De-inventorying efforts of legacy wastes stored in LLW Quonsets (B433, B432, and B431) also continued. Wastes are undergoing additional qualification and inspection to ensure transportation and waste criteria compliance are met. This activity has generated approximately 305 m^3 of LLW to date, which is safely stored in certified transportation packages awaiting shipment to CRL in 2023. A reflux boiler, comprising 65.8 m^3 of LLW, was shipped to an offsite vendor for processing due to its physical size not meeting the CRL waste acceptance criteria.

Table 44 summarizes the quantities of radioactive waste generated in 2022 that was sent to each storage location.

Table 45 summarized the volumes of solid low-level radioactive waste originating from each facility in 2022. Table 46 summarizes the volumes of solid intermediate-level radioactive waste originating from facilities in 2022.

Table 44: Radioactive Waste by Storage Location

Storage Facility	Volume (m^3)	
	2021	2022
Low-Level Quonsets	0.0	0.0
Intermediate-Level Waste Bunkers	2.5	0.0
Soil Storage Compound	0.0	0.0
Total	2.5	0.0

Table 45: Low-Level Radioactive Waste Generated by Facility

Facility of Origin	2021		2022	
	Compactable Waste Volume (m^3)	Non-Compactable Waste Volume (m^3)	Compactable Waste Volume (m^3)	Non-Compactable Waste Volume (m^3)
Building 100	1.5	0.0	0.5	0.0
Building 200	0.0	875.6	0.0	0.0
Building 300	0.0	0.0	0.0	0.0
Building 303	0.0	0.0	0.0	0.0

LLW Bunker 6	0.0	9.0	0.0	0.0
LLW Bunker 5	0.0	360.0	0.0	70.0
Affected Lands	0.0	0.0	0.0	0.0
Soil Storage Compound	0.0	0.0	0.0	0.0
Total	**62.1 (5.0)[a]**	**1244.6**	**11.0[b]**	**70.1**
Total after Compaction	**1249.6**		**81.1**	

a This volume of compactable waste was reduced to 5.0 m^3. It is not possible to determine accurate post consolidation volumes attributed to individual facilities because all of the waste is being combined during the compaction process.

b This volume of compactable waste was not reduced due to the WL Supercompactor being taken off-line for future disassembly and re-use at CRL.

Table 46: Intermediate-Level Radioactive Waste Generated by Facility

Facility of Origin	Volume (m^3)	
	2021	2022
Affected Lands	0.0	0.0
Building 200	77.5	0.0
Shielded Facilities (HCF & IFTF)	0.0	0.02

Total	921	3.2	341.6	2.52

WL continues to utilize external vendors for selected waste requiring treatment. Table 48 summarizes the amount of hazardous waste collected and transferred off-site for processing.

Table 48: Summary of Amounts of Hazardous Waste Shipped Off-Site

Waste Type	Volume (m^3) (Weight (kg))	
	2021	2022
Solid Hazardous Waste Shipped Off-Site For Disposition	8.20 (4,859.5)	14.22 (7605.4)
Liquid Hazardous Waste Shipped Off-Site for Disposition	3.88 (2,948.0)	6.02 (670.8)
Total	12.08 (7,807.5)	9.24 (826.2)

Clearable waste from Controlled Areas was monitored in-situ. Clean bagged waste was monitored using the bag monitor located in Building 300; all bagged waste met the screening criteria and was deemed to be suitable for unconditional release in 2022.

Whiteshell Laboratories continued to reuse or recycle as much material as practicable, consistent with CNL's Integrated Waste Strategy; this includes both recyclable materials sent to the municipal recycling facility and other material-specific facilities throughout Manitoba. Waste Management Program representatives exercised a proactive approach to ensure waste was properly segregated at the source of origin to maximize the amount of material that could be reused or recycled.

Table 49 summarizes the routes of non-active wastes and breaks it down by amount, material type, of recyclable waste shipped off-site.

Table 49: Clean and Recycled Waste Shipped Off-Site

Material[a]	Volume (m^3) (Weight (kg))	
	2021	**2022**
Dispositioned in WL Inactive Landfill	0	0
Dispositioned in Off-Site Landfills [a]	130 (39,070)	64 (47,810)
Batteries	0	0
Concrete (reuse off-site)	1454 (1,789,448)	1783 (1,943,450)
Fluorescent Lights	0.5 (170)	1 (265)
Office Recycling (Cardboard, Containers) [b]	5 (1,390)	4 (1,800)
Metal Recycle	470 (197,880)	153 (71,690)
Shredded Paper Recycled	38 (6,750)	13 (2,250)
Waste Electrical and Electronic Equipment	9 (3,464)	0 (0)
Asbestos Containing Material Dispositioned in WL Asbestos Disposal Site [c]	0	0
Asbestos Containing Material Dispositioned in Off-Site Landfills	526 (532,920)	334 (367,000)
Total	2,632.5 (2,571,092)	2,352.0 (2,434,265)

a WL Inactive Landfill stopped receiving waste mid-2019 to support the environmental risk assessment. Non-active waste is directed to off-site licensed landfills.

b This recycling waste pertains to office recycling that is generated on a daily basis that is accepted a municipal recycling facilities.

c The WL Asbestos Disposal Site stopped receiving waste in 2019 to support the environmental risk assessment. Non-active asbestos is directed to off-site licensed landfills.

Improvements continue to be addressed for processing and storage space for non-routine waste materials (e.g., mixed waste and large contaminated items), as well as large volumes of radioactive wastes generated from decommissioning activities. Mitigation measures put in place in 2022 included leveraging the Recoverable Surface Storage and Staging Area, for the interim storage of cargo containers containing radioactive wastes in the WMA awaiting further processing, characterization and/or packaging to be considered compliant for off-site disposition.

11.1.1.1 Liquid Waste Generation

During 2022, 117.3 m^3 of low-level liquid was processed in the Building 300 LLLWTS and 2.3 m^3 in the Building 100 LLLWTS, for a total of 119.6 m^3 of low-level liquid waste processed through the two systems.

11.2 Decommissioning Plan

Whiteshell Laboratories adheres to the CNL Cleanup Functional Support Area. See Section 11.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [1].

Progress on Decommissioning and Environmental Remediation activities with an update on the associated regulatory documents as guided by the Cleanup Function is summarized in the sections that follow.

As per the Licence Conditions Handbook for WL [2], CNSC are notified of revisions to the Detailed Decommissioning Plans (DDPs) for WL.

11.2.1 Decommissioning and Demolition Program

Table 50 lists the WL DDPs and their status as of 2022.

Table 50: Overview of WL Detailed Decommissioning Plans

Facility	DDP Document Title	Document #	Status
Shielded Facilities	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 2 - Shielded Facilities	WLDP-21400-DDP-001, Revision 1, 2016	Facility is operational and decommissioning activities ongoing. DDP Volume is available for use (revision planned for 2023).
Van de Graaff Accelerator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 3 - Van de Graaff Accelerator	RC-2143-3, Revision 1, 2000	Facility has been decommissioned. End-state report completed.
Neutron Generator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 4 - Neutron Generator	RC-2143-4, Revision 1, 2000	Facility has been decommissioned. End-state report completed.

Facility	DDP Document Title	Document #	Status
Active Liquid Waste Treatment Centre	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 5 - Active Liquid Waste Treatment Centre Building 200	WLDP-25400-DDP-001, Revision 0, 2011	Facility has been decommissioned. Demolition complete – site cleanup remains to be completed. End-state report in development. DDP available for use.
Whiteshell Reactor-1 (WR-1)	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 6 - Whiteshell Reactor-1: Building 100	WLDP-26400-DDP-001, Revision 3, 2015 (Complete Dismantlement and Removal Approach)	Facility has been shut down and currently under monitoring and surveillance – Storage-with-surveillance plan under revision. Complete Dismantlement and Removal approach has been approved by the CNSC (Revision 3). Environmental Assessment process for in situ decommissioning is in progress, Revision 4 to be revised with final Environmental Assessment submission (note: copy of Revision 5 submitted for review of comment disposition to CNSC prior to final Environmental Assessment submission). DDP Volume (Revision 3) is available for use.
		WLDP-26400-DDP-001, Revision 5, 2021 (In Situ Decommissioning Approach)	
Concrete Canister Storage Facility	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 7 - Concrete Canister Storage Facility	WLDP-22500-DDP-001, Revision 1, 2017	Facility is operational. DDP was sent to the CNSC and comments received (to be dispositioned).
Waste Management Area	Volume 8 - WMA Part 1: Standpipes Area	WLDP-36500-DDP-001	Facility is operational. DDP under development.
	Volume 8 - WMA Part 2: Intermediate - Level Waste Bunkers, Building 417 and Amine Tanks	WLDP-24900-DDP-001	Facility is operational. DDP under development.
	Volume 8 - WMA Part 3: Low Level Waste Liabilities	WLDP-24400-DDP-001, Revision 5, 2021	Facility is operational and decommissioning activities ongoing. DDP Volume is available for use.

Facility	DDP Document Title	Document #	Status
R&D Facilities Complex	Volume 9 - Building 300	WLDP-23500-DDP-001 (RC-2143-9), Revision 0, 2007	Facility is operational. DDP Volume is available for use (revision planned for 2023).
	Volume 9 - Building 300_Addendum	WLDP-23500-DDP-001_AD, Revision 2, 2018	
Decontamination Centre	Volume 10 - Decontamination Centre Building 411	WLDP-27400-DDP-001, Revision 0, 2011	Facility has been decommissioned. End-state report completed.
Health and Safety Facilities	Volume 11 - Building 402 and 305	WLDP-37000-DDP-001, Revision 2, 2020	Decommissioning activities ongoing. Demolition complete – site cleanup remains to be completed. End-state report in development. DDP Volume is available for use.
DDP Volume 12	Volume 12 - WL Licensed Site Supporting and General Infrastructure: North-Side	WLDP-32000-DDP-001, Revision 0, 2009	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 1: South-Side Buildings	RC-2143-12, Revision 1, 2006	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 3: Outer Area Buildings and Facilities	WLDP-33000-DDP-001, Revision 1, 2008	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 4: Site Services	WLDP-34000-DDP-001, Revision 1, 2013	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 5: Site Affected Lands and Contaminated Structures	WLDP-35000-DDP-001, Revision 1, 2012	Decommissioning activities ongoing. DDP Volume is available for use.

11.2.1.1 Detailed Decommissioning and Execution

No WL facility DDPs were revised in 2022. Table 51 provides a summary of decommissioning and demolition statuses for WL in 2022.

Table 51: Summary of WL Decommissioning and Demolition Status by Facility in 2022

Facility	Decommissioning and Demolition Status
B402/305	Building Demolished
B200	Building Demolished
WMA	Active Decommissioning
Site Affected Lands and Contaminated Structures	Active Decommissioning

Two buildings were demolished in 2022, where operational wastes were dispositioned, building services isolated and industrial hazardous materials removed prior to demolition where feasible.

Demolition of Buildings 402 and 305 was completed in early 2022. The demolition of the buildings included remediation and abatement of asbestos-containing materials, specifically the mastic tar adhered between the masonry and exterior wall, and PCBs found within window glazing and exterior caulking and general demolition of construction and demolition materials.

Legacy wastes stored in the LLW Quonsets (Building 431, 432 and 433) and LLW Bunker 5 continued to be retrieved in 2022. Wastes are undergoing visual examination, destructive and non-destructive characterization, and packaging to ensure transportation and waste criteria compliance are met, before waste can be dispositioned to CRL. This work is scheduled to be complete in 2023.

Operational cleanout of B405 was completed in 2022 in preparation for its future demolition scheduled in 2023. Materials removed included repurposed office furniture which were distributed throughout the site for reuse, and general office waste, which consisted mostly of paper which was routed for recycling. The exterior and interior of the building were also radiologically surveyed for clearance.

Decommissioning progress is also discussed in the facility sections (Appendix A through Appendix G).

11.2.1.2 End State Reporting

There were no end-state reports completed in 2022.

12 Security

12.1 Security Program

Whiteshell Laboratories adheres to CNL's Security Functional Support Area. See Section 12 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [1].

The Whiteshell Site Security Report [48] outlines the security arrangements that are in place at the WL site. The Security Functional Support Area consists of processes, procedures, and staff to manage the continuous operation and response to security incidents; the Security Functional Support Area and procedures are reviewed and updated as required to address operational requirements.

Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers stated in REGDOC-2.2.4, *Fitness for Duty, Volume III Nuclear Security Officer Medical, Physical and Psychological Fitness* [49].

CNL-WL received notification from the CNSC on the closure of all seven (7) enforcement items from a 2021 Type II Security inspection. Notices of Non-Compliance closure was granted as CNL-WL completed all actions required to address the enforcement items listed in them.

12.1.1 Security Events

In 2022, there were 0 security events that affected WL.

13 Safeguards and Non-Proliferation

13.1 Safeguards Program

Whiteshell Laboratories adheres to CNL's Nuclear Materials and Safeguards Management Functional Support Area. See Section 13 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [1].

13.1.1 IAEA Activities

The IAEA conducted various types of activities as part of the safeguards approach for CNL, including, but not limited to, IAEA safeguards seals changes, human surveillance, implementation and/or maintenance of IAEA safeguards monitoring equipment, and technical visits. A list of IAEA inspections conducted at all CNL sites can be found in Section 1.2, Management System of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [1], with WL inspections discussed below and in Section 1.3.2.

A Physical Inventory Verification inspection was completed by the IAEA on 2022 May 02. This inspection was a sampling of accessible items containing Special Fissionable Material.

The IAEA also completed a Design Information Verification inspection on 2022 May 03. The activities associated with the Design Information Verification included:

- Verification of the Design Information Questionnaire:
- Verification of the site and general building design;
- Verification of containment integrity; and
- Verification of operational status of the facility.

Two actions were raised and have been completed based on the Physical Inventory Verification and Design Information Verification inspections.

The IAEA requested a Complimentary Access at the Whiteshell site on 2022 June 01. The purpose of a Complimentary Access is to assure the absence of undeclared nuclear materials and activities, to resolve a question or an inconsistency relating to correctness and completeness of the information provided in Canada's annual update to the IAEA, and to confirm the decommissioned status of a facility. This activity included a tour of the Building 300 Shielded Facilities and Laboratories and the former sites of Building 200 and Building 402 which have been demolished.

14 Packaging and Transport

14.1 Packaging and Transport Program

Whiteshell Laboratories adheres to CNL's Transportation of Dangerous Goods Functional Support Area, which includes the requirements of the Packaging and Transport SCA. See Section 14 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [1].

Activities in 2022 included:

- Transportation of 342 m^3 of low-level waste and 2.5 m^3 intermediate-level waste consigned off-site and safely delivered to CRL;
- In early 2022, the Used Fuel Transportation Package (UFTP) Safety Analysis Report (SAR) Addendum was approved by the CNSC [Certification Number CDN/2052/B(U)-96 (Rev. 9)]. The UFTP, which is owned by the Nuclear Waste Management Organization, has been leased with the intention that the UFTP will be the Type B Transportation Package for high-level waste transportation operations from WL to the CRL site. The certificate issued by the CNSC in 2022 includes the non-enriched CANDU[9] fuels only. In support of the second phase of the UFTP licensing, the Nuclear Waste Management Organization will submit the UFTP SAR for Mixed Fuel Types to the CNSC in early 2023.

14.1.1 Shipments

At WL, 42 radioactive transport packages making up 28 loads were safely and successfully sent off-site in 2022.

[9] Canada Deuterium Uranium, registered trademark of AECL

15 Other Matters of Regulatory Interest

15.1 Public Information and Disclosure Program

Whiteshell Laboratories adheres to the Corporate Public Information Program. See Section 15 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [1].

The Public Information Program document [50] is intended to cover communication activities that occur within CNL's immediate neighbouring communities. This document was prepared in accordance with CNSC regulatory document REGDOC-3.2.1, *Public Information and Disclosure* [51].

15.1.1 Outreach and Stakeholder Engagement

CNL shares information with the public through a number of activities including conducting public information sessions, media releases, the corporate website, a toll-free line, social media accounts and involvement in community events (see Table 52). Employees are CNL's greatest ambassadors, they are kept informed of developments so that they can also share information with relatives, friends, and neighbours. In 2022 June, following the safety pause, WL began holding weekly all staff meetings. The meetings have proved to be effective in keeping staff informed.

Table 52: Public Engagements for Whiteshell Laboratories

Date	Location	Activity
January 18, 2022	Webinar	Regulatory Process for the NPD and WR1 In Situ Disposal Projects - 2022 January
March 22, 2022	Webinar	NPD & WR-1 Webinar - The design of the WR-1 and NPD reactors and In-Situ Disposal
May 10, 2022	Webinar	NPD/WR-1 Webinar: Overview of the Environmental Impact Statements
May 12, 2022	Virtual	Public Liaison Committee meeting
September 8-10, 2022	Thunder Bay	FireCon Trade Show – booth to communicate about transportation of waste
September 28, 2022	Webinar	NPD and WR-1 Webinar Who Supports an Environmental Assessment Project
November 2, 2022	WL	Take Our Kids to Work Day – 16 students attended for presentations, activities and tours
November 22, 2022	Webinar	Whiteshell Laboratories: Past, Present & Future
November 30, 2022	WL	Public Liaison Committee meeting

CNL engaged with the public on WL using a number of avenues. Notably, the Public Liaison Committee meeting was held in person in 2022 November for the first time since the onset of COVID. The members, several of whom had changed since the fall municipal election, were first given a presentation on WL. The presentation gave a brief history of the site for the benefit of the new members and then highlighted progress on the project and looked into the site's future. The Public Liaison Committee members then went on a bus tour of the main campus and the WMA.

15.1.2 Public Consultation

CNL actively works to engage local stakeholders on matters related to WL activities. In 2022, a number of methods were deployed to gain feedback from and create discussion with interested parties including: public polls, webinars, social media, and feedback forms available online and at external events, and responses provided to inquiries. CNL strives to create open and transparent communication with all identified stakeholders, and to address concerns and respond to all inquiries.

CNL engaged a consultant to conduct a public attitude survey in 2022 December, in advance of engagement planned for spring 2023 on the WL Land Use and End State plan. The purpose of the survey was to gauge public opinion and understanding about the WL Restoration Project. Results indicated generally positive attitudes towards CNL and the WL Restoration Project.

Completed by phone with 368 residents in Eastern Manitoba, the public attitude survey revealed that 60% of respondents view CNL as trustworthy, 59% view CNL as capable, and 56% view CNL as transparent. The survey also found that 51% are very or somewhat familiar with CNL, 62% are familiar with the WL site, 60% consider CNL very or somewhat approachable, and 53% believe that CNL is somewhat or very committed to the best interests of the region.

Results showed that people in the communities surrounding the WL site are most concerned about the environmental impact of the decommissioning process, particularly the effects on plants and wildlife, and how nuclear waste will be managed. They are also worried about the economic impact on local jobs. CNL uses the results of the public attitude survey to tailor its communications and engagement approach.

Throughout 2022, CNL received 36 community inquiries related to WL (see Table 53), largely through the public webinars.

Table 53: Whiteshell Laboratories Restoration Project Public Inquiries

Nature of Enquiry	Number
Transportation	6
Health	1
Environmental Protection	22
Small Modular Reactors (SMRs)	1
Whiteshell Laboratories Restoration Project	6

15.1.3 Traditional and Online Communications

15.1.3.1 Website

CNL's Whiteshell Decommissioning external web page had 2,864 page views in 2022, while the WR-1 Reactor Decommissioning page had 1,407.

To support the Whiteshell projects and site, CNL's use of social media was an effective tool to promote events, share and receive information, and generally engage with the public. As Table 54 through Table 56 show, social media has been an effective tool to reach and engage stakeholders. Table 58 shows that CNL also shared information through a community information bulletin.

Community updates and announcements are made on the external CNL.ca website, as noted in Table 57 and Table 58.

15.1.3.2 Newsletters

CONTACT is CNL’s external, bilingual newsletter. It is distributed to community stakeholders, businesses and approximately 8,000 homes in the region surrounding WL, and is available online at CNL.ca. This publication informs the reader on activities undertaken at CNL’s WL and profiles CNL’s community activities. Two issues of *CONTACT* were distributed in 2022 (Fall 2022, Winter 2021 was distributed in February 2022) and included the following topics:

- WL Restoration Project and WR-1 updates
- Link to the public survey

- Highlights of public and Indigenous engagement activities
- CNL initiatives in the community, demonstrating commitment to economic generation, sponsorship, donations and participation in community events
- Workforce Employee transition plans
- Standpipes/Bunkers Waste Retrieval System updates
- Waste transportation information
- In fall 2022, CNL re-introduced the newsletter for WL employees called The Loop. The newsletter features Whiteshell-specific news for all staff, as well as personal announcements and other topics of interest to employees. Electronic versions were distributed by email and were available on CNL's intranet, and printed copies were posted throughout the site. Two issues were produced 2022.
- Media Releases

CNL issued one media release in 2022, announcing WL's new environmental monitoring program, Niigan Aki (see Table 59).

15.1.4 Education/Science & Technology Communities

In 2022, WL attended one event at FW Gilbert School in Pinawa and hosted students of staff members in person for Take Our Kids to Work Day (see Table 61).

Table 61: School Tours/Presentations

Date	Location	School
November 1, 2022	Pinawa	FW Gilbert School - for community recognition ceremony
November 2, 2022	WL	Take Our Kids to Work Day – 16 students attended for presentations, activities and tours
November 2, 2022	WL	Take Our Kids to Work Day – 16 students attended for presentations, activities and tours

15.1.5 Ongoing Projects

15.1.5.1 WR-1 In Situ Decommissioning Environmental Assessment

The proposed WR-1 in situ decommissioning project is a key part of CNL's overall integrated approach to safely manage and reduce Canada's legacy liabilities. The Environmental Assessment process for the project includes a requirement that WR-1 project information be made available to neighbouring communities, Indigenous communities and organizations, and stakeholder groups through a variety of mechanisms to ensure access to fact-based information. Engagement activities conducted in support of this requirement included social media and website content, presentations, meetings, site tours and fulfilling stakeholder requests for information. In 2022, CNL submitted the revised draft EIS for the WR-1 Project to the Canadian Nuclear Safety Commission (CNSC).

Project-specific webpages and content were produced for the WR-1 Project and included: fact sheets, info-graphics, downloadable posters, project descriptions and quick reference material. All information is available in both official languages at www.cnl.ca/wr-1.

15.2 Engagement with Indigenous Communities

CNL recognizes the importance of, and places value on, ongoing engagement with Indigenous communities and organizations. CNL's engagement efforts follow the guidance in CNSC REGDOC-3.2.2, *Indigenous Engagement* [52].

CNL seeks to provide Indigenous communities and organizations with effective access to timely information about ongoing activities at the WL site and the possible effects of these activities to community members and the environment, and to seek feedback from the communities regarding traditional and current uses in the vicinity of the WL site, planned and ongoing project-related activities, programs, timelines, environmental protection and mitigation measures, long-term benefits and economic opportunities.

Through engagement activities on the WLRP, CNL continues to build on years of engagement with Indigenous Nations including Sagkeeng First Nation, Black River First Nation, Hollow Water First Nation, Brokenhead Ojibway Nation, Wabaseemoong Independent Nations, Grand Council Treaty #3, and the Red River Métis (engaged via the Manitoba Métis Federation (MMF)). Major project updates are shared with Iskatewizaagegan #39 Independent First Nation, Shoal Lake

Independent Nation #40, and Northwest Angle #33, with opportunities for further engagement available to those communities at their discretion.

Table 62 lists the engagement activities from 2022. Further details on Indigenous Engagements are available through the Indigenous Engagement Report [53].

Although the COVID-19 pandemic limited in-person/on-site engagements in 2022, ongoing bilateral working group meetings with members from First Nations and the Red River Métis were productive. While virtual platforms will remain a tool of engagement, CNL expects to see a return to more on-site engagements in 2023, giving community members a first-hand look at project operations and opportunities.

Areas of interest identified by First Nations and the MMF in 2022 included employment and contracting opportunities, and environmental monitoring and protection programs. In response, CNL shared various job opportunities directly with the Indigenous community employment and training staff where identified. CNL developed corporate strategies related to reconciliation actions and to procurement opportunities for Indigenous businesses, and will request input from First Nations and the Red River Métis on these strategies in 2023.

During the 2021 Regulatory Oversight Report meeting, Sagkeeng First Nation (SFN) and the MMF provided recommendations on how CNL can continue to progress its relationship with the communities through more active involvement of community members in CNL's environmental monitoring activities. CNL values these recommendations, and is working with First Nations and the Red River Métis communities to co-develop well-defined, community led environmental monitoring programs that focus on sampling and analyzing results identified by the communities as most important to them. In 2022 December, leadership from Sagkeeng First Nation, CNL and AECL participated in a traditional signing ceremony for the new independent Sagkeeng Community Environmental Monitoring Program. Sagkeeng First Nation named the program Niigan Aki, meaning Land First, through a cultural ceremony.

CNL has and will continue to work closely with the SFN to support and fund monitoring initiatives including Niigan Aki. The program is currently under development by SFN and their technical/environmental advisors, and it is understood that it will focus on their traditional and cultural values including country foods. The monitoring is planned for both on-site at the WL Restoration Project and in SFN's traditional territory away from the project site. To promote more in-depth, ongoing communication with SFN, CNL also funds monthly working group meetings, the SFN Community Liaison Committee, and a part time Community Liaison Officer position.

CNL has also committed to collaborating with other communities including a MMF wildlife and environmental monitoring program for the WL site.

Through ongoing communication and engagements, and with direction from Indigenous community representatives, CNL modified the WL environmental monitoring program to include Valued Components, identified by the communities, such as the harvesting of wild mushrooms, wild berries and wild rice, and the potential to sample sturgeon and traditional medicinal plants in the project area. Adding these elements builds CNL's knowledge and increases the confidence of community members that traditional foods and medicines on and near the Whiteshell site can be safely harvested and consumed. With the aforementioned Niigan Aki (CEMP) and MMF-led programs, the expectation is that this list of Valued Components could grow as the community-based environmental monitors get out onto the lands, both within the project area as well as the surrounding area, with the full support of CNL staff.

CNL recognizes the importance of Traditional Knowledge and Land Use Studies and has supported the development of these studies in the context of the WR-1 project. CNL is interested in developing Long-Term Relationship Agreements with Nations that support their capacity to participate meaningfully in the WLRP. While recent focus has been on the WR-1 project EIS, environmental monitoring and other matters, CNL is committed to developing these agreements when the Nations are ready to move forward with these discussions.

Further to these initiatives, CNL supports and provides funds to all Indigenous communities including the Red River Métis' participation on the Indigenous Advisory Committee. These initiatives have and will continue to improve communication about site activities, and provide another avenue for open and transparent discussion about the project. In addition, CNL remains committed to notifying First Nations and the Red River Métis of WL events that may impact traditional activities off site.

15.2.1 Engagement Objectives

As part of its corporate, environmental, and social responsibility, CNL recognizes the value of ongoing engagement with the First Nations and the Red River Métis (represented by the MMF) through the course of the environmental assessment process for the WR-1 Project and engagement on the overall site restoration project. Through two-way information-sharing and other engagement activities, CNL seeks to build awareness of its plans and activities, and, learn about interests and concerns of the First Nations and the Red River Métis in an effort to strengthen mutual understanding, and pursue opportunities for collaboration and long-term relationships.

CNL engages with First Nations and Red River Métis leadership, representatives and members on the potential effects of the WR-1 Project and the WLRP on the environment and on Indigenous and/or treaty rights including rights to trap, hunt, fish, gather and conduct cultural ceremonies.

CNL has five overarching Indigenous engagement goals:

- **Build awareness and mutual understanding**, and demonstrate CNL's long-term commitment and approach to safe and responsible management of AECL's radioactive waste and decommissioning liabilities (e.g., through project and site monitoring activities), by supporting and facilitating opportunities for mutual learning, including current and traditional land use, and values and perspectives on nuclear decommissioning, environmental remediation and radioactive waste management.

- **Share information on the project, including the potential effects on the environment.** This includes developing meaningful, user-friendly information and communication products for the First Nations and the Red River Métis, and providing accessible and current information on Project activities.
- **Seek input and feedback from the First Nations and the Red River Métis** regarding Project-related activities, and traditional and current uses of the land surrounding the WL site. Initiate early and meaningful two-way communication between CNL and the First Nations and the MMF to determine the best methods for sharing information and to provide opportunities for Indigenous peoples to provide input on Project considerations including design, the environmental assessment process, and assessment of effects. This includes exploring opportunities for Indigenous economic participation on the Project.
- **Develop long-lasting relationships with the First Nations and the Manitoba Métis Federation** to support their continued involvement in the Project, as well as community healing and reconciliation. These relationships will extend beyond the scope of the environmental assessment process for the WR-1 project.
- **Meet or where possible exceed all regulatory-based communication and engagement requirements** and facilitate engagement that reflects current memorandums of understanding and contribution agreements, that takes into account the interests, needs and capacity of each Indigenous Nation.

15.2.2 Identified Indigenous Communities

CNL developed a list of the Indigenous communities and organizations with a potential interest in the WR-1 Project and the WLRP. The identification of the First Nations and the Red River Métis was based on consultation with the CNSC, through CNL's previous Indigenous engagements, and through the use of publicly available sources of information including:

- First Nation and the Red River Métis and organization websites;
- The Aboriginal and Treaty Rights Information System (ATRIS; Government of Canada and INAC 2016); and
- Crown-Indigenous Relations and Northern Affairs Canada First Nation community profiles.

The list was based on the identified potential or established Indigenous or treaty rights of the First Nations and the Red River Métis and is provided in Table 62 with a brief rationale for inclusion. The inclusion of specific Nations considers the nature of the established and/or claimed rights, and potential effects on those rights caused by the proposed project, based on a preliminary assessment of existing and available information. As such, the working list is subject to change based on information and dialogue with the identified First Nations, the Red River Métis, and Indigenous organizations. Involvement in CNL engagement is at the discretion of each community and subject to community preferences and availability.

Table 62: Identified Indigenous Communities

First Nations, the Red River Métis or Organizations	Identification Rationale
Sagkeeng First Nation (Treaty No. 1 and 3)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the WL site. Occupy one reserve located 52 kilometres (km) north of the WL site, and downstream along the Winnipeg River. Existing relationship and interest in the WL site. The WL site is within the boundaries of the area over which Sagkeeng claims unsurrendered Aboriginal title, a proceeding for which is ongoing in the Manitoba Court of King's Bench.
Brokenhead Ojibway Nation (Treaty No. 1)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the WL site. Occupy three reserves: 44 km northwest, 55 km northwest and 73 km southwest of the WL site respectively. Interest expressed comments on Project Description.
Manitoba Métis Federation	The MMF is the official democratic and self-governing political representative for the Métis Nation's Manitoba Métis Community. The MMF is considered the government of the Red River Métis. Potential asserted and/or established Métis harvesting rights in the vicinity of the Project. Interest expressed comments on Project Description.
Black River First Nation (Treaty No. 5)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the WL site. Occupy one reserve 75 km north of the WL site.
Hollow Water First Nation (Treaty No. 5)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the WL site. Occupy one reserve, 113 km north of the WL site.
Shoal Lake No. 40 (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the WL site. Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. Occupy three reserves: 94 km southeast, 110 km southeast and 140 km southeast of the WL site, respectively.
Iskatewizaagegan No. 39 Independent First Nation (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the WL site. Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. Occupy four reserves: 93 km southeast, 102 km southeast, 110 km southeast and 140 km southeast of the WL site, respectively.
Northwest Angle No. 33 (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the WL site. Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. Occupy three reserves: 111 km southeast, 140 km southeast and 176 km southeast of the WL site, respectively.

First Nations, the Red River Métis or Organizations	Identification Rationale
Wabaseemoong Independent Nations (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the WL site. Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. Occupy four reserves: 80 km east, 85 km east, 95 km east and 140 km southeast of the WL site, respectively.
Grand Council of Treaty 3	Umbrella treaty organization which represents 28 First Nations and 5 with potential interest in the Project. Treaty 3 territory includes parts of eastern Manitoba, including the WL site.
Chiefs of Ontario	First Nations umbrella organization that represents 133 First Nations and 4 with potential interest in the Project

15.2.3 Summary of Engagement

Environmental monitoring and environmental protection are consistent and important topics of discussion meetings between CNL and First Nations and the Red River Métis. CNL has provided an open invitation for Indigenous community participation in the WL Environmental Protection Program. CNL has also shared the annual Environmental Protection Program schedule for monitoring activities so that interested Nations can identify and participate in activities that are of specific interest to them.

In 2022, CNL hosted five environmental monitoring activities that included mushroom collecting, blueberry picking, a bat survey and field monitoring with the MMF, Black River First Nation and Hollow Water First Nation. CNL also participated in 43 virtual meetings, including monthly working group meetings with Sagkeeng First Nation, Manitoba Métis Federation, Black River First Nation, Hollow Water First Nation, Brokenhead Ojibway Nation Wabaseemoong Independent Nations, and Grand Council of Treaty #3.

Over the year, CNL and SFN focused on the development of the community-led CEMP at WL, which was recognized through a traditional signing ceremony for SFN, CNL and AECL in December. The SFN Community Liaison Committee and Liaison Officer had sought out guidance from local SFN Elders and, through the passing of tobacco, the CEMP received a traditional name, Niigan Aki, meaning Land First. It is expected that SFN will begin activities under the CEMP in 2023, which will have the full support of CNL and AECL.

CNL also continued to work closely with the MMF with a focus on developing a *Harvesting Sample Collection Program* led by the Red River Métis. Both parties are working toward finalizing this program in 2023 with the expectation that MMF monitoring will begin soon after.

Environmental monitoring discussions have been ongoing with Black River First Nation and Hollow Water First Nation, as well as with Grand Council Treaty #3, with expectations for more positive progress as we work toward more formal monitoring programs that involve the communities to the degree they wish.

Through engagements, and with direction from Indigenous community representatives, CNL modified the WL environmental monitoring program to include Valued Components identified by the communities such as the harvesting of wild mushrooms, wild berries and wild rice, and the potential to sample sturgeon and traditional medicinal plants in the project area. Adding these elements builds CNL's knowledge and increases the confidence of community members that traditional foods and medicines on and near the Whiteshell site can be safely harvested and consumed. With the aforementioned Niigan Aki (CEMP) and MMF-led programs, the expectation is that this list of Valued Components could grow as the community-based environmental monitors get out onto the lands, both within the project area as well as the surrounding area, with the full support of CNL staff.

Table 63 lists all Indigenous engagement activities related to the WLRP from 2022, with further details available in the Indigenous Engagement Report [53].

Table 63: CNL Indigenous Engagement Activities for 2022

Date	Event	Location
Sagkeeng First Nation		
January 5, 2022	CNL held a teleconference to go over Sagkeeng's comments on WR-1 EIS Section 4.0 (Indigenous Engagement) and to confirm the list of interests and concerns was complete.	Virtual
January 31, 2022	CNL sent Sagkeeng a revised copy of Section 4.0 (Indigenous Engagement) and Section 6.7 (Human Ecological Health).	Virtual
February 03, 2022	Sagkeeng provided CNL with drafts of Sagkeeng's Community Environmental Monitoring Program and Healing and Resiliency Action Plan.	N/A
February 22, 2022	Technical Working Group Meeting with AECL and Sagkeeng.	Virtual
March 02, 2022	SFN provided an overview of the Healing and Resiliency Action Plan.	Virtual
March 09, 2022	CNL, AECL, and Sagkeeng held further discussions on Sagkeeng's scope of work for the Community Environmental Monitoring Program.	Virtual
March 22, 2022	Two CNL representatives met with Sagkeeng's community liaison committee to get to know each other and learn more about the WR-1 Project.	Virtual
April 06, 2022	Technical Working Group Meeting with Sagkeeng First Nation to discuss the scope of work for SFN's Community Environmental Monitoring Program and repackaging of SFN's interests and concerns table.	Virtual
May 10, 2022	CNL, AECL, and Sagkeeng walked through Sagkeeng interests and concerns table and discussed the upcoming in-person workshop on Sagkeeng's Community Environmental Monitoring Program.	Virtual
May 20, 2022	CNL and Sagkeeng discussed the logistics of the Guardianship Workshop.	Virtual

Date	Event	Location
June 15, 2022	CNL representatives met with Sagkeeng and AECL representatives for a workshop to negotiate on Sagkeeng's Community Environmental Monitoring Program that would help to reduce fear and stigma associated with the WL site and its surroundings.	In-person, Winnipeg
June 16, 2022	Day 2 of a tri-lateral workshop involving AECL, CNL and Sagkeeng representatives to agree on the terms of Sagkeeng's Community Environmental Monitoring Program and confirmed the interest and concerns table accurately Sagkeeng's state interests and concerns.	In-person, Winnipeg
July 19, 2022	Sagkeeng Community Liaison Committee WR-1 Tour involving nine community members.	In-person, WL Site
July 13, 2022	Informed the community that CNL has officially submitted the revised EIS to the CNSC.	Email/Letter
August 25, 2022	Sagkeeng Technical Working Committee Budget Meeting.	Virtual
September 07, 2022	CNL-AECL-Sagkeeng First Nation consultation meeting.	Virtual
September 20, 2022	Sagkeeng confirmed they accepted CNL's final edits to the contribution agreement to support SFN's Community Environmental Monitoring Program	Email
October 20, 2022	CNL sent a letter and email informing SFN where to access relevant portions of the updated sections of the WR-1 EIS for review and validation.	Email/Letter
November 02, 2022	CNL-AECL-SFN Technical Working Group meeting.	Virtual
November 16, 2022	Letter sent regarding the beginning of the Land Use End State community engagement and polling kick-off.	Letter/Email
November 18, 2022	Email from SFN indicating that they have reviewed Section 4 and the Engagement Log of the EIS and encourage submission of the document to the CNSC	Email
December 05, 2022	Meeting with SFN to discuss and plan for upcoming Community Environmental Monitoring Program signing ceremony.	Virtual
December 07, 2022	CNL-AECL-SFN Technical Working Group meeting.	Virtual
December 12, 2022	CNL-AECL-SFN Historical signing ceremony at the Sagkeeng Healing Lodge for the community based Environmental Monitoring Program given the traditional name Niigan Aki.	In-person – Sagkeeng FN
December 16, 2022	CNL sent an email indicating that the WR-1 EIS was resubmitted to the CNSC for review.	Email
Manitoba Métis Federation		
January 06, 2022	Meeting with the MMF to discuss their review of the EIS.	Virtual
January 06, 2022	The MMF send feedback on the draft relationship agreement.	Virtual

Date	Event	Location
February 18, 2022	CNL provided MMF with a revised draft for the relationship agreement.	N/A
February 27, 2022	Provided a donation to support the Manitoba Métis Federation's Annual General Assembly and registered for a booth.	N/A
March 02, 2022	CNL and MMF's communication director met to discuss co-developing an infographic in preparation for MMF's Annual General Assembly.	Virtual
March 24-27, 2022	CNL participated in the MMF's Annual General Assembly. CNL had a booth at the event and engaged with Red River Métis citizens on the WL Restoration Project.	In-person- Winnipeg
March 29, 2022	CNL walked MMF and their consultants through the repackaged interest and concerns table, and discussed their review and timeline. CNL and the MMF also discussed Red River Métis rights, claims, and interests.	Virtual
April 25, 2022	Teleconference with MMF to walk through Interest and Concerns table.	Virtual
May 18, 2022	CNL walked through Interests and Concerns table based on the MMF's suggestions.	Virtual
May 25, 2022	Discussion with the MMF on their Relationship Agreement Clause.	Virtual
May 26, 2022	Environmental Monitoring discussion.	Virtual
July 6, 2022	Manitoba Métis Federation Monthly Meeting.	Virtual
July 28, 2022	MMF representative attended Groundwater Monitoring Collection and looked at nesting locations.	In-person, WL site
August 10, 2022	CNL participated in MMF Community Consult Meeting in Lac du Bonnet. CNL shared information on their environmental monitoring program.	In-person, Lac du Bonnet
August 17, 2022	Métis Citizens participated in a bat survey at the WL Site	In-person, WL site
September 07, 2022	MMF/CNL working group meeting.	Virtual
October 14-16, 2022	Attended and set-up CNL booth at the MMF Annual General Assembly	In-person – Winnipeg
October 20, 2022	CNL sent a letter and email informing MMF where to access relevant portions of the updated sections of the WR-1 EIS for review and validation.	Email/Letter

Date	Event	Location
November 16, 2022	Letter sent regarding the beginning of the Land Use End State community engagement and polling kick-off	Letter/Email
November 16, 2022	Meeting held with MMF Environmental staff re: future monitoring at WLRP.	Virtual
November 22, 2022	MMF-CNL Monthly working group meeting.	Virtual
December 01, 2022	Environmental field monitoring with MMF.	In-person, WL site
December 07, 2022	Meeting with MMF - focused on EIS submission and future MMF led Harvesters Sampling/Monitoring Plan.	Virtual
December 16, 2022	CNL sent an email indicating that the WR-1 EIS was resubmitted to the CNSC for review.	Email
Black River First Nation, Hollow Water First Nation, Brokenhead Ojibway Nation		
February 08, 2022	WR-1 Project Update with Black River First Nation (BRFN) and Hollow Water First Nation (HWFN) and discussion of next steps for engagement.	Virtual
February 16, 2022	Co-developing infographics with BRFN and HWFN.	Virtual
March 15, 2022	CNL informed BRFN and HWFN that CNL would be repackaging their interests and concerns table as a result of CNSC feedback on a similar project.	Email
April 13, 2022	BRFN and HWFN Monthly Teleconference.	Virtual
May 10, 2022	CNL Met with BRFN and HWFN to discuss the status of the WR 1 submission	Virtual
May 11, 2022	Monthly Update with BRFN and HWFN that included a walk-through of the revised interests and concerns table.	Virtual
May 25, 2022	Discussion with BRFN and HWFN on the upcoming tour.	Virtual
June 9, 2022	Site tour with BRFN/HWFN Core Engagement Team.	In-person, WL Site
June 13, 2022	CNL requested confirmation from the communities that the interests and concerns table reflected their feedback.	Email
July 13 2022	Discussion about CNL's participation in BRFN and HWFN Treaty Days.	Virtual
July 13, 2022	Monthly meeting with BRFN/HWFN.	Virtual
July 13, 2022	Informed the community that CNL has officially submitted the revised EIS to the CNSC.	Email/Letter
July 28, 2022	BRFN/HWFN Berry Picking at Underground Research Lab Site.	In-person, WL Site
August 17, 2022	BRFN/HWFN Monthly Meeting.	Virtual

Date	Event	Location
September 08, 2022	BRFN and HWFN participated in mushroom collection from three locations around the WL Site.	In-person, WL site
September 14, 2022	CNL-BRFN-HWFN Monthly working group meeting. CNL, BRFN, and HWFN discussed extending the existing relationship agreement and coordinating future environmental monitoring activities.	Virtual
September 20, 2022	CNL sent an invitation to BRFN, HWFN and Brokenhead Ojibway Nation to participate in a webinar on the WR-1 Decommissioning Project.	Email
September 29, 2022	Nine members and knowledge holders from BRFN and HWFN participated in a medicinal plant walk at the Whiteshell Laboratories site.	In-person, WL site
October 20, 2022	CNL sent a letter and email informing BRFN and HWFN where to access relevant portions of the updated sections of the WR-1 EIS for review and validation.	Email/Letter
October 27, 2022	CNL-BRFN-HWFN Monthly working group meeting.	Virtual
November 16, 2022	Letter sent regarding the beginning of the Land Use End State community engagement and polling kick-off.	Letter/Email
November 17, 2022	CNL-BRFN-HWFN Monthly working group meeting.	Virtual
December 13, 2022	CNL provided a copy of the commitments list to BRFN and HWFN for discussion and review at the monthly meeting.	Email/Attachment
December 14, 2022	CNL-BRFN-HWFN Monthly working group meeting.	Virtual
December 16, 2022	CNL sent an e-mail indicating that it had resubmitted the WR-1 EIS to the CNSC for review.	Email
Wabaseemoong Independent Nations (WIN)		
May 06, 2022	Walk through of changes CNL made to Interests and concerns table based WIN's feedback.	Virtual
July 13, 2022	Informed the community that CNL has officially submitted the revised EIS to the CNSC.	Email/Letter
October 20, 2022	CNL sent a letter and email informing WIN where to access relevant portions of the updated sections of the WR-1 EIS for review and validation.	Email/Letter
November 12, 2022	Discussion with WIN Liaison to discuss Whiteshell activities and if WIN were still interested in engagement with WL. Liaison indicated that they will work with GCT3 going forward.	Phone call

Date	Event	Location
November 16, 2022	Letter sent regarding the beginning of the Land Use End State community engagement and polling kick-off.	Email/Letter
December 16, 2022	CNL sent an email indicating that it had resubmitted the WR-1 EIS to the CNSC for review.	Email
Grand Council Treaty 3 (GCT3)		
June 29, 2022	CNL informed GCT3 that the draft EIS had been submitted.	Telephone call
July 13, 2022	Informed the community that CNL has officially submitted the revised EIS to the CNSC.	Email/Letter
September 23, 2022	Working group meeting held with GCT3 with a focus on waste transportation.	Virtual
October 21, 2022	CNL provided an update to GCT3 on the status of the WR-1 EIS.	Email/Letter
November 10, 2022	CNL-GCT3 Working group meeting.	Virtual
November 16, 2022	Letter sent regarding the beginning of the Land Use End State community engagement and polling kick-off.	Letter/Email
December 15, 2022	CNL-GCT3 monthly working group meeting.	Virtual
December 16, 2022	CNL sent an email indicating that it had resubmitted the WR-1 EIS to the CNSC for review.	Email
December 19, 2022	CNL provided detailed responses to GCT3 to questions submitted following the December monthly meeting.	Email

15.2.4 CNL’s Long-Term Relationship with Indigenous Peoples

CNL recognizes First Nations and the Red River Métis as stewards of the land and is working towards developing meaningful long-term relationships with each Nation that occupies and has traditional territories and/or modern-day interests near its site operations. CNL recognizes each Nation has its own unique set of interests and concerns associated with both the WR-1 decommissioning project and the WLRP.

As such, CNL is committed to taking a holistic, relationship-based and distinctions-based approach to engagement to ensure each Nation’s interests and concerns are addressed appropriately. CNL also works closely with AECL, the federal Crown Corporation responsible for oversight of the WLRP, to address interests and concerns regarding all aspects of the project.

This shift in CNL’s approach from project-based to relationship and distinction-based engagement supports more meaningful actions to build foundations for trust, understanding, and mutually beneficial relationships, including addressing broader issues and concerns such as the historical selection of the WL site.

CNL is currently working with each Nation to formalize these relationships through relationship-building and corresponding agreements. These agreements are intended to help enable greater integration of Traditional Knowledge, ceremony, and cultural and stewardship practices in the decommissioning, monitoring, and closure of the project. These agreements will also enable dialogue and participation through the development of monitoring programs, culturally appropriate communications, and trauma-informed engagement. In addition, the agreements help to enhance community engagement, build trust and strengthen relationship-building, and provide mechanisms that facilitate Indigenous participation and input into CNL's environmental monitoring program, economic development and procurement opportunities, future land use, and other areas of collaboration.

CNL is currently negotiating separate relationship agreements with Black River First Nation, Hollow Water First Nation, Sagkeeng First Nation and the Red River Métis, and is committed to ongoing meaningful engagement that leads to finalizing these agreements.

16 Acronyms

α	Alpha
ACMR	Annual Compliance Monitoring Report (formerly Annual Safety Review (ASR) or Annual Compliance Report (ACR))
AECL	Atomic Energy of Canada Limited
ALARA	As Low as Reasonably Achievable
ALWTC	Active Liquid Waste Treatment Centre
ATG	Analytical Test Group
β/γ	Beta-Gamma
BOD	Biochemical Oxygen Demand
Bq	Becquerels
BRFN	Black River First Nation
CANDU	Canada Deuterium Uranium
CBOD	Carbonaceous Biochemical Oxygen Demand
CCSF	Concrete Canister Storage Facility
CEMP	Community Environmental Monitoring Program
CRL	Chalk River Laboratories
CNL	Canadian Nuclear Laboratories
CNSC	Canadian Nuclear Safety Commission
COVID-19	Novel Coronavirus Disease 2019
Cs	Cesium
CSA	Canadian Standards Association
CSD	Criticality Safety Document
DCP	Dose Control Point
DDP	Detailed Decommissioning Plans
EIS	Environmental Impact Statement
EOC	Emergency Operations Centre
ERM	Environmental Remediation Management
GCT3	Grand Council Treaty 3
GHG	Greenhouse Gas

HCF	Hot Cell Facility
HWFN	Hollow Water First Nation
IAEA	International Atomic Energy Agency
ICP	Inductively Coupled Plasma Spectrometry
IFTF	Immobilized Fuel Test Facility
ILW	Intermediate-Level Waste
ImpAct	Improvement Action
ISO	International Standards Organization
LLD	Lower Limit of Detection
LLLW	Low-Level Liquid Waste
LLLWTS	Low-Level Liquid Waste Treatment System
LLW	Low-Level Waste
LMDL	Laboratory Method Detection Limit
MMF	Manitoba Métis Federation
MPNU	Most Probable Number Unit
MRAD	Multi-Media Radiochemistry
NEW	Nuclear Energy Worker
NNC	Notice of Non-Compliance
NPRI	National Pollutant Release Inventory
OSH	Occupational Safety and Health
PAD	Personal Alarming Dosimeter
PCB	Polychlorinated Biphenyl
PIP	Periodic Inspection Plan
PM	Particulate Matter
REGDOC	Regulatory Document
RMDL	Regulation Method Detection Limit
RP	Radiation Protection
SAR	Safety Analysis Report
SCA	Safety and Control Area
SF	Shielded Facilities

SFN	Sagkeeng First Nation
SMAGS	Shielded Modular Above Ground Storage
TLD	Thermoluminescent Dosimeters
TSS	Total Suspended Solids

Appendix A Concrete Canister Storage Facility

A.1 Operations

The Concrete Canister Storage Facility is operated under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [54]. Concrete storage canisters located at the CCSF have been used at WL since 1975 to store irradiated fuel; there are currently 16 canisters in use.

During 2022, routine operations in the CCSF were carried out by staff in the Site and Nuclear Operations Branch.

The CCSF was operated in compliance with practices and procedures approved for operation. All required surveys and inspections were completed in 2022, with the exception of air sampling from Canister C-8 – see Section A.2.1 for more information.

In 2022, training two of three Operations Technologist trainees continued with one trainee assigned to Site operations for the year. A new Facility Authority was appointed for the WMA and CCSF. Total Site and Nuclear Operations personnel for the CCSF and WMA included a Facility Authority, a Facility Manager, a Facility Supervisor/Operator, two Operator trainees and two WMA Utility workers.

In 2022, the CCSF continued to maintain the minimum staffing requirements outlined in the CCSF Facility Authorization [54]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the CCSF in 2022. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities operating procedures. WL is behind in the 5 year procedure updates and are scheduled to complete the updates in 2023. A revised Facility Authorization document was sent to CNSC along with the Nuclear Safety Note for fuel retrieval (see Section 4.1.1), and will be further revised in 2023 to address CNSC comments.

A.2 Compliance Monitoring

A.2.1 Air Effluent Monitoring of Canister Liners

Each canister has a closed air-circulating system to monitor the internal space between the canister liner and the sealed fuel basket for the presence of fission products and moisture. Canisters are monitored for one week per month between April and November, dependant on weather. This year readings began in May and concluded in September. Despite multiple attempts flow could not be established in the Canister 8 air lines, these air lines have had issues in previous years obtaining flow. The normal approach to establishing air flow through lines was unsuccessful. During each air sampling period in 2022 attempts were made to recover a sample.

The gross beta activity was below or near the detection limit of 0.04 Bq/m^3 for all canisters that were measured.

There was no visible moisture detected from the internal canister space during 2022 monitoring from the canister with air circulation, however, the silica gel used in the counting did change colour from blue to pink indicating moisture in the air is present.

A.2.2 Monitoring of Ground and Surface Water

Figure 15 shows the drainage area surrounding the CCSF. Further details on monitoring and results of monitoring ground and surface water can also be found in Sections 9.4.1.3 and 9.5.1.4, and compliance results for the CCSF are described below.

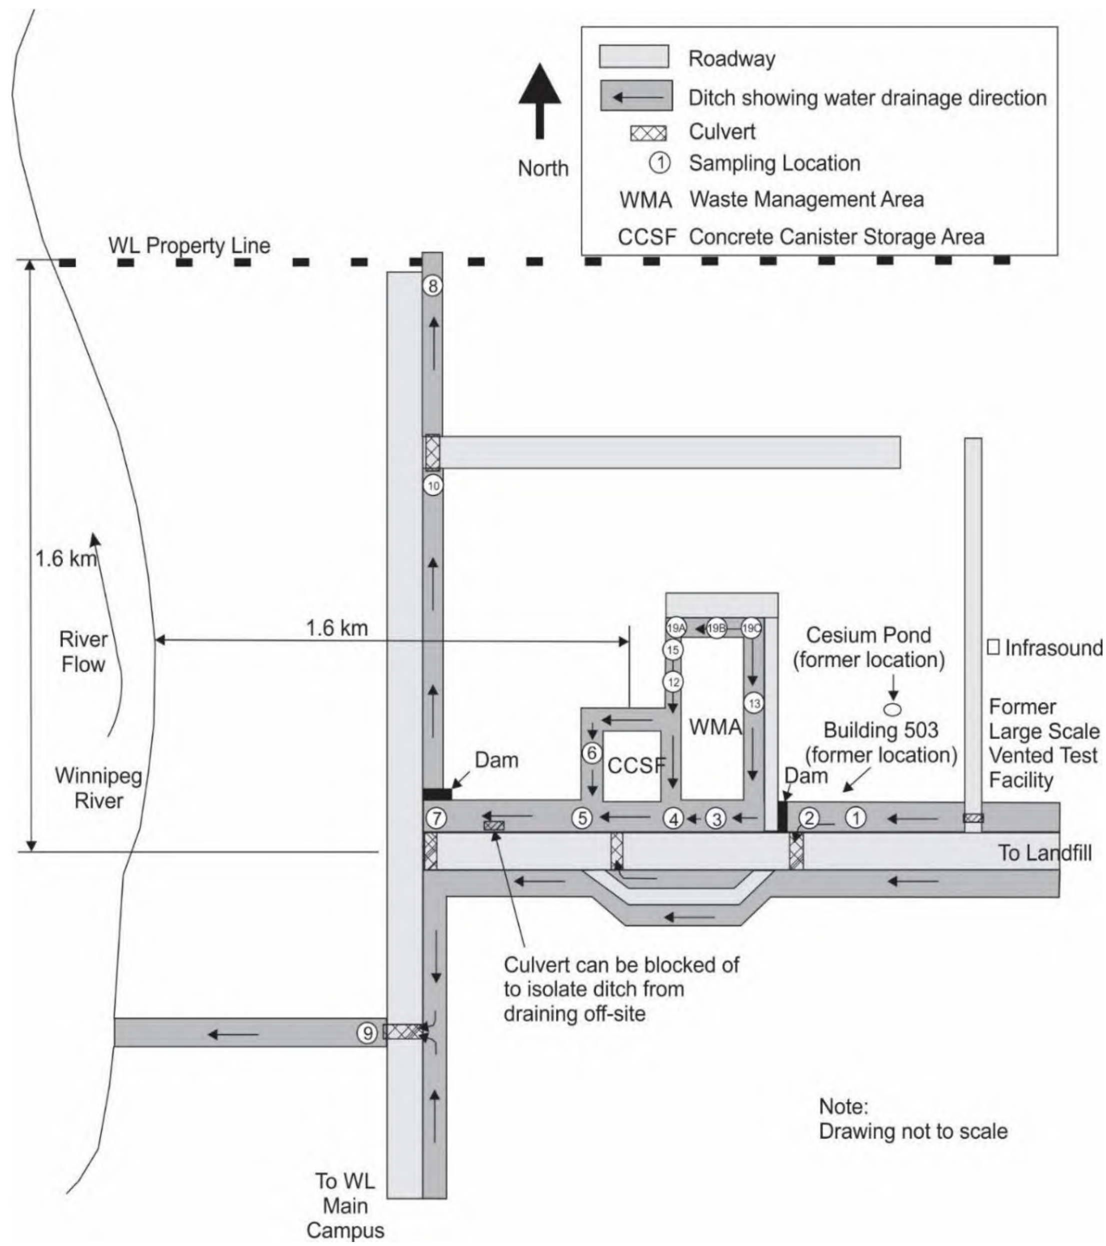

Figure 15: Surface Water Drainage Sample Points

Groundwater samples from deep-well sites in the vicinity of the CCSF are obtained twice yearly; the results are reported and discussed in Appendix D of this report.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the canisters. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

Table 64, Table 65, Table 66 and Table 67 list the results of the surface-water samples taken from the vicinity of the CCSF and WMA during 2022. Operational control-monitoring data from previous years has been included for completeness.

If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry analysis and processed for Strontium (Sr)-90. Gamma spectrometry analysis provides individual results for Cobalt (Co)-60, Niobium (Nb)-94, Antimony (Sb)-125, Cs-134, Cs-137 (Barium (Ba)-137m), Promethium (Pm)-147 and Americium (Am)-241.

If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry analysis and uranium analysis. Uranium analysis has also been conducted for other sampling locations below the limit this year. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration established by Health Canada [37]. If uranium is detected, the result is evaluated against the Maximum Acceptable Concentration for uranium (0.5 Bq/L).

Ditch Location 5 and Ditch Location 6 samples (see Figure 15 for sampling locations) receive surface drainage from the CCSF. The alpha activities at Location 5 and 6 were below the trigger level of 0.5 Bq/L, except for Location 5 on May 03 where a sample measurement indicated 0.62 Bq/L. The uranium analysis for the sample indicated 10.5 ppb. The average for this location is 8.55 ppb for 2022, which is lower than values measured in the last five years Table 66.

The ditch sample collected and points 5 and 6 contained elevated levels of tritium when compared to background measures obtained remote from the WMA (see Table 66), which did not exceed the associated Maximum Acceptable Drinking Water concentration of 7,000 Bq/L [37]. The activity seen is from the WMA as discussed in Appendix D.

A.3 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [16]. There were no Category 1 and 2 changes in 2022.

A.4 Equipment Performance, Planned Maintenance Testing and Inspections

All canisters are checked for deviation from vertical annually. Out of 16 canisters, all displayed slight deviations from vertical in 2022. None of the canisters had a deviation greater than 1°. In 2022, Canister C5 had a deviation of 0.8° to the east and 0.9° to the south. This deviation and those observed on other canisters show that they all display slight movements in response to changing soil moisture conditions and related swelling and contraction of the clay layer. If a canister was noted either through vertical deviation measurements or visually to be trending beyond a 2-3° deviation, corrective measures such as bracing would be considered.

There were no canister loading or unloading operations in 2022.

As required by Section 8 of the Facility Authorization [54], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests were complete. The inspections were all completed.

Whiteshell Laboratories staff conducted general site inspections during each quarter of 2022. Minor fence repairs and infilling was done along the base of the fence to meet security requirements as required.

In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however, existing cracks and pour pockets were regularly checked for changes and it has been noted that edges of many pour pockets are more brittle as has been noted since 2020. No patching or coating of canisters was done in 2022. No increased radiation field was noted from the canisters.

A.4.1 Canister Site Monitoring and Surveillance

GAMMA FIELD SURVEYS

Gamma exposure rates from the canisters were measured quarterly in 2022. These readings were taken in compass directions north-east-south-west, on contact, and 2.0 m from the canister wall at an elevation of 2.0 m above grade level.

No gamma field anomalies were found during 2022.

Table 68 shows the averaged gamma near contact exposure rates measured during 2022, and for the previous four years.

Table 68: Summary of Average Gamma Radiation for Near Contact Measurements from Fuelled Canisters (mrem/h)

a The measurements were made using a BOT P200 survey meter. The instruments are calibrated in mR/h and it is assumed 1 mR/h =1 mrem/h

AIR MONITORING

Air monitoring was conducted on each of the canisters in the CCSF in 2022. This involved an air pump that circulates air from an outlet line on the canister through a Dexter filter and returns it through an inlet line. These readings are taken once per month over a period of approximately one work week during warm weather months. Typically this is the six months of the year when air temperatures are normally above zero. Only 5 measurements were made (May through September due to colder weather in October). As discussed above in Section A.2.1, flow could not be established in the Canister 8 air lines in 2021 or 2022. Attempts to clear the lines were unsuccessful.

Table 69 shows the averaged beta readings on each filter measured during 2022, and for the previous four years.

Table 69: Summary of Average Beta Radiation Measurements from Fuelled Canisters (Bq/filter)

A.5 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the CCSF as part of routine operations.

See Section 11.1 Waste Management Program for summaries of any volume of radioactive solid and/or liquid waste generated in the CCSF in 2022.

A.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the CCSF as part of routine operations.

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

Appendix B Active Liquid Waste Treatment Center

B.1 Operations

The Active Liquid Waste Treatment Center in Building 200 did not operate in 2022, as the building was previously demolished.

Demolition of Building 200 above grade and 1.5m below grade were completed in 2021 October. The demolition footprint is still fenced and protected. The fence will remain until the potentially contaminated ground can be remediated.

Appendix C Shielded Facilities

C.1 Operations

The WL Shielded Facilities (SF) operates under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [55]. The SF, consisting of the Hot Cell Facility (HCF) and the IFTF, are located in the R&D Complex (Building 300), and are operated by personnel in the Site and Nuclear Operations Branch.

The HCF Cells 1 to 5 and IFTF Cell 13 remain operational while HCF Cells 6 to 11 have been shut down and partially dismantled. The Waste Handling Area, located in the IFTF, was operated for compaction and assaying of radioactive waste.

Operations and decommissioning activities were conducted throughout the year. Operations activities included:

- maintenance of HCF and IFTF ventilation system equipment;
- replacement of high-efficiency particulate air filters;
- packaging and storage of radioactive waste;
- cleanup activities; and
- routine maintenance to ensure compliance with the site licence.

Routine operations in the SF were carried out by operating staff from the Site and Nuclear Operations Branch.

There were no organizational changes in 2022. The minimum staffing requirements outlined in the SF Facility Authorization [55] were maintained at levels to provide the needed operational and safety support.

No program changes were made for the SF in 2022. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities operating procedures. WL is behind in the 5 year procedure updates and are scheduled to complete the updates in 2023.

C.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [16]. There were no Category 1 and 2 changes in 2022.

C.3 Equipment Performance, Planned Maintenance Testing and Inspections

Issues with missed and archived preventive maintenance activities was identified in 2021 and previously reported to the CNSC. A corrective action plan was developed, and continues to be implemented in order to fix the issues and prevent recurrence. Equipment tests and inspections were completed. Monthly housekeeping and fire prevention inspections were completed.

VENTILATION SYSTEM

Maintenance activities requiring part of the ventilation system to be taken down occurred without incident. The IFTF ventilation system has two active exhaust fans, one being a backup in case of failure. The backup exhaust fan was taken out of service while its corresponding air flow damper is being replaced.

The required annual routine Poly-Alpha-Olefin testing of the HCF high-efficiency particulate air filters were successfully conducted.

C.4 Wastes Generated

See Section 11.1 Waste Management Program for WL summaries of the volume of radioactive solid and liquid wastes generated in the SF in 2022.

LOW-LEVEL SOLID WASTE

In 2022, the SF generated 7.5 m^3 of compactable low-level radioactive solid waste and 0.1 m^3 of non-compactable waste.

Table 70 lists the annual low-level solid waste generated in the SF for 2022 and the previous four years.

Table 70: Solid Wastes Generated

Total Volume	2018	2019	2020	2021	2022
Low-Level Solid Waste (m^3)	73.3	64.3	10.9	45.6	7.5
Medium-Level Solid Waste (m^3)	0	0	0	0	0

MEDIUM-LEVEL SOLID WASTE

In 2022 the SF generated 0.02 m^3 of medium-level (intermediate-level) radioactive solid waste. Table 70 lists the annual medium-level solid waste generated for 2022 and the previous four years.

LOW-LEVEL LIQUID WASTE SYSTEM

In 2022, 117.3 m^3 of low-level liquid waste was processed through the Building 300 low-level liquid waste system (see Appendix E).

MEDIUM-LEVEL LIQUID WASTE SYSTEM

All the medium-level liquid waste (intermediate-level liquid waste) from the HCF cells collects in the HCF sump tank, AD Tank 1. The liquid is transferred via a manually controlled pump from AD Tank 1 through a filtration system to AD Tank 14 in the IFTF. The liquid from all other HCF medium-level liquid waste drains and all IFTF medium-level liquid waste drains flows by gravity to AD Tank 14.

In 2022, there were no transfers of medium level liquid waste.

Table 87 lists the annual liquid waste generated for 2022 and for the previous four years.

C.5 Effluents Released

Liquid radioactive and hazardous effluents were discharged from the SF as part of routine operations are provided and discussed in Section 9, Environmental Protection.

Appendix D Waste Management Area

D.1 Operations

The Waste Management Area operated under the WL Site Licence [1], in accordance with the requirements of the *Facility Authorization for the Operation of the Waste Management Area at the Whiteshell Laboratories* [56]. During 2022, the WMA at WL was operated and monitored by staff in the Site and Nuclear Operations Branch.

In 2022, the WMA was operated in compliance with approved practices and procedures.

Routine operations in the WMA were carried out by the Facility Manager, Facility Supervisor, WMA Operators and two WMA-based utility workers, with support from other Site and Nuclear Operations, Radiation Protection, and Environmental Monitoring personnel as required.

In 2022, training of two of three Operations Technologist trainees continued with one trainee temporarily assigned to Site Operations starting in 2022 May. A new Facility Authority was appointed for the WMA and CCSF.

In 2022, the WMA continued to maintain the minimum staffing requirements outlined in the Facility Authorization [56]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the WMA in 2022. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities operating procedures. WL is behind in the 5 year procedure updates and are scheduled to complete the updates in 2023.

D.1.1 Inventory Additions And Deletions

Changes in inventory are reported in Table 71 and for the purposes of reporting WMA inventory (fission products are defined as radioactive material originating from irradiated fuel).

Activation products are defined as any material that has been activated in a neutron flux, including corrosion products. The radioactivity values listed are those recorded at the time of storage.

D.1.2 Low-Level Solid Waste

Details of wastes transferred to the WMA are provided in Section 11.1.1. Waste generated from decommissioning work on the site was generally shipped to CRL for storage, although some waste was stored in the WMA. The stored volume of waste is listed in Table 71.

D.1.3 Industrial Waste

There were no additions of industrial chemical waste during 2022.

Table 71: Additions to Low-Level Waste Inventory

Period	Storage Locations	Volume (m^3)	Fission Products (GBq)	Activation Products (TBq)
Total Accumulation to 2021 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433.	18,798.84	1,967.38	330.58
Additions for 2022	Buildings 431 to 433	0	0	0
Removals for 2022	LLW Bunker 6	0	0	0
	LLW Bunker 5	360	1.14	0
	Buildings 431 to 433	65.8*	2.54	0
Total Accumulation as of 2022 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433	18,373.04	1,963.70	330.58

* Reflux Boiler

D.2 Compliance Monitoring

D.2.1 Monitoring And Surface Water

SURFACE WATER

Figure 15 shows the drainage area surrounding the WMA.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the WMA. The WMA and CCSF share a network of perimeter compliance monitoring ditches with designated sampling locations. Water samples are collected in these sample locations for analyses when there is sufficient flowing water present but only once in a given week during flow events. This avoids putting particular emphasis on a given week for sample results. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

In 2022, there were ten sampling periods where the ditch flow met the required flow conditions in at least some sample locations. In spring the runoff was larger than in 2021 due to a series of snowfall events in late winter and a series of rain storms in spring to summer. This is in notable contrast to 2021 when light snow and limited precipitation was received. A recorded amount of precipitation of 687 mm occurred in 2022, in contrast to 395 mm in 2021, which was a ten year low for recorded precipitation.

In an effort to streamline the operational environmental monitoring process, surface water samples are initially analyzed for gross beta, gross alpha, and tritium. The results are then evaluated using the following screening criteria:

If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry, and processed for Sr-90. Gamma spectrometry provides individual results for Co-60, Nb-94, Sb-125, Cs-134, Cs-137 (Ba-137m), Pm-147, Am-241.

If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry and uranium analysis, however, as was the case last several years, all water samples were tested for uranium. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration established by Health Canada [37]. If uranium is detected, the result is evaluated against the Maximum Acceptable Concentration for uranium (0.5 Bq/L or 20 ppb).

Levels of beta activity at ditch sample Locations 1 to 7 (Table 72) all remained below 10 Bq/L. Based on historical data, it is conservatively assumed that the beta activity in the surface water is Sr-90 in secular equilibrium with Y-90. While some locations showed beta activity levels in the ditch water remaining below the drinking water screening level of 1 Bq/L, all were below the drinking water limit of 5 Bq/L for Sr-90 and 10 Bq/L for Cs-137 [57]. Compliance with Guidelines for Canadian Drinking Water [37] may be inferred if the measurement for gross alpha and gross beta is less than 0.5 Bq/L and 1.0 Bq/L, respectively. There were exceedances of the Canadian Drinking Water [37] standard of 1.0 Bq/L gross beta (Table 72) in 2022 at sample points 3, 4, 5, and 7.

The alpha activity levels in the surface water are presented in Table 73, and were below 0.5 Bq/L except for Location 7 on 2022 April 28 (0.8 Bq/L). Uranium results are presented in Table 74.

Locations 19 A, B and C had been established to monitor for the uranium values believed to result from the use of local Lac du Bonnet Batholith granitic rock as base material for the SMAGS foundation as well as Cs-137 from the soil recovered from the former Cesium Pond that was stored in the area. Lac du Bonnet Batholith granitic rock had been also used for berm support material for the Cesium Pond pile, however that material was removed from the WMA in 2018. The Lac du Bonnet Batholith granite is noted to have elevated naturally occurring uranium. Sample results were obtained in 2022, and indicated uranium values greater than background values and higher than other sample points surrounding the WMA (Table 74).

As shown in Table 75, the tritium results are below the Maximum Acceptable Concentration of 7000 Bq/L [37]. Locations 19 A, B and C were, while originally chosen for sampling for the potential migration of Cs-137 due to the presence of the Cesium Pond soil pile, also show elevated tritium levels, with the highest values at location 19A with a sample result of 1067 Bq/L. It is believed the source relates to waste stored in Trench 19 near the northwest corner of the WMA.

The WMA contains a number of trenches with varying amounts of low-level radioactive waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. Based on the initial modelling [58], it was proposed that tritium would be present in the ditches (including the Locations 3 through 7 and 19 A, B and C) and possibly reach levels as high as 37 kBq/L. While tritium is elevated at some locations immediately around the WMA, periodic monitoring of the ditches has indicated that the levels of tritium at the points (Locations 8 and 9) leaving CNL property remain quite low (below an average value of 5.6 Bq/L in 2022).

The data includes continuing documentation of a spill incident that occurred in 1979 near ILW Bunker 3, from the reference sample point (Location 3) in the southeast section of the WMA, as shown in Figure 15 and Figure 16. In 2017, sampling Location 3 was reconfigured to allow preparations for future bunker and standpipe remediation. Surface water at this location serves as an indicator of movement of water from ILW Bunkers 1, 2 and 3. The most mobile radionuclide (tritium) is below the associated Maximum Acceptable Concentration. The levels of tritium in the surface water and groundwater are below the radiation screening criteria used for identifying contaminants of potential ecological concern (COPECs) of $1.27x10^7$ Bq/L [59]. Gross alpha and gross beta at Location 3 remained low. Table 72 through Table 75 include the historical monitoring at Ditch Locations 19 A, B and C, water flow permitting.

The Cesium Pond soil (Cs-137) that was stored in the WMA adjacent to SMAGS was removed in 2017. Table 76 reflects this circumstance and shows that no migration of Cs-137 to these ditches had occurred.

As Trench 16 has a known quantity of Technetium-99 (Tc-99), Tc-99 measurements were performed as part of ditch water monitoring in 2022. The values in (Table 77) are at or below limit of detection. The Tc-99 limit for drinking water is 200 Bq/L [57]. Due to the low values Tc-99 is not measured at the control point.

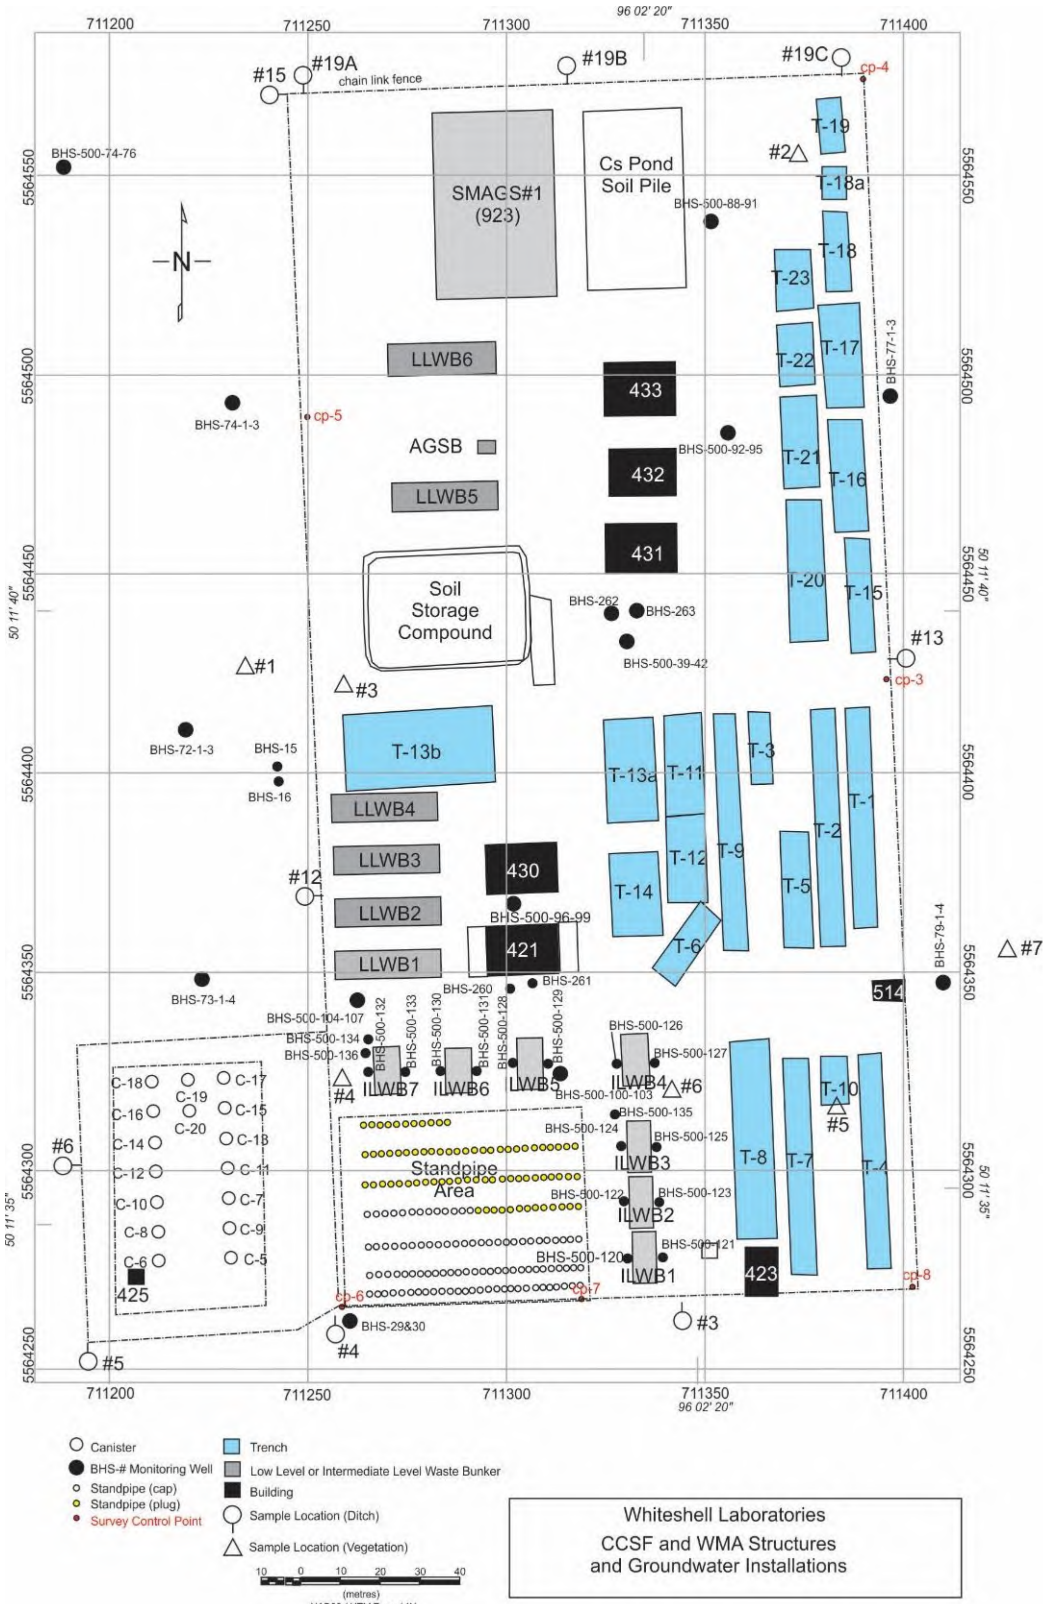

Figure 16: Ground Water Sample Points

INTERMEDIATE - LEVEL WASTE BUNKERS NEAR FIELD WELLS

A series of shallow near field wells were installed adjacent to the ILW bunkers in the WMA in 2015 (Figure 15). Groundwater samples were taken from the wells and from water in the ILW Bunkers for comparison. Cs-137, Sr-90, and tritium were selected as the radionuclides for monitoring of the potential for contaminant migration. Cs-137 was selected as the least mobile, with a high affinity for bonding with clay-based minerals, Sr-90 is more mobile but will bond with sand, and tritium is the most mobile that moves with water. Cs-137 and Sr-90 require a pathway (e.g., a construction joint or crack) to migrate from a bunker. In 2022, Sr-90 was noted to be a maximum of 26 Bq/L adjacent to ILW Bunker 1, and 39 Bq/L adjacent to ILW Bunker 3. For all other locations, the Sr-90 and Cs-137 levels were minor or negligible. Tritium can move through concrete without cracks by diffusion with water movement. The results indicate no migration of Cs-137 (Table 78) from the ILW Bunkers, and Sr-90 (Table 79) and tritium levels (Table 80) that are orders of magnitude below the levels observed in the water in the adjacent ILW Bunkers. At ILW Bunker 3, the tritium results remain high (a maximum of 150411 Bq/L) and moderately high at ILW Bunker 5 (a maximum of 7092 Bq/L).

A series of water measurements had been made as a confirmatory check in 2020 for the presence of base neutral chemicals (e.g., benzenes, ethylenes) and PCBs. These measurements indicated these chemicals were not present in the water around the bunkers. The measurement was not repeated in 2022.

WATER TABLE WELLS AND DEEP WELLS

Water samples were collected from wells in and around the WMA (Figure 16) in the spring and fall of 2022. The gross alpha and gross beta results are summarized in Table 81. The beta activity levels in the clay, and basal zone wells remained below the drinking water screening level of 1 Bq/L. The clay till showed a result slightly above 1 Bq/L. All zones were below the limit for Sr-90 (5 Bq/L) and Cs-137 (10 Bq/L) [37]. The average alpha activity in the samples collected from the clay-till wells showed a slight increase compared to results from the past five years.

Uranium concentrations in the basal zone wells ranged from 0 to 0.27 Bq/L. The concentrations in the Clay zone wells ranged from 0.26 to 2.32 Bq/L, and in the clay till from 0 to 4.05 Bq/L. Since it is known that the local well waters within the Canadian Shield contain naturally occurring uranium [60], the presence of uranium and its progeny are not unexpected and are considered to account for the levels of alpha. Low levels of tritium were noted in the clay (9.02 Bq/L) and clay-till (12.78 Bq/L). This is not unexpected as these overburden layers are impacted by tritium in the WMA. The basal layer showed 4.77 Bq/L which is close to the limit of detection.

Table 81: Monitoring Data Water Table Wells and Deep Wells

WMA Sample Locations	2018 Avg. (Bq/L)	2019 Avg. (Bq/L)	2020 Avg. (Bq/L)	2021 Avg (Bq/L)	2022 Avg (Bq/L)	2022 Avg. Range (Bq/L)

c The value calculated from the concentration of uranium in the water sample

HIGH-LEVEL LIQUID WASTE TRAY WATER

Monitoring of the high-level liquid waste tank tray water was carried out to confirm there is no leakage from the residue remaining in the storage tanks. This is sampled in the summer months. The sample results indicated no leakage has occurred from the tanks. The data are

summarized in Table 82. In the late fall of 2004, the high-level liquid waste had been removed from high-level liquid waste Tank 2 and transferred to the SF for cementation. A heel of waste remains to be removed. High-level liquid waste Tank 1 remains empty.

Table 82: Monitoring Data High-Level Liquid Waste Tank Tray Water

WMA Sample Locations	2018 Avg (Bq/L)	2019 Avg (Bq/L)	2020 Avg (Bq/L)	2021 Avg (Bq/L)	2022 Avg (Bq/L)	2022 Range (Bq/L)
Total Beta [a]						
Tank Tray Water	13.8	12.1	11.2	17.7	7.0	(0.2 – 12.8)
Total Alpha [b]						
Tank Tray Water	0.69	1.5	0.95	0.2	0.2	(0.1 – 0.3)

a The reference nuclide for total beta is Sr-90, gamma results indicate that approximately 13 Bq/L of the gross beta activity is due to K-40.
b The reference nuclide for total alpha is Pu-239

D.2.1.1 RADIATION FIELD MEASUREMENTS

Radiation field measurements are taken semi-annually at established points (normally every 38 m) along the perimeter fence. The 2022 radiation field measurements were similar to those in 2021. The data is summarized in Table 83.

Table 83: Perimeter Fence Monitoring Data

WMA	Radiation Field (µSv/h)					
	2018 Avg	2019 Avg	2020 Avg	2021 Avg	2022 Avg	2022 Range

East Fence	0.3	0.4	0.3	0.2	0.3	0.1 – 0.4

D.2.1.2 VEGETATION

In 2022, vegetation samples were collected at monitoring locations within the WMA (Figure 16), and at a control location unaffected by WL operations. The gross beta results are

summarized in Table 84. Potassium (K)-40 represents the majority of gross beta activity in most of the samples. The levels of gross beta in the samples are due to a combination of K-40 and Sr-90/Y-90, with a minor contribution from Cs-137. The average Sr-90 contribution for the vegetation samples in the WMA is 6% (12% for Sr-90/Y-90). Results were historically reported as Bq/m^2 as there was the potential for deposition of radioactivity via airborne emissions from the former WL Incinerator and former Baler operations. The incinerator and baler have not been in operation for many years and have been decommissioned. The results are now presented as Bq/kg and represent the uptake of radioactivity from impacted areas near the sampling locations.

Table 84: Waste Management Area Vegetation Monitoring Data

WMA Sample Locations	Average Gross Beta[a] (Bq/kg)

b Adjacent to the WMA outside of the fence boundary
c Ambient Radiation monitor Stations Background Samples
d Until 2012 this sampling point was in the North-West area after 2012 it was moved to the North-East area.

D.3 Facility Changes

All facility changes are performed as per the approved Engineering Change Control procedure [16]. Category 1 and 2 changes are discussed below.

Work to prepare for extraction of waste from the Intermediate Level Bunkers and Standpipes was begun in 2017 and continued into 2022 with most of the physical preparatory work done with continued fabrication of extraction equipment off site. Design documents were being prepared for modifications to the grounds surrounding the ILW bunkers and Standpipes to facilitate waste recovery. No modifications were made in those areas in 2022.

The surface pad to the east of the north access road within the WMA was placed into service as the Recoverable Surface Staging and Storage Area and is used to store Seacan containers containing waste, and also allows for oversized items. The Seacan containers or oversized items are those awaiting processing, characterization and packaging for off-site shipment. This was required to allow Building 923 (SMAGS) to be converted to a Cask Loading Facility.

Building 923 is in the process of being converted to the Cask Loading Facility. The Cask Loading Facility took delivery of the components of a waste transfer station. The station was delivered as components to be assembled on site. Due to the need to provide a level concrete pad and the requirement for warm weather, installation of the pad and subsequent installation of the transfer station was delayed until 2023. Work to commission the 15 ton crane installed in 2021 began in 2022.

The process to convert Low Level Waste Bunker #6 to the Intermediate-Level Liquid Waste Treatment Centre, Building 202, began in 2022. This primarily focussed on roof coating and coating of the walls of the future tank area in the west end of the structure.

D.4 Equipment Performance, Planned Maintenance Testing and Inspections

During 2022, the bunkers and other structures in the WMA remained fit for service. Building 923 and Low Level Waste Bunker #6 remain removed from operations pending their conversion to the Cask Loading Facility and Intermediate Level Liquid Waste Treatment Centre respectively. Building 421 continued to operate as a waste examination and re-packaging area, making use of the Temporary Ventilated Enclosure. Modifications are required to the placement of the portable high-efficiency particulate air filter to meet fire program requirements and the Engineering Change Control process is being followed to effect the change. The building remains in a safe modified operational status while this change is being made.

Medium-Level Waste Bunker 4 did not have new waste placed in 2022 and remains ~70% full. Medium-Level Waste Bunker 6 is ~60% full; however it is not accepting waste due to water ingress issues. Medium-Level Waste Bunker 7 is ~86% full. The percentage full values are estimates only. Road transportable totes of liquid waste remain in the heated Building 430 pending future processing. Building 431 contains historic waste which is in the process of being characterized and packaged. Building 432 and Building 433 also contain various historic wastes and wastes held in various stages of characterization and repacking operations.

A small seepage of an oily substance first noted in 2020 was again noted at the central gasket, near the south wall base of LLW Bunker 1. The substance was sampled in 2020 and found to contain oil and likely degraded liquid organic. The volume was small in 2020 and remained so in both 2021 and 2022. Seepage only occurred during hot weather, and as weather cooled the seepage stopped. The area will continue to be monitored. The bunker is slated for remediation of its waste in the next few years.

The Soil Storage Compound remained empty of stored waste. There are three empty standpipes in the standpipe area.

In-service storage facilities were inspected for water ingress during routine waste emplacement operations. Filled storage facilities with accessible drainage sumps were inspected monthly during the summer months, when water ingress is most likely. Caulking of the roofs of all the WMA Quonset buildings with waterproof sealant was completed in 2010 resulting in reduced indications of water ingress during rainy weather. Re-caulking was done in 2014 and again in 2018 and 2021. No caulking was done in 2022.

In 2015, shallow wells were installed beside each of the Medium/Intermediate Level Bunkers. These near field wells have been sampled annually. Results are discussed in Section D.2.1 under “Intermediate - Level Waste Bunkers Near Field Wells”, and indicates limited migration of tritium beside the ILW bunkers, in particular ILW Bunker 3. There is no evidence that would lead CNL to conclude there is currently any significant contaminant migration pathway from the ILW Bunkers.

Compliance monitoring in the WMA and CCSF perimeter ditches have found limited levels of contaminants, mainly tritium in the north WMA ditch, but still below drinking water guidelines, suggesting the waste storage structures and natural barriers of low permeability clay soil and upwards groundwater flow are performing as expected.

As required by Section 8 of the Facility Authorization [56], most routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, however, two tests, both on transformers were not completed (see Section 6.1.2). These will be completed in 2023. Monthly housekeeping and fire prevention inspections were completed. An annual inspection of WL WMA concrete bunkers was conducted, in accordance with the Periodic Inspection Plan [19], and is further discussed in Section 6.

D.5 Wastes Generated

Solid radioactive waste was generated in the WMA as part of routine operations. This was mostly bagged waste generated from routine operations.

See Section 11.1 Waste Management Program for summaries of the volume of radioactive solid waste generated in the Waste Management Area in 2022.

Liquid radioactive waste was generated in the WMA as part of routine operations.

In 2022, a total of 858 L of water was pumped from ILW Bunker 6, no water was pumped from ILW Bunker 4 or ILW Bunker 7. The sumps are pumped out by Site and Nuclear Operations personnel using a WMA tanker with pump rig. The water collected in the tanker is later transferred to double walled totes. There totes are retained in Building 430 pending future processing.

The Building 923 sump tank and the Soil Storage Compound were both sampled as required and their water found not to be active in all cases. Water was directed to the WMA ditches from these locations. No other storage facilities and collection sumps at the WMA required pumping.

D.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the WMA as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection. There are no liquid effluents generated from this facility.

Appendix E Auxiliary Operation Facilities

E.1 Operations

The Auxiliary Operating Facilities are operated under the WL Site Licence [1].

There were no changes in the staffing for the operating staff responsible for the auxiliary facilities in 2022. There were no organizational changes.

No program changes were made for the auxiliary facilities in 2022. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities operating procedures. WL is behind in the 5 year procedure updates and are scheduled to complete the updates in 2023.

Research and Development Facilities Complex (Building 300)

Building 300 was the primary research laboratory for the site, housing a wide range of nuclear R&D programs. The building comprised an area of ~17,000 m^2 and was built in seven stages from 1964 to 1982. The building contained 68 laboratories as well as numerous offices. The south end high-bay area contained experimental activities that required large areas and significant headroom; RD-14M and RD-17 experimental loops were located in the South High Bay.

During 2022, WL Site and Nuclear Operation's staff and user groups in Building 300 carried out routine operations which included:

- Non-radiological laundry activities.
- Respirator fit test / maintenance activities.
- Sample management office lab.
- Environmental lab.
- Cleanup activities associated with decommissioning.
- Routine building and system maintenance; and
- Surveillance to ensure compliance with the site licence.

Health and Safety Facilities (Buildings 402 and 305)

Building 402 had three floors comprising an area of ~2,162 m^2, housing WL dosimetry services and Environmental Management laboratories. The CNL facilities in Building 402 include a whole-body counting facility, TLD readers, environmental laboratories, and a Cs-137 Gamma Calibrator.

Demolition of Buildings 402 and 305 worked around the Whole Body Counter until the Whole Body Counter structure was moved into its new location, Building 543 in 2022 January. Building 543 is still waiting for services (electrical) to be connected and turned over to Radiation Protection Branch so that the Whole Body Counter instrumentation can be set-up, commissioned and put back into service. Demolition of Building 402 was completed in 2022

March. The B402 footprint is still waiting to be cleaned up and verified clean before the fence will be removed and the site released from decommissioning.

E.2 Facility Changes

All facility changes were performed using the Engineering Change Control procedure [16]. There were no Category 1 and 2 changes in 2022.

E.3 Equipment Performance, Planned Maintenance Testing and Inspections

All maintenance and non-routine work in these facilities that may affect the safe operation of facilities, systems, and laboratories, or that may present a hazard to the general public are conducted in accordance with CNL's work permit system.

All routine maintenance for systems required to be operational was carried out, and all equipment tests and inspections were completed.

E.4 Wastes Generated

There were minimal amounts of radioactive and/or hazardous wastes generated in the facilities as part of routine operations.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the facilities in 2022.

Building 300 generated 0.0 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2022.

Building 402 generated 0.0 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2022.

After processing at the Waste Handling Area, all waste would be shipped to the WMA for storage.

See Table 85 for a summary of solid wastes for the last five years.

Table 85: Low-Level Solid Waste Generation – Buildings 300, 402,411

	2018	2019	2020	2021	2022
Building 300 (m^3)	4.5	0.4	0.3	0.0	0.0
Building 402 (m^3)	1	0.7	0.2	0.8	0.0
Building 411 (m^3)	7.6*	0.2*	0.0	0.0	0.0

* Legacy waste processed in 2018 for Building 411 that was decommissioned in 2017.

There was no liquid radioactive and/or hazardous waste generated in 2022 in this facility.

RESEARCH AND DEVELOPMENT (BUILDING 300) LOW-LEVEL LIQUID WASTE SYSTEM

Radioactive LLLW flows from the SF and Building 300 to the low-level liquid waste collection tanks, in Building 300 Room B-33. An accurate determination of the individual SF or Building 300 contribution cannot be made as both locations flow into these common tanks. The sources of water from Building 300 are limited and the major contributor is the radiological decontamination service facilities in the IFTF.

During 2022, 117.3 m^3 of low-level liquid was processed through the Building 300 LLLWTS. Table 86 shows the historical volumes of LLLW processed through the Building 300 LLLWTS and also the total volume of Building 300 and Building 100 LLLW processed.

Table 86: Historical Records of Low-Level Liquid Waste Processed

	2018	2019	2020	2021	2022
Total Combined Low-Level Waste Liquid Processed (m^3)	131.5	189.3	107	88.2	119.6
Low-Level Waste Liquid Processed in Building 300 (m^3)	123	186.5	99	78.3	117.3

The total activities given below are the combination of the Shielded Facilities, Building 300, and Building 100 active liquid effluents produced.

As determined by total-beta analysis, the beta radioactivity content in the effluent releases to the Outfall from the holding tanks at the Building 300 and Building 100 LLLWTS during 2022 was 0.01 GBq, compared with 0.01 GBq released during 2021. The maximum release in a month during the year was 0.001 GBq which is a small fraction of the administrative level of 0.48 GBq per month. This level conservatively assumes that all of the activity is due to Cs-137, which is the most restrictive isotope of those present, or potentially present.

As determined by total-alpha analysis, the alpha radioactivity content in effluent releases to the outfall was 0.001 GBq for 2022 compared with 0.001 GBq released during 2021. The maximum release in a month during the year was 3.2E-04 GBq which is a small fraction of the administrative level of 0.56 GBq per month. This level conservatively assumed that all the activity is due to Am-241 which is the most restrictive isotope of those expected to be present in this waste stream.

Table 87 provides a summary of the total activity released for both the Building 100 and Building 300 LLLWTS. Annual Release Limit values for radionuclides in liquid effluents for WL are based on the DRL [33].

Table 87: Building 100 and Building 300 LLLWTS Radioactive Releases

Radionuclide	Total 2022 Effluent (GBq)	Annual Release Limit[a] (GBq/a)	Total 2022 Effluent as a % of Annual Release Limit	Peak Release	
				Max. Monthly Release (GBq)	% of[b] Monthly DRL
Total (Total-Beta Analysis)[c]	0.01	–	–	0.001	–
Sr-90	1.05×10^{-3}	1.56×10^{2}	0.67×10^{-3}	1.49×10^{-4}	1.14×10^{-3}
Cs-137	4.03×10^{-3}	1.39×10^{2}	2.89×10^{-3}	8.66×10^{-4}	7.47×10^{-3}
Total Alpha (As Pu-239 Equivalent)[d]	1.2×10^{-3}	1.33×10^{1}	9.02×10^{-3}	3.16 x 10-4	2.85×10^{-2}
Historical Data Total Effluent (GBq)					
	2018	2019	2020	2021	2022
Total (Total-Beta Analysis)[c]	0.02	0.01	0.01	0.01	0.01

a The annual release limit is calculated by multiplying the DRL by 12.

b DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The beta particulate emitters are considered to be Cs-137, the most restrictive isotope of those identified or potentially present. The DRL is 1.16×10^{1} GBq/month [33].

c A total beta analysis results in a conservative (higher) estimate of the total amount of activity, which is more accurately determined by measuring the individual radionuclides by radiochemical or gamma spectrometry methods.

d DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The alpha particulate emitters are considered to be Pu-239, the most restrictive isotope of those identified or potentially present. The DRL is 1.11 GBq/month [33].

E.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from these facilities. Radioactive wastewater generated in Building 300 was pumped to the LLLWTS in Building 300 Room B-33.

Any liquid and/or gaseous releases from the facilities are provided and discussed in Section 9, Environmental Protection.

Appendix F WR-1 Facility

F.1 Operations

Activities in Whiteshell Reactor 1 (WR-1) were conducted under the WL site licence [1] from the CNSC, in accordance with the requirements of *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [61]. The status of the WR-1 facility in its shut down, de-fuelled, and partially decommissioned state is described in *The WR-1 Reactor Phase 1 Decommissioning Project Interim End-State Report - Facility Description* [62]. The facility is monitored and maintained as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [61]. *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [61] is in the process of being updated.

Routine operations in the WR-1 facility, as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [61], were carried out by the three (two and one trainee) Site and Nuclear Operations Technologists assigned to Building 100. Throughout the course of 2022, the number of Building 100 staff increased to four (two and two trainees). Staffing was maintained at levels to provide the needed operational and safety support and maintain the minimum staffing requirements outlined in *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [61].

In 2018, approximately 20 m^3 of low concentration (3.4 E06 Bq/L) tritiated water was found in the thermoshield and bioshield cooling systems. This water is still in the systems, awaiting a decision on how to remove this water as the systems were not designed to be drained. Investigation is also ongoing to determine what the impact would be if this water is left in situ as part of the proposed in situ disposal of WR-1.

No program changes were made for WR-1 in 2022. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities operating procedures. WL is behind in the 5 year procedure updates and are scheduled to complete the updates in 2023.

F.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [16]. There were no Category 1 and 2 changes in 2022.

F.3 Equipment Performance, Planned Maintenance Testing and Inspections

During 2022, the operations status of WR-1 remained unchanged. There were no changes to the reactor’s equipment.

Issues with missed and archived preventive maintenance activities was identified in 2021 and previously reported to the CNSC. A corrective action plan was developed, and continues to be implemented in order to fix the issues and prevent recurrence. All monthly housekeeping and fire prevention inspections were completed.

F.4 Wastes Generated

Solid Radioactive and/or Hazardous Wastes

See Section 11.1 Waste Management Program for summaries of the volume of any volume of radioactive solid and/or liquid waste generated in WR-1 in 2022.

Solid radioactive waste was generated in the facility as part of routine operations. This consisted of mainly operational supplies such as Tyvek suits.

During 2022, 0.5 m^3 of low-level radioactive compactable waste and no non-compactible waste were generated from Building 100/WR-1 operations and sent to the Waste Handling Area for compaction.

There were no new hazardous solid wastes generated from Building 100/WR 1.

Liquid Radioactive and/or Hazardous Wastes

During 2022, 2.3 m^3 of low-level radioactive liquid waste was generated from Building 100/ WR-1 operations, the majority from the WR-1 sumps. Appendix E has more information on the liquid waste processed. There were no hazardous liquid wastes generated from this facility.

F.5 Effluents Released

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection.

Appendix G Non-Nuclear Facilities

G.1 Operations

The WL non-nuclear facilities status and changes for 2022 are as noted in Table 88.

Table 88: Operating Summary of Non-Nuclear Facilities

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
303	Containment Test Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed
304	Waste Clearance Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed
306	Waste Clearance Facility	Removed in 2016	None	None	Buildings & Lands D&D Project Personnel	Building removed, pad retained, End-State Report to be completed
308	Large Scale Vented Combustion Test Facility	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
309	Large Scale Vented Combustion Test Facility -Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
310	Large Scale Vented Combustion Test Facility -Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
311	Large Scale Vented Combustion Test Facility Hydrogen Storage	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
401	Security, Reception, Firehall and Security Monitoring Room	Operational	None	None	All Site/Visitors	No change
405	Lunchroom/Offices (formerly the Library)	Shut down	None	None	All Site/Visitors	Operational cleanup in preparation for demolition
408	Stores	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
409	Cold Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
412	Offices/Machine Shop	Operational	None	None	All Site/Visitors	No change
413	Quonset: Cold Storage	Shut down	None	None	Security and Common Services	Preparing for demolition

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
414	Controlled Area 2 Entrance	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
415	Warm Storage	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
416	Heated Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
418	Active Area Storage	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
420	Cold Garage	Shut down	None	None	Transportation, Security and Stores	Preparing for demolition
422	Outfall Monitoring Station	Operational	None	None	Environmental Monitoring and Maintenance	No change
424	WR-1 Organic Monitoring Building	Removed in 2020	None	None	Facilities	Building removed,, End-State Report to be completed
426	Quonset: Cold Storage	Shut down	None	None	Utility	Preparing for demolition
427	Cold Mechanical Storage	Removed in 2016	None	None	Facilities	Building removed, pad retained, End-state Report to be completed
428	Cold Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
429	Quonset: Cold Storage	Shut down	None	None	Maintenance	Preparing for demolition
505	Fire/Security Training (formerly R&D Lab)	Removed in 2016	None	None	Environmental	The building and pad were previously decommissioned, 3 environmental monitoring wells have been installed
531	Asbestos/PCB Storage	Operational	None	None	Facilities	No change
540	Modular Office Complex	Operational	None	New	Facilities	Modular Trailer office complex installed in parking lot
543	Dosimetry Building	Under Construction	None	New	Facilities	Start of construction 2021 To be completed 2022

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
570	Hazardous Chemical Storage	Operational	None	None	Facilities, Waste Management	Relocated from Building 402 to near Building 300 Shielded Facilities. Placed back in Operation.
597	Portable Boiler Building 1	Out of Operation	None	None	Powerhouse Operators and Maintenance	Taken out of Service due to shutdown of Building 200
598	Portable Boiler Building 2	Operational	None	None	Powerhouse Operators and Maintenance	No change
902	Pump House	Operational	None	None	Powerhouse Operators and Maintenance	No change
903	Water Filtration Plant	Operational	None	None	Powerhouse Operators and Maintenance	No change
904	Fire Protection Water System	Operational	None	None	Powerhouse Operators and Maintenance	No change

911	Powerhouse	Operational	None	None	Powerhouse Operators and Maintenance	No change
913	Main Substation (Owned by MB Hydro)	Operational	None	None	Manitoba Hyd ro	No change
914	Main Power Distribution	Operational	None	None	Powerhouse Operators and Maintenance	No change
916	Communications System	Operational	None	None	Security and Maintenance	No change
917	Supervisory Control and Alarm	Operational	None	None	Security and Maintenance	No change
918	Clarified Water System	Shut Down Mid-1980s	None	None	Powerhouse Operators and Maintenance	No change
921	Access Tunnel	Operational	None	None	All Site/Visitors	No change

[a] Security personnel perform regular patrols of all site buildings

There were no policy, program or procedural changes for the non-nuclear facilities in 2022. There were no changes in organization in 2022.

In 2022, the Facility continued to maintain the minimum staffing requirements to provide the needed operational and safety support.

G.2 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [16]. There were no Category 1 and 2 changes in 2022.

G.3 Equipment Performance, Planned Maintenance Testing and Inspections

Leaks occurred in the fire/ process water mains west of Building 543 and south of the site substation systems. Leaks were isolated by closing valves, no systems were impaired and no compensatory measures were required. Other equipment for all the non-nuclear facilities, including any safety-related systems, performed as designed and required during 2022.

G.4 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the non-nuclear facilities as part of routine operations.

G.5 Effluents Released

There were no radioactive and/or hazardous effluents (gaseous or liquid) released into the environment from the facilities as part of routine operations.

There was 1.45E+09 L of effluent released from buildings Building 422 (Outfall Monitoring Station) and 4.15E+07 L of effluent released from Building 907 (Sewage Lift Station and Lagoons). There was one lagoon discharge in the fall of 2022. Results are discussed in Section 9.

Landfill Dugout Water Monitoring

The WL landfill is surrounded by six dugouts where surface water collects. These dugouts are sampled as part of the ongoing operational control monitoring for the facility. In 2022, the total precipitation was 687 mm over the year, an increase from 2021 (395 mm). The location of the dugouts are shown in Figure 17. Dugout 22 is used as the Control and is about 300 m away from the landfill to the north-northeast, and would not be affected by facility operations.

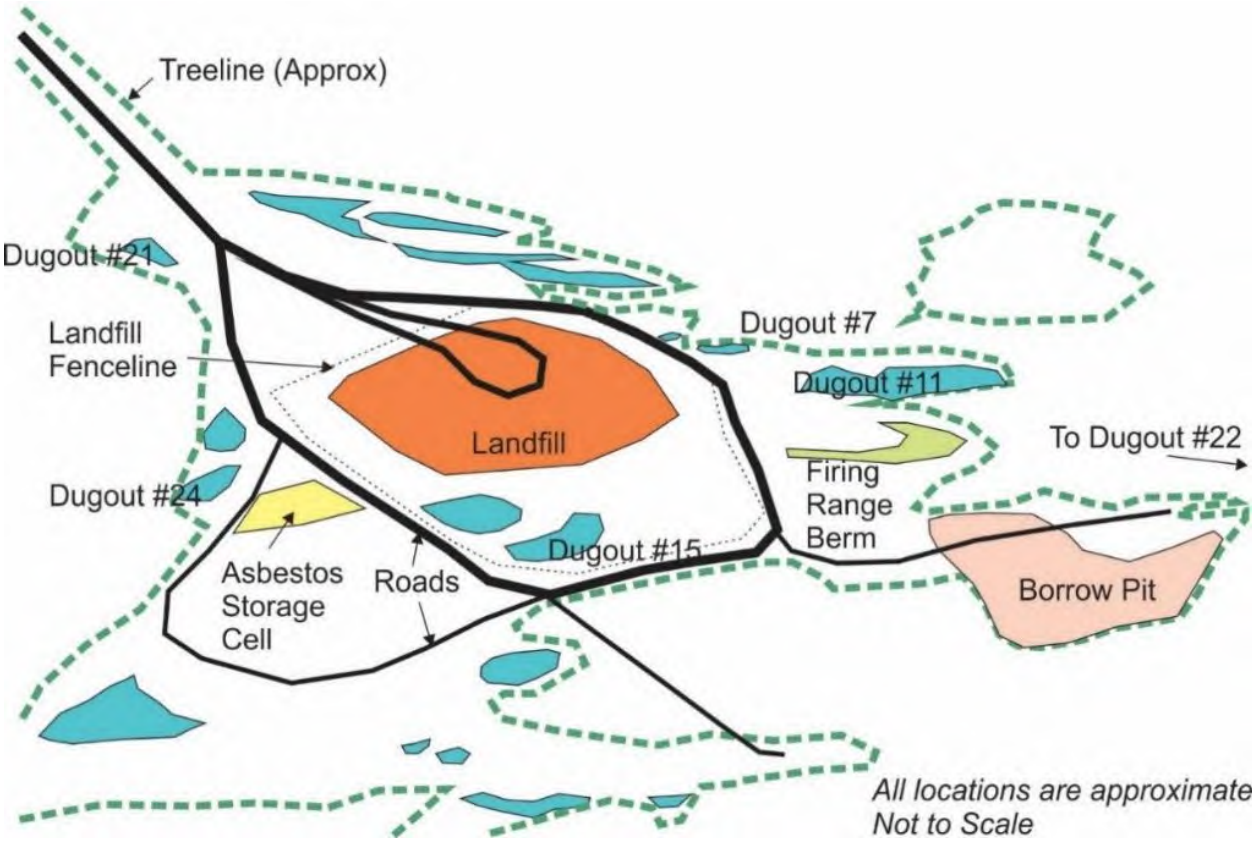

Figure 17: WL Landfill Area Showing Approximate Locations of Monitored Dugouts

The results from the sample analysis for alpha and beta from these dugouts are provided in Low levels of tritium (9 Bq/L) were detected in one of the landfill wells (water table) starting in 2011. Its appearance in the groundwater resulted in initiation of the surface (dugout) water measurement of tritium. Tritium has been detected in landfill Dugout 15 for the past eight years, and a low value was noted in Dugout 24 in 2011, 2012, 2016, and although a higher amount was noted in 2018 (76 Bq/L), the value returned to background in 2019 and remained there through 2022. The tritium level in Dugout 15 was 25 Bq/L, following a decreasing trend since 2020. All results are well below drinking water limits of 7,000 Bq/L. The other dugouts do not appear to contain tritium, as levels comparable to blank samples analyzed from 2013 to 2022 that contain < 5 Bq/L of tritium were recorded. Tritium results from the landfill dugouts are shown in Table 91.

Table 89 and Table 90 respectively. All alpha results for 2022 were at the detection limits, and are below the drinking water screening level of 0.50 Bq/L. The Beta result in Dugout 7 was above the drinking water screening level of 1.0 Bq/L. Other Beta results were lower. Other than the Dugout 7 Beta result, results for 2022 are consistent with previous results obtained from 2017 to 2021. The increase has been noted and monitoring will be continued next year.

Low levels of tritium (9 Bq/L) were detected in one of the landfill wells (water table) starting in 2011. Its appearance in the groundwater resulted in initiation of the surface (dugout) water

measurement of tritium. Tritium has been detected in landfill Dugout 15 for the past eight years, and a low value was noted in Dugout 24 in 2011, 2012, 2016, and although a higher amount was noted in 2018 (76 Bq/L), the value returned to background in 2019 and remained there through 2022. The tritium level in Dugout 15 was 25 Bq/L, following a decreasing trend since 2020. All results are well below drinking water limits of 7,000 Bq/L. The other dugouts do not appear to contain tritium, as levels comparable to blank samples analyzed from 2013 to 2022 that contain < 5 Bq/L of tritium were recorded. Tritium results from the landfill dugouts are shown in Table 91.

Table 89: Gross Alpha Results from the Landfill Dugouts

Dugout #22	< 4	< 4	< 4	< 3	< 5	NA
Dugout #24	< 4	76	< 4	< 4	< 5	< 4

NA sample not available

When initially detected in the dugouts, it was assumed that it was possible that tritium emissions from the WR-1 Building 100 deposited in the ponds surrounding the landfill, and was subsequently drawn in to the water table. After consideration, it was determined that the most likely source of tritium is the landfill. The presence of above background tritium in only a few dugouts cannot be explained by air borne deposition. The highest tritium activities are found in the dugouts and wells in closest proximity to the landfill. Due to its 10 m height, the landfill has a higher hydraulic head than the local terrain, including the asbestos storage cell, and thus will be more likely to contribute leached contaminants to the shallow ground water system. Due to local groundwater flow directions (toward the south and southwest), Dugouts 15 and 24 are more likely to receive contaminants from the migration of water from the landfill. As the landfill had been in operation for over 50 years, the potential for a historic error in placement is greater for the landfill than the adjacent asbestos storage cell.

The water testing conducted in 2018 included Sr-90 and Tc-99, two potentially mobile radionuclides. In 2018, near detection levels of Sr-90 were noted in Dugout 21 and near detection limit levels of Tc-99 were noted in Dugouts 21 and 24. In 2019, only Sr-90 was tested, and was found to be at the detection limit. In 2020, both Sr-90 and Tc-99 were again measured. Sr-90 was at the detection limit and Tc-99 was not detected. In 2022 (see Table 92), as in 2021, no Sr-90 analysis was conducted as per the instructions provided to lab to only analyze if gross Beta exceeded 5 Bq/L. Tc-99 was again below the detection limit. The water from these dugouts and wells is not used for human consumption. All results were below drinking water limits of 5 Bq/L for Sr-90 and 200 Bq/L for Tc-99.

Table 92: Sr-90 and Tc-99 Results from the landfill Dugouts in 2022

Sample Location	(Bq/L)	
	Sr-90	Tc-99
Dugout #7	NA	ND
Dugout #11	NA	ND
Dugout #15	NA	ND
Dugout #21	NA	ND
Dugout #22	NA	NA
Dugout #24	NA	ND

NA – No Analysis Gross Beta below analysis trigger limit.

ND – Non Detect

The water from the dugouts was also tested for a suite of non-radiological parameters including total metals, mercury, nitrate + nitrite, sulphate, chloride, sodium, potassium, calcium, magnesium, sulphur, total ammonia (N), phosphorus, phenols and volatile organics (including benzene, toluene, ethylbenzene and xylene). Elevated levels of boron were detected in Dugout #15, a continuation of results from 2018 onwards (Table 93). The value in 2022 remained under the Drinking Water Guideline for Boron (5,000 µg/L). Dugout #24 showed 264 µg/L in 2022, and all other dugouts showed values below detection limits.

Table 93: Boron Results from the Landfill Dugout #15

Sample Location	(µg/L)				
	2018	2019	2020	2021	2022
Dugout #15	5,460	8,460	2,040	3,760	1,170

Molybdenum remained at detection limits from 2020 through 2022. In 2022, Manganese remained higher than drinking water guidelines of 50 µg/L in Dugout #15 (58 µg/L). No other parameters were detected at concentrations of concern.

Groundwater results will be discussed in the annual Environmental Monitoring report [32]. Sediment sampling of one of the dugouts was conducted as part of the Environmental Assessment Follow-up Program and will be reported in [31].

Landfill Dugout Sediment Monitoring

Sediment sampling of the dugouts was conducted in 2017 as part of the Environmental Assessment Follow-up Program. The analysis of the sediment included a full suite of metals, mercury, lead, PCBs and for radioactivity, including Sr-90. There were elevated levels of molybdenum in the surface sediment of one dugout (Dugout 24) and no other contaminants of potential concern noted. Molybdenum can be found naturally in the environment (minerals containing iron, bismuth, or copper) as well as being a component of man-made items such as filaments, X-ray tubes, screens, grids for radios, spark plugs, contacts, induction heating elements, and/or part of a waste stream from man-made processes (burning of fossil fuels). The source of the molybdenum is being investigated as part of the assessment of the Landfill prior to closure. Monitoring of the sediments in the dugouts around the Landfill is planned to continue every 5 years (from 2017) as well as annual monitoring of the water, and as such, sediment sampling was conducted in 2022. Molybdenum was still slightly elevated in Dugout 24.

Further investigation will be conducted during the eventual closure of the landfill and will also be reported in the Environmental Assessment Follow-up Program [31].

Landfill Radiological Monitoring

Annual radiological monitoring of the Landfill surface was performed as a confirmatory measure in the past. As of 2022, this monitoring was no longer required from the Radiation

Protection Program as the Landfill had not been physically opened to accept waste for several years. Bins for accepting radiologically clean scrap metal and scrap wood had been installed in 2020. Two years of monitoring showed no change, with the results showing readings consistent with background levels at the Landfill fence line. Table 94 provides survey results at the top of the Landfill. For some years monitoring was performed at the base of the pile, and more recently monitoring was performed around the perimeter of the fenced area of the Landfill.

Table 94: Landfill Radiological Monitoring

Sample Location	(μR/h)				
	2018	**2019**	**2020**	**2021**	**2022**
Landfill Top Surface	8 - 10	6 -12	6 - 12[2]	10	NA
Landfill Base	NR	5 - 8[1]	5 - 8[1]	10	NA

NR – Not recorded

NA – Not available - discontinued

EXECUTIVE SUMMARY

This annual compliance monitoring report for the 2021 calendar year has been prepared as per licence condition 3.2 of the Whiteshell Laboratories Licence NRTEDL-W5-8.00/2024 and CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Facilities and Uranium Mines and Mills* as a summary report of annual compliance monitoring and operational performance.

Canadian Nuclear Laboratories (CNL) would like to acknowledge Canada's Indigenous Peoples and their traditional territories upon which CNL carries out its work. CNL also wishes to confirm its commitment to being an active participant in Canada's journey towards healing and reconciliation.

This annual compliance report provides CNL 2021 performance data for WL and is organized by 14 Safety and Control Areas (SCAs)[1], as well as a report on each of the WL nuclear and non-nuclear facilities.

The following provides overall performance highlights for 2021 activities:

- All licensed activities continued to be carried out safely and securely.
- No member of the public received a radiation dose that exceeded any regulatory limit.
- No worker at WL received a dose in excess of any of the respective radiation dose limits for radiation workers, as defined in the Radiation Protection Regulations.
- All releases of radioactive material in WL effluents during 2021 were below their respective Derived Release Limits (DRL).
- Demolition of Building 200, the former Active Liquid Waste Treatment Centre (ALWTC), is complete, and Building 402/305, the former Health and Safety Facilities, is partly demolished.
- The WL site maintained safe and compliant performance under COVID-19 Pandemic conditions and protocols.

Below is a summary of the annual compliance report for calendar year 2021.

- **SCA - Management System**: WL has continued its focus on implementation of the corporate management system, as well as the WL Quality Assurance program for decommissioning. After having no Canadian Nuclear Safety Commission (CNSC) inspections in 2020, four inspections were carried out in 2021.
- **SCA - Human Performance Management**: A significant effort towards training individuals in human performance related areas continued as a result of the fieldwork pause in 2020 November. Another outcome of the fieldwork pause was the development and delivery of the initial Annual General Employee Training which goes

[1] The CNSC evaluates how well licensees meet regulatory requirements and CNSC expectations for the performance of programs in 14 safety and control areas.

over site and project updates, as well as review of policies and procedures. This will be updated and delivered annually to all employees.

- **SCA - Operating Performance**: WL decommissions and operates its facilities according to prescribed programs and procedures, and monitors safety performance in the operational area through the concept of "events". The total number of internal event reports raised continues to show a strong reporting culture. There were six CNSC reportable events in 2021.
- **SCA - Safety Analysis**: Effective Safety Analysis Reports and Facility Authorizations continue to be in place for WL's nuclear facilities, helping meet health, safety, security, environmental and regulatory requirements. Safety analyses continue to be developed for the standpipe/bunker remediation, Intermediate-Level Liquid Waste Processing Centre and Cask Loading facilities being constructed in the Waste Management Area.
- **SCA - Physical Design**: The Certificate of Authorization was renewed with Engineers Geoscientists Manitoba, authorizing CNL to engage in the practice of professional engineering in Manitoba. The new revised WL Pressure Boundary Quality Assurance Plan was accepted by Inspection and Technical Services Manitoba and a new Certificate of Authorization was issued.
- **SCA - Fitness for Service**: The Periodic Inspection Plan (PIP), previously developed to confirm the ongoing fitness-for-service of the concrete storage facilities at the Waste Management Area (WMA), continued implementation with no significant issues identified. Regular preventative or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service. Missed maintenance of safety-related systems was reported to CNSC, and a corrective action plan was developed that will fix the issues and prevent recurrence.
- **SCA - Radiation Protection**: No worker received a whole-body dose (including committed) in excess of any of the respective dose limits for radiation workers as defined in the Radiation Protection Regulations, and average individual doses remain a small fraction of these limits. Maximum dose to a person working at WL was 0.6 mSv and collective doses remained below 50 person-mSv (19.0 person-mSv) for 2021. Members of the public received no measureable radiation doses.
- **SCA - Conventional Health and Safety**: Implementation of CNL's Occupational Safety and Health program at WL continues to drive improvements in safety and safety culture. Safety advisories are regularly issued to staff about imminent issues that could impact their safety. There were no lost-time injuries at WL in 2021.
- **SCA - Environmental Protection**: The results of the radiological and non-radiological effluent monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment. Radiological emissions were 0.00019% of the Derived Release Limit (DRL) for air emissions and 0.47% of the DRL for liquids. The monitoring program confirms that the WL site is operating in a manner that protects workers, the

public, and the environment. WL maintained their ISO-14001 registration, and are compliant to a number of CSA environmental standards.

- **SCA - Emergency Management and Fire Protection**: The Emergency Management program at WL continued to be focussed on supporting COVID-19 planning and coordination efforts, providing procedures and guidance to enable work to continue safely in this dynamic situation. A third party Fire Protection Audit was conducted, and resolution to findings will be tracked through the corrective action program.
- **SCA - Waste Management**: WL continued to reuse or recycle as much material as was practicable. Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects, including disposition of 924 m^3 of radioactive waste to Chalk River Laboratories (CRL), and 271 m^3 (37,145 kg) of recycled waste shipped off-site. The WL Site Overview Detailed Decommissioning Plan was revised and accepted by CNSC.
- **SCA – Security**: The Security Program at WL supports the CNL Corporate Security mandate and addresses the regulatory requirements for high-security sites. Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers as required by the CNSC.
- **SCA - Safeguards**: There were no issues identified with International Atomic Energy Agency (IAEA) Safeguards inspections conducted at WL. The IAEA also provided human surveillance and IAEA seal verification, removal and reapplication during canister inspection activities.
- **SCA - Packaging and Transport**: There were 68 radioactive transport packages making up 53 loads that were safely and successfully sent off-site, including approximately 921 m^3 of low-level waste and 3 m^3 of intermediate-level waste shipped to CRL.
- **Other matters of regulatory interest**: Two virtual meetings of the WL Public Liaison Committee took place. Numerous public information sessions and Indigenous engagements (mainly virtual) were held on the Whiteshell Reactor 1 (WR-1) in-situ decommissioning and overall activities of the WL Closure Project, including four Webinars.
- **Facilities** (operating nuclear facilities, permanently shut down facilities, facilities being decommissioned and the non-nuclear facilities): All the licensed activities in these facilities continue to be carried out safely and securely with acceptable radiation doses to personnel and releases to the environment. The following notable facility-specific activities took place: the Active Liquid Waste Treatment Centre, Building 200, completed demolition, and significant progress was made in demolition of the Health and Safety Facilities, Building 402/305.

CNL is committed to achieve high standards of operational safety and security. The information and data presented in this report support the conclusion that safe and secure performance was achieved at the Whiteshell Laboratories site, while enhancements were implemented to further improve results.

ACKNOWLEDGEMENT

The “Author” of this document would like to thank the many Whiteshell Laboratories authors and reviewers from the various Functional Support Areas and Facilities for their production of the individual sections of the report.

CNL’s Continued COVID Pandemic Response

For a detailed description of CNL’s robust mitigation initiatives and controls to protect its employees, contractors, visitors and Site operations from the COVID pandemic, see the Executive Summary in the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories*.

TABLES

INTRODUCTION

Whiteshell Laboratories (WL) was established by Atomic Energy of Canada Limited (AECL) in the early 1960s to carry out nuclear research and development activities. The site is a Class 1B nuclear facility which encompasses an area of 4,375 hectares. The WL site is located near Pinawa, Manitoba; approximately 100 kilometres northeast of Winnipeg, on the eastern bank of the Winnipeg River. AECL made a business decision in 1997 to discontinue most of the research programs and operations at WL. Subsequently, AECL received government concurrence in 1998 to proceed with actions to achieve closure of WL. This work transitioned to Canadian Nuclear Laboratories (CNL) who are carrying out the work to achieve site closure on behalf of the site owner, AECL.

Activities are now underway to complete the orderly decommissioning of the WL site, following the general plan laid out in the Comprehensive Study Report supporting the approval of the Environmental Assessment of the WL Decommissioning Project. The exception to this is the change in strategy for Whiteshell Reactor (WR) -1 (see the Decommissioning Strategies Section below).

Name:	Whiteshell Laboratories
Location:	*1 Ara Mooradian Way* *Pinawa, Manitoba* *R0E 1L0*

Licence Information and Reporting Period

This annual compliance monitoring report is produced to comply with licence condition 3.2 of the Whiteshell Laboratories Licence NRTEDL-W5-8.00/2024 [1], in accordance with the compliance verification criteria Compliance Monitoring: Annual Report of the *Licence Conditions Handbook (LCH) for Whiteshell Laboratories,* herein referred to as “Licence Conditions Handbook” [2], and section 3 Annual Compliance Monitoring Report of CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills* [3]. Information included in this report is for the period of 2021 January 01 to December 31.

This report provides site-specific information to supplement information in the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4], which provides corporate updates to 14 Safety and Control Areas as they are applied across all of CNL.

The intent of this report is to provide sufficient detail to demonstrate how Whiteshell Laboratories programs are meeting the regulatory requirements as specified in the licence [1] and the LCH for Whiteshell Laboratories [2].

Facilities Included in this Report

Appendices Appendix A through G of the report provide information that is pertinent to the Nuclear and Non-Nuclear Facilities (including operating and permanently shut down facilities, and facilities being decommissioned).

The Nuclear Facilities included in this report are: Concrete Canister Storage Facility, Active Liquid Waste Treatment Center, Shielded Facilities, Waste Management Area, Research and Development Facilities Complex (Building 300), Health and Safety Facilities (Building 402 and Building 305), and WR-1 Reactor.

Summary of Licensed Activities

There are no new licenced activities.

Decommissioning Strategies

As discussed since 2015, work is underway to complete decommissioning of the entire WL site (current schedule is to be complete in 2027). This includes leaving in-situ the selected WMA trenches as per the Comprehensive Study Report under institutional control, and transporting active waste off-site for disposal or storage. A significant departure from the end-states defined in the Comprehensive Study Report is in situ decommissioning (also referred to as in situ disposal) of the WR-1 reactor. Work continues for an environmental assessment and regulatory approvals required for this proposed change. The Environmental Impact Statement supporting this is in progress.

Financial Guarantees

CNSC was previously sent a letter from the Honorable G. Rickford [5], advising that as an agent of Her Majesty in Right of Canada, AECL’s liabilities associated with the decommissioning of WL are ultimately liabilities of Her Majesty in Right of Canada (note: AECL retains ownership of the lands, assets and liabilities associated with CNL's licences). This financial guarantee remains valid and in effect, as per the communication issued on 2020 August 25 [6].

1 Management System

1.1 Management System Program

Whiteshell Laboratories adheres to the Corporate Management System. See Section 1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL Quality Assurance Plan [7] supports the CNL Management System Manual [8] and summarizes the processes and practices applicable to WL licensed activities, while still retaining compliance to CSA N286-12 [9] and N286.6-98 [10].

1.2 Audits, Inspections and Self-Assessments

As per the requirements of the Management System [8], both Safety Control Areas and Facilities conduct various audits, inspections, and self-assessments to ensure that the management system is functioning according to expectations and that any policy, programmatic, or procedural deficiencies are identified and appropriate actions taken to resolve them.

All actions resulting from audits, inspections, reviews and self-assessments are being managed and tracked through CNL's Corrective Action Program.

1.2.1 Audits

See Section 1.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4] for a list of all CNL-wide Audits for the reporting year 2021.

1.2.1.1 External Audits

The external audits conducted at Whiteshell Laboratories are summarized in the table below.

Table 1: External Audits

Title	Type of Audit	No. of Non-Compliances Raised	No. of Non-Compliances Completed
SAI Global Recertification Audit of the WL Environmental Management System	14000:2015	0	Not applicable
PLC Fire Safety Solutions Audit of the Fire Protection Program	CSA N393	31	0

For the Fire Protection Program audit, the non-compliances related mostly to missing documentation for inspection, testing and maintenance activities. The audit report was received late in 2021, and a corrective action plan is to be submitted to CNSC staff in early 2022.

1.2.1.2 Internal Quality Audits

There were no internal audits completed by the Quality Audits and Processes branch specific to Whiteshell Laboratories in 2021.

1.2.2 Inspections

CNSC Inspections

The following CNSC Inspections were conducted at Whiteshell Laboratories.

Table 2: CNSC Inspections for 2021

Inspection No.	Area Inspected	No. of NNC[a]s	No. of NNC[a]s Completed
CNL-WL-2021-01	Human Performance Management	2	2
CNL-WL-2021-02	Management System	6	6
CNL-WL-2021-03	General	3	0
CNL-WL-NSD-T2-2021-001	Security	7	0

a NNC – Notice of Non-Compliance

Inspections by Other Regulatory Bodies

A Physical Inventory Verification (PIV) inspection was carried out by the IAEA on 2021 May 26. This inspection was a sampling of accessible items containing Special Fissionable Material. A Design Information Verification inspection was carried out by the IAEA on 2021 May 25-27. This inspection verified the information provided in the Design Information Questionnaire.

Transport Canada conducted a virtual Transport of Dangerous Goods (TDG) inspection at WL in 2021 and did not find any non-conformances.

1.2.3 Self-Assessments

In 2021, there were 18 self-assessments conducted at Whiteshell Laboratories covering various aspects of the management system, including both safety and control areas, and various facilities.

Table 3: List of Self-Assessment Conducted at Whiteshell Laboratories in 2021

Title	Facility/Department
Effectiveness of Industrial Hygiene Instrumentation	WL Occupational Safety and Health (OSH)
Workload on the SMO	WL Environmental Management (EM)
WL Integrated Work Control	WL Site and Nuclear Operations
TDG Requirements	WL Waste Management

Movement of Radioactive and Non-Radioactive Materials	WL Waste Management
Registration and control of radiation sources	WL Radiation Protection (RP)
WL RP Program Compliance Review	WL RP
WL-510400-OI-366-01 - WL Lock Out Tag Out (LOTO)	WL Site and Nuclear Operations
900-510400-MCP-032 - Work Permit	WL Site and Nuclear Operations
WL EM QA Plan WL-514200-QAP-001 to 17025, Document Control	WL EM
Compliance to ISO/IEC 17025:2017 Document Control	WL EM
Compliance to ISO/IEC 17025:2017 Risk Assessment Process	WL EM
Compliance to ISO/IEC 17025:2017 Improvement	WL EM
WL Radiation Dose Reporting to NEW Workers for 2020 Doses	WL RP
Manager Dose Control Points and RP Training Designation Annual Reviews for 2021	WL RP
REGDOC 2.12.1, High Security Sites: Nuclear Response Force Section 7	WL Emergency Services
REGDOC 2.10.1 Section 2.2.1, Emergency Response Organization and Staffing	WL ES
Impairment Notification and Compensatory Measures	WL ES

1.3 Management Reviews

The Quality Assurance Program/Management System Review for 2018/19 and 2019/20 was completed. The review identified 6 actions, all of which are completed.

2 Human Performance Management

2.1 Human Performance Program

Whiteshell Laboratories adheres to the Corporate Human Performance (HU) Program. See Section 2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

2.1.1 Program Improvements and Accomplishments

The effectiveness of the HU program at WL has been enhanced through the following improvements:

- Following the 10 week fieldwork pause in 2020 November to address an adverse trend in human performance, WL gradually increased fieldwork throughout 2021 February. WL executed an extensive Corrective Action Plan, which included comprehensive reviews and updates to procedures and a significant investment in employee training. Improvements implemented included increased supervisor presence in the field, in depth review of proper use of tools and equipment, procedure awareness and compliance, sharing of lessons learned, and better pre- and post-job briefs. WL also performed several self-assessments through the integrated assessment plan and implemented new work control metrics.
- In 2021 May, Performance Assurance reintroduced the two-level rigorous review of ImpAct records by re-instating the Management Screening Team (MST) weekly meeting. MST's mandate is to provide management level review and oversight of the ImpAct record and ensure it has sufficient and accurate information to let the Management Review Meeting (MRM) team conduct their review. The MST assesses and recommends the significance level, cause determination effort, cause statement and the Responsible Manager. MRM provides Director level (and above) oversight for the ImpAct Corrective Action Program. The MRM team confirms, or modifies as appropriate, decisions made by the MST.
- In 2021 August, a three day TapRooT® Essentials Course was delivered to nine (9) WL Employees. The virtual sessions were taught by an external root cause analysis and investigation expert who guided immersive learning activities using interactive presentation technology, group exercises, and two-way interaction. TapRooT® is a powerful tool in conducting investigations and has already been used to augment CNL's current cause analysis techniques.
- WL enlisted the support of the recently formed CNL Strike Team, comprised of experts from across CNL, to conduct a causal analysis for a discovered adverse condition regarding the WL Preventative Maintenance program (see ERM-21-3009 in Table 5). Unlike the usual Apparent Cause Analysis or Root Cause Analysis processes, the Strike Team's causal analysis used a Facts Issues Causes Actions table. Doing the investigation in this manner allowed the team to develop the causal analysis and corrective actions in

a concise and timely manner. This tool will be beneficial for future investigations that may need to be conducted.

2.2 Training programs

Whiteshell Laboratories adheres to the Corporate Training and Development Functional Support Area. See Section 2 of the Annual Compliance *Monitoring Report for Canadian Nuclear Laboratories* for details [4].

2.2.1 Program Improvements and Accomplishments

The effectiveness of WL Training Program has been enhanced through the following improvements:

- Revisions to the content for the New Employee/Contractor Orientation to reflect current policies and procedures for working on site.
- WL introduced the Integrated Work Control Core 5 Elements course, which provides contractors with training that combines the 5 core courses delivered during the safety stand down: Work Permit Authorization, Job Safety Analysis, Pre-job Brief, Stop/Pause Work and Integrated Work Controls.
- Development of the initial Annual General Employee Training to review site and project updates, as well as policies and procedures. This will be updated and delivered annually to all employees.
- Updates and improvements to the content and media for the Radiation Group 4 Training delivered to all employees and contractors coming to site.
- Major revisions to the Delivering Practical Training course. Content now includes adult learning and learning principles content. This course is required for any employee who conducts on-the-job training and functional checkouts for skills assessments.
- Redevelopment of the Waste Management & Fundamentals courses to include updates to policies and procedures in our Waste Management Program.
- Revisions to the content and materials for Vehicle Spotter Training. Delivery to all staff who are required to have spotter training.
- Development of the 'Training Matrix tool' which allows managers and supervisors to quickly look up the training status of their teams.

2.2.2 Systematic Approach to Training

CNL maintains a list of positions and roles requiring Systematic Approach to Training (SAT) training programs in compliance with REGDOC-2.2.2, Personnel Training [11].

Training and Development evaluated the training programs for listed positions and roles at WL against the main elements of SAT. The results led to initial individual action plans which are being managed and further evaluated by the Curriculum Review Committees. Additional corrective actions and program improvements will be identified and managed by the

Curriculum Review Committees going forward. Since the initial analysis of the listed positions, dedicated Training and Development personnel have been hired and assigned to support WL in the completion of the action items identified. Curriculum Review Committees for the WL WMA and Shielded Facilities have been established and progress on the actions is underway.

2.2.3 Required Training

Some WL listed positions and roles require additional training documentation development to achieve full SAT-compliance. Current workers are qualified based on existing training programs combined with their years of experience in the role. Existing training programs include classroom training, practical training, computer-based training, and mentor style training. These experienced workers will assist as Subject Matter Experts (SMEs), in the development of training documentation that is required to achieve full SAT-compliance.

All Whiteshell Laboratories personnel, both employees and contractors, are adequately trained (and refreshed) to ensure safe operation of their facilities and to conduct work under the licence [1]. Section 2 of the Annual Compliance Monitoring Report for Canadian Nuclear Laboratories [4] provides the 2021 CNL Employee and Manager/Supervisor required training. Table 4 provides a list of federally/provincially legislated training courses that appear in position-specific training plans at Whiteshell Laboratories.

Table 4: Whiteshell Laboratories Operating Staff Training in 2021

Course Code	Course Title	No. of Attendees
OSH-1001-Online	Crane (Safe Indoor Hoist) – Theory	44
OSH-1002-Online	Lift Truck Operation – Theory	40
OSH-1003-Online	Aerial Work Platform – Theory	59

OSH-3005	Working at Heights – Practical	88
HU-1036-Online	Pre job Brief	12

2.2.4 Contractor Training

Before accessing the Whiteshell Laboratories, contractors are required to complete the following training:

- Contractor Safety Orientation
- Radiation Protection Group 4
- Integrated Work Control Core 5 Elements (Work Permit Authorization, Job Safety Analysis, Pre-job Brief, Stop/Pause Work and Integrated Work Controls)
- CNL COVID Awareness

WL utilizes the contract terms and conditions, in addition verifying and approving the contractor company's safety programs and training records, to ensure contractors are qualified to work at WL.

WL oversees contractors' work in the field and all WL work control protocols apply.

2.2.5 Training Evaluations Summary

In 2021 WL continued to utilize trainee feedback forms to capture learner input as part of training program improvement and maintenance activities. Also, there were 16 documented Observation and Coaching sessions related to training events. These evaluations are reviewed weekly by Training and Development staff and training program improvements are managed through applicable training change processes.

3 Operating Performance

3.1 Operating Program

Whiteshell Laboratories adheres to the Operating and Decommissioning Functional Support Areas. See Section 3.1 and Section 11.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Whiteshell Laboratories decommissions and operates its facilities according to prescribed programs and procedures. Operating performance is monitored through the nuclear performance assurance review board and other internal assessment activities such as self-assessments and audits (see Section 1.2).

3.1.1 Operations / Decommissioning Operations

Operational details on facilities identified in the *Site Licences, Certificates, Permits, Building/Facility Contacts, and Licence Representatives* [12] for Whiteshell Laboratories are given in Appendix A through F.

3.1.1.1 Conduct of Operations

Conduct of operations documents ensure appropriate integration and adequate reflection of safe operation practices to meet the business requirements.

3.1.1.2 Modification to Facilities and Processes

All temporary and permanent modifications to facilities at WL are made following defined Engineering Change Control [13] processes.

Relevant modifications to WL facilities are given in Appendix A through G.

3.2 Reporting Requirements

3.2.1 Reportable Events to CNSC

In 2021, there were 6 events that occurred at Whiteshell Laboratories that were deemed reportable to the CNSC. They are listed in Table 5.

Table 5: Reportable Events to the CNSC at Whiteshell Laboratories in 2021

Event No.	Title	SCA	Facility (if applicable)
ERM-21-3585	WL Injury - Medical Aid - Slip, Trip, Fall (Leg Injury)	Operating Performance	WL Building 300 (Research and Development)
ERM-21-3009	WL Reportable Event – Missed maintenance of safety related systems as per the Shielded Facilities Facility Authorization	Operating Performance	WL Shielded Facilities

HSSE-21-1772	WL - Radiation Source Found in Area Radiation Monitor Removed from B305 Electron Accelerator	Radiation Protection	WL Building 402 (Health and Safety)
ERM-21-1732	WL Environmental Protection: Hydraulic Leak at the Building 200 Demolition site involving a contractor's Hyster 550 Fork Lift (Rental Unit)	Environmental Protection	WL Building 200 (Active Liquid Waste Treatment Centre)
ERM-21-1651	WL Reportable Event - Building 402 Fire Protection System Impairment	Fire Protection	WL Building 402 (Health and Safety)
ERM-21-1036	WL - Incomplete Inventory Results in Misclassification of Shipment	Packaging and Transport	

3.2.2 Reportable Events to Other Regulators

Reports to other regulatory agencies consisted of:

- 1 Hazardous Occurrence Investigation Reports (HOIR) was made to Employment and Social Development Canada (see Section 8.1.3 for further details)
- 2 reports made to Environment and Climate Change Canada (see Section 9.5.2.4 for further details).

3.2.3 Trending of Events Related to Operational Activities

As events at Whiteshell Laboratories occur, they are recorded in the Improvement Action (ImpAct[2]) system. This information is regularly reviewed and analyzed to identify any trends. To identify trends Event Code based trend reports are also prepared to analyse ImpAct data on monthly bases. Monthly site wide and WL specific trend reports are prepared by CRL Performance Assurance and shared with WL. WL specific trends are also specified in the monthly Contractor Assurance System scorecard.

The following trends were identified and raised as ImpActs:

- ERM-21-1299, WL TREND – No Purchase Order in Place Prior to Commitments of Contract Service Providers Coming to Site
- ERM-21-3088, WL TREND - Misuse of WHMIS (Workplace Hazardous Materials Information System) when labelling or storing hazardous waste.
- ERM-21-3132, WL TREND – Increased Vehicle Accident Incident Reports (VAIR), Equipment and/or Passenger Vehicles on site and in main parking lot at WL.
- HSSE-21-3283, WL TREND – Barrier Crossings.

[2] ImpAct – Abbreviation for Improvement and Action. It is an internal process used to identify events, problems, non-conformities, opportunities for improvements, and personnel injuries. The process also identifies and tracks actions to correct or remediate problems.

The use of the ImpAct process continues to foster the internal reporting of lower significance level events (Level 4 and some Level 3), affording the opportunity to implement continuous improvement initiatives through a robust Corrective Action Program.

In 2021, a total of 424 ImpActs were raised by CNL employees at WL.

The reporting of lower significance level events continues to be encouraged (e.g., Near Miss Reporting – see Section 8, which is an industry best practice), and efforts to improve safety culture (Event Free Tools use, Event Free Day Reset, Observation and Coaching, etc.) have been adopted by both management and staff.

The following table summarizes ImpActs raised over the past 5 years by Significance Level[3].

Table 6: Number of ImpActs raised at Whiteshell Laboratories

Year	Level 0[a]	Level 1	Level 2	Level 3	Level 4	Total
2017	5	0	0	42	448	496
2018	10	0	0	39	532	581
2019	8	0	0	54	547	609
2020	13	0	3	58	276	350
2021	5	0	2	81	336	424

a Level 0 will be assigned if the ImpAct is deemed to be a "non- problem" and a recommendation to close the Impact will be given.

3.2.4 Notification of Conflicts or Inconsistencies

In 2021, there were no conflicts or inconsistencies identified between licence conditions, codes or standards, operations, programs, methods, or regulatory documents referenced in the Whiteshell Laboratories Licence [1] or *Licence Conditions Handbook* [2].

3 Significance Level: Levels assigned to an event (SL1 being most significant, SL4 being least significant) based on the actual or potential result in safety, environmental, or business consequences.

4 Safety Analysis

4.1 Safety Analysis Program

Whiteshell Laboratories adheres to the Corporate Safety Analysis Functional Support Area. See Section 4.1 of the Annual Compliance Monitoring Report for Canadian Nuclear Laboratories for details [4].

4.1.1 Safety Analysis Reports

Safety Analysis Reports (SARs) are produced to demonstrate that the facilities are appropriately designed to meet health, safety, security, environmental and regulatory requirements, and operated safely. These SARs form part of the basis for a set of limiting conditions for safe operation that are documented within Facility Authorizations for each nuclear facility. At WL, three facilities have SARs and Facility Authorizations: Shielded Facilities (SF), WMA and Concrete Canister Storage Facility (CCSF). The ALWTC SAR and Facility Authorization documents were previously obsoleted in 2020 [14]. Assessments are in progress to determine if the SF and WMA SARs need to be revised. The CCSF SAR is being updated to address upcoming fuel retrieval activities.

A SAR is being prepared for the standpipe/bunker remediation, Intermediate-Level Liquid Waste Processing Centre and conversion of the SMAGS building to a Cask Loading Facility. This document will be an addendum to the existing WMA SAR and will be submitted to the CNSC before these facilities are operated.

4.2 Nuclear Criticality Safety Program

Whiteshell Laboratories adheres to the Corporate Nuclear Criticality Functional Support Area. See Section 4.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

As the Nuclear Criticality Safety Program is a companywide program, enhancements and improvements made were intended to target all sites including WL and are identified in [4].

4.2.1 Nuclear Criticality Safety Documents

The WL Criticality Safety Documents (CSDs) for the Waste Management Area (CSD-27), the Cask Loading Facility (formerly the Whiteshell Laboratories SMAGS Building B923) (CSD-73) were conditionally accepted and the Intermediate-Level Liquid Waste Processing Centre (CSD-74), Concrete Canister Storage Facility (CSD 11), and the Fuel Basket Transfer Flask (CSD-54) are in progress to allow retrieval of waste from the WMA and CCSF. The remaining WL CSDs have not been updated during this review period.

5 Physical Design

5.1 Design Program

Whiteshell Laboratories adheres to the Corporate Design Functional Support Area. See Section 5.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Design Authority and Design Engineering Functional Support Area maintains and controls the design basis for all design activities performed at WL.

In 2021 March, the Certificate of Authorization was renewed with Engineers Geoscientists Manitoba. This authorizes CNL to engage in the practice of professional engineering in the province of Manitoba in accordance with the provisions of The Engineering and Geoscientific Professions Act.

5.1.1 Safety Related Structures Systems and Components

In 2021, the Design Authority and Design Engineering Program ensured that any structures, systems and components important to safety met and maintained their design basis, and any changes made were controlled through the Engineering Change Control Process [13].

5.2 Pressure Boundary Program

Whiteshell Laboratories adheres to the Corporate Pressure Boundary Functional Support Area. See Section 5.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Pressure Boundary Functional Support Area applies to design, procurement, fabrication, installation, examination, testing, repair, modification, construction and maintenance of pressure retaining systems and components performed by CNL at WL.

The *WL Pressure Boundary (PB) Quality Assurance (QA) Plan* [15] details the specific scopes of pressure boundary work carried out at WL, as permitted by the Certificates of Authorization issued by Inspection and Technical Services (ITS) Manitoba, describes the controls, authorities, and responsibilities applicable at the WL site, and is consistent with CNL's PB Program requirements.

The revised *PB QA Plan* [15] was accepted by ITS and a new Certificate of Authorization was issued on 2021 August 10. The new certificate of Authorization permits CNL to perform Pressure Boundary work as described in the Quality Assurance Plan until expiry in 2024 August.

The CNSC has previously been notified of revisions to the *PB QA Plan* [15], as per the *Licence Conditions Handbook.*

6 Fitness for Service

6.1 Fitness for Service Program

Whiteshell Laboratories adheres to a Fitness for Service Program through its Maintenance Functional Support Area. See Section 6.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Site and Nuclear Operations Branch provides monitoring and operation of building's processes and support systems. Housekeeping inspections are performed monthly to provide a formal walkthrough of facilities to ensure compliance for specific areas relating to facility performance. Further inspections are conducted of waste storage structures by qualified personnel to maintain them in a fit for service state.

Operating procedure reviews are conducted on a five year cycle. Currently the Operating Procedures are under review; some of these procedures have reached the five-year timeline for review and those are being prioritized for review and updating. As facilities are decommissioned procedures related to those buildings or processes are obsoleted. Procedures to operate the facilities in order to enable decommissioning efforts are prepared as required.

Details on various inspection and maintenance activities are provided in the following sub sections.

6.1.1 Planned Maintenance, Testing & Inspections

As part of Fitness for Service, WL staff ensure that critical systems, structures and components related to the safe decommissioning of WL are understood and that activities are put in place to assure their safe continued operation as they age. An integrated set of programs and activities ensures that performance requirements for all critical systems, structures and components are met on an ongoing basis. These processes include:

- Maintenance, In-Service Inspection and Functional Testing, where preventive maintenance work done in the facilities is tracked to ensure it is completed.
- WL operational regulatory tasks are tracked on a weekly basis to ensure required compliance and facility checks are completed, this includes the tasks set out in the Facility Authorization documents.
- Inspections required to meet the conditions of WR-1 Monitoring and Surveillance Plan.
- Inspections of waste storage structures for fitness for service.

6.1.2 Equipment Fitness for Service/Equipment Performance

Preventive maintenance of safety-related systems in WL's nuclear facilities is carried out by qualified maintainers, in accordance with the facility's Facility Maintenance Plan, and approved maintenance procedures. Preventive Maintenance is defined as the pre-planned routine testing, calibration, inspection, service, and overhaul of safety-related systems, structures, and components. Preventive maintenance is performed to prevent failures from occurring and to

assure the continuing capability of the system, structure or component to perform its design function. The maintenance tasks and frequencies specified in the Facility Maintenance Plan are based on recommendations from qualified WL engineering and maintenance personnel, plus vendor's data where available. Situations where there is evidence of deteriorating conditions or suggestions of an increased probability of upcoming failure are addressed as they are identified. Regular preventive or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service. Maintenance scheduling is conducted with assistance of a Computerized Maintenance Management System which outputs preventive maintenance tasks for scheduling by maintenance and work planning staff.

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed and is being implemented that will fix the issues and prevent recurrence. The effectiveness of the corrective action plan will be investigated upon completion of the actions.

6.1.3 Condition of Structures

Waste storage structures include the WMA bunkers and CCSF concrete canisters.

As a requirement of the Environmental Assessment Follow-up Program, a Periodic Inspection Plan (PIP) for WL Concrete Bunkers [16] was developed in 2007 and continues to be implemented to confirm the ongoing fitness-for-service of the concrete storage facilities (termed "bunkers") at the WMA. The PIP describes methods for conducting scheduled inspection surveys of these structures. The inspection is defined as examination, measurement and testing work done, to ensure the bunker systems are functioning as designed and the bunkers remain fit-for-service. The inspections are documented annually, with preventive maintenance and repairs occurring as needed. As the bunkers at the WMA are removed from service as part of the overall decommissioning of the WL site, they will be removed from the inspection process. The 2021 annual inspection of WL WMA concrete bunkers was conducted in accordance with the PIP [16].

Although the SMAGS building (Building 923) is not a bunker it has been included in the bunker inspection. Building 923 is being converted to the Cask Loading Facility, and during this conversion and subsequent re-commissioning for its new purpose, it will not store waste. A repair, conducted in 2016, to the north wall of Building 923 that extended into the core of the slab, remained stable through 2021 with no new crack expressions (the walls of Building 923 are pre-cast concrete slabs). All other repair items for the bunkers and Building 923 were minor in nature and were tracked through the WL work request system.

The concrete canisters are inspected quarterly for concrete spalls and any changes in the hairline cracks of the concrete. In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however existing cracks and pour pockets were regularly checked for changes. Requests for patching were placed in 2021, and several canisters will require more extensive patching of pour pockets that have gradually become more noticeable over time, however no increased radiation field was noted.

Environmental monitoring was conducted in the ditches at the perimeters of the WMA and the CCSF and show no evidence that any activity has been released from the bunkers, SMAGS or concrete canisters.

7 Radiation Protection

7.1 Radiation Protection Program

Whiteshell Laboratories adheres to the Corporate Radiation Protection Functional Support Area. See Section 7 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Whiteshell Laboratories uses the Chalk River Laboratories (CRL) licensed Dosimetry Service Provider for external and internal dosimetry for site/facility staff and contractors.

Whiteshell Laboratories staff and contractors who work at the WL site are assigned Thermoluminescent Dosimeters (TLDs) to monitor for external radiation exposures.

7.1.1 ALARA Initiatives and Activities

As Low as Reasonably Achievable (ALARA) and Radiation Protection (RP) program improvement initiatives and activities performed at WL in 2021 included:

- Radiological hazard and precaution sheets were reviewed and updated as required to remove statements such as “at the Surveyor’s discretion” or “as directed by RP Surveyor”.
- Enhanced personal protective clothing and equipment requirements were implemented for work in Radiological Safety Zone 2 and 3 work areas.
- Guidelines were developed and implemented for field RP staff for consistent completion of radioactive material transit/storage tags.
- Radiological surveys completed in WL nuclear facilities to confirm absence or identify unknown and unmarked historical or legacy contaminated materials and areas.
- Facility review completed for the adequacy of radioactive material storage areas.
- Field compliance check list developed and implemented for use by field RP staff during facility housekeeping inspections.
- Guidelines provided for RP staff when knee pads or other additional measures are needed to prevent inadvertent knee contaminations when working in contaminated environments.
- New CNL RP program requirement for formal registration of long term radioactive material storage areas was implemented for any new storage areas, and work started on registration of pre-existing facility storage areas.
- WL site procedure developed for the dose monitoring program for WL workers, contractors and visitors.

WL RP performance metrics are measured and tracked weekly through WL Closure Project status reports and quarterly through the WL Nuclear Performance Assurance Review Board. These are designed to identify and address program and performance deficiencies and

opportunities for improvement, establish and effectively implement corrective and preventative action plans.

7.1.2 Dose Control

Regular radiation surveys are performed by RP staff to confirm: the radiological safety zones are correctly designated; areas with local elevated radiation doses rates are posted in accordance with the RP Regulations; and sufficient access control provisions are in place. In 2021, there were no occurrences of dose rates exceeding permissible levels for the designated radiological safety zones and there were no occurrences of work places with accessible dose rates exceeding 25 µSv/h not being posted or with inadequate access control.

Electronic Personal Alarming Dosimeters (PADs) are worn by workers in addition to TLD badges to track and control job specific daily and accumulated doses. The PADs have dose and dose rate alarms which are established by job specific radiological work assessments. The dose alarms are a back-out condition and the dose rate alarms are an alert condition. Table 7 summarizes maximum daily recorded doses and dose rates for PAD work in 2021 and the previous four years, and a summary of PAD alarms. In 2021, the maximum PAD recorded daily dose received by a worker was 0.22 mSv and the highest dose rate measured in the year was 3.1 mSv/h. These were associated with planned exposures associated with decommissioning activities in the Building 200 ALWTC, and removal and packaging hot cell roughing filters in the WL Shielded Facilities. There were no PAD dose alarms and 78 PAD dose rate alarms in 2021. The distribution of PAD dose rate alarms over the past 5 years is summarized in Table 8.

There was an increase in the number of low level dose rate alarms in 2021 due to increased decommissioning and operations activities in the WMA associated with the removal, characterization and packaging of low level radioactive waste from waste storage buildings. These low level dose rate alarms helped alert workers of dose rate areas they did not need to be working in, and thus helped to maintain low doses to workers.

Table 7: Personal Alarming Dosimeter Summary

	2017	2018	2019	2020	2021
PAD – Maximum Daily Dose (mSv)	0.17	0.24	0.42	0.28	0.22
PAD – Maximum Dose Rate (mSv/h)	1.99	4.95	5.82	5.56	3.10

Table 8: Distribution of Number of PAD Dose Rate Alarms 2017-2021

Year	Dose Rate Alarm Set Point (mSv/h)							
	≤0.10	>0.10 - <0.25	0.25 - < 0.50	0.50 - < 1.0	1.0 – < 2.5	2.5 - < 5.0	5.0 - < 10	≥ 10
2021	11	20	22	16	7	2	0	0
2020	10	2	1	5	9	1	1	0
2019	9	0	2	12	4	2	0	0
2018	22	0	13	5	31	3	0	0
2017	22	3	26	2	5	0	0	0

At the beginning of 2021, managers assigned and confirmed Dose Control Points (DCPs) for employees and contractors. DCPs are used by managers and supervisors to perform individual whole-body dose management for worker radiation dose for non-emergency work situations. DCPs of either 1 mSv or 2 mSv are assigned by WL managers and represent the worker's maximum allowable dose for the calendar year. The DCPs may be adjusted as necessary during the year upon approval of a Health Physicist after confirmation that additional dose is justified. At the end of 2021, there were no individuals with an assigned DCP higher than 2 mSv, 28 individuals with an assigned DCP of 2, and the remainder of workers with a DCP of 1 mSv. No worker dose exceeded their assigned DCP in 2021.

7.1.3 Contamination Control

Regular contamination surveys of workplaces, material transfers, and personnel exiting nuclear facilities and controlled areas, are used to confirm the absence of unknown contaminated material or the spread of contamination. Workplace air monitors are employed to confirm the adequacy of controls, and to warn of abnormal or unplanned airborne contamination conditions.

Table 9 shows the number of personnel, workplace and material contamination events identified in 2021 and over the past five years. None of the contamination events in 2021 resulted in a recordable whole-body, skin or internal dose.

Material contaminations increased from 1 in 2020 to 11 in 2021. This increase was due to historical surplus equipment being found with low level contamination during operational cleanup activities (8), building decommissioning waste disposition (1), and as a result of operational activities (2). There were no worker skin or clothing contaminations in 2021.

In 2021, there were no airborne contamination exposure events and no radioactive material spills.

The following table outlines contamination events that occurred at Whiteshell Laboratories in 2021:

Table 9: Contamination Events

	Skin and Clothing Contamination				Workplace Contamination	
	Skin[a]	Personal Clothing[a]	Radiological Work Clothing[b]	Total	Surface[c,d]	Vehicle / Materials [b, c]
2017/18 FY	0	0	1	1	3	
2018/19 FY	1	0	5	6	6	0
2019 CY	3	0	4	7	2	4
2020 CY	2	0	3	5	1	1
2021 CY	0	0	0	0	1	11

a Total surface contamination found is greater than 1 Bq/cm^2 beta-gamma or 0.2 Bq/cm^2 alpha over a 100 cm^2 averaging area.

b Total surface contamination found is greater than 4 Bq/cm^2 beta-gamma or 0.4 Bq/cm^2 alpha over a 100 cm^2 averaging area.

c Removable surface contamination found is greater than 0.2 Bq/cm^2 beta-gamma or 0.01 Bq/cm^2 alpha over a 300 cm^2 averaging area for Contamination Zone 1 areas

d Removable surface contamination found is greater than 10 times the maximum allowable levels for Contamination Zone 2 and higher designated areas.

7.1.4 Sealed Sources

Radiation sources are registered and tracked in accordance with CNL procedures.

In 2021, there were no lost or stolen radiation sources. Leak testing was completed as required with all sources passing their leak tests.

As of 2021 December 31, the total number of registered sealed or contained sources at WL, was 53. One Cesium (Cs)-137 source was added to the registry, and one mixed Cs-137 liquid standard and one Cs-137 gamma irradiator were removed from the registry. The liquid standard was evaporated and dispositioned as radioactive waste. The Cs-137 calibrator was transported back to the manufacturer.

7.2 Dosimetry

7.2.1 Interpretation of Reported Dose Quantities

WL uses the CRL licensed Dosimetry Service Provider for external and internal dosimetry for CNL staff, non-CNL employees and visitors. Compliance with the regulatory document REGDOC 2.7.2, *Dosimetry*, Volume II [17] requires external exposure measurements to meet performance criteria with respect to the measurement of personal dose equivalent, $H_p(d)$. This is the quantity currently measured using TLDs worn on the trunk of the body. External whole-body dose (photon) and external surface (photon plus beta) dose as reported herein can be interpreted as $H_p(10)$ (for photons) and $H_p(0.07)$ (for photons and betas), respectively. Effective

dose is the sum of the components external penetrating, neutron, tritium and non-tritium committed effective dose.

External radiation whole-body and skin doses are individually monitored using TLDs for persons entering or working in either radiological Controlled or Supervised Areas at WL[4].

Extremity dosimeters are worn for a defined job by a person who is likely to receive an extremity dose exceeding 1 mSv and significantly greater than a surface dose as monitored by their TLD, or if there is a reasonable probability that an extremity will be exposed to a beta and/or photon dose rate greater than 10 mSv/h.

Neutron dosimeters are issued to individuals who may be exposed to neutrons resulting in dose in excess of 1 mSv in a year or where accidental neutron exposures are possible.

WL staff participate in a routine bioassay program when there is a reasonable probability of receiving a committed effective dose from occupational intakes exceeding 1 mSv per year.

7.2.2 Radiation Doses to Personnel

Table 10 to Table 13 summarize the monitored radiation doses at the WL site for 2021. Doses are summarized for employees, contractors and visitors and are subdivided into Nuclear Energy Worker (NEW) and non-NEW status. Doses in the tables of this report do not include doses received by WL employees and contractors working at sites other than WL. Two visitors had NEW status that were associated with prior NEW requirements and visits within CNL as a whole, these two instances were CNSC and IAEA staff.

In 2021, there were no exceptions for individual monitoring of non-CNL employees and visitors at WL, other than drivers of delivery trucks and building demolition debris haulers in radiological Supervised Areas.

There were no operations of exposure devices in 2021 which required employees or contractors to be placed on a two-week dosimetry period, and there were no formal dose calculations required during 2021 for local area skin contamination.

No neutron dosimeters were assigned to employees during 2021.

In 2021, 180 individuals underwent internal bioassay, which involved urinalysis and/or whole-body counting. Eleven individuals underwent confirmatory and follow-up Pu-in-urine bioassay monitoring and there were no individuals requiring tritium-in-urine monitoring. No committed effective dose estimates were necessary as a result of any bioassay sampling in 2021.

In May of 2021 the building (B402) that housed the WL Whole Body Counter (WBC) began decommissioning and demolition and a new building (B543) is currently being commissioned to house the WBC. It is anticipated that the new facility will be ready for occupancy sometime in the spring of 2022. During this outage, workers who normally participate in annual or bi-annual WBCs were evaluated against the site's current radiological activities to determine which

---

[4] Exceptions are authorized on a case-by-case basis by the responsible RP Program Manager or RP Program Functional Support Manager (exceptions are noted in Section 7.2.2).

workers required alternative monitoring. Workers with reasonable potential for an intake which warranted alternate monitoring were placed on a gamma spectrometry in urine analysis (provided by CRL Dosimetry Services) which provides similar minimum detectable doses to the WBC analysis. Additional random (biased toward likelihood of an intake) urine bioassay monitoring of workers who did not meet the alternative monitoring criteria is being undertaken until the new facility is ready.

Table 10: Effective Dose for Whiteshell Laboratories

Monitored Person Type		Total # of Persons	Dose Range (mSv)							Individual Dose (mSv)			Collective Dose (p·mSv)
			0	0.01-0.50	0.51-1.00	1.01-5.00	5.01-10.00	10.01-20.00	>20.00

a All quantities are measured in mSv unless otherwise noted.

b Average of all measured doses that exclude the zero dose value, rounded to two decimal places.

c Average of all measured doses that include the zero dose value, rounded to two decimal places.

d Visitor NEWs are persons who were former employee and/or contractor NEWs, but who have returned to the site as visitor while retaining their historical NEW status.

7.2.2.1 Discussion of Dose Data

The Regulatory effective dose limit for a NEW in a calendar year is 50 mSv. The maximum individual effective dose to a NEW at WL in 2021 was 0.57 mSv and the site collective dose was 18.99 p-mSv.

The Regulatory effective dose limit for a NEW in a five-year period is 100 mSv. The maximum individual effective dose to a NEW at WL for the current five-year dosimetry period from 2021 to 2025 at WL was 0.57 mSv.

The Regulatory skin dose limit for a NEW in a calendar is 500 mSv. The maximum individual skin dose to a NEW at WL in 2021 was 0.94 mSv and the site collective dose was 23.47 p-mSv.

The Regulatory hands and feet dose limit for a NEW in a calendar is 500 mSv. The maximum individual hands and feet dose to a NEW at WL in 2021 was 1.86 mSv and the site collective dose was 7.26 p-mSv.

The Regulatory effective dose limit for a pregnant NEW is 4 mSv for the remainder of their pregnancy. In 2021, the maximum individual effective dose from the time the pregnancy was declared to the end of the pregnancy term was 0.05 mSv.

The Regulatory effective dose limit for non-NEWs is 1 mSv in a calendar year. In 2021, the maximum individual effective dose to a non-NEW at WL was 0.11 mSv.

Table 14 provides a summary of radiation doses by worker group in 2021. The majority of radiation doses were received by RP, Nuclear Operations and Trades staff.

7.2.2.2 Radiation Dose Changes or Trends

Table 15 shows external whole body dose received from 2017 to 2021, and Figure 1 displays the maximum individual and collective dose from 2001-2021.

Worker doses decreased in 2021 with the completion of higher dose extensive decommissioning activities in Building 200 (ALWTC) in 2020. The site collective dose decreased from 33 p-mSv in 2020 to 19 p-mSv in 2021. The number of workers receiving occupational doses above 0.2 mSv in a calendar year decreased from 25 workers in 2020 to 11 workers 2021. This a significant decrease compared to a maximum number of 42 workers in 2017. There were no workers receiving an annual radiation dose above 1 mSv in 2021.

Main contribution to radiation dose in 2021 was radioactive tanks removal during B200 demolition activities, and operational replacement of hot cell roughing filters. There was increased waste handling in 2021 with the start of the removal, characterization and packaging of low level radioactive waste packages from storage facilities in the WMA. However, these activities had only a small contribution to site worker doses.

7.2.3 Program Exceedances

During 2021, radiation dose to all persons working at WL were below the WL dose Action Levels [2] and the respective CNSC regulatory limits [18]. In addition, there were no individual doses exceeding their respective DCP as a result of activities at WL.

Table 14: Summary of Worker Group Radiation Doses at WL for 2021

	Total Number of Persons	Individual Whole-Body Dose (Effective Dose[a])		Collective Whole-Body Dose (Effective Dose[a])	Collective Surface Dose (photon plus neutron plus beta)	Collective Extremity
		Average[b] (mSv)	Maximum (mSv)	p·mSv	p·mSv	p·mSv
Nuclear Facilities:						
SF Staff (HCF and IFTF)[c]	5	0.18	0.49	0.91	0.92	1.83
WR1 and ALWTC Staff	5	0.07	0.14	0.37	0.37	0
WMA and CCSF Staff[c]	6	0.07	0.21	0.39	0.39	0
Support Workgroups:						
Radiation Protection Staff [d]	41	0.11	0.43	4.43	6.02	1.06
Trades Staff [e]	48	0.09	0.57	4.31	6.35	4.37
All Remaining Staff:						
Other Staff [f]	513	0.02	0.19	8.48	9.32	0
WL Site[g]:	618	0.03	0.57	18.89	23.37	7.26

a Includes photon and neutron; there were no tritium committed effective doses for 2021.

b Average of all measured doses that includes the zero dose values, rounded to two decimal places. Includes employees and contractors.

c SF= Shielded Facilities; HCF = Hot Cell Facilities; IFTF = Immobilized Fuel Test Facility; ALWTC= Active Liquid Waste Treatment Center; WMA= Waste Management Area; CCSF= Concrete Canister Storage Facilities; WR1 = An experimental test reactor built at WL – WR-1 featured an organic liquid coolant.

d Radiation Protection staff include Radiation Surveyors, Radiation Protection Assistants, Contamination Monitors, and Decontamination Operators.

e Trades staff provide services for all listed facilities and decommissioning activities as well as the WL

site in general.

f Other staff is comprised of all remaining staff and includes decommissioning, administrative, management, engineering, quality assurance, researchers, contractors and tenants.

g WL Site includes 393 CNL staff (WL and staff visiting from other CNL sites) and 225 contractors working at the WL site during 2021. This tally does not include visitor doses.

Table 15: WL External Whole-Body Dose Performance 2017 to 2021

Performance Metric	2017	2018	2019	2020	2021
Site Collective Worker Dose (p-mSv)	19.9	40.2	49.6	33.4	18.9
Max Individual Worker Dose (mSv)	1.41	1.65	3.09	2.97	0.57
Number of Workers > 0.2 mSv in a year	42	39	38	25	11
Number of Workers > 1 mSv in a year	1	12	14	8	0
PAD[a] – Maximum Daily Dose (mSv)	0.17	0.24	0.40	0.28	0.22
PAD – Maximum Dose Rate (mSv/h)	1.99	4.95	5.82	5.56	3.1

a Personal Alarming dosimeter.

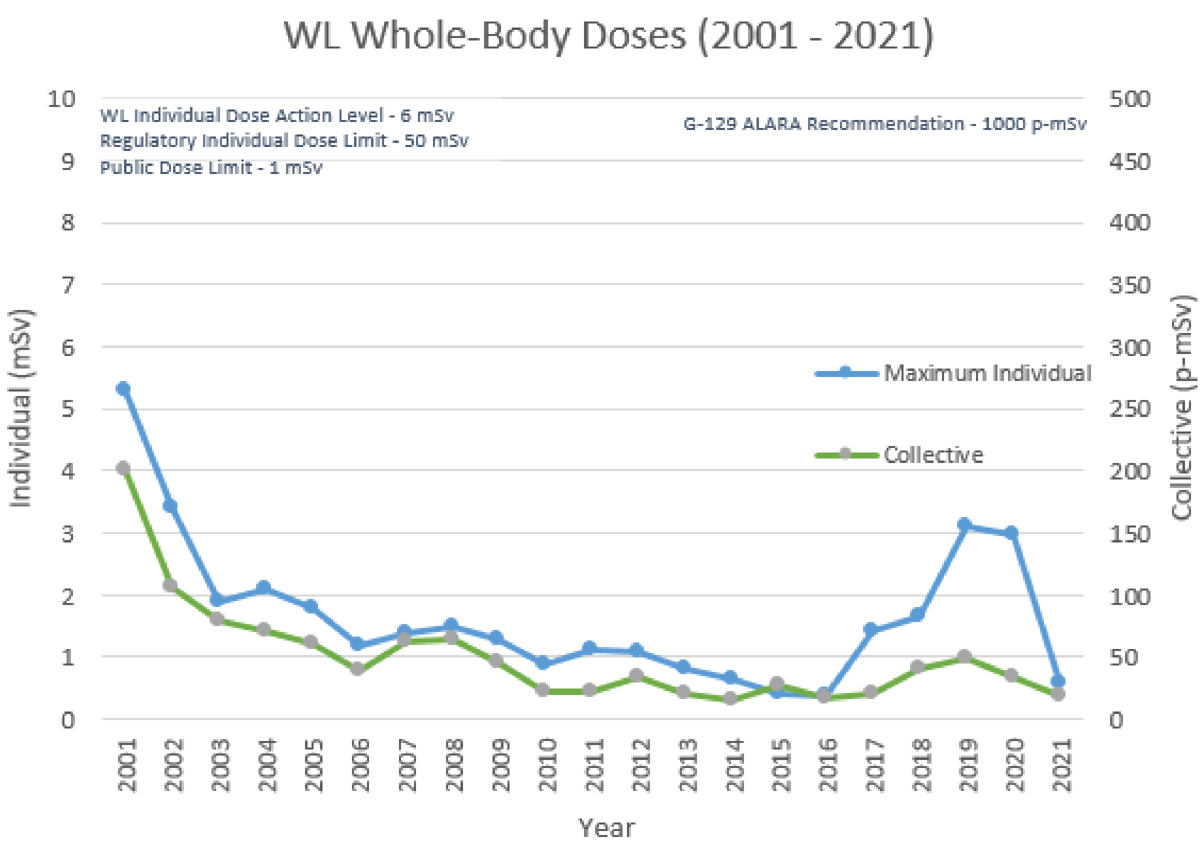

Figure 1: Whole-Body Effective Doses (2001 – 2021)

8 Conventional Health and Safety

8.1 Conventional Health and Safety Program

Whiteshell Laboratories adheres to the Corporate Conventional Health and Safety Functional Support Area. See Section 8 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In support of reducing the number and impact of incidents with the potential for injuries or incidents at WL, the following initiatives are continuing or began in 2021:

- To support project work, WL OSH purchased noise dosimeters, a sound calibrator, Jerome Mercury detector and Colorimetric Badges for chemical detection.
- OSH presence in the field continued at pre-job briefings, walk downs and daily work plan meetings together with early involvement in the planning process have contributed to WL's internal safety success.
- Contractors continued to be "pre-qualified" prior to bidding on WL contracts. The pre-qualification process involves reviewing safety statistics and the safety programs of the potential bidders.
- WL continued to participate in the Rapid Learning Morning Call to quickly share safety information with all CNL sites, as well as gather safety information relevant for the WL site.
- Increased contractor oversight continued by participating in activities such as site visits, pre-job briefs, pre-bid meetings and OSH orientation for contractors.
- There were 11 internal Safety Advisories and 2 Learning Advisories sent to WL site employees. The bulletins are intended to inform WL employees about imminent issues that could impact their safety. WL continued to be proactive in the approach to safety.
- Near Miss reporting (a known industry best practice) continued with a focus on early hazard recognition and strong situational awareness culture, supporting the minimization or elimination of hazards prior to resulting in injury (see Table 16).
- Near Miss reporting at WL always includes an investigation/fact finding session. The majority of Near Miss reports also generate an ImpAct. Whether an ImpAct is generated or not, the possibility of a human error trap being involved in the Near Miss incident is always considered, evaluated and followed up as appropriate.
- OSH Program weekly review of company injury/illness reports in support of recognizing trends and disseminating lessons learned.
- Focus on disability management / return to work in support of minimizing the impact to an injured employee and subsequent days lost.
- Promoted the Stop/Pause protocol.

Table 16: Summary of WL Near Miss Reporting

Year	2017	2018	2019	2020	2021
Near Miss Reported	60	53	46	10	26

8.1.1 Site Safety and Health Committee

The Site Safety and Health Committee is the principal forum at WL for joint employee/ management consultation and development of solutions to safety and health concerns at the WL site. The WL Site Safety and Health Committee meets on a monthly basis.

In 2021, the WL Site Safety and Health Committee received 93 inquiries out of which 6 remained open and in progress. There was one inquiry carried over from 2020. The Site Safety and Health Committee acts as an oversight body, therefore these actions are largely related to the Site Safety and Health Committee's need for more information that provides them with assurance of the effectiveness of the actions of the functional safety groups on site.

8.1.2 Inspections

There were 61 site health and safety inspections completed in 2021.

8.1.3 HOIRs and Lost-Time Injuries

There was one hazardous occurrences at Whiteshell Laboratories that was reported to Employment and Social Development Canada in 2021. CNSC staff received a copy of this notification, as per the requirements of the CNSC REGDOC-3.1.2 [3].

The following is a summary of injury rate data for the last 5 years.

Table 17: Summary of Whiteshell Laboratories Injury Rate Data

	2017	2018	2019	2020	2021
Whiteshell Laboratories					
Person Hours Worked	706,000	688,000	642,000	584,030	684000
Lost-Time Injuries	3	1	0	1	0
Working Days Lost	27	5	0	2	0
Frequency[a]	0.85	0.25	0	0.34	0
Severity[b]	7.76	1.45	0	0.68	0
Whiteshell Laboratories Contractors[c]					
Lost Time Injuries	1	0	0	0	0
Working Days Lost	0[d]	0	0	0	0

a Frequency rate equals # of Lost-Time Injuries x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).

b Severity rate equals # of Working Days Lost x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).

c The Number of Person Hours worked are not divulged by Contractors. As such, Frequency and Severity rates cannot be calculated.

d Number of days lost is unknown as the contractor terminated the employee.

The Recordable Lost Time Injury rate over the last five years at WL in Manitoba is significantly lower than local lost-time injury rates for construction (3.7) and manufacturing (2.4), as per the data from the Workers Compensation Board of Manitoba found in *The Manitoba Workplace Injury and Illness Statistics Report 2010-2019* (safemanitoba.com).

No Assurance of Voluntary Compliance or Directions were issued by Employment and Social Development Canada in 2021.

9 Environmental Protection

9.1 Environmental Protection Program

WL adheres to the Corporate Environmental Protection (EnvP) Functional Support Area. See Section 9 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

WL has an integrated Environmental Protection Program designed to track radiological and non-radiological contaminants throughout the different compartments of the geosphere, atmosphere, and biosphere, and consists of three distinct programs: the Effluent Verification Monitoring Program, the Environmental Monitoring Program, and the Groundwater Monitoring Program. The WL Environmental Protection Program is designed to implement the requirements of:

- CSA N288.4-10, *Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [19],
- CSA N288.5-11, *Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [20],
- CSA N288.6-12, *Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills* [21],
- CSA N288.7-15, *Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [22],
- CSA N288.8-17, *Establishing and Implementing Action Levels for Releases to the Environment from Nuclear Facilities* [23], and
- ISO 14001:2015, *Environmental Management Systems* [24].

The integrated Environmental Protection Program is dynamic in nature, meaning that it is continually evolving based on various sources of information received.

Program documentation is updated on an ongoing and/or required basis.

This report will focus and discuss the implementation of the WL Effluent Verification Monitoring Plan [25]. This plan defines the methodologies and protocols followed in performing the effluent verification monitoring required in CSA N288.5-11 [20].

The WL site has maintained its ISO 14001 [24] registration in 2021 with initial registration in 2010.

The CNSC has previously been notified of revisions to *Environmental Protection documents* [26], as per the *Licence Conditions Handbook.*

9.2 Quality Assurance

In order to ensure that the data collected through the program is valid, the laboratories performing monitoring for the program have strong Quality Assurance/ Quality Control programs as required by CSA N288.5 [20]. General quality assurance objectives for CNL's

Environmental Protection Program are set out in quality assurance plans. Radiological analysis is conducted in accordance with laboratory-specific environmental monitoring quality assurance plans. The plans include detailed working procedures for field operations, laboratory operations, laboratory administration, equipment performance, and quality verification of analytical results. The plans were written to align to ISO/IEC 17025 [27] for analytical laboratories.

Whiteshell Laboratories' Environmental Management group conducts frequent internal checks of their technical capabilities as they perform their measurements. These are called Quality Verification Tests, and are grouped as follows according to purpose:

- *Reproducibility Tests*, such as measurement of sample replicates, establish the relative precision of the method(s). To be acceptable, replicate measurements must agree within limits established by long-term method performance.
- *Accuracy Tests*, such as blanks or samples, each spiked with known amounts of the analyte(s), establish the presence or absence of any biases due to sample matrix, sample preparation, or instrument function. To meet acceptance criteria, the spike quantity must be recovered within limits established by long-term method performance.

Environmental Management performed 3247 quality verification tests during 2021 on WL's radiochemical counting equipment. Of these tests, 99.6% fully complied with acceptance criteria. The results of these tests are shown Table 18.

Table 18: Whiteshell Laboratories' Summary of Quality Verification Test Performed

Method	No. of Tests	No. of Failures	% Pass
Total Alpha (Instrumentation)	1188	4	99.7
Total Beta (Instrumentation)	1188	5	99.6
Gamma (Instrumentation)	647	0	100.00
Tritium	224	4	98.2
2021 Total	**3247**	**13**	**99.6**

In 2021, the WL Effluent verification program continued performing regular field Quality Verification testing on the Outfall, Lagoon, and Ditch effluent sampling (Table 19). The program is using traveling blanks to determine and account for any possible introduction of contamination into the sample being analyzed by the sampling methodology being employed by the program, and the program is also collecting duplicate samples to demonstrate sampling reproducibility.

Table 19: Whiteshell Laboratories' Summary of Field Quality Verification Tests Performed

*: Not all 2021 data has been received from the contract laboratory.
LMDL = Laboratory Method Detection Limit

It is important to note that not all of the radiological results for 2021 have been received from the contract laboratories carrying out the analysis of samples (see also Section 9.4.1.3.2). At the time of writing this report, results received to date indicate that out of the 146 duplicate quality verification tests, 130 of these tests meet the acceptance criteria (+/- 20% of the actual result) of the program, to yield an 89% pass rate. A larger number of duplicates failed this year, with the majority of the failures being related to the metal concentrations being observed at the Outfall monitoring station. CNL is attributing this increase in failures to the fact that the metal concentrations being observed in the effluent are near the detection limit. This leads to results with low concentrations and high variability being produced, which will increase the likelihood of a failure in the duplicates being observed. This is supported by the large number of results classified as not being detected, and the low concentrations of metals being observed at the Outfall as seen in Table 32. No further action by CNL is needed to address the failures.

Reviewing the travelling blank data, and comparing it to the field results, the environmental program has concluded that the water source being used for the travel blank is slightly contaminated with Copper, Lead, Zinc, Chloroform, and Bromodichloromethane. The traveling blank results for these parameters are not reflective of contamination being picked up while sampling in regards to these parameters.

In 2021, the WL Environmental Management group took part in four inter-laboratory comparison studies. Two of these studies, which focused on radiological analyses, were offered through the Environmental Research Associates. The other two studies which focused on non-radiological analyses, were offered through the Canadian Association for Laboratory

Accreditation. The results of the WL Environmental Monitoring laboratory performance are shown in Table 20 and Table 21. There were four unacceptable test results out of thirty for the Environmental Research Associates inter-laboratory comparison studies, resulting in an 87% pass rate. The four unacceptable test results related to the gross alpha and gross beta analysis of water samples. The WL radiochemical counting laboratory is working on determining the cause of the problem, and until the cause has been identified, all quantitative analyses of this nature are being contracted out to a third party laboratory. The laboratory is in the process of ruling out possible factors. The areas the laboratory are currently reviewing includes the process for evaporation and ashing samples being utilized to prepare samples. The previously used method was required to change due to equipment limitations in the new environmental laboratories. The standard stock solutions that are used for the creation of the calibration curves used in this analysis may have also been compromised.

For the Proficiency Testing Canada inter-laboratory comparison studies, a 100% pass rate was achieved.

Table 20: Environmental Research Association Inter-Laboratory Comparison Program for CNL WL - 2021

MRAD* Study	Matrix	Analyte	Units	MRAD Assigned Value	WL Reported Value	Acceptance Limits	Performance Evaluation

9.3 Supplementary Studies

In 2020, the WL site began to do temporary enhanced monitoring on the effluent verification ditches for the year. The enhanced monitoring is being done to confirm the absence of a number of radiological and non-radiological parameters. The enhanced monitoring involved doing an open scan for Volatile Organic Carbons, semi-volatile organic carbons, and an expansion of the metals and gamma isotopes list currently being used to monitor the ditches.

Whiteshell is reviewing the data, and is deciding whether there is a need to add any of these parameters to the effluent verification monitoring program going forward. This study was on going in 2021, and will be continued into 2022 due to the limited number of ditch sampling events that occurred in 2021.

9.4 Effluent Monitoring - Radiological

This section addresses the licence requirement regarding radiological monitoring of airborne and liquid effluents for the WL site, located on the Winnipeg River near Pinawa, Manitoba. It also addresses the effluent monitoring requirements listed under the Environmental Assessment Follow-Up Program [28] for WL.

Results of environmental monitoring and progress on the Environmental Assessment Follow-Up Program work packages will be provided in their respective annual reports, *Environmental Monitoring in 2021 at Whiteshell Laboratories* [29] and *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28].

9.4.1 Effluent Monitoring

9.4.1.1 Site Effluent Verification Monitoring System and Results Evaluation

Monitoring locations for airborne and liquid effluent streams are representative of the final discharge to the off-site environment, and may include the combined discharge from a number of facilities. Additional monitoring points are maintained at upstream locations as an aid in identifying the specific sources of emissions. Sampling system design ensures that samples are representative of the total content of the stream at each location.

Figure 2 includes a map of the effluent monitoring locations/effluent streams at WL.

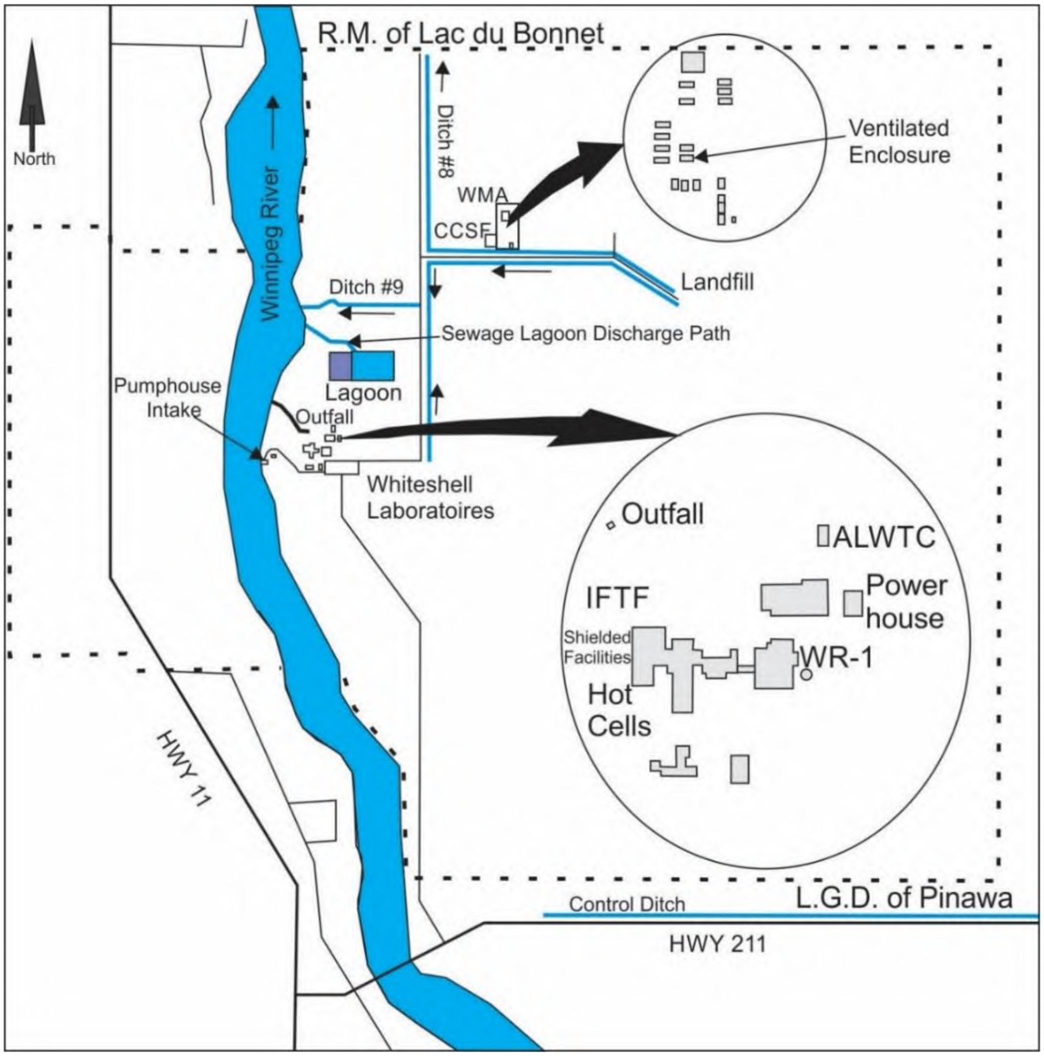

Figure 2: Effluent Monitoring Locations

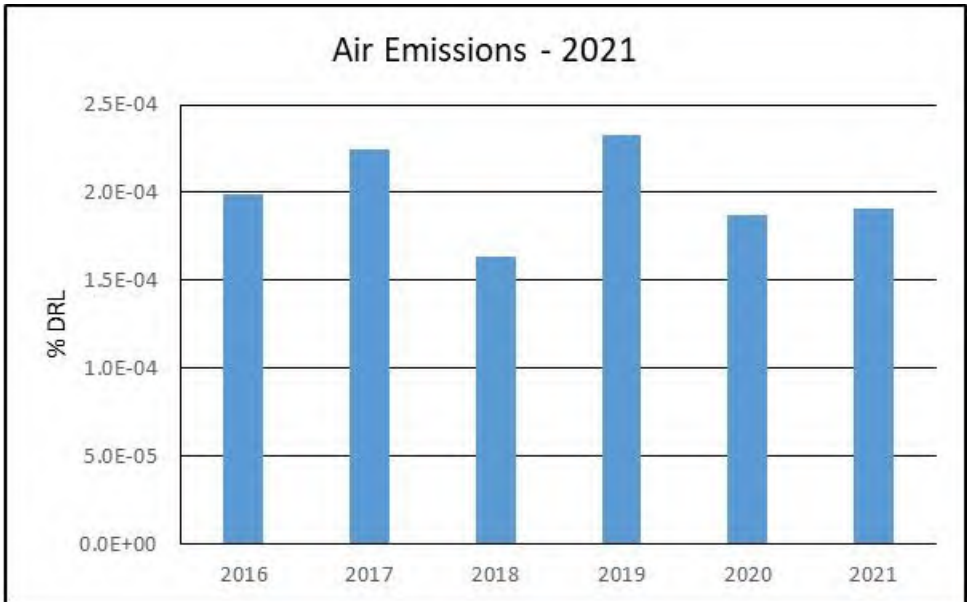
Effluent streams are monitored for all groups of radionuclides that are likely to be present and significant contributors to the total, expressed as a percentage of applicable DRLs [30]. The DRLs in use at WL came into effect on 2021 January 31. All current and historical data in this report has been compared against these DRLs. Monitoring is conducted either by direct measurement on location or by sampling and laboratory analysis. In many cases, gross-measurement parameters (e.g., gross beta) are monitored and reported rather than specific radionuclides. This is done provided that either the relative composition of radionuclides indicated by the gross parameter is not likely to vary significantly, or total emissions of the gross parameter are very small relative to the DRLs. For comparison with DRLs, the gross parameters are always evaluated conservatively. They are either assumed to consist solely of the most restrictive radionuclide, based on DRL value that is likely to be present in measurable quantities, or are assumed to be the radionuclide(s) known to be present in the effluent. To ensure proper selection of the DRL values, the effluents are periodically characterized using, for example, gamma spectrometry to identify individual gamma emitters, or chemical extraction

and analysis of individual beta emitting radionuclides, such as Strontium (Sr)-90, complemented by examination of historical data.

The significance of the measured radioactive materials in airborne and liquid effluents is assessed by comparison with DRLs that relate the releases to the potential radiation dose to the identified, most exposed groups (i.e., critical groups). DRLs are the upper limits for releases of radionuclides in airborne or liquid effluents from a facility or site. WL's DRLs were calculated in accordance with the principles and methodology in CSA N288.1-08 [31]. The DRL for a particular radionuclide is derived from the regulatory dose limit for members of the public, 1 mSv in a year, as specified in the Radiation Protection Regulations under the Nuclear Safety and Control Act [32]. The intention of the DRL is to establish a release limit such that compliance with it will give reasonable assurance that the annual regulatory dose limit for members of the public is not exceeded. Weekly DRLs are calculated and applied for airborne effluents, and monthly DRLs for liquid effluents.

For multiple effluents and radionuclides at a site, verifying that the sum of all releases as a percentage of the respective DRLs is less than 100% provides a reasonable assurance[5] that the annual dose limits have not been exceeded. This is a conservative approach since the critical group may differ for different release paths and radionuclides. The actual releases are a very small fraction of the DRL as discussed in the following sections and shown in Figure 3. As discussed in Section 9.4.1.3.2, the increase in 2019 to 2021 liquid effluents is due to an increase in detection limit values for Am-241 and Plutonium (Pu)-239/240. When the activities of radionuclide contaminants are not detected it is standard practice to report detection limit values as if they were observed concentrations. For example, Pu isotope activities were always detection level values and Am-241 and Cs-137 activities are very close to detection levels.

[5] The effluent DRL model and assumptions are further verified annually through results from the WL environmental monitoring program. The program assesses radiation doses to members of the public using direct measurements of radioactivity in the environment (e.g., in air, water, and food).



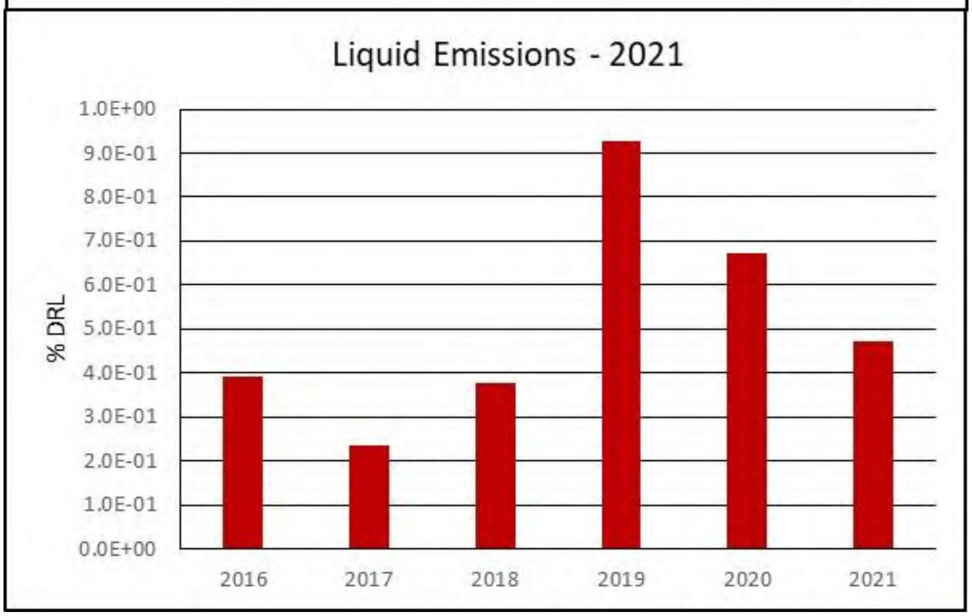


Figure 3: Trends for Airborne and Liquid Emissions form WL for 2016 to 2021

(Note: The Liquid Emissions for 2021 need to be corrected to include October to December data. This will be revised upon receipt of the data.)

Analytical models of all significant environmental pathways to an individual in the critical group are used in the DRL calculations. DRLs for WL have been calculated for a large number of radionuclides, many of which are currently not detected in site effluents. Derived Release Limit calculations (of a wide range of radionuclides) provide a means of determining which radionuclides may be significant dose contributors. Thus, they aid in determining which nuclides warrant inclusion in the monitoring program, and in interpreting monitoring results.

Performance is also measured against the regulatory Administrative and Action Levels[6] as specified in Reference [33]. The Action Levels were calculated based on current CNSC guidance to meet CSA N288.8 [23] and to better reflect current waste streams, and were released for use based on an implementation date of 2017 January 01.

9.4.1.2 Airborne Effluents Monitoring

9.4.1.2.1 Monitoring Points, Schedules and Parameters

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. These activities include waste compaction in the Waste Handling Area, located in the Immobilized Fuel Testing Facility (IFTF), and decommissioning activities in the ALWTC. The main sources of airborne radioactive effluents, as a result of this work and historical activities at WL, are the:

- Hot Cells Facility (Building 300)
- Immobilized Fuel Test Facility (Building 300)
- Reactor Building (Building 100)
- ALWTC (Building 200)

Air effluents from Buildings 100 and 300 were sampled continuously throughout the year. The frequency and type of monitoring will continue to be evaluated over time, and adjusted to reflect findings from the monitoring activities. The current monitoring schedule and locations are noted in Table 22. Cessation of a monitoring activity will occur once it can be shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant by regulatory requirements or community concerns. Any proposals on modifications to the monitoring program will be communicated to CNSC staff. In 2020, Building 200 (ALWTC) was prepared for demolition and the ventilation system was shut down in 2020 October. Monitoring of stack effluents for Building 200 ceased after 2020 October 13, and the building was demolished in 2021. Therefore the reported air emissions in 2021 do not include emissions from Building 200, which is no longer included in the monitoring schedule (Table 22).

[6] Action Level – In the context of CNL's Environmental Protection Program, an "Action Level" for radioactive emissions is a release rate of radioactive emissions that, if reached, may represent a loss of control of performance for a facility's environmental protection program or emission control system. Releases above Action Levels must be investigated and reported to CNSC staff. Action Levels for WL radioactive effluents are lower than the DRLs.

Table 22: Radiological Air Effluent Monitoring Schedule – 2021

Sample Location	Sample Collection		Analytical Method and/or Parameter			
	Frequency	Method	Gross Beta	Gross Alpha	Tritium	Gamma Spec
Building 100 Stack	Cont	GFA Filter	W	W	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Bubbler	N/A	N/A	W	N/A
Building 300 HCF	Cont	GFA Filter	W	N/A	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Millipore Filter	N/A	W	N/A	N/A
Building 300 IFTF	Cont	GFA Filter	W	N/A	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Millipore Filter	N/A	W	N/A	N/A

Cont The air effluent is measured but passing a continuous sample of the exhaust through a filter. The GFA filter is normally used for beta-gamma, the Millipore normally for alpha, charcoal or silver zeolite for radioiodine, and a water Bubbler for tritium.

W Weekly

N/A Not Applicable

The air to be monitored from the buildings and facilities is drawn past sample probes located in the exhaust vents, pumped through filters and then returned to the exhausts. The WL maintenance planning team performs the measurements for the stack flows and the RP team measures the Sampler flow. The sampler flows at WL are checked during each sample collection period to ensure that they are within the established acceptance criteria, and are re-measured and verified on an annual basis. The release factors are calculated by the WL Environmental Management staff and verified independently on an annual basis. Activities measured in the laboratory are used in conjunction with sampler and exhaust stack flow rates to calculate the release in Becquerels (Bq). The Lower Limit of Detection (LLD) is the product of the release factor of the source and the laboratory Minimum Detectable Activity. For a given radionuclide, the Minimum Detectable Activity and LLD can vary, as they are calculated assuming a 30-minute count time and average detector efficiency, both of which can change.

Derived Release Limits have been calculated for 74 radionuclides for airborne effluents at WL [30]. Separate DRLs have been calculated for on-site workers and for members of the public at the site boundary. For gross alpha and gross beta activities, the DRL applied is the most restrictive from amongst those of the radionuclides that could be present (Sr-90 for gross beta and Pu-239 and Pu-240 for gross alpha).

Sampling procedures, field operating procedures, laboratory procedures, equipment performance checks, quality verification procedures, and laboratory administrative procedures are described in detail in the governing WL Environmental Management documentation.

9.4.1.2.2 Monitoring Results

The airborne emission results are summarized in Table 23 and Figure 3 for the years 2016 to 2021. Average weekly emissions, in Becquerels, are shown for gross alpha, and gross beta for facilities in Buildings 100, 200, and 300. Emissions from Building 100 also includes tritium. In addition, the current year releases, the average release for the past five years and the maximum weekly emissions as a percent of the DRL are given. Emissions from these identified release points are added for each year to provide an indicator of the performance of the site. The reader should be aware that the values for 2021 in Table 23 represent averages that include detection limit values where nothing has actually been detected. The releases from the Reactor Building include gross beta and tritium values that are always above detection, and gross alpha numbers that are often detection limits. The gross alpha releases from the HCF are normally detection levels and the gross beta are often, but not always detection levels. The gross alpha values from the IFTF are always detection limits and the gross beta are a mixture of detects and non-detects.

Airborne emissions remain a small fraction of the release limit. The result for 2021 (0.00019% of the DRL) is similar to 2020, and slightly lower than the average for the last five years. Total site gross alpha in 2021 is lower than in 2020 and the last five years average. It remains near detection limit values. The gross beta emissions are slightly more than in 2020 and similar to the last five-year average. In 2021, the air emissions from all facilities were below Administrative Levels and regulatory Action Levels. In 2021, Building 200 no longer contributed to air emissions. The average values of the previous five years shows that Building 200 had contributed 16 percent of the total alpha air emissions and 8 percent of the total beta air emissions.

Tritium emissions from the WR-1 stack were higher than in 2020 and slightly less than the five year average. During the Phase 1 Decommissioning of WR-1, all bulk heavy water was removed from WR-1, and an exhaustive process of eliminating heavy water and tritium from the reactor piping and tanks occurred. It was concluded that over the lifetime of WR-1, tritiated heavy water was adsorbed into the pipe and tank walls and probably also into concrete walls and floors. Therefore, the moderator system continues to be purged with air flow in order to remove additional tritium from the system and the tritium removal rates have been measured. The tritium emissions from the facility fluctuate with the humidity and temperature as the tritiated water is drawn out of the system. The maximum releases were all below the administrative level (1.52E+10 Bq/week) for the facility and well below the Action Level (7.62E+10 Bq/week) and DRL (1.65E+15 Bq/week). As many gross alpha and gross beta measurements are at or below the LLD, the yearly variations within these extremely small numbers are of very little consequence.

Localized operational workplace air monitoring is conducted as part of the Radiation Protection Program, and this was performed during operational shutdown and decontamination activities associated with Building 100, and work in the Shielded Facilities and Concrete Canister Storage Facility. Outdoor Workplace Air Sampler monitoring was performed for Building 200 demolition. Environmental airborne dust monitoring was performed close to the east, north,

west and south boundaries of the WL campus during building demolitions. The results of the 2021 dust monitoring are described in the *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28].

9.4.1.3 Liquid Effluent Monitoring

9.4.1.3.1 Monitoring Points, Schedules and Parameters

Figure 2 shows the locations of the sources of liquid effluents to the Winnipeg River, including the Outfall, the Lagoon and the numbered ditches.

The primary source of liquid radioactive effluents is the process water outflow (Outfall), which discharges continuously to the Winnipeg River. The discharge from the Outfall is composed of storm water runoff from paved roadways, around buildings through the weeping tile system, cooling water used in process and experimental facilities, and discharges from the Low Level Liquid Waste treatment systems tanks based in Building 100 and Building 300. The ALWTC was taken out of service in 2017 as part of preparations for the decommissioning of Building 200. Holding tanks collect water containing low levels of radioactivity, as a result of cleanup activities associated with operational and decommissioning work, as well as historical activities at WL. The current monitoring schedule and locations are listed in Table 24.

A/R As Required.
N/A Not Applicable.

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. Specific activities that may have influenced the 2021 liquid releases are similar to those for the past five years, and include cleaning of footwear and respirators. Radiation Protection introduced the use of disposable rubber shoe covers in 2018, which reduced the contribution from the washing of footwear. The water from these cleaning activities is combined with Building 300 sump water into the Building 300 receiver tanks. Sump water from Building 100 is now directed to the Building 100 receiver tanks. The liquids from these holding tanks are discharged to the Winnipeg River through the Outfall.

An automatic sampler continuously samples the outflow from the Outfall, proportional to its rate of flow. A weekly screening sample (4 L), representative of effluent released from the Outfall during the preceding week, is collected and submitted for uranium and gross beta analysis and scanned by gamma spectrometry.

Monthly composite samples (at least 32 L) are gathered for analysis of total uranium, gross alpha, gross beta, tritium, radio strontium and other radionuclides (Am-241, Cs-137) by gamma spectrometry. Starting in 2017, 3 month composite samples were collected for Pu-239/240, Pu-238 and Pu-241 isotopic analyses. Monitoring for Carbon (C-14) and tritium in Outfall samples was initiated in 2020 because they are known to exist in WR-1, and decommissioning activities have a potential for releasing these isotopes. The activities of tritium and C-14 at the Outfall continued to be below the lower limits of detection.

The secondary source of liquid effluent is the Sewage Lagoon (Lagoon). The Lagoon collects sanitary and wastewater from most buildings on the site, as well as from the laundry facility. The minimum residence time for the lagoon is equal to the amount of time the secondary cell is isolated from the primary cell, to allow for biodegradation and settling. This is typically around 45 days. Prior to each planned discharge, the secondary cell is isolated, and tested for a series of non-radiological parameters (discussed in detail later). If these are acceptable, the accumulated contents of the secondary cell only are released to the Winnipeg River via a small drainage ditch leaving the Lagoon’s north side. In 2021, the lagoon was not discharged at all because there was enough freeboard that a discharge was not necessary.

Whenever there is a discharge, the outflow of the Lagoon is continuously sampled during the discharge. The resulting composite sample is analyzed for gross alpha, gross beta, and radio strontium, and it is also scanned by gamma spectrometry.

Small quantities of radionuclides at levels seen at the Ditch 7 and Ditch 8 sampling locations, are also released to the Winnipeg River from the two ditches indicated in Figure 2. Water from the recharge area east of the WMA is diverted around the WMA to the west-flowing Ditch 9 and into the Winnipeg River. The other, Ditch 8, running northward, drains the land north of the WMA up to the site boundary and beyond. The volume of water in the ditches and resulting flow to the river is entirely dependent on rainfall and spring runoff. Precipitation (395 mm) in 2021 was less than in 2020 (441 mm), and in 2019 (646 mm). The winter of 2021 was very dry. The spring precipitation was normal, but the early summer was unusually dry. Normal amounts of precipitation were observed for August, October and November. Due to the low

precipitation, ditches were only sampled six times during March, April, May and June. The August and October precipitation was captured by the dry ground and there was no moving water in the ditches to be sampled any time after June.

One-litre water samples to be analyzed for radioactivity are collected from the two ditches carrying drainage from the WMA whenever there is sufficient flow from runoff to enable sampling of discharge to the river. At the same time, samples were also collected from the northern ditch bordering Highway 211. This is far enough from CNL's operation to be a reasonable background (Control) sample[7]. The samples are analyzed for gross alpha, gross beta, gamma spec and tritium. If the level of the gross beta measurement exceeds 10 Bq/L, the samples are submitted for radio strontium analysis. Uranium activities are calculated from uranium concentrations obtained from total metals analysis. Surface water samples are collected in and around the WL WMA from locations upstream from these two ditches. The results of these operational control samples are reported in Appendix D of this report.

Derived Release Limits for 63 radionuclides were calculated for liquid effluents at WL [30]. Gross alpha and gross beta measurements provide a quick measurement of the total alpha and beta radioactivity produced by a number of radionuclides, without having to test for those radionuclides. However, as in the case of airborne effluents, the most restrictive DRLs apply to gross beta and gross alpha activity: Cs-137 for beta activity and Pu-239 and Pu-240 for alpha activity. With the introduction of total uranium (U) and isotopic plutonium analysis for the processed outfall, a comparison can be made to the individual contributors to the gross alpha activity. Therefore the comparison to the %DRL of the individual isotopes is presented and the sum of those reported. This is also the case for gross beta.

9.4.1.3.2 Monitoring Results

The liquid emission results[8] are summarized in Table 26 and Figure 3 for the years 2016 to 2021. Average monthly emissions, in Becquerels, are shown for gross alpha, gross beta, total U (including U-234, U-235, and U-238), Am-241, Sr-90 and Cs-137 for the releases from the Outfall and the Lagoon. The monitoring of tritium from the Outfall began in 2019. In addition, quarterly activities of Pu-239/240 and Pu-238 were reported for Outfall effluents. A plot of the monthly Cs-137 and Sr 90 releases as Bq from the Outfall in 2021 is compared with radioactivity (Bq) discharged to the Outfall from the Low Level Liquid Waste (LLLW) treatment systems in Figure 4. Discharges to the Outfall from the LLLW treatment tanks occurred in all months. The total releases of Sr-90 and Cs-137 from the tanks in 2021 were 1.13E+06 Bq and 4.01E+06 Bq, respectively. These releases were only a fraction of the total Sr-90 (2.6E+07 Bq) and Cs-137 (1.3E+07 Bq) releases from the Outfall. There was little correlation between the patterns of

7 The Control Ditch sample is collected from a location not influenced by CNL's operation, and therefore serves as an indicator of the natural background conditions in the area.

8 As mentioned in Section 9.2, not all of the radiological results for 2021 have been received from the contract laboratories due to a number of issues, solely impacting the Outfall results for 2021 October through December. Once received, this document will be revised and reissued. The red font text in this section indicates text that will or may need to be updated.

releases from the tanks with the pattern of releases from the Outfall because the tank releases were only a small fraction of the total releases. The additional Sr-90 and Cs-137 activities noted at the Outfall may be from pre-existing contamination in the storm drain system from historical site contamination events and historical radioactivity disposition in the storm drain line from Building 200 LLLW discharges. Some of this contamination may have been from unplanned emissions from the Hot Cells in the 1970's, although more likely from the Building 200 drain line. The high Sr-90 and Cs-137 releases from the Outfall during April, May and August correlate with higher rainfall during these months. The periods of high precipitation are believed to flush contamination into the Outfall from storm drains and previously contaminated process piping.

Note, all monthly releases from the Outfall were well below the administrative release level[9]. Releases of gross alpha were less than the 2020 releases and the five year average. Gross beta releases in 2021 were also less than the 2020 releases and the five year average. Sr-90 releases in 2021 were lower than in 2020 and the five year average. The Cs-137 releases were similar to 2020 releases and below the five year averages. Am-241 releases were greater than 2020 releases. The total uranium releases were slightly lower than in 2020. The relatively constant emissions of gross alpha, gross beta, Sr-90 and Cs-137 from the Outfall over the years suggest a constant source, more like contaminated piping than the effects of recent decommissioning activities. Pu-239/240 and Pu-238 releases were very low, being based on detection level concentrations (% of the DRL less than 0.27). In 2021, Outfall water was also analyzed for the presence of C-14, which could be introduced by the discharge tanks from Building 100. C-14 was below detection levels (varying from 0.99 to 1.26 Bq/L) in Outfall samples. Given that the DRL for C-14 is 1.06E+08 Bq/month, the detection limit of 1.26 Bq/L would correspond to a %DRL value of 0.18. Measurements of C-14 in site intake water from Building 902 were also below detection values.

[9] An Administrative Level is a CNL internal reporting level for radioactive emissions by way of an individual effluent stream. The Administrative Levels are established and maintained by CNL to provide timely warning of above normal radioactive emissions, with the intent of aiding in the application of the ALARA process.

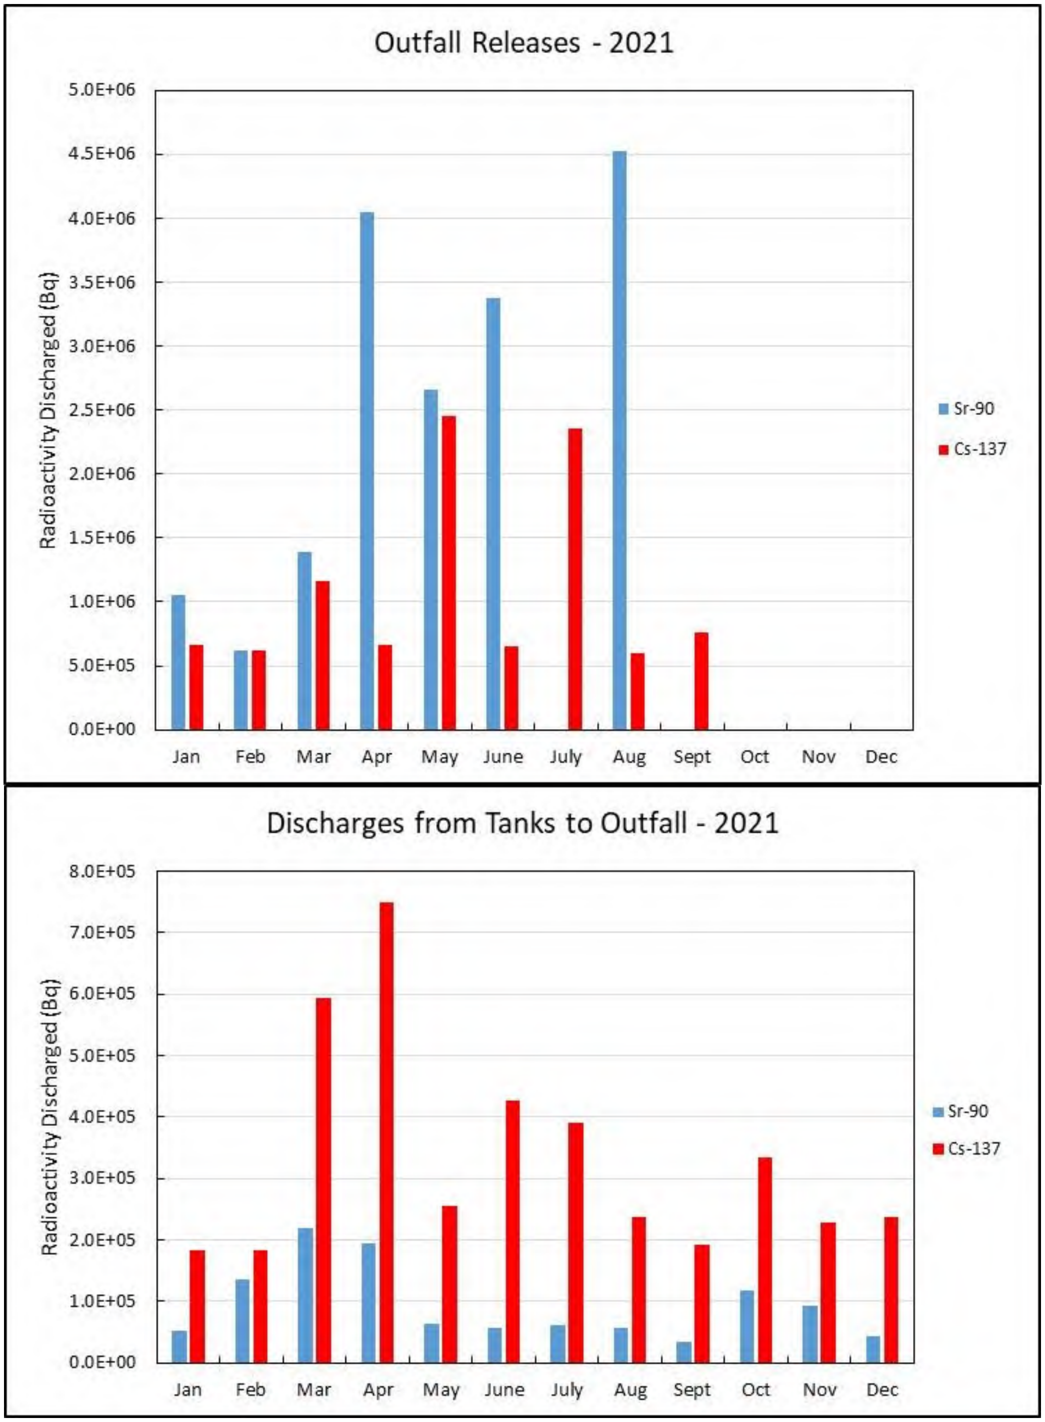

Figure 4: Radioactivity on Outfall Releases and Discharge from Active Liquid Waste Treatment Tanks for 2021

As stated above there were no Lagoon discharges in 2021 and so there are no results to report. In 2021 the lagoons did not contribute to the total liquid discharges from the site.

The averaged results for the two drainage ditches and control sample are shown in Table 25. The reported errors are the standard deviations of parameter values indicating their variability between different sampling events.

a Compliance with Guidelines for Canadian Drinking Water [34] may be inferred if the measurement for the gross alpha and gross beta are less than 0.5 Bq/L and 1.0 Bq/L, respectively. LLD is based on a 1 L sample resulting in less than 100 mg of sample ash and counted for 100 minutes.
b LLD = Lower Limit of Detection.
c Uncertainties are expressed as the standard deviation of the average activity of the processed samples.

During 2021, the gross beta activities in Ditches 8 and 9 were higher than in 2020. The 2021 gross alpha activities were lower in Ditch 8 and slightly higher in Ditch 9 compared to 2020. The average gross beta values were similar to the control sample collected off of Highway 211, given the variability in their values. The gross alpha values were similar to the control ditch. The control sample is unaffected by CNL's operations. Compliance with the *Guidelines for Canadian Drinking Water Quality* [34] may be inferred for gross beta activity since the measurements are all less than 1.0 Bq/L. The gross alpha activity was below the drinking water screening level of 0.5 Bq/L for all samples. The local well waters within the Canadian Shield contain naturally occurring uranium [35] at levels ranging from 0.04 Bq/L to in excess of 2.5 Bq/L. Vertical flow occurs in the surficial Clay unit and in the intermediate Clay Till unit. The head gradient is upward leading the water in these layers to discharge to the surface. Naturally occurring

uranium and its progeny are contributors to the total alpha activity, and could account for levels seen in some of the ditch water samples. In addition, naturally occurring alpha emitters may be present in suspended sediment in some of the samples.

As discussed in Appendix D of this report, the WMA contains a number of trenches with varying amounts of low-level radioactive and conventional waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. The amount measured in drainage Ditch 8 (4.6±0.5 Bq/L) and Ditch 9 (4.7±0.4 Bq/L) were not significantly different from that noted at the control location (4.4±0.9 Bq/L). A number of ditches close to WMA are known to contain tritium. In 2021, the amount of tritium reaching the Ditch 8 and 9 locations was not significant. The tritium activities measured at all three ditch locations are much lower than the Guidelines for Canadian Drinking Water Maximum Acceptable Concentration for tritium (7000 Bq/L) [34].

Table 26 summarizes the data for releases of liquid effluents[10] for the years 2016 to 2021. The average monthly releases, expressed as a percent of the DRLs, are added for the various sources on site to provide a quantitative indicator of the performance of the site. The average total release for 2021 was 0.49% of the DRL, which is lower than 2020 and the five-year average (0.51%). The main reason for the higher 2019, 2020 and 2021 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. The highest monthly release from the Outfall in 2021 was Pu-239/240 at 0.29% of the DRL. There were no lagoon discharges in 2021.

9.4.2 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is determined for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results as a result of equipment failure, maintenance/calibration outages, or operator action requires “unavailability” to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 27) for monitoring equipment on effluent streams with effluent rates that are normally ≥ 0.5% of weekly DRLs are set more stringent (for unplanned unavailability) than for those streams with normal effluent rates < 0.5% of weekly DRLs. Unavailability is expressed in hours of unmonitored effluent releases per year, and applies separately to each monitored parameter, on each effluent stream.

[10] The radioactivity from Ditches 8 and 9 was found to be below the Canadian Drinking Water Screening Level [34] for both gross beta and gross alpha activity, within the uncertainty of the analysis. Tritium levels were well below the Canadian Drinking Water Maximum Acceptable Level. The contributions were considered insignificant due to the small volume of release, and are not included in the liquid release table.

Table 26: Radionuclides in Liquid Effluents from WL – 2016 to 2021

a In 2018 monitoring for Outfall began for U-total, Pu-239/240 and Pu-238. In the Lagoon Pu-239/240 was calculated from gross alpha mass balance. The %DRL is reported for these isotopes instead of gross alpha. Note that Pu isotope activities are detection level values and Am-241 and Cs-137 activities are very close to detection levels.

b Gross beta releases are not included in the %DRL totals as the regulated components of the gross beta (Cs-137 and Sr-90) are already accounted.

Table 27: Effluents Monitoring Equipment Unavailability – 2021

	Unavailability Criteria[a]		Number of Exceedances
Air effluent streams with normal emission rate ≥ 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	84 hours/year/stream	0
Air effluent streams with normal emission rate < 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0
Continuously monitored liquid effluent streams.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0

a See Table 7 in 900-509200-STD-009.

Unavailability criteria (see Table 27) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2021, there were no instances in which the unavailability criteria (Table 27) outlined above were exceeded. In Building 100 there was one instance when the stack pump went down for a long weekend, resulting in 112.5 hours of unplanned loss of air monitoring. In the Shielded Facilities there were three instances of planned loss of monitoring because class III power was shut down for electrical equipment inspections. The total planned loss of monitoring, affecting the Hot Cells and IFTF was 6.5 hours. There were 3 instances of planned unavailability to Outfall monitoring that were due to required electrical power supply shut down to facilitate decommissioning activities, this amounted to a total of 5.2 planned hours of monitoring unavailability for liquids. There was one instance of unplanned Outfall monitoring, amounting to 14 hours, occurred when the motor on the sampling equipment at the outfall monitoring station failed and required replacing. In each instance an estimate of the release during unavailability was calculated as per procedure. In each instance, an estimate of the release during unavailability is calculated per procedure (if the lost time is 5 percent or greater of the total monitoring interval).

9.4.3 Overall Performance

Figure 3 summarizes the data presented in Table 23 and Table 26 on site-wide airborne and liquid emissions, expressed as totals of percentages of DRLs (the lower rows of the tables) for the years 2016 to 2021. The average emissions for the past six years continue to be very small. Liquid emissions of radioactive material from WL in 2021 were below CNL's Administrative Levels and Action Levels, and continue to be very small compared with the applicable DRLs [30]. All air emissions were below CNL's Administrative Levels and Action Levels.

Total radioactive airborne emissions from the WL site during 2021 continue to be very low, averaging 0.00019% of the DRL, which is similar to 2020 and lower than in 2019.

Radioactivity in the WL liquid releases for 2021 was 0.47% of the DRL which is lower than in 2020 (0.67%) and the last five-year average (0.51%). The main reason for the higher 2019 to 2020 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. Pu-239/240, at detection limit values, was the primary contributor to the Outfall, averaging 0.17% of the DRL. The level of tritium activity noted in the two ditches carrying drainage from the WMA remains well below the Maximum Acceptable Concentration for Drinking Water.

The 2021 release results, as well as the previous years' trends, indicate that CNL has taken reasonable precautions to control the release of radioactive nuclear substances within the site, and into the environment, as a result of the licensed activity. All airborne and liquid release results are consistent with the clean-up and operational activities associated with decommissioning of the site.

The results of the monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment.

9.5 Effluent Monitoring – Non-Radiological

This section addresses the licence requirement on hazardous substances monitoring of liquid and airborne effluents for the WL site for 2021. It also fulfills similar effluent monitoring requirements listed under Work Package 1 of the *Environmental Assessment Follow-Up Program* [28].

9.5.1 Liquid Effluent Monitoring

9.5.1.1 Monitoring Points, Schedule, and Parameters

Whiteshell Laboratories staff members collect samples for non-radiological parameters from eight different monitoring points. The first four are the Sewage Lagoon (referred to as the Lagoon) at point of discharge to the Lagoon drainage ditch, the Process Outfall (referred to as the Outfall), the North drainage ditch (referred to as Ditch 8), and the West drainage ditch (referred to as Ditch 9). These effluents flow directly to the Winnipeg River. Two monitoring locations measure internal process wastes leaving the Low-Level Liquid Waste Treatment Systems (LLLWTS) from Building 300 and Building 100. The remaining two monitoring locations are used as background monitoring locations, and are the Intake water taken from the Winnipeg River at the Pump House (Building 902), and a control ditch on provincial Highway 211. More details for each monitoring area are provided in the sections that follow.

Referring to Section 9.4 of this report, Figure 2 shows the locations of the waste stream sources monitored, and where appropriate, their source or release points to the Winnipeg River. Ditch 8 meets the river some distance downstream (north) of the site boundary.

Table 28 lists the non-radiological parameters monitored at the inlet and effluent streams sampled, and the sampling schedule that is followed. The WL monitoring program follows the

protocols from the Ontario Ministry of Environment [36] in its Municipal/Industrial Strategy for Abatement program. Under that system, parameters that are normally measured by the same analytical technique are grouped into numbered Analytical Test Groups. These are described in Table 29, which includes information about the Regulatory Method Detection Limit (RMDL), Laboratory Method Detection Limit (LMDL) and the Smallest Reporting Increment (SRI). The LMDL and SRI were decided following protocol. The WL monitoring program also meets the requirements set out in the Federal Wastewater Systems Effluent Regulations [37], and the standards from CSA N288.5-11, *Effluent Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* [20].

a ATG = Analytical Test Group; BOD = Biochemical Oxygen Demand; CBOD = Carbonaceous Biochemical Oxygen Demand; TSS = Total Suspended Solids.

b The Monthly = grab sample taken once within each month.

Intake water was sampled each month as grab-samples are drawn from the wet well of the Pump House (Building 902).

In 2021, there was no discharging of the Lagoon.

At the Outfall, daily monitoring and weekly samples are collected for non-radiological parameters.

The ditches are sampled only when water is flowing freely within them, and at a maximum frequency of once per week. This occurs after snowmelt or significant rainfall, of which there were six events in 2021.

Whenever a tank was discharged at either of the Low Level Liquid Waste Treatment System's (LLLWTS), the effluent was sampled.

9.5.1.2 Analytical Protocol and Results Evaluation

With minor modification, the protocols for sample collection, and result reporting used here, are adopted from the Ontario Ministry of Environment publication *Protocol for the Sampling and Analysis of Industrial/Municipal Wastewate*r [36]. The protocols are used under Ontario's industry-specific effluent monitoring and limits regulations. The system supplies a justifiable set of methods to ensure that the final reported result is representative of the effluent sampled. Guidance is given on sampling of wastewater streams, sample handling including pre-treatment, and acceptable analytical techniques. Some of these are common to more than one parameter, so they are grouped into Analytical Test Groups, listed in Table 29. Ontario Ministry of Environment protocols were used again this year, as they have been historically. It should be noted that the Manitoba government has no such comprehensive protocols for sample collection, preservation, analyses, and result reporting.

Table 29: Listing of Analytical Test Groups

a The method ICP = Inductively Coupled Plasma Spectrometry. This is a common method for metals analysis.

b The unit MPNU = Most Probable Number Unit, as reported by accredited contract laboratory. The MPNU is a common estimate of bacterial counts, especially for sewage effluent.

c RMDL = Regulation Method Detection Limit

d The LMDL = Laboratory Method Detection Limit (“MDL” also used).

e The SRI = Smallest Reporting Increment.

9.5.1.3 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is found for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results because of equipment failure, maintenance/calibration outages or operator action requiring “unavailability” to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 27) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2021, there were no instances in which the unavailability criteria (Table 27) outlined above were exceeded. There were no instances of non-radiological air monitoring unavailability. There were 3 instances of planned unavailability to Outfall monitoring that were due to required electrical power supply shut down to facilitate decommissioning activities. This amounted to a total of 5.2 planned hours of monitoring unavailability for liquids. One instance of unplanned Outfall monitoring, amounting to 14 hours, occurred when the motor on the sampling equipment at the outfall monitoring station failed and required replacing. In each instance an estimate of the release during unavailability is calculated per procedure (if the lost time is 5 percent or greater of the total monitoring interval).

9.5.1.4 Monitoring Results

In the following sections, there are two types of presentation formats used in reporting the results obtained in 2021. These include an averages summary table and a comparison against the CNL’s Monthly Guideline Acceptance criteria, for the effluent at identified monitoring locations.

9.5.1.4.1 Averages Summary Table

Summarized results for 2021 are presented in Table 30 through Table 34. The first two columns in the tables identify the Ministry of Environment ATG and parameter names [36]. The next three give the CNL monthly guideline concentration, LMDL (Table 29) and units for each measurement. The next six columns provide comparison of the average concentrations reported for the five previous years, followed by their arithmetic mean. The next seven

columns have a summary of the results for the 2021 monitoring period (explained further below).

WL previously discontinued on-site analysis of most of the non-radiological parameters. The samples are now shipped to external ISO 17025 accredited laboratories through a sample management office. The LMDL for the laboratory analyzing the parameter is provided in Table 29.

Within the 2021 results section, the number of samples included in the average ("# Spl.") is reported. This number is not constant down the table. It depends on the sampling frequency chosen for each parameter, and sample mixing to prepare composites for analysis. The next column (labelled "ND's") gives the number of samples in which the analyte was not detected and was therefore deemed a "zero" result.

The minimum, maximum and average values of each parameter are based on individual results and not monthly averages. These results are given in the tables found at the end of the section, and include any results that were zero by virtue of being non-detectable in the laboratory. The relative standard deviation of all results is also reported, expressed as a percentage of the average. This number allows some evaluation of scatter inherent in the samples and measurement method. Usually, sample variability dominates (i.e., the effluent composition changes over time).

In Table 31 through Table 34, yearly average values for parameters marked with an asterisk show that a monthly guideline was exceeded for at least one month during the calendar year being presented.

For convenience, the total annual load to the environment (Winnipeg River) represented by each of the analytes is also presented, expressed in kilograms. The calculation process is described in detail in Section 9.5.1.5 (where the results for the Lagoon and Outfall monitoring points have been collected in Table 36, and compared to the previous five years).

Table 30: Averages Summary for Intake

a All results below the LMDL, originally flagged as "< DL" when reported, are only estimates.
b Averages were calculated by setting to zero results reported as "< DL."
c Monthly Guide is from CNL's limits for non-radiological parameters in liquid effluents procedure. For mercury, the Daily Guideline is given instead, as there is no Monthly Guideline specified
d # Spl. is the number of samples analyzed and reported.
e NDs is the number of samples in which analyte was not detected (i.e., Code = "< DL," result = 0).
f RSTD = Relative Standard Deviation
N/A = not applicable
Notes: Any averages with an asterisk show that a monthly guideline was exceeded in one or more months for the given parameter in the year.

Discharges of effluent coming from the new low level liquid waste treatment systems are being combined, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.2 Monthly Guideline Acceptance

CNL guidelines were used as the basis against which emissions from WL were evaluated. They are not regulatory requirements, but instead have been adopted by CNL to routinely evaluate the environmental significance of both process-type and non-process type discharges from WL. Table 35 supplies a summary of each of the liquid effluent parameters that had exceeded its CNL monthly guideline in 2021 or at any time during the previous five years.

As with the average summary table provided, for each monitoring point, the first two columns in the table identify the Ministry of Environment ATG and parameter names. The next three columns give the CNL monthly guideline concentration, LMDL, and the units of measurement. The next six columns present the monthly guideline acceptance for each of the five previous years and the average of those five years expressed as a percentage. The last three columns show the number of months during which discharges occurred, the number of times the monthly guideline was exceeded for each parameter, and the subsequent percent of times the parameter levels met the acceptance criteria.

To assess any significant level of change and evaluate program performance, this table will be referred to in each section discussing monitoring point results.

Table 35: Parameters that Failed to Conform to CNL Monthly Guidelines

						Monthly Guideline Acceptance (%) for Previous Five Years						Results for Year 2021		
Effluent Stream	**ATG**	**Parameter**	**Monthly Guide**	**LMDL**	**Unit**	**2016**	**2017**	**2018**	**2019**	**2020**	**Average**	**# Mth.**	**> Monthly Guide**	**Accept (%)**
LLLWTS /ALWTC	6	Phosphorus	1.0	0.003	mg/L	100	100	100	83	100	96.6	12	4	67
	8	TSS	25	1.0	mg/L	100	78	92	100	92	92.4	12	0	100
	9	Copper	0.5	0.0005	mg/L	100	67	33	42	58	60.0	12	2	83
	9a	Iron	1.0	0.010	mg/L	67	44	50	83	42	57.2	12	8	33
	9	Zinc	0.5	0.005	mg/L	100	100	100	100	100	100	12	1	92
	14	Phenolics	0.02	0.0010	mg/L	100	100	92	100	100	98.4	12	0	100

Notes:

- Effluent stream parameters which have not exceeded a monthly guideline in the current year or in the previous five years have not been included to this table.
- Discharges of effluent coming from the new low level liquid waste treatment systems are being considered as emanating from the ALWTC, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.3 Monthly Guideline Plots

For parameters that have a value higher than a CNL monthly guideline, the monthly plot of values is shown for that parameter at the monitoring point. This year there were 9 months when one of four parameters (Iron, Copper, Phosphorous and Zinc from the LLLWTS had monthly values higher than CNL monthly guidelines. Figure 5 shows the number of times the monthly guidelines have been exceeded at any monitoring point over the last five years. Plots are displayed in Figure 6, Figure 7, Figure 8 and Figure 9 for each parameter, and the explanations for the observed high values can be found in Section 9.5.1.4.6. The monthly or daily guideline limit for the parameter in question is shown by a broken red line in the corresponding figures.

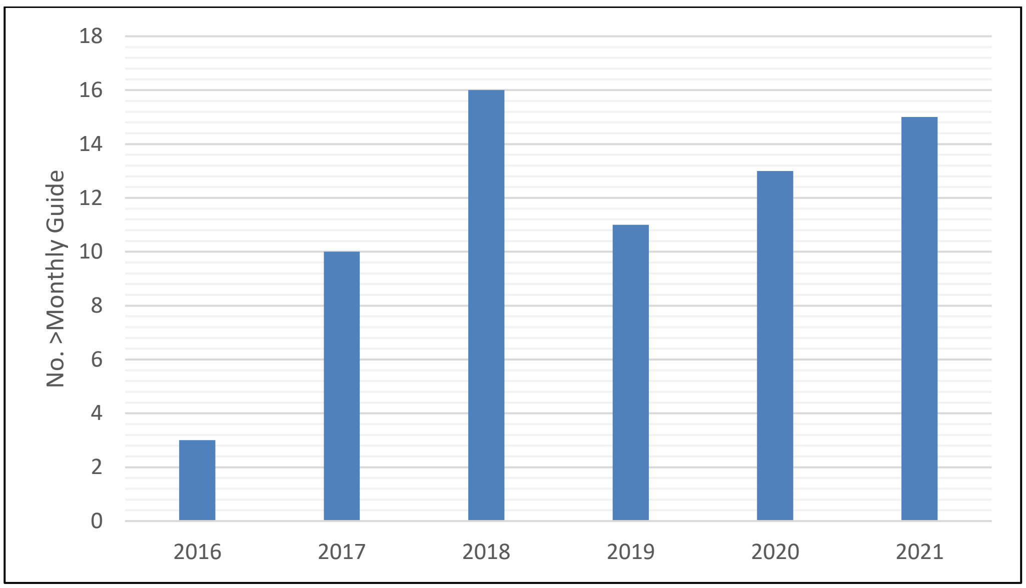

Figure 5: Non-Radiological Monitored Effluent Parameters Above Monthly Guidelines

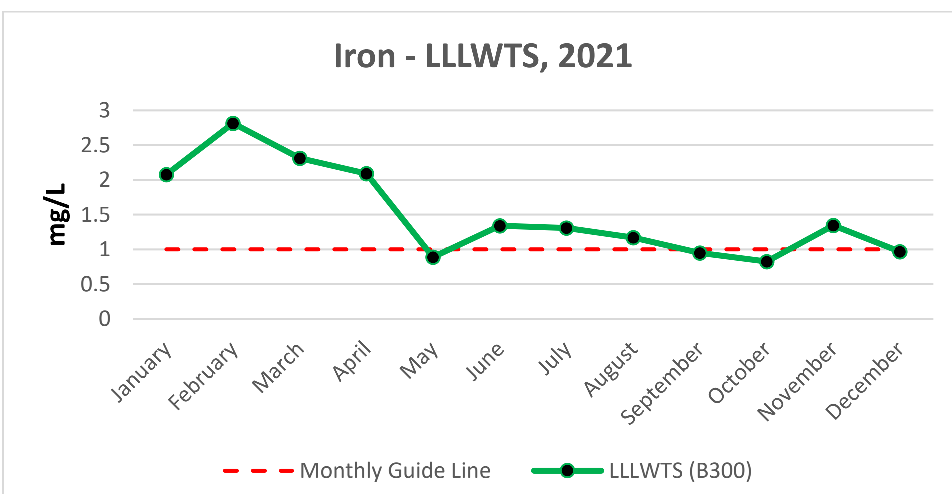

Figure 6: Monthly Average Iron Concentrations of Effluents from the Low-Level Liquid Waste

Treatment System for 2021

9.5.1.4.4 Monitoring of Intake Water from the Winnipeg River

Except for bottled drinking water, all the water needed to run the WL site is drawn from the neighbouring Winnipeg River at the Intake. The amount of water drawn from the Winnipeg River varies from year-to-year.

Grab-samples are collected each month from the Building 902 wet well to assess the levels of certain parameters that may be entering the site directly from the Winnipeg River. The measurements are summarized in Table 30, where they are compared to available data for the previous five years. Figure 10 shows the estimated amount of water used monthly for 2021.

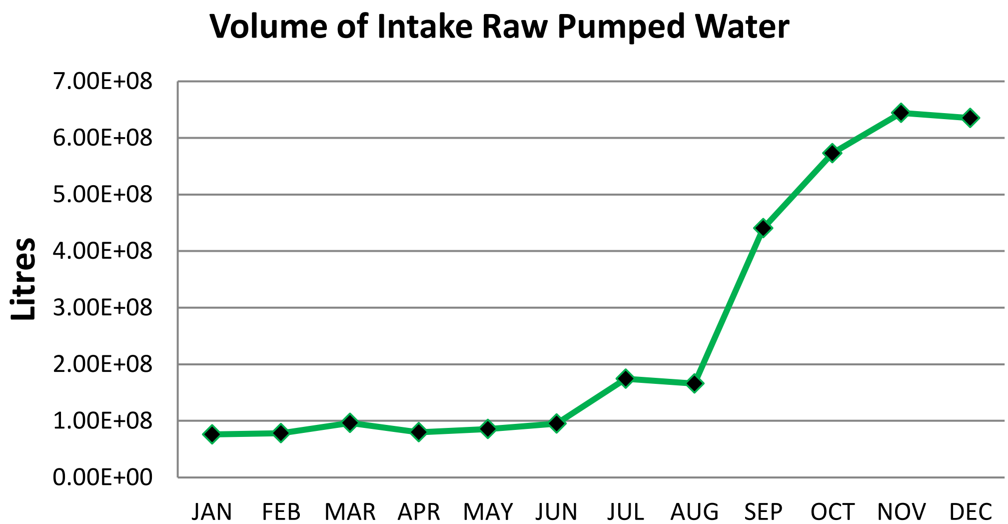

Figure 10: Monthly 2021 Intake Raw Pumped Water for the WL Usage

The following are notable points for the 2021 Intake water from the Winnipeg River:

- The Pump House flow meter recorded that 3.14E+06 m^3 of water was pumped from the river over the year.
- Compared to the five-year average, increased concentrations (> 10%) were seen for Chromium, Copper, Nickel, and Bromodichloromethane.
- Parameters that had their concentrations improve (> 10% decrease) this year compared to the average seen for the last five years are Phosphorus, TSS, Iron, Lead, Mercury, Phenolics, chloroform, and Oil & Grease.
- Water consumption for the site drastically increases during misting operations that are employed during building demolition. As these operation progress into sub-zero temperatures, a further increase is also observed, as a high flow of water is utilized to ensure the water lines do not freeze.

Intake water results can have a significant impact on the environmental performance of the WL site and they will continue to be monitored closely.

9.5.1.4.5 Monitoring of Liquid Effluents to the Winnipeg River

Two effluent streams, the Lagoon and Process Outfall, discharge significant volumes of water to the Winnipeg River. Normal surface land run off also reaches the river through Ditches 8 and 9. Results from monitoring each of these sources are discussed below.

9.5.1.4.5.1 Lagoon

The WL Lagoon secondary cell was not discharged during 2021. With reduced personnel on site due to the COVID-19 pandemic, the occupancy of Building 540 (modular office complex) which

has its bio-waste diverted offsite, and the low level of precipitation observed in 2021, the lagoon had enough freeboard to allow the site to operate into 2022 without discharging.

The total amount of effluent discharged from the Lagoon in 2021 was 0 m^3.

If the lagoon was discharged, the Lagoon would be tested for CBOD, fecal and total coliform bacteria, and acute lethality (a biological assessment on the survivability of trout in the proposed effluent). These samples are collected by the Lagoon operators at defined areas in the secondary cell after isolation of the cell occurs. During discharge, grab-samples would be collected close to the pipe emptying into the receiving ditch that leads to the Winnipeg River. Individual samples for most parameters would be collected on a weekly basis during the discharge.

The vertical scale from which surface height is found was carefully adjusted to read absolute depth from the original floor of the Lagoon. This was done because the equation for calculating the contained volume in the secondary cell for any depth is derived from the calculation for the volume of a rectangular trapezoidal trough:

Volume (in L) = Height x [Width_Bottom x Length_Bottom
+ 0.5(Width-Width_Bottom) Length_Bottom
+ 0.5(Length-Length_Bottom) Width_Bottom
+ (1/3) (Width-Width_Bottom) (Length-Length_Bottom)]

Knowing the dimensions and geometry, the contained volume in the secondary cell can be calculated accurately for any depth using the following equation:

$$\text{Volume (in L)} = 636\,655 * d + 206.886 * d^2 + 0.02133 * d^3 \text{ for depth "d" (in cm)}$$

The position of the Lagoon's water surface would be recorded once or twice daily while emptying. The daily flow would then be calculated from changes in the contained volume. This permits the calculation of volume-weighted concentrations and overall loads (see Section 9.5.1.5). Volume-weighted averages for a given period (month or year) are given by summing the product of the concentration for each day multiplied by the volume released that day, then dividing that sum by the total volume discharged during the period. Unlike other monitoring points (which are continuous or batch releases of fixed volume), the Lagoon discharge flow rate can vary widely. The variation makes weighting corrections highly significant in deciding meaningful average concentrations.

Discharging of the secondary cell is only allowed to proceed after initial testing. Once discharging begins, the pH is checked daily throughout the discharge period.

Table 31 summarizes the results of the fall discharge. Some notable points are:

- There was no effluent discharged from the lagoon in 2021.

9.5.1.4.5.2 Process Outfall

The Outfall monitoring station functioned as expected during 2021. The total discharge volume was 1.15 GL. This volume is lower than the previous five-year average of 1.23 GL.

The Outfall discharges continuously. Measurements were performed on the samples weekly. This provided 52 samples of each parameter for the year.

Table 32 summarizes the results obtained, and compares them to averages for the previous five years. Notable results for the Outfall are:

- There were no instances of CNL's monthly guidelines being exceeded at the Outfall monitoring station.
- The only parameters that had a significant increase (> 10%) compared to the 5-year average were TSS, Copper, Nickel, and Zinc. The increased TSS loads are a reflection of the demolition activities occurring on site, while sediment controls are put in place to mitigate the impact, an increased load of sediments are entering the storm drain system. The increase in nickel and copper concentrations being observed are related to the elevated levels being observed at the intake this year. Zinc is being detected close to the detection limit, a slight increase seen in the concentrations is having a significant percentage increase being measured in the Outfall, especially since the 5-year average concentration is below the method detection limit.
- Compared to the five-year average, Phosphorus, bromodichlormethane, chloroform, Phenolics, and Oil and Grease concentration levels significantly decreased (>10%).
- Quarterly Acute Lethality Testing on the Outfall effluent was not successful in 2021, as CNL missed collecting samples for the second and third quarter of the calendar year. A corrective action plan has been developed to prevent reoccurrence.
- Acute Lethality Testing for the outfall effluent in first and fourth quarter showed no mortality on the rainbow trout tested.

Overall, there were no concerns about the effluent discharged from Outfall during 2021.

9.5.1.4.5.3 Drainage Ditches

Much of the land surrounding key remote facilities at WL is drained by two structures. Ditch 8 drains the land north of the WMA up to the northern site boundary and beyond. Water from the landfill and recharge area on the east is diverted instead around the WMA to the west-flowing Ditch 9, and into the Winnipeg River. These ditches are monitored for radiological and non-radiological content. The radiological part is discussed in Section 9.4 of this report and the non-radiological part is discussed here.

Ditches 8 and 9 were grab-sampled each time water was flowing off-site. This was after heavy rainfalls, of which there were six events from 2021 April to October. At these same times, a sample was collected from the northern ditch bordering Highway 211. This is far enough from CNL operations to be a reasonable background (Control). It was not possible to measure the

flow rates at any of the locations, or to sample representatively over entire rain events; therefore, no loads can be calculated.

Comparison is made to CNL guidelines (although they are intended for process discharges). All values were below CNL monthly guidelines this year. The measurement data are summarized in Table 33. The following are notable points for the 2021 ditches results:

- There were only six sampling events for the ditches. The sample events were also predominately influenced by the spring melt as four of the six events were related to water flows experienced during this period, in other years rain fall events made up the majority of the sampling events.
- Zinc and Mercury were the parameters that had a significantly higher concentration (>10%) than the previous five-year average for Ditch 8. The parameters that had a significantly higher concentration (>10%) than the previous five-year average for Ditch 9 were Phosphorus, Copper, Zinc, and Mercury. The control ditch had TSS and Copper being observed at significantly higher concentrations (>10%) than the previous five-year average.
- Metal concentrations detected are very close to the detection limit, so a slight increase seen in the concentrations has a significant percentage increase being observed in Ditch 8 and Ditch 9.
- The five year average for phosphorus in ditch #9 was higher this year due to the reduced sampling. It is not uncommon for the spring melt to observe elevated phosphorus concentrations due to the decaying vegetation from the fall, but the phosphorus concentrations throughout the summer during rainfall events are typically lower and would drive the average down.
- All concentrations remain well below the CNL’s monthly guideline limit and pose no concern.
- All parameters measured in Ditch 8 and Ditch 9 are comparable to those measured within the Control Ditch, indicating that WL had negligible effects on the environment through these two pathways.

It should be noted that sediment control measures were put in place for projects in the WMA in 2021, as was the case in previous years.

9.5.1.4.6 Internal Liquid Discharge Monitoring

Building 300 and Building 100 both have a LLLWTS; each system represents a major area that generated low-level radioactive liquid wastes. Individual tank releases are monitored for operational control purposes.

A full tank must be emptied while a second tank is being filled. When full, tanks are sampled; if the pH and radioactivity levels meet discharge criteria, they are discharged. The LLLWTS tank pre-discharge criteria do not include all parameters listed in CNL's non radiological guideline limit values; however, the post-discharge analysis includes all these parameters. CNL staff have

determined, through historical data analysis from post-discharge samples, if the pH in the tank is adjusted to neutral, all other parameters will normally meet the guideline limit values. All post-discharge data is reviewed to ensure this process is working as intended, and program requirements are met. All effluents pass through a 5-micron bag filter to the Process Outfall, leading via the Outfall to the Winnipeg River.

The tanks in the new system have a smaller holding capacity so the frequency of discharges has increased. The new system was designed with a shorter life span in mind than the earlier system that was employed by CNL. This was done to align with the decommissioning schedule being implemented by CNL. Discharging requires a day or less to complete, and can be more gradual if needed.

Grab-samples are taken after the filter, and at the beginning of each release from the individual tanks. Measurements are performed on the effluent of each discharge to measure pH and conductivity. For other analytes, grab-samples are collected and analyzed by a designated laboratory to complete the characterization of the effluent being discharged.

In regards to monitoring the non-radiological parameters of the effluent for this reporting period, discharges of the new systems are being compared to the discharges from the ALWTC that was used in previous years. This allows for comparisons of the previous 5-years of effluent to continue to be made, as the effluent streams emanating from the Research and Development (R&D) Complex in Building 300 and Building 100 should still be similar enough that a comparison is worthwhile.

In 2021, 0.09 ML was discharged from the LLLWTS.

The weighted averages of the joint releases from the LLLWTS are presented in Table 34 and monthly plots for the parameters that exceed the monthly guidelines are in Figure 6, Figure 7, Figure 8, and Figure 9.

The following are notable results for 2021:

- None of the monthly exceedances that occurred at the LLLWTS resulted in exceedances being observed at the Outfall monitoring location downstream in the process.
- There were increases (> 10%) in the annual average concentrations of Phosphorus, Chromium, Lead, Nickel, and Oil and Grease, compared to the previous five-year average results.
- The Iron concentration coming from the LLLWTS exceeded the CNL monthly guidelines eight times (January, February, March, April, June, July, August, and November). The overall Iron concentration seen for the year is lower than the previous 5-years. The introduction of the environmental laboratories in Building 300 at the end of 2019 increased the amount of Iron being introduced into the system (through the lab processing soil samples), as a number of the drain lines in the environmental laboratories are being directed to the LLLWTS in the facility. The majority of the effluent being generated by the environmental laboratories does not require the treatment

operations offered by this system, but it is possible it is affecting the effluent stream non-radiological characteristics.

- Early in 2021 (January-March), it was identified that the environmental laboratories and sample management office practises were having a negative impact on the effluent, as acid wash water and the clean out of expired acid-preserved sampling bottles was not properly being neutralized prior to disposal down the drainage system. In Figure 6, the drop in iron concentrations in the LLLWTS effluent can be observed when cleaning practises were improved. The improper disposal of the acidified wash water is being identified as the major cause of the increased metal concentrations being observed in the first four months of the calendar year.
- The Copper concentration coming from the LLLWTS exceeded the CNL monthly guidelines two times in 2021 (February and March). Frequent exceedances are being seen in relation to the new tank systems that were installed in Building 300 as a decision was made to use copper piping in the new system instead of the stainless steel that was used in the old system. As soon as the new tanks were commissioned and used, the copper concentrations of the generated effluent noticeably increased to the guideline limit, but the concentration seen at the Outfall is still well below the monthly guideline limits.
- The Zinc concentration coming from the LLLWTS exceeded the CNL monthly guidelines a single time in February.
- The phosphorus concentration in the Building 300 effluent has effectively doubled, and exceeded the CNL monthly guideline limit four times throughout the calendar year (March, August, September, and November). As this trend did not exceed a monthly administrative level it was not identified until all the data was compiled for the year, and the cause of this increase is currently unknown. The plot of the monthly concentrations for phosphorous appears to be correlated with the increased cleaning frequency (due to muddy work boots) that would be associated with the spring and the fall periods. CNL will begin with reviewing the current selection of cleaning products being utilized in Building 300.

9.5.1.5 Loading Calculations

For the Lagoon, the volume-weighted average concentration of a parameter was calculated as follows:

1. The measured concentration for each day was averaged with that of the next day;
2. The average was multiplied by the estimated volume discharged over the 24-hour period;
3. The products for all days were summed, then;
4. The resulting sum was divided by the total volume released during the period (Spring, Fall or entire year). The load was then given as the product of the calculated volume-weighted average concentration, multiplied by the total volume for the period.

At the Outfall, the total discharge volume for each month was multiplied by the monthly average concentration of the parameter.

Table 36 shows the results from the calculations described above, grouped by parameter and by final outflow source. All mass-related parameters are shown. The table also compares them to previous years, and to the five-year averages.

Note that LLLWTS discharges are not included here, as they are reflected in the Outfall loads, and ditches are also not included as lack of flow data prevents their calculation.

When examining the WL site total loads, notable results are:

- The Lagoon did not contribute to the observed loads in 2021 as it was not discharged.
- TSS, Nickel and Zinc are the parameters that had a load increase greater than 10% when compared to the five-year average.
- Unlike 2020, this increase in overall load for TSS is not tied to a similar increase being observed at the intake and is directly tied to demolition work occurring on site for 2021.
- The increase in the Nickel load is related to the increase in Nickel concentrations being observed in the Intake water being utilized by the site.
- The increase in Zinc is being attributed to the results at the Outfall over the years being detected very close to the detection limit, so a slight increase seen in the concentrations has a significant percentage increase.
- Phosphorus, Chromium, Mercury, Lead, and Oil and Grease had a significant decrease of 10% or more in their loads when compared to the 5-year average.

Table 36: Loading for the Current Year and Previous Five Years

ATG	Parameter	Monitoring Point	Loadings from Previous Five Years (kg) [a]						Results for Year 2021

a Averages were calculated by setting to zero results reported as “< DL.”
b # Spl. is the number of samples analyzed and reported.
c NDs is the number of samples in which analyte was not detected (i.e., Code = “< DL”, result = 0).

9.5.2 Airborne Effluent Monitoring

Airborne emissions from the WL site are compiled on an annual basis for the purpose of reporting under the National Pollutant Release Inventory (NPRI) and the federal Greenhouse Gas (GHG) report. These emissions are also recorded for trending and improvement purposes. Radiological releases are covered in Section 9.4 of this report. Only non-radiological releases to the air will be covered in the following sections.

9.5.2.1 Fuel Use for Building Heating

Historically, the main stationary source for non-radiological emissions to air from the WL site was the Powerhouse which supplied district heating to various buildings on the site (see Figure 2). Starting in 2013, use of, and emissions from Number 2 fuel oil heating operations at the Powerhouse, ceased due to the completion of building conversions to either propane or electrical heating. Subsequently, a substantial increase was seen for cleaner burning propane used on site. Table 37 presents WL heating fuel consumption from 2016 to 2021. Fuel consumption continues to trend downward (see Section 9.7.2 and Figure 11).

Table 37: Fuel Use for Building Heating from WL

		Data for Previous Five Years						Data for 2021
Parameter	**Unit**	**2016**	**2017**	**2018**	**2019**	**2020**	**Average**

a Energy released calculated from consumption at 3.868E-05 TJ/L for Number 2 fuel oil.

b Energy released calculated from consumption at 2.718E-05 TJ/L for propane

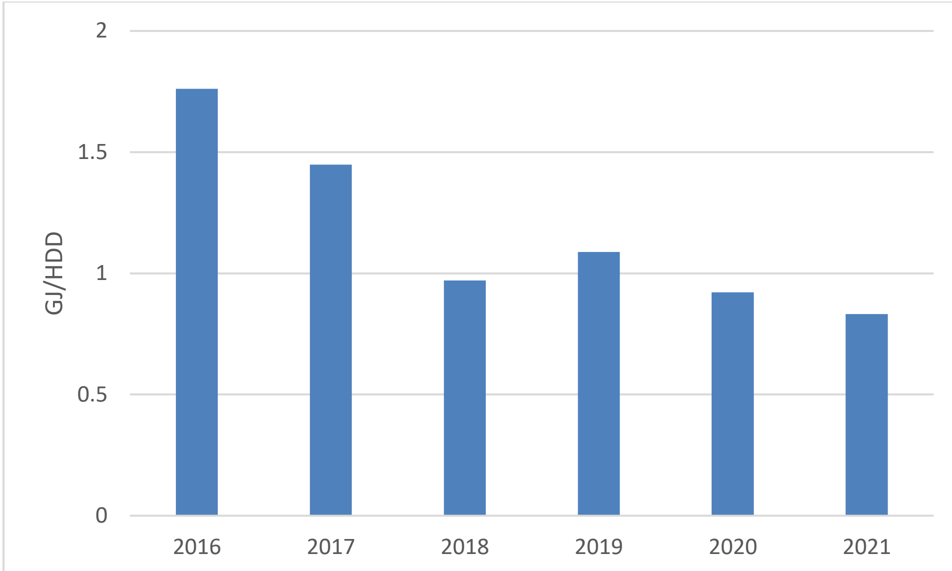

Figure 11: Annual Heating Energy Use from Fossil Fuels (per Heating Degree Days)

9.5.2.2 Reporting Under the National Pollutant Release Inventory

Under the authority of the *Canadian Environmental Protection Act*, 1999 [38], WL currently calculates releases of Part 4 substances for the NPRI program, using government reporting guidelines [39]. These releases to air include emissions caused by burning of Number 2 fuel oil and propane for heating (as discussed above), as well as diesel fuel used from site generators, dust emissions from unpaved roads, and excavation projects.

Emission factors are applied to fuel consumption data, as well as estimated kilometres travelled on unpaved roads, to determine the amount of Criteria Air Contaminants (CACs) that are generated on site. Criteria Air Contaminants consist of carbon monoxide, oxides of nitrogen, sulphur dioxide, total (filterable) particulate matter (PM), and particulate matter below 10 microns (PM_{10}), particulate matter below 2.5 microns ($PM_{2.5}$), and Volatile Organic Compounds. Dust emissions from excavation projects were estimated based on a calculation for total particulate matter generated per excavation day. Dust generated from demolition activities in 2021 will be captured in the *2021 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories* [28].

Table 38 outlines the annual CACs generated from site activities, and shows a small decrease in emissions seen in 2021 compared to the 5-year average for the values for total particulate matter, PM_{10}, and $PM_{2.5}$. The PM_{10} value met the NPRI reporting threshold this year, and is reported to Environment and Climate Change Canada. Road dust emissions were the major contributor to meeting these reporting thresholds.

Table 38: Stationary Combustion Data and Emissions from WL

Parameter	Unit	Data for Previous Five Years						Data for 2021	NPRI Reporting Threshold
		2016	2017	2018	2019	2020	Average		
Airborne Emissions									
NO_x (as NO_2)	Mg	0.908	0.753	0.536	0.621	0.602	0.684	0.331	20
SO_2	Mg	0.023	0.020	0.014	0.016	0.017	0.018	0.005	20
CO	Mg	0.399	0.348	0.233	0.271	0.256	0.301	0.162	20

PM_{10}	Mg	3.853	3.499	3.726	2.712	2.281	3.214	2.091	0.5
$PM_{2.5}$	Mg	0.415	0.376	0.391	0.292	0.249	0.345	0.218	0.3
Volatile Organic Compounds	Mg	0.071	0.059	0.042	0.049	0.048	0.0538	0.026	10

9.5.2.3 Greenhouse Gas Emissions

Under the authority of the *Canadian Environmental Protection Act*, 1999 [38] WL must calculate releases under the GHGs emissions notice [40] providing the facility emits over 10,000 tonnes of carbon dioxide equivalent or more within the calendar-year.

Greenhouse Gas emissions from WL include carbon dioxide, methane, and nitrous oxide. Emissions are primarily from the burning of propane, the use of diesel generators, the on-site transportation fleet, the on-site landfill, and open-pit wood burning. They are measured in CO_2 equivalent tonnes which is a measure used to compare between gases that have different Global Warming Potential (GWP).

Table 39 outlines the GHG emissions from the WL site for the last six years. These emissions from the site have decreased significantly from 2020. This decrease can be attributed to the decrease in propane needed to heat the site in 2021 as shown in Table 37. There was a decrease in the number of heating degree days (i.e., decreased demand for building heat based on temperature) in 2021, this combined with the fact Building 200 did not require any building heating during the calendar year, and Buildings 402 and 305 no longer had to be heated starting in the fall of 2021 due to demolition activities. Overall, greenhouse gases in 2021 are 29% less than the average for the last 5 years.

Table 39: Greenhouse Gas Emissions

Parameter	Releases from Previous Five Years						2021 Releases
	2016	2017	2018	2019	2020	5-yr. Avg.	
GHG CO_2e tonnes	1883	1873	1678	1756	1692	1776	1177

Note: GHG CO2e tonnes - A unit of measure used to compare between gases that have different GWP. For example, the GWP for methane is 25. This means that emissions of one metric ton of methane is equivalent to emissions of 25 metric tons of carbon dioxide.

9.5.2.4 Halocarbons

In the atmosphere, halocarbons contribute both to global warming and to ozone depletion, via separate mechanisms. Losses of halocarbon refrigerants and fire suppressants are reported semi-annually to Environment and Climate Change Canada, following the Federal Halocarbon Regulations [41]. All releases greater than 10 kg are considered reportable.

As seen in Table 40, there were two reportable releases of halocarbons in 2021. Both releases were related to the Building 100 chiller system. The first release occurred in 2021 April. During maintenance activities it was discovered that 15.5 kgs of R-134a refrigerant escaped from the chiller system through a leak of one of the shut off values on the equipment. Upon replacement of the shut off valve it was observed that the threads of the valve were compromised. The second leak occurred in 2021 October. During maintenance activities to take the equipment offline for the season, it was discovered that 16.3 kgs of R-134a refrigerant escaped from the chiller system through a faulty solenoid valve.

Table 40: Halocarbon Losses from WL

			Losses from Previous Five Years (kg)					Losses in 2021	
Type	**Global Warming Potential[b]**	**Ozone Depleting Potential[c]**	**2016**	**2017**	**2018**	**2019**	**2020**	**Number of Losses**	**Annual Loss (kg)**
Refrigerants[a]									
CFC (R-11)	4 600	1	0	0	0	0	0	0	0

a CFC = Chlorofluorocarbons; HCFC = Hydrochlorofluorocarbons; HFC = Hydrofluorocarbons
b GWP per unit mass, compared to CO2 = 1.00
c Ozone Depleting Potential per unit mass, compared to CFC R-11 = 1.00
d The data for the CFC+HCFC(R-502) is from [41]

9.5.3 Overall Performance

The non-radiological effluent monitoring program set up by CNL continues to supply valuable information about the potential impacts of operations on the Winnipeg River, and thus the local environment.

There were no discharges from the Outfall and Lagoon which exceeded the current monthly guideline limits placed on CNL in 2021.

9.6 Regulatory Limit Exceedances and Contamination Incidents

There were no Regulatory Limit exceedances or reportable events in 2021.

9.7 Discussion of Improvement Initiatives

The following sections describe some of the ongoing efforts the WL site is undertaking to enhance the effluent verification monitoring program.

9.7.1 Monitoring Site Intake Water and Outfall Effluent

In 2020, the WL site expanded the monitoring program to encompass additional parameters at the site's Intake and Outfall monitoring station. This expansion resulted from the enhanced monitoring that was performed on the Intake and the Outfall in 2019 to address the gaps in baseline data when assessed against the monitoring criteria in Table 19-1 of the *WL Effluent Verification Monitoring Plan* [25]. It was decided that when there was a 20% change in concentration when comparing the results for a given parameter at the Intake and Outfall, that these parameters would be incorporated in the effluent verification monitoring program.

Under this criteria, Total Organic Carbon, Strontium, Uranium, Magnesium, Potassium, Sodium, and the volatiles Bromodichloromethane, chloroform and Toluene have been added to the list of parameters being measured at these stations. Currently, CNL can show that the source of the Potassium and Sodium being introduced to the Outfall is a result of the sanding/salting activities that occur on site as the weather transitions into and out of sub-zero temperatures. The Bromodichloromethane and chloroform are by-products resulting from the site's chlorination practises. The remaining parameters are currently not tied to a source, and CNL is planning to do temporary upstream process monitoring (monitoring at LLLWTS in Buildings 100 and 300) to try to be able to explain the operational source of the increase.

In order to be compliant with REGDOC-2.9.1 [42] it was determined that the effluent verification monitoring program needed to include acute lethality testing at the Outfall monitoring station.

Although the need to monitor for these parameters is currently captured in *WL Effluent Verification Monitoring Plan* [25], WL laboratories acknowledges that the plan needs to be updated to reflect that these parameters are actively being monitored, and plans to revise Reference [25] in 2022.

9.7.2 Reducing Energy Use from Fossil Fuels

The largest quantity of non-radiological effluents to air comes from burning fossil fuels, to heat the site buildings. Starting in 2013, use of and emissions from Number 2 fuel oil heating operations at the Powerhouse ceased due to the completion of building conversions to either propane or electrical heating.

Figure 11 shows the annual fossil energy consumption since 2016, relative to the number of Heating Degree Days in each year. Heating Degree Days are calculated for each day as the difference between 18°C and the median ambient temperature.

From Figure 11, it is apparent that energy use has started to stabilize and any further reductions will be resulting from final closure of site buildings, reducing or removing their heating supply. Beginning in 2020 October, Building 200 no longer had to be heated as demolition activities on the building began at this time. In 2021 September, Buildings 305 and 402 no longer required to be heated as demolition activities began on these buildings.

9.8 Environmental Assessment Follow-Up and Monitoring

Details about the Environmental Assessment Follow-Up and Monitoring Program are discussed in the *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28] (to be issued to the CNSC by 2022 June 30).

10 Emergency Management and Fire Protection

10.1 Emergency Preparedness Program

Whiteshell Laboratories adheres to the Corporate Emergency Preparedness Functional Support Area. See Section 10.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL program continues to adapt to the changes on site, including the demolition of buildings/assets, the construction of temporary structures, the number and composition of staffing levels, and the organisational structure. Vacated buildings are transitioned from building emergency procedures to construction/demolition oriented emergency placards.

Planning for and responding to COVID-19 continued as a primary focus for the Emergency Preparedness Functional Support Area at WL in 2021, providing procedures and guidance to enable work to continue safely in this dynamic situation. This was safely managed, without an outbreak at WL, despite the pandemic impact on Manitoba.

10.1.1 Drills and Exercises

The ongoing COVID-19 Pandemic continues to make running in-person emergency scenarios a challenge, especially with our external partners. For 2021, drill and exercise development focused on scenarios that allow for adequate physical spacing and still yield quality learning and evaluation potential.

In 2021, a total of 143 exercises and drills were delivered at WL. This is a significant step up from the 94 drills/exercises delivered in 2020. While not quite back to pre-pandemic levels, this increase signifies an adjustment in the program to the new normal of the current environment. Table 41 provides details on the number and type of the exercises and drills conducted in 2021.

Table 41: WL Emergency Preparedness Exercises – 2021

Type of Drill or Exercise	Number Completed in 2021
Fire Drills	2
Site-wide Specialty Drills	106
Table Top Exercises [a]	5
Targeted Communication Exercise	17
Site-wide Communication Exercise	12
Field Exercises (Functional)	1

a Table Tops include specific EOC Skill workshops as well. Each workshop focuses on a unique aspect of the EOC and includes a small practice scenario.

10.1.2 Training

There was no change to the Emergency Operations Centre (EOC) staff structure in 2021. Building emergency teams are being maintained for all occupied structures on site. Fewer occupied structures has resulted in a decrease in the number of team members required.

10.1.3 Status of Emergency Resources and Facilities

Whiteshell Laboratories maintains a physical EOC, and conducts monthly tests of the technical equipment stored for use in that location. Repairs, improvements and updates are requested as required and when identified. All checks were completed in 2021. A cache of emergency food rations is also maintained at WL, which have a five year shelf life. The rations were replaced in 2019. The cache is stored in a secure location and the condition of the cases is checked annually.

10.1.3.1 Emergency Operation Center

As part of WL's EOC framework, there are two teams of EOC staff, and an alternate person for each of the team positions that can be engaged to cover for members of either of the two teams. These two teams operate on a two week on-call rotation. One EOC member retired in 2021 and his trained alternate was able to step straight into this position.

There were no emergency events requiring activation of the EOC in 2021.

10.1.3.2 Mobile Nuclear Laboratory

Canadian Nuclear Laboratories continues to maintain the Mobile Nuclear Laboratory (MNL) for response both on-site and off-site. The unit continues to be maintained by WL Radiation Protection staff and is inspected at a regular interval to maintain control of inventory and equipment.

There were no emergency events requiring the activation of the MNL in 2021.

10.1.3.3 Equipment Checks

Respirators make up the majority of the equipment in the strategically placed emergency cabinets that remain on site. These cabinets are opened and inspected monthly by Radiation Protection staff. Once a satisfactory inspection is complete, the cabinets are re-sealed and signed off by the inspector. All scheduled checks were completed in 2021.

There were no emergency events requiring the use of this equipment in 2021.

10.1.3.4 Public Address System

The Public Address (PA) system is the primary system used for communicating emergency events to WL employees. The system functioned normally in 2021.

10.1.3.5 Secondary Emergency Signals

The WL site still employs an exterior siren as a redundant form of emergency alerting. The system is no longer required and was replaced by the PA system as the primary alerting system. This system will continue to be used as a redundant alerting system until either the equipment fails completely (there have previously been some issues with the equipment) or the building it is mounted to is decommissioned and demolished.

10.1.3.6 EOC Notification System

WL continued to use the Everbridge Mass Notification system in 2021. The system continues to perform well, with a 100% response rate to all monthly communication tests (see Table 42) for the third year in a row.

Table 42: WL EOC Communication Tests: 2021

Y= Yes N= No	January	February	March	April	May	June	July	August	September	October	November	December
EOC Commander	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Liaison Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Env. Protection Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Safety Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Planning Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Logistics Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Operations Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Nuclear Facilities Representative	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

In addition to these regularly scheduled monthly drills, a random quarterly drill is conducted. These drills are scheduled for random times and dates, including weekends, evenings and work hours. These random drills include the expanded EOC teams, including all alternates and non-routine staff. Table 43 identifies the response rates of the 2021 WL EOC Staff to the Quarterly Random EOC call out drills, with an average of 94% response. Only responses received within an hour of the notification being sent out are considered a positive response, the rest are considered ‘no response’.

Table 43: WL EOC Random Quarterly Communication Tests: 2021

	Q1	Q2	Q3	Q4
Response Percentage	96%	100%	88%	92%

10.1.4 External Collaborations

In 2021 contact was maintained with a variety of external emergency response/management organizations and interested public groups. Due to COVID-19 many of these were once again virtual meetings or connections. WL EmP:

- Engaged with the LGD of Pinawa Emergency Operations Centre staff for local response planning purposes.
- Participated in the Manitoba Provincial Flood and Forest Fire forecasting sessions.
- Continued to participate on the Manitoba Municipal Relations Governance COVID-19 teleconference meetings throughout 2021, though with decreasing frequency as the year progressed.
- Maintained working relationships with Manitoba Emergency Measures Organization staff through less formal interactions this year, including regional response officers and the Critical Infrastructure protection program staff.
- Attended the Provincial emergency management conference, which brought many Local, Provincial and Federal stakeholders together to share best practices and lessons learned on a variety of relevant topics.
- Maintained membership with the Prairie Region (Manitoba and Saskatchewan) of the Federal Coordination Working Group. The Federal Coordination Working Group helps WL maintain ties with representatives from multiple federal agencies including (but not limited to) Public Safety Canada, the Royal Canadian Mounted Police (RCMP), Health Canada, Department of Defence, Public Health Agency of Canada, and Environment & Climate Change Canada, in order to support organizational planning and response.

10.1.5 Unplanned Emergency Events

There were no incidents requiring initiation of the WL Site Emergency Plan occurred during 2021.

10.2 Fire Protection Program

Whiteshell Laboratories adheres to the Corporate Fire Protection Functional Support Area. See Section 10.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

There were no reportable fire events at WL in 2021.

10.2.1 Fire Response Drills

In 2021, WL was unable to conduct all the fire drills that it identifies as an annual requirement in accordance with the National Fire Code of Canada [43] and CSA standard N393-13 Fire Protection for Facilities that Process Handle, or Store Nuclear Substances [44]. This deviation has been captured as part of an internal self-assessment and a corrective action plan is being developed to ensure these are adequately planned and executed.

10.2.2 External Collaborations

Whiteshell Laboratories and the Town of Pinawa signed a Fire Protection Service Agreement in 2019 to improve Mutual Aid support capabilities. The agreement is still in effect. Interdepartmental training has been interrupted by the COVID-19 pandemic, but will be resumed as soon as it is safe to do so.

10.2.3 Third Party Audits & Inspections

As per the requirements of CSA N393-13, *Fire Protection for Facilities that Process, Handle, or Store Nuclear Material Substances* [44], a third party Fire Protection Audit was conducted in 2021. The findings are being collated and their resolution will be tracked through the corrective action program (see also Section 1.2.1.1).

10.2.4 Fire Hazard Analysis

All fire hazard analysis documentation for buildings requiring a fire hazard analysis have been reviewed and are being evaluated against the decommissioning schedule. A corrective action plan was developed and submitted to the CNSC outlining the timeline for Fire Hazard Analysis documentation review and revisions.

11 Waste Management

11.1 Waste Management Program

Whiteshell Laboratories adheres to the Corporate Waste Management Functional Support Area. See Section 11.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Waste Management Program continues to provide effective and efficient delivery of Waste Management services.

Significant activities for the Waste Management Program include:

- Continued to refine and communicate the Integrated Waste Strategy to integrate waste lifecycle management across all CNL-operated sites and to capture the CNL baseline waste strategies and defined pathways for all CNL wastes.
- Collaboration between CRL and WL Programs to effectively disposition radioactive wastes, leading to the advancement of remediation and transportation projects.
- Enhanced support to existing activities and new activities in support of the new schedule for the WL Closure Project. The support improved segregation protocols and ensured continued adherence to waste processes.

The waste acceptance criteria for three of the waste receiving facilities on-site (including the Waste Handling Area and the WMA storage facilities) remained unchanged for 2021.

11.1.1 Waste Management Operations

Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects. The packaged solid radioactive wastes were stored in designated storage facilities in the WL WMA depending on the hazard level and packaging, as well as dispositioned to CRL for interim storage.

Demolition of Buildings 402 and 305 began in 2021 and is on target to be complete early 2022. A total of 2,246 m³ clean waste was generated in 2021; 1,290 m³ of concrete material was dispositioned to an off-site receiver for future re-use, 450 m³ of metal was recycled, while 483 m³ of asbestos-containing material and 17 m³ of polychlorinated biphenyl (PCB) contaminated materials were dispositioned to appropriate off-site waste receivers.

Decommissioning on the south area of the WL main campus continued, which involved asbestos abatement and remediation of high temperature water lines, generating approximately 188 m³ of clean concrete waste; 28.5 m³ of this volume contained asbestos-containing materials which was sent to an approved off-site licensed facility.

Building 200 Active Liquid Waste Treatment Centre demolition was completed. A total of 1,077 m³ of Low-Level Waste (LLW) and 77.5 m³ of Intermediate - Level Waste[11] (ILW) waste

[11] In this context, ILW refers to any waste that does not meet the proposed Near Surface Disposal Facility (NSDF) Waste Acceptance Criteria (WAC) and requires storage in ILW facilities at CRL.

was generated; of this LLW total, 876 m³ has been safely dispositioned to CRL, with the remaining 201 m³ and 77.5 m³ of ILW waste safely stored in certified transportation packages awaiting shipment to CRL in 2022.

De-inventorying efforts of legacy waste stored in LLW Bunker 5 began. Wastes are undergoing additional qualification and inspection to ensure transportation and waste criteria compliance are met. This activity has generated 360 m³ of LLW to date, which are safely stored in certified transportation packages awaiting shipment to CRL in 2022.

Table 44 summarizes the quantities of radioactive waste generated in 2021 that was sent to each storage location. Table 45 summarizes the volumes of solid low-level radioactive waste originating from each facility in 2021. Table 46 summarizes the volumes of solid intermediate-level radioactive waste originating from facilities in 2021. Table 47 summarizes the volumes of solid low-level and intermediate-level radioactive waste transported to CRL for disposition.

Table 44: Radioactive Waste by Storage Location

Storage Facility	Volume (m³)	
	2020	2021
Low-Level Quonsets	32.3	0
Intermediate-Level Waste Bunkers	0	2.5
SMAGS[a]	4.1	0
Soil Storage Compound	0	0
Total	36.4	2.5

a Shield Modular Above Ground Storage (note: SMAGS is no longer used for waste storage)

Table 45: Low-Level Radioactive Waste Generated by Facility

Facility of Origin	2020		2021	
	Compactable Waste Volume (m³)	Non-Compactable Waste Volume (m³)	Compactable Waste Volume (m³)	Non-Compactable Waste Volume (m³)
Building 100	0.8	9.2	1.5	0.0
Building 200	7.2	198.9	0.0	875.6
Building 300	0.3	0.0	0.0	0.0
Building 303	0.0	0.0	0.0	0.0
Building 304	0.0	0.0	0.0	0.0

Total	527.7	26.3	921	3.2

a Shielded Modular Above Ground Storage – legacy waste generated from various decommissioning projects.

Clearable waste from Controlled Areas was monitored in-situ. Clean bagged waste was monitored using the bag monitor located in Building 300 where WL's laundry facility is now stationed; all bagged waste met the screening criteria and was deemed to be suitable for unrestricted release in 2021.

Whiteshell Laboratories continued to reuse or recycle as much material as practicable; this includes both recyclable materials sent to the municipal recycling facility and other material-specific facilities throughout Manitoba. Waste Management Program representatives exercised a proactive approach to ensure waste was properly segregated at the source of origin to maximize the amount of material that could be reused or recycled.

Table 48 summarizes the disposition pathway of non-active wastes, while Table 49 summarizes the amount, by material type, of recyclable waste shipped off-site.

Table 48: Non-Active Waste Disposition Pathways

Disposition Location	Volume (m^3)	
	2020	**2021**
WL Asbestos Disposal Site [a]	0	0
WL Burn Pit	247	189
WL Inactive Landfill	0	0
Recycling[b] **Sent Off-Site**	513	271
Off-Site Landfill [c]	1,256	1,352
Total	2,016	1,812

a The WL Asbestos Disposal Site stopped receiving waste in 2019 to support the environmental risk assessment. Non-active asbestos is directed to off-site licensed landfills.

b This recycling waste pertains to office recycling that is generated on a daily basis that is accepted at municipal recycling facilities.

c WL Inactive Landfill stopped receiving waste mid-2019 to support the environmental risk assessment. Non-active waste is directed to off-site licensed landfills.

Table 49: Recycled Waste Shipped Off-Site

Material[a]	Weight (kg)	
	2020	**2021**
Aluminum	0	0
Batteries Shipped	0	0
Batteries Recycled	227	0
Cardboard[b]	0	0

Copper and Brass	0	0
E-Waste Shipped	347	3,464
E-Waste Sold	0	0
Ferrous Metals	108,457	26,231
Glass	0	0
Lumber	0	0
Plastic Shipped	0	0
Plastic Sold	0	0
Stainless Steel	0	0
Lead	0	7,450
Total	109,031	37,145

a This recycling waste pertains to material that is sold or charged to be taken to a material specific recycling facility.

b Cardboard is sent to a municipal recycling facility and inclusive in Table 48.

Improvements were made in preventing waste accumulation inside of buildings and transferring the waste to appropriate waste facilities immediately after generation. Improvements continue to be addressed in reference to the lack of processing and storage space for non-routine waste materials (e.g., mixed waste and large contaminated items), as well as large volumes radioactive wastes generated from decommissioning activities. Mitigation measures put in place in 2021 included finalizing a Nuclear Safety Note for the interim storage of cargo containers containing radioactive wastes in the WMA. This area is referred to as the Recoverable Surface Storage and Staging Area (RSSSA), and consists of an outdoor, above ground storage pad to enable the storage and loading of solid low-level waste in sea land containers and storage of oversize LLW items which are awaiting further processing, characterization and/or packaging to be considered compliant for off-site disposition. Additionally, satellite transshipment areas were established north of the WMA and one by the B200 demolition to reduce additional handling and improve efficiencies with off-site disposition of waste.

11.1.1.1 Liquid Waste Generation

During 2021, 78.9 m^3 of low-level liquid was processed in the Building 300 LLLWTS and 9.9 m^3 in the Building 100 LLLWTS, for a total of 88.8 m^3 of low-level liquid waste processed through the two systems.

11.2 Decommissioning Plan

Whiteshell Laboratories adheres to the Corporate Cleanup Functional Support Area. See Section 11.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

11.2.1 Program Overview, Achievements and Accomplishments

As per the Licence Conditions Handbook for WL [2], CNSC have been notified of revisions to the Detailed Decommissioning Plan (DDP) for WL [45].

11.2.2 Land Use Program

Table 50 provides a summary of the status of the WL Site's Overview DDP.

Table 50: Overview Decommissioning and Cleanup Plan Updates for WL in 2021

Document Reference	Key Activity Status in Year	Effective Date (if applicable)
WLDP-02000-DDP-001	Approved by Regulator	December, 2021

The Overview DDP was revised, submitted to the CNSC, and approved for use in 2021.

11.2.3 Decommissioning and Demolition Program

Table 51 lists the WL DDPs and their status as of 2021.

Table 51: Overview of WL Detailed Decommissioning Plans

Facility	DDP Document Title	Document #	Status
Shielded Facilities	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 2 - Shielded Facilities	WLDP-21400-DDP-001, Revision 1, 2016	Facility is operational and decommissioning activities ongoing. DDP Volume is available for use.
Van de Graaff Accelerator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 3 - Van de Graaff Accelerator	RC-2143-3, Revision 1, 2000	Facility has been decommissioned.

11.2.3.1 Detailed Decommissioning Planning and Execution

Table 52 provides a summary of WL facility DDPs that were revised in 2021.

Table 52: Summary of WL Detailed Decommissioning Plans in 2021

Facility	Document Status	Document Name and Reference	Effective Date	Document Highlights
WMA	Current Published	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 8 - WMA: Part 3 - Low Level Waste Liabilities, WLDP-24400-DDP-001, Revision 5	April, 2021	DDP was submitted to and accepted by CNSC staff.

Table 53 provides a summary of decommissioning and demolition statuses for WL in 2021.

Table 53: Summary of WL Decommissioning and Demolition Status by Facility in 2021

Facility	Decommissioning and Demolition Status
B402	Active Decommissioning
B200	Building Demolished
B413	Active Decommissioning
B420	Active Decommissioning
B426	Active Decommissioning
B429	Active Decommissioning
WMA	Active Decommissioning
Site Affected Lands and Contaminated Structures	Active Decommissioning

Several buildings and structures were decommissioned in 2021, where operational wastes were dispositioned, building services isolated and industrial hazardous materials removed prior to demolition where feasible.

Demolition of Buildings 402 and 305 began, and is expected to be completed early 2022. The demolition of the buildings included remediation and abatement of asbestos-containing materials, specifically the mastic tar adhered between the masonry and exterior wall, and PCB's found within window glazing and exterior caulking and general demolition of construction and demolition materials.

Remediation of the south-side of the main campus continued. Phase one field work was completed, which consisted of remediating the high temperature water lines. Phase two field work to excavate and remove underground electrical bus ducts, isolate fire water, domestic water, storm drains and sanitary drain systems will commence in 2022. The exterior of Buildings 413, 420, 426 and 429 were radiologically surveyed for clearance, with interior portions to be completed in 2022.

Building 200 was successfully demolished, which involved the above and below grade structure, while the building footprint was backfilled. Remediation of this footprint was strategically adjusted to align with future remediation of the surrounding lands known to be contaminated from historical spills associated with the building. This will ensure remediation of the known contamination is completed in one phase, avoiding the potential of creating additional volumes of waste that may be generated from migration of contaminants within the soil.

Legacy wastes stored in the LLW Quonsets (Building 431, 432 and 433) and LLW Bunker 5 began to be retrieved in 2021. Wastes are undergoing visual examination, destructive and non-destructive characterization, and packaging to ensure transportation and waste criteria compliance are met, before waste can be dispositioned to CRL. This work is scheduled to be complete in 2022.

Decommissioning progress is also discussed in the facility sections (Appendix A through Appendix G).

11.2.3.2 End State Reporting

Table 54 provides a summary of end-state reports completed for WL in 2021.

Table 54: Summary of WL Decommissioning and Demolition End-State Reports in 2021

Facility	Document Type	Document Status	Document Name and Reference	Submission Date (if applicable)
Building 514 (WMA)	End State Report	Submitted to CNSC	Decommissioning and Demolition of Organic Coolant Incinerator Complex (B514), WLDP-24400-ESDR-001, Revision 1	July, 2021

12 Security

12.1 Security Program

Whiteshell Laboratories adheres to the Corporate Security Functional Support Area. See Section 12 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Whiteshell Site Security Report [46] outlines the security arrangements that are in place at the WL site. The Security Functional Support Area consists of processes, procedures, and staff to manage the continuous operation and response to security incidents; the Security Functional Support Area and procedures are reviewed and updated as required to address operational requirements.

Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers stated in REGDOC-2.2.4, *Fitness for Duty, Volume III Nuclear Security Officer Medical, Physical and Psychological Fitness* [47].

Hours of Work Exceedances

As per REGDOC-2.2.4, *Fitness for Duty: Managing Worker Fatigue* [47] Sections 4.2 and 4.3, CNL has recorded all exceedances of hours of work for Security's safety-sensitive positions. See Table 55 below for a list of exceedances for 2021. NOTE: COVID pandemic had a direct contribution to Table 55 in order to ensure minimum shift complement.

Table 55: Hours of Work Exceedances for Nuclear Security Officers and Tiered Response Force Personnel at WL in 2021.

A CNSC Type II Security Compliance Inspection was carried out - see Section 1.2.2. A corrective action plan was submitted to the CNSC to address findings.

CNL-WL received notification from the CNSC on the closure of one (1) enforcement item, Directive WL-SEC-19-T2-001-D01 – Training. The Directive closure was granted as CNL-WL completed all actions required to address the enforcement items listed in the Directive.

12.1.1 Security Events

In 2021, there were no security events that affected the Whiteshell Laboratories.

13 Safeguards and Non-Proliferation

13.1 Safeguards Program

Whiteshell Laboratories adheres to the Corporate Nuclear Materials and Safeguards Management (NM&SM) Functional Support Area. See Section 13 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

13.1.1 IAEA Activities

The IAEA conducted various types of activities as part of the safeguards approach for CNL, including, but not limited to, IAEA safeguards seals changes, human surveillance, implementation and/or maintenance of IAEA safeguards monitoring equipment, and technical visits. A list of IAEA inspections conducted at all CNL sites can be found in Section 1.2, Management System of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In 2021 May-June, 14 of 16 WL concrete canisters were re-welded, during which the IAEA provided oversight. The IAEA also verified and changed the IAEA seals attached to the canisters to maintain continuity of knowledge. Minor difficulty was encountered during resealing of one canister and the IAEA inspector decided to employ an alternate sealing arrangement. In 2021 September, the other two canisters were re-welded, during which IAEA provided oversight, including resealing the one canister into the original configuration as it was operationally preferable.

A Physical Inventory Verification (PIV) inspection was completed by an attending IAEA inspector on 2021 May 25. This inspection was a sampling of accessible items containing Special Fissionable Material.

The IAEA also completed a Design Information Verification (DIV) inspection on 2021 May 25 - 27. The activities associated with the DIV included:

- Verification of the Design Information Questionnaire:
- Verification of the site and general building design;
- Verification of containment integrity; and
- Verification of operational status of the facility.

14 Packaging and Transport

14.1 Packaging and Transport Program

Whiteshell Laboratories adheres to the Corporate Transportation of Dangerous Goods (TDG) Functional Support Area, which includes the requirements of the Packaging and Transport SCA. See Section 14 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Packaging and Transport SCA covers the safe packaging and transport of nuclear substances and radiation devices. The TDG Functional Support Area applies to any activities involving the transportation of dangerous goods to or from CNL sites. The TDG Functional Support Area provides an operational framework for the safe off-site transport of dangerous goods by conforming to all applicable laws and regulations, as well as company policies and procedures.

The Waste Certification & Transportation branch is a centralized organizational department responsible for planning, coordinating and executing radioactive waste shipments from the WL site to the off-site disposal or storage facilities in a safe and compliant manner, including having fully trained Radioactive Material Shippers as authorized under the CNL TDG Functional Support Area.

Significant activities in 2021 included:

- Transportation of 921 m^3 of low-level waste and 3.2 m^3 intermediate-level waste sent off-site and safely delivered to CRL;
- Throughout 2021, additional technical assessments and studies on the WL used fuel inventory were completed in support of the licensing application of the Used Fuel Transportation Package (UFTP). These assessments were focused on the WL mixed fuel types (i.e., enriched and experimental fuel types, including Uranium Carbide and Uranium Metal fuel types) and the physical operation of the UFTP. The UFTP, which is owned by the Nuclear Waste Management Organization, has been leased with the intention that the UFTP will be the Type B Transportation Package for high-level waste transportation operations starting in 2022 (due to the COVID-19 Pandemic, these transportation operations were delayed and subsequently pushed out from 2020). There is a two-step licensing strategy for the UFTP, with the first phase focusing on licensing the UFTP for non-enriched CANDU fuels and the second phase focusing on WL's inventory of mixed fuel types. The phase UFTP Safety Analysis Report (SAR) Addendum was submitted to the CNSC in 2019 May, with updates provided throughout 2020, and acceptance is anticipated in early 2022. The UFTP SAR for Mixed Fuel Types (representing phase two) will be submitted in 2022, following the CNSC's acceptance of the phase 1 SAR addendum. Additional accomplishments throughout 2021 include the revision and acceptance of the revised UFTP pre-shipment leak tests, the progression of detailed planning and operational readiness deliverables, and the completion of field trials with the UFTP, Shielded Interface Module (SIM) and Fuel Transfer Flask.

- Award of the subcontract to Nuclear Assurance Corporation (NAC) to design and fabricate Type B casks, cask handling equipment and on-site services needed to support ILW transport to CRL was completed. Two versions of the OPTImal Modular Universal Shipping (OPTIMUS) casks, the OPTIMUS-H and OPTIMUS-L were accepted for use after their licence review and received. Personnel from WL and CRL participated in a week long training session, qualifying them on the use, loading and transport of the casks.
- Extensive training was conducted to site personnel responsible for the handling and packaging of radioactive waste materials, which included Class 7 RAM Material – Handler Training, as well as Waste Management and Packaging Fundamental Training, which was developed to capture the requirements to compliantly process, load, and handle waste materials into certified transport packages, as well as the various waste receivers' waste acceptance criteria.

14.1.1 Shipments

At WL, 68 radioactive transport packages making up 53 loads were safely and successfully sent off-site in 2021. One reportable event occurred in 2021 (see ImpAct ERM-21-1036 in Table 5) where a consignment of waste material was misclassified in accordance with the Packaging and Transport of Nuclear Substances Regulations [48] and IAEA Safe Transport of Radioactive Material [49], due to an incomplete inventory of the package's contents. Several corrective and remedial actions were completed to address the event.

15 Other Matters of Regulatory Interest

15.1 Public Information and Disclosure Program

Whiteshell Laboratories adheres to the Corporate Public Information Program. See Section 15 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Public Information Program document [50] is intended to cover communication activities that occur within CNL's immediate neighbouring communities. This document was prepared in accordance with CNSC regulatory document REGDOC-3.2.1, *Public Information and Disclosure* [51].

15.1.1 Outreach and Stakeholder Engagement

WL shares information with the public through a number of activities including conducting public information sessions, media releases, the corporate website, a toll-free line, social media accounts and involvement in community events. As employees are CNL's greatest ambassadors, they are kept informed of developments so that they can also share information with their relatives, friends, and neighbours.

CNL engaged with the public on WL using a number of tactics. During the COVID-19 pandemic, engagement followed public health and corporate guidelines and was primarily virtual. Table 56 presents public engagements from 2021.

Table 56: Public Engagements for Whiteshell Laboratories

Date	Location	Activity

April 20, 2021	Webinar	WL Closure Project: Environmental Protection
May 18, 2021	Webinar	WR-1 Reactor Decommissioning Fact or Fiction Webinar
September 21, 2021	Webinar	WL Closure Project: Project update
November 16, 2021	Webinar	WL Closure Project: Environmental Protection
November 24, 2021	Winnipeg, MB	Emerging issues conference 2021: The net-zero future investing in sustainability

15.1.2 Public Consultation

CNL actively works to engage local stakeholders on matters related to WL activities. In 2021, a number of methods were deployed to gain feedback from and create discussion with interested parties including: breakfast sessions, social media, and feedback forms available online and at external events, and responses provided to inquiries. CNL strives to create open and transparent communication with all identified stakeholders, and to address concerns and respond to all inquiries.

Throughout 2021, CNL received 21 community inquiries related to WL (Table 57), largely through the WR-1 Breakfast Session/Webinar series.

Table 57: Whiteshell Laboratories Closure Project Public Inquiries

Nature of Enquiry	Number
Transportation	3
Environmental protection	7
Whiteshell Laboratories Closure Project	11

15.1.3 Traditional and Online Communications

15.1.3.1 Website

CNL's Whiteshell Decommissioning web page had 1,667 page views in 2021.

To support the Whiteshell projects and site, CNL has used social media to promote events, share and receive information, and generally engage with the public. As Table 58, Table 59 and Table 60 show that social media has been an effective tool to reach and engage stakeholders. Table 61 shows that CNL also shared information through a community information bulletin.

Definitions:

Engagements - Measures how much and how often others interact with you and your content in social media.

Shares or retweets - Measures how often the message was shared or forwarded on the twitter website.

Table 58: Facebook Metrics for WL-related Posts*

15.1.3.2 Newsletters

CONTACT is CNL's external, bilingual newsletter. It is distributed to community stakeholders, businesses and approximately 8,000 homes in the region surrounding WL, and is available on www.cnl.ca. This publication informs the reader on activities undertaken at CNL's Whiteshell Laboratories and profiles CNL's community activities. Two issues of *CONTACT* were distributed in 2021 and included the following topics:

- WL Closure Project and WR-1 updates
- Highlights of public and Indigenous engagement activities
- CNL initiatives in the community, demonstrating commitment to economic generation, sponsorship, donations and participation in community events
- CNL's COVID-19 response
- Employee transition
- Environmental stewardship, including steps CNL has taken to reduce greenhouse gas emissions, protect wildlife and minimize waste.

15.1.3.3 Media Releases

During 2021, there were seven articles written by media on the Whiteshell Closure Project (see Table 62).

Table 62: Media Coverage for 2021

Date	Article	Title of Publication
January 2021	Canada's Radioactive Waste Policy Review	LGD of Pinawa Municipal Quarterly Newsletter

July 15, 2021	Pinawa erosion responsibility in question	The Clipper
September 2, 2021	CNEA continues funding North Forge East with three-year deal	The Clipper

15.1.4 Ongoing Projects

15.1.4.1 WR-1 In-Situ Decommissioning Environmental Assessment

The proposed WR-1 in situ decommissioning project (also referred to as in situ disposal) is a key part of CNL's overall integrated approach to safely manage and reduce Canada's legacy liabilities. The Environmental Assessment (EA) process for the project includes a requirement that WR-1 project information be made available to neighbouring communities, Indigenous communities and organizations, and stakeholder groups through a variety of mechanisms to ensure accessibility of fact-based information. Engagement activities conducted in support of this requirement included social media and website content, presentations, meetings, site tours and fulfilling stakeholder requests for information.

Project-specific webpages and content were produced for the WR-1 Project and included: fact sheets, info-graphics, downloadable posters, project descriptions and quick reference material. All information is available in both official languages at www.cnl.ca/wr-1.

15.2 Indigenous Engagement

CNL follows CNSC REGDOC-3.2.2 *Indigenous Engagement* [52] which sets out requirements and guidance for licensees on Indigenous engagement. CNL recognizes and values ongoing engagement with Indigenous communities and organizations in the spirit of truth and reconciliation.

15.2.1 Engagement Objectives

As part of its corporate, environmental, and social responsibility, CNL recognizes and encourages the ongoing engagement of the First Nations and the Red River Métis (represented by the Manitoba Métis Federation) through the course of the environmental assessment process for the WR-1 Project and engagement on the overall site closure project. Through information-sharing and engagement activities, CNL seeks to build awareness and learn about interests and concerns in an effort to strengthen mutual understanding and pursue

opportunities for collaboration and long-term relationships. CNL engages with First Nations and Red River Métis leadership, representatives and members on the potential effects of the WR-1 Project and the Whiteshell Laboratories Closure Project (WLCP) on the environment and on Indigenous and/or treaty rights including rights to trap, hunt, fish, gather and conduct cultural ceremonies.

CNL has five overarching Indigenous engagement goals:

- **Build awareness and mutual understanding** by supporting and facilitating opportunities for mutual learning on topics including current and traditional use, values and perspectives on nuclear decommissioning, environmental remediation and radioactive waste management, in order to demonstrate CNL's long-term commitment and approach to safe and responsible management of radioactive waste and decommissioning liabilities (e.g., through site monitoring activities).
- **Share information on the project**, including the potential effects on the environment. This includes developing meaningful, user-friendly information and communication products for the First Nations and the Red River Métis, and providing accessible and current information on project activities.
- **Seek input and feedback from the First Nations and the Red River Métis** on project-related activities, and traditional and current uses of the land surrounding the WR-1 project site. Initiate early and meaningful two-way communication between CNL and the First Nations and the Red River Métis to determine the best methods for sharing information and to provide opportunities for Indigenous Peoples to give input on project considerations including design, the EA process, and assessment of impacts.
- **Develop long-lasting relationships with the First Nations and the Red River Métis** to support their continued involvement in the project, community healing and reconciliation. This will extend beyond the scope of the EA process for WR-1.
- **Meet or where possible exceed all regulatory-based communication and engagement requirements** and facilitate engagement that reflects current memorandums of understanding and contribution agreements, and that takes into account the interests, needs and schedule of each Indigenous Nation.

15.2.2 Identified Indigenous Communities

CNL developed a list of the First Nations and the Red River Métis with a potential interest in the WR-1 Project and the WLCP. The identification of the First Nations and the Red River Métis was based on consultation with the CNSC, through CNL's previous Indigenous engagements, and through the use of publicly available sources of information including:

- First Nation and the Red River Métis and organization websites;
- The Aboriginal and Treaty Rights Information System (ATRIS; Government of Canada and INAC 2016); and
- Crown-Indigenous Relations and Northern Affairs Canada First Nation community profiles.

The list was based on the identified potential or established Indigenous or treaty rights of the First Nations and the Red River Métis and is provided in Table 63 with a brief rationale for inclusion. The inclusion of specific Nations considers the nature of the established and/or claimed rights and potential effects on those rights caused by the proposed project, based on a preliminary assessment of existing and available information. As such, the working list is subject to change based on information and dialogue with the identified First Nations, the Red River Métis, and Indigenous organizations.

Table 63: Identified Indigenous Communities

First Nations, the Red River Métis or Organizations	Identification Rationale
Sagkeeng First Nation (Treaty No. 1 and 3)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy one reserve located 52 kilometres (km) north of the WL site, and downstream along the Winnipeg River. Existing relationship and interest in the Whiteshell Laboratories site.
Brokenhead Ojibway Nation (Treaty No. 1)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy three reserves: 44 km northwest, 55 km northwest and 73 km southwest of the Whiteshell Laboratories site respectively. Interest expressed comments on Project Description.
Manitoba Métis Federation (MMF)	The MMF is the official democratic and self-governing political representative for the Métis Nation's Manitoba Métis Community. The MMF is considered the government of the Red River Métis. Potential asserted and/or established Métis harvesting rights in the vicinity of the Project. Interest expressed comments on Project Description.
Black River First Nation (Treaty No. 5)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy one reserve 75 km north of the Whiteshell Laboratories site.
Hollow Water First Nation (Treaty No. 5)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Occupy one reserve, 113 km north of the Whiteshell Laboratories site.
Shoal Lake No. 40 (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy three reserves: 94 km southeast, 110 km southeast and 140 km southeast of the Whiteshell Laboratories site, respectively.
Iskatewizaagegan No. 39 Independent First Nation (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site.

First Nations, the Red River Métis or Organizations	Identification Rationale
	Occupy four reserves: 93 km southeast, 102 km southeast, 110 km southeast and 140 km southeast of the Whiteshell Laboratories site, respectively.
Northwest Angle No. 33 (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy three reserves: 111 km southeast, 140 km southeast and 176 km southeast of the Whiteshell Laboratories site, respectively.
Wabaseemoong Independent Nations (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy four reserves: 80 km east, 85 km east, 95 km east and 140 km southeast of the Whiteshell Laboratories site, respectively.
Grand Council of Treaty 3	Umbrella treaty organization which represents 28 First Nations and 5 with potential interest in the Project. Treaty 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site.
Chiefs of Ontario	First Nations umbrella organization that represents 133 First Nations and 4 with potential interest in the Project

15.2.3 Summary of Engagement

Table 64 lists CNL's Indigenous engagement activities related to the WLCP from 2021. Further details on Indigenous engagements are available in the Indigenous Engagement Report [53].

Table 64: CNL Indigenous Engagement Activities for 2021

Date	Event	Location
Sagkeeng First Nation (SFN)		
January 5	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
February 18	Discussion on the application of Free Prior and Informed Consent on the WR-1 Project	Teleconference
March 9	Discussion with Chief and Council on engagement with Sagkeeng's members	Teleconference
April 6	Leadership discussion on Sagkeeng's Psychosocial Impact Assessment Report	Teleconference
April 15	Site Tour with Sagkeeng's Liaison Officer	On-Site Visit
June 16	CNL, AECL, and Sagkeeng participated in first Technical Working Group meeting	Teleconference
June 17	Sagkeeng's Liaison Officer visits the site to record video for National Indigenous Peoples Day	On-Site Visit
July 14	Sagkeeng's Liaison Officer participated in a bat survey on site	On-Site Visit
July 19	CNL, AECL, and Sagkeeng participated in second Technical Working Group meeting	Teleconference
August 11	Sagkeeng's Liaison Officer participated in a site tour	On-Site Visit
August 12	Sagkeeng's participated in the preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 17	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
August 24	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
September 7	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
September 14	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
September 22	Sagkeeng's Liaison Officer participated in Trauma-informed Engagement Training with CNL, AECL, and the CNSC	In-person, Winnipeg
September 28	Sagkeeng's participated in the second preliminary discussion of the Indigenous Advisory Committee	In-person, Winnipeg
November 10	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
November 15	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
December 15	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
Manitoba Metis Federation		
January 6	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
February 8	Technical Workshop on WR-1 Groundwater Monitoring	Teleconference
February 18	Environmental Monitoring and MMF Green Initiatives Discussion	Teleconference

Date	Event	Location
March 2	Technical Workshop on Alternative Means Assessment and VC Components	Teleconference
March 9	Discussion on developing a relationship agreement	Teleconference
March 17	Overview presentation on the site's Environmental Protection Program	Teleconference
May 11	Wrap-up Meeting for Technical Workshops	Teleconference
May 25	Discussion on participation in site field monitoring	Teleconference
June 2	Discussion on WR-1 draft commitments and relationship agreement	Teleconference
June 3	Update on Whiteshell Laboratories Closure Project	Teleconference
June 14	MMF participated in groundwater monitoring, a songbird survey, and a turtle search at the site	On-Site Visit
June 18	Discussion on developing a relationship agreement	Teleconference
June 22	MMF participated in a bat survey on site	On-Site Visit
June 23	MMF participated in the a second bat survey on site	On-Site Visit
July 14	MMF participated in the a third bat survey on site	On-Site Visit
August 12	MMF participated in the preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 13	MMF hosted a leadership discussion with CNL's President and AECL's	In-person, Winnipeg
August 16	MMF observed river sediment, soil, and vegetation sampling	On-site Visit
August 19	MMF, CNL, and the CNSC participated in a trilateral meeting	Teleconference
August 19	Discussion on collaborating on a green initiative	Teleconference
September 8	MMF participated in Mushroom collection at site	On-Site Visit
September 21	Discussion on developing a relationship agreement	Teleconference
September 28	MMF participated in a second preliminary discussion on developing the Indigenous Advisory Committee	In-person, Winnipeg
October 20	Alpha Targeted Therapy Discussion	Teleconference

Date	Event	Location
November 17	Alpha Targeted Therapy Discussion	Teleconference
November 22	Discussion on developing a relationship agreement	Teleconference
December 2	Discussion on developing a relationship agreement	Teleconference
Black River First Nation, Hollow Water First Nation, Brokenhead Ojibway Nation		
February 1	Discussion on developing a relationship agreement	Teleconference
April 1	CNL, Black River First Nation, and Hollow Water First Nation sign a relationship agreement	E-mail
May 18	Discussion on onboarding the newly appointed liaison officer	Teleconference
May 25	Liaison officer participated in a site tour	On-Site Visit
June 1	Liaison officer onboarding discussion	Teleconference
June 23	Participating in site monitoring discussion	Teleconference
July 6	Participating in site monitoring discussion	Teleconference
July 14	Liaison officer participates in bat survey	On-Site Visit
August 12	Communities participate in preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 16	Liaison officer participates in observation of river sediment, soil, and vegetation sampling	On-Site Visit
August 19	WR-1 Environmental Impact Statement Document review discussion	Teleconference
September 20	Update on Site Decommissioning Activities	Teleconference
September 28	Communities participate in second preliminary discussion of the Indigenous Advisory Committee	Teleconference
November 10	Six-month Relationship Agreement Discussion	Teleconference
December 13	Update meeting of community liaison committee development	Teleconference

15.2.4 CNL's Long-Term Relationship with Indigenous Peoples

CNL recognizes First Nations and the Red River Métis as stewards of the land and is working towards developing meaningful long-term relationships with each Nation that occupies and has traditional territories and/or modern-day interests near its site operations. CNL recognizes each Nation has its own unique set of interests and concerns associated with both the WR-1 decommissioning project and the WLCP is committed to taking a distinctions based approach to engagement to ensure each Nation's interests and concerns are addressed. CNL also takes a

holistic, relationship-based approach to engagement with each Nation, working closely with AECL, to help address interests and concerns regarding all aspects of the WLCP.

This shift in CNL's Indigenous engagement approach from project based engagement to a holistic, relationship and distinction-based approach will support meaningful actions to build foundations for trust, understanding, and mutually beneficial relationships, including addressing broader issues and concerns such as the historical siting of the Whiteshell Laboratories site.

CNL is currently working with each Nation to formalize these relationships through relationship-building and corresponding agreements. These agreements are intended to help enable greater integration of Traditional Knowledge, ceremony, and cultural and stewardship practices in the decommissioning, monitoring, and closure of the project. These agreements will also enable dialogue and participation through the development of monitoring programs, culturally appropriate communications, and trauma-informed engagement. In addition, the agreements help to enhance community engagement, build trust and strengthen relationship-building, and provide mechanisms that facilitate Indigenous participation and input into CNL's environmental monitoring program, economic development and procurement opportunities, future land use, and other areas of collaboration.

CNL has signed a relationship agreement with Black River First Nation and Hollow Water First Nation. Relationship agreements with Sagkeeng First Nation and the Red River Métis are contemplated, and steps are being taken to negotiate such agreements. CNL is committed to ongoing engagement and finalizing these agreements.

CNL continues to build relationships with local First Nations and the Red River Métis to support overall decommissioning of the Whiteshell Laboratories site, including the WR-1 Project. CNL is committed to learning about Indigenous values through ceremony and ongoing dialogue, and discussing, incorporating, and addressing concerns to the extent possible.

16 Acronyms

α	Alpha
ACMR	Annual Compliance Monitoring Report (formerly Annual Safety Review (ASR) or Annual Compliance Report (ACR))
AECL	Atomic Energy of Canada Limited
ALWTC	Active Liquid Waste Treatment Center

Appendix A Concrete Canister Storage Facility

A.1 Operations

The Concrete Canister Storage Facility (CCSF) is operated under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [54]. Concrete storage canisters located at the CCSF have been used at WL since 1975 to store irradiated fuel; there are currently 16 canisters in use.

During 2021, staff of the Site and Nuclear Operations Branch monitored the operation of the CCSF.

The CCSF was operated in compliance with practices and procedures approved for operation. All required surveys and inspections were completed in 2021.

Routine operations in the CCSF were carried out by staff in the Site and Nuclear Operations Branch.

With the recognition of increased work in the CSSF and WMA, three operator trainees were hired, with two of the trainees starting in late 2021. A senior operator was appointed as Facility Supervisor.

In 2021, the CCSF continued to maintain the minimum staffing requirements outlined in the CCSF Facility Authorization [54]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the CCSF in 2021. Procedures for the Facility began their updates as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

A.2 Compliance Monitoring

A.2.1 Air Effluent Monitoring of Canister Liners

Each canister has a closed air-circulating system to monitor the internal space between the canister liner and the sealed fuel basket for the presence of fission products and moisture. Canisters are monitored for one week per month between April and November, dependant on weather. This year readings began in May and concluded in October. Despite multiple attempts flow could not be established in the Canister 8 air lines, these air lines have had issues in previous years obtaining flow. The normal approach to establishing air flow through lines was unsuccessful. Attempts will be made in 2022 to clear the line again.

The gross beta activity was below or near the detection limit of 0.04 Bq/m^3 for all canisters that were measured.

There was no visible moisture detected from the internal canister space during 2021 monitoring, however, the silica gel used in the counting did change colour from blue to pink indicating moisture in the air is present.

A.2.2 Monitoring of Ground and Surface Water

Figure 12 shows the drainage area surrounding the CCSF. Further details on monitoring and results of monitoring ground and surface water can also be found in Sections 9.4.1.3 and 9.5.1.4, and compliance results for the CCSF are described below.

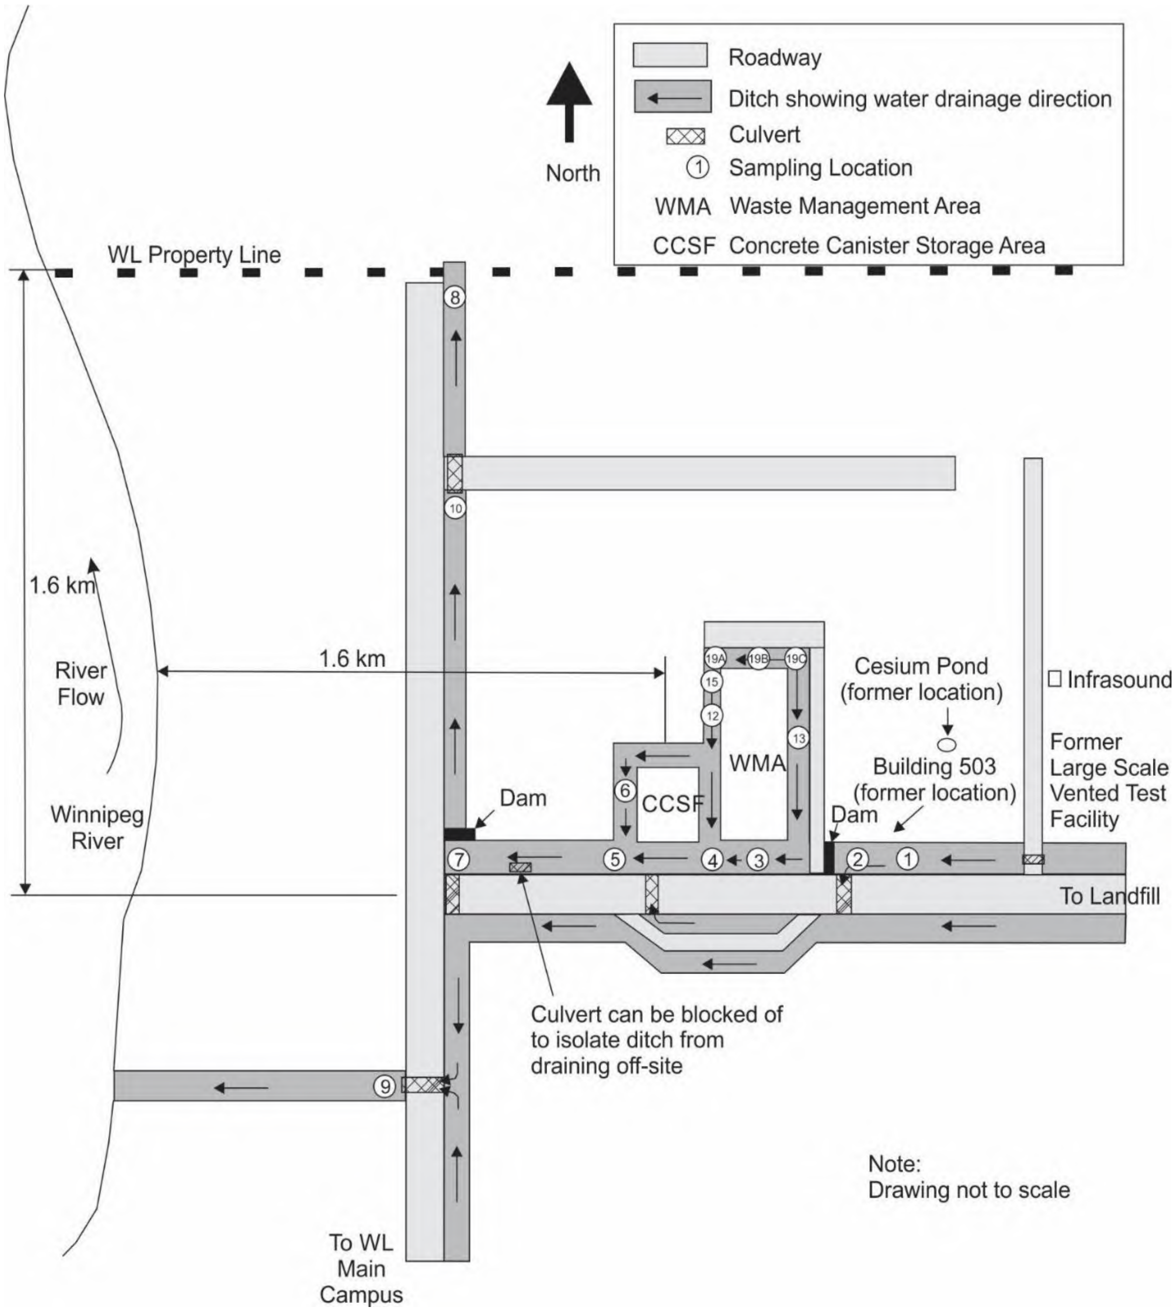

Figure 12: Surface Water Drainage Sample Points

Groundwater samples from deep-well sites in the vicinity of the CCSF are obtained twice yearly; the results are reported and discussed in Appendix D of this report.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the canisters. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry analysis and processed for Strontium (Sr)-90. Gamma spectrometry analysis provides individual results for Cobalt (Co)-60, Niobium (Nb)-94, Antimony (Sb)-125, Cesium (Cs)-134, Cs-137 (Barium (Ba)-137m), Promethium (Pm)-147 and Americium (Am)-241.

If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry analysis and uranium analysis. Uranium analysis has also been conducted for other sampling locations below the limit this year. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration established by Health Canada [34]. If uranium is detected, the result is evaluated against the Maximum Acceptable Concentration for uranium (0.5 Bq/L).

Ditch Location 5 and Ditch Location 6 samples (see Figure 12 for sampling locations) could contain surface drainage from the CCSF, however, due to drought conditions and limited snow fall over the 2020/2021 winter, there was only one day with sufficient ditch water movement. This did not include Locations 5 and 6.

The alpha activities were below the trigger level of 0.5 Bq/L.

Table 65, Table 66, Table 67 and Table 68 list the results of the surface-water samples taken from the vicinity of the CCSF and WMA during 2021. Operational control-monitoring data from previous years has been included for completeness.

The ditch sample collected immediately downstream from the WMA (Location 7) contained elevated levels of tritium[12] (see Table 67), which did not exceed the associated Maximum Acceptable Drinking Water concentration of 7,000 Bq/L [34]. The activity seen is from the WMA as discussed in Appendix D.

[12] Tritium analysis of samples from Ditch Locations 5 and 6 was previously discontinued due to the higher levels of tritium (~4000 Bq/L) noted at upstream locations associated with the WMA.

A.3 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [13]. There were no major facility changes made in 2021.

A.4 Equipment Performance, Planned Maintenance Testing and Inspections

All canisters are checked for deviation from vertical annually. Out of 16 canisters, all displayed slight deviations from vertical in 2021. None of the canisters had a deviation greater than 1°. In 2021, Canister C5 had a deviation of 0.8° to the east. This deviation and those observed on other canisters show that they all display slight movements in response to changing soil moisture conditions and related swelling and contraction of the clay layer. If a canister was noted either through vertical deviation measurements or visually to be trending beyond a 2-3° deviation, corrective measures such as bracing would be considered.

There were no canister loading or unloading operations in 2021.

As required by Section 8 of the Facility Authorization [54], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests were complete. The inspections were all completed.

Whiteshell Laboratories staff conducted general site inspections during each quarter of 2021. The general appearance and fencing were found to be satisfactory on each inspection. Minor infilling was done along the base of the fence to meet security requirements.

In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however, existing cracks and pour pockets were regularly checked for changes and it has been noted that edges of many pour pockets are more brittle as was noted in 2020. Selective patching is done of these pour pockets, only minor patching was conducted in 2021. No increased radiation field was noted from the canisters.

A.4.1 Canister Site Monitoring and Surveillance

GAMMA FIELD SURVEYS

Gamma exposure rates from the canisters were measured quarterly in 2021. These readings were taken in compass directions north-east-south-west, on contact, and 2.0 m from the canister wall at an elevation of 2.0 m above grade level.

No gamma field anomalies were found during 2021.

Table 69 shows the averaged gamma near contact exposure rates measured during 2021, and for the previous four years.

Table 69: Summary of Average Gamma Radiation for Near Contact Measurements from Fuelled Canisters (mrem/h)

a The measurements were made using a BOT P200 survey meter. The instruments are calibrated in mR/h and it is assumed 1 mR/h =1 mrem/h

AIR MONITORING

Air monitoring was conducted on each of the canisters in the CCSF in 2021. This involved an air pump that circulates air from an outlet line on the canister through a Dexter filter and returns it through an inlet line. These readings are taken once per month over a period of approximately one work week during warm weather months. Typically this is the six months of the year when air temperatures are normally above zero. As 2021 was a drier, warmer year, 7 months of sampling were done. As discussed above in Section A.2.1, flow could not be established in the Canister 8 air lines.

One anomalous but still low reading was found in Canister 20 leading to an average of 1.8 Bq/filter for the year. As the other readings were zero, this reading was retained but it is not indicative of a trend. Canister 13 and 16 had single readings slightly greater at 1 Bq/filter. The values may also relate to some disturbances of contamination on the baskets by the previous year's visual observations and the air flow from sampling.

Table 70 shows the averaged beta readings on each filter measured during 2021, and for the previous four years.

Table 70: Summary of Average Beta Radiation Measurements from Fuelled Canisters (Bq/filter)

A.5 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the CCSF as part of routine operations.

See Section 11.1 Waste Management Program for summaries of any volume of radioactive solid and/or liquid waste generated in the CCSF in 2021.

A.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the CCSF as part of routine operations.

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

Appendix B Active Liquid Waste Treatment Center

B.1 Operations

The Active Liquid Waste Treatment Center (ALWTC) in Building 200 did not operate in 2021.

Previously, in 2020 October, CNL notified the CNSC that the ALWTC, Building 200 was being demolished and had requested that the Facility Authorization [55] and the Safety Analysis Report [56] associated with the ALWTC be removed from the Whiteshell Laboratories LCH [14]. CNSC granted this request in 2020 December [57].

In 2017, new LLLWTS began operation in Buildings 100 and 300. All of the Building 100 low level liquid waste is now being tested, treated and controlled release to the river in the Building 100 LLLWTS and likewise in Building 300.

In 2020 October, the last of the operating systems in Building 200 were shut down and isolated (ventilation and compressed air systems). The building was rendered cold and dark and demolition of the building started later in 2020 October. Demolition of Building 200 above grade and 1.5m below grade were completed in 2021 October. The demolition footprint is still fenced and protected. The fence will remain until the potentially contaminated ground can be remediated.

B.2 Facility Changes

The demolition of the building was completed in 2021 October.

B.3 Wastes Generated

No solid radioactive or hazardous waste was generated in the ALWTC as part of routine operations.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the ALWTC during demolition activities in 2021.

B.4 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the ALWTC as part of routine operations.

Appendix C Shielded Facilities

C.1 Operations

The WL Shielded Facilities (SF) operates under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [58]. The SF, consisting of the Hot Cell Facility (HCF) and the IFTF, are located in the R&D Complex (Building 300), and are operated by personnel in the Site and Nuclear Operations Branch.

The HCF Cells 1 to 5 and IFTF Cell 13 remain operational while HCF Cells 6 to 11 have been shut down and partially dismantled. The Waste Handling Area, located in the IFTF, was operated for compaction and assaying of radioactive waste.

Operations and decommissioning activities were conducted throughout the year. Operations activities included:

- maintenance of HCF and IFTF ventilation system equipment;
- replacement of HEPA filters;
- packaging and storage of radioactive waste;
- cleanup activities; and
- routine maintenance to ensure compliance with the site licence.

Routine operations in the SF were carried out by operating staff from the Site and Nuclear Operations Branch.

There were no organizational changes in 2021. Although there was a reduction in the staffing for the operating staff responsible for the SF in 2021, the minimum staffing requirements outlined in the SF Facility Authorization [58] was maintained at levels to provide the needed operational and safety support.

No program changes were made for the SF in 2021. Procedures are being updated as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

C.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [13].

C.3 Equipment Performance, Planned Maintenance Testing and Inspections

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence.

Equipment tests and inspections were completed with the exception of a secondary Intermediate-Level Liquid Waste containment tank leak detector due to a defective probe. Compensatory measures were put in place until the detector was repaired. Monthly housekeeping and fire prevention inspections were completed.

VENTILATION SYSTEM

Maintenance activities requiring part of the ventilation system to be taken down occurred without incident.

The annual routine Poly-Alpha-Olefin testing of the HCF HEPA filters were successfully conducted.

C.4 Wastes Generated

See Section 11.1 Waste Management Program for WL summaries of the volume of radioactive solid and liquid wastes generated in the SF in 2021.

LOW-LEVEL SOLID WASTE

In 2021, the SF generated 45.6 m^3 of compactable low-level radioactive solid waste and no non-compactable waste.

The Waste Handling Area processed 62.1 m^3 of low-level radioactive solid waste which was reduced to 5 m^3. A portion of this waste was generated in the SF, and the remainder came from all of the nuclear facilities and decommissioning projects at WL where waste is being generated.

Table 71 lists the annual low-level solid waste generated in the SF for 2021 and the previous four years.

Table 71: Solid Wastes Generated

Total Volume	2017	2018	2019	2020	2021
Low-Level Solid Waste (m^3)	0.4	73.3	64.3	10.9	45.6
Medium-Level Solid Waste (m^3)	0	0	0	0	0

MEDIUM-LEVEL SOLID WASTE

In 2021 the SF generated no medium-level (intermediate-level) radioactive solid waste. Table 71 lists the annual medium-level solid waste generated for 2021 and the previous four years.

LOW-LEVEL LIQUID WASTE SYSTEM

In 2021, 99 m^3 of low-level liquid waste was processed through the Building 300 low-level liquid waste system (see Appendix E).

MEDIUM-LEVEL LIQUID WASTE SYSTEM

All the medium-level liquid waste (intermediate-level liquid waste) from the HCF cells collects in the HCF sump tank, AD Tank 1. The liquid is transferred via a manually controlled pump from AD Tank 1 through a filtration system to AD Tank 14 in the IFTF. The liquid from all other HCF medium-level liquid waste drains and all IFTF medium-level liquid waste drains flows by gravity to AD Tank 14.

In 2021, there was one transfer of 0.1 m^3 medium-level liquid waste to transportable totes that is being stored for future disposition.

Table 88 lists the annual aqueous waste generated for 2021 and for the previous four years.

C.5 Effluents Released

Liquid radioactive and hazardous effluents were discharged from the SF as part of routine operations are provided and discussed in Section 9, Environmental Protection.

Appendix D Waste Management Area

D.1 Operations

The Waste Management Area (WMA) operated under the WL Site Licence [1], in accordance with the requirements of the *Facility Authorization for the Operation of the Waste Management Area at the Whiteshell Laboratories* [59]. During 2021, the WMA at WL was operated and monitored by staff in the Site and Nuclear Operations Branch.

In 2021, the WMA was operated in compliance with approved practices and procedures.

Routine operations in the WMA were carried out by the Facility Manager, Facility Supervisor, WMA Operators and two WMA based utility workers, with support from other Site and Nuclear Operations personnel and Environmental Monitoring personnel as required.

In 2021, the staffing of the WMA was increased. A Facility Supervisor (Senior Operations Technician) was appointed and three additional Operations Technologist trainees were hired.

In 2021, the WMA continued to maintain the minimum staffing requirements outlined in the Facility Authorization [59]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the WMA in 2021. Procedures are being updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

D.1.1 Inventory Additions And Deletions

Changes in inventory are reported in Table 72 and for the purposes of reporting WMA inventory (fission products are defined as radioactive material originating from irradiated fuel).

Activation products are defined as any material that has been activated in a neutron flux, including corrosion products. The radioactivity values listed are those recorded at the time of storage.

D.1.2 Low-Level Solid Waste

Details of wastes transferred to the WMA are provided in Section 11.1.1. Waste generated from decommissioning work on the site was generally shipped to CRL for storage, although some waste was stored in the WMA. Some of the inventory of stored waste in WMA was sent to CRL for storage pending future disposal. The stored volume of waste is listed in Table 72.

D.1.3 Industrial Waste

There were no additions of industrial chemical waste during 2021.

Table 72: Additions to Low-Level Waste Inventory

Period	Storage Locations	Volume (m^3)	Fission Products (GBq)	Activation Products (TBq)
Total Accumulation to 2020 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433.	18,798.84	1,967.38	330.58
Additions for 2021	Building 431 to 433	0	0	0
Removals for 2021	LLW Bunker 6 Buildings 431 to 433	9 0	13 0	0 0
Total Accumulation as of 2021 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433	18,789.84	1,954.38	330.58

D.2 Compliance Monitoring

D.2.1 Monitoring And Surface Water

SURFACE WATER

Figure 12 shows the drainage area surrounding the WMA.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the WMA. The WMA and CCSF share a network of perimeter compliance monitoring ditches with designated sampling locations. Water samples are collected in these sample locations for analyses when there is sufficient flowing water present. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period. In 2021, there was only one day where the ditch flow met the required flow conditions in some sample locations due to the light snow pack leading to limited snow melt, limited rainfall and dry soil conditions.

A recorded amount of precipitation of 395 mm occurred in 2021, which was less than the 441 mm recorded in 2020, and is a ten year low for recorded precipitation. The low precipitation is reflective of an ongoing drought in the area.

In an effort to streamline the operational environmental monitoring process, surface water samples are initially analyzed for gross beta, gross alpha, and tritium. The results are then evaluated using the following screening criteria:

- If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry, and processed for Sr-90. Gamma spectrometry provides individual results for Co-60, Nb-94, Sb-125, Cs-134, Cs-137 (Ba-137m), Pm-147, Am-241.

- If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry and uranium analysis, however, as was the case last year, all water samples were tested for uranium. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration (MAC) established by Health Canada [34]. If uranium is detected, the result is evaluated against the MAC for uranium (0.5 Bq/L or 20 ppb).

Levels of beta activity at ditch sample Locations 1 to 7 (Table 73) all remained well below 10 Bq/L. Based on historical data, it is conservatively assumed that the beta activity in the surface water is Sr-90 in secular equilibrium with Y-90. Most beta activity levels in the ditch water remained below the drinking water screening level of 1 Bq/L, and below the drinking water limit of 5 Bq/L for Sr-90 and 10 Bq/L for Cs-137 [60]. Compliance with Guidelines for Canadian Drinking Water [34] may be inferred if the measurement for gross alpha and gross beta is less than 0.5 Bq/L and 1.0 Bq/L, respectively. There were no exceedances of the Canadian Drinking Water [34] standard of 1.0 Bq/L (Table 73) in 2021.

The alpha activity levels in the surface water are presented in Table 74, and were below the trigger level of 0.5 Bq/L. Uranium results are presented in Table 75.

There was no flow at Locations 19 A, B and C in 2021. In past years, the uranium values recorded at these locations are believed to result from the use of local Lac du Bonnet Batholith granitic rock as base material for the SMAGS foundation. This rock had been also used for berm support material for the Cesium Pond pile, however that material was removed from the WMA in 2018. The Lac du Bonnet Batholith granite is noted to have naturally occurring uranium.

As shown in Table 76, the tritium results are below the Maximum Acceptable Concentration of 7000 Bq/L [34] at all locations with only one result above near-detection limits of 124 Bq/L at Location 7 in 2021. Other locations had no flow or near non-detection of tritium. Locations 19 A, B and C were originally chosen for sampling for the potential migration of cesium-137 due to the presence of the Cesium Pond soil pile. Although the Cesium Pond soil has been removed, CNL will continue to monitor locations 19 A, B and C due to the elevated levels of tritium.

The WMA contains a number of trenches with varying amounts of low-level radioactive waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. Based on the initial modelling [61], it was proposed that tritium would be present in the ditches (including the Locations 3 through 7 and 19 A, B and C) and possibly reach levels as high as 37 kBq/L. While tritium is slightly elevated immediately around the WMA, periodic monitoring of the ditches has indicated that the levels of tritium at the points (Locations 8 and 9) leaving CNL property remain quite low (below an average value of 4.7 Bq/L in 2021). With the low flow volumes, tritium was only detected in one location. Although the amount measured in Locations 1 to 7 are above that noted at the Control location, the levels are much lower than the Maximum Acceptable Concentration in drinking water for tritium (7000 Bq/L).

Table 73, Table 74, and Table 75 present the WMA surface-water sampling data. The data represents continuing documentation of a spill incident that occurred in 1979 near ILW Bunker 3, from the reference sample point (Location 3) in the southeast section of the WMA, as shown

in Figure 12 and Figure 13. In 2017, sampling Location 3 was reconfigured to allow preparations for future bunker and standpipe remediation, but the location was dry this year due to the dry summer. Surface water at this location serves as an indicator of movement of water from ILW Bunkers 1, 2 and 3. The most mobile radionuclide (tritium) is below the associated Maximum Acceptable Concentration. The levels of tritium in the surface water and groundwater are below the radiation screening criteria used for identifying contaminants of potential ecological concern (COPECs) of 1.27×10^7 Bq/L [62]. These tables, and Table 76, have been expanded to include the historical monitoring at Ditch Locations 19 A, B and C, water flow permitting.

The Cesium Pond soil (Cs-137) that was stored in the WMA adjacent to SMAGS was removed in 2017. There was no flow recorded in the north WMA ditch in 2021 (Locations 19 A, B and C) (Figure 13). Table 77 reflects this circumstance and shows that previous years indicated no migration of Cs-137 to these ditches.

As Trench 16 has a known quantity of Technetium-99 (Tc-99), Tc-99 measurements were performed as part of ditch water monitoring in 2021. Only one value near the limit of detection was measured (Table 78) The Tc-99 limit for drinking water is 200 Bq/L [60] and the measurement is well below this level.

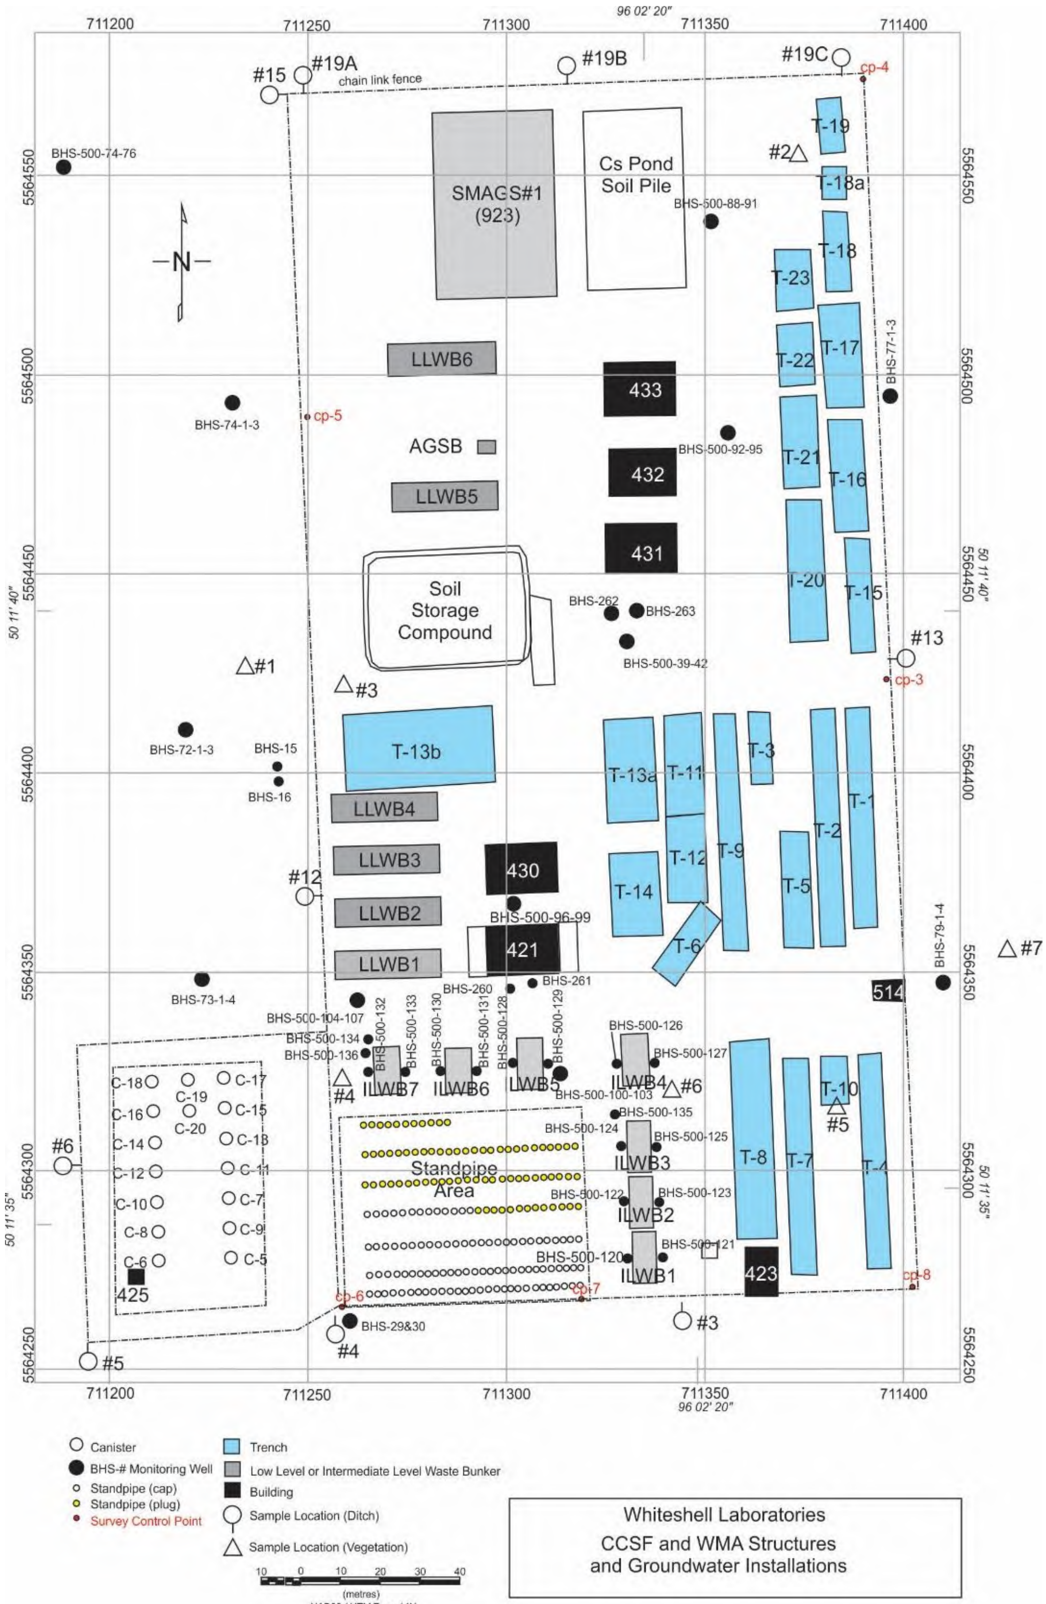

Figure 13: Ground Water Sample Points

INTERMEDIATE - LEVEL WASTE BUNKERS NEAR FIELD WELLS

A series of shallow near field wells were installed adjacent to the ILW bunkers in the WMA in 2015 (Figure 12). Groundwater samples were taken from the wells and from water in the ILW Bunkers for comparison. Cs-137, Sr-90, and tritium were selected as the radionuclides for monitoring of the potential for contaminant migration. Cs-137 was selected as the least mobile, with a high affinity for bonding with clay-based minerals, Sr-90 is more mobile but will bond with sand, and tritium is the most mobile that moves with water. Cs-137 and Sr-90 require a pathway (e.g., a construction joint or crack) to migrate from a bunker. In 2021, Sr-90 was noted to be a maximum of 34 Bq/L adjacent to ILW Bunker 1, and 20 Bq/L adjacent to ILW Bunker 3. For all other locations, the Sr-90 and Cs-137 levels were minor or negligible. Tritium can move through concrete without cracks by diffusion with water movement. The results indicate no migration of Cs-137 (Table 79) from the ILW Bunkers, and Sr-90 (Table 80) and tritium levels (Table 81) that are orders of magnitude below the levels observed in the water in the adjacent ILW Bunkers. At ILW Bunker 3, the tritium results remain high (126,326 Bq/L) and moderately high at ILW Bunker 5 (11,051 Bq/L).

A series of water measurements were made as a confirmatory check in 2020 for the presence of base neutral chemicals (e.g., benzenes, ethylenes) and PCBs. These measurements indicated these chemicals were not present in the water around the bunkers. The measurement was not repeated in 2021.

WATER TABLE WELLS AND DEEP WELLS

Water samples were collected from wells in and around the WMA (Figure 13) in the spring and fall of 2021. The gross alpha and gross beta results are summarized in Table 82. The beta activity levels in the clay, clay till and basal zone wells remained below the drinking water screening level of 1 Bq/L. All zones were below the limit for Sr-90 (5 Bq/L) and Cs-137

(10 Bq/L) [34]. The average alpha activity in the samples collected from the Basal zone wells was below the screening level.

Uranium concentrations in the basal zone wells ranged from 0 to 0.59 Bq/L. The concentrations in the Clay zone wells ranged from 0.19 to 3.60 Bq/L, and in the clay till from 0 to 1.61 Bq/L. Since it is known that the local well waters within the Canadian Shield contain naturally occurring uranium [63], the presence of uranium and its progeny are not unexpected and are considered to account for the levels of alpha. Low levels of tritium were noted in the clay (23.29 Bq/L) and clay-till (11.33 Bq/L). This is not unexpected as these overburden layers are impacted by tritium in the WMA.

Table 82: Monitoring Data Water Table Wells and Deep Wells

WMA Sample Locations	2017 Avg. (Bq/L)	2018 Avg. (Bq/L)	2019 Avg. (Bq/L)	2020 Avg. (Bq/L)	2021 Avg (Bq/L)	2021 Avg. Range (Bq/L)
Total Beta [a]

Basal	4.08	4.63	5.66	3.48	3.59	3.16 to 4.62

a The reference nuclide for total beta is Sr-90
b The reference nuclide for total alpha is natural uranium
c The value calculated from the concentration of uranium in the water sample

HIGH-LEVEL LIQUID WASTE TRAY WATER

Monitoring of the high-level liquid waste tank tray water was carried out to confirm there is no leakage from the residue remaining in the storage tanks. This is sampled in the summer months. The sample results indicated no leakage has occurred from the tanks. The data are

summarized in Table 83. In the late fall of 2004, the high-level liquid waste had been removed from high-level liquid waste Tank 2 and transferred to the SF for cementation. A heel of waste remains to be removed. High-level liquid waste Tank 1 remains empty.

Table 83: Monitoring Data High-Level Liquid Waste Tank Tray Water

WMA Sample Locations	2017 Avg (Bq/L)	2018 Avg (Bq/L)	2019 Avg (Bq/L)	2020 Avg (Bq/L)	2021 Avg (Bq/L)	2021 Range (Bq/L)
Total Beta [a]						
Tank Tray Water	13.8	13.8	12.1	11.2	17.7	13.6 to 25.3
Total Alpha [b]						
Tank Tray Water	0.65	0.69	1.5	0.95	0.2	0.1 to 0.4

a The reference nuclide for total beta is Sr-90, gamma results indicate that approximately 13Bq/L of the gross beta activity is due to K-40.

b The reference nuclide for total alpha is Pu-239

D.2.1.1 RADIATION FIELD MEASUREMENTS

Radiation field measurements are taken semi-annually at established points (normally every 38 m) along the perimeter fence. The 2021 radiation field measurements were similar to those in 2020. The data is summarized in Table 84.

Table 84: Perimeter Fence Monitoring Data

WMA	Radiation Field (µSv/h)					
	2017 Avg	2018 Avg	2019 Avg	2020 Avg	2021 Avg	2021 Range
Spring Survey						
South Fence	0.2	0.2	0.2	0.3	0.2	0.1 – 0.3
West Fence	0.4	0.4	0.4	0.3	0.3	0.1 – 0.6
North Fence	0.2	0.2	0.2	0.4	0.2	0.1 – 0.3
East Fence	0.3	0.3	0.3	0.2	0.4	0.1 – 0.5
Fall Survey						
South Fence	0.2	0.2	0.2	0.4	0.3	0.2 – 0.3
West Fence	0.4	0.4	0.5	0.3	0.4	0.2 – 0.6
North Fence	0.2	0.2	0.2	0.3	0.3	0.2 – 0.4
East Fence	0.3	0.3	0.4	0.3	0.2	0.1 – 0.5

D.2.1.2 VEGETATION

In 2021, vegetation samples were collected at monitoring locations within the WMA (Figure 13), and at a control location unaffected by WL operations. The gross beta results are

summarized in Table 85. Potassium (K)-40 represents the majority of gross beta activity in most of the samples. The levels of gross beta in the samples are due to a combination of K-40 and Sr-90/Y-90, with a minor contribution from Cs-137. The average Sr-90 contribution for the vegetation samples in the WMA is 6% (12% for Sr-90/Y-90). Results were historically reported as Bq/m^2 as there was the potential for deposition of radioactivity via airborne emissions from the former WL Incinerator and former Baler operations. The incinerator and baler have not been in operation for many years and have been decommissioned. The results are now presented as Bq/kg and represent the uptake of radioactivity from impacted areas near the sampling locations.

Table 85: Waste Management Area Vegetation Monitoring Data

WMA Sample Locations	Average Gross Beta[a] (Bq/kg)				
	2017 Avg	2018 Avg	2019 Avg	2020 Avg	2021Avg
North-East Area[d]	NA	672	450	196	207
Mid-West Area	1619	411	155	173	190
South-West Area	275	414	NA	296	243
South-East Area	460	409	441	230	246
Control Sample[b]	379	187	210	162	171

East of ILW Bunkers 3 and 4	NA	672	450	NA	218

a The reference nuclide for beta is Sr-90
b Adjacent to the WMA outside of the fence boundary
c Ambient Radiation monitor Stations Background Samples
d Until 2012 this sampling point was in the North-West area after 2012 it was moved to the North-East area. Only a single set of vegetation samples was taken as of 2017 as uptake occurs over the summer. Range is no longer included because of this change.

In 2021, the Facility continued to maintain the minimum staffing requirements outlined in the Facility Authorization [59]. Three trainee operators were hired in 2021 to begin increasing staffing to meet with planned decommissioning activities. Staffing was maintained at levels to provide the needed operational and safety support.

D.3 Facility Changes

All facility changes are performed as per the approved Engineering Change Control procedure [13].

Work to prepare for extraction of waste from the Intermediate Level Bunkers and Standpipes was begun in 2017 and continued into 2021 with most of the physical preparatory work done with continued fabrication of extraction equipment off site.

The pad to the east of the north access road had the requisite safety analysis and procedural documents prepared. The pad is now designated as the Recoverable Surface Staging and Storage Area and will be placed into service in 2022 to store Seacan containers containing

waste and oversized items. The Seacan containers or items will be awaiting processing, characterization and packaging for off-site shipment. This was required to allow Building 923 (SMAGS) to be converted to a Cask Loading Facility (CLF).

Building 923 is in the process of being converted to the CLF. In 2021 this included installation of a 15 ton overhead crane, additional lighting and ventilation ducting and an air handling unit. Interior shielding walls were also erected. The current interior equipment is awaiting commissioning and connection of additional power. Further installation work will be done in 2022.

The WR-1 Phase 1 decommissioning waste material was stored in Buildings 432 and 433 in the WMA. Approximately 96% of the WR-1 Phase 1 decommissioning waste stored in Buildings 432 and 433 had been processed by the end of 2016. One oversized crate along with five asbestos crates remain in Building 433 at the end of 2021. Through 2021, work to characterize the contents of B431, B432 and B433 occurred. This effort will continue in 2022 with off site shipping planned.

The marine container used for storing sealed sources that was transferred from Building 430 in the WMA to the Standpipes Protected Area to meet revised security regulations from the CNSC in 2015, remained in place through 2021. Sources are still held pending future dispositioning.

The process to convert Low Level Waste Bunker #6 to the Intermediate-Level Liquid Waste Treatment Centre, Building 202, began in 2021. Work consisted of removal of waste that had been temporarily returned to the bunker due to restrictions in work crews and shipments related to the COVID-19 Pandemic. Once the waste was removed, interior surveys were conducted in preparation for the next phases of work in 2022.

Removal of waste from Low Level Waste Bunker #5 began in 2021. The waste removal is a component of the decommissioning effort for the WMA, and will extend into 2022.

The Waste Transshipment Area outside the northern perimeter of the WMA had its footprint extended and pad upgraded to improve areas of formerly soft ground. The Waste Transshipment Area allows for holding shipments of waste that are ready to be shipped. The larger area will support the planned pace of waste extraction from the WMA.

In 2021, the Waste Transshipment Area also provided access through a west gate in that area to allow for construction of a road along the west side of the WMA. Pads off the west side of that road will host transformers and generators to provide Class IV and Class III power to waste extraction and processing equipment to be installed in the WMA. A non-active organic material laydown area was established on the north end stub of the west road to allow for an area for organic material from the development of the Waste Transshipment Area pad improvement and west road to be retained.

A replacement section of the north fence running from the west side of Building 923 to the east edge of the Recoverable Surface Staging and Storage Area was installed. This fence included an expanded width north gate to allow shipping containers to be transported without having to

raise them above the fence. The fence replacement was done to correct fence sections that were leaning outwards.

On the south side of the WMA, a new well nest was installed to the south of the south road. This well nest was installed to provide groundwater measurements outside of the zone of influence of the work conducted at the WMA. The previous wells fulfilling this role are now too close to the Protected Area expansion to be considered outside the zone of influence and will be used as part of the monitoring network for that area.

A bedrock well was installed to the west of the WMA-CCSF. This provided improved coverage at depth to monitor for potential contaminant migration.

D.4 Equipment Performance, Planned Maintenance Testing and Inspections

During 2021, the bunkers and other structures in the WMA remained fit for service. Building 923 and Low Level Waste Bunker #6 were removed from operations pending their conversion to the Cask Loading Facility and Intermediate Level Liquid Waste Treatment Centre respectively. Building 421 continued to operate as a waste examination and re-packaging area, making use of the Temporary Ventilated Enclosure.

Medium-Level Waste Bunker 4 did not have new waste placed in 2021 and remains ~70% full. Medium-Level Waste Bunker 6 is ~60% full; however it is not accepting waste due to water ingress issues. Medium-Level Waste Bunker 7 is ~86% full with one placement occurring. The percentage full values are estimates only. Road transportable totes of liquid waste remain in the heated Building 430 pending future processing. Building 431 contains historic waste which is in the process of being characterized and packaged. Building 432 and Building 433 also contain various historic wastes and wastes held in various stages of characterization and repacking operations.

A small seepage of an oily substance first noted in 2020 was again noted at the central gasket, near the south wall base of LLW Bunker 1. The substance was sampled in 2020 and found to contain oil and likely degraded liquid organic. The volume was small in 2020 and remained so in 2021. Seepage again only occurred during hot weather, and as weather cooled the seepage stopped. The area will continue to be monitored. The bunker is slated for remediation of its waste in the next few years.

The Soil Storage Compound remained empty of stored waste soil bags. There are three empty standpipes in the standpipe area.

In-service storage facilities were inspected for water ingress during routine waste emplacement operations. Filled storage facilities with accessible drainage sumps were inspected monthly during the summer months, when water ingress is most likely. Caulking of the roofs of all the WMA Quonset buildings with waterproof sealant was completed in 2010 resulting in reduced indications of water ingress during rainy weather. Re-caulking was done in 2014 and again in 2018 and 2021.

In 2015, shallow wells were installed beside each of the Medium/Intermediate Level Bunkers. These near field wells have been sampled annually. Results are discussed in Section D.2.1 under “Intermediate - Level Waste Bunkers Near Field Wells”, and indicates limited migration of tritium beside the ILW bunkers, in particular ILW Bunker 3. There is no evidence that would lead CNL to conclude there is currently any significant contaminant migration pathway from the ILW Bunkers.

Compliance monitoring in the WMA and CCSF perimeter ditches have only found limited levels of contaminants, below drinking water guidelines, suggesting the waste storage structures and natural barriers of low permeability clay soil and upwards groundwater flow are performing as expected. In 2021, the weather was extremely dry and spring melt similarly limited to surface water in ditches was limited to a single set of measurements on one date in May.

As required by Section 8 of the Facility Authorization [59], most routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, however, two tests, both on transformers were not completed in 2021. Monthly housekeeping and fire prevention inspections were completed. An annual inspection of WL WMA concrete bunkers was conducted, in accordance with the Periodic Inspection Plan [16], and is further discussed in Section 6.

D.5 Wastes Generated

Solid radioactive waste was generated in the WMA as part of routine operations. This was mostly bagged waste generated from routine operations.

See Section 11.1 Waste Management Program for summaries of the volume of radioactive solid waste generated in the Waste Management Area in 2021.

Liquid radioactive waste was generated in the WMA as part of routine operations.

In 2021, approximately 564 L of water was removed from ILW Bunker 4, 863 L of water was removed from ILW Bunker 6 and approximately 114 L of water was removed from ILW Bunker 7. Low Level Waste Bunker 1 had 8 L from the west sump and 227 L from the east sump removed, and Low Level Waste Bunker 2 had 84 L from the west sump and 202 L from the removed from the east sump. The sumps are pumped out by Site and Nuclear Operations personnel using a WMA tanker with pump rig. The water collected in the tanker is later transferred to double walled totes. There totes are retained pending future processing.

The Building 923 sump tank and the Soil Storage Compound were both sampled as required and their water found not to be active in all cases. Water was directed to the WMA ditches. No other storage facilities and collection sumps at the WMA required pumping.

D.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the WMA as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection. There are no liquid effluents generated from this facility.

Appendix E Auxiliary Operation Facilities

E.1 Operations

The Auxiliary Operating Facilities are operated under the WL Site Licence [1].

There were no changes in the staffing for the operating staff responsible for the auxiliary facilities in 2021. There were no organizational changes.

No program changes were made for the auxiliary facilities in 2021. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

Research and Development Facilities Complex (Building 300)

Building 300 was the primary research laboratory for the site, housing a wide range of nuclear R&D programs. The building comprised an area of ~17,000 m^2 and was built in seven stages from 1964 to 1982. The building contained 68 laboratories as well as numerous offices. The south end high-bay area contained experimental activities that required large areas and significant headroom; RD-14M and RD-17 experimental loops were located in the South High Bay.

The research program in the Stage 6 (RD-14M) area was completed in 2018, and operational shutdown was started. The operational shutdown, decontamination, and decommissioning of the remainder of the building was completed in 2015. The demolition of Stages 4 and 7 was completed in 2016. The demolition of Stage 6 was completed in 2019.

During 2021, WL Site and Nuclear Operation's staff and user groups in Building 300 carried out routine operations which included:

- Non-radiological laundry activities.
- Respirator fit test / maintenance activities.
- Ongoing CNL Nuclear Engineering & Systems Analysis R&D activities.
- Cleanup activities associated with decommissioning.
- Routine building and system maintenance; and
- Surveillance to ensure compliance with the site licence.

Health and Safety Facilities (Buildings 402 and 305)

Building 402 has three floors comprising an area of ~2,162 m^2, housing WL dosimetry services and Environmental Management laboratories. The CNL facilities in Building 402 include a whole-body counting facility, TLD readers, environmental laboratories, and a Cs-137 Gamma Calibrator.

Environmental and Dosimetry services continued to operate in Building 402 until 2021 May.

In 2021, routine operations were carried out and supervised by Site and Nuclear Operations personnel. Operational cleanout of Buildings 402 and 305 continued and demolition of Building 402 started in 2021 November. Demolition of the building worked around the Whole Body Counter which was scheduled to move in early 2022.

E.2 Facility Changes

All facility changes were performed using the Engineering Change Control procedure [13]. The environmental and Dosimetry services were moved to Building 300. Building 402 was completely isolated and rendered cold and dark in 2021 July.

E.3 Equipment Performance, Planned Maintenance Testing and Inspections

All maintenance and non-routine work in these facilities that may affect the safe operation of facilities, systems, and laboratories, or that may present a hazard to the general public are conducted in accordance with CNL's work permit system.

All routine maintenance for systems required to be operational was carried out, and all equipment tests and inspections were completed up until Building 402 went cold and dark.

E.4 Wastes Generated

There were minimal amounts of radioactive and/or hazardous wastes generated in the facilities as part of routine operations.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the facilities in 2021.

Building 300 generated 0.0 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2021.

Building 402 generated 0.8 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2021.

After processing at the Waste Handling Area, all waste was shipped to the WMA for storage.

See Table 86 for a summary of solid wastes for the last five years.

Table 86: Low-Level Solid Waste Generation – Buildings 300, 402,411

	2017	2018	2019	2020	2021
Building 300 (m^3)	14.7	4.5	0.4	0.3	0.0
Building 402 (m^3)	2.8	1	0.7	0.2	0.8
Building 411 (m^3)	355.1	7.6**	0.2**	0.0	0.0

* Volume prior to compaction, all compactable waste is consolidated at the Waste Handling Area.

** Legacy waste processed in 2018 for Building 411 that was decommissioned in 2017.

There was no liquid radioactive and/or hazardous waste generated in 2021 in this facility.

RESEARCH AND DEVELOPMENT (BUILDING 300) LOW-LEVEL LIQUID WASTE SYSTEM

Radioactive LLLW flows from the SF and Building 300 to the low-level liquid waste collection tanks, in Building 300 Room B-33. An accurate determination of the individual SF or Building 300 contribution cannot be made as both locations flow into these common tanks. The

sources of water from Building 300 are limited and the major contributor is the radiological decontamination service facilities in the IFTF.

During 2021, 78.3 m^3 of low-level liquid was processed through the Building 300 LLLWTS. Table 87 shows the historical volumes of LLLW processed through the Building 300 LLLWTS and also the total volume of Building 300 and Building 100 LLLW processed.

Table 87 - Historical Records of Low-Level Liquid Waste Processed

	2017	2018	2019	2020	2021
Total Combined Low-Level Waste Liquid Processed (m^3)[a]	172.3[b]	131.5[c]	189.3[c]	107	88.2
Low-Level Waste Liquid Processed in Building 300 (m^3)[d]	46	123	186.5	99	78.3

a All low-level liquid waste processed in Active Liquid Waste Treatment Centre for 2014-2016. This total includes laundry and decontamination and ALWTC facilities for 2014 and 2015. For 2016 the total is Building 100 and Building 300 and ALWTC. After 2017 all low-level liquid waste is processed in Building 100 and Building 300.

b This includes 126 m^3 of low-level liquid waste that was processed through the Active Liquid Waste Treatment Centre in Building 200.

c All Low-Level Liquid Waste processed through the low-level liquid waste treatment systems in Building 100 and Building 300.

d Building 300 LLLWTS came online in 2017 July.

The total activities given below are the combination of the Shielded Facilities, Building 300, and Building 100 active liquid effluents produced.

As determined by total-beta analysis, the beta radioactivity content in the effluent releases to the Outfall from the holding tanks at the Building 300 and Building 100 LLLWTS during 2021 was 0.01 GBq, compared with 0.01 GBq released during 2020. The maximum release in a month during the year was 0.001 GBq which is a small fraction of the administrative level of 0.48 GBq per month. This level conservatively assumes that all of the activity is due to Cs-137, which is the most restrictive isotope of those present, or potentially present.

As determined by total-alpha analysis, the alpha radioactivity content in effluent releases to the outfall was 0.001 GBq for 2021 compared with 0.001 GBq released during 2020. The maximum release in a month during the year was 1.4E-04 GBq which is a small fraction of the administrative level of 0.56 GBq per month. This level conservatively assumed that all the activity is due to Am-241 which is the most restrictive isotope of those expected to be present in this waste stream.

Table 88 provides a summary of the total activity released for both the Building 100 and Building 300 LLLWTS. Annual Release Limit values for radionuclides in liquid effluents for WL are based on the DRL [30]. These values were revised in 2016. An error was discovered in Table 88, note “d” in previous years’ reports. The alpha DRL was listed as 1.11×10^1 GBq/month, and should have read 1.11 GBq/month. The annual release limits for alpha were calculated using the correct value for DRL. The % of monthly DRL for alpha was calculated using the wrong DRL value. This made the % of monthly DRL for alpha a factor of 10 lower than the true value.

Observed levels of alpha in WL's LLLW active releases are sufficiently low that even with this correction, levels are well below the DRL. This correction was made for the 2021 values.

Table 88 – Building 100 and Building 300 LLLWTS Radioactive Releases

Radionuclide	**Total 2021 Effluent (GBq)**	**Annual Release Limit[a] (GBq/a)**	**Total 2021 Effluent as a % of Annual Release Limit**	**Peak Release**	
				Max. Monthly Release (GBq)	**% of[b] Monthly DRL**
Total (Total-Beta Analysis) [c]	0.01	–	–	0.001	–
Sr-90	1.02×10^{-3}	1.56×10^{2}	0.76×10^{-3}	2.18×10^{-4}	1.87×10^{-3}
Cs-137	3.74×10^{-3}	1.39×10^{2}	2.69×10^{-3}	5.95×10^{-4}	5.12×10^{-3}
Total Alpha (As Pu-239 Equivalent) [d]	0.86×10^{-3}	1.33×10^{1}	6.46×10^{-3}	1.35 x 10-4	1.22×10^{-2}
Historical Data Total Effluent (GBq)					
	2017[e]	2018[e]	2019[e]	2020[e]	2021
Total (Total-Beta Analysis) [c]	0.04	0.02	0.01	0.01	0.01

a The annual release limit is calculated by multiplying the DRL by 12.

b DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The beta particulate emitters are considered to be Cs-137, the most restrictive isotope of those identified or potentially present. The DRL is 1.16×10^{1} GBq/month [30].

c A total beta analysis results in a conservative (higher) estimate of the total amount of activity, which is more accurately determined by measuring the individual radionuclides by radiochemical or gamma spectrometry methods.

d DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The alpha particulate emitters are considered to be Pu-239, the most restrictive isotope of those identified or potentially present. The DRL is 1.11 GBq/month [30].

e Year's 2014 to 2016 effluent was all processed in ALWTC. 2017 effluent was processed in ALWTC and Building 300 LLWTS. From 2018 on, all effluent was processed in Buildings 300 and 100 LLWTS.

E.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from these facilities. Radioactive wastewater generated in Building 300 was pumped to the LLLWTS in Building 300 Room B-33.

Any liquid and/or gaseous releases from the facilities are provided and discussed in Section 9, Environmental Protection.

Appendix F WR-1 Facility

F.1 Operations

Activities in Whiteshell Reactor 1 (WR-1) were conducted under the WL site licence [1] from the CNSC, in accordance with the requirements of *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64]. The status of the WR-1 facility in its shut down, de-fuelled, and partially decommissioned state is described in *The WR-1 Reactor Phase 1 Decommissioning Project Interim End-State Report - Facility Description* [65]. The facility is monitored and maintained as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64].

Routine operations in the WR-1 facility, as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64], were carried out by the five (four and one trainee) Site and Nuclear Operations Technologists assigned to Building 100. Throughout the course of 2021, the number of Building 100 staff dropped to three (two and one trainee) with plans to hire additional staff. Building 100 continued to maintain the minimum staffing requirements outlined in the Facility Authorization [64]. Staffing was maintained at levels to provide the needed operational and safety support.

In 2018, approximately 20 m³ of low concentration (3.4 E06 Bq/L) tritiated water was found in the thermoshield and bioshield cooling systems. This water is still in the systems, awaiting a decision on how to remove this water as the systems were not designed to be drained. Investigation is also ongoing to determine what the impact would be if this water is left in situ as part of the proposed in situ disposal of WR-1.

No program changes were made for WR-1 in 2021. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

F.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [13].

F.3 Equipment Performance, Planned Maintenance Testing and Inspections

During 2021, the operations status of WR-1 remained unchanged. There were no changes to the reactor's equipment.

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence. All Monthly housekeeping and fire prevention inspections were completed.

F.4 Wastes Generated

Solid Radioactive and/or Hazardous Wastes

See Section 11.1 Waste Management Program for summaries of the volume of any volume of radioactive solid and/or liquid waste generated in WR-1 in 2021.

Solid radioactive waste was generated in the facility as part of routine operations. This consisted of mainly operational supplies such as Tyvek suits.

During 2021, 1.5 m^3 of low-level radioactive compactable waste and no non-compactible waste were generated from Building 100/WR-1 operations and sent to the Waste Handling Area for compaction.

There were no new hazardous solid wastes generated from Building 100/WR 1.

Liquid Radioactive and/or Hazardous Wastes

Liquid radioactive and no hazardous waste was generated in the facility as part of routine operations.

During 2021, 9.9 m^3 of low-level radioactive liquid waste was generated from Building 100/ WR-1 operations, the majority from the WR-1 sumps. Appendix E has more information on the liquid waste processed. There were no hazardous liquid wastes generated from this facility.

F.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the facility as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection.

Appendix G Non-Nuclear Facilities

G.1 Operations

The WL non-nuclear facilities status and changes for 2021 are as noted in Table 89.

Table 89: Operating Summary of Non-Nuclear Facilities

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
303	Containment Test Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed

[a] Security personnel perform regular patrols of all site buildings

There were no policy, program or procedural changes for the non-nuclear facilities in 2021. There were no changes in organization in 2021.

In 2021, the Facility continued to maintain the minimum staffing requirements to provide the needed operational and safety support.

G.2 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [13].

G.3 Equipment Performance, Planned Maintenance Testing and Inspections

Systems and equipment for all the non-nuclear facilities, including any safety-related systems, performed as designed and required during 2021 with the exception of Compressed Air Systems where one of the three compressors was not operational (awaiting parts). In addition, issues with some gas detection systems were part of the missed preventive maintenance activities that was reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence.

Routine maintenance was carried out, and equipment tests and inspection were completed in 2021 with no significant results.

G.4 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the non-nuclear facilities as part of routine operations.

G.5 Effluents Released

There were no radioactive and/or hazardous effluents (gaseous or liquid) released into the environment from the facilities as part of routine operations.

There was 1.15E+09 L of effluent released from buildings Building 422 (Outfall Monitoring Station) and 0 L of effluent released from Building 907 (Sewage Lift Station and Lagoons) as there was no lagoon release in 2021.

Landfill Dugout Water Monitoring

The WL landfill is surrounded by six dugouts where surface water collects. These dugouts are sampled as part of the ongoing operational control monitoring for the facility. In 2021, the precipitation was low over the year (395 mm) and the dugouts had low water levels during the summer sampling period. The location of the dugouts are shown in Figure 14. Dugout 22 is used as the Control and is about 300 m away from the landfill to the north-northeast, and would not be affected by facility operations.

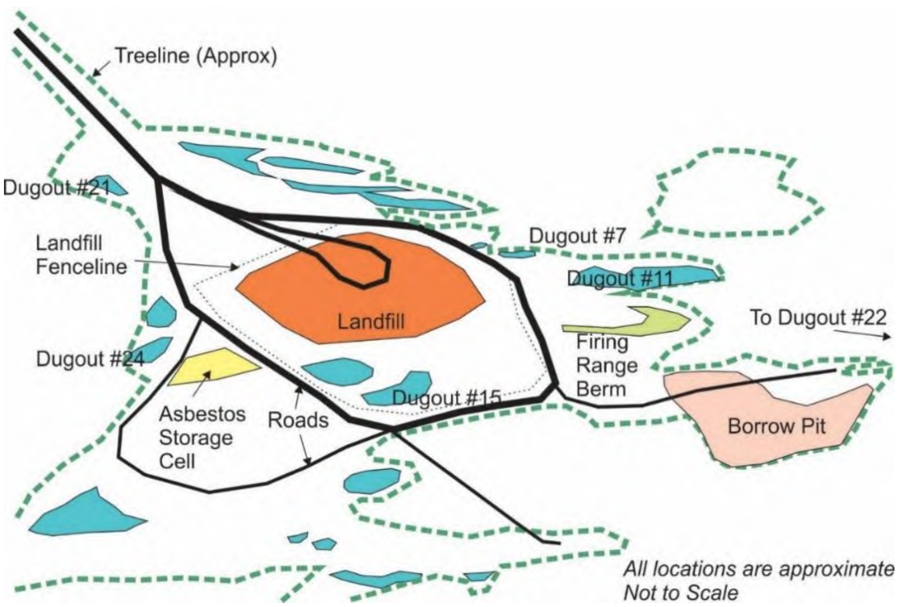

Figure 14: WL Landfill Area Showing Approximate Locations of Monitored Dugouts

The results from the sample analysis for alpha and beta from these dugouts are provided in Table 90 and Table 91 respectively. All alpha results for 2021 were at the detection limits, and are below the drinking water screening level of 0.50 Bq/L. All beta results for 2021 were near the detection limits, and are below the drinking water screening level of 1.0 Bq/L. Both alpha and beta results for 2021 are consistent with previous results obtained from 2016 to 2020.

Table 90: Gross Alpha Results from the Landfill Dugouts

Sample	Gross Alpha (Bq/L)					
Location	2016	2017	2018	2019	2020	2021
Dugout #7	< 0.14	< 0.17	< 0.17	0.07	<0.05	<0.05
Dugout #11	< 0.10	< 0.14	< 0.14	< 0.05	<0.05	0.05

Dugout #24	< 0.18	< 0.19	< 0.19	0.29	<0.05	<0.05

Table 91: Gross Beta Results from the Landfill Dugouts

Sample	Gross Beta (Bq/L)					
Location	**2016**	**2017**	**2018**	**2019**	**2020**	**2021**
Dugout #7	0.19	0.17	0.17	0.11	0.07	0.08
Dugout #11	0.07	0.02	< 0.10	< 0.05	< 0.05	0.01
Dugout #15	0.35	< 0.07	< 0.07	0.12	0.16	0.30
Dugout #21	0.12	< 0.05	< 0.05	Dry	< 0.05	0.13
Dugout #22	< 0.06	< 0.13	0.13	< 0.05	0.05	0.05
Dugout #24	0.26	0.08	< 0.08	0.25	0.06	0.10

Low levels of tritium (9 Bq/L) were detected in one of the landfill wells (water table) starting in 2011. Its appearance in the groundwater resulted in initiation of the surface (dugout) water measurement of tritium. Tritium has been detected in landfill Dugout 15 for the past eight years, and a low value was noted in Dugout 24 in 2011, 2012, 2016, and although a higher amount was noted in 2018 (76 Bq/L), the value returned to background in 2019 and remained there through 2021. The higher tritium level in Dugout 15 was 93 Bq/L, approximately one-half of that measured in 2019 (212 Bq/L). All results are well below drinking water limits of 7,000 Bq/L. The other dugouts do not appear to contain tritium, as levels comparable to blank samples analyzed from 2013 to 2021 that contain < 5 Bq/L of tritium were recorded. Tritium results from the landfill dugouts are shown in Table 92.

Table 92: Results from the Landfill Dugouts

Sample	Tritium (Bq/L)					
Location	**2016**	**2017**	**2018**	**2019**	**2020**	**2021**
Dugout #7	< 4	< 4	< 4	< 3	< 4	< 5
Dugout #11	< 4	< 4	< 4	< 4	18	< 5
Dugout #15	98	82	105	212	54	93
Dugout #21	< 4	NA	< 4	Dry	< 3	< 5
Dugout #22	< 4	< 4	< 4	< 4	< 3	< 5
Dugout #24	5.5	< 4	76	< 4	< 4	< 5

NA sample not available

When initially detected in the dugouts, it was assumed that it was possible that tritium emissions from the WR-1 Building 100 deposited in the ponds surrounding the landfill, and was subsequently drawn in to the water table. After consideration, it was determined that the most likely source of tritium is the landfill. The presence of above background tritium in only a few dugouts cannot be explained by air borne deposition. The highest tritium activities are found in the dugouts and wells in closest proximity to the landfill. Due to its 10 m height, the landfill has

a higher hydraulic head than the local terrain, including the asbestos storage cell, and thus will be more likely to contribute leached contaminants to the shallow ground water system. Due to local groundwater flow directions (toward the south and southwest), Dugouts 15 and 24 are more likely to receive contaminants from the migration of water from the landfill. As the landfill had been in operation for over 50 years, the potential for a historic error in placement is greater for the landfill than the adjacent asbestos storage cell.

The water testing conducted in 2018 included Sr-90 and Tc-99, two potentially mobile radionuclides. In 2018, near detection levels of Sr-90 were noted in Dugout 21 and near detection limit levels of Tc-99 were noted in Dugouts 21 and 24. In 2019, only Sr-90 was tested, and was found to be at the detection limit. In 2020, both Sr-90 and Tc-99 were again measured. Sr-90 was at the detection limit and Tc-99 was not detected. In 2021 (Table 93), no Sr-90 analysis was conducted as per the instructions provided to lab to only analyze if gross Beta exceeded 5 Bq/L. Tc-99 was again below the detection limit. The water from these dugouts and wells is not used for human consumption. All results were below drinking water limits of 5 Bq/L for Sr-90 and 200 Bq/L for Tc-99.

Table 93: Sr-90 and Tc-99 Results from the landfill Dugouts in 2021

Sample Location	(Bq/L)	
	Sr-90	Tc-99
Dugout #7	NA	ND
Dugout #11	NA	ND
Dugout #15	NA	ND
Dugout #21	NA	ND
Dugout #22	NA	ND
Dugout #24	NA	ND

NA – No Analysis Gross Beta below analysis trigger limit.

ND – Non Detect

The water from the dugouts was also tested for a suite of non-radiological parameters including total metals, mercury, nitrate + nitrite, sulphate, chloride, sodium, potassium, calcium, magnesium, sulphur, total ammonia (N), phosphorus, phenols and volatile organics (including benzene, toluene, ethylbenzene and xylene). Elevated levels of boron were detected in Dugout #15, a continuation of results from 2017 onwards (Table 94). The value in 2021 remained under the Drinking Water Guideline for Boron (5,000 µg/L). Dugout #24 showed 431 µg/L in 2021, all other dugouts showed values below detection limits.

Table 94: Boron Results from the Landfill Dugout #15

Sample Location	(µg/L)				
	2017	2018	2019	2020	2021
Dugout #15	1630	5460	8460	2040	3760

Molybdenum remained at detection limits from 2020 through 2021. In 2021, Manganese remained higher than drinking water guidelines of 50 µg/L in Dugout #15 (509 µg/L). No other parameters were detected at concentrations of concern.

Groundwater results will be discussed in the annual Environmental Monitoring report [29]. Sediment sampling of one of the dugouts was conducted as part of the Environmental Assessment Follow-up Program and will be reported in [28].

Landfill Dugout Sediment Monitoring

Sediment sampling of the dugouts was conducted in 2017 as part of the Environmental Assessment Follow-up Program. The analysis of the sediment included a full suite of metals, mercury, lead, PCBs and for radioactivity, including Sr-90. There were elevated levels of molybdenum in the surface sediment of one dugout (Dugout 24) and no other contaminants of potential concern noted. Molybdenum can be found naturally in the environment (minerals containing iron, bismuth, or copper) as well as being a component of man-made items such as filaments, X-ray tubes, screens, grids for radios, spark plugs, contacts, induction heating elements, and/or part of a waste stream from man-made processes (burning of fossil fuels). The source of the molybdenum is being investigated as part of the assessment of the Landfill prior to closure. Monitoring of the sediments in the dugouts around the landfill is planned to continue every 5 years (from 2017) as well as annual monitoring of the water, as such no sediment sampling was conducted in 2021.

Further investigation will be conducted during the eventual closure of the landfill and will also be reported in the Environmental Assessment Follow-up Program [28].

Landfill Radiological Monitoring

Annual radiological monitoring of the landfill surface is performed as a confirmatory measure. The results show readings consistent with background levels at the landfill fence line. Table 95 provides a five year listing of survey results at the top of the landfill. For some years monitoring was performed at the base of the pile, and more recently monitoring was performed around the perimeter of the fenced area of the landfill.

Table 95: Landfill Radiological Monitoring

Sample Location	(µR/h)				
	2017	2018	2019	2020	2021
Landfill Top Surface	10-16	8 - 10	6 -12	6 - 12[2]	10
Landfill Base	< 20	NR	5 - 8[1]	5 - 8[1]	10

NR – Not recorded

EXECUTIVE SUMMARY

This report provides revised Derived Release Limits (DRLs) for the operation of Canadian Nuclear Laboratories' (CNL's) Whiteshell Laboratories (WL). These DRLs supersede the values established in 2016 [1].

The DRLs were calculated using the same methodology as in 2016 [1], which is based on Canadian Standards Association (CSA) Guideline N288.1-08, which was developed with Canadian Nuclear Safety Commission (CNSC) involvement. The DRL calculations were performed using the Integrated Model for Probabilistic Assessment of Contaminant Transport (IMPACT) computer code, which embodies the recommended methodology. Previous versions of this code have been validated against experimental data and have been confirmed to be compliant with CSA Standard N286.7, which addresses the quality assurance of computer programs. The results of the DRL assessment were extensively verified to ensure the accuracy of the calculations.

The assumptions regarding the locations and characteristics of population groups located around the WL site are documented and justified. In following the current DRL modelling guidance, conservative assumptions and parameter values were adopted for exposures and intakes, and best-estimate values were used for many environmental transfer parameters and contaminated food source fractions. To the extent possible, site-specific values were used for parameters describing environmental conditions at the WL site, adding to the accuracy of the assessment.

In 2016, DRL's were calculated for one stack location, two roof vent locations and one Waste Management Area (WMA) location for airborne effluents, and for one liquid effluent release location. However, based on the introduction of three new systems in the WMA and the release of tritiated water (HTO) from one or more of these systems, the airborne DRLs had to be recalculated.

The potential critical groups considered in the assessment were the same as in 2016 [1], which include three farm groups having full-time occupancy and a farm group that has limited occupancy. Within these groups, six different age classes were considered, and for the two infant age classes, three milk sources were assessed (cow milk, breast milk and formula milk). Considering the number of release locations, potential critical groups and age classes included in the modelling, the WL DRL study is deemed comprehensive.

For airborne effluents, DRLs for 12 radionuclides are approximately 2% lower than the 2016 DRLs [1]. For one radionuclide (Zn-65), the bounding release location changed from B200 to the WMA and the magnitude of the DRL was lowered by 1%. A new DRL was added for HTO released from the WMA (5.61E+14 Bq week^{-1}) and the previous DRL for HTO released from B100 (1.65E+15 Bq week $^{-1}$) [1] is still valid.

There is no change to the liquid effluent from the 2016 DRLs [1].

1. INTRODUCTION

1.1 Revision of WL DRLs

This report provides revised Derived Release Limits (DRLs) for emissions of radioactive materials in both airborne and liquid effluents from Canadian Nuclear Laboratories' (CNL) Whiteshell Laboratories (WL) site during normal operation. The WL DRLs have been revised because of the introduction of three new systems in the Waste Management Area (WMA) and the release of tritiated water (HTO) from one or more of these systems. As a result of these changes, the airborne effluent DRLs had to be recalculated. The airborne effluent DRLs in this report supersede those established in 2016 [1], with no change to the liquid effluent DRLs.

The methodology used in the recalculation of the DRLs is identical to that used in 2016 [1]. It is the recommended DRL calculation methodology that is documented in the Canadian Standards Association (CSA) Guideline N288.1-08 [2] (hereafter referred to as N288.1), which is based on the earlier CANDU Owner's Group (COG) DRL Guidance (hereafter referred to as the CDG) [3]. The Canadian Nuclear Safety Commission (CNSC) participated in the preparation of N288.1 [2].

In following N288.1 [2], only values associated with critical group exposure factors, occupancy factors and intake rates are treated conservatively. Other parameters such as the fractions of food and water intakes drawn from contaminated sources have been assigned realistic values. This is intended to reduce the degree of conservatism in the DRLs, as it is broadly recognized that multiple conservatisms yield dose projections that are not representative of the critical group concept (i.e., the projections are representative of extreme individuals). On the same basis, best-estimate values were used for environmental transfer parameters to provide better agreement between model predictions and actual measured environmental concentrations.

1.2 The IMPACT Computer Code

Integrated Model for Probabilistic Assessment of Contaminant Transport (IMPACT) [4], the modelling software used to calculate the DRLs, implements almost all aspects of the methodology recommended in the N288.1 [2]. It includes a database of parameter values, as well as user-friendly interfaces to facilitate the input of scenario-specific information. It outputs compartmental radionuclide concentrations and dose rates as well as DRLs.

The DRL calculations reported here were carried out using the same version (Version 5.4.0) of the IMPACT [4] code and database that was used in 2016 [1]. This version of the code incorporates all the sub models required for application at WL, including methods for calculating dispersion in a river and air immersion dose rates from three-dimensional plumes of contaminated airborne material. The default database has been updated with error corrections as of 2010 July 9 [5]. The software has been subject to validation and verification testing as discussed in [6] and [7]. The development of the previous version of the code (Version 5.2.2) was analyzed and found to be consistent [8] with the requirements of CSA Standard N286.7 [9], which relates to software quality assurance. The development of Version 5.4.0 was also guided by, and is expected to meet the requirements of, that standard.

1.3 The Whiteshell Laboratories Site

The 4,375-hectare WL site is located in the Local Government District of Pinawa in southeastern Manitoba, about 100 km northeast of Winnipeg. Most of the site and all the facilities are located on the east bank of the Winnipeg River (Figure 1-1), which in this area, flows from south to north.

The WL site is in the zone of transition between farmland to the west and the exposed part of the Precambrian Shield to the east, and is overlain by glacial till and sediments. The surrounding terrain is relatively flat, except for the small hills on both sides of the river. Part of the surrounding land is used for farming, with the rest being wooded. Sport fishing is carried out in the Winnipeg River, but there is no commercial fishing in the area.

The area surrounding WL is sparsely populated. The nearest population centres are Lac du Bonnet (population approximately 1,000, located 8.6 km north), Pinawa (population approximately 1,500, located 13.4 km east-southeast), River Hills (population less than 100, located 11.8 km south) and Seven Sisters (population less than 100, located 8.9 km south-southeast) (Figure 1-1). Of greater interest for this study are farms which are much closer to WL.

A near-field map of the WL site is shown in Figure 1-2. There are four main sources of airborne radioactive effluents at WL: Building 100 (B100) (reactor building), Building 200 (B200) (Active – Liquid Waste Treatment Centre) and Building 300 (B300) (shielded facilities and other laboratories), which are located in the complex of buildings in the main part of the site (WL-Main), and the WMA. In the previous DRL [1], the only sources of airborne effluents in the WMA were from the compactor/baler and incinerator. However, three new systems in the WMA will be introduced; the Standpipe Waste Retrieval System (SWRS), the Bunker Waste Retrieval System/Sorting and Conditioning Unit (BWRS/SCU), and the Intermediate Level Liquid Treatment System (ILLTS), which will also contribute to airborne effluents. The compactor/baler and incinerator are no longer in service, but they are discussed in this report to clarify the changes between the 2016 DRL [1] report and this assessment. The only significant source of liquid radioactive effluents from the site is the process outfall from the new Level Liquid Waste (LLLW) processing systems, which began operation in B100 and B300. All of the B100 low level liquid waste is now being tested, treated and released in a controlled manner to the river in the B100 LLLW system and likewise in B300. All of the collection tanks in B200 were then isolated and taken out of service. The B200 sumps have also been taken out of service, and any water collected from the sumps and associated piping was put into drums for processing.

The WL site is currently being decommissioned by CNL. There are no longer tenant businesses on site. There are farm workers on land leased from CNL on the west bank of the Winnipeg River (Farm E). They are not classified as Nuclear Energy Workers and their radiation exposure is not required to be monitored.

Farm E is the farming location which is closest to a source of WL effluents. However, farm workers are present at this location for only a limited duration each year. The closest farming property with year-round occupancy (Farm F) is also on the west bank of the Winnipeg River, but it is further downriver.

The DRLs presented in this report were calculated assuming the current WL site boundary and the supervised area, as shown by a black line in Figure 1-2. If the site boundary and/or the supervised area are to be reduced as a result of ongoing decommissioning of the WL site, and there are changes in the use of affected land, then the impact on DRLs will need to be evaluated.

Figure 1-1 Location of WL Site

Figure 1-2 Near-Field Map of WL Site Showing Effluent Release Locations and Potential Critical Group Locations

2. DERIVED RELEASE LIMITS

CNL's nuclear facilities are required to operate in such a way that radionuclide releases to the environment are well below their DRLs. These limits represent release rates that correspond to critical group exposures at the public dose limit. They are calculated by the licensee from the combined radiation dose that a member of the public receives through all pathways of exposure to a radionuclide that is routinely released to the environment. The DRLs are based on individual doses to average members of a critical group. The critical group is defined so as to represent a group of individuals likely to receive the highest exposures to radionuclides released from a particular source.

Where two or more potential critical groups exist and it is not obvious which would receive the greatest dose, separate calculations are made for each group. Similarly, separate calculations are performed for each age class within a group. The DRL for the radionuclide in question is set equal to the smallest DRL across the age classes and potential critical groups.

N288.1 considers only three age classes (adult, 10-year-old child and 1-year-old infant). However, in the current assessment, the six age classes defined in the International Commission on Radiological Protection (ICRP)-72 [10] and the CDG were considered. These are adult, 15-year-old teenager, 10-year-old child, 5-year-old child, 1-year-old infant and 3-month-old infant.

A separate DRL is calculated for each radionuclide released. However, in order to simplify compliance monitoring some radionuclides can be grouped. For example, the gross beta/gamma-emitting radionuclides released to air (and similarly to water) can be grouped together and the DRL for the most restrictive radionuclide can be applied to that group.

Since the DRL for a given radionuclide (or radionuclide group) is calculated as though only that radionuclide was present in the effluent, facilities must operate to satisfy the following additional condition:

$$\sum \frac{R_i}{DRL_i} < 1.0 \qquad (1)$$

where: R_i is the release rate of the i^{th} radionuclide (or group), DRL_i is the derived release limit for that radionuclide, and the summation takes place over all n radionuclides for releases to both air and water from all effluents.

This condition ensures that all releases combined will not cause a member of the public to receive a dose in excess of the public dose limit.

In order to ensure that this condition is met, and in order to keep public doses as low as reasonably achievable, WL facilities operate with releases at a small fraction of the DRL.

DRLs are calculated assuming that releases from the facility are reasonably continuous and that long-term steady-state is reached in the environment. Consequently, the doses and DRLs calculated in this report are not likely to be indicative of doses that would result from short-term incidents involving abnormal radioactive releases.

Since DRLs reflect the annual dose limit, they can be calculated as annual releases. However, for operational control purposes, airborne release limits are expressed in terms of a period of one week and liquid limits are expressed in terms of a period of one month. Therefore, the DRLs calculated in this assessment are also expressed in these terms.

3. DOSE LIMITS FOR MEMBERS OF THE PUBLIC

The dose limits for members of the public, as set out in the CNSC Radiation Protection Regulations [11], are given in Table 3-1. These limits are based on the 1991 recommendations of the ICRP [12], and are intended to prevent deterministic effects and to limit the occurrence of stochastic effects to an acceptable level.

Table 3-1
Dose Limits for Members of the Public

Application		**Annual Dose Limits ($mSv\ a^{-1}$)**
Effective Dose ($D_{effective}$)		1
Equivalent Dose	Skin (D_{skin})	50
	Lens of the Eye (D_L)	15
	Hands and Feet	50

Paragraph S29 of ICRP Publication 60 [12] recommends that restrictions on effective dose are sufficient to ensure the avoidance of deterministic effects in all body tissues and organs except possibly the lens of the eye and the skin, which may be subject to localized exposures. Hence, there is no equivalent dose limit for other body tissues and organs.

Section 2.1.2 of the CDG [3] states "It has been shown that the equivalent dose to the lens of the eye will not be limiting for the purpose of setting Derived Release Limits [13]. For the lens dose (D_L) to be limiting, it must be true that D_L >15* ($D_{effective}$) and D_L >0.3* (D_{skin}). This condition is met only for Kr-83m, and the dose from this radionuclide is insignificant in comparison to other noble gases. Thus, calculations of effective dose and skin dose are sufficient for determining facility DRLs." Accordingly, only the effective and the skin doses were calculated in this WL analysis.

The possibility of the release of some energetic beta-emitting radionuclides being limited by skin dose was checked. Skin dose calculations were made for all external dose situations (air immersion, groundshine, beachshine and water immersion) for all radionuclides. In no case was the DRL based on skin dose lower than the DRL based on effective dose; hence, only the results for effective doses are discussed further.

4. CALCULATION OF DERIVED RELEASE LIMITS

The steps taken in this assessment to recalculate the DRLs for WL were identical to those used in 2016 [1], which are as follows:

1. Identify the potentially most affected members of the public, determine their characteristics with respect to exposure to radionuclides released from WL to the environment, and select a set of potential critical groups that will form the basis for the DRLs. Determine the parameter values for these groups (Section 5).
2. Identify and characterize the sources of airborne and liquid effluents, the factors influencing atmospheric and aquatic dispersion, and the specific radionuclides to be included (Sections 6 and 7).
3. Identify the environmental pathways models to be used in calculating the DRLs and any assumptions to be made in applying them (Sections 5 and 8).
4. Specify values for the transfer parameters and other data used in the model calculations and any assumptions to be made in applying them (Sections 5, 6 and 8).
5. Set up the model scenarios with the appropriate modelling software (IMPACT) (Section 9).
6. Perform a screening analysis to reduce the number of potential critical groups and release locations for which detailed dose calculations are required (Section 10).
7. Execute the final DRL calculations for each combination of effluent type, radionuclide, critical group, age class and potentially bounding release location (Section 9).
8. Determine the most restrictive DRLs for each radionuclide for airborne and liquid effluents from the DRLs based on the different age classes of the critical group and potentially bounding release locations (Section 11).
9. Confirm the results (Section 12).

Site-specific data were used in the calculations, where possible.

5. CRITICAL GROUPS

5.1 General Discussion

A critical group is a relatively homogeneous group of members of the public who represent the people most highly exposed to radionuclides released from a facility. This may be by virtue of their location or characteristics. DRLs are calculated from the mean dose in the critical group per unit radionuclide release. Recently, N288.1 has replaced the term "average member of the critical group" with the term "representative person". This is a purely cosmetic change. N288.1 states that the representative person "is the equivalent of … the average member of the critical group". The term "critical group" will be used here.

The critical groups considered in the recalculation of the DRLs for WL are identical to those used in 2016 [1]. Potential critical groups have been characterized based on site-specific information rather than by making hypothetical worst-case assumptions. Assumptions related to exposure pathways, occupancy factors, and fractions of the diet that consisted of local food and water were confirmed by interviewing some WL employees residing in surrounding communities. The local fractions applied in this DRL assessment were checked against the default recommendations in Table G.9c of N288.1 in 2016 [1] and were found to be conservative. Assumptions related to newly added pathways in IMPACT were consistent with the recent 2007 Chalk River Laboratories (CRL) DRL calculations [6] and 2010 Nuclear Power Demonstration Site DRL calculations [14].

5.2 Potential Critical Groups

In applying the critical group concept discussed above, a range of types of potential critical groups were identified as being representative of different locations and characteristics of population groups residing in the vicinity of WL.

5.2.1 Potential Critical Groups for Airborne Effluents

For airborne effluents, two types of potential critical groups were considered: farms that have year-round occupants and raise livestock (Farms A, D and F in Figure 1-2), and a farm that has limited occupancy and grows canola (Farm E). Table 5-1 gives the distances and directions of these groups from B200 at WL. The livestock farms are located adjacent to the WL site boundary and lie in high-frequency wind-direction sectors (N, S and NNW) from the effluent sources. A potential critical group location closer to the WMA than Farm A was not selected because the terrain to the east of Farm A is not suitable for farming.

Table 5-1
Distance and Direction of Airborne Effluent Potential Critical Groups from Building 200

Potential Critical Group	Location Relative to Building 200		
	Distance (m)	Direction	
		Degrees from North	Sector
Farm A (livestock)	2,993	353	N
Farm D (livestock and honey)	2,913	177	S
Farm E (canola)	1,313	258	WSW
Farm F (livestock)	2,708	335	NNW

A wide range of types and scales of farming exists on both sides of the Winnipeg River from Seven Sisters Falls to Lac du Bonnet. While it is more common for a particular farm to specialize in one animal product, in this assessment it was conservatively assumed that the livestock farm groups grow most of the animal products that they consume. All the livestock farms were assumed to be identical, except that honey is only produced at Farm D and is supplied to all others.

The canola farm (Farm E) was conservatively assumed to be occupied for only 16 hours per day, for two weeks for planting, two weeks for fertilizing and two weeks for harvesting (total of 672 hours per year).

Individual members of the public who occasionally carry out recreational activities (e.g., boating, fishing and swimming) on the Winnipeg River, closer to the WL site than the locations of the above mentioned potential critical groups, are not explicitly considered in the DRL assessment. This is because these activities are not typical for population groups in the area, but are done by a few extreme individuals. In the recent CRL DRL calculations [6], a scoping analysis was carried out to show that the radiological risk from short-term, occasional occupancy of the river close to CRL is not significantly higher than that from the chronic exposure received by the more remote critical groups over extended periods of time. There is no reason to suspect that the risk for similar extreme individuals at WL would be significantly higher.

In view of the nature of the potential critical groups, screening calculations were performed to reduce the number of combinations of potential critical groups and release location for which detailed dose calculations were required. The screening calculations identified Farm A as the critical group for all nuclides except HTO (see Section 10.1 for details). For an HTO release from B100, Farm F was identified as the critical group. The characteristics of these two groups are the same and only the characteristics of these groups are discussed further in subsequent sections.

5.2.2 Critical Group for Liquid Effluents

Dilution and dispersion studies by Merritt ([15] and [16]) have shown that effluents released from the process outfall move downstream along the east bank of the Winnipeg River and do not reach the west bank in the vicinity of WL. Therefore, the critical group for liquid effluents is obvious, being Farm A on the east bank of the Winnipeg River, adjacent to the site boundary and 2,810 m downstream of the release point (Figure 1-2).

5.3 Characteristics of the Critical Groups

5.3.1 Critical Groups for Airborne Effluents (Farm A or F)

The group members:

- reside on a full-time basis at their assumed locations,
- maintain a large garden from which they obtain a significant fraction of their fruit and vegetable needs (see Section 5.4.2 for information on food sources),
- are self-sufficient in meeting their milk, poultry and egg requirements, and semi self-sufficient in beef and pork,
- feed their animals entirely on forage grown on their farm,
- meet their honey requirements by acquiring it from another local farm,
- partake in hunting on their own property to fulfill their game (deer) meat requirement,
- obtain their water from a well located on the property, and
- use a backyard swimming pool filled with well water during four months of the year.

The exposure pathways applicable to the critical groups are summarized in Table 5-2.

Table 5-2
Airborne Exposure Pathways Applicable to the Critical Groups (Farm A or F)

Pathway	Comments
Air Inhalation	✔
Air Immersion	✔
Water Immersion	✔ (well)
Groundshine (airborne deposition)	✔
Incidental Soil Ingestion	✔
Water Ingestion	✔ (well)

a) Animal Uptake via Forage Ingestion	✔
b) Animal Uptake via Water Ingestion	✔ Livestock – well Game – pond
c) Animal Uptake via Inhalation	✔
d) Animal Uptake via Soil Ingestion	✔

5.3.2 Critical Group for Liquid Effluents (Farm A)

The group members:

- reside on a full-time basis at their assumed location,
- obtain their water for domestic needs (drinking, washing) from the river,
- maintain a large garden from which they supply a significant fraction of their fruit and vegetable needs,
- irrigate their lawns and gardens (a total area of 2,500 m^2) with river water,
- do not irrigate forage crops (hay, grain, corn),

- are self-sufficient in meeting their milk, poultry and egg requirements, and semi self-sufficient for beef and pork,
- water their animals with river water,
- swim in the river during the summer months and in a pool filled with river water during the remainder of the year,
- spend a fraction of the time occupying the shoreline for recreational purposes, and
- fish in the Winnipeg River, from which they obtain a fraction of their fish ingestion needs.

The exposure pathways applicable to the critical group are summarized in Table 5-3.

Table 5-3
Liquid Exposure Pathways Applicable to the Critical Group (Farm A)

Pathway	Comments
Air Inhalation (from volatilized radionuclides following irrigation)	✔
Air Immersion (from volatilized radionuclides following irrigation)	✔
Water Immersion	✔

a) Animal Uptake via Water Ingestion	✔

5.4 Critical Group Parameters

5.4.1 Water Sources

The water source assumptions for the critical groups are summarized in Table 5-4 and are justified in the discussions below.

Table 5-4
Water Source Assumptions

Critical Group	Drinking		Washing and Bathing		Swimming		Irrigation		Animals	
	Source	Percentage	Source	Percentage	Source	Percentage	Source	Percentage	Source	Percentage
Airborne Effluents	Well	100	Well	100	Pool filled with well water	100*	Well**	100	Well for livestock, Pond for deer	100
Liquid Effluents	Winnipeg River	100	Winnipeg River	100	Winnipeg River beaches and swimming pools filled with Winnipeg River water	100	Winnipeg River	100	Winnipeg River for livestock Pond for deer	100

* An outdoor pool is assumed to be operated for only four summer months in a year.
** Grey shading indicates pathways and exposures that are not included in the calculations.

For the groups considered in this assessment, water was assumed to be used for the following applications:

- drinking by humans,
- showering, washing and other domestic uses,
- swimming,
- lawn and/or garden irrigation, and
- animal watering.

Some inhabitants of the banks of the Winnipeg River, in the vicinity of WL, use well water and some use river water. In the absence of detailed population survey information, average values for the usage of water that is radiologically contaminated by WL effluents could not be derived and applied. Instead, it was generally assumed that 100% of the water is obtained from sources that are radiologically contaminated by WL effluents.

In N288.1 [2], the only surface water bodies that are assumed to become contaminated by airborne effluents are small ponds. This distinction is made because larger bodies (lakes and rivers) provide significant dilution of activity deposited locally from the atmosphere. Moreover, natural removal processes are more effective for larger water bodies. As a result, concentrations are lower in large water bodies, reducing the significance of the water exposure pathways.

5.4.1.1 Drinking Water Assumptions

For liquid effluent modelling, the critical group was conservatively assumed to draw all their water from the Winnipeg River. Thus, 100% of the drinking water was assumed to be contaminated.

For modelling airborne effluents, the critical groups were assumed to obtain their drinking water from wells, which were assumed to be contaminated.

5.4.1.2 Immersion Assumptions (external exposures from washing, bathing and swimming)

For modelling airborne effluents, the critical groups were conservatively assumed to obtain all their water for washing and bathing from wells, which were assumed to be contaminated.

For liquid effluent modelling, 100% of the water for washing and bathing was assumed to be contaminated because it was conservatively assumed to come from the Winnipeg River.

Immersion exposure from swimming in the Winnipeg River during three summer months was assumed for the critical group for liquid effluents. Immersion exposures from swimming in a pool, supplied with water from the Winnipeg River, for the remainder of the year was also assumed. In reality, a pool at a hotel in Lac du Bonnet (filled with municipal water taken from the River) is accessible to the public. However, in this assessment, a community pool was conservatively assumed to be located at the location of the critical group, where river water concentrations are much higher than those at the Lac du Bonnet municipal water intake point.

For modelling airborne effluents, members of the critical groups were assumed to swim in a pool filled with well water during four months of the year.

5.4.1.3 Irrigation Assumptions

In N288.1 [2], lawn and garden irrigation with well water is not included in the modelling of airborne effluents. Inclusion is normally not warranted because the relative contribution of radioactivity to soil and plant tissue from irrigation is usually minor compared to the contribution from direct atmospheric deposition. On this basis, irrigation was not included in the modelling of the critical groups for airborne effluents.

In contrast, irrigation was included in the modelling of the critical group for liquid effluents. Lawn and garden watering was assumed to be done using water from the Winnipeg River.

5.4.1.4 Animal Watering Assumptions

It is discussed in the 2007 CRL DRL report [6] that a well (and not a river) is commonly used for watering of livestock. However, to be conservative, in this assessment it was assumed that livestock are watered from wells when modelling airborne effluents, and they receive water drawn from the Winnipeg River when modelling liquid effluents.

Deer are more likely to drink from small streams and ponds in forested areas than the exposed banks of the Winnipeg River. Therefore, it was assumed that game (deer) drink only from small contaminated ponds at the locations of the critical groups. Therefore, the ingestion of contaminated water by deer was modelled for airborne effluents only.

5.4.2 Food Sources

The percentages of the various food items in the diet of the critical groups that were assumed to come from contaminated sources are summarized in Table 5-5. The percentages are based upon site-specific information and judgement rather than statistical analysis, and are justified in the discussions in Sections 5.4.2.1 through 5.4.2.3 below.

Table 5-5
Percentage of Food from Contaminated Sources

Critical Group	Terrestrial Animal Products							Plant Products				Fish
	Beef	Pork	Poultry	Venison	Eggs	Cow or Breast Milk	Honey	Fruit	Above-Ground Vegetables	Potatoes	Grain	
Airborne Effluents	50	50	100	100	100	100	100*	15	25	100	0**	0
Liquid Effluents	50	50	100	0	100	100	0	15	25	100	0	30

* Honey is produced on Farm D only and supplied to the critical group.
** Grey shading indicates pathways and exposures that are not included in the calculations.

In general, the percentages of food products from contaminated sources were assumed to be higher than those recommended in Table G9c of N288.1 [2]. The exceptions were: the contaminated fruit percentage was reduced from 20% to 15 %, the contaminated grain percentage was reduced from 1% to 0% and the contaminated fish percentage was reduced from 100% to 30%.

5.4.2.1 Plant Products

The critical groups were assumed to grow 15% of the fruit that they eat. N288.1 gives a default value of 20%, which is appropriate for climate conditions in southern Ontario, Quebec and New Brunswick. Since southern Manitoba has a harsher climate, a lower percentage is considered reasonable.

The critical groups were assumed to grow 25% of the above ground vegetables and 100% of the potatoes (including other root vegetables) in their diet.

As stated in the 2001 DRL report [17], there are some farms in the neighbourhood of WL that produce grain (wheat and oats), but these crops are sold to large companies and the contamination in the final food products is diluted to negligible levels. Therefore, consumption of contaminated grain was not included in the calculations.

The contaminated percentages discussed above apply for modelling both airborne and liquid effluents, for which crop contamination occurs through airborne deposition and irrigation, respectively.

5.4.2.2 Terrestrial Animal Products

Currently, no animal products are produced at the locations of the critical groups. However, within 10 km of WL there is a mix of beef and dairy farms, with some of their products are being consumed on the farms. At about 20 km south-southeast from WL, there are farmers who are self-sufficient in milk, chicken and eggs, and semi self-sufficient in beef and pork. It is possible that a farmer in the vicinity of WL could start producing beef, pork, poultry, eggs and milk, with some being for their own consumption. However, it is unlikely that they would be self-sufficient in beef and pork. Therefore, it was conservatively assumed that the critical groups are 50% self-sufficient in beef and pork, and 100% self-sufficient in poultry, eggs and milk, as was done in the 2001 DRL calculations [17].

The milk consumed by the 1-year-old infant was assumed to be either 100% cow milk or 100% formula milk. The formula milk was assumed to be prepared with local contaminated water. Either 100% formula milk or 100% breast milk was assumed to be the source of milk for the 3-month-old infant.

Deer is the main game animal in the area, and the critical groups were assumed to hunt and get all the venison required from their own property. As the deer are assumed to drink from small ponds on the property and not from the Winnipeg River, the venison is contaminated by airborne effluents from WL, but not by liquid effluents.

For modelling airborne effluents, it was assumed that 100% of the honey consumed is contaminated because it is available locally from Farm D. For modelling liquid effluents, the honey was assumed to be uncontaminated because the bees generally feed on forage crops, which are not contaminated by liquid effluents.

5.4.2.3 Fish

The critical group exposed to liquid effluents was assumed to eat fish caught nearby in the Winnipeg River. This is reasonable given that fishing is a popular activity in the area. It was assumed that 30% of the total fish consumed is contaminated. This was based on interviews with local sportsmen.

5.4.3 Intake Rates for Humans

The assumed intake rates for food, water, soil, sediment and air are shown in Table 5-6. Most of these values are the recommended default values provided in Tables 17, 18, 19 and G9c, and Clause 7.10.2 of N288.1 for three of the age classes; and Tables 4-15, 4-16, 4-17 and G20c, and Clause 5.11 of the CDG for all of the age classes. These are the 90th or 95th percentiles of their respective distributions, which is consistent with the philosophy of using conservative values for intake rates. The adult intake rates are those for a male.

Table 5-6
Intake Rates of Food, Water, Soil and Air

Food Categories and Items	3-Month-Old Nursing Infant	3-Month-Old Formula-Milk-Drinking Infant	1-Year-Old Cow-Milk-Drinking Infant	1-Year-Old Formula-Milk-Drinking Infant	5-Year-Old Child	10-Year-Old Child	15-Year-Old Teenager	Adult (Male)	Nursing Mother
Freshwater Fish(kg a^{-1})	0.31	0.31	0.91	0.91	2.69	3.1	3.48	7.41	4.75
Milk (mother's milk or cow’s milk) (L a^{-1})	416	0*	371	0*	277	305	327	265	170
Beef + Beef Offal + Veal + Lamb + Rabbit (kg a^{-1})	6.1	6.1	5.4	5.4	9.6	15	20	34	22
Venison (kg a^{-1})	6.1	6.1	5.4	5.4	9.6	15	20	34	22
Pork (kg a^{-1})	0	0	3.2	3.2	7.3	11	15	29	19
Poultry (kg a^{-1})	0	0	4.6	4.6	7.7	9.8	11	20	13
Eggs (kg a^{-1})	2.9	2.9	8.4	8.4	9.6	11	15	30	19
Honey (kg a^{-1})	0.8	0.8	0.34	0.34	0.91	1.1	1.1	2	1.3
Fruit and Berries (kg a^{-1})	69	69	66	66	92	93	91	174	112
Above-Ground Vegetables + Mushrooms (kg a^{-1})	26	26	44	44	91	114	144	236	152
Potatoes (kg a^{-1})	4.6	4.6	23	23	47	63	80	104	67
Total Water Intake (L a^{-1})	0	347	0	358	365	511	657	840	840
Soil Intake (kg a^{-1})	0.044	0.044	0.044	0.044	0.12	0.12	0.12	0.12	0.12
Sediment Intake (kg a^{-1})	0.044	0.044	0.044	0.044	0.12	0.12	0.12	0.12	0.12
Inhalation Rates (m^3 a^{-1})	1,140	1,140	2,740	2,740	6,390	7,850	8,210	8,400	8,400

* Formula-milk-drinking infants (3-month-old and 1-year-old) have zero milk intake and proportionately higher water intake.

Since beef offal, veal, lamb and rabbit are a small percentage of the diet in the WL area, they were combined into the “beef +” category in Table 5-6. Similarly, mushrooms were combined with above-ground vegetables.

The venison intake rates of the critical groups were assumed to be much higher than those recommended in N288.1 and the CDG because deer hunting is much more common among farmers in the WL area than in the general population. The intakes for the “beef +” category in Table 5-6 were assumed to be correspondingly lower, such that the total intake from these two categories is the same as in N288.1 and the CDG. This adjustment ensures a balanced energy intake for the receptors. Because of the abundance of deer in the area, it was assumed that the intakes from the venison and “beef +” categories were equal, which is similar to what was assumed in the 2007 CRL DRL calculations [6].

The DRLs were not calculated for a nursing mother, but her intake rates were required to estimate radionuclide concentrations in breast milk fed to infants. The nursing mother was modelled in the same way as a terrestrial animal, but with intake rates being at the 90th percentiles rather than the median values that were used for other terrestrial animals. The higher values were used because of the increased energy requirements resulting from lactation. These intake rates are similar to those recommended by Wong [18].

5.4.4 Occupancy Factors

The occupancy factors applied to the critical groups and the different age classes were in general the recommended default values in N288.1, which include full-time residential occupancy at the assumed receptor location.

An exception was with respect to swimming occupancy. For modelling liquid effluents, beach swimming was assumed to be based on a three-month period per year, rather than a four-month period, because the Winnipeg River water is colder than the average on which the N288.1 recommendations are based. N288.1 assumes that swimming takes place indoors during the period when beach swimming does not, so the pool occupancy is based on eight months per year. However, for the WL calculations, it was assumed that the critical group swims in an indoor pool during nine months per year.

6. SOURCE CHARACTERISTICS AND DISPERSION

6.1 Airborne Effluents

6.1.1 Sources

Airborne effluents are discharged at four locations: the B100 stack, the B200 roof vent, the B300 roof vent and the WMA. In the 2016 DRL [1], although the WMA had two sources (the incinerator and the compactor/baler), they were treated as one. This was reasonable because they were close to each other and had similar release heights, so that at the downwind distances of the potential critical groups, the differences had a marginal impact on radionuclide concentrations. However, now that three new systems (the SWRS, the BWRS/SCU and the ILLTS) will be introduced in the WMA, the sources of airborne effluents in the WMA were re-evaluated.

6.1.2 Atmospheric Dispersion Model

Atmospheric dispersion was modelled using the sector-averaged Gaussian model described in N288.1 and implemented in IMPACT 5.4.0.

The characteristics of the sources are shown in Table 6-1, together with the dimensions of the adjacent building.

Table 6-1
Source Characteristics and Building Dimensions Considered in the Atmospheric Dispersion Model

Parameter	B100	B200	B300	WMA			
				Compactor/ Baler**	SWRS	BWRS/ SCU	ILLTS
Physical Height of Release (m)	30.4	0	0	7.3	7.92	7.92	5.18
Stack Inside Diameter (m)	1.98	-	-	-	0.203	0.254	0.127
Stack Exit Velocity (m s^{-1})	4.6	-	-	-	15.24	15.24	0.00080
Stack Gas Temperature (°C)	25	-	-	-	28.06*	28.06*	10
Ambient Air Temperature (°C)	0.4	-	-	-	0.4	0.4	0.4
Height of Nearby Building (m)	18.5	7.6	12	5.5	5.5	5.5	5.5
Smallest Horizontal Dimension of Nearby Building (m)	55	12.8	35	12.5	12.5	12.5	12.5
Cross-Sectional Area of Nearby Building (m^2)	1,000	100	400	70	70	70	70

* An average of the winter and summer values.

** The compactor/baler is no longer in service, but it is discussed in this report to clarify the changes between 2016 DRL [1] and this assessment.

The B100 stack was treated as an elevated source with excess momentum and buoyancy, and accompanying plume rise. The release was assumed to be affected to some extent by the wake of the adjacent building. The B200 and B300 roof vents were treated as ground-level sources because of building entrainment occurring at them.

In the 2016 DRL [1], the WMA was treated as an elevated source, but without excess momentum and buoyancy. Even though the incinerator stack (12.2 m high) and the roof vent of the compactor/baler (7.3 m high) were both sources of airborne effluents, a conservative value of 7.3 m was used for the release height in the calculations. However, with the introduction of the three new systems (SWRS, BWRS/SCU and ILLTS), all the WMA parameter values need to be compared to determine which ones should be used in the new DRL calculations.

Effective release height is an important intermediate parameter when modelling releases from different geometries. When comparing the parameter values in Table 6-1, it is expected that the effective release heights corresponding to the SWRS and the BWRS/SCU will be higher than that of the compactor/baler, as modelled in the 2016 DRL [1]. On the other hand, the effective release height of the ILLTS will be lower to the ground than that of the compactor/baler, as modelled in the previous DRL [1], resulting in higher air concentrations from that source. This initially indicates that the doses will be the highest from the ILLTS, and the WMA DRLs should be calculated using its release geometry. However, effective release height is not only dependent on release geometry, but also on the stability class and the wind speed class (as defined in Table 6-3). To establish their overall effect, the effective release heights were extracted using a research and development (R&D) tool CSA-DRL [19]. The results (see Figure 6-1) demonstrate that the effective release height corresponding to the ILLTS geometry will be lowest in all cases compared to the other three release geometries. This also indicates that the doses will be the highest from the ILLTS and, thus, the DRL will be the lowest (and most conservative) for all radionuclides when calculated using the ILLTS geometry.

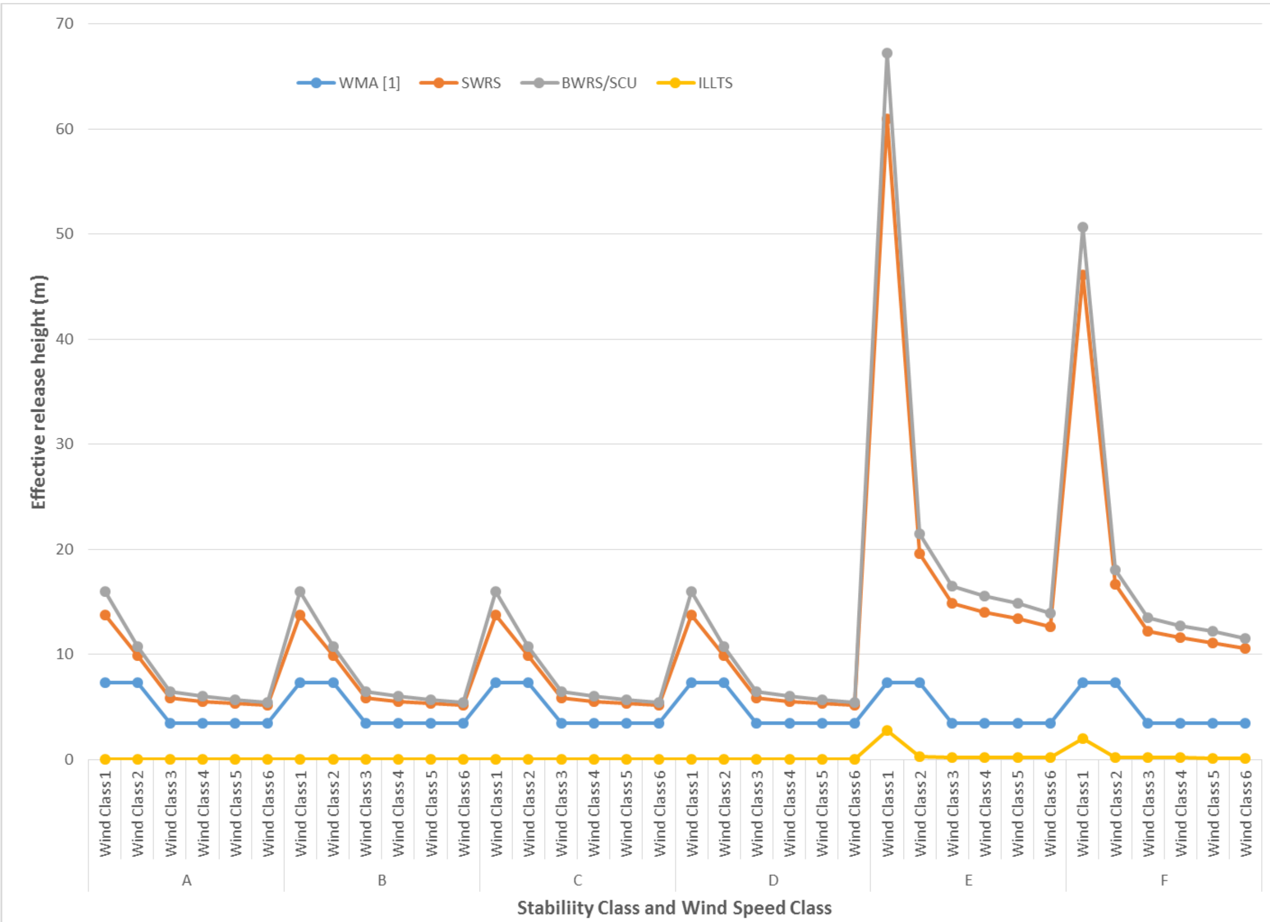

Figure 6-1 Comparison of the Effective Release Heights Corresponding to Each Stability Class and Each Wind Speed Class for the WMA Release Location

A sample calculation was then carried out in IMPACT [4] for a unit release (1 Bq s^{-1}) of Cs-137 from the SWRS, the BWRS/SCU and the ILLTS to compare the total dose to an adult at the critical group A location. The results from the 2016 DRL [1] and the current calculations are compared in Table 6-2. It can be seen that the highest dose was predicted using the ILLTS geometry and, therefore, all WMA DRLs calculated using this geometry will be conservative.

Table 6-2
Example Dose from Unit Release of Cs-137 to Show a Combined Effect of Release Geometry, Stability Classes and Wind Speed Classes

Release Location	Total Dose (Sv a^{-1})
Compactor/Baler	4.01E-08
SWRS	2.07E-08
BWRS/SCU	1.90E-08
ILLTS	4.08E-08

Site-specific meteorological data collected routinely by CNL at WL in the past were used in the dispersion calculations. Temperature, wind speed, wind direction and standard deviation of wind direction were measured at heights of 6, 25 and 61 m on the tower located within a 2-ha clearing about 300 m south-west of B300. Quality-assured values for each of these variables are available every hour from 1988 to 1995. The data from the 6-year period (1990-1995, inclusive) were used for the present calculations. The 25-m level of the tower is at about the same height as the B100 stack. Meteorological conditions are, therefore, similar at the two locations and the 25-m data were used in calculations involving releases from B100. In contrast, B200 and B300 were treated as the ground-level sources and releases from the WMA occur from a short stack. The 6-m data represent best the meteorological conditions experienced by low-level releases and were used for these sources.

Limited, more recent meteorological data is available for the WL site. Environment Canada routinely measures temperature and wind data at a single level above the ground surface. However, the older CNL data is more suitable for the current DRL calculations for the following reasons:

- multi-level temperature measurements can be used to significantly improve estimates of the atmospheric stability class,
- higher-level data better represents the meteorological conditions experienced by the release from B100,
- the quality assurance of the selected CNL data is believed to be better than that of the Environment Canada data, and
- although there may have been some changes in meteorological conditions over the last 23 years, these are relatively small considering the uncertainties in the atmospheric dispersion modelling.

The CNL data from the period of 1990-1995 were also used in the 2001 DRL [17] calculations.

For each tower level, triple joint frequency distributions of wind speed, wind direction and stability class were calculated from the hourly data. The full triple joint frequency distributions are reported in Appendix A. Wind roses for the two measurement levels are shown in

Figure 6-2 and Figure 6-3. The average wind speeds in each wind speed class, which were also required by the model, are listed in Table 6-3.

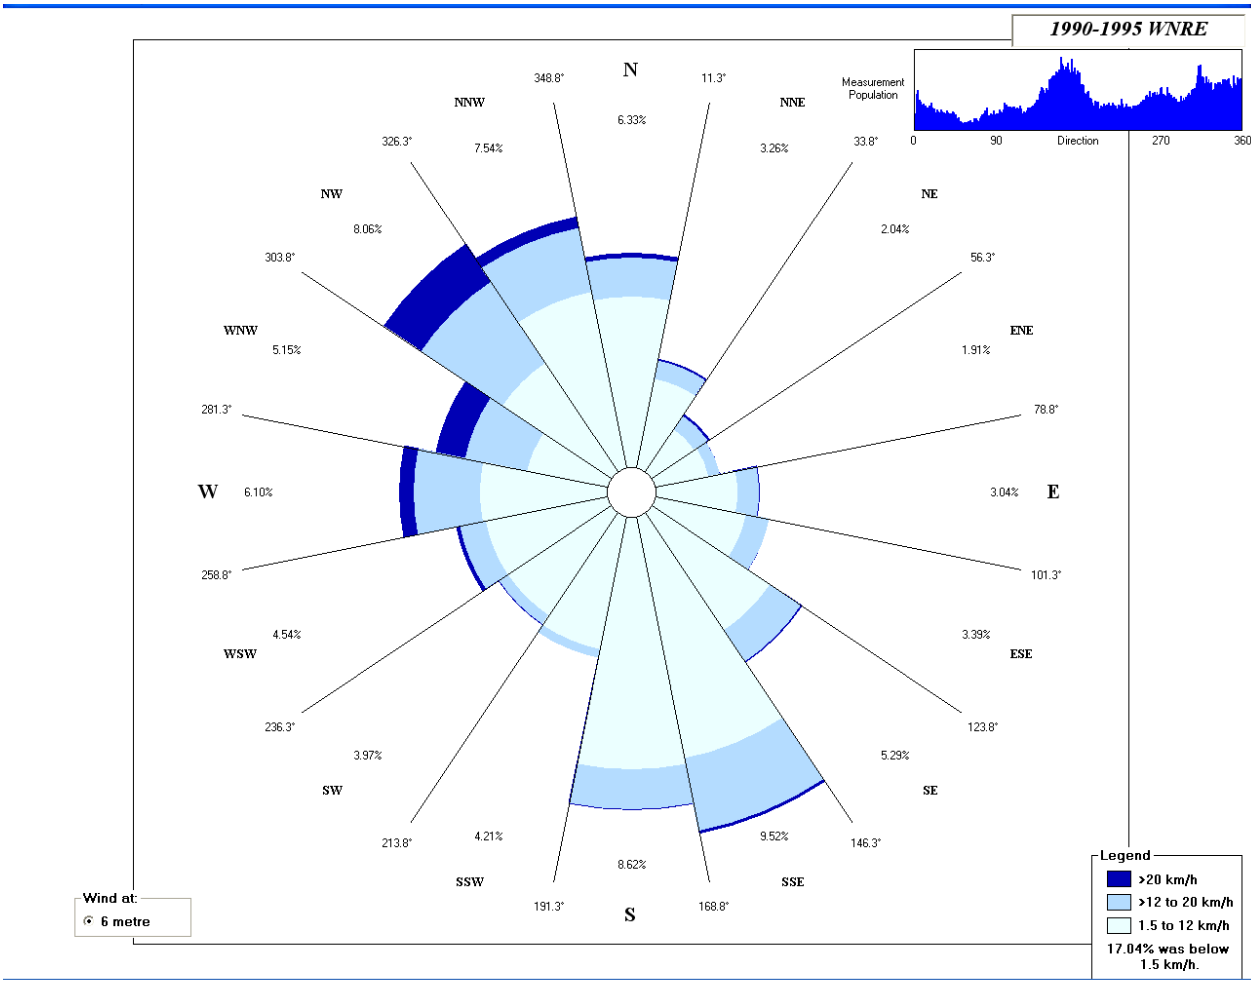

Figure 6-2 Wind Rose Diagram for the 6-m Level

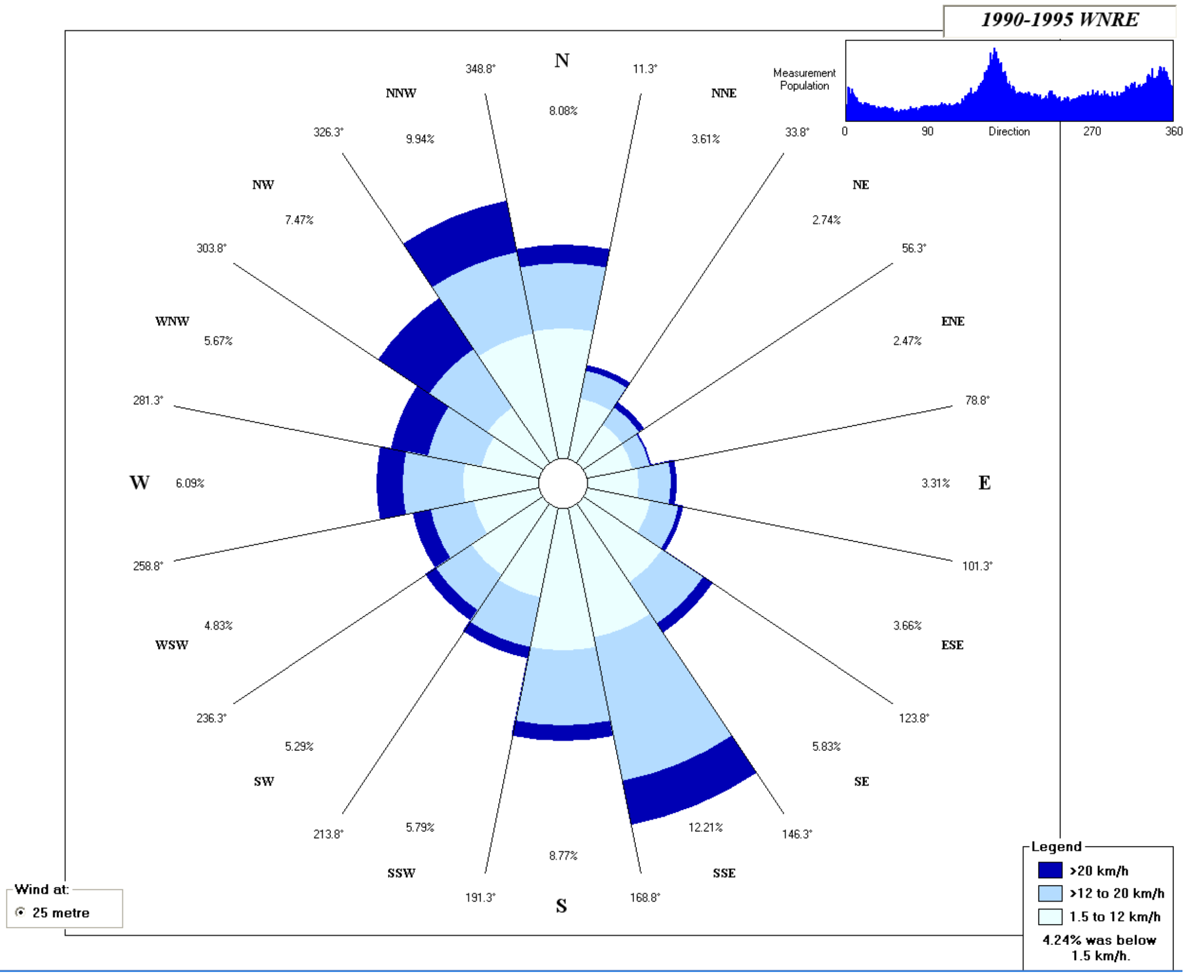

Figure 6-3 Wind Rose Diagram for the 25-m Level

Table 6-3
Mean Wind Speeds for each Wind Speed Class

Wind Speed Class	Wind Speed Range ($m\ s^{-1}$)	Mean Speed ($m\ s^{-1}$)	
		6-m Level	25-m Level
1	0-2	0.85	1.14
2	2-3	2.47	2.50
3	3-4	3.44	3.47
4	4-5	4.42	4.45
5	5-6	5.44	5.45
6	> 6	7.05	7.28

The land between the sources and the potential critical groups is partly wooded and partly farmland. Therefore, the meteorological roughness length was set equal to 0.4 m, as was done in the 2001 DRL [17] calculations.

All other parameters required to calculate atmospheric dispersion were assigned the values recommended in N288.1 [2].

6.2 Liquid Effluents

6.2.1 Sources

At the WL site, liquid effluents are discharged to the Winnipeg River continuously through the process outfall, twice a year from the sewage lagoon and intermittently through small natural streams. Of these sources, only the process outfall (shown as “Outfall” in Figure 1-2) is significant enough for explicit inclusion in the calculation of DRLs. As has been done in the past, the DRLs calculated for the process outfall can be applied to the sewage lagoons because the distance between the two sources is small compared to their distances from the critical group.

6.2.2 River Dispersion Model

The concentrations of radionuclides in the river water, at the location of the water intake for the critical group, have been calculated using the two-dimensional advection-dispersion model of N288.1 [2]. The model parameters include the river width, the river depth, the current velocity, the longitudinal and lateral dispersion coefficients, the offshore distance to the release point and the offshore distance to the point of water intake.

The river width was estimated from a topographic map to be 470 m. Based on the average river flow rate of 1.01E6 L s^{-1} for the period 2003-2008 [20] and Merritt’s study [15], the current velocity was estimated to be 0.28 m s^{-1}. Based on this width, flow rate and velocity, the river depth was estimated to be 7.7 m. The release point is located 8 m offshore. The offshore distance to the point of water intake was conservatively assumed to be 8 m also.

N288.1 [2] recommends that values of longitudinal and lateral dispersion coefficients for the model are best determined from site-specific dispersion studies. In the 2001 DRL calculations [17], the dilution resulting at the location of the water intake was estimated based on the results of a short-term tracer test [15]. However, the radionuclide concentrations measured subsequently during routine monitoring of river water at a location 1,930 m downstream of the release point and 880 m upstream of the point of water intake were consistently much higher than estimates based on the measured release rates and the dilution estimated from the tracer test. This has led to doubts as to the applicability of the results of the tracer test in the DRL calculations.

Therefore, for the 2016 DRL [1] calculations, it was decided to calibrate the river model using Sr-90 and C-137 concentration data obtained from ten years (2003-2012) of routine monitoring of the river water at the location 1,930 m downstream of the release point, the river water upstream of the release point and the effluent in the process outfall ([20], [21], [22] and [23]). In this calibration, the longitudinal dispersion coefficient was set equal to 150 $m^2\ s^{-1}$, the value recommended by N288.1 [2] for the Ottawa River downstream of the CRL site. This was done because data limitations made it impossible to estimate independent values of the longitudinal and lateral coefficients, and because the model predictions are very insensitive to the value of the longitudinal dispersion coefficient. The value for the Ottawa River was selected because the Ottawa River is similar in size to the Winnipeg River. The lateral dispersion coefficient was calibrated to be 7.4E-7 $m^2\ s^{-1}$.

7. RADIONUCLIDES

The DRLs have been calculated for all thirty radionuclides that have been recently found or are reasonably expected to be found in WL's airborne and liquid effluents (see Table 7-1). In the 2016 DRL [1], an airborne effluent DRL was calculated for HTO released from B100 only. However, based on the introduction of three new systems in the WMA and the release of HTO from one or more of these systems, a separate airborne effluent DRL was calculated for HTO released from the WMA.

Table 7-1
Radionuclides Considered for Airborne and Liquid Effluents

Am-241	Fe-55	Pu-240
Am-243 (Np-239d, Pu-239dd)	HTO**	Pu-241 (Am-241d)
C-14*	I-129	Pu-242
Ce-144 (Pr-144d)	Mn-54	Sb-125 (Te-125md)
Cm-244	Nb-94	Sr-90 (Y-90d)
Co-60	Ni-63	Tc-99
Cs-134	Np-237 (Pa-233d)	U-234
Cs-137 (Ba-137md)	Pm-147	U-235 (Th-231d)
Eu-152	Pu-238 (U-234d)	U-238 (Th-234d, Pa-234mdd)
Eu-154	Pu-239	Zn-65

* For airborne effluents, C-14 was assumed to be released as CO_2.

** For airborne effluents, HTO was assumed to be released from B100 and the WMA.

In Table 7-1, radioactive daughters which are possibly significant (e.g., Np-239d, Pu-239dd) are given in parentheses after their parent (e.g., Am-243). They are not released directly, but the ingrowth of these daughters and their transfer through the environment were modelled explicitly in IMPACT [4], and were taken into account in determining the DRL for the parent. The letter 'd' following the radionuclide name indicates the first daughter, and the letters "dd" indicates the second daughter.

8. ENVIRONMENTAL PATHWAYS MODELS

8.1 General Discussion

The environmental pathways models described in N288.1 [2] were used in this analysis. These are illustrated in Figure 8-1 and Figure 8-2 as flowcharts, which provide a summary of the environmental compartments and transfer mechanisms applied in the current modelling for the critical groups. Each compartment treated in the model is numbered and the quantity in compartment i is denoted by X_i. Transfer from compartment i to compartment j is characterized by a transfer parameter P_{ij}, such that the amount present in compartment j under steady-state conditions due to transfer from compartment i is $P_{ij}X_i$. The various compartments, transfer parameters and their units are summarized in Table 8-1 and Table 8-2.

* For C-14 and radioiodine only.

** For HTO only.

The application of the models from N288.1 [2] to the WL assessment is discussed briefly in the sections below, emphasizing the few cases where it was necessary to deviate from the recommended models and parameter values.

8.2 Special Radionuclides

8.2.1 Tritium and Carbon 14

As recommended in N288.1 [2], the models used to calculate the DRLs for HTO and C-14 were based mainly on specific activity (SA) concepts. For tritium, SA models were used for all pathways except for the final calculation of doses, where an uptake model was used instead. For C-14, SA models were used for all pathways except transfers to animals (where a transfer factor was used, which was still derived from SA consideration), and the calculation of dose (where an uptake model was used). HTO absorption by skin was taken into account by increasing the dose from HTO inhalation by 50%, as recommended in N288.1 [2].

HTO can form stable bonds with carbon in plants and animals, in which case it is known as organically bound tritium (OBT). The DRLs for HTO take into account OBT formed in the environment.

The default parameter values recommended in N288.1 [2] were used throughout the tritium and C-14 models.

8.2.2 I-129

I-129 was modelled in the same manner as other radionuclides except that, in the case of liquid effluents, its volatile nature was taken into account by including volatilization following irrigation. Resulting air inhalation and immersion doses were calculated from the air concentrations estimated by the model.

8.3 Special Receptors

In order to facilitate the modelling of infant dose from the consumption of mother's breast milk, the concentrations of radionuclides in the milk were calculated. This modelling was carried out in IMPACT by modelling the lactating mother in the same way as a terrestrial animal and considering breast milk to be an animal product. The animal transfer models in N288.1 [2] were used for the mother, as shown in Figure 8-3. The nursing mother's intakes of food, water and air were discussed and listed in Section 5.4.3 and Table 5-6. Values for all of the other parameters required by the model were left at the default values in the IMPACT database. Figure 8-3 is provided to demonstrate only the contribution from mother's milk to infant's ingestion dose. Infants receive additional doses from other pathways as shown in Figure 8-1 and Figure 8-2.

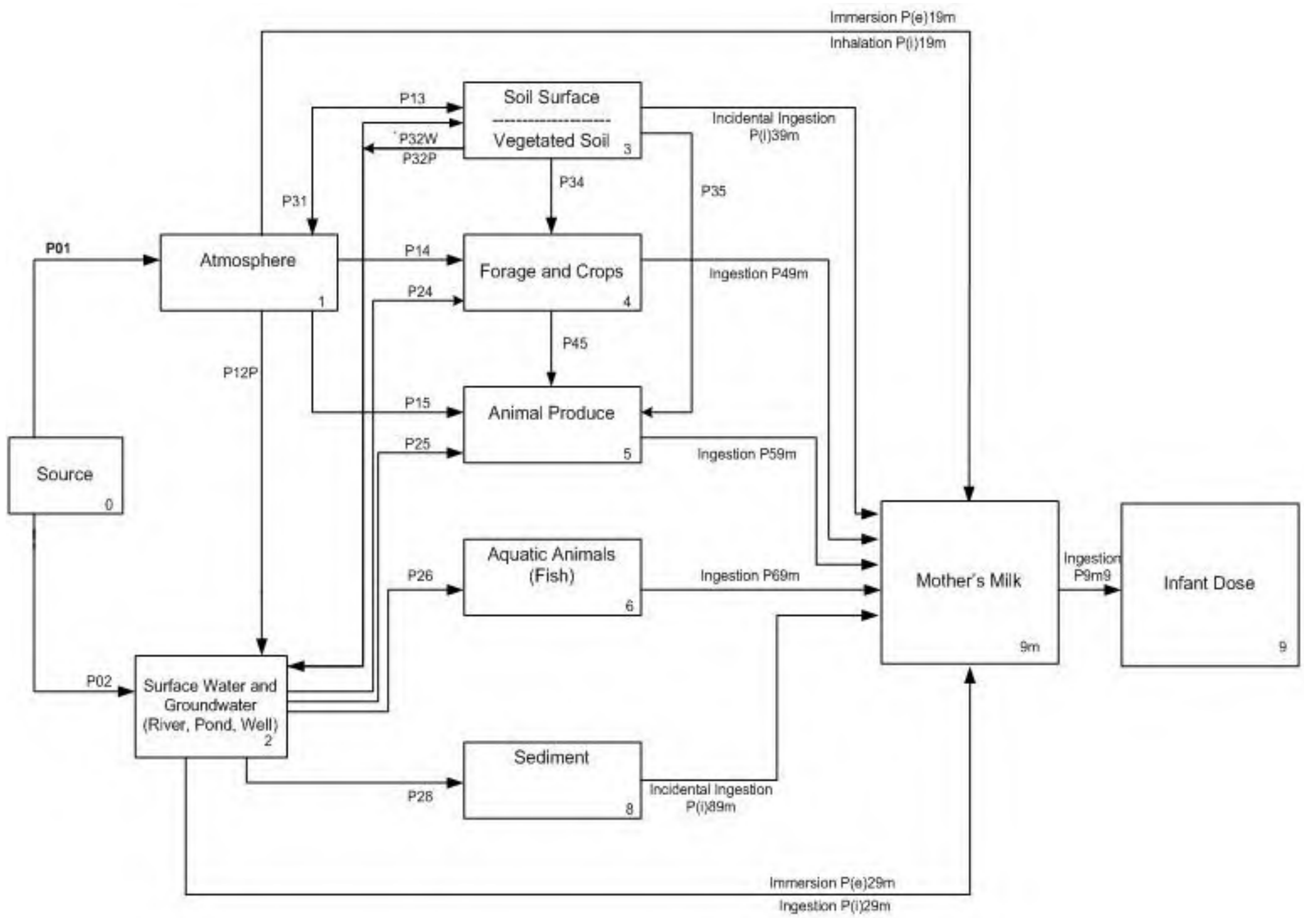

Figure 8-3 Supplemental Model for Mother's Milk

8.4 Other Parameter Values

8.4.1 Soil Types

The surface soil in the vicinity of WL was assumed to be clay, based on the recommendations of Killey [24]. The subsoil was conservatively assumed to be sand.

8.4.2 Well Depth

In areas having clay over bedrock, water supply wells are most likely to extend into the bedrock until some sufficiently permeable fracture zone is encountered, possibly at depths up to 100 m [22]. However, in some areas close to the WL site, sands and sandy till are present and it is possible to obtain a domestic water supply with a very shallow (5-10 m depth) dug well. Since the shallow supply well is conservative, a well depth of 6 m was assumed in this assessment.

The dose results generated from the DRL modelling demonstrate that the groundwater pathway is not of great importance for most radionuclides. However, for HTO, Tc-99 and Np-237, well water ingestion is one of the dominant pathways.

8.4.3 Pond Model

Although, in reality, ponds are fed by precipitation, groundwater and surface water inflows, only precipitation and groundwater inflow were included in the IMPACT pond model. This is conservative because uncontaminated surface water inflow flushes radioactivity from the pond.

The parameter values assumed for the small ponds that were assumed to provide drinking water for deer are listed in Table 8-3. These are the values suggested in N288.1 [2]. In the IMPACT default database, the value for the sediment dry bulk density was found to be incorrect and the database maintainers were notified of this error.

Table 8-3
Parameters Values used in the Pond Model

Parameter	Value
Effective Soil Porosity	0.2
Pond Surface Area (m^2)	5000
Pond Depth (m)	2
Horizontal Linear Groundwater Velocity (m s^{-1})	1.58E-7
Groundwater Inflow Rate to Pond (L s^{-1})	5.06E-3
Sediment Dry Bulk Density (kg m^{-3})	400

8.4.4 Wet Deposition Velocity

The calculation of the wet deposition velocity involves a term f_{pj}, which is defined as the fraction of the time that precipitation occurs when the wind blows from sector j. Precipitation data routinely collected by CNL at WL, in the past, is incomplete in that it does not include the contribution from snow. Therefore, the f_{pj} values were created using Environment Canada's meteorological data for the WL site for the period of 2004 May to 2009 April, inclusive (see Table 8-4).

Table 8-4
Values of f_{pj}

Sector	f_{pj} Value
N	0.087
NNE	0.114
NE	0.111
ENE	0.084
E	0.072
ESE	0.064
SE	0.061
SSE	0.04
S	0.047
SSW	0.047
SW	0.052
WSW	0.053
W	0.057
WNW	0.071
NW	0.065
NNW	0.061

The calculation of the wet deposition velocity also requires a value for the annual average precipitation (rain + snow). The value measured at WL for the period of 1971 to 2000 [25], 565 mm, was used.

8.4.5 Volatilization from Irrigation Water

The critical group associated with liquid releases was assumed to irrigate its backyard gardens and lawns with contaminated water. In the calculations, the size of the irrigated area was assumed to be 50 m by 50 m, which was intended to account for a front yard, a back yard and a large garden plot. In calculating air concentrations following volatilization of volatile radionuclides (HTO, C-14 and I-129), the receptor was placed on the contaminated field, implying continuous exposure to the re-emitted activity.

8.4.6 Absolute Humidity

Values of annual average absolute humidity, average absolute humidity over the snow-free period and average absolute humidity over the growing season are required for modelling HTO. For the WL area, the snow-free period is approximately from May 15 to November 15, and the growing season is estimated to be from June 1 to September 30. Based on Environment Canada data measured at the WL site between 2008 October 1 and 2009 September 30, the following humidity values were used: annual average absolute humidity 0.00541 L m^{-3}, average absolute humidity over the snow-free period 0.0085 L m^{-3}, and average absolute humidity over the growing season 0.0102 L m^{-3}.

8.4.7 External Dose Coefficients

There are two approaches to modelling the contributions of daughter radionuclides to the dose resulting from the release of a parent radionuclide to the environment. The preferred approach is to explicitly model the ingrowth of these daughters, their transfer through the environment and the resulting dose from them. A second approach which is simpler, but in certain cases less accurate, is to explicitly model the parent only and include the contributions to dose from the daughters in the dose coefficients (DCFs). IMPACT has been designed so that either approach can be used. For the current DRL calculations, the explicit approach was used. However, the external DCFs in the default IMPACT database include the contributions of daughters. Since there is a potential for errors when correcting the many external DCFs, and since the external doses are either much less than the ingestion doses or the contributions from the daughters to external doses are much less than those from the parent, the default external DCFs were used for the current calculations. This approach is slightly conservative.

8.4.8 Additional Changes to IMPACT Default Database

Table 8-5 shows changes to parameter values in the IMPACT default database that were made for the WL assessment and are not described elsewhere in this report.

Table 8-5
Other Parameter Values in the IMPACT Default Database that were Modified for the WL Calculations

Compartment	Parameter Name	Unit	IMPACT Default Database Value	Value Used in WL Model	Reference and Comment
Surface Water (River)	Partition coefficient for Np	$L\ kg^{-1}$	25	40	N288.1 Clause 7.8.2
Surface Water (Pond)	Partition coefficient for Np	$L\ kg^{-1}$	65	125	N288.1 Clause 6.6.2.2
Surface Water (Pond)	Net Precipitation Rate	$mm\ a^{-1}$	369	6	=WL precipitation rate – WL evapotranspiration rate, [26]
Groundwater (Well)	Rate of Infiltration to Aquifer	$m^3\ m^{-2}\ s^{-1}$	4.757E-9	4.043E-9	Assumed same as soil infiltration rate below, although N288.1 Clause 6.5.2.2 suggests that it can be lower than soil.
Soil	Infiltration Rate	$m^3\ m^{-2}\ s^{-1}$	1.142E-8	4.043E-9	= 0.5 (WL precipitation rate – 0.31) $m\ a^{-1}$, N288.1 Clause 6.3.6.3
Soil (link from water via air)	Annual Average Irrigation Rate	$L\ m^{-2}\ s^{-1}$	Not available	1.1E-5	N288.1 Clause 7.2.3.2.2
Terrestrial Plants	Fraction of Plant Carbon Derived from Air (all sources other than irrigation water)	-	1	0.7 or 1.0*	N288.1 Clauses 6.4.9.3 and 7.3.4.3
Sediment (River)	Partition coefficient for Np	$L\ kg^{-1}$	25	40	N288.1 Clause 7.8.2
Sediment (Pond)	Partition coefficient for Np	$L\ kg^{-1}$	65	125	N288.1 Clause 6.6.2.2
Dose	Fraction of Year Spent Swimming in a Surface Water Body (Beach Swimming)	-	0.014	0.011	Based on 3 months per year
Dose	Fraction of Year Spent Swimming in a Pool Filled with River Water	-	0.028	0.032	Based on 9 months per year
Full Simulation	Facility Life	years	Not available	57	When the 2010 DRLs were calculated, WL site had been in existence for 47 years (opened in 1963) and the DRLs were expected to be used for another 10 years.

* This value is set at 0.7 when calculating liquid effluent DRLs, but is set at 1 when calculating airborne effluent DRLs.

9. MODELLING SCENARIOS

9.1 General Discussion

In the 2016 DRL [1], a scenario file was set up using IMPACT [4]. A map covering the region of interest was imported into the model and calibrated to ensure the UTM coordinates were properly aligned. All effluent release locations and potential critical group locations were then entered into the model. Links between compartments were set up, including transfers between adjacent environmental compartments, and between the potential critical groups and their food supply locations. All site-specific and scenario-specific parameters needed by the pathways models were then incorporated.

Once the scenario file was finalized, eight sub-scenario files were created. Four of these were for screening calculations for airborne effluents. Two were for detailed calculations for airborne releases of all radionuclides, except HTO, one for each potentially bounding release location. Another was for detailed calculations of the release of HTO from B100. The final one was for detailed calculations for liquid effluents. For each combination of effluent type, radionuclide, critical group, age class and potentially bounding release location, calculations of dose rate per unit release were carried out by running IMPACT. The results were searched to identify the highest dose rates per unit release for each combination of effluent type and radionuclide among all age classes and potentially bounding release locations. These dose rates per unit release were then used to calculate the DRLs for each combination of effluent type and radionuclide. For each of these combinations, the dominant exposure pathway and its percent contribution to the dose rate were also determined.

In the current assessment, from the scenario files described above, the file corresponding to the WMA airborne releases was modified to include the release of HTO and to replace the release geometry of the compactor/baler with that of the ILLTS. The results of the analysis are presented in Section 11.

9.2 Scenarios for Airborne Effluent Modelling

Table 9-1 lists the UTM coordinates of the release locations and potential critical group locations considered in the analysis of airborne effluents.

Table 9-1
Release and Potential Critical Group Locations for Airborne Effluent Modelling

Location	Easting (m)	Northing (m)
Release		
Building 100 Stack	709,909	5,562,658
Building 200	709,928	5,562,834
Building 300	709,714	5,562,668
WMA Gate	711,322	5,564,260
Potential Critical Group		
Farm A	709,547	5,565,803
Farm D	710,067	5,559,924
Farm E	708,642	5,562,571
Farm F	708,783	5,565,288

The exposure pathways for the critical groups for airborne effluents are air inhalation, air immersion, water immersion, groundshine, soil ingestion, water ingestion, plant ingestion and ingestion of terrestrial animal products.

9.3 Scenario for Liquid Effluent Modelling

Table 9-2 lists the UTM coordinates of the release and critical group locations considered in the analysis of liquid effluents.

Table 9-2
Release and Critical Group Locations for Liquid Effluent Modelling

Location	Easting (m)	Northing (m)
Release		
WL Process Outfall	709,474	5,562,997
Critical Group		
Farm A	709,547	5,565,803

The exposure pathways for the critical group for liquid effluents are air inhalation, air immersion, water immersion, groundshine, soil and sediment ingestion, water ingestion, plant ingestion, ingestion of terrestrial animal products, fish ingestion and beach shine.

10. SCREENING CALCULATIONS FOR AIRBORNE EFFLUENTS

10.1 Potential Critical Groups and Release Locations

As in the 2016 DRL [1], screening calculations for airborne effluents were performed to reduce the number of combinations of potential critical groups and release locations for which detailed dose calculations were required.

In view of the similar nature of the potential critical groups, the screening was based on:

1. The predicted annual-average air concentrations at each group location, resulting from a unit release of each radionuclide at a release location. Concentrations at Farm E were multiplied by a factor of 0.08 to account for the fact that it has limited occupancy (672 hrs per year).
2. The predicted annual-average soil concentration at each group location, resulting from a unit release of each radionuclide at a release location, except for C-14 and HTO, for which doses do not depend on soil concentration. Concentrations at Farm E were multiplied by a factor of 0.08 to account for the limited occupancy.

Table 10-1 shows the predicted air concentrations for a subset of the radionuclides released, along with the predicted air concentrations of their daughters. Predictions for all released radionuclides having daughters are included to illustrate the differing effects of ingrowth for different combinations of potential critical groups and release locations. Also included in Table 10-1 are predictions for the slowest- and fastest-decaying released radionuclides that have no daughters, I-129 and Zn-65. Predictions for HTO, which was previously released from B100 only, now includes separate predictions for HTO released from the WMA. The highest concentrations for each radionuclide are indicated by yellow shading.

Even though the air concentrations in the WMA have increased by approximately 2% for all radionuclides, the release location and critical group corresponding to the highest concentration for each radionuclide remain the same as in the 2016 DRL [1]. For all radionuclides, except Pu-239dd (second daughter of released radionuclide Am-243) and HTO (released from both B100 and the WMA), the highest predicted air concentrations are for the combination of Farm A and release from B200. For Pu-239dd, the air concentration is also highest at Farm A, but in this case in combination with release from B300. However, the air concentrations of Pu-239dd are ten orders of magnitude lower than those of its parent, Am-243, so the dose contribution from Pu-239dd will be negligible compared to that of Am-243 and it need not be considered further. Although Farm E is the potential critical group closest to release locations B100, B200 and B300, it has limited occupancy and is not located in one of the high-frequency wind-direction sectors relative to them (Figure 1-2, Figure 6-2 and Figure 6-3). Therefore, the scaled predicted air concentrations at this group location are lower than the concentrations at other group locations. Although the WMA is closer to Farm A than B200 is, the WMA is not the bounding release location for air concentrations because Farm A is in a low-frequency wind-direction sector relative to the WMA (Figure 1-2 and Figure 6-2).

For HTO released from the WMA, the air concentration is also highest at Farm A, but in this case in combination with release from the WMA. This is because HTO is only released from B100 and the WMA, and each case was treated individually to allow for separate DRLs. For HTO released from the B100, the highest predicted air concentration is at Farm F, not at Farm A. This is because releases from B100 were assumed to be driven by the meteorological conditions typical of a height of 25 m, whereas releases from the other locations were assumed to be driven by the meteorological conditions typical of a height of 6 m. The meteorological conditions at these two heights differ significantly (Figure 1-2 and Figure 6-2).

Table 10-1
Predicted Air Concentrations (Bq m^{-3}) at Potential Critical Group Locations as a Result of the Unit Release of Radionuclide (1 Bq s^{-1}) to the Atmosphere at a Release Location

Radionuclide	Release from B100				Release from B200				Release from B300				Release from WMA**

* The values listed for Farm E are the predicted concentrations multiplied by a factor of 0.08 to account for the limited occupancy.

** The predicted air concentrations for releases from the WMA are revised values from the 2016 DRL [1].

† Separate HTO DRLs are required for B100 and the WMA, thus, both are shaded yellow.

Table 10-2 shows the predicted soil concentrations for a subset of the radionuclides released (except for C-14 and HTO), along with the predicted soil concentrations of their daughters. The highest concentrations for each radionuclide are indicated by yellow shading.

Even though the soil concentrations in the WMA have increased by approximately 2% for all radionuclides, the release location and critical group corresponding to the highest concentration for each radionuclide remain the same as in the 2016 DRL [1]. The highest predicted soil concentrations are for the combination of Farm A and release from the WMA for all parent radionuclides, except I-129. Farm A also has the highest predicted air concentrations, but the release location resulting in the highest air concentrations is different (B200). The difference is because precipitation occurs more frequently when the wind is blowing toward Farm A from the WMA than when it is blowing from B200 (see Figure 1-2 and Table 8-4), with the net result being more wet deposition and higher soil concentrations, even though the air concentrations are lower.

For I-129, the highest predicted soil concentration is for the same combination as the highest predicted air concentration (Farm A and B200). This is because, for I-129, wet deposition is less significant than dry deposition, whereas the opposite is true for the other radionuclides of interest. The washout ratio for I-129 is much lower than that for the other radionuclides (1.6e5 vs 5.5e6), and the dry deposition velocity for I-129 is higher (7.5e-3 m s^{-1} vs. 1.4E-3 m s^{-1}).

For many of the daughter radionuclides, the highest predicted soil concentrations are for the combination of Farm A and release from B300. However, the soil concentrations of the daughters are several orders of magnitude lower than those of the parents, so they can be ignored.

In summary, based on the results of the screening calculations in the 2016 DRL [1], detailed dose calculations were required for only three combinations of potential critical group and release locations: Farm F and B100 for HTO, Farm A and B200 for radionuclides other than HTO, and Farm A and the WMA for radionuclides other than HTO. However, based on the results of the current screening calculations, detailed dose calculations need to be revised for the combination of Farm A and the WMA (using the ILLTS geometry) for all radionuclides with the addition of HTO.

Table 10-2
Predicted Soil Concentrations (Bq kg^{-1}dw) at Potential Critical Group Locations as a Result of the Unit Release of Radionuclide (1 Bq s^{-1}) to the Atmosphere at a Release Location

Radionuclide	Release from B100				Release from B200				Release from B300				Release from WMA

* The values listed for Farm E are the predicted concentrations multiplied by a factor of 0.08 to account for the limited occupancy.

11. DRL RESULTS

For each effluent type, the DRL for a given radionuclide was calculated from:

$$DRL_i = \frac{DL_{eff}}{D_i} \quad (2)$$

where: DRL_i is the derived release limit for radionuclide i (Bq s^{-1}), DL_{eff} is the annual effective dose limit for members of the public (0.001 Sv a^{-1}), D_i is the dose rate per unit release rate ((Sv a^{-1})/(Bq s^{-1})) for radionuclide i, summed over all applicable exposure pathways, for the age class leading to the highest dose.

The calculated DRLs for each radionuclide are summarized in Table 11-1 and Table 11-2 for airborne and liquid effluents, respectively. For airborne effluents, the DRLs are expressed on a weekly basis and for liquid effluents they are expressed on a monthly basis. The tables also provide information on the bounding age classes, the dominant exposure pathways and the percent contributions from the dominant pathways to the total dose rates.

Table 11-1

FI: fish (ingestion)

For airborne effluents, B200 is the bounding release location for sixteen of the thirty radionuclides. The WMA is the bounding release location for all others, except for HTO, released from B100. The adult is the bounding age class for eleven radionuclides, with air inhalation being the dominant pathway for seven of these. For all other radionuclides, except one, infant age classes are bounding with ingestion of terrestrial animal products and mother's milk being the dominant pathway for half of these.

For liquid effluents, there are no changes from the 2016 DRLs [1]. The 3-month-old formula-milk-drinking infant is the bounding age class for twenty-three radionuclides, with water ingestion being the dominant pathway for seventeen of these and groundshine being the dominant pathway for the remainder.

12. VERIFICATION

In the 2016 DRL [1], the analysis assumptions, the selection of input parameter values, the contents of IMPACT code input files and the determination of DRLs were verified in several ways. Draft assumptions and the selection of some key input parameter values were reviewed by appropriate CNL staff prior to the start of calculations. As the DRL results were generated, those for selected radionuclides (C-14, Co-60, Cs-134, Cs-137 (Ba-137m), HTO (OBT), I-129, Pu-239, Sr-90 (Y-90) and Ce-144 (Pr-144)) were checked using the independent code CSA-DRL. Finally, the assumptions, input files and calculated DRLs were independently verified through a comprehensive internal CNL review [27].

The initial checking using the CSA-DRL code did not identify any problems with the results generated using the IMPACT code. The final CNL verification identified two errors with the selection of input parameter values, one of which was significant. This review also identified one minor transcription error in the input files. These errors were subsequently corrected.

Subsequently, it was realized by the authors that there was an error in the screening calculations. This was corrected, although it did not significantly change the results.

In the current assessment, all the changes relating to the airborne effluent DRL calculations were made by Sohan Chouhan and independently verified by Bruce Reavie and Lisa Campagna [28] to ensure that they were successfully transcribed into the IMPACT code [4]. Compilations of the IMPACT results into the summary DRLs were also verified.

13. COMPARISON OF REVISED DRLS WITH PREVIOUS VALUES

The revised DRLs have been compared with those established in 2016 [1]. Reasons for the differences were mentioned briefly in Section 1 and 6 of this report.

In summary, for 12 radionuclides from airborne effluents, the revised DRLs are approximately 2% lower than the 2016 DRLs [1]. For one radionuclide (Zn-65), the bounding release location changed from B200 to the WMA and the magnitude of the DRL was lowered by 1%. The main reason for the decreases in the DRLs is the introduction of the three new systems (SWRS, BWRS/SCU and ILLTS) in the WMA, which resulted in lowering the effective release height. A new DRL was added for HTO released from the WMA (5.61E+14 Bq week^{-1}) and the previous DRL for HTO released from B100 (1.65E+15 Bq week $^{-1}$) [1] is still valid. The reason for this addition is the release of HTO from one or more of the three new systems in the WMA.

There is no change to the liquid effluent DRLs.

EXECUTIVE SUMMARY

This annual compliance monitoring report for the 2019 calendar year has been prepared as per licence condition 3.2 of the Whiteshell Laboratories (WL) Licence NRTEDL-W5-8.00/2024 and CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills* as a summary report of annual compliance monitoring and operational performance.

This annual compliance report provides Canadian Nuclear Laboratories (CNL) 2019 performance data for WL and is organized by 14 Safety and Control Areas (SCAs)[1], as well as a report on each of the WL nuclear and non-nuclear facilities.

The following provides overall performance highlights for 2019 activities:

- There were no serious process failures at WL.
- All licensed activities continued to be carried out safely and securely.
- No member of the public received a radiation dose that exceeded any regulatory limit.
- No worker at WL received a dose in excess of any of the respective radiation dose limits for radiation workers, as defined in the Radiation Protection Regulations.
- All releases of radioactive material in WL effluents during 2019 were below their respective derived release limits.
- Significant progress was made on decommissioning of Building 200, the former Active Liquid Waste Treatment Centre.
- The RD-14M (Building 300, Stage 6) and Large-Scale Vented Combustion test facilities were decommissioned and demolished.
- The WL site licence was successfully renewed for five years, effective 2020 January 01.

Below is a summary of the annual compliance report for calendar year 2019.

- **SCA - Management System:** WL has continued its focus on implementation of the corporate management system, as well as the WL Quality Assurance program for decommissioning, based on Canadian Standards Association (CSA) N286.6 and aligned with CSA N286-12, monitored through many means including audits, inspections, self-assessments and program/management system reviews.
- **SCA - Human Performance Management:** WL initiated a “Pay it Forward Parking” initiative to recognize the outstanding work that goes on in the workplace, promoting CNL’s Safety Culture and use of Event Free Tools, and recognizing those who go above and beyond their normal duties.
- **SCA - Operating Performance:** WL decommissions and operates its facilities according to prescribed programs and procedures, and monitors safety performance in the operational area through the concept of “events”. The total number of internal event reports raised continues to show a strong reporting culture. There was one Canadian Nuclear Safety Commission (CNSC) reportable event.

[1] The CNSC evaluates how well licensees meet regulatory requirements and CNSC expectations for the performance of programs in 14 safety and control areas.

- **SCA - Safety Analysis:** Effective Safety Analysis Reports and Facility Authorizations continue to be in place for WL's nuclear facilities, helping meet health, safety, security, environmental and regulatory requirements.
- **SCA - Physical Design:** The Certificate of Authorization was renewed with Engineers Geoscientists Manitoba, authorizing CNL to engage in the practice of professional engineering in Manitoba.
- **SCA - Fitness for Service:** The Periodic Inspection Plan (PIP), previously developed to confirm the ongoing fitness-for-service of the concrete storage facilities at the Waste Management Area (WMA), continued implementation with no significant issues identified. The PIP was revised to address some changes. Regular preventative or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service.
- **SCA - Radiation Protection:** No worker received a whole-body dose (including committed) in excess of any of the respective dose limits for radiation workers as defined in the Radiation Protection Regulations, and average individual doses remain a small fraction of these limits. Maximum dose to a person working at WL was 3.1 mSv and collective doses remained below 50 person-mSv (49.6 person-mSv) for 2019. Members of the public received no measureable radiation doses. The Controlled Area reduction initiative was completed for the WL site north side.
- **SCA - Conventional Health and Safety:** Implementation of CNL's Occupational Safety and Health program at WL continues to drive improvements in safety and safety culture, resulting in no lost time injuries in 2019.
- **SCA - Environmental Protection:** The results of the radiological and non-radiological effluent monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment. Radiological emmissions were 0.00023% of the Derived Release Limit (DRL) for air emissions and 0.93% of the DRL for liquids. The monitoring program confirms that the WL site is operating in a manner that protects workers, the public, and the environment. WL maintained their ISO-14001 registration, and are compliant to a number of CSA environmental standards.
- **SCA - Emergency Management and Fire Protection**: The Emergency Management program at WL was focussed on supporting the establshment of a Tiered Response Force (TRF). For the Fire Protection program, a fire response needs analysis was completed.
- **SCA - Waste Management:** WL continued to reuse or recycle as much material as was practicable. Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects, including disposition of 1,511 m^3 of radioactive waste to CRL, and 410 m^3 (804,170 kg) of recycled waste shipped off-site.
- **SCA – Security:** The Security Program at WL supports the CNL Corporate Security mandate and addresses the regulatory requirements for security. Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers as required by the CNSC. As a result of a CNSC Order, an implementation plan addressing the Order was accepted by the CNSC, and includes the standing up of a Tiered Response Force, for which training has commenced. A "Force-on-Force" security training exercise under direct CNSC Staff observation was successfully completed.

- **SCA - Safeguards:** There were no issues identified with International Atomic Energy Agency (IAEA) Safeguards inspections conducted at WL. One internal verification inspection was conducted with no recordable findings.
- **SCA - Packaging and Transport:** There was approximately 1,483 m³ of low-level waste and 28 m³ of intermediate-level waste safely shipped to Chalk River Laboratories (CRL).
- **Other matters of regulatory interest:** Two meetings of the WL Public Liaison Committee took place, an Open House was held attracting approximately 300 visitors, and numerous public information sessions and Indigenous engagements were held on the Whiteshell Reactor 1 (WR-1) in-situ decommissioning and overall activities of the WL Closure Project. A traditional Indigenous ceremony with Sagkeeng First Nation and Turtle Lodge was held on site.
- **Facilities** (operating nuclear facilities, permanently shutdown facilities, facilities being decommissioned and the non-nuclear facilities): All the licensed activities in these facilities continue to be carried out safely and securely with acceptable radiation doses to personnel and releases to the environment. The following notable facility-specific activities took place: significant progress in decommissioning the Active Liquid Waste Treatment Centre, Building 200; two significant former experimental facilities, RD-14M and the Large-Scale Vented Combustion Test Facilty, were decommissioned and demolished; at the Waste Management Area (WMA) the old Protected Area fence that enclosed the standpipes area alone was removed, and the Soil Storage Compound was emptied of stored soil bags, with the waste packaged and shipped off site; and commenced decommissioning of the Containment Test Facility (B303) and Waste Clearance Facility (B304).

CNL is committed to achieving high standards of operational safety and security. The information and data presented in the report support the conclusion that safe and secure performance is being achieved at the Whiteshell Laboratories (WL) site, while enhancements are being implemented to further improve results.

ACKNOWLEDGEMENT

The “Author” of this document would like to thank the many WL authors and reviewers from Facilities and Program for their production of the individual sections of the report.

0. INTRODUCTION

Whiteshell Laboratories (WL) was established by Atomic Energy of Canada Limited (AECL) in the early 1960s to carry out nuclear research and development activities. The site is a Class 1B nuclear facility which encompasses an area of 4,375 hectares. The WL site is located near Pinawa, Manitoba; approximately 100 kilometres northeast of Winnipeg, on the east bank of the Winnipeg River. AECL made a business decision in 1997 to discontinue most of the research programs and operations at WL. Subsequently, AECL received government concurrence in 1998 to proceed with actions to achieve closure of WL.

In 2014, Canadian Nuclear Laboratories (CNL) Ltd. was created as a wholly owned subsidiary of AECL. Implementation of the Government-Owned, Contractor-Operated model was achieved with share transfer of CNL from AECL to Canadian National Energy Alliance (CNEA) in 2015 September.

Activities are now underway to complete the orderly decommissioning of the WL site, following the general plan laid out in the Comprehensive Study Report supporting the approval of the Environmental Assessment of the WL Decommissioning Project. The exception to this is the change in strategy for Whiteshell Reactor (WR) -1 (see Section 0.5).

0.1 Site/Facility Name, Location & Ownership

Name: Whiteshell Laboratories (WL)

Location: 1 Ara Mooradian Way
Pinawa, Manitoba
R0E 1L0

0.2 Licence Information and Reporting Period

This annual compliance monitoring report is produced to comply with licence condition 3.2 of the Whiteshell Laboratories (WL) Licence NRTEDL-W5-8.00/2024 [1], in accordance with the compliance verification criteria Compliance Monitoring: Annual Report of the *Licence Conditions Handbook* for Whiteshell Laboratories (WL), herein referred to as “Licence Conditions Handbook” [2]., and Section 3 Annual Compliance Monitoring Report of CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills* [3]. Information included in this report is for the period of 2019 January 01 to December 31.

This report provides site-specific information to supplement information in *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4], which provides corporate updates to 14 Safety and Control Areas as they are applied across all CNL sites.

The intent of this report is to provide sufficient detail to demonstrate how WL programs are meeting the regulatory requirements as it pertains to the licence [1] and *Licence Conditions Handbook for* Whiteshell Laboratories (WL) [2].

0.3 Facilities Included in this Report

Appendices A through G of the report provide information that is pertinent to the Nuclear and Non-Nuclear Facilities (including operating and permanently shut down facilities, and facilities being decommissioned).

The Nuclear Facilities are: Concrete Canister Storage Facility, Active Liquid Waste Treatment Center, Shielded Facilities, Waste Management Area, Research and Development Facilities Complex (Building 300), Health and Safety Facilities (Building 402 and B305), and WR-1 Reactor.

0.4 Summary of Licenced Activities

There are no new licenced activities. The WL Site Licence was successfully renewed in 2019 for five years, effective 2020 January 01.

0.5 Site Development, Investment and/or Decommissioning Strategies

As discussed in 2015, work is underway to complete decommissioning of the entire WL site (current schedule is to be complete in 2027). This includes leaving in-situ the selected Waste Management Area (WMA) trenches as per the Comprehensive Study Report under institutional control, and transporting active waste off-site for disposal or storage. A significant departure from the end-states defined in the Comprehensive Study Report is in situ decommissioning (also referred to as in situ disposal) of the WR-1 reactor. Work continues for an environmental assessment and regulatory approvals required for this change. The Environmental Impact Statement supporting this is in progress.

0.6 Financial Guarantees

CNSC was previously sent a letter from the Honorable G. Rickford [5], advising that as an agent of Her Majesty in Right of Canada, AECL’s liabilities associated with the decommissioning of WL are ultimately liabilities of Her Majesty in Right of Canada (note: AECL retains ownership of the lands, assets and liabilities associated with CNL's licences). This financial guarantee is mpt time limited, thus remains valid and in effect.

1. MANAGEMENT SYSTEM

1.1 Management System Program

Whiteshell Laboratories (WL) adheres to the Corporate Management System. See Section 1 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL Quality Assurance Plan [6] supports the CNL Management System Manual [7] and summarizes the processes and practices applicable to WL licensed activities, while still retaining compliance to CSA N286-12 [8] and N286.6-98 [9].

1.1.1 Updates to Management System Documents

The Canadian Nuclear Safety Commission (CNSC) has previously been notified of revisions to the Quality Assurance Plans and/or other high level documents, as per the *Licence Conditions Handbook* [2]. There were no updates specific to WL in 2019.

1.2 Audits and Inspections

See Section 1.2 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4] for a list of all CNL External Audits for the reporting year 2019.

As per the requirements of the Management System [7], both Safety Control Areas (SCA's) and Facilities conduct various self-assessments to ensure that the management system is functioning in according to expectations and that any policy, programmatic, or procedural deficiencies are identified and appropriate action taken to resolve any deficiencies.

One audit was conducted at WL in 2019:

- SAI Global audit on WL Environmental Management System to ISO 14001:2015 – This audit identified six opportunities for improvement which resulted in six actions. Five actions have been completed and one is in progress, none of the actions are overdue.

All actions resulting from audits, inspections, reviews and self-assessments are being managed and tracked through CNL's Corrective Action Program (CAP).

1.2.1 Internal Quality Audits

There were no internal audits completed by the Quality Audits and Processes branch specific to WL in 2019.

1.2.2 Inspections

1.2.2.1 CNSC Inspections

The following CNSC Inspections were conducted at **Whiteshell Laboratories (WL)**.

Table 1: CNSC Inspections for 2019

Inspection No.	Date	Area Inspected	No. of Actions Notices	No. of Actions in Progress
CNL-WL-2019-01	June 06-07	Packaging and Transport Program	2	1
CNL-WL-2019-02	August 06-08	Emergency Management and Fire Protection Programs	2	3
WL-SEC-19-T2-001	August 26-28	Security	1	n/a

Two Type II Compliance inspections were conducted at WL by CNSC staff in 2019. The first compliance based inspection, focussed on Packaging and Transport program, had two Action Notices (ensure procedure for shipping and receiving is up to date and ensure the status of re-useable packages is clearly labelled and easily identified) and two recommendations. Four actions were raised. Three actions are closed, one is open, and none are overdue. The second compliance based inspection, focussed on the Emergency Management and Fire Protection programs, resulted in two Action Notices (ensure SCBA[2] cylinders are marked, purged, and refilled on an annual basis and repair a damaged fire door), and four recommendations. Four actions were raised. One action is closed, three are open, and none are overdue. The CNSC has closed all Action Notices from both compliance inspections.

A Type II Security inspection was also conducted, and is discussed in Section 12.

1.2.2.2 Inspections by Other Regulatory Bodies

A Design Information Verification inspection was carried out by the International Atomic Energy Agency (IAEA) on 2019 September 06. This inspection verified the information provided in the Design Information Questionnaire (DIQ). The IAEA requested that the DIQ be updated to reflect the changes to the WMA fence line and new buildings.

Transport Canada conducted an Transport of Dangerous Goods (TDG) inspection at WL in 2019 and noted four non-conformances (missing parentheses of subsidiary class for a shipment of Chlorine, inconsistent wording with the consignor's declaration as specified by the IAEA Safe Transport paragraph 547 on WL's bill of lading, proof of classification not clearly demonstrated on documentation and incorrect label category applied based on a package's transport index) and three recommendations. Four actions were raised. All actions are closed and resolved.

[2] SCBA - Self-Contained Breathing Apparatus

1.3 Management Reviews

A WL Quality Assurance Program/Management System Review was completed for 2017/18 to evaluate the effectiveness of the management system. The review identified one action, which is complete. The 2018/19 review has been initiated.

2. HUMAN PERFORMANCE MANAGEMENT

2.1 Human Performance Program

Whiteshell Laboratories (WL) adheres to the Corporate Human Performance Program. See Section 2 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The effectiveness of the CNL's Human Performance Program (HU) has been enhanced through the following improvement:

"Pay it Forward Parking" Initiative: WL participates in a program called "Pay it Forward Parking" that provides a prime parking spot for an individual for one month. Created in an effort to recognize the outstanding work that goes on in WL's workplace, HU is working towards recognizing employees who promote CNL's Safety Culture, use the Event Free Tools, as well as those who go above and beyond their normal duties.

2.2 Training program

2.2.1 Required Training

All WL personnel, both employees and contractors are adequately trained (and refreshed) to ensure safe operation of their facilities and to conduct work at WL. Table 2 summarizes training completed by WL operational employees during 2019.

The WL training plans are consistent with CNL's corporate training policies and programs. Employee training plans are based on CNL policies, according to position specific requirement and Managers discretion.

Table 2: WL Operating Staff Training in 2019

Course Code	Course Title	No. of Attendees
OSH-1001	Crane (Safe Indoor Hoist) – Theory	2
OSH-1002	Lift Truck Operation – Theory	2
OSH-1003	Aerial Platform – Theory (R3)	11
OSH-1004	Lock Out / Tag Out	110
OSH-1005	Working at Heights	89
OSH-1007	Asbestos Module 6E	22
OSH-3001-A	Crane (Safe Indoor Hoist) – Generic Practical	2
OSH-3002-A	Lift Truck Operation – Generic Practical	2
OSH-3003	Aerial Platform – Generic Practical	5
ODT-577	Employee Orientation – WL	11
HU-1038	Human Performance Awareness – Fundamentals & Nuclear Safety Culture	6
HU-2001	Human Performance and Event Free Tools Line Led Refresher	6
HU-1036-Online	Pre job Brief	17

3. OPERATING PERFORMANCE

3.1 Operating Program

Whiteshell Laboratories (WL) adheres to the Corporate Operating and Decommissioning Programs. See Section 3.1 and Section 11.2 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Whiteshell Laboratories decommissions and operates its facilities according to prescribed programs and procedures. Operating performance is monitored through the nuclear performance assurance review and other internal assessment activities such as self-assessments and audits (see Section 1.2).

3.1.1 Operations / Decommissioning Operations

Operational details on facilities identified in the *Site Licences, Certificates, Permits, Building/Facility Contacts, and Licence Representatives* [10] for WL are given in Appendix A through Appendix F.

3.1.1.1 Conduct of Operations

Conduct of operations documents ensure appropriate integration and adequate reflection of safe operation practices to meet the business requirements.

3.1.1.2 Modification to Facilities and Processes

All temporary and permanent modifications to facilities at WL are made following defined Engineering Change Control [11] processes.

Relevant modifications to WL facilities are given in Appendix A through Appendix G.

3.2 Reporting Requirements

3.2.1 Reportable Events

In 2019, there was one event that occurred at WL that was deemed reportable to the CNSC. It is listed in Table 3.

Table 3: Reportable Events (CNSC) at WL in 2019

Event No.	Title	SCA	Facility (if applicable)
P&NO-19-0177	Security Equipment Malfunction	Security	WL Waste Management Area

A summary of events reportable to CNSC staff for 2019 and the previous four years by significance level are provided in Table 4.

Table 4: Total of WL Reportable Events by Significance Level – Five Year Summary

Year	Level 1	Level 2	Level 3	Level 4	Total
2015	0	0	0	0	0
2016	0	0	4	1	5
2017	0	0	3	1	4
2018	0	0	0	0	0
2019	0	0	1	0	1

Table 5 provides a summary, comparing the total number of reportable events categorized as Nuclear Facility, Health, Safety, Security, Environment and Quality (HSSE&Q) Program, and Other, for the years 2015 through 2019. The Improvement Action (ImpAct[3]) number and event title of all WL reportable events is provided in Table 3.

Table 5: Total Number of WL Reportable Events Categorized by Nuclear Facility, Program and Other

	Nuclear Facility	HSSE Program	Other	Total
Reportable Events in 2015	0	0	0	0
Reportable Events in 2016	1	4	0	5
Reportable Events in 2017	1	3	0	4
Reportable Events in 2018	0	0	0	0
Reportable Events in 2019	0	1	0	1

Reports to other regulatory agencies consisted of one Hazardous Occurrence Investigation Report (HOIR) made to Employment and Social Development Canada (see Section 8 Conventional Health and Safety for further details) and two reports made to Environment and Climate Change Canada / Manitoba Sustainable Development (see Section 9 Environmental Protection for further details).

3.2.2 Trending of Events Related to Operational Activities

As events at WL occur, they are recorded in the ImpAct system. This information is regularly reviewed to identify any trends.

The use of the ImpAct process continues to foster the internal reporting of lower significance level events (Level 4 and some Level 3), affording the opportunity to implement continuous improvement initiatives through a robust Corrective Action Program.

[3] ImpAct – Abbreviation for Improvement and Action. It is an internal process used to identify events, problems, non-conformities, opportunities for improvements, and personnel injuries. The process also identifies and tracks actions to correct or remediate problems.

In 2019, a total of 609 ImpActs were raised by CNL employees at WL (report is based on responsible department). The total number of events categorized by significance level for 2019 and the previous four years is provided in Table 6. There was an increase this year, and is within the normal variation expected year-to-year. The level of reporting is indicative of a strong reporting culture, with better quality ImpActs being raised due to the maturity of the organization.

The reporting of lower significance level events continues to be encouraged (e.g., Near Miss Reporting – see Section 8, which is an industry best practice), and efforts to improve safety culture (Event Free Tools use, Event Free Day Reset, Observation and Coaching, etc.) have been adopted by both management and staff.

Table 6: Number of ImpActs raised at WL

Year	Level 0[a]	Level 1	Level 2	Level 3	Level 4	Total
2015	12	0	3	44	577	636
2016	9	0	1	25	491	526
2017	5	0	0	42	448	496
2018	10	0	0	39	532	581
2019	8	0	0	54	547	609

a Level 0 will be assigned if the ImpAct is deemed to be a “non - problem” and a recommendation to close the ImpAct will be given.

4. SAFETY ANALYSIS

4.1 Safety Analysis Program

Whiteshell Laboratories (WL) adheres to the Corporate Safety Analysis Program. See Section 4.1 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

4.1.1 Safety Analysis Reports

Safety Analysis Reports (SARs) are produced to demonstrate that the facilities are appropriately designed to meet health, safety, security, environmental and regulatory requirements, and operated safely. These SARs form part of the basis for a set of limiting conditions for safe operation that are documented within Facility Authorizations for each nuclear facility. At WL, four facilities have SARs and Facility Authorizations: Shielded Facilities (SF), Waste Management Area (WMA), Concrete Canister Storage Facility (CCSF), and Active Liquid Waste Treatment Centre (ALWTC). There were no changes to the SARs in 2019.

The ALWTC is undergoing decommissioning. During this process, hazards addressed in the SAR, including safety-related systems that are no longer needed, will be removed. The ALWTC SAR and Facility Authorization documents will be obsoleted once decommissioning of the ALWTC is complete.

A SAR is being developed for the standpipe/bunker remediation, Intermediate Level Liquid Waste (ILLW) Processing System and use of the Shielded Modular Above Ground Storage (SMAGS) building for cask loading/testing. This document will be an addendum to the existing WMA SAR and will be submitted to the CNSC for acceptance, before these facilities are operated.

4.2 Nuclear Criticality Safety Program

Whiteshell Laboratories (WL) adheres to the Corporate Nuclear Criticality Program. See Section 4.2 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The effectiveness of the Nuclear Criticality Safety (NCS) program was enhanced by:

- Continuing to provide technical and regulatory site-wide support to various CNL groups to improve and strengthen the Program processes.
- Holding semi-annual meetings with CNSC staff, to provide updates on the status of the NCS program.

4.2.1 Nuclear Criticality Safety Documents

The WL Criticality Safety Documents (CSD) for the CCSF (CSD-11), the WMA (CSD-27), and the SMAGS Building (CSD-73) were updated and acceptance was granted by the CNL's Nuclear Criticality Safety Panel. Note that the SMAGS Building CSD was previously included in the WMA CSD (CSD-27). The CNSC has previously been notified of revisions to these *Criticality Safety Documents* [12] and [13], as per the *Licence Condition Handbook* [2].

5. PHYSICAL DESIGN

5.1 Design Program

Whiteshell Laboratories (WL) adheres to the Corporate Design Program. See Section 5.1 of *CNL Annual Compliance Monitoring Report for 2019* for details [4].

In 2019 March, a Certificate of Authorization was renewed with Engineers Geoscientists Manitoba. This authorizes CNL to engage in the practice of professional engineering in the province of Manitoba in accordance with the provisions of The Engineering and Geoscientific Professions Act.

5.1.1 Safety Related Structures Systems and Components

Any changes affecting safety related Safety Related Structures at WL were controlled through the Engineering Change Control Process [11].

5.2 Pressure Boundary Program

Whiteshell Laboratories (WL) adheres to the Corporate Pressure Boundary Program. See Section 5.2 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The *WL Pressure* B*oundary Quality Assurance (QA) Manual* [14] defines the pressure boundary measures applicable to WL facilities and is consistent with CNL's PB Program requirements.

The *Pressure Boundary Quality Assurance Manual* [14] was previously accepted by Inspection and Technical Services Manitoba. A Certificate of Authorization permits CNL to perform Pressure Boundary work as described in the Quality Assurance Manual until expiry in 2021 March.

6. FITNESS FOR SERVICE

6.1 Fitness for Service Program

The Site and Nuclear Operations Branch provides monitoring and operation of building's, processes and support systems. Housekeeping inspections are performed monthly to provide a formal walkthrough of facilities to ensure compliance for specific areas relating to facility performance. Further inspections are conducted of waste storage structures by qualified personnel to maintain them in a fit for service state.

Operating procedures reviews are conducted on a five year cycle. As facilities are decommissioned procedures are obsoleted. Procedures to operate the facilities in order to enable decommissioning efforts are prepared as required.

Details on various inspection and maintenance activities are provided in the following sub sections.

6.1.1 Planned Maintenance, Testing & Inspections

As part of Fitness for Service WL staff ensure that critical systems, structures and components related to the safe decommissioning of WL are understood and that activities are put in place to assure their safe continued operation as they age. An integrated set of programs and activities that ensure that performance requirements for all critical systems, structures and components are met on an ongoing basis. These processes include:

- Maintenance, In-Service Inspection and Functional Testing, where preventive maintenance work done in the facilities is tracked to ensure it is completed.
- WL operational regulatory tasks are tracked on a weekly basis to ensure required compliance and facility checks are completed, this includes the tasks set out in the Facility Authorization documents.
- Inspections required to meet the conditions of WR-1 Monitoring and Surveillance Plan.
- Inspections of waste storage structures for fitness for service.

6.1.2 Equipment Fitness for Service/Equipment Performance

Preventive maintenance of safety-related systems in WL's nuclear facilities is carried out by qualified maintainers, in accordance with the facility's Facility Maintenance Plan, and approved maintenance procedures. Preventive Maintenance is defined as the pre-planned routine testing, calibration, inspection, service, and overhaul of safety-related systems, structures, and components. Preventive maintenance is performed to prevent failures from occurring and to assure the continuing capability of the system, structure or component to perform its design function. The maintenance tasks and frequencies specified in the Facility Maintenance Plan are based on recommendations from qualified WL engineering and maintenance personnel, plus vendor's data where available. Situations where there is evidence of deteriorating conditions or suggestions of an increased probability of upcoming failure are addressed as they are identified. Regular preventive or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service. Maintenance scheduling is conducted with assistance of a Computerized Maintenance Management System which outputs preventive maintenance tasks for scheduling by maintenance and work planning staff.

6.1.3 Condition of Structures

Waste storage structures include the WMA bunkers and CCSF concrete canisters.

As a requirement of the Environmental Assessment Follow-up Program, a Periodic Inspection Plan (PIP) for WL Concrete Bunkers [15] has been developed and implemented to confirm the ongoing fitness-for-service of the concrete storage facilities (termed “bunkers”) at the WMA. The PIP describes methods for conducting scheduled inspection surveys of these structures. The inspection is defined as examination, measurement and testing work done to ensure the bunker systems are functioning as designed and the bunkers remain fit-for-service. The inspections are documented annually, with preventive maintenance and repairs occurring as needed. As the bunkers at the WMA are removed from service as part of the overall decommissioning of the WL site they will be removed from the inspection process. The annual inspection of WL WMA concrete bunkers was conducted in accordance with the PIP [15]. In 2019 the PIP was updated to account for a reduction in the well water chemistry measurements from spring and fall to spring only. The reduction was acceptable due to the stability of the measurements.

Although the SMAGS building is not a bunker it is included in the bunker inspection. A repair, conducted in 2016, to the north wall of SMAGS that extended into the core of the slab, remained stable through 2019 with no new crack expressions (the walls of SMAGS are pre-cast concrete slabs). All other repair items for the bunkers and SMAGS were minor in nature and were tracked through the WL work request system.

The concrete canisters are inspected quarterly for concrete spalls and any changes in the hairline cracks of the concrete. In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however, existing cracks and pour pockets were regularly checked for changes. Only minor patching was conducted in 2019. No increased field was noted. There was no degradation of the exposed metallic portions of the canisters. Note: no concrete canisters were opened in 2019

Environmental monitoring is conducted in the ditches at the perimeters of the WMA and the CCSF and show no evidence that any activity has been released from the bunkers, SMAGS or concrete canisters.

7. RADIATION PROTECTION

7.1 Radiation Protection Program

Whiteshell Laboratories (WL) adheres to the Corporate Radiation Protection Program. See Section 7 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

7.1.1 ALARA Initiatives and Activities

As Low as Reasonably Achievable (ALARA) and Radiation Protection (RP) program improvement initiatives and activities performed at WL in 2019 include:

- WL Controlled Area reduction initiative completed for the WL site north side;
- Waste Transhipment Controlled Area established north of the WL WMA;
- Excel macro spreadsheet implemented for reporting weekly worker personal alarming dose summaries to support higher dose risk decommissioning activities;
- Introduction of air ventilated full body plastic suits for high airborne contamination risk work;
- Introduction of water and chemical resistant protective suits;
- Air dispersion model developed to support planning of nuclear facility demolition;
- Implementation of a radioactive and contaminated material transfer form and awareness training provided to nuclear facility and decommissioning project personnel; and
- Process established for the registration of radioactive material storage areas.

The planning of radiological work is integrated into the WL site work control and planning process. Health Physics and Radiation Surveyor staff are engaged in the provision of radiological safety and ALARA assessments, providing authoritative advice regarding radiation protection matters, preparing radiological safe work documents, providing oversight of the execution of radiation work and in the planning and conduct of radiological clearance surveys. Health Physics staff develop radiological work assessments in support of the safe planning and conduct of WL decommissioning activities. Radiological clearance plans, surveys and release reports are completed for building demolitions.

WL RP performance metrics are measured and tracked weekly through WL Closure Project status reports and quarterly through the WL Nuclear Performance Assurance Review Board. These are designed to identify and address program and performance deficiencies and opportunities for improvement, establish and effectively implement corrective and preventative action plans.

The following are planned RP Program and ALARA improvements activities for 2020:

- Reconfiguration of the WMA Controlled Area exit building and change facility;
- Implementation of gamma walk-through monitors at the exit from the WL site north side and entry into the new module office complex at the WMA;
- Introduction of alpha-beta scintillation floor contamination monitors for building release monitoring;
- Introduction of hooded powered air-purifying respirators;
- Formal registration of radioactive material storage areas;

- Preparation of site specific RP procedure for movement of materials and equipment; and
- Clarification of site processes for the de-registration and disposal of radiation sources.

7.1.2 Dose Control

Regular radiation surveys are performed by RP staff to confirm: the radiological safety zones are correctly designated; areas with local elevated radiation doses rates are posted in accordance with the RP Regulations; and sufficient access control provisions are in place. In 2019, there were no occurrences of dose rates exceeding permissible levels for the designated radiological safety zones and there were no occurrences of work places with accessible dose rates exceeding 25 µSv/h not being posted or with inadequate access control.

Electronic Personal Alarming Dosimeters (PADs) are worn by workers in addition to Thermoluminescent Dosimeters (TLD) badges to track and control job specific daily and accumulated doses. The PADs have dose and dose rate alarms which are established by job specific radiological work assessments. The dose alarms are a back-out condition and the dose rate alarms are an alert condition. In 2019, the maximum PAD recorded daily dose received by a worker was 0.42 mSv and the highest dose rate measured in the year was 5.82 mSv/h. These were associated with planned exposures associated with decommissioning activities in the B200 ALWTC. There were no PAD dose alarms in 2019.

At the beginning of 2019 managers assigned and confirmed Dose Control Points (DCPs) for employees and contractors. DCPs are used by First Line Managers and Supervisors to perform individual whole-body dose management for worker radiation dose for non-emergency work situations. DCPs of either 1 mSv or 2 mSv are assigned by WL managers and represent the worker's maximum allowable dose for the calendar year. The DCPs may be adjusted as necessary during the year upon approval of a Health Physicist after confirmation that additional dose is justified. At the end of 2019, there were 4 individuals with an assigned DCP of 4 mSv, 6 individuals with an assigned DCP of 3 mSv, 49 individuals with an assigned DCP of 2 and the remainder of workers with a DCP of 1 mSv. No worker dose exceeded their assigned DCP in 2019.

7.1.3 Contamination Control

Regular contamination surveys of workplaces, material transfers and personnel exiting nuclear facilities and controlled areas are used to confirm the absence of unknown contaminated material or the spread of contamination. Workplace air monitors are employed to confirm the adequacy of controls and to warn of abnormal of unplanned airborne contamination conditions.

Table 7 shows the number of personnel, workplace and material contamination events identified in 2019 and over the past five years. None of the contamination events in 2019 resulted in a worker whole-body, skin or internal dose.

In 2019 April there was a series of skin and worker clothing contaminations during the removal of radioactive piping from the B200 ALWTC. A review of the events concluded the levels of contamination and the friability of the material exceeded the capability of available PPE&C (suit, hood and respirator). All potential high airborne contamination work on the WL site was suspended and new air ventilated pressurized suits were purchased, commissioned and implemented. There has been no reoccurrence of contamination incidences.

In 2019, material contaminations were associated with historical surplus equipment being found with low level contamination during operational clean-up surveys or during material transfer surveys.

In 2019, there were no airborne contamination exposure events and no radioactive material spills.

Table 7: Contamination Events 2015-2019

	Skin and Clothing Contamination				Workplace Contamination	
	Skin[a]	Personal Clothing[a]	Work Clothing[b]	Total	Surface[c,d]	Vehicle / Materials[b,c]
2019 Calendar year	3	0	4	7	2	4
2018/19 Fiscal year	1	0	5	6	6	0
2017/18 Fiscal year	0	0	1	1	3	
2016/17 Fiscal year	1	0	0	1	8	
2015/16 Fiscal year	0	0	0	0	3	

a Total surface contamination found is greater than 1 Bq/cm^2 beta-gamma or 0.2 Bq/cm^2 alpha over a 100 cm^2 averaging area
b Total surface contamination found is greater than 4 Bq/cm^2 beta-gamma or 0.4 Bq/cm^2 alpha over a 100 cm^2 averaging area
c Removable surface contamination found is greater than 0.2 Bq/cm^2 beta-gamma or 0.01 Bq/cm^2 alpha over a 300 cm^2 averaging area for Contamination Zone 1 areas.
d Removable surface contamination found is greater than 10 times the maximum allowable levels for Contamination Zone 2 and higher designated areas.

7.1.4 Sealed Sources

Radiation sources are registered and tracked in accordance with CNL procedures.

In 2019, there were no lost or stolen radiation sources. Leak testing was completed as required with all sources passing their leak tests.

As of 2019 December 31, the total number of registered sealed, or contained sources and x-ray emitting devices at WL, was 53. Four sources were added to the registry which included:

- AmBe neutron check source that was removed out of waste storage from the WL WMA,
- Co-60 Gamma Cell received from ACSION Industries for safe storage, and
- Two RP training check sources that were found to be unregistered

One source was removed from the registry which was a Cf-252 source sent for waste storage at the WL WMA.

7.2 Dosimetry

WL uses the Chalk River Laboratories (CRL) licensed Dosimetry Service Provider (DSP) for external and internal dosimetry for CNL staff, non-CNL employees and visitors. Compliance with the regulatory standard S-106 [16] has required external exposure measurements meet performance criteria with respect to the measurement of personal dose equivalent, $H_p(d)$. This is the quantity currently measured using TLDs worn on the trunk of the body. External whole-body dose (photon) and external surface (photon plus beta) dose as reported herein can be interpreted as $H_p(10)$ (for photons) and $H_p(0.07)$ (for photons and betas), respectively. Effective dose is the sum of the components external penetrating, neutron, tritium and non-tritium committed effective dose.

External radiation whole-body and skin doses are individually monitored using TLDs for persons entering or working in either radiological Controlled or Supervised Areas at WL[4].

Extremity dosimeters are worn for a defined job by a person who is likely to receive an extremity dose exceeding 1 mSv and significantly greater than a surface dose as monitored by their TLD, or if there is a reasonable probability that an extremity will be exposed to a beta and/or photon dose rate greater than 10 mSv/h.

Neutron dosimeters are issued to individuals who may be exposed to neutrons resulting in dose in excess of 1 mSv in a year or where accidental neutron exposures are possible.

WL staff participate in a routine bioassay program when there is a reasonable probability of receiving a Committed Effective Dose (CED) from occupational intakes exceeding 1 mSv per year.

7.2.1 Radiation Doses to Personnel

Table 8 to Table 11 summarize the monitored radiation doses at the WL site for 2019. Doses are summarized for employees, contractors and visitors and are subdivided into Nuclear Energy Worker (NEW) and non-NEW status. Doses in the tables of this report do not include doses received by WL employees and contractors working at sites other than WL.

In 2019, there were five authorized exceptions for individual monitoring of non-CNL employees and visitors at WL. The exceptions were for several site tours, an open house and a CNSC nuclear security exercise.

There were no operations of exposure devices in 2019 which required employees or contractors to be placed on a two-week dosimetry period and there were no formal dose calculations required during 2019 for local area skin contamination.

Neutron dosimeters were assigned to six employees during the movement of neutron sources on site in 2019. All neutron doses were below the detection threshold. Doses are summarized in Table 11.

In 2019, 188 individuals underwent internal bioassay, which involved urinalysis and/or whole-body counting. Fourteen individuals underwent confirmatory and follow-up Pu-in-urine bioassay monitoring and there were no individuals requiring tritium-in-urine monitoring. No committed effective doses estimates were necessary as a result of any bioassay sampling in 2019.

[4] Exceptions are authorized on a case-by-case basis by the responsible RP Program Manager or RP Program Functional Support Manager (exceptions are noted in Section 7.2.1).

For all dose tables reported in this section below, the following footnotes apply:

[a] All doses are in mSv unless otherwise identified.
[b] Average of all measured doses that excludes the zero dose values, rounded to two decimal places.
[c] Average of all measured doses that includes the zero dose values, rounded to two decimal places.

7.2.1.1 Discussion of Dose Data

The Regulatory effective dose limit for a NEW in a calendar year is 50 mSv. The maximum individual effective dose to a NEW at WL in 2019 was 3.09 mSv and the site collective dose was 49.6 p-mSv.

The Regulatory effective dose limit for a NEW in a five-year period is 100 mSv. The maximum individual effective dose to a NEW at WL for the five-year dosimetry period from 2015 to 2019 at WL was 5.08 mSv.

The Regulatory skin dose limit for a NEW in a calendar is 500 mSv. The maximum individual skin dose to a NEW at WL in 2019 was 7.47 mSv and the site collective dose was 110.12 p-mSv.

The Regulatory hands and feet dose limit for a NEW in a calendar is 500 mSv. The maximum individual hands and feet dose to a NEW at WL in 2019 was 37.77 mSv and the site collective dose was 273.61 p-mSv.

The Regulatory effective dose limit for a pregnant NEW is 4 mSv for the remainder of their pregnancy. In 2019, the maximum individual effective dose from the time the pregnancy was declared at WL was 0.00 mSv.

The Regulatory effective dose limit for non-NEWs is 1 mSv in a calendar year. In 2019, the maximum individual effective dose to a non-NEW at WL was 0.00 mSv.

Table 12 provides a summary of radiation doses by worker group in 2019. The majority of radiation doses were received by RP staff and Trades staff and 85% of their doses being attributable to B200 ALWTC decommissioning activities.

7.2.1.2 Radiation Dose Changes or Trends

Table 13 shows external whole body dose received from 2015 to 2019 and Figure 1 displays the maximum individual and collective dose from 2001-2019.

Worker doses have been on the rise since 2017 as WL decommissioning activities began to focus on buildings and facilities with increased radiological hazards. The increase in dose in the past several years can be attributed primarily to the decommissioning activities of Building 200 (active liquid waste treatment center). The number of workers receiving occupational doses above 0.2 mSv in a calendar year has been staying steady at about 40 workers in recent years. The number of workers receiving doses above 1 mSv has also increased in the past two years but remains below 15 workers.

7.2.2 RP Program Exceedances

During 2019, radiation dose to all persons working at WL were below the WL dose Action Levels [1] and the respective CNSC regulatory limits [17]. In addition, there were no individual doses exceeding their respective DCP as a result of activities at WL.

Table 12: Summary of Worker Group Radiation Doses at WL for 2019

	Total Number of Persons	Individual Whole-Body Dose (Effective Dose[a])		Collective Whole-Body Dose (Effective Dose[a])	Collective Surface Dose (photon plus neutron plus beta)	Collective Extremity
		Average[b] (mSv)	Maximum (mSv)	Person·mSv	Person·mSv	Person·mSv
Nuclear Facilities						
SF Staff (HCF and IFTF)[c]	5	0.29	0.47	1.46	3.67	5.93
	5	0.05	0.06	0.24	0.24	0
WMA and CCSF Staff	4	0.12	0.29	0.46	0.47	0
Support Workgroups						
Radiation Protection Staff [d]	43	0.49	2.60	21.16	47.20	105.02
Trades Staff [e]	52	0.36	3.09	18.90	40.67	138.94
All Remaining Staff						
Other Staff [f]	491	0.02	0.48	7.39	7.87	23.72
WL Site[g]	600	0.08	3.09	49.61	100.12	273.61

a Includes photon and neutron; there were no tritium committed effective doses for 2019.
b Average of all measured doses that includes the zero dose values, rounded to two decimal places. Includes employees and contractors.
c HCF = Hot Cell Facilities; IFTF = Immobilized Fuel Test Facility; WR1 = An experimental test reactor built at WL – WR-1 featured an organic liquid coolant.
d Radiation Protection staff include Radiation Surveyors, Radiation Protection Assistants, Contamination Monitors, and Decontamination Operators.
e Trades staff provide services for all listed facilities and decommissioning activities as well as the WL site in general.
f Other staff is comprised of all remaining staff and includes decommissioning, administrative, management, engineering, quality assurance, researchers, contractors and tenants.
g WL Site includes 411 CNL staff (WL and staff visiting from other CNL sites) and 189 contractors working at the WL site during 2019.

Table 13: WL External Whole-Body Dose Performance 2015 to 2019

Performance Metric	2019	2018	2017	2016	2015
Site Collective Worker Dose (p-mSv)	49.6	40.2	19.9	16.5	29.2
Max Individual Worker Dose (mSv)	3.09	1.65	1.41	0.36	0.42
Number of Workers > 0.2 mSv in a year	38	39	42	30	16
Number of Workers > 1 mSv in a year	14	12	1	0	0
PAD[a] – Maximum Daily Dose (mSv)	0.40	0.24	0.17	0.08	0.12
PAD – Maximum Dose Rate (mSv/h)	5.82	4.95	1.99	1.44	2.08

a Personal alarming dosimeter.

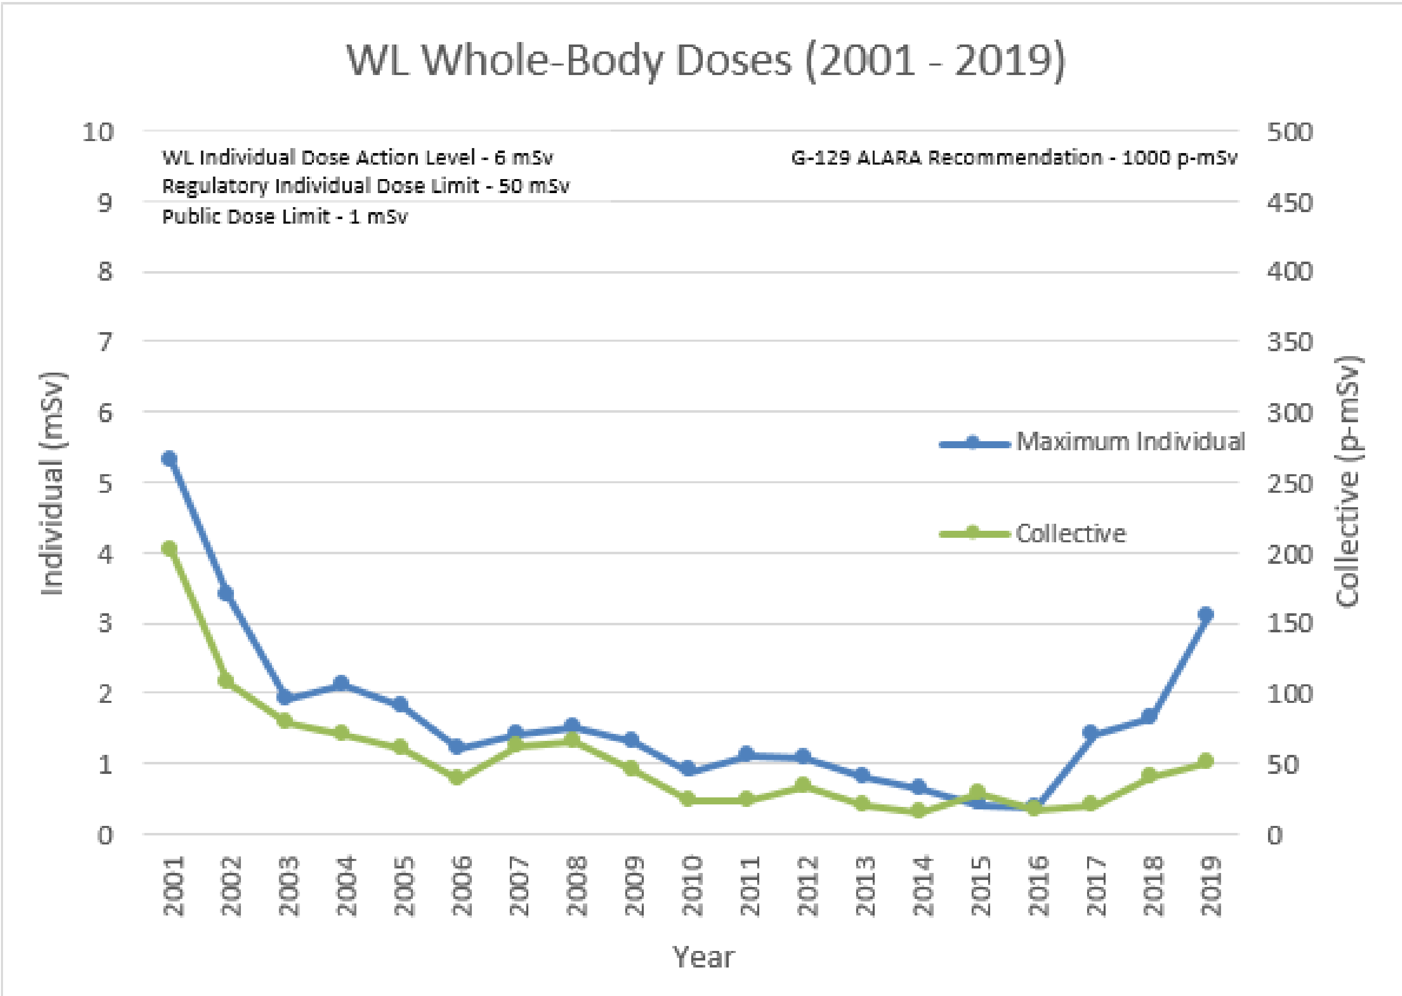

Figure 1: Whole-Body Effective Doses (2001 – 2019)

8. CONVENTIONAL HEALTH AND SAFETY

8.1 Conventional Health and Safety Program

Whiteshell Laboratories (WL) adheres to the Corporate Conventional Health and Safety Program. See Section 8 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

A number of Occupational Safety and Health (OSH) Program initiatives were undertaken in 2019, including:

- WL OSH specialists continued to work with the Health Centre on conducting the required audiology testing.
- OSH presence in the field continued at pre-job briefings, walk downs and daily work plan meetings together with early involvement in the planning process have contributed to WL's internal safety success.
- Contractors continued to be "pre-qualified" prior to bidding on WL contracts. The pre-qualification process involves reviewing safety statistics and the safety programs of the potential bidders.
- WL continued to participate in the Rapid Learning Morning Call to quickly share safety information with all CNL sites, as well as gather safety information relevant for the WL site.
- Increased contractor oversight continued by participating in activities such as site visits, pre-job briefs, pre-bid meetings and OSH orientation for contractors.
- There were 17 internal Safety Advisories sent to WL site employees in 2019. The bulletins are intended to inform WL employees about imminent issues that could impact their safety. Whiteshell Laboratories continued to be proactive in the approach to safety.

In support of reducing the number and impact of incidents with the potential for injuries or incidents at WL, the following initiatives are continuing:

- Near Miss Reporting (a known industry best practice) with a focus on early hazard recognition and strong situational awareness culture, supporting the minimization or elimination of hazards prior to resulting in injury (see Table 14). Near Miss reporting at WL always includes an investigation/fact finding session. The majority of Near Miss reports also generate an ImpAct. Whether an ImpAct is generated or not, the possibility of a human error trap being involved in the Near Miss incident is always considered, evaluated and followed up as appropriate.
- OSH Program weekly review of company injury/illness reports in support of recognizing trends and disseminating lessons learned.
- Focus on disability management / return to work in support of minimizing the impact to an injured employee and subsequent days lost.

Table 14: Summary of WL Near Miss Reporting

Year	2015	2016	2017	2018	2019
Near Miss Reported	90	79	60	53	46

Summary of changes to the OSH Program procedures/processes:

- A review / re-assessment of areas previously defined as Confined Space at the Whiteshell site was completed. Previously, confined spaces were identified based on a belief that only one of the Federal regulatory criteria needed to be met in order to be classified as such. The procedural/Regulatory review noted that all of the criteria needs to be met in order to declare an area a confined space. This resulted in a reduction of the number of currently identified confined spaces.

8.1.1 Site Safety and Health Committee

The Site Safety and Health Committee is the principal forum at WL for joint employee/ management consultation and development of solutions to safety and health concerns at the WL site. The WL Site Safety and Health Committee meets on a monthly basis.

In 2019, the WL Site Safety and Health Committee received 17 inquiries out of which 1 remained open and in progress. Additionally there were 2 carried over from 2018. The Site Safety and Health Committee acts as an oversight body, therefore these actions are largely related to the Site Safety and Health Committee's need for more information that provides them with assurance of the effectiveness of the actions of the functional safety groups on site.

8.1.2 Inspections

There were 54 site health and safety inspections completed in 2019.

8.1.3 Lost-Time Injuries

There were 0 lost time injuries reported to Employment and Social Development in 2019 at WL. There was one (1) Hazard Occurrence at WL that was reported to Employment and Social Development in 2019. CNSC staff CNSC staff were made aware of this occurrence.

A summary of injury rate data for 2019 and the previous four years is shown in Table 15 below.

Table 15: Summary of WL Injury Rate Data

	2015	2016	2017	2018	2019
Person Hours Worked	741,000	684,450	706,000	688,000	642,000*
Lost-Time Injuries	0	1	3	1	0
Working Days Lost	0	5	27	5	0
Frequency [a]	0	0.29	0.85	0.28	0
Severity [b]	0	1.46	7.76	1.45	0

a Frequency rate equals # of Lost-Time Injuries x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).
b Severity rate equals # of Working Days Lost x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).
* Person Hours Worked calculation based on 321 Full Time Employees x 40 hrs/ week x 50 weeks / Year (321 employees x 2000 hrs)

No Assurance of Voluntary Compliance or Directions were issued by Employment and Social Development Canada in 2019.

9. ENVIRONMENTAL PROTECTION

9.1 Environmental Protection Program

Whiteshell Laboratories (WL) adheres to the Corporate Environmental Protection (EnvP) Program. See Section 9 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Now and in the future, improvements in the WL Environmental Protection program will be gained through the implementation of:

- CSA N288.4-10, Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills [18],
- CSA N288.5-11, Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills [19],
- CSA N288.6-12, Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills [20]
- CSA N288.7-15, Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills [21],
- CSA N288.8-17, Establishing and Implementing Action Levels for Releases to the Environment from Nuclear Facilities [22], and
- ISO 14001:2015, Environmental Management Systems [23].

In 2019, to align with the requirements of the above Canadian Standards Association (CSA) standards, CNL WL has been incorporating the requirements outlined in the standards into its environmental monitoring program documentation. The requirements of standards will be part of CNL WL's integrated environmental monitoring program designed to track radiological and non-radiological contaminants throughout the different compartments of the geosphere, atmosphere, and biosphere, and consists of three distinct programs: the Effluent Verification Monitoring Program, the Environmental Monitoring Program and the Groundwater Monitoring Program. The integrated environmental monitoring program is dynamic in nature, meaning that it is continually evolving based on various sources of information received.

Program documentation is updated on an ongoing and/or required basis.

The WL site has maintained its ISO 14001 registration in 2019 with initial registration in 2010.

9.2 Quality Assurance

In order to ensure that the data collected through the program is valid, the laboratories performing monitoring for the program have strong Quality Assurance/ Quality Control (QA/QC) programs as required by CSA N288.5 [19]. General quality assurance objectives for CNL's Environmental Protection Program are set out in quality assurance plans. Radiological analysis is conducted in accordance with laboratory-specific environmental monitoring quality assurance plans. The plans include detailed working procedures for field operations, laboratory operations, laboratory administration, equipment performance, and quality verification of analytical results. The plans were written to align to ISO/IEC 17025 [24] for analytical laboratories.

Whiteshell Laboratories Environmental Management group conducts frequent internal checks of their technical capabilities as they perform their measurements. These are called Quality Verification Tests, and are grouped as follows according to purpose:

- *Reproducibility Tests*, such as measurement of sample replicates, establish the relative precision of the method(s). To be acceptable, replicate measurements must agree within limits established by long-term method performance.
- *Accuracy Tests*, such as blanks or samples, each spiked with known amounts of the analyte(s), establish the presence or absence of any biases due to sample matrix, sample preparation, or instrument function. To meet acceptance criteria, the spike quantity must be recovered within limits established by long-term method performance.

Environmental Management performed 2402 quality verification tests during 2019 on WL's radiochemical counting equipment. Of these tests, 97.5 % fully complied with acceptance criteria. The results of these tests are shown Table 16.

Table 16: Whiteshell Laboratories' Summary of Quality Verification Test Performed

Method	No. of Tests	No. of Failures	% Pass
Total Alpha (Instrumentation)	479	5	98.9
Total Beta (Instrumentation)	493	11	97.8
Gamma (Instrumentation)	523	12	97.7
Tritium	1102	32	97.1
2019 Total	**2597**	**60**	**97.7**

In 2019, the WL Effluent verification program began performing regular field Quality Verification testing on the outfall, lagoon, and ditch effluent sampling (Table 17). The program is using traveling blanks to determine and account for any possible introduction of contamination into the sample being analyzed by the sampling methodology being employed by the program, and the program is also collecting duplicate samples to demonstrate sampling reproducibility.

Table 17: Whiteshell Laboratories' Summary of Field Quality Verification Tests Performed

LMDL = Laboratory Method Detection Limit

Out of the 128 quality verification tests, 127 of these tests meet the acceptance criteria of the program, to yield a 99% pass rate.

In 2019, the WL Environmental Management group participated in four inter-laboratory comparison studies. Two of these studies, which focused on radiological analyses, were offered through the Environmental Research Associates. The other two studies which focused on non-radiological analyses were offered through the Canadian Association for Laboratory Accreditation. The results of the WL Environmental Monitoring laboratory performance are shown in Table 18 and Table 19. There was one unacceptable test result out of thirty for the Environmental Research Associates inter-laboratory comparison studies, resulting in a 96.7% pass rate. For the Canadian Association for Laboratory Accreditation inter-laboratory comparison studies a 100% pass rate was achieved.

Table 18: Environmental Research Association Inter-Laboratory Comparison Program for CNL WL - 2019

MRAD Study	Matrix	Analyte	Units	MRAD Assigned Value	WL Reported Value	Acceptance Limits	Performance Evaluation
MRAD-30	Air Filter Radionuclides	Americium-241	(pCi/Filter)	18.7	18.84	13.3 - 24.9	Acceptable

CALA Canadian Association for Laboratory Accreditation

9.3 Supplementary Studies

In 2019, the WL site, temporarily expanded the monitoring program to encompass additional parameters to be monitored for at the site's intake and outfall monitoring station for 6 months. This was done to verify and provide justification that the environmental monitoring program is properly identifying and analyzing for the appropriate contaminates of concern being released into the environment through the site's operations. This study will be discussed in more detail in Sections 9.5.1.4.4, and 9.5.1.4.5.2, and has led to an expansion of the parameters monitored for in 2020 at various monitoring locations around site.

9.4 Effluent Monitoring - Radiological

This section addresses the licence requirement regarding radiological monitoring of airborne and liquid effluents for the WL site, located on the Winnipeg River near Pinawa, Manitoba. It also addresses the effluent monitoring requirements listed under the Environmental Assessment Follow-Up Program [25] for WL.

Results of environmental monitoring and progress on the Environmental Assessment Follow-Up Program work packages will be provided in their respective annual reports, Environmental Monitoring in 2019 at Whiteshell Laboratories [26] and 2019 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories [27].

9.4.1 Airborne Effluent Monitoring

9.4.1.1 Site Effluent Verification Monitoring System and Results Evaluation

Monitoring locations for airborne and liquid effluent streams are representative of the final discharge to the off-site environment, and may include the combined discharge from a number of facilities. Additional monitoring points are maintained at upstream locations as an aid in identifying the specific sources of emissions. Sampling system design ensures that samples are representative of the total content of the stream at each location.

Figure 2 includes a map of the effluent monitoring locations/effluent streams at WL.

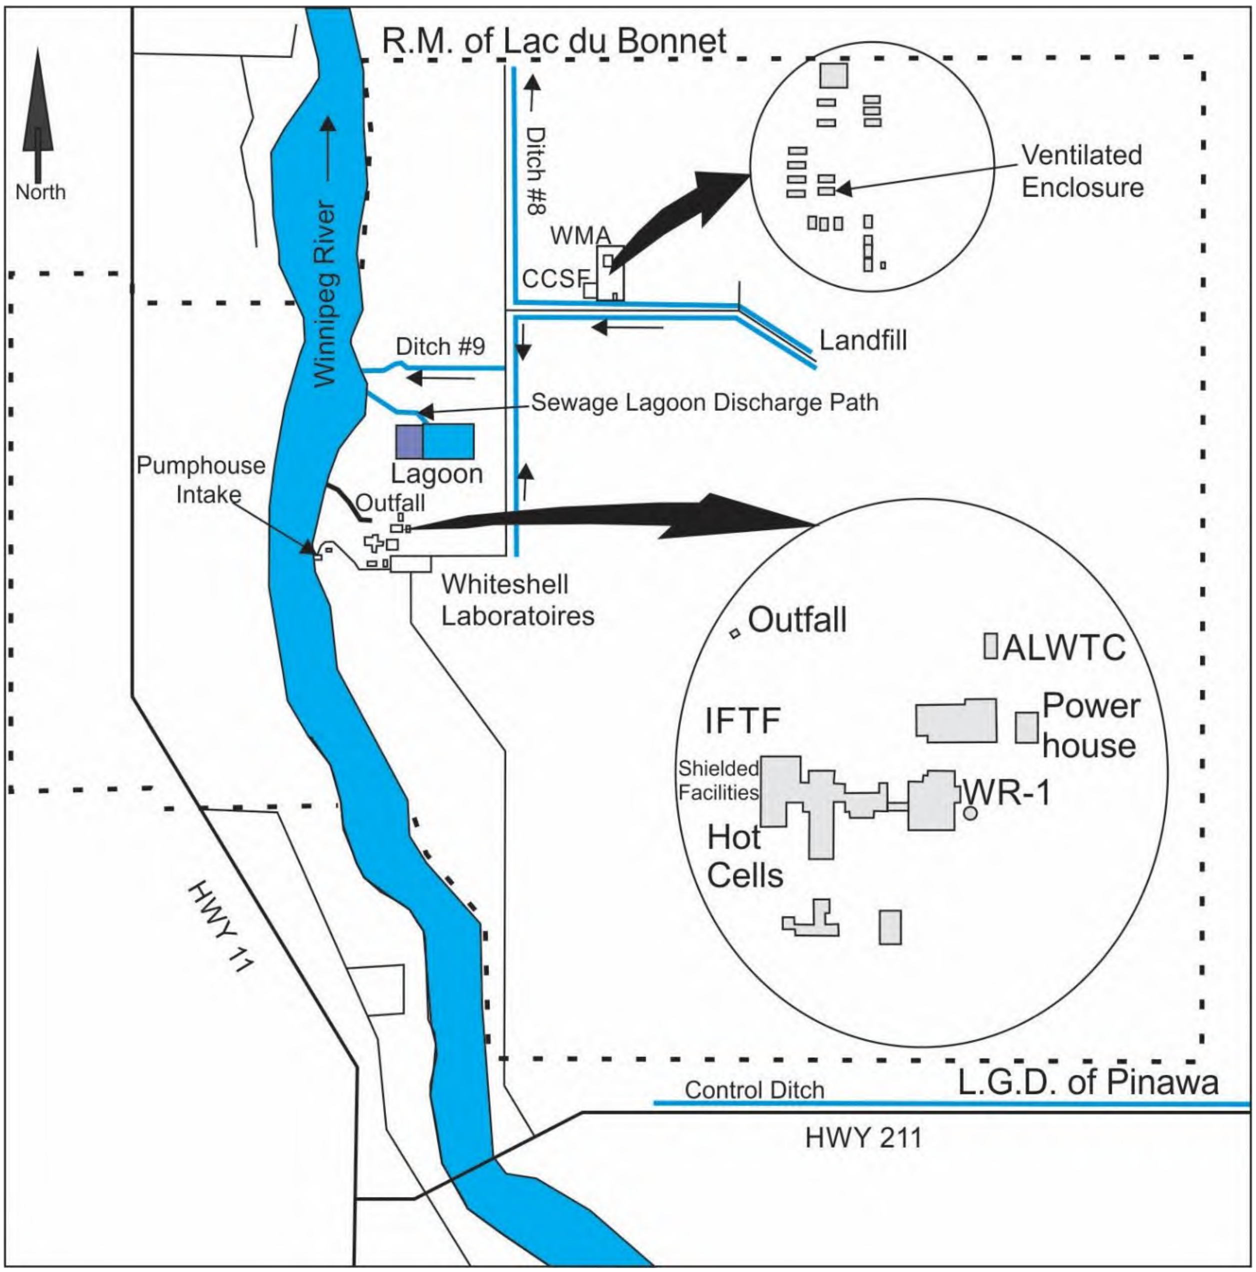

Figure 2: Effluent Monitoring Locations

Effluent streams are monitored for all groups of radionuclides that are likely to be present and significant contributors to the total, expressed as a percentage of applicable Derived Release Limits (DRLs) [28]. The DRLs now in use at WL came into effect on 2016 September 01. All current and historical data in this report has been compared against these DRLs. Monitoring is conducted either by direct measurement on location or by sampling and laboratory analysis. In many cases, gross-measurement parameters (e.g., gross beta particulates) are monitored and reported rather than specific radionuclides. This is done provided that either the relative composition of radionuclides indicated by the gross parameter is not likely to vary significantly, or total emissions of the gross parameter are very small relative to the DRLs. For comparison with DRLs, the gross parameters are always evaluated conservatively. They are either assumed to consist solely of the most restrictive radionuclide, based on DRL value that is likely to be present in measurable quantities, or are assumed to be the radionuclide(s) known to be present in the effluent. To ensure proper selection of the DRL values, the effluents are periodically characterized using, for example, gamma spectrometry to identify individual gamma emitters, or chemical extraction and analysis of individual beta emitting radionuclides, such as Sr-90, complemented by examination of historical data.

The significance of the measured radioactive materials in airborne and liquid effluents is assessed by comparison with DRLs that relate the releases to the potential radiation dose to the identified, most exposed groups (i.e., critical groups). DRLs are the upper limits for releases of radionuclides in airborne or liquid effluents from a facility or site. WL's DRLs were calculated in accordance with the principles and methodology in the CSA CAN/CSA-N.288.1-M87 [29]. The DRLs have been revised to meet the current CAN/CSA N288.1-08 [30], and these were accepted by the CNSC in 2016 August. The DRL for a particular radionuclide is derived from the regulatory dose limit for members of the public, 1 mSv in a year, as specified in the Radiation Protection Regulations under the Nuclear Safety and Control Act [31]. The intention of the DRL is to establish a release limit such that compliance with it will give reasonable assurance that the annual regulatory dose limit for members of the public is not exceeded. Weekly DRLs are calculated and applied for airborne effluents, and monthly DRLs for liquid effluents.

For multiple effluents and radionuclides at a site, verifying that the sum of all releases as a percentage of the respective DRLs is less than 100% provides a reasonable assurance[5] that the annual dose limits are not exceeded. This is a conservative approach since the critical group may differ for different release paths and radionuclides. The actual releases are a very small fraction of the DRL as discussed in the following sections and shown in Figure 3. As discussed in Section 9.4.1.3.2, the increase in 2019 liquid effluents is due to the higher detection limit values for Am-241 and Pu-239/240.

[5] The effluent DRL model and assumptions are further verified annually through results from the WL environmental monitoring program. The program assesses radiation doses to members of the public using direct measurements of radioactivity in the environment (e.g., in air, water, and food).

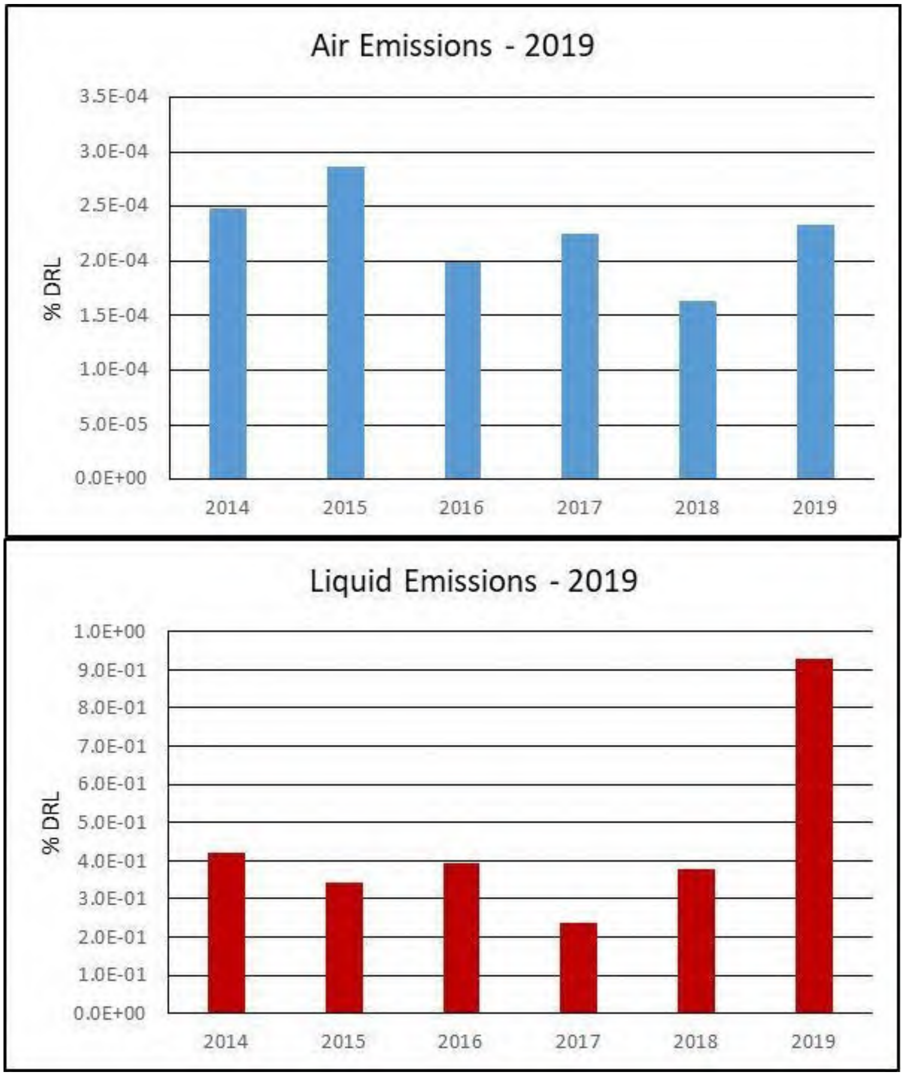

Figure 3: Trends for Airborne and Liquid Emissions form WL for 2014 to 2019

Analytical models of all significant environmental pathways to an individual in the critical group are used in the DRL calculations. DRLs for WL have been calculated for a large number of radionuclides, many of which are currently not detected in site effluents. Derived Release Limit calculations (of a wide range of radionuclides) provide a means of determining which radionuclides may be significant dose contributors. Thus, they aid in determining which nuclides warrant inclusion in the monitoring program, and in interpreting monitoring results.

Performance is also measured against the regulatory Action Levels[6] derived from the DRLs as specified in Reference [28]. The Action levels were recalculated based on current CNSC guidance and to better reflect current waste streams, and were released for use based on an implementation date of 2017 January 01.

---

[6] Action Level – In the context of CNL's Environmental Protection Program, an "Action Level" for radioactive emissions is a release rate of radioactive emissions that, if reached, may represent a loss of control of performance for a facility's environmental protection program or emission control system. Releases above Action Levels must be investigated and reported to CNSC staff. Action Levels for WL radioactive effluents are lower than the DRLs.

9.4.1.2 Airborne Effluents Monitoring

9.4.1.2.1 Monitoring Points, Schedule and Parameters

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. These activities include waste compaction in the Waste Handling Area, located in the Immobilized Fuel Testing Facility (IFTF), sampling and characterization activities within the WR-1 Reactor Building, and decommissioning activities in the ALWTC. The main sources of airborne radioactive effluents, as a result of this work and historical activities at WL, are the:

- Hot Cells Facility (Building 300)
- Immobilized Fuel Test Facility (Building 300)
- Reactor Building (Building 100)
- Active Liquid Waste Treatment Centre (ALWTC) (Building 200)

Air effluents from Buildings 100, 200 and 300 are sampled continuously throughout the year. The frequency and type of monitoring will continue to be evaluated over time, and adjusted to reflect findings from the monitoring activities. The current monitoring schedule and locations are noted in Table 20. Cessation of a monitoring activity will occur once it can be shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant by regulatory requirements or community concerns. Any proposals on modifications to the monitoring program will be communicated to CNSC staff.

Table 20: Radiological Air Effluent Monitoring Schedule – 2019

Sample Location	Sample Collection		Analytical Method and/or Parameter			
	Frequency	Method	Gross Beta	Gross Alpha	Tritium	Gamma Spec

	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Millipore Filter	N/A	W	N/A	N/A

Cont The air effluent is measured by passing a continuous sample of the exhaust through a filter. The GFA filter is normally used for beta-gamma, the Millipore normally for alpha, charcoal or silver zeolite for radioiodine, and a water bubbler for tritium.
W Weekly
N/A Not Applicable

The air to be monitored from the buildings and facilities is drawn past sample probes located in the exhaust vents, pumped through filters and then returned to the exhausts. The stack flows and sampler flows at WL are measured and verified on an annual basis by WL Engineering. The sampler flows at WL are checked during each sample collection period to ensure that they are within the established acceptance criteria, and are re-measured and verified on an annual basis. The release factors are calculated by the WL Environmental Management staff and verified independently on an annual basis. Activities measured in the laboratory are used in conjunction with sampler and exhaust stack flow rates to calculate the release in Becquerels (Bq). The Lower Limit of Detection (LLD) is the product of the release factor of the source and the laboratory Minimum Detectable Activity. For a given radionuclide, the Minimum Detectable Activity and LLD can vary, as they are calculated assuming a 30-minute count time and average detector efficiency, both of which can change.

Derived Release Limits have been calculated for 74 radionuclides for airborne effluents at WL [28]. Separate DRLs have been calculated for on-site workers and for members of the public at the site boundary. For gross alpha and gross beta activities, the DRL applied is the most restrictive from amongst those of the radionuclides that could be present (strontium-90 for gross beta and plutonium-239 and plutonium-240 for gross alpha).

Sampling procedures, field operating procedures, laboratory procedures, equipment performance checks, quality verification procedures, and laboratory administrative procedures are described in detail in the governing WL Environmental Management documentation.

9.4.1.2.2 Monitoring Results

The airborne emission results are summarized in Table 21 and Figure 3 for the years 2014 to 2019. Average weekly emissions, in Becquerels, are shown for gross alpha, and gross beta for facilities in Buildings 100, 200, and 300. Emissions from Building 100 also includes tritium. In addition, the current year releases, the average release for the past five years and the maximum weekly emissions as a percent of the DRL are given. Emissions from these identified release points are added for each year to provide an indicator of the performance of the site. Airborne emissions remain a small fraction of the release limit. The result for 2019 (0.00023% of the DRL) is greater than for 2018, and for the average for the last five years. Total site gross alpha in 2019 is similar to 2018 and the last five years average. It remains near detection limit values. The gross beta emissions are greater than in 2018 and the last five-year averages. During the week of April 16-23, the gross beta emissions for the DA-1 filter exceeded the Administrative Level for the Hot Cells facility. The subsequent evaluation of Hot Cells operations indicated no breach of the air filtration system. The likely cause of the abnormal exceedance was the dislodging of a hot particle from the historically contaminated Hot Cell stack.

Tritium emissions from the WR-1 stack were greater than 2018, but lower than the five year average. During the Phase 1 Decommissioning of WR-1, all bulk heavy water was removed from WR-1, and an exhaustive process of eliminating heavy water and tritium from the reactor piping and tanks occurred. It was concluded that over the lifetime of WR-1, tritiated heavy water was adsorbed into the pipe and tank walls and probably also into concrete walls and floors. Therefore, the moderator system continues to be purged with air flow in order to remove additional tritium from the system and the tritium removal rates have been measured. The tritium emissions from the facility fluctuate with the humidity and temperature as the tritiated water is drawn out of the system. The maximum releases were all below the administrative limit (1.52E10 Bq/week) for the facility and well below the Action Level (7.62E10 Bq/week) and DRL (1.65E15 Bq/week). As many gross alpha and gross beta measurements are at or below the LLD, the yearly variations within these extremely small numbers are of very little consequence. Localized operational workplace air monitoring is conducted as part of the Radiation Protection Program, and this was performed during operational shutdown and decontamination activities associated with Buildings 100 and 200, and work in the Shielded Facilities and Concrete Canister Storage Facility. Airborne dust monitoring was performed for building demolitions, demonstrating that in 2019 no radioactivity was released to the air from demolitions. The results of this monitoring are described in the 2019 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories [27].

a The DRLs shown are for members of the public at the WL boundary as described in reference [11].

b Gross alpha releases are conservatively assumed to consist of Pu-239 and Pu-240, and Gross beta releases are assumed to be Sr-90, the radionuclides with the most restrictive DRLs and likely to be present in the effluent.

N/A Not Applicable

Note that the 2016 values for Total Beta (as %DRL) and Total (%DRL) were reported incorrectly in the 2016 and 2017 annual reports.

9.4.1.3 Liquid Effluents Monitoring

9.4.1.3.1 Monitoring Points, Schedule and Parameters

Figure 2 shows the locations of the sources of liquid effluents to the Winnipeg River, including the Outfall, the Lagoon and the numbered ditches.

The primary source of liquid radioactive effluents is the process water outflow (Outfall), which discharges continuously to the Winnipeg River. The discharge from the Outfall is composed of storm water runoff from paved roadways or around buildings, cooling water used in process and experimental facilities, and holding tank discharges including those from the new active liquid waste treatment system tanks based in Building 100 and Building 300. The ALWTC was taken out of service in 2017 as part of preparations for the decommissioning of Building 200. Holding tanks collect water containing low levels of radioactivity, as a result of cleanup activities associated with operational and decommissioning work, as well as historical activities at WL. The current monitoring schedule and locations are listed in Table 22.

Table 22: Radiological Liquid Effluent Monitoring Schedule – 2019

Sample Location	Sample Collection		Analytical Methods and Parameters								
Location Name	Frequency	Method	Beta Screen	Gross Beta	Gross Alpha	Tritium	Gamma Spec (liquid)	Gamma Spec (ash)	Sr-90 (ash)	U-238 Pu-239/240 Pu-238	C-14

We Weekly, when ditches have flowing water, usually after a rain or snow melt. Note that 2018 was a low precipitation year with very little running water.
Qc Quarterly composite, composite of samples collected during a 3 month period
A/R As Required.
N/A Not Applicable.
a Screening sample only.

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. Specific activities that may have influenced the 2019 liquid releases are similar to those for the past five years, and include cleaning of footwear and respirators. Radiation Protection introduced the use of disposable rubber shoe covers, which reduced the contribution from the washing of footwear in 2018. The water from these cleaning activities is combined with Building 300 sump water into the Building 300 receiver tanks. Sump water from Building 100 is now directed to the Building 100 receiver tanks. The liquids from these holding tanks are discharged to the Winnipeg River through the Outfall.

An automatic sampler continuously samples the outflow from the Outfall, proportional to its rate of flow. A weekly screening sample (4L), representative of effluent released from the Outfall during the preceding week, is collected and submitted for uranium and gross beta analysis and scanned by gamma spectrometry.

Monthly composite samples (at least 20 L) are gathered for analysis of total uranium, gross alpha, gross beta, tritium, radio strontium and other radionuclides (americium-241, cesium-137) by gamma spectrometry. Starting in 2017, 3 month composite samples were collected for plutonium-239/240, plutonium-238 and plutonium-241 isotopic analyses. In 2019 Outfall samples were analyzed for carbon-14 and tritium because they are known to exist in WR1 and decommissioning activities have a potential for releasing these isotopes. Carbon-14 and tritium analyses were initiated as a check on this possibility.

The secondary source of liquid effluent is the Sewage Lagoon (Lagoon). The Lagoon collects sanitary and wastewater from most buildings on the site, as well as from the laundry facility. Lagoon water residence time is more than three months, to allow for biodegradation and settling. Prior to each planned discharge, the secondary cell is isolated, and tested for a series of non-radiological parameters (discussed in detail later). If these are acceptable, the accumulated contents of the secondary cell only are released to the Winnipeg River via a small drainage ditch leaving the Lagoon's north side. In 2019 the lagoon was only discharged in the fall because an environmental risk assessment sample campaign was underway in the spring and there was enough freeboard that a spring discharge was not necessary.

The outflow of the Lagoon is continuously sampled during discharge. The resulting composite sample is analyzed for gross alpha, gross beta, and radio strontium and it is also scanned by gamma spectrometry.

Small quantities of radionuclides at levels seen at the control point are also released to the Winnipeg River from the two ditches indicated in Figure 2. Water from the recharge area east of the WMA is diverted around the WMA to the west-flowing Ditch 9 and into the Winnipeg River. The other, Ditch 8, running northward, drains the land north of the WMA up to the site boundary and beyond. The volume of water in the ditches and resulting flow to the river is entirely dependent on rainfall and spring runoff. Precipitation (646 mm) in 2019 was more than in 2018 (467 mm), and in 2017 (519 mm). The amount of precipitation in the spring and summer of 2019 was relatively low, but September experienced an unusually high amount of precipitation. Ditches were sampled 11 times during April to the end of June. During the summer they were sampled only 1 time in July. During September and October there were 6 ditch sampling events. As a result of low precipitation in the summer the amount of times ditches had running water was limited during the summer months of July and August.

One-litre water samples to be analyzed for radioactivity are collected from the two ditches carrying drainage from the WMA whenever there is sufficient flow from runoff to enable sampling of discharge to the river. At the same time, samples were also collected from the northern ditch bordering Highway 211. This is far enough from CNL's operation to be a reasonable background (Control) sample[7] . The samples are analyzed for gross alpha, gross beta and tritium. If the level of the gross beta measurement exceeds 10 Bq/L, the samples are submitted for gamma spectrometric and radio strontium analysis. If the alpha activity is above 0.5 Bq/L, the samples are submitted for gamma spectrometric and uranium analysis. Surface water samples are collected in and around the WL WMA from locations upstream from these two ditches. The results of these operational control samples are reported in Appendix D of this report.

Derived Release Limits for 63 radionuclides were calculated for liquid effluents at WL [28]. Gross alpha and gross beta measurements provide a quick measurement of the total alpha and beta radioactivity produced by a number of radionuclides, without having to test for those radionuclides. However, as in the case of airborne effluents, the most restrictive DRLs apply to gross beta and gross alpha activity: Cesium-137 for beta activity and plutonium-239 and plutonium-240 for alpha activity. With the introduction of total uranium and isotopic plutonium analysis for the processed outfall, a comparison can be made to the individual contributors to the gross alpha activity. Therefore the comparison to the %DRL of the individual isotopes is presented and the sum of those reported. This is also the case for gross beta.

9.4.1.3.2 Monitoring Results

The liquid emission results are summarized in Table 24 and Figure 3 for the years 2014 to 2019. Average monthly emissions, in Becquerels, are shown for gross alpha, gross beta, total U (including uranium-234, uranium-235, and uranium-238), americium-241, strontium-90 and cesium-137 for the releases from the Outfall and the Lagoon. In addition, quarterly activities of plutonium-239/240 and plutonium-238 were reported for Outfall effluents. A plot of the monthly cesium-137 and strontium 90 releases as Bq from the Outfall in 2019 is compared with radioactivity (Bq) discharged to the Outfall from the Low Level Liquid Waste (LLLW) treatment systems in Figure 4. Discharges to the Outfall from the LLLW treatment tanks occurred in all months. The total releases of strontium-90 and cesium-137 from the tanks in 2019 were 2.79E06 Bq and 8.27E06 Bq, respectively. These releases were only a fraction of the total strontium-90 (3.73E07 Bq) and cesium-137 (1.37E07 Bq) releases from the Outfall. There was a slight correlation between the patterns of releases from the tanks with the pattern of releases from the Outfall. However, the fluctuations in releases from the tanks are too small to account for the magnitude of fluctuations of Outfall releases. The additional strontium-90 and cesium-137 activities noted at the Outfall may be from pre-existing contamination in the storm drain system from historical site contamination events and historical radioactivity disposition in the storm drain line from B200 LLLW discharges. Some of this contamination may have been from unplanned emissions from the Hot Cells in the 1970's, although more likely from the Building 200 drain line. Strontium-90 and cesium-137 releases from the Outfall peaked in October. A possible reason was that the summer of 2019 was dry. Strong rain events occurred in September and October (as evidenced by the increase in ditch sampling), and these may have flushed contamination into the Outfall from storm drains and previously contaminated process piping. Note, all monthly releases from the Outfall were well below the administrative release level[8]. Releases of gross alpha were higher than the 2018 releases and the five year average. Gross

[7] The Control Ditch sample is collected from a location not influenced by CNL's operation, and therefore serves as an indicator of the natural background conditions in the area.

[8] An Administrative Level is a CNL internal reporting level for radioactive emissions by way of an individual effluent stream. The Administrative Levels are established and maintained by CNL to provide timely warning of above normal radioactive emissions, with the intent of aiding in the application of the As Low as Reasonably Achievable (ALARA) process.

beta releases in 2019 were slightly higher than the 2018 and five year average releases. Strontium-90 releases in 2019 were higher than in 2018, but less than the five year average. The cesium-137 releases were slightly below 2018 releases and the five year averages. Americium-241 and total uranium releases were higher than 2018 releases. The relatively constant emissions of gross alpha, gross beta, strontium-90 and cesium-137 from the Outfall over the years suggest a constant source, more like contaminated piping than the effects of recent decommissioning activities. Plutonium-239/240 and plutonium-238 releases were very low, being based on detection level concentrations (% of the DRL less than 0.29). In 2019, Outfall water was also analyzed for the presence of Carbon-14, which could be introduced by the discharge tanks from Building 100. Carbon-14 was below detection levels (varying from 1.36 to 1.65 Bq/L) in Outfall samples. Given that the DRL for Carbon-14 is 1.06E+08 Bq/month, the detection limit of 1.65 Bq/L would correspond to a %DRL value of 0.23. Measurements of Carbon-14 in site intake water from Building 902 were also below detection values.

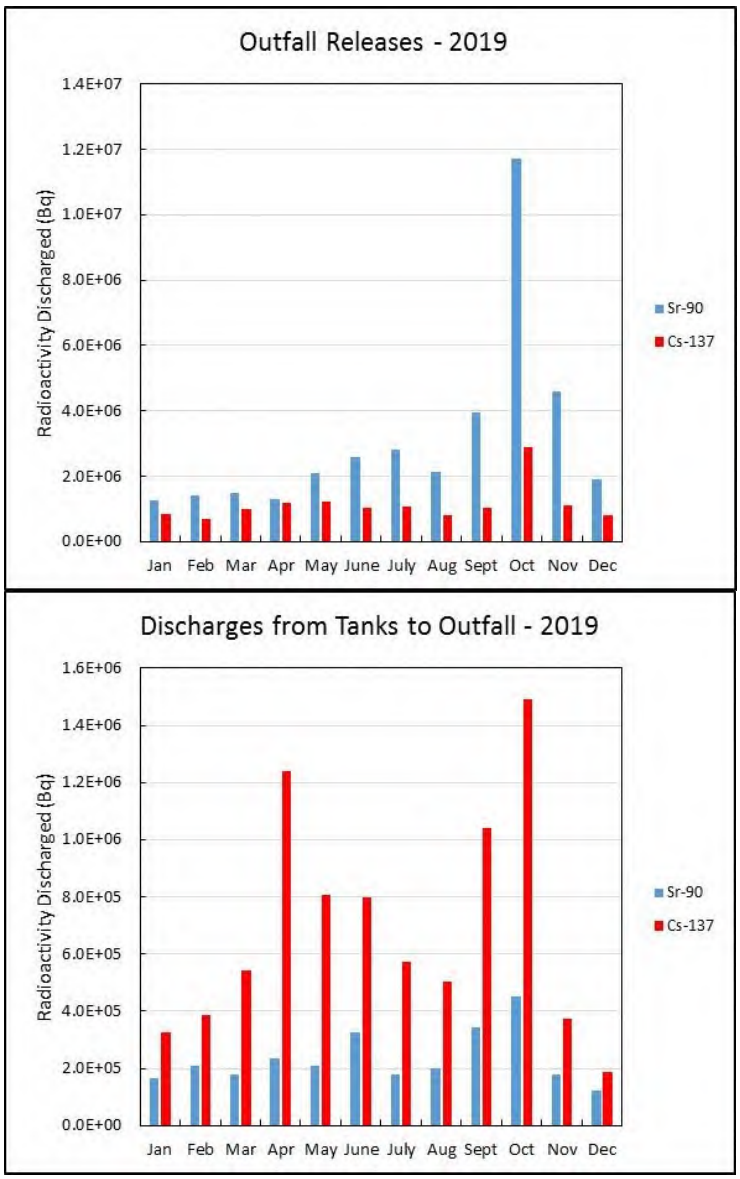

Figure 4: Radioactivity on Outfall Releases and Discharge from Active Liquid Waste Treatment Tanks for 2019

The 2019 Lagoon discharge occurred only in the fall because an environmental risk assessment sample campaign was underway in the spring and there was enough freeboard that a spring discharge was not necessary. The Lagoon gross alpha releases were higher than 2018 values, and below the five year average (Table 24). Activities of total uranium (natural), americium-241 and plutonium-239/240 determined for lagoon samples were higher than in 2018. The uranium activity accounts for about a third of the gross alpha activity, and it was assumed that the remaining gross alpha activity could be accounted by the activity of americium- 241 and plutonium-239/240. It should be noted that the activities of these latter two elements are detection limit values and that their combined activities are greater than gross alpha by about a factor 2. Therefore, the actual releases of americium-241 and plutonium- 239/240 are actually less than reported here. The % DRL values of total uranium, americium-241 and plutonium-239/240 (which are reported instead of gross alpha) were very low (0.0015, 0.059 and 0.066 % DRL, respectively). The gross beta, strontium-90, and cesium-137 discharges were higher than in 2018. Releases of strontium 90 and cesium-137 were below 0.002% and 0.006% of their respective DRLs. All releases were well below administrative release levels.

The averaged results for the two drainage ditches and control sample are shown in Table 23.

a Compliance with Guidelines for Canadian Drinking Water [32] may be inferred if the measurement for the gross alpha and gross beta are less than 0.5 Bq/L and 1.0 Bq/L, respectively. Lower Limit of Detection is based on a 1 L sample resulting in less than 100 mg of sample ash and counted for 100 minutes.
b LLD = Lower Limit of Detection.
c Uncertainties are expressed as the standard deviation of the average activity of the processed samples.

During 2019 the gross beta activities in Ditches 8 and 9 were lower than in 2018. The 2019 gross alpha activities were lower in Ditch 8 and higher in Ditch 9 compared to 2018. The summer of 2019 was rather dry and was followed by a fall with many rain events. The gross beta values were similar to the control sample collected off of Highway 211. However, the gross alpha values were higher than the control ditch. The control sample is unaffected by CNL's operations. Compliance with the Guidelines for Canadian Drinking Water

Quality [32] may be inferred for gross beta activity since the measurements are all less than 1.0 Bq/L. The gross alpha activity was below the drinking water screening level of 0.5 Bq/L for all samples. The local well waters within the Canadian Shield contain naturally occurring uranium [33] at levels ranging from 0.04 Bq/L to in excess of 2.5 Bq/L. Vertical flow occurs in the surficial Clay unit and in the intermediate Clay Till unit. The head gradient is upward leading the water in these layers to discharge to the surface. Naturally occurring uranium and its progeny are contributors to the total alpha activity, and could account for levels seen in some of the ditch water samples. In addition, naturally occurring alpha emitters may be present in suspended sediment in some of the samples.

The alpha and beta results remained below the trigger levels for gamma spectrometry, strontium-90 and uranium analysis mentioned in Section 9.4.1.3.1. As discussed in Appendix D of this report, the WMA contains a number of trenches with varying amounts of low-level radioactive and conventional waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. The amount measured in drainage Ditch 9 (10 ± 18 Bq/L) is above that noted at the control location (<4 Bq/L). This can be attributed to migration from the WMA. The tritium activities measured at all three ditch locations are much lower than the Guidelines for Canadian Drinking Water Maximum Acceptable Concentration for tritium (7000 Bq/L) [32].

Table 24 summarizes the data for releases of liquid effluents[9] for the years 2014 to 2019. The average monthly releases, expressed as a percent of the DRLs, are added for the various sources on site to provide a quantitative indicator of the performance of the site. The average total release for 2019 was 0.93% of the DRL, which is higher than 2018 and the five-year average (0.36%). The main reason for the higher 2019 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. The highest monthly release in 2019 was plutonium-238 from the Outfall at 0.83 % of the DRL.

9.4.2 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is determined for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results as a result of equipment failure, maintenance/calibration outages, or operator action requires “unavailability” to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 25) for monitoring equipment on effluent streams with effluent rates that are normally ≥ 0.5% of weekly DRLs are set more stringent (for unplanned unavailability) than for those streams with normal effluent rates < 0.5% of weekly DRLs. Unavailability is expressed in hours of unmonitored effluent releases per year, and applies separately to each monitored parameter, on each effluent stream.

[9] The radioactivity from Ditches 8 and 9 was found to be below the Canadian Drinking Water Screening Level [32] for both gross beta and gross alpha activity, within the uncertainty of the analysis. Tritium levels were well below the Canadian Drinking Water Maximum Acceptable Level. The contributions were considered insignificant due to the small volume of release, and are not included in the liquid release table.

Table 24: Radionuclides in Liquid Effluents from WL – 2014 to 2019

Location/ Parameter	DRL (Bq/mo)	Action Level (Bq/mo)	2014 (Bq/mo)	2015 (Bq/mo)	2016 (Bq/mo)	2017 (Bq/mo)	2018 (Bq/mo)	Five-Year Average		2019		2019 Maximum

a In 2018 monitoring for Outfall began for U-total, Pu-239/240 and Pu-238. In the Lagoon Pu-239/240 was calculated from gross alpha mass balance. The %DRL is reported for these isotopes instead of gross alpha. Note that Pu isotope activities are detection level values and Am-241 activities are very close to detection levels.

b Gross beta releases are not included in the %DRL totals as the regulated components of the gross beta (Cs-137 and Sr-90) are already accounted.

Table 25: Effluents Monitoring Equipment Unavailability – 2019

	Unavailability Criteria [a]		Number of Exceedances
Air effluent streams with normal emission rate ≥ 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	84 hours/year/stream	0
Air effluent streams with normal emission rate < 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0
Continuously monitored liquid effluent streams.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0

a See Table 7 in 900-509200-STD-009.

Unavailability criteria (see Table 25) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2019, there were no instances in which the unavailability criteria (Table 25) outlined above were exceeded. There were no instances of air monitoring unavailability. There were 4 instances of planned unavailability to Outfall monitoring were due to required maintenance that affected the electrical power supply 3 times and the water flow once. The total time of monitoring unavailability in 2019 was 9.3 h. In each instance an estimate of the release during unavailability was calculated as per procedure. Monitoring unavailability also occurred during the fall discharge of the Lagoon when the auto sampler failed due to frozen sample lines. Although the daily grab samples provided a reasonable substitute for auto sampling, strictly speaking there was a loss of monitoring for the remainder of the discharge. The total time for loss of unplanned monitoring, was 107 hours.

9.4.3 Overall Performance

Figure 3 summarizes the data presented in Table 21 and Table 24 on site-wide airborne and liquid emissions, expressed as totals of percentages of DRLs (the lower rows of the tables) for the years 2014 to 2019. The average emissions for the past six years continue to be very small. Liquid emissions of radioactive material from WL in 2019 were below CNL's Administrative Levels and Action Levels, and continue to be very small compared with the applicable DRLs [28]. During the week of April 16-23 the gross beta emissions for the DA-1 filter exceeded the Administrative Level for the Hot Cells facility. The subsequent evaluation of Hot Cells operations indicated no breach of the air filtration system. The likely cause of the abnormal exceedance was the dislodging of a hot particle from the historically contaminated Hot Cell stack. With this exception, all air emissions were below CNL's Administrative Levels and Action Levels.

Total radioactive airborne emissions from the WL site during 2019 continue to be very low, averaging 0.00023% of the DRL.

Radioactivity in the WL liquid releases for 2019 was 0.93% of the DRL which is higher than in 2018 and the last five-year average (0.36%). The main reason for the higher 2019 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. Plutonium-238, at detection limit values, was the primary contributor to the Outfall, averaging 0.35% of the

DRL. The primary contributors for Lagoon emissions were plutonium-239/240 and americium-241, averaging 0.0.066% and 0.059% of the DRL, respectively. Both of these contributors had activities at detection level values. The level of tritium activity noted in the two ditches carrying drainage from the WMA remains well below the Maximum Acceptable Concentration for Drinking Water.

The 2019 release results as well as the previous years' trends indicate that CNL has taken reasonable precautions to control the release of radioactive nuclear substances within the site, and into the environment, as a result of the licensed activity. All airborne and liquid release results are consistent with the clean-up and operational activities associated with decommissioning of the site.

The results of the monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment.

9.5 Effluent Monitoring – Non-Radiological

This section addresses the licence requirement regarding hazardous substances monitoring of liquid and airborne effluents for the WL site for 2019. It also fulfills similar effluent monitoring requirements listed under Work Package 1 of the *Environmental Assessment Follow-Up Program* [25].

9.5.1 Liquid Effluent Monitoring

9.5.1.1 Monitoring Points, Schedule and Parameters

Whiteshell Laboratories staff members collect samples for non-radiological parameters from eight different monitoring points. The first four are the Sewage Lagoon (referred to as the Lagoon) at point of discharge to the Lagoon drainage ditch, the Process Outfall (referred to as the Outfall), the North drainage ditch (referred to as Ditch 8), and the West drainage ditch (referred to as Ditch 9). These effluents flow directly to the Winnipeg River. Two monitoring locations measure internal process wastes leaving the Low Level Liquid Waste Treatment Systems (LLLWTS) from Building 300 and Building 100. The remaining two monitoring locations are utilized as background monitoring locations, and are the Intake water taken from the Winnipeg River at the Pump House (Building 902), and a control ditch on provincial highway 211. More details for each monitoring area are provided in the sections to follow.

Referring back to Section 9.4 of this report, Figure 2 shows the locations of the waste stream sources monitored, and where appropriate, their source or release points to the Winnipeg River. Ditch 8 meets the river some distance downstream (north) of the site boundary.

Table 26 lists the non-radiological parameters monitored at the inlet or effluent streams sampled, and the sampling schedule followed. The WL monitoring program follows the protocols from the Ontario Ministry of Environment [34] in its Municipal/Industrial Strategy for Abatement program. Under that system, parameters that are normally measured by the same analytical technique are grouped into numbered Analytical Test Groups (ATGs). These are described in Table 27, which includes information about the Regulatory Method Detection Limit (RMDL), Laboratory Method Detection Limit (LMDL) and the Smallest Reporting Increment (SRI). The LMDL and SRI were determined in accordance with protocol. The WL monitoring program also meets the regulations set out in the Federal Wastewater Systems Effluent Regulations [35], and the standards from CSA N288.4-10, *Environmental Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* [18].

Table 26: Schedule for Non-Radiological Monitoring at WL

ATG[a]	Parameter	Intake[b]	Lagoon	Outfall	Ditches 8, 9 & Control	LLLWTS TANKS

25	Oil & Grease	Monthly	Discharge	Discharge	Discharge	Discharge	Discharge

a ATG = Analytical Test Group; BOD = Biochemical Oxygen Demand; CBOD = Carbonaceous Biochemical Oxygen Demand; TSS = Total Suspended Solids.
b The Monthly = grab sample taken once within each month.

Intake water was sampled each month as grab-samples are drawn from the wet well of the Pump House (Building 902).

Discharging the Lagoon in 2019 required 10 days between October 21st and October 31st in the fall, and there was no discharging of the Lagoon in the spring. The lagoon was not discharged during the spring, to enable sampling campaigns to be conducted on the lagoon cells and the discharge pathway. Prior to the fall discharge, grab samples of the lagoon effluent were collected for Carbonaceous Biochemical Oxygen Demand (CBOD), acute lethality test[10], and coliform[11] measurements. Remaining lagoon parameters were analyzed in samples that were collected daily and weekly during flow periods.

At the Outfall, daily monitoring and weekly samples are collected for non-radiological parameters.

The ditches are sampled only when water is flowing freely within them, and at a maximum frequency of once per week. This occurs after snowmelt or significant rainfall, of which there were eighteen events in 2019.

Whenever a tank was discharged at either of the LLLWTS's, the effluent was sampled.

---

10 The acute lethality test is a pass/fail type of test that is required to be performed by the federal Wastewater Systems Effluent Regulations [35] that came into force 2015 January 01.

11 Coliform bacteria are a commonly used bacterial indicator of sanitary quality of foods and water.

9.5.1.2 Analytical Protocol and Results Evaluation

With minor modification, the protocols for sample collection, and result reporting used here, are adopted from the Ontario Ministry of Environment publication *Protocol for the Sampling and Analysis of Industrial/Municipal Wastewate*r [34]. The protocols are used under Ontario's industry-specific effluent monitoring and limits regulations. The system provides a defensible set of methods to ensure that the final reported result is representative of the effluent sampled. Guidance is given on sampling of wastewater streams, sample handling including pre-treatment, and acceptable analytical techniques. Some of these are common to more than one parameter, so they are grouped into ATGs, listed in Table 27. Ontario Ministry of Environment protocols were used again this year, as they have been historically. It should be noted that the Manitoba government has no such comprehensive protocols for sample collection, preservation, analyses and result reporting.

Table 27: Listing of Analytical Test Groups

25	Oil & Grease	Gravimetry	mg/L	1	--	--	1.0

a The method ICP = Inductively Coupled Plasma Spectrometry. This is a common method for metals analysis.
b The unit MPNU = Most Probable Number Unit, as reported by accredited contract laboratory. The MPNU is a very common estimate of bacterial counts, especially for sewage effluent.
c RMDL = Regulation Method Detection Limit
d The LMDL = Laboratory Method Detection Limit ("MDL" also used).
e The SRI = Smallest Reporting Increment.

9.5.1.3 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is determined for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results as a result of equipment failure, maintenance/calibration outages or operator action requiring “unavailability” to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 25) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2019, there were no instances in which the unavailability criteria (Table 25) outlined above were exceeded. There were no instances of air monitoring unavailability. The 4 instances of planned unavailability to Outfall monitoring were due to required maintenance that affected the electrical power supply 3 times and the water flow once. The total time of monitoring unavailability in 2019 was 9.3 h. In each instance an estimate of the release during unavailability was calculated as per procedure.

9.5.1.4 Monitoring Results

In the following sections, there are two types of presentation formats used in reporting the results obtained in 2019. These include an averages summary table and a comparison against the CNL’s Monthly Guideline Acceptance criteria, for the effluent at identified monitoring locations.

9.5.1.4.1 Averages Summary Table

Summarized results for 2019 are presented in Table 28 through Table 32. The first two columns in the tables identify the Ministry of Environment ATG and parameter names [34]. The next three give the CNL monthly guideline concentration, LMDL (Table 27) and units for each measurement. Generally, the next six columns provide for comparison, the average concentrations reported for the five previous years, followed by their arithmetic mean. The next seven columns contain a summary of the results for the 2019 monitoring period (explained further below).

CNL WL previously discontinued on-site analysis of most of the non-radiological parameters. The samples are now shipped to external ISO 17025 accredited laboratories through a sample management office. The LMDL for the laboratory analyzing the parameter is provided in Table 27.

Within the 2019 results section, the number of samples included in the average (“# Spl.”) is reported. This number is not constant down the table. It depends on the sampling frequency chosen for each parameter, and sample mixing to prepare composites for analysis. The next column (labelled “ND’s”) gives the number of samples in which the analyte was not detected and was therefore deemed a “zero” result.

The minimum, maximum and average values of each parameter are based on individual results and not monthly averages. These results are given in the tables located at the end of the section, and include any results that were zero by virtue of being non-detectable in the laboratory. The relative standard deviation of all results is also reported, expressed as a percentage of the average. This number permits some evaluation of scatter inherent in the samples and measurement method. Usually, sample variability dominates (i.e., the effluent composition changes over time).

In Table 29 through Table 32, yearly average values for parameters marked with an asterisk indicate that a monthly guideline was exceeded for at least one month during the course of the calendar year being presented.

For convenience, the total annual load to the environment (Winnipeg River) represented by each of the analytes is also presented, expressed in kilograms. The calculation process is described in detail in Section 9.5.1.5 (where the results for the Lagoon and Outfall monitoring points have been collected together in Table 34, and compared to the previous five years).

Table 28: Averages Summary for Intake

--	Number of Batches Discharged			--	2	2	2	2	1	2	1						

a Monthly Guide is from WL's non-radioactive effluent limits procedure. For mercury, the Daily Guideline is given instead, as there is no Monthly Guideline specified.
b # Spl. is the number of samples analyzed and reported.
c NDs is the number of samples in which analyte was not detected (i.e. Code = "< DL", result = 0).
d RSTD = Relative Standard Deviation
e MPNU = MPN Units, as given by Most Probable Number bacterial estimation technique.
f The Lagoon discharges are considered to occur in two "months" – Spring and Fall. Note: The 2019 Spring Discharge = 0 L; 2018 Fall discharge = 3.83E+07 L.

Notes: Any averages with an asterisk indicate that a monthly guideline was exceeded in one or more months for the given parameter in the year.
N/A = not applicable.
Acute lethality test results are discussed in Section 9.5.1.4.5.1

--	Number of batches discharged			--	82	34	14	24	50	41	68							

a All results below the LMDL, originally flagged as "< DL" when reported, are only estimates.
b Averages were calculated by setting to zero results reported as "< DL."
c Monthly Guide is from CNL's limits for non-radiological parameters in liquid effluents procedure. For mercury, the Daily Guideline is given instead, as there is no Monthly Guideline specified
d # Spl. is the number of samples analyzed and reported.
e NDs is the number of samples in which analyte was not detected (i.e., Code = "< DL", result = 0).
f RSTD = Relative Standard Deviation
N/A = not applicable

Notes: Any averages with an asterisk indicate that a monthly guideline was exceeded in one or more months for the given parameter in the year.
Discharges of effluent coming from the new low level liquid waste treatment systems are being combined together, as it allows for comparisons to the data collected over the previous 5 years.

9.5.1.4.2 Monthly Guideline Acceptance

CNL guidelines were used as the basis against which emissions from WL were evaluated. The CNL guideline limits are derived from the most recent legislation available. They are not regulatory requirements, but instead have been adopted by CNL to routinely evaluate the environmental significance of both process-type and non-process type discharges from WL. Table 33 provides a summary of each of the liquid effluent parameters that had exceeded its CNL monthly guideline in 2019 or at any time during the previous five years.

As with the average summary table provided for each monitoring point, the first two columns in the table identify the Ministry of Environment ATG and parameter names. The next three give the CNL monthly guideline concentration, LMDL, and the units of measurement. The next six columns present the monthly guideline acceptance for each of the five previous years and the average of those five years expressed as a percentage. The last three columns indicate the number of months during which discharges occurred, the number of times the monthly guideline was exceeded for each parameter, and the subsequent percent of times the parameter levels met the acceptance criteria.

In order to assess any significant level of change and evaluate program performance, this table will be referred to in each section discussing monitoring point results.

Table 33: Parameters that Failed to Conform to CNL Monthly Guidelines

						Monthly Guideline Acceptance (%) for Previous Five Years						Results for Year 2019		
Effluent Stream	**ATG**	**Parameter**	**Monthly Guide**	**LMDL**	**Unit**	**2014**	**2015**	**2016**	**2017**	**2018**	**Average**	**# Mth.**	**> Monthly Guide**	**Accept (%)**
LLLWTS /ALWTC	6	Phosphorus	1.0	0.003	mg/L	100	100	100	100	100	100	12	2	83
LLLWTS /ALWTC	8	TSS	25	1.0	mg/L	92	92	100	78	92	90.8	12	0	100
LLLWTS /ALWTC	9	Copper	0.5	0.0005	mg/L	75	67	100	67	33	68.4	12	7	42
LLLWTS /ALWTC	9a	Iron	1.0	0.010	mg/L	83	75	67	44	50	63.8	12	2	83
LLLWTS /ALWTC	12	Mercury	1.0	0.0020	µg/L	92	100	100	100	100	98.4	12	0	100
LLLWTS /ALWTC	14	Phenolics	0.02	0.0010	mg/L	100	100	100	100	92	98.4	12	0	100
Outfall	8	TSS	25	1.0	mg/L	100	83	100	100	100	96.6	12	0	100

- Effluent stream parameters which have not exceeded a monthly guideline in the current year or in the previous five years have not been included to this table.
- Discharges of effluent coming from the new low level liquid waste treatment systems are being considered as emanating from the ALWTC, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.3 Monthly Guideline Plots

For parameters that have a value higher than a CNL monthly guideline, the monthly plot of values is shown for that particular parameter at the monitoring point. This year there were eleven occurrences when one of three parameters (Copper, Iron, and Phosphorus) from the LLLWTS had monthly values higher than CNL monthly guidelines. Figure 5, show the number of times the monthly guidelines have been exceeded at any monitoring point over the last five years. Plots are displayed in Figure 6, Figure 7, and Figure 8 for each parameter, and the explanations for the observed high values can be found in Section 9.5.1.4.6. The monthly or daily guideline limit for the parameter in question is indicated by a broken red line in the corresponding figures.

9.5.1.4.4 Monitoring of Intake Water from the Winnipeg River

Except for bottled drinking water, all of the water required to operate the WL site is drawn from the neighbouring Winnipeg River at the Intake. The amount of water drawn from the Winnipeg River varies from year-to-year.

Grab-samples are collected each month from the Building 902 wet well to assess the levels of certain parameters that may be entering the site directly from the Winnipeg River. The measurements are summarized in Table 28, where they are compared to available data for the previous five years. Figure 9 shows the estimated amount of water used monthly for 2019.

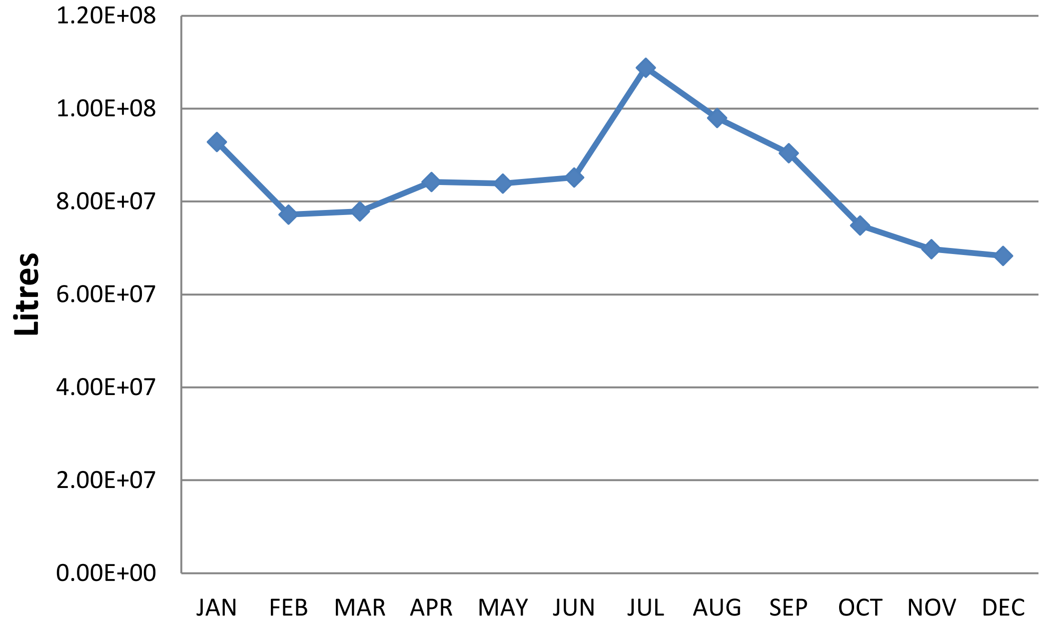

Figure 9: Monthly 2019 Intake Raw Pumped Water for the WL Usage

The following are notable points for the 2019 Intake water from the Winnipeg River:

- The Pump House flow meter recorded that 1.01E+06 m^3 of water was pumped from the river over the year.
- Compared to the five-year average, increased concentrations (> 10%) were only observed for Total Suspended Solids.
- Parameters that had their concentrations improve (> 10% decrease) this year compared to the average observed for the last five years are Phosphorus, Chromium, Copper, Iron, Lead, Nickel, Zinc, Mercury, Phenolics and Oil & Grease.
- Water consumption for the site increases during the summer months as the chillers and air compressors that are operated in the summer are cooled by the river water.

Intake water results can have a significant impact on the apparent environmental performance of the WL site and they will continue to be monitored closely. In 2019, the WL site temporarily expanded the monitoring program to encompass additional parameters at the site's intake and outfall monitoring station for 6 months. This was done to verify and provide justification that the environmental monitoring program is properly identifying and analyzing for the appropriate contaminant of concern being released into the environment through the site's operations.

The concentrations observed at the intake are used as the base line to determine if measured concentrations at the outfall are a result of site operations. The additional parameters that were looked at were the following:

Neutral Extractables, Chlorinated Extractables, Chemical Oxygen Demand, Dissolved Nitrate, Dissolved Organic Carbon, Total Organic Carbon, Chloride, Aluminium, Antimony, Arsenic, Barium, Beryllium, Bismuth, Boron, Cadmium, Cobalt, Lithium, Manganese, Molybdenum, Selenium, Silicon, Strontium, Thallium, Tin, Titanium, Uranium, Vanadium, Zirconium, Calcium, Magnesium, Potassium, Sodium, and Volatiles.

The results of this study will be summarized in more detail in the Outfall Section 9.5.1.4.5.2.

9.5.1.4.5 Monitoring of Liquid Effluents to the Winnipeg River

Two effluent streams, the Lagoon and Process Outfall, discharge significant volumes of water to the Winnipeg River. Normal surface land run off also reaches the river through Ditches 8 and 9. Results from monitoring each of these sources are discussed below.

9.5.1.4.5.1 Lagoon

The WL Lagoon secondary cell had only one period of discharge during the 2019 calendar year. This period of discharge occurred in the fall between October 21st and October 31st. There was no discharge in the spring as various sampling campaigns for the environmental assessment follow-up report and the environmental risk assessment for the lagoon were being conducted during this time period. The total amount of effluent discharged from the Lagoon in 2019 was 38,300 m^3.

Prior to discharging, the Lagoon was tested for CBOD, fecal and total coliform bacteria, and acute lethality (a biological assessment on the survivability of trout in the proposed effluent). These samples are collected by the Lagoon operators at defined areas in the secondary cell after isolation of the cell occurs. During fall discharge, grab-samples were collected close to the pipe emptying into the receiving ditch that leads to the Winnipeg River. Individual samples for most parameters are collected on a weekly basis during the course of the discharge.

The vertical scale from which surface height is determined was carefully adjusted to read absolute depth from the original floor of the Lagoon. This was done because the equation for calculating the contained volume in the secondary cell for any depth is derived from the calculation for the volume of a rectangular trapezoidal trough:

$$\begin{aligned}\text{Volume (in L)} &= \text{Height x [Width\_Bottom x Length\_Bottom} \\ &+ 0.5\text{(Width-Width\_Bottom) Length\_Bottom} \\ &+ 0.5\text{(Length-Length\_Bottom) Width\_Bottom} \\ &+ (1/3)\text{ (Width-Width\_Bottom) (Length-Length\_Bottom)]}\end{aligned}$$

Knowing the dimensions and geometry, the contained volume in the secondary cell can be calculated accurately for any depth using the following equation:

$$\text{Volume (in L)} = 636\,655{*}d + 206.886{*}d^2 + 0.02133{*}d^3 \text{ for depth “d” (in cm)}$$

The position of the Lagoon’s water surface was recorded once or twice daily while emptying. The daily flow was calculated from changes in the contained volume. This permitted calculation of volume-weighted concentrations and overall loads (see Section 9.5.1.5). Volume-weighted averages for a given period (month or year) are given by summing the product of the concentration for each day multiplied by the volume released that day, then dividing that sum by the total volume discharged during the period. Unlike other monitoring points (which are continuous or batch releases of nearly fixed volume), the Lagoon discharge flow rate can vary widely. The variation makes weighting corrections highly significant in determining meaningful average concentrations.

The fall discharge of the secondary cell was allowed to proceed after initial testing. Once discharging begins, the pH is monitored daily throughout the discharge period.

Table 29 summarizes the results of the fall discharge. Some notable points are:

- Compared to the five-year average, there was an increase in concentrations (> 10%) for fecal coliforms, Conductivity and Nickel. For the metal parameter concentrations a noticeable increase was observed, although all increases are still well below the guideline limits and measured at such low concentrations that a small increase in concentration leads to a large percentage increase.
- Compared to the five-year averages, CBOD, Unionized Ammonia, Total Residual Chlorine, Phosphorus, Total Suspended Solid (TSS, Chromium, Copper, Iron, Lead, Mercury, Zinc, Phenolics, and Oil & Grease were all substantially lower (> 10% decrease).
- No trout mortality was observed in the spring lagoon effluent sample that underwent acute lethality testing.
- The Total Residual Chlorine concentrations was at the proposed Wastewater System Effluent Regulations limit for 2019. The cloudy and wet fall contributed to the high levels of chlorine being observed, as there would be limited chlorine breakdown occurring in this weather.

The WL Lagoon discharge was compared against the limits set by the federal government in the Wastewater Systems Effluent Regulations in The Canadian Gazette [35]. The limits in force were met in all cases.

The results of the federally regulated parameters are indicated below:

- Carbonaceous Biochemical Oxygen Demand - annual volume weighted average was 0 mg/L, which is less than the 25 mg/L limit.
- TSS - annual volume weighted average was 1 mg/L which is less than the 25 mg/L limit.
- Un-ionized Ammonia - the maximum concentration was 0.0011 mg/L which is less than 1.25 mg/L limit.
- Total Residual Chlorine - annual volume weighted average was 0.02 mg/L which is at the 0.02 mg/L limit (limit not in force until 2021).

9.5.1.4.5.2 Process Outfall

The Outfall monitoring station functioned as expected during 2019. The total discharge volume was 1.25 GL. This volume is lower than the previous five-year average of 1.28 GL.

The Outfall discharges continuously. Measurements were performed on the samples weekly. This provided 53 samples of each parameter for the year.

Table 30 summarizes the results obtained, and compares them to averages for the previous five years. Notable results for the Outfall are:

- There were no instances of CNL’s monthly guidelines being exceeded at the Outfall monitoring station.
- The only parameters that had a significant increase (> 10%) compared to the 5 year average were TSS and conductivity.
- Compared to the five year average, Phosphorus, Chromium, Copper, Iron, Lead, Nickel, Mercury, Zinc, Phenolics and Oil and Grease concentration levels significantly decreased (>10%) .

Overall, the Process Outfall and sampling station operated successfully during 2019.

As indicated in Section 9.5.1.4.4, in 2019 the WL site temporarily expanded the monitoring program to encompass additional parameters at the site's intake and outfall monitoring station. The results of this study indicated that there were significant increases (>20 %) observed in the following parameter concentrations when compared to the intake concentrations.

Dissolved Nitrate, Total Organic Carbon, Strontium, Uranium, Magnesium, Potassium, Sodium, and the volatiles Bromodichloromethane, chloroform and Toluene. Currently, CNL is able to identify that the source of the Potassium and Sodium being introduced to the outfall is a result from the sanding/salting activities that occur on site as the weather transitions into and out of sub-zero temperatures. The Bromodichloromethane and chloroform are by-products result from the site's chlorination practises. The remaining parameters are currently not tied to a source, and CNL will be expanding the monitoring program to include looking for these parameters at upstream monitoring locations in hopes of being able to identify a source for them.

Going forward the environmental monitoring program will continue to monitor for the parameters mentioned above in the intake and the outfall, and will begin reporting on them in this annual report.

9.5.1.4.5.3 Drainage Ditches

Much of the land surrounding key remote facilities at WL is drained by two structures. Ditch 8 drains the land north of the WMA up to the northern site boundary and beyond. Water from the landfill and recharge area on the east is diverted instead around the WMA to the west-flowing Ditch 9, and into the Winnipeg River. These ditches are monitored for radiological and non-radiological content. The radiological part is discussed in Section 9.4 of this report and the non-radiological part is discussed here.

Ditches 8 and 9 were grab-sampled each time water was flowing off-site. This was after heavy rainfalls, of which there were eighteen events from 2019 April to October. At these same times, a sample was collected from the northern ditch bordering Highway 211. This is far enough from CNL operations to be a reasonable background (Control). It was not possible to measure the flow rates at any of the locations, or to sample representatively over entire rain events; therefore, no loads can be calculated.

Comparison is made to CNL guidelines (although they are intended for process discharges). All values were below CNL monthly guidelines this year. The measurement data are summarized in Table 31. The following are notable points for the 2019 ditches results:

- The rain event that occurred on September 3rd did not have a sample collected from the control ditch, due to a beaver dam obstructing the ditch flow.
- Conductivity was the only parameters that had a higher concentration than the previous five-year average for Ditch 8. The only parameters that had a higher concentration than the previous five-year average for Ditch 9 were Conductivity and Nickel. The control ditch also had readings higher than the previous five-year average for Conductivity, Copper, Iron, Nickel, and Zinc.
- All metal concentrations detected are so close to the detection limit, a small increase observed in the concentrations is having a large percentage increase being observed in Ditch 9 and the Control Ditch.
- The majority of the remaining parameters improved by more than 10% or stayed relatively the same for Ditch 8 and Ditch 9 when compared to the previous five years.
- All concentrations still remain well below the CNL's monthly guideline limit and pose no concern.

- All parameters measured in Ditch 8 and Ditch 9 were below or comparable to those measured within the Control Ditch, indicating that WL had negligible effects on the environment through these two pathways.

It should be noted that sediment control measures were put in place for projects in the WMA in 2019, as was the case in previous years.

9.5.1.4.6 Internal Liquid Discharge Monitoring

Building 300 and Building 100 both have a LLLWTS; each system represents a major area that generated low-level radioactive liquid wastes. Individual tank releases are monitored for operational control purposes.

A full tank must be emptied while a second tank is being filled. When nearly full, tanks are sampled; if the pH and radioactivity levels meet discharge criteria, they are discharged. The LLLWTS tank pre-discharge criteria does not include all parameters listed in CNL's non radiological guideline limit values, however the post-discharge analysis includes all of these parameters. CNL staff have determined, through historical data analysis from post-discharge samples, if the pH in the tank is adjusted to neutral, all other parameters will normally meet the guideline limit values. All post-discharge data is reviewed to ensure this process is working as intended, and program requirements are met. All effluents pass through a 5-micron bag filter to the Process Outfall, leading via the Outfall to the Winnipeg River.

The tanks in the new system have a smaller holding capacity so the frequency of discharges has increased. The new system was designed with a shorter life span in mind than the previous system that was employed by CNL. This was done to align with the decommissioning schedule being implemented by CNL. Discharging generally requires a day or less to complete, and can be more gradual if required.

Grab-samples are taken after the filter, and at the beginning of each release from the individual tanks. Measurements are performed on the effluent of each discharge to determine pH and conductivity. For other analytes, grab-samples are collected and analyzed by a designated laboratory to complete the characterization of the effluent being discharged.

In regards to monitoring the non-radiological parameters of the effluent for this reporting period, discharges of the new systems are being compared to the discharges from the ALWTC that was used in previous years. This allows for comparisons of the previous 5-years of effluent to continue to be made, as the effluent streams emanating from the R&D Complex in Building 300 and Building 100 should still be similar enough that a comparison is worthwhile.

In 2019, 0.19 ML was discharged from the LLLWTS.

The weighted averages of the combined releases from the LLLWTS are presented in Table 32 and monthly plots for the parameters that exceed the monthly guidelines are in Figure 6, Figure 7, and Figure 8.

The following are notable results for 2019:

- None of the monthly exceedances that occurred at the LLLWTS resulted in exceedances being observed at the Outfall monitoring location downstream in the process.
- There were increases (> 10%) in the annual average concentrations of Phosphorus and Copper, compared to the previous five year average results.

- The Iron concentration coming from the LLLWTS exceeded the CNL monthly guidelines two times (November, December). The overall Iron concentration observed for the year is lower than the previous years. The elevated levels observed in the LLLWTS align with some work that required manholes on site to be dewatered to permit employee access. This water was pumped into totes, and was relocated to the LLLWTS for treatment and disposal.
- The Copper concentration coming from the LLLWTS exceeded the CNL monthly guidelines seven times in 2019 (April, June, August, September, and October did not have an exceedance). Frequent exceedances are being observed in relation to the new tank systems that were installed in Building 300 as a decision was made to use copper piping in the new system instead of the stainless steel that was used in the old system. As soon as the new tanks were commissioned and utilized, the copper concentrations of the generated effluent noticeably increased to the guideline limit, but the concentration observed at the Outfall remains well below the monthly guideline limits.

  In November and December, the copper concentrations observed in these two months approximately doubled, as a result of the water relocations that enabled the manhole work.
- The Phosphorus concentration coming from the LLLWTS exceeded the CNL monthly guidelines two times (January, February). The elevated levels observed in the in the LLLWTS align with some work that was being performed for Building 200 on site. At this time pipe removal of the old active liquid waste treatment center was underway. Residual liquid or materials left in the pipe are suspected to be the source of the phosphorus, as it known that the decontamination center used high phosphorus containing compounds for decontamination of tools and equipment.

9.5.1.5 Loading Calculations

For the Lagoon and Outfall, volume-weighted loads were calculated (explained below), expressed in kilograms. All analytical data used previously in calculating averages are represented in the load.

For the Lagoon, the volume-weighted average concentration of a parameter was calculated as follows:

1. The measured concentration for each day was averaged with that of the next day;
2. The average was multiplied by the estimated volume discharged over the 24-hour period;
3. The products for all days were summed, then;
4. The resulting sum was divided by the total volume released during the period (Spring, Fall or entire year). The load was then given as the product of the calculated volume-weighted average concentration, multiplied by the total volume for the period.

At the Outfall, the total discharge volume for each month was multiplied by the monthly average concentration of the parameter.

Table 34 contains the results of calculations described above, grouped by parameter and by final outflow source. All mass-related parameters are shown. The table also compares them to previous years, and to the five-year averages.

Note that LLLWTS discharges are not included here, as they are reflected in the Outfall loads, and ditches are also not included as lack of flow data prevents their calculation.

When examining the WL site total loads, notable results are:

- TSS was the only parameter that had a load increase greater than 10% when compared to its previous five-year average. This increase in overall load is similar to the percentage increased observed at the intake over the same 5 year period, and as a result the percentage observed at the outfall.
- All other parameters had a significant decrease of 10% or more in their loads.

The sum of all parameter loads (6174 kg) has increased compared to last year (2735 kg) and is lower than the five-year average (7027 kg).

Table 34: Loading for the Current Year and Previous Five Years

ATG	Parameter	Monitoring Point	Loadings from Previous Five Years (kg) [a]						Results for Year 2019

a Averages were calculated by setting to zero results reported as “< DL.”
b # Spl. is the number of samples analyzed and reported.
c NDs is the number of samples in which analyte was not detected (i.e., Code = “< DL”, result = 0).

9.5.2 Airborne Effluents

Airborne emissions from the WL site are compiled on an annual basis for the purpose of reporting under the National Pollutant Release Inventory (NPRI) and the federal Greenhouse Gas (GHG) report. These emissions are also recorded for trending and improvement purposes. Radiological releases are covered in Section 9.4 of this report. Only non-radiological releases to the air will be covered in the following sections.

9.5.2.1 Fuel Use for Building Heating

Historically, the main stationary source for non-radiological emissions to air from the WL site was the Powerhouse which supplied district heating to various buildings on the site (see Figure 2). Starting in 2013 May, use of, and emissions from Number 2 fuel oil heating operations at the Powerhouse, ceased due to the completion of building conversions to either propane or electrical heating. Subsequently, a substantial increase was seen in the amount of cleaner burning propane used on site. Table 35 presents WL heating fuel consumption from 2014 to 2019. Generally, fuel consumption continues to trend downward (see Section 9.7.2 and Figure 10).

Table 35: Fuel Use for Building Heating from WL

		Data for Previous Five Years						Data for 2019
Parameter	**Unit**	**2014**	**2015**	**2016**	**2017**	**2018**	**Average**	
Fuel Burned

a Energy released calculated from consumption at 3.868E-05 TJ/L for Number 2 fuel oil.
b Energy released calculated from consumption at 2.718E-05 TJ/L for propane

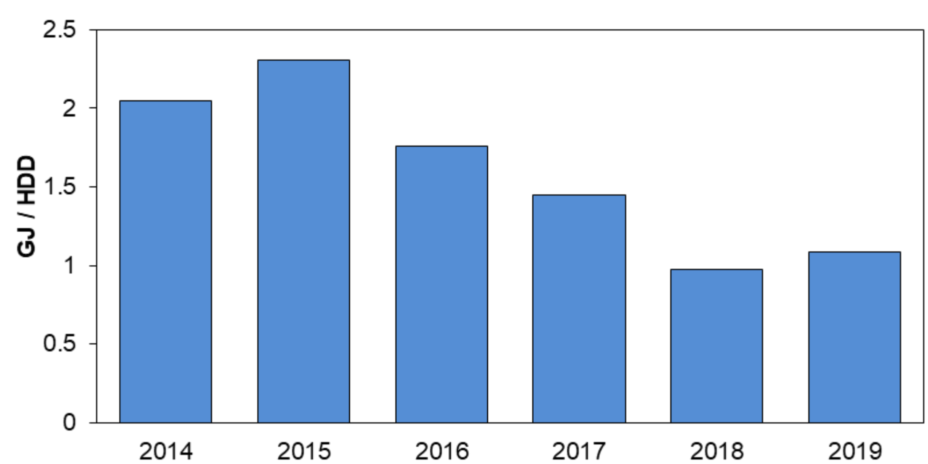

Figure 10: Annual Heating Energy Use from Fossil Fuels (per Heating Degree Days)

9.5.2.2 Reporting Under the National Pollutant Release Inventory (NPRI)

Under the authority of the *Canadian Environmental Protection Act*, 1999 [36], WL currently calculates releases of Part 4 substances for the NPRI program, using government reporting guidelines [38]. These releases to air include emissions caused by burning of Number 2 fuel oil and propane for heating (as discussed above), as well as diesel fuel used from site generators, dust emissions from unpaved roads, and excavation projects.

Emission factors are applied to fuel consumption data, as well as estimated kilometres travelled on unpaved roads, to determine the amount of Criteria Air Contaminants (CSDs) that are generated on site. Criteria Air Contaminants consist of carbon monoxide, oxides of nitrogen, sulphur dioxide, total (filterable) particulate matter (PM), and particulate matter below 10 microns (PM_{10}), particulate matter below 2.5 microns ($PM_{2.5}$), and Volatile Organic Compounds. Dust emissions from excavation projects were estimated based on a calculation for total particulate matter generated per excavation day. Dust generated from demolition activities in 2019 will be captured in the 2019 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories [27].

Table 36 outlines the annual Criteria Air Contaminants (CACs) generated from site activities. Prior to 2012, annual reports provided CACs for burning of fuels for heating only. However, to remain consistent with government reporting under the NPRI, the full suite of calculated CAC emissions were reported in 2012 and will continue to be reported as such.

Table 36 shows a small increase in emissions observed in 2019 compared to the 5-year average for the values for total particulate matter, PM_{10}, and $PM_{2.5}$. These values all met the NPRI reporting threshold this year, and are reported to Environment and Climate Change Canada. Road dust emissions were the major contributor to meeting these reporting thresholds. This year small segments of unpaved roads on the main campus were included for the road dust calculations that were not applied previously in the previous years. Estimated vehicle travel on the unpaved road to the landfill and all main campus unpaved road travel was added to the estimate this year. Although these segments of road have less vehicle traffic, they were added into the calculations for inclusiveness.

Table 36: Stationary Combustion Data and Emissions from WL

		Data for Previous Five Years						Data for 2019	NPRI Reporting Threshold
Parameter	**Unit**	**2014**	**2015**	**2016**	**2017**	**2018**	**Average**		
Airborne Emissions									
NO_x (as NO_2)	Mg	1.030	1.044	0.908	0.753	0.536	0.8542	0.621	20
SO_2	Mg	0.022	0.026	0.023	0.020	0.014	0.021	0.016	20
CO	Mg	0.475	0.461	0.399	0.348	0.233	0.383	0.271	20
TPM	Mg	19.57	16.36	15.022	13.651	14.562	15.833	10.574	20
PM_{10}	Mg	5.011	4.199	3.853	3.499	3.726	4.058	2.712	0.5
$PM_{2.5}$	Mg	0.532	0.454	0.415	0.376	0.391	0.434	0.292	0.3
Volatile Organic Compounds	Mg	0.081	0.082	0.071	0.059	0.042	0.067	0.049	10

9.5.2.3 Greenhouse Gas Reporting

Under the authority of the *Canadian Environmental Protection Act*, 1999 [36] WL is required to calculate releases under the GHGs emissions notice [37] providing the facility emits over 50,000 tonnes of carbon dioxide equivalent or more within the 2019 calendar-year.

GHG emissions from WL include carbon dioxide, methane and nitrous oxide. Emissions are primarily from the burning of propane, the use of diesel generators, the on-site transportation fleet, the on-site landfill and open-pit wood burning. They are measured in CO_2 equivalent tonnes which is a measure used to compare between gases that have different Global Warming Potential (GWP).

Table 37 outlines the GHG emissions from the WL site for the last six years. These emissions from the site have increased slightly from 2018. This small increase can be attributed to the increase in propane required to heat the site in 2019 as shown in Table 35. There was an increase in the number of heating degree days (i.e. increased demand for building heat based on temperature) in 2019. Overall greenhouse gases are 6% less than the average for the last 5 years.

Table 37: Greenhouse Gas Emissions

Parameter	Releases from Previous Five Years						2019 Releases
	2014	2015	2016	2017	2018	5-yr. Avg.	
GHG CO_2e tonnes	1940	1957	1883	1873	1678	1866	1756

Notes: GHG CO_2e tonnes - A unit of measure used to compare between gases that have different Global Warming Potentials (GWP). For example, the GWP for methane is 25. This means that emissions of one metric ton of methane is equivalent to emissions of 25 metric tons of carbon dioxide.

9.5.2.4 Halocarbons

In the atmosphere, halocarbons contribute both to global warming and to ozone depletion, via separate mechanisms. Losses of halocarbon refrigerants and fire suppressants are reported semi-annually to Environment and Climate Change Canada, pursuant to the Federal Halocarbon Regulations [39]. All releases greater than 10 kg are considered reportable.

As seen in Table 38, there were no reportable releases of halocarbons in 2019.

Table 38: Halocarbon Losses from WL

			Losses from Previous Five Years (kg)					Losses in 2019	
Type	**Global Warming Potential[b]**	**Ozone Depleting Potential[c]**	**2014**	**2015**	**2016**	**2017**	**2018**	**Number of Losses**	**Annual Loss (kg)**
Refrigerants[a]									
CFC (R-11)	4 600	1	0	0	0	0	0	0	0
CFC (R-12)	10 600	1	0	0	0	0	0	0	0
CFC+HCFC (R-502)[d]	4.1	0.28	0	0	0	0	0	0	0
HCFC (R-22)	1 700	0	26.39	0	0	0	0	0	0
HFC (R-134a)	1 300	0	0	0	0	12.47	0	0	0
Fire Suppressants									
Halon (R-1301)	6 900	10	0	0	0	0	0	0	0

a CFC = Chlorofluorocarbons; HCFC = Hydrochlorofluorocarbons; HFC = Hydrofluorocarbons
b Global Warming Potential per unit mass, relative to CO2 = 1.00
c Ozone Depleting Potential per unit mass, relative to CFC R-11 = 1.00
d The data for the CFC+HCFC(R-502) is from [39]

9.5.3 Overall Performance

The non-radiological effluent monitoring program established by CNL continues to supply valuable information about the potential impacts of operations on the Winnipeg River, and thus the local environment.

There were zero discharges from the Outfall and Lagoon which exceeded the current monthly guideline limits placed on CNL.

The fall discharge of the Lagoon this year was at the proposed Total Residual Chlorine limit. The overcast rainy fall contributed to CNL being at the limit, but the reduction in Chlorine use and changes to operation of the lagoon allowed CNL to meet the Total residual Chlorine limit despite not having the favourable weather which would have further reduced the Total Residual Chlorine concentrations in the water. This limit comes into force in 2021 as per the “Wastewater Systems Effluent Regulations” in *The Canadian Gazette* [35]. The site’s chlorination practices that have been adjusted over the last few years continued to prove successful in 2019, and will be applied in the future.

9.6 Regulatory Limit Exceedances and Contamination Incidents

There were no Regulatory Limit exceedances to report in 2019. However, CNL did have two reportable contamination incidents to the Winnipeg River (see Table 39). Both of these incidents were reported to Manitoba Sustainable development, and are related to a fuel leakage from the motor of the environmental field boat. The second incident was connected to the initial incident as it was caused by the misdiagnosis of the problem afflicting the motor during the initial repair.

Table 39: Reportable Events (Environmental Protection) at WL in 2019

Event No.	Title	Reportable Agency
ERM-19-3292	WL - Small fuel (gasoline) leak from boat motor into Winnipeg River - small volume approximately 30 ml.	Manitoba Sustainable Development
ERM-19-3460	WL EnvP: WL - Small fuel (gasoline) leak from boat motor into Winnipeg River - small volume < 500 ml	Manitoba Sustainable Development

9.7 Discussion of Improvement Initiatives

The following sections describe some efforts made during 2019 to identify, understand and/or remove sources of some monitored substances.

9.7.1 Monitoring Site Intake Water

Monthly samples of Intake water (from the Pump House wet well) were collected and measured for the usual effluent parameters.

In past years, monitoring of Intake water provided useful insights into apparent increases that could not be explained by internal events, allowing attention to be focused on those issues that can be influenced to improve. Monthly sampling will continue and will include an expansion for parameters being analyzed in 2020. This includes the addition of the following parameters: Dissolved Nitrate, Total Organic Carbon, Strontium, Uranium, Magnesium, Potassium, Sodium, and the volatiles Bromodichloromethane, Chloroform and Toluene.

9.7.2 Reducing Energy Use from Fossil Fuels

The largest quantity of non-radiological effluents to air comes from burning fossil fuels, in order to heat the site buildings. Starting in 2013 May, use of and emissions from Number 2 fuel oil heating operations at the Powerhouse ceased due to the completion of building conversions to either propane or electrical heating.

Figure 10 shows the annual fossil energy consumption since 2014, relative to the number of Heating Degree Days in each year. Heating Degree Days are calculated for each day as the difference between 18°C and the median ambient temperature.

From Figure 10, it is apparent that energy use has started to stabilize and any further reductions will be resulting from final closure of site buildings, reducing or removing their heating supply.

9.8 Environmental Assessment Follow-Up and Monitoring

Details about the Environmental Assessment Follow-Up and Monitoring Program are discussed in the *2019 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [27] (to be issued to the CNSC by 2020 June 30).

10. EMERGENCY MANAGEMENT AND FIRE PROTECTION

10.1 Emergency Preparedness Program

Whiteshell Laboratories (WL) adheres to the Corporate Emergency Preparedness (EmP) Program. See Section 10.1 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

As buildings are vacated at WL, the Building Emergency Teams are either dissolved or incorporated into the building to which they have moved. All occupied buildings at WL maintain adequate Building Emergency Teams.

10.1.1 Drills, Training, and Exercises

Two new Emergency Operations Center (EOC) staff members were oriented to the WL EOC and incorporated into the team in 2019. There was no change to the EOC staff structure, only personnel changes.

An aggressive drill and exercise schedule was planned for WL in 2019. However, operational changes were made on 2019 June 14th to comply with the CNSC Security Order (#9336) that resulted in a significant shift in the program's focus for the last half of the year. This resulted in many of the scheduled exercises being postponed or cancelled. In an effort to support the creation of the Tiered Response Force (TRF) at WL, EmP created and delivered multiple courses for the Force. EmP also assisted with field level training drills, and conducted a week of mini scenarios in preparation for the CNSC required force on force exercise, verifying the capability of the new TRF.

In 2019, a total of 218 exercises and drills were delivered at WL. This is a marginal increase over the 184 drills/exercises delivered in 2018.

The evaluations conducted through these exercises and drills generated 70 opportunities for improvement across the site and the EmP program. Table 40 provides details on the number and type of the exercises and drills conducted in 2019.

Table 40: WL Emergency Preparedness Exercises – 2019

Type of Drill or Exercise	Number Completed in 2019
Fire Drills	11
Site-wide Specialty Drills	160
Table Tops[a]	6
Targeted Communication Exercise	17
Site-wide Communication Exercise	12
Field Exercises (Functional)	12

a Table Tops include specific EOC Skill workshops as well. Each workshop focuses on a unique aspect of the EOC and includes a small practice scenario to conclude the workshop.

10.1.2 Status of Emergency Resources and Facilities

Whiteshell Laboratories maintains emergency facilities and resources, including the following.

10.1.2.1 Emergency Operation Center (EOC)

As part of WL's EOC framework there are two teams of EOC staff, and a backup team of alternates that can be engaged to cover for members of the two teams. These two teams operate on a two week on-call rotation.

All EOC technical equipment is checked monthly, with repairs, improvements and updates being installed as required and when identified. The system that enables the EOC to see a single camera view in the EOC was upgraded to enable multiple views.

All perishable EOC goods and supplies are checked annually and replaced as required.

There were no emergency events requiring activation of the EOC in 2019.

10.1.2.2 Mobile Nuclear Laboratory

Canadian Nuclear Laboratories still maintains the Mobile Nuclear Laboratory (MNL) for response both on-site and off-site. The unit continues to be maintained by WL Radiation Protection staff and is inspected at a regular interval to maintain control of inventory and equipment.

There were no emergency events requiring the activation of the MNL in 2019.

10.1.2.3 Equipment Checks

Respirators make up the majority of the equipment in the emergency cabinets. Due to the ongoing decommissioning activities, the number of respirators required in each location was assessed by EmP and RP staff in 2019. As a result, some inventories were reduced to reflect the new realities of the site, others were removed completely. The emergency-related equipment in most facilities is stored in strategically placed emergency cabinets. These cabinets are opened and inspected monthly. Once a satisfactory inspection is complete, the cabinets are re-sealed and signed off by the inspector. All scheduled checks were completed in 2019.

There were no emergency events requiring the use of this equipment in 2019.

10.1.2.4 Public Address System

The Public Address (PA) system is the primary system used for communicating emergency events to WL employees. The system functioned normally in 2019.

10.1.2.5 Secondary Emergency Signals

The WL site still employs an exterior siren as a redundant form of emergency alerting. The system is no longer required and was replaced by the PA system as the primary alerting system. This system will continue to be used as a redundant alerting system until either the equipment fails completely (there have previously been some issues with the equipment) or the building it is mounted to is decommissioned and demolished.

10.1.2.6 EOC Notification System

2019 was the first full calendar year that WL used the Everbridge Mass Notification system. There was a 100% response rate to all monthly communication tests (see Table 41) in 2019. This demonstrates the effectiveness of the notification system. The system has increased the effectiveness of the notification process while simultaneously reducing the burden of activation on the operator.

Table 41: WL Emergency Operations Center Communication Tests: 2019

	January	February	March	April	May	June	July	August	September	October	November	December

Y= Yes
N= No

In addition to these regularly scheduled monthly drills, a random quarterly drill is conducted. These drills are scheduled for random times and dates, including weekends, evenings and work hours. These random drills include the expanded EOC team and all the alternates. Table 42 identifies the response rates of the 2019 WL EOC Staff to the Quarterly Random EOC call out drills.

Table 42: WL Emergency Operations Center Random Quarterly Communication Tests: 2019

# of Participants	32	16	33	30
# who Responded	32	16	32	30
Response Percentage	100%	100%	97%	100%

a Only the Core EOC team was used for this test, which is the reason for the lower numbers.
b The Q4 drill was delivered early in Q1 of 2020, but is being counted as part of 2019. A second drill will be run in Q1 of 2020 that will be counted as part of the 2020 exercises.

10.1.3 External Collaborations

Contact is maintained with a variety of other emergency response/management organizations and interested public groups.

10.1.3.1 Local Agencies

A joint exercise was conducted with the Regional Health Authority, Emergency Medical Services in 2019. WL continues to maintain a working relationship with the Local Government District (LGD) of Pinawa. Scheduling conflicts prevented a joint exercise between the WL site and the Pinawa Fire Department in 2019, but another exercise will be scheduled in 2020.

10.1.3.2 Federal Interactions

The EmP Program Manager continues to maintain membership with the Manitoba Section of the Federal Coordination Working Group. The Federal Coordination Working group helps WL maintain ties with representatives from multiple federal agencies including (but not limited to) Public Safety Canada, the Royal Canadian Mounted Police (RCMP), Health Canada, Department of Defence, Public Health Agency of Canada, and Environment & Climate Change Canada, in order to bolster organizational resilience. The relationship with the RCMP continues to be heavily invested in, with several joint training exercises being delivered in 2019. WL continues to offer up decommissioned buildings to the RCMP for training prior to demolition. This ongoing training continues to increase their knowledge and comfort with the WL site and site operations. The various teams have also participated in joint exercises with WL staff, enhancing realism for staff and providing opportunities to practice integration.

10.1.4 Unplanned Emergency Events

No incidents requiring initiation of the WL Site Emergency Plan occurred during 2019.

10.2 Fire Protection Program

Whiteshell Laboratories (WL) adheres to the Corporate Fire Protection Program. See Section 10.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In 2018, the Fire Protection Program completed a gap analysis and implementation plan to enable the transition to CSA standard N393 *Fire Protection for Facilities that Process Handle, or Store Nuclear Substances* [40]. The following improvements were implemented in 2019:

- Fire Response Needs Analysis was completed.

There were no reportable fire events at WL in 2019.

10.2.1 Fire Response Drills

Fire drills are conducted annually in accordance with NFPA 801 [41], the National Fire Code of Canada [42] and CSA standard N393-13 *Fire Protection for Facilities that Process Handle, or Store Nuclear Substances* [40].

All fire response drills for the facilities at the Whiteshell site were completed in 2019.

10.2.2 External Collaborations

Whiteshell Laboratories and the Town of Pinawa signed a Fire Protection Service Agreement to improve Mutual Aid support capabilities.

Firefighters engage in training programs to improve response operations throughout the year. Significant aspects of response-based training included the following:

- 32 personnel are qualified to awareness training in confined space rescue.
- 16 personnel are qualified in NFPA 1006 rope rescue operations.
- 21 personnel are qualified to emergency medical responder level.
- 14 personnel are qualified to NFPA 472 Hazmat operations level.

10.2.3 Third Party Audits & Inspections

A third party Fire Protection Audit was conducted in 2018 February. The next audit, as per the requirements of CSA N393-13, *Fire Protection for Facilities that Process, Handle, or Store Nuclear Material Substances* [40], is scheduled for 2021.

10.2.4 Fire Hazard Analysis

All fire hazard analysis documentation for buildings requiring a fire hazard analysis have been reviewed and are being evaluated against the decommissioning schedule. Any Fire Hazard Analysis documentation requiring revisions will be updated in 2020.

11. WASTE MANAGEMENT

11.1 Waste Management Program

Whiteshell Laboratories (WL) adheres to the Corporate Waste Management Program. See Section 11.1 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Waste Management Program continues to provide effective and efficient delivery of Waste Management services.

Significant activities for the Waste Management Program include:

- Continued to refine and communicate the Integrated Waste Strategy to integrate waste lifecycle management across all CNL-operated sites and to capture the CNL baseline waste strategies and defined pathways for all CNL wastes.
- Collaboration between CRL and WL Programs to effectively disposition radioactive wastes, leading to the advancement of remediation and transportation projects.
- Enhanced support to existing activities and new activities in support of the new schedule for the WL Closure Project. The support improved segregation protocols and ensured continued adherence to waste processes.

The waste acceptance criteria for three of the waste receiving facilities on-site (including the Waste Clearance Facility, Waste Handling Area and the WMA storage facilities) remained unchanged for 2019. It should be noted the Waste Clearance Facility was taken out of service late 2019 to support its demolition in 2020. It was determined by management no replacement facility was required as materials can be radiological released in-situ.

11.1.1 Waste Management Operations

Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects. The packaged solid radioactive wastes were stored in designated storage facilities in the WL WMA depending on the hazard level and packaging, as well as dispositioned to CRL for interim storage.

Demolition of the Large Scale Vented Combustion Test Facility (LSCVTF) consisting of Buildings 308, 309, 310 and 311 (B308, B309, B310 and B311) located in the outer area of the WL site was decommissioned. A total of 962 m^3 clearable waste was generated from the demolition; 702 m^3, consisting of metal and concrete, was recycled while 260 m^3, consisting of asphalt shingles and asbestos-containing tiles, was dispositioned to an off-site waste receiver.

Building 414, used as the controlled access/exit point to and from the Controlled Area 2 on the north end of the site was demolished. A total of 2.2 m^3 of clearable was generated; 0.1 m^3 of metal was sent to an off-site metal recycler while 2.1 m^3 of waste was dispositioned to an off-site waste receiver.

Stage 6 of B300 Research and Development Complex, also known as RD-14M, was demolished. A total of 780 m^3 of clearable was generated; 310 m^3 of construction and demolition debris was dispositioned to an off-site waste receiver, 270 m^3 of metal was sent to an off-site metal recycler and 200 m^3 of concrete was processed (rubblized and separated of rebar) for re-use by the WL site.

The Soil Storage Compound (SSC) was de-inventoried in 2019. The contaminated material, consisting of soil and gravel, was packaged at the WMA in certified transportation packages. A total of 201 m^3 of low-level waste (LLW) was generated and dispositioned to CRL.

Decommissioning of Building 200 Active Liquid Waste Treatment Centre continues, generating 186.8 m^3 of LLW in 2019, which is packaged in certified transportation packages and staged at the WMA. Disposition of waste to CRL is scheduled for 2020.

Operational clean-out of the Low-Level Bunker 6 was completed in 2019, which produced 406 m^3 of LLW. Drummed soil, palletized concrete, compacted bales and other miscellaneous waste items were safely packaged in certified transportation packages in the WMA and are staged in the Waste Transshipment Area. Disposition to CRL will be in 2020.

De-inventorying efforts of legacy waste stored in SMAGS continued in 2019. A total of 834 m^3 of LLW and 28 m^3 of intermediate-level[12] waste (ILW) was transported to CRL. Thirty-one bins remain, undergoing additional qualification and inspection of waste contents to ensure transportation and waste criteria compliance are met, and will be shipped to CRL in 2020.

Table 43 summarizes the quantities of radioactive waste generated in 2019 that was sent to each storage location. Table 44 summarizes the volumes of solid low-level radioactive waste originating from each facility in 2019. Table 45 summarizes the volumes of solid intermediate-level radioactive waste originating from facility in 2019. Table 46 summarizes the volumes of solid low-level and intermediate-level radioactive waste transported to Chalk River Laboratories for disposition.

Table 43: Radioactive Waste by Storage Location

Storage Facility	Volume (m^3)	
	2018	2019
Low-Level Quonsets (B431, B432, B433)	21.9	59.6
Intermediate-Level Waste Bunkers	0.0	0
SMAGS[a]	35.0	46.0
Soil Storage Compound	0.0	0.0

a Shield Modular Above Ground Storage

[12] In this context, ILW refers to any waste that does not meet the proposed Near Surface Disposal Facility (NSDF) Waste Acceptance Criteria (WAC) and requires storage in ILW facilities at CRL.

Table 44: Low-Level Radioactive Waste Generated by Facility

Facility of Origin	2018		2019	
	Compactable Waste Volume (m^3)	Non-Compactable Waste Volume (m^3)	Compactable Waste Volume (m^3)	Non-Compactable Waste Volume (m^3)
Building 100	4.5	0.0	4.8	0.0
Building 200	35.9	77.9	19.1	167.7
Building 300	2.6	0.5	0.0	0.4

Building 304	0.0	0.0	0.0	0.0
Building 309 (LSVCTF) [a]	0.0	0.0	0.0	0.2
Building 402	0.5	0.5	0.7	0.0
Building 411 [a]	7.4	0.2	0.2	0.0
Building 421	0.7	2.5	0.2	0.0
Building 511	0.0	0.0	0.0	0.0
Building 514 [a]	3.5	114.0	0.0	0.0
Concrete Canister Storage Facility	0.0	0.0	0.0	0.0
Shielded Facilities (HCF & IFTF) [b]	64.3	9.0	101.4	0.0
Waste Handling Area	18.2	0.0	0.0	0.0
Waste Management Area	25.6	0.0	6.9	0.0
LLW Bunker 6	0.4	0.0	13.6	406
Affected Lands	2.5	1.0	0.1	1.7
Soil Storage Compound [c]	0.0	0.0	0.0	201.0
Total	**166.1 (25.0)**[13]	**205.6**	**162.0 (15.0)** [14]	**766.8**
Total after Compaction	**230.6**		**781.8**	

a Building demolished.
b Operational compactable waste volumes were generated as a result of the refurbishment of the hot cell manipulators.
c The soil storage compound was de-inventoried in 2019.

Table 45: Intermediate-Level Radioactive Waste Generated by Facility

Facility of Origin	Volume (m^3)	
	2018	2019
Affected Lands	0.72	0.0
Building 200	0.96	0.0
Total	1.68	0.0

13 This volume of compactable waste was reduced to 25.0 m^3. It is not possible to determine accurate post-consolidation volumes attributed to individual facilities because all of the waste is being combined during the compaction process.

14 This volume of compactable waste was reduced to 15.0 m^3. It is not possible to determine accurate post-consolidation volumes attributed to individual facilities because all of the waste is being combined during the compaction process.

Table 46: Radioactive Wastes Transported to CRL for Disposition

Facility of Origin	2018		2019	
	LLW Volume (m^3)	ILW Volume (m^3)	LLW Volume (m^3)	ILW Volume (m^3)
Building 411	84.0	0.0	168.0	0.0
Building 514	0.0	0.0	252.0	0.0
WMA (Cesium Pond Soil)	826.0	0.0	28.0	0.0
WMA (Legacy Sources)	0.0	3.1	0.0	0.0
Soil Storage Compound	0.0	0.0	201.0	0.0
SMAGS[a]	344.0	0.0	834.0	28.0
Total	1,254.0	3.1	1,483.0	28.0

a Shield Modular Above Ground Storage – legacy waste generated from various decommissioning projects

Likely clean waste from Controlled Areas was monitored in-situ or at the Waste Clearance Facility (WCF). Clean bagged waste was monitored using the bag monitor located in the IFTF facility where WL's laundry facility is now stationed; all bagged waste met the unconditional clearance criteria and was deemed to be clean and suitable for unrestricted release in 2019.

Whiteshell Laboratories continued to reuse or recycle as much material as practicable; this includes both recyclable material sent to the municipal recycling facility and other material-specific facilities throughout Manitoba. Waste Management Program representatives exercised a proactive approach to ensure waste was properly segregated at the source of origin to maximize the amount of material that could be reused or recycled.

Table 47 summarizes the disposition pathway of non-active waste.

Table 48 summarizes the amount, by material type, of recyclable waste shipped off-site.

Table 47: Non-Active Waste Disposition Pathways

Disposition Location	Volume (m^3)	
	2018	2019
WL Asbestos Disposal Site	0	0
WL Burn Pit	84 [a]	0
WL Inactive Landfill	367	543
Recycling [b] Sent Off-Site	262	410
Off-Site Landfill [c]	0	777
Total	**713**	**1,730**

a Increased volume of vegetation sent to the Burn Pit due to the expansion of the Protected Area in the WMA.

b This recycling waste pertains to office recycling that is generated on a daily basis that is accepted a municipal recycling facilities

c WL's Inactive Landfill stopped receiving waste mid-2019 to support the environmental risk assessment. Non-active waste is directed to off-site licensed landfills.

Table 48: Recycled Waste Shipped Off-Site

Material[a]	Weight (kg)	
	2018	**2019**
Aluminum	0	0
Batteries Shipped	196	1,708
Batteries Recycled	533	882
Cardboard [b]	544	0
Copper and Brass	0	0
E-Waste Shipped	876	0
E-Waste Sold	0	0
Ferrous Metals	269,788	798,574
Glass	0	0
Lumber	0	0
Plastic Shipped	0	0
Plastic Sold	0	0
Stainless Steel	0	0
Lead	857	3006
Total	**272,261**	**804,170**

a This recycling waste pertains to material that is sold or charged to be taken to a material specific recycling facility.
b Cardboard is sent to a municipal recycling facility and inclusive in Table 47.

Improvements were made in preventing waste accumulation inside of buildings and transferring the waste to appropriate waste facilities immediately after generation. Improvements continue to be addressed in reference to the lack of processing and storage space for non-routine waste materials (e.g., mixed waste and large contaminated items), as well as large volumes radioactive wastes generated from decommissioning activities. Mitigation measures that will be put in place in 2020 include developing an Independent Safety Assessment (ISA) for the interim storage of cargo containers containing radioactive wastes in the WMA while transportation documentation and acceptance from off-site waste receivers are pending.

Following each inspection, the findings were communicated to the identified waste owners for remedial or corrective actions.

11.1.1.1 Liquid Waste Generation

During 2019, 186.5 m^3 of low-level liquid was processed in the B300 LLLWTS and 2.8 m^3 in the B100 LLLWTS, for a total of 189.1 m^3 of low-level liquid waste processed through the two systems.

11.2 Decommissioning Plan

Several buildings and structures were decommissioned in 2019, where operational wastes were dispositioned, building services isolated and industrial hazardous materials removed prior to demolition.

The Stage 6 of B300 Research and Development Complex, also known as RD-14M, structure and services were completely removed within 1 m of the building footprint, excluding the radiologically cleared concrete foundation and footings below 1.5 m below grade. Final clearance of soils beneath the building and remaining building foundation was completed before the excavated area was backfilled and restored to match the surrounding grade.

The Large-Scale Vented Combustion Test Facility (LSVCTF), consisting of four buildings in the outer area of the WL site and surrounding security control fence, was completed removed within 1 m of the building footprints. The site was backfilled and landscaped to grade.

The B414 Controlled Area 2 Entrance was demolished to grade. The concrete pad and subsequent clearance of soils will be performed at a later date in conjunction with affected lands work.

B200 decommissioning activities involved the continued removal of process systems and equipment to reduce source term hazards. The focus of work involved radiological and waste characterization of tanks, application of fixatives to prepare tanks for future size reduction, and removal and packaging of processing piping, gloveboxes and sample stations.

Decommissioning progress is also discussed in the facility sections (Appendix A through Appendix G).

Table 49 lists the WL Detailed Decommissioning Plans (DDPs) and their status as of 2019.

Table 49: Overview of WL Detailed Decommissioning Plans

Facility	DDP Document Title	Document #	Status
Whiteshell Laboratories	The Whiteshell Laboratories Detailed Decommissioning Plan: Volume 1 - Program Overview	WLDP-02000-DDP-001 (RC-2143-1, Rev. 4), January 2002	To be Cancelled and Superseded by WLDP-02000-DDP-001, Rev.0.
	The Whiteshell Laboratories Detailed Decommissioning Plan: Volume 1 - Program Overview	WLDP-02000-DDP-001, Revision 0, 2019	Current version of DDP Volume 1 submitted to CNSC for acceptance.
Shielded Facilities	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 2 - Shielded Facilities	WLDP-21400-DDP-001, Revision 1, 2016	Facility is operational and decommissioning activities ongoing. DDP Volume is available for use.
Van de Graaff Accelerator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 3 - Van de Graaff Accelerator	RC-2143-3, Revision 1, 2000	Facility has been decommissioned.
Neutron Generator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 4 - Neutron Generator	RC-2143-4, Revision 1, 2000	Facility has been decommissioned.
Active Liquid Waste Treatment Centre	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 5 - Active Liquid Waste Treatment Centre Building 200	WLDP-25400-DDP-001, Revision 0, 2011	Facility is being decommissioned. DDP Volume is available for use.
Whiteshell Reactor-1 (WR-1)	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 6 - Whiteshell Reactor-1: Building 100	WLDP-26400-DDP-001, Revision 3, 2015 (Complete Dismantlement and Removal Approach) WLDP-26400-DDP-001, Revision 4, 2017 (In Situ Decommissioning Approach)	Facility has been shut down and currently under M&S. Complete Dismantlement and Removal approach has been approved by the CNSC. EA process for ISD is in progress, Revision 4 to be revised with final EA submission. DDP Volume (Revision 3) is available for use.
Concrete Canister Storage Facility	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 7 - Concrete Canister Storage Facility	WLDP-22500-DDP-001, Revision 1, 2017	Facility is operational. DDP was sent to the CNSC for information and comments received (to be dispositioned).

Facility	DDP Document Title	Document #	Status
Waste Management Area	Volume 8 - WMA Part 1: Standpipes Area	WLDP-36500-DDP-001, Revision 0, 2016	Facility is operational DDP under development.
	Volume 8 - WMA Part 2: Intermediate Level Waste Bunkers, Building 417 and Amine Tanks	WLDP-24900-DDP-001, Revision 1, 2017	Facility is operational. DDP under development.
	Volume 8 - WMA Part 3: Low Level Waste Liabilities	WLDP-24400-DDP-001, Revision 4, 2019	Facility is operational. DDP was sent to the CNSC for acceptance and comments received (to be dispositioned)
Research and Development Facilities Complex	Volume 9 - Building 300	WLDP-23500-DDP-001 (RC-2143-9), Revision 0, 2007	Facility is operational. DDP Volume is available for use.
	Volume 9 - Building 300_Addendum	WLDP-23500-DDP-001_AD, Revision 2, 2018	
Decontamination Centre	Volume 10 - Decontamination Centre Building 411	WLDP-27400-DDP-001, Revision 0, 2011	Facility has been decommissioned.
Health and Safety Facilities	Volume 11 - Building 402 and 305	WLDP-37000-DDP-001	Facility has been shut down and currently under M&S. DDP under development.
DDP Volume 12	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 1: South-Side Buildings	RC-2143-12, Revision 1, 2006	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure: North-Side	WLDP-32000-DDP-001, Revision 0, 2009	Operational and decommissioning activities ongoing. DDP Volume is available for use. Note: This DDP is “Part 2” of Volume 12.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 3: Outer Area Buildings and Facilities	WLDP-33000-DDP-001, Revision 1, 2008	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 4: Site Services	WLDP-34000-DDP-001, Revision 1, 2013	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 5: Site Affected Lands and Contaminated Structures	WLDP-35000-DDP-001, Revision 1, 2012	Decommissioning activities ongoing. DDP Volume is available for use.

12. SECURITY

12.1 Security Program

Whiteshell Laboratories (WL) adheres to the Corporate Security Program. See Section 12 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The *Whiteshell Site Security Report* [43] outlines the security arrangements that are in place at the WL site. The Security program consists of processes, procedures, and staff to manage the continuous operation and response to security incidents; the Security Program and procedures are reviewed and updated as required to address operational requirements.

Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers stated in the Fitness for Duty, Volume III Nuclear Security Officer Medical, Physical and Psychological Fitness document [44].

A CNSC Type II Compliance Inspection was conducted 2019 August 26-28, resulting in one Directive. A response letter, addressing the Directive, is due to the CNSC by 2020 February 19.

CNL-WL has one open enforcement item (Order). An implementation plan to address the Order has been submitted and accepted by the CNSC. All actions identified in the implementation plan are to be completed by 2020 May 01, the main action being the standing up of a Tiered Response Force (TRF).

The CNSC 2019 biennial security exercise was successfully conducted on 2019 November 28, which included testing the capabilities of the first groups of TRF trainees. The exercise report is being completed and is due to the CNSC by 2020 February 14. Any improvements or actions identified in the exercise report will be tracked via the corrective action program.

12.1.1 Security Events

In 2019, there was one low safety-significant security event at WL, reported to CNSC (see Section 3.2.1).

13. SAFEGUARDS AND NON-PROLIFERATION

13.1 Safeguards Program

Whiteshell Laboratories (WL) adheres to the Corporate Nuclear Materials and Safeguards Management (NM&SM) Program. See Section 13 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

13.1.1 IAEA Activities

A Design Information Verification inspection was carried out by the IAEA on 2019 September 06.

The activities associated with the Design Information Verification included:

- Verification of the DIQ;
- Verification of the site and general building design;
- Verification of containment integrity; and
- Verification of operational status of the facility.

The IAEA requested that the DIQ be updated to reflect the changes to the WMA fence line and new buildings.

A discussion of IAEA inspections conducted at WL can be found in Section 1.2.2.2. A list of IAEA inspections conducted at all CNL sites can be found in Section 1.2.2, Management System of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4].

14. PACKAGING AND TRANSPORT

14.1 Packaging and Transport Program

Whiteshell Laboratories (WL) adheres to the Corporate Transportation of Dangerous Goods Program, which includes the requirements of the Packaging and Transport SCA. See Section 14 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Packaging and Transport SCA covers the safe packaging and transport of nuclear substances and radiation devices. The TDG Program applies to any activities involving the transportation of dangerous goods to or from CNL sites. The TDG Program provides an operational framework for the safe off-site transport of dangerous goods by conforming to all applicable laws and regulations, as well as company policies and procedures.

The Waste Certification & Transportation branch is a centralized organizational department responsible for planning, coordinating and executing radioactive waste shipments from the WL site to the off-site disposal or storage facilities in a safe and compliant manner, including having fully trained Radioactive Material (RAM) Shippers as authorized under the CNL TDG Program.

Significant activities in 2019 included:

- Transportation of 1,483 m^3 of low-level waste and 28 m^3 intermediate-level waste sent off-site and safely delivered to CRL;
- Throughout 2019, additional technical assessments and studies on the WL used fuel inventory were completed in support of the licensing application of the Used Fuel Transportation Package (UFTP). The UFTP, which is owned by the Nuclear Waste Management Organization, has been leased with the intention that the UFTP will be the Type B Transportation Package for high-level waste transportation operations starting in 2020. There is a two-step licensing strategy for the UFTP, with the first phase focusing on licensing the UFTP for non-enriched CANDU fuels and the second phase focusing on WL's inventory of enriched and experimental fuels, including Uranium Carbide and Uranium Metal fuel types. The phase one UFTP Safety Analysis Report (SAR) Addendum was submitted to the CNSC in 2019 May. The UFTP SAR for Mixed Fuel Types (representing phase two) is under development, with an expected submission to the CNSC in 2020.

14.1.1 Shipments

At WL, 382 radioactive transport packages making up 63 loads were safely and successfully sent off-site in 2019. Whiteshell Laboratories complied with the Packaging and Transport of Nuclear Substances Regulations [45] and IAEA Safe Transport of Radioactive Material [46].

15. OTHER MATTERS OF REGULATORY INTEREST

15.1 Public Information and Disclosure Program

Whiteshell Laboratories (WL) adheres to the Corporate Public Information Program. See Section 15 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Public Information Program document [47] is intended to cover communication activities that occur within CNL's immediate neighbouring communities. This document was prepared in accordance with CNSC regulatory document Public Information and Disclosure [48].

15.1.1 Outreach and Stakeholder Engagement

WL shares information with the public through a number of activities including conducting public information sessions, media releases, the corporate website, a toll-free line, social media accounts and involvement in community events. Employees are CNL's greatest ambassadors and they are kept informed of developments so that they can also share information with their relatives, friends, and neighbours. The Whiteshell Laboratories site engages with the public at a number of activities. For 2019, these activities are listed in Table 50.

Table 50: Whiteshell Laboratories Engagement Activities in 2019

Date	Activity
January 3	Springwell School Tour
February 5	North Forge East funding announcement
March 3	WR-1 website updated
April 3	Filming of "Still Standing" on the Whiteshell Site
April 11	Site tour and meeting with Red River College
Spring	*CONTACT* newsletter distributed to approximately 8,000 homes
May 21	Public Liaison Committee meeting
May 24	Lac du Bonnet Trade Fair
May 31	SunRise School Division School Board tour and meeting
June 8	Whiteshell Laboratories Open House
June 18	Public tour
July 16	WR-1 Update to the LGD of Pinawa
August 6	Public Tour
September 16	Public Tour
November 6	Take Your Kids to Work day including tour of WR-1
November 12	WR-1 Breakfast Session: Reactor Characterization
November 14	Public Liaison Committee meeting
December	*CONTACT* newsletter distributed to approximately 8,000 homes

15.1.2 Public Consultation

WL actively works to engage local stakeholders on matters related to CNL activities. In 2019 a number of methods were deployed to gain feedback from and create discussion with interested parties including: feedback forms being made available online and at external events, technical meetings and focus groups being held and responses to inquiries being answered. WL strives to create open and transparent communication with all identified stakeholders.

Throughout 2019 CNL received 49 community inquiries related to WL. CNL works to address and respond to all inquiries.

Table 51: Whiteshell Laboratories Closure Project Public Inquiries

Nature of Enquiry	Number
In situ decommissioning of WR-1	33
Media	3
General Information and Tours	8
Asset Donation	5

15.1.3 Traditional and Online Communications

See Section 15 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

15.1.3.1 Website

See Section 15 of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

CNL's Whiteshell Decommissioning web page had 2,891 page views in 2019.

15.1.3.2 Newsletters

CONTACT is an external newsletter distributed to community stakeholders and to residences and businesses in communities surrounding WL, and is available on www.cnl.ca. This publication informs the reader on activities undertaken at CNL's Whiteshell Laboratories and profiles CNL's community activities. Approximately 8,000 homes in the region receive this bilingual newsletter. A spring and winter edition of *CONTACT* was issued in 2019. Since November 2017, four newsletters have been released with topics including the following:

- WL Closure Project and WR-1 Updates
- Highlights of public and Indigenous engagement activities
- Community initiatives demonstrating commitment to economic generation, sponsorship, donations and participation in community events
- Employee Profiles
- Environmental Stewardship including steps to reduce greenhouse gas emissions, wildlife protection and waste minimization

15.1.3.3 Media Releases

There is regular local and provincial media coverage regarding CNL's Whiteshell Laboratories and included 20 articles during the 2019 calendar year. See Table 52.

Table 52: Whiteshell Laboratories Closure Project Media Coverage for 2019

Date	Article	Title of Publication
January 3	Modular Reactor momentum building	The Clipper
January 9	CNL employees support local communities	The Clipper
February 20	North Forge East receives funding	The Clipper
March 14	SNC-Lavalin controversy reaches into Manitoba	Winnipeg Free Press
May 21	A Magical Machine	Discover Magazine
August 22	CNL to renew decommissioning licence	The Clipper
August 23	CNL applies to renew Whiteshell Laboratories Decommissioning Licence	Winnipeg River Advocate
September 26	Ceremony for CNL decommissioning	The Clipper
October 3	Modular Reactor momentum building	The Clipper
October 4	Indigenous knowledge keepers host ceremony at Pinawa Nuclear site	Winnipeg River Advocate
October 9	National Commission holds hearing for CNL renewal	The Clipper
October 9	CNL employees support local communities	The Clipper
November 7	CNL Breakfast Session to discuss decommissioning	The Clipper
November 9	Pinawa’s toxic predicament hurts Lake Winnipeg	Winnipeg Free Press
November 19	Nuclear Power vs Fossil Fuels	Winnipeg Free Press
December 4	Pallister Unaware of Nuclear Energy Pact	Winnipeg Free Press
December 6	Nuclear Option	Winnipeg Free Press
December 20	Small Nuclear Reactors no solution to Climate Change	Winnipeg Free Press
December 20	On Site Disposal of Nuclear Reactors is not acceptable	Sierra Club Foundation website
December 24	CN Nuclear Option	Winnipeg Free Press

15.1.4 Whiteshell Public Liaison Committee

Completing its sixteenth consecutive year of operation, the independently facilitated Whiteshell Public Liaison Committee continued to meet in 2019. Meeting minutes are recorded and actions are tracked and filed for reference. Over the year, two meetings were held: May 21 and November 14. Both meetings were held onsite, with a tour of the site provided to interested attendees after the May 21 meeting. Below are some highlights of the presentations from the meetings held in 2019:

- WL Closure Project Progress Update and Look Ahead,
- End State process and engagement
- WR-1 Environmental Assessment Update,
- WL Site Licence Update,
- Update from the Community Regeneration Partnership Committee.

The committee is comprised of community and stakeholder representatives (as given below), consisting of elected officials and community interest groups. Its mandate is to provide an opportunity for open dialogue between community stakeholders and WL senior management on WL's various environmental and decommissioning projects.

The Whiteshell Public Liaison Committee is represented by:

- Local Government District Pinawa,
- Rural Municipality (RM) of Lac du Bonnet,
- Town of Lac du Bonnet,
- Town of Powerview Pine Falls,
- Town of Beausejour,
- RM of Brokenhead,
- RM of Whitemouth,
- RM of Alexander, and
- Manitoba Sustainable Development.

15.1.5 Ongoing Projects

15.1.5.1 WR-1 In Situ Decommissioning Environmental Assessment

The proposed WR-1 in situ decommissioning (also referred to as in situ disposal) Environmental Assessment (EA) is a key project identified by CNL as part of the overall integrated approach to safely manage and reduce Canada's legacy liabilities. It is a requirement in support of the EA process that the WR 1 project information be made available to CNL neighbouring communities and stakeholder groups through a variety of mechanisms to ensure accessibility of fact-based information. Engagement activities were conducted in support of this requirement through a variety of methods including social media and website content, WR-1 in situ decommissioning Presentations, Meetings, Site Tours and Information Sharing with Stakeholders.

Project specific webpages and content were produced for the WR-1 In Situ Disposal Project. Content included: fact sheets, info graphics, downloadable posters, project descriptions and quick reference material. All information is available in both official languages. See www.cnl.ca/wr-1.

15.2 Indigenous Engagement

WL's Public Information Program, which seeks to build awareness and understanding for the work that CNL carries out on behalf of Canadians, is an established platform to sustain open and honest communications. CNL also follows CNSC RegDoc-3.2.2 Public and Indigenous Engagement: Indigenous Engagement which sets out requirements and guidance for licensees on Indigenous engagement. CNL recognizes and values the ongoing engagement with Indigenous communities. Through its engagement activities, CNL seeks to inform Indigenous groups of ongoing activities at the WL site and the possible effects of these activities to members of communities and the environment, and to seek feedback from the communities regarding traditional and current uses in the vicinity of the WL site.

Through its engagement activities, WL has been able to solicit and respond to First Nations and Métis community input. First Nations and Métis communities have sought more information and engagement on jobs, contracting opportunities, and environmental protection. CNL has supported the completion of traditional knowledge and land use studies for Indigenous communities in order to further learn what is important to local communities in terms of land use and value components and how CNL may impact that. CNL has been working with local First Nations and Métis communities to provide reasonable capacity, and at the same time has engaged communities with opportunities to better understand concerns and build positive relationships. Table 52 lists the engagement activities from 2019. Further details on Indigenous Engagements are available through the Indigenous Engagement Report.

Table 53: First Nations and Métis Engagement Activities in 2019

Date	Event / Activity	Attendance / Correspondence
January 08	Preparatory meeting for Sagkeeng First Nation Alternative Means Workshop	• 1 representative of Sagkeeng First Nation • 2 representatives of CNL
January 10	Recurring monthly meeting with Manitoba Metis Federation, CNL, CNSC	• 3 representative of Manitoba Metis Federation • 3 representatives of CNL • 3 representatives of CNSC
January 18	Preparatory meeting for Sagkeeng First Nation Alternative Means Workshop	• 1 representative of Sagkeeng First Nation • 2 representatives of CNL
February 06	South East Regional Development Council (SERDC) visit to the Whiteshell Site	• 2 Representatives of SERDC • 2 Representatives of CNL
February 13 -15	Sagkeeng First Nation Alternative Means Workshop	• 7 Sagkeeng community members • 5 CNL • 3 AECL • 4 CNSC
February 15	Meeting and site tour with Black River First Nation Councillor	• 1 Representative of Black River First Nation • 1 Representative of CNL
February 26	Recurring monthly meeting with Manitoba Metis Federation, CNL, CNSC	• 3 representative of Manitoba Metis Federation • 3 representatives of CNL • 3 representatives of CNSC
March 03	Trip with Black River First Nation to Waste Management Symposia	• 1 Representative of Black River First Nation
March 14	Meeting in Winnipeg with Manitoba Metis Federation of Traditional Knowledge and Land Use Occupancy study actions	• 4 representative of Manitoba Metis Federation • 4 representatives of CNL • CNSC on the phone
March 18	Sagkeeng First Nation Turtle Lodge Ceremony	• 7 Sagkeeng community members • 2 CNL • 2 AECL • 2 CNSC
April 26	Recurring monthly meeting with Manitoba Metis Federation, CNL, CNSC	• 3 representative of Manitoba Metis Federation • 3 representatives of CNL • 3 representatives of CNSC
May 14 - 16	Vision Quest Conference and Trade Show	• 1 Representative from CNL • 1 Representative from North Forge East

Date	Event / Activity	Attendance / Correspondence
May 28	Recurring monthly meeting with Manitoba Metis Federation, CNL, CNSC	• 3 representative of Manitoba Metis Federation • 3 representatives of CNL • 3 representatives of CNSC
June 03	Traditional knowledge study WL site tour	• 22 representative of Black River, Brokenhead, Hollow Water First Nations • 3 representatives of CNL • 3 representative of HTFC Planning & Design
June 04	Traditional knowledge study workshop	• 22 representative of Black River, Brokenhead, Hollow Water First Nations • 3 representatives of CNL • 3 representative of HTFC • 2 representatives of CNSC
June 08	WL site public open house and tour	• ~300 registrants
July 04	Meeting to discuss Traditional Ceremony on WL site and tour	• 3 representatives from Turtle Lodge • 2 representatives from CNL • 1 representative from AECL
July 31	Manitoba Metis Federation (MMF) Meeting with Procurement re Opportunities	• 2 representatives from MMF • 2 representatives from CNL
August 01	Manitoba Metis Federation Observation of CNL's Environmental Monitoring Program	• 1 representative of Manitoba Metis Federation • 3 representatives from CNL
August 15	Manitoba Metis Federation Observation of CNL's Environmental Monitoring Program	• 1 representative of Manitoba Metis Federation • 3 representatives from CNL
September 10	Update meeting with Sagkeeng First Nation and CNSC	• 1 representative from Sagkeeng (OKT Law firm) • 1 representative from CNL • Up to 6 representatives from CNSC
September 13	Traditional Indigenous Ceremony with Sagkeeng First Nation and Turtle Lodge	• 7 representatives from Sagkeeng • 10 representatives from Turtle Lodge • 2 representatives from Hollow Water • 2 representatives from CNSC • 2 representatives from AECL • 3 representatives from CNL plus staff
September 18	Community Meeting with Sagkeeng First Nation	• 7 representatives from Sagkeeng • 6 representatives from CNSC • 4 representatives from CNL
September 20 - 22	Manitoba Metis Federation Annual General Assembly	• 4 representatives from CNL

Date	Event / Activity	Attendance / Correspondence
September 25	Update on Traditional Knowledge Study with Black River, Brokenhead and Hollow Water	• 1 representative from Black River • 2 representatives from Brokenhead • 1 representative from Hollow Water • 2 representatives from HTFC Planning & Design • 1 representative from CNSC • 1 representative from CNL
September 26	Recurring monthly meeting with Manitoba Metis Federation, CNL, CNSC	• 3 representative of Manitoba Metis Federation • 3 representatives of CNL • 3 representatives of CNSC
October 04	Manitoba Metis Federation Observation of CNL's Environmental Monitoring Program and check-in on MMF satisfaction with the process	• 1 representative of Manitoba Metis Federation • 5 representatives from CNL
October 10	Manitoba Metis Federation Observation of CNL's Environmental Monitoring Program	• 1 representative of Manitoba Metis Federation • 3 representatives from CNL
October 22	Manitoba Metis Federation Celebration of the 175th anniversary of Louis Riel's birthday	• 3 representatives from CNL for the dinner
November 01	Manitoba Metis Federation meeting with AECL and CNL re post site closure Environmental Monitoring	• 3 representatives from MMF • 2 representatives from AECL • 2 representatives from CNL
November 25	Regular Update meeting with Sagkeeng and CNSC	• 2 representatives from Sagkeeng • 7 representatives from CNSC • 2 representatives from CNL
November 26	Recurring monthly meeting with Manitoba Metis Federation, CNL, CNSC	• 3 representative of Manitoba Metis Federation • 3 representatives of CNL • 3 representatives of CNSC
December 03	Meeting with MMF re topics arising from monthly meeting actions as well as Intervention	• 5 representatives from MMF • 4 representatives from CNL
December 05	Meeting with Black River, Brokenhead and Hollow Water regarding roll-out of Traditional Knowledge Study	• 21 representatives from Black River and Brokenhead • 2 representatives from HTFC • 3 representatives from CNSC • 3 representatives from CNL • 2 representatives from AECL
December 11	Long-term relationship workshop with Sagkeeng Anicinabe	• 8 representatives from Sagkeeng First Nation • 6 representatives from CNL

16. ACRONYMS

AECL	Atomic Energy of Canada Limited
ALARA	As Low As Reasonably Achievable (economic and social factors being taken into account)
ALWTC	Active Liquid Waste Treatment Center

APPENDIX A CONCRETE CANISTER STORAGE FACILITY

A.1 FACILITY OPERATION

The Concrete Canister Storage Facility (CCSF) is operated under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [49]. Concrete storage canisters located at the CCSF have been used at WL since 1975 to store irradiated fuel; there are currently 16 canisters in use.

During 2019, staff of the Site and Nuclear Operations Branch monitored the operation of the CCSF.

The CCSF was operated in compliance with practices and procedures approved for operation. All required surveys and inspections were completed in 2019.

Routine operations in the CCSF were carried out by staff in the Site and Nuclear Operations Branch.

A.1.1 RADIATION EXPOSURE

Waste Management Area facility staff from the Site and Nuclear Operations Branch operated the CCSF. Radiation exposures received by the staff are listed under the Waste Management Area (see Section D), since measured doses are attributed to waste management operations in that facility.

Staff operating the CCSF participated in routine bioassay testing which involved a semi-annual or annual whole-body count and/or gross beta of urine samples every 60 days. There was no indication of any internal radiation exposures to facility personnel.

There were no doses exceeding CNL's Action Levels or CNSC regulatory limits to personnel as a result of operating the CCSF during 2019.

A.1.2 COMPLIANCE MONITORING

A.1.2.1.1 Air Effluent Monitoring of Canister Liners

Each canister has a closed air-circulating system to monitor the internal space between the canister liner and the sealed fuel basket for the presence of fission products and moisture. Canisters are monitored for one week per month between April and November, dependant on weather. This year readings began in May and concluded in October.

The gross beta activity was below or near the detection limit of 0.04 Bq/m^3 for all canisters.

There was no visible moisture detected from the internal canister space during 2019 monitoring, however, the silica gel used in the counting did change colour from blue to pink indicating moisture in the air is present.

A.1.2.1.2 Monitoring of Ground and Surface Water

Figure 11 shows the drainage area surrounding the CCSF. Further details on monitoring and results of monitoring ground and surface water can also be found in Sections 9.4.1.3 and 9.5.1.4, compliance results for the CCSF are described below.

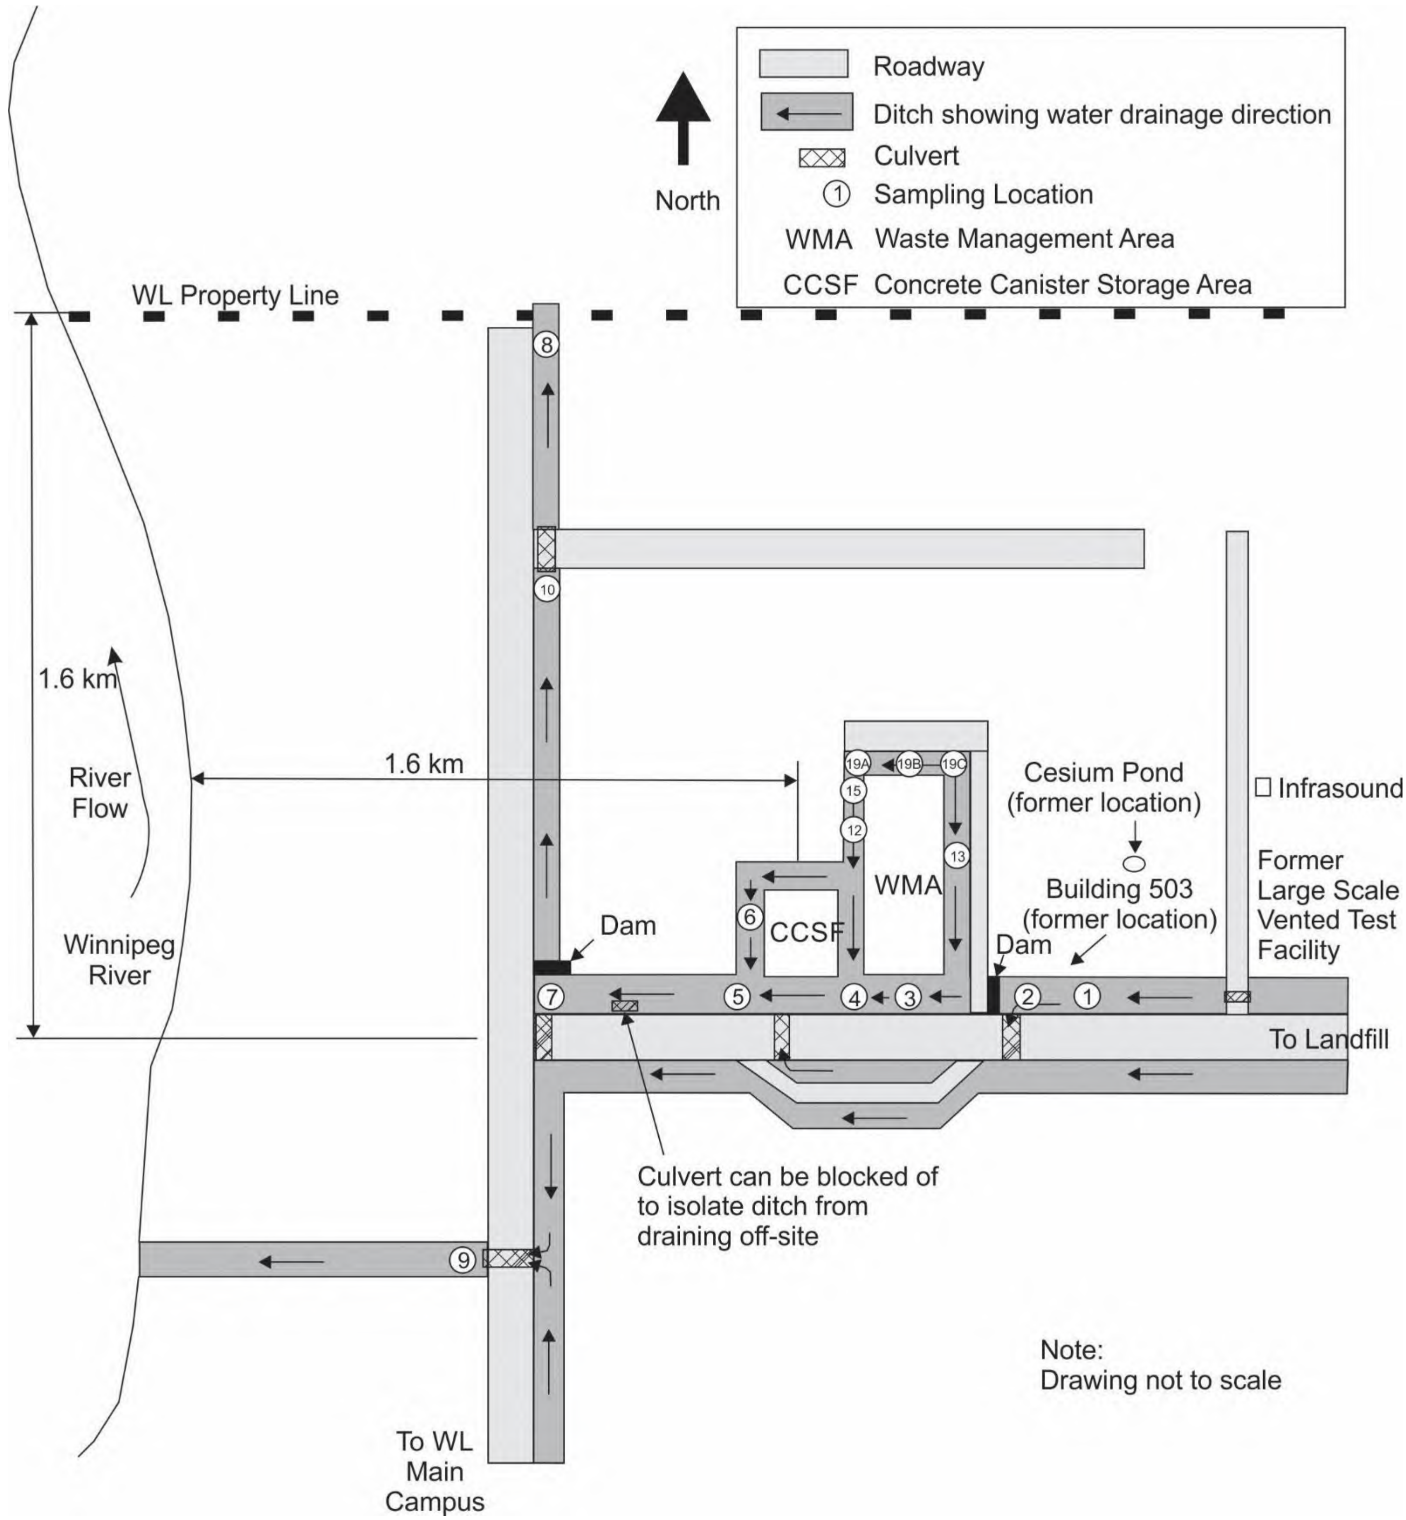

Figure 11: Surface Water Drainage Sample Points

Groundwater samples from deep-well sites in the vicinity of the CCSF are obtained twice yearly; the results are reported and discussed in Section D.1.5.1.3 of this report.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the canisters. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry analysis and processed for Sr-90. Gamma spectrometry analysis provides individual results for Co-60, Nb-94, Sb-125, Cs-134, Cs-137 (Ba-137m), Pm-147 and Am-241.

If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry analysis and uranium analysis. Uranium analysis has also been conducted for other sampling locations below the limit this year. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration established by Health Canada [32]. If uranium is detected, the result is evaluated against the Maximum Acceptable Concentration for uranium (0.5 Bq/L).

Note that in some occasions locations were sampled on a two day period due to rain conditions on those periods. Ditch Location 5 and Ditch Location 6 samples (see Figure 11 for sampling locations) could contain surface drainage from the CCSF. The gross beta level in Ditch Location 5 and Ditch Location 6 did not reach the trigger level (10 Bq/L) for gamma spectrometry and strontium analysis this year. The highest value noted (2.22 Bq/L) was in Ditch 5 on October 22. Half of this activity would be attributable to Sr-90 (assuming secular equilibrium with Y-90) at the applicable Maximum Acceptable Concentration of 5.0 Bq/L, and the remaining activity is below the Maximum Acceptable Concentration for Y-90 (30 Bq/L).

The alpha activities were below the trigger level of 0.5 Bq/L, except for three samples; on May 02 Ditch Location 5 and Ditch Location 6, and on October 22 and 24 combined sample date one sample from Ditch Location 19B, reached the gross alpha trigger level for gamma spectrometry and uranium analysis. Location 5 had a value of 26 ppb uranium, Location 6 had a value of 22 ppb on May 02 and Location 19B had a value of 16 ppb on the September 30-October 01 combined sampling date. Location 5 had a value of 26 ppb uranium, Location 6 had a value of 22 ppb on May 02 and Location 4 had a value of 18 ppb on the October 22 and 24 combined sampling date.

Ditch samples collected immediately downstream from the WMA (Locations 5, 6 and 7) contained elevated levels of tritium[15] (see Table 53). None of these samples exceeded the associated Maximum Acceptable Concentration of 7,000 Bq/L [32]. The activity seen is likely from the WMA as discussed in Section D.1.5.1.1.

There is no evidence to indicate that any activity has been released to the ground or surface water as a result of operations within the CCSF in 2019.

Table 54, Table 55, Table 56 and Table 57 list the results of the surface-water samples taken from the vicinity of the CCSF and WMA during 2019. Operational control-monitoring data from previous years has been included for completeness.

[15] Tritium analysis of samples from Ditch Locations 5 and 6 was previously discontinued due to the higher levels of tritium (~ 4000 Bq/L) noted at upstream locations associated with the WMA.

A.2 FACILITY DOCUMENTATION AND STAFFING

There were no changes in the staffing or organization for the operating staff responsible for the CCSF in 2019.

No program changes were made for the CCSF in 2019. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

In 2019, the CCSF continued to maintain the minimum staffing requirements outlined in the CCSF Facility Authorization [49]. Staffing was maintained at levels to provide the needed operational and safety support.

A.3 FACILITY CHANGES

All facility changes were performed as per the approved Engineering Change Control procedure [11]. There were no major facility changes made in 2019.

A.4 FACILITY EQUIPMENT PERFORMANCE

All canisters are checked for deviation from vertical annually. Out of 16 canisters, all displayed slight deviations from vertical in 2019. None of the canisters had a deviation greater than 1°. In 2019, Canister C5 had a deviation of 0.7° to the west compared to 2018 when it displayed a deviation of 0.8° to the east. This deviation and those seen on other canisters show that they all display slight movements in response to changing soil moisture conditions and related swelling and contraction of the clay layer. If a canister was noted either through vertical deviation measurements or visually to be trending beyond a 2-3° deviation, corrective measures such as bracing would be considered.

There were no canister loading or unloading operations in 2019.

A.5 PLANNED MAINTENANCE TESTING AND INSPECTIONS

As required by Section 8 of the Facility Authorization [49], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests were complete. The inspections were all completed.

Whiteshell Laboratories staff conducted general site inspections during each quarter of 2019. The general appearance and fencing were found to be satisfactory on each inspection. Minor infilling was done along the base of the fence to meet security requirements.

In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however, existing cracks and pour pockets were regularly checked for changes. Only minor patching was conducted in 2019. No increased radiation field was noted from the canisters. There was no degradation of the exposed metallic portions of the canisters. One of the wood poster boxes containing zone information was replaced due to environment-related degradation.

A.5.1 CANISTER SITE MONITORING AND SURVEILLANCE

A.5.1.1.1 Gamma Field Surveys

Gamma exposure rates from the canisters were measured quarterly in 2019. These readings were taken in compass directions north-east-south-west, on contact, and 2.0 m from the canister wall at an elevation of 2.0 m above grade level.

No field anomalies were found during 2019, and there was no change in results as compared with previous surveys.

Table 58 shows the averaged gamma near contact exposure rates measured during 2019, and for the previous four years.

Table 58: Summary of Average Gamma Radiation for Near Contact Measurements from Fuelled Canisters (mrem/h)

	0.16	0.18	0.11	0.11	2015		0.12	0.12	0.14	0.12	2015

a The measurements were made using a BOT P200 survey meter. The instruments are calibrated in mR/h and it is assumed 1 mR/h = 1 mrem/h

A.5.1.1.2 Air Monitoring

Air monitoring was conducted on each of the canisters in the CCSF in 2019. This involves an air pump that circulates air from and outlet line on the canister through a Dexter filter and returns it through an inlet line. These readings are taken once per month over a period of approximately one work week during warm weather months. Typically this is the six months of the year when air temperatures are normally above zero.

No anomalies were found during 2019, and there was no change in results as compared with previous surveys.

Table 59 shows the averaged beta on each filter measured during 2019, and for the previous four years.

Table 59: Summary of Average Beta Radiation Measurements from Fuelled Canisters (Bq/filter)

Canister Number	Average Air Sampling Measurements			Canister Number	Average Air Sampling Measurements

A.6 WASTES GENERATED

There were no radioactive and/or hazardous wastes generated in the CCSF as part of routine operations.

A.6.1 SOLID RADIOACTIVE AND/OR HAZARDOUS WASTES

See Section 11.1 Waste Management Program for summaries of the volume of solid radioactive and /or hazardous waste generated in the CCSF in 2019.

A.6.2 LIQUID RADIOACTIVE AND/OR HAZARDOUS WASTES

See Section 11.1 Waste Management Program for summaries of the volume of liquid radioactive and / or hazardous waste generated in the CCSF in 2019.

A.7 EFFLUENTS RELEASED

There were no radioactive and/or hazardous effluents (gaseous or liquid) released into the environment from the CCSF as part of routine operations.

A.7.1 LIQUID RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

A.7.2 GASEOUS RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

APPENDIX B ACTIVE LIQUID WASTE TREATMENT CENTER

B.1 FACILITY OPERATION

The Active Liquid Waste Treatment Center (ALWTC) in Building 200 (B200) is operated under the WL Site Licence [1], in accordance with the requirements of the ALWTC Facility Authorization [50] while facilitating and harmonizing the decommissioning activities as prescribed in the established work plan. During 2019, the ALWTC was monitored and operated by Site and Nuclear Operations Branch personnel.

The facility was operated on an 8-hour, five-day per week basis, Monday to Friday, with on-call emergency response outside of normal working hours Saturdays, Sundays, and Holidays during 2019.

In 2017 August, new LLLWTS began operation in B100 and B300. All of the B100 low level liquid waste is now being tested, treated and controlled release to the river in the B100 LLLWTS and likewise in B300. All of the collection tanks in B200 were then isolated and taken out of service. The B200 sumps have also been taken out of service and any water collected from the sumps and associated piping is put into drums for processing. Decommissioning of the Low-Level Liquid Waste (LLLW) and Intermediate-Level Liquid Waste (ILLW) systems in B200 are underway.

Passive evaporation from Tank 807 ILLW is no longer conducted, nor is any ILLW stored in B200. The contents of Tank 807 was pumped into road-transportable containers in 2013, and the first shipment of this liquid was sent to an offsite processing facility for volume reduction. The remaining liquid is stored in road-transportable containers (5,400 L) in a Quonset in the WMA. Plans are underway to purchase and install a LLLW and ILLW waste processing facility in LLW Bunker 6 at the WMA, and then process the stored liquid waste onsite.

Routine operations in the ALWTC were carried out by four operating staff and one trainee from the Site and Nuclear Operations Branch.

B.1.1 RADIATION EXPOSURES

The operation of the ALWTC was carried out by the Site and Nuclear Operations Branch who also provide shut-down and surveillance activities for the WR-1 reactor. Radiation exposures received by staff are listed under WR-1 Reactor (see Appendix F), since they were not recorded separately from B100 operations

The ALWTC operations staff participated in routine bioassay testing which involved an annual whole-body count and/or gross beta of urine samples every 60 days. There was no indication of any internal radiation exposures to facility personnel.

There were no doses exceeding CNSC regulatory limits or CNL’s Action Levels to personnel as a result of ALWTC operations during 2019.

B.2 FACILITY DOCUMENTATION AND STAFFING

There were no changes in the staffing or organization for the operating staff responsible for the ALWTC in 2019.

No program changes were made for the ALWTC in 2019. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

In 2019, the facility continued to maintain the minimum staffing requirements outlined in the ALWTC Facility Authorization [50]. Staffing was maintained at levels to provide the needed operational and safety support.

B.3 FACILITY CHANGES

All facility changes were performed as per the approved *Engineering Change Control* procedure [11]. Building 200 was turned over to decommissioning near the end of 2017 to begin the decommissioning of the building. Decommissioning of the LLLW systems was completed in 2019. All of the laundry, decontamination, WR-1 and Building 300 LLLW collection systems in B200 have been removed except for the collection tanks. The removal of the ILLW system is well under way in 2019.

B.4 FACILITY EQUIPMENT PERFORMANCE

The Facility operated satisfactorily in 2019.

B.4.1 LOW-LEVEL LIQUID WASTE SYSTEM

The low-level liquid waste system is shut down and being decommissioned.

B.4.2 MEDIUM-LEVEL LIQUID WASTE SYSTEM

The medium-level liquid waste (intermediate-level liquid waste) system is no longer in use and is being decommissioned.

B.4.3 VENTILATION SYSTEM

Routine Poly-Alpha-Olefin testing of the exhaust High Efficiency Particulate Air (HEPA) filter was carried out satisfactorily in 2019 May and November. All filters had acceptable penetrations of less than 0.03% in both tests.

B.5 PLANNED MAINTENANCE TESTING AND INSPECTIONS

As required by Section 8 of the Facility Authorization [50], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests and inspections were completed. Monthly housekeeping and fire prevention inspections were completed.

B.6 WASTES GENERATED AND EFFLUENTS RELEASED

There were no radioactive and/or hazardous wastes generated in the ALWTC as part of routine operations.

B.6.1 WASTES GENERATED

B.6.2 SOLID RADIOACTIVE AND/OR HAZARDOUS WASTES

See Section 11.1 Waste Management Program for summaries of the volume of solid radioactive and/or hazardous waste generated in the facility in 2019.

During 2019, 161 m^3 of low-level solid radioactive waste and 6.7 m^3 of intermediate-level solid radioactive waste was generated from ALWTC decommissioning activities.

B.6.3 LIQUID RADIOACTIVE AND/OR HAZARDOUS WASTES

There were no liquid radioactive and / or hazardous waste generated in the facility as part of routine operations.

Decommissioning of low-level and intermediate-level liquid systems generated 0 m^3 of liquid waste for 2019.

B.7 EFFLUENTS RELEASED

There were no radioactive and/or hazardous effluents (gaseous or liquid) released into the environment from the ALWTC as part of routine operations.

B.7.1 LIQUID RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

There was no liquid effluent released to the Outfall from the ALWTC in 2019.

Non-radiological liquid releases from this facility are discussed in Section 9.5 of this report. There were no hazardous liquid wastes released from this facility.

B.7.2 GASEOUS RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

Radioactive air emissions form the facility are included in Section 9.4 of this report. There were no hazardous gaseous wastes released from this facility.

APPENDIX C SHIELDED FACILITIES

C.1 FACILITY OPERATION

The WL Shielded Facilities (SF) operates under the WL site licence [1], in accordance with the requirements of the Facility Authorization [51]. The SF, consisting of the Hot Cell Facility (HCF) and the IFTF, are located in the R&D Complex (Building 300), and are operated by personnel in the Site and Nuclear Operations Branch.

The HCF Cells 1 to 5 and IFTF Cell 13 remain operational while HCF Cells 6 to 11 have been shutdown and partially dismantled. The Waste Handling Area, located in the IFTF, was operated for compaction and assaying of radioactive waste.

Operations and decommissioning activities were conducted throughout the year. Operations activities included:

- maintenance of HCF and IFTF ventilation system equipment;
- replacement of HEPA filters;
- packaging and storage of radioactive waste;
- cleanup activities; and
- routine maintenance to ensure compliance with the site licence.

Routine operations in the SF were carried out by operating staff from the Site and Nuclear Operations Branch.

C.1.1 RADIATION EXPOSURE

The average and maximum whole-body effective dose received by SF staff for 2019 were 0.29 mSv and 0.47 mSv respectively. The average and maximum individual equivalent dose to the skin were 0.73 mSv and 1.39 mSv respectively. The whole body effective collective dose was 1.46 person·mSv for SF staff. The average extremity dose was 1.19 mSv and the maximum dose was 1.62 mSv.

There was no need for tritium monitoring in the SF during 2019.

The SF staff participated in routine bioassay testing, which involved a bi-annual whole-body count, and gross beta of urine samples every 60 days. There was no indication of any internal radiation exposures to facility personnel.

There were no doses exceeding CNSC regulatory limits or CNL’s Action Levels to personnel as a result of SF operation during 2019.

C.2 FACILITY DOCUMENTATION AND STAFFING

There were no changes in the staffing for the operating staff responsible for the SF in 2019. There were no organizational changes.

No program changes were made for the SF in 2019. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

In 2019, the SF continued to maintain the minimum staffing requirements outlined in the Facility Authorization [51]. Staffing was maintained at levels to provide the needed operational and safety support.

C.3 FACILITY CHANGES

All facility changes were performed as per the approved Engineering Change Control procedure [11]. The high temperature heat detectors in Hot Cells 1-5 and Cell 13 that alarmed locally, were added to the WL site Fire Alarm system in 2019 as part of the Hot Cells Restoration project.

C.4 FACILITY EQUIPMENT PERFORMANCE

The Facility operated satisfactorily in 2019 with the exception of the Hot Cell alarm panel as listed in C.4.2. Also the Hot Cells Manipulator electronic controls were upgraded to improve efficiencies and reliability as part of the Hot Cells Restoration project.

C.4.1 VENTILATION SYSTEM

The ventilation system was rebalanced in 2019 to improve air efficiencies as part of the Hot Cells Restoration project. Planned project and maintenance activities requiring part of the ventilation system to be taken down occurred without incident.

C.4.1.1.1 High Efficiency Particulate Air Filter Performance

The annual routine Poly-Alpha-Olefin testing of the HCF and IFTF HEPA filters were conducted and all filters passed.

C.4.2 ALARM TESTING

An alarm-testing program has been in place in the SF throughout its operational history. In 2019 the SF alarms were fully operational with the exception of 2019 September 17-30, where there was a Hot Cells alarm panel electronic board failure resulting in an impairment of the Hot Cell facility. Compensatory measures were put in place to provide alarm coverage during this time.

C.5 PLANNED MAINTENANCE TESTING AND INSPECTIONS

As required by Section 8 of the Facility Authorization [51], all routine maintenance for safety related systems was carried out as per the facility maintenance plan, and all equipment tests and inspections were complete.

C.6 WASTES GENERATED

C.6.1 SOLID RADIOACTIVE AND/OR HAZARDOUS WASTES

C.6.1.1.1 Low-Level Solid Waste

In 2019, the SF generated 101.4 m^3 of compactable low-level radioactive solid waste and 0 m^3 of non-compactable waste.

The Waste Handling Area processed 162.0 m^3 of low-level radioactive solid waste which was reduced to 15 m^3. A portion of this waste was generated in the SF, and the remainder came from all of the nuclear facilities and decommissioning projects at WL where waste is being generated.

Table 60 lists the annual low-level solid waste generated in the SF for 2019 and the previous four years.

Table 60: Solid Wastes Generated

Total Volume	2015	2016	2017	2018	2019
Low-Level Solid Waste (m^3)	25.0	47.7	0.4	73.3	101.4
Medium-Level Solid Waste (m^3)	0	0	0	0	0

C.6.1.1.2 Medium-Level Solid Waste

In 2019, the SF generated no medium-level (intermediate-level) radioactive solid waste. Table 60 lists the annual medium-level solid waste generated for 2019 and the previous four years.

C.6.2 LIQUID RADIOACTIVE AND/OR HAZARDOUS WASTES

See Section 11.1 Waste Management Program for summaries of the volume of liquid radioactive and/or hazardous waste generated in the SF on 2019.

C.6.2.1.1 Low-Level Liquid Waste System

In 2019, 186.5 m^3 of low-level liquid waste was processed through the B300 low-level liquid waste system (see Appendix E).

C.6.2.1.2 Medium-Level Liquid Waste System

All the medium-level liquid waste (intermediate-level liquid waste) from the HCF cells collects in the HCF sump tank, AD Tank 1. The liquid is transferred via a manually controlled pump from AD Tank 1 through a filtration system to AD Tank 14 in the IFTF. The liquid from all other HCF medium-level liquid waste drains and all IFTF medium-level liquid waste drains flows by gravity to AD Tank 14.

In 2019, there was one transfer of 1.2 m^3 medium-level liquid waste to transportable totes that is being stored for future disposition.

Table 61 lists the annual aqueous waste generated for 2019 and also for the previous four years.

Table 61: Building 300 Liquid Waste Volumes Transferred to the ALWTC

Year	Low-Level Waste System[a]		Medium-Level Waste System[b]
	Total Volume (m^3)	Activity	Total Volume (m^3)
2015	74.5	0.045GBq β 0.002GBq γ 0.001GBq α	0
2016	195.4	0.039GBq β 0.006GBq γ 0.004GBq α	0
2017	164.0	0.073GBq β 0.007GBq γ 0.003GBq α	0

2018	123.0	0.016GBq β 0.006GBq γ 0.003GBq α	0
2019	186.5	1.35E+07GBq β 8.23E+06GBq γ 2.66E+06 GBq α	1.2

a Total volume for Building 300 (Sumps).
b Total volume can be attributed to the SF.

C.7 EFFLUENTS RELEASED

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

C.7.1 LIQUID RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Liquid radioactive and/or hazardous effluents were discharged from the SF as part of routine operations.

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

C.7.2 GASEOUS RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

APPENDIX D WASTE MANAGEMENT AREA

D.1 FACILITY OPERATION

The Waste Management Area (WMA) operated under the WL site licence [1], in accordance with the requirements of the *Facility Authorization for the Operation of the Waste Management Area at the Whiteshell Laboratories* [52]. Limiting Condition of Operation #9 was modified in 2019 to permit excavations deeper than 4.5 m under a set of controlled circumstances. This change was necessary in order to prepare for decommissioning activities. The change was reviewed and approved by the CNSC. During 2019, the WMA at WL was operated and monitored by staff in the Site and Nuclear Operations Branch.

In 2019, the WMA was operated in compliance with approved practices and procedures.

Routine operations in the WMA were carried out by the Facility Manager, WMA Operator and two WMA based utility workers, with support from other Site and Nuclear Operations personnel as required.

D.1.1 RADIATION EXPOSURES

Staff from the Site and Nuclear Operations Branch operated the WMA. The average and maximum individual whole-body effective dose received by WMA facility staff for 2019 were 0.12 mSv and 0.29 mSv respectively. The average and maximum individual equivalent dose to the skin were 0.12 mSv and 0.30 mSv respectively. The collective effective dose was 0.46 person·mSv. There were no extremity doses in 2019.

Waste Management Area staff participated in routine bioassay testing which involved bi-annual whole-body counts and gross beta of urine samples every 60 days. There was no indication of any internal radiation exposures to facility personnel.

There were no doses exceeding CNSC regulatory limits or CNL's Action Levels to personnel as a result of WMA operations during 2019.

D.1.2 INVENTORY ADDITIONS AND DELETIONS

Changes in inventory are reported in Table 62 and for the purposes of reporting WMA inventory (fission products are defined as radioactive material originating from irradiated fuel).

Activation products are defined as any material that has been activated in a neutron flux, including corrosion products. The radioactivity values listed are those recorded at the time of storage.

D.1.3 LOW-LEVEL SOLID WASTE

Details of wastes transferred to the WMA are provided in Section 11.1.1. Waste generated from decommissioning work on the site was generally shipped to CRL for storage, although some waste was stored in the WMA. Some of the inventory of stored waste in WMA was sent to CRL for storage pending future disposal. The stored volume of waste is listed in Table 62.

D.1.4 INDUSTRIAL WASTE

There were no additions of industrial chemical waste during 2019.

Table 62: Additions to Low-Level Waste Inventory

Period	Storage Locations	Volume (m^3)	Fission Products (GBq)	Activation Products (TBq)
Total Accumulation to 2018 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433, and Building 923	21,034.86	2,501.88	330.6
Additions for 2019	Building 923, SSC, B431 to B433	106	1.35	0.00
Removals for 2019	Building 923 SSC LLW Bunker 6 B411 B514	862 201 406 126 252	345.98 2.93 0.04 6.27 0.14	0.00 0.00 0.00 0.00 0.00
Total Accumulation as of 2019 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433, Building 923 and SSC	19,293.86	2,147.87	330.6

D.1.5 COMPLIANCE MONITORING

D.1.5.1 Monitoring and Surface Water

D.1.5.1.1 Surface Water

Figure 11 shows the drainage area surrounding the WMA.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the WMA. The WMA and CCSF share a network of perimeter compliance monitoring ditches with designated sampling locations. Water samples are collected in these sample locations for analyses when there is sufficient flowing water present. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

A recorded amount of precipitation of 646 mm occurred in 2019, which was more than the 467 mm recorded in 2018. A period of high rainfall occurred in the fall of 2019 (>200 mm in September).

In an effort to streamline the operational environmental monitoring process, surface water samples are initially analyzed for gross beta, gross alpha, and tritium. The results are then evaluated using the following screening criteria:

- If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry, and processed for Sr-90. Gamma spectrometry provides individual results for Co-60, Nb-94, Sb-125, Cs-134, Cs-137 (Ba-137m), Pm-147, Am-241.
- If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry and uranium analysis, however, this year all water samples were tested for uranium. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration established by Health Canada [32]. If uranium is detected, the result is evaluated against the Maximum Acceptable Concentration (MAC) for uranium (0.5 Bq/L or 20 ppb).

Levels of beta activity near detection limits were noted for Ditch sample Locations 1 to 7 (Table 63). Based on historical data, it is conservatively assumed that the beta activity in the surface water is Sr-90 in secular equilibrium with Y-90. Most beta activity levels in the ditch water remained below the drinking water screening level of 1 Bq/L and well below the drinking water limit of 5 Bq/L for Sr-90 and 10 Bq/L for Cs-137. Compliance with Guidelines for Canadian Drinking Water [32] may be inferred if the measurement for gross alpha and gross beta is less than 0.5 Bq/L and 1.0 Bq/L, respectively.

The alpha activity levels in the surface water are presented in Table 64, and were below the trigger level of 0.5 Bq/L, except for three samples; on May 02 Ditch Location 5 and Ditch Location 6, and on October 23 and 24 combined sample date one sample from Ditch Location 19B, reached the gross alpha trigger level for gamma spectrometry and uranium analysis. Location 5 had a value of 26 ppb uranium, Location 6 had a value of 22 ppb on May 02. Location 5, 6, and 7 had values of 24, 26, and 22 respectively on samples taken May 06 and 07. Location 19B had a value of 16 ppb on September 30-October 01 combined sampling date. The values at Locations 5, 6 and 7 slightly exceeded the MAC in May, but returned below this level in samples taken later in the year. Uranium results are presented in Table 65.

The uranium values recorded at locations 19 A and B are believed to result from the use of local Lac du Bonnet Batholith granitic rock as base material for the SMAGS foundation. This rock had been also used for berm support material for the Cesium Pond pile, however that material was removed from the WMA in 2018 and is currently stored east of the WMA at the former Cesium Pond location. The Lac du Bonnet Batholith granite is noted to have naturally occurring uranium. Uranium sample results were only available for the September 30 to October 01 sampling at Locations 19 A and B. There was no flow this year at Location 19C.

As shown in Table 66, the tritium results are below the Maximum Acceptable Concentration of 7000 Bq/L [32] at all locations. The elevated readings that existed in this area in previous years likely resulted from migration of tritium in the clay columns from WR-1 stored in Trench 23. Trench 23 is nearest Location 19C, with flow towards 19B and 19A along the drainage direction of the ditch towards the west. The summer was dry likely limiting migration to the ditch from Trench 23. At Locations 1 to 7, downstream of Locations 19 A, B and C, the highest reading was 773 Bq/L. Locations 8 and 9 had average tritium values of 6 Bq/L and 10 Bq/L respectively. Tritium detected at Locations 3 and 19 A, B and C would contribute to that seen in Locations 4, 5 and 7. Location 3 is believed to also have contributions of tritium from Location 19 C. Locations 19 A, B and C were originally chosen for sampling for the potential migration of cesium-137 due to the presence of the Cesium Pond soil pile. Although the Cesium Pond soil has been removed, CNL will continue to monitor locations 19 A, B and C due to the elevated levels of tritium.

The WMA contains a number of trenches with varying amounts of low-level radioactive waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. Based on the initial modelling [53], it was proposed that tritium would be present in the ditches (including the Locations 3 through 7 and 19 A, B and C) and possibly reach levels as high as 37 kBq/L. While tritium is elevated immediately around the WMA, periodic monitoring of the ditches has indicated that the levels of tritium at the points (Locations 8 and 9) leaving CNL property remain quite low (below an average value of 10 Bq/L in 2019). Although the amount measured in Locations 1 to 7 are above that noted at the Control location, the levels are much lower than the Maximum Acceptable Concentration in drinking water for tritium (7000 Bq/L).

Carbon 14 was noted with a value of 3.1 Bq/L in the east ditch of the WMA (Location 13), which is several orders of magnitude less than the Canadian Drinking Water Guideline of 200 Bq/L [32]. A potential source for the C-14 may be from residue from barrels previously held in the area of Trench 1 and 2 while awaiting incineration in the now decommissioned Building 514 incinerator on the east side of the WMA. It may also relate to potential surface clay fissuring from the dry summer in 2019 followed by a high rainfall period in September allowing migration of contaminants from adjacent trenches through the clay fissures prior to the clay self-sealing with expansion from water uptake. Further measurements will be taken in 2020 as ditch water flows permit.

Table 63, Table 64, and Table 65 present the WMA surface-water sampling data. The data represents continuing documentation of a spill incident that occurred in 1979 near Intermediate-Level Waste (ILW) Bunker 3, at the reference sample point (Location 3) in the southeast section of the WMA, as shown in Figure 11 and Figure 12. In 2017, sampling Location 3 had been reconfigured to allow preparations for future bunker and standpipe remediation, but the location was dry this year due to dry summer. Surface water at this location serves as an indicator of movement of water from ILW Bunkers 1, 2 and 3. While it has been confirmed that there is water in the bunkers, there is no indication of contaminant movement at levels of concern. The most mobile radionuclide (tritium) is below the associated Maximum Acceptable Concentration. The levels of tritium in the surface water and groundwater is below the radiation screening criteria used for identifying contaminants of potential ecological concern (COPECs) of 1.27×10^{7} Bq/L [54]. These tables, and Table 66, have been expanded to include the historical monitoring at Ditch Locations 19 A, B and C.

The Cesium Pond soil (Cs-137) that was stored in the WMA adjacent to SMAGS was removed in 2017. Water tested at Locations 19 A, B and C along the north perimeter ditch of the WMA (Figure 12) has given no indication of Cesium-137 migration to the ditches (Table 67).

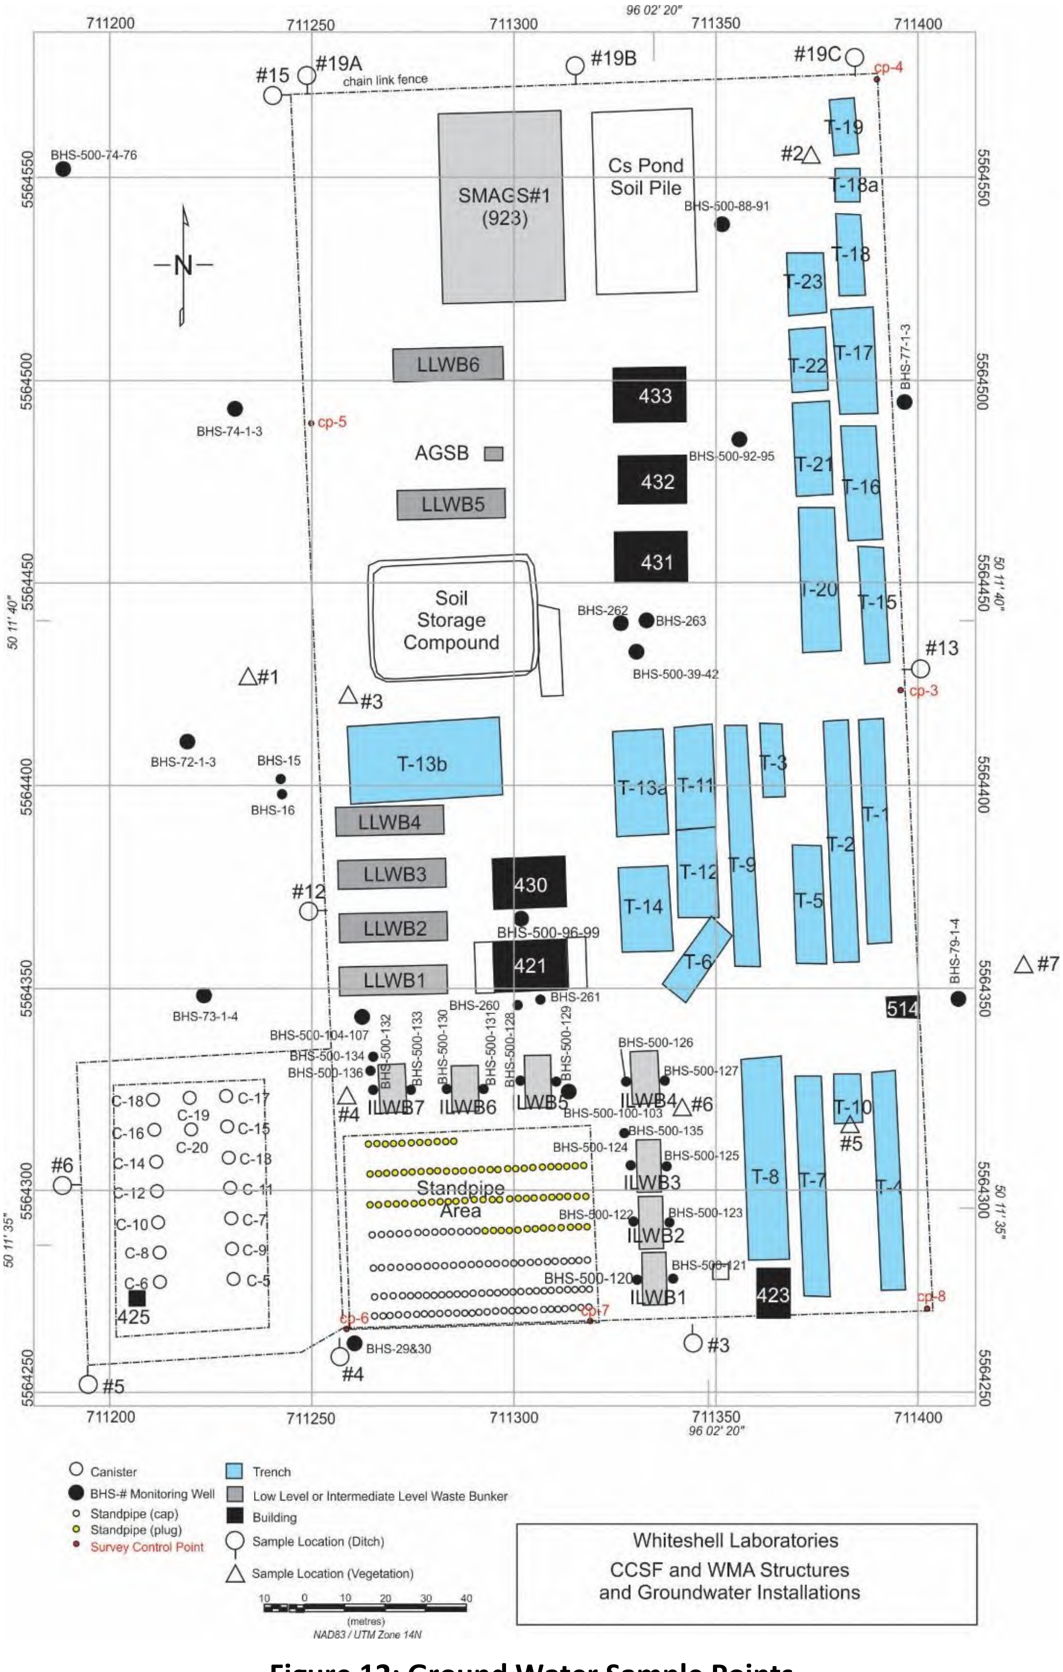

Figure 12: Ground Water Sample Points

D.1.5.1.2 Intermediate Level Waste Bunkers Near Field Wells

A series of shallow near field wells were installed adjacent to the Intermediate Level Waste bunkers in the WMA in 2015 (Figure 11). Groundwater samples were taken from the wells and from water in the Intermediate Level Waste Bunkers for comparison. Cs-137, Sr-90, and tritium were selected as the radionuclides for monitoring of the potential for contaminant migration. Cs-137 was selected as the least mobile, with a high affinity for bonding with clay-based minerals, Sr-90 is more mobile and will bond with sand, and tritium the most mobile that moves with water. Cs-137 and Sr-90 require a pathway (e.g., a construction joint or crack) to migrate from a bunker. In 2019, Sr-90 was noted to be a maximum of 22 Bq/L adjacent to ILW Bunker 1, and < 7 Bq/L adjacent to ILW Bunker 3. For all other locations the Sr-90 and Cs-137 levels were negligible. Tritium can move through concrete without cracks by diffusion with water movement. The results indicate no migration of Cs-137 (Table 68) from the Intermediate Level Waste Bunkers, and Sr-90 (Table 69) and tritium levels (Table 70) that are orders of magnitude below the levels observed in the water in the adjacent Intermediate Level Waste Bunkers. The tritium levels immediately adjacent to the west side of ILW Bunker 3 and the east side of ILW Bunker 5 that were showing upward trends, are within the range of previous results. Tritium adjacent to ILW Bunker 2 has shown an increase in 2019 (4274 Bq/L).

D.1.5.1.3 Water Table Wells and Deep Wells

Water samples were collected from wells in and around the WMA (Figure 12) in the spring and fall of 2019. The gross alpha and gross beta results are summarized in Table 71. The beta activity levels in the clay, clay till and basal zone wells remained below the drinking water screening level of 1 Bq/L. All zones were below the limit for Sr-90 (5 Bq/L) and Cs 137 (10 Bq/L) [32]. The average alpha activity in the samples collected from the Basal zone wells was below the screening level.

Uranium concentrations in the basal zone wells ranged from 0 to 0.19 Bq/L. The concentrations in the Clay zone wells ranged from 0.33 to 3.40 Bq/L, and in the clay till from 0 to 1.88 Bq/L. Since it is known that the local well waters within the Canadian Shield contain naturally occurring uranium [55], the presence of uranium and its progeny are not unexpected and are considered to account for the levels of alpha. Low levels of tritium were noted in the clay (8.07 Bq/L) and clay-till (14.07 Bq/L). This is not unexpected as these overburden layers are impacted by tritium in the WMA.

Table 71: Monitoring Data Water Table Wells and Deep Wells

WMA Sample Locations	2015 Avg. (Bq/L)	2016 Avg. (Bq/L)	2017 Avg. (Bq/L)	2018 Avg. (Bq/L)	2019 Avg. (Bq/L)	2019 Avg. Range (Bq/L)
Total Beta [a]						
Clay	1.21	0.67	0.35	0.29	0.42	0.05 to 1.80
Clay Till	0.86	0.54	0.36	0.25	0.26	0.05 to 1.20
Basal	0.67	0.39	0.16	0.13	0.34	0.05 to 7.00
Total Alpha [b]						
Clay	0.54	1.05	1.01	1.03	0.87	0.05 to 4.20
Clay Till	0.36	0.60	0.77	0.72	0.75	0.10 to 3.20
Basal	0.21	0.18	0.10	0.12	0.22	0.05 to 4.20
Total Uranium [c]						
Clay	0.01	0.86	0.90	0.88	0.86	0.33 to 3.40
Clay Till	0.54	0.55	0.52	0.62	0.60	0.00 to 1.88
Basal	0.03	0.01	0.01	0.04	0.01	0.00 to 0.19
Total Tritium						
Clay	12.4	11.86	11.60	11.36	8.07	3.42 to 39.18
Clay Till	12.3	12.04	13.36	13.51	14.07	3.42 to 83.29
Basal	< 4[d]	5.32	4.08	4.63	5.66	3.38 to 72.85

a The reference nuclide for total beta is Sr-90
b The reference nuclide for total alpha is natural uranium
c The value is calculated from the concentration of uranium in the water samples
d Well BHS 500-101 had tritium (15.8 Bq/L)

D.1.5.1.4 High-Level Liquid Waste Tray Water

Quarterly monitoring of the high-level liquid waste tank tray water was carried out to confirm there is no leakage from the residue remaining in the storage tanks. The sample results indicated no leakage has occurred from the tanks. The data are summarized in Table 72. In the late fall of 2004, the high-level liquid waste had been removed from high-level liquid waste Tank 2 and transferred to the SF for cementation. A heel of waste remains to be removed. High-level liquid waste Tank 1 remains empty.

Table 72: Monitoring Data High-Level Liquid Waste Tank Tray Water

WMA Sample Locations	2015 Avg (Bq/L)	2016 Avg (Bq/L)	2017 Avg (Bq/L)	2018 Avg (Bq/L)	2019 Avg (Bq/L)	2019 Range (Bq/L)
Total Beta [a]						
Tank Tray Water	12.8	11.9	13.8	13.8	12.1	9 to 14
Total Alpha[b]						
Tank Tray Water	< 0.6	< 0.6	0.65	0.69	1.5	1.5 to 2.0

a The reference nuclide for total beta is Sr-90, gamma results indicate that approximately 13 Bq/L of the gross beta activity is due to K-40.
b The reference nuclide for total alpha is Pu-239

D.1.5.2 Radiation Field Measurements

Radiation field measurements are taken semi-annually at established points (normally every 38 m) along the perimeter fence. The 2019 radiation field measurements were similar to those in 2018. The data are summarized in Table 73.

Table 73: Perimeter Fence Monitoring Data

WMA	Radiation Field (µSv/h)					
	2015 Avg	**2016 Avg**	**2017 Avg**	**2018 Avg**	**2019 Avg**	**2019 Range**
Spring Survey						
South Fence	0.33	0.3	0.2	0.2	0.2	0.2
West Fence	0.48	0.5	0.4	0.4	0.4	0.2-0.7
North Fence	0.33	0.4	0.2	0.2	0.2	0.2-0.3
East Fence	0.34	0.3	0.3	0.3	0.3	0.2-0.5
Fall Survey						
South Fence	0.23	0.2	0.2	0.2	0.2	0.1-0.3
West Fence	0.42	0.4	0.4	0.4	0.5	0.3-0.8
North Fence	0.43	0.2	0.2	0.2	0.2	0.1-0.4
East Fence	0.39	0.3	0.3	0.3	0.4	0.1-0.8

D.1.5.3 Vegetation

In 2019, vegetation samples were collected at monitoring locations within the WMA (Figure 12), and at a control location unaffected by WL operations. The gross beta results are summarized in Table 74. In 2019, as since 2017, the samples were only collected in the late summer-fall as it was determined that the uptake occurs over the summer, so the fall measurements presented in since 2017 are more conservative than previous years. As was the case last year, K-40 still represents the majority of gross beta activity in most of the samples. The levels of gross beta in the samples are due to a combination of K-40 and Sr-90/Y-90, with a minor contribution from Cs-137. For 2019, the average Sr-90 contribution for the vegetation samples in the WMA is 6% (12% for Sr-90/Y-90). Results were historically reported as Bq/m^2 as there was the potential for deposition of radioactivity via airborne emissions from the former WL Incinerator and former Baler operations. The incinerator and baler have not been in operation for many years and have been decommissioned. The results are now presented as Bq/kg and represent the uptake of radioactivity from impacted areas near the sampling locations.

Table 74: Waste Management Area Vegetation Monitoring Data

WMASample Locations	Average Gross Beta[a] (Bq/kg)				
	2015 Avg	**2016 Avg**	**2017 Avg**	**2018 Avg**	**2019 Avg**
North-East Area[d]	488	488	NA	672	450
Mid-West Area	477	578	1619	411	155
South-West Area	707	575	275	414	NA
South-East Area	538	751	460	409	441
Control Sample[b]	397	632	379	187	210
Background Sample[c]	519	592	419	324	317
East of ILW Bunkers 3 and 4	488	488	NA	672	450

a The reference nuclide for beta is Sr-90

b Adjacent to the WMA outside of fence boundary

c Ambient Radiation Monitor Stations Background Samples

d Until 2012 this sampling point was in the North-West area after 2012 it was moved to the North-East area.
Only a single set of vegetation samples was taken as of 2017 as uptake occurs over the summer. Range is no longer included because of this change.

D.2 FACILITY DOCUMENTATION AND STAFFING

There were no changes in the staffing or organization for the operating staff responsible for the WMA in 2019.

No program changes were made for the WMA in 2019. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

In 2019, the WMA continued to maintain the minimum staffing requirements outlined in the Facility Authorization [52]. Staffing was maintained at levels to provide the needed operational and safety support.

D.3 FACILITY CHANGES

All facility changes are performed as per the approved Engineering Change Control procedure [11].

Work to prepare for extraction of waste from the Intermediate Level Bunkers and Standpipes was begun in 2017 and continued into 2019. This included testing and activation of the expanded Protected Area that encompasses the Standpipes and Intermediate Level Bunkers. The old Protected Area fence that enclosed the standpipes area alone was removed along with the old poles for security lighting.

The WR-1 Phase 1 decommissioning waste material was stored in Buildings 432 and 433 in the WMA. Approximately 96% of the WR-1 Phase 1 decommissioning waste stored in B432 and B433 was processed by the end of 2016. Nine oversized crates remain in B433, and five asbestos containing crates that moved to B430 were returned to B433 and remained there as of the end of 2019.

The Soil Storage Compound has been emptied of stored soil bags, with the waste packaged and shipped off site.

The marine container used for storing sealed sources that was transferred from Building 430 in the WMA to the standpipes Protected Area to meet revised security regulations from the CNSC in 2015, remained in place through 2019, with a number of sources having been transferred for offsite storage - the remainder are still held pending future dispositioning.

Building 923 (SMAGS) waste is being transferred to CRL. This process began in 2018 and continued in 2019. This will allow the building to be re-purposed for loading of intermediate level waste shipping casks.

Low Level Waste Bunker #6 has largely been emptied of waste, with most being packaged for offsite shipment. Some waste was removed and returned to the bunker pending completion of characterization work and shipping plans.

Construction began on an access structure on the east side of Low Level Waste Bunker #5 to facilitate waste retrieval operations planned in 2020.

A Waste Transshipment Area was established outside the northern perimeter to allow for shipments of waste to be held and loaded for offsite shipment.

D.4 FACILITY EQUIPMENT PERFORMANCE

During 2019, the bunkers and other structures in the WMA remained fit for service. Waste stored in SMAGS is being removed, and this process will be completed in 2020. Repackaging of soil stored in drums and concrete stored on pallets from LLW Bunker 6 was begun in late 2018, and continued in 2019. The low level waste will be shipped to CRL. Medium-Level Waste Bunker 4 did not have new waste placed in 2019 and remains ~70% full. Medium-Level Waste Bunker 6 is ~60% full; however it is not accepting waste due to water ingress issues.

Medium-Level Waste Bunker 7 is ~85% full. The percentage full values are estimates only. Road transportable totes of liquid waste formerly stored in B431 were transferred to the heated B430 pending future processing. B431 contains historic waste and is used as temporary storage for waste repackaging-characterization operations. B432 and B433 contain various historic wastes and wastes held in various stages of repacking operations.

The Soil Storage Compound is empty of stored waste soil bags. There are three empty standpipes in the standpipe area.

In-service storage facilities were inspected for water ingress during routine waste emplacement operations. Filled storage facilities with accessible drainage sumps were inspected monthly during the summer months, when water ingress is most likely. Caulking of the roofs of all the WMA Quonset buildings with waterproof sealant was completed in 2010 resulting in reduced indications of water ingress during rainy weather. Re-caulking was done in 2014 and again in 2018. No caulking was required in 2019.

In 2015, shallow wells were installed beside each of the Medium/Intermediate Level Bunkers. These near field wells have been sampled annually. Results are discussed in Section D.1.5.1.2 and indicate limited migration of tritium beside the ILW bunkers and no evidence that would lead CNL to conclude there is currently any significant contaminant migration pathway from the ILW Bunkers.

Compliance monitoring in the WMA and CCSF perimeter ditches have only found limited levels of contaminants, below drinking water guidelines, suggesting the structures and barriers of soil and upwards groundwater flow are performing as expected.

D.5 PLANNED MAINTENANCE TESTING AND INSPECTIONS

As required by Section 8 of the Facility Authorization [52], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests and inspections were completed. Monthly housekeeping and fire prevention inspections were completed. An annual inspection of WL WMA concrete bunkers was conducted, in accordance with the Periodic Inspection Plan [15], and is further discussed in Section 6.

D.6 WASTES GENERATED

As a result of routine operations solid radioactive waste and liquid radioactive waste were generated in the WMA.

D.6.1 SOLID RADIOACTIVE AND/OR HAZARDOUS WASTES

See Section 11.1 Waste Management Program for summaries of the volume of solid radioactive and/or hazardous waste generated in the WMA in 2019. There was 6.9 m^3 of solid compactable wastes and no solid non-compactable wastes generated in this facility during 2019 from operational activities.

D.6.2 LIQUID RADIOACTIVE AND/OR HAZARDOUS WASTES

See Section 11.1 Waste Management Program for summaries of the volume of liquid radioactive and/or hazardous waste generated in the WMA in 2019.

In 2019, approximately 1988 L of water was removed from storage facilities and collection sumps at the WMA. Of this total, 260 L was from ILW Bunker 4, 1661 L was from ILW Bunker 6, and 67 L from Bunker 7; neither

Above Ground Storage Bunker 8 nor ILW Bunker 4 required pumping in 2018. No water was required to be pumped from the Low Level Bunkers sumps in 2019.

D.7 EFFLUENTS RELEASED

There were no radioactive and/or hazardous effluents (gaseous or liquid) released into the environment from the WMA as part of routine operations.

D.7.1 LIQUID RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

There are no liquid effluents generated from this facility.

D.7.2 GASEOUS RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

The incinerator was decommissioned in 2018. There are no other radiological airborne releases from this facility. There were no hazardous air gaseous effluents released from this facility.

APPENDIX E AUXILIARY OPERATING FACILITIES

E.1 FACILITY OPERATION

The Auxiliary Operating Facilities are operated under the WL Site Licence [1].

Research and Development Facilities Complex (Building 300)

Building 300 was the primary research laboratory for the site, housing a wide range of nuclear R&D programs. The building comprised an area of ~17,000 m^2 and was built in seven stages from 1964 to 1982. The building contained 68 laboratories as well as numerous offices. The south end high-bay area contains experimental activities that required large areas and significant headroom; RD-14M and RD-17 experimental loops are located in the South High Bay.

The research program in the South High Bay area was completed in 2018, and operational shutdown was started. The operational shutdown, decontamination, and decommissioning of the remainder of the building was completed in 2015. The demolition of Stages 4 and 7 was completed in 2016. The demolition of RD-14M was completed in 2019.

During 2019, WL Site and Nuclear Operation's staff and user groups in Building 300 carried out routine operations which included:

- Non rad laundry activities;
- Respirator fit test / maintenance activities;
- Ongoing CNL Nuclear Engineering & Systems Analysis R&D activities;
- Cleanup activities associated with decommissioning;
- Routine building and system maintenance; and
- Surveillance to ensure compliance with the site licence.

Decommissioning work conducted in 2019 included the finishing up of the decommissioning of the LLLW holding tanks in room B-38 to be in a demo ready state as well as the disposition of staged waste from past activities.

Health and Safety Facilities (Building 402 and B305)

Building 402 has three floors comprising an area of ~2,162 m^2, housing WL dosimetry services and Environmental Management laboratories. The CNL facilities in Building 402 include a whole-body counting facility, TLD readers, environmental laboratories, and a Cs-137 Gamma Calibrator.

During 2017 the private business tenant left B305 and the area was repurposed. A licensed gamma cell belonging to the former tenant remained, and in 2019 the gamma cell was moved from Building 305 to the source container located inside the Protected Area of the Waste Management Area (WMA) for storage until a more permanent disposition path is determined.

During 2019, routine operations were carried out and supervised by Site and Nuclear Operations personnel.

E.1.1 RADIATION EXPOSURE

There were no doses exceeding CNSC regulatory limits or CNL's Action Levels to personnel as a result of the operation of the Auxiliary Operating Facilities during 2019. A detailed account of employees' radiological exposures is provided in Section 7.

E.2 FACILITY DOCUMENTATION AND STAFFING

There were no changes in the staffing for the operating staff responsible for the auxiliary facilities in 2019. There were no organizational changes.

No program changes were made for the auxiliary facilities in 2019. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

E.3 FACILITY CHANGES

All facility changes were performed using the *Engineering Change Control* procedure [11]. There were no major facility changes made in 2019.

E.4 FACILITY EQUIPMENT PERFORMANCE

All facility changes were performed as per design requirements and specifications.

E.5 PLANNED MAINTENANCE TESTING AND INSPECTIONS

All maintenance and non-routine work in these facilities that may affect the safe operation of facilities, systems, and laboratories, or that may present a hazard to the general public are conducted in accordance with CNL's work permit system.

All routine maintenance for systems required to be operational was carried out, and all equipment tests and inspections were completed.

E.6 WASTES GENERATED

There were no radioactive and/or hazardous wastes generated in the facility as part of routine operations.

E.6.1 SOLID RADIOACTIVE AND/OR HAZARDOUS WASTES

Building 300 generated 0 m^3 of compactable and 0.4 m^3 of non-compactable low-level radioactive solid waste in 2019.

Building 402 generated 0.7 m^3 of compactable and 0.0 m^3 of non-compactable low-level radioactive solid waste in 2019.

Building 411 site (decommissioned in 2017) had 0.2 m^3 of compactable and 0 m^3 of non-compactable low-level radioactive solid legacy waste processed in 2019.

After processing at the Waste Handling Area, all waste was shipped to the WMA for storage.

See Table 75 for a summary of solid wastes for the last five years.

Table 75: Low-Level Solid Waste Generation – Buildings 300, 402,411

	2015*	2016*	2017	2018	2019
Building 300 (m^3)	48.5	203.3	14.7	4.5	0.4
Building 402 (m^3)	1.4	3.4	2.8	1	0.7
Building 411 (m^3)	19	74.9	355.1	7.6**	0.2**

* Volume prior to compaction, all compactable waste is consolidated at the WHA
** Legacy waste processed in 2018 for building 411 that was decommissioned in 2017

See Section 11.1 Waste Management Program for summaries of the volume of solid radioactive and/or hazardous waste generated in the facility in 2019.

E.6.2 LIQUID RADIOACTIVE AND/OR HAZARDOUS WASTES

There was no liquid radioactive and/or hazardous waste generated in 2019 in this facility.

See Section 11.1 Waste Management Program for summaries of the volume of liquid radioactive and/or hazardous waste generated in the facility in 2019.

E.6.2.1 Research and Development (Building 300) Low-Level Liquid Waste System

Radioactive LLLW flows from the SF and Building 300 to the low-level liquid waste collection tanks, in B300 Room B-33. An accurate determination of the individual SF or Building 300 contribution cannot be made as both locations flow into these common tanks. The sources of water from Building 300 are limited and the major contributor is the radiological decontamination service facilities in the IFTF.

During 2019, 186 m^3 of low-level liquid was processed through the B300 LLLWTS. Table 76 shows the historical volumes of LLLW processed through the B300 LLLWTS and also the total volume of B300 and B100 LLLW processed.

Table 76: Historical Records of Low-Level Liquid Waste Processed

	2015	2016	2017	2018	2019
Total Combined Low-Level Waste Liquid Processed (m^3)[a]	512	230	172.3[b]	131.5[c]	189.3[c]
Low-Level Waste Liquid Processed in B300 (m^3)[d]	74	195	46	123	186.5

a All low level liquid waste processed in Active Liquid Waste Treatment Centre for 2014-2016. This total includes laundry and decontamination and ALWTC facilities for 2014 and 2015. For 2016 the total is B100 and B300 and ALWTC. After 2017 all low level liquid waste is processed in B100 and B300.
b This includes 126 m^3 of low level liquid waste that was processed through the Active Liquid Waste Treatment Centre in Building 200.
c All Low-Level Liquid Waste processed through the low-level liquid waste treatment systems in B100 and B300.
d B300 LLLWTS came online in 2017 July.

The total activities given below are the combination of the Shielded Facilities, B300, and B100 active liquid effluents produced.

As determined by total-beta analysis, the beta radioactivity content in the effluent releases to the Outfall from the holding tanks at the B300 and B100 LLLWTS during 2019 was 0.01 GBq, compared with 0.02 GBq released during 2018. The maximum release in a month during the year was 0.0004 GBq which is a small fraction of the administrative level of 0.48 GBq per month. This level conservatively assumes that all of the activity is due to Cs-137, which is the most restrictive isotope of those present, or potentially present.

As determined by total-alpha analysis, the alpha radioactivity content in effluent releases to the outfall was 0.0027 GBq for 2019 compared with 0.0026 GBq released during 2018. The maximum release in a month during the year was 6.1E-05 GBq which is a small fraction of the administrative level of 0.56 GBq per month. This level conservatively assumed that all the activity is due to Americium-241 which is the most restrictive isotope of those expected to be present in this waste stream.

Table 77 provides a summary of the total activity released for both the B100 and B300 LLLWTS. Annual Release Limit values for radionuclides in liquid effluents for WL are based on the DRL [28]. These values were revised in 2016.

Table 77: B100 and B300 LLLWTS Radioactive Releases

Radionuclide	Total 2019 Effluent (GBq)	Annual Release Limit[a] (GBq/a)	Total 2019 Effluent as a % of Annual Release Limit	Peak Release	
				Max. Monthly Release (GBq)	% of[b] Monthly DRL
Total (Total-Beta Analysis)[c]	0.01	–	–	0.0004	–
Sr-90	2.79×10^{-3}	1.56×10^{2}	1.78×10^{-3}	1.27×10^{-4}	1.09×10^{-3}
Cs-137	8.27×10^{-3}	1.39×10^{2}	5.94×10^{-3}	2.77×10^{-4}	2.38×10^{-3}
Total Alpha (As Pu-239 Equivalent)[d]	2.69×10^{-3}	1.33×10^{1}	2.02×10^{-2}	6.07×10^{-5}	5.47×10^{-4}
Historical Data Total Effluent (GBq)					
	2015[e]	**2016[e]**	**2017[e]**	**2018[e]**	**2019[e]**
Total (Total-Beta analysis)[c]	0.14	0.04	0.04	0.02	0.01

a The annual release limit is calculated by multiplying the DRL by 12.
b Derived Release Limits and most restrictive isotope for the LLLW systems was changed in 2016. The beta particulate emitters are considered to be Cs-137, the most restrictive isotope of those identified or potentially present. The DRL is 1.16×10^{1} GBq/month [28].
c A total beta analysis results in a conservative (higher) estimate of the total amount of activity, which is more accurately determined by measuring the individual radionuclides by radiochemical or gamma spectrometry methods.
d Derived Release Limits and most restrictive isotope for the LLLW systems was changed in 2016. The alpha particulate emitters are considered to be Pu-239, the most restrictive isotope of those identified or potentially present. The DRL is 1.11×10^{1} GBq/month [28].
e Years 2014 to 2016 effluent was all processed in ALWTC. 2017 effluent was processed in ALWTC and B300 LLLWTS. 2018 had all effluent processed in B300 and B100 LLWTS.

E.7 EFFLUENTS RELEASED

There were no radioactive or hazardous, liquid or gaseous effluents released from these facilities. Radioactive wastewater generated in Building 300 was pumped to the LLLWTS in B300 Room B-33.

E.7.1 LIQUID RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

E.7.2 GASEOUS RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

APPENDIX F WR-1 REACTOR

F.1 FACILITY OPERATION

Activities in Whiteshell Reactor 1 (WR-1) were conducted under the WL site licence [1] from the CNSC, in accordance with the requirements of *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [56]. The status of the WR-1 facility in its shut down, de-fuelled, and partially decommissioned state is described in *The WR-1 Reactor Phase 1 Decommissioning Project Interim End-State Report - Facility Description* [57]. The facility is monitored and maintained as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [56].

In 2017, the new LLLWTS as described in Section F.3 collected approximately 1000 L of liquid which was not enough to process and pump out to the river. This amount was carried over and processed in 2018. In 2019, the LLLW system processed a total of 2.8 m^3 of liquid waste.

Routine operations in the WR-1 facility, as defined by T*he Monitoring and Surveillance Plan for the WR-1 Deferment Period* [56], were carried out by the five (four and one trainee) Site and Nuclear Operations Technologists assigned to Building 100.

F.1.1 RADIATION EXPOSURES

Site and Nuclear Operations Branch personnel monitored the WR-1 facility. Site and Nuclear Operations staff that monitor WR-1 also support decommissioning activities in the ALWTC. Any such exposures were not recorded separately from those for other operations. The average and maximum individual whole-body effective dose received by facility staff for 2019 were 0.05 mSv and 0.06 mSv respectively. The average and maximum individual equivalent dose to the skin were 0.05 mSv and 0.06 mSv respectively. The collective effective dose was 0.24 person·mSv. There were no extremity doses in 2019.

The Site and Nuclear Operations Branch personnel participated in routine bioassay testing which involved bi-annual whole-body counts and gross beta of urine samples every 60 days. There was no indication of any internal radiation exposures to facility personnel.

There were no doses exceeding CNL's Action Levels or CNSC regulatory limits to personnel as a result of WR-1 activities during 2019.

F.2 FACILITY DOCUMENTATION AND STAFFING

There were no changes in the staffing or organization for the operating staff responsible for WR-1 in 2019.

No program changes were made for WR-1 in 2019. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

F.3 FACILITY CHANGES

All facility changes were performed as per the approved Engineering Change Control procedure [11]. .

Operational clean-up activities (covered under the current Environmental Assessment) were continued in the WR-1 facility, as well as sampling and characterization work in support of the source term study. These activities included the removal of the Transparent Header Test Facility (THTF) and the sampling of the sand in the crawlspace. The THTF was located in room 648 and consisted of a full scale cast acrylic transparent header and thirty transparent polyvinyl chloride (PVC) feeder tubes. It was a full scale model of a CANDU Primary Heat Transport System header. The THTF was removed to gain access to the floor slabs that the THFT was built on in order to help enable future decommissioning activities of the building.

Approximately 20 m³ of low concentration (3.4E06 Bq/L) tritiated water was found in the thermoshield and bioshield cooling systems. This water is still in the systems, awaiting a decision on how to remove this water as the systems were not designed to be drained.

F.4 FACILITY EQUIPMENT PERFORMANCE

During 2019, the operations status of WR-1 remained unchanged. There were no changes to the reactor's equipment. Facility maintenance was done as per the facility maintenance plan.

F.5 PLANNED MAINTENANCE TESTING AND INSPECTIONS

During 2019, all planned activities for systems required to be operated, tested and inspected were carried out as per the approved facility maintenance plan. Monthly housekeeping and fire prevention inspections were completed.

F.6 WASTES GENERATED

There were no radioactive and/or hazardous wastes generated in the facility as part of routine operations.

F.6.1 SOLID RADIOACTIVE AND/OR HAZARDOUS WASTES

Solid radioactive and/or hazardous waste was generated in the facility as part of routine operations. This consisted of mainly operational supplies such as Tyvek suits.

See Section 11.1 Waste Management Program for summaries of the volume of solid radioactive and/or hazardous waste generated in the facility in 2019. During 2019, 4.8 m^3 of low-level radioactive compactable waste and 0 m^3 non-compactible waste was generated from Building 100/WR-1 operations, and sent to the Waste Handling Area for compaction.

There were no new hazardous solid wastes generated from Building 100/WR 1.

F.6.2 VENTILATION SYSTEM

The system operated satisfactorily during 2019. A chiller system was operated as required through the summer months. Routine Poly-Alpha-Olefin testing of the Building 100 HEPA filters was carried out satisfactorily. All filters had acceptable penetrations of less than 0.03%

F.6.3 LIQUID RADIOACTIVE AND/OR HAZARDOUS WASTES

Liquid radioactive and no hazardous waste was generated in the facility as part of routine operations.

See Section 11.1 Waste Management Program for summaries of the volume of liquid radioactive and/or hazardous waste generated in WR-1 in 2019.

During 2019, 2.8 m^3 of low-level radioactive liquid waste was generated from Building 100/ WR-1 operations, the majority from the WR-1 sumps. Section E.6.2.1 in Appendix E has more information on the liquid waste processed. There were no hazardous liquid wastes generated from this facility.

F.7 EFFLUENTS RELEASED

There were no radioactive and/or hazardous effluents (gaseous or liquid) released into the environment from the facility as part of routine operations.

F.7.1 LIQUID RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

There are no liquid effluents generated from this facility.

F.7.2 GASEOUS RADIOACTIVE AND/OR HAZARDOUS EFFLUENTS

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

Radioactive air emissions from the facility are included in Section 9.4 of this report. There were on hazardous air emissions from this facility.

APPENDIX G NON-NUCLEAR FACILITIES

G.1 FACILITY OPERATION

The WL non-nuclear facilities status and changes for 2019 are as noted in Table 78.

Table 78: Operating Summary of Non-Nuclear Facilities

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
303	Containment Test Facility	Shut Down in 2019	None	None	Buildings & Lands D&D Project Personnel, Facilities	Decommissioning initiated
304	Waste Clearance Facility	Shut Down in 2019	None	None	Buildings & Lands D&D Project Personnel, Facilities	Decommissioning initiated
306	Waste Clearance Facility	Removed in 2016	None	Removed from Use	Buildings & Lands D&D Project Personnel	Building removed, pad retained, End-State Report to be completed
308	Large Scale Vented Combustion Test Facility	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
309	Large Scale Vented Combustion Test Facility - Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
310	Large Scale Vented Combustion Test Facility - Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
311	Large Scale Vented Combustion Test Facility Hydrogen Storage	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
401	Security, Reception, Firehall and Security Monitoring Room	Operational	None	None	All Site/Visitors	No change
405	Lunchroom/Offices (formerly the Library)	Operational	None	None	All Site/Visitors	No change
408	Stores	Removed in 2017	None	Removed from Use	Facilities	Decommissioned, End-State Report to be completed
409	Cold Storage	Removed in 2016	None	Removed from Use	Facilities	Decommissioned, End-State Report to be completed
412	Offices/Machine Shop	Operational	None	None	All Site/Visitors	No change
413	Quonset: Cold Storage	Operational	None	None	Security and Common Services	No change
414	Controlled Area 2 Entrance	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
415	Warm Storage	Removed in 2017	None	Removed from Use	Facilities	Decommissioned, End-State Report to be completed
416	Heated Storage	Removed in 2016	None	Removed from Use	Facilities	Decommissioned, End-State Report to be completed

917	Supervisory Control and Alarm	Operational	None	None	Security and Maintenance	No change
918	Clarified Water System	Shut Down Mid-1980s	None	None	Powerhouse Operators and Maintenance	No change
921	Access Tunnel	Operational	None	None	All Site/Visitors	No change

G.1.1 RADIATION EXPOSURE

There were no doses exceeding CNSC regulatory limits or CNL's Action Levels to personnel as a result of the operation of the non-nuclear facilities during 2019. A detailed account of employee's radiological exposures is provided in Section 7.

G.2 FACILITY DOCUMENTATION AND STAFFING

There were no policy, program or procedural changes for the non-nuclear facilities in 2019. There were no changes in organization in 2019, two senior staff retired and two new trainee Operators were hired.

G.3 FACILITY CHANGES

All facility changes were managed in accordance with the *Engineering Change Control* procedures [11].

G.4 FACILITY EQUIPMENT PERFORMANCE

Systems and equipment for all the non-nuclear facilities, including any safety-related systems, performed as designed and required during 2019, as noted in Table 78.

G.5 PLANNED MAINTENANCE TESTING AND INSPECTIONS

Routine maintenance was carried out, and equipment tests and inspection were completed in 2019 with no significant results, as noted in Table 42.

G.6 WASTES GENERATED

There were no radioactive and/or hazardous wastes generated in Non-Nuclear Facilities as part of routine operations.

G.6.1 DECOMMISSIONED BUILDINGS AND EFFLUENTS RELEASED

In 2019, four non-nuclear facilities, the Large Scale Vented Combustion Test Facility buildings, consisting of B308, B309, B310 and B311, were decommissioned. The final End-State Decommissioning Report will be prepared when all the other non-nuclear buildings on the South-side and North-side have been decommissioned. Decommissioning activities also commenced for Buildings 303, 304 and 424.

There were 1.25E+09 L and 3.83E+07 L of effluent released from buildings B422 (Outfall Monitoring Station) and B907 (Sewage Lift Station and Lagoons) respectively.

G.6.2 LANDFILL DUGOUT WATER MONITORING

The WL landfill is surrounded by six dugouts where surface water collects. These dugouts are sampled as part of the ongoing operational control monitoring for the facility. In 2019 the dugouts had very low water levels or were dry during the summer sampling period. The location of the dugouts are shown in Figure 13. Dugout 22 is used as the Control and is about 300 m away from the landfill to the north-northeast, and would not be affected by facility operations.

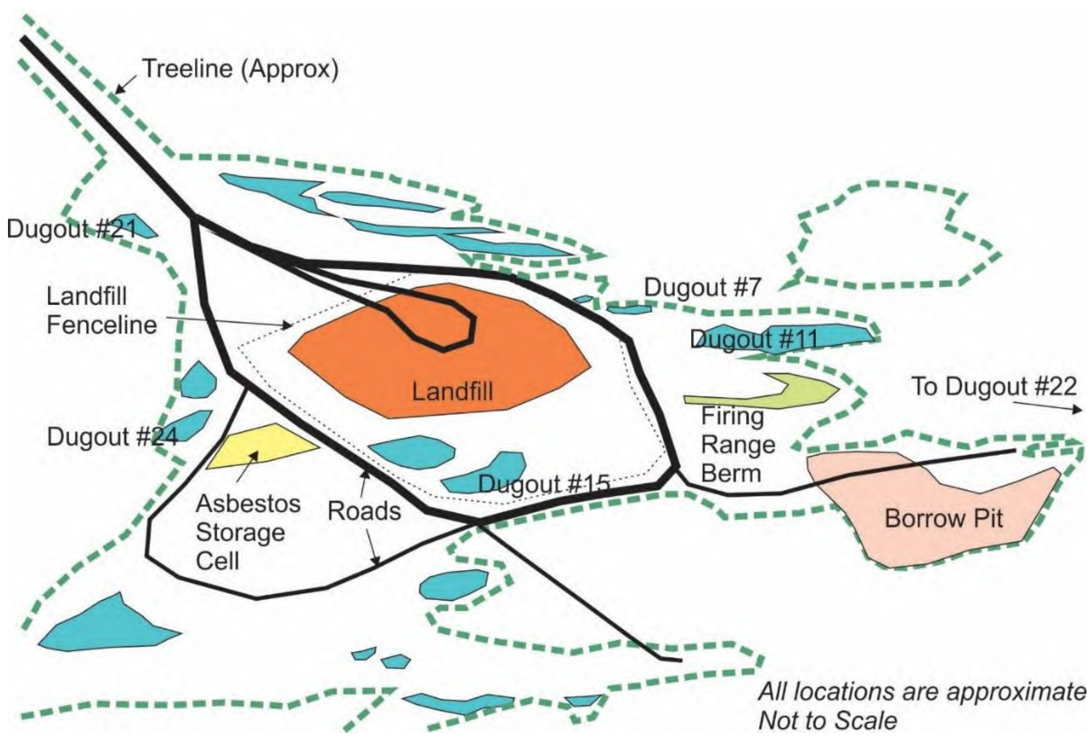

Figure 13: WL Landfill Area Showing Approximate Locations of Monitored Dugouts

The results from the sample analysis for alpha and beta from these dugouts are provided in Table 79 and Table 80 respectively. All alpha results for 2019 were at the detection limits, and are below the drinking water screening level of 0.50 Bq/L. All beta results for 2019 were near the detection limits, and are below the drinking water screening level of 1.0 Bq/L. Both alpha and beta results for 2019 are consistent with previous results obtained from 2014 to 2018.

Table 79: Gross Alpha Results from the Landfill Dugouts

Sample	**Gross Alpha (Bq/L)**					
Location	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**
Dugout #7	< 0.07	< 0.11	< 0.14	< 0.17	< 0.17	0.07
Dugout #11	< 0.07	< 0.10	< 0.10	< 0.14	< 0.14	< 0.05
Dugout #15	0.12	< 0.16	0.16	0.10	0.10	0.28
Dugout #21	0.06	< 0.12	0.16	0.07	0.07	Dry
Dugout #22	0.08	< 0.13	< 0.11	< 0.14	< 0.14	0.11
Dugout #24	< 0.13	< 0.16	< 0.18	< 0.19	< 0.19	0.29

Table 80: Gross Beta Results from the Landfill Dugouts

Sample	**Gross Beta (Bq/L)**					
Location	**2014**	**2015**	**2016**	**2017**	**2018**	**2019**
Dugout #7	0.04	0.17	0.19	0.17	0.17	0.11
Dugout #11	0.06	0.09	0.07	0.02	< 0.10	< 0.05
Dugout #15	0.19	0.40	0.35	< 0.07	< 0.07	0.12
Dugout #21	0.11	< 0.12	0.12	< 0.05	< 0.05	Dry
Dugout #22	< 0.04	< 0.13	< 0.06	< 0.13	0.13	< 0.05
Dugout #24	0.07	0.39	0.26	0.08	< 0.08	0.25

Low levels of tritium (9 Bq/L) were detected in one of the landfill wells (water table) starting in 2011. Its appearance in the groundwater resulted in initiation of the surface (dugout) water measurement of tritium. Tritium has been detected in landfill Dugout 15 for the past seven years, and a small amount was noted in Dugout 24 in 2011, 2012, 2016, and although a higher amount was noted in 2018 (76 Bq/L), the value returned to background in 2019. The higher tritium level in Dugout 15 in 2019 is double the tritium level measured in 2018 - this may be the result of the higher amount of evaporation in 2019 leading to a concentration in the dugout water. All results are well below drinking water limits of 7000 Bq/L. The other dugouts do not appear to contain tritium, as levels comparable to blank samples analyzed from 2013 to 2019 that contain < 4 Bq/L of tritium were recorded. Tritium results from the landfill dugouts are shown in Table 81.

Table 81: Results from the Landfill Dugouts

Sample Location	Tritium (Bq/L)					
	2014	2015	2016	2017	2018	2019
Dugout #7	< 4	< 4	< 4	< 4	< 4	< 3
Dugout #11	< 4	< 4	< 4	< 4	< 4	< 4
Dugout #15	33	41	98	82	105	212
Dugout #21	< 4	< 4	< 4	NA	< 4	Dry
Dugout #22	< 4	< 4	< 4	< 4	< 4	< 4
Dugout #24	< 4	< 4	5.5	< 4	76	< 4

NA sample not available

When initially detected in the dugouts, it was assumed that it was possible that tritium emissions from the WR-1 Building 100 deposited in the ponds surrounding the landfill, and was subsequently drawn in to the water table. After consideration, it was determined that the most likely source of tritium is the landfill. The presence of above background tritium in only a few dugouts cannot be explained by air borne deposition. The highest tritium activities are found in the dugouts and wells in closest proximity to the landfill. Due to its 10 m height, the landfill has a higher hydraulic head than the local terrain, including the asbestos storage cell, and thus will be more likely to contribute leached contaminants to the shallow ground water system. Due to local groundwater flow directions (toward the south and southwest), Dugouts 15 and 24 are more likely to receive contaminants from the migration of water from the landfill. As the landfill has been in operation for over 50 years, the potential for a historic error in placement is greater for the landfill than the adjacent asbestos storage cell.

The water testing was conducted in 2018 to include Sr-90 and Tc-99 (Table 82), two potentially mobile radionuclides. In 2018, near detection levels of Sr-90 were noted in Dugout 21 and near detection limit levels of Tc-99 were noted in Dugouts 21 and 24. All results were below drinking water limits of 5 Bq/L for Sr-90 and 200 Bq/L for Tc-99. In 2019, only Sr-90 was measured, and was found to be at the detection limit. The water from these dugouts and wells is not used for human consumption.

Table 82: Sr-90 and Tc-99 Results from the landfill Dugouts in 2019

Sample Location	(Bq/L)	
	Sr-90	Tc-99
Dugout #7	< 0.10	NA
Dugout #11	< 0.10	NA
Dugout #15	< 0.10	NA
Dugout #21	Dry	Dry
Dugout #22	< 0.10	NA
Dugout #24	< 0.10	NA

The water from the dugouts was also tested for a suite of non-radiological parameters including total metals, mercury, nitrate + nitrite, sulphate, chloride, sodium, potassium, calcium, magnesium, sulphur, total ammonia

(N), phosphorus, phenols and volatile organics (including benzene, toluene, ethylbenzene and xylene). Elevated levels of boron (8460 ug/L) were detected in 2019 in Dugout #15, this is higher than in 2018 (5460 ug/L), a continued increase in boron levels from 2017 (1630 ug/L). The value in the last two years is higher than the Drinking Water Guideline for that parameter (5000 ug/L). Molybdenum decreased to 74 ppb in 2019 from 145 ppb in 2018 in Dugout #21, remaining higher than the Drinking Water Guideline for that parameter (73 ug/L). Manganese was found to be at or higher than drinking water guidelines of 50 ug/L in Dugout #7 (50 ug/L), Dugout #15 (96 ug/L), and Dugout #24 (74 ug/L). No volatile organics were detected, and no other parameters were detected and/or at concentrations of concern.

Groundwater results will be discussed in the annual environmental monitoring report [26]. Sediment sampling of one of the dugouts was conducted as part of the Environmental Assessment Follow-up Program and will be reported in [27].

G.6.3 LANDFILL DUGOUT SEDIMENT MONITORING

Sediment sampling of the dugouts was conducted in 2017 as part of the Environmental Assessment Follow-up Program. The analysis of the sediment included a full suite of metals, mercury, lead, PCBs and for radioactivity, including Sr-90. There were elevated levels of molybdenum in the surface sediment of one dugout (Dugout 24) and no other contaminants of potential concern noted. Molybdenum can be found naturally in the environment (minerals containing iron, bismuth, or copper) as well as being a component of man-made items such as filaments, X-ray tubes, screens, grids for radios, spark plugs, contacts, induction heating elements, and/or part of a waste stream from man-made processes (burning of fossil fuels). The source of the molybdenum is being investigated as part of the assessment of the Landfill prior to closure. Monitoring of the sediments in the dugouts around the landfill is planned to continue every 5 years (from 2017) as well as annual monitoring of the water, as such no sediment sampling was conducted in 2019.

Further investigation will be conducted during the eventual closure of the landfill and will also be reported in the Environmental Assessment Follow-up Program.

EXECUTIVE SUMMARY

This annual compliance monitoring report for the 2020 calendar year has been prepared as per licence condition 3.2 of the Whiteshell Laboratories Licence NRTEDL-W5-8.00/2024 and CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Facilities and Uranium Mines and Mills* as a summary report of annual compliance monitoring and operational performance.

This annual compliance report provides Canadian Nuclear Laboratories (CNL) 2020 performance data for WL and is organized by 14 Safety and Control Areas (SCAs)[1], as well as a report on each of the WL nuclear and non-nuclear facilities.

The following provides overall performance highlights for 2020 activities:

- There were no serious process failures at WL.
- All licensed activities continued to be carried out safely and securely.
- No member of the public received a radiation dose that exceeded any regulatory limit.
- No worker at WL received a dose in excess of any of the respective radiation dose limits for radiation workers, as defined in the Radiation Protection Regulations.
- All releases of radioactive material in WL effluents during 2020 were below their respective Derived Release Limits (DRL).
- Significant progress was made on decommissioning of Building 200, the former Active Liquid Waste Treatment Centre (ALWTC), with the building now partly demolished.
- The WL site maintained safe and compliant performance under COVID-19 Pandemic conditions and protocols.

Below is a summary of the annual compliance report for calendar year 2020.

- **SCA - Management System**: WL has continued its focus on implementation of the corporate management system, as well as the WL Quality Assurance program for decommissioning, based on Canadian Standards Association (CSA) N286.6 and aligned with CSA N286-12, monitored through many means including audits, inspections, self-assessments and program/management system reviews.
- **SCA - Human Performance Management**: A significant effort towards training individuals in human performance related areas was initiated as a result of the fieldwork pause in November, and training of Apparent Cause Analysts is complete.
- **SCA - Operating Performance**: WL decommissions and operates its facilities according to prescribed programs and procedures, and monitors safety performance in the operational area through the concept of "events". The total number of internal event reports raised continues to show a strong reporting culture. There were four Canadian Nuclear Safety Commission (CNSC) reportable events.
- **SCA - Safety Analysis**: Effective Safety Analysis Reports and Facility Authorizations continue to be in place for WL's nuclear facilities, helping meet health, safety, security, environmental and regulatory

[1] The CNSC evaluates how well licensees meet regulatory requirements and CNSC expectations for the performance of programs in 14 safety and control areas.

requirements. The ALWTC Safety Analysis Report and Facility Authorization documents were obsoleted as the facility is now being demolished.

- **SCA - Physical Design**: The Certificate of Authorization was renewed with Engineers Geoscientists Manitoba, authorizing CNL to engage in the practice of professional engineering in Manitoba.
- **SCA - Fitness for Service**: The Periodic Inspection Plan (PIP), previously developed to confirm the ongoing fitness-for-service of the concrete storage facilities at the Waste Management Area (WMA), continued implementation with no significant issues identified. Regular preventative or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service.
- **SCA - Radiation Protection**: No worker received a whole-body dose (including committed) in excess of any of the respective dose limits for radiation workers as defined in the Radiation Protection Regulations, and average individual doses remain a small fraction of these limits. Maximum dose to a person working at WL was 3.0 mSv and collective doses remained below 50 person-mSv (33.3 person-mSv) for 2020. Members of the public received no measureable radiation doses. The Controlled Area reduction initiative was completed for the WL site north side.
- **SCA - Conventional Health and Safety**: Implementation of CNL's Occupational Safety and Health program at WL continues to drive improvements in safety and safety culture. Safety advisories are regularly issued to staff about imminent issues that could impact their safety.
- **SCA - Environmental Protection**: The results of the radiological and non-radiological effluent monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment. Radiological emissions were 0.00019% of the Derived Release Limit (DRL) for air emissions and 0.67% of the DRL for liquids. The monitoring program confirms that the WL site is operating in a manner that protects workers, the public, and the environment. WL maintained their ISO-14001 registration, and are compliant to a number of CSA environmental standards.
- **SCA - Emergency Management and Fire Protection**: The Emergency Management program at WL was focussed on supporting COVID-19 planning and coordination efforts.
- **SCA - Waste Management**: WL continued to reuse or recycle as much material as was practicable. Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects, including disposition of 554 m^3 of radioactive waste to Chalk River Laboratories (CRL), and 513 m^3 (109,031 kg) of recycled waste shipped off-site.
- **SCA – Security**: The Security Program at WL supports the CNL Corporate Security mandate and addresses the regulatory requirements for high-security sites. Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers as required by the CNSC. The CNSC Order, which included the requirement to stand up a Tiered Response Force, was closed.
- **SCA - Safeguards**: There were no issues identified with International Atomic Energy Agency (IAEA) Safeguards inspections conducted at WL. The IAEA Technical group visited for planning use of remote camera monitoring equipment to support the upcoming fuel shipping campaign to CRL.

- **SCA - Packaging and Transport**: There were 230 radioactive transport packages making up 36 loads that were safely and successfully sent off-site, including approximately 528 m^3 of low-level waste and 26 m^3 of intermediate-level waste shipped to CRL.
- **Other matters of regulatory interest**: One virtual meeting of the WL Public Liaison Committee took place, with the other meeting replaced by a written update due to the COVID-19 pandemic. Numerous public information sessions and Indigenous engagements (mainly virtual) were held on the Whiteshell Reactor 1 (WR-1) in-situ decommissioning and overall activities of the WL Closure Project.
- **Facilities** (operating nuclear facilities, permanently shut down facilities, facilities being decommissioned and the non-nuclear facilities): All the licensed activities in these facilities continue to be carried out safely and securely with acceptable radiation doses to personnel and releases to the environment. The following notable facility-specific activities took place: significant progress in decommissioning the Active Liquid Waste Treatment Centre, Building 200, with the building now approximately 50% demolished; all waste has been removed from Shielded Modular Above Ground Storage (SMAGS) in preparation to turn the Building 923 into a Cask Loading Facility; work to prepare for extraction of waste from the Intermediate Level Bunkers and Standpipes continued with commencement of off-site fabrication of extraction equipment; operational cleanout of the Health and Safety Facilities Buildings 402 and 305 was started in preparation for decommissioning/demolition; plus three non-nuclear facilities, the Containment Test Facility Building 303, Waste Clearance Facility Building 304, and the WR-1 Organic Monitoring Building 424 were demolished.

CNL is committed to achieve high standards of operational safety and security. The information and data presented in this report support the conclusion that safe and secure performance is being achieved at the Whiteshell Laboratories site, while enhancements are being implemented to further improve results.

TABLE OF CONTENTS

FIGURES

TABLES

INTRODUCTION

Whiteshell Laboratories (WL) was established by Atomic Energy of Canada Limited (AECL) in the early 1960s to carry out nuclear research and development activities. The site is a Class 1B nuclear facility which encompasses an area of 4,375 hectares. The WL site is located near Pinawa, Manitoba; approximately 100 kilometres northeast of Winnipeg, on the eastern bank of the Winnipeg River. AECL made a business decision in 1997 to discontinue most of the research programs and operations at WL. Subsequently, AECL received government concurrence in 1998 to proceed with actions to achieve closure of WL.

Activities are now underway to complete the orderly decommissioning of the WL site, following the general plan laid out in the Comprehensive Study Report supporting the approval of the Environmental Assessment of the WL Decommissioning Project. The exception to this is the change in strategy for Whiteshell Reactor (WR) -1 (see the Decommissioning Strategies Section below).

Name:	**Whiteshell Laboratories**
Location:	1 Ara Mooradian Way Pinawa, Manitoba R0E 1L0

Licence Information and Reporting Period

This annual compliance monitoring report is produced to comply with licence condition 3.2 of the Whiteshell Laboratories Licence NRTEDL-W5-8.00/2024 [1], in accordance with the compliance verification criteria Compliance Monitoring: Annual Report of the *Licence Conditions Handbook* (LCH) *for* Whiteshell Laboratories (WL), herein referred to as "Licence Conditions Handbook") [2], and Section 3 Annual Compliance Monitoring Report of CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills* [3]. Information included in this report is for the period of 2020 January 01 to December 31.

This report provides site-specific information to supplement information in the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4], which provides corporate updates to the 14 Safety and Control Areas as they are applied across all CNL.

The intent of this report is to provide sufficient detail to demonstrate how WL programs are meeting the regulatory requirements as it pertains to the licence [1] and the LCH for WL [2].

Facilities Included in this Report

Appendices A through G of the report provide information that is pertinent to the Nuclear and Non-Nuclear Facilities (including operating and permanently shut down facilities, and facilities being decommissioned).

The Nuclear Facilities included in this report are: Concrete Canister Storage Facility, Active Liquid Waste Treatment Center, Shielded Facilities, Waste Management Area, Research and Development Facilities Complex (Building 300), Health and Safety Facilities (Building 402 and Building 305), and WR-1 Reactor.

Summary of Licenced Activities

There are no new licenced activities. The WL Site Licence was previously renewed in 2019 for five years, effective 2020 January 01.

Decommissioning Strategies

As discussed in 2015, work is underway to complete decommissioning of the entire WL site (current schedule is to be complete in 2027). This includes leaving in-situ the selected WMA trenches as per the Comprehensive Study Report under institutional control, and transporting active waste off-site for disposal or storage. A significant departure from the end-states defined in the Comprehensive Study Report is in situ decommissioning (also referred to as in situ disposal) of the WR-1 reactor. Work continues for an environmental assessment and regulatory approvals required for this change. The Environmental Impact Statement supporting this is in progress.

Financial Guarantees

CNSC was previously sent a letter from the Honorable G. Rickford [5], advising that as an agent of Her Majesty in Right of Canada, AECL’s liabilities associated with the decommissioning of WL are ultimately liabilities of Her Majesty in Right of Canada (note: AECL retains ownership of the lands, assets and liabilities associated with CNL's licences). This financial guarantee remains valid and in effect, as per the communication issued on 2020 August 25 [6].

1 MANAGEMENT SYSTEM

1.1 Management System Program

WL adheres to the Corporate Management System. See Section 1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL Quality Assurance Plan [7] supports the CNL Management System Manual [8] and summarizes the processes and practices applicable to WL licensed activities, while still retaining compliance to CSA N286-12 [9] and N286.6-98 [10].

1.2 Audits, Inspections and Self-Assessments

See Section 1.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4] for a list of all CNL-wide Audits for the reporting year 2020.

As per the requirements of the Management System [8], both Safety Control Areas and Facilities conduct various audits, inspections, and self-assessments to ensure that the management system is functioning in according to expectations and that any policy, programmatic, or procedural deficiencies are identified and appropriate actions taken to resolve any deficiencies.

All actions resulting from audits, inspections, reviews and self-assessments are being managed and tracked through CNL's Corrective Action Program (CAP).

1.2.1 Audits

See Section 1.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4] for a list of all CNL-wide Audits for the reporting year 2020.

External Audits

The external audit conducted at WL is summarized in the table below.

Table 1: External Audits

Title	Type of Audit	No. of Actions Raised	No. of Actions Completed
SAI Global S2 Surveillance Audit of the WL Environmental Management System	14001:2015	2	0

Internal Quality Audits

The internal audit completed by the Quality Audits and Processes branch in 2020 is summarized in the table below.

Table 2: Internal Quality Audits

Title	Audit Scope	No. of Actions Raised	No. of Actions Completed
Quality Audit of Environmental Protection	14001:2015	3	0

1.2.2 Inspections

CNSC Inspections

There were no CNSC inspections conducted at WL in 2020.

Inspections by Other Regulatory Bodies

A Physical Inventory Verification (PIV) inspection was carried out by the IAEA on 2020 November 04. This inspection was a sampling of accessible items containing Special Fissionable Material and changing of two IAEA Canister Seals. A Design Information Verification inspection was carried out by the IAEA on 2020 November 05. This inspection verified the information provided in the Design Information Questionnaire.

1.2.3 Self-Assessments

In 2020, there were 14 self-assessments conducted at WL covering various aspects of the Management System, including both safety and control areas, and various facilities.

Table 3: List of Self-Assessment Conducted at WL in 2020

Title	Facility/Department
Assessed the registration and control of radiation sources	WL Radiation Protection (RP)
Assessed the WL radiation dose reporting to NEW workers	WL RP
Assessed the WL RP Program Compliance Review	WL RP
Self-assessment on the WL Industrial Hygiene instrumentation inventories effectiveness	WL Occupational Safety and Health (OSH)
Self-assessment on Fall Protection Personal Protective Equipment (PPE) and High Angle Rescue (HAR) Equipment	WL OSH
Effectiveness of the implementation of the OSH Program at WL	WL OSH
Assessed the WL Sample Management Office	WL Environmental Protection
Assessed WL-510400-OI-366-01 – WL Lock Out Tag Out (LOTO)	WL Site and Nuclear Operations
Assessed the WL Integrated Work Control Process Procedure	WL Site and Nuclear Operations

Title	Facility/Department
Effectiveness and implementation of the Waste Management Specific Block Training provided at WL	WL Waste Management
Assessed records (Section 37 of the Nuclear Security Regulations SOR-2000-209	WL Emergency Services
Compliance of WL EM QA Plan WL-514200-QAP-001 to 17025, Control of Records.	WL Environmental Management
Compliance of Whiteshell Environmental Monitoring to the Whiteshell Environmental Monitoring QA Plan WL-514200-QAP-001 and to ISO/IEC 17025:2017, Internal Audits and Self-Assessments.	WL Environmental Management
Compliance of WL EM QA Plan WL-514200-QAP-001 Rev 1, Section 8.9 Management Reviews to ISO/IEC 17025:2017	WL Environmental Management

1.3 Management Reviews

A Quality Assurance Program/Management System Review is in progress for 2018/19 and 2019/20.

2 HUMAN PERFORMANCE MANAGEMENT

2.1 Human Performance Program

WL adheres to the Corporate Human Performance (HU) Program. See Section 2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

2.1.1 Program Improvements and Accomplishments

The effectiveness of the HU program at WL has been enhanced through the following improvements:

- Apparent Cause Analysis (ACA) – In 2020 January, WL experienced a Site Event Day Reset (S-EDFR), and this event revealed a gap in the number of certified Cause Analysts on-site. WL had not conducted an ACA in a few years, therefore WL engaged the aid of a trained Cause Analyst from the Port Hope site. The analyst conducted the ACA and, at the same time, trained and certified five WL analysts. WL will continue the development of their newly certified Cause Analysts by partaking in the upcoming CNL sponsored TapRoot training initiative that will take place in 2021.
- Prior to the reduced operations as a result of the COVID-19 pandemic, WL personnel travelled CRL to observe and benchmark with the CRL Performance Assurance Team.
- For 2020, WL had planned to educate WL staff on the various Performance Assurance activities. The COVID-19 Pandemic hindered delivery of in-person training of the course *HU-1038 Human Performance Awareness – Fundamentals and Nuclear Safety Culture*. As a result, WL actively engaged the Performance Assurance Program to enable WL employees to participate remotely in the newly developed virtual HU-1038 sessions.
- On 2020 November 16, the WL Closure Project (WLCP) went into a ten-week fieldwork pause in response to an adverse trend in human performance. As a corrective action, the project took a proactive response to address several human performance issues and apparent gaps within WL's programs. A multidisciplinary team made up of OSH, RP and Work Planning professionals from across the CNL organization were assembled to guide and support the WL team through remobilization of field work. This team has been and will continue into 2021 to conduct comprehensive reviews and gap analyses of all relevant documentation governing and guiding the training of staff, and conduct of RP, OSH and Integrated Work Control (IWC) programs, with an emphasis on Job Hazard Analysis / Job Safety Analysis and IWC processes. Roll out of Phase A – Drive Accountability and Strengthen Communication initiative is underway. Meetings continue to be held with each level of the management team to review and gain feedback on the initiatives identified following an employee listening campaign on safety. A significant effort towards training individuals in these areas has been initiated.

As a follow up to safety concerns expressed by the WL Site Safety and Health Committee to the CNL Health and Safety Policy Committee, the WL General Manager held a series of listening campaigns to gather feedback about concerns employees might have about site safety. Feedback received has been rolled up into actions for management to implement as part of the above fieldwork pause initiatives, with the remainder assigned to the Site Safety and Health Committee for resolution.

2.2 Training Program

2.2.1 Program Improvements and Accomplishments

The effectiveness of WL Training Program has been enhanced through the following improvements:

- WL Training developed and provided in person Return to Work COVID-19 training to employees and contractors.
- Through the COVID-19 pandemic restrictions and a largely remote workforce, WL Training provided virtual ergonomic awareness documentation and one-on-one assessments to remote workers to ensure work areas were ergonomically sound.
- WL New Employee Orientation (NEO) evaluation was initiated.

2.2.2 Required Training

CNL maintains a list of positions and roles requiring SAT training programs in compliance with REGDOC-2.2.2, Personnel Training [11].

Training and Development evaluated the training programs for listed positions and roles at WL against the main elements of SAT. The results led to initial individual action plans which are being managed and further evaluated by the Curriculum Review Committees (CRC). Additional corrective actions and program improvements will be identified and managed by the CRCs going forward.

Some WL listed positions and roles require additional training documentation development to achieve full SAT-compliance. Current workers are qualified based on existing training programs combined with their years of experience in the role. Existing training programs include classroom training, practical training, computer-based training, and mentor style training. These experienced workers will assist as Subject Matter Experts (SMEs), in the development of training documentation that is required to achieve full SAT-compliance.

All WL personnel, both employees and contractors are adequately trained (and refreshed) to ensure safe operation of their facilities and to conduct work under the licence [1]. Table 4 provides a list of federally/provincially legislated training courses that appear in position-specific training plans at WL.

Table 4: WL Operating Staff Training in 2020

Course Code	Course Title	No. of Attendees
FIRE-1001-Online	Fire Prevention	97
FIRE-3001	Fire Extinguisher – Practical	104
OSH-1001-Online	Crane (Safe Indoor Hoist) – Theory	3
OSH-1002-Online	Lift Truck Operation – Theory	10
OSH-1003	Aerial Platform – Theory	20
OSH-1003-Online	Aerial Work Platform – Theory	10
OSH-1004	Lock Out / Tag Out	54
OSH-1004-Online	Lock Out / Tag Out Exam	27
OSH-1004-Virtual	Lock Out / Tag Out (Virtual)	27

Course Code	Course Title	No. of Attendees
OSH-1005	Working at Heights	69
OSH-1005-Online	Working at Heights	34
OSH-1005-Virtual	Working at Heights (Virtual)	4
OSH-1006	Confined Space Entry	14
OSH-1006-Online	Confined Space Exam	7
OSH-1007	Asbestos Module 6E	6
OSH-1033-Online	Ladder Safety	20
OSH-1034-Online	Hazard Prevention Program	20
OSH-1042-Online	WHMIS – 2015	18
OSH-1046-Online	Heat Stress	9
OSH-3003	Aerial Platform – Generic Practical	10
OSH-3003-Multi	Aerial Platform – Practical (All Equipment Codes)	5
OSH-3005	Working at Heights – Practical	34
OSH-9060-Online	MSDS Online Viewer Training	1
TD-1016-Online	Preventing Violence in the Workplace	16
TD-9030-Online	Harassment Prevention	39
HU-1038	Human Performance Awareness – Fundamentals & Nuclear Safety Culture	34
HU-1036-Online	Pre job Brief	24

2.2.3 Contractor Training

Before accessing the Whiteshell Laboratories (WL) site, contractors are required to complete the following in person training:

- Contractor Safety Orientation,
- Radiation Protection Group 4 (if required),
- CNL Contractor Code of Conduct, and
- CNL COVID-19 Awareness and Daily COVID-19 screening.

WL utilizes the contract terms and conditions, in addition verifying and approving the contractor company's safety programs and training records, to ensure contractors are qualified to work at WL.

WL oversees contractors' work in the field and all WL work control protocols apply.

2.2.4 Training Evaluations Summary

In 2020 there were nine Tired Response Force (TRF) Instructor Evaluations performed and documented in CNL's electronic records repository, ATOM.

In addition, WL utilizes trainee feedback forms to capture learner input as part of training program improvement and maintenance activities.

3 OPERATING PERFORMANCE

3.1 Operating Program

WL adheres to the Corporate Operating and Decommissioning Programs. See Section 3.1 and Section 11.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Whiteshell Laboratories decommissions and operates its facilities according to prescribed programs and procedures. Operating performance is monitored through the nuclear performance assurance review board and other internal assessment activities such as self-assessments and audits (see Section 1.2).

The CNSC has previously been notified of revisions to Facility Authorization documents [12] (note that this was the voiding of a Facility Authorization), as per the *Licence Conditions Handbook*.

3.1.1 Operations / Decommissioning Operations

Operational details on facilities identified in the *Site Licences, Certificates, Permits, Building/Facility Contacts, and Licence Representatives* [13] for WL are given in Appendix A through Appendix F.

3.1.1.1 Conduct of Operations

Conduct of operations documents ensure appropriate integration and adequate reflection of safe operation practices to meet the business requirements.

3.1.1.2 Modification to Facilities and Processes

All temporary and permanent modifications to facilities at WL are made following defined Engineering Change Control [14] processes.

Relevant modifications to WL facilities are given in Appendix A through G.

3.2 Reporting Requirements

3.2.1 Reportable Events

In 2020, there were 4 events that occurred at WL that were deemed reportable to the CNSC. They are listed in the table below.

Table 5: Reportable Events to the CNSC at WL in 2020

Event No.	Title	SCA	Facility (if applicable)
ERM-20-0126	WL- Reportable Event - Failure to Submit Notification to CNSC of Revised Criticality Safety Document (CCSF-123400-CSD-001 / CSD-11)	Operating Program	WL CCSF
ERM-20-1140	WL - Breach of Security Protocol	Security	N/A
ERM-20-1772	WL - Reportable Event – Non Compliance to the WL Waste Management Area Facility Authorization WLWMA-00583-FA-001	Operating Program	WL WMA
ERM-20-2412	WL - Reportable Event - Confirmed COVID-19 Case at WL	Other	N/A

Reports to other regulatory agencies consisted of three Hazardous Occurrence Investigation Reports (HOIR) made to Employment and Social Development Canada (see Section 8 Conventional Health and Safety for further details).

3.2.2 Trending of Events Related to Operational Activities

As events at WL occur, they are recorded in the Improvement Action (ImpAct[2]) system. This information is regularly reviewed and analyzed to identify any trends. Event Code based trend reports are also prepared to analyse ImpAct data on monthly bases to identify trends. Monthly site wide and WL specific trend reports are prepared by CRL Performance Assurance and shared with WL. WL specific trends are also specified in the monthly Contractor Assurance System scorecard.

The following trends were identified and raised as ImpActs:

- ERM-20-2866, WL - Adverse Trend in Safety Events at Whiteshell, and
- ERM-20-2920, WL TREND - Engineering Change Control (ECC) Non-Compliance.

The use of the ImpAct process continues to foster the internal reporting of lower significance level events (Level 4 and some Level 3), affording the opportunity to implement continuous improvement initiatives through a robust Corrective Action Program.

In 2020, a total of 350 ImpActs were raised by CNL employees at WL (report is based on responsible department). ImpActs raised in 2020 being lower than previous years is due to the reduction in operations and a large number of employees working from home as a result of the COVID-19 pandemic.

The reporting of lower significance level events continues to be encouraged (e.g., Near Miss Reporting – see Section 8, which is an industry best practice), and efforts to improve safety culture (Event Free Tools use, Event Free Day Reset, Observation and Coaching, etc.) have been adopted by both management and staff.

The following table summarizes ImpActs raised over the past 5 years.

Table 6: Number of ImpActs raised at WL

Year	Level 0[a]	Level 1	Level 2	Level 3	Level 4	Total
2016	9	0	1	25	491	526
2017	5	0	0	42	448	496
2018	10	0	0	39	532	581
2019	8	0	0	54	547	609
2020	13	0	3	58	276	350

a Level 0 will be assigned if the ImpAct is deemed to be a “duplicate or non- problem” and a recommendation to close the Impact will be given.

2 ImpAct – Abbreviation for Improvement and Action. It is an internal process used to identify events, problems, non-conformities, opportunities for improvements, and personnel injuries. The process also identifies and tracks actions to correct or remediate problems.

4 SAFETY ANALYSIS

4.1 Safety Analysis Program

WL adheres to the Corporate Safety Analysis Program. See Section 4.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

4.1.1 Safety Analysis Reports

Safety Analysis Reports (SARs) are produced to demonstrate that the facilities are appropriately designed to meet health, safety, security, environmental and regulatory requirements, and operated safely. These SARs form part of the basis for a set of limiting conditions for safe operation that are documented within Facility Authorizations for each nuclear facility. At WL, three facilities have SARs and Facility Authorizations: Shielded Facilities (SF), WMA and Concrete Canister Storage Facility (CCSF). The ALWTC SAR and Facility Authorization documents were obsoleted in 2020 [12]. An assessment is in progress to determine if the SF SAR needs to be revised.

A SAR is being prepared for the standpipe/bunker remediation, Intermediate-Level Liquid Waste (ILLW) Processing Centre and conversion of the SMAGS building to a Cask Loading Facility. This document will be an addendum to the existing WMA SAR and will be submitted to the CNSC for acceptance, before these facilities are operated.

4.2 Nuclear Criticality Safety Program

WL adheres to the Corporate Nuclear Criticality Program. See Section 4.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The effectiveness of the Nuclear Criticality Safety (NCS) program at WL has been enhanced through the following:

- Continuing to provide technical and regulatory site-wide support to various CNL groups to improve and strengthen the Program processes.
- Holding semi-annual meetings with CNSC staff, to provide updates on the status of the NCS program.
- Providing general NCS training to WL.
- Providing NCS Program review on WL engineering risk assessments.

4.2.1 Nuclear Criticality Safety Documents

The WL Criticality Safety Documents (CSDs) for the Waste Management Area (CSD-27), the Cask Loading Facility (formally the Whiteshell Laboratories SMAGS Building B923) (CSD-73) and the Intermediate-Level Liquid Waste Processing Centre (CSD-74) are in progress to allow retrieval of waste from the WMA. The remaining WL CSDs have not been updated during this review period.

5 PHYSICAL DESIGN

5.1 Design Program

WL adheres to the Corporate Design Program. See Section 5.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In 2020 March, a Certificate of Authorization was renewed with Engineers Geoscientists Manitoba. This authorizes CNL to engage in the practice of professional engineering in the province of Manitoba in accordance with the provisions of The Engineering and Geoscientific Professions Act.

5.1.1 Safety Related Structures Systems and Components

Any changes affecting Safety Related Structures, Systems and Components (SSC) at WL were controlled through the Engineering Change Control Process [14].

5.2 Pressure Boundary Program

WL adheres to the Corporate Pressure Boundary Program. See Section 5.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL *Pressure* B*oundary (PB) Quality Assurance (QA) Manual* [15] defines the pressure boundary measures applicable to WL facilities and is consistent with CNL's PB Program requirements.

The *Pressure Boundary Quality Assurance Manual* [15] was previously accepted by Inspection and Technical Services (ITS) Manitoba. A Certificate of Authorization, issued by ITS, permits CNL to perform Pressure Boundary work as described in the Quality Assurance Manual until expiry in 2021 March. The process of updating the *Pressure Boundary Quality Assurance Manual* [15] and renewal of this Certificate of Authorization will commence in 2021 January.

6 FITNESS FOR SERVICE

6.1 Fitness for Service Program

The Site and Nuclear Operations Branch provides monitoring and operation of building's, processes and support systems. Housekeeping inspections are performed monthly to provide a formal walkthrough of facilities to ensure compliance for specific areas relating to facility performance. Further inspections are conducted of waste storage structures by qualified personnel to maintain them in a fit for service state.

Operating procedure reviews are conducted on a five year cycle. As facilities are decommissioned procedures are obsoleted. Procedures to operate the facilities in order to enable decommissioning efforts are prepared as required.

Details on various inspection and maintenance activities are provided in the following sub sections.

6.1.1 Planned Maintenance, Testing & Inspections

As part of Fitness for Service, WL staff ensure that critical systems, structures and components related to the safe decommissioning of WL are understood and that activities are put in place to assure their safe continued operation as they age. An integrated set of programs and activities that ensure that performance requirements for all critical systems, structures and components are met on an ongoing basis. These processes include:

- Maintenance, In-Service Inspection and Functional Testing, where preventive maintenance work done in the facilities is tracked to ensure it is completed.
- WL operational regulatory tasks are tracked on a weekly basis to ensure required compliance and facility checks are completed, this includes the tasks set out in the Facility Authorization documents.
- Inspections required to meet the conditions of WR-1 Monitoring and Surveillance Plan.
- Inspections of waste storage structures for fitness for service.

6.1.2 Equipment Fitness for Service/Equipment Performance

Preventive maintenance of safety-related systems in WL's nuclear facilities is carried out by qualified maintainers, in accordance with the facility's Facility Maintenance Plan, and approved maintenance procedures. Preventive Maintenance is defined as the pre-planned routine testing, calibration, inspection, service, and overhaul of safety-related systems, structures, and components. Preventive maintenance is performed to prevent failures from occurring and to assure the continuing capability of the system, structure or component to perform its design function. The maintenance tasks and frequencies specified in the Facility Maintenance Plan are based on recommendations from qualified WL engineering and maintenance personnel, plus vendor's data where available. Situations where there is evidence of deteriorating conditions or suggestions of an increased probability of upcoming failure are addressed as they are identified. Regular preventive or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service. Maintenance scheduling is conducted with assistance of a Computerized Maintenance Management System which outputs preventive maintenance tasks for scheduling by maintenance and work planning staff.

6.1.3 Condition of Structures

Waste storage structures include the WMA bunkers and CCSF concrete canisters.

As a requirement of the Environmental Assessment Follow-up Program, a Periodic Inspection Plan (PIP) for WL Concrete Bunkers [16] has been developed and implemented to confirm the ongoing fitness-for-service of the concrete storage facilities (termed “bunkers”) at the WMA. The PIP describes methods for conducting scheduled inspection surveys of these structures. The inspection is defined as examination, measurement and testing work done, to ensure the bunker systems are functioning as designed and the bunkers remain fit-for-service. The inspections are documented annually, with preventive maintenance and repairs occurring as needed. As the bunkers at the WMA are removed from service as part of the overall decommissioning of the WL site they will be removed from the inspection process. The 2020 annual inspection of WL WMA concrete bunkers was conducted in accordance with the PIP [16].

Although the SMAGS building is not a bunker it is included in the bunker inspection. A repair, conducted in 2016, to the north wall of SMAGS that extended into the core of the slab, remained stable through 2020 with no new crack expressions (the walls of SMAGS are pre-cast concrete slabs). All other repair items for the bunkers and SMAGS were minor in nature and were tracked through the WL work request system.

The concrete canisters are inspected quarterly for concrete spalls and any changes in the hairline cracks of the concrete. In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however, existing cracks and pour pockets were regularly checked for changes. Requests for patching were placed in 2020, several canisters will require more extensive patching of pour pockets that have gradually become more noticeable over time, however no increased field was noted. There was no degradation of the exposed metallic portions of the canisters. Fifteen of sixteen canisters were opened in 2020 to allow for borescope inspections of the accessible portions of the fuel baskets. The visible portions of the baskets appeared to be in good condition.

Environmental monitoring was conducted in the ditches at the perimeters of the WMA and the CCSF and show no evidence that any activity has been released from the bunkers, SMAGS or concrete canisters.

7 RADIATION PROTECTION

7.1 Radiation Protection Program

WL adheres to the Corporate Radiation Protection Program. See Section 7 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

7.1.1 ALARA Initiatives and Activities

As Low as Reasonably Achievable (ALARA) and Radiation Protection (RP) program improvement initiatives and activities performed at WL in 2020 included:

- Reconfiguration of the WMA Controlled Area exit building and change facility;
- Waste Holding Controlled Area established on north side of WL site;
- Implementation of gamma walk-through monitors at the exit from the WL site north side and entry into the new module office complex at the WMA;
- Introduction of alpha-beta scintillation floor contamination monitors for building release monitoring;
- Implementation of survey meter calibrations by an external RP instrumentation calibration service
- Acquisition and use of water misting equipment for nuclear facility demolition;
- Formal registration of radioactive material storage areas; and
- Clarification of site processes for the de-registration and disposal of radiation sources.

The planning of radiological work is integrated into the WL site work control and planning process. Health Physics and Radiation Surveyor staff are engaged in the provision of radiological safety and ALARA assessments, providing authoritative advice regarding radiation protection matters, preparing radiological safe work documents, providing oversight of the execution of radiation work, and in the planning and conduct of radiological clearance surveys. Health Physics staff develop radiological work assessments in support of the safe planning and conduct of WL decommissioning activities. Radiological clearance plans, surveys and release reports are completed for building demolitions.

WL RP performance metrics are measured and tracked weekly through WL Closure Project status reports and quarterly through the WL Nuclear Performance Assurance Review Board. These are designed to identify and address program and performance deficiencies and opportunities for improvement, establish and effectively implement corrective and preventative action plans.

7.1.2 Dose Control

Regular radiation surveys are performed by RP staff to confirm: the radiological safety zones are correctly designated; areas with local elevated radiation doses rates are posted in accordance with the RP Regulations; and sufficient access control provisions are in place. In 2020, there were no occurrences of dose rates exceeding permissible levels for the designated radiological safety zones and there were no occurrences of work places with accessible dose rates exceeding 25 µSv/h not being posted or with inadequate access control.

Electronic Personal Alarming Dosimeters (PADs) are worn by workers in addition to Thermoluminescent Dosimeters (TLD) badges to track and control job specific daily and accumulated doses. The PADs have dose and dose rate alarms which are established by job specific radiological work assessments. The dose alarms are a back-out condition and the dose rate alarms are an alert condition[3]. Table 7 summarizes maximum daily recorded doses and dose rates for PAD work in 2020 and previous four years, and a summary of PAD alarms. In 2020, the maximum PAD recorded daily dose received by a worker was 0.28 mSv and the highest dose rate measured in the year was 5.56 mSv/h. These were associated with planned exposures associated with decommissioning activities in the Building 200 ALWTC. There were no PAD dose alarms and 28 PAD dose rate alarms in 2020. The PAD alarms are summarized in Table 7.

Table 7: Personal Alarming Dosimeter Summary

	2016	2017	2018	2019	2020
PAD – Maximum Daily Dose (mSv)	0.08	0.17	0.24	0.42	0.28
PAD – Maximum Dose Rate (mSv/hr)	1.44	1.99	4.95	5.82	5.56

At the beginning of 2020, managers assigned and confirmed Dose Control Points (DCPs) for employees and contractors. DCPs are used by First Line Managers and Supervisors to perform individual whole-body dose management for worker radiation dose for non-emergency work situations. DCPs of either 1 mSv or 2 mSv are assigned by WL managers and represent the worker's maximum allowable dose for the calendar year. The DCPs may be adjusted as necessary during the year upon approval of a Health Physicist after confirmation that additional dose is justified, planned and optimized. At the end of 2020, there was 1 individual with a readjusted DCP of 4 mSv, 4 individuals with a readjusted DCP of 3 mSv, 23 individuals with an assigned DCP of 2 mSv, and the remainder of workers with a DCP of 1 mSv. Workers with readjusted DCPs were approved by a Health Physicist for planned radiological work associated with Building 200 decommissioning. No worker dose exceeded their assigned DCP in 2020.

7.1.3 Contamination Control

Regular contamination surveys of workplaces, material transfers and personnel exiting nuclear facilities and controlled areas are used to confirm the absence of unknown contaminated material or the spread of contamination. Workplace air monitors are employed to confirm the adequacy of controls and to warn of abnormal of unplanned airborne contamination conditions.

Table 8 shows the number of personnel, workplace and material contamination events identified in 2020 and over the past five years. None of the contamination events in 2020 resulted in a recordable whole-body, skin or internal dose.

In 2020, material contaminations were associated with historical surplus equipment being found with low level contamination during operational clean-up surveys or during material transfer surveys.

In 2020, there were no airborne contamination exposure events and no radioactive material spills.

The following table outlines contamination events that occurred at WL in 2020 and over the past five years:

---

[3] PAD dose rate alarm set points are selected to alert workers of the presence of local areas of higher gamma dose rates or an unexpected increase in work area dose rates. Work may continue if repositioning to a lower dose rate area below the alarm point and dose rates are confirmed to below dose rate back-out points.

Table 8: Contamination Events

	Skin and Clothing Contamination				Workplace Contamination	
	Skin[a]	**Personal Clothing**[a]	**Radiological Work Clothing**[b]	**Total**	**Surface**[c,d]	**Vehicle / Materials**[b,c]
2016/17 FY	1	0	0	1	8	
2017/18 FY	0	0	1	1	3	
2018/19 FY	1	0	5	6	6	0
2019 CY	3	0	4	7	2	4
2020 CY	2	0	3	5	1	1

a Total surface contamination found is greater than 1 Bq/cm^2 beta-gamma or 0.2 Bq/cm^2 alpha over a 100 cm^2 averaging area.
b Total surface contamination found is greater than 4 Bq/cm^2 beta-gamma or 0.4 Bq/cm^2 alpha over a 100 cm^2 averaging area.
c Removable surface contamination found is greater than 0.2 Bq/cm^2 beta-gamma or 0.01 Bq/cm^2 alpha over a 300 cm^2 averaging area for Contamination Zone 1 areas
d Removable surface contamination found is greater than 10 times the maximum allowable levels for Contamination Zone 2 and higher designated areas.

7.1.4 Sealed Sources

Radiation sources are registered and tracked in accordance with CNL procedures.

In 2020, there were no lost or stolen radiation sources. Leak testing was completed as required with all sources passing their leak tests.

As of 2020 December 31, the total number of registered sealed or contained sources at WL, was 54. Two Cesium (Cs)-137 instrument calibration sources were added to the registry and one Americium (Am)-241 source was removed from the registry and sent for waste storage at the WL WMA.

7.2 Dosimetry

WL uses the CRL licensed Dosimetry Service Provider (DSP) for external and internal dosimetry for CNL staff, non-CNL employees and visitors. Compliance with the regulatory standard S-106 [17] requires external exposure measurements to meet performance criteria with respect to the measurement of personal dose equivalent, $H_p(d)$. This is the quantity currently measured using TLDs worn on the trunk of the body. External whole-body dose (photon) and external surface (photon plus beta) dose as reported herein can be interpreted as $H_p(10)$ (for photons) and $H_p(0.07)$ (for photons and betas), respectively. Effective dose is the sum of the components external penetrating, neutron, tritium and non-tritium committed effective dose.

External radiation whole-body and skin doses are individually monitored using TLDs for persons entering or working in either radiological Controlled or Supervised Areas at WL[4].

[4] Exceptions are authorized on a case-by-case basis by the responsible RP Program Manager or RP Program Functional Support Manager (exceptions are noted in Section 7.2.1).

Extremity dosimeters are worn for a defined job by a person who is likely to receive an extremity dose exceeding 1 mSv and significantly greater than a surface dose as monitored by their TLD, or if there is a reasonable probability that an extremity will be exposed to a beta and/or photon dose rate greater than 10 mSv/h.

Neutron dosimeters are issued to individuals who may be exposed to neutrons resulting in dose in excess of 1 mSv in a year or where accidental neutron exposures are possible.

WL staff participate in a routine bioassay program when there is a reasonable probability of receiving a committed effective dose from occupational intakes exceeding 1 mSv per year.

7.2.1 Radiation Doses to Personnel

Table 9 to Table 12 summarize the monitored radiation doses at the WL site for 2020. Doses are summarized for employees, contractors and visitors and are subdivided into Nuclear Energy Worker (NEW) and non-NEW status. Doses in the tables of this report do not include doses received by WL employees and contractors working at sites other than WL.

In 2020, there were no exceptions for individual monitoring of non-CNL employees and visitors at WL.

There were no operations of exposure devices in 2020 which required employees or contractors to be placed on a two-week dosimetry period, and there were no formal dose calculations required during 2020 for local area skin contamination.

No neutron dosimeters were assigned to employees during 2020.

In 2020, 168 individuals underwent internal bioassay, which involved urinalysis and/or whole-body counting. Sixteen individuals underwent confirmatory and follow-up Pu-in-urine bioassay monitoring and there were no individuals requiring tritium-in-urine monitoring. No committed effective dose estimates were necessary as a result of any bioassay sampling in 2020.

Table 9: Effective Dose for WL

Monitored Person Type		Total # of Persons	Dose Range (mSv)							Individual Dose (mSv)			Collective Dose (person·mSv)
			0	0.01-0.50	0.51-1.00	1.01-5.00	5.01-10.00	10.01-20.00	>20.00

c Average of all measured doses that include the zero dose value, rounded to two decimal places.
d Visitor NEWs are persons that were historically employee and/or contractor NEWs, but have returned to WL as visitor while retaining their historical NEW status.

7.2.1.1 Discussion of Dose Data

The Regulatory effective dose limit for a NEW in a calendar year is 50 mSv. The maximum individual effective dose to a NEW at WL in 2020 was 2.97 mSv and the site collective dose was 33.4 p-mSv.

The Regulatory effective dose limit for a NEW in a five-year period is 100 mSv. The maximum individual effective dose to a NEW at WL for the five-year dosimetry period from 2016 to 2020 at WL was 7.24 mSv.

The Regulatory skin dose limit for a NEW in a calendar is 500 mSv. The maximum individual skin dose to a NEW at WL in 2020 was 6.80 mSv and the site collective dose was 61.2 p-mSv.

The Regulatory hands and feet dose limit for a NEW in a calendar is 500 mSv. The maximum individual hands and feet dose to a NEW at WL in 2020 was 6.46 mSv and the site collective dose was 51.4 p-mSv.

The Regulatory effective dose limit for a pregnant NEW is 4 mSv for the remainder of their pregnancy. In 2020, the maximum individual effective dose from the time the pregnancy was declared at WL was 0.01 mSv to the end of the calendar year.

The Regulatory effective dose limit for non-NEWs is 1 mSv in a calendar year. In 2020, the maximum individual effective dose to a non-NEW at WL was 0.00 mSv.

Table 13 provides a summary of radiation doses by worker group in 2020. The majority of radiation doses were received by RP and Trades staff, and 79% of their doses were attributable to Building 200 ALWTC decommissioning activities.

7.2.1.2 Radiation Dose Changes or Trends

Table 14 shows external whole body dose received from 2016 to 2020, and Figure 1 displays the maximum individual and collective dose from 2001-2020.

Worker doses have been on the rise since 2017, as WL decommissioning activities began to focus on buildings and facilities with increased radiological hazards. The increase in dose in the past several years can be attributed primarily to the decommissioning activities of Building 200 (ALWTC). The number of workers receiving occupational doses above 0.2 mSv in a calendar year has been staying steady at about 40 workers in recent years with 2020 being down to 25 workers. The number of workers receiving doses above 1 mSv reduced to below 10 workers from below 15 workers the previous year.

7.2.2 Program Exceedances

During 2020, radiation dose to all persons working at WL were below the WL dose Action Levels [2] and the respective CNSC regulatory limits [18]. In addition, there were no individual doses exceeding their respective DCP as a result of activities at WL.

Table 13: Summary of Worker Group Radiation Doses at WL for 2020

	Total Number of Persons	Individual Whole-Body Dose (Effective Dose[a])		Collective Whole-Body Dose (Effective Dose[a])	Collective Surface Dose (photon plus neutron plus beta)	Collective Extremity
		Average[b] (mSv)	Maximum (mSv)	Person·mSv	Person·mSv	Person·mSv
Nuclear Facilities						
SF Staff (HCF and IFTF)[c]	6	0.10	0.20	0.58	1.35	0.71
WR1 and ALWTC Staff	4	0.05	0.09	0.20	0.20	0
WMA and CCSF Staff[c]	5	0.06	0.19	0.32	0.32	0
Support Workgroups						
Radiation Protection Staff [d]	42	0.31	2.40	13.20	26.03	29.32
Trades Staff [e]	47	0.26	2.97	12.29	26.09	19.27
All Remaining Staff						
Other Staff [f]	384	0.02	0.49	6.85	7.18	2.11
WL Site[g]	488	0.07	2.97	33.44	61.17	51.41

a Includes photon and neutron; there were no tritium committed effective doses for 2020.

b Average of all measured doses that includes the zero dose values, rounded to two decimal places. Includes employees and contractors.

c HCF = Hot Cell Facilities; IFTF = Immobilized Fuel Test Facility; ALWTC= Active Liquid Waste Treatment Center; WMA= Waste Management Area; CCSF= Concrete Canister Storage Facilities; WR1 = An experimental test reactor built at WL – WR-1 featured an organic liquid coolant.

d Radiation Protection staff include Radiation Surveyors, Radiation Protection Assistants, Contamination Monitors, and Decontamination Operators.

e Trades staff provide services for all listed facilities and decommissioning activities as well as the WL site in general.

f Other staff is comprised of all remaining staff and includes decommissioning, administrative, management, engineering, quality assurance, researchers, contractors and tenants.

g WL Site includes 348 CNL staff (WL and staff visiting from other CNL sites) and 140 contractors working at the WL site during 2020.

Table 14: WL External Whole-Body Dose Performance 2016 to 2020

Performance Metric	2020	2019	2018	2017	2016
Site Collective Worker Dose (p-mSv)	33.44	49.6	40.2	19.9	16.5
Max Individual Worker Dose (mSv)	2.97	3.09	1.65	1.41	0.36
Number of Workers > 0.2 mSv in a year	25	38	39	42	30
Number of Workers > 1 mSv in a year	8	14	12	1	0
PAD[a] – Maximum Daily Dose (mSv)	0.28	0.40	0.24	0.17	0.08
PAD – Maximum Dose Rate (mSv/h)	5.56	5.82	4.95	1.99	1.44

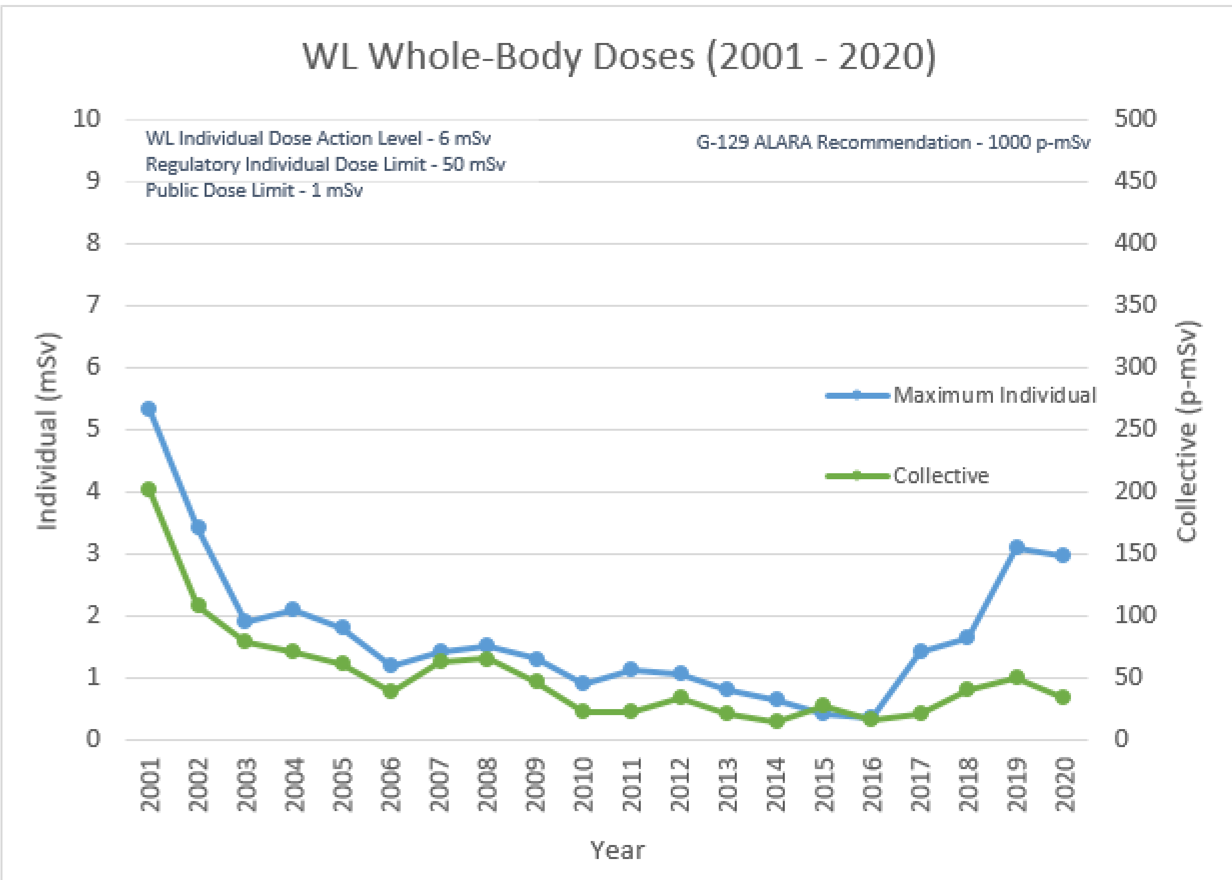

Figure 1: Whole-Body Effective Doses (2001 – 2020)

8 CONVENTIONAL HEALTH AND SAFETY

8.1 Conventional Health and Safety Program

WL adheres to the Corporate Conventional Health and Safety Program. See Section 8 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In support of reducing the number and impact of incidents with the potential for injuries or incidents at WL, the following initiatives are continuing or began in 2020:

- WL OSH specialists continued to work with the Health Centre on conducting the required audiology testing.
- OSH presence in the field continued at pre-job briefings, walk downs and daily work plan meetings together with early involvement in the planning process have contributed to WL’s internal safety success.
- Contractors continued to be “pre-qualified” prior to bidding on WL contracts. The pre-qualification process involves reviewing safety statistics and the safety programs of the potential bidders.
- WL continued to participate in the Rapid Learning Morning Call to quickly share safety information with all CNL sites, as well as gather safety information relevant for the WL site.
- Increased contractor oversight continued by participating in activities such as site visits, pre-job briefs, pre-bid meetings and OSH orientation for contractors.
- There were 19 internal Safety Advisories sent to WL site employees. The bulletins are intended to inform WL employees about imminent issues that could impact their safety. WL continued to be proactive in the approach to safety.
- Near Miss Reporting (a known industry best practice) continued with a focus on early hazard recognition and strong situational awareness culture, supporting the minimization or elimination of hazards prior to resulting in injury (see Table 15). Near Miss reporting at WL always includes an investigation/fact finding session. The majority of Near Miss reports also generate an ImpAct. Whether an ImpAct is generated or not, the possibility of a human error trap being involved in the Near Miss incident is always considered, evaluated and followed up as appropriate.
- OSH Program weekly review of company injury/illness reports in support of recognizing trends and disseminating lessons learned.
- Focus on disability management / return to work in support of minimizing the impact to an injured employee and subsequent days lost.
- See Section 2.1.1 for a discussion on the initiatives taken as a result of the 2020 November WL fieldwork pause.

Table 15: Summary of WL Near Miss Reporting

Year	2016	2017	2018	2019	2020
Near Miss Reported	79	60	53	46	10

Summary of changes to the OSH Program procedures/processes:

- A review / re-assessment of Personal Protective Equipment and Clothing (PPE&C), specifically head protection, at the Whiteshell site was completed. This resulted in revealing that the type, class and expiration of hard hats on site did not meet the requirements. A hard hat campaign was initiated to remove all expired hard hats in addition to obtaining the appropriate class and type for the work being carried out on site.

8.1.1 Site Safety and Health Committee

The Site Safety and Health Committee is the principal forum at WL for joint employee/ management consultation and development of solutions to safety and health concerns at the WL site. The WL Site Safety and Health Committee meets on a monthly basis.

In 2020, the WL Site Safety and Health Committee received 93 inquiries out of which 6 remained open and in progress. There was one inquiry carried over from 2019. The Site Safety and Health Committee acts as an oversight body, therefore these actions are largely related to the Site Safety and Health Committee's need for more information that provides them with assurance of the effectiveness of the actions of the functional safety groups on site.

8.1.2 Inspections

There were 50 site health and safety inspections completed in 2020.

8.1.3 HOIRs and Lost-Time Injuries

There was 1 lost time injury reported to Employment and Social Development in 2020 at WL. There were 3 hazardous occurrences (HOIRs) at WL that were reported to Employment and Social Development Canada in 2020. CNSC staff received copies of these notifications, as per the requirements of the CNSC REGDOC-3.1.2 [3].

The following is a Summary of injury rate data for the last 5 years.

Table 16: Summary of WL Injury Rate Data

	2016	2017	2018	2019	2020
WL Employees					
Person Hours Worked	684,450	706,000	688,000	642,000	584,030
Lost-Time Injuries	1	3	1	0	1
Working Days Lost	5	27	5	0	2
Frequency[a]	0.29	0.85	0.28	0	0.34
Severity[b]	1.46	7.76	1.45	0	0.68
WL Contractors[c]					
Lost Time Injuries	0	1	0	0	0
Working Days Lost	0	0[d]	0	0	0

a Frequency rate equals # of Lost-Time Injuries x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).

b Severity rate equals # of Working Days Lost x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).

c The Number of Person Hours worked are not divulged by Contractors, as such Frequency and Severity rates cannot be calculated.

d Number of days lost is unknown as the contractor terminated the employee.

No Assurance of Voluntary Compliance or Directions were issued by Employment and Social Development Canada in 2020.

9 ENVIRONMENTAL PROTECTION

9.1 Environmental Protection Program

WL adheres to the Corporate Environmental Protection (EnvP) Program. See Section 9 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

WL has an integrated Environmental Protection Program designed to track radiological and non-radiological contaminants throughout the different compartments of the geosphere, atmosphere, and biosphere, and consists of three distinct programs: the Effluent Verification Monitoring Program, the Environmental Monitoring Program, and the Groundwater Monitoring Program. The WL Environmental Protection Program is designed to implement the requirements of:

- CSA N288.4-10, *Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [19],
- CSA N288.5-11, *Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [20],
- CSA N288.6-12, *Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills* [21],
- CSA N288.7-15, *Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [22],
- CSA N288.8-17, *Establishing and Implementing Action Levels for Releases to the Environment from Nuclear Facilities* [23], and
- ISO 14001:2015, *Environmental Management Systems* [24].

The integrated Environmental Protection Program is dynamic in nature, meaning that it is continually evolving based on various sources of information received.

Program documentation is updated on an ongoing and/or required basis.

This report will focus and discuss the implementation of the WL Effluent Verification Monitoring Plan [25]. This plan defines the methodologies and protocols followed in performing the effluent verification monitoring required in CSA N288.5-11 [20].

The WL site has maintained its ISO 14001 [24] registration in 2020 with initial registration in 2010.

The CNSC has previously been notified of revisions to *Environmental Protection documents* [26], as per the *Licence Conditions Handbook.*

9.2 Quality Assurance

In order to ensure that the data collected through the program is valid, the laboratories performing monitoring for the program have strong Quality Assurance/ Quality Control (QA/QC) programs as required by CSA N288.5 [20]. General quality assurance objectives for CNL's Environmental Protection Program are set out in quality assurance plans. Radiological analysis is conducted in accordance with laboratory-specific environmental monitoring quality assurance plans. The plans include detailed working procedures for field operations, laboratory operations, laboratory administration, equipment performance, and quality verification of analytical results. The plans were written to align to ISO/IEC 17025 [27] for analytical laboratories.

Whiteshell Laboratories Environmental Management group conducts frequent internal checks of their technical capabilities as they perform their measurements. These are called Quality Verification Tests, and are grouped as follows according to purpose:

- *Reproducibility Tests*, such as measurement of sample replicates, establish the relative precision of the method(s). To be acceptable, replicate measurements must agree within limits established by long-term method performance.
- *Accuracy Tests*, such as blanks or samples, each spiked with known amounts of the analyte(s), establish the presence or absence of any biases due to sample matrix, sample preparation, or instrument function. To meet acceptance criteria, the spike quantity must be recovered within limits established by long-term method performance.

Environmental Management performed 2,470 quality verification tests during 2020 on WL's radiochemical counting equipment. Of these tests, 98.4% fully complied with acceptance criteria. The results of these tests are shown Table 17.

Table 17: Whiteshell Laboratories' Summary of Quality Verification Test Performed

Method	No. of Tests	No. of Failures	% Pass
Total Alpha (Instrumentation)	705	4	99.4
Total Beta (Instrumentation)	705	20	97.2
Gamma (Instrumentation)	396	2	99.5
Tritium	664	13	98.0
2020 Total	**2470**	**39**	**98.4**

In 2020, the WL Effluent verification program continued performing regular field Quality Verification testing on the Outfall, Lagoon, and Ditch effluent sampling (Table 18). The program is using traveling blanks to determine and account for any possible introduction of contamination into the sample being analyzed by the sampling methodology being employed by the program, and the program is also collecting duplicate samples to demonstrate sampling reproducibility.

In 2020, the WL Effluent verification program missed collecting a traveling blank for the Fall Discharge. In the event that abnormal effluent data was observed in the Lagoon samples, this traveling blank would be ruling out the possibility that the abnormal result was due to the process of transporting the samples, or due to other factors in the sampling environment besides the effluent. With no abnormal effluent data being generated from the lagoon, the impact of missing this sample is minimal, but the environmental program understands the importance of the sample and remains committed to collecting it in the future.

Table 18: Whiteshell Laboratories' Summary of Field Quality Verification Tests Performed

Method	Traveling Blanks		Duplicates

LMDL = Laboratory Method Detection Limit

Out of the 164 quality verification tests, 154 of these tests meet the acceptance criteria of the program, to yield a 95% pass rate. Reviewing the travelling blank data, and comparing it to the field results, the environmental program has concluded that the source being used for the travel blank water is slightly contaminated with Copper, Lead, Chloroform, and Bromodichloromethane. The traveling blank results for these parameters are not reflective of contamination being picked up while sampling.

In 2020, the WL Environmental Management group took part in four inter-laboratory comparison studies. Two of these studies, which focused on radiological analyses, were offered through the Environmental Research Associates. The other two studies which focused on non-radiological analyses were offered through the Canadian Association for Laboratory Accreditation. The results of the WL Environmental Monitoring laboratory performance are shown in Table 19 and Table 20. There were four unacceptable test results out of thirty for the Environmental Research Associates inter-laboratory comparison studies, resulting in an 87% pass rate. The four unacceptable test results related to the analysis of a single sample, and the error resulted from the analyst processing and reporting on the wrong sample.

For the Proficiency Testing Canada inter-laboratory comparison studies, a 100% pass rate was achieved.

Table 19: Environmental Research Association Inter-Laboratory Comparison Program for CNL WL - 2020

MRAD* Study	Matrix	Analyte	Units	MRAD Assigned Value	WL Reported Value	Acceptance Limits	Performance Evaluation
MRAD-32	Air Filter Radionuclides	Americium-241	(pCi/Filter)	74.7	33.87	53.3 - 99.6	Not Acceptable

9.3 Supplementary Studies

In 2020, the WL site began to do temporary enhanced monitoring on the effluent verification ditches for the year. The enhanced monitoring is being done to confirm the absence of a number of radiological and non-radiological parameters. The enhanced monitoring involved doing an open scan for Volatile Organic Carbons, semi-volatile organic carbons, and an expansion of the metals and gamma isotopes list currently being used to monitor the ditches.

Whiteshell is reviewing the data, and is deciding whether there is a need to add any of these parameters to the effluent verification monitoring program going forward.

9.4 Effluent Monitoring - Radiological

This section addresses the licence requirement regarding radiological monitoring of airborne and liquid effluents for the WL site, located on the Winnipeg River near Pinawa, Manitoba. It also addresses the effluent monitoring requirements listed under the Environmental Assessment Follow-Up Program [28] for WL.

Results of environmental monitoring and progress on the Environmental Assessment Follow-Up Program work packages will be provided in their respective annual reports, *Environmental Monitoring in 2020 at Whiteshell Laboratories* [29] and *2020 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28].

9.4.1 Effluent Monitoring

9.4.1.1 Site Effluent Verification Monitoring System and Results Evaluation

Monitoring locations for airborne and liquid effluent streams are representative of the final discharge to the off-site environment, and may include the combined discharge from a number of facilities. Additional monitoring points are maintained at upstream locations as an aid in identifying the specific sources of emissions. Sampling system design ensures that samples are representative of the total content of the stream at each location.

Figure 2 includes a map of the effluent monitoring locations/effluent streams at WL.

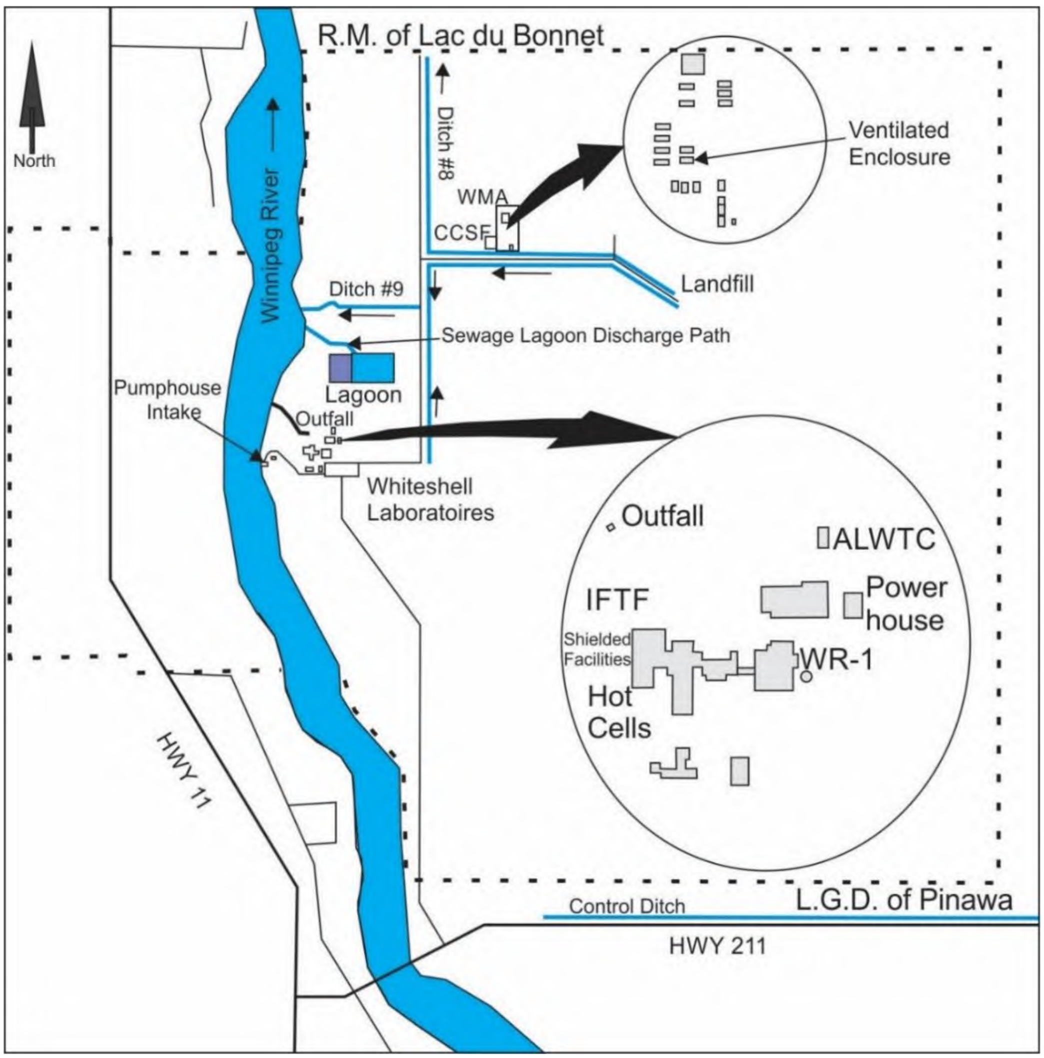

Figure 2: Effluent Monitoring Locations

Effluent streams are monitored for all groups of radionuclides that are likely to be present and significant contributors to the total, expressed as a percentage of applicable DRLs [30]. The DRLs now in use at WL came into effect on 2016 September 01. All current and historical data in this report has been compared against these DRLs. Monitoring is conducted either by direct measurement on location or by sampling and laboratory analysis. In many cases, gross-measurement parameters (e.g., gross beta) are monitored and reported rather than specific radionuclides. This is done provided that either the relative composition of radionuclides indicated by the gross parameter is not likely to vary significantly, or total emissions of the gross parameter are very small relative to the DRLs. For comparison with DRLs, the gross parameters are always evaluated conservatively. They are either assumed to consist solely of the most restrictive radionuclide, based on DRL value that is likely to be present in measurable quantities, or are assumed to be the radionuclide(s) known to be present in the effluent. To ensure proper selection of the DRL values, the effluents are periodically characterized using, for example, gamma spectrometry to identify individual gamma emitters, or chemical extraction and analysis of individual beta emitting radionuclides, such as Strontium (Sr)-90, complemented by examination of historical data.

The significance of the measured radioactive materials in airborne and liquid effluents is assessed by comparison with DRLs that relate the releases to the potential radiation dose to the identified, most exposed groups (i.e., critical groups). DRLs are the upper limits for releases of radionuclides in airborne or liquid effluents from a facility or site. WL's DRLs were calculated in accordance with the principles and methodology in the CSA CAN/CSA-N.288.1-M87 [31]. The DRLs have been revised to meet the current CAN/CSA N288.1-08 [32], and these were accepted by the CNSC in 2016 August. The DRL for a particular radionuclide is derived from the regulatory dose limit for members of the public, 1 mSv in a year, as specified in the Radiation Protection Regulations under the Nuclear Safety and Control Act [33]. The intention of the DRL is to establish a release limit such that compliance with it will give reasonable assurance that the annual regulatory dose limit for members of the public is not exceeded. Weekly DRLs are calculated and applied for airborne effluents, and monthly DRLs for liquid effluents.

For multiple effluents and radionuclides at a site, verifying that the sum of all releases as a percentage of the respective DRLs is less than 100% provides a reasonable assurance[5] that the annual dose limits have not been exceeded. This is a conservative approach since the critical group may differ for different release paths and radionuclides. The actual releases are a very small fraction of the DRL as discussed in the following sections and shown in Figure 3. As discussed in Section 9.4.1.3.2, the increase in 2019 and 2020 liquid effluents is due to the higher detection limit values for Am-241 and Plutonium (Pu)-239/240.

[5] The effluent DRL model and assumptions are further verified annually through results from the WL environmental monitoring program. The program assesses radiation doses to members of the public using direct measurements of radioactivity in the environment (e.g., in air, water, and food).

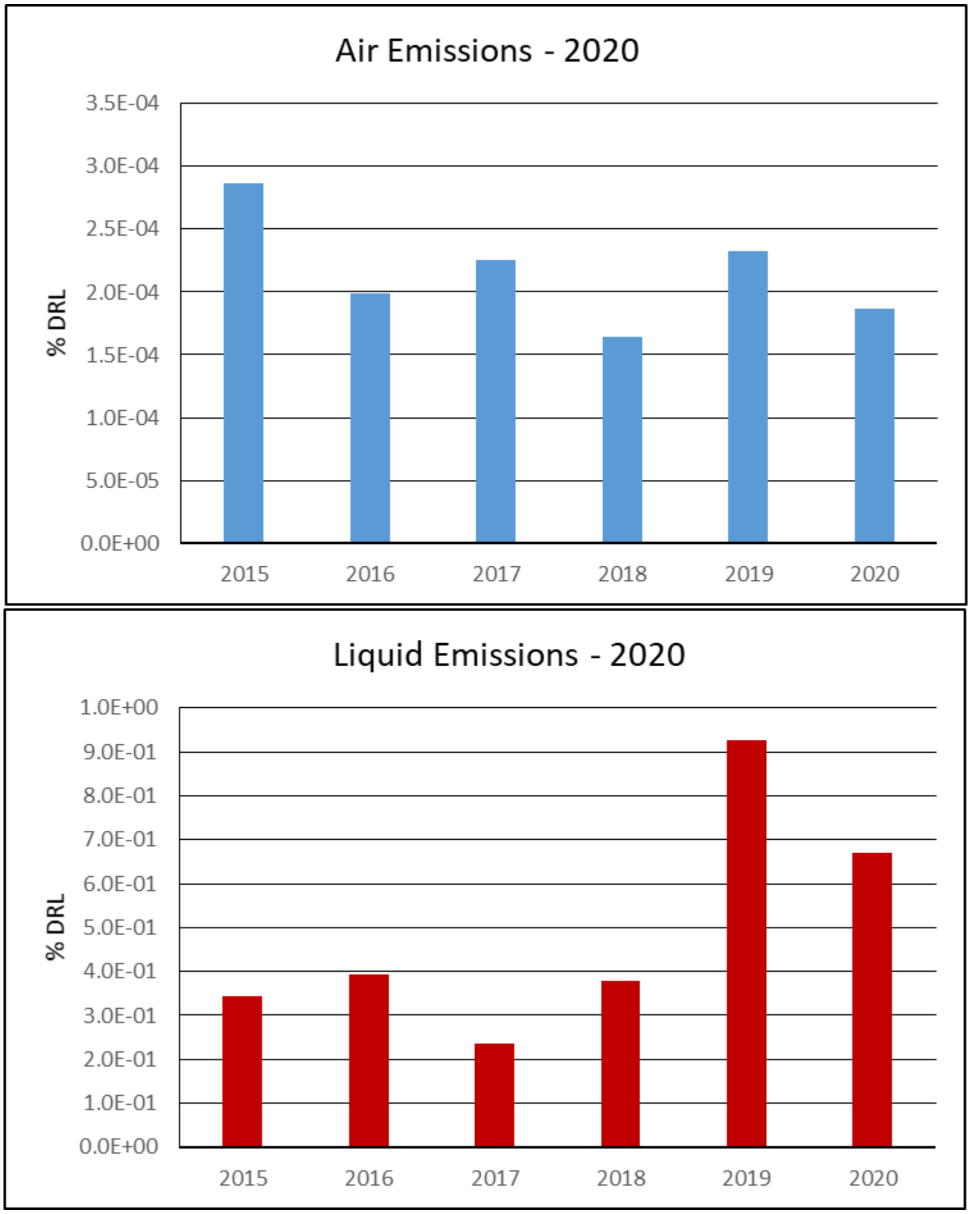

Figure 3: Trends for Airborne and Liquid Emissions form WL for 2015 to 2020

(Note: The Liquid Emissions for 2020 need to be corrected to include the actual 4 quarter Pu isotope data expected in the beginning of March.)

Analytical models of all significant environmental pathways to an individual in the critical group are used in the DRL calculations. DRLs for WL have been calculated for a large number of radionuclides, many of which are currently not detected in site effluents. Derived Release Limit calculations (of a wide range of radionuclides) provide a means of determining which radionuclides may be significant dose contributors. Thus, they aid in determining which nuclides warrant inclusion in the monitoring program, and in interpreting monitoring results.

Performance is also measured against the regulatory Action Levels[6] derived from the DRLs as specified in Reference [30]. The Action levels were recalculated based on current CNSC guidance and to better reflect current waste streams, and were released for use based on an implementation date of 2017 January 01.

9.4.1.2 Airborne Effluents Monitoring

9.4.1.2.1 Monitoring Points, Schedules and Parameters

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. These activities include waste compaction in the Waste Handling Area, located in the Immobilized Fuel Testing Facility (IFTF), and decommissioning activities in the ALWTC. The main sources of airborne radioactive effluents, as a result of this work and historical activities at WL, are the:

- Hot Cells Facility (Building 300)
- Immobilized Fuel Test Facility (Building 300)
- Reactor Building (Building 100)
- Active Liquid Waste Treatment Centre (ALWTC) (Building 200)

Air effluents from Buildings 100, 200 and 300 are sampled continuously throughout the year. The frequency and type of monitoring will continue to be evaluated over time, and adjusted to reflect findings from the monitoring activities. The current monitoring schedule and locations are noted in Table 21. Cessation of a monitoring activity will occur once it can be shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant by regulatory requirements or community concerns. Any proposals on modifications to the monitoring program will be communicated to CNSC staff. In 2020, Building 200 (ALWTC) was prepared for demolition and the ventilation system was shut down in 2020 October. Monitoring of stack effluents for Building 200 ceased after October 13. The reported air emissions in 2020 for this building represent average weekly emissions up to this point in time.

[6] Action Level – In the context of CNL's Environmental Protection Program, an "Action Level" for radioactive emissions is a release rate of radioactive emissions that, if reached, may represent a loss of control of performance for a facility's environmental protection program or emission control system. Releases above Action Levels must be investigated and reported to CNSC staff. Action Levels for WL radioactive effluents are lower than the DRLs.

Table 21: Radiological Air Effluent Monitoring Schedule – 2020

Cont The air effluent is measured but passing a continuous sample of the exhaust through a filter. The GFA filter is normally used for beta-gamma, the Millipore normally for alpha, charcoal or silver zeolite for radioiodine, and a water Bubbler for tritium.

W Weekly

N/A Not Applicable

The air to be monitored from the buildings and facilities is drawn past sample probes located in the exhaust vents, pumped through filters and then returned to the exhausts. The WL maintenance planning team performs the measurements for the stack flows and the RP team measures the Sampler flow. The sampler flows at WL are checked during each sample collection period to ensure that they are within the established acceptance criteria, and are re-measured and verified on an annual basis. The release factors are calculated by the WL Environmental Management staff and verified independently on an annual basis. Activities measured in the laboratory are used in conjunction with sampler and exhaust stack flow rates to calculate the release in Becquerels (Bq). The Lower Limit of Detection (LLD) is the product of the release factor of the source and the laboratory Minimum Detectable Activity. For a given radionuclide, the Minimum Detectable Activity and LLD can vary, as they are calculated assuming a 30-minute count time and average detector efficiency, both of which can change.

Derived Release Limits have been calculated for 74 radionuclides for airborne effluents at WL [30]. Separate DRLs have been calculated for on-site workers and for members of the public at the site boundary. For gross alpha and gross beta activities, the DRL applied is the most restrictive from amongst those of the radionuclides that could be present (Sr-90 for gross beta and Pu-239 and Pu-240 for gross alpha).

Sampling procedures, field operating procedures, laboratory procedures, equipment performance checks, quality verification procedures, and laboratory administrative procedures are described in detail in the governing WL Environmental Management documentation.

9.4.1.2.2 Monitoring Results

The airborne emission results are summarized in Table 22 and Figure 3 for the years 2015 to 2020. Average weekly emissions, in Becquerels, are shown for gross alpha, and gross beta for facilities in Buildings 100, 200, and 300. Emissions from Building 100 also includes tritium. In addition, the current year releases, the average release for the past five years and the maximum weekly emissions as a percent of the DRL are given. Emissions from these identified release points are added for each year to provide an indicator of the performance of the site. Airborne emissions remain a small fraction of the release limit. The result for 2020 (0.00019% of the DRL) is less than for 2019, and for the average for the last five years. Total site gross alpha in 2020 is slightly higher than in 2019 and the last five years average. It remains near detection limit values. The gross beta emissions are less than in 2019 and similar to the last five-year average. In 2020, the air emissions from all facilities were below Administrative Levels and regulatory Action Levels.

Tritium emissions from the WR-1 stack were less than 2019 and the five year average. During the Phase 1 Decommissioning of WR-1, all bulk heavy water was removed from WR-1, and an exhaustive process of eliminating heavy water and tritium from the reactor piping and tanks occurred. It was concluded that over the lifetime of WR-1, tritiated heavy water was adsorbed into the pipe and tank walls and probably also into concrete walls and floors. Therefore, the moderator system continues to be purged with air flow in order to remove additional tritium from the system and the tritium removal rates have been measured. The tritium emissions from the facility fluctuate with the humidity and temperature as the tritiated water is drawn out of the system. The maximum releases were all below the administrative level (1.52E+10 Bq/week) for the facility and well below the Action Level (7.62E+10 Bq/week) and DRL (1.65E+15 Bq/week). As many gross alpha and gross beta measurements are at or below the LLD, the yearly variations within these extremely small numbers are of very little consequence. Localized operational workplace air monitoring is conducted as part of the Radiation Protection Program, and this was performed during operational shutdown and decontamination activities associated with Buildings 100 and 200, and work in the Shielded Facilities and Concrete Canister Storage Facility. Environmental airborne dust monitoring was performed close to the east, north, west and south boundaries of the WL campus during building demolitions. This monitoring demonstrated that in 2020 no significant airborne radioactivity was released off site from building demolitions. The results of this monitoring are described in the *2020 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28].

9.4.1.3 Liquid Effluent Monitoring

9.4.1.3.1 Monitoring Points, Schedules and Parameters

Figure 2 shows the locations of the sources of liquid effluents to the Winnipeg River, including the Outfall, the Lagoon and the numbered ditches.

The primary source of liquid radioactive effluents is the process water outflow (Outfall), which discharges continuously to the Winnipeg River. The discharge from the Outfall is composed of storm water runoff from paved roadways, around buildings through the weeping tile system, cooling water used in process and experimental facilities, and holding tank discharges including those from the new active liquid waste treatment system tanks based in Building 100 and Building 300. The ALWTC was taken out of service in 2017 as part of preparations for the decommissioning of Building 200. Holding tanks collect water containing low levels of radioactivity, as a result of cleanup activities associated with operational and decommissioning work, as well as historical activities at WL. The current monitoring schedule and locations are listed in Table 23.

a Screening sample only.

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. Specific activities that may have influenced the 2020 liquid releases are similar to those for the past five years, and include cleaning of footwear and respirators. Radiation Protection introduced the use of disposable rubber shoe covers, which reduced the contribution from the washing of footwear in 2018. The water from these cleaning activities is combined with Building 300 sump water into the Building 300 receiver tanks. Sump water from Building 100 is now directed to the Building 100 receiver tanks. The liquids from these holding tanks are discharged to the Winnipeg River through the Outfall.

An automatic sampler continuously samples the outflow from the Outfall, proportional to its rate of flow. A weekly screening sample (4 L), representative of effluent released from the Outfall during the preceding week, is collected and submitted for uranium and gross beta analysis and scanned by gamma spectrometry.

Monthly composite samples (at least 40 L) are gathered for analysis of total uranium, gross alpha, gross beta, tritium, radio strontium and other radionuclides (Am-241, Cs-137) by gamma spectrometry. Starting in 2017, 3 month composite samples were collected for Pu-239/240, Pu-238 and Pu-241 isotopic analyses. In 2020, Outfall samples were analyzed for Carbon (C)-14 and tritium because they are known to exist in WR-1 and decommissioning activities have a potential for releasing these isotopes. The activities of tritium and C-14 at the Outfall continued to be below the lower limits of detection.

The secondary source of liquid effluent is the Sewage Lagoon (Lagoon). The Lagoon collects sanitary and wastewater from most buildings on the site, as well as from the laundry facility. Lagoon water residence time is more than three months, to allow for biodegradation and settling. Prior to each planned discharge, the secondary cell is isolated, and tested for a series of non-radiological parameters (discussed in detail later). If these are acceptable, the accumulated contents of the secondary cell only are released to the Winnipeg River via a small drainage ditch leaving the Lagoon's north side. In 2020, the lagoon was only discharged in the fall because there was enough freeboard that a spring discharge was not necessary.

The outflow of the Lagoon is continuously sampled during discharge. The resulting composite sample is analyzed for gross alpha, gross beta, and radio strontium, and it is also scanned by gamma spectrometry.

Small quantities of radionuclides at levels seen at the control point are also released to the Winnipeg River from the two ditches indicated in Figure 2. Water from the recharge area east of the WMA is diverted around the WMA to the west-flowing Ditch 9 and into the Winnipeg River. The other, Ditch 8, running northward, drains the land north of the WMA up to the site boundary and beyond. The volume of water in the ditches and resulting flow to the river is entirely dependent on rainfall and spring runoff. Precipitation (441 mm) in 2020 was less than in 2019 (646 mm), and in 2018 (467 mm). The winter, spring and fall of 2020 were relatively dry. The highest precipitation was received in June, July and August. Ditches were sampled 15 times during April to the beginning of October, with 1 to 3 sampling sessions per month.

One-litre water samples to be analyzed for radioactivity are collected from the two ditches carrying drainage from the WMA whenever there is sufficient flow from runoff to enable sampling of discharge to the river. At the same time, samples were also collected from the northern ditch bordering Highway 211. This is far enough from CNL's operation to be a reasonable background (Control) sample[7]. The samples are analyzed for gross alpha, gross beta and tritium. If the level of the gross beta measurement exceeds 10 Bq/L, the samples are

7 The Control Ditch sample is collected from a location not influenced by CNL's operation, and therefore serves as an indicator of the natural background conditions in the area.

submitted for gamma spectrometric and radio strontium analysis. If the alpha activity is above 0.5 Bq/L, the samples are submitted for gamma spectrometric and uranium analysis. Surface water samples are collected in and around the WL WMA from locations upstream from these two ditches. The results of these operational control samples are reported in Appendix D of this report.

Derived Release Limits for 63 radionuclides were calculated for liquid effluents at WL [30]. Gross alpha and gross beta measurements provide a quick measurement of the total alpha and beta radioactivity produced by a number of radionuclides, without having to test for those radionuclides. However, as in the case of airborne effluents, the most restrictive DRLs apply to gross beta and gross alpha activity: Cs-137 for beta activity and Pu-239 and Pu-240 for alpha activity. With the introduction of total uranium (U) and isotopic plutonium analysis for the processed outfall, a comparison can be made to the individual contributors to the gross alpha activity. Therefore the comparison to the %DRL of the individual isotopes is presented and the sum of those reported. This is also the case for gross beta.

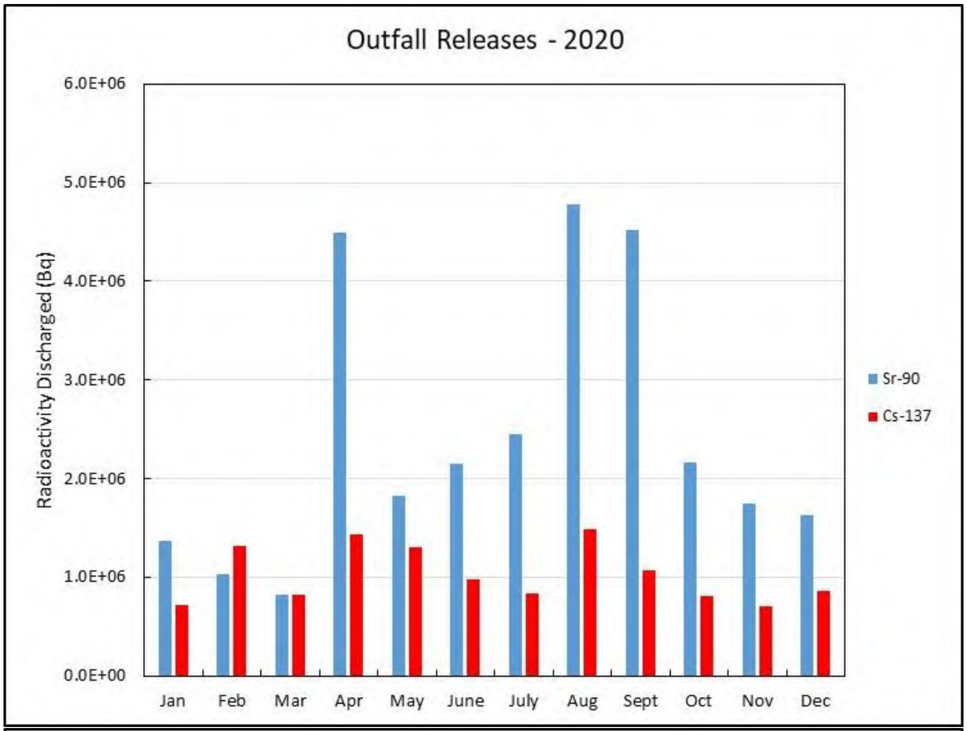
9.4.1.3.2 Monitoring Results

The liquid emission results are summarized in Table 25 and Figure 3 for the years 2015 to 2020. Average monthly emissions, in Becquerel's, are shown for gross alpha, gross beta, total U (including U-234, U-235, and U-238), Am-241, Sr-90 and Cs-137 for the releases from the Outfall and the Lagoon. In addition, quarterly activities of Pu-239/240 and Pu-238 were reported for Outfall effluents. A plot of the monthly Cs-137 and Sr 90 releases as Bq from the Outfall in 2020 is compared with radioactivity (Bq) discharged to the Outfall from the Low Level Liquid Waste (LLLW) treatment systems in Figure 4. Discharges to the Outfall from the LLLW treatment tanks occurred in all months. The total releases of Sr-90 and Cs-137 from the tanks in 2020 were 2.23E+06 Bq and 4.55E+06 Bq, respectively. These releases were only a fraction of the total Sr-90 (2.90E+07 Bq) and Cs-137 (1.23E+07 Bq) releases from the Outfall. There was little correlation between the patterns of releases from the tanks with the pattern of releases from the Outfall because the tank releases were only a small fraction of the total releases. The additional Sr-90 and Cs-137 activities noted at the Outfall may be from pre-existing contamination in the storm drain system from historical site contamination events and historical radioactivity disposition in the storm drain line from Building 200 LLLW discharges. Some of this contamination may have been from unplanned emissions from the Hot Cells in the 1970's, although more likely from the Building 200 drain line. Sr-90 and Cs-137 releases from the Outfall were highest in April and August-September. The April peak correlates with spring snow melt, while a high rain event toward the end of August likely triggered the August-September peak. Periods of high precipitation are believed to flush contamination into the Outfall from storm drains and previously contaminated process piping.

At the end of 2020, the results of weekly Outfall screening tests indicated the release of higher than normal Cs-137 activities in November that came within half an administrative level. There was a close correlation in time with Building 200 (ALWTC) demolition activities. Although these results were not yet corroborated by the more accurate results of ash analyses, CNL chose to notify the CNSC and to disclose to the public. Subsequently, monthly composite results from ash analyses showed that November Cs-137 activities were not higher than usual. An investigation into the discrepancy between the two analyses revealed that a routine step in the analytical process for the weekly screening samples was not performed properly, resulting in an incorrect result. Specifically, the Cs-137 peak from the background was not being accounted for in the gamma spectrum for the sample, producing erroneously high Cs-137 results.

Note, all monthly releases from the Outfall were well below the administrative release level[8]. Releases of gross alpha were slightly less than the 2019 releases, and higher than the five year average. Gross beta releases in 2020 were similar to the 2019 releases and higher than the five year average. Sr-90 releases in 2020 were lower than in 2019 and the five year average. The Cs-137 releases were slightly below 2019 releases and the five year averages. Am-241 and total uranium releases were lower than 2019 releases. The relatively constant emissions of gross alpha, gross beta, Sr-90 and Cs-137 from the Outfall over the years suggest a constant source, more like contaminated piping than the effects of recent decommissioning activities. Pu-239/240 and Pu-238 releases were very low, being based on detection level concentrations (% of the DRL less than 0.21). In 2020, Outfall water was also analyzed for the presence of C-14, which could be introduced by the discharge tanks from Building 100. C-14 was below detection levels (varying from 0.86 to 1.26 Bq/L) in Outfall samples. Given that the DRL for C-14 is 1.06E+08 Bq/month, the detection limit of 1.65 Bq/L would correspond to a %DRL value of 0.23. Measurements of C-14 in site intake water from Building 902 were also below detection values.

[8] An Administrative Level is a CNL internal reporting level for radioactive emissions by way of an individual effluent stream. The Administrative Levels are established and maintained by CNL to provide timely warning of above normal radioactive emissions, with the intent of aiding in the application of the ALARA process.



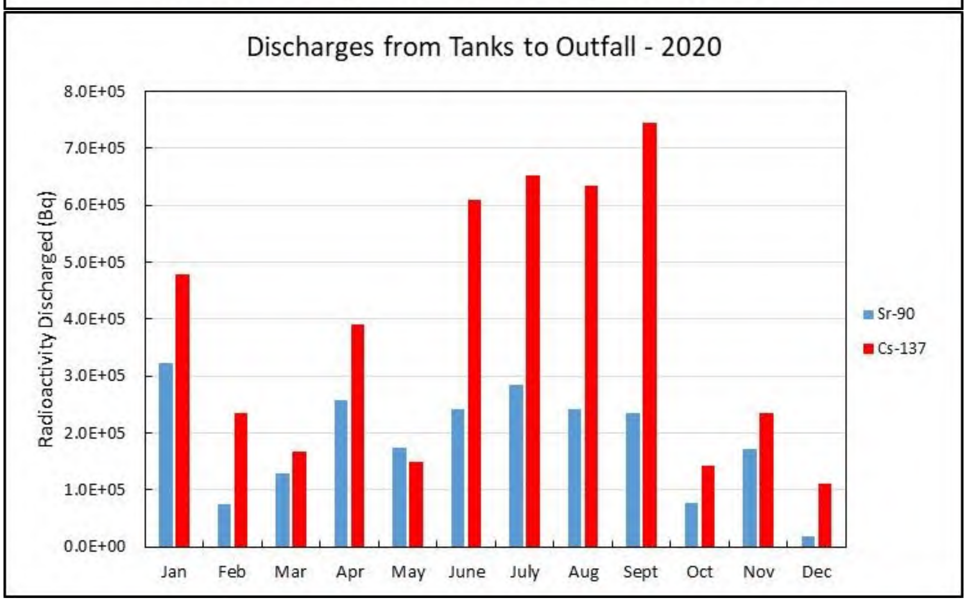


Figure 4: Radioactivity on Outfall Releases and Discharge from Active Liquid Waste Treatment Tanks for 2020

The 2020 Lagoon discharge occurred only in the fall because there was enough freeboard that a spring discharge was not necessary. The Lagoon gross alpha releases were higher than 2019 values and the five year average (Table 25). Activities of total uranium (natural) and Am-241 were lower than in 2019, while plutonium-239/240 determined for lagoon samples was higher than in 2019. In 2020, the uranium activity accounted for about 8 percent of the gross alpha activity. Based on the reported activities, the remaining gross alpha activity could be accounted for by the activity of Am-241 and Pu-239/240. It should be noted that the activities of these latter two elements are at detection limit values. Therefore, the actual releases of Am-241 and Pu- 239/240 are less than reported here. The % DRL values of total uranium, Am-241 and Pu-239/240 (which are reported instead of gross alpha) were very low (0.001, 0.051 and 0.087 % DRL, respectively). The gross beta and Sr-90 discharges were higher than in 2019, while the Cs-137 discharges were lower. Releases of Sr 90 and Cs-137 were below 0.002% and 0.005% of their respective DRLs. All releases were well below administrative release levels.

The averaged results for the two drainage ditches and control sample are shown in Table 24.

a Compliance with Guidelines for Canadian Drinking Water [34] may be inferred if the measurement for the gross alpha and gross beta are less than 0.5 Bq/L and 1.0 Bq/L, respectively. LLD is based on a 1 L sample resulting in less than 100 mg of sample ash and counted for 100 minutes.

b LLD = Lower Limit of Detection.

c Uncertainties are expressed as the standard deviation of the average activity of the processed samples.

During 2020, the gross beta activities in Ditches 8 and 9 were lower than in 2019. The 2020 gross alpha activities were lower in Ditch 8 and in Ditch 9 compared to 2019. The gross beta values were similar to the control sample collected off of Highway 211. Given the variability in their values, the gross alpha values were similar to the control ditch. The control sample is unaffected by CNL's operations. Compliance with the *Guidelines for Canadian Drinking Water Quality* [34] may be inferred for gross beta activity since the measurements are all less than 1.0 Bq/L. The gross alpha activity was below the drinking water screening level of 0.5 Bq/L for all samples. The local well waters within the Canadian Shield contain naturally occurring uranium [35] at levels ranging from 0.04 Bq/L to in excess of 2.5 Bq/L. Vertical flow occurs in the surficial Clay unit and in the intermediate Clay Till unit. The head gradient is upward leading the water in these layers to discharge to the surface. Naturally occurring uranium and its progeny are contributors to the total alpha activity, and could account for levels seen in some of the ditch water samples. In addition, naturally occurring alpha emitters may be present in suspended sediment in some of the samples.

The alpha and beta results remained below the trigger levels for gamma spectrometry, Sr-90 and uranium analysis mentioned in Section 9.4.1.3.1. As discussed in Appendix D of this report, the WMA contains a number of trenches with varying amounts of low-level radioactive and conventional waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. The amount measured in drainage Ditch 8 (4.3±0.5 Bq/L) and Ditch 9 (6.5±6.5 Bq/L) were not significantly different from that noted at the control location (4.7±0.9 Bq/L). A number of ditches close to WMA are known to contain tritium. In 2020, the amount of tritium reaching the Ditch 8 and 9 locations was not significant. The tritium activities measured at all three ditch locations are much lower than the Guidelines for Canadian Drinking Water Maximum Acceptable Concentration for tritium (7000 Bq/L) [34].

Table 25 summarizes the data for releases of liquid effluents[9] for the years 2015 to 2020. The average monthly releases, expressed as a percent of the DRLs, are added for the various sources on site to provide a quantitative indicator of the performance of the site. The average total release for 2020 was 0.67% of the DRL, which is lower than 2019 and higher than the five-year average (0.45%). The main reason for the higher 2019 and 2020 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. The highest monthly release from the Outfall in 2020 was Pu-239/240 at 0.27 % of the DRL. The primary contributors for Lagoon emissions were Pu-239/240 and Am-241, averaging 0.087% and 0.050% of the DRL, respectively. Both of these contributors had activities at detection level values.

9.4.2 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is determined for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results as a result of equipment failure, maintenance/calibration outages, or operator action requires “unavailability” to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 26) for monitoring equipment on effluent streams with effluent rates that are normally ≥ 0.5% of weekly DRLs are set more stringent (for unplanned unavailability) than for those streams with normal effluent rates < 0.5% of weekly DRLs. Unavailability is expressed in hours of unmonitored effluent releases per year, and applies separately to each monitored parameter, on each effluent stream.

---

9 The radioactivity from Ditches 8 and 9 was found to be below the Canadian Drinking Water Screening Level [34] for both gross beta and gross alpha activity, within the uncertainty of the analysis. Tritium levels were well below the Canadian Drinking Water Maximum Acceptable Level. The contributions were considered insignificant due to the small volume of release, and are not included in the liquid release table.

a In 2018 monitoring for Outfall began for U-total, Pu-239/240 and Pu-238. In the Lagoon Pu-239/240 was calculated from gross alpha mass balance. The %DRL is reported for these isotopes instead of gross alpha. Note that Pu isotope activities are detection level values and Am-241 activities are very close to detection levels.

b Gross beta releases are not included in the %DRL totals as the regulated components of the gross beta (Cs-137 and Sr-90) are already accounted.

Table 26: Effluents Monitoring Equipment Unavailability – 2020

	Unavailability Criteria[a]		Number of Exceedances
Air effluent streams with normal emission rate ≥ 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	84 hours/year/stream	0
Air effluent streams with normal emission rate < 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0
Continuously monitored liquid effluent streams.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0

a See Table 7 in 900-509200-STD-009.

Unavailability criteria (see Table 26) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2020, there were no instances in which the unavailability criteria (Table 26) outlined above were exceeded. There were 2 instances of unplanned air monitoring unavailability for tritium in the Building 100 effluent stream, due to air leaks. The total amount of unplanned loss of air monitoring was 111 hours. There were 2 instances of planned unavailability to Outfall monitoring that were due to required electrical power supply shut down. This amounted to a total of 5 planned hours of monitoring unavailability for liquids. One instance of unplanned Outfall monitoring, amounting to 4 hours, occurred when the supply of process water from Building 100 was accidentally cut off. In each instance an estimate of the release during unavailability was calculated as per procedure.

9.4.3 Overall Performance

Figure 3 summarizes the data presented in Table 22 and Table 25 on site-wide airborne and liquid emissions, expressed as totals of percentages of DRLs (the lower rows of the tables) for the years 2015 to 2020. The average emissions for the past six years continue to be very small. Liquid emissions of radioactive material from WL in 2020 were below CNL's Administrative Levels and Action Levels, and continue to be very small compared with the applicable DRLs [30]. All air emissions were below CNL's Administrative Levels and Action Levels.

Total radioactive airborne emissions from the WL site during 2020 continue to be very low, averaging 0.00019% of the DRL, which is lower than in 2019.

Radioactivity in the WL liquid releases for 2020 was 0.67% of the DRL which is lower than in 2019 (0.93%) and higher than last five-year average (0.45%). The main reason for the higher 2019 and 2020 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. Pu-239/240, at detection limit values, was the primary contributor to the Outfall, averaging 0.21% of the DRL. The primary contributors for Lagoon emissions were Pu-239/240 and Am-241, averaging 0.0.087% and 0.050% of the DRL, respectively. Both of these contributors had activities at detection level values. The level of tritium activity noted in the two ditches carrying drainage from the WMA remains well below the Maximum Acceptable Concentration for Drinking Water.

The 2020 release results as well as the previous years' trends indicate that CNL has taken reasonable precautions to control the release of radioactive nuclear substances within the site, and into the environment, as a result of the licensed activity. All airborne and liquid release results are consistent with the clean-up and operational activities associated with decommissioning of the site.

The results of the monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment.

9.5 Effluent Monitoring – Non-Radiological

This section addresses the licence requirement on hazardous substances monitoring of liquid and airborne effluents for the WL site for 2020. It also fulfills similar effluent monitoring requirements listed under Work Package 1 of the *Environmental Assessment Follow-Up Program* [28].

9.5.1 Liquid Effluent Monitoring

9.5.1.1 Monitoring Points, Schedule, and Parameters

Whiteshell Laboratories staff members collect samples for non-radiological parameters from eight different monitoring points. The first four are the Sewage Lagoon (referred to as the Lagoon) at point of discharge to the Lagoon drainage ditch, the Process Outfall (referred to as the Outfall), the North drainage ditch (referred to as Ditch 8), and the West drainage ditch (referred to as Ditch 9). These effluents flow directly to the Winnipeg River. Two monitoring locations measure internal process wastes leaving the Low-Level Liquid Waste Treatment Systems (LLLWTS) from Building 300 and Building 100. The remaining two monitoring locations are used as background monitoring locations, and are the Intake water taken from the Winnipeg River at the Pump House (Building 902), and a control ditch on provincial Highway 211. More details for each monitoring area are provided in the sections to follow.

Referring to Section 9.4 of this report, Figure 2 shows the locations of the waste stream sources monitored, and where appropriate, their source or release points to the Winnipeg River. Ditch 8 meets the river some distance downstream (north) of the site boundary.

Table 27 lists the non-radiological parameters monitored at the inlet or effluent streams sampled, and the sampling schedule followed. The WL monitoring program follows the protocols from the Ontario Ministry of Environment [36] in its Municipal/Industrial Strategy for Abatement program. Under that system, parameters that are normally measured by the same analytical technique are grouped into numbered Analytical Test Groups (ATGs). These are described in Table 28, which includes information about the Regulatory Method Detection Limit (RMDL), Laboratory Method Detection Limit (LMDL) and the Smallest Reporting Increment (SRI). The LMDL and SRI were decided following protocol. The WL monitoring program also meets the regulations set out in the Federal Wastewater Systems Effluent Regulations [37], and the standards from CSA N288.4-10, *Environmental Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* [19].

Table 27: Schedule for Non-Radiological Monitoring at WL

17	Toluene	Monthly	-	Discharge	-	-	-
25	Oil & Grease	Monthly	Discharge	Discharge	Discharge	Discharge	Discharge

a ATG = Analytical Test Group; BOD = Biochemical Oxygen Demand; CBOD = Carbonaceous Biochemical Oxygen Demand; TSS = Total Suspended Solids.

b The Monthly = grab sample taken once within each month.

c Quarterly testing began with the third Quarter in the 2020 calendar year.

Intake water was sampled each month as grab-samples are drawn from the wet well of the Pump House (Building 902).

Discharging the Lagoon in 2020 required 15 days between October 14 and October 29 in the fall, and there was no discharging of the Lagoon in the spring. Prior to the fall discharge, grab samples of the lagoon effluent were collected for Carbonaceous Biochemical Oxygen Demand (CBOD), acute lethality test[10], and coliform[11] measurements. Remaining lagoon parameters were analyzed in samples that were collected daily and weekly during flow periods.

At the Outfall, daily monitoring and weekly samples are collected for non-radiological parameters.

The ditches are sampled only when water is flowing freely within them, and at a maximum frequency of once per week. This occurs after snowmelt or significant rainfall, of which there were fifteen events in 2020.

Whenever a tank was discharged at either of the LLLWTS's, the effluent was sampled.

9.5.1.2 Analytical Protocol and Results Evaluation

With minor modification, the protocols for sample collection, and result reporting used here, are adopted from the Ontario Ministry of Environment publication *Protocol for the Sampling and Analysis of Industrial/Municipal Wastewate*r [36]. The protocols are used under Ontario's industry-specific effluent monitoring and limits regulations. The system supplies a justifiable set of methods to ensure that the final reported result is representative of the effluent sampled. Guidance is given on sampling of wastewater streams, sample handling including pre-treatment, and acceptable analytical techniques. Some of these are common to more than one parameter, so they are grouped into ATGs, listed in Table 28. Ontario Ministry of Environment protocols were used again this year, as they have been historically. It should be noted that the Manitoba government has no such comprehensive protocols for sample collection, preservation, analyses, and result reporting.

---

[10] The acute lethality test is a pass/fail type of test that is required to be performed by the federal Wastewater Systems Effluent Regulations [37] that came into force 2015 January 01.

[11] Coliform bacteria are a commonly used bacterial indicator of sanitary quality of foods and water.

a The method ICP = Inductively Coupled Plasma Spectrometry. This is a common method for metals analysis.

b The unit MPNU = Most Probable Number Unit, as reported by accredited contract laboratory. The MPNU is a common estimate of bacterial counts, especially for sewage effluent.

c RMDL = Regulation Method Detection Limit

d The LMDL = Laboratory Method Detection Limit ("MDL" also used).

e The SRI = Smallest Reporting Increment.

9.5.1.3 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is found for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results because of equipment failure, maintenance/calibration outages or operator action requiring "unavailability" to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 26) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2020, there were no instances in which the unavailability criteria (Table 26) outlined above were exceeded. There were no instances of non-radiological air monitoring unavailability. There were 2 instances of planned unavailability to Outfall monitoring that were due to required electrical power supply shut down. This amounted to a total of 5 planned hours of monitoring unavailability for liquids. One instance of unplanned Outfall monitoring, amounting to 4 hours, occurred when the supply of process water from Building 100 was accidentally cut off. In each instance an estimate of the release during unavailability was calculated as per procedure.

9.5.1.4 Monitoring Results

In the following sections, there are two types of presentation formats used in reporting the results obtained in 2020. These include an averages summary table and a comparison against the CNL's Monthly Guideline Acceptance criteria, for the effluent at identified monitoring locations.

9.5.1.4.1 Averages Summary Table

Summarized results for 2020 are presented in Table 29 through Table 33. The first two columns in the tables identify the Ministry of Environment ATG and parameter names [36]. The next three give the CNL monthly guideline concentration, LMDL (Table 28) and units for each measurement. The next six columns provide comparison of the average concentrations reported for the five previous years, followed by their arithmetic mean. The next seven columns have a summary of the results for the 2020 monitoring period (explained further below).

WL previously discontinued on-site analysis of most of the non-radiological parameters. The samples are now shipped to external ISO 17025 accredited laboratories through a sample management office. The LMDL for the laboratory analyzing the parameter is provided in Table 28.

Within the 2020 results section, the number of samples included in the average ("# Spl.") is reported. This number is not constant down the table. It depends on the sampling frequency chosen for each parameter, and sample mixing to prepare composites for analysis. The next column (labelled "ND's") gives the number of samples in which the analyte was not detected and was therefore deemed a "zero" result.

The minimum, maximum and average values of each parameter are based on individual results and not monthly averages. These results are given in the tables found at the end of the section, and include any results that were zero by virtue of being non-detectable in the laboratory. The relative standard deviation of all results is also reported, expressed as a percentage of the average. This number allows some evaluation of scatter inherent in the samples and measurement method. Usually, sample variability dominates (i.e., the effluent composition changes over time).

In Table 30 through Table 33, yearly average values for parameters marked with an asterisk show that a monthly guideline was exceeded for at least one month during the calendar year being presented.

For convenience, the total annual load to the environment (Winnipeg River) represented by each of the analytes is also presented, expressed in kilograms. The calculation process is described in detail in Section 9.5.1.5 (where the results for the Lagoon and Outfall monitoring points have been collected in Table 35, and compared to the previous five years).

Table 29: Averages Summary for Intake

					Monitoring Point: Site Intake

a All results below the LMDL, originally flagged as "< DL" when reported, are only estimates.

b Averages were calculated by setting to zero results reported as "< DL."

c Monthly Guide is from CNL's limits for non-radiological parameters in liquid effluents procedure. For mercury, the Daily Guideline is given instead, as there is no Monthly Guideline specified

d # Spl. is the number of samples analyzed and reported.

e NDs is the number of samples in which analyte was not detected (i.e., Code = "< DL," result = 0).

f RSTD = Relative Standard Deviation

N/A = not applicable

Notes: Any averages with an asterisk show that a monthly guideline was exceeded in one or more months for the given parameter in the year.

Discharges of effluent coming from the new low level liquid waste treatment systems are being combined, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.2 Monthly Guideline Acceptance

CNL guidelines were used as the basis against which emissions from WL were evaluated. The CNL guideline limits are derived from the most recent legislation available. They are not regulatory requirements, but instead have been adopted by CNL to routinely evaluate the environmental significance of both process-type and non-process type discharges from WL. Table 34 supplies a summary of each of the liquid effluent parameters that had exceeded its CNL monthly guideline in 2020 or at any time during the previous five years.

As with the average summary table provided, for each monitoring point, the first two columns in the table identify the Ministry of Environment ATG and parameter names. The next three give the CNL monthly guideline concentration, LMDL, and the units of measurement. The next six columns present the monthly guideline acceptance for each of the five previous years and the average of those five years expressed as a percentage. The last three columns show the number of months during which discharges occurred, the number of times the monthly guideline was exceeded for each parameter, and the subsequent percent of times the parameter levels met the acceptance criteria.

To assess any significant level of change and evaluate program performance, this table will be referred to in each section discussing monitoring point results.

Table 34: Parameters that Failed to Conform to CNL Monthly Guidelines

						Monthly Guideline Acceptance (%) for Previous Five Years						Results for Year 2020		
Effluent Stream	**ATG**	**Parameter**	**Monthly Guide**	**LMDL**	**Unit**	**2015**	**2016**	**2017**	**2018**	**2019**	**Average**	**# Mth.**	**> Monthly Guide**	**Accept (%)**
LLLWTS /ALWTC	6	Phosphorus	1.0	0.003	mg/L	100	100	100	100	83	100	12	0	100
	8	TSS	25	1.0	mg/L	92	100	78	92	100	90.8	12	1	92
	9	Copper	0.5	0.0005	mg/L	67	100	67	33	42	68.4	12	5	58
	9a	Iron	1.0	0.010	mg/L	75	67	44	50	83	63.8	12	7	42
	14	Phenolics	0.02	0.0010	mg/L	100	100	100	92	100	98.4	12	0	100
Outfall	8	TSS	25	1.0	mg/L	83	100	100	100	100	96.6	12	0	100

Notes:

- Effluent stream parameters which have not exceeded a monthly guideline in the current year or in the previous five years have not been included to this table.
- Discharges of effluent coming from the new low level liquid waste treatment systems are being considered as emanating from the ALWTC, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.3 Monthly Guideline Plots

For parameters that have a value higher than a CNL monthly guideline, the monthly plot of values is shown for that parameter at the monitoring point. This year there were eleven occurrences when one of three parameters (Iron, Copper, and Total Suspended Solids (TSS)) from the LLLWTS had monthly values higher than CNL monthly guidelines. Figure 5 shows the number of times the monthly guidelines have been exceeded at any monitoring point over the last five years. Plots are displayed in Figure 6, Figure 7, and Figure 8 for each parameter, and the explanations for the observed high values can be found in Section 9.5.1.4.6. The monthly or daily guideline limit for the parameter in question is shown by a broken red line in the corresponding figures.

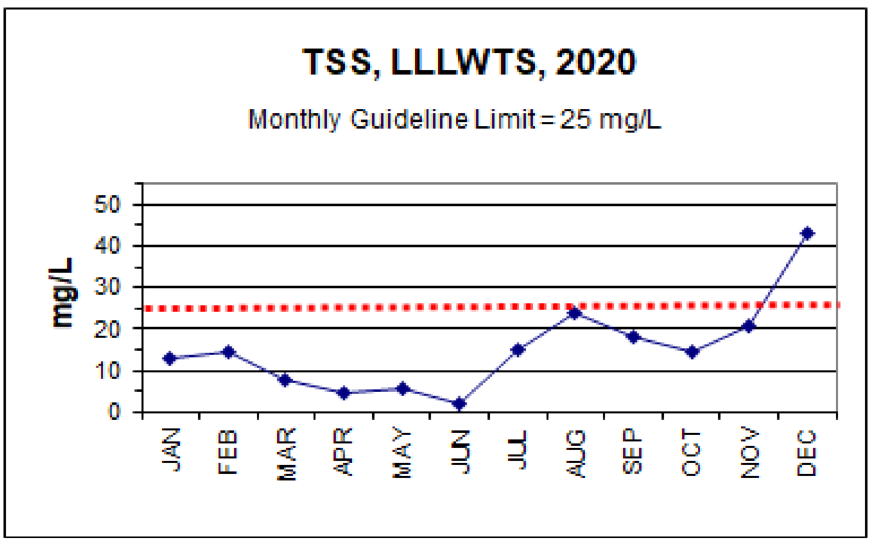

Figure 8: Monthly Average TSS Concentration of Effluents from the Low-Level Liquid Waste Treatment Systems for 2020

9.5.1.4.4 Monitoring of Intake Water from the Winnipeg River

Except for bottled drinking water, all the water needed to run the WL site is drawn from the neighbouring Winnipeg River at the Intake. The amount of water drawn from the Winnipeg River varies from year-to-year.

Grab-samples are collected each month from the Building 902 wet well to assess the levels of certain parameters that may be entering the site directly from the Winnipeg River. The measurements are summarized in Table 29, where they are compared to available data for the previous five years. Figure 9 shows the estimated amount of water used monthly for 2020.

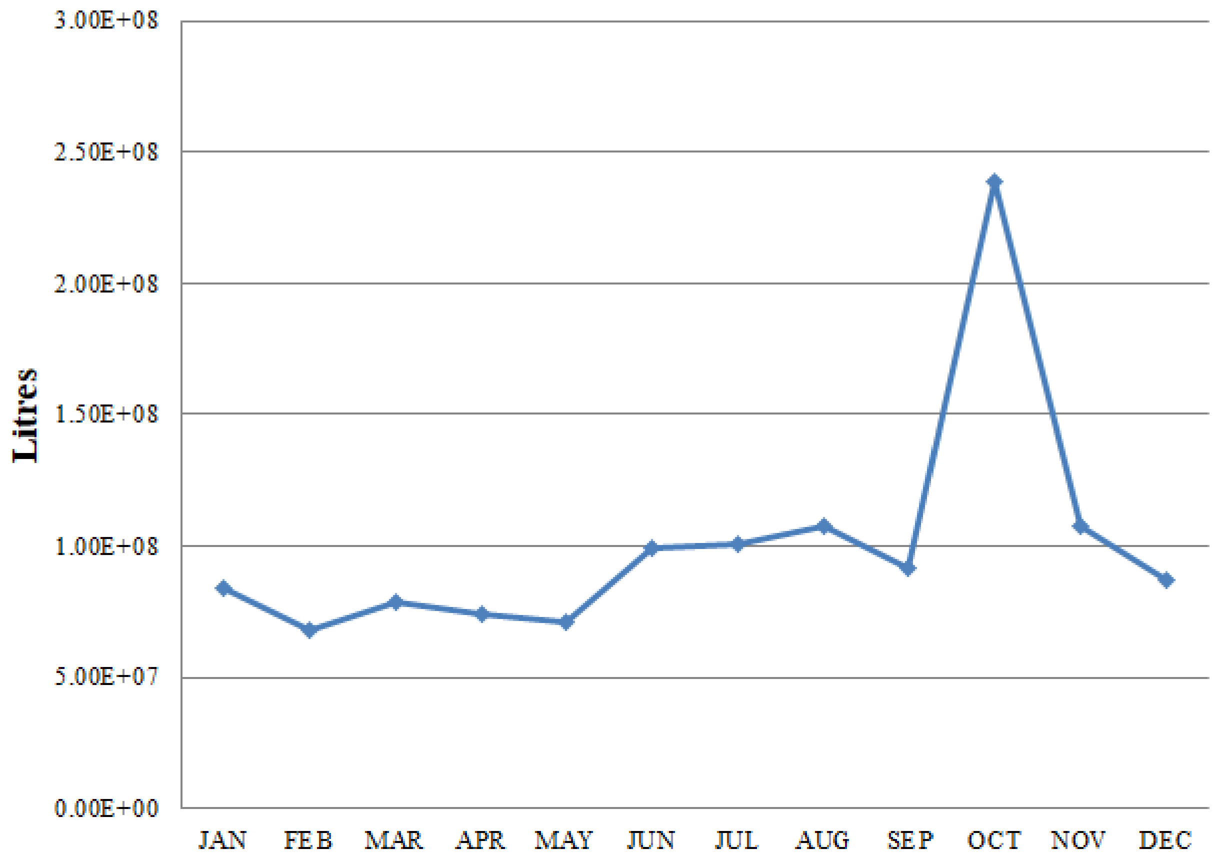

Figure 9: Monthly 2020 Intake Raw Pumped Water for the WL Usage

The following are notable points for the 2020 Intake water from the Winnipeg River:

- The Pump House flow meter recorded that 1.21E+06 m^3 of water was pumped from the river over the year.
- Compared to the five-year average, increased concentrations (> 10%) were seen for TSS, Chromium, and Zinc.
- Parameters that had their concentrations improve (> 10% decrease) this year compared to the average seen for the last five years are Phosphorus, Iron, Lead, Nickel, Mercury, Phenolics and Oil & Grease.
- Water consumption for the site increases during the summer months as the chillers and air compressors that are used in the summer are cooled by the river water.
- The spike in October in water usage was related to the Building 200 demolition which began in October. The water was used for dust control for the demolition of the building.

Intake water results can have a significant impact on the environmental performance of the WL site and they will continue to be monitored closely. In 2020, the WL site expanded the monitoring program to encompass additional parameters at the site's intake and Outfall monitoring station. This was done to verify and supply justification that the effluent monitoring program is properly identifying and analyzing for the proper contaminants of concern being released into the environment through the site's operations.

The concentrations seen at the intake are used as the base line to determine if measured concentrations at the Outfall are a result of site operations. The additional parameters that were included in the effluent monitoring program were the following: Total Organic Carbon, Manganese, Strontium, Uranium, Potassium, Bromodichloromethane, chloroform, and Toluene.

9.5.1.4.5 Monitoring of Liquid Effluents to the Winnipeg River

Two effluent streams, the Lagoon and Process Outfall, discharge significant volumes of water to the Winnipeg River. Normal surface land run off also reaches the river through Ditches 8 and 9. Results from monitoring each of these sources are discussed below.

9.5.1.4.5.1 Lagoon

The WL Lagoon secondary cell had only one period of discharge during the 2020 calendar year. This period of discharge occurred in the fall between October 14 and October 29. There was no discharge in the spring. The total amount of effluent discharged from the Lagoon in 2020 was 30,838 m^3.

Prior to discharging, the Lagoon was tested for CBOD, fecal and total coliform bacteria, and acute lethality (a biological assessment on the survivability of trout in the proposed effluent). These samples are collected by the Lagoon operators at defined areas in the secondary cell after isolation of the cell occurs. During fall discharge, grab-samples were collected close to the pipe emptying into the receiving ditch that leads to the Winnipeg River. Individual samples for most parameters are collected on a weekly basis during the discharge.

The vertical scale from which surface height is found was carefully adjusted to read absolute depth from the original floor of the Lagoon. This was done because the equation for calculating the contained volume in the secondary cell for any depth is derived from the calculation for the volume of a rectangular trapezoidal trough:

$$\begin{aligned}\text{Volume (in L)} &= \text{Height x [Width\_Bottom x Length\_Bottom} \\ &+ 0.5\text{(Width-Width\_Bottom) Length\_Bottom} \\ &+ 0.5\text{(Length-Length\_Bottom) Width\_Bottom} \\ &+ (1/3)\text{ (Width-Width\_Bottom) (Length-Length\_Bottom)]}\end{aligned}$$

Knowing the dimensions and geometry, the contained volume in the secondary cell can be calculated accurately for any depth using the following equation:

$$\text{Volume (in L)} = 636\ 655{*}d + 206.886{*}d^2 + 0.02133{*}d^3 \text{ for depth “d” (in cm)}$$

The position of the Lagoon's water surface was recorded once or twice daily while emptying. The daily flow was calculated from changes in the contained volume. This permitted calculation of volume-weighted concentrations and overall loads (see Section 9.5.1.5). Volume-weighted averages for a given period (month or year) are given by summing the product of the concentration for each day multiplied by the volume released that day, then dividing that sum by the total volume discharged during the period. Unlike other monitoring points (which are continuous or batch releases of fixed volume), the Lagoon discharge flow rate can vary widely. The variation makes weighting corrections highly significant in deciding meaningful average concentrations.

The fall discharge of the secondary cell was allowed to proceed after initial testing. Once discharging begins, the pH is checked daily throughout the discharge period.

Table 30 summarizes the results of the fall discharge. Some notable points are:

- Compared to the five-year average, there was an increase in concentrations (> 10%) for Total Residual Chlorine, Total Coliforms, Fecal Coliforms, Conductivity, and TSS.
- Compared to the five-year averages, CBOD, Unionized Ammonia, pH, Phosphorus, Chromium, Copper, Iron, Nickel, Lead, Mercury, Zinc, Phenolics, and Oil & Grease were all lower (> 10% decrease).
- No trout mortality was seen in the fall lagoon effluent sample that underwent acute lethality testing.

The WL Lagoon discharge was compared against the limits set by the federal government in the Wastewater Systems Effluent Regulations in The Canadian Gazette [37]. The limits in force were met in all cases.

The results of the federally regulated parameters are discussed below:

- Carbonaceous Biochemical Oxygen Demand - annual volume weighted average was 0 mg/L, which is less than the 25 mg/L limit.
- TSS - annual volume weighted average was 1 mg/L which is less than the 25 mg/L limit.
- Un-ionized Ammonia - the maximum concentration was 0.0011 mg/L which is less than 1.25 mg/L limit.
- In 2020, WL found out that the proposed Wastewater System Effluent Regulations limit for Total Residual Chlorine coming into effect in 2021 is not applicable for the operation of the WL Lagoon because the WL site does not chlorinate their wastewater.

9.5.1.4.5.2 Process Outfall

The Outfall monitoring station functioned as expected during 2020. The total discharge volume was 1.21 GL. This volume is lower than the previous five-year average of 1.26 GL.

The Outfall discharges continuously. Measurements were performed on the samples weekly. This provided 52 samples of each parameter for the year.

Table 31 summarizes the results obtained, and compares them to averages for the previous five years. Notable results for the Outfall are:

- There were no instances of CNL's monthly guidelines being exceeded at the Outfall monitoring station.
- The only parameters that had a significant increase (> 10%) compared to the 5-year average were TSS, Copper, Iron, and Zinc. All metal concentrations detected are so close to the detection limit, a slight increase seen in the concentrations is having a significant percentage increase being seen in the Outfall.
- Compared to the five-year average, Phosphorus, Chromium, Lead, Nickel, Mercury, Phenolics and Oil and Grease concentration levels significantly decreased (>10%).
- In the third quarter of 2020, CNL began performing Acute Lethality Testing on the Outfall effluent on a quarterly basis. No trout mortality was seen in either of the quarterly samples collected in 2020.

Overall, the Process Outfall and sampling station ran successfully during 2020.

In 2020 the WL site expanded the monitoring program to encompass additional parameters at the site's intake and Outfall monitoring station.

Total Organic Carbon, Strontium, Uranium, Magnesium, Potassium, Sodium, and the volatiles Bromodichloromethane, chloroform and Toluene. Currently, CNL can show that the source of the Potassium and Sodium being introduced to the Outfall is a result from the sanding/salting activities that occur on site as the weather transitions into and out of sub-zero temperatures. The Bromodichloromethane and chloroform are by-products that result from the site's chlorination practises. The remaining parameters are currently not tied to a source, and CNL will be expanding the monitoring program to include looking for these parameters at upstream monitoring locations in hopes of being able to find a source for them.

Going forward the environmental monitoring program will continue to monitor for the parameters mentioned above in the Intake and the Outfall, and will be report on them in this annual report.

9.5.1.4.5.3 Drainage Ditches

Much of the land surrounding key remote facilities at WL is drained by two structures. Ditch 8 drains the land north of the WMA up to the northern site boundary and beyond. Water from the landfill and recharge area on the east is diverted instead around the WMA to the west-flowing Ditch 9, and into the Winnipeg River. These ditches are monitored for radiological and non-radiological content. The radiological part is discussed in Section 9.4 of this report and the non-radiological part is discussed here.

Ditches 8 and 9 were grab-sampled each time water was flowing off-site. This was after heavy rainfalls, of which there were fifteen events from 2020 April to October. At these same times, a sample was collected from the northern ditch bordering Highway 211. This is far enough from CNL operations to be a reasonable background (Control). It was not possible to measure the flow rates at any of the locations, or to sample representatively over entire rain events; therefore, no loads can be calculated.

Comparison is made to CNL guidelines (although they are intended for process discharges). All values were below CNL monthly guidelines this year. The measurement data are summarized in Table 32. The following are notable points for the 2020 ditches results:

- Phosphorus, TSS, Iron were the parameters that had a higher concentration than the previous five-year average for Ditch 8. The parameters that had a higher concentration than the previous five-year average for Ditch 9 were TSS, Iron, Nickel, Zinc, and Mercury. The control ditch had no parameters having observed concentrations higher than the previous five-year average.
- All metal concentrations detected are very close to the detection limit, so a slight increase seen in the concentrations has a significant percentage increase being observed in Ditch 8 and Ditch 9.
- All concentrations remain well below the CNL's monthly guideline limit and pose no concern.
- All parameters measured in Ditch 8 and Ditch 9 are comparable to those measured within the Control Ditch, indicating that WL had negligible effects on the environment through these two pathways.

It should be noted that sediment control measures were put in place for projects in the WMA in 2020, as was the case in previous years.

9.5.1.4.6 Internal Liquid Discharge Monitoring

Building 300 and Building 100 both have a LLLWTS; each system represents a major area that generated low-level radioactive liquid wastes. Individual tank releases are monitored for operational control purposes.

A full tank must be emptied while a second tank is being filled. When full, tanks are sampled; if the pH and radioactivity levels meet discharge criteria, they are discharged. The LLLWTS tank pre-discharge criteria do not include all parameters listed in CNL's non radiological guideline limit values; however, the post-discharge analysis includes all these parameters. CNL staff have determined, through historical data analysis from post-discharge samples, if the pH in the tank is adjusted to neutral, all other parameters will normally meet the guideline limit values. All post-discharge data is reviewed to ensure this process is working as intended, and program requirements are met. All effluents pass through a 5-micron bag filter to the Process Outfall, leading via the Outfall to the Winnipeg River.

The tanks in the new system have a smaller holding capacity so the frequency of discharges has increased. The new system was designed with a shorter life span in mind than the earlier system that was employed by CNL. This was done to align with the decommissioning schedule being implemented by CNL. Discharging requires a day or less to complete, and can be more gradual if needed.

Grab-samples are taken after the filter, and at the beginning of each release from the individual tanks. Measurements are performed on the effluent of each discharge to find pH and conductivity. For other analytes, grab-samples are collected and analyzed by a designated laboratory to complete the characterization of the effluent being discharged.

In regards to monitoring the non-radiological parameters of the effluent for this reporting period, discharges of the new systems are being compared to the discharges from the ALWTC that was used in previous years. This allows for comparisons of the previous 5-years of effluent to continue to be made, as the effluent streams emanating from the Research and Development (R&D) Complex in Building 300 and Building 100 should still be similar enough that a comparison is worthwhile.

In 2020, 0.11 ML was discharged from the LLLWTS.

The weighted averages of the joint releases from the LLLWTS are presented in Table 33 and monthly plots for the parameters that exceed the monthly guidelines are in Figure 6, Figure 7, and Figure 8.

The following are notable results for 2020:

- None of the monthly exceedances that occurred at the LLLWTS resulted in exceedances being seen at the Outfall monitoring location downstream in the process.
- There were increases (> 10%) in the annual average concentrations of Phosphorus, Conductivity, and TSS, compared to the previous five-year average results.
- The Iron concentration coming from the LLLWTS exceeded the CNL monthly guidelines seven times (January, July, August, September, October, November, and December). The overall Iron concentration seen for the year is lower than the previous 5-years.
- The Copper concentration coming from the LLLWTS exceeded the CNL monthly guidelines five times in 2020 (January, February, March, November, and December). Frequent exceedances are being seen in relation to the new tank systems that were installed in Building 300 as a decision was made to use copper piping in the new system instead of the stainless steel that was used in the old system. As soon

as the new tanks were commissioned and used, the copper concentrations of the generated effluent noticeably increased to the guideline limit, but the concentration seen at the Outfall is still well below the monthly guideline limits.

- The TSS concentration coming from the LLLWTS exceeded the CNL monthly guidelines a single time in December.
- This was an abnormal year for the effluent produced from the LLLWTS. The cause of the increase in Iron and TSS concentrations has not been fully determined. There are two suspected causes. The first being the fact that reduced operations that CNL undertook to mitigate the spread of COVID-19, and then the safety shutdown the site entered in November, resulted in less facility operationally generated effluent being produced. This led to the effluent to display characteristics of the passive water generated by the facility (i.e., Groundwater collected by the sump pits). The other suspected cause is the relocation of the environmental laboratories from Building 402 to the Shielded Facilities. The environmental laboratories frequently work with soil, and may be introducing TSS and Iron into the system as a number of the drain lines in the environmental laboratories are being directed to the LLLWTS in the facility. The majority of the effluent being generated by the environmental laboratories does not require the treatment operations offered by this system, but it is possible it is affecting the effluent stream non-radiological characteristics. Effluent generated from the environmental labs was previously being directed to the domestic system on site and would have been discharged through the lagoon. These increases in concentration are not having a detrimental effect on the water quality at the Outfall, as all concentrations being observed are below guideline limits.

For the Lagoon and Outfall, volume-weighted loads were calculated (explained below), expressed in kilograms. All analytical data used previously in calculating averages are represented in the load.

9.5.1.5 Loading Calculations

For the Lagoon, the volume-weighted average concentration of a parameter was calculated as follows:

1. The measured concentration for each day was averaged with that of the next day;
2. The average was multiplied by the estimated volume discharged over the 24-hour period;
3. The products for all days were summed, then;
4. The resulting sum was divided by the total volume released during the period (Spring, Fall or entire year). The load was then given as the product of the calculated volume-weighted average concentration, multiplied by the total volume for the period.

At the Outfall, the total discharge volume for each month was multiplied by the monthly average concentration of the parameter.

Table 35 shows the results from the calculations described above, grouped by parameter and by final outflow source. All mass-related parameters are shown. The table also compares them to previous years, and to the five-year averages.

Note that LLLWTS discharges are not included here, as they are reflected in the Outfall loads, and ditches are also not included as lack of flow data prevents their calculation.

When examining the WL site total loads, notable results are:

- Total Residual Chlorine, TSS, and Copper are the parameters that had a load increase greater than 10% when compared to the five-year average.
- This increase in overall load for TSS is similar to the increase observed for the TSS concentration at the intake over the same 5-year period.
- All other parameters, excluding Iron, had a significant decrease of 10% or more in their loads when compared to the 5-year average.

For the parameters that have been monitored for at least the last 5 years, the sum of the total parameter loads (7,207 kg) has increased compared to last year (6,174 kg), and is higher than the five-year average (6,766 kg). This difference is mostly due to the elevated concentration for TSS been seen in the Outfall this year.

Table 35: Loading for the Current Year and Previous Five Years

ATG	Parameter	Monitoring Point	Loadings from Previous Five Years (kg) [a]						Results for Year 2020		
			2015	2016	2017	2018	2019	Average	# Spl. [b]	NDs[c]	Load (kg)

a Averages were calculated by setting to zero results reported as “< DL.”
b # Spl. is the number of samples analyzed and reported.
c NDs is the number of samples in which analyte was not detected (i.e., Code = “< DL”, result = 0).

9.5.2 Airborne Effluent Monitoring

Airborne emissions from the WL site are compiled on an annual basis for the purpose of reporting under the National Pollutant Release Inventory (NPRI) and the federal Greenhouse Gas (GHG) report. These emissions are also recorded for trending and improvement purposes. Radiological releases are covered in Section 9.4 of this report. Only non-radiological releases to the air will be covered in the following sections.

9.5.2.1 Fuel Use for Building Heating

Historically, the main stationary source for non-radiological emissions to air from the WL site was the Powerhouse which supplied district heating to various buildings on the site (see Figure 2). Starting in 2013, use of, and emissions from Number 2 fuel oil heating operations at the Powerhouse, ceased due to the completion of building conversions to either propane or electrical heating. Subsequently, a substantial increase was seen for cleaner burning propane used on site. Table 36 presents WL heating fuel consumption from 2015 to 2020. Fuel consumption continues to trend downward (see Section 9.7.2 and Figure 10).

Table 36: Fuel Use for Building Heating from WL

		Data for Previous Five Years						Data for 2020
Parameter	**Unit**	**2015**	**2016**	**2017**	**2018**	**2019**	**Average**

a Energy released calculated from consumption at 3.868E-05 TJ/L for Number 2 fuel oil.

b Energy released calculated from consumption at 2.718E-05 TJ/L for propane

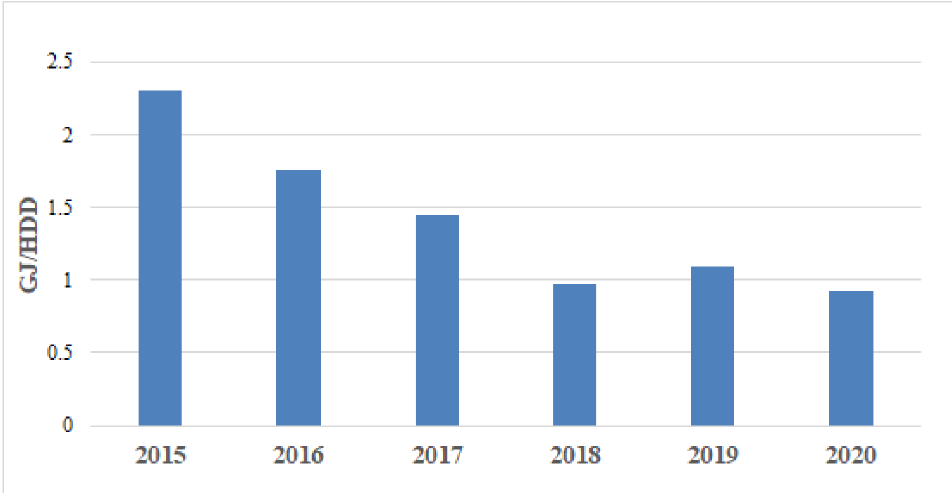

Figure 10: Annual Heating Energy Use from Fossil Fuels (per Heating Degree Days)

9.5.2.2 Reporting Under the National Pollutant Release Inventory

Under the authority of the *Canadian Environmental Protection Act*, 1999 [38], WL currently calculates releases of Part 4 substances for the NPRI program, using government reporting guidelines [39]. These releases to air include emissions caused by burning of Number 2 fuel oil and propane for heating (as discussed above), as well as diesel fuel used from site generators, dust emissions from unpaved roads, and excavation projects.

Emission factors are applied to fuel consumption data, as well as estimated kilometres travelled on unpaved roads, to determine the amount of Criteria Air Contaminants (CACs) that are generated on site. Criteria Air Contaminants consist of carbon monoxide, oxides of nitrogen, sulphur dioxide, total (filterable) particulate matter (PM), and particulate matter below 10 microns (PM_{10}), particulate matter below 2.5 microns ($PM_{2.5}$), and Volatile Organic Compounds. Dust emissions from excavation projects were estimated based on a calculation for total particulate matter generated per excavation day. Dust generated from demolition activities in *2020 will be captured in the 2020 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories* [28].

Table 37 outlines the annual CACs generated from site activities. Prior to 2012, annual reports supplied CACs for burning of fuels for heating only. However, to remain consistent with government reporting under the NPRI, the full suite of calculated CAC emissions was reported in 2012 and will continue to be reported as such.

Table 37 shows a small decrease in emissions seen in 2020 compared to the 5-year average for the values for total particulate matter, PM_{10}, and $PM_{2.5}$. These values all met the NPRI reporting threshold this year, and are reported to Environment and Climate Change Canada. Road dust emissions were the major contributor to meeting these reporting thresholds.

Table 37: Stationary Combustion Data and Emissions from WL

Parameter	Unit	Data for Previous Five Years						Data for 2020	NPRI Reporting Threshold
		2015	2016	2017	2018	2019	Average		
Airborne Emissions									
NO_x (as NO_2)	Mg	1.044	0.908	0.753	0.536	0.621	0.772	0.0602	20
SO_2	Mg	0.026	0.023	0.020	0.014	0.016	0.020	0.017	20
CO	Mg	0.461	0.399	0.348	0.233	0.271	0.342	0.256	20
TPM	Mg	16.36	15.022	13.651	14.562	10.574	14.034	8.883	20
PM_{10}	Mg	4.199	3.853	3.499	3.726	2.712	3.598	2.281	0.5
$PM_{2.5}$	Mg	0.454	0.415	0.376	0.391	0.292	0.386	0.249	0.3
Volatile Organic Compounds	Mg	0.082	0.071	0.059	0.042	0.049	0.061	0.048	10

9.5.2.3 Greenhouse Gas Emissions

Under the authority of the *Canadian Environmental Protection Act*, 1999 [38] WL must calculate releases under the GHGs emissions notice [40] providing the facility emits over 50,000 tonnes of carbon dioxide equivalent or more within the 2019 calendar-year.

Greenhouse Gas emissions from WL include carbon dioxide, methane, and nitrous oxide. Emissions are primarily from the burning of propane, the use of diesel generators, the on-site transportation fleet, the on-site landfill, and open-pit wood burning. They are measured in CO_2 equivalent tonnes which is a measure used to compare between gases that have different Global Warming Potential (GWP).

Table 38 outlines the GHG emissions from the WL site for the last six years. These emissions from the site have decreased slightly from 2019. This decrease can be attributed to the decrease in propane needed to heat the site in 2020 as shown in Table 36. There was a decrease in the number of heating degree days (i.e., decreased demand for building heat based on temperature) in 2020, and Building 200 no longer had to be heated starting in 2020 October. Overall, greenhouse gases are 8% less than the average for the last 5 years.

Table 38: Greenhouse Gas Emissions

Parameter	Releases from Previous Five Years						2020 Releases
	2015	2016	2017	2018	2019	5-yr. Avg.	
GHG CO_2e tonnes	1957	1883	1873	1678	1756	1829	1692

Note: GHG CO2e tonnes - A unit of measure used to compare between gases that have different GWP. For example, the GWP for methane is 25. This means that emissions of one metric ton of methane is equivalent to emissions of 25 metric tons of carbon dioxide.

9.5.2.4 Halocarbons

In the atmosphere, halocarbons contribute both to global warming and to ozone depletion, via separate mechanisms. Losses of halocarbon refrigerants and fire suppressants are reported semi-annually to

Environment and Climate Change Canada, following the Federal Halocarbon Regulations [41]. All releases greater than 10 kg are considered reportable.

As seen in Table 39, there were no reportable releases of halocarbons in 2020.

Table 39: Halocarbon Losses from WL

			Losses from Previous Five Years (kg)					Losses in 2020	
Type	Global Warming Potential[b]	Ozone Depleting Potential[c]	2015	2016	2017	2018	2019	Number of Losses	Annual Loss (kg)
Refrigerants[a]									
CFC (R-11)	4 600	1	0	0	0	0	0	0	0
CFC (R-12)	10 600	1	0	0	0	0	0	0	0
CFC+HCFC (R-502)[d]	4.1	0.28	0	0	0	0	0	0	0
HCFC (R-22)	1 700	0	0	0	0	0	0	0	0
HFC (R-134a)	1 300	0	0	0	12.47	0	0	0	0
Fire Suppressants									
Halon (R-1301)	6 900	10	0	0	0	0	0	0	0

a CFC = Chlorofluorocarbons; HCFC = Hydrochlorofluorocarbons; HFC = Hydrofluorocarbons
b GWP per unit mass, compared to CO2 = 1.00
c Ozone Depleting Potential per unit mass, compared to CFC R-11 = 1.00
d The data for the CFC+HCFC(R-502) is from [41]

9.5.3 Overall Performance

The non-radiological effluent monitoring program set up by CNL continues to supply valuable information about the potential impacts of operations on the Winnipeg River, and thus the local environment.

There were zero discharges from the Outfall and Lagoon which exceeded the current monthly guideline limits placed on CNL.

9.6 Regulatory Limit Exceedances and Contamination Incidents

There were no Regulatory Limit exceedances, or reportable events to report in 2020.

9.7 Discussion of Improvement Initiatives

The following sections describe some efforts made during 2020 to identify, understand and/or remove sources of some monitored substances.

9.7.1 Monitoring Site Intake Water and Outfall Effluent

In 2020 the WL site expanded the monitoring program to encompass additional parameters at the site's Intake and Outfall monitoring station. This expansion resulted from the enhanced monitoring that was performed on the Intake and the Outfall in 2019. It was decided that when there was a 20% change in concentration seen when comparing the results for a given parameter at the Intake and Outfall, that these parameters would be incorporated in the effluent verification monitoring program, in order for CNL to learn more about the operational impact of these parameters.

Total Organic Carbon, Strontium, Uranium, Magnesium, Potassium, Sodium, and the volatiles Bromodichloromethane, chloroform and Toluene have been added to the list of parameters being measured at these stations. Currently, CNL can show that the source of the Potassium and Sodium being introduced to the Outfall is a result from the sanding/salting activities that occur on site as the weather transitions into and out of sub-zero temperatures. The Bromodichloromethane and chloroform are by-products resulting from the site's chlorination practises. The remaining parameters are currently not tied to a source, and CNL is planning to do temporary upstream process monitoring (monitoring at LLLWTS in Buildings 100 and 300) to try to be able to explain the operational source of the increase.

Going forward, the environmental monitoring program will continue to monitor for the parameters mentioned above in the Intake and the Outfall, and will report on the impact that operations is having in regards to these parameters in this annual report.

9.7.2 Reducing Energy Use from Fossil Fuels

The largest quantity of non-radiological effluents to air comes from burning fossil fuels, to heat the site buildings. Starting in 2013, use of and emissions from Number 2 fuel oil heating operations at the Powerhouse ceased due to the completion of building conversions to either propane or electrical heating.

Figure 10 shows the annual fossil energy consumption since 2015, relative to the number of Heating Degree Days in each year. Heating Degree Days are calculated for each day as the difference between 18°C and the median ambient temperature.

From Figure 10, it is apparent that energy use has started to stabilize and any further reductions will be resulting from final closure of site buildings, reducing or removing their heating supply. Beginning in 2020 October, Building 200 no longer had to be heated as demolition activities on the building began.

9.8 Environmental Assessment Follow-Up and Monitoring

Details about the Environmental Assessment Follow-Up and Monitoring Program are discussed in the *2020 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28] (to be issued to the CNSC by 2021 June 30).

10 EMERGENCY MANAGEMENT AND FIRE PROTECTION

10.1 Emergency Preparedness Program

WL adheres to the Corporate Emergency Preparedness Program. See Section 10.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL program continues to adapt to the changes on site, including the demolition of buildings/assets, the construction of temporary structures, the number and composition of staffing levels, and the organisational structure. Vacated buildings are transitioned from building emergency procedures to construction/demolition oriented placards.

COVID-19 planning and coordination was the primary focus for the Emergency Preparedness Program at WL in 2020. Supporting the WL site by providing procedures and guidelines that supported the ever evolving provincial efforts and enabled work to continue safely.

10.1.1 Drills and Exercises

Due to the COVID-19 Pandemic and the hazards it presents, all non-essential and high risk drills and exercises were suspended in 2020. Emergency preparedness staff was re-assigned to pandemic planning, response and recovery operations.

The drills that were conducted after 2020 March were performed in a virtual or physically distanced table top style setting, following all prevention guidelines, to ensure absolute safety for participants and facilitators. In 2020, a total of 94 exercises and drills were delivered at WL. This is a significant drop when compared to the 218 drills/exercises delivered in 2019. Table 40 provides details on the number and type of the exercises and drills conducted in 2020.

Table 40: WL Emergency Preparedness Exercises – 2020

Type of Drill or Exercise	Number Completed in 2020
Fire Drills	10
Site-wide Specialty Drills	56
Table Tops[a]	2
Targeted Communication Exercise	17
Site-wide Communication Exercise	8
Field Exercises (Functional)	1

a Table Tops include specific EOC Skill workshops as well. Each workshop focuses on a unique aspect of the EOC and includes a small practice scenario.

10.1.2 Training

There was no change to the Emergency Operations Centre (EOC) staff structure or personnel in 2020. Due to the moving of staff offices on site there was a need to re-assign some of the building emergency team members and to assign three new members. Due to the COVID-19 Pandemic, it was decided not to run the three new members through the full building emergency team training course, but instead had one-on-one sessions to orient them to the procedures and their responsibilities. Once the COVID-19 Pandemic subsides to a safe level, this training will be formally completed.

10.1.3 Status of Emergency Resources and Facilities

Whiteshell Laboratories maintains an EOC, and conducts monthly tests of the technical equipment stored for use in that location. Repairs, improvements and updates are installed as required and when identified. In 2020, only eight of the monthly checks were completed as normally scheduled. To support the reduced operations as a result of the COVID-19 Pandemic that occurred in March, all the EOC laptops were loaned out to support WL staff in working remotely. As the EOC would only be activated virtually during significant COVID-19 restrictions, and as most of the WL EOC staff had CNL issued laptops, there was minimal risk in letting these leave the EOC. No monthly checks were conducted while the computers were out on loan. Monthly checks began again once some of the computers were returned as staff began returning to the site.

Emergency Preparedness also maintains a supply of emergency food rations, which have a five year shelf life. The rations were replaced in 2019 and only require a visual inspection/accounting once per year, which was completed.

10.1.3.1 Emergency Operation Center

As part of WL's EOC framework, there are two teams of EOC staff, and a backup person for each of the team positions that can be engaged to cover for members of either of the two teams. These two teams operate on a two week on-call rotation. There were no changes to the EOC teams in 2020.

All perishable EOC goods and supplies are checked annually and replaced as required.

There were no emergency events requiring activation of the EOC in 2020. The COVID-19 situation was managed by a companywide Pandemic Planning Committee, with oversight from the Crisis Management Team (which includes senior management representatives from the WL Site).

10.1.3.2 Mobile Nuclear Laboratory

Canadian Nuclear Laboratories continues to maintain the Mobile Nuclear Laboratory (MNL) for response both on-site and off-site. The unit continues to be maintained by WL Radiation Protection staff and is inspected at a regular interval to maintain control of inventory and equipment.

There were no emergency events requiring the activation of the MNL in 2020.

10.1.3.3 Equipment Checks

Respirators make up the majority of the equipment in the strategically placed emergency cabinets that remain on site. These cabinets are opened and inspected monthly by Radiation Protection staff. Once a satisfactory inspection is complete, the cabinets are re-sealed and signed off by the inspector. All scheduled checks were completed in 2020.

There were no emergency events requiring the use of this equipment in 2020.

10.1.3.4 Public Address System

The Public Address (PA) system is the primary system used for communicating emergency events to WL employees. The system functioned normally in 2020.

10.1.3.5 Secondary Emergency Signals

The WL site still employs an exterior siren as a redundant form of emergency alerting. The system is no longer required and was replaced by the PA system as the primary alerting system. This system will continue to be used as a redundant alerting system until either the equipment fails completely (there have previously been some issues with the equipment) or the building it is mounted to is decommissioned and demolished.

10.1.3.6 EOC Notification System

WL continued to use the Everbridge Mass Notification system in 2020. The system continues to perform well, with a 100% response rate to all monthly communication tests (see Table 41) for the second year in a row.

Table 41: WL EOC Communication Tests: 2020

Y= Yes **N= No**	**January**	**February**	**March**	**April**	**May**	**June**	**July**	**August**	**September**	**October**	**November**	**December**
EOC Commander	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Liaison Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Env. Protection Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Safety Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Planning Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Logistics Section Chief	Y	n/a*	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Operations Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Nuclear Facilities Representative	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

* Both Logistics Section Chiefs were scheduled to be away during this drill, their alternate (who is not part of the monthly drill) was covering at this time.

In addition to these regularly scheduled monthly drills, a random quarterly drill is conducted. These drills are scheduled for random times and dates, including weekends, evenings and work hours. These random drills include the expanded EOC teams, including all the alternates. Table 42 identifies the response rates of the 2020 WL EOC Staff to the Quarterly Random EOC call out drills.

Table 42: WL EOC Random Quarterly Communication Tests: 2020

	Q1	Q2[a]	Q3	Q4
Response Percentage	100%	n/a	96%	100%

a The Q2 drill was scheduled during the COVID-19 shutdown when only minimum safe staffing was on site, as a result this drill was not conducted.

10.1.4 External Collaborations

Contact is maintained with a variety of other emergency response/management organizations and interested public groups. 2020 was an interesting year for external collaboration due to the COVID-19 Pandemic. None of the planned interactions occurred, but different groups and opportunities for collaboration were available.

10.1.4.1 Local Agencies

WL supported both the Local Government District of Pinawa and the Town of Lac du Bonnet emergency operations centres with planning support and resources during the early part of the COVID-19 crisis. A joint emergency exercise was scheduled between the WL site and the Pinawa Fire Department in 2020, but had to be cancelled due to restrictions on training by the Fire Mutual Aid District as a result of the COVID-19 Pandemic.

10.1.4.2 Provincial Interactions

WL EmP was invited to participate in the Cross Sector Provincial Critical Infrastructure and Municipal Relations Governance COVID-19 teleconference meetings throughout 2020 in support of WL's COVID-19 response. These two meeting allowed WL to engage with the province for clarification on COVID-19 guidelines and orders. During the lull between the first and second wave of COVID-19 in Manitoba, WL EmP was also able to participate in the Manitoba Association of Emergency Coordinators Conference, which brought all Provincial stakeholders together, including all levels of government to share best practices, and review current and potential new legislation.

10.1.4.3 Federal Interactions

The EmP Program Manager continues to maintain membership with the Manitoba Section of the Federal Coordination Working Group. The Federal Coordination Working Group helps WL maintain ties with representatives from multiple federal agencies including (but not limited to) Public Safety Canada, the Royal Canadian Mounted Police (RCMP), Health Canada, Department of Defence, Public Health Agency of Canada, and Environment & Climate Change Canada, in order to support organizational response.

10.1.5 Unplanned Emergency Events

No incidents requiring initiation of the WL Site Emergency Plan occurred during 2020.

10.2 Fire Protection Program

WL adheres to the Corporate Fire Protection Program. See Section 10.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

There were no reportable fire events at WL in 2020.

10.2.1 Fire Response Drills

Fire drills are conducted annually in accordance with the National Fire Code of Canada [42] and CSA standard N393-13 Fire Protection for Facilities that Process Handle, or Store Nuclear Substances [43].

All fire response drills for the facilities at the Whiteshell site were completed in 2020.

10.2.2 External Collaborations

Whiteshell Laboratories and the Town of Pinawa signed a Fire Protection Service Agreement in 2019 to improve Mutual Aid support capabilities. The agreement is still in effect.

Firefighters engaged in training programs to improve response operations throughout the year. Significant aspects of response-based training included the following:

- 24 personnel are qualified to awareness training in confined space rescue.
- 15 personnel are qualified in NFPA 1006 rope rescue operations.
- 39 personnel are qualified to standard first aid level C.
- 14 personnel are qualified to NFPA 472 Hazmat operations level.

10.2.3 Third Party Audits & Inspections

A third party Fire Protection Audit was conducted in 2018 February. The next audit, as per the requirements of CSA N393-13, *Fire Protection for Facilities that Process, Handle, or Store Nuclear Material Substances* [43], is scheduled for 2021.

10.2.4 Fire Hazard Analysis

All fire hazard analysis documentation for buildings requiring a fire hazard analysis have been reviewed and are being evaluated against the decommissioning schedule. A corrective action plan will be developed to identify the required steps to ensure that Fire Hazard Analysis documentation requiring revisions will be updated as needed.

11 WASTE MANAGEMENT

11.1 Waste Management Program

WL adheres to the Corporate Waste Management Program. See Section 11.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Waste Management Program continues to provide effective and efficient delivery of Waste Management services.

Significant activities for the Waste Management Program include:

- Continued to refine and communicate the Integrated Waste Strategy to integrate waste lifecycle management across all CNL-operated sites and to capture the CNL baseline waste strategies and defined pathways for all CNL wastes.
- Collaboration between CRL and WL Programs to effectively disposition radioactive wastes, leading to the advancement of remediation and transportation projects.
- Enhanced support to existing activities and new activities in support of the new schedule for the WL Closure Project. The support improved segregation protocols and ensured continued adherence to waste processes.

The waste acceptance criteria for three of the waste receiving facilities on-site (including the Waste Handling Area and the WMA storage facilities) remained unchanged for 2020.

11.1.1 Waste Management Operations

Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects. The packaged solid radioactive wastes were stored in designated storage facilities in the WL WMA depending on the hazard level and packaging, as well as dispositioned to CRL for interim storage.

Demolition of north-side Buildings 303, 304 and 424 was completed. These buildings were formerly the Containment Test Facility, Waste Clearance Facility and the WR-1 Organic Monitor Building. A total of 200 m^3 clearable waste was generated from their demolition; 175 m^3, consisting of construction and demolition debris and asbestos-containing materials, was dispositioned to an off-site waste receiver, while 25 m^3 of metal was recycled.

Decommissioning on the south and north areas of the WL main campus began, which involved asbestos abatement and remediation of eight high temperature water manholes, generating approximately 20 m^3 of waste. All asbestos and non-asbestos insulation, cloth and metal cladding, and jacketing systems on the manholes, were successfully removed and dispositioned to approved licensed facilities. An additional 1,000 m^3 of legacy clean waste stored on the south-side, consisting of concrete (which was rubbilized and segregated of metal rebar for reuse), concrete contaminated with asbestos-containing material, and metal was dispositioned offsite, which was a major clean-up activity to enable the future characterization and remediation of the south-side affected lands planned in 2021.

The Pneumatic Transfer Line (PTL) System West Side located between Building 300 and the IFTF, consisting of polyethylene, asbestos cement conduit and concrete manholes, was decommissioned, which resulted in 20.2

m^3 of waste was generated. This waste primarily consisted of clean asbestos waste; 0.2 m^3 of this volume consisted of Low-Level Waste (LLW) which was compacted with site wide LLW operational waste.

Final decommissioning activities of Building 200 Active Liquid Waste Treatment Centre were completed, enabling the start of the building's demolition in late 2020. 199 m^3 of LLW and 6 m^3 of Intermediate - Level Waste[12] (ILW) waste was generated; of this total, 151 m^3 has been safely dispositioned to CRL, with the remaining 54 m^3 of LLW safely stored in certified transportation packages awaiting shipment to CRL in 2021.

De-inventorying efforts of legacy waste stored in SMAGS was completed in 2020, prompting the same efforts to be diverted to the LLW Quonsets (Building 431, 432 and 433). This activity generated a total of 34.4 m^3 of LLW and 21 m^3 of ILW, which was transported to CRL. The remaining waste in the LLW Quonsets will undergo additional qualification and inspection of waste contents to ensure transportation and waste criteria compliance are met and is to be shipped to CRL in 2021.

Ground remediation east of SMAGS in the WMA was performed to enable the establishment of an outdoor storage pad, referred to as the Recoverable Surface Storage Area (RSSA). A total of 264 m^3 LLW was generated, of which 152 m^3 is stored in certified transportation packages awaiting disposition to CRL, which is scheduled in 2021.

Intrusive inspection of the concrete canisters was successfully executed, which involved support from the IAEA and CRL resources. Completion of this activity supports planning efforts to safely retrieve the high-level wastes intended for transport and storage at CRL starting in 2021.

Table 43 summarizes the quantities of radioactive waste generated in 2020 that was sent to each storage location. Table 44 summarizes the volumes of solid low-level radioactive waste originating from each facility in 2020.

[12] In this context, ILW refers to any waste that does not meet the proposed Near Surface Disposal Facility (NSDF) Waste Acceptance Criteria (WAC) and requires storage in ILW facilities at CRL.

Table 45 summarizes the volumes of solid intermediate-level radioactive waste originating from facilities in 2020. Table 46 summarizes the volumes of solid low-level and intermediate-level radioactive waste transported to CRL for disposition.

Table 43: Radioactive Waste by Storage Location

Storage Facility	Volume (m^3)	
	2019	2020
Low-Level Quonsets (B431, B432, B433)	59.6	32.3
Intermediate-Level Waste Bunkers	0	0

Total	1,483.0	28.0	527.7	26.3

a Shielded Modular Above Ground Storage – legacy waste generated from various decommissioning projects.

Clearable waste from Controlled Areas was monitored in-situ. Clean bagged waste was monitored using the bag monitor located in the IFTF facility where WL's laundry facility is now stationed; all bagged waste met the screening criteria and was deemed to be suitable for unrestricted release in 2020.

Whiteshell Laboratories continued to reuse or recycle as much material as practicable; this includes both recyclable materials sent to the municipal recycling facility and other material-specific facilities throughout Manitoba. Waste Management Program representatives exercised a proactive approach to ensure waste was properly segregated at the source of origin to maximize the amount of material that could be reused or recycled.

WL summarizes the disposition pathway of non-active waste.

Table 48 summarizes the amount, by material type, of recyclable waste shipped off-site.

Table 47: Non-Active Waste Disposition Pathways

Disposition Location	Volume (m^3)	
	2019	2020
WL Asbestos Disposal Site [a]	0	0
WL Burn Pit	0	247
WL Inactive Landfill	543	0
Recycling[b] **Sent Off-Site**	410	513
Off-Site Landfill [c]	777	1,256
Total	1,730	2,016

a The WL Asbestos Disposal Site stopped receiving waste in 2019 to support the environmental risk assessment. Non-active asbestos is directed to off-site licensed landfills.

b This recycling waste pertains to office recycling that is generated on a daily basis that is accepted at municipal recycling facilities.

c WL Inactive Landfill stopped receiving waste mid-2019 to support the environmental risk assessment. Non-active waste is directed to off-site licensed landfills.

Table 48: Recycled Waste Shipped Off-Site

Material[a]	Weight (kg)	
	2019	2020
Aluminum	0	0
Batteries Shipped	1,708	0
Batteries Recylced	882	227
Cardboard[b]	0	0
Copper and Brass	0	0
E-Waste Shipped	0	347
E-Waste Sold	0	0
Ferrous Metals	798,574	108,457
Glass	0	0
Lumber	0	0
Plastic Shipped	0	0
Plastic Sold	0	0
Stainless Steel	0	0
Lead	3,006	0
Total	804,170	109,031

a This recycling waste pertains to material that is sold or charged to be taken to a material specific recycling facility.

b Cardboard is sent to a municipal recycling facility and inclusive in Table 47

Improvements were made in preventing waste accumulation inside of buildings and transferring the waste to appropriate waste facilities immediately after generation. Improvements continue to be addressed in reference to the lack of processing and storage space for non-routine waste materials (e.g., mixed waste and large contaminated items), as well as large volumes radioactive wastes generated from decommissioning activities. Mitigation measures put in place in 2020 included developing a Nuclear Safety Note for the interim storage of cargo containers containing radioactive wastes in the WMA (to be finalized in 2021). The area supporting this initiative is referred to as the Recoverable Surface Storage Area (RSSA), and consists of an outdoor, above ground storage pad to enable the storage and loading of solid low-level waste in sea land containers and storage of oversize LLW items which are awaiting further processing, characterization and/or packaging to be considered compliant for off-site disposition.

11.1.1.1 Liquid Waste Generation

During 2020, 99 m^3 of low-level liquid was processed in the Building 300 LLLWTS and 7.9 m^3 in the Building 100 LLLWTS, for a total of 106.9 m^3 of low-level liquid waste processed through the two systems.

11.2 Decommissioning Plan

Several buildings and structures were decommissioned in 2020, where operational wastes were dispositioned, building services isolated and industrial hazardous materials removed prior to demolition.

Demolition of north-side Buildings 303, 303 Annex, 304 and 424 was completed. The decommissioning of the buildings included the associated services and structures except for the concrete pads, which will be demolished and removed the north-side (main campus) site remediation work is executed.

The Pneumatic Transfer Lines located between Building 300 and the Immobilized Fuel Transfer Facility were fully decommissioned. All polyethylene tubing, asbestos cement conduit and associated manholes were removed, and the underlying soil surveyed and backfilled.

To advance the remediation of the south-side of the main campus, the former concrete rubble pile was packaged and dispositioned off-site. The material consisted of both clean concrete, which was processed (rubbilized and segregated of rebar) to support future reuse, and concrete contaminated with asbestos-containing material which was disposed of in an off-site licensed facility.

Building 200 decommissioning activities involved the continued removal of process systems and equipment to reduce source term hazards. The focus of work involved radiological and waste characterization of tanks, application of fixatives to prepare tanks for future size reduction, and removal and packaging of process piping. Decommissioning was completed mid-2020, enabling building demolition. Approximately 50% of the building was demolished; the remaining portion of the building has been placed in a safe state following an engineering evaluation, with access to the building restricted. Demolition will resume in 2021.

Legacy waste stored in SMAGS was successfully emptied and dispositioned to CRL for storage, supporting the ILW Cask Loading Facility (CLF) infrastructure project. De-inventory efforts expanded to the LLW Quonsets (Building 431, 432 and 433), however the waste will need to be processed and qualified to ensure transportation and waste criteria compliance are met before waste can be dispositioned to CRL. This work is scheduled in 2021.

Decommissioning progress is also discussed in the facility sections (Appendix A through Appendix G).

Table 49 lists the WL Detailed Decommissioning Plans (DDPs) and their status as of 2020.

Table 49: Overview of WL Detailed Decommissioning Plans

Facility	DDP Document Title	Document #	Status
	The Whiteshell Laboratories Detailed Decommissioning Plan: Volume 1 - Program Overview	WLDP-02000-DDP-001 (RC-2143-1, Rev. 4), January 2002	To be Cancelled and Superseded by WLDP-02000-DDP-001, Rev.0.
	The Whiteshell Laboratories Detailed Decommissioning Plan: Volume 1 - Program Overview	WLDP-02000-DDP-001, Revision 0, 2019	Revision 0 of DDP Volume 1 submitted to CNSC for acceptance, and comments were received. To be dispositioned.
Shielded Facilities	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 2 - Shielded Facilities	WLDP-21400-DDP-001, Revision 1, 2016	Facility is operational and decommissioning activities ongoing. DDP Volume is available for use.
Van de Graaff Accelerator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 3 - Van de Graaff Accelerator	RC-2143-3, Revision 1, 2000	Facility has been decommissioned.
Neutron Generator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 4 - Neutron Generator	RC-2143-4, Revision 1, 2000	Facility has been decommissioned.
Active Liquid Waste Treatment Centre	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 5 - Active Liquid Waste Treatment Centre Building 200	WLDP-25400-DDP-001, Revision 0, 2011	Facility is being decommissioned. DDP Volume is available for use.
Whiteshell Reactor-1 (WR-1)	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 6 - Whiteshell Reactor-1: Building 100	WLDP-26400-DDP-001, Revision 3, 2015 (Complete Dismantlement and Removal Approach)	Facility has been shut down and currently under monitoring and surveillance. Complete Dismantlement and Removal approach has been approved by the CNSC (Revision 3). EA process for ISD is in progress, Revision 4 to be revised with final EA submission. DDP Volume (Revision 3) is available for use.
		WLDP-26400-DDP-001, Revision 4, 2017 (In Situ Decommissioning Approach)	
Concrete Canister Storage Facility	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 7 - Concrete Canister Storage Facility	WLDP-22500-DDP-001, Revision 1, 2017	Facility is operational. DDP was sent to the CNSC for information and comments received (to be dispositioned).
Waste Management Area	Volume 8 - WMA Part 1: Standpipes Area	WLDP-36500-DDP-001	Facility is operational DDP under development.
	Volume 8 - WMA Part 2: Intermediate - Level Waste Bunkers, Building 417 and Amine Tanks	WLDP-24900-DDP-001	Facility is operational. DDP under development.
	Volume 8 - WMA Part 3: Low Level Waste Liabilities	WLDP-24400-DDP-001, Revision 3, 2018	Facility is operational. DDP was sent to the CNSC for acceptance, and comments received. To be dispositioned.
R&D Facilities Complex	Volume 9 - Building 300	WLDP-23500-DDP-001 (RC-2143-9), Revision 0, 2007	Facility is operational. DDP Volume is available for use.

Facility	DDP Document Title	Document #	Status
	Volume 9 - Building 300_Addendum	WLDP-23500-DDP-001_AD, Revision 2, 2018	
Decontamination Centre	Volume 10 - Decontamination Centre Building 411	WLDP-27400-DDP-001, Revision 0, 2011	Facility has been decommissioned.
Health and Safety Facilities	Volume 11 - Building 402 and 305	WLDP-37000-DDP-001	Operational and decommissioning activities ongoing. DDP Volume is available for use.
DP Volume 12	Volume 12 - WL Licensed Site Supporting and General Infrastructure: North-Side	WLDP-32000-DDP-001, Revision 0, 2009	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 1: South-Side Buildings	RC-2143-12, Revision 1, 2006	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 3: Outer Area Buildings and Facilities	WLDP-33000-DDP-001, Revision 1, 2008	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 4: Site Services	WLDP-34000-DDP-001, Revision 1, 2013	Operational and decommissioning activities ongoing. DDP Volume is available for use.
	Volume 12 - WL Licensed Site Supporting and General Infrastructure-Part 5: Site Affected Lands and Contaminated Structures	WLDP-35000-DDP-001, Revision 1, 2012	Decommissioning activities ongoing. DDP Volume is available for use.

12 SECURITY

12.1 Security Program

WL adheres to the Corporate Security Program. See Section 12 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Whiteshell Site Security Report [44] outlines the security arrangements that are in place at the WL site. The Security program consists of processes, procedures, and staff to manage the continuous operation and response to security incidents; the Security Program and procedures are reviewed and updated as required to address operational requirements.

Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers stated in REGDOC-2.2.4, *Fitness for Duty, Volume III Nuclear Security Officer Medical, Physical and Psychological Fitness* [45].

Due to the COVID-19 Pandemic, no CNSC Type II Compliance Inspections for the Security Program were conducted in 2020.

CNL-WL received notification from the CNSC on the closure of one enforcement item, Order #9336. Order closure was granted as CNL-WL completed all actions required to address the enforcement items listed in the Order, including the standing up of a Tiered Response Force (TRF), for which training has been completed.

CNL-WL has one open enforcement item (Directive WL-SEC-19-T2-001-D01 – Training). An action plan was submitted to the CNSC resulting in 7 actions required to address the Directive. All actions were completed in 2020. A letter requesting closure of the Directive was sent to the CNSC.

12.1.1 Security Events

In 2020, there was one security event that affected WL, the details of which are considered Classified-Confidential. Information relating to this event were provided to CNSC staff. Corrective actions were completed, and the event is now closed.

13 SAFEGUARDS AND NON-PROLIFERATION

13.1 Safeguards Program

WL adheres to the Corporate Nuclear Materials and Safeguards Management (NM&SM) Program. See Section 13 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

13.1.1 IAEA Activities

The IAEA conducted various types of activities as part of the safeguards approach for CNL, including, but not limited to, IAEA safeguards seals changes, human surveillance, implementation and/or maintenance of IAEA safeguards monitoring equipment, and technical visits. A list of IAEA inspections conducted at all CNL sites can be found in Section 1.2, Management System of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The IAEA Technical group performed a technical visit to the WL Concrete Canister Storage Facility on 2020 October 01 for planning use of remote camera monitoring equipment to support the upcoming fuel shipping campaign to CRL.

WL Projects conducted intrusive inspections of the WL Concrete Canisters from 2020 October 20 to November 07, during which the IAEA provided oversight and verified and changed the IAEA canister seals.

A Physical Inventory Verification (PIV) inspection was carried out by the IAEA on 2020 November 04. This inspection was a sampling of accessible items containing Special Fissionable Material and changing of 2 IAEA canister seals.

A Design Information Verification (DIV) inspection was carried out by the IAEA on 2020 November 05. The activities associated with the DIV included:

- Verification of the Design Information Questionnaire:
- Verification of the site and general building design;
- Verification of containment integrity; and
- Verification of operational status of the facility.

A discussion of IAEA inspections conducted at WL can be found in Section 1.2.2. A list of all IAEA inspections conducted at all CNL sites can be found in Section 1.2.2, Management System of *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4].

14 PACKAGING AND TRANSPORT

14.1 Packaging and Transport Program

WL adheres to the Corporate Transportation of Dangerous Goods Program, which includes the requirements of the Packaging and Transport SCA. See Section 14 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Packaging and Transport SCA covers the safe packaging and transport of nuclear substances and radiation devices. The Transportation of Dangerous Goods (TDG) Program applies to any activities involving the transportation of dangerous goods to or from CNL sites. The TDG Program provides an operational framework for the safe off-site transport of dangerous goods by conforming to all applicable laws and regulations, as well as company policies and procedures.

The Waste Certification & Transportation branch is a centralized organizational department responsible for planning, coordinating and executing radioactive waste shipments from the WL site to the off-site disposal or storage facilities in a safe and compliant manner, including having fully trained Radioactive Material Shippers as authorized under the CNL TDG Program.

Significant activities in 2020 included:

- Transportation of 528 m^3 of low-level waste and 26 m^3 intermediate-level waste sent off-site and safely delivered to CRL;
- Throughout 2020, additional technical assessments and studies on the WL used fuel inventory were completed in support of the licensing application of the Used Fuel Transportation Package (UFTP). These assessments were focused on the WL mixed fuel types (i.e., enriched and experimental fuel types, including Uranium Carbide and Uranium Metal fuel types) and the physical operation of the UFTP. The UFTP, which is owned by the Nuclear Waste Management Organization, has been leased with the intention that the UFTP will be the Type B Transportation Package for high-level waste transportation operations starting in 2021 (due to the COVID-19 Pandemic, these transportation operations were delayed and subsequently pushed out from 2020). There is a two-step licensing strategy for the UFTP, with the first phase focusing on licensing the UFTP for non-enriched CANDU fuels and the second phase focusing on WL's inventory of mixed fuel types. The phase UFTP Safety Analysis Report (SAR) Addendum was submitted to the CNSC in 2019 May, with updates provided throughout 2020. The UFTP SAR for Mixed Fuel Types (representing phase two) will be submitted following CNSC acceptance of the SAR Addendum. Additional accomplishments throughout 2020 include the completion of the physical commissioning of the UFTP, the completion of fabrication and Factory Acceptance Testing of the Shielded Interface Module (SIM) for UFTP loading, the inactive commissioning of the UFTP-SIM stack-up at CRL, and the completion of intrusive inspections of the used fuel baskets stored within the Concrete Canister Storage Facility.
- Award of the subcontract to Nuclear Assurance Corporation (NAC) to design and fabricate Type B casks, cask handling equipment and on-site services needed to support ILW transport to CRL was completed. Two versions of the OPTImal Modular Universal Shipping (OPTIMUS) casks, the OPTIMUS-H and OPTIMUS-L are expected for receipt in 2021 pending licence review and acceptance for use.

14.1.1 Shipments

At WL, 230 radioactive transport packages making up 36 loads were safely and successfully sent off-site in 2020. Whiteshell Laboratories complied with the Packaging and Transport of Nuclear Substances Regulations [46] and IAEA Safe Transport of Radioactive Material [47].

15 OTHER MATTERS OF REGULATORY INTEREST

15.1 Public Information and Disclosure Program

WL adheres to the Corporate Public Information Program. See Section 15 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Public Information Program document [48] is intended to cover communication activities that occur within CNL's immediate neighbouring communities. This document was prepared in accordance with CNSC regulatory document REGDOC-3.2.1, *Public Information and Disclosure* [49].

15.1.1 Communications

See Section 15 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4]

15.1.1.1 Website and Social Media

CNL's Whiteshell Decommissioning web page had 15,987 page views in 2020; this includes boosted and targeted social media advertising as well as information posts.

To support the Whiteshell projects and site, CNL has used social media to promote events, share and receive information, and generally engage with the public. As Table 50 and Table 51 show, social media has been an effective tool to reach and engage stakeholders. CNL's post on 2020 April 16 sharing the support CNL's Whiteshell Laboratories was giving to the COVID-19 response had a high level of engagement with 363 individuals interacting with the content. The high level of engagement on this post demonstrates CNL's success at notifying stakeholders of CNL's involvement in the community in which they are a part of.

Definitions:

Engagements - Measures how much and how often others interact with you and your content in social media.

Shares or retweets - Measures how often the message was shared or forwarded on the twitter website.

Table 50 – Facebook Metrics for WL-Raelated Posts*

Date of Post	Engagement	Shares
2020 January 22	108	14
2020 April 3	874	52
2020 April 16	363	12
2020 June 11	8	0
2020 June 21	816	65
2020 July 20	100	3

* Social media data is current as of 2021 April

15.1.1.2 Newsletters

CONTACT is an external newsletter distributed to community stakeholders and to residences and businesses in communities surrounding WL, and is available on www.cnl.ca. This publication informs the reader on activities undertaken at CNL's Whiteshell Laboratories and profiles CNL's community activities. Approximately 8,000 homes in the region receive this bilingual newsletter. A spring edition of *CONTACT* was issued in 2020. Since November 2017, five newsletters have been released with topics including the following:

- WL Closure Project and WR-1 Updates
- Highlights of public and Indigenous engagement activities
- Community initiatives demonstrating commitment to economic generation, sponsorship, donations and participation in community events
- Employee Profiles
- Environmental Stewardship including steps to reduce greenhouse gas emissions, wildlife protection and waste minimization

15.1.1.3 Media Coverage

During the 2020 calendar year, media coverage on the Whiteshell Closure Project was fairly light with eight articles in total. See Table 52.

Table 52 – Media Coverage for 2020

Date	Article	Publication
2020 January 09	CNL Licence Renewed for Decommissioning	*The Clipper*
2020 January 23	North Forge receives CNEA Fund Support	*The Clipper*
2020 January	From the Council Chambers of Mayor Blair Skinner	*LGD of Pinawa Municipal Quarterly Newsletter*
2020 January 27	Letter to the PM, Parliament re: Canada's federally owned radioactive Waste	*Hill Times*
2020 April 09	Regional food banks seek additional support	*The Clipper*
2020 April 30	CNL offers support during COVID-19 crisis	*The Clipper*
2020 June	Radiation: Harnessing a Natural Phenomenon	*Discover Magazine*
2020 July 30	Nuclear Waste Disposal Plan Fuels Frustration	*Winnipeg Free Press*

15.1.2 Outreach and Stakeholder Engagement

WL shares information with the public through a number of activities including conducting public information sessions, media releases, the corporate website, a toll-free line, social media accounts and involvement in community events. Employees are CNL's greatest ambassadors and they are kept informed of developments so that they can also share information with their relatives, friends, and neighbours. The Whiteshell Laboratories site engages with the public at a number of activities. For 2020, these activities are listed in Table 53.

Table 53: Public Engagements

Date	Location	Activity
2020 January 15	Pinawa, Manitoba	Community Regeneration Partnership meeting
2020 February 04	Pinawa, Manitoba	WR-1 Breakfast Session: Alternatives Analysis
2020 February 17	Whiteshell Laboratories	Tour of the WR-1 reactor to a University of Manitoba Physics Professor
2020 February 29	Winnipeg, Manitoba	WR-1 Presentation to the Association of Engineers & Geoscientists of Manitoba, Filipino sector
2020 May 05	Email update	Public Liaison Committee update via email with an invitation to contact CNL to discuss or with questions
2020 June 23	Virtual	WR-1 Breakfast Webinar: Post Closure Safety Assessment
2020 July 11	Hard-copy mail-out	CONTACT newsletter distributed to approximately 8000 homes
2020 August 20	Lac du Bonnet, Manitoba	CNL booth at the Lac du Bonnet Night Market
2020 August 25	Virtual	WR-1 Breakfast Webinar: Isolation and Containment Barriers
2020 September 05	Lac du Bonnet, Manitoba	CNL booth at the Lac du Bonnet Home and Cottage Expo
2020 September 24	Whiteshell Laboratories	Presentation on the Whiteshell Laboratories history and current decommissioning, following by a site tour to Manitoba Environmental Industries Association (MEIA), Assistant Deputy Minister Conservation and Climate, Director of Environmental Compliance and Enforcement Branch, Industry Workforce Development, Economic Development and Training, Lac du Bonnet MLA
2020 September 29	Virtual	WR-1 Breakfast Webinar: Formulation and Testing of Grout
2020 October 05	Pinawa, Manitoba	Whiteshell Community Regeneration Partnership Meeting
2020 October 05	Whiteshell Laboratories	Tour of the Whiteshell site to the Mayor of Pinawa and two representatives from StarCore Nuclear
2020 November 24	Virtual	Public Liaison Committee meeting

15.1.3 Public Consultation

WL actively works to engage local stakeholders on matters related to CNL activities. In 2020, a number of methods were deployed to gain feedback from and create discussion with interested parties including: participation in trade shows, breakfast sessions, social media, and feedback forms being made available online and at external events, and responses to inquiries being answered. WL strives to create open and transparent communication with all identified stakeholders, and works to address and respond to all inquiries.

Throughout 2020, CNL received 10 community inquiries related to WL (Table 54), largely through the WR-1 Breakfast Session/Webinar series.

Table 54: Whiteshell Laboratories Closure Project Public Inquiries

Nature of Enquiry	Number
Request for Documentation (Licencing, WR-1 EIS)	3
WR-1 Environmental Assessment Schedule	1
WR-1 Safety Case	2
WR-1 Alternative Means	4

15.1.4 Whiteshell Public Liaison Committee

Completing its seventeenth consecutive year of operation, the independently facilitated Whiteshell Public Liaison Committee continued to meet in 2020. Meeting minutes are recorded and actions are tracked and filed for reference. Due to the COVID-19 pandemic, the spring meeting was substituted with a written update emailed to participants in May, along with an invitation to contact CNL with questions or to discuss issues. The Committee met virtually November 24. Below are some highlights of the written update and November 24 presentation:

- WL Closure Project response to the COVID-19 Pandemic and support to the community,
- WL Closure Project Progress Update and Look Ahead,
- Environmental Monitoring and protection of the environment,
- WR-1 Environmental Assessment Update,
- CNSC Regulatory Oversight Review,
- Public and Indigenous Engagement and involvement in the communities,
- Update from the Community Regeneration Partnership Committee.

The committee is comprised of community and stakeholder representatives (as given below), consisting of elected officials and community interest groups. Its mandate is to provide an opportunity for open dialogue between community stakeholders and WL senior management on WL's various environmental and decommissioning projects.

The Whiteshell Public Liaison Committee is represented by:

- Local Government District Pinawa,
- Rural Municipality (RM) of Lac du Bonnet,
- Town of Lac du Bonnet,
- Town of Powerview Pine Falls,
- Town of Beausejour,
- RM of Brokenhead,

- RM of Whitemouth,
- RM of Alexander, and
- Manitoba Sustainable Development.

15.1.5 Whiteshell Laboratories Community Regeneration Partnership

The Whiteshell Laboratories Community Regeneration Partnership was formed as a result of the forthcoming closure of the WL site, and driven by a desire by both the Whiteshell region and CNL to encourage post-closure economic development. The partnership consists of municipalities, economic development organizations, Indigenous communities and CNL. Two meetings took place in 2020 providing opportunities for CNL to provide Project updates to participants and to seek feedback on the Whiteshell Closure Project and the WR-1 Decommissioning Project.

15.1.6 Ongoing Projects

15.1.6.1 WR-1 In Situ Decommissioning Environmental Assessment

The proposed WR-1 in situ decommissioning (also referred to as in situ disposal) Environmental Assessment (EA) is a key project identified by CNL as part of the overall integrated approach to safely manage and reduce Canada's legacy liabilities. It is a requirement in support of the EA process that the WR-1 project information be made available to CNL neighbouring communities and stakeholder groups through a variety of mechanisms to ensure accessibility of fact-based information. Engagement activities were conducted in support of this requirement through a variety of methods including social media and website content, WR-1 in situ disposal Presentations, Meetings, Site Tours and Information Sharing with Stakeholders.

Project specific webpages and content were produced for the WR-1 Decommissioning Project. Content includes: fact sheets, info graphics, downloadable posters, project descriptions and quick reference material. All information is available in both official languages. See www.cnl.ca/wr-1.

15.2 Indigenous Engagement

CNL follows CNSC REGDOC-3.2.2 Public and Indigenous Engagement: Indigenous Engagement [50] which sets out requirements and guidance for licensees on Indigenous engagement. CNL recognizes and values the ongoing engagement with Indigenous communities. Through its engagement activities, CNL seeks to inform Indigenous communities of ongoing activities at the WL site and the possible effects of these activities to members of communities and the environment, and to seek input and feedback from the communities regarding decommissioning of the Whiteshell Laboratories, the WR-1 Decommissioning Project, environmental monitoring, and to understand traditional and current uses in the vicinity of the WL site.

Through its engagement activities, WL has been able to solicit and respond to First Nations and Métis community input. First Nations and Métis communities have sought more information and engagement on environmental protection, understanding of the in situ disposal proposal and other options, economic opportunities, and the future plans for the WL site. CNL has been working with local First Nations and Métis communities to provide reasonable capacity, and at the same time has engaged communities with opportunities to better understand concerns and build positive relationships.

Table 55 lists the engagement activities from 2020. Further details on Indigenous Engagements are available through the Indigenous Engagement Report.

Table 55: Indigenous Engagement

Date	Event / Activity	Involved Parties	Details
Sagkeeng First Nation (SFN)			
2020 January 20	Memorandum of Understanding	SFN CNL	CNL and SFN sign an MOU to provide capacity support to review CNL's responses to Sagkeeng's comments on the EIS.
2020 February 18	Letter from SFN	SFN	CNL received a letter from the SFN Chief regarding the Alternative Means Assessment and other items.
2020 March 06	Meeting with CNL and SFN	SFN CNL OKT Law The Firelight Group	Review of 2020 February 18 letter from the SFN Chief to CNL and issues noted. Discussed Long Term Relationship Agreement (LTRA).
2020 May 04	Letter from CNL to SFN	SFN CNL	CNL provided responses to questions posted during the March 06 meeting.
2020 June 15	Memorandum of Understanding	SFN CNL	CNL and SFN sign an MOU to fund the completion of Sagkeeng's Alternative Means Assessment.
2020 June 30	Meeting with CNL and SFN	SFN OKT Law CNL	Review of CNL's offer to fund a community liaison position and description of what that role entails.
2020 July 17	Meeting with CNL and SFN	OKT Law CNL	Indigenous Liaison, LTRA, Environmental Monitoring, Regular Recurring Meetings.
2020 August 11	Meeting with CNL and SFN	SFN CNL	CNL met with Sagkeeng's new Indigenous Liaison. Discussed; overview of WL Closure Project, WR-1 ISD project and engagement with SFN to date; and took a preliminary site tour.
2020 August 12	Teleconference	Firelight CNL	Firelight, Sagkeeng's Consultant, provided an update of progress to date on Sagkeeng's Alternatives Assessment work.
2020 August 27	E-mail	SFN CNL	CNL provided an update on engagement activities with community liaison and draft training plan.
2020 September 05	Memorandum of Understanding	SFN CNL	CNL and Sagkeeng sign an MOU to providing funding for a community liaison position.

Date	Event / Activity	Involved Parties	Details
2020 September 08	Site Visit	Sagkeeng's Liaison CNL	Sagkeeng's community liaison came to site; CNL provided an overview of the history of the facility and the proposed decommissioning of the WR-1 reactor.
2020 September 15	Teleconference with Sagkeeng's Lawyer	OKT Law CNL	Sagkeeng's Lawyer and CNL reviewed and discussed Action Items.
2020 September 30	Tree Survey; Workplan Workshop	Sagkeeng's Liaison CNL	Sagkeeng's liaison and CNL met to commence the development of a work plan to guide CNL's future engagement with Sagkeeng's membership. Sagkeeng participated in a tree survey on site and discussed the process with the environmental team.
2020 October 19	Alternative Means Assessment Report	SFN CNL	CNL received Sagkeeng's final report on their Alternative Means Assessment.
2020 October 20	Contribution Agreement	SFN CNL	CNL and Sagkeeng signed a contribution agreement to support Firelight Group's review to CNL's responses to Sagkeeng's comments on the EIS.
2020 October 20	Environmental Monitoring	BRFN HWFN MMF SFN CNL	Community representatives observed fish processing on site and the environmental monitoring team provided an overview presentation.
2020 October 28	Psycho-social Assessment Letter	SFN CNL	CNL received Sagkeeng's completed Psycho-social Assessment Report.
2020 November 02	Teleconference	SFN CNL	Provided an update and discussed setting up follow up workshop to develop key deliverables for engaging Sagkeeng.
2020 November 03	Briefing Note update	SFN OKT Law	CNL provided Sagkeeng representatives with a briefing note for chief and council on CNL's monthly engagement activities.
2020 November 12	Teleconference	SFN Narratives Inc. OKT Law CNSC CNL	Sagkeeng Representatives presented an overview of the psycho-social report and CNL and CNSC asked questions.
2020 November 16	Letter – Sagkeeng's EIS Comments	SFN CNL	CNL received Sagkeeng's feedback on CNL's responses to Sagkeeng's comments on the EIS.

Date	Event / Activity	Involved Parties	Details
2020 November 19	Teleconference – Alternative Means Assessment Overview	SFN Firelight Group CNSC CNL	Sagkeeng presented an overview of the alternative means assessment report and CNL and CNSC asked questions.
2020 November 25	Invitation – CNL's Industry Day	SFN CNL	CNL, in partnership with the Organization of Canadian Nuclear Industries (OCNI), invited community members to participate in the 2020 virtual CNL Industry Day.
2020 November 25	Teleconference	SFN CNL	Sagkeeng's liaison and CNL met to discuss engaging Sagkeeng's membership during the pandemic.
2020 November 26	Teleconference	SFN CNL CNSC AECL	CNL hosted a meeting with Sagkeeng to discuss Sagkeeng's comments and CNL's proposed responses. This meeting took place prior to CNL drafting their responses to test their proposed next steps to address Sagkeeng's concerns (Part I).
2020 December 01	Teleconference	SFN CNL CNSC AECL	CNL hosted a meeting with Sagkeeng to discuss Sagkeeng's comments and CNL's proposed responses. This meeting took place prior to CNL drafting their responses to test their proposed next steps to address Sagkeeng's concerns (Part II).
Manitoba Metis Federation (MMF)			
2020 January 28	Meeting with CNL, MMF and CNSC	MMF CNL CNSC AECL	Monthly update meeting.
2020 March 06	Meeting with CNL, MMF and CNSC	MMF CNL CNSC	Monthly update meeting.
2020 March 24	Meeting with CNL, MMF and CNSC	MMF CNL CNSC	Monthly update meeting.
2020 April 27	Meeting with CNL, MMF and CNSC	MMF CNL CNSC	Monthly update meeting.
2020 May 25	Meeting with CNL, MMF and CNSC	MMF CNL CNSC	Monthly update meeting.

Date	Event / Activity	Involved Parties	Details
2020 June 22	Meeting with CNL, MMF and CNSC	MMF CNL CNSC	Monthly update meeting.
2020 July 06	Environmental Monitoring	MMF CNL	MMF Observed Waste Shipment from Pre-Job to Strapping.
2020 July 06	Meeting with CNL and MMF	MMF CNL	Presentation to MMF on CNL's Transportation of Waste and Emergency Response Capabilities.
2020 August 20	Letter	MMF CNL	CNL provided MMF with CNL's responses to MMF comments on the draft 2017 and 2019 EIS.
2020 August 26	Teleconference Meeting with CNL and Manitoba Métis Federation	MMF CNL	Introduced CNL's Indigenous Engagement Officer and discussed comments on Indigenous Advisory Committee – Participation Agreement.
2020 September 10	E-mail Update	MMF CNL	Provide a list of all fall environmental monitoring activities and invited MMF to participate.
2020 September 17	Environmental Monitoring: Mushroom Collection	MMF CNL	MMF participated in mushroom collection with CNL's environmental monitoring team.
2020 October 14	Métis Cultural Awareness Training	Louis Riel Institute CNL	Métis Cultural Awareness Training provided by the Louis Riel Institute. The cultural awareness training was the first semi-virtual training provided by the Louis Riel Institute, where half of the participants attended online and half were in-person.
2020 October 20	Environmental Monitoring	BRFN HWFN MMF SFN CNL	Community representatives observed fish processing on site and the environmental monitoring team provided an overview presentation.
2020 October 26	Teleconference	MMF CNL	CNL and the MMF met to discuss MMF's feedback on CNL's comments and CNL's proposed next steps.
2020 November 12	Teleconference	MMF CNL	CNL and the MMF had a follow-up meeting to discuss agenda for our coming meeting, the development of a Contribution Agreement for Fall Monitoring Activities; Update on MMF's review of CNL's Indigenous Advisory Committee Outline and community liaison Job Description.

Date	Event / Activity	Involved Parties	Details
2020 November 26	Teleconference – Workshop #1	MMF CNL	CNL hosted a meeting with MMF to discuss areas of interest and possible areas of collaboration. The communication protocol MMF recommend CNL follow, in accordance with MMF’s resolution #8, was also discussed.
Brokenhead Ojibway Nation (BON)			
2020 April 03	Teleconference	BRFN BON HWFN CNL CNSC	CNL provided an update on decommissioning activities.
2020 August 20	Phone call	BON	BON confirmed they do not want to participate in the IAC and was content to continue to engage through the regulatory process.
2020 August 26	Meeting with CNL and HTFC Consultant	HTFC CNL	Meeting with Consultant representing BRFN, BON, and HWFN. Discussed initial thoughts on the Indigenous Advisory Committee – Participation Agreement.
2020 September 14	Invitation – Email	CNL BON	CNL invited BON to participate in their fall environmental monitoring. No response received.
2020 September 15	Letter	CNL BON	CNL provide BON with responses to the community’s comments on the 2017 Draft EIS. Confirmed receipt and forwarded to Chief and Council.
2020 September 16	Invitation – E-mail	CNL BON	Invitation to attend CNL's WR-1 reakfast session webinar - 2020 September 29. No RSVP received.
Black River First Nation (BRFN)			
2020 March 16	Teleconference	BRFN CNL	Discussed next steps and meeting to review the IR responses.
2020 April 03	Teleconference	BRFN BON HWFN CNL CNSC	Discuss the decommissioning of the Whiteshell Site.
2020 August 26	Meeting with CNL and Consultant	HTFC CNL	Meeting with Consultant representing BRFN, BON, and HWFN. Discussed initial thoughts on the Indigenous Advisory Committee – Participation Agreement

Date	Event / Activity	Involved Parties	Details
2020 September 02	Teleconference	CNL BRFN HWFN HTFC Planning & Design	Meeting to discuss the Indigenous Advisory Committee and Black River and HWFNs Engagement Organizational Framework.
2020 September 16	Invitation	CNL BRFN	CNL sent out an invitation to community members to attend the final breakfast session.
2020 October 20	Environmental Monitoring	BRFN HWFN MMF, SFN CNL	Community representatives observed fish processing on site and the environmental monitoring team provided an overview presentation.
2020 October 27	Teleconference – Engagement Proposal	HTFC Planning and Design CNL	HTFC and CNL met to discuss their proposed engagement structure and budget proposal.
2020 November 02	Teleconference – Engagement Proposal	HTFC Planning and Design CNL	HTFC presented an overview of their engagement structure and budget proposal. CNL asked preliminary questions about their proposal
2020 November 12	Teleconference – Engagement Proposal	HTFC Planning and Design CNL	CNL met to discuss their engagement structure and budget proposal.
Hollow Water First Nation (HWFN)			
2020 April 03	Teleconference	BRFN BON HWFN CNL CNSC	Discuss the decommissioning of the Whiteshell Site.
2020 August 26	Meeting with Consultant	HTFC CNL	Meeting with Consultant representing BRFN, BON, and HWFN. Discussed initial thoughts on the Indigenous Advisory Committee – Participation Agreement.
2020 September 02	Teleconference	CNL BRFN HWFN HTFC Planning & Design	Meeting to discuss the Indigenous Advisory Committee and Black River and HWFNs Engagement Organizational Framework.

Date	Event / Activity	Involved Parties	Details
2020 September 16	Invitation	HWFN CNL	CNL sent out an invitation to attend the final breakfast session to all Indigenous participants and encouraged the community to attend.
2020 October 20	Environmental Monitoring	BRFN HWFN MMF, SFN CNL	Community representatives observed fish processing on site and the environmental monitoring team provided an overview presentation.
2020 October 27	Teleconference – Engagement Proposal	HTFC Planning and Design CNL	HTFC and CNL met to discuss their proposed engagement structure and budget proposal.
2020 November 2	Teleconference – Engagement Proposal	HTFC Planning and Design CNL	HTFC presented an overview of their engagement structure and budget proposal. CNL asked preliminary questions about their proposal.
2020 November 12	Teleconference – Engagement Proposal	HTFC Planning and Design CNL	CNL met to discuss their engagement structure and budget proposal.
Wabaseemoong Independent Nations (WIN)			
2020 August 19	Letter	CNL WIN	CNL submitted CNL's responses to Wabaseemoong comments on the EIS.
2020 September 10	Invitation - Email	CNL WIN	CNL provided a list of all fall environmental monitoring activities and invited the community to participate.
2020 September 16	Invitation – Email	CNL WIN	CNL sent the community an invitation to CNL's final breakfast session webinar.
2020 October 08	Email – Site Tour	CNL WIN	CNL proposed a date for the site tour and requested a meeting to discuss Wabaseemoong's comments on the EIS
2020 October 29	Email – Site Tour	CNL WIN	CNL followed up to determine whether Wabaseemoong wanted to discuss CNL's responses to their comments. CNL to date has not received a response.
Grand Council of Treaty 3 (GCT3)			
2020 July 21	Site tour	GCT3 CNL	Tour of WR-1 and the WMA.
2020 August 12	Meeting with CNL and GCT3	GCT3 CNL	Introductory meeting between Grand Council Treaty #3 and CNL's Indigenous Engagement Officer to discuss the WR-1 ISD project.

Table 56: Identified Indigenous Communities

Indigenous Communities and/or Representative Organizations	Identification Rationale and Proximity to WR-1*
Sagkeeng First Nation (Treaty No. 1 and 3)	Potential, asserted and/or established Indigenous and Treaty rights exist in the vicinity of the Project. Proximity to the WL site. Occupy one reserve located 52 kilometres (km) north of the WL site, and downstream along the Winnipeg River. Existing relationship and interest in the WL site.
Brokenhead Ojibway Nation (Treaty No. 1)	Potential, asserted and/or established Indigenous and Treaty rights exist in the vicinity of the Project. Proximity to the WL site. Occupy three reserves: 44 km northwest, 55 km northwest and 73 km southwest of the WL site respectively. Interest expressed, comments on Project description.
Manitoba Metis Federation (MMF)	The MMF is the official democratic and self-governing political representative for the Métis Nation's Manitoba Métis Community. Potential, asserted and/or established Métis harvesting rights in the vicinity of the Project. Interest expressed, comments on Project Description.
Black River First Nation (Treaty No. 5)	Potential, asserted and/or established Indigenous and Treaty rights exist in the vicinity of the Project. Proximity to the WL site. Occupy one reserve 75 km north of the WL site.
Hollow Water First Nation (Anishinaabe (Ojibwa) (Treaty No. 5)	Potential, asserted and/or established Indigenous and Treaty rights exist in the vicinity of the Project. Occupy one reserve, 113 km north of the WL site.
Shoal Lake No. 40 (Treaty No. 3)	Potential, asserted and/or established Indigenous and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. Occupy three reserves: 94 km southeast, 110 km southeast and 140 km southeast of the WL site, respectively.
Iskatewizaagegan No. 39 Independent First Nation (Shoal Lake No. 39 First Nation) (Treaty No. 3)	Potential, asserted and/or established Indigenous and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. Occupy four reserves: 93 km southeast, 102 km southeast, 110 km southeast and 140 km southeast of the WL site respectively.

Indigenous Communities and/or Representative Organizations	Identification Rationale and Proximity to WR-1*
Northwest Angle No. 33 (Treaty No. 3)	Potential, asserted and/or established Indigenous and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. Occupy three reserves: 111 km southeast, 140 km southeast and 176 km southeast of the WL site, respectively.
Wabaseemoong Independent Nations (also known as Wabaseemoong Independent Nations of One Man Lake, Swan Lake and White Dog) (Treaty No. 3)	Potential, asserted and/or established Indigenous and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the WL site. Occupy four reserves: 80 km east, 85 km east, 95 km east and 140 km southeast of the WL site, respectively.
Grand Council of Treaty 3 (specific to this project includes: Shoal Lake No. 40 First Nation, Iskatewizaagegan No. 39 Independent First Nation (Shoal Lake No. 39 First Nation), Northwest Angle No. 33, Wabaseemoong Independent Nations, and Sagkeeng First Nation)	Umbrella treaty organization which represents 28 First Nations and 5 with potential interest in the Project. Treaty 3 territory includes parts of eastern Manitoba, including the WL site.
Chiefs of Ontario (specific to this project includes: Shoal Lake No. 40 First Nation, Iskatewizaagegan No. 39 Independent First Nation (Shoal Lake No. 39 First Nation), Northwest Angle No. 33, and Wabaseemoong Independent Nations)	First Nations umbrella organization that represents 133 First Nations and 4 with potential interest in the Project.

16 ACRONYMS

AECL	Atomic Energy of Canada Limited
ALARA	As Low As Reasonably Achievable (economic and social factors being taken into account)
ALWTC	Active Liquid Waste Treatment Center
ATG	Analytical Test Group
CBOD	Carbonaceous Biochemical Oxygen Demand
CCSF	Concrete Canister Storage Facility
CNL	Canadian Nuclear Laboratories
CNSC	Canadian Nuclear Safety Commission
CRL	Chalk River Laboratories
CSA	Canadian Standards Association
CSD	Criticality Safety Document
DCP	Dose Control Point
DDP	Detailed Decommissioning Plan
DL	Detection Limit
DRL	Derived Release Limits
EA	Environmental Assessment
EmP	Emergency Preparedness
EOC	Emergency Operations Center
GHG	Greenhouse Gas
GWP	Global Warming Potential
HCF	Hot Cell Facility
HCFC	Hydrochlorofluorocarbons
HEPA	High Efficiency Particulate Air (Filter)
HU	Human Performance
IAEA	International Atomic Energy Alliance
IFTF	Immobilized Fuel Test Facility
ILLW	Intermediate – Level Liquid Waste
ILW	Intermediate – Level Waste
ImpAct	Improvement Actions

LGD	Local Government District
LLD	Lower Limit of Detection
LLW	Low – Level Waste
LLLW	Low – Level Liquid Waste
LLLWTS	Low – Level Liquid Waste Treatment Center
LMDL	Laboratory Method Detection Limit
LSVCTF	Large Scale Vented Combustion Test Facility
MPNU	Most Probable Number of Units
NFPA	National Fire Protection Association
NPRI	National Pollutant Release Inventory
PAD	Personal Alarming Dosimeters
PIP	Periodic Inspection Plan
PM	Particulate Matter
R&D	Research and Development
RAM	Radioactive Material
RM	Rural Municipality
RMDL	Regulatory Method Detection Limit
RP	Radiation Protection
RSTD	Relative Standard Deviation
SAR	Safety Analysis Report
SCA	Safety Control Area
SF	Shielded Facilities
SMAGS	Shielded Modular Above Ground Storage
SRI	Smallest Reporting Increment
TDG	Transportation of Dangerous Goods
TLD	Thermoluminescent Dosimeters
TSS	Total Suspended Solids
UFTP	Used Fuel Transportation Package
WL	Whiteshell Laboratories
WMA	Waste Management Area
WR-1	Whiteshell Reactor 1

APPENDIX A Concrete Canister Storage Facility

A.1 Operations

The Concrete Canister Storage Facility (CCSF) is operated under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [51]. Concrete storage canisters located at the CCSF have been used at WL since 1975 to store irradiated fuel; there are currently 16 canisters in use.

During 2020, staff of the Site and Nuclear Operations Branch monitored the operation of the CCSF.

The CCSF was operated in compliance with practices and procedures approved for operation. All required surveys and inspections were completed in 2020.

Routine operations in the CCSF were carried out by staff in the Site and Nuclear Operations Branch.

There were no changes in the staffing or organization for the operating staff responsible for the CCSF in 2020.

In 2020, the CCSF continued to maintain the minimum staffing requirements outlined in the CCSF Facility Authorization [51]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the CCSF in 2020. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

A.2 Compliance Monitoring

A.2.1 Air Effluent Monitoring of Canister Liners

Each canister has a closed air-circulating system to monitor the internal space between the canister liner and the sealed fuel basket for the presence of fission products and moisture. Canisters are monitored for one week per month between April and November, dependant on weather. This year readings began in May and concluded in October.

The gross beta activity was below or near the detection limit of 0.04 Bq/m^3 for all canisters.

There was no visible moisture detected from the internal canister space during 2020 monitoring, however, the silica gel used in the counting did change colour from blue to pink indicating moisture in the air is present.

A.2.2 Monitoring of Ground and Surface Water

Figure 11 shows the drainage area surrounding the CCSF. Further details on monitoring and results of monitoring ground and surface water can also be found in Sections 9.4.1.3 and 9.5.1.4, compliance results for the CCSF are described below.

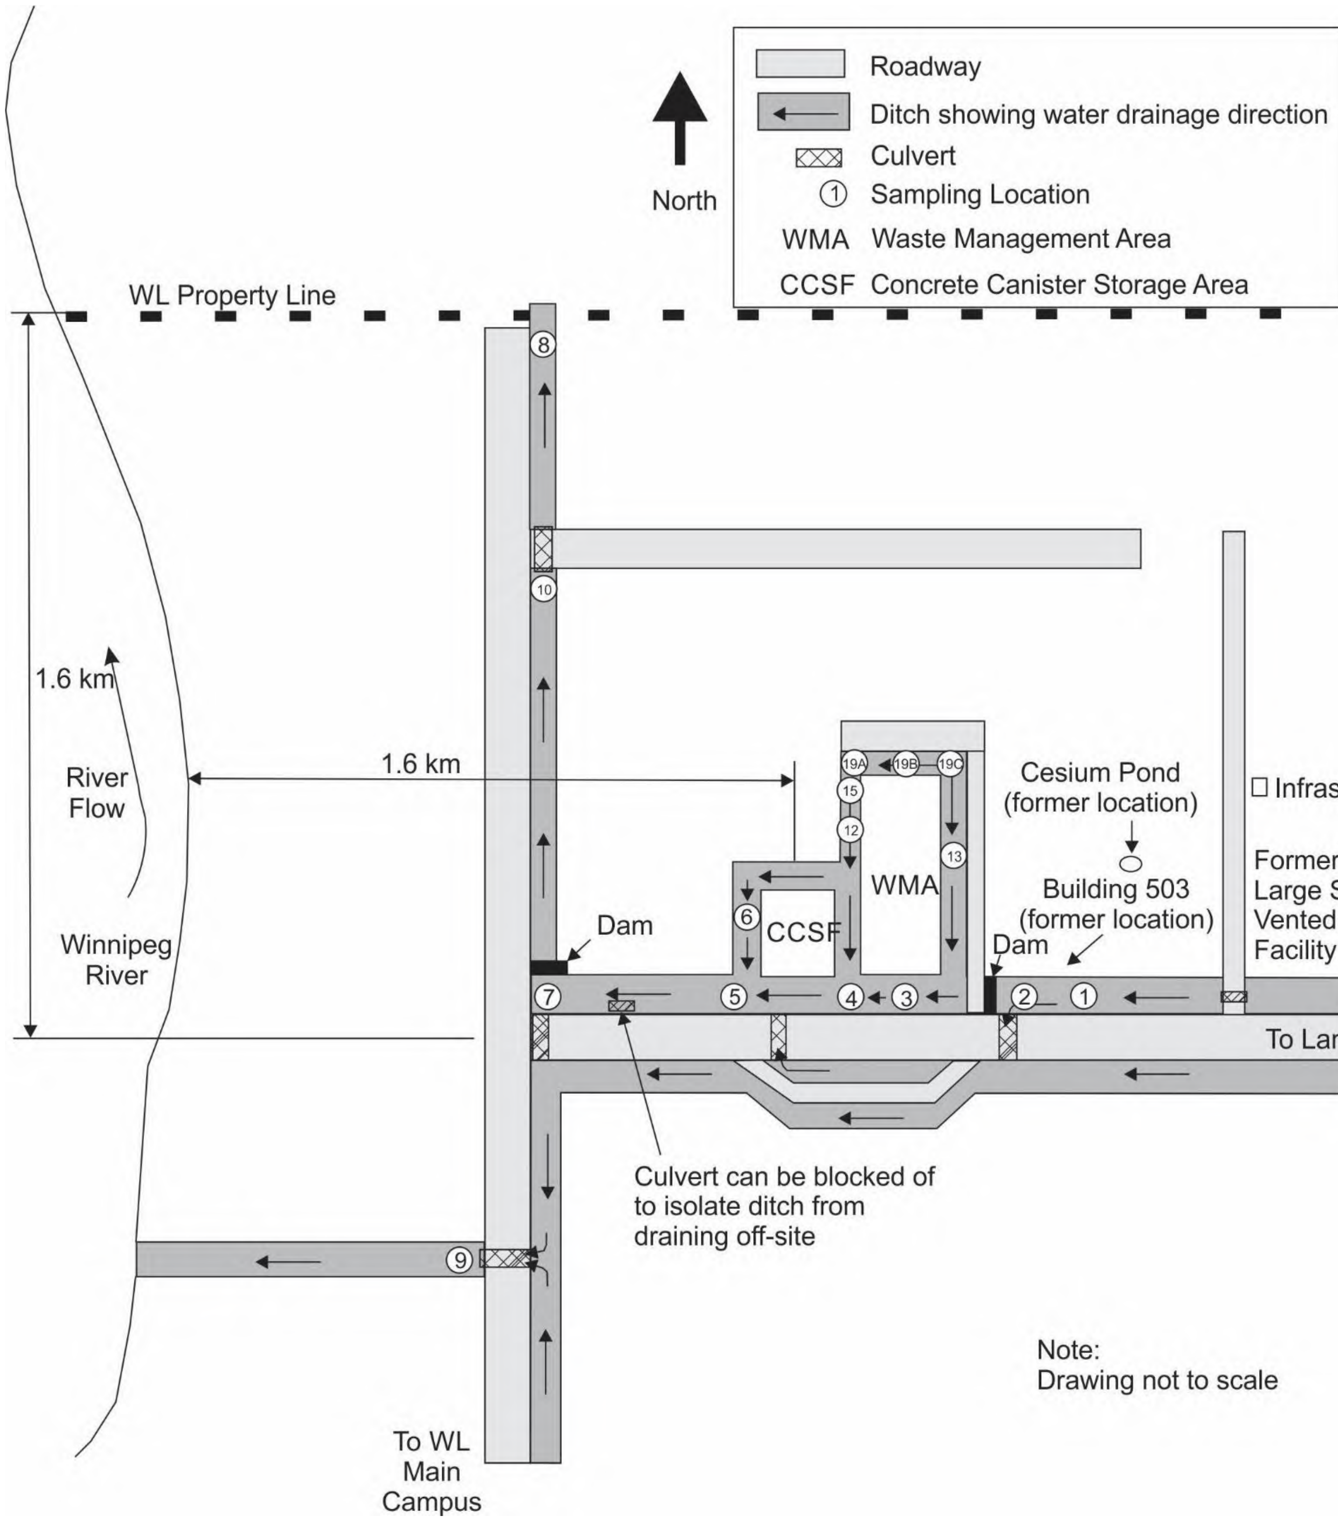

Figure 11: Surface Water Drainage Sample Points

Groundwater samples from deep-well sites in the vicinity of the CCSF are obtained twice yearly; the results are reported and discussed in Appendix D of this report.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the canisters. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry analysis and processed for Sr-90. Gamma spectrometry analysis provides individual results for Co-60, Nb-94, Sb-125, Cs-134, Cs-137 (Ba-137m), Pm-147 and Am-241.

If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry analysis and uranium analysis. Uranium analysis has also been conducted for other sampling locations below the limit this year. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration established by Health Canada [34]. If uranium is detected, the result is evaluated against the Maximum Acceptable Concentration for uranium (0.5 Bq/L).

Note that in some occasions locations were sampled on a two day period due to rain conditions on those periods. Ditch Location 5 and Ditch Location 6 samples (see Figure 11 for sampling locations) could contain surface drainage from the CCSF. The gross beta level in Ditch Location 5 and Ditch Location 6 did not reach the trigger level (10 Bq/L) for gamma spectrometry and strontium analysis this year. The highest value noted (0.95 Bq/L) was in Ditch 5 from the June 8 and 10 measurement set. Half of this activity would be attributable to Sr-90 (assuming secular equilibrium with Y-90) at the applicable Maximum Acceptable Concentration of 5.0 Bq/L, and the remaining activity is below the Maximum Acceptable Concentration for Y-90 (30 Bq/L).

The alpha activities were below the trigger level of 0.5 Bq/L, with the exception of Location 5 (0.80 Bq/L) from the June 8 and 10 measurement set.

Ditch samples collected immediately downstream from the WMA (Locations 5, 6 and 7) contained elevated levels of tritium[13] (see Table 59). None of these samples exceeded the associated Maximum Acceptable Concentration of 7,000 Bq/L [34]. The activity seen is likely from the WMA as discussed in Appendix D.

Table 57, Table 58, Table 59 and Table 60 list the results of the surface-water samples taken from the vicinity of the CCSF and WMA during 2020. Operational control-monitoring data from previous years has been included for completeness.

[13] Tritium analysis of samples from Ditch Locations 5 and 6 was previously discontinued due to the higher levels of tritium (~4000 Bq/L) noted at upstream locations associated with the WMA.

A.3 FACILITY CHANGES

All facility changes were performed as per the Engineering Change Control procedure [14]. There were no major facility changes made in 2020.

A.4 Equipment Performance, Planned Maintenance Testing and Inspections

During 2020, a program to examine the accessible basket parts was done using a remote borescope camera.

All canisters are checked for deviation from vertical annually. Out of 16 canisters, all displayed slight deviations from vertical in 2020. None of the canisters had a deviation greater than 1°. In 2020, Canister C5 had a deviation of 0.7° to the east. This deviation and those seen on other canisters show that they all display slight movements in response to changing soil moisture conditions and related swelling and contraction of the clay layer. If a canister was noted either through vertical deviation measurements or visually to be trending beyond a 2-3° deviation, corrective measures such as bracing would be considered.

There were no canister loading or unloading operations in 2020.

As required by Section 8 of the Facility Authorization [51], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests were complete. The inspections were all completed.

Whiteshell Laboratories staff conducted general site inspections during each quarter of 2020. The general appearance and fencing were found to be satisfactory on each inspection. Minor infilling was done along the base of the fence to meet security requirements.

In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however, existing cracks and pour pockets were regularly checked for changes and it has been noted that edges of many pour pockets are more brittle than in the past. Selective patching is done of these pour pockets, only minor patching was conducted in 2020. No increased radiation field was noted from the canisters. There was no degradation of the exposed metallic portions of the canisters.

A.4.1 Canister Site Monitoring and Surveillance

Gamma Field Surveys

Gamma exposure rates from the canisters were measured quarterly in 2020. These readings were taken in compass directions north-east-south-west, on contact, and 2.0 m from the canister wall at an elevation of 2.0 m above grade level.

No field anomalies were found during 2020, but there was a slight decrease in the average readings on Canister C-18.

Table 61 shows the averaged gamma near contact exposure rates measured during 2020, and for the previous four years.

Table 61: Summary of Average Gamma Radiation for Near Contact Measurements from Fuelled Canisters (mrem/h)

a The measurements were made using a BOT P200 survey meter. The instruments are calibrated in mR/h and it is assumed 1 mR/h =1 mrem/h

Air Monitoring

Air monitoring was conducted on each of the canisters in the CCSF in 2020. This involves an air pump that circulates air from and outlet line on the canister through a Dexter filter and returns it through an inlet line. These readings are taken once per month over a period of approximately one work week during warm weather months. Typically this is the six months of the year when air temperatures are normally above zero.

No anomalies were found during 2020, and there was no change in results as compared with previous surveys.

Table 62 shows the averaged beta readings on each filter measured during 2020, and for the previous four years.

Table 62: Summary of Average Beta Radiation Measurements from Fuelled Canisters (Bq/filter)

Canister Number	Average Air Sampling Measurements			Canister Number	Average Air Sampling Measurements

A.5 WASTES GENERATED

There were no radioactive and/or hazardous wastes generated in the CCSF as part of routine operations.

See Section 11.1 Waste Management Program for summaries of any volume of radioactive solid and/or liquid waste generated in the CCSF in 2020.

A.6 EFFLUENTS RELEASED

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the CCSF as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection.

APPENDIX B Active Liquid Waste Treatment Center

B.1 Operations

The Active Liquid Waste Treatment Center (ALWTC) in Building 200 is operated under the WL Site Licence [1], in accordance with the requirements of the ALWTC Facility Authorization [52] while facilitating and harmonizing the decommissioning activities as prescribed in the established work plan. During 2020, the ALWTC was monitored and operated by Site and Nuclear Operations Branch personnel.

In 2017, new LLLWTS began operation in Buildings 100 and 300. All of the Building 100 low level liquid waste is now being tested, treated and controlled release to the river in the Building 100 LLLWTS and likewise in Building 300. All of the collection tanks in Building 200 were then isolated and taken out of service. The Building 200 sumps have also been taken out of service and any water collected from the sumps and associated piping is put into drums for processing. Decommissioning of the Low-Level Liquid Waste (LLLW) and Intermediate-Level Liquid Waste (ILLW) systems in Building 200 are underway.

Passive evaporation from Tank 807 ILLW is no longer conducted, nor is any ILLW stored in Building 200. The contents of Tank 807 was pumped into road-transportable containers in 2013, and the first shipment of this liquid was sent to an offsite processing facility for volume reduction. The remaining liquid is stored in road-transportable containers (5,400 L) in a Quonset in the WMA. Plans are underway to purchase and install a LLLW and ILLW waste processing facility in LLW Bunker 6 at the WMA, and then process the stored liquid waste onsite.

In 2020 October, the last of the operating systems in Building 200 were shut down and isolated (ventilation and compressed air systems). The building was rendered cold and dark and demolition of the building started later in October. At the end of 2020 November, the demolition of Building 200 was halted and placed into a safe state due to a safety shutdown by CNL of the Whiteshell Site. The building remained in this state for the remainder of 2020. Demolition of Building 200 will be completed in 2021.

Routine operations in the ALWTC were carried out by four operating staff from the Site and Nuclear Operations Branch.

There were no changes in the staffing or organization for the operating staff responsible for the ALWTC in 2020. There was a change in Facility Authority as communicated to the CNSC [53].

All operating procedures and other associated procedures for Building 200 have also been cancelled. In 2020, the facility continued to maintain the minimum staffing requirements outlined in the ALWTC Facility Authorization [52]. Staffing was maintained at levels to provide the needed operational and safety support.

In October 2020, CNL notified the CNSC that the ALWTC, Building 200 is being demolished and requested that the Facility Authorization [52] and the Safety Analysis Report [54] associated with the ALWTC be removed from the Whiteshell Laboratories LCH [12]. CNSC granted this request in December [55].

B.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [14]. Building 200 was turned over to decommissioning near the end of 2017 to begin the decommissioning of the building. Decommissioning of the LLLW systems was completed in 2019. All the laundry, decontamination, WR-1 and

Building 300 LLLW collection systems in Building 200 have been removed except for the collection tanks. The removal of the ILLW system was completed in 2020. The demolition of the building is approximately 50% complete at the end of 2020.

B.3 Equipment Performance, Planned Maintenance Testing and Inspections

The Facility operated satisfactorily in 2020.

As required by Section 8 of the Facility Authorization [52], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests and inspections were completed. Monthly housekeeping and fire prevention inspections were completed.

Low-Level Liquid Waste System

The low-level liquid waste system is shut down and decommissioned.

Medium-Level Liquid Waste System

The medium-level liquid waste (intermediate-level liquid waste) system is no longer in use and is decommissioned.

Ventilation System

Routine Poly-Alpha-Olefin testing of the exhaust High Efficiency Particulate Air (HEPA) filter was carried out satisfactorily in 2020 May. All filters had acceptable penetrations of less than 0.03%. The November testing was not required because the ventilation had been shut down and demolition of the building started.

B.4 Wastes Generated

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the ALWTC in 2020.

There were no liquid radioactive and/or hazardous wastes generated in the ALWTC as part of routine operations.

Decommissioning of low-level and intermediate-level liquid systems generated 1 m^3 of liquid waste for 2020.

B.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the ALWTC as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection.

APPENDIX C Shielded Facilities

C.1 Operations

The WL Shielded Facilities (SF) operates under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [56]. The SF, consisting of the Hot Cell Facility (HCF) and the IFTF, are located in the R&D Complex (Building 300), and are operated by personnel in the Site and Nuclear Operations Branch.

The HCF Cells 1 to 5 and IFTF Cell 13 remain operational while HCF Cells 6 to 11 have been shut down and partially dismantled. The Waste Handling Area, located in the IFTF, was operated for compaction and assaying of radioactive waste.

Operations and decommissioning activities were conducted throughout the year. Operations activities included:

- maintenance of HCF and IFTF ventilation system equipment;
- replacement of HEPA filters;
- packaging and storage of radioactive waste;
- cleanup activities; and
- routine maintenance to ensure compliance with the site licence.

Routine operations in the SF were carried out by operating staff from the Site and Nuclear Operations Branch.

There were no changes in the staffing for the operating staff responsible for the SF in 2020. There were no organizational changes. In 2020, the SF continued to maintain the minimum staffing requirements outlined in the SF Facility Authorization [56]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the SF in 2020. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

C.2 FACILITY CHANGES

All facility changes were performed as per the approved Engineering Change Control procedure [14].

C.3 Equipment Performance, Planned Maintenance Testing and Inspections

As required by Section 8 of the Facility Authorization [56], all routine maintenance for safety related systems was carried out as per the facility maintenance plan, and all equipment tests and inspections were complete. Monthly housekeeping and fire prevention inspections were completed.

Ventilation System

Maintenance activities requiring part of the ventilation system to be taken down occurred without incident.

The annual routine Poly-Alpha-Olefin testing of the HCF HEPA filters were successfully conducted except for Cell 13 as it required filters changes. Cell 13 was taken out of service until the filters can be replaced.

C.4 Wastes Generated

See Section 11.1 Waste Management Program for WL summaries of the volume of any volume of radioactive solid and/or liquid waste generated in the SF in 2020.

Low-Level Solid Waste

In 2020, the SF generated 10.8 m^3 of compactable low-level radioactive solid waste and 0.1 m^3 of non-compactable waste.

The Waste Handling Area processed 162.0 m^3 of low-level radioactive solid waste which was reduced to 15 m^3. A portion of this waste was generated in the SF, and the remainder came from all of the nuclear facilities and decommissioning projects at WL where waste is being generated.

Table 63 lists the annual low-level solid waste generated in the SF for 2020 and the previous four years.

Table 63: Solid Wastes Generated

Total Volume	2016	2017	2018	2019	2020
Low-Level Solid Waste (m^3)	47.7	0.4	73.3	64.3	10.9
Medium-Level Solid Waste (m^3)	0	0	0	0	0

Medium-Level Solid Waste

In 2020 the SF generated no medium-level (intermediate-level) radioactive solid waste. Table 63 lists the annual medium-level solid waste generated for 2020 and the previous four years.

Low-Level Liquid Waste System

In 2020, 99 m^3 of low-level liquid waste was processed through the Building 300 low-level liquid waste system (see Appendix E).

Medium-Level Liquid Waste System

All the medium-level liquid waste (intermediate-level liquid waste) from the HCF cells collects in the HCF sump tank, AD Tank 1. The liquid is transferred via a manually controlled pump from AD Tank 1 through a filtration system to AD Tank 14 in the IFTF. The liquid from all other HCF medium-level liquid waste drains and all IFTF medium-level liquid waste drains flows by gravity to AD Tank 14.

In 2020, there was one transfer of 0.12 m^3 medium-level liquid waste to transportable totes that is being stored for future disposition.

Table 64 lists the annual aqueous waste generated for 2020 and also for the previous four years.

Table 64: Building 300 Liquid Waste Volumes

Year	Low-Level Waste System[a]		Medium-Level Waste System[b]
	Total Volume (m^3)	Activity	Total Volume (m^3)
2016	195.4	0.039GBq β 0.006GBq γ 0.004GBq α	0
2017	164.0	0.073GBq β 0.007GBq γ 0.003GBq α	0
2018	123.0	0.016GBq β 0.006GBq γ 0.003GBq α	0
2019	186.5	0.035GBq β 0.008GBq γ 0.0027GBq α	1.2
2020	99	0.046GBq β 0.001GBq γ 0.008GBq α	0.12

a Total volume for Building 300 (Sumps)
b Total volume can be attributed to the SF

C.5 EFFLUENTS RELEASED

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection.

Liquid radioactive and/or hazardous effluents were discharged from the SF as part of routine operations.

APPENDIX D Waste Management Area

D.1 Operations

The Waste Management Area (WMA) operated under the WL Site Licence [1], in accordance with the requirements of the *Facility Authorization for the Operation of the Waste Management Area at the Whiteshell Laboratories* [57]. During 2020, the WMA at WL was operated and monitored by staff in the Site and Nuclear Operations Branch.

In 2020, the WMA was operated in compliance with approved practices and procedures.

Routine operations in the WMA were carried out by the Facility Manager, WMA Operator and two WMA based utility workers, with support from other Site and Nuclear Operations personnel and Environmental Monitoring personnel as required.

There were no changes in the staffing or organization for the operating staff responsible for the WMA in 2020. There was a change in Facility Authority as communicated to the CNSC [53].

In 2020, the WMA continued to maintain the minimum staffing requirements outlined in the Facility Authorization [57]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the WMA in 2020. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

D.1.1 Inventory Additions And Deletions

Changes in inventory are reported in Table 65 and for the purposes of reporting WMA inventory (fission products are defined as radioactive material originating from irradiated fuel).

Activation products are defined as any material that has been activated in a neutron flux, including corrosion products. The radioactivity values listed are those recorded at the time of storage.

D.1.2 Low-Level Solid Waste

Details of wastes transferred to the WMA are provided in Section 11.1.1. Waste generated from decommissioning work on the site was generally shipped to CRL for storage, although some waste was stored in the WMA. Some of the inventory of stored waste in WMA was sent to CRL for storage pending future disposal. The stored volume of waste is listed in Table 65.

D.1.3 Industrial Waste

There were no additions of industrial chemical waste during 2020.

Table 65: Additions to Low-Level Waste Inventory

Period	Storage Locations	Volume (m^3)	Fission Products (GBq)	Activation Products (TBq)
Total Accumulation to 2019 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433, and Building 923	19,293.86	2,147.87	330.59
Additions for 2020	Building 923, SSC, Building 431 to 433	32.33	16.97	0.00
Removals for 2020	Building 923 SSC LLW Bunker 6 B411 B514	112.50 14.00 182.00 198.80 20.40	0.16 52.70 48.50 85.90 10.20	0.00 0.00 0.01 0.00 0.00
Total Accumulation as of 2020 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433, Building 923 and SSC	18,798.84	1,967.38	330.58

D.2 Compliance Monitoring

D.2.1 Monitoring And Surface Water

Surface Water

Figure 11 shows the drainage area surrounding the WMA.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the WMA. The WMA and CCSF share a network of perimeter compliance monitoring ditches with designated sampling locations. Water samples are collected in these sample locations for analyses when there is sufficient flowing water present. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

A recorded amount of precipitation of 441 mm occurred in 2020, which was less than the 646 mm recorded in 2019. The majority of the precipitation was rainfall in July (90mm) and August (111mm) of 2020. The low precipitation is reflective of a drought year in the area.

In an effort to streamline the operational environmental monitoring process, surface water samples are initially analyzed for gross beta, gross alpha, and tritium. The results are then evaluated using the following screening criteria:

- If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry, and processed for Sr-90. Gamma spectrometry provides individual results for Co-60, Nb-94, Sb-125, Cs-134, Cs-137 (Ba-137m), Pm-147, Am-241.
- If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry and uranium analysis, however, as was the case last year, all water samples were tested for uranium. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable

Concentration (MAC) established by Health Canada [34]. If uranium is detected, the result is evaluated against the MAC for uranium (0.5 Bq/L or 20 ppb).

Levels of beta activity at ditch sample Locations 1 to 7 (Table 66) all remained well below 10 Bq/L. Based on historical data, it is conservatively assumed that the beta activity in the surface water is Sr-90 in secular equilibrium with Y-90. Most beta activity levels in the ditch water remained below the drinking water screening level of 1 Bq/L and below the drinking water limit of 5 Bq/L for Sr-90 and 10 Bq/L for Cs-137 [58]. Compliance with Guidelines for Canadian Drinking Water [34] may be inferred if the measurement for gross alpha and gross beta is less than 0.5 Bq/L and 1.0 Bq/L, respectively. In several measurements there were exceedances of the Canadian Drinking Water [34] standard of 1.0 Bq/L (Table 66), however no increasing trend was noted and all values for beta had returned below 1.0 Bq/L by the final measurements of the year on 2020 August 31.

The alpha activity levels in the surface water are presented in Table 67, and were below the trigger level of 0.5 Bq/L, except for the measurements on 2020 June 8 and 10. This represents one set of samples taken over those two days. Uranium values recorded from those samples ranged from 2.62 ppb at Location 1 to 29.40 ppb at Location 6. Uranium results are presented in Table 68.

There was no flow at Locations 19 A, B and C in this year. In past years, the uranium values recorded at these locations are believed to result from the use of local Lac du Bonnet Batholith granitic rock as base material for the SMAGS foundation. This rock had been also used for berm support material for the Cesium Pond pile, however that material was removed from the WMA in 2018. The Lac du Bonnet Batholith granite is noted to have naturally occurring uranium.

As shown in Table 69, the tritium results are below the Maximum Acceptable Concentration of 7000 Bq/L [34] at all locations. Tritium was measured at a maximum of 600.6 Bq/L at Location 3, with all other results through the year lower than that value. Location 3 receives surface water from a swale that leads north from the location alongside ILW Bunkers 1-4, and overland drainage from the south trenches, including Trench 7, which is known to contain tritium containing waste. Tritium detected at Location 3 would contribute to that seen in Locations 4, 5 and 7. In 2020, no flow occurred at and thus no measurements were made at Locations 19 A, B and C. The elevated readings that existed in this area in previous years likely resulted from migration of tritium in the clay columns from WR-1 stored in Trench 23. Trench 23 is nearest Location 19C. Locations 19 A, B and C were originally chosen for sampling for the potential migration of cesium-137 due to the presence of the Cesium Pond soil pile. Although the Cesium Pond soil has been removed, CNL will continue to monitor locations 19 A, B and C due to the elevated levels of tritium.

The WMA contains a number of trenches with varying amounts of low-level radioactive waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. Based on the initial modelling [59], it was proposed that tritium would be present in the ditches (including the Locations 3 through 7 and 19 A, B and C) and possibly reach levels as high as 37 kBq/L. While tritium is elevated immediately around the WMA, periodic monitoring of the ditches has indicated that the levels of tritium at the points (Locations 8 and 9) leaving CNL property remain quite low (below an average value of 4.5 Bq/L in 2020). Although the amount measured in Locations 1 to 7 are above that noted at the Control location, the levels are much lower than the Maximum Acceptable Concentration in drinking water for tritium (7000 Bq/L).

From the 2020 April 01 and 02 samples, Carbon 14 was noted with a value of 14.3 Bq/L in the east ditch of the WMA (Location 13), which is an order of magnitude less than the Canadian Drinking Water Guideline of

200 Bq/L [34]. Other values measured at Location 13 were 1.3 Bq/L on April 07, 2.5 Bq/L on June 08, 1.9 Bq/L on July 14 and 1.4 Bq/L on August 31, and 1.8 Bq/L at Location 10. Location 10 is to the east of the WMA and is unaffected by surface water flow from the WMA. A potential source for the C-14 at Location 13 may be from residue from barrels previously held in the area of Trench 1 and 2 while awaiting incineration in the now decommissioned Building 514 incinerator on the east side of the WMA. It may also relate to potential surface clay fissuring from the dry summers in 2019 and 2020. The reading from 2020 April may represent mobilization from initial meltwater. Further measurements will be taken in 2021 as ditch water flows permit.

Table 66, Table 67, and Table 68 present the WMA surface-water sampling data. The data represents continuing documentation of a spill incident that occurred in 1979 near ILW Bunker 3, at the reference sample point (Location 3) in the southeast section of the WMA, as shown in Figure 11 and Figure 12. In 2017, sampling Location 3 was reconfigured to allow preparations for future bunker and standpipe remediation, but the location was dry this year due to dry summer. Surface water at this location serves as an indicator of movement of water from ILW Bunkers 1, 2 and 3. The most mobile radionuclide (tritium) is below the associated Maximum Acceptable Concentration. The levels of tritium in the surface water and groundwater is below the radiation screening criteria used for identifying contaminants of potential ecological concern (COPECs) of 1.27×10^{7} Bq/L [60]. These tables, and Table 69, have been expanded to include the historical monitoring at Ditch Locations 19 A, B and C.

The Cesium Pond soil (Cs-137) that was stored in the WMA adjacent to SMAGS was removed in 2017. There was no flow recorded in the north WMA ditch in 2020 (Locations 19 A, B and C) (Figure 12). Table 70 reflects this circumstance and shows that previous years indicated no migration of Cs-137 to these ditches.

As Trench 16 has a known quantity of Technetium-99 (Tc-99), ditch water measurements were made in 2020 to determine if the radioisotope was present. Sample Location 13, nearest Trench 16, gave an average value of 1.66 Bq/L from three readings (April 01/02, April 07 and July 14). Other sample locations provided similar low values of Tc-99 (Table 71) suggesting values are at the limit of detection. The Tc-99 limit for drinking water is 200 Bq/L [58].

Table 66: Gross Beta Activity of Surface Water Samples from Ditches Around the Canister and Waste Management Area

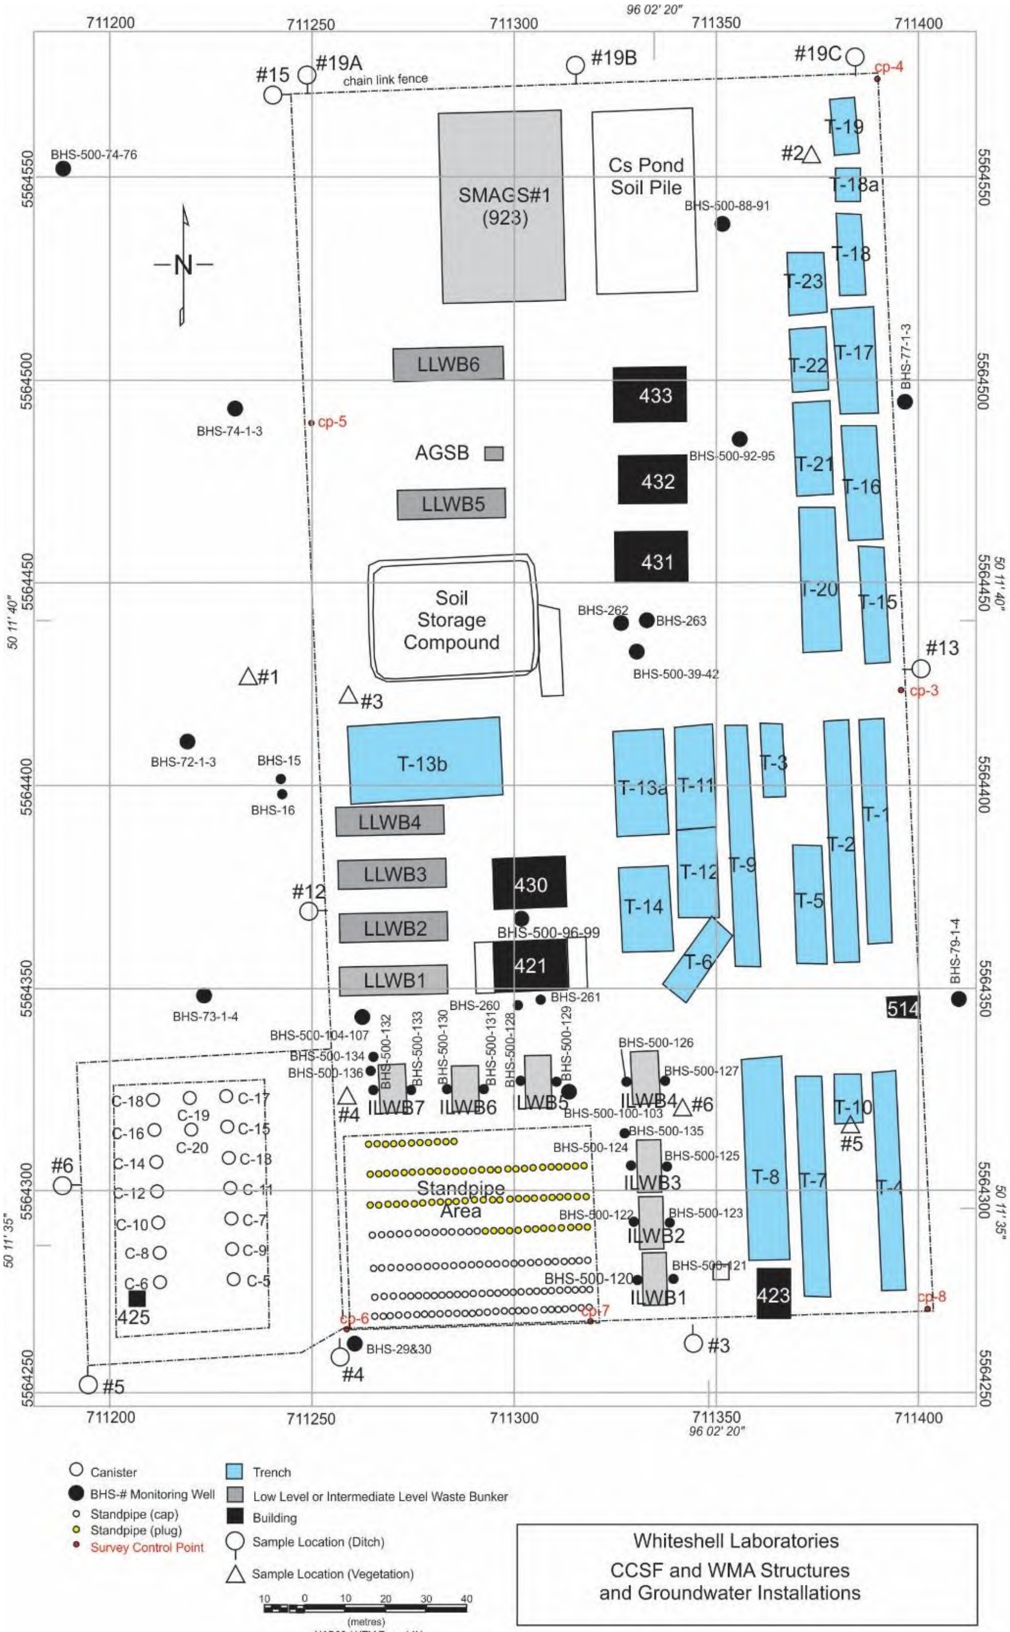

Figure 12: Ground Water Sample Points

Intermediate - Level Waste Bunkers Near Field Wells

A series of shallow near field wells were installed adjacent to the Intermediate - Level Waste bunkers in the WMA in 2015 (Figure 11). Groundwater samples were taken from the wells and from water in the Intermediate - Level Waste Bunkers for comparison. Cs-137, Sr-90, and tritium were selected as the radionuclides for monitoring of the potential for contaminant migration. Cs-137 was selected as the least mobile, with a high affinity for bonding with clay-based minerals, Sr-90 is more mobile but will bond with sand, and tritium is the most mobile that moves with water. Cs-137 and Sr-90 require a pathway (e.g., a construction joint or crack) to migrate from a bunker. In 2020, Sr-90 was noted to be a maximum of 25 Bq/L adjacent to ILW Bunker 1, and < 13 Bq/L adjacent to ILW Bunker 3. For all other locations, the Sr-90 and Cs-137 levels were minor or negligible. Tritium can move through concrete without cracks by diffusion with water movement. The results indicate no migration of Cs-137 (Table 72) from the Intermediate - Level Waste Bunkers, and Sr-90 (Table 73) and tritium levels (Table 74) that are orders of magnitude below the levels observed in the water in the adjacent Intermediate - Level Waste Bunkers. At ILW Bunker 3, the tritium results remain high, with a second year of increasing values at BHS-500-124.

A series of water measurements was made as a confirmatory check in 2020 for the presence of base neutral chemicals (e.g., benzenes, ethylenes) and PCBs. These measurements indicated these chemicals were not present in the water around the bunkers.

Water Table Wells and Deep Wells

Water samples were collected from wells in and around the WMA (Figure 12) in the spring and fall of 2020. The gross alpha and gross beta results are summarized in Table 75. The beta activity levels in the clay, clay till and basal zone wells remained below the drinking water screening level of 1 Bq/L. All zones were below the limit for Sr-90 (5 Bq/L) and Cs 137 (10 Bq/L) [34]. The average alpha activity in the samples collected from the Basal zone wells was below the screening level.

Uranium concentrations in the basal zone wells ranged from 0 to 0.99 Bq/L. The concentrations in the Clay zone wells ranged from 0.23 to 1.41 Bq/L, and in the clay till from 0 to 1.37 Bq/L. Since it is known that the local well waters within the Canadian Shield contain naturally occurring uranium [61], the presence of uranium and its progeny are not unexpected and are considered to account for the levels of alpha. Low levels of tritium were noted in the clay (7.56 Bq/L) and clay-till (21.31 Bq/L). This is not unexpected as these overburden layers are impacted by tritium in the WMA.

In 2020, sampling of wells for DDT was conducted in wells within and surrounding the WMA as a confirmatory check. No DDT was detected.

Table 75: Monitoring Data Water Table Wells and Deep Wells

High-Level Liquid Waste Tray Water

Monitoring of the high-level liquid waste tank tray water was carried out to confirm there is no leakage from the residue remaining in the storage tanks. This is sampled in the summer months. The sample results indicated no leakage has occurred from the tanks. The data are summarized in Table 76. In the late fall of 2004, the high-level liquid waste had been removed from high-level liquid waste Tank 2 and transferred to the SF for cementation. A heel of waste remains to be removed. High-level liquid waste Tank 1 remains empty.

Table 76: Monitoring Data High-Level Liquid Waste Tank Tray Water

WMA Sample Locations	2016 Avg (Bq/L)	2017 Avg (Bq/L)	2018 Avg (Bq/L)	2019 Avg (Bq/L)	2020 Avg (Bq/L)	2020 Range (Bq/L)
Total Beta [a]						
Tank Tray Water	11.9	13.8	13.8	12.1	11.2	4.1 to 16.7
Total Alpha [b]						
Tank Tray Water	< 0.6	0.65	0.69	1.5	0.95	0.13 to 1.5

a The reference nuclide for total beta is Sr-90, gamma results indicate that approximately 13Bq/L of the gross beta activity is due to K-40.

b The reference nuclide for total alpha is Pu-239

D.2.1.1 Radiation Field Measurements

Radiation field measurements are taken semi-annually at established points (normally every 38 m) along the perimeter fence. The 2020 radiation field measurements were similar to those in 2019. The data is summarized in Table 77.

Table 77: Perimeter Fence Monitoring Data

WMA	Radiation Field (µSv/h)					
	2016 Avg	2017 Avg	2018 Avg	2019 Avg	2020 Avg	2020 Range
Spring Survey

North Fence	0.2	0.2	0.2	0.2	0.3	0.1-0.5
East Fence	0.3	0.3	0.3	0.4	0.3	0.2-0.5

D.2.1.2 Vegetation

In 2020, vegetation samples were collected at monitoring locations within the WMA (Figure 12), and at a control location unaffected by WL operations. The gross beta results are summarized in Table 78. In 2020, as since 2017, the samples were only collected in the late summer-fall as it was determined that the uptake occurs over the summer, so the fall measurements presented since 2017 are more conservative than previous years. Potassium (K)-40 represents the majority of gross beta activity in most of the samples. The levels of gross beta in the samples are due to a combination of K-40 and Sr-90/Y-90, with a minor contribution from Cs-137. The average Sr-90 contribution for the vegetation samples in the WMA is 6% (12% for Sr-90/Y-90).

Results were historically reported as Bq/m^2 as there was the potential for deposition of radioactivity via airborne emissions from the former WL Incinerator and former Baler operations. The incinerator and baler have not been in operation for many years and have been decommissioned. The results are now presented as Bq/kg and represent the uptake of radioactivity from impacted areas near the sampling locations.

Table 78: Waste Management Area Vegetation Monitoring Data

WMA Sample Locations	Average Gross Beta[a] (Bq/kg)				
	2016 Avg	2017 Avg	2018 Avg	2019 Avg	2020 Avg
North-East Area[d]	488	NA	672	450	196
Mid-West Area	578	1619	411	155	173
South-West Area	575	275	414	NA	296
South-East Area	751	460	409	441	230
Control Sample[b]	632	379	187	210	162
Background Sample[c]	592	419	324	317	203
East of ILW Bunkers 3 and 4	488	NA	672	450	NA

a The reference nuclide for beta is Sr-90
b Adjacent to the WMA outside of the fence boundary
c Ambient Radiation monitor Stations Background Samples
d Until 2012 this sampling point was in the North-West area after 2012 it was moved to the North-East area. Only a single set of vegetation samples was taken as of 2017 as uptake occurs over the summer. Range is no longer included because of this change.

D.3 Facility Changes

All facility changes are performed as per the approved Engineering Change Control procedure [14].

Work to prepare for extraction of waste from the Intermediate Level Bunkers and Standpipes was begun in 2017 and continued into 2020 with most of the physical preparatory work done in starting fabrication of extraction equipment off site. A pad to the east of the north access road within the WMA was constructed. The pad will provide a location for seacans containing waste to be stored awaiting processing, characterization and packaging for off-site shipment. This was required to allow Building 923 (SMAGS) to be converted to use a Cask Loading Facility. Waste from SMAGS has been removed from the building, a limited amount of that removed waste was held in Quonsets through 2020 due to restrictions in work crews and shipments related to the COVID-19 pandemic.

The WR-1 Phase 1 decommissioning waste material was stored in Buildings 432 and 433 in the WMA. Approximately 96% of the WR-1 Phase 1 decommissioning waste stored in Buildings 432 and 433 was processed by the end of 2016. Nine oversized crates remain in Building 433, and five asbestos containing crates that moved to Building 430 were returned to Building 433 and remained there as of the end of 2020.

The marine container used for storing sealed sources that was transferred from Building 430 in the WMA to the Standpipes Protected Area to meet revised security regulations from the CNSC in 2015, remained in place through 2020. Sources are still held pending future dispositioning.

Low Level Waste Bunker #6 has largely been emptied of waste, with most being packaged for offsite shipment and removed from the site. Some waste was removed and returned to the bunker pending completion of characterization work through 2020 due to restrictions in work crews and shipments related to the COVID-19 Pandemic. Planning to convert Low Level Waste Bunker #6 to process Intermediate-Level Liquid Waste began in 2020.

Construction was completed on an access structure on the east side of Low Level Waste Bunker #5 to facilitate decommissioning of the bunker starting with waste retrieval operations planned initially in 2020, with work now planned for 2021 due to reduced operations as a result of the COVID-19 Pandemic and the fieldwork pause in November.

A Waste Transshipment Area outside the northern perimeter to allow for holding shipments of waste that are ready to be shipped, began modifications to increase its surface area and to allow access to the planned road along there west exterior of the WMA. The road to access transformers and generators to support extraction equipment was surveyed, with construction now planned for 2021.

D.4 Equipment Performance, Planned Maintenance Testing and Inspections

During 2020, the bunkers and other structures in the WMA remained fit for service. Waste stored in SMAGS was removed in 2020. Medium-Level Waste Bunker 4 did not have new waste placed in 2020 and remains ~70% full. Medium-Level Waste Bunker 6 is ~60% full; however it is not accepting waste due to water ingress issues. Medium-Level Waste Bunker 7 is ~85% full. The percentage full values are estimates only. Road transportable totes of liquid waste remain in the heated Building 430 pending future processing. Building 431 contains historic waste and is used as temporary storage for waste repackaging-characterization operations. Building 432 and Building 433 contain various historic wastes and wastes held in various stages of repacking operations. A small seepage of an oily substance was noted at the central gasket, near the base of the LLW Bunker 1 wall. The substance was sampled and found to contain oil and likely degraded liquid organic. The volume was small and the area was cleaned up. Seepage only occurred during hot weather, and as weather cooled the seepage stopped. The area will continue to be monitored. The bunker is slated for remediation of its waste in the next few years.

The Soil Storage Compound is empty of stored waste soil bags. There are three empty standpipes in the standpipe area.

In-service storage facilities were inspected for water ingress during routine waste emplacement operations. Filled storage facilities with accessible drainage sumps were inspected monthly during the summer months, when water ingress is most likely. Caulking of the roofs of all the WMA Quonset buildings with waterproof sealant was completed in 2010 resulting in reduced indications of water ingress during rainy weather. Re-caulking was done in 2014 and again in 2018. No caulking was done in 2020.

In 2015, shallow wells were installed beside each of the Medium/Intermediate Level Bunkers. These near field wells have been sampled annually. Results are discussed in Section D.2.1 under “Intermediate - Level Waste Bunkers Near Field Wells”, and indicates limited migration of tritium beside the ILW bunkers, in particular ILW Bunker 3. There is no evidence that would lead CNL to conclude there is currently any significant contaminant migration pathway from the ILW Bunkers.

Compliance monitoring in the WMA and CCSF perimeter ditches have only found limited levels of contaminants, below drinking water guidelines, suggesting the waste storage structures and natural barriers of low permeability clay soil and upwards groundwater flow are performing as expected.

As required by Section 8 of the Facility Authorization [57], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests and inspections were completed. Monthly housekeeping and fire prevention inspections were completed. An annual inspection of WL WMA concrete bunkers was conducted, in accordance with the Periodic Inspection Plan [16], and is further discussed in Section 6.

D.5 Wastes Generated

As a result of routine operations solid radioactive waste and liquid radioactive waste were generated in the WMA.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the WMA in 2020.

There was 2.5 m^3 of solid compactable wastes and no solid non-compactable wastes generated in this facility during 2020 from operational activities.

In 2020, approximately 1069 L of water was removed from ILW Bunker 6; no other storage facilities and collection sumps at the WMA required pumping.

D.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the WMA as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection. There are no liquid effluents generated from this facility.

The incinerator was decommissioned in 2018. There are no other radiological airborne releases from this facility.

APPENDIX E Auxiliary Operation Facilities

E.1 Operations

The Auxiliary Operating Facilities are operated under the WL Site Licence [1].

There were no changes in the staffing for the operating staff responsible for the auxiliary facilities in 2020. There were no organizational changes. There was a change in Facility Authority as communicated to the CNSC [53].

No program changes were made for the auxiliary facilities in 2020. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

Research and Development Facilities Complex (Building 300)

Building 300 was the primary research laboratory for the site, housing a wide range of nuclear R&D programs. The building comprised an area of ~17,000 m^2 and was built in seven stages from 1964 to 1982. The building contained 68 laboratories as well as numerous offices. The south end high-bay area contained experimental activities that required large areas and significant headroom; RD-14M and RD-17 experimental loops were located in the South High Bay.

The research program in the Stage 6 (RD-14M) area was completed in 2018, and operational shutdown was started. The operational shutdown, decontamination, and decommissioning of the remainder of the building was completed in 2015. The demolition of Stages 4 and 7 was completed in 2016. The demolition of Stage 6 was completed in 2019.

During 2020, WL Site and Nuclear Operation's staff and user groups in Building 300 carried out routine operations which included:

- Non-radiological laundry activities.
- Respirator fit test / maintenance activities.
- Ongoing CNL Nuclear Engineering & Systems Analysis R&D activities.
- Cleanup activities associated with decommissioning.
- Routine building and system maintenance; and
- Surveillance to ensure compliance with the site licence.

In support of decommissioning work conducted in 2020, the Sample Management Office, and Environmental labs and offices, were relocated from Building 402 to Building 300.

Health and Safety Facilities (Buildings 402 and 305)

Building 402 has three floors comprising an area of ~2,162 m^2, housing WL dosimetry services and Environmental Management laboratories. The CNL facilities in Building 402 include a whole-body counting facility, TLD readers, environmental laboratories, and a Cs-137 Gamma Calibrator.

During 2017 the private business tenant left Building 305, and the area was repurposed. A licensed gamma cell belonging to the former tenant remained, and in 2019 the gamma cell was moved from Building 305 to the source container located inside the Protected Area of the Waste Management Area (WMA) for storage until a more permanent disposition path is determined.

In 2020, routine operations were carried out and supervised by Site and Nuclear Operations personnel. Operational cleanout of Buildings 402 and 305 were started in preparation for decommissioning/demolition.

E.2 Facility Changes

All facility changes were performed using the Engineering Change Control procedure [14]. The Sample Management Office, and Environmental labs and offices, were relocated from Building 402 to Building 300.

E.3 Equipment Performance, Planned Maintenance Testing and Inspections

All maintenance and non-routine work in these facilities that may affect the safe operation of facilities, systems, and laboratories, or that may present a hazard to the general public are conducted in accordance with CNL's work permit system.

All routine maintenance for systems required to be operational was carried out, and all equipment tests and inspections were completed.

E.4 Wastes Generated

There were minimal amounts of radioactive and/or hazardous wastes generated in the facilities as part of routine operations.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the facilities in 2020.

Building 300 generated 0.3 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2020.

Building 402 generated 0.2 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2020.

After processing at the Waste Handling Area, all waste was shipped to the WMA for storage.

See Table 79 for a summary of solid wastes for the last five years.

Table 79: Low-Level Solid Waste Generation – Buildings 300, 402,411

	2016*	2017	2018	2019	2020
Building 300 (m^3)	203.3	14.7	4.5	0.4	0.3
Building 402 (m^3)	3.4	2.8	1	0.7	0.2
Building 411 (m^3)	74.9	355.1	7.6**	0.2**	0.0

* Volume prior to compaction, all compactable waste is consolidated at the Waste Handling Area.

** Legacy waste processed in 2018 for Building 411 that was decommissioned in 2017.

There was no liquid radioactive and/or hazardous waste generated in 2020 in this facility.

Research and Development (Building 300) Low-Level Liquid Waste System

Radioactive LLLW flows from the SF and Building 300 to the low-level liquid waste collection tanks, in Building 300 Room B-33. An accurate determination of the individual SF or Building 300 contribution cannot be made as both locations flow into these common tanks. The sources of water from Building 300 are limited and the major contributor is the radiological decontamination service facilities in the IFTF.

During 2020, 99 m^3 of low-level liquid was processed through the Building 300 LLLWTS Table 80 shows the historical volumes of LLLW processed through the Building 300 LLLWTS and also the total volume of Building 300 and Building 100 LLLW processed.

Table 80 - Historical Records of Low-Level Liquid Waste Processed

	2016	2017	2018	2019	2020
Total Combined Low-Level Waste Liquid Processed (m^3)[a]	230	172.3[b]	131.5[c]	189.3[c]	107
Low-Level Waste Liquid Processed in Building 300 (m^3)[d]	195	46	123	186.5	99

a All low-level liquid waste processed in Active Liquid Waste Treatment Centre for 2014-2016. This total includes laundry and decontamination and ALWTC facilities for 2014 and 2015. For 2016 the total is Building 100 and Building 300 and ALWTC. After 2017 all low-level liquid waste is processed in Building 100 and Building 300.

b This includes 126 m^3 of low-level liquid waste that was processed through the Active Liquid Waste Treatment Centre in Building 200.

c All Low-Level Liquid Waste processed through the low-level liquid waste treatment systems in Building 100 and Building 300.

d Building 300 LLLWTS came online in 2017 July.

The total activities given below are the combination of the Shielded Facilities, Building 300, and Building 100 active liquid effluents produced.

As determined by total-beta analysis, the beta radioactivity content in the effluent releases to the Outfall from the holding tanks at the Building 300 and Building 100 LLLWTS during 2020 was 0.01 GBq, compared with 0.01 GBq released during 2019. The maximum release in a month during the year was 0.001 GBq which is a small fraction of the administrative level of 0.48 GBq per month. This level conservatively assumes that all of the activity is due to Cs-137, which is the most restrictive isotope of those present, or potentially present.

As determined by total-alpha analysis, the alpha radioactivity content in effluent releases to the outfall was 0.0011 GBq for 2020 compared with 0.0027 GBq released during 2019. The maximum release in a month during the year was 1.9E-04 GBq which is a small fraction of the administrative level of 0.56 GBq per month. This level conservatively assumed that all the activity is due to Am-241 which is the most restrictive isotope of those expected to be present in this waste stream.

Table 81 provides a summary of the total activity released for both the Building 100 and Building 300 LLLWTS. Annual Release Limit values for radionuclides in liquid effluents for WL are based on the DRL [30]. These values were revised in 2016.

Table 81 – Building 100 and Building 300 LLLWTS Radioactive Releases

Radionuclide	Total 2020 Effluent (GBq)	Annual Release Limit[a] (GBq/a)	Total 2020 Effluent as a % of Annual Release Limit	Peak Release	
				Max. Monthly Release (GBq)	% of[b] Monthly DRL
Total (Total-Beta Analysis) [c]	0.01	–	–	0.001	–
Sr-90	$2.23x\ 10^{-3}$	1.56×10^{2}	$1.47x\ 10^{-3}$	3.16×10^{-4}	2.72×10^{-3}
Cs-137	$4.55x\ 10^{-3}$	1.39×10^{2}	$3.27x\ 10^{-3}$	7.44×10^{-4}	6.41×10^{-3}
Total Alpha (As Pu-239 Equivalent) [d]	1.06×10^{-3}	1.33×10^{1}	$7.96x\ 10^{-3}$	1.89x 10-4	1.70×10^{-3}
Historical Data Total Effluent (GBq)					
	2016[e]	2017[e]	2018[e]	2019[e]	2020[e]
Total (Total-Beta Analysis) [c]	0.04	0.04	0.02	0.01	0.01

a The annual release limit is calculated by multiplying the DRL by 12.

b DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The beta particulate emitters are considered to be Cs-137, the most restrictive isotope of those identified or potentially present. The DRL is 1.16×10^{1} GBq/month [30].

c A total beta analysis results in a conservative (higher) estimate of the total amount of activity, which is more accurately determined by measuring the individual radionuclides by radiochemical or gamma spectrometry methods.

d DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The alpha particulate emitters are considered to be Pu-239, the most restrictive isotope of those identified or potentially present. The DRL is 1.11×10^{1} GBq/month [30].

e Year's 2014 to 2016 effluent was all processed in ALWTC. 2017 effluent was processed in ALWTC and Building 300 LLWTS. From 2018 on, all effluent was processed in Buildings 300 and 100 LLWTS.

E.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from these facilities. Radioactive wastewater generated in Building 300 was pumped to the LLLWTS in Building 300 Room B-33.

Any liquid and/or gaseous releases from the facilities are provided and discussed in Section 9, Environmental Protection.

APPENDIX F WR-1 Facility

F.1 Operations

Activities in Whiteshell Reactor 1 (WR-1) were conducted under the WL site licence [1] from the CNSC, in accordance with the requirements of *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [62]. The status of the WR-1 facility in its shut down, de-fuelled, and partially decommissioned state is described in *The WR-1 Reactor Phase 1 Decommissioning Project Interim End-State Report - Facility Description* [63]. The facility is monitored and maintained as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [62].

In 2020, the LLLW system processed a total of 7.9 m^3 of liquid waste.

Routine operations in the WR-1 facility, as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [62], were carried out by the five (four and one trainee) Site and Nuclear Operations Technologists assigned to Building 100.

In 2018 approximately 20 m^3 of low concentration (3.4E06 Bq/L) tritiated water was found in the thermoshield and bioshield cooling systems. This water is still in the systems, awaiting a decision on how to remove this water as the systems were not designed to be drained. Investigation is also ongoing to determine what the impact would be if this water is left in situ as part of the proposed in situ disposal of WR-1.

In 2020, the Building 100 continued to maintain the minimum staffing requirements outlined in the Facility Authorization [62]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for WR-1 in 2020. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

F.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [14].

F.3 Equipment Performance, Planned Maintenance Testing and Inspections

During 2020, the operations status of WR-1 remained unchanged. There were no changes to the reactor’s equipment, and all facility maintenance was done as per the facility maintenance plan.

During 2020, all planned activities for systems required to be operated, tested and inspected were carried out as per the approved facility maintenance plan. Monthly housekeeping and fire prevention inspections were completed. There was some ventilation characterization work carried out in WR-1 in 2020 in support of future decommissioning activities. These were done in areas where ventilation ducts will need to be removed and packaged as waste regardless of which decommission plan is executed for WR-1.

F.4 Wastes Generated

There were no radioactive and/or hazardous wastes generated in WR-1 as part of routine operations.

See Section 11.1 Waste Management Program for summaries of the volume of any volume of radioactive solid and/or liquid waste generated in WR-1 in 2020.

Solid Radioactive and/or Hazardous Wastes

Solid radioactive and/or hazardous waste was generated in the facility as part of routine operations. This consisted of mainly operational supplies such as Tyvek suits.

During 2020, 0.8 m^3 of low-level radioactive compactable waste and 9.2 m^3 non-compactible waste were generated from Building 100/WR-1 operations and sent to the Waste Handling Area for compaction.

There were no new hazardous solid wastes generated from Building 100/WR 1.

Liquid Radioactive and/or Hazardous Wastes

Liquid radioactive and no hazardous waste was generated in the facility as part of routine operations.

During 2020, 7.9 m^3 of low-level radioactive liquid waste was generated from Building 100/ WR-1 operations, the majority from the WR-1 sumps. Section WL in Appendix E has more information on the liquid waste processed. There were no hazardous liquid wastes generated from this facility.

F.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the facility as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection.

APPENDIX G Non-Nuclear Facilities

G.1 Operations

The WL non-nuclear facilities status and changes for 2020 are as noted in Table 82.

Table 82: Operating Summary of Non-Nuclear Facilities

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
303	Containment Test Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed
304	Waste Clearance Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed
306	Waste Clearance Facility	Removed in 2016	None	None	Buildings & Lands D&D Project Personnel	Building removed, pad retained, End-State Report to be completed
308	Large Scale Vented Combustion Test Facility	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
309	Large Scale Vented Combustion Test Facility -Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
310	Large Scale Vented Combustion Test Facility -Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
311	Large Scale Vented Combustion Test Facility Hydrogen Storage	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
401	Security, Reception, Firehall and Security Monitoring Room	Operational	None	None	All Site/Visitors	No change
405	Lunchroom/Offices (formerly the Library)	Operational	None	None	All Site/Visitors	No change
408	Stores	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
409	Cold Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
412	Offices/Machine Shop	Operational	None	None	All Site/Visitors	No change
413	Quonset: Cold Storage	Operational	None	None	Security and Common Services	No change
414	Controlled Area 2 Entrance	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
415	Warm Storage	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
416	Heated Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
418	Active Area Storage	Removed in 2017	None	None	Facilities	Decommissioned, End-State Report to be completed
420	Cold Garage	Operational	None	None	Transportation, Security and Stores	No change
422	Outfall Monitoring Station	Operational	None	None	Environmental Monitoring and Maintenance	No change
424	WR-1 Organic Monitoring Building	Removed in 2020 l	None	None	Facilities	Building removed,, End-State Report to be completed
426	Quonset: Cold Storage	Operational	None	None	Utility	No change
427	Cold Mechanical Storage	Removed in 2016	None	None	Facilities	Building removed, pad retained, End-state Report to be completed
428	Cold Storage	Removed in 2016	None	None	Facilities	Decommissioned, End-State Report to be completed
429	Quonset: Cold Storage	Operational	None	None	Maintenance	No change
505	Fire/Security Training (formerly R&D Lab)	Removed in 2016	None	None	Environmental	The building and pad were previously decommissioned, 3 environmental monitoring wells have been installed
531	Asbestos/PCB Storage	Operational	None	None	Facilities	No change
540	Modular Office Complex	Operational	None	New	Facilities	Modular Trailer office complex installed in parking lot
570	Hazardous Chemical Storage	Operational	None	None	Facilities, Waste Management	Relocated from Building 402 to near Building 300 Shielded Facilities. Temporarily out of Operation
597	Portable Boiler Building 1	Out of Operation	None	None	Powerhouse Operators and Maintenance	Taken out of Service due to shutdown of Building 200

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
598	Portable Boiler Building 2	Operational	None	None	Powerhouse Operators and Maintenance	No change
902	Pump House	Operational	None	None	Powerhouse Operators and Maintenance	No change
903	Water Filtration Plant	Operational	None	None	Powerhouse Operators and Maintenance	No change
904	Fire Protection Water System	Operational	None	None	Powerhouse Operators and Maintenance	No change
905	Process Water System	Operational	None	None	Powerhouse Operators and Maintenance	No change
906	Storm Drainage System	Operational	None	None	Maintenance	No change
907	Sewage Lift Station and Lagoons	Operational	None	None	Powerhouse Operators and Maintenance	No change
911	Powerhouse	Operational	None	None	Powerhouse Operators and Maintenance	No change
913	Main Substation (Owned by MB Hydro)	Operational	None	None	Manitoba Hydro	No change
914	Main Power Distribution	Operational	None	None	Powerhouse Operators and Maintenance	No change
916	Communications System	Operational	None	None	Security and Maintenance	No change
917	Supervisory Control and Alarm	Operational	None	None	Security and Maintenance	No change
918	Clarified Water System	Shut Down Mid-1980s	None	None	Powerhouse Operators and Maintenance	No change
921	Access Tunnel	Operational	None	None	All Site/Visitors	No change

[a] Security personnel perform regular patrols of all site buildings

There were no policy, program or procedural changes for the non-nuclear facilities in 2020. There were no changes in organization in 2020, the Section Head left the company, and the Senior Operator assumed the role on a delegate basis. The two Operator trainees became full Operators.

G.2 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [14].

In 2020, three non-nuclear facilities, Buildings 303, 304 and 424 were decommissioned. The final End-State Decommissioning Report will be prepared when all the other non-nuclear buildings on the South-side and North-side have been decommissioned.

G.3 Equipment Performance, Planned Maintenance Testing and Inspections

Systems and equipment for all the non-nuclear facilities, including any safety-related systems, performed as designed and required during 2020, as noted in Table 82.

Routine maintenance was carried out, and equipment tests and inspection were completed in 2020 with no significant results, as noted in Table 82.

G.4 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the non-nuclear facilities as part of routine operations.

G.5 Effluents Released

There were 1.21E+09 L and 3.08E+07 L of effluent released from buildings Building 422 (Outfall Monitoring Station) and Building 907 (Sewage Lift Station and Lagoons) respectively.

Landfill Dugout Water Monitoring

The WL landfill is surrounded by six dugouts where surface water collects. These dugouts are sampled as part of the ongoing operational control monitoring for the facility. In 2020, the precipitation was low over the year (441 mm) and the dugouts had low water levels during the summer sampling period. The location of the dugouts are shown in Figure 13. Dugout 22 is used as the Control and is about 300 m away from the landfill to the north-northeast, and would not be affected by facility operations.

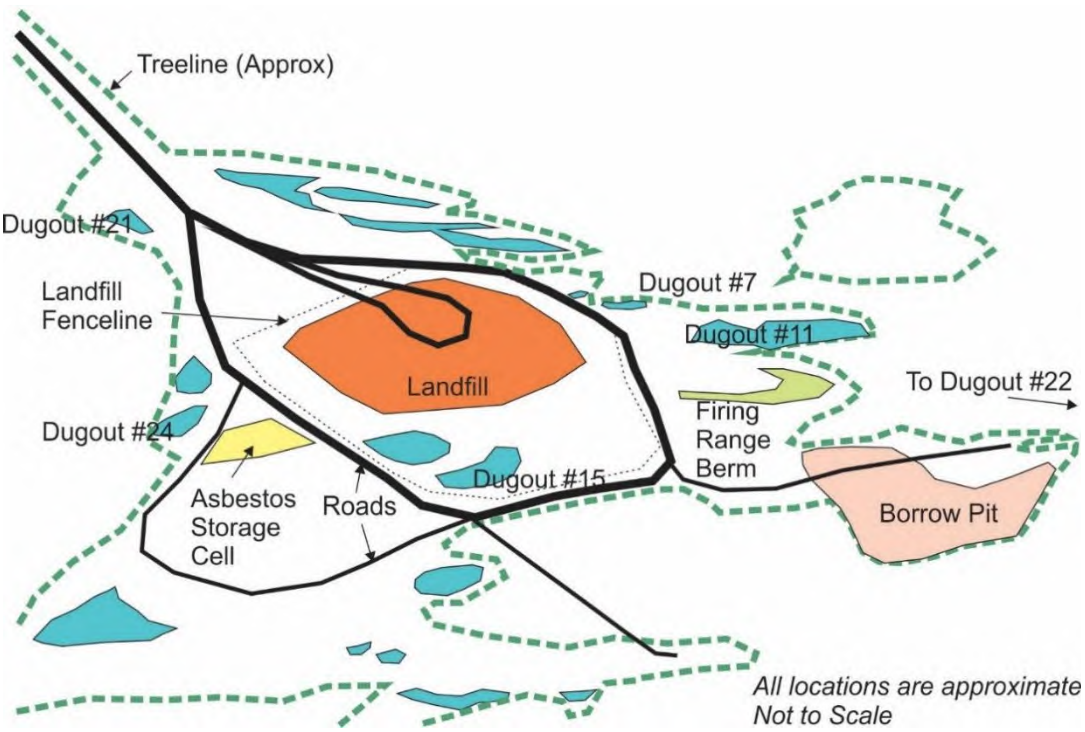

Figure 13: WL Landfill Area Showing Approximate Locations of Monitored Dugouts

The results from the sample analysis for alpha and beta from these dugouts are provided in Table 83 and Table 84 respectively. All alpha results for 2020 were at the detection limits, and are below the drinking water screening level of 0.50 Bq/L. All beta results for 2020 were near the detection limits, and are below the drinking water screening level of 1.0 Bq/L. Both alpha and beta results for 2020 are consistent with previous results obtained from 2015 to 2019.

Table 83: Gross Alpha Results from the Landfill Dugouts

Sample	Gross Alpha (Bq/L)					
Location	2015	2016	2017	2018	2019	2020

Low levels of tritium (9 Bq/L) were detected in one of the landfill wells (water table) starting in 2011. Its appearance in the groundwater resulted in initiation of the surface (dugout) water measurement of tritium. Tritium has been detected in landfill Dugout 15 for the past eight years, and a small amount was noted in Dugout 24 in 2011, 2012, 2016, and although a higher amount was noted in 2018 (76 Bq/L), the value returned to background in 2019 and remained there in 2020. The higher tritium level in Dugout 15 was 54 Bq/L, approximately one-quarter that measured in 2019 (212 Bq/L). All results are well below drinking water limits of 7,000 Bq/L. The other dugouts do not appear to contain tritium, as levels comparable to blank samples analyzed from 2013 to 2020 that contain < 4 Bq/L of tritium were recorded. Tritium results from the landfill dugouts are shown in Table 85.

Table 85: Results from the Landfill Dugouts

Sample	Tritium (Bq/L)					
Location	2015	2016	2017	2018	2019	2020

Dugout #15	41	98	82	105	212	54
Dugout #21	< 4	< 4	NA	< 4	Dry	< 3
Dugout #22	< 4	< 4	< 4	< 4	< 4	< 3
Dugout #24	< 4	5.5	< 4	76	< 4	< 4

NA sample not available

When initially detected in the dugouts, it was assumed that it was possible that tritium emissions from the WR-1 Building 100 deposited in the ponds surrounding the landfill, and was subsequently drawn in to the water table. After consideration, it was determined that the most likely source of tritium is the landfill. The presence of above background tritium in only a few dugouts cannot be explained by air borne deposition. The highest tritium activities are found in the dugouts and wells in closest proximity to the landfill. Due to its 10 m height, the landfill has a higher hydraulic head than the local terrain, including the asbestos storage cell, and thus will be more likely to contribute leached contaminants to the shallow ground water system. Due to local groundwater flow directions (toward the south and southwest), Dugouts 15 and 24 are more likely to receive contaminants from the migration of water from the landfill. As the landfill had been in operation for over 50 years, the potential for a historic error in placement is greater for the landfill than the adjacent asbestos storage cell.

The water testing conducted in 2018 included Sr-90 and Tc-99, two potentially mobile radionuclides. In 2018, near detection levels of Sr-90 were noted in Dugout 21 and near detection limit levels of Tc-99 were noted in Dugouts 21 and 24. In 2019, only Sr-90 was tested, and was found to be at the detection limit. In 2020, both Sr-90 and Tc-99 were again measured (Table 86). Sr-90 was at the detection limit and Tc-99 was not detected. The water from these dugouts and wells is not used for human consumption. All results were below drinking water limits of 5 Bq/L for Sr-90 and 200 Bq/L for Tc-99.

Table 86: Sr-90 and Tc-99 Results from the landfill Dugouts in 2020

Sample Location	(Bq/L)	
	Sr-90	**Tc-99**
Dugout #7	< 0.10	ND
Dugout #11	< 0.10	ND
Dugout #15	< 0.10	ND
Dugout #21	< 0.10	ND
Dugout #22	< 0.10	ND
Dugout #24	< 0.10	ND

ND – Non Detect

The water from the dugouts was also tested for a suite of non-radiological parameters including total metals, mercury, nitrate + nitrite, sulphate, chloride, sodium, potassium, calcium, magnesium, sulphur, total ammonia (N), phosphorus, phenols and volatile organics (including benzene, toluene, ethylbenzene and xylene). Elevated levels of boron were detected in in Dugout #15, a continuation of results from 2017 onwards (Table 87). The value in 2020 returned to under the Drinking Water Guideline for Boron (5,000 ug/L).

Table 87: Boron Results from the Landfill Dugout #15

Sample Location	(uq/L)			
	2017	**2018**	**2019**	**2020**
Dugout #15	1630	5460	8460	2040

Molybdenum decreased to detection limits in 2020 in Dugout #21; it had been measured as above 74 ppb in 2019 from 145 ppb in 2018. In 2020, Manganese was found to be at or higher than drinking water guidelines of 50 ug/L in Dugout #15 (232 ug); in 2019 it had been measured at 96 ug/L. No other parameters were detected and/or at concentrations of concern.

Groundwater results will be discussed in the annual Environmental Monitoring report [26]. Sediment sampling of one of the dugouts was conducted as part of the Environmental Assessment Follow-up Program and will be reported in [28].

Landfill Dugout Sediment Monitoring

Sediment sampling of the dugouts was conducted in 2017 as part of the Environmental Assessment Follow-up Program. The analysis of the sediment included a full suite of metals, mercury, lead, PCBs and for radioactivity, including Sr-90. There were elevated levels of molybdenum in the surface sediment of one dugout (Dugout 24) and no other contaminants of potential concern noted. Molybdenum can be found naturally in the environment (minerals containing iron, bismuth, or copper) as well as being a component of man-made items such as filaments, X-ray tubes, screens, grids for radios, spark plugs, contacts, induction heating elements, and/or part of a waste stream from man-made processes (burning of fossil fuels). The source of the molybdenum is being investigated as part of the assessment of the Landfill prior to closure. Monitoring of the sediments in the dugouts around the landfill is planned to continue every 5 years (from 2017) as well as annual monitoring of the water, as such no sediment sampling was conducted in 2020.

Further investigation will be conducted during the eventual closure of the landfill and will also be reported in the Environmental Assessment Follow-up Program [28].

Landfill Radiological Monitoring

Annual radiological monitoring of the landfill surface is performed as a confirmatory measure. The results show readings consistent with background levels at the landfill fence line. Table 88 provides a five year listing of survey results at the top of the landfill. In 2019, metal waste collection containers were sited on top of the landfill to collect inactive waste for offsite shipment. For some years monitoring was performed at the base of the pile, and more recently monitoring was performed around the perimeter of the fenced area of the landfill.

Table 88: Landfill Radiological Monitoring

Sample Location	(μR/h)				
	2016	**2017**	**2018**	**2019**	**2020**
Landfill Top Surface	10-15	10-16	8 - 10	6 -12	6 - 12[2]
Landfill Base	< 20	< 20	NR	5 - 8[1]	5 - 8[1]

EXECUTIVE SUMMARY

This annual compliance monitoring report for the 2021 calendar year has been prepared as per licence condition 3.2 of the Whiteshell Laboratories Licence NRTEDL-W5-8.00/2024 and CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Facilities and Uranium Mines and Mills* as a summary report of annual compliance monitoring and operational performance.

Canadian Nuclear Laboratories (CNL) would like to acknowledge Canada's Indigenous Peoples and their traditional territories upon which CNL carries out its work. CNL also wishes to confirm its commitment to being an active participant in Canada's journey towards healing and reconciliation.

This annual compliance report provides CNL 2021 performance data for WL and is organized by 14 Safety and Control Areas (SCAs)[1], as well as a report on each of the WL nuclear and non-nuclear facilities.

The following provides overall performance highlights for 2021 activities:

- All licensed activities continued to be carried out safely and securely.
- No member of the public received a radiation dose that exceeded any regulatory limit.
- No worker at WL received a dose in excess of any of the respective radiation dose limits for radiation workers, as defined in the Radiation Protection Regulations.
- All releases of radioactive material in WL effluents during 2021 were below their respective Derived Release Limits (DRL).
- Demolition of Building 200, the former Active Liquid Waste Treatment Centre (ALWTC), is complete, and Building 402/305, the former Health and Safety Facilities, is partly demolished.
- The WL site maintained safe and compliant performance under COVID-19 Pandemic conditions and protocols.

Below is a summary of the annual compliance report for calendar year 2021.

- **SCA - Management System**: WL has continued its focus on implementation of the corporate management system, as well as the WL Quality Assurance program for decommissioning. After having no Canadian Nuclear Safety Commission (CNSC) inspections in 2020, four inspections were carried out in 2021.
- **SCA - Human Performance Management**: A significant effort towards training individuals in human performance related areas continued as a result of the fieldwork pause in 2020 November. Another outcome of the fieldwork pause was the development and delivery of the initial Annual General Employee Training which goes

1 The CNSC evaluates how well licensees meet regulatory requirements and CNSC expectations for the performance of programs in 14 safety and control areas.

over site and project updates, as well as review of policies and procedures. This will be updated and delivered annually to all employees.

- **SCA - Operating Performance**: WL decommissions and operates its facilities according to prescribed programs and procedures, and monitors safety performance in the operational area through the concept of “events”. The total number of internal event reports raised continues to show a strong reporting culture. There were six CNSC reportable events in 2021.
- **SCA - Safety Analysis**: Effective Safety Analysis Reports and Facility Authorizations continue to be in place for WL’s nuclear facilities, helping meet health, safety, security, environmental and regulatory requirements. Safety analyses continue to be developed for the standpipe/bunker remediation, Intermediate-Level Liquid Waste Processing Centre and Cask Loading facilities being constructed in the Waste Management Area.
- **SCA - Physical Design**: The Certificate of Authorization was renewed with Engineers Geoscientists Manitoba, authorizing CNL to engage in the practice of professional engineering in Manitoba. The new revised WL Pressure Boundary Quality Assurance Plan was accepted by Inspection and Technical Services Manitoba and a new Certificate of Authorization was issued.
- **SCA - Fitness for Service**: The Periodic Inspection Plan (PIP), previously developed to confirm the ongoing fitness-for-service of the concrete storage facilities at the Waste Management Area (WMA), continued implementation with no significant issues identified. Regular preventative or corrective maintenance and testing of WL’s safety-related systems were carried out to ensure the systems were fit-for-service. Missed maintenance of safety-related systems was reported to CNSC, and a corrective action plan was developed that will fix the issues and prevent recurrence.
- **SCA - Radiation Protection**: No worker received a whole-body dose (including committed) in excess of any of the respective dose limits for radiation workers as defined in the Radiation Protection Regulations, and average individual doses remain a small fraction of these limits. Maximum dose to a person working at WL was 0.6 mSv and collective doses remained below 50 person-mSv (19.0 person-mSv) for 2021. Members of the public received no measureable radiation doses.
- **SCA - Conventional Health and Safety**: Implementation of CNL’s Occupational Safety and Health program at WL continues to drive improvements in safety and safety culture. Safety advisories are regularly issued to staff about imminent issues that could impact their safety. There were no lost-time injuries at WL in 2021.
- **SCA - Environmental Protection**: The results of the radiological and non-radiological effluent monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment. Radiological emissions were 0.00019% of the Derived Release Limit (DRL) for air emissions and 0.45% of the DRL for liquids. The monitoring program confirms that the WL site is operating in a manner that protects workers, the

public, and the environment. WL maintained their ISO-14001 registration, and are compliant to a number of CSA environmental standards.

- **SCA - Emergency Management and Fire Protection**: The Emergency Management program at WL continued to be focussed on supporting COVID-19 planning and coordination efforts, providing procedures and guidance to enable work to continue safely in this dynamic situation. A third party Fire Protection Audit was conducted, and resolution to findings will be tracked through the corrective action program.
- **SCA - Waste Management**: WL continued to reuse or recycle as much material as was practicable. Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects, including disposition of 924 m^3 of radioactive waste to Chalk River Laboratories (CRL), and 271 m^3 (37,145 kg) of recycled waste shipped off-site. The WL Site Overview Detailed Decommissioning Plan was revised and accepted by CNSC.
- **SCA – Security**: The Security Program at WL supports the CNL Corporate Security mandate and addresses the regulatory requirements for high-security sites. Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers as required by the CNSC.
- **SCA - Safeguards**: There were no issues identified with International Atomic Energy Agency (IAEA) Safeguards inspections conducted at WL. The IAEA also provided human surveillance and IAEA seal verification, removal and reapplication during canister inspection activities.
- **SCA - Packaging and Transport**: There were 68 radioactive transport packages making up 53 loads that were safely and successfully sent off-site, including approximately 921 m^3 of low-level waste and 3 m^3 of intermediate-level waste shipped to CRL.
- **Other matters of regulatory interest**: Two virtual meetings of the WL Public Liaison Committee took place. Numerous public information sessions and Indigenous engagements (mainly virtual) were held on the Whiteshell Reactor 1 (WR-1) in-situ decommissioning and overall activities of the WL Closure Project, including four Webinars.
- **Facilities** (operating nuclear facilities, permanently shut down facilities, facilities being decommissioned and the non-nuclear facilities): All the licensed activities in these facilities continue to be carried out safely and securely with acceptable radiation doses to personnel and releases to the environment. The following notable facility-specific activities took place: the Active Liquid Waste Treatment Centre, Building 200, completed demolition, and significant progress was made in demolition of the Health and Safety Facilities, Building 402/305.

CNL is committed to achieve high standards of operational safety and security. The information and data presented in this report support the conclusion that safe and secure performance was achieved at the Whiteshell Laboratories site, while enhancements were implemented to further improve results.

ACKNOWLEDGEMENT

The “Author” of this document would like to thank the many Whiteshell Laboratories authors and reviewers from the various Functional Support Areas and Facilities for their production of the individual sections of the report.

CNL’s Continued COVID Pandemic Response

For a detailed description of CNL’s robust mitigation initiatives and controls to protect its employees, contractors, visitors and Site operations from the COVID pandemic, see the Executive Summary in the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories*.

TABLES

INTRODUCTION

Whiteshell Laboratories (WL) was established by Atomic Energy of Canada Limited (AECL) in the early 1960s to carry out nuclear research and development activities. The site is a Class 1B nuclear facility which encompasses an area of 4,375 hectares. The WL site is located near Pinawa, Manitoba; approximately 100 kilometres northeast of Winnipeg, on the eastern bank of the Winnipeg River. AECL made a business decision in 1997 to discontinue most of the research programs and operations at WL. Subsequently, AECL received government concurrence in 1998 to proceed with actions to achieve closure of WL. This work transitioned to Canadian Nuclear Laboratories (CNL) who are carrying out the work to achieve site closure on behalf of the site owner, AECL.

Activities are now underway to complete the orderly decommissioning of the WL site, following the general plan laid out in the Comprehensive Study Report supporting the approval of the Environmental Assessment of the WL Decommissioning Project. The exception to this is the change in strategy for Whiteshell Reactor (WR) -1 (see the Decommissioning Strategies Section below).

Name:	Whiteshell Laboratories
Location:	*1 Ara Mooradian Way* *Pinawa, Manitoba* *R0E 1L0*

Licence Information and Reporting Period

This annual compliance monitoring report is produced to comply with licence condition 3.2 of the Whiteshell Laboratories Licence NRTEDL-W5-8.00/2024 [1], in accordance with the compliance verification criteria Compliance Monitoring: Annual Report of the *Licence Conditions Handbook (LCH) for Whiteshell Laboratories,* herein referred to as “Licence Conditions Handbook” [2], and section 3 Annual Compliance Monitoring Report of CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills* [3]. Information included in this report is for the period of 2021 January 01 to December 31.

This report provides site-specific information to supplement information in the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4], which provides corporate updates to 14 Safety and Control Areas as they are applied across all of CNL.

The intent of this report is to provide sufficient detail to demonstrate how Whiteshell Laboratories programs are meeting the regulatory requirements as specified in the licence [1] and the LCH for Whiteshell Laboratories [2].

Facilities Included in this Report

Appendices Appendix A through G of the report provide information that is pertinent to the Nuclear and Non-Nuclear Facilities (including operating and permanently shut down facilities, and facilities being decommissioned).

The Nuclear Facilities included in this report are: Concrete Canister Storage Facility, Active Liquid Waste Treatment Center, Shielded Facilities, Waste Management Area, Research and Development Facilities Complex (Building 300), Health and Safety Facilities (Building 402 and Building 305), and WR-1 Reactor.

Summary of Licensed Activities

There are no new licenced activities.

Decommissioning Strategies

As discussed since 2015, work is underway to complete decommissioning of the entire WL site (current schedule is to be complete in 2027). This includes leaving in-situ the selected WMA trenches as per the Comprehensive Study Report under institutional control, and transporting active waste off-site for disposal or storage. A significant departure from the end-states defined in the Comprehensive Study Report is in situ decommissioning (also referred to as in situ disposal) of the WR-1 reactor. Work continues for an environmental assessment and regulatory approvals required for this proposed change. The Environmental Impact Statement supporting this is in progress.

Financial Guarantees

CNSC was previously sent a letter from the Honorable G. Rickford [5], advising that as an agent of Her Majesty in Right of Canada, AECL's liabilities associated with the decommissioning of WL are ultimately liabilities of Her Majesty in Right of Canada (note: AECL retains ownership of the lands, assets and liabilities associated with CNL's licences). This financial guarantee remains valid and in effect, as per the communication issued on 2020 August 25 [6].

1 Management System

1.1 Management System Program

Whiteshell Laboratories adheres to the Corporate Management System. See Section 1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL Quality Assurance Plan [7] supports the CNL Management System Manual [8] and summarizes the processes and practices applicable to WL licensed activities, while still retaining compliance to CSA N286-12 [9] and N286.6-98 [10].

1.2 Audits, Inspections and Self-Assessments

As per the requirements of the Management System [8], both Safety Control Areas and Facilities conduct various audits, inspections, and self-assessments to ensure that the management system is functioning according to expectations and that any policy, programmatic, or procedural deficiencies are identified and appropriate actions taken to resolve them.

All actions resulting from audits, inspections, reviews and self-assessments are being managed and tracked through CNL's Corrective Action Program.

1.2.1 Audits

See Section 1.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4] for a list of all CNL-wide Audits for the reporting year 2021.

1.2.1.1 External Audits

The external audits conducted at Whiteshell Laboratories are summarized in the table below.

Table 1: External Audits

Title	Type of Audit	No. of Non-Compliances Raised	No. of Non-Compliances Completed
SAI Global Recertification Audit of the WL Environmental Management System	14000:2015	0	Not applicable
PLC Fire Safety Solutions Audit of the Fire Protection Program	CSA N393	31	0

For the Fire Protection Program audit, the non-compliances related mostly to missing documentation for inspection, testing and maintenance activities. The audit report was received late in 2021, and a corrective action plan is to be submitted to CNSC staff in early 2022.

1.2.1.2 Internal Quality Audits

There were no internal audits completed by the Quality Audits and Processes branch specific to Whiteshell Laboratories in 2021.

1.2.2 Inspections

CNSC Inspections

The following CNSC Inspections were conducted at Whiteshell Laboratories.

Table 2: CNSC Inspections for 2021

Inspection No.	Area Inspected	No. of NNC[a]s	No. of NNC[a]s Completed
CNL-WL-2021-01	Human Performance Management	2	2
CNL-WL-2021-02	Management System	6	6
CNL-WL-2021-03	General	3	0
CNL-WL-NSD-T2-2021-001	Security	7	0

a NNC – Notice of Non-Compliance

Inspections by Other Regulatory Bodies

A Physical Inventory Verification (PIV) inspection was carried out by the IAEA on 2021 May 26. This inspection was a sampling of accessible items containing Special Fissionable Material. A Design Information Verification inspection was carried out by the IAEA on 2021 May 25-27. This inspection verified the information provided in the Design Information Questionnaire.

Transport Canada conducted a virtual Transport of Dangerous Goods (TDG) inspection at WL in 2021 and did not find any non-conformances.

1.2.3 Self-Assessments

In 2021, there were 18 self-assessments conducted at Whiteshell Laboratories covering various aspects of the management system, including both safety and control areas, and various facilities.

Table 3: List of Self-Assessment Conducted at Whiteshell Laboratories in 2021

Title	Facility/Department
Effectiveness of Industrial Hygiene Instrumentation	WL Occupational Safety and Health (OSH)
Workload on the SMO	WL Environmental Management (EM)
WL Integrated Work Control	WL Site and Nuclear Operations
TDG Requirements	WL Waste Management

Movement of Radioactive and Non-Radioactive Materials	WL Waste Management
Registration and control of radiation sources	WL Radiation Protection (RP)

Impairment Notification and Compensatory Measures	WL ES

1.3 Management Reviews

The Quality Assurance Program/Management System Review for 2018/19 and 2019/20 was completed. The review identified 6 actions, all of which are completed.

2 Human Performance Management

2.1 Human Performance Program

Whiteshell Laboratories adheres to the Corporate Human Performance (HU) Program. See Section 2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

2.1.1 Program Improvements and Accomplishments

The effectiveness of the HU program at WL has been enhanced through the following improvements:

- Following the 10 week fieldwork pause in 2020 November to address an adverse trend in human performance, WL gradually increased fieldwork throughout 2021 February. WL executed an extensive Corrective Action Plan, which included comprehensive reviews and updates to procedures and a significant investment in employee training. Improvements implemented included increased supervisor presence in the field, in depth review of proper use of tools and equipment, procedure awareness and compliance, sharing of lessons learned, and better pre- and post-job briefs. WL also performed several self-assessments through the integrated assessment plan and implemented new work control metrics.
- In 2021 May, Performance Assurance reintroduced the two-level rigorous review of ImpAct records by re-instating the Management Screening Team (MST) weekly meeting. MST's mandate is to provide management level review and oversight of the ImpAct record and ensure it has sufficient and accurate information to let the Management Review Meeting (MRM) team conduct their review. The MST assesses and recommends the significance level, cause determination effort, cause statement and the Responsible Manager. MRM provides Director level (and above) oversight for the ImpAct Corrective Action Program. The MRM team confirms, or modifies as appropriate, decisions made by the MST.
- In 2021 August, a three day TapRooT® Essentials Course was delivered to nine (9) WL Employees. The virtual sessions were taught by an external root cause analysis and investigation expert who guided immersive learning activities using interactive presentation technology, group exercises, and two-way interaction. TapRooT® is a powerful tool in conducting investigations and has already been used to augment CNL's current cause analysis techniques.
- WL enlisted the support of the recently formed CNL Strike Team, comprised of experts from across CNL, to conduct a causal analysis for a discovered adverse condition regarding the WL Preventative Maintenance program (see ERM-21-3009 in Table 5). Unlike the usual Apparent Cause Analysis or Root Cause Analysis processes, the Strike Team's causal analysis used a Facts Issues Causes Actions table. Doing the investigation in this manner allowed the team to develop the causal analysis and corrective actions in

a concise and timely manner. This tool will be beneficial for future investigations that may need to be conducted.

2.2 Training programs

Whiteshell Laboratories adheres to the Corporate Training and Development Functional Support Area. See Section 2 of the Annual Compliance *Monitoring Report for Canadian Nuclear Laboratories* for details [4].

2.2.1 Program Improvements and Accomplishments

The effectiveness of WL Training Program has been enhanced through the following improvements:

- Revisions to the content for the New Employee/Contractor Orientation to reflect current policies and procedures for working on site.
- WL introduced the Integrated Work Control Core 5 Elements course, which provides contractors with training that combines the 5 core courses delivered during the safety stand down: Work Permit Authorization, Job Safety Analysis, Pre-job Brief, Stop/Pause Work and Integrated Work Controls.
- Development of the initial Annual General Employee Training to review site and project updates, as well as policies and procedures. This will be updated and delivered annually to all employees.
- Updates and improvements to the content and media for the Radiation Group 4 Training delivered to all employees and contractors coming to site.
- Major revisions to the Delivering Practical Training course. Content now includes adult learning and learning principles content. This course is required for any employee who conducts on-the-job training and functional checkouts for skills assessments.
- Redevelopment of the Waste Management & Fundamentals courses to include updates to policies and procedures in our Waste Management Program.
- Revisions to the content and materials for Vehicle Spotter Training. Delivery to all staff who are required to have spotter training.
- Development of the ‘Training Matrix tool’ which allows managers and supervisors to quickly look up the training status of their teams.

2.2.2 Systematic Approach to Training

CNL maintains a list of positions and roles requiring Systematic Approach to Training (SAT) training programs in compliance with REGDOC-2.2.2, Personnel Training [11].

Training and Development evaluated the training programs for listed positions and roles at WL against the main elements of SAT. The results led to initial individual action plans which are being managed and further evaluated by the Curriculum Review Committees. Additional corrective actions and program improvements will be identified and managed by the

Curriculum Review Committees going forward. Since the initial analysis of the listed positions, dedicated Training and Development personnel have been hired and assigned to support WL in the completion of the action items identified. Curriculum Review Committees for the WL WMA and Shielded Facilities have been established and progress on the actions is underway.

2.2.3 Required Training

Some WL listed positions and roles require additional training documentation development to achieve full SAT-compliance. Current workers are qualified based on existing training programs combined with their years of experience in the role. Existing training programs include classroom training, practical training, computer-based training, and mentor style training. These experienced workers will assist as Subject Matter Experts (SMEs), in the development of training documentation that is required to achieve full SAT-compliance.

All Whiteshell Laboratories personnel, both employees and contractors, are adequately trained (and refreshed) to ensure safe operation of their facilities and to conduct work under the licence [1]. Section 2 of the Annual Compliance Monitoring Report for Canadian Nuclear Laboratories [4] provides the 2021 CNL Employee and Manager/Supervisor required training. Table 4 provides a list of federally/provincially legislated training courses that appear in position-specific training plans at Whiteshell Laboratories.

Table 4: Whiteshell Laboratories Operating Staff Training in 2021

Course Code	Course Title	No. of Attendees
OSH-1001-Online	Crane (Safe Indoor Hoist) – Theory	44
OSH-1002-Online	Lift Truck Operation – Theory	40
OSH-1003-Online	Aerial Work Platform – Theory	59
OSH-1004-Online	Lock Out / Tag Out Exam	28
OSH-1004-Virtual	Lock Out / Tag Out (Virtual)	28
OSH-1005-Online	Working at Heights – Theory	84
OSH-1006	Confined Space Entry	14
OSH-1006-Online	Confined Space Exam	15
OSH-1006-Virtual	Confined Space Entry (Virtual)	25
OSH-1007	Asbestos Module 6E	51
OSH-1033-Online	Ladder Safety	27
OSH-1034-Online	Hazard Prevention Program	31
OSH-1042-Online	WHMIS – 2015	40
OSH-1046-Online	Heat Stress	7
OSH-3001-E	Crane – Safe Indoor Hoist – Practical – Jib Crane	3
OSH-3001-F	Crane – Safe Indoor Hoist – Practical – Bridge Crane	3

OSH-3001-J	Crane – Safe Indoor Hoist – Practical Gantry Crane	2
OSH-3001-K	Crane – Safe Indoor Hoist – Practical	1
OSH-3001-L	Crane – Safe Indoor Hoist Only	13
OSH-3001-MULTI	Crane – Safe Indoor Hoist – Practical – All Equipment Codes	8
OSH-3002-C	Lift Truck Practical – Counter Balance	18
OSH-3002-MULTI	Lift Truck Operation – Practical/All Equipment Codes	4
OSH-3003-B	Aerial Work Platform Practical – Articulating Boom 60 ft (or less)	21
OSH-3003-C	Aerial Work Platform Practical – Rough Terrain Scissor Lift	27
OSH-3003-D	Aerial Work Platform Practical – Scissor Lift	25
OSH-3003-E	Aerial Work Platform Practical – Single Person Up-Up	1
OSH-3003-Multi	Aerial Platform – Practical (All Equipment Codes)	34
OSH-3005	Working at Heights – Practical	88
HU-1036-Online	Pre job Brief	12

2.2.4 Contractor Training

Before accessing the Whiteshell Laboratories, contractors are required to complete the following training:

- Contractor Safety Orientation
- Radiation Protection Group 4
- Integrated Work Control Core 5 Elements (Work Permit Authorization, Job Safety Analysis, Pre-job Brief, Stop/Pause Work and Integrated Work Controls)
- CNL COVID Awareness

WL utilizes the contract terms and conditions, in addition verifying and approving the contractor company’s safety programs and training records, to ensure contractors are qualified to work at WL.

WL oversees contractors’ work in the field and all WL work control protocols apply.

2.2.5 Training Evaluations Summary

In 2021 WL continued to utilize trainee feedback forms to capture learner input as part of training program improvement and maintenance activities. Also, there were 16 documented Observation and Coaching sessions related to training events. These evaluations are reviewed weekly by Training and Development staff and training program improvements are managed through applicable training change processes.

3 Operating Performance

3.1 Operating Program

Whiteshell Laboratories adheres to the Operating and Decommissioning Functional Support Areas. See Section 3.1 and Section 11.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Whiteshell Laboratories decommissions and operates its facilities according to prescribed programs and procedures. Operating performance is monitored through the nuclear performance assurance review board and other internal assessment activities such as self-assessments and audits (see Section 1.2).

3.1.1 Operations / Decommissioning Operations

Operational details on facilities identified in the *Site Licences, Certificates, Permits, Building/Facility Contacts, and Licence Representatives* [12] for Whiteshell Laboratories are given in Appendix A through F.

3.1.1.1 Conduct of Operations

Conduct of operations documents ensure appropriate integration and adequate reflection of safe operation practices to meet the business requirements.

3.1.1.2 Modification to Facilities and Processes

All temporary and permanent modifications to facilities at WL are made following defined Engineering Change Control [13] processes.

Relevant modifications to WL facilities are given in Appendix A through G.

3.2 Reporting Requirements

3.2.1 Reportable Events to CNSC

In 2021, there were 6 events that occurred at Whiteshell Laboratories that were deemed reportable to the CNSC. They are listed in Table 5.

Table 5: Reportable Events to the CNSC at Whiteshell Laboratories in 2021

Event No.	Title	SCA	Facility (if applicable)
ERM-21-3585	WL Injury - Medical Aid - Slip, Trip, Fall (Leg Injury)	Operating Performance	WL Building 300 (Research and Development)
ERM-21-3009	WL Reportable Event – Missed maintenance of safety related systems as per the Shielded Facilities Facility Authorization	Operating Performance	WL Shielded Facilities

HSSE-21-1772	WL - Radiation Source Found in Area Radiation Monitor Removed from B305 Electron Accelerator	Radiation Protection	WL Building 402 (Health and Safety)
ERM-21-1732	WL Environmental Protection: Hydraulic Leak at the Building 200 Demolition site involving a contractor's Hyster 550 Fork Lift (Rental Unit)	Environmental Protection	WL Building 200 (Active Liquid Waste Treatment Centre)
ERM-21-1651	WL Reportable Event - Building 402 Fire Protection System Impairment	Fire Protection	WL Building 402 (Health and Safety)
ERM-21-1036	WL - Incomplete Inventory Results in Misclassification of Shipment	Packaging and Transport	

3.2.2 Reportable Events to Other Regulators

Reports to other regulatory agencies consisted of:

- 1 Hazardous Occurrence Investigation Reports (HOIR) was made to Employment and Social Development Canada (see Section 8.1.3 for further details)
- 2 reports made to Environment and Climate Change Canada (see Section 9.5.2.4 for further details).

3.2.3 Trending of Events Related to Operational Activities

As events at Whiteshell Laboratories occur, they are recorded in the Improvement Action (ImpAct[2]) system. This information is regularly reviewed and analyzed to identify any trends. To identify trends Event Code based trend reports are also prepared to analyse ImpAct data on monthly bases. Monthly site wide and WL specific trend reports are prepared by CRL Performance Assurance and shared with WL. WL specific trends are also specified in the monthly Contractor Assurance System scorecard.

The following trends were identified and raised as ImpActs:

- ERM-21-1299, WL TREND – No Purchase Order in Place Prior to Commitments of Contract Service Providers Coming to Site
- ERM-21-3088, WL TREND - Misuse of WHMIS (Workplace Hazardous Materials Information System) when labelling or storing hazardous waste.
- ERM-21-3132, WL TREND – Increased Vehicle Accident Incident Reports (VAIR), Equipment and/or Passenger Vehicles on site and in main parking lot at WL.
- HSSE-21-3283, WL TREND – Barrier Crossings.

[2] ImpAct – Abbreviation for Improvement and Action. It is an internal process used to identify events, problems, non-conformities, opportunities for improvements, and personnel injuries. The process also identifies and tracks actions to correct or remediate problems.

The use of the ImpAct process continues to foster the internal reporting of lower significance level events (Level 4 and some Level 3), affording the opportunity to implement continuous improvement initiatives through a robust Corrective Action Program.

In 2021, a total of 424 ImpActs were raised by CNL employees at WL.

The reporting of lower significance level events continues to be encouraged (e.g., Near Miss Reporting – see Section 8, which is an industry best practice), and efforts to improve safety culture (Event Free Tools use, Event Free Day Reset, Observation and Coaching, etc.) have been adopted by both management and staff.

The following table summarizes ImpActs raised over the past 5 years by Significance Level[3].

Table 6: Number of ImpActs raised at Whiteshell Laboratories

Year	Level 0[a]	Level 1	Level 2	Level 3	Level 4	Total
2017	5	0	0	42	448	496
2018	10	0	0	39	532	581
2019	8	0	0	54	547	609
2020	13	0	3	58	276	350
2021	5	0	2	81	336	424

a Level 0 will be assigned if the ImpAct is deemed to be a “non- problem” and a recommendation to close the Impact will be given.

3.2.4 Notification of Conflicts or Inconsistencies

In 2021, there were no conflicts or inconsistencies identified between licence conditions, codes or standards, operations, programs, methods, or regulatory documents referenced in the Whiteshell Laboratories Licence [1] or *Licence Conditions Handbook* [2].

3 Significance Level: Levels assigned to an event (SL1 being most significant, SL4 being least significant) based on the actual or potential result in safety, environmental, or business consequences.

4 Safety Analysis

4.1 Safety Analysis Program

Whiteshell Laboratories adheres to the Corporate Safety Analysis Functional Support Area. See Section 4.1 of the Annual Compliance Monitoring Report for Canadian Nuclear Laboratories for details [4].

4.1.1 Safety Analysis Reports

Safety Analysis Reports (SARs) are produced to demonstrate that the facilities are appropriately designed to meet health, safety, security, environmental and regulatory requirements, and operated safely. These SARs form part of the basis for a set of limiting conditions for safe operation that are documented within Facility Authorizations for each nuclear facility. At WL, three facilities have SARs and Facility Authorizations: Shielded Facilities (SF), WMA and Concrete Canister Storage Facility (CCSF). The ALWTC SAR and Facility Authorization documents were previously obsoleted in 2020 [14]. Assessments are in progress to determine if the SF and WMA SARs need to be revised. The CCSF SAR is being updated to address upcoming fuel retrieval activities.

A SAR is being prepared for the standpipe/bunker remediation, Intermediate-Level Liquid Waste Processing Centre and conversion of the SMAGS building to a Cask Loading Facility. This document will be an addendum to the existing WMA SAR and will be submitted to the CNSC before these facilities are operated.

4.2 Nuclear Criticality Safety Program

Whiteshell Laboratories adheres to the Corporate Nuclear Criticality Functional Support Area. See Section 4.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

As the Nuclear Criticality Safety Program is a companywide program, enhancements and improvements made were intended to target all sites including WL and are identified in [4].

4.2.1 Nuclear Criticality Safety Documents

The WL Criticality Safety Documents (CSDs) for the Waste Management Area (CSD-27), the Cask Loading Facility (formerly the Whiteshell Laboratories SMAGS Building B923) (CSD-73) were conditionally accepted and the Intermediate-Level Liquid Waste Processing Centre (CSD-74), Concrete Canister Storage Facility (CSD 11), and the Fuel Basket Transfer Flask (CSD-54) are in progress to allow retrieval of waste from the WMA and CCSF. The remaining WL CSDs have not been updated during this review period.

5 Physical Design

5.1 Design Program

Whiteshell Laboratories adheres to the Corporate Design Functional Support Area. See Section 5.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Design Authority and Design Engineering Functional Support Area maintains and controls the design basis for all design activities performed at WL.

In 2021 March, the Certificate of Authorization was renewed with Engineers Geoscientists Manitoba. This authorizes CNL to engage in the practice of professional engineering in the province of Manitoba in accordance with the provisions of The Engineering and Geoscientific Professions Act.

5.1.1 Safety Related Structures Systems and Components

In 2021, the Design Authority and Design Engineering Program ensured that any structures, systems and components important to safety met and maintained their design basis, and any changes made were controlled through the Engineering Change Control Process [13].

5.2 Pressure Boundary Program

Whiteshell Laboratories adheres to the Corporate Pressure Boundary Functional Support Area. See Section 5.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Pressure Boundary Functional Support Area applies to design, procurement, fabrication, installation, examination, testing, repair, modification, construction and maintenance of pressure retaining systems and components performed by CNL at WL.

The *WL Pressure Boundary (PB) Quality Assurance (QA) Plan* [15] details the specific scopes of pressure boundary work carried out at WL, as permitted by the Certificates of Authorization issued by Inspection and Technical Services (ITS) Manitoba, describes the controls, authorities, and responsibilities applicable at the WL site, and is consistent with CNL's PB Program requirements.

The revised *PB QA Plan* [15] was accepted by ITS and a new Certificate of Authorization was issued on 2021 August 10. The new certificate of Authorization permits CNL to perform Pressure Boundary work as described in the Quality Assurance Plan until expiry in 2024 August.

The CNSC has previously been notified of revisions to the *PB QA Plan* [15], as per the *Licence Conditions Handbook.*

6 Fitness for Service

6.1 Fitness for Service Program

Whiteshell Laboratories adheres to a Fitness for Service Program through its Maintenance Functional Support Area. See Section 6.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Site and Nuclear Operations Branch provides monitoring and operation of building's processes and support systems. Housekeeping inspections are performed monthly to provide a formal walkthrough of facilities to ensure compliance for specific areas relating to facility performance. Further inspections are conducted of waste storage structures by qualified personnel to maintain them in a fit for service state.

Operating procedure reviews are conducted on a five year cycle. Currently the Operating Procedures are under review; some of these procedures have reached the five-year timeline for review and those are being prioritized for review and updating. As facilities are decommissioned procedures related to those buildings or processes are obsoleted. Procedures to operate the facilities in order to enable decommissioning efforts are prepared as required.

Details on various inspection and maintenance activities are provided in the following sub sections.

6.1.1 Planned Maintenance, Testing & Inspections

As part of Fitness for Service, WL staff ensure that critical systems, structures and components related to the safe decommissioning of WL are understood and that activities are put in place to assure their safe continued operation as they age. An integrated set of programs and activities ensures that performance requirements for all critical systems, structures and components are met on an ongoing basis. These processes include:

- Maintenance, In-Service Inspection and Functional Testing, where preventive maintenance work done in the facilities is tracked to ensure it is completed.
- WL operational regulatory tasks are tracked on a weekly basis to ensure required compliance and facility checks are completed, this includes the tasks set out in the Facility Authorization documents.
- Inspections required to meet the conditions of WR-1 Monitoring and Surveillance Plan.
- Inspections of waste storage structures for fitness for service.

6.1.2 Equipment Fitness for Service/Equipment Performance

Preventive maintenance of safety-related systems in WL's nuclear facilities is carried out by qualified maintainers, in accordance with the facility's Facility Maintenance Plan, and approved maintenance procedures. Preventive Maintenance is defined as the pre-planned routine testing, calibration, inspection, service, and overhaul of safety-related systems, structures, and components. Preventive maintenance is performed to prevent failures from occurring and to

assure the continuing capability of the system, structure or component to perform its design function. The maintenance tasks and frequencies specified in the Facility Maintenance Plan are based on recommendations from qualified WL engineering and maintenance personnel, plus vendor's data where available. Situations where there is evidence of deteriorating conditions or suggestions of an increased probability of upcoming failure are addressed as they are identified. Regular preventive or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service. Maintenance scheduling is conducted with assistance of a Computerized Maintenance Management System which outputs preventive maintenance tasks for scheduling by maintenance and work planning staff.

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed and is being implemented that will fix the issues and prevent recurrence. The effectiveness of the corrective action plan will be investigated upon completion of the actions.

6.1.3 Condition of Structures

Waste storage structures include the WMA bunkers and CCSF concrete canisters.

As a requirement of the Environmental Assessment Follow-up Program, a Periodic Inspection Plan (PIP) for WL Concrete Bunkers [16] was developed in 2007 and continues to be implemented to confirm the ongoing fitness-for-service of the concrete storage facilities (termed "bunkers") at the WMA. The PIP describes methods for conducting scheduled inspection surveys of these structures. The inspection is defined as examination, measurement and testing work done, to ensure the bunker systems are functioning as designed and the bunkers remain fit-for-service. The inspections are documented annually, with preventive maintenance and repairs occurring as needed. As the bunkers at the WMA are removed from service as part of the overall decommissioning of the WL site, they will be removed from the inspection process. The 2021 annual inspection of WL WMA concrete bunkers was conducted in accordance with the PIP [16].

Although the SMAGS building (Building 923) is not a bunker it has been included in the bunker inspection. Building 923 is being converted to the Cask Loading Facility, and during this conversion and subsequent re-commissioning for its new purpose, it will not store waste. A repair, conducted in 2016, to the north wall of Building 923 that extended into the core of the slab, remained stable through 2021 with no new crack expressions (the walls of Building 923 are pre-cast concrete slabs). All other repair items for the bunkers and Building 923 were minor in nature and were tracked through the WL work request system.

The concrete canisters are inspected quarterly for concrete spalls and any changes in the hairline cracks of the concrete. In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however existing cracks and pour pockets were regularly checked for changes. Requests for patching were placed in 2021, and several canisters will require more extensive patching of pour pockets that have gradually become more noticeable over time, however no increased radiation field was noted.

Environmental monitoring was conducted in the ditches at the perimeters of the WMA and the CCSF and show no evidence that any activity has been released from the bunkers, SMAGS or concrete canisters.

7 Radiation Protection

7.1 Radiation Protection Program

Whiteshell Laboratories adheres to the Corporate Radiation Protection Functional Support Area. See Section 7 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Whiteshell Laboratories uses the Chalk River Laboratories (CRL) licensed Dosimetry Service Provider for external and internal dosimetry for site/facility staff and contractors.

Whiteshell Laboratories staff and contractors who work at the WL site are assigned Thermoluminescent Dosimeters (TLDs) to monitor for external radiation exposures.

7.1.1 ALARA Initiatives and Activities

As Low as Reasonably Achievable (ALARA) and Radiation Protection (RP) program improvement initiatives and activities performed at WL in 2021 included:

- Radiological hazard and precaution sheets were reviewed and updated as required to remove statements such as “at the Surveyor’s discretion” or “as directed by RP Surveyor”.
- Enhanced personal protective clothing and equipment requirements were implemented for work in Radiological Safety Zone 2 and 3 work areas.
- Guidelines were developed and implemented for field RP staff for consistent completion of radioactive material transit/storage tags.
- Radiological surveys completed in WL nuclear facilities to confirm absence or identify unknown and unmarked historical or legacy contaminated materials and areas.
- Facility review completed for the adequacy of radioactive material storage areas.
- Field compliance check list developed and implemented for use by field RP staff during facility housekeeping inspections.
- Guidelines provided for RP staff when knee pads or other additional measures are needed to prevent inadvertent knee contaminations when working in contaminated environments.
- New CNL RP program requirement for formal registration of long term radioactive material storage areas was implemented for any new storage areas, and work started on registration of pre-existing facility storage areas.
- WL site procedure developed for the dose monitoring program for WL workers, contractors and visitors.

WL RP performance metrics are measured and tracked weekly through WL Closure Project status reports and quarterly through the WL Nuclear Performance Assurance Review Board. These are designed to identify and address program and performance deficiencies and

opportunities for improvement, establish and effectively implement corrective and preventative action plans.

7.1.2 Dose Control

Regular radiation surveys are performed by RP staff to confirm: the radiological safety zones are correctly designated; areas with local elevated radiation doses rates are posted in accordance with the RP Regulations; and sufficient access control provisions are in place. In 2021, there were no occurrences of dose rates exceeding permissible levels for the designated radiological safety zones and there were no occurrences of work places with accessible dose rates exceeding 25 µSv/h not being posted or with inadequate access control.

Electronic Personal Alarming Dosimeters (PADs) are worn by workers in addition to TLD badges to track and control job specific daily and accumulated doses. The PADs have dose and dose rate alarms which are established by job specific radiological work assessments. The dose alarms are a back-out condition and the dose rate alarms are an alert condition. Table 7 summarizes maximum daily recorded doses and dose rates for PAD work in 2021 and the previous four years, and a summary of PAD alarms. In 2021, the maximum PAD recorded daily dose received by a worker was 0.22 mSv and the highest dose rate measured in the year was 3.1 mSv/h. These were associated with planned exposures associated with decommissioning activities in the Building 200 ALWTC, and removal and packaging hot cell roughing filters in the WL Shielded Facilities. There were no PAD dose alarms and 78 PAD dose rate alarms in 2021. The distribution of PAD dose rate alarms over the past 5 years is summarized in Table 8.

There was an increase in the number of low level dose rate alarms in 2021 due to increased decommissioning and operations activities in the WMA associated with the removal, characterization and packaging of low level radioactive waste from waste storage buildings. These low level dose rate alarms helped alert workers of dose rate areas they did not need to be working in, and thus helped to maintain low doses to workers.

Table 7: Personal Alarming Dosimeter Summary

	2017	2018	2019	2020	2021
PAD – Maximum Daily Dose (mSv)	0.17	0.24	0.42	0.28	0.22
PAD – Maximum Dose Rate (mSv/h)	1.99	4.95	5.82	5.56	3.10

Table 8: Distribution of Number of PAD Dose Rate Alarms 2017-2021

Year	Dose Rate Alarm Set Point (mSv/h)							
	≤0.10	>0.10 - <0.25	0.25 - < 0.50	0.50 - < 1.0	1.0 – < 2.5	2.5 - < 5.0	5.0 - < 10	≥ 10
2021	11	20	22	16	7	2	0	0
2020	10	2	1	5	9	1	1	0
2019	9	0	2	12	4	2	0	0
2018	22	0	13	5	31	3	0	0
2017	22	3	26	2	5	0	0	0

At the beginning of 2021, managers assigned and confirmed Dose Control Points (DCPs) for employees and contractors. DCPs are used by managers and supervisors to perform individual whole-body dose management for worker radiation dose for non-emergency work situations. DCPs of either 1 mSv or 2 mSv are assigned by WL managers and represent the worker's maximum allowable dose for the calendar year. The DCPs may be adjusted as necessary during the year upon approval of a Health Physicist after confirmation that additional dose is justified. At the end of 2021, there were no individuals with an assigned DCP higher than 2 mSv, 28 individuals with an assigned DCP of 2, and the remainder of workers with a DCP of 1 mSv. No worker dose exceeded their assigned DCP in 2021.

7.1.3 Contamination Control

Regular contamination surveys of workplaces, material transfers, and personnel exiting nuclear facilities and controlled areas, are used to confirm the absence of unknown contaminated material or the spread of contamination. Workplace air monitors are employed to confirm the adequacy of controls, and to warn of abnormal or unplanned airborne contamination conditions.

Table 9 shows the number of personnel, workplace and material contamination events identified in 2021 and over the past five years. None of the contamination events in 2021 resulted in a recordable whole-body, skin or internal dose.

Material contaminations increased from 1 in 2020 to 11 in 2021. This increase was due to historical surplus equipment being found with low level contamination during operational cleanup activities (8), building decommissioning waste disposition (1), and as a result of operational activities (2). There were no worker skin or clothing contaminations in 2021.

In 2021, there were no airborne contamination exposure events and no radioactive material spills.

The following table outlines contamination events that occurred at Whiteshell Laboratories in 2021:

Table 9: Contamination Events

	Skin and Clothing Contamination				Workplace Contamination	
	Skin[a]	Personal Clothing[a]	Radiological Work Clothing[b]	Total	Surface[c,d]	Vehicle / Materials [b, c]
2017/18 FY	0	0	1	1	3	
2018/19 FY	1	0	5	6	6	0
2019 CY	3	0	4	7	2	4
2020 CY	2	0	3	5	1	1
2021 CY	0	0	0	0	1	11

a Total surface contamination found is greater than 1 Bq/cm^2 beta-gamma or 0.2 Bq/cm^2 alpha over a 100 cm^2 averaging area.
b Total surface contamination found is greater than 4 Bq/cm^2 beta-gamma or 0.4 Bq/cm^2 alpha over a 100 cm^2 averaging area.
c Removable surface contamination found is greater than 0.2 Bq/cm^2 beta-gamma or 0.01 Bq/cm^2 alpha over a 300 cm^2 averaging area for Contamination Zone 1 areas
d Removable surface contamination found is greater than 10 times the maximum allowable levels for Contamination Zone 2 and higher designated areas.

7.1.4 Sealed Sources

Radiation sources are registered and tracked in accordance with CNL procedures.

In 2021, there were no lost or stolen radiation sources. Leak testing was completed as required with all sources passing their leak tests.

As of 2021 December 31, the total number of registered sealed or contained sources at WL, was 53. One Cesium (Cs)-137 source was added to the registry, and one mixed Cs-137 liquid standard and one Cs-137 gamma irradiator were removed from the registry. The liquid standard was evaporated and dispositioned as radioactive waste. The Cs-137 calibrator was transported back to the manufacturer.

7.2 Dosimetry

7.2.1 Interpretation of Reported Dose Quantities

WL uses the CRL licensed Dosimetry Service Provider for external and internal dosimetry for CNL staff, non-CNL employees and visitors. Compliance with the regulatory document REGDOC 2.7.2, *Dosimetry*, Volume II [17] requires external exposure measurements to meet performance criteria with respect to the measurement of personal dose equivalent, $H_p(d)$. This is the quantity currently measured using TLDs worn on the trunk of the body. External whole-body dose (photon) and external surface (photon plus beta) dose as reported herein can be interpreted as $H_p(10)$ (for photons) and $H_p(0.07)$ (for photons and betas), respectively. Effective

dose is the sum of the components external penetrating, neutron, tritium and non-tritium committed effective dose.

External radiation whole-body and skin doses are individually monitored using TLDs for persons entering or working in either radiological Controlled or Supervised Areas at WL[4].

Extremity dosimeters are worn for a defined job by a person who is likely to receive an extremity dose exceeding 1 mSv and significantly greater than a surface dose as monitored by their TLD, or if there is a reasonable probability that an extremity will be exposed to a beta and/or photon dose rate greater than 10 mSv/h.

Neutron dosimeters are issued to individuals who may be exposed to neutrons resulting in dose in excess of 1 mSv in a year or where accidental neutron exposures are possible.

WL staff participate in a routine bioassay program when there is a reasonable probability of receiving a committed effective dose from occupational intakes exceeding 1 mSv per year.

7.2.2 Radiation Doses to Personnel

Table 10 to Table 13 summarize the monitored radiation doses at the WL site for 2021. Doses are summarized for employees, contractors and visitors and are subdivided into Nuclear Energy Worker (NEW) and non-NEW status. Doses in the tables of this report do not include doses received by WL employees and contractors working at sites other than WL. Two visitors had NEW status that were associated with prior NEW requirements and visits within CNL as a whole, these two instances were CNSC and IAEA staff.

In 2021, there were no exceptions for individual monitoring of non-CNL employees and visitors at WL, other than drivers of delivery trucks and building demolition debris haulers in radiological Supervised Areas.

There were no operations of exposure devices in 2021 which required employees or contractors to be placed on a two-week dosimetry period, and there were no formal dose calculations required during 2021 for local area skin contamination.

No neutron dosimeters were assigned to employees during 2021.

In 2021, 180 individuals underwent internal bioassay, which involved urinalysis and/or whole-body counting. Eleven individuals underwent confirmatory and follow-up Pu-in-urine bioassay monitoring and there were no individuals requiring tritium-in-urine monitoring. No committed effective dose estimates were necessary as a result of any bioassay sampling in 2021.

In May of 2021 the building (B402) that housed the WL Whole Body Counter (WBC) began decommissioning and demolition and a new building (B543) is currently being commissioned to house the WBC. It is anticipated that the new facility will be ready for occupancy sometime in the spring of 2022. During this outage, workers who normally participate in annual or bi-annual WBCs were evaluated against the site's current radiological activities to determine which

---

4 Exceptions are authorized on a case-by-case basis by the responsible RP Program Manager or RP Program Functional Support Manager (exceptions are noted in Section 7.2.2).

workers required alternative monitoring. Workers with reasonable potential for an intake which warranted alternate monitoring were placed on a gamma spectrometry in urine analysis (provided by CRL Dosimetry Services) which provides similar minimum detectable doses to the WBC analysis. Additional random (biased toward likelihood of an intake) urine bioassay monitoring of workers who did not meet the alternative monitoring criteria is being undertaken until the new facility is ready.

Table 10: Effective Dose for Whiteshell Laboratories

Monitored Person Type		Total # of Persons	Dose Range (mSv)							Individual Dose (mSv)			Collective Dose (p·mSv)

d Visitor NEWs are persons who were former employee and/or contractor NEWs, but who have returned to the site as visitor while retaining their historical NEW status.

7.2.2.1 Discussion of Dose Data

The Regulatory effective dose limit for a NEW in a calendar year is 50 mSv. The maximum individual effective dose to a NEW at WL in 2021 was 0.57 mSv and the site collective dose was 18.99 p-mSv.

The Regulatory effective dose limit for a NEW in a five-year period is 100 mSv. The maximum individual effective dose to a NEW at WL for the current five-year dosimetry period from 2021 to 2025 at WL was 0.57 mSv.

The Regulatory skin dose limit for a NEW in a calendar is 500 mSv. The maximum individual skin dose to a NEW at WL in 2021 was 0.94 mSv and the site collective dose was 23.47 p-mSv.

The Regulatory hands and feet dose limit for a NEW in a calendar is 500 mSv. The maximum individual hands and feet dose to a NEW at WL in 2021 was 1.86 mSv and the site collective dose was 7.26 p-mSv.

The Regulatory effective dose limit for a pregnant NEW is 4 mSv for the remainder of their pregnancy. In 2021, the maximum individual effective dose from the time the pregnancy was declared to the end of the pregnancy term was 0.05 mSv.

The Regulatory effective dose limit for non-NEWs is 1 mSv in a calendar year. In 2021, the maximum individual effective dose to a non-NEW at WL was 0.11 mSv.

Table 14 provides a summary of radiation doses by worker group in 2021. The majority of radiation doses were received by RP, Nuclear Operations and Trades staff.

7.2.2.2 Radiation Dose Changes or Trends

Table 15 shows external whole body dose received from 2017 to 2021, and Figure 1 displays the maximum individual and collective dose from 2001-2021.

Worker doses decreased in 2021 with the completion of higher dose extensive decommissioning activities in Building 200 (ALWTC) in 2020. The site collective dose decreased from 33 p-mSv in 2020 to 19 p-mSv in 2021. The number of workers receiving occupational doses above 0.2 mSv in a calendar year decreased from 25 workers in 2020 to 11 workers 2021. This a significant decrease compared to a maximum number of 42 workers in 2017. There were no workers receiving an annual radiation dose above 1 mSv in 2021.

Main contribution to radiation dose in 2021 was radioactive tanks removal during B200 demolition activities, and operational replacement of hot cell roughing filters. There was increased waste handling in 2021 with the start of the removal, characterization and packaging of low level radioactive waste packages from storage facilities in the WMA. However, these activities had only a small contribution to site worker doses.

7.2.3 Program Exceedances

During 2021, radiation dose to all persons working at WL were below the WL dose Action Levels [2] and the respective CNSC regulatory limits [18]. In addition, there were no individual doses exceeding their respective DCP as a result of activities at WL.

Table 14: Summary of Worker Group Radiation Doses at WL for 2021

	Total Number of Persons	Individual Whole-Body Dose (Effective Dose[a])		Collective Whole-Body Dose (Effective Dose[a])	Collective Surface Dose (photon plus neutron plus beta)	Collective Extremity
		Average[b] (mSv)	Maximum (mSv)	p·mSv	p·mSv	p·mSv
Nuclear Facilities:						
SF Staff (HCF and IFTF)[c]	5	0.18	0.49	0.91	0.92	1.83
WR1 and ALWTC Staff	5	0.07	0.14	0.37	0.37	0
WMA and CCSF Staff[c]	6	0.07	0.21	0.39	0.39	0
Support Workgroups:						
Radiation Protection Staff [d]	41	0.11	0.43	4.43	6.02	1.06
Trades Staff [e]	48	0.09	0.57	4.31	6.35	4.37
All Remaining Staff:						
Other Staff [f]	513	0.02	0.19	8.48	9.32	0
WL Site[g]:	618	0.03	0.57	18.89	23.37	7.26

a Includes photon and neutron; there were no tritium committed effective doses for 2021.

b Average of all measured doses that includes the zero dose values, rounded to two decimal places. Includes employees and contractors.

c SF= Shielded Facilities; HCF = Hot Cell Facilities; IFTF = Immobilized Fuel Test Facility; ALWTC= Active Liquid Waste Treatment Center; WMA= Waste Management Area; CCSF= Concrete Canister Storage Facilities; WR1 = An experimental test reactor built at WL – WR-1 featured an organic liquid coolant.

d Radiation Protection staff include Radiation Surveyors, Radiation Protection Assistants, Contamination Monitors, and Decontamination Operators.

e Trades staff provide services for all listed facilities and decommissioning activities as well as the WL

site in general.

f Other staff is comprised of all remaining staff and includes decommissioning, administrative, management, engineering, quality assurance, researchers, contractors and tenants.

g WL Site includes 393 CNL staff (WL and staff visiting from other CNL sites) and 225 contractors working at the WL site during 2021. This tally does not include visitor doses.

Table 15: WL External Whole-Body Dose Performance 2017 to 2021

Performance Metric	2017	2018	2019	2020	2021
Site Collective Worker Dose (p-mSv)	19.9	40.2	49.6	33.4	18.9
Max Individual Worker Dose (mSv)	1.41	1.65	3.09	2.97	0.57
Number of Workers > 0.2 mSv in a year	42	39	38	25	11
Number of Workers > 1 mSv in a year	1	12	14	8	0
PAD[a] – Maximum Daily Dose (mSv)	0.17	0.24	0.40	0.28	0.22
PAD – Maximum Dose Rate (mSv/h)	1.99	4.95	5.82	5.56	3.1

a Personal Alarming dosimeter.

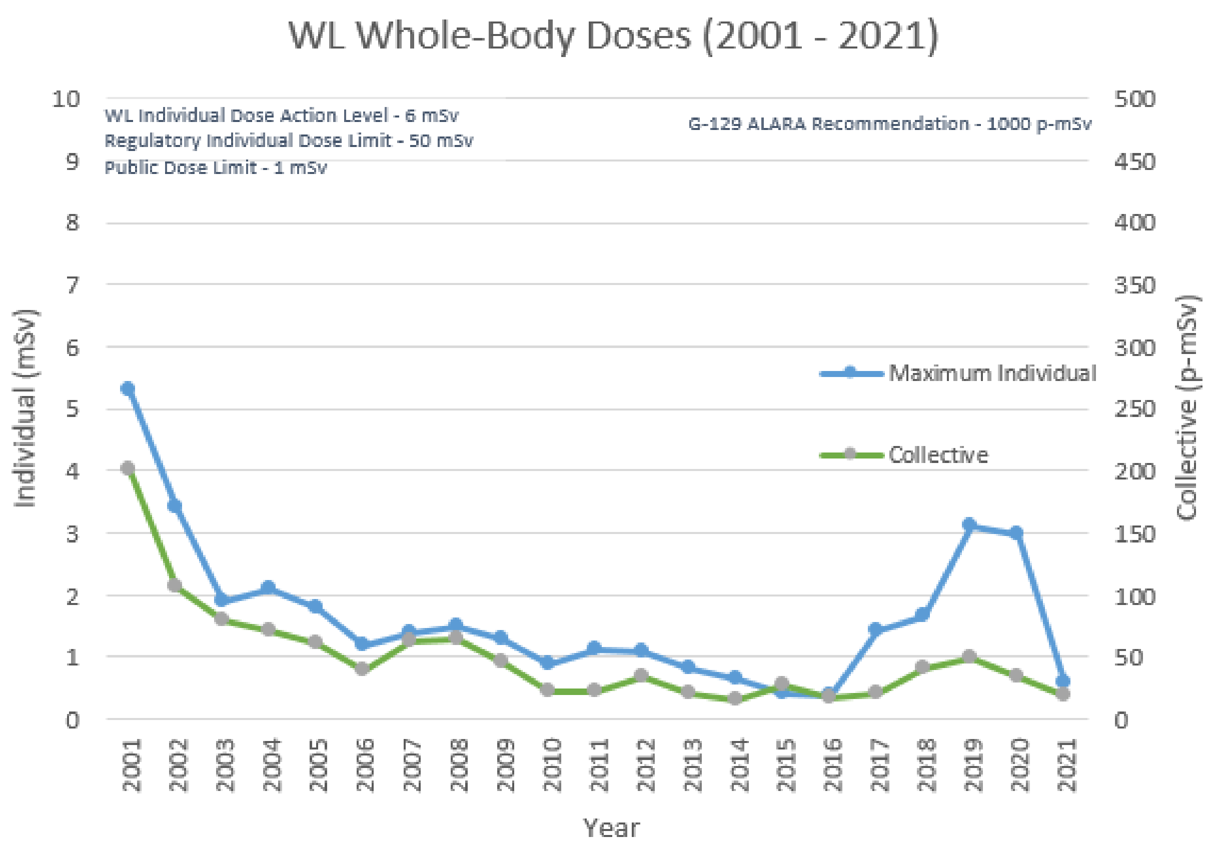

Figure 1: Whole-Body Effective Doses (2001 – 2021)

8 Conventional Health and Safety

8.1 Conventional Health and Safety Program

Whiteshell Laboratories adheres to the Corporate Conventional Health and Safety Functional Support Area. See Section 8 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In support of reducing the number and impact of incidents with the potential for injuries or incidents at WL, the following initiatives are continuing or began in 2021:

- To support project work, WL OSH purchased noise dosimeters, a sound calibrator, Jerome Mercury detector and Colorimetric Badges for chemical detection.
- OSH presence in the field continued at pre-job briefings, walk downs and daily work plan meetings together with early involvement in the planning process have contributed to WL's internal safety success.
- Contractors continued to be "pre-qualified" prior to bidding on WL contracts. The pre-qualification process involves reviewing safety statistics and the safety programs of the potential bidders.
- WL continued to participate in the Rapid Learning Morning Call to quickly share safety information with all CNL sites, as well as gather safety information relevant for the WL site.
- Increased contractor oversight continued by participating in activities such as site visits, pre-job briefs, pre-bid meetings and OSH orientation for contractors.
- There were 11 internal Safety Advisories and 2 Learning Advisories sent to WL site employees. The bulletins are intended to inform WL employees about imminent issues that could impact their safety. WL continued to be proactive in the approach to safety.
- Near Miss reporting (a known industry best practice) continued with a focus on early hazard recognition and strong situational awareness culture, supporting the minimization or elimination of hazards prior to resulting in injury (see Table 16).
- Near Miss reporting at WL always includes an investigation/fact finding session. The majority of Near Miss reports also generate an ImpAct. Whether an ImpAct is generated or not, the possibility of a human error trap being involved in the Near Miss incident is always considered, evaluated and followed up as appropriate.
- OSH Program weekly review of company injury/illness reports in support of recognizing trends and disseminating lessons learned.
- Focus on disability management / return to work in support of minimizing the impact to an injured employee and subsequent days lost.
- Promoted the Stop/Pause protocol.

Table 16: Summary of WL Near Miss Reporting

Year	2017	2018	2019	2020	2021
Near Miss Reported	60	53	46	10	26

8.1.1 Site Safety and Health Committee

The Site Safety and Health Committee is the principal forum at WL for joint employee/ management consultation and development of solutions to safety and health concerns at the WL site. The WL Site Safety and Health Committee meets on a monthly basis.

In 2021, the WL Site Safety and Health Committee received 93 inquiries out of which 6 remained open and in progress. There was one inquiry carried over from 2020. The Site Safety and Health Committee acts as an oversight body, therefore these actions are largely related to the Site Safety and Health Committee's need for more information that provides them with assurance of the effectiveness of the actions of the functional safety groups on site.

8.1.2 Inspections

There were 61 site health and safety inspections completed in 2021.

8.1.3 HOIRs and Lost-Time Injuries

There was one hazardous occurrences at Whiteshell Laboratories that was reported to Employment and Social Development Canada in 2021. CNSC staff received a copy of this notification, as per the requirements of the CNSC REGDOC-3.1.2 [3].

The following is a summary of injury rate data for the last 5 years.

Table 17: Summary of Whiteshell Laboratories Injury Rate Data

	2017	2018	2019	2020	2021
Whiteshell Laboratories					
Person Hours Worked	706,000	688,000	642,000	584,030	684000
Lost-Time Injuries	3	1	0	1	0
Working Days Lost	27	5	0	2	0
Frequency[a]	0.85	0.25	0	0.34	0
Severity[b]	7.76	1.45	0	0.68	0
Whiteshell Laboratories Contractors[c]					
Lost Time Injuries	1	0	0	0	0
Working Days Lost	0[d]	0	0	0	0

a Frequency rate equals # of Lost-Time Injuries x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).

b Severity rate equals # of Working Days Lost x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).

c The Number of Person Hours worked are not divulged by Contractors. As such, Frequency and Severity rates cannot be calculated.

d Number of days lost is unknown as the contractor terminated the employee.

The Recordable Lost Time Injury rate over the last five years at WL in Manitoba is significantly lower than local lost-time injury rates for construction (3.7) and manufacturing (2.4), as per the data from the Workers Compensation Board of Manitoba found in *The Manitoba Workplace Injury and Illness Statistics Report 2010-2019* (safemanitoba.com).

No Assurance of Voluntary Compliance or Directions were issued by Employment and Social Development Canada in 2021.

9 Environmental Protection

9.1 Environmental Protection Program

WL adheres to the Corporate Environmental Protection (EnvP) Functional Support Area. See Section 9 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

WL has an integrated Environmental Protection Program designed to track radiological and non-radiological contaminants throughout the different compartments of the geosphere, atmosphere, and biosphere, and consists of three distinct programs: the Effluent Verification Monitoring Program, the Environmental Monitoring Program, and the Groundwater Monitoring Program. The WL Environmental Protection Program is designed to implement the requirements of:

- CSA N288.4-10, *Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [19],
- CSA N288.5-11, *Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [20],
- CSA N288.6-12, *Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills* [21],
- CSA N288.7-15, *Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [22],
- CSA N288.8-17, *Establishing and Implementing Action Levels for Releases to the Environment from Nuclear Facilities* [23], and
- ISO 14001:2015, *Environmental Management Systems* [24].

The integrated Environmental Protection Program is dynamic in nature, meaning that it is continually evolving based on various sources of information received.

Program documentation is updated on an ongoing and/or required basis.

This report will focus and discuss the implementation of the WL Effluent Verification Monitoring Plan [25]. This plan defines the methodologies and protocols followed in performing the effluent verification monitoring required in CSA N288.5-11 [20].

The WL site has maintained its ISO 14001 [24] registration in 2021 with initial registration in 2010.

The CNSC has previously been notified of revisions to *Environmental Protection documents* [26], as per the *Licence Conditions Handbook.*

9.2 Quality Assurance

In order to ensure that the data collected through the program is valid, the laboratories performing monitoring for the program have strong Quality Assurance/ Quality Control programs as required by CSA N288.5 [20]. General quality assurance objectives for CNL's

Environmental Protection Program are set out in quality assurance plans. Radiological analysis is conducted in accordance with laboratory-specific environmental monitoring quality assurance plans. The plans include detailed working procedures for field operations, laboratory operations, laboratory administration, equipment performance, and quality verification of analytical results. The plans were written to align to ISO/IEC 17025 [27] for analytical laboratories.

Whiteshell Laboratories' Environmental Management group conducts frequent internal checks of their technical capabilities as they perform their measurements. These are called Quality Verification Tests, and are grouped as follows according to purpose:

- *Reproducibility Tests*, such as measurement of sample replicates, establish the relative precision of the method(s). To be acceptable, replicate measurements must agree within limits established by long-term method performance.
- *Accuracy Tests*, such as blanks or samples, each spiked with known amounts of the analyte(s), establish the presence or absence of any biases due to sample matrix, sample preparation, or instrument function. To meet acceptance criteria, the spike quantity must be recovered within limits established by long-term method performance.

Environmental Management performed 3247 quality verification tests during 2021 on WL's radiochemical counting equipment. Of these tests, 99.6% fully complied with acceptance criteria. The results of these tests are shown Table 18.

Table 18: Whiteshell Laboratories' Summary of Quality Verification Test Performed

Method	No. of Tests	No. of Failures	% Pass
Total Alpha (Instrumentation)	1188	4	99.7
Total Beta (Instrumentation)	1188	5	99.6
Gamma (Instrumentation)	647	0	100.00
Tritium	224	4	98.2
2021 Total	**3247**	**13**	**99.6**

In 2021, the WL Effluent verification program continued performing regular field Quality Verification testing on the Outfall, Lagoon, and Ditch effluent sampling (Table 19). The program is using traveling blanks to determine and account for any possible introduction of contamination into the sample being analyzed by the sampling methodology being employed by the program, and the program is also collecting duplicate samples to demonstrate sampling reproducibility.

Table 19: Whiteshell Laboratories' Summary of Field Quality Verification Tests Performed

2021 Total	**224**	**--**	**148**	**89%**

LMDL = Laboratory Method Detection Limit

It is important to note that not all of the radiological results for 2021 have been received from the contract laboratories carrying out the analysis of samples (see also Section 9.4.1.3.2). At the time of writing this report, results received to date indicate that out of the 148 duplicate quality verification tests, 132 of these tests meet the acceptance criteria (+/- 20% of the actual result) of the program, to yield an 89% pass rate. A larger number of duplicates failed this year, with the majority of the failures being related to the metal concentrations being observed at the Outfall monitoring station. CNL is attributing this increase in failures to the fact that the metal concentrations being observed in the effluent are near the detection limit. This leads to results with low concentrations and high variability being produced, which will increase the likelihood of a failure in the duplicates being observed. This is supported by the large number of results classified as not being detected, and the low concentrations of metals being observed at the Outfall as seen in Table 32. No further action by CNL is needed to address the failures.

Reviewing the travelling blank data, and comparing it to the field results, the environmental program has concluded that the water source being used for the travel blank is slightly contaminated with Copper, Lead, Zinc, Chloroform, and Bromodichloromethane. The traveling blank results for these parameters are not reflective of contamination being picked up while sampling in regards to these parameters.

In 2021, the WL Environmental Management group took part in four inter-laboratory comparison studies. Two of these studies, which focused on radiological analyses, were offered through the Environmental Research Associates. The other two studies which focused on non-radiological analyses, were offered through the Canadian Association for Laboratory Accreditation. The results of the WL Environmental Monitoring laboratory performance are shown in Table 20 and Table 21. There were four unacceptable test results out of thirty for the Environmental Research Associates inter-laboratory comparison studies, resulting in an 87% pass rate. The four unacceptable test results related to the gross alpha and gross beta analysis of water samples. The WL radiochemical counting laboratory is working on determining the cause of the problem, and until the cause has been identified, all quantitative analyses of this nature are being contracted out to a third party laboratory. The laboratory is in the process of ruling out possible factors. The areas the laboratory are currently reviewing includes the process for evaporation and ashing samples being utilized to prepare samples. The previously used method was required to change due to equipment limitations in the new environmental laboratories. The standard stock solutions that are used for the creation of the calibration curves used in this analysis may have also been compromised.

For the Proficiency Testing Canada inter-laboratory comparison studies, a 100% pass rate was achieved.

Table 20: Environmental Research Association Inter-Laboratory Comparison Program for CNL WL - 2021

MRAD* Study	Matrix	Analyte	Units	MRAD Assigned Value	WL Reported Value	Acceptance Limits	Performance Evaluation
MRAD-34	Air Filter Radionuclides	Americium-241	(pCi/Filter)	60.2	64.20	43.0 – 80.3	Acceptable

9.3 Supplementary Studies

In 2020, the WL site began to do temporary enhanced monitoring on the effluent verification ditches for the year. The enhanced monitoring is being done to confirm the absence of a number of radiological and non-radiological parameters. The enhanced monitoring involved doing an open scan for Volatile Organic Carbons, semi-volatile organic carbons, and an expansion of the metals and gamma isotopes list currently being used to monitor the ditches.

Whiteshell is reviewing the data, and is deciding whether there is a need to add any of these parameters to the effluent verification monitoring program going forward. This study was on going in 2021, and will be continued into 2022 due to the limited number of ditch sampling events that occurred in 2021.

9.4 Effluent Monitoring - Radiological

This section addresses the licence requirement regarding radiological monitoring of airborne and liquid effluents for the WL site, located on the Winnipeg River near Pinawa, Manitoba. It also addresses the effluent monitoring requirements listed under the Environmental Assessment Follow-Up Program [28] for WL.

Results of environmental monitoring and progress on the Environmental Assessment Follow-Up Program work packages will be provided in their respective annual reports, *Environmental Monitoring in 2021 at Whiteshell Laboratories* [29] and *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28].

9.4.1 Effluent Monitoring

9.4.1.1 Site Effluent Verification Monitoring System and Results Evaluation

Monitoring locations for airborne and liquid effluent streams are representative of the final discharge to the off-site environment, and may include the combined discharge from a number of facilities. Additional monitoring points are maintained at upstream locations as an aid in identifying the specific sources of emissions. Sampling system design ensures that samples are representative of the total content of the stream at each location.

Figure 2 includes a map of the effluent monitoring locations/effluent streams at WL.

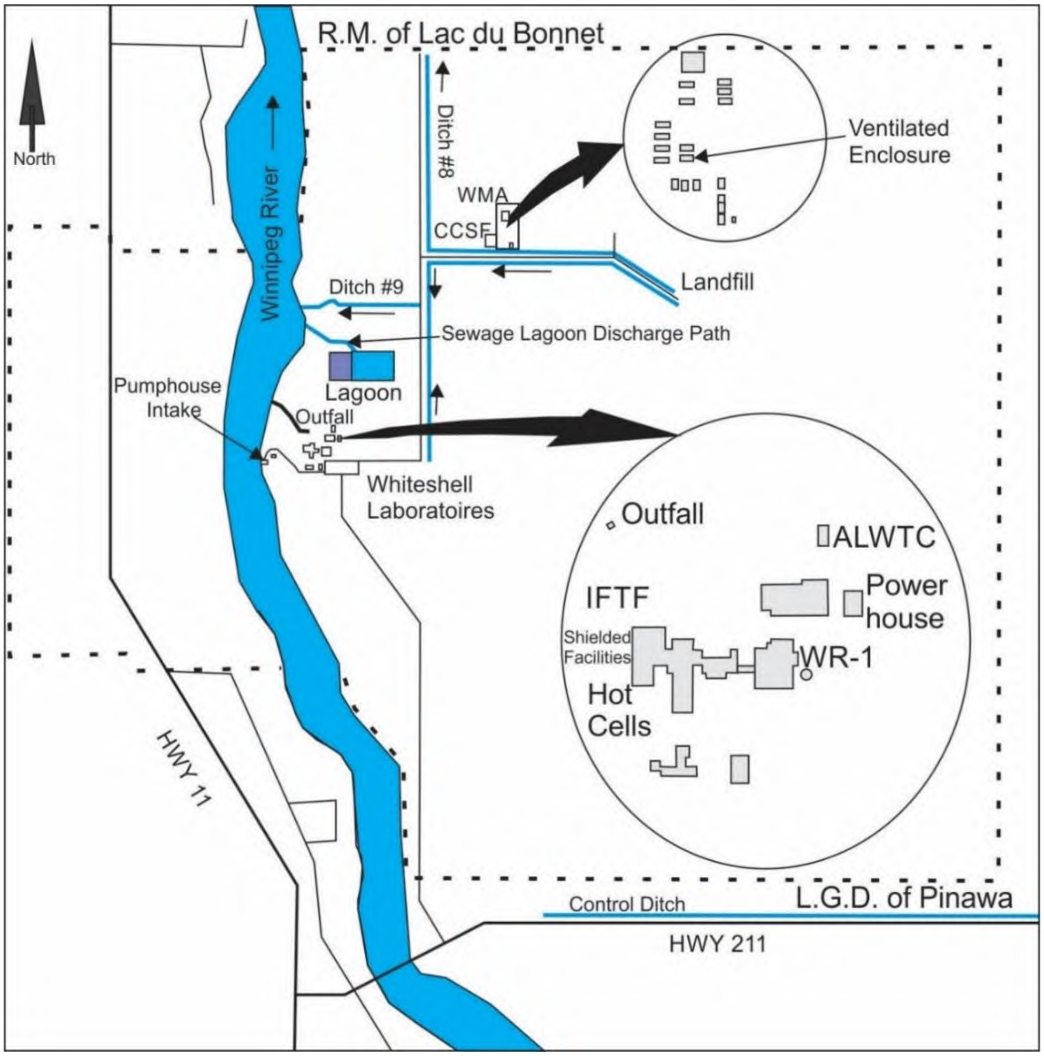

Figure 2: Effluent Monitoring Locations

Effluent streams are monitored for all groups of radionuclides that are likely to be present and significant contributors to the total, expressed as a percentage of applicable DRLs [30]. The DRLs in use at WL came into effect on 2021 January 31. All current and historical data in this report has been compared against these DRLs. Monitoring is conducted either by direct measurement on location or by sampling and laboratory analysis. In many cases, gross-measurement parameters (e.g., gross beta) are monitored and reported rather than specific radionuclides. This is done provided that either the relative composition of radionuclides indicated by the gross parameter is not likely to vary significantly, or total emissions of the gross parameter are very small relative to the DRLs. For comparison with DRLs, the gross parameters are always evaluated conservatively. They are either assumed to consist solely of the most restrictive radionuclide, based on DRL value that is likely to be present in measurable quantities, or are assumed to be the radionuclide(s) known to be present in the effluent. To ensure proper selection of the DRL values, the effluents are periodically characterized using, for example, gamma spectrometry to identify individual gamma emitters, or chemical extraction

and analysis of individual beta emitting radionuclides, such as Strontium (Sr)-90, complemented by examination of historical data.

The significance of the measured radioactive materials in airborne and liquid effluents is assessed by comparison with DRLs that relate the releases to the potential radiation dose to the identified, most exposed groups (i.e., critical groups). DRLs are the upper limits for releases of radionuclides in airborne or liquid effluents from a facility or site. WL's DRLs were calculated in accordance with the principles and methodology in CSA N288.1-08 [31]. The DRL for a particular radionuclide is derived from the regulatory dose limit for members of the public, 1 mSv in a year, as specified in the Radiation Protection Regulations under the Nuclear Safety and Control Act [32]. The intention of the DRL is to establish a release limit such that compliance with it will give reasonable assurance that the annual regulatory dose limit for members of the public is not exceeded. Weekly DRLs are calculated and applied for airborne effluents, and monthly DRLs for liquid effluents.

For multiple effluents and radionuclides at a site, verifying that the sum of all releases as a percentage of the respective DRLs is less than 100% provides a reasonable assurance[5] that the annual dose limits have not been exceeded. This is a conservative approach since the critical group may differ for different release paths and radionuclides. The actual releases are a very small fraction of the DRL as discussed in the following sections and shown in Figure 3. As discussed in Section 9.4.1.3.2, the increase in 2019 to 2021 liquid effluents is due to an increase in detection limit values for Am-241 and Plutonium (Pu)-239/240. When the activities of radionuclide contaminants are not detected it is standard practice to report detection limit values as if they were observed concentrations. For example, Pu isotope activities were always detection level values and Am-241 and Cs-137 activities are very close to detection levels.

[5] The effluent DRL model and assumptions are further verified annually through results from the WL environmental monitoring program. The program assesses radiation doses to members of the public using direct measurements of radioactivity in the environment (e.g., in air, water, and food).

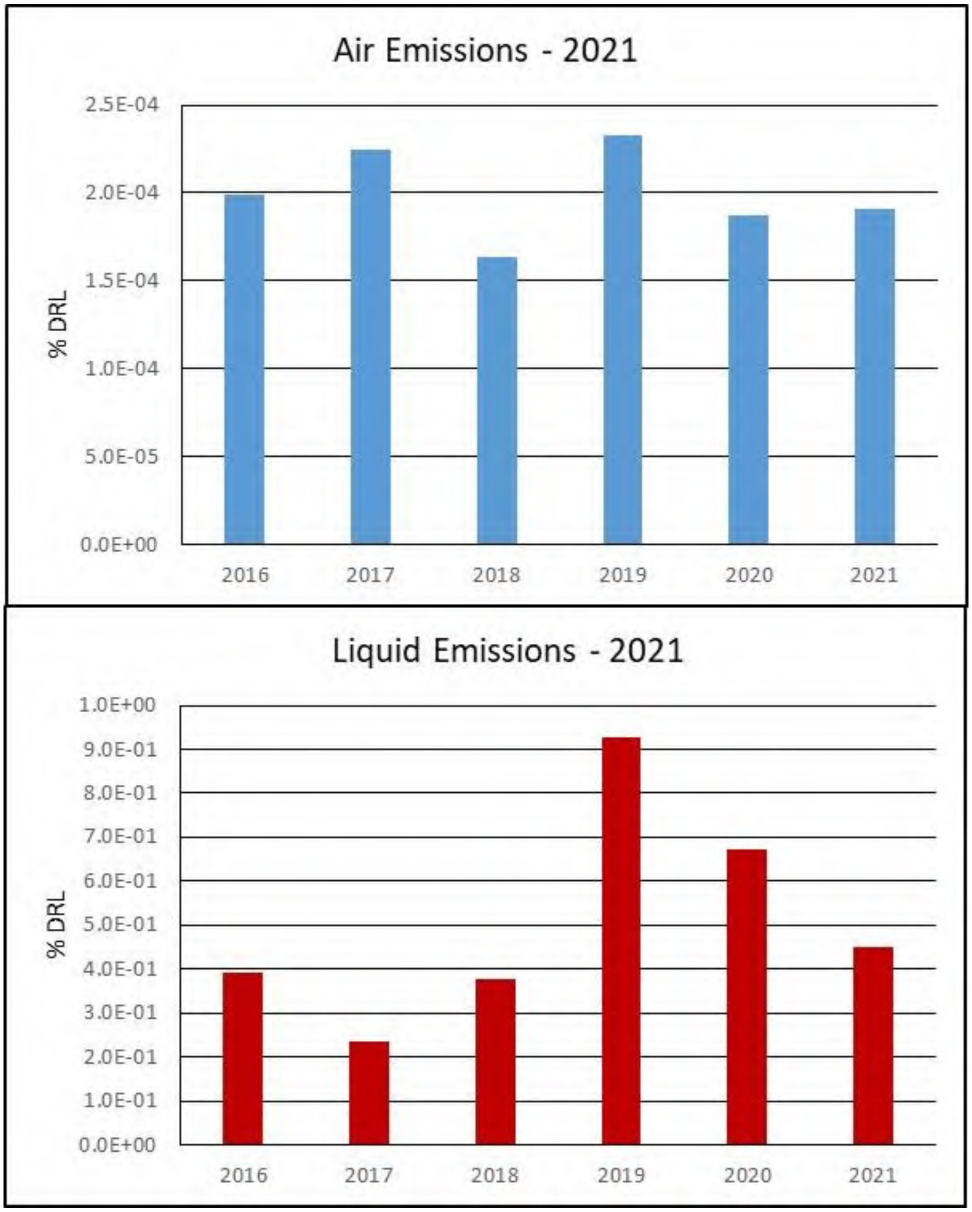

Figure 3: Trends for Airborne and Liquid Emissions form WL for 2016 to 2021

Analytical models of all significant environmental pathways to an individual in the critical group are used in the DRL calculations. DRLs for WL have been calculated for a large number of radionuclides, many of which are currently not detected in site effluents. Derived Release Limit calculations (of a wide range of radionuclides) provide a means of determining which radionuclides may be significant dose contributors. Thus, they aid in determining which nuclides warrant inclusion in the monitoring program, and in interpreting monitoring results.

Performance is also measured against the regulatory Administrative and Action Levels[6] as specified in Reference [33]. The Action Levels were calculated based on current CNSC guidance to meet CSA N288.8 [23] and to better reflect current waste streams, and were released for use based on an implementation date of 2017 January 01.

9.4.1.2 Airborne Effluents Monitoring

9.4.1.2.1 Monitoring Points, Schedules and Parameters

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. These activities include waste compaction in the Waste Handling Area, located in the Immobilized Fuel Testing Facility (IFTF), and decommissioning activities in the ALWTC. The main sources of airborne radioactive effluents, as a result of this work and historical activities at WL, are the:

- Hot Cells Facility (Building 300)
- Immobilized Fuel Test Facility (Building 300)
- Reactor Building (Building 100)
- ALWTC (Building 200)

Air effluents from Buildings 100 and 300 were sampled continuously throughout the year. The frequency and type of monitoring will continue to be evaluated over time, and adjusted to reflect findings from the monitoring activities. The current monitoring schedule and locations are noted in Table 22. Cessation of a monitoring activity will occur once it can be shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant by regulatory requirements or community concerns. Any proposals on modifications to the monitoring program will be communicated to CNSC staff. In 2020, Building 200 (ALWTC) was prepared for demolition and the ventilation system was shut down in 2020 October. Monitoring of stack effluents for Building 200 ceased after 2020 October 13, and the building was demolished in 2021. Therefore the reported air emissions in 2021 do not include emissions from Building 200, which is no longer included in the monitoring schedule (Table 22).

[6] Action Level – In the context of CNL's Environmental Protection Program, an "Action Level" for radioactive emissions is a release rate of radioactive emissions that, if reached, may represent a loss of control of performance for a facility's environmental protection program or emission control system. Releases above Action Levels must be investigated and reported to CNSC staff. Action Levels for WL radioactive effluents are lower than the DRLs.

Table 22: Radiological Air Effluent Monitoring Schedule – 2021

Sample Location	Sample Collection		Analytical Method and/or Parameter			
	Frequency	Method	Gross Beta	Gross Alpha	Tritium	Gamma Spec
Building 100 Stack	Cont	GFA Filter	W	W	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Bubbler	N/A	N/A	W	N/A
Building 300 HCF	Cont	GFA Filter	W	N/A	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Millipore Filter	N/A	W	N/A	N/A
Building 300 IFTF	Cont	GFA Filter	W	N/A	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Millipore Filter	N/A	W	N/A	N/A

Cont The air effluent is measured but passing a continuous sample of the exhaust through a filter. The GFA filter is normally used for beta-gamma, the Millipore normally for alpha, charcoal or silver zeolite for radioiodine, and a water Bubbler for tritium.

W Weekly

N/A Not Applicable

The air to be monitored from the buildings and facilities is drawn past sample probes located in the exhaust vents, pumped through filters and then returned to the exhausts. The WL maintenance planning team performs the measurements for the stack flows and the RP team measures the Sampler flow. The sampler flows at WL are checked during each sample collection period to ensure that they are within the established acceptance criteria, and are re-measured and verified on an annual basis. The release factors are calculated by the WL Environmental Management staff and verified independently on an annual basis. Activities measured in the laboratory are used in conjunction with sampler and exhaust stack flow rates to calculate the release in Becquerels (Bq). The Lower Limit of Detection (LLD) is the product of the release factor of the source and the laboratory Minimum Detectable Activity. For a given radionuclide, the Minimum Detectable Activity and LLD can vary, as they are calculated assuming a 30-minute count time and average detector efficiency, both of which can change.

Derived Release Limits have been calculated for 74 radionuclides for airborne effluents at WL [30]. Separate DRLs have been calculated for on-site workers and for members of the public at the site boundary. For gross alpha and gross beta activities, the DRL applied is the most restrictive from amongst those of the radionuclides that could be present (Sr-90 for gross beta and Pu-239 and Pu-240 for gross alpha).

Sampling procedures, field operating procedures, laboratory procedures, equipment performance checks, quality verification procedures, and laboratory administrative procedures are described in detail in the governing WL Environmental Management documentation.

9.4.1.2.2 Monitoring Results

The airborne emission results are summarized in Table 23 and Figure 3 for the years 2016 to 2021. Average weekly emissions, in Becquerels, are shown for gross alpha, and gross beta for facilities in Buildings 100, 200, and 300. Emissions from Building 100 also includes tritium. In addition, the current year releases, the average release for the past five years and the maximum weekly emissions as a percent of the DRL are given. Emissions from these identified release points are added for each year to provide an indicator of the performance of the site. The reader should be aware that the values for 2021 in Table 23 represent averages that include detection limit values where nothing has actually been detected. The releases from the Reactor Building include gross beta and tritium values that are always above detection, and gross alpha numbers that are often detection limits. The gross alpha releases from the HCF are normally detection levels and the gross beta are often, but not always detection levels. The gross alpha values from the IFTF are always detection limits and the gross beta are a mixture of detects and non-detects.

Airborne emissions remain a small fraction of the release limit. The result for 2021 (0.00019% of the DRL) is similar to 2020, and slightly lower than the average for the last five years. Total site gross alpha in 2021 is lower than in 2020 and the last five years average. It remains near detection limit values. The gross beta emissions are slightly more than in 2020 and similar to the last five-year average. In 2021, the air emissions from all facilities were below Administrative Levels and regulatory Action Levels. In 2021, Building 200 no longer contributed to air emissions. The average values of the previous five years shows that Building 200 had contributed 16 percent of the total alpha air emissions and 8 percent of the total beta air emissions.

Tritium emissions from the WR-1 stack were higher than in 2020 and slightly less than the five year average. During the Phase 1 Decommissioning of WR-1, all bulk heavy water was removed from WR-1, and an exhaustive process of eliminating heavy water and tritium from the reactor piping and tanks occurred. It was concluded that over the lifetime of WR-1, tritiated heavy water was adsorbed into the pipe and tank walls and probably also into concrete walls and floors. Therefore, the moderator system continues to be purged with air flow in order to remove additional tritium from the system and the tritium removal rates have been measured. The tritium emissions from the facility fluctuate with the humidity and temperature as the tritiated water is drawn out of the system. The maximum releases were all below the administrative level (1.52E+10 Bq/week) for the facility and well below the Action Level (7.62E+10 Bq/week) and DRL (1.65E+15 Bq/week). As many gross alpha and gross beta measurements are at or below the LLD, the yearly variations within these extremely small numbers are of very little consequence.

Localized operational workplace air monitoring is conducted as part of the Radiation Protection Program, and this was performed during operational shutdown and decontamination activities associated with Building 100, and work in the Shielded Facilities and Concrete Canister Storage Facility. Outdoor Workplace Air Sampler monitoring was performed for Building 200 demolition. Environmental airborne dust monitoring was performed close to the east, north,

west and south boundaries of the WL campus during building demolitions. The results of the 2021 dust monitoring are described in the *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28].

9.4.1.3 Liquid Effluent Monitoring

9.4.1.3.1 Monitoring Points, Schedules and Parameters

Figure 2 shows the locations of the sources of liquid effluents to the Winnipeg River, including the Outfall, the Lagoon and the numbered ditches.

The primary source of liquid radioactive effluents is the process water outflow (Outfall), which discharges continuously to the Winnipeg River. The discharge from the Outfall is composed of storm water runoff from paved roadways, around buildings through the weeping tile system, cooling water used in process and experimental facilities, and discharges from the Low Level Liquid Waste treatment systems tanks based in Building 100 and Building 300. The ALWTC was taken out of service in 2017 as part of preparations for the decommissioning of Building 200. Holding tanks collect water containing low levels of radioactivity, as a result of cleanup activities associated with operational and decommissioning work, as well as historical activities at WL. The current monitoring schedule and locations are listed in Table 24.

Table 24: Radiological Liquid Effluent Monitoring Schedule – 2021

Sample Location	Sample Collection		Analytical Methods and Parameters

Disch Per discharge, up to twice a year for the Lagoon.
Wc Weekly composite, composite of samples collected during the week.
Mc Monthly composite, composite of samples collected during the month.
We Weekly, when ditches have flowing water, usually after a rain or snow melt. Note that 2021 was a low precipitation year with very little running water.
Qc Quarterly composite, composite of samples collected during a 3 month period
A/R As Required.
N/A Not Applicable.

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. Specific activities that may have influenced the 2021 liquid releases are similar to those for the past five years, and include cleaning of footwear and respirators. Radiation Protection introduced the use of disposable rubber shoe covers in 2018, which reduced the contribution from the washing of footwear. The water from these cleaning activities is combined with Building 300 sump water into the Building 300 receiver tanks. Sump water from Building 100 is now directed to the Building 100 receiver tanks. The liquids from these holding tanks are discharged to the Winnipeg River through the Outfall.

An automatic sampler continuously samples the outflow from the Outfall, proportional to its rate of flow. A weekly screening sample (4 L), representative of effluent released from the Outfall during the preceding week, is collected and submitted for uranium and gross beta analysis and scanned by gamma spectrometry.

Monthly composite samples (at least 32 L) are gathered for analysis of total uranium, gross alpha, gross beta, tritium, radio strontium and other radionuclides (Am-241, Cs-137) by gamma spectrometry. Starting in 2017, 3 month composite samples were collected for Pu-239/240, Pu-238 and Pu-241 isotopic analyses. Monitoring for Carbon (C-14) and tritium in Outfall samples was initiated in 2020 because they are known to exist in WR-1, and decommissioning activities have a potential for releasing these isotopes. The activities of tritium and C-14 at the Outfall continued to be below the lower limits of detection.

The secondary source of liquid effluent is the Sewage Lagoon (Lagoon). The Lagoon collects sanitary and wastewater from most buildings on the site, as well as from the laundry facility. The minimum residence time for the lagoon is equal to the amount of time the secondary cell is isolated from the primary cell, to allow for biodegradation and settling. This is typically around 45 days. Prior to each planned discharge, the secondary cell is isolated, and tested for a series of non-radiological parameters (discussed in detail later). If these are acceptable, the accumulated contents of the secondary cell only are released to the Winnipeg River via a small drainage ditch leaving the Lagoon's north side. In 2021, the lagoon was not discharged at all because there was enough freeboard that a discharge was not necessary.

Whenever there is a discharge, the outflow of the Lagoon is continuously sampled during the discharge. The resulting composite sample is analyzed for gross alpha, gross beta, and radio strontium, and it is also scanned by gamma spectrometry.

Small quantities of radionuclides at levels seen at the Ditch 7 and Ditch 8 sampling locations, are also released to the Winnipeg River from the two ditches indicated in Figure 2. Water from the recharge area east of the WMA is diverted around the WMA to the west-flowing Ditch 9 and into the Winnipeg River. The other, Ditch 8, running northward, drains the land north of the WMA up to the site boundary and beyond. The volume of water in the ditches and resulting flow to the river is entirely dependent on rainfall and spring runoff. Precipitation (395 mm) in 2021 was less than in 2020 (441 mm), and in 2019 (646 mm). The winter of 2021 was very dry. The spring precipitation was normal, but the early summer was unusually dry. Normal amounts of precipitation were observed for August, October and November. Due to the low

precipitation, ditches were only sampled six times during March, April, May and June. The August and October precipitation was captured by the dry ground and there was no moving water in the ditches to be sampled any time after June.

One-litre water samples to be analyzed for radioactivity are collected from the two ditches carrying drainage from the WMA whenever there is sufficient flow from runoff to enable sampling of discharge to the river. At the same time, samples were also collected from the northern ditch bordering Highway 211. This is far enough from CNL's operation to be a reasonable background (Control) sample[7]. The samples are analyzed for gross alpha, gross beta, gamma spec and tritium. If the level of the gross beta measurement exceeds 10 Bq/L, the samples are submitted for radio strontium analysis. Uranium activities are calculated from uranium concentrations obtained from total metals analysis. Surface water samples are collected in and around the WL WMA from locations upstream from these two ditches. The results of these operational control samples are reported in Appendix D of this report.

Derived Release Limits for 63 radionuclides were calculated for liquid effluents at WL [30]. Gross alpha and gross beta measurements provide a quick measurement of the total alpha and beta radioactivity produced by a number of radionuclides, without having to test for those radionuclides. However, as in the case of airborne effluents, the most restrictive DRLs apply to gross beta and gross alpha activity: Cs-137 for beta activity and Pu-239 and Pu-240 for alpha activity. With the introduction of total uranium (U) and isotopic plutonium analysis for the processed outfall, a comparison can be made to the individual contributors to the gross alpha activity. Therefore the comparison to the %DRL of the individual isotopes is presented and the sum of those reported. This is also the case for gross beta.

9.4.1.3.2 Monitoring Results

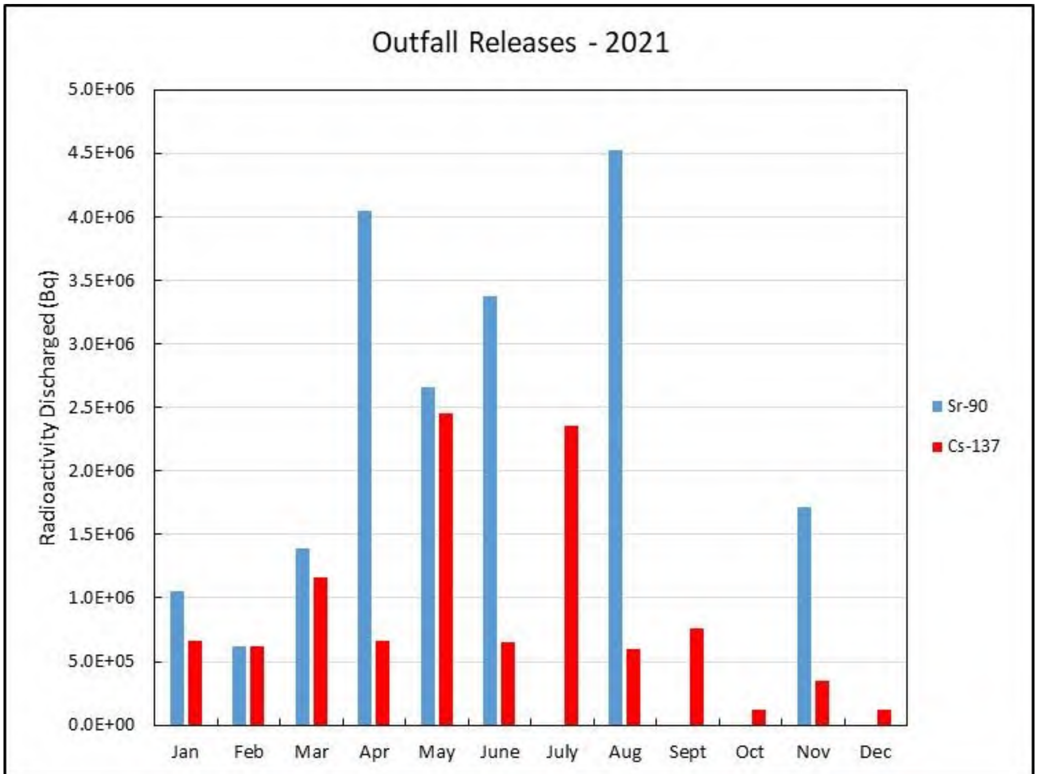
The liquid emission results are summarized in Table 26 and Figure 3 for the years 2016 to 2021. Average monthly emissions, in Becquerels, are shown for gross alpha, gross beta, total U (including U-234, U-235, and U-238), Am-241, Sr-90 and Cs-137 for the releases from the Outfall and the Lagoon. The monitoring of tritium from the Outfall began in 2019. In addition, quarterly activities of Pu-239/240 and Pu-238 were reported for Outfall effluents. A plot of the monthly Cs-137 and Sr 90 releases as Bq from the Outfall in 2021 is compared with radioactivity (Bq) discharged to the Outfall from the Low Level Liquid Waste (LLLW) treatment systems in Figure 4. Discharges to the Outfall from the LLLW treatment tanks occurred in all months. The total releases of Sr-90 and Cs-137 from the tanks in 2021 were 1.13E+06 Bq and 4.01E+06 Bq, respectively. These releases were only a fraction of the total Sr-90 (1.9E+07 Bq) and Cs-137 (1.0E+07 Bq) releases from the Outfall. There was little correlation between the patterns of releases from the tanks with the pattern of releases from the Outfall because the tank releases were only a small fraction of the total releases. The additional Sr-90 and Cs-137 activities noted at the Outfall may be from pre-existing contamination in the storm drain system from historical

[7] The Control Ditch sample is collected from a location not influenced by CNL's operation, and therefore serves as an indicator of the natural background conditions in the area.

site contamination events and historical radioactivity disposition in the storm drain line from Building 200 LLLW discharges. Some of this contamination may have been from unplanned emissions from the Hot Cells in the 1970's, although more likely from the Building 200 drain line. The high Sr-90 and Cs-137 releases from the Outfall during April, May and August correlate with higher rainfall during these months. The periods of high precipitation are believed to flush contamination into the Outfall from storm drains and previously contaminated process piping.

Note, all monthly releases from the Outfall were well below the administrative release level[8]. Releases of gross alpha were less than the 2020 releases and the five year average. Gross beta releases in 2021 were also less than the 2020 releases and the five year average. Sr-90 releases in 2021 were lower than in 2020 and the five year average. The Cs-137 releases were less than the 2020 releases and the five year averages. Am-241 releases were similar to 2020 releases. The total uranium releases were slightly lower than in 2020. The relatively constant emissions of gross alpha, gross beta, Sr-90 and Cs-137 from the Outfall over the years suggest a constant source, more like contaminated piping than the effects of recent decommissioning activities. Pu-239/240 and Pu-238 releases were very low, being based on detection level concentrations (% of the DRL less than 0.27). In 2021, Outfall water was also analyzed for the presence of C-14, which could be introduced by the discharge tanks from Building 100. C-14 was below detection levels (varying from 0.99 to 1.26 Bq/L) in Outfall samples. Given that the DRL for C-14 is 1.06E+08 Bq/month, the detection limit of 1.26 Bq/L would correspond to a %DRL value of 0.18. Measurements of C-14 in site intake water from Building 902 were also below detection values.

[8] An Administrative Level is a CNL internal reporting level for radioactive emissions by way of an individual effluent stream. The Administrative Levels are established and maintained by CNL to provide timely warning of above normal radioactive emissions, with the intent of aiding in the application of the ALARA process.



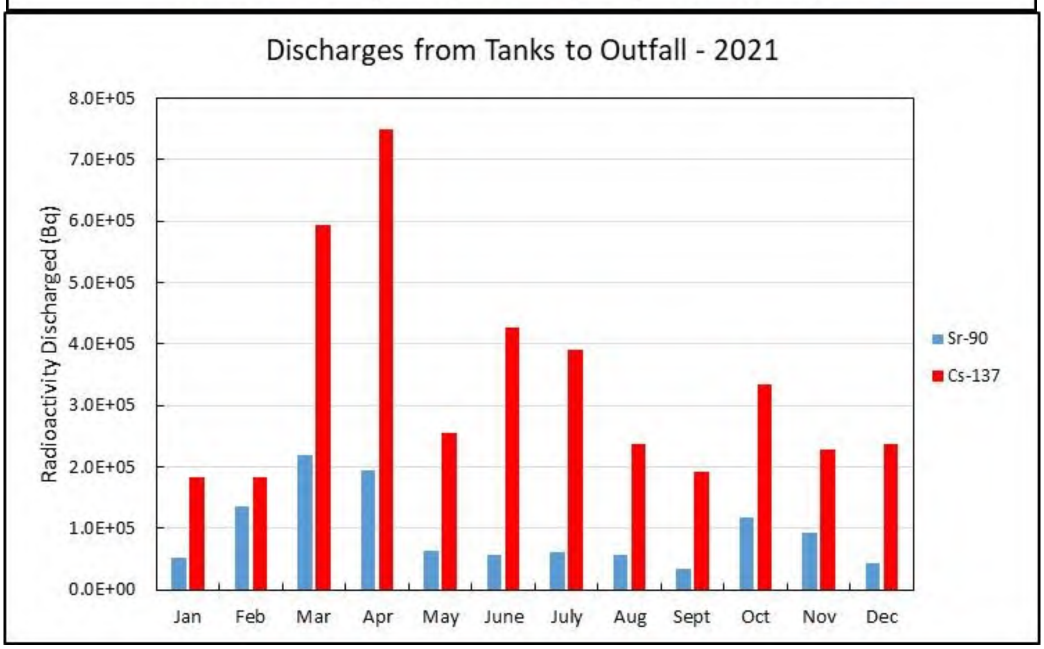


Figure 4: Radioactivity on Outfall Releases and Discharge from Active Liquid Waste Treatment Tanks for 2021

As stated above there were no Lagoon discharges in 2021 and so there are no results to report. In 2021 the lagoons did not contribute to the total liquid discharges from the site.

The averaged results for the two drainage ditches and control sample are shown in Table 25. The reported errors are the standard deviations of parameter values indicating their variability between different sampling events.

a Compliance with Guidelines for Canadian Drinking Water [34] may be inferred if the measurement for the gross alpha and gross beta are less than 0.5 Bq/L and 1.0 Bq/L, respectively. LLD is based on a 1 L sample resulting in less than 100 mg of sample ash and counted for 100 minutes.
b LLD = Lower Limit of Detection.
c Uncertainties are expressed as the standard deviation of the average activity of the processed samples.

During 2021, the gross beta activities in Ditches 8 and 9 were higher than in 2020. The 2021 gross alpha activities were lower in Ditch 8 and slightly higher in Ditch 9 compared to 2020. The average gross beta values were similar to the control sample collected off of Highway 211, given the variability in their values. The gross alpha values were similar to the control ditch. The control sample is unaffected by CNL's operations. Compliance with the *Guidelines for Canadian Drinking Water Quality* [34] may be inferred for gross beta activity since the measurements are all less than 1.0 Bq/L. The gross alpha activity was below the drinking water screening level of 0.5 Bq/L for all samples. The local well waters within the Canadian Shield contain naturally occurring uranium [35] at levels ranging from 0.04 Bq/L to in excess of 2.5 Bq/L. Vertical flow occurs in the surficial Clay unit and in the intermediate Clay Till unit. The head gradient is upward leading the water in these layers to discharge to the surface. Naturally occurring

uranium and its progeny are contributors to the total alpha activity, and could account for levels seen in some of the ditch water samples. In addition, naturally occurring alpha emitters may be present in suspended sediment in some of the samples.

As discussed in Appendix D of this report, the WMA contains a number of trenches with varying amounts of low-level radioactive and conventional waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. The amount measured in drainage Ditch 8 (4.6±0.5 Bq/L) and Ditch 9 (4.7±0.4 Bq/L) were not significantly different from that noted at the control location (4.4±0.9 Bq/L). A number of ditches close to WMA are known to contain tritium. In 2021, the amount of tritium reaching the Ditch 8 and 9 locations was not significant. The tritium activities measured at all three ditch locations are much lower than the Guidelines for Canadian Drinking Water Maximum Acceptable Concentration for tritium (7000 Bq/L) [34].

Table 26 summarizes the data for releases of liquid effluents[9] for the years 2016 to 2021. The average monthly releases, expressed as a percent of the DRLs, are added for the various sources on site to provide a quantitative indicator of the performance of the site. The average total release for 2021 was 0.45% of the DRL, which is lower than 2020 and the five-year average (0.51%). The main reason for the higher 2019, 2020 and 2021 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. The highest monthly release from the Outfall in 2021 was Pu-239/240 at 0.29% of the DRL. There were no lagoon discharges in 2021.

9.4.2 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is determined for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results as a result of equipment failure, maintenance/calibration outages, or operator action requires “unavailability” to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 27) for monitoring equipment on effluent streams with effluent rates that are normally ≥ 0.5% of weekly DRLs are set more stringent (for unplanned unavailability) than for those streams with normal effluent rates < 0.5% of weekly DRLs. Unavailability is expressed in hours of unmonitored effluent releases per year, and applies separately to each monitored parameter, on each effluent stream.

[9] The radioactivity from Ditches 8 and 9 was found to be below the Canadian Drinking Water Screening Level [34] for both gross beta and gross alpha activity, within the uncertainty of the analysis. Tritium levels were well below the Canadian Drinking Water Maximum Acceptable Level. The contributions were considered insignificant due to the small volume of release, and are not included in the liquid release table.

Table 26: Radionuclides in Liquid Effluents from WL – 2016 to 2021

a In 2018 monitoring for Outfall began for U-total, Pu-239/240 and Pu-238. In the Lagoon Pu-239/240 was calculated from gross alpha mass balance. The %DRL is reported for these isotopes instead of gross alpha. Note that Pu isotope activities are detection level values and Am-241 and Cs-137 activities are very close to detection levels.

b Gross beta releases are not included in the %DRL totals as the regulated components of the gross beta (Cs-137 and Sr-90) are already accounted.

Table 27: Effluents Monitoring Equipment Unavailability – 2021

	Unavailability Criteria[a]		Number of Exceedances
Air effluent streams with normal emission rate ≥ 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	84 hours/year/stream	0
Air effluent streams with normal emission rate < 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0
Continuously monitored liquid effluent streams.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0

a See Table 7 in 900-509200-STD-009.

Unavailability criteria (see Table 27) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2021, there were no instances in which the unavailability criteria (Table 27) outlined above were exceeded. In Building 100 there was one instance when the stack pump went down for a long weekend, resulting in 112.5 hours of unplanned loss of air monitoring. In the Shielded Facilities there were three instances of planned loss of monitoring because class III power was shut down for electrical equipment inspections. The total planned loss of monitoring, affecting the Hot Cells and IFTF was 6.5 hours. There were 3 instances of planned unavailability to Outfall monitoring that were due to required electrical power supply shut down to facilitate decommissioning activities, this amounted to a total of 5.2 planned hours of monitoring unavailability for liquids. There was one instance of unplanned Outfall monitoring, amounting to 14 hours, occurred when the motor on the sampling equipment at the outfall monitoring station failed and required replacing. In each instance an estimate of the release during unavailability was calculated as per procedure. In each instance, an estimate of the release during unavailability is calculated per procedure (if the lost time is 5 percent or greater of the total monitoring interval).

9.4.3 Overall Performance

Figure 3 summarizes the data presented in Table 23 and Table 26 on site-wide airborne and liquid emissions, expressed as totals of percentages of DRLs (the lower rows of the tables) for the years 2016 to 2021. The average emissions for the past six years continue to be very small. Liquid emissions of radioactive material from WL in 2021 were below CNL’s Administrative Levels and Action Levels, and continue to be very small compared with the applicable DRLs [30]. All air emissions were below CNL’s Administrative Levels and Action Levels.

Total radioactive airborne emissions from the WL site during 2021 continue to be very low, averaging 0.00019% of the DRL, which is similar to 2020 and lower than in 2019.

Radioactivity in the WL liquid releases for 2021 was 0.45% of the DRL which is lower than in 2020 (0.67%) and the last five-year average (0.51%). The main reason for the higher 2019 to 2020 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. Pu-239/240, at detection limit values, was the primary contributor to the Outfall, averaging 0.17% of the DRL. The level of tritium activity noted in the two ditches carrying drainage from the WMA remains well below the Maximum Acceptable Concentration for Drinking Water.

The 2021 release results, as well as the previous years' trends, indicate that CNL has taken reasonable precautions to control the release of radioactive nuclear substances within the site, and into the environment, as a result of the licensed activity. All airborne and liquid release results are consistent with the clean-up and operational activities associated with decommissioning of the site.

The results of the monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment.

9.5 Effluent Monitoring – Non-Radiological

This section addresses the licence requirement on hazardous substances monitoring of liquid and airborne effluents for the WL site for 2021. It also fulfills similar effluent monitoring requirements listed under Work Package 1 of the *Environmental Assessment Follow-Up Program* [28].

9.5.1 Liquid Effluent Monitoring

9.5.1.1 Monitoring Points, Schedule, and Parameters

Whiteshell Laboratories staff members collect samples for non-radiological parameters from eight different monitoring points. The first four are the Sewage Lagoon (referred to as the Lagoon) at point of discharge to the Lagoon drainage ditch, the Process Outfall (referred to as the Outfall), the North drainage ditch (referred to as Ditch 8), and the West drainage ditch (referred to as Ditch 9). These effluents flow directly to the Winnipeg River. Two monitoring locations measure internal process wastes leaving the Low-Level Liquid Waste Treatment Systems (LLLWTS) from Building 300 and Building 100. The remaining two monitoring locations are used as background monitoring locations, and are the Intake water taken from the Winnipeg River at the Pump House (Building 902), and a control ditch on provincial Highway 211. More details for each monitoring area are provided in the sections that follow.

Referring to Section 9.4 of this report, Figure 2 shows the locations of the waste stream sources monitored, and where appropriate, their source or release points to the Winnipeg River. Ditch 8 meets the river some distance downstream (north) of the site boundary.

Table 28 lists the non-radiological parameters monitored at the inlet and effluent streams sampled, and the sampling schedule that is followed. The WL monitoring program follows the

protocols from the Ontario Ministry of Environment [36] in its Municipal/Industrial Strategy for Abatement program. Under that system, parameters that are normally measured by the same analytical technique are grouped into numbered Analytical Test Groups. These are described in Table 29, which includes information about the Regulatory Method Detection Limit (RMDL), Laboratory Method Detection Limit (LMDL) and the Smallest Reporting Increment (SRI). The LMDL and SRI were decided following protocol. The WL monitoring program also meets the requirements set out in the Federal Wastewater Systems Effluent Regulations [37], and the standards from CSA N288.5-11, *Effluent Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* [20].

Table 28: Schedule for Non-Radiological Monitoring at WL

a ATG = Analytical Test Group; BOD = Biochemical Oxygen Demand; CBOD = Carbonaceous Biochemical Oxygen Demand; TSS = Total Suspended Solids.

b The Monthly = grab sample taken once within each month.

Intake water was sampled each month as grab-samples are drawn from the wet well of the Pump House (Building 902).

In 2021, there was no discharging of the Lagoon.

At the Outfall, daily monitoring and weekly samples are collected for non-radiological parameters.

The ditches are sampled only when water is flowing freely within them, and at a maximum frequency of once per week. This occurs after snowmelt or significant rainfall, of which there were six events in 2021.

Whenever a tank was discharged at either of the Low Level Liquid Waste Treatment System's (LLLWTS), the effluent was sampled.

9.5.1.2 Analytical Protocol and Results Evaluation

With minor modification, the protocols for sample collection, and result reporting used here, are adopted from the Ontario Ministry of Environment publication *Protocol for the Sampling and Analysis of Industrial/Municipal Wastewate*r [36]. The protocols are used under Ontario's industry-specific effluent monitoring and limits regulations. The system supplies a justifiable set of methods to ensure that the final reported result is representative of the effluent sampled. Guidance is given on sampling of wastewater streams, sample handling including pre-treatment, and acceptable analytical techniques. Some of these are common to more than one parameter, so they are grouped into Analytical Test Groups, listed in Table 29. Ontario Ministry of Environment protocols were used again this year, as they have been historically. It should be noted that the Manitoba government has no such comprehensive protocols for sample collection, preservation, analyses, and result reporting.

Table 29: Listing of Analytical Test Groups

ATG	Parameter Name	Method[a]	Unit[b]	RMDL[c]	CNL LMDL[d]	CNL SRI[e]	Contracted Lab's LMDL

17	Toluene	GC-MS	mg/L	--	--	--	0.0004
25	Oil & Grease	Gravimetry	mg/L	1	--	--	1.0

a The method ICP = Inductively Coupled Plasma Spectrometry. This is a common method for metals analysis.

b The unit MPNU = Most Probable Number Unit, as reported by accredited contract laboratory. The MPNU is a common estimate of bacterial counts, especially for sewage effluent.

c RMDL = Regulation Method Detection Limit

d The LMDL = Laboratory Method Detection Limit (“MDL” also used).

e The SRI = Smallest Reporting Increment.

9.5.1.3 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is found for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results because of equipment failure, maintenance/calibration outages or operator action requiring “unavailability” to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 27) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2021, there were no instances in which the unavailability criteria (Table 27) outlined above were exceeded. There were no instances of non-radiological air monitoring unavailability. There were 3 instances of planned unavailability to Outfall monitoring that were due to required electrical power supply shut down to facilitate decommissioning activities. This amounted to a total of 5.2 planned hours of monitoring unavailability for liquids. One instance of unplanned Outfall monitoring, amounting to 14 hours, occurred when the motor on the sampling equipment at the outfall monitoring station failed and required replacing. In each instance an estimate of the release during unavailability is calculated per procedure (if the lost time is 5 percent or greater of the total monitoring interval).

9.5.1.4 Monitoring Results

In the following sections, there are two types of presentation formats used in reporting the results obtained in 2021. These include an averages summary table and a comparison against the CNL’s Monthly Guideline Acceptance criteria, for the effluent at identified monitoring locations.

9.5.1.4.1 Averages Summary Table

Summarized results for 2021 are presented in Table 30 through Table 34. The first two columns in the tables identify the Ministry of Environment ATG and parameter names [36]. The next three give the CNL monthly guideline concentration, LMDL (Table 29) and units for each measurement. The next six columns provide comparison of the average concentrations reported for the five previous years, followed by their arithmetic mean. The next seven

columns have a summary of the results for the 2021 monitoring period (explained further below).

WL previously discontinued on-site analysis of most of the non-radiological parameters. The samples are now shipped to external ISO 17025 accredited laboratories through a sample management office. The LMDL for the laboratory analyzing the parameter is provided in Table 29.

Within the 2021 results section, the number of samples included in the average ("# Spl.") is reported. This number is not constant down the table. It depends on the sampling frequency chosen for each parameter, and sample mixing to prepare composites for analysis. The next column (labelled "ND's") gives the number of samples in which the analyte was not detected and was therefore deemed a "zero" result.

The minimum, maximum and average values of each parameter are based on individual results and not monthly averages. These results are given in the tables found at the end of the section, and include any results that were zero by virtue of being non-detectable in the laboratory. The relative standard deviation of all results is also reported, expressed as a percentage of the average. This number allows some evaluation of scatter inherent in the samples and measurement method. Usually, sample variability dominates (i.e., the effluent composition changes over time).

In Table 31 through Table 34, yearly average values for parameters marked with an asterisk show that a monthly guideline was exceeded for at least one month during the calendar year being presented.

For convenience, the total annual load to the environment (Winnipeg River) represented by each of the analytes is also presented, expressed in kilograms. The calculation process is described in detail in Section 9.5.1.5 (where the results for the Lagoon and Outfall monitoring points have been collected in Table 36, and compared to the previous five years).

Table 30: Averages Summary for Intake

					Monitoring Point: Site Intake

ATG	**Parameter**	**Monthly Guide [b]**	**LMDL**	**Unit**	**2016**	**2017**	**2018**	**2019**	**2020**	**Average**	**# Spl.[c]**	**NDs[d]**	**Min.**	**Max.**	**Avg.**	**RSTD[e] (%)**	**Load (kg)**
25	Oil & Grease	15	1.0	mg/L	0.82	0.19	0.10	0.02	0	0.226	52	50	0	6.80	0.15	627	188
--	Estimated Flow (total volume for year)			m^3	1.41E+06	1.13E+06	1.16E+06	1.25E+06	1.21E+06	1.23E+06	1.15E+06						

a All results below the LMDL, originally flagged as “< DL” when reported, are only estimates.

b Monthly Guide is from WL’s non-radioactive effluent limits procedure. For mercury, the Daily Guideline is given instead, as there is no Monthly Guideline specified.

c # Spl. is the number of samples analyzed and reported.

d NDs is the number of samples in which analyte was not detected (i.e., Code = “< DL,” result = 0).

e RSTD = Relative Standard Deviation

f New parameter (2020) being tracked by the effluent monitoring program

N/A = Not Applicable.

Acute lethality test results are discussed in Section 9.5.1.4.5.1

Note: There were no monthly guideline exceeds for any monitored parameter.

a All results below the LMDL, originally flagged as "< DL" when reported, are only estimates.
b Averages were calculated by setting to zero results reported as "< DL."
c Monthly Guide is from CNL's limits for non-radiological parameters in liquid effluents procedure. For mercury, the Daily Guideline is given instead, as there is no Monthly Guideline specified
d # Spl. is the number of samples analyzed and reported.
e NDs is the number of samples in which analyte was not detected (i.e., Code = "< DL," result = 0).
f RSTD = Relative Standard Deviation
N/A = not applicable
Notes: Any averages with an asterisk show that a monthly guideline was exceeded in one or more months for the given parameter in the year.

Discharges of effluent coming from the new low level liquid waste treatment systems are being combined, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.2 Monthly Guideline Acceptance

CNL guidelines were used as the basis against which emissions from WL were evaluated. They are not regulatory requirements, but instead have been adopted by CNL to routinely evaluate the environmental significance of both process-type and non-process type discharges from WL. Table 35 supplies a summary of each of the liquid effluent parameters that had exceeded its CNL monthly guideline in 2021 or at any time during the previous five years.

As with the average summary table provided, for each monitoring point, the first two columns in the table identify the Ministry of Environment ATG and parameter names. The next three columns give the CNL monthly guideline concentration, LMDL, and the units of measurement. The next six columns present the monthly guideline acceptance for each of the five previous years and the average of those five years expressed as a percentage. The last three columns show the number of months during which discharges occurred, the number of times the monthly guideline was exceeded for each parameter, and the subsequent percent of times the parameter levels met the acceptance criteria.

To assess any significant level of change and evaluate program performance, this table will be referred to in each section discussing monitoring point results.

Table 35: Parameters that Failed to Conform to CNL Monthly Guidelines

						Monthly Guideline Acceptance (%) for Previous Five Years						Results for Year 2021		
Effluent Stream	**ATG**	**Parameter**	**Monthly Guide**	**LMDL**	**Unit**	**2016**	**2017**	**2018**	**2019**	**2020**	**Average**	**# Mth.**	**> Monthly Guide**	**Accept (%)**
LLLWTS /ALWTC	6	Phosphorus	1.0	0.003	mg/L	100	100	100	83	100	96.6	12	4	67
	8	TSS	25	1.0	mg/L	100	78	92	100	92	92.4	12	0	100
	9	Copper	0.5	0.0005	mg/L	100	67	33	42	58	60.0	12	2	83
	9a	Iron	1.0	0.010	mg/L	67	44	50	83	42	57.2	12	8	33
	9	Zinc	0.5	0.005	mg/L	100	100	100	100	100	100	12	1	92
	14	Phenolics	0.02	0.0010	mg/L	100	100	92	100	100	98.4	12	0	100

Notes:

- Effluent stream parameters which have not exceeded a monthly guideline in the current year or in the previous five years have not been included to this table.
- Discharges of effluent coming from the new low level liquid waste treatment systems are being considered as emanating from the ALWTC, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.3 Monthly Guideline Plots

For parameters that have a value higher than a CNL monthly guideline, the monthly plot of values is shown for that parameter at the monitoring point. This year there were 9 months when one of four parameters (Iron, Copper, Phosphorous and Zinc from the LLLWTS had monthly values higher than CNL monthly guidelines. Figure 5 shows the number of times the monthly guidelines have been exceeded at any monitoring point over the last five years. Plots are displayed in Figure 6, Figure 7, Figure 8 and Figure 9 for each parameter, and the explanations for the observed high values can be found in Section 9.5.1.4.6. The monthly or daily guideline limit for the parameter in question is shown by a broken red line in the corresponding figures.

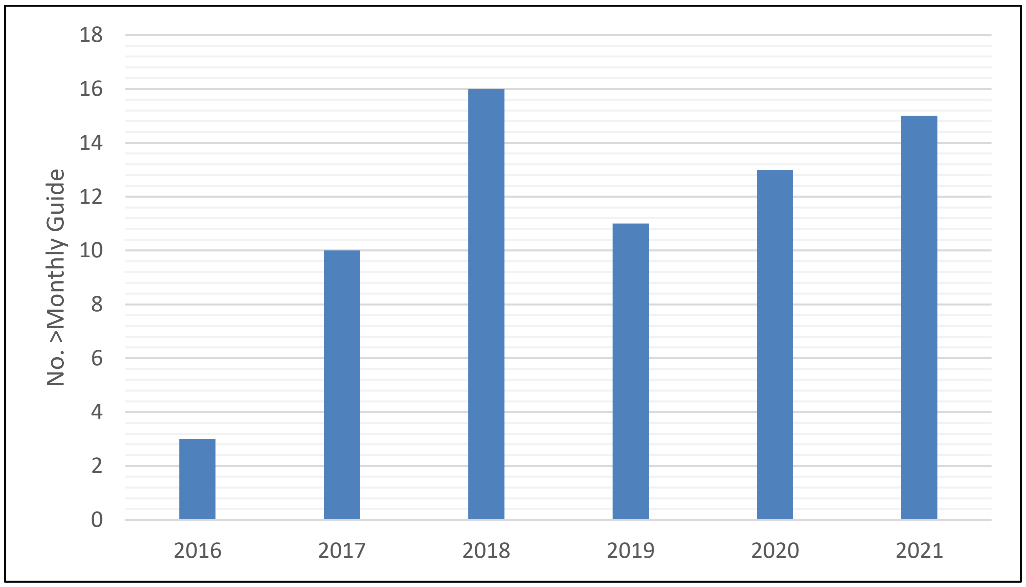

Figure 5: Non-Radiological Monitored Effluent Parameters Above Monthly Guidelines

9.5.1.4.4 Monitoring of Intake Water from the Winnipeg River

Except for bottled drinking water, all the water needed to run the WL site is drawn from the neighbouring Winnipeg River at the Intake. The amount of water drawn from the Winnipeg River varies from year-to-year.

Grab-samples are collected each month from the Building 902 wet well to assess the levels of certain parameters that may be entering the site directly from the Winnipeg River. The measurements are summarized in Table 30, where they are compared to available data for the previous five years. Figure 10 shows the estimated amount of water used monthly for 2021.

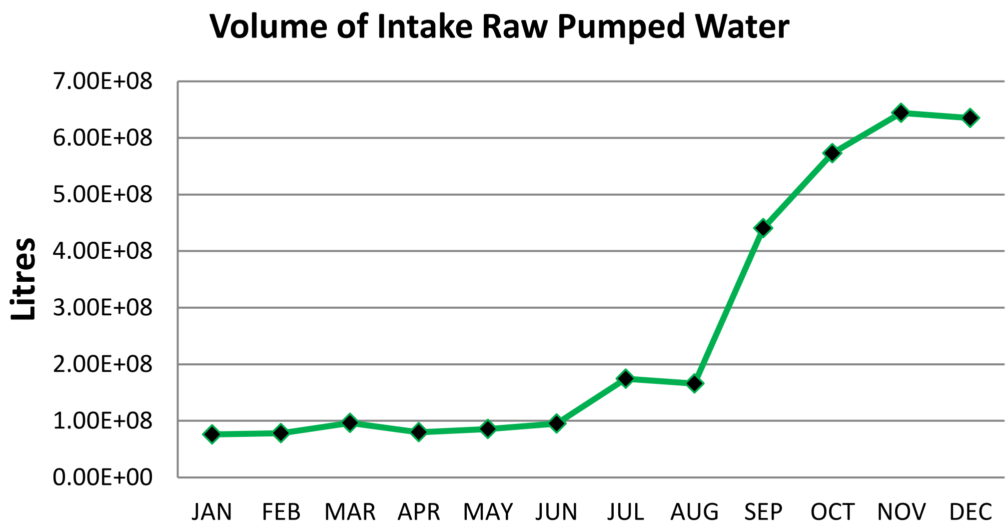

Figure 10: Monthly 2021 Intake Raw Pumped Water for the WL Usage

The following are notable points for the 2021 Intake water from the Winnipeg River:

- The Pump House flow meter recorded that 3.14E+06 m^3 of water was pumped from the river over the year.
- Compared to the five-year average, increased concentrations (> 10%) were seen for Chromium, Copper, Nickel, and Bromodichloromethane.
- Parameters that had their concentrations improve (> 10% decrease) this year compared to the average seen for the last five years are Phosphorus, TSS, Iron, Lead, Mercury, Phenolics, chloroform, and Oil & Grease.
- Water consumption for the site drastically increases during misting operations that are employed during building demolition. As these operation progress into sub-zero temperatures, a further increase is also observed, as a high flow of water is utilized to ensure the water lines do not freeze.

Intake water results can have a significant impact on the environmental performance of the WL site and they will continue to be monitored closely.

9.5.1.4.5 Monitoring of Liquid Effluents to the Winnipeg River

Two effluent streams, the Lagoon and Process Outfall, discharge significant volumes of water to the Winnipeg River. Normal surface land run off also reaches the river through Ditches 8 and 9. Results from monitoring each of these sources are discussed below.

9.5.1.4.5.1 Lagoon

The WL Lagoon secondary cell was not discharged during 2021. With reduced personnel on site due to the COVID-19 pandemic, the occupancy of Building 540 (modular office complex) which

has its bio-waste diverted offsite, and the low level of precipitation observed in 2021, the lagoon had enough freeboard to allow the site to operate into 2022 without discharging.

The total amount of effluent discharged from the Lagoon in 2021 was 0 m^3.

If the lagoon was discharged, the Lagoon would be tested for CBOD, fecal and total coliform bacteria, and acute lethality (a biological assessment on the survivability of trout in the proposed effluent). These samples are collected by the Lagoon operators at defined areas in the secondary cell after isolation of the cell occurs. During discharge, grab-samples would be collected close to the pipe emptying into the receiving ditch that leads to the Winnipeg River. Individual samples for most parameters would be collected on a weekly basis during the discharge.

The vertical scale from which surface height is found was carefully adjusted to read absolute depth from the original floor of the Lagoon. This was done because the equation for calculating the contained volume in the secondary cell for any depth is derived from the calculation for the volume of a rectangular trapezoidal trough:

Volume (in L) = Height x [Width_Bottom x Length_Bottom
+ 0.5(Width-Width_Bottom) Length_Bottom
+ 0.5(Length-Length_Bottom) Width_Bottom
+ (1/3) (Width-Width_Bottom) (Length-Length_Bottom)]

Knowing the dimensions and geometry, the contained volume in the secondary cell can be calculated accurately for any depth using the following equation:

Volume (in L) = 636 655*d + 206.886*d^2 + 0.02133*d^3 for depth “d” (in cm)

The position of the Lagoon’s water surface would be recorded once or twice daily while emptying. The daily flow would then be calculated from changes in the contained volume. This permits the calculation of volume-weighted concentrations and overall loads (see Section 9.5.1.5). Volume-weighted averages for a given period (month or year) are given by summing the product of the concentration for each day multiplied by the volume released that day, then dividing that sum by the total volume discharged during the period. Unlike other monitoring points (which are continuous or batch releases of fixed volume), the Lagoon discharge flow rate can vary widely. The variation makes weighting corrections highly significant in deciding meaningful average concentrations.

Discharging of the secondary cell is only allowed to proceed after initial testing. Once discharging begins, the pH is checked daily throughout the discharge period.

Table 31 summarizes the results of the fall discharge. Some notable points are:

- There was no effluent discharged from the lagoon in 2021.

9.5.1.4.5.2 Process Outfall

The Outfall monitoring station functioned as expected during 2021. The total discharge volume was 1.15 GL. This volume is lower than the previous five-year average of 1.23 GL.

The Outfall discharges continuously. Measurements were performed on the samples weekly. This provided 52 samples of each parameter for the year.

Table 32 summarizes the results obtained, and compares them to averages for the previous five years. Notable results for the Outfall are:

- There were no instances of CNL's monthly guidelines being exceeded at the Outfall monitoring station.
- The only parameters that had a significant increase (> 10%) compared to the 5-year average were TSS, Copper, Nickel, and Zinc. The increased TSS loads are a reflection of the demolition activities occurring on site, while sediment controls are put in place to mitigate the impact, an increased load of sediments are entering the storm drain system. The increase in nickel and copper concentrations being observed are related to the elevated levels being observed at the intake this year. Zinc is being detected close to the detection limit, a slight increase seen in the concentrations is having a significant percentage increase being measured in the Outfall, especially since the 5-year average concentration is below the method detection limit.
- Compared to the five-year average, Phosphorus, bromodichlormethane, chloroform, Phenolics, and Oil and Grease concentration levels significantly decreased (>10%).
- Quarterly Acute Lethality Testing on the Outfall effluent was not successful in 2021, as CNL missed collecting samples for the second and third quarter of the calendar year. A corrective action plan has been developed to prevent reoccurrence.
- Acute Lethality Testing for the outfall effluent in first and fourth quarter showed no mortality on the rainbow trout tested.

Overall, there were no concerns about the effluent discharged from Outfall during 2021.

9.5.1.4.5.3 Drainage Ditches

Much of the land surrounding key remote facilities at WL is drained by two structures. Ditch 8 drains the land north of the WMA up to the northern site boundary and beyond. Water from the landfill and recharge area on the east is diverted instead around the WMA to the west-flowing Ditch 9, and into the Winnipeg River. These ditches are monitored for radiological and non-radiological content. The radiological part is discussed in Section 9.4 of this report and the non-radiological part is discussed here.

Ditches 8 and 9 were grab-sampled each time water was flowing off-site. This was after heavy rainfalls, of which there were six events from 2021 April to October. At these same times, a sample was collected from the northern ditch bordering Highway 211. This is far enough from CNL operations to be a reasonable background (Control). It was not possible to measure the

flow rates at any of the locations, or to sample representatively over entire rain events; therefore, no loads can be calculated.

Comparison is made to CNL guidelines (although they are intended for process discharges). All values were below CNL monthly guidelines this year. The measurement data are summarized in Table 33. The following are notable points for the 2021 ditches results:

- There were only six sampling events for the ditches. The sample events were also predominately influenced by the spring melt as four of the six events were related to water flows experienced during this period, in other years rain fall events made up the majority of the sampling events.
- Zinc and Mercury were the parameters that had a significantly higher concentration (>10%) than the previous five-year average for Ditch 8. The parameters that had a significantly higher concentration (>10%) than the previous five-year average for Ditch 9 were Phosphorus, Copper, Zinc, and Mercury. The control ditch had TSS and Copper being observed at significantly higher concentrations (>10%) than the previous five-year average.
- Metal concentrations detected are very close to the detection limit, so a slight increase seen in the concentrations has a significant percentage increase being observed in Ditch 8 and Ditch 9.
- The five year average for phosphorus in ditch #9 was higher this year due to the reduced sampling. It is not uncommon for the spring melt to observe elevated phosphorus concentrations due to the decaying vegetation from the fall, but the phosphorus concentrations throughout the summer during rainfall events are typically lower and would drive the average down.
- All concentrations remain well below the CNL's monthly guideline limit and pose no concern.
- All parameters measured in Ditch 8 and Ditch 9 are comparable to those measured within the Control Ditch, indicating that WL had negligible effects on the environment through these two pathways.

It should be noted that sediment control measures were put in place for projects in the WMA in 2021, as was the case in previous years.

9.5.1.4.6 Internal Liquid Discharge Monitoring

Building 300 and Building 100 both have a LLLWTS; each system represents a major area that generated low-level radioactive liquid wastes. Individual tank releases are monitored for operational control purposes.

A full tank must be emptied while a second tank is being filled. When full, tanks are sampled; if the pH and radioactivity levels meet discharge criteria, they are discharged. The LLLWTS tank pre-discharge criteria do not include all parameters listed in CNL's non radiological guideline limit values; however, the post-discharge analysis includes all these parameters. CNL staff have

determined, through historical data analysis from post-discharge samples, if the pH in the tank is adjusted to neutral, all other parameters will normally meet the guideline limit values. All post-discharge data is reviewed to ensure this process is working as intended, and program requirements are met. All effluents pass through a 5-micron bag filter to the Process Outfall, leading via the Outfall to the Winnipeg River.

The tanks in the new system have a smaller holding capacity so the frequency of discharges has increased. The new system was designed with a shorter life span in mind than the earlier system that was employed by CNL. This was done to align with the decommissioning schedule being implemented by CNL. Discharging requires a day or less to complete, and can be more gradual if needed.

Grab-samples are taken after the filter, and at the beginning of each release from the individual tanks. Measurements are performed on the effluent of each discharge to measure pH and conductivity. For other analytes, grab-samples are collected and analyzed by a designated laboratory to complete the characterization of the effluent being discharged.

In regards to monitoring the non-radiological parameters of the effluent for this reporting period, discharges of the new systems are being compared to the discharges from the ALWTC that was used in previous years. This allows for comparisons of the previous 5-years of effluent to continue to be made, as the effluent streams emanating from the Research and Development (R&D) Complex in Building 300 and Building 100 should still be similar enough that a comparison is worthwhile.

In 2021, 0.09 ML was discharged from the LLLWTS.

The weighted averages of the joint releases from the LLLWTS are presented in Table 34 and monthly plots for the parameters that exceed the monthly guidelines are in Figure 6, Figure 7, Figure 8, and Figure 9.

The following are notable results for 2021:

- None of the monthly exceedances that occurred at the LLLWTS resulted in exceedances being observed at the Outfall monitoring location downstream in the process.
- There were increases (> 10%) in the annual average concentrations of Phosphorus, Chromium, Lead, Nickel, and Oil and Grease, compared to the previous five-year average results.
- The Iron concentration coming from the LLLWTS exceeded the CNL monthly guidelines eight times (January, February, March, April, June, July, August, and November). The overall Iron concentration seen for the year is lower than the previous 5-years. The introduction of the environmental laboratories in Building 300 at the end of 2019 increased the amount of Iron being introduced into the system (through the lab processing soil samples), as a number of the drain lines in the environmental laboratories are being directed to the LLLWTS in the facility. The majority of the effluent being generated by the environmental laboratories does not require the treatment

operations offered by this system, but it is possible it is affecting the effluent stream non-radiological characteristics.

- Early in 2021 (January-March), it was identified that the environmental laboratories and sample management office practises were having a negative impact on the effluent, as acid wash water and the clean out of expired acid-preserved sampling bottles was not properly being neutralized prior to disposal down the drainage system. In Figure 6, the drop in iron concentrations in the LLLWTS effluent can be observed when cleaning practises were improved. The improper disposal of the acidified wash water is being identified as the major cause of the increased metal concentrations being observed in the first four months of the calendar year.
- The Copper concentration coming from the LLLWTS exceeded the CNL monthly guidelines two times in 2021 (February and March). Frequent exceedances are being seen in relation to the new tank systems that were installed in Building 300 as a decision was made to use copper piping in the new system instead of the stainless steel that was used in the old system. As soon as the new tanks were commissioned and used, the copper concentrations of the generated effluent noticeably increased to the guideline limit, but the concentration seen at the Outfall is still well below the monthly guideline limits.
- The Zinc concentration coming from the LLLWTS exceeded the CNL monthly guidelines a single time in February.
- The phosphorus concentration in the Building 300 effluent has effectively doubled, and exceeded the CNL monthly guideline limit four times throughout the calendar year (March, August, September, and November). As this trend did not exceed a monthly administrative level it was not identified until all the data was compiled for the year, and the cause of this increase is currently unknown. The plot of the monthly concentrations for phosphorous appears to be correlated with the increased cleaning frequency (due to muddy work boots) that would be associated with the spring and the fall periods. CNL will begin with reviewing the current selection of cleaning products being utilized in Building 300.

9.5.1.5 Loading Calculations

For the Lagoon, the volume-weighted average concentration of a parameter was calculated as follows:

1. The measured concentration for each day was averaged with that of the next day;
2. The average was multiplied by the estimated volume discharged over the 24-hour period;
3. The products for all days were summed, then;
4. The resulting sum was divided by the total volume released during the period (Spring, Fall or entire year). The load was then given as the product of the calculated volume-weighted average concentration, multiplied by the total volume for the period.

At the Outfall, the total discharge volume for each month was multiplied by the monthly average concentration of the parameter.

Table 36 shows the results from the calculations described above, grouped by parameter and by final outflow source. All mass-related parameters are shown. The table also compares them to previous years, and to the five-year averages.

Note that LLLWTS discharges are not included here, as they are reflected in the Outfall loads, and ditches are also not included as lack of flow data prevents their calculation.

When examining the WL site total loads, notable results are:

- The Lagoon did not contribute to the observed loads in 2021 as it was not discharged.
- TSS, Nickel and Zinc are the parameters that had a load increase greater than 10% when compared to the five-year average.
- Unlike 2020, this increase in overall load for TSS is not tied to a similar increase being observed at the intake and is directly tied to demolition work occurring on site for 2021.
- The increase in the Nickel load is related to the increase in Nickel concentrations being observed in the Intake water being utilized by the site.
- The increase in Zinc is being attributed to the results at the Outfall over the years being detected very close to the detection limit, so a slight increase seen in the concentrations has a significant percentage increase.
- Phosphorus, Chromium, Mercury, Lead, and Oil and Grease had a significant decrease of 10% or more in their loads when compared to the 5-year average.

Table 36: Loading for the Current Year and Previous Five Years

ATG	Parameter	Monitoring Point	Loadings from Previous Five Years (kg) [a]						Results for Year 2021

a Averages were calculated by setting to zero results reported as "< DL."
b # Spl. is the number of samples analyzed and reported.
c NDs is the number of samples in which analyte was not detected (i.e., Code = "< DL", result = 0).

9.5.2 Airborne Effluent Monitoring

Airborne emissions from the WL site are compiled on an annual basis for the purpose of reporting under the National Pollutant Release Inventory (NPRI) and the federal Greenhouse Gas (GHG) report. These emissions are also recorded for trending and improvement purposes. Radiological releases are covered in Section 9.4 of this report. Only non-radiological releases to the air will be covered in the following sections.

9.5.2.1 Fuel Use for Building Heating

Historically, the main stationary source for non-radiological emissions to air from the WL site was the Powerhouse which supplied district heating to various buildings on the site (see Figure 2). Starting in 2013, use of, and emissions from Number 2 fuel oil heating operations at the Powerhouse, ceased due to the completion of building conversions to either propane or electrical heating. Subsequently, a substantial increase was seen for cleaner burning propane used on site. Table 37 presents WL heating fuel consumption from 2016 to 2021. Fuel consumption continues to trend downward (see Section 9.7.2 and Figure 11).

Table 37: Fuel Use for Building Heating from WL

		Data for Previous Five Years						Data for 2021
Parameter	**Unit**	**2016**	**2017**	**2018**	**2019**	**2020**	**Average**

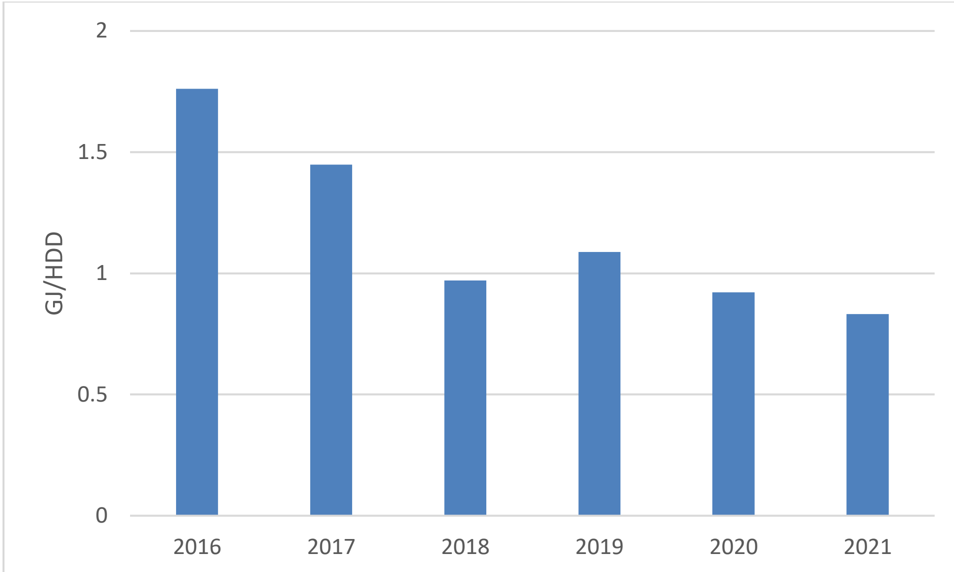

Figure 11: Annual Heating Energy Use from Fossil Fuels (per Heating Degree Days)

9.5.2.2 Reporting Under the National Pollutant Release Inventory

Under the authority of the *Canadian Environmental Protection Act*, 1999 [38], WL currently calculates releases of Part 4 substances for the NPRI program, using government reporting guidelines [39]. These releases to air include emissions caused by burning of Number 2 fuel oil and propane for heating (as discussed above), as well as diesel fuel used from site generators, dust emissions from unpaved roads, and excavation projects.

Emission factors are applied to fuel consumption data, as well as estimated kilometres travelled on unpaved roads, to determine the amount of Criteria Air Contaminants (CACs) that are generated on site. Criteria Air Contaminants consist of carbon monoxide, oxides of nitrogen, sulphur dioxide, total (filterable) particulate matter (PM), and particulate matter below 10 microns (PM_{10}), particulate matter below 2.5 microns ($PM_{2.5}$), and Volatile Organic Compounds. Dust emissions from excavation projects were estimated based on a calculation for total particulate matter generated per excavation day. Dust generated from demolition activities in 2021 will be captured in the *2021 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories* [28].

Table 38 outlines the annual CACs generated from site activities, and shows a small decrease in emissions seen in 2021 compared to the 5-year average for the values for total particulate matter, PM_{10}, and $PM_{2.5}$. The PM_{10} value met the NPRI reporting threshold this year, and is reported to Environment and Climate Change Canada. Road dust emissions were the major contributor to meeting these reporting thresholds.

Table 38: Stationary Combustion Data and Emissions from WL

Parameter	Unit	Data for Previous Five Years						Data for 2021	NPRI Reporting Threshold
		2016	2017	2018	2019	2020	Average		
Airborne Emissions									
NO_x (as NO_2)	Mg	0.908	0.753	0.536	0.621	0.602	0.684	0.331	20
SO_2	Mg	0.023	0.020	0.014	0.016	0.017	0.018	0.005	20
CO	Mg	0.399	0.348	0.233	0.271	0.256	0.301	0.162	20

PM_{10}	Mg	3.853	3.499	3.726	2.712	2.281	3.214	2.091	0.5
$PM_{2.5}$	Mg	0.415	0.376	0.391	0.292	0.249	0.345	0.218	0.3
Volatile Organic Compounds	Mg	0.071	0.059	0.042	0.049	0.048	0.0538	0.026	10

9.5.2.3 Greenhouse Gas Emissions

Under the authority of the *Canadian Environmental Protection Act*, 1999 [38] WL must calculate releases under the GHGs emissions notice [40] providing the facility emits over 10,000 tonnes of carbon dioxide equivalent or more within the calendar-year.

Greenhouse Gas emissions from WL include carbon dioxide, methane, and nitrous oxide. Emissions are primarily from the burning of propane, the use of diesel generators, the on-site transportation fleet, the on-site landfill, and open-pit wood burning. They are measured in CO_2 equivalent tonnes which is a measure used to compare between gases that have different Global Warming Potential (GWP).

Table 39 outlines the GHG emissions from the WL site for the last six years. These emissions from the site have decreased significantly from 2020. This decrease can be attributed to the decrease in propane needed to heat the site in 2021 as shown in Table 37. There was a decrease in the number of heating degree days (i.e., decreased demand for building heat based on temperature) in 2021, this combined with the fact Building 200 did not require any building heating during the calendar year, and Buildings 402 and 305 no longer had to be heated starting in the fall of 2021 due to demolition activities. Overall, greenhouse gases in 2021 are 29% less than the average for the last 5 years.

Table 39: Greenhouse Gas Emissions

Parameter	Releases from Previous Five Years						2021 Releases
	2016	2017	2018	2019	2020	5-yr. Avg.	
GHG CO_2e tonnes	1883	1873	1678	1756	1692	1776	1177

Note: GHG CO2e tonnes - A unit of measure used to compare between gases that have different GWP. For example, the GWP for methane is 25. This means that emissions of one metric ton of methane is equivalent to emissions of 25 metric tons of carbon dioxide.

9.5.2.4 Halocarbons

In the atmosphere, halocarbons contribute both to global warming and to ozone depletion, via separate mechanisms. Losses of halocarbon refrigerants and fire suppressants are reported semi-annually to Environment and Climate Change Canada, following the Federal Halocarbon Regulations [41]. All releases greater than 10 kg are considered reportable.

As seen in Table 40, there were two reportable releases of halocarbons in 2021. Both releases were related to the Building 100 chiller system. The first release occurred in 2021 April. During maintenance activities it was discovered that 15.5 kgs of R-134a refrigerant escaped from the chiller system through a leak of one of the shut off values on the equipment. Upon replacement of the shut off valve it was observed that the threads of the valve were compromised. The second leak occurred in 2021 October. During maintenance activities to take the equipment offline for the season, it was discovered that 16.3 kgs of R-134a refrigerant escaped from the chiller system through a faulty solenoid valve.

Table 40: Halocarbon Losses from WL

			Losses from Previous Five Years (kg)					Losses in 2021	
Type	**Global Warming Potential[b]**	**Ozone Depleting Potential[c]**	**2016**	**2017**	**2018**	**2019**	**2020**	**Number of Losses**	**Annual Loss (kg)**
Refrigerants[a]									
CFC (R-11)	4 600	1	0	0	0	0	0	0	0
CFC (R-12)	10 600	1	0	0	0	0	0	0	0

Halon (R-1301)	6 900	10	0	0	0	0	0	0	0

a CFC = Chlorofluorocarbons; HCFC = Hydrochlorofluorocarbons; HFC = Hydrofluorocarbons
b GWP per unit mass, compared to CO2 = 1.00
c Ozone Depleting Potential per unit mass, compared to CFC R-11 = 1.00
d The data for the CFC+HCFC(R-502) is from [41]

9.5.3 Overall Performance

The non-radiological effluent monitoring program set up by CNL continues to supply valuable information about the potential impacts of operations on the Winnipeg River, and thus the local environment.

There were no discharges from the Outfall and Lagoon which exceeded the current monthly guideline limits placed on CNL in 2021.

9.6 Regulatory Limit Exceedances and Contamination Incidents

There were no Regulatory Limit exceedances or reportable events in 2021.

9.7 Discussion of Improvement Initiatives

The following sections describe some of the ongoing efforts the WL site is undertaking to enhance the effluent verification monitoring program.

9.7.1 Monitoring Site Intake Water and Outfall Effluent

In 2020, the WL site expanded the monitoring program to encompass additional parameters at the site's Intake and Outfall monitoring station. This expansion resulted from the enhanced monitoring that was performed on the Intake and the Outfall in 2019 to address the gaps in baseline data when assessed against the monitoring criteria in Table 19-1 of the *WL Effluent Verification Monitoring Plan* [25]. It was decided that when there was a 20% change in concentration when comparing the results for a given parameter at the Intake and Outfall, that these parameters would be incorporated in the effluent verification monitoring program.

Under this criteria, Total Organic Carbon, Strontium, Uranium, Magnesium, Potassium, Sodium, and the volatiles Bromodichloromethane, chloroform and Toluene have been added to the list of parameters being measured at these stations. Currently, CNL can show that the source of the Potassium and Sodium being introduced to the Outfall is a result of the sanding/salting activities that occur on site as the weather transitions into and out of sub-zero temperatures. The Bromodichloromethane and chloroform are by-products resulting from the site's chlorination practises. The remaining parameters are currently not tied to a source, and CNL is planning to do temporary upstream process monitoring (monitoring at LLLWTS in Buildings 100 and 300) to try to be able to explain the operational source of the increase.

In order to be compliant with REGDOC-2.9.1 [42] it was determined that the effluent verification monitoring program needed to include acute lethality testing at the Outfall monitoring station.

Although the need to monitor for these parameters is currently captured in *WL Effluent Verification Monitoring Plan* [25], WL laboratories acknowledges that the plan needs to be updated to reflect that these parameters are actively being monitored, and plans to revise Reference [25] in 2022.

9.7.2 Reducing Energy Use from Fossil Fuels

The largest quantity of non-radiological effluents to air comes from burning fossil fuels, to heat the site buildings. Starting in 2013, use of and emissions from Number 2 fuel oil heating operations at the Powerhouse ceased due to the completion of building conversions to either propane or electrical heating.

Figure 11 shows the annual fossil energy consumption since 2016, relative to the number of Heating Degree Days in each year. Heating Degree Days are calculated for each day as the difference between 18°C and the median ambient temperature.

From Figure 11, it is apparent that energy use has started to stabilize and any further reductions will be resulting from final closure of site buildings, reducing or removing their heating supply. Beginning in 2020 October, Building 200 no longer had to be heated as demolition activities on the building began at this time. In 2021 September, Buildings 305 and 402 no longer required to be heated as demolition activities began on these buildings.

9.8 Environmental Assessment Follow-Up and Monitoring

Details about the Environmental Assessment Follow-Up and Monitoring Program are discussed in the *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28] (to be issued to the CNSC by 2022 June 30).

10 Emergency Management and Fire Protection

10.1 Emergency Preparedness Program

Whiteshell Laboratories adheres to the Corporate Emergency Preparedness Functional Support Area. See Section 10.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL program continues to adapt to the changes on site, including the demolition of buildings/assets, the construction of temporary structures, the number and composition of staffing levels, and the organisational structure. Vacated buildings are transitioned from building emergency procedures to construction/demolition oriented emergency placards.

Planning for and responding to COVID-19 continued as a primary focus for the Emergency Preparedness Functional Support Area at WL in 2021, providing procedures and guidance to enable work to continue safely in this dynamic situation. This was safely managed, without an outbreak at WL, despite the pandemic impact on Manitoba.

10.1.1 Drills and Exercises

The ongoing COVID-19 Pandemic continues to make running in-person emergency scenarios a challenge, especially with our external partners. For 2021, drill and exercise development focused on scenarios that allow for adequate physical spacing and still yield quality learning and evaluation potential.

In 2021, a total of 143 exercises and drills were delivered at WL. This is a significant step up from the 94 drills/exercises delivered in 2020. While not quite back to pre-pandemic levels, this increase signifies an adjustment in the program to the new normal of the current environment. Table 41 provides details on the number and type of the exercises and drills conducted in 2021.

Table 41: WL Emergency Preparedness Exercises – 2021

Type of Drill or Exercise	Number Completed in 2021
Fire Drills	2
Site-wide Specialty Drills	106
Table Top Exercises [a]	5
Targeted Communication Exercise	17
Site-wide Communication Exercise	12
Field Exercises (Functional)	1

a Table Tops include specific EOC Skill workshops as well. Each workshop focuses on a unique aspect of the EOC and includes a small practice scenario.

10.1.2 Training

There was no change to the Emergency Operations Centre (EOC) staff structure in 2021. Building emergency teams are being maintained for all occupied structures on site. Fewer occupied structures has resulted in a decrease in the number of team members required.

10.1.3 Status of Emergency Resources and Facilities

Whiteshell Laboratories maintains a physical EOC, and conducts monthly tests of the technical equipment stored for use in that location. Repairs, improvements and updates are requested as required and when identified. All checks were completed in 2021. A cache of emergency food rations is also maintained at WL, which have a five year shelf life. The rations were replaced in 2019. The cache is stored in a secure location and the condition of the cases is checked annually.

10.1.3.1 Emergency Operation Center

As part of WL's EOC framework, there are two teams of EOC staff, and an alternate person for each of the team positions that can be engaged to cover for members of either of the two teams. These two teams operate on a two week on-call rotation. One EOC member retired in 2021 and his trained alternate was able to step straight into this position.

There were no emergency events requiring activation of the EOC in 2021.

10.1.3.2 Mobile Nuclear Laboratory

Canadian Nuclear Laboratories continues to maintain the Mobile Nuclear Laboratory (MNL) for response both on-site and off-site. The unit continues to be maintained by WL Radiation Protection staff and is inspected at a regular interval to maintain control of inventory and equipment.

There were no emergency events requiring the activation of the MNL in 2021.

10.1.3.3 Equipment Checks

Respirators make up the majority of the equipment in the strategically placed emergency cabinets that remain on site. These cabinets are opened and inspected monthly by Radiation Protection staff. Once a satisfactory inspection is complete, the cabinets are re-sealed and signed off by the inspector. All scheduled checks were completed in 2021.

There were no emergency events requiring the use of this equipment in 2021.

10.1.3.4 Public Address System

The Public Address (PA) system is the primary system used for communicating emergency events to WL employees. The system functioned normally in 2021.

10.1.3.5 Secondary Emergency Signals

The WL site still employs an exterior siren as a redundant form of emergency alerting. The system is no longer required and was replaced by the PA system as the primary alerting system. This system will continue to be used as a redundant alerting system until either the equipment fails completely (there have previously been some issues with the equipment) or the building it is mounted to is decommissioned and demolished.

10.1.3.6 EOC Notification System

WL continued to use the Everbridge Mass Notification system in 2021. The system continues to perform well, with a 100% response rate to all monthly communication tests (see Table 42) for the third year in a row.

Table 42: WL EOC Communication Tests: 2021

Y= Yes N= No	January	February	March	April	May	June	July	August	September	October	November	December
EOC Commander	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Liaison Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Env. Protection Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Safety Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Planning Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Logistics Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Operations Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Nuclear Facilities Representative	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

In addition to these regularly scheduled monthly drills, a random quarterly drill is conducted. These drills are scheduled for random times and dates, including weekends, evenings and work hours. These random drills include the expanded EOC teams, including all alternates and non-routine staff. Table 43 identifies the response rates of the 2021 WL EOC Staff to the Quarterly Random EOC call out drills, with an average of 94% response. Only responses received within an hour of the notification being sent out are considered a positive response, the rest are considered ‘no response’.

Table 43: WL EOC Random Quarterly Communication Tests: 2021

	Q1	Q2	Q3	Q4
Response Percentage	96%	100%	88%	92%

10.1.4 External Collaborations

In 2021 contact was maintained with a variety of external emergency response/management organizations and interested public groups. Due to COVID-19 many of these were once again virtual meetings or connections. WL EmP:

- Engaged with the LGD of Pinawa Emergency Operations Centre staff for local response planning purposes.
- Participated in the Manitoba Provincial Flood and Forest Fire forecasting sessions.
- Continued to participate on the Manitoba Municipal Relations Governance COVID-19 teleconference meetings throughout 2021, though with decreasing frequency as the year progressed.
- Maintained working relationships with Manitoba Emergency Measures Organization staff through less formal interactions this year, including regional response officers and the Critical Infrastructure protection program staff.
- Attended the Provincial emergency management conference, which brought many Local, Provincial and Federal stakeholders together to share best practices and lessons learned on a variety of relevant topics.
- Maintained membership with the Prairie Region (Manitoba and Saskatchewan) of the Federal Coordination Working Group. The Federal Coordination Working Group helps WL maintain ties with representatives from multiple federal agencies including (but not limited to) Public Safety Canada, the Royal Canadian Mounted Police (RCMP), Health Canada, Department of Defence, Public Health Agency of Canada, and Environment & Climate Change Canada, in order to support organizational planning and response.

10.1.5 Unplanned Emergency Events

There were no incidents requiring initiation of the WL Site Emergency Plan occurred during 2021.

10.2 Fire Protection Program

Whiteshell Laboratories adheres to the Corporate Fire Protection Functional Support Area. See Section 10.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

There were no reportable fire events at WL in 2021.

10.2.1 Fire Response Drills

In 2021, WL was unable to conduct all the fire drills that it identifies as an annual requirement in accordance with the National Fire Code of Canada [43] and CSA standard N393-13 Fire Protection for Facilities that Process Handle, or Store Nuclear Substances [44]. This deviation has been captured as part of an internal self-assessment and a corrective action plan is being developed to ensure these are adequately planned and executed.

10.2.2 External Collaborations

Whiteshell Laboratories and the Town of Pinawa signed a Fire Protection Service Agreement in 2019 to improve Mutual Aid support capabilities. The agreement is still in effect. Interdepartmental training has been interrupted by the COVID-19 pandemic, but will be resumed as soon as it is safe to do so.

10.2.3 Third Party Audits & Inspections

As per the requirements of CSA N393-13, *Fire Protection for Facilities that Process, Handle, or Store Nuclear Material Substances* [44], a third party Fire Protection Audit was conducted in 2021. The findings are being collated and their resolution will be tracked through the corrective action program (see also Section 1.2.1.1).

10.2.4 Fire Hazard Analysis

All fire hazard analysis documentation for buildings requiring a fire hazard analysis have been reviewed and are being evaluated against the decommissioning schedule. A corrective action plan was developed and submitted to the CNSC outlining the timeline for Fire Hazard Analysis documentation review and revisions.

11 Waste Management

11.1 Waste Management Program

Whiteshell Laboratories adheres to the Corporate Waste Management Functional Support Area. See Section 11.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Waste Management Program continues to provide effective and efficient delivery of Waste Management services.

Significant activities for the Waste Management Program include:

- Continued to refine and communicate the Integrated Waste Strategy to integrate waste lifecycle management across all CNL-operated sites and to capture the CNL baseline waste strategies and defined pathways for all CNL wastes.
- Collaboration between CRL and WL Programs to effectively disposition radioactive wastes, leading to the advancement of remediation and transportation projects.
- Enhanced support to existing activities and new activities in support of the new schedule for the WL Closure Project. The support improved segregation protocols and ensured continued adherence to waste processes.

The waste acceptance criteria for three of the waste receiving facilities on-site (including the Waste Handling Area and the WMA storage facilities) remained unchanged for 2021.

11.1.1 Waste Management Operations

Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects. The packaged solid radioactive wastes were stored in designated storage facilities in the WL WMA depending on the hazard level and packaging, as well as dispositioned to CRL for interim storage.

Demolition of Buildings 402 and 305 began in 2021 and is on target to be complete early 2022. A total of 2,246 m^3 clean waste was generated in 2021; 1,290 m^3 of concrete material was dispositioned to an off-site receiver for future re-use, 450 m^3 of metal was recycled, while 483 m^3 of asbestos-containing material and 17 m^3 of polychlorinated biphenyl (PCB) contaminated materials were dispositioned to appropriate off-site waste receivers.

Decommissioning on the south area of the WL main campus continued, which involved asbestos abatement and remediation of high temperature water lines, generating approximately 188 m^3 of clean concrete waste; 28.5 m^3 of this volume contained asbestos-containing materials which was sent to an approved off-site licensed facility.

Building 200 Active Liquid Waste Treatment Centre demolition was completed. A total of 1,077 m^3 of Low-Level Waste (LLW) and 77.5 m^3 of Intermediate - Level Waste[10] (ILW) waste

[10] In this context, ILW refers to any waste that does not meet the proposed Near Surface Disposal Facility (NSDF) Waste Acceptance Criteria (WAC) and requires storage in ILW facilities at CRL.

was generated; of this LLW total, 876 m³ has been safely dispositioned to CRL, with the remaining 201 m³ and 77.5 m³ of ILW waste safely stored in certified transportation packages awaiting shipment to CRL in 2022.

De-inventorying efforts of legacy waste stored in LLW Bunker 5 began. Wastes are undergoing additional qualification and inspection to ensure transportation and waste criteria compliance are met. This activity has generated 360 m³ of LLW to date, which are safely stored in certified transportation packages awaiting shipment to CRL in 2022.

Table 44 summarizes the quantities of radioactive waste generated in 2021 that was sent to each storage location. Table 45 summarizes the volumes of solid low-level radioactive waste originating from each facility in 2021. Table 46 summarizes the volumes of solid intermediate-level radioactive waste originating from facilities in 2021. Table 47 summarizes the volumes of solid low-level and intermediate-level radioactive waste transported to CRL for disposition.

Table 44: Radioactive Waste by Storage Location

Storage Facility	Volume (m³)	
	2020	2021
Low-Level Quonsets	32.3	0
Intermediate-Level Waste Bunkers	0	2.5
SMAGS[a]	4.1	0
Soil Storage Compound	0	0
Total	36.4	2.5

a Shield Modular Above Ground Storage (note: SMAGS is no longer used for waste storage)

Table 45: Low-Level Radioactive Waste Generated by Facility

Facility of Origin	2020		2021	
	Compactable Waste Volume (m³)	Non-Compactable Waste Volume (m³)	Compactable Waste Volume (m³)	Non-Compactable Waste Volume (m³)
Building 100	0.8	9.2	1.5	0.0
Building 200	7.2	198.9	0.0	875.6

Total	527.7	26.3	921	3.2

a Shielded Modular Above Ground Storage – legacy waste generated from various decommissioning projects.

Clearable waste from Controlled Areas was monitored in-situ. Clean bagged waste was monitored using the bag monitor located in Building 300 where WL's laundry facility is now stationed; all bagged waste met the screening criteria and was deemed to be suitable for unrestricted release in 2021.

Whiteshell Laboratories continued to reuse or recycle as much material as practicable; this includes both recyclable materials sent to the municipal recycling facility and other material-specific facilities throughout Manitoba. Waste Management Program representatives exercised a proactive approach to ensure waste was properly segregated at the source of origin to maximize the amount of material that could be reused or recycled.

Table 48 summarizes the disposition pathway of non-active wastes, while Table 49 summarizes the amount, by material type, of recyclable waste shipped off-site.

Table 48: Non-Active Waste Disposition Pathways

Disposition Location	Volume (m^3)	
	2020	2021
WL Asbestos Disposal Site [a]	0	0
WL Burn Pit	247	189
WL Inactive Landfill	0	0
Recycling[b] **Sent Off-Site**	513	271
Off-Site Landfill [c]	1,256	1,352
Total	2,016	1,812

a The WL Asbestos Disposal Site stopped receiving waste in 2019 to support the environmental risk assessment. Non-active asbestos is directed to off-site licensed landfills.

b This recycling waste pertains to office recycling that is generated on a daily basis that is accepted at municipal recycling facilities.

c WL Inactive Landfill stopped receiving waste mid-2019 to support the environmental risk assessment. Non-active waste is directed to off-site licensed landfills.

Table 49: Recycled Waste Shipped Off-Site

Material[a]	Weight (kg)	
	2020	2021
Aluminum	0	0
Batteries Shipped	0	0
Batteries Recycled	227	0
Cardboard[b]	0	0

Copper and Brass	0	0
E-Waste Shipped	347	3,464
E-Waste Sold	0	0
Ferrous Metals	108,457	26,231
Glass	0	0
Lumber	0	0
Plastic Shipped	0	0
Plastic Sold	0	0
Stainless Steel	0	0
Lead	0	7,450
Total	109,031	37,145

a This recycling waste pertains to material that is sold or charged to be taken to a material specific recycling facility.

b Cardboard is sent to a municipal recycling facility and inclusive in Table 48.

Improvements were made in preventing waste accumulation inside of buildings and transferring the waste to appropriate waste facilities immediately after generation. Improvements continue to be addressed in reference to the lack of processing and storage space for non-routine waste materials (e.g., mixed waste and large contaminated items), as well as large volumes radioactive wastes generated from decommissioning activities. Mitigation measures put in place in 2021 included finalizing a Nuclear Safety Note for the interim storage of cargo containers containing radioactive wastes in the WMA. This area is referred to as the Recoverable Surface Storage and Staging Area (RSSSA), and consists of an outdoor, above ground storage pad to enable the storage and loading of solid low-level waste in sea land containers and storage of oversize LLW items which are awaiting further processing, characterization and/or packaging to be considered compliant for off-site disposition. Additionally, satellite transshipment areas were established north of the WMA and one by the B200 demolition to reduce additional handling and improve efficiencies with off-site disposition of waste.

11.1.1.1 Liquid Waste Generation

During 2021, 78.9 m^3 of low-level liquid was processed in the Building 300 LLLWTS and 9.9 m^3 in the Building 100 LLLWTS, for a total of 88.8 m^3 of low-level liquid waste processed through the two systems.

11.2 Decommissioning Plan

Whiteshell Laboratories adheres to the Corporate Cleanup Functional Support Area. See Section 11.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

11.2.1 Program Overview, Achievements and Accomplishments

As per the Licence Conditions Handbook for WL [2], CNSC have been notified of revisions to the Detailed Decommissioning Plan (DDP) for WL [45].

11.2.2 Land Use Program

Table 50 provides a summary of the status of the WL Site's Overview DDP.

Table 50: Overview Decommissioning and Cleanup Plan Updates for WL in 2021

Document Reference	Key Activity Status in Year	Effective Date (if applicable)
WLDP-02000-DDP-001	Approved by Regulator	December, 2021

The Overview DDP was revised, submitted to the CNSC, and approved for use in 2021.

11.2.3 Decommissioning and Demolition Program

Table 51 lists the WL DDPs and their status as of 2021.

Table 51: Overview of WL Detailed Decommissioning Plans

Facility	DDP Document Title	Document #	Status
Shielded Facilities	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 2 - Shielded Facilities	WLDP-21400-DDP-001, Revision 1, 2016	Facility is operational and decommissioning activities ongoing. DDP Volume is available for use.

11.2.3.1 Detailed Decommissioning Planning and Execution

Table 52 provides a summary of WL facility DDPs that were revised in 2021.

Table 52: Summary of WL Detailed Decommissioning Plans in 2021

Facility	Document Status	Document Name and Reference	Effective Date	Document Highlights
WMA	Current Published	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 8 - WMA: Part 3 - Low Level Waste Liabilities, WLDP-24400-DDP-001, Revision 5	April, 2021	DDP was submitted to and accepted by CNSC staff.

Table 53 provides a summary of decommissioning and demolition statuses for WL in 2021.

Table 53: Summary of WL Decommissioning and Demolition Status by Facility in 2021

Facility	Decommissioning and Demolition Status
B402	Active Decommissioning
B200	Building Demolished
B413	Active Decommissioning
B420	Active Decommissioning
B426	Active Decommissioning
B429	Active Decommissioning
WMA	Active Decommissioning
Site Affected Lands and Contaminated Structures	Active Decommissioning

Several buildings and structures were decommissioned in 2021, where operational wastes were dispositioned, building services isolated and industrial hazardous materials removed prior to demolition where feasible.

Demolition of Buildings 402 and 305 began, and is expected to be completed early 2022. The demolition of the buildings included remediation and abatement of asbestos-containing materials, specifically the mastic tar adhered between the masonry and exterior wall, and PCB's found within window glazing and exterior caulking and general demolition of construction and demolition materials.

Remediation of the south-side of the main campus continued. Phase one field work was completed, which consisted of remediating the high temperature water lines. Phase two field work to excavate and remove underground electrical bus ducts, isolate fire water, domestic water, storm drains and sanitary drain systems will commence in 2022. The exterior of Buildings 413, 420, 426 and 429 were radiologically surveyed for clearance, with interior portions to be completed in 2022.

Building 200 was successfully demolished, which involved the above and below grade structure, while the building footprint was backfilled. Remediation of this footprint was strategically adjusted to align with future remediation of the surrounding lands known to be contaminated from historical spills associated with the building. This will ensure remediation of the known contamination is completed in one phase, avoiding the potential of creating additional volumes of waste that may be generated from migration of contaminants within the soil.

Legacy wastes stored in the LLW Quonsets (Building 431, 432 and 433) and LLW Bunker 5 began to be retrieved in 2021. Wastes are undergoing visual examination, destructive and non-destructive characterization, and packaging to ensure transportation and waste criteria compliance are met, before waste can be dispositioned to CRL. This work is scheduled to be complete in 2022.

Decommissioning progress is also discussed in the facility sections (Appendix A through Appendix G).

11.2.3.2 End State Reporting

Table 54 provides a summary of end-state reports completed for WL in 2021.

Table 54: Summary of WL Decommissioning and Demolition End-State Reports in 2021

Facility	Document Type	Document Status	Document Name and Reference	Submission Date (if applicable)
Building 514 (WMA)	End State Report	Submitted to CNSC	Decommissioning and Demolition of Organic Coolant Incinerator Complex (B514), WLDP-24400-ESDR-001, Revision 1	July, 2021

12 Security

12.1 Security Program

Whiteshell Laboratories adheres to the Corporate Security Functional Support Area. See Section 12 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Whiteshell Site Security Report [46] outlines the security arrangements that are in place at the WL site. The Security Functional Support Area consists of processes, procedures, and staff to manage the continuous operation and response to security incidents; the Security Functional Support Area and procedures are reviewed and updated as required to address operational requirements.

Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers stated in REGDOC-2.2.4, *Fitness for Duty, Volume III Nuclear Security Officer Medical, Physical and Psychological Fitness* [47].

Hours of Work Exceedances

As per REGDOC-2.2.4, *Fitness for Duty: Managing Worker Fatigue* [47] Sections 4.2 and 4.3, CNL has recorded all exceedances of hours of work for Security's safety-sensitive positions. See Table 55 below for a list of exceedances for 2021. NOTE: COVID pandemic had a direct contribution to Table 55 in order to ensure minimum shift complement.

Table 55: Hours of Work Exceedances for Nuclear Security Officers and Tiered Response Force Personnel at WL in 2021.

Limits:			2021			
			Q1	Q2	Q3	Q4
4.2	**1.**	**>16 hrs in a 24-hour period**	3	4	7	4
4.2	**2.**	**> 28 hrs in a 48-hour period**	15	21	28	11
4.2	**3.**	**> 120 hrs in a 14-day period**	6	4	1	1
4.3	**2. d.**	**Min recovery 48 hrs after 2 consecutive nights**	19	11	5	15
4.3	**2. d.**	**Min recovery 72 hrs after 3 consecutive nights**	2	5	3	2
		Total	45	45	44	33

A CNSC Type II Security Compliance Inspection was carried out - see Section 1.2.2. A corrective action plan was submitted to the CNSC to address findings.

CNL-WL received notification from the CNSC on the closure of one (1) enforcement item, Directive WL-SEC-19-T2-001-D01 – Training. The Directive closure was granted as CNL-WL completed all actions required to address the enforcement items listed in the Directive.

12.1.1 Security Events

In 2021, there were no security events that affected the Whiteshell Laboratories.

13 Safeguards and Non-Proliferation

13.1 Safeguards Program

Whiteshell Laboratories adheres to the Corporate Nuclear Materials and Safeguards Management (NM&SM) Functional Support Area. See Section 13 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

13.1.1 IAEA Activities

The IAEA conducted various types of activities as part of the safeguards approach for CNL, including, but not limited to, IAEA safeguards seals changes, human surveillance, implementation and/or maintenance of IAEA safeguards monitoring equipment, and technical visits. A list of IAEA inspections conducted at all CNL sites can be found in Section 1.2, Management System of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In 2021 May-June, 14 of 16 WL concrete canisters were re-welded, during which the IAEA provided oversight. The IAEA also verified and changed the IAEA seals attached to the canisters to maintain continuity of knowledge. Minor difficulty was encountered during resealing of one canister and the IAEA inspector decided to employ an alternate sealing arrangement. In 2021 September, the other two canisters were re-welded, during which IAEA provided oversight, including resealing the one canister into the original configuration as it was operationally preferable.

A Physical Inventory Verification (PIV) inspection was completed by an attending IAEA inspector on 2021 May 25. This inspection was a sampling of accessible items containing Special Fissionable Material.

The IAEA also completed a Design Information Verification (DIV) inspection on 2021 May 25 - 27. The activities associated with the DIV included:

- Verification of the Design Information Questionnaire:
- Verification of the site and general building design;
- Verification of containment integrity; and
- Verification of operational status of the facility.

14 Packaging and Transport

14.1 Packaging and Transport Program

Whiteshell Laboratories adheres to the Corporate Transportation of Dangerous Goods (TDG) Functional Support Area, which includes the requirements of the Packaging and Transport SCA. See Section 14 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Packaging and Transport SCA covers the safe packaging and transport of nuclear substances and radiation devices. The TDG Functional Support Area applies to any activities involving the transportation of dangerous goods to or from CNL sites. The TDG Functional Support Area provides an operational framework for the safe off-site transport of dangerous goods by conforming to all applicable laws and regulations, as well as company policies and procedures.

The Waste Certification & Transportation branch is a centralized organizational department responsible for planning, coordinating and executing radioactive waste shipments from the WL site to the off-site disposal or storage facilities in a safe and compliant manner, including having fully trained Radioactive Material Shippers as authorized under the CNL TDG Functional Support Area.

Significant activities in 2021 included:

- Transportation of 921 m^3 of low-level waste and 3.2 m^3 intermediate-level waste sent off-site and safely delivered to CRL;
- Throughout 2021, additional technical assessments and studies on the WL used fuel inventory were completed in support of the licensing application of the Used Fuel Transportation Package (UFTP). These assessments were focused on the WL mixed fuel types (i.e., enriched and experimental fuel types, including Uranium Carbide and Uranium Metal fuel types) and the physical operation of the UFTP. The UFTP, which is owned by the Nuclear Waste Management Organization, has been leased with the intention that the UFTP will be the Type B Transportation Package for high-level waste transportation operations starting in 2022 (due to the COVID-19 Pandemic, these transportation operations were delayed and subsequently pushed out from 2020). There is a two-step licensing strategy for the UFTP, with the first phase focusing on licensing the UFTP for non-enriched CANDU fuels and the second phase focusing on WL's inventory of mixed fuel types. The phase UFTP Safety Analysis Report (SAR) Addendum was submitted to the CNSC in 2019 May, with updates provided throughout 2020, and acceptance is anticipated in early 2022. The UFTP SAR for Mixed Fuel Types (representing phase two) will be submitted in 2022, following the CNSC's acceptance of the phase 1 SAR addendum. Additional accomplishments throughout 2021 include the revision and acceptance of the revised UFTP pre-shipment leak tests, the progression of detailed planning and operational readiness deliverables, and the completion of field trials with the UFTP, Shielded Interface Module (SIM) and Fuel Transfer Flask.

- Award of the subcontract to Nuclear Assurance Corporation (NAC) to design and fabricate Type B casks, cask handling equipment and on-site services needed to support ILW transport to CRL was completed. Two versions of the OPTImal Modular Universal Shipping (OPTIMUS) casks, the OPTIMUS-H and OPTIMUS-L were accepted for use after their licence review and received. Personnel from WL and CRL participated in a week long training session, qualifying them on the use, loading and transport of the casks.
- Extensive training was conducted to site personnel responsible for the handling and packaging of radioactive waste materials, which included Class 7 RAM Material – Handler Training, as well as Waste Management and Packaging Fundamental Training, which was developed to capture the requirements to compliantly process, load, and handle waste materials into certified transport packages, as well as the various waste receivers' waste acceptance criteria.

14.1.1 Shipments

At WL, 68 radioactive transport packages making up 53 loads were safely and successfully sent off-site in 2021. One reportable event occurred in 2021 (see ImpAct ERM-21-1036 in Table 5) where a consignment of waste material was misclassified in accordance with the Packaging and Transport of Nuclear Substances Regulations [48] and IAEA Safe Transport of Radioactive Material [49], due to an incomplete inventory of the package's contents. Several corrective and remedial actions were completed to address the event.

15 Other Matters of Regulatory Interest

15.1 Public Information and Disclosure Program

Whiteshell Laboratories adheres to the Corporate Public Information Program. See Section 15 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Public Information Program document [50] is intended to cover communication activities that occur within CNL's immediate neighbouring communities. This document was prepared in accordance with CNSC regulatory document REGDOC-3.2.1, *Public Information and Disclosure* [51].

15.1.1 Outreach and Stakeholder Engagement

WL shares information with the public through a number of activities including conducting public information sessions, media releases, the corporate website, a toll-free line, social media accounts and involvement in community events. As employees are CNL's greatest ambassadors, they are kept informed of developments so that they can also share information with their relatives, friends, and neighbours.

CNL engaged with the public on WL using a number of tactics. During the COVID-19 pandemic, engagement followed public health and corporate guidelines and was primarily virtual. Table 56 presents public engagements from 2021.

Table 56: Public Engagements for Whiteshell Laboratories

Date	Location	Activity
March 2, 2021	Pinawa, MB	Presentation and meeting with Local Government District of Pinawa Council and Mayor
April 20, 2021	Webinar	WL Closure Project: Environmental Protection
May 18, 2021	Webinar	WR-1 Reactor Decommissioning Fact or Fiction Webinar
September 21, 2021	Webinar	WL Closure Project: Project update
November 16, 2021	Webinar	WL Closure Project: Environmental Protection
November 24, 2021	Winnipeg, MB	Emerging issues conference 2021: The net-zero future investing in sustainability

15.1.2 Public Consultation

CNL actively works to engage local stakeholders on matters related to WL activities. In 2021, a number of methods were deployed to gain feedback from and create discussion with interested parties including: breakfast sessions, social media, and feedback forms available online and at external events, and responses provided to inquiries. CNL strives to create open and transparent communication with all identified stakeholders, and to address concerns and respond to all inquiries.

Throughout 2021, CNL received 21 community inquiries related to WL (Table 57), largely through the WR-1 Breakfast Session/Webinar series.

Table 57: Whiteshell Laboratories Closure Project Public Inquiries

Nature of Enquiry	Number
Transportation	3
Environmental protection	7
Whiteshell Laboratories Closure Project	11

15.1.3 Traditional and Online Communications

15.1.3.1 Website

CNL's Whiteshell Decommissioning web page had 1,667 page views in 2021.

To support the Whiteshell projects and site, CNL has used social media to promote events, share and receive information, and generally engage with the public. As Table 58, Table 59 and Table 60 show that social media has been an effective tool to reach and engage stakeholders. Table 61 shows that CNL also shared information through a community information bulletin.

Definitions:

Engagements - Measures how much and how often others interact with you and your content in social media.

Shares or retweets - Measures how often the message was shared or forwarded on the twitter website.

Table 58: Facebook Metrics for WL-related Posts*

Date of Post	Engagement	Shares
February 16, 2021	3	0
March 29, 2021	3	1

Date	Bulletin
January 28, 2021	Whiteshell Monitoring

15.1.3.2 Newsletters

CONTACT is CNL's external, bilingual newsletter. It is distributed to community stakeholders, businesses and approximately 8,000 homes in the region surrounding WL, and is available on www.cnl.ca. This publication informs the reader on activities undertaken at CNL's Whiteshell Laboratories and profiles CNL's community activities. Two issues of *CONTACT* were distributed in 2021 and included the following topics:

- WL Closure Project and WR-1 updates
- Highlights of public and Indigenous engagement activities
- CNL initiatives in the community, demonstrating commitment to economic generation, sponsorship, donations and participation in community events
- CNL's COVID-19 response
- Employee transition
- Environmental stewardship, including steps CNL has taken to reduce greenhouse gas emissions, protect wildlife and minimize waste.

15.1.3.3 Media Releases

During 2021, there were seven articles written by media on the Whiteshell Closure Project (see Table 62).

Table 62: Media Coverage for 2021

Date	Article	Title of Publication
January 2021	Canada's Radioactive Waste Policy Review	LGD of Pinawa Municipal Quarterly Newsletter

March 24, 2021	Who decides where nuclear waste goes	Winnipeg Free Press
March 26, 2021	Nuclear waste solution	Winnipeg Free Press
July 15, 2021	Pinawa erosion responsibility in question	The Clipper
September 2, 2021	CNEA continues funding North Forge East with three-year deal	The Clipper

15.1.4 Ongoing Projects

15.1.4.1 WR-1 In-Situ Decommissioning Environmental Assessment

The proposed WR-1 in situ decommissioning project (also referred to as in situ disposal) is a key part of CNL's overall integrated approach to safely manage and reduce Canada's legacy liabilities. The Environmental Assessment (EA) process for the project includes a requirement that WR-1 project information be made available to neighbouring communities, Indigenous communities and organizations, and stakeholder groups through a variety of mechanisms to ensure accessibility of fact-based information. Engagement activities conducted in support of this requirement included social media and website content, presentations, meetings, site tours and fulfilling stakeholder requests for information.

Project-specific webpages and content were produced for the WR-1 Project and included: fact sheets, info-graphics, downloadable posters, project descriptions and quick reference material. All information is available in both official languages at www.cnl.ca/wr-1.

15.2 Indigenous Engagement

CNL follows CNSC REGDOC-3.2.2 *Indigenous Engagement* [52] which sets out requirements and guidance for licensees on Indigenous engagement. CNL recognizes and values ongoing engagement with Indigenous communities and organizations in the spirit of truth and reconciliation.

15.2.1 Engagement Objectives

As part of its corporate, environmental, and social responsibility, CNL recognizes and encourages the ongoing engagement of the First Nations and the Red River Métis (represented by the Manitoba Métis Federation) through the course of the environmental assessment process for the WR-1 Project and engagement on the overall site closure project. Through information-sharing and engagement activities, CNL seeks to build awareness and learn about interests and concerns in an effort to strengthen mutual understanding and pursue

opportunities for collaboration and long-term relationships. CNL engages with First Nations and Red River Métis leadership, representatives and members on the potential effects of the WR-1 Project and the Whiteshell Laboratories Closure Project (WLCP) on the environment and on Indigenous and/or treaty rights including rights to trap, hunt, fish, gather and conduct cultural ceremonies.

CNL has five overarching Indigenous engagement goals:

- **Build awareness and mutual understanding** by supporting and facilitating opportunities for mutual learning on topics including current and traditional use, values and perspectives on nuclear decommissioning, environmental remediation and radioactive waste management, in order to demonstrate CNL's long-term commitment and approach to safe and responsible management of radioactive waste and decommissioning liabilities (e.g., through site monitoring activities).
- **Share information on the project**, including the potential effects on the environment. This includes developing meaningful, user-friendly information and communication products for the First Nations and the Red River Métis, and providing accessible and current information on project activities.
- **Seek input and feedback from the First Nations and the Red River Métis** on project-related activities, and traditional and current uses of the land surrounding the WR-1 project site. Initiate early and meaningful two-way communication between CNL and the First Nations and the Red River Métis to determine the best methods for sharing information and to provide opportunities for Indigenous Peoples to give input on project considerations including design, the EA process, and assessment of impacts.
- **Develop long-lasting relationships with the First Nations and the Red River Métis** to support their continued involvement in the project, community healing and reconciliation. This will extend beyond the scope of the EA process for WR-1.
- **Meet or where possible exceed all regulatory-based communication and engagement requirements** and facilitate engagement that reflects current memorandums of understanding and contribution agreements, and that takes into account the interests, needs and schedule of each Indigenous Nation.

15.2.2 Identified Indigenous Communities

CNL developed a list of the First Nations and the Red River Métis with a potential interest in the WR-1 Project and the WLCP. The identification of the First Nations and the Red River Métis was based on consultation with the CNSC, through CNL's previous Indigenous engagements, and through the use of publicly available sources of information including:

- First Nation and the Red River Métis and organization websites;
- The Aboriginal and Treaty Rights Information System (ATRIS; Government of Canada and INAC 2016); and
- Crown-Indigenous Relations and Northern Affairs Canada First Nation community profiles.

The list was based on the identified potential or established Indigenous or treaty rights of the First Nations and the Red River Métis and is provided in Table 63 with a brief rationale for inclusion. The inclusion of specific Nations considers the nature of the established and/or claimed rights and potential effects on those rights caused by the proposed project, based on a preliminary assessment of existing and available information. As such, the working list is subject to change based on information and dialogue with the identified First Nations, the Red River Métis, and Indigenous organizations.

Table 63: Identified Indigenous Communities

First Nations, the Red River Métis or Organizations	Identification Rationale
Sagkeeng First Nation (Treaty No. 1 and 3)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy one reserve located 52 kilometres (km) north of the WL site, and downstream along the Winnipeg River. Existing relationship and interest in the Whiteshell Laboratories site.
Brokenhead Ojibway Nation (Treaty No. 1)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy three reserves: 44 km northwest, 55 km northwest and 73 km southwest of the Whiteshell Laboratories site respectively. Interest expressed comments on Project Description.
Manitoba Métis Federation (MMF)	The MMF is the official democratic and self-governing political representative for the Métis Nation's Manitoba Métis Community. The MMF is considered the government of the Red River Métis. Potential asserted and/or established Métis harvesting rights in the vicinity of the Project. Interest expressed comments on Project Description.
Black River First Nation (Treaty No. 5)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy one reserve 75 km north of the Whiteshell Laboratories site.
Hollow Water First Nation (Treaty No. 5)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Occupy one reserve, 113 km north of the Whiteshell Laboratories site.
Shoal Lake No. 40 (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy three reserves: 94 km southeast, 110 km southeast and 140 km southeast of the Whiteshell Laboratories site, respectively.
Iskatewizaagegan No. 39 Independent First Nation (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site.

First Nations, the Red River Métis or Organizations	Identification Rationale
	Occupy four reserves: 93 km southeast, 102 km southeast, 110 km southeast and 140 km southeast of the Whiteshell Laboratories site, respectively.
Northwest Angle No. 33 (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy three reserves: 111 km southeast, 140 km southeast and 176 km southeast of the Whiteshell Laboratories site, respectively.
Wabaseemoong Independent Nations (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy four reserves: 80 km east, 85 km east, 95 km east and 140 km southeast of the Whiteshell Laboratories site, respectively.
Grand Council of Treaty 3	Umbrella treaty organization which represents 28 First Nations and 5 with potential interest in the Project. Treaty 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site.
Chiefs of Ontario	First Nations umbrella organization that represents 133 First Nations and 4 with potential interest in the Project

15.2.3 Summary of Engagement

Table 64 lists CNL's Indigenous engagement activities related to the WLCP from 2021. Further details on Indigenous engagements are available in the Indigenous Engagement Report [53].

Table 64: CNL Indigenous Engagement Activities for 2021

Date	Event	Location
Sagkeeng First Nation (SFN)		
January 5	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
February 18	Discussion on the application of Free Prior and Informed Consent on the WR-1 Project	Teleconference
March 9	Discussion with Chief and Council on engagement with Sagkeeng's members	Teleconference
April 6	Leadership discussion on Sagkeeng's Psychosocial Impact Assessment Report	Teleconference
April 15	Site Tour with Sagkeeng's Liaison Officer	On-Site Visit
June 16	CNL, AECL, and Sagkeeng participated in first Technical Working Group meeting	Teleconference
June 17	Sagkeeng's Liaison Officer visits the site to record video for National Indigenous Peoples Day	On-Site Visit
July 14	Sagkeeng's Liaison Officer participated in a bat survey on site	On-Site Visit
July 19	CNL, AECL, and Sagkeeng participated in second Technical Working Group meeting	Teleconference
August 11	Sagkeeng's Liaison Officer participated in a site tour	On-Site Visit
August 12	Sagkeeng's participated in the preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 17	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
August 24	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
September 7	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
September 14	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
September 22	Sagkeeng's Liaison Officer participated in Trauma-informed Engagement Training with CNL, AECL, and the CNSC	In-person, Winnipeg
September 28	Sagkeeng's participated in the second preliminary discussion of the Indigenous Advisory Committee	In-person, Winnipeg
November 10	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
November 15	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
December 15	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
Manitoba Metis Federation		
January 6	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
February 8	Technical Workshop on WR-1 Groundwater Monitoring	Teleconference
February 18	Environmental Monitoring and MMF Green Initiatives Discussion	Teleconference

Date	Event	Location
March 2	Technical Workshop on Alternative Means Assessment and VC Components	Teleconference
March 9	Discussion on developing a relationship agreement	Teleconference
March 17	Overview presentation on the site's Environmental Protection Program	Teleconference
May 11	Wrap-up Meeting for Technical Workshops	Teleconference
May 25	Discussion on participation in site field monitoring	Teleconference
June 2	Discussion on WR-1 draft commitments and relationship agreement	Teleconference
June 3	Update on Whiteshell Laboratories Closure Project	Teleconference
June 14	MMF participated in groundwater monitoring, a songbird survey, and a turtle search at the site	On-Site Visit
June 18	Discussion on developing a relationship agreement	Teleconference
June 22	MMF participated in a bat survey on site	On-Site Visit
June 23	MMF participated in the a second bat survey on site	On-Site Visit
July 14	MMF participated in the a third bat survey on site	On-Site Visit
August 12	MMF participated in the preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 13	MMF hosted a leadership discussion with CNL's President and AECL's	In-person, Winnipeg
August 16	MMF observed river sediment, soil, and vegetation sampling	On-site Visit
August 19	MMF, CNL, and the CNSC participated in a trilateral meeting	Teleconference
August 19	Discussion on collaborating on a green initiative	Teleconference
September 8	MMF participated in Mushroom collection at site	On-Site Visit
September 21	Discussion on developing a relationship agreement	Teleconference
September 28	MMF participated in a second preliminary discussion on developing the Indigenous Advisory Committee	In-person, Winnipeg
October 20	Alpha Targeted Therapy Discussion	Teleconference

Date	Event	Location
November 17	Alpha Targeted Therapy Discussion	Teleconference
November 22	Discussion on developing a relationship agreement	Teleconference
December 2	Discussion on developing a relationship agreement	Teleconference
Black River First Nation, Hollow Water First Nation, Brokenhead Ojibway Nation		
February 1	Discussion on developing a relationship agreement	Teleconference
April 1	CNL, Black River First Nation, and Hollow Water First Nation sign a relationship agreement	E-mail
May 18	Discussion on onboarding the newly appointed liaison officer	Teleconference
May 25	Liaison officer participated in a site tour	On-Site Visit
June 1	Liaison officer onboarding discussion	Teleconference
June 23	Participating in site monitoring discussion	Teleconference
July 6	Participating in site monitoring discussion	Teleconference
July 14	Liaison officer participates in bat survey	On-Site Visit
August 12	Communities participate in preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 16	Liaison officer participates in observation of river sediment, soil, and vegetation sampling	On-Site Visit
August 19	WR-1 Environmental Impact Statement Document review discussion	Teleconference
September 20	Update on Site Decommissioning Activities	Teleconference
September 28	Communities participate in second preliminary discussion of the Indigenous Advisory Committee	Teleconference
November 10	Six-month Relationship Agreement Discussion	Teleconference
December 13	Update meeting of community liaison committee development	Teleconference

15.2.4 CNL's Long-Term Relationship with Indigenous Peoples

CNL recognizes First Nations and the Red River Métis as stewards of the land and is working towards developing meaningful long-term relationships with each Nation that occupies and has traditional territories and/or modern-day interests near its site operations. CNL recognizes each Nation has its own unique set of interests and concerns associated with both the WR-1 decommissioning project and the WLCP is committed to taking a distinctions based approach to engagement to ensure each Nation's interests and concerns are addressed. CNL also takes a

holistic, relationship-based approach to engagement with each Nation, working closely with AECL, to help address interests and concerns regarding all aspects of the WLCP.

This shift in CNL's Indigenous engagement approach from project based engagement to a holistic, relationship and distinction-based approach will support meaningful actions to build foundations for trust, understanding, and mutually beneficial relationships, including addressing broader issues and concerns such as the historical siting of the Whiteshell Laboratories site.

CNL is currently working with each Nation to formalize these relationships through relationship-building and corresponding agreements. These agreements are intended to help enable greater integration of Traditional Knowledge, ceremony, and cultural and stewardship practices in the decommissioning, monitoring, and closure of the project. These agreements will also enable dialogue and participation through the development of monitoring programs, culturally appropriate communications, and trauma-informed engagement. In addition, the agreements help to enhance community engagement, build trust and strengthen relationship-building, and provide mechanisms that facilitate Indigenous participation and input into CNL's environmental monitoring program, economic development and procurement opportunities, future land use, and other areas of collaboration.

CNL has signed a relationship agreement with Black River First Nation and Hollow Water First Nation. Relationship agreements with Sagkeeng First Nation and the Red River Métis are contemplated, and steps are being taken to negotiate such agreements. CNL is committed to ongoing engagement and finalizing these agreements.

CNL continues to build relationships with local First Nations and the Red River Métis to support overall decommissioning of the Whiteshell Laboratories site, including the WR-1 Project. CNL is committed to learning about Indigenous values through ceremony and ongoing dialogue, and discussing, incorporating, and addressing concerns to the extent possible.

16 Acronyms

α	Alpha
ACMR	Annual Compliance Monitoring Report (formerly Annual Safety Review (ASR) or Annual Compliance Report (ACR))
AECL	Atomic Energy of Canada Limited
ALWTC	Active Liquid Waste Treatment Center
β/γ	Beta-Gamma
CCSF	Concrete Canister Storage Facility
CNEA	Canadian National Energy Alliance Limited

Appendix A Concrete Canister Storage Facility

A.1 Operations

The Concrete Canister Storage Facility (CCSF) is operated under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [54]. Concrete storage canisters located at the CCSF have been used at WL since 1975 to store irradiated fuel; there are currently 16 canisters in use.

During 2021, staff of the Site and Nuclear Operations Branch monitored the operation of the CCSF.

The CCSF was operated in compliance with practices and procedures approved for operation. All required surveys and inspections were completed in 2021.

Routine operations in the CCSF were carried out by staff in the Site and Nuclear Operations Branch.

With the recognition of increased work in the CSSF and WMA, three operator trainees were hired, with two of the trainees starting in late 2021. A senior operator was appointed as Facility Supervisor.

In 2021, the CCSF continued to maintain the minimum staffing requirements outlined in the CCSF Facility Authorization [54]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the CCSF in 2021. Procedures for the Facility began their updates as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

A.2 Compliance Monitoring

A.2.1 Air Effluent Monitoring of Canister Liners

Each canister has a closed air-circulating system to monitor the internal space between the canister liner and the sealed fuel basket for the presence of fission products and moisture. Canisters are monitored for one week per month between April and November, dependant on weather. This year readings began in May and concluded in October. Despite multiple attempts flow could not be established in the Canister 8 air lines, these air lines have had issues in previous years obtaining flow. The normal approach to establishing air flow through lines was unsuccessful. Attempts will be made in 2022 to clear the line again.

The gross beta activity was below or near the detection limit of 0.04 Bq/m^3 for all canisters that were measured.

There was no visible moisture detected from the internal canister space during 2021 monitoring, however, the silica gel used in the counting did change colour from blue to pink indicating moisture in the air is present.

A.2.2 Monitoring of Ground and Surface Water

Figure 12 shows the drainage area surrounding the CCSF. Further details on monitoring and results of monitoring ground and surface water can also be found in Sections 9.4.1.3 and 9.5.1.4, and compliance results for the CCSF are described below.

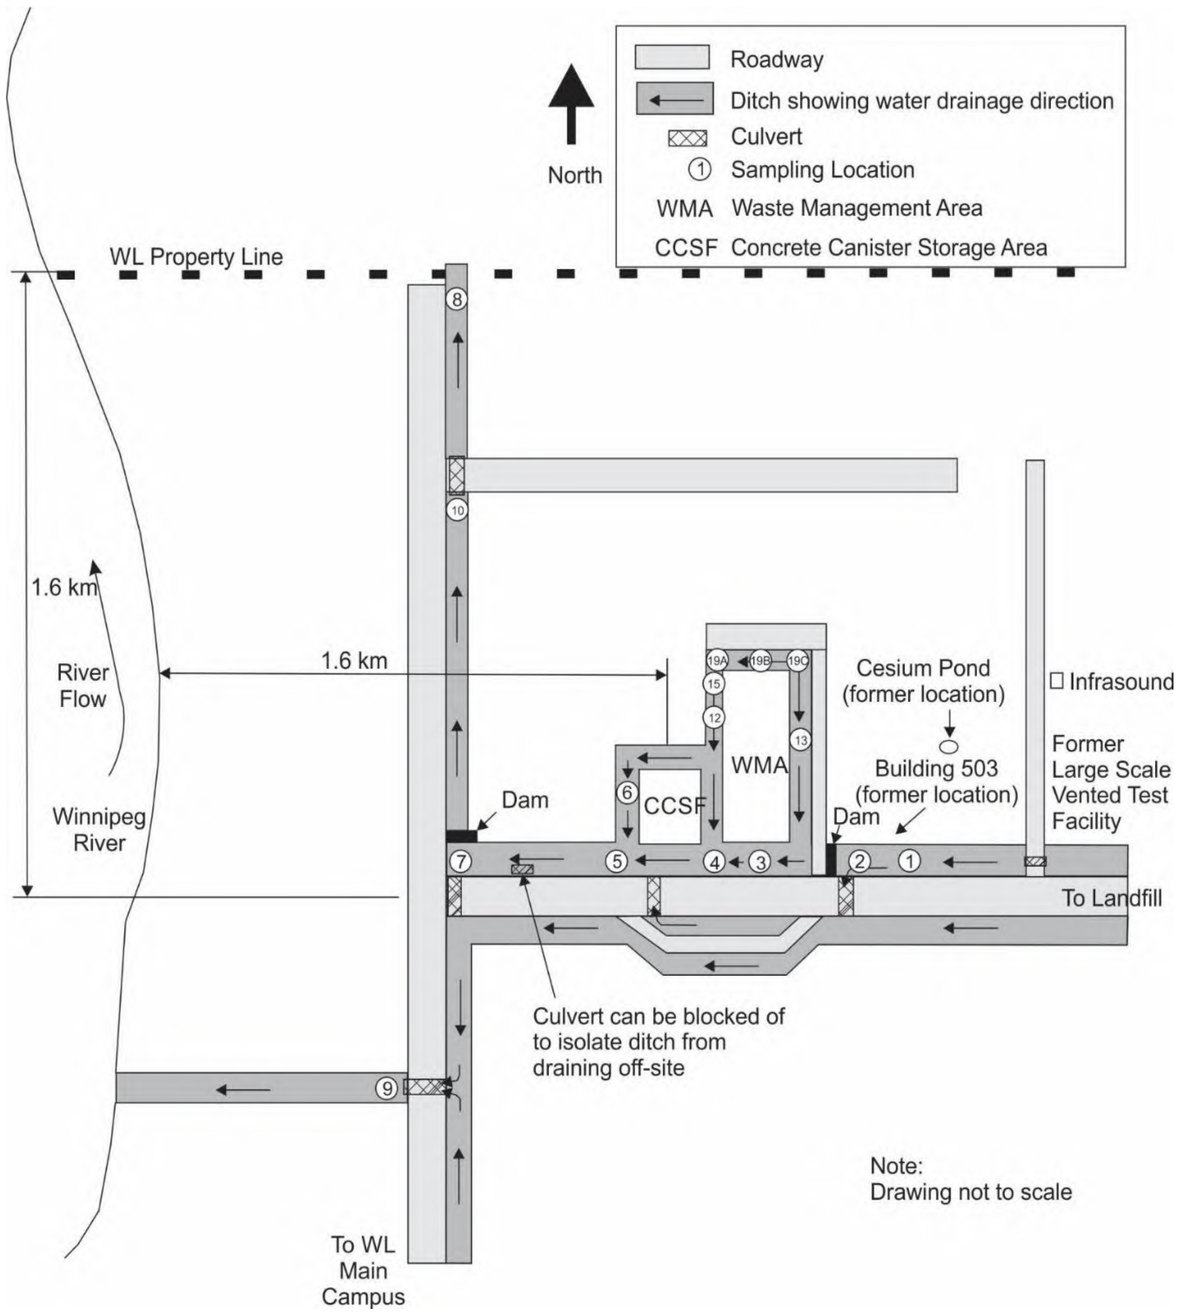

Figure 12: Surface Water Drainage Sample Points

Groundwater samples from deep-well sites in the vicinity of the CCSF are obtained twice yearly; the results are reported and discussed in Appendix D of this report.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the canisters. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry analysis and processed for Strontium (Sr)-90. Gamma spectrometry analysis provides individual results for Cobalt (Co)-60, Niobium (Nb)-94, Antimony (Sb)-125, Cesium (Cs)-134, Cs-137 (Barium (Ba)-137m), Promethium (Pm)-147 and Americium (Am)-241.

If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry analysis and uranium analysis. Uranium analysis has also been conducted for other sampling locations below the limit this year. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration established by Health Canada [34]. If uranium is detected, the result is evaluated against the Maximum Acceptable Concentration for uranium (0.5 Bq/L).

Ditch Location 5 and Ditch Location 6 samples (see Figure 12 for sampling locations) could contain surface drainage from the CCSF, however, due to drought conditions and limited snow fall over the 2020/2021 winter, there was only one day with sufficient ditch water movement. This did not include Locations 5 and 6.

The alpha activities were below the trigger level of 0.5 Bq/L.

Table 65, Table 66, Table 67 and Table 68 list the results of the surface-water samples taken from the vicinity of the CCSF and WMA during 2021. Operational control-monitoring data from previous years has been included for completeness.

The ditch sample collected immediately downstream from the WMA (Location 7) contained elevated levels of tritium[11] (see Table 67), which did not exceed the associated Maximum Acceptable Drinking Water concentration of 7,000 Bq/L [34]. The activity seen is from the WMA as discussed in Appendix D.

[11] Tritium analysis of samples from Ditch Locations 5 and 6 was previously discontinued due to the higher levels of tritium (~4000 Bq/L) noted at upstream locations associated with the WMA.

A.3 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [13]. There were no major facility changes made in 2021.

A.4 Equipment Performance, Planned Maintenance Testing and Inspections

All canisters are checked for deviation from vertical annually. Out of 16 canisters, all displayed slight deviations from vertical in 2021. None of the canisters had a deviation greater than 1°. In 2021, Canister C5 had a deviation of 0.8° to the east. This deviation and those observed on other canisters show that they all display slight movements in response to changing soil moisture conditions and related swelling and contraction of the clay layer. If a canister was noted either through vertical deviation measurements or visually to be trending beyond a 2-3° deviation, corrective measures such as bracing would be considered.

There were no canister loading or unloading operations in 2021.

As required by Section 8 of the Facility Authorization [54], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests were complete. The inspections were all completed.

Whiteshell Laboratories staff conducted general site inspections during each quarter of 2021. The general appearance and fencing were found to be satisfactory on each inspection. Minor infilling was done along the base of the fence to meet security requirements.

In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however, existing cracks and pour pockets were regularly checked for changes and it has been noted that edges of many pour pockets are more brittle as was noted in 2020. Selective patching is done of these pour pockets, only minor patching was conducted in 2021. No increased radiation field was noted from the canisters.

A.4.1 Canister Site Monitoring and Surveillance

GAMMA FIELD SURVEYS

Gamma exposure rates from the canisters were measured quarterly in 2021. These readings were taken in compass directions north-east-south-west, on contact, and 2.0 m from the canister wall at an elevation of 2.0 m above grade level.

No gamma field anomalies were found during 2021.

Table 69 shows the averaged gamma near contact exposure rates measured during 2021, and for the previous four years.

Table 69: Summary of Average Gamma Radiation for Near Contact Measurements from Fuelled Canisters (mrem/h)

	0.22	0.25	0.15	0.13	2017		0.16	0.11	0.18	0.18	2017

a The measurements were made using a BOT P200 survey meter. The instruments are calibrated in mR/h and it is assumed 1 mR/h =1 mrem/h

AIR MONITORING

Air monitoring was conducted on each of the canisters in the CCSF in 2021. This involved an air pump that circulates air from an outlet line on the canister through a Dexter filter and returns it through an inlet line. These readings are taken once per month over a period of approximately one work week during warm weather months. Typically this is the six months of the year when air temperatures are normally above zero. As 2021 was a drier, warmer year, 7 months of sampling were done. As discussed above in Section A.2.1, flow could not be established in the Canister 8 air lines.

One anomalous but still low reading was found in Canister 20 leading to an average of 1.8 Bq/filter for the year. As the other readings were zero, this reading was retained but it is not indicative of a trend. Canister 13 and 16 had single readings slightly greater at 1 Bq/filter. The values may also relate to some disturbances of contamination on the baskets by the previous year's visual observations and the air flow from sampling.

Table 70 shows the averaged beta readings on each filter measured during 2021, and for the previous four years.

Table 70: Summary of Average Beta Radiation Measurements from Fuelled Canisters (Bq/filter)

Canister Number	Average Air Sampling Measurements			Canister Number	Average Air Sampling Measurements

A.5 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the CCSF as part of routine operations.

See Section 11.1 Waste Management Program for summaries of any volume of radioactive solid and/or liquid waste generated in the CCSF in 2021.

A.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the CCSF as part of routine operations.

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

Appendix B Active Liquid Waste Treatment Center

B.1 Operations

The Active Liquid Waste Treatment Center (ALWTC) in Building 200 did not operate in 2021.

Previously, in 2020 October, CNL notified the CNSC that the ALWTC, Building 200 was being demolished and had requested that the Facility Authorization [55] and the Safety Analysis Report [56] associated with the ALWTC be removed from the Whiteshell Laboratories LCH [14]. CNSC granted this request in 2020 December [57].

In 2017, new LLLWTS began operation in Buildings 100 and 300. All of the Building 100 low level liquid waste is now being tested, treated and controlled release to the river in the Building 100 LLLWTS and likewise in Building 300.

In 2020 October, the last of the operating systems in Building 200 were shut down and isolated (ventilation and compressed air systems). The building was rendered cold and dark and demolition of the building started later in 2020 October. Demolition of Building 200 above grade and 1.5m below grade were completed in 2021 October. The demolition footprint is still fenced and protected. The fence will remain until the potentially contaminated ground can be remediated.

B.2 Facility Changes

The demolition of the building was completed in 2021 October.

B.3 Wastes Generated

No solid radioactive or hazardous waste was generated in the ALWTC as part of routine operations.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the ALWTC during demolition activities in 2021.

B.4 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the ALWTC as part of routine operations.

Appendix C Shielded Facilities

C.1 Operations

The WL Shielded Facilities (SF) operates under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [58]. The SF, consisting of the Hot Cell Facility (HCF) and the IFTF, are located in the R&D Complex (Building 300), and are operated by personnel in the Site and Nuclear Operations Branch.

The HCF Cells 1 to 5 and IFTF Cell 13 remain operational while HCF Cells 6 to 11 have been shut down and partially dismantled. The Waste Handling Area, located in the IFTF, was operated for compaction and assaying of radioactive waste.

Operations and decommissioning activities were conducted throughout the year. Operations activities included:

- maintenance of HCF and IFTF ventilation system equipment;
- replacement of HEPA filters;
- packaging and storage of radioactive waste;
- cleanup activities; and
- routine maintenance to ensure compliance with the site licence.

Routine operations in the SF were carried out by operating staff from the Site and Nuclear Operations Branch.

There were no organizational changes in 2021. Although there was a reduction in the staffing for the operating staff responsible for the SF in 2021, the minimum staffing requirements outlined in the SF Facility Authorization [58] was maintained at levels to provide the needed operational and safety support.

No program changes were made for the SF in 2021. Procedures are being updated as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

C.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [13].

C.3 Equipment Performance, Planned Maintenance Testing and Inspections

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence.

Equipment tests and inspections were completed with the exception of a secondary Intermediate-Level Liquid Waste containment tank leak detector due to a defective probe. Compensatory measures were put in place until the detector was repaired. Monthly housekeeping and fire prevention inspections were completed.

VENTILATION SYSTEM

Maintenance activities requiring part of the ventilation system to be taken down occurred without incident.

The annual routine Poly-Alpha-Olefin testing of the HCF HEPA filters were successfully conducted.

C.4 Wastes Generated

See Section 11.1 Waste Management Program for WL summaries of the volume of radioactive solid and liquid wastes generated in the SF in 2021.

LOW-LEVEL SOLID WASTE

In 2021, the SF generated 45.6 m^3 of compactable low-level radioactive solid waste and no non-compactable waste.

The Waste Handling Area processed 62.1 m^3 of low-level radioactive solid waste which was reduced to 5 m^3. A portion of this waste was generated in the SF, and the remainder came from all of the nuclear facilities and decommissioning projects at WL where waste is being generated.

Table 71 lists the annual low-level solid waste generated in the SF for 2021 and the previous four years.

Table 71: Solid Wastes Generated

Total Volume	2017	2018	2019	2020	2021
Low-Level Solid Waste (m^3)	0.4	73.3	64.3	10.9	45.6
Medium-Level Solid Waste (m^3)	0	0	0	0	0

MEDIUM-LEVEL SOLID WASTE

In 2021 the SF generated no medium-level (intermediate-level) radioactive solid waste. Table 71 lists the annual medium-level solid waste generated for 2021 and the previous four years.

LOW-LEVEL LIQUID WASTE SYSTEM

In 2021, 99 m^3 of low-level liquid waste was processed through the Building 300 low-level liquid waste system (see Appendix E).

MEDIUM-LEVEL LIQUID WASTE SYSTEM

All the medium-level liquid waste (intermediate-level liquid waste) from the HCF cells collects in the HCF sump tank, AD Tank 1. The liquid is transferred via a manually controlled pump from AD Tank 1 through a filtration system to AD Tank 14 in the IFTF. The liquid from all other HCF medium-level liquid waste drains and all IFTF medium-level liquid waste drains flows by gravity to AD Tank 14.

In 2021, there was one transfer of 0.1 m^3 medium-level liquid waste to transportable totes that is being stored for future disposition.

Table 88 lists the annual aqueous waste generated for 2021 and for the previous four years.

C.5 Effluents Released

Liquid radioactive and hazardous effluents were discharged from the SF as part of routine operations are provided and discussed in Section 9, Environmental Protection.

Appendix D Waste Management Area

D.1 Operations

The Waste Management Area (WMA) operated under the WL Site Licence [1], in accordance with the requirements of the *Facility Authorization for the Operation of the Waste Management Area at the Whiteshell Laboratories* [59]. During 2021, the WMA at WL was operated and monitored by staff in the Site and Nuclear Operations Branch.

In 2021, the WMA was operated in compliance with approved practices and procedures.

Routine operations in the WMA were carried out by the Facility Manager, Facility Supervisor, WMA Operators and two WMA based utility workers, with support from other Site and Nuclear Operations personnel and Environmental Monitoring personnel as required.

In 2021, the staffing of the WMA was increased. A Facility Supervisor (Senior Operations Technician) was appointed and three additional Operations Technologist trainees were hired.

In 2021, the WMA continued to maintain the minimum staffing requirements outlined in the Facility Authorization [59]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the WMA in 2021. Procedures are being updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

D.1.1 Inventory Additions And Deletions

Changes in inventory are reported in Table 72 and for the purposes of reporting WMA inventory (fission products are defined as radioactive material originating from irradiated fuel).

Activation products are defined as any material that has been activated in a neutron flux, including corrosion products. The radioactivity values listed are those recorded at the time of storage.

D.1.2 Low-Level Solid Waste

Details of wastes transferred to the WMA are provided in Section 11.1.1. Waste generated from decommissioning work on the site was generally shipped to CRL for storage, although some waste was stored in the WMA. Some of the inventory of stored waste in WMA was sent to CRL for storage pending future disposal. The stored volume of waste is listed in Table 72.

D.1.3 Industrial Waste

There were no additions of industrial chemical waste during 2021.

Table 72: Additions to Low-Level Waste Inventory

Period	Storage Locations	Volume (m^3)	Fission Products (GBq)	Activation Products (TBq)
Total Accumulation to 2020 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433.	18,798.84	1,967.38	330.58
Additions for 2021	Building 431 to 433	0	0	0
Removals for 2021	LLW Bunker 6 Buildings 431 to 433	9 0	13 0	0 0
Total Accumulation as of 2021 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433	18,789.84	1,954.38	330.58

D.2 Compliance Monitoring

D.2.1 Monitoring And Surface Water

SURFACE WATER

Figure 12 shows the drainage area surrounding the WMA.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the WMA. The WMA and CCSF share a network of perimeter compliance monitoring ditches with designated sampling locations. Water samples are collected in these sample locations for analyses when there is sufficient flowing water present. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period. In 2021, there was only one day where the ditch flow met the required flow conditions in some sample locations due to the light snow pack leading to limited snow melt, limited rainfall and dry soil conditions.

A recorded amount of precipitation of 395 mm occurred in 2021, which was less than the 441 mm recorded in 2020, and is a ten year low for recorded precipitation. The low precipitation is reflective of an ongoing drought in the area.

In an effort to streamline the operational environmental monitoring process, surface water samples are initially analyzed for gross beta, gross alpha, and tritium. The results are then evaluated using the following screening criteria:

- If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry, and processed for Sr-90. Gamma spectrometry provides individual results for Co-60, Nb-94, Sb-125, Cs-134, Cs-137 (Ba-137m), Pm-147, Am-241.

- If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry and uranium analysis, however, as was the case last year, all water samples were tested for uranium. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration (MAC) established by Health Canada [34]. If uranium is detected, the result is evaluated against the MAC for uranium (0.5 Bq/L or 20 ppb).

Levels of beta activity at ditch sample Locations 1 to 7 (Table 73) all remained well below 10 Bq/L. Based on historical data, it is conservatively assumed that the beta activity in the surface water is Sr-90 in secular equilibrium with Y-90. Most beta activity levels in the ditch water remained below the drinking water screening level of 1 Bq/L, and below the drinking water limit of 5 Bq/L for Sr-90 and 10 Bq/L for Cs-137 [60]. Compliance with Guidelines for Canadian Drinking Water [34] may be inferred if the measurement for gross alpha and gross beta is less than 0.5 Bq/L and 1.0 Bq/L, respectively. There were no exceedances of the Canadian Drinking Water [34] standard of 1.0 Bq/L (Table 73) in 2021.

The alpha activity levels in the surface water are presented in Table 74, and were below the trigger level of 0.5 Bq/L. Uranium results are presented in Table 75.

There was no flow at Locations 19 A, B and C in 2021. In past years, the uranium values recorded at these locations are believed to result from the use of local Lac du Bonnet Batholith granitic rock as base material for the SMAGS foundation. This rock had been also used for berm support material for the Cesium Pond pile, however that material was removed from the WMA in 2018. The Lac du Bonnet Batholith granite is noted to have naturally occurring uranium.

As shown in Table 76, the tritium results are below the Maximum Acceptable Concentration of 7000 Bq/L [34] at all locations with only one result above near-detection limits of 124 Bq/L at Location 7 in 2021. Other locations had no flow or near non-detection of tritium. Locations 19 A, B and C were originally chosen for sampling for the potential migration of cesium-137 due to the presence of the Cesium Pond soil pile. Although the Cesium Pond soil has been removed, CNL will continue to monitor locations 19 A, B and C due to the elevated levels of tritium.

The WMA contains a number of trenches with varying amounts of low-level radioactive waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. Based on the initial modelling [61], it was proposed that tritium would be present in the ditches (including the Locations 3 through 7 and 19 A, B and C) and possibly reach levels as high as 37 kBq/L. While tritium is slightly elevated immediately around the WMA, periodic monitoring of the ditches has indicated that the levels of tritium at the points (Locations 8 and 9) leaving CNL property remain quite low (below an average value of 4.7 Bq/L in 2021). With the low flow volumes, tritium was only detected in one location. Although the amount measured in Locations 1 to 7 are above that noted at the Control location, the levels are much lower than the Maximum Acceptable Concentration in drinking water for tritium (7000 Bq/L).

Table 73, Table 74, and Table 75 present the WMA surface-water sampling data. The data represents continuing documentation of a spill incident that occurred in 1979 near ILW Bunker 3, from the reference sample point (Location 3) in the southeast section of the WMA, as shown

in Figure 12 and Figure 13. In 2017, sampling Location 3 was reconfigured to allow preparations for future bunker and standpipe remediation, but the location was dry this year due to the dry summer. Surface water at this location serves as an indicator of movement of water from ILW Bunkers 1, 2 and 3. The most mobile radionuclide (tritium) is below the associated Maximum Acceptable Concentration. The levels of tritium in the surface water and groundwater are below the radiation screening criteria used for identifying contaminants of potential ecological concern (COPECs) of 1.27×10^7 Bq/L [62]. These tables, and Table 76, have been expanded to include the historical monitoring at Ditch Locations 19 A, B and C, water flow permitting.

The Cesium Pond soil (Cs-137) that was stored in the WMA adjacent to SMAGS was removed in 2017. There was no flow recorded in the north WMA ditch in 2021 (Locations 19 A, B and C) (Figure 13). Table 77 reflects this circumstance and shows that previous years indicated no migration of Cs-137 to these ditches.

As Trench 16 has a known quantity of Technetium-99 (Tc-99), Tc-99 measurements were performed as part of ditch water monitoring in 2021. Only one value near the limit of detection was measured (Table 78) The Tc-99 limit for drinking water is 200 Bq/L [60] and the measurement is well below this level.

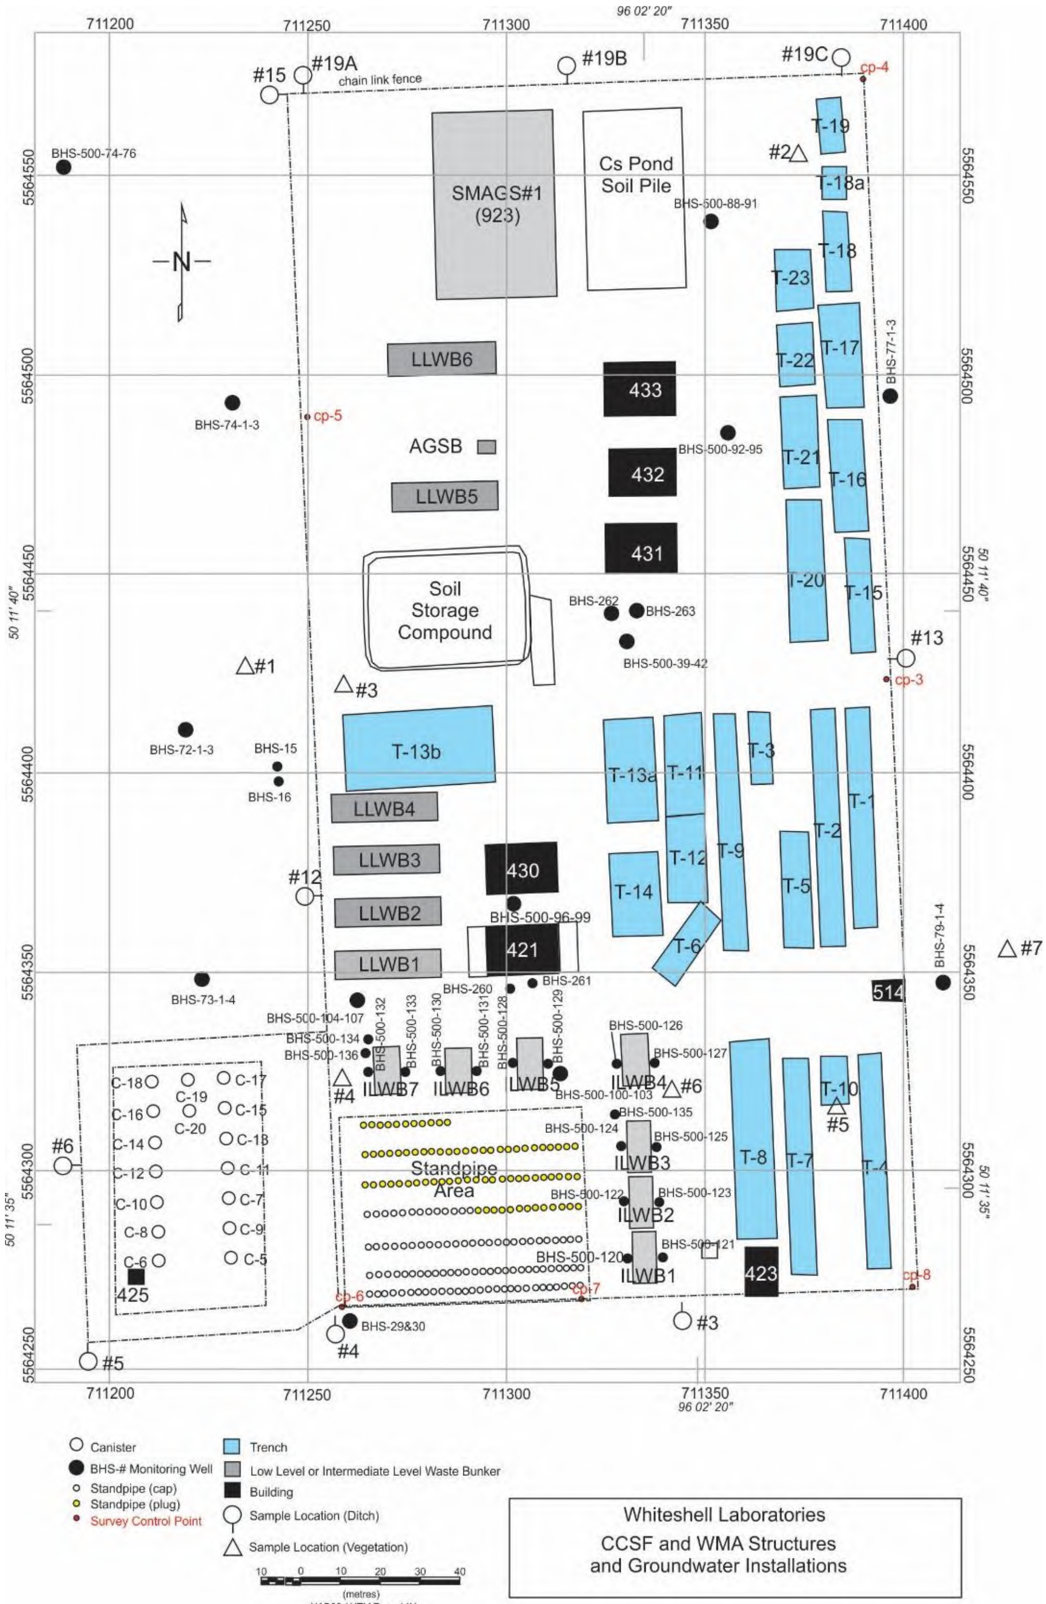

Figure 13: Ground Water Sample Points

INTERMEDIATE - LEVEL WASTE BUNKERS NEAR FIELD WELLS

A series of shallow near field wells were installed adjacent to the ILW bunkers in the WMA in 2015 (Figure 12). Groundwater samples were taken from the wells and from water in the ILW Bunkers for comparison. Cs-137, Sr-90, and tritium were selected as the radionuclides for monitoring of the potential for contaminant migration. Cs-137 was selected as the least mobile, with a high affinity for bonding with clay-based minerals, Sr-90 is more mobile but will bond with sand, and tritium is the most mobile that moves with water. Cs-137 and Sr-90 require a pathway (e.g., a construction joint or crack) to migrate from a bunker. In 2021, Sr-90 was noted to be a maximum of 34 Bq/L adjacent to ILW Bunker 1, and 20 Bq/L adjacent to ILW Bunker 3. For all other locations, the Sr-90 and Cs-137 levels were minor or negligible. Tritium can move through concrete without cracks by diffusion with water movement. The results indicate no migration of Cs-137 (Table 79) from the ILW Bunkers, and Sr-90 (Table 80) and tritium levels (Table 81) that are orders of magnitude below the levels observed in the water in the adjacent ILW Bunkers. At ILW Bunker 3, the tritium results remain high (126,326 Bq/L) and moderately high at ILW Bunker 5 (11,051 Bq/L).

A series of water measurements were made as a confirmatory check in 2020 for the presence of base neutral chemicals (e.g., benzenes, ethylenes) and PCBs. These measurements indicated these chemicals were not present in the water around the bunkers. The measurement was not repeated in 2021.

WATER TABLE WELLS AND DEEP WELLS

Water samples were collected from wells in and around the WMA (Figure 13) in the spring and fall of 2021. The gross alpha and gross beta results are summarized in Table 82. The beta activity levels in the clay, clay till and basal zone wells remained below the drinking water screening level of 1 Bq/L. All zones were below the limit for Sr-90 (5 Bq/L) and Cs-137

(10 Bq/L) [34]. The average alpha activity in the samples collected from the Basal zone wells was below the screening level.

Uranium concentrations in the basal zone wells ranged from 0 to 0.59 Bq/L. The concentrations in the Clay zone wells ranged from 0.19 to 3.60 Bq/L, and in the clay till from 0 to 1.61 Bq/L. Since it is known that the local well waters within the Canadian Shield contain naturally occurring uranium [63], the presence of uranium and its progeny are not unexpected and are considered to account for the levels of alpha. Low levels of tritium were noted in the clay (23.29 Bq/L) and clay-till (11.33 Bq/L). This is not unexpected as these overburden layers are impacted by tritium in the WMA.

Table 82: Monitoring Data Water Table Wells and Deep Wells

WMA Sample Locations	2017 Avg. (Bq/L)	2018 Avg. (Bq/L)	2019 Avg. (Bq/L)	2020 Avg. (Bq/L)	2021 Avg (Bq/L)	2021 Avg. Range (Bq/L)

HIGH-LEVEL LIQUID WASTE TRAY WATER

Monitoring of the high-level liquid waste tank tray water was carried out to confirm there is no leakage from the residue remaining in the storage tanks. This is sampled in the summer months. The sample results indicated no leakage has occurred from the tanks. The data are

summarized in Table 83. In the late fall of 2004, the high-level liquid waste had been removed from high-level liquid waste Tank 2 and transferred to the SF for cementation. A heel of waste remains to be removed. High-level liquid waste Tank 1 remains empty.

Table 83: Monitoring Data High-Level Liquid Waste Tank Tray Water

WMA Sample Locations	2017 Avg (Bq/L)	2018 Avg (Bq/L)	2019 Avg (Bq/L)	2020 Avg (Bq/L)	2021 Avg (Bq/L)	2021 Range (Bq/L)
Total Beta [a]						
Tank Tray Water	13.8	13.8	12.1	11.2	17.7	13.6 to 25.3
Total Alpha [b]						
Tank Tray Water	0.65	0.69	1.5	0.95	0.2	0.1 to 0.4

a The reference nuclide for total beta is Sr-90, gamma results indicate that approximately 13Bq/L of the gross beta activity is due to K-40.

b The reference nuclide for total alpha is Pu-239

D.2.1.1 RADIATION FIELD MEASUREMENTS

Radiation field measurements are taken semi-annually at established points (normally every 38 m) along the perimeter fence. The 2021 radiation field measurements were similar to those in 2020. The data is summarized in Table 84.

Table 84: Perimeter Fence Monitoring Data

WMA	Radiation Field (µSv/h)					
	2017 Avg	2018 Avg	2019 Avg	2020 Avg	2021 Avg	2021 Range
Spring Survey						
South Fence	0.2	0.2	0.2	0.3	0.2	0.1 – 0.3
West Fence	0.4	0.4	0.4	0.3	0.3	0.1 – 0.6
North Fence	0.2	0.2	0.2	0.4	0.2	0.1 – 0.3
East Fence	0.3	0.3	0.3	0.2	0.4	0.1 – 0.5
Fall Survey						
South Fence	0.2	0.2	0.2	0.4	0.3	0.2 – 0.3

North Fence	0.2	0.2	0.2	0.3	0.3	0.2 – 0.4
East Fence	0.3	0.3	0.4	0.3	0.2	0.1 – 0.5

D.2.1.2 VEGETATION

In 2021, vegetation samples were collected at monitoring locations within the WMA (Figure 13), and at a control location unaffected by WL operations. The gross beta results are

summarized in Table 85. Potassium (K)-40 represents the majority of gross beta activity in most of the samples. The levels of gross beta in the samples are due to a combination of K-40 and Sr-90/Y-90, with a minor contribution from Cs-137. The average Sr-90 contribution for the vegetation samples in the WMA is 6% (12% for Sr-90/Y-90). Results were historically reported as Bq/m^2 as there was the potential for deposition of radioactivity via airborne emissions from the former WL Incinerator and former Baler operations. The incinerator and baler have not been in operation for many years and have been decommissioned. The results are now presented as Bq/kg and represent the uptake of radioactivity from impacted areas near the sampling locations.

Table 85: Waste Management Area Vegetation Monitoring Data

WMA Sample Locations	Average Gross Beta[a] (Bq/kg)				
	2017 Avg	2018 Avg	2019 Avg	2020 Avg	2021Avg

South-East Area	460	409	441	230	246
Control Sample[b]	379	187	210	162	171
Background Sample[c]	419	324	317	203	157
East of ILW Bunkers 3 and 4	NA	672	450	NA	218

a The reference nuclide for beta is Sr-90
b Adjacent to the WMA outside of the fence boundary
c Ambient Radiation monitor Stations Background Samples
d Until 2012 this sampling point was in the North-West area after 2012 it was moved to the North-East area. Only a single set of vegetation samples was taken as of 2017 as uptake occurs over the summer. Range is no longer included because of this change.

In 2021, the Facility continued to maintain the minimum staffing requirements outlined in the Facility Authorization [59]. Three trainee operators were hired in 2021 to begin increasing staffing to meet with planned decommissioning activities. Staffing was maintained at levels to provide the needed operational and safety support.

D.3 Facility Changes

All facility changes are performed as per the approved Engineering Change Control procedure [13].

Work to prepare for extraction of waste from the Intermediate Level Bunkers and Standpipes was begun in 2017 and continued into 2021 with most of the physical preparatory work done with continued fabrication of extraction equipment off site.

The pad to the east of the north access road had the requisite safety analysis and procedural documents prepared. The pad is now designated as the Recoverable Surface Staging and Storage Area and will be placed into service in 2022 to store Seacan containers containing

waste and oversized items. The Seacan containers or items will be awaiting processing, characterization and packaging for off-site shipment. This was required to allow Building 923 (SMAGS) to be converted to a Cask Loading Facility (CLF).

Building 923 is in the process of being converted to the CLF. In 2021 this included installation of a 15 ton overhead crane, additional lighting and ventilation ducting and an air handling unit. Interior shielding walls were also erected. The current interior equipment is awaiting commissioning and connection of additional power. Further installation work will be done in 2022.

The WR-1 Phase 1 decommissioning waste material was stored in Buildings 432 and 433 in the WMA. Approximately 96% of the WR-1 Phase 1 decommissioning waste stored in Buildings 432 and 433 had been processed by the end of 2016. One oversized crate along with five asbestos crates remain in Building 433 at the end of 2021. Through 2021, work to characterize the contents of B431, B432 and B433 occurred. This effort will continue in 2022 with off site shipping planned.

The marine container used for storing sealed sources that was transferred from Building 430 in the WMA to the Standpipes Protected Area to meet revised security regulations from the CNSC in 2015, remained in place through 2021. Sources are still held pending future dispositioning.

The process to convert Low Level Waste Bunker #6 to the Intermediate-Level Liquid Waste Treatment Centre, Building 202, began in 2021. Work consisted of removal of waste that had been temporarily returned to the bunker due to restrictions in work crews and shipments related to the COVID-19 Pandemic. Once the waste was removed, interior surveys were conducted in preparation for the next phases of work in 2022.

Removal of waste from Low Level Waste Bunker #5 began in 2021. The waste removal is a component of the decommissioning effort for the WMA, and will extend into 2022.

The Waste Transshipment Area outside the northern perimeter of the WMA had its footprint extended and pad upgraded to improve areas of formerly soft ground. The Waste Transshipment Area allows for holding shipments of waste that are ready to be shipped. The larger area will support the planned pace of waste extraction from the WMA.

In 2021, the Waste Transshipment Area also provided access through a west gate in that area to allow for construction of a road along the west side of the WMA. Pads off the west side of that road will host transformers and generators to provide Class IV and Class III power to waste extraction and processing equipment to be installed in the WMA. A non-active organic material laydown area was established on the north end stub of the west road to allow for an area for organic material from the development of the Waste Transshipment Area pad improvement and west road to be retained.

A replacement section of the north fence running from the west side of Building 923 to the east edge of the Recoverable Surface Staging and Storage Area was installed. This fence included an expanded width north gate to allow shipping containers to be transported without having to

raise them above the fence. The fence replacement was done to correct fence sections that were leaning outwards.

On the south side of the WMA, a new well nest was installed to the south of the south road. This well nest was installed to provide groundwater measurements outside of the zone of influence of the work conducted at the WMA. The previous wells fulfilling this role are now too close to the Protected Area expansion to be considered outside the zone of influence and will be used as part of the monitoring network for that area.

A bedrock well was installed to the west of the WMA-CCSF. This provided improved coverage at depth to monitor for potential contaminant migration.

D.4 Equipment Performance, Planned Maintenance Testing and Inspections

During 2021, the bunkers and other structures in the WMA remained fit for service. Building 923 and Low Level Waste Bunker #6 were removed from operations pending their conversion to the Cask Loading Facility and Intermediate Level Liquid Waste Treatment Centre respectively. Building 421 continued to operate as a waste examination and re-packaging area, making use of the Temporary Ventilated Enclosure.

Medium-Level Waste Bunker 4 did not have new waste placed in 2021 and remains ~70% full. Medium-Level Waste Bunker 6 is ~60% full; however it is not accepting waste due to water ingress issues. Medium-Level Waste Bunker 7 is ~86% full with one placement occurring. The percentage full values are estimates only. Road transportable totes of liquid waste remain in the heated Building 430 pending future processing. Building 431 contains historic waste which is in the process of being characterized and packaged. Building 432 and Building 433 also contain various historic wastes and wastes held in various stages of characterization and repacking operations.

A small seepage of an oily substance first noted in 2020 was again noted at the central gasket, near the south wall base of LLW Bunker 1. The substance was sampled in 2020 and found to contain oil and likely degraded liquid organic. The volume was small in 2020 and remained so in 2021. Seepage again only occurred during hot weather, and as weather cooled the seepage stopped. The area will continue to be monitored. The bunker is slated for remediation of its waste in the next few years.

The Soil Storage Compound remained empty of stored waste soil bags. There are three empty standpipes in the standpipe area.

In-service storage facilities were inspected for water ingress during routine waste emplacement operations. Filled storage facilities with accessible drainage sumps were inspected monthly during the summer months, when water ingress is most likely. Caulking of the roofs of all the WMA Quonset buildings with waterproof sealant was completed in 2010 resulting in reduced indications of water ingress during rainy weather. Re-caulking was done in 2014 and again in 2018 and 2021.

In 2015, shallow wells were installed beside each of the Medium/Intermediate Level Bunkers. These near field wells have been sampled annually. Results are discussed in Section D.2.1 under "Intermediate - Level Waste Bunkers Near Field Wells", and indicates limited migration of tritium beside the ILW bunkers, in particular ILW Bunker 3. There is no evidence that would lead CNL to conclude there is currently any significant contaminant migration pathway from the ILW Bunkers.

Compliance monitoring in the WMA and CCSF perimeter ditches have only found limited levels of contaminants, below drinking water guidelines, suggesting the waste storage structures and natural barriers of low permeability clay soil and upwards groundwater flow are performing as expected. In 2021, the weather was extremely dry and spring melt similarly limited to surface water in ditches was limited to a single set of measurements on one date in May.

As required by Section 8 of the Facility Authorization [59], most routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, however, two tests, both on transformers were not completed in 2021. Monthly housekeeping and fire prevention inspections were completed. An annual inspection of WL WMA concrete bunkers was conducted, in accordance with the Periodic Inspection Plan [16], and is further discussed in Section 6.

D.5 Wastes Generated

Solid radioactive waste was generated in the WMA as part of routine operations. This was mostly bagged waste generated from routine operations.

See Section 11.1 Waste Management Program for summaries of the volume of radioactive solid waste generated in the Waste Management Area in 2021.

Liquid radioactive waste was generated in the WMA as part of routine operations.

In 2021, approximately 564 L of water was removed from ILW Bunker 4, 863 L of water was removed from ILW Bunker 6 and approximately 114 L of water was removed from ILW Bunker 7. Low Level Waste Bunker 1 had 8 L from the west sump and 227 L from the east sump removed, and Low Level Waste Bunker 2 had 84 L from the west sump and 202 L from the removed from the east sump. The sumps are pumped out by Site and Nuclear Operations personnel using a WMA tanker with pump rig. The water collected in the tanker is later transferred to double walled totes. There totes are retained pending future processing.

The Building 923 sump tank and the Soil Storage Compound were both sampled as required and their water found not to be active in all cases. Water was directed to the WMA ditches. No other storage facilities and collection sumps at the WMA required pumping.

D.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the WMA as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection. There are no liquid effluents generated from this facility.

Appendix E Auxiliary Operation Facilities

E.1 Operations

The Auxiliary Operating Facilities are operated under the WL Site Licence [1].

There were no changes in the staffing for the operating staff responsible for the auxiliary facilities in 2021. There were no organizational changes.

No program changes were made for the auxiliary facilities in 2021. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

Research and Development Facilities Complex (Building 300)

Building 300 was the primary research laboratory for the site, housing a wide range of nuclear R&D programs. The building comprised an area of ~17,000 m^2 and was built in seven stages from 1964 to 1982. The building contained 68 laboratories as well as numerous offices. The south end high-bay area contained experimental activities that required large areas and significant headroom; RD-14M and RD-17 experimental loops were located in the South High Bay.

The research program in the Stage 6 (RD-14M) area was completed in 2018, and operational shutdown was started. The operational shutdown, decontamination, and decommissioning of the remainder of the building was completed in 2015. The demolition of Stages 4 and 7 was completed in 2016. The demolition of Stage 6 was completed in 2019.

During 2021, WL Site and Nuclear Operation's staff and user groups in Building 300 carried out routine operations which included:

- Non-radiological laundry activities.
- Respirator fit test / maintenance activities.
- Ongoing CNL Nuclear Engineering & Systems Analysis R&D activities.
- Cleanup activities associated with decommissioning.
- Routine building and system maintenance; and
- Surveillance to ensure compliance with the site licence.

Health and Safety Facilities (Buildings 402 and 305)

Building 402 has three floors comprising an area of ~2,162 m^2, housing WL dosimetry services and Environmental Management laboratories. The CNL facilities in Building 402 include a whole-body counting facility, TLD readers, environmental laboratories, and a Cs-137 Gamma Calibrator.

Environmental and Dosimetry services continued to operate in Building 402 until 2021 May.

In 2021, routine operations were carried out and supervised by Site and Nuclear Operations personnel. Operational cleanout of Buildings 402 and 305 continued and demolition of Building 402 started in 2021 November. Demolition of the building worked around the Whole Body Counter which was scheduled to move in early 2022.

E.2 Facility Changes

All facility changes were performed using the Engineering Change Control procedure [13]. The environmental and Dosimetry services were moved to Building 300. Building 402 was completely isolated and rendered cold and dark in 2021 July.

E.3 Equipment Performance, Planned Maintenance Testing and Inspections

All maintenance and non-routine work in these facilities that may affect the safe operation of facilities, systems, and laboratories, or that may present a hazard to the general public are conducted in accordance with CNL's work permit system.

All routine maintenance for systems required to be operational was carried out, and all equipment tests and inspections were completed up until Building 402 went cold and dark.

E.4 Wastes Generated

There were minimal amounts of radioactive and/or hazardous wastes generated in the facilities as part of routine operations.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the facilities in 2021.

Building 300 generated 0.0 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2021.

Building 402 generated 0.8 m^3 of compactable and no non-compactable low-level radioactive solid waste in 2021.

After processing at the Waste Handling Area, all waste was shipped to the WMA for storage.

See Table 86 for a summary of solid wastes for the last five years.

Table 86: Low-Level Solid Waste Generation – Buildings 300, 402,411

	2017	2018	2019	2020	2021
Building 300 (m^3)	14.7	4.5	0.4	0.3	0.0
Building 402 (m^3)	2.8	1	0.7	0.2	0.8
Building 411 (m^3)	355.1	7.6**	0.2**	0.0	0.0

* Volume prior to compaction, all compactable waste is consolidated at the Waste Handling Area.

** Legacy waste processed in 2018 for Building 411 that was decommissioned in 2017.

There was no liquid radioactive and/or hazardous waste generated in 2021 in this facility.

RESEARCH AND DEVELOPMENT (BUILDING 300) LOW-LEVEL LIQUID WASTE SYSTEM

Radioactive LLLW flows from the SF and Building 300 to the low-level liquid waste collection tanks, in Building 300 Room B-33. An accurate determination of the individual SF or Building 300 contribution cannot be made as both locations flow into these common tanks. The

sources of water from Building 300 are limited and the major contributor is the radiological decontamination service facilities in the IFTF.

During 2021, 78.3 m^3 of low-level liquid was processed through the Building 300 LLLWTS. Table 87 shows the historical volumes of LLLW processed through the Building 300 LLLWTS and also the total volume of Building 300 and Building 100 LLLW processed.

Table 87 - Historical Records of Low-Level Liquid Waste Processed

	2017	2018	2019	2020	2021
Total Combined Low-Level Waste Liquid Processed (m^3)[a]	172.3[b]	131.5[c]	189.3[c]	107	88.2
Low-Level Waste Liquid Processed in Building 300 (m^3)[d]	46	123	186.5	99	78.3

a All low-level liquid waste processed in Active Liquid Waste Treatment Centre for 2014-2016. This total includes laundry and decontamination and ALWTC facilities for 2014 and 2015. For 2016 the total is Building 100 and Building 300 and ALWTC. After 2017 all low-level liquid waste is processed in Building 100 and Building 300.

b This includes 126 m^3 of low-level liquid waste that was processed through the Active Liquid Waste Treatment Centre in Building 200.

c All Low-Level Liquid Waste processed through the low-level liquid waste treatment systems in Building 100 and Building 300.

d Building 300 LLLWTS came online in 2017 July.

The total activities given below are the combination of the Shielded Facilities, Building 300, and Building 100 active liquid effluents produced.

As determined by total-beta analysis, the beta radioactivity content in the effluent releases to the Outfall from the holding tanks at the Building 300 and Building 100 LLLWTS during 2021 was 0.01 GBq, compared with 0.01 GBq released during 2020. The maximum release in a month during the year was 0.001 GBq which is a small fraction of the administrative level of 0.48 GBq per month. This level conservatively assumes that all of the activity is due to Cs-137, which is the most restrictive isotope of those present, or potentially present.

As determined by total-alpha analysis, the alpha radioactivity content in effluent releases to the outfall was 0.001 GBq for 2021 compared with 0.001 GBq released during 2020. The maximum release in a month during the year was 1.4E-04 GBq which is a small fraction of the administrative level of 0.56 GBq per month. This level conservatively assumed that all the activity is due to Am-241 which is the most restrictive isotope of those expected to be present in this waste stream.

Table 88 provides a summary of the total activity released for both the Building 100 and Building 300 LLLWTS. Annual Release Limit values for radionuclides in liquid effluents for WL are based on the DRL [30]. These values were revised in 2016. An error was discovered in Table 88, note “d” in previous years’ reports. The alpha DRL was listed as 1.11×10^1 GBq/month, and should have read 1.11 GBq/month. The annual release limits for alpha were calculated using the correct value for DRL. The % of monthly DRL for alpha was calculated using the wrong DRL value. This made the % of monthly DRL for alpha a factor of 10 lower than the true value.

Observed levels of alpha in WL's LLLW active releases are sufficiently low that even with this correction, levels are well below the DRL. This correction was made for the 2021 values.

Table 88 – Building 100 and Building 300 LLLWTS Radioactive Releases

Radionuclide	Total 2021 Effluent (GBq)	Annual Release Limit[a] (GBq/a)	Total 2021 Effluent as a % of Annual Release Limit	Peak Release	
				Max. Monthly Release (GBq)	% of[b] Monthly DRL
Total (Total-Beta Analysis) [c]	0.01	–	–	0.001	–
Sr-90	1.02×10^{-3}	1.56×10^{2}	0.76×10^{-3}	2.18×10^{-4}	1.87×10^{-3}
Cs-137	3.74×10^{-3}	1.39×10^{2}	2.69×10^{-3}	5.95×10^{-4}	5.12×10^{-3}
Total Alpha (As Pu-239 Equivalent) [d]	0.86×10^{-3}	1.33×10^{1}	6.46×10^{-3}	1.35 x 10-4	1.22×10^{-2}
Historical Data Total Effluent (GBq)					
	2017[e]	2018[e]	2019[e]	2020[e]	2021
Total (Total-Beta Analysis) [c]	0.04	0.02	0.01	0.01	0.01

a The annual release limit is calculated by multiplying the DRL by 12.

b DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The beta particulate emitters are considered to be Cs-137, the most restrictive isotope of those identified or potentially present. The DRL is 1.16×10^{1} GBq/month [30].

c A total beta analysis results in a conservative (higher) estimate of the total amount of activity, which is more accurately determined by measuring the individual radionuclides by radiochemical or gamma spectrometry methods.

d DRLs and most restrictive isotope for the LLLW systems was changed in 2016. The alpha particulate emitters are considered to be Pu-239, the most restrictive isotope of those identified or potentially present. The DRL is 1.11 GBq/month [30].

e Year's 2014 to 2016 effluent was all processed in ALWTC. 2017 effluent was processed in ALWTC and Building 300 LLWTS. From 2018 on, all effluent was processed in Buildings 300 and 100 LLWTS.

E.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from these facilities. Radioactive wastewater generated in Building 300 was pumped to the LLLWTS in Building 300 Room B-33.

Any liquid and/or gaseous releases from the facilities are provided and discussed in Section 9, Environmental Protection.

Appendix F WR-1 Facility

F.1 Operations

Activities in Whiteshell Reactor 1 (WR-1) were conducted under the WL site licence [1] from the CNSC, in accordance with the requirements of *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64]. The status of the WR-1 facility in its shut down, de-fuelled, and partially decommissioned state is described in *The WR-1 Reactor Phase 1 Decommissioning Project Interim End-State Report - Facility Description* [65]. The facility is monitored and maintained as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64].

Routine operations in the WR-1 facility, as defined by *The Monitoring and Surveillance Plan for the WR-1 Deferment Period* [64], were carried out by the five (four and one trainee) Site and Nuclear Operations Technologists assigned to Building 100. Throughout the course of 2021, the number of Building 100 staff dropped to three (two and one trainee) with plans to hire additional staff. Building 100 continued to maintain the minimum staffing requirements outlined in the Facility Authorization [64]. Staffing was maintained at levels to provide the needed operational and safety support.

In 2018, approximately 20 m^3 of low concentration (3.4 E06 Bq/L) tritiated water was found in the thermoshield and bioshield cooling systems. This water is still in the systems, awaiting a decision on how to remove this water as the systems were not designed to be drained. Investigation is also ongoing to determine what the impact would be if this water is left in situ as part of the proposed in situ disposal of WR-1.

No program changes were made for WR-1 in 2021. Procedures are updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

F.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [13].

F.3 Equipment Performance, Planned Maintenance Testing and Inspections

During 2021, the operations status of WR-1 remained unchanged. There were no changes to the reactor's equipment.

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence. All Monthly housekeeping and fire prevention inspections were completed.

F.4 Wastes Generated

Solid Radioactive and/or Hazardous Wastes

See Section 11.1 Waste Management Program for summaries of the volume of any volume of radioactive solid and/or liquid waste generated in WR-1 in 2021.

Solid radioactive waste was generated in the facility as part of routine operations. This consisted of mainly operational supplies such as Tyvek suits.

During 2021, 1.5 m^3 of low-level radioactive compactable waste and no non-compactible waste were generated from Building 100/WR-1 operations and sent to the Waste Handling Area for compaction.

There were no new hazardous solid wastes generated from Building 100/WR 1.

Liquid Radioactive and/or Hazardous Wastes

Liquid radioactive and no hazardous waste was generated in the facility as part of routine operations.

During 2021, 9.9 m^3 of low-level radioactive liquid waste was generated from Building 100/ WR-1 operations, the majority from the WR-1 sumps. Appendix E has more information on the liquid waste processed. There were no hazardous liquid wastes generated from this facility.

F.5 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the facility as part of routine operations.

Any liquid and/or gaseous releases from the facility are provided and discussed in Section 9, Environmental Protection.

Appendix G Non-Nuclear Facilities

G.1 Operations

The WL non-nuclear facilities status and changes for 2021 are as noted in Table 89.

Table 89: Operating Summary of Non-Nuclear Facilities

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
303	Containment Test Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed
304	Waste Clearance Facility	Removed in 2020	None	Removed from use	Facilities	Building removed, pad retained, End-State Report to be completed
306	Waste Clearance Facility	Removed in 2016	None	None	Buildings & Lands D&D Project Personnel	Building removed, pad retained, End-State Report to be completed
308	Large Scale Vented Combustion Test Facility	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed
309	Large Scale Vented Combustion Test Facility -Local Services	Removed in 2019	None	None	Facilities	Decommissioned, End-State Report to be completed

911	Powerhouse	Operational	None	None	Powerhouse Operators and Maintenance	No change
913	Main Substation (Owned by MB Hydro)	Operational	None	None	Manitoba Hy dro	No change
914	Main Power Distribution	Operational	None	None	Powerhouse Operators and Maintenance	No change
916	Communications System	Operational	None	None	Security and Maintenance	No change
917	Supervisory Control and Alarm	Operational	None	None	Security and Maintenance	No change

Building Number	Building Function	Operating Status	Reportable Events	Operating Status Changes	Authorized Personnel [a]	Comments
918	Clarified Water System	Shut Down Mid-1980s	None	None	Powerhouse Operators and Maintenance	No change
921	Access Tunnel	Operational	None	None	All Site/Visitors	No change

[a] Security personnel perform regular patrols of all site buildings

There were no policy, program or procedural changes for the non-nuclear facilities in 2021. There were no changes in organization in 2021.

In 2021, the Facility continued to maintain the minimum staffing requirements to provide the needed operational and safety support.

G.2 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [13].

G.3 Equipment Performance, Planned Maintenance Testing and Inspections

Systems and equipment for all the non-nuclear facilities, including any safety-related systems, performed as designed and required during 2021 with the exception of Compressed Air Systems where one of the three compressors was not operational (awaiting parts). In addition, issues with some gas detection systems were part of the missed preventive maintenance activities that was reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence.

Routine maintenance was carried out, and equipment tests and inspection were completed in 2021 with no significant results.

G.4 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the non-nuclear facilities as part of routine operations.

G.5 Effluents Released

There were no radioactive and/or hazardous effluents (gaseous or liquid) released into the environment from the facilities as part of routine operations.

There was 1.15E+09 L of effluent released from buildings Building 422 (Outfall Monitoring Station) and 0 L of effluent released from Building 907 (Sewage Lift Station and Lagoons) as there was no lagoon release in 2021.

Landfill Dugout Water Monitoring

The WL landfill is surrounded by six dugouts where surface water collects. These dugouts are sampled as part of the ongoing operational control monitoring for the facility. In 2021, the precipitation was low over the year (395 mm) and the dugouts had low water levels during the summer sampling period. The location of the dugouts are shown in Figure 14. Dugout 22 is used as the Control and is about 300 m away from the landfill to the north-northeast, and would not be affected by facility operations.

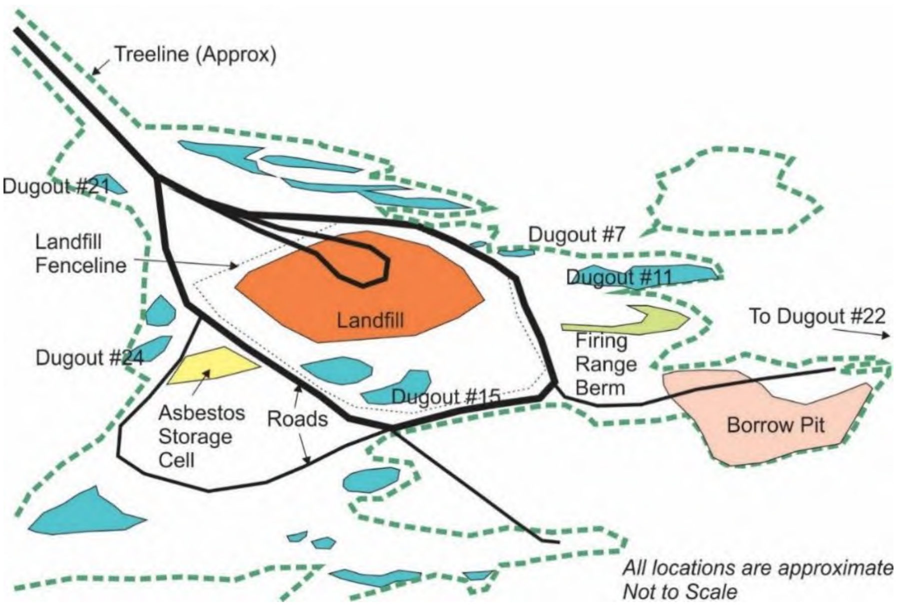

Figure 14: WL Landfill Area Showing Approximate Locations of Monitored Dugouts

The results from the sample analysis for alpha and beta from these dugouts are provided in Table 90 and Table 91 respectively. All alpha results for 2021 were at the detection limits, and are below the drinking water screening level of 0.50 Bq/L. All beta results for 2021 were near the detection limits, and are below the drinking water screening level of 1.0 Bq/L. Both alpha and beta results for 2021 are consistent with previous results obtained from 2016 to 2020.

Table 90: Gross Alpha Results from the Landfill Dugouts

Sample	Gross Alpha (Bq/L)					
Location	2016	2017	2018	2019	2020	2021
Dugout #7	< 0.14	< 0.17	< 0.17	0.07	<0.05	<0.05
Dugout #11	< 0.10	< 0.14	< 0.14	< 0.05	<0.05	0.05

Dugout #24	0.26	0.08	< 0.08	0.25	0.06	0.10

Low levels of tritium (9 Bq/L) were detected in one of the landfill wells (water table) starting in 2011. Its appearance in the groundwater resulted in initiation of the surface (dugout) water measurement of tritium. Tritium has been detected in landfill Dugout 15 for the past eight years, and a low value was noted in Dugout 24 in 2011, 2012, 2016, and although a higher amount was noted in 2018 (76 Bq/L), the value returned to background in 2019 and remained there through 2021. The higher tritium level in Dugout 15 was 93 Bq/L, approximately one-half of that measured in 2019 (212 Bq/L). All results are well below drinking water limits of 7,000 Bq/L. The other dugouts do not appear to contain tritium, as levels comparable to blank samples analyzed from 2013 to 2021 that contain < 5 Bq/L of tritium were recorded. Tritium results from the landfill dugouts are shown in Table 92.

Table 92: Results from the Landfill Dugouts

Sample	Tritium (Bq/L)					
Location	2016	2017	2018	2019	2020	2021
Dugout #7	< 4	< 4	< 4	< 3	< 4	< 5
Dugout #11	< 4	< 4	< 4	< 4	18	< 5
Dugout #15	98	82	105	212	54	93
Dugout #21	< 4	NA	< 4	Dry	< 3	< 5
Dugout #22	< 4	< 4	< 4	< 4	< 3	< 5
Dugout #24	5.5	< 4	76	< 4	< 4	< 5

NA sample not available

When initially detected in the dugouts, it was assumed that it was possible that tritium emissions from the WR-1 Building 100 deposited in the ponds surrounding the landfill, and was subsequently drawn in to the water table. After consideration, it was determined that the most likely source of tritium is the landfill. The presence of above background tritium in only a few dugouts cannot be explained by air borne deposition. The highest tritium activities are found in the dugouts and wells in closest proximity to the landfill. Due to its 10 m height, the landfill has

a higher hydraulic head than the local terrain, including the asbestos storage cell, and thus will be more likely to contribute leached contaminants to the shallow ground water system. Due to local groundwater flow directions (toward the south and southwest), Dugouts 15 and 24 are more likely to receive contaminants from the migration of water from the landfill. As the landfill had been in operation for over 50 years, the potential for a historic error in placement is greater for the landfill than the adjacent asbestos storage cell.

The water testing conducted in 2018 included Sr-90 and Tc-99, two potentially mobile radionuclides. In 2018, near detection levels of Sr-90 were noted in Dugout 21 and near detection limit levels of Tc-99 were noted in Dugouts 21 and 24. In 2019, only Sr-90 was tested, and was found to be at the detection limit. In 2020, both Sr-90 and Tc-99 were again measured. Sr-90 was at the detection limit and Tc-99 was not detected. In 2021 (Table 93), no Sr-90 analysis was conducted as per the instructions provided to lab to only analyze if gross Beta exceeded 5 Bq/L. Tc-99 was again below the detection limit. The water from these dugouts and wells is not used for human consumption. All results were below drinking water limits of 5 Bq/L for Sr-90 and 200 Bq/L for Tc-99.

Table 93: Sr-90 and Tc-99 Results from the landfill Dugouts in 2021

Sample Location	(Bq/L)	
	Sr-90	Tc-99
Dugout #7	NA	ND
Dugout #11	NA	ND
Dugout #15	NA	ND
Dugout #21	NA	ND
Dugout #22	NA	ND
Dugout #24	NA	ND

NA – No Analysis Gross Beta below analysis trigger limit.

ND – Non Detect

The water from the dugouts was also tested for a suite of non-radiological parameters including total metals, mercury, nitrate + nitrite, sulphate, chloride, sodium, potassium, calcium, magnesium, sulphur, total ammonia (N), phosphorus, phenols and volatile organics (including benzene, toluene, ethylbenzene and xylene). Elevated levels of boron were detected in Dugout #15, a continuation of results from 2017 onwards (Table 94). The value in 2021 remained under the Drinking Water Guideline for Boron (5,000 µg/L). Dugout #24 showed 431 µg/L in 2021, all other dugouts showed values below detection limits.

Table 94: Boron Results from the Landfill Dugout #15

Sample Location	(µg/L)				
	2017	2018	2019	2020	2021
Dugout #15	1630	5460	8460	2040	3760

Molybdenum remained at detection limits from 2020 through 2021. In 2021, Manganese remained higher than drinking water guidelines of 50 µg/L in Dugout #15 (509 µg/L). No other parameters were detected at concentrations of concern.

Groundwater results will be discussed in the annual Environmental Monitoring report [29]. Sediment sampling of one of the dugouts was conducted as part of the Environmental Assessment Follow-up Program and will be reported in [28].

Landfill Dugout Sediment Monitoring

Sediment sampling of the dugouts was conducted in 2017 as part of the Environmental Assessment Follow-up Program. The analysis of the sediment included a full suite of metals, mercury, lead, PCBs and for radioactivity, including Sr-90. There were elevated levels of molybdenum in the surface sediment of one dugout (Dugout 24) and no other contaminants of potential concern noted. Molybdenum can be found naturally in the environment (minerals containing iron, bismuth, or copper) as well as being a component of man-made items such as filaments, X-ray tubes, screens, grids for radios, spark plugs, contacts, induction heating elements, and/or part of a waste stream from man-made processes (burning of fossil fuels). The source of the molybdenum is being investigated as part of the assessment of the Landfill prior to closure. Monitoring of the sediments in the dugouts around the landfill is planned to continue every 5 years (from 2017) as well as annual monitoring of the water, as such no sediment sampling was conducted in 2021.

Further investigation will be conducted during the eventual closure of the landfill and will also be reported in the Environmental Assessment Follow-up Program [28].

Landfill Radiological Monitoring

Annual radiological monitoring of the landfill surface is performed as a confirmatory measure. The results show readings consistent with background levels at the landfill fence line. Table 95 provides a five year listing of survey results at the top of the landfill. For some years monitoring was performed at the base of the pile, and more recently monitoring was performed around the perimeter of the fenced area of the landfill.

Table 95: Landfill Radiological Monitoring

Sample Location	(µR/h)				
	2017	2018	2019	2020	2021
Landfill Top Surface	10-16	8 - 10	6 -12	6 - 12[2]	10

EXECUTIVE SUMMARY

This annual compliance monitoring report for the 2021 calendar year has been prepared as per licence condition 3.2 of the Whiteshell Laboratories Licence NRTEDL-W5-8.00/2024 and CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Facilities and Uranium Mines and Mills* as a summary report of annual compliance monitoring and operational performance.

Canadian Nuclear Laboratories (CNL) would like to acknowledge Canada's Indigenous Peoples and their traditional territories upon which CNL carries out its work. CNL also wishes to confirm its commitment to being an active participant in Canada's journey towards healing and reconciliation.

This annual compliance report provides CNL 2021 performance data for WL and is organized by 14 Safety and Control Areas (SCAs)[1], as well as a report on each of the WL nuclear and non-nuclear facilities.

The following provides overall performance highlights for 2021 activities:

- All licensed activities continued to be carried out safely and securely.
- No member of the public received a radiation dose that exceeded any regulatory limit.
- No worker at WL received a dose in excess of any of the respective radiation dose limits for radiation workers, as defined in the Radiation Protection Regulations.
- All releases of radioactive material in WL effluents during 2021 were below their respective Derived Release Limits (DRL).
- Demolition of Building 200, the former Active Liquid Waste Treatment Centre (ALWTC), is complete, and Building 402/305, the former Health and Safety Facilities, is partly demolished.
- The WL site maintained safe and compliant performance under COVID-19 Pandemic conditions and protocols.

Below is a summary of the annual compliance report for calendar year 2021.

- **SCA - Management System**: WL has continued its focus on implementation of the corporate management system, as well as the WL Quality Assurance program for decommissioning. After having no Canadian Nuclear Safety Commission (CNSC) inspections in 2020, four inspections were carried out in 2021.
- **SCA - Human Performance Management**: A significant effort towards training individuals in human performance related areas continued as a result of the fieldwork pause in 2020 November. Another outcome of the fieldwork pause was the development and delivery of the initial Annual General Employee Training which goes

[1] The CNSC evaluates how well licensees meet regulatory requirements and CNSC expectations for the performance of programs in 14 safety and control areas.

over site and project updates, as well as review of policies and procedures. This will be updated and delivered annually to all employees.

- **SCA - Operating Performance**: WL decommissions and operates its facilities according to prescribed programs and procedures, and monitors safety performance in the operational area through the concept of "events". The total number of internal event reports raised continues to show a strong reporting culture. There were six CNSC reportable events in 2021.
- **SCA - Safety Analysis**: Effective Safety Analysis Reports and Facility Authorizations continue to be in place for WL's nuclear facilities, helping meet health, safety, security, environmental and regulatory requirements. Safety analyses continue to be developed for the standpipe/bunker remediation, Intermediate-Level Liquid Waste Processing Centre and Cask Loading facilities being constructed in the Waste Management Area.
- **SCA - Physical Design**: The Certificate of Authorization was renewed with Engineers Geoscientists Manitoba, authorizing CNL to engage in the practice of professional engineering in Manitoba. The new revised WL Pressure Boundary Quality Assurance Plan was accepted by Inspection and Technical Services Manitoba and a new Certificate of Authorization was issued.
- **SCA - Fitness for Service**: The Periodic Inspection Plan (PIP), previously developed to confirm the ongoing fitness-for-service of the concrete storage facilities at the Waste Management Area (WMA), continued implementation with no significant issues identified. Regular preventative or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service. Missed maintenance of safety-related systems was reported to CNSC, and a corrective action plan was developed that will fix the issues and prevent recurrence.
- **SCA - Radiation Protection**: No worker received a whole-body dose (including committed) in excess of any of the respective dose limits for radiation workers as defined in the Radiation Protection Regulations, and average individual doses remain a small fraction of these limits. Maximum dose to a person working at WL was 0.6 mSv and collective doses remained below 50 person-mSv (19.0 person-mSv) for 2021. Members of the public received no measureable radiation doses.
- **SCA - Conventional Health and Safety**: Implementation of CNL's Occupational Safety and Health program at WL continues to drive improvements in safety and safety culture. Safety advisories are regularly issued to staff about imminent issues that could impact their safety. There were no lost-time injuries at WL in 2021.
- **SCA - Environmental Protection**: The results of the radiological and non-radiological effluent monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment. Radiological emissions were 0.00019% of the Derived Release Limit (DRL) for air emissions and 0.47% of the DRL for liquids. The monitoring program confirms that the WL site is operating in a manner that protects workers, the

public, and the environment. WL maintained their ISO-14001 registration, and are compliant to a number of CSA environmental standards.

- **SCA - Emergency Management and Fire Protection**: The Emergency Management program at WL continued to be focussed on supporting COVID-19 planning and coordination efforts, providing procedures and guidance to enable work to continue safely in this dynamic situation. A third party Fire Protection Audit was conducted, and resolution to findings will be tracked through the corrective action program.
- **SCA - Waste Management**: WL continued to reuse or recycle as much material as was practicable. Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects, including disposition of 924 m^3 of radioactive waste to Chalk River Laboratories (CRL), and 271 m^3 (37,145 kg) of recycled waste shipped off-site. The WL Site Overview Detailed Decommissioning Plan was revised and accepted by CNSC.
- **SCA – Security**: The Security Program at WL supports the CNL Corporate Security mandate and addresses the regulatory requirements for high-security sites. Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers as required by the CNSC.
- **SCA - Safeguards**: There were no issues identified with International Atomic Energy Agency (IAEA) Safeguards inspections conducted at WL. The IAEA also provided human surveillance and IAEA seal verification, removal and reapplication during canister inspection activities.
- **SCA - Packaging and Transport**: There were 68 radioactive transport packages making up 53 loads that were safely and successfully sent off-site, including approximately 921 m^3 of low-level waste and 3 m^3 of intermediate-level waste shipped to CRL.
- **Other matters of regulatory interest**: Two virtual meetings of the WL Public Liaison Committee took place. Numerous public information sessions and Indigenous engagements (mainly virtual) were held on the Whiteshell Reactor 1 (WR-1) in-situ decommissioning and overall activities of the WL Closure Project, including four Webinars.
- **Facilities** (operating nuclear facilities, permanently shut down facilities, facilities being decommissioned and the non-nuclear facilities): All the licensed activities in these facilities continue to be carried out safely and securely with acceptable radiation doses to personnel and releases to the environment. The following notable facility-specific activities took place: the Active Liquid Waste Treatment Centre, Building 200, completed demolition, and significant progress was made in demolition of the Health and Safety Facilities, Building 402/305.

CNL is committed to achieve high standards of operational safety and security. The information and data presented in this report support the conclusion that safe and secure performance was achieved at the Whiteshell Laboratories site, while enhancements were implemented to further improve results.

ACKNOWLEDGEMENT

The “Author” of this document would like to thank the many Whiteshell Laboratories authors and reviewers from the various Functional Support Areas and Facilities for their production of the individual sections of the report.

CNL’s Continued COVID Pandemic Response

For a detailed description of CNL’s robust mitigation initiatives and controls to protect its employees, contractors, visitors and Site operations from the COVID pandemic, see the Executive Summary in the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories*.

TABLES

INTRODUCTION

Whiteshell Laboratories (WL) was established by Atomic Energy of Canada Limited (AECL) in the early 1960s to carry out nuclear research and development activities. The site is a Class 1B nuclear facility which encompasses an area of 4,375 hectares. The WL site is located near Pinawa, Manitoba; approximately 100 kilometres northeast of Winnipeg, on the eastern bank of the Winnipeg River. AECL made a business decision in 1997 to discontinue most of the research programs and operations at WL. Subsequently, AECL received government concurrence in 1998 to proceed with actions to achieve closure of WL. This work transitioned to Canadian Nuclear Laboratories (CNL) who are carrying out the work to achieve site closure on behalf of the site owner, AECL.

Activities are now underway to complete the orderly decommissioning of the WL site, following the general plan laid out in the Comprehensive Study Report supporting the approval of the Environmental Assessment of the WL Decommissioning Project. The exception to this is the change in strategy for Whiteshell Reactor (WR) -1 (see the Decommissioning Strategies Section below).

Name:	Whiteshell Laboratories
Location:	*1 Ara Mooradian Way* *Pinawa, Manitoba* *R0E 1L0*

Licence Information and Reporting Period

This annual compliance monitoring report is produced to comply with licence condition 3.2 of the Whiteshell Laboratories Licence NRTEDL-W5-8.00/2024 [1], in accordance with the compliance verification criteria Compliance Monitoring: Annual Report of the *Licence Conditions Handbook (LCH) for Whiteshell Laboratories,* herein referred to as “Licence Conditions Handbook” [2], and section 3 Annual Compliance Monitoring Report of CNSC REGDOC-3.1.2, *Reporting Requirements, Volume I: Non-Power Reactor Class I Nuclear Facilities and Uranium Mines and Mills* [3]. Information included in this report is for the period of 2021 January 01 to December 31.

This report provides site-specific information to supplement information in the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4], which provides corporate updates to 14 Safety and Control Areas as they are applied across all of CNL.

The intent of this report is to provide sufficient detail to demonstrate how Whiteshell Laboratories programs are meeting the regulatory requirements as specified in the licence [1] and the LCH for Whiteshell Laboratories [2].

Facilities Included in this Report

Appendices Appendix A through G of the report provide information that is pertinent to the Nuclear and Non-Nuclear Facilities (including operating and permanently shut down facilities, and facilities being decommissioned).

The Nuclear Facilities included in this report are: Concrete Canister Storage Facility, Active Liquid Waste Treatment Center, Shielded Facilities, Waste Management Area, Research and Development Facilities Complex (Building 300), Health and Safety Facilities (Building 402 and Building 305), and WR-1 Reactor.

Summary of Licensed Activities

There are no new licenced activities.

Decommissioning Strategies

As discussed since 2015, work is underway to complete decommissioning of the entire WL site (current schedule is to be complete in 2027). This includes leaving in-situ the selected WMA trenches as per the Comprehensive Study Report under institutional control, and transporting active waste off-site for disposal or storage. A significant departure from the end-states defined in the Comprehensive Study Report is in situ decommissioning (also referred to as in situ disposal) of the WR-1 reactor. Work continues for an environmental assessment and regulatory approvals required for this proposed change. The Environmental Impact Statement supporting this is in progress.

Financial Guarantees

CNSC was previously sent a letter from the Honorable G. Rickford [5], advising that as an agent of Her Majesty in Right of Canada, AECL’s liabilities associated with the decommissioning of WL are ultimately liabilities of Her Majesty in Right of Canada (note: AECL retains ownership of the lands, assets and liabilities associated with CNL's licences). This financial guarantee remains valid and in effect, as per the communication issued on 2020 August 25 [6].

1 Management System

1.1 Management System Program

Whiteshell Laboratories adheres to the Corporate Management System. See Section 1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL Quality Assurance Plan [7] supports the CNL Management System Manual [8] and summarizes the processes and practices applicable to WL licensed activities, while still retaining compliance to CSA N286-12 [9] and N286.6-98 [10].

1.2 Audits, Inspections and Self-Assessments

As per the requirements of the Management System [8], both Safety Control Areas and Facilities conduct various audits, inspections, and self-assessments to ensure that the management system is functioning according to expectations and that any policy, programmatic, or procedural deficiencies are identified and appropriate actions taken to resolve them.

All actions resulting from audits, inspections, reviews and self-assessments are being managed and tracked through CNL's Corrective Action Program.

1.2.1 Audits

See Section 1.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* [4] for a list of all CNL-wide Audits for the reporting year 2021.

1.2.1.1 External Audits

The external audits conducted at Whiteshell Laboratories are summarized in the table below.

Table 1: External Audits

Title	Type of Audit	No. of Non-Compliances Raised	No. of Non-Compliances Completed
SAI Global Recertification Audit of the WL Environmental Management System	14000:2015	0	Not applicable
PLC Fire Safety Solutions Audit of the Fire Protection Program	CSA N393	31	0

For the Fire Protection Program audit, the non-compliances related mostly to missing documentation for inspection, testing and maintenance activities. The audit report was received late in 2021, and a corrective action plan is to be submitted to CNSC staff in early 2022.

1.2.1.2 Internal Quality Audits

There were no internal audits completed by the Quality Audits and Processes branch specific to Whiteshell Laboratories in 2021.

1.2.2 Inspections

CNSC Inspections

The following CNSC Inspections were conducted at Whiteshell Laboratories.

Table 2: CNSC Inspections for 2021

Inspection No.	Area Inspected	No. of NNC[a]s	No. of NNC[a]s Completed
CNL-WL-2021-01	Human Performance Management	2	2
CNL-WL-2021-02	Management System	6	6
CNL-WL-2021-03	General	3	0
CNL-WL-NSD-T2-2021-001	Security	7	0

a NNC – Notice of Non-Compliance

Inspections by Other Regulatory Bodies

A Physical Inventory Verification (PIV) inspection was carried out by the IAEA on 2021 May 26. This inspection was a sampling of accessible items containing Special Fissionable Material. A Design Information Verification inspection was carried out by the IAEA on 2021 May 25-27. This inspection verified the information provided in the Design Information Questionnaire.

Transport Canada conducted a virtual Transport of Dangerous Goods (TDG) inspection at WL in 2021 and did not find any non-conformances.

1.2.3 Self-Assessments

In 2021, there were 18 self-assessments conducted at Whiteshell Laboratories covering various aspects of the management system, including both safety and control areas, and various facilities.

Table 3: List of Self-Assessment Conducted at Whiteshell Laboratories in 2021

Title	Facility/Department
Effectiveness of Industrial Hygiene Instrumentation	WL Occupational Safety and Health (OSH)
Workload on the SMO	WL Environmental Management (EM)
WL Integrated Work Control	WL Site and Nuclear Operations
TDG Requirements	WL Waste Management

Movement of Radioactive and Non-Radioactive Materials	WL Waste Management
Registration and control of radiation sources	WL Radiation Protection (RP)
WL RP Program Compliance Review	WL RP
WL-510400-OI-366-01 - WL Lock Out Tag Out (LOTO)	WL Site and Nuclear Operations
900-510400-MCP-032 - Work Permit	WL Site and Nuclear Operations
WL EM QA Plan WL-514200-QAP-001 to 17025, Document Control	WL EM
Compliance to ISO/IEC 17025:2017 Document Control	WL EM
Compliance to ISO/IEC 17025:2017 Risk Assessment Process	WL EM
Compliance to ISO/IEC 17025:2017 Improvement	WL EM
WL Radiation Dose Reporting to NEW Workers for 2020 Doses	WL RP
Manager Dose Control Points and RP Training Designation Annual Reviews for 2021	WL RP
REGDOC 2.12.1, High Security Sites: Nuclear Response Force Section 7	WL Emergency Services
REGDOC 2.10.1 Section 2.2.1, Emergency Response Organization and Staffing	WL ES
Impairment Notification and Compensatory Measures	WL ES

1.3 Management Reviews

The Quality Assurance Program/Management System Review for 2018/19 and 2019/20 was completed. The review identified 6 actions, all of which are completed.

2 Human Performance Management

2.1 Human Performance Program

Whiteshell Laboratories adheres to the Corporate Human Performance (HU) Program. See Section 2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

2.1.1 Program Improvements and Accomplishments

The effectiveness of the HU program at WL has been enhanced through the following improvements:

- Following the 10 week fieldwork pause in 2020 November to address an adverse trend in human performance, WL gradually increased fieldwork throughout 2021 February. WL executed an extensive Corrective Action Plan, which included comprehensive reviews and updates to procedures and a significant investment in employee training. Improvements implemented included increased supervisor presence in the field, in depth review of proper use of tools and equipment, procedure awareness and compliance, sharing of lessons learned, and better pre- and post-job briefs. WL also performed several self-assessments through the integrated assessment plan and implemented new work control metrics.
- In 2021 May, Performance Assurance reintroduced the two-level rigorous review of ImpAct records by re-instating the Management Screening Team (MST) weekly meeting. MST's mandate is to provide management level review and oversight of the ImpAct record and ensure it has sufficient and accurate information to let the Management Review Meeting (MRM) team conduct their review. The MST assesses and recommends the significance level, cause determination effort, cause statement and the Responsible Manager. MRM provides Director level (and above) oversight for the ImpAct Corrective Action Program. The MRM team confirms, or modifies as appropriate, decisions made by the MST.
- In 2021 August, a three day TapRooT® Essentials Course was delivered to nine (9) WL Employees. The virtual sessions were taught by an external root cause analysis and investigation expert who guided immersive learning activities using interactive presentation technology, group exercises, and two-way interaction. TapRooT® is a powerful tool in conducting investigations and has already been used to augment CNL's current cause analysis techniques.
- WL enlisted the support of the recently formed CNL Strike Team, comprised of experts from across CNL, to conduct a causal analysis for a discovered adverse condition regarding the WL Preventative Maintenance program (see ERM-21-3009 in Table 5). Unlike the usual Apparent Cause Analysis or Root Cause Analysis processes, the Strike Team's causal analysis used a Facts Issues Causes Actions table. Doing the investigation in this manner allowed the team to develop the causal analysis and corrective actions in

a concise and timely manner. This tool will be beneficial for future investigations that may need to be conducted.

2.2 Training programs

Whiteshell Laboratories adheres to the Corporate Training and Development Functional Support Area. See Section 2 of the Annual Compliance *Monitoring Report for Canadian Nuclear Laboratories* for details [4].

2.2.1 Program Improvements and Accomplishments

The effectiveness of WL Training Program has been enhanced through the following improvements:

- Revisions to the content for the New Employee/Contractor Orientation to reflect current policies and procedures for working on site.
- WL introduced the Integrated Work Control Core 5 Elements course, which provides contractors with training that combines the 5 core courses delivered during the safety stand down: Work Permit Authorization, Job Safety Analysis, Pre-job Brief, Stop/Pause Work and Integrated Work Controls.
- Development of the initial Annual General Employee Training to review site and project updates, as well as policies and procedures. This will be updated and delivered annually to all employees.
- Updates and improvements to the content and media for the Radiation Group 4 Training delivered to all employees and contractors coming to site.
- Major revisions to the Delivering Practical Training course. Content now includes adult learning and learning principles content. This course is required for any employee who conducts on-the-job training and functional checkouts for skills assessments.
- Redevelopment of the Waste Management & Fundamentals courses to include updates to policies and procedures in our Waste Management Program.
- Revisions to the content and materials for Vehicle Spotter Training. Delivery to all staff who are required to have spotter training.
- Development of the ‘Training Matrix tool’ which allows managers and supervisors to quickly look up the training status of their teams.

2.2.2 Systematic Approach to Training

CNL maintains a list of positions and roles requiring Systematic Approach to Training (SAT) training programs in compliance with REGDOC-2.2.2, Personnel Training [11].

Training and Development evaluated the training programs for listed positions and roles at WL against the main elements of SAT. The results led to initial individual action plans which are being managed and further evaluated by the Curriculum Review Committees. Additional corrective actions and program improvements will be identified and managed by the

Curriculum Review Committees going forward. Since the initial analysis of the listed positions, dedicated Training and Development personnel have been hired and assigned to support WL in the completion of the action items identified. Curriculum Review Committees for the WL WMA and Shielded Facilities have been established and progress on the actions is underway.

2.2.3 Required Training

Some WL listed positions and roles require additional training documentation development to achieve full SAT-compliance. Current workers are qualified based on existing training programs combined with their years of experience in the role. Existing training programs include classroom training, practical training, computer-based training, and mentor style training. These experienced workers will assist as Subject Matter Experts (SMEs), in the development of training documentation that is required to achieve full SAT-compliance.

All Whiteshell Laboratories personnel, both employees and contractors, are adequately trained (and refreshed) to ensure safe operation of their facilities and to conduct work under the licence [1]. Section 2 of the Annual Compliance Monitoring Report for Canadian Nuclear Laboratories [4] provides the 2021 CNL Employee and Manager/Supervisor required training. Table 4 provides a list of federally/provincially legislated training courses that appear in position-specific training plans at Whiteshell Laboratories.

Table 4: Whiteshell Laboratories Operating Staff Training in 2021

Course Code	Course Title	No. of Attendees
OSH-1001-Online	Crane (Safe Indoor Hoist) – Theory	44
OSH-1002-Online	Lift Truck Operation – Theory	40
OSH-1003-Online	Aerial Work Platform – Theory	59
OSH-1004-Online	Lock Out / Tag Out Exam	28
OSH-1004-Virtual	Lock Out / Tag Out (Virtual)	28
OSH-1005-Online	Working at Heights – Theory	84
OSH-1006	Confined Space Entry	14
OSH-1006-Online	Confined Space Exam	15
OSH-1006-Virtual	Confined Space Entry (Virtual)	25
OSH-1007	Asbestos Module 6E	51
OSH-1033-Online	Ladder Safety	27
OSH-1034-Online	Hazard Prevention Program	31
OSH-1042-Online	WHMIS – 2015	40
OSH-1046-Online	Heat Stress	7
OSH-3001-E	Crane – Safe Indoor Hoist – Practical – Jib Crane	3
OSH-3001-F	Crane – Safe Indoor Hoist – Practical – Bridge Crane	3

OSH-3001-J	Crane – Safe Indoor Hoist – Practical Gantry Crane	2
OSH-3001-K	Crane – Safe Indoor Hoist – Practical	1
OSH-3001-L	Crane – Safe Indoor Hoist Only	13
OSH-3001-MULTI	Crane – Safe Indoor Hoist – Practical – All Equipment Codes	8
OSH-3002-C	Lift Truck Practical – Counter Balance	18
OSH-3002-MULTI	Lift Truck Operation – Practical/All Equipment Codes	4
OSH-3003-B	Aerial Work Platform Practical – Articulating Boom 60 ft (or less)	21
OSH-3003-C	Aerial Work Platform Practical – Rough Terrain Scissor Lift	27
OSH-3003-D	Aerial Work Platform Practical – Scissor Lift	25
OSH-3003-E	Aerial Work Platform Practical – Single Person Up-Up	1
OSH-3003-Multi	Aerial Platform – Practical (All Equipment Codes)	34
OSH-3005	Working at Heights – Practical	88
HU-1036-Online	Pre job Brief	12

2.2.4 Contractor Training

Before accessing the Whiteshell Laboratories, contractors are required to complete the following training:

- Contractor Safety Orientation
- Radiation Protection Group 4
- Integrated Work Control Core 5 Elements (Work Permit Authorization, Job Safety Analysis, Pre-job Brief, Stop/Pause Work and Integrated Work Controls)
- CNL COVID Awareness

WL utilizes the contract terms and conditions, in addition verifying and approving the contractor company’s safety programs and training records, to ensure contractors are qualified to work at WL.

WL oversees contractors’ work in the field and all WL work control protocols apply.

2.2.5 Training Evaluations Summary

In 2021 WL continued to utilize trainee feedback forms to capture learner input as part of training program improvement and maintenance activities. Also, there were 16 documented Observation and Coaching sessions related to training events. These evaluations are reviewed weekly by Training and Development staff and training program improvements are managed through applicable training change processes.

3 Operating Performance

3.1 Operating Program

Whiteshell Laboratories adheres to the Operating and Decommissioning Functional Support Areas. See Section 3.1 and Section 11.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Whiteshell Laboratories decommissions and operates its facilities according to prescribed programs and procedures. Operating performance is monitored through the nuclear performance assurance review board and other internal assessment activities such as self-assessments and audits (see Section 1.2).

3.1.1 Operations / Decommissioning Operations

Operational details on facilities identified in the *Site Licences, Certificates, Permits, Building/Facility Contacts, and Licence Representatives* [12] for Whiteshell Laboratories are given in Appendix A through F.

3.1.1.1 Conduct of Operations

Conduct of operations documents ensure appropriate integration and adequate reflection of safe operation practices to meet the business requirements.

3.1.1.2 Modification to Facilities and Processes

All temporary and permanent modifications to facilities at WL are made following defined Engineering Change Control [13] processes.

Relevant modifications to WL facilities are given in Appendix A through G.

3.2 Reporting Requirements

3.2.1 Reportable Events to CNSC

In 2021, there were 6 events that occurred at Whiteshell Laboratories that were deemed reportable to the CNSC. They are listed in Table 5.

Table 5: Reportable Events to the CNSC at Whiteshell Laboratories in 2021

Event No.	Title	SCA	Facility (if applicable)
ERM-21-3585	WL Injury - Medical Aid - Slip, Trip, Fall (Leg Injury)	Operating Performance	WL Building 300 (Research and Development)
ERM-21-3009	WL Reportable Event – Missed maintenance of safety related systems as per the Shielded Facilities Facility Authorization	Operating Performance	WL Shielded Facilities

HSSE-21-1772	WL - Radiation Source Found in Area Radiation Monitor Removed from B305 Electron Accelerator	Radiation Protection	WL Building 402 (Health and Safety)
ERM-21-1732	WL Environmental Protection: Hydraulic Leak at the Building 200 Demolition site involving a contractor's Hyster 550 Fork Lift (Rental Unit)	Environmental Protection	WL Building 200 (Active Liquid Waste Treatment Centre)
ERM-21-1651	WL Reportable Event - Building 402 Fire Protection System Impairment	Fire Protection	WL Building 402 (Health and Safety)
ERM-21-1036	WL - Incomplete Inventory Results in Misclassification of Shipment	Packaging and Transport	

3.2.2 Reportable Events to Other Regulators

Reports to other regulatory agencies consisted of:

- 1 Hazardous Occurrence Investigation Reports (HOIR) was made to Employment and Social Development Canada (see Section 8.1.3 for further details)
- 2 reports made to Environment and Climate Change Canada (see Section 9.5.2.4 for further details).

3.2.3 Trending of Events Related to Operational Activities

As events at Whiteshell Laboratories occur, they are recorded in the Improvement Action (ImpAct[2]) system. This information is regularly reviewed and analyzed to identify any trends. To identify trends Event Code based trend reports are also prepared to analyse ImpAct data on monthly bases. Monthly site wide and WL specific trend reports are prepared by CRL Performance Assurance and shared with WL. WL specific trends are also specified in the monthly Contractor Assurance System scorecard.

The following trends were identified and raised as ImpActs:

- ERM-21-1299, WL TREND – No Purchase Order in Place Prior to Commitments of Contract Service Providers Coming to Site
- ERM-21-3088, WL TREND - Misuse of WHMIS (Workplace Hazardous Materials Information System) when labelling or storing hazardous waste.
- ERM-21-3132, WL TREND – Increased Vehicle Accident Incident Reports (VAIR), Equipment and/or Passenger Vehicles on site and in main parking lot at WL.
- HSSE-21-3283, WL TREND – Barrier Crossings.

[2] ImpAct – Abbreviation for Improvement and Action. It is an internal process used to identify events, problems, non-conformities, opportunities for improvements, and personnel injuries. The process also identifies and tracks actions to correct or remediate problems.

The use of the ImpAct process continues to foster the internal reporting of lower significance level events (Level 4 and some Level 3), affording the opportunity to implement continuous improvement initiatives through a robust Corrective Action Program.

In 2021, a total of 424 ImpActs were raised by CNL employees at WL.

The reporting of lower significance level events continues to be encouraged (e.g., Near Miss Reporting – see Section 8, which is an industry best practice), and efforts to improve safety culture (Event Free Tools use, Event Free Day Reset, Observation and Coaching, etc.) have been adopted by both management and staff.

The following table summarizes ImpActs raised over the past 5 years by Significance Level[3].

Table 6: Number of ImpActs raised at Whiteshell Laboratories

Year	Level 0[a]	Level 1	Level 2	Level 3	Level 4	Total
2017	5	0	0	42	448	496
2018	10	0	0	39	532	581
2019	8	0	0	54	547	609
2020	13	0	3	58	276	350
2021	5	0	2	81	336	424

a Level 0 will be assigned if the ImpAct is deemed to be a “non- problem” and a recommendation to close the Impact will be given.

3.2.4 Notification of Conflicts or Inconsistencies

In 2021, there were no conflicts or inconsistencies identified between licence conditions, codes or standards, operations, programs, methods, or regulatory documents referenced in the Whiteshell Laboratories Licence [1] or *Licence Conditions Handbook* [2].

3 Significance Level: Levels assigned to an event (SL1 being most significant, SL4 being least significant) based on the actual or potential result in safety, environmental, or business consequences.

4 Safety Analysis

4.1 Safety Analysis Program

Whiteshell Laboratories adheres to the Corporate Safety Analysis Functional Support Area. See Section 4.1 of the Annual Compliance Monitoring Report for Canadian Nuclear Laboratories for details [4].

4.1.1 Safety Analysis Reports

Safety Analysis Reports (SARs) are produced to demonstrate that the facilities are appropriately designed to meet health, safety, security, environmental and regulatory requirements, and operated safely. These SARs form part of the basis for a set of limiting conditions for safe operation that are documented within Facility Authorizations for each nuclear facility. At WL, three facilities have SARs and Facility Authorizations: Shielded Facilities (SF), WMA and Concrete Canister Storage Facility (CCSF). The ALWTC SAR and Facility Authorization documents were previously obsoleted in 2020 [14]. Assessments are in progress to determine if the SF and WMA SARs need to be revised. The CCSF SAR is being updated to address upcoming fuel retrieval activities.

A SAR is being prepared for the standpipe/bunker remediation, Intermediate-Level Liquid Waste Processing Centre and conversion of the SMAGS building to a Cask Loading Facility. This document will be an addendum to the existing WMA SAR and will be submitted to the CNSC before these facilities are operated.

4.2 Nuclear Criticality Safety Program

Whiteshell Laboratories adheres to the Corporate Nuclear Criticality Functional Support Area. See Section 4.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

As the Nuclear Criticality Safety Program is a companywide program, enhancements and improvements made were intended to target all sites including WL and are identified in [4].

4.2.1 Nuclear Criticality Safety Documents

The WL Criticality Safety Documents (CSDs) for the Waste Management Area (CSD-27), the Cask Loading Facility (formerly the Whiteshell Laboratories SMAGS Building B923) (CSD-73) were conditionally accepted and the Intermediate-Level Liquid Waste Processing Centre (CSD-74), Concrete Canister Storage Facility (CSD 11), and the Fuel Basket Transfer Flask (CSD-54) are in progress to allow retrieval of waste from the WMA and CCSF. The remaining WL CSDs have not been updated during this review period.

5 Physical Design

5.1 Design Program

Whiteshell Laboratories adheres to the Corporate Design Functional Support Area. See Section 5.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Design Authority and Design Engineering Functional Support Area maintains and controls the design basis for all design activities performed at WL.

In 2021 March, the Certificate of Authorization was renewed with Engineers Geoscientists Manitoba. This authorizes CNL to engage in the practice of professional engineering in the province of Manitoba in accordance with the provisions of The Engineering and Geoscientific Professions Act.

5.1.1 Safety Related Structures Systems and Components

In 2021, the Design Authority and Design Engineering Program ensured that any structures, systems and components important to safety met and maintained their design basis, and any changes made were controlled through the Engineering Change Control Process [13].

5.2 Pressure Boundary Program

Whiteshell Laboratories adheres to the Corporate Pressure Boundary Functional Support Area. See Section 5.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Pressure Boundary Functional Support Area applies to design, procurement, fabrication, installation, examination, testing, repair, modification, construction and maintenance of pressure retaining systems and components performed by CNL at WL.

The *WL Pressure Boundary (PB) Quality Assurance (QA) Plan* [15] details the specific scopes of pressure boundary work carried out at WL, as permitted by the Certificates of Authorization issued by Inspection and Technical Services (ITS) Manitoba, describes the controls, authorities, and responsibilities applicable at the WL site, and is consistent with CNL's PB Program requirements.

The revised *PB QA Plan* [15] was accepted by ITS and a new Certificate of Authorization was issued on 2021 August 10. The new certificate of Authorization permits CNL to perform Pressure Boundary work as described in the Quality Assurance Plan until expiry in 2024 August.

The CNSC has previously been notified of revisions to the *PB QA Plan* [15], as per the *Licence Conditions Handbook.*

6 Fitness for Service

6.1 Fitness for Service Program

Whiteshell Laboratories adheres to a Fitness for Service Program through its Maintenance Functional Support Area. See Section 6.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Site and Nuclear Operations Branch provides monitoring and operation of building's processes and support systems. Housekeeping inspections are performed monthly to provide a formal walkthrough of facilities to ensure compliance for specific areas relating to facility performance. Further inspections are conducted of waste storage structures by qualified personnel to maintain them in a fit for service state.

Operating procedure reviews are conducted on a five year cycle. Currently the Operating Procedures are under review; some of these procedures have reached the five-year timeline for review and those are being prioritized for review and updating. As facilities are decommissioned procedures related to those buildings or processes are obsoleted. Procedures to operate the facilities in order to enable decommissioning efforts are prepared as required.

Details on various inspection and maintenance activities are provided in the following sub sections.

6.1.1 Planned Maintenance, Testing & Inspections

As part of Fitness for Service, WL staff ensure that critical systems, structures and components related to the safe decommissioning of WL are understood and that activities are put in place to assure their safe continued operation as they age. An integrated set of programs and activities ensures that performance requirements for all critical systems, structures and components are met on an ongoing basis. These processes include:

- Maintenance, In-Service Inspection and Functional Testing, where preventive maintenance work done in the facilities is tracked to ensure it is completed.
- WL operational regulatory tasks are tracked on a weekly basis to ensure required compliance and facility checks are completed, this includes the tasks set out in the Facility Authorization documents.
- Inspections required to meet the conditions of WR-1 Monitoring and Surveillance Plan.
- Inspections of waste storage structures for fitness for service.

6.1.2 Equipment Fitness for Service/Equipment Performance

Preventive maintenance of safety-related systems in WL's nuclear facilities is carried out by qualified maintainers, in accordance with the facility's Facility Maintenance Plan, and approved maintenance procedures. Preventive Maintenance is defined as the pre-planned routine testing, calibration, inspection, service, and overhaul of safety-related systems, structures, and components. Preventive maintenance is performed to prevent failures from occurring and to

assure the continuing capability of the system, structure or component to perform its design function. The maintenance tasks and frequencies specified in the Facility Maintenance Plan are based on recommendations from qualified WL engineering and maintenance personnel, plus vendor's data where available. Situations where there is evidence of deteriorating conditions or suggestions of an increased probability of upcoming failure are addressed as they are identified. Regular preventive or corrective maintenance and testing of WL's safety-related systems were carried out to ensure the systems were fit-for-service. Maintenance scheduling is conducted with assistance of a Computerized Maintenance Management System which outputs preventive maintenance tasks for scheduling by maintenance and work planning staff.

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed and is being implemented that will fix the issues and prevent recurrence. The effectiveness of the corrective action plan will be investigated upon completion of the actions.

6.1.3 Condition of Structures

Waste storage structures include the WMA bunkers and CCSF concrete canisters.

As a requirement of the Environmental Assessment Follow-up Program, a Periodic Inspection Plan (PIP) for WL Concrete Bunkers [16] was developed in 2007 and continues to be implemented to confirm the ongoing fitness-for-service of the concrete storage facilities (termed "bunkers") at the WMA. The PIP describes methods for conducting scheduled inspection surveys of these structures. The inspection is defined as examination, measurement and testing work done, to ensure the bunker systems are functioning as designed and the bunkers remain fit-for-service. The inspections are documented annually, with preventive maintenance and repairs occurring as needed. As the bunkers at the WMA are removed from service as part of the overall decommissioning of the WL site, they will be removed from the inspection process. The 2021 annual inspection of WL WMA concrete bunkers was conducted in accordance with the PIP [16].

Although the SMAGS building (Building 923) is not a bunker it has been included in the bunker inspection. Building 923 is being converted to the Cask Loading Facility, and during this conversion and subsequent re-commissioning for its new purpose, it will not store waste. A repair, conducted in 2016, to the north wall of Building 923 that extended into the core of the slab, remained stable through 2021 with no new crack expressions (the walls of Building 923 are pre-cast concrete slabs). All other repair items for the bunkers and Building 923 were minor in nature and were tracked through the WL work request system.

The concrete canisters are inspected quarterly for concrete spalls and any changes in the hairline cracks of the concrete. In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however existing cracks and pour pockets were regularly checked for changes. Requests for patching were placed in 2021, and several canisters will require more extensive patching of pour pockets that have gradually become more noticeable over time, however no increased radiation field was noted.

Environmental monitoring was conducted in the ditches at the perimeters of the WMA and the CCSF and show no evidence that any activity has been released from the bunkers, SMAGS or concrete canisters.

7 Radiation Protection

7.1 Radiation Protection Program

Whiteshell Laboratories adheres to the Corporate Radiation Protection Functional Support Area. See Section 7 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

Whiteshell Laboratories uses the Chalk River Laboratories (CRL) licensed Dosimetry Service Provider for external and internal dosimetry for site/facility staff and contractors.

Whiteshell Laboratories staff and contractors who work at the WL site are assigned Thermoluminescent Dosimeters (TLDs) to monitor for external radiation exposures.

7.1.1 ALARA Initiatives and Activities

As Low as Reasonably Achievable (ALARA) and Radiation Protection (RP) program improvement initiatives and activities performed at WL in 2021 included:

- Radiological hazard and precaution sheets were reviewed and updated as required to remove statements such as “at the Surveyor’s discretion” or “as directed by RP Surveyor”.
- Enhanced personal protective clothing and equipment requirements were implemented for work in Radiological Safety Zone 2 and 3 work areas.
- Guidelines were developed and implemented for field RP staff for consistent completion of radioactive material transit/storage tags.
- Radiological surveys completed in WL nuclear facilities to confirm absence or identify unknown and unmarked historical or legacy contaminated materials and areas.
- Facility review completed for the adequacy of radioactive material storage areas.
- Field compliance check list developed and implemented for use by field RP staff during facility housekeeping inspections.
- Guidelines provided for RP staff when knee pads or other additional measures are needed to prevent inadvertent knee contaminations when working in contaminated environments.
- New CNL RP program requirement for formal registration of long term radioactive material storage areas was implemented for any new storage areas, and work started on registration of pre-existing facility storage areas.
- WL site procedure developed for the dose monitoring program for WL workers, contractors and visitors.

WL RP performance metrics are measured and tracked weekly through WL Closure Project status reports and quarterly through the WL Nuclear Performance Assurance Review Board. These are designed to identify and address program and performance deficiencies and

opportunities for improvement, establish and effectively implement corrective and preventative action plans.

7.1.2 Dose Control

Regular radiation surveys are performed by RP staff to confirm: the radiological safety zones are correctly designated; areas with local elevated radiation doses rates are posted in accordance with the RP Regulations; and sufficient access control provisions are in place. In 2021, there were no occurrences of dose rates exceeding permissible levels for the designated radiological safety zones and there were no occurrences of work places with accessible dose rates exceeding 25 µSv/h not being posted or with inadequate access control.

Electronic Personal Alarming Dosimeters (PADs) are worn by workers in addition to TLD badges to track and control job specific daily and accumulated doses. The PADs have dose and dose rate alarms which are established by job specific radiological work assessments. The dose alarms are a back-out condition and the dose rate alarms are an alert condition. Table 7 summarizes maximum daily recorded doses and dose rates for PAD work in 2021 and the previous four years, and a summary of PAD alarms. In 2021, the maximum PAD recorded daily dose received by a worker was 0.22 mSv and the highest dose rate measured in the year was 3.1 mSv/h. These were associated with planned exposures associated with decommissioning activities in the Building 200 ALWTC, and removal and packaging hot cell roughing filters in the WL Shielded Facilities. There were no PAD dose alarms and 78 PAD dose rate alarms in 2021. The distribution of PAD dose rate alarms over the past 5 years is summarized in Table 8.

There was an increase in the number of low level dose rate alarms in 2021 due to increased decommissioning and operations activities in the WMA associated with the removal, characterization and packaging of low level radioactive waste from waste storage buildings. These low level dose rate alarms helped alert workers of dose rate areas they did not need to be working in, and thus helped to maintain low doses to workers.

Table 7: Personal Alarming Dosimeter Summary

	2017	2018	2019	2020	2021
PAD – Maximum Daily Dose (mSv)	0.17	0.24	0.42	0.28	0.22
PAD – Maximum Dose Rate (mSv/h)	1.99	4.95	5.82	5.56	3.10

Table 8: Distribution of Number of PAD Dose Rate Alarms 2017-2021

Year	Dose Rate Alarm Set Point (mSv/h)							
	≤0.10	>0.10 - <0.25	0.25 - < 0.50	0.50 - < 1.0	1.0 – < 2.5	2.5 - < 5.0	5.0 - < 10	≥ 10
2021	11	20	22	16	7	2	0	0
2020	10	2	1	5	9	1	1	0
2019	9	0	2	12	4	2	0	0
2018	22	0	13	5	31	3	0	0
2017	22	3	26	2	5	0	0	0

At the beginning of 2021, managers assigned and confirmed Dose Control Points (DCPs) for employees and contractors. DCPs are used by managers and supervisors to perform individual whole-body dose management for worker radiation dose for non-emergency work situations. DCPs of either 1 mSv or 2 mSv are assigned by WL managers and represent the worker's maximum allowable dose for the calendar year. The DCPs may be adjusted as necessary during the year upon approval of a Health Physicist after confirmation that additional dose is justified. At the end of 2021, there were no individuals with an assigned DCP higher than 2 mSv, 28 individuals with an assigned DCP of 2, and the remainder of workers with a DCP of 1 mSv. No worker dose exceeded their assigned DCP in 2021.

7.1.3 Contamination Control

Regular contamination surveys of workplaces, material transfers, and personnel exiting nuclear facilities and controlled areas, are used to confirm the absence of unknown contaminated material or the spread of contamination. Workplace air monitors are employed to confirm the adequacy of controls, and to warn of abnormal or unplanned airborne contamination conditions.

Table 9 shows the number of personnel, workplace and material contamination events identified in 2021 and over the past five years. None of the contamination events in 2021 resulted in a recordable whole-body, skin or internal dose.

Material contaminations increased from 1 in 2020 to 11 in 2021. This increase was due to historical surplus equipment being found with low level contamination during operational cleanup activities (8), building decommissioning waste disposition (1), and as a result of operational activities (2). There were no worker skin or clothing contaminations in 2021.

In 2021, there were no airborne contamination exposure events and no radioactive material spills.

The following table outlines contamination events that occurred at Whiteshell Laboratories in 2021:

Table 9: Contamination Events

	Skin and Clothing Contamination				Workplace Contamination	
	Skin[a]	Personal Clothing[a]	Radiological Work Clothing[b]	Total	Surface[c,d]	Vehicle / Materials [b, c]
2017/18 FY	0	0	1	1	3	
2018/19 FY	1	0	5	6	6	0
2019 CY	3	0	4	7	2	4
2020 CY	2	0	3	5	1	1
2021 CY	0	0	0	0	1	11

a Total surface contamination found is greater than 1 Bq/cm^2 beta-gamma or 0.2 Bq/cm^2 alpha over a 100 cm^2 averaging area.
b Total surface contamination found is greater than 4 Bq/cm^2 beta-gamma or 0.4 Bq/cm^2 alpha over a 100 cm^2 averaging area.
c Removable surface contamination found is greater than 0.2 Bq/cm^2 beta-gamma or 0.01 Bq/cm^2 alpha over a 300 cm^2 averaging area for Contamination Zone 1 areas
d Removable surface contamination found is greater than 10 times the maximum allowable levels for Contamination Zone 2 and higher designated areas.

7.1.4 Sealed Sources

Radiation sources are registered and tracked in accordance with CNL procedures.

In 2021, there were no lost or stolen radiation sources. Leak testing was completed as required with all sources passing their leak tests.

As of 2021 December 31, the total number of registered sealed or contained sources at WL, was 53. One Cesium (Cs)-137 source was added to the registry, and one mixed Cs-137 liquid standard and one Cs-137 gamma irradiator were removed from the registry. The liquid standard was evaporated and dispositioned as radioactive waste. The Cs-137 calibrator was transported back to the manufacturer.

7.2 Dosimetry

7.2.1 Interpretation of Reported Dose Quantities

WL uses the CRL licensed Dosimetry Service Provider for external and internal dosimetry for CNL staff, non-CNL employees and visitors. Compliance with the regulatory document REGDOC 2.7.2, *Dosimetry*, Volume II [17] requires external exposure measurements to meet performance criteria with respect to the measurement of personal dose equivalent, $H_p(d)$. This is the quantity currently measured using TLDs worn on the trunk of the body. External whole-body dose (photon) and external surface (photon plus beta) dose as reported herein can be interpreted as $H_p(10)$ (for photons) and $H_p(0.07)$ (for photons and betas), respectively. Effective

dose is the sum of the components external penetrating, neutron, tritium and non-tritium committed effective dose.

External radiation whole-body and skin doses are individually monitored using TLDs for persons entering or working in either radiological Controlled or Supervised Areas at WL[4].

Extremity dosimeters are worn for a defined job by a person who is likely to receive an extremity dose exceeding 1 mSv and significantly greater than a surface dose as monitored by their TLD, or if there is a reasonable probability that an extremity will be exposed to a beta and/or photon dose rate greater than 10 mSv/h.

Neutron dosimeters are issued to individuals who may be exposed to neutrons resulting in dose in excess of 1 mSv in a year or where accidental neutron exposures are possible.

WL staff participate in a routine bioassay program when there is a reasonable probability of receiving a committed effective dose from occupational intakes exceeding 1 mSv per year.

7.2.2 Radiation Doses to Personnel

Table 10 to Table 13 summarize the monitored radiation doses at the WL site for 2021. Doses are summarized for employees, contractors and visitors and are subdivided into Nuclear Energy Worker (NEW) and non-NEW status. Doses in the tables of this report do not include doses received by WL employees and contractors working at sites other than WL. Two visitors had NEW status that were associated with prior NEW requirements and visits within CNL as a whole, these two instances were CNSC and IAEA staff.

In 2021, there were no exceptions for individual monitoring of non-CNL employees and visitors at WL, other than drivers of delivery trucks and building demolition debris haulers in radiological Supervised Areas.

There were no operations of exposure devices in 2021 which required employees or contractors to be placed on a two-week dosimetry period, and there were no formal dose calculations required during 2021 for local area skin contamination.

No neutron dosimeters were assigned to employees during 2021.

In 2021, 180 individuals underwent internal bioassay, which involved urinalysis and/or whole-body counting. Eleven individuals underwent confirmatory and follow-up Pu-in-urine bioassay monitoring and there were no individuals requiring tritium-in-urine monitoring. No committed effective dose estimates were necessary as a result of any bioassay sampling in 2021.

In May of 2021 the building (B402) that housed the WL Whole Body Counter (WBC) began decommissioning and demolition and a new building (B543) is currently being commissioned to house the WBC. It is anticipated that the new facility will be ready for occupancy sometime in the spring of 2022. During this outage, workers who normally participate in annual or bi-annual WBCs were evaluated against the site’s current radiological activities to determine which

---

[4] Exceptions are authorized on a case-by-case basis by the responsible RP Program Manager or RP Program Functional Support Manager (exceptions are noted in Section 7.2.2).

workers required alternative monitoring. Workers with reasonable potential for an intake which warranted alternate monitoring were placed on a gamma spectrometry in urine analysis (provided by CRL Dosimetry Services) which provides similar minimum detectable doses to the WBC analysis. Additional random (biased toward likelihood of an intake) urine bioassay monitoring of workers who did not meet the alternative monitoring criteria is being undertaken until the new facility is ready.

Table 10: Effective Dose for Whiteshell Laboratories

Monitored Person Type		Total # of Persons	Dose Range (mSv)							Individual Dose (mSv)			Collective Dose (p·mSv)
			0	0.01-0.50	0.51-1.00	1.01-5.00	5.01-10.00	10.01-20.00	>20.00

7.2.2.1 Discussion of Dose Data

The Regulatory effective dose limit for a NEW in a calendar year is 50 mSv. The maximum individual effective dose to a NEW at WL in 2021 was 0.57 mSv and the site collective dose was 18.99 p-mSv.

The Regulatory effective dose limit for a NEW in a five-year period is 100 mSv. The maximum individual effective dose to a NEW at WL for the current five-year dosimetry period from 2021 to 2025 at WL was 0.57 mSv.

The Regulatory skin dose limit for a NEW in a calendar is 500 mSv. The maximum individual skin dose to a NEW at WL in 2021 was 0.94 mSv and the site collective dose was 23.47 p-mSv.

The Regulatory hands and feet dose limit for a NEW in a calendar is 500 mSv. The maximum individual hands and feet dose to a NEW at WL in 2021 was 1.86 mSv and the site collective dose was 7.26 p-mSv.

The Regulatory effective dose limit for a pregnant NEW is 4 mSv for the remainder of their pregnancy. In 2021, the maximum individual effective dose from the time the pregnancy was declared to the end of the pregnancy term was 0.05 mSv.

The Regulatory effective dose limit for non-NEWs is 1 mSv in a calendar year. In 2021, the maximum individual effective dose to a non-NEW at WL was 0.11 mSv.

Table 14 provides a summary of radiation doses by worker group in 2021. The majority of radiation doses were received by RP, Nuclear Operations and Trades staff.

7.2.2.2 Radiation Dose Changes or Trends

Table 15 shows external whole body dose received from 2017 to 2021, and Figure 1 displays the maximum individual and collective dose from 2001-2021.

Worker doses decreased in 2021 with the completion of higher dose extensive decommissioning activities in Building 200 (ALWTC) in 2020. The site collective dose decreased from 33 p-mSv in 2020 to 19 p-mSv in 2021. The number of workers receiving occupational doses above 0.2 mSv in a calendar year decreased from 25 workers in 2020 to 11 workers 2021. This a significant decrease compared to a maximum number of 42 workers in 2017. There were no workers receiving an annual radiation dose above 1 mSv in 2021.

Main contribution to radiation dose in 2021 was radioactive tanks removal during B200 demolition activities, and operational replacement of hot cell roughing filters. There was increased waste handling in 2021 with the start of the removal, characterization and packaging of low level radioactive waste packages from storage facilities in the WMA. However, these activities had only a small contribution to site worker doses.

7.2.3 Program Exceedances

During 2021, radiation dose to all persons working at WL were below the WL dose Action Levels [2] and the respective CNSC regulatory limits [18]. In addition, there were no individual doses exceeding their respective DCP as a result of activities at WL.

Table 14: Summary of Worker Group Radiation Doses at WL for 2021

	Total Number of Persons	Individual Whole-Body Dose (Effective Dose[a])		Collective Whole-Body Dose (Effective Dose[a])	Collective Surface Dose (photon plus neutron plus beta)	Collective Extremity
		Average[b] (mSv)	Maximum (mSv)	p·mSv	p·mSv	p·mSv
Nuclear Facilities:						
SF Staff (HCF and IFTF)[c]	5	0.18	0.49	0.91	0.92	1.83
WR1 and ALWTC Staff	5	0.07	0.14	0.37	0.37	0
WMA and CCSF Staff[c]	6	0.07	0.21	0.39	0.39	0
Support Workgroups:						
Radiation Protection Staff [d]	41	0.11	0.43	4.43	6.02	1.06
Trades Staff [e]	48	0.09	0.57	4.31	6.35	4.37
All Remaining Staff:						
Other Staff [f]	513	0.02	0.19	8.48	9.32	0
WL Site[g]:	618	0.03	0.57	18.89	23.37	7.26

a Includes photon and neutron; there were no tritium committed effective doses for 2021.

b Average of all measured doses that includes the zero dose values, rounded to two decimal places. Includes employees and contractors.

c SF= Shielded Facilities; HCF = Hot Cell Facilities; IFTF = Immobilized Fuel Test Facility; ALWTC= Active Liquid Waste Treatment Center; WMA= Waste Management Area; CCSF= Concrete Canister Storage Facilities; WR1 = An experimental test reactor built at WL – WR-1 featured an organic liquid coolant.

d Radiation Protection staff include Radiation Surveyors, Radiation Protection Assistants, Contamination Monitors, and Decontamination Operators.

e Trades staff provide services for all listed facilities and decommissioning activities as well as the WL

site in general.

f Other staff is comprised of all remaining staff and includes decommissioning, administrative, management, engineering, quality assurance, researchers, contractors and tenants.

g WL Site includes 393 CNL staff (WL and staff visiting from other CNL sites) and 225 contractors working at the WL site during 2021. This tally does not include visitor doses.

Table 15: WL External Whole-Body Dose Performance 2017 to 2021

Performance Metric	2017	2018	2019	2020	2021
Site Collective Worker Dose (p-mSv)	19.9	40.2	49.6	33.4	18.9
Max Individual Worker Dose (mSv)	1.41	1.65	3.09	2.97	0.57
Number of Workers > 0.2 mSv in a year	42	39	38	25	11
Number of Workers > 1 mSv in a year	1	12	14	8	0
PAD[a] – Maximum Daily Dose (mSv)	0.17	0.24	0.40	0.28	0.22
PAD – Maximum Dose Rate (mSv/h)	1.99	4.95	5.82	5.56	3.1

a Personal Alarming dosimeter.

8 Conventional Health and Safety

8.1 Conventional Health and Safety Program

Whiteshell Laboratories adheres to the Corporate Conventional Health and Safety Functional Support Area. See Section 8 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In support of reducing the number and impact of incidents with the potential for injuries or incidents at WL, the following initiatives are continuing or began in 2021:

- To support project work, WL OSH purchased noise dosimeters, a sound calibrator, Jerome Mercury detector and Colorimetric Badges for chemical detection.
- OSH presence in the field continued at pre-job briefings, walk downs and daily work plan meetings together with early involvement in the planning process have contributed to WL's internal safety success.
- Contractors continued to be "pre-qualified" prior to bidding on WL contracts. The pre-qualification process involves reviewing safety statistics and the safety programs of the potential bidders.
- WL continued to participate in the Rapid Learning Morning Call to quickly share safety information with all CNL sites, as well as gather safety information relevant for the WL site.
- Increased contractor oversight continued by participating in activities such as site visits, pre-job briefs, pre-bid meetings and OSH orientation for contractors.
- There were 11 internal Safety Advisories and 2 Learning Advisories sent to WL site employees. The bulletins are intended to inform WL employees about imminent issues that could impact their safety. WL continued to be proactive in the approach to safety.
- Near Miss reporting (a known industry best practice) continued with a focus on early hazard recognition and strong situational awareness culture, supporting the minimization or elimination of hazards prior to resulting in injury (see Table 16).
- Near Miss reporting at WL always includes an investigation/fact finding session. The majority of Near Miss reports also generate an ImpAct. Whether an ImpAct is generated or not, the possibility of a human error trap being involved in the Near Miss incident is always considered, evaluated and followed up as appropriate.
- OSH Program weekly review of company injury/illness reports in support of recognizing trends and disseminating lessons learned.
- Focus on disability management / return to work in support of minimizing the impact to an injured employee and subsequent days lost.
- Promoted the Stop/Pause protocol.

Table 16: Summary of WL Near Miss Reporting

Year	2017	2018	2019	2020	2021
Near Miss Reported	60	53	46	10	26

8.1.1 Site Safety and Health Committee

The Site Safety and Health Committee is the principal forum at WL for joint employee/ management consultation and development of solutions to safety and health concerns at the WL site. The WL Site Safety and Health Committee meets on a monthly basis.

In 2021, the WL Site Safety and Health Committee received 93 inquiries out of which 6 remained open and in progress. There was one inquiry carried over from 2020. The Site Safety and Health Committee acts as an oversight body, therefore these actions are largely related to the Site Safety and Health Committee's need for more information that provides them with assurance of the effectiveness of the actions of the functional safety groups on site.

8.1.2 Inspections

There were 61 site health and safety inspections completed in 2021.

8.1.3 HOIRs and Lost-Time Injuries

There was one hazardous occurrences at Whiteshell Laboratories that was reported to Employment and Social Development Canada in 2021. CNSC staff received a copy of this notification, as per the requirements of the CNSC REGDOC-3.1.2 [3].

The following is a summary of injury rate data for the last 5 years.

Table 17: Summary of Whiteshell Laboratories Injury Rate Data

	2017	2018	2019	2020	2021
Whiteshell Laboratories					
Person Hours Worked	706,000	688,000	642,000	584,030	684000
Lost-Time Injuries	3	1	0	1	0
Working Days Lost	27	5	0	2	0
Frequency[a]	0.85	0.25	0	0.34	0
Severity[b]	7.76	1.45	0	0.68	0
Whiteshell Laboratories Contractors[c]					
Lost Time Injuries	1	0	0	0	0
Working Days Lost	0[d]	0	0	0	0

a Frequency rate equals # of Lost-Time Injuries x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).

b Severity rate equals # of Working Days Lost x 200 000 hrs of exposure divided by person hours worked (based on 100 Full Time workers).

c The Number of Person Hours worked are not divulged by Contractors. As such, Frequency and Severity rates cannot be calculated.

d Number of days lost is unknown as the contractor terminated the employee.

The Recordable Lost Time Injury rate over the last five years at WL in Manitoba is significantly lower than local lost-time injury rates for construction (3.7) and manufacturing (2.4), as per the data from the Workers Compensation Board of Manitoba found in *The Manitoba Workplace Injury and Illness Statistics Report 2010-2019* (safemanitoba.com).

No Assurance of Voluntary Compliance or Directions were issued by Employment and Social Development Canada in 2021.

9 Environmental Protection

9.1 Environmental Protection Program

WL adheres to the Corporate Environmental Protection (EnvP) Functional Support Area. See Section 9 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

WL has an integrated Environmental Protection Program designed to track radiological and non-radiological contaminants throughout the different compartments of the geosphere, atmosphere, and biosphere, and consists of three distinct programs: the Effluent Verification Monitoring Program, the Environmental Monitoring Program, and the Groundwater Monitoring Program. The WL Environmental Protection Program is designed to implement the requirements of:

- CSA N288.4-10, *Environmental Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [19],
- CSA N288.5-11, *Effluent Monitoring Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [20],
- CSA N288.6-12, *Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills* [21],
- CSA N288.7-15, *Groundwater Protection Programs at Class I Nuclear Facilities and Uranium Mines and Mills* [22],
- CSA N288.8-17, *Establishing and Implementing Action Levels for Releases to the Environment from Nuclear Facilities* [23], and
- ISO 14001:2015, *Environmental Management Systems* [24].

The integrated Environmental Protection Program is dynamic in nature, meaning that it is continually evolving based on various sources of information received.

Program documentation is updated on an ongoing and/or required basis.

This report will focus and discuss the implementation of the WL Effluent Verification Monitoring Plan [25]. This plan defines the methodologies and protocols followed in performing the effluent verification monitoring required in CSA N288.5-11 [20].

The WL site has maintained its ISO 14001 [24] registration in 2021 with initial registration in 2010.

The CNSC has previously been notified of revisions to *Environmental Protection documents* [26], as per the *Licence Conditions Handbook.*

9.2 Quality Assurance

In order to ensure that the data collected through the program is valid, the laboratories performing monitoring for the program have strong Quality Assurance/ Quality Control programs as required by CSA N288.5 [20]. General quality assurance objectives for CNL's

Environmental Protection Program are set out in quality assurance plans. Radiological analysis is conducted in accordance with laboratory-specific environmental monitoring quality assurance plans. The plans include detailed working procedures for field operations, laboratory operations, laboratory administration, equipment performance, and quality verification of analytical results. The plans were written to align to ISO/IEC 17025 [27] for analytical laboratories.

Whiteshell Laboratories' Environmental Management group conducts frequent internal checks of their technical capabilities as they perform their measurements. These are called Quality Verification Tests, and are grouped as follows according to purpose:

- *Reproducibility Tests*, such as measurement of sample replicates, establish the relative precision of the method(s). To be acceptable, replicate measurements must agree within limits established by long-term method performance.
- *Accuracy Tests*, such as blanks or samples, each spiked with known amounts of the analyte(s), establish the presence or absence of any biases due to sample matrix, sample preparation, or instrument function. To meet acceptance criteria, the spike quantity must be recovered within limits established by long-term method performance.

Environmental Management performed 3247 quality verification tests during 2021 on WL's radiochemical counting equipment. Of these tests, 99.6% fully complied with acceptance criteria. The results of these tests are shown Table 18.

Table 18: Whiteshell Laboratories' Summary of Quality Verification Test Performed

Method	No. of Tests	No. of Failures	% Pass
Total Alpha (Instrumentation)	1188	4	99.7
Total Beta (Instrumentation)	1188	5	99.6
Gamma (Instrumentation)	647	0	100.00
Tritium	224	4	98.2
2021 Total	**3247**	**13**	**99.6**

In 2021, the WL Effluent verification program continued performing regular field Quality Verification testing on the Outfall, Lagoon, and Ditch effluent sampling (Table 19). The program is using traveling blanks to determine and account for any possible introduction of contamination into the sample being analyzed by the sampling methodology being employed by the program, and the program is also collecting duplicate samples to demonstrate sampling reproducibility.

Table 19: Whiteshell Laboratories' Summary of Field Quality Verification Tests Performed

*: Not all 2021 data has been received from the contract laboratory.
LMDL = Laboratory Method Detection Limit

It is important to note that not all of the radiological results for 2021 have been received from the contract laboratories carrying out the analysis of samples (see also Section 9.4.1.3.2). At the time of writing this report, results received to date indicate that out of the 146 duplicate quality verification tests, 130 of these tests meet the acceptance criteria (+/- 20% of the actual result) of the program, to yield an 89% pass rate. A larger number of duplicates failed this year, with the majority of the failures being related to the metal concentrations being observed at the Outfall monitoring station. CNL is attributing this increase in failures to the fact that the metal concentrations being observed in the effluent are near the detection limit. This leads to results with low concentrations and high variability being produced, which will increase the likelihood of a failure in the duplicates being observed. This is supported by the large number of results classified as not being detected, and the low concentrations of metals being observed at the Outfall as seen in Table 32. No further action by CNL is needed to address the failures.

Reviewing the travelling blank data, and comparing it to the field results, the environmental program has concluded that the water source being used for the travel blank is slightly contaminated with Copper, Lead, Zinc, Chloroform, and Bromodichloromethane. The traveling blank results for these parameters are not reflective of contamination being picked up while sampling in regards to these parameters.

In 2021, the WL Environmental Management group took part in four inter-laboratory comparison studies. Two of these studies, which focused on radiological analyses, were offered through the Environmental Research Associates. The other two studies which focused on non-radiological analyses, were offered through the Canadian Association for Laboratory

Accreditation. The results of the WL Environmental Monitoring laboratory performance are shown in Table 20 and Table 21. There were four unacceptable test results out of thirty for the Environmental Research Associates inter-laboratory comparison studies, resulting in an 87% pass rate. The four unacceptable test results related to the gross alpha and gross beta analysis of water samples. The WL radiochemical counting laboratory is working on determining the cause of the problem, and until the cause has been identified, all quantitative analyses of this nature are being contracted out to a third party laboratory. The laboratory is in the process of ruling out possible factors. The areas the laboratory are currently reviewing includes the process for evaporation and ashing samples being utilized to prepare samples. The previously used method was required to change due to equipment limitations in the new environmental laboratories. The standard stock solutions that are used for the creation of the calibration curves used in this analysis may have also been compromised.

For the Proficiency Testing Canada inter-laboratory comparison studies, a 100% pass rate was achieved.

Table 20: Environmental Research Association Inter-Laboratory Comparison Program for CNL WL - 2021

MRAD* Study	Matrix	Analyte	Units	MRAD Assigned Value	WL Reported Value	Acceptance Limits	Performance Evaluation
MRAD-34	Air Filter Radionuclides	Americium-241	(pCi/Filter)	60.2	64.20	43.0 – 80.3	Acceptable

	C15-4	pH	(pH units)	8.52	8.55		

9.3 Supplementary Studies

In 2020, the WL site began to do temporary enhanced monitoring on the effluent verification ditches for the year. The enhanced monitoring is being done to confirm the absence of a number of radiological and non-radiological parameters. The enhanced monitoring involved doing an open scan for Volatile Organic Carbons, semi-volatile organic carbons, and an expansion of the metals and gamma isotopes list currently being used to monitor the ditches.

Whiteshell is reviewing the data, and is deciding whether there is a need to add any of these parameters to the effluent verification monitoring program going forward. This study was on going in 2021, and will be continued into 2022 due to the limited number of ditch sampling events that occurred in 2021.

9.4 Effluent Monitoring - Radiological

This section addresses the licence requirement regarding radiological monitoring of airborne and liquid effluents for the WL site, located on the Winnipeg River near Pinawa, Manitoba. It also addresses the effluent monitoring requirements listed under the Environmental Assessment Follow-Up Program [28] for WL.

Results of environmental monitoring and progress on the Environmental Assessment Follow-Up Program work packages will be provided in their respective annual reports, *Environmental Monitoring in 2021 at Whiteshell Laboratories* [29] and *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28].

9.4.1 Effluent Monitoring

9.4.1.1 Site Effluent Verification Monitoring System and Results Evaluation

Monitoring locations for airborne and liquid effluent streams are representative of the final discharge to the off-site environment, and may include the combined discharge from a number of facilities. Additional monitoring points are maintained at upstream locations as an aid in identifying the specific sources of emissions. Sampling system design ensures that samples are representative of the total content of the stream at each location.

Figure 2 includes a map of the effluent monitoring locations/effluent streams at WL.

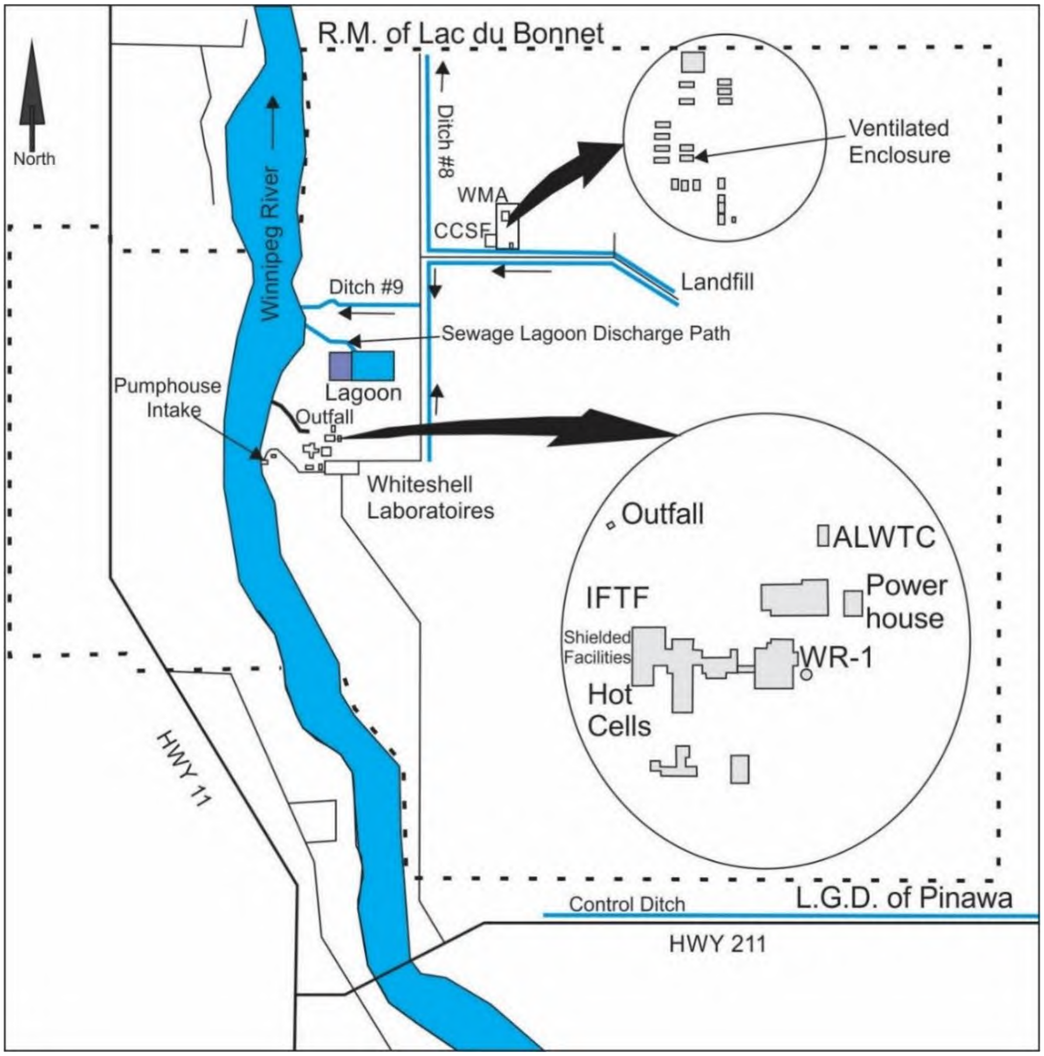

Figure 2: Effluent Monitoring Locations

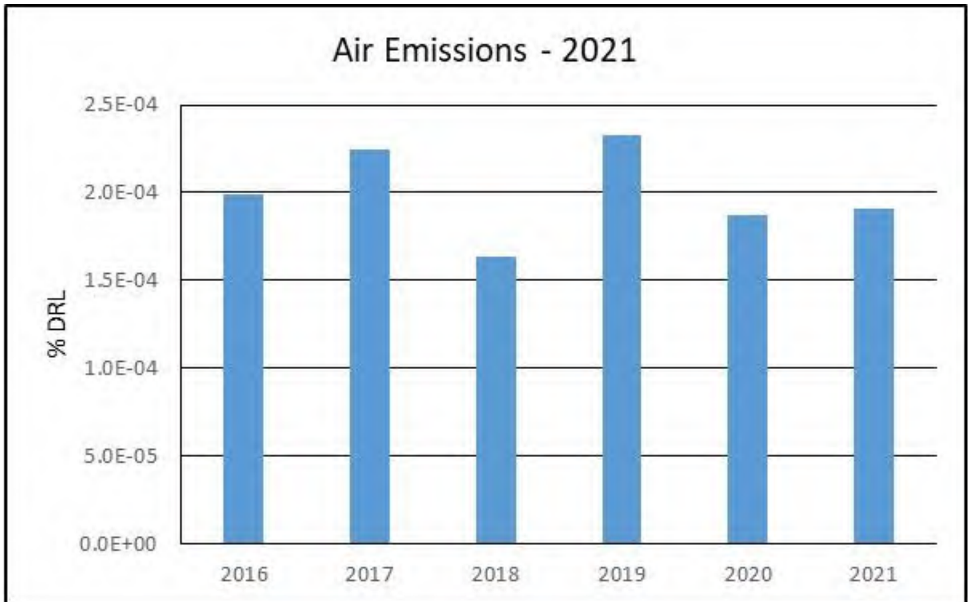
Effluent streams are monitored for all groups of radionuclides that are likely to be present and significant contributors to the total, expressed as a percentage of applicable DRLs [30]. The DRLs in use at WL came into effect on 2021 January 31. All current and historical data in this report has been compared against these DRLs. Monitoring is conducted either by direct measurement on location or by sampling and laboratory analysis. In many cases, gross-measurement parameters (e.g., gross beta) are monitored and reported rather than specific radionuclides. This is done provided that either the relative composition of radionuclides indicated by the gross parameter is not likely to vary significantly, or total emissions of the gross parameter are very small relative to the DRLs. For comparison with DRLs, the gross parameters are always evaluated conservatively. They are either assumed to consist solely of the most restrictive radionuclide, based on DRL value that is likely to be present in measurable quantities, or are assumed to be the radionuclide(s) known to be present in the effluent. To ensure proper selection of the DRL values, the effluents are periodically characterized using, for example, gamma spectrometry to identify individual gamma emitters, or chemical extraction

and analysis of individual beta emitting radionuclides, such as Strontium (Sr)-90, complemented by examination of historical data.

The significance of the measured radioactive materials in airborne and liquid effluents is assessed by comparison with DRLs that relate the releases to the potential radiation dose to the identified, most exposed groups (i.e., critical groups). DRLs are the upper limits for releases of radionuclides in airborne or liquid effluents from a facility or site. WL's DRLs were calculated in accordance with the principles and methodology in CSA N288.1-08 [31]. The DRL for a particular radionuclide is derived from the regulatory dose limit for members of the public, 1 mSv in a year, as specified in the Radiation Protection Regulations under the Nuclear Safety and Control Act [32]. The intention of the DRL is to establish a release limit such that compliance with it will give reasonable assurance that the annual regulatory dose limit for members of the public is not exceeded. Weekly DRLs are calculated and applied for airborne effluents, and monthly DRLs for liquid effluents.

For multiple effluents and radionuclides at a site, verifying that the sum of all releases as a percentage of the respective DRLs is less than 100% provides a reasonable assurance[5] that the annual dose limits have not been exceeded. This is a conservative approach since the critical group may differ for different release paths and radionuclides. The actual releases are a very small fraction of the DRL as discussed in the following sections and shown in Figure 3. As discussed in Section 9.4.1.3.2, the increase in 2019 to 2021 liquid effluents is due to an increase in detection limit values for Am-241 and Plutonium (Pu)-239/240. When the activities of radionuclide contaminants are not detected it is standard practice to report detection limit values as if they were observed concentrations. For example, Pu isotope activities were always detection level values and Am-241 and Cs-137 activities are very close to detection levels.

[5] The effluent DRL model and assumptions are further verified annually through results from the WL environmental monitoring program. The program assesses radiation doses to members of the public using direct measurements of radioactivity in the environment (e.g., in air, water, and food).



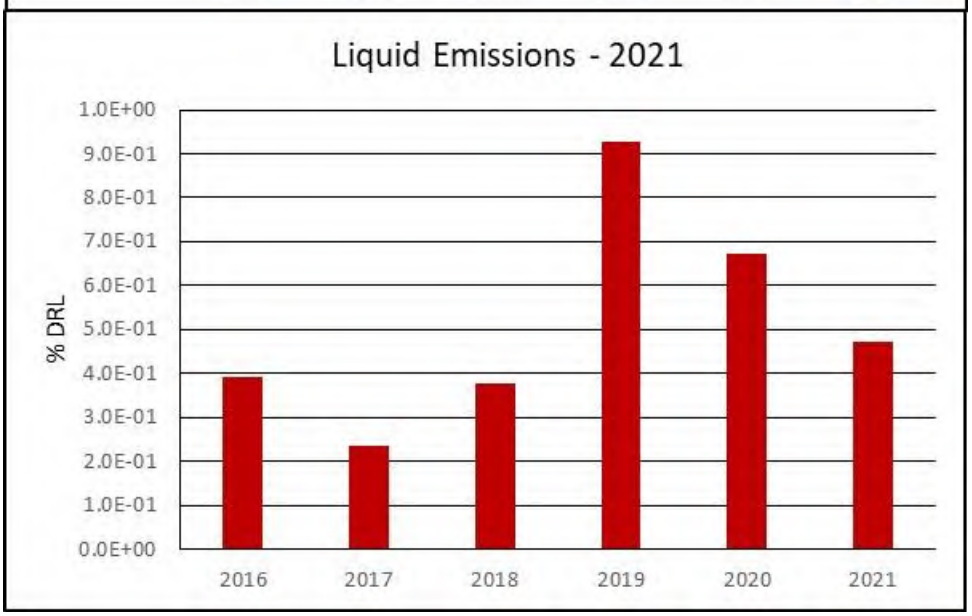


Figure 3: Trends for Airborne and Liquid Emissions form WL for 2016 to 2021

(Note: The Liquid Emissions for 2021 need to be corrected to include October to December data. This will be revised upon receipt of the data.)

Analytical models of all significant environmental pathways to an individual in the critical group are used in the DRL calculations. DRLs for WL have been calculated for a large number of radionuclides, many of which are currently not detected in site effluents. Derived Release Limit calculations (of a wide range of radionuclides) provide a means of determining which radionuclides may be significant dose contributors. Thus, they aid in determining which nuclides warrant inclusion in the monitoring program, and in interpreting monitoring results.

Performance is also measured against the regulatory Administrative and Action Levels[6] as specified in Reference [33]. The Action Levels were calculated based on current CNSC guidance to meet CSA N288.8 [23] and to better reflect current waste streams, and were released for use based on an implementation date of 2017 January 01.

9.4.1.2 Airborne Effluents Monitoring

9.4.1.2.1 Monitoring Points, Schedules and Parameters

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. These activities include waste compaction in the Waste Handling Area, located in the Immobilized Fuel Testing Facility (IFTF), and decommissioning activities in the ALWTC. The main sources of airborne radioactive effluents, as a result of this work and historical activities at WL, are the:

- Hot Cells Facility (Building 300)
- Immobilized Fuel Test Facility (Building 300)
- Reactor Building (Building 100)
- ALWTC (Building 200)

Air effluents from Buildings 100 and 300 were sampled continuously throughout the year. The frequency and type of monitoring will continue to be evaluated over time, and adjusted to reflect findings from the monitoring activities. The current monitoring schedule and locations are noted in Table 22. Cessation of a monitoring activity will occur once it can be shown that an effect has stabilized or has been reduced to a level where it is no longer considered significant by regulatory requirements or community concerns. Any proposals on modifications to the monitoring program will be communicated to CNSC staff. In 2020, Building 200 (ALWTC) was prepared for demolition and the ventilation system was shut down in 2020 October. Monitoring of stack effluents for Building 200 ceased after 2020 October 13, and the building was demolished in 2021. Therefore the reported air emissions in 2021 do not include emissions from Building 200, which is no longer included in the monitoring schedule (Table 22).

6 Action Level – In the context of CNL's Environmental Protection Program, an "Action Level" for radioactive emissions is a release rate of radioactive emissions that, if reached, may represent a loss of control of performance for a facility's environmental protection program or emission control system. Releases above Action Levels must be investigated and reported to CNSC staff. Action Levels for WL radioactive effluents are lower than the DRLs.

Table 22: Radiological Air Effluent Monitoring Schedule – 2021

Sample Location	Sample Collection		Analytical Method and/or Parameter			
	Frequency	Method	Gross Beta	Gross Alpha	Tritium	Gamma Spec
Building 100 Stack	Cont	GFA Filter	W	W	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Bubbler	N/A	N/A	W	N/A
Building 300 HCF	Cont	GFA Filter	W	N/A	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Millipore Filter	N/A	W	N/A	N/A
Building 300 IFTF	Cont	GFA Filter	W	N/A	N/A	W
	Cont	Charcoal Filter (Cartridge)	N/A	N/A	N/A	W
	Cont	Millipore Filter	N/A	W	N/A	N/A

Cont The air effluent is measured but passing a continuous sample of the exhaust through a filter. The GFA filter is normally used for beta-gamma, the Millipore normally for alpha, charcoal or silver zeolite for radioiodine, and a water Bubbler for tritium.

W Weekly

N/A Not Applicable

The air to be monitored from the buildings and facilities is drawn past sample probes located in the exhaust vents, pumped through filters and then returned to the exhausts. The WL maintenance planning team performs the measurements for the stack flows and the RP team measures the Sampler flow. The sampler flows at WL are checked during each sample collection period to ensure that they are within the established acceptance criteria, and are re-measured and verified on an annual basis. The release factors are calculated by the WL Environmental Management staff and verified independently on an annual basis. Activities measured in the laboratory are used in conjunction with sampler and exhaust stack flow rates to calculate the release in Becquerels (Bq). The Lower Limit of Detection (LLD) is the product of the release factor of the source and the laboratory Minimum Detectable Activity. For a given radionuclide, the Minimum Detectable Activity and LLD can vary, as they are calculated assuming a 30-minute count time and average detector efficiency, both of which can change.

Derived Release Limits have been calculated for 74 radionuclides for airborne effluents at WL [30]. Separate DRLs have been calculated for on-site workers and for members of the public at the site boundary. For gross alpha and gross beta activities, the DRL applied is the most restrictive from amongst those of the radionuclides that could be present (Sr-90 for gross beta and Pu-239 and Pu-240 for gross alpha).

Sampling procedures, field operating procedures, laboratory procedures, equipment performance checks, quality verification procedures, and laboratory administrative procedures are described in detail in the governing WL Environmental Management documentation.

9.4.1.2.2 Monitoring Results

The airborne emission results are summarized in Table 23 and Figure 3 for the years 2016 to 2021. Average weekly emissions, in Becquerels, are shown for gross alpha, and gross beta for facilities in Buildings 100, 200, and 300. Emissions from Building 100 also includes tritium. In addition, the current year releases, the average release for the past five years and the maximum weekly emissions as a percent of the DRL are given. Emissions from these identified release points are added for each year to provide an indicator of the performance of the site. The reader should be aware that the values for 2021 in Table 23 represent averages that include detection limit values where nothing has actually been detected. The releases from the Reactor Building include gross beta and tritium values that are always above detection, and gross alpha numbers that are often detection limits. The gross alpha releases from the HCF are normally detection levels and the gross beta are often, but not always detection levels. The gross alpha values from the IFTF are always detection limits and the gross beta are a mixture of detects and non-detects.

Airborne emissions remain a small fraction of the release limit. The result for 2021 (0.00019% of the DRL) is similar to 2020, and slightly lower than the average for the last five years. Total site gross alpha in 2021 is lower than in 2020 and the last five years average. It remains near detection limit values. The gross beta emissions are slightly more than in 2020 and similar to the last five-year average. In 2021, the air emissions from all facilities were below Administrative Levels and regulatory Action Levels. In 2021, Building 200 no longer contributed to air emissions. The average values of the previous five years shows that Building 200 had contributed 16 percent of the total alpha air emissions and 8 percent of the total beta air emissions.

Tritium emissions from the WR-1 stack were higher than in 2020 and slightly less than the five year average. During the Phase 1 Decommissioning of WR-1, all bulk heavy water was removed from WR-1, and an exhaustive process of eliminating heavy water and tritium from the reactor piping and tanks occurred. It was concluded that over the lifetime of WR-1, tritiated heavy water was adsorbed into the pipe and tank walls and probably also into concrete walls and floors. Therefore, the moderator system continues to be purged with air flow in order to remove additional tritium from the system and the tritium removal rates have been measured. The tritium emissions from the facility fluctuate with the humidity and temperature as the tritiated water is drawn out of the system. The maximum releases were all below the administrative level (1.52E+10 Bq/week) for the facility and well below the Action Level (7.62E+10 Bq/week) and DRL (1.65E+15 Bq/week). As many gross alpha and gross beta measurements are at or below the LLD, the yearly variations within these extremely small numbers are of very little consequence.

Localized operational workplace air monitoring is conducted as part of the Radiation Protection Program, and this was performed during operational shutdown and decontamination activities associated with Building 100, and work in the Shielded Facilities and Concrete Canister Storage Facility. Outdoor Workplace Air Sampler monitoring was performed for Building 200 demolition. Environmental airborne dust monitoring was performed close to the east, north,

west and south boundaries of the WL campus during building demolitions. The results of the 2021 dust monitoring are described in the *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28].

9.4.1.3 Liquid Effluent Monitoring

9.4.1.3.1 Monitoring Points, Schedules and Parameters

Figure 2 shows the locations of the sources of liquid effluents to the Winnipeg River, including the Outfall, the Lagoon and the numbered ditches.

The primary source of liquid radioactive effluents is the process water outflow (Outfall), which discharges continuously to the Winnipeg River. The discharge from the Outfall is composed of storm water runoff from paved roadways, around buildings through the weeping tile system, cooling water used in process and experimental facilities, and discharges from the Low Level Liquid Waste treatment systems tanks based in Building 100 and Building 300. The ALWTC was taken out of service in 2017 as part of preparations for the decommissioning of Building 200. Holding tanks collect water containing low levels of radioactivity, as a result of cleanup activities associated with operational and decommissioning work, as well as historical activities at WL. The current monitoring schedule and locations are listed in Table 24.

Table 24: Radiological Liquid Effluent Monitoring Schedule – 2021

Cleanup and operational activities associated with decommissioning the site have been underway since 2003 January. Specific activities that may have influenced the 2021 liquid releases are similar to those for the past five years, and include cleaning of footwear and respirators. Radiation Protection introduced the use of disposable rubber shoe covers in 2018, which reduced the contribution from the washing of footwear. The water from these cleaning activities is combined with Building 300 sump water into the Building 300 receiver tanks. Sump water from Building 100 is now directed to the Building 100 receiver tanks. The liquids from these holding tanks are discharged to the Winnipeg River through the Outfall.

An automatic sampler continuously samples the outflow from the Outfall, proportional to its rate of flow. A weekly screening sample (4 L), representative of effluent released from the Outfall during the preceding week, is collected and submitted for uranium and gross beta analysis and scanned by gamma spectrometry.

Monthly composite samples (at least 32 L) are gathered for analysis of total uranium, gross alpha, gross beta, tritium, radio strontium and other radionuclides (Am-241, Cs-137) by gamma spectrometry. Starting in 2017, 3 month composite samples were collected for Pu-239/240, Pu-238 and Pu-241 isotopic analyses. Monitoring for Carbon (C-14) and tritium in Outfall samples was initiated in 2020 because they are known to exist in WR-1, and decommissioning activities have a potential for releasing these isotopes. The activities of tritium and C-14 at the Outfall continued to be below the lower limits of detection.

The secondary source of liquid effluent is the Sewage Lagoon (Lagoon). The Lagoon collects sanitary and wastewater from most buildings on the site, as well as from the laundry facility. The minimum residence time for the lagoon is equal to the amount of time the secondary cell is isolated from the primary cell, to allow for biodegradation and settling. This is typically around 45 days. Prior to each planned discharge, the secondary cell is isolated, and tested for a series of non-radiological parameters (discussed in detail later). If these are acceptable, the accumulated contents of the secondary cell only are released to the Winnipeg River via a small drainage ditch leaving the Lagoon’s north side. In 2021, the lagoon was not discharged at all because there was enough freeboard that a discharge was not necessary.

Whenever there is a discharge, the outflow of the Lagoon is continuously sampled during the discharge. The resulting composite sample is analyzed for gross alpha, gross beta, and radio strontium, and it is also scanned by gamma spectrometry.

Small quantities of radionuclides at levels seen at the Ditch 7 and Ditch 8 sampling locations, are also released to the Winnipeg River from the two ditches indicated in Figure 2. Water from the recharge area east of the WMA is diverted around the WMA to the west-flowing Ditch 9 and into the Winnipeg River. The other, Ditch 8, running northward, drains the land north of the WMA up to the site boundary and beyond. The volume of water in the ditches and resulting flow to the river is entirely dependent on rainfall and spring runoff. Precipitation (395 mm) in 2021 was less than in 2020 (441 mm), and in 2019 (646 mm). The winter of 2021 was very dry. The spring precipitation was normal, but the early summer was unusually dry. Normal amounts of precipitation were observed for August, October and November. Due to the low

precipitation, ditches were only sampled six times during March, April, May and June. The August and October precipitation was captured by the dry ground and there was no moving water in the ditches to be sampled any time after June.

One-litre water samples to be analyzed for radioactivity are collected from the two ditches carrying drainage from the WMA whenever there is sufficient flow from runoff to enable sampling of discharge to the river. At the same time, samples were also collected from the northern ditch bordering Highway 211. This is far enough from CNL's operation to be a reasonable background (Control) sample[7]. The samples are analyzed for gross alpha, gross beta, gamma spec and tritium. If the level of the gross beta measurement exceeds 10 Bq/L, the samples are submitted for radio strontium analysis. Uranium activities are calculated from uranium concentrations obtained from total metals analysis. Surface water samples are collected in and around the WL WMA from locations upstream from these two ditches. The results of these operational control samples are reported in Appendix D of this report.

Derived Release Limits for 63 radionuclides were calculated for liquid effluents at WL [30]. Gross alpha and gross beta measurements provide a quick measurement of the total alpha and beta radioactivity produced by a number of radionuclides, without having to test for those radionuclides. However, as in the case of airborne effluents, the most restrictive DRLs apply to gross beta and gross alpha activity: Cs-137 for beta activity and Pu-239 and Pu-240 for alpha activity. With the introduction of total uranium (U) and isotopic plutonium analysis for the processed outfall, a comparison can be made to the individual contributors to the gross alpha activity. Therefore the comparison to the %DRL of the individual isotopes is presented and the sum of those reported. This is also the case for gross beta.

9.4.1.3.2 Monitoring Results

The liquid emission results[8] are summarized in Table 26 and Figure 3 for the years 2016 to 2021. Average monthly emissions, in Becquerels, are shown for gross alpha, gross beta, total U (including U-234, U-235, and U-238), Am-241, Sr-90 and Cs-137 for the releases from the Outfall and the Lagoon. The monitoring of tritium from the Outfall began in 2019. In addition, quarterly activities of Pu-239/240 and Pu-238 were reported for Outfall effluents. A plot of the monthly Cs-137 and Sr 90 releases as Bq from the Outfall in 2021 is compared with radioactivity (Bq) discharged to the Outfall from the Low Level Liquid Waste (LLLW) treatment systems in Figure 4. Discharges to the Outfall from the LLLW treatment tanks occurred in all months. The total releases of Sr-90 and Cs-137 from the tanks in 2021 were 1.13E+06 Bq and 4.01E+06 Bq, respectively. These releases were only a fraction of the total Sr-90 (2.6E+07 Bq) and Cs-137 (1.3E+07 Bq) releases from the Outfall. There was little correlation between the patterns of

[7] The Control Ditch sample is collected from a location not influenced by CNL's operation, and therefore serves as an indicator of the natural background conditions in the area.

[8] As mentioned in Section 9.2, not all of the radiological results for 2021 have been received from the contract laboratories due to a number of issues, solely impacting the Outfall results for 2021 October through December. Once received, this document will be revised and reissued. The red font text in this section indicates text that will or may need to be updated.

releases from the tanks with the pattern of releases from the Outfall because the tank releases were only a small fraction of the total releases. The additional Sr-90 and Cs-137 activities noted at the Outfall may be from pre-existing contamination in the storm drain system from historical site contamination events and historical radioactivity disposition in the storm drain line from Building 200 LLLW discharges. Some of this contamination may have been from unplanned emissions from the Hot Cells in the 1970's, although more likely from the Building 200 drain line. The high Sr-90 and Cs-137 releases from the Outfall during April, May and August correlate with higher rainfall during these months. The periods of high precipitation are believed to flush contamination into the Outfall from storm drains and previously contaminated process piping.

Note, all monthly releases from the Outfall were well below the administrative release level[9]. Releases of gross alpha were less than the 2020 releases and the five year average. Gross beta releases in 2021 were also less than the 2020 releases and the five year average. Sr-90 releases in 2021 were lower than in 2020 and the five year average. The Cs-137 releases were similar to 2020 releases and below the five year averages. Am-241 releases were greater than 2020 releases. The total uranium releases were slightly lower than in 2020. The relatively constant emissions of gross alpha, gross beta, Sr-90 and Cs-137 from the Outfall over the years suggest a constant source, more like contaminated piping than the effects of recent decommissioning activities. Pu-239/240 and Pu-238 releases were very low, being based on detection level concentrations (% of the DRL less than 0.27). In 2021, Outfall water was also analyzed for the presence of C-14, which could be introduced by the discharge tanks from Building 100. C-14 was below detection levels (varying from 0.99 to 1.26 Bq/L) in Outfall samples. Given that the DRL for C-14 is 1.06E+08 Bq/month, the detection limit of 1.26 Bq/L would correspond to a %DRL value of 0.18. Measurements of C-14 in site intake water from Building 902 were also below detection values.

[9] An Administrative Level is a CNL internal reporting level for radioactive emissions by way of an individual effluent stream. The Administrative Levels are established and maintained by CNL to provide timely warning of above normal radioactive emissions, with the intent of aiding in the application of the ALARA process.

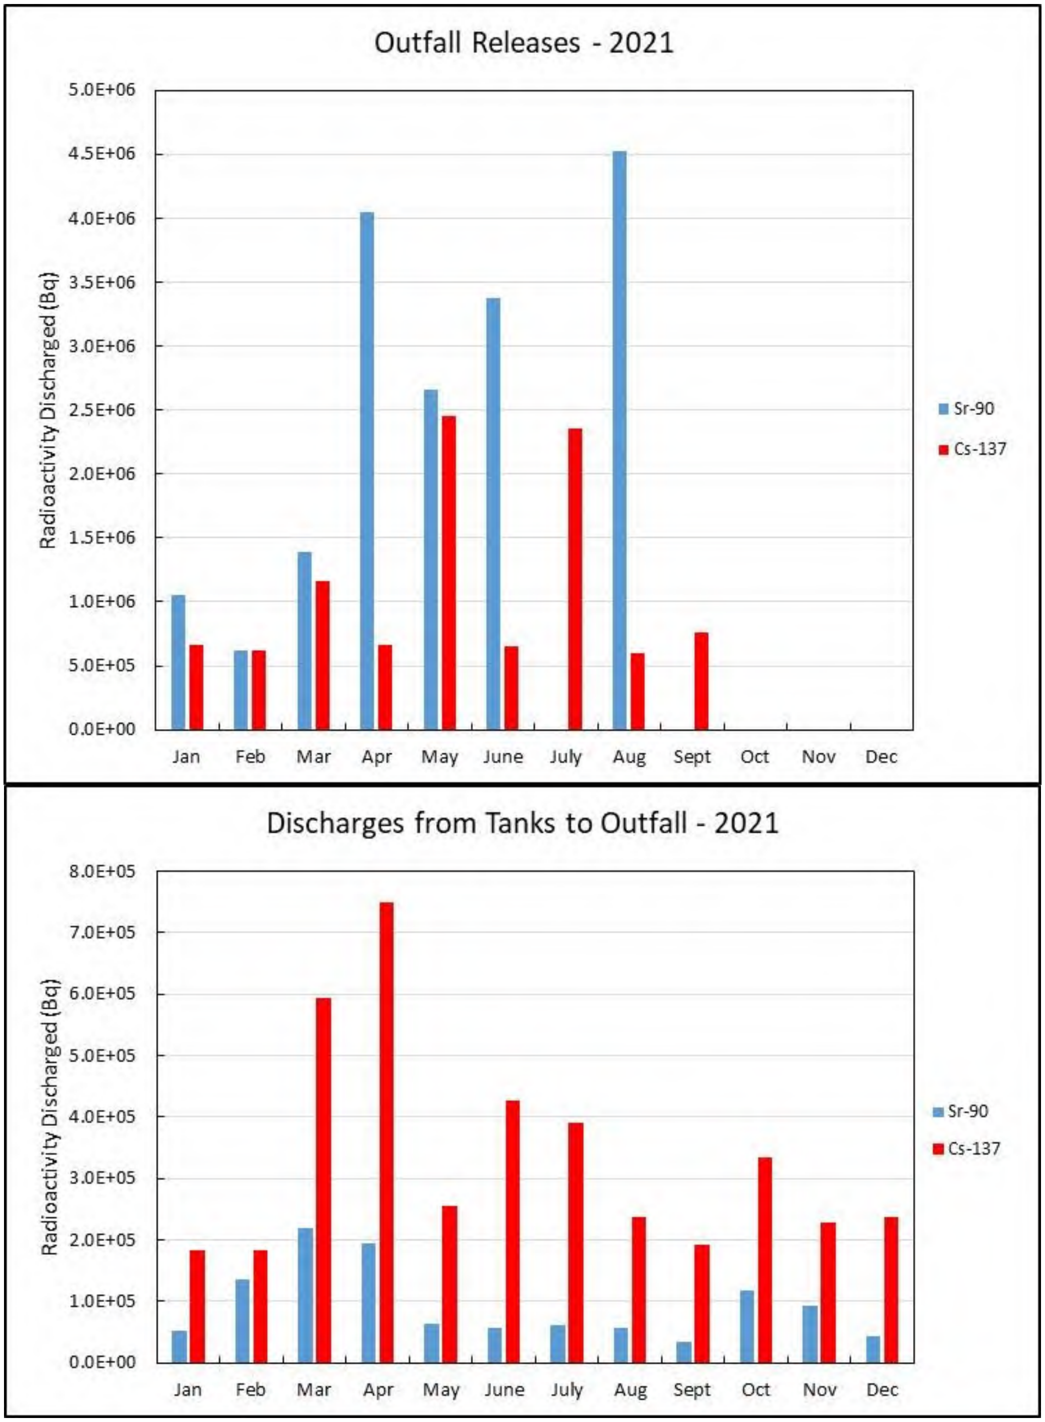

Figure 4: Radioactivity on Outfall Releases and Discharge from Active Liquid Waste Treatment Tanks for 2021

As stated above there were no Lagoon discharges in 2021 and so there are no results to report. In 2021 the lagoons did not contribute to the total liquid discharges from the site.

The averaged results for the two drainage ditches and control sample are shown in Table 25. The reported errors are the standard deviations of parameter values indicating their variability between different sampling events.

a Compliance with Guidelines for Canadian Drinking Water [34] may be inferred if the measurement for the gross alpha and gross beta are less than 0.5 Bq/L and 1.0 Bq/L, respectively. LLD is based on a 1 L sample resulting in less than 100 mg of sample ash and counted for 100 minutes.
b LLD = Lower Limit of Detection.
c Uncertainties are expressed as the standard deviation of the average activity of the processed samples.

During 2021, the gross beta activities in Ditches 8 and 9 were higher than in 2020. The 2021 gross alpha activities were lower in Ditch 8 and slightly higher in Ditch 9 compared to 2020. The average gross beta values were similar to the control sample collected off of Highway 211, given the variability in their values. The gross alpha values were similar to the control ditch. The control sample is unaffected by CNL's operations. Compliance with the *Guidelines for Canadian Drinking Water Quality* [34] may be inferred for gross beta activity since the measurements are all less than 1.0 Bq/L. The gross alpha activity was below the drinking water screening level of 0.5 Bq/L for all samples. The local well waters within the Canadian Shield contain naturally occurring uranium [35] at levels ranging from 0.04 Bq/L to in excess of 2.5 Bq/L. Vertical flow occurs in the surficial Clay unit and in the intermediate Clay Till unit. The head gradient is upward leading the water in these layers to discharge to the surface. Naturally occurring

uranium and its progeny are contributors to the total alpha activity, and could account for levels seen in some of the ditch water samples. In addition, naturally occurring alpha emitters may be present in suspended sediment in some of the samples.

As discussed in Appendix D of this report, the WMA contains a number of trenches with varying amounts of low-level radioactive and conventional waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. The amount measured in drainage Ditch 8 (4.6±0.5 Bq/L) and Ditch 9 (4.7±0.4 Bq/L) were not significantly different from that noted at the control location (4.4±0.9 Bq/L). A number of ditches close to WMA are known to contain tritium. In 2021, the amount of tritium reaching the Ditch 8 and 9 locations was not significant. The tritium activities measured at all three ditch locations are much lower than the Guidelines for Canadian Drinking Water Maximum Acceptable Concentration for tritium (7000 Bq/L) [34].

Table 26 summarizes the data for releases of liquid effluents[10] for the years 2016 to 2021. The average monthly releases, expressed as a percent of the DRLs, are added for the various sources on site to provide a quantitative indicator of the performance of the site. The average total release for 2021 was 0.49% of the DRL, which is lower than 2020 and the five-year average (0.51%). The main reason for the higher 2019, 2020 and 2021 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. The highest monthly release from the Outfall in 2021 was Pu-239/240 at 0.29% of the DRL. There were no lagoon discharges in 2021.

9.4.2 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is determined for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results as a result of equipment failure, maintenance/calibration outages, or operator action requires “unavailability” to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 27) for monitoring equipment on effluent streams with effluent rates that are normally ≥ 0.5% of weekly DRLs are set more stringent (for unplanned unavailability) than for those streams with normal effluent rates < 0.5% of weekly DRLs. Unavailability is expressed in hours of unmonitored effluent releases per year, and applies separately to each monitored parameter, on each effluent stream.

10 The radioactivity from Ditches 8 and 9 was found to be below the Canadian Drinking Water Screening Level [34] for both gross beta and gross alpha activity, within the uncertainty of the analysis. Tritium levels were well below the Canadian Drinking Water Maximum Acceptable Level. The contributions were considered insignificant due to the small volume of release, and are not included in the liquid release table.

Table 26: Radionuclides in Liquid Effluents from WL – 2016 to 2021

TOTAL as %DRL	**-**	**-**	**3.24E-01**	**2.61E-01**	**3.79E-01**	**9.27E-01**	**6.71E-01**		**5.10E-01**		**4.72E-01**		**9.06E-01**

a In 2018 monitoring for Outfall began for U-total, Pu-239/240 and Pu-238. In the Lagoon Pu-239/240 was calculated from gross alpha mass balance. The %DRL is reported for these isotopes instead of gross alpha. Note that Pu isotope activities are detection level values and Am-241 and Cs-137 activities are very close to detection levels.

b Gross beta releases are not included in the %DRL totals as the regulated components of the gross beta (Cs-137 and Sr-90) are already accounted.

Table 27: Effluents Monitoring Equipment Unavailability – 2021

	Unavailability Criteria[a]		Number of Exceedances
Air effluent streams with normal emission rate ≥ 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	84 hours/year/stream	0
Air effluent streams with normal emission rate < 0.5% of weekly DRL.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0
Continuously monitored liquid effluent streams.	Planned	168 hours/year/stream	0
	Unplanned	288 hours/year/stream	0

a See Table 7 in 900-509200-STD-009.

Unavailability criteria (see Table 27) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2021, there were no instances in which the unavailability criteria (Table 27) outlined above were exceeded. In Building 100 there was one instance when the stack pump went down for a long weekend, resulting in 112.5 hours of unplanned loss of air monitoring. In the Shielded Facilities there were three instances of planned loss of monitoring because class III power was shut down for electrical equipment inspections. The total planned loss of monitoring, affecting the Hot Cells and IFTF was 6.5 hours. There were 3 instances of planned unavailability to Outfall monitoring that were due to required electrical power supply shut down to facilitate decommissioning activities, this amounted to a total of 5.2 planned hours of monitoring unavailability for liquids. There was one instance of unplanned Outfall monitoring, amounting to 14 hours, occurred when the motor on the sampling equipment at the outfall monitoring station failed and required replacing. In each instance an estimate of the release during unavailability was calculated as per procedure. In each instance, an estimate of the release during unavailability is calculated per procedure (if the lost time is 5 percent or greater of the total monitoring interval).

9.4.3 Overall Performance

Figure 3 summarizes the data presented in Table 23 and Table 26 on site-wide airborne and liquid emissions, expressed as totals of percentages of DRLs (the lower rows of the tables) for the years 2016 to 2021. The average emissions for the past six years continue to be very small. Liquid emissions of radioactive material from WL in 2021 were below CNL's Administrative Levels and Action Levels, and continue to be very small compared with the applicable DRLs [30]. All air emissions were below CNL's Administrative Levels and Action Levels.

Total radioactive airborne emissions from the WL site during 2021 continue to be very low, averaging 0.00019% of the DRL, which is similar to 2020 and lower than in 2019.

Radioactivity in the WL liquid releases for 2021 was 0.47% of the DRL which is lower than in 2020 (0.67%) and the last five-year average (0.51%). The main reason for the higher 2019 to 2020 liquid releases was an increase in the detection limit values for Am-241 and Pu-239/240, since both isotopes were below detection limits. Pu-239/240, at detection limit values, was the primary contributor to the Outfall, averaging 0.17% of the DRL. The level of tritium activity noted in the two ditches carrying drainage from the WMA remains well below the Maximum Acceptable Concentration for Drinking Water.

The 2021 release results, as well as the previous years' trends, indicate that CNL has taken reasonable precautions to control the release of radioactive nuclear substances within the site, and into the environment, as a result of the licensed activity. All airborne and liquid release results are consistent with the clean-up and operational activities associated with decommissioning of the site.

The results of the monitoring program demonstrate that controls for the release of potentially hazardous substances currently in place at WL continue to provide substantial protection of the environment.

9.5 Effluent Monitoring – Non-Radiological

This section addresses the licence requirement on hazardous substances monitoring of liquid and airborne effluents for the WL site for 2021. It also fulfills similar effluent monitoring requirements listed under Work Package 1 of the *Environmental Assessment Follow-Up Program* [28].

9.5.1 Liquid Effluent Monitoring

9.5.1.1 Monitoring Points, Schedule, and Parameters

Whiteshell Laboratories staff members collect samples for non-radiological parameters from eight different monitoring points. The first four are the Sewage Lagoon (referred to as the Lagoon) at point of discharge to the Lagoon drainage ditch, the Process Outfall (referred to as the Outfall), the North drainage ditch (referred to as Ditch 8), and the West drainage ditch (referred to as Ditch 9). These effluents flow directly to the Winnipeg River. Two monitoring locations measure internal process wastes leaving the Low-Level Liquid Waste Treatment Systems (LLLWTS) from Building 300 and Building 100. The remaining two monitoring locations are used as background monitoring locations, and are the Intake water taken from the Winnipeg River at the Pump House (Building 902), and a control ditch on provincial Highway 211. More details for each monitoring area are provided in the sections that follow.

Referring to Section 9.4 of this report, Figure 2 shows the locations of the waste stream sources monitored, and where appropriate, their source or release points to the Winnipeg River. Ditch 8 meets the river some distance downstream (north) of the site boundary.

Table 28 lists the non-radiological parameters monitored at the inlet and effluent streams sampled, and the sampling schedule that is followed. The WL monitoring program follows the

protocols from the Ontario Ministry of Environment [36] in its Municipal/Industrial Strategy for Abatement program. Under that system, parameters that are normally measured by the same analytical technique are grouped into numbered Analytical Test Groups. These are described in Table 29, which includes information about the Regulatory Method Detection Limit (RMDL), Laboratory Method Detection Limit (LMDL) and the Smallest Reporting Increment (SRI). The LMDL and SRI were decided following protocol. The WL monitoring program also meets the requirements set out in the Federal Wastewater Systems Effluent Regulations [37], and the standards from CSA N288.5-11, *Effluent Monitoring Programs at Class 1 Nuclear Facilities and Uranium Mines and Mills* [20].

25	Oil & Grease	Monthly	Discharge	Discharge	Discharge	Discharge	Discharge

a ATG = Analytical Test Group; BOD = Biochemical Oxygen Demand; CBOD = Carbonaceous Biochemical Oxygen Demand; TSS = Total Suspended Solids.

b The Monthly = grab sample taken once within each month.

Intake water was sampled each month as grab-samples are drawn from the wet well of the Pump House (Building 902).

In 2021, there was no discharging of the Lagoon.

At the Outfall, daily monitoring and weekly samples are collected for non-radiological parameters.

The ditches are sampled only when water is flowing freely within them, and at a maximum frequency of once per week. This occurs after snowmelt or significant rainfall, of which there were six events in 2021.

Whenever a tank was discharged at either of the Low Level Liquid Waste Treatment System's (LLLWTS), the effluent was sampled.

9.5.1.2 Analytical Protocol and Results Evaluation

With minor modification, the protocols for sample collection, and result reporting used here, are adopted from the Ontario Ministry of Environment publication *Protocol for the Sampling and Analysis of Industrial/Municipal Wastewate*r [36]. The protocols are used under Ontario's industry-specific effluent monitoring and limits regulations. The system supplies a justifiable set of methods to ensure that the final reported result is representative of the effluent sampled. Guidance is given on sampling of wastewater streams, sample handling including pre-treatment, and acceptable analytical techniques. Some of these are common to more than one parameter, so they are grouped into Analytical Test Groups, listed in Table 29. Ontario Ministry of Environment protocols were used again this year, as they have been historically. It should be noted that the Manitoba government has no such comprehensive protocols for sample collection, preservation, analyses, and result reporting.

Table 29: Listing of Analytical Test Groups

25	Oil & Grease	Gravimetry	mg/L	1	--	--	1.0

a The method ICP = Inductively Coupled Plasma Spectrometry. This is a common method for metals analysis.

b The unit MPNU = Most Probable Number Unit, as reported by accredited contract laboratory. The MPNU is a common estimate of bacterial counts, especially for sewage effluent.

c RMDL = Regulation Method Detection Limit

d The LMDL = Laboratory Method Detection Limit ("MDL" also used).

e The SRI = Smallest Reporting Increment.

9.5.1.3 Unavailability of Effluent Verification Monitoring

The unavailability of effluent verification monitoring is found for all on-line Environmental Protection Program monitors as follows:

- Absence of monitoring or monitoring results because of equipment failure, maintenance/calibration outages or operator action requiring "unavailability" to be assigned.
- Routine sample media changes on the monitoring equipment are not considered to be part of unavailability of the equipment.
- Unavailability criteria (see Table 27) are set separately for planned and unplanned events.

Examples of planned unavailability include routine maintenance or inspections, and calibration activities, while unplanned unavailability includes events such as detection and repair of unexpected monitor or monitoring equipment failures.

In 2021, there were no instances in which the unavailability criteria (Table 27) outlined above were exceeded. There were no instances of non-radiological air monitoring unavailability. There were 3 instances of planned unavailability to Outfall monitoring that were due to required electrical power supply shut down to facilitate decommissioning activities. This amounted to a total of 5.2 planned hours of monitoring unavailability for liquids. One instance of unplanned Outfall monitoring, amounting to 14 hours, occurred when the motor on the sampling equipment at the outfall monitoring station failed and required replacing. In each instance an estimate of the release during unavailability is calculated per procedure (if the lost time is 5 percent or greater of the total monitoring interval).

9.5.1.4 Monitoring Results

In the following sections, there are two types of presentation formats used in reporting the results obtained in 2021. These include an averages summary table and a comparison against the CNL's Monthly Guideline Acceptance criteria, for the effluent at identified monitoring locations.

9.5.1.4.1 Averages Summary Table

Summarized results for 2021 are presented in Table 30 through Table 34. The first two columns in the tables identify the Ministry of Environment ATG and parameter names [36]. The next three give the CNL monthly guideline concentration, LMDL (Table 29) and units for each measurement. The next six columns provide comparison of the average concentrations reported for the five previous years, followed by their arithmetic mean. The next seven

columns have a summary of the results for the 2021 monitoring period (explained further below).

WL previously discontinued on-site analysis of most of the non-radiological parameters. The samples are now shipped to external ISO 17025 accredited laboratories through a sample management office. The LMDL for the laboratory analyzing the parameter is provided in Table 29.

Within the 2021 results section, the number of samples included in the average ("# Spl.") is reported. This number is not constant down the table. It depends on the sampling frequency chosen for each parameter, and sample mixing to prepare composites for analysis. The next column (labelled "ND's") gives the number of samples in which the analyte was not detected and was therefore deemed a "zero" result.

The minimum, maximum and average values of each parameter are based on individual results and not monthly averages. These results are given in the tables found at the end of the section, and include any results that were zero by virtue of being non-detectable in the laboratory. The relative standard deviation of all results is also reported, expressed as a percentage of the average. This number allows some evaluation of scatter inherent in the samples and measurement method. Usually, sample variability dominates (i.e., the effluent composition changes over time).

In Table 31 through Table 34, yearly average values for parameters marked with an asterisk show that a monthly guideline was exceeded for at least one month during the calendar year being presented.

For convenience, the total annual load to the environment (Winnipeg River) represented by each of the analytes is also presented, expressed in kilograms. The calculation process is described in detail in Section 9.5.1.5 (where the results for the Lagoon and Outfall monitoring points have been collected in Table 36, and compared to the previous five years).

Table 30: Averages Summary for Intake

					Monitoring Point: Site Intake													
					Averages from Previous Five Years[a]						Results for Year 2021							
ATG	Parameter	Monthly Guide[b]	LMDL	Unit	2016	2017	2018	2019	2020	Average	# Spl.[c]	NDs[d]	Min.	Max.	Avg.[a]	RSTD (%)[e]	Load (kg)

b Averages were calculated by setting to zero results reported as "< DL."
c Monthly Guide is from CNL's limits for non-radiological parameters in liquid effluents procedure. For mercury, the Daily Guideline is given instead, as there is no Monthly Guideline specified
d # Spl. is the number of samples analyzed and reported.
e NDs is the number of samples in which analyte was not detected (i.e., Code = "< DL," result = 0).
f RSTD = Relative Standard Deviation
N/A = not applicable
Notes: Any averages with an asterisk show that a monthly guideline was exceeded in one or more months for the given parameter in the year.

Discharges of effluent coming from the new low level liquid waste treatment systems are being combined, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.2 Monthly Guideline Acceptance

CNL guidelines were used as the basis against which emissions from WL were evaluated. They are not regulatory requirements, but instead have been adopted by CNL to routinely evaluate the environmental significance of both process-type and non-process type discharges from WL. Table 35 supplies a summary of each of the liquid effluent parameters that had exceeded its CNL monthly guideline in 2021 or at any time during the previous five years.

As with the average summary table provided, for each monitoring point, the first two columns in the table identify the Ministry of Environment ATG and parameter names. The next three columns give the CNL monthly guideline concentration, LMDL, and the units of measurement. The next six columns present the monthly guideline acceptance for each of the five previous years and the average of those five years expressed as a percentage. The last three columns show the number of months during which discharges occurred, the number of times the monthly guideline was exceeded for each parameter, and the subsequent percent of times the parameter levels met the acceptance criteria.

To assess any significant level of change and evaluate program performance, this table will be referred to in each section discussing monitoring point results.

Table 35: Parameters that Failed to Conform to CNL Monthly Guidelines

						Monthly Guideline Acceptance (%) for Previous Five Years						Results for Year 2021		
Effluent Stream	**ATG**	**Parameter**	**Monthly Guide**	**LMDL**	**Unit**	**2016**	**2017**	**2018**	**2019**	**2020**	**Average**	**# Mth.**	**> Monthly Guide**	**Accept (%)**
LLLWTS /ALWTC	6	Phosphorus	1.0	0.003	mg/L	100	100	100	83	100	96.6	12	4	67
	8	TSS	25	1.0	mg/L	100	78	92	100	92	92.4	12	0	100
	9	Copper	0.5	0.0005	mg/L	100	67	33	42	58	60.0	12	2	83
	9a	Iron	1.0	0.010	mg/L	67	44	50	83	42	57.2	12	8	33
	9	Zinc	0.5	0.005	mg/L	100	100	100	100	100	100	12	1	92
	14	Phenolics	0.02	0.0010	mg/L	100	100	92	100	100	98.4	12	0	100

Notes:

- Effluent stream parameters which have not exceeded a monthly guideline in the current year or in the previous five years have not been included to this table.
- Discharges of effluent coming from the new low level liquid waste treatment systems are being considered as emanating from the ALWTC, as it allows for comparisons to the data collected over the previous 5 years

9.5.1.4.3 Monthly Guideline Plots

For parameters that have a value higher than a CNL monthly guideline, the monthly plot of values is shown for that parameter at the monitoring point. This year there were 9 months when one of four parameters (Iron, Copper, Phosphorous and Zinc from the LLLWTS had monthly values higher than CNL monthly guidelines. Figure 5 shows the number of times the monthly guidelines have been exceeded at any monitoring point over the last five years. Plots are displayed in Figure 6, Figure 7, Figure 8 and Figure 9 for each parameter, and the explanations for the observed high values can be found in Section 9.5.1.4.6. The monthly or daily guideline limit for the parameter in question is shown by a broken red line in the corresponding figures.

9.5.1.4.4 Monitoring of Intake Water from the Winnipeg River

Except for bottled drinking water, all the water needed to run the WL site is drawn from the neighbouring Winnipeg River at the Intake. The amount of water drawn from the Winnipeg River varies from year-to-year.

Grab-samples are collected each month from the Building 902 wet well to assess the levels of certain parameters that may be entering the site directly from the Winnipeg River. The measurements are summarized in Table 30, where they are compared to available data for the previous five years. Figure 10 shows the estimated amount of water used monthly for 2021.

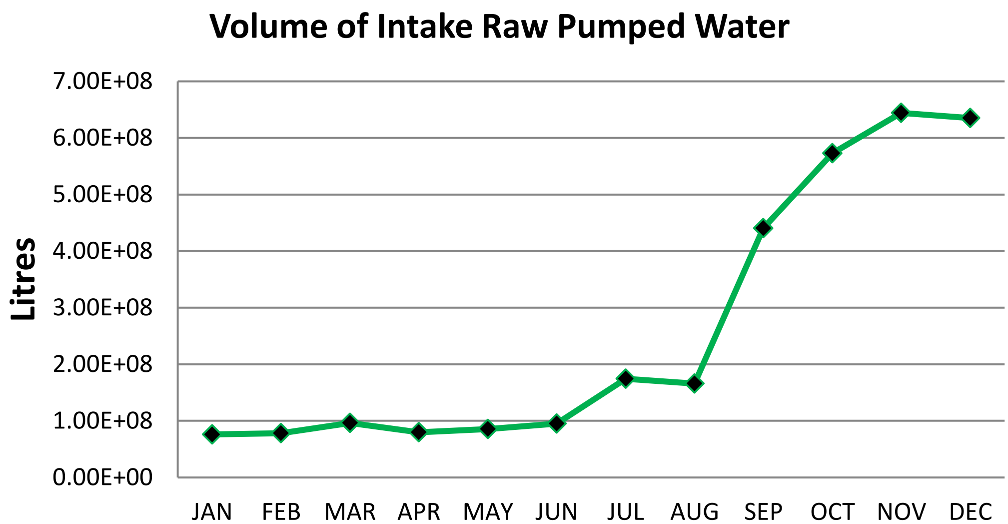

Figure 10: Monthly 2021 Intake Raw Pumped Water for the WL Usage

The following are notable points for the 2021 Intake water from the Winnipeg River:

- The Pump House flow meter recorded that 3.14E+06 m^3 of water was pumped from the river over the year.
- Compared to the five-year average, increased concentrations (> 10%) were seen for Chromium, Copper, Nickel, and Bromodichloromethane.
- Parameters that had their concentrations improve (> 10% decrease) this year compared to the average seen for the last five years are Phosphorus, TSS, Iron, Lead, Mercury, Phenolics, chloroform, and Oil & Grease.
- Water consumption for the site drastically increases during misting operations that are employed during building demolition. As these operation progress into sub-zero temperatures, a further increase is also observed, as a high flow of water is utilized to ensure the water lines do not freeze.

Intake water results can have a significant impact on the environmental performance of the WL site and they will continue to be monitored closely.

9.5.1.4.5 Monitoring of Liquid Effluents to the Winnipeg River

Two effluent streams, the Lagoon and Process Outfall, discharge significant volumes of water to the Winnipeg River. Normal surface land run off also reaches the river through Ditches 8 and 9. Results from monitoring each of these sources are discussed below.

9.5.1.4.5.1 Lagoon

The WL Lagoon secondary cell was not discharged during 2021. With reduced personnel on site due to the COVID-19 pandemic, the occupancy of Building 540 (modular office complex) which

has its bio-waste diverted offsite, and the low level of precipitation observed in 2021, the lagoon had enough freeboard to allow the site to operate into 2022 without discharging.

The total amount of effluent discharged from the Lagoon in 2021 was 0 m^3.

If the lagoon was discharged, the Lagoon would be tested for CBOD, fecal and total coliform bacteria, and acute lethality (a biological assessment on the survivability of trout in the proposed effluent). These samples are collected by the Lagoon operators at defined areas in the secondary cell after isolation of the cell occurs. During discharge, grab-samples would be collected close to the pipe emptying into the receiving ditch that leads to the Winnipeg River. Individual samples for most parameters would be collected on a weekly basis during the discharge.

The vertical scale from which surface height is found was carefully adjusted to read absolute depth from the original floor of the Lagoon. This was done because the equation for calculating the contained volume in the secondary cell for any depth is derived from the calculation for the volume of a rectangular trapezoidal trough:

Volume (in L) = Height x [Width_Bottom x Length_Bottom
+ 0.5(Width-Width_Bottom) Length_Bottom
+ 0.5(Length-Length_Bottom) Width_Bottom
+ (1/3) (Width-Width_Bottom) (Length-Length_Bottom)]

Knowing the dimensions and geometry, the contained volume in the secondary cell can be calculated accurately for any depth using the following equation:

Volume (in L) = $636\,655 \cdot d + 206.886 \cdot d^2 + 0.02133 \cdot d^3$ for depth “d” (in cm)

The position of the Lagoon’s water surface would be recorded once or twice daily while emptying. The daily flow would then be calculated from changes in the contained volume. This permits the calculation of volume-weighted concentrations and overall loads (see Section 9.5.1.5). Volume-weighted averages for a given period (month or year) are given by summing the product of the concentration for each day multiplied by the volume released that day, then dividing that sum by the total volume discharged during the period. Unlike other monitoring points (which are continuous or batch releases of fixed volume), the Lagoon discharge flow rate can vary widely. The variation makes weighting corrections highly significant in deciding meaningful average concentrations.

Discharging of the secondary cell is only allowed to proceed after initial testing. Once discharging begins, the pH is checked daily throughout the discharge period.

Table 31 summarizes the results of the fall discharge. Some notable points are:

- There was no effluent discharged from the lagoon in 2021.

9.5.1.4.5.2 Process Outfall

The Outfall monitoring station functioned as expected during 2021. The total discharge volume was 1.15 GL. This volume is lower than the previous five-year average of 1.23 GL.

The Outfall discharges continuously. Measurements were performed on the samples weekly. This provided 52 samples of each parameter for the year.

Table 32 summarizes the results obtained, and compares them to averages for the previous five years. Notable results for the Outfall are:

- There were no instances of CNL's monthly guidelines being exceeded at the Outfall monitoring station.
- The only parameters that had a significant increase (> 10%) compared to the 5-year average were TSS, Copper, Nickel, and Zinc. The increased TSS loads are a reflection of the demolition activities occurring on site, while sediment controls are put in place to mitigate the impact, an increased load of sediments are entering the storm drain system. The increase in nickel and copper concentrations being observed are related to the elevated levels being observed at the intake this year. Zinc is being detected close to the detection limit, a slight increase seen in the concentrations is having a significant percentage increase being measured in the Outfall, especially since the 5-year average concentration is below the method detection limit.
- Compared to the five-year average, Phosphorus, bromodichlormethane, chloroform, Phenolics, and Oil and Grease concentration levels significantly decreased (>10%).
- Quarterly Acute Lethality Testing on the Outfall effluent was not successful in 2021, as CNL missed collecting samples for the second and third quarter of the calendar year. A corrective action plan has been developed to prevent reoccurrence.
- Acute Lethality Testing for the outfall effluent in first and fourth quarter showed no mortality on the rainbow trout tested.

Overall, there were no concerns about the effluent discharged from Outfall during 2021.

9.5.1.4.5.3 Drainage Ditches

Much of the land surrounding key remote facilities at WL is drained by two structures. Ditch 8 drains the land north of the WMA up to the northern site boundary and beyond. Water from the landfill and recharge area on the east is diverted instead around the WMA to the west-flowing Ditch 9, and into the Winnipeg River. These ditches are monitored for radiological and non-radiological content. The radiological part is discussed in Section 9.4 of this report and the non-radiological part is discussed here.

Ditches 8 and 9 were grab-sampled each time water was flowing off-site. This was after heavy rainfalls, of which there were six events from 2021 April to October. At these same times, a sample was collected from the northern ditch bordering Highway 211. This is far enough from CNL operations to be a reasonable background (Control). It was not possible to measure the

flow rates at any of the locations, or to sample representatively over entire rain events; therefore, no loads can be calculated.

Comparison is made to CNL guidelines (although they are intended for process discharges). All values were below CNL monthly guidelines this year. The measurement data are summarized in Table 33. The following are notable points for the 2021 ditches results:

- There were only six sampling events for the ditches. The sample events were also predominately influenced by the spring melt as four of the six events were related to water flows experienced during this period, in other years rain fall events made up the majority of the sampling events.
- Zinc and Mercury were the parameters that had a significantly higher concentration (>10%) than the previous five-year average for Ditch 8. The parameters that had a significantly higher concentration (>10%) than the previous five-year average for Ditch 9 were Phosphorus, Copper, Zinc, and Mercury. The control ditch had TSS and Copper being observed at significantly higher concentrations (>10%) than the previous five-year average.
- Metal concentrations detected are very close to the detection limit, so a slight increase seen in the concentrations has a significant percentage increase being observed in Ditch 8 and Ditch 9.
- The five year average for phosphorus in ditch #9 was higher this year due to the reduced sampling. It is not uncommon for the spring melt to observe elevated phosphorus concentrations due to the decaying vegetation from the fall, but the phosphorus concentrations throughout the summer during rainfall events are typically lower and would drive the average down.
- All concentrations remain well below the CNL's monthly guideline limit and pose no concern.
- All parameters measured in Ditch 8 and Ditch 9 are comparable to those measured within the Control Ditch, indicating that WL had negligible effects on the environment through these two pathways.

It should be noted that sediment control measures were put in place for projects in the WMA in 2021, as was the case in previous years.

9.5.1.4.6 Internal Liquid Discharge Monitoring

Building 300 and Building 100 both have a LLLWTS; each system represents a major area that generated low-level radioactive liquid wastes. Individual tank releases are monitored for operational control purposes.

A full tank must be emptied while a second tank is being filled. When full, tanks are sampled; if the pH and radioactivity levels meet discharge criteria, they are discharged. The LLLWTS tank pre-discharge criteria do not include all parameters listed in CNL's non radiological guideline limit values; however, the post-discharge analysis includes all these parameters. CNL staff have

determined, through historical data analysis from post-discharge samples, if the pH in the tank is adjusted to neutral, all other parameters will normally meet the guideline limit values. All post-discharge data is reviewed to ensure this process is working as intended, and program requirements are met. All effluents pass through a 5-micron bag filter to the Process Outfall, leading via the Outfall to the Winnipeg River.

The tanks in the new system have a smaller holding capacity so the frequency of discharges has increased. The new system was designed with a shorter life span in mind than the earlier system that was employed by CNL. This was done to align with the decommissioning schedule being implemented by CNL. Discharging requires a day or less to complete, and can be more gradual if needed.

Grab-samples are taken after the filter, and at the beginning of each release from the individual tanks. Measurements are performed on the effluent of each discharge to measure pH and conductivity. For other analytes, grab-samples are collected and analyzed by a designated laboratory to complete the characterization of the effluent being discharged.

In regards to monitoring the non-radiological parameters of the effluent for this reporting period, discharges of the new systems are being compared to the discharges from the ALWTC that was used in previous years. This allows for comparisons of the previous 5-years of effluent to continue to be made, as the effluent streams emanating from the Research and Development (R&D) Complex in Building 300 and Building 100 should still be similar enough that a comparison is worthwhile.

In 2021, 0.09 ML was discharged from the LLLWTS.

The weighted averages of the joint releases from the LLLWTS are presented in Table 34 and monthly plots for the parameters that exceed the monthly guidelines are in Figure 6, Figure 7, Figure 8, and Figure 9.

The following are notable results for 2021:

- None of the monthly exceedances that occurred at the LLLWTS resulted in exceedances being observed at the Outfall monitoring location downstream in the process.
- There were increases (> 10%) in the annual average concentrations of Phosphorus, Chromium, Lead, Nickel, and Oil and Grease, compared to the previous five-year average results.
- The Iron concentration coming from the LLLWTS exceeded the CNL monthly guidelines eight times (January, February, March, April, June, July, August, and November). The overall Iron concentration seen for the year is lower than the previous 5-years. The introduction of the environmental laboratories in Building 300 at the end of 2019 increased the amount of Iron being introduced into the system (through the lab processing soil samples), as a number of the drain lines in the environmental laboratories are being directed to the LLLWTS in the facility. The majority of the effluent being generated by the environmental laboratories does not require the treatment

operations offered by this system, but it is possible it is affecting the effluent stream non-radiological characteristics.

- Early in 2021 (January-March), it was identified that the environmental laboratories and sample management office practises were having a negative impact on the effluent, as acid wash water and the clean out of expired acid-preserved sampling bottles was not properly being neutralized prior to disposal down the drainage system. In Figure 6, the drop in iron concentrations in the LLLWTS effluent can be observed when cleaning practises were improved. The improper disposal of the acidified wash water is being identified as the major cause of the increased metal concentrations being observed in the first four months of the calendar year.
- The Copper concentration coming from the LLLWTS exceeded the CNL monthly guidelines two times in 2021 (February and March). Frequent exceedances are being seen in relation to the new tank systems that were installed in Building 300 as a decision was made to use copper piping in the new system instead of the stainless steel that was used in the old system. As soon as the new tanks were commissioned and used, the copper concentrations of the generated effluent noticeably increased to the guideline limit, but the concentration seen at the Outfall is still well below the monthly guideline limits.
- The Zinc concentration coming from the LLLWTS exceeded the CNL monthly guidelines a single time in February.
- The phosphorus concentration in the Building 300 effluent has effectively doubled, and exceeded the CNL monthly guideline limit four times throughout the calendar year (March, August, September, and November). As this trend did not exceed a monthly administrative level it was not identified until all the data was compiled for the year, and the cause of this increase is currently unknown. The plot of the monthly concentrations for phosphorous appears to be correlated with the increased cleaning frequency (due to muddy work boots) that would be associated with the spring and the fall periods. CNL will begin with reviewing the current selection of cleaning products being utilized in Building 300.

9.5.1.5 Loading Calculations

For the Lagoon, the volume-weighted average concentration of a parameter was calculated as follows:

1. The measured concentration for each day was averaged with that of the next day;
2. The average was multiplied by the estimated volume discharged over the 24-hour period;
3. The products for all days were summed, then;
4. The resulting sum was divided by the total volume released during the period (Spring, Fall or entire year). The load was then given as the product of the calculated volume-weighted average concentration, multiplied by the total volume for the period.

At the Outfall, the total discharge volume for each month was multiplied by the monthly average concentration of the parameter.

Table 36 shows the results from the calculations described above, grouped by parameter and by final outflow source. All mass-related parameters are shown. The table also compares them to previous years, and to the five-year averages.

Note that LLLWTS discharges are not included here, as they are reflected in the Outfall loads, and ditches are also not included as lack of flow data prevents their calculation.

When examining the WL site total loads, notable results are:

- The Lagoon did not contribute to the observed loads in 2021 as it was not discharged.
- TSS, Nickel and Zinc are the parameters that had a load increase greater than 10% when compared to the five-year average.
- Unlike 2020, this increase in overall load for TSS is not tied to a similar increase being observed at the intake and is directly tied to demolition work occurring on site for 2021.
- The increase in the Nickel load is related to the increase in Nickel concentrations being observed in the Intake water being utilized by the site.
- The increase in Zinc is being attributed to the results at the Outfall over the years being detected very close to the detection limit, so a slight increase seen in the concentrations has a significant percentage increase.
- Phosphorus, Chromium, Mercury, Lead, and Oil and Grease had a significant decrease of 10% or more in their loads when compared to the 5-year average.

Table 36: Loading for the Current Year and Previous Five Years

ATG	Parameter	Monitoring Point	Loadings from Previous Five Years (kg) [a]						Results for Year 2021		
			2016	2017	2018	2019	2020	Average	# Spl. [b]	NDs[c]	Load (kg)

a Averages were calculated by setting to zero results reported as “< DL.”
b # Spl. is the number of samples analyzed and reported.
c NDs is the number of samples in which analyte was not detected (i.e., Code = “< DL”, result = 0).

9.5.2 Airborne Effluent Monitoring

Airborne emissions from the WL site are compiled on an annual basis for the purpose of reporting under the National Pollutant Release Inventory (NPRI) and the federal Greenhouse Gas (GHG) report. These emissions are also recorded for trending and improvement purposes. Radiological releases are covered in Section 9.4 of this report. Only non-radiological releases to the air will be covered in the following sections.

9.5.2.1 Fuel Use for Building Heating

Historically, the main stationary source for non-radiological emissions to air from the WL site was the Powerhouse which supplied district heating to various buildings on the site (see Figure 2). Starting in 2013, use of, and emissions from Number 2 fuel oil heating operations at the Powerhouse, ceased due to the completion of building conversions to either propane or electrical heating. Subsequently, a substantial increase was seen for cleaner burning propane used on site. Table 37 presents WL heating fuel consumption from 2016 to 2021. Fuel consumption continues to trend downward (see Section 9.7.2 and Figure 11).

Table 37: Fuel Use for Building Heating from WL

		Data for Previous Five Years						Data for 2021
Parameter	**Unit**	**2016**	**2017**	**2018**	**2019**	**2020**	**Average**

b Energy released calculated from consumption at 2.718E-05 TJ/L for propane

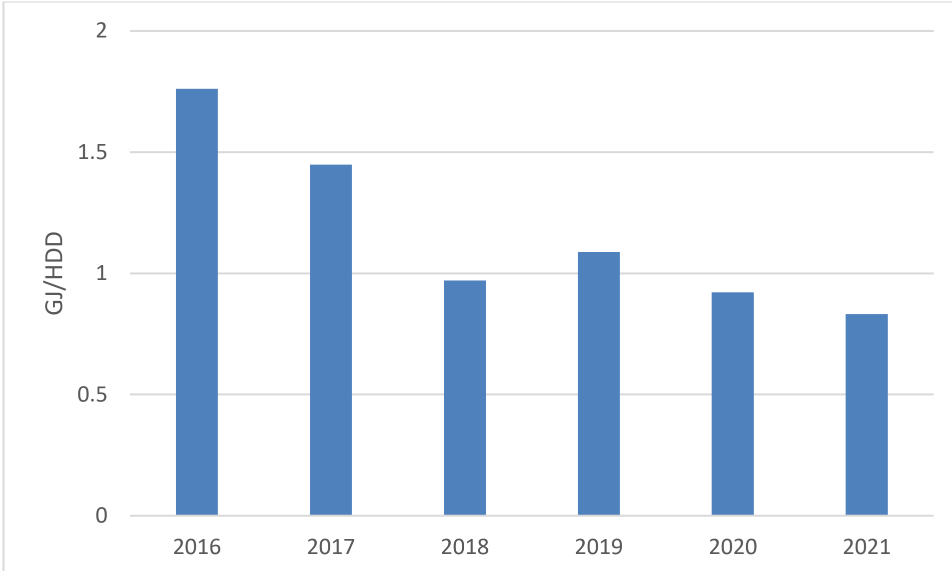

Figure 11: Annual Heating Energy Use from Fossil Fuels (per Heating Degree Days)

9.5.2.2 Reporting Under the National Pollutant Release Inventory

Under the authority of the *Canadian Environmental Protection Act*, 1999 [38], WL currently calculates releases of Part 4 substances for the NPRI program, using government reporting guidelines [39]. These releases to air include emissions caused by burning of Number 2 fuel oil and propane for heating (as discussed above), as well as diesel fuel used from site generators, dust emissions from unpaved roads, and excavation projects.

Emission factors are applied to fuel consumption data, as well as estimated kilometres travelled on unpaved roads, to determine the amount of Criteria Air Contaminants (CACs) that are generated on site. Criteria Air Contaminants consist of carbon monoxide, oxides of nitrogen, sulphur dioxide, total (filterable) particulate matter (PM), and particulate matter below 10 microns (PM_{10}), particulate matter below 2.5 microns ($PM_{2.5}$), and Volatile Organic Compounds. Dust emissions from excavation projects were estimated based on a calculation for total particulate matter generated per excavation day. Dust generated from demolition activities in 2021 will be captured in the *2021 Progress Report on the Environmental Assessment Follow-up Program for Whiteshell Laboratories* [28].

Table 38 outlines the annual CACs generated from site activities, and shows a small decrease in emissions seen in 2021 compared to the 5-year average for the values for total particulate matter, PM_{10}, and $PM_{2.5}$. The PM_{10} value met the NPRI reporting threshold this year, and is reported to Environment and Climate Change Canada. Road dust emissions were the major contributor to meeting these reporting thresholds.

Table 38: Stationary Combustion Data and Emissions from WL

Parameter	Unit	Data for Previous Five Years						Data for 2021	NPRI Reporting Threshold
		2016	2017	2018	2019	2020	Average		
Airborne Emissions									
NO_x (as NO_2)	Mg	0.908	0.753	0.536	0.621	0.602	0.684	0.331	20

PM_{10}	Mg	3.853	3.499	3.726	2.712	2.281	3.214	2.091	0.5
$PM_{2.5}$	Mg	0.415	0.376	0.391	0.292	0.249	0.345	0.218	0.3
Volatile Organic Compounds	Mg	0.071	0.059	0.042	0.049	0.048	0.0538	0.026	10

9.5.2.3 Greenhouse Gas Emissions

Under the authority of the *Canadian Environmental Protection Act*, 1999 [38] WL must calculate releases under the GHGs emissions notice [40] providing the facility emits over 10,000 tonnes of carbon dioxide equivalent or more within the calendar-year.

Greenhouse Gas emissions from WL include carbon dioxide, methane, and nitrous oxide. Emissions are primarily from the burning of propane, the use of diesel generators, the on-site transportation fleet, the on-site landfill, and open-pit wood burning. They are measured in CO_2 equivalent tonnes which is a measure used to compare between gases that have different Global Warming Potential (GWP).

Table 39 outlines the GHG emissions from the WL site for the last six years. These emissions from the site have decreased significantly from 2020. This decrease can be attributed to the decrease in propane needed to heat the site in 2021 as shown in Table 37. There was a decrease in the number of heating degree days (i.e., decreased demand for building heat based on temperature) in 2021, this combined with the fact Building 200 did not require any building heating during the calendar year, and Buildings 402 and 305 no longer had to be heated starting in the fall of 2021 due to demolition activities. Overall, greenhouse gases in 2021 are 29% less than the average for the last 5 years.

Table 39: Greenhouse Gas Emissions

Parameter	Releases from Previous Five Years						2021 Releases
	2016	2017	2018	2019	2020	5-yr. Avg.	
GHG CO_2e tonnes	1883	1873	1678	1756	1692	1776	1177

Note: GHG CO2e tonnes - A unit of measure used to compare between gases that have different GWP. For example, the GWP for methane is 25. This means that emissions of one metric ton of methane is equivalent to emissions of 25 metric tons of carbon dioxide.

9.5.2.4 Halocarbons

In the atmosphere, halocarbons contribute both to global warming and to ozone depletion, via separate mechanisms. Losses of halocarbon refrigerants and fire suppressants are reported semi-annually to Environment and Climate Change Canada, following the Federal Halocarbon Regulations [41]. All releases greater than 10 kg are considered reportable.

As seen in Table 40, there were two reportable releases of halocarbons in 2021. Both releases were related to the Building 100 chiller system. The first release occurred in 2021 April. During maintenance activities it was discovered that 15.5 kgs of R-134a refrigerant escaped from the chiller system through a leak of one of the shut off values on the equipment. Upon replacement of the shut off valve it was observed that the threads of the valve were compromised. The second leak occurred in 2021 October. During maintenance activities to take the equipment offline for the season, it was discovered that 16.3 kgs of R-134a refrigerant escaped from the chiller system through a faulty solenoid valve.

Table 40: Halocarbon Losses from WL

			Losses from Previous Five Years (kg)					Losses in 2021	
Type	**Global Warming Potential[b]**	**Ozone Depleting Potential[c]**	**2016**	**2017**	**2018**	**2019**	**2020**	**Number of Losses**	**Annual Loss (kg)**
Refrigerants[a]									
CFC (R-11)	4 600	1	0	0	0	0	0	0	0
CFC (R-12)	10 600	1	0	0	0	0	0	0	0
CFC+HCFC (R-502)[d]	4.1	0.28	0	0	0	0	0	0	0
HCFC (R-22)	1 700	0	0	0	0	0	0	0	0
HFC (R-134a)	1 300	0	0	12.47	0	0	0	2	31.8
Fire Suppressants									
Halon (R-1301)	6 900	10	0	0	0	0	0	0	0

a CFC = Chlorofluorocarbons; HCFC = Hydrochlorofluorocarbons; HFC = Hydrofluorocarbons
b GWP per unit mass, compared to CO2 = 1.00
c Ozone Depleting Potential per unit mass, compared to CFC R-11 = 1.00
d The data for the CFC+HCFC(R-502) is from [41]

9.5.3 Overall Performance

The non-radiological effluent monitoring program set up by CNL continues to supply valuable information about the potential impacts of operations on the Winnipeg River, and thus the local environment.

There were no discharges from the Outfall and Lagoon which exceeded the current monthly guideline limits placed on CNL in 2021.

9.6 Regulatory Limit Exceedances and Contamination Incidents

There were no Regulatory Limit exceedances or reportable events in 2021.

9.7 Discussion of Improvement Initiatives

The following sections describe some of the ongoing efforts the WL site is undertaking to enhance the effluent verification monitoring program.

9.7.1 Monitoring Site Intake Water and Outfall Effluent

In 2020, the WL site expanded the monitoring program to encompass additional parameters at the site's Intake and Outfall monitoring station. This expansion resulted from the enhanced monitoring that was performed on the Intake and the Outfall in 2019 to address the gaps in baseline data when assessed against the monitoring criteria in Table 19-1 of the *WL Effluent Verification Monitoring Plan* [25]. It was decided that when there was a 20% change in concentration when comparing the results for a given parameter at the Intake and Outfall, that these parameters would be incorporated in the effluent verification monitoring program.

Under this criteria, Total Organic Carbon, Strontium, Uranium, Magnesium, Potassium, Sodium, and the volatiles Bromodichloromethane, chloroform and Toluene have been added to the list of parameters being measured at these stations. Currently, CNL can show that the source of the Potassium and Sodium being introduced to the Outfall is a result of the sanding/salting activities that occur on site as the weather transitions into and out of sub-zero temperatures. The Bromodichloromethane and chloroform are by-products resulting from the site's chlorination practises. The remaining parameters are currently not tied to a source, and CNL is planning to do temporary upstream process monitoring (monitoring at LLLWTS in Buildings 100 and 300) to try to be able to explain the operational source of the increase.

In order to be compliant with REGDOC-2.9.1 [42] it was determined that the effluent verification monitoring program needed to include acute lethality testing at the Outfall monitoring station.

Although the need to monitor for these parameters is currently captured in *WL Effluent Verification Monitoring Plan* [25], WL laboratories acknowledges that the plan needs to be updated to reflect that these parameters are actively being monitored, and plans to revise Reference [25] in 2022.

9.7.2 Reducing Energy Use from Fossil Fuels

The largest quantity of non-radiological effluents to air comes from burning fossil fuels, to heat the site buildings. Starting in 2013, use of and emissions from Number 2 fuel oil heating operations at the Powerhouse ceased due to the completion of building conversions to either propane or electrical heating.

Figure 11 shows the annual fossil energy consumption since 2016, relative to the number of Heating Degree Days in each year. Heating Degree Days are calculated for each day as the difference between 18°C and the median ambient temperature.

From Figure 11, it is apparent that energy use has started to stabilize and any further reductions will be resulting from final closure of site buildings, reducing or removing their heating supply. Beginning in 2020 October, Building 200 no longer had to be heated as demolition activities on the building began at this time. In 2021 September, Buildings 305 and 402 no longer required to be heated as demolition activities began on these buildings.

9.8 Environmental Assessment Follow-Up and Monitoring

Details about the Environmental Assessment Follow-Up and Monitoring Program are discussed in the *2021 Progress Report on the Environmental Assessment Follow-Up Program for Whiteshell Laboratories* [28] (to be issued to the CNSC by 2022 June 30).

10 Emergency Management and Fire Protection

10.1 Emergency Preparedness Program

Whiteshell Laboratories adheres to the Corporate Emergency Preparedness Functional Support Area. See Section 10.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The WL program continues to adapt to the changes on site, including the demolition of buildings/assets, the construction of temporary structures, the number and composition of staffing levels, and the organisational structure. Vacated buildings are transitioned from building emergency procedures to construction/demolition oriented emergency placards.

Planning for and responding to COVID-19 continued as a primary focus for the Emergency Preparedness Functional Support Area at WL in 2021, providing procedures and guidance to enable work to continue safely in this dynamic situation. This was safely managed, without an outbreak at WL, despite the pandemic impact on Manitoba.

10.1.1 Drills and Exercises

The ongoing COVID-19 Pandemic continues to make running in-person emergency scenarios a challenge, especially with our external partners. For 2021, drill and exercise development focused on scenarios that allow for adequate physical spacing and still yield quality learning and evaluation potential.

In 2021, a total of 143 exercises and drills were delivered at WL. This is a significant step up from the 94 drills/exercises delivered in 2020. While not quite back to pre-pandemic levels, this increase signifies an adjustment in the program to the new normal of the current environment. Table 41 provides details on the number and type of the exercises and drills conducted in 2021.

Table 41: WL Emergency Preparedness Exercises – 2021

Type of Drill or Exercise	Number Completed in 2021
Fire Drills	2
Site-wide Specialty Drills	106
Table Top Exercises [a]	5
Targeted Communication Exercise	17
Site-wide Communication Exercise	12
Field Exercises (Functional)	1

a Table Tops include specific EOC Skill workshops as well. Each workshop focuses on a unique aspect of the EOC and includes a small practice scenario.

10.1.2 Training

There was no change to the Emergency Operations Centre (EOC) staff structure in 2021. Building emergency teams are being maintained for all occupied structures on site. Fewer occupied structures has resulted in a decrease in the number of team members required.

10.1.3 Status of Emergency Resources and Facilities

Whiteshell Laboratories maintains a physical EOC, and conducts monthly tests of the technical equipment stored for use in that location. Repairs, improvements and updates are requested as required and when identified. All checks were completed in 2021. A cache of emergency food rations is also maintained at WL, which have a five year shelf life. The rations were replaced in 2019. The cache is stored in a secure location and the condition of the cases is checked annually.

10.1.3.1 Emergency Operation Center

As part of WL's EOC framework, there are two teams of EOC staff, and an alternate person for each of the team positions that can be engaged to cover for members of either of the two teams. These two teams operate on a two week on-call rotation. One EOC member retired in 2021 and his trained alternate was able to step straight into this position.

There were no emergency events requiring activation of the EOC in 2021.

10.1.3.2 Mobile Nuclear Laboratory

Canadian Nuclear Laboratories continues to maintain the Mobile Nuclear Laboratory (MNL) for response both on-site and off-site. The unit continues to be maintained by WL Radiation Protection staff and is inspected at a regular interval to maintain control of inventory and equipment.

There were no emergency events requiring the activation of the MNL in 2021.

10.1.3.3 Equipment Checks

Respirators make up the majority of the equipment in the strategically placed emergency cabinets that remain on site. These cabinets are opened and inspected monthly by Radiation Protection staff. Once a satisfactory inspection is complete, the cabinets are re-sealed and signed off by the inspector. All scheduled checks were completed in 2021.

There were no emergency events requiring the use of this equipment in 2021.

10.1.3.4 Public Address System

The Public Address (PA) system is the primary system used for communicating emergency events to WL employees. The system functioned normally in 2021.

10.1.3.5 Secondary Emergency Signals

The WL site still employs an exterior siren as a redundant form of emergency alerting. The system is no longer required and was replaced by the PA system as the primary alerting system. This system will continue to be used as a redundant alerting system until either the equipment fails completely (there have previously been some issues with the equipment) or the building it is mounted to is decommissioned and demolished.

10.1.3.6 EOC Notification System

WL continued to use the Everbridge Mass Notification system in 2021. The system continues to perform well, with a 100% response rate to all monthly communication tests (see Table 42) for the third year in a row.

Table 42: WL EOC Communication Tests: 2021

Y= Yes N= No	January	February	March	April	May	June	July	August	September	October	November	December
EOC Commander	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Liaison Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Env. Protection Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Safety Officer	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Planning Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Logistics Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Operations Section Chief	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Nuclear Facilities Representative	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

In addition to these regularly scheduled monthly drills, a random quarterly drill is conducted. These drills are scheduled for random times and dates, including weekends, evenings and work hours. These random drills include the expanded EOC teams, including all alternates and non-routine staff. Table 43 identifies the response rates of the 2021 WL EOC Staff to the Quarterly Random EOC call out drills, with an average of 94% response. Only responses received within an hour of the notification being sent out are considered a positive response, the rest are considered 'no response'.

Table 43: WL EOC Random Quarterly Communication Tests: 2021

	Q1	Q2	Q3	Q4
Response Percentage	96%	100%	88%	92%

10.1.4 External Collaborations

In 2021 contact was maintained with a variety of external emergency response/management organizations and interested public groups. Due to COVID-19 many of these were once again virtual meetings or connections. WL EmP:

- Engaged with the LGD of Pinawa Emergency Operations Centre staff for local response planning purposes.
- Participated in the Manitoba Provincial Flood and Forest Fire forecasting sessions.
- Continued to participate on the Manitoba Municipal Relations Governance COVID-19 teleconference meetings throughout 2021, though with decreasing frequency as the year progressed.
- Maintained working relationships with Manitoba Emergency Measures Organization staff through less formal interactions this year, including regional response officers and the Critical Infrastructure protection program staff.
- Attended the Provincial emergency management conference, which brought many Local, Provincial and Federal stakeholders together to share best practices and lessons learned on a variety of relevant topics.
- Maintained membership with the Prairie Region (Manitoba and Saskatchewan) of the Federal Coordination Working Group. The Federal Coordination Working Group helps WL maintain ties with representatives from multiple federal agencies including (but not limited to) Public Safety Canada, the Royal Canadian Mounted Police (RCMP), Health Canada, Department of Defence, Public Health Agency of Canada, and Environment & Climate Change Canada, in order to support organizational planning and response.

10.1.5 Unplanned Emergency Events

There were no incidents requiring initiation of the WL Site Emergency Plan occurred during 2021.

10.2 Fire Protection Program

Whiteshell Laboratories adheres to the Corporate Fire Protection Functional Support Area. See Section 10.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

There were no reportable fire events at WL in 2021.

10.2.1 Fire Response Drills

In 2021, WL was unable to conduct all the fire drills that it identifies as an annual requirement in accordance with the National Fire Code of Canada [43] and CSA standard N393-13 Fire Protection for Facilities that Process Handle, or Store Nuclear Substances [44]. This deviation has been captured as part of an internal self-assessment and a corrective action plan is being developed to ensure these are adequately planned and executed.

10.2.2 External Collaborations

Whiteshell Laboratories and the Town of Pinawa signed a Fire Protection Service Agreement in 2019 to improve Mutual Aid support capabilities. The agreement is still in effect. Interdepartmental training has been interrupted by the COVID-19 pandemic, but will be resumed as soon as it is safe to do so.

10.2.3 Third Party Audits & Inspections

As per the requirements of CSA N393-13, *Fire Protection for Facilities that Process, Handle, or Store Nuclear Material Substances* [44], a third party Fire Protection Audit was conducted in 2021. The findings are being collated and their resolution will be tracked through the corrective action program (see also Section 1.2.1.1).

10.2.4 Fire Hazard Analysis

All fire hazard analysis documentation for buildings requiring a fire hazard analysis have been reviewed and are being evaluated against the decommissioning schedule. A corrective action plan was developed and submitted to the CNSC outlining the timeline for Fire Hazard Analysis documentation review and revisions.

11 Waste Management

11.1 Waste Management Program

Whiteshell Laboratories adheres to the Corporate Waste Management Functional Support Area. See Section 11.1 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Waste Management Program continues to provide effective and efficient delivery of Waste Management services.

Significant activities for the Waste Management Program include:

- Continued to refine and communicate the Integrated Waste Strategy to integrate waste lifecycle management across all CNL-operated sites and to capture the CNL baseline waste strategies and defined pathways for all CNL wastes.
- Collaboration between CRL and WL Programs to effectively disposition radioactive wastes, leading to the advancement of remediation and transportation projects.
- Enhanced support to existing activities and new activities in support of the new schedule for the WL Closure Project. The support improved segregation protocols and ensured continued adherence to waste processes.

The waste acceptance criteria for three of the waste receiving facilities on-site (including the Waste Handling Area and the WMA storage facilities) remained unchanged for 2021.

11.1.1 Waste Management Operations

Radioactive, clearable and hazardous wastes were generated from both ongoing operational activities and decommissioning projects. The packaged solid radioactive wastes were stored in designated storage facilities in the WL WMA depending on the hazard level and packaging, as well as dispositioned to CRL for interim storage.

Demolition of Buildings 402 and 305 began in 2021 and is on target to be complete early 2022. A total of 2,246 m^3 clean waste was generated in 2021; 1,290 m^3 of concrete material was dispositioned to an off-site receiver for future re-use, 450 m^3 of metal was recycled, while 483 m^3 of asbestos-containing material and 17 m^3 of polychlorinated biphenyl (PCB) contaminated materials were dispositioned to appropriate off-site waste receivers.

Decommissioning on the south area of the WL main campus continued, which involved asbestos abatement and remediation of high temperature water lines, generating approximately 188 m^3 of clean concrete waste; 28.5 m^3 of this volume contained asbestos-containing materials which was sent to an approved off-site licensed facility.

Building 200 Active Liquid Waste Treatment Centre demolition was completed. A total of 1,077 m^3 of Low-Level Waste (LLW) and 77.5 m^3 of Intermediate - Level Waste[11] (ILW) waste

[11] In this context, ILW refers to any waste that does not meet the proposed Near Surface Disposal Facility (NSDF) Waste Acceptance Criteria (WAC) and requires storage in ILW facilities at CRL.

was generated; of this LLW total, 876 m³ has been safely dispositioned to CRL, with the remaining 201 m³ and 77.5 m³ of ILW waste safely stored in certified transportation packages awaiting shipment to CRL in 2022.

De-inventorying efforts of legacy waste stored in LLW Bunker 5 began. Wastes are undergoing additional qualification and inspection to ensure transportation and waste criteria compliance are met. This activity has generated 360 m³ of LLW to date, which are safely stored in certified transportation packages awaiting shipment to CRL in 2022.

Table 44 summarizes the quantities of radioactive waste generated in 2021 that was sent to each storage location. Table 45 summarizes the volumes of solid low-level radioactive waste originating from each facility in 2021. Table 46 summarizes the volumes of solid intermediate-level radioactive waste originating from facilities in 2021. Table 47 summarizes the volumes of solid low-level and intermediate-level radioactive waste transported to CRL for disposition.

Table 44: Radioactive Waste by Storage Location

Storage Facility	Volume (m³)	
	2020	2021
Low-Level Quonsets	32.3	0
Intermediate-Level Waste Bunkers	0	2.5
SMAGS[a]	4.1	0
Soil Storage Compound	0	0
Total	36.4	2.5

a Shield Modular Above Ground Storage (note: SMAGS is no longer used for waste storage)

Table 45: Low-Level Radioactive Waste Generated by Facility

Facility of Origin	2020		2021	
	Compactable Waste Volume (m³)	Non-Compactable Waste Volume (m³)	Compactable Waste Volume (m³)	Non-Compactable Waste Volume (m³)
Building 100	0.8	9.2	1.5	0.0
Building 200	7.2	198.9	0.0	875.6
Building 300	0.3	0.0	0.0	0.0
Building 303	0.0	0.0	0.0	0.0
Building 304	0.0	0.0	0.0	0.0
Building 402	0.2	0.0	0.8	0.0
Building 421	0.0	0.0	0.0	0.0
Concrete Canister Storage Facility	0.0	0.0	0.0	0.0

Shielded Facilities (HCF & IFTF)	10.8	0.1	45.6	0.0
Waste Handling Area	0.0	0.0	0.0	0.0
Waste Management Area	2.5	0.0	14.2	0.0
LLW Bunker 6	0.8	0.0	0.0	9.0
LLW Bunker 5	0.0	0.0	0.0	360.0
Affected Lands	0.2	0.0	0.0	0.0
SSC	0.0	0.0	0.0	0.0
Total	**22.7 (5.0)[a]**	**208.2**	**62.1 (5.0)[b]**	**1244.6**
Total after Compaction	**213.2**		**1249.6**	

a This volume of compactable waste was reduced to 5.0 m³. It is not possible to determine accurate post-consolidation volumes attributed to individual facilities because all of the waste is being combined during the compaction process.

b This volume of compactable waste was reduced to 5.0 m³. It is not possible to determine accurate post-consolidation volumes attributed to individual facilities because all of the waste is being combined during the compaction process.

Table 46: Intermediate-Level Radioactive Waste Generated by Facility

Facility of Origin	Volume (m^3)	
	2020	2021
Affected Lands	0.0	0.0
Building 200	5.8	77.5
Total	5.8	77.5

Total	527.7	26.3	921	3.2

a Shielded Modular Above Ground Storage – legacy waste generated from various decommissioning projects.

Clearable waste from Controlled Areas was monitored in-situ. Clean bagged waste was monitored using the bag monitor located in Building 300 where WL's laundry facility is now stationed; all bagged waste met the screening criteria and was deemed to be suitable for unrestricted release in 2021.

Whiteshell Laboratories continued to reuse or recycle as much material as practicable; this includes both recyclable materials sent to the municipal recycling facility and other material-specific facilities throughout Manitoba. Waste Management Program representatives exercised a proactive approach to ensure waste was properly segregated at the source of origin to maximize the amount of material that could be reused or recycled.

Table 48 summarizes the disposition pathway of non-active wastes, while Table 49 summarizes the amount, by material type, of recyclable waste shipped off-site.

Table 48: Non-Active Waste Disposition Pathways

Disposition Location	Volume (m^3)	
	2020	2021
WL Asbestos Disposal Site [a]	0	0
WL Burn Pit	247	189
WL Inactive Landfill	0	0
Recycling[b] Sent Off-Site	513	271
Off-Site Landfill [c]	1,256	1,352
Total	2,016	1,812

a The WL Asbestos Disposal Site stopped receiving waste in 2019 to support the environmental risk assessment. Non-active asbestos is directed to off-site licensed landfills.

b This recycling waste pertains to office recycling that is generated on a daily basis that is accepted at municipal recycling facilities.

c WL Inactive Landfill stopped receiving waste mid-2019 to support the environmental risk assessment. Non-active waste is directed to off-site licensed landfills.

Table 49: Recycled Waste Shipped Off-Site

Material[a]	Weight (kg)	
	2020	2021
Aluminum	0	0
Batteries Shipped	0	0
Batteries Recycled	227	0
Cardboard[b]	0	0

Copper and Brass	0	0
E-Waste Shipped	347	3,464
E-Waste Sold	0	0
Ferrous Metals	108,457	26,231
Glass	0	0
Lumber	0	0
Plastic Shipped	0	0
Plastic Sold	0	0
Stainless Steel	0	0
Lead	0	7,450
Total	109,031	37,145

a This recycling waste pertains to material that is sold or charged to be taken to a material specific recycling facility.

b Cardboard is sent to a municipal recycling facility and inclusive in Table 48.

Improvements were made in preventing waste accumulation inside of buildings and transferring the waste to appropriate waste facilities immediately after generation. Improvements continue to be addressed in reference to the lack of processing and storage space for non-routine waste materials (e.g., mixed waste and large contaminated items), as well as large volumes radioactive wastes generated from decommissioning activities. Mitigation measures put in place in 2021 included finalizing a Nuclear Safety Note for the interim storage of cargo containers containing radioactive wastes in the WMA. This area is referred to as the Recoverable Surface Storage and Staging Area (RSSSA), and consists of an outdoor, above ground storage pad to enable the storage and loading of solid low-level waste in sea land containers and storage of oversize LLW items which are awaiting further processing, characterization and/or packaging to be considered compliant for off-site disposition. Additionally, satellite transshipment areas were established north of the WMA and one by the B200 demolition to reduce additional handling and improve efficiencies with off-site disposition of waste.

11.1.1.1 Liquid Waste Generation

During 2021, 78.9 m^3 of low-level liquid was processed in the Building 300 LLLWTS and 9.9 m^3 in the Building 100 LLLWTS, for a total of 88.8 m^3 of low-level liquid waste processed through the two systems.

11.2 Decommissioning Plan

Whiteshell Laboratories adheres to the Corporate Cleanup Functional Support Area. See Section 11.2 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

11.2.1 Program Overview, Achievements and Accomplishments

As per the Licence Conditions Handbook for WL [2], CNSC have been notified of revisions to the Detailed Decommissioning Plan (DDP) for WL [45].

11.2.2 Land Use Program

Table 50 provides a summary of the status of the WL Site's Overview DDP.

Table 50: Overview Decommissioning and Cleanup Plan Updates for WL in 2021

Document Reference	Key Activity Status in Year	Effective Date (if applicable)
WLDP-02000-DDP-001	Approved by Regulator	December, 2021

The Overview DDP was revised, submitted to the CNSC, and approved for use in 2021.

11.2.3 Decommissioning and Demolition Program

Table 51 lists the WL DDPs and their status as of 2021.

Table 51: Overview of WL Detailed Decommissioning Plans

Facility	DDP Document Title	Document #	Status
Shielded Facilities	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 2 - Shielded Facilities	WLDP-21400-DDP-001, Revision 1, 2016	Facility is operational and decommissioning activities ongoing. DDP Volume is available for use.
Van de Graaff Accelerator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 3 - Van de Graaff Accelerator	RC-2143-3, Revision 1, 2000	Facility has been decommissioned.
Neutron Generator	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 4 - Neutron Generator	RC-2143-4, Revision 1, 2000	Facility has been decommissioned.
Active Liquid Waste Treatment Centre	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 5 - Active Liquid Waste Treatment Centre Building 200	WLDP-25400-DDP-001, Revision 0, 2011	Facility has been decommissioned. End-state report in development.
Whiteshell Reactor-1 (WR-1)	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 6 - Whiteshell Reactor-1: Building 100	WLDP-26400-DDP-001, Revision 3, 2015 (Complete Dismantlement and Removal Approach)	Facility has been shut down and currently under monitoring and surveillance. Complete Dismantlement and Removal approach has been

Facility	DDP Document Title	Document #	Status
		WLDP-26400-DDP-001, Revision 5, 2021 (In Situ Decommissioning Approach)	approved by the CNSC (Revision 3). EA process for ISD is in progress, Revision 4 to be revised with final EA submission (note: copy of Revision 5 submitted for review of comment disposition to CNSC prior to final EA submission). DDP Volume (Revision 3) is available for use.
Concrete Canister Storage Facility	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 7 - Concrete Canister Storage Facility	WLDP-22500-DDP-001, Revision 1, 2017	Facility is operational. DDP was sent to the CNSC and comments received (to be dispositioned).
Waste Management Area	Volume 8 - WMA Part 1: Standpipes Area	WLDP-36500-DDP-001	Facility is operational DDP under development.

11.2.3.1 Detailed Decommissioning Planning and Execution

Table 52 provides a summary of WL facility DDPs that were revised in 2021.

Table 52: Summary of WL Detailed Decommissioning Plans in 2021

Facility	Document Status	Document Name and Reference	Effective Date	Document Highlights
WMA	Current Published	Whiteshell Laboratories Detailed Decommissioning Plan: Volume 8 - WMA: Part 3 - Low Level Waste Liabilities, WLDP-24400-DDP-001, Revision 5	April, 2021	DDP was submitted to and accepted by CNSC staff.

Table 53 provides a summary of decommissioning and demolition statuses for WL in 2021.

Table 53: Summary of WL Decommissioning and Demolition Status by Facility in 2021

Facility	Decommissioning and Demolition Status
B402	Active Decommissioning
B200	Building Demolished
B413	Active Decommissioning
B420	Active Decommissioning
B426	Active Decommissioning
B429	Active Decommissioning
WMA	Active Decommissioning
Site Affected Lands and Contaminated Structures	Active Decommissioning

Several buildings and structures were decommissioned in 2021, where operational wastes were dispositioned, building services isolated and industrial hazardous materials removed prior to demolition where feasible.

Demolition of Buildings 402 and 305 began, and is expected to be completed early 2022. The demolition of the buildings included remediation and abatement of asbestos-containing materials, specifically the mastic tar adhered between the masonry and exterior wall, and PCB's found within window glazing and exterior caulking and general demolition of construction and demolition materials.

Remediation of the south-side of the main campus continued. Phase one field work was completed, which consisted of remediating the high temperature water lines. Phase two field work to excavate and remove underground electrical bus ducts, isolate fire water, domestic water, storm drains and sanitary drain systems will commence in 2022. The exterior of Buildings 413, 420, 426 and 429 were radiologically surveyed for clearance, with interior portions to be completed in 2022.

Building 200 was successfully demolished, which involved the above and below grade structure, while the building footprint was backfilled. Remediation of this footprint was strategically adjusted to align with future remediation of the surrounding lands known to be contaminated from historical spills associated with the building. This will ensure remediation of the known contamination is completed in one phase, avoiding the potential of creating additional volumes of waste that may be generated from migration of contaminants within the soil.

Legacy wastes stored in the LLW Quonsets (Building 431, 432 and 433) and LLW Bunker 5 began to be retrieved in 2021. Wastes are undergoing visual examination, destructive and non-destructive characterization, and packaging to ensure transportation and waste criteria compliance are met, before waste can be dispositioned to CRL. This work is scheduled to be complete in 2022.

Decommissioning progress is also discussed in the facility sections (Appendix A through Appendix G).

11.2.3.2 End State Reporting

Table 54 provides a summary of end-state reports completed for WL in 2021.

Table 54: Summary of WL Decommissioning and Demolition End-State Reports in 2021

Facility	Document Type	Document Status	Document Name and Reference	Submission Date (if applicable)
Building 514 (WMA)	End State Report	Submitted to CNSC	Decommissioning and Demolition of Organic Coolant Incinerator Complex (B514), WLDP-24400-ESDR-001, Revision 1	July, 2021

12 Security

12.1 Security Program

Whiteshell Laboratories adheres to the Corporate Security Functional Support Area. See Section 12 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Whiteshell Site Security Report [46] outlines the security arrangements that are in place at the WL site. The Security Functional Support Area consists of processes, procedures, and staff to manage the continuous operation and response to security incidents; the Security Functional Support Area and procedures are reviewed and updated as required to address operational requirements.

Nuclear Security Officers assigned regular duties continued to meet the physical and psychological fitness requirements for Security Officers stated in REGDOC-2.2.4, *Fitness for Duty, Volume III Nuclear Security Officer Medical, Physical and Psychological Fitness* [47].

Hours of Work Exceedances

As per REGDOC-2.2.4, *Fitness for Duty: Managing Worker Fatigue* [47] Sections 4.2 and 4.3, CNL has recorded all exceedances of hours of work for Security's safety-sensitive positions. See Table 55 below for a list of exceedances for 2021. NOTE: COVID pandemic had a direct contribution to Table 55 in order to ensure minimum shift complement.

Table 55: Hours of Work Exceedances for Nuclear Security Officers and Tiered Response Force Personnel at WL in 2021.

Limits:			2021			
			Q1	Q2	Q3	Q4
4.2	**1.**	**>16 hrs in a 24-hour period**	3	4	7	4
4.2	**2.**	**> 28 hrs in a 48-hour period**	15	21	28	11
4.2	**3.**	**> 120 hrs in a 14-day period**	6	4	1	1
4.3	**2. d.**	**Min recovery 48 hrs after 2 consecutive nights**	19	11	5	15
4.3	**2. d.**	**Min recovery 72 hrs after 3 consecutive nights**	2	5	3	2
		Total	45	45	44	33

A CNSC Type II Security Compliance Inspection was carried out - see Section 1.2.2. A corrective action plan was submitted to the CNSC to address findings.

CNL-WL received notification from the CNSC on the closure of one (1) enforcement item, Directive WL-SEC-19-T2-001-D01 – Training. The Directive closure was granted as CNL-WL completed all actions required to address the enforcement items listed in the Directive.

12.1.1 Security Events

In 2021, there were no security events that affected the Whiteshell Laboratories.

13 Safeguards and Non-Proliferation

13.1 Safeguards Program

Whiteshell Laboratories adheres to the Corporate Nuclear Materials and Safeguards Management (NM&SM) Functional Support Area. See Section 13 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

13.1.1 IAEA Activities

The IAEA conducted various types of activities as part of the safeguards approach for CNL, including, but not limited to, IAEA safeguards seals changes, human surveillance, implementation and/or maintenance of IAEA safeguards monitoring equipment, and technical visits. A list of IAEA inspections conducted at all CNL sites can be found in Section 1.2, Management System of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

In 2021 May-June, 14 of 16 WL concrete canisters were re-welded, during which the IAEA provided oversight. The IAEA also verified and changed the IAEA seals attached to the canisters to maintain continuity of knowledge. Minor difficulty was encountered during resealing of one canister and the IAEA inspector decided to employ an alternate sealing arrangement. In 2021 September, the other two canisters were re-welded, during which IAEA provided oversight, including resealing the one canister into the original configuration as it was operationally preferable.

A Physical Inventory Verification (PIV) inspection was completed by an attending IAEA inspector on 2021 May 25. This inspection was a sampling of accessible items containing Special Fissionable Material.

The IAEA also completed a Design Information Verification (DIV) inspection on 2021 May 25 - 27. The activities associated with the DIV included:

- Verification of the Design Information Questionnaire:
- Verification of the site and general building design;
- Verification of containment integrity; and
- Verification of operational status of the facility.

14 Packaging and Transport

14.1 Packaging and Transport Program

Whiteshell Laboratories adheres to the Corporate Transportation of Dangerous Goods (TDG) Functional Support Area, which includes the requirements of the Packaging and Transport SCA. See Section 14 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Packaging and Transport SCA covers the safe packaging and transport of nuclear substances and radiation devices. The TDG Functional Support Area applies to any activities involving the transportation of dangerous goods to or from CNL sites. The TDG Functional Support Area provides an operational framework for the safe off-site transport of dangerous goods by conforming to all applicable laws and regulations, as well as company policies and procedures.

The Waste Certification & Transportation branch is a centralized organizational department responsible for planning, coordinating and executing radioactive waste shipments from the WL site to the off-site disposal or storage facilities in a safe and compliant manner, including having fully trained Radioactive Material Shippers as authorized under the CNL TDG Functional Support Area.

Significant activities in 2021 included:

- Transportation of 921 m³ of low-level waste and 3.2 m³ intermediate-level waste sent off-site and safely delivered to CRL;
- Throughout 2021, additional technical assessments and studies on the WL used fuel inventory were completed in support of the licensing application of the Used Fuel Transportation Package (UFTP). These assessments were focused on the WL mixed fuel types (i.e., enriched and experimental fuel types, including Uranium Carbide and Uranium Metal fuel types) and the physical operation of the UFTP. The UFTP, which is owned by the Nuclear Waste Management Organization, has been leased with the intention that the UFTP will be the Type B Transportation Package for high-level waste transportation operations starting in 2022 (due to the COVID-19 Pandemic, these transportation operations were delayed and subsequently pushed out from 2020). There is a two-step licensing strategy for the UFTP, with the first phase focusing on licensing the UFTP for non-enriched CANDU fuels and the second phase focusing on WL's inventory of mixed fuel types. The phase UFTP Safety Analysis Report (SAR) Addendum was submitted to the CNSC in 2019 May, with updates provided throughout 2020, and acceptance is anticipated in early 2022. The UFTP SAR for Mixed Fuel Types (representing phase two) will be submitted in 2022, following the CNSC's acceptance of the phase 1 SAR addendum. Additional accomplishments throughout 2021 include the revision and acceptance of the revised UFTP pre-shipment leak tests, the progression of detailed planning and operational readiness deliverables, and the completion of field trials with the UFTP, Shielded Interface Module (SIM) and Fuel Transfer Flask.

- Award of the subcontract to Nuclear Assurance Corporation (NAC) to design and fabricate Type B casks, cask handling equipment and on-site services needed to support ILW transport to CRL was completed. Two versions of the OPTImal Modular Universal Shipping (OPTIMUS) casks, the OPTIMUS-H and OPTIMUS-L were accepted for use after their licence review and received. Personnel from WL and CRL participated in a week long training session, qualifying them on the use, loading and transport of the casks.
- Extensive training was conducted to site personnel responsible for the handling and packaging of radioactive waste materials, which included Class 7 RAM Material – Handler Training, as well as Waste Management and Packaging Fundamental Training, which was developed to capture the requirements to compliantly process, load, and handle waste materials into certified transport packages, as well as the various waste receivers' waste acceptance criteria.

14.1.1 Shipments

At WL, 68 radioactive transport packages making up 53 loads were safely and successfully sent off-site in 2021. One reportable event occurred in 2021 (see ImpAct ERM-21-1036 in Table 5) where a consignment of waste material was misclassified in accordance with the Packaging and Transport of Nuclear Substances Regulations [48] and IAEA Safe Transport of Radioactive Material [49], due to an incomplete inventory of the package's contents. Several corrective and remedial actions were completed to address the event.

15 Other Matters of Regulatory Interest

15.1 Public Information and Disclosure Program

Whiteshell Laboratories adheres to the Corporate Public Information Program. See Section 15 of the *Annual Compliance Monitoring Report for Canadian Nuclear Laboratories* for details [4].

The Public Information Program document [50] is intended to cover communication activities that occur within CNL's immediate neighbouring communities. This document was prepared in accordance with CNSC regulatory document REGDOC-3.2.1, *Public Information and Disclosure* [51].

15.1.1 Outreach and Stakeholder Engagement

WL shares information with the public through a number of activities including conducting public information sessions, media releases, the corporate website, a toll-free line, social media accounts and involvement in community events. As employees are CNL's greatest ambassadors, they are kept informed of developments so that they can also share information with their relatives, friends, and neighbours.

CNL engaged with the public on WL using a number of tactics. During the COVID-19 pandemic, engagement followed public health and corporate guidelines and was primarily virtual. Table 56 presents public engagements from 2021.

Table 56: Public Engagements for Whiteshell Laboratories

Date	Location	Activity
March 2, 2021	Pinawa, MB	Presentation and meeting with Local Government District of Pinawa Council and Mayor
April 20, 2021	Webinar	WL Closure Project: Environmental Protection
May 18, 2021	Webinar	WR-1 Reactor Decommissioning Fact or Fiction Webinar
September 21, 2021	Webinar	WL Closure Project: Project update
November 16, 2021	Webinar	WL Closure Project: Environmental Protection
November 24, 2021	Winnipeg, MB	Emerging issues conference 2021: The net-zero future investing in sustainability

15.1.2 Public Consultation

CNL actively works to engage local stakeholders on matters related to WL activities. In 2021, a number of methods were deployed to gain feedback from and create discussion with interested parties including: breakfast sessions, social media, and feedback forms available online and at external events, and responses provided to inquiries. CNL strives to create open and transparent communication with all identified stakeholders, and to address concerns and respond to all inquiries.

Throughout 2021, CNL received 21 community inquiries related to WL (Table 57), largely through the WR-1 Breakfast Session/Webinar series.

Table 57: Whiteshell Laboratories Closure Project Public Inquiries

Nature of Enquiry	Number
Transportation	3
Environmental protection	7
Whiteshell Laboratories Closure Project	11

15.1.3 Traditional and Online Communications

15.1.3.1 Website

CNL's Whiteshell Decommissioning web page had 1,667 page views in 2021.

To support the Whiteshell projects and site, CNL has used social media to promote events, share and receive information, and generally engage with the public. As Table 58, Table 59 and Table 60 show that social media has been an effective tool to reach and engage stakeholders. Table 61 shows that CNL also shared information through a community information bulletin.

Definitions:

Engagements - Measures how much and how often others interact with you and your content in social media.

Shares or retweets - Measures how often the message was shared or forwarded on the twitter website.

Table 58: Facebook Metrics for WL-related Posts*

Date of Post	Engagement	Shares

15.1.3.2 Newsletters

CONTACT is CNL's external, bilingual newsletter. It is distributed to community stakeholders, businesses and approximately 8,000 homes in the region surrounding WL, and is available on www.cnl.ca. This publication informs the reader on activities undertaken at CNL's Whiteshell Laboratories and profiles CNL's community activities. Two issues of *CONTACT* were distributed in 2021 and included the following topics:

- WL Closure Project and WR-1 updates
- Highlights of public and Indigenous engagement activities
- CNL initiatives in the community, demonstrating commitment to economic generation, sponsorship, donations and participation in community events
- CNL's COVID-19 response
- Employee transition
- Environmental stewardship, including steps CNL has taken to reduce greenhouse gas emissions, protect wildlife and minimize waste.

15.1.3.3 Media Releases

During 2021, there were seven articles written by media on the Whiteshell Closure Project (see Table 62).

Table 62: Media Coverage for 2021

Date	Article	Title of Publication
January 2021	Canada's Radioactive Waste Policy Review	LGD of Pinawa Municipal Quarterly Newsletter
January 20, 2021	O'Regan All In On Unnatural Resources	Winnipeg Free Press
March 18, 2021	CNL contributes to Pinawa daycare upgrades	The Clipper

March 26, 2021	Nuclear waste solution	Winnipeg Free Press
July 15, 2021	Pinawa erosion responsibility in question	The Clipper
September 2, 2021	CNEA continues funding North Forge East with three-year deal	The Clipper

15.1.4 Ongoing Projects

15.1.4.1 WR-1 In-Situ Decommissioning Environmental Assessment

The proposed WR-1 in situ decommissioning project (also referred to as in situ disposal) is a key part of CNL's overall integrated approach to safely manage and reduce Canada's legacy liabilities. The Environmental Assessment (EA) process for the project includes a requirement that WR-1 project information be made available to neighbouring communities, Indigenous communities and organizations, and stakeholder groups through a variety of mechanisms to ensure accessibility of fact-based information. Engagement activities conducted in support of this requirement included social media and website content, presentations, meetings, site tours and fulfilling stakeholder requests for information.

Project-specific webpages and content were produced for the WR-1 Project and included: fact sheets, info-graphics, downloadable posters, project descriptions and quick reference material. All information is available in both official languages at www.cnl.ca/wr-1.

15.2 Indigenous Engagement

CNL follows CNSC REGDOC-3.2.2 *Indigenous Engagement* [52] which sets out requirements and guidance for licensees on Indigenous engagement. CNL recognizes and values ongoing engagement with Indigenous communities and organizations in the spirit of truth and reconciliation.

15.2.1 Engagement Objectives

As part of its corporate, environmental, and social responsibility, CNL recognizes and encourages the ongoing engagement of the First Nations and the Red River Métis (represented by the Manitoba Métis Federation) through the course of the environmental assessment process for the WR-1 Project and engagement on the overall site closure project. Through information-sharing and engagement activities, CNL seeks to build awareness and learn about interests and concerns in an effort to strengthen mutual understanding and pursue

opportunities for collaboration and long-term relationships. CNL engages with First Nations and Red River Métis leadership, representatives and members on the potential effects of the WR-1 Project and the Whiteshell Laboratories Closure Project (WLCP) on the environment and on Indigenous and/or treaty rights including rights to trap, hunt, fish, gather and conduct cultural ceremonies.

CNL has five overarching Indigenous engagement goals:

- **Build awareness and mutual understanding** by supporting and facilitating opportunities for mutual learning on topics including current and traditional use, values and perspectives on nuclear decommissioning, environmental remediation and radioactive waste management, in order to demonstrate CNL's long-term commitment and approach to safe and responsible management of radioactive waste and decommissioning liabilities (e.g., through site monitoring activities).
- **Share information on the project**, including the potential effects on the environment. This includes developing meaningful, user-friendly information and communication products for the First Nations and the Red River Métis, and providing accessible and current information on project activities.
- **Seek input and feedback from the First Nations and the Red River Métis** on project-related activities, and traditional and current uses of the land surrounding the WR-1 project site. Initiate early and meaningful two-way communication between CNL and the First Nations and the Red River Métis to determine the best methods for sharing information and to provide opportunities for Indigenous Peoples to give input on project considerations including design, the EA process, and assessment of impacts.
- **Develop long-lasting relationships with the First Nations and the Red River Métis** to support their continued involvement in the project, community healing and reconciliation. This will extend beyond the scope of the EA process for WR-1.
- **Meet or where possible exceed all regulatory-based communication and engagement requirements** and facilitate engagement that reflects current memorandums of understanding and contribution agreements, and that takes into account the interests, needs and schedule of each Indigenous Nation.

15.2.2 Identified Indigenous Communities

CNL developed a list of the First Nations and the Red River Métis with a potential interest in the WR-1 Project and the WLCP. The identification of the First Nations and the Red River Métis was based on consultation with the CNSC, through CNL's previous Indigenous engagements, and through the use of publicly available sources of information including:

- First Nation and the Red River Métis and organization websites;
- The Aboriginal and Treaty Rights Information System (ATRIS; Government of Canada and INAC 2016); and
- Crown-Indigenous Relations and Northern Affairs Canada First Nation community profiles.

The list was based on the identified potential or established Indigenous or treaty rights of the First Nations and the Red River Métis and is provided in Table 63 with a brief rationale for inclusion. The inclusion of specific Nations considers the nature of the established and/or claimed rights and potential effects on those rights caused by the proposed project, based on a preliminary assessment of existing and available information. As such, the working list is subject to change based on information and dialogue with the identified First Nations, the Red River Métis, and Indigenous organizations.

Table 63: Identified Indigenous Communities

First Nations, the Red River Métis or Organizations	Identification Rationale
Sagkeeng First Nation (Treaty No. 1 and 3)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy one reserve located 52 kilometres (km) north of the WL site, and downstream along the Winnipeg River. Existing relationship and interest in the Whiteshell Laboratories site.
Brokenhead Ojibway Nation (Treaty No. 1)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy three reserves: 44 km northwest, 55 km northwest and 73 km southwest of the Whiteshell Laboratories site respectively. Interest expressed comments on Project Description.
Manitoba Métis Federation (MMF)	The MMF is the official democratic and self-governing political representative for the Métis Nation’s Manitoba Métis Community. The MMF is considered the government of the Red River Métis. Potential asserted and/or established Métis harvesting rights in the vicinity of the Project. Interest expressed comments on Project Description.
Black River First Nation (Treaty No. 5)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Proximity to the Whiteshell Laboratories site. Occupy one reserve 75 km north of the Whiteshell Laboratories site.
Hollow Water First Nation (Treaty No. 5)	Asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Occupy one reserve, 113 km north of the Whiteshell Laboratories site.
Shoal Lake No. 40 (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy three reserves: 94 km southeast, 110 km southeast and 140 km southeast of the Whiteshell Laboratories site, respectively.
Iskatewizaagegan No. 39 Independent First Nation (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site.

First Nations, the Red River Métis or Organizations	Identification Rationale
	Occupy four reserves: 93 km southeast, 102 km southeast, 110 km southeast and 140 km southeast of the Whiteshell Laboratories site, respectively.
Northwest Angle No. 33 (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy three reserves: 111 km southeast, 140 km southeast and 176 km southeast of the Whiteshell Laboratories site, respectively.
Wabaseemoong Independent Nations (Treaty No. 3)	Potential asserted and/or established Aboriginal and Treaty rights exist in the vicinity of the Project. Treaty No. 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site. Occupy four reserves: 80 km east, 85 km east, 95 km east and 140 km southeast of the Whiteshell Laboratories site, respectively.
Grand Council of Treaty 3	Umbrella treaty organization which represents 28 First Nations and 5 with potential interest in the Project. Treaty 3 territory includes parts of eastern Manitoba, including the Whiteshell Laboratories site.
Chiefs of Ontario	First Nations umbrella organization that represents 133 First Nations and 4 with potential interest in the Project

15.2.3 Summary of Engagement

Table 64 lists CNL's Indigenous engagement activities related to the WLCP from 2021. Further details on Indigenous engagements are available in the Indigenous Engagement Report [53].

Table 64: CNL Indigenous Engagement Activities for 2021

Date	Event	Location
Sagkeeng First Nation (SFN)		
January 5	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
February 18	Discussion on the application of Free Prior and Informed Consent on the WR-1 Project	Teleconference
March 9	Discussion with Chief and Council on engagement with Sagkeeng's members	Teleconference
April 6	Leadership discussion on Sagkeeng's Psychosocial Impact Assessment Report	Teleconference
April 15	Site Tour with Sagkeeng's Liaison Officer	On-Site Visit
June 16	CNL, AECL, and Sagkeeng participated in first Technical Working Group meeting	Teleconference
June 17	Sagkeeng's Liaison Officer visits the site to record video for National Indigenous Peoples Day	On-Site Visit
July 14	Sagkeeng's Liaison Officer participated in a bat survey on site	On-Site Visit
July 19	CNL, AECL, and Sagkeeng participated in second Technical Working Group meeting	Teleconference
August 11	Sagkeeng's Liaison Officer participated in a site tour	On-Site Visit
August 12	Sagkeeng's participated in the preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 17	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
August 24	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
September 7	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
September 14	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
September 22	Sagkeeng's Liaison Officer participated in Trauma-informed Engagement Training with CNL, AECL, and the CNSC	In-person, Winnipeg
September 28	Sagkeeng's participated in the second preliminary discussion of the Indigenous Advisory Committee	In-person, Winnipeg
November 10	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
November 15	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
December 15	CNL, AECL, and Sagkeeng participated in a Technical Working Group meeting	Teleconference
Manitoba Metis Federation		
January 6	WR-1 Environmental Impact Statement Section Review Meeting	Teleconference
February 8	Technical Workshop on WR-1 Groundwater Monitoring	Teleconference
February 18	Environmental Monitoring and MMF Green Initiatives Discussion	Teleconference

Date	Event	Location
March 2	Technical Workshop on Alternative Means Assessment and VC Components	Teleconference
March 9	Discussion on developing a relationship agreement	Teleconference
March 17	Overview presentation on the site's Environmental Protection Program	Teleconference
May 11	Wrap-up Meeting for Technical Workshops	Teleconference
May 25	Discussion on participation in site field monitoring	Teleconference
June 2	Discussion on WR-1 draft commitments and relationship agreement	Teleconference
June 3	Update on Whiteshell Laboratories Closure Project	Teleconference
June 14	MMF participated in groundwater monitoring, a songbird survey, and a turtle search at the site	On-Site Visit
June 18	Discussion on developing a relationship agreement	Teleconference
June 22	MMF participated in a bat survey on site	On-Site Visit
June 23	MMF participated in the a second bat survey on site	On-Site Visit
July 14	MMF participated in the a third bat survey on site	On-Site Visit
August 12	MMF participated in the preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 13	MMF hosted a leadership discussion with CNL's President and AECL's	In-person, Winnipeg
August 16	MMF observed river sediment, soil, and vegetation sampling	On-site Visit
August 19	MMF, CNL, and the CNSC participated in a trilateral meeting	Teleconference
August 19	Discussion on collaborating on a green initiative	Teleconference
September 8	MMF participated in Mushroom collection at site	On-Site Visit
September 21	Discussion on developing a relationship agreement	Teleconference
September 28	MMF participated in a second preliminary discussion on developing the Indigenous Advisory Committee	In-person, Winnipeg
October 20	Alpha Targeted Therapy Discussion	Teleconference

Date	Event	Location
November 17	Alpha Targeted Therapy Discussion	Teleconference
November 22	Discussion on developing a relationship agreement	Teleconference
December 2	Discussion on developing a relationship agreement	Teleconference
Black River First Nation, Hollow Water First Nation, Brokenhead Ojibway Nation		
February 1	Discussion on developing a relationship agreement	Teleconference
April 1	CNL, Black River First Nation, and Hollow Water First Nation sign a relationship agreement	E-mail
May 18	Discussion on onboarding the newly appointed liaison officer	Teleconference
May 25	Liaison officer participated in a site tour	On-Site Visit
June 1	Liaison officer onboarding discussion	Teleconference
June 23	Participating in site monitoring discussion	Teleconference
July 6	Participating in site monitoring discussion	Teleconference
July 14	Liaison officer participates in bat survey	On-Site Visit
August 12	Communities participate in preliminary discussion of the Indigenous Advisory Committee	On-Site Visit
August 16	Liaison officer participates in observation of river sediment, soil, and vegetation sampling	On-Site Visit
August 19	WR-1 Environmental Impact Statement Document review discussion	Teleconference
September 20	Update on Site Decommissioning Activities	Teleconference
September 28	Communities participate in second preliminary discussion of the Indigenous Advisory Committee	Teleconference
November 10	Six-month Relationship Agreement Discussion	Teleconference
December 13	Update meeting of community liaison committee development	Teleconference

15.2.4 CNL's Long-Term Relationship with Indigenous Peoples

CNL recognizes First Nations and the Red River Métis as stewards of the land and is working towards developing meaningful long-term relationships with each Nation that occupies and has traditional territories and/or modern-day interests near its site operations. CNL recognizes each Nation has its own unique set of interests and concerns associated with both the WR-1 decommissioning project and the WLCP is committed to taking a distinctions based approach to engagement to ensure each Nation's interests and concerns are addressed. CNL also takes a

holistic, relationship-based approach to engagement with each Nation, working closely with AECL, to help address interests and concerns regarding all aspects of the WLCP.

This shift in CNL's Indigenous engagement approach from project based engagement to a holistic, relationship and distinction-based approach will support meaningful actions to build foundations for trust, understanding, and mutually beneficial relationships, including addressing broader issues and concerns such as the historical siting of the Whiteshell Laboratories site.

CNL is currently working with each Nation to formalize these relationships through relationship-building and corresponding agreements. These agreements are intended to help enable greater integration of Traditional Knowledge, ceremony, and cultural and stewardship practices in the decommissioning, monitoring, and closure of the project. These agreements will also enable dialogue and participation through the development of monitoring programs, culturally appropriate communications, and trauma-informed engagement. In addition, the agreements help to enhance community engagement, build trust and strengthen relationship-building, and provide mechanisms that facilitate Indigenous participation and input into CNL's environmental monitoring program, economic development and procurement opportunities, future land use, and other areas of collaboration.

CNL has signed a relationship agreement with Black River First Nation and Hollow Water First Nation. Relationship agreements with Sagkeeng First Nation and the Red River Métis are contemplated, and steps are being taken to negotiate such agreements. CNL is committed to ongoing engagement and finalizing these agreements.

CNL continues to build relationships with local First Nations and the Red River Métis to support overall decommissioning of the Whiteshell Laboratories site, including the WR-1 Project. CNL is committed to learning about Indigenous values through ceremony and ongoing dialogue, and discussing, incorporating, and addressing concerns to the extent possible.

16 Acronyms

α	Alpha
ACMR	Annual Compliance Monitoring Report (formerly Annual Safety Review (ASR) or Annual Compliance Report (ACR))
AECL	Atomic Energy of Canada Limited
ALWTC	Active Liquid Waste Treatment Center
β/γ	Beta-Gamma
CCSF	Concrete Canister Storage Facility
CNEA	Canadian National Energy Alliance Limited
CNL	Canadian Nuclear Laboratories
CNSC	Canadian Nuclear Safety Commission
COVID-19	Novel Coronavirus Disease 2019
CRL	Chalk River Laboratories

Appendix A Concrete Canister Storage Facility

A.1 Operations

The Concrete Canister Storage Facility (CCSF) is operated under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [54]. Concrete storage canisters located at the CCSF have been used at WL since 1975 to store irradiated fuel; there are currently 16 canisters in use.

During 2021, staff of the Site and Nuclear Operations Branch monitored the operation of the CCSF.

The CCSF was operated in compliance with practices and procedures approved for operation. All required surveys and inspections were completed in 2021.

Routine operations in the CCSF were carried out by staff in the Site and Nuclear Operations Branch.

With the recognition of increased work in the CSSF and WMA, three operator trainees were hired, with two of the trainees starting in late 2021. A senior operator was appointed as Facility Supervisor.

In 2021, the CCSF continued to maintain the minimum staffing requirements outlined in the CCSF Facility Authorization [54]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the CCSF in 2021. Procedures for the Facility began their updates as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

A.2 Compliance Monitoring

A.2.1 Air Effluent Monitoring of Canister Liners

Each canister has a closed air-circulating system to monitor the internal space between the canister liner and the sealed fuel basket for the presence of fission products and moisture. Canisters are monitored for one week per month between April and November, dependant on weather. This year readings began in May and concluded in October. Despite multiple attempts flow could not be established in the Canister 8 air lines, these air lines have had issues in previous years obtaining flow. The normal approach to establishing air flow through lines was unsuccessful. Attempts will be made in 2022 to clear the line again.

The gross beta activity was below or near the detection limit of 0.04 Bq/m^3 for all canisters that were measured.

There was no visible moisture detected from the internal canister space during 2021 monitoring, however, the silica gel used in the counting did change colour from blue to pink indicating moisture in the air is present.

A.2.2 Monitoring of Ground and Surface Water

Figure 12 shows the drainage area surrounding the CCSF. Further details on monitoring and results of monitoring ground and surface water can also be found in Sections 9.4.1.3 and 9.5.1.4, and compliance results for the CCSF are described below.

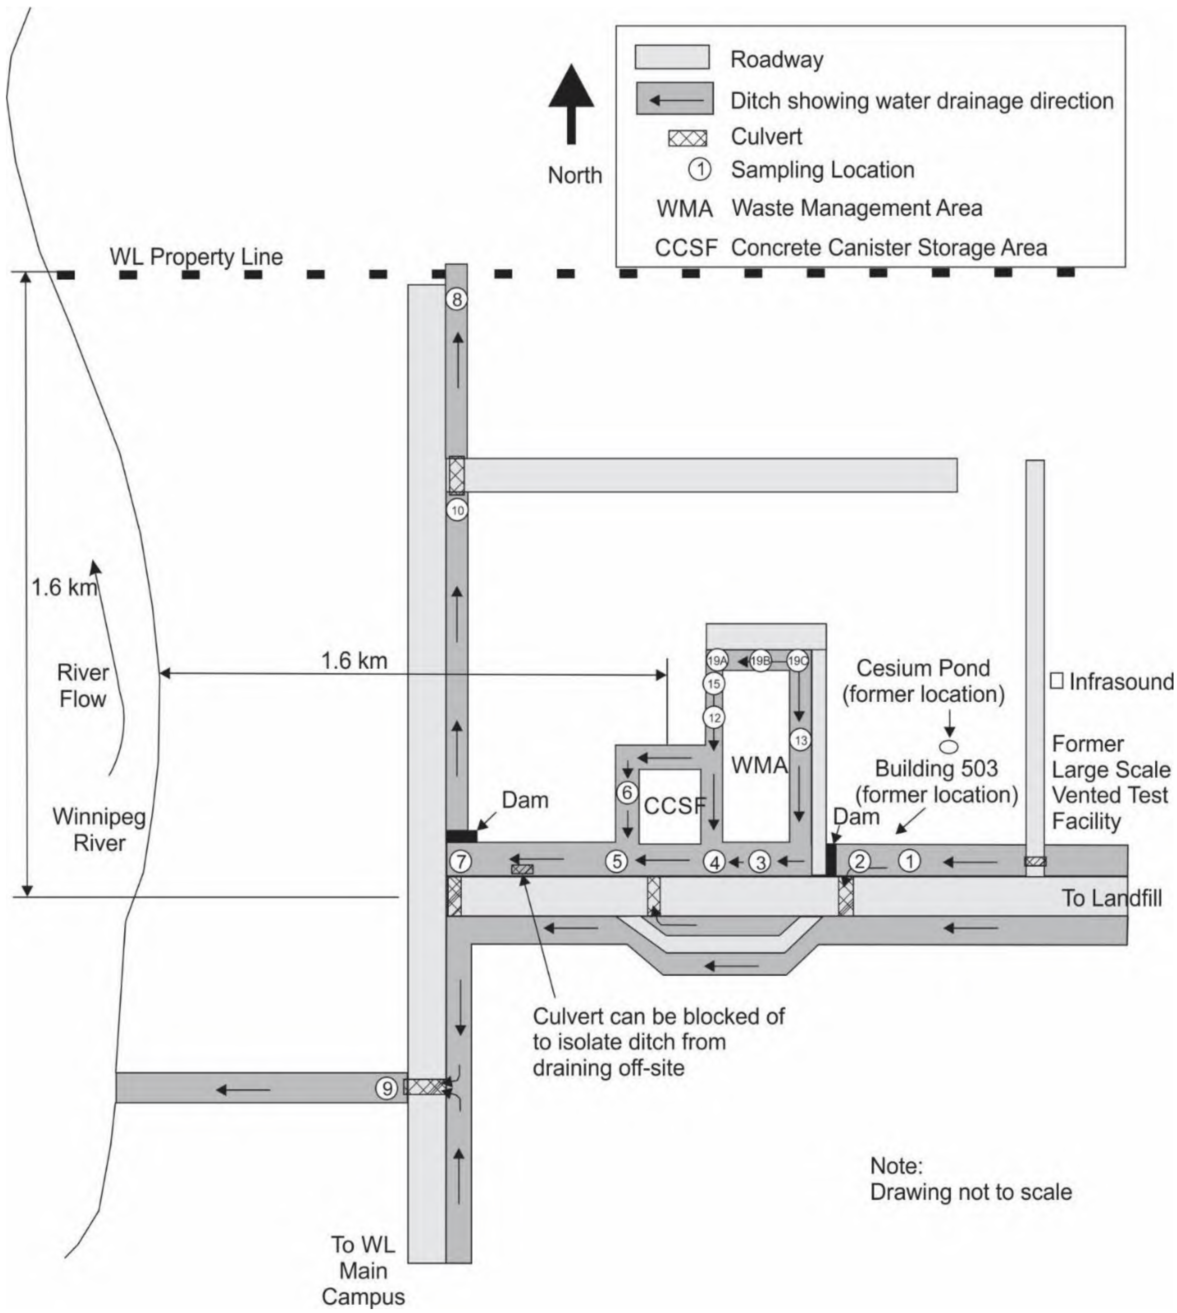

Figure 12: Surface Water Drainage Sample Points

Groundwater samples from deep-well sites in the vicinity of the CCSF are obtained twice yearly; the results are reported and discussed in Appendix D of this report.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the canisters. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period.

If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry analysis and processed for Strontium (Sr)-90. Gamma spectrometry analysis provides individual results for Cobalt (Co)-60, Niobium (Nb)-94, Antimony (Sb)-125, Cesium (Cs)-134, Cs-137 (Barium (Ba)-137m), Promethium (Pm)-147 and Americium (Am)-241.

If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry analysis and uranium analysis. Uranium analysis has also been conducted for other sampling locations below the limit this year. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration established by Health Canada [34]. If uranium is detected, the result is evaluated against the Maximum Acceptable Concentration for uranium (0.5 Bq/L).

Ditch Location 5 and Ditch Location 6 samples (see Figure 12 for sampling locations) could contain surface drainage from the CCSF, however, due to drought conditions and limited snow fall over the 2020/2021 winter, there was only one day with sufficient ditch water movement. This did not include Locations 5 and 6.

The alpha activities were below the trigger level of 0.5 Bq/L.

Table 65, Table 66, Table 67 and Table 68 list the results of the surface-water samples taken from the vicinity of the CCSF and WMA during 2021. Operational control-monitoring data from previous years has been included for completeness.

The ditch sample collected immediately downstream from the WMA (Location 7) contained elevated levels of tritium[12] (see Table 67), which did not exceed the associated Maximum Acceptable Drinking Water concentration of 7,000 Bq/L [34]. The activity seen is from the WMA as discussed in Appendix D.

---

[12] Tritium analysis of samples from Ditch Locations 5 and 6 was previously discontinued due to the higher levels of tritium (~4000 Bq/L) noted at upstream locations associated with the WMA.

A.3 Facility Changes

All facility changes were performed as per the Engineering Change Control procedure [13]. There were no major facility changes made in 2021.

A.4 Equipment Performance, Planned Maintenance Testing and Inspections

All canisters are checked for deviation from vertical annually. Out of 16 canisters, all displayed slight deviations from vertical in 2021. None of the canisters had a deviation greater than 1°. In 2021, Canister C5 had a deviation of 0.8° to the east. This deviation and those observed on other canisters show that they all display slight movements in response to changing soil moisture conditions and related swelling and contraction of the clay layer. If a canister was noted either through vertical deviation measurements or visually to be trending beyond a 2-3° deviation, corrective measures such as bracing would be considered.

There were no canister loading or unloading operations in 2021.

As required by Section 8 of the Facility Authorization [54], all routine maintenance for systems required to be operational was carried out as per the facility maintenance plan, and all equipment tests were complete. The inspections were all completed.

Whiteshell Laboratories staff conducted general site inspections during each quarter of 2021. The general appearance and fencing were found to be satisfactory on each inspection. Minor infilling was done along the base of the fence to meet security requirements.

In most cases, quarterly inspections of fuelled canisters have shown no significant cracking or spallation of concrete, however, existing cracks and pour pockets were regularly checked for changes and it has been noted that edges of many pour pockets are more brittle as was noted in 2020. Selective patching is done of these pour pockets, only minor patching was conducted in 2021. No increased radiation field was noted from the canisters.

A.4.1 Canister Site Monitoring and Surveillance

GAMMA FIELD SURVEYS

Gamma exposure rates from the canisters were measured quarterly in 2021. These readings were taken in compass directions north-east-south-west, on contact, and 2.0 m from the canister wall at an elevation of 2.0 m above grade level.

No gamma field anomalies were found during 2021.

Table 69 shows the averaged gamma near contact exposure rates measured during 2021, and for the previous four years.

a The measurements were made using a BOT P200 survey meter. The instruments are calibrated in mR/h and it is assumed 1 mR/h =1 mrem/h

AIR MONITORING

Air monitoring was conducted on each of the canisters in the CCSF in 2021. This involved an air pump that circulates air from an outlet line on the canister through a Dexter filter and returns it through an inlet line. These readings are taken once per month over a period of approximately one work week during warm weather months. Typically this is the six months of the year when air temperatures are normally above zero. As 2021 was a drier, warmer year, 7 months of sampling were done. As discussed above in Section A.2.1, flow could not be established in the Canister 8 air lines.

One anomalous but still low reading was found in Canister 20 leading to an average of 1.8 Bq/filter for the year. As the other readings were zero, this reading was retained but it is not indicative of a trend. Canister 13 and 16 had single readings slightly greater at 1 Bq/filter. The values may also relate to some disturbances of contamination on the baskets by the previous year's visual observations and the air flow from sampling.

Table 70 shows the averaged beta readings on each filter measured during 2021, and for the previous four years.

Table 70: Summary of Average Beta Radiation Measurements from Fuelled Canisters (Bq/filter)

A.5 Wastes Generated

There were no radioactive and/or hazardous wastes generated in the CCSF as part of routine operations.

See Section 11.1 Waste Management Program for summaries of any volume of radioactive solid and/or liquid waste generated in the CCSF in 2021.

A.6 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the CCSF as part of routine operations.

Releases from the facility are provided and discussed in Section 9, Environmental Protection.

Appendix B Active Liquid Waste Treatment Center

B.1 Operations

The Active Liquid Waste Treatment Center (ALWTC) in Building 200 did not operate in 2021.

Previously, in 2020 October, CNL notified the CNSC that the ALWTC, Building 200 was being demolished and had requested that the Facility Authorization [55] and the Safety Analysis Report [56] associated with the ALWTC be removed from the Whiteshell Laboratories LCH [14]. CNSC granted this request in 2020 December [57].

In 2017, new LLLWTS began operation in Buildings 100 and 300. All of the Building 100 low level liquid waste is now being tested, treated and controlled release to the river in the Building 100 LLLWTS and likewise in Building 300.

In 2020 October, the last of the operating systems in Building 200 were shut down and isolated (ventilation and compressed air systems). The building was rendered cold and dark and demolition of the building started later in 2020 October. Demolition of Building 200 above grade and 1.5m below grade were completed in 2021 October. The demolition footprint is still fenced and protected. The fence will remain until the potentially contaminated ground can be remediated.

B.2 Facility Changes

The demolition of the building was completed in 2021 October.

B.3 Wastes Generated

No solid radioactive or hazardous waste was generated in the ALWTC as part of routine operations.

See Section 11.1 Waste Management Program for WL summaries of any volume of radioactive solid and/or liquid waste generated in the ALWTC during demolition activities in 2021.

B.4 Effluents Released

There were no radioactive and/or hazardous effluents (liquid or gaseous) released into the environment from the ALWTC as part of routine operations.

Appendix C Shielded Facilities

C.1 Operations

The WL Shielded Facilities (SF) operates under the WL Site Licence [1], in accordance with the requirements of the Facility Authorization [58]. The SF, consisting of the Hot Cell Facility (HCF) and the IFTF, are located in the R&D Complex (Building 300), and are operated by personnel in the Site and Nuclear Operations Branch.

The HCF Cells 1 to 5 and IFTF Cell 13 remain operational while HCF Cells 6 to 11 have been shut down and partially dismantled. The Waste Handling Area, located in the IFTF, was operated for compaction and assaying of radioactive waste.

Operations and decommissioning activities were conducted throughout the year. Operations activities included:

- maintenance of HCF and IFTF ventilation system equipment;
- replacement of HEPA filters;
- packaging and storage of radioactive waste;
- cleanup activities; and
- routine maintenance to ensure compliance with the site licence.

Routine operations in the SF were carried out by operating staff from the Site and Nuclear Operations Branch.

There were no organizational changes in 2021. Although there was a reduction in the staffing for the operating staff responsible for the SF in 2021, the minimum staffing requirements outlined in the SF Facility Authorization [58] was maintained at levels to provide the needed operational and safety support.

No program changes were made for the SF in 2021. Procedures are being updated as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

C.2 Facility Changes

All facility changes were performed as per the approved Engineering Change Control procedure [13].

C.3 Equipment Performance, Planned Maintenance Testing and Inspections

Issues with missed and archived preventive maintenance activities was identified in 2021 and reported to the CNSC (see ImpAct ERM-21-3009 in Table 5). A corrective action plan was developed that will fix the issues and prevent recurrence.

Equipment tests and inspections were completed with the exception of a secondary Intermediate-Level Liquid Waste containment tank leak detector due to a defective probe. Compensatory measures were put in place until the detector was repaired. Monthly housekeeping and fire prevention inspections were completed.

VENTILATION SYSTEM

Maintenance activities requiring part of the ventilation system to be taken down occurred without incident.

The annual routine Poly-Alpha-Olefin testing of the HCF HEPA filters were successfully conducted.

C.4 Wastes Generated

See Section 11.1 Waste Management Program for WL summaries of the volume of radioactive solid and liquid wastes generated in the SF in 2021.

LOW-LEVEL SOLID WASTE

In 2021, the SF generated 45.6 m^3 of compactable low-level radioactive solid waste and no non-compactable waste.

The Waste Handling Area processed 62.1 m^3 of low-level radioactive solid waste which was reduced to 5 m^3. A portion of this waste was generated in the SF, and the remainder came from all of the nuclear facilities and decommissioning projects at WL where waste is being generated.

Table 71 lists the annual low-level solid waste generated in the SF for 2021 and the previous four years.

Table 71: Solid Wastes Generated

Total Volume	2017	2018	2019	2020	2021
Low-Level Solid Waste (m^3)	0.4	73.3	64.3	10.9	45.6
Medium-Level Solid Waste (m^3)	0	0	0	0	0

MEDIUM-LEVEL SOLID WASTE

In 2021 the SF generated no medium-level (intermediate-level) radioactive solid waste. Table 71 lists the annual medium-level solid waste generated for 2021 and the previous four years.

LOW-LEVEL LIQUID WASTE SYSTEM

In 2021, 99 m^3 of low-level liquid waste was processed through the Building 300 low-level liquid waste system (see Appendix E).

MEDIUM-LEVEL LIQUID WASTE SYSTEM

All the medium-level liquid waste (intermediate-level liquid waste) from the HCF cells collects in the HCF sump tank, AD Tank 1. The liquid is transferred via a manually controlled pump from AD Tank 1 through a filtration system to AD Tank 14 in the IFTF. The liquid from all other HCF medium-level liquid waste drains and all IFTF medium-level liquid waste drains flows by gravity to AD Tank 14.

In 2021, there was one transfer of 0.1 m^3 medium-level liquid waste to transportable totes that is being stored for future disposition.

Table 88 lists the annual aqueous waste generated for 2021 and for the previous four years.

C.5 Effluents Released

Liquid radioactive and hazardous effluents were discharged from the SF as part of routine operations are provided and discussed in Section 9, Environmental Protection.

Appendix D Waste Management Area

D.1 Operations

The Waste Management Area (WMA) operated under the WL Site Licence [1], in accordance with the requirements of the *Facility Authorization for the Operation of the Waste Management Area at the Whiteshell Laboratories* [59]. During 2021, the WMA at WL was operated and monitored by staff in the Site and Nuclear Operations Branch.

In 2021, the WMA was operated in compliance with approved practices and procedures.

Routine operations in the WMA were carried out by the Facility Manager, Facility Supervisor, WMA Operators and two WMA based utility workers, with support from other Site and Nuclear Operations personnel and Environmental Monitoring personnel as required.

In 2021, the staffing of the WMA was increased. A Facility Supervisor (Senior Operations Technician) was appointed and three additional Operations Technologist trainees were hired.

In 2021, the WMA continued to maintain the minimum staffing requirements outlined in the Facility Authorization [59]. Staffing was maintained at levels to provide the needed operational and safety support.

No program changes were made for the WMA in 2021. Procedures are being updated as necessary as part of the five-year review cycle for WL Nuclear Facilities Operating Procedures.

D.1.1 Inventory Additions And Deletions

Changes in inventory are reported in Table 72 and for the purposes of reporting WMA inventory (fission products are defined as radioactive material originating from irradiated fuel).

Activation products are defined as any material that has been activated in a neutron flux, including corrosion products. The radioactivity values listed are those recorded at the time of storage.

D.1.2 Low-Level Solid Waste

Details of wastes transferred to the WMA are provided in Section 11.1.1. Waste generated from decommissioning work on the site was generally shipped to CRL for storage, although some waste was stored in the WMA. Some of the inventory of stored waste in WMA was sent to CRL for storage pending future disposal. The stored volume of waste is listed in Table 72.

D.1.3 Industrial Waste

There were no additions of industrial chemical waste during 2021.

Table 72: Additions to Low-Level Waste Inventory

Period	Storage Locations	Volume (m^3)	Fission Products (GBq)	Activation Products (TBq)
Total Accumulation to 2020 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433.	18,798.84	1,967.38	330.58
Additions for 2021	Building 431 to 433	0	0	0
Removals for 2021	LLW Bunker 6 Buildings 431 to 433	9 0	13 0	0 0
Total Accumulation as of 2021 December 31	Trenches 1 to 23, LLW 1 to 6, Buildings 431 to 433	18,789.84	1,954.38	330.58

D.2 Compliance Monitoring

D.2.1 Monitoring And Surface Water

SURFACE WATER

Figure 12 shows the drainage area surrounding the WMA.

Surface drainage water samples would provide the first indication of any abnormal activity levels attributed to the WMA. The WMA and CCSF share a network of perimeter compliance monitoring ditches with designated sampling locations. Water samples are collected in these sample locations for analyses when there is sufficient flowing water present. The frequency of surface drainage sampling is controlled by the amount of spring runoff and the amount of rainfall throughout the spring-to-fall period. In 2021, there was only one day where the ditch flow met the required flow conditions in some sample locations due to the light snow pack leading to limited snow melt, limited rainfall and dry soil conditions.

A recorded amount of precipitation of 395 mm occurred in 2021, which was less than the 441 mm recorded in 2020, and is a ten year low for recorded precipitation. The low precipitation is reflective of an ongoing drought in the area.

In an effort to streamline the operational environmental monitoring process, surface water samples are initially analyzed for gross beta, gross alpha, and tritium. The results are then evaluated using the following screening criteria:

- If the beta activity in the surface water is above 10 Bq/L, an aliquot of the sample is submitted for gamma spectrometry, and processed for Sr-90. Gamma spectrometry provides individual results for Co-60, Nb-94, Sb-125, Cs-134, Cs-137 (Ba-137m), Pm-147, Am-241.

- If the alpha activity in the surface water is above 0.5 Bq/L, the sample is submitted for gamma spectrometry and uranium analysis, however, as was the case last year, all water samples were tested for uranium. Any detected gamma isotopes are evaluated against the applicable Maximum Acceptable Concentration (MAC) established by Health Canada [34]. If uranium is detected, the result is evaluated against the MAC for uranium (0.5 Bq/L or 20 ppb).

Levels of beta activity at ditch sample Locations 1 to 7 (Table 73) all remained well below 10 Bq/L. Based on historical data, it is conservatively assumed that the beta activity in the surface water is Sr-90 in secular equilibrium with Y-90. Most beta activity levels in the ditch water remained below the drinking water screening level of 1 Bq/L, and below the drinking water limit of 5 Bq/L for Sr-90 and 10 Bq/L for Cs-137 [60]. Compliance with Guidelines for Canadian Drinking Water [34] may be inferred if the measurement for gross alpha and gross beta is less than 0.5 Bq/L and 1.0 Bq/L, respectively. There were no exceedances of the Canadian Drinking Water [34] standard of 1.0 Bq/L (Table 73) in 2021.

The alpha activity levels in the surface water are presented in Table 74, and were below the trigger level of 0.5 Bq/L. Uranium results are presented in Table 75.

There was no flow at Locations 19 A, B and C in 2021. In past years, the uranium values recorded at these locations are believed to result from the use of local Lac du Bonnet Batholith granitic rock as base material for the SMAGS foundation. This rock had been also used for berm support material for the Cesium Pond pile, however that material was removed from the WMA in 2018. The Lac du Bonnet Batholith granite is noted to have naturally occurring uranium.

As shown in Table 76, the tritium results are below the Maximum Acceptable Concentration of 7000 Bq/L [34] at all locations with only one result above near-detection limits of 124 Bq/L at Location 7 in 2021. Other locations had no flow or near non-detection of tritium. Locations 19 A, B and C were originally chosen for sampling for the potential migration of cesium-137 due to the presence of the Cesium Pond soil pile. Although the Cesium Pond soil has been removed, CNL will continue to monitor locations 19 A, B and C due to the elevated levels of tritium.

The WMA contains a number of trenches with varying amounts of low-level radioactive waste. Tritium was identified as potentially capable of migrating to the ditches surrounding the WMA. Based on the initial modelling [61], it was proposed that tritium would be present in the ditches (including the Locations 3 through 7 and 19 A, B and C) and possibly reach levels as high as 37 kBq/L. While tritium is slightly elevated immediately around the WMA, periodic monitoring of the ditches has indicated that the levels of tritium at the points (Locations 8 and 9) leaving CNL property remain quite low (below an average value of 4.7 Bq/L in 2021). With the low flow volumes, tritium was only detected in one location. Although the amount measured in Locations 1 to 7 are above that noted at the Control location, the levels are much lower than the Maximum Acceptable Concentration in drinking water for tritium (7000 Bq/L).

Table 73, Table 74, and Table 75 present the WMA surface-water sampling data. The data represents continuing documentation of a spill incident that occurred in 1979 near ILW Bunker 3, from the reference sample point (Location 3) in the southeast section of the WMA, as shown

in Figure 12 and Figure 13. In 2017, sampling Location 3 was reconfigured to allow preparations for future bunker and standpipe remediation, but the location was dry this year due to the dry summer. Surface water at this location serves as an indicator of movement of water from ILW Bunkers 1, 2 and 3. The most mobile radionuclide (tritium) is below the associated Maximum Acceptable Concentration. The levels of tritium in the surface water and groundwater are below the radiation screening criteria used for identifying contaminants of potential ecological concern (COPECs) of $1.27x10^7$ Bq/L [62]. These tables, and Table 76, have been expanded to include the historical monitoring at Ditch Locations 19 A, B and C, water flow permitting.

The Cesium Pond soil (Cs-137) that was stored in the WMA adjacent to SMAGS was removed in 2017. There was no flow recorded in the north WMA ditch in 2021 (Locations 19 A, B and C) (Figure 13). Table 77 reflects this circumstance and shows that previous years indicated no migration of Cs-137 to these ditches.

As Trench 16 has a known quantity of Technetium-99 (Tc-99), Tc-99 measurements were performed as part of ditch water monitoring in 2021. Only one value near the limit of detection was measured (Table 78) The Tc-99 limit for drinking water is 200 Bq/L [60] and the measurement is well below this level.

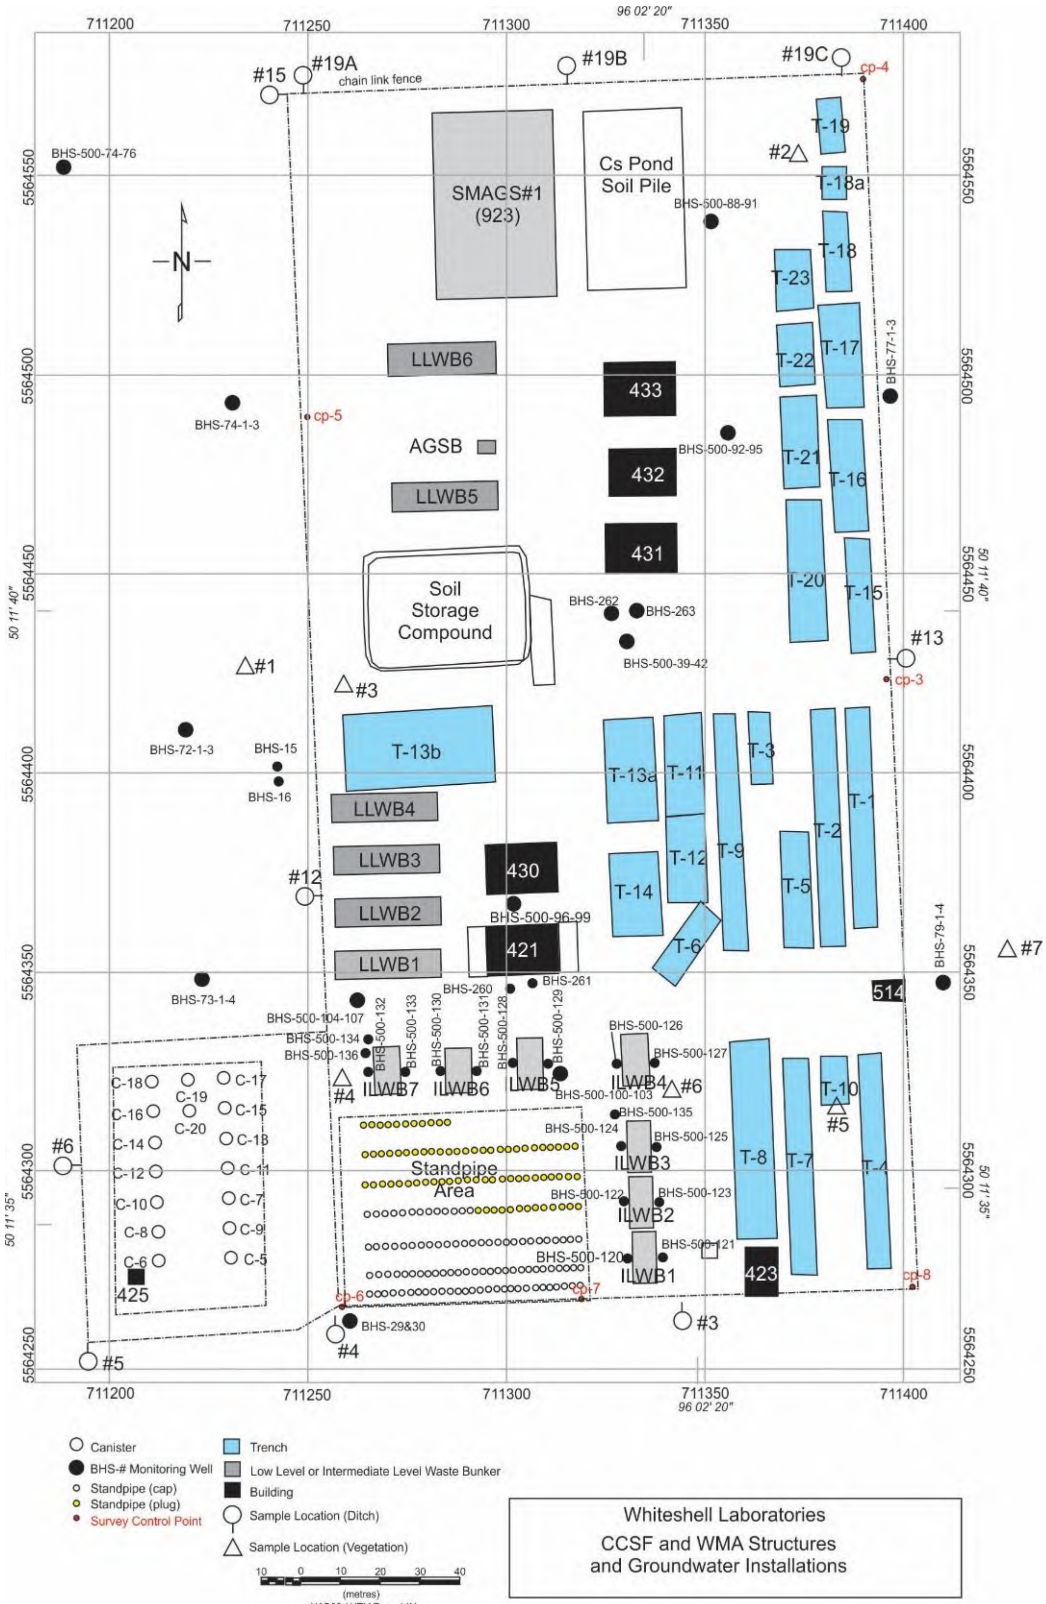

Figure 13: Ground Water Sample Points

INTERMEDIATE - LEVEL WASTE BUNKERS NEAR FIELD WELLS

A series of shallow near field wells were installed adjacent to the ILW bunkers in the WMA in 2015 (Figure 12). Groundwater samples were taken from the wells and from water in the ILW Bunkers for comparison. Cs-137, Sr-90, and tritium were selected as the radionuclides for monitoring of the potential for contaminant migration. Cs-137 was selected as the least mobile, with a high affinity for bonding with clay-based minerals, Sr-90 is more mobile but will bond with sand, and tritium is the most mobile that moves with water. Cs-137 and Sr-90 require a pathway (e.g., a construction joint or crack) to migrate from a bunker. In 2021, Sr-90 was noted to be a maximum of 34 Bq/L adjacent to ILW Bunker 1, and 20 Bq/L adjacent to ILW Bunker 3. For all other locations, the Sr-90 and Cs-137 levels were minor or negligible. Tritium can move through concrete without cracks by diffusion with water movement. The results indicate no migration of Cs-137 (Table 79) from the ILW Bunkers, and Sr-90 (Table 80) and tritium levels (Table 81) that are orders of magnitude below the levels observed in the water in the adjacent ILW Bunkers. At ILW Bunker 3, the tritium results remain high (126,326 Bq/L) and moderately high at ILW Bunker 5 (11,051 Bq/L).

A series of water measurements were made as a confirmatory check in 2020 for the presence of base neutral chemicals (e.g., benzenes, ethylenes) and PCBs. These measurements indicated these chemicals were not present in the water around the bunkers. The measurement was not repeated in 2021.

WATER TABLE WELLS AND DEEP WELLS

Water samples were collected from wells in and around the WMA (Figure 13) in the spring and fall of 2021. The gross alpha and gross beta results are summarized in Table 82. The beta activity levels in the clay, clay till and basal zone wells remained below the drinking water screening level of 1 Bq/L. All zones were below the limit for Sr-90 (5 Bq/L) and Cs-137

(10 Bq/L) [34]. The average alpha activity in the samples collected from the Basal zone wells was below the screening level.

Uranium concentrations in the basal zone wells ranged from 0 to 0.59 Bq/L. The concentrations in the Clay zone wells ranged from 0.19 to 3.60 Bq/L, and in the clay till from 0 to 1.61 Bq/L. Since it is known that the local well waters within the Canadian Shield contain naturally occurring uranium [63], the presence of uranium and its progeny are not unexpected and are considered to account for the levels of alpha. Low levels of tritium were noted in the clay (23.29 Bq/L) and clay-till (11.33 Bq/L). This is not unexpected as these overburden layers are impacted by tritium in the WMA.

Table 82: Monitoring Data Water Table Wells and Deep Wells

WMA Sample Locations	2017 Avg. (Bq/L)	2018 Avg. (Bq/L)	2019 Avg. (Bq/L)	2020 Avg. (Bq/L)	2021 Avg (Bq/L)	2021 Avg. Range (Bq/L)
Total Beta [a]						
Clay	0.35	0.29	0.42	0.26	0.43	0.19 to 1.39
Clay Till	0.36	0.25	0.26	0.30	0.45	0.09 to 1.06
Basal	0.16	0.13	0.34	0.11	0.25	0.11 to 0.91
Total Alpha [b]						
Clay	1.01	1.03	0.87	0.52	0.67	0.27 to 2.81
Clay Till	0.77	0.72	0.75	0.80	0.58	0.07 to 1.21
Basal	0.10	0.12	0.22	0.14	0.19	0.03 to 0.48
Total Uranium [c]						
Clay	0.90	0.88	0.86	0.70	0.82	0.19 to 3.60
Clay Till	0.52	0.62	0.60	0.71	0.55	0.003 to 1.61
Basal	0.01	0.04	0.01	0.06	0.03	0.003 to 0.59
Total Tritium						
Clay	11.60	11.36	8.07	7.56	10.37	3.11 to 55
Clay Till	13.36	13.51	14.07	21.31	11.33	3.32 to 65.21
Basal	4.08	4.63	5.66	3.48	3.59	3.16 to 4.62

a The reference nuclide for total beta is Sr-90
b The reference nuclide for total alpha is natural uranium
c The value calculated from the concentration of uranium in the water sample

HIGH-LEVEL LIQUID WASTE TRAY WATER

Monitoring of the high-level liquid waste tank tray water was carried out to confirm there is no leakage from the residue remaining in the storage tanks. This is sampled in the summer months. The sample results indicated no leakage has occurred from the tanks. The data are

summarized in Table 83. In the late fall of 2004, the high-level liquid waste had been removed from high-level liquid waste Tank 2 and transferred to the SF for cementation. A heel of waste remains to be removed. High-level liquid waste Tank 1 remains empty.

Table 83: Monitoring Data High-Level Liquid Waste Tank Tray Water

WMA Sample Locations	2017 Avg (Bq/L)	2018 Avg (Bq/L)	2019 Avg (Bq/L)	2020 Avg (Bq/L)	2021 Avg (Bq/L)	2021 Range (Bq/L)
Total Beta [a]						
Tank Tray Water	13.8	13.8	12.1	11.2	17.7	13.6 to 25.3
Total Alpha [b]						
Tank Tray Water	0.65	0.69	1.5	0.95	0.2	0.1 to 0.4

a The reference nuclide for total beta is Sr-90, gamma results indicate that approximately 13Bq/L of the gross beta activity is due to K-40.

b The reference nuclide for total alpha is Pu-239

D.2.1.1 RADIATION FIELD MEASUREMENTS

Radiation field measurements are taken semi-annually at established points (normally every 38 m) along the perimeter fence. The 2021 radiation field measurements were similar to those in 2020. The data is summarized in Table 84.

Table 84: Perimeter Fence Monitoring Data

WMA	Radiation Field (µSv/h)					
	2017 Avg	2018 Avg	2019 Avg	2020 Avg	2021 Avg	2021 Range
Spring Survey						
South Fence	0.2	0.2	0.2	0.3	0.2	0.1 – 0.3
West Fence	0.4	0.4	0.4	0.3	0.3	0.1 – 0.6
North Fence	0.2	0.2	0.2	0.4	0.2	0.1 – 0.3
East Fence	0.3	0.3	0.3	0.2	0.4	0.1 – 0.5
Fall Survey						
South Fence	0.2	0.2	0.2	0.4	0.3	0.2 – 0.3
West Fence	0.4	0.4	0.5	0.3	0.4	0.2 – 0.6
North Fence	0.2	0.2	0.2	0.3	0.3	0.2 – 0.4
East Fence	0.3	0.3	0.4	0.3	0.2	0.1 – 0.5

D.2.1.2 VEGETATION

In 2021, vegetation samples were collected at monitoring locations within the WMA (Figure 13), and at a control location unaffected by WL operations. The gross beta results are

summarized in Table 85. Potassium (K)-40 represents the majority of gross beta activity in most of the samples. The levels of gross beta in the samples are due to a combination of K-40 and Sr-90/Y-90, with a minor contribution from Cs-137. The average Sr-90 contribution for the vegetation samples in the WMA is 6% (12% for Sr-90/Y-90). Results were historically reported as Bq/m^2 as there was the potential for deposition of radioactivity via airborne emissions from the former WL Incinerator and former Baler operations. The incinerator and baler have not been in operation for many years and have been decommissioned. The results are now presented as Bq/kg and represent the uptake of radioactivity from impacted areas near the sampling locations.

Table 85: Waste Management Area Vegetation Monitoring Data

WMA Sample Locations	Average Gross Beta[a] (Bq/kg)				
	2017 Avg	2018 Avg	2019 Avg	2020 Avg	2021Avg
North-East Area[d]	NA	672	450	196	207
Mid-West Area	1619	411	155	173	190
South-West Area	275	414	NA	296	243
South-East Area	460	409	441	230	246
Control Sample[b]	379	187	210	162	171
Background Sample[c]	419	324	317	203	157
East of ILW Bunkers 3 and 4	NA	672	450	NA	218

a The reference nuclide for beta is Sr-90
b Adjacent to the WMA outside of the fence boundary
c Ambient Radiation monitor Stations Background Samples
d Until 2012 this sampling point was in the North-West area after 2012 it was moved to the North-East area. Only a single set of vegetation samples was taken as of 2017 as uptake occurs over the summer. Range is no longer included because of this change.

In 2021, the Facility continued to maintain the minimum staffing requirements outlined in the Facility Authorization [59]. Three trainee operators were hired in 2021 to begin increasing staffing to meet with planned decommissioning activities. Staffing was maintained at levels to provide the needed operational and safety support.

D.3 Facility Changes

All facility changes are performed as per the approved Engineering Change Control procedure [13].

Work to prepare for extraction of waste from the Intermediate Level Bunkers and Standpipes was begun in 2017 and continued into 2021 with most of the physical preparatory work done with continued fabrication of extraction equipment off site.

The pad to the east of the north access road had the requisite safety analysis and procedural documents prepared. The pad is now designated as the Recoverable Surface Staging and Storage Area and will be placed into service in 2022 to store Seacan containers containing

waste and oversized items. The Seacan containers or items will be awaiting processing, characterization and packaging for off-site shipment. This was required to allow Building 923 (SMAGS) to be converted to a Cask Loading Facility (CLF).

Building 923 is in the process of being converted to the CLF. In 2021 this included installation of a 15 ton overhead crane, additional lighting and ventilation ducting and an air handling unit. Interior shielding walls were also erected. The current interior equipment is awaiting commissioning and connection of additional power. Further installation work will be done in 2022.
