 to 1997.
- **Waste Management Area (WMA)**: Used for storage of low level radioactive wastes (LLW) and intermediate radioactive wastes (ILW), irradiated fuel waste, high level wastes (HLW), and other hazardous chemicals, the WMA includes a variety of buildings, unlined earth trenches, in-ground concrete bunkers and other storage bunkers, concrete stand pipes, and amine storage tanks (see figure 3.3 in section 3.2.4).

[1] Referred to henceforth as the Lagoon.

- **Whiteshell Reactor #1 (WR-1), B100**: Used from 1965 to 1985 to demonstrate the organic-cooled reactor concept, using heavy water as the moderator. The facility was also used for engineering tests on fuels, fuel channels and reactor coolants. After shutdown in 1985, the reactor was defueled and placed in a safe, secure, shutdown state. The irradiated fuel from WR-1 is currently stored in the CCSF.

The WL site has one main continuous liquid effluent discharge point into the Winnipeg River, the Process Water Outfall[2], located about 8 meters offshore on east side of the river.

See figure 1.3 for the original WL site layout and location of the Process Outfall. Detail on the progress of the decommissioning activities related to the buildings and infrastructure at the WL site can be found in section 1.2.3.

[2] Referred to henceforth as the Process Outfall.

1.2.2 Project Overview

As described in CMD 19-H4, following AECL's 1997 decision to discontinue operations and close the WL site, an initial strategy for decommissioning was developed [41]. The proposed strategy included the following stages:

- ***Decontamination and clean up*:** Bringing nuclear and radioisotope buildings and facilities into a safe, secure, interim end state and completely decommissioning the Van de Graaf Accelerator and Neutron Generator.
- ***Storage-with-Surveillance:*** Conducting monitoring and surveillance of remaining buildings and facilities, placing most waste management facilities in the WMA into a passive control state, as well as establishing interim processing, handling and storage facilities (required for monitoring, surveillance and decommissioning project activities).
- ***Final decommissioning*:** Completely decommissioning the WL site to the final end state. During this stage, infrastructure refurbishment and rebuilding were expected to be required, in order to maintain the facilities under monitoring and surveillance.

This strategy explained that a safety case for the *in situ* disposal of 21 LLW trenches in the WMA and river sediments downstream of the Process Outfall would be provided to, and assessed by the CNSC at a future date [34][41]. These activities were also expected to be followed by a 200 year period of institutional control, during which performance of any *in situ* disposal components would be monitored and controlled by CNL, with regulatory oversight by the CNSC [41 to 42].

In April of 2002, AECL submitted an application to the CNSC to replace their existing NRTEOL with a six–year decommissioning licence, in order to begin implementing their proposed decommissioning strategy. In a two-part public hearing, held on September 12th and November 14th of the same year, the Commission considered submissions from intervenors, CNSC staff and AECL, including the *Whiteshell Laboratories Decommissioning Project Comprehensive Study Report* [41] which was produced in accordance with the EA requirements under the *Canadian Environmental Assessment Act, 1992* (CEAA 1992) (see section 2.2 for more information on this EA). The Commission accepted CNSC staff recommendations and concluded that the approved activities to be carried out under the initial licence would result in the safe shutdown of facilities and gathering of information necessary for the planning, preparation and assessment of future decommissioning activities. In 2003, the Commission granted a decommissioning licence (NRTEDL) that was valid until December 31, 2008 [43].

In April of 2008, AECL submitted an application to renew this decommissioning licence for a 10 year licence period, in order to complete ongoing decommissioning activities, based on an accelerated schedule. Although the original decommissioning plan had not been fundamentally altered, deferment periods[3] had been eliminated wherever possible, allowing AECL to reduce the number of years for storage-with-surveillance activities [44]. In a public hearing held on November 5th of the same year, the Commission renewed the WL site NRTEDL from January 1, 2009 until December 31, 2018 [45].

[3] A period of monitoring and surveillance when no significant decommissioning work is in progress.

Following the restructuring of AECL in 2014, several administrative changes were made to the NRTEDL. In November 2014, the licence was transferred to CNL from AECL. In January 2016, the address of the facility was changed, and a new licence in the updated licence format and a Licence Condition Handbook (LCH) were issued to CNL. No changes to authorized activities were introduced in the updated licence or LCH [46].

On May 16, 2016, the CNSC received a Project Description from CNL proposing an alternative strategy (*in situ*) to decommissioning the WR-1 reactor, to the existing decommissioning strategy of dismantlement. The CNSC determined that the proposed project to *in situ* decommission the WR-1 reactor would require a federal EA, pursuant to *Canadian Environmental Assessment Act, 2012* (CEAA 2012). The official public record of this EA process can found on the Canadian Environmental Assessment Registry website (reference no: 80124). The regulatory review process for the proposed *in situ* strategy under the CEAA 2012 and the NSCA are still underway. The proposed *in situ* strategy for the WR-1 project is thus out of scope from this licence renewal.

Given that more time is needed by CNL to address public, Indigenous and federal comments in the ongoing EA for the proposed *in situ* WR-1 reactor and the need to continue approved decommissioning activities for the site, on March 13, 2018 CNL submitted a request for a one year licence renewal. This request included no changes to the existing activities or licence conditions, and was approved by the Commission on August 1, 2018. The licence was extended until December 31, 2019 [47].

According to the accelerated project plan, CNL plans to have the entire WL site decommissioned to its final end-state within the requested 10 year licence period. Furthermore, in addition to the ongoing EA and associated documents related to the proposed *in situ* strategy for the WR-1, CNL intend to develop and present a safety case to CNSC staff, in order to gain authorization for *in situ* disposal of 21 underground LLW trenches. The concept for *in situ* disposal of these trenches was included under the decommissioning licence in 2003 by the Commission, but the safety case must still be approved. This is expected to be completed and submitted to the CNSC over the next licencing period [34].

1.2.3 Decommissioning Progress

Since the granting of the initial decommissioning licence in 2003, many planned activities have been completed. Table 1.1 provides a summary of decommissioning activities to date [1][14][34][35][44].

Table 1.1: Decommissioning activities completed to date

Facility	Activities and components completed	Completed
Active Liquid Waste Treatment Center (B200)	• Cementation of Active Liquid Wastes from historical fuel reprocessing experiments completed • Building shut down, operationally cleaned up and final decommissioning commenced	Previous licence period
Concrete Canister Storage Facility (CCFS)	• No activities - continued operations, in support of decommissioning	-

Facility	Activities and components completed	Completed
Decontamination Center (B411)	• Relocation and reconfiguration of laundry and decontamination services • Building decommissioned and demolished • Building debris packaged and transported off site	Previous licence period
Neutron Generator	• Dismantled and removed	Prior to 2005
Sewage Lagoon	• No activities. Continued operations, in support of decommissioning	-
Shielded Facilities (SF) (B300) and other Main Campus nuclear facilities	• Decommissioning and demolition of hot cell 12 (hot cells 6-11 share ventilation with cells 1-5) and storage blocks dismantled and sealed • Decommissioning and demolition of SF warm cells 14 to 18	Between 2005 and 2007
Shielded Facilities (SF) (B300) and other Main Campus nuclear facilities	• Decommissioning and demolition of radioisotope laboratories (including main radioisotope Research and Development complex) • Thermal Hydraulics Test Facility shut down and clean up commenced	Previous Licence period
Van de Graff Accelerator	• Dismantled and removed	Prior to 2005
Waste Management Area	• Shielded Modular Above-Ground Storage (SMAGs) building constructed and brought to operational status, in order to enable future decommissioning plans • Contaminated Soil Storage Facility constructed	Previous Licence period
Waste Management Area	• Remaining Experimental Cesium Pond soil waste excavated, packaged and transported offsite	Between 2017 and 2018
WR-1 Building (B100)	• Remaining unirradiated WR-1 fuel material removed from the WL site • Planning and design activities for later activities	Previous Licence period
Other site activities	• Central oil-fired heating system shut down and transition of building heating to electric/propane; related fuel storage tanks also removed • Final decommissioning of SLOWPOKE Demonstration Reactor completed - all major components were removed • Shutdown and demolishment of various non-nuclear buildings	Previous Licence period

CNSC staff regularly report on the performance of licensees to the Commission. In 2012, an update was provided on the status of the decommissioning progress [48] at the WL site, as well as in 2014 [49] and 2016 [50]. In 2018, the WL site was included in the 2017 *CNL Progress Update for CNL's Prototype Waste Facilities, Whiteshell Laboratories and Port Hope Area Initiative* (CMD 18-M30) [51]. As noted in these updates, CNL has planned, implemented and completed decommissioning activities in accordance with CNSC approved decommissioning plans, and CNSC staff have been satisfied with the overall performance.

The planned activities for the requested 10 year licence period are outlined in table 1.2.

Table 1.2: Remaining facilities to be decommissioned and related activities

Facility to be decommissioned	Proposed activities and components
Active Liquid Waste Treatment Center (B200)	• Decommissioning of remaining ALWTC equipment (in progress), and demolition of the building
Concrete Canister Storage Facility (CCFS)	• Complete defueling and decommissioning/demolition of the CCSF and the Demonstration Canister Storage Site and remediation of the area • Retrieval of fuel baskets from canisters, transfer to a certified shipping container for transport to CRL for storage • Decontamination of empty canisters with radioactive contamination as needed, and demolishment
Sewage Lagoon	• Options for decommissioning the Lagoon are currently being evaluated, and an Environmental and Human Health Risk Assessment is underway
Shielded Facilities (B300) and other Main Campus nuclear facilities	• Decommissioning of remaining Hot Cells and associated active exhaust ducting, active drain systems, and radioisotope laboratories (maintained to support future decommissioning activities) • Decommissioning of remaining facilities and systems in B300 and demolition of buildings, once operations have ceased
Waste Management Area	• Deactivation, demolishment and/or remediation of all buildings, structures, and grounds within the WL site WMA (with the exception of 21 LLW trenches – See figure 1.4) • Retrieval, characterization and re-packaging of LLW, ILW, and HLW from underground trenches and waste bunkers (as necessary), for shipment to a suitable licensed storage/disposal facility
WR-1 Building (B100)	• Complete remediation and removal of the building • All activated and contaminated components removed, packaged and dispositioned at off-site facilities • Facility structure decontaminated and demolished
Other site activities	• Decommissioning and demolition of all remaining non-nuclear buildings and support infrastructure (e.g., administrative offices, non-active laboratories, workshops, storage buildings, vehicle garages, shipping and receiving areas)

2.0 REGULATORY OVERSIGHT

The CNSC regulates nuclear facilities and activities in Canada to protect the environment and the health and safety of persons in a manner that is consistent with Canadian environmental policies, acts and regulations and with Canada's international obligations. The CNSC assesses the environmental effects of nuclear facilities and activities at every phase of their lifecycle. This section of the EPR Report discusses the CNSC's regulatory oversight of environmental protection (EP) measures at the WL site.

To meet CNSC's regulatory requirements, CNL is responsible for implementing and maintaining EP measures that identify, control and (where necessary) monitor all releases of radiological and hazardous substances and effects on human health and the environment, from the WL site. These EP measures must comply with, or have implementation plans in place to comply with, the regulatory requirements included in the WL decommissioning licence. The regulatory requirements for the WL site can be found throughout the Regulatory Oversight section.

2.1 Environmental Protection Reviews and Assessments

Under the NSCA, an assessment of the environment is part of the ongoing lifecycle EP framework, whereby EPR Reports such as this one, are produced. No decision is made on the EPR itself, as the information is intended to inform and support the regulatory decision being sought from the Commission by the licensing matter explained in the body of the staff CMD 19-H4.

Depending on the scope and impact of project activities, legislation such as the CEAA 2012 and the former CEAA 1992 may require the completion of an EA [52]. The purpose of an EA is to identify the possible environmental effects of a proposed project, and determine whether these effects can be adequately mitigated to protect the environment and heath of persons. A positive EA decision, by the commission, concluding no significant adverse effects is required before a licence can be granted.

The following section provides information on the Comprehensive Study EA [53] completed under the former CEAA 1992, as well as information regarding elements of the EA FUP. The EA FUP verifies the accuracy of the predictions of the EA and the effectiveness of the mitigation measures. The CNSC ensures that EA FUPs within the CNSC's mandate are incorporated into the licensing process.

2.1.1 Comprehensive Study EA under CEAA 1992

Under the former CEAA 1992 [52], an EA was conducted for the currently licensed decommissioning activities at the WL site. In 1999, AECL began to prepare plans for decommissioning of the facilities located on the WL site, and as described in section 1.2, later applied to the CNSC for a decommissioning licence. Under CEAA 1992, the CNSC determined that a Comprehensive Study EA was required. This EA was carried out by the CNSC and the Department of Fisheries and Oceans Canada (DFO), who were designated as Responsible Authorities (RAs) under this former Act.

A document outlining the scope of the project and assessment was issued by the CNSC in December 1999, following consultation with the public and other federal and provincial government departments. In 2001, the *Whiteshell Laboratories Decommissioning Project Comprehensive Study Report* (CSR) [41] was produced by AECL, in accordance with the requirements of the EA process.

Following CNSC and DFO staff findings that all of the CEAA 1992 requirements had been adequately fulfilled, in 2002 the Minister of the Environment agreed that the project was not likely to cause significant adverse environmental effects, taking into account the implementation of mitigation measures [554]. CNSC rendered a licensing decision in December 2002, and the decommissioning licence was granted [43].

The EA process identified the need for an EA FUP [4] designed to validate the predicted environmental effects and effectiveness of the mitigation measures. Further details of this are provided in section 2.1.2.

2.1.2 EA Follow-Up Program

In May 2002, CNL submitted a draft EA FUP for the WL site, to the CNSC and DFO. Following incorporation of feedback from both RAs, the program was finalized in June 2002. AECL has submitted Annual Progress Reports on the EA FUP since the 2002 approval of the EA FUP, and CNL continues to meet this commitment.

The objectives of the EA FUP are as follows [4]:

- verify the accuracy of the EA
- determine the effectiveness of any mitigation measures that have been implemented
- optimize the monitoring and surveillance program at the WL site
- confirm that appropriate mitigation measures are implemented
- develop appropriate responses to unforeseen events
- identify effects of the project that may not have been predicted

Achievement of these objectives continues to be accomplished using monitoring, surveillance and inspection activities, which are supported by planning, data collection, analysis, evaluation and reporting. The program is structured around nine themes of work, referred to as Work Packages. These Work Packages are shown in table 2.1, along with the associated Work Tasks and overall status.

Table 2.1: Environmental assessment Follow-Up Program elements and status [4][25][55]

#	Work package	Component	Description	Completed activities and status
1	Routine environmental monitoring program (EMP)	Environmental	Establishment of an EMP in order to confirm the CSR EA conclusions, as well as ensure remediation measures are effective throughout all phases.	Monitoring has continued over the entirety of the project life-cycle, and these activities are ongoing. As decommissioning activities continue, this program adapts as needed.
2	Air and meteorology	Environmental	Collection of monitoring data, in order to establish a site baseline, as well as ongoing collection and monitoring of data (during building demolition), in order to ensure effectiveness of mitigation measures, and that environmental effects remain insignificant.	Monitoring stations related to air and meteorology were established, collection of baseline data has been completed, and various buildings have been demolished. The collection of data and monitoring continues.
3	Fitness for service (FFS) of WMA Facilities	Interim Storage and End state Support	An initial assessment of the fitness-for–service of structures where storage would continue during decommissioning activities, including validation of facility integrity and geological/ hydrogeological conditions around facilities.	Various activities have been completed, including: confirmation of structural integrity of buildings, evaluation of potential impact of containment transport from individual storage facilities / areas, establishment of remediation criteria related to containment transport impacts, relative to waste removal to final disposal. CNL continues to evaluate potential impacts of containment transport from storage facilities and areas, as well as remediation requirements and timeframes, where appropriate.
4	Confirmation of hydrogeological conditions at the WMA	Interim Storage and End state Support	Enhanced hydrogeological monitoring in order to evaluate fitness-for–service of interim storage structures, as well as collect detailed information needed in order to develop safety case for *in situ* disposal of LLW trenches.	Detailed planning for enhanced monitoring system completed. Although many activities have been completed, installation and refurbishment of monitoring wells, evaluation and reporting on interim storage environment, as well as monitoring and data collection for the safety analysis to support LLW *in situ* end state are all ongoing.

5	Interim remediation of WMA Facilities	Interim Storage and End state Support	Interim remediation plans for structures and areas of the site where facility life-cycle would not be adequate to manage the wastes.	The following activities are and have been ongoing: recovery of, processing, packaging and provision of enhanced interim storage of irradiated fuel (from standpipes), and other wastes; retrieval of LLW from trenches not suitable for *in situ* disposal (irradiator reactor components in trench #6, soil and waste contaminated by WR-1 waste water in trench #10, arsenic from trench #1 and others).
6	Inactive Landfill Enhanced Monitoring	Interim Storage and End state Support	Enhanced monitoring in order to confirm the integrity of hydrogeological environment, control groundwater impacts and collect data in preparation for site closure.	Detailed planning for enhanced monitoring system completed, along with installation and refurbishment of monitoring wells. Evaluation of interim storage environment, monitoring and data collection, as well as preparation of a closure plan will continue over the decommissioning period.
7	Sewage Lagoons Enhanced Monitoring	Interim Storage and End state Support	Enhanced monitoring in order to confirm compliance of discharges, assess impacts to groundwater and the Winnipeg river, as well as development of a closure plan.	Detailed planning for enhanced monitoring system completed, along with installation and refurbishment of monitoring wells. Monitoring and collection of data, compliance evaluation, assessment of groundwater impacts, as well as preparation of a closure plan are all ongoing.
8	River Sediments Enhanced Monitoring	Interim Storage and End state Support	Enhanced monitoring of river sediments in order to ensure the CSR assessment remains valid, as decommissioning activities continue.	Identification of depositional areas above the hydroelectric dam sites for core sampling completed, agreement signed with DFO and CNSC for target sampling locations, as well as collection and analyzation of Caesium-137, following which a baseline was established. Re-sampling will continue at 20, 40 and 60 year marks (years 2026, 2046 and 2066, respectively), in order to validate CSR conclusions.
9	Establish and maintain project communications mechanisms	Public communication	Interactive public communication activities in order to continue communications with stakeholders, including municipal governments, Indigenous people, other interested parties and members of the public in the WL site region.	Communication contact list was assembled and verified, input was solicited from stakeholders in the contact list, in order to establish formal and informal communication measures and communication processes, based on this feedback. Communications will be ongoing for the remainder of project activities.

CNSC staff continue to review the follow-up activities, in order to ensure that the EA FUP objectives are being met. To date, CNL has continued to implement follow-up activities as required. EA FUP elements associated with the monitoring of emissions and effluents or the receiving environment are incorporated within the environmental management program, as needed.

2.2 Detailed Decommissioning Plan

Decommissioning activities for research and test facilities such as those at the WL site are regulated by the CNSC. The following sub-section provides high level information with respect to the Detailed Decommissioning Plan.

Decommissioning plans document the decommissioning strategy and end-state objectives; the major decontamination, disassembly and remediation steps; the approximate quantities and types of waste generated; an overview of the principal hazards and protection strategies; and an estimate of cost. As a full lifecycle regulator, the CNSC will continue to monitor and remain aware of the end state of the WL site. As decommissioning activities are completed, they are expected to result in a decrease in both radiological and hazardous releases to the environment, as the WL site reaches its eventual end state.

The decommissioning strategy for the WL site is documented in the *Whiteshell Laboratories Detailed Decommissioning Plan: Volume 1 – Program Overview* [3] (along with 11 subsequent volumes).

CNL is planning, implementing and completing decommissioning activities, in accordance with detailed decommissioning plans. Revisions to the program overview are currently underway, and subsequent volumes are developed when so required by CNL. Through analysis of these plans, staff can provide a high level assessment of how the project/environmental interactions will change over time.

Progress on activities at the WL site can be found in section 1.2.2 of this report, and in further detail in the Waste Management SCA of the CMD 19-H4.

2.3 Regulatory Framework

The EP program at the WL site was designed and implemented in accordance with REGDOC 2.9.1-2013, and includes derived release limits (DRLs) (N288.1-08) and public dose modelling. The licensee has also re-evaluated their EP program against the latest version of REGDOC 2.9.1-2017 and the associated CSA standards. Specific implementation dates are shown in table 2.2 below.

Table 2.2: Status of WL site Environmental Protection Measures with respect to implementation of regulatory documents and standards

Regulatory document or standard	Status
CNSC Regulatory Document REGDOC 2.9.1 *Environmental Protection: Policies, Programs and Procedures* (2013) [56]	Implemented
CSA N288.1-08, G*uidelines for calculating derived release limits for radioactive material in airborne and liquid effluents for normal operation of nuclear facilities* [57]	Implemented
CSA N294-09 (reaffirmed 2014), *Decommissioning of Facilities Containing Nuclear Substances* [58]	Implemented.
CSA N288.4-10, *Environmental monitoring programs at Class I nuclear facilities and uranium mines and mills* [59]	Scheduled: January 1, 2020
CSA N288.5-11, *Effluent Monitoring Program at Class I Nuclear Facilities and Uranium Mines and Mills* [60]	Scheduled: January 1, 2020
CSA N288.6-12, *Environmental risk assessment at Class I nuclear facilities and uranium mines and mills* [61]	Scheduled: January 1, 2020
CSA N288.7-15, *Groundwater protection programs at class I nuclear facilities and uranium mines and mills* [62]	Scheduled January 1, 2020
CSA N288.8-17, *Establishing and implementing action levels to control releases to the environment from nuclear facilities* [63]	Scheduled: January 1, 2020
CNSC Regulatory Document REGDOC 2.9.1, *Environmental Principles, Assessments and Protection Measures, version 1.1* (2017) [64]	Scheduled: January 1, 2020

CNSC staff confirm that CNL has either implemented programs in accordance with the relevant EP regulatory documents or standards, or has implementation plans in place [34]. CNL has committed to a schedule such that their programs will be designed and implemented, in accordance with REGDOC-2.9.1-2017 [64] and the full range of associated CSA standards within the initial year of relicensing (i.e., January 1, 2020).

In addition to requiring the evaluation of programs against regulatory documents and standards and the submission of these programs to the CNSC, licensees are also required to regularly report on the results of these programs. Reporting requirements are specified within the *Radiation Protection Regulations* [65] (public dose), the licensees accepted programs or as specified within the LCH.

CNL is required to submit Annual Compliance Monitoring Reports, including an environmental monitoring report that details the results of the environmental protection measures related to the decommissioning of the WL site. These annual reports and any associated special studies are reviewed by CNSC staff for compliance and verification as well as trending. The 2018 annual report summary is available on CNL's website [66].

As noted in section 1.2.3 of this EPR Report, CNSC staff provided updates to the Commission on the status of the decommissioning progress at the WL site, which included reports on the performance of activities conducted at CNL sites, in 2012 [48], 2014 [49], 2016 [50] and in 2018 [51]. Furthermore, Regulatory Oversight Reports (ROR) are the CNSC's standard mechanism for updating the Commission on the operation and regulatory performance of licensed facilities. A ROR addressing CNL operated facilities in Canada, including the WL site, will be reported to the Commission in November of 2019.

2.3.1 Environmental Protection Measures

To meet CNSC's regulatory requirements under REGDOC-2.9.1 [56][64], CNL is responsible for implementing and maintaining EP measures that identify, control and monitor releases of radioactive and hazardous substances and effects on human health and the environment, from the WL site. EP measures are an important component of the overall requirement for licensees to make adequate provision for protection of the environment.

This and the following sub-sections provide a brief summary of the WL site EP framework and the status of each specific EP measure, relative to the latest regulatory document or CSA standard. Section 3.0 of this EPR Report summarizes the results of these programs/measures against relevant regulatory limits, environmental quality objectives/guidelines and discusses any trends of interest.

CNL was required to update the Environmental Protection Program (EnvP) during the previous licence period, in order to conform to REGDOC-2.9.1-2013 [56]. The program includes the following elements:

- Environmental Management System (EMS)
- Effluent Emissions Control and Monitoring:
    - derivation of Derived Release Limits (DRLs) in accordance with CSA N288.1-08
    - Effluent Verification Monitoring Program (EVMP)
- Receiving Environment Monitoring Program:
    - Environmental Monitoring Program (EMP)
    - Groundwater Monitoring Program (GWMP)
- EA FUP (section 2.2)

Further details on these programs can be found in the following sub-sections.

2.3.2 Environmental Management System

An EMS refers to the management of an organization's environmental policies, programs and procedures in a comprehensive, systematic, planned and documented manner. It includes the organizational structure, planning and resources for developing, implementing and maintaining policy for environmental protection. The EMS serves as a management tool for integrating all of a licensees EP measures in a documented, managed and auditable process by:

- identifying and managing non-compliances and corrective actions within the activities, through internal and external inspections and audits
- summarizing and reporting the performance of these activities both internally (licensee management) and externally (Commission and public)
- training of personnel involved in these activities
- ensuring the availability of resources (i.e., qualified personnel, organizational infrastructure, technology and financial resources)
- defining and delegating roles, responsibilities and authorities essential to effective management

CNL has established and implemented an EMS for the WL site in accordance with REGOC-2.9.1-2013 [56]. The WL site has an EMS that has been registered to CAN/ISO 14001-2004 *Environmental Management Systems – Requirements with Guidance for Use* [67] since 2010. In 2018, the WL site EMS was recertified to ISO 14001-2015 [68]. CNSC staff have concluded that CNL has developed and implemented an EMS program at the WL site in compliance with CNSC regulatory requirements.

2.3.3 Environmental Risk Assessment

An environmental risk assessment (ERA) of nuclear facilities is a systematic process used to identify, quantify and characterize the risk posed by contaminants and physical stressors in the environment on human and other biological receptors, including the magnitude and extent of the potential effects associated with a facility. The ERA serves as the basis for the development of site-specific effluent and EMPs. These programs in turn inform and refine future revisions of the ERA.

As required by REGDOC-2.9.1-2013 [56], the 2001 CSR was used to inform the WL site EP measures for the previous licencing period. For the proposed licence period, CNL will be updating their EP measures in order to meet the requirements of REGDOC-2.9.1-2017 [64], which requires the establishment and maintenance of a site wide ERA, in accordance with CSA N288.6-12 *Environmental risk assessment at Class I nuclear facilities and uranium mines and mills* [61].

ERAs for the Lagoon and WMA are currently underway [35] in order to support future CNL decision-making related to site activities, and will be provided within the upcoming licence period. These will be followed by a site-wide ERA, prior to the January 2020 implementation date as outlined in table 2.2. The outcomes of these ERAs will help inform the updating of EP measures as needed and will be reported on through the Regulatory Oversight Report for CNL sites.

2.3.4 Effluent and Emissions Control and Monitoring

Controls on environmental releases are established in order to provide protection to the environment, as well as respect the principles of sustainable development and pollution prevention. The effluent and emissions prevention and control measures are established on the basis of industry best practice, the application of principles of optimization (e.g., in design) and as low as reasonably achievable (ALARA) principles, respect of legislated limits and results of an ERA (or in this case, the CSR produced under CEAA 1992 [41]).

The WL LCH contains site-specific DRLs [69] and Action Levels (ALs) [70], in order to control radiological effluents and emissions. The DRLs have been calculated using CSA N288.1-08, a radionuclide transport and exposure model that can be used to back-calculate release rates based on limiting exposure to a specified member of the public (representative person) to a dose less than the 1 mSv per year, the regulatory dose limit (as prescribed within the *Radiation Protection Regulations* [65]). The ALs in place at the WL site are set at a fraction of the DRL, in order to serve as an early warning of potential loss of control.

The most recent DRLs were provided for the WL site in 2016 [69], developed in accordance with CSA N288.1-08. In January 2020, CNL plans to transition to new ALs, with the implementation of CSA N288.8-17, scheduled for January 2020. These new ALs will be derived from actual operating expectations and performance, in accordance with CSA N288.8. This will likely result in significantly lower ALs than those currently in use.

CNL has established an Effluent Verification Monitoring Plan [71] at the WL site, which is in compliance with REGDOC-2.9.1-2013 [56]. CNL has indicated that it will be revised to address the additional requirements and guidance associated with REGDOC 2.9.1-2017 [64] and CSA Standard N288.5-11, *Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [60].

Based on review and assessment of the EVMP results presented in CNL's reports, CNSC staff conclude that the EVMP currently in place for the WL site continues to protect the public and the environment.

2.3.5 Environmental Monitoring Program

CNSC requires licensees to design and implement an EMP specific to the monitoring and assessment requirements associated with their facility, and the environment within which the facility is situated. The program is required to:

- measure contaminants in surrounding environmental media of the facility or site
- determine the effects if any on the of the site or facility operation on people and the environment
- serve as a secondary support to the EVMP to demonstrate the effectiveness of emission controls and the adequacy of effluent monitoring

More specifically, the program must obtain the environmental data necessary for the calculation of public dose, in order to demonstrate compliance with the public dose limit (1 mSv per year). The program design must also address the potential environmental interactions identified at the site (as identified in the CSR produced under CEAA 1992 [41]). The major focus at the WL site is on radiation and radionuclides, though hazardous substances are included within monitoring activities associated with the sewage lagoons and site groundwater. Section 3.0 of this EPR Report provides a summary of the results of site monitoring activities and an evaluation of the current state of the environment at the WL site, including dose to the public.

CNSC staff confirm that for the previous licence period, CNL conducted their EMP as per their current licensing basis, and were in compliance with REGDOC-2.9.1-2013 [56].

2.4 Greenhouse Gas Emissions

A core element of the CNSC requirement for an EMS is the identification of all regulatory requirements applicable to the facility whether under the NSCA or other federal or provincial legislation. The EMS must ensure that programs are in place to respect these requirements.

While there are a range of broadly applicable federal environmental regulations (e.g., petroleum products storage tanks, environmental emergency regulations), the management of GHG emissions has been identified as a national priority.

Under the federal *Canadian Environmental Protection Act, 1999* (CEPA, 1999) [72], CNL is required to monitor and report on GHG emissions [73]. Since 2013, nuclear facilities that emit more than the 50,000 tons of CO_2 equivalent (CO_2e) emission reporting threshold on an annual basis must report their GHG emissions. The WL site has been well below all GHG emission thresholds since 2013; however, CNL continues to report GHG emissions from the site in their Annual Compliance Monitoring Report. Information on GHG emissions at the WL site can be found in section 3.1.1.2.

The CNSC maintains a collaborative working relationship with Environment and Climate Change Canada through a formal Memorandum of Understanding. This ensures a coordinated regulatory approach is achieved with respect to meeting all federal requirements associated with environmental protection.

3.0 STATUS OF THE ENVIRONMENT

The following sections of this EPR Report include summaries of project-environment interactions that were assessed by CNSC staff and deemed to be of specific public, Indigenous and/or regulatory interest including atmospheric, aquatic, terrestrial and hydrogeological environments and human health, for the licence application by CNL to renew the WL site licence.

It should be noted that environmental components are regularly reviewed through annual reporting requirements and CNSC compliance verification activities, as detailed in other areas of this report. These are reported to the Commission in the environmental protection safety and control areas of licensing Commission Member Documents and RORs.

This section provides a summary of the status of the environment around the WL site. It first includes a description of the radiological and hazardous releases to the environment (section 3.2), followed by an assessment of any potential effects to human health and the environment, as a result of exposure to these contaminants (section 3.3). Further, sub-sections of section 3.3 provide general descriptions of the environment itself, at and around the WL site.

3.1 Releases to the Environment

3.1.1 Airborne Releases

3.1.1.1 Radiological Emissions

As part of the WL site EVMP, releases to the atmosphere are continuously monitored throughout the year. The main sources of radiological emissions at the site are from the WR-1 Building (B100) stack, the ALWTC (B200) roof vent, and the Hot Cells Facility and Immobilized Fuel Facility (B300) roof vent. For each of these facilities, radiological emissions are measured for gross alpha and gross beta. Additionally, tritium releases from the reactor building as a result of continuous airflow purging of the moderator system are also routinely collected and analyzed.

Table 3.1 provides annual release of radionuclides to the atmosphere for the licence period of 2009 to 2018, compared against DRLs developed by CNL and accepted by CNSC to ensure releases to the environment will not exceed the annual regulatory public dose limit of 1 mSv per year, which is recognized to be protective of human health. As shown in table 3.1, the radiological emissions from the WL site remain at a very small fraction of the DRLs.

Table 3.1: Annual radionuclide airborne releases from the WL site compared with applicable release limits (2009 – 2018) [5 to 14]

Emission	Tritium (Bq/yr)	Gross beta particulates (Caesium-137) (Bq/yr)	Gross alpha particulates (Pu-239) (Bq/yr)
DRL *(2009-2015)**	3.97E+16	6.19E+11	3.95E+16
2009	2.08E+10	6.24E+05	1.09E+05
2010	2.86E+10	7.80E+05	1.04E+05
2011	3.12E+10	3.38E+05	1.14E+05
2012	1.87E+11	4.06E+05	1.04E+05
2013	3.48E+10	3.95E+05	8.84E+04
2014	3.48E+10	3.95E+05	8.84E+04
2015	9.88E+10	2.29E+05	9.88E+04
DRL *(2016-2018)*	8.58E+15	3.60E+11	9.00E+10
2016	3.24E+10	2.12E+05	9.46E+04
2017	5.04E+10	2.24E+05	9.36E+04
2018	1.30E+10	1.70E+05	9.36E+04

*As described in section 2.3.4, DRLs ensure emissions do not exceed the public dose limit of 1 mSv per year.

3.1.1.2 Hazardous Emissions

The main sources of non-radiological emissions at the WL site are from the use of Number 2 fuel oil for heating, diesel fuel for site generators, and dust generation from sandblasting, excavation projects and vehicle traffic on site. It should be noted that in 2013, Number 2 fuel oil was replaced with propane. These sources release small quantities of carbon monoxide, nitrogen oxides, sulphur dioxide, hydrocarbons, and particulate matter. These substances are monitored for trending and continuous improvement purposes and are reportable to the National Pollutant Release Inventory (NPRI) if reporting thresholds are exceeded [74]. Table 3.2 provides the total annual hazardous emissions from the WL site and the NPRI reporting thresholds.

Table 3.2: Total annual hazardous emissions from the WL site (2009 to 2018) [15 to 24]

Parameter (Mg/year)	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	NPRI reporting threshold (Mg/year) [75]
Nitrogen oxides (NOx as NO_2)	9.06	7.86	7.24	6.20	3.65	1.03	1.04	0.91	0.75	0.54	20
Sulphur dioxide (SO_2)	2.67	2.32	2.14	1.66	0.89	0.02	0.03	0.02	0.02	0.01	20
Carbon monoxide (CO)	1.89	1.64	1.51	1.30	0.88	0.47	0.46	0.40	0.35	0.23	20
Total particulate matter ($PM_{10\ \&\ 2.5}$)	0.75	0.65	0.6	39.69*	42.51*	19.57	16.36	15.02	13.65	14.56	20
PM_{10}	0.38	0.33	0.30	10.26*	10.92*	5.01*	4.20*	3.85*	3.50*	3.72*	0.5
$PM_{2.5}$	0.09	0.08	0.07	1.11*	1.14*	0.53*	0.54*	0.41*	0.38*	0.39*	0.3
Volatile organic compounds	0.08	0.07	0.06	0.11	0.08	0.08	0.08	0.07	0.06	0.04	10

* As TPM, PM10 and PM2.5 were over the threshold, these were reported to NPRI. Increases in these parameters are a result of increased road dust from gravel roads and periods of dry weather.

GHG emissions from the WL site consist primarily of carbon dioxide, methane and nitrous oxides as a result of burning propane, use of diesel generators, on-site transportation, on-site landfill, and open-pit wood burning. They are measured in CO_2e tonnes which is a measure used to compare between gases that have different Global Warming Potential (GWP). Eliminating the use of Number 2 fuel for heating in 2013 reduced the average GHG emissions by 43%.

Hazardous emissions to air are reduced as decommissioning activities continue and demolished buildings no longer require heating (table 3.3). This decline is expected to continue with ongoing decommissioning activities. During the previous licence period, GHG releases remained below the reporting requirement of 10,000 CO_2e tonnes/a [76].

Table 3.3: Total estimated annual greenhouse gas emissions from the WL site (2009-2018) [15 to 24]

Year	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018
Greenhouse Gas (CO_2e tonnes/a)*	8,596	7,463	8,056	6,310	4,260	1,940	1,957	1,883	1,873	1,678

* CO_2e tonnes: A unit of measure used to compare between GHGs with different GWPs. For example, the GWP for methane is 25. This means that emissions of one metric ton of methane are equivalent to emissions of 25 metric tons of CO_2. In 2013, the GWP for methane and nitrous oxide were changed from 21 to 25 and 310 to 298 respectively under the *CEPA, 1999* Notice with Respect to Reporting of GHGs for 2013.

3.1.1.3 Conclusions

Based on CNSC staff's review of the results of CNL's EVMP, CNSC staff conclude that CNL's reported releases of nuclear substances to the atmospheric environment from the WL site have remained below CNSC approved DRLs for air emissions during the current licensing period. Additionally, CNL continues to monitor and report on hazardous substances released to the atmosphere, including the monitoring of GHG emissions. CNL continues to provide adequate protection of people and the environment from atmospheric releases.

3.1.2 Waterborne Releases

As part of the WL site EVMP, releases of radiological and hazardous contaminants to surface water are monitored on a weekly basis throughout the year. The main sources of effluent releases at the WL site are from the Process Outfall and the Lagoon. The Outfall effluent is composed of stormwater runoff from paved roadways around buildings, cooling water used in process and experimental facilities, and holding tank discharges including those from the ALWTC. The discharge locations are shown in figure 3.1.

Figure 3.1: WL site and discharge locations Process Outfall and, Lagoon (modified from figure 11-1 [14])

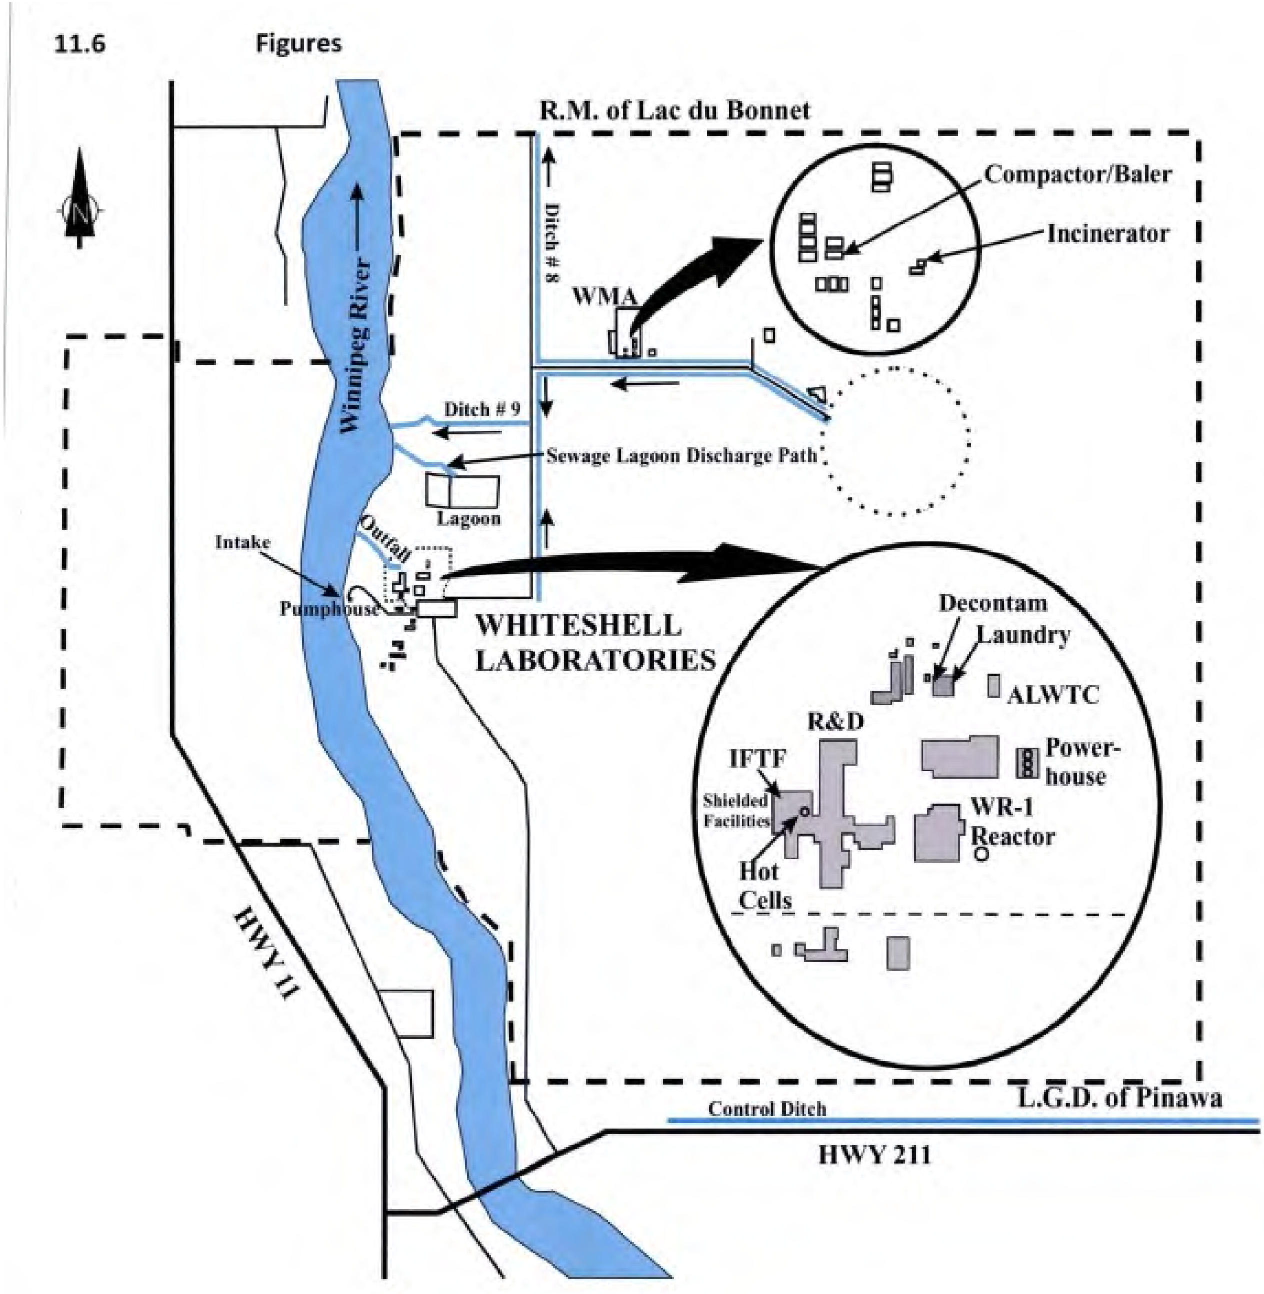

Figure 11-1
Effluent Monitoring Locations

The Lagoon collects and treats prior to discharge, sanitary and wastewater from most buildings on the site, as well as from the laundry facility.

3.1.2.1 Radiological Effluent

Radiological effluent releases are measured for gross alpha and beta, total uranium, plutonium-239/240, americium-241, strontium-90 and caesium-137. Table 3.4 provides the total annual releases of radionuclides to the Winnipeg River for the licence period 2009-2018. The total annual releases are compared against DRLs developed by CNL and accepted by CNSC to ensure releases to the environment will not exceed the annual regulatory public dose limit of 1 mSv per year. As shown in table 3.4, the total annual releases of radionuclides from the WL site remain at a very small fraction of the DRLs.

Table 3.4: Total annual waterborne releases of radionuclides from the Process Outfall and Lagoon at the WL site (2009 – 2018) [15 to 24]

Effluent	Gross Alpha (Bq/yr)	Strontium-90 (Bq/yr)	Caesium-137 (Bq/yr)
DRL *(2009-2015)*	3.36E+12[1]	1.75E+13	2.89E+12
2009	9.84E+07	1.44E+08	1.56E+08
2010	1.13E+08	1.56E+08	1.32E+08
2011	9.60E+07	1.20E+08	9.60E+07
2012	1.08E+08	1.19E+08	9.12E+07
2013	1.14E+08	6.96E+07	6.36E+07
2014	3.48E+07	4.68E+07	4.32E+07
2015	4.08E+07	3.96E+07	1.68E+07
DRL *(2016-2018)*	1.33E+10[2]	1.56E+11	1.39E+11
2016	4.68E+07	6.00E+07	1.44E+07
2017	3.84E+07	6.72E+07	1.92E+07
2018	3.96E+06	3.20E+07	1.51E+07

[1] DRL for gross alpha is that for Am-241, which was identified as the radionuclide with the most restrictive DRL.
[2] DRL for gross alpha is that for Pu-239/Pu-240, which is identified as the radionuclide with the most restrictive DRL.

3.1.2.2 Hazardous Effluent

As with radiological contaminants, the main sources of hazardous substances from liquid effluent at the WL site are from the Process Outfall and the Lagoon. Table 3.5 provides annual monthly average concentrations of hazardous contaminants released from the Process Outfall into the Winnipeg River for the licence period 2009-2018. With the decrease in site activities and completion of decommissioning work, discharges at the Process Outfall have consistently decreased since 2009. CNSC staff conduct routine compliance verification of the Process Outfall releases by comparing against CNL non-radioactive effluent limits, also provided in table 3.5 [77]. As shown in table 3.5, the hazardous effluent releases from the Process Outfall remain well below the effluent limits.

The Lagoon is a second contributor of hazardous substances to the Winnipeg River, discharging approximately 25 times less water than the Process Outfall in 2017. Table 3.6 provides annual monthly average concentrations of hazardous contaminants released from the Lagoon into the Winnipeg River for the licence period 2009-2018. CNSC staff conduct compliance verification of the lagoon effluent by comparing against CNL's non-radioactive effluent limits, which include those required under the Federal Wastewater System Effluent Regulations (FWSERs). As shown in table 3.6, the hazardous effluent from the Lagoon remain below the effluent limits [77].

Table 3.5: Annual monthly average concentrations of hazardous releases from the WL site Process Outfall (2009 – 2018) [15 to 24][77]

Parameter	(Unit)	Effluent limit[1,2]	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018

[2] Effluent limits apply to the monthly average release concentrations, with the exception of COBD, TSS, total residual chlorine, and un-ionized ammonia, which apply to annual average release concentrations as per Section 6(2) of the FWTSRs.
[3] Daily Internal Control Level.

3.1.3 Conclusions

CNSC staff have assessed radiological and hazardous releases to the environment from the WL site during the licensing period. Radiological releases to the atmosphere and to the Winnipeg River were below their respective DRLs. With the exception of chlorine, hazardous releases to the Winnipeg River were below release limits. Chlorine is discussed in section 3.2.2.1.

3.2 Environmental Effects Assessment – Licensing Activities

As noted in section 2.2 of this report, a CSR was produced for the WL site in 2001 [41]. This CSR, along with the support of Annual Safety Reports submitted by the licensee, were reviewed and assessed, and inform this section of the EPR Report.

The following sub-sections discuss the impacts of decommissioning activities at the WL site and provide CNSC staff's conclusions on whether CNL will continue to make adequate provision for the protection of the environment and human health.

Each sub-section also presents an overview and assessment of the predicted effects, using the results of both environmental monitoring and modelling as documented in the CSR and annual reports, in order to determine whether the environment and human health are, and will continue to be, protected as decommissioning continues.

The assessment of predicted effects of the project was carried out in a step-wise manner as follows:

- identifying potential environmental and health effects
- determining whether the environment and health of persons are protected

A review was conducted for all components related to the project, but only a selection of topics are presented in detail in this section.

3.2.1 Atmospheric Environment

An assessment of the atmospheric environment at the WL site consists of characterizing both the meteorological conditions around the WL site, as well as assessing the ambient air quality. Meteorological conditions such as wind speed, wind direction and precipitation are monitored in order to assess the extent of the atmospheric dispersion of contaminants released to the atmosphere, the rates of contaminant deposition, and to determine predominant wind directions which are used to identify critical receptor locations from the air pathway. Based on extensive meteorological data collected, the predominant wind directions are both to and from the north northwest and from the northwest with average annual wind speeds of approximately10 km/h [78].

Ambient air monitoring is used to confirm that ambient air quality as a result of atmospheric releases from the facility due to decommissioning and demolition activities remain at levels protective of human health and the environment. As part of the EMP, CNL conducts monitoring of ambient gamma radiation, as well as ambient dust during demolition activities.

3.2.1.1 Ambient Gamma Dose Monitoring

As part of the EA FUP, ambient gamma dose monitoring is conducted at the WL site, in order to ensure gamma levels within the controlled area fence, site perimeter, and in the town of Pinawa are within regional background levels. Table 3.7 provides the 5-year average total gamma dose rate levels. Over this period, gamma dose rates have remained within the expected regional background.

Table 3.7: Total gamma dose rates from the WL site [15 to 33]

Location	5-year average (mSv/a)
Average background dose in Winnipeg [79]	4.1
Controlled area fence	0.54
Facility perimeter	0.53
Pinawa area	
Town yard	0.53
Pinawa golf course	0.50
Hospital	0.43

3.2.1.2 Airborne Dust Monitoring

CNL initiates dust control measures during building demolition activities. These measures include the use of containment and suppression techniques, such as wetting, as well as restricting activities during high wind conditions. During demolition activities, CNL also conducts ambient monitoring for total suspended particulates (TSP) to ensure that the release of fine dust is minimized and controlled to levels below Canada's National Ambient Air Quality Objectives (NAAQO) [80].

The TSP concentrations during all 2017 demolition activities ranged between 0.7 – 831 $\mu g/m^3$, with the average daily TSP concentrations at 150 $\mu g/m^3$, compared to the tolerable daily NAAQO of 400 $\mu g/m^3$. Although there were occasional exceedances of the NAAQO, these were attributed primarily to elevated background concentrations caused by forest fires and the use of gas generators, and any residual risk to people or the environment from demolition activities is unlikely.

3.2.1.3 Conclusion

Based on CNSC staff's review of the CSR, the annual EMP results and EA FUP results for the licensing period of 2009-2018, CNSC staff conclude that ambient air quality remains at levels protective of human health and the environment.

3.2.2 Aquatic Environment

An assessment of the aquatic environment at the WL site consists of characterizing water conditions, sediment quality and the health of aquatic ecosystems (including the consideration of species at risk) around the WL site. This includes assessing the possibility of exposure of aquatic species to contaminated sediments in the Winnipeg River, which supports a diverse fish community with spawning, rearing and foraging habitats. Walleye, northern pike, lake whitefish, white sucker and shorthead redhorse are routinely captured upstream and downstream of the WL site, where various forage fish species can also be found.

CNL monitors radionuclide concentrations in water and sediments of the Winnipeg River as well as in fish tissue to evaluate any potential impacts that decommissioning and demolition activities may have on the environment and the public. Since releases of hazardous substances from the Process Outfall and the Lagoon are low (section 3.1.2), monitoring of hazardous substances in surface water and fish in Winnipeg River is not part of the EMP (see section 3.3.2.1).

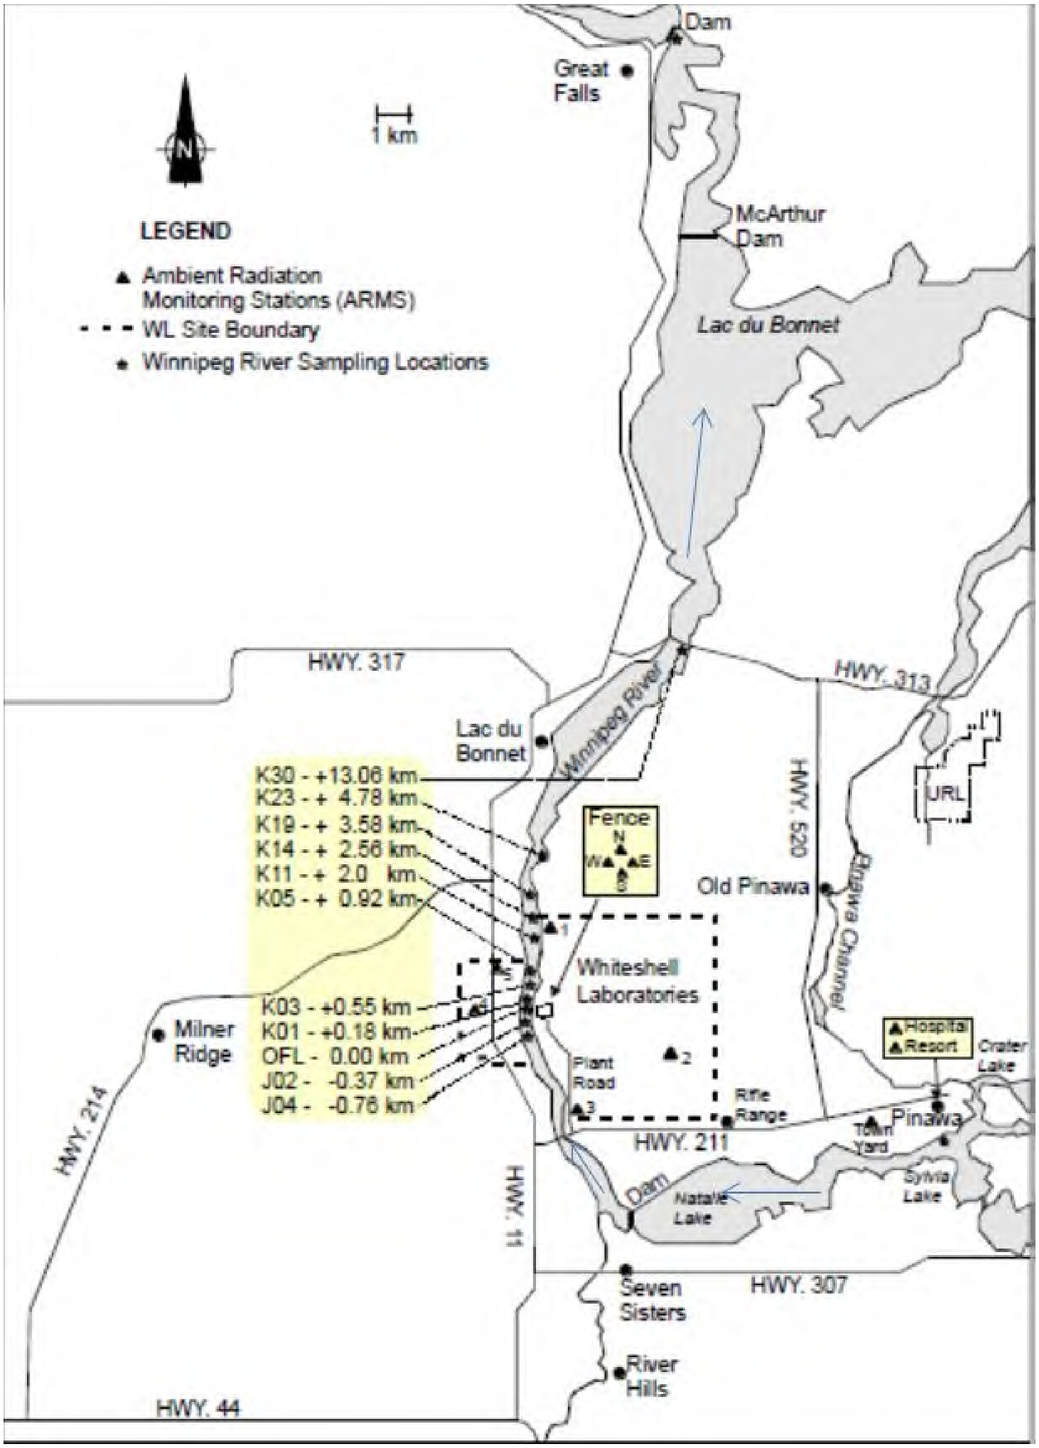
3.2.2.1 Water quality in the Winnipeg River

Radiological Substances

As part of their EMP, CNSC requires CNL to collect monthly composite samples of Winnipeg River water from four locations: near Pinawa, which is approximately 17 km upstream of the Process Outfall; 2 km downstream at the WL site property boundary; 10 km downstream at the Lac du Bonnet water intake; and 28 km downstream at the Great Falls generating station (figure 3.2).

The upstream monitoring station is a reference location because it is not exposed to releases from the WL site. Levels of radiological substance at this upstream site near Pinawa are thus considered ambient levels. These ambient levels are used for comparison with radiological levels in the Winnipeg River, downstream of the site, in order to determine if the WL site discharge increases levels of radiological substances. Water samples are analysed for tritium, strontium-90, gross beta, caesium-137 and potassium-40 [23], which were identified in the 2001 CSR. Sample locations are shown in figure 3.2.

Figure 3.2: Sediment and water monitoring locations on the Winnipeg River upstream and downstream of the WL site[4] [23]



[4] Water quality locations are identified as black circles and sediment sampling locations are highlighted in yellow and blue arrows indicate direction of the Winnipeg River flow.

Temporal trends in radiological substances concentrations are shown in table 3.8. Two kilometers downstream from the Process Outfall, gross beta, potassium-40 and strontium-90 are higher than upstream. Activity concentrations of these radionuclides return to levels measured upstream at 10 and 28 km downstream of the Process Outfall. It should be noted that gross beta activity concentrations have decreased since 2009 (table 3.8), likely because of reduction in operations. Caesium-137 (table 3.8), tritium and gross alpha (for which data are not shown because concentrations downstream were similar to upstream) activity concentrations in the Winnipeg River downstream of the Process Outfall remain similar to ambient levels upstream. This confirms that the WL site operations are not an important source of alpha emitting radionuclides, caesium-137 or tritium. The assessment of environmental risk from these surface water concentrations are discussed in section 3.2.2.3.

Table 3.8: Temporal trends in mean activity concentrations (mBq/L*) in Winnipeg River upstream and downstream of the WL site (2009 – 2017) [23]

Hazardous Substances

As presented in section 3.1.2 above, CNSC requires CNL to measure hazardous substances in the Process Outfall and the Lagoon. However, CNSC does not require CNL to measure hazardous substances in the Winnipeg River, because hazardous substances concentrations in the liquid effluent are generally below the Canadian Council of Ministers of the Environment (CCME) water quality guideline for the protection of aquatic life. Comparisons of liquid effluent concentrations to the CCME water quality guideline are presented in the following section, in order to explain why hazardous substances are not monitored in the Winnipeg River.

The Process Outfall discharges continuously to the Winnipeg River and is the main effluent in terms of volume (table 3.5). Levels of hazardous substances (pH, chromium, nickel, and phenolics) in effluent are currently below the CCME water quality guideline for the protection of aquatic life [81]. Other substances such as copper and mercury have been consistently above the CCME water quality guideline in the effluent. Copper levels were approximately 10 times the CCME guideline from 2009 to 2012. Since then, these levels have decreased, but remain slightly above the guideline. Also, mercury was consistently higher than the CCME water quality guideline prior to 2017 (table 3.5), but has since been below 0.1 µg/L. Below this level, bioaccumulation of mercury in fish is low and not of concern [82].

On occasion, zinc, iron, lead and phosphorus have been above the CCME water quality guideline. From 2009 to 2014, zinc was found to be slightly above the CCME water quality guideline, but has since decreased below the guideline. On occasion, iron and phosphorus have been above the CCME water quality guideline. These rare exceedances of iron are not of environmental concern because it is an essential element to aquatic life. With regards to phosphorus exceedances in 2014 and 2015, it is not expected to contribute significantly to eutrophication of the Winnipeg River.

The Lagoon water is discharged occasionally to the Winnipeg River, but frequency and volumes have decreased over the years (table 3.6). The Winnipeg River discharges a million times more water than the Lagoon. Levels of hazardous substances (pH, total suspended solids, chromium, iron, lead, nickel and, phenolics) in the Lagoon effluent have been consistently below the CCME water quality guideline for the protection of aquatic life [81]. Other substances are consistently or on occasion above the CCME water quality guideline in the Lagoon effluent.

For instance, mercury has been consistently above the CCME water quality guideline but decreased to below detection limits in 2017 and 2018. Similarly, phosphorus has consistently decreased in the effluent to levels seen in aquatic environment with average productivity. Copper was above the CCME guideline from 2009 to 2013 and zinc was above the CCME water quality guideline in 2011, but both have since decreased to below their respective CCME water quality guideline. Finally, iron was above the CCME water quality guideline in 2018, but is not of environmental concern because it is an essential element to aquatic life.

Total residual chlorine was often above the CNL effluent limit (table 3.6). CNSC staff does not have concerns with these frequent exceedances because the water flow rate of the Winnipeg River is a millions times higher than what the Lagoon discharges annually, which provides ample potential for dilution of chlorine [83] in the Winnipeg River. Total residual chlorine is therefore not a concern to the health of the Winnipeg River ecosystem.

In contrast to the Winnipeg River, CNSC requires CNL to monitor hazardous substances in the north and west ditches (ditch 8 and ditch 9, respectively), similar to the Process Outfall and the

Lagoon. These are intermittent streams during rain events. Ditch 9 flows to the Winnipeg River, whereas ditch 8 flows to the north. Tables 3.9 and 3.10 provide annual average concentrations of hazardous substances in surface water of the ditches from 2009 to 2018. Hazardous substances concentrations are compared against the CCME guideline for the protection of the aquatic life. As shown in these tables, the concentrations in ditches 8 and 9 were similar to those measured in a nearby unaffected creek. On occasion, copper and mercury were above the CCME water quality guideline and ambient levels measured in a nearby unaffected creek.

Table 3.9: Total annual average hazardous substances concentration for WL site Ditch 8 (northbound) (2009 – 2018) [15 to 24] compared against *Federal Water Quality* (CCME) Guidelines [81] *

Parameter	(Unit)	CCME Guideline	Background*	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018

* Values in red are above CCME guidelines for protection of aquatic life and natural background concentrations measured in an unaffected ditch, which are discussed in more detail in section 3.2.2.

As explained above, CNL is not required to measure hazardous substances in water of the Winnipeg River. However, the province of Manitoba does monitor water quality for hazardous substances at the Powerview Dam, 30 km downstream of the WL site. Table 3.11 indicates that the maximum concentrations of metals are all below the CCME water quality guideline for the protection of the environment, except for aluminum.

For aluminum, naturally present amounts of aluminum in North American rivers range from 12 µg/L to 2250 µg/L [84]. Recent American studies [84 to 85] on aluminum toxicity suggest that a water quality guideline of 100 µg/L is very protective of the environment. In rivers with high organic matter like the Winnipeg River, CNSC staff concur with the American studies [85] that a safe level of aluminum is around 300 µg/L [85]. In 2017, aluminum levels in the WL site water intake was at 150 µg/L, similar to the effluent concentrations [86], which indicates that the WL site does not contribute to an increase in aluminum levels in the Winnipeg River. It is CNSC staff's conclusion that there is no risk to aquatic ecosystems from current levels of aluminum in the Winnipeg River. Although far from the site, provincial monitoring indicates the risk to aquatic organisms living in the water column of the Winnipeg River is negligible.

Table 3.11 Average (maximum) concentrations of metals from 2009 to 2018 at the Powerview Dam on Winnipeg River, 30 km downstream of the WL site [15 to 24]

Metal	Al	As	Cd	Cu	Cr	Mo	Ni	Se	U	Zn
Value (µg/L)	163 (239)	0.8 (1.7)	0.007 (0.008)	1.2 (1.3)	0.1 (0.1)	0.2 (0.2)	0.8 (1.0)	0.1 (0.2)	0.1 (0.2)	0.2 (0.3)
CCME Guideline [81]	100	5	0.09	2	1	73	25	1	15	7

Overall, most hazardous substances in wastewater from the Process Outfall and the Lagoon, as well as surface water in ditches 8 and 9, were below the CCME water quality guideline for the protection of aquatic life. Despite the occasional levels of aluminum above the CCME water quality guideline, considering that the annual water flow of the Winnipeg River is 100,000 and 1,000,000 times the annual Process Outfall and lagoon discharge, levels of hazardous substances are expected to be well below the CCME water quality guideline for the protection of aquatic life. CNSC staff therefore conclude that the Winnipeg River is adequately protected from releases of hazardous substances. For this reason, CNL is not required to monitor hazardous substances in the Winnipeg River.

As for ditch 8, for which runoff water drains to the north only during rain events, levels of hazardous substances were all below CCME guidelines in 2018 (table 3.9). While there were some exceedances of the CCME guidelines prior to 2018, these exceedances are not of concern because ditches are not aquatic habitats since water only flows during rain events.

3.2.2.2 Sediment quality in the Winnipeg River

As radiological and hazardous substances have accumulated in sediments downstream of the WL site since 1964, CNSC requires CNL to monitor radiological substances in the sediments of the Winnipeg River to assess environmental risk associated with historical releases. This section discusses potential risk of radiological and hazardous substances in sediments.

Radiological Substances

Winnipeg River sediments are collected on an annual basis [87] from 11 locations ranging from 0.8 km upstream to 13.1 km downstream of the WL site Process Outfall, as shown in figure 3.2. Results from the latest 2017 sampling campaign are detailed in table 3.12.

Gross alpha is similar between upstream and downstream sediments as it was the case in surface water. However, gross beta activity is higher at the Process Outfall, as well as 0.5 and 13 km downstream, compared to upstream samples. Gross beta activity was also higher in surface water 2 km downstream of the Process Outfall.

Caesium-137, is also higher at the Process Outfall, as well as 0.8, 3 and 13 kilometers downstream, in comparison to upstream (table 3.12) [23]. This is in contrast with surface water where caesium-137 concentrations downstream were similar to upstream of the Process Outfall from 2009 to 2017. This higher concentration of caesium-137 in sediments is the result of historical higher releases of caesium-137, prior to 2009 [15][88].

Caesium-137 is a mobile element, and the sediment monitoring data suggest that some caesium-137 is recirculated downstream in the Winnipeg River. Since caesium-137 is a beta-emitter, it also explains the similar gross beta pattern in sediments. Strontium-90, which was elevated in surface water 2 km downstream of the Process Outfall (table 3.8), was below the detection limit of 0.0001 Bq/Kg (data are not shown because concentrations are below detection limits). Potassium-40 appears slightly higher a kilometer downstream of the Process Outfall, similar to surface water concentrations. The risk to aquatic biota from radiological substances concentration in sediment is not of concern, as is further discussed in section 3.2.2.3, Dose Assessment to Non-Human Biota.

Table 3.12: Radionuclide activities in sediment (Bq/Kg dry weight) upstream and downstream of the WL site [23]

Location (see figure 3.2)	Distance (Km)	Gross alpha	Gross beta	Potassium-40	Caesium-137
J04	-0.76*	396	655	606	10
J06	-0.37*	348	616	550	10
Process Outfall	0	350	817	580	183
K01	0.15	291	562	645	9
K03	0.52	407	864	588	49
K05	0.79	365	662	580	179
K14	2.56	386	600	580	15
K30	13.06	346	725	614	24

*A (-) indicates a upstream measurement.

Hazardous Substances

In support of the CSR in 2001, CNSC staff requested that CNL sample sediments twice within the center of the plume, in a background area and downstream of the operations. Metal concentrations were enriched in sediment exposed to discharge from the Process Outfall, compared to background sediments (table 3.13). Despite this enrichment, none of the metal concentrations were above sediment quality guidelines [85]. Next sediment monitoring for hazardous substances is expected in 2021.

Note that the sediment quality guideline for cadmium is below measurable levels and levels in the outfall area were similar to background. Hence, cadmium is not a concern at the site.

Table 3.13: Hazardous substance concentrations (mg/kg) in the Winnipeg River sediments directly in the Process Outfall and downstream of the WL site in 2001

Substance	Background[1]	Plume[1]	Downstream[1]	ISQG[2]	PEL[3]	LEL[4]
Cadmium	1.3	1.3	1.6	0.6	3.5	-

Zinc	10.8	15.7	28	120	320	-

1 Concentrations [88]
2 Interim sediment quality guideline [89]
3 Probable effects level [89]
4 Lowest effect levels [90]

3.2.2.3 Aquatic ecosystem health in the Winnipeg River

Consideration of Species at Risk

The Winnipeg River supports a diverse fish community with spawning, rearing and foraging habitats. CNL has identified fish and fish habitat in and around the WL site [40].

Fish species occurring in the Winnipeg River and within the vicinity of the WL site are forage fish including minnows, suckers, sculpins and darters. Predatory fish species reported in the area include Walleye, Northern Pike and Smallmouth Bass. Walleye, northern pike, lake whitefish, white sucker and shorthead redhorse, are routinely captured upstream and downstream of the WL site, during annual environmental monitoring [2][40].

The carmine shiner is the only fish species listed on schedule 1 of the *Species at Risk Act* (SARA) living in the Winnipeg River and in the vicinity of the WL site [91]. The known distribution of the carmine shiner is limited to the Winnipeg River, at the base of Whitemouth Falls (located approximately 7 km upstream of the WL site), and its tributaries [92]. DFO has published an Action Plan for the Carmine Shiner in Canada in order to help this species recover, as part of their SARA Action Plan Series [93].

Radiological Levels in Fish Tissue

As part of their EMP, CNL caught three species of fish (white sucker, walleye and northern Pike) in the Winnipeg River at a location upstream and four species (white sucker, walleye and northern pike and whitefish) downstream during the fall period on an annual basis. In 2017, three individual fish were caught per species and per location. The flesh was analysed for gross beta activity and scanned by gamma spectroscopy, which provided values for caesium-137 and potassium-40. The downstream locations and the upstream Sylvia Lake location are identified in figure 3.2.

A five year average of caesium-137, potassium-40, and gross beta activity in fish flesh is provided in table 3.14 for the years 2012 to 2017. This table indicates that caesium-137 is enriched in all fish species downstream of the WL site, compared to fish caught upstream in Sylvia Lake. This result supports the observed accumulation of caesium-137 in sediments (see section 3.2.2.2). Caesium-137 has accumulated in sediments as a result of historical releases prior to 2009 [15][88]. The contribution of caesium-137 to dose to these fish and the implication on their health is discussed in the next section.

Table 3.14 Five year average of radionuclide activities in fish flesh (2012 – 2017) (Bq/Kg fresh weight) for three species upstream and downstream of WL site [23]

	Upstream	2 km downstream	5 km downstream
White sucker			
Caesium-137	0.77	0.48	1.70
Potassium-40	137	135	121
Gross Beta	142	135	135
Walleye			
Caesium-137	0.61	0.87	0.81
Potassium-40	130	125	138
Gross Beta	132	141	143
Pike			
Caesium-137	0.40	0.54	0.44
Potassium-40	126	115	133
Gross Beta	136	130	137
Whitefish			
Caesium-137	0.33	0.44	0.48
Potassium-40	141	133	141
Gross Beta	148	137	141

Dose Assessment to Non-Human Biota

In 1973, benthic invertebrate community monitoring upstream and downstream of the WL site indicated that organisms dwelling in the Winnipeg River sediment were not affected by releases from the site [94]. In 2001, CNL calculated radiological doses to organisms dwelling in the Winnipeg River sediment. Maximum predicted dose was 0.76 µGy/hr, which is lower than the 10 µGy/hr benchmark [95]. CNSC staff reviewed CNL dose calculations and concluded that organisms living in the Winnipeg River sediments directly downstream of the Process Outfall and Lagoon were not affected by radiological exposure at that time [88].

For this EPR Report, CNSC staff modelled radiological dose to aquatic biota using the ERICA tool [95]. In their assessment, CNSC staff considered maximum activities of tritium, strontium-90 and most importantly, caesium-137 in water and sediments. Maximum modelled dose to organisms dwelling into sediments was 1.4 µGy/h, which is lower than the 10 µGy/hr benchmark, demonstrating no adverse effects on biota. The modelled dose to benthic and pelagic fish was below the dose predicted to organisms inhabiting sediments. Caesium-137 accumulation in fish tissue is therefore not of concern.

CNSC staff confirm that aquatic organisms living in the Winnipeg River downstream of the WL site, including species at risk, remain protected from historical and current radiological exposure.

3.2.2.4 Conclusion

Based on annual monitoring of fish, water and sediment, CNSC staff confirm that aquatic organisms living in the Winnipeg River downstream of the WL site remain protected. CNL continues to provide adequate protection of the environment from releases to surface water.

3.2.3 Terrestrial Environment

An assessment of potential effects on terrestrial biota at the WL site consists of characterizing local terrestrial habitat and terrestrial species and consideration of terrestrial species at risk. This includes assessing the possibility of exposure to radioactivity in native vegetation and wildlife, radiological and hazardous soil quality along with physical stressors that may be disruptive to both human and ecological receptors.

In the immediate vicinity of the WL site, there are approximately 10 to 20 m of surficial overburden soils overlying the Precambrian bedrock. These overburden soils include glacial, glaciofluvial and alluvial deposits. At the WMA, where extensive test hole drilling has taken place prior to and since site development, the overburden soils were found to comprise 0.5 m of organic-rich soil horizon overlying 1.5 m of silt, 2.5 m of clay, 5 m of clayey till, and 3 to 5 m of stratified sand.

The terrestrial habitat in and around the WL site consists of wetland areas to the east, and forest species and abandoned farm fields vegetated with grasses and shrubs to the west.

Over 50 species of mammals can be expected to be found around the WL site, along with a large variety of bird species and amphibians. A wide diversity of amphibians are also present in the vicinity of the WL site,

CNL monitors radionuclide concentrations in soils around the WMA, in order to evaluate any potential impacts that decommissioning and demolition activities may have on terrestrial biota, including vegetation and wildlife.

3.2.3.1 Soil Quality at the Perimeter of WMA

In general, the surficial soil distribution in the low-lying areas to the northwest and west, as well as away from major streams, comprise peats in areas of poor drainage. Improved drainage conditions in these areas leads to the development of humic gleysols and brunisols, while underlying outwash sands and gravels lead to the development of brunisols. Soil development near the Winnipeg River includes peaty humic gleysols on lacustrine silts and clays, but the inherently more effective surface drainage at these locations generally retards peat development. Precambrian bedrock outcrops generally have only partial lichen and moss cover, although peat soil is common in depressions.

Radiological Substances

The WL site EMP includes measurements of radioactivity in soils. Table 3.15 provides a summary of the radioactivity found in the surface soils collected in 2017 at the perimeter locations of Standpipe Rows E, F, and G in the WMA (refer to figure 1.4 for Standpipe locations).

Table 3.15: Radioactivity in surface soil near Standpipe Rows of WL WMA, 2017 [23, table B-13]

Location	Gross beta (Bq/g)	Gross alpha (Bq/g)	Potassium-40 (Bq/g)	Strontium-90 (Bq/g)	Caesium-137 (Bq/g)
Location E (1 m East of WMA Fence at Standpipe Row E)					
Perimeter (7m south)	1.00	0.70	0.54	0.10	0.01
Perimeter (8m south)	1.90	0.80	0.71	0.31	0.09
Perimeter (9m south)	1.99	1.00	0.66	0.12	0.06
Perimeter (9m west)	2.45	1.20	0.68	0.12	0.12
Location F (1 m East of WMA Fence at Standpipe Row F)					
Perimeter (9m west)	1.47	0.90	0.62	0.05	0.01
Location G (1 m East of WMA Fence at Standpipe Row G)					
Perimeter (9m north)	1.70	0.70	0.73	0.09	0.06
Perimeter (9m west)	0.95	0.64	0.54	0.04	0.01
NSRDR clearance level	NA	1.0	10	1.0	0.1

The alpha activity detected in the 2017 soil samples is most likely from naturally occurring alpha emitters such as uranium and thorium present in the soil. Two samples were at or slightly above the *Nuclear Substance and Radiation Devices Regulation (NSRDR) Clearance Level* [96] of 1.0 Bq/g (not including Potassium-40). The strontium-90 levels at the perimeter locations were below the NSRDR Clearance Level of 1.0 Bq/g. Caesium-137 activity at the perimeter locations were similar to the normal background levels for this radionuclide (0.02 to 0.11 Bq/g for this part of Manitoba) and at the NSRDR Clearance Level of 0.1 Bq/g. Therefore, there is negligible risk to members of the public.

Core samples were collected from the perimeter of the standpipe area in 2005 and additional work was conducted in 2011 and 2012. Radioactivity of groundwater (from routine environmental monitoring), and the soil samples from this study indicate there is no significant radioactive migration from the waste management facilities. Refinement and supplementary monitoring of the groundwater continues to support this finding.

Hazardous Substances

In 2008, AECL documented the nine sampling campaigns conducted at the Inactive Landfill and Lagoon in order to obtain the baseline conditions for these areas, and to identify the need for remediation that may be required. Soil samples were collected at locations where there was potential for radiological and hazardous contamination.

Most of the soil samples collected at the landfill and Lagoon areas demonstrated background levels of metals. Some concentrations of nickel, boron, cadmium, molybdenum, beryllium, aluminum, cobalt, chromium, copper and iron were above the background and/or above the most restrictive CCME Soil Quality Guidelines for agricultural land use [97]. It was concluded that the hazardous levels are such that there is no serious detriment to the local environment other than the fact that the land is probably not suitable for use as farmland. However, these levels in general meet the guidance criteria for residential/parkland, commercial and industrial land use.

3.2.3.2 Terrestrial Habitat and Terrestrial Biota

Black spruce is the common plant species in the easterly portions of the WL site, however jack pine is also present in this area, along a ridge of well drained sandy soil. The forest species to the west of the site consist of ash and poplar growing in poorly drained clay plains. Blueberries are common along the sides of the plant road south of the site.

Mammalian species that are common and widespread in the area include the snowshoe hare, American red squirrel, meadow vole, red fox and white-tailed deer. Not only is the white-tailed deer present on WL site, they have also established a wintering area. The white-tailed deer is considered to be an important species for the traditional communities and game species in the area. Recently, moose have also been sighted on the south-east portion of the WL property.

A bat survey conducted in 2015 at the WL site indicated that bats were not roosting within buildings at the site, but rather can be found roosting in the forested areas of the site.

A large variety of bird species can be expected to occur in the vicinity of the WL site. Bird migratory staging areas are present on and near the site, and the Winnipeg River is an important migratory corridor for many bird species including: common loon, red-necked grebe, horned grebe, double-crested cormorant, American white pelican, Bonaparte's gull, common tern, Caspian tern, lesser scaup, greater scaup and bald eagle.

Despite the generally harsh winter conditions of the WL site, about 10 species of amphibians can be found, the majority of which are frogs. These include the spring peeper, grey tree frog, striped chorus frog, wood frog and northern leopard frog, which are common and widespread, as well as the green frog and the mink frog, which are less common and widespread. Only four reptile species can be found on site; two turtle and two snake species, both of which are common and widespread. The common garter snake is widely distributed and prevalent in the region, but little is known about the exact status of the redbelly snake found in the area. All the reptile species hibernate to survive the harsh winters and hibernacula are a potentially important ecological feature in the region. None are known to exist on the WL site. In spring, the reptiles become active and enter their breeding cycle, which may involve special areas for egg-laying; none are known to be located in the WL controlled area.

Consideration of Terrestrial Species at Risk

Table 3.16 lists a number of threatened and endangered species under the federal *SARA*, and Manitoba's *Endangered Species and Ecosystems Act* (ESEA) that are likely to be present in the vicinity of the site, or the Winnipeg River. The possible presence of these species on the site was also indicated by the Manitoba Conversation Data Centre.

Table 3.16: Status for terrestrial Species at Risk (ESEA and SARA)

Species	Status	
	ESEA [98]	SARA [99]
Birds		
Bank swallow	Not Listed	Threatened
Barn swallow	Not Listed	Threatened
Bobolink	Not Listed	Threatened
Canada warbler	Threatened	Threatened
Chimney swift	Threatened	Threatened
Common nighthawk	Threatened	Threatened
Eastern wood pewee	Not Listed	Special Concern
Golden-winged warbler	Threatened	Threatened
Horned grebe	Not Listed	Special Concern
Least bittern	Endangered	Threatened
Loggerhead shrike	Endangered	Endangered
Olive-sided flycatcher	Threatened	Threatened
Peregrine falcon	Endangered	Special Concern
Piping plover	Endangered	Endangered
Red-headed woodpecker	Threatened	Threatened
Short Eared owl	Threatened	Special Concern
Trumpeter swan	Endangered	Not Listed
Whip-poor-will	Threatened	Threatened
Yellow rail	Not Listed	Special Concern
Mammals		
Grey fox	Not Listed	Threatened
Little brown myotis	Endangered	Endangered
Northern myotis	Endangered	Endangered
Reptiles		
Snapping turtle	Not Listed	Special Concern
Insects		
Monarch	Not Listed	Special Concern
Yellow banded bumble bee	Not Listed	Special concern
Plants		
Gattinger's agalinis	Endangered	Endangered
Rough agalinis	Endangered	Endangered
Western silvery aster	Threatened	Threatened
Ironweed	Endangered	Not listed

CNL have recently placed netting on buildings in the WMA, in order to discourage nesting of barn swallows and bats. New structures have also been constructed on site, in order to support the nesting of these species in alternative locations, as well as to prevent future nesting in buildings that are undergoing demolition. CNL plans to monitor these structures.

Species at risk can be difficult to include in dose and risk calculations due to incomplete knowledge of their exposure factors. While not all species at risk are specifically assessed, an effort was made to by CNL ensure that the species selected have similar feeding habits, so that surrogate species can be used to infer dose and risk for the species at risk either present or potentially present on the WL site.

Physical Stressors

Physical stressors, such as noise and vibration, are relevant to both human and ecological receptors, and are generated during decommissioning and demolition activities. As part of the CSR, impacts of noise and vibration from decommissioning activities were assessed. It was identified that any noise generated would be short-term and sporadic, confined during daytime activities, and that affected wildlife, such as deer and moose, could temporarily relocate to other suitable habitats. Additionally, dense tree coverage across the site provides a natural noise barrier between site activities and potential noise receptors around the WL site. CNSC staff reviewed CNL's assessment and concluded that no residual effects, including habitat loss, from noise and vibration would be expected.

During the current licensing period, decommissioning and demolition activities were not continuous but performed intermittently. Due to the above factors, CNSC staff conclude that are likely no residual effects from physical stressors including noise and vibration to the terrestrial environment.

Assessment of Potential Effects on Terrestrial Biota

The WL site EMP includes measurements of radioactivity in vegetation and in wildlife. Trends of concentrations for caesium-137, strontium-90, potassium-40, gross beta and gross alpha activities in vegetation and wildlife samples are presented in tables 3.17 and 3.18, respectively, along with the Ambient Radiation Monitoring Stations (ARMS) where they were taken.

Table 3.17: Radioactivity in vegetation [23]

Radioactivity (Bq/kg fresh weight)						
Parameter	**2012**	**2013**	**2014**	**2015**	**2016**	**2017**
WL perimeter, 3.2 km N (ARMS #1)						
Caesium-137	< 11	< 4	< 14	< 12	< 7	< 5
Strontium-90	5.2	1.3	2.5	2.1	3.0	2.4
Potassium-40	399	308	524	785	648	350
Gross Beta	502	347	547	668	594	429
Gross Alpha	31	20	110	55	45	95
WL perimeter, 3.4 km SSE (ARMS #3)						
Caesium-137	< 11	< 5	< 6	< 9	<4	< 3
Strontium-90	2.8	2.0	5.5	2.3	3.2	13.2
Potassium-40	211	206	395	789	899	301
Gross Beta	299	319	547	686	734	375
Gross Alpha	18	27	41	87	27	51
WL perimeter, 2.2 km W (ARMS #4)						
Caesium-137	< 7	< 6	< 7	< 8	< 4	< 5
Strontium-90	4.1	1.0	1.9	2.6	1.7	1.9
Potassium-40	322	554	593	671	584	464
Gross Beta	438	333	411	589	500	488
Gross Alpha	4	25	61	32	49	28
WL perimeter, 2.4 km NW (ARMS #5)						
Caesium-137	< 9	< 3	< 7	< 5	< 9	< 5
Strontium-90	4.6	0.5	1.1	1.3	0.6	< 0.8
Potassium-40	314	213	423	736	1140	400
Gross Beta	486	274	701	613	972	383
Gross Alpha	60	25	26	34	46	42
West of WMA and north of Canister Area (WMA #1)						
Caesium-137	< 8	< 3	< 6	< 6	< 5	< 4
Strontium-90	5.3	1	2.1	2.4	11.5	1.8
Potassium-40	328	551	306	481	912	370
Gross Beta	447	374	334	481	795	379
Gross Alpha	68	40	27	98	41	43
East of WMA near incinerator (WMA #7)						
Caesium-137	-	-	< 4	< 11	< 4	< 4
Strontium-90	-	-	7.4	9.6	6.4	2.7
Potassium-40	-	-	581	502	640	312
Gross Beta	-	-	465	493	662	342
Gross Alpha	-	-	37	28	23	33

Table 3.18: Radioactivity in wildlife (collected and analyzed road kills) [23 to 24]

Year	Gross beta	Potassium-40	Caesium-137
Grouse			
1998*	67	89	2.6
1998*	91	135	0.9
2003	72	112	0.8
2005	20	28	0.2
2006	172	214	3.9
2015	83	151	< 0.3
2016	177	130	1.0
Average	97	123	1.4
Method detection limit	2	6	0.3
Deer			
2011	129	135	0.7
2013	92	63	0.2
2014	119	98	7
2016	120	101	1.5
2018*	130	101	18
2018*	131	100	1.0
Average	115	99	2.4
Method detection limit	2	6	0.3

*Data occurs twice, due to two road kills in 1998 (grouse) and 2018 (deer).

These data indicate that in many instances the total radioactivity measured in vegetation and wildlife samples is due to natural radionuclides (for example Potassium-40). Caesium-137 levels in wildlife samples were below the detection limits, which ranged between 3 and 14 Bq/kg over the 2009-2018 licence period. They were also generally below the background level of 4 Bq/kg in all vegetation samples. Levels of strontium-90 and alpha activity in vegetation were detectable and in general within the range of previous years. The caesium-137 activity in the flesh of grouse and deer was relatively low (for example, the background level of caesium-137 in deer flesh is 2 Bq/kg) [23]. CNSC staff used the RESRAD model to estimate potential doses to the vegetation and wildlife based on the maximum measured radioactivity in the samples collected at the WL site. These estimates were several orders of magnitude below the most conservative radiation dose screening criteria for terrestrial biota.

3.2.3.3 Conclusion

Based on CNSC staff's review of the results of the EMP at the WL site and assessment of potential radiological dose to terrestrial receptors, CNSC staff confirm that terrestrial biota and soil quality remain protected from radiological exposures and no significant adverse effects are likely as a result of radioactive releases from the WL site. The hazardous contamination of soil within the WL site is mostly localized to the WMA, Inactive Landfill and Lagoon areas and is not expected to result in significant adverse effects to terrestrial biota since metal concentrations in general do not exceed the respective CCME soil environmental quality guidelines.

3.2.4 Hydrogeological Environment

An assessment of the hydrogeological environment at the WL site consists of identifying potential sources of groundwater contamination on the site, determining the extent of contamination, if any, which could lead to a pathway for exposure to human and/or non-human receptors, and determining the significance of any exposure from this pathway. Additionally, the hydrogeological assessment confirms whether control measures in place continue to remain effective in protecting the environment.

Potential sources of radiological and hazardous groundwater contamination include contamination of groundwater from the WMA, Inactive Landfill and Lagoon, as well as from two groundwater and surface water drainage ditches around the site.

Groundwater from the WL site flows from east to west towards the Winnipeg River. The surficial overburden soils on the WL site consist of layers of silt, clay, clay till, and basal sand overlaying Precambrian bedrock. The water table is located within the silt layer (0 to 3 m below ground surface) and fluctuates seasonally as a result of snow melt, precipitation and evapotranspiration. Figure 1.2 in section 1.2 provides an aerial view of the WMA, Inactive Landfill, Lagoon, and Main Campus relative to the Winnipeg River.

The north and west drainage ditches (ditch 8 and ditch 9) are also used to collect and divert shallow groundwater around the WMA. Water from the recharge area east of the WMA is diverted around the WMA towards the west and discharges into the Winnipeg River, while water north of the WMA is diverted through the second ditch towards the north site boundary. The presence of the ditches does promote some lateral flow in the silt, clay, and clay till units. This water is sampled as part of the WL site EMP, and monitoring results show levels to be at background.

3.2.4.1 Groundwater Quality

Groundwater is monitored for radiological and hazardous substances around the WMA, the Lagoon, and the Inactive Landfill to assess the extent and significance of any contamination around these structures and ensure that any contamination is localized. Groundwater is not used as a source of potable water on the WL site.

Radiological Contaminants in Groundwater

Radiological contaminants are monitored in groundwater as part of the WL site EMP and include gross beta, gross alpha, and tritium.

Waste Management Area

Groundwater quality is monitored from 70 groundwater monitoring wells around the WMA (see figure 3.3). Around the WMA, groundwater monitoring wells within the clay, clay-till, and basal sand layers and bedrock are sampled and analyzed. Table 3.19 provides a summary of the radiological groundwater quality monitoring results from all wells in and surrounding the WMA. The *Guidelines for Canadian Drinking Water Quality* [100] are also provided, for comparison only. As stated previously, groundwater on the WL site is not used as a source of drinking water.

Table 3.19: Average radionuclide concentrations in groundwater around the WMA (2013-2017) [15 to 33]

Surficial layer	Gross beta (Bq/L)	Gross alpha (Bq/L)	Tritium (Bq/L)
Drinking Water Guidelines [100]	1	0.5	7000
Clay	0.35 – 1.21	0.54 – 1.05	7.2 – 12.4
Clay till	0.36 – 0.86	0.35 – 0.77	9.0 – 13.4
Basal sand aquifer	0.16 – 0.65	0.1 – 0.2	3.4 – 5.2
Bedrock	0.15 – 0.82	0.17 – 0.55	3.4 – 4.4

A number of below-grade ILW bunkers are known to have groundwater inflow. Groundwater in the vicinity of these structures is monitored for caesium-137, strontium-90 and tritium as indicators of potential contaminant migration. Monitoring results over the past licensing period have shown elevated concentrations of tritium adjacent to a number of the ILW bunkers; however, these results have also shown that this contamination is localized within the clay and clay till layers. Given the low hydraulic conductivity, migration is limited. CNL will continue monitoring to confirm the extent of tritium migration. Slightly elevated concentrations of strontium-90 have also been measured in the groundwater adjacent to the ILW Bunker 1, but concentrations remain orders of magnitude below those measured in water samples within the bunker itself, demonstrating that migration is limited. In all cases groundwater contamination around the ILW bunkers remains localized, and the bunkers and surrounding clay layer are serving as an effective means of containment.

Within the WMA, water from the Soil Storage Compound and SMAGS waste facilities is collected by sumps. Monitoring results during the licensing period confirm that no leaks have been detected and that these structures are operating as designed.

Figure 3.3: WL site WMA Wells [23, figure A.2]

Note: Map not to scale.

Groundwater monitored from other structures around the WMA site, including the CCSF provide no evidence that indicate there has been any contamination of groundwater as a result of operations.

Lagoon

The Lagoon is located in the area adjacent to the Winnipeg River. Groundwater is sampled from 10 wells located in the water table and basal sand aquifer around the Lagoon during the spring. There is no impact from this groundwater to the Winnipeg River. Monitoring results of radiological contaminants in groundwater around the Lagoon are summarized in table 3.20.

Table 3.20: Average radionuclide concentrations in groundwater around the Lagoon (2013-2017) [15 to 33]

Surficial layer	Gross beta (Bq/L)	Gross alpha (Bq/L)	Tritium (Bq/L)
Drinking Water Guidelines [100]	1	0.5	7000
Water table	0.14 – 0.93	0.24 – 0.53	3.4 – 4.1
Basal sand aquifer	0.79 – 2.4	1.0 – 3.3	3.3 – 4.1

Inactive Landfill

The Inactive Landfill is located in the upland recharge area to the east of the WMA. Groundwater samples are collected from 13 wells located in the water table and basal sand aquifer around the Landfill area during the spring. Groundwater quality results have shown that contaminant levels are consistent with regional background concentrations. There is no impact from this groundwater to the Winnipeg River. Table 3.21 provides a summary of the groundwater quality monitoring results around the Inactive Landfill.

Table 3.21: Average radionuclide concentrations in groundwater around the Inactive Landfill (2013-2017) [15 to 33]

Surficial Layer	Gross beta (Bq/L)	Gross alpha (Bq/L)	Tritium (Bq/L)
Drinking Water Guidelines [100]	1	0.5	7000
Water table	0.1 – 0.44	0.08 – 0.19	4.2 – 8.4
Basal Sand Aquifer	0.16 – 0.71	0.07 – 0.78	3.3 – 4.0

WL Site Main Campus

Currently there are 29 groundwater monitoring wells around the WL Main Campus. In 2018 groundwater quality monitoring was initiated, and will be reported on in future annual reports. CNCS staff will assess these results as they become available.

Hazardous Contaminants in Groundwater

Hazardous substance parameters are also measured in groundwater wells around the WMA, Lagoon, and inactive landfill. Samples are analyzed for a range of metals, volatile organic compounds and hydrocarbons, which may be present in groundwater originating from stored waste on site. These include chromium, copper, iron, lead, zinc, arsenic, uranium, mercury, nitrate, nitrite, ammonia, chloride, volatile organic compounds (such as benzene, toluene, ethylbenzene, xylene, and acetone) and HB40 (organic coolant oil used during the operation of the WR-1 reactor). Results from groundwater well sampling around the WMA, Lagoon, and Inactive Landfill show that with the exception of uranium, iron and sulphate, concentrations of contaminants are within federal and provincial water quality guidelines and are consistent with previous groundwater assessments. In Manitoba, background concentrations of uranium, iron and sulphate are naturally high, and the results have shown these levels to be within expected regional background [97][101 to 102]. Considering that groundwater on site is not used as a source of drinking water, there is no expected impact from hazardous contaminants in groundwater to people or the environment.

Table 3.22 provides a summary of uranium concentrations in groundwater around the WMA, Lagoon and Inactive Landfill. The drinking water quality guideline for uranium is provided for comparison only. As stated previously, groundwater on the WL site is not used as a source of drinking water. Water from the Winnipeg River, may be a source of drinking water, and an assessment of surface water quality in the Winnipeg River (table 3.11), shows concentrations of uranium to be at 0.0002 mg/L, which is below the drinking water quality guideline of 0.02 mg/L.

Table 3.22: Average uranium concentrations in groundwater around the WMA, Lagoon, and Inactive Landfill (2013-2017) [15 to 33]

Surficial layer	WMA (mg/L)	Lagoon (mg/L)	Inactive landfill (mg/L)	*Uranium Drinking Water Guideline* (mg/L) [100]
Water table	-	0.012 – 0.013	0.001 – 0.002	0.02
Clay	0.032 – 0.040	-	-	
Clay Till	0.02 – 0.022	-	-	
Basal Sand Aquifer	0.0003 – 0.0004	0.056 – 0.090	0.0022 – 0.0036	
Bedrock	0.0008 – 0.0036	-	-	

3.2.4.2 Conclusion

CNSC staff have reviewed and assessed the hydrogeological environment around the WL site. Groundwater quality monitoring results around the WMA, Lagoon, and Inactive Landfill confirm that with the exception of localized contamination within the WMA, concentrations of radiological and hazardous contaminants in groundwater are below provincial and federal guidelines or within background.

Annual groundwater monitoring data indicate that there are elevated tritium concentrations at certain locations on the WL site, specifically around the WMA. However, tritium in groundwater does not extend beyond the WMA as contaminant migration is reduced by the clay and clay till layers. CNSC staff will continue to review CNL's groundwater monitoring results around the WL site, including areas around the WMA, Lagoon and Inactive Landfill.

As onsite groundwater is not used as a source of drinking water, there is no direct human health risk from this pathway. Based on a review of the most recent annual reports and the results from CNL's GWMP and annual environmental monitoring data, CNSC staff conclude that there are no adverse effects on the groundwater from the WL site and CNL continues to provide adequate protection of the hydrogeological environment.

3.2.5 Human Environment

An assessment of the human environment at the WL site consists of identifying critical groups located in proximity to the WL site, and whether the aforementioned environmental pathways will have an impact on these human receptors. Critical groups included residents of farms that are located in proximity to the WL site, as well as individuals engaging in harvesting of country foods (particularly local Indigenous communities, which continue to use the WL for traditional activities – see section 7.0). It is also acknowledged that humans perform other recreational activities in proximity to the WL site (swimming, fishing, hiking, camping and others), including hunting and trapping, however these activities are not considered representative of critical population groups [40].

Radiological and hazardous substance releases to the environment are monitored by CNL's EVMP and further assessed through the EMP. For radiological dose assessment, results of these monitoring and control activities are used to determine doses to members of the public and to ensure that doses remain below the regulatory limit.

For hazardous substance exposures, an approach encompassing a semi-quantitative pathways analysis was used to determine if members of the public would likely be exposed through air, water or the food chain.

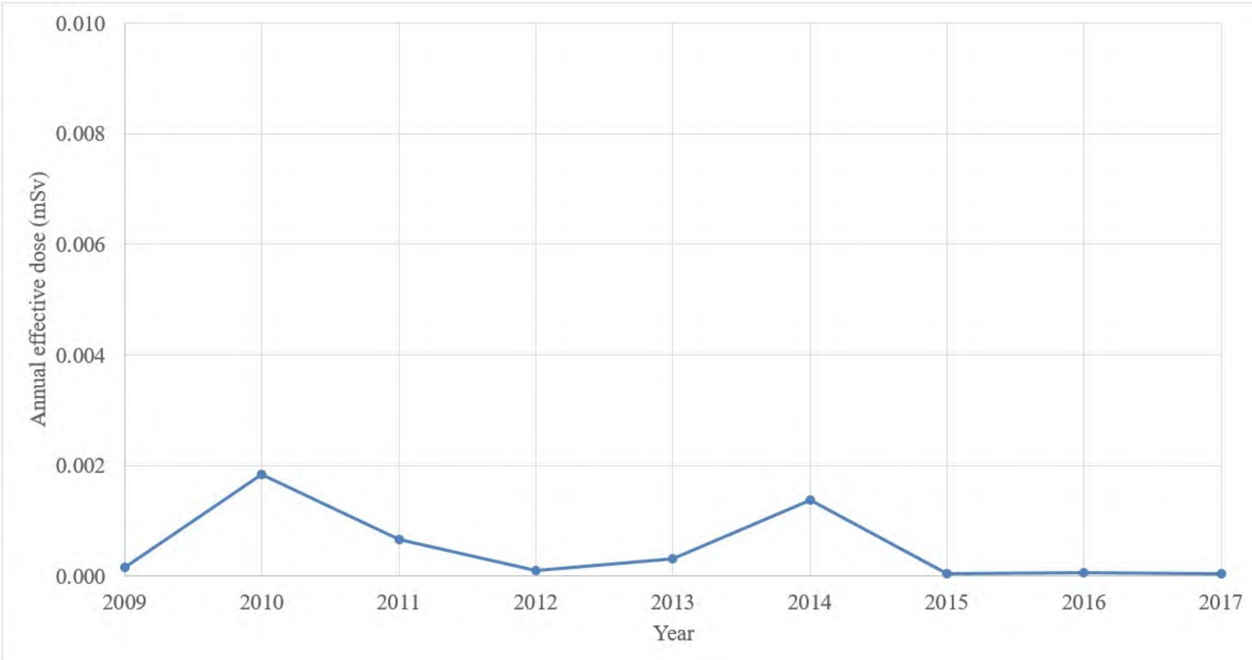
3.2.5.1 Public Exposure - Radiological

The CNSC's *Radiation Protection Regulations* [65] prescribe radiation dose limits to protect the public from exposure to radiation as a result of licensed activities. The annual effective dose limit for a member of the public is 1 mSv per year.

The annual doses to persons residing in the vicinity of the WL site are due to releases of radiological substances to the Winnipeg River, as well as from airborne emissions from various facilities on the site. The members of the public with the highest calculated exposure are residents located at a farm 3 km north of Building 200. These residents are assumed to reside year-round at the farm, to consume a significant fraction of fruits and vegetables grown at the farm, and are assumed to obtain all of their drinking water from the Winnipeg River, downstream of the WL site. Liquid effluents contribute almost entirely to the annual dose to these residents. They mainly originate from the Process Outfall, which consists of stormwater runoff from roadways and around buildings on the site, cooling water used in process and experimental faculties, water from holding tank discharges, as well as the active liquid waste treatment system tanks at Buildings 100 and 300. The remainder of liquid effluents originates from the sewage Lagoon, which collects sanitary and wastewater from most buildings on the site as well as from the laundry facility.

The annual doses to residents in vicinity of the WL site have been calculated based on environmental monitoring data as well as from measurements of airborne effluents. The dose to these farm residents in 2017, based on environmental monitoring, was 0.05 µSv (5×10^{-5} mSv) per year. The trend from 2009 to 2017 is shown in figure 3.4. During that period, the annual dose to the public did not exceed 0.002 mSv. The annual dose limit for members of the public, as stipulated in the *Radiation Protection Regulations* is 1 mSv. The annual dose from background radiation in the Winnipeg area is 4.1 mSv. This includes exposures from cosmic radiation, natural radioactivity in the ground and in food, as well as from radon.

Figure 3.4: Maximum calculated annual effective dose for a member of the public due to site releases of nuclear substances: 2009 to 2017 [15 to 23][25 to 33]*



* Annual effective dose over the previous licence period has remained consistently well below the annual public dose limit of 1 mSv per year. The variance shown in figure 3.4 is not considered by CNSC staff to be significant, and presents no concern with respect to risk to members of the public.

The 2017 dose to the public from the WL site remained well below the regulatory limit of 1mSv per year. Over the licensing period, CNL continued to ensure protection of members of the public in accordance with the *Radiation Protection Regulations* [65].

3.2.5.2 Public Exposure – Hazardous Substances

Effects on public health were assessed to determine if there was potential for exposure of members of the public to contaminants through several routes of exposure such as air, water or the food chain. This assessment included an evaluation of air quality, drinking water quality (surface water and groundwater), water quality of the Winnipeg River for recreational activities, and exposure to contaminants. The assessment did not include exposure to hazardous substances through consumption of food in the vicinity of the WL site, although the potential for exposure through this pathway is expected to be limited.

As onsite groundwater is not a source of drinking water, there is no direct exposure of humans from this pathway.

Measurements of hazardous substances contaminants in WL site effluents from the Lagoon and Process Outfall discharging to the Winnipeg River also indicated that concentrations of these substances did not exceed the monthly guideline limits. Monitoring of water quality of the Winnipeg River 40 km downstream from the WL site for hazardous substance parameters also indicated that, with the exception of aluminium, levels of metals are well below the Canadian drinking water quality guidelines (table 3.23). However, aluminum is an abundant element in the Earth’s crust (about 8 %) and elevated levels of this element in natural waters is not uncommon

[103][104]. Varying amounts of aluminum in North American rivers has been reported in the literature [105]. It is also unclear what, if any, aluminum contribution to the Winnipeg River has been made through operations at the WL site. Overall, it can be surmised that risk to human health via the drinking water ingestion pathway would be negligible.

Table 3.23: Average (and maximum) concentrations of metals from 2008 to 2018 measured at the water sampling station near the Powerview Dam on Winnipeg River, downstream of the WL site, from Manitoba Department of Sustainable Development [106]

Metal	Al	As	Cd	Cu	Cr	Mo	Ni	Se	U	Zn
Value (µg/L)	163 (239)	0.8 (1.7)	0.007 (0.008)	1.2 (1.3)	0.1 (0.1)	0.2 (0.2)	0.8 (1.0)	0.1(0 .2)	0.1 (0.2)	0.2 (0.3)
Canadian Drinking Water Quality Guideline (µg/L) [107]	100	10	5	1000	5	-	-	5	20	5000
WHO *Drinking Water Quality Guideline* (µg/L) [108]	900	10	3	2000	50	70	70	40	30	3000

Monitoring of hazardous substances atmospheric emissions from the WL site included contaminants such as nitrogen oxides, sulphur dioxide, carbon monoxide, particular matter (PM $_{10}$ and $PM_{2.5}$), and volatile organic compounds. Results of this monitoring suggest that risk to human health via the inhalation route of exposure would be negligible.

Characterization of hazardous substances contaminants in soil media and food near the site is not available. However, based on data reported for atmospheric emissions, which is the dominant source of deposition onto soil and food resources, exposure of humans to these contaminants via the ingestion pathway is likely to be limited.

Given that decommissioning activities are not expected to result in increased emissions of hazardous substances to air and surface water, it can be inferred that overall risk to human health is characterized as low.

3.2.5.3 Conclusion

Results of environmental monitoring indicated that dose to members of the public are well below the regulatory dose limit of 1 mSv per year. CNL ascertained to annual dose using the results of the effluent and EMPs at the WL site. These are described in section 3 of this report. The dose to residents living year-round on a farm near the WL site was calculated to be 0.05 µSv in 2017. A 10-year trend of the annual effective dose to exposed members of the public showed a downward trend. An evaluation of the routes of exposure to human receptors from groundwater, surface water, airborne emission, soil and food suggested that overall risk to health of members of the public from radiation was low.

Given that the decommissioning activities at WL are not expected to increase emission of radiological and hazardous substances to air and surface water, it can be inferred that the overall risk to human health is characterized as low.

4.0 CNSC INDEPENDENT ENVIRONMENTAL MONITORING PROGRAM

The CNSC has implemented its IEMP to verify that the public and the environment around licensed nuclear facilities are protected. It is separate from, but complementary to the CNSC's ongoing compliance verification program. The IEMP involves taking samples from public areas around the facilities, and measuring and analyzing the amount of radiological and hazardous contaminant substances in those samples. CNSC staff collect the samples and send them to the CNSC's laboratory for testing and analysis.

4.1 IEMP at the Whiteshell Laboratories Site

The IEMP was completed in 2017 around the WL site. The 2017 IEMP sampling plan for the WL site focused on radioactive contaminants. A site-specific sampling plan was developed based on the CNL's approved EMP and the CNSC's regulatory experience with the site. In 2017, CNSC staff collected air, soil, sediment, vegetation, food and water samples in publicly accessible areas outside the WL site perimeter.

CNSC staff sampled the following in the vicinity of the WL site:

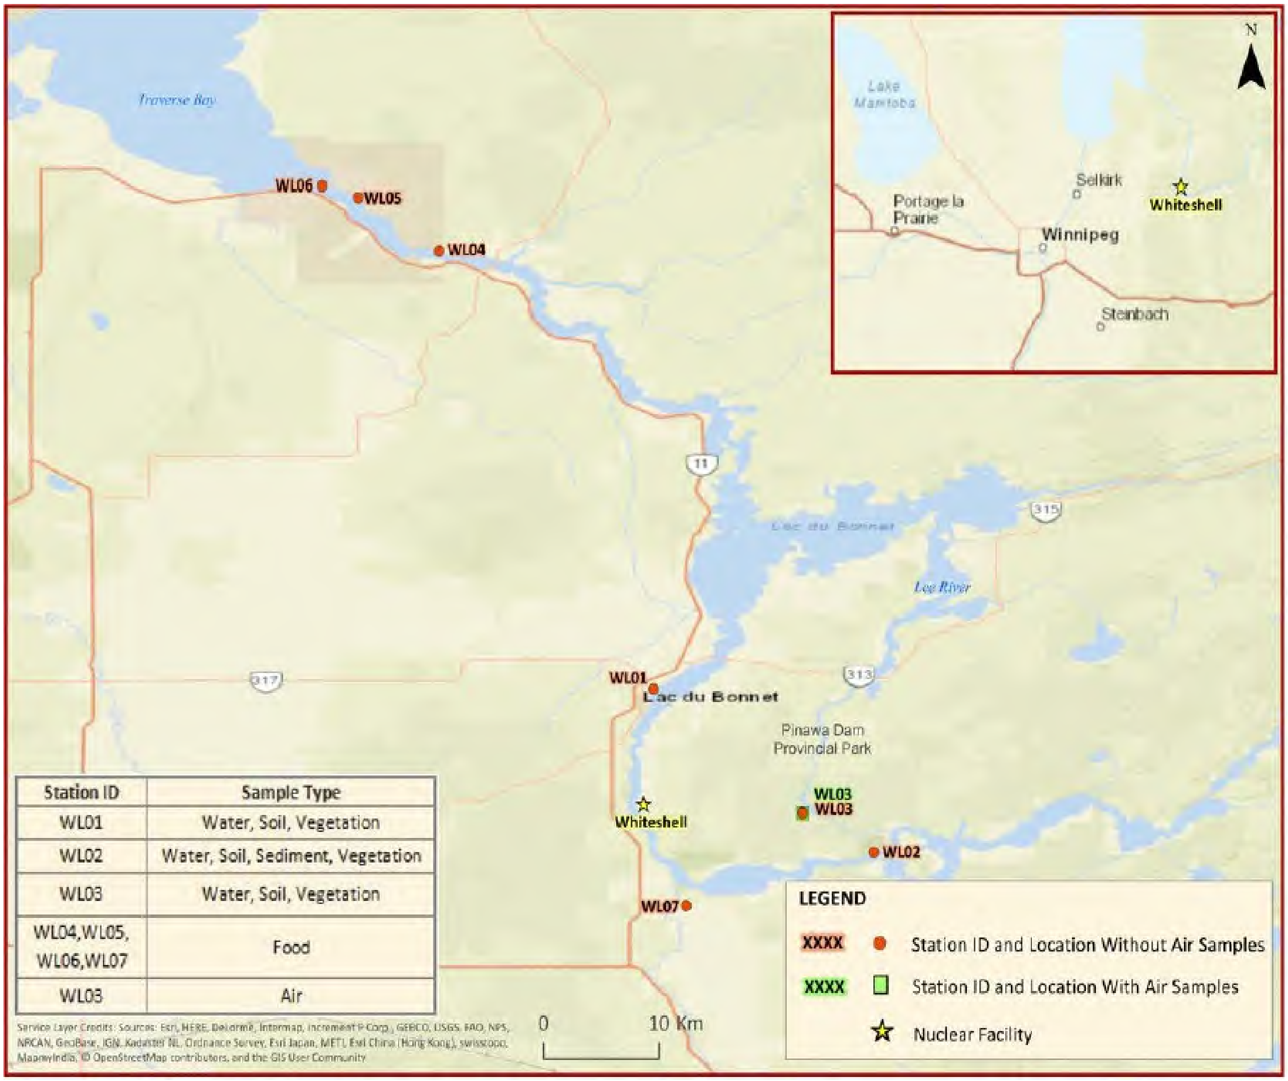
- air (1 location)
- water (3 locations)
- soil and sediment (4 locations)
- grass and wild vegetation (3 locations)
- food (6 locations)

Samples collected were analyzed by qualified laboratory specialists in the CNSC's laboratory in Ottawa, using appropriate protocols. CNSC staff measured the following:

- radioactive particulates, including caesium-137, cobalt-60, organically bound tritium, tritiated water, gross alpha and gross beta

Figure 4.1 provides an overview of the WL site and sample locations for the 2017 IEMP sampling campaign, and the IEMP results are published on the CNSC's website [36].

Figure 4.1: Location overview of the sample locations [36]



4.2 Sampling with Sagkeeng Anicinabe

It is a priority for the CNSC that IEMP sampling reflects Indigenous traditional land use, values and knowledge where possible. In addition to planned IEMP sampling activities, three fish were sampled on this trip, in collaboration with the Sagkeeng Anicinabe (Sagkeeng).

In May 2017, Sagkeeng and CNSC staff met to discuss the proposed *in situ* decommissioning of the WR-1 and IEMP. During that meeting Sagkeeng requested that fish from the Winnipeg River be sampled. Together, CNSC staff and Sagkeeng caught a northern pike sample, downstream from the WL site. Sampling results were provided to Sagkeeng in April 2018 and CNSC staff have made themselves available to discuss the results with the community. CNSC staff will continue to work with Indigenous communities in future sampling campaigns and will take into account any available IK studies to ensure meaningful results are obtained.

4.3 Summary of Results

The levels of radioactivity in all of the aforementioned samples were below available guidelines and CNSC screening levels, details of which can be found in the IEMP Technical Information Fact Sheet [109]. These screening levels are based on conservative assumptions about the exposure that would result in a dose of 0.1 mSv per year, which represents one tenth of the CNSC's public dose limit of 1 mSv per year. No health or environmental impacts are expected at these levels.

The IEMP results for 2017 indicate that the public and the environment in the vicinity of WL site are protected and that there are no expected health impacts. These results are consistent with the results submitted by CNL, demonstrating that the licensee's environmental protection program protects the health and safety of people and the environment.

5.0 HEALTH STUDIES

The following section draws from the results of regional health studies to provide further independent verification that the health of people living near the WL site is protected. The health of populations around the WL site are monitored by various organizations and institutions in Manitoba and disease rates are compared to other populations to detect any potential health outcomes that may be of concern. CNSC staff keep abreast of any new publications related to the health of populations living near nuclear facilities.

There are several health studies and reports that assessed the health of populations living the near WL site. The CNSC continues to carefully monitor and conduct health studies to ensure the protection of human health. Additional information on health studies related to nuclear facilities is available on the CNSC webpage on Health Studies [110].

The following sections provide a list of health studies carried out in the region.

5.1 Population and Community Health Studies and Reports

5.1.1 Interlake-Eastern Regional Health Authority (2014)

The Interlake-Eastern Regional Health Authority (RHA) and Community Health Assessment (2014) examines factors that affect the health of people living in areas serviced by the Interlake-Eastern Regional RHA and health outcomes within the populations, including those near the WL site [111]. Cardiovascular diseases (i.e., heart disease and stroke) are the leading cause of death in the region, followed by cancer. The region's cancer incidence rates are similar to the whole of Manitoba. The prevalence of related key risk factors was also assessed. The percentage of regional residents who currently smoke (23%) was slightly higher than that of Manitoba (20%). Similarly, the proportion of residents who are overweight or obese (62.3%) was slightly higher than the Manitoba average (56.4%).

This community health assessment also provides data on First Nations living in the region. The majority of the data are for First Nations living on reserve, which represents 80% of the First Nations population in the region. The Interlake-Eastern RHA summarizes data from CancerCare Manitoba 2013-2014 [112], and the First Nations Regional Health Survey 2008–2010 [113], which are also further described below. The cancer incidence rate for First Nations living on reserve within the Interlake-Eastern RHA was 629.6 cases per 100,000 people which was statistically significantly higher than the Manitoba average of 471.2 cases per 100,000 people and the regional average of 471.8 cases per 100,000 people. Furthermore, cancer survival rates were statistically significantly lower for First Nations living on reserve in the region compared to the provincial average.

First Nations in the region were well below the regional average for breast cancer, cervical, and colorectal cancer screening. Cancer screening increases the likelihood of early detection and treatment, and can improve cancer survival. The daily smoking rate for First Nations adults on reserve in the region (48.1%) was higher than the rate of First Nations living off reserve (16.4%), Manitoba (19.6%) and Canada (19.0%). Tobacco smoking is the main cause of cancer, especially lung cancer.

5.1.2 Manitoba Health (2016–2017)

The Manitoba Health, Seniors and Active Living's Annual Statistics Report describes Manitoba's population, health utilization and health status using key health indicators [114]. In Manitoba, the five most common causes of death include: heart disease (27.7%), cancer (27.1%), respiratory disease (8.6%), mental/behavioural issues (7.9%), and injuries (7.5%). The population within the Interlake-Eastern RHA have a slightly higher premature death rate compared to the Manitoba average, but also have higher rates of heart attacks, which may account for this increase [114]. However, there is no information provided on whether these differences are statistically significant.

5.1.3 CancerCare Manitoba Reports (2013–2014), (2015)

CancerCare Manitoba released a Community Health Assessment Report (2013–14) that examines cancer risk factors (such as smoking and limited physical activity), wait times for screening and treatment, and incidence, mortality and survival rates. Risk factors for cancer such as obesity, smoking and alcohol consumption, show considerable variation by region and are frequently higher in the North. In Manitoba, 23.4 % of the population are obese (this does not include individuals who are overweight), and 19.6 % are smokers [112].

The 2015 Annual Statistics Report, based on data from the Manitoba Cancer Registry, found lung cancer to be the most commonly diagnosed cancer site in Manitoba, followed by breast cancer. This is consistent with the leading cancer sites for Canada in 2015 [114]; however, the cancer mortality rate in Manitoba is slightly lower than the national rate [116].

5.1.4 Cancer Incidence in First Nations living in Manitoba

In Manitoba, First Nations people constitute almost 10% of the population. A study by Decker et al. (2016) looked at the prevalence of breast cancer and colorectal cancer incidence in First Nations in Manitoba compared to the provincial rate from 1984–2008 [117]. Historically, First Nations in Manitoba have had lower rates of cancer and chronic diseases than other Manitoba residents. However, the rate of cancer incidence and cancer mortality appears to be increasing due to changes in behavioural, environmental, other social factors and lower rates of participation in early cancer screening activities. Further, as life expectancy increases and people live into old age, we see an increase in cancer incidence and mortality rates.

Although overall breast cancer incidence remains lower for First Nations women compared to the provincial rate, the rate among First Nations women increased more rapidly from 1984–2008.

Likewise, the breast cancer mortality rate increased among First Nations women, whereas the provincial mortality rate decreased [117]. Similar increases in breast cancer incidence and mortality among Indigenous peoples has been observed elsewhere, in Greenland, New Zealand, United States and elsewhere in Canada. One of the factors that may influence this increase is breast cancer screening among First Nations women. Demers et al. (2015) assessed breast cancer screening rates among First Nations women compared to all other Manitoba women [117]. First Nations women had lower rates of mammography (a method to screen for breast cancer) compared to all other Manitoba women [118].

The incidence of colorectal cancer among First Nations people has also increased, and in 1999–2003, it surpassed the rate for all Manitobans. Although colorectal cancer mortality rate for all Manitobans declined over time, the colorectal cancer mortality rate for First Nations people increased by a factor of eight. Similarly, another study by Decker et al. (2015), found that First Nations living in Manitoba were less likely to have colorectal cancer screening [119].

5.1.5 First Nations Regional Health Survey (2008–2010)

The First Nations Regional Health Survey (RHS) Phase 2 (2008-2010): Manitoba Regional Report [120] was designed, developed, and delivered by Indigenous peoples across Canada. The self-report survey was supported by the Manitoba Chiefs-in Assembly. The report presents a snapshot of a variety of health indicators, including self-assessment of health, access to care, and socio-economic factors in First Nations people of Manitoba for 2008–2010, as well as providing data on involvement in traditional activities on lands, and related culturally based indicators.

For health outcomes the two most prevalent chronic diseases amongst Manitoba First Nation adults are hypertension (high blood pressure) and diabetes, with the vast majority being type 2 diabetes. In terms of health risk factors, approximately 50% of young adults (18–34) and adults (35–54) are daily smokers with lower rates for those age 55 and older. Access to health care is also a major issue; 55.8% of adults indicate that they have less access to health services compared to the general Canadian population, mainly due to long wait times and lack of health care providers [120].

5.2 Summary of Health Studies

Reviewing and conducting health studies and reports is an important component of ensuring that the people living near nuclear facilities are protected. The population and community health studies and reports indicate that common causes of death among the Manitoba populations (provincial, Interlake-Eastern RHA, and First Nations) include heart disease and cancer. This is similar to other provinces in Canada where heart disease and cancers are the two leading causes of death, aside from Nunavut, where heart disease and respiratory diseases are the leading causes of death [121].

The above health studies are descriptive studies which compare the occurrence of health outcomes within a population at a certain time in a given geographical area to the “expected” occurrence of the disease in a stable reference population (such as the general population of the province or Canada). Descriptive studies have some limitations, such as: 1) the results are averaged over a group and do not look at the individual level, and 2) individual exposures are not known, and they cannot be used to determine the cause of a health outcome, however they are used to generate hypotheses regarding potential risk factors for health outcomes. For further information regarding advantages and disadvantages of health study designs please see INFO-0812 [122].

These health studies and reports provide a snapshot of the health of people living near the WL site. CNL currently meets CNSC's regulatory requirements. Based on exposure and health data, CNSC staff have not observed and do not expect to observe any adverse health outcomes due to the presence of the WL site.

6.0 OTHER REGIONAL MONITORING PROGRAMS

There are several regional monitoring programs carried out by other levels of government, which the CNSC has reviewed to confirm that the environment and the health of persons around the WL site are protected. A summary of the findings of these programs are provided below.

The Radiation Protection Bureau of Health Canada manages the Canadian Radiological Monitoring Network (CRMN) [123]. The CRMN routinely collects drinking water, precipitation, atmospheric water vapour, air particulate, and external gamma dose for radioactivity analysis at 26 monitoring locations. The closest CRMN monitoring location to the WL site is in Winnipeg. The results at the Winnipeg station for 2017 and 2018 are consistent with data from previous years and are well below the acceptable public dose limit.

In addition, Health Canada has complemented its CRMN network with a Fixed Point Surveillance (FPS) system [124]. The FPS functions as a real-time radiation detection system designed to monitor public dose from radioactive materials in the air, including atmospheric releases associated with nuclear facilities and activities both nationally and internationally. Monitoring stations continuously measure gamma radioactivity levels from ground-deposited (ground-shine) and airborne contaminants.

Health Canada measures the radiation dose rate as Air KERMA (Kinetic Energy Released in unit MAss of Material) reported as nanoGray per hour (nGy/h) of absorbed dose. These measurements are conducted every 15 minutes at 79 sites of its FPS network across the country. Air KERMA is also measured for three radioactive noble gases associated with nuclear fission which may escape into the atmosphere during normal operation of nuclear facilities. These three noble gases are Argon-41, Xenon-133 and Xenon-135. CNSC staff converted the absorbed dose rate to an effective dose, reported in mSv per year, which allows for comparison to annual background dose estimates and the regulatory public dose limit.

The 2017 and 2018 total external gamma doses reported for the FPS network near Winnipeg are similar to the Canadian average for natural background from gamma (the range is 0.007 – 0.027 mSv per year). These results indicate that total external gamma dose at these stations is not significantly influenced by activities at the WL site. Further evidence of this is provided by the extremely low activity levels reported for the noble gases, as outlined in table 6.1. All of the results are significantly below the public dose limit of 1 mSv.

Table 6.1: Annual external gamma doses (mSv per year[1]) for 2017 and 2018 at the Fixed Point Surveillance network monitoring stations associated with the WL site.

Monitoring stations near Whiteshell	External gamma dose				
	Year	All gamma sources	Monitored noble gases (Fission products)		
			Argon-41	Xenon-133	Xenon-135
Winnipeg	2017	0.011	*	*	*
Winnipeg	2018	0.011	*	*	*

*No data is reported when results were below the minimum detectable dose
[1] Assumptions: adult located at monitoring station for 24 hours a day, 365 days per year. Air KERMA in nanoGray corrected. Total Dose: 0.69 mSv for every Gray of absorbed dose measured: Argon-41: 0.74; Xenon-133: 0.75; Xenon-135: 0.67.

7.0 INDIGENOUS KNOWLEDGE STUDIES

The CNSC acknowledges the importance of working with and integrating IK into staff assessments and regulatory activities, when provided to the CNSC by Indigenous communities. One way in which the CNSC integrates IK is through collaboration and understanding of IK studies pertaining to CNSC regulated facilities and activities. These studies provide community-specific knowledge of the land, waters, and resources where CNSC-regulated facilities are located and of the potential or existing interactions of those facilities with Indigenous communities' historic and current land use, values, rights and interests. The studies and IK contained within them, represent the distinct Indigenous perspective on their specific interests, exercise of their rights, and potential impacts on the same.

In January 2019, CNSC staff received an IK study from the Manitoba Metis Federation (the MMF, which is the democratically elected, self government representative of the Manitoba Metis Community) [37][38] pertaining to the proposed *in situ* decommissioning activities for the WR-1 reactor at the WL site, located within their traditional territories. This study was supported by the CNSC's Participant Funding Program (PFP), as part of the WR-1 EA and licensing review process (which is separate from this licence renewal process), and conducted in order to provide CNSC staff and CNL with Indigenous-specific knowledge and perspectives of the proposed decommissioning activities for the WR-1 reactor. This study also assessed the potential impacts of the newly proposed *In Situ* Decommissioning of the WR-1 Project to Manitoba Metis Community's historic connection to, contemporary use of, and occupancy of this portion of their traditional territory.

CNSC staff are currently reviewing the MMF's study in detail and are working with the MMF on how to best incorporate and reflect the information into CNSC's regulatory review processes and activities pertaining to the WL site, including the ongoing review of the proposed *In Situ* Decommissioning of the WR-1 Project that is the subject of a separate EA and licensing review process. For the purposes of the WL site licence renewal and this EPR, the information provided in the study has not been incorporated into the Environmental Effects Assessment section of this report (section 3.2). CNSC staff require more time to adequately consult and collaborate with the MMF, in order to ensure the contents of their study is appropriately and respectfully integrated into CNSC regulatory processes and assessments, and that potential impacts on rights and concerns identified in the studies are adequately addressed, mitigated and resolved.

CNSC staff recognize that MMF has unique values and interests. Their IK study provides a distinct set of data and perspectives that help the CNSC better understand how the MMF view the proposed WR-1 decommissioning activities and the WL site's interaction with their traditional territory, along with key VCs that are considered vital to their citizens, in exercising their Indigenous rights. The relevant VCs and baseline conditions detailed in the study has been summarized at a high level in this EPR Report, in order to acknowledge all information available to CNSC staff, which will be fulsomely examined and incorporated in collaboration with MMF moving forward.

The CNSC endeavours to collaborate with Indigenous communities in order to ensure IK is appropriately protected, managed and reflected in resulting documentation, where appropriate. The following section discussing the MMF study has been reviewed by the MMF, in advance of publishing this EPR Report. MMF has given CNSC staff permission to include this content and have collaborated in compiling the respective portions of Section 7.

Notwithstanding this collaborative approach, it is important to read their report in its entirety for the full context of the information provided below, including the distinct Indigenous-perspectives captured in each study, and acknowledge that this section reflects a high-level summary of the information.

In addition, CNSC staff received in January 2019 an IK study from Sagkeeng pertaining to the proposed *in situ* decommissioning activities for the WR-1 reactor at the WL site, located within their traditional territory. This study was also supported by the CNSC's Participant Funding Program (PFP), as part of the WR-1 EA and licensing review process (which is separate from this licence renewal process), and conducted in order to provide CNSC staff and CNL with Indigenous-specific knowledge and perspectives of the proposed *In Situ* Decommissioning of the WR-1 Project. This study also assessed the potential impacts of the newly proposed *In Situ* Decommissioning of the WR-1 Project to Sagkeeng's historic connection to, contemporary use of, and occupancy of this portion of their traditional territory.

Sagkeeng has clarified with CNSC staff that the scope of their study is specific to the *In Situ* Decommissioning of the WR-1 Project and does not include inputs from Sagkeeng members on the management of the whole WL site or anything beyond WR-1. This was a project-specific Land Use and Occupancy Study and its results cannot be automatically interpolated to extend and encompass other issues relating to the WL site, or Sagkeeng territory. Therefore, CNSC staff have not included a summary of the Sagkeeng study in this EPR Report, which is specific to the WL site licence renewal process.

The concerns raised in Sagkeeng's study are primarily focused on the proposed *In Situ* Decommissioning of the WR-1 Project and not specific to the renewal of the WL site. CNSC staff are committed to working with Sagkeeng leadership and community members to help address the concerns raised in their study, with relation to the proposed *In Situ* Decommissioning of the WR-1 Project. CNSC staff will continue to work to meaningfully incorporate the values and information provided by Sagkeeng into CNSC's regulatory processes and activities, including the EA and licensing process for the proposed *In Situ* Decommissioning of the WR-1 Project and to fulfill its obligations related to the duty to consult and accommodate, where appropriate, and uphold the honour of the Crown in relation to the proposed activities.

7.1 Manitoba Metis Federation

In 2018, the MMF undertook a Traditional Knowledge, Occupancy and Land Use Study, in collaboration with Shared Value Solutions (SVS), related to the proposed *In Situ* Decommissioning of the WR-1 Project [37]. The study had three stated main goals:

1. Provide evidentiary data of how Metis harvesters who participated in the study are using the lands and waters around the WR-1 Reactor site;
2. Provide information on consumption frequency and quantity as it relates to harvested country foods relied on by Metis harvesters within a 50 km area around the WR-1 Reactor site;
3. Provide this information in a format that is consistent with the current MMF Metis Land Use and Occupancy data so that the study can build upon this existing information.

Although the focus of the study was primarily on the *In Situ* Decommissioning of the WR-1 Project, the scope of this study is relevant to the WL site under consideration for licence renewal as it highlights various concerns of MMF community members (also known as MMF Citizens) and includes evidence about MMF Citizens past and present use of the WL site and surrounding area to exercise their Metis specific rights, practices and traditions. However, it is important to note that the study is specific to the proposed decommissioning activities for the WR-1 project and the building in which it resides[5], not the WL site as a whole.

7.1.1 Study Scope and Valued Ecosystem Components

The information in the study is based on interviews with 10 citizens and harvesters from the Manitoba Metis Community, conducted between November 19 and 23, 2018. Participants were selected through self-identification on a consumption survey mailed to Metis citizens that attended a MMF information and engagement meeting held in Lac Du Bonnet, MB, as well as through phone contact with MMF Citizens holding Metis harvesting cards.

The data collected for this study was obtained using a map biography process, involving the marking of locations of features identified during interview discussion on digital maps using the ESRI Arc Geographic Information System program. At the same time, interview participants provided descriptions associated with the data points. This information was augmented by oral interviews, where participants shared traditional knowledge of the land through direct recollections, family stories, perceptions of the areas in question, and future hopes for the study areas.

The data provided in these interviews are discussed and analyzed as site-specific use values, geographically located within a particular proximity to the proposed *In Situ* Decommissioning of the WR-1 Project according to two scales (as described in table 7.1). Furthermore, table 7.2 contains the details of the number of site-specific use values, according to location type including observed changes to the environment.

[5]Referred to in this section, for purposes of this study, as the WR-1 facility.

Table 7.1: Manitoba Metis Federation Study Areas [37]

Study area	Description
100 m Study Area	This area includes the Winnipeg River, between Seven Sisters to the mouth of Lake Winnipeg, as well as Lac du Bonnet and the Lee River. In addition to these water bodies, a 100 m buffer on either side of these bodies are included in this Study Area.
25 km Study Area	This area represents a 25 km buffer around the WR-1 site.

Table 7.2: Manitoba Metis Federation locations of Land Use and Occupancy [37]

Location types	100 m Study area	25 km Study Area (including 100 m Study Area)
Access routes	12	23
Fishing locations	38	44
Trapping / snaring locations	-	3
Gathering locations	-	18
Commercial guiding or other commercial land use	-	3
Changes to environment	15	32
Hunting locations	2	8
Demographic locations	2	41
Locations of cultural significance	2	11
Other land use (Ice-fishing huts)	2	2
Total	**75**	**192**

In addition to the 192 sites of land use and occupancy (LUO) identified within the 25 km study area, an additional 232 locations of LUO were identified by participants, for a total of 424 Metis LUO locations. Each of these identified Metis LUO locations represents evidence of the exercise of Metis specific s. 35 rights, practices, or traditions in the study area. The temporal scope of this use is according to "current use", which is defined as within the lifetime of the interview participant. These results cannot be considered a comprehensive representation of all Manitoba Metis Community LUO in the study areas, but rather provide a reasonable representation of the information that is available from a small sample of the Manitoba Metis Community, based on the limited interviews undertaken and study scope.

In addition to the detailed description of these LUO locations identified in this study, MMF produced a *Review of Draft Valued Components (VCs) and Related Measurement Endpoints and Indicators for the Project Environmental Impact Statement (EIS)* [38]. Table 7.3 contains all of the VCs identified in both documents. The VCs identified by the MMF specifically relate to environmental components that, if affected by the *In Situ* Decommissioning of the WR-1 Project activities, could potentially have corresponding impacts on s. 35 Metis rights. Many of the specific biota VC species were identified based upon MMF Citizens providing evidence in the interviews and study of direct consumption and reliance on these species for substance purposes.

In addition, the *Review of Draft Valued Components (VCs) and Related Measurement Endpoints and Indicators for the Project Environmental Impact Statement (EIS)* highlighted that a distinctions-based approach, which considers the Manitoba Metis Community's VCs as distinct from other Indigenous and non-Indigenous VCs, would more accurately and meaningfully identify, measure, and consider impacts on MMF Citizens. CNSC will be working with the MMF through the WR-1 EA and licensing process to ensure the different impacts, uses, and considerations for each VC are considered through a Metis-specific lens as the CNSC acknowledges the distinct knowledge, perspective, and experience of MMF Citizens.

Table 7.3: Valued components identified by the Manitoba Metis Federation [37][38]

Category	Valued components
Air	Air Quality
Water	Surface water and groundwater quality (drinking water)
Sediment	Sediment quality
Soil	Soil quality and quantity
Biota	Fish: walleye / pickerel, lake sturgeon, carmine shiner, lake whitefish, smallmouth bass, jackfish / northern pike, suckers, goldeye, mooneye, perch, and catfish Aquatic Invertebrates: benthic invertebrates
	Birds: geese, ducks, ruffed grouse, spruce grouse, partridge, horned grebe, trumpeter swan, mallard, barn swallow, and golden-winged warbler, American robin, loggerhead shrike Mammals: moose, white-tailed deer, marten, rabbit, squirrel, weasel, mink, meadow vole, common shrew, snowshoe hare, white-tailed deer, red fox, northern myotis and little brown myotis Invertebrates: earthworm Reptiles: snapping turtle
	Plants: wild rice, berries (blueberries, pin cherries, cranberries, Saskatoon berries, chokecherries, gooseberries, strawberries, raspberries and wild plums); Labrador tea, fiddleheads and hawthorn nuts; other aquatic and terrestrial plants, including grasses and shrubs, including flowers; trees including poplar, spruce, jackpine, birch; flowers
Ecosystem	Various areas that serve as habitat, including: marsh habitat, for wild rice, as well as jackfish and water fowl; fish habitat for sturgeon and jackfish, in order to ensure self-sustaining and ecologically effective fish populations; plant and berry, bird, mammal and reptile habitat, more generally
Human	Socioeconomic: government finances, business opportunities, community well-being, infrastructure and services, employment and income
	Human Health: public health and safety, worker health
	Traditional land and resource use: hunting, fishing, trapping, plant and berry gathering, as well as outdoor recreation and tourism, capacity for continued land tenure and use, tubing on the water, access to boat launches, land and water trails, gathering of firewood
	Cultural and Archaeological Sites: protection and preservation of cultural and archaeological sites; gathering places, picnic areas, swimming areas
	Sense of well-being: connection to the land, spiritual practices

7.1.2 Reported Impacts to Manitoba Metis Federation Citizens

Overall, the study demonstrated that MMF Citizens rely on and use the land and waters around the WL site for various cultural and traditional activities, and have done so both prior to the construction of the WR-1 and WL site and continue to do so in the present day. MMF Citizens interviewed for the study expressed concerns about degradation of water quality and resources, and the impacts of extreme weather events on the WL site leading to potential impacts to human and environmental health in the 100m and 25km study areas and beyond. Study participants stressed how contamination of the land, waters and species that they value and rely on to maintain their Metis specific traditions, exercise their rights, and feed their families, both in and around the WL site, could have cascading impacts on MMF Citizens (through impacts to aquatic and terrestrial resources, contamination of resources relied on, and their cultural ways of life).

The MMF interviewees expressed a desire to have a better understanding of all activities taking place on the WL site, potential impacts of these activities, and the mitigation measures in place. The study expressly recommended further engagement between CNSC and the MMF to further address these potential impacts and concerns.

The study concluded that many MMF Citizens have concerns based on their harvesting experience about contamination and the quality of water, plants, fish, wild rice, medicines, berries, wildlife and plant species in their traditional territory, including the WL site. MMF Citizens expressed that they would like further information regarding the safety of these resources to help address their perception of potential or real contamination or risk of traditional resources. The study also provided evidence by Metis Citizens that a perception of a contamination risk associated with the WL site could impact their s. 35 harvesting activities in the study area and result in avoidance behaviours that affect Metis Citizens preferred means of exercising their s. 35 rights.

The study also provided evidence of outstanding questions regarding the progress of decommissioning activities at the WL site and overall timelines. Interviewees requested more frequent communication on these topics from CNL and the CNSC, and wish to participate in the planning and oversight of these activities in order to ensure that Metis laws of harvest and harvesting timeframes are adequately considered. Throughout the upcoming WR-1 EA process and the lifecycle regulation of the WL site, the CNSC will continue to work with the MMF to address these concerns and perceptions, including providing regular updates on the WL site and decommissioning activities and assessing potential impacts and VCs identified in their IK study and through consultation.

Given the concerns raised and desire for continued stewardship of Metis traditional territories, interviewees demonstrated an interest in serving as equal partners in problem solving and decision-making regarding land use and decommissioning activities on and around the WL site, to help contribute to the sustainability of their traditional territories, including preservation and accessibility for future generations.

7.1.3 Conclusion

The experiences and values of the Metis Citizens interviewed in the Metis Traditional Knowledge, Occupancy and Land Use Study describe the importance of various sites in proximity to the WL site relating to hunting, trapping and fishing activities, harvesting activities, as well as overall well-being and way of life of the Manitoba Metis Community.

The data collected in this study demonstrates how in and around the WL site has been, and continues to be, used by MMF Citizens for activities that are important to the Manitoba Metis Community's culture, traditions, rights and ongoing livelihood. Furthermore, the detailed accounts reveal evidence of the participants' concern that these cultural practices and exercise of their Metis-specific s. 35 rights have been impacted by activities at the WL site and that there are ongoing concerns regarding potential impacts associated with the decommissioning and other proposed activities.

Through this study MMF has identified a number of VCs of significance to their rights, culture and interests, in and around the WL site. These include resources such as water, medicines and subsistence resources (plants, berries, fish and game), the associated traditional activities, such as harvesting, hunting, and trapping, as well as Metis ways of life, incorporating concepts such as sense of place, identity, connection to the land, psychological well-being, ceremonial practices, and methods of knowledge-sharing.

CNSC staff are committed to working with MMF leadership and Citizens to help address the concerns raised in the study, with relation to the WL site. CNSC staff will continue to work meaningfully with the MMF to incorporate the values and information provided in their IK study into CNSC's regulatory processes and activities, including the EA and licensing process for the proposed *In Situ* Decommissioning of the WR-1 Project and to fulfill its related duty to consult and accommodate, where appropriate, and uphold the honour of the Crown in relation to the proposed activities.

8.0 RECOMMENDATIONS AND CONCLUSIONS

The EPR conducted for the WL Nuclear Research and Test Establishment Decommissioning Licence concludes that CNL has taken adequate provisions for the health of persons and the protection of the environment and will continue to do so in the future.

CNSC staff reviewed CNL's licence application and the documents submitted in support of the application, as well as the CSR, annual reports, and compliance verification activities conducted at the WL site. CNSC staff conclude the licence application and supporting documents submitted in support of the application are satisfactory and meet CNSC's regulatory requirements.

CNSC staff also reviewed the results from other regional monitoring programs conducted by other levels of government, which substantiate CNSC staff's conclusion that the environment and health of persons are protected from operations at the WL site. CNSC staff also conducted IEMP sampling around the WL site in 2017. Both the regional monitoring results and IEMP results confirm that the public and the environment around the WL site are protected and that there are no health impacts as a result of ongoing activities. These results are consistent with the results submitted by CNL, demonstrating that the licensee's environmental programs protect the health of persons and the environment.

CNSC staff acknowledge the concerns raised by MMF in information they have provided to the CNSC, including through their IK study. CNSC staff are committed to working with MMF leadership and citizens to help address the concerns raised. The values and information provided by this IK study will be meaningfully incorporated into CNSC's regulatory work and activities, including, but not limited to the EA for the *In Situ* Decommissioning of the WR-1 Project.

This EPR focused on items of current public and regulatory interest, including physical stressors, releases to air, groundwater and surface water from ongoing operations and activities related to ongoing decommissioning activities. CNSC staff conclude that the potential risk from physical stressors and radiological and hazardous releases to the atmospheric, terrestrial, hydrogeological, aquatic and human environment are low to negligible. However, CNSC staff expect that CNL will conduct a site-wide ERA in accordance with REGDOC-2.9.1 and the CSA Standard N288.6-12, *Environmental Risk Assessment at Class I Nuclear Facilities and Uranium Mines and Mills* during the next licensing period

This EPR conducted for the renewal of the WL NRTEDL concludes that CNL has and will continue to make adequate provision for the protection of the environment and the health of persons. CNSC staff will continue to verify and ensure that, through ongoing licensing and compliance activities and reviews, the environment and the health of persons are protected and will continue to be protected over the proposed licence period.

The information provided in this EPR Report supports the recommendation by CNSC staff in CMD 19-H4 to renew CNL's Nuclear Research and Test Establishment Decommissioning Licence for the WL site (NRTEDL-W5-8.05/2019) for a period of ten years.

ACRONYMS

Acronym	Term
AECL	Atomic Energy Canada Limited

ESEA	Endangered Species and Ecosystems Act (Manitoba)
EVMP	Effluent Verification Monitoring Program
FFS	Fitness for Service
FPS	Fixed Point Surveillance
FWSER	Federal Wastewater System Effluent Regulations
Go-Co	Government-owned, Contractor-operated
GHG	Greenhouse Gas
GMP	Groundwater Monitoring Program
GWP	Global Warming Potential
HLW	High Level Waste
IEMP	Independent Environmental Monitoring Program
IK	Indigenous Knowledge
ILW	Intermediate Level Waste
KERMA	Kinetic Energy Released in unit MAss of Material
LCH	Licence Condition Handbook
LLW	Low Level Waste
LUO	Land Use and Occupancy
mSv	Millisievert
MMF	Manitoba Metis Federation
NAAQO	National Ambient Air Quality Objectives
NPRI	National Pollutant Release Inventory
NRTEOL	Nuclear Research and Test Establishment Operating Licence
NRTEDL	Nuclear Research and Test Establishment Decommissioning

	Licence
NSCA	*Nuclear Safety and Control Act*
NSRDR	Nuclear Substance and Radiation Devices Regulation
PFP	Participant Funding Program
PM	Particulate Matter
RA	Responsible Authority
ROR	Regulatory Oversight Report
Sagkeeng	Sagkeeng Anicinabe
SARA	*Species at Risk Act*
SF	Shielded Facility
SVS	Shared Value Solutions
TSP	Total suspended particulates
VCs	Valued Components
WL	Whiteshell Laboratories
WMA	Waste Management Area
WR-1	Whiteshell Reactor #1

PART TWO

Part two provides all relevant information pertaining directly to the licence, including:

[1] Any proposed changes to the conditions, licensing period, or formatting of an existing licence;

[2] The proposed licence;

[3] The draft licence conditions handbook; and

[4] The current licence.

PROPOSED LICENCE CHANGES

Overview

CNL currently operates Whiteshell Laboratories under the Nuclear Research and Test Establishment Decommissioning Licence, NRTEDL-W5-8.05/2019[1]. The proposed licence incorporates the standard licence conditions and standard format.

Licence Conditions

The proposed licence incorporates the standard licence conditions applicable to the WL site.

Licence Format

The proposed licence uses the standard format.

Licence Period

CNL has requested a renewal of the WL licence for a period of 10 years until December 31, 2029. Based on CNSC staff review of the CNL application, performance history, and supporting information, CNSC staff support CNL's request for a licence period of 10 years. Over the proposed 10 year period, CNSC staff would provide regular reporting on regulatory oversight conducted at the WL site in public Commission proceedings.

PROPOSED LICENCE

The proposed Licence is provided on the following pages of the document.

e-Doc 5768606 (WORD)

e-Doc 59632032 (PDF)

NUCLEAR RESEARCH AND TEST ESTABLISHMENT DECOMMISSIONING LICENCE

WHITESHELL LABORATORIES

I) LICENCE NUMBER: **NRTEDL-W5-8.06/2029**

II) LICENSEE: Pursuant to section 24 of the *Nuclear Safety and Control Act*, this licence is issued to

Canadian Nuclear Laboratories Ltd
Laboratoires Nucléaires Canadiens Ltée
286 Plant Road
Chalk River, Ontario
K0J 1J0

III) LICENCE PERIOD: This licence is valid from January 1, 2020 and remains in effect until December 31, 2029 unless otherwise suspended, amended, revoked or replaced.

IV) LICENSED ACTIVITIES:

This licence authorizes the licensee to:

a) operate and decommission the Whiteshell Laboratories (hereinafter “WL”) located in Pinawa, Province of Manitoba as further described in the Whiteshell Laboratories *Licence Conditions Handbook* (LCH) ,

b) produce, possess, process, refine, transfer, use, package, manage, and store the nuclear substances that are required for, associated with or arise from the activities described in a),

c) possess, use, produce and transfer prescribed equipment that is required for, associated with, or arises from the activities described in a),

d) possess, use and transfer prescribed information that is required for, associated with, or arises from the activities described in a),

e) carry out the site preparation, construction or construction modification or undertaking that is required for, associated with or arise from the activities described in a).

V) EXPLANATORY NOTES:

(i) Nothing in this licence shall be construed to authorize non-compliance with any other applicable legal obligation or restriction.

(ii) Unless otherwise provided for in this licence, words and expressions used in this licence have the same meaning as in the *Nuclear Safety and Control Act* and associated Regulations.

(iii) The Whiteshell Laboratories Licence Conditions Handbook (LCH) provides compliance verification criteria used to verify compliance with the conditions set out in this licence, including information regarding delegation of authority and applicable versions of documents and a process for version control of codes, standards or other documents that are used as compliance verification criteria.

VI) CONDITIONS:

G GENERAL

G.1 The licensee shall conduct the activities described in Part IV of this licence in accordance with the licensing basis, defined as:

(i) the regulatory requirements set out in the applicable laws and regulations;

(ii) the conditions and safety and control measures described in the facility's or activity's licence and the documents directly referenced in that licence; and

(iii) the safety and control measures described in the licence application and the documents needed to support that licence application;

unless otherwise approved in writing by the Canadian Nuclear Safety Commission (hereinafter "the Commission").

G.2 The licensee shall give written notification of changes to the facility or its operation, including deviation from design, operating conditions, policies, programs and methods referred to in the licensing basis.

G.3 The licensee shall maintain a financial guarantee for decommissioning that is acceptable to the Commission.

G.4 The licensee shall implement and maintain a public information and disclosure program.

1 MANAGEMENT SYSTEM

1.1 The licensee shall implement and maintain a management system.

2 HUMAN PERFORMANCE MANAGEMENT

2.1 The licensee shall implement and maintain a human performance program.

2.2 The licensee shall implement and maintain a training program.

3 OPERATING PERFORMANCE

3.1 The licensee shall implement and maintain an operating program, which includes a set of operating limits.

3.2 The licensee shall implement and maintain a program for reporting to the Commission or a person authorized by the Commission.

4 SAFETY ANALYSIS

4.1 The licensee shall implement and maintain a safety analysis program.

4.2 The licensee shall implement and maintain a nuclear criticality safety program.

5 PHYSICAL DESIGN

5.1 The licensee shall implement and maintain a design program.

5.2 The licensee shall implement and maintain a pressure boundary program.

6 FITNESS FOR SERVICE

6.1 The licensee shall implement and maintain a fitness for service program.

7 RADIATION PROTECTION

7.1 The licensee shall implement and maintain a radiation protection program, which includes a set of action levels. When the licensee becomes aware that an action level has been reached, the licensee shall notify the Commission within seven days.

8 CONVENTIONAL HEALTH AND SAFETY

8.1 The licensee shall implement and maintain a conventional health and safety program.

9 ENVIRONMENTAL PROTECTION

9.1 The licensee shall implement and maintain an environmental protection program, which includes a set of action levels. When the licensee becomes aware that an action level has been reached, the licensee shall notify the Commission within seven days.

10 EMERGENCY MANAGEMENT AND FIRE PROTECTION

10.1 The licensee shall implement and maintain an emergency preparedness program.

10.2 The licensee shall implement and maintain a fire protection program.

11 WASTE MANAGEMENT

11.1 The licensee shall implement and maintain a waste management program.

11.2 The licensee shall implement and maintain a decommissioning plan.

12 SECURITY

12.1 The licensee shall implement and maintain a security program.

13 SAFEGUARDS AND NON-PROLIFERATION

13.1 The licensee shall implement and maintain a safeguards program.

14 PACKAGING AND TRANSPORT

14.1 The licensee shall implement and maintain a packaging and transport program.

SIGNED at OTTAWA, ______________________.

TABLE OF CONTENTS

INTRODUCTION

The general purpose of the Licence Conditions Handbook (LCH) is to identify and clarify the relevant parts of the licensing basis for each licence condition. This will help ensure that the licensee performs the licensed activities at the Whiteshell Laboratories (WL) in accordance with the licensing basis for WL and the intent of the WL licence. The LCH should be read in conjunction with the licence.

The LCH typically has three parts under each licence condition: the Preamble, Compliance Verification Criteria (CVC), and Guidance. The Preamble explains, as needed, the regulatory context, background, and/or history related to the licence condition. CVC are criteria used by CNSC staff to verify and oversee compliance with the licence condition. Guidance is non-mandatory information, including direction, on how to comply with the licence condition.

The documents referenced in the LCH by e-Access numbers are not publicly available. The links provided in the LCH are references to the internal CNSC electronic filing system, and those documents cannot be opened from outside of the CNSC network.

Current versions of the licensing basis publications, licensee documents that require notification of change, and guidance documents referenced in the LCH are tracked in the document *Licensing Documents for Whiteshell Laboratories-WL-Specific* (e-Doc 5776580) and -*Company-Wide* (e-Doc 5507946), which are controlled by the Canadian Nuclear Laboratories Regulatory Program Division and are available to the licensee upon request.

Most CNSC documents referenced in the LCH are available through the CNSC public website. Documents listed on the CNSC website may contain prescribed information as defined by the *General Nuclear Safety and Control Regulations*. Information in these documents will be made available only to stakeholders with appropriate security clearance on a valid need to know basis.

The licensee documents referenced in the LCH are not publicly available; they contain proprietary information or prescribed information as defined by the *General Nuclear Safety and Control Regulations*.

Domestic and international standards (in particular consensus standards produced by the CSA Group) are an important component of the CNSC's regulatory framework. Standards support the regulatory requirements established through the *Nuclear Safety and Control Act* (NSCA), its regulations and licences by setting out the necessary elements for acceptable design and performance at a regulated facility or a regulated activity. Standards are one of the tools used by the CNSC to evaluate whether licensees are qualified to carry out licensed activities.

The CNSC offers complimentary access to the CSA Group suite of nuclear standards through the CNSC website. This access platform allows interested stakeholders to view these standards online through any device that can access the Internet.

Up to date lists of the nuclear and support facilities at WL that are subject to CNSC regulatory oversight, and legacy facilities that were placed under care and maintenance or undergoing decommissioning under buildings removal plans, are maintained in the CNL document 900-514300-LST-001, *Site Licences, Certificates, Permits, Facilities and Representatives*.

Appendix A to the LCH provides definitions of terms and a list of acronyms used throughout it.

More information on the LCH is available in the CNSC document titled *How to Write a Licence Conditions Handbook* (LCH) (e-Doc 4967591).

G. GENERAL

Licence Condition G.1: Licensing Basis

The licensee shall conduct the activities described in Part IV of this licence in accordance with the licensing basis, defined as:

- **(i) the regulatory requirements set out in the applicable laws and regulations;**
- **(ii) the conditions and safety and control measures described in the facility's or activity's licence and the documents directly referenced in that licence; and**
- **(iii) the safety and control measures described in the licence application and the documents needed to support that licence application;**

unless otherwise approved in writing by the Canadian Nuclear Safety Commission (hereinafter "the Commission").

Preamble:

The licensing basis sets the boundary conditions for acceptable performance at a regulated facility or activity, and thus establishes the basis for the CNSC's compliance program in respect of that regulated facility or activity. The degree to which the regulatory requirements are applied to WL facilities and activities should reflect their importance to health and safety of persons, environment, national security, international obligations to which Canada has agreed, licensee's quality and economic expectations, the complexity of facility or activity, and the possible consequences if accidents occur or the activity is carried out incorrectly.

Where the licence condition requires the licensee to implement and maintain a particular program, the licensee documents that describe and implement the program are part of the licensing basis. Programs required by licence conditions or referred to in the LCH may or may not be health, safety, security, environment, and quality programs as defined in the Canadian Nuclear Laboratories Ltd. (CNL)'s management system.

Compliance Verification Criteria:

Part (i) of the Licensing Basis

Part (i) of the licensing basis refers to applicable laws and regulations. There are many federal and provincial acts and regulations, and international laws, agreements, guidelines, etc., applicable to activities performed at WL.

The laws, regulations and international agreements for which CNSC has a regulatory role are:

- *Nuclear Safety and Control Act* (NSCA) and its regulations;
- *Canadian Environmental Assessment Act*, 2012 (CEAA, 2012) and its regulations;
- *Transportation of Dangerous Goods Act* and its regulations;
- *Canada Labour Code* and *Canada Occupational Health and Safety Regulations*;
- *Nuclear Liability and Compensation Act* and its regulations;
- *Fisheries Act* (CNSC responsibilities are defined in the *Memorandum of Understanding between the CNSC and Fisheries and Oceans Canada*); and
- Canada/IAEA safeguards agreements.

All Memoranda of Understandings between the CNSC and other regulatory agencies or government departments are available on the CNSC Webpage under Acts and Regulations/Domestic Arrangements.

Through its decision of October 22, 2014, the Commission, pursuant to section 7 of the NSCA, exempted CNL from the requirements of sections 15.01 and 15.02 of the CNSC *Class II Nuclear Facilities and Prescribed Equipment Regulations* in relation to the requirement for a certified radiation safety officer (e-Doc 4543516).

Part (ii) of the Licensing Basis

Part (ii) of the licensing basis refers to the conditions and the safety and control measures included in the WL licence and in the documents directly referenced in the licence.

Under the standardized format and content, the WL licence requires the licensee to implement and maintain certain programs. For the purpose of meeting a licence requirement, a program may be a series of documented, coordinated activities, not necessarily a single document.

Part (iii) of the Licensing Basis

Part (iii) of the licensing basis refers to the safety and control measures described in the licence application and the documents needed to support that licence application. The safety and control measures include important aspects of that documentation such as, but not limited to: the facility-specific design basis and operational information documented in the most recent safety analysis and operational limits and conditions documents.

Part (iii) of the licensing basis also includes safety and control measures outlined in CNSC regulatory documents, CSA standards, and other standards, codes and references that are cited in the application or in the licensee's supporting documentation.

Applicable licensee documents are listed in the LCH under the heading "Licensee Documents that Require Notification of Change". Applicable CNSC regulatory documents, CSA standards and other documents are listed in the LCH under the heading "Licensing Basis Publications". The licensee documents listed in the LCH could cite other documents that also contain safety and control measures (i.e., there may be safety and control measures in "nested" references in the application). The licensee documents listed in the LCH and their "nested" references define the licensing basis for the programs required by the WL licence as long as they include safety and control measures.

Regulatory Role of the Licensing Basis

The licensing basis is established when the Commission renders its decision regarding the licence application.

Licence condition G.1 requires the licensee to conduct the licensed activities in accordance with the licensing basis. For activities that are found to be not in accordance with the licensing basis, the licensee shall take action as soon as practicable to return to a state consistent with the licensing basis, taking into account the risk significance of the situation.

The applicability of the licensing basis publications may be graded based on the specific of activity being considered.

CNSC Staff's Approach to Assessing the Licensing Basis for Whiteshell Laboratories

The licence condition G.1 is not intended to unduly inhibit the ongoing management and operation of the facility or the licensee's ability to adapt to changing circumstances and continuously improve, in accordance with its management system. Where the licensing basis refers to specific configurations, methods, solutions, designs, etc., the licensee is free to propose alternate approaches as long as they remain, overall, in accordance with the licensing basis and have a neutral or positive impact on health, safety, the environment, security, and safeguards. However, the licensee shall assess changes to confirm that operations remain in accordance with the licensing basis. The assessment shall be documented and made available to CNSC staff upon request.

For any proposed activity to be carried out on the WL, CNSC staff will review the information submitted by CNL to independently determine if the proposed activity remains within the licensing basis. CNSC staff assess a proposed activity as being within the licensing basis based on the hazard and risk of the change, and its impact on the overall safety of the WL.

CNSC staff will submit to the Commission for consideration any proposed activity which CNSC staff consider to be outside the licensing basis. If the Commission grants approval to such an activity, it will become part of the licensing basis for WL and reflected in updates to LCH as appropriate.

Activities Included in the Whiteshell Laboratories Licensing Basis

Conduct of licensed activities at WL includes:

a) operate and decommission the Whiteshell Laboratories (hereinafter "WL") located in Pinawa, Province of Manitoba as further described in the Whiteshell Laboratories Licence Conditions Handbook (LCH) ,
b) produce, possess, process, refine, transfer, use, package, manage, and store the nuclear substances that are required for, associated with or arise from the activities described in a),
c) possess, use, produce and transfer prescribed equipment that is required for, associated with, or arises from the activities described in a),
d) possess, use and transfer prescribed information that is required for, associated with, or arises from the activities described in a),
e) carry out the site preparation, construction or construction modification or undertaking that is required for, associated with or arise from the activities described in a).

A complete list of all nuclear facilities at WL is found in 900-514300-LST-001, "Site Licences, Certificates, Permits, Facilities and Representatives".

Licence Application Documents and Supporting Documents

Document Number	Document Title	e-Doc
WLD-CNNO-18-0033-L	Application for Renewal of the Nuclear Research and Test Establishment Decommissioning Licence for the Whiteshell Laboratories	5715784
WLD-CNNO-18-0034-L	Application for Renewal of the Nuclear Research and Test Establishment Decommissioning Licence for the Whiteshell Laboratories (Supporting Information for CNSC Staff)	5715800

Guidance:

The CNSC regulatory document REGDOC-3.5.3, *Regulatory Fundamentals*, outlines the CNSC's regulatory philosophy and approach to applying the *Nuclear Safety and Control Act*. It provides information for licensees, applicants and the public, and contains neither guidance nor requirements. In particular, subsection 6.1.1 of the REGDOC-3.5.3 provides information about the licensing basis.

When the licensee becomes aware that a proposed change or activity might be outside the licensing basis, it should first seek direction from CNSC staff regarding the potential acceptability of this change or activity. The licensee should take into account that certain types of proposed changes might require significant lead times before CNSC staff can make recommendations and/or the Commission can properly consider them.

Licence Condition G.2: Notification of Changes

The licensee shall give written notification of changes to the facility or its operation, including deviation from design, operating conditions, policies, programs and methods referred to in the licensing basis.

Preamble:

Most changes to the WL and its facilities are captured as changes to corresponding licensee's documents. The LCH identifies licensee documents that require written notification of changes to the CNSC.

Compliance Verification Criteria:

The licensee shall, as a minimum, notify CNSC staff of changes to licensee's documents identified in the LCH. The written notification of change shall include a copy of the revised document and a description of the change.

CNL program requirements documents (PRDs) and program description documents (PDDs) are accompanied by governing document indices (GDIs). The licensee shall provide updated versions of PDDs quarterly and GDIs annually or upon request from CNSC.

Licensee documents listed in the LCH are subdivided into groups having different requirements for notification of change.

Prior Notification Requirement	Definition
Requires prior notification	The licensee shall submit the revised document to the CNSC as far in advance of planned implementation as practicable, but not less than 30 days prior to planned implementation. The licensee shall allow sufficient time for the CNSC to review the change proportionate to its complexity and the importance of the safety and control measures being affected. This is denoted by a Y in the column "prior notification". Where a document or some part of it requires acceptance by CNSC staff prior to implementation, a footnote has been added to the notification column.
Requires notification at time of implementation	The licensee shall notify the CNSC at the time of implementing a revised document. This is denoted by a N in the column "prior notification".

Changes that may affect the licensing basis, including any change that is not captured as a change to a document listed in the LCH (e.g., construction of new facilities/buildings, transitioning any facility/building from one phase of its life cycle to another, or infrastructure improvements at WL), requires written prior notification to the CNSC to verify they are in accordance with the licensing basis.

For any change that is outside the licensing basis defined in subsection G.1 of the LCH, the licensee shall obtain Commission approval before proceeding with the change.

Guidance:

For proposed changes that would not be in accordance with the licensing basis, the guidance for licence condition G.1 applies.

Licence Condition G.3: Financial Guarantee

The licensee shall maintain a financial guarantee for decommissioning that is acceptable to the Commission.

Preamble:

The *General Nuclear Safety and Control Regulations* requires that a licence application contains "*a description of any proposed financial guarantee relating to the activity to be licensed*".

The financial guarantee for decommissioning is to be reviewed and revised by the licensee every 5 years, or; when required by the Commission or person authorized by the Commission, or; following a revision to the cost estimate for decommissioning if it significantly impacts the financial guarantee.

The financial guarantee for WL is in the form of an expressed commitment from Atomic Energy of Canada Ltd (AECL) which is a Schedule III, Part 1 Crown Corporation under the *Financial Administration Act* and an agent of Her Majesty in Right of Canada. As an agent of Her Majesty in Right of Canada, AECL's liabilities are ultimately liabilities of Her Majesty in Right of Canada. While the restructuring of AECL has seen the ownership of Canadian Nuclear Laboratories Ltd. (CNL) transferred to a private-sector contractor, the Canadian National Energy Alliance (CNEA), AECL retains ownership of the lands, assets and liabilities associated with CNL's licences. These liabilities have been officially recognized by the Minister of Natural Resources in a letter dated July 31, 2015 (e-Doc 4803454, 4815508).

Compliance Verification Criteria:

The financial guarantee for decommissioning shall be reviewed and revised by the licensee every 5 years, when requested by the CNSC, or following a revision to the cost estimate for decommissioning or changes to the decommissioning strategy which significantly impacts the financial guarantee.

Licensee Documents that Require Notification of Change

Document Number	Document Title	e-Doc	Prior Notification
145-NRCANNO-15-0.001	Relating to Provision of Financial Guarantees for AECL Sites	5794303	N/A

Guidance:

Guidance Documents

Document Number	Document Title	Version
G-206	Financial Guarantee for the Decommissioning of Licensed Activities	2000

Licence Condition G.4: Public Information and Disclosure Program

The licensee shall implement and maintain a public information and disclosure program.

Preamble:

Class I Nuclear Facilities Regulations require that an application for a licence shall contain the proposed program to inform persons living in the vicinity of the site of the general nature and characteristics of the anticipated effects on the environment and the health and safety of persons that may result from the activity to be licensed.

The primary goal of the public information program, as it relates to the licensed activities, is to ensure that information related to the health, safety and security of persons and the environment, and other issues associated with the lifecycle of nuclear facilities are effectively communicated to the public. The public information program includes a public disclosure protocol describing the information and the medium of disclosure in regard to information and reports of interest to the public.

SCA – MANAGEMENT SYSTEM

Licence Condition 1.1: Management System

The licensee shall implement and maintain a management system.

Preamble:

Safe and reliable operation of nuclear facilities requires a commitment and adherence to a set of management system principles and, consistent with those principles, the implementation of planned and systematic processes that achieve expected results. The management system focuses on safety in all business activities and supports the safe conduct of licensed activities at CNL.

The *Class I Nuclear Facilities Regulations* require that an application for a licence shall contain the proposed management system for the activity to be licensed, including measures to promote and support safety culture.

The *General Nuclear Safety and Control Regulations* require that a licence application contain the applicant's organizational management structure, including the internal allocation of functions, responsibilities and authority.

The management system is in place to satisfy the requirements set out in the NSCA, regulations made pursuant to the NSCA, the licence and the measures necessary to ensure that safety is of paramount consideration in the implementation of the management system. The management system promotes and supports a healthy safety culture. Characteristics of a healthy safety culture are as follows:

- Safety is a clearly recognized value;
- Accountability for safety is clear;
- Safety is integrated into all activities;
- A safety leadership process exists; and
- Safety culture is learning driven

SCA – HUMAN PERFORMANCE MANAGEMENT

Licence Condition 2.1: Human Performance Program

The licensee shall implement and maintain a human performance program.

Preamble:

Human performance is the outcome of human behaviours, functions and actions in a specified environment, reflecting the ability of workers and management to meet the system's defined performance under the conditions in which the system will be employed.

Human factors are factors that influence human performance as it relates to the safety of a nuclear facility or activity over all the phases, including design, operation, maintenance, and decommissioning. These factors may include the characteristics of the person, task, equipment, organization, environment, and training. The application of human factors to issues such as interface design, training, procedures, organization and job design may affect the reliability of humans performing tasks under various conditions.

The human performance program addresses and integrates the range of human factors that influence human performance, including but not limited to:

- The provision of qualified workers;
- The reduction of human error;
- Organizational support for safe work activities;
- The continuous improvement of human performance; and
- Monitoring hours of work.

The *General Nuclear Safety and Control Regulations* require the licensee to: ensure the presence of sufficient number of qualified staff; train the workers; and ensure the workers follow procedures and safe work practices.

The *Class I Nuclear Facilities Regulations* require that an application for a licence shall contain the proposed human performance program for the activity to be licensed, including measures ensure workers fitness for duty.

Compliance Verification Criteria:

G-323	Ensuring Presence of Sufficient Qualified Staff at Class I Nuclear Facilities: Minimum Staff Complement	2007

Licence Condition 2.2: Training Program

The licensee shall implement and maintain a training program.

Preamble:

This licence condition requires the licensee to develop and implement training programs for workers.

It also provides the requirements regarding the program and processes necessary to support responsibilities of, qualifications and requalification training of persons at the nuclear facility.

As defined by the *General Nuclear Safety and Control Regulations*, a worker is a person who performs work that is referred to in a licence. This includes contractors and temporary employees. Training requirements apply equally to these types of workers as to the licensee's own employees.

The *General Nuclear Safety and Control Regulations* require that licensees ensure that there are a sufficient number of properly trained and qualified workers to safely conduct the licensed activities.

The *Class I Nuclear Facilities Regulations* require that applicants for a Class I facility licence describe the training programs which have been implemented, and that licence applications include the proposed responsibilities, qualification requirements, training program and requalification program for workers; along with the results that have been achieved in implementing the program for recruiting, training and qualifying workers.

Compliance Verification Criteria:

SCA – OPERATING PERFORMANCE

Licence Condition 3.1: Operating Program

The licensee shall implement and maintain an operating program, which includes a set of operating limits.

Preamble:

The *Class I Nuclear Facilities Regulations* require that a licence application contain the proposed measures, policies, methods and procedures for safely operating and maintaining the nuclear facility.

The operational limits and conditions for WL are currently documented in

- Facility Authorizations, and
- laboratory protocols, criticality safety documents and other documents for other workplaces where operations with fissionable materials are performed involving handling, use, processing, movement and storage

Compliance Verification Criteria:

Licensee Documents that Require Notification of Change

Document Number	Document Title	e-Doc	Prior Notice
900-505240-PDD-001	Program Description Document: Construction	5507946	N
900-505240-PRD-001	Program Requirements Document: Construction	5507946	Y
900-505250-PDD-001	Program Description Document: Commissioning	5507946	N
900-505250-PRD-001	Program Requirements Document: Commissioning	5507946	Y
AECL-FA-22	Facility Authorization for the Operation of the Concrete Canister Storage Facility at Whiteshell Laboratories	5776580	Y[1]
AECL-FA-25	Facility Authorization for the Operation of the Active Liquid Waste Treatment Centre at Whiteshell Laboratories	5776580	Y[1]
WLSF-00583-FA-001	Facility Authorization for the Operation of the Shielded Facilities at Whiteshell Laboratories	5776580	Y[1]
WLWMA-00583-FA-001	Facility Authorization for the Operation of the Waste Management Area at Whiteshell Laboratories	5776580	Y[1]

[1] Notification is required only for non-administrative changes. If administrative changes are made, the licensee shall provide updated facility authorizations to CNSC staff at the end of the next quarter.

WL Facilities Operations

The operational limits and conditions shall define the conditions that must be met to prevent situations or events that might lead to accidents, or to mitigate the consequences of accidents should they occur. The updated operational limits and conditions shall be based on safety analyses.

Limits and conditions for normal operation shall include limits on operating parameters, stipulation for minimum amount of operable equipment, actions to be taken by the operating staff in the event of deviations from the operational limits and conditions, and the time allowed for completing these actions.

The licensee shall review, revise and reissue as appropriate the operational limits and conditions when required due to changes in technologies, regulations, operational information or physical configuration.

Construction and operation of New Nuclear Facilities

The licensee may construct or install facilities, buildings, structures, components or equipment only if that construction or installation is compliant with the licensing basis.

Facilities in Permanent Safe Shutdown State

The licensee shall develop and maintain storage-with-surveillance plans (SWS plans) for Class I and Class II nuclear facilities in permanent safe shutdown state. The licensee shall maintain those facilities in permanent safe shutdown state according to the SWS plan for the facility. The SWS plans may also be combined with DDPs when the decommissioning is taking place in several phases.

Facilities under Decommissioning

See LCH Section 11.2 for details regarding the decommissioning of individual facilities at WL.

Modifications to Facilities and Processes

The licensee shall ensure that modifications to WL facilities do not negatively impact safe operation of the facility. The licensee shall define the process for making permanent or temporary modifications to operational limits and conditions. Such modifications shall be justified by analyses and safety reviews.

The licensee may only modify facilities, buildings, structures, components or equipment in compliance with the licensing basis.

The licensee shall ensure that:

(a) all temporary modifications are identified at the point of application and at any relevant control positions;

(b) operating personnel are informed of any modifications and their consequences for facility operations;

(c) the temporary modifications are reviewed and approved before installation; the review shall be documented to demonstrate the scope and conclusion of the review;

(d) the number of simultaneous temporary modifications is kept to a minimum;

(e) the duration of temporary modifications is limited and specified prior to implementation;

(f) testing is performed after installation and removal of the temporary modification;

(g) temporary modifications are shown on affected documents; and

(h) the facility is returned to the original state when the temporary modification is no longer needed.

Sealed Sources

The licensee shall ensure the sealed sources are controlled (by maintaining an inventory of sealed sources, and tracking and reporting their transfer) in order to achieve the objectives stated in paragraph 5.(a) of section II of IAEA's *Code of Conduct on the Safety and Security of Radioactive Sources*.

The inventory of sealed sources shall contain all sealed sources, both in use and in storage, of any category of sources as defined in Table 1 of the IAEA safety guide RS-G-1.9 *Categorization of Radioactive Sources*. The licensee shall provide details of their inventory at the CNSC staff's request.

<u>Guidance:</u>

None provided.

Licence Condition 3.2: Reporting Requirements

The licensee shall implement and maintain a program for reporting to the Commission or a person authorized by the Commission.

Preamble:

This licence condition sets the requirements for reporting information to CNSC, including compliance monitoring and operational performance, event reporting, and various types of notifications.

Many reportable occurrences included in REGDOC-3.1.2 do not necessarily show a degradation of licensee's performance, and do not fall under CNSC definition of a "reportable event" as included in REGDOC-3.6 Glossary of CNSC Terminology.

Compliance Verification Criteria:

Licensing Basis Publications

Document Number	Document Title	Version	Effective Date
REGDOC-3.1.2	Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills	2018	January 1, 2020

Licensee Documents that Require Notification of Change

Document Number	Document Title	e-Doc	Prior Notice
900-514300-MCP-006	CNL Reporting to Regulatory Agencies	5507946	N

Compliance Monitoring: Annual Reporting

The licensee shall by the following dates submit to the Commission or any person authorized by the Commission, the following reports covering the preceding calendar year as follows:

1) By April 30th of each year:

a) the operation and maintenance of the following facilities: Concrete Canister Storage Facility, Active-Liquid Waste Treatment Centre, Shielded Facilities, Waste Management Area, Building 300 (Research and Development) and Building 402 (Health and Safety), summarizing facility and equipment performance and changes, changes to operating policies, changes in organization, reportable events, personnel radiation exposures, releases of nuclear substances from the facilities, and releases of hazardous substances from the facilities;

b) the status of the WR-1 Reactor, summarizing facility and equipment performance and changes, changes to operating policies, changes in organization, reportable events, personnel radiation exposures, releases of nuclear substances from the facilities, and releases of hazardous substances from the facilities;

c) a summary of changes to non-nuclear facilities and structures;

d) decommissioning activities associated with the following facilities: Concrete Canister Storage Facility, Active-Liquid Waste Treatment Centre, Shielded Facilities, Waste Management Area, Building 300 (Research and Development), Building 402 (Health and Safety) and WR-1 reactor, summarizing facility and equipment performance and changes, changes to operating policies, changes in organization, reportable events, personnel radiation exposures, releases of nuclear substances from the facilities, and release of hazardous substances from the facilities;

e) changes to emergency authorities and organization, updates or changes to the radiation emergency procedures, status/changes in other program documentation, training activities, drill and exercise activities, status of emergency resources and facilities, interactions with outside agencies, and unplanned events in which the emergency response organization has been tested;

f) the results of the effluent monitoring for nuclear substances, hazardous substances and personnel radiation exposures for WL.

2) By June 30th of each year:

a) the results of environmental monitoring for nuclear and hazardous substances;

b) the results and activities of the Environmental Assessment Follow-Up Program for Whiteshell Laboratories.

3) If an action level has been reached as set out in LC 7.1 and 9.1, the licensee shall submit a final written report of the matter within 45 days of becoming aware of the matter.

Guidance:

Event Reporting

To encourage reporting of situations or events that may result in improvement actions, event reporting should not be used as a tool for assessing or measurement of nuclear safety, or as a basis for assessing the licensee’s performance.

For low safety significance events where CNL has already provided a preliminary report verbally and where no significant additional information is likely to be determined from further investigation, CNL may elect to combine the submission of a written preliminary report with a written full report. CNSC staff may request additional information to be provided in order to achieve regulatory close out.

Compliance Monitoring: Annual Reporting

The annual reports should follow, where appropriate, the format and content presented in Appendix B of REGDOC-3.1.2.

SCA – SAFETY ANALYSIS

Licence Condition 4.1: Safety Analysis Program

The licensee shall implement and maintain a safety analysis program.

Preamble:

All event sequences which can occur in a nuclear facility must be analyzed to ensure safe operation. A deterministic safety analysis evaluates the facility's responses to such events by using predetermined rules and assumptions. The objectives of the deterministic safety analysis are stated in CSA N292.0.

The *General Nuclear Safety and Control Regulations* require that a licence application contain a description and the results of any analyses performed.

The *Class I Nuclear Facilities Regulations* require, amongst other requirements, that an application for a licence to operate a Class I nuclear facility contains a final safety analysis report, and additional supporting information.

The licensee holds the responsibility for ensuring that the safety analysis is accurate and meets the regulatory requirements, and shall maintain adequate capability to perform or procure safety analysis and to train safety analysts.

Compliance Verification Criteria:

Licensing Basis Publications

For compliance verification criteria for Safety Analysis refer to the CSA N292 series documents in LCH Section 11.1.

Licensee Documents that Require Notification of Change

Document Number	Document Title	e-Doc	Prior Notice
900-508770-PDD-001	Program Description Document: Safety Analysis	5507946	N
900-508770-PRD-001	Program Requirements Document: Safety Analysis	5507946	Y

WLDP-36410-SAR-001	Safety and Hazards Analysis for the Shielded Modular Above-Ground Storage Facilities at Whiteshell Laboratories	5507946	Y[1]

[1] Notification is required only for non-administrative changes. If administrative changes are made, the licensee shall provide updated safety analyses to CNSC staff at the end of the next quarter.

Guidance:

Guidance Documents

Document Number	Document Title	Version
IAEA SSR-4	Safety of Nuclear Fuel Cycling Facilities	2017
IAEA TECDOC-1267	Procedures for Conducting Probabilistic Safety Assessment for Non-reactor Nuclear Facilities	2002
IAEA GSR Part 4, Rev. 1	Safety Assessment for Facilities and Activities	2016

Licence Condition 4.2: Nuclear Criticality Safety Program

The licensee shall implement and maintain a nuclear criticality safety program.

Preamble:

This licence condition requires the licensee to develop, implement and maintain a nuclear criticality safety program to ensure that the upper subcritical limits established in the criticality safety documents will not be exceeded under both normal and credible abnormal conditions (events or event sequences having the frequency of occurrence equal to or more than 10^{-6}/year) during operations with fissionable materials outside reactors.

Compliance Verification Criteria:

Licensing Basis Publications

Document Number	Document Title	Version	Effective Date
REGDOC 2.4.3	Nuclear Criticality Safety	2018	January 1, 2020

Licensee Documents that Require Notification of Change

900-508550-PRD-001	Program Requirements Document: Nuclear Criticality Safety	5507946	Y

For legacy activities or projects, the licensee may implement the requirements of the nuclear criticality safety on a graded approach, with appropriate criteria for categorization according to their safety significance. The legacy items are those nuclear criticality safety related activities and projects where work has begun prior to November 1, 2011.

Guidance:

None provided.

SCA – PHYSICAL DESIGN

Licence Condition 5.1: Design Program

The licensee shall implement and maintain a design program.

Preamble:

The *Class I Nuclear Facilities Regulations* require that a licence application contain a description of the structures, systems and components, and relevant documentation of the facility design.

A design program ensures that the facility design is managed using a well-defined systematic approach.

Implementing and maintaining a design program confirms that safety-related SSCs and any modifications to them continue to meet their design bases given new information arising over time and taking changes in the external environment into account. It also confirms that SSCs continue to be able to perform their safety functions under all facility states. An important cross-cutting element of a design program is design basis management.

Licence Condition 5.2: Pressure Boundary Program

The licensee shall implement and maintain a pressure boundary program.

Preamble:

A pressure boundary program is comprised of the many programs, processes and procedures and associated controls that are required to ensure compliance with CSA standard N285.0, which defines the technical requirements for the design, procurement, fabrication, installation, modification, repair, replacement, testing, examination and inspection of pressure-retaining and containment systems, including their components and supports.

Compliance Verification Criteria:

Licensing Basis Publications

Document Number	Document Title	Revision	Effective Date

WL-508140-QAM-001	Pressure Boundary Quality Assurance Manual	5776580	Y

For the Whiteshell Laboratories, compliance with this licence condition will be assessed by the following;

a) Subject to b) and c) below, the licensee shall design, manufacture, fabricate, procure, install, modify, repair, test, examine, inspect or otherwise perform work related to vessels, boilers, systems, piping, fittings, parts, components and supports according to the specifications in CSA standards N285.0-08, B51-03 (R2014) or other codes and standards approved or prescribed by the Commission.

   Where indicated by these standards, the licensee shall obtain the following regulatory approvals for this work:

i) registered designs;

ii) accepted overpressure protection reports;

iii) approval of applicable standards and code classification;

iv) registered welding and brazing procedures;

v) qualified welders, welding operators, brazers and examination personnel;

vi) accepted quality assurance programs; and

vii) accepted plans and procedures (certificate(s) of authorization).

b) CNL may classify as Class 6 systems or sections of systems that contain tritium or other radioactive substances, if the consequence of failure limit of 20 mSv effective acute whole body dose is not exceeded.

c) CNL shall carry out the activities listed in a) above in accordance with B51-03 (R2014), or other codes and standards approved or prescribed by the Commission, for pressure boundary systems and components that do not contain nuclear substances, do not adversely impact a nuclear safety system, or do not cause an unreasonable risk involving nuclear substances at WL.

d) CNL shall operate vessels, boilers, systems, piping, fittings, parts, components, and supports safely and keep them in a safe condition. The licensee shall:

i) follow accepted plans and procedures to test, maintain, or alter overpressure protection devices;

ii) comply with operating limits specified in certificates, orders, designs, overpressure protection reports, and applicable codes and standards;

iii) inspect and perform material surveillance according to accepted schedules, plans and procedures;

iv) have any certified boiler or vessel that is in operation or use inspected and certified by an authorized inspector according to an accepted schedule; and

v) ensure that vessels, boilers, systems, piping, fittings, parts, components and supports have markings, as specified in the applicable standards.

e) CNL shall keep proper records of regulatory approvals and other documents required as set out in a) through d), and the standards applicable to the work or equipment.

f) In addition to any reporting requirements of the *Nuclear Safety and Control Act* and its associated Regulations, CNL shall report promptly to the Commission and to the Manitoba Department of Labour and Immigration when the licensee learns of any failure of a pressure boundary that has caused injury, death or property damage.

SCA – RADIATION PROTECTION

Licence Condition 7.1: Radiation Protection Program

The licensee shall implement and maintain a radiation protection program, which includes a set of action levels. When the licensee becomes aware that an action level has been reached, the licensee shall notify the Commission within seven days.

Preamble:

The Radiation Protection Regulations (RPR) requires that the licensee implement a radiation protection program and also ascertain and record doses for each person who performs any duties in connection with any activity that is authorized by the NSCA or is present at a place where that activity is carried out. This program must ensure that doses to persons do not exceed prescribed dose limits and are kept as low as reasonably achievable (ALARA), social and economic factors being taken into account. Also, the program ensures that occupational exposures are ascertained and recorded in accordance with the Radiation Protection Regulations through the establishment of dosimetry requirements.

The regulatory dose limits to workers and the public are explicitly provided in the RPR. The RPR also specifies the requirements related to action levels (ALs) and indicate that the licence will be used to identify their notification timeframes. ALs relate to the parameters of dose to workers.

ALs are designed to alert licensees before regulatory dose limits are reached. By definition, if an AL is reached, a loss of control of some part of the associated radiation protection program may have occurred, and specific action is required, as defined in the RPR and the licence. ALs are not intended to be static and are to reflect prevailing circumstances at the WL site.

Compliance Verification Criteria:

Licensee Documents that Require Notification of Change

Document Number	Document Title	e-Doc	Prior Notice
900-508740-PDD-001	Program Description Document: Radiation Protection	5507946	N
900-508740-PRD-001	Program Requirements Document: Radiation Protection	5507946	Y

Document Number	Document Title	Version

G-129, Rev. 1	Keeping Radiation Exposures and Doses "As Low as Reasonably Achievable (ALARA)"	2004
G-228	Developing and Using Action Levels	2001
G-91	Ascertaining and Recording Radiation Doses to Individuals	2003
GD-150	Designing and Implementing a Bioassay Program	2014

The licensee should conduct a documented review and, if necessary, revise the ALs at least once every five years in order to validate their effectiveness. The results of such reviews should be provided to CNSC staff.

SCA – CONVENTIONAL HEALTH AND SAFETY

Licence Condition 8.1: Conventional Health and Safety Program

The licensee shall implement and maintain a conventional health and safety program.

Preamble:

The *Class I Nuclear Facilities Regulations* requires that a licence application contain the proposed worker health and safety policies and procedures.

As a federal regulated site, WL is also subject to the requirements of *Canada Labour Code* and *Canada Occupational Health and Safety Regulations*.

Compliance Verification Criteria:

Licensee Documents that Require Notification of Change

Document Number	Document Title	e-Doc	Prior Notice
900-510400-PDD-001	Program Description Document: Occupational Safety and Health	5507946	N

The *Ministry of Employment, Workforce Development and Labour* is mandated with overseeing and enforcing compliance with the *Canada Labour Code* and its regulations.

Guidance:

None provided.

SCA – ENVIRONMENTAL PROTECTION

Licence Condition 9.1: Environmental Protection Program

The licensee shall implement and maintain an environmental protection program, which includes a set of action levels. When the licensee becomes aware that an action level has been reached, the licensee shall notify the Commission within seven days.

Preamble:

The *Class I Nuclear Facilities Regulations* requires that a licence application contain information related to environmental protection. The *General Nuclear Safety and Control Regulations* requires every licensee to take all reasonable precautions to protect the environment. The *Radiation Protection Regulations* prescribe the radiation dose limits for the general public of 1 mSv per calendar year.

The *Radiation Protection Regulations* specify requirements related to "Action Levels" and indicate that the licence will be used to identify the action levels and the notification timeframes.

The release of hazardous substances is regulated by Environment and Climate Change Canada through various acts and regulations, as well as by the CNSC.

The environmental protection SCA includes the following:

- Effluent and emissions control (releases);
- Environmental management system (EMS);
- Assessment and monitoring;
- Protection of the public; and
- Environmental Risk Assessment.

Action levels (ALs) for environmental releases are calculated by the licensees and aim to alert licensees of a potential loss of control of their environmental protection program. By definition, if an action level is reached, a loss of control of some part of the associated environmental protection program may have occurred, and specific action is required. ALs are not intended to be static and are to reflect operating conditions at the WL site.

Compliance Verification Criteria:

The licensee will implement and maintain programs to ensure environmental protection as set out in licensing basis (LCH Section 1.1).

CSA N286, included in LCH Section 1.1, defines other specific compliance verification criteria that support environmental protection.

Licensing Basis Publications

AECL Document No 03704 001	Environmental Assessment Follow up Program for Whiteshell Laboratories	5776580	Y

The licensee will implement all follow-up actions identified as a result of environmental assessments, and shall report the progress to CNSC staff on an annual basis.

The licensee will ensure effluent monitoring for nuclear and hazardous substances is designed, implemented and managed to respect applicable laws/regulation and to incorporate best practices. The effluent monitoring program will provide for control of airborne and waterborne effluents. The licensee will control, monitor and record releases of radioactive and/or hazardous substances such that the releases do not exceed the reference levels (limits).

The licensee will establish the DRLs in accordance with CSA N288.1. The dose to the critical group due to the sum of all radioactive releases shall not exceed 1 mSv.

The licensee will conduct an updated site-wide environmental risk assessment (ERA) in accordance with the CSA Standard N288.6-12 *Environmental Risk Assessment at Class I Nuclear Facilities and Uranium Mines and Mills* taking into account current conditions at the WL site.

The licensee will control radiological releases to ALARA, within the DRLs, and take action to investigate and correct the cause(s) of increased releases should they occur. The licensee shall report the releases in accordance with LCH Section 3.2.

SCA – EMERGENCY MANAGEMENT AND FIRE PROTECTION

Licence Condition 10.1: Emergency Preparedness Program

The licensee shall implement and maintain an emergency preparedness program.

Preamble:

This licence condition requires the licensee to establish an emergency preparedness program to prepare for, to respond to, and to recover from the effects of accidental radiological/nuclear and/or hazardous substance release. As part of the emergency preparedness program, the licensee establishes an onsite emergency response plan and an emergency response organization and makes arrangements for coordinating off-site activities and cooperating with external response organizations throughout all phases of an emergency.

The Class I *Nuclear* Facilities Regulations requires measures to prevent or mitigate the effects of accidental releases of nuclear substances and hazardous substances on the environment, the health and safety of persons and the maintenance of national security, including measures to assist, notify, report to off-site authorities including the testing of the implementation of these measures.

A security response to malevolent acts is governed by a separate plan under the Nuclear Security program (see LCH Section 12.1) but provisions of the licensee site security report apply to any associated potential threat of release of radioactive material - for example, the need for off-site notification, situation updates and confirmation of any radioactive releases.

Liquid release response and radioactive materials transportation emergency response plan are also governed by separate plans (See LCH Sections 9.1 and 14.1, respectively).

WL has a communication program that covers a broad spectrum – community interface meetings, newsletters, websites, committees and various panels.

WL provides the local municipalities and the province (as required, federal) with hazard information that can be used for community communications during an emergency.

Licence Condition 10.2: Fire Protection Program

The licensee shall implement and maintain a fire protection program.

Preamble:

Licensees require a comprehensive fire protection program to ensure the licensed activities do not result in unreasonable risk to the health and safety of persons and to the environment due to fire and to ensure that the licensee is able to efficiently and effectively respond to emergency fire situations.

Fire protection provisions, including response, are required for the design, construction, commissioning, operation, and decommissioning of nuclear facilities, including structures, systems, and components (SSCs) that directly support the plant and the protected area. External events such as an aircraft crash or security threats are addressed in LCH Section 12.1.

The *National Fire Code of Canada* sets out technical provisions regulating (a) activities related to the construction, use or demolition of buildings and facilities; (b) the condition of specific elements of buildings and facilities; (c) the design or construction of specific elements of facilities related to certain hazards; and (d) protection measures for the current or intended use of buildings.

The *National Building Code of Canada* sets out technical provisions for the design and construction of new buildings. It also applies to the alteration, change of use and demolition of existing buildings.

Compliance Verification Criteria:

Licensing Basis Publications

Document Number	Document Title	Version	Effective Date
CSA N393	Fire protection for facilities that process, handle, or store nuclear substances	2013 (R2016)	Jan 1, 2020
	National Fire Code of Canada	2010	Jan 1, 2020
	National Fire Code of Canada	2015	TBD
	National Building Code of Canada	2010	Jan 1, 2020
	National Building Code of Canada	2015	TBD

Licensee Documents that Require Notification of Change

Document Number	Document Title	e-Doc	Prior Notice
900-508720-PDD-001	Program Description Document: Fire Protection	5507946	N
900-508720-PRD-001	Program Requirements Document: Fire Protection	5507946	Y
900-508720-MCP-006	Impairment, Notification and Compensatory Measures	5507946	N

Where CSA standard N393 requires items to be submitted to CNSC for review and/or acceptance, the licensee shall document the item in sufficient detail to ensure it is safe to proceed. The licensee may implement that item without prior review and/or acceptance from CNSC staff. Changes of use or modifications for which the fire screening assessment indicates no potential impact on fire protection design basis, goals or criteria may not be subject to any further third-party review or require submission to the CNSC.

The licensee shall submit the results of third-party reviews required by CSA N393 (review of modifications, review of performance-based design or operation, fire protection program audit, and evaluation of fire response capability). The results of these reviews shall be submitted to CNSC staff no later than six months after the review together with any corrective action plans with compensatory measures for identified non-compliances.

Fire Response

In accordance with N393, the licensee shall arrange for third party audits of the fire response capability at the frequencies stated in N393. The purpose of a Third Party Audit is to provide an in-depth analysis of the Industrial Fire Brigade (IFB) fire response performance against applicable regulatory criteria. A fire response is a planned, coordinated and controlled activity to provide emergency response to a fire. The audit is to analyze and ensure competencies of the IFB against CSA N393 standard and the referred NFPA 600 and 1081 standards.

An independent third party auditor is required to be an expert in the discipline, normally firefighting and qualified through specific education and relevant experience. The third party auditor is required to be independent or at "arm's length" from the facility to ensure impartiality. The review shall be of sufficient depth and detail to allow the reviewer to attest with reasonable confidence on the competencies of the IFB at the facility.

Guidance:

Where CSA N393 does not address a fire protection topic or issue in whole, or where additional guidance is beneficial, the standards and recommended practices set out by the NFPA are used as guidance by CNSC staff in determining the adequacy of a fire protection measure. The results of the Third Party Audit report will typically consist of a report which compares the requirements of the applicable codes and standards against the implementation of the fire protection program or the Fire Response exercised (based on the scope of the audit). The report should identify any non-compliance and formulate a conclusion on whether the licensee fire protection program or IFB meets the requirements of N393.

SCA – WASTE MANAGEMENT

Licence Condition 11.1: Waste Management Program

The licensee shall implement and maintain a waste management program.

Preamble:

The scope of this licence condition covers internal waste-related programs that form part of the WL operations. Topics include waste management, waste characterization, waste minimization and waste management practices.

Compliance Verification Criteria:

Licensing Basis Publications

Document Number	Document Title	Version	Effective Date
CSA N292.0	General principles for the management of radioactive waste and irradiated fuel	2014	January 1, 2020
CSA N292.2	Interim dry storage of irradiated fuel	2013 (R2015)	January 1, 2020
CSA N292.3	Management of low- and intermediate-level radioactive waste	2014	January 1, 2020
CSA N292.6	Long-term management of radioactive waste and irradiated fuel	2018	TBD

Licence Condition 11.2: Decommissioning Plan

The licensee shall maintain a decommissioning plan.

Preamble:

Class I Nuclear Facilities Regulations requires that a licence application contain the proposed plan for decommissioning of the nuclear facility or of the site. The decommissioning plan for WL site is documented in the *Whiteshell Laboratories Detailed Decommissioning Plan – Volume 1 – Program Overview* and the associated cost estimate.

Whiteshell Laboratories is undergoing decommissioning in a staged manner. Consequently, it is noted that not all volumes of the detailed decommissioning plan have been developed, as they are developed when so required by CNL. For volumes not yet developed, decommissioning activities cannot proceed without CNSC concurrence.

Compliance Verification Criteria:

SCA – SECURITY

Licence Condition 12.1: Security Program

The licensee shall implement and maintain a security program.

Preamble:

The *General Nuclear Safety and Control Regulations* require that a licence application contain information related to site access control and measures to prevent loss or illegal use, possession or removal of the nuclear substance, prescribed equipment or prescribed information.

The *Class I Nuclear Facilities Regulations* require that a licence application contain the proposed measures to prevent acts of sabotage or attempted sabotage at the nuclear facility.

The *Nuclear Security Regulations* require that a licence application contain specific information related to nuclear security, stipulates the requirements for high-security sites, and contains specific requirements pertaining to the transportation of Category I, II or III nuclear material.

The *Nuclear Security Regulations* require that a licensee of a high security site:

- maintain at all times a qualified onsite nuclear response force;
- obtain the applicable certifications, before issuing an authorization to a nuclear security officer;
- prevent and detect unauthorized entry into a protected area or inner area; and
- prevent unauthorized entry of weapons and explosive substances into a protected area or inner area.

Compliance Verification Criteria:

SCA – SAFEGUARDS AND NON-PROLIFERATION

Licence Condition 13.1: Safeguards Program

The licensee shall implement and maintain a safeguards program.

Preamble:

Safeguards is a system of inspection and other verification activities undertaken by the International Atomic Energy Agency (IAEA) in order to evaluate a Member State's compliance with its obligations pursuant to its safeguards agreements with the IAEA.

The *General Nuclear Safety and Control Regulations* requires the licensee to take all necessary measures to facilitate Canada's compliance with any applicable safeguards agreement.

The *Class I Nuclear Facilities Regulations* requires that a licence application contain information on the licensee's proposed measures to facilitate Canada's compliance with any applicable safeguards agreement.

Canada has entered into a safeguards agreement with the IAEA pursuant to its obligations under the Treaty on the Non-Proliferation of Nuclear Weapons. The objective of the Canada/IAEA Safeguards Agreement is for the IAEA to provide assurance on an annual basis to Canada and to the international community that all declared nuclear materials are in peaceful, non-explosive uses and that there is no indication of undeclared nuclear materials or activities. This conclusion confirms that Canada is in compliance with its obligations under the following Canada/IAEA Safeguards Agreement:

- *Treaty on the Non-Proliferation of Nuclear Weapons*;
- *Agreement Between the Government of Canada and the International Atomic Energy Agency for the Application of Safeguards in Connection with the Treaty on the Non-Proliferation of Nuclear Weapons*; and
- *Protocol Additional to the Agreement Between Canada and the International Atomic Energy Agency for the Application of Safeguards in Connection with the Treaty on the Non-Proliferation of Nuclear Weapons*.

These are reproduced in information circulars INFCIRC/140, INFCIRC/164, and INFCIRC/164/Add. 1.

Compliance Verification Criteria:

The licensee shall obtain prior written approval of the CNSC, for any changes to operation, equipment or procedures requested by the licensee that would affect the implementation of safeguards measures.

Guidance:

None Provided.

SCA – PACKAGING AND TRANSPORT

Licence Condition 14.1: Packaging and Transport Program

The licensee shall implement and maintain a packaging and transport program.

Preamble:

The *Class I Nuclear Facilities Regulations* require that a licence application contain information on the proposed procedures for transporting nuclear substances and hazardous substances.

The transport of nuclear substances or hazardous substances must be done in accordance with the requirements of the *Packaging and Transport of Nuclear Substances Regulations, 2015*, (PTNSR) and *Transportation of Dangerous Goods Regulations* (TDGR) set out by Transport Canada.

IAEA document SSR-6 *Regulations for the Safe Transport of Radioactive Material (2018 Edition)* is incorporated by reference in PTNSR. These Regulations establish standards of safety which provide an acceptable level of control of the radiation, criticality and thermal hazards to persons, property and the environment that are associated with the transport of radioactive material.

Compliance Verification Criteria:

Licensing Basis Publications

Document Number	Document Title	Version	Effective Date
IAEA SSR-6	Regulations for the Safe Transport of Radioactive Material (2012 Edition)	2018	January 1, 2020

Licensee Documents that Require Notification of Change

Document Number	Document Title	e-Doc	Prior Notice
900-508520-PDD-001	Program Description Document: Transportation of Dangerous Goods	5507946	N
900-508520-PRD-001	Program Requirements Document: Transportation of Dangerous Goods	5507946	Y

The licensee shall implement and maintain a packaging and transport program that will be in compliance with all the regulatory requirements set out in the Transport Canada TDGR and in the CNSC PTNSR.

Shipments of nuclear substances within the WL site where access to the property is controlled are exempted from the application of the PTNSR.

Based on the current versions of the PTNSR and TDGR, for the packaging and transport of nuclear substances

(a) to and from the WL site, both PTNSR and TDGR apply.

(b) between the WL facilities:

- according to paragraph 2(2)(*d*) of the PTNSR, the PTNSR do not apply to the transport of nuclear substances within the WL site, except for sections 6 and 7. Sections 6 and 7 refer to the CNSC *Nuclear Security Regulations*, specifically to the transport of Category I, II or III nuclear material.
- TDGR do not apply per subsection 1.25 of those regulations.

APPENDIX A: DEFINITIONS AND ACRONYMS

1. DEFINITIONS

The following is a list of definitions of words or expressions used in the LCH that may need clarification; they are defined for the purpose of the LCH only. All other terms and expressions used in the LCH are consistent with the definitions provided in the NSCA, the regulations made pursuant to the NSCA, or in the CNSC regulatory document REGDOC-3.6 *Glossary of CNSC Terminology*.

Approval – Commission's permission to proceed, for situations or changes where the licensee would be:

- not compliant with a regulatory requirements set out in applicable laws and regulations;
- not compliant with a licence condition; and
- not in the safe direction but the objective of the licensing basis is met.

Boundary Conditions – procedural, administrative rules and operating limits for ensuring safe operation of the facility based on safety analyses and any applicable regulatory requirements.

Compliance Verification Criteria – regulatory criteria used by CNSC staff to verify compliance with the licence conditions.

Design Basis – the entire range of conditions for which the nuclear facility is designed, in accordance with established design criteria, and for which damage to the fuel and/or the release of radioactive material is kept within authorized limits.

Effective Date – the date that a given document becomes effective within the licensing period. The effective date is either set to the licence issue date or to a future date when the given document becomes effective.

Guidance – guidance in the LCH is non-mandatory information, including direction, on how to comply with the licence condition.

Program(s) – a documented group of planned activities, procedures, processes, standards and instructions coordinated to meet a specific purpose.

Qualified Staff – trained licensee staff, deemed competent and qualified to carry out tasks associated with their respective positions.

Safe Direction – changes in facility safety levels that would not result in:

(a) a reduction in safety margins;

(b) a breakdown of barrier;

(c) an increase (in certain parameters) above accepted limits;

(d) an increase in risk;

(e) impairment(s) of safety systems;

(f) an increase in the risk of radioactive releases or spills of hazardous substances;

(g) injuries to workers or members of the public;

(h) introduction of a new hazard;

(i) reduction of the defence-in-depth provisions;

(j) reducing the capability to control, cool and contain the reactor while retaining the adequacy thereof; or

(k) causing hazards or risks different in nature or greater in probability or magnitude than those stated in the safety analysis of the nuclear facility.

Safety and Control Measures – measures or provisions which demonstrate that the applicant:

(i) is qualified to carry on the licensed activities; and

(ii) has made adequate provision for the protection of the environment, the health and safety of persons, the maintenance of national security and any measures required to implement international obligations to which Canada has agreed.

Written Notification – a physical or electronic communication between CNSC staff and a person authorized to act on behalf of the licensee.

e-Doc 5492696 (PDF)

NUCLEAR RESEARCH AND TEST ESTABLISHMENT DECOMMISSIONING LICENCE

WHITESHELL LABORATORIES

I) LICENCE NUMBER: **NRTEDL-W5-8.05/2019**

II) LICENSEE: Pursuant to section 24 of the *Nuclear Safety and Control Act*, this licence is issued to

Canadian Nuclear Laboratories Limited
286 Plant Road
Chalk River, Ontario
K0J 1J0

III) LICENCE PERIOD: This licence is valid from January 1, 2019 and remains in effect until December 31, 2019 unless otherwise suspended, amended, revoked or replaced.

IV) LICENSED ACTIVITIES:

This licence authorizes the licensee to:

a) operate and decommission the Whiteshell Laboratories (hereinafter "WL") located in Pinawa, Province of Manitoba as further described in the Whiteshell Laboratories *Licence Conditions Handbook* (LCH) ,

b) produce, possess, process, refine, transfer, use, package, manage, import, export and store the nuclear substances that are required for, associated with or arise from the activities described in a),

c) possess, use, produce and transfer prescribed equipment that is required for, associated with, or arises from the activities described in a),

d) possess, use and transfer prescribed information that is required for, associated with, or arises from the activities described in a),

e) carry out the site preparation, construction or construction modification or undertaking that is required for, associated with or arise from the activities described in a).

V) EXPLANATORY NOTES:

(i) Nothing in this licence shall be construed to authorize non-compliance with any other applicable legal obligation or restriction.

(ii) Unless otherwise provided for in this licence, words and expressions used in this licence have the same meaning as in the *Nuclear Safety and Control Act* and associated Regulations.

(iii) The Whiteshell Laboratories Licence Conditions Handbook (LCH) provides compliance verification criteria used to meet the conditions of this licence. The LCH also provides information regarding delegation of authority and applicable versions of documents.

VI) CONDITIONS:

1 GENERAL

1.1 The licensee shall conduct the activities described in Part IV of this licence in accordance with the licensing basis, defined as:

(i) the regulatory requirements set out in the applicable laws and regulations

(ii) the conditions and safety and control measures described in the facility's or activity's licence and the documents directly referenced in that licence

(iii) the safety and control measures described in the licence application and the documents needed to support that licence application

unless otherwise approved in writing by the Canadian Nuclear Safety Commission (hereinafter "the Commission").

1.2 The licensee shall, in the event of any conflict or inconsistency between licence conditions, codes or standards or regulatory documents referenced in this licence, direct the conflict or inconsistency to the Commission, or a person authorized by the Commission, for resolution.

1.3 The licensee shall give written notification of changes to the facility or its operation, including deviation from design, operating conditions, policies, programs and methods referred to in the licensing basis.

1.4 The licensee shall ensure that every contractor working at the facility complies with this licence.

1.5 The licensee shall maintain a financial guarantee for decommissioning that is acceptable to the Commission.

1.6 The licensee shall comply with all commitments defined in the NRTEDL-W5-8.04/2018 LCH.

1.7 The licensee shall implement and maintain a public information and disclosure program.

1.8 The licensee shall implement and report on the progress of the Environmental Assessment Follow-Up Program.

2 DECOMMISSIONING

2.1 The licensee shall conduct decommissioning activities in accordance with Volumes 1 to 12 of the Whiteshell Laboratories Detailed Decommissioning Plan.

2.2 The licensee shall implement and maintain decommissioning policies, programs and procedures.

2.3 The licensee shall not make modifications to, or deviate from the design, operating conditions, purposes, methods, procedures or limits described in the safety analysis reports and/or operational limits and conditions documents that would result in an impact on health, safety or the environment that is different in nature or greater in magnitude or probability than that described in those documents without prior approval of the Commission or a person authorized by the Commission.

2.4 The licensee shall submit the project design requirements for construction of the approved second SMAG storage building prior to the commencement of construction activities described in paragraph e) of Part IV of this licence.

2.5 The licensee shall not carry out the activities referred to in paragraph a) of Part IV of this licence that relate to the completed construction activities in paragraph e) of Part IV of this licence for the approved second SMAG storage building until the submission of a commissioning report that is acceptable to the Commission.

3 SAFETY AND CONTROL AREA LICENCE CONDITIONS

MANAGEMENT SYSTEM

3.1 The licensee shall implement and maintain a management system.

4 HUMAN PERFORMANCE MANAGEMENT

4.1 The licensee shall implement and maintain a human performance program.

4.2 The licensee shall implement and maintain a training program.

5 OPERATING PERFORMANCE

5.1 The licensee shall implement and maintain a program for reporting to the Commission or a person authorized by the Commission.

6 SAFETY ANALYSIS

6.1 The licensee shall implement and maintain a safety analysis program.

6.2 The licensee shall implement and maintain a nuclear criticality safety program.

7 PHYSICAL DESIGN

7.1 The licensee shall implement and maintain a design program.

7.2 The licensee shall implement and maintain a pressure boundary program.

8 FITNESS FOR SERVICE

8.1 The licensee shall implement and maintain a fitness for service program.

9 RADIATION PROTECTION

9.1 The licensee shall implement and maintain a radiation protection program, which includes a set of action levels. When the licensee becomes aware that an action level has been reached, the licensee shall notify the Commission within seven days.

10 CONVENTIONAL HEALTH AND SAFETY

10.1 The licensee shall implement and maintain a conventional health and safety program.

11 ENVIRONMENTAL PROTECTION

11.1 The licensee shall implement and maintain an environmental protection program, which includes a set of action levels. When the licensee becomes aware that an action level has been reached, the licensee shall notify the Commission within seven days.

12 EMERGENCY MANAGEMENT AND FIRE PROTECTION

12.1 The licensee shall implement and maintain an emergency preparedness program.

12.2 The licensee shall implement and maintain a fire protection program.

13 WASTE MANAGEMENT

13.1 The licensee shall implement and maintain a waste management program.

13.2 The licensee shall maintain a cost estimate for decommissioning.

14 SECURITY

14.1 The licensee shall implement and maintain a security program.

15 SAFEGUARDS AND NON-PROLIFERATION

15.1 The licensee shall implement and maintain a safeguards program.

16 PACKAGING AND TRANSPORT

16.1 The licensee shall implement and maintain a packaging and transport program.

SIGNED at OTTAWA, AUG 0 1 2018.

File

Dr. Michael Binder
President and Chief Executive Officer
Canadian Nuclear Safety Commission
P.O. Box 1046, Station B
Ottawa, Ontario K1P 5S9

Dear Dr. Binder:

I am writing in response to your letter of July 15, 2015, with respect to the Canadian Nuclear Safety Commission's (CNSC) requirement for all of its licensees to establish sufficient funds for the decommissioning of their nuclear facilities, i.e. financial guarantees under paragraph 3(1)(l) of the *General Nuclear Safety and Control Regulations* made pursuant to the *Nuclear Safety and Control Act*.

Atomic Energy of Canada Limited (AECL) is a Schedule III, Part I Crown corporation under the *Financial Administration Act* and an agent of Her Majesty in Right of Canada. As an agent of Her Majesty in Right of Canada, AECL's liabilities are ultimately liabilities of Her Majesty in Right of Canada.

While the restructuring of AECL will see the ownership of Canadian Nuclear Laboratories Limited (CNL) transferred to a private-sector contractor, AECL will retain ownership of the lands, assets and liabilities associated with CNL's licences. Specifically, this letter addresses the licences held by CNL for the Chalk River Laboratories, the Whiteshell Laboratories, the Port Hope project, the Port Granby project, and the following three prototype power reactors: Nuclear Power Demonstration, Douglas Point and Gentilly-1.

Consistent with the policy of the Government of Canada that Her Majesty need not restate her commitment in the form of a guarantee, I trust that this letter will serve to address the requirement of the Commission.

Sincerely,

Greg Rickford

The Honourable Greg Rickford, P.C., M.P.
Minister of Natural Resources and Minister for the
Federal Economic Development Initiative for Northern Ontario

c.c.: Mr. Jon Lundy, Chief Transition Officer, Atomic Energy of Canada Limited
Mr. Ramzi Jammal, Executive Vice-President and Chief Regulatory Operations Officer, Canadian Nuclear Safety Commission

P.O. Box 1046, Station B
OTTAWA, Ontario K1P 5S9

OPERATIONS
Office of the Vice-President & CNO

Submission of Information Regarding Financial Guarantees for all Atomic Energy of Canada Limited Sites Operated by Canadian Nuclear Laboratories

Dear Ms. Murthy:

The purpose of this letter is to submit to Canadian Nuclear Safety Commission (CNSC) staff information recently received [1] by Canadian Nuclear Laboratories (CNL) from Atomic Energy of Canada Limited (AECL) regarding the requirements under the *Nuclear Safety and Control Act* to make funding provisions for decommissioning financial guarantees. The information received relates specifically to liabilities associated with the nuclear licensed sites that are owned by AECL, and operated by CNL under a Government owned – Contractor operated (GoCo) contract.

Accordingly, please find enclosed the letter received from AECL [1], which explicitly confirms that the provisions of financial guarantees previously stated in 2015 [2], by the then Minister of Natural Resources, are reaffirmed as remaining valid.

CNL trusts that the submission of references [1] and [2] will be satisfactory for the purposes of CNSC staff, in their consideration of AECL's liabilities and for providing decommissioning financial guarantees for the sites that are managed by CNL on behalf of AECL under the GoCo contract.

If you should have any questions with respect to the foregoing, please contact me directly or Mr. Shaun Cotnam, CNL's Chief Regulatory Officer at 613-639-1353.

Yours sincerely,

Phillip Boyle
Vice-President, Operations
Chief Nuclear Officer
Site Licence Holder – Chalk River Laboratories
Phone: 613-584-3311, ext. 42408
Email: Phillip.boyle@cnl.ca

Enclosures – (2)

Table of Contents

Section **Page**

1. Scope and Applicability

This Company-wide Interpretation document applies to all activities unique to the Nuclear Criticality Safety (NCS) Function performed by Canadian Nuclear Laboratories (CNL) at the Chalk River Laboratories (CRL) and Whiteshell Laboratories (WL) sites.

The scope of the NCS Function includes the control and oversight of operations involving the handling, storage, processing, and transportation of fissionable material (FM) and the long-term management of nuclear waste. It is applicable during the construction, operation, decommissioning, or abandonment of the licensed facility.

The following is outside the scope of the NCS Function:

- Operations with FM inside nuclear reactors; and
- Events leading to nuclear criticality arising from terrorism, sabotage, or other malicious acts.

2. Purpose

The NCS Function establishes the framework for ensuring that accidental nuclear criticality is prevented and that the consequences of accidental nuclear criticality are mitigated during operations with FM outside nuclear reactors.

3. Definitions and Acronyms

This document relies primarily on word meaning as found in common dictionaries. The CNL current *Glossary of Terms and Definitions* [1] contains specific meanings for those words that require further clarification.

The definitions and acronyms in this section are those owned or created by the NCS Function.

3.1 Definitions

Accidents or Accident Sequences	Events or event sequences, including external events, that lead to violation of the subcriticality margin (that is, to exceeding the upper subcritical limit) [2].
Active Engineered Control	A physical device that uses active sensors, electrical components, or moving parts to maintain safe process conditions without any required human action [2].
Areal Density	The product of the thickness of a uniform slab and the density of fissionable material within the slab; hence, areal density is the mass of fissionable material per unit area of slab. For non-uniform slurries, the areal density limits are valid for a horizontal slab subject to gravitational settling, provided the restrictions for uniform slurries are met throughout [2].

Array	Any fixed configuration of fissile or fissionable material units maintained by mechanical devices [2].
Balance After Processing	The balance of fissionable material that was known to be present but cannot be accounted for due to physical processing or uncertainties in measurement. Examples of Balance After Processing include material caught in air filters, residue, dust, and shavings generated by cutting, grinding, etc.
Benchmark Experiment	With respect to nuclear criticality safety, a well-characterized experiment at the critical state that may be used to establish the reliability of calculational methods [2].
Controlled Parameter	A parameter that is kept within specified limits and, when varied, influences the margin of subcriticality [2].
Conservatism	The use of assumptions that make predictions regarding consequences more severe than if best-estimate assumptions had been used [2].
Conservative Calculations	Calculations that are designed to over-predict a parameter with the intention that the reality will not be greater than the prediction. These calculations can be based on simplifications of the processes being simulated (the structure of a model) or on limits of data values used in the model [2].
Credible Abnormal Conditions	Accidents or accident sequences that have a frequency of occurrence equal to or more than one in a million years [2].
Criticality Accident	The release of energy as a result of accidental production of a self-sustaining or divergent neutron chain reaction [2].
Criticality Accident Alarm System	A radiation detection system meeting the requirements established in Section 3.0 of REGDOC-2.4.3 [3] that reliably detects the occurrence of a criticality accident in a prescribed area and promptly alerts personnel.
Criticality Safety Analysis	The process used to demonstrate that an adequate margin of subcriticality is maintained under normal and credible abnormal conditions.

Criticality Safety Control	Structures, systems, equipment, components, and activities of personnel that are relied on to prevent accidents or to mitigate their potential consequences [2]. Criticality Safety Controls are categorized as one of the following (see relevant definitions for each): • Passive Engineered Control • Active Engineered Control • Enhanced Administrative Control • Simple Administrative Control
Criticality Safety Document	A document that identifies and defines all known nuclear criticality safety concerns; documents nuclear criticality safety assumptions, requirements, limits, and controls; and demonstrates subcriticality [2].
Cross-section (σ), Neutron	The proportionality factor that relates the rate of a specified reaction to the product of the number of neutrons per second impinging normally onto a unit area of a thin target and the number of target nuclei per unit area. It may be considered a small area assigned to each target nucleus, usually expressed in barns (i.e., 10^{-24} cm^2) [4].
Depleted Uranium	Uranium that contains ^{235}U in a concentration that is less than that normally found in nature. With respect to nuclear criticality safety, the concentration of this isotope is less than 0.71 percent by weight [2].
Double Contingency Principle	A characteristic or attribute of a process that has incorporated sufficient safety factors so that at least two unlikely, independent, and concurrent changes in process conditions are required before a nuclear criticality accident is possible [2].
Effective Neutron Multiplication Factor	**Physically**, the ratio of the total number of neutrons produced during a time interval (excluding neutrons produced by sources whose strengths are not a function of fission rate) to the total number of neutrons lost by absorption and leakage during the same interval [2]. **Mathematically** (computationally), the eigenvalue number that, when divided into the actual mean number of neutrons emitted per fission in an assembly of materials, would make the calculated result for the nuclear chain reaction of that assembly critical [2].

Enhanced Administrative Control	A procedurally required or prohibited human action, combined with a physical device that alerts an operator to take action to maintain safe process conditions, or that otherwise adds substantial assurance of the required human performance [2].
Enriched Uranium	Uranium having a higher abundance of the fissile isotopes (^{235}U, ^{233}U, or a combination of both) than natural uranium [2].
Excessive Radiation Dose	In a nuclear criticality accident, any dose to personnel corresponding to an absorbed dose from neutrons and gamma rays equal to or greater than 0.12 gray in free air [2].
Fertile Material	Nuclear material that can be converted into special fissionable material through the capture of one neutron per nucleus. There are two naturally occurring fertile materials: ^{238}U and ^{232}Th. Through the capture of neutrons followed by two beta decays, these fertile materials are converted to fissionable ^{239}Pu and ^{233}U, respectively [2].
Fissile Material	A material, other than natural uranium, that is capable of sustaining a thermal neutron chain reaction [2].
Fissile Nuclide	A nuclide capable of undergoing fission by interaction with slow neutrons provided the effective thermal neutron production cross-section, $\upsilon\sigma_f$, exceeds the effective thermal neutron absorption cross-section σ_a [2].
Fission	Disintegration of a nucleus (usually Th, U, Pu, or heavier) into two (rarely more) masses of similar order of magnitude, accompanied by a large release of energy and the emission of neutrons [4].
Fission Cross-Section	See the definitions for *fission* and *cross-section*. The fission cross-section is designated as σ_f.
Fissionable Material	Any material that can undergo nuclear fission [2].
Fixed Moderator	A moderator with an established geometric relationship to the locations occupied by the fixed neutron absorber and fissionable material [2].
Fixed Neutron Absorbers	Neutron absorbers in solids with an established geometric relationship to the locations occupied by fissionable material [2].

High-Enriched Uranium	Uranium containing 20 percent or more by weight of isotope ^{235}U, isotope ^{233}U, or combined ^{233}U and ^{235}U. Also called highly-enriched uranium [2].
Immediate Evacuation Zone	The area surrounding a potential criticality accident location that must be evacuated without hesitation if a criticality accident alarm signal is activated [2].
Logarithmic Energy Decrement	The decrease per collision in the logarithm of the neutron energy [5].
Long-Term Management of Nuclear Waste	The long-term management of radioactive nuclear waste by means of storage or disposal, including handling, treatment, conditioning, or transport for the purpose of storage or disposal. Also called long-term waste management [2].
Low-Enriched Uranium	Enriched uranium containing less than 20 percent by weight of isotope ^{235}U, ^{233}U, or combined ^{233}U and ^{235}U [2].
Minimum Accident of Concern	An accident resulting in a dose to free air of 0.20 gray in the first minute at a distance of 2 metres from the reacting material [2].
Minimum Critical Mass	The smallest mass of a fissionable material which, under specific conditions (neutron reflection, neutron moderation, geometry, etc.), can result in a self-sustaining fission chain reaction.
Moderating Ratio	The moderating ratio is the ratio of the macroscopic slowing down power (a product of the logarithmic energy decrement and the macroscopic neutron scattering cross section) to the macroscopic cross-section for absorption. The higher the moderating ratio, the more effectively the material performs as a moderator [5].
Moderator Control Area	An area defined by a Criticality Safety Document in which moderators are limited and controlled for nuclear criticality safety [2].
Natural Uranium	Uranium that contains ^{235}U in a concentration that is normally found in nature. With respect to nuclear criticality safety, the concentration of this isotope is equal to or less than 0.71 percent by weight [2].

Neutron Absorber	A neutron-capture material; that is, a substance with a large neutron absorption cross-section. When neutron absorption is not desired, a neutron absorber may be called a neutron poison. Some examples of neutron absorbers are [2]: • boron, used in some shutdown systems • some of the products generated during fission that have a high neutron absorption cross-section, such as ^{135}Xe and ^{149}Sm
Neutron Absorption	A neutron-induced reaction, including fission, in which the neutron disappears as a free particle [6].
Neutron Absorption Cross-Section	See definitions for *neutron absorption* and *cross-section.* The neutron absorption cross-section is designated as σ_a.
Neutron Leakage	Transport of neutrons by their physical motion from one region to another or from a system as a whole [7].
Neutron Moderation	The process of decreasing the energy of neutrons through successive collisions with moderator nuclei without appreciable competing capture [2].
Neutron Moderator	A material used to slow down or “moderate” neutrons produced by nuclear fuel. The moderator reduces neutron energy by scattering without appreciable capture. Materials of prime concern are those containing light nuclei with large scattering cross-sections and relatively low absorption cross-sections [2].
Neutron Reflection	The process in which neutrons that would otherwise leak from a material volume are returned as a result of scattering from a surrounding material [7].
Neutron Reflector	Material outside the core of a fissionable system capable of scattering back to the core some neutrons that would otherwise escape [4].
Neutron Scattering	Reaction between a neutron and a nucleus in which the net result is a change in the neutron energy and direction of travel [7].
Neutron Scattering Cross-Section	See the definitions for *neutron scattering* and *cross-section*. The scattering cross-section is designated as σ_s.

Non-Nuclear Criticality Controlled Area	A defined area (e.g., a building, a series of labs, a waste management area, an on-site flask, or transfer package) that is permitted to contain quantities of fissionable material that satisfy the Canadian Nuclear Safety Commission exemption criteria for nuclear criticality safety (Section 5.1).
Normal Conditions	Conditions or ranges of conditions that are expected during normal or routine operation.
Nuclear Criticality	A self-sustaining chain reaction of nuclear fission [2].
Nuclear Criticality Controlled Area	A defined area (e.g., a building, a series of labs, a waste management area, an on-site flask, or transfer package) that is permitted to contain quantities of fissionable material that do not satisfy one of the Canadian Nuclear Safety Commission exemption criteria for nuclear criticality safety (Section 5.1).
Nuclear Criticality Safety	Protection against the consequences of a criticality accident, preferably by prevention of the accident [2].
Operations with Fissionable Material	Any activity involving the handling, use, processing, movement, and storage of fissionable material and the long-term management of nuclear waste containing fissionable material [2].
Passive Engineered Control	A device that uses only fixed physical design features to maintain safe process conditions without any required human action [2].
Reactivity	A quantity (k_{eff} – 1) / k_{eff}, where k_{eff} is the effective neutron multiplication factor. The reactivity of a subcritical assembly is a negative quantity indicating the degree of subcriticality. The reactivity of a critical assembly is zero [2].
Representative Nuclear Criticality Accident	A postulated nuclear criticality accident that is used to demonstrate compliance with the CNSC criticality safety requirements on the mitigation of nuclear criticality accident consequences [2].
Simple Administrative Control	A procedural human action that is prohibited or required to maintain safe process conditions [2].
Single-Parameter Limit	The limiting value assigned to a single controlled parameter that results in a subcritical system under specified conditions. Single parameter limits allow for uncertainties in the calculations and experimental data used in its derivation but not for contingencies such as double batching or inaccuracies in analytical determinations.

Special Fissionable Material	Fissionable material that contains fissile isotopes (excluding natural uranium, depleted uranium, and natural thorium).
Subcritical Limit	The limiting value assigned to a controlled parameter that results in a subcritical system under specified conditions. The subcritical limit allows for uncertainties in the calculations and experimental data used in its derivation but not for contingencies such as double batching or inaccuracies in analytical determinations [2].
Time-Limited Amendment	A document that amends a Criticality Safety Document in order to demonstrate the safety of operations that are not covered under the Criticality Safety Document.
Upper Subcritical Limit	The maximum allowed value of the calculated effective multiplication factor (k_{eff}) or of a single-parameter subcritical limit, under both normal and credible abnormal conditions, including allowance for the bias, uncertainty in the bias, and an administrative margin of subcriticality [2].

3.2 Acronyms

AEC	Active Engineered Control
BAP	Balance After Processing
CAAS	Criticality Accident Alarm System
CHI	Criticality Hazard Identification
CSA	Criticality Safety Analysis
CSC	Criticality Safety Control
CSD	Criticality Safety Document
DCP	Double Contingency Principle
DU	Depleted Uranium
EAC	Enhanced Administrative Control
EU	Enriched Uranium
FM	Fissionable Material
HEU	High-Enriched Uranium / Highly-Enriched Uranium
IEZ	Immediate Evacuation Zone
k_{eff}	Effective Neutron Multiplication Factor
LEU	Low-Enriched Uranium

MAGIC MERV HD	Mass Absorption Geometry Interaction Concentration Moderation Enrichment Reflection Volume Heterogeneity Density
MCM	Minimum Critical Mass
NCCA	Nuclear Criticality Controlled Area
NCCO	Nuclear Criticality Control Officer
NCS	Nuclear Criticality Safety
NT	Natural Thorium
NU	Natural Uranium
PEC	Passive Engineered Control
SAC	Simple Administrative Control
SFM	Special Fissionable Material
SCL	Subcritical Limit
SPL	Single-Parameter Limit
TLA	Time-Limited Amendment
USL	Upper Subcritical Limit

4. Roles and Responsibilities

The sections below contain only functional responsibilities (i.e., responsibilities related to setting rules and controls, and oversight of the implementation of those rules and controls). Additional procedural responsibilities are established in the suite of NCS implementing documents. Where applicable, these documents are referenced in the sections below.

4.1 Nuclear Criticality Safety Functional Support Manager

The NCS Functional Support Manager (FSM) has the overall responsibility to ensure that the NCS FSA implements effective processes that meet all NCS regulatory requirements as per the CRL and WL Licence Conditions Handbooks (LCHs) [8] [9] and the *NCS Program Requirements Document (PRD)* [10].

As per the FSM responsibilities established in the *CNL Management System Manual* [11], the NCS FSM is responsible for:

- Ensuring that all applicable NCS requirements are implemented in appropriate implementing documents;
- Acting as a final authority for interpretation and applicability of NCS functional requirements to Line Management;

- Performing applicability reviews on new and revised NCS requirements, identifying the impacts, and planning the strategy for implementation;
- Establishing and implementing the NCS attributes and training expectations for the training and qualification of NCS FSA personnel;
- Ensuring that the quality of documentation that is under the direct purview of the NCS FSA meets the NCS Function requirements and overall company requirements;
- Establishing and maintaining effective relationships and coordination of the NCS FSA interfaces with Atomic Energy of Canada (AECL), Canadian Nuclear Safety Commission (CNSC) staff, and oversight organizations; and
- Developing and performing assessments in accordance with *Integrated Assessment Plan* [12] to evaluate the implementation of program elements in order to verify that NCS FSA requirements are adequately implemented.

4.2 Nuclear Criticality Safety Functional Support Manager Designate

The NCS Program Manager normally fulfills this role.

As per the FSM Designate responsibilities established in the *CNL Management System Manual* [11], the NCS FSA Designate is responsible for:

- Assisting the NCS FSM in fulfilling the responsibilities listed in Section 4.1;
- Maintaining effective communication and working relationships with Line Management and other FSM Designates;
- Interfacing with facilities, projects, and other support organizations to ensure that the quality of documentation under the direct purview of the NCS FSA meets the NCS Function requirements and overall company requirements;
- Maintaining proficient knowledge of the NCS FSA requirements;
- Providing support to Line Management by identifying and interpreting the applicable NCS FSA requirements;
- Developing NCS FSA implementing documents;
- Supporting and monitoring NCS training and qualification programs to ensure that NCS requirements are implemented effectively and the applicable employees are trained and qualified to perform their work;
- Participating in internal or third-party audits and other assessments and reviews, as requested;
- Being familiar with events and issues related to NCS within facilities, projects, and other support organizations and assisting in developing the associated corrective action plans and lessons learned; and

- Supporting assessments evaluating the implementation of program elements to verify that NCS FSA requirements are adequately implemented.

In addition to this, the NCS FSA Designate is responsible for:

- Performing responsibilities pertaining to NCS Program Officers listed in Section 4.3.

4.3 Nuclear Criticality Safety Program Officer

NCS Program Officers are responsible for:

- Maintaining proficient knowledge of the requirements of the NCS FSA, and of current NCS regulations, standards, guides and codes;
- Providing NCS support and oversight to ensure that the requirements of the NCS FSA are being implemented effectively;
- Performing work in accordance with NCS FSA processes and procedures;
- Reviewing the following to ensure that NCS FSA requirements are being implemented:
    - Procedures related to operations with FM in NCCAs;
    - General and area-specific NCS training material;
    - Emergency Procedures for areas with a Criticality Accident Alarm System (CAAS) installed or adjacent buildings that would be impacted by the actuation of a CAAS;
    - Pre-Incident Plans for response to a fire in NCCAs;
- Developing and delivering NCS training; and
- Performing responsibilities pertaining to Criticality Safety Analysts listed in Section 4.4.

4.4 Criticality Safety Analysts

Criticality Safety Analysts are responsible for:

- Performing work in accordance with NCS FSA processes and procedures; and
- Providing advice and guidance to CNL personnel on technical NCS matters, as required.

4.5 Safety Analysts

Safety Analysts support the development of Criticality Safety Analysis (CSA). Safety Analysts are responsible for:

- Performing work in accordance with NCS FSA processes and procedures; and
- Providing advice and guidance to NCS personnel on safety analysis matters related to NCS, as required.

4.6 Line Management of NCCAs and Non-NCCAs

Line Managers (e.g., Facility Authority, Manager, Director, etc.) are responsible for ensuring that work is performed safely by implementing and ensuring operations are conducted within CNL's requirements in their respective department/facility [11].

In addition to the Line Management responsibilities established in the *CNL Management System Manual* [11], Line Management of areas containing FM is responsible for ensuring that the requirements of the NCS Program are implemented in their area, as established in Table 1.

Table 1: Responsibilities for Line Management of NCCAs and Non-NCCAs

Responsibility	NCCA	Non-NCCA
Accept overall responsibility for the nuclear criticality safety of the operations in the area, and provide regular and systematic oversight to ensure that all applicable NCS requirements (as documented in this document and the *NCS for Operations* Standard [13]) are adhered to.	✓	✓
Ensure that all operations involving FM have been evaluated for NCS in a CSD or TLA, and that the NCS Panel has accepted the CSD or TLA prior to the operations being performed.	✓	
Ensure that all limits, restrictions, and Criticality Safety Controls (CSCs) established in the applicable CSD and all active TLAs are adhered to.	✓	
Ensure that all limits and restrictions established in the CNSC exemption criteria for NCS (see Section 5.1) are adhered to.		✓
Appoint an NCCO and NCCO Designates as per the Standard for *Qualification and Appointment of NCCOs* [14]. If an NCCA does not have an appointed NCCO, **<u>all operations with FM are halted, and the NCS FSA is notified</u>**. Under exceptional circumstances where prompt NCCO action is required to ensure either safety or compliance with NCS Functional requirements, Line Management for the NCCA may perform specific actions in the place of the NCCO upon receipt of written approval from the NCS FSA.	✓	
Ensure their staff have been assigned the correct training categorization and have completed and maintained the associated required NCS training (including refresher training) as per the *NCS Training* Standard [15].	✓	✓
Ensure completion of the NCS Compliance Assessment on an annual basis as per the *NCS Compliance Assessment* Standard [16].	✓	✓

Responsibility	NCCA	Non-NCCA
Ensure that issues and unplanned events related to NCS are promptly communicated to the NCS Function.	✓	✓

4.7 Employees in NCCAs and Non-NCCAs

Employees in NCCAs are responsible for:

- Working within the limits and restrictions established in the applicable CSD(s) and all active TLAs; and
- Promptly reporting issues and unplanned events related to NCS to Line Management and the NCCO.

Employees in Non-NCCAs are responsible for:

- Working within the limits and restrictions established by the CNSC exemption criteria for NCS (see Section 5.1); and
- Promptly reporting issues and unplanned events related to NCS to Line Management.

4.8 Nuclear Criticality Control Officers

NCCOs and NCCO Designates are appointed as per the Standard for *Qualification and Appointment of NCCOs* [14], and are responsible for:

- Overseeing operations involving FM within an NCCA to ensure compliance with all requirements established in the applicable CSD(s) and all active TLAs.
- Promptly reporting issues and unplanned events related to Line Management and the NCS FSA.

4.9 Nuclear Criticality Safety Panel

The NCS Panel is a subcommittee of the Safety Review Committee (SRC) comprised of members with broad skills and expertise in at least the following: criticality safety analysis, chemistry, decommissioning, operations, and physics [17]. They are responsible for performing independent review and acceptance of [18]:

- Documentation that has satisfactorily demonstrated NCS for activities involving FM and on-site transport packages used to transport FM;
- Documentation that evaluates the requirements for CAAS for existing and new NCCAs, including documentation that justifies the removal of CAAS from existing NCCAs; and
- Criticality safety analysis of CNL-owned transport packages used in the shipment of FM off-site before these transport packages are submitted to the CNSC for licensing.

4.10 Training & Development

The Training and Development FSA is responsible for [19]:

- Ensuring NCS-related training is included in training plans according to the requirements established in the *NCS Training* Standard [15]; and
- Supporting the development of NCS training (including the training of NCS FSA staff and of NCCA and Non-NCCA staff).

4.11 Fire Protection

The Fire Protection FSA is responsible for [20]:

- Including NCS information in building-specific Pre-Incident Plans and submitting these plans to the NCS FSA for review; and
- Participating in the emergency response to CAAS actuation.

4.12 Security

The Security FSA is responsible for [21]:

- Participating in the emergency response to CAAS actuation.

4.13 Emergency Preparedness

The Emergency Preparedness FSA is responsible for [22]:

- Incorporating NCS requirements for buildings with CAAS and adjacent buildings that would be impacted by the actuation of a CAAS into their emergency drill plans and submitting these to the NCS FSA for review; and
- Incorporating criticality accident mitigation measures into emergency response activities.

5. Functional Programs

The NCS Function establishes the framework for ensuring that accidental nuclear criticality is prevented, and the consequences of accidental nuclear criticality are mitigated during operations with FM outside nuclear reactors.

The NCS function at CNL implements standards and regulations as described in the *Nuclear Criticality Safety PRD* [10].

The following are the foundation of the NCS FSA:

- NCS principles and requirements are part of the foundation of CNL's *Nuclear Safety Policy* [23];
- All operations with FM are demonstrated to be subcritical under both normal and credible abnormal conditions (accidents or accident sequences that have a frequency of

occurrence equal to or more than once in a million years) by using quantitative or semi-quantitative methods;

- Upper subcritical limits (USLs) are not exceeded under all normal and credible abnormal conditions;
- The consequences of a potential criticality accident are mitigated to limit the on-site and off-site doses; and
- CNL is compliant with site licence requirements for NCS through NCS Program processes and procedures.

Figure 1 presents an overview of the NCS FSA processes.

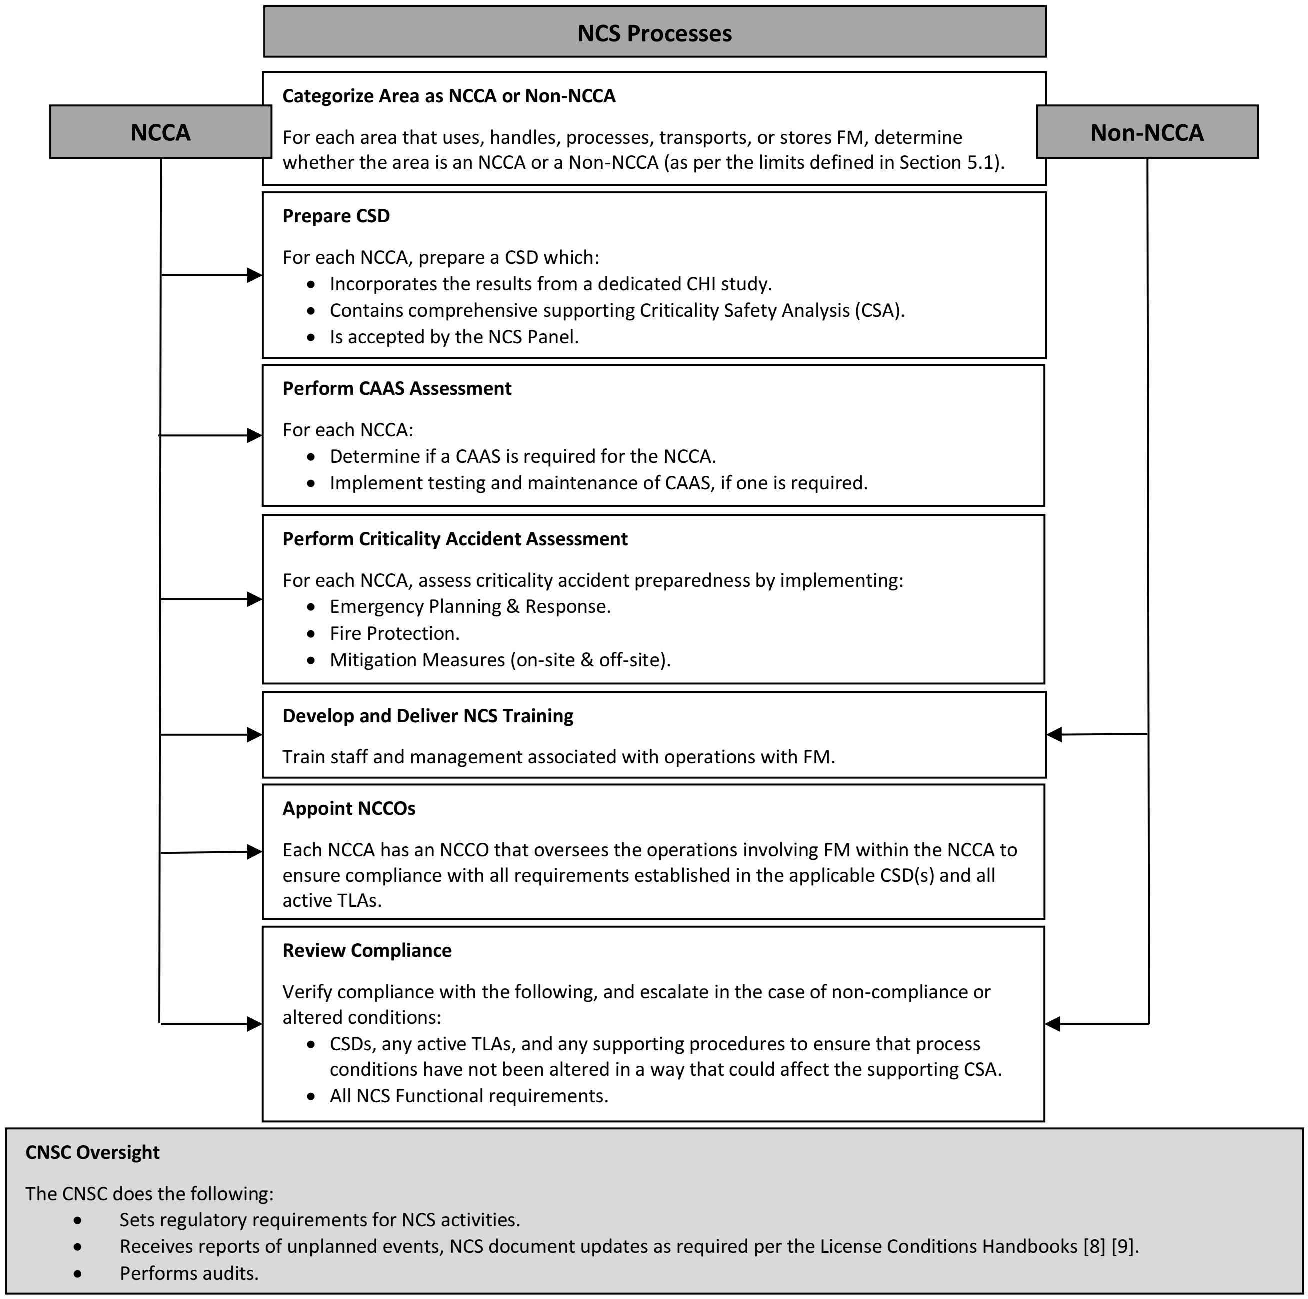

Figure 1: Process Flow Overview – Nuclear Criticality Safety

5.1 Nuclear Criticality Controlled Areas & Non-Nuclear Criticality Controlled Areas

The CNSC exemption criteria for NCS is defined as follows [3]:

1. Less than 100 g of ^{233}U, or ^{235}U, or ^{239}Pu, or any combination of these three isotopes in FM combined in any proportion; or

2. An unlimited quantity of natural or depleted uranium or natural thorium, if no other FM nor significant quantities of graphite, heavy water, beryllium, or other moderators more effective than light water are present in the area; or
3. Less than 200 kg in total of natural or depleted uranium or natural thorium if some other FM is present in the area, but the total amount of fissile nuclides in the FM is less than 100 g.

A Non-NCCA is a defined area (e.g., a building, a series of labs, a waste management area, an on-site flask, or transfer package) that is permitted to contain quantities of FM that satisfy one of the criteria listed above. An NCCA is a defined area (e.g., a building, a series of labs, a waste management area, an on-site flask, or transfer package) that is permitted to contain quantities of FM that do not satisfy one of the criteria listed above.

Nuclear sources and standards that meet the following criteria are exempt from consideration when defining an area as an NCCA or Non-NCCA:

- Any single source or standard that contains ≤ 1 g FM.
- Any number of sources or standards provided the total amount contained within the sources and standards is ≤ 10 g FM.

5.2 Processes / Activities

The NCS FSA processes and activities are described in the sections below.

5.2.1 Control of Fissionable Material

To ensure the control of FM, Line Management follows NCS FSA procedures and documents summarized in the *NCS Governing Document Index* [24].

Nuclear criticality is a risk associated with using, processing, handling, moving, and storing FM. The quantity of FM in both NCCAs and Non-NCCAs is an important criticality control parameter. Therefore, each NCCA and Non-NCCA must maintain accurate inventories of FM to support effective criticality control. FM is used, handled, moved, processed, and stored in a controlled manner, with procedures and training in place, to ensure that limits and restrictions are not exceeded, and criticality safety controls are implemented.

Access to areas where FM is used, handled, processed, or stored is controlled.

FM accounting and procedure adherence are essential to NCS. Line Management, NCCOs, and staff of NCCAs and Non-NCCAs know the locations and the amount of FM in their area, maintain accurate FM inventories and follow the requirements and processes of the *Nuclear Materials and Safeguards Management* FSA [25]. The movement of FM on-site follows the requirements and procedures covered under the *Nuclear Materials and Safeguards Management* FSA [25].

5.2.2 Criticality Safety Documents and Time-Limited Amendments for Nuclear Criticality Controlled Areas

Each NCCA has a CSD (and potentially one or several TLAs) that has been accepted by the NCS Panel. The NCS FSA supports the preparation, development, and review of CSDs.

The process for generating a CSD or TLA is documented in the Management Control Procedure for *Preparing a CSD or TLA* [26]. Inputs to the preparation of a CSD or TLA include:

- Criticality Safety Analysis: All NCCAs have criticality safety analysis as part of their CSD. This demonstrates that a sufficient safety margin has been established and will be maintained under all normal and credible abnormal conditions. The requirements for Criticality Safety Analysis are established in the *Criticality Safety Analysis* Standard [27].
- A CHI study: This type of study provides a systematic approach for the identification of credible abnormal conditions (events or event sequences that have an expected frequency of occurrence equal to or greater than 10^{-6}/year) and supports the identification of CSCs. The findings from the CHI study are inputs to the CSA, which is incorporated in the CSD. The requirements for CHIs are established in the *CHI Study* Standard [28].

Off-site transport packages are exempt from having a CSD, provided that the transport package is CNSC-certified, has a valid Safety Analysis Report (SAR), and is used according to the limits and restrictions in the SAR and the CNSC certificate.

5.2.3 Nuclear Criticality Safety Training

The content of the general NCS training is developed by the NCS FSA in collaboration with Training and Development (T&D). NCCA-specific training is developed by the NCCA with the support of NCS and T&D. NCS training is provided to all workers (employees or contractors) who work at CNL sites where NCS requirements apply. More information on NCS training requirements and categorizations can be found in the *NCS Training* standard [15].

All NCS training (general and area-specific) is reviewed and evaluated by the NCS Program staff periodically (and as needed). NCCA-specific training prepared by the NCCA staff is reviewed by the NCS Program staff when it is updated and prior to implementation.

5.2.4 Nuclear Criticality Safety Conduct of Operations

Procedures that impact NCS are reviewed by the NCS FSA staff.

Operations for which NCS is a concern (i.e., those conducted within NCCAs) are governed by operating procedures that incorporate NCS to ensure the safe and efficient conduct of operations.

Procedures incorporate the limits and restrictions for criticality control (from the applicable CSD and all active TLAs). Note that in some cases where the inclusion of complex limits and/or restrictions might present a Human Performance (HU) error trap, it may be appropriate for the procedure to direct the user to the applicable CSD and/or TLA. These procedures specify any parameters that are to be controlled. Procedures are provided for monitoring, testing, and maintaining process equipment listed for criticality control in the CSD and all active TLAs. They are written such that no credible, single, inadvertent departure from a procedure can cause a criticality accident.

A review of operations is performed to verify that procedures are being followed and that process conditions have not been altered in such a way that would affect the applicable criticality safety analysis (documented in the applicable CSD). This review can be documented during the criticality safety compliance self-assessment (see Section 5.2.5), which must be conducted on a yearly basis. Procedures shall be revised as changes become desirable.

5.2.5 Nuclear Criticality Safety Compliance Assessments

An NCS Compliance Assessment is completed annually by each NCCA and Non-NCCA as per the *NCS Compliance Assessment* Standard [16]. These assessments are reviewed by NCS Program Staff and are designed to help the areas identify and resolve potential safety and/or compliance vulnerabilities should any exist.

For NCCAs, this assessment aids in verifying that procedures related to NCS are being followed and that process conditions have not been altered in a way that affects the NCS analysis in the applicable CSD and all active TLAs. This assessment also aids in verifying compliance with the NCS Function requirements.

For Non-NCCAs, this assessment aids in verifying compliance with the NCS Function requirements.

5.2.6 Qualification and Appointment of NCCOs

NCCOs are responsible for overseeing operations involving FM in an NCCA to ensure compliance with all requirements established in the applicable CSD(s) and any active TLAs. The process for qualifying and appointing NCCOs ensures that candidates are evaluated against consistent qualification requirements and that their suitability for the role is assessed in a controlled manner prior to formal appointment.

This process is described in the *Qualification and Appointment of NCCOs* Standard [14]. The NCCO appointment is performed by NCCA Management.

Each NCCA must have an NCCO in order to perform operations with FM. If an NCCA does not have an appointed NCCO, **<u>all operations with FM are halted, and the NCS FSA is notified</u>**. Under exceptional circumstances where prompt NCCO action is required to ensure either safety or compliance with NCS Functional requirements, Line Management for the NCCA may perform specific actions in the place of the NCCO only upon receipt of written approval from the NCS Function.

5.2.7 Criticality Accident Alarm System (CAAS)

A CAAS is required in any NCCA where inadvertent criticality can occur, and excessive radiation dose to personnel is credible should the inadvertent criticality occur. The methodology for assessing whether a CAAS is discussed in [29]. For areas that are determined to require a CAAS, an assessment is performed to determine the appropriate number and locations for the detectors [30]. The purpose of this assessment is to ensure that the installed CAAS is able to respond to the minimum accident of concern.

Periodic maintenance and testing of CAAS is necessary to ensure the instrument performs as intended. Each NCCA with a CAAS is responsible for ensuring that the CAAS is maintained and tested regularly, following guidelines in REGDOC-2.4.3 [3] and *Radiation Protection Instrumentation* [31]:

- CAAS is tested after modifications or repairs;
- Each detector is tested at least annually; and
- New CAAS installations are successfully commissioned prior to operational use.

5.2.8 Fire Protection

Guidelines for firefighting within NCCAs areas are based on comparisons of the risks of accidental criticality with the risks of postulated fires for the respective areas. The introduction of moderators is considered during firefighting activities and is included in the Pre-Incident Plans developed by the *Fire Protection* FSA staff [20].

5.2.9 Mitigation Measures – On-Site and Off-Site

The NCS Function supports NCCAs in the determination of suitable on-site and off-site criticality accident mitigation measures (e.g., protective measures are in place to limit on-site radiological dose to personnel and off-site dose consequences).

- On-site: NCCAs demonstrate that adequate mitigation measures are put in place to limit on-site radiological dose to personnel;
- Off-site: NCCAs demonstrate that adequate mitigation measures are in place such that off-site consequences of a criticality accident, as calculated from the start of the accident, do not violate criteria established as a trigger for a temporary public evacuation.

5.3 Non-Compliances (or Unplanned Events)

The process for unplanned event reporting to the CNSC [32] is followed to determine if a non-compliance or an unplanned event is reportable to the CNSC (not all non-compliances and unplanned events related to criticality safety are reportable).

Any potential non-compliance with the NCS FSA procedures, requirements, CSDs/TLAs, or change in process condition that could alter the supporting CSA is reported immediately to the

NCS FSA for review. Examples of potential non-compliance (or unplanned event) related to NCS include:

- With respect to a CSD or TLA: exceedance of any limit, failure to adhere to a restriction, failure to implement a CSC, or the conduct of a work activity that is not bounded by the CSD criticality safety analysis for normal operating conditions.
- With respect to NCS Functional requirements: failure to implement any requirements established in the NCS FSA implementing documents; and /or
- Any NCS-related incident of a potentially hazardous nature that was not analyzed in the CSD for NCCAs or exceeding the exemption criteria in non-NCCAs.

5.4 Records and Documentation

Permanent records and documentation associated with the FSA include:

- NCS Function interpretation and implementing documents (e.g., Program Requirements Document, Program Description Document, Management Control Procedures, Standards);
- CSDs and TLAs;
- NCS Analyses and technical evaluations in support of NCS (e.g., Software Validation Report, off-site dose consequences, etc.);
- NCS Panel Acceptance documentation;
- CHI studies;
- CAAS needs assessment;
- CAAS detector location and dose contour evaluations;
- General NCS training material; and
- NCCO Training Qualification Card.

6. Interfaces

6.1 Internal Interfaces

Functions/Lines Interfaced With	Interface Activity/Purpose (Type of Information Exchanged)	Interface Mechanism	Primary Interface Contact(s)
Line Management of NCCAs	Guidance and technical expertise for CSD and TLA development, changes in activities (design and operational changes), the appointment of NCCOs, information and recommendation on CAAS, and verification of compliance, reporting of unplanned events.	CSDs, TLAs, NCCO acceptance forms, compliance assessments, criticality safety analysis, CHI studies, and unplanned event reports.	Line Manager responsible for the area.
Line Management of Non-NCCAs	Guidance and technical expertise, verification of compliance, and reporting of unplanned events.	Compliance assessments and unplanned event reports.	Line Manager responsible for the area.
Nuclear Response & Analysis (NRA) Branch (S&T)	Perform criticality safety analysis upon request from NCS Program	CSDs, TLAs, technical evaluations, and reports	Section Head of Nuclear Systems and Radiation Analysis in NRA Branch

Functions/Lines Interfaced With	Interface Activity/Purpose (Type of Information Exchanged)	Interface Mechanism	Primary Interface Contact(s)
Design (Engineering)	Documentation on the design of new and modified buildings and/or systems is reviewed to ensure applicable requirements related to NCS are being met and to determine if engineered barriers need to be designed to ensure criticality safety of an area. Design lifetime of the area is taken into account at the planning and design stage for a new or existing NCCA. Develop design specifications for CAAS.	Notification via ECC checklist for NCS, e-mail, telephone, and meetings	Design Subject Matter Expert (SME)
Integrated Work Control (IWC)	Document assessment for activities that may impact NCS	Hazard Screening Checklist Tool, Job Hazard Analyses	Any staff completing the IWC
Nuclear Materials and Safeguards Management (NM&SM)	Modifications to the permissions in the Integrated Nuclear Materials Accounting System (INMAS) for appointed NCCOs, modifications to the mass limits with integrated NCCAs	E-mail, INMAS	NM&SM Program Specialists and Nuclear Materials Assistants
Fire Protection	Pre-Incident Plans for all areas on-site that have FM are reviewed by an NCS SME to ensure they include NCS measures.	Pre-Incident Plans	Fire Protection SME

Functions/Lines Interfaced With	Interface Activity/Purpose (Type of Information Exchanged)	Interface Mechanism	Primary Interface Contact(s)
Emergency Preparedness	Emergency planning and response for criticality accidents, yearly criticality drills and exercises for areas with a CAAS, review of emergency response issues/concerns for areas with CAAS, documentation of immediate evacuation routes and zones for areas with a CAAS or impacted by a CAAS.	Criticality drills and exercises, memos, and technical evaluations documents	Emergency Preparedness SME
Radiation Protection (RP)	Ensure immediate evacuation zones and evacuation routes are determined and documented for NCCAs with CAAS. Ensure CAAS detectors are placed in the correct location for new facilities that require a CAAS installed, as per criticality analysis/detector location analysis performed by the NCS Function SMEs.	Memos, technical documents, CAAS detector placement for new facilities	RP SME
Engineering Safety and Licensing	Participates in CHI study meetings and/or writes CHI study documents (e.g., CHI plan, CHI report).	CHI study	Safety Analysis SME
Training & Development (T&D)	Ensures criticality safety training is incorporated for NCCAs Training Development / Delivery	NCCO quarterly reports, training curriculum review committee quarterly meetings, training session	T&D Training SME and Coordinators

Functions/Lines Interfaced With	Interface Activity/Purpose (Type of Information Exchanged)	Interface Mechanism	Primary Interface Contact(s)
Safety Review Committee's sub-committee: NCS Panel	Provides independent review and acceptance of documentation relating to criticality safety (e.g., CSDs, time-limited amendments, CAAS justification)	Meetings, correspondence	NCS Panel Chair and Technical Secretary
Transportation of Dangerous Goods	Ensures review of new/revised criticality safety analysis for transportation packages with Fissionable Material consignment is carried out by NCS Program SMEs	Review of documentation	Transportation of Dangerous Goods SME

6.2 External Interfaces

Groups Interfaced With	Interface Activity/Purpose (Type of Information Exchanged)	Interface Mechanism	Primary Interface Contact(s)
CNSC	Correspondence on reportable events, program/CSD updates, and requests for information.	Letters, e-mails, meetings, telephone	CNSC Project Officer and Technical Officer
American Nuclear Society (ANS)	Participation in working groups on ANS-8 criticality safety standards through the NCS Division.	Working group meetings, conferences	ANS working group members
International Standards Organization (ISO)	Participation in working group on criticality safety; review of proposed and draft standards related to criticality safety.	Standards Council of Canada (SCC) web-based system to review standards, annual working group meetings	SCC and SCC working group Chair

Revision History

Rev. No.	Date	Details of Rev.	Authored By	Reviewed By	Approved By
3.1	2023/07/26	Issued as “Approved for Use”.	K. Erlandson	Z. Barnicoat	D. Garrick
3.1D1	2022/10/04	Issued for “Review and Comment”. Minor changes include: • New PRD template • Update from 145-508550-PS-001 to 900-508550-MCP-001398 • Update from N292.0-14 to N292.0-19 • Resolved transcription error from REGDOC-2.4.3, Section 3.3.1.	K. Erlandson	Z. Barnicoat C. Gallagher S. Toelly	
3	2021/09/02	Issued as “Approved for Use”.	R. Dranga	J. Wang	J. Turcotte

Rev. No.	Date	Details of Rev.	Authored By	Reviewed By	Approved By
3D1	2021/07/30	Issued for “Review and Comment”. Annual Document Review; New PRD template applied, including: removal of References section; and relocation of implementing documents that do not reside within the NCS function to the Notes/Comments column; Removed references to ANSI/ANS 8.x Standards; Realigned requirements to applicable section in REGDOC-2.4.3 and removed references to RD/GD-327; Added back requirements that were missed in Revision 2 (but existed in prior revisions) associated with Sections 6.4, 6.5, 7.4, 8.3, 11.4, 12.8, 13.7; Added CSA N292.0-14 as per Requirements Management Database.	R. Dranga	C. Ball Z. Barnicoat K. Boniface J. Carver J. Turcotte J. Wang	
2	2020/05/31	Issued as “Approved for Use”.	M. Boileau	K. Boniface	J. Turcotte
2D1	2020/02/04	Issued for “R&C”. Update document to reference the updated Regulatory Document for Nuclear Criticality Safety REGDOC 2.4.3. Provide more granularity associated with requirements from REGDOC 2.4.3.	M. Boileau	C. Ball Z. Barnicoat K. Boniface J. Carver Y. Dube G. Edwards	

Rev. No.	Date	Details of Rev.	Authored By	Reviewed By	Approved By
1D1	2018/11/12	Issued for "Review and Comment". Minor revision: updated document template; updated information to reflect new Licence Condition Handbook; revised document numbers in references and throughout the document; removed old requirement #5 (LCH clause 4.8 (5)) since this requirement has been removed from the new LCH; removed old requirements #46 and #47 (ANSI/ANS/ANS 8.9 standard) since standard has been withdrawn and is not referenced in RD-327; removed Section 7.2 and Section 7.3 since these criticality safety analysis requirements have been incorporated in 900-508550-STD-002 Criticality Safety Analysis, the NCS Panel Terms of Reference and Standard, and 900-508550-STD-003 Criticality Hazards Identification Study	R. Dranga	C. Ball Y. Dube G. Edwards C. McNally J. Turcotte J. Wang	
0	2017/02/03	Issued as "Approved for Use". Supersedes 145-508550-OV-001, Nuclear Criticality Safety, and 145-508550-REQ-001, Nuclear Criticality Safety Requirements	C. McNally	K. Leroux	K. Leroux

Table of Contents

Section **Page**

1. Scope and Applicability

This company-wide document applies to all activities unique to the Nuclear Criticality Safety Functional Support Area performed by Canadian Nuclear Laboratories (CNL) at the Chalk River Laboratories (CRL) and Whiteshell Laboratories (WL) sites.

2. Purpose

The following is a mapping of requirement source documents to the Management System documentation that implements those requirements. It reflects the current operational implementation of the requirements. Given the diverse nature of the CNL business, the dynamic nature of the regulatory environment, and the complexity of the regulations, the mapping is not intended to be complete for every possible requirement.

3. Requirements and Flowdown

- *Nuclear Criticality Safety*, Version 1.1, REGDOC-2.4.3, Canadian Nuclear Safety Commission, September 2020

Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
Procedures	be governed by written procedures. All persons participating in these operations shall understand and be familiar with the procedures. The procedures shall specify all parameters that they are intended to control. They should be such that no single, inadvertent departure from a procedure can cause a criticality accident.	Safety for Operations	
Section 2.3.2.4 Materials Control	Movement of FM shall be controlled, including any labelling, signage and area posting. Appropriate material labelling, signs, and area posting shall be maintained specifying material identification and all limits on parameters subject to procedural control.	900-508550-PDD-001, Nuclear Criticality Safety 900-508550-STD-005, Nuclear Criticality Safety for Operations	900-508510-PDD-001, Nuclear Materials and Safeguards Management
Section 2.3.2.5 Equipment Control	For any new activities or projects (including new or modified process or process lines) it shall be ascertained that all equipment is consistent in dimensions and materials with the assumptions that were made to ensure subcriticality.	900-508550-STD-005, Nuclear Criticality Safety for Operations 900-508550-MCP-002, Preparing a Criticality Safety Document or Time-Limited Amendment	
Section 2.3.2.6 Quality Management Program	The NCS Function conforms to the CNL established quality management program and records management process.		900-514200-PDD-001, Quality
Section 2.3.2.7 Operational Control	Operational control shall follow CNL processes and requirements for reporting deviations in procedures, review lessons learned from other organizations	900-508550-STD-005, Nuclear Criticality Safety for Operations	900-514000-PDD-001, Performance Assurance

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	and initiate improvements.		
Section 2.3.2.8 Operational Reviews	Frequent (at least annually) reviews of operations shall be performed to verify that procedures are being followed and that process conditions have not been altered in any way that would affect the applicable criticality safety analysis. These reviews shall be conducted in consultation with operating personnel, by individuals who are knowledgeable in nuclear criticality safety and who, to the extent practicable, are not immediately responsible for the operation.	900-508550-STD-005, Nuclear Criticality Safety for Operations 900-508550-STD-004, Nuclear Criticality Safety Compliance Assessment	
Section 2.3.2.9 Emergency Procedures	Emergency procedures are prepared and approved by management. These procedures include information related to nuclear criticality safety.		900-508730-PDD-001, Emergency Preparedness
Section 2.3.3 Technical Practices	Nuclear criticality safety shall be ensured by means of preventive measures that are, as far as reasonably achievable, established in the design; that is, by engineered nuclear criticality safety controls.	900-508550-STD-002, Criticality Safety Analysis	
Section 2.3.3.1 Controlled Parameters	All controlled parameters and their limits shall be specified. The influence of variations in these parameters on the k^{eff} of the system shall be understood.	900-508550-STD-002, Criticality Safety Analysis 900-508550-PDD-001, Nuclear Criticality Safety	
Section 2.3.3.2 Availability and Reliability	The licensee shall ensure that the necessary levels of availability and reliability are maintained for nuclear criticality safety controls,	900-508550-STD-002, Criticality Safety Analysis	900-508200-MCP-005, Surveillance Testing

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	as established by the process analysis for normal and credible abnormal conditions.		
Section 2.3.3.3 Geometry Control	All dimensions and nuclear properties on which reliance is placed shall be verified prior to the beginning of operations, and control shall be exercised to maintain them. Reliance should be placed on equipment design in which dimensions are limited rather than on administrative controls. Process areas where criticality control vessels contain significant quantities of nuclear materials in liquid form should be equipped with alarms to prevent overfilling and drip trays of appropriate capacity and critically safe configuration.	900-508550-STD-002, Criticality Safety Analysis 900-508550-MCP-002, Preparing a Criticality Safety Document or Time-Limited Amendment 900-508550-PDD-001, Nuclear Criticality Safety	
Section 2.3.3.5 Subcritical Limit	Where applicable data are available, subcritical limits shall be established on bases derived from experiments, with adequate allowance for uncertainties in the data. In the absence of directly applicable experimental measurements, the limits may be derived from calculations made by a method shown by comparison with experimental data to be valid.	900-508550-STD-002, Criticality Safety Analysis	
Section 2.3.3.6 Neutron Reflection	Where applicable, neutron reflection shall be considered as a parameter for criticality control. Careful consideration shall be given to systems where significant thicknesses of other common structural materials	900-508550-STD-002, Criticality Safety Analysis	

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	which may be more effective neutron reflectors than water.		
Section 2.3.3.7 Neutron Interaction	Consideration shall be given to neutron interaction between units when at least two units containing fissionable materials are present.	900-508550-STD-002, Criticality Safety Analysis	
Section 2.3.4 Validation of a Calculational Method	Suitable calculational methods for determining the subcritical state of a system shall be selected and justified (validated) in accordance with an applicable Quality Assurance standard.	145-123400-SVR-001, Validation Report for KENO V.a Applications for Criticality Safety Applications	
Section 2.3.4.1 Establishment of Bias	Bias shall be established by correlating the results of critical and exponential experiments with results obtained for these same systems by the calculational method being validated.	145-123400-SVR-001, Validation Report for KENO V.a Applications for Criticality Safety Applications	
Section 2.3.4.3 Bias uncertainties	The uncertainty in the bias shall contain allowances for the following: • The uncertainties in the experimental conditions, • The lack of accuracy and precision in the calculational method; and • The extension of the area (or areas) of applicability. The margin in k_{eff} (or other correlating parameter) shall be applied such that it is sufficient to ensure that conditions will actually be subcritical.	145-123400-SVR-001, Validation Report for KENO V.a Applications for Criticality Safety Applications	
Section 2.3.4.4 Computer dependence	If the calculational method involves a computer program, checks shall be performed to confirm that the mathematical		900-514200-QAP-002, Analytical, Scientific and Design Computer Programs

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	operations are performed as intended. Any changes in the computer program shall be followed by reconfirmation that the mathematical operations are performed as intended.		
Section 2.3.4.6 Validation Report	A written report of the validation shall be prepared which includes: • A description of the method, • Experimental data and parameters derived from the data, • The area of applicability, • The bias and uncertainties, • The margin of sub criticality, with justification, and • The upper subcritical limit.	145-123400-SVR-001, Validation Report for KENO V.a Applications for Criticality Safety Applications	
Section 2.4 Single-parameter Limits for Fissile Nuclides Section 2.5 Multiparameter Control	An adequate administrative margin of sub-criticality shall be applied to ensure compliance with section 2.3.2.2 Process Analysis of REGDOC-2.4.3, for single / multi parameter limits on ^{233}U, ^{235}U and plutonium. Process specifications shall incorporate margins to protect against uncertainties in process variables and against a limit being accidently exceeded.	900-508550-STD-002, Criticality Safety Analysis	
Section 3.3.1 General	A criticality alarm system shall be installed in areas where an inadvertent criticality can occur and where excessive radiation dose to personnel is credible should the inadvertent criticality occur. Where alarm systems are	900-508550-PDD-001, Nuclear Criticality Safety 900-508550-MCP-001398, Needs Assessment – Criticality Accident Alarm System	900-508730-PRD-001, Emergency Preparedness

Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	installed, emergency procedures shall be maintained.	900-508550-STD-005, Nuclear Criticality Safety for Operations	
Section 3.3.2 Coverage	The need for such a system shall be evaluated for all activities in which the inventory of fissionable materials in individual unrelated areas exceeds the subcritical mass limits noted as follow: • All activities involving ^{233}U, ^{235}U, and ^{239}Pu, in which the inventory of fissionable materials exceeds 500 g of ^{233}U, 700 g of ^{235}U, 450 g of ^{239}Pu, or 450 g of any combination of these three isotopes, • For all activities involving fissionable materials, in which neutron moderators or reflectors more effective than light water are present or unique material configuration exists such that critical mass requirements may be less than the subcritical mass limits listed above, and • For all activities in which inventory of fissionable materials exceeds 80% of the appropriate critical mass if subcritical mass limits listed above are not applicable. In areas where criticality alarm coverage is required, a means shall be provided to detect a criticality and to signal that prompt protective action is	900-508550-PDD-001, Nuclear Criticality Safety 900-508550-MCP-001398, Needs Assessment – Criticality Accident Alarm System 900-508550-STD-005, Nuclear Criticality Safety for Operations	

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	required.		
Section 3.3.3 Criticality Alarm	Criticality alarm signals shall: • Be for prompt evacuation or other protective action, and • Be distinctive from other signals or alarms that require a different response. The signal generator shall be automatically and promptly actuated upon detection of a criticality accident. After actuation, the signal generators shall continue to function as required by emergency procedures. The number and placement of criticality alarm signal generators shall be such that the signals are adequate to notify personnel promptly.	900-508550-PDD-001, Nuclear Criticality Safety 153-123540-440-002 Process for Criticality Accident Alarm System (CAAS) Detector Placement Analysis for Facilities at CRL.	
Section 3.3.4 Dependability	Consideration shall be given to the avoidance of false alarms. In redundant systems, failure of any single channel shall not prevent compliance with the detection criterion of the alarm system. Where portable instruments are used to augment the installed criticality alarm system, the usage of portable instruments shall be evaluated to determine appropriate criteria are met. The criteria shall be specified in procedures. Detectors shall not fail to trigger an alarm when subjected to		900-508740-STD-018 Radiation Protection Instrumentation

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	intense radiation exceeding 1000 Gy/h.		
Section 3.4 Criteria for System Design	The system shall be designed for high reliability. The system shall be designed to produce the criticality alarm signal within 0.5 s of detector recognition of a criticality accident. The system shall be designed to respond immediately, and the alarm trip point shall be set low enough to detect the minimum accident of concern. The basis for the minimum accident of concern shall be justified (default or documented alternative). The alarm actuation shall occur as a result of the minimum duration of the transient (can be assumed to be 1 ms). The placement of detectors shall be consistent with the alarm trip point and with the detection criterion.	900-508550-PDD-001, Nuclear Criticality Safety	900-508740-STD-018, Radiation Protection Instrumentation
Section 3.5 Testing	CAAS functionality (alarm signals, manual resets and manual actuation), CAAS dependability, reliability, and CAAS design criteria shall be followed and include requirements for dependability, reliability, response time, detection, sensitivity, and placement. CAAS testing criteria is required and includes initial tests, special tests, response to radiation, periodic tests, corrective action	900-508550-PDD-001, Nuclear Criticality Safety 900-508550-STD-005, Nuclear Criticality Safety for Operations	900-514000-PDD-001, Performance Assurance 900-511300-PDD-001, Information Management 900-514300-STD-001, Nuclear Criticality Safety Panel Review and Acceptance

Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	and test procedures, records of tests, and out of service criteria.		
Section 3.6 Employee Familiarization	Where CAAS is installed, emergency procedures shall be maintained. Instructions regarding response to criticality alarm signals shall be posted at strategic locations within areas requiring alarm coverage.	900-508550-STD-005, Nuclear Criticality Safety for Operations	900-508550-STD-001, Nuclear Criticality Safety Training 900-508730-STD-002, Emergency Management 900-508730-MCP-001, Building Emergency Procedures
Section 6.3.1. Administrative Practices	Methods of storage control and operational practices approved by management shall be described in written procedures, the users of which shall be familiar with them. Limits for storage shall be posted. Access to storage areas shall be controlled.	900-508550-STD-005, Nuclear Criticality Safety for Operations	
Section 6.3.2 Technical Practices Section 6.4 Parameters, Limits and Conditions Section 6.5 Other Applications	Storage facilities and structures shall be designed, fabricated and maintained in accordance with good engineering practices. Fissile material shall be stored in such a way that accident nuclear criticality resulting from fire or from flood, earthquake, or other natural calamities is not a concern. Where the presence of significant quantities of combustible materials is unavoidable, a fire protection system shall be installed. Shelving shall be sturdy and non-combustible.	900-508550-STD-002, Criticality Safety Analysis	

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	Containers of fissile materials in areas with sprinkler systems shall be designed to prevent accumulation of water. Good housekeeping shall be incorporated as an important part of nuclear criticality safety practices.		
Section 7.3 Criteria for adequate shielding and confinement Section 7.4 Criticality safety practices	Shielding and confinement design criteria are required when: • All operations and manipulations involving fissile and fissionable materials are conducted remotely by persons located outside the shielded area, and • Shielding and confinement provided are adequate to meet the radiation dose limits discussed in Section 7.3.2 of REGDOC-2.4.3.	900-508550-STD-002, Criticality Safety Analysis	
Section 8.3 Nuclear Criticality Safety Practices	Criteria for nuclear criticality safety and control of plutonium-uranium fuel mixtures outside reactors shall be applied.	900-508550-STD-002, Criticality Safety Analysis	
Section 10 Nuclear Criticality Safety Control of Selected Actinide Nuclides (all subsections)	Nuclear criticality control of selected actinides ^{232}U, ^{234}U, ^{237}Np, ^{236}Pu, ^{238}Pu, ^{240}Pu, ^{241}Pu, ^{242}Pu, ^{241}Am, ^{242m}Am, ^{243}Am, ^{242}Cm, ^{243}Cm, ^{244}Cm, ^{245}Cm, ^{246}Cm, ^{247}Cm, ^{249}Cf, ^{251}Cf shall be applied for nuclear criticality safety evaluations involving the listed isotopes.	900-508550-STD-002, Criticality Safety Analysis	
Section 11.3 General Safety Criteria Section 11.4	Prior to first use of, or before implementing changes to, any operation or system involving handling, transportation, storage,	900-508550-PDD-001, Nuclear Criticality Safety 900-508550-STD-002,	

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
Criteria to establish subcriticality	or long-term waste management of reactor fuel outside reactors, a criticality safety evaluation shall be performed and documented. Prior to commencing operations, an assessment shall be performed to confirm the adequacy of the criticality safety evaluation. In performing the criticality safety evaluation de composition and nuclear characteristics of the fuel shall be considered and implemented as needed.	Criticality Safety Analysis 900-508550-STD-005, Nuclear Criticality Safety for Operations	
Section 12.3.1 Management Responsibilities	Management shall: • Accept overall responsibility of operations and provide regular and systematic oversight, • Formulate nuclear criticality safety policy and make it known to all employees involved in operations with fissionable materials, • Assign responsibility and delegate commensurate authority to implement established policy, • Provide personnel familiar with the physics of nuclear criticality and with associated safety practices to furnish technical guidance appropriate to the scope of operations, • Establish a method of monitoring the nuclear criticality safety program,	900-508550-PDD-001, Nuclear Criticality Safety 900-508550-STD-005, Nuclear Criticality Safety for Operations	900-514100-MAN-001, Canadian Nuclear Laboratories Management System Manual 900-514100-LST-001, Functional Authorities 900-508200-POL-001, Nuclear Safety

Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	procedural requirements, and shall report their findings to management, and • Upon request, participate in the verification of compliance with nuclear criticality safety specifications for intended new or modified processes or equipment.		
Section 12.4 Operating Procedures	Operating procedures shall include those controls and limits significant to NCS, and be periodically reviewed by supervisory personnel and NCS staff, and approved by management. Deviations from these procedures shall be reported, investigated, corrected as appropriate and documented. Action shall be taken to prevent reoccurrence. Operations shall be reviewed (at least annually) to ensure that process conditions have not been altered so as to affect the nuclear criticality safety evaluation.	900-508550-STD-005, Nuclear Criticality Safety for Operations 900-508550-STD-004, Nuclear Criticality Safety Compliance Assessment	
Section 12.5 Process Evaluation for Nuclear Criticality Safety (Nuclear Criticality Safety Evaluations)	• Before the start of a new operation with fissionable material, or before an existing operation is changed, it shall be determined and documented that the entire process is subcritical under both normal and credible abnormal conditions,	900-508550-MCP-002, Preparing a Criticality Safety Document or Time-Limited Amendment 900-508550-STD-002, Criticality Safety Analysis 900-508550-STD-003,	900-514300-STD-001, Nuclear Criticality Safety Panel Review and Acceptance

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	• The nuclear criticality safety evaluation shall determine and explicitly identify the controlled parameters and their associated limits upon which nuclear criticality safety depends. The effect of changes in these parameters, or in the conditions to which they apply, shall be understood, • The nuclear criticality safety evaluation shall be documented with sufficient detail, clarity, and lack of ambiguity to allow independent judgment of results, and • Before the start of operation, there shall be an independent assessment that confirms the adequacy of the nuclear criticality safety evaluation.	Criticality Hazards Identification Study	
Section 12.6 Material Control	• The movement of fissionable materials shall be controlled as specified in documented procedures. • Appropriate material labelling and area posting shall be maintained, specifying material identification and all limits on parameters that are subject to procedural criticality control. • If reliance for criticality control is placed on neutron-absorbing materials that are	900-508550-PDD-001, Nuclear Criticality Safety 900-508550-STD-005, Nuclear Criticality Safety for Operations 900-508550-STD-002, Criticality Safety Analysis	900-508510-PDD-001, Nuclear Materials and Safeguards Management 900-508520-PDD-001, Transportation of Dangerous Goods

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	incorporated into process materials or equipment, procedural control shall be exercised to maintain their continued presence with the intended distributions and concentrations. • Access to areas where fissionable material is handled, processed, or stored shall be controlled. • Control of spacing, mass, density and geometry of fissionable material shall be maintained.		
Section 12.7 Planned Response to Nuclear Criticality Accidents	Emergency procedures shall: • Be prepared, • Be approved by management, • Clearly designate evacuation routes, • Provide for shutting off ventilation to prevent release of fission gases, and • Address re-entry procedures and the membership of the response team. Training shall be provided for personnel in the evacuation area (or equivalent for transient personnel). The personnel assembly area shall be: • Designated, • Established to provide personnel accountability, and	900-508550-STD-001, Nuclear Criticality Safety Training 900-508550-PDD-001, Nuclear Criticality Safety 900-508550-STD-005, Nuclear Criticality Safety for Operations	900-508730-PRD-001, Emergency Preparedness RADP-508740-EP-004, Radiation Surveyor Response to Criticality Alarms

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	• Monitored for radiation intensity appropriate equipment and approved procedures Drills shall be: • Conducted at least annually, and • Announced in advance. Evacuation routes shall be clearly identified. Arrangements shall be made in advance for the care and treatment of injured and exposure persons. The possibility of personnel contamination by radioactive materials shall be considered.		
Section 12.8 Nuclear Criticality Safety Program	The NCS Program must identify applicable standards, guidelines and CNSC requirements, list the requirements, define a model for the implementation of these requirements, identify responsibilities raising from these requirements, and identify and document the administrative margin of subcriticality and methodologies used to ensure that the upper subcritical limit is not exceeded	900-508550-PDD-001, Nuclear Criticality Safety	
Section 13.4 Program Responsibilities	• Management shall establish a nuclear criticality safety training program that provides confidence in the continuing proficiency of personnel, • Supervisors shall ensure that their staffs are suitably trained, and	900-508550-STD-001, Nuclear Criticality Safety Training 900-508550-STD-005, Nuclear Criticality Safety for Operations	

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	• Nuclear criticality safety staff shall participate in the development of the training program and its implementation.		
Section 13.5 Program Structure	• Training and refresher training shall be determined and documented, • Refresher training shall be provided at least every 2 years, and • The content of the training shall be tailored to the job responsibility.	900-508550-STD-001, Nuclear Criticality Safety Training 900-508550-TM-001, Nuclear Criticality Training Manual	
Section 13.6 Program content	Criticality safety training shall include the following: • Health effects of criticality accidents, • Recognition and response to criticality alarms, • Examples of the reduction in the received dose as a function of distance, time and shielding. • Emphasis on the need for prompt evacuation, • Factors that are relevant to criticality safety, • Single parameter limits appropriate to the facility, • Illustration of criticality safety appropriate to the area, • The concept of contingencies for checking the validity of criticality safety limits, • The nuclear (criticality) safety policy.	900-508550-STD-001, Nuclear Criticality Safety Training 900-508550-PDD-001, Nuclear Criticality Safety	900-510200-PDD-001, Training and Development

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	• The facility policy for the use of checklists, sign-off sheets, and documentation in the execution of procedures that are pertinent to criticality safety, • Relevant procedures that pertain to criticality safety and emphasis on criticality safety limits, controls and emergency procedures, • The policy that relates to situations not covered by procedures and to situations in which the safety of the operations is in question, and • The employee's right to question any operations that they believe may not be safe.		
Section 13.7 Evaluation	• The criticality safety training program shall be evaluated periodically, documenting the process and the results, • Satisfactory completion of training shall be based upon a pre-determined performance criteria, • Identified weaknesses [of personnel] shall be addressed by additional training, • Acceptance of the adequacy of the individual's total training record shall be the responsibility of the immediate supervisor and of any other organizational	900-508550-STD-001, Nuclear Criticality Safety Training 900-508550-PDD-001, Nuclear Criticality Safety	900-510200-PDD-001, Training and Development

	units designated by management, and • The employee's training record shall be documented and retained for a minimum of four years Management may specify a longer period of time for retention.		
Section 15.3.1 Administrative Practices for Limitation and Control of Moderators	Written procedures shall: • Include the nuclear criticality safety limits and controls of operation, • Be provided for monitoring, testing, and maintenance to ensure that the limits and controls specified in process evaluations are maintained, and • Be provided for moderator sampling and analysis as required by the process evaluation Moderator control areas shall be identified to personnel in accordance with facility specific practices. Posting shall include appropriate limits and/or means for moderator control. Moderator control requirements shall be included in firefighting plans. Training in understanding and complying with moderator limits and controls shall be provided to appropriate personnel as part of nuclear criticality safety training.	900-508550-STD-005, Nuclear Criticality Safety for Operations 900-508550-STD-002, Criticality Safety Analysis 900-508550-MCP-002, Preparing a Criticality Safety Document or Time-Limited Amendment 153-508720-TE-001, Evaluation of Effects of Fire Fighting Methods on Nuclear Criticality Safety in Nuclear Criticality Controlled Areas (NCCAS) at CRL and WL	

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
Section 15.3.2 Process Evaluation for Limitation and Control of Moderators	The process evaluation shall: • Define the moderator control area and explicitly identify the limits, controls and engineered barriers for that area. • Address properties of all materials present that could change the moderator content (see Notes/Comments), • Address moderators present in, introduced to, or accumulated in a moderator control area, either by design or by accident. • Address the distribution of the moderators within the fissionable material and between discrete fissionable material units. Non-uniform distribution of moderators that might occur during mechanical (e.g., mixing), thermal, or chemical processes shall also be addressed. • Address moderators that might be encountered during maintenance, decontamination, construction, and non-operational activities, • Address the need for special controls involving fire prevention and suppression, and	900-508550-STD-005, Nuclear Criticality Safety for Operations 153-508720-TE-001, Evaluation of Effects of Fire Fighting on Nuclear Criticality Safety in Nuclear Criticality Safety in Nuclear Criticality Controlled Areas (NCCAS) at CRL and WL 900-508550-MCP-002, Preparing a Criticality Safety Document or Time-Limited Amendment 900-508550-STD-002, Criticality Safety Analysis 900-508550-PDD-001, Nuclear Criticality Safety	

Nuclear Criticality Safety, REGDOC-2.4.3			
Section and Title	**Description**	**Implementing Document(s)**	**Notes/Comments**
	• Establish the requirements for moderator measurement necessary to ensure specified limits and controls are maintained.		
Section 15.4 Engineered Practices for Moderator Control Areas	• Moderator control areas shall be provided with engineered barriers as required by the process evaluation, and • Fissionable material processing equipment and containers used in moderator controlled areas shall be designed, constructed, and made to limit and control moderators in accordance with the process evaluation. • Systems that penetrate a moderator control area and normally contain moderators shall have limits and controls as required by the process evaluation, • Systems (such as ventilation ducts, compressed gas lines, electrical conduits, and drains) that penetrate a moderator control area, but do not normally contain moderators, shall have controls as required by the process evaluation, and • Fire control in moderator control areas shall	900-508550-MCP-002, Preparing a Criticality Safety Document or Time-Limited Amendment 900-508550-STD-002, Criticality Safety Analysis 153-508720-TE-001, Evaluation of Effects of Fire Fighting Methods on Nuclear Criticality Safety in Nuclear Criticality Controlled Areas (NCCAS) at CRL and WL 900-508550-STD-005, Nuclear Criticality Safety for Operations 900-508550-PDD-001, Nuclear Criticality Safety

	incorporate the design features identified by the process evaluation.		
Section 16 Nuclear Criticality Accident Emergency Planning and Response (all subsections)	Management shall be responsible to ensure that emergency planning and response is implemented for areas on site where a criticality accident alarm system is installed. Emergency response planning shall be conducted and documented to identify potential criticality accident locations and establish immediate evacuation zones. An emergency response plan shall be established and maintained, including guidance to management, technical staff and response personnel for response to a criticality accident. Emergency procedures shall be maintained for each area where a CAAS is installed or has been identified as required, and in adjacent buildings that are within the immediate evacuation zone. Emergency planning and response related to nuclear criticality safety accidents includes training for emergency responders.	900-508550-PDD-001, Nuclear Criticality Safety 900-508550-STD-005, Nuclear Criticality Safety for Operations 900-508550-STD-001, Nuclear Criticality Safety Training 153-123540-440-001, Process for Dose Contour Calculations for non-Credible Postulated Accidents in Facilities at CRL 153-123540-440-002, Process for Criticality Accident Alarm System (CAAS) Detector Placement Analysis for Facilities at CRL	900-508730-STD-002, Emergency Management 900-508730-MCP-001, Building Emergency Procedures CRL-508730-ERP-001, Chalk River Laboratories Site Emergency Response Plan

4. Requirements Applicability

All requirements identified above are applicable to both the CRL and WL sites.

5. Requirements Specifying Assessment Activities

The requirements specifying assessment activities section provides a summary and traceability of the requirements that indicate a compliance need for an assessment.

SUMMARY

Canadian Nuclear Laboratories (CNL) is required, as a condition of its Nuclear Research and Test Establishment Decommissioning Licence for Whiteshell Laboratories (WL), to submit to the Canadian Nuclear Safety Commission (CNSC) a series of annual reports. Collectively, these reports summarize the results of monitoring radiation exposures to personnel, the results of monitoring radioactive and non-radioactive materials in airborne and liquid effluents, and the results of environmental monitoring at and around the site.

Measurements of radiation levels and radioactive contamination within and outside the WL site boundary were performed during 2023. These measurements verified that levels of radiation and radioactive contamination due to operations at the site, as well as the resulting radiation doses to members of the public, continue to be below regulatory limits[†] and guidelines [1].

Monitoring of potential liquid effluent exposure pathways confirmed very small but measurable contributions from WL operational and decommissioning activities to downstream concentrations of radionuclides in Winnipeg River water (Cesium-137). This correlates with effluent monitoring results [2]. Radioactive contaminants in Winnipeg River water remain very small fractions of allowable levels defined in the Canadian Drinking Water Standard [1].

Radioactivity assaying of groundwater, soil and native vegetation conducted this year and earlier years indicate there is no significant radioactive migration from the waste management facilities.

Monitoring of potential atmospheric effluent exposure pathways did not indicate any measurable dose contributions from the site activities in excess of natural background levels. This is also consistent with effluent monitoring results, which indicated that airborne emissions dose contributions were very small (1.5×10^{-6} mSv/a).

The 2023 environmental monitoring results correlate with the activities that were conducted during the current year and previous years. These results and effluent monitoring results at the release points continue to support the dispersion pathway models on which the Derived Release Limits are based within the uncertainty of the results at these low levels.

In 2010, the Canadian Standards Association (CSA) issued a new version of standard, CSA N288.4-10 [3] which explicitly includes the protection of the environment in conformance with the regulations under the *Nuclear Safety and Control Act* [4]. It addresses monitoring of radiological and non-radiological contaminants, physical stressors, potential biological effects, and pathways for both human and non-human biota. Implementation of N288.4-10 (R 2015) involved a transition of the existing Environmental Monitoring Program to meet the requirements of the standard.

Participation in laboratory proficiency tests and internal quality verification tests were both used to assess the performance of analytical methods needed to produce the data included in

[†] The regulatory limit for non-occupational effective radiation dose to members of the public from operations and products involving ionizing radiation (excluding medical procedures) is 1 mSv per year [1].

this report. The results were acceptable based on established acceptance criteria. Findings from program audits and assessments were minor in nature and are being addressed.

The estimated dose to the most exposed members of the public due to radioactivity in WL effluents, based on the effluent and environmental monitoring results for 2023, is summarized in Table 1 and illustrated in Figure 1. Note that the doses from liquid effluents for 2023 and previous years were calculated using consumption rates consistent with updated DRLs. Based on the data presented in this report, the estimated dose for 2023 from air effluent pathways continues to be small (1.5 x 10^{-6} mSv/a). The dose from liquid effluents (5.9 x 10^{-5} mSv/a), based on environmental monitoring data, is higher than that observed in 2022, but within the range of the previous five years. The estimated 2023 total effective dose of 5.9 x 10^{-5} mSv/a remains a small fraction (0.0059 %) of the regulatory public dose limit of 1 mSv/a. As a percentage of the typical average natural background radiation dose an adult would experience in Canada, WL effluents would contribute 0.0018 % (see Table 1). Overall, the environmental impact can be characterized as low risk, in that the potential for human or ecological impacts is low, and overall trending indicates stable performance.

Table 1: Total Estimated Doses to Critical Groups Based on Monitoring at Whiteshell Laboratories, 2018 to 2023

Effluent Pathways	Airborne	Liquid From Effluents	Liquid From Environmental Monitoring
Critical Group	**Adults and Infants Living at Boundary**	**Adult Living Downstream**	**Adult Living Downstream**
2018 Total Effective Dose (mSv/a)	1.6 E-06	3.79 E-03	3.6 E-05
2019 Total Effective Dose (mSv/a)	2.3 E-06	9.27 E-03	8.7 E-05
2020 Total Effective Dose (mSv/a)	1.9 E-06	6.71 E-03	2.9 E-06
2021 Total Effective Dose (mSv/a)	1.9 E-06	4.49 E-03	1.1 E-05
2022 Total Effective Dose (mSv/a)	1.5 E-06	5.78 E-03	2.1 E-05
2023 Total Effective Dose (mSv/a)	1.5 E-06	2.00 E-03	5.9 E-05
As % of annual public dose limit, 1 mSv.	1.5 E-04	2.00 E-01	5.9 E-03
As % of typical average background radiation dose in Canada, 3.3 mSv.	4.5 E-05	6.06 E-02	1.8 E-03

1. Introduction

1.1 Purpose and Scope

Canadian Nuclear Laboratories (CNL) is required, as a condition of its Nuclear Research and Test Establishment Decommissioning Licence [5] for Whiteshell Laboratories (WL), to submit to the Canadian Nuclear Safety Commission (CNSC) a series of annual reports. Collectively, these reports summarize the results of monitoring radiation exposures to personnel, the results of monitoring radioactive and non-radioactive materials in airborne and liquid effluents, and the results of environmental monitoring at and around the site. They also describe the progress made on the work tasks identified in the Environmental Assessment Follow-Up Program (EAFP) [6] for the current year.

This report, WL-509243-ACMR-2023, addresses for the calendar year 2023, the licence requirement regarding radiological and non-radiological environmental monitoring at and around the WL site. It also addresses the radiological environmental monitoring requirements listed under Work Package #1 of the EAFP [6]. The results and interpretation of the additional monitoring conducted in 2023 as part of the other work packages listed in the EAFP will be included in the WL Decommissioning Project Environmental Assessment reports, generated as part of the EAFP Program. Annual progress on the work packages, including references to these reports, is detailed in the EAFP report [7]. The routine Environmental Monitoring Program (EMP) may be modified to include additional sampling based on the results of these studies.

Results of personnel dose monitoring, non-radiological, and radiological effluent monitoring can be found in the WL Annual Compliance Monitoring Report [8].

This report does not cover results of environmental monitoring for operational control purposes within individual facilities as that information is included and discussed in the WL Annual Compliance Monitoring Report [8].

1.2 Whiteshell Laboratories Site, Facilities and Operations

1.2.1 Whiteshell Laboratories Facilities and Operations

The 4375 hectare WL site (Figure 22 in Appendix A) is owned by Atomic Energy of Canada Ltd. (AECL) and operated by CNL under a licence [1] issued by the CNSC. It is located about 100 km east northeast of Winnipeg, along the east bank of the Winnipeg River. It is downstream from the towns of Pinawa and Seven Sisters Falls, and upstream of the communities of Lac du Bonnet and Pine Falls.

The Whiteshell Reactor 1 (WR-1) organic-cooled experimental test reactor was shut down in 1985. In 1997 the federal government and AECL decided to discontinue research programs and decommission WL. Clean up and operational activities associated with the decommissioning of the site have been underway since 2003.

The major operating facilities are the Shielded Facilities and the Waste Management Area (WMA). The Shielded Facilities includes the Hot Cell Facility and the Immobilized Fuel Test Facility area, which includes a decontamination center and waste processing/handling area.

Since the decommissioning of the Active Liquid Waste Treatment Center (ALWTC) near the end of 2017, the major sources of radiological airborne effluent releases from the site are the Hot Cell Facility, the Immobilized Fuel Test Facility and WR-1. The primary source of liquid effluent releases at WL is the process water outfall (Outfall), which discharges continuously to the Winnipeg River. The secondary source of liquid effluent is the sewage lagoon (Lagoon), which is normally discharged semi-annually to the Winnipeg River.

Figure 22 in Appendix A is a regional map showing the location of the WL site, major geographical features including the Winnipeg River, the local roads network, and the nearby communities.

1.2.2 Summary of Contaminant Pathways

The monitoring and evaluation of environmental impacts from WL operations is carried out using a wide range of effluent and environmental monitoring activities that enable the measurement of contaminant concentrations and loadings in every significant environmental compartment involved in the migration of contaminants through the environment. The network of contaminant pathways is illustrated schematically in Figure 2, with the first tier of potential impacts from a facility or operation being its effluents (airborne and liquid) and, for some facilities, groundwater.

Liquid effluents, whether storm water, or treated facility wastewater, can affect the quality of nearby surface waters, in turn leading to exposure to humans living downstream of the site. These exposures may result from the ingestion of water or food (e.g., fish) that has come into contact with the water, and from direct exposure through swimming or bathing.

Airborne effluents lead to exposure to humans through inhalation and air immersion. Some airborne effluents may also be deposited onto soils, vegetation, and surface waters, and lead to ingestion exposures through the consumption of water, plant and animal products. The monitoring of contaminants in airborne and liquid effluents, and in the different environmental compartments (e.g., surface water, drinking water, produce, game animals, etc.) along exposure pathways, is therefore an important element in evaluating the impacts of WL operations to the public. Through similar pathways, liquid and airborne effluents can lead to exposure to ecological receptors at the WL site.

The transfer of contaminants from facilities and site operations to soils may have an impact on the quality of groundwater, as infiltrating rainwater and snow melt flush contaminants downward into the water table. Unlike the contaminant migration associated with airborne and liquid effluents, this form of contaminant migration in the environment occurs very slowly, due to the slow velocity of groundwater movement and the tendency of most contaminants to adsorb to soil particulate and organic matter, reducing their mobility. Nevertheless, contaminants that do exhibit mobility in groundwater flow systems eventually discharge into surface waters on the WL site, which drain to the Winnipeg River or discharge directly to the Winnipeg River. Sampling of groundwater is therefore another important element in evaluating the impacts of site operations.

Figure 2 illustrates the pathways along which monitoring is carried out in support of the EMP. This integrated approach to environmental monitoring ensures the evaluation of impacts on the environment from WL facilities and operations is carried out in a logical and comprehensive manner.

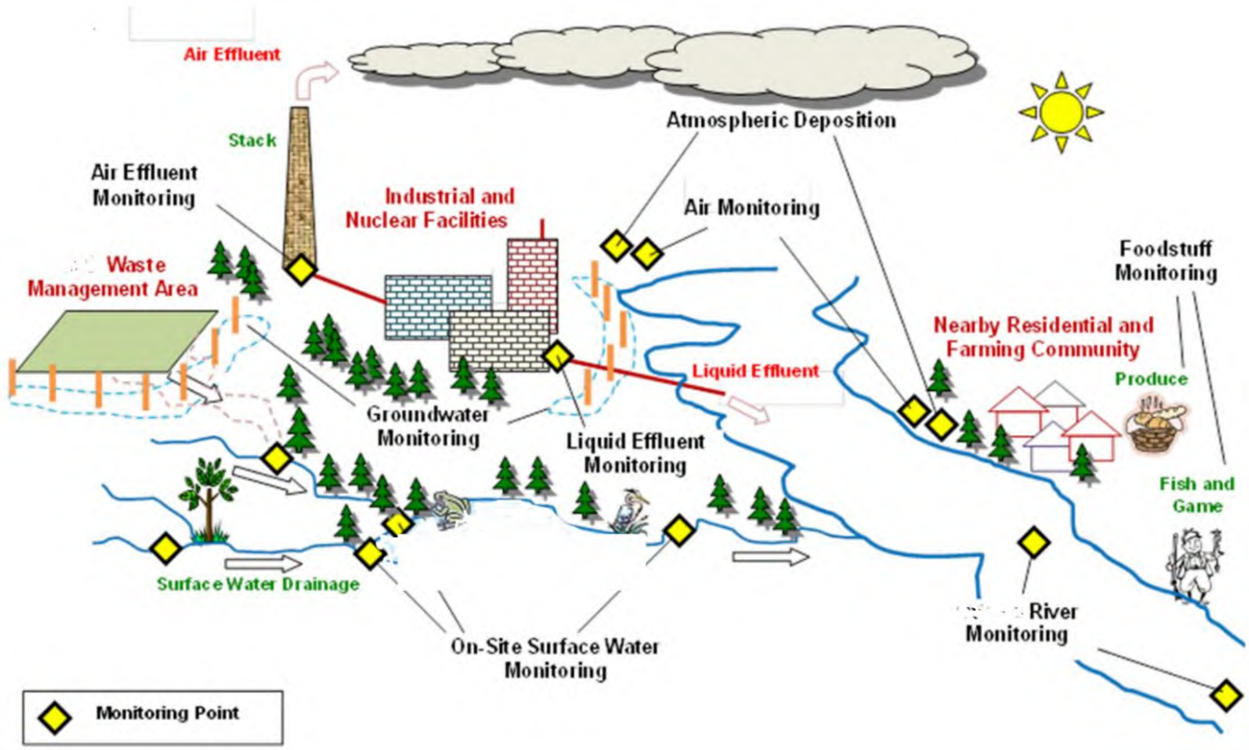

Figure 2: Integrated WL Environmental Monitoring Program

1.2.3 Annual Report Structure

This annual report is structured to allow readers to easily understand the network of monitoring and the results of specific monitoring activities, in addition to providing an overview of the overall impact (performance) of the WL site.

- Section 2 summarizes the objectives of the EMP.
- Section 3 summarizes modifications to the EMP.
- Section 4 summarizes and assesses the field and laboratory Quality Assurance (QA) results.
- Section 5 summarizes the results of effluent monitoring at the WL site, with detailed results reported in the WL Annual Compliance Monitoring Report [8]
- Section 6 provides detailed results of environmental, groundwater and biodiversity monitoring, representing the impact of WL operations and providing a measure of the impact of WL operations from contaminant transport through various environmental media including surface water, ambient air, and foodstuffs.

- Section 7 provides a detailed assessment of dose to the public from WL operations. This assessment utilizes the exposure pathways and assumptions used in the derivation of the Derived Release Limits (DRLs) for the WL site [9], providing a means of validating the monitoring results against the transport modelling underlying the DRLs.
- Section 8 summarizes the results of investigative studies carried out over the year, which can be initiated for several reasons. These may provide the data required to reduce uncertainty in monitoring, increase knowledge of the behaviour of contaminants in the environment, or investigate specific EMP findings.
- Section 9 provides a discussion of Environmental Assessment at WL.
- Section 10 provides concluding remarks.

2. Whiteshell Laboratories Environmental Monitoring Program

Canadian Nuclear Laboratories maintains a comprehensive Environmental Monitoring Program.

The Canadian Standards Association standard CSA N288.4-10 [10] explicitly includes the protection of the environment in conformance with the regulations under the *Nuclear Safety and Control Act* [11]. WL's Implementation of N288.4-10 has involved the transition of the existing EMP to meet the requirements of the new standard. WL's Integrated EMP [12] is designed to track radiological and non-radiological contaminants throughout the different compartments of the geosphere, atmosphere, and biosphere and consists of three distinct programs: the Effluent Verification Monitoring Program (EVMP), the Environmental Monitoring Program and the Groundwater Monitoring Program (GWMP) [13].

2.1 Environmental Monitoring Program Scope and Objectives

Canadian Nuclear Laboratories maintains a comprehensive EMP at the WL site in order to achieve the following primary objectives:

- To assess the level of risk on human health and safety, and the potential biological effects in the environment of the contaminants and physical stressors of concern arising from the facility;
- To demonstrate compliance with limits on the concentration and/or intensity of contaminants and physical stressors in the environment or their effect on the environment;
- To check, independently of effluent monitoring, on the effectiveness of containment and effluent control, and provide public assurance of the effectiveness of containment and effluent control;

- To verify the predictions made by an Environmental Risk Assessment (ERA) (or equivalent), Derived Release Limit (DRL) model, and/or Environmental Assessment (EA), refine the models used in the ERA (or equivalent), DRL[1] model and/or EA, or reduce the uncertainty in the predictions made by the ERA (or equivalent), DRL model and/or EA;
- Further to the objectives described above, which provides an indication on effectiveness of effluent control, where waste storage facilities and contaminated lands exist, the objective is to provide an indication of unusual or unforeseen conditions that might require corrective action or additional monitoring such as groundwater monitoring.

The Program is also designed to:

- Provide data required to support site restoration programs, site operations or to plan for future stages of the facility lifecycle (e.g., decommissioning);
- Provide resources and data that may be of value during the response to an accident or upset condition, and in the recovery from such an event;
- Demonstrate due diligence;
- Meet a stakeholder commitment as required; and
- Fulfill other business purposes (e.g., monitoring emissions to support international treaties).

The design of the EMP takes into account the facilities and processes at the site, past and present emissions from the site, the environmental pathways leading to radiation dose to the most exposed members of the public (i.e., critical groups) as identified by the DRL calculations, and to biota, as well as various other scientific and public considerations.

3. Modifications to the EMP

The Environmental Protection program includes the sampling of several environmental media at various locations at the site and in surrounding communities, representing potential pathways for radiation exposure to members of the public. It also includes media and sample locations serving as trend indicators. Monitored environmental media include ambient air, precipitation, surface, and groundwater including the Winnipeg River, vegetables, fish, game, soil and river sediments. The WL effluent and environmental monitoring activities conducted in 2023 are shown in

[1] The DRL for a given radionuclide is the release rate that would cause a member of the public to receive a dose equal to the regulatory annual dose limit due to the release of the radionuclide during normal operation of a nuclear facility over the period of a calendar year. They are derived based on pathways modelling. The DRL values for the WL site are provided in Reference [9].

Table 2.

Table 2: Summary of WL Monitoring Activities

Environmental Component	Sampling Location	Parameters	Sampling Frequency	Proposed Changes for 2024
Air	WL Perimeter and Off-Site	γ (Thermoluminescent Dosimeters (TLDs)	Continuous	No change
	WL Site	Dust Particulates (TSP, $PM_{2.5}$ Gross α/β, γ-spec)	Continuous during building demolition	No Change
Air	WL Site	Quantities of fuel combusted for building heating. Diesel burned in their standby generators. Quantity of Total (filterable) Particulate Matter[2] Record of Dust Control Treatments and Site Inspections Halocarbon	Annually internal worksheet tools are used to perform the calculations required to report to the NPRI. In addition, Environment Canada provides companies with various calculators (road dust, landfill gas) Annually all releases of halocarbons are recorded and those over 10 kg are reported to Environment Canada	No Change
Air Effluents	WL Facilities (B100 (WR1), Shielded Facilities)	Gross α/β, γ-spec, tritium[3]	Continuous	No Change
Noise	WL Site	Noise monitoring	During periods of high activity	No change

2 As the result of travel on gravel roads, sand blasting activities, use of gas-powered vehicles, propane tanks, other CO_2 emissions.

3 Tritium analysis is only required for Building 100 air effluent.

Environmental Component	Sampling Location	Parameters	Sampling Frequency	Proposed Changes for 2024
Topography	Surface drainage areas	Visual inspection of OFS pipe (above ground) for evidence of subsidence Visual Inspection of WMA ditch system and other drainage pathways identified in Storm Water Management plan. Visual Inspection of the Winnipeg River Bank in the vicinity of the WL site	Semi-Annually	No change
Surface Water	Winnipeg River	Gross α/β, Sr-90, Tritium, γ-spec, non-radiological (total metals including U)	Daily to Weekly, monthly composite analyzed	No change
	WMA Ditches[4]	Tritium, Uranium, Gross α/β, C-14 γ-spec, Sr-90 (as required), Isotopic Pu (as required), Tc-99 non-radiological (total metals including U)	Periodically during ice free periods[5]	No change
	Landfill Dugouts	Gross α/β, Tritium, Sr-90, γ-spec, non-radiological (total metals including uranium) Tc-99	Annually	No change

4 If gross beta levels are above 10 Bq/L, the samples are submitted for strontium-90 analysis. If the alpha activity is above 0.5 Bq/L and gross alpha is not accounted for by uranium, and americium-241 is present in the gamma spec, the samples are submitted for isotopic plutonium analysis. Additional analyses may be performed at Facility Management or Environmental Protection Program Manager request.

5 Ditch locations are checked and, if water is flowing, are sampled after rain events greater than 5 millimetre of rain in a 24-hour period, preceded by at least 48 hours of no precipitation. Samples are also taken during the spring (snow) melt and not more than weekly unless there is some operational concern that triggers additional sampling.

Environmental Component	Sampling Location	Parameters	Sampling Frequency	Proposed Changes for 2024
	Primary Cell of the Sewage Lagoon	Gross α/β, γ-spec	Prior to isolation from Secondary Cell and/or Discharge	No change.
	Main Campus Miscellaneous (manholes, excavations, sumps)	Gross α/β, γ-spec, pH, visual inspection for film, sheen or discoloration, deleterious substances, and conductivity	Prior to pump-out/relocation	No change
	B417 Tank catch/containment tray	Gross α/β, γ-spec	Monthly (April to October)	No change
	B923 Sump, SSC Sump, SSC Standing Water, WMA Misc Sumps and WMA standing water (excavations)	Gross α/β, γ-spec, tritium, pH, visual inspection for film, sheen or discoloration, deleterious substances, and conductivity	Prior to pump-out/relocation	No change
Atmospheric Deposition	Off-Site	Gross α/β, γ-spec	Monthly	No change
Groundwater	WMA[6]	Gross α/β, Sr-90, tritium, γ-spec, uranium non-radiological, field measurement of pH, conductivity and temperature water level measurements	Semi-Annually	No change

6 If gross beta levels are above 2 Bq/L the samples are submitted for gamma spectrometric analysis, if it exceeds 5 Bq/L the samples are submitted for strontium-90 analysis. If the alpha activity is above 0.5 Bq/L, the samples are submitted for gamma spectrometric analysis and possibly isotopic plutonium analysis. Additional analyses may be performed at Facility Management or Environmental Protection Program Manager request.

Environmental Component	Sampling Location	Parameters	Sampling Frequency	Proposed Changes for 2024
	Landfill, Lagoon	Gross α/β, γ-spec, Sr-90 (as required) tritium, U non-radiological, field measurement of pH, conductivity and temperature water level measurements	Annually (Spring)	No change
	Main Campus (including locations in the vicinity of, and up and down gradient of, WR-1)	Gross α/β, γ-spec, Sr-90 (as required), tritium, U non-radiological, field measurement of pH, conductivity and temperature Water Level measurements	Semi-Annually (basal and bedrock), Annually (water table and clay-till)	No change
Liquid Effluents	B100 (WR-1) and B300 tanks, Outfall Sampling Location Sewage Lagoon, Ditch location 8, 9 and Control	Gross α/β, tritium, γ-spec. Sr-90, U, non-radiological, Pu-238, Pu-239/240[7], C-14[8]	Continuous on discharge	No change
Sediments	Winnipeg River (depositional zone cores)	Gross α/β, γ-spec, Sr-90 (composite for each sample) and non-radiological parameters	Every 20 years starting 2006[9]	No change
	Winnipeg River (surface sediment)	Gross α/β, γ-spec, Sr-90 (composite sample for each location)	Annually	No change

7 Plutonium (quarterly composite) analysis (plutonium-238, plutonium-239/240) is performed on outfall effluent.

8 Carbon-14 analysis is performed on Building 100 tank discharges and on the Outfall Sampling location.

9 For Deposition Areas, thirteen cores are collected at each site. Depositional zones are to be sampled every 20 years to verify validity of EA conclusions.

Environmental Component	Sampling Location	Parameters	Sampling Frequency	Proposed Changes for 2024
Fish[10]	Winnipeg River (one upstream location and two downstream)	Gross β, γ-spec	Annually	No change
Wildlife Deer, Bear, Grouse, Rabbit	On-Site, Off-Site	Gross α/β, γ-spec, Sr-90 (bone)	As Available[11]	No change
Garden Crop[12] Includes mushrooms and wild berries	Up and Downstream of Whiteshell Laboratories	Gross α/β, γ-spec, and Sr-90, total and organically bound tritium	Annually	No change
Honey/Canola[13]	Off-site local sources	Gross α/β, γ-spec, Sr-90, total and organically bound tritium	Annually	No change
Beef/Pork/Lamb/ Poultry	Off-site local sources	Gross α/β, γ-spec	Annually	No change
Native Vegetation	WL Perimeter ARMs, WMA	Gross α/β, γ-spec, Sr-90, total and organically bound tritium	Annually	No change
Soils	WMA affected areas	Gross α/β, Sr-90, γ-spec	Annually	No change

10 Fish netting activities must be in compliance with the annual permit issued under the Fisheries Act (Manitoba). Report of these activities must also be completed as the conditions listed in the permit.

11 Animals are obtained by CNL staff through road kills and/or from local trappers. Animal collection activities must be in compliance with the permit issued under the Wildlife Act. Reporting of these activities must also be completed as per the conditions listed in the permit. Species (normally deer, moose, bear, grouse or rabbit) sex and age should be reported to the WL Environmental Specialist along with the radioactivity in Bq/kg, fresh weight for flesh (and bone - for deer/moose).

12 Leafy vegetables should include local wild mushrooms and fruit should include local wild berries (possible choices -blue berries, Saskatoon berries, raspberries, strawberries, plums, gooseberries, chokecherries, pin cherries) [14].

13 This is an air deposition pathway, canola, honey, poultry, pork, and beef can be obtained from the local colony near Whitemouth. Background samples can be obtained from local stores that bring in produce from un-impacted areas.

Environmental Component	Sampling Location	Parameters	Sampling Frequency	Proposed Changes for 2024
Soils/sediments	Excavations/Land Clearance[14]	Gross α/β, γ-spec, non-radiological parameters (	Pre-clearance	No change
	Landfill Dugouts	Gross α/β, γ-spec, non-radiological parameters	Every 5 years (starting 2007)	No change
	Sewage Lagoon flocculent and Discharge Paths	Gross α/β, γ-spec, Sr-90, non-radiological parameters	Every 5 years (starting 1999)	No change
Land Surveys	On-Site, Off-Site	γ-spec	Annually[15]	No change
Species at Risk (Barn Swallows and Bats)	On-Site	Monitor Compensatory Habitat	Installed in 2018	No change
Wildlife Mortality	On-Site (plant road)	Track wildlife mortality (including birds, reptiles and mammals)	Continuous as reported by staff	No change

4. Quality Assurance

General quality assurance (QA) objectives for CNL's Environmental Monitoring Program are set out in an Environmental Management quality assurance plan, and for laboratory handling of TLD dosimeters, in a dosimetry services quality assurance manual. In 2023 samples were also sent to off-site contract labs that were ISO 17025 certified.

Radiological analysis is conducted in accordance with laboratory-specific environmental monitoring quality assurance processes, including detailed working procedures for field operations, laboratory operations, laboratory administration, equipment performance, and quality verification of analytical results. These are written in an effort to conform to the Standards Council of Canada CAN P 4D (ISO/IEC 17025) [15] for analytical laboratories.

The following sections discuss the results of laboratory inter-comparison activities in 2023.

4.1 Radiological Analysis

The Environmental Management group conducts frequent internal checks of their technical capabilities as they perform their measurements. These are referred to as Quality Verification tests, and are grouped as follows according to purpose:

---

14 If gross beta levels are not accounted for by potassium-40 and cesium-137 (or other beta/gamma emitters), strontium-90 analysis is performed.

15 Land Gamma (Road Survey) must be performed in the fall before the first snowfall.

- *Contamination Tests*, such as measurement of the reagent blank, establish the level of analyte present resulting from contamination of the analysis system or system components. Acceptance criteria for these performance tests are related to each analyte's method detection limit.
- *Reproducibility Tests*, such as measurement of sample replicates, establish the relative precision of the method(s). To be acceptable, replicate measurements must agree within limits established by long-term method performance.
- *Accuracy Tests*, such as blanks or samples, each spiked with known amounts of the analyte(s), establish the presence or absence of any biases due to sample matrix, sample preparation, or instrument function. To meet acceptance criteria, the spike quantity must be recovered within limits established by long-term method performance.

Table 3 summarizes the results of internal quality verification tests conducted by Environmental Management at WL. As a part of the sampling program, 5405 quality verification tests were performed in 2023. Performance, accuracy, and precision were verified by means of spike and duplicate tests and by laboratory and field blank and spiked blank tests. Results are for four (4) different methods with an overall pass rate of 98.8%.

In 2023, the WL Environmental Management group took part in four inter-laboratory comparison studies. Two of these studies, which focused on radiological analyses, were offered through the Environmental Research Associates. The other two studies which focused on non-radiological analyses, were offered through the Canadian Association for Laboratory Accreditation. The results of the WL Environmental Monitoring laboratory performance are shown in

Table 4 and Table 5.

For all inter-laboratory tests pertaining to the effluent verification monitoring program CNL, had a 100% passing rate. However, the inter-laboratory test for soil failed because cesium-137, cobalt-60 and zinc-75 were significantly higher than expected. The reason for the failure has not been established. All the other isotopes passed and they were not consistently high. Testing of previous MRAD soil samples consistently produced the same results as before. This suggests that the gamma spec equipment was functioning properly and the MRAD sample contained more cesium-137, cobalt-60 and zinc-75 than expected.

Table 3: Results of Radiological Internal Quality Verification Tests at WL, 2023

Method	No. of Tests	No. of Failures	% Pass
Total Alpha Instrumentation	1212	10	99.2
Total Beta Instrumentation	1061	23	97.8
Gamma Instrumentation	2904	12	99.6
Tritium	228	18	92.1
2023 Total	5405	63	98.8

4.2 Non-Radiological Analysis

With the exception of HB-40 analysis, pH and conductivity, all the samples which required non-radiological analyses were sent to contract laboratories in 2023.

Certificates of analysis were reviewed and results of all the analyses were verified to be within acceptance criteria.

In 2023, the WL Environmental Management group participated in a semi-annual proficiency testing program offered through Proficiency Testing Canada (PTC). There were two inter-laboratory testing performed on the non-radiological parameters in 2023. As shown in Table 5, all results were satisfactory.

Table 5: Whiteshell Laboratories Performance in PTC Proficiency Testing Program, 2023

4.3 Sample Management Office

The following samples for 2023 were sent to a contract laboratory for analysis:

1. Animal, fish and vegetation samples for gross alpha, gross beta and Gamma Spectrometry (Gspec).
2. Soil and sediments for gross alpha, gross beta and gamma spectroscopy.
3. Groundwater samples for gross alpha, gross beta, strontium-90, and gamma spectroscopy analysis.
4. Surface water samples that included ditches, rivers and Outfall.

Certificates of analysis were reviewed and results of all the analyses were verified to be within acceptance criteria.

4.4 Audit and Inspections

As per the requirements of the Management System [16], both Safety Control Areas (SCA's) and Facilities conduct various self-assessments to ensure that the management system is functioning according to expectations and that any policy, programmatic, or procedural deficiencies are identified and appropriate action taken to resolve any deficiencies. See the WL Annual Compliance Monitoring Report [8] and specifically the ISO 14001 EMS audit report.There was also a CSA-N288 Compliance audit performed in November.

All actions resulting from audits, inspections, reviews and self-assessments are being managed and tracked through CNL's Problem Identification and Resolution Program.

5. Summary of Emissions from Whiteshell Laboratories

5.1 Summary of Radioactive Emissions from Whiteshell Laboratories

Cleanup and operational activities associated with the decommissioning of the site have been underway since 2003 January. Specific sources that may have influenced the 2023 air releases included the Hot Cells Facility (Building 300), the Immobilized Fuel Test Facility (Building 300) and the Reactor Building (Building 100). The sources contributing to the liquid releases are the Outfall and the Lagoon. The discharge from the Outfall is composed of storm water runoff from paved roadways or around buildings, cooling water used in process and experimental facilities, and holding tank discharges from the active liquid waste treatment system tanks based in Building 100 and Building 300. Specific activities that may have influenced the 2023 liquid releases are similar to those for the past five years. The use of disposable rubber shoe covers was introduced in 2018 to reduce the impact of shoe cover washing on the waste stream.

The Lagoon collects sanitary and wastewater from most buildings on the site, as well as from the laundry facility. Lagoon water residence time is more than three months, to allow for biodegradation and settling. Prior to each planned discharge, the secondary cell is isolated, and tested for a series of non-radiological parameters (discussed in the WL Annual Compliance Monitoring Report [8]). If these are acceptable, the accumulated contents of the secondary cell only are released to the Winnipeg River via a small drainage ditch leaving the Lagoon's north side. The outflow of the Lagoon is continuously sampled during discharge. The resulting composite sample is analyzed for gross alpha, gross beta, and radio-strontium and it is also scanned by gamma spectrometry. In 2023 the Lagoon was not discharged because the annual precipitation was low and as a result freeboard in the Lagoon was low enough that a discharge was not required.

Detailed results of the monitoring of radioactive material in airborne and liquid effluents from the WL site are in the WL Annual Compliance Monitoring Report [8]. This section contains brief summaries of airborne and liquid releases from WL during 2023. The releases are expressed as average quantities per monitoring period (in Becquerels) and as percentages of the applicable Derived Release Limit (DRL[16]) [9] based on the most exposed members of the public outside the site boundaries. These limits came into effect on 2021 January 31. Data are reported against the revised DRLs, and any tables/figures with previous years' data were re-calculated against the revised DRLs for proper comparisons. Table 6 and Table 7 also indicate the critical groups outside the sites, and the dominant exposure pathways to the critical groups, as identified by the DRL calculations [9], using the methodology of the National Standard of Canada, N288.1-08 [17]. Farm A is located just north of the WL boundary. Farm D, Farm E and Farm F are on the west side of the Winnipeg River. Note that for liquid releases (Table 7) the % DRL is given for

[16] Derived Release Limits are the upper limits, approved by the CNSC, for releases of radioactive materials in emissions from a nuclear facility or site. They are derived based on the dose limit for members of the public by means of environmental pathway analysis. The DRL values in effect for the WL site are contained in Reference [9].

the alpha emitting radionuclides instead of for gross alpha. For practical purposes, the sum of site releases during the year, as percent of the DRLs multiplied by the dose limit (1 mSv), represents a generally conservative radiation dose estimate to the most exposed members of the public, due to emissions from the site. All releases were below the regulatory Action Levels[17] derived from the DRLs, as specified in [5] and [18].

Table 6: Whiteshell Laboratories Air Emissions – Average Releases in 2023 and Dominant Dose Pathways

Radionuclide	DRL* (Bq/week)	Average Release [8]		Dominant Dose Pathway [9]	Critical Group [9]
		(Bq/week)	(%DRL)		
Tritium	1.65E+15	4.04E+08	2.45E-05	Water Ingestion	Adults at Farm F
Gross Beta Particulates (as Sr-90)	6.79E+09	2.74E+03	4.03E-05	Terrestrial Animals and Mother's Milk (ingestion)	Infants at Farm A
Gross Alpha Particulates (as Pu-239)	1.73E+09	1.47E+03	8.51E-05	Air Inhalation	Adults at Farm A
WL Total – Airborne			**1.50E-04**		

* DRL based on critical groups outside the site [9]

Table 7: Whiteshell Laboratories Liquid Emissions – Average Release in 2023 and Dominant Dose Pathways

Radionuclide	DRL* (Bq/month)	Average Release [8]		Dominant Dose Pathway [9]	Critical Group [9]
		(Bq/month)	(%DRL)		
Uranium (total)	1.25E+10	8.59E+05	6.88E-03	Water Ingestion	Infants at Farm A

WL Total – Liquid			**2.00E-01**		

* DRL based on critical groups outside the site [9]

[17] Action Level – In the context of CNL's Environmental Protection Program, an "Action Level" for radioactive emissions is a release rate of radioactive emissions that, if reached, may represent a loss of control of performance for a facility's environmental protection program or emission control system. Releases above Action Levels must be investigated and reported to the CNSC. Action Levels for WL radioactive effluents are lower than the DRLs.

5.2 Summary of Non-Radiological Emissions from Whiteshell Laboratories

This section addresses the licence requirement regarding hazardous substances monitoring of airborne and liquid effluents for the WL site for 2023.

5.2.1 Airborne Non-Radiological Emissions

Airborne emissions from the WL site are compiled on an annual basis for the purpose of reporting under the National Pollutant Release Inventory (NPRI) and the federal Greenhouse Gas report. The releases to air include emissions caused by burning of Number 2 fuel oil and propane for heating, as well as diesel fuel used from site generators, dust emissions from unpaved roads, sandblasting and excavation projects.

Emission factors are applied to fuel and sandblasting product consumption data, as well as estimated kilometres travelled on unpaved roads, to determine the amount of Criteria Air Contaminants (CACs) that are generated on site. Criteria Air Contaminants consist of carbon monoxide, oxides of nitrogen, sulphur dioxide, total (filterable) particulate matter (PM), and particulate matter below 10 microns (PM_{10}), particulate matter below 2.5 microns ($PM_{2.5}$), and Volatile Organic Compounds. Dust emissions from excavation projects were estimated based on a calculation for total particulate matter generated per excavation day. Dust generated from demolition activities in 2023 are captured in the EAFP report [7].

Table 8 outlines the annual CACs generated from site activities, and shows a large increase in emissions seen in 2022 compared to the 5-year average for the values for total particulate matter, PM10, and PM2.5. This is a result of CNL not applying any dust suppressant to the gravel roadways in 2022. In 2023 CNL resumed the application of dust suppression, resulting in a significant decrease in total particulate matter, PM10, and PM2.5. As a result the Whiteshell site dust emissions returned to values similar to previous years and only needed to report on PM10, as before.

Under the authority of the Canadian Environmental Protection Act, 1999 (CEPA, 1999), WL is required to calculate releases under the Greenhouse Gas (GHGs) emissions notice providing the facility emits over 10,000 tonnes of carbon dioxide equivalent or more within the 2023 calendar-year. GHG emissions from WL include carbon dioxide, methane and nitrous oxide. Emissions are primarily from the burning of propane, the use of diesel generators, the on-site transportation fleet, the on-site landfill and open-pit wood burning. They are reported in CO_2 equivalent tonnes which is a measure used to compare between gases that have different Global Warming Potential (GWP).

GHG emissions from the WL site were similar to 2022 and have decreased significantly from 2018-2020 (Table 9). This decrease can be attributed to the decrease in propane required to heat the site from 2021 through 2023. Building 200 did not require any building heating since 2020, and Buildings 402 and 305 no longer had to be heated starting in the fall of 2021 due to demolition activities. Overall, greenhouse gases in 2023 are 26% less than the average for the last 5 years.

In the atmosphere, halocarbons contribute both to global warming and to ozone depletion, via separate mechanisms. Losses of halocarbon refrigerants and fire suppressants are reported semi-annually to Environment and Climate Change Canada, pursuant to the Federal Halocarbon Regulations. All releases greater than 10 kg are considered reportable. There were no reportable releases of halocarbons in 2023.

Table 8: WL Stationary Combustion Data and Emissions from 2018 to 2023

Parameter	Unit	Data for Previous Five Years						Data for 2023	NPRI Reporting Threshold
		2018	2019	2020	2021	2022	Average		
Airborne Emissions									
NO_x (as NO_2)	Mg	0.536	0.621	0.602	0.331	0.485	0.569	0.617	20
SO_2	Mg	0.014	0.016	0.017	0.005	0.014	0.014	0.025	20
CO	Mg	0.233	0.271	0.256	0.162	0.202	0.254	0.218	20
PM (total particulate)	Mg	14.562	10.574	8.883	8.174	46.9	11.17	10.516	20
PM_{10}	Mg	3.726	2.712	2.281	2.091	11.97	2.862	2.702	0.5
$PM_{2.5}$	Mg	0.391	0.292	0.249	0.218	1.21	0.305	0.298	0.3
Volatile Organic Compounds	Mg	0.042	0.049	0.048	0.026	0.038	0.045	0.049	10

Table 9: Greenhouse Gas Emissions from 2018 to 2023

Parameter	Releases from Previous Five Years						2023 Releases
	2018	2019	2020	2021	2022	5-yr. Avg.	
GHG CO_2e tonnes	1,678	1,756	1,692	1,177	1,215	1,635	1,203

Notes:

GHG CO_2e tonnes - A unit of measure used to compare between gases that have different Global Warming Potentials (GWP). For example, the GWP for methane is 25. This means that emissions of one metric ton of methane is equivalent to emissions of 25 metric tons of carbon dioxide. In 2013, the GWP for methane and nitrous oxide were changed from 21 to 25 and 310 to 298 respectively under the *Canadian Environmental Protection Act Notice with Respect to Reporting of Greenhouse Gases for 2013* [19]

5.2.2 Liquid Non-Radiological Emissions

The non-radiological effluent monitoring program established by CNL continues to supply valuable information about the potential impacts of operations on the Winnipeg River, and thus the local environment. Two effluent streams, the Lagoon and Process Outfall, discharge significant volumes of water to the Winnipeg River. Normal surface land run off also reaches the river through Ditches Locations 8 and 9. Non-radiological emissions to the river are summarized as loadings, expressed as kg released per year. Table 10 summarizes emission loadings of non-radiological parameters for the Lagoon and Outfall. Ditches are not included in loading calculations because the volumes discharged could not be quantified.

For the Lagoon, the volume-weighted average concentration of a parameter was calculated as follows:

1. The measured concentration for each day was averaged with that of the next day;
2. The average was multiplied by the estimated volume discharged over the 24-hour period;
3. The products for all days were summed, then;
4. The resulting sum was divided by the total volume released during the period (Spring, Fall or entire year). The load was then given as the product of the calculated volume-weighted average concentration, multiplied by the total volume for the period.

At the Outfall, the total discharge volume for each month was multiplied by the monthly average concentration of the parameter. Table 10 contains the results of calculations described above, grouped by parameter and by final outflow source. All mass-related parameters are shown. The table also compares them to previous years, and to the five-year averages.

When examining the WL site total loads, notable results are:

- Phenolics and oil and grease are the parameters that had a load increase greater than 10% when compared to the five-year average. These parameters are typically non-detects or at concentrations around the detection level, so when they are detected, they have an impact on the overall load.
- The majority of loads decreased in 2023. This is due to the safety stand down that occurred in 2023, which reduced operations on site from May to December. Another contributor to the decrease is the street sweeping operations were conducted after the spring melt in 2023.

Table 10: Loading for Current Year and Previous Five Years

ATG	Parameter	Monitoring Point	Loadings from Previous Five Years (kg) [a]						Results for Year 2023		
			2018	2019	2020	2021	2022	Average	# Spl. [b]	NDs[c]	Load (kg)

a Averages were calculated by setting to zero results reported as "< DL."

b # Spl. is the number of samples analyzed and reported.

c NDs is the number of samples in which analyte was not detected (i.e., Code = "< DL", result = 0).

6. Environmental Monitoring Program Activities

An Environmental Monitoring Program is implemented at the WL site to meet the objectives described in Section 2.1. Cessation of a monitoring activity will occur once it can be shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant by regulatory requirements or community concerns. This is also consistent with N288.4-10. Any proposals on modifications to the monitoring program will be communicated to the CNSC.

In a continuing environmental monitoring program, radioactivity is measured in a number of media at various environmental sampling points near the WL site. In addition, groundwater is monitored for several non-radiological parameters. Many of the sampling locations discussed in this report are shown in Figure 22 through Figure 27 in Appendix A. This report contains monitoring results for year 2023, including measurements of:

- radioactivity in waters of the Winnipeg River,
- radioactivity and non-radiological parameters in groundwater,
- radioactivity in flesh of fish from the Winnipeg River,
- radioactivity in cultivated (garden) vegetables,
- radioactivity in native vegetation and soils,
- radioactivity in river-bottom sediments of the Winnipeg River,
- radioactivity in deer and grouse,
- ambient gamma radiation in air,
- atmospheric deposits of radioactive material, and
- land gamma radiation.

Meteorological data are being maintained by Environment Canada for their purposes and the data are available to CNL staff, if needed.

6.1 Environmental Monitoring Results

The results of all environmental monitoring activities in 2023 are presented and discussed in this section, with the focus being on:

- the fate of **waterborne contaminants** from the source areas (e.g., process Outfall, Lagoon and waste storage areas) through the geosphere in groundwater, into and through the biosphere along surface water drainage routes, and entering the Winnipeg River and other off-site areas; and
- the fate of **airborne contaminants** from the source areas (e.g., stacks and roof vents) through the atmosphere, into and through the biosphere via deposition, reaching the boundary of the WL site and entering off-site areas.

Performance in this context was evaluated by characterizing the concentrations of contaminants of concern in groundwater, surface water, and air. Contaminant trends were reviewed and compared to historical trends, background concentrations, and benchmark values (BVs). The background concentrations and benchmarks are shown in Table 11 and Table 12. The comparison to background screening criteria serves to distinguish between “affected” and “unaffected” surface waters. The criteria consists of site-specific background concentrations that are determined by monitoring conditions at one or more reference areas that are on or near the WL site and have not been adversely affected by WMA operations. The mean plus two standard deviations (of the five (5) most recent years) was used as an upper limit of background. This method is prescribed by the Ministry of the Environment and cited in [10]. It should be noted that the locations selected to represent reference water quality data could be impacted by atmospheric releases from WL operations. This is certainly the case for tritium, which in regions remote from any reactor facility in Canada is present at concentrations of about 3 Bq/L.

Table 12 and Table 13 serve to identify anomalous conditions and areas of potential impact. Some BVs represent the level above which ecological effects could potentially occur. For radioactive contaminants, the BVs are based on a combination of generic environmental concentrations below which no effects are expected [20], and site-specific concentrations, whereas non-radioactive contaminants consist of either generic toxicological benchmarks or provincial and federal water quality guidelines [21], [22], and [23]. Exceedance of a BV does not necessarily indicate that ecological impacts would occur, but instead indicates that there is some potential for ecological impacts.

Impacts on groundwater quality are assessed by subjecting the collected data to a systematic assessment process that includes screening against groundwater quality criteria and trend analysis.

For ambient gamma radiation in air, radioactivity is expressed in units of Grays or Sieverts per time unit, as appropriate. In all other cases, gross beta and gross alpha activity are measured, and expressed in units of Becquerel per weight, volume, or area. The gross activity measurements provide a good indication of the total radioactivity, and in most cases are supplemented with spectral measurements for individual radionuclides that may be responsible for the gross activity. For example, Outfall and Lagoon samples are analyzed for total uranium (U), plutonium-239/240 (Pu-239/240), plutonium-238 (Pu-238) and americium-241 (Am-241). The gamma spectrum is scanned for artificially produced radionuclides, as well as for naturally occurring ones such as potassium-40 (K-40) and beryllium-7 (Be-7). In many instances, it is apparent that the gross activity is mainly due to the natural radionuclides. For conservative estimates of dose caused by the activity, it is usually assumed that the gross activity is entirely caused by the most radiologically toxic radionuclide (one with the most restrictive DRL) that is usually assumed that the gross activity is entirely caused by the most radiologically toxic radionuclide (one with the most restrictive DRL) that is likely to be present in significant quantities in the specimens, and contribute to the parameter being measured, for example, Strontium-90 (Sr-90) for gross beta. Tritium analysis of selected surface and ground water samples and uranium analysis of groundwater samples continued this year. Non-radiological parameters were selected based on a review of the reference hazard information and on-site effluent data.

Whiteshell Laboratories' Environmental Management group maintains a complete set of sampling procedures, field-operating procedures, equipment performance checks, quality verification procedures, and laboratory administrative procedures.

Trends have been presented, for the period 2018 to 2023, along with the average values for the past five years. For the 2023 data, uncertainties based on standard deviations are shown. The method detection limits (MDLs) based on normal sample sizes and count times for the various analyses have been included in the tables. Values lower than the associated MDL are indicated as such by the less than symbol (<) along with the associated MDL value. The MDL for a given sample may vary due to differences in sample aliquot sizes, count times, and/or detector efficiencies. The MDL value has been included in the calculation of averages.

Incremental doses that could be caused by effluents from WL have been estimated for adults and infants in the critical group outside the WL site. It is assumed that these individuals ingest Winnipeg River water, Winnipeg River fish, game animals, and vegetables irrigated with

Winnipeg River water. In 2023 the consumption of water and fish from the Winnipeg River contributed to potential dose to the critical group.

Whiteshell Laboratories site biodiversity is also discussed, as waterborne and airborne contaminants from WL operations can have an impact on Valued Ecosystem Components (VECs) health and habitat. Section 6.9 identifies potential WL VECs, projects and permit requirements.

Table 11: Environmental Monitoring Radiological Method Detection Limits (MDL), Background Values and Benchmark Values

Environmental Medium	Parameter	Unit	MDL[18]	Background Value (BG)	Source	Benchmark Value (BV)	Source
Air Quality and Noise	TLDs	µGy/a	85 [19]	< 1200 145-515	[24] [25]	< 2,000 (WL Main Campus)[20] < 10,000 (WL WMA. Canister Area)	[26] BV is the geometric mean plus 3 times the standard deviation of 2012 to 2017 (perimeter fence for main campus and canister area for WMA)
	Land Gamma Survey	nSv/h	10	< 60	[26] (mean plus 2s of background of 2012 to 2017 data)	< 500	[26]
	Noise	dB	28-42	47	[27]	85	[28]
Wet/Dry Deposition[21]	Gross Alpha	Bq/m^2	1	2	BG is mean plus (n-1) times the standard deviation of 2012 to 2017 [26]	3	[26], BV - average value for this station for 2012 to 2017 plus three standard deviations.
	Gross Beta	Bq/m^2	6	14		13 (17)	[29], BV in () is average value of results for this station for 2012 to 2017 plus three

18 MDLs were calculated using background or blank values as per EPA MDL method 40 CFR Part 136 Table 37 or are from Annual Compliance Monitoring Reports normally based on sample size, count times and counting statistics or value is from Contract Lab analysis sheet.

19 Detection limit calculated using background values from 2012 to 2017.

20 The benchmark values were assessed against radiological safety zone classifications. The main campus is expected to be very low radiation hazard (< 0.5 microsievert/hour/< 4380 microgray per year) and the WMA and Canister Areas are expected to be low radiation hazard (> 0.5 but less than 10 microsievert/hour/< 87600 microgray per year)

21 The MDL is based on a rain pail (1,320 cm^2) or snow sheet sample (1,320 cm^2) resulting in 0.2 g of sample ash and counted 100 min for gross beta and strontium-90 analysis, and 400 minutes for gross alpha or 800 min for cesium-137, and potassium-40 analysis.

Environmental Medium	Parameter	Unit	MDL[18]	Background Value (BG)	Source	Benchmark Value (BV)	Source
							standard deviations.
	Cesium-137	Bq/m^2	0.1	0.3		3 (0.3)	
	Potassium-40	Bq/m^2	6	12		14	[26], BV - average value for this station for 2012 to 2017 plus three standard deviations.
	Strontium-90 [22]	Bq/m^2	0.5	0.7		3 (1)	[28], BV () average value for this station for 2012 to 2017 plus three standard deviations.
Surface water (not used as drinking water)[23]	Gross Alpha	Bq/L	0.30	0.3	BG is geometric mean plus two times the standard deviation of 2009 to 2017 control locations data Maxxam[24] MDL	16.2 (20)	MDL based on Control Ditch Location data 2009 to 2018 [20], [30]
	Gross Beta	Bq/L	0.30	0.3		666 (10)	
	Potassium-40	Bq/L	10	0.3		291 3 (for WMA catch/ containment tray[25])	[22]
	Cesium-137	Bq/L	1	< 1	Maxxam[24] MDL	NA	Maxxam[24] MDL NA

22 Strontium-90 analysis of atmospheric deposition samples was discontinued in 2019. Tritium analysis was considered due to emissions from WR1 (1.5E+09 Bq/wk) but discounted as the average release of tritium from the site is 9E-05 %DRL.

23 Control ditch location unaffected by WL operations. These are normally collected s 1 liters samples and are ashed before alpha, beta and gamma counting.

24 Maxxam Analytics Inc., https://www.maxxamlabs.com/

25 Alert Environmental Specialist if the cesium-137 activity in the Catch/Containment Tray exceeds 3.0 Bq/L at any time.

Environmental Medium	Parameter	Unit	MDL[18]	Background Value (BG)	Source	Benchmark Value (BV)	Source

27 Local well waters within the Canadian Shield contain naturally occurring uranium [31] at concentrations >100 ppb, the presence of uranium and its progeny are not unexpected. The reason for high uranium concentrations can be attributed to the presence of dissolved carbonate which is effective for leaching naturally occurring uranium from minerals under oxidizing conditions.

28 Normally collected as a one litre samples, gamma MDL is based on counting a 500 mL sample for 30 minutes and three 1 mL samples counted for alpha and beta. These samples include sump water, manhole water and standing water from excavations. Gross alpha is assumed to be americium-241 and gross beta is assumed to be strontium-90.

Environmental Medium	Parameter	Unit	MDL[18]	Background Value (BG)	Source	Benchmark Value (BV)	Source
Surface water (used as drinking water)	Cesium-137	Bq/L	0.003	0.007	BG is average plus two standard deviations of 2007 to 2017 of upstream (SFD) data [26]	10	[21]
	Gross Alpha	Bq/L	0.023	0.050		0.5	[21]
	Gross Beta	Bq/L	0.023	0.090		5	[21]
	Potassium-40	Bq/L	0.040	0.087		NA	
	Strontium-90	Bq/L	0.003	0.009		5	[21]
	Americium-241	Bq/L	0.006	< 0.002		0.7	[22]
	Total Uranium	Bq/L (ppb)	0.003 (0.1)	0.025 (<10)		0.5 (20)	[21]
	Tritium oxide	Bq/L	3	7		7,000 (5.0 background level[29])	[21]
Fish	Gross beta	Bq/kg (fresh weight)	5	200	BG is the geometric mean plus 2 times the standard deviation of 2012 to 2017 upstream data (rounded) [26]	250	BV is geometric mean plus 5 times the standard deviation of 2012 to 2017 upstream data (rounded)
	K-40		6	200		250	
	Cs-137		1	1.7		4[30]	[26]
Game, Livestock	Gross alpha	Bq/kg (fresh weight)	5	<11	[33], [14]	33	[33], [14]
	Gross beta		5	Deer – 162 Grouse – 233	BG is the geometric mean plus 2 times the standard deviation of 2001 to 2016 data (outer areas)	Deer – 193 Grouse – 294	BV is 3 times the geometric mean of 2001 to 2016 data
	Cesium-137		1	Deer - 6 Grouse – 5		Deer [31] - 33 Grouse – 45	

29 Background levels of tritium taken from Health Canada's Canadian Radiological Monitoring Network – tritium in drinking water (saved as excel file).

30 The concentration of cesium-137 in fish would have to be 1750 Bq/kg to trigger an ALARA (0.05 mSv/a) review.

31 The concentration of cesium-137 in game would have to be 240 Bq/kg to trigger an ALARA (0.050 mSv/a) review.

Environmental Medium	Parameter	Unit	MDL[18]	Background Value (BG)	Source	Benchmark Value (BV)	Source
	Potassium-40		100	Deer - 149 Grouse – 260		Deer - 174 Grouse – 320

6.2 Waterborne Contaminants

Figure 3 summarizes the sources of surface water contaminants and the paths taken by these contaminants to reach the Winnipeg River. Some surface waters in the WL Supervised Area are affected by past and present activities at the WMA, and are routinely monitored for radioactive contaminants as part of the Effluent Verification Monitoring Program, operational control monitoring and the Environmental Monitoring Program. The results of the effluent verification and operational control monitoring are found in the WL Annual Compliance Monitoring Report [8].

These surface waters are not used for human consumption. With the current restrictions on access, members of the public are not permitted on the WL site without authorization and direct supervision. The potential health risks to humans are therefore limited to the discharge of contaminants to the Winnipeg River and liquid effluent outfall.

This monitoring is complemented by routine groundwater monitoring. Groundwater is often the initial pathway for the migration of dissolved contaminants released from past and present activities at the WMA, and (inadvertently) from some facilities in the built-up portion of the WL site. The measurement of groundwater quality around the perimeters of such facilities and WMA provides a way to monitor the condition and behaviour of the facilities and operations. The Ground Water Monitoring Program [44] was established for this purpose. Groundwater monitoring results are discussed in Section 6.3.

Table 2 provides a summary of the monitoring schedule including a list of parameters analyzed in ground and surface waters.

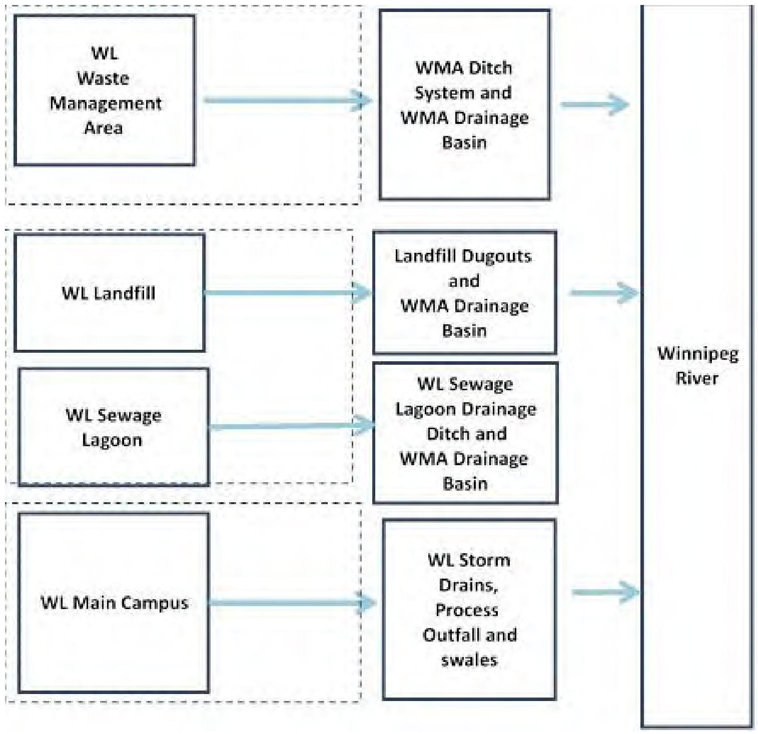

Figure 3: Whiteshell Laboratories Site Model Overview

6.3 Groundwater within the Whiteshell Laboratories Site

The viability of the borehole network is integral to demonstrating the robustness of the geological and hydrogeological barrier system. Activities undertaken as part of the ongoing assessment of the WMA, Lagoon and Landfill physical and chemical hydrogeological conditions [44], [45] and the work tasks in the EAFP have ensured on-going inspection of the existing well network. Current well locations are shown in Figure 23 and Figure 24 in Appendix A. The stratigraphic units sampled by wells in various locations include the shallow Bedrock which is overlain by the Basal unit (with sand and gravel giving higher hydraulic conductivity). The Basal unit is overlain by lower permeability Clay Till and Clay.

The Bedrock well at the WMA was installed to complete the network required to validate the conceptual model and lower boundary of groundwater flow at the WMA (see Figure 26 in Appendix A). The wells at the upland recharge area were installed to monitor the recharge conditions in the sand aquifer that contributes to discharge conditions at the WMA. The wells at the landfill were installed to verify the absence of flow from the landfill to the east. Ongoing monitoring confirms that groundwater flow is to the south and southwest, away from the Pinawa Channel.

Manual water level monitoring is conducted in the spring and fall in all 500-series wells. Evaluation of the data has determined that the groundwater flow conditions vary seasonally, and the spring and fall periods provide adequate representation of overall flow conditions needed for on-going assessment. The reduced requirement for manual measurements is offset by a recommendation for additional automated water level recording at the WMA, Lagoon and Landfill.

A review of the radiological and non-radiological source term for the facilities, and confirmation of flow conditions in the Clay, Clay Till and Basal stratigraphic units, has allowed for a refinement of the selection of wells and target parameters of potential concern. This effort is part of the WL Decommissioning Project Environmental Assessment Follow-Up Program [1], which requires that CNL refine and enhance the monitoring already in place at WL.

The routine environmental monitoring program has been, and will continue to be, modified to include the recommendations presented as part of the on-going assessment. Further discussion on the recommendations for the groundwater monitoring program and how these will improve the existing program is included in the EAFP report [7]. The complete results of the assessment will be included in the WL Decommissioning Project Environmental Assessment reports generated as part of the EAFP.

6.3.1 Radiological Monitoring of the Groundwater

Analysis of the groundwater for radiological parameters (gross beta, gross alpha, tritium and uranium) was conducted during 2023. Samples were collected from the Basal zone wells of the WMA during the spring and fall. They were also collected from selected locations in the Basal zone and water table of the Lagoon and Landfill area during the spring.

6.3.1.1 WMA

Water samples were collected from water table and deep wells in and around the WL WMA in spring and fall of 2023. The locations of all wells and piezometers are shown in Figure 23 and Figure 24 in Appendix A. Figure 26 (Appendix A) indicates the location of WL Facilities and surface drainage and layout.

The wells are in supervised areas within the WL site boundary. Discharge conditions were predominant in 2008 to 2023 although there was a very small area in the central portion of the WMA that had slight recharge conditions in 2023.

The WMA well data is reviewed based on the geologic unit it resides in as recommended in the groundwater monitoring plan [44]. This would allow for interpretation of the flow of parameters detected. Vertical flow occurs in the surficial Clay unit and in the intermediate Clay Till unit. The head gradient is upward leading the water in these layers to discharge to the surface. The surface water is monitored through the ditch network. Lateral flow occurs in the deeper Basal unit, and over the Bedrock. The low permeability of the Clay and Clay Till layers serve as a natural barrier to the groundwater as they retard the movement of potential contaminants. The facilities in the WMA reside at depths within the Clay and-Clay-Till units. The pathways that can potentially result in lateral contamination migration away from each facility area are of particular interest.

The tritium, uranium, gross beta and gross alpha results for the samples collected from the wells in the WMA during the spring and fall of 2023 are summarized in Table 41 in Appendix B.

Compliance with Guidelines for Canadian Drinking Water [21] may be inferred if the measurement for gross alpha and gross beta is less than 0.5 Bq/L and 1.0 Bq/L, respectively. If the level of the gross beta measurement exceeds 1 Bq/L the samples are submitted for gamma spectrometric analysis for cesium-137 and potassium-40. If the gross alpha activity exceeds 0.5 Bq/L the samples are submitted for gamma spectrometry to check for gamma emitting radionuclides, such as Am-241.

Average gross beta, gross alpha and uranium activity results are presented in Table 13. The table includes data dating back to 2013 to provide a better indication of temporal trends. The alpha activity in the basal and bedrock zones was below the screening level of 0.5 Bq/L [21]. The alpha activity was above the screening level in a few wells in the clay and clay-till zones. The well (BHS 500-140) installed during 2021 in the clay-till south of the WMA still measured the highest gross alpha (5.60 Bq/L) and uranium (261 ppb) activity, although the alpha activity was a factor 10 lower than when it was first sampled in 2022. This is higher than in any other well in the vicinity of the WMA, and is similar to the uranium concentrations and alpha activities observed in main campus wells. The high alpha is a consequence of the high uranium which is naturally present. It is natural uranium and not from the WMA for the following reasons:

- the groundwater flow direction is east to west and not north to south which would bring uranium from the WMA to this location,
- such uranium concentrations are not observed elsewhere in the WMA,
- these high uranium concentrations can be expected in the Whiteshell area, as discussed below,
- these concentrations are also observed on the main campus upstream from the WR-1 reactor.

The spatial distribution of alpha activity in the clay and clay-till zones is illustrated in Figure 28 in Appendix A. Gamma spectrometry and uranium analysis were performed on those samples above 0.5 Bq/L. As noted in previous years, the 2023 gamma spectrometry analysis indicated only the presence of naturally occurring potassium-40 and uranium progeny. Uranium and its progeny would contribute to the alpha activity in the samples. The distribution of dissolved uranium in the clay and clay-till zones is illustrated in Figure 29 (Appendix A).

Concentrations of uranium in the bedrock groundwater ranged from 0.23 to 2.31 ppb. Concentrations in the Clay zone wells ranged from 11.5 to 96.9 ppb, and in the Clay Till from 0.10 to 261 ppb (Table 41 in Appendix B). The waters from a number of wells from the Clay and Clay Till were above the Drinking Water Limit of 20 ppb (0.5 Bq/L) for uranium. Since it is known that the local well waters within the Canadian Shield contain naturally occurring uranium [46] at concentrations >100 ppb, the presence of uranium and its progeny are not unexpected. The reason for high uranium concentrations can be attributed to the presence of dissolved carbonate which is effective for leaching naturally occurring uranium from minerals under oxidizing conditions.

The beta activity levels in bedrock and the basal zone wells remained well below the drinking water screening level of 1 Bq/L. In 2023, with six exceptions, groundwater beta activities in the Clay zone and Clay Till were also below the drinking water screening level. Gamma analysis indicated the presence of naturally occurring potassium-40 and uranium progeny, both of which would contribute to the beta activity in the samples. No anthropogenic isotopes such as cesium-137 or Co-60 were detected in the samples.

Tritium was detected in samples collected from the clay-till wells BHS 79-2 (9 Bq/L), BHS 500-99 (22 Bq/L), BHS 500-102 (56 and 53 Bq/L), BHS 500-78 (15 Bq/L), and BHS 500-96 (20 Bq/L). The clay zone had detected tritium in BHS 500-103 (57 and 45 Bq/L), BHS 500-101 (8 and 10 Bq/L) and BHS 30 (25 Bq/L). Tritium was also found in the basal wells BHS 500-63 (22 Bq/L), BHS 500-71 (15 Bq/L) and BHS 86 (7 Bq/L). Tritium detection occurs in the area where transient reversals in recharge / discharge conditions have been noted in the WMA [7]. Tritium lateral distributions in the basal, clay-till and clay units are depicted in Figure 30 in Appendix A. These results are less than the Drinking Water guideline for tritium of <7000 Bq/L [21].

The WMA contains a number of trenches with varying amounts of low-level radioactive and conventional waste. Trench 7, located at the southeast end of the WMA, contains 87% of the inventory of tritium in the WMA. Some of the wells having elevated levels of tritium appear to be near or in the flow direction from Trench 7. There are unlined trenches in the north end of the WMA that also contain tritium. The contamination migration model [47] for the WMA unlined trenches proposed that tritium would be mobile and potentially present in the ground and surface water around the WMA. Contaminant migration modeling also indicated in-situ disposal provided no significant risk to human health or the environment.

The average alpha, beta and uranium activities in the WMA wells within the clay, clay-till, bedrock, and basal zone for the past five years are shown in Table 13 and displayed in Figure 4, Figure 5 and Figure 6. There is general agreement between the gross alpha and the uranium concentrations from year to year as shown in Figure 5 and Figure 6. Activity levels are fairly similar taking uncertainty into account.

The average beta activity (0.37 Bq/L) for the wells located in the basal sand is higher than the average, but remains below the drinking water screening level (1 Bq/L) [21] as noted in the years since 2011, and lower than that seen in the clay and clay-till wells. The clay (0.61 Bq/L) was higher than in 2022, while the clay-till (0.64 Bq/L) zone was lower than 2022 levels, but higher than the average for the previous five years. The average beta activity in the bedrock (0.29 Bq/L) is less than the 2022 value and higher than the average of previous five years since 2018.

The average alpha activities in the basal and bedrock zone wells (0.29 Bq/L and 0.31 Bq/L, respectively) are below the screening level (0.5 Bq/L) [21]. The values seen for the basal zone wells are lower than those in 2022 but higher than the average values for the previous five years. The average bedrock alpha activity is lower than in 2022, but higher than the five year average. The average alpha activities in the clay zone (0.67 ± 0.39 Bq/L) are higher than 2022 and less than the five year average. Alpha activities in clay-till zone (0.94 ± 1.18 Bq/L) are lower than in 2022 and the average of previous five years. The average uranium activities in the clay and clay-till (0.80 and 0.91 Bq/L, respectively) are above the screening level, which is not unexpected due to the contributions from natural uranium. Some variation in the alpha activity is noted and no persistent pattern from year to year has been observed.

The average uranium activity in the clay zone is slightly lower than the average of previous five years. The average uranium activity in the clay-till wells was higher than the past five years and remains elevated from that seen in the basal and bedrock zones. The uranium activity in the basal zone wells hovers around the detection limit for most locations.

The average overall activities in the clay and clay-till wells are higher than that noted in the basal zone wells. The activity associated with the clay zone wells has been generally the highest. However, with the addition of the new well south of WMA the average clay-till activities are the highest.

Based on the results of total beta, total alpha and uranium activity it is difficult to say whether vertical or lateral movement of radionuclides from the WMA facility has occurred, particularly since these activities were most likely from natural sources. Tritium would provide the best indication of contaminant migration from the facility. As mentioned above, there is some evidence that migration of tritium has occurred.

Notes:

1. Average of previous five years.
2. NA = not available
3. Uncertainties are expressed as the standard error of the mean for average activities measured.
4. ***Maximum Acceptable Concentration in Drinking Water for gross beta (as strontium-90) is 5.0 Bq/L, for gross alpha (as uranium) is 0.5 Bq/L, and for uranium is 0.5 Bq/L, as specified by Health Canada [21].

****Uranium concentrations were converted from µg/L to Bq/L by using the generally accepted conversion factor of 0.025 Bq/mg uranium [21].

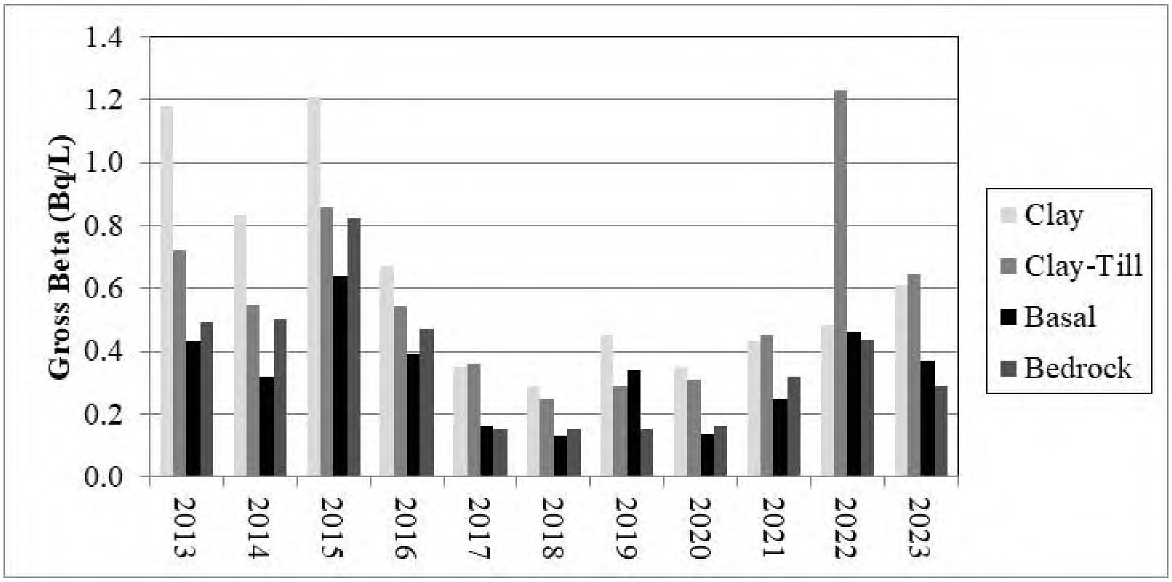

Figure 4: Gross Beta Activity in WMA Wells, 2013 to 2023

The MAC for gross beta in drinking water (as strontium-90), specified by Health Canada, is 5 Bq/L [21].

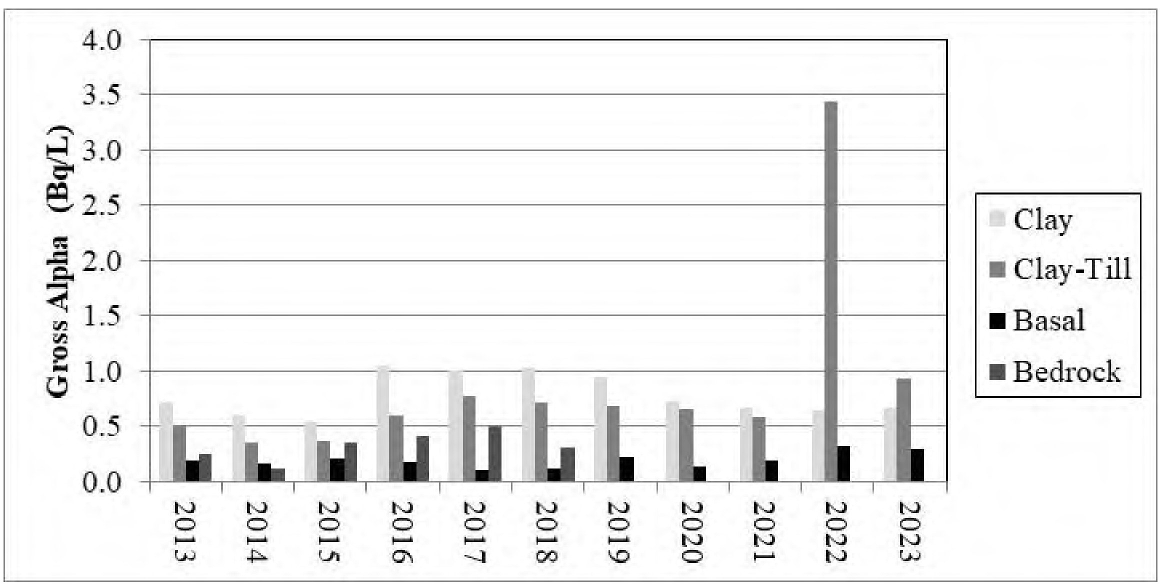

Figure 5: Gross Alpha Activity in WMA Wells, 2013 to 2023

The MAC for gross alpha in drinking water (as natural uranium) is 0.5 Bq/L [21].

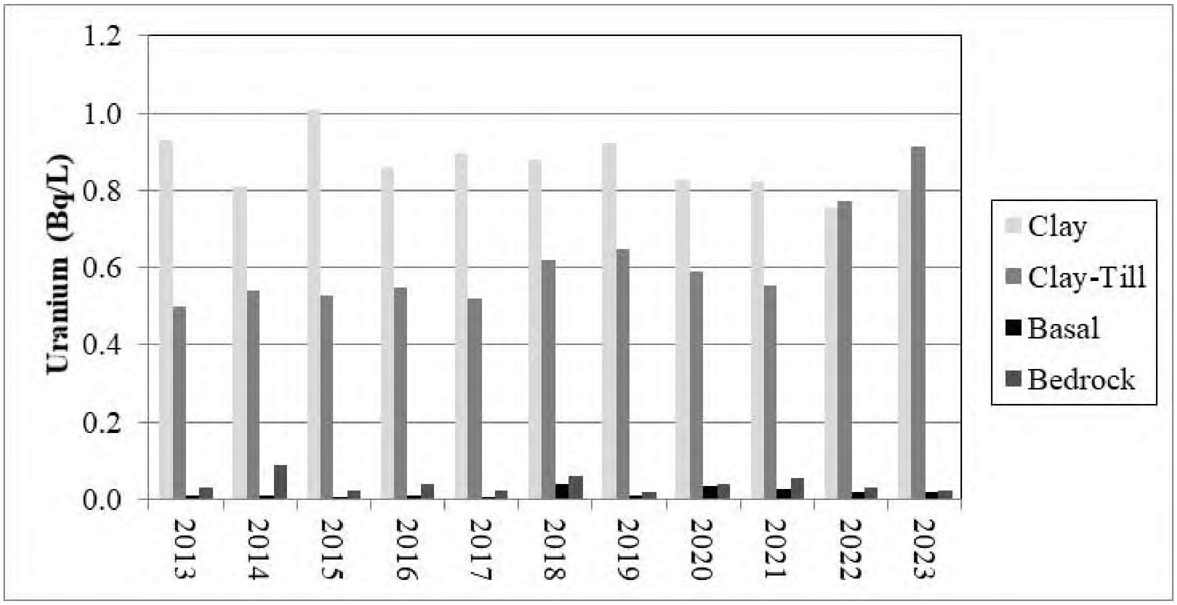

Figure 6: Uranium Activity in WMA Wells, 2013 to 2023

6.3.1.2 Lagoon and Landfill

Samples were collected from the wells in the Lagoon and Landfill areas on site during the spring of 2023. The uranium, tritium, gross alpha and gross beta results are summarized in Table 42 and Table 43 in Appendix B.

In 2023 the gross beta activities in all water table wells in the lagoon area were below the drinking water screening level (1 Bq/L). Basal unit well BHS 500-14 (1.39 Bq/L) had gross beta above the drinking screening level. Gamma spectrometry of these samples indicated the presence of naturally occurring potassium-40 and uranium progeny. This would account for the elevated gross beta. Two of the four water table wells and all basal unit wells in the lagoon area had alpha activity levels at or above the screening level of 0.5 Bq/L. Gamma analysis of the remaining wells indicated the presence of naturally occurring uranium progeny. In addition, all samples contained uranium in concentrations ranging from 11 to 158 ppb with the highest levels noted in the basal unit. Uranium and its progeny are contributors to the total alpha activity. The Drinking Water Limit for uranium is 20 ppb. Local well waters within the Canadian Shield [31], [48] contain naturally occurring uranium (>100 ppb) and therefore its presence at these levels is not unexpected.

The beta activities detected in the landfill wells were below the screening level of 1.0 Bq/L. All alpha activities in the landfill wells were below the screening level of 0.5 Bq/L. All samples were below the Drinking Water Limit for uranium (20 ppb).

Tritium in the Landfill wells was detected in wells BHS 500-4 (7.14 Bq/L), BHS 500-13 (4.2 Bq/L), and BHS 500-56 (24.92 Bq/L). All were well below the Drinking Water Limit (7000 Bq/L). The water from these wells is not used for human consumption. As discussed in the WL Annual Compliance Monitoring Report [8], low levels of tritium (212 Bq/L) were detected in 2019 in the surface water (dugout #15) near the landfill. Although this activity is well below the drinking water limit for tritium (7000 Bq/L), it is higher than expected.

The most likely source of tritium is the Landfill, based on the following arguments. The highest tritium activities found in dugouts and wells are in close proximity to the Landfill. Due to its 10 m height the Landfill has a higher hydraulic head than the local terrain and will contribute leached contaminants to the shallow groundwater system. Due to the local groundwater flow direction (toward the south and southwest) dugouts 15 and 24, and well BHS 500-56 are more likely to receive contaminants from the Landfill than the asbestos site. Furthermore, the Landfill has been in operation for a much longer time frame than the asbestos site, increasing the probability that something was placed there by mistake and providing more time for contaminants to reach dugouts and well locations. In 2021 the lack of detected tritium in wells was likely the result of lower precipitation and less leaching of tritium from the landfill. In 2022 the amount of precipitation was at record highs and likely contributed to the presence of detectable tritium in some landfill wells.

6.3.1.3 Main Campus Wells

Samples were collected from the wells in the Whiteshell Main Campus areas during the spring and fall of 2023. The uranium, tritium, gross alpha and gross beta results are summarized in Table 44 in Appendix A. It should be noted that many Main Campus wells have low permeability and do not produce very much water. Those wells which do not produce enough water for sampling are not considered in this report. The general lack of water also restricts the number of analyses that can be performed. Since 2023 had less precipitation than normal the near surface clay zone wells did not have enough water for sampling. The main purposes of these wells were to contribute in the development of a hydrogeological model for the Whiteshell site and to provide background information on radioactivity in groundwater.

In 2023 the average gross beta activities in clay-till wells (0.77 Bq/L) was below the drinking water screening level (1 Bq/L). The average gross beta in basal wells (1.12 Bq/L) was slightly higher than the screening level. All of the wells from the bedrock have gross beta activities (with an average of 5.15 Bq/L) which are above the drinking water screening level. Table 44 in Appendix A shows that the high gross beta is associated with very high uranium concentrations in bedrock wells. The beta is not attributed to dissolved K-40 or Sr-90 in the groundwater. The exact source of the beta is not known, but is likely attributed to uranium decay series isotopes released from the host rock to groundwater.

Tritium activities measured in main campus wells in 2023 were close to or below detection levels. This is expected as the main campus wells are not close to a known tritium source.

In 2023 gross alpha activities in the main campus wells were well above the screening level of 0.5 Bq/L. Average gross alpha activities were 1.28 Bq/L in clay-till and 1.04 Bq/L in the basal zone. These alpha activities can be accounted for by the presence of natural uranium, with average concentrations of 62 µg/L in clay-till and 66 µg/L in the basal. The average gross alpha activity in bedrock of 30.6 Bq/L, with low and high activities of 5.5 and 75 Bq/L were significantly higher. The average uranium concentration of 367 µg/L accounts for about half the alpha activity. The alpha activities were measured after radon has had a chance to decay away, so the most likely source for the alpha is radium-226. Groundwater samples were not analyzed for radium-226 in 2020, but were in 2021. Radium-226 accounted for 5 percent of the total alpha activity. In 2023 radium-226 accounted for 6 to 14 percent of total alpha activity. There was no evidence of americium-241 in the groundwater. The poor mass balance between total alpha and measured alpha emitters in the sampled water is likely because the water does not represent the entire system, which includes the rock that contains uranium associated with mineral phases. Alpha emitting decay products with short half-lives are released to the mobile groundwater phase captured by sampling. In 2023 the highest bedrock groundwater uranium concentrations (820 and 886 ppb) were in well nest 2 located upstream of main campus. Downstream locations in well nest 4 and 7 had significantly lower uranium concentrations of 37 to 210 ppb. This indicates that the source of uranium is not anthropogenic.

6.3.2 Non-Radiological Monitoring Groundwater

Analysis of the groundwater for non-radiological parameters (chromium, copper, iron, lead, zinc, arsenic, mercury, nitrate, nitrite, ammonia, chloride, volatile organic compounds (including but not limited to, benzene, toluene, ethylbenzene, xylene, and acetone) and HB-40[42]) were conducted in 2022[43]. Samples were collected from the basal and bedrock zone wells of the WMA during the spring and fall. Samples were also collected from selected locations in the basal zone and water table of the Lagoon and Landfill area during the spring. The non-radiological data have been evaluated in the EAFP report [7]. The following discussion presents an overview of non-radiological contaminants in groundwater.

6.3.2.1 Waste Management Area

Review of the groundwater in the clay, clay-till, basal and bedrock zones of the WMA indicated that the level of chromium was below the associated MAC in Drinking Water of 0.05 mg/L [21]. The highest chromium concentrations were in the clay and clay-till. Copper concentrations were below the associated Aesthetic Objective (AO)[44] for copper (1.0 mg/L) [21]. The highest copper concentrations (average = 0.008 ± 0.003 mg/L) were in the clay zone. The concentration of iron in the groundwater of the WMA ranges from <0.005 to 4.10 mg/L. The average iron values in groundwater from the clay (0.20 ± 0.39 mg/L) were below the AO (0.3 mg/L), while the average iron values from the clay-till (0.63 ± 0.93 mg/L), basal (0.61 ± 1.00 mg/L) and

[42] The primary coolant feedstock for the WR-1 reactor was HB-40, also known as OS-84. Both HB-40 and OS-84 are product codes coined by Monsanto Chemical Company (now Solutia Inc.), the coolant supplier. These codes refer to a complex mixture of organic compounds often described as “partially hydrogenated terphenyls”.

[43] Analysis of magnesium, calcium and sulphate was performed on selected wells in the WMA as part of the Periodic Inspection Program. This data is discussed in the EAFP report [7].

[44] An Aesthetic Objective (AO) applies to certain substances or characteristics of drinking water that can affect its acceptance by consumers or interfere with practices for supplying good water. For certain parameters, both AOs and health-related guidelines (maximum acceptable concentrations) [21] have been derived. Only where AOs are specified, the values are below those considered to constitute a health hazard. This is the case for copper, iron, zinc, chloride and sulphate.

bedrock (0.91 ± 0.96 mg/L) were significantly higher than the AO. The high dissolved iron concentrations in the clay-till, basal and bedrock indicate the presence of low redox conditions. Concentrations of iron exceeding the AO are very common in Manitoba [48].

With the exception of BHS-500-80 (0.039 ± 0.004 mg/L) in the basal, all wells had a lead concentration below the associated MAC of 0.01mg/L [21]. The concentration of zinc in the samples ranged from < 0.005 to 0.025 mg/L, which is below the AO of 5 mg/L [21]. The zinc concentration was higher in the clay and clay-till compared to the basal and bedrock. The arsenic concentrations within the WMA groundwater wells ranged from < 0.0001 to 0.0021 mg/L, which were all under the MAC of 0.01 mg/L. Most mercury concentrations were below detection levels and all well below the MAC of 0.001 mg/L.

In 2023 there was no evidence for the presence of benzene, toluene, ethylbenzene, xylene, or HB40 (a hydrocarbon oil). Chloride was below its applicable AO of 250 mg/L. The levels in the wells were below the 10 mg/L MAC for nitrate [21] in all wells.

6.3.2.2 Lagoon and Landfill

Review of the Landfill groundwater indicated that the level of chromium ranged from <0.001 to 0.0097 mg/L, and all samples were below the associated MAC of 0.05 mg/L [21]. In 2019 the chromium concentration in well BHS 500-01 was determined to be 0.124 mg/L, whereas in 2020, 2021, 2022 and 2023 it was <0.001 mg/L. This confirms that a filtration issue had affected the 2019 result.

Copper concentrations ranged from <0.0003 to 0.006 mg/L which is below the associated AO for copper (1.0 mg/L) [21]. The concentration of iron in the groundwater ranged from <0.005 to 0.405 mg/L. There was one high sample above the AO (0.3 mg/L). Most concentrations of lead were below the detection limit of the method (0.0002 mg/L) and all were below the associated MAC of 0.01 mg/L [21]. The concentration of zinc in the samples was ranged from < 0.005 mg/L to 0.025 mg/L, which is well below the AO of 5 mg/L [21].

Arsenic concentrations in landfill wells ranged from < 0.0005 to 0.0186 mg/L. Wells in which arsenic concentrations are above the MAC of 0.010 mg/L include the basal Landfill wells BHS 500-1 (0.014 mg/L) and BHS 500-60 (0.0186 mg/L). Some areas of Manitoba are known to have groundwater concentrations of arsenic (ranging from 0.001 to 0.025 mg/L) which would naturally be over the drinking water guidelines [21]. The mercury levels were below the MAC of 0.001 mg/L, with all concentrations below the detection limit of 0.000002 mg/L.

Chloride was below its applicable AO of 250 mg/L, and the values for the wells were below the MAC for nitrate (10 mg/L) [21].

Analysis of non-radiological parameters of the lagoon groundwater is limited to the basal zone. Chloride concentrations in all wells were below their AO of 250 mg/L, and the water in all the wells in this area was below the MAC for nitrate (10 mg/L) [21]. Chromium concentrations were between < 0.005 and <0.0194 mg/L and all samples were below the associated MAC of 0.05 mg/L [21]. Copper concentrations were all <0.001 and 0.007 mg/L which are below the associated AO for copper (1.0 mg/L) [21]. The basal wells in the Lagoon had an average iron concentration of 0.74 ± 0.56 mg/L. These high iron concentrations suggest that groundwater in the basal unit was from low redox conditions. All lead, and most mercury concentrations were below their respective detection limits of 0.001, and 0.000002 mg/L. The one exception was well BHS 500-43 with 0.0000025 mg/L mercury. Zinc concentrations were all < 0.005 and below the AO of 5 mg/L [21].

Arsenic concentrations ranged from <0.0005 to 0.0013 mg/L, all below the MAC of 0.010 mg/L for arsenic.

6.4 Monitoring of Surface Water

6.4.1 Winnipeg River Water

Monthly composite samples of Winnipeg River water were collected from four locations: near Pinawa, about 17 km upstream of the Outfall; 2 km downstream at the WL boundary; 10 km downstream at the Lac du Bonnet water intake; and 28 km downstream at the Great Falls generating station (see Figure 22 in Appendix A). The Pinawa location serves as the background location for this data set. In 2023, the samples were analysed for tritium, strontium-90, gross beta, and gross alpha. In addition, the samples were submitted for gamma spectrometric analysis, which provided values for cesium-137 and potassium-40. The monthly results are shown in Table 37 to Table 40 in Appendix B. Data for 2013 to 2023, along with the previous five years' average values are shown in Table 14 and in Figure 7 to Figure 9.

The gross alpha activity in the samples at all locations continues to be at or near the lower limit of detection for the method (see Table 37 to Table 40 in Appendix B) and less than the average of previous five years. The upstream value (0.012 Bq/L) is similar to the downstream locations at the K-11 (0.012 Bq/L), Lac du Bonnet (0.010 Bq/L) and Great Falls Dam (0.012 Bq/L). These are lower than the established background value (0.050 Bq/L) and benchmark value (0.5 Bq/L) shown in Table 11.

The gross beta activity in the samples includes contributions from potassium-40, cesium-137 and strontium-90. The beta activity detected in 2023 at the upstream location (0.078 Bq/L), at K11 (0.058 Bq/L), at Lac du Bonnet (0.047 Bq/L) and at Great Falls (0.033 Bq/L) are not that different from their respective 2022 activities (0.057 Bq/L, 0.069 Bq/L, 0.047 Bq/L, 0.074 Bq/L). The gross beta activities sampled upstream, at K11, at Lac du Bonnet and at Great Falls, are less than the five year averages. Variations in gross beta activities seem to be accounted for mainly by the variations in potassium-40 levels. The gross beta activities are near the background value of 0.09 Bq/L but well below the screening level (1 Bq/L) for drinking water and the benchmark value of 5 Bq/L).

Potassium 40 activity (0.133 Bq/L) found at the upstream location is less than the 2022 value (0.158 Bq/L), but greater than the previous year's average. The levels seen at K-11 location are higher than those in 2022 and the previous five year average. Potassium-40 activity detected at Lac du Bonnet was greater than that in 2022 and the five year average. The levels reported at Great Falls Dam are greater than 2022 values and the five year average. They are above the background level (0.09 Bq/L). Potassium-40 is naturally occurring and not affected by WL's operation, and would be affected by suspended solids in the samples.

The cesium-137 activity found in the 2023 samples is similar to the 2022 values (Table 14) and below the background level (0.007 Bq/L). The strontium-90 activities found upstream were higher than in 2022, and the 2023 values at K11, Lac du Bonnet and Great Falls. Most strontium-90 activities were less than background levels (0.009 Bq/L) and well below the benchmark level (5 Bq/L). The river water results for 2023, and the previous five years, are consistent with the expected minimum impact from the liquid effluents from the WL site, reported in the WL Annual Compliance Monitoring Report [8].

The upstream values for anthropogenic parameters are compared with those of downstream locations in Figure 7, Figure 8 and Figure 9. The value for cesium-137 activity at the upstream location (0.003 Bq/L) is slightly lower than that of the downstream value at Great Falls (Table 14), suggesting a small impact on cesium-137 from WL discharges in 2023. In recent years the differences in upstream and downstream cesium-137 have been small and remained very small fractions of the benchmark values (Maximum Acceptable Concentrations (MACs) in drinking water specified by Health Canada [21]). The downstream activities of strontium-90 were not higher than the upstream activity. This suggests that there was no contribution to dose to downstream recipients from strontium-90 in 2022 (Table 52 in Appendix B). All downstream values are lower than established background values and benchmark values (Table 11).

Notes:

1. Uncertainties are expressed as the standard deviation for the average activities measured per month.
2. Method Detection Limit (MDL) are given in Table 11.
3. Maximum Acceptable Concentration in drinking water for strontium-90 and gross beta (as strontium-90) is 5.0 Bq/L, for cesium-137 is 10.0 Bq/L, for tritium is 7000 Bq/L, and for gross alpha (as total uranium) is 0.5 Bq/L [21]
4. Five year average

The tritium activities detected in the river water samples this year are shown in Table 14. They were all actually based on detection limit values and the error values given in the table are standard deviations of the reported detection limits. They are below background level (7 Bq/L). The tritium activity detected upstream was not significantly different than in downstream samples. The source of the upstream tritium was likely from the atmosphere. The values are well below the Maximum Acceptable Concentration (MAC) in drinking water (7000 Bq/L) [21].

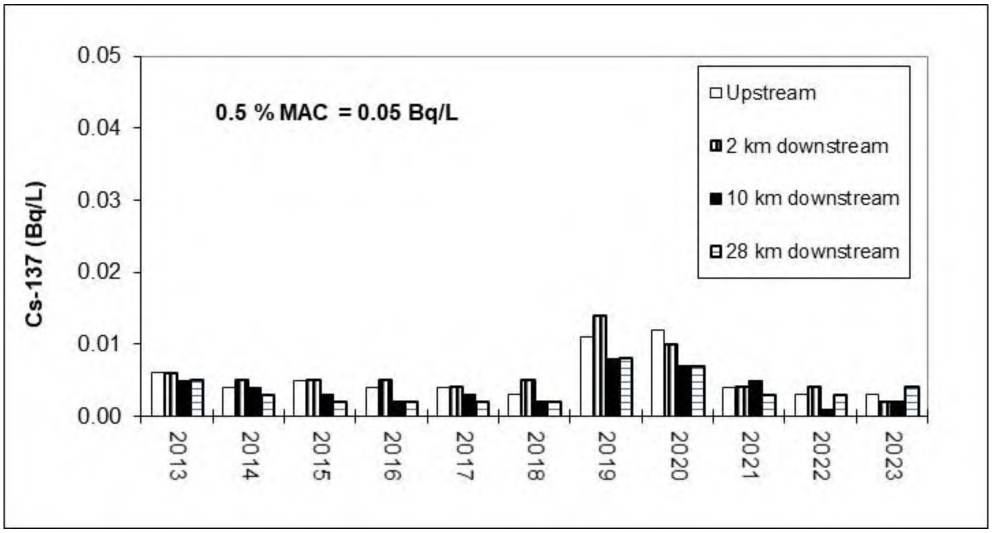

Figure 7: Cesium 137 in Winnipeg River Water, 2013 to 2023

The MAC for cesium-137 in drinking water, specified by Health Canada, is 10 Bq/L [21].

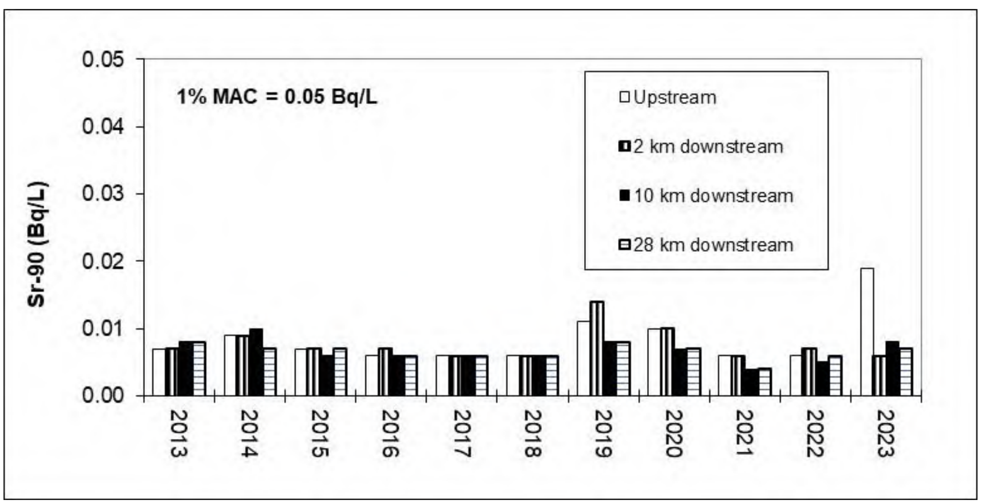

Figure 8: Strontium-90 in Winnipeg River Water, 2013 to 2023

The MAC for strontium-90 in drinking water, specified by Health Canada, is 5 Bq/L [21].

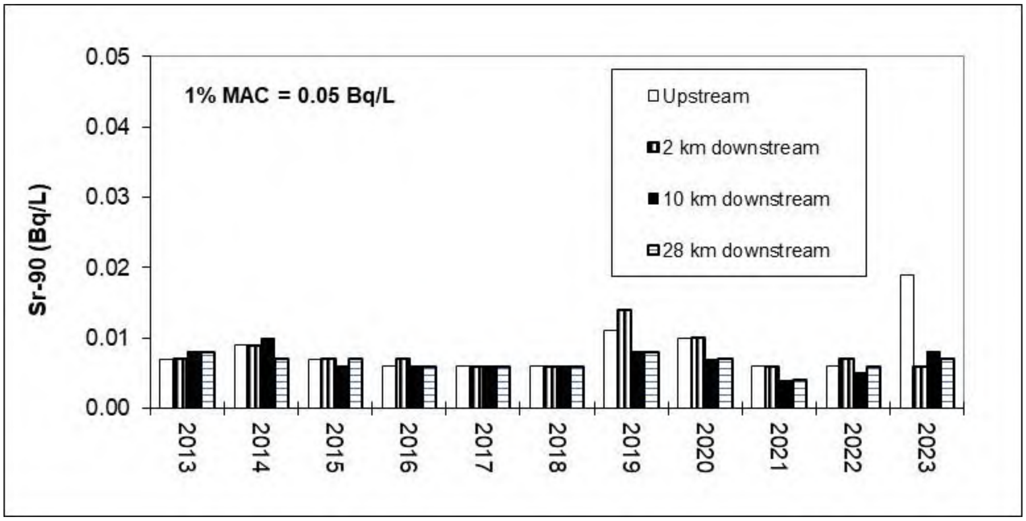

Figure 9: Gross Beta Activity in Winnipeg River Water, 2013 to 2023

The MAC for gross beta in drinking water (as strontium-90), specified by Health Canada, is 5 Bq/L [21].

Table 15 shows the mean, maximum, and minimum daily flow rates for 2013 to 2023 of the Winnipeg River, recorded by Manitoba Hydro at the Seven Sisters generating station, upstream of WL. The 2023 mean daily flow rate, at 615 m^3/s, was below the 2022 flow rate (1564 m^3/s) and the average of previous ten years (1015 m^3/s). The highest river flows in 2023 were from January through June, but then decreased to a relatively constant flow for the rest of the year, except for a small increase in December. River flow is monitored in support of the DRL model in use at WL, and a range of flow from 300 – 2500 m^3/s is typical for the area [46].

6.5 Airborne Contaminants

6.5.1 Radioactivity in Atmospheric Deposition at Pinawa

Monitoring of total wet and dry atmospheric deposits is primarily intended to serve as a gross trend indicator since it represents an intermediate step in environmental exposure pathways. It also serves as a baseline for emergency preparedness purposes and provides confirmation of the absence of significant quantities of radioactive particulate material in airborne emissions.

Deposition of radioactive material due to atmospheric precipitation was measured at the Pinawa town yard, located about 9 km east of WL and 2 km west of Pinawa (see Figure 22 in Appendix A). Rainfall was collected in a container lined with a plastic bag and mounted 1 m above ground. Snowfall was collected on aluminum sheets at ground level or in lined rainfall containers. Samples were analyzed monthly for gross beta, gross alpha, cesium-137, and potassium-40. Strontium-90 analysis was discontinued in 2020 because strontium-90 results were always below detection levels. The monthly average deposition in units of Becquerel per square meter (Bq/m^2) is shown in Table 16 for the years 2018 to 2023, along with the average for the past five years. The yearly data for gross alpha, gross beta, strontium-90, cesium-137 and potassium-40 is shown in Table 16 and Figure 10. The level of gross beta activity seen is less than that observed in 2022 and the average of the last five years. It is less than the established background level (14 Bq/m^2) and the benchmark level of 13 Bq/m^2, but less than the benchmark value of 17 Bq/m^2) in Table 11. The gross alpha activity is less than in 2022, the average of the last five years and the background level (2 Bq/m^2). The level of potassium-40 was less than observed in 2022 and the average of the last five years. It was less than the background level (12 Bq/m^2). The primary contributor to the gross beta activity continues to be potassium-40, a naturally occurring isotope. The activity of cesium-137 was less than in 2022 and the average of the past five years. It was similar to the background level (0.3 Bq/m^2). The variations in gross alpha, gross beta and potassium-40 from year to year are likely due to dusts that may have fallen into the lined containers. The higher than normal amount of precipitation may have resulted in an increase in atmospheric deposition of radioactivity. Some values are above background values, while all values are below established benchmark values Table 11. These values are consistent with normal background values reported for southern Ontario [49].

Table 16: Monthly Average Atmospheric Deposition of Radioactivity through Precipitation at Pinawa, 2018 to 2023

Monthly Average Deposition (Bq/m^2)								
	2018	2019	2020	2021	2022	Five-Year Average	MDL*	2023
Gross Beta	11.8	15.3	16.1	10.0	15.5	13.7	0.2	9.2 ± 3.6
Gross Alpha	1.6	3.7	3.5	1.5	2.5	2.5	0.3	1.8 ± 0.9
Strontium-90	0.2	0.3	ND	ND	ND	0.3	0.3	ND
Cesium-137	0.2	0.6	0.5	0.3	0.5	0.4	0.6	0.3 ± 0.06
Potassium-40	10.1	7.8	7.3	7.6	9.8	8.5	6	9.2 ± 3.7

Notes:

1. Uncertainties are expressed as the standard deviations of the average activity of the processed samples.
2. * The MDL values are consistent with Table 11
3. Strontium-90 analyses were discontinued in 2019 March since strontium-90 is always at detection levels.

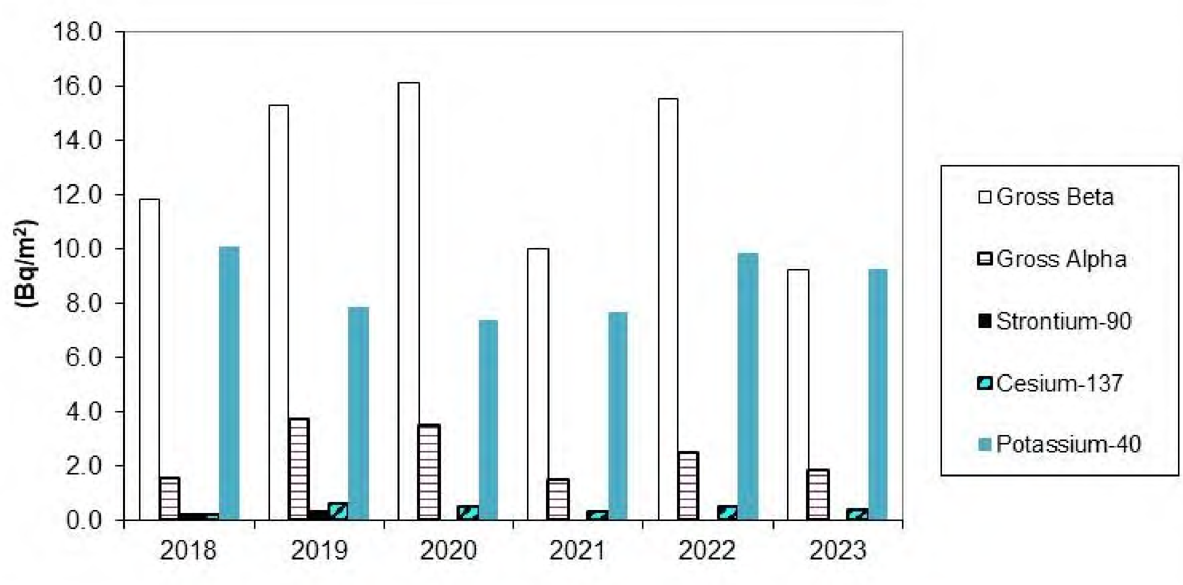

Figure 10: Monthly Average Deposition of Radioactivity through Precipitation at Pinawa, 2018 to 2023

6.5.2 Monitoring of Ambient Radiation in Air

The annual ambient gamma radiation at WL and the surrounding area is monitored by means of thermoluminescent lithium fluoride dosimeters (TLDs). The six Ambient Radiation Monitoring

Stations (ARMS) have been monitored since 1966. The locations of the ARMS are indicated on Figure 22 in Appendix A. Five of the ARMS stations are situated within 4 km of the Building 100 stack and are arranged according to the prevailing wind direction. The sixth is located near Pinawa, about 11 km to the east-southeast. Starting in 1986, TLD packages were mounted at various locations along the fence enclosing the WL site active area. Another series of TLD packages were installed in 1987 along the WMA fence, and in 1994 a series of TLDs were installed along the Canister Area fence. As mentioned in Section 1.1, this report does not cover results of environmental monitoring for operational control purposes within individual facilities. The results for the TLDs within the WL WMA and Canister area are to be included in the WL Annual Compliance Monitoring Report [8].

The TLDs are placed 1 m above the ground surface and continuously record gamma radiation over the calendar year.

These results and the average reading for the past five years, for locations along the WL controlled area fence, the WL perimeter and at Pinawa are shown in Table 17 in units of microgray per year (µGy/a). Please note that the ARMS #2 TLD location (east-southeast) is currently inaccessible. A TLD will not be deployed to that location in the future. Data from the Pinawa town yard will be used as the new east-south east location for ambient gamma radiation. Figure 11 shows the statistical means of the readings from the TLDs at the Controlled Area fence, Site Perimeter (ARMS), and Pinawa, respectively, for the years 2018 to 2023. The reported values include the gamma background caused by terrestrial and cosmic radiation. Land ambient gamma-radiation background measured as part of the preoperational environmental surveys for WL in 1964 was found to range from 2.1 to 3.6 nCi/kg h [24]. In air, this converts to 700 to 1,200 µGy/a, which is about the same as the current levels. This is as expected, since at present WL has no operating reactors or fuel processing experiments, and therefore no emissions of noble gases. Since the background and the readings are about the same, the background has not been subtracted from the readings. Levels of natural terrestrial background exposure can vary considerably at different locations at times, due to factors such as types of rock and soil, type and source of material used for building construction, building ventilation, depth of snow cover, and levels of soil moisture.

Data in Table 17 and Figure 11 show that average ambient gamma radiation at the perimeter and Pinawa locations has remained at levels below the background value of 1,200 µGy/a [50]. The locations along the fence of the controlled area have typically experienced radiation levels above preoperational levels. The TLD readings recorded for 2023 correspond to average ambient dose rates ranging from 2 to 5 µR/h[45] . These levels are a fraction of the maximum allowable level of 50 µR/h in a Radiation Zone 1 area. The 2023 results of the controlled area, Site Perimeter and Pinawa are all higher than 2022 and the average of the last five years. In 2018 the TLD outdoor packaging was modified and when the TLDs were recovered from the field it was noted that the packaging contained significant quantities of water/ice. This could have provided shielding or affected the TLDs, resulting in significantly lower gamma radiation readings, particularly for the Site Perimeter and Pinawa. In 2021, the TLDs started to be double

[45] One µR/h is equivalent to an observed dose rate in air (Air Kerma) of 10 nGy/h.

bagged and inspected twice to prevent water ingress in the TLD packaging. Sources of recorded ambient radiation are likely due to a combination of stack emissions from the facilities, and storage of nuclear material within the controlled area fence.

Notes:

1. Uncertainties are based on the standard deviations of 3 TLD measurements (Controlled Area Fence).
2. Natural background, caused by cosmic and terrestrial sources, has not been subtracted.
3. NA - Data not available because of vandalism, damage of TLDs or outlier.
4. *The values presented represent dose in air.

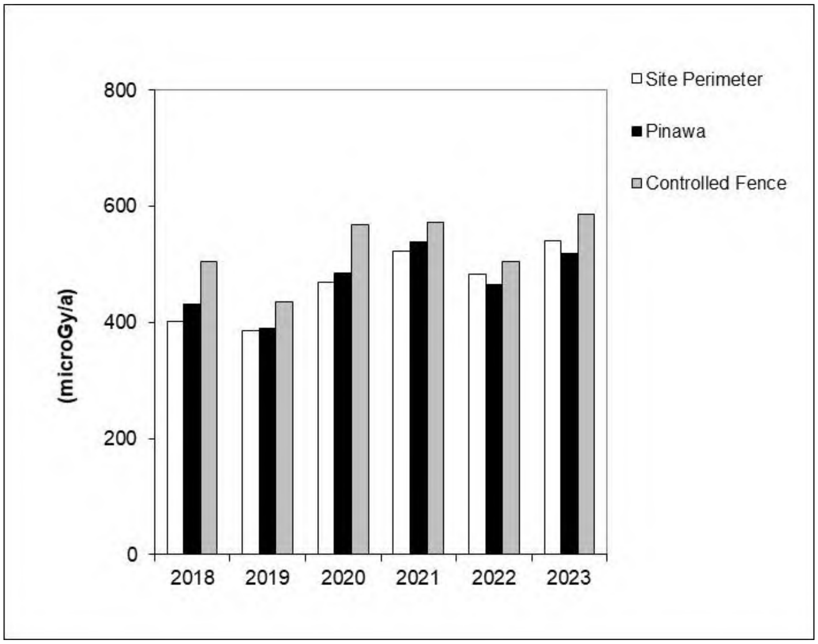

Figure 11: Ambient Gamma Radiation in Air at Whiteshell Laboratories and Vicinity, 2018 to 2023

6.5.3 Land Gamma Radiation

The dose rate due to ambient-gamma radiation was measured once in 2023 at control points on roads within a 16 km radius surrounding the WL site. The survey was done from a slowly moving vehicle, using a MicroSpec 3 gamma monitor. The survey is part of the terrestrial monitoring performed to provide verification that there has not been a build-up of radioactivity due to deposition of air emissions from the site. This monitoring serves primarily as a gross trend indicator providing, for example, baseline data for emergency preparedness and response purposes. It also provides an indication of radiation fields that may be emanating from buildings on site where radioactive materials are stored or processed. Results for 13 survey points in the off-site public area and 11 points within the WL site are shown in Table 18 . These locations are identified in Figure 22 in Appendix A. The 2023 results for off-site are slightly lower than 2022 dose rates. They were below the established background level (60 nSv/h). The higher dose rates at Building 923 were first noted in 2019 as work began involving the transfer of waste packages from Building 923. In 2021 there was an increased gamma dose on the south side of Buildings 200 and 411 due to the demolition of Building 200. This high dose was still observed in 2023 at a higher rate than in 2022.

The maximum values near operating facilities are higher than off-site locations indicating radiological activity on the ground level due to operations is localized to the site. The mean gamma dose rates are below benchmark value < 500 nSv/h and not of concern but provide useful baseline data.

Notes:

1. Uncertainty in measurements made using the MicroSpec 3 is estimated to be 30% (2 stdev). Values were measured in nSv/h. The detection limit for the instrument is approximately 10 nSv/h.

6.6 Monitoring of Food Stuff

6.6.1 Fish

During the fall of 2023 white sucker, walleye and pike were caught in the Winnipeg River at one location upstream of WL and two downstream locations. One Whitefish was also caught at a downstream location. The flesh was analyzed for gross beta activity and scanned by gamma spectroscopy, which provided values for cesium-137 and potassium-40. The downstream locations and the upstream Sylvia Lake location are marked on Figure 22 in Appendix A. All locations are part of the Winnipeg River system. The detailed results, including length, weight, and activity in Bq/kg fresh weight for eviscerated flesh, are given in Table 45, Table 46 and Table 47 in Appendix B. A summary of cesium-137, potassium-40, and gross beta activity in fish flesh is given in Table 19 for the years 2018 to 2023, along with the five-year average values.

The gross beta activity in all sample types collected for 2023 is mostly accounted for by potassium-40, a naturally occurring isotope. Figure 12 to Figure 15 and the values in Table 19 indicate that over the last five years, the cesium-137 activity in walleye, pike and whitefish only caught at the downstream locations was generally higher than that in upstream fish. The cesium-137 activity in white sucker collected from downstream locations tends to be similar to or less than that of upstream locations. In 2023 most cesium -137 activities are detection level values, with the exception of a walleye and a pike caught at the 5 km downstream location.

The average levels of cesium-137 in walleye (0.54 Bq/kg), white sucker (0.74 Bq/kg) and pike (0.25 Bq/kg) at the upstream location are slightly higher than those observed in 2022 and less than the five-year average for walleye (1.05 Bq/kg), sucker (0.89 Bq/kg) and pike (0.80 Bq/kg). This was because the contract lab produced better detection levels for cesium in 2022 and 2023. At the 0 to 2 km downstream location the cesium-137 activities in white sucker (0.42 Bq/kg), walleye (0.76 Bq/kg) and pike (0.29 Bq/kg) were lower than their respective five year averages (0.86, 0.99 and 1.00 Bq/kg). At the 5 km downstream location the cesium-137 activities in white sucker (0.48 Bq/kg) and walleye (0.68 Bq/kg) were lower than their respective five year averages (0.81 and 0.94 Bq/kg). The cesium-137 activity in pike (2.03 Bq/kg) was higher than the five year average (0.98 Bq/kg). In 2023 there was higher cesium-137 activity in downstream walleye and pike. White sucker had higher cesium-137 in the upstream sample.

If, for example, the level of cesium-137 activity was 1.50 Bq/kg fresh weight in fish it would result in a dose of ~ 4.4×10^{-6} mGy/d to the fish, which is well below the dose benchmark values of 400 µGy/h (9.6 mGy/d) for aquatic biota. It is also below the dose benchmark of 0.6 mGy/d recommended by the CNSC. Assessment of the maximum potential dose to members of the public from fish ingestion in 2023 indicates a small dose because there was a small difference between upstream and downstream cesium-137 in fish. Section 7 summarizes dose calculations attributed to the ingestion of food and water.

6.6.2 Wildlife within the Ambient Radiation Monitoring Stations of Whiteshell Laboratories

Road kills in the region covered by the Ambient Radiation Monitoring Stations (ARMS) of WL are normally collected and analysed for radioactivity. Locations of ARMS can be found in Figure 22 in Appendix A. The number of animals collected is dependent on the number of dead animals that WL staff are able to respond to upon notification. The flesh portion of each animal is sent to an external ISO 17025 accredited laboratory for analysis of gross alpha, gross beta, and gamma spectroscopy to measure the activity of a number of radionuclides, such as cesium-137 and potassium-40.

In 2023, one female deer was collected on the plant road.

Analyses of deer flesh for gross beta activity, cesium-137 and potassium-40 are summarized in Table 20. The gross beta value for deer collected in 2023 (93 Bq/kg) was less than for 2022 (106 Bq/kg) and the average for the previous three years (109 Bq/kg). The beta activity can be explained by naturally occurring potassium-40. The cesium-137 activity in 2023 deer (0.19 Bq/kg) was lower than the average for the previous three years (1.2 Bq/kg), and for 2022 (0.3 Bq/kg).

The background level of cesium-137 activity in deer flesh for the region is ~6.0 Bq/kg. A benchmark value of 33 Bq/kg is used to assess the cesium-137 results for deer within the vicinity of WL. The benchmark value is three times the geometric mean of cesium-137 activity found in deer outside the vicinity of WL for the period of 2001 to 2016. The cesium-137 activity (18 Bq/kg fresh weight) found in the deer would result in an incremental dose of ~ 0.0001 mGy/d to the deer, which is well below the dose benchmark values of 100 µGy/h (2.4 mGy/d) (United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) 2008) for terrestrial biota. It is also below the dose benchmark of 0.6 mGy/d recommended by the Canadian Nuclear Safety Commission. Section 7 assesses the role of game ingestion on doses to the public. The assessment for 2023 considered the difference between the cesium-137 activity in the 2023 deer sample (0.19 Bq/kg) and the background activity in deer for the area (6 Bq/kg).

CNL continues to make every effort to minimize the impact of Whiteshell Laboratories operations on local wildlife. All controlled areas are surrounded by security fences which help prevent wildlife from accessing affected areas. Air emissions are kept as low as reasonably achievable which reduces the effect of aerial deposition. Liquid effluent streams are monitored at several locations to identify any potential sources of emissions. The data is evaluated and remedial measures are taken as required.

In 2019 CNL began collecting local beef for analyses for radioactivity by a contract lab. The results of beef analyses from 2019 through 2023 are shown in Table 21. In previous years the cesium-137 activity was reported at detection levels. In 2023 an improvement in detection limits showed a detected cesium-137 activity of 0.3 Bq/kg. Radioactivity in beef flesh can be compared to that of deer flesh, as is done in Table 11. The background and benchmark values in Table 21 are the values for deer flesh discussed above. Since the cesium-137 activity was less than 6 Bq/kg there is no apparent dose to the public from consumption of local beef from CNL activities.

Table 20: Radioactivity in Deer within the ARMS of WL

Deer (Bq/kg)

6.6.3 Cultivated Vegetables

Radioactivity was measured in root and fruit type crops obtained from local gardens, each irrigated with Winnipeg River water. Tomatoes, squash and zucchini are considered fruit. The root vegetable category is the average of carrots, beets and potatoes. Lettuce and cabbage are used to represent leafy vegetables. The gardens are located either upstream or downstream of the Outfall. Analyses have been completed for gross alpha activity, gross beta activity, strontium-90, potassium-40, cesium-137 and beryllium-7 (Table 48 in Appendix B).

Radioactivity in cultivated vegetables, for the years 2018 to 2023, along with the five year average value are detailed in Table 22. Attainable detection limits vary with the size of sample provided and the contract lab performing the analyses.

The 2023 gross beta values for both upstream and downstream samples are mostly accounted for by potassium-40, which is a naturally occurring radionuclide. The gross beta activity in fruit type vegetables in upstream and downstream samples was 79 and 67 Bq/kg, respectively. The gross beta activities for root vegetables upstream and downstream are 148 and 116 Bq/kg, respectively. The trend for root vegetable data collected from 2018 until 2023 is illustrated in Figure 16.

As a result of improved detection limits, in 2023 gross alpha was detected in all samples and strontium-90 activities were detected at low levels in two upstream samples. In previous years high detection limits had presented an obstacle for properly interpreting the results of radioactivity in vegetables. In 2021 all but the downstream root sample the reported detection limits were too high by 2 orders of magnitude. As indicated by operational experience (see Table 11 and Table 22) detection limits of <100 Bq/kg reported in 2020 and 2021 do not reflect radioactivity in cultivated vegetables. The 2022 detection limits represent a return to acceptable values. Since the high detection limits do not represent radioactivity for certain radioisotopes, detection limits of >100 Bq/kg were excluded from average calculations for gross alpha, strontium-90, and cesium-137. Detection limits of >1000 Bq/kg were excluded from average calculations for potassium-40 and beryllium-7. A detection limit of <100 Bq/kg was not considered unreasonable for potassium-40.

In 2023 strontium-90 activity in upstream fruit (<0.06 Bq/kg), root vegetables (0.05 Bq/kg), and leafy vegetables (0.1 Bq/kg) was not significantly different from their respective downstream values of <0.06, <0.04 and <0.1 Bq/kg. Strontium-90 activities have been low over the past five years, and showed no statistical difference between the upstream and downstream locations. There was no persistent trend noted for root or fruit vegetables.

In 2023 cesium-137 activity in upstream fruit (<0.21 Bq/kg), root vegetables (<0.38 Bq/kg), and leafy vegetables (<0.47 Bq/kg) was not significantly different from their respective downstream values of <0.38, <0.35 and <0.47 Bq/kg. Cesium-137 activities have been low over the past five years, and showed no statistical difference between the upstream and downstream locations. There was no persistent trend noted for root or fruit vegetables.

Since there was no difference between upstream and downstream results for garden vegetables, the potential dose to members of the public from vegetable ingestion has been assessed to be nil in Section 7.3.3.

Organically Bound Tritium (OBT) and Tritium (HTO) were added as parameters for garden crop (fruit and root) in 2017 as they were identified as a potential pathway for human exposure (ingestion) via air and liquid emissions. In 2018 the tritium activities in all vegetables were below the method detection levels, which varied from 9.3 to 11.1 Bq/kg. Organically bound tritium was also below detection limits, which varied from 2.33 to 17.1 Bq/kg. Since the tritium activity in garden crop vegetables was below detection limit levels and benchmark values for native vegetation and garden crop (Table 11), and water ingestion is the dominant dose pathway, tritium analysis of garden crop vegetables was discontinued in 2019. Tritium analyses resumed in 2023 to obtain data for a longer time frame to ensure tritium remains below detection.

The respective HTO activities in upstream fruit, root vegetables and leafy vegetables were 16.1, < 10 and 0.69 Bq/kg. In downstream vegetables the respective HTO activities in fruit, root vegetables and leafy vegetables were < 4.6, 38.6 and 29.3 Bq/kg. OBT was below detection in most samples. The respective OBT values for upstream fruit, root vegetables and leafy vegetables were <7.7, <7.0 and 7.64 Bq/kg. Downstream respective OBT values for fruit, root vegetables and leafy vegetables were <6.2, <3.9 and <6.6 Bq/kg.

6.6.4 Wild Food

In 2023, sampling and analyses were performed for wild food which included local source honey, mushrooms, blueberries and wild rice. Results are summarized in Table 23. In 2023 the local honey was obtained from River Hill's Apiary, located approximately 12 km south of the WL site. The wild rice was purchased at a local market. The mushrooms were collected from three locations within a 17 km radius of the Whiteshell Main Campus. The south east location was within the Whiteshell Provincial Park at a distance of 15 km. The north east location, at a distance of 17 km, was situated near the site of the former Underground Research Laboratory. The north west location was on Provincial Highway 214, at a distance of 5 km. The blueberries were collected at the site of the former Underground Research Laboratory with assistance from members of the Black River First Nation.

The analysis for HTO and OBT in wild foods had been discontinued because previous year's results were below detection and well below benchmark values. However, analysis for HTO and OBT resumed in 2023 to obtain data over a sufficient time period to confirm that tritium does not need to be analyzed. The honey had a gross beta activity below the detection level of <335 Bq/kg. Gross Beta activity can normally be accounted for by potassium-40 activity, but in this case the detection level of gross beta was too high to make any useful comparisons with potassium-40 activity. The gross alpha, strontium-90 and cesium-137 activities were below their respective detection limits of <141 Bq/kg, <8 Bq/kg and <0.37 Bq/kg. The wild rice had a gross alpha activity less than the detection limit. The gross beta activity in wild rice was 231 ± 45 Bq/kg. Gross alpha, and strontium -90 were below detection limits in wild rice. Cesium-137 in wild rice was 0.55 ± 1.6 Bq/kg. The OBT was 20 ± 2 Bq/kg, while the sample was too dry for an HTO measurement. Blueberries had a gross beta activity of 27.8 ± 5.6 Bq/kg and a gross alpha of 1.12 ± 0.2 Bq/kg. The gross beta activity is accounted for by postasium-40. The activity of cesium-137 was < 0.47 Bq/kg in blueberries. The activity of strontium-90 was 0.2 ± 0.04 Bq/kg. Since this was only the second year of sampling for blueberries, CNL does not have background values for radioactivity in local blueberries.

The mushroom harvest did not differentiate on species type and included all mushroom varieties present. The beryllium-7 activities in mushrooms were below detection. The gross beta activities were similar in the south-east and north-west, and lower in the north-east. Potassium-40 accounted for most of the beta activity. The respective strontium -90 activities in the south-east, north-east and north-west locations were 0.7 ± 0.2, 0.9 ± 0.2, and 0.3 ± 00, Bq/kg. Cesium-137 was about ten times higher in the north-west sample compared to the south-east and north-east samples, which had respective activities of < 0.45 and 2.03 ± 0.045 Bq/kg. In 2019 and 2021 the north-west sample also had the higher cesium-137. In 2022 the north-east samples had the highest cesium-137. The HTO activity in the south-east mushrooms was 34.5 Bq/kg. The HTO in the other locations and the OBT activities in all locations were below detection.

The Cs-137 activity in mushrooms reflects the activity in the soil organic layer, and depends on the mushroom species that were collected. In the current sampling program no attempt was made to select particular mushroom species because of the need to collect 1 kg samples. Since the samples represent a mixture of mushroom species, the variation in results could reflect the variation in mushroom species. The south east and north east locations represent typical boreal settings, while the north-west location is on Milner ridge, a sandier and drier setting that used to be a sand bar on the shore of post glacial lake Agassiz. The mushrooms collected here had a different distribution of species compared to the other two locations. The sample date within the growing season may also influence the types of mushrooms species collected. Since the mushroom samples represent a mixture of different species we do not have usable BV values at this time. It is CNL's plan to refine mushroom sampling in the future in an attempt to focus on certain mushroom species.

For most parameters, the BV value is based on 3 times the geometric mean of 2001 to 2016 data. These values are given in Table 11. The monitoring of honey and mushrooms has recently begun, and their BV have not been included in Table 11 since their monitoring period has been too short to determine BV values. For the case of tritium in honey, BV values for honey were taken from 1) CNSC, Recommendations from the Tritium Studies Synthesis Report, 2019 January [34], and 2) Derived Release Limits for CNL's Whiteshell Laboratories, WL-509211-RRD-001, 2021 [9].

Notes:

1. Activities are reported per fresh weight.
2. For security improvement and fire control, the soil and vegetation was removed from the area just outside the WMA fence and replaced with gravel.

LLD = Lower Limit of Detection.
NR = Not Reported by contract lab.
NA = Not Available

6.7 Monitoring of Native Vegetation and Soil

6.7.1 Native Vegetation

Terrestrial vegetation samples consisting of mixed grasses, weeds, and clover are collected at a mature growth stage in the fall. The vegetation from an area of several m^2 are processed. The resulting ash is submitted for gross beta and gross alpha counting, as well as gamma spectroscopy. The vegetation is cut to ensure that soil and root material are not included in the sample. The results for native vegetation for 2023 are provided in Table 49 in Appendix B. Figure 22 in Appendix A shows the locations of the ARMS stations, and Figure 23 (Appendix A) shows the sample locations near the WMA. The data for the period of 2018 to 2023 along with the five-year average values are shown in Table 24.

As stated in previous reports, no trends are evident at the ARMS sampling locations. The gross beta activity[46] is mostly accounted for by the potassium-40. In all cases gross beta results for 2023 are lower than in 2022 and the 5 year averages. As mentioned previously potassium-40 is a naturally occurring isotope and is present in all soil and vegetation samples.

The alpha activities for most samples were lower than in 2022 and the averages of the previous five years. The one exception is the sample from location WMA#1.

With the exception of ARMS#8 (0.8 Bq/kg) the cesium-137 activity in all locations was below the detection limit, which varied from 0.2 to 0.8 Bq/kg. The background level for cesium-137 is 4.0 Bq/kg [51], [52] for this part of Manitoba. The cesium-137 results for 2023 are lower than previous years due to improved detection limits, and well below the benchmark value of 21 Bq/kg.

Low activities of strontium-90 were detected in most ARMS samples. In WMA#1 and WMA#7 strontium-90 was less than in 2022 and the average of the previous five years. Potassium-40 was less than the average of the previous five years. The gross beta was also lower than the average of the previous five years for all locations, which is expected since potassium-40 accounts for gross beta.

The presence of any low levels of strontium-90 activity in the native vegetation at the ARMS locations are likely the result of aerial deposition from current and historical site structures.

Analysis for OBT and HTO resumed in 2023. The HTO activities varied from <3 to 14 Bq/kg. The OBT activities varied from <6 to 23 Bq/kg. The highest OBT was from location ARMS#4.

As mentioned in Section 1.1, this report does not cover results of environmental monitoring for operational control purposes within individual facilities. The results for additional vegetation sampling within the WL WMA are included in the WL Annual Compliance Monitoring Report [8].

[46] In 2015 potassium-40 was once again used to establish the beta efficiency of the detectors.

6.7.2 Soil

A summary of the radioactivity found in the surface soils collected in 2023 at the perimeter locations [53] of Standpipe Rows E, F, and G in the WMA are given in Table 50 in Appendix B.

The alpha activities observed in the 2023 samples ranged from 0.07 to 0.22 Bq/g, and in all cases were well below the benchmark for WMA soils (100 Bq/g). There was no indication of the presence of americium-241 or plutonium isotopes. The alpha activity is most likely from naturally occurring alpha emitters such as uranium and thorium present in the soil. All samples were below the Nuclear Substance and Radiation Devices Regulation (NSRDR) Clearance Level of 1.0 Bq/g [54] for radionuclides of natural origin. Except for one sample at Location E (1.77 Bq/g), the strontium-90 activities for the surface soils at the perimeter locations were below the NSRDR Clearance Level of 1.0 Bq/g [54], and well below the benchmark of 2000 Bq/g. Cesium 137 activity at the perimeter locations (0.001-0.051 Bq/g) are similar to the normal background levels for cesium-137 (0.02 to 0.11 Bq/g [40] for this part of Manitoba, and at the NSRDR Clearance Level of 0.1 Bq/g [54]. The activity is well below the benchmark value of 0.8 Bq/g. Radioactivity assaying of groundwater (from routine environmental monitoring), and the soil assays from this study indicate there is no significant radioactive migration from the waste management facilities.

Remediation of the soil near the standpipes will be conducted in accordance with the Comprehensive Study Report [55] in which it was stated that management plans for the contaminated soils near the standpipes will be prepared and documented as part of the Detailed Decommissioning Plan. Progress on this work is reported in the WL Annual Compliance Monitoring Report [8].

6.8 Monitoring of River Sediment

River bottom sediments were collected from 12 locations along the Winnipeg River, ranging from 0.8 km upstream to 13.1 km downstream of the Outfall (see Figure 22 in Appendix A). Three samples, each consisting of the top centimeter of the sediment were collected using a coring tool at each location, and the average and standard deviation of the three readings for each location have been recorded. The core diameters were 2.8 cm, giving a sampled river bottom area of 6.2 cm^2. Table 25, Table 26, Table 27 and Table 28 show the gross alpha, gross beta, potassium-40, and cesium-137 activities (in Bq/kg dry weight) of the river-bottom sediments from the 12 locations along the Winnipeg River for the years 2018 to 2023, along with the corresponding five-year average. Table 51 in Appendix B shows the distance from shore, the depth of water at each sampling site, and the weights of each of the three samples collected at every site.

In 2023, the gross alpha activity detected in the samples ranged from 180 Bq/kg to 677 Bq/kg. The alpha activity in these samples is due to naturally occurring isotopes such as U-238 or Th-232 and their progeny, as both upstream and downstream samples contain similar levels. In addition, gamma spectrometry of the samples confirmed the presence of uranium and thorium progeny. All samples are below the NSRDR Clearance Level of 1,000 Bq/kg [54] for sediments of natural origin. The background value for gross alpha is 600 Bq/kg and the benchmark value for gross alpha is 2E+05 Bq/kg, or 1000 Bq/kg as natural uranium (Table 11).

The gross beta activity in the sediment includes contributions from naturally occurring potassium-40 and from cesium-137. The majority of the beta activity for all locations is most likely from naturally occurring potassium-40. The gross beta activities measured in 2023 ranged from 413 to 1697 Bq/kg and for 8 out 12 cases were higher than observed in 2022 and the averages of the previous 5 years, with no trends being observed. The sum of cesium-137 and potassium-40 activities were equivalent with gross beta activities, taking into account the sum of the uncertainties of the cesium-137 and potassium-40 values. Any beta activity in excess of cesium-137 and potassium-40 activities would be assumed to be strontium-90/Y-90. Most gross beta activities were below the natural background of 900 Bq/kg and all well below the benchmark value of 2E+04 Bq/kg (Table 11).

All cesium-137 activity levels were below the lower limit of detection of 10 Bq/kg and below the five year average values. All samples collected in 2023 were below the NSRDR Clearance Level of 100 Bq/kg [54] and well below the benchmark value of 1E+05 Bq/kg (Table 11). The activity at the OFL location has historically varied from < 5 Bq/kg to 75500 Bq/kg [55]. Variation of activity is not unexpected for all samples due to the highly localized and spotty nature of the contamination in the river sediments. This year to year variability can be seen for OFL, K01, K03 and K05 in Table 28 . Sample collection is difficult as the river bottom has a rocky bottom exposed at the sampling locations due to the erosion created by the river current. The results from the sampling location are plotted in Figure 17. An attempt will be made in 2024 to lower the detection limits of cesium-137 and potassium-40 by collecting larger amounts of sediment. On-going evaluation of the river sediments is covered by the Environmental Assessment Follow-up Program [1] for the Whiteshell Site. Dose estimates to critical group members were not calculated for exposure to river bottom sediments since it is highly unlikely that a person would be exposed through this route.

Table 25: Gross Alpha Activity in Winnipeg River Sediments, 2018 to 2023

Location Code and Distance from Outfall (km)		Gross Alpha (Bq/kg dry weight)								
		2018	2019	2020	2021	2022	Five-Year Average	2023		
J04	-0.76 (upstream)	224	467	467	333	127	324	310	±	89

6.9 Biodiversity

As a federal land owner, CNL is committed, and has legal obligations, to protect the environment and maintain the goal of sustainable development. CNL has the obligation to conduct environmental reviews of the impact of its operations with special consideration given to a sub-set of environmental values that have been identified as sensitive and important to the scientific and local communities, also known as valued ecosystem components (VECs). Among the list of VECs present at WL, species at risk and their habitat, along with other not-at-risk species have been identified as important. In order to fulfill legal and operational requirements, CNL continues to monitor species at risk in an effort to understand species distribution and abundance throughout the site.

In 2023, monitoring included identifying all nesting bird species on WL buildings, site infrastructure and lands. Much of the work completed in 2023 was done to increase knowledge of biodiversity and support the proposed WR-1 project. In addition, knowledge gained enhances the Species at Risk awareness program and supports compliance related to decommissioning activities on the site. During 2023, there was one wildlife mortality, a White-tailed deer, on the plant road. There were no mortalities of species at risk.

Nest Identification Survey

In the summer of 2023, avian management took place during the migratory bird breeding window from the beginning of April to the end of August. Nesting Birds were documented in the wildlife tracking spreadsheet. The following information was gathered: the observation date; the status, number of and type of species occupying the nest; the location and status of the nest; the surroundings of the nest; and if eggs, hatchlings or fledglings were present. A notification e-mail would be sent to the building/area owner and a barricade would be erected with signage to notify staff of the active nest.

During the bird breeding season, one species at risk (Barn swallow) and several migratory bird species were found nesting on the Whiteshell site - Eastern phoebe, American robin, Killdeer, Cliff swallow, Tree swallow and Sandhill Cranes.

Bat Surveys

In 2014, Canada released an emergency order for the listing of small bodied bat species that hibernate in caves to Schedule 1 of the Species at Risk Act (SARA). At that time, these bat populations began to see a dramatic decline due to White Nose Syndrome (WNS). Manitoba is home to 6 different bat species, two of which are listed as ‘endangered’ on Schedule 1 of SARA: Little Brown Myotis (*Myotis lucifugus*) and Northern Myotis (*Myotis septentrionalis*).

As defined in the SARA, individual bats are protected under sub-section 32 and it is prohibited to damage or destroy their residence as per sub-section 33. A residence is defined by the Act as a dwelling-place that is occupied or habitually occupied by one or more individuals during all or part of their life cycles, including breeding, rearing, staging, wintering, feeding or hibernating. For bats species, both roosting and overwinter habitat are considered a residence and afforded protection under sub-section 33 of SARA.

Due to the listing of these bats, CNL conducted an assessment to determine if any of its operations would have an impact on these species. It was concluded that buildings such as the WR-1 reactor building that are scheduled for decommissioning should be assessed to determine if their removal would impact any bat species that could be using the facility.

Monitoring for bat roosting at WR-1 is an important commitment of the Environmental Impact Statement (EIS) for the proposed in-situ decommission of WR-1. If bats are confirmed to be using the WR-1 structure as habitat through pre-disturbance surveys, offsetting potential habitat loss in the form of bat boxes may be required when WR-1 is decommissioned.

In 2023, two exit surveys in July and August were conducted around WR-1. No bats were observed exiting the WR-1 Building. However, some bird species were noted to be using core holes into building 100. The holes were made to execute work for the islanding project, and personnel were contacted to ensure that the holes were capped on the inside to prevent wildlife from obtaining a pathway into the building.

Bats were detected and recorded on the outdoor passive and active acoustic recorders in July and August. The data was analyzed using Kaleidoscope Pro Analysis software. The software analyses the recorded echolocations and automatically identifies the bat species present. In July and August three species were identified: the Hoary, Silver Haired and Big Brown Bats. These are migratory species of bats. No bats that are protected by the Species at Risk Act were detected during the studies.

Over two summers of exit surveys in which a total of four exit surveys were conducted, no bats were observed exiting the facility, including no species at risk bats However, if the building was being used as a maternity roost or roosting location for a large number of bats it would be more easily observed. Due to the lack of visual confirmation of bats exiting the facility and the timing and frequency of the calls recorded, it is believed that the WR-1 building is not currently being used as roosting habitat. In addition, a 2023 inspection was planned to be conducted to investigate internal spaces of WR-1. However, this work was not completed due to a safety stand down. This work will need to be planned in 2024.

Turtle Study

The two turtle species at the WL site and surrounding forested areas are the snapping turtle (*C. serpentina*) and the western painted turtle (*C. marginata bellii*). In the summer of 2023, a turtle search was performed on site once a week from May 16th to August 31st by driving along both sides of the Waste Management Area access road, Landfill road, Lagoon loop, Plant road and the road to B902. The road to B902 was added this year due to its proximity to the Winnipeg River and potential for nesting. The original four roads were selected due to their high volume of traffic. All five roads were surveyed each time the survey was performed. If a turtle was found during the survey, the following information was gathered: the species of turtle, its location, general condition, and activity. No turtle mortalities were found on any of the surveyed roads.

Both species of turtles were found on the Whiteshell grounds in 2023 either through road surveys or chance observations. There is a likelihood for these turtles to cross the road as there are dugouts' on either side of the road.

6.9.1 Site Permits

A Scientific Collection Permit: 67580134 was obtained for Fish collection activities. A Wildlife Scientific Permit: WB26588 for roadkill collection, valid from 2023 through 2028 was also obtained. A beaver dam removal and wildlife kill permit (beaver) were obtained to clear beaver activity from the main drainage ditch discharging to the river (near ditch sample location 9).

6.10 Incorporation of Culturally Important Plants

Canadian Nuclear Laboratories is committed to the incorporation of culturally important plants as a Valued Component (VC) into the Environmental Monitoring Program. Culturally important VCs include medicines and foods consisting of plants and fungus. To make this happen CNL needs to understand which plants and fungus are of cultural interest, where should they be sampled and can they be found in sufficient quantity (~2 kg) to be suitable for analyses.

To this end a walk down of areas of the WL site was previously performed in 2022 September with Indigenous elders to identify the presence of plants that are of interest for providing a source of traditional medicine and food. This knowledge is intended to help CNL's understanding of the value of the WL site as a potential source of traditional plants. In addition it will be used to enhance WL's Environmental Monitoring program by including selected plants to determine whether traditional plants harvested from the WL site are safe to eat, and to quantify the limit of any contamination that might have spread from the site.

Due to the safety stand down, no follow up walk downs were performed in 2023.

7. Assessment of Doses to the Public

7.1 General

Section 7.2 examines and assesses the radiation doses for 2023, due to emissions from the WL site. The doses calculated are to the most exposed off site members of the public (i.e., critical groups) as identified in the WL DRL document [9] for the site. Critical groups are an identifiable, relatively homogeneous group of members of the public who, as a result of their location, age, diet and habits, are representative of those people expected to receive the highest radiation doses as a result of emissions of a given radionuclide from a given source. The potential critical groups which have been identified for the WL site are shown in Table 29 and Figure 18.

Table 29: Potential Critical Groups for Whiteshell Laboratories

Air Effluent Critical Groups	Liquid Effluent Critical Groups
Farms A, D, F	Farm A
Farm E	

Dose calculations are performed for a hypothetical adult and 3-month old infant, using the results of environmental monitoring at and around critical group locations, for air effluent and liquid effluent exposure pathways. The characteristics assigned to these individuals are conservative such that the doses calculated are expected to be higher than the maximum dose that might be measured for any actual individual.

The dose assessments are based on the results of environmental monitoring of the dominant environmental pathways leading to critical group dose, where the monitoring indicates an actual or potential contribution from CNL above normal background.

Dose conversion factors for calculating effective dose from ingestion, or exposure to surfaces contaminated by radionuclides are consistent with the WL DRL document [9].

For comparison with the dose estimates below, the current regulatory limit of effective dose to members of the public from human activities involving ionizing radiation (excluding medical diagnostic or treatment procedures) is 1 mSv/a. Average values for annual background doses to adults from natural sources of radiation and from medical diagnostic procedures, reported by the National Council on Radiation Protection and Measurement (NCRP) [50] and the United Nations Scientific Committee on the Effects of Atomic Radiation (UNSCEAR) [52] are given in Table 30. Actual background doses can vary considerably at different locations and different countries (one or more orders of magnitude) depending on various factors such as elevation above sea level, local geology, and housing construction.

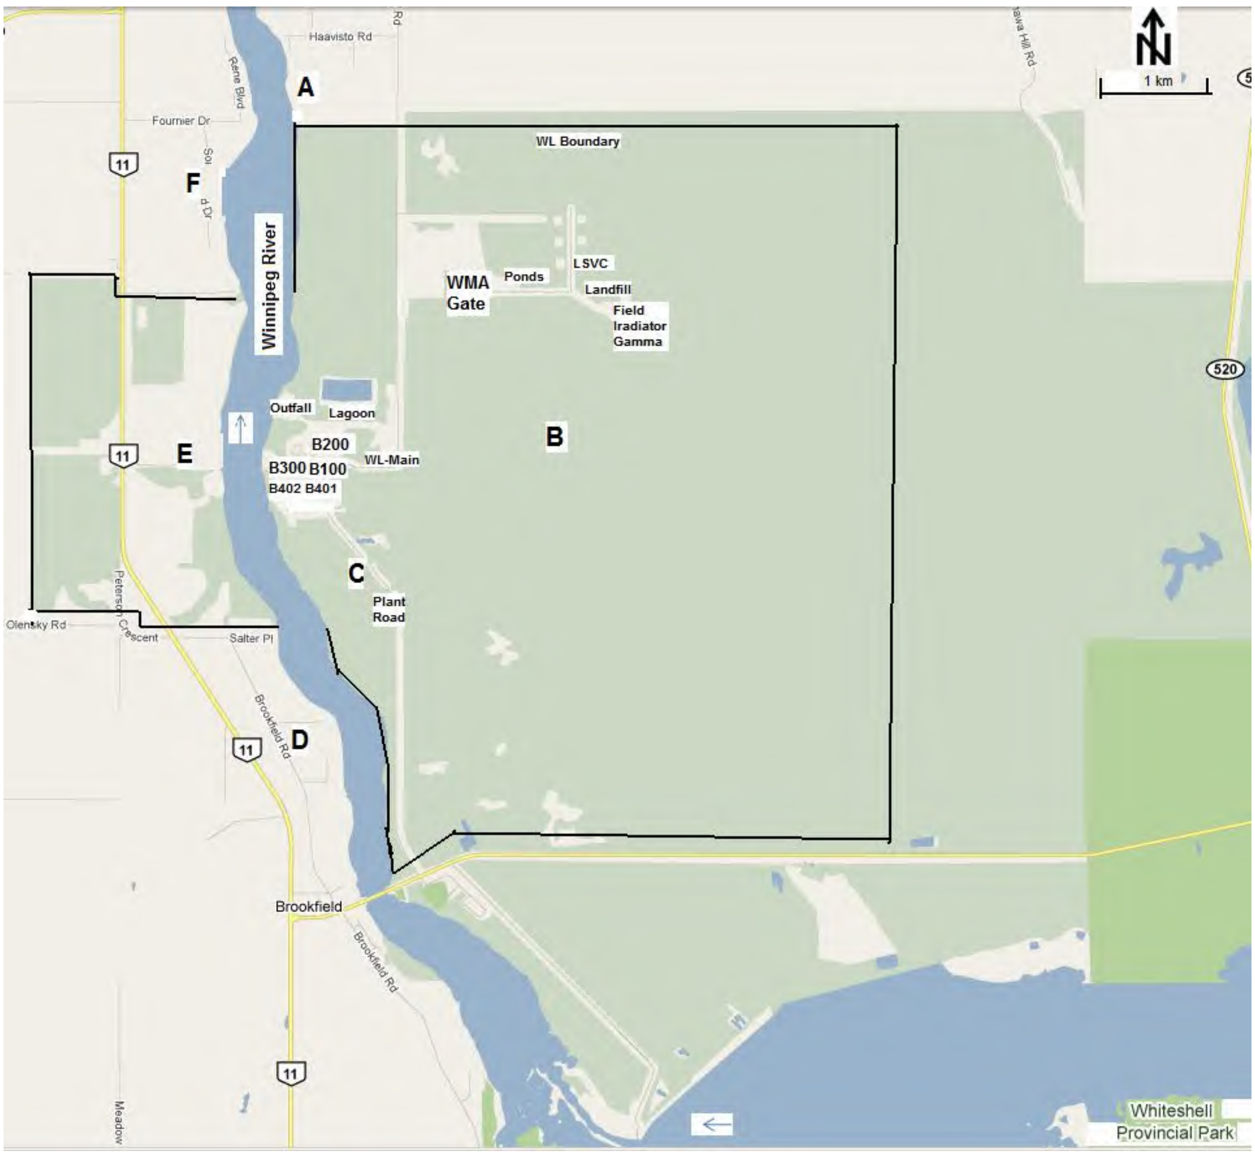

Figure 18: Map of WL Site Showing Location of Farm A, D, E and F

Table 30: Typical Annual Average Doses from Natural Background, Medical Diagnostics, and Consumer Products

Source of Exposure	Annual Average Effective Dose (mSv)
Natural Sources:	
• Cosmic Radiation (Canada) [56]	0.39
• Terrestrial Gamma Radiation (Canada) [56]	0.23
• Radionuclides in the Body (Except Radon) (Worldwide) [56]	0.30
• Radon and its Decay Products (Worldwide) [56]	1.30
Consumer Products and Services (Worldwide) [57]	0.025 to 0.095
Medical Diagnostic Procedures (Industrialized Countries) [57]	1.1
Total Dose (Natural Sources Plus Medical Procedures Plus Consumer Products and Services)	**3.3**

The general equation used for calculating dose due to nuclide n is;

Equation 1:

$$Dose\left(nuclide\ \ n\right) \;=\; C(n)\cdot DCF\ \cdot I\cdot G$$

where:

C(n) = incremental concentration of nuclide n (Bq/L or Bq/kg),

DCF = dose conversion factor,

I = consumption rate (L/a or kg/a), and

G = fraction from local sources (unitless).

Units vary according to the case being considered. Ingestion DCFs are consistent with those used in the WL DRL document [9]. These can also be found in International Commission on Radiological Protection (ICRP) 72 [57] and the Health Canada publication [58], respectively. Dose calculations are described in the following sections, and the calculation steps are shown in Table 52 in Appendix B.

Another factor that can be considered is an adjustment factor to take into account for the effects of food processing. Equation 1 was modified by adding a unitless food processing factor (*ρ)* to make Equation 2 below.

Equation 2:

$$Dose\left(nuclide\ \ n\right) \;=\; C(n)\cdot \rho\cdot DCF\ \cdot I\cdot G$$

where:

ρ = adjustment factor for food processing (unitless)

7.2 Whiteshell Laboratories Air Effluent Exposure Pathways

7.2.1 Air Effluents Exposure Pathways

The DRL model for WL identifies four potential critical groups for airborne effluents [9]. Farms A, D and F have year-round occupants and raise livestock. Farm E has limited occupancy and raises canola.

Dose for all air emissions pathways was estimated by multiplying the WL total air release (Table 6), as a fraction of the DRL, by 1 mSv. This value, along with those calculated for 2017 to 2022, are included in Table 1.

The pathways included in the dose assessment for airborne effluents (Figure 19) are those that have the potential to contribute significantly to dose from exposure to the radionuclides above background levels. They include ingestion of game animal meat. Other radionuclides and exposure pathways that may result in negligible doses to members of the public were not included in the dose assessment.

7.2.2 Ingestion of Game Animal (Deer, Grouse) Meat

The ingestion of game animal meat is a dominant pathway for airborne effluent scenarios [9] for exposure to cesium-137 (part of gross beta) which is potentially present in WL effluent. The annual dose to critical groups was estimated from the average measured radioactivity in game animal meat (e.g., deer, grouse) obtained from within about 25 km of the WL site, including animals from the site itself. The values used in the dose calculations represent averages of samples collected during the past three years. Since there are few samples obtained in one year, using a three-year average provides a larger data set from which a more realistic dose estimate can be calculated. The contributions from WL were obtained by subtracting the average concentrations in large game animals collected from locations greater than 25 km away from the WL site, from the average concentrations in animals collected from within 25 km of the site.

The annual effective dose to members of the Farm A critical groups from ingestion of large game animal meat was estimated using Equation 2 above, and the total dose is presented in Table 31. A deer meat consumption rate of 34 kg per year for adults and 6.1 kg per year for 3-month old infants was used in dose calculations [9]. The calculated dose is based on the assumption that 100% of the deer meat consumed by members of the critical group is contaminated, and that the effect of food processing on radioactivity in the meat is negligible. In 2023 the calculated dose from the ingestion of large game animals is nil because the difference in background concentrations in animals close to the WL site and further away is zero and therefore no dose is expected due to WL operations.

7.2.3 Ingestion of Garden Produce

The determination of dose received from the ingestion of garden produce in 2023 and previous years has focused on the dose received from waterborne effluents. The calculated dose was based on comparing the radioactivity in vegetables grown downstream from that in vegetables grown upstream. This does not address any doses received from airborne effluents. To address doses from airborne effluents one needs to compare the activity in local vegetables with that in vegetables grown at a distance of more than 50 km from the Whiteshell site.

As part of an investigative study, in 2024 vegetables will be obtained from one or more locations that are more than 50 km from the Whiteshell site. The activity from these vegetables will serve as the basis for establishing background radioactivity that has not been influenced by airborne effluents from Whiteshell. The results of this study will be reported in Section 7.2.3 of the WL Environmental Monitoring Report for 2024.

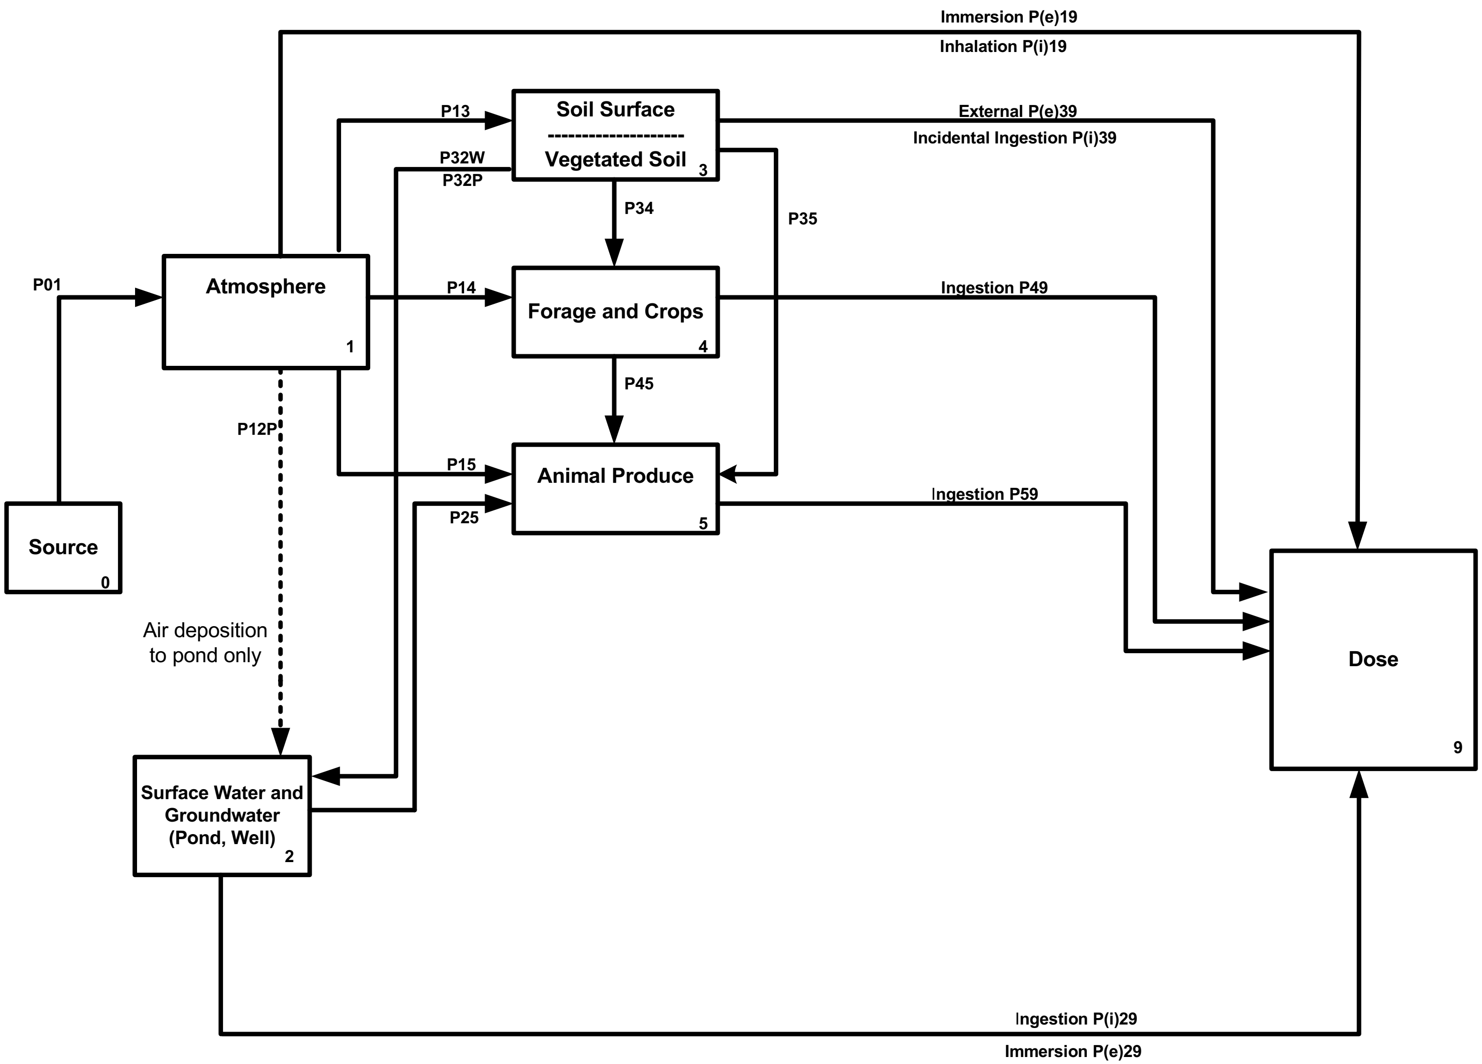

Figure 19: Environmental Transfer Model for Airborne Effluent Modelling

Table 31: Dose to Critical Group at Farm A from Ingestion of Large Game Animal Meat

Radionuclide	Concentration in Game Animal Meat above Background (Bq/kg fresh weight)	Dose Coefficient for Ingestion (Sv/Bq)		Effective Dose (mSv/a)	
		Adult	Infant	Adult	Infant
^{137}Cesium	0.0	1.3E-08	1.2E-08	nil	nil
^{90}Strontium (bone)	0.0	2.8E-08	7.3E-08	nil	nil
			Total Dose	nil	nil

7.3 Liquid Effluent Exposure Pathways

The DRL model for WL identifies one potential critical group for liquid effluents including residential group at Farm A [9]. The radionuclides included in the dose assessment for liquid effluents were those that were known or expected to be released from the WL site in 2023, and were detectable at the critical group locations or have the potential to contribute significantly to the dose to any critical group.

The pathways included in the dose assessment for liquid effluents are those that have the potential to contribute significantly to the dose from exposure to the radionuclides above. They include ingestion of water and consumption of fish. Ingestion of garden vegetables has been included although not identified as a dominant dose pathway. Other radionuclides and environmental exposure pathways that may result in negligible doses to members of the public were not included in the dose assessment because the radionuclides were not detected above background and/or above detection limits.

Dose estimates for beach sediments based on the river bottom sediment data were not considered since it is highly unlikely (less than 1%) that a person would be exposed through this route.

Figure 20 represents the environmental transfer model of liquid effluent exposure pathways to human receptors used for public dose calculation at Whiteshell, including the dose contribution from each pathway in 2023.

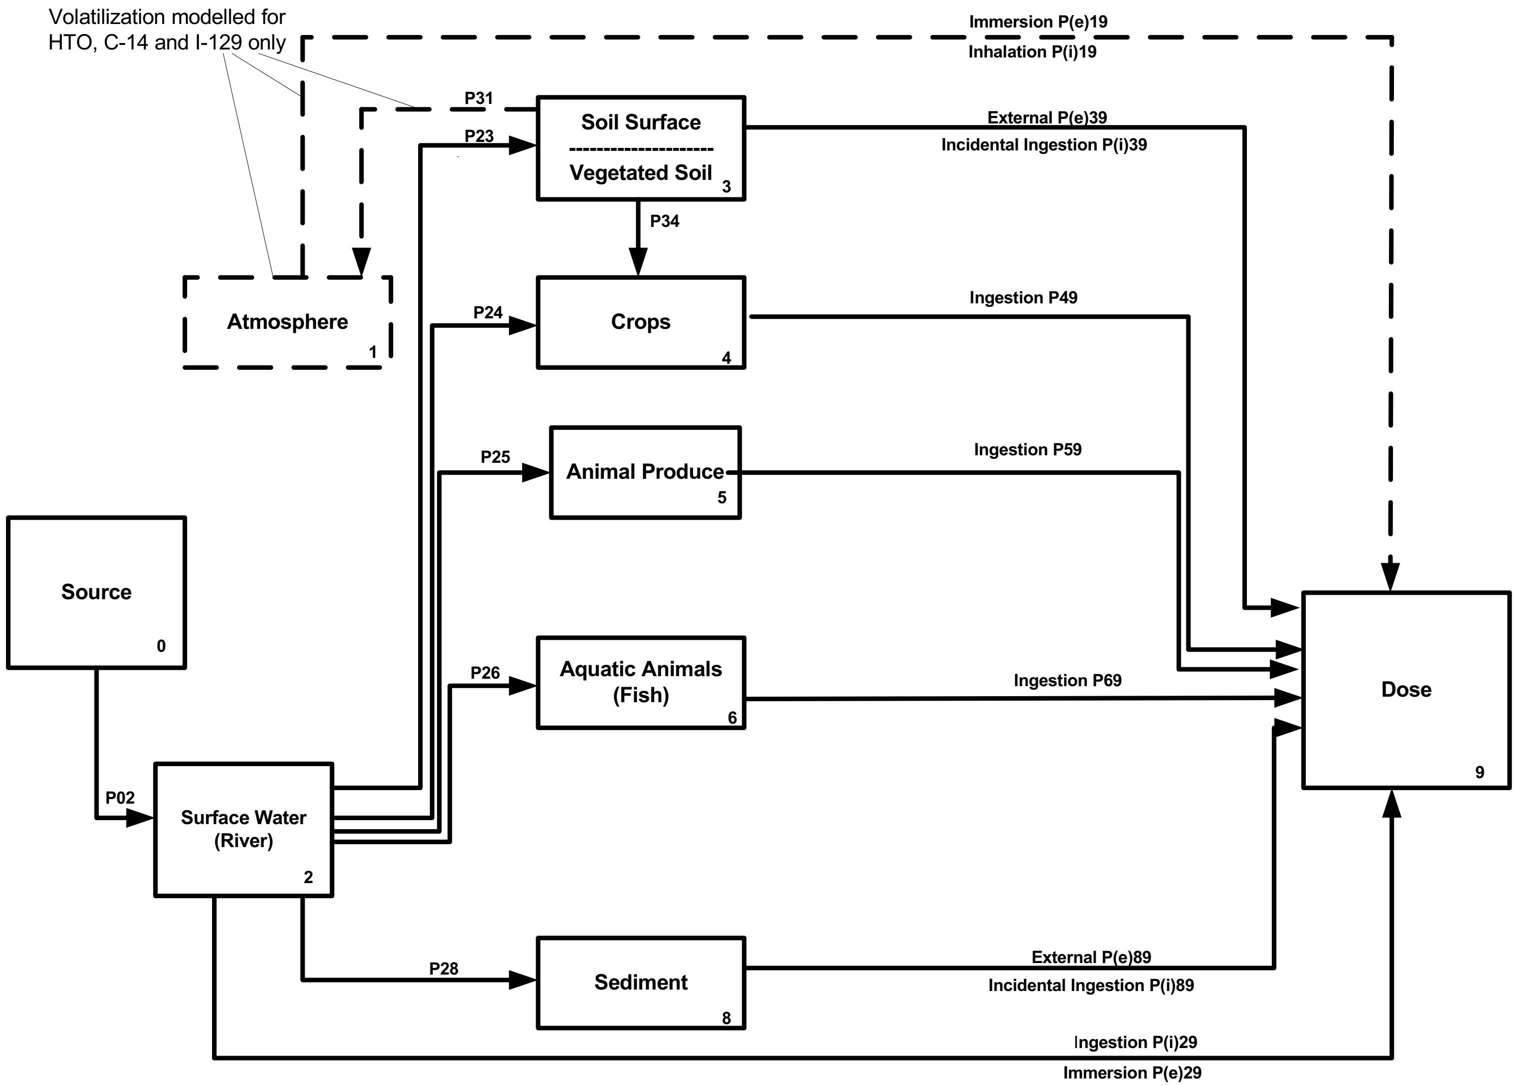

Figure 20: Environmental Transfer Model for Liquid Effluent Modelling

7.3.1 Water Ingestion

Water ingestion is identified in the DRL model as a dominant pathway for exposure to americium-241, plutonium-238, plutonium-239, plutonium-240, uranium (all part of gross alpha), technecium-99, strontium-90, cesium-137 (part of gross beta) and tritium, which are potentially present in WL effluent. The gross alpha activity continues to be at or near the lower limit of detection for the method and within the range of previous years. These are all lower than the established background value (0.050 Bq/L). This shows that in 2023, emissions from WL did not contribute to the dose from exposure to alpha emitting radionuclides in Winnipeg River drinking water. Tritium also was not found above background levels in river water and therefore does not contribute to dose. Other radionuclides present in WL effluent (cesium-137, and strontium-90) were included in the dose calculations as verification that their contribution to dose is negligible. The dose contribution from WL was obtained by subtracting the measured concentrations at Pinawa, which is located upstream of the WL site, from the highest concentration found at one of the three downstream locations at K-11, Lac du Bonnet or Great Falls. Using the concentrations at Pinawa for background correction was considered to provide more realistic dose estimates.

The annual effective dose from ingestion of water was estimated using Equation 1 and the total dose is presented in Table 32. A water intake rate of 840 L per year for adults and 347 L per year for three month old formula-drinking infants was used in dose calculations. The calculated dose is based on the assumption that 100% of the drinking water for the residential critical groups at Farm A is supplied by a water system that draws water from the Winnipeg River, and that the drinking water does not undergo any filtration or other pre-treatment processes prior to consumption.

In 2023 the cesium-137 activity detected in downstream river water samples was 0.0010 Bq/L higher than in upstream samples. The strontium-90 activity in downstream samples was the same as in the upstream, providing no dose. Therefore, in 2023 only the ingestion of cesium-137 through drinking water is considered to give doses to adults and children. As shown in Table 32 and Table 52 in Appendix B, the total incremental doses for adults and infants due to drinking water were 1.09×10^{-5} mSv/a and 4.16×10^{-6} mSv/a, respectively.

Table 32: Dose to Critical Groups at Farm A from Ingestion of Water

Radionuclide	Concentration in Drinking Water above Background (Bq/L)	Dose Coefficient for Ingestion (Sv/Bq)		Effective Dose (mSv/a)	
		Adult	Infant	Adult	Infant
Cesium-137	0.0010	1.3E-08	1.2E-08	1.09E-05	4.16E-06
Strontium-90	0.0000	2.8E-08	7.3E-08	nil	nil
			Total Dose	1.09E-05	4.16E-06

7.3.2 Fish Ingestion

Fish ingestion is identified in the DRL model as a dominant pathway for exposure to cesium-137. Other radionuclides (Cs-134 and Zn-65) were identified but are not present in WL effluent. The annual dose to residents of Farm A due to cesium-137 in walleye were estimated. Concentration data were used from samples from Pinawa (Sylvia Lake) and the locations 2 km and 5 km downstream of the Outfall. Assumed consumption rates were 7.41 kg/year for adults and 0.31 kg/a for three month old infants [9]. It is assumed that the fraction of fish locally consumed is 0.3 (the G parameter in equation 1). In 2023 downstream Pike samples had cesium-137 activity that was higher than upstream pike by 1.67 Bq/kg. This results in incremental doses due to fish ingestion of 4.83E-05 mSv/a for adults and 1.86E-06 mS/a for infants, as indicated in Table 33.

Table 33: Dose to Critical Group from Ingestion of Fish

Radionuclide	Concentration in Fish above Background (Bq/kg)	Dose Coefficient for Ingestion (Sv/Bq)		Effective Dose (mSv/a)	
		Adult	Infant	Adult	Infant
^{137}Cesium	1.67	1.3×10^{-8}	1.2×10^{-8}	4.83E-05	1.86E-06
			Total Dose	4.83E-05	1.86E-06

7.3.3 Ingestion of Garden Produce

The DRL model for the WL site identifies Farm A as the bounding critical group for dose from ingestion of garden produce [9]. This is considered an airborne and liquid effluent pathway, although the contribution of radioactivity to soil and plant tissue from irrigation is usually minor compared to the contribution from direct atmospheric deposition. Contaminant uptake in garden produce is primarily via roots and foliar deposition. Although ingestion of produce irrigated with potentially contaminated water was included in modelling of dose to the potential critical groups for liquid effluents in the DRL model, it was not identified as being a significant exposure pathway [9]. It is identified as a dominant dose pathway for cerium-144 (air deposition) which is not present in WL effluent. If cerium-144 were present it would be detected by gamma spectrometry and included in gross beta result.

The annual effective dose to Farm A residents from consumption of garden produce was estimated using the measured concentrations of tritium, cesium-137, and gross beta activity (corrected for potassium-40 contribution) in produce grown downstream of the Process Outfall. The contribution from WL was obtained by subtracting the measured concentrations in produce grown at the upstream reference location from the measured concentrations in downstream produce. This background correction was applied in an effort to provide more realistic dose estimates.

The annual effective dose to residents of Farm A from ingestion of garden produce are estimated using Equation 2. The model used to calculate the derived release limits, provided different intake rates for all three produce types. The intake rates are now applied to the individual produce types listed in Table 34 for adults and three-month old infants.

Table 34: Intake Rates of Vegetables

Food Categories and Items	Infant	Adult
Fruit and berries (kg/a)	66	174
Above ground vegetables + mushrooms (kg/a)	44	236
Root type vegetables (kg/a)	23	104

It was assumed that 15% of fruit, 25% of above ground vegetables and 100% of root type vegetables consumed during the year was grown locally (i.e., was potentially from a contaminated source) [9]. The effect of food processing on radioactivity in garden produce was assumed to be negligible.

As mentioned in Section 6.3.3, the contract lab used to analyze vegetables produced acceptable detection limits, which had not been the case in 2020 and 2021. In 2023 the cesium-137 and strontium-90 activities in fruit, leafy vegetables and root vegetables were at or below detection limits and showed no statistical difference between vegetables in upstream and downstream locations. Therefore, the potential dose to members of the public from fruit and root vegetable ingestion is nil (Table 35). Cerium-144 was not detected in the gamma spectrometric analysis of upstream and downstream vegetables. The gross beta results when corrected for potassium-40 contributions is nil therefore dose from Ce-144 is assumed to be nil.

Table 35: Dose from Liquid borne Effluents to Critical Group at Farm A from Ingestion of Garden Produce

Radionuclide	Concentration in Garden Produce above Background (Bq/kg fresh weight)	Dose Coefficient for Ingestion (Sv/Bq)		Effective Dose (mSv/a)	
		Adult	Infant	Adult	Infant
^{137}Cesium	0.00	1.3E-08	1.2E-08	nil	nil
^{90}Strontium	0.00	2.8E-08	7.3E-08	nil	nil
			Total Dose	nil	nil

7.4 Total Estimated Dose to Critical Groups

It can be noted from Figure 21 and Table 36 that the total incremental doses due to water, fish game and vegetable ingestion for adults and infants, are 5.9 x 10^{-5} mSv/a and 6.02 x 10^{-6} mSv/a, respectively. This can also be expressed as 5.9 x 10^{-3} % and 6.02 x 10^{-4} %, respectively of the annual regulatory limit of 1 mSv/a. Figure 21 is a plot of the doses estimated in the above sections.

Table 36 shows the dose estimates for 2018 to 2023 along with the five year average. The 2023 data for water ingestion was less than for 2022 for adults and infants. However, the dose from fish ingestion was higher than in 2022. The total estimated dose to exposed members of the public due to radioactivity in WL effluents in 2023 is higher for adults and lower for infants compared to the average of the last five years.

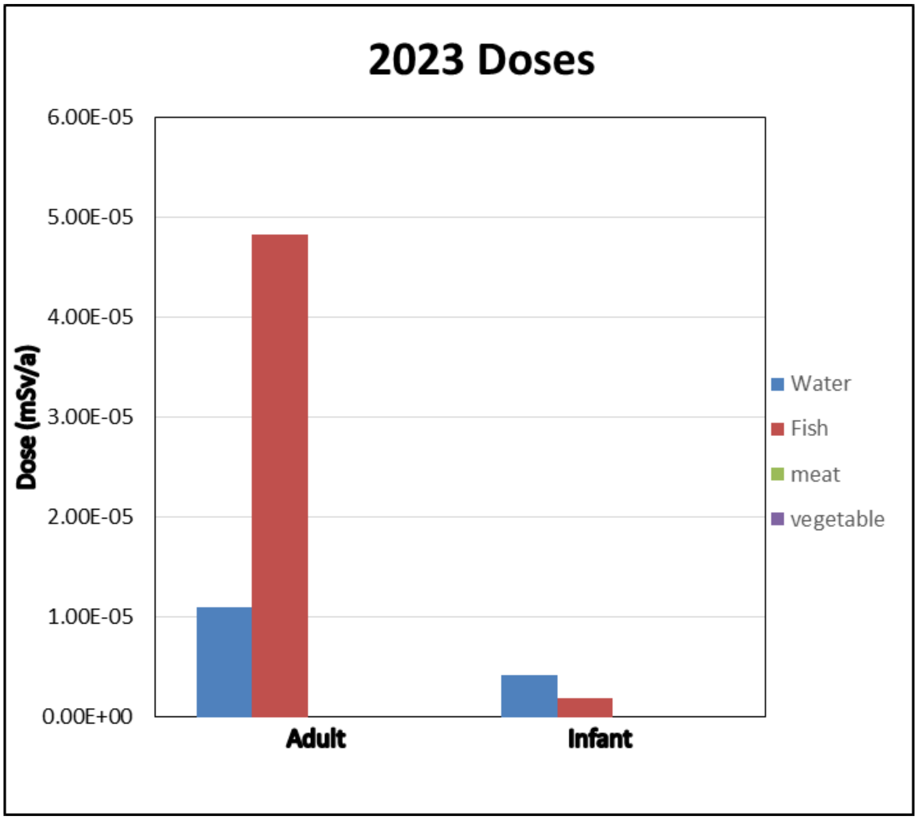

Figure 21: Estimates of Incremental Doses Due to Effluents from Whiteshell Laboratories, 2023

Table 36: Estimated Dose from WL Effluents, 2018 to 2023

	2018	2019	2020	2021	2022	Five-Year Average	2023
Dose to Adult (mSv/a)							
Water Ingestion	2.2E-05	8.0E-05	nil	4.5E-05	1.52E-05	3.2E-05	1.09E-05
Fish Ingestion	1.4E-05	6.9E-06	2.9E-06	nil	5.78E-06	7.4E-06	4.83E-05
Game Meat Ingest.	nil	nil	nil	nil	nil	nil	nil
Vegetable Ingestion	nil	nil	nil	nil	nil	nil	nil
Total	3.6E-05	8.7E-05	2.9E-06	4.5E-05	2.10E-05	4.0E-05	5.9E-05
Dose to Infant (mSv/a)							
Water Ingestion	8.3E-06	6.3E-05	nil	4.2E-06	8.41E-06	1.7E-05	4.16E-06
Fish Ingestion	5.6E-07	2.7E-07	1.1E-07	nil	2.23E-07	2.9E-07	1.86E-06

Game Meat Ingest.	nil	nil	nil	nil	nil	nil	nil
Vegetable Ingestion	nil	nil	nil	nil	nil	nil	nil
Total	8.9E-06	6.3E-05	1.1E-07	4.2E-06	8.64E-06	1.7E-05	6.02E-06

nil – no statistical difference between upstream and downstream data.

N/A- No samples were collected.

8. Investigative Studies

A review of non-radiological parameters measured in WL's Intake and Outfall waters for the years 2012 to 2017 was undertaken. The results of the parameters analyzed indicated that there is no degradation of the Winnipeg River water quality as a result of CNL operations and no need to expand the environmental monitoring program to include non-radiological parameter analysis of river water.

9. WL Environmental Assessment

The WL environmental assessment was conducted in accordance with the Canadian Environmental Assessment Act [42]. As part of the environmental assessment process the CNSC identified the need for a follow-up program. Accordingly, the Comprehensive Study Report submitted to the CNSC and ultimately to the Canadian Environmental Assessment Agency included a description of the planned follow-up program [1]. In his decision, the Minister also recommended that the mitigation measures and commitment to enhanced monitoring be implemented. Monitoring implemented as part of the Environmental Assessment Follow-Up Program (EAFP) will follow the requirements in CSA N288.4 [12], N288.5 [11] and N288.7 [59] series of standards.

The annual progress report on the EAFP [1] continues to assess the environmental performance of the site against the EAFP objectives, and identifies the need for modifications to the effluent, environmental, and groundwater monitoring programs. Progress on the work tasks associated with the EAFP are reported in the annual EAFP report [7].

In 2021, an Environmental Risk Assessment for the Landfill and Lagoon was completed and the report was sent to the CNSC for information. This document was prepared in support of the Landfill and Lagoon closures. A site-wide Environmental Risk Assessment was completed in 2023, in accordance with per CSA N288.6-12 [60], and was submitted to CNSC for review.

The identification and mitigation of environmental risks associated with routine and non-routine activities within CNL operated sites is a significant element of the CNL Environmental Management System (EMS). The environmental reviews of routine and non-routine work provide the processes and requirements for assessing environmental risks of project specific work. Significant Environmental Aspects (SEA) are identified and documented and where applicable, operational controls are put in place.

10. Conclusions

Monitoring of potential atmospheric effluent exposure pathways did not indicate any significant dose contributions from WL operations. This is consistent with effluent monitoring results, which indicated that airborne emissions were very small (1.5 x 10^{-6} mSv/a). Monitoring of potential liquid effluent exposure pathways has indicated that in 2023 the contributors to liquid effluent exposure was the consumption of water and fish. In 2023, the cesium-137 activity was higher in downstream river water compared to upstream samples. Therefore, in 2023 the ingestion of cesium-137 through drinking water is considered to give a dose of 1.09 x 10^{-5} mSv/a to adults and 4.16 x 10^{-6} mSv/a to infants. One deer was sampled in 2023. The average cesium-137 activity in the sampled deer was below background, resulting in no dose for adults and infants. The incremental doses due to fish ingestion were 4.83 x 10^{-5} mSv/a for adults and 1.86 x 10^{-6} mSv/a for infants. Dose rates from consuming vegetables were nil in 2023. Radioactive contaminants in Winnipeg River water remained very small fractions of allowable levels defined in the Canadian Drinking Water Standard [21].

The groundwater monitoring program has demonstrated there is no significant radioactive migration from the waste management facilities.

Participation in laboratory proficiency tests and internal quality verification tests were both used to assess the performance of analytical methods used to produce the data included in this report. The results were satisfactory. Findings from program audits and assessments were minor in nature and are being addressed. There were no findings that resulted in requiring changes to the Environmental Monitoring Program.

Monitoring results for the calendar year 2023 confirmed that levels of radioactivity in the environment outside the WL site boundary due to work conducted at the site, as well as the resulting radiation doses to members of the public, were well below regulatory limits[47] and guidelines.

10.1 Overall Environmental Performance

The combined operation of the radiological environmental monitoring program, the non-radiological environmental monitoring program, and the groundwater monitoring comprises contaminant pathway monitoring, results of which are discussed in an integrated manner in this report. This contaminant pathways monitoring enables the tracking of contaminants throughout the different compartments of the geosphere and biosphere, allowing conclusions to be drawn on the overall environmental impact of WL site operations and decommissioning activities.

Overall, the environmental impact can be characterized as low risk, in that the potential for human or ecological impacts is low because measured concentrations are well below benchmark values, and overall trending indicates stable performance.

[47] The regulatory limit for non-occupational effective radiation dose to members of the public from operations and products involving ionizing radiation (excluding medical procedures) is 1 mSv per year.

11.2 Terms

Action Level	Action Level for radioactive emissions is a quantity or rate of radioactive emissions that, if reached, may represent a loss of control of performance of a facility's environmental protection program or emission control systems, and triggers a requirement for specific actions to be taken.
Anthropogenic	Man-made
Biosphere	The regions of the surface and atmosphere of the Earth where living organisms exist.

Drinking Water MAC	0.2			10			5			10			7000			NA		

Notes:

1. Gross Alpha releases are conservatively assumed to consist of total uranium, the radionuclide with the most restrictive MAC and likely to be present.
2. Gross Beta releases are conservatively assumed to consist of strontium-90, the radionuclide with the most restrictive MAC and likely to be present.
3. The MDL is based on a 40 L sample resulting in 1 g of sample ash, and counted 400 min for gross alpha, 100 min for gross beta and strontium-90 analysis, or counted 800 min for potassium-40 and cesium-137 analysis.
4. NA = not available.
5. Uncertainties of individual results are expressed as ± two standard deviations based on counting statistics; uncertainties of the average are expressed as the standard deviation of the population group.
6. LLD = Lower Limit of Detection.

MDL*	1			4			0.10			7.0			0.87			20		

Notes:

1. Uncertainties and MDLs are provided by contract lab.

LD = Lower Limit of Detection.

Table 49: Radioactivity in Native Vegetation at Whiteshell Laboratories and Vicinity, 2023

Sample Location	Sample Date	Gross Beta (Bq/kg)	Gross Alpha (Bq/kg)	K-40 (Bq/kg)	SR-90 (Bq/kg)	Cs-137 (Bq/kg)	Tritium (Bq/kg)	OBT (Bq/kg)
WL Perimeter								
Arms #1	11-Aug-23	41 ± 8	3.1 ± 0.6	38 ± 3	1.75 LLD	0.2 LLD	11 ± 1.3	15 ± 1.4
Arms #3	11-Aug-23	33 ± 7	3.8 ± 0.8	25 ± 4	0.97 LLD	0.3 LLD	3 LLD	10 LLD
Arms #4	11-Aug-23	48 ± 10	6.0 ± 0.4	38 ± 3	1.11 LLD	0.2 LLD	10 ± 1.1	23 ± 2.1
Arms #5	11-Aug-23	51 ± 10	5.8 ± 1.2	35 ± 5	0.78 LLD	0.8 LLD	14 ± 1.6	6 LLD
West of WMA & North of Canister Area								
WMA 1	11-Aug-23	58 ± 12	7.7 ± 1.5	53 ± 3	0.9 LLD	0.4 LLD	9 ± 1	22 ± 2
East of WMA & Near Incinerator								
WMA 7	11-Aug-23	59 ± 12	4.0 ± 0.8	52 ± 4	1.0 LLD	0.2 LLD	7 LLD	9 LLD

Notes:

1. Activities are reported per fresh weight.
2. For security improvement and fire control, the soil and vegetation was removed from the area just outside the WMA fence and replaced with gravel.

LLD = Lower Limit of Detection

ND = Not Determined

Table 50: Radioactivity in Surface Soil Near Standpipe Rows E, F and G of Whiteshell Laboratories Waste Management Area, 2023 (EFG SOIL)

Location	Gross Beta (Bq/g)	Gross Alpha (Bq/g)	K-40 (Bq/g)	Sr-90 (Bq/g)	Cs-137 (Bq/g)	Am-241 (Bq/g)
Location E - 1 m East of WMA Fence at Standpipe Row E						
Perimeter (7m south)	0.84 ± 0.17	0.20 ± 0.04	0.48 ± 0.05	1.77 ± 0.39	0.051 ± 0.004	0.003 LLD
Perimeter (8m south)	0.70 ± 0.14	0.19 ± 0.04	0.50 ± 0.03	0.63 ± 0.14	0.039 ± 0.001	0.004 LLD
Perimeter (9m south)	0.16 LLD	0.22 ± 0.05	0.46 ± 0.05	0.14 LLD	0.029 ± 0.003	0.003 LLD
Perimeter (9m west)	0.37 ± 0.07	0.13 ± 0.03	0.45 ± 0.06	0.14 LLD	0.001 ± .0004	0.003 LLD
Location F - 1 m East of WMA Fence at Standpipe Row F						
Perimeter (9m west)	0.47 ± 0.09	0.14 ± 0.03	0.46 ± 0.05	0.13 LLD	0.001 ±.0003	0.0023 LLD
Location G - 1 m East of WMA Fence at Standpipe Row G						
Perimeter (9m north)	0.58 ± 0.12	0.07 ± 0.01	0.40 ± 0.05	0.25 LLD	0.017 ± 0.002	0.004 LLD
Perimeter (9m west)	0.51 ± 0.10	0.17 ± 0.03	0.45 ± 0.00	0.04 LLD	0.004 ± 0.000	0.0004 LLD
NSRDR Clearance Level [14]	NA	1(1)	10	1.0	0.10	

Notes:

1. Alpha activity assumed to be from radionuclides of natural origin.
2. Uncertainties of individual results and LLD values are provided by the contract lab.
3. NA = Not Applicable, ND = Not Detected.

Table 51: Field Data, Winnipeg River Sediment Samples, 2023

Location Code and Distance from Outfall (km)	Sample Number	Core Depth (cm)	Wet Sample Weight (g)	Water Depth (m)	Distance from Shore (m)
J04 (-0.76 km)	001	1	15.3	2.0	3.0
	002	1	16.8	2.0	3.0
	003	1	18.6	2.0	3.0
