| IR-57 | - | NRCan | Fish and fish habitat | <p>Section 7.3.3.2</p> <p>Appendix 7-A, sections 3.1.2 and 3.7</p> <p>Appendix 7-C, section 2.5.2</p> | <p>Context: The Proponent's conceptual model of groundwater flow in the Local Study Area (EIS, sec 7.3.3, Figure 7.3-7) involves an unconfined Upper system hosted by overburden and the Upper sandstone aquifer, and a Lower confined system hosted by the Lower Sandstone Aquifer. The Intermediate Sandstone aquitard acts as a confining unit. Vertical heads gradients are directed downwards west of the Phoenix deposit and upwards beneath surface water receptors including Whitefish Lake (EIS, sec. 7.3.3.2).</p> <p>Using head data from nested monitoring wells (Appendix 7-A, sec. 3.1.2, Table 3-1) the Proponent calculates upward gradients in cluster WR-607, between the Lower Sandstone aquifer and the Upper Sandstone aquifer. In cluster LA-5, an upward gradient is calculated between the Upper Sandstone and the overburden unit (Appendix 7-A, Table 3-5). In areas west and south-west of the Phoenix deposit, groundwater is estimated to flow downward under a vertical gradient of approximately 0.015 m/m (Appendix 7-A, p.3-15).</p> <p>Rationale: In NRCan's opinion, the Proponent's interpretation of vertical head gradients in the LSA is not fully accurate. For the "Up-Gradient" monitoring well cluster, the tabulated head data (Appendix 7-A, Table 3-1) and data logger hydrographs (Appendix 7-A, Appendix B) indicate a downward gradient (0.014 m/m) from the overburden unit to the Intermediate Sandstone and an upward gradient (0.056 m/m) from the Lower Sandstone to the Intermediate Sandstone. Head data from the "NW" monitoring well cluster indicate a similar pattern of downward (0.016 m/m) and upward (0.014 m/m) gradients converging in the Intermediate Sandstone. In the "Downgradient" and "SE" monitoring well clusters, head observations and data logger hydrographs indicate downward gradients from the shallow aquifer system but essentially equal heads in the Intermediate and Lower Sandstones. This more complex picture of groundwater flow systems in the LSA does not appear to have been captured in the Proponent's conceptual model. Given the importance of the baseline hydrogeological regime for predicting the transport and fate of COPCs in the post-decommissioning period, the Proponent needs to demonstrate that the numerical groundwater flow model accounts for observed vertical head gradients.</p> | <p>In section 2.5.2 of Appendix 7-C (Calibration Results), the Proponent should demonstrate that the numerical groundwater flow model reproduces quantitatively or at least qualitatively the vertical head gradients calculated from observations in the nested monitoring well clusters (Appendix 7-A, Table 3-1).</p> | | Accepted |

|--------------|----------------|-------|-----------------------|---|---|--|----------------------|----------|
| IR-58 | - | ECCC | Fish and fish habitat | Section 7.3.2.4, Ore Deposit | <p>Context: The Proponent states that the Phoenix ore bodies are long and narrow (approximately 25 to 50 m wide) and are located within or near a graphitic pelite unit. Hydrothermal alteration associated with the ore zone is a discontinuous envelope of clay alteration and a sulphide-cemented rock zone that extends into the overlying sandstone and the underlying basement (Figure 7.3-3). This black, clay-rich zone is approximately 3 m thick on average and locally hydraulically isolates the ore zone from the overlying sandstones and underlying weathered basement rock.</p> <p>Rationale: As indicated by the Proponent, a 3 m black clay rich zone isolates the ore zone from the overlying sandstones and underlying weathered basement rock. It is, however, unclear whether this discontinuous clay layer will prevent downward migration of uranium-bearing solution into the Paleo-weathered basement rock or horizontal flow along the unconformity surface to escape into the environment. Escape of uranium-bearing solution into the environment will have a negative effect on the receiving environment.</p> | <p>1. Verify that there will be no downward migration of mining solution into the paleo- weathered basement rock or that there is no flow along the unconformity surface.</p> <p>2. If downward migration of the mining solution occurs, explain how it will be mitigated.</p> | | Accepted |
| IR-59 | - | CNSC | Fish and fish habitat | Section 7.4 Assessment of Project-related Effects, Figure 7.4-2 (p. 7-56) | <p>Context: Figure 7.4-2: Simulated Change in Groundwater Discharge and Flow through Whitefish Lake Over the Life of the Project appears to be missing information.</p> <p>Rationale: Legend is included below the image, but the Legend box is blank. The green dotted line is not represented by anything in the legend.</p> | <p>Please update this Figure to ensure it is complete, and that features are properly indicated in the legend.</p> | | Accepted |
| IR-60 | - | NRCan | Fish and fish habitat | Section 7.4.2.1 Appendix 7-C, section 5.2.1, Appendix B | <p>Context: In the discussion of the limitations of the numerical groundwater flow model (Appendix 7-C, sec. 5.2.1), the Proponent invokes the well known modeling principles of "Occam's razor" and "Parsimony" which guided the parametrization of hydraulic conductivity in model layers. The Proponent states that hydrogeologic property values were applied uniformly for, among other units, the Lower Sandstone aquifer beyond the immediate area of desilicified materials. However, in the layer parametrization for the Lower Sandstone aquifer (Appendix 7-C, Appendix B, Figure B-5), NRCan notes a large zone of enhanced conductivity (1 E-05 m/s) extending south from Kratchkowsky Lake, which contrasts with the value (2 E-07 m/s) assigned elsewhere outside the desilicified zone. NRCan also notes the extremely detailed parametrization of hydraulic conductivity in the clay cap overlying the ore zone where borehole control is dense (Appendix 7-C, Appendix B, Figure B-6).</p> <p>Rationale: In NRCan's opinion, these model features appear to violate the principle of "Parsimony" and require greater justification supported by field observations.</p> | <p>NRCan requests that the Proponent provide justification based on field evidence for the multiple hydraulic conductivity zones assigned to the Lower Sandstone aquifer and the clay cap above the ore zone.</p> | | Accepted |

|--------------|----------------|------|-------------------------|--|--|--|---|----------|
| IR-61 | - | CNSC | Geology and Groundwater | Section 7.4.2 | <p>Context: There is no discussion of potential induced seismicity from mining processes.</p> <p>Rationale: Induced seismicity may lead to a loss of process as identified for natural seismicity.</p> | Please provide information on the potential mining-induced seismicity. | <p>This IR is accepted. However, it is requested that Denison review the draft EIS for inaccuracy of scientific terms which cast doubt on the credibility of the EIS, such as the use of the term “inducted seismic” instead of “induced seismicity” in section 7.4.2.4.</p> <p>CNSC staff suggests that Denison review the entire draft EIS once again to address similar inaccuracies.</p> <p>See AD-72 in the Advice to Proponent table [reference to come].</p> | Accepted |
| IR-62 | - | ECCC | Fish and fish habitat | Section 7.4.2, Potential Project-related Effects | <p>Context: The Proponent indicates that the mining area includes:</p> <ul style="list-style-type: none">the ‘active mining area’, which is the target ore zone;a zone extending between 11 and 13 m above the active mining area that represents the maximum vertical height over which the injected mining fluids will migrate upwards from the ore zone during active mining; anda zone extending 50 m vertically upwards from the active mining area (that incorporates the active mining area and the 11 to 13 m zone defined in the previous bullet) that was selected to account for potential upset conditions. <p>Rationale: It is not clear to ECCC how the Proponent would be able to limit the mining solution migration within 11 & 13 m above active mining as the maximum vertical height over which the injected mining fluid will migrate. As the mining fluid will be injected under pressure into zones with possible presence of fractures, the pressure may also cause additional fractures and given that the solution is warm/hot will possibly dissolve the other cementing material in the sandstone above, making it difficult to accurately predict where the solution will migrate to.</p> | <ol style="list-style-type: none">1. Explain plans to limit the upward migration of mining solution into the overlying layer to 11 and 13m above the ore zone.2. Explain what impacts will occur if the mining solution migrates beyond the predicted height. | | Accepted |
| IR-63 | - | CNSC | Geology and groundwater | Section 7.4.2.1, Potential Effect #1: Groundwater Quantity – Construction to Decommissioning Appendix 7-C, Section 2.7, Groundwater Conditions During Mine Operations | <p>Context: The numerical groundwater model described was calibrated to observed water level and stream baseflow data. Table 7.4-3 in the EIS indicates that Denison recognizes the potential for freeze wall operation to impact groundwater quantity. To simulate this impact, the model was adapted to reduce recharge (to 50%) within the freeze wall area, reduce hydraulic conductivity associated with the vertical freeze walls, and simulate pumping within the freeze wall area. Recovery from pumping and effects on discharge to groundwater discharge to Whitefish Lake are discussed in the potential effects section.</p> <p>Rationale: Although this assessment considered drawdown of the water table and discharge to Whitefish Lake, the discussion did not address the potential effects of operating the freeze wall on the local and semi-regional groundwater regimes. What would the pathway be for groundwater to pass around the freeze wall? What is the basis for the parameters selected, e.g., 50% recharge and lower hydraulic conductivity for freeze well? These factors need to</p> | Please provide a more fulsome discussion on the impact of freeze wall operations on local and semi-regional groundwater regimes and potential receptors. Please provide the rationale for assumptions made for key model parameters (e.g., selection of 50% recharge, hydraulic conductivity value used to represent freeze wall). In addition, please discuss the potential pathways for groundwater flow around the freeze wall, complete with figures demonstrating these pathways. | | Accepted |

| | | | | | be considered when evaluating the potential impacts of freeze well operations on groundwater flow conditions and corresponding receptors. | | | |
| IR-64 | - | ECCC CNSC | Fish and fish habitat | Section: 7.4.2.2, Potential Effect #2: Terrain Morphology and Stability – Operation Appendix 7-A, Appendix K (p. 12) | <p>Context: The Proponent stated that the geological assessment predicted maximum vertical displacement in altered sandstone immediately above the mining area (17.5 cm). A very minor change in elevation at ground surface (of less than 7.5 cm) was predicted within a discrete and localized area overlying the ore body. The modelling work is considered to provide a worst-case bounding scenario. If subsidence were to occur over the lifetime of the Project, or in the years following mining, the extent of vertical displacement is not expected to exceed that predicted in the modelling, which is based on an assumed volume extraction.</p> <p>Rationale: ECCC notes that the thickness of the ore zone has an average thickness of 5 m with a range of 2 to 17 m, and is 25-50 m wide and that the overburden rock above the ore zone measures about 400 m. Therefore, it is not clear how the Proponent determined that the surface expression of a subsidence on the surface if it occurs will be limited to 7.5 cm and localized. A subsidence greater than 7.5 cm, implies that the void in the ore zone will be narrower, and will affect the amount of water migrating through the zone.</p> <p>It was the recommendation of the consultant who conducted the work in Appendix K that more accurate material properties should be used for future modelling.</p> | <p>Explain:</p> <ul style="list-style-type: none">Will this be revisited with updated data based on extraction feasibility results?How will the surface expression of a subsidence will be limited to 7.5 cm and localized? <p>Suggestions for mitigation and follow-up measures: ECCC recommends that the Proponent consider implementing remediation measures immediately after mining to prevent subsidence from occurring in the first place.</p> | | Accepted |
| IR-65 | - | CNSC | Geology and Groundwater | Section 7.4.2.2 | <p>Context: It is stated the maximum subsidence is 7.5cm based on modeling with an assumed volume extraction. Has subsidence from dewatering/pumping and from lack of inflow of groundwater due to freeze wall been considered?</p> <p>Rationale: Surface facilities and wells may be impacted if there is unaccounted for subsidence.</p> | Please provide additional details for any dewatering/pumping induced subsidence. | | Accepted |
| IR-66 | - | CNSC | Geology and Groundwater | Section 7, Table 7.5-1, Row 1, Column 6 | <p>Context: Column 6 in Table 7.5-1 indicates the mitigation measures for a valued component. For Row 1, Geology, there is no description of mitigation measures but only that contingency plans will be developed if based on monitoring.</p> <p>Rationale: Subsidence may impact wells and surface infrastructure.</p> | Please provide additional details on monitoring and contingency plans related to the geological environment (e.g., subsidence), including triggers for implementing such plans. | | Accepted |
| IR-67 | - | CNSC | Geology and groundwater | Section 7.6.2.1 (Remediation Objectives) | <p>Context: Metallurgical testing, including batch reaction, coreflood testing and column tests are mentioned frequently throughout Sections 2 and 7 of the EIS. Outside of the composition of restored solutions from coreflood tests #2B and 3C, results from these various tests are not reported in the EIS or any associated</p> | 1. Please provide a summary of the results and the analysis of results of the metallurgical tests within the EIS, or provide the technical supporting document with this information, and ensure the documentation is appropriately referenced in the EIS. This should include sample information for cores (e.g., mineralogy, | | Accepted |

|--------------|----------------|-------|-----------------------|---|--|--|----------------------|----------|
| | | | | | Appendices. Rationale: The results from metallurgical testing are important to a number of items discussed in the EIS, including (but not limited to): evolution of hydrochemistry during remediation, source of salts in Lower Sandstone Aquifer porewaters, process plans, industrial wastewater treatment, estimating composition and volume of process precipitates, and composition of mining fluids and leachate. In particular, the EIS posits that mining area decommissioning objectives are achievable based on metallurgical testing and provides these objectives in Table 2.3-3. CNSC staff need to understand the specifics of this metallurgical testing, given its importance for the development and justification for mining and remediation activities. Denison must also provide information demonstrating that the proposed restoration actions and remediation targets are As Low As Reasonably Achievable (ALARA). | location, U content, depth), test conditions (e.g., duration, # of iterations, column length, flow rate, temperature, pressure, sample frequency, influent/effluent composition), as well as results and how they are pertinent to the development of ISR activities. 2. Please provide further clarification/justification on how results from two singular coreflood tests (i.e., Coreflood #2B and Coreflood #3C) can justify large-scale remediation activities and targets following solution mining. 3. Please provide material demonstrating that the proposed restoration actions and remediation targets are ALARA. | | |
| IR-68 | - | NRCan | Fish and fish habitat | Section 7.6.2.2.3 Appendix 7-C, sections 3.3, 4.1, 4.4.4 and 4.7 | Context: Sources terms for the COPCs considered in 3D reactive transport modeling are given by the composition of "Restoration Solution #1", which the Proponent believes is representative of groundwater quality in the ore zone after remediation at decommissioning (Appendix 7-C, sec. 3.3, Table 3-5; sec 4.0). The Proponent considers COPC source terms as "initial conditions" for groundwater quality in the ore zone at the start of the model simulation period. During the simulation, no additional mass of COPCs is transferred to groundwater in the ore zone. Rationale: In NRCan's opinion, this representation of COPC sources is not conservative as it fails to account for various long-term slow mass release processes. These processes could include redissolution of secondary phases formed during ISR mining (e.g., radium-bearing gypsum or barite, jarosite, alunite) and migration of unrecovered lixiviant or restored solution from low-permeability regions or stagnant zones that were not fully swept during mining or remediation. NRCan notes that scenario #2 in the Proponent's transport prediction uncertainty analysis (Appendix 7-C, sec. 4.7) does consider an extended source release period for protons (desorption from chlorite). However, in NRCan's opinion, additional modeling scenarios should consider extended-release periods for other COPCs as well. | NRCan requests that the Proponent's reactive transport prediction uncertainty analysis (Appendix 7-C, sec. 4.7) consider extended source release periods for additional COPCs. | | Accepted |
| IR-69 | - | NRCan | Fish and fish habitat | Section 7.6.2.2.3 Appendix 7-C, sections 3.1 and 3.2 | Context: For hydrogeological and geochemical assessments in support of ISR projects, the Proponent identifies two aspects of primary importance (Appendix 7-C, sec. 3.1). These are a) groundwater remediation (Appendix 7-C, sec. 3.1.1); and b) the assimilative capacity of host rocks downgradient from the ore zone (Appendix 7-C, sec. 3.1.2). According to the Proponent, the | NRCan requests that the Proponent provide a detailed description of the expected mineralogical and hydrogeochemical changes occurring within the ore and barrier zones as a result of the injection of acidic lixiviant. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------------------|--|---|--|--|----------------------|----------|
| | | | | | <p>objective of groundwater remediation at decommissioning is to achieve water quality in the mined zone that does not pose a risk to receptors at the point of exposure. Assimilative capacity refers to the ability of groundwater-rock reactions to naturally sequester or attenuate COPCs migrating from the ore zone during the post-decommissioning period.</p> <p>Rationale: However, in NRCan's opinion, the Proponent has neglected to mention the most fundamental aspect for hydrogeological and geochemical assessments in support of ISR projects. That aspect is the choice of ISR lixiviant and its effects on the mineralogy and hydrogeochemistry of the ore zone during mining operations. The Proponent provides information on the pre-mining mineralogy (Appendix 7-C, sec. 3.2.1) and hydrogeochemistry (Appendix 7-C, sec. 3.2.2) but no information on their expected changes as a result of ISR mining. This Information is important when considering source terms in reactive transport modeling.</p> | | | |
| IR-70 | - | CNSC ECCC | Fish and fish habitat Geology and groundwater | Section 7.6.2.2.3, Evaluation of Geochemical Reactive Transport Appendix 7-C, Section 4.4.2, Sub-Domain Model Hydrogeologic Parameters | <p>Context: The EIS indicates that “changes to hydrogeological conditions within the mining area were considered during development of the 3D sub-domain model. Dissolution of ore within the active mining area is expected to enhance ... hydraulic conductivity”.</p> <p>In Section 4.7 (Prediction Uncertainty Analysis), predictive uncertainty scenarios are provided. For scenario 7, the hydraulic conductivity (K) of the ore zone was increased even further than initial model assumptions. The value used is not indicated in the text.</p> <p>Rationale: A hydraulic conductivity (K) value of 5x10-6 m/s, which is a factor of five (5) greater than the value assumed for the ore zone, was applied in the base case numerical model to account for this impact. It is unclear from the information provided in Section 7 of the EIS or associated Appendices what the basis of this five-fold increase in K value for the ore zone, and how this was judged to be conservative, or to adequately represent anticipated conditions. This parameter is important as it impacts the rate at which contaminants flow from the ore zone following mining activities. Due to the dissolution of uranium, larger voids will likely be created, and the hydraulic conductivity may increase by more than a factor of 5 compared to pre-project material. Therefore, a variation of at least one or two orders of magnitude for hydraulic conductivity should be used in the sensitivity analysis. Having a representative, conservative value for hydraulic conductivity is essential for understanding groundwater as a pathway of contaminant transport to Whitefish Lake and potential impacts to</p> | Please provide a more fulsome discussion on the anticipated impacts of mining on permeability of the ore zone due to mining activities in the EIS or in an Appendix. The value used for scenario 7 of the prediction uncertainty analysis should be provided. The scientific rationale for the use of a K value only a factor of five greater than the value assumed for the ore zone in the 3D regional model should be provided, alternatively, provide simulation results for a more conservative scenario. Specifically, this discussion should address the potential effects of mechanical permeability enhancement with tools, dissolution of ore, gas plugging, chemical plugging, plugging due to ion exchange, and mechanical plugging. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-------------------------|---|---|--|--|----------|
| | | | | | aquatic life. The K value used in the predictive uncertainty analysis should be reported. | | | |
| IR-71 | - | CNSC | Geology and groundwater | Section 7.7.1, Climate Change Considerations | <p>Context: The report states that in a scenario of increased precipitation and decreased/constant evaporation, climate change may result in greater flows in the Wheeler River drainage system and increased recharge to groundwater, which would correspond to increased groundwater discharge to Whitefish Lake. Additionally, it is also stated that climate change was evaluated qualitatively.</p> <p>Rationale: It is not clear why the impacts of increased evapotranspiration associated with higher average temperatures were not considered, even though these are likely outcomes of temperature increases due to climate change in areas such as the Prairies (Climate trends and projections - Canada.ca). It is also not clear why climate change considerations were not assessed quantitatively.</p> | Please provide a discussion on potential effects of increased evapotranspiration, as well as decreased groundwater recharge for the study area. Provide justification for performing qualitative assessment of impacts of climate change rather than a quantitative one. | <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>The effect of climate change on groundwater recharge in Prairies or Canada is generally uncertain due to the large degree of uncertainty in the modelling of future recharge although future changes in temperature and precipitation are expected to alter groundwater recharge (through changes to runoff, evapotranspiration, and snow accumulation). While CNSC staff accepts the response on potential effects of increased evapotranspiration, as well as decreased groundwater recharge for the study area, no justification has been provided on why quantitative analysis was not completed to address the effect of climate change on groundwater recharge.</p> | Accepted |
| IR-72 | - | CNSC | Geology and groundwater | Section 7.8.2, Groundwater Monitoring | <p>Context: Monitoring seems to consider COPCs from surface facilities, and excursion of pumped mine fluid in the Lower Sandstone Aquifer. There does not appear any discussion on how the proposed monitoring program considers potential excursions of brine from freeze wells.</p> <p>Rationale: It is unclear how potential excursions of brine from freeze wells will be monitored. Would this be through the fiber optic cables installed within the freeze well network? Or would it be achieved in the monitoring well clusters? If this is the case, how would an excursion of brine from a freeze well be differentiated from an excursion of mining solution?</p> | Please provide further information regarding how potential excursions of brine from freeze wells will be monitored as part of the proposed groundwater monitoring program. | | Accepted |
| IR-73 | - | CNSC | Geology and groundwater | Section 7.8.2.2, In Situ Recovery Mining Area Appendix 7-A, Appendix C | <p>Context: The EIS recommends that a follow-up study be carried out to supplement available data on hydraulic conductivity in the Desilicified Zone (DSZ).</p> <p>Rationale: Appendix C (Summary of Hydraulic Testing Data and Conductivity Values) of Appendix 7A indicates that only n = 6 hydraulic conductivity values are available for the DSZ, one of which appears unreliable due to a problem with packer sealing. This is relatively few values compared to the Intermediate and Lower Sandstones. Additionally, limited hydraulic head data from boreholes screened in the DSZ is available (GWR-037, GWR-012 and GWR-014; See Figures 16/17 in Appendix 7-A) – most information appears to originate from open core holes. The information presented in its current form is insufficient considering the importance of this zone as a preferential pathway for contaminants following remediation activities, and the heterogeneity of the unit due to intense hydrothermal alteration and fracturing. Further</p> | As per the EIS recommendations, please provide additional information to supplement available data on hydraulic conductivity in the DSZ. Please provide the following information as part of the follow-up study: <ol style="list-style-type: none">1. identification of the vertical conductivity (KV) as there is an upward flow component (isotropy was assumed in DSZ for numerical model, this assumption must be verified)2. quantification of the horizontal and vertical flow gradients in the DSZ; and3. identification and mapping of any structures with the potential to influence groundwater flow in the DSZ, such as fracture/fault zones. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-------------------------|---|--|---|----------------------|----------|
| | | | | | information regarding hydrogeological properties and groundwater flow would aid greatly in validating and refining the numerical groundwater model. | | | |
| IR-74 | - | CNSC | Geology and Groundwater | Section 7.8.2.3 | <p>Context: It is stated in Section 7.8.2.3 (p. 7-113, main EIS report) that, at the Post-Decommissioning Stage, “Excursion are signaled by a change in water quality that is outside of that bounded by modelling predictions”, and “The model predictions spatiotemporally bound COPC concentrations in the subsurface that do not pose a risk to the receiving environment. Water quality that is outside of this bounding is defined as representing a material increase over a meaningful period compared to the predicted values either in rate of change or magnitude of change of COPC concentrations.”</p> <p>Rationale: It is not clear in which locations (e.g., is it in the mining area, or downstream of the mining area, or anywhere else?) the water quality is used to compare with the model predictions to determine if excursion occurs.</p> | Please clarify in which locations the water quality data is used to compare with the model predictions to determine if excursion occurs. | | Accepted |
| IR-75 | - | CNSC | Geology and Groundwater | Appendix 7-A, Appendix K | <p>Context: The geomechanical study showed that the stability of the remnant ore zone and surrounding rock mass is highly sensitive to the magnitude of the material properties. To quantify this risk, the Proponent conducted a sensitivity analysis to assess the influence that material properties have on the stability of key stratigraphic layers. The results of the sensitivity analyses suggest that small variations in the cohesion magnitude and angle of internal friction may significantly influence the stability of the altered sandstone, ore zone, and upper and lower clays.</p> <p>Rationale: By considering the potential uncertainties and risks in association with the geomechanical study and the empirically derived rock mass strength parameters and the non-site specific physical parameters of different rock formations used for the modeling, the Proponent’s consultant suggests to define a laboratory testing program to address data gaps in the current geotechnical data and increase confidence in the material properties, and use more accurate material properties to model the phased extraction of uranium-enriched rock and assess the associated risks for cavity collapse and failure in the steel casing. CNSC staff concurs with these suggestions.</p> | Please provide a plan to implement recommendations for further detailed geomechanical studies to reduce the uncertainties and risks in association with the stability and deformation analyses of ore zone rock matrix and its overlying rock mass formations and assess their impacts on the mine operation. | | Accepted |
| IR-76 | - | CNSC | Geology and Groundwater | Appendix 7-A, Appendix K (p. 12) | <p>Context: Based on the consultant’s report, the modeled vertical strain is approaching or exceeding the tensile and compressive yield limits for steel casing.</p> <p>Rationale: Failure of steel casing may result in process loss or alter groundwater flow and quality.</p> | Please provide additional details on how casing integrity will be monitored and potential effects mitigated. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------------------|--|--|--|---|---|----------|
| IR-77 | - | CNSC | Geology and Groundwater | Appendix 7-A, Appendix K Results of a Geomechanical Study Investigating the Influence of Uranium Extraction on Mining-Cavity Stability for the Wheeler River Uranium Project (Revision 1) | <p>Context: It is reported in the appendix K report, within Appendix 7-A, that both phase I scoping analysis and phase II detailed strip model were investigated by numerical modelling. The analysis discussed influence on host rock stability as a result of incremental increase in volumetric extraction and graded conservative treatment of material properties.</p> <p>Rationale: As critical components of a numerical geomechanical simulation, initial and boundary conditions are crucially important to the confidence and reliability of the modelling results. However, this information is absent from the current report. In-situ principal stresses largely affects the stability of the excavated host rock, and the vertical strain and surface subsidence. This information is also absent in current form.</p> | Please provide details on the boundary and initial conditions applied on stress loading and strain for the numerical analysis. In particular, the in-situ principal stresses, which are critical to correct understanding of the excavation disturbance to the host rock, should be provided and justified as appropriate. | | Accepted |
| IR-78 | - | CNSC ECCC | Fish and fish habitat Geology and groundwater | Appendix 7-A, Section 3.5.2, Porosity Appendix 7-C, Section 2.3.2.1, Porosity Values | <p>Context: This section of the report outlines the estimated/assumed effective porosity values. The only reference provided is for permeameter testing on rock core samples (Scibek, 2019).</p> <p>Additionally, the report states that “As tracer test results to estimate effective porosity were unavailable at the time of modelling, effective porosity values for the sandstone bedrock and basement units were sourced from literature values”, where literature values are effective porosities from the Cigar Lake study (AECL, 1994), situated approximately 40 km NE of Wheeler River. No on-site Wheeler River field data was used to justify this value. Additionally,, in the Cigar Lake study, the authors reported that, because results from tracer tests and pumping tests were unavailable, “a practical approach was adopted, i.e., to use the porosity values obtained from laboratory measurements made on core samples, and to assume that those numbers were close to the average field kinematic (effective) porosity values”.</p> <p>Rationale: The source of reported effective porosity values is unclear from Section 3.5.2 in Appendix A (e.g. literature review, field work, laboratory work).</p> <p>In Section 2.3.2.1 of Appendix 7-C, there is a lack of clarity regarding the effective porosity data used in the numerical model. It appears that no site-specific data derived from tracer tests or pumping tests is used in the numerical model. Given that effective porosity directly correlates to seepage velocity and by extension transport time and distribution of COPCs in groundwater, it is an important parameter. Given its relative importance for contaminant fate and transport, effective porosity should be based on field measurements, or at the very least accounted for in the sensitivity analysis.</p> | <p>1. Please provide the reference for the data substantiating the assumed effective porosity values reported in Appendix 7-A and used in the numerical model in Appendix 7-C.</p> <p>2. Please provide information on how the site-specific effective porosity values from tracer tests or pumping tests, were considered in the numerical models. Section 2.2.1.4 of the EIS asserts that tracer tests were carried out in 2021 – this information should thus be available for improving/updating models. Alternatively, provide a sensitivity analysis for the effective porosity in the Desilicified Zone, or contaminant transport simulation results with more conservative effective porosity values.</p> | <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>Effective porosity is an important parameter to understanding groundwater flow and contaminant transport. The Proponent states that “As tracer test results to estimate effective porosity were unavailable at the time of modelling, effective porosity values for the sandstone bedrock and basement units were sourced from literature values”, including porosities from the Cigar Lake study (AECL, 1994), situated approximately 40 km NE of Wheeler River. No on-site Wheeler River field data was used to explain this value. Additionally, in the Cigar Lake study, the authors reported that, because results from tracer tests and pumping tests were unavailable, “a practical approach was adopted, i.e., to use the porosity values obtained from laboratory measurements made on core samples, and to assume that those numbers were close to the average field kinematic (effective) porosity values”.</p> <p>In response to the IR, the Proponent explained and supported their methodology for selecting a value for effective porosity. This method included consideration of literature values and a regional analogue at Cigar Lake. ECCC notes that a tracer test was conducted, the results of which were not considered in the selection of the effective porosity parameter.</p> <p>If field test data is available that is potentially relevant to determining effective porosity, it should be included in the EIS when discussing effective porosity. The field test data should also be made available for ECCC to review, to confirm the conclusions reached by the Proponent. ECCC acknowledges that other sources of information can be useful when explaining the most appropriate value for effective porosity such as literature values and regional analogues, as per the Proponent’s IR response. However, field test results should be presented in the EIS and considered as a part of such an explanation. If the Proponent feels that not utilizing field test data is the most accurate approach when selecting an effective porosity value, then this conclusion should be reached with consideration of the field test data as a part of the evaluation.</p> <p>Provide a discussion of how the effective porosity values are selected, including a discussion</p> | Accepted |

|--------------|----------------|------|-------------------------|--|---|--|--|----------|
| | | | | | | | of how field test results were considered. This information is necessary to confirm that the selected effective porosity values are valid. This also relates to IR-52. | |
| IR-79 | - | CNSC | Geology and groundwater | Appendix 7-A, Section 4, Groundwater Chemistry | <p>Context: Table 4-1 in Section 4 of Appendix 7-A provides groundwater monitoring results from sampling activities carried out at 26 monitoring wells in 2019, 2020, and 2021. The majority of these wells were only sampled once (n = 8) or twice (n = 17). In some cases (Lower Sandstone Aquifer/Intermediate Sandstone Aquitard), the variability of results between sampling events is quite high. Data for the Paleoweathered Zone is sparse.</p> <p>Rationale: Insufficient information is presented in the EIS and associated Appendices to concretely define baseline groundwater chemistry for the different hydrostratigraphic units. As defined in the CNSC’s Generic Guidelines for the Preparation of an EIS: “Based on the scope of the project, the EIS will present sufficiently detailed baseline information to determine the effects the project could have on the VCs and analyze those effects”. This is particularly important given certain features of the study area (i.e., presence of zones of thermal alteration/desilicification, as well as hydraulically active fractures/faults), and the need to adequately characterize baseline conditions in the Desilicified Zone downgradient from the proposed mining area. As an example, the US Nuclear Regulatory Commission (NRC) typically requires a minimum of four (4) quarterly samples from (i) surficial aquifers, (ii) production aquifers, (iii) overlying aquifers, and (iv) underlying aquifers to characterize preoperational groundwater quality (E. Striz, pers. comm.).</p> | Please provide the statistical basis (number of samples and variability) by which “baseline” is defined and the justification that the current information is sufficient to adequately characterize groundwater quality. In order to ensure sufficient baseline information is collected, further iterations of sample collection for groundwater monitoring wells in all defined hydrostratigraphic units may be required. In addition, groundwater quality downgradient from the proposed mining area should be further characterized to assess spatial influence of alteration and hydraulically active features, | | Accepted |
| IR-80 | - | CNSC | Geology and groundwater | Appendix 7-A, Section 4.3.3, Hydrochemistry by Hydrostratigraphic Unit | <p>Context: This section provides data for groundwater samples collected during the Cigar Lake analogue study and Millennium Project for further regional context. The previous studies are heavily referenced to support interpretations made for the conceptual site model.</p> <p>Rationale: The Piper Plots in Figure 26 are difficult to interpret (many overlapping circles with variegated colors), and Cigar Lake samples plot predominantly as Na/K-Cl/SO4 groundwater facies. Conversely, samples collected as part of the Phoenix Project (current), plot either as Ca-HCO3 or Ca-SO4/Cl groundwater facies. No explanation is provided for the observed hydrogeochemical differences between groundwater from the Phoenix project and the Cigar Lake analogue study/Millennium Project.</p> | Please provide additional clarity to and interpretation of Figure 26 in Appendix 7-A, including a revision to the Figure to allow for easier interpretation. This could include clear identification of end members, as well as arrows indicating proposed evolution of groundwater chemistry. Further discussion should be provided describing observed differences between groundwater chemistry at the Phoenix project compared to Millenium/Cigar Lake. | | Accepted |
| IR-81 | - | CNSC | Geology and groundwater | Appendix 7-A, Section 4.3.3, Hydrochemistry by Hydrostratigraphic Unit | <p>Context: The report states in the description of hydrochemistry of the Lower Sandstone Aquifer that, “On the basis of groundwater chemistry and tritium values in that groundwater, the authors (of the Cigar Lake analogue study in 1994) concluded that the groundwater reflected a younger water component that had</p> | Provide a further discussion on the interpretation of tritium in groundwater, rather than echoing conclusions from the Cigar Lake analogue study. Consideration should be given to the assertion that modern meteoric water circulates at depth in the Lower Sandstone Aquifer. Collection and analysis of stable | | Accepted |

|--------------|----------------|------|-------------------------|--|---|--|---|----------|
| | | | | | <p>penetrated to depth along hydraulically active fractures/faults. The same conclusion is made here (in the Wheeler River EIS) for the Phoenix study area – meaning that fracture/fault conditions are such that some areas of the MFa are characterized by younger/recharge groundwaters”.</p> <p>Rationale: Tritium results for most wells in the Lower Sandstone Aquifer (MFa) reported in Table 4-1 of Appendix 7-A exhibit tritium concentrations <15 Bq/L for the 2020 sample, and 0.1 or <0.1 Bq/L for the 2021 sample. Tritium in modern precipitation typically varies from 1 – 3 Bq/L. Conclusions made in the text are not supported by data, especially given that tritium values are not reported in the EIS for local precipitation or surface water. This is important in reinforcing the assumption from the conceptual model that modern meteoric water circulates at depth in the Lower Sandstone Aquifer.</p> | <p>isotope (e.g., $\delta^2\text{H}$, $\delta^{18}\text{O}$) samples is a cost-effective solution which would greatly improve understanding of groundwater hydrology and support the development of a conceptual model.</p> | | |
| IR-82 | - | CNSC | Geology and groundwater | <p>Appendix 7-A, Section 4.3.3, Hydrochemistry by Hydrostratigraphic Unit</p> <p>Appendix 7-C, Section 3.5</p> | <p>Context: A. In-field measurements of Oxidation-Reduction Potential (ORP) for three (3) out of twenty-six (26) groundwater samples are presented in Table 4-1 of Appendix 7-A. Although sparse, these values are also used to characterize redox conditions for representative groundwaters in Table 3-5 of Appendix 7-C.</p> <p>B. In Section 3.5.5 of Appendix 7-C it is stated that groundwaters in the PHREEQC model were allowed to equilibrate with atmospheric concentrations of oxygen, resulting in oxidizing subsurface conditions. In Section 3.7 of Appendix 7-C it states that input files for 3D reactive transport were generated based on outcomes for PHREEQC modelling. However, in reading Section 4 of Appendix 7-C, it is unclear whether this assumption (equilibration with atmospheric oxygen) was carried forward for the 3D model.</p> <p>C. As per p. 3.49 of Appendix 7-C, “A small amount of reactive pyrite was assumed for the first 500 m of transport away from the ore zone in the model, primarily in the desilicified sediments of the Lower Sandstone Aquifer, and deeper portion of the Intermediate Sandstone Aquitard”.</p> <p>Rationale: A. Given the importance of redox conditions for U mobilization and precipitation/dissolution of minerals (e.g., pyrite/metal oxyhydroxides) and the corresponding influence on contaminant transport from both a modelling and monitoring perspective, these should be further characterized. It should also be noted that the measurement of Oxidative-Reductive Potential (ORP) in natural waters can be complex and difficult due to the variability and disequilibrium of natural systems and issues inherent to electrode calibration (e.g., Schuring et al., 2000). Measurements of redox couples (e.g., As(III)/As(V); Fe(II)/Fe(III); S(-</p> | <p>1. Provide further discussions and information (i.e., ORP measurements or analytical data for redox couples) on redox conditions at the Phoenix site. Particular focus should be given to the spatial heterogeneity of redox processes. Tools such as the reference provided [2] below provide an example of simplified framework for characterizing redox conditions in aquifers.</p> <p>2. Clarify assumptions regarding initial redox conditions for the 3D solute transport model.</p> <p>3. Provide the % reactive pyrite by weight assumed for models in the text. Justification for proportions used, such as analytical data, should also be provided.</p> <p>Reference: [2] Jurgens, B.C., McMahon, P.B., Chapelle, F.H., and Eberts, S.M., 2009, An Excel workbook for identifying redox processes in ground water: U.S. Geological Survey Open-File Report 2009–1004 8 p.</p> | <p>Please see AD-65 in the Advice to Proponent table.</p> | Accepted |

| IR-83 | - | CNSC | Geology and Groundwater | Appendix 7-A, Section 7.4.2.2 and Appendix K | <p>Context: Leaching of uranium from the ore zone will generate voids within the ore zone, which could fail and collapse. Failure of the voids would cause displacement in overlying rocks, which will lead to the eventual ground subsidence. Based on the developed geological model, a geomechanical study was conducted to assess potential maximum vertical displacement in the overlying rock formations and predict the ground subsidence. While a layer of altered sandstone is modeled above the ore zone, the desilicified zone, a zone that is comprised of completely to partially unconsolidated sands and has very low rock quality, high fracture intensity, and high friability, and low strength in the area overlying and east of the Phoenix deposit, appears not to have been included in the model for geomechanical modeling. The evaluated displacement/deformation in the overlying rock formation and the resulted ground subsidence would not be conservative without including the desilicified zone.</p> <p>Rationale: Stability of the ore zone rock matrix and the potential displacement/deformation in the overlying rock formations when voids in the extracted ore zone collapse are critical for protecting the overlying aquifers, preventing substantial ground subsidence, safeguarding casing integrity, and mitigating plug-off of the remaining ore as well as efficiently mining extraction. The deformed zone in the overlying rock formations will change in hydraulic conductivity that will impact on the assessment of potential effects on groundwater flow and contaminant transport in the zone. Therefore, the rock mass behavior including and above the ore zone should be adequately understood and the potential displacement/deformation should be assessed and quantified with adequately defined geological model.</p> | Please provide details whether and how the desilicified zone is considered in the geomechanical modeling of the detailed strip model. Such details should include figures and the linkage between the geomechanical model including the determination of strength parameters of the desilicified zone and the geological model including information on the core delineation of the desilicified zone. | | Accepted |
| IR-84 | - | CNSC | Geology and Groundwater | Appendix 7-C | <p>Context: It is stated in Section 2.5.2.4 (p. 2.35, Appendix 7-C) that “In addition to calibrating to water level elevations targets, the</p> | 1. |--------------|----------------|-----|----------------------|---|--|------------------------------|----------------------|--------|
| | | | | | <p>combinations of parameter values that met statistical calibration criteria. If each hydro-stratigraphic units within the whole model domain were treated as parameter zones that can have varied hydraulic conductivity values, a different combination of parameter values could be obtained that meet statistical calibration criteria too.</p> <p>Rationale: The parameter values for parameter zones between the mining area and Whitefish Lake is important in determining the hydraulic connection between the mining area and Whitefish Lake. Parameter values in other parameter zones could also be important. For example, if the K values for the intermediate sandstone aquitard are significantly larger than in the current calibration results, the interaction between the upper sandstone aquifer and the lower sandstone aquifer could be more active, and the mined-out zone could be more active hydraulically and groundwater in the minded-out zone could have a shorter residence time than in the current calibrated model.</p> <p>Additionally, it is noted that Figure 2.19 (p. 2.46, Appendix 7-C) illustrates the parameter zone for the intermediate sandstone aquitard. However, Figure 2.20 (p. 2.49, Appendix 7-C) did not include the intermediate sandstone aquitard in the results.</p> | | | |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-------------------------|---|---|---|----------------------|----------|
| IR-88 | - | CNSC | Geology and Groundwater | Appendix 7-C | <p>Context: The conceptual hydrogeological model includes upper sandstone aquifer, intermediate sandstone aquitard, and lower sandstone aquifer. The desilicified zone above the ore zone have enhanced hydraulic conductivity. The boundary condition for the lower sandstone aquifer on the west (upstream) side was assigned to have specified head, which provide source of water for the lower sandstone aquifer.</p> <p>As a result of the conceptual model setup, the upper sandstone aquifer is hydraulically active and the groundwater residence time within the upper sandstone aquifer is relative short. In contrast, the lower sandstone aquifer (and the ore zone) is hydraulically inactive, and the groundwater residence time in the lower sandstone aquifer is relatively long (as shown in the particle tracking results in Figure 7.6-2 (p. 7-71, main EIS report), and the simulated plume for chloride in Figure 7.6-7(p. 7-86, main EIS report)).</p> <p>It is stated in Section 2.6.4 (Appendix 7-C) that “As noted above in section 2.6.3, it is estimated that 99% of the groundwater discharge to Whitefish Lake is derived from groundwater that has only flowed through shallow deposits (i.e., Overburden and Upper Sandstone Aquifers). Contribution of deep groundwater flow through the Desilicified Zone within the Intermediate Sandstone Aquitard is estimated to be < 1% of the groundwater discharging to Whitefish Lake”. This simulation result is reflective of the conceptual model.</p> <p>Section 7.3.3.3 (p. 7-42) states that “The Lower Sandstone Aquifer is characterized spatially by two types of groundwater. The first groundwater type is most like that observed in the Local Flow System. This reflects hydraulically active fractures and fault systems that allow fresh recharge water to penetrate and mix with deeper waters in the aquifer. The second type of groundwater is within the zone of thermal alteration around the ore zone”.</p> <p>The hydraulic connectivity of the ore zone with the upper sandstone aquifer has important implication on the groundwater restoration. The ore zone is not hydraulically active locally because it is enclosed by a clay zone before the mining operation. But if it is located within a hydraulically active area, or on a groundwater flow pathway that is hydraulically active, the mined-out zone (with much larger porosity and hydraulic conductivity) could become active hydraulically after mining operation is finished.</p> <p>Figure 7.6-7 (p. 7-86, main EIS report) shows that the chloride plume is most persistent within the mined-out mining area. This seems to indicate the mined-out zone is hydraulically inactive after the mining operation is finished.</p> | <p>It is recommended to conduct the following work to demonstrate if the mined-out zone is hydraulically active:</p> <ol style="list-style-type: none">1. Determine the groundwater residence time in the lower sandstone aquifer and compare it with the simulated residence time in the numerical model.2. Conduct additional particle tracking to demonstrate where groundwater originating from the mined-out zone flow towards (forward tracking) and where groundwater flowing towards the mined-out zone originates from. This would help determine why groundwater in the mined-out zone is not hydraulically active.3. Conduct sensitivity analysis to investigate the effect of higher K values for the intermediate sandstone aquitard and the K and porosity values of the mined-out zone on the plume migration. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-----------------------|---|---|---|--|---------------------|
| | | | | | <p>It is stated in Section 7.3.3.2 (p. 7-37, main EIS report) that “Exploration boreholes drilled in the Phoenix area, where left unplugged, have the potential to provide preferential flow paths between the Overburden and Upper and Lower Sandstone Aquifers. Exploration holes were reportedly grouted approximately 10 to 20 m above and below the ore zone, resulting in open holes remaining throughout the overlying materials. These portions of the open holes may act as open conduits for groundwater flow through the 400 m of Athabasca Group Sandstone.” So, there is possibility that the unplugged borehole could increase the hydraulic connection between the upper and lower sandstone aquifer.</p> <p>Rationale: It is important to understand if the larger area containing ore zone is hydraulically active. Additional confidence would be gained if there is any other evidence that support that the area containing the ore zone is not hydraulically active, and groundwater residence time in the lower sandstone aquifer surrounding the ore zone is comparable with the simulated results.</p> <p>Table 2-4 (p. 2.16, Appendix 7-C) shows the effective porosity (0.01-0.05) of the ore body. Figure B7 (p. B.8, Appendix 7-C) shows that the calibrated K values for the mined-out zone is 1x10-6 m/s. Section 3.5.2 (p. 3.24, Appendix 7-C) states that “The same average linear velocity was assumed for the mining area (source zone), following from the discussion in Section 4.4.2, where the hydraulic conductivity value in this zone following mining was set to 5x10-6 m/s, and a porosity of 0.2 is assumed for the ore zone (Table 4-2)”. It is not clear what the justification is for the selection of the porosity and K values for the mined-out area, and whether they are conservative. It is also not clear, what the potential impact on the groundwater flow and COPCs transport would be If the mined-out zones collapse.</p> | | | |
| IR-89 | - | ECCC | Fish and fish habitat | Appendix 7-C, Numerical Modelling: Post-Decommissioning Evaluation, | Context: The Proponent states that a hydraulic conductivity value of 5x10-6 m/s was uniformly assigned to the model layers representing the Desilicified Zone. They additionally state that this value is consistent with packer and pumping tests screened in this unit that have interpreted hydraulic conductivity values ranging | 1. Provide an in-depth rationale for choosing a value of 5x10-6 m/s as the base case for the hydraulic conductivity, in both the PH REdox EQUilibrium (PHREEQC) and Finite-Element Ground Water Flow (FEFLOW) models. | <u>The Proponent has not adequately responded to the IR and has indicated in their response that they do not agree with ECCC’s previous advice relating to the sufficiency of the conservative sensitivity analysis. The Desilicified Zone is a critical layer in the hydrogeological model because it represents a key potential pathway of contaminants to Whitefish Lake.</u> | <u>Not Accepted</u> |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-----------------------|---|---|--|---|---------------------|
| | | | | Section 2.3.1.4, Desilicified Zone | <p>from 1x10-6 to 3x10-5 m/s (Appendix C), with a geomean of 6.0x10-6 m/s.</p> <p>Considering that the Desilicified Zone is of particular interest because it is the main pathway for the COPC to reach Whitefish lake, and that hydraulic conductivities are not entirely understood, ECCC recommends that a larger range of hydraulic conductivities be simulated to understand potential effects on fish and fish habitat.</p> <p>Rationale: The Desilicified Zone is a critical layer in the hydrogeological model as it represents a key potential pathway of contaminants to Whitefish Lake. The base case hydraulic conductivity value (5x10-6 m/s) is even lower than the geometric mean, not to mention the highest value found. When simulating geochemical processes and contaminant transport within this important pathway a more conservative approach should be employed. Modifying this parameter will affect travel times and distribution of COPC in the subsurface.</p> | <p>2. Provide a rationale for keeping the sensitivity analysis within one order of magnitude considering the lack of physical data on the Desilicified Zone. Alternatively, provide contaminant transport simulation results with more conservative hydraulic conductivity (e.g., more than 3x10-5 m/s) values in the Desilicified Zone.</p> <p>See also related: IR-96.</p> | <p><u>However, ECCC advises that the Proponent has not adequately considered conservative scenarios in its sensitivity analysis.</u></p> <p><u>In their response, the Proponent states that “The scenarios tested hydraulic conductivity values for the desilicified zone as high as 3.7x10-5 m/s (realization 7 – predictive uncertainty case 5), which is two times higher than any measured value within this hydrogeologic unit,...” This is inconsistent with the values presented in the Revised Draft Environmental Impact Statement Section 7 – Geology and Groundwater, where the maximum field values are presented as 3.0x10-5 m/s. The approach presented does not demonstrate a conservative scenario for evaluating the extent of potential travel times to Whitefish Lake.</u></p> <p><u>The Proponent should test a K value in the desilicified zone with a value at least an order of magnitude higher than the highest field K values in order to provide a conservative scenario for potential travel times to Whitefish Lake.</u></p> <p><u>The Revised Draft Environmental Impact Statement, Section 7, has a revised geometric mean for hydraulic conductivities in the desilicified zone where the value was changed from 6.0 x10⁻⁶ m/s to 4.8x10⁻⁶ m/s with no explanation regarding how this new value was obtained. The Proponent should clarify why this change was made, and provide any supporting evidence.</u></p> <p><u>Note to Denison: This IR is still under discussion.</u></p> | |
| IR-89 | IR-89-R1 | ECCC | Fish and fish habitat | Appendix 7-C, Numerical Modelling: Post-Decommissioning Evaluation, Section 2.3.1.4, Desilicified Zone IR-89 Response from Denison | <p>Context: The Proponent states that the range of hydraulic conductivities considered in sensitivity analysis was limited to values that fit within a calibration constrained uncertainty analysis of the model.</p> <p>Considering that the Desilicified Zone is of particular interest because it is the main pathway for the COPC to reach Whitefish lake, and that hydraulic conductivities are not entirely understood, ECCC recommends that a larger range of hydraulic conductivities be simulated to understand potential effects on the aquatic environment.</p> <p>The Proponent clarified the details of the calibration-constrained uncertainty analysis that was used for parameter bounding within the model, with hydraulic conductivity sensitivity bounds determined based on model calibration values that were supported by the available physical data.</p> <p>Rationale: ECCC agrees that calibration constrained uncertainty analysis using hydraulic head field data is useful to determine probable upper limits of K values. However, there is always some degree of uncertainty in groundwater data and models. Sources of such uncertainty may include errors, lack of complete and representative field data to determine key parameters, or any number of heterogeneities associated with groundwater systems over large scales. Such uncertainties will always exist and can be accounted for by conducting a sensitivity analysis that accounts for the lack of physical data in the Desilicified Zone by running</p> | Expand the sensitivity analysis of hydraulic conductivity outside of calibration constrained parameters to account for the lack of physical data in the Desilicified Zone. | <p><u>See IR-89 (above). Note to Denison: This IR is still under discussion.</u></p> | <u>Not Accepted</u> |

| | | | | | modelling scenarios using parameters that are outside of the calibration constrained values. | | | |
| IR-90 | - | ECCC | Fish and fish habitat | Appendix 7-C, Section 2.4 and 2.6 | <p>Context: Hydraulic conductivities and hydraulic gradients play an important role in groundwater flow, geochemical modeling, and contaminant transport for the PHREEQC and FEFLOW models. Although there is an important vertical component to the contaminant transport, there is no distinction made between lateral and vertical hydraulic conductivities of hydraulic gradients.</p> <p>Rationale: According to the conceptual model, there is an important vertical aspect to the groundwater flow thus incorporating any vertical hydraulic gradient or hydraulic conductivity information into the calibration would increase confidence in the results.</p> <p>Providing a distinct value for vertical hydraulic conductivity will improve the accuracy of the model in regards to the transport of contaminants to Whitefish Lake through the Desilicified zone, which is important to understand potential impacts to aquatic life.</p> | <ol style="list-style-type: none">1. Explain if the vertical and lateral hydraulic gradients and hydraulic conductivities are assumed to be equivalent.2. Provide a rationale for not distinguishing between vertical and lateral hydraulic gradients.3. Alternatively, provide both lateral and vertical hydraulic gradient estimates and the implications on contaminant transport. | | Accepted |
| IR-91 | - | NRCan | Fish and fish habitat | Appendix 7-C, section 2.5.2 | <p>Context: The numerical model calibration quality plot (Appendix 7-C, sec. 2.5.2.1, Figure 2-13) contains a small error. The vertical (simulated heads) and horizontal (observed heads) axes do not have the same scales (499 to 521 masl versus 499 to 522 masl). Therefore, the line of ideal fit is offset.</p> <p>Rationale: As a result, NRCan notes that observed heads in the 510-512 masl range are underpredicted by the model. NRCan also notes that the calibration statistics (Appendix 7-C, sec.2.5.2.3) are highly leveraged by two data points from open boreholes south of Kratchkowsky Lake where simulated values are largely controlled by the nearby constant-head boundary in the Lower Sandstone aquifer (520 masl).</p> | The Proponent should correct the scales on the axes of Figure 2-13 in Appendix 7-C. The Proponent should also comment on the effect on calibration of the clustering of most observation wells in the ore zone. | | Accepted |
| IR-92 | - | CNSC | Geology and groundwater | Appendix 7-C, Section 3.2.1, Mineralogical Composition | <p>Context: Table 3-2 summarizes the clay content of the Athabasca Group sandstones and the Paleoweathered Zone. Although minimum, maximum and median values are provided, the number of samples and variability of the dataset are not. Rationale for incorporating illite into reactive transport modelling and excluding kaolinite/dichlorite is provided in the text.</p> <p>From p. 3.29 in Appendix 7-C: “The illite content was based on the normative clay composition determined from site-specific corehole elemental analysis (median illite by mass is 7.68%; Table 3-2) and using portable infra-red mineral analysis indicating median illite content by mass is 13.1% (data not shown)”</p> | <ol style="list-style-type: none">1. Please provide in Table 3- the number of samples and variability of the datasets used to estimate the clay content of hydrostratigraphic units for the model. Include results from infrared mineral analysis in the text if the information is used to support assumptions for modelling.2. Please provide further information/discussion within the EIS relating to the assumptions of clay content in hydrostratigraphic units for modelling. Provide further justification and rationale as to why total clay content in the Athabasca Group sandstones and Desilicified Zone is assumed to be illite, and how this assumption is conservative. This discussion could include a comparison of the properties (cation exchange capacity, surface area) of illite vs. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-------------------------|--|--|---|----------------------|----------|
| | | | | | <p>From p. 3.30 in Appendix 7-C: “Using the minor amount of illite compared to the more dominant chlorite is conservative in that not all sorptive capacity of the clays is accounted for in the simulated paleoweathered zone”. This conservative assumption appears contrary to assumptions for the desilicified zone (DSZ) and Athabasca Group sandstones “Illite was used to represent the total clay content, which varies from 1.74% to 5.85% by mass in the hydrostratigraphic units within the Athabasca Group sandstones and Desilicified Zone”.</p> <p>Rationale: Information is missing in the EIS regarding the clay composition of hydrostratigraphic units. Results from infrared mineral analysis are not reported.</p> <p>The assumption for the solute transport model is that all clays in the downgradient DSZ are illite. However, clay content in the Read Formation (Lower Sandstone Aquifer) downgradient of the ore zone is low in illite (0.42%) compared to kaolinite (0.52%) and dichlorite (1.18%). A value of 3.9% illite clay by weight is used for the DSZ, but Table 3-2 indicates median content is 2.42% illite. It is not clear why illite was used to represent total clay content for the DSZ, as opposed to the conservative assumptions used for the Paleoweathered Zone, nor has any basis or justification been given.</p> | kaolinite vs. dichlorite for the anticipated range of subsurface conditions (pH, redox, U concentrations, etc.). | | |
| IR-93 | - | CNSC | Geology and Groundwater | Appendix 7-C, Table 3-10: Properties of Adsorbing Mineral Phases | <p>Context: In Appendix 7-C, section 3.5.6.2.2 Ion Exchange and Surface Complexation, the consideration of ion exchange and surface complexation and the corresponding parameters and chemical reaction are discussed.</p> <p>Rationale: The site density of sorbent Goethite was reported in Table 3-10 to be 1.6E3 mol/kg. Taking into account the specific surface area of 60 m2/g, this equals to 1600/6E4 mol/m2, or 0.0266 mol/m2, 1.6e4 sites/nm2.</p> <p>This value largely overestimates the site density of goethite, which is reported to be in the range of 2~6 sites/nm2. The reference used in the EIS report indicates the similar range of variation for this specific parameter.</p> <p>There are plenty of similar studies on SCM of iron oxides in literature. It is suggested to consult with more than one single study to enhance the reliability of model parameters.</p> <p>The overestimation of sorption site density will directly result in underestimation of the affected COPCs’ concentrations in pore fluid. This will result in underestimation of COPC transport plume in the affected underground space, and potentially the dissolved concentrations in the hydrogeological sink.</p> | Please provide additional evidence to justify the model parameter of site density for goethite, applied to the numerical model. If necessary, the reactive transport modelling should be re-run to update the contents presented in the EIS report. | | Accepted |

|--------------|----------------|------|-------------------------|---|---|---|--|----------|
| | | | | | | | | |
| IR-94 | - | CNSC | Geology and Groundwater | Appendix 7-C, Numerical modelling: post-decommissioning evaluation, Section 3.5.5, Subsurface Conditions Incorporated | <p>Context: It is reported in this section the assumed subsurface conditions that were applied in the geochemical site conceptual models. Critical phenomenon of pH tail was mentioned. Inclusion and exclusion of corresponding geochemical reactions were discussed briefly.</p> <p>Rationale: It was reported that the residual reduced minerals of uraninite and pyrite were not included in the modelling of the remediated mining area. The argument was based on consideration of the upstream groundwater, passing through the mined zone, will not be oxidizing and groundwater conditions are expected to be similar to pre-mine conditions. However, this ignores the pH tail effect that releases proton H+ sorbed to solid surface during ISR flooding. By ignoring this process, there is a potential risk of underestimating the source terms for some key COPCs. Exclusion of uraninite and pyrite in remediated mining area modelling is contradictory to pH-tail effect. The justification is not sufficient in the current form.</p> | Please provide additional evidence to justify the approach for excluding uraninite and pyrite from the analysis of remediated mining area. This may require the results from additional modelling. | | Accepted |
| IR-95 | - | CNSC | Geology and Groundwater | Appendix 7-C, Table 3-11 | <p>Context: The Table 3-11 reported the Solid-Phase Concentrations and Partitioning Constants for COPCs. Data were both measured and simulated.</p> <p>Rationale: It is unclear how the partition coefficients of various COPCs upon desilicified and paleoweathered rocks were obtained. It was not reported at what pH were these Kd analyzed. Sorption of chemicals on solid phase is known to be pH dependent. It is unclear whether pH influence was considered in the measurement and analysis of apparent partition coefficients.</p> <p>In addition, uptake of metals on clay is highly nonlinear, and always has a maximum capacity. Even with a very strong affinity towards specific metal ions, the sorption will be saturated at elevated concentrations. Therefore, assuming a linear correlation needs to be cautious of the concentration range of target COPC species, and the applicable sorption capacity of the clay mineral.</p> <p>In the current model, only the linear form of sorption is considered, although with discussion of Kd value selection. Additional rationale is needed to justify if the applied methodology is sufficient for assessment.</p> | Please justify the choice of applying a linear form partition coefficient for the modelling and assessment, and whether it provides a conservative approach to the assessment results. Clarity around the experimental conditions during the measurement of partitioning coefficient of various COPCs on the target rocks may help support this assumption. | | Accepted |
| IR-96 | - | CNSC | Geology and groundwater | Appendix 7-C, Section 4.4.4, Sub-Domain Model | <p>Context: From the text, “Transport parameters were specified for diffusion (1x10-9 m2/s), longitudinal dispersivity (10 m along the plume trajectory), and transverse dispersivity (5 m)”. The source of this information is not provided in Appendix 7-C. It is unclear if the</p> | 1. Please provide the source of the numerical value used for diffusion and longitudinal and transverse dispersivity, and provide justification if default values by the model code were used. | <i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i> | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|---|--|---|---|----------|
| | | | | Transport Boundary Conditions | <p>values used are defaults in the modelling software, from literature, from small-scale laboratory tests, or are site-specific values determined through tracer tests.</p> <p>Rationale: The use of a calibrated flow model does not imply that the solute transport model is calibrated. The transport parameters (such as effective porosity, dispersivity and reactive transport parameters) can only be calibrated by matching simulated and observed spatial and/or temporal distributions of a solute. Sensitivity analysis indicates that decreasing longitudinal and transverse dispersivities by a factor of two resulted in exceedances of groundwater criteria for both selenium (Se) and cobalt (Co). Given the clear influence of these values on contaminant transport, it is important that transfer parameter values are justified in the solute transport model. In addition, the influence of large-scale heterogeneity on dispersion and solute transport predictions should be discussed, to identify any uncertainty in the model predictions, and provide confidence that the applied model is adequately representing groundwater flow and solute transport.</p> <p>Further guidance on solute transport modelling can be found in BC MOE (2012) [1].</p> <p>Reference: [1] British Columbia Ministry of the Environment (BC MOE). 2012. Guidelines for Groundwater Modelling to Assess Impacts of Proposed Natural Resource Development Activities. Report no. 194001, 385 p.</p> | <p>2. Please provide a discussion on the influence of large-scale heterogeneity on dispersion and solute transport predictions in the modelling report.</p> <p>See also related: IR-89.</p> | <p>CNSC staff appreciate the comprehensive information provided relating to longitudinal dispersivity and variation based on scale. However, it should be noted that guidance from Gelhar et al. (1992) and the BC MOE (2012) indicate that horizontal transverse dispersivity values should be approximately 1 order of magnitude lower than longitudinal dispersivity values, and vertical transverse dispersivity values should be approximately 2 orders of magnitude lower than longitudinal dispersivity. For the model presented in the EIS, transverse dispersivity is represented by a singular value of 5 meters, with the supporting rationale that the Gelhar et al. (1992) identified 5 meters as a representative value. It is important to note that the Gelhar et al. (1992) paper considered 5 meters to be representative for horizontal transverse dispersivity and identified that vertical transverse dispersivity is smaller than horizontal transverse dispersivity. Additionally, it is important to note that Petrotek (2021) used a transverse dispersivity of 1 m in their numerical models of the ore zone aquifer. CNSC staff thus request that Denison provide further information relating to why horizontal and vertical transverse dispersivity are represented using a singular value, and how this value is considered appropriate to represent both dimensions.</p> <p>Reference: Petrotek 2021. Groundwater Model Report Phase 1, Phoenix Deposit Wheeler River Project. Prepared for Denison Mines. December 2021.</p> | |
| IR-97 | - | ECCC | Fish and fish habitat | Appendix 7-C, Figures 4-6, 4-7a, 4-7b, 4-8a, 4-8b, 4-9a, 4-9b | <p>Context: Appendix 7, Figures 4-6, 4-7a, 4-7b, 4-8a, 4-8b, 4-9a, 4-9b present contaminant transport simulations of chloride, selenium, cadmium, and uranium. All simulations use initial condition concentrations at t=0 (or end of mining operations. In the 3D FEFLOW contaminant transport model it is not clear why initial condition concentrations were chosen rather than a constant concentration boundary.</p> <p>It is also unclear if mining activities will cause mobilization of the contaminants beyond the end of operations.</p> <p>Rationale: The choice of boundary conditions may impact the predicted transport of contaminants that reach Whitefish Lake through groundwater, which may have impacts to aquatic life.</p> | <p>1. Explain and clarify if mining operations will mobilize contaminants beyond operations?</p> <p>2. Clarify if the source of contamination, (e.g., uranium, selenium) will cease after operations?</p> <p>3. For the 3D model please provide the rationale for using initial concentrations rather than constant concentration boundary conditions for contaminant concentrations.</p> | <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>It should be noted that the fate and transport simulations of the COCs are dependent on groundwater flow. Therefore, the Proponent’s conclusions on the transport of COCs, may need to be revisited depending on how IR-89 is resolved.</p> | Accepted |
| IR-98 | - | CNSC | Change to an environmental component due | Section 8, Aquatic Environment | <p>Context: It states in EIS in Section 8.3.7.1 (p. 8-151) that "Cameco’s Key Lake Operation will overlap spatially and temporally with the Project".</p> | <p>Please provide supporting information to demonstrate whether discharges from the proposed operation will not eventually flow into a reference lake used by another existing operation.</p> | | Accepted |

|--------------|----------------|------|---|---|--|--|--|--------------|
| | | | to hazardous contaminants | | Rationale: It is not clear whether there is the possibility that planned Denison discharges would eventually flow into and influence a background reference lake used by Key Lake operation. | | | |
| IR-99 | - | CNSC | Aquatic environment | Section 8, Water Quality, Table 8.2-13 | Context: Table 8.2-13 shows the maximum concentration of hazardous and radiological COPC's in surface water throughout the local study area. However, the concentration for all constituents is stated as mg/L. Rationale: It is unusual for radiological COPC's to be displayed in mg/L, radiological constituents are typically displayed in Bq/L | Please use Bq/L when displaying concentration of radiological COPC's. If this was a typographical error in the table, please indicate as such and revise the table to indicate values are indeed in Bq/L. Please also review other tables displaying concentrations of radiological constituents to ensure this error is not repeated in other tables. | | Accepted |
| IR-100 | - | HC | Indigenous Peoples' health / Socio- economic conditions | Section 8, (p. 8-195) Section 8.5.3, Table 8.5-2, (p. 8-226) | <p>Mercury is excluded as a COPC in the assessment. Inadequate consideration of mercury and methylmercury in fish and other country foods, and use of incorrect Hg-related health guideline values can underestimate the risks to human health among country food consumers.</p> <p>Context: Section 8 states “Mercury has not been identified as a COPC for the Project as it is currently not present in the receiving environment (i.e., background condition) at detectable concentrations and will not be produced as part of the mine process; therefore, it will not be discharged to the aquatic environment.</p> <p>However, it is understood that potential nutrient enrichment-related effects are possible and can be linked to increases in mercury in the environment” (p. 8-195).</p> <p>Table 8.5-2 shows that there is mercury present in the tissues of Northern Pike and White Sucker sampled in the waterbodies within the local study area and in Russell Lake. These fish are regularly consumed by nearby communities according to the ERFN 2017 dietary survey.</p> <p>In Section 8.5.3, fish tissue concentrations are compared to Health Canada’s human health risk- based maximum permissible mercury concentration (0.5 µg/g wet weight), which is applicable to most species of commercially sold fish rather than country foods.</p> <p>Rationale: It is recommended that mercury be listed as a COPC considering it is in fact present in fish tissue under existing conditions, the significant consumption of fish by the local Indigenous communities, and its toxicological significance to human health.</p> | <p>1. Include mercury (including methylmercury) as a COPC in the assessment given the baseline presence of mercury in sampled fish, the potential increase of methylmercury in receiving waters due to nutrient enrichment resulting from the Project, the significant fish consumption by the local population and that country foods, particularly fish, are an important source of dietary exposure to mercury.</p> <p>2. Assess health risks from fish consumption by calculating hazard quotients for baseline and predicted methylmercury levels in country foods using Health Canada’s pTDI for methylmercury (Health Canada, 2007).</p> <p>3. Clarify whether mercury data represented throughout the EIS represents total mercury, inorganic mercury or methylmercury.</p> <p>Suggestions for mitigation and follow-up measures: Health Canada recommends including methylmercury in the list of COPCs to be monitored in fish throughout all project phases.</p> <p>See also related Advice to the Proponent: AD-31.</p> | <p>This IR remains not accepted. It is unclear what threshold concentration(s) of mercury in fish would trigger further assessment of potential health risks.</p> <p>The response to IR-100 includes a commitment to monitor mercury concentrations in fish, and to assess potential health risks if concentrations are greater than that used to derive the Government of Saskatchewan (GoS) guidelines for fish consumption (last updated in 2015). However, using this concentration as a threshold would not be protective of human health if the local population consumes greater quantities than the published consumption guideline.</p> <p>Please provide the following information:</p> <ol style="list-style-type: none">Discuss how the fish consumption rates from average and high traditional foods consumer groups (Section 10-A, Table 4-4: Annual Food Intakes for Components of the Human Receptor’s Diet) relate to the GoS fish consumption limits for general and sensitive populations.Justify the use of GoS guidelines for fish consumption for mercury monitoring in fish and as a trigger for possible management actions. | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------------------|-----------------------|---|---|--|--|--------------|
| | | | | | <p>Further, the Health Canada provisional tolerable daily intake (pTDI) value of 0.2 µg/kg/bw/day (Health Canada, 2007) is a more appropriate reference level when evaluating consumption of mercury in fish by Indigenous people, as it allows for the consideration of food consumption patterns in the risk assessment that differ from the general population and is protective of the most sensitive sub-group (i.e., developing foetus).</p> <p>It is important to note that methylmercury, rather than inorganic mercury, is generally the predominant mercury species present in fish and is also the most toxicologically significant form. The assumption of 100% of mercury in fish and other country food items being present as methylmercury ensures that the potential health risks are not underestimated. It is unclear, however, if the mercury data presented throughout the EIS represent total mercury, inorganic mercury or methylmercury.</p> | | | |
| IR-101 | - | ECCC CNSC | Fish and fish habitat | Section 8.1.1.3, Section 8.2.1.3 Aquatic Environment | <p>Context: In Section 8.1.1.3 Spatial and Temporal Boundaries the Project Area, Local Study Area (LSA) and Regional Study Area (RSA) are established as they pertain to surface water quantity. The same is done in Section 8.2.1.3 for surface water quality. In Section 8.1.1.3 Figure 8.1-4, the locations of the Project Area, LSA, RSA and surface water features and monitoring stations are provided.</p> <p>However, the locations of wetlands located near the Project area and within the LSA and RSA have not been provided. The location of wetlands within or near the Project footprint, as well as the other wetlands existing within the LSA can be confirmed from Part II _S9 Terrestrial Environment, Section 9.2.3.3 Figure 9.2.-8, including the wetland classifications. There appears to be at least one shallow open water wetland and several bogs located within the Project Area. There is no consideration of wetlands or potential effects to wetland hydrology, surface water or sediment quality throughout the aquatic environment assessments. There is no baseline information regarding wetlands and their status as fish habitat and ecological function, or assessment of potential effects to flow rates, water levels, water quality, sediment quality, or biota.</p> <p>Rationale: There is currently not enough information provided for ECCC to provide advice on the potential risks of the proposed Project to wetland hydrology, surface water and sediment quality within the LSA. This pathway of effects is important to assess in terms of potential effects to wetland habitat availability and quality due to changes in flow rates, water levels, water quality, sediment transport, sediment quality and potential effects to terrestrial and aquatic receptors. It is necessary to evaluate if changes in groundwater and surface water runoff flows and routing will affect water levels and habitat availability within wetlands. Potential</p> | <ol style="list-style-type: none">1. Provide baseline information regarding wetland characterization within the Project Area and LSA, including: locations, wetland type, size, water surface elevation, depth, water flow pathways, and the presence of wildlife receptors including presence of fish/fish habitat within the Aquatic Environment section of the draft EIS. If this information is available in annexes or baseline studies, summarize it within the main body of the Aquatic Environment section of the draft EIS with references to respective documents for review.2. Provide baseline information on wetland surface water and sediment quality characterization for wetlands within the Project footprint.3. Provide an assessment of potential effects to wetlands within the LSA and potential effects to ecological receptors during all phases of the proposed Project.4. Provide further information on mitigation measures and monitoring that would be applied for the protection of wetlands. | <p>Responses to items one and four have been accepted, but items two and three require additional information.</p> <p>For item two, the Proponent has not included justification regarding why they have relied on measurements upstream and downstream of the wetlands over direct measurements in the wetland areas within their response. Please provide the missing justification for item two, as well as describe how baseline information will be used to further assess the effectiveness of mitigation measures. Water and sediment quality in wetlands differ than those in stream and lakes systems because of their distinct biota and hydrology. In wetlands, there is a greater cycling of nutrients, more nutrients and metals can be sequestered in sediment, and metal toxicity modifying water quality factors such as pH and dissolved organic carbon are not the same as in streams and lakes. Baseline data on water and sediment quality in wetlands are necessary to evaluate potential effects on fish and fish habitat of proposed discharge to Whitefish Lake upstream of the wetlands. The information would also be used to assess possible effectiveness of proposed mitigation measures.</p> <p>For item three, the Proponent has not provided the predicted sediment quality impacts within item three, which is part of the wetlands assessment that was requested.</p> <p>Please also update Section 8.3 to include additional information on predicted sediment quality impacts to wetlands and to provide an assessment of potential effects to wetlands from sediment quality changes within the LSA.</p> <p>This Information is required in order to identify and define potential effect pathways linked to project-related changes to wetland sediment quality and assess effects on wetland functions, fish and fish habitat, and other valued components. Potential effect pathways in wetlands can be different than those in lakes and streams and warrant a separate assessment.</p> | Not Accepted |

| | | | | | effects from COPCs and radionuclides to surface water and sediment, or potential effects to ecological receptors within wetlands have not been evaluated. | | | |
| IR-102 | - | ECCC CNSC | Fish and fish habitat | Section 8.1.3.1 Appendix 8-C, including Appendix II, Table 1 (p. 2) | <p>Context: Only one measured-results dataset for baseline stream flow exists that is relevant to the Project data from the Water Survey of Canada (WSC) station for Wheeler River (06DA005), and the Proponent used constructed records. The Proponent states that data from 06DA005 was used to extend local hydrometric station records and calculate baseline water quantity metrics. However, this was done through a complex combination of daily data correlation or monthly unit area runoff relationship, with or without offset, where some stations were based off constructed records instead of the real long-term dataset at 06DA005 (see Section 8.1.3.1 and Appendix II of Appendix 8-C, Table 1, p.2 (PDF p. 569)). Appendix 8-C references previous reports in its own appendices, but no equations are shown and there is no description of the accuracy of the fit, or explanation for not referring back to the one dataset (WSC station). Subsequent statistics calculated from these constructed records (e.g., 7Q10 needed for SK water licenses) would be affected by this uncertainty.</p> <p>Rationale: Fish habitat can be altered by changes to depositional and erosional patterns in streams. Confidence in the Proponent’s estimate of baseline water quantity, and by extension Project effects to fish habitat, cannot be established without a complete description of the method applied, as well as a discussion of its accuracy.</p> | <p>1. Provide more information on the extension of Project hydrometric station data using WSC station 06DA005.</p> <p>2. Discuss the accuracy of any correlations/relationships and justify any deviations from simple unit area runoff relationships in the estimation of baseline water quantity values for the Project hydrometric stations. Constructing records from records that are themselves constructed is not recommended.</p> <p>3. If baseline water quantity metrics need to be revised, discuss (if any) resulting changes to the effects assessment.</p> | | Accepted |
| IR-103 | - | ECCC CNSC | Fish and fish habitat | Section 8.1.3.4 Climate Change Influenced Extreme Events | <p>Context: The Proponent notes that Intensity duration frequency (IDF) curves are used to estimate the size of water management structures around a site and that the IDF curves are often specific to climate monitoring stations.</p> <p>The Proponent used the IDF_CC Tool 5.0 developed by the Institute for Catastrophic Loss Reduction (2021) which generates Intensity Duration Frequency (IDF) curves at ungauged locations in order to estimate future IDF curve values under influences of climate change. This tool generates sub-daily values at ungauged locations by interpolation and distance weighing from gauged locations.</p> <p>Rationale: IDF trends exhibit random behavior at some locations and correlated behavior at other locations. The choice of gauged locations will infer the statistics for the ungauged locations, including the IDF trends. Without identification of the gauged locations, it is not possible to assess if the modelled data is realistic or not. If the modelled data is not accurate the design of water management structures on the site may not be sufficient resulting</p> | Provide the gauged stations used to generate the sub daily duration values found in Table 8.1-6: Baseline of Intensity Duration Frequency data. | <p>See AD-73 in the Advice to Proponent table [reference to come].</p> <p><u>Note to Denison:</u> This IR is conditionally accepted. Denison’s commitment to providing the requested information related to the IDF (1 in 100 year 24-hour rainfall) and demonstrate climate change resilience of the project (conduct climate risk and resilience assessment) during licensing should be captured in the Commitments Register.</p> <p>Once Denison has added a commitment related to updating the IDF (1 in 100 year 24-hour rainfall) and demonstrate climate change resilience of the project (conduct climate risk and resilience assessment) in the Commitments Register, this can be accepted.</p> <p><u>Proposed rationale text for posting:</u> <i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>In the Context and Rationale of AD-15 in the Annex 1 – Denison Response, ECCC recommends that the Proponent consult CSA PLUS 4013:19 (2019) <i>Technical guide: Development, interpretation and use of rainfall intensity- duration-frequency (IDF) information: Guideline for Canadian water resources practitioners</i> regarding the</p> | Accepted |

|--------------|----------------|-----|----------------------|---|--|------------------------------|---|--------|
| | | | | | in the potential for impacts to the Project from flooding or extreme weather events. | | <p>consideration of future changes in short-duration precipitation extremes. In IR-103, ECCC indicated that in order to assess the accuracy of the Intensity duration frequency (IDF) curves, ECCC required that the Proponent provide the gauged stations generating the values for the modelled data. The Proponent provided the closest gauged stations, however, the future short duration precipitation values were based on statistical relationships fitted between local scale observed extreme precipitation and modelled simulations extremes.</p> <p>Additionally, REGDOC-2.9.1 (Appendix 1A) stipulates that “<i>The applicant shall also take into account any potential effects of climate change on the project, including an assessment of whether the project might be sensitive to changes in climate conditions during its lifecycle</i>” and Section 5.1.5 of “ECCC’s Strategic Assessment of Climate Change” states “<i>All proponents will be required... to provide information in the Impact Statement on how the project is resilient to and at risk from both the current and future impacts of a changing climate.</i>” CNSC staff review of Section 15.3.2, 15.4.2 and 15.5.3 of the draft EIS show that the vulnerabilities of the project (infrastructures and project activities) and the associated risk (likelihood and consequence) due to potential increase in climate change hazards (in Section 15.3.2 and 15.4.2) due to climate change throughout the life cycle of the project is not presented in detail. It is also not clear from Section 15.4.2 that the mitigation measures in Table 15.4-1 have considered the additional risk due to the impact of climate change. On page 15-19 of the draft EIS states that: “Denison will apply adaptive management that includes monitoring climate factors so that they can proactively mitigate or prevent adverse climate effects on the Project.” Denison did not provide details on how climate factors will be considered within their adaptive management plans.</p> <p>Rationale: Estimates of future short duration precipitation that are based on statistical relationships fitted between local scale observed extreme precipitation and modelled simulations extremes, such as the approach used by the Proponent, are unlikely to provide reliable projections. This is because the amount of information regarding changes in local-scale observed extreme precipitation contained in short records is not sufficient to constrain a regression (model the statistical relationship) between local and larger scale simulations (Li et al., 2019; ECCC 2022). An alternative approach is to base future projections on a comprehensive assessment that integrates climate science understanding and model projections over a large region. The recent Canadian Standards Association (CSA 2019) guidance on IDF for Canadian Water Resources practitioners provides such an assessment. In terms of adaptive management, the Proponent should clearly outline what climate factors will be monitored to mitigate or prevent adverse climate-related effects. This should include information on when and how the climate factors would be monitored and under what circumstances particular adaptive management approaches would be applied. In addition, considering anticipated project life of 37 years, the climate-infrastructure interactions should be assessed to identify climate vulnerabilities of project infrastructures and operations/activities for all phases of the project. This allows climate risk evaluations and propose adaptation measures accordingly. It is difficult to determine how potential changes in future climate will affect project infrastructures and operations/activities and the associated risk (likelihood and consequences) based on the information provided in Section 15.5.3 (p.15-19) of Draft EIS.</p> <p>In order to assess the Proponent’s adaptive management strategies for future extreme precipitation events, ECCC requests that the Proponent consult the CSA (2019) guidance when using future IDF projections in the Project design and provide revised estimates of the</p> | |

| | | | | | | | <p>potential future changes in short-duration precipitation extremes over the Project’s duration.</p> <p>1. Provide revised estimates of the potential future changes in short-duration precipitation extremes over the Project’s duration as relevant to the Project design.</p> <p>2. Demonstrate how the CSA (2019) guidance will be incorporated in the Project design when developing and considering future IDF projections and estimates of the potential future changes in short-duration precipitation extremes.</p> <p>3. Demonstrate project resilience to climate change (considering all potential climate sensitive natural hazards including hazards in Section 15.3.2 and 15.4.2) by conducting climate change risk and resilience assessment that includes risk treatment/adaptation measures. CNSC staff recommends proponent to utilize “<i>ECCC (2022). Draft technical guide related to the Strategic Assessment of Climate Change: Assessing climate change resilience</i>” as a guide. Other recommended best practice guides include “<i>Infrastructure Canada (2023). Climate Lens General Guidance – Version 2.1. Infrastructure Canada - Investing in Canada Infrastructure Program Climate Lens - General Guidance</i>” and “<i>MAC (2021). Guide on Climate Change Adaption for the Mining Sector. Mining Association of Canada (MAC)</i>”.</p> <p>References CSA Group. (2019). Technical guide: Development, interpretation and use of rainfall intensity-duration-frequency (IDF) information: Guideline for Canadian water resources practitioners. <i>CSA PLUS 4013 :19</i>. https://www.csagroup.org/store/product/2703080/, <i>ECCC (2022). Draft Technical guide related to the Strategic Assessment of Climate Change: Assessing climate change resilience</i>. https://www.strategicasessmentclimatechange.ca/28896/widgets/117114/documents/77106 Li, C., Zwiers, F., Zhang, X., & Li, G. (2019). How much information is required to well constrain local estimates of future precipitation extremes? <i>Earth’s Future</i>, 11-24.</p> | |
| IR-104 | - | ECCC | Fish and fish habitat | <p>Section 8.1.3.4.2 Probable Maximum Precipitation (PMP) Events</p> <p>Appendix 8C</p> | <p>Context and Rationale: The Proponent notes: “The probable maximum precipitation (PMP) event is a design standard value for an extreme rainfall event. The PMP event does not have an estimated return period but is instead based on the theoretical maximum amount of water that a storm could produce based on the maximum persisting dew point.”</p> <p>The Proponent provides a PMP value of 489.3 mm, which is based on data and methodologies available in 1999, taken from the Atmospheric Environment Branch Report (1999), Report Number AHSD-R99-01. The Proponent references Appendix 8C for details. Appendix 8C contains no supplementary information other than what is already provided in Section 8.1.3.4.2.</p> <p>The assumptions and methodologies presented in the report are the results of time series analyses available in 1999. As time series evolve so do the derived statistics. In order to assess potential flood risks and impacts to the Project from flooding, data that is current</p> | <p>1. Provide a revised PMP value (using up to date data) or justify the use of a PMP that is based on data and methodologies from 1999 as opposed to a more recent time series analysis.</p> <p>2. Describe the alternative methods for determining PMP values that were considered. Include descriptions of both “statistical” outcomes and “rational” outcomes as applicable.</p> <p>Technical Discussion Required: Yes</p> | <p>Response to IR-104 is accepted by CNSC staff based solely on the Denison’s response (E-DOC#-7220826, p.47/112) that states “<i>Despite Denison’s reiteration that the PMP is adequate for the EA level design basis, Denison is committed to revisiting the estimates per CNSC’s recommendations, as applicable, for the licensing phase of the Project.</i>”</p> <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>There are an additional 24 years of meteorological datasets since the 1999 study thus all historical rainfall extremes including those since 1999 study should be considered to estimate up to date PMP at the Project site The proponent’s justification on whether the 1999 or 1994 PMP estimates are current and conservative should be substantiated based on meteorological data analysis. An estimation of updated PMP is achievable by the proponent as meteorological data is freely available and accessible from ECCC and the proponent should provide a revised PMP.</p> | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|---|--|--|--|---|--|--------------|
| | | | | | and representative of the changing climate is needed. The Proponent should explain why they've used data from 1999 rather than using up to date data, describe what alternative methods for determining PMP they have considered, and describe how they will support their use of 489.3 mm as a PMP, or describe how they will generate a refreshed PMP. The main factor that influences the statistical data output is the length of the time series hence the reason to keep the statistical data. The PMP values can be substantially (>10%) different if two decades of data is used in the statistical analysis. | | <p>The Proponent should also clarify how recent the data used to calculate the PMP or the time series is and explain the use of an older data set that will not produce as accurate of a PMP value as a more recent data set would produce, even when estimates are conservative.</p> <p>Specifically, a. Explain the rationale for the use of the data set which was used to derive the PMP. B. Clarify if the PMP and/or the time series was calculated using more recent data.</p> <p>This will allow for an accurate evaluation of the validity of results derived from the data sets selected by the Proponent.</p> | |
| IR-105 | - | Directorate of Fisheries and Oceans (DFO) | Fish and fish habitat | Section 8.1.4.1, Potential interactions between project and valued component/key indicators Surface Water Quantity Section 8.1.4.2.2, Surface Water Taking 8.3.4.1, Potential interactions between project and valued component/key indicators | Context: Table 8.1-8 and Table 8.3-6 in the EIS indicates a potential for freeze wall operation to influence groundwater interactions and surface water quantity and as a result, impact fish and fish habitat. Section 8.1.4.2.2 references Section 7 Geology and Groundwater for details on potential impacts. In addition, IR-63 notes the groundwater model does not describe the pathway in which groundwater would pass around the freeze wall during operation and any resulting potential effects on groundwater discharge to Whitefish Lake. Rationale: As per IR-63, the groundwater model analysis is insufficient to make conclusions on the potential effects of the freeze wall on groundwater discharge into Whitefish Lake. DFO requires this information to fully understand if altered groundwater regimes will result in changes to Whitefish Lake water levels and any potential impacts to fish and fish habitat as a result of changing water levels. | <p>1. Provide a more fulsome analysis of the potential impact of freeze wall operations on local and semi-regional groundwater regimes, and subsequently to fish and fish habitat within Whitefish Lake. The analysis should provide a rationale of how the scope of the groundwater model is relevant to and able to detect changes at the scale of fish and fish habitat.</p> <p>2. If impacts to fish and fish habitat in Whitefish Lake are predicted to occur due to changes in the groundwater regime, describe any mitigation measures that could be used to avoid these impacts.</p> <p>3. If impacts are predicted that cannot be avoided, characterize residual effects on fish and fish habitat.</p> | | Accepted |
| IR-106 | - | CNSC | Change to an environmental component due to hazardous contaminants | Section 8.1.4.2.3, Surface Water Discharge | Context: It is stated in this section under construction that all site contact water will be held in the Clean Waste Rock Pond. Rationale: It is unclear from this section what will happen to the contact water held in the Clean Waste Rock Pond, and whether it will be removed from site or released at a later time. What is the contingency plan if more contact water is produced during construction than the Clean Waste Rock Pond has capacity for. | Please indicate what will happen to the contact water stored in the Clean Waste Rock Pond during construction activities, will it be released after the wastewater treatment plant is installed? Further, please describe the contingency plan if contact water produced exceeds estimates and will exceed the volume of the clean waste rock pond? | | Accepted |
| IR-107 | - | CNSC ECCC | Aquatic environment | Section 8.2.3.3, Existing Surface Water Quality | Context: Under the methodology and metrics section (8.2.3.1) it is stated baseline water quality was sampled in 2016, 2018, and 2019. Looking at the data in Appendix A of Appendix 8D it seems that some waterbodies have little data available for baseline characterization. For example, Whitefish Lake only has 3 and 5 samples taken between its two sample stations, with sampling frequency seeming intermittent. Rationale: The amount of data available for baseline water quality | Please clarify which data quality objectives were used for the baseline characterization data. Please provide justification whether the number of datapoints collected with inconsistent frequency in baseline surface water characterization is sufficient to meet data quality objectives and to adequately characterize the baseline, and whether Denison is confident that the data collected is enough for a robust water quality baseline characterization. | <p>Before this IR is accepted, the Proponent is requested to provide the statistical correlation analysis to confirm that data is correlated.</p> <p>Additionally, the four expectations set out in the rationale for status have not been adequately responded to. The Proponent should incorporate the following information into the EIS and ERA:</p> <p>1. Provide raw baseline data (perhaps in an appendix).</p> | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|---|---|--|---|--------------|
| | | | | | <p>characterization does not seem sufficient to adequately characterize the baseline and the variation it would experience. An effective baseline characterization is vital to ensure water quality is indeed not being affected by the Project. In addition, it is not clear if data quality objectives were applied to determine baseline information was adequate.</p> <p>To meet CEAA 2012 requirements, and CNSC expectations outlined in REGDOC 2.9.1, Environmental Principles Assessments and Protection Measures, the applicant is required to complete a characterization of the baseline environment.</p> <p>As described in REGDOC 2.9.1 Appendix B.2, Characterization of the Baseline Environment for Environmental Assessment Under CEAA 2012, the “baseline information should be sufficient to support the use of an aquatic dispersion model to conduct the site-specific ERA and to support an assessment of the effects of the environment on the facility or activity”</p> <p>In addition, the “applicant or licensee should include an assessment of any limitations or gaps in the quality and extent of baseline data and methods, as well as the method(s) by which they have been addressed.”</p> | Suggestions for mitigation and follow-up measures: CNSC recommends that additional water samples are collected and analyzed at a consistent frequency to ensure a robust baseline | <ol style="list-style-type: none">2. Provide summary statistics for baseline datasets, which at a minimum should include: mean, standard deviation, 95th percentiles, minimum, maximum, and number of samples. Present summary statistics by season (i.e., freshet, summer, fall and under-ice), and include comparisons to relevant water quality guidelines.3. Identify potential gaps in baseline datasets, and indicate how data gaps will be addressed. Describe the planned baseline monitoring to be conducted including, but not limited to, addressing any data gaps.4. Demonstrate that the combined existing baseline data and planned baseline monitoring will yield dataset(s) that provide robust water quality baseline characterization of seasonal conditions (i.e., freshet, summer, fall, under-ice during winter), including a range of flow conditions. <p>The Proponent should also incorporate the additional baseline data collected into the analysis and conclusions of the finalized EIS and ERA.</p> <p>Concerning the other aspects of the IR, these responses are accepted based on Denison’s commitment to conduct periodic sampling prior to construction to strengthen existing environmental data. CNSC staff will review this information to ensure EA predictions remain valid and recommend collecting samples in the fall to spring timeframe, as samples from these seasons is sparse in the current dataset.</p> | |
| IR-108 | - | ECCC | Change to an environmental component due to hazardous contaminants | Section 8.2.3.3 Aquatic Environment | <p>Context: Tables 8.2-2 and 8.2-3 provide summaries of the baseline surface water quality in the LSA. No justifications for the selection of water quality guidelines have been provided. COPCs that require calculations based on other parameters such as hardness, pH, or temperature to derive guidelines (i.e., ammonia, cobalt, zinc, etc.) should be indicated within the table, with a note specifying the parameter values used in the calculations, so that thresholds may be confirmed. No baseline data for un-ionized ammonia has been provided, which is a Schedule 4 substance requiring monitoring under the MDMER. For cobalt, manganese, and vanadium, Federal Environmental Quality Guidelines (FEQGs) and/or CCME Canadian Water Quality Guidelines (CWQGs) for the Protection of Aquatic Life have not been included. A guideline of 26 mg/L has been provided for molybdenum as a Saskatchewan Environmental Quality Guidelines (SEQG), however the actual SEQG is 31 mg/L and the CCME CWQG is 0.073 mg/L.</p> <p>Rationale: In order to assess potential changes to surface water quality from Project related activities, ECCC requires that data on all parameters that require MDMER effluent and receiving environment monitoring be provided for assessment, including accurate water quality guidelines where available.</p> | <ol style="list-style-type: none">1. Update Tables 8.2-2 and 8.2-3 to include all COPCs that require effluent characterization and receiving environment monitoring under the MDMER.2. Update Tables 8.2-2 and 8.2-3 to include missing or corrected water quality guidance thresholds, and information on values used to derive thresholds for COPCs that are dependent on general parameters. | <p>The IR has only been partially resolved. In item one, temperature is still missing from updated tables in attachment IR-108, 8.2-2 and 8.2-3. The Proponent should add this to the tables.</p> <p>In item two, Tables 8.2-2 and 8.2-3 still contain numerous incorrect guidelines. Additionally, the information on values used to derive thresholds for COPCs that are dependent on general parameters contain inconsistencies which should be corrected or explained.</p> <p>The table does not specify if metal concentrations are total or dissolved. The long-term benchmark column includes both guidelines for dissolved metals (e.g. aluminum, manganese) and total metals (e.g. iron, selenium). The table should be updated to clarify if metal concentrations are total or dissolved and include the appropriate benchmarks.</p> <p>For metal parameters, for which guidelines are dependent on environmental modifying parameters, site specific environmental parameters should be used to select the most appropriate guideline. Specific inconsistencies noted are:</p> <ul style="list-style-type: none">• Aluminum – guideline may change depending on site specific pH.• Ammonia (as N) – should be calculated at site specific pH and water temperature reached during the summer.• Ammonia (un-ionized) – The CCME long-term guideline is 0.019 mg/L, so the reference is incorrect.• Boron – The CCME has both short- and long-term guidelines for total boron (29 & 1.5 mg/L) which should be included in the tables. | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|--|---|--|--------------|
| | | | | | | | <ul style="list-style-type: none">Chromium – The type of chromium should be specified. The benchmark specified is the CCME guideline for hexavalent chromium, it is not clear if this was also used for the measured concentrations.Cobalt – The FEQG added as a benchmark includes a specific hardness range and does not apply to the soft waters found on site and should be removed. The guideline is for water with hardness between 52-396 mg/L and table footnote #2 states: “<i>Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).</i>”Copper - the CCME guideline applied for copper is out-dated (1987) and does not reflect the current state of science. The FEQG for copper (2021) reflects the current science utilizing the biotic ligand model and is a more appropriate screening criterion.Dissolved phosphorous & phosphorous – Table footnote #17 states the guidelines for a meso-eutrophic waterbody were used. Use of this guideline should be justified because all sample locations except one had non-detectable phosphorous and dissolved phosphorous concentrations with a detection limit on the upper end of the oligotrophic cutoff, indicating oligotrophic status. Though dissolved phosphorous concentrations were detected at site LB-2, phosphorous concentrations at this site were not detectable, which suggests issues with the measurements. These measurements are therefore not reliable enough to base a trophic status for the region.Manganese – Table footnote #3 states pH of 7.5 and hardness of 15 mg/L were used to calculate the benchmark for dissolved manganese. Justification is required for using a hardness above the site-specific hardness used in footnote #2 (5.26 mg/L) and site-specific pH should be used.Nickel – The long-term benchmark has been changed from the CCME guideline of 0.025 mg/L total nickel to the WHO drinking water guideline of 0.070 mg/L. It is noted that a drinking water quality guideline may not be protective of aquatic life and the more stringent CCME guideline for the protection of aquatic life is the more appropriate benchmark for the receiving environment so the original benchmark should be retained.Strontium – The guideline added for strontium (205 mg/L) is incorrect. The FEQG for dissolved strontium is 2.5 mg/L | |
| IR-108 | IR-108-R1 | ECCC | Change to an environmental component due to | Section 8.2.3.3 Aquatic Environment IR-108 Response from Denison | <p>Context: Incorrect benchmark environmental quality guidelines and guidelines that cannot be verified remain within the updated Tables 8.2-2 and 8.2-3 provided in the Proponent’s response. The Proponent provided an Aluminum Saskatchewan Environmental Quality Guidelines (SEQG) value of 0.005 mg/L in both tables. This is incorrect and appears to be the guideline for irrigation, not the guideline for protection of aquatic biota. The Proponent provided a Molybdenum SEQG of 26 mg/L in both tables. This value is incorrect. The correct SEQG for Molybdenum is 31 mg/L and the Canadian Water Quality Guideline (CWQG) is 0.073 mg/L. The Proponent provided a Nitrate SEQG of 13.29 mg/L in both tables. This value is incorrect. The correct SEQG for Nitrate is 3 mg/L and the CWQG is 13 mg/L.</p> <p>Rationale: In order to verify the benchmark environmental quality guidelines that are calculated based on environmental modifying</p> | <p>1. Update Tables 8.2-2 and 8.2-3 to include footnotes with the concentrations of environmental modifying parameters such as pH, hardness and DOC used to derive guidelines for Aluminum, Cadmium, Copper, Lead, Manganese, Nickel and Zinc.</p> <p>2. Update Tables 8.2-2 and 8.2-3 to include the correct benchmark guideline value for Aluminum, Molybdenum and Nitrate. Include the concentrations of environmental modifying parameters needed for deriving guidelines. If the most stringent guideline value is not selected for use, provide a rationale for use of the chosen guideline.</p> <p>3. Update Tables 8.2-2 and 8.2-3 to include the calculated guideline value for manganese and the environmental modifying parameter concentrations used to calculate the</p> | Item one has been partially addressed, but additional corrections to the footnotes of Tables 8.2-2 and 8.2-3 are needed for copper, manganese, nickel and zinc. Additionally, table footnote #9 does not specify the DOC, pH or hardness values used to calculate the dissolved zinc benchmark. The Proponent should provide the corrections to Tables 8.2-2 and 8.2-3, as well as specify the DOC, pH and hardness values used to calculate the dissolved zinc benchmark. Follow up to items two and three can be found under IR-108. | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|--|--|--|--|----------|
| | | | | | factors such as pH, hardness and dissolved organic carbon (DOC), the specific concentrations of these environmental modifying parameters used in the calculations must be provided. Additionally, incorrect benchmarks for Aluminum, Molybdenum, and Nitrate remain within the updated tables provided by the Proponent. No benchmark was provided for Manganese. It is not clear if Total Chromium or Hexavalent Chromium was measured as the table does not specify, and the benchmark provided was for Hexavalent Chromium. This information is required to understand potential changes to surface water quality from Project related activities and facilitate threshold confirmation. Use of the incorrect threshold could allow for effluent to be discharged at the wrong concentration. | guideline. A benchmark environmental quality guideline has not been provided for Manganese, however a chronic CWQG guideline exists that can be derived based on environmental modifying parameter concentrations. Update Tables 8.2-2 and 8.2-3 to specify if Total Chromium or Hexavalent Chromium was measured. See also related IR-115-R1. | | |
| IR-109 | - | ECCC | Change to an environmental component due to hazardous contaminants | Section 8.2.4.1.1 Aquatic Environment | <p>Context: In this section it is stated “Treated water from the IWWTP will be pumped to the three Effluent Monitoring and Release Ponds (each 3,300 m3). These ponds will be designed to hold effluent for 72 hours for testing before discharge to the environment” (p. 8-75). It is unclear what procedure will be followed if effluent in monitoring ponds does not meet discharge requirements following testing.</p> <p>Additionally, it is also stated that “Treated water in the Effluent Monitoring and Release Ponds will be monitored prior to release to a surface waterbody or injected into groundwater via deep well injection.” However, the MDMER pursuant to the Fisheries Act requires all mine effluent and seep. From the mine site that contain deleterious substances be discharged through a final discharge point.</p> <p>Rationale: In order to fully understand effluent management, more information is required regarding the procedure for managing effluent in monitoring ponds that does not meet discharge requirements. It is unclear how effluent that does not meet discharge requirements will be managed if it needs re-treatment and re-testing prior to discharge.</p> <p>ECCC reminds the Proponent that Project effluent from all final discharge points must meet federal legislation requirements.</p> | Provide further information regarding management of effluent in monitoring ponds that does not meet the requirements for discharge under the MDMER. | | Accepted |
| IR-110 | - | ECCC | Change to an environmental component due to hazardous contaminants | Section 8.2.4.1.1 Aquatic Environment Appendix 8-E, Section 2.1 | <p>Context: It is stated that the diffuser at the final effluent discharge point will be located in approximately 3m of water. However, in Figure 8.2-5 displaying the location of the proposed diffuser and lake bathymetry, the diffuser location seems to be located in 2-2.5m of water. A similar image in Figure 1 Section 2.0 of Appendix 8-E also indicates that the diffuser seems to be located in 2-2.5m of water. Additionally, while thermal effects are unlikely, this cannot</p> | Provide confirmation of the diffuser depth and location. ECCC requests the opportunity to review the finalized diffuser design once it is available. | <p><u>This IR is conditionally accepted. As Denison is unable to provide the finalized diffuser design, a commitment should be captured in the Commitments Register that the final diffuser configuration will not change the environmental assessment conclusions of risk to aquatic receptors and that water quality will remain below guidelines.</u></p> <p><u>Once Denison has added a commitment that the final diffuser design will not change the environmental assessment conclusions of risk to aquatic receptors and that water quality will remain below guidelines to the Commitments Register, this can be accepted.</u></p> | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|---|---|--|--|----------|
| | | | | | <p>be confirmed until a more detailed diffuser design is provided for review.</p> <p>Updated Rationale: The Proponent should confirm the location and depth of the proposed diffuser in order to confirm that modelling predictions for effluent discharged into the receiving environment are accurate.</p> <p>A review of the final discharge design is necessary to confirm the location and depth of the proposed diffuser and modelling predictions for effluent discharged into the receiving environment.</p> | | <p><u>Note, if there are deviations from predicted effluent and near-field surface water concentrations of COPCs and risk to aquatic receptors due to the finalized diffuser design, this would be addressed through Denison identifying and implementing mitigation measures (e.g., treatment) to ensure that the environmental assessment conclusions of risk to aquatic receptors will not change and that water quality will remain below guidelines.</u></p> <p><u>Proposed rationale text for posting: Denison has captured a commitment in the Commitments Register that the final diffuser configuration will not change the environmental assessment conclusions of risk to aquatic receptors and that water quality will remain below guidelines, so this IR has been accepted.</u></p> <p><u>Any outstanding issues will be further assessed as part of licensing technical reviews, prior to the granting of a license.</u></p> <p><u>Note to Denison: This IR is still under discussion, but the expected path forward is conditional acceptance, with a commitment from Denison that it be captured in the Commitments Register that the final diffuser configuration will not change the environmental assessment conclusions of risk to aquatic receptors and that water quality will remain below guidelines.</u></p> <p><u>With this commitment, it would be expected that any outstanding issues (ie. if there are deviations from predicted effluent and near-field surface water concentrations of COPCs and risk to aquatic receptors due to the finalized diffuser design) will be further assessed as part of licensing technical reviews, prior to the granting of a license.</u></p> | |
| IR-111 | - | CNSC | Fish and fish habitat | Section 8.2.4.2.2, Controlled Discharge | <p>Context: This section of the EIS indicated that the scenario was assessed using a conservative assumption of a continuous freshwater withdrawal rate of 40.5 m3/hr, and a continuous effluent discharge rate of 81.0 m3/hr.</p> <p>Rationale: The withdrawal rate assessed is half of the effluent rate, it is unclear from the text where the other half of the volume of effluent is coming from, if not drawn from the lake.</p> | Please clarify where the other half of the total volume of effluent discharged is from in the water balance between water intake and effluent. | | Accepted |
| IR-112 | - | ECCC | Change to an environmental component due to hazardous contaminants | Section 8.2.4.2.2, Aquatic Environment Appendix 8-E, Section 1.2.1 Appendix 10-A (ERA), Section 3.1 | <p>Context: This section of the EIS states that, “for the purpose of assessing the scenario of greatest potential effects, the Project was assessed as having a continuous freshwater withdrawal rate of 40.5 m³/hr and a continuous effluent discharge rate of 81.0 m³/hr.” (p. 8-21)</p> <p>However, several sentences later it is stated that, “The approach to assessing Project-related effects on the Surface Water Quality VC was conservative for the following reasons: The assessment was based on a continuous (year-round) discharge rate at an expected average effluent discharge of 0.0101 m3/s (or 36.5 m3/hr) throughout Construction, Operation, and Decommissioning...”</p> <p>This is a continuous theme throughout Section 8, Aquatic Environment, where the discharge rate for the surface water quality assessment changes between 36.5 m3/hr and 81.0 m3/hr.</p> | <p>1. Confirm that the surface water quantity, quality, and aquatic biota risk assessments and modelling, were conducted using the discharge rate for 36.5 m3/hr within the draft EIS.</p> <p>2. Revise any statements or conclusions in the draft EIS to improve clarity about the usage of the maximum upper bound discharge rate of 81 m3/hr. Remove statements regarding use of the discharge rate of 81 m3/hr during modelling and risk assessments to the receiving environment as needed.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|--|---|--|--|--------------|
| | | | | | <p>However, in Appendix 10-A (ERA) the 36.5 m3/hr discharge rate is the only value used for the near and far-field modelling.</p> <p>It should be made clear in the main body of the draft EIS that the average effluent discharge rate of 36.5 m3/hr has been used as the input for the near- and far-field modelling for effluent, surface water and sediment quality predictions. The maximum upper bound discharge rate is 81 m3/hr; however, modelling for effluent, surface water and sediment quality was not completed for this discharge rate.</p> <p>Rationale: It remains unclear throughout the draft EIS that all predictions of COPC concentrations in effluent, and receiving environment surface water and sediment are based upon the effluent discharge rate of 36.5 m3/hr, and not the maximum upper bound discharge rate of 81 m3/hr. All conclusions about risk to the environment and aquatic and terrestrial biota must make this clear. If the Proponent wishes to make conclusions based on the maximum upper bound discharge rate of 81 m3/hr, modelling needs to be conducted using this rate of discharge.</p> | | | |
| IR-113 | - | ECCC | Change to an environmental component due to hazardous contaminants | Section 8.2.4.2.3 and Section 8.4.7.6, Aquatic Environment | <p>Context: No quantitative assessment of climate change has been conducted. Representative concentration pathways (RPC) projections for climate change have not been integrated with near- and far-field modelling to assess impacts to surface water quality or sediment quality in the future.</p> <p>Rationale: Changes in air and water temperatures, precipitation, snow melt, ice formation, etc., due to climate change can all influence COPC concentrations in surface water and sediment. It is not possible to assess the potential impacts from climate change on predicted surface water and sediment COPC concentrations with the current information.</p> | <p>Provide a quantitative analysis of the potential impacts of predicted COPCs from mine effluent to surface water and sediment quality with climate change scenarios for the Project lifespan incorporated into modelling. Include modelling predictions regarding the influence of changes to air and water temperatures, precipitation, snow melt, ice formation, etc., on COPC concentrations in surface water and sediment.</p> | <p>The Proponent has not adequately responded to the IR. The Proponent suggests that the requested quantitative analysis is not necessary and contends that potential climate change effects on water quality should instead be addressed through mitigation measures, monitoring and adaptive management.</p> <p>The Proponent’s approach does not sufficiently characterize the range of potential effluent and water quality predictions. Climate change analysis is lacking, and a sensitivity analysis was not conducted in order to further understand uncertainty and drivers of the model results. Further, some aspects of water quality modeling are not sufficiently conservative, including use of the geometric mean (instead of the 95th percentile) as the baseline concentration for constituents, and pooling data from all lakes, which would mask any differences between the lakes.</p> <p>It is therefore not known whether water quality exceedances may be predicted under climate change scenarios. Without estimating the potential influence of climate change on water quality, it is unclear whether the proposed water quality mitigation measures are adequate.</p> <p>The Proponent should conduct a sensitivity analysis on water quality predictions for low and high precipitation scenarios, including the potential influences of climate change to assist in fulfilling the IR from the previous round.</p> <p>This information is required to assess the potential for significant adverse effects to the environment. If additional baseline information is required, it should be sourced or otherwise collected.</p> | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------------------|--|--|--|--|---|--------------|
| IR-113 | IR-113-R1 | ECCC | Fish and fish habitat | Section 8.2.4.2.3 and Section 8.4.7.6, Aquatic Environment IR-113 Response from Denison | <p>Context: The Proponent states the following, “The PMP is very conservative (e.g., assumes effectively a full year of precipitation in one event) under both existing and future conditions (climate change)”. This statement suggests that the PMP value utilized considers future climate changes such as possible changes in the frequency or intensity of extreme precipitation events.</p> <p>Rationale: As noted by the Proponent, increases in extreme rainfall are anticipated with a warmer climate. For precipitation extremes across Canada, the relative change in event frequency is expected to be larger for more extreme and rarer events. Given that the extreme precipitation is expected to intensify in the future (Kunkel et al. 2013), the Proponent should consider how these potential changes will influence design values such as PMP.</p> | <p>Clarify if climate change has been considered in the PMP value provided. If it has not been considered, discuss how potential increases in PMP have been and/or need to be considered in the Project design.</p> <p><u>Reference</u> Kunkel, K., Karl, T. R., Easterling, D. R., Redmond, K., Young, J., Yin, X., & Hennon, P. (2020). Probable maximum precipitation and climate change. <i>Geophysical Research Letters</i>, 1402-1408.</p> | <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>The Proponent has not clarified if climate change has been considered in the PMP value provided or discussed how potential increases in PMP have been or need to be considered in the Project design.</p> <p>Thermodynamic effects on atmospheric moisture will lead to intensification of local extreme precipitation in the future. Probable maximum precipitation (PMP) is defined as the greatest accumulation of precipitation for a given duration meteorologically possible for an area (Kunkel et al., 2013). PMP values may increase with climate change.</p> <p>In the response to IR-113 R1, the Proponent states that “the design basis PMP is robust and inclusive of projected total annual precipitation under a high carbon scenario”. It is unclear from this statement how the analysis provided indicates that the PMP is inclusive of climate change.</p> <p>The Proponent should clarify how the analysis that they provided shows that the design PMP considers climate change, and indicate if or how the potential for increased PMP has informed site water management for the mine life and into post-closure and considered in the development of mitigation measures.</p> <p>Reference: Kunkel, K. | IR-114 | - | ECCC CNSC | Change to an environmental component due to hazardous contaminants | Section 8.2.4.2.3 and Section 8.2.4.2.4 | <p>Context: Tables 8.2-9, 8.2-10 and 8.2-13 demonstrate predicted maximum effluent concentrations of COPCs and maximum predicted receiving environment concentrations in the near- and far-field. General parameters such as temperature, pH, conductivity, etc. that would require Project thresholds and monitoring under the MDMER have not been provided in this table. Lead, nickel, TSS and un-ionized ammonia were not provided, despite all being Schedule 4 substances with maximum monthly concentrations under the MDMER. Aluminum, iron, nitrate, thallium, and manganese have not been provided despite being required parameters under Schedule 5 Section 4 of the MDMER for effluent characterization.</p> <p>For zinc, it is unclear how guidelines have been calculated when CCME thresholds can only be derived with hardness values <250 mg/L. Additionally, water quality thresholds appear to have been calculated using estimated effluent concentrations rather than receiving environment baseline concentrations.</p> | <p>1. Update all tables to include all COPCs with required monitoring under the MDMER including acute and chronic thresholds.</p> <p>2. Ensure all selected water quality thresholds are derived using baseline receiving environment concentrations and use water quality guidelines that are protective of aquatic biota.</p> <p>3. Provide baseline data on the concentrations of methylmercury in surface water, sediment and fish tissues (i.e., large-bodied sports fish and small-bodied forage fish) in the LSA and RSA receiving environment to establish a baseline prior to potential Project impacts.</p> <p>4. Provide an assessment of risk from methylmercury to ecological receptors due to changes in sulphate concentrations in effluent, and potential deposition of mercury from Project related atmospheric emissions in the receiving environment.</p> | <p><u>In response to the FIRT’s previous review, Denison provided responses to the following outstanding requests from ECCC:</u></p> <p><u>1. Update all tables to include missing data for mercury, aluminum, total suspended solids, iron, thallium, manganese, nitrate and phosphorus.</u></p> <p><u>2. Update tables to include predictions of total hardness concentrations (in mg/L CaCO3) in effluent and the receiving environment.</u></p> <p><u>3. Update tables to include acute water quality thresholds to ensure COPCs do not have the potential to be acutely lethal at the end-of-pipe.</u></p> <p><u>4. Ensure that all selected water quality thresholds are derived using baseline receiving environment concentrations and use water quality guidelines that are protective of aquatic biota.</u></p> <p><u>The Proponent has resolved item two and four of the above, but items one and three require additional follow up.</u></p> <p><u>The Proponent has responded fully to items two and four of the request.</u></p> <p>Regarding item one, further corrections to Table 8.2-13 are necessary:</p> <ul style="list-style-type: none">There are several inconsistencies in the footnotes:<ul style="list-style-type: none">numbers 2 & 3 are missing in the footnotes at the bottom;there is no reference to footnote 2 in the table; and | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-----------------------|---|---|--|---|--------------|
| | | | | | <p>Mercury has been identified as a COPC of interest to Indigenous groups for the proposed Project. Table 8.2-8 indicates that background concentrations of mercury in LA-5 are low, and predicted effluent concentrations are also low. However, no information has been provided on background methylmercury concentrations or expected atmospheric deposition of mercury from Project related emissions. Predicted effluent concentrations of 3915 mg/L of sulphate are quite high, and sulphate is known to increase mercury methylation rates in aquatic environments.</p> <p>Rationale: A review of all modelling results for all COPCs under the MDMER will assist ECCC in understanding the potential risks to the receiving environment. ECCC recommends the use of the most stringent guidelines for the protection of aquatic biota. All water quality thresholds should be derived from receiving environment parameters to determine any baseline receiving environment and effluent COPC exceedances of water quality thresholds.</p> <p>Increased sulphate availability can lead to increased methylation rates of mercury and methylmercury in sediment and surface water. Methylmercury is a toxin that can bioaccumulate within the food chain and present risks to aquatic biota and wildlife consuming aquatic biota. Potential changes to methylmercury concentrations in water quality, sediment and fish tissues should be assessed due to the proposed sulphate loadings in effluent.</p> <p>Additionally, in accordance with the MDMERs, Denison will be required to demonstrate that their effluent quality meets the limits in the MDMER. Denison is expected to provide the predicted effluent quality for lead, nickel, and un-ionized ammonia to demonstrate compliance with the MDMERs.</p> | | <ul style="list-style-type: none">○ The asterisk “*”, which is sometimes used to qualify the source of screening concentration, is not defined.• Screening criteria are missing for aluminum and iron, and should be sourced from CCME or SEQG rather than the MDMER as listed in the table.• Uranium-234 and uranium-238 are missing from the table, even though they have been identified as contaminants of potential concern.• Proposed screening criteria for cobalt, copper, manganese, nickel, phosphorous and un-ionized ammonia are inadequate, see comment in IR-108 & IR-108-R1.• Alkalinity and nitrate have been added to the table as requested, however predicted maximum concentrations are only presented for Whitefish Lake Middle and South. The proponent should describe why there are no estimates for these parameters in other lakes, and how they intend to fill these gaps.• Un-ionized ammonia appears in two separate lines in the table with concentrations differing by 3-4 orders of magnitude and different screening values. A single line entry with accurate values should be retained. The Proponent should provide an explanation for the error in order to give the reviewer confidence that the correct values are retained.• The column with screening values does not always use the most conservative value from Table 8.2-8. See comment IR-115 for request to provide justifications. <p>Table 8.2-14 should be updated with corrections to screening criteria necessary for this IR as well as for IR-108 and IR-115. Additional follow up for Table 8.2-10 can be found under IR-108 and IR-108-R1.</p> <p>In the Proponent’s response to item three of the IR, Table 8.2-10 is missing the source for the short-term screening criteria value for arsenic. The Proponent should update Table 8.2-10 to include the source for the short-term screening criteria value for arsenic.</p> | |
| IR-115 | - | ECCC | Fish and fish habitat | Section 8.2.4.2.3 Aquatic Environment Appendix 10-A (ERA), Section 3.1.1.1 | <p>Context: Table 8.2-8 demonstrates baseline concentrations of COPCs in LA-5 South Whitefish Lake, their respective water quality guidelines from applicable sources, and proposed Project thresholds. General parameters such as temperature, pH, conductivity, etc. that would require Project thresholds and monitoring under the MDMER have not been provided in this table. Lead, nickel, Total Suspended Solids (TSS) and un-ionized ammonia were not provided, despite all being Schedule 4 substances with maximum monthly concentrations under the MDMER. Aluminum, iron, nitrate, thallium, and manganese have not been provided despite being required parameters under Schedule 5 Section 4 of the MDMER for effluent characterization. Water quality thresholds appear to have been calculated using estimated effluent concentrations rather than receiving environment baseline concentrations. The water quality objective selected for molybdenum is the 31 mg/L SEQG rather than the CCME guideline of 0.073 mg/L.</p> | <p>1. Update Table 8.2-8 to include all COPCs with required monitoring under the MDMER.</p> <p>2. Ensure all selected water quality thresholds are derived using baseline receiving environment concentrations and are at levels protective of aquatic life.</p> <p>3. Provide additional information to justify the use of the selected water quality guideline for molybdenum.</p> | Please see the response to IR-115-R1 (below). | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-----------------------|---|---|---|---|--------------|
| | | | | | Rationale: ECCC recommends the use of guidelines that will ensure the protection of aquatic biota. All water quality thresholds should be derived from receiving environment parameters to determine any baseline receiving environment and effluent COPC exceedances of water quality thresholds. | | | |
| IR-115 | IR-115-R1 | ECCC | Fish and fish habitat | Section 8.2.4.2.3 Aquatic Environment Appendix 10-A (ERA), Section 3.1.1.1 IR-115 Response from Denison | <p>Context: In the Proponent’s response to item two, it is mentioned that the derived water quality thresholds used in Table 8.2-8 and in the assessment (Section 8.2.4.2.3, Aquatic Environment; Appendix 10-A (ERA), Section 3.1.1.1) are based on hardness concentrations found in effluent. The Proponent mentions that hardness derived from IWWTP discharge will consider IWWTP discharge on the receiving environment and provide “a reasonable estimate of expected hardness in effluent”. However, this does not consider induced hardness (i.e., hardness concentration increases in the receiving environment over the lifecycle of the Project) from effluent contributions as a Project effect; the receiving environment baseline concentrations of hardness have been altered due to inputs from Project effluent. Providing only one estimate of expected effluent hardness in the receiving environment is not an appropriate means of conducting the effects assessment.</p> <p>Additionally, the following COPCs have not been included in the updated table provided in the Proponent’s response: un-ionized ammonia, aluminum, iron, manganese, thallium and total dissolved solids (TDS). It is noted that these COPCs are also subject to monitoring requirements under the <i>Metal and Diamond Mining Effluent Regulations</i> (MDMER).</p> <p>Rationale: Background concentrations of un- ionized ammonia, aluminum, iron, thallium, manganese and TDS are required to determine potential effects to the environment. The Proponent will also require this information to satisfy their obligations under the MDMER.</p> <p>The purpose of the surface water quality assessment is to determine if changes to the receiving environment over the project lifecycle will have significant adverse effects on biota. Changes from baseline in hardness concentrations in the receiving environment due to the deposition of effluent is a Project related effect and therefore providing a single baseline water quality threshold which is applicable only to one set of conditions is not an appropriate method to evaluate impacts across a shifting hardness baseline.</p> | <p>1. Update Table 8.2-8 to include the following COPCs: un-ionized ammonia, aluminum, iron, manganese, thallium and total dissolved solids (TDS).</p> <p>2. Update Table 8.2-8 to include background concentrations of total hardness (in mg/L CaCO3) in the receiving environment.</p> <p>3. Provide rationale that all selected water quality thresholds are derived using baseline receiving environment concentrations and are at levels protective of aquatic life.</p> <p>See also related IR-108-R1</p> | <p>The Proponent has not fully responded to the previous round’s IR. For items one and two, some of the information provided on contaminants of potential concern (COPCs) and the background concentrations of hardness in the receiving environment is not sufficiently conservative. Item three requested rationale that all selected water quality thresholds (i.e., screening criteria) are at levels protective of aquatic life, which was not provided.</p> <p>The updated Table 8.2-8 provides two short-term and two long-term screening criteria for each parameter. The screening criteria reflect calculated screening criteria for both background hardness and project-induced hardness, however, it is unclear which criteria the Proponent intends to apply in their assessment since four separate criteria are provided (see IR-114).</p> <p>The information presented in Table 8.2-8 indicates there are no background water quality exceedances of guidelines. However, it is noted that several screening criteria do not reflect the most conservative guidelines, which is not consistent with the approach described in Appendix 10-A (Environmental Risk Assessment). For some examples, the short-term screening criteria value of 500 mg/L for nitrate is much higher than the BC MOE nitrate guideline of 32.8 mg/L., the long-term criteria for un-ionized ammonia of 6.87 mg/L is much higher than the CCME guideline of 0.019 mg/L and the MDMER limit, and the long-term phosphorus screening criteria represent a trigger range that is two to three trophic levels above background, which is much higher than the CCME guidance framework recommends. The Proponent should review and update Table 8.2-8 to provide conservative screening criteria for all parameters, and include a consideration of the CCME, FEQG, SEQG, and BC MOE when selecting the screening criteria. Screening criteria selection should be informed by the most conservative guidelines. Cases where the Proponent does not propose to apply the most conservative screening criteria should be accompanied with a discussion and rationale for the selection. The Proponent should also specifically state which criteria will be used in screening, how these criteria will be or are applied, how the EA conclusions are informed by the criteria, and whether any EA conclusions are altered by changes to screening criteria.</p> | Not Accepted |

|--------------|----------------|------|--|--|--|--|----------------------|----------|
| | | | | | Water hardness is an environmental modifying factor, various concentrations of hardness influence the toxicity of other COPCs in the aquatic environment. Using water quality thresholds that have been derived from high effluent hardness concentrations will not be protective of aquatic biota, particularly in the early stages of the project lifecycle when receiving environment water quality will be similar to baseline water quality. | | | |
| IR-116 | - | ECCC | Change to an environmental component due to hazardous contaminants | Section 8.2.4.2.5, Section 8.4.4.2.5 and Section 8.5.4.2.3 | <p>Context: Tables 8.2-14, 8.4-9 and 8.5-5 demonstrate predicted mass flux (in mg/s) of COPCs in groundwater during the future centuries scenario. The table does not provide any information on actual surface water concentrations of COPCs or accumulation in concentrations over time. It is not possible to determine what the COPC concentrations in surface water and sediment will be during the future centuries scenario with the current information.</p> <p>Additionally, only a subset of parameters have been provided in this table based on parameters that were elevated in effluent after treatment. Groundwater may have a variety of different COPCs with elevated concentrations as it will migrate directly from the ore body area and not receive treatment.</p> <p>Rationale: It is not possible for ECCC to assess the predicted concentrations of COPCs in surface water and sediment, and therefore risk to aquatic biota during the future centuries scenario with the provided information.</p> | <p>1. Provide the predicted water and sediment quality concentrations of COPCs in the receiving environment for the future centuries scenario.</p> <p>2. Include data for a greater suite of COPCs that were assessed as having potential to be at elevated concentrations in groundwater.</p> | | Accepted |
| IR-117 | - | CNSC | Human health with respect to hazardous contaminants | Section 8.2.4, Table 8.2-9 | <p>Context: CNSC staff note that some of the effluent quality predictions in the EIS are quite high for a uranium mine and mill facility compared to the existing facilities.</p> <p>For example, the upper bound effluent quality of molybdenum is 2.5 mg/L. In 2021, the highest monthly mean concentration at the existing uranium mine and mill facilities is 0.213 mg/L.</p> <p>Also, the upper bound effluent quality of copper is 0.022 mg/L. In 2021, the highest monthly mean concentration at the existing uranium mine and mill facilities is 0.002 mg/L.</p> <p>Rationale: Surface water quality models should be based on the anticipated effluent quality. From discussions with Denison, it appears that the effluent quality predictions may change based on the results of more bench scale tests that are still being conducted and continued optimization of the design of the water treatment plant.</p> | <p>Please provide the anticipated effluent quality of the constituents of potential concern during normal operations.</p> <p>Once Denison has refined the effluent quality predictions, Denison is expected to update the inputs into the surface water quality model.</p> | | Accepted |
| IR-118 | - | ECCC | Change to an environmental component due | Section 8.2.6.1, Section 8.4.6.1 and Section 8.5.6.1, | <p>Context: It is unclear if Tables 8.2-16, 8.4-12, 8.5-7 and 8.5-8 take into consideration potential effects from groundwater seepages of COPCS to surface water and sediment quality in the future</p> | Provide further information regarding how groundwater seep. Of COPCs may have future impacts to surface water quality, | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---------------------------|---|--|--|--|----------|
| | | | to hazardous contaminants | Aquatic Environment | centuries scenario. No information regarding the future centuries scenario has been provided in the rationale summary for ratings. Rationale: Groundwater seepage of COPCs may have future impacts to surface water quality, sediment quality and aquatic receptors; however, the extent of residual effects is unclear without further information. | sediment quality, and aquatic receptors, and any residual effects that may persist. | | |
| IR-119 | - | CNSC | Fish and fish habitat | Section 8.3.1.2, Table 8.3-1, Sediment quality | Context: Sediment quality isn’t considered a key indicator for fish and fish habitat, but the accumulation of contaminants in sediment porewater without habitat alteration is similar to the key indicator 'change in surface water quality from baseline conditions' that is considered. Rationale: It is not clear whether sediment was just considered for physical disturbance, and why chemical changes are missing from key indicator list for fish and fish habitat. | Please provide the rationale for exclusion of sediment quality from the key indicator list for fish and fish habitat. | | Accepted |
| IR-120 | - | CNSC | Aquatic species | Section 8.3.3 and 8.5, Aquatic Environment | Context: Although downstream impacts are not predicted by Denison it is important from an ecosystem perspective to establish baseline locations to monitor for potential cumulative effects to the aquatic environment due to the Key Lake and Wheeler River Operations to ensure the aquatic environment is being protected from cumulative impacts. Denison should consider adding a far-field exposure location and collecting baseline aquatic ecosystem baseline data in Russell Lake including: <ul style="list-style-type: none">• Water quality/chemistry• Sediment chemistry/quality• Benthic invertebrate chemistry /community• Large-bodied fish tissue/chemistry Rationale: Russell Lake is identified as part of the RSA for the aquatic environment, but it appears that no detailed aquatic baseline data was completed in far-field location in Russell Lake. In addition, several Indigenous Nations and communities and local resource users have indicated that Russell Lake is an important body of water both culturally for traditional use and was once used as commercial fishery. | If Denison has not collected baseline aquatic studies in the far-field downstream receiving environment of Russell Lake, please provide a rationale for why. If a far-field Russell Lake location was sampled as part of baseline data collection, more information about the process and results with regards to sampling at Russell Lake should be included in the EIS. This information would be valuable to help determine potential cumulative effects downstream in the Russell Lake drainage system (due to the Key Lake Operation) which has been identified as a key concern and area of interest by several Indigenous Nations and communities. | Response is accepted, but also see AD-51 in the Advice to Proponent table. | Accepted |
| IR-121 | - | CNSC | Fish and fish habitat | Section 8.3.3.1, Methodology and Metrics | Context: In the description of methodology for fish communities and spawning surveys, there’s no mention that could be found for an any evaluation of fish condition, other than sexual condition. Rationale: Exposure to other pre-existing stressors could result in abnormal conditions or deformation(s) in existing population, but the extent of existing conditions should be evaluated to ascertain | Please provide reference to where fish condition is considered or provide a justification for its exclusion. | Response is accepted, but also see AD-52 in the Advice to Proponent table. | Accepted |

|--------------|----------------|------|---|---|---|---|--|--------------|
| | | | | | whether the rate is increasing as a result of proposed activities once in operation. | | | |
| IR-122 | - | CNSC | Fish and fish habitat | Section 8.3.8, Monitoring and Follow-up | <p>Context: Section 8.3.8 of the EIS states: “Changes in fish communities/populations will be assessed through comparison of Construction, Operation, and Decommissioning results to pre-development.”</p> <p>Rationale: Tracking changes in fish communities / populations in reference lakes over time should be conducted, as reference lakes can be used to differentiate natural temporal variation with potential project impacts.</p> | Please include reference lakes, and if it is provided, please reference where in the EIS these are discussed. If there are no reference lakes, these should be included in the monitoring program. | Response is accepted, but also see AD-53 in the Advice to Proponent table. | Accepted |
| IR-123 | - | ECCC | Change to an environmental component due to radiological contaminants | Section 8.4.3.2.3, Aquatic Environment Appendix 8-D, Table 3-5 | <p>Context: Table 8.4-3 provides a summary of the baseline concentrations of COPCs in sediments in the LSA. Sediment quality thresholds and justification for the selection of those thresholds have not been provided. Table 3-5 in Appendix 8-D does provide benchmarks but the selection of benchmarks is not discussed, and the most stringent guidelines are not used for some COPCs. Additionally, there is no data provided for sediment concentrations of mercury, which is a COPC that requires surface water quality monitoring and effluent characterization under the MDMER.</p> <p>Rationale: Further information should be provided regarding any exceedances of sediment quality thresholds in baseline concentrations of COPCs, which should be recommended for further assessment of risk due to effluent discharges.</p> | <p>1. Provide sediment quality thresholds and justification for the selection of those thresholds for comparison against measured baseline COPC concentrations in the LSA.</p> <p>2. Provide data on baseline concentrations of mercury in sediment.</p> <p>3. Identify any COPCs with baseline concentrations that exceed sediment quality thresholds in the LSA.</p> | | Accepted |
| IR-124 | - | ECCC | Change to an environmental component due to hazardous contaminants | Section 8.4.4.2.3, Aquatic Environment | <p>Context: Table 8.4-7 provides maximum concentrations of surface water COPCs in sediment. The following COPCs, which are required to evaluate the risk from effluent to sediment quality, were not evaluated:</p> <ol style="list-style-type: none">1. COPCs that have monitoring requirements in receiving environment surface water and effluent under the MDMER,2. COPCs that exceed water quality guidelines in effluent, and,3. COPCs that have baseline concentrations that exceed sediment quality thresholds in the receiving environment. <p>Rationale: Due to the lack of information on COPCs with baseline concentrations that exceed sediment quality guidelines, and COPCs that require monitoring under the MDMER, a determination on risk to sediment quality and aquatic biota cannot be made.</p> | <p>1. Provide the information on baseline exceedances of COPCs in sediment.</p> <p>2. Provide an assessment of risk for any COPCs that have baseline exceedances of sediment quality thresholds in the receiving environment.</p> <p>3. Provide an assessment of risk from any COPCs that require monitoring in the receiving environment and effluent under the MDMER. Please include any COPCs in effluent that will exceed water quality guidelines.</p> | <p>The Proponent has not fully responded to the previous round’s IR.</p> <p>The modeling of surface water and sediment COPC’s described in Appendix 10-A show results for the receiving waterbodies, but it is not clear how the results for the COPC concentrations for water quality and sediment quality calculated for each of the water bodies, shown in Figure 6-1 and 6-2 respectively, are being interpreted. The Proponent has not explained if these modeled values are based on the worst-case scenarios that account for environmental variables such as seasonal changes in hydrology and chemistry or if they have only accounted for changes in operational effluent discharge scenarios to consider the upper bound discharge rates. Additionally, it is unclear whether depositional areas for sediment were identified based on hydrological data. Additional information is also needed regarding baseline exceedances of sediment COPC thresholds and the associated risk assessment of mine operations on the receiving water body.</p> <p>The Proponent should consider maximum COPC scenarios for the receiving water bodies in baseline assessments and the risk assessment, including seasonal variability and sediment depositional areas to determine whether the baseline assessment and risk assessment fully considered the effects of the operations of the proposed mine. The Proponent should provide supplemental information to aid in determining if the environmental model has considered environmental variability such as seasonal changes in water levels, flows and sedimentation.</p> | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|--|--|--|---|--------------|
| | | | | | | | <p>The Proponent should also demonstrate that the model has considered a reasonable expected worst case scenario, such as a 100 year return.</p> <p>This IR is addressing quality of inputs (ex. baseline data, conservatism of scenarios modelled, environmental variability, etc.) in to modelling. This information is required to assess the conservatism of modelling the bounding conditions and potential for significant adverse effects to the environment.</p> | |
| IR-124 | IR-124-R1 | ECCC | Change to an environmental component due to hazardous contaminants | Section 8.4.4.2.3, Aquatic Environment IR-124 Response from Denison | <p>Context: In the Proponent’s response it is stated, “Schedule 5 parameters will be monitored as per the MDMER once under this regulation (i.e., meeting regulated criteria of discharge to the environment [50 m3/day). Please refer to Table 8.2-13 of attachment IR-114. In these cases, COPCs including Schedule 4 parameters were below screening criteria.”</p> <p>If concentrations of Schedule 5 parameters in effluent exceed water quality thresholds, these parameters are necessary for ECCC to examine in the risk assessment to determine the potential for effluent to be acutely lethal and for adverse effects to aquatic biota. These parameters will also be required to be characterized under Section 4, 5 and 7 of the MDMER. As per CSA N288.6-22 Section 7.2.5.2.1, “Screening of environmental concentrations of chemical and radiochemical substances released to the environment should be performed to identify COPCs for further evaluation in the risk assessment. Both measured concentrations and concentrations calculated from release rates may be used in the screening analysis. The screening concentrations should be compared to screening criteria, and chemicals that exceed screening criteria should be identified as COPCs.”</p> <p>As per CSA N288.6-22 Section 7.2.5.4.2, “If COPCs exceed the screening level for one medium, they should be carried forward into the EcoRA for all media that are likely to contribute to exposure. For example, for a given COPC, if a water screening benchmark is exceeded, the same COPC should be carried forward for sediment if its concentration was above the detection limit.”</p> <p>Additionally, updated Table 8.2-13 of attachment IR-114 has been found to be insufficient due to maximum concentrations in surface water for mercury, aluminum, total suspended solids, iron, thallium, manganese, nitrate and phosphorus being absent and the use of incorrect water quality thresholds.</p> <p>Rationale: Due to the lack of information on COPCs with concentrations that exceed water quality thresholds in effluent, a determination on risk to sediment quality and aquatic biota cannot be made.</p> | Provide an assessment of risk from any MDMER Schedule 5 parameters that are required to be characterized in effluent and in surface water quality in the receiving environment and that have effluent concentrations that will exceed water quality guidelines derived from environmental baseline conditions. | <p>The Proponent has not fully responded to the previous round’s IR. The modeling of surface water and sediment COPC’s described in Appendix 10-A, Figure 6-1 and 6-2 respectively shows results for the receiving waterbodies. However, it is unclear if these modeled values are based on the worst-case scenarios that account for environmental variables such as seasonal changes in hydrology and chemistry, or if they have only accounted for changes in operational effluent discharge scenarios to consider the upper bound discharge rates. The Proponent’s responses regarding baseline exceedances of COPC thresholds in the receiving waterbodies require additional information regarding environmental variability, including but not limited to seasonal changes in water levels, flows and sedimentation, in order to determine whether the model has considered environmental variability. The Proponent should also demonstrate that the model has fully considered a reasonably expected worst case scenario, such as a 100-year return period for the above variables.</p> <p>The Proponent should include a consideration of the maximum COPC scenario for the receiving water bodies in baseline assessments and the risk assessment, including seasonal variability and sediment depositional areas, to consider the effects of the operations of the proposed mine.</p> <p>This IR is addressing quality of inputs (ex. baseline data, conservatism of scenarios modelled, environmental variability, etc.) in to modelling. This information is required to assess the conservatism of modelling the bounding conditions and potential for significant adverse effects to the environment.</p> | Not Accepted |

|--------------|----------------|------|-----------------------|---|--|--|--|--------------|
| IR-125 | - | CNSC | Fish and fish habitat | Section 8.5, Aquatic Environment and Fish health | <p>Context: Indigenous Knowledge studies and information collected in relation to the Project clearly identified the importance of water quality and fish health to local Indigenous peoples and is discussed throughout the Draft EIS. For example:</p> <ul style="list-style-type: none">“Russell is one lake where I commercially fish. How will this effluent impact the water quality, fish health? Will I be able to sell fish from here? If there is going to water” pollution, I just want to know” (19-LK-ERFNTrip-134.255) ““How are you going to protect the water quality? We are concerned about mercury in fish, other animals, etc. Is there mercury or arsenic in the uranium solution?” (p. 8-53) <p>Rationale: Several Indigenous Nations and communities and local resources users have indicated Russell Lake is an important body of water both culturally for traditional use and was used as commercial fishery in the past and from an aquatic ecosystem perspective.</p> | <p>One of the many mitigation measures mentioned throughout the aquatic environment section states:</p> <p>“Denison will work with the associated communities to develop and implement the Project-specific monitoring programs and a framework to share the results for the purpose of assessing the performance of the water management system.” (p.10-32)</p> <p>Has Denison considered the collection of additional baseline fish tissue species that are of importance to Indigenous Nations and communities and local cabin owners from Russell Lake? Assuming the species would be walleye (commercially and recreationally) and lake white whitefish that is traditionally an important species consumed.</p> <p>Please provide more information on the engagement to date on the development of the Surface Water Management Program and Monitoring program that Denison is developing and engagement to date with interested Indigenous Nations and communities in the region on fish and fish health.</p> | Response is accepted, but also see AD-51 in the Advice to Proponent table. | Accepted |
| IR-126 | - | ECCC | Aquatic species | Section 8.5.3 Appendix 10-A (ERA), Section 5.3.1.1.8 | <p>Context: The Proponent has used the US Environmental Protection Agency (US EPA) guidelines for the assessment of selenium fish tissue concentrations in Section 8.5.3 of the draft EIS and in the Environmental Risk Assessment (ERA) in Appendix 10-A (ERA) of Section 10.</p> <p>Rationale: ECCC’s Federal Environmental Quality Guidelines of 6.7 ug/g dry weight fish whole body tissue for selenium should be used, as it is more protective than the US EPA guidelines.</p> | <p>Update the selenium fish tissue assessment in the draft EIS and the Wheeler River ERA (Appendix 10-A (ERA) in Section 10) as needed using ECCC’s FEQG.</p> | <p>The Proponent did not compare their predictions for fish tissue selenium to the FEQGs in the ERA as requested. Furthermore, in their response the Proponent does not use available species-specific moisture content and conversion factors available for northern pike and lake whitefish when converting muscle selenium concentrations to whole-body selenium concentrations. This means that the Proponent’s prediction likely underestimates the selenium tissue concentrations in the fish. Consequently, the hazard quotients reported are lower than expected.</p> <p>Additionally, the method used by the Proponent to predict selenium concentrations in northern pike and lake whitefish does not appear to include dietary uptake and bioaccumulation of selenium, only direct contact with pore water and overlying water is considered (Table 5-5 in Appendix 10A; Section 2.2.2 of Appendix A to Appendix 10-A). Selenium uptake through the aquatic food web has been shown to result in bioaccumulation of selenium in aquatic-dependent wildlife and resulting in reproductive impairments and malformations (ECCC 2022). Dietary sources of selenium would typically be expected to be the main contribution to tissue concentrations of selenium compared to selenium uptake from water. In most situations, the conversion of inorganic selenium to organic selenium through uptake from water into periphyton/algae is the rate limiting step of selenium bioaccumulation into higher level organisms including benthic invertebrates and fish. This step is affected by many environmental parameters (e.g. temperature, substrate, lentic/lotic environment). Considering that the effluent discharge contains 42 ug/L selenium, consideration of dietary selenium is warranted.</p> <p>The Proponent should update the final EIS with the following information:</p> | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|--|---|---|--|----------|
| | | | | | | | <ol style="list-style-type: none">Update the ERA with the assessment of selenium concentrations in fish tissue to include a comparison of selenium fish tissue concentrations to ECCC FEQG guidelines for either fish whole body tissue (6.7 ug/g dry weight) or fish egg/ovary tissue (14.7 ug/g dry weight) <u>using</u> species-specific moisture content and muscle : whole body and/or egg-ovary : muscle conversion factors (see Tables B-1b, Table B-3, Table B-4, and Table B-5 in US EPA (2021)).Update the ERA for the assessment of selenium concentrations in fish tissue using a method that considers dietary uptake and bioaccumulation in order to determine predicted fish tissue concentrations of selenium in northern pike and lake whitefish. This is recommended to be done over all Project phases for both the Expected Case and sensitivity scenarios. <p>Provide predicted fish tissue selenium concentrations that include the range of variability of data used to develop the tissue selenium predictions. Only one output value without a confidence interval is provided for each location and species (see Table B.5 in Appendix B of Appendix 10-A).</p> | |
| IR-127 | - | CNSC | Aquatic environment | Appendix 8-E, Section 1.2.1, Hydrological Inputs | <p>Context: Within this section it states that the 7Q10 low flow rate used in the mixing assessment “was provided verbally to Ecometrix by NewFields Canada during a project meeting on 26 April 2022”</p> <p>Rationale: The statement that this value was provided verbally is not an infallible method of communicating data, as the value could have been misheard, misremembered, or recorded improperly.</p> | Please verify that the 7Q10 value used in the assessment is the correct value determined by NewFields. | | Accepted |
| IR-128 | - | CNSC | Current use of lands and resources for traditional purposes | Section 9 Various pages in section 11.1, Land and Indigenous Resource Use Section 12 Section 14 | <p>Context: The increased road traffic (14-18 trucks per day during construction/operations) may have indirect impact on ungulates, furbearers and wood land caribou presence/absence for traditional and subsistence hunting have been raised to CNSC staff when meeting with Indigenous Nations and communities and are presented in the EIS.</p> <p>Rationale: The increased traffic and therefore dispersal of game (moose, woodland caribou) due to increased traffic has been raised as a concern with respect to increased mortality on wildlife and decreased ability to practice traditional rights.</p> | <p>How have the potential residual impacts with respect to increased traffic and noise (due to current and future operations) been communicated to Indigenous Nations and communities who use the road #914 for cultural and traditional activities (such as moose harvesting, berry picking and small game and birds)?</p> <p>Please provide any additional information on the engagement that has taken place to date with Indigenous Nations and communities with respect to concerns and potential impacts on current use of lands and resources due to increased road traffic, and any mitigation measures proposed by Indigenous Nations and communities to minimize the potential impacts.</p> | Response is accepted, but also see AD-54 in the Advice to Proponent table. | Accepted |
| IR-129 | - | CNSC | Current use of lands and resources for traditional purposes | Section 9 Section 10 Section 11, including Section 11.1.4.3.1 (p. 11-46) Section 12 Section 16 | <p>Context: ERFN indicated they are concerned about declining moose populations from an influx of hunters; more people may be accessing the area year after year, and worried populations may be affected by the Project (21-EN-ERFN-473.13).</p> <p>Further, the EIS highlights that: “Vehicle collisions are the most likely source of direct mortality for moose. Effective mitigation measures (e.g., breaks in snowbanks; speed limits; and exclusion</p> | <p>Please provide additional information on the discussions Denison has had with Indigenous Nations and communities on how to mitigate any residual project impacts on their traditional harvesting activities of large game such as moose.</p> <p>More information is required to determine if Denison has engaged directly with ERFN/KML and other Indigenous Nations who utilize the area to harvest moose to determine current baseline harvest numbers that provide subsistence, continued</p> | Response is accepted, but also see AD-62 in the Advice to Proponent table. | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|----------|--|---|---|--|----------------------|----------|
| | | | | | <p>fencing around contaminated waste pads and ponds) will be implemented to reduce moose mortality.” (p. 11-46)</p> <p>Rationale: The Technical Guidance for Assessing the Current Use of Lands and Resources for Traditional Purposes under CEAA 2012 notes: “The views of affected Aboriginal groups on mitigation be considered and included in the EIS. This could assist in ensuring that the environmental effects on the current use of land and resources for traditional purposes are at an acceptable level for the community.”</p> <p>Sources for indirect moose mortality (e.g., increased hunter access, changes to health due to sensory disturbances, changes to predator-prey dynamics) may result in mortality outside the Wildlife LSA. The residual effect of change in moose mortality is likely to occur. Although mitigation measures are expected to reduce, but not fully eliminate, the residual effect on moose.</p> <p>The potential residual impact on the moose and other large game populations in the broader regional study area may potentially impact Indigenous treaty rights, culture, and community well-being if the harvesting of moose and large game declines due to increased traffic, noise, and vehicle mortality or increased outside hunting pressure.</p> | <p>cultural identity and community well-being, as well as discussions on how the Project could potentially impact moose populations and the harvesting of moose for traditional practices.</p> | | |
| IR-130 | - | H. Mulye | Physical stressors (noise and vibration) on wildlife | Section 9, Terrestrial Environment | <p>Context: Sensory disturbances such as noise have been identified as stressors for selected wildlife (Ungulates, Furbearers, and Woodland Caribou), birds and amphibians in the Project area. However, there is no consideration of impacts from vibrations on these species. Also, impacts of noise and vibration on reptiles have not been assessed in the Project area.</p> <p>Rationale: While noise has been qualitatively assessed for selected wildlife, birds, and amphibians, there is no consideration of project-related vibrations as a sensory disturbance/physical stressor. Sensitive terrestrial species (specifically, herpetofauna, amphibians, invertebrates, and caribou) can be impacted by vibrations emanating from the operation of heavy machinery, blasting activities, and other anthropogenic activities at the Project site.</p> <p>Also, impacts of physical stressors (noise and vibration) on reptiles were not assessed. These species should be included in this assessment due to their sensitivity to noise and vibrations.</p> | <p>Please provide a discussion of impacts of physical stressors (specifically vibrations) on wildlife, birds, and amphibians in the Project area. Specific mitigation measures and/or monitoring for impacts from project-related vibrations should be considered, as appropriate.</p> <p>Also, include reptiles in the assessment of project-related noise and vibrations as sensory disturbance/physical stressor, or a justification for their exclusion.</p> | | Accepted |
| IR-131 | - | ECCC | Migratory birds, Wildlife and Wildlife Habitat | Section 9, Terrestrial Environment | <p>Context and Rationale: As per the requirement outlined in Section 79 of the Species at Risk Act (SARA): <i>The person must identify the adverse effects of the project on the listed wildlife species and its critical habitat and, if the project is carried out, must ensure that</i></p> | <p>Identify all species at risk listed on Schedule 1 of the Species at Risk Act and their critical habitat that are likely to be affected by the Project and describe how they may be adversely affected by the Project. Describe what measures will be taken to avoid or</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-------------------------------|---|--|---|--|----------|
| | | | | | <i>measures are taken to avoid or lessen those effects and to monitor them. The measures must be taken in a way that is consistent with any applicable recovery strategy and action plans. This is accomplished by ensuring that the Proponent has identified, avoided, lessened and will monitor effects to species at risk.</i> As per the CNSC’s Generic Guidelines for the Preparation of an EIS pursuant to the Canadian Environmental Assessment Act, 2012: <i>“The EIS will then describe mitigation measures that are specific to each environmental effect identified. Measures will be written as specific commitments that clearly describe how the Proponent intends to implement them and the environmental outcome the mitigation is designed to address. The EIS will describe mitigation measures in relation to species and/or critical habitat listed under the Species at Risk Act (SARA). These mitigation measures will be consistent with any SARA permit, applicable recovery strategy and/or action plan”.</i> The draft EIS neither lists the adverse effects to all listed schedule 1 SARA species, nor outlines the measures that will be taken to avoid or lessen these effects. The Proponent references that additional species-specific mitigations will be detailed in environmental management plans but has not provided those plans for review. | lessen the effects of each Project activity and stage, and how these effects will be monitored to ensure they are avoided or minimized. | | |
| IR-132 | - | ECCC | Wildlife and Wildlife habitat | Section 9, Terrestrial Environment | Context and Rationale: ECCC has identified that three species at risk arthropods (yellow banded bumble bee, transverse lady beetle, and nine-spotted lady beetle) have ranges overlapping the Project area and these were not mentioned in the draft EIS. | 1. Conduct an effects assessment for arthropod species at risk. 2. Explain what mitigation measures will be used to minimize potential effects. | | Accepted |
| IR-133 | - | ECCC | | Section 9, Terrestrial Environment | Context and Rationale: There is potential for some species at risk (e.g., myotis species, barn or bank swallows, common nighthawk) to be attracted to and use mine infrastructure (buildings, roads etc.) once constructed for nesting, roosting, or foraging. Details on mitigation measures and adaptive management with respect to attraction to Project components should be identified to assess residual and cumulative impacts to species at risk. | For all Project phases, describe the mitigation measures and adaptive management to prevent and minimize effects on species at risk that may utilize mine infrastructure. | | Accepted |
| IR-134 | - | ECCC | Wildlife and Wildlife habitat | Section 9, Terrestrial Environment | Context and Rationale: The draft EIS states in multiple places that vegetation clearing may occur year-round. In order to correspond with the timing of emergence from hibernation, tree clearing should not be conducted during the bat roosting period. If maternity roost trees are removed after pregnant females have established a roost area, there is a higher likelihood of abortion than there would be otherwise. Species-specific mitigations are required to protect bat SAR. | Provide important roosting dates for bat species at risk in the Project area. | The Proponent provided a complete response regarding the roosting dates for bat species at risk, however follow-up IRs are required. See follow-up IR-134-R1. | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|---|---|---|---|--------------|
| IR-134 | IR-134-R1 | ECCC | Wildlife and Wildlife habitat | Section 9, Terrestrial Environment | <p>Context: The Proponent has committed to conduct pre-construction and pre-clearing surveys for multiple species, however the timing and methods for the surveys were not provided. Knowing the survey methodology for pre-construction and pre-clearing for little brown myotis and northern myotis is important for assessing cumulative impacts, effectiveness of adaptive management strategies as well as determining how bat species were considered in the EIS.</p> <p>Rationale: ECCC can determine whether the methodology the Proponent will use to collect data is appropriate and if the methodology would contribute to a more complete understanding cumulative effects and adaptive management strategies.</p> <p>A clear outline of how timing has been considered and incorporated into the methodologies is required to understand how sensitive periods for bats, such as roosting, have been considered in the EIS. An understanding of the methodologies and how these sensitive periods are being considered is required to evaluate the effectiveness of mitigation strategies and adaptive management strategies which are being developed by the Proponent.</p> | The information provided by the Proponent regarding the roosting dates and potential habitat for bats is complete, however, the information related to the pre-construction and pre-clearing surveys is missing details on important habitat features for bat species at risk. As two Species at Risk Act (SARA) schedule 1 listed bat species, little brown myotis (Myotis lucifugus) and northern myotis (Myotis septentrionalis) have been identified in the Project area, effects need to be identified, avoided, lessened and monitored. | <p>The Proponent indicated that wildlife sweeps would be completed within a period of seven days prior to project activities. Wildlife sweeps will be conducted rather than conducting species-specific surveys focused on species at risk. Sweeps will be based on timing of the Project and related activities focused on identifying features such as hibernacula that may require mitigation.</p> <p>The Proponent also indicated that the methods associated with these sweeps will be tailored to species at risk (including bats) that may potentially be using the habitat.</p> <p>Species specific surveys are required to reliably identify rare species, such as species at risk, which may not be captured by more general wildlife sweeps. It remains unclear how the Proponent will complete wildlife sweeps, identify appropriate mitigation measures and implement those, or how these measures will be assessed for effectiveness.</p> <p>Information is outstanding on how surveys will be tailored to species at risk. ECCC recommendsIt is requested that the Proponent to provide information on the methods that will be used for tailored surveys to species at risk, including bats or for the Proponent to provide a discussion on why these methods cannot be developed as part of this review.</p> <p>For further clarity, Denison is expected to describe how the pre-construction and pre-clearing survey methods are targeted/tailored for each SAR, where surveys will be performed to address SAR habitat, and the approximate timing prior to disturbance along with appropriate scientific rationale. At a minimum, one paragraph must be provided for each SAR specifically addressing the items above.</p> <p>Also see: IR-142-159-167-R1</p> | Not Accepted |
| IR-135 | - | ECCC | Migratory birds, Wildlife and Wildlife Habitat | Section 9, Terrestrial Environment | <p>Context and Rationale: The mitigation measures for birds and wildlife presented in the draft EIS are very general. Additional detail is required for a complete assessment of residual and cumulative Project effects to birds and wildlife.</p> <p>The Proponent has committed to providing a number of plans including, a Decommissioning Plan, a Spill Response Plan, a Waste Management Plan, a Surface Water Monitoring Plan, a Remediation and Closure Plan, a Radiation Protection Plan, a Soil and Vegetation Monitoring Plan, a Wildlife Monitoring Plan, and a Woodland Caribou Management Plan. In order to assess potential affects to migratory birds and wildlife from Project related activities, ECCC requires details on species-specific mitigation measures, and monitoring plans.</p> | <p>The following information should be included in the various plans and should be provided for review during the environmental assessment:</p> <ol style="list-style-type: none">1. For all Project phases, describe the species-specific mitigation measures and responses to prevent and minimize effects on migratory birds or species at risk (SAR) birds and mammals that may utilize mine infrastructure.2. Explain how light pollution will be managed and what specific mitigation measures will be used to minimize effects to migratory birds and SAR birds and mammals.3. Provide details on what methods will be used for erosion control and how they will prevent sediment from entering waters frequented by migratory birds or SAR. Explain what actions will be taken if the erosion control measures are not successful. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|---|---|----------------------|----------|
| | | | | | | 4. Provide details on noise and other sensory disturbance monitoring and mitigations if noise levels surpass thresholds. 5. Describe time windows and species- specific mitigations related to maintenance activities such as vegetation management, road or building repair and stream crossing replacements. | | |
| IR-136 | - | CNSC | Soil Salvage Monitoring | Section 9.1.8.2 | <p>Context: The Proponent plans to salvage and stockpile soil and organic matter/peat in order to use it in reclamation activities during decommissioning. Periodic monitoring of the stockpiles is proposed to be conducted to verify that soil and organic matter/peat are delineated, stripped, handled, and stockpiled as recommended, and to evaluate the stability of salvaged soil, e.g., in relation to potential erosion and/or degradation. It is unclear whether monitoring includes soil quality in terms of concentrations of COPCs.</p> <p>Rationale: It is expected that project-related activities (road and airport traffic, drilling) can result in open-source (i.e., fugitive) dust and process-source dust (incl. radionuclides), which can accumulate and result in changes in soil quality of the stockpiled soil and organic matter/peat as described in Sections 9.1.4.2.2 and 9.1.4.2.3).</p> | Please clarify if COPC concentrations monitoring is planned to be performed for stockpiled soil and organic matter/peat. | | Accepted |
| IR-137 | - | ECCC | Migratory birds, Wildlife and Wildlife Habitat, Vegetation and Wetlands | <p>Section 9.2.1.3, Spatial and Temporal Boundaries for Vegetation and Ecosystems, Listed Plant Species and Wetlands</p> <p>Section 9.3.1.3.1, Spatial Boundaries for Ungulates, Furbearers and Woodland Caribou</p> <p>9.4.1.3.1, Spatial Boundaries for Raptors, Migratory Breeding Birds, and Bird Species at Risk</p> | <p>Context and Rationale: The CNSC’s Generic Guidelines for the Preparation of an EIS Pursuant to the Canadian Environmental Assessment Act, 2012 states that: “The EIS will describe the spatial boundaries, including local and regional study areas, for each VC to be used to assess the potential adverse environmental effects of the Project and provide a rationale for each boundary.</p> <p>Spatial boundaries will be defined taking into account the appropriate scale and spatial extent of potential environmental effects, community knowledge and Indigenous knowledge, current or traditional land and resource use by Indigenous groups, ecological, technical, social and cultural considerations.”</p> <p>The information provided in the EIS does not enable a biologically relevant assessment of the Project’s effects.</p> <p>The Proponent did not provide rationale for the selection of study areas for individual vegetation, wildlife or migratory bird valued components (VC). Different VCs may have different spatial boundaries for the LSA and/or RSA. For wildlife and bird VCs, the LSA is defined as a 1.7-km buffer from the Project area, and the RSA is defined as a 6.6-km buffer around the LSA. There is no information on how the spatial boundaries were derived.</p> | <p>Provide a biologically relevant rationale for the delineated study boundaries (LSA and RSA) for all different valued components. Include the following information:</p> <ul style="list-style-type: none">• Descriptions of how the RSA and LSA boundaries were derived for all VCs. <p>Specific to boreal caribou:</p> <p><u>Project Footprint:</u></p> <ul style="list-style-type: none">• Include a 500-m buffer of area of maximum physical disturbance to represent functional habitat loss for boreal caribou <p><u>LSA:</u></p> <ul style="list-style-type: none">• Include a description of how the LSA takes into account boreal caribou avoidance of disturbed areas, predator access to undisturbed areas, reduction in connectivity and sensory disturbance to individuals. <p><u>RSA:</u></p> <ul style="list-style-type: none">• Include a description of how the RSA used in the draft EIS is an accurate representation of the SK1 boreal caribou range; or | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|-----|----------------------|---|---|---|----------------------|--------|
| | | | | | <p>Specific to Woodland Caribou, boreal population (hereafter referred to as boreal caribou):</p> <p><u>Project Footprint</u>: In a scientific assessment of critical habitat (Environment Canada, 2011) [1] ECCC demonstrated that the application of a 500-m buffer to mapped anthropogenic features best represents the combined effects of increased predation and avoidance on caribou population trends at the national scale. Adding a 500-m buffer to the Project footprint is required to represent functional habitat loss.</p> <p>The draft EIS does not appear to use a buffer for their Project area. The draft EIS (Section 9.3.1.3.1) states: “Project Area: the area within which the Project and all components/activities are located (i.e., the area of maximum physical disturbance). The Project Area covers 169.6 ha and is not VC-specific, but consistent throughout the EA.” (p. 9-168)</p> <p><u>LSA</u>: The defined LSA for boreal caribou has to consider avoidance of disturbed areas, predator access to undisturbed areas, reduction in connectivity and sensory disturbance. This required information is not detailed in the draft EIS.</p> <p>Adverse effects of Projects including predator and prey access to undisturbed areas, reduction in connectivity, and sensory disturbance to individual boreal caribou can vary and extend several kilometers depending on Project activities and ecological context. At minimum, the LSA should capture the above-mentioned effects.</p> <p>For boreal caribou, the Project footprint should be defined as the immediate area to be cleared, plus a 500-m buffer to represent functional habitat loss. Following this guidance, the LSA should be defined as a buffer of the Project footprint with the 500-m buffer.</p> <p><u>RSA</u>: The Amended Recovery Strategy for Woodland Caribou (Rangifer tarandus caribou), Boreal Population, in Canada states: <i>Mitigation of adverse effects from individual projects/activities will require a coordinated approach and management of cumulative effects within and among ranges. A cumulative effects assessment is essential to position the proposed project/activity in the context of all current and future development activities. The cumulative effects assessment will:</i></p> <ul style="list-style-type: none">• <i>Assess the impact of all disturbances (anthropogenic and natural) at the range-scale;</i>• <i>Monitor habitat conditions, including the amount of current disturbed and undisturbed habitat, and amount of habitat being restored;</i> | <ul style="list-style-type: none">• Re-do the assessment with the RSA at the scale of the range <p>See also related IRs: IR-154 and IR-156.</p> | | |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|---|---|---|---|----------|
| | | | | | <ul style="list-style-type: none">Account for planned disturbances; andAssess the distribution of disturbance in large ranges for risk of range retraction in parts of the range. <p>The proposed Project’s cumulative effects for boreal caribou are possible at the scale of the SK1 boreal caribou range. The RSA used for boreal caribou for this Project is only 40,173.6 ha, compared to the SK1 range, which is 18,034,870 ha. As such, it is too small to capture cumulative effects to this species and does not follow the Scientific Assessment to Support the Identification of Critical Habitat for Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal Population, in Canada (Environment Canada, 2011) or the Amended Recovery Strategy for Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal Population, in Canada.</p> <p>Reference: [1] Scientific Assessment to Support the Identification of Critical Habitat for Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal Population, in Canada (Environment Canada, 2011).</p> | | | |
| IR-138 | - | CNSC | COPC in Lichen | Section 9.2.4.2.2 Appendix 10-A (ERA) | <p>Context: A quantitative assessment using modelling dispersion and uptake of COPCs in the environment was completed for the Project as part of the ERA, to support conclusions drawn in the EIS. In Appendix 10-A (ERA), COPCs in plant tissue was estimated for lichen. Table 5-5 of the ERA (p. 5.24) named “Complete Exposure Pathways for All Selected Ecological Receptors to be Assessed using the IMPACT Model” lists the exposure pathway for lichen as direct contact on soil.</p> <p>Rationale: Airborne COPC can deposition on lichen and subsequently enter the food chain; therefore, the “contact with air” pathway should be considered. In fact, lichen species are frequently used to monitor the deposition and accumulation of airborne contaminants (e.g., dust, metals). It is also noted that based on sampling results of the 2017 baseline studies, lichen frequently contain higher concentrations of COPC than blueberry (compare Table 9.2-6 and Table 9.2-7 in the EIS), especially at sampling sites with elevated concentrations (e.g., RSV9 and RSV10).</p> | <p>Please include the exposure pathway of direct deposition (dry and wet) of airborne contaminants on lichen in the quantitative ERA, or justify why this exposure pathway was not considered.</p> <p>See also related: IR-189.</p> | | Accepted |
| IR-139 | - | ECCC | Change to an environmental component due to hazardous contaminants | Section 9.2.5.2.7, Waste and Hazardous Materials Management | <p>Context: In this section, the Proponent outlines various measures to mitigate air emissions, including implementation of the air quality programs within the Environmental Management System, regular maintenance and inspection of equipment, and elimination of unnecessary idling of equipment. However, the intention to use industry-standard emission control systems has not been substantiated.</p> | <p>Confirm if vehicles and equipment will be equipped with Tier 4 engines where feasible.</p> | <p>Response is accepted, but also see AD-55 in the Advice to Proponent table.</p> | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------------------|--|---|--|---|---|----------|
| | | | | | Rationale: For the protection of air quality, it is important to specify the emission standards that equipment will have (e.g., Tier 3 or Tier 4 engines). Vehicles and equipment with Tier 4 engines have much lower emissions of contaminants than those with Tier 3 engines. If non-Tier 4 engines are used, ECCC recommends that best management practices are followed, including proper maintenance of the engine and anti-idling measures. | | | |
| IR-140 | - | CNSC | Change in the Areal Extent of Wetlands | Section 9.2.6.4 | Context: Predicted residual effects on the areal extent of wetlands include the direct effect of loss of wetlands and several indirect effects of alteration of wetlands. As stated in the EIS, wetlands can exhibit low resilience and high susceptibility to disturbance. At the same time, wetlands tend to support a high species diversity, and are considered to have a moderate to high potential to support listed plant species. Lastly, wetlands are rare on the landscape compared to terrestrial ecosites (see Table 9.2-5). Rationale: Several wetland ecosites (BS19/24, BS25, BS27) occur only in small areas (< 30 ha) in the RSA but are predicted to experience disturbance of 6-64%, most notably the ecosite BS19/24 where 0.8 of 1.2 ha are predicted to be disturbed. It is noted that wetlands are scattered throughout the landscape as shown in Figure 9.2-8. More information is requested regarding the ecological impact of this disturbance. | 1. Please provide a discussion on the ecological impact of disturbance to rare wetland ecosites. 2. Please provide information on whether adequate other habitat is available for species impacted in these disturbed sites in close proximity, taking into account the home ranges of susceptible species. 3. Please provide additional information on whether wetland connectivity is maintained through the landscape within the LSA/RSA. See also related: IR-141. Suggestions for mitigation and follow-up measures: CNSC recommends that Denison conduct monitoring of species present in wetlands before and after disturbance, with a focus on listed plant species. | | Accepted |
| IR-141 | - | ECCC | Wetlands | Section 9.2.6.4.1 | Context and Rationale: The Proponent states that: “Direct loss of wetlands has been mitigated by reducing the size of the Project Area to the extent practicable during Project design. However, up to 0.5 ha (less than 0.1%) of all wetlands within the Terrestrial RSA are anticipated to be removed from the Project Area during Construction (Table 9.2-16).” Information is not provided on whether wetlands in the terrestrial RSA are considered ecologically, economically or socially important to the region. Information on the regional importance of the wetlands that will be lost is needed in order to assess effects, including a wetland compensation plan if the wetlands are considered regionally important. | 1. Provide information that accounts for whether wetlands are considered ecologically, economically and socially important to the region. 2. If the above is affirmative provide a wetland compensation plan to offset the loss. Consistent with the Operational Framework For Use of Conservation Allowance [1] a minimum ratio of 2:1 should be the starting point when determining the amount to be offset. [1] Available at : https://publications.gc.ca/site/eng/9.696852/publication.html See also related: IR-138. | | Accepted |
| IR-142 | - | ECCC CNSC | Wildlife and Wildlife habitat | Section 9.3.3.2.1 Scientific Literature Review – Wolverine Section 9.3.5 Mitigation Measures | Context: The Proponent did not conduct any field work to identify potential wolverine dens in the Project area and therefore did not present any mitigations for the potential impacts to wolverine dens. In Section 9.3.3.2.1, the Proponent states: “Denning females are | 1. Please provide additional information on whether the lost and/or altered wolverine habitat overlaps with wolverine home ranges. | The information provided by the Proponent is complete, however, a follow up IR regarding survey methods for all pre-construction and pre-clearing surveys is required. See follow-up IR-142-159-167. | Accepted |

|----------------------------|-------------------|------|-------------------------------|--|---|---|---|--------------|
| | | | | Section 9.3.6 Residual Effects Evaluation | <p>sensitive to disturbance during denning season in February to April and may abandon their dens and, in some cases, their litter, which may decrease their reproductive success. “</p> <p>In Section 9.3.6, the Proponent states: “In the Project Area, 145.0 ha or 100% of available wolverine habitat is assumed to be removed and will not be available to wolverine for the duration of the Project (Table 9.3-13). Similarly, 145.0 ha (3.4%) of available wolverine habitat within the Wildlife LSA is anticipated to be removed, all from the Project Area, during site clearing in Construction. In the Terrestrial RSA, up to 0.5% (145.0 ha; from the Project Area) of available wolverine habitat is anticipated to be removed during site clearing in Construction.”</p> <p>The residual effect assessment estimates that 8.2% of available wolverine habitat within the Terrestrial RSA may be altered or lost (Table 9.3-20).</p> <p>Rationale: As Wolverine is a Species at Risk Act Schedule 1 listed species, effects need to be identified, avoided, lessened and monitored. Mitigations, such as setback distances, should be used to protect important habitat features, such as dens.</p> <p>Wolverine occupy large home ranges and, therefore, need vast tracts of undisturbed land to maintain viable populations. The species avoids most human footprint types and linear features.</p> | <p>2. Describe any important wolverine habitat feature (i.e., dens) that may be lost as a result of the Project.</p> <p>3. Assess the need for pre- construction/pre-clearing surveys to identify any wolverine denning sites.</p> <p>4. Please provide additional information on whether the remaining, available, undisturbed wolverine habitat size is suitable to maintain populations.</p> | | |
| IR-142 IR-159 IR-167 | IR-142-159-167-R1 | ECCC | Wildlife and Wildlife Habitat | <p>Reference to EIS: Section 9.3.3.3, Baseline Studies Section 9.3.5 Mitigation Measures</p> <p>IR 142, 159, and 167 Responses from Denison</p> | <p>Context: The Proponent has committed to conduct pre-construction and pre-clearing surveys for multiple species, however the timing and methods for the surveys were not provided.</p> <p>Rationale: Knowing the survey methodology for pre-construction and pre-clearing surveys across multiple species is important because the Proponent is intending to collect data so that ECCC can determine whether the methodology used to collect the data is appropriate and if the methodology would contribute to understanding cumulative effects and adaptive management. Understanding how timing has been considered and incorporated into the methodologies is required to understand how sensitive periods, such as nesting, breeding, foraging and migration, have been considered in the EIS. An understanding of the methodologies and how these sensitive periods are being considered is required to evaluate the effectiveness of mitigation strategies and adaptive management being developed by the Proponent for each species mentioned in IR-142, IR-159 and IR-167.</p> | Provide survey methodology and timing for all preconstruction and pre-clearing surveys, including avian and species at risk surveys (caribou, wolverine). | <p>The Proponent notes that:</p> <ul style="list-style-type: none">• Site clearing and other works that involve disturbance of vegetation and/or soil will be completed in winter.• Pre-disturbance wildlife sweeps would be conducted by qualified biologists at least seven days prior to any scheduled vegetation/land disturbance.• Mitigation measures to avoid or minimize adverse effects on identified features are not species specific.• The methods associated with these pre-construction and pre-clearing sweeps will be tailored to species at risk that may potentially be using habitats at certain times of the year.• Methods will include searching for potential roost trees for bat species, as per protocols included in the Wildlife Habitat Features Field Guide (BC Ministry of Environment and Climate Change Strategy, Ecosystems Branch 2019). If sensitive features are found, then they will be documented, and data collected would inform the development and implementation of appropriate mitigation measures. <p>It is unclear what is meant by “surveys are not species-specific” but sweeps will be “tailored to the species at risk”. It is also unclear how mitigation measures will be developed and implemented in a seven-day period.</p> | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-------------------------------|---|---|---|--|----------|
| | | | | | | | <p>In order for ECCC and CNSC to provide advice on potential effects to SAR based on the habitat potential mapping, the development of species-specific mitigation measures needs to be produced for review during this assessment process. The Proponent also needs to provide details on follow up and monitoring programs that are in place to confirm that the mitigation measures implemented are effective.</p> <p>In addition, ongoing monitoring is required for SAR. Denison is expected to describe the planned monitoring and follow-up programs for SAR. Denison must justify how the proposed methods are adequate to provide a baseline for each SAR, to verify that mitigation measures are effective, and to allow for statistically robust comparison to assess potential impacts on SAR over the lifecycle of the project.</p> | |
| IR-143 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.3.3, Baseline Studies | <p>Context and Rationale: The baseline caribou data is insufficient to understand potential Project impacts to this species. Presence/absence detection was provided by camera traps, incidental observations, winter track and pellet survey.</p> <p>Additional information and analyses on caribou use of the landscape during all life stages of the Project area is required to assess impacts and to determine significance of impact from the Project to caribou.</p> | <p>Provide details on the baseline caribou data including:</p> <ul style="list-style-type: none">• Revision of map 9.3-8 to include all observations, categorized by type, season and year (see also IR-145); and• Description of seasonal use of the LSA, RSA and caribou range.• Description of Project areas used by caribou.• Description of future studies planned to assess habitat use by caribou. Include specific details on how many additional years of aerial surveys will be completed to assess the caribou baseline conditions. <p>Utilizing additional data noted above and specified in IR-145, explain how caribou use of the area could be affected by the Project throughout all seasons and life stages (e.g., calving, post-calving, rutting, wintering).</p> <p>See also related: IR-152.</p> | | Accepted |
| IR-144 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.3.3, Baseline Studies – map 9.3-8 | <p>Context and Rationale: The mapping of caribou observations during baseline studies provided in Figure 9.3-8, “Caribou Sign Observations in the Wildlife Study Areas,” is insufficient to enable conclusions to be drawn. ECCC is not able to review the spatial aspect of caribou observations without a map of all available observations. Additional information is available, as stated in Section 9.3.3.3.3:</p> <p><i>“A total of 200 observations were made between 2017 and 2019 and recorded as either caribou sign (i.e., tracks, pellets, and evidence of feeding activity based on ground feeding craters and arboreal feeding evidence) or photographs (collected through the wildlife camera study) to document caribou presence in the LSA and RSA. Most observations occurred in the Terrestrial RSA, with observations concentrated in the north and southeast portions.</i></p> <p><i>Three observations occurred in the southeast portion of the Wildlife LSA, and no caribou sign was observed in the Project Area. Figure</i></p> | <p>Update map 9.3-8 to show all caribou observations during baseline studies, broken down by type of observation (camera, incidental, pellet, track) and season/year when the observation was made. Include additional data from the Province of Saskatchewan (see also IR-145) to help characterize caribou use on a spatial map.</p> | | Accepted |

| | | | | | <i>9.3-8 provides an overview of some caribou sign observed during the baseline studies.”</i> | | | |
| IR-145 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.3.3, Woodland Caribou | <p>Context and Rationale: The Proponent has not provided sufficient information on how caribou use the landscape, including identification of areas for different life stages of caribou (calving, post-calving, rutting and wintering).</p> <p>The University of Saskatchewan published a report entitled Population and habitat ecology of boreal caribou and their predators in the Saskatchewan Boreal Shield. This report contains information on habitat types that are used during different life stages. Additionally, Appendix H of the Amended Recovery Strategy for the Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal Population, in Canada 20202 [1] details habitat characteristics required by boreal caribou to carry out life processes necessary for survival and recovery.</p> <p>The scientific literature review (Section 9.3.3.3.1) on Woodland Caribou states: “While calving areas have not been documented within the SK1 range, it is recognized that caribou may use open fen and treed bog habitat types for calving during the spring/summer period. In Saskatchewan, caribou habitat used during the calving season in the SK2 range demonstrated a strong selection for treed muskegs, but avoidance of jack pine, mixed hardwood stands, and roads (Dyke 2008).”</p> <p>ECCC is not able to verify the Proponent’s effects assessment without sufficient information on important habitat or biophysical attributes for caribou within the study areas.</p> <p>[1] https://www.canada.ca/en/environment-climate-change/services/species-risk-public-registry/recovery-strategies/woodland-caribou-boreal-2020.html#toc0</p> | <p>1. Provide, based off existing literature or available data and the Amended Recovery Strategy for Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal Population, in Canada:</p> <ul style="list-style-type: none">information on known important habitat features or biophysical attributes in Project areas for different caribou life stages (calving, post-calving, rutting, wintering),a map(s) of the type and spatial extent of important caribou habitat features or biophysical attributes of the study areas as defined in Appendix H of the Recovery Strategy,<ul style="list-style-type: none">mapping should be at the RSA/LSA level as well as larger-scale mapping at the scale of the Project footprint. <p>2. Assess the potential direct and indirect effects based on additional information on caribou from bullet A above.</p> <p>See also related IRs: IR-143 and IR-152.</p> <p>Suggestions for mitigation and follow-up measures: ECCC recommends that the Proponent contact the Province of Saskatchewan to enquire about obtaining caribou telemetry data in the Project area. The data can be analyzed to determine important habitat features in the Project area.</p> | | Accepted |
| IR-143 IR-144 | IR-143-144-R1 | ECCC | Wildlife and Wildlife Habitat | Section 9.3.3.3, Baseline Studies IR-143 and 144 Responses from Denison | <p>Context: In the IR-143 response, the Proponent states: “As described in the EIS, caribou may use open fen and treed bog habitat types for calving during the spring/summer period. Information from Indigenous Knowledge (IK) was included in the EIS, including potential calving areas in the Terrestrial RSA.” The Proponent provided a revised Map 9.3-8 to display these features.</p> <p>Rationale: While the revised Map 9.3-8 shows seasonal use, it is challenging to see the overlapping spatial and temporal features. The map is not adequate for fully understanding the seasonality of the data. The scale provided does not allow for a proper assessment of seasonal use, including differentiation of habitat use such as calving, movement or wintering habitats.</p> | Provide individual maps by season and survey type or with larger scale insets that show areas with overlapping spatial and temporal features. | | Accepted |

|--------------|----------------|------|-------------------------------|---|--|--|----------------------|----------|
| IR-146 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.3.3.1, Woodland Caribou, Scientific Literature Review - Predation | <p>Context and Rationale: The information on impacts of predation and apparent competition for caribou in relation to the proposed Project are insufficient.</p> <p>In the section on caribou predators (9.3.3.3.1), the Proponent provided details on densities of wolves and their overlap with caribou and speaks of apparent competition. The Proponent did not examine other predators, such as black bear.</p> <p>The analysis on impacts of predation and apparent competition is insufficient since known predators have been omitted without explanation from the assessment of effects. ECCC is not able to verify the Proponent’s effects assessment since important species have not been considered in the assessment.</p> | Provide further information and analyses on all potential predators of caribou, including impacts from apparent competition. | | Accepted |
| IR-147 | - | ECCC | SAR – Boreal Caribou | Section 9.3.4.2.1, Alteration and/or Loss of Habitat | <p>Context and Rationale: The process of in-situ recovery mining will likely create changes to the surface topography and potential ground subsidence as well as changes to groundwater elevations. These changes can affect the plant communities and ecosite types.</p> <p>In Section 9.3.4.2.1 the Proponent states that: “Following decommissioning and reclamation, wildlife habitat is expected to recover to baseline conditions.”</p> <p>A more thorough explanation regarding post-decommissioning landscape is required to assess Project impacts.</p> | <p>1. Provide further rationale and/or analysis regarding the return of wildlife habitat to baseline conditions post- decommissioning. Incorporate other environmental impacts including:</p> <ul style="list-style-type: none">• Ground subsidence and impacts on wildlife habitat• Changes to aquifers and impacts on wildlife habitat <p>2. Describe reclamation activities/measures, including temporal information that will be implemented to help in the recovery to baseline conditions.</p> | | Accepted |
| IR-148 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.4.2.1, Alteration and/or Loss of Habitat | <p>Context and Rationale: ECCC analyzes disturbance for caribou at the range level, in this case within the SK1 range. However, the Proponent did not provide an adequate assessment of total disturbance at the range level. The draft EIS (Section 9.3.4.2.1 p. 9-211) reads: “The SK1 Boreal Shield Woodland Caribou Management Unit has relatively low levels of anthropogenic disturbance and was exposed to large fire disturbances in the past 40 years (ECCC 2019). Environment and Climate Change Canada (2019) identified this caribou population as being self-sustaining at a threshold of 40% undisturbed habitat with the total anthropogenic disturbance not exceeding 5% of their habitat. The current anthropogenic disturbance levels (without areas burnt by past forest fires) for the study areas are below this threshold (with the exception of the already disturbed Project Area) and are estimated as: 24.8 ha (14.6%) for the Project Area, 168 ha (3.5%) for the Wildlife LSA, and 599 ha (1.5%) for the Terrestrial RSA.”</p> <p>Analysis of habitat disturbance should be calculated at the range level in order to assess impacts and determine significance.</p> <p>Analysis should be consistent with the methodology described in</p> | <p>Provide the following in order to support analysis of habitat disturbance:</p> <ol style="list-style-type: none">1. Calculation of total disturbance including natural and anthropogenic disturbance at the range level.2. Description of effects on existing habitat at the scale of the range (for < 40% undisturbed habitat in the SK1). Include:<ul style="list-style-type: none">• an account (and GIS file if available) of existing habitat affected, using the following formula: (Project footprint + 500m buffer) – overlapping (permanent alteration(s) + 500m buffer)3. A map of the SK1 range showing all disturbed and undisturbed habitat, including predicted disturbance (direct and indirect) resulting from the Project.4. Description of whether the Project is expected to compromise the ability of the range to be restored to the undisturbed habitat threshold, and provide a rationale for the conclusion. <p>See also related: IR-154.</p> | | Accepted |

| | | | | | the document Scientific Assessment to Support the Identification of Critical Habitat for Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal Population, in Canada (Environment Canada, 2011) [1]. [1] https://publications.gc.ca/site/eng/401605/publication.html , p. 28/41 | | | |
| IR-149 | - | ECCC CNSC | Wildlife and Wildlife habitat | Section 9.3.5.2, Additional Wildlife-specific Mitigation Measures | <p>Context: The EIS describes that ongoing research is performed to inform the development of a Woodland Caribou Management Plan. This includes studies on the effectiveness of linear disruption features on predator/prey movements, and a field program for long-term reclamation planning. Moreover, it is stated that the Plan will include a detailed assessment of the need for habitat offsets.</p> <p>The draft EIS Section 9.3.5.2 states: “A wildlife monitoring plan and a Woodland Caribou Management Plan will be developed to address wildlife-specific mitigation measures based on proven and accepted mitigation following standard industry guidelines and BMPs. The plans will provide guidance to avoid or minimize potential adverse effects of the Project on wildlife and wildlife habitat, including monitoring and follow-up programs, as appropriate. It will be in place during all phases of the Project and will be subject to ongoing review and revision as required. If monitoring identifies a need for additional or revised mitigation measures, a process of adaptive management (as described in the plan) will be triggered.”</p> <p>Rationale: The draft EIS does not present sufficient species-specific mitigation measures for boreal caribou. ECCC is not able to assess potential residual impacts to caribou without specific mitigations.</p> <p>Since the Woodland Caribou Management Plan is still under development, it is difficult to judge whether the measures will be adequate to mitigate and/or offset potential project effects on Woodland caribou and its critical habitat.</p> | <p>Provide the Woodland Caribou Management Plan, to demonstrate effective mitigation of potential project effects, along with wildlife-specific mitigation measures for review.</p> <p>The Plan should be informed by and consistent with the Boreal Caribou Recovery Strategy and demonstrate that avoidance and minimization measures will be applied to mitigate for predicted Project effects to boreal caribou and its critical habitat prior to considering offsetting measures. That is, the Plan should follow the mitigation hierarchy and information should be provided as outlined below:</p> <ol style="list-style-type: none">1. AVOID: Describe all measures that will be taken to avoid effects to boreal caribou and avoid the destruction or alteration boreal caribou critical habitat.2. MINIMIZE: Describe all measures that will be taken to minimize the effects to boreal caribou and minimize the destruction of boreal caribou critical habitat.3. RESTORE ON-SITE: describe the measures that will be taken to restore disturbed areas of the Project, related to construction, operation and maintenance, on boreal caribou critical habitat, remaining after considering the avoidance and minimization measures.4. Characterize the risk of the adverse effects that are likely to result from the Project on boreal caribou and its critical habitat after avoidance minimization, and onsite restoration measures have been considered.5. OFFSET: Describe the measures that will be implemented outside the Designated Project area to mitigate adverse effects, destruction or alteration of boreal caribou critical habitat by the Designated Project during construction and operation.6. Characterize the risk of the adverse effects that are likely to result from the Project on boreal caribou and its critical habitat after avoidance, minimization, onsite restoration, and offset measures have been considered. <p>Describe all relevant uncertainties on the effectiveness of the measures to address adverse effects on boreal caribou and the rationale for the selected measure, in light of the mitigation hierarchy.</p> | <p>Note to Denison: This would be accepted if Denison is able to make a commitment as noted below. The proposed path forward on this IR is to develop a commitment to be added to Denison’s Commitment Register, related to Denison’s offsetting plan meeting the objectives of the province’s Caribou, Boreal recovery strategy. The language around this is still in discussion, and the text in draft.</p> <p>Current Rationale: The IR has not been fully resolved. The Proponent has updated Appendix 9-F to link caribou data, habitat/ecosite data and habitat suitability in its analysis which remain unchanged from conclusions provided in the EIS and has committed to monitoring using remote cameras for presence of caribou within the Project Footprint and within the Terrestrial RSA as part of the Environmental Management System. However, the Caribou Management Framework is still lacking the requested information on the amount of offset required to mitigate effects to caribou. Without the intended outcomes of the offsetting plan, there remains uncertainty regarding whether effects are adequately addressed in a manner that is consistent with the species Recovery Strategy. Additionally, the generic mitigation measures have not been updated to include factors, such as sensory disturbances, during important life stages.</p> <p>In order for ECCC and CNSC to provide additional technical advice on potential impacts to caribou, the Proponent would need to provide the previously requested information on the amount of habitat required to mitigate the adverse effects to caribou resulting from the Project and update the mitigation measures to include factors, such as sensory disturbances, during important life stages.</p> <p><u>Given that ECCC and CNSC understand that the Province of Saskatchewan and ECCC’s Canadian Wildlife Service are in communication on the Denison’s caribou management plans, and the province’s offsetting plan is underway, if Denison are willing to add a commitment to the Commitments Register, this IR could be resolved. The commitment text would include the commitment that “Denison’s offsetting plan will meet the objectives of the Recovery Strategy for the Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal population, in Canada.”</u></p> <p><u>Proposed rationale text for posting: Denison has captured their commitment related to caribou management and offsetting in the Commitments Register, so this IR has been accepted.</u></p> | <u>Accepted</u> |

| | | | | | | See also related IRs: IR-157. | | |
| IR-149 | IR-149-R1A | ECCC | Wildlife and Wildlife Habitat | Section 9.3.5.2, Additional Wildlife specific Mitigation Measures Proponent response to IR-149 IR-149 Response by Denison | <p>Context: Much of the information presented in the Conceptual Caribou Management Plan is qualitative in nature and does not present specific details regarding a quantitative assessment of impacts following measures to avoid, minimize, and restore on-site and then assess residual effects and determine the offset required to counterbalance the remaining impacts. This is required to understand if offsetting is sufficient to address impacts to caribou. The Proponent also does not provide details on methods that will be used for pre- disturbance wildlife clearance surveys. ECCC is aware that that the Proponent will be participating in restoration trials as part of the ‘Developing Eco-restoration Together’ program.</p> <p>Rationale: ECCC requires the quantitative details on the assessment of impacts to be included within the Conceptual Caribou Management Plan to adequately assess how the Proponent has applied the mitigation hierarchy. Details on the methods that will be used for pre- disturbance wildlife clearance surveys will also be required to verify that the Proponent has adequately considered how they have avoided, mitigated, or restored impacts to caribou.</p> <p>While ECCC understands that the Proponent will be participating in restoration trials as part of the ‘Developing Eco-restoration Together’ program, however, more clarity on the Proponent’s role in the program and the scope of the program is required. Details such as how the outcomes of these programs will result in mitigation measures and offsetting requirements and additional clarity on the scope of the program should also be provided so that ECCC can understand the objectives and deliverables of the program.</p> | <ol style="list-style-type: none">1. Provide a quantitative assessment of impacts following measures to avoid, minimize and restore on-site and then assess residual effects and determine the offset required to counterbalance the remaining impacts.2. Provide details on methods to be used for pre- disturbance wildlife clearance surveys.3. Provide details on the Proponent’s role in the Developing Eco-restoration Together program and how that work may be used in offsetting requirements.4. Provide the scope (i.e., quantitative habitat amount) of the Eco-restoration Together program. | <p>Note to Denison: -The proposed path forward on this IR is to develop a commitment to be added to Denison’s Commitment Register, related to Denison’s offsetting plan meeting the objectives of the province’s Caribou, Boreal recovery strategy. The language around this is still in discussion, and the text in draft.</p> <p>Item two has not been resolved, but this is also in discussion, given overlap with IR-134.</p> <p><u>Updated Rationale (item two is still in discussion):</u></p> <p><u>In responding to item one, the Proponent has not provided a quantitative assessment of impacts following measures to avoid, minimize, restore on-site or offset. The updated draft Caribou Management Framework indicates that the Proponent will use the SK ENV caribou offset calculator to inform decisions on the required offset amount. Without information on the amount of offsetting that will be implemented, ECCC cannot advise on whether the amount is appropriate in the context of the species Recovery Strategy. A follow up to IR 149-R1A can be found within the Advice to the Proponent document.</u></p> <p><u>With regards to Item one, given that ECCC and CNSC understand that the Province of Saskatchewan and ECCC’s Canadian Wildlife Service are in communication on the Denison’s caribou management plans, and the province’s offsetting plan is underway, if Denison are willing to add a commitment to the Commitments Register, this IR could be resolved. The commitment text would include the commitment that “Denison’s offsetting plan will meet the objectives of the Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal population, in Canada.”</u></p> <p><u>Proposed rationale text for posting: Denison has captured their commitment related to one, with regards to caribou management and offsetting in the Commitments Register, so this IR has been accepted.</u></p> <p><u>In responding to item two, the Proponent has clarified that the use of wildlife sweeps will be used for pre-construction and pre-clearing surveys, however there is no information on the methodology that will be used to collect data. The Proponent notes that these sweeps will not be species-specific but will be based on timing of Project related activities. Without documenting how data will be collected (i.e., to identify which species are in the area) there is uncertainty as to whether the methodology implemented will provide relevant results. Additionally, the Proponent notes that methods associated with these surveys will be tailored to species at risk that may potentially be using habitats at certain times of the year; but have provided no method on how these sweeps will be tailored. ECCC suggests the Proponent explain how data will be collected during wildlife sweeps and provide the method on how the sweeps will be tailored to species at risk.</u></p> <p><u>Items three and four have been resolved as the Proponent is no longer using the Eco-Restoration Together Program as part of their offsetting plan. Items one and two remain outstanding.</u></p> | <u>TBD</u> |

| | | | | | | | Items three and four have been resolved as the Proponent is no longer using the Eco-Restoration Together Program as part of their offsetting plan. Items one and two remain outstanding. | |
| IR-149 | IR-149-R1B | ECCC | Wildlife and Wildlife Habitat | Section 9.3.5.2, Additional Wildlife specific Mitigation Measures Proponent response to IR-149 IR-149 Response by Denison | Context: Section 4.2.2 of the Conceptual Caribou Mitigation plan states: “locating excessive noise generating activities such as the concrete batching operation as far away from sensitive wildlife locations as possible;”. However, no specific mitigation measures are mentioned for impacts to caribou due to noise generated from the Project air strip. Rationale: Noise from the air traffic using the air strip will also generate excessive noise that can impact caribou. Additional information on the timing and frequency of air traffic, as well as specific mitigations related to impacts from air traffic, including mitigations related to frequency and timing of flights, will be necessary to evaluate impacts to caribou due to air strip noise. | 1. Provide additional information on the timing and frequency of air traffic using the Project air strip. 2. Provide specific mitigations related to impacts from air traffic, including mitigations related to frequency and timing of flights. | Item two has been accepted as the Proponent has provided potential measures likely to be incorporated into operations of the airstrip, but item one remains outstanding. The information requested was not provided as the Proponent notes it is too early in the planning phase to provide this information. Once flight schedules have been determined, the Proponent should share them for review. If this cannot be provided at this time, the Proponent should provide information on the frequency and approximate timing of flights, as well as any periods of restricted activity planned for mitigation purposes. In addition, Denison is expected to provide details on specific mitigation measures to address sensory impacts to caribou, such as restricted activity periods to accommodate for the caribou calving season, or different flight paths. Please see the related follow up advice for IR-149-R1B in the Advice to the Proponent document. | Not Accepted |
| IR-150 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.5.2.1, Best Management Practices for working in Boreal Woodland Caribou Range in Saskatchewan | Context and Rationale: In the draft EIS Section 9.3.5.2.1, the Proponent states: “Denison proactively initiated research to provide field-based findings on the effectiveness of linear disruption features on predator/prey movements.” “Results will help the development of proactive and meaningful restoration strategies as an ongoing part of the overall Project (Omnia 2022). Additionally, the 2023 field program will support a program that uses the results from the 2021/2022 Caribou Trail Study in long-term reclamation planning. The program will be led by the University of Saskatchewan and is funded by Denison, an Indigenous-owned environmental company, the Northwest Communities Environmental Services (Métis owned), Mitacs, and the Natural Science and Engineering Research Council of Canada through an alliance grant. The Caribou Trail Study and the reclamation plan will culminate with the development of a Woodland Caribou Management Plan.” ECCC is available to support the Proponent through review of study programs should those programs be made available during the review process. ECCC requests to see the 2021/2022 study to further our review of caribou use in the Project area. | Provide the report for 2021/2022 Caribou Trail study for long-term reclamation planning for ECCC review. | | Accepted |
| IR-151 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.6.4 | Context and Rationale: In the analysis of residual and cumulative effects for woodland caribou, information and analyses on impacts to connectivity and movement across the landscape is lacking. | 1. Using available reports and data, provide an analysis of impacts to landscape connectivity for woodland caribou at the LSA and Range scales. 2. Determine whether the Project is expected to result in a | | Accepted |

|--------------|----------------|------|--|---|---|--|----------------------|----------|
| | | | | | | reduction of connectivity within or between the ranges and provide a rationale for the conclusion. Describe how movement corridor(s) may be affected by Project activities and infrastructure. | | |
| IR-152 | - | CNSC | Woodland Caribou Residual Effects Evaluation | Section 9.3.6.4, Appendix 9-B | <p>Context: Baseline studies for Woodland caribou include:</p> <ul style="list-style-type: none">• Winter Track Count Survey to assess presence, abundance, feeding activity, and ecosite affiliation;• Pellet Group/Browse Availability Survey to detect presence and abundance of caribou, and frequency of occurrence and abundance of lichen;• Covert Camera Survey to determine presence and use of linear features (roads, trails, and hand-cut lines). <p>The Saskatchewan Conservation Strategy for Boreal Woodland caribou [1] states that caribou are very susceptible to predation during the calf-rearing period, and populations are extremely sensitive to even minor changes in mortality rates.</p> <p>Rationale: It is unclear if, or how, any data on seasonal and spatial use of habitat was considered in the residual effect analysis, for example summer/winter home ranges, sensitive life stages including calving (e.g., location of calving sites). It should be noted that the English River First Nation have identified caribou calving areas in the vicinity of the Project footprint.</p> <p>Reference: [1] Saskatchewan Ministry of Environment. 2013. Conservation Strategy For Boreal Woodland Caribou (Rangifer tarandus caribou) in Saskatchewan. Saskatchewan Ministry of Environment. Fish and Wildlife Technical Report 2014.</p> | <p>Please provide a summary of available baseline data on habitat use during all seasons and life stages, in particular sensitive stages such as calving, and how habitat use during all seasons and life stages was considered in the residual effect analysis.</p> <p>See also IR-145 and IR-143.</p> | | Accepted |
| IR-153 | - | CNSC | Woodland Caribou Residual Effects Evaluation | Section 9.3.6.4.1 | <p>Context: According to ECCC (2020), forest fires can directly alter habitat, making it unsuitable for boreal caribou (e.g., through loss of mature conifer stands, loss of lichens and other forage plants, barriers to movement). Boreal caribou generally do not return to burned areas for several decades until the forest is old enough to support lichens and other food sources, although they may make limited use of burned areas to feed on new growth.</p> <p>The residual effects evaluation of alteration and/or habitat loss lists ecosites BS3 and BS7 (regenerating forest types) as available habitat in Table 9.3-22, which represent 43.5% of the Regional Study Area.</p> <p>Rationale: It is unclear whether the ecosites BS3 and BS7 (regenerating forest types) represent suitable habitat for Woodland caribou year-round. More information is required on the habitat</p> | <p>1.Please provide further information on the suitability of ecosites BS3 and BS7 for Woodland caribou in different life stages.</p> <p>2. Please provide the results of a residual effect analysis not including ecosites BS3 and BS7 for conservatism.</p> <p>3. If 2 leads to habitat fragmentation, consider connectivity of habitat patches in the residual effect analysis.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|---|---|--|----------------------|----------|
| | | | | | quality (e.g., time since last forest fire) and suitability for different life stages of caribou. For conservatism, it is recommended to perform a second residual effect analysis not including regenerating forest ecosites. | | | |
| IR-154 | - | CNSC | Woodland Caribou Alteration and/or Loss of Habitat | Section 9.3.6.4.1 | Context: Lichen, the primary food source for Woodland caribou (up to 70% of the year-round diet), can be exposed to airborne contaminants and dust deposition at distances of 1–40 km (e.g., increased metal concentrations or dust were detected in lichen at distances of 1–40 km from a mine site [1, 2]). Rationale: Further information is requested on how the potential for contamination of the food source “lichen” is reflected in the applied buffers of direct and indirect disturbance for woodland caribou. References: [1] Watkinson et al. (2021). Effects of dust deposition from diamond mining on subarctic plant communities and barren-ground caribou forage. Journal of Environmental Quality 50(4): 990-1003. Doi: 10.1002/jeq2.20251. [2] Chen et al. (2017). Does dust from arctic mines affect caribou forage? Journal of Environmental Protection 8(3): 258-276. Doi: 10.4236/jep.2017.83020. | 1. Please provide additional justification for how the potential for contamination of the food source “lichen” is reflected in the applied buffers for sensory disturbance. See also related IRs: IR-137, IR-148 and IR-156. Suggestions for mitigation and follow-up measures: CNSC recommends the following: <ul style="list-style-type: none">COPC in Lichen monitoring is recommended in transects from the Project site to assess COPC concentrations and confirm whether the chosen buffer is conservative. | | Accepted |
| IR-155 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.6.4.1, Alteration and/or Loss of Habitat | Context and Rationale: In Section 9.3.6.4.1 of the draft EIS, the Proponent presents figure 9.3-14 and table 9.3-22, which “depicts available woodland caribou habitat in the Project study areas” and provide a summary of available Woodland Caribou Habitat in the Project Area, Wildlife Local Study Area, and the Terrestrial Regional Study Area. The Proponent does not provide a biologically relevant explanation on the ecosites that are considered available woodland caribou habitat. According to the amended recovery strategy for Caribou, all habitat within SK1 range has been designated as critical habitat. To align with best current knowledge and the amended recovery strategy, the map and table should show the biophysical attributes, as outlined in Appendix H of the recovery strategy. | 1. Provide a biologically relevant explanation about how available caribou habitat was determined or determine available habitat based on new data from the province of Saskatchewan (See IR-145). 2. Consider referencing Appendix H of the Amended Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal Population, in Canada 2020 to define important biophysical features. | | Accepted |
| IR-156 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.6.4.1 Section 9.3.7.3.1 | Context and Rationale: In Section 9.3.6.4.1 of the draft EIS, the Proponent identified that 142 ha of available caribou habitat within the Project footprint will be directly impacted or lost, while an additional 1,165 ha will be indirectly impacted by Project activities such as sensory disturbance. They assessed the residual and | Provide a revised assessment of residual and cumulative effects, taking into consideration that the disturbance within the SK1 range is above the disturbance management threshold required for survival and recovery of the species. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|-----|----------------------|---|---|--|----------------------|--------|
| | | | | | <p>cumulative effect of alteration to habitat for woodland caribou as not significant: “The residual effect of alteration and/or loss of available woodland caribou habitat is not expected to result in a change that will alter caribou habitat integrity to the point where it would not be able to sustain the regional woodland caribou population. Therefore, the effect is assessed as not significant.”</p> <p>Section 9.3.7.3.1 of the draft EIS states: “It is not expected that the cumulative effects of alteration and/or loss of habitat will alter the integrity of woodland caribou habitat within the Terrestrial RSA to the point where it is not sustainable or available to contribute to ecological functions. Therefore, the cumulative effects resulting from the Project’s residual effect interacting with residual effects from other projects and activities is predicted to be not significant.”</p> <p>For the residual effect of alteration and/or loss of available caribou habitat (Section 9.3.6.4.1, Table 9.3-24), the Proponent assessed the magnitude as low, the geographic extent as local, the duration as long-term, the frequency as frequent, the reversibility as fully reversible, the context as high and the likelihood as likely. The rationale provided by the Proponent is insufficient to determine the accuracy of these assessments, given the lack of data and the small size of the assessment area. ECCC does not support the residual effects assessment of low magnitude, given the uncertainties related to seasonal use by caribou in the Project area and the current level of disturbance in the SK1 range.</p> <p>For the cumulative effect of alteration and/or loss of available caribou habitat (Section 9.3.7.3.3 , Table 9.3-30), the Proponent assessed the magnitude as moderate, the geographic extent as beyond the RSA, the duration as long-term, the frequency as frequent, the reversibility as fully reversible, the context as high, the likelihood as likely, the significance as not significant and the level of confidence as moderate. The rationale provided by the Proponent is insufficient to determine the accuracy of these assessments, given the lack to data presented for caribou and the small size of the RSA, compared to the SK1 region. ECCC does not support the conclusion of the cumulative effects assessments or for the level of confidence.</p> <p>The Amended Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal Population, in Canada 2020 states that the range is currently at the 60% disturbance management threshold. Therefore, any activity likely to result in the alteration or destruction of critical habitat may impact on the species survival and recovery. In addition, the Proponent’s assessment was based on information that was lacking data on calving, wintering and rutting areas, and connectivity and caribou</p> | See also related IRs: IR-137 and IR-154. | | |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-------------------------------|---|--|--|--|-----------------|
| | | | | | movements. The absence of considerations of the regional context of disturbance does not provide a conclusion based on best available information. | | | |
| IR-157 | - | ECCC | Wildlife and Wildlife habitat | Section 9.3.9 Ungulates, Furbearer and Woodland Caribou Summary | <p>Context and Rationale: The Proponent has committed to developing a Woodland Caribou Management Plan, which will include a “detailed assessment for the need for habitat offsets.” The Woodland Caribou Management Plan will support ECCC’s review of the Proponent’s assessment of residual effects following mitigation and offsetting.</p> <p>This plan should consider ECCC’s Operational Framework for Use of Conservation Allowances (ECCC, 2012). ECCC is available to assist the Proponent in the determination of appropriate offsets that would balance against Project adverse effects after the application of measures to avoid, minimize and restore on-site are adopted.</p> <p>Based on the Amended Recovery Strategy for the Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal Population, in Canada 2020, anthropogenic impacts to local caribou populations experience a lag effect, which occurs over extended periods. This lag effect needs to be adequately considered when proposing offsets.</p> <p>ECCC is available to assist the Proponent in understanding how critical habitat is described in the Recovery Strategy and the determination of appropriate offsets that would balance against Project effects based on the predicted impacts to caribou habitat.</p> | <p>Provide the Woodland Caribou Management Plan for review. The plan should clearly demonstrate efforts to avoid and minimize any Project effects and restore on-site any disturbed areas prior to the consideration of offsetting. Details on how severity of disturbance and vulnerability of the species were considered should be explained.</p> <p>See also related: IR-149.</p> <p>Suggestions for mitigation and follow-up measures: ECCC notes that the Woodland Caribou Management Plan should clearly explain efforts to address Project effects, including any contribution to cumulative adverse effects, after it has been determined that all options in the previous steps of the mitigation hierarchy (i.e., avoidance, and minimization,) have been fully considered and applied.</p> <p>In the Woodland Caribou Management Plan, provide details on how the factors outlined in the Operational Framework for Use of Conservation Allowances (ECCC, 2012) were considered in determining the offsetting amounts, including the severity of disturbance and vulnerability of the caribou population. Important factors including time lag (the amount of time from restoration work to when the habitat would be considered caribou habitat) would also need to be considered.</p> <p>ECCC typically recommends a minimum offset multiplier of 4:1 (offset outcome: area disturbed). This is a benchmark ratio applied to a project that is in the lower end of the risk spectrum, such as one with a low severity impact adversely affecting a low vulnerability ecological component. In general, the minimum 4:1 multiplier accounts for time-lags to restoration, uncertainty in outcomes, a precautionary approach, and the adverse impact itself in its specific context. Offset multipliers are variable and determined by project-specific circumstances and associated risks and uncertainties.</p> | <p>Note to Denison: This would be accepted if Denison is able to make a commitment as noted below. The proposed path forward on this IR is to develop a commitment to be added to Denison’s Commitment Register, related to Denison’s offsetting plan meeting the objectives of the province’s Caribou, Boreal recovery strategy. The language around this is still in discussion, and the text in draft.</p> <p><u>Updated Rationale:</u></p> <p>The updated draft Caribou Management Framework provided by the Proponent is still lacking information regarding offsetting location, amount, habitat type, habitat quality, etc. The Proponent notes that SK ENV is developing a boreal caribou habitat offset calculator, and that the Caribou Management Framework will be finalized using that tool as part of the provincial approvals, but information gaps remain on the amount of habitat offset required to mitigate Project effects.</p> <p>The Caribou Management Framework should be updated with this outstanding information.</p> <p>Given that ECCC and CNSC understand that the Province of Saskatchewan and ECCC’s Canadian Wildlife Service are in communication on the Denison’s caribou management plans, and the province’s offsetting plan is underway, if Denison are willing to add a commitment to the Commitments Register, this IR could be resolved. The commitment text would include the commitment that “Denison’s offsetting plan will meet the objectives of the Recovery Strategy for the Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal population, in Canada.”</p> <p>Proposed rationale text for posting: Denison has captured their commitment related to caribou management and offsetting in the Commitments Register, so this IR has been accepted.</p> | <u>Accepted</u> |
| IR-158 | - | ECCC | Migratory birds | Section 9.4.1.2, Key Indicators and Measurable Parameters | <p>Context and Rationale: In Section 9.4.1.2 the Proponent outlined key indicators for “Migratory Breeding Birds” which includes Waterbirds and Waterfowl, Upland Game Birds and Migratory Songbirds. These are broad categories, which do not allow for assessment of the variation in habitat requirements or ecology of individual species or guilds.</p> | Identify focal species/guilds for each key indicator species within the Migratory Breeding Birds valued components. Provide an updated analysis of Project effects on migratory birds. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------|---|---|---|----------------------|----------|
| | | | | | <p>Updated Rationale: The Proponent should identify additional focal species that can serve as indicator species by representing anticipated impacts to a broader guild of species. Indicator species should be demonstrably sensitive to the potential effect of interest, and suitable for inferring effects on other species.</p> <p>Species may be grouped into guilds for assessment based on similarities in ecology or vulnerability to Project effects, such as species at elevated risk of collision with vehicle traffic.</p> <p>By identifying focal species or guilds for each key indicator species within the Migratory Breeding Birds Valued Components (VCs), ECCC would be able to accurately review the Proponent’s assessment of impacts and mitigation measures in order to assess the accuracy of the Proponent’s conclusions and provide expert advice on the mitigation measures.</p> | | | |
| IR-159 | - | ECCC | Migratory birds | 9.4.3.2.3 Baseline Studies – Migratory Songbirds Appendix 9-B, Section 2.10.2, Results | <p>Context and Rationale: Information presented in the draft EIS is insufficient to accurately predict Project impacts to breeding birds. The Proponent collected a single year of breeding songbird point counts and aerial waterfowl surveys (including avian species at risk). A single year of surveys in which birds may be unusually scarce or abundant could severely compromise interpretation of post-construction monitoring data.</p> <p>Additionally, data presented in the draft EIS is from 2017 and ECCC advises that more recent data is needed for a comprehensive baseline to verify Project impacts.</p> <p>Data from the Saskatchewan Conservation Data Centre (HABISask), the Saskatchewan Breeding Bird Atlas and the Boreal avian Modelling project contain information on avian densities and avian species at risk that could supplement field data.</p> <p>The national standard for major projects recommends a minimum of two years of field surveys to be provided, so that temporal variability can be considered when comparing post-construction against baseline records and other available data.</p> <p>Updated Rationale: ECCC recommends that for major projects, a minimum of two years of field surveys should be provided so that temporal variability can be considered when comparing post-construction against baseline records and other available data. More recent data is needed due to landscape changes that may have occurred since 2017 as well as cumulative effects that have occurred in that time. Additionally, if there was an unusually high population density of birds in 2017 due to extraneous circumstances, Project effects may be attributed to a non-existent</p> | Supplement breeding bird point count data and aerial waterfowl data collected during 2017 with additional pre-construction field data or existing post-2017 data/modelling to provide a comprehensive baseline that can be used to verify Project impacts during construction and operational phases. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------|---|---|--|----------------------|----------|
| | | | | | <p>decline in the population when the discrepancy can be due to natural variability.</p> <p>A more recent baseline will account for interannual variation and any regional effects and will allow for a more accurate review of mitigation and follow-up measures. Data from the Saskatchewan Conservation Data Centre (HABISask), the Saskatchewan Breeding Bird Atlas and the Boreal Avian Modelling project contain information on avian densities and avian species at risk that could supplement field data.</p> | | | |
| IR-160 | - | ECCC | Migratory birds | Section 9.4.3.2.3 Baseline Studies – Migratory Songbirds | <p>Context and Rationale: ECCC advises that the results of the field studies need to be interpreted/analyzed in the context of the study area. The Proponent presents results on areas with highest richness and diversity but does not make a link to habitat that will be lost or experience indirect effects.</p> <p>Updated Rationale: Results regarding the effects of the Project, including a discussion on habitat types that will be lost or indirectly impacted during the life of the Project, and a discussion on the overall impact on the avian community including results from baseline studies as well as other supplemental information as per IR-159 are required to assess the validity of the Proponent’s conclusions and should be used in effects assessment.</p> | <p>Provide results interpreted in the context of Project direct and indirect effects. Include discussion on the habitat types that will be lost or indirectly impacted during the Project and the overall impact on the avian community, using results from the analysis of baseline studies and other supplemental data (as per IR-159).</p> <p>Discussion should support the conclusions of the effects assessment.</p> <p>See also related IRs: IR-161 and IR-162.</p> | | Accepted |
| IR-161 | - | CNSC | Bird Species at Risk | Section 9.4.3.3 Appendix 10-A (ERA) | <p>Context: For the assessment of effects on Bird Species at Risk (SAR), in the EIS it was decided to use representative species for certain SAR birds:</p> <ul style="list-style-type: none">• Olive-sided Flycatcher and Common Nighthawk were selected to represent Barn Swallow.• Yellow Rail and Rusty Blackbird were selected as substitutes for Horned Grebe. <p>No further rationale is provided to demonstrate that the identified surrogate species are representative of the Barn Swallow and Horned Grebe in the EIS. For example, do they share a common diet?</p> <p>Moreover, in the residual effects assessment, limited discussion is provided on the conservatism of chosen suitable habitat types for both surrogate and represented species, in the calculation of habitat loss and alteration, as well as change in mortality. For example, how does habitat for Common Nighthawk and Barn Swallow overlap (do they use identical habitat types?) and how does this affect the calculation of habitat loss and alteration used to evaluate the magnitude of residual effect?</p> | <p>1. Please provide additional information to justify the selection of surrogate species for Barn Swallow and Horned Grebe in the EIS. This should include a description of the similarity of SAR and associated surrogate species and any relevant uncertainties.</p> <p>2. Please provide conservative estimates of habitat loss and alteration for the represented and not directly assessed species (Barn Swallow, Horned Grebe).</p> <p>3. Please provide clarity as to why different surrogate species are used for Horned Grebe between the EIS and ERA.</p> <p>See also related IRs: IR-160 and IR-162.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------|---|---|---|----------------------|----------|
| | | | | | <p>Finally, in the ERA, Lesser Scaup is the surrogate for Horned Grebe. Yellow Rail is also represented by Lesser Scaup but Rusty Blackbird is represented by Olive-sided Flycatcher.</p> <p>Rationale: It is unclear what criteria were applied to select surrogate species for Barn Swallow and Horned Grebe, and how the chosen surrogates relate to Barn Swallow and Horned Grebe in terms of habitat type and range, nesting, and feeding requirements etc.</p> <p>There is also inconsistency with respect to the use of surrogate species for the Horned Grebe between the EIS and ERA supporting document.</p> | | | |
| IR-162 | - | ECCC | Migratory birds | Section 9.4.3.3, Bird Species at Risk | <p>Context and Rationale: Not all avian species at risk present in the study area were included as Key Indicators in the avian species at risk (SAR) valued component (VC). Barn swallow and horned grebe were recorded in the study area, but not included as VCs. Additionally, bank swallow may inhabit the Project area. Impacts to Species at Risk Act Schedule 1 listed species need to be identified, avoided, lessened and monitored.</p> <p>In Section 9.4.3.3. the Proponent states: “It is acknowledged that the listed Barn Swallow (<i>Hirundo rustica</i>) and Horned Grebe (<i>Podiceps auratus</i>) could potentially occur in the Terrestrial RSA. Incidental observations occurred during the baseline studies (Appendix 9-B). To focus the effects assessment on a few key species (described in the following) it was decided to use Olive-sided Flycatcher and Common Nighthawk to represent Barn Swallow as well, and to use Yellow Rail and Rusty Blackbird as a substitute for Horned Grebe. Unlike Horned Grebe, Yellow Rail and Rusty Blackbird are also listed provincially.”</p> <p>Barn swallow, bank swallow and horned grebe may have different nesting habitat requirements than the representative species discussed in the draft EIS. An explanation of how differing species are representative of one another is required, or if an explanation cannot be provided, the species should be assessed individually.</p> <p>Updated Rationale: The management plans for these three species demonstrate the variability in their habitat selection.</p> <p>The Management Plan for the Yellow Rail (<i>Coturnicops noveboracensis</i>) in Canada (Environment Canada, 2013) states “Yellow Rails inhabit shallow wetlands and other wet areas with grass-like vegetation. They breed in wetlands such as damp hay fields or meadows, floodplains, bogs, upper levels of estuaries, salt marshes (Bookhout 1995, Alvo and Robert 1999, COSEWIC</p> | <p>1. Explain how nesting habitat requirements of barn swallow is represented by common nighthawk and olive-sided flycatcher as a VC or assess individually each SAR that overlaps with the Project and is likely to be affected.</p> <p>2. Explain how nesting habitat requirements of horned grebe are represented by yellow rail and rusty blackbird as a VC, or assess individually each SAR that overlaps with the Project and is likely to be affected.</p> <p>3. Assess individually each SAR that overlaps with the Project and is likely to be affected.</p> <p>See also related IRs: IR-160 and IR-161.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------|---|---|---|----------------------|----------|
| | | | | | <p>2009), shallow prairie wetlands, and wet montane meadows (Peabody 1922, Sherrington 1994, Popper and Stern 2000). “</p> <p>The Management Plan for the Rusty blackbird (<i>Euphagus carolinus</i>) in Canada (Environment Canada 2015), states: “Rusty Blackbirds tend to select breeding sites with a combination of freshwater bodies with shallow water and emergent vegetation for foraging that are adjacent to wetlands with conifers or tall shrubs with cover for nesting (Matsuoka et al. 2010a, Matsuoka et al. 2010b, Greenberg et al. 2011).”</p> <p>The Management Plan for the Horned Grebe (<i>Podiceps auritus</i>), Western population, in Canada (ECCC, 2022) states: “The Horned Grebe breeds in small (generally 0.5 to 2 ha, but ranging from 0.24 to 18.2 ha), shallow (at least 20 cm deep, but on average 40 cm), and usually fishless, perennial wetlands, but they can also nest on larger lakes with shallow edges and sufficient emergent vegetation. Breeding sites usually contain at least 40% open water with beds of emergent vegetation, such as sedges (<i>Carex</i> spp.), rushes (<i>Juncus</i> spp.) and cattails (<i>Typha</i> spp.) (Faaborg 1976, Kuczynski et al. 2012, Routhier 2012, Stedman 2018).”</p> <p>Due to differing habitat selection and use, ECCC recommends that each selected VC is given an individual assessment with specific mitigation measures. This will allow for a more accurate review of the chosen mitigation measures.</p> | | | |
| IR-163 | - | ECCC | Migratory birds | Section 9.4.3.3.3, Baseline Studies – Avian species at risk VCs | <p>Context and Rationale: The baseline studies and data analysis for species at risk (SAR) birds is insufficient to accurately predict Project effects.</p> <p>ECCC recommends the use of predictive modeling in relation to survey data and habitat attributes to produce distribution and density maps. Sites within the study area that support particularly high densities or diversity of an individual species, based on direct observation and, where appropriate, distribution or occupancy models, would greatly improve confidence in Project impact predictions.</p> <p>Additional information on specific habitat use or models of habitat used by SAR would facilitate a more complete analysis of Project effects.</p> | Provide additional information, including mapping/modelling of specific habitat requirements for each avian species at risk or provide a justification of models used in the draft EIS. | | Accepted |
| IR-164 | - | ECCC | Migratory birds | Section 9.4.4.2.1, Alteration and/or Loss of Habitat – Migratory Breeding Birds | <p>Context and Rationale: The discussion on impacts to migratory songbirds presented by the Proponent is not sufficient to understand the impacts on various guilds of birds (e.g., aerial insectivores, forest birds, wetland birds, habitat specialists).</p> <p>As per IR-158, focal representative species/guilds should be used as</p> | <p>1. Provide further discussion on impacts to different focal species/guilds within the Migratory Breeding Birds Valued Component.</p> <p>2. Provide mapping of important features or habitat types that</p> | | Accepted |

|--------------|----------------|------------------|----------------------|--|---|---|----------------------|----------|
| | | | | | <p>key indicators (KI) in the Migratory Breeding Birds Valued Component. A greater level of detail on Project impacts to migratory songbirds with differing habitat requirements is needed for a fulsome assessment of effects.</p> <p>Updated Rationale: A greater level of detail, including a discussion on impacts to different focal species and/or guilds within the Migratory Breeding Birds Valued Component, is required for a more fulsome assessment of effects and identification of mitigation measures. Additionally, mapping detailing important features or habitat types that will be lost due to the Project for different guilds of migratory birds will be required to assess Project effects. This information will be required in order for the Proponent to apply adaptive management, and for ECCC to review the adequacy of these management plans.</p> | <p>will be lost due to the Project for different guilds of migratory birds.</p> | | |
| IR-165 | - | CNSC ECCC | Birds (all species) | Section 9.4.4.2.2 Section 9.4.5.2.4, Avian Deterrence and Prevention of Entrapment Appendix 10-A (ERA) | <p>Context: On p. 9-364 of the EIS, it is stated that exposure to hazardous materials through contact with contaminated waste ponds could affect avian health and contribute to mortality.</p> <p>However, the ERA places the avian receptors only in waterbodies and locations outside of the Project area (see Figure 5-2 in the ERA), i.e., Whitefish Lake, McGowan Lake, the inlet to Russell Lake, and Kratchkowsky Lake.</p> <p>Further, there are insufficient details on the potential effects of the water quality in the water management and treatment facilities on birds, species at risk, and other wildlife, including the risk of bioaccumulation of contaminants. The Proponent should assess potential effects of water quality from these areas using applicable CCME guidelines.</p> <p>Rationale: It is unclear whether the ecological risk assessment based on the chosen exposure locations is protective and conservative for avian species potentially exposed to contaminated waste ponds on the Project site.</p> <p>While mitigation measures such as physical, visual, and/or auditory deterrents are proposed in Section 9.4.5.2.4, the possibility of avian species coming into contact with waste ponds cannot be excluded based on the available information in the EIS. The possibility of birds, species at risk, and other wildlife accessing the water management and treatment facilities for drinking water or other purposes is not discussed in the draft EIS.</p> | <p>Please perform an ecological risk assessment with avian receptors located at the contaminated waste ponds, including:</p> <ol style="list-style-type: none">1. Describe and analyze the possibility of birds, species at risk and other wildlife using the water or waste management facilities and provide an analysis to determine if there is a risk to wildlife that may access these areas.2. Identify the potential toxicity of water management ponds to aquatic migratory birds and species at risk (SAR).3. Describe what measures will be taken if the waters are found to be toxic to migratory birds and SAR. <p>Suggestions for mitigation and follow-up measures: CNSC recommends that Denison ensure adequate mitigation measures are implemented to minimize the potential for avian exposure to pond waters.</p> | | Accepted |
| IR-166 | - | ECCC | Migratory birds | Section 9.4.5.2 Additional Avian Species-specific | <p>Context and Rationale: Avian species-specific mitigation measures are not presented in the draft EIS. The Proponent has committed to providing a variety of environmental management plans.</p> | <p>Provide details on species-specific mitigations for species at risk (SAR) and other avian species that will include:</p> | | Accepted |

|--------------|----------------|------|----------------------|---|---|--|--|----------|
| | | | | Mitigation Measures | <p>Section 9.4.5.2 reads: “Additional mitigation measures specific to the Raptors, Migratory Breeding Birds, and Bird Species at Risk VCs, in accordance with the Migratory Birds Convention Act, and tailored to Project features will be incorporated into various Project management and monitoring plans such as the, erosion and sediment controls, soil and vegetation monitoring, wildlife monitoring, the Decommissioning Plan, air quality monitoring, Spill Response Plan, Radiation Protection Plan, surface water and effluent monitoring, and Waste Management Plan.”</p> <p>Migratory birds, the nests of migratory birds and/or their eggs can be inadvertently harmed or disturbed as a result of many activities, including but not limited to clearing trees and other vegetation, draining or flooding land, or using fishing gear; this is known as incidental take. This inadvertent harming, killing, disturbance or destruction of migratory birds, nests and eggs is prohibited under the MBCA. Incidental take, in addition to harming individual birds, nests or eggs, can have long-term consequences for migratory bird populations in Canada, especially through the cumulative effects of many different incidents. For further details, please refer to the Avoiding Harm to Migratory Birds website at: https://www.canada.ca/en/environment-climate-change/services/avoiding-harm-migratory-birds.html</p> <p>In order to assess the effectiveness of species-specific mitigations and need for additional mitigations ECCC requires details on the species-specific mitigation measures proposed, and the monitoring plans.</p> | <ul style="list-style-type: none">• details on what activity restrictions will be implemented for migratory birds and SAR and when they will be applied;• details on mitigations used during regular maintenance activities such as vegetation management (e.g., mowing), access road repair (e.g., aggregate stockpiles), and infrastructure repair;• details on methods used to detect species listed on Schedule 1 of the <i>Migratory Birds Convention Act</i> (e.g., Pileated Woodpecker) and mitigations/setback distances and timing to reduce risk to these species. | | |
| IR-167 | - | ECCC | Migratory birds | Section 9.4.5.2.1 Work Timing Windows and Habitat Disturbance | <p>Context and Rationale: The Proponent has stated that when it is not practicable to clear outside of the breeding bird window, they will conduct pre-clearing surveys. Section 9.4.5.2.1 states: “Prior to commencing any site clearing (i.e., vegetation clearing and/or soil disturbance) during the nesting season, pre-clearing nest surveys will be conducted at that location within the Project Area.”</p> <p>ECCC does not recommend the use of nest searches or pre-clearing surveys for active bird nests during the breeding season as a mitigation, given the difficulty associated with finding nests reliably and the high likelihood of disturbing nesting birds when searching. Instead, ECCC recommends that clearing and grubbing activities not be conducted during the breeding bird season.</p> <p>The Migratory Birds Regulations 2022 (MBR 2022) brings new scenarios that need to be considered:</p> | <p>Provide the following information:</p> <ul style="list-style-type: none">• details on how vegetation clearing related to site development will be conducted to minimize risk to migratory birds and species at risk (SAR).• the timing window that will be used for vegetation removal to reduce risk to migratory birds and SAR | Response is accepted, but also see AD-57 in the Advice to Proponent table and follow-up IR-142-159-167-R1. | Accepted |

| | | | | | <ol style="list-style-type: none">Most migratory birds:<ul style="list-style-type: none">Nests are protected only when they are in use or when live eggs or chicks are present.Migratory birds listed in MBR 2022 Schedule 1:<ul style="list-style-type: none">For the 18 species of migratory birds identified on Schedule 1, the MBR 2022 provide year-round nest protection until they can be deemed abandoned.Migratory birds listed under SARA:<ul style="list-style-type: none">For some SARA listed migratory birds, the residence prohibition (s.33) will protect nests that are not active, but are re-used in subsequent years, and the critical habitat prohibition (s.58) will protect nests that are part of the critical habitat identification. Those prohibitions apply everywhere in Canada and at all times of the year. In these cases, a SARA permit will be required. | | | |
| IR-168 | - | ECCC | Migratory birds | Section 9.4.5.2.4, Avian Deterrence and Prevention of Entrapment | <p>Context and Rationale: The Proponent mentions that avian deterrents will be used on power transmission lines, buildings and other Project infrastructure. However, the Proponent does not mention any deterrents that will be used for deterring birds from the water or waste management facilities.</p> <p>Details on deterrents for all Project components should be identified to assess residual and cumulative impacts to migratory birds.</p> | <p>Provide information on avian deterrents to be used to prevent birds or other wildlife entering water or waste management ponds.</p> <p>2. Explain how proposed timing of use of deterrents will reduce risk of migratory birds making contact with treatment waters outside of the nesting season (i.e., during migration and stop overuse).</p> <p>3. Explain which deterrents will be used, which deterrents were considered, and what alternative, adaptive measures will be considered if deterrents are unsuccessful for any Project components.</p> | | Accepted |
| IR-169 | - | ECCC | Migratory birds | Section 9.4.6.3, Residual Effects Evaluation for Migratory Birds, Table 9.4-15 and Map 9.4-11 | <p>Context and Rationale: The analysis of available habitat types for migratory songbirds appears incorrect.</p> <p>In their interpreted ecosite mapping, the Proponent identified 25 different ecosite types. In their table 9.4-15 and map 9.4-11, the Proponent only lists 8 ecosite types that are available migratory songbird habitat. Section 9.4.6 Residual Effects Evaluation for Migratory Songbirds reads: “Considering the baseline data (Appendix 9-B), migratory songbird habitat is described in the following text without species-specific differentiation and referred to as available habitat for migratory songbirds. Based on the baseline study results, 66.8%, 52.2%, and 50.7% of the Project Area, Wildlife LSA, and Terrestrial RSA, respectively, are assumed to provide available habitat for migratory songbirds (Table 9.4-15).”</p> <p>All Project areas, except some anthropogenic features and open water, would be considered available habitat for migratory songbirds. Although some ecosite types may have lower density</p> | <p>1. Explain how information in Table 9.4-15 and map 9.4-11 were derived.</p> <p>2. Explain why other habitat types were not considered as available habitat for migratory songbirds.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------|---|---|--|--|--------------|
| | | | | | and diversity, it is expected that all ecosites provide migratory songbird habitat. | | | |
| IR-170 | - | ECCC | Migratory birds | Section 9.4.6.4, Residual Effects Evaluation for Bird SAR, Table 9.4-19 | <p>Context and Rationale: The table and map presented by the Proponent do not appear representative of all available habitat for common nighthawk (CONI). Although CONI do preferentially use open areas such as gravel (often an anthropogenic disturbance) and regenerating forest, as identified in the draft EIS, they also use rock outcrops that can be within forested areas. As this area lies within the pre- Cambrian shield, there are likely rock outcrops that are also available habitat.</p> <p>As aerial insectivores, CONI select nesting areas in close proximity to wetlands or lakes where there is abundant forage.</p> <p>Rationale: Habitat requirements and preferences for all species at risk is required for developing effective mitigations and adaptive management.</p> | <p>1. Provide an updated table and map that considers all available habitat for common nighthawk.</p> <p>2. Additionally, as part of environmental management plans the Proponent should include species-specific mitigations that are biologically relevant to all the species at risk for all Project phases and components.</p> | <p>Item one was accepted, but item two remains outstanding. In Section 9.4.5.2.1, the Proponent has not included species specific mitigations for all species at risk, including common nighthawk. The Proponent should include species specific mitigations for all species at risk, including common nighthawk, so that ECCC can provide advice on the extent of Project impacts to these species.</p> <p>Additionally, the Proponent indicates that prior to site clearing during the nesting season (period from March 15 to August 31), pre-clearing nest surveys will be conducted. ECCC does not typically recommend nest surveys as a pre-clearing activity (please refer to the Advice to the Proponent relating to IR-170). In some instances, surveying for breeding activity using non-invasive methods could be required to determine species presence, and for some migratory birds SAR it may be required to survey for nest trees (residences) prior to clearing as these have year-round protection through SARA and a permit may be required.</p> <p>Specifically, it is not adequate to group SAR together (e.g., all birds) due to the unique life history and habitat requirements of each individual SAR. Denison is expected to provide species-specific mitigation measures for each SAR separately.</p> | Not Accepted |
| IR-171 | - | ECCC | Migratory birds | Section 9.4.6.4, Residual Effects Evaluation | <p>Context and Rationale: Section 9.4.6.4 Residual Effects Evaluation for Bird SAR – Common Nighthawk reads: “Progressive reclamation is anticipated to begin during Construction. However, a conservative approach is used, with Common Nighthawk (CONI) habitat in the Project Area considered to be unavailable for the duration of the Project, only becoming available as habitat following Post-Decommissioning (i.e., during the regeneration of vegetation following Decommissioning).”</p> <p>CONI may nest on the roadsides of access roads within the Project area. As such, the Project area should still be considered available habitat for the duration of the Project and appropriate mitigations and adaptive management should be discussed for this species.</p> | <p>Develop mitigation plans appropriate for avoiding collisions of common nighthawks with vehicles, when and where nighthawks are observed foraging near or roosting on gravel roads. Demonstrate how the planned mitigation activities will result in reduced residual effects from this pathway.</p> | | Accepted |
| IR-172 | - | CNSC | Birds (all species) | Section 9.4.6.4.2 | <p>Context: Populations of listed species may be less resilient to changes in mortality.</p> <p>CSA N288.6:22 Clause 7.2.4.3 states that effects on a few individuals of endangered, threatened, or vulnerable species would not be acceptable.</p> <p>The residual effects assessment for “Change in Mortality” for bird species at risk states that Project mitigation measures identified in Section 9.4.5 are expected to limit interactions between bird species at risk and potential sources of direct and indirect mortality. However, the mitigation measures are not discussed with</p> | <p>Please provide a discussion on mitigation measures with respect to their effectiveness in minimizing mortality for bird species at risk, for which effects on a few individuals would not be acceptable.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------|--|--|---|--|--------------|
| | | | | | respect to their effectiveness to limit interactions, specifically for bird species at risk. Rationale: It is unclear if the proposed mitigation measures are effective in preventing mortality in bird species at risk for which even only a few deaths could negatively impact the population. | | | |
| IR-173 | - | ECCC | Migratory birds | Section 9.4.8 Monitoring and Follow-up | Context and Rationale: Monitoring and follow up programs are part of adaptive management and implementation of additional mitigations. In Section 9.4.8 the Proponent states: “Considering the Project planning, baseline survey results, and proposed mitigation measures, no follow-up programs are considered to be warranted at this time.” Project impacts related to mortality of birds, such as collisions with the transmission line, mortality along roads and use of waste and water management facilities should be monitored during all phases of the Project and adaptively managed. | Provide details on the follow-up program to monitor impacts to avian mortality. The follow-up plan should include: <ul style="list-style-type: none">Monitoring of avian use of waste and water facilitiesMonitoring of mortality along access roadsMonitoring of mortality related to transmission linesMonitoring of effectiveness of avian deterrents. | | Accepted |
| IR-174 | - | ECCC | SAR – Bats | Appendix 9-B, Denison Mines Corporation Wheeler River Project, Terrestrial Environment, Wildlife and Vegetation Baseline Inventory, Section 2.1.4 Acoustic Bat Surveys | Context: The Proponent conducted acoustic surveys for bats and confirmed presence of two Species at Risk Act (SARA) schedule 1 listed bat species in the Project area, little brown myotis (Myotis lucifugus) and northern myotis (Myotis septentrionalis). However, the Proponent did not do an effects assessment of either of these bat species. Rationale: Although bats are present in the study area, no work was done to identify hibernaculum or maternal roosting sites. All species at risk that are expected to be present in the Project area should be assessed and species-specific mitigations detailed. | <ol style="list-style-type: none">Conduct an effects assessment for little brown myotis and northern myotis, including the likelihood that tree clearing during the bat roosting period, is likely to ‘kill’, ‘harm’, or ‘harass’ Little Brown Myotis and Northern Myotis and its ability to carry out its life processes.Describe and map locations of suitable myotis hibernacula and/or maternal roost habitat within the Local Study Area and Regional Study Area and explain how these habitats may be affected by Project activities.Describe what mitigation measures will be taken to avoid the breeding period for bats.Describe any pre-construction/pre- clearing surveys will be conducted to identify any hibernaculum and maternal roosting sites. Describe how monitoring will support adaptive management. | <p><u>Note to Denison:</u> There is additional text being drafted related to this topic, but it is still under review and may provide clarity on the outstanding request.</p> <p>Items one, three, and four have been accepted, but the response to item 2, regarding describing and mapping of locations of suitable myotis hibernacula and/or maternal roost habitat within the Local Study Area and Regional Study Area and an explanation of how these habitats may be affected by Project activities, is outstanding.</p> <p>In responding to item two, the Proponent has provided a map of species detected and frequency of detection in the local study area over two days on July 22 and 23, 2019. ECCC notes that analysis is lacking for the regional study area, despite a few autonomous recording units (ARUs) that were placed outside the LSA.</p> <p>Data from two consecutive days in the same month is not an accepted method to document baseline occurrences associated with suitable habitat. The legend for Figure 2-9 is not clear in that frequency of detection is mapped based on two criteria: little brown myotis and little brown/northern myotis.</p> <p>The Proponent should use a scientifically defensible method to document baseline occurrences associated with suitable habitat. The Proponent should clarify the legend and explain the values found within it, including if the turquoise dot represent occurrence of both little brown and northern myotis.</p> <p><u>Baseline data for bat SAR must be adequate to capture within and between year variability and to allow for statistically robust comparison to assess potential impacts on SAR over the lifecycle of the project. In this regard, Denison is expected to provide additional baseline data for bat SAR. If Denison choses to rely on literature data, a justification of applicability to the</u></p> | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-----------------------------|---|---|---|--|----------|
| | | | | | | | <p>project is required. Nevertheless, Denison is expected to at a minimum commit to additional baseline monitoring prior to any disturbance, and to provide a description of the monitoring methods for review. These baseline surveys must be focused on suitable habitat for bat SAR that is to be identified through the requested mapping.</p> <p>To close this IR, Denison must:</p> <ol style="list-style-type: none">1. Clarify the legend of Figure 2-9 with respect to frequency of detection2. Provide suitable bat SAR habitat information in the form of a map3. Provide additional baseline data for bat SAR based on literature sources and justify applicability to the project4. Provide a description of proposed methods for bat SAR field monitoring for review5. Commit to an EA commitment to collect additional bat SAR field baseline data prior to disturbance | |
| IR-175 | - | CNSC | Provincially Listed Species | Appendix 9-B; section 2.2.2 | <p>Context: Vegetation and wildlife habitat characterization field surveys were completed in 2017, based on which ecosite factsheets were prepared. The factsheets list observations of two provincially listed plant species with a rank of S3 (vulnerable/rare to uncommon; Table 2.4-2) according to the Saskatchewan Conservation Data Centre, which are not discussed in the main EIS document:</p> <ul style="list-style-type: none">• Angle-leaved sundew (<i>Drosera anglica</i>) observed in ecosites BS19, BS20, BS22, BS25• Neat Spike-rush (<i>Eleocharis nitida</i>) observed in ecosite BS25 <p>Table 9.2-12 in section 9.2.6.2.1 of the EIS indicates that there may be indirect disturbance to some of these ecosites (BS19, BS20, BS25). In section 9.2.6.3.1 it is discussed that listed plant species are not likely to return once lost from a specific location.</p> <p>Rationale: Given that not all areas in the revised Project footprint were surveyed for listed plant species in baseline studies, there is uncertainty as to whether any species were missed, in particular those that have been observed in ecosites present in the LSA/RSA (e.g., <i>Drosera anglica</i> and <i>Eleocharis nitida</i>, see also Appendix 2 Table of Appendix 9-B). It should also be noted that rare plant surveys were completed in summer 2017 only (section 2.4.2 of Appendix 9-B), which may underestimate annual rare species that may be dormant in the seed bank in some years due to specific seed emergence requirements.</p> <p>It is acknowledged that the Proponent committed to pre-construction listed plant surveys targeted on ecosites encountered in the Project Area but not previously surveyed, as well as ecosites within the Project Area with high potential to support listed plants.</p> | <ol style="list-style-type: none">1. Please provide a discussion on the potential risks from indirect effects on ecosites with observed rare plant species2. Please provide additional information on the ecosites included in the planned pre-construction listed plant surveys <p>Suggestions for mitigation and follow-up measures: CNSC recommends focusing monitoring on ecosites that have known observations of listed plant species outside of the Project Area (e.g., BS19, BS20, BS22, BS25).</p> | | Accepted |

|--------------|----------------|------|---|---|--|---|--|----------|
| | | | | | More information is requested on the potential indirect effects on rare plant species as well as the planned pre-construction surveys. | | | |
| IR-176 | - | CNSC | Human Health with respect to radiation exposure | Section 10.1.4.2.1 Section 10.1.6.1.4 Appendix 10-A (ERA) | <p>Context: In section 10.1.4.2.1, the Proponent provides an evaluation of air quality constituents of potential concern to human health. It states: “A screening value for radon gas of 200 becquerels per cubic metre (Bq/m3) was available from Health Canada, which applies to total radon including background sources (Health Canada 2009). The radon concentrations which were predicted are incremental concentrations (i.e., above background) and were therefore compared to the applicable incremental screening value of 60 Bq/m3 for indoor air established by the Canadian Nuclear Safety Commission (CNSC) (Health Canada 2010a; Radiation Protection Regulations. SOR/2000-203).”</p> <p>The 60 Bq/m3 radon concentration value also appears in section 7.1.2 of Appendix 10-A (ERA).</p> <p>Further in section 10.1.6.1.4, it is stated: “Radon dose was calculated separately from the dose due to other radionuclides; however, the predicted radon concentration was compared against the CNSC incremental concentration limit of 60 Bq/m3.”</p> <p>The Radiation Protection Regulations do not stipulate a limit for radon above background for sites licensed by the CNSC. The effective dose limits for Nuclear Energy Workers (NEWs) and persons that are not NEWs are listed in section 13 of these regulations, and in subsection 1(3) of these regulations for the general public.</p> <p>The annual effective dose from all sources associated with the licensed activities and within the scope of the Nuclear Safety Control Act and Regulations must be compared to the applicable effective dose limit. For members of the public this limit is 1 mSv per calendar year.</p> <p>In Section 4.2.5.3 of Appendix 10-A (ERA), there appears to be no reference mentioned for the radon equilibrium factors. These factors are a significant input into the dose calculations for radon.</p> <p>Rationale: The reason for the requested change is to ensure consistency with the Radiation Protection Regulations.</p> | <p>The EIS and appendices should be aligned with the Radiation Protection Regulations by:</p> <ol style="list-style-type: none">1. Removing the reference to a 60 Bq/m3 limit.2. Reporting the assessment results as the total dose, from all radionuclides combined including radon progeny, and by comparing this annual effective dose to the effective dose limit. <p>Provide a summary of the conservative assumptions that have been included in the dose calculations.</p> <p>Provide a reference that shows how the radon equilibrium factors were determined.</p> | | Accepted |
| IR-177 | - | HC | Change to an environmental component due | Section 10.1.4.2.1 (p. 10-22) Appendix 10-A | <p>Context: Section 10.1.4.2.1 states that, “Screening values for radionuclide concentrations in ambient air were not available. All relevant radionuclides were assessed in the HHRA in terms of their contribution to the total radiological dose to human and ecological</p> | <p>1. Assess predicted radionuclides in Section 10 Appendix 10-A (ERA) using appropriate available screening values. Alternatively, provide a justification for why a screening wasn’t conducted for</p> | Response is accepted, but also see AD-55 in the Advice to Proponent table. | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|-----|--|---|--|--|----------------------|----------|
| | | | to radiological contaminants | (ERA) : Appendix B Table B.9, Ref. 19-2638 Section 6, Table 6.1-1 (p. 6-7) | receptors” (p. 10-22). Section 10 Appendix 10-A (ERA) states that, “No formal screening was conducted for radionuclides. However, since radiation dose to human receptors is of public and regulatory interest, the radionuclides in the uranium-238 decay series are carried forward as COPCs for further assessment” (Appendix 10-A (ERA): Appendix B Ref. 19-2638). Table 6.1-1 lists radionuclides as a key indicator for air quality, but only uranium and radon are considered in Section 6, and Section 10 Table B.9 does not include doses from uranium progeny in air. Rationale: Health Canada recommends using screening values that are available for radionuclides if they are appropriate for the dose and if the screening values have listed assumptions (such as particulate size and worker exposure time that can be adapted to in Denison’s models). Two examples are ICRP 96, which CNSC uses in their regulatory reports to derive reference air quality values for Pb-210, Ra-226, and Th-230 (CNSC: Regulatory Oversight Report for Uranium Mines and Mills in Canada 2019); and Health Canada’s Guidelines for Management of NORM (Health Canada: Canadian Guidelines for the Management of Naturally Occurring Radioactive Materials, 2011). | radionuclides despite the availability of screening values (e.g., ICRP 96 and NORM Guidelines, 2011). 2. Clarify if uranium progenies in air are considered in the atmospheric transport and air quality modelling and are simply not reported, or if they are not included in the models because no screening criteria are available. | | |
| IR-178 | - | HC | Change to an environmental component due to hazardous contaminants | Section 10.1.4.2.1 (p. 10-22) Section 6.1.4.2, Potential Project Related Effects (p. 6-31) | The Baseline + Project scenario was not provided for radon levels. Context: Section 6.1.4.2 states that the predicted levels for radon were not added to the respective baseline air quality levels (p. 6-31), and further explains that “In all modelled phases of the Project, annual average radon concentrations at receptors beyond the Property Boundary are expected to be indiscernible from background levels.” In Section 10.1.6.1.4, a different approach to evaluating predicted radon levels is mentioned: “the predicted radon concentration was compared against the CNSC incremental concentration limit of 60 BQ/m3”(p. 10-44). Rationale: Without a rationale as to why baseline levels of radon were not included in the assessment, HC cannot fully evaluate the appropriateness of the air quality assessment. While Health Canada is of the opinion that using background radon levels as a screening value is appropriate in this case from a health perspective, different approaches to screening predicted radon levels in different sections appear to be used (i.e., background radon levels vs. CNSC incremental concentration). | 1. Provide further information on whether and how baseline radon concentrations in air were determined. 2. Include baseline radon concentrations in the predicted total concentrations when comparing to existing guidelines; alternatively, provide a rationale for why baseline concentrations of radon were not included. 3. Discuss the potential health implications of the project-only increment-over-baseline radon levels | | Accepted |

|--------------|----------------|------|---|--|--|--|--|----------|
| IR-179 | - | CNSC | Groundwater quality decommissioning objectives. | Section 10.1.4.2.2, Release of Treated Effluent to Whitefish Lake During Decommissioning | <p>Context: It is stated that “This process would continue until the recovered water meets acceptable groundwater quality decommissioning objectives”.</p> <p>Rationale: The information provided does not include groundwater quality decommissioning objectives nor a reference to these objectives.</p> | Please provide groundwater quality decommissioning objectives or a reference to the information. | | Accepted |
| IR-180 | - | CNSC | Human health with respect to hazardous contaminants | Section 10.1.6.1.1, Human Receptors Selection and Characterization | <p>Context: Within the Human Health assessment, offsite receptors during the operation period are only considered downstream of Whitefish Lake. The only identified concern was for Se to the Fisher/Trapper located at Russel Lake. This section cites Indigenous Knowledge as informing the receptor selection and location.</p> <p>Rationale: While the assessment is fairly conservative in the assumptions made on intake and receptor habits, it stands to reason that if the trapper receptor was located closer to the operation, such as at McGowan or Whitefish Lakes, this exceedance of Se could be more pronounced.</p> <p>In terms of maintaining a conservative assessment, if the most vulnerable receptor can be shown to be protected at the point of highest expected COPC concentration, it can be concluded that this receptor would be protected further away from the Project. Considering this, why was the hunter/trapper receptor not also assessed at Whitefish or McGowan Lake? Was Indigenous Knowledge specific in mentioning Whitefish or McGowan Lakes were not used for the activities carried out by identified receptors?</p> | <p>Please provide justification for excluding a receptor from occupancy at lakes closer to the Project during operation (McGowan, Whitefish). Alternatively, conduct a risk assessment to a receptor at these lakes during operation to determine if there is a predicted risk that may require monitoring or mitigation.</p> <p>Suggestions for mitigation and follow-up measures: CNSC recommends the following:</p> <ul style="list-style-type: none">Assessment of a receptor located closer to the point of effluent release may need to be considered to ensure there are negligible risksIf Se is expected to exceed hazard quotients further upstream, selenium removal technology may be required as part of the effluent treatment process as a mitigation measure. Other COPC’s exceeding an HQ of 1 may also be identified under this process that could require specific monitoring or mitigation measures. | Response is accepted, but also see AD-59 in the Advice to Proponent table. | Accepted |
| IR-181 | - | CNSC | Human Health with respect to radiation exposure | Section 10.1.6.1.4 | <p>Context: In section 10.1.6.1.4, it is stated: “The maximum incremental radon concentration at the camp worker site during Operation was predicted to be 12.4 Bq/m3, which is below the CNSC limit of 60 Bq/m3 for incremental radon.”</p> <p>As per IR-176, there is no such CNSC limit for incremental radon.</p> <p>The camp worker would be considered a person who is not a nuclear energy worker (NEW) and subject to the dose limits of section 13 and 14 of the Radiation Protection Regulations, not the dose limit for the general public as per subsection 1(3) of the Radiation Protection Regulations. The CNSC has regulatory requirements for the ascertainment and recording of doses of radiation as per section 5 of the Radiation Protection Regulations. Every licensee must ascertain and record the magnitude of exposure to radon progeny, the effective dose and equivalent dose received by and committed to a person who performs duties in connection with any activity that is authorized by the Nuclear Safety and Control Act or is present at a place where that activity is</p> | <p>The EIS and appendices should be aligned with the Radiation Protection Regulations by:</p> <ol style="list-style-type: none">Removing the reference to a 60 Bq/m3 limit for incremental radon.Revising all references to the ‘public dose limit’ applied to camp workers (non-NEWs) to align with section 13 and 14 of the Radiation Protection Regulations. <p>The Proponent should explain why the radon dose for the camp worker appears as 0.13 mSv/year in one instance and 0.02 mSv/year in another.</p> <p>The Proponent is also asked to provide the rationale as to why a non-NEW has a higher radon dose than a NEW.</p> | | Accepted |

|--------------|----------------|------|---|---|--|---|--|----------|
| | | | | | <p>carried on.</p> <p>The camp worker performs duties in connection with the licensed activity and is present at the location where the activity is carried out. Hence, they are not considered to be a member of the general public (who has no connection with the activity)</p> <p>Further, the Proponent indicates that the maximum incremental radon dose to the camp worker was estimated to be 0.13 mSv/year during Operation. The assessment assumes that the camp worker spends 100% of the time indoors. Table 10.1-11 shows the maximum total incremental dose for the camp worker to be 0.02 mSv/year. This appears to be a discrepancy.</p> <p>Table 5.2 in Appendix 10-C provides internal annual dose from radon inhalation. The radon doses to some NEW workers (9.44E-02 mSv/a Driller 1 and 1.03E-01 mSv/a Wellfield Operator 1, 2) here appear less than the radon dose (0.13 mSv/year from section 10.1.6.1.4) to the camp worker, who is a non-nuclear energy worker.</p> <p>Rationale: The reason for the requested change is to ensure consistency with the Radiation Protection Regulations and the environmental impact statement.</p> | | | |
| IR-182 | - | HC | Change to an environmental component due to radiological contaminants | Section 10.1.6.1.4, (p. 10-44) | <p>Context: Section 10.1.6.1.4 states, “The limit is incremental and is exclusive of natural background, such as natural levels of radon and medical exposures. A dose constraint of 0.3mSv/yr was established for the public from all radionuclides and all pathways for the Project, as recommended by Health Canada (2010a). The dose constraint represents a dose lower than the public dose limit that ensures the combined dose from multiple sources does not result in exceedance of the public dose limit. Radon dose was calculated separately from the dose due to other radionuclides; however, the predicted radon concentration was compared against the CNSC incremental concentration limit of 60 BQ/m3” (p. 10-44).</p> <p>Rationale: Calculating radon separately from all radionuclides may underestimate the health risks by not considering combined doses from multiple sources when comparing to the public dose limit constraint of 0.3 mSv/yr recommended by Health Canada (2010a).</p> | 1. Provide clarification on how combined doses from all sources would be accounted for in respecting the public dose limit of 0.3 mSV/yr if radon concentrations are being calculated separately. | Response is accepted, but also see AD-65 in the Advice to Proponent table. | Accepted |
| IR-183 | - | CNSC | Human Health with respect to radiation exposure | Section 10.2 Appendix 10-C | <p>Context: Exposure scenarios for workers have been identified and high-level summaries of the assumptions and resultant dose estimates have been provided. However, the detailed dose calculations have not been provided.</p> <p>Rationale: The method used to estimate effective, equivalent and</p> | Provide the dose calculations for deriving the dose estimates for workers in all exposure scenarios, for at least the most dose significant scenarios. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|---|--|----------------------|----------|
| | | | | | committed dose is required to be verified. Sample dose calculations should be included, to confirm use of acceptable input data, for at least the most dose significant scenarios. | | | |
| IR-184 | - | CNSC | Human Health with respect to radiation exposure | Section 10.2 Appendix 10-C, 2.0 | <p>Context: It is stated in Appendix 10-C, section 2.0 that: “In addition, the CNSC has proposed a 100 mSv 5-year equivalent dose to lens of eye, in accordance with recent recommendations of the International Commission for Radiological Protection (ICRP, 2012a). This implies an average annual equivalent dose to lens of 20 mSv/a and will be considered as an applicable dose limit for workers.”</p> <p>As per section 14 of the Radiation Protection Regulations, the equivalent dose limit for the lens of an eye for nuclear energy workers (NEWs), effective January 1, 2021, is 50 mSv in a one-year dosimetry period.</p> <p>Rationale: The reason of the requested change is to ensure consistency with the Radiation Protection Regulations.</p> | The EIS and Appendix 10-C should be aligned with the Radiation Protection Regulations regarding the equivalent dose limit for the lens of an eye for NEWs. | | Accepted |
| IR-185 | - | CNSC | Human Health with respect to radiation exposure | Section 10.2.3.2 Appendix 10-C Table 3.10-3.12 | <p>Context: The Geometries for External Exposure Scenarios Modelled in MicroShield for Sources in various locations were provided in tables 3.10-3.12 in appendix 10-C. The doses from those scenarios were omitted.</p> <p>Rationale: The method used to estimate effective, equivalent, and committed dose is required to be verified. Sample dose calculations should be included, to confirm use of acceptable input data.</p> | The Proponent is asked to provide all the necessary information and assumptions required to perform the MicroShield calculations independently and to list the resulting calculated values from the listed scenarios. | | Accepted |
| IR-186 | - | CNSC | Human Health with respect to radiation exposure | Section 10.2.3.2.4 Section 10.2.3.2.6 Section 10.2.4 Appendix 10-C, Section 3.2 | <p>Context: In sections 10.2.3.2.4 and 10.2.3.2.6, as well as section 3.2 of Appendix 10-C, the Proponent has stated that workers in the drying and packaging areas of the processing plant will be required to wear powered air purifying respirators (PAPR) to reduce/eliminate inhalation exposure.</p> <p>Further in section 10.2.4, which elaborates mitigation measures, it is stated: “For the drying and packaging/loading areas of the ISR plant, use of PAPR has been assumed. It will be needed in these areas, and it has been planned in these areas to substantially reduce doses from inhalation of uranium dust. Dust levels in these areas will be monitored and kept ALARA.”</p> <p>The use of respirators appears to be in contradiction of the requirements of section 13 of the Uranium Mines and Mills Regulations, which states: <i>No licensee shall rely on the use of a respirator to comply with the Radiation Protection Regulations unless the use of the respirator (a) is for a temporary or unforeseen situation; and (b) is permitted by the code of practice referred to in the licence.</i></p> | <p>Provide the rationale for mandating the use of respirators by workers in the drying and packaging areas of the processing plant.</p> <p>Include the demonstration of the application of the hierarchy of control for radiological protection within the design of these areas of the processing plant.</p> <p>Justify that this approach complies with section 13 of the Uranium Mines and Mills Regulations.</p> | | Accepted |

|--------------|----------------|------|--|---|--|---|--|--------------|
| IR-189 | - | CNSC | Woodland Caribou Ecological Model | Appendix 10-A (ERA) | <p>Context: In the ERA (p. C.12, section 2.3.6 Woodland Caribou) it is stated: “For the ecological model a diet comprised of 50% browse, 20% lichen and 30% macrophytes is assumed for the woodland caribou.”</p> <p>In the EIS, section 9.3.3.3.1, it is stated: “Research has shown that up to 70% of the year-round diet of caribou may consist of ground and arboreal lichens.”</p> <p>Rationale: It is unclear whether the assumptions in the ecological model in the ERA regarding Woodland caribou diet are conservative, given only 20% lichen intake in the model. Lichen is known to accumulate COPC such as metals and dust from the atmosphere.</p> | <p>Please provide additional evidence to support that those Woodland Caribou who may have higher consumption rates of lichen as part of their diet, will remain protected. This can be provided through including a second model that assumes 70% lichen in the diet.</p> <p>See also related: IR-138.</p> | | Accepted |
| IR-190 | - | HC | Change to an environmental component due to hazardous contaminants | Appendix 10-A (ERA), Table 3-8 (p. 3.31) and Table 3-9 (p. 3.36) Appendix 6, Table 5 (p. 16) | <p>NO2 criteria is not being consistently compared.</p> <p>Context: Provincial and federal air quality criteria/screening values for NO2 have been used inconsistently.</p> <p>Table 3-9 in Appendix 10-A (ERA) uses the 2015 Saskatchewan Ambient Air Quality Standards (SAAQS) value of 300 µg/m3 to compare the maximum concentrations of NO2 at receptor locations for the 1-hour average period, while Table 5 of Appendix 6 uses the 2025 Canadian Ambient Air Quality Standards (CAAQS) of 79µg/m3 for the same average period time.</p> <p>Rationale: By utilizing the SAAQS screening value for NO2, the maximum concentrations at receptor locations exceed the 1-hour threshold solely during the decommissioning stage (Table 3-9). However, if the 2025 CAAQS are applied, the screening values would be exceeded at receptor locations for all project phases. It is best practice to use the more protective air quality standards to evaluate potential human health risks associated with project activities.</p> | <p>1. Compare the predicted maximum concentrations to the most protective applicable air quality standards available. Alternatively, provide a rationale as to why the SAAQS for NO2 were used rather than the more protective 2025 CAAQS to determine potential exceedances and screen for the need for additional mitigation measures.</p> <p>Suggestions for mitigation and follow-up measures: Health Canada recommends use of the standards from the 2025 CAAQS for NO2 in future mitigation and follow-up plans.</p> | <p>The response to IR-190 acknowledges the predicted exceedances of the CAAQS for NO₂. However, the revised information does not appear to have been carried through to all the health risk assessment documents.</p> <p>HC notes that the new CAAQS for NO₂ also recognizes that there is no population health threshold for human health effects; therefore, any increase in exposure will result in an incremental population risk (Environment Canada and Health Canada, 2012; CCME, 2000). In other words, NO₂ is considered a non-threshold substance, meaning that health effects may occur at any level of exposure. Therefore, guideline values should not be construed as limits to which polluting up to is allowed.</p> <p>Please provide the following information:</p> <ol style="list-style-type: none">1. Present modelled concentrations at the nearest human receptor site (i.e., Risk 2 - seasonal resident at McGowan Lake) in Tables 3-9, 3-10 and 3-11).2. Correct/update Section 3.2.1.3.1: <i>Nitrogen Dioxide</i>, of Revised DRAFT EIS Appendix 10-A (February 2024), as follows:<ol style="list-style-type: none">a. Remove references to the 1970’s National Ambient Air Quality Objectives (NAAQOs) for NO₂. These objectives are no longer relevant and do <u>not</u> support the exclusion of NO₂ from further consideration as a COPC (Ref. AD-67);b. Acknowledge that modelled results exceed the 1-h NO₂ CAAQs at the <i>camp workers location</i> and <i>fence line</i> during all project phases; and,c. Consider NO₂ a COPC for further quantitative assessment and characterize the potential health risk related to 1-h exposure to NO₂.3. Characterize potential health risks from 1-h exposure to NO₂ using HC’s guidance. Alternatively, use the updated 2021 WHO Global Air Quality Guidelines for annual and 24-h NO₂ exposures when calculating hazard quotients.4. Discuss how the proposed mitigation measures to minimize residual effects of the Project on air quality, as identified in Section 16.1.1 of the Revised DRAFT EIS (January 2024), address the health risks identified in Chapter 10. Also specify whether any additional air quality monitoring and/or mitigation measures are proposed specifically to address human health risks. <p>Editorial Revisions</p> | Not Accepted |

| IR-190 | IR-190-R1 | HC | Change to an environmental component due to hazardous contaminants | <p>Section 6.1.3.2.2 (p. 6-21) Table 6.1-8 (p. 6-22); and, Table 6.1-9 (p. 6-22)</p> <p>Section 6.1.8 (p.6-44)</p> <p>IR-190 Response from Denison</p> | <p>Limitations with the proposed use of passive NO₂ monitoring would not allow comparison of measurement results to the 2025 CAAQS for 1-hour NO₂.</p> <p>Context: In response to IR-190, there was agreement to using the 2025 CAAQS for NO₂ in future mitigation and follow-up plans, which Health Canada supports. However, the proposed air quality monitoring and follow-up plans (Chapter 6.1.8) anticipate continued use passive NO₂ samplers, which do not measure hourly (1-hour) concentrations.</p> <p>Section 6.1.3.2.2 indicates that the assessment makes use of passive samplers to measure NO₂ at two sampling locations. The results from those samplers are presented in tables 6.1-8 and 6.1-9, for a ~30-day sampling period (i.e., a total concentrations for NO₂ in ambient air over ~30 days).</p> <p>While passive samplers provide measurement data for comparison to the annual 2025 CAAQS for NO₂, measurement data for the 1-hour NO₂ standard commonly requires use of an active sampler.</p> <p>Rationale: Health Canada encourages the monitoring of air contaminants when exceedances or near-exceedances of air quality criteria, standards and/or guidance values are predicted or reported, to:</p> <ul style="list-style-type: none"> determine the accuracy of predictions; help verify whether standards are being met; and, assist with implementing or modifying mitigation measures. | <p>1. Provide additional details on proposed air quality monitoring for NO₂ that will allow for comparisons to both the 1-hour and annual 2025 CAAQS and how that will be used to support mitigation and follow-up plans. Distinguish between comparisons with measured and modelled monitoring data, as well as use of passive and active samplers.</p> <p>2. If multiple approaches will be used to monitor NO₂ (e.g., use of passive and/or active samplers, modifications due to differences between project phases, etc.), describe their intended contribution to the monitoring objectives and outcomes (e.g., determine the accuracy of predictions; assist with implementing or modifying mitigation measures).</p> | <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>Please provide the following information:</p> <p>1. Clarify the conditions under which a switch from passive to continuous monitoring would be warranted (e.g., if the 30-d measured NO₂ concentration, after conversion to a 1-h concentration, approaches or exceeds the 1-h CAAQS value).</p> | Accepted |
| IR-191 | - | HC | Change to an environmental | Appendix 10-A (ERA), Table 3-9 (p. | Non-threshold substances are not included in screening and monitoring plans. | 1. Include PM2.5 and PM10 in the secondary air quality screening for short and long- term exposure at human receptors. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|-----|---|---|--|---|----------------------|--------|
| | | | component due to hazardous contaminants | 3.36) and Table 3-10 (p. 3.46) Section 6.1.8 (p. 6-44) | <p>Context: Fine particulate matter (PM2.5) is not being considered further in secondary air quality screening for short and long-term exposure at human and ecological receptors because it is not predicted to exceed the screening values of the Ontario Ambient Air Quality Criteria (OAAQC) or the Canadian Ambient Air Quality Standards (CAAQS) for both annual and 24-hour average periods (Tables 3-9 and 3-10). Furthermore, it is not compared against the baseline for analysis.</p> <p>Table 3-9 indicates that coarse PM (PM10) is predicted to exceed the 24-hour CAAQS during all phases of the Project. However, Appendix 10-A p. 3.46 states that, “There were no exceedances of PM2.5 which is generally considered to be a more reliable indicator of potential health effects. However, health effects would be infrequent and reversible, subsiding after exposure; therefore, PM10 was not considered for further quantitative assessment in the ERA.”</p> <p>PM10 and PM2.5 were not included in the air quality monitoring plan (Section 6.1.8).</p> <p>Rationale: Particulate matter and NO2 are considered non-threshold pollutants, meaning that health effects can occur at any level of exposure, The CAAQS for PM2.5 PM.10, and NO2 recognize that there is no population health threshold for human health effects; therefore, any increase in exposure will result in an incremental population risk (Environment Canada and Health Canada, 2012; CCME, 2000). The CAAQS values should not be construed as limits to which polluting up to is allowed. In addition, based on the principles of keeping clean areas clean and continuous improvement, proposed mitigation measures should not be confined to meeting the standards but should also be targeted towards reducing population exposure to CACs associated with the proposed project.</p> <p>Furthermore, although health risks associated with PM2.5 are higher than those associated with PM10, both fractions are considered non- threshold pollutants and identified by IARC (2013) as causes of cancer.</p> <p>Reference: [1] International Agency for Research on Cancer (IARC). 2013. IARC monographs on the evaluation of carcinogenic risks to humans. Volume 109. Outdoor air pollution. Lyon: International Agency for Research on Cancer.</p> | <p>2. Include PM10 and PM2.5 in the air quality monitoring plan as they are non- threshold substances.</p> <p>3. Provide a discussion of the significance of predicted exceedances of health- based standards.</p> <p>4. Identify additional mitigation measures to reduce concentrations of non- threshold air contaminants associated with the Project.</p> <p>Suggestions for mitigation and follow-up measures: Health Canada recommends use of the <u>2025 CAAQS Management Levels</u> to develop mitigation measures that reduce project contributions of non-threshold pollutants (e.g., PM2.5, NO2).</p> | | |

|--------------|----------------|------|--|--|--|---|---|--------------|
| IR-192 | - | CNSC | Human Health with respect to radiation exposure | Appendix 10-A (ERA), Section 3.1.1.2, including Tables 3-1 and 3-2 | <p>Context: Section 3.1.1.2 in Appendix 10-A (ERA) provides the method of how select constituents including cadmium, chromium, selenium and lead-210 were determined. This section does not mention how the other constituents as listed in Tables 3-1 and 3-2 are determined.</p> <p>The values for Th-230 and U-238 in Table 3-1 are unexpected. Typically, these values should be at equilibrium.</p> <p>Rationale: The technical basis for the selection of constituents of concern is required as part of the environmental and human health risk assessments.</p> | <p>1. Provide the methodology of how all listed constituents are determined.</p> <p>2. Provide the rationale as to why Th-230 and U-238 are not in equilibrium.</p> | | Accepted |
| IR-193 | - | ECCC | Change to an environmental component due to hazardous contaminants | Appendix 10-A (ERA), Section 3.1.1.2 Section 8.2.4.2.3 | <p>Context: Appendix 10-A (ERA) Table 3-1 ‘Screening of Effluent Quality against Surface Water Quality Guidelines for the Wheeler River ERA’ does not include acute water quality thresholds for all COPCs compared against predicted effluent quality. For example, it is stated that the final effluent quality discharge target for uranium is 0.057 mg/L. However, the CCME water short term (acute) water quality guidelines for the protection of aquatic life is 0.033 mg/L. The proposed effluent discharge target for uranium exceeds the acute water quality guidelines, indicating effluent may pose the risk of being acutely lethal to aquatic biota at end-of-pipe.</p> <p>All water quality thresholds should be derived from receiving environment parameters, and there are discrepancies between the values used in Appendix 10-A (ERA) Table 3-1 and the values presented in Tables 8.2-8 and 8.2-10 in Section 8.2.4.2.3 of the draft EIS. No selected screening value for TSS has been calculated from baseline conditions. Un-ionized ammonia, which is a regulated Schedule 4 substance under the MDMER, has not been included.</p> <p>Rationale: A review of all modelling results for all COPCs under the MDMER will assist ECCC in understanding the potential risks to the receiving environment.</p> | <p>1. Provide acute and chronic water quality thresholds for all required COPCs with monitoring required under the MDMER.</p> <p>2. Ensure all water quality thresholds are derived from receiving environment baseline parameters and that these thresholds are consistently applied throughout the draft EIS.</p> | <p>The previous round’s IR has not been fully met. When responding to item one, the Proponent did not update Table 3-1 in Appendix 10-A. And the rationale provided relates to Table 8.2-10, which is not part of the request. The Proponent should update Table 3-1 in Appendix 10-A to include un-ionized ammonia, mercury and phosphorous and should incorporate these parameters into the risk assessment as needed. The Proponent should also correct the following inconsistencies in Table 3-1 in Appendix 10-A:</p> <ul style="list-style-type: none">Table footnote #11 refers to the strontium guideline; strontium is not included in the table and the footnote is also not referenced in the table,Please refer to IR108 for comments on derivation of aluminum, chromium, copper, nickel, manganese and cobalt thresholds. <p>The Proponent responded to item two by modifying Tables 8.2-8 and 8.2-10 to include both acute and chronic water quality thresholds. The Proponent should update Table 3-1 in Appendix 10-A with the corrections flagged in comments IR-108 and IR-114 then update the risk assessment to incorporate these parameters and values as needed.</p> | Not Accepted |
| IR-194 | - | ECCC | Aquatic species | Appendix 10-A (ERA), Section 3.1.1.2 and Section 3.1.2.3 | <p>Context: In the ERA, COPCs should be selected for further assessment based upon the following factors:</p> <ol style="list-style-type: none">COPC concentrations in effluent that exceed selected water quality guidelines for the protection of aquatic biota, andBaseline COPC concentrations in the LSA that exceed selected surface water and sediment quality guidelines for the protection of aquatic biota. <p>However, only COPCs that had concentrations in effluent that exceeded guidelines were assessed further. Baseline concentrations of COPCs in sediment were not considered. In</p> | <p>1. As noted in IR-114, provide the information on predicted effluent quality for COPCs with required monitoring under the MDMER.</p> <p>2. Provide the information on predicted maximum receiving environment surface water concentrations for COPCs with required monitoring under the MDMER in IR-114.</p> <p>3. Update the ERA to assess the risk of any additional MDMER COPC concentrations in effluent that exceed water quality guidelines.</p> | <p><u>Note to Denison:</u> There are multiple elements of this IR outstanding. This IR is being conditionally accepted for the purposes of the EA process, but these issues will need to be resolved during the licensing process. It is expected that a fully revised ERA that both incorporates revisions following closure of EA related IRs and addresses outstanding issues that will be further assessed during the licensing review. This commitment should be captured in the Commitments Register, and relates to various IRs in this table.</p> <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> | Accepted |

|--------------|----------------|------|--|---|---|---|--|--------------|
| | | | | | <p>addition to this, not all COPCs that require monitoring under the MDMER had predicted effluent concentrations. From Section 8.2.3.3 Table 8.2-2 of the Aquatic Environment Report, it appears Aluminum in McGowan Lake and Whitefish Lake South and North, and pH in Whitefish Lake North exceed water quality guidelines. Predicted effluent concentrations or near-field surface water concentrations for Aluminum and pH are not provided.</p> <p>Rationale: It is not possible to determine if there is risk from effluent to the receiving environment and aquatic receptors based on the current information provided.</p> | <p>4. Update the ERA to assess the risk of COPCs that had elevated baseline water and sediment quality concentrations in the receiving environment.</p> | <p>Item one of the IR has been met. However additional information is required for items two, three, and four. Similar to ECCC’s rationale provided for IR-124, “the ERA primarily relies on modelling results to identify the maximum predicted levels of COPCs in the receiving environment.” However, due to the upper bound discharge rates being the only model input evaluated, it is unclear whether the model considered scenarios where maximum COPCs might occur as the exclusion of other environmental variables may have resulted in inaccurate maximum environmental concentrations of the COPCs.</p> <p>The Proponent’s responses regarding baseline exceedances of COPC thresholds in the receiving waterbodies requires additional information. The modeling of surface water and sediment COPC’s described in Appendix 10-A, Figures 6-1 and 6-2 respectively, show results for the receiving waterbodies. However, it is unclear if these modeled values are based on the worst-case scenarios that account for environmental variables such as seasonal changes in hydrology and chemistry, or if they have only accounted for changes in operational effluent discharge scenarios to consider the upper bound discharge rates. Including the upper bounds of operational effluent discharges regardless of the variability of the receiving environmental conditions is important factor for determining whether the baseline data and risk assessment fully considered the effects of the operations of the proposed mine, including environmental concentrations of the COPCs, on water quality.</p> <p>The Proponent should provide baseline data and a risk assessment that includes consideration of maximum COPC scenarios for the receiving water bodies, including seasonal variability and sediment depositional areas. The Proponent should provide supplemental information to identify if the environmental model has considered environmental variability such as seasonal changes in water levels, flows and sedimentation. The Proponent should also demonstrate that the model has considered a reasonable expected worst case scenario, such as a 100 year return.</p> | |
| IR-195 | - | ECCC | Change to an environmental component due to hazardous contaminants | Appendix 10-A (ERA), Section 3.1.2.1 | <p>Context: Figure 3-2 depicts modelled concentrations of COPCs in the receiving environment surface water during all Project phases. Effluent discharge rates during Operations and Decommissioning are not anticipated to differ significantly. However, COPC concentrations seem to decrease rapidly after the end of the operations period despite effluent releases continuing into the decommissioning phase.</p> <p>Rationale: There has been no information provided on predicted changes in effluent COPC concentrations and discharge rates during the decommissioning phase. It remains unclear how COPC concentrations would decrease so quickly following the end of operations.</p> | <p>1. Provide further information on modelled maximum COPC concentrations for each individual Project phase with estimated timing for peak concentrations to appear in the receiving environment.</p> <p>2. Provide further information on predicted effluent quality during the Project decommissioning phase.</p> <p>3. Update ERA figures and conclusions as needed.</p> | <p>Item one has been partially met. The corrections made to Table 3-3 of Appendix 10-A do not match the values which were submitted as the first round IR response (Tables IR195-1 and IR195-2 (Modelled Maximum COPC Concentrations in Sediment by Individual Project Phase)). The Proponent should confirm which table contains the correct information, and make any necessary corrections to the revised draft EIS with an explanation for the differences.</p> | Not Accepted |
| IR-196 | - | ECCC | Change to an environmental component due to hazardous contaminants | Appendix 10-A (ERA), Section 3.1.2.3 | <p>Context: Table 3-6 provides predicted maximum sediment concentrations of COPCs compared to sediment quality guidelines. Several selected sediment screening values are not the most stringent sediment quality guidelines, with no justification provided. Additionally, copper and lead appear to be missing</p> | <p>1. Provide further information and justification for the selection of less stringent thresholds.</p> <p>2. Update the ERA as needed.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|--|--|---|---|-----------------|
| | | | | | <p>guidelines that are available from the Burnett-Seidel and Liber (2013) study.</p> <p>Rationale: The most stringent guidelines should be used for the sediment quality risk assessment in the ERA. Use of the most stringent guidelines will allow the most protective assessment to analyze risks to the receiving environment, aquatic and terrestrial biota.</p> | | | |
| IR-197 | - | ECCC | Aquatic species | Appendix 10-A (ERA), Section 3.2 | <p>Context: It remains unclear if atmospheric deposition from Project related emissions has been incorporated into modelling for the ERA and surface water and sediment quality assessments.</p> <p>Rationale: While expected Project air emissions are unlikely to have direct impacts on the aquatic receiving environment and aquatic biota, this Project effect pathway may have indirect effects through accumulation of COPCs over time or deposition of contaminants that are not expected in effluent, which should be evaluated with predicted emissions data incorporated into water quality modelling predictions.</p> | Incorporate atmospheric deposition from Project-related emissions into water quality modelling and assess any Project related effects to aquatic receptors from this pathway. | <p>The Proponent is not using the correct CSA standard to address this information requirement. The response refers to guidance from CSA N288.1 (i.e., <i>Guidelines for modelling radionuclide environmental transport, fate and exposure associated with the normal operation of nuclear facilities</i>), however, the information requirement specifies CSA N288.6, which is a different standard.</p> <p>In lieu of requesting information on atmospheric deposition of all contaminants of potential concern (COPC) to surface water and associated effects, the Proponent should:</p> <ol style="list-style-type: none">1. Provide an estimate of atmospheric deposition of mercury (all species) from Project-related emissions. Include a sensitivity analysis as well as expected seasonal variations in the deposition rate with an emphasis on accumulated deposition for the lake ice breakup period.2. Update water quality mercury predictions (all species) for Whitefish Lake using scenario(s) that incorporate atmospheric deposition from Project-related emissions. Based on the findings, assess any Project-related effects to aquatic receptors from mercury (all species). Discuss potential effects on sediment quality.3. Discuss how the response was informed by the CSA N288.6 standard (i.e., <i>Environmental risk assessments at class I nuclear facilities and uranium mines and mills</i>. CSA Group; February 2022). | Not Accepted |
| IR-198 | - | HC | Change to an environmental component due to radiological contaminants | Appendix 10-A (ERA) Appendix B, Tables B.7 and B.8 Ref. 19-2638 Appendix 10-A (ERA), Table 4-3 Ref. 19-2638 (p. 4.17) | <p>Context: Section 10 Appendix 10-A (ERA) contains Table 4-3 (p. 4.17), which lists ingestion rates for traditional foods and includes the category “organs” for Mammals.</p> <p>Tables B.7 and Table B.8 in Section 10 Appendix 10-A (ERA) Ref. 19-2638 provide the predicted concentrations of radionuclides for ecological receptors during the Project phases and during future centuries, respectively. They list the concentrations of radionuclides in moose and in moose organs, which is presented as a single cumulative organ value. Other terrestrial and aquatic animals (such as the black bear and woodland caribou) that are a part of the traditional diet of nearby Indigenous communities have higher concentrations of radionuclides than moose, yet concentrations are not provided for organs of these species.</p> <p>Rationale: While Health Canada is not aware of transfer factors to</p> | <ol style="list-style-type: none">1. Provide more clarification on how the mammalian organ ingestion rates are calculated (which animals and relative contribution percentages).2. Provide a rationale for why concentrations of radionuclides were not assessed in organs of animals (other than moose) that are consumed as country foods by Indigenous people harvesting in the area. | <p>Note To Denison: we are in discussions about this IR being conditionally accepted and a potential commitment.</p> | <u>Accepted</u> |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|--|--|--|----------|
| | | | | | individual organs, or to organs in animals that are not ruminants, it would be beneficial to have a better understanding of radionuclide concentrations in the organs of other animals that may be consumed by local Indigenous communities. | | | |
| IR-198 | IR-198-R1 | HC | Change to an environmental component due to radiological contaminants | Annex 1 Response to Information Requests (Denison Mining) – August 18, 2023 IR-198 Response from Denison – COPC Concentrations in Organs (Pages 74, and 354-357 of 419) Appendix 10-A (ERA) | <p><i>Environmental Risk Assessment for Wheeler River</i> (September 9, 2022) does not include an assessment of radionuclides based on their mass concentrations in country foods (the assessment is only based on radionuclide concentrations).</p> <p>Context: As part of the response to IR-198 estimated Pb-210 concentrations in moose organ and caribou organ of 7.15 and 49.4 mg/kg (ww) are reported, respectively. However, Appendix 10-A: <i>Environmental Risk Assessment for Wheeler River</i> (September 9, 2022) does not include an assessment of lead among the non-radionuclide COPCs.</p> <p>Using the organ meat consumption figure from the Patuanak community (16.2 g/day), exposure to Pb-210 from caribou organ meat is estimated at over 11 ug/kg bw per day (based on the response to IR-198) which would be close to 10 times greater than the 95th percentile dietary lead exposure estimates for the general Canadian population consuming retail foods.</p> <p>Rationale: While the abundance of radionuclides may pose a health risk with respect to radioactivity, their presence as chemical contaminants may also have an impact on health. This is demonstrated by the case of Pb-210 described above. Due to their potential toxicological significance to human health, Health Canada recommends assessing arsenic, cadmium, lead and mercury as part of country food assessment, regardless of the method employed to determine COPCs.</p> | <p>1. Provide a rationale on why radionuclide mass concentrations were not assessed for their impact to human health.</p> <p>2. Provide an assessment of Lead (Pb) as a chemical contaminant (non-radionuclide) COPC to better understand potential health risks and inform management, mitigation, monitoring and/or follow-up planning.</p> | <p><u>Note To Denison:</u> This IR is being conditionally accepted. If Denison commits to monitoring lead and mercury in country foods, as well as including these in any further assessment conducted to determine their potential risk to human health from consumption of country foods, this IR can be resolved.</p> <p>This commitment would include:</p> <ol style="list-style-type: none">1. Establishing/confirming baseline concentrations of Hg in water, sediment, and fish tissues before construction;2. Regular monitoring during construction, operation and post-closure; and,3. Undertaking an HHRA should monitoring results exceed established/confirmed baseline levels, to inform decisions on adaptive management and mitigation measures. <p><i><u>Thise Proposed rationale text for posting:</u> Denison has captured their commitment related to monitoring lead and mercury in country foods, as well as including- <u>arsenic, cadmium, lead, and mercury these</u>-in any further assessment conducted to determine their potential risk to human health from consumption of country foods. This commitment includes <u>(would include)</u>:</i></p> <ol style="list-style-type: none">1. Establishing/confirming baseline concentrations of Hg in water, sediment, and fish tissues before construction;3. Regular monitoring during construction, operation and post-closure; and,4. Undertaking an HHRA should monitoring results exceed established/confirmed baseline levels, to inform decisions on adaptive management and mitigation measures <p><i>This IR has been accepted for the purposes of the current EA process, and the aforementioned issues will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> | Accepted |
| IR-199 | - | ECCC | Change to an environmental component due to hazardous contaminants | Appendix 10-A (ERA), Sections 3.2.1 and 3.3.1, Wheeler River Project IMPACT Model | <p>Context: Model calibrated concentrations of selenium, uranium, and lead- 210 are under-predicted compared to measured baseline concentrations for water quality in the IMPACT modelling based on Figure 3-2. Calibrated concentrations of cobalt are under-predicted and there is poor agreement between model calibrated and measured concentrations of arsenic, lead-210, polonium-210, and radium-226 for sediment quality in Figure 3-3.</p> <p>Rationale: It is unclear how poor agreement between model calibrated and measured baseline concentrations of COPCs impacts the near-field and far-field modelling predictions of COPCs during all Project phases. It is also unclear why measured concentrations of COPCS could not be used directly as model inputs when there was poor agreement.</p> | <p>1. Provide justification as to why model calibrated concentration inputs of COPCs were preferable for use in predictive modelling of water and sediment quality over measured baseline concentrations.</p> <p>2. Provide a rationale detailing how under- or over-predicted model calibrated COPC concentration inputs influence IMPACT model predictions and uncertainty for water and sediment quality. Provide specific details on how this may impact the risk analysis for parameters that have been highlighted as having poor agreement between calibrated and measured concentrations (i.e., arsenic, selenium, uranium, lead-210, polonium-210, and radium-226).</p> | <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>The Proponent has not fully responded to either item for this IR. In the response for item one, the table provided in the response supports the statement added to Section 3.2.1 of Appendix A from Appendix 10-A, that there is little difference between the geometric and arithmetic means for parameter concentrations in water. It is important to clarify if this is also the case for sediment. Apart from arsenic and radionuclides, all modelled sediment concentrations are at or below geometric mean for sediment. Given that geometric means are typically lower than arithmetic means (and at most equal) this might indicate a consistent underestimation by the model for parameter concentrations in sediment. The proponent indicates that the geometric mean is more representative of the central value of the data distribution. ECCC does not support this view because a median or mode would be used to find a central value,</p> | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|-----|----------------------|---|-----------------------|------------------------------|--|--------|
| | | | | | | | <p>depending on what was meant. The geometric mean may have been used because it is less influenced by outlier values, but these should be analyzed and removed if necessary before calculating the mean, as described in Section 6.3.3.6 of CSA N288.6:22. The only reference to geometric means in CSA N288.6:22 is for calculating means of literature values. Otherwise, when considering field data, an arithmetic mean is referred to.</p> <p>Typically, parameter concentration statistics are calculated individually for each site to highlight differences and help identify more sensitive sites. Differences between sites are expected because of differences in lake size, catchment area and other environmental factors. Pooling data from all sites smooths out high and low values, which compounds the smoothing done by using a geometric mean. This reduction in precision causes unreliability when evaluating model predictions, since the range of parameter concentrations at baseline is not well characterized.</p> <p>To address the lack of clarity, the Proponent should provide a table comparing arithmetic and geometric means for parameter concentrations in sediment, as they have done for water concentrations. If differences are significant, then modify graphs in Figure 3-3 of Appendix A from Appendix 10-A to compare arithmetic means of baseline data with modelled results. For parameters with sufficient data to calculate meaningful statistics, the Proponent should demonstrate that concentrations in Russell Lake are not significantly different than those in McGowan and Whitefish Lakes. If water quality is significantly different between lakes, then the Proponent should modify graphs in Figure 3-2 of Appendix A from Appendix 10-A to compare lake-specific baseline and modelled concentrations.</p> <p>In the response to item two, the statement “<i>it is not appropriate to calibrate the model to baseline conditions as we are most interested in impacted conditions</i>” is incorrect, because the point of calibration is to demonstrate the model correctly simulates site conditions to predict concentrations. Inaccurate model predictions during baseline indicate the site and its system of interactions is not well understood, and the model would not be able to produce accurate predictions during operations either. Section 7.3.6 of CSA N288.6:22 states “<i>The models may be calibrated to give the best possible agreement with available monitoring data so that risk assessors can have confidence in model-predicted concentrations for areas and media that are poorly represented in monitoring programs.</i>” The monitoring data is insufficient to characterize baseline concentrations for most of the parameters in water since there are often less than 50% of samples with concentrations above the detection limits. This limits the parameters that can be used to evaluate the model to concentrations in water of chloride, sulphate and arsenic, as well as concentrations in sediment. The Proponent should demonstrate the accuracy of the model by comparing model outputs with measured concentrations for those parameters where there is sufficient data to calculate meaningful averages, quantify model uncertainty, and discuss the influence of uncertainty on risk assessment conclusions.</p> <p>Denison is expected to:</p> <ol style="list-style-type: none">1. Calculate the model to baseline conditions, compare arithmetic and geometric means for parameter concentrations in sediment;2. Calibrate model to baseline conditions;3. Calculate parameter concentration statistics individually for each site; and4. Modify graphs as needed if significant differences are observed. | |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|-----|---|--|--|--|----------------------|----------|
| IR-200 | - | HC | Indigenous Peoples' health / Socio- economic conditions | Section 10 (p. 4.10) Appendix 10-A (ERA), Table 4-4 (p. 4.19) | <p>Indigenous consultation should be included in the Country Foods analysis.</p> <p>Context: The Proponent obtained country food consumption data through engagement with a single local fisher/trapper and from a dietary survey administered by CanNorth to the English River First Nations (ERFN) in 2017. However, the potential health risks to consumers of traditional food were only assessed using the data obtained from the CanNorth dietary survey. Section 10 of the EIS <i>states the following</i>: “The diet assumptions for the fisher/trapper are conservative and are based on engagement with a local fisher/trapper. The diet of the fisher/trapper is representative of one person, who consumes a unique composition and quantity of traditional foods (e.g., ingestion rate of 175 kg/yr of caribou, equivalent to approximately 2 to 3 servings per day). Most people fishing, hunting, and trapping in the Local Study Area and Regional Study Area would consume traditional foods more consistent with the average traditional foods consumer diet which was developed from the ERFN country foods study. In comparison, the ERFN country foods study in Section 10 Appendix 10-A (ERA) Table 4- 4 indicates a caribou ingestion rate of 2.6 kg/yr (1 to 2 servings per month) and a total game ingestion rate of 21.3 kg/yr” (p. 4.10).</p> <p>Rationale: Health Canada is in general agreement that the dietary habits of the local fisher/trapper may be an outlier and not necessarily representative of most of the local population. However, a rationale has not been provided to demonstrate whether and how the 2017 ERFN dietary survey results are representative of consumption patterns of local Indigenous communities. Also, it is unclear whether or how the ERFN dietary survey results account for the consumption patterns of vulnerable or more sensitive subgroups (e.g., heavy consumers, children and women of child-bearing age)</p> | <p>1. Evaluate the suitability of using the 2017 EFRN survey results and consider surveying additional community members (such as local hunters/trappers) to obtain more representative country food consumption rates for use in the traditional foods risk assessment, and for communicating the results to the communities.</p> <p>2. Additionally, consider evaluating consumption patterns (and applicable TRVs) of sensitive or vulnerable populations (e.g., elders, toddlers, women of childbearing age) in the traditional food risk assessment and provide risk levels for these sub-groups separately.</p> <p>Suggestions for mitigation and follow-up measures: Health Canada recommends providing the community with the opportunity to validate the ERFN 2017 survey results.</p> | | Accepted |
| IR-200 | IR-200-R1 | HC | Indigenous People'' health / Socio- economic conditions | Section 10 (p. 4.10) Appendix 10-A (ERA), Table 4-4 (p. 4.19) IR-200 Response from Denison | <p>The traditional foods risk assessment should be updated to include an “Intense Land User” scenario and consider all relevant sub-groups.</p> <p>Context: See ‘Rationale for Status’ in IR-200</p> <p>Rationale: Health Canada notes that the response to IR-1 confirms that the use, diet and consumption rates used to assess the “Trapper” receptor are representative of “intensive land users” from the ERFN and possibly others. This change in the assumption is significant and should be integrated into the traditional foods risk assessment. Suggestions and follow-up measures have been provided to assist in responding to this information request, which benefits from the clarity provided in response to IR-1.</p> <p>Health Canada also notes that the response to IR-200 did not consider evaluating consumption patterns (and applicable TRVs) of</p> | <p>1. Update assumptions used in the risk assessment to reflect the new information provided in response to IR-1. (e.g., the <i>ERFN Trapper’s use of the area as representative of current and future land users</i>).</p> <p>2. Update the risk assessment in the EIS and ERA for the “Trapper” receptor (i.e., Intensive Land Users) to account for the representative nature of their described diet (i.e., consumption rates and composition).</p> <p>3. Update the rationale and decisions related to management, mitigation, monitoring and follow-up. Include a specific discussion for those COPCs that contribute to elevated health risks among “intensive land users” and those raised by Indigenous communities (i.e., selenium, mercury & cadmium).</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|--|--|--|---|----------------------|----------|
| | | | | | sensitive or vulnerable populations (e.g., elders, toddlers, women of childbearing age) in the traditional food risk assessment and provide risk levels for these sub-groups separately. | 4. Revise receptor’s descriptor/title from “Trapper” to “Intensive land users” throughout the EIS and ERA to be consistent with proposed revisions made in response to IR-1. Consider evaluating consumption patterns (and applicable TRVs) of sensitive or vulnerable populations (e.g., elders, toddlers, women of childbearing age) in the traditional food risk assessment and provide risk levels for these sub-groups separately. Alternatively, provide a fulsome rationale to justify their exclusion. | | |
| IR-201 | - | ECCC | Aquatic species | Appendix 10-A (ERA), Section 5.0 | Context: For the ERA methodology the Proponent followed CSA N288.6-12 for the assessment of risk to aquatic biota from radionuclide and non-radionuclide COPCs. This is the 2012 version, and a more recent 2022 version was publicly released. Rationale: The Proponent should review the most up-to-date version of the standard to ensure no changes to the methodology of the COPC exposure assessment are required for the ERA. | Update the COPC exposure assessment methodology in the ERA using the most recent CSA N288.6-22 standard, as needed. | | Accepted |
| IR-202 | - | CNSC | QA/QC | Appendix 10-A (ERA), Section 6.0- Quality Assurance | Context: This section provides only Quality Assurance (QA) of the ERA, including planning and preparation of the ERA. Rational: The Quality Control (QC) aspects are not included. Both QA and QC aspects provide confidence that ERA results are defensible and fit for use in decision-making. The N288.6 (Clause 10.2) requires that “Appropriate QA/QC requirements shall exist for all aspects of the ERA and should be specified prior to conducting the ERA”. | Please include appropriate QC aspects, as per a Clause 10.2 of the N288.6. | | Accepted |
| IR-203 | - | CNSC | Sediment Quality and Benthic Invertebrates | Appendix 10-A (ERA), Section 6.2 Future Centuries Sensitivity Analysis | Context: This section of the ERA states “If treated effluent was released at the maximum upper bound discharge rate, the modelled concentrations of all COPCs are expected to be below their corresponding sediment quality guidelines.” It appears from Figure 6-2: “Comparison of maximum concentrations of COPCs in sediment at expected and upper bound discharge rate” that cadmium and vanadium would be over their sediment quality guidelines indicated if maximum upper bound discharge rates are used. Rationale: It is not clear which is correct; the statement that no exceedances of sediment quality guidelines when considering the maximum upper limit effluent release, or the figures indicating there could be exceedances for cadmium and vanadium. This discrepancy in the ERA should be explained and corrected. | Please provide clarity on if cadmium and vanadium are expected to be over the sediment quality guidelines for the maximum upper bound discharge rate scenario. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|--|---|---|----------|
| IR-204 | - | CNSC | Human health with respect to hazardous contaminants | Appendix 10-A (ERA), 7.1.1, Non-radiological Human Health Risk Assessment | <p>Context: In the human health risk assessment of the non-radiological COPCs, it was determined that the Project incremental HQ was predicted to remain below 0.2 for all non-carcinogens and all pathways during all phases of the Project, except for selenium for the fisher/trapper at Russell Lake from the fish ingestion pathway.</p> <p>Rationale: Given that the fisher/trapper receptor will likely be exposed to higher concentrations of selenium from the consumption of fish at Russell Lake, there is an elevated risk of selenosis in exposed individuals. This potential for selenosis would be further exacerbated in individuals who consume fish taken from other lakes closer to the mining operation. There is, however, no discussion of mitigation of these risks to exposed individuals.</p> | <p>Please provide a discussion of measures that could be applied to mitigate the risk of selenosis in exposed individuals who consume fish from Russell Lake and other waterbodies closer to the mining operation.</p> <p>Suggestions for mitigation and follow-up measures: CNSC recommends the following:</p> <ul style="list-style-type: none">Selenium abatement technologies may be considered to eliminate or reduce selenium in effluent entering the lake system.If HQs continue to exceed 0.2, then it may be necessary to post fish consumption advisories, in consultation with the Medical Officer of Health for the jurisdiction where the Project is located. | | Accepted |
| IR-205 | - | CNSC | Geology and Groundwater | Section 7, appendix H | <p>Context: In this appendix the analytical concentration of various groundwater samples taken from monitoring wells is reported.</p> <p>Rationale: There is one sample labeled as “Tracer Tank” with no definition available in the current report. It is difficult to judge whether the results presented are relevant to the EIS and how it may impact the findings therein.</p> | <p>Please clarify the definition of “tracer tank”.</p> | | Accepted |
| IR-206 | - | CNSC | Current use of lands and resources for traditional purposes | Section 11 Section 12 Section 15 Section 16 | <p>Context: Impacts to Lands and Resources Use have been identified by Indigenous Nations and communities.</p> <p>Rationale: Additional information is required to demonstrate whether Indigenous Nations and communities were engaged directly by Denison regarding the cumulative effects assessment, significance determination and residual effects, and thus the overall conclusions on potential adverse impacts of the Project on the potential or established Indigenous and/or treaty rights and effects of changes to the environment on Indigenous peoples, pursuant to paragraph 5(1)(c) of the CEAA 2012.</p> | <p>Please describe any outstanding or residual issues or concerns raised by Indigenous Nations and communities that Denison was unable to address. In addition, outline any plans to find solutions or continue discussions with the potentially impacted Indigenous Nations and communities.</p> | | Accepted |
| IR-207 | - | CNSC | Current use of lands and resources for traditional purposes | Section 11, Perceived Risks to Lands and Resources | <p>Context: The EIS states: “Resource users may also experience changes in their perception of the quality of resources for consumption such as the palatability of fish or wildlife or have apprehensions about the safety of resources for consumption. These changes may affect the patterns of ILRU during all Project phases including Post Decommissioning. The ERFN refer to this indicator as a “psycho-social’ effect, meaning that even if people know their fears are “<i>perceived fears, the fear ... is real and has real impacts on ERFN members’ perception of their overall health and well-being</i>” (ERFN and SVS 2022a).” (p. 11-11)</p> | <p>How does Denison plan to work directly with Indigenous Nations and communities who currently use the potentially impacted areas, including the RSA, to mitigate and monitor the perceived risks and/changes to the RSA?</p> <p>Has Denison had discussions with the potential impacted Indigenous Nations and communities on how fear and avoidance behaviors and related impacts on traditional land use will be mitigated, especially within the RSA?</p> <p>Additional information is needed to determine if Denison has engaged directly with the Indigenous Nations and communities to develop potential mitigation measures to address fear and</p> | <p>Response is accepted, but also see AD-60 in the Advice to Proponent table.</p> | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|--|---|----------------------|----------|
| | | | | | <p>Resource harvesters may experience Project-related disturbances and, depending on how these changes are perceived, it may cause some resource harvesters to avoid the Project Area.</p> <p>Reductions in harvests may occur based on fear or uncertainty about the ongoing quality of country foods. For example, <i>“People stopped picking berries in this area when Key Lake mine was established because of concerns about health impacts”</i> (ERFN and SVS 2022b).</p> <p>Rationale: CNSC’s Generic Guidelines for the Preparation of an EIS state: “The EIS will document specific suggestions raised by Indigenous groups for mitigating the effects of changes to the environment on Indigenous peoples (section 5(1)(c) of CEAA 2012). For the mitigation measures intended to address the effects of changes to the environment for Indigenous peoples, the Proponent must discuss the residual effects with the Indigenous groups prior to submitting the EIS.”</p> <p>These changes may affect the patterns of ILRU during all Project phases including Post Decommissioning.</p> | <p>avoidance impacts, such as a community monitoring program, which could help to reduce the perceived risk to lands and resource use through education, collaboration, and long-term monitoring with Indigenous Nations, in order to build trust.</p> <p>Suggestions for mitigation and follow-up measures: It is recommended that Denison consider engaging with potentially impacted Indigenous Nations and communities on the collaborative development and implementation of a monitoring program to help address concerns about potential impacts on lands and resources as a result of the Project. The program(s) could help to monitor changes over time related the potential perceived risk of contamination of the land from Project activities and subsequent effects on the quality of fish, vegetation, and wildlife resources, which in turn could affect the safety of traditional foods and human health, and impacts on culture practices, and overall community well-being that travel to region yearly.</p> | | |
| IR-208 | - | CNSC | Indigenous physical and cultural heritage | Tables 11.1-3, 11.1-4 and 11.1-5 Section 11.1.3.2.6 | <p>Context: Black bear is listed as a species hunted by several Indigenous nations, including Pinehouse residents. CNSC participated in an in-person engagement with Pinehouse residents in October 2022 and bears eating waste was identified as a concern for hunting and consumption.</p> <p>Rationale: Perceived risk of eating animals that are contaminated by hazardous or radiological wastes could deter community members from harvesting animals that are normally part of their traditional diet. Fencing for waste was specified as a deterrent for human trespassers, not animals.</p> | Please specify measures that Denison will take to ensure bears and other animals do not scavenge from waste facilities. | | Accepted |
| IR-209 | - | CNSC | Indigenous Peoples' health / Socio-economic conditions | Section 12.1.4.2.1 (p. 12-22) Section 12.1.5 Section 12.1.6.2 | <p>Context: KML indicates that working at a mine camp could inhibit community members from participating in cultural activities and sharing them with family and community members, resulting in a loss of cultural knowledge and language, thus impact knowledge transmission (p. 12-22).</p> <p>Rationale: Denison addresses this by briefly identifying culturally sensitive policies which would eliminate residual effects (p. 12-30)</p> | Please provide detailed proposed mitigation measure for KML’s concerns related to loss of cultural knowledge and language should they work for Denison. | | Accepted |
| IR-210 | - | CNSC | Current use of lands and resources for traditional purposes | Section 12.1.4.2.2, Potential Effect 2: Change in Traditional Diet, Perceived Suitability | <p>Context: The EIS states: “Project activities could change the perceived suitability of country foods. An ecological risk assessment (ERA) was conducted to consider both radiological and toxicological risks to ecological receptors such as terrestrial and aquatic invertebrates, terrestrial and aquatic vegetation, fish, and</p> | Given concerns with psycho-social impacts and the influence of perception discussed by ERFN earlier on in the EIS, does Denison have information on the perspectives from Indigenous Nations and communities to validate this conclusion is applicable? | | Accepted |

|--------------|----------------|------|----------------------------|---|--|---|----------------------|----------|
| | | | | of Country Foods (p. 12-26) | <p>terrestrial and aquatic mammals and birds. Results for the radiological assessment predicted no exceedances of the radiation dose benchmark for the ecological receptors. For non-radiological COPCs, no exceedances were predicted except for selenium in fish from Russell Lake, based on a conservative dietary assumption for one resource user. The traditional foods diet for the fisher/trapper is conservative as it assumes that their annual fish consumption (183 kg of fish per year) would be obtained from Russell Lake, meaning the exceedance of the benchmark for selenium from fish would only occur if fish were only sourced from this one lake. This one exceedance could potentially change the perceived safety of country foods for community members and make country foods a less desirable part of a traditional diet.</p> <p><u>Experience from other uranium operations in northern Saskatchewan suggests that resource use will continue despite the potential selenium exceedance. An examination of members of the Hatchet Lake Denesų́łné First Nation who live in Wollaston Lake near the Rabbit Lake operation found that over years of being active on the landscape both with and without the presence of the uranium industry, members had developed their own culturally appropriate practice of risk assessment and management based on their relationship with the land. Hatchet Lake Denesų́łné First Nation members appear to be more concerned with the direct effects of uranium mining on the local environment and less concerned about uranium mining’s effects on their health through consumption of plants and animals. This is likely due to their high level of confidence in recognizing affected plants and wildlife and avoiding them (Elias et al. 1997).</u></p> <p>The usage patterns of the ERFN Trapper have similarly allowed for continued use and access to areas proximal to other uranium operations. The ERFN Trapper had a positive relationship with other uranium operations in the ILRU LSA. He also continued to trap (i.e., used his trapline in Fur Block N-18), fish, and opportunistically pick berries, and consumed those resources during operations (KPI Program 2021). Good relationships between Denison and a new trapper who eventually takes over the trapline from the ERFN Trapper would promote continued use.” (p. 12-26)</p> <p>Rationale: The underlined reference suggests that negative perceptions may not prevent traditional resource users from continuing to consume, due to adaptation to potential risks in the environment.</p> | | | |
| IR-211 | - | CNSC | Accidents and Malfunctions | Section 14.6.1, Bounding Scenario | Context: Scenario 1 describes a spill of uranium concentrate into the lake. It’s not clear how the ecological risk assessment was | Please clarify why grouse, vole, and deer were chosen as receptors for the ecological risk assessment performed for | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|-----|---|---|--|---|----------------------|----------|
| | | | | 1, Vehicle Accident and Aquatic Release of Radioactivity | <p>performed. It is stated that sediment concentrations in post-remediation conditions are expected to exceed the benthic invertebrate benchmark and that these results indicate that a spill of uranium concentrate could potentially affect benthic invertebrate populations following a spill, but the spatial extent would be limited. For water, it is stated that when evaluating the potential effect, a comparison was made between the results of the estimated short-term water quality 1,892 µg/L (1.892 mg/kg) and the guideline (33 µg/L). This indicates that there may be some aquatic species that could be affected, but the effects are expected to be transient as the water concentration quickly drops to a long-term level of 0.19 µg/L. However, when looking at dose to other receptors, the results of the ecological risk assessment indicated short-term ingestion of contaminated water resulting from an accident would not result in potential risks to grouse, vole, or deer, however rationale for how these receptors were chosen is not provided.</p> <p>Rationale: It’s not clear from the EIS, why the receptors grouse, vole, and deer were chosen to evaluate ecological effects from a potential spill, and why they differ from receptors in the ERA. It is also not clear if the pathway from sediment ingestion/contact was considered for semi-aquatic receptors as they could be exposed to the increased concentrations post-spill. It is also not clear if SARA species exposure to sediment and water post-spill was considered.</p> | accidents and malfunctions scenario 1 and clarify if the sediment pathway to receptors post-spill was considered, as well as if SARA species were considered. | | |
| IR-212 | - | HC | Human health with respect to hazardous contaminants | Section 14 (p. 14-3) Appendix 16-C (p. 14 & 15) | <p>The follow-up plan does not sufficiently describe how various parties will be engaged in the design, implementation, and review of monitoring programs.</p> <p>Context: Section 14 of the EIS states that “The overarching fear of contamination from the mine is woven in to almost every other concern noted by participants in the TK study. It is worth acknowledging this concern separately given the potential for mental health impacts related to people’s experiences of fear and anxiety” (p. 14- 3).</p> <p>The commitment regarding monitoring and follow-up activities appears limited to “<i>shar[ing] information in a transparent manner with the General Public, and specifically those Communities of Interest and Nearby Land Users with whom Denison is regularly engaging about the Project. Such an information-sharing program would consider the involvement of the Regulators to make sure the information available addresses the issues identified as concerns</i>” (p. 14).</p> <p>Rationale: Country food safety is not regulated federally unless foods are sold commercially. Certain aspects of country food safety</p> | <p>1. Provide details of how local, provincial and federal authorities, and Indigenous Nations and communities will be engaged in developing the follow-up and monitoring program, including the information-sharing program.</p> <p>2. Describe the steps that will be taken if there are any exceedances of established benchmarks or deviation from predictions.</p> <p>Suggestions for mitigation and follow-up measures: Health Canada recommends that the Proponent’s plan for communicating follow-up results (environmental and country foods) aims at, among other things, responding to community concerns regarding country foods to minimize avoidance of this resource. This goes beyond a passive dissemination of information and developing a strategy based on dialogue and the direct involvement of communities in monitoring, surveillance, and risk communication activities.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------------|---|---|---|----------------------|----------|
| | | | | | and availability may be covered by provincial regulators. It is unclear whether and how various levels of government and potentially affected communities would be involved in the development of the follow-up and monitoring program. It is also unclear what the information sharing program entails and how it would inform any adaptive management if monitoring results deviated from the prediction | | | |
| IR-213 | - | CNSC | Accidents and Malfunctions | Section 14.5.3 Appendix 14-A | <p>Context: The Proponent states that the assessment of accidents and malfunctions began with the initial identification of hazard scenarios. Hazard scenarios were identified using a systematic approach that considered the existence of sources of hazards and initiating events for the Project in consideration of Project activities and components.</p> <p>The hazard identification was conducted to identify a comprehensive list of potential project-related accident and malfunction scenarios associated with the key project components and activities with further details provided in Appendix 14-A. The initial hazards were then screened qualitatively based on likelihood and consequence to determine overall risk level using a risk matrix approach. Bounding scenarios were then selected from this initial list of hazard scenarios.</p> <p>The results of numerical analyses (RESPEC, 2021) of detailed strip model suggest that the deformation imposed on the cemented steel casing from downward movement of the rock mass may exceed the assumed casing-strain yield limits and the failure limit locally after extracting the uranium ore. However, this potential hazard is not identified in the hazard identification.</p> <p>Rationale: Exceedance of steel casing yield limits and failure limit would either compromise the steel casing integrity or damage the steel casing and result in the leakage of injected solution, which could impact on mine operation and contaminate the surrounding groundwater.</p> | Please include the hazard of steel casing yield or damage in the table of hazard identification evaluation and conduct an initial risk screening and further detailed assessment as required. | | Accepted |
| IR-214 | - | CNSC | Accidents and Malfunctions | Section 14.5.3 Appendix 14-A, section 3.2.3 | <p>Context: Hazard scenarios were identified using a systematic approach that considered the existence of sources of hazards and initiating events for the Project in consideration of Project activities and components. Details for how each of these project components and activities are considered in the initial hazard scenario identification process are provided in the accidents and malfunctions TSD (see Appendix 14-A; Ecometrix 2022).</p> <p>However, in Table 3-1 to Table 3-14 in Appendix A of Appendix 14-A, the following inconsistencies were identified:</p> <ol style="list-style-type: none">consequences for the hazards ID# 1.1, 1.5, 1.7, 14.2 include occupational major injuries; however, the severity | Please clarify or correct all inconsistent and/or inaccurate information in Tables 3-1 to 3-14 in Appendix A of Appendix 14-A. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|--|--|----------------------|----------|
| | | | | | <p>(S) is denoted as number 2 that appears to be inconsistent with consequence rating number in Figure 14.5-2</p> <p>ii. Hazard ID# 1.5 has a L=2, but it is described as a highly unlikely event, which is inconsistent with the term in Figure 14.5-2</p> <p>iii. Hazards ID# 3.6 and 3.7 have a L=1, but they are described as low probability event that is inconsistent with the term in Figure 14.5-2</p> <p>iv. Hazards ID# 8.2, 8.3, 9.1, 10.1 to 10.5, 11.1, 11.5 have a L=1, but they are described as unlikely events, which are inconsistent with the term in Figure 14.5-2. Rationale needs to be provided how stockpile erosion is considered to have a L=1</p> <p>v. Hazard ID# 12.1 has a L=2 and S=3, but it's risk ranking is moderate, which is inconsistent with the term in Figure 14.5-2</p> <p>vi. Hazard ID# 13.3 has a L=2. Based on the operation experience in the similar projects in the northern Saskatchewan, ponds lining failure and leakage is a very likely event. Rationale needs to be provided to support L=2 or change the number for L.</p> <p>Rationale: Inconsistent or inaccurate/incorrect information was included in Accidents and Malfunctions assessment.</p> | | | |
| IR-215 | - | CNSC | Human health with respect to hazardous contaminants | Section 14.6 | <p>Context: One of the potential risks of a uranium mine and mill is a spill of untreated effluent.</p> <p>Rationale: In the EIS, it doesn't appear that the scenario of a spill of untreated effluent to the environment has been considered.</p> <p>A failure of the piping containing the untreated effluent could result in an uncontrolled release to the environment and could affect the groundwater, soil quality, and terrestrial biota.</p> | Please evaluate and provide the results for a bounding scenario of a spill of untreated effluent or provide justification for its exclusion. | | Accepted |
| IR-216 | - | CNSC | Human Health with respect to radiation exposure | Section 14.6.1 Section 14.6.7 Appendix 14-A | <p>Context: Radiological doses to human receptors, including workers (i.e., driver(s) of the vehicles), from the Bounding Scenarios 1 (Vehicle Accident Including Rollover, Collision, Run Off Road) and 7 (Vehicle Accident Including Rollover, Collision, Run Off Road) have not been assessed.</p> <p>Rationale: An estimate of the effective doses to human receptors, including workers, are required to determine whether the expected doses meet the dose limits set out in the Radiation Protection Regulations.</p> | Provide estimates (including calculations) of the potential radiological doses to human receptors, including workers, resulting from Bounding Scenarios 1 and 7. | | Accepted |
| IR-217 | - | CNSC | Accidents and Malfunctions | Sections 14.6.1 and 14.6.2 | <p>Context: Highway 914 crosses the Wheeler River 10 km southwest of the access road junction. A vehicle accident, including a rollover,</p> | Please provide information on all water crossings along the transportation corridor and justification why bounding scenarios | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------------|--|---|---|----------------------|----------|
| | | | | | <p>collision, or run off road, at or near the bridge could potentially result in a release of uranium concentrate and release of fuels and chemicals into the surface water at this location. Denison believes that a release of uranium concentrate and a release of fuels and chemicals at this location would bound the releases at any other water crossing along the transportation corridor. However, no information on what other water crossings along the transportation corridor exist and how bounding scenarios 1 and 2 would bound the risk of releasing uranium concentrate and fuels and chemicals at other crossings.</p> <p>Rationale: The release of uranium concentrate and fuels and chemicals at water crossings would contaminate the water body at the crossings and pose a risk to the environment and public health.</p> | <p>1 and 2 would bound the effects of the accidental releases of uranium concentrate and fuels and chemicals at these crossings.</p> | | |
| IR-218 | - | CNSC | Accidents and Malfunctions | Sections 14.6.1.1 and 14.6.1.4 | <p>Context: Table 14.6-1 indicates that the average flow of Wheeler River south of Russel Lake is 17,340 L/s or 17.34 m3/s. This rate is used for uranium dissolution rate calculation. However, in section 14.6.1.4, it states that the average annual flow is 24.3 m3/s. In Table 14.6-3, the last two rows appear to be added wrongly.</p> <p>It also states that sediment quality results are shown in Table 14.6-5 for post-remediation conditions. During minimum flow conditions, the affected volume is expected to be smaller, resulting in a higher sediment concentration. In comparison, higher flow conditions are expected to result in a greater footprint and lower concentrations. However, in Table 14.6-5, the average sediments concentration and porewater concentration appear to be incorrect and switched between average flow and maximum flow.</p> <p>Rationale: Inconsistent/inaccurate information provided in the EIS.</p> | <p>Please clarify and correct the inconsistent information on average flow rate of Wheeler River at the crossing and incorrect information in Table 14.6-3, and average sediment concentration and porewater concentration under average and maximum flow conditions in Table 14.6-5.</p> | | Accepted |
| IR-219 | - | CNSC | Accidents and Malfunctions | Sections 14.6.1.1.1 and 14.6.1.4.1; Sections 5.1.1 and 8.1 of Appendix 14-A | <p>Context: When assessing the release characterization of Bounding Scenario 1, the Proponent assumed that 95% of the released uranium concentrate can be recovered from the release location without sufficient justification, and that different water column depths, i.e., 10 cm and 5 cm, and average water depth of 1.2 m at the release location were used without explanation.</p> <p>Rationale: As the recovery rate of the uranium concentrate would have an impact on the assessment of its potential effects, it is necessary to understand how the recovery rate and water level were selected for assessing this bounding scenario.</p> | <p>Provide further rationale for assuming 95% recovery rate and for using different water column depths for uranium concentrate release characterization.</p> | | Accepted |
| IR-220 | - | CNSC | Accidents and Malfunctions | Section 14.6.1.1.1 Appendix 14-A, Section 5.1.1 | <p>Context: The Proponent states that based on drum deformations performed in a previous analysis (McSweeney et al. 2004), if a drum experienced a crush force of 100,000 lbs., then the deformation of the drum would cause the lid to detach from the</p> | <p>Please provide information and/or rationale as to whether drum stacking would impact drum failure at different speeds and confirm whether 55% drum fail for such an accident is still valid.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------------|---|---|---|----------------------|----------|
| | | | | | <p>drum. Using this drum failure mechanism, and assuming the drums weigh 450 kg and are arranged four across in the truck, at a speed of 48 km/h, the front 25% of the drums would fail, at 60 km/h to 97 km/h 55% would fail, at 145 km/h 75% would fail, and at ≥193 km/h all would fail. Given that the speed of the truck is likely between 60 km/h to 97 km/h, it was concluded that less than 55% of the drums would fail upon a traffic accident scenario.</p> <p>It is assumed to be 40 drums per shipment, so some stacking or rows of drums should be expected in this scenario. The drums stacked above could be at greater risk of deformation in a traffic accident. It is not clear whether drums stacking was considered in the previous study cited by the Proponent and whether less than 55% fail is still an adequate percentage of drum failures in such traffic accident scenarios if drums stacking is needed.</p> <p>Rationale: Drum failure percentage will impact the release quantity of uranium in such an accident scenario and then impact the consequence assessment. Therefore, the drum failure should be adequately assessed and supported with sufficient information and justification.</p> | | | |
| IR-221 | - | CNSC | Accidents and Malfunctions | Section 14.6.1.3, Appendix 14-A, Section 7.1 | <p>Context: It is projected that there would be about 100 drums packaged per mill operating day. One trip per day for 330 days per year is assumed for the probability evaluation. This means 100 drums per trip, which is inconsistent with description in section 14.6.1.1.1 where assuming 40 drums in one shipment per day.</p> <p>Rationale: Shipments per day will impact the probability evaluation, and number of drums per trip will impact the release of uranium during an accident.</p> | Please clarify the number of shipments per day and number of drums per shipment that are expected and re-calculate the probability as necessary. | | Accepted |
| IR-222 | - | CNSC | Accidents and Malfunctions | Section 14.6.2.4 | <p>Context: Bounding Scenario 2 consists of the aquatic release of fuel and hazardous chemicals due to traffic accidents. The EIS states that amongst the fuels considered for this scenario, the consequences of the release of gasoline and solvents are bounded by the consequences associated with the release of diesel. Both gasoline and solvents are lighter with higher vapour pressure; therefore, they have a shorter half-life in the aquatic environment and a lesser tendency for adsorption to sediments and suspended solids in the water column. There is no other justification provided to show that the release of diesel can bound other chemicals such as sulfuric acid and sodium hydroxide that are heavier than diesel.</p> <p>Rationale: The release of either sulfuric acid or sodium hydroxide during accident could change the water PH significantly at the releasing location, which would post a negative impact on the local environment.</p> | Please provide further justification that the consequences of the release of sulfuric acid and sodium hydroxide can be bounded by the consequences associated with the release of diesel. | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|--|---|----------------------|----------|
| IR-223 | - | CNSC | Accidents and Malfunctions | Section 14.6.4.1 Appendix 7-A, Appendix K | <p>Context: The EIS states that the 3D strip numerical model predicted that stresses and displacements did not show instability in the altered sandstone or basement rock at the location where a freeze wall would be placed around the Phoenix Deposit boundary (RESPEC 2021). The potential damage to the freeze wall due to mine-induced stresses and displacements under this scenario is excluded.</p> <p>Rationale: One outer section of the freeze wall (i.e., north-east freeze wall of the phase 4 mining area) and some internal cross walls are located in the desilicified zone. The RESPEC 2021 report (i.e., Appendix K of Appendix 7-A) appears not to have included the desilicified zone in the geomechanical modeling, nor is provided the stresses and the displacements/deformation of the area northeast of the phase 4 ore body where a significant extent of the desilicified zone exists.</p> | <p>Please provide information on the stresses and displacements/deformation of the area northeast of the phase 4 ore body from the geomechanical studies to demonstrate the resulted stresses and displacements will not impact on the freeze wall integrity after IRs for geomechanical studies for ore extraction are addressed.</p> <p>Technical Discussion Required: Yes</p> | | Accepted |
| IR-224 | - | CNSC | Human Health with respect to radiation exposure | Section 14.6.5.4 Appendix 14-A | <p>Context: For the Bounding Scenario 5 (Process System and Piping Failure), doses to receptors at distances of 100 and 500 metres (0.25 and 0.01 mSv respectively) are predicted. The assessment also indicated that the dose to the unprotected worker staying inside the processing plant during the spill could exceed the 50 mSv dose limit specified by CNSC if workers did not leave the area quickly after the spill.</p> <p>The Proponent did not provide the dose calculations for deriving the dose estimates.</p> <p>Rationale: The method used to estimate effective, equivalent, and committed dose is required to be verified. Sample dose calculations should be included, to confirm use of acceptable input data.</p> | <p>Provide the dose calculations for deriving the dose estimates for workers and members of the public for Bounding Scenario 5 (Process System and Piping Failure).</p> | | Accepted |
| IR-225 | - | CNSC | Human Health with respect to radiation exposure | Section 14.6.5.4 Appendix 14-A | <p>Context: With the Bounding Scenario 5 (Process System and Piping Failure), the Proponent states that Denison ensures that the process is designed to include control measures to reduce the exposure to both workers and members of the public as low as achievable. The measures would ensure that the processing plant is adequately ventilated, and that spills or leaks are detected by loss of system pressure, observation, or flow imbalance.</p> <p>It is not indicated where these additional measures have been detailed/elaborated within the EIS.</p> <p>Rationale: Control measures to reduce the exposure to both workers and members of the public as low as achievable, that are identified in the assessment of Bounding Scenario 5, must be formally documented to ensure that they are carried over into the engineered design of the processing plant.</p> | <p>Provide details on how the control measures to reduce the exposure to both workers and members of the public, identified in the assessment of Bounding Scenario 5, have been formally documented and incorporated in the engineered design of the processing facility.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|---|--|----------------------|----------|
| IR-226 | - | CNSC | Accidents and Malfunctions | Sections 14.6.6.1 and 14.6.6.4 | <p>Context: It is stated that in the case of the accident and for a release amount of 1 kg inside the processing plant, the dose to offsite receptors at 200 m from the Project site was calculated to be less than the CNSC public dose limit of 1 mSv. The analysis also indicated that the dose to a worker in a full-face-piece powered air-purifying respirator who stays in the area would be 88 mSv, which exceeds the annual worker dose limit of 50 mSv.</p> <p>Rationale: Section 14.6.6.1 indicates that 2 kg of uranium concentrate could be released in case of the accident. No rationale is provided why 1 kg rather than 2 kg uranium concentrate is used for dose calculation. If 2 kg is used as the source term, the dose to offsite receptors at 200m and workers in the area would be higher.</p> | Please provide the rationale for using a source term of 1 kg rather than 2 kg of uranium concentrate for the dose calculation to offsite receptors and workers. If sufficient rationale cannot be provided, the doses to offsite receptors and workers should be recalculated using 2 kg uranium concentrate, and the results provide. | | Accepted |
| IR-227 | - | CNSC | Accidents and Malfunctions | Section 14.6.6.1.1 | <p>Context: Bounding Scenario 6 involves a fire and/or explosion within the processing plant, resulting in the release of a large amount uranium to the atmosphere. The airborne source term for this scenario is estimated with equation developed by the United States Department of Energy (USDOE), where the respirable faction is assumed to only include particles of 10 mm and smaller.</p> <p>Rationale: No rationale was provided to support the consideration of only 10 mm and smaller particles. As provided in Table 14.6-3, the particle size of uranium <15 mm is less than 20%. Majority of the uranium particle size is larger than 10 mm. The airborne source term is an important factor for the effects assessment and should be calculated with transparent and justified information/data.</p> | Provide rationale for only considering 10 mm and smaller particles for the respirable fraction. | | Accepted |
| IR-228 | - | CNSC | Human Health with respect to radiation exposure | Section 14.6.6.4 Appendix 14-A | <p>Context: For the Bounding Scenario 6 (Facility Fire and/or Explosion), the predicted dose is less than 1 mSv to a member of the public 200 metres away from the Project site. The analysis also indicated that the dose to a worker in a full-face powered air-purifying respirator who stays in the area would be 88 mSv, which exceeds the annual worker dose limit of 50 mSv.</p> <p>The Proponent did not provide the dose calculations for deriving the dose estimates.</p> <p>Rationale: The method used to estimate effective, equivalent, and committed dose is required to be verified. Sample dose calculations should be included, to confirm use of acceptable input data.</p> | Provide the dose calculations for deriving the dose estimates for workers and members of the public for Bounding Scenario 6 (Facility Fire and/or Explosion). | | Accepted |
| IR-229 | - | CNSC | Human Health with respect to radiation exposure | Section 14.6.6.4 Appendix 14-A | <p>Context: With the Bounding Scenario 6 (Facility Fire and/or Explosion), the Proponent states that Denison would ensure that the design of the plant includes control measures to reduce the exposure to both workers and members of the public to levels that</p> | Provide details on how the control measures to reduce the exposure to both workers and members of the public, identified in the assessment of Bounding Scenario 6, have been formally | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|----------------------------|---|--|---|----------------------|----------|
| | | | | | are as low as achievable. The measures would ensure that the processing plant is adequately ventilated. It is not indicated where these additional measures have been detailed/elaborated within the EIS. Rationale: Control measures to reduce the exposure to both workers and members of the public as low as achievable, that are identified in the assessment of Bounding Scenario 6, must be formally documented to ensure that they are carried over into the engineered design of the processing plant. | documented and incorporated in the engineered design of the processing facility. | | |
| IR-230 | - | CNSC | Accidents and Malfunctions | Section 14.6.7.4 | Context: It is stated that a conservative penetration time of 15 min was applied in the assessment. Based on this assumption, the maximum depth of contamination could be 90 cm (for penetration rate of 0.1 cm/s). It is not clear why the penetration time of 15 minutes is considered conservative as the penetration time would depend on the time needed for the emergency response team to respond. It is also stated that the wide range of the calculated velocities is a result of variation of soil conditions and the slope of the surface. The distance that the groundwater can travel under these extreme (i.e., conservative) conditions ranges from 0.15 m to 100 m. It is not clear how the groundwater travel distance of 0.15m and 100m is calculated. Rationale: The penetration time will influence the penetration depth of the released materials, which in turn, considering the groundwater travel distance, will impact the potential areas and volumes of contaminated soils and shallow groundwater. | Please provide justification for applying 15 minutes of penetration time, and why it is considered conservative. In addition, please provide information on how the groundwater travel distance of 0.15 m and 100 m was obtained. | | Accepted |
| IR-231 | - | CNSC | Accidents and Malfunctions | Sections 14.6.6.4 and 14.6.6.5 | Context: The EIS states that in the unlikely event of an unmitigated accidental release of uranium due to a dryer explosion, doses to the workers are expected to have a moderate effect, while doses to members of the public are expected to have a minor effect. Based on this evaluation, the severity of the consequences of this accident and malfunction scenario is predicted to be moderate. In consideration of both probability and consequences, the overall risk related to Bounding Scenario 6 is predicted to be low. Rationale: When there is an explosion within the process plant, it is likely there will have worker fatality. The severity of the consequences of an explosion would be catastrophic and the risk of Bounding Scenario 6 would be higher. | Please re-evaluate the consequence and the risk of Bounding Scenario 6 by considering the potential worker fatality resulted from an explosion. | | Accepted |
| IR-232 | - | ECCC | Change to an environmental | Appendix 14-A, Table 3-7, ID# 7.1 | Context: The Proponent indicates in Appendix 14-A, Table 3-7 that a release of sulfuric acid is a low consequence event therefore | 1. Provide the volume and the concentration of sulfuric acid that will be stored on site. | | Accepted |

|--------------|----------------|------------------|---|---|---|--|----------------------|--------------|
| | | | component due to hazardous contaminants | Appendix 14-A, Table 5-5 | <p>would not require further assessment. However, according to a Safety Datasheet on high concentrated sulfuric acid (ICSC–0362 - SULFURIC ACID, concentrated (> 51% and < 100%) (ilo.org)), the substance is incompatible with certain materials and can give off toxic fumes. Furthermore, it reacts with various metals to produce hydrogen gas, which is explosive.</p> <p>The Proponent provides estimates of chemicals, including sulfuric acid, to be transported to site in Appendix 14-A, Table 5-5. The annual consumption of sulfuric acid is estimated at 15,417 m3, in 617 trucks per year, but the concentration is not stated.</p> <p>Rationale: Given the high reactivity and inherent corrosive nature of sulfuric acid combined with the volume and concentration that may be stored on site, ECCC requests that the Proponent provide a detailed risk assessment related to a terrestrial spill of sulfuric acid, specifically at the processing plant.</p> | 2. Provide a detailed risk assessment of the fate and behavior of sulfuric acid during a release into the environment. | | |
| IR-233 | - | HC | Human health with respect to hazardous contaminants | Appendix 14-A, Section 8.7 (p. 8.10) | <p>An effects assessment for a transportation accident scenario involving radioactive materials was not included.</p> <p>Context: The Proponent provided an effects assessment relating to a diesel spill on the ground (Section 14 Appendix 14-A, Section 8.7). However, no information was provided regarding the potential human health effects of a uranium concentrate release at the two locations considered (Section 14 Appendix 14-A p. 8.10).</p> <p>Rationale: An accident involving radioactive material may have an impact on human receptors, based on the proximity of receptors and the proposed response protocols.</p> | 1. Assess and describe the potential health effects (chemical and radiological) of a transportation accident involving a uranium concentrate spill at the following locations: a) km 160 of Hwy 914, which is the location of a cultural camp that has been established by the ERFN. b) km 67 of Hwy 914, which is a gathering location for the Kineepik Métis Local associated with the Northern Village of Pinehouse. c) All other potential sites of importance for the public and Indigenous peoples. | | Accepted |
| IR-234 | | CNSC | Effect of Environment | Section 15.2.2 | <p>Context: Effects of seismic events on the uranium extraction and post decommissioning are not assessed.</p> <p>Rationale: Seismic events could further exacerbate the stability of the voids induced by the uranium extraction, which will result in extra stresses and displacements/deformation in the overlying rock formations. These extra stresses and displacements/deformation could impact on the mine operation and post decommissioning groundwater flow and contaminant transport.</p> | <p>Please provide an assessment of seismic events on the mine-induced voids stability and the resulted effects on the mine operation and post decommissioning.</p> <p>Technical Discussion Required: Yes</p> | | Accepted |
| IR-235 | - | ECCC CNSC | Fish and fish habitat | Section 15.5.2, Expected Environmental Conditions | <p>Context: In this section it is stated that: “Table 15.5-1 and Table 15.5-2 summarize the predicted mean values of the climate variables for the Tomblin Lake regional grid unit, following the RPC4.5 and RCP8.5 scenarios, respectively, as indicated by the Climate Atlas (PCC 2019).”</p> | 1. Provide the source of the data displayed in Max 1-Day Precipitation (mm) category in Tables 15.5.1 and 15.5-2. 2. Provide detailed calculations for the following average values: <ul style="list-style-type: none">25.9 mm 26.7 mm in Table 15.5-1: Predicted Climate Conditions of a RCP4.5 Moderate Carbon Future | | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------------------|-----------------------|---|---|--|----------------------|--------------|
| | | | | | <p>RCP4.5 represents predicted climate conditions of a moderate carbon future.</p> <p>RCP8.5 represents predicted climate conditions under a high carbon future.</p> <p>The values shown in Tables 15.5-1 and 15.5-2 show averages of 25.9 and 26.7 mm for RCP4.5 and 25.9/27.5 mm for RCP8.5. These values do not correspond to the source indicated by the Proponent.</p> <p>Rationale: Based on the Proponent’s description we would expect to find the same values for “Max 1-Day Precipitation (mm)”in the Climate Atlas for RCP4.5 and RCP8.5 scenarios. ECCC was unable to duplicate the results.</p> <p>ECCC queried the Climate Atlas for Tomblin Lake and returned a result of “Region Geikie River.” https://climateatlas.ca/find-local-data</p> <p>ECCC then queried the Climate Atlas for Max 1 Day Precipitation (mm). https://climateatlas.ca/data/grid/782/maxdaypr_2030_85/line https://climateatlas.ca/data/grid/782/maxdaypr_2030_45/line The results displayed an array of values ranging from 83.6 mm (2050) to 87.3mm (2092) for a Regional Concentration Pathway RCP8.5 scenario and values ranging from 48.9mm (2050) to 89.5 mm (2083) for an RCP4.5 scenario.</p> <p>These values do not match the averages shown in Tables 15.5-1 and 15.5-2.</p> | <ul style="list-style-type: none">25.9 mm 27.5 mm in Table 15.5-2: Predicted Climate Conditions of a RCP8.5 High Carbon Future <p>3. Explain how the data shown in Tables 15.5.1 and 15.5.2 were used in the precipitation risk assessment.</p> <p>4. Denote the differences between “mean”, “value/max value”, and “fluctuation”, in the calculation of extreme event risk.</p> <p>5. Compare model derived data against:</p> <ol style="list-style-type: none">Natural variability of the observed data.Variability in the statistics generated via observation based time series. <p>Technical Discussion Required: Yes</p> | | |
| IR 236 | - | ECCC ERAD | Fish and fish habitat | Section 15.5.2, Expected Environmental Conditions | <p>Context: It is stated that, “Table 15.5-1 and Table 15.5-2 summarize the predicted mean values of the climate variables for the Tomblin Lake regional grid unit...”</p> <p>As per the Proponent’s description, Tomblin Lake was chosen as representative location for Wheeler when Climate Atlas was used as data source.</p> <p>Rationale: In those two tables, for the “Max 1-Day Precipitation (mm)” the historical average is given as 24.1mm. Local time series analysis for the climatic region in which Wheeler Project is located provide averages (for 1-day max precipitation) of approximately 30+ mm.</p> <p>It is the Proponent’s responsibility to keep the required database current and up to date, because the length of the time series</p> | <p>1. Provide a clear explanation on how the historical mean for 1-Day Max Precipitation was calculated.</p> <p>2. Compare the values obtained via various means (ex: copied from the internet, modeled via some online algorithm, derived from specialty literature), against time series analysis based on observations.</p> <p>Technical Discussion Required: Yes</p> | | Not Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|-------------------------------------|---|---|--|----------------------|----------|
| | | | | | influences all derived statistics. Statistical analysis of extreme events is highly dependent of the mean with extreme values reaching values 3 to 4 times higher than the mean. | | | |
| IR-237 | | CNSC | EA follow-up and monitoring program | Appendix 16-C throughout, including Table 1.5-1: Wheeler River Monitoring and Follow-up Program Summary (p. 8-15) | <p>Context: CNSC’s Generic Guidelines for the Preparation of an EIS state: “The EIS should provide discussion on the follow-up program’s requirements, and include:</p> <ul style="list-style-type: none">objectives and structure of the follow-up program and the VCs targeted by the programtabular summary and explanatory text of the main components of the program including:<ul style="list-style-type: none">a description of each monitoring activity under that component<u>which of the two generic program objectives the activity is relevant to (e.g., verify EA predictions, determine effectiveness of mitigation measures)</u>the specific statement from the EA that goes along with that generic objective and will be the focus for that activity (e.g., program objective: verify predicted effects; environmental assessment effect: no potential adverse effects)the specific monitoring objective for that activityplanned schedule<u>roles and responsibilities to be played by the Proponent, regulatory agencies, Indigenous people, local and regional organizations and others in the design, implementation and evaluation of the program results</u><u>possible involvement of independent researchers</u><u>program funding sources</u>information management and reporting (reporting frequency, methods and format)<u>possible opportunities for the Proponent to include the participation of the public and Indigenous groups, during the development and implementation of the program</u> <p><u>The follow-up program plan should be sufficiently described in the EIS to allow independent judgment as to the likelihood that it will deliver the type, quantity and quality of information required to reliably verify predicted effects (or absence of them) and confirm the effectiveness of mitigation measures.”</u> (Section 11)</p> <p>Rationale: The Summary of Monitoring and Follow-up Programs provided in Appendix 16-C contains very high-level information,</p> | <p>It is recognized that this document will evolve over the planning process and be finalized prior to the EA Decision; however, as plans are developed and revised, CNSC staff expect that updates will be made to this document and provided with any future versions of the EIS.</p> <p>Appendix 16-C Summary of Monitoring and Follow-up Programs must include sufficient details to allow CNSC staff to determine the likelihood that it will deliver the type, quantity and quality of information required to reliably verify predicted effects (or absence of them) and confirm the effectiveness of mitigation measures. This includes concrete monitoring plans (sampling locations, frequency, etc.).</p> <p>Additionally, please incorporate any relevant information included in the EIS into this Summary.</p> | | Accepted |

| Original IR# | Follow-Up IR # | SME | Project Effects Link | Reference to EIS, appendices, or supporting documentation | Context and Rationale | Information Requirement (IR) | Rationale for Status | Status |
|--------------|----------------|------|---|---|---|--|---|----------|
| | | | | | <p>and while some of the aspects detailed in the Generic EIS Guidelines are included, the aspects underlined are missing or appear incomplete.</p> <p>Further, all information from throughout the EIS should be incorporated into this Summary. For example, the EIS notes that: “Groundwater samples will be collected at least monthly and semi-annually in the wells within the freeze wall and on the freeze wall perimeter, respectively” (p. 7-109) and that “At least five to seven multi-well clusters are proposed across the mined area (Figure 7.8-2). Sampling will include KI parameters or the full suite of COPC at different times in the remediation process” (p. 7-111).</p> <p>These details (only examples) are not included in Appendix 16-C.</p> | | | |
| IR-238 | - | CNSC | Current use of lands and resources for traditional purposes | Various sections of the EIS, including: Section 8 Section 9 Section 10 Section 11 Section 12 Section 15 Section 16 Appendix 16-C (p. 3) | <p>Context: The EIS indicates that “further detailed [follow-up and monitoring programs] will be developed as Project designs are finalized that may influence the nature, frequency, and locations of monitoring. In addition, input from regulatory agencies, the public and Indigenous Peoples will be considered.” (Appendix 16-C, p.3)</p> <p>It is not clear in several section(s) of the EIS and the Indigenous Engagement Report, whether Denison has provided the interested Indigenous Nations and communities with the opportunity to participate in the development, implementation, and review of monitoring and mitigation measures, as per the guidance of REGDOC-3.2.2 and CNSC’s Generic EIS Guidelines.</p> <p>Rational: As outlined in Section 11 of CNSC’s Generic Guidelines for the Preparation of an EIS, please include roles and responsibilities to be played by the Proponent, regulatory agencies, Indigenous people, local and regional organizations and others in the design, implementation and evaluation of the monitoring program results as well as possible opportunities for the Proponent to include the participation of the public and Indigenous Nations and communities, during the development and implementation of the program.</p> | <p>Please provide additional information to demonstrate whether Indigenous Nations and communities were engaged directly on the potential mitigation and monitoring measures to address the concerns raised regarding potential impacts of the Project on the potential or established Indigenous and/or treaty rights.</p> <p>Provide a rationale if this engagement has not been completed. As the Project develops, please provide concrete actions Denison will take in the follow-up and monitoring programs to engage Indigenous Peoples to alleviate concerns and incorporate their interests, and when this engagement is planned to take place.</p> | <p>This response has not been accepted.</p> <p>Please provide additional information and updates on engagement activities to the EIS and IER (to date) that demonstrate whether Indigenous Nations and communities have been engaged directly on the potential mitigation and monitoring measures to address the concerns raised regarding potential impacts of the Project on the potential or established Indigenous and/or treaty rights. See also AD-62 in the Advice to Proponent table.</p> | Accepted |

Annex 3 Draft Advice to Proponent Table

Federal Indigenous Review Team (FIRT) – Advice to the Proponent for the Wheeler River Environmental Impact Statement (EIS) May 2024**The [March 2023 Advice to the Proponent table](#) and [November 2023 Advice to the Proponent table](#) with Denison’s responses are available below

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ¹ | Context and Rationale | Advice to the Proponent |
|--------|--|--|--|---|
| AD-72 | Canadian Nuclear Safety Commission (CNSC) | Section 7.4.2 | Denison’s response to IR-61 was accepted, but the term “inducted seismic” should be updated to “induced seismicity” in section 7.4.2.4 | CNSC staff requests that Denison review the draft EIS for inaccuracy of scientific terms which cast doubt on the credibility of the EIS, such as the use of the term “inducted seismic” instead of “induced seismicity” in section 7.4.2.4. It is suggested that Denison review the entire revised EIS once again to address similar inaccuracies. |
| AD-73 | CNSC | Section 8.1.3.4.2 Probable Maximum Precipitation (PMP) Events Appendix 8C | In Section (List of Appendices, p. iv) of “S8_App 8-C Hydrological Effects Assessment Report Wheeler River” states “Appendix III- Response to IR-103”. This is incorrect and refers to IR-103. | This reference should be edited to “Appendix III- Response to IR-102.” |
| AD-74 | Environment and Climate Change Canada (ECCC) | Section 2.2.3 Project Description Proponent response to IR-12-R1B | The Proponent provided maps of the proposed water management structures for the road to the airstrip and the airstrip in Attachment IR-12. However, they should commit to including them in the Final EIS. Inclusion of these maps will allow for improved understanding of site water management and transportation of non-contact water. | ECCC recommends that the Proponent Include maps of the proposed water management structures for the road to the airstrip and the air strip, provided in Attachment IR-12, in the Final EIS. |
| AD-75 | ECCC | Section 8 (Aquatic Environment); Appendix 10-A (ERA) | The predicted effluent concentration of 42 ug/L for the proposed Project represents a very high concentration of selenium. For comparison, the Canadian Council of Ministers of the Environment (CCME) guideline is 1 ug/L (January, 2022: Proposed Approach for Coal Mining Effluent Regulations – Discussion Document (canada.ca)) | Given the high selenium concentrations predicted in the discharge, ECCC recommends that the Proponent: <ul style="list-style-type: none">Identifies effective mitigation measures (including source control) to avoid effects in the receiving environment, and Analyzes the extent to which selenium concentrations in effluent can be reduced. |
| AD-76 | ECCC | Section 2.2.3 Project Description Proponent response to IR-12 | While the Proponent did provide in Attachment IR-12 the requested proposed water management structures, for the road to airstrip and the airstrip, the information surrounding the proposed water management structures is found within multiple documents which makes it difficult for readers to understand the resulting impacts to water quality. | The proposed water management structures for the road to airstrip and the airstrip should be included in the Final EIS to allow for the effects of these structures to be more readily understandable. Additionally, the Proponent should respond to questions within a single document to reduce the complexity involved in understanding the environmental effects of the Project. |
| AD-77 | ECCC | Section 8.4.4.2.3, Aquatic Environment IR-124-R1 Response from Denison | CSA N288.6-22 is the latest standard for the nuclear industry for the assessment of risk associated with releases from the nuclear industry to the environment. The statistical and environmental considerations required in the establishment of baseline data as well as the use of mathematical models are set out in the standard to ensure that the risk assessments are defensible. | The Proponent should apply CSA N288.6-22 to risk assessment for sediment where appropriate. |
| AD-78 | ECCC | Section 9.3.3.3, Baseline Studies Section 9.3.5 Mitigation Measures IR 142, 159, and 167 Responses from Denison IR-142-159-167-R1 | It is unclear how conducting wildlife sweeps seven days in advance will adequately identify and mitigate for all species, especially species at risk. Similarly, uncertainty remains regarding how adaptive management mechanisms will be triggered. Note that active terrestrial nest searches for birds, including avian species at risk, are generally not recommended by ECCC or the province of Saskatchewan (Publications Centre) | The Proponent should develop species specific mitigation measures, and provide these for review. Species specific mitigations should take into account the ecology of individual species at risk, including habitat requirements, nesting/denning or other important landscape features and timing of life stages as they relate to project construction and operation. The Proponent should conduct literature |

¹ Unless otherwise stated, the section noted refers to the draft EIS

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ¹ | Context and Rationale | Advice to the Proponent |
|--------|------------|---|--|---|
| | | IR-170 | <p>saskatchewan.ca) because they are likely to cause disruption to breeding activities and are largely ineffective for passerines.</p> <p>However, if avian nest searches in simple habitats (as outlined in the <u>Guidelines to avoid harm to migratory birds</u>) are undertaken, then information should be provided on methods and timing for review. Conducting a nest search seven days in advance of works may be too far in advance to detect all possible nests. Nest searches should be conducted as close to the clearing or construction dates as possible. Developing species specific mitigation measures based on habitat potential mapping, prior to nest searches, can reduce construction delays, as advice on these measures would be available for implementation.</p> <p>For certain projects or locations, additional more specialized surveys may be warranted (e.g., radar surveys, or foot-based counts of colonially nesting birds).</p> | reviews to find proven mitigations for all species at risk within the project area. ECCC is available to discuss these measures with the Proponent. |
| AD-79 | ECCC | Section 9.3.6.4 IR-149-R1B | <p>In their IR response, the Proponent states “English River First Nation and SVS (2022) compiled an IK study documenting current and past land use, knowledge of the land, and participants’ perspectives on potential Project effects, as well as cumulative effects from past mining and other developments. The report identified a wildlife corridor used by several species, including woodland caribou. The corridor runs between Cree Lake (approximately 40km southwest of the Terrestrial RSA and Russell Lake (in the southern portion of the Terrestrial RSA (Feature 1001-09; ERFN and SVS 2022). The report identified a caribou calving area: Feature 1009-07 covering large portions of the Terrestrial RSA with the exception of the most western, northern, and eastern extents. This area is also described as offering good caribou habitat year-round (ERFN and SVS 2022).”</p> <p>The Proponent has also provided mapping showing that there are calving areas within the RSA.</p> <p>Calving is an important life history function that occurs within specific biophysical attributes. It is important to mitigate these effects.</p> | Since both the mapping provided as part of the EIS and the English River First Nation study indicates that there is calving areas within the RSA, incorporating mitigation measures related to timing of sensory disturbances during calving season into the Caribou Management Framework would enhance the caribou management plan. |
| AD-80 | ECCC | Section 9.4.1.2, Key Indicators and Measurable Parameters IR-158 | <p>The Proponent identified key indicator species for migratory songbirds, waterbirds and upland game birds, but did not provide any justification on why these species were chosen. It is important to understand why a certain species was chosen as an indicator in order to assess whether the that species possesses similar life history characteristics.</p> | <p>During pre-construction, construction and operational monitoring, the Proponent should consider any trends and changes to the avian community, including the key indicator species which are representative of other species that may be more difficult to monitor for implementation of adaptive management. (see IR-159 for additional input).</p> <p>Appendix 9-D provides an assessment of three additional key indicator species (Barn Swallow, Bank Swallows, Horned Grebe). All eight key indicators for avian species at risk should be accounted for.</p> |
| AD-81 | ECCC | 9.4.3.2.3 Baseline Studies – Migratory Songbirds Appendix 9-B, Section 2.10.2, Results IR-159 | <p>Although the Proponent notes that the supplemental data did not result in a different conclusion in the EIS and would not require updates to the mitigation measures, it was acknowledged that the data did provide further context for the RSA. Interpreting the original baseline data as well as the supplemental data in the context of the Project (i.e. what species were at what densities in which areas/ecosites) provides a more robust baseline with which to compare construction and operational monitoring data. This is particularly important in the context of species’ natural variability.</p> | Even if the supplemental data did not change the conclusions in the EIS, the data is essential for comparison reasons. Data collected during construction and operational monitoring should be compared with baseline data to test predications on impacts from the project, and whether mitigation measures are effective. |
| AD-82 | ECCC | Section 9.3.3.3, Baseline Studies IR-143 and 144 Responses from the Proponent | <p>In their IR response, the Proponent notes that “the majority of these data points illustrated in Figure 2-2 and Figure 2-3 in revised draft EIS Appendix 9-F are located beyond the LSA and to the north and east of the Project Area.”</p> | ECCC advises that the Caribou Management Framework should consider the entire LSA as being used by caribou for all their life functions and that mitigation |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ¹ | Context and Rationale | Advice to the Proponent |
|--------|------------|--|---|--|
| | | | <p>ECCC notes that the baseline studies done for the Project were limited in scope and scale, and the map showing telemetry data from the province of Saskatchewan shows caribou use throughout the LSA and RSA.</p> <p>ECCC notes that trail camera, pellet, incidental and telemetry data only provide a small snapshot of actual habitat use.</p> | <p>measures, including offsetting, be developed with the understanding that this Project poses a medium level risk to caribou using the area.</p> |
| AD-83 | ECCC | Section 9.3.3.3, Baseline Studies IR-149-R1A IR-152. | <p>ECCC notes that the Proponent indicates a commitment to continuing to work with the province regarding caribou offsetting through the finalization of the Caribou Management Framework.</p> | <p>ECCC notes that at this time there are not enough details in the Caribou Management Framework for ECCC to provide advice on the appropriateness of the offsetting measures.</p> |
| AD-84 | ECCC | Section 9.3.5.2, Additional Wildlife specific Mitigation Measures Proponent response to IR-149 | <p>ECCC notes that Figure 2.4 of Appendix 9-F, shows that there is suitable calving habitat in close proximity to the airstrip, including within the LSA just west of the airstrip and along the Wheeler River at the southeast end of the LSA. ECCC notes that information is not yet available on the timing and frequency of air traffic.</p> <p>The Proponent has provided some potential measures likely to be incorporated into operations of the airstrip. The Proponent states that they will use the most direct path, however, important areas for caribou (e.g. calving grounds) may be located along the most direct route. Figure 2.4 of Appendix 9-F, shows that there is suitable calving habitat in close proximity to the airstrip, including within the LSA just west of the airstrip and along the Wheeler River at the southeast end of the LSA.</p> | <p>ECCC advises that mitigation and monitoring should be developed to address sensory impacts as a result of the airstrip. The Caribou Management Framework should incorporate consideration of the proximity of air traffic to important landscape features for caribou, as well as timing of flights during important life stages (e.g. calving).</p> |
| AD-85 | ECCC | Section 9.3.6.4.1 Section 9.3.7.3.1 | <p>The Proponent notes that the size of the SK1 Boreal Shield range is estimated at 18,034,870 ha (ECCC 2020), resulting in an estimated additional Project-related disturbance of 0.001% at the scale of the SK1 Boreal Shield Woodland Caribou Management Unit. The Proponent concludes that the contribution of the Project to cumulative effects on woodland caribou within the SK1 conservation unit are negligible.</p> | <p>Although the Proponent has provided information to show that the Project has negligible impacts at range scale, this Project poses a medium risk to caribou at the local and regional scale due to the proximity of important features for caribou within the LSA and RSA. Mitigations for sensory disturbance during critical life stages such as calving should be developed and included within the Caribou Management Framework. Measures to monitor the effectiveness of implementation are also needed.</p> |
| AD-86 | ECCC | Section 9.3.5.2 Appendix 9-E Wheeler River Project Caribou Management Framework | <p>Much of the information presented in the Wheeler River Project Caribou Management Framework is qualitative in nature and does not present specific details regarding a quantitative assessment of impacts following measures to avoid, minimize, restore on-site and determine the offset. This is required in order to understand if offsetting is sufficient to address impacts to caribou.</p> <p>The updated Wheeler River Project Caribou Management Framework indicates that the Proponent will use the SK ENV caribou offset calculator. Without information on the amount of offsetting that will be implemented, ECCC cannot advise on whether the amount is appropriate in the context of the species Recovery Strategy.</p> <p>Although the Proponent has provided an updated draft Caribou Management Framework, information regarding offsetting remains outstanding. The Proponent notes that SK ENV is developing a boreal caribou habitat offset calculator and that the Caribou Management Framework will be finalized using that tool as part of the provincial approvals.</p> | <p>Information is still lacking on the amount of habitat offset required to balance against Project effects. Therefore, the Caribou Management Framework should be updated with outstanding information.</p> <p>The Proponent should consider offsetting effects associated with this Project. However, ECCC is unable to specify an offsetting amount at this time as there was insufficient information provided by the Proponent. ECCC acknowledges that the Proponent has committed to working on their offset plan with the province of Saskatchewan. However, offsetting measures, outputs, and priority locations should be confirmed in draft plans and submitted for review. Without additional information on the Proponent’s mitigation measures, including offsetting measures, ECCC cannot provide advice on whether project effects will be mitigated.</p> |

Federal Indigenous Review Team (FIRT) – Advice to the Proponent for the Wheeler River Environmental Impact Statement (EIS) November 2023

** The new [newest Advice to Proponent table](#) is available above

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ² | Context and Rationale | Advice to the Proponent |
|--------|------------|---|---|--|
| AD-50 | ECCC | Section 2.2.1.4.2, Wellfield Operation Section 2.2.1.4.2.2, Secondary Containment of Mining Solution – Pumping | Providing a report or memo by the Proponent’s consultant Newmans Geotechnique Inc. as a public record will more effectively explain the “information on the freeze wall integrity and basis for the design, which relies on site field data and lived experience from several exiting [sic] Saskatchewan mining operations”, than a summary (attachment IR-10) of the material presented by Greg Newman during the meeting with the FIRT on April 19, 2023. | The response from the Proponent in IR-10 is accepted based on the meeting between ECCC, Denison and the CNSC, as well as the Proponent’s consultant and the presentation by Greg Newman (Newmans Geotechnique Inc.) as well as the summary of the meeting noted in attachment IR-10. However, the Proponent should provide a public record of the consultant’s memo or a report that explains the details of the freeze wall containment and monitoring that were provided during the April 19, 2023 meeting instead of the summary provided by the Proponent in attachment IR-10. |
| AD-51 | CNSC | Section 8.3.3 and 8.5, Aquatic Environment and Fish health | Denison has committed to additional baseline data gather as part of their response to IR-107. | Also related to IR-120 and IR-125, CNSC staff recommend Russell Lake be included in this baseline collection to increase the robustness of the established baseline in the final EIS. |
| AD-52 | CNSC | Section 8.3.3.1, Methodology and Metrics | Denison has indicated that exposure to other pre-existing stressors could result in abnormal conditions or deformation(s) in existing population, but the extent of existing conditions should be evaluated to ascertain whether the rate is increasing as a result of proposed activities once in operation. | Related to IR-121, CNSC staff recommend that Denison add text to EIS to reflect that no gross abnormalities in fish were observed during field work. |
| AD-53 | CNSC | Section 8.3.8, Monitoring and Follow-up | Section 8.3.8 of the EIS states: "Changes in fish communities/populations will be assessed through comparison of Construction, Operation, and Decommissioning results to pre-development." Tracking changes in fish communities / populations in reference lakes over time should be conducted, as reference lakes can be used to differentiate natural temporal variation with potential project impacts. Denison has committed to inclusion of reference lakes in study designs used to assess changes in fish communities / populations over time. | Related to IR-122, CNSC staff recommend that Denison strengthen discussion of reference lakes, and their use, in EIS. |
| AD-54 | CNSC | Section 9 Various pages in section 11.1, Land and Indigenous Resource Use Section 12 Section 14 | The increased road traffic (14-18 trucks per day during construction/operations) may have indirect impact on ungulates, furbearers and wood land caribou presence/absence for traditional and subsistence hunting have been raised to CNSC staff when meeting with Indigenous Nations and communities and are presented in the EIS. | Related to IR-128, Denison should have follow-up discussions with the Ministry of Saskatchewan Highways, Indigenous Nations and communities (including KML and ERFN) and stakeholders regarding adding additional pull-outs to the highway to ensure safety for northern residents. |
| AD-55 | ECCC | Section 9.2.5.2.7, Waste and HazardousMaterials Management | Vehicles and equipment with engines adhering to Tier 4 emission standards should be employed where feasible in order to minimize emissions. Regardless of engine tier used, best management practices should be followed, including proper maintenance of engines and anti-idling measures. | Related to IR-139, the Proponent should commit to following best management practices regarding the use of vehicles and equipment, including proper maintenance of engines and anti-idling measures. |
| AD-56 | ECCC | Section 9.3.1.3.1, Spatial Boundaries for Ungulates, | The EIS and the IR response did not provide sufficient information to understand how the Regional Study Area (RSA) boundaries for caribou were determined. | Related to IR-137, An assessment typically involves setting a geographic area for the assessment for the direct and indirect effects of a proposed project; this area is |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ² | Context and Rationale | Advice to the Proponent |
|--------|------------|--|--|---|
| | | Furbearers and Woodland Caribou | | <p>sometimes referred to as the Local Study Area (LSA). ECCC advises that the LSA is likely to extend beyond the Project footprint and a 500m buffer. ECCC demonstrated that the application of a 500m buffer to mapped anthropogenic features best represents the combined effects of increased predation and avoidance on caribou population trends at the national scale (Environment Canada, 2011). However, adverse effects of projects including predator and prey access to undisturbed areas, reduction in connectivity, and sensory disturbance to individuals of boreal caribou can vary and extend several kilometers depending on project activities and ecological context. The LSA should at the minimum capture the above-mentioned effects.</p> <p>A Proponent will also set a geographic area for the assessment within which the cumulative effects of the proposed Project are possible; this is sometimes referred to as the RSA. Typically the range(s) is(are) the proper scale to assess cumulative effects. However, assessing cumulative effects may require a different approach for large continuous ranges than for smaller discrete ranges. The impact of disturbance that may be concentrated in part of a large continuous range may be masked given the size of the range. For large continuous range it may be relevant to assess cumulative effects at the scale of the range but also at a smaller scale.</p> <p>The Proponent should consult with experts of the relevant jurisdiction in order to determine the local and regional study area, and provide a justification of the extent of the study areas in the impact statement.</p> |
| AD-57 | ECCC | Section 9.4.5.2.1 Work Timing Windows and Habitat Disturbance | <p>In their response to IR-167, the Proponent states: “Site clearing and other works that involve disturbance of vegetation and/or soil will be completed during least-risk timing windows for migratory birds and SAR (i.e., winter), where practical, to avoid disturbance during sensitive time periods. It is noted that additional information related to timing windows and species as it concerns Project activities has been provided in response to IR-134.</p> <p>Pre-clearing surveys will be conducted and set-back buffers implemented, as needed. The pre-clearance surveys will be completed prior to all clearing events, regardless of the time of year / season when clearing is set to occur. If nests or tree cavities should be encountered during pre-construction surveys or ongoing monitoring activities, any subsequent Project activities will be in accordance with the 2022 Migratory Birds Regulations.”</p> <p>ECCC does not recommend the use of nest searches or pre-clearing surveys for active bird nests during the breeding season as a mitigation. Instead, ECCC recommends that clearing and grubbing activities not be conducted during the breeding bird season.</p> <p>ECCC does not recommend active nest searches in most cases and for most species, in part because there is a great degree of difficulty associated with reliably detecting nests and a high likelihood of disturbing or damaging active nests while searching.</p> <p>Exceptions to the general nesting period exist, and these include interannual variation and nest searches for certain species which may breed outside of these general periods. Under the MBCA it is prohibited to destroy a nest with a live bird or viable egg, even if this occurs outside of what might be considered a normal nesting period.</p> | <p>Related to IR-167, provide details on how vegetation clearing related to site development will be conducted to avoid harm to migratory birds and species at risk (SAR).</p> |
| AD-58 | HC | Section 10.1.4.2.1 (p. 10-22) | Section 6 of the Draft EIS contains Table 6.1-1 (p. 6-7), which lists radionuclides as a key indicator for air quality. | Related to IR-177, consider rewording Table 6.1-1 to “radon” instead of “radionuclides” to avoid confusion. |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ² | Context and Rationale | Advice to the Proponent |
|--------|------------|--|--|--|
| | | Appendix 10-A (ERA): Appendix B Table B.9, Ref. 19-2638 Section 6, Table 6.1-1 (p. 6-7) | Only uranium and radon are considered in Section 6, and Section 10 Table B.9 does not include doses from uranium progeny in air. | |
| AD-59 | CNSC | Section 10.1.6.1.1, Human Receptors Selection and Characterization | <p>Within the Human Health assessment, offsite receptors during the operation period are only considered downstream of Whitefish Lake. The only identified concern was for Se to the Fisher/Trapper located at Russel Lake. This section cites Indigenous Knowledge as informing the receptor selection and location.</p> <p>While the assessment is fairly conservative in the assumptions made on intake and receptor habits, it stands to reason that if the trapper receptor was located closer to the operation, such as at McGowan or Whitefish Lakes, this exceedance of Se could be more pronounced.</p> <p>In terms of maintaining a conservative assessment, if the most vulnerable receptor can be shown to be protected at the point of highest expected COPC concentration, it can be concluded that this receptor would be protected further away from the project. Considering this, why was the hunter/trapper receptor not also assessed at Whitefish or McGowan Lake? Was Indigenous Knowledge specific in mentioning Whitefish or McGowan Lakes were not used for the activities carried out by identified receptors?</p> | <p>Denison has addressed IR-180, but has not considered the suggestion for establishment of additional treatment technologies of COPCs.</p> <p>CNSC staff maintains that there may be the need to establish additional treatment for effluent should environmental monitoring during operation indicate COPC's are accumulating in the environment beyond what is anticipated in the EIS.</p> <p>This is a firm reminder that this will be evaluated as part of the licensing phase of the project, should it proceed.</p> |
| AD-60 | CNSC | Section 11, Perceived Risks to Lands and Resources | <p>The EIS states: "Resource users may also experience changes in their perception of the quality of resources for consumption such as the palatability of fish or wildlife or have apprehensions about the safety of resources for consumption. These changes may affect the patterns of ILRU during all Project phases including Post Decommissioning. The ERFN refer to this indicator as a "psycho-social" effect, meaning that even if people know their fears are "<i>perceived fears, the fear ... is real and has real impacts on ERFN members' perception of their overall health and well-being</i>" (ERFN and SVS 2022a)." (p. 11-11)</p> <p>CNSC's Generic Guidelines for the Preparation of an EIS state: "The EIS will document specific suggestions raised by Indigenous groups for mitigating the effects of changes to the environment on Indigenous peoples (section 5(1)(c) of CEAA 2012). For the mitigation measures intended to address the effects of changes to the environment for Indigenous peoples, the Proponent must discuss the residual effects with the Indigenous groups prior to submitting the EIS." These changes may affect the patterns of ILRU during all Project phases including Post Decommissioning.</p> | <p>Related to IR-207, as Denison continues to work with Indigenous Communities of Interest on community specific monitoring regimes, please provide additional information in the IER on any updates on engagement activities to date that have taken place with KML and ERFN and any other Indigenous Nations and communities who utilize the area, with respect to follow-up monitoring plans that are being developed to support the Project licensing and permitting.</p> <p>If Denison has made commitments with respect to this, this is information that should also be included in the commitments report.</p> |
| AD-61 | CNSC | Various sections of the EIS, including: Section 9 Section 10 Section 11, including Section 11.1.4.3.1 (p. 11-46) Section 12 Section 16 | <p>ERFN indicated they are concerned about declining moose populations from an influx of hunters; more people may be accessing the area year after year, and worried populations may be affected by the Project (21-EN-ERFN-473.13).</p> <p>Further, the EIS highlights that: "Vehicle collisions are the most likely source of direct mortality for moose. Effective mitigation measures (e.g., breaks in snowbanks; speed limits; and exclusion fencing around contaminated waste pads and ponds) will be implemented to reduce moose mortality." (p. 11-46)</p> <p>To address potential concerns specific to Project related effects to wildlife species of interest to the Indigenous Communities of Interest, Denison has committed to collaborating with ERFN and KML on a monitoring regime suited to each of their interests and needs.</p> | Related to IR-129, Denison needs to ensure that the proposed monitoring regime with ERFN, KML and other Indigenous Nations who utilize the area are included in the commitments table for future EIS submissions. |
| AD-62 | CNSC | Various sections of the EIS, including: Section 8 | IR-238 requested that Denison provide additional information to demonstrate whether Indigenous Nations and communities were engaged directly on the potential mitigation and | Related to IR-238, If Denison has made commitments with respect to engagement activities with Indigenous Nations and communities on potential , this is information that should be included in the commitments report. |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ² | Context and Rationale | Advice to the Proponent |
|--------|------------|---|--|---|
| | | Section 9 Section 10 Section 11 Section 12 Section 15 Section 16 Appendix 16-C (p. 3) | monitoring measures to address the concerns raised regarding potential impacts of the Project on the potential or established Indigenous and/or treaty rights. As well, it requested that Denison provide a rationale if this engagement has not been completed. As the Project develops, please provide concrete actions Denison will take in the follow-up and monitoring programs to engage Indigenous Peoples to alleviate concerns and incorporate their interests, and when this engagement is planned to take place. | |
| AD-63 | ECCC | Appendix 6-C Climate Baseline and GHG Emissions Report | ECCC recommended that the identification of the sources of GHG emissions and quantification of these emissions be described for the post-decommissioning phase, as was done for the other phases. ECCC recommended that the Proponent discuss the potential impacts that the Project may have on Canada’s ability to meet its climate-related targets, following the guidance of the Strategic Assessment of Climate Change (SACC) and the Draft Technical Guide Related to the Strategic Assessment of Climate Change: Guidance on quantification of net GHG emissions, impact on carbon sinks, mitigation measures, net-zero plan and upstream GHG assessment. | Related to AD-18 , ECCC recommends the identification of the sources of GHG emissions and quantification of these emissions be described for the post decommissioning phase. This information will be useful for future development of a net-zero plan. |
| AD-64 | ECCC | Appendix 6-C Climate Baseline and Greenhouse Gas Emissions Report | ECCC noted that more specific data, such as regional data from provinces, forest companies, or literature may be available. The use of Table 20 of the draft Technical Guide does not apply. ECCC recommended that the Proponent also consider biomass that are not aboveground and confirm whether soil carbon is taken into account, as well as wetlands. ECCC recommended that the Proponent provide a quantitative and qualitative description of the Project’s impact on carbon sinks, following the guidance of the SACC and the draft Technical Guide. | Related to AD-19 , ECCC recommends that the Proponent revisit the land use calculation provided in the draft Environmental Impact Statement as the use of Table 20 of the draft Technical Guide for the above ground mass of vegetation species is not appropriate. This table is for above-ground woody vegetation in cropland systems which does not apply in this instance. A simple site survey would determine above-ground biomass on site using basic information such as site class and species. More specific data, such as regional data from provinces, forest companies, or literature may be available, while generic national data is available (e.g., Biomass Estimates for Major Boreal Forest Species in West-Central Canada (publications.gc.ca), Canada’s Forest Biomass Resources: Deriving Estimates from Canada’s Forest Inventory (nrcan.gc.ca)). ECCC reiterates the advice that the Proponent provide information regarding the consideration of biomass that are not above ground, specifically whether soil carbon and wetlands are taken into account. ECCC also restates the advice that the Proponent provide a quantitative and qualitative description of the Project’s impact on carbon sinks, following the guidance of the SACC and the draft Technical Guide. |
| AD-65 | CSNC | Appendix 7-A, Section 4.3.3, Hydrochemistry by Hydrostratigraphic Unit Appendix 7-C, Section 3.5 | In response to IR-82, Denison highlights the importance of the S redox couple (S(2-)/S(6+)) near the ore zone. | Related to IR-82, CNSC staff recommend that Denison consider the inclusion of hydrogen sulfide test kits for in-field measurements of H2S to supplement qualitative interpretations (e.g., absence of "rotten egg" odor associated with sulfide) relating to redox conditions. |
| AD-66 | ECCC | Appendix 7-C, Numerical Modelling: Post Decommissioning Evaluation,Section 2.3.1.4, Desilicified Zone | The Proponent states in both the EIS and their response that a hydraulic conductivity value of 5x10-6 m/s was uniformly assigned to the model layers representing the Desilicified Zone. They additionally state that this value is consistent with packer and pumping tests screened in this unit that have interpreted hydraulic conductivity values ranging from 1x10 ⁻⁶ to 3x10 ⁻⁵ m/s (Appendix C), with a geomean of 6.0x10 ⁻⁶ m/s. In their IR response, the Proponent stated that the hydraulic conductivity used as the model base case (5x10 ⁻⁶ m/s) is similar enough to the geometric mean value (6x10 ⁻⁶ m/s) that no | Related to IR-89, while repeat modelling using the geometric mean hydraulic conductivityof 6x10 ⁻⁶ m/s is not required, include a statement in the EIS to indicate that the geometric mean hydraulic conductivity was not used in the model and providing justification for using the value of 5x10 ⁻⁶ m/s instead. |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ² | Context and Rationale | Advice to the Proponent |
|--------|--------------------|--|--|---|
| | | | <p>consequential change to the model would occur if the geometric mean were to be used. The use of the value of 5x10⁻⁶ m/s as the model base case was not substantiated.</p> <p>ECCC accepts the response to Part 1 of the IR as the Proponent has stated that 5x10⁻⁶ m/s and 6x10⁻⁶ m/s are similar enough hydraulic conductivities that redoing modelling with the geometric mean is not expected to consequentially change outputs for either the PHREEQC orFEFLOW model. However, the reasoning for selecting the value of 5x10⁻⁶m/s was not clear.</p> | |
| AD-67 | Health Canada (HC) | Appendix 10-A, Section 3.2.1.3.1, p.3.43-3.44 | <p>Inappropriate use of an outdated standard in assessing health and environmental effect(s) from short-term exposure to nitrogen dioxide (NO₂).</p> <p>The Draft EIS technical supporting document (Appendix 10-A) appears to misinterpret Health Canada’s 2016 Human Health Risk Assessment for Ambient Nitrogen Dioxide (NO₂) in setting its screening criteria and evaluating the health impacts from exposure to Nitrogen Dioxide. The document states:</p> <p><i>“Health Canada published a national one-hour maximum acceptable level of 400 µg/m³ for NO₂ in ambient air using a risk assessment approach (Health Canada, 2016b). This value considers sensitive human populations.”</i></p> <p>This statement is inaccurate.</p> <p>As indicated in Health Canada’s 2016 publication, this value (400 µg/m³) refers to the National Ambient Air Quality Objective (NAAQO) for NO₂, developed in the 1970s. The Canadian Ambient Air Quality Standards (CAAQS) were later developed in consideration of both human health and the environment to replace existing Canada-wide standards, including the NAAQOs, and in many cases are the most stringent Canadian air quality standard, guideline or objective.</p> <p>The new CAAQS for NO₂ also recognizes that there is no population health threshold for human health effects; therefore, any increase in exposure will result in an incremental population risk (Environment Canada and Health Canada, 2012; CCME, 2000). In other words, NO₂ is considered to be a non-threshold substances, meaning that health effects may occur at any level of exposure. Therefore, guideline values should not be construed as limits to which polluting up to is allowed.</p> | <p>The CAAQS are recommended as the most stringent air quality standard for assessing health and environmental effect(s) from short-term exposure to NO₂ in the project.</p> <p>The CAAQS are generally calculated for specific multi-year averages and for a particular statistical form so that extreme and unpredictable events do not drive risk management. However, if the data is not available for comparison to a full CAAQS timeframe, Health Canada suggests using model results for at least one calendar year to allow for a basic comparison with the CAAQS statistical form. The modelling results should be able to indicate the frequency of CAAQS exceedances, which can be used in the discussion as to whether any anticipated human health impacts are anticipated</p> <p>Modelled predictions within an air quality assessment’s study area should be compared to the most stringent air quality standards, guidelines or objectives applicable to the region that may be affected by project activities. In this case, CAAQS are the most stringent levels and CAAQS are not restricted to applications only within the context of the Air Quality Management System (AQMS). Evaluation against the CAAQS may be considered in determining the nature and severity of the project’s impact on air quality levels and the resulting mitigation measures that may be required to maintain good air quality levels or to prevent an exceedance of the CAAQS.</p> <p>As health effects can occur even at levels of exposure below the limits set out in the CAAQS, they should not be viewed as “pollute-up-to” levels. It should be acknowledgeable that health risks exist below the guidelines. In addition, the principles of keeping clean areas clean and continuous improvement are operative, thus proposed mitigation measures should not be confined to meeting the standards, but should also be targeted towards reducing population exposure to CACs associated with the proposed project.</p> <p>This advice is also relevant to IR-190 and may be of use in responding to that request for a comparison of the predicted maximum concentrations to the most protective applicable air quality standards available (i.e., CAAQS).</p> |
| AD-68 | ECCC | Appendix 16-A Summary of Residual Effects Appendix 16-B Summary of Cumulative Effects | <p>ECCC recommended the inclusion of an assessment of potential GHG mitigation measures throughout all phases of the Project including a Best Available Technologies / Best Environmental Practices (BAT/BEP) Determination, as described in Section 3.2 of the draft Technical Guide.</p> <p>ECCC also recommended the development of a credible Net-Zero Plan on how to achieve the target of 0 kt CO₂ eq/year, for the year 2050 and beyond, following the guidance of the SACC and the draft Technical Guide.</p> | <p>Related to AD-49, ECCC notes the comment provided by the Proponent stating, “Denison will consider the option of preparing a climate resiliency assessment with consideration to best available technologies / environmental practices (BAT/BEP) as well as a net-zero plan as the Project advances”. ECCC continues to recommend that the Proponent align with best practices by including in the EIS a Best Available Technologies / Best Environmental Practices (BAT/BEP) Determination and a credible Net-Zero Plan on how to achieve the target of 0 kt CO₂ eq/year, for the year 2050 and beyond, following the guidance of the SACC and the draft Technical Guide.</p> |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ² | Context and Rationale | Advice to the Proponent |
|--------|------------|--|--|--|
| AD-69 | CNSC | Appendix 16-C | <p>The EIS and the Summary of Monitoring and Follow-up Programs provided in Appendix 16-C contains very high-level information. It is not clear which monitoring programs will be employed to demonstrate regulatory compliance, and compliance with the commitments Denison has made to its Indigenous and non-Indigenous Stakeholders.</p> <p>The CNSC’s Generic Guidelines for the Preparation of an Environmental Impact Statement (EIS), also state: “The EIS will then describe mitigation measures that are specific to each environmental effect identified. Measures will be written as specific commitments that clearly describe how the proponent intends to implement them and the environmental outcome the mitigation is designed to address.</p> <p>CNSC staff requested in the March 2023 letter to Denison (e-Doc 6991467) a Commitments Table for the Wheeler River EIS. This letter requested information of all commitments made by Denison with detailed information such as:</p> <ul style="list-style-type: none">✓ details of the commitment✗ which phase(s) of the project will the commitment be carried out (e.g., all phases)✓ where the commitment is referenced (which document, table, etc. and where it can be found)✗ how this commitment will be tracked (project EA follow-up program, site-wide programs, etc.) <p>Several commitments to Indigenous Nations and communities from the August 2023 submission appear to be missing from this table and should be included in the next submission.</p> | <p>For the next draft EIS submission, the evergreen Commitments Table should be updated to include:</p> <ul style="list-style-type: none">• which phase(s) of the project will the commitment be carried out (e.g., all phases)• how this commitment will be tracked (project EA follow-up program, site-wide programs, etc.) and;• all commitments to Indigenous Nations and communities |
| AD-70 | ECCC | Appendix 16-C Summary of Monitoring & Follow-up Programs | <p>ECCC recommended that the Proponent consider developing a GHG follow-up program to measure and compare actual GHG emissions against the EIS estimates, including reporting the Project’s actual emissions and updating the emissions estimates as needed.</p> | <p>Related to AD-48, ECCC acknowledges that the Project will likely be required to report annually per section 46 of the Canadian Environmental Protection Act as the annual emissions are likely to be over 10,000 tonnes of CO2e. However, ECCC’s suggestion incorporates additional components to align with the goal outlined in Appendix 16-C of the draft EIS to “assess the environmental performance of the project relative to the predictive assessment that has been completed in support of the environmental assessment process”. This would involve comparing actual vs. estimated emissions following the terms of the SACC’s net GHG emissions equation and evaluating the effectiveness of GHG-related mitigation measures.</p> |
| AD-71 | ECCC | Conceptual Caribou Management Plan | <p>Section 4.2.1 of the Conceptual Caribou Management Plan states that "The Project components are also west of the known home range of woodland caribou (based on tracking data received by the Ministry of Environment; Figure 4-2), although the absence of data does not mean the absence of caribou and Denison has observed caribou in the area." Calculation of home range is normally based on statistical analyses of telemetry data. Home range cannot be inferred from telemetry points and incidental observations from a map</p> | <p>Related to IR-149, the Conceptual Caribou Management Plan should be corrected to remove the reference to caribou home range.</p> |

|--------|---|--|---|---|--|
| AD-01 | Canadian Nuclear Safety Commission (CNSC) | Glossary sections | <p>There are terms used throughout the EIS that may either need defining, or inclusion in the glossary.</p> <ul style="list-style-type: none">“Bounding”, “bounding case” and “bound” are used frequently throughout the EIS to describe the scope of the assessment. For example, p. 2-6 the EIS States: “Denison has bound the environmental assessment above the deposit...”“Laydown”. P. 2-54 states: “During Construction, Denison plans to create a laydown area next to the future domestic landfill to temporarily store construction waste. Examples of materials include clean wood, plastics, metal, and concrete. The construction laydown area will not be lined, but it will have a berm surrounding the area to minimize run-on and runoff.”“Deflagration” (p. 2-22)“Speed of sound” The EIS states: “Deflagration means the material burns slower than the speed of sound, thus no shock waves are generated. Propellant permeability enhancement methods reach injection pressures of up to 8,000 psi and are near instantaneous over periods of milli seconds...” (p. 2-22) - Explain briefly what is meant by “speed of sound”“Dries” (p. 2-65): “the main dries will be located in the processing plant”“Scarified” 2-84 Laydown areas will be scarified, covered with 0.5 to 1.0 m of stockpiled overburden, and vegetated with native, self-sustaining species.“Furblock” (p. 4-29)“Cutlines” (p. 4-101) | Add this terminology to either one of the early glossaries, or when describing the methodology, in order to help readers understand these terms (particularly non-technical readers, such as Indigenous peoples and members of the public). | Thank you for the advice comment. This will be addressed once the EIS is updated following the conclusion of the information requirement (IR) process. |
| AD-02 | CNSC | General | Mining solution and lixiviant are used interchangeably throughout the EIS. When both are used periodically, may be difficult for a member of the public to recognize that these are one in the same (mining fluid seems more often used). | Be consistent in how this is referred to, in order to ensure it’s clear to readers that these are one and the same. | Thank you for the advice comment. This will be addressed once the EIS is updated following the conclusion of the information requirement (IR) process. |
| AD-03 | CNSC | Throughout the Executive Summary (ES) and draft EIS | <p>Errors in formatting and grammar were identified throughout ES and EIS. Some examples are underlined below:</p> <ul style="list-style-type: none">“often referred to as “the final uranium product (yellowcake” (ES, p.16)“Whitefish Lake;;” (ES, p.47)“Forest fires are common throughout most of northern Saskatchewan, however, and are an important natural disturbance of northern boreal forest ecosystems” (p.72) | Please correct these and any other formatting, spelling or grammatical errors. | Thank you for the advice comment. This will be addressed once the EIS is updated following the conclusion of the information requirement (IR) process. |

| AD-06 | Environment and Climate Change Canada (ECCC) | Section 2.2.3.8, Project Description | <p>In this section it is stated that: “The third step of the Industrial Wastewater Treatment Plant (IWWTP) is anticipated to further neutralize and improve the remaining water quality proposed to be achieved with further pH adjustments through agitated tanks and a clarifier with negligible solids generation expected at this stage. Several additional technologies including ion exchange are being evaluated as part of an ongoing Best Available Technology Study to be complete as part of future permitting.” ECCC would be interested in reviewing this study when it becomes available.</p> <p>Considering that the third step of the effluent treatment process in the IWWTP is still undergoing development, ECCC cannot make final conclusions regarding the efficacy of the treatment process. When final treatment technologies have been evaluated and selected, ECCC would like to review this information to allow for release to the environment.</p> | ECCC requests the opportunity to review the Best Available Technology Study and selected treatment technologies for the IWWTP when the report becomes available. | The BATEA information for the IWWTP will be included in Denison’s application to the CNSC for a license to operate. As such, ECCC can direct their review request for review to the CNSC. |
| AD-07 | TC | Section 2.2.5.3 | <p>With respect to the proposed airstrip, under the <i>Aeronautics Act</i>, the proposed airstrip would be considered an “aerodrome”, which is defined as:</p> <p>“aerodrome means any area of land, water (including the frozen surface thereof) or other supporting surface used, designed, prepared, equipped or set apart for use either in whole or in part for the arrival, departure, movement or servicing of aircraft and includes any buildings, installations and equipment situated thereon or associated therewith.”</p> <p>Aerodromes, including the one proposed by Denison, are subject to the <i>Aeronautics Act</i> and the Canadian Aviation Regulations (CARs).</p> | <p>*This advice pertains to the regulatory phase.*</p> <p>The proponent must notify the Minister of Transport of the proposed airstrip (aerodrome). This notification, being a summary report to the Minister of Transport, is required by section 307 of the CARs (CARs 307). CARs 307 also requires Denison to undertake consultation in the prescribed manner before it constructs the proposed aerodrome at the mine site. Details of the consultation are to be included in the above-mentioned summary report to the Minister of Transport.</p> <p>CARs 307 identifies the requirement to consult to include anyone seeking to undertake a prescribed aerodrome work at a certified or non-certified aerodrome, whether it is the creation of a new aerodrome or, at an existing aerodrome, lengthening an existing runway or making a new one. The Regulation also provides minimum expectations for how the consultation should be conducted, including timelines, who to notify and under what circumstances. The intent of the Regulation is to compel consultation in advance of an aerodrome work that will result in sustained and regular impact on interested parties as identified in the Regulation.</p> | Acknowledged and Denison will address this in the regulatory phase as highlighted. |

|--------|------------|--|--|--|--|
| | | | | <p>As the proposed aerodrome will not be within 4 kilometres of a city or built-up area, under CARs 307, the proponent is required to consult the following interested parties:</p> <ul style="list-style-type: none">(i) the Minister of Transport,(ii) the providers of air navigation services,(iii) the operator of a certified or registered aerodrome located within a radius of 30 nautical miles from the location of the proposed aerodrome work,(iv) the authority responsible for a protected area located within a radius of 4 000 m from the location of the proposed aerodrome work,(v) any local land use authority where the proposed aerodrome work is to be carried out, and(vi) the owner of any land bordering the land on which the proposed aerodrome work is to be carried out. <p>Proponents are encouraged to share their plans with the local land use authority before the consultation period. The local land use authority may have information about other nearby projects or developments that could impact on the proponent's plans.</p> <p>In summary, regarding the airstrip (aerodrome), the proponent must complete the consultation and file the summary report with the Minister of Transport, prior to commencing construction of the aerodrome.</p> <p>Further details can be found at: https://laws-lois.justice.gc.ca/eng/regulations/SOR-96-433/FullText.html#s-307.01.</p> <p>TC recommends that the proponent contact TC's Aerodromes Group at CASPNR-SACRPN@tc.gc.ca before starting the consultation, to ensure it is completed in accordance with CARs 307.</p> | |
| AD-08 | CNSC | Figs. 3.4-1, 4.3. 1, and where applicable throughout the EIS | Some maps in the EIS do not contain highway numbers. | Please consider including the highway numbers on the maps early in the Draft EIS when laying out the project location so the reader can become familiar with road network within northern Saskatchewan when discussions take place. | Thank you for the advice comment. This will be addressed once the EIS is updated following the conclusion of the information requirement (IR) process. |
| AD-09 | CNSC | Section 4, including Figures 4.3.1 and/or 4.3.2 and where applicable throughout the EIS. | The maps included in the EIS in sections do not have any Treaty boundaries. First Nation Treaties should be included on the map. Not all First Nations reserves, and boundaries are included on the map such as Cree Lake and Slush Lake, please include on map and consider adding others from the NAD. | It is recommended that Denison update the maps in these sections to include Treaty Boundaries and community locations are included on the Project location map in Figure 4.3.2 and other maps throughout the entire EIS where applicable. | Thank you for the advice comment. This will be addressed, as possible, once the EIS is updated following the conclusion of the information requirement (IR) process. |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|--|---|--|--|
| | | | | | |
| AD-10 | CNSC | Section 4 | Overall, CNSC believes that Denison is abiding by the communications strategies and products identified in their PIDP, but would be interested in additional information that is available. | While CNSC staff are satisfied that the proponent meets the requirements with this EIS, further clarity and detail on the strategic planning behind these communications activities would be beneficial and would further support the overall goals of the Project’s engagement activities. | Acknowledged. Further details on the Public Information Program and Public Disclosure will form part of the documentation submitted in support of the CNSC licensing for the Project. |
| AD-11 | CNSC | Section 4 Indigenous Engagement Report (IER) | There is a summary of what engagement activities will occur moving forward. However, it is not clear which engagement activities/meetings will occur during the different stages of the EA/ project life cycle. Please provide additional details upon submission of the Final EIS. | Denison should consider clarifying in the updated IER which engagement activities will occur during each stage of the project moving forward as per Reg Doc 3.2.2 before submitting the Final EIS. | The engagement activities as outlined in the draft EIS are reflective of the iterative nature of engagement with respect to the Project. At the time of the filing of the final EIS, Denison will describe the status of engagement and future expected engagement activities to occur, which will continue to be aligned with the requirements of Reg Doc 3.2.2. |
| AD-12 | CNSC | Section 4 IER | Information included in the EIS Section 4 and IER regarding engagement activities, communication and issues and concerns raised will need to be updated when the next version of the EIS is submitted. The EIS and IER will need to be updated to include information from Fall of 2022 until approximately two months prior to the submission date of the next EIS. | When re-submitting the EIS, ensure that the engagement log, issues and concerns tables and information about engagement activities done to date have been updated. No action needed only advice to update this section before submission with most up to date engagement activities including any that take place with other Indigenous Nations and communities not included in the Draft EIS. | Acknowledged. |
| AD-13 | CNSC | Section 4 IER | Denison states that validation of VC selection was completed with ERFN, the Northern Village of Beauval, the Northern Village of Pinehouse Lake, and the Northern Hamlet of Patuanak (hereafter Beauval, Pinehouse, and Hamlet of Patuanak, respectively). The EIS states that this was completed through a shared online survey. The EIS also indicates that YNLR was also included in this process. | How has Denison validated VC selection with the other Indigenous Nations and communities that have showed interest and if so, by what methods (survey’s, engagement, meetings, review of Draft sections etc.?) Did Indigenous Nations and communities select any VC’s that were not included in the EIS and if so why not? Please elaborate and provide more details in the EIS on any other methods used including engagement sessions that were completed with Indigenous Nations and communities, through in-person community workshops, VC selection approval through early review of Draft EIS sections. | Section 4 of the draft EIS describes the approach taken related to the Indigenous and non-Indigenous Communities of Interest in relation to the Wheeler River Project. Denison has engaged with these entities regarding the validation of the VC selection. Denison has not undertaken VC validation activities with other Indigenous Nations or communities that have shown interest in the Project, owing to the systematic approach to engagement Denison has been following. This approach is consistent with the methodology presented to the CNSC by Denison in early 2020, for which confirmation was received in mid-2020 and reflected in the draft EIS. All activities undertaken in relation to engagement on VCs are currently described in the EIS; there are no additional details to add. Denison can confirm that it is unaware of additional or new VCs brought forward by other Indigenous Nations or communities that are not suitably captured within the current draft EA approach. |
| AD-14 | CNSC | Section 4.3.1, Pg 246 | On this page, Denison states that MN-S is “currently structured with a President, an Executive, a Provincial Metis Council, Regional Presidents, and Local Presidents. The wording of ‘Regional President’ is incorrect and should be changed to say, ‘Regional Director’. | Please update all wording of “Regional President” to “Regional Director” when referring to MN-S. | Thank you for the advice comment. This will be corrected in the final EIS. |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|--|---|---|--|
| AD-15 | ECCC | Sections 5.3.4 (Table 5.3-3); 8.1.3.3 Climate Change; 8.1.3.4 Climate Change Influenced Extreme Events; Table 15.4-1: Summary of Potential Effects of Short-term Extreme Weather Events on the Project and Associated Mitigation; Section 15.5 Climate Change. | <p>The Proponent indicates that the Project’s full lifetime is roughly 40 years (including the post-decommissioning phase) and that climate conditions are important design considerations for a number of sensitive aspects of the Project. Potential future climate changes and their potential effects on the Project and Valued Components (VCs) are described in various sections of the draft EIS. Notably, in Section 15.5.2, ensemble mean projections are provided for several climate variables for two future time periods and emissions scenarios (RCP 4.5 and 8.5). In Section 8.1.3.4, the Proponent describes possible future changes in short-duration precipitation extremes (based on Intensity Duration Frequency or IDF curves from the IDF_CC tool) and indicates that an increase in their frequency and magnitude may occur over the Project lifetime “... and may require consideration for greater storage and conveyance capacity for Project water management infrastructure” (p.8-41).</p> <p>The Proponent indicates that aspects of the Project are being designed to meet standards based on design values that appear to be derived from observed (i.e. historical) climate conditions (e.g. water management infrastructure; see Table 15.4-1). In Section 15.5.3, they indicate that an adaptive management approach will be used to address some aspects of future climate change as necessary. For example, page 15-19 of the draft EIS states that: “Denison will develop an Emergency Preparedness and Response Program for the Project to address forest fires and extreme weather that may occur. If unforeseen effects on the Project occur from longer and more severe forest fire seasons associated with climate change, or increased frequency or severity of extreme weather (e.g., ice storms, snowstorms, flooding), Denison will apply adaptive management that includes monitoring climate factors so that they can proactively mitigate or prevent adverse climate effects on the Project.” (Emphasis added).</p> | <p>ECCC recommends that when considering potential future climate change and relevant effects on the Project, the Proponent consider the range of variability from the ensemble of models (not just the ensemble mean). ECCC also recommends that the Proponent consult the 2019 Canadian Standards Association Guidance on Intensity Duration Frequency for Canadian Water Resources practitioners , which provides examples of alternative methodologies to estimate future return values for design as needed.</p> <p>In terms of adaptive management, ECCC recommends that the Proponent clearly outline what climate factors will be monitored to mitigate or prevent adverse climate-related effects. This should include information on when and how the climate factors would be monitored and under what circumstances particular adaptive management approaches would be applied.</p> | <p>Please see response to IR-15, IR-103, IR-104, IR-235, and IR-236.</p> <p>The probable maximum precipitation (PMP) value of 493 mm selected for design of water management infrastructure, such as ponds, is similar to total annual precipitation (456 mm from Key Lake station, and 483 mm from 1981-2020 climate normals).</p> <p>The selected PMP is well above (>5 times higher): 1) current/measured 24-hour maximum precipitation, 2) modelled 1 in 100 year 24-hour return for current conditions, 3) modelled 1:100 year 24 hour return for a future (2020-2050) period, 4) the predicted maximum 1-day precipitation under different emissions scenarios for the future (including RCP8.5 in the 2021-2050 period).</p> <p>For comparison to the design PMP of 493 mm:</p> <ul style="list-style-type: none">- the measured maximum 24-hour precipitation from Key Lake station was 42.9 mm and 72 mm from 1981-2020 climate normals.- the modelled existing/current 1 in 100 year, 24 hour return using the IDF_CC Tool for the Wheeler River Project site was 79.9 mm and at the Key Lake area was 56.4 mm.- the modelled future (2020-2050) climate 1 in 100 year, 24 hour return using the IDF_CC Tool for the Wheeler River Project site was 88.6 mm and at the Key Lake area was 62.0 mm.- the predicted future climate (2021-2050) under the highest CO2e emissions scenario (RCP 8.5) shows maximum 1-day precipitation of 25.9 mm. <p>The PMP is much higher (> 5 times higher) than the observed and predicted 24-hour maximum precipitation and the 1:100 year 24 hour return. Completing the design using a large PMP provides confidence that the water management infrastructure will be sufficient and function under future climates as it relates to potential changes in precipitation.</p> |
| AD-16 | CNSC | Section 5.10 (p.70) and throughout the EIS | <p>In section 5.10 of the ES, where the seven scenarios are listed, formatting is inconsistent. Likelihood is in quotes in some places, but not in all.</p> <p>Not significant is bolded inconsistently throughout the EIS.</p> <p>As well, in many cases noted as “not significant”, where others note “are not expected to have a significant effect”.</p> | <p>Suggest making formatting consistent if going to use quotes and bolding to highlight sections of the text.</p> <p>Also, validate that use of “not significant” and “are not expected to have a significant effect” are consistently used (where appropriate).</p> | <p>Thank you for the advice comment. This will be addressed, as possible, once the EIS is updated following the conclusion of the information requirement (IR) process.</p> |
| AD-17 | ECCC | Appendix 6-A Air Quality Technical | Some of the off-road vehicles have an emission rating of Tier 2 but in Appendix 6-A Section A.10 the Proponent claims that “for non- | ECCC recommends that the Proponent choose engines that meet the most stringent emission standards to the extent possible, which | Please see response to IR-139. |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|--|--|---|--|
| | | Supporting Document A.10 | road diesel combustion, Tier 4 emission factors were assumed”. Choosing an engine with a lower Tier will increase emissions in NOx significantly and the Proponent should be using the best available technologies to minimize environmental impacts. | are Tier 4 for the compression-ignition engines, during all phases of the Project. | |
| AD-18 | ECCC | Appendix 6-C, Climate Baseline and GHG Emissions Report | <p>Understanding Project emissions is important to inform analysis of a Project’s potential impact on Canada’s emissions targets and climate change commitments.</p> <p>ECCC notes that Section 4.0 and Appendix C: Greenhouse Gas Emissions Calculations of Appendix 6-C identifies the source of emissions and quantifies them in the construction, operation, and decommissioning phases of the Project, in accordance with the Draft Technical Guide Related to the SACC (Draft Technical Guide). While ECCC recognizes that the emissions will be relatively small in the post-decommissioning phase, the identification and quantification of the emissions in this phase is not found in the draft Environmental Impact Statement (EIS). The post- decommissioning phase is expected to last 15 years, likely going past 2050.</p> <p>The draft EIS does not discuss emission intensities of the Project, only the grid electricity. The draft EIS also does not discuss the Project’s potential impacts on Canada’s climate targets.</p> | <p>ECCC recommends that the identification of the sources of Greenhouse Gas (GHG) emissions and quantification of these emissions be described for the post-decommissioning phase, as done for the other phases.</p> <p>ECCC recommends the Proponent include discussion on the emission intensities of the mining of the product, following the guidance of the SACC and the Draft Technical Guide.</p> <p>ECCC recommends that the Proponent discuss the potential impacts that the Project may have on Canada’s ability to meet its climate-related targets, following the guidance of the SACC and the Draft Technical Guide.</p> | <p>The Post-Decommissioning phase only includes monitoring (physical, chemical, and biological) and regulatory site inspections. These activities are not expected to generate any significant GHG releases. Notwithstanding, the calculated GHG emissions estimates for Construction, Operation and Decommissioning are expected to be sufficiently conservative to capture any incidental GHG releases during monitoring and inspection activities.</p> <p>The EIS anticipated an annual average production rate of approximately 4,082 metric tonnes of U₃O₈ and an annual net GHG releases of 30,702 metric tonnes CO₂e over the operations phase of the project. The annualized GHG intensity during operations is estimated at 7.5 tonnes of CO₂e / tonnes of U₃O₈.</p> <p>Section 2.5 of the EIS provides a summary of the anticipated GHG releases and a comparison to the nation- and province-wide GHG emissions. The project is expected to contribute less than 0.0043% to the nation-wide annual average. Given this very low contribution, the project is not expected to impact Canada’s ability to meet its climate-related objectives and targets.</p> <p>Also see response for AD-19 (second paragraph).</p> |
| AD-19 | ECCC | Appendix 6-C, Climate Baseline and GHG Emissions Report | <p>The draft EIS lacks information related to estimates of impact on carbon sinks and emissions from land-use changes. As land use shifts from a vegetated site prior to development, to an industrialized site, removal of vegetation and peat will have impacts on carbon sinks and construction emissions.</p> <p>Section 6, Appendix 6-C, 4.1.2 Land Use Change states that site-specific information of above-ground mass of vegetation was not available and default data from Table 20 of the Draft Technical Guide were applied. The default data is contained in this table is not applicable in this case, as they represent aboveground woody vegetation in cropland systems.</p> <p>ECCC recognizes that the usage of the median value of 0.51 for the carbon content is reasonable.</p> <p>From the information given in the draft EIS, it does not seem that the soil carbon was taken into account. In the absence of detailed information, the Proponent assumed that the area cleared would also be excavated (and drained in the case of wetland areas) which would create significant additional emissions from soil disturbances and drainage.</p> <p>Section 4.1.2 also states the Project involves clearing an area of</p> | <p>Land Use Change Regarding the lack of site-specific information of above-ground mass of vegetation, an initial site survey on-site using basic information such as site class and species would assist in determining the above-ground biomass. More specific data, such as regional data from provinces, forest companies, or literature may be available, and generic national data is available (e.g., Fo148-1-2E.pdf (publications.gc.ca), 4775.pdf (nrcan.gc.ca)).</p> <p>ECCC recommends that the Proponent also consider biomass that are not aboveground and confirm whether soil carbon is taken into account, as well as wetlands.</p> <p><i>Carbon Sinks</i> ECCC recommends that the Proponent provide a quantitative and qualitative description of the Project’s impact on carbon sinks, following the guidance of the SACC and the Draft Technical Guide.</p> | <p>Limited site-specific data were available to characterize land use change and impacts on carbon sinks. As such, the use of default values from the SACC/IPCC in conjunction with some limited habitat/vegetation data (extracted from Chapter 9.2 Terrestrial Environment – Vegetation and Ecosystems, Listed Plant Species and Wetlands) was employed and is considered reasonable at this stage of the assessment. Please note that additional information on the land use change GHG calculations can be found in Appendix 6-C Climate Baseline and Greenhouse Gas Emissions Report.</p> <p>In accordance with our discussions with the CNSC, Denison is committed to re-assessing the GHG and climate change components of the EIS and other elements of the SACC once more detailed, site-specific data becomes available (i.e., detailed feasibility and engineering studies). This is expected to include more detailed study around overall GHG emissions, carbon sinks and mitigation options, best available technologies / best environmental practices, climate resiliency, net-zero carbon planning and offsetting.</p> |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|---|---|--|--|
| | | | approximately 169.6 hectares. There are no estimates on the impact on carbon sinks related to the Project. | | |
| AD-20 | NRCan | Section 7.3.1, Physical Geography | Drumlins and eskers in the region trend Northeast to Southwest as opposed to northwest to southeast as written on page 7, line 18. Correct orientations are used on page 7, line 23. | NRCan recommends revising the text. Please refer to 250 000 scale Surficial Geology Lines from Quaternary mapping, CSRS NAD83 Zone 13, Saskatchewan Geological Survey 2017. | Acknowledged. The typo in the draft EIS, Section 7.3.1 will be corrected in the final EIS. In Section 7.3.1. the text will be updated to say the following: “The most important associated topographic features in the region are the northeast to southwest trending drumlins and eskers...” See also response to IR-54. |
| AD-21 | NRCan | Section 7.3.2.3, Metacrystalline Basement Rock | Pegmatite missing from list of basement rock types. | NRCan suggests addition of pegmatite to the list of basement rock types as shown on Figure 7.3-6. | Denison will update the final EIS per NRCan’s suggestion. |
| AD-22 | NRCan | Section 7.3.3.1, Aquifer Properties, Section 7.3.2.3, Metacrystalline Basement Rock, Appendix 7A, 2.0, 2.3.1, 2.3.2 | The terms “metacrystalline” and “metagranitic gneiss” are not frequently used terms in scientific literature. Gneiss is, by definition, a metamorphic rock. | NRCan suggests revision to “Crystalline Basement rocks” or “Basement metamorphic rocks”, and “granitic gneiss” as used in Figure 7.3-6. Please refer to Oxford Dictionary of Earth Sciences. | Denison will update the final EIS per NRCan’s suggestion. |
| AD-23 | NRCan | Appendix 7A, 2.3.1, Metacrystalline basement rock | Orogeny is the process, orogen (or orogenic belt) is the feature produced by orogeny. | NRCan suggests replacing “Tran Hudson Orogeny” with Trans Hudson Orogen”. | Denison will update the final EIS per NRCan’s suggestion. |
| AD-24 | NRCan | Appendix 7A, 2.3.1, Metacrystalline basement rock | Quartzite is by definition a metamorphic rock, and the term is used later without the meta-prefix. | NRCan suggests replacement of the term “meta-quartzite” with “quartzite”. | Denison will update the final EIS per NRCan’s suggestion. |
| AD-25 | NRCan | Appendix 7A, 2.3.4, Athabasca Group Sandstones and Conglomerates | Sands are unlithified, whereas you are referring to grain sizes in this case. | In Table 2-1, NRCan suggests replacing the term “sands” with “grain sizes” under MFc and MFb descriptions. | Denison will update the final EIS per NRCan’s suggestion. |
| AD-26 | NRCan | Appendix 7A, 2.3.5, Overburden | Typo on page 2, line 7: “A grain size sample was collected in GWR-033 from approximately 9 m below ground surface, and the same consisted of 8.8% clay (less than 4 µm). | NRCan suggests revision of “same” to “sample” and clay to “clay-sized” grains. | Denison will update the final EIS per NRCan’s suggestion. |
| AD-27 | CNSC | Section 8.2.1.3 – Spatial and Temporal Boundaries | It is noted that McGowan Lake is an identified reference lake for the Key Lake Mill site. With the establishment of the Wheeler River mine, effluent would be flowing into McGowan Lake, which could potentially interfere with Key Lake’s environmental monitoring program by compromising McGowan Lake’s baseline conditions. Depending on the loading of COPC’s into McGowan Lake and resultant water concentrations, it may no longer be accepted as an acceptable reference lake for use by Key Lake. This would require Cameco to modify their monitoring program at the Key Lake Mill. | The CNSC advises Denison to communicate with Cameco to ensure they are aware of this situation. Coordination between the two companies may be necessary to ensure Key Lakes environmental monitoring program is not compromised. It is recommended to discuss this potential issue with Cameco ahead of time to determine the best path forward. | Denison will communicate with Cameco through the Saskatchewan Mining Association to highlight the timing of the start of the Project as it may relate to Cameco’s use of regional lakes for reference lake purposes. McGowan Lake will no longer be suitable as a reference lake for Cameco once the Wheeler River Project starts operating, since it will be downstream of treated effluent release. Alpha Lake (LA-9 in Denison’s aquatic baseline studies) will likely be outside of any influence from Denison’s activities. |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|---|---|--|---|
| | | | | | Please note that Denison has previously been in communication with the Saskatchewan Ministry of Environment, Environmental Protection Branch regarding the baseline study work Denison completed as part of the Environmental Assessment process and the potential changes to McGowan lake (a Cameco's reference lake) from the proposed Wheeler Project. Reference: Email from Janna Switzer (Denison) to George Bihun (MOE) on May 12, 2020. |
| AD-28 | ECCC | Section 8.2.4.2.3 Appendix 10-A, Section 3.1.1.2 | <p>Tables 8.2-9 and 8.2-10 in Section 8.2.4.2.3 Part II_S8 Aquatic Environment and Table 3-1 in Appendix 10-A Section 3.1.1.2 demonstrate predicted maximum effluent concentrations of Constituents of Potential Concern (COPCs) and maximum predicted receiving environment concentrations.</p> <p>The final effluent quality discharge target for uranium is 0.057 mg/L. However, the Canadian Council of Ministers of the Environment (CCME) water short-term (acute) water quality guidelines for the protection of aquatic life is 0.033 mg/L. The proposed effluent discharge target for uranium exceeds the acute water quality guideline, indicating effluent may pose the risk of being acutely lethal to aquatic biota at end-of-pipe. While uranium is not a Schedule 4 substance with prescribed concentration limits under the Metal and Diamond Mining Effluent Regulations (MDMER), the MDMER requires the characterization of uranium concentrations in effluent under Schedule 5, and requires that all mine effluent released from final discharge points be non-acutely lethal.</p> <p>Under Schedule 5 Section 9(d) of the MDMER, the Proponent will likely be required to conduct selenium fish tissue sampling if average annual concentrations of selenium in effluent equals or exceeds 5 ug/L.</p> | Discharges from the proposed Project will alter water quality in the immediate receiving area, and this may include some sublethal effects on aquatic biota, which must be minimized. It remains the Proponent's responsibility to adhere to the MDMER to ensure that effluent at the end-of-pipe from all final discharge points be non-acutely lethal and meet requirements for prescribed deleterious substances under Schedule 4 of the regulations. | Denison fully understands its obligations with respect to the MDMER and will comply with the MDMER end of pipe effluent discharge criteria. |
| AD-29 | CNSC | Section 8.3.3 Figures 8.3.5 etc. 8.5-4 | It does not appear that aquatic baseline sampling maps for Russell Lake have LAB 1 and 2 locations showing the baseline sampling locations within Russell Lake. (Figures 8.3.5). Please update the Figures throughout aquatic environment section to include of the baseline sampling studies/ locations within Russell Lake. | Please update maps and sections in EIS to reflect aquatic baseline studies that were completed. | Thank you for the advice comment. This will be addressed, as possible, once the EIS is updated following the conclusion of the information requirement (IR) process. |
| AD-30 | CNSC | EIS sections 8.4.3.2.4 Benthic Invertebrate Community and 8.4.7.6 Climate Change Considerations | <p>ECCC EEM guidance recommends the use of multiple reference areas as it offers the greatest statistical power to detect a meaningful difference between a reference area and an exposure area and can also give an indication of variability among reference areas. It is also important to incorporate multiple reference locations into the study design to aid in designing against spatial confounding factors.</p> <p>Section 3 of the Aquatic Environment Baseline Study Report details the similarities between benthic invertebrate communities by using the mean Bray-Curtis index between sampling locations and the</p> | Considering climate change may change the lake conditions from baseline conditions, and that there is already natural variability between lakes that will be used as reference lakes and exposure lakes, it could become difficult to show changes to sediment/benthic invertebrates are not due to project activities, therefore there is a recommendation to ensure the current baseline data is adequate, and to consider if additional data, and addition of additional reference stations, will be needed moving forward. | Changes in landscape influence and lake conditions are not limited to those brought about by climate change. The preparation of a study design under the MDMER EEM program strives to ensure that a single reference area or multiple reference areas are as representative of a control condition as possible. Best practice is to undertake an analysis of candidate reference areas using the existing baseline information and investigate their utility as controls prior to project development. A preliminary EEM study can be completed that will allow for a Before-After-Control-Impact study design, that will provide the ability to monitor change not only in |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|--|---|---|--|
| | | | <p>median reference condition for the lake group size. It’s not clear in the EIS if there are any issues expected to be able to use this data to compare project effect locations to references sites into the future, as some sampling locations are currently not very similar to the reference sites.</p> <p>In addition, climate change could affect the sediment and benthic communities in the future. The EIS states “the frequency and magnitude of extreme precipitation events have the potential to change water levels and flows in the RSA, which may affect sediment transport, deposition, and therefore benthic invertebrate habitat. Changes to average and upper and lower bounds of ambient temperatures may also affect aquatic habitat, which in turn may affect benthic invertebrate communities. Climate change over the life of the Project (i.e., 35 to 40 years) will be monitored as part of the Project’s environmental monitoring programs, and influences on water quality, sediment quality, and benthic invertebrates will require adaptive management to mitigate any potential effects of the Project that may be exacerbated by climate-related changes on the aquatic environment”. It is recommended to ensure that appropriate number/location of reference sites are sampled to enable any changes to sediment or benthic invertebrate communities that may be due to climate changes, and not project effects, are able to be assessed.</p> | | <p>the exposure areas, but in the reference areas, thereby allowing for a reasonable assessment of potential mine related impacts.</p> |
| AD-31 | CNSC | Section 8.4.6.1, Residual Effects Characterization | <p>The EIS states “Local Indigenous communities have expressed direct concern with respect to mercury. Mercury has not been identified as a COPC for the Project as it is currently not present in the receiving environment (i.e., background condition) at detectable concentrations and will not be produced as part of the mine process; therefore, it will not be discharged to the aquatic environment. However, it is understood that potential nutrient enrichment-related effects are possible and can be linked to increases in mercury in the environment.” Based off concerns from Indigenous communities, and the fact that phosphate is a COPC in the effluent, and elevated concentrations of mercury were measured near the Kratchkowsky Lake bottom, adding methylmercury to the environment sampling plans may be beneficial.</p> | <p>Please consider adding methylmercury to the environment sampling plans (such as fish dorsal muscle) in order to confirm there are no unexpected effects of the project on levels, and to satisfy stakeholder concerns.</p> | <p>Refer to response to IR-100.</p> |
| AD-32 | CNSC | Section 9.1.8.3, Appendix 10-A (ERA) section 3.2.1.5 | <p>It appears there is no consistency between the assessment of soil quality in the ERA and the baseline soil sampling program presented in the EIS. The baseline program includes 10 soil permanent sampling locations (Appendix 9-B, section 2.5). Sampling at these locations is proposed to be continued during the Operation Phase, and monitoring data will be compiled and reported annually/periodically (EIS section 9.1.8.3).</p> | <p>Please clarify how baseline measured data on COPC concentrations in soil is considered in the current and future iterations of the ERA.</p> | <p>Baseline measured soil data were used in the ERA to characterize the existing environment. The IMPACT model was used to predict the Project contributions for the Project phases above baseline. The baseline soil concentrations used in the model are provided in Section 3.5.1 and Table 3-8 of Appendix A in Appendix 10-A (ERA).</p> |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|--|---|---|---|
| | | | Conversely, the ERA estimates and predicts concentrations of COPC in soil based on atmospheric deposition. Furthermore, the location of ecological receptors in the ERA (Figure 5-2) is different from the permanent soil sampling plot locations (Appendix 9-B, Figure 2.5-1). It is unclear why measured baseline soil quality data were not discussed in the ERA and whether future monitoring data will be considered in the ERA to verify accuracy of predicted COPC concentrations | | The ERA will be revised according to the periodic review requirements in CSA N288.6-22 which will reflect ongoing data collected from monitoring programs. |
| AD-33 | CNSC | Section 9.3.3.1.2 | <p>Indigenous knowledge is summarized with regard to moose, including:</p> <ul style="list-style-type: none">• Calving sites close to the Wheeler River, with lots of muskeg in the area. A moose calving area is located in the Terrestrial RSA, southwest of the Project Area.• A wildlife corridor is used by moose, running between Cree Lake (outside and to the west of the Terrestrial RSA) and Russel Lake (in the southern portion of the Terrestrial RSA). <p>It is unclear how this information is incorporated into the residual effects assessment.</p> | Please clarify how Indigenous knowledge on moose calving sites and corridors in the RSA is incorporated into the residual effects assessment for the key indicator “moose”. | <p>The sites identified by IK were explicitly considered in the impact assessment as indicated by their identification as overlapping with the Terrestrial RSA as noted in the question. However, the areas were not expressly discussed in the residual effects assessment because there is no anticipated spatial overlap of those areas with direct or indirect Project effects.</p> <p>The Indigenous Knowledge provided by ERFN and SVS (2022) identifies a moose calving site (Feature 1001-08) ~ 2 km southwest, and a wildlife corridor ~6 km south of the Project Area (as depicted in Figure 4. Map B, page 16 of ERFN and SVS 2022). Both areas are within the Terrestrial RSA but outside the Wildlife LSA. The reference to “Calving sites close to the Wheeler River...” refers to a broad area that is 45 km east of the Project Area, well beyond interactions with the Project Area.</p> <p>The presence of the areas identified through IK was acknowledged in Section 9.3.3.1.2 (Information from Indigenous Knowledge, Local Knowledge, and Engagement) in Part II, Sec. 9 of the Draft EIS. The assessment (Sec. 9.3.4.2) considered alteration and/or habitat loss at the LSA and RSA scale. Section 9.3.4.2.1 (pg. 9-210) summarizes the effects on moose habitat as follows: “Habitat alteration through sensory disturbance effects (such as noise, dust deposition, and artificial light) is expected to result in reduced habitat quality and effectiveness near Project components and infrastructure reaching beyond the Project Area into the Wildlife LSA....”</p> <p>Further, Sec. 9.3.6.2.1 (Alteration and/or Loss of Habitat, pg. 9-230) identifies that an area within a 500 m radius of the Project Area will be influenced by the Project and likely make the habitat within that area less suitable for use by moose. Therefore, the effects of the Project on moose calving have been appropriately assessed and are expected to be contained within the Wildlife LSA. That affected area does not overlap with the moose calving site or the wildlife corridor identified by IK.</p> |
| AD-34 | CNSC | Appendix 9-B | Baseline studies for birds are restricted to short time frames in one year only, for example: | Please consider conducting surveys following CWS’s recommendations or provide an explanation as to how current | The data collected as part of the baseline studies for birds was focused on the habitat types and areas most likely to be disturbed as a result of the Project. Conducting additional baseline surveys for |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|-----------------------------------|--|---|---|---|
| | | | <ul style="list-style-type: none">Breeding Songbird Point Count Call Survey (June 7 and 17, 2017)Aerial Waterfowl and Raptor Stick Nest Survey (June 15 and 16, 2017) <p>The Canadian Wildlife Service (2022) recommends:</p> <ul style="list-style-type: none">Consider the potential effects of projects on birds throughout the year and document the distribution and abundance of birds in all seasons. Some species may be under-represented in existing data bases due to temporally restricted periods of detectability.Explicitly target species at risk and other focal species.Conduct at least two years of field surveys as a national standard for major projects, so that temporal variability can be considered in future comparisons to baseline data. <p>Reference: Canadian Wildlife Service. 2022. Guidance Regarding Data Needed to Support Assessment of Project Effects on Birds. Environment and Climate Change Canada, Gatineau, Quebec. 80 p.</p> | baseline data for birds is sufficient to characterize the existing environment. | waterfowl, raptors, and breeding birds is not anticipated to result in changes to the assessment outcomes and predictions made as part of the effects assessment, which was habitat-based, for avian species. The assessment methods used a conservative approach with the assumption that following the implementation of site-specific mitigation measures, the proposed Project activities would have a residual effect on these species guilds regardless of species presence on site. However, to supplement the species data that were collected as part of the baseline field program, Denison is willing to acquire additional information on species presence in the RSA from existing sources, specifically from the Saskatchewan Breeding Bird Atlas (Birds Canada). However, collection and consideration of this information is not expected to affect the findings and/or conclusions stated in the draft EIS as the assessment was habitat-based to address all species. |
| AD-35 | CNSC | Section 10, IMPACT MODEL | Denison discusses details of the IMPACT model but has not provided scenario(s) used to facilitate review. | Please consider providing CNSC with the IMPACT model scenario file(s) in the spirit of regulatory cooperation. | The intent of Appendix A to Appendix 10-A is to provide the inputs used for the IMPACT model as well as all of the characteristics for human and ecological receptors. Where site-specific data were not used in the model it can be assumed that default values from CSA N288.1-20 were used in the IMPACT model. As such, Denison does not intend to provide the scenario files. |
| AD-36 | English River First Nation (ERFN) | Section 10.1.3.2, Traditional Foods Diet (p. 10-15) | The EIS States: "The ERFN is comprised of seven reserve lands across Saskatchewan" (p. 10-15) While this is accurately reflecting a source document, the source document is incorrect. | Please update to "The ERFN is comprised of seven historical settlements that have now grown into 19 different reserves across Saskatchewan" | Thank you for the advice comment. This will be addressed, as possible, once the EIS is updated following the conclusion of the information requirement (IR) process. |
| AD-37 | CNSC | Section 10.1.9, Human Health Summary and Appendix 10-A – 4.4.1 Risk Estimation | The Human Health section of the EIS, as well as the ERA, indicates that there is an exceedance for selenium for the fisher/trapper receptor, with the Project estimated to contribute to the majority of this exceedance (0.93 of the HQ). While the assessment is conservative by assuming an increase intake rate of fish solely sourced from Russel Lake, the precautionary principle should be considered to ensure in reality the HQ for selenium remains below 1, even under conservative assumptions. | Please conduct of effluent, water, and aquatic organism monitoring (as already suggested in EIS) to confirm HQ's are highly conservative in the EIS modelling and receptors remain protected. Should it be determined Se concentrations are increasing in the environment at such a rate as there may be in impact to the environment or human health, installation of a selenium removal circuit into the effluent treatment process should be considered. The proponent should ensure that the proposed wastewater treatment system design incorporates the capability for expansion or upgrades in alignment with the precautionary approach, pollution prevention, and continuous improvement. | Denison acknowledges that a robust effluent and environmental monitoring program will be developed to confirm all EIS modelling predictions. The ERA will be revised according to the periodic review requirements in CSA N288.6-22 which will reflect ongoing data collected from monitoring programs. |
| AD-38 | CNSC | Appendix 10-A (ERA) | It is unclear if measured or modelled COPC concentrations in blueberry were used in the calculations of human receptor dose. Similarly, it is unclear if measured or modelled COPC concentrations | Please clarify if measured or modelled COPC concentrations in blueberry / lichen were used in the calculations of human and ecological receptor dose. | Measured baseline lichen data were used in the ERA to characterize the existing environment. The IMPACT model was used to predict the Project contributions for the Project phases above baseline. |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|--|--|--|--|
| | | | <p>in lichen and blueberry were used in the calculations of ecological receptor dose.</p> <p>CSA N288.6-22, Clause 7.3.6 states that “Measured concentrations of COPCs should be used, where possible, in the exposure assessment.” Please see the Clause for further information.</p> | | <p>Measured baseline blueberry data were used for model calibration to determine if there was good agreement between measured data and modelled data. The IMPACT model was used to predict both baseline and Project contributions for blueberries. The ERA will be revised according to the periodic review requirements in CSA N288.6-22 which will reflect ongoing data collected from monitoring programs.</p> |
| AD-39 | CNSC | Appendix 10-A (ERA), Table 2-2 | <p>Table 2-2: Estimated Home Ranges of Selected Terrestrial Ecological Receptors</p> <p>Based on the reference McLoughlin et al. (2016), the Home Range for Woodland Caribou is indicated as “Expected = 80 km2” which represents the mean range sizes pooled over the two study years for calving/post-calving. The indicated Minimum (67 km2) and Maximum (267 km2), however, do not relate to the calving/post-calving stage, which is not clearly stated in Table 2-2. In contrast, these values are actually mean range size values for autumn/rut and early winter, respectively, as described in the source document on Page 83 (McLoughlin et al., 2016). It should be noted that in terms of true minimum and maximum, the source document states that individual home ranges, based on up to two years of GPS locations, varied in size from 16.2 km2 to 1363.9 km2 (Page 82 of McLoughlin et al., 2016).</p> <p>Reference: McLoughlin et al. 2016. Population dynamics and critical habitat of woodland caribou in the Saskatchewan Boreal Shield. Interim Project Report, 2013–2016. Department of Biology, University of Saskatchewan, Saskatoon. 162 pp. Available online at http://mcloughlinlab.ca/lab/wp-content/uploads/2019/06/2013-2016-SK-Boreal-Shield-Caribou-Project-Interim-Report-Nov-18-2016.pdf</p> | Please provide clear details on the source of the home range values listed in Table 2-2. | <p>Denison acknowledges the comment and will add clarification in Table 2-2 of Appendix A in Appendix 10-A that the minimum represents the autumn/rut and the maximum represents the early winter.</p> |
| AD-40 | CNSC | Appendix 10-A (ERA) section 3.2.1.5 | <p>Although the soil type selected in the ERA for modeling of atmospheric deposition to soil is sandy soil, organic soils have been delineated and characterized (section 9.1.3.3 of the EIS) as valued component (i.e., “Organic Matter/Peat”). It is unclear if the soil quality modeling performed in the ERA is protective for soil types other than sandy soil.</p> | Please clarify if COPC modeling based on sandy soil is protective of organic/peaty soil and provide justification. | <p>The majority of the soil in the Project Area and LSA is considered sandy soil. Section 9.1.3.2 of the EIS states "Mineral soils are associated with upland sites and (in all likelihood) anthropogenically disturbed land that, together, correspond with >99% of the Project Area and 91.5% of the LSA (Figure 9.1-8). The predominate mineral soils within the RSA have been classified as Sandy Dystric Brunisols (Smith et al. 2011)." Organic matter/peat was included as a VC in the EIS because of the concern regarding drying and losing biological function through groundwater interactions, and not in terms of assessment of soil quality. Additionally, Section 9.1.3.3 of the EIS acknowledges that organic soils is limited in the Project Area. As such, this comment is considered not applicable.</p> |
| AD-41 | CNSC | Appendix 10-A (ERA), Table 5-5 | <p>Table 5-5: Complete Exposure Pathways for All Selected Ecological Receptors to be Assessed using the IMPACT Model</p> | Please add the pathway “direct contact in water” to Table 5-5 and revise all calculations accordingly. | <p>Table 5-5 will be revised to state “direct contact in water” for phytoplankton. No calculation changes are needed.</p> |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|---|---|---|---|
| | | | The exposure pathway for phytoplankton is stated as “direct contact in sediment”, however, phytoplankton live suspended in the water column. It is acknowledged that in the IMPACT modelling report, phytoplankton is described with an occupancy factor of 1 in water (Table 2-5). | | |
| AD-42 | CNSC | Appendix 10-A (ERA), Table B.12 | <p>Table B.12: Sample Calculation – Adult Recreational Fisher/Hunter (McGowan Lake) Dose and Risk Calculations for Selenium</p> <p>The source for the Terrestrial Plant Ingestion Dose for Labrador tea and blueberry is stated as “Table C.5”, however, this table could not be located.</p> | Please provide the referred-to Table C.5 or an alternate source of information for the Terrestrial Plant Ingestion Dose for Labrador tea and blueberry. | Thank you for the advice comment. This will be addressed, as possible, once the EIS is updated following the conclusion of the information requirement (IR) process. |
| AD-43 | CNSC | Appendix 10-A (ERA), Environmental Risk Assessment for Wheeler River Technical Support Document | <p>The ERA is prepared by Ecometrix and submitted to Denison Mines. It is unclear if the ERA submitted has been reviewed and accepted by the proponent (Denison Mines).</p> <p>CSA N286-12 clause 9.5.5 specifies that “the selected supplier’s technical documents that are required to be submitted shall be reviewed and accepted”.</p> <p>Meeting these CSA N286-12 requirements will ensure that the proponent has control of the purchased services as a future licensee applicant.</p> | Provide clarifications if ERA documents have been reviewed and accepted by the proponent. | See response to IR-202 which indicates that Denison reviewed and accepted the ERA. This text will be added to Appendix 10-A. |
| AD-44 | CNSC | Section 11 | It is not clear whether all of the interested Indigenous Nations and communities were engaged on the results and findings of the Heritage Resources Impact Assessments (HHRIA) or just ERFN? | CNSC staff would appreciate an update on any engagement activities that have taken place with regards to any of the HHRIAs for the Project, or any site or thing that is of historical, archaeological, paleontological or architectural significance as requested by other Indigenous Nations and communities to date. | <p>Denison confirms that the results of the Project-related HRIAs were discussed with ERFN, as they expressed interest in further understanding the nature of the work undertaken.</p> <p>The Saskatchewan Ministry of Parks, Culture and Sport, Heritage Conservation Branch (HCB) administers The Heritage Property Act. Regulatory approval as per section 63 of The Heritage Property Act (GS 80) was granted for the Project for the two separate HRIAs (HCB File No. 16-2102, December 14, 2017 and HCB File No. 19-933 February 12th, 2020).</p> <p>The results of the HRIAs were included and formed part of the draft EIS. Comments made by Indigenous communities on this section of the EIS will therefore be responded to accordingly by Denison, where appropriate.</p> <p>Additionally, as noted in Section 11.3.2, “The Heritage Resource Management Plan (HRMP) was informed by engagement with ERFN, who recommended that the HRMP should include a mechanism to involve Indigenous communities where appropriate (21-EN-ERFN-591.1; 21-EN-ERFN-591.2) (see Appendix 11-B).”</p> |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|--------------------|--|--|---|---|
| | | | | | The mechanism to involve Indigenous communities has been included in the HRMP and allows for general notification to Indigenous communities should an artefact be found, which provides flexibility to engage all appropriate Indigenous nations accordingly. |
| AD-45 | CNSC | Section 11.1.4.5.2. Perceived Suitability/Safe Use of Resources (p. 11-59) | <p>The EIS States: “Section 2.6.1 in Section 2 describes the extensive review of mining methods that led to the decision to adopt the ISR mining method.” (p. 11-59).</p> <p>This reference is not correct, as this section does not contain a review of the mining methods.</p> | Please update this to reflect the appropriate section. | Thank you for the advice comment. This will be addressed, as possible, once the EIS is updated following the conclusion of the information requirement (IR) process. |
| AD-46 | TC | Section 14.6.7.2 | <p>Transport Canada would like to clarify that although the proponent may use a third party to assist in developing emergency response assistance plans (ERAPs), it is the proponent’s responsibility to submit the ERAP application(s) to Transport Canada, per Section 7(1) of the <i>Transportation of Dangerous Goods Act, 1992</i> as follows:</p> <p>Emergency response assistance plan</p> <p>7 (1) No person shall import, offer for transport, handle or transport dangerous goods in a quantity or concentration that is specified by regulation — or that is within a range of quantities or concentrations that is specified by regulation — unless the person has an emergency response assistance plan that is approved under this section before</p> <p>(a) importing the dangerous goods;</p> <p>(b) offering the dangerous goods for transport; or</p> <p>(c) handling or transporting the dangerous goods, in the case where no other person is required to have an emergency response assistance plan under paragraph (a) or (b) in respect of that handling or transporting.</p> | <p>*This advice pertains to the regulatory phase.*</p> <p>Transport Canada notes that the sentence highlighted in yellow below is incorrect and should be revised or removed. While a contractor could assist the proponent to develop the ERAP(s), it is the responsibility of the proponent to apply to Transport Canada for approval of the plan(s).</p> <p>14.6.7.2 Design and Mitigation Considerations</p> <p>Principal traffic risk mitigation measures include:</p> <ul style="list-style-type: none">• traffic control measures such as speed limits;• travel management plans;• spill and emergency response planning; and• driver training. <p>Additionally, Denison considered several provisions to make sure that the effects of a terrestrial release of hazardous materials are as low as practicable. In addition to transportation mitigations listed for Scenarios 1 and 2, the following provisions were considered.</p> <ul style="list-style-type: none">• The <i>Transportation of Dangerous Goods Act, 1992</i> (Government of Canada 2019) outlines the requirements for entities that transport dangerous goods to establish emergency response assistance plans. These plans list specialized personnel and equipment that are required for responding to an incident. It is expected that a contractor responsible for the transportation of uranium concentrate, fuel, and hazardous chemicals would develop these plans. | Acknowledged. Section 14 will be updated in the final EIS to clearly state that while a contractor could assist Denison to develop the ERAP(s), it is Denison’s responsibility to apply to Transport Canada for approval of the plan(s). |
| AD-47 | Health Canada (HC) | Appendix 14-A (p. 8-9) | <p>Context: No emergency response plan has been provided within the draft EIS, which states that emergency response plans will be developed in the future (Section 14 Appendix 14-A, p.8-9).</p> <p>Rationale: For any emergency event, Health Canada considers the protection of human health as a primary consideration in the</p> | <p>It is recommended that Denison develop an emergency response plan in consultation with potentially affected communities and stakeholders that includes, but is not limited to, the following:</p> <p>1. All relevant contact information of the communities, especially related to km 160 of Hwy 914, which is the location of a cultural</p> | <p>Denison acknowledges the comment and thanks Health Canada for the recommendations as to the development of its Emergency Response Plan.</p> <p>As noted in the draft EIS, Denison has committed to the development of an Emergency Preparedness and Response</p> |

| Ref. # | Department | Reference to EIS, appendices, or supporting documentation ³ | Context and Rationale | Advice to the Proponent | Denison Response |
|--------|------------|--|--|---|--|
| | | | <p>development of emergency preparedness and response plans. This includes monitoring for human health impacts and the provision of health-related guidance. Further, this will be a requirement of the licensing process.</p> <p>The proponent should ensure that the emergency response plans consider the protection of all relevant potential human receptors that could be impacted by an onsite or project-related off-site accident involving the release of chemical and/or radiological substances.</p> | <p>camp that has been established by the English River First Nation and km 67 of Hwy 914 that is a gathering location for the Kineepik Metis Local associated with the Northern Village of Pinehouse.</p> <p>2. Description of the mechanisms for communication with communities in case of an emergency.</p> <p>3. Description of the partnership with and the training of local communities and local responders (see Section 14 Appendix 14-B, p.1).</p> <p>4. Description of mutual aid agreements with neighboring industries/municipalities, where appropriate.</p> | <p>Program as a component of its Environmental Management System (EMS). The objectives of the program are generically consistent with the recommendations that have been provided and Denison, as it has demonstrated to date, is committed to meaningful engagement with communities of interest and will solicit input and advice during all aspects of program development.</p> <p>For reference it is noted that as it concerns its EMS framework documentation hierarchy it is expected that three levels of documentation will be developed – Programs, Plans and Procedures. The emergency preparedness and response documentation will follow this hierarchy and input from interested parties will be solicited during all phase of program/plan/procedure development. Denison intends to develop this documentation as it advances through the licensing phase of Project realization.</p> |
| AD-48 | ECCC | Appendix 16-C, Summary of Monitoring and Follow-up Programs | Appendix 16-C does not include consideration of any monitoring and follow-up programs regarding GHGs. | ECCC recommends that the Proponent consider developing a GHG follow-up program to measure and compare actual GHG emissions against the draft EIS estimates, including reporting the Project’s actual emissions and updating the emissions estimates as needed. | Denison anticipates being subject to ECCC’s reporting requirements for emitters over 10,000 tonnes CO2e and the information is collected under section 26 of the Canadian Environmental Protection Act. This was noted in the draft EIS, Section 2.5 Greenhouse Gas Emissions. |
| AD-49 | ECCC | Appendix 16-A Summary of Residual Effects Appendix 16-B Summary of Cumulative Effects | ECCC notes that GHG mitigation measures have not been considered for the Project. Furthermore, the Project’s lifetime is expected to extend into 2050 and beyond. Consistent with the information requirements of the SACC, and aligning with Canada’s commitment to achieve net-zero GHG emissions by 2050, the Proponent should provide a credible plan that describes how the Project will achieve net-zero emissions by 2050. | <p>ECCC recommends that the draft EIS include an assessment of potential GHG mitigation measures throughout all phases of the Project. This could include a Best Available Technologies / Best Environmental Practices (BAT/BEP) Determination, as described in Section 3.2 of the Draft Technical Guide.</p> <p>ECCC also recommends that the Proponent provide a credible Net-Zero Plan on how to achieve the target of 0 kt CO2 eq/year, for the year 2050 and beyond, following the guidance of the SACC and the Draft Technical Guide.</p> | <p>GHGs were not included as a VC or KI in the draft EIS and as such, there are no specific GHG-related mitigation measures in Appendix 16. However, many of the mitigation measures for the VC Air Quality related to combustion products would also be associated with a reduction in the Project’s Scope 1 emissions. As noted in the draft EIS, Section 2.5, at this stage in the Project Denison will look for opportunities to optimize energy management and improve the energy intensity of the Project where practical. Also see response for AD-19 (second paragraph).</p> <p>Denison will consider the option of preparing a climate resiliency assessment with consideration to best available technologies / environmental practices (BAT/BEP) as well as a net-zero plan as the Project advances. Section 2.5 of the EIS provides a summary of the anticipated GHG releases and a comparison to the nation- and province-wide GHG emissions. The project is expected to contribute less than 0.0043% to the nation-wide annual average. Given this very low contribution, the project is not expected to impact Canada’s ability to meet its climate-related objectives and targets.</p> |

Wheeler River Joint IR Technical Meetings – FIRT and Denison

June 2024 (Round 3 Submission)

Objective of Meetings:

The meeting aimed to provide an opportunity for Denison to pose questions and for the Federal Independent Review Team (FIRT) to provide clarifications. Emphasis was placed on addressing the information requirements (IR) subject to discussion, focusing on information gaps, requirements/regulations essential for determining significant adverse effects.

Meeting #1: Wheeler River IR Meetings (IR-100, IR-190 and IR-198-R1)

Presentation: edoc: 7299864

Date: June 5, 2024 2-3:15PM

Attendees:

- In-person: CNSC: Jes Way, Wish Yen; Denison and consultants: Janna Switzer, Carolanne Inglis-McQuay, Brian Fraser
- Virtual: CNSC: Said Hamlat, Samantha Longo; HC: Paul Partridge, Cassidy Dutchak, Ninon Lyrette, Luc Pelletier, Rosalie Awad and Guillaume Colas; ECCC: Marcus Edino, Heather Konopski, Ian Parsons, Robert Nissen; Denison and consultants: Sarah Benson, Pamela Bennett, Jason Dietrich, Rina Parker, Brianne England

IR-100

- Wheeler would not be contributing mercury to the environment, but concern is with existing mercury in the environment.
- Denison's intent is not to use SK guidelines for fish consumption, will be using HC guidance
- HC's best practice is to consider mercury for Indigenous foods, as they are worried that there may be risks in consumption for Nations and communities. It would be to Denison's benefit to have baseline conditions that can be compared to if there are elevated levels identified during monitoring.
 - HC understands Denison's commitment to monitor mercury in country foods, and that no anticipated mercury increases for the project. But there is a more elaborate relationship with nutrient loading and methylmercury
 - Mercury not being carried forward is the basis of the comment – reviewer has no understanding of the basis of this information. HC is trying to better understand potential risk and asking to model baseline conditions – understanding baseline conditions needed to be able to assess, and have this clearly documented to substantiate conclusions.
 - Usual practice to include mercury, since there are fish and fish consumers, precautionary approach, in case there is a potential disturbance of sediment.
 - Denison noted that this has not come up from Nations as a concern.
 - Validating will be done through ERFN monitoring program.
- IR Response needs more details around the potential risks, monitoring results and how assessments could be used to ensure risks are mitigated.
- HC would want to see commitments from Denison to meet CSA standards if appropriate in the ERA under adaptive management.

- Country foods monitoring program needs to have a mechanism for triggers which will use a back-calculated value instead of the Province of Saskatchewan's values.
- If confirm baseline conditions, there is commitment that going forward with project, no matter what data says, will need to run through ERA in the future.
- Have a baseline and should be no increase, if don't see changes, no need to undertake further assessment.

IR-190

- Denison did not identify NO₂ as a COPC, and thus did not carry it through for quantitative assessment
 - 2a. HC appreciates that Denison will remove references to the outdated 1970 guidelines.
 - 2b. editorial changes, needed, these will be made.
 - 2c. Industry best practice for non-threshold air pollutants is to carry it forward to risk assessment.
 - HC asked what criteria is being using to exclude NO₂ as a COPC – studies point to higher levels of concentrations. HC would typically expect use of the most conservative guideline – because it's short term exceedance, no annual effects, lots of conservative assumptions.
 - HC currently finds the rationale for excluding NO₂ as a COPC is not strong enough and the risk assessment isn't detailed enough. HC is looking for information and best practices from Denison to describe the risks around NO₂ as a COPC. Describe the risk, provide discussions around the uncertainty, proposed policies around activities that would generate NO₂ and how Denison plans to mitigate risks. Include potential risks for workers who are off-duty and characterize the risk with a storyline.
 - Response should describe all conservatism used to come to the conclusions. HC is looking for Denison to "show their work"
 - Proposal by Denison to include qualitative discussion to better justify reasoning for excluding, acknowledge short term exceedance and exposures.
 - HC looking for Denison to better show their work – beef up discussions on risk characterizations, calculations and results are essential.
 - HC advocates for mitigations such as Tier 4 engines or monitoring.
 - Sam advises Denison review the [CSA 288.6:22 standard](#) and to ensure the "Shall" statements are considered. Any exceedances in CAAQS might require a quantitative assessment and this compliance could be moved to the ERA review at the licensing phase.
 - HC would like to review the quantitative assessment for NO₂ at the EA phase, not the licensing phase.
- Edits following SME review of minutes:
 - HC would add that it emphasized that the CAAQS should not be used as pollute up to levels and that health effects can occur at all levels of exposure.
 - The discussion on proactive measures to reduce NO₂ emissions appears to be missing from these notes (e.g., use of Tier 4 engines, regular maintenance and repair of engines, anti-idling policies, monitoring, etc.). HC would request inclusion of a bullet to document this discussion point.

- HC is unclear about use of the term “secondary” in the Action Items for IR-190: *“Final EIS will be edited text to remove reference to 1970s criteria and clarify the discussion of “secondary” screening of NO₂ and rationale to not carry NO₂ forward in the risk assessment.”* HC would suggest that CNSC provide further clarification or remove the word “secondary”.

| IR # | Summary of Discussion | Action / Next Steps |
|-----------|---|--|
| IR-100 | <p>Denison clarified to HC that in the Round 2 response to IR-190-R1, Denison did not propose to use Government of Saskatchewan fish consumption guidelines.</p> <p>In response to this IR, Denison will clarify the information/commitments/plan already provided on IR-212 (country food monitoring framework) and edit commitment 8-44 to reflect adaptive management on how country food monitoring data influences ERA updates (which are regularly done through the licence requirements per CNSC oversight and N288.6).</p> | <p>Denison’s response will outline the commitment in the EIS to the overall development of trigger levels through the country food monitoring program. They do not plan to calculate the trigger levels for the purpose of the IR but would describe how it would be calculated and used. Same generic adaptive management cycle for all aspects of monitoring and follow up cycle.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by HC and CNSC.</p> |
| IR-190 | <p>There was agreement to some aspect of the discussion (remove 1970s reference) but lack of agreement on approach to exceedance of NO₂ criteria.</p> <p>Denison OK to provide further detail but would continue to screen out, as opposed to screening in and carrying forward in risk assessment as “best practice”, as suggested by HC. Denison does not agree with HC’s suggested approach as there is no requirement or criteria for a 1 hour NO₂, HQ exceedance and it is a less preferred way to communicate the actual risk to public, Indigenous communities, and workers.</p> <p>CNSC’s ERA representative (Said) agreed that Denison’s proposed approach sounded reasonable.</p> | <p>Final EIS will be edited text to remove reference to 1970s criteria and clarify the discussion of “secondary” screening of NO₂ and rationale to not carry NO₂ forward in the risk assessment. The discussion could include HQ values to satisfy HC info needs within the IR but not within the final EIS.</p> <p>Denison plans to provide a response using the approach outlined in the meeting in place of the SME (HC) ask to determine the Hazard Quotient (HQ).</p> <p>Action – Jes to validate with Said (complete) – Said and Jeffrey Indicated that they were comfortable with the path forward and to review the clarification through IR response.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by HC and CNSC.</p> |
| IR-190 R1 | Not directly discussed, but closely associated with parent IR (IR-190 above) | <p>This IR was conditionally accepted. To be carried over to licensing.</p> <p>As part of licensing, Denison will clarify the conditions under which a switch from passive to continuous monitoring would be warranted (e.g., if the 30-d measured NO₂ concentration, after conversion to a 1-h concentration, approaches or exceeds the 1-h CAAQS value.</p> |
| IR-198-R1 | Not discussed directly, but this IR is closely related to IR-100 | This IR was conditionally accepted, pending commitment. |

Meeting #2: Wheeler River IR Meetings (IR-107, IR-110 and IR-113)

Presentation: e-doc: 7299865

Date: June 5, 2024 3:15-4:15PM

Attendees:

- In-person: CNSC: Nana Kwamena, Jes Way, Wish Yen, Jeffrey Lam; Denison and consultants: Janna Switzer, Carolanne Inglis-McQuay, Brian Fraser
- Virtual: Said Hamlat, Samantha Longo, Daniel Sauvé, ECCC: Marcus Edino, Heather Konopski, Trish Auser, Ian Parsons; Denison and consultants: Sarah Benson, Pamela Bennett, Jason Dietrich, Rina Parker, Brianne England

IR-107

- Denison offered to share the analysis conducted by comparing all lakes in the LSA with Whitefish Lake. The analysis compares percentage changes between the geometric mean of all lakes and Whitefish Lake.
 - It was noted that all raw baseline data is provided in A-1 of Appendix 8-D, so instead of re-sharing, CNSC would re-share information in EIS documentation
 - **Action:** CNSC to share out the links for the draft EIS submissions which will include supplemental technical documents for this IR (Draft EIS - Appendix 8-D - Appendix A-1). **(Completed).** Should anyone else need it:
 - File Link: <https://denisonmines.egnyte.com/fl/27VG5YKWPY/TRANSFER>
 - Password: be2AvBVRjAMa
- To resolve the IR, CNSC requested that Denison provide the conservatism perspective that was shared during the technical meeting as part of the submission for review. Denison's current approach of data pooling has resulted in a loss of resolution. Denison has indicated that the inputs used in models are in the draft EIS.
- Low sample size:
 - Looking at table 1, to characterize seasonal conditions would require enough data to develop baseline statistics to allow for comparison of seasonal conditions. Not seeing how data supports being able to characterize at this point.
 - Not a lot of samples per season for that particular site, hard to access in the middle of winter due to weather conditions and safety (samples have been taken in early and late parts of the year and not directly in winter – pooling data over this time)
 - One of CNSC's regulatory requirements to show baseline demonstrates seasonal characterization. No winter sample is a gap.
 - Denison are committed to do more as have more people at the site, where possible. Won't be able to get all locations over winter, but by pooling data and having good reasonable availability, confidence that representative enough.
- Pooled data:
 - Denison pooled the data for the different lakes - because it's consistent with locality and parameters, were able to use this and actually use geometric mean of information as a water quality for COPCs of interest.
 - ECCC: concerns with pooled data and geometric mean, less conservative approaches. By pooling, it eliminates differences between lakes (understand similar, but will need to be

making comparisons against baseline quality conditions, so will need to have baseline characterization for each of the lakes).

- Pooling of data = losing more resolution than if using water body by water body basis
 - statistical analysis shows water bodies more or less the same and have adequate conservatism in the assessment
- Denison noted that used a conservative approach in terms of inputs to the model, acknowledge that modeling will need to be re-done in the licensing phase, as will have to meet regulations in order to discharge, and options within mitigation realm to mitigate and minimize impacts; these will be levels that have to be pulled and will be worked through in the permitting process.
- Denison proposes a commitment to resolve this through the permitting process as a commitment to provide additional information as 1-2 years of water quality data can't be shared in the next 3 months. Denison commits to provide the requested baseline information which will be collected as part of the pre-construction monitoring to bolster the data. Should there be differences to the current conclusions of the draft EIS, Denison will work with regulators to remodel and reassess.
- **Action:** SMEs to review shared data, and CNSC-ECCC can take this discussion offline.

IR-110

- Denison will revise the language of the commitment to ensure that the diffuser will be designed to meet the predictions in the draft EIS. (Denison feels this is redundant as the EIS is meant to bound the Project).

IR-113

- Denison hopes that the commitment to update analysis and predictions incorporating new data collected during the licensing for operation period would be acceptable.
- Not discussed - for discussion on June 14.

| IR # | Summary of Discussion | Action / Next Steps |
|--------|---|--|
| IR-107 | <p>Denison's understanding is that this IR is resolved. Denison will provide the action / next steps information.</p> <p>New information (WQ data) will be incorporated into the application for the licence to operate application, along with new effluent quality predictions.</p> | <p>The IR considers 4 actions:</p> <ol style="list-style-type: none"> 1. Provide raw baseline data (perhaps in an appendix). <i>Data is already on record in the EIS - CNSC to share links with ECCC.</i> 2. Provide summary statistics for baseline datasets, which at a minimum should include: mean, standard deviation, 95th percentiles, minimum, maximum, and number of samples. Present summary statistics by season (i.e., freshet, summer, fall and under-ice), and include comparisons to relevant water quality guidelines. <i>Data is already on record in the EIS - CNSC to share links with ECCC.</i> 3. Identify potential gaps in baseline datasets, and indicate how data gaps will be addressed. Describe the planned baseline monitoring to be conducted including, but not limited to, addressing any data gaps. <i>Denison can provide as narrative in response to IR. No changes to the final EIS.</i> 4. Demonstrate that the combined existing baseline data and planned baseline monitoring will yield dataset(s) that provide robust water quality baseline characterization of seasonal conditions (i.e., freshet, summer, fall, under-ice during winter), including a range of flow conditions. <i>Denison can</i> |

| | | |
|--------|---|--|
| | | <p><i>provide analysis that supports this in an IR response. No changes to the final EIS.</i></p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> |
| IR-110 | Denison to clarify/reword existing commitment on diffuser design. | <p>Denison to clarify/reword existing commitment on diffuser design in Version 2 of the Commitments Register.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> |

Meeting #3: Wheeler River IR Meetings (IR-115, IR-115-R1, IR-124, IR-126, IR-194, IR-197)

Presentations: e-doc: 7299866 and 7299867

Date: June 6, 2024 11AM-12PM EST

Attendees:

- In-person: CNSC: Nana Kwamena, Jes Way, Konrad Gorzkowski; Denison and consultants: Janna Switzer, Brian Fraser
- Virtual: CNSC: Melissa Fabian Mendoza, Said Hamlat, Samantha Longo, Daniel Sauvé; ECCC: Marcus Edino, Heather Konopski, Duck Kim, Trish Auser, Ian Parsons, Elizabeth Ashby, Robert Nissen; Denison and consultants: Sarah Benson, Pamela Bennett, Jason Dietrich, Rina Parker, Carolanne Inglis-McQuay, Brianne England

IR-115 and IR-115-R1

- Denison requests CNSC as the regulating authority confirm the guidelines for the effluent discharge. Criteria should be narrowed down and defined based on federal/provincial licensing/permitting requirements. Denison will reassess if there are new CCME guidelines in the future.
- In providing conservative criteria for parameters – some examples that would be higher than provincial criteria, and some lower – justification for criteria should be provided:
 - Table outlines criteria, short term and long term – provide clarification on how criteria will be used.
 - Details will be determined and provided at point of licensing. If it does change when look at available guidelines and make choice, any changes to the conclusions should be shared.
 - Regardless of which are used, Denison have completed assessment based on selected criteria which is extremely conservative - when go to licensing and permitting, criteria will be based on licensing requirements.
- The response presents four screening criteria (two short-term and two long-term) for each parameter. ECCC requests clarification on which particular criteria will be used for screening each parameter, how these criteria will be applied, and the guidelines used for development of these criteria
 - When would they be used and why chosen?

IR-124 and IR-124-R1

- Are there specific areas within watersheds or lakes where sediments might accumulate more than other areas? Main intent of IR is to identify if this sort of scenario has been evaluated.
 - Has not been evaluated, can be confirmed over time through monitoring data, for purposes of representing the regional study area
- ECCC requests the details shared during the technical meeting and additional context be provided in writing for ECCC to review and assess. ECCC notes that the main intent of the IR is to identify whether deposition would accumulate in a specific area of the lake which could impact the environment or habitat more than others.
 - **Action:** Presentations to be provided (**complete**)
- Should the response for IR-124 be satisfactory, it should also resolve IR-124-R1

IR-126

- CNSC requests that Denison provide the methodology for BAFs and other published studies used to support this IR. Please consider the Mining Association of Canada's published guidance for selenium.
- SMEs want to understand potentially significant adverse effects:
 - What are the concentrations of selenium in benthic invertebrates?
 - Bioaccumulation factor is based on studies all over norther SK, developed using measured data at various other uranium mine sites. Looking at uptake over time.
 - Basing approach on monitoring data from years of accumulated data in norther SK water bodies. In response, can point out where in the appendix that has this information. It's in the impact value which has all information used. Appendix A to the ERA in Section 3.6.1.?
- Please share the uranium mine studies for SMEs to review – different methodology and would be good to review references and have background on it.
 - ECCC does not think the studies are required to help close off the IR, but will be required for the ERA review in terms of licensing and any information to substantiate Denison's methodology should be provided for the EA process.
 - **Action:** CNSC would expect that any references used to underpin the responses be included and provided as part of the responses to IR package. Denison to provide any references required to support response or assessment.
- Concerned about effluent discharge amount – volume of flow that that will discharge is significantly lower
- The BAFs, methodologies and monitoring information may be enough to close the IR.
- **Action:** Denison will discuss offline whether methodologies and monitoring data can be provided.

IR-197

- What additional information is ECCC is asking for? SME understanding that IR had specific CSA standard N288.6
- Atmospheric deposition is the standard used (see clause from N288.1), so Denison feels it is appropriate to use N288.1 here as opposed to N288.6
 - **Action:** Trish will talk to Duck.

- With regards to atmospheric deposition of mercury, there is none and Denison has no additional information to provide.
- Not expecting mercury deposition from mine, but request this be something included in follow up, to confirm that none.

| IR # | Summary of Discussion | Action / Next Steps |
|-----------|--|---|
| IR-115 | The theme of this discussion was to provide further clarity/rationale on the use of WQOs as two short term and two long term WQOs were shown. Denison can follow up with written response explanation of four criteria referenced and how they will be used. ECCC to review the conservatisms that were introduced in the EIS and specifically with respect to the near-field WQ model. | <p>Denison to provide further clarity/rationale on the use of WQOs as well as WQO hierarchy in an IR response. Rational will not affect the outcome of the EIS. Denison will confirm consistency in all the places the WQOs show up and are used in the EIS and TSDs.</p> <p>The response presents four criteria (two short-term and two long-term) for each parameter. Denison to clarify which particular criteria will be used for screening each parameter, how these criteria will be applied, and the guidelines used for development of these criteria.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> |
| IR-115 R1 | Discussed in same context as IR-115 | Same as outlined for IR-115 |
| IR-124 | <p>In this IR, ECCC is asking for information on the manner in which the sediment quality predictions were made.</p> <p>Denison clarified where this information is available in the EIS (mainly in Appendix A to Appendix 10-A). The sediment model represents deposition in the whole lake using partition equations. There is not a significant release of particulates; therefore, the dominant process is expected to be partitioning not particle settling – TSS in effluent is low (6 mg/L).</p> <p>Two models were utilized in the EIS for different purposes. The near-field model assessed different flow scenarios including low flow, and the IMPACT Model was used as the regional model for the risk assessment. The risk assessment focuses on the expected case. Conservative assumptions in both the near-field model and in the IMPACT model were outlined (refer to PowerPoint presentation).</p> | <p>As part of an IR response, Denison to provide further clarity on the manner in which the sediment quality predictions were made and discussion about the fact that we have not underpredicted effects.</p> <p>All lakes were considered depositional. The Kd values used describe the relationships between the constituent concentrations in water and sediment and are based on monitoring data collected over years in the Athabasca Basin (including in the Wheeler drainage). Also, the analysis considered both expected and upper bound cases and we think the sediment predictions provide suitable bounds for the analysis. The Wheeler River environmental monitoring program will be used to validate the predictions and if the data indicates that changes to the Kds are needed, it will be made through routine ERA updates.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> |
| IR-124 R1 | Discussed in same context as IR-124 | |

| | | |
|--------|--|---|
| IR-126 | <p>Denison and CNSC to discuss offline, Denison may follow up with references to studies that led to development of northern Saskatchewan bioaccumulation factor. Written follow up explanations in responses to points 1 and 3 will be provided.</p> | <p>As part of this IR response, Denison to provide further clarity on the method used, some updated calculations and information on bioaccumulation factors for selenium. This includes text on how the selenium BAFs were derived for the fish species modelled. The BAF was derived using monitoring data (water and fish tissue data) from other uranium mines in northern Saskatchewan. The BAF includes uptake via the food chain (water to algae and algae to invertebrate, and invertebrate to fish), but it is assessed as one number looking at the transfer from water to fish. Using the monitoring fish tissue data to derive the BAF inherently includes the food chain components. This is standard risk assessment practice and is consistent with guidance in CSA N288.6.</p> <p>Denison will calculate both the fish whole body and fish egg ovary concentrations to compare against the ECCC guidelines using the conversion factors in US EPA in an IR response. As indicated by the reviewer – all are below the guideline.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> <p>Denison to provide references to CNSC that underpin the responses to this topic, and what was developed.</p> |
| IR-194 | Accepted and moved to licensing. | This IR was conditionally accepted. Pending commitment, and to be carried over to licensing. |
| IR-197 | <p>CSA N288 guidance documents are used in an integrated manner and there was confusion from ECCC on reference to the relevant CSA guidelines as though there was an error found. Denison is confident the standards have been used appropriately. In Denison's opinion, this IR was beyond the scope of IRs at this stage of the project review. There is no reason why a mercury-to-air-to-water calculation would be needed for ECCC to advise on the EA conclusions.</p> | <p>In Denison's opinion, this IR was beyond the scope of IRs at this stage of the project review. The rationale for why a mercury-to-air-to-water calculation would be needed for ECCC to advise on the EA conclusions is unclear. No change to the final EIS will be made.</p> <p>Denison's position is that this IR should be closed without further back and forth. However, if needed, Denison can provide clarifications (presented in the meeting PowerPoint presentation) as an IR response (CNSC to advise if this is required).</p> <p>Action: Unresolved. ECCC to consider presentation details and for further offline discussion between ECCC and CNSC.</p> |

Meeting #4: Wheeler River IR Meetings: SARA and Migratory Birds (IR-134-R1, IR142-159-167-R1, IR-149, IR-149-R1A, 149-R1B, IR-157, IR-170 and IR-174)

Presentation: e-doc: 7299862

Date: June 6, 2024 3-3:50PM EST

Attendees:

- In-person: CNSC: Nana Kwamena, Jes Way; Denison and consultants: Janna Switzer, Brian Fraser
- Virtual: Melissa Fabian Mendoza, Said Hamlat, Verena Sesin; CNSC: Marcus Edino, Heather Konopski, Kristin Mozel; Denison and consultants: Sarah Benson, Pamela Bennett, Brianne England, Carolanne Inglis-McQuay

IR-134, IR-142-159-167-R1, IR-149-R1A, IR-170

- Denison shared an example of a table providing information on species specific sweeps; would like to provide concise summaries
- ECCC indicated this is exactly what was being requested. Table entries with what is being considered for each of the different species at risk

IR-149 and 157

- ECCC has been working collaboratively with the province on understanding how the provincial offset requirements for Boreal Caribou meet the objectives of the Federal Recovery Strategy:
 - As part of the SARA s.11 agreement with Saskatchewan, the province has committed to developing an offsetting tool, which will need to be reviewed by ECCC. However, we have not yet completed a formal review.
 - There is nothing in the s.11 agreement to say that ECCC must approve or support the SK calculator.
 - Not as simple as Denison meeting province's offsetting requirements
 - Denison: Offset commitment to meet the range plan of the province, while province needs to meet recovery strategy of ECCC,
 - Province's calculator hasn't been reviewed by ECCC, and ECCC are looking for assurance that offset calculator meeting federal requirements
- ECCC interest and jurisdiction falls under section 79 of the SARA act, also indigenous interest in species, which is subject to CEAA, 2012.
- In general, recovery strategy related to biophysical features. Even if population is stable, if one bad fire year, could be over the disturbance threshold.

IR-149-R1B

- Denison mentioned that minimal air traffic is expected; Denison looking for specific guidance needed to resolve this IR
 - From ECCC's perspective, the main concern is frequency and timing of flights. If it's 1 or 5, this makes a big difference in disruption to caribou.
 - Lots of potential calving habitat that is in proximity to the project. If there are known calving grounds – what are mitigations? If calving is observed in areas previously not known for calving, what actions will be taken?
 - Looking for mitigations during calving – no fly zones/times or re-routing of flight paths during sensitive periods.

- Mitigation measures are of concern from ECCC caribou biologists – Denison notes that there are no known calving zones in the area.
- Denison asserted that they have information from province of Saskatchewan that there are no concerns regarding calving grounds in proximity to the project and mitigations aren't needed. ECCC requests that Denison provide this information.
- Indigenous knowledge from the EIS indicated that caribou calve near the Wheeler River, but there was no locational data presented. ECCC requested that Denison provide greater detail on the Indigenous knowledge of caribou calving, such as proximity to the project (if unable to give specific details due to confidentiality concerns).

IR-174

- Denison walked through responses to the IR points 1 to 5
- 2:
 - From ECCC - map scale is too large. Looking for something that is more focused on project footprint, in order to better demonstrate proximity (a smaller scale map); should demonstrate known habitats and habitat suitability
 - ECCC noted that mapping of suitable habitat will be required for determining pre-construction survey locations, so this mapping can be used for multiple purposes.
 - Denison indicated that they could do this, but the roosting area would be a focus (map would have no new information)
- 3. From ECCC - If map demonstrates known habitats and habitat suitability, can be tied into #2
- 4. From ECCC - As noted in when discussing previous topic, this would suffice
- 5. Denison - EA commitment to collect additional baseline data. ECCC would accept a commitment to collect additional data between now and pre-clearing, as want to ensure have the data for that assessment.

| IR # | Summary of Discussion | Action / Next Steps |
|-------------------|---|--|
| IR-134-R1 | Information requested in these IRs has been provided in various places in the EIS and IR responses; however, Denison can provide more concise summaries to support the resolution of these IRs. An example for bats was reviewed with ECCC during the meeting; the reviewer agreed this summary would close out this IR if it can be provided for all SAR. Denison agreed to prepare similar tables for the remaining SAR and provide them to ECCC. | Denison to provide pre-clearing summary tables for each SAR in the area for ECCC's review, as part of an IR response. Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC. |
| IR-142-159-167-R1 | See notes for IR-134-R1; a number of IRs were discussed together under the theme of pre-clearance sweeps. | |
| IR-149 | Denison's understanding is that by meeting the Provincial offset requirements, the company will be meeting the objectives of the recovery strategy since the Province is responsible for caribou management. Further certainty is needed before the language | Denison's understanding is that by meeting the Provincial offset requirements, as part of the Saskatchewan range planning, the company will be meeting the objectives of the recovery strategy since the Province is responsible for caribou management. |

| | | |
|-------------------|---|--|
| | provided in ECCC's proposed EA commitment can be translated into Denison's commitment register. | Action: Unresolved. Further discussion is required on this topic by CNSC and ECCC. |
| IR-149 R1A | See notes for IR-134-R1; a number of IRs were discussed together under the theme of pre-clearance sweeps. | |
| IR-149 R1B | Primary CWS concern is for disturbance related to calving. It is Denison's opinion that this comment should not be an IR at this stage of the review; the EIS concluded there were no significant effects to caribou with the application of mitigation measures which were outlined in the EIS. While some additional information can be provided (see action / next step column), Denison reiterates that the EIS was completed with the appropriate level of detail expected at this stage of the Project. | <p>Denison can provide the following in an IR response:</p> <ul style="list-style-type: none"> • Anticipated aircraft traffic at the Project airstrip is expected to be minimal, at approximately five flights per week during Operation (this was noted in the EIS; opportunities to optimize the flight schedule will be completed by Denison as the Project advances). • Mitigation measures likely to be incorporated into the operation of the airstrip, with respect to air traffic, would include, as safety allows, maintaining as direct approach and departure flight paths as possible, and obtaining appropriate altitudes, and leaving the LSA and RSA, as quickly as is safely reasonable. • Flight paths can be adjusted based on the location of caribou observations, as it safe and practical to do so. <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> <p>Note from ECCC: ECCC disagrees with the proponent's conclusions. Any impact to critical habitat is considered a significant impact that will require offsetting. The entire project area (including areas that have been previously impacted) contain the biophysical features required for caribou recovery. Even though the project footprint is small, and the caribou population is stable in SK1, the impact is still significant.</p> |
| IR-157 | See notes for IR-149 | |
| IR-170 | See notes for IR-134-R1; a number of IRs were discussed together under the theme of pre-clearance sweeps. | |
| IR-174 | Clarification of the legend in Figure 2-9 was provided (refer to PowerPoint slides). No hibernacula (i.e., caves, mines, buildings with stable and specific temperatures per COSEWIC 2013) are expected in the Project Area. Bat maternal roost potential habitat can be provided in a map form, using existing baseline data, existing ecosite data, and literature data. | In an IR response, Denison will provide an updated version of Appendix 9-F Figure 2-9 Bat Species Observed within the Wildlife Study Areas to 1) zoom in on the Project Area, and 2) un-shade the Project Area. Bat pre-clearance sweep details will be provided as part of IR-134-R1. A roost potential map will be developed as part of this IR response, using existing |

| | | |
|--|--|--|
| | | baseline data, existing ecosite data, and literature data. Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC. |
|--|--|--|

Meeting #5: Technical IR Discussions on Wheeler River EA Project (IR-89 and IR-89-R1)

Presentation: e-doc: 7299863

Date: June 6, 2024 4-5PM EST

Attendees:

- In-person: CNSC: Nana Kwamena, Jes Way; Denison and consultants: Janna Switzer, Brian Fraser
- Virtual: Melissa Fabian Mendoza, Said Hamlat, , Quinn Zheng, Marcus Edino, Heather Konopski, Duck Kim, Jordan Hollman; Denison and consultants: Sarah Benson, Pamela Bennett, Brianne England

IR-89, IR-89-R1

- The decilified zone is an important pathway between the ore-zone and Whitefish Lake; would expect a conservative value - an order of magnitude higher in a sensitivity analysis
- ECCC is requesting that Denison complete traditional sensitivity analysis by increasing parameters to demonstrate the robustness of the model and provide an understanding of what could occur in an extreme (unrealistic) scenario, whereas Denison has conducted simulations. Differences in professional opinion were shared:
 - ECCC noted that when look at simulations, determining probable cases that would occur. When look at sensitivity analysis, looking for sensitivity - not a calibrated data set. If increase sensitivity, how does model react to an increase in the sensitivity of parameter? It isn't expected that this will match field observed data, and it isn't considered as a probable scenario. View as a sensitivity analysis, not a worst case scenario.
 - Denison noted that they have modeled what they expect to occur at site and have evaluated probable uncertainty, bounded by observational data that have collected - what is potentially probably at the site. Do not want to produce scenarios that could be construed as representative of what might occur in documentation that will be reviewed by the public. Ran scenarios that they considered realistic, and CNSC has mechanisms to refine through the licensing process (at this stage, sensitivity analysis is a nice to have).
- Denison acknowledged that that do not provide a very fulsome rationale for the change in the median K value in the EIS, and that there is information that is erroneously included, as well as inconsistencies in the values, as a range of values were not updated
- Denison has corrected the geomean and ECCC will review to determine if it's acceptable.

| IR # | Summary of Discussion | Action / Next Steps |
|--------------|---|--|
| IR-89 | Minor updates to the revised draft EIS were presented and will be corrected in the final EIS (refer to PowerPoint slides). A summary of uncertainty | IR response will be developed to address this IR, which outlines minor revisions to information presented in the revised draft EIS (and as described in the PowerPoint presentation). The response will also |

| | | |
|----------|---|---|
| | <p>scenarios tested for geomean K value in desilicified zone (DSZ) were presented.</p> <p>ECCC: Desilicified zone is an important feature in the contaminant transport pathway from the mining zone to the receiving surface water body. ECCC expect Denison to do another sensitivity analysis in terms of K for the desilicified zone to understand the “safety margin” in the current modeling results.</p> <p>Denison summarized the sensitivity analysis they have done in terms of K values for the desilicified zone, and argued that further sensitivity analysis might be able to provide benefit (something nice to have but not a must).</p> | <p>include reference to the existing follow-up commitment related to the DSZ (commitment 7-20 in Version 1 of the Commitments Register).</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC. Further discussion required between CNSC and ECCC.</p> <p>Notes from Quinn: In the online meeting with Denison, they proposed that they will update the groundwater model before decommissioning when more information would be available about the site geology, particularly the desilicified zone. Considering the sensitivity analysis Denison have conducted so far, this seems an acceptable path forward.</p> |
| IR-89 R1 | See note for IR-89 above | |

Meeting #6: Wheeler River IR Meetings PMP and Climate Change (IR-103, IR-113,

Presentation: e-doc: 7306089

Date: June 14, 2024 1:30-2PM EST

Attendees:

- Denison: Brian Fraser, Brianne England, Janna Switzer, Pamela Bennett, Sarah Benson, Jason Dietrick
- CNSC: Jessica Way, Tesfaye Tarekegn, Melissa Fabian Mendoza, Rain Noakes
- ECCC: Marcus Edino, Trish Auser, Catalin Obreja, Emma Watson, Ian Parsons, Paula Siwik

IR-103

- Denison developed Civil Earthworks Criteria and a Stormwater Management Plan (IR-12).
- The need for a sensitivity analysis will affect the determination of significant adverse effects.
- The distinction between contaminated/uncontaminated areas and contact/non-contact water.
- The Intensity-Duration-Frequency (IDF) with climate considerations (89mm) is used to design conveyance infrastructure of non-contact water.
- Adaptive management and continual improvement will occur throughout the life of the Project.
- The Decommissioning Plan will consider future climate scenarios for landform design and cover infiltration rates.

IR-113

- Denison disagrees that a quantitative climate change assessment is required for the EIS, based on the short period (10yrs. Operations + 5yrs. Decommissioning), future precipitation predictions indicate an increase in the potential assimilative capacity within the receiving environment, the design basis Probable Maximum Precipitation (PMP) bounds projected annual precipitation under high carbon scenario, effluent discharge monitored (Metal & Diamond Mining Effluent Regulations Schedule 4 & 5), discharge limited seasonally/periodically under low flow (flow

proportioned of fixed dilution discharge), adaptive management to adjust discharge during climate-induced changes in flow.

- Denison does not yet have information on how the different precipitation scenarios would affect water quality predictions, limits information would have during EA to look at effects. SMEs would see this as something that would be done in the EA, as it informs how water quality model responds to low and high precipitation scenarios, and understanding water quality, important to understand for effects, and feeds into mitigations. If treatment is needed, if management of additional water is needed, there is a benefit to understanding if mitigations are adequate.
- **Action:** CNSC/ECCC to look back at what was provided in first two rounds of information (Appendix 6-C and 8-C) - have looked at future climate scenario. In response to round one response of IR
- Sensitivity analysis hasn't specifically been provided – ECCC sees utility in work that has been done here, but don't see that meets the same need and understanding range of water quality that could occur under a low and high precipitation scenario. It's quite essential information to understand at the EA stage.
 - Denison feels that that have looked at practical scenarios and have bound significantly
 - SMEs note that sensitivity analysis could be used to reduce uncertainty on how water quality would behave under precipitation extremes. Data already has aspects that make it not as conservative, as were raised in other meetings on water quality, so there is already uncertainty. Important to look at how the model would react to how sensitive it is to precipitation extremes.
 - Denison suggested also see presentation from IR-115-R1 – Denison can put it all together so have full picture – **Action:** for SMEs to consider this information
- Denison suggests a sensitivity analysis on water quality predictions for low/high precipitation scenarios (including climate change induced) can be completed during operational licensing, as per REGDOC-2.9.2.

| IR # | Summary of Discussion | Action / Next Steps |
|--------|---|---|
| IR-103 | This IR is conditionally accepted. ECCC asked per the IR that Denison commit to providing the confidence intervals related to the IDF (1 in 100 year 24-hour rainfall) and demonstrate climate change resilience of the project (conduct climate risk and resilience assessment) during licensing. Denison explained that it has incorporated future climate (2020-2050 period) in the IDF to derive the 1 in 100 year 24 hour storm event for management of non-contact water. This is above the IDF curve based on current climate (79.9 mm). As noted, ECCC would like to see confidence intervals around a 1:100yr 24 hour IDF curve. Overall project climate change resilience was presented in Section 15 of the EIS. | For future IDF that considers climate change, Denison will provide language for the commitment register to evaluate the the uncertainty in projections of IDF derived 1:100 24 hour events as part of the licensing process. This IR was conditionally accepted. Pending commitment, and to be carried over to licensing. |
| IR-113 | During the EA, ECCC would like to see a sensitivity analysis on water quality predictions (site and receiving environment) for low and high precipitation scenarios, including the potential influences of climate change. Denison believes it has adequately considered expected changes in conditions that may be associated | If required, Denison can provide a summary of the rationale on this topic provided to date, along with a plan for mitigation measures for effluent release during low flow periods. |

| | | |
|------------------|--|--|
| | <p>with climate change in a narrative manner and provided rationale as to why quantitative (model) analyses are not necessarily required. Denison suggests that sensitivity analysis on water quality predictions for low and high precipitation scenarios, including the potential influences of climate change could be completed as part of operational licensing and as applicable to REGDOC-2.9.2, and/or alternatively REGDOC 2.9.1.</p> <p>CNSC has indicated that the issue should be taken offline for discussion between CNSC and Denison.</p> | <p>Action: Unresolved. Further discussion is required on this topic by CNSC and ECCC.</p> |
| IR-113 R1 | <p>Not discussed directly, but this IR is closely related to IR-113.</p> | <p>This IR is being carried over to licensing.</p> |

Meeting #7: Wheeler River IR Meetings: Water Quality Topics (IR-18, IR-101, IR-108, IR-108-R1, IR-114, IR-193, IR-195)

Presentations: e-doc: 7306092 and 7306102

Date: June 14, 2024 2-2:45PM EST

Attendees:

- Denison: Brian Fraser, Brianne England, Janna Switzer, Pamela Bennett, Sarah Benson, Rina Parker, Jason Dietrich
- CNSC: Jessica Way, Melissa Fabian Mendoza, Rain Noakes, Jeffrey Lam
- ECCC: Marcus Edino, Sarah Forte, Ian Parsons, Paula Siwik

IR-18

- Item #1
 - The requested parameters (pH, temperature, hardness, alkalinity, conductivity) were added to Table 2.2-1 and Appendix 8-E.
 - Denison expected to correct the proposed effluent conductivity added to Table 2.2-1 and Appendix 8-E.
 - Predicted conductivity is impossible with Total Dissolved Solids (TDS) reported in Table 2.2-1.
 - ECCC: concerns around TDS not because changes impact the outcomes, asking for the changes so that can confirm themselves.
 - Will provide this information to look at prior to conclusion of this EIS technical review.
 - Denison will provide additional information for conductivity and TDS as part of operational licensing.
- Item #3
 - Addressed in IR-108, IR114, and IR-115.
- Item #4
 - Denison is to follow REGDOC-2.9.2 guidance to develop effluent discharge targets. CNSC to engage with ECCC when necessary.

- Denison is committed to periodic pre-construction sampling to strengthen environmental data and will update the analysis and predictions incorporating any new data collected during the operational licensing process; no changes to the EIS are expected.

IR-101

- Item #2: Denison to justify taking wetland measurements upstream and downstream rather than directly in the wetland.
- Item #3: Denison will provide sediment quality impacts for the requested wetland assessment.
- K_d (soil-water partition coefficient) values presented in table 3-6 of the ERA and have been checked against the W_r measurement data (figure 3-2 and 3-3 of the ERA).
 - Commitments on page 8, proposed resolution: K_d values give a good suggestion of what would be reasonable impacts on the receiving environment.
- Denison clarified that the wetlands are not cut off (likely good exchange) from the main basin of the lake and, therefore, assumes that the lake environment is as likely to be depositional as the nearshore wetland habitat.
- Denison committed to collecting additional pre-construction baseline information within wetlands for water and sediment quality.
- Denison proposes that the EEM study (committed to for IR-126) could include an investigation of the difference in water and sediment quality near and offshore.
- **Action:** ECCC needs to confirm with colleagues to determine if what Denison shared will be adequate.

IR-108 & IR-108-R1

- Denison will update Tables 8.2-2 and 8.2-3 to include all Contaminants of Potential Concern (COPC) that require effluent characterization and receiving environment monitoring under the MDMER.
 - The list of parameters in this comment for the round 3 response also included boron, dissolved phosphorous and strontium, which do not require monitoring under the MDMER. These would have to be updated as well.
- Denison will update Tables 8.2-2 and 8.2-3 to include missing/corrected water quality guidance thresholds and information on values used to derive COPC thresholds (dependent on general parameters).

IR-114

- Item #1: Update all tables to include missing data for mercury, aluminum, Total Suspended Solids (TSS), iron, thallium, manganese, nitrate, and phosphorous.
- Item #3: Ensure that all water quality thresholds are derived from baseline receiving environment concentrations and that water quality guidelines protect aquatic biota.
- Denison stated that screening was completed using the most stringent guidelines. The Near-field water quality models were re-run using updated acute and chronic benchmarks; no parameters of concern were identified.

IR-193

- Acute and chronic water quality threshold request – in ERA can acknowledge that won't be able to release above acute guidelines, but intent is not to update ERA with acute guidelines.

- Denison indicated that they will add unionized ammonia, mercury and phosphorous to ERA Table 3-1. They then get screened out so it isn't necessary to look at them further. This corresponds to the last bullet in their slide on the topic.
- **Action:** ECCC will need to consult on this language.
 - ECCC consulted with colleagues and determined that this proposal is adequate.

IR-195

- Values in updated ERA are the correct values. One small change not reflected in IR, chloride and sulphate concentrations in predicted effluent quality went down. Values in updated EIS are core values.
 - Predicted chloride and sulfate concentrations were reduced due to additional testing by Denison, were identified as being able to be lowered through bench testing process. Chloride originally based on accurate guideline.
 - Denison committed to providing a short written explanation as to why (effluent quality, decreased sulfate, and chloride) the values in Tables IR195-1 and IR195-2 have changed in between the draft EIS and IR response.

| IR # | Summary of Discussion | Action / Next Steps |
|--------|---|--|
| IR-18 | As per the discussion on related IRs (IR-107 and IR-115), new information including updated WQ data and effluent quality predictions (which will include TDS and conductivity) will be incorporated into the application for the licence to operate and ERA updates at that time. Updates to Table 2.2-1 and Appendix 8-, can be made in the final EIS and included as an IR response now; however, these changes do not change the conclusions of the EIS. | <p>Denison will provide updated Section 8 tables in an IR response. Additionally, Denison will provide information to support that the clarifications/revisions indicate do not in fact change the conclusions of the EIS.</p> <p>Denison also understands its obligations and reaffirms them as it concerns REGDOC 2.9.2 (discharge criteria) and will follow the process laid out by CNSC.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> |
| IR-101 | Denison confirmed ECCC is specifically asking about wetlands downstream of the effluent release point. Denison clarified that these wetlands are more accurately described as littoral areas (i.e., they are not cut-off from the main lake) of the downstream receivers and not independent wetland complexes. Sediment quality predictions in the lakes were made by applying a partition coefficient, Kd, to describe partitioning of constituents between water and sediment. The Kd values were developed from local data from the RSA and apply equally to nearshore (and the wetland/littoral areas) and offshore habitats downstream of effluent release. Additionally, Denison has committed to the collection of additional baseline information within the nearshore (wetlands) for water quality and sediment quality prior to construction as part of operational licensing (commitment 8-46) and to | <p>Action for ECCC to discuss internally and review information already available to them (in revised draft EIS and in IR responses). ECCC reviewer will consider the information presented to date and confirm with colleagues whether the information is adequate. Denison to provide wetland-related commitments for 1) preliminary EEM (provided with responses to IR-111 and IR-126) and 2) pre-operational wetland sampling (existing commitment 8-46) in an IR response.</p> <p>Action: Unresolved. Further discussion is required on this topic by CNSC and ECCC.</p> |

| | | |
|------------------|--|--|
| | complete a pre-construction preliminary EEM for the site. | |
| IR-108 | Discussion is supportive of including MDMER Schedule 4 effluent characterization parameters and correcting WQOs in Tables 8.2-2 and 8.2-3. | EIS Tables 8.2-2 and 8.2-3 will be updated and provided as part of an IR response. Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC. |
| IR-108 R1 | See notes on IR-108 | |
| IR-114 | Denison clarified that the screening was based on the most stringent of the four guidelines/criteria. No additional parameters from the revised draft EIS have been identified as being of concern. | Denison will provide additional/corrected information in a revised IR response. Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC. |
| IR-193 | The ERA is focused on chronic effects, consistent with N288.6. Denison can update Appendix 10-A to include unionized ammonia, mercury, and phosphorus in the Table, but note this is not going through the ERA because they are below the screening values. Denison can provide this updated Appendix 10-A table in the IR response. | An updated screening table will be provided which includes the requested COPCs (Table 3-1 in Appendix 10-A). The COPCs will be shown as screened out and not carried forward through the ERA. Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC. |
| IR-195 | Clarification of discrepancies between numbers in IR table compared to what was presented in the revised draft EIS was provided by Denison. In an IR response, Denison can explain why the numbers changed / new information from bench testing related to SO4 and Cl. | Denison will prepare an IR response will include clarifications and minor updates to Table 3-3 of Appendix 10-A, and specially an explanation as to why values for SO4 and Cl had been updated. Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC. |

Meeting #8: Wheeler River IR Meetings (IR-12 and IR-12-R1)

Presentation: e-doc: 7306104

Date: June 14, 2024 3 to 3:30PM EST

Attendees:

- Denison: Brian Fraser, Brianne England, Janna Switzer, Pamela Bennett, Sarah Benson, Xavier LuDac, Jason Dietrick, Rina Parker, Zachary Hart
- CNSC: Jessica Way, Konrad Gorzkowski, Jeffrey Lam, Melissa Fabian Mendoza, Rain Noakes
- ECCC: Marcus Edino, Reg Ejeckam, Sarah Forte, Ian Parsons, Paula Siwik, Catalin Obreja

Summary:

IR-12

- Denison believes that the water management design information in the revised draft EIS is appropriate for the EA and this project stage and fit-for-purpose to support the assessment of potential effects.
- Additional details on water management and runoff infrastructure engineering design will be provided as part of licensing and permitting.
- Design strategy concept (site water divided into two streams):
 - "Contact water" – potentially contaminated water to be managed through site water infrastructure and conveyed to the Industrial Wastewater Treatment Plant (IWWTP).
 - "Non-contact" water would not be treated in the IWWTP.
 - The only mitigation proposed would be for sediment control. Any other contaminants would be small spills and would be addressed by the spill plans.
- 493mm PMP used for potentially contaminated areas with contact water.
- 89mm 1:100 for non-contaminated areas with non-contact water.
- ECCC asked about use of glycol at the airstrip. Denison responded that it would be used in a specific area where the runoff would be collected.

IR-12-R1A (DENISON RESPONSE)

- Water treatment flows and effluent discharge would not vary between normal operations and 24-hour PMP.
- Non-contact water is not routed through the IWWTP.
- The wellfield runoff pond has been designed to accommodate the PMP.

| IR # | Summary of Discussion | Action / Next Steps |
|-------|---|---|
| IR-12 | <p>Denison presented the water management design concept and overall design basis. This includes contact and non-contact water, based on the characteristics of the water in relation to mine-related wastes. Recognizing that information on water management is scattered throughout the EIS and in responses to various IRs, Denison offered to provide, as part of an IR response, consolidated information in the form of a site water management plan commensurate with the stage of the Project. The plan will collate information presented to date and provide updated information that has become available since the design has progressed. The plan would consider/discuss/include:</p> <ul style="list-style-type: none">• Design strategy and basis (criteria)• An updated site drainage map• Estimates of volumes of water to be managed in the contact and non-contact management areas• Discussion of potential COPCs in the contact and non-contact management areas;• Description of mitigation measures to manage potential COPCs in the contact and non-contact management areas | <p>Denison will provide, as part of an IR response, consolidated information in the form of a site water management plan commensurate with the stage of the Project.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> |

| | | |
|--------------|--|--|
| | <ul style="list-style-type: none"> Proposed monitoring | |
| IR-12 R1A | Denison explained that non-contact water will not be captured and treated; as such, there would be no influence of precipitation (normal v. PMP event) on water treatment and effluent release rates. Water management features in the contact water area (ISR wellfield and processing plant area) are designed to the PMP. | <p>This will be clarified in the IR response and proposed site water management plan.</p> <p>Denison to provide clarification through an interim IR response for SME Review. For review by ECCC and CNSC.</p> |

Discussion of Round 3 IR-89 and IR-89-R1 Comments

Elizabeth Haack, Ph.D, P.Chem. (AB) and
Paul Martin, M.Sc., P.Eng. (ON, SK)

June 6, 2024

Synopsis of IR-89 and IR-89-R1 Comments and Responses

- Round 2 – Response (February 2024)
 - Detailed response, including additional scenario with higher K value (1.4×10^{-4} m/s) in the Desilicified zone (DSZ) provided as Attachment
 - Acknowledged: rationale for change in median measured K value for the DSZ not well explained (IR-89 or AD-66)
- Round 3 – Context, Rationale and IR (May 2024)
 - Test a K value in the DSZ with a value at least an order of magnitude higher than the highest field K values
 - Clarify why the geomean K value for the DSZ was modified and provide any supporting evidence.

| ATTACHMENT IR-89-R1 | |
|---|--|
| Original IR Number | IR-89 |
| Follow Up IR Number | IR-89-R1 |
| Dept. | ECCC |
| Project effects link | Fish and fish habitat |
| Reference to EIS, appendices, or supporting documentation | Appendix 7-C, Numerical Modelling: Post- Decommissioning Evaluation, Section 2.3.1.4, Desilicified Zone IR-89 Response from Denison |
| Context and Rationale (Original IR) | <p>Context: The Proponent states that the range of hydraulic conductivities considered in sensitivity analysis was limited to values that fit within a calibration constrained uncertainty analysis of the model.</p> <p>Considering that the Desilicified Zone is of particular interest because it is the main pathway for the COPC to reach Whitefish lake, and that hydraulic conductivities are not entirely understood, ECCC recommends that a larger range of hydraulic conductivities be simulated to understand potential effects on the aquatic environment.</p> <p>The Proponent clarified the details of the calibration-constrained uncertainty analysis that was used for parameter bounding within the model, with hydraulic conductivity sensitivity bounds determined based on model calibration values that were supported by the available physical data.</p> <p>Rationale: ECCC agrees that calibration constrained uncertainty analysis using hydraulic head field data is useful to determine probable upper limits of K values. However, there is always some degree of uncertainty in groundwater data and models. Sources of such uncertainty may include errors, lack of complete and representative field data to determine key parameters, or any number of heterogeneities associated with groundwater systems over large scales. Such uncertainties will always exist and can be accounted for by conducting a sensitivity analysis that accounts for the lack of physical data in the Desilicified Zone by running modelling scenarios using parameters that are outside of the calibration constrained values.</p> |
| Information Requirement (Original IR) | Expand the sensitivity analysis of hydraulic conductivity outside of calibration constrained parameters to account for the lack of physical data in the Desilicified Zone |

Calculation of median K value for the Desilicified Zone

| GWR-025 | | MFa | 6.60E-06 | Packer stayed inflated | Packer test | Scibek, 2019 | Vertical | 374.0 | 380.0 |
| GWR-033 | | MFa | 4.00E-06 | Pumping well | Pseudo Pump Test | Appendix D | Vertical | 345.6 | 351.6 |
| GWR-048 | | MFa | 2.70E-06 | | Pumping test | Petrotek, 2021 | Vertical | 379.0 | 382.0 |
| WR-555 | | MFa, Barrier Zones, Ore zone | 2.00E-06 | | Packer test | Golder, 2014 | Vertical | 365.5 | 409.5 |
| WR-594 | | MFa | 2.50E-07 | | Open Hole | SRK, 2015 | Oriented | 451.2 | 489.0 |
| WR-601 | | MFa and Basement | 1.30E-06 | | Packer test | SRK, 2015 | Oriented | 376.2 | 822.0 |

Calculated geomean K value for Desilicified Zone = 4.8×10^{-6} m/s

Calculated geomean value for Desilicified Zone erroneously including measured value in the LSA at WR-405

Results from the pumping test are most reliable (0.56 x the calculated geomean value)

Friability

SW

WR-405

NE

Packer interval at WR-405 was attributed to Lower Sandstone Aquifer as there is lower friability within the packer interval than is present in the DSZ

Acknowledged: (Ecometrix) Updates to Draft EIS inconsistent with respect to geomean value and, specifically, the range of values included in the geomean value calculation

Table 7.3-2: Summary of Hydrostratigraphic Unit Properties

| Hydrostratigraphic Units | Field-Based Hydraulic Conductivity (m/s) | | Effective Porosity (%) | Storage ² |
|---|--|-------------------------|------------------------|-------------------------|
| | Range | Geomean ¹ | | |
| Overburden Aquifer/Aquitard | 3 x 10 ⁻⁶ and 2 x 10 ⁻⁴ | - | 25% (sand); 18% (till) | 20% (Sy) |
| Upper Sandstone Aquifer | 4 x 10 ⁻⁷ to 1 x 10 ⁻⁴ | 3.7 x 10 ⁻⁶ | 1 to 5% | 1x10 ⁻⁵ (Ss) |
| Intermediate Bedrock Aquitard | 1 x 10 ⁻¹⁰ to 3.8 x 10 ⁻⁶ | 8.4 x 10 ⁻⁹ | 1 to 10% | |
| Desilicified Zone | 1 x 10 ⁻⁶ to 3 x 10 ⁻⁵ | 6.04 x 10 ⁻⁶ | | |
| Lower Sandstone Aquifer | 7.8 x 10 ⁻⁸ to 3 x 10 ⁻⁵ | 2.2 x 10 ⁻⁶ | | |
| Upper and Lower Barrier Zone Aquitard (clay cap and sulphide-cemented rock) | Hydraulic tests have not been completed on these units as they are relatively thin in comparison to overlying/underlying units. ³ | | 1 to 10% | 1x10 ⁻⁶ (Ss) |
| Ore Zone Aquifer | | | | |
| Basement Aquitard | 1.1 x 10 ⁻¹¹ to 1.1 x 10 ⁻⁵ | 4.8 x 10 ⁻⁹ | | |

Notes

- 1 A geomean value was not calculated for the Overburden Aquifer/Aquitard or the Upper and Lower Barrier zone as only two measurements were available for each unit.
- 2 Sy values expressed as a percent of total volume. Ss values expressed in units of 1/m.
- 3 Screened intervals of the wells often intercept the ore zone and upper or lower barrier zones. Elevated hydraulic conductivity values were interpreted to reflect the ore zone aquifer and lower values reflect the barrier zone aquitard.

Correction needs to be made to the range reported to specify that the maximum tested hydraulic conductivity value was 2.0×10^{-5} (m/s).

Summary of Uncertainty Scenarios Tested for Geomean K value in Desilicified Zone

| K Value Measured (m/s) | K Value Assumed in Model (Base Case; m/s) | K Value applied in Sensitivity Analysis (2022 Draft EIS; m/s) | IR (2 nd Round; Feb 2024) | Statement |
|--|---|---|--|--|
| 1×10^{-6} to 2×10^{-5} Geomean = 4.8×10^{-6} | 5×10^{-6} | Uncertainty Scenario 5: 3.7×10^{-5} | | Scenario 5 was selected to represent parameter combinations that resulted in greater groundwater flow to Whitefish Lake (compared to base case). Value used is 2 (1.85) x higher than any measured value, and 7.4 x higher than base case calibration |
| | | | IR-55, Alternative Calibration 1.4×10^{-4} m/s | 28 x higher than base case 50 x higher than pumping tests (most reliable measure) |

Modelling work is sufficiently bounding for EIS.

Under all uncertainty scenarios tested, EIS conclusions hold

Table IR-89-R1-1: Peak Groundwater Concentrations Reaching Whitefish Lake: Alternative Scenarios Consistent with Observed Conditions (all concentrations in mg/L)

| COPC | Groundwater Quality Screening Criteria | EIS Base Case | 1. IR-55 Alternative Calibration (K _{ISA} = 1.0E-7 m/s; K _{OSZ} = 1.4E-4 m/s) | 2. IR-70 High Ore Zone Hydraulic Conductivity Post Decommissioning (K _{OSZ} = 5.0E-5 m/s) | 3a. IR-71 20% Lower Groundwater Recharge | 3b. IR-71 20% Higher Groundwater Recharge | 4. Note: two editorial updates to Scenario 1 were made on June 6, 2024 to facilitate round 3 IR discussions: 1) K value was corrected (from 4.0x10⁻⁵ m/s to 1.4x10⁻⁴ m/s) and 2) Mn was unbolded because it does not exceed the screening criteria

Thank You

Discussion of Round 3 IR-100, IR-190, IR-198-R1 Comments

Rina Parker, M.A.Sc., P.Eng.

June 5, 2024

IR-100 Mercury in Fish

| IR-100 (ROUND 3, May 31, 2024) | Discussion |
|--|---|
| <p>This IR remains not accepted. It is unclear what threshold concentration(s) of mercury in fish would trigger further assessment of potential health risks.</p> <p>The response to IR-100 includes a commitment to monitor mercury concentrations in fish, and to assess potential health risks if concentrations are greater than that used to derive the Government of Saskatchewan (GoS) guidelines for fish consumption (last updated in 2015). However, using this concentration as a threshold would not be protective of human health if the local population consumes greater quantities than the published consumption guideline.</p> <p>Please provide the following information:</p> <ol style="list-style-type: none">1. Discuss how the fish consumption rates from average and high traditional foods consumer groups (Section 10-A, Table 4-4: Annual Food Intakes for Components of the Human Receptor's Diet) relate to the GoS fish consumption limits for general and sensitive populations.2. Justify the use of GoS guidelines for fish consumption for mercury monitoring in fish and as a trigger for possible management actions. | <p>To clarify, Denison has not committed to using the Government of Saskatchewan guidelines for fish consumption and identified in the Round 2 IR response "Denison agrees to use Health Canada's 2007 provisional tolerable daily intake (pTDI) values of 0.20 µg/kg bw/day for young children and women of childbearing age for future assessments, or the relevant updated value at that time."</p> <p>Denison outlined in the response to IR-212 a conceptual trigger-response mechanism related to interpreting results from country foods sampled, which would also apply to mercury.</p> <ul style="list-style-type: none">- Compare fish tissue concentrations for mercury against measured fish tissue concentrations from the Wheeler River baseline program.- If an increasing trend relative to baseline is observed, verify result, investigate potential cause of increasing trend- Determine if change from baseline is significant and greater than trigger value |

Mercury

- The results of the Wheeler River baseline fish tissue sampling program showed measured fish tissue concentrations near the Project in the range of 0.01 to 0.48 mg/kg
- From ERA (Appendix 10-A, Table 4-4)
 - Fish consumption (average consumer): 26.65 kg/yr (0.07 kg/d)
 - Fish consumption (high consumer): 183.44 kg/yr (0.5 kg/d)
- Will develop trigger value as part of country foods monitoring program development.

IR-190 CAAQS for NO₂

| IR-190 (ROUND 3, May 31, 2024) | Discussion |
|---|--|
| <p>The response to IR-190 acknowledges the predicted exceedances of the CAAQS for NO₂. However, the revised information does not appear to have been carried through to all the health risk assessment documents.</p> <p>HC notes that the new CAAQS for NO₂ also recognizes that there is no population health threshold for human health effects; therefore, any increase in exposure will result in an incremental population risk (Environment Canada and Health Canada, 2012; CCME, 2000). In other words, NO₂ is considered a non-threshold substance, meaning that health effects may occur at any level of exposure. Therefore, guideline values should not be construed as limits to which polluting up to is allowed.</p> <p>Please provide the following information:</p> <ol style="list-style-type: none"> 1. Present modelled concentrations at the nearest human receptor site (i.e., Risk 2 - seasonal resident at McGowan Lake) in Tables 3-9, 3-10 and 3-11). 2. Correct/update Section 3.2.1.3.1: <i>Nitrogen Dioxide</i>, of Revised DRAFT EIS Appendix 10-A (February 2024), as follows: <ol style="list-style-type: none"> a. Remove references to the 1970's National Ambient Air Quality Objectives (NAAQOs) for NO₂. These objectives are no longer relevant and do <u>not</u> support the exclusion of NO₂ from further consideration as a COPC (Ref. AD-67); b. Acknowledge that modelled results exceed the 1-h NO₂ CAAQSs at the <i>camp workers location</i> and <i>fence line</i> during all project phases; and, c. Consider NO₂ a COPC for further quantitative assessment and characterize the potential health risk related to 1-h exposure to NO₂. 3. Characterize potential health risks from 1-h exposure to NO₂ using HC's guidance. Alternatively, use the updated 2021 WHO Global Air Quality Guidelines for annual and 24-h NO₂ exposures when calculating hazard quotients. 4. Discuss how the proposed mitigation measures to minimize residual effects of the Project on air quality, as identified in Section 16.1.1 of the Revised DRAFT EIS (January 2024), address the health risks identified in Chapter 10. Also specify whether any additional air quality monitoring and/or mitigation measures are proposed specifically to address human health risks. | <ol style="list-style-type: none"> 1. See tables on next slide – this can be added to the ERA tables 2. The following updates will be made as requested. <ol style="list-style-type: none"> a) References to the 1970's National Ambient Air Quality Objectives (NAAQOs) for NO₂ will be removed. b) ERA acknowledges exceedances of 1-h NO₂ CAAQSs at the <i>camp workers location</i> and <i>fence line</i> during all project phases (editorial edits will be made as suggested in the IR response) c) It is not planned to add NO₂ as a COPC for further quantitative assessment. There are no exceedances of long-term CAAQS. The model has a number of conservative assumptions associated with it <ol style="list-style-type: none"> a) Assumption that diesel generators will be used; however, it is anticipated that power will be obtained from the provincial grid. b) Assumption that emission sources operate concurrently at their individual maximum rates of production to estimate the worst-case emission rates 3. Since NO₂ is not identified as a COPC hazard quotients are not calculated. Note that there are no 24 hour or annual exceedances of NO₂ guidelines. 4. As identified in IR-190-R1 NO₂ monitoring is planned during all Phases of the Project. Monitoring will include passive sampling and will follow an adaptive management process to identify if more frequent monitoring is needed. |

NO₂ Concentrations and Exceedances

| Location | Name | NO ₂ 1 hr ug/m ³ | | | NO ₂ annual ug/m ³ | | |
|----------------------------------|-------|--|-----------|-----------------|--|-----------|-----------------|
| | | Construction | Operation | Decommissioning | Construction | Operation | Decommissioning |
| On-Site Ecological Location | Risk1 | 124.32 | 116.30 | 120.86 | 8.34 | 4.41 | 7.08 |
| Trapper (LA1) - McGowan Lake | Risk2 | 42.97 | 40.18 | 41.64 | 4.65 | 3.97 | 4.60 |
| Camp Worker | Risk3 | 180.95 | 274.83 | 355.07 | 17.1 | 11.3 | 16.4 |
| Seasonal Resident (Russell Lake) | Risk4 | 22.9 | 24.0 | 22.7 | 4.0 | 3.8 | 4.0 |

IR-198-R1 Monitoring Lead and Mercury

| IR-198-R1 (ROUND 3, May 31, 2024) | Discussion |
|--|-----------------------------------|
| <p>Note To Denison: This IR is being conditionally accepted. If Denison commits to monitoring lead and mercury in country foods, as well as including these in any further assessment conducted to determine their potential risk to human health from consumption of country foods, this IR can be resolved.</p> <p>This commitment would include:</p> <ol style="list-style-type: none">1. Establishing/confirming baseline concentrations of Hg in water, sediment, and fish tissues before construction;2. Regular monitoring during construction, operation and post-closure; and,3. Undertaking an HHRA should monitoring results exceed established/confirmed baseline levels, to inform decisions on adaptive management and mitigation measures. <p>The Proposed rationale text for posting: Denison has captured their commitment related to monitoring lead and mercury in country foods, as well as including arsenic, cadmium, lead, and mercury in any further assessment conducted to determine their potential risk to human health from consumption of country foods.</p> <p>This commitment includes (would include):</p> <ol style="list-style-type: none">1. Establishing/confirming baseline concentrations of Hg in water, sediment, and fish tissues before construction; 3[sic].2. Regular monitoring during construction, operation and post-closure; and,3. Undertaking an HHRA should monitoring results exceed established/confirmed baseline levels, to inform decisions on adaptive management and mitigation measures <p>This IR has been accepted for the purposes of the current EA process, and the aforementioned issues will be further assessed as part of licensing technical reviews, prior to the granting of a license.</p> | <p>This IR has been accepted.</p> |

Thank You

Discussion of Round 3 IR-107 and IR-113 Comments

Jason Dietrich, M.Sc., Rina Parker, M.A.Sc., P.Eng.
Brian Fraser, M.Sc.

June 5, 2024

IR-107 Round Three Comments

| IR (ROUND 3, May 31, 2024) | Status -May 31, 2024 |
|--|----------------------|
| <p>Before this IR is accepted, the Proponent is requested to provide the statistical correlation analysis to confirm that data is correlated.</p> <p>Additionally, the four expectations set out in the rationale for status have not been adequately responded to. The Proponent should incorporate the following information into the EIS and ERA:</p> <ol style="list-style-type: none">1) Provide raw baseline data (perhaps in an appendix).2) Provide summary statistics for baseline datasets, which at a minimum should include: mean, standard deviation, 95th percentiles, minimum, maximum, and number of samples. Present summary statistics by season (i.e., freshet, summer, fall and under-ice), and include comparisons to relevant water quality guidelines.3) Identify potential gaps in baseline datasets, and indicate how data gaps will be addressed. Describe the planned baseline monitoring to be conducted including, but not limited to, addressing any data gaps.4) Demonstrate that the combined existing baseline data and planned baseline monitoring will yield dataset(s) that provide robust water quality baseline characterization of seasonal conditions (i.e., freshet, summer, fall, under-ice during winter), including a range of flow conditions. <p>The Proponent should also incorporate the additional baseline data collected into the analysis and conclusions of the finalized EIS and ERA.</p> <p>Concerning the other aspects of the IR, these responses are accepted based on Denison's commitment to conduct periodic sampling prior to construction to strengthen existing environmental data. CNSC staff will review this information to ensure EA predictions remain valid and recommend collecting samples in the fall to spring timeframe, as samples from these seasons is sparse in the current dataset.</p> | <p>Not Accepted</p> |

IR-107 Statistical analysis to confirm data is correlated or similar

1. Analysis was conducted by comparing all Lakes in LSA vs. LA-5 and compared the percent (%) change between the geometric mean of all lakes and LA-5.
2. The results of this analysis indicated consistency between lakes with the percent difference less than 10% for the majority of COPCs and less than 12% for all COPCs.
3. Additional information will be provided as part of this IR for review

IR-107 additional expectations

1. Provide raw baseline data (perhaps in an appendix).
 2. Provide summary statistics for baseline datasets, which at a minimum should include: mean, standard deviation, 95th percentiles, minimum, maximum, and number of samples. Present summary statistics by season (i.e., freshet, summer, fall and under-ice), and include comparisons to relevant water quality guidelines.
- All raw baseline data was provided in Appendix A-1 of Appendix 8-D of the EIS.
 - Appendix A-1 of Appendix 8-D included the following: mean, SD, 75th percentile, 95th percentile, minimum, maximum, sample size (n) and screening against criteria by date.

IR-107 additional expectations

3. Identify potential gaps in baseline datasets, and indicate how data gaps will be addressed. Describe the planned baseline monitoring to be conducted including, but not limited to, addressing any data gaps.
4. Demonstrate that the combined existing baseline data and planned baseline monitoring will yield dataset(s) that provide robust water quality baseline characterization of seasonal conditions (i.e., freshet, summer, fall, under-ice during winter), including a range of flow conditions.

Denison feels strongly that the baseline water quality data collected are suitable for the purposes of the EIS and the application of additional conservatism in the use of the data provide a conservative (i.e., protective) framework for evaluating potential effects.

Denison has committed to periodic sampling prior to construction to strengthen existing environmental data.

Denison will commit to update the analysis and predictions incorporating any new data collected during the licencing process, but there is not expectation that here would be any change to the EIS conclusions.

IR-107 additional expectations

IR-113 Round Three Comments

| IR (ROUND 3, May 31, 2024) | Status -May 31, 2024 |
|---|----------------------|
| <p>The Proponent should conduct a sensitivity analysis on water quality predictions for low and high precipitation scenarios, including the potential influences of climate change to assist in fulfilling the IR from the previous round.</p> <p>This information is required to assess the potential for significant adverse effects to the environment. If additional baseline information is required, it should be sourced or otherwise collected.</p> | <p>Not Accepted</p> |

IR-113

Denison disagrees that a qualitative climate change assessment is required at this time for the purposes of the EIS because:

- 1) The duration of the project (15 years) is of short duration within the context of climate change thereby making it unlikely that large scale changes in precipitation and temperature will occur.
- 2) The design basis PMP is robust and inclusive of projected total annual precipitation under a high carbon scenario.
- 3) Effluent discharge will be monitored as per the MDMER Schedules 4 and 5;
- 4) Under scenarios of low flow condition, discharge can be limited seasonally or periodically and specific to the assimilative capacity of the receiver (flow proportioned of fixed dilution discharge);
- 5) Adaptive management and adjustment to discharge timing and volume as needed over time to meet criteria based on climate induced changes in flow.

IR-113

Denison suggests that a sensitivity analysis on water quality predictions for low and high precipitation scenarios, including the potential influences of climate change can be completed as part of licensing and as applicable to REGDOC-2.9.2.

This would be consistent with the approach of further analysis conducted as part of licensing and following collection of additional water quality data to support such modelling.

Thank You

Discussion of Round 3 IR-115 and IR-115-R1 Comments

IR-115 / 115-R1 Round Three Comments

| IR (ROUND 3, May 31, 2024) | Status -May 31, 2024 |
|--|----------------------------|
| <p>The Proponent has not fully responded to the previous round's IR. For items one and two, some of the information provided on contaminants of potential concern (COPCs) and the background concentrations of hardness in the receiving environment is not sufficiently conservative. Item three requested rationale that all selected water quality thresholds (i.e., screening criteria) are at levels protective of aquatic life, which was not provided.</p> <p>The updated Table 8.2-8 provides two short-term and two long-term screening criteria for each parameter. The screening criteria reflect calculated screening criteria for both background hardness and project-induced hardness, however, it is unclear which criteria the Proponent intends to apply in their assessment since four separate criteria are provided (see IR-114).</p> <p>The information presented in Table 8.2-8 indicates there are no background water quality exceedances of guidelines. However, it is noted that several screening criteria do not reflect the most conservative guidelines, which is not consistent with the approach described in Appendix 10-A (Environmental Risk Assessment). For some examples, the short-term screening criteria value of 500 mg/L for nitrate is much higher than the BC MOE nitrate guideline of 32.8 mg/L., the long-term criteria for un-ionized ammonia of 6.87 mg/L is much higher than the CCME guideline of 0.019 mg/L and the MDMER limit, and the long-term phosphorus screening criteria represent a trigger range that is two to three trophic levels above background, which is much higher than the CCME guidance framework recommends. The Proponent should review and update Table 8.2-8 to provide conservative screening criteria for all parameters, and include a consideration of the CCME, FEQG, SEQG, and BC MOE when selecting the screening criteria. Screening criteria selection should be informed by the most conservative guidelines. Cases where the Proponent does not propose to apply the most conservative screening criteria should be accompanied with a discussion and rationale for the selection. The Proponent should also specifically state which criteria will be used in screening, how these criteria will be or are applied, how the EA conclusions are informed by the criteria, and whether any EA conclusions are altered by changes to screening criteria.</p> | <p>Not Accepted</p> |

IR-115-R1 – However, it is noted that several screening criteria do not reflect the most conservative guidelines, which is not consistent with the approach described in Appendix 10-A (Environmental Risk Assessment).

The approach taken in the ERA and EIS was as follows:

1. Is there a Saskatchewan provincial screening criteria available?
2. Is there a federal screening criteria available?
3. Use the most stringent of either of these two for the assessment
4. Where there is not screening criteria either federally or provincially, use an available criteria from another jurisdiction.

The most stringent criteria in any jurisdiction was not deemed reasonable for the purposes of the EIS nor was this the intention of the methods described in Appendix 10-A or the ERA. This can be corrected to reflect the hierarchy above.

IR-115-R1 – Item three requested rationale that all selected water quality thresholds (i.e., screening criteria) are at levels protective of aquatic life, which was not provided

1. We used the criteria protective of aquatic life. These criteria are typically derived to be protective of the all life stages of all species.
2. The nearfield analysis was conducted with high conservatism
 - Average effluent rate of 36.5 m³/hr and continuous flow – this is an unlikely scenario
 - The water quality analysis was conducted for each of the low flow scenarios (i.e., 7Q10 low flow, monthly low flow, and monthly average flow) for the receiving water environment
 - Ninety-fifth percentile (95%) concentrations of constituents at baseline condition were used in modelling potential effects.
 - Based on pilot tests completed for the IWWTP to date, sulphate, chromium, molybdenum, TSS, and selenium have been identified as having potential management needs. However, for each of these parameters, the estimated discharge concentrations provided were conservative in nature with a contingency factor of 2 to 3 times.

IR-115-R1 – four separate criteria are provided (see IR-114).

The updated Table 8.2-8 provides two short-term and two long-term screening criteria for each parameter. The screening criteria reflect calculated screening criteria for both background hardness and project-induced hardness.

For the majority of parameters, the prediction is that effluent will be below long-term criteria at the background screening criteria except for sulphate, chromium and molybdenum (Nearfield model)

Parameters whose available assimilative capacity exceed short term criteria listed in Table 8.2-10 for both sets of screening criteria (background and induced) include chloride, TSS, arsenic, cadmium, copper, manganese, uranium, and zinc. (Nearfield model)

IR-115-R1 – four separate criteria are provided (see IR-114).

But Denison has committed to the following mitigation and must meet REGDOC 2.9.2

- Develop site-specific effluent treatment to treat COPCs to appropriate release limits in accordance with provincial standards and licence/permit conditions.
- Discharge effluent under a scenario that will meet provincial and federal discharge criteria as identified through permitting. Scenarios may include:
 - – discharging at a fixed rate while maintaining an appropriate minimum dilution ratio (i.e., discharge when able to meet the required dilution ratio and cease discharge during periods when unable to meet the necessary dilution ratio);
 - – discharging under a variable waste load allocation (i.e., discharge an appropriate effluent volume based on flow in the receiver to maintain minimum dilution ratio); and
 - – managing discharge via a hybrid of these (i.e., discharge effluent at a fixed rate to maintain the required dilution ratio, but the fixed rate can be varied on a seasonal basis based on flow).

We feel strongly that analysis and screening is adequate for the purposes of the EIS and the application of additional conservatism in the use of the data provide a conservative (i.e., protective) framework for evaluating potential effects.

Denison has committed to periodic sampling prior to construction to strengthen existing environmental data and will commit to update the analysis and predictions incorporating any new data collected during the licencing process, but there is no expectation that there would be any change to the EIS conclusions.

Thank You

Discussion of Round 3 IR-124, IR-124-R1, IR-126, IR-197 Comments

Rina Parker, M.A.Sc., P.Eng.

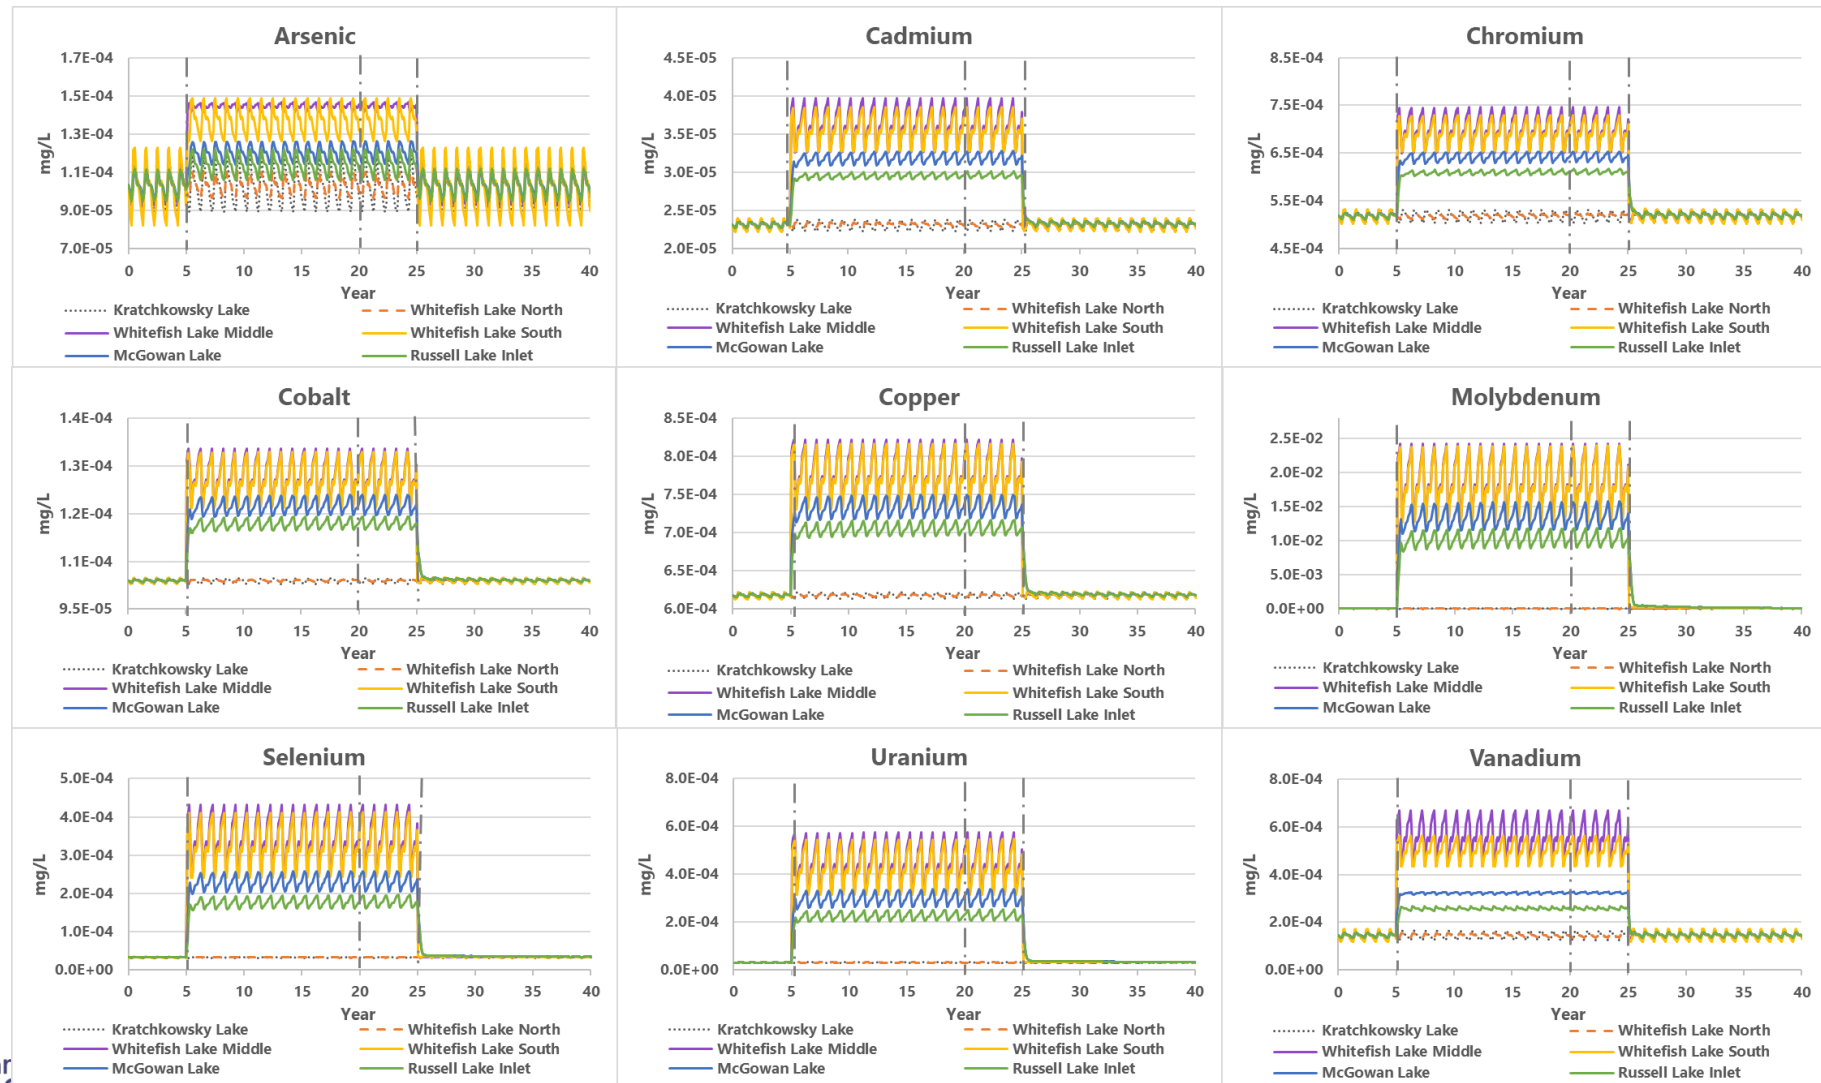

June 6, 2024

IR-124 Surface Water and Sediment Modelling

| IR-124 (ROUND 3, May 31, 2024) | Discussion |
|--|--|
| <p>The Proponent has not fully responded to the previous round's IR.</p> <p>The modeling of surface water and sediment COPC's described in Appendix 10-A show results for the receiving waterbodies, but it is not clear how the results for the COPC concentrations for water quality and sediment quality calculated for each of the water bodies, shown in Figure 6-1 and 6-2 respectively, are being interpreted. The Proponent has not explained if these modeled values are based on the worst-case scenarios that account for environmental variables such as seasonal changes in hydrology and chemistry or if they have only accounted for changes in operational effluent discharge scenarios to consider the upper bound discharge rates. Additionally, it is unclear whether depositional areas for sediment were identified based on hydrological data. Additional information is also needed regarding baseline exceedances of sediment COPC thresholds and the associated risk assessment of mine operations on the receiving water body.</p> <p>The Proponent should consider maximum COPC scenarios for the receiving water bodies in baseline assessments and the risk assessment, including seasonal variability and sediment depositional areas to determine whether the baseline assessment and risk assessment fully considered the effects of the operations of the proposed mine. The Proponent should provide supplemental information to aid in determining if the environmental model has considered environmental variability such as seasonal changes in water levels, flows and sedimentation. The Proponent should also demonstrate that the model has considered a reasonable expected worst case scenario, such as a 100 year return.</p> <p>This IR is addressing quality of inputs (ex. baseline data, conservatism of scenarios modelled, environmental variability, etc.) in to modelling. This information is required to assess the conservatism of modelling the bounding conditions and potential for significant adverse effects to the environment.</p> | <ul style="list-style-type: none">• Figure 6-1 and Figure 6-2 in Appendix 10-A are referring to the sensitivity analysis which specifically looks at the difference between expected and upper bound effluent discharge rates. All other parameters are unchanged from the expected case.• Appendix A to the ERA is called " Wheeler River Project IMPACT Model" provides detailed information on the equations used, assumptions made and inputs used in the IMPACT model• The IMPACT Model considers monthly fluctuations in flows in all waterbodies. This is described in Section 3.1 of Appendix A. |

Modelled Water Concentrations during Project Phases

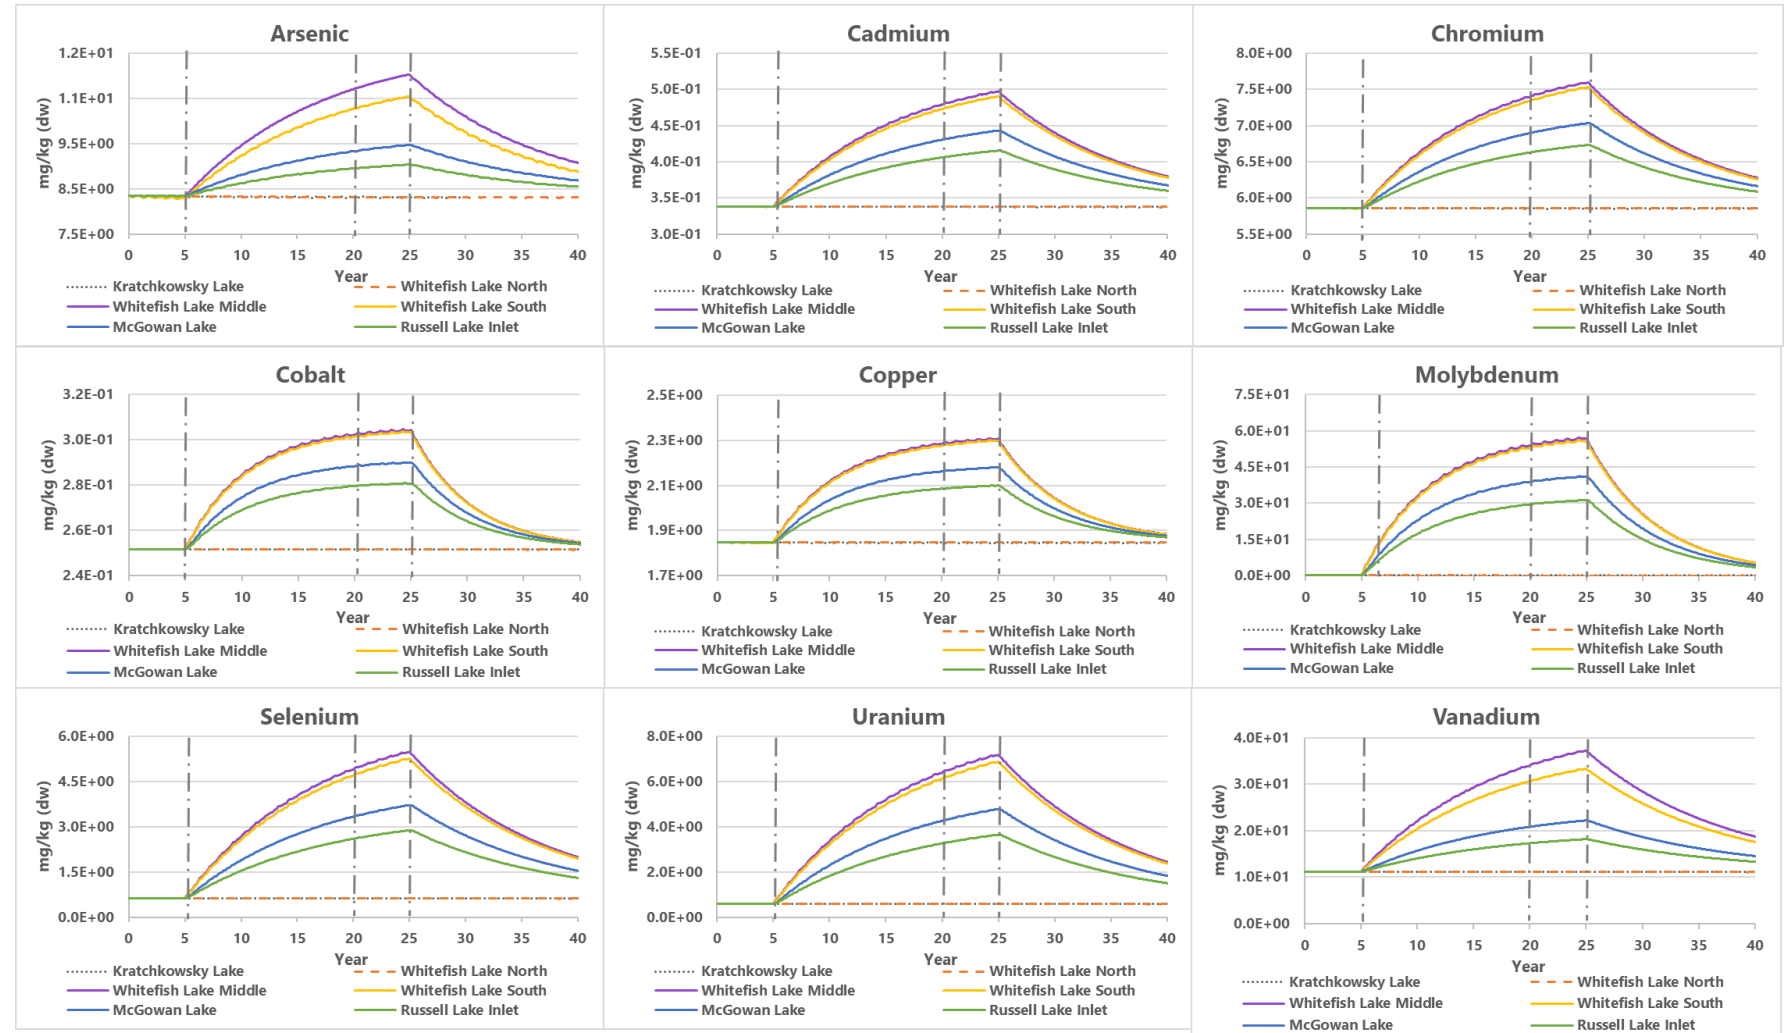

Figure 3-2 in
Appendix 10-A

Modelled Sediment Concentrations during Project Phases

Figure 3-3 in
Appendix 10-A

The sediment model represents deposition in the whole lake using partition equations. There is not a significant release of particulates; therefore, the dominant process is expected to be partitioning not particle settling – TSS in effluent is low (6 mg/L).

Near-field Model and IMPACT Model

- Two models were utilized for different purposes. The near-field model assessed different flow scenarios including low flow, and the IMPACT Model was used as the regional model for the risk assessment. The risk assessment focuses on the expected case.
- There are numerous conservative assumptions in the near-field model
 - The water quality analysis was conducted for each of the low flow scenarios (i.e., 7Q10 low flow, monthly low flow, and monthly average flow) for the receiving water environment
 - Ninety-fifth percentile (95th %) concentrations of constituents at baseline condition were used in modelling potential effects.
 - Average effluent rate of 36.5 m³/hr and continuous flow – this is an unlikely scenario
 - Effluent quality is conservative, as many based on pilot tests completed for the IWWTP to date with a contingency factor of 1 to 3 times incorporated for conservatism.

Near-field Model and IMPACT Model

- There are numerous conservative assumptions in the IMPACT model
 - Ecological receptor assumptions: home ranges are selected based on expected home range during sensitive life stages, 100% residency assumptions for wildlife to capture risk from exposure from life stage of interest.
 - Human receptor assumptions: traditional foods diet is conservative and reflects both average and high consumers. The amount of traditional food obtained from the Project area is conservative based on current understanding of land use.
 - The results shown in the ERA represents the maximum dose/risk receptors would receive over the Project phases
 - Toxicity reference values uses incorporate safety and uncertainty factors

IR-124-R1 Surface Water and Sediment Modelling

| IR-124-R1 (ROUND 3, May 31, 2024) | Discussion |
|---|--|
| <p>The Proponent has not fully responded to the previous round's IR. The modeling of surface water and sediment COPC's described in Appendix 10-A, Figure 6-1 and 6-2 respectively shows results for the receiving waterbodies. However, it is unclear if these modeled values are based on the worst-case scenarios that account for environmental variables such as seasonal changes in hydrology and chemistry, or if they have only accounted for changes in operational effluent discharge scenarios to consider the upper bound discharge rates. The Proponent's responses regarding baseline exceedances of COPC thresholds in the receiving waterbodies require additional information regarding environmental variability, including but not limited to seasonal changes in water levels, flows and sedimentation, in order to determine whether the model has considered environmental variability. The Proponent should also demonstrate that the model has fully considered a reasonably expected worst case scenario, such as a 100-year return period for the above variables.</p> <p>The Proponent should include a consideration of the maximum COPC scenario for the receiving water bodies in baseline assessments and the risk assessment, including seasonal variability and sediment depositional areas, to consider the effects of the operations of the proposed mine.</p> | <p>To clarify, the environmental risk assessment considers both seasonal variability including changes in monthly flows as well as consideration of sediment deposition in the whole lake.</p> |

IR-126 Selenium

| IR-126 (ROUND 3, May 31, 2024) | Discussion |
|--|---|
| <p>The Proponent did not compare their predictions for fish tissue selenium to the FEQGs in the ERA as requested. Furthermore, in their response the Proponent does not use available species-specific moisture content and conversion factors available for northern pike and lake whitefish when converting muscle selenium concentrations to whole-body selenium concentrations. This means that the Proponent's prediction likely underestimates the selenium tissue concentrations in the fish. Consequently, the hazard quotients reported are lower than expected. Additionally, the method used by the Proponent to predict selenium concentrations in northern pike and lake whitefish does not appear to include dietary uptake and bioaccumulation of selenium, only direct contact with pore water and overlying water is considered (Table 5-5 in Appendix 10A; Section 2.2.2 of Appendix A to Appendix 10-A). Selenium uptake through the aquatic food web has been shown to result in bioaccumulation of selenium in aquatic-dependent wildlife and resulting in reproductive impairments and malformations (ECCC 2022). Dietary sources of selenium would typically be expected to be the main contribution to tissue concentrations of selenium compared to selenium uptake from water. In most situations, the conversion of inorganic selenium to organic selenium through uptake from water into periphyton/algae is the rate limiting step of selenium bioaccumulation into higher level organisms including benthic invertebrates and fish. This step is affected by many environmental parameters (e.g. temperature, substrate, lentic/lotic environment). Considering that the effluent discharge contains 42 ug/L selenium, consideration of dietary selenium is warranted.</p> <p>The Proponent should update the final EIS with the following information:</p> <ol style="list-style-type: none"> 1. Update the ERA with the assessment of selenium concentrations in fish tissue to include a comparison of selenium fish tissue concentrations to ECCC FEQG guidelines for either fish whole body tissue (6.7 ug/g dry weight) or fish egg/ovary tissue (14.7 ug/g dry weight) <u>using</u> species-specific moisture content and muscle : whole body and/or egg-ovary : muscle conversion factors (see Tables B-1b, Table B-3, Table B-4, and Table B-5 in US EPA (2021)). 2. Update the ERA for the assessment of selenium concentrations in fish tissue using a method that considers dietary uptake and bioaccumulation in order to determine predicted fish tissue concentrations of selenium in northern pike and lake whitefish. This is recommended to be done over all Project phases for both the Expected Case and sensitivity scenarios. 3. Provide predicted fish tissue selenium concentrations that include the range of variability of data used to develop the tissue selenium predictions. Only one output value without a confidence interval is provided for each location and species (see Table B.5 in Appendix B of Appendix 10-A). | <ol style="list-style-type: none"> 1. Round 2 IR response provided a comparison against the ECCC FEQG by converting the muscle tissue concentrations to whole-body tissue concentrations using generic conversion values. The dry weight to fresh weight conversion factor used was 0.25. Based on measured dry weight content in fish (northern pike and white sucker the dry weight content ranged from 0.24 to 0.26 which is consistent with literature values; therefore, there is no need to change. (see next slide for additional results). 2. The ERA has done what the reviewer is requesting. The ERA utilizes a bioaccumulation factor (BAF) model from water to tissue to conservatively reflect all the multi-media contributions to update. The BAFs are provided in Appendix A to the ERA in Section 3.6.1. 3. The fish tissue selenium concentrations represent the maximum concentration over the Project phases. This is the most conservative result. |

IR-126 Selenium

- White Sucker - Good agreement between literature and measured
 - Moisture Content (Table B-1b): 77.37
 - Moisture Content Baseline Data: 76.55%
 - Moisture Content CSA N288.1: 75%
- Table B-4 of US EPA (2021) provides muscle to whole-body correction factor for white sucker (1.34)

| | | | | IR-Response | Updated |
|-----------|----------|----------|----------|-------------|------------|
| Fish | | Muscle | Muscle | Whole Body | Whole Body |
| Species | Lake | ug/g fw | ug/g dw | ug/g dw | ug/g dw |
| W. Sucker | Ref | 1.46E-01 | 5.84E-01 | 4.60E-01 | 4.65E-01 |
| | WL North | 1.43E-01 | 5.72E-01 | 4.50E-01 | 4.55E-01 |
| | WL Mid | 1.74E+00 | 6.96E+00 | 5.48E+00 | 5.54E+00 |
| | WL South | 1.66E+00 | 6.64E+00 | 5.23E+00 | 5.28E+00 |
| | McGowan | 1.06E+00 | 4.24E+00 | 3.34E+00 | 3.37E+00 |
| | Russell | 8.06E-01 | 3.22E+00 | 2.54E+00 | 2.57E+00 |

Conclusion: There is minimal difference between previous assumptions and updated assumptions.
All results still below the ECCC FEQG of 6.7 µg/g dry weight

Selenium in White Sucker over Time (LA-5)

IR-197 Atmospheric Deposition

| IR-197 (ROUND 3, May 31, 2024) | Discussion |
|--|--|
| <p>The Proponent is not using the correct CSA standard to address this information requirement. The response refers to guidance from CSA N288.1 (i.e., <i>Guidelines for modelling radionuclide environmental transport, fate and exposure associated with the normal operation of nuclear facilities</i>), however, the information requirement specifies CSA N288.6, which is a different standard.</p> <p>In lieu of requesting information on atmospheric deposition of all contaminants of potential concern (COPC) to surface water and associated effects, the Proponent should:</p> <ol style="list-style-type: none"> 1. Provide an estimate of atmospheric deposition of mercury (all species) from Project-related emissions. Include a sensitivity analysis as well as expected seasonal variations in the deposition rate with an emphasis on accumulated deposition for the lake ice breakup period. 2. Update water quality mercury predictions (all species) for Whitefish Lake using scenario(s) that incorporate atmospheric deposition from Project-related emissions. Based on the findings, assess any Project-related effects to aquatic receptors from mercury (all species). Discuss potential effects on sediment quality. 3. Discuss how the response was informed by the CSA N288.6 standard (i.e., Environmental risk assessments at class I nuclear facilities and uranium mines and mills. CSA Group; February 2022). | <ol style="list-style-type: none"> 1. There are no Project-related emissions of mercury to air therefore the request to estimate atmospheric deposition of mercury from Project-related emissions is not applicable. The Round 2 IR response provided an example for uranium to show how atmospheric deposition to lakes is considered minor. 2. There are no Project-related emissions of mercury to air therefore the request to estimate atmospheric deposition of mercury from Project-related emissions is not applicable. 3. The CSA N288.6 standard provides guidance on conducting environmental risk assessment, but does not provide detailed guidance on fate and transport models. The CSA N288.6 standard refers to other documents for the details. This includes CSA N288.1. For example, Clause 1.4 of N288.6 states "An understanding of the fate and transport of contaminants in the environment is necessary for performing an ERA; however, a detailed discussion of fate and transport models is outside the scope of this Standard. The risk assessor should consult CSA N288.1 for information on these concepts. Examples of additional models are provided in Clause 6.3.7." The examples of models provided include N288.1 as well as the IMPACT model which implements the equations in N288.1. |

Thank You

Denison Mines Corp. Wheeler River Project

June 6, 2024

Terrestrial Environment

Round 3 Information Requirements (IRs)

Agenda

- Terrestrial Environment
- Remaining IRs
 - Species-specific information for pre-clearance sweeps
 - IR-134-R1: Bats
 - IR-149-R1A: caribou
 - IR-142, IR-159, IR-167-R1: SAR in general
 - IR-170: SAR, including nighthawk
 - Bats
 - IR-174
 - Caribou
 - Caribou offset commitment
 - IR-149, IR-157
 - Caribou mitigations related to Project flights
 - IR-149-R1B

Terrestrial Environment

Draft EIS Section 9.3 Ungulates, Furbearers, and Woodland Caribou and 9.4 Raptors, Migratory Breeding Birds, and Bird Species at Risk – *Habitat-based assessments*

• Ungulates, Furbearers, and Woodland Caribou

Key Indicators:

Moose
Wolverine, Pine Marten, Mink, Muskrat
Woodland Caribou

Direct habitat loss
Sensory disturbance
Collisions with project vehicles & equipment
Harvest and/or predation

Potential Effects Considered:

Amount of habitat that may be altered or lost relative to its availability in the Terrestrial RSA
Mortalities directly or indirectly attributable to the Project

• Raptors, Migratory Breeding Birds, & Bird Species at Risk

Key Indicators:

Bald Eagle, Osprey
Waterbirds and Waterfowl
Upland Game Birds
Migratory Songbirds
Common Nighthawk
Short-eared Owl
Yellow Rail
Rusty Blackbird
Olive-sided Flycatcher

Direct habitat loss
Sensory disturbance
Collisions with project vehicles & equipment
Incidental take of birds, nests, eggs

Potential Effects Considered:

Amount of habitat that may be altered or lost relative to its availability in the Terrestrial RSA
Mortalities directly or indirectly attributable to the Project

Terrestrial Environment Valued Components

- Terrain
- Soil
- Organic Matter/Peat
- Vegetation and Ecosystems
- Listed Plant Species
- Wetlands
- Ungulates
- Furbearers
- Woodland Caribou
- Raptors
- Migratory Breeding Birds
- Bird Species at Risk

Terrestrial Environment – Species at Risk (SAR)

Wildlife Valued Components, Key Indicators, and Measurable Parameters included in the Habitat-based Assessment

| Valued Component | Key Indicator | Measurable Parameter |
|----------------------|------------------------|--|
| Furbearers | Wolverine | Amount of habitat (km ²) (not necessarily occupied) that may be altered or lost relative to its availability in the Regional Study Area (RSA). |
| | | The number of wolverine mortalities directly or indirectly attributable to the Project. |
| Woodland Caribou | Woodland caribou | Amount of habitat (km ²) (not necessarily occupied) that may be altered or lost relative to its availability in the RSA. |
| | | The number of woodland caribou mortalities directly or indirectly attributable to the Project. |
| Bird Species at Risk | Common Nighthawk | Percentage of habitat for Common Nighthawk altered/lost directly or indirectly as a result of Project activities. The number of Common Nighthawk mortalities directly or indirectly attributable to the Project. |
| | Rusty Blackbird | Percentage of habitat for Rusty Blackbird altered/lost directly or indirectly as a result of Project activities. The number of rusty blackbird mortalities directly or indirectly attributable to the Project |
| | Olive-sided Flycatcher | Percentage of habitat for Olive-sided Flycatcher altered/lost directly or indirectly as a result of Project activities. The number of Olive-sided Flycatcher mortalities directly or indirectly attributable to the Project |
| | Short-eared Owl | Percentage of habitat for Short-eared Owl altered/lost directly or indirectly as a result of Project activities. The number of Short-eared Owl mortalities directly or indirectly attributable to the Project. |
| | Yellow Rail | Percentage of habitat for Yellow Rail altered/lost directly or indirectly as a result of Project activities. |
| | | The number of Yellow Rail mortalities directly or indirectly attributable to the Project. |

Terrestrial Environment – Species at Risk (SAR)

- Supplemental information generated during EIS review:
 - IR responses
 - Round 1 – submitted August 2023
 - Round 2 – submitted February 2024
 - Revised draft EIS new appendices:
 - Appendix 9-D Wildlife Species At Risk
 - Additional information for 9 SAR which were not included in the draft EIS as KIs.
 - The information provided in the SAR appendix includes a summary of the life history requirements, the expected Project effects, proposed mitigation measures, and anticipated residual effects on these listed species.
 - Appendix 9-E Caribou Management Framework
 - Appendix 9-F Supplemental Information Generated During the Draft EIS Review

Terrestrial Environment – Remaining IRs

Species-specific information for pre-clearance sweeps

IR-134-R1: Bats

IR-142, IR-159, IR-167-R1: SAR in general

IR-149-R1A: caribou

IR-170: SAR, including nighthawk

- Various IRs requesting details on how pre-clearance sweeps will be tailored to SAR
 - Denison's EIS has concluded there are no significant effects on wildlife and bird SAR.
 - Denison believes we have provided sufficient information in the EIS and IR responses for the federal government to make a determination as to the effect of the Project on SAR, within the approved scope of the Project and *CEAA 2012*.
 - Details related to management plans are under development to support CNSC licensing and provincial permitting.
 - We also note that ongoing SAR management is under Provincial jurisdiction.
 - Information requested in these IRs has been provided in various places in the EIS and IR responses; however, Denison can provide more concise summaries to support the resolution of these IRs (example on next slide)
 - We request the opportunity to meet and discuss draft details with ECCC directly in the next 1-2 weeks, prior to submitting a formal IR response

Terrestrial Environment – Remaining IRs

Species-specific information for pre-clearance sweeps

IR-134-R1: Bats

IR-142, IR-159, IR-167-R1: SAR in general

IR-149-R1A: caribou

IR-170: SAR, including nighthawk

| Species of Concern | Important Habitat and Needs | Survey Target Areas | Survey Technique | Timing | Information Source |
|--------------------------------------|--|---|---|-------------|---|
| Little Brown Myotis and Northern Bat | The presence of large snags, tree cavities, is an important attribute in old growth forest stands that provides maternity roosts and day roosts for northern myotis and little brown bats. Building are also used. | Treed areas with the largest diameter and/or older trees. Focus on older forest, or areas with large snags in younger forest within the project footprint (majority is regenerating forest 1-5m). | Daytime visual search of trees and potential roost sites. Systematic meandering search of areas to be cleared during active bat season. Focus on searching for roost features (snags, cracks, stumps, cavities, bark peeling) and bat sign (e.g., guano). | May to Sept | Broders et al. 2005; Garroway and Broders 2008; Park and Broders 2012; Ford et al. 2016; Randall et al. 2014; Resources Information Standards Committee (RISC). 2022. |
| | Foraging habitat in proximity to roosting sites is also an important factor in roost selection. | Treed areas in proximity to clearings, wetlands and open water. | | | |

Terrestrial Environment – Remaining IRs

Bats: IR-174

To close this IR, Denison must:

1. Clarify the legend of Figure 2-9 with respect to frequency of detection
 - Total number of passes and/or buzzes detected (Appendix 9-B Terrestrial Baseline).
2. Provide suitable bat SAR habitat information in the form of a map
 - Literature data, existing ecosite data, and existing bat survey data can be used to develop habitat maps, as part of the response to this IR.
 - We expect no hibernacula in the Project Area (i.e., caves, mines, buildings with stable and specific temperatures per COSEWIC 2013). Terrain is low relief due to flat-lying sandstone and almost continuous cover of sandy glacial deposits (i.e., surface is predominately sand textured); there are no mines or building in the Project Area.
3. Provide additional baseline data for bat SAR based on literature sources and justify applicability to the project
 - See point 2.
4. Provide a description of proposed methods for bat SAR field monitoring for review
 - Denison can summarize the proposed methods for discussion with ECCC in the next 1-2 weeks (see previous 2 slides).
5. Commit to an EA commitment to collect additional bat SAR field baseline data prior to disturbance
 - We believe the habitat-based information in Appendix 9-D (see *summary on next slide*), plus additional mapping as part of Point 2 above, is sufficient for the EA stage. If any EA commitments are being considered, they would be follow-up only and not be used for significance determination.

Appendix 9-D Table 4.1 (excerpt)

| Component | Wildlife SAR | Measurable Parameters | Project Activities Resulting in Primary Interactions | Project Phase | Species-Specific Mitigation Measures ¹ | Predicted Residual Effect | Significance |
|-------------------------|--|--|---|-----------------|---|--|---|
| Terrestrial Environment | Little brown myotis Northern myotis | Amount of habitat that is altered or lost relative to its availability in the Terrestrial RSA. | <ul style="list-style-type: none"> Development of access roads and air strip. Site preparation and earthworks; clearing, leveling and grading of the Project Area. On-site and off-site operation of vehicles and transport of materials. Air transportation for workers. | Construction | <ul style="list-style-type: none"> Vegetation clearing activities will occur outside of roosting periods, when practical. Pre- disturbance wildlife clearance surveys will be completed to identify site-specific habitat features such as maternal roosting sites and hibernacula used by bat species. If features are identified in the Project Footprint, appropriate setbacks and/or timing windows will be implemented in accordance with the SARGSS (SK MOE 2017 (that will also be defined in the Wildlife Management Plan). In the event a maternal roosting site is identified on the Project Footprint, exclusionary methods (e.g., installing a one-way bat exit) will be implemented following the summer maternity roost season. This installation would allow for bats to leave but not the ability to re-enter the roosting site. Locations of these site-specific habitat features used by bats will be communicated to appropriate Project personnel and the requirement to limit disturbance in these areas will be implemented. Specific exclusion methods will be added as mitigation measures (Section 9.4.5 of the final EIS) to prevent access to buildings and other infrastructure. | Alteration and/or loss of habitat: predicted to be low magnitude, local geographical extent, long-term duration, frequent, fully reversible. | Not Significant: the predicted residual effect of alteration and/or loss of habitat is not expected to alter the integrity of the habitat for bat species within the Terrestrial RSA to the point where it is not sustainable or available to contribute to ecological functions. |
| | | | <ul style="list-style-type: none"> On-site and off-site operation of vehicles and transport of materials. Air transportation for workers. | Operation | | | |
| | | | <ul style="list-style-type: none"> Demolition and disposal of non-salvageable surface infrastructure and materials. On-site and off-site operation of vehicles and transport of materials. Reclamation of disturbed areas. | Decommissioning | | | |
| | | Mortalities directly or indirectly attributable to the Project. | <ul style="list-style-type: none"> Development of access roads and air strip. Site preparation and earthworks; clearing, leveling and grading of the Project Area. On-site and off-site operation of vehicles and transport of materials. Air transportation for workers. | Construction | | Change in mortality: predicted to be low magnitude, local in geographical extent, long-term duration, infrequent, and fully reversible. | The predicted residual effect of change in mortality is not expected to alter the integrity of the regional populations of the bat species to the point where they are not sustainable or available to contribute to ecological functions |
| | | | <ul style="list-style-type: none"> On-site and off-site operation of vehicles and transport of materials. Air transportation for workers. | Operation | | | |

Terrestrial Environment – Remaining IRs

Caribou offset commitment: IR-149 and IR-157

- ECCC notes IRs are accepted if Denison commits to the following:
 - *Denison's offsetting plan will meet the objectives of the Recovery Strategy for the Woodland Caribou (*Rangifer tarandus caribou*), Boreal population, in Canada*

Our understanding is that by meeting the Provincial offset requirements, we are meeting the objectives of the recovery strategy since the Province is responsible for caribou management.

Terrestrial Environment – Remaining IRs

Caribou offset commitment: IR-149 and IR-157

- Denison's EIS has concluded there are no significant effects on caribou.
- The caribou population in SK1 is stable and SK1 is not at the disturbance threshold, based on recent update from Saskatchewan Ministry of Environment (SK ENV 2023):
 - 53% disturbed, 47% undisturbed – i.e., SK1 conservation unit is currently below the disturbance threshold of 40% undisturbed habitat.
- Denison has committed to offsetting with SK ENV.
 - Denison will need approval through the province for offsetting and this must be accomplished through the provincial offsetting framework.
 - Our understanding is that if ECCC does not agree with ENV's offsetting plans, this is a federal-provincial government issue, not a proponent issue related to an EA under CEAA 2012.

Terrestrial Environment – Remaining IRs

Caribou mitigation: IR-149-R1B

| Round 2 IR | Denison's response | Round 3 IR |
|--|--|--|
| <p>1. Provide additional information on the timing and frequency of air traffic using the Project air strip.</p> <p>2. Provide specific mitigations related to impacts from air traffic, including mitigations related to frequency and timing of flights.</p> | <p>Please see response to IR-149.</p> <p>In addition, in direct response to IR-149-R1B the following is noted.</p> <p>The flight schedules have not yet been determined at this relatively early stage of planning for the Project.</p> <p>Mitigation measures likely to be incorporated into the operation of the airstrip, with respect to air traffic, would include, as safety allows, maintaining as direct approach and departure flight paths as possible, and obtaining appropriate altitudes, and leaving the LSA and RSA, as quickly as is safely reasonable.</p> <p> Denison Mines</p> | <p>Item two has been accepted as the Proponent has provided potential measures likely to be incorporated into operations of the airstrip, but item one remains outstanding. The information requested was not provided as the Proponent notes it is too early in the planning phase to provide this information. Once flight schedules have been determined, the Proponent should share them for review. If this cannot be provided at this time, the Proponent should provide information on the frequency and approximate timing of flights, as well as any periods of restricted activity planned for mitigation purposes.</p> <p>In addition, Denison is expected to provide details on specific mitigation measures to address sensory impacts to caribou, such as restricted activity periods to accommodate for the caribou calving season, or different flight paths.</p> <p>Please see the related follow up advice for IR-149-R1B in the Advice to the Proponent document.</p> |

Terrestrial Environment – Remaining IRs

Caribou mitigation: IR-149-R1B

- This comment should not be an IR at this stage of the review.
 - The EIS concluded there are no significant effects on caribou, which included the assessment of habitat alteration due to sensory disturbances, including the operation of an airstrip.
 - It is not reasonable, in Denison's view, that flight schedules have to be defined at this early stage of the Project.
- While some additional information can be provided (*see bullets below*), we reiterate that the EIS was completed with the appropriate level of detail expected at this stage of the Project.
 - Anticipated aircraft traffic at the Project airstrip is expected to be minimal, at approximately five flights per week during Operation.
 - Mitigation measures likely to be incorporated into the operation of the airstrip, with respect to air traffic, would include, as safety allows, maintaining as direct approach and departure flight paths as possible, and obtaining appropriate altitudes, and leaving the LSA and RSA, as quickly as is safely reasonable.
 - If ECCC has specific additional recommendations for mitigation measures, we would ask that they provide them for our consideration.

- Department: ECCC
- Project Effects Link: Change to an environmental component due to hazardous contaminants
- Reference to EIS, appendices, or supporting documentation: Section 2.2.3, Project Description

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, July 9, 2024) |
|--------------|----------------|---|--|--|--|---|---|--|
| IR-12 | - | <p>Context: There is not enough information provided within the draft EIS and site water infrastructure designs to determine if the infrastructure will sufficiently contain mine site contact and noncontact water runoff. It is unclear how water management will occur during all proposed Project stages at the Project airstrip, which is located away from the main Project site. No information has been provided regarding water that may come into contact with fuels and oils from machinery on the air strip, how and where that contaminated water will be treated, and how surface runoff around the airstrip will be managed. Additionally, it is unclear if contaminants from heavy machinery on roads have been considered during runoff collection plans throughout the mine Project site. Water management at the airstrip and roads can have impacts on surface water quality and sediment quality and contaminants (e.g., Hydrocarbons) from these sources should be considered in overall site water management plans.</p> <p>In Section 2.2.3.1 a site drainage plan for contact and non-contact water has been provided in Figure 2.2-17, and water balances have been provided for the different Project phases in Figures 2.2-14 to 2.2- 16. In Section 2.2.3.4 a volume of 30,000m3 for the process water pond is provided, and it is stated that the process water pond has the capacity to contain Probable Maximum Precipitation (PMP) event estimated to be 483.3mm while allowing for 1.0m of freeboard. However, there are no estimates on the total volume of water that may be drained from the overall site infrastructure (i.e., the well field, processing areas, etc.) during a 24-hr PMP event. Additionally, in Figure 2.2.17 culvert locations are provided, however there is no further information on culvert designs, flow ratings and capacity for PMP events.</p> <p>Rationale: In order to be able to understand site water management and flood risk potential, more information needs to be provided regarding the site water infrastructure designs and capture volumes during PMP events. This information will aid ECCC in understanding how contact and non-contact water will be conveyed throughout the site. Runoff from roads and the site airstrip will contain contaminants from vehicles, heavy machinery, aircrafts and de-icing practices. Additional information on the runoff collection systems and expected contaminant concentrations for the site airstrip and roads is needed to determine if the receiving environment and aquatic and terrestrial receptors are protected.</p> | <p>1. Provide information on how contact and non-contact water from the site airstrip will be managed. Include information on potential contaminant characterization and loadings and an assessment of risk to the environment.</p> <p>2. Provide further information on how potential contaminants in runoff from roads have been considered in the site water management. Include information on potential contaminant characterization and loadings and an assessment of risk to the environment.</p> <p>3. Provide estimated volumes of water to be drained from overall site infrastructure (such as the mine terrace, airstrip, camp area etc.), during a 24-hr PMP event.</p> <p>4. Provide additional information on culvert designs and conveyance capacity for PMP events.</p> | <p>1. and 2. Denison’s approach to site water management is keep non-contact water “clean” – that is, the management approach provides that non-contact water does not come into contact with site aspects that may impart constituents/contaminants of concern and that non-contact water mingles with contact water. Contact water is water expected at the wellfield and processing plant terrace (refer to runoff collection arrows shown in draft EIS Figure 2.2-17), and also includes leachate collected from landfills. As such, runoff from the airstrip and site roads is considered non-contact water and will not be actively managed. However, should a spill occur, the spill response plan will be followed. Details of Denison’s response plans will be developed to support licensing as part of the Waste Management and Emergency Management and Fire Protection programs. By following best practice and mitigation measures outlined in the EIS, Denison does not anticipate a need to continually manage water at the airstrip or along site roads as the water here will be clean, non-contact runoff. Examples of relevant mitigation measures include:</p> <ul style="list-style-type: none">• Project components including equipment and machinery will be regularly maintained and inspected to make sure they are in good working order.• Fuel storage and distribution infrastructure will be constructed in accordance with applicable legislation requirements.• Fuels will be stored in approved, above-ground, double-walled storage tank(s) equipped with secondary containment in accordance with provincial regulations and standards.• A wash bay will be available to clean items, equipment, and vehicles that may have been in contact with potential contaminants. <p>Refer to Section 14 of the draft EIS for the screening and evaluation of various accident and malfunction scenarios. Should unplanned events or conditions occur, it will be important for Denison to address and respond in an appropriate manner. Details of Denison's response plans will be developed to support licensing as part of the Waste Management and Emergency Management and Fire Protection programs. Additionally, should unexpected water pooling be observed at the airstrip or site roads during Operation, temporary water removal means such as vac trucks or sump pumps could be employed and the areas would be re-graded to minimize water accumulation.</p> <p>3. As indicated in the response to IR-12, points 1 and 2 above, Denison expects contact water requiring management is at the wellfield and processing plant terrace (refer to runoff collection arrows shown in draft EIS Figure 2.2-17). For this area, the volume of water expected during a 24-hour PMP of 493 mm is approximately 37,240 m3. The wellfield runoff pond has been sized appropriately (38,200 m3 with 1 m of freeboard) to contain this volume of water.</p> <p>4. Details related to culvert design and conveyance capacity are being developed as part of ongoing engineering activities. Culverts will be a designed with a sufficient size and length to convey water around the site during a PMP event.</p> | <p>This response has not been accepted, for the following reasons (numbers correspond with original IR):</p> <p>1-2. In Figure 2.2-17 (Site Drainage Plan with Flow Direction and Culvert Locations) of EIS, site drainage or water management layout is not included for the access road to the airport and the airport area although they constitute part of the Project site. Although surface run off from airstrip or site road are mainly expected to be clean or non-contact water, CNSC expects Denison to provide information on water management system to mitigate risk of flooding and erosion at the airport and the access road. In addition, the access road connecting the mining site with airport crosses two streams (Kratchkowsky Creek and Hart Creek) that flow into Whitefish Lake, CNSC staff expects Denison to ascertain that culverts or crossings will be designed in such a manner that the flood hazard does not increase. Therefore, CNSC staff request that Decision provide information on how the surface runoff generated at airstrip and airport access road would be managed.</p> <p>3. CNSC accepts estimated total volume of runoff from the wellfield area to Wellfield Pond however the PMP value of 489.3mm is obtained from 1999 study [A.1], based on historical rainfall data pre -1998, which appears to require updated PMP value.</p> <p>CNSC requests that Denison use a PMP value that is estimated using historical rainfall data that includes the most up to date meteorological data or provide justification on the validity of the current PMP.</p> <p>Further, the site infrastructure runoff water has not been considered in the water management infrastructure. Site water management planning should consider the capture of noncontact water to understand the potential effects of contaminants from non-contact water on the surrounding environment.</p> <p>Please also see follow-up IR-12-R1A and IR-12-R1B, related to this IR.</p> <p>Reference: [A.1] Atmospheric & Hydrologic Sciences Division – Atmospheric Environment Branch. 1999. Environment Canada Prairie & Northern Region – Point Probable Maximum Precipitation for the Prairie Provinces. Regina, Saskatchewan. Report No. AHSD – R99 – 01.</p> | <p>1-2. The water management design information presented in the draft EIS is considered appropriate at the EA stage and for this stage of the Project and fit-for-purpose to support the assessment of potential effects. The detailed design information on site water management infrastructure and runoff management requested in this IR and related IRs (i.e., IR-12-R1A and IR-12-R1B) will be provided to the CNSC and province as part of licensing and permitting.</p> <p>Nevertheless, and building on information provided previously, additional information and context regarding site water management and design concepts is provided as follows:</p> <ul style="list-style-type: none">• Conceptual site drainage maps spanning the full Project Area scale has been provided in Attachment IR-12 to this IR response table as context for the reviewer.• Design for the access roads and airstrip will in general be such that runoff will be encouraged through appropriate grading to drain away and not pond on or near the road or airstrip.• The overall vision for non-contact water along the access roads and airstrip is to use shallow ditching to dissipate the energy of runoff, to promote settling of suspended solids and allow the runoff to report to ground via natural grades that flow away from the infrastructure and into the natural drainage systems.• The condition of the airstrip and roads would be inspected and maintained routinely. For example, should unexpected water pooling be observed at the airstrip or site roads during Operation, temporary water removal means such as vac trucks or sump pumps could be employed, and the areas would be re-graded to minimize water accumulation.• Infrastructure features that are within 50 to 100 m (depending on grade) of waterbodies and that are associated with cleared land where there is no vegetated buffer may require additional erosion management / controls to ensure protection of the waterbodies from unmitigated suspended solids inputs. A map showing the distance of Project components to waterbodies is available in Attachment IR-12 as context for the reviewer. The map shows for example, that four waterbodies (waterbody numbers 1, 16, 23, and 86) are within 100 m of the Project footprint where potential erosion protection measures may be employed. The details of erosion control measures at these locations will be outlined in the Environmental Management System to support licensing.• Conceptually, minimizing changes in surface drainage patterns and watersheds is an important mitigation measure in the surface water quantity assessment. Collecting and managing non-contact water along roads and at the airstrip would result in a larger potential Project effect on surface water quantity associated with changes in surface drainage patterns and is not preferred.• As described in the draft EIS, the proposed crossings at Kratchkowsky Creek and Hart Creek are not culverts, but clear span bridges. Clear span bridges are designed to completely span a watercourse without interfering with the channel bed and banks.• As a reminder to ECCC that the road to the Project’s proposed airstrip follows an existing, decommissioned road, the Fox Lake Road.• The Project is located within the Wheeler Upland Landscape Area of the Athabasca Plain Ecoregion within | <p>Item one of the IR has been accepted, but a follow-up item of advice can be found within the Advice to the Proponent table [reference to come].</p> <p>There is outstanding information required to resolve item two. The Proponent did provide the requested proposed water management structures in Attachment IR-12; however, for the road to airstrip and the airstrip, the water management strategy does not include any containment structures or information about runoff quality.</p> <p>Contaminants may be contained in non-contact water from all site infrastructure, including the airstrip, roads, and the camp area. This information is required in order to make a determination on significant adverse effects, as it relates to potential impacts to water quality and fish, which are assessed as part of the EA process.</p> <p>The Proponent should confirm that the proposed water management structures, for the roads, camp pad, operation, substation and airstrip, will be included in the Final EIS. The Proponent should also describe how quality of runoff from infrastructure will be monitored, and what proposed mitigation and management measures will be taken if necessary.</p> <p><i>With regards to items three and four, these have been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>Denison is expected to address the following:</p> <ol style="list-style-type: none">3. From FIRT’s Information Request Rationale (2023-12-05): CNSC requests that Denison use a PMP value that is estimated using historical rainfall data that includes the most up to date meteorological data or provide justification on the validity of the current PMP.4. From Denison submission of responses to IRs (2023-08-18): Details related to culvert design and conveyance capacity are being developed as part of ongoing engineering activities. Culverts will be a designed with a sufficient size and length to convey water around the site during a PMP event. | <p>Refer to Attachment IR-12, IR-12-R1A, and IR-112-R1B (Round 3) below.</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, July 9, 2024) |
|--------------|----------------|--|--------------------------|---|---|---|---|--|
| | | | | | | <p>the Boreal Shield Ecozone of Saskatchewan. The area is characterized by Brunisolic soils which are typically sandy, well-drained soil. Standing water is not a common occurrence and the well-drained characteristics of the region support the plans to divert non-contact water to ground, and as noted made surfaces would be graded to promote drainage and discourage pooling.</p> <ul style="list-style-type: none">• Please refer to our initial response to IR-12 (refer to Annex 1, IR-12 on page 6/419) for additional context on best practice and mitigation measures related to water management and also the scoping and evaluation of accident and malfunction scenarios in the draft EIS.• Importantly, the conceptual management scheme outlined above for non-contact water runoff is consistent with other roads and airstrips in the region – that is, runoff is not currently captured from other roads and airstrips in the region as envisioned by the review comment. This includes infrastructure associated with Saskatchewan Ministry of Highways and Infrastructure, existing uranium mines and mills, and communities including First Nation communities. It is not practical to do so and collection of non-contact water is not needed based on risk and moreover as noted above is to be avoided so as not to necessarily affect water quantity in local drainages and sub-drainages. <p>3. The reviewer is referred to the response to IR-103 for a discussion regarding the PMP and its suitability and relevance given available data and different methods of calculation included that provided by CSA guidance. Notwithstanding the information provided in response to IR-103 Denison is committed to revisiting this issued as per CNSC’s recommendations, as applicable, for the licensing phase of the Project. To reiterate, Denison believes it has fulfilled its information requirements for the EIS as outlined in the EA guidance provided by the province and federal government, including CEEA 2012, and that the FIRT has been provided with the appropriate level of detail on the water management topic for drawing conclusions on the EA process. Notwithstanding that, Denison recognizes that further information will be required as the Project moves past the EA and into the licensing and permitting phases. It is Denison's opinion that this comment is not an IR related to the EIS. A request for clarification or additional information on a detailed design aspect would need to be responded to by the Denison as part of the licensing process; however, this level of detail is not necessary for drawing conclusions on the EA process.</p> | | |
| <i>n/a</i> | IR-12-R1A | <p>Context: Runoff water from site infrastructure such as the airstrip and roads may be categorized as non-contact water because it does not come into contact with contaminants of potential concern (COPCs) directly from mining operations infrastructure. However, it still has the potential to contain deleterious substances from mine-related activities such as operation of vehicles, including heavy machinery and aircraft, spills, fire management practices, and snow removal practices. The Metal and Diamond Mining Effluent Regulations (MDMER) pursuant to the Fisheries Act requires all mine effluent and seepage from the mine site that contains deleterious substances be discharged through a final discharge point. This includes deleterious substances in non-contact water from all site infrastructure including the airstrip, roads, and camp area.</p> <p>Rationale: All mine effluent and seepage that contains deleterious substances must be discharged through a final discharge point.</p> | <i>n/a</i> | <i>n/a</i> | <p>1. Update site water management plans to include management of potentially deleterious substances contained in non-contact water from all site infrastructure.</p> <p>2. Provide updated estimates of water volumes to be drained and managed from overall site infrastructure (including runoff from roads, airstrip, camp area, etc.) during the different Project phases. Include updated information on water treatment flows, capacity and effluent discharge during normal operations, and a 24-hr Probable Maximum Precipitation (PMP) Event.</p> | <p>1 and 2. Denison understands the prohibition related to deleterious substances under Section 36 of the Fisheries Act and Denison affirms its commitment to ensuring no such events occur. However, in the context of this IR, we interpret ECCC is connecting the concept of deleterious substances under MDMER (those constituents identified in Part 1(3) i.e., arsenic; copper; cyanide; lead; nickel; zinc; suspended solids; radium 226; and un-ionized ammonia.) with the general concept of deleterious substance per the Fisheries Act. Mine effluent associated with MDMER defined deleterious substances will be discharged through a final discharge point to Whitefish Lake, and this has been reflected in the water management information presented in the draft EIS, including Section 2.2.3. The IR is suggesting Denison collects runoff water from the airstrip and roads with the rationale that this is needed in order to collect potential contact water associated with hydrocarbons spills (the text in rationale notes: This includes site non-contact water which has the potential to contain deleterious substances such as those released from vehicles, machinery, aircrafts, spills, and de-icing practices). As indicated in the draft EIS and in our initial response to IR-12 (refer to Annex 1, IR-12 on</p> | <p>The Proponent has not adequately answered either part of the IR.</p> <p>An updated site water management plan that includes the management of all water that has been in contact with project infrastructure and updated estimates of water volumes to be drained and managed from overall site infrastructure (including runoff from roads, airstrip, camp area, etc.) are required to understand the potential effects of contaminants on the surrounding environment. The Proponent should include updated information on water treatment, flows, capacity and effluent discharge during normal operations, and a 24-hr Probable Maximum Precipitation (PMP) Event.</p> | <p>Refer to Attachment IR-12, IR-12-R1A, and IR-112-R1B below.</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, July 9, 2024) |
|--------------|----------------|---|--------------------------|---|--|--|----------------------------|---|
| | | <p>This includes site non-contact water which has the potential to contain deleterious substances such as those released from vehicles, machinery, aircrafts, spills, and de-icing practices. The Proponent has not included how non-contact water runoff from site infrastructure will be captured within site water management planning. To understand the potential effects of contaminants from non-contact water on the surrounding environment, site water management planning needs to be updated to include the capture of non-contact water.</p> | | | | <p>page 6/419), should a spill occur, the spill response plan will be followed. The details of Denison's response plans will be developed to support licensing as part of the Waste Management and Emergency Management and Fire Protection programs. Importantly, hydrocarbons are not mine waste-related deleterious substances perm MDMER definition. Collecting and treating non-contact runoff throughout the life of the Project would mean Denison collects an extremely large volume of clean water to protect against infrequent hydrocarbon spills which will be cleaned up in the appropriately scaled process (spill response), in terms of cost and risk to the environment. No other roads or airstrips in the region (including those associated with uranium mine and mill operations) requires the collection and treatment of runoff water from infrastructure such as roads and airstrips. It is not practical to do so and based on risk, the collection of non-contact water is not required.</p> <p>The road or trail to the airstrip is currently an unmaintained road: the decommissioned Fox Lake Road. For road upgrades and airstrip construction, Denison will be using material from the borrow area. Borrow pit area selection was based on geotechnical program completed in 2021 which did not identify any potential for ARD/ML. Further works are ongoing part of engineering activities and with confirmation of characterization through assays of representative samples. As such, the material used to upgrade roads and construct the airstrip will not be a source of metals or ARD.</p> <p>Denison will implement erosion control measures at infrastructure locations within 50 to 100 m of a waterbody (refer to response to IR-12 above and to Attachment IR-12, Figure IR-12-5: Distance from Project Footprint to Waterbodies) where required (i.e., at locations where there is no vegetated buffer adjacent to the waterbodies).</p> <p>In consideration of the above, Denison maintains that the runoff at the airstrip and roads are non-contact water. The water management mandate for the Wheeler River Project is to keep clean water clean and minimize the total volume of water requiring management, treatment, and discharge. In the draft and revised draft EIS, Denison has evaluated potential Project effects on surface drainage in Section 8.1, as part of the Project-surface water quantity interaction of Project overprinting of drainage areas. As noted in the draft EIS, Section 8.4.1.4.2.1, this assessment was appropriately focused on areas of active water collection. It was noted that the road and airstrip were not considered to affect hydrology materially. Both may potentially redirect some flow and have a small influence on the timing of concentration of runoff and infiltration rates; however, in general, they are anticipated to have a very small influence and are not expected to change runoff volumes at assessment nodes.</p> | | |
| | IR-12-R1B | <p>Context: The Proponent has clarified that there is no infrastructure in place for management of non-contact water from site infrastructure that may contain COPCs, including but not limited to roads, the airstrip, and the campground.</p> <p>Rationale: To understand the potential effects of contaminants from non-contact water on the surrounding environment, site water management planning needs to be updated to include the type of infrastructure and its location for the capture of non-contact water</p> | n/a | n/a | Provide a map marking the locations of proposed surface drainage structures for runoff collection including collection ditches, culverts, diversion ditches, perimeter berms, collection ponds and other similar structures. | <p>It is Denison's opinion that this comment is not an IR related to the EIS. A request for clarification or additional information on a detailed design aspect would need to be responded to by Denison as part of the permitting and licensing process; however, this level of detail is not necessary for drawing conclusions on the EA process. In the draft and revised draft EIS, Denison has evaluated potential Project effects on surface drainage in Section 8.1, as part of the Project-surface water quantity interaction of Project overprinting of drainage areas. As noted in the draft EIS, Section 8.4.1.4.2.1, this assessment was appropriately focused on areas of active water collection. It was noted that the road and airstrip were not considered to affect hydrology materially. Both may potentially redirect some flow and have a small influence on the timing of concentration of runoff and infiltration rates; however, in general, they are anticipated to have a very small influence and are not expected to change runoff volumes at assessment nodes.</p> <p>Notwithstanding the above, Denson has provided the reviewer with additional, conceptual site drainage maps in Attachment IR-12, Figures IR-12-1, IR-12-2, IR-12-3, and IR-12-4; these are supplemental to the site drainage map provided in the draft EIS Figure 2.2-17.</p> | n/a (accepted) | Refer to Attachment IR-12, IR-12-R1A, and IR-112-R1B below. |

Attachment IR-12, IR-12-R1A, IR-12-R1B (Round 3)

In response to IR-12 and related IRs 12-R1A and 12-R1B Denison offers the following that has been divided into two parts.

In **Part 1**, an updated site water management plan is presented commensurate with the stage of the EA process for Wheeler River Project (or Project). That is, the site water management plan is largely conceptual at this time; however, Denison is able to provide additional information that builds on information presented previously in the EIS and supporting documentation including Round 1 and Round 2 IR responses as the Project-related engineering design process is advancing in parallel with the EA.

In **Part 2**, Denison has prepared specific responses to specific questions raised in IRs 12, 12-R1A and 12-R1B that are not necessary fully described by Part 1 of the response.

Part 1 – Wheeler River Project Site Water Management Plan

Introduction

The following conceptual Site Water Management Plan (SWMP, or Plan) has been prepared in response to the third round (May 2024) of Federal Indigenous Review Team (FIRT) information requirements (IRs) regarding the Wheeler River Project (Project) Environmental Impact Statement (EIS) submission. The information offered herein builds on information provided previously by Denison Mines (Denison) in the EIS, its supporting documents, and responses to Round 1 (March 2023) and Round 2 (November 2023) FIRT IRs.

As noted, the Plan builds on information provided previously by Denison; but further seeks to consolidate this information into once place for ease of reference, as well as provide additional water management related detail that has been developed as Project-related engineering design has been advancing in parallel with the environmental assessment process. The Plan describes the SWMP design concept, its design basis, the delineation of so-called “contact” versus “non-contact” water management areas on the Project site, water management structures / infrastructure, the quantities of water that would be expected to be managed within the water management areas under normal and event-related conditions and monitoring.

The SWMP is provided with a conceptual level of detail and information commensurate with the stage of development of the Project and advancement of engineering design. Further detail and documentation, including engineering design to support construction, regarding site water management will be developed as the Project moves from the environmental assessment (EA) process into permitting and licensing, initially for site preparation and construction, subsequently for operations and ultimately for decommissioning.

Design Concept

The Project’s design concept related to site water management is to keep clean water clean and minimize the total volume of water requiring more active management, treatment, and discharge. Denison will achieve this by 1) diverting clean, non-contact runoff around Project components and 2) collecting contact water for treatment in the Industrial Wastewater treatment Plant (IWWTP),

and eventual release to Whitefish Lake. In general terms and within the context of this Plan, the following definitions are provided for contact and non-contact waters:

- Contact water is potentially contaminated as the result of interaction with Project process/structures/infrastructure and therefore requires management through site water infrastructure and conveyance to the IWWTP prior to controlled release to the environment.
- Non-contact water is suitable for direct release to the environment with appropriate, conventional best management practices and mitigation measures.

The rationale for the distinction of the two water types and management strategies is primarily associated with the desire to affect local hydrology as little as possible by only diverting runoff from natural catchments and sub-catchments where it is deemed necessary to protect water quality. Conceptually, minimizing changes in surface drainage patterns and watersheds is an important mitigation measure in the surface water quantity assessment. Collecting and managing non-contact water would result in a larger potential Project effect on surface water quantity associated with changes in surface drainage patterns and is not preferred.

Design Basis

For the purpose of contact and non-contact water management, the following design bases have been assumed.

For the contact water portion of the system, all water management structures/infrastructure would be designed to contain an event equivalent to 493 mm of precipitation over a 24-hour period (herein referred to as the 24-hour probable maximum precipitation (PMP) event). By definition, events exceeding this magnitude would be conveyed to the environment through purposely built emergency spillways so that the structural integrity of the structures/infrastructure would be maintained and not result in further event related consequences. For context, this volume of water is greater than the average annual precipitation recorded at nearby Key Lake (refer to Appendix D to Appendix 6-C) for the period 2011 through 2020 that was 456 mm.

For the non-contact water portion of the system, all water management structures/infrastructure would be designed to withstand an event equivalent to 89 mm of precipitation over a 24-hour period (herein referred to as the 24-hour intensity-duration frequency (IDF) event). This event is the 1 in 100 year return event and was calculated utilizing the publicly available web-based intensity-duration-frequency tool that is pre-loaded with 898 Environment and Climate Change Canada rain stations. This number was derived based on the projection of conditions for the period 2020 - 2050 for the Wheeler River Project site coordinates and therefore considers the time period that overlaps with the time period when water is likely to be actively managed on the site (i.e., construction, operation, initial phase of decommissioning).

Delineation of Catchments Areas

For the purpose of defining water management areas / nodes within and adjacent to the Project site, a series of maps delineating catchments areas based on local topography and drainage patterns have been developed. The delineation of key catchments at the Project site is shown in Figures 1 to 5 below.

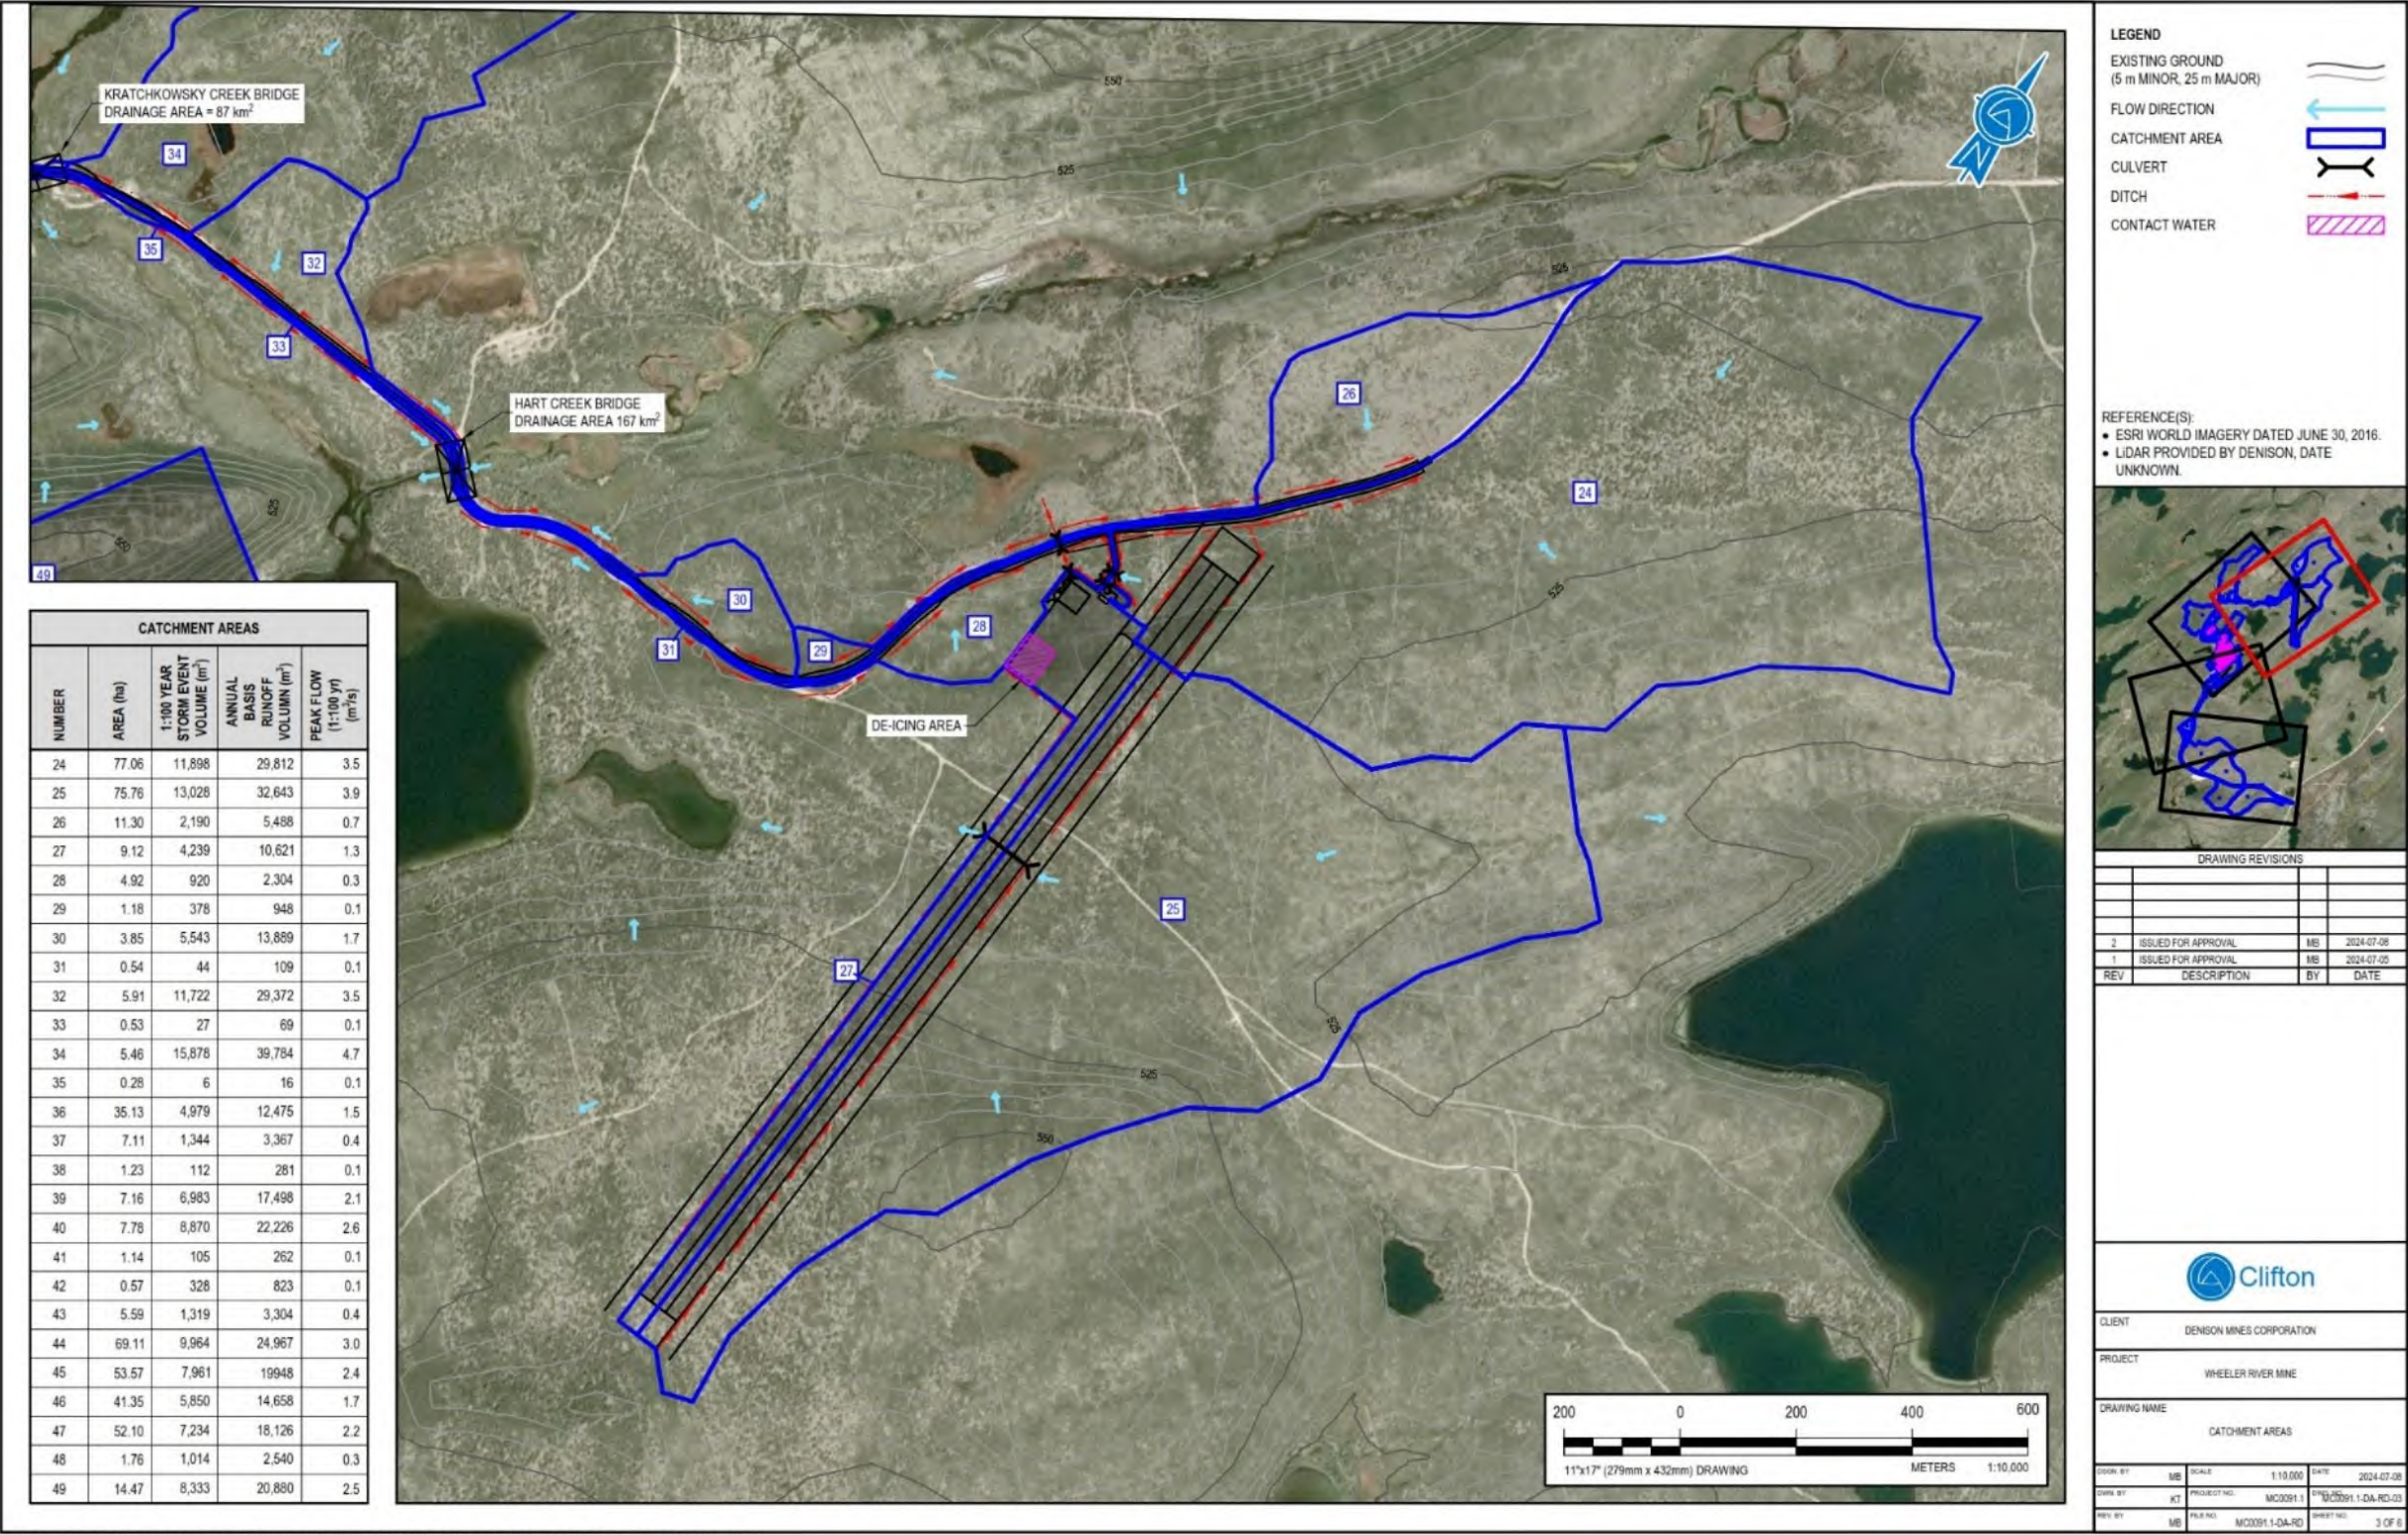

Figure 1: Site water management catchment areas – layout 1 of 5: Airstrip and portion of airstrip access road

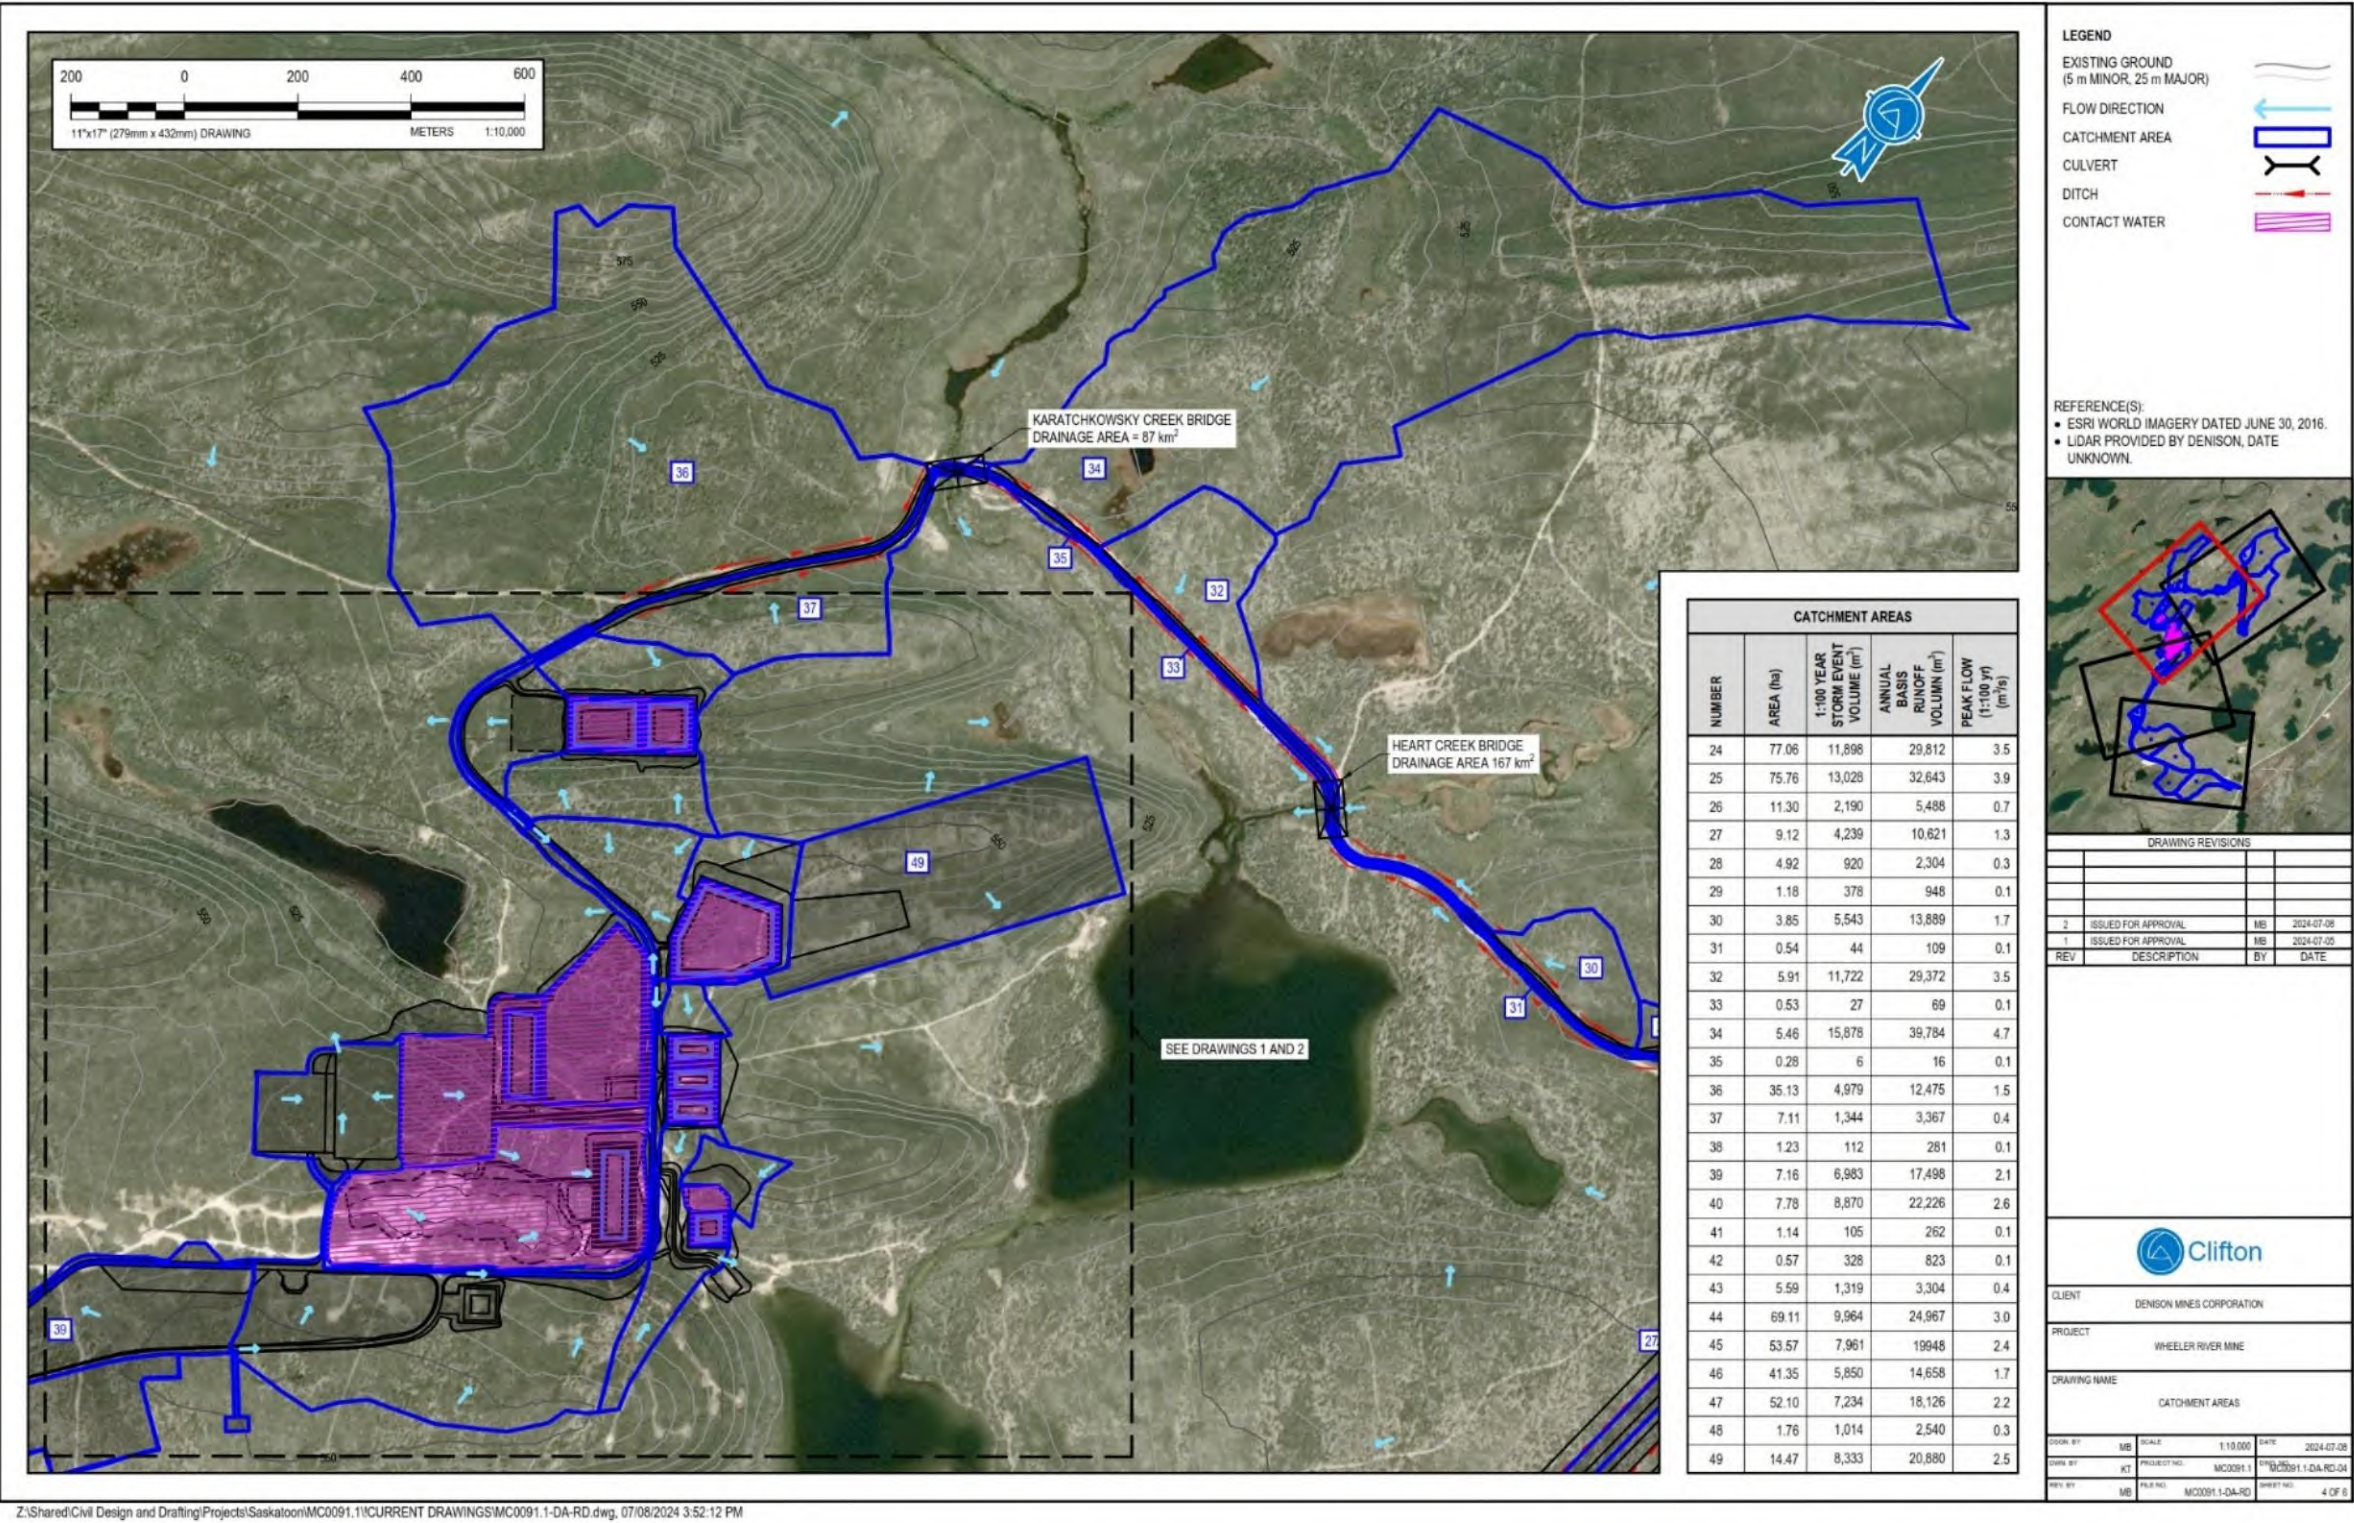

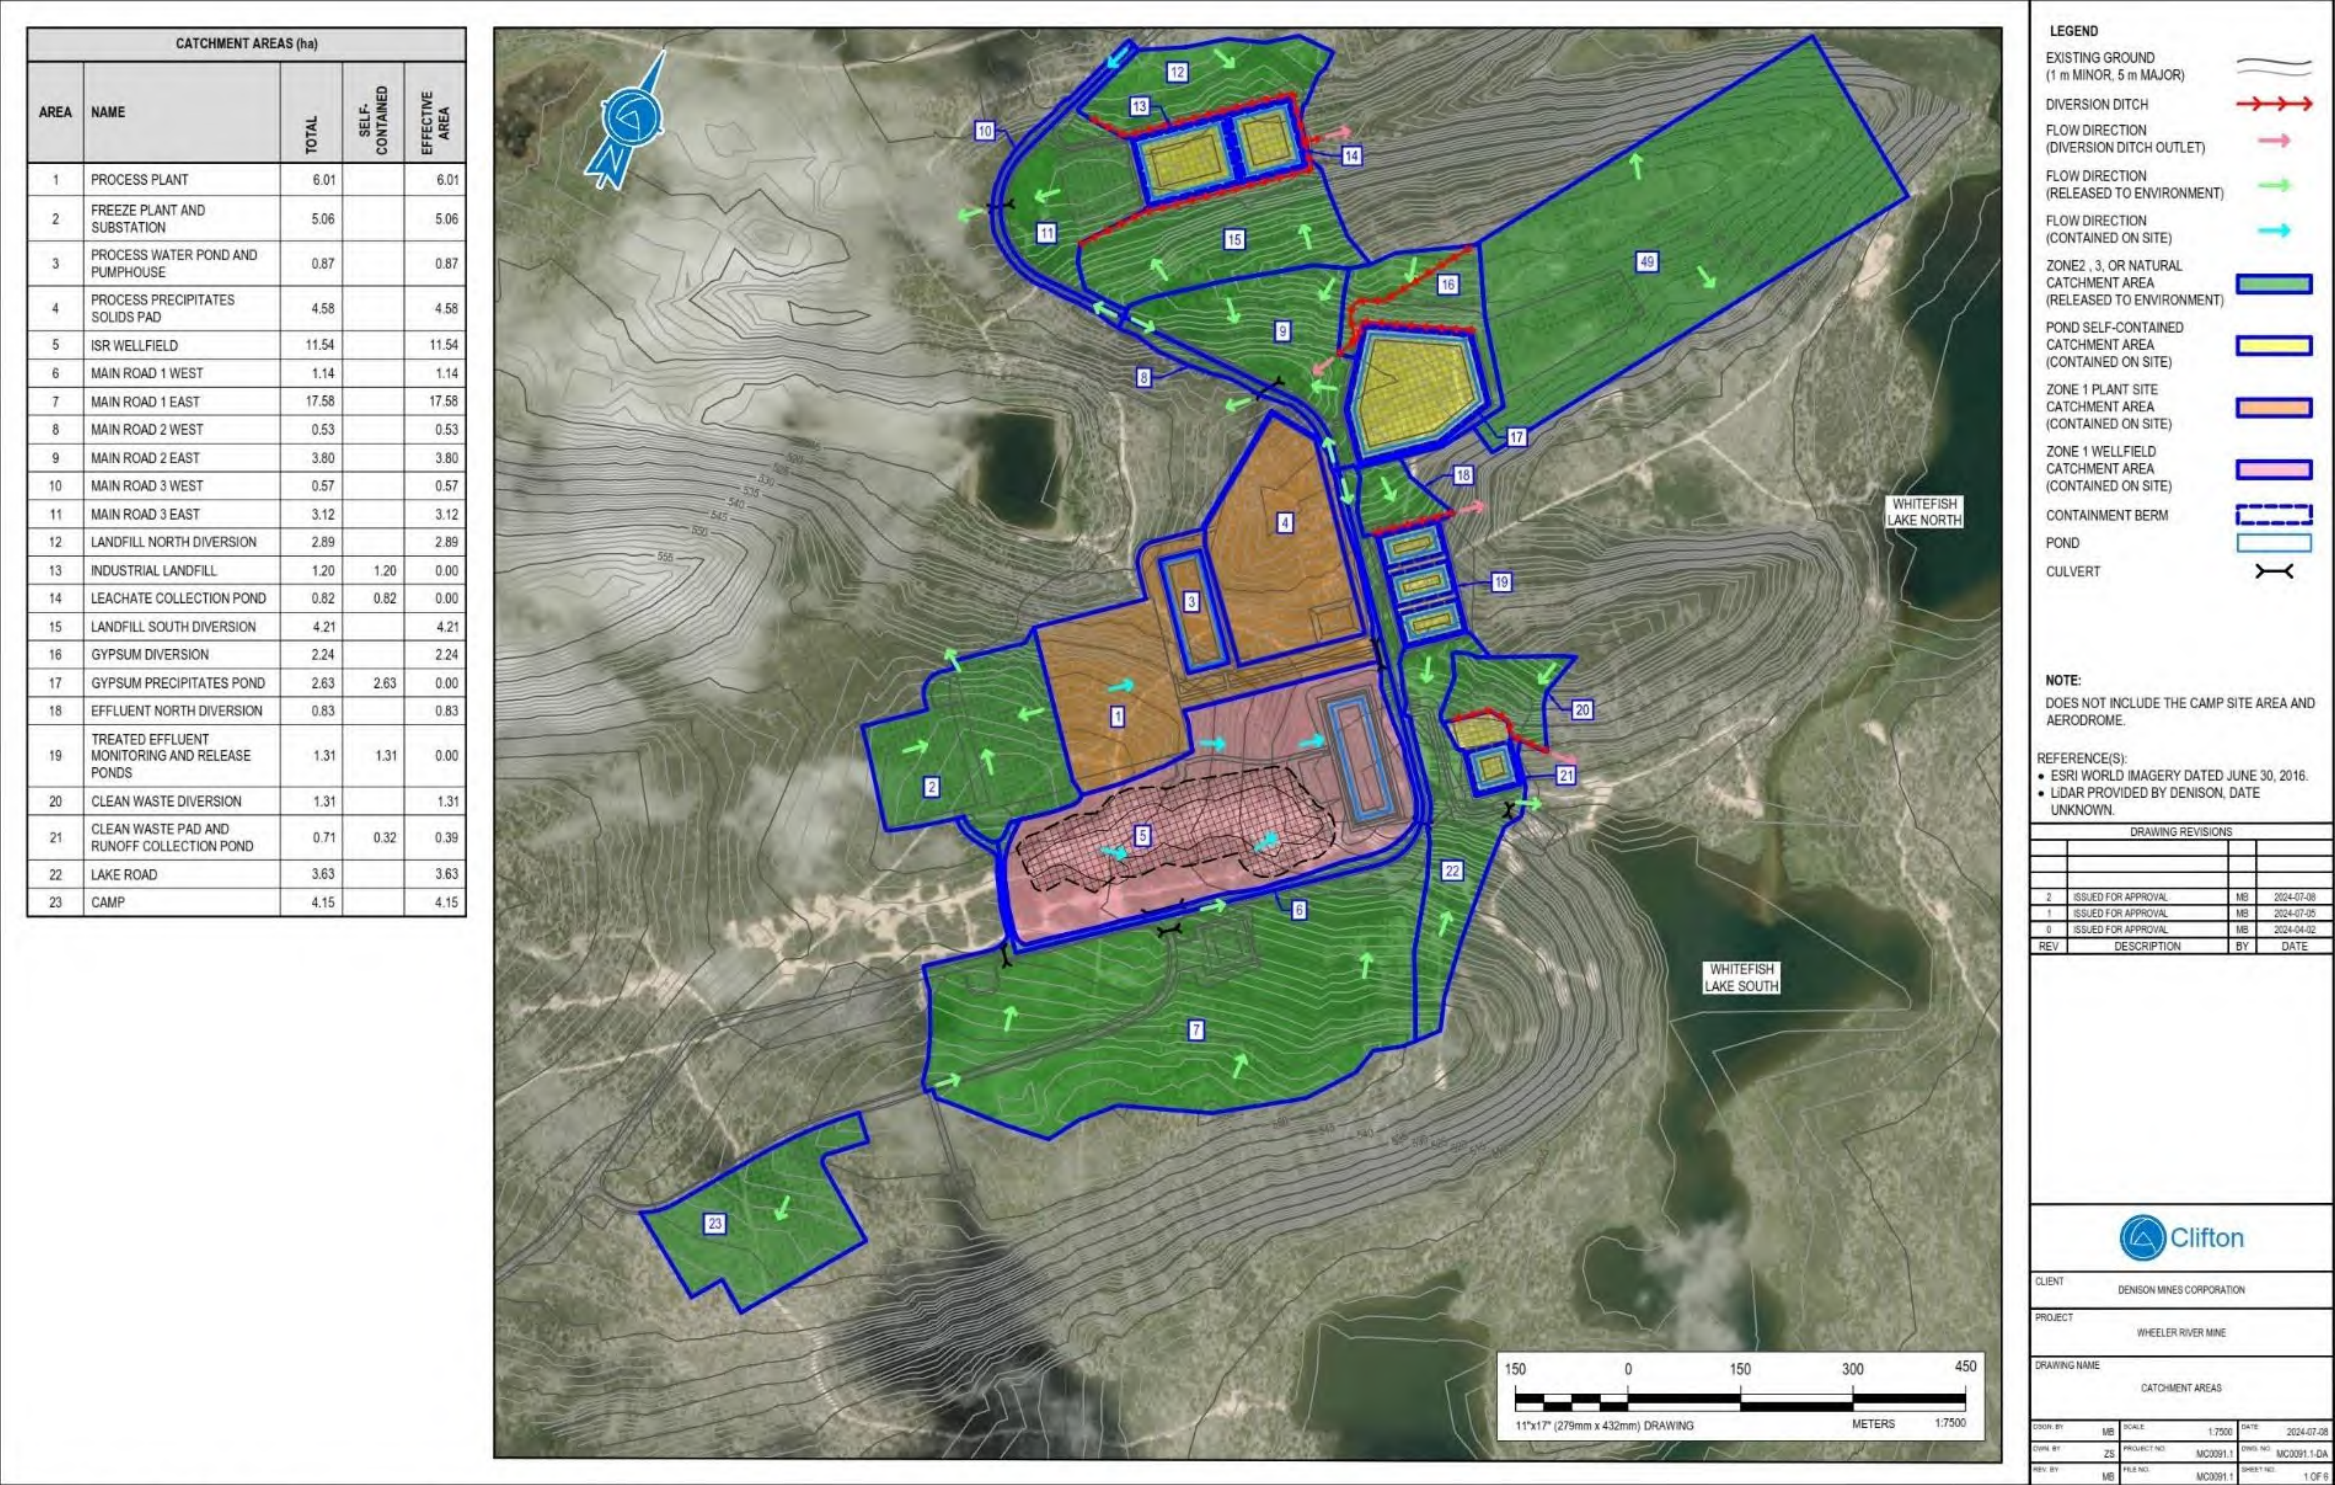

Figure 2: Site water management catchment areas – layout 2 of 5: Airstrip access road

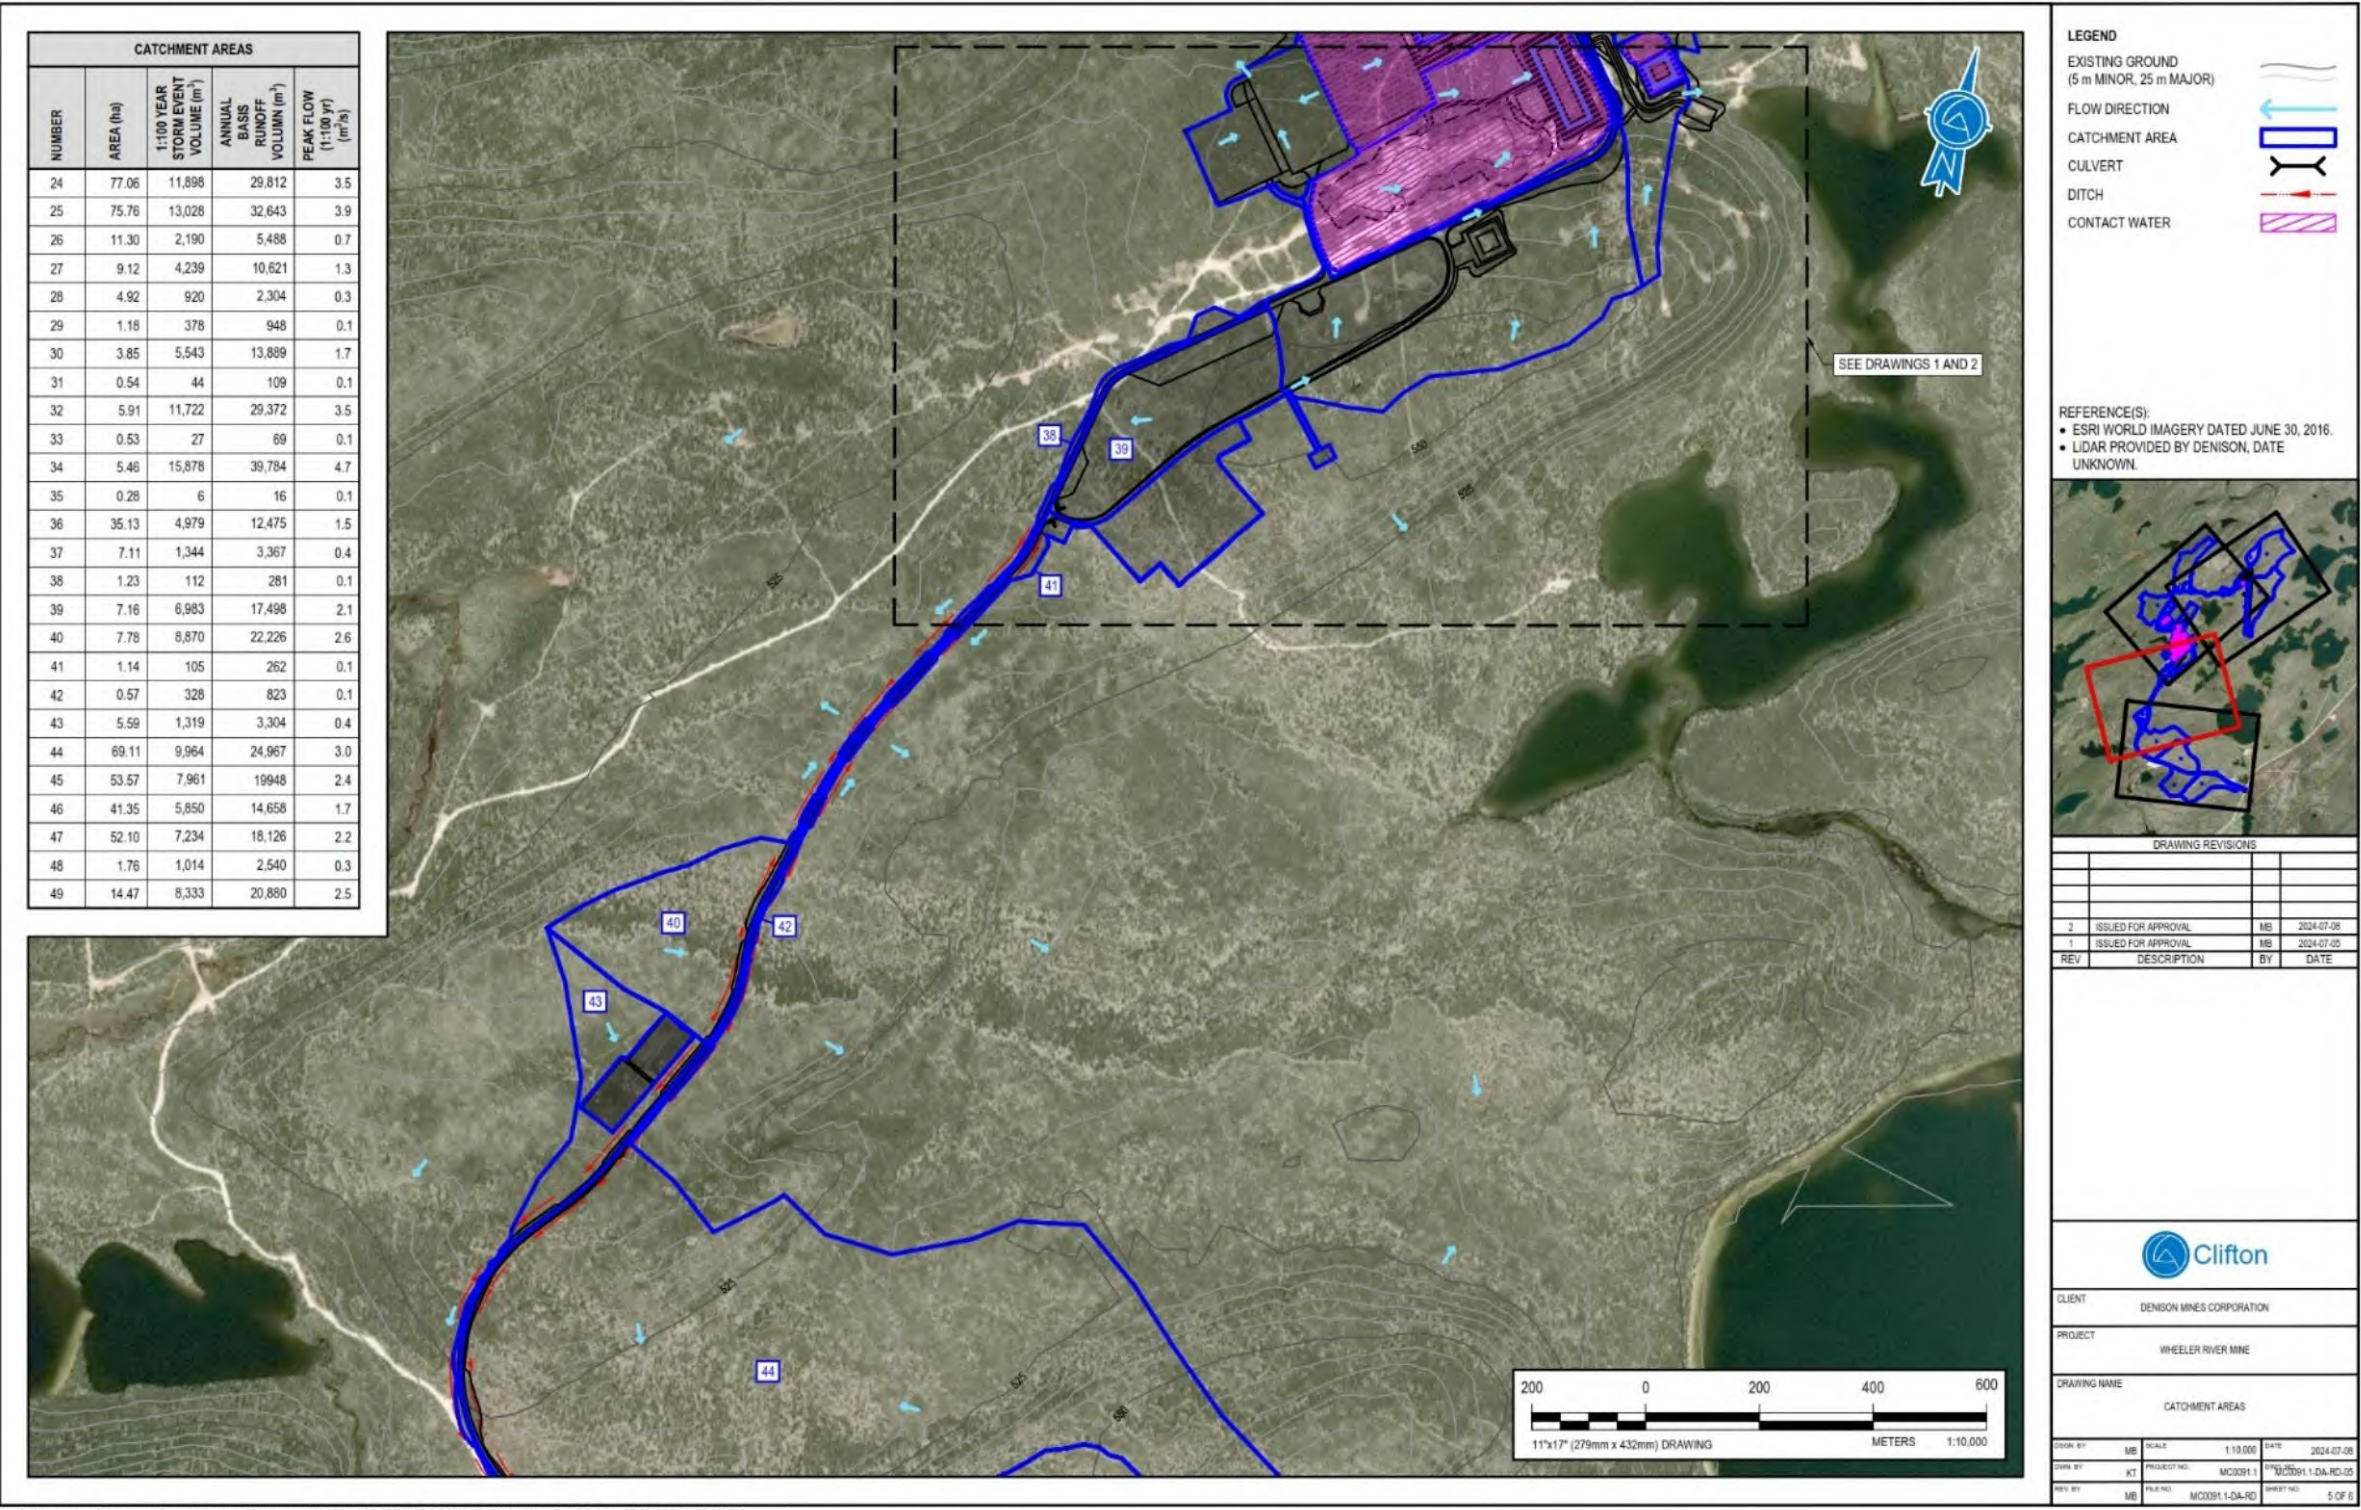

Figure 4: Site water management catchment areas – layout 4 of 5: Access road south of main Project area

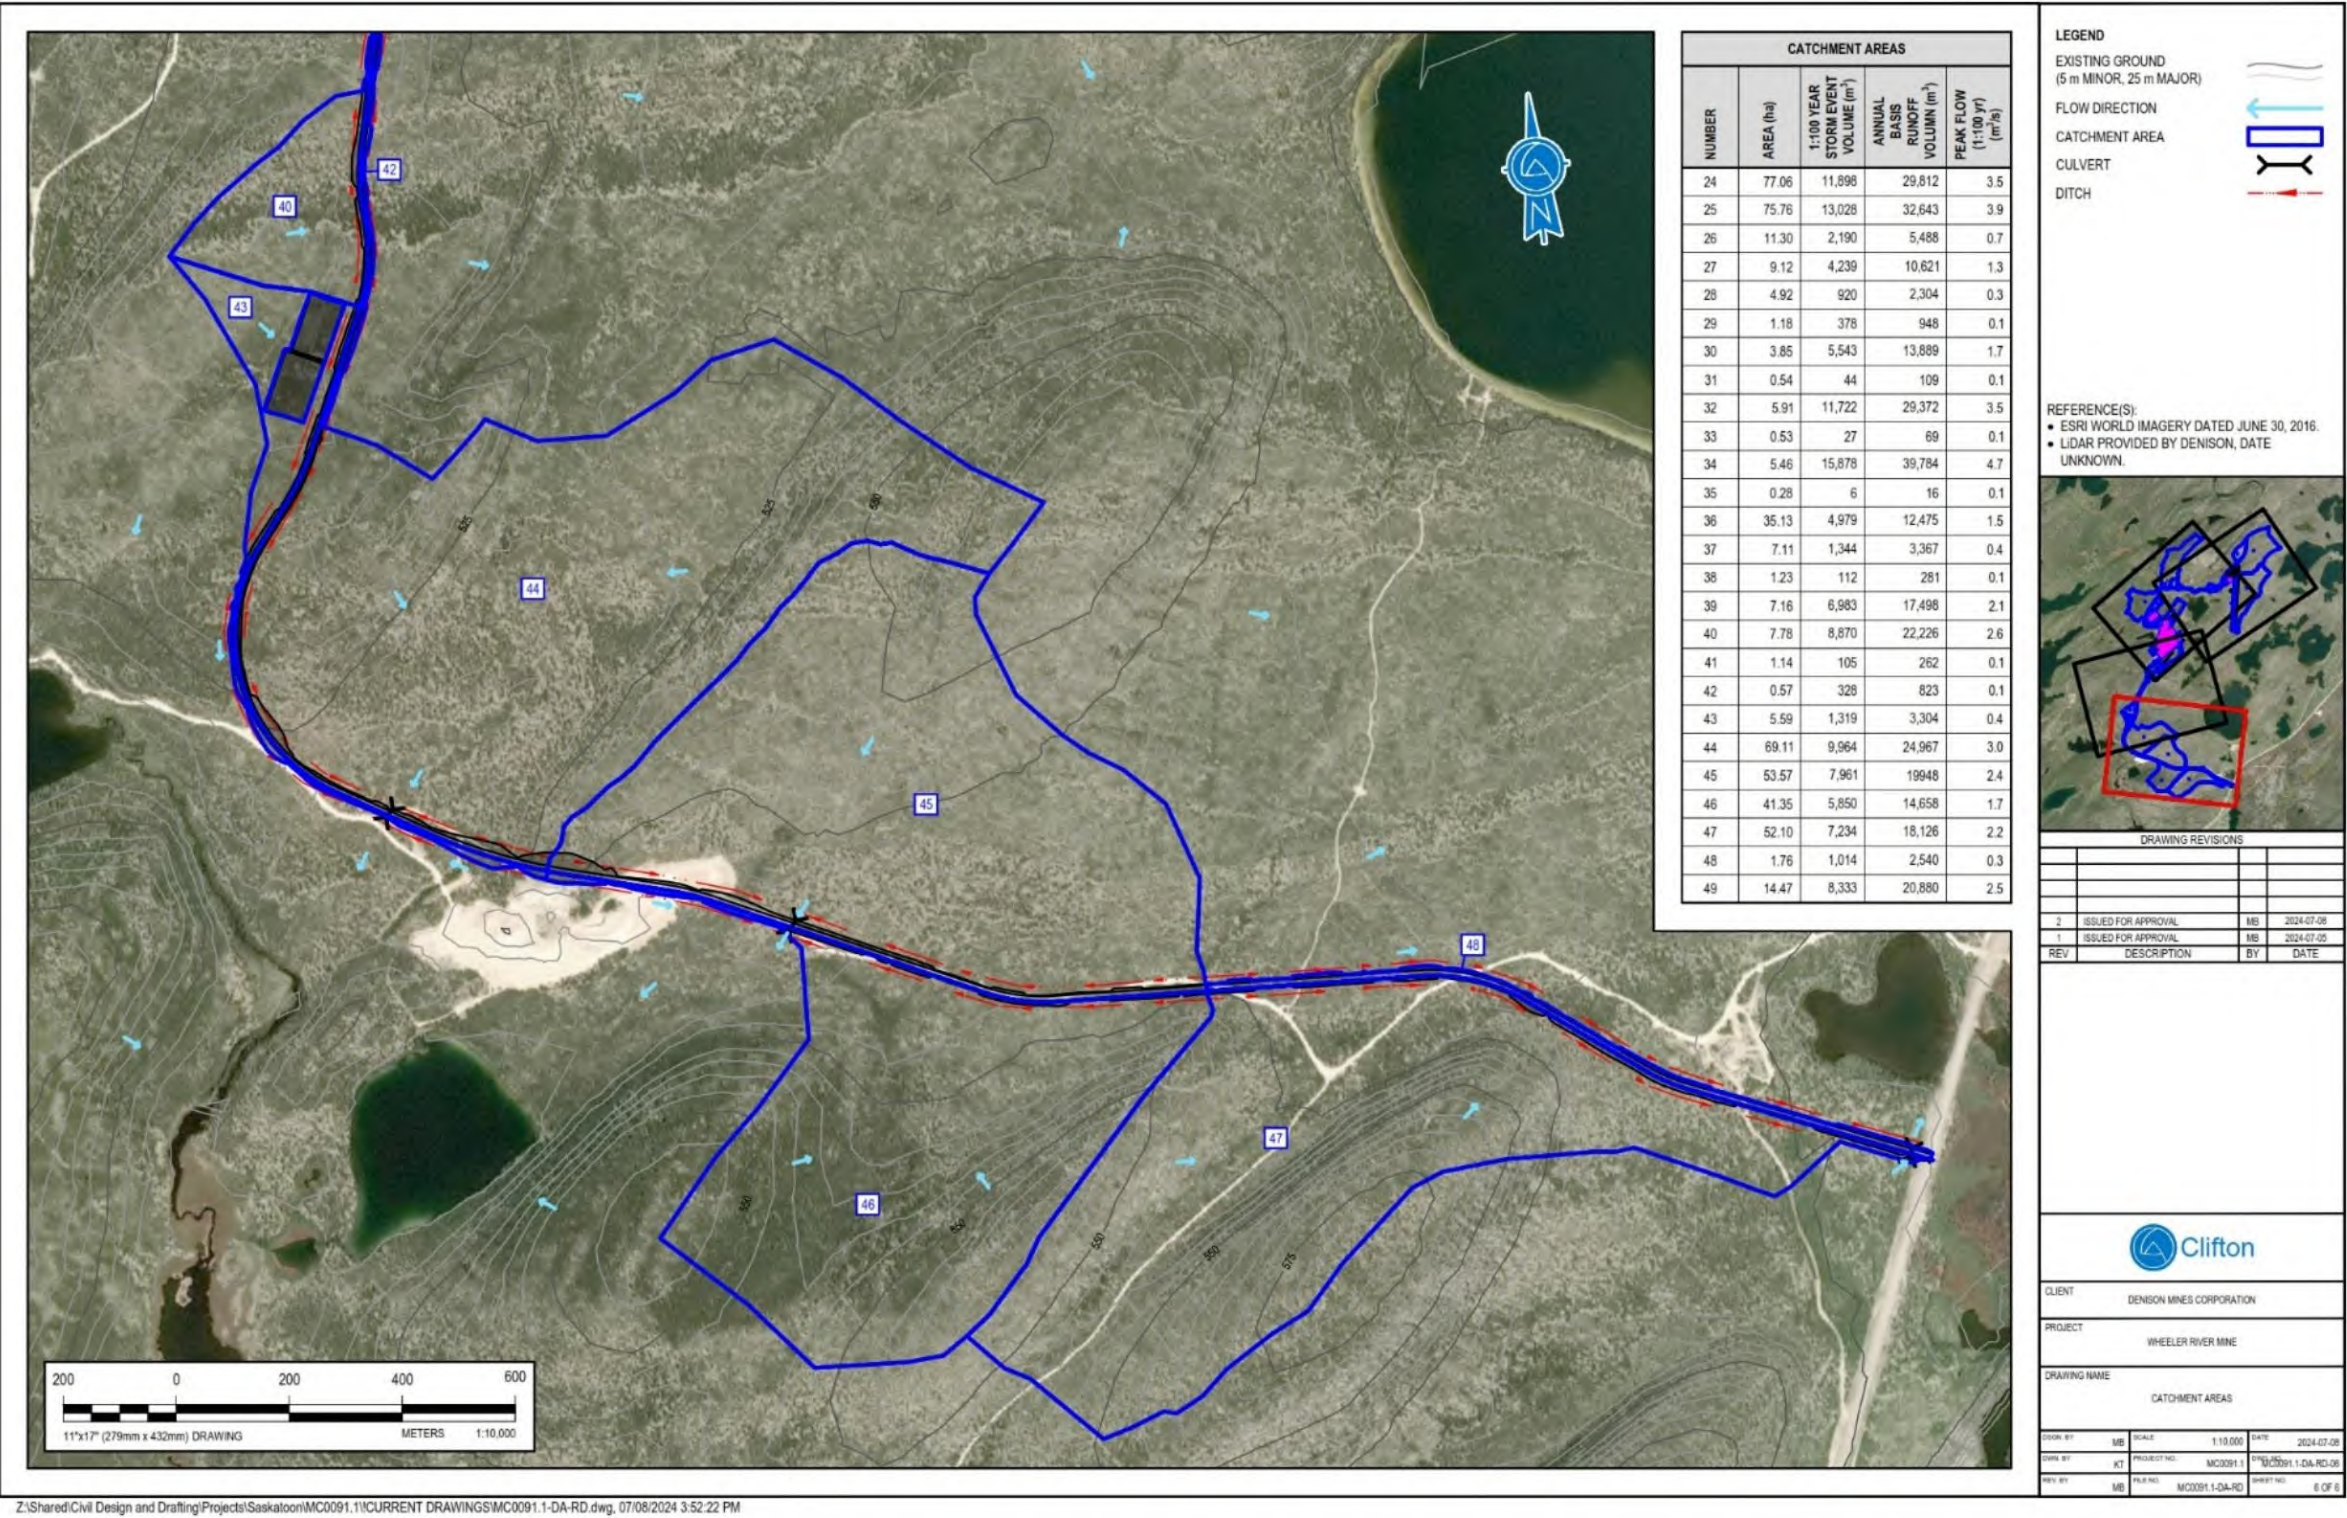

Figure 5: Site water management catchment areas – layout 5 of 5: Access road connection to Highway 914

Screening of Constituents of Potential Concern (COPCs) and Non-contact Water Source Areas

The screening of constituents of potential concern (COPCs) in non-contact water is provided in Table 1 and is organized in terms of catchment characteristics / land use and Project components within or adjacent to the catchments. A screening was not completed here for contact water, as Denison has previously outlined the need to collect and treat this water (refer to Section 2.3.3 of the EIS).

A description of the Project's landscape, key Project components and activities, and management system plans are included here to facilitate the screening exercise.

Setting

The Project is located within the Wheeler Upland Landscape Area of the Athabasca Plain Ecoregion within the Boreal Shield Ecozone of Saskatchewan. The area is characterized by Brunisolic soils which are typically sandy, well-drained soil. Standing water is not a common occurrence.

Ground surface topography regionally has been shaped by glacial and fluvial processes active for over tens of thousands of years. The terrain is characterized by northeast to southwest trending drumlins and eskers, with small variations in elevation (ranging 480 to 590 m above sea level) resulting in a gently sloping terrain. Most of the Project Area consists of upland forest ecosite. Refer to Figure 1-6 in the EIS for a summary of landscape features and current site conditions.

Airstrip

The airstrip will be constructed and maintained using locally-sourced granular material. Denison will be using material from the borrow area (overburden material). Borrow pit area selection was based on geotechnical program completed in 2021 which did not identify any potential for ARD/ML. Further works are ongoing part of engineering activities and with confirmation of characterization through assays of representative samples. As such, the material used to construct and maintain the airstrip will not be a source of metals or ARD.

Design for airstrip will in general be such that runoff will be encouraged through appropriate grading to drain away and not pond on or near the airstrip. The condition of the airstrip will be inspected and maintained routinely. For example, should unexpected water pooling be observed at the airstrip during Operation, temporary water removal means such as vac trucks or sump pumps could be employed, and the areas would be re-graded to minimize water accumulation.

All fueling and de-icing activities will occur in specifically designed areas to collect any hydrocarbons and de-icing fluids. Collected waters will be characterized and brought to the Project site for treatment, shipped offsite to an approved facility or released to environment if water quality allows.

Roads

Mainland access to the site will be from Highway 914. A 7-km section of road will be constructed from the highway to the Project site and a 5-km long road will also be constructed from the Project site to the airstrip; the total road length is 12 km. The road or trail to the airstrip is currently an

unmaintained road: the decommissioned Fox Lake Road. Additional site roads will include, for instance, a service loop to the camp.

Roads will be constructed of locally-source granular subbase and base. For road upgrades and maintenance, Denison will be using material from the borrow area (overburden material). Borrow pit area selection was based on geotechnical program completed in 2021 which did not identify any potential for ARD/ML. Further works are ongoing part of engineering activities and with confirmation of characterization through assays of representative samples. As such, the material used to construct, upgrade, and maintain roads will not be a source of metals or ARD. Design for roads will in general be such that runoff will be encouraged through appropriate grading to drain away and not pond on or near the road. The condition of site roads will be inspected and maintained routinely. For example, should unexpected water pooling be observed during Operation, temporary water removal means such as vac trucks or sump pumps could be employed, and the areas would be re-graded to minimize water accumulation.

In terms of material being transported on the site roads, the final product (yellowcake) will be transported in sealed drums from the processing plant south to the public highway network. With the selection of the in-situ recovery method the Project does not involve transporting large volumes of mine waste rock around the site.

Stream Crossings

Two water crossings (Kratchkowsky Creek and Hart Creek) will be installed along the road from the Project site to the airstrip. Both stream crossings occur along the section of the road which is an existing, unmaintained road (the decommissioning Fox Lake Road). The crossings will be designed, constructed, and maintained to avoid causing harm to fish and fish habitat and will be clear span bridges. Clear span bridges are designed to completely span a watercourse without interfering with the channel bed and banks.

Miscellaneous Project Components

In the SWMP, specific consideration is given to other areas of the Project including the diversion ditches at the main Project area, borrow area, camp, freeze plant and substation based on the delineation of catchments / land uses. Infrastructure in these areas will be constructed using locally-source material from the borrow area and are subject to Project-wide management system and best management practices. Any specifics of relevance to water quality are provided in Table 1.

Management System

We note that accident and malfunctions screening and assessment was completed in Section 14 of the EIS. The SWMP and screening of COPCs contained herein focuses on more routine events within the Project design basis, for example discrete leaks or spills of hydrocarbons from equipment. Events outside of the design basis were appropriately considered in Section 14 of the EIS. For instance, through the hazard identification process (see Appendix 14-A Section 3.0 and Appendix A), the release of fuel (diesel) was carried forward for more detailed analysis.

While details of Denison's management system programs and plans will be developed to support licensing, for context on the SWMP a description of key topics is provided here.

Erosion and Sediment Control (ESC):

Soil erosion is a natural process, but erosion is increased when land is disturbed. Erosion can result in sedimentation. The main concern is erosion caused by precipitation and run off. Erosion control is any measure undertaken to reduce the potential for erosion to occur (SK MHI 2012). Sediment control is any measure implemented to reduce the potential for sediment to be transported and/or deposited beyond the limits of the site (SK MHI 2012). Erosion control will be viewed as a first defense when protecting downstream aquatic habitats, while sediment control will be implemented as a contingency plan. Denison will focus on preventing soil erosion in order to reduce sedimentation and potential effects to the aquatic environment. In selecting the appropriate ESC treatment for areas of the Project, Denison will consider both temporary and permanent measures. Selection of ESC measures are dependent on site slopes, drainage patterns, existing vegetation and other site-specific conditions. Erosion control measures may include preventing or minimizing ground disturbance when working near water, maintaining/retaining as much vegetation as possible, erosion control blankets, and rip rap. Sediment control measures may include wattles and silt fencing.

Spill Response Plan:

Should unplanned events or conditions occur, it will be important for Denison to address and respond in an appropriate manner. Denison will identify and reduce the potential for accidents and emergency situations, and implement emergency response plans that will protect the health and safety of its workers, contractors, the public and the environment. Spill response plans would include procedures for worker and environment protection, details about personnel protection equipment, and procedures to evaluate exposures during a spill.

Radiation Protection Program:

The Radiation Protection Program has been designed, and will be implemented, such that Denison complies with, or exceeds, the level of radiation safety that is required by the applicable regulations and Denison's Environment, Health, Safety and Sustainability Policy. Areas within the Operation are designated according to potential radiological hazards and contamination control requirements. The movement and accumulation of all forms of radioactive contamination will be monitored via dosimetry and area monitoring. Contamination control measures will be in place to minimize the spread of radioactive materials into unintended locations.

Waste Management Program:

The Waste Management Program provides the framework that confirms Denison's licensed activities involving the processing, storage, and disposal of wastes are performed in a manner that complies with applicable regulatory and licence requirements and protects workers, the public, and the environment. The Waste Management Program includes identification of waste inventory and the characteristics of the waste (radiological and hazardous non-radiological). The program also includes waste segregation, waste packaging, and transfer requirements,

and the plan for storage or disposal of wastes. The Waste Management Program outlines the principles of reduction/reuse/recycle/and recovery (4 Rs) applied at the Project.

Personnel and Contractor Training and Performance Management Program:

A Personnel and Contractor Training and Performance Management Program would be developed to ensure all Project related personnel are fully equipped to effectively implement their work functions, in particular consideration of how job function may affect the environment, including worker and public health, within the context of the Environment Management System (EMS). Measurement of performance provides the means to Denison to foster a culture of continuous improvement.

Table 1: Screening of Constituents of Potential Concern (COPCs) in Water Catchments

| Catchment Description | Catchment IDs | Constituent Group | Risk to Aquatic Environment | Management / Mitigation | Summary |
|-----------------------|----------------|-------------------------|---|---|---|
| Airstrip | 24, 25, 27, 28 | Metals (metal leaching) | Metal leaching can occur when certain minerals in rocks containing metals are exposed to air and water. If the material used to construct, and maintain the airstrip contains metals, then there is the potential for metals to leach into runoff, and report to the surrounding environment, where there is the potential for negative effects on the aquatic environment. | <ul style="list-style-type: none">The borrow pit area selected for construction and maintenance of various Project components was based on geotechnical program completed in 2021 which did not identify any potential for ARD/ML. Further works are ongoing part of engineering activities and with confirmation of characterization through assays of representative samples. | At the airstrip, the infrastructure design in combination with management plans (e.g., geochemical characterization of borrow material, spill response plans, ESC) and best management practices result in a determination that runoff in this area is classified as non-contact water . |
| | | Acid Rock Drainage | Acid rock drainage (ARD) is a process where sulfide minerals in rocks react with air and water to produce sulfuric acid, which then leaches metals from the rocks. If the material used to construct and maintain the airstrip results in ARD, the quality of runoff will be impacted and there is the potential for negative effects on the aquatic environment. | <ul style="list-style-type: none">The borrow pit area selected for construction and maintenance of various Project components was based on geotechnical program completed in 2021 which did not identify any potential for ARD/ML. Further works are ongoing part of engineering activities and with confirmation of characterization through assays of representative samples. | |
| | | Nutrients | None expected | n/a | |
| | | Hydrocarbons | A release of hydrocarbons such as diesel, gasoline, or jet fuel to the environment poses a threat to aquatic organisms. | <ul style="list-style-type: none">All fueling and de-icing activities will occur in specifically designed areas to collect any hydrocarbons and de-icing fluids.<ul style="list-style-type: none">Collected waters will be characterized and brought to the project site for treatment, shipped offsite to an approved facility or released to environment if water quality allows.Personnel training.Spill Response Plan will be in place throughout the life of the Project.Appropriate spill response kits will be positioned adjacent to areas where hazardous materials such as hydrocarbons are stored in accordance with the Spill Response Plan.Fuel storage and distribution infrastructure will be constructed in accordance with applicable legislation requirements.Fuels will be stored in approved, above-ground, double-walled storage tank(s) equipped with secondary containment in accordance with provincial regulations and standards. | |
| | | Suspended solids | Erosion and the resulting sedimentation can have a number of impacts on the aquatic environment (WSA 2024): sediments can cover the small spaces between productive rock or gravel habitats; increased levels of sediment in the water can displace aquatic organisms from prime habitat into less suitable areas; cloudy or turbid waters affect visual predators' ability to forage; high levels of suspended sediment in the water can affect fish and other aquatic organisms' ability to breath; and turbid water absorbs more sunlight energy increasing the water temperature, which in turn, does not allow the water to hold as much oxygen. | <ul style="list-style-type: none">Restrict all construction activities to the approved construction footprint.Leave vegetated buffer zones around watercourses and other sensitive features when developing/operating supporting infrastructure.Implement best management practices associated with erosion and sediment control (ESC). | |

| Catchment Description | Catchment IDs | Constituent Group | Risk to Aquatic Environment | Management / Mitigation | Summary |
|-----------------------|---------------|--------------------|--|--|---|
| | | | runoff, and report to the surrounding environment, where there is the potential for negative effects on the aquatic environment. | ongoing part of engineering activities and with confirmation of characterization through assays of representative samples. | spill response plans, ESC) and best management practices result in a determination that runoff in this area is classified as non-contact water . |
| | | Acid Rock Drainage | Acid rock drainage is a process where sulfide minerals in rocks react with air and water to produce sulfuric acid, which then leaches metals from the rocks. If the camp foundations/pads are constructed of sulfide containing material, then there may be potential for ARD to occur, the quality of runoff will be impacted, and there is the potential for negative effects on the aquatic environment. | <ul style="list-style-type: none"> The borrow pit area selected for construction and maintenance of various Project components was based on geotechnical program completed in 2021 which did not identify any potential for ARD/ML. Further works are ongoing part of engineering activities and with confirmation of characterization through assays of representative samples. | |
| | | Nutrients | None expected. | n/a | |
| | | Hydrocarbons | A release of hydrocarbons such as diesel, gasoline, or jet fuel to the environment poses a threat to aquatic organisms. | <ul style="list-style-type: none"> Spill Response Plan will be in place throughout the life of the Project Appropriate spill response kits will be positioned adjacent to areas where hazardous materials such as hydrocarbons are stored in accordance with the Spill Response Plan. A minimum 100 m distance from any waterbody will be maintained for fuel storage, refueling activities, or equipment servicing. Project components including equipment and machinery will be regularly maintained and inspected to make sure they are in good working order. A wash bay will be available to clean items, equipment, and vehicles that may have been in contact with potential contaminants. | |
| | | Suspended solids | Erosion and the resulting sedimentation can have a number of impacts on the aquatic environment (WSA 2024): sediments can cover the small spaces between productive rock or gravel habitats; increased levels of sediment in the water can displace aquatic organisms from prime habitat into less suitable areas; cloudy or turbid waters affect visual predators' ability to forage; high levels of suspended sediment in the water can affect fish and other aquatic organisms' ability to breathe; and turbid water absorbs more sunlight energy increasing the water temperature, which in turn, does not allow the water to hold as much oxygen. | <ul style="list-style-type: none"> Restrict all construction activities to the approved construction footprint. Leave vegetated buffer zones around watercourses and other sensitive features when developing/operating supporting infrastructure. Implement best management practices associated with ESC, with a particular focus on Project components and activities located within 50 to 100 m of a waterbody where required (i.e., at locations where there is no vegetated buffer adjacent to the waterbodies). Refer to Figure 6 below. Traffic control measures. | |
| | | Other Chemicals | Radionuclides are a potential contaminant associated with the Project activities. | <ul style="list-style-type: none"> A wash bay will be available to clean items, equipment, and vehicles that may have been in contact with potential contaminants. Administrative controls will be in place to control radioactive materials and radiological clearance: All objects (equipment, vehicles, etc.) from potentially contaminated work areas that need to be transported off-site as non-radioactive materials must be thoroughly cleaned and checked for contamination prior to release. | |

Notes:

As described earlier in the SWMP, the screening completed in Table 1 is based on routine or normal operating conditions. Accidents and malfunction type risks were assessed separately in Section 14 of the EIS and mitigations associated with accident and malfunction events have been incorporated and described in that analysis in the EIS.

n/a = not applicable

ARD = acid rock drainage

ARD/ML = acid rock drainage/metal leaching

ESC = erosion and sediment control

Figure 6: Distance from Project Footprint to Waterbodies

Delineation of Contact and Non-contact Water Source Areas on the Site

Based on information in the EIS and additional clarifications contained here, contact water is expected at the wellfield, processing plant terrace, the refueling and de-icing area at the airstrip, and leachate collection areas at the landfills. Contact water will be collected in various ponds and eventually routed through the IWWTP for treatment prior to release to Whitefish Lake.

Based on the screening completed in Table 1 using Figures 1 through 5, the non-contact water areas are locations where clean water can be diverted away from Project infrastructure. Through design and implementation of best management practices, the catchment areas described above were determined to contain non-contact water. The runoff from these areas will not be collected and treated.

Estimation of Typical and Event Volumes from Contact and Non-contact Water Source Areas

Refer to Figures 1 to 5 for information on the size of individual catchment areas, the volume of water expected on an annual basis and with a 1:100 year storm event, and the peak flow associated with a 1:100 year storm event.

At the wellfield and processing plant terrace the volume of water expected during a 24-hour PMP of 493 mm is approximately 37,240 m³. The wellfield runoff pond has been sized appropriately (38,200 m³ with 1 m of freeboard) to contain this volume of water.

Water Management Structures

The Stormwater Management Plan associated with non-contact water uses shallow ditching to dissipate the energy of runoff, to promote settling of suspended solids and allow the runoff to report to ground via natural grades that flow away from the infrastructure and into the natural drainage systems. The approximate location of proposed ditches are shown in Figures 1 through 5.

Diversion ditching of non-contact water away from disturbed and developed areas. Diversion ditching is designed to divert as much clean non-contact surface water as reasonably possible away from any disturbed areas, facilities or works where that water may become contaminated, including but not limited to the wellfield, processing plant area, and waste management areas.

Road ditch inverts adjacent to roadways and graveled pads should be lower than the subgrade at the shoulder and ditches will be designed based on specific criteria for slopes (sideslopes, longitudinal slopes), bottom widths, a range of velocities, and a minimum freeboard (refer to Table 2). Ditch design criteria will be refined as the Project advances.

Table 2: Preliminary Ditch Design Criteria

| Ditch Element | Design Criteria |
|----------------------------------|--|
| Conveyance Capacity Requirements | a) 1:100 yr., 24 hr. event for diversion ditches and non-contact water collection ditches b) 24 hr. PMP event critical ditches where upset would be considered a release to environment (i.e., contact water) |
| Manning's Roughness Coefficient | n = 0.030 |

| | |
|------------------------------|--|
| Preferred Ditch Sideslopes | 3H:1V |
| Maximum Ditch Sideslopes | 2H:1V (with depth restrictions and possible sideslope erosion protection determined on case-by-case basis) |
| Minimum Longitudinal Slope | 0.20% |
| Maximum Longitudinal Slope | 2.00% (steeper ditching require engineered channels) |
| Minimum Velocity | 0.3 m/s |
| Maximum Velocity | 0.73 m/s (subject to variance dependent on ditch bottom materials) |
| Preferred Ditch Bottom Width | 1200 mm |
| Minimum Ditch Bottom Width | 600 mm |
| Minimum Ditch Freeboard | 200 mm (below road finished grade shoulder to 1:100 yr 24 hour rain event) |

Armouring such as rip-rap or re-vegetation will be required for erosion prone areas on all road slopes and ditching. Because of the sandy soil conditions of this site, erosion control will be an important consideration in design for all ditching and grading features due to high erodibility of the soils. Ditches require armouring for a minimum horizontal distance of 3 metres around culvert inlets, or as determined by hydraulic modeling. The general rule for protecting the downstream of a culvert is that armouring of three (3) pipe diameters should be used for each 1 m/s of velocity reduction required.

Monitoring and Compliance

Site water management plan monitoring will be conducted, primarily to confirm the best management practices related to ESC are functioning as intended. Routine inspections and management would be completed to document the effectiveness of the ESC measures, and any maintenance or replacement of ESC structures would be completed as required.

The EIS Section 2.9 Management System outlines the framework to support EIS review. The Project's detailed management programs and plans will be developed to support licensing and permitting. Of relevance to this Plan, the following is noted:

- The Spill Response Plan will outline how Denison will appropriately respond to and clean-up any unexpected spills. Spill reporting to Saskatchewan Ministry of Environment, ECCC, and the public will be required depending on the nature of the spill.
- The Effluent and Emissions Monitoring Plan includes sampling plans for stormwater during construction.
- The Construction Management Plan incorporates environmental considerations. Construction activities with higher potential risk of ESC problems include excavation and borrow areas, clearing and grubbing, ditch construction, and earthwork near/across streams and lakes
- Environment inspections will be conducted at various project areas on a frequency specified in future licences and permits. This may include for instance daily and weekly

inspections of fuel storage tanks, ponds, pads, lines, etc. to ensure compliance with operational conditions, best management practices and other requirements. Inspection (and sampling) plans for non-contact water mitigation measures such as silt fencing will coincide with precipitation events and spring runoff.

Various aspects of Project monitoring will not only be included in Denison's management system documentation but also included as conditions in permits, authorizations, and licences. The Provincial laws governing development in, or near, water are set out in *The Environmental Management and Protection Act, 2010* and *The Environmental Management and Protection (General) Regulations*. Denison will apply to the Saskatchewan Water Security Agency for an Aquatic Habitat Protection Work for any work near water and will adhere to the conditions of the permit. Fish and fish habitat are protected by provisions of the *Fisheries Act*. The Project will be constructed, operated and decommissioned in a manner compliant with Section 36 of the *Fisheries Act*. The Ministry of Environment enforces provincial legislation in collaboration with federal regulators.

Education and Training

Denison will provide education and training to staff and contractors about the importance of non-contact water management and best practices associated with erosion and sediment control. This helps ensure that everyone involved in the safe Construction, Operation and Decommissioning of the Project understands their role in protecting the aquatic environment.

In Closing

Denison views the EIS as an important planning tool that will be used to support future activities and represents one stage in the rigorous overall approvals process for a uranium mining facility in Canada. Denison is completing a sequential EA and licensing process for the Project. In the EIS, a framework for the EMS is provided along with a clear commitment for Denison to include Project design and water management-related mitigation measures into the EMS documents as they are developed / as the Project proceeds through the licensing and permitting phases. We trust that the FIRT has been provided with the appropriate level of detail on the water management topic for drawing conclusions on the EA process, and the summary contained in this SWMP will facilitate ECCC's review.

Part 2 – Response to Specific Questions Raised in IRs 12, 12-R1A and 12-R1B

The table below highlights questions raised in IRs 12, 12-R1A and 12-R1B that weren't necessary fully described by the updated site water management plan (see Part 1).

| Question from the IR | Denison Response |
|--|---|
| From FIRT's Information Request Rationale (2023-12-05): CNSC requests that Denison use a PMP value that is estimated using historical rainfall data that includes the most up to date meteorological data or provide justification on the validity of the current PMP. | Denison understands that validation of the current PMP will be assessed as part of CNSC licensing. |
| From Denison submission of responses to IRs (2023-08-18): Details related to culvert design and conveyance capacity are being developed as part of ongoing engineering activities. Culverts will be a designed with a sufficient size and length to convey water around the site during a PMP event. | Project design is bound by the EIS. Culverts within contact water areas are being designed to convey water associated with a PMP event. |
| The Proponent should include updated information on water treatment, flows, capacity and effluent discharge during normal operations, and a 24-hr Probable Maximum Precipitation (PMP) Event. | Non-contact water is not collected and routed through the industrial wastewater treatment plant (IWWTP). The wellfield runoff pond has been designed to accommodate the PMP. Influent to the IWWTP would be metered into the plant, per the treatment design rates and there would be no changes in effluent release rates beyond the assessed rates and plant design criteria. |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3; June 26, 2024) |
|--------------|----------------|--|---|--|--|--|--|--|
| IR-18 | - | <p>Context: In Table 2.2-1 the upper bound Industrial Wastewater Treatment Plant (IWWTP) effluent quality final discharge targets for Constituents of Potential Concern (COPCs) are provided. General parameters (e.g., temperature, pH, etc.), and several Schedule 4 Substances with maximum authorized concentrations (lead, nickel, suspended solids, and un-ionized ammonia) under the Metal and Diamond Mining Effluent Regulations (MDMER) have not been provided in this table. There are several COPCs (aluminum, mercury, iron, nitrate, thallium, phosphorus and manganese) for effluent characterization under Schedule 5 Section 4 of the MDMER that have not been provided in this table. Additionally, no information on water quality guidelines has been provided in this table.</p> <p>Furthermore, it is stated that the final effluent quality discharge target for uranium is 0.057 mg/L. However, the Canadian Council of Ministers of the Environment (CCME) water short term (acute) water quality guidelines for the protection of aquatic life is 0.033 mg/L. The proposed effluent discharge target for uranium exceeds the acute water quality guidelines, indicating effluent may pose the risk of being acutely lethal to aquatic biota at end-of-pipe.</p> <p>Rationale: ECCC requests the Proponent include the general water quality parameters that influence water quality thresholds, parameters in Schedule 4 and Schedule 5 Section 4 of the MDMER, and their respective water quality guidelines for consideration and transparency.</p> <p>Discharges from the proposed Project will alter water quality in the immediate receiving area, and this may include some sublethal effects on aquatic biota, which must be minimized. It remains the Proponent's responsibility to adhere to the MDMER to ensure that effluent at the end-of-pipe from all final discharge points be non- acutely lethal and meet requirements for prescribed deleterious substances under Schedule 4 of the regulations.</p> | <p>1. Update Table 2.2-1 and Appendix 8-E to include all general parameters required for environmental effects monitoring: pH, temperature, hardness, alkalinity, and conductivity.</p> <p>2. Update Table 2.2-1 and Appendix 8-E to include missing Schedule 4 Substances under the MDMER with maximum authorized concentrations: lead, nickel, suspended solids, and un-ionized ammonia.</p> <p>3. Update Table 2.2-1 and Appendix 8-E to include missing Schedule 5 Section 4 parameters required for effluent characterization under the MDMER: aluminum, mercury, iron, nitrate, thallium, phosphorus and manganese.</p> <p>4. Include all acute and chronic water quality thresholds for each parameter in Table 2.2-1 and Appendix 8-E.</p> <p>5. Describe additional mitigation measures that can be considered to minimize impacts to aquatic biota from uranium concentrations in effluent.</p> | <p>Denison fully understands its obligations with respect to the MDMER and will comply with the MDMER end of pipe effluent discharge criteria and other requirements of the regulations. The lack of the MDMER general parameters and Schedule 4 substances in the draft EIS table 2.2-1 should not be misconstrued to mean Denison was not intending to meet these requirements. Rather these tables were developed based on rigorous screening to identify COPCs and then model these in the receiving environment. Table 2.2-1 in the draft EIS is not reflective of the proposed monitoring parameters during effluent release. Regardless, Denison will update the table; please see the response below.</p> <p>1) Please see attachment IR-18 for updated Table 2.2-1 which is consistent with the updated Table 8.2-10 (as updated for IR-114). Parameters specific to Schedule 4 have been assessed and predicted. Schedule 5 parameters are included where available. As Schedule 5 parameters do no have screening criteria, they will be monitored by Denison consistent with the MDMER upon falling under this regulation.</p> <p>2) Please see attachment IR-18 for updated Table 2.2-1 which is consistent with the updated Table 8.2-10 (as updated for IR-114). Parameters specific to Schedule 4 have been assessed and predicted.</p> <p>3) Please see attachment IR-18 for updated Table 2.2-1 which is consistent with the updated Table 8.2-10 (as updated for IR-114). Parameters specific to Schedule 4 have been assessed and predicted. Schedule 5 parameters are included where available. As Schedule 5 parameters do no have screening criteria, they will be monitored by Denison consistent with the MDMER upon falling under this regulation.</p> <p>4) Please see attachment IR-18 for updated Table 2.2-1 which is consistent with the updated Table 8.2-10 (as updated for IR-114). Applicable screening criteria have been updated to identify most applicable acute or chronic thresholds for the protection of aquatic life.</p> <p>5) As noted in response to IR-16 and IR-17 effluent discharge criteria as depicted in the draft EIS provide a bounding scenario of the basis of the assessment of Project effects and final effluent quality will meet prescribe limits developed through licensing and permitting, as informed by the BATEA evaluation process. In that context, it is expected that the uranium concentration in effluent would be lower then assumed for the purpose of the evaluation in the draft EIS and it is understood that uranium concentrations (or concentrations of other constituents) that resulted in acute toxicity would be not be permitted. Accordingly, the need for and types of mitigation measures as might be needed for uranium (or other constituents) would be developed as part of the process of developing final effluent quality limits in the permitting and licensing processes.</p> | <p>This response has not been accepted.</p> <p>ECCC requested that the Proponent update Table 2.2-1 and Appendix 8-E to include all general water quality parameters required for environmental effects monitoring, including pH, temperature, hardness, alkalinity and conductivity. This information was not provided in the updated table in the Proponent's response. ECCC also requested that the Proponent Update Table 2.2-1 and Appendix 8-E to include missing Schedule 5 Section 4 parameters required for effluent characterization under the Metal and Diamond Mining Effluent Regulations (MDMER) including aluminum, iron, nitrate, thallium and manganese. The Proponent has not provided the requested information for aluminum, iron, nitrate, thallium and manganese. In the Proponent's response it is stated that, "Schedule 5 parameters are included where available." However, it is unclear if this means that the requested effluent characterization concentrations for these parameters is currently unknown, or if these parameters are expected to have negligible concentrations in the effluent. Furthermore, ECCC requested that the Proponent include all acute and chronic water quality thresholds under the most stringent of the MDMER, CCME, and/or Provincial Guidelines for each parameter in Table 2.2-1 and Appendix 8-E. This information has not been provided as only chronic toxicity guidelines have been provided.</p> <p>The Proponent is legally required to meet MDMER release targets and intends to continue to refine effluent quality predictions as part of the BATEA assessment and licensing phase of the Project. ECCC must advise the CNSC of predicted effects of COPCs to surface water quality and recognize the Proponent's legal requirement to comply with the MDMER. Therefore, proposed and draft effluent targets must be reviewed against the requirements of the regulations and with an eye to any potential effects to the receiving environment for both regulated and other effluent parameters. It is necessary for ECCC to review effluent targets for general water quality parameters and MDMER Schedule 5 Section 4 parameters required for effluent characterization and environmental effects monitoring to determine if effluent at the end-of-pipe from all final discharge points is not predicted to be acutely lethal. Additionally, the predicted uranium effluent concentration currently exceeds the acute water quality guidelines for the protection of aquatic life. Table 2.2-1 does not currently provide the information necessary to verify acute and chronic thresholds.</p> <p>Therefore, please see the following reiterated requests:</p> <p>1. Update Table 2.2-1 and Appendix 8-E to include all general parameters required for environmental effects monitoring: pH, temperature, hardness, alkalinity, and conductivity.</p> <p>2. Update Table 2.2-1 and Appendix 8-E to include the following missing Schedule 5 Section 4 parameters required for effluent characterization: aluminum, iron, nitrate, thallium, and manganese. Provide further explanation if this information is not available.</p> <p>3. Include all acute and chronic water quality thresholds for each parameter in Table 2.2-1 and Appendix 8-E. Include information on the concentrations of modifying environmental factors (i.e. pH, hardness, etc.) used to calculate these guidelines as footnotes.</p> <p>4. Provide a clear commitment to ECCC for continued consultation on developing effluent discharge targets including a review of final predicted effluent discharge targets once available.</p> | <p>The effluent modelling work presented in the draft EIS focused on COPCs which were predicted based on expected Project activities and water treatment processes and selected following CSA N288.6 Environmental Risk Assessments At Class I Nuclear Facilities And Uranium Mines And Mills. The CNSC participates in CSA documents and endorses use of this document.</p> <p>Schedule 5 of the MDMER outlines the various requirements of Environmental Effects Monitoring (EEM) Studies once a mine is subject to the regulation. The MDMER requires EEM as a condition for the authorization to deposit effluent into waters frequented by fish. Environmental effects monitoring involves assessing whether effluents are having an effect on receiver water quality, fish, fish habitat, and use of fish by humans. Schedule 5 of the MDMER is not a predictive section of the regulation to be used to direct EA scope. It is applicable to operational metal mines.</p> <p>Many MDMER parameters including those in Schedule 5, Section 4 identified by ECCC were not selected for analysis during lab studies completed by Denison to support the EIS, since they were not COPCs associated with IWWTP design. Information from laboratory tests is not available at this stage for all of the MDMER parameters. Further, MDMER Schedule 5 Section 4 include a list of parameters to be monitored (not modelled) and many of the 'missing' parameters have no associated limits under MDMER. Denison is committed to meet all requirements of MDMER, which includes future EEM programs.</p> <p>With respect to the bullet items in the IR the following is noted.</p> <p>1. Table 2.2-1 and Appendix 8-E have been updated to include all general water quality parameters required for environmental effects monitoring, including pH, temperature, hardness, alkalinity and conductivity.</p> <p>2. Table 2.2-1 and Appendix 8-E have been updated to include the following missing Schedule 5 Section 4 parameters required for effluent characterization: aluminum, iron, nitrate, thallium, and manganese.</p> <p>3. Updates to Table 2.2-1 and Appendix 8-E Include all acute and chronic water quality thresholds for each parameter as well as information on the concentrations of modifying environmental factors (i.e. pH, hardness, etc.) used to calculate these guidelines as footnotes.</p> <p>4. Denison is committed to meet the requirements of the MDMER as previously stated. Denison is also committed to working through the process of identifying discharge criteria as stipulated under Provincial legislation for mine effluent discharge as part of the application for an approval to operate a pollutant control facility as well as per the requirements and conditions of the CNSC, the licensing body for the Project. Denison will follow the advice of the CNSC with regard to requirements for further consultation with ECCC.</p> | <p>In response to the FIRT's previous review, Denison provided responses to the following outstanding requests from ECCC:</p> <ol style="list-style-type: none">1. Update Table 2.2-1 and Appendix 8-E to include all general parameters required for environmental effects monitoring: pH, temperature, hardness, alkalinity, and conductivity.2. Update Table 2.2-1 and Appendix 8-E to include the following missing Schedule 5 Section 4 parameters required for effluent characterization: aluminum, iron, nitrate, thallium, and manganese. Provide further explanation if this information is not available.3. Include all acute and chronic water quality thresholds for each parameter in Table 2.2-1 and Appendix 8-E. Include information on the concentrations of modifying environmental factors (i.e. pH, hardness, etc.) used to calculate these guidelines as footnotes.4. Provide a clear commitment to ECCC for continued consultation on developing effluent discharge targets including a review of final predicted effluent discharge targets once available. <p>The Proponent has resolved item two of the above, but items one, three, and four require additional follow up.</p> <p>For item one, the requested parameters (pH, temperature, hardness, alkalinity and conductivity) were added to Table 2.2-1 in the revised draft EIS and the tables in Appendix 8-E. However, the predicted conductivity presented would not be possible given the TDS reported in Table 2.2-1, and this inconsistency has been found throughout Section 8 and its appendices. Conductivity in µS/cm is typically 1.25-2 times TDS in mg/L, whereas the value in the table is 0.0034 times the TDS concentration. This item is not resolved, but can be carried over to licensing. The Proponent will be expected to correct the proposed effluent conductivity added to Table 2.2-1 and in Appendix 8-E.</p> <p>Follow up for item three is addressed in IR-108, IR-114 and IR-115.</p> <p>To address item four, the Proponent will have to follow the guidance and requirements in REGDOC-2.9.2 to develop effluent discharge targets. The CNSC will engage with ECCC during this process as necessary.</p> | <p>As stated, Denison has resolved item two of the above and items one, three, and four are addressed below with follow up commitments.</p> <ol style="list-style-type: none">1. As discussed during the June 14, 2024 meeting with ECCC, the information provided for conductivity and TDS in the EIS was consistent with what was available from effluent bench tests. Denison agrees to update the analysis and predictions incorporating pre construction water quality data available (including conductivity and TDS) during the operational licencing process, but there is no expectation there will be any change to the EIS conclusions.3. Follow up for item three is addressed in IR-108, IR-114 and IR-1154. Denison commits to following the guidance and requirements in REGDOC-2.9.2 to develop effluent discharge targets as part of operational licensing and in consultation with the CNSC. |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 28, 2024) |
|--------------|----------------|---|--|---|---|---|--|--|
| IR-89 | - | <p>Context: The Proponent states that a hydraulic conductivity value of 5x10-6 m/s was uniformly assigned to the model layers representing the Desilicified Zone. They additionally state that this value is consistent with packer and pumping tests screened in this unit that have interpreted hydraulic conductivity values ranging from 1x10-6 to 3x10-5 m/s (Appendix C), with a geomean of 6.0x10-6 m/s.</p> <p>Considering that the Desilicified Zone is of particular interest because it is the main pathway for the COPC to reach Whitefish lake, and that hydraulic conductivities are not entirely understood, ECCC recommends that a larger range of hydraulic conductivities be simulated to understand potential effects on fish and fish habitat.</p> <p>Rationale: The Desilicified Zone is a critical layer in the hydrogeological model as it represents a key potential pathway of contaminants to Whitefish Lake. The base case hydraulic conductivity value (5x10-6 m/s) is even lower than the geometric mean, not to mention the highest value found. When simulating geochemical processes and contaminant transport within this important pathway a more conservative approach should be employed. Modifying this parameter will affect travel times and distribution of COPC in the subsurface.</p> | <p>1. Provide an in-depth rationale for choosing a value of 5x10-6 m/s as the base case for the hydraulic conductivity, in both the PHREDOX EQUilibrium (PHREEQC) and Finite-Element Ground Water Flow (FEFLOW) models.</p> <p>2. Provide a rationale for keeping the sensitivity analysis within one order of magnitude considering the lack of physical data on the Desilicified Zone. Alternatively, provide contaminant transport simulation results with more conservative hydraulic conductivity (e.g., more than 3x10-5 m/s) values in the Desilicified Zone.</p> <p>See also related: IR-96.</p> | <p>1) Application of 5E-6 as the value for hydraulic conductivity within the desilicified zone is appropriate; the values of 5E-6 and 6E-6 are essentially the same number, particularly at the scale over which it is applied. We agree that the hydraulic conductivity of the desilicified zone is an important parameter to the fate and transport of dissolved minerals from the ore zone toward Whitefish Lake; that is why scenarios 4, 5, and 6 were designed to evaluate the prediction uncertainty related to the uncertainty of the desilicified zone, along with other hydraulic conductivity values along the transport migration pathway. Further, we recognize that packer tests provide a small-scale sample indication of the representative hydraulic conductivity, and as shown in the literature (Bradbury and Muldoon, 2000), such local tests are rarely representative of large-scale (i.e., macro) hydraulic conductivities. Macro-scale hydraulic conductivities are best determined using a large-scale pumping test or a model calibrated to observed water levels, which is the approach we completed; the value of 5E-6 for the desilicified zone hydraulic conductivity provides an excellent match to observed water levels and baseflow discharge. In addition, packer tests in fractured rock tend to bias the hydraulic conductivity to be higher than is representative on the large scale, as testing is generally targeted on observed fracture zones. Given all this, we reaffirm that the applied hydraulic conductivity of 5E-6 is representative for the conductivity of the desilicified zone.</p> <p>2) Calibration-constrained uncertainty analyses were performed (i.e., the state of the practice) to evaluate the range of potential hydraulic conductivity values that could exist within the desilicified zone while still maintaining calibration. That analysis is presented in section 2.8 of Appendix 7-C. The most conservative of the parameter scenarios that are consistent with the field observational data were used for the prediction uncertainty analyses presented in Appendix 7-C, section 4.7. Scenarios 4, 5, and 6 explore higher hydraulic conductivity values which are supported by the observation data (i.e., calibration-constrained uncertainty analysis). The range of desilicified-zone hydraulic conductivity incorporated within those scenarios (Figure 2-21) is 1.6 to 3.2 m/d (i.e., 1.8E-5 to 3.7E-5 m/s); 3.2 m/d was the highest conductivity value for the desilicified zone (referred to as the Altered Zone within the Intermediate Aquitard on Figure 2-21) for all 50 calibrated realizations generated using PEST. As such, the EIS presented the prediction uncertainty with the highest hydraulic conductivity values supported by the observation data. It would not be appropriate to test scenarios with even higher values of hydraulic conductivity which would not be supported by the field observed groundwater levels. Thus, we do not feel it is appropriate to test scenarios where the hydraulic conductivity of the desilicified zone is orders of magnitude greater than suggested by field observations.</p> <p>References: Bradbury K. R., and M.A. Muldoon. 1990. "Hydraulic Conductivity Determinations in Unlithified Glacial and Fluvial Materials." Groundwater and Vadose Zone Monitoring. ASTM STP 1053. D.M. Nielsen and A. I. Johnson Editors., American Society for Testing and Materials. Philadelphia, 1990. pp. 138-151.</p> | <p>This response has not been accepted.</p> <p>The Proponent used calibration-constrained uncertainty analysis to establish boundaries when conducting sensitivity analysis of hydraulic conductivity in the groundwater model.</p> <p>For sensitivity analysis to adequately manage uncertainty, parameter values that are outside of those determined by calibration-constrained uncertainty analysis should be used. There always exists some degree of uncertainty in using hydrogeologic data as a complete representation of a regional groundwater system. This uncertainty can be accounted for by broadening parameter ranges in a sensitivity analysis. Limiting sensitivity analysis to calibration-constrained values implies that available field data is a perfect and complete representation of the broader groundwater system, which may not be an accurate assumption.</p> <p>Considering the limitations of available physical data in the Desilicified Zone, a more conservative sensitivity analysis is required in order to adequately assess how contaminants may flow towards Whitefish Lake.</p> <p>Please also see follow-IR-89-R1, and AD-66 in the Advice to Proponent table.</p> | <p>In our SME’s experience, traditional “sensitivity analysis” where individual parameters are arbitrarily varied by within a subjective range can produce simulations which are inconsistent with the field-observed data. Such simulations should not be part of an EIS, as they can provide misleading results.</p> <p>Calibration-constrained uncertainty approach does not assume the data or the representation of the system are perfect or complete. Calibration-constrained models do not require a perfect fit to all the observed data, which is a recognition that there is measurement noise and structural noise present in every model. In addition, potential error in that data was accounted for by rounding the observed water levels to the nearest 0.1m (i.e., the data were not considered “perfect”) and allowing a general fit to all data (i.e., residuals are present at each observation point). Further, the analysis does not consider the data provide a “complete representation of the broader groundwater system” nor does it imply the data provides a “perfect and complete representation of the broader groundwater system”. Instead, the calibration-constrained approach tests sets of parameters within a broad range, wherein only parameters which are well informed by available observation data are constrained, while parameters not constrained by calibration data are allowed to vary more freely (i.e., to the degree that they do not otherwise impact the well-informed parameters).</p> <p>For the uncertainty assessment presented in the draft EIS, hydraulic conductivity parameters along the flow path between the ore zone and Whitefish Lake were allowed to vary within a 4-order of magnitude range (i.e., 1x10⁻⁸ to 1x10⁻⁴ m/s) to find alternative parameter sets that achieve a reasonable match to observation data. With this approach, values are not varied independently, but rather parameter combinations are sought that explore the potential 4-order of magnitude range for parameters, while maintaining a match to field-observed conditions.</p> <p>The most conservative of the calibrated scenarios obtained through the calibration-constrained approach presented within the EIS (i.e., those which achieved acceptable calibration statistics) were chosen for additional transport simulations. The scenarios tested hydraulic conductivity values for the desilicified zone as high as 3.7x10⁻⁵ m/s (realization 7 – predictive uncertainty case 5), which is two times higher than any measured value within this hydrogeologic unit, and 7.4 times higher than the base case calibration. Hydraulic conductivity values as high as 8.1x10⁻⁵ m/s were also tested within portions of the lower sandstone aquifer. In addition, the simulation documented as part of IR-55 presents a model wherein the hydraulic conductivity of the desilicified zone is 1x10⁻⁴ m/s, which is 20 times higher than the base case.</p> <p>In summary, we reaffirm that we have already provided an ample demonstration of the potential range of outcomes which are supported by the observation data at the site.</p> | <p>The Proponent has not adequately responded to the IR and has indicated in their response that they do not agree with ECCC’s previous advice relating to the sufficiency of the conservative sensitivity analysis. The Desilicified Zone is a critical layer in the hydrogeological model because it represents a key potential pathway of contaminants to Whitefish Lake. However, ECCC advises that the Proponent has not adequately considered conservative scenarios in its sensitivity analysis.</p> <p>In their response, the Proponent states that “<i>The scenarios tested hydraulic conductivity values for the desilicified zone as high as 3.7x10-5 m/s (realization 7 – predictive uncertainty case 5), which is two times higher than any measured value within this hydrogeologic unit,...</i>” This is inconsistent with the values presented in the Revised Draft Environmental Impact Statement Section 7 – Geology and Groundwater, where the maximum field values are presented as 3.0x10-5 m/s. The approach presented does not demonstrate a conservative scenario for evaluating the extent of potential travel times to Whitefish Lake.</p> <p>The Proponent should test a K value in the desilicified zone with a value at least an order of magnitude higher than the highest field K values in order to provide a conservative scenario for potential travel times to Whitefish Lake.</p> <p>The Revised Draft Environmental Impact Statement, Section 7, has a revised geometric mean for hydraulic conductivities in the desilicified zone where the value was changed from 6.0 x10⁻⁶ m/s to 4.8x10⁻⁶ m/s with no explanation regarding how this new value was obtained. The Proponent should clarify why this change was made, and provide any supporting evidence.</p> | <p>The Information Request is to evaluate potential travel times to Whitefish Lake (i.e., prediction uncertainty), whereas during the meeting June 6th, 2024, the reviewer phrased the request as a sensitivity analysis. The two terms have an important distinction. We submit that a prediction uncertainty analysis is the most relevant for the EIS, and that is why it has been the focus of our IR responses and the EIS documentation (i.e., Appendix 7C - Sections 2.7 and 4.6).</p> <p>A sensitivity analysis is not considered as valuable as a prediction uncertainty analysis. A sensitivity analysis measures the change in primary model output (i.e., hydraulic head for a groundwater flow model) due to a change in an input parameter (e.g., the hydraulic conductivity value applied for the Desilicified Zone). While a sensitivity analysis is part of model calibration and prediction uncertainty analysis, it is not considered a valuable stand-alone deliverable.</p> <p>It should be noted that parameter sensitivity (i.e., change in hydraulic head at monitoring point locations due to an incremental change in parameter values) is implicitly completed as part of all PEST simulations and stored in the Jacobian matrix, which is used to guide parameter estimation and objective function optimization (i.e., the sum of squared residuals). As such, parameter sensitivities were explored within the Denison modelling assessment.</p> <p>However, as parameter sensitivity values change depending on the location in solution space (i.e., how close you are to the objective function minimum), an individual snapshot of parameter sensitivity is of limited value, as it does not directly inform the EIS questions (i.e., the potential mass transport from the proposed mining development). This is why we believe that parameter sensitivity analysis is not as relevant to the EIS as the parameter uncertainty analysis presented.</p> <p>As stated in previous responses, as the range of parameter uncertainty evaluated is already beyond the range of data measured by a factor of 7 and did not produce significantly different peak concentrations at Whitefish Lake, it is our interpretation that extending this to a factor of 10 would not result in higher peak concentrations reaching this receptor.</p> <p>As such, we (Denison’s SME for the hydrogeological assessment) feel the prediction uncertainty analysis presented as part of the EIS reporting is already comprehensive and the requested additional analysis would not change the EA determination.</p> <p>It is acknowledged that there were some typographical errors in the reporting of K values for the Desilicified Zone in the Updated Draft EIS that will be corrected in the Final EIS. Further, rationale for the update to the geomean K value for the Desilicified Zone has been provided in an updated version of the Attachment IR-89-R1 (Round 3 response) at the end of this file.</p> <p>Denison also notes that the predicted changes to the regional groundwater do not begin until the remediation of the mining zone is complete and post decommissioning. It is expected that additional hydrogeological modeling for decommissioning will be required at the end of the operational phase with updated (relevant) data to support a final remediation criterion. This process will require approval by the CNSC and the Saskatchewan Ministry of Environment through the licensing and permitting processes.</p> <p>Changes to the Final EIS to correct the typographical errors are in:</p> <p>Final EIS: Table 7.3-2.</p> <p>Appendix 7-A: Table 3-4, Section 3.4.4, Section 4.3.3, and Table 5-2.</p> <p>Appendix 7-C; Section 2.3.1.5.</p> |

ATTACHMENT IR-89-R1 (from Round 2 response)

Introduction

Simulations of conditions that extend beyond the range of conditions supported by the monitoring data (i.e., calibration-constrained conditions) is inappropriate for an EIS as it suggests that unrepresentative, potentially misleading scenarios should be tested, documented, and presented as potential outcomes. In the SME's view this would confuse the groundwater transport and associated risk discussions.

While we do not support development of un-calibrated scenarios for inclusion within the EIS, additional scenarios that did not violate field observation data were evaluated as part of this response. These scenarios further demonstrate the robust nature of the hydrogeologic setting, which has been shown to have a high assimilative capacity.

Additional groundwater flow and geochemical reactive transport modelling scenarios were performed in response to:

1. IR-55, wherein the hydraulic conductivity of the Intermediate Sandstone Aquitard was increased to a maximum value of $1.0\text{E-}7$ m/s, and other parameter values, including the hydraulic conductivity of the Desilicified Zone, were increased to maintain a calibrated condition.
2. IR-70, wherein a higher hydraulic conductivity within the Ore Zone post-decommissioning was tested. This is an uncertain parameter which is unconstrained by calibration data.
3. IR-71, wherein uncertainty in future groundwater recharge rates were evaluated by varying rates by +/- 20%. Future groundwater recharge is an uncertain parameter which is unconstrained by calibration data.
4. IRs 78 & 88, wherein the effective porosity of the Paleoweathered zone was reduced by an order of magnitude to allow the initial source mass to migrate toward receptors 10-times faster. Effective porosity of the Paleoweathered zone is an uncertain parameter which is unconstrained by calibration data.
5. IR-96, wherein the transverse dispersivity was reduced to 1m to be consistent with ratios of longitudinal-to-transverse dispersivity published in the literature (e.g., Gelhar et al.; 1992) based on anisotropic settings. Transverse dispersivity is an uncertain parameter which is unconstrained by calibration data.

Post-Decommissioning Scenarios: Simulation Approach

Post-decommissioning reactive transport was evaluated using the same sub-domain model as was used for all other scenarios presented within the EIS. The sub-domain model area and mesh were unchanged from previous simulations.

Where applicable (i.e., for IR-55), groundwater flow boundary condition values were updated to reflect the revised groundwater flow solution, and the hydrogeologic property values were updated to match those within the alternatively calibrated groundwater flow model. For all other

simulations, only individual parameter values (e.g., hydraulic conductivity, recharge, porosity or dispersivity) were altered.

Transport boundary conditions and parameters were left unchanged from the Base Case condition. The 3D geochemical reactive transport simulation was completed using FEFLOW coupled with PiChem (i.e., the same approach followed for earlier simulations). The PHREEQC database, boundary and initial conditions, and simulation approach were the same as described within the EIS for the Base Case scenario. The full suite of 31 constituents was applied for selected scenarios, however as those simulations can take 3 to 4 weeks to complete, not all scenarios were able to be run with the full suite of constituents.

1. IR-55 Scenario: Higher Hydraulic Conductivity - Intermediate Sandstone Aquitard

The IR-55 scenario documents an alternative calibrated groundwater flow model which was developed with a hydraulic conductivity of $1.0\text{E-}07$ m/s within the Intermediate Sandstone Aquitard. This scenario also contained higher hydraulic conductivity values within the Desilicified Zone ($1.4\text{E-}04$ m/s) and Lower Sandstone Aquifer ($4.1\text{E-}05$ m/s); as such, the deeper units along the flow path between the Ore Zone and Whitefish Lake were all simulated as having increased hydraulic conductivity values. To maintain calibration, shallow materials along the flow path between the Ore Zone and Whitefish Lake were simulated to have a lower hydraulic conductivity than the Base Case (e.g., Overburden and Upper Sandstone Aquifer). For a full list of parameter values see the IR-55 groundwater flow response.

In general, the alternative calibrated model does not fit the observation data as well as the Base Case simulation presented within the EIS; however, the calibration statistics are acceptable. The alternative calibrated groundwater flow model results in higher volumes of groundwater flow converging upon Whitefish Lake, which lead to greater dilution potential for flow from depth, through the Ore Zone/mining area. As such, it is considered a less-conservative modelled scenario than those already presented within the EIS.

2. IR-70 Scenario: Higher Hydraulic Conductivity – Ore Zone

The hydraulic conductivity of the material remaining post mining within the Ore Zone, and the surrounding clay-rich or sulphide cemented units (i.e., natural barriers), is uncertain. Review comments have suggested that the impact of a higher value for hydraulic conductivity within the Ore Zone needs to be evaluated. While the hydraulic conductivity of the Ore Zone is not considered critical to predictions as it is only a small portion of the source area (i.e., 6% of the assumed Post-Decommissioning source mass), an additional scenario was performed to reflect the uncertainty in the post-mining hydraulic conductivity within the Ore Zone and the surrounding barrier zones; for this scenario the Ore Zone and natural barriers were treated as one uniform zone. As this is a future condition after the uranium ore and associated minerals have been removed, this parameter cannot be calibrated with current data. It is expected that the hydraulic conductivity of the Ore Zone and barriers will be enhanced due to mining, and thus a conservatively high hydraulic conductivity value of $5.0\text{E-}05$ m/s was assigned for this scenario. This value reflects the understanding that the voids created through mining will be infilled with the overlying desilicified sandstone (i.e., the altered sandstone within the Lower Sandstone Aquifer), and may have a higher hydraulic conductivity than currently within the Lower Sandstone Aquifer (i.e., $5.0\text{E-}06$ m/s).

3. a), b) IR-71 Scenario: Lower / Higher Groundwater Recharge

Recognizing that future climate conditions are uncertain, and that the predicted timespan of migration of chemical constituents from within the mining area to Whitefish Lake requires centuries to millennia, the future climate is uncertain. A reduction in groundwater recharge is considered most likely due to enhanced evapotranspiration and surface water runoff; such a reduction would reduce groundwater flow rates which is considered to be less conservative than scenarios presented within the EIS. While current groundwater recharge can be calibrated based on field observations (e.g., stream baseflow, water level fluctuations, etc.), groundwater recharge in future centuries cannot be calibrated.

Review of future climate predictions presented by Environment Canada (climatedata.ca – Key Lake) indicates precipitation will increase by 11 to 15%, and temperature will increase by 2.5 to 4.6°C. The future change in groundwater recharge is not specified but based on the range of variability that others (e.g., Erler et. al., 2019) have found for the foreseeable future (i.e., end of century), a range of +/- 20% was selected for future recharge simulations.

4. IR-78 & 88 Scenario: Lower Effective Porosity within the Paleoweathered Zone

Effective porosity within the units where constituents of potential concern (COPCs) will remain post-mining will affect the persistence of COPCs within the source area, and the residence time within deeper units. Simulations within the EIS illustrate that the most persistent portion of the source area is within the Paleoweathered bedrock, and so the uncertainty of the effective porosity within this unit is considered to be most relevant. As noted in Appendix 7-C of the revised Draft EIS (Table 4-2), the effective porosity within the Paleoweathered zone was enhanced to account for potential matrix diffusion effects. The scenario herein presents the change in predicted conditions if the effective porosity of the Paleoweathered zone is reduced by an order of magnitude, as would be consistent with lesser matrix diffusion effects. This value is not constrained by model calibration.

5. IR-96 Scenario: Lower Transverse Dispersivity

Dispersivity values incorporated within geochemical reactive transport calculations impact the degree of mass spreading as hydrogeologic heterogeneities are experienced. A wealth of literature is available to document that longer plumes experience greater dispersion as they flow through larger volumes of heterogeneous subsurface materials. While reviewers agree with the magnitude of dispersivity values applied within the EIS scenarios, the ratio of dispersivity along the flow paths (i.e., longitudinal) to perpendicular from the flow paths (i.e., transverse) was questioned. In settings with high degrees of anisotropy created by depositional variations (e.g., horizontally stratified sediments such as fluvial sands with silt interbeds), the ratio between longitudinal and transverse dispersivity has been shown to be 100:1 (Gelhar et al.; 1992), particularly for the transverse dispersion component across lower conductivity features such as silt interbeds within sand aquifers (i.e., vertical transverse dispersion in a horizontally dominated flow field). For the Denison Mines setting, where the hydrogeologic material of interest is within hydrothermally altered (i.e., desilicified) sandstone, transverse dispersion is expected to be relatively high and isotropic to be consistent with the isotropic hydraulic conductivity of desilicified sediments.

Further, as flow is not horizontally dominated (e.g., vertically upward flow through the Desilicified Zone) differentiating transverse components of dispersivity is not appropriate for this setting.

Since this parameter cannot practically be field verified, nor is it constrained through groundwater flow model calibration, an additional scenario with a lower transverse dispersion rate, such that a 10:1 ratio of longitudinal to transverse dispersion was evaluated.

Reactive Transport Predictions at Whitefish Lake

Table IR-89-R1-1 presents the transport results simulated for the above scenarios; the Base Case conditions are also provided for comparison. In general, the peak concentrations reaching Whitefish Lake were similar to the Base Case simulation and are within the range of simulation results presented within the EIS. As such these simulation results do not further expand the range of potential outcomes already presented. Further, the simulations indicate that groundwater quality screening criteria (GQSC) are only exceeded for dissolved manganese and iron, as was presented within the EIS.

1. IR-55 Scenario: Higher Hydraulic Conductivity - Intermediate Sandstone Aquitard

For the IR-55 scenario, which had a hydraulic conductivity of $1.0\text{E-}07$ m/s within the Intermediate Sandstone Aquitard, concentrations were simulated to be lower (i.e., less conservative) than the Base Case scenario. This is expected to be due to enhanced mixing with fresh water as a result of higher volumes of groundwater flow through those zones with higher hydraulic conductivity values. Under the IR-55 alternative calibrated case, the hydraulic gradient remained relatively unchanged to be consistent with the observed water levels, and thus the groundwater flow rates converging on Whitefish Lake were increased (see simulated baseflow: IR-55), resulting in a decreased contribution of flow from the deep aquifers relative to the total volumetric groundwater flow into Whitefish lake. This results in an overall reduction in the peak concentrations of COPCs in groundwater beneath Whitefish Lake.

2. IR-70 Scenario: Higher Hydraulic Conductivity – Ore Zone

Simulating a higher hydraulic conductivity for the Ore Zone post mining produced similar peak concentrations reaching Whitefish Lake as the Base Case scenario. As an increase of the hydraulic conductivity by more than one order of magnitude did not make an appreciable difference in the simulated peak concentrations reaching Whitefish Lake, we re-affirm that the hydraulic conductivity of the Ore Zone is not a controlling parameter for mass discharge reaching Whitefish Lake. This is consistent with the mass within the Ore Zone being a relatively small percentage (e.g., 6% uranium by mass) of the total dissolved-phase mass in the mining area Post-Decommissioning, as conceptualized in the model.

3. a), b) IR-71 Scenario: Lower / Higher Groundwater Recharge

The scenarios where future groundwater recharge was varied by +/- 20% due to future climate change did not appreciably change peak concentrations reaching Whitefish Lake. The findings of these simulations also support the IR-71 response wherein climate change was not simulated because it was expected to produce lower peak COPC concentrations at Whitefish Lake than the

Base Case. The simulation with lower groundwater recharge is interpreted to produce a lower hydraulic gradient, and thus a lower rate of groundwater flow from the mining area, than the Base Case. Conversely the higher groundwater recharge case provides more a greater volume of water moving through the sub-surface, resulting in a smaller relative contribution from the mining area. Both cases result in similar, but lower peak concentrations reaching Whitefish Lake.

4. IR-78 & 88 Scenario: Lower Effective Porosity within the Paleoweathered Zone

Reduction of the effective porosity within the Paleoweathered bedrock was shown to have the largest impact on simulated peak COPC concentrations reaching Whitefish Lake. Slightly higher peak concentrations than the Base Case were simulated for a suite of COPCs (i.e., As, Cd, Co, P, Ra, Se, Sr, U, Zn). This simulation reflects a reduced ability for matrix diffusion to contain mass within the Paleoweathered zone and slowly release it over time. With the exception of dissolved iron (Fe) and manganese (Mn) concentrations, none of the other (relatively) elevated COPC concentrations reached levels above GQSC within the simulated timeframe. Based on simulated trends, showing decreasing concentrations at depth, additional COPC concentrations are not expected to exceed GQSC even further into the future.

5. IR-96 Scenario: Lower Transverse Dispersivity

Reduction of the transverse dispersivity to maintain a ratio of 10:1 for the longitudinal to transverse dispersivity values resulted in higher COPC concentrations reaching Whitefish Lake than for the Base Case. For this scenario, the longitudinal dispersivity remained at the Base Case level (i.e., 10 m), while the transverse dispersivity value was reduced to 1m (5m in the Base Case). As in the other simulated cases, with the exception of dissolved iron (Fe) and manganese (Mn) concentrations, none of the other COPC concentrations reached levels above GQSC within the simulated timeframe.

Table IR-89-R1-1: Peak Groundwater Concentrations Reaching Whitefish Lake: Alternative Scenarios Consistent with Observed Conditions (all concentrations in mg/L)

| COPC | Groundwater Quality Screening Criteria | EIS Base Case | 1. IR-55 Alternative Calibration (K _{ISA} = 1.0E-7 m/s; K _{DSZ} = 4.0E-5 m/s) | 2. Summary of Additional Simulation Results

Additional long-term predictive simulations of COPC transport were undertaken to evaluate the areas of uncertainty highlighted within the second round IRs. Scenarios tested were limited to those that were consistent with, or did not contradict, available observations. The areas of uncertainty included:

- 1) Hydraulic conductivity of the Intermediate Sandstone Aquitard ($1.0\text{E-}07$ m/s), Desilicified Zone ($1.4\text{E-}04$ m/s), and Lower Sandstone Aquifer ($4.1\text{E-}05$ m/s). The alternative calibrated scenario presented contained higher hydraulic conductivities than the Base Case model for each of these hydrogeologic units with increases of 10, 28, and 4, respectively.
- 2) Hydraulic conductivity of the Ore Zone post-decommissioning was increased to $5.0\text{E-}05$ m/s, which is a factor of 10 higher than the overlying Lower Sandstone Aquifer. It is considered to reflect a very high value that could result due to the dissolution mining process.
- 3) Groundwater recharge was varied by $\pm 20\%$ to evaluate potential future climate change impacts on groundwater flow and subsequent COPC transport.
- 4) The effective porosity of the Paleoweathered zone was lowered by a factor of 10 to evaluate a case where the mass was less persistent within this unit, which is the deepest portion of the source zone.
- 5) The transverse dispersivity value was lowered by a factor of 5 to achieve the requested 10:1 ratio between longitudinal and transverse dispersivity values.

All additional scenarios produced similar predicted peak COPC concentrations reaching Whitefish Lake. All scenarios produced concentrations of primary COPCs at Whitefish Lake that are below the groundwater quality screening criteria established, with the exception of iron and manganese due to naturally high background levels, as reported within the EIS.

The key understanding gained, or further supported, through these simulations is that the natural groundwater system has a high assimilative capacity such that reasonable changes to parameters do not produce concentrations of COPCs at Whitefish Lake that exceed the groundwater quality screening criteria (with the exceptions of dissolved manganese and iron, which naturally occur at elevated concentrations). As the peak concentrations reaching Whitefish Lake do not exceed groundwater quality screening criteria within these additional scenarios, no additional or enhanced risk to the natural environment is expected.

ATTACHMENT IR-89-R1 (Round 3 response)

Denison has corrected typographical errors in the Updated Draft EIS in the final EIS pertaining to the geomean hydraulic conductivity values for the Desilicified Zone (DSZ). ECCC is correct in noting that a lack of detail was provided on how the updated geomean K value in the DSZ reported in the Updated Draft EIS was arrived upon/calculated. Details on this matter are provided in Section 4.0, below.

Sections 1.0 through 3.0 of this IR response are unchanged from the response provided to Round 2 IR comments on February 10, 2024.

1.0 Introduction

Simulations of conditions that extend beyond the range of conditions supported by the monitoring data (i.e., calibration-constrained conditions) is inappropriate for an EIS as it suggests that unrepresentative, potentially misleading scenarios should be tested, documented, and presented as potential outcomes. In the SME's view this would confuse the groundwater transport and associated risk discussions.

While we do not support development of un-calibrated scenarios for inclusion within the EIS, additional scenarios that did not violate field observation data were evaluated as part of this response. These scenarios further demonstrate the robust nature of the hydrogeologic setting, which has been shown to have a high assimilative capacity.

Additional groundwater flow and geochemical reactive transport modelling scenarios were performed in response to:

1. IR-55, wherein the hydraulic conductivity of the Intermediate Sandstone Aquitard was increased to a maximum value of $1.0\text{E-}7$ m/s, and other parameter values, including the hydraulic conductivity of the Desilicified Zone, were increased to maintain a calibrated condition.
2. IR-70, wherein a higher hydraulic conductivity within the Ore Zone post-decommissioning was tested. This is an uncertain parameter which is unconstrained by calibration data.
3. IR-71, wherein uncertainty in future groundwater recharge rates were evaluated by varying rates by +/- 20%. Future groundwater recharge is an uncertain parameter which is unconstrained by calibration data.
4. IRs 78 & 88, wherein the effective porosity of the Paleoweathered zone was reduced by an order of magnitude to allow the initial source mass to migrate toward receptors 10-times faster. Effective porosity of the Paleoweathered zone is an uncertain parameter which is unconstrained by calibration data.
5. IR-96, wherein the transverse dispersivity was reduced to 1m to be consistent with ratios of longitudinal-to-transverse dispersivity published in the literature (e.g., Gelhar et al.; 1992) based on anisotropic settings. Transverse dispersivity is an uncertain parameter which is unconstrained by calibration data.

2.0 Post-Decommissioning Scenarios: Simulation Approach

Post-decommissioning reactive transport was evaluated using the same sub-domain model as was used for all other scenarios presented within the EIS. The sub-domain model area and mesh were unchanged from previous simulations.

Where applicable (i.e., for IR-55), groundwater flow boundary condition values were updated to reflect the revised groundwater flow solution, and the hydrogeologic property values were updated to match those within the alternatively calibrated groundwater flow model. For all other simulations, only individual parameter values (e.g., hydraulic conductivity, recharge, porosity or dispersivity) were altered.

Transport boundary conditions and parameters were left unchanged from the Base Case condition. The 3D geochemical reactive transport simulation was completed using FEFLOW coupled with PiChem (i.e., the same approach followed for earlier simulations). The PHREEQC database, boundary and initial conditions, and simulation approach were the same as described within the EIS for the Base Case scenario. The full suite of 31 constituents was applied for selected scenarios, however as those simulations can take 3 to 4 weeks to complete, not all scenarios were able to be run with the full suite of constituents.

1. IR-55 Scenario: Higher Hydraulic Conductivity - Intermediate Sandstone Aquitard

The IR-55 scenario documents an alternative calibrated groundwater flow model which was developed with a hydraulic conductivity of $1.0\text{E-}07$ m/s within the Intermediate Sandstone Aquitard. This scenario also contained higher hydraulic conductivity values within the Desilicified Zone ($1.4\text{E-}04$ m/s) and Lower Sandstone Aquifer ($4.1\text{E-}05$ m/s); as such, the deeper units along the flow path between the Ore Zone and Whitefish Lake were all simulated as having increased hydraulic conductivity values. To maintain calibration, shallow materials along the flow path between the Ore Zone and Whitefish Lake were simulated to have a lower hydraulic conductivity than the Base Case (e.g., Overburden and Upper Sandstone Aquifer). For a full list of parameter values see the IR-55 groundwater flow response.

In general, the alternative calibrated model does not fit the observation data as well as the Base Case simulation presented within the EIS; however, the calibration statistics are acceptable. The alternative calibrated groundwater flow model results in higher volumes of groundwater flow converging upon Whitefish Lake, which lead to greater dilution potential for flow from depth, through the Ore Zone/mining area. As such, it is considered a less-conservative modelled scenario than those already presented within the EIS.

2. IR-70 Scenario: Higher Hydraulic Conductivity – Ore Zone

The hydraulic conductivity of the material remaining post mining within the Ore Zone, and the surrounding clay-rich or sulphide cemented units (i.e., natural barriers), is uncertain. Review comments have suggested that the impact of a higher value for hydraulic conductivity within the Ore Zone needs to be evaluated. While the hydraulic conductivity of the Ore Zone is not considered critical to predictions as it is only a small portion of the source area (i.e., 6% of the assumed Post-Decommissioning source mass), an additional scenario was performed to reflect the uncertainty in the post-mining hydraulic conductivity within the Ore Zone and the surrounding barrier zones; for this scenario the Ore Zone and natural barriers were treated as one uniform zone. As this is a future condition after the uranium ore

and associated minerals have been removed, this parameter cannot be calibrated with current data. It is expected that the hydraulic conductivity of the Ore Zone and barriers will be enhanced due to mining, and thus a conservatively high hydraulic conductivity value of $5.0\text{E-}05$ m/s was assigned for this scenario. This value reflects the understanding that the voids created through mining will be infilled with the overlying desilicified sandstone (i.e., the altered sandstone within the Lower Sandstone Aquifer), and may have a higher hydraulic conductivity than currently within the Lower Sandstone Aquifer (i.e., $5.0\text{E-}06$ m/s).

3. a), b) IR-71 Scenario: Lower / Higher Groundwater Recharge

Recognizing that future climate conditions are uncertain, and that the predicted timespan of migration of chemical constituents from within the mining area to Whitefish Lake requires centuries to millennia, the future climate is uncertain. A reduction in groundwater recharge is considered most likely due to enhanced evapotranspiration and surface water runoff; such a reduction would reduce groundwater flow rates which is considered to be less conservative than scenarios presented within the EIS. While current groundwater recharge can be calibrated based on field observations (e.g., stream baseflow, water level fluctuations, etc.), groundwater recharge in future centuries cannot be calibrated.

Review of future climate predictions presented by Environment Canada (climatedata.ca – Key Lake) indicates precipitation will increase by 11 to 15%, and temperature will increase by 2.5 to 4.6°C. The future change in groundwater recharge is not specified but based on the range of variability that others (e.g., Erler et al., 2019) have found for the foreseeable future (i.e., end of century), a range of +/- 20% was selected for future recharge simulations.

4. IR-78 & 88 Scenario: Lower Effective Porosity within the Paleoweathered Zone

Effective porosity within the units where constituents of potential concern (COPCs) will remain post-mining will affect the persistence of COPCs within the source area, and the residence time within deeper units. Simulations within the EIS illustrate that the most persistent portion of the source area is within the Paleoweathered bedrock, and so the uncertainty of the effective porosity within this unit is considered to be most relevant. As noted in Appendix 7-C of the revised Draft EIS (Table 4-2), the effective porosity within the Paleoweathered zone was enhanced to account for potential matrix diffusion effects. The scenario herein presents the change in predicted conditions if the effective porosity of the Paleoweathered zone is reduced by an order of magnitude, as would be consistent with lesser matrix diffusion effects. This value is not constrained by model calibration.

5. IR-96 Scenario: Lower Transverse Dispersivity

Dispersivity values incorporated within geochemical reactive transport calculations impact the degree of mass spreading as hydrogeologic heterogeneities are experienced. A wealth of literature is available to document that longer plumes experience greater dispersion as they flow through larger volumes of heterogeneous subsurface materials. While reviewers agree with the magnitude of dispersivity values applied within the EIS scenarios, the ratio of dispersivity along the flow paths (i.e., longitudinal) to perpendicular from the flow paths (i.e., transverse) was questioned. In settings with high degrees of anisotropy created by depositional variations (e.g., horizontally stratified sediments such as fluvial sands with silt interbeds), the ratio between longitudinal and transverse dispersivity has been shown to be 100:1 (Gelhar et al.; 1992), particularly for the transverse dispersion component across lower conductivity features such as silt interbeds within sand aquifers (i.e., vertical transverse dispersion in a

horizontally dominated flow field). For the Denison Mines setting, where the hydrogeologic material of interest is within hydrothermally altered (i.e., desilicified) sandstone, transverse dispersion is expected to be relatively high and isotropic to be consistent with the isotropic hydraulic conductivity of desilicified sediments. Further, as flow is not horizontally dominated (e.g., vertically upward flow through the Desilicified Zone) differentiating transverse components of dispersivity is not appropriate for this setting.

Since this parameter cannot practically be field verified, nor is it constrained through groundwater flow model calibration, an additional scenario with a lower transverse dispersion rate, such that a 10:1 ratio of longitudinal to transverse dispersion was evaluated.

3.0 Reactive Transport Predictions at Whitefish Lake

Table IR-89-R1-1 presents the transport results simulated for the above scenarios; the Base Case conditions are also provided for comparison. In general, the peak concentrations reaching Whitefish Lake were similar to the Base Case simulation and are within the range of simulation results presented within the EIS. As such these simulation results do not further expand the range of potential outcomes already presented. Further, the simulations indicate that groundwater quality screening criteria (GQSC) are only exceeded for dissolved manganese and iron, as was presented within the EIS.

1. IR-55 Scenario: Higher Hydraulic Conductivity - Intermediate Sandstone Aquitard

For the IR-55 scenario, which had a hydraulic conductivity of $1.0\text{E-}07$ m/s within the Intermediate Sandstone Aquitard, concentrations were simulated to be lower (i.e., less conservative) than the Base Case scenario. This is expected to be due to enhanced mixing with fresh water as a result of higher volumes of groundwater flow through those zones with higher hydraulic conductivity values. Under the IR-55 alternative calibrated case, the hydraulic gradient remained relatively unchanged to be consistent with the observed water levels, and thus the groundwater flow rates converging on Whitefish Lake were increased (see simulated baseflow: IR-55), resulting in a decreased contribution of flow from the deep aquifers relative to the total volumetric groundwater flow into Whitefish lake. This results in an overall reduction in the peak concentrations of COPCs in groundwater beneath Whitefish Lake.

2. IR-70 Scenario: Higher Hydraulic Conductivity – Ore Zone

Simulating a higher hydraulic conductivity for the Ore Zone post mining produced similar peak concentrations reaching Whitefish Lake as the Base Case scenario. As an increase of the hydraulic conductivity by more than one order of magnitude did not make an appreciable difference in the simulated peak concentrations reaching Whitefish Lake, we re-affirm that the hydraulic conductivity of the Ore Zone is not a controlling parameter for mass discharge reaching Whitefish Lake. This is consistent with the mass within the Ore Zone being a relatively small percentage (e.g., 6% uranium by mass) of the total dissolved-phase mass in the mining area Post-Decommissioning, as conceptualized in the model.

3. a), b) IR-71 Scenario: Lower / Higher Groundwater Recharge

The scenarios where future groundwater recharge was varied by +/- 20% due to future climate change did not appreciably change peak concentrations reaching Whitefish Lake. The findings of these simulations also support the IR-71 response wherein climate change was not simulated because it was expected to produce lower peak COPC concentrations at Whitefish Lake than the Base Case. The

simulation with lower groundwater recharge is interpreted to produce a lower hydraulic gradient, and thus a lower rate of groundwater flow from the mining area, than the Base Case. Conversely the higher groundwater recharge case provides more a greater volume of water moving through the sub-surface, resulting in a smaller relative contribution from the mining area. Both cases result in similar, but lower peak concentrations reaching Whitefish Lake.

4. IR-78 & 88 Scenario: Lower Effective Porosity within the Paleoweathered Zone

Reduction of the effective porosity within the Paleoweathered bedrock was shown to have the largest impact on simulated peak COPC concentrations reaching Whitefish Lake. Slightly higher peak concentrations than the Base Case were simulated for a suite of COPCs (i.e., As, Cd, Co, P, Ra, Se, Sr, U, Zn). This simulation reflects a reduced ability for matrix diffusion to contain mass within the Paleoweathered zone and slowly release it over time. With the exception of dissolved iron (Fe) and manganese (Mn) concentrations, none of the other (relatively) elevated COPC concentrations reached levels above GQSC within the simulated timeframe. Based on simulated trends, showing decreasing concentrations at depth, additional COPC concentrations are not expected to exceed GQSC even further into the future.

5. IR-96 Scenario: Lower Transverse Dispersivity

Reduction of the transverse dispersivity to maintain a ratio of 10:1 for the longitudinal to transverse dispersivity values resulted in higher COPC concentrations reaching Whitefish Lake than for the Base Case. For this scenario, the longitudinal dispersivity remained at the Base Case level (i.e., 10 m), while the transverse dispersivity value was reduced to 1m (5m in the Base Case). As in the other simulated cases, with the exception of dissolved iron (Fe) and manganese (Mn) concentrations, none of the other COPC concentrations reached levels above GQSC within the simulated timeframe.

Table IR-89-R1-1: Peak Groundwater Concentrations Reaching Whitefish Lake: Alternative Scenarios Consistent with Observed Conditions (all concentrations in mg/L)

| COPC | Groundwater Quality Screening Criteria | EIS Base Case | 1. IR-55 Alternative Calibration (K _{ISA} = 1.0E-7 m/s; K _{DSZ} = 1.4E-4 m/s) | 2. Summary of Additional Simulation Results

Additional long-term predictive simulations of COPC transport were undertaken to evaluate the areas of uncertainty highlighted within the second round IRs. Scenarios tested were limited to those that were consistent with, or did not contradict, available observations. The areas of uncertainty included:

- 1) Hydraulic conductivity of the Intermediate Sandstone Aquitard ($1.0\text{E-}07$ m/s), Desilicified Zone ($1.4\text{E-}04$ m/s), and Lower Sandstone Aquifer ($4.1\text{E-}05$ m/s). The alternative calibrated scenario presented contained higher hydraulic conductivities than the Base Case model for each of these hydrogeologic units with increases of 10, 28, and 4, respectively.
- 2) Hydraulic conductivity of the Ore Zone post-decommissioning was increased to $5.0\text{E-}05$ m/s, which is a factor of 10 higher than the overlying Lower Sandstone Aquifer. It is considered to reflect a very high value that could result due to the dissolution mining process.
- 3) Groundwater recharge was varied by +/- 20% to evaluate potential future climate change impacts on groundwater flow and subsequent COPC transport.
- 4) The effective porosity of the Paleoweathered zone was lowered by a factor of 10 to evaluate a case where the mass was less persistent within this unit, which is the deepest portion of the source zone.
- 5) The transverse dispersivity value was lowered by a factor of 5 to achieve the requested 10:1 ratio between longitudinal and transverse dispersivity values.

All additional scenarios produced similar predicted peak COPC concentrations reaching Whitefish Lake. All scenarios produced concentrations of primary COPCs at Whitefish Lake that are below the groundwater quality screening criteria established, with the exception of iron and manganese due to naturally high background levels, as reported within the EIS.

The key understanding gained, or further supported, through these simulations is that the natural groundwater system has a high assimilative capacity such that reasonable changes to parameters do not produce concentrations of COPCs at Whitefish Lake that exceed the groundwater quality screening criteria (with the exceptions of dissolved manganese and iron, which naturally occur at elevated concentrations). As the peak concentrations reaching Whitefish Lake do not exceed groundwater quality screening criteria within these additional scenarios, no additional or enhanced risk to the natural environment is expected.

4.0 Geomean Hydraulic Conductivity Calculation for the Desilicified Zone

This response is also related to the response provided to AD-66, on February 10, 2024.

There was an error made during the calculation of the geomean hydraulic conductivity value (K) for the Desilicified Zone as part of the Draft EIS, submitted in October, 2022. Within the Draft EIS, available field-testing based estimates of hydraulic conductivity values for the Wheeler River project were compiled in Table C-1 (Appendix 7-A). The error made in calculating the geomean K value is detailed in Figure IR-89-R1-1, which shows an excerpt of Table C-1 from the Draft EIS (Appendix 7-A). Specifically, the K value of 3×10^{-5} m/s estimated from a packer test at WR-405 was included erroneously in the original geomean K value calculation for the Desilicified Zone. We reviewed the interval tested at WR-405 (356.4 – 379.6 m deep) with respect to delineation of the Lower Sandstone Aquifer and Desilicified Zone. Shown in Figure IR-89-R1-2 is a cross section displaying rock core friability, the interpreted extent

of the Desilicified Zone presented Appendix 7-A of the Draft EIS, and the packer interval at WR-405. This figure illustrates that the packer interval, and thus the associated K value at WR-405, is representative of the Lower Sandstone Aquifer, and not the Desilicified Zone, as was documented in Table C-1 of Appendix 7-A in the (October, 2022) Draft EIS. Thus, during preparation of the Updated Draft EIS, submitted in February, 2024, the error was corrected; omitting the packer test within WR-405, the geomean K value for the Desilicified Zone was recalculated to be 4.8×10^{-6} m/s.

Noted also is that in correcting the geomean K value for the Desilicified Zone in the Updated EIS, the associated range of K values from the field testing was erroneously not updated. That has been corrected in the Final EIS. The correct range of field-measured K values for the Desilicified Zone is 1×10^{-6} m/s to 2×10^{-5} m/s, as shown in Figure IR-89-R1-1. The calibrated K value for the Desilicified Zone was 5×10^{-6} m/s, which is in the middle of the observed range, and consistent with the revised geomean value.

Table C-1 Summary of Hydraulic Testing Data and Conductivity Values

| Well Name | Hydrostratigraphic Unit | Lithologic Unit | Estimated K (m/s) | Comment | Type of Hydraulic Test | Reference | Direction | Depth to Screen/ Packer (m) | |
|-----------|-------------------------|------------------------------|-------------------|--|------------------------|----------------|-----------|-----------------------------|--------|
| | | | | | | | | Top | Bottom |
| WR-555 | Desilicified Zone | MFb | 1.00E-06 | Did packer seal? | Packer test | Golder, 2014 | Vertical | 213.7 | 256.5 |
| WR-555 | | MFb | 1.00E-05 | | Packer test | Golder, 2014 | Vertical | 255.9 | 298.5 |
| GWR-014 | | MFc | 8.70E-06 | | Packer test | Scibek, 2019 | Vertical | 149.0 | 158.0 |
| WR-555 | | MFa | 2.00E-05 | | Packer test | Golder, 2014 | Vertical | 281.7 | 363.3 |
| GWR-047 | | MFb | 2.70E-06 | | Pumping test | Petrotek, 2021 | Vertical | 279.0 | 282.2 |

|--------------|----------------|--|---|---|--|--|--|---|
| IR-100 | - | <p>Mercury is excluded as a COPC in the assessment. Inadequate consideration of mercury and methylmercury in fish and other country foods, and use of incorrect Hg-related health guideline values can underestimate the risks to human health among country food consumers.</p> <p>Context: Section 8 states “Mercury has not been identified as a COPC for the Project as it is currently not present in the receiving environment (i.e., background condition) at detectable concentrations and will not be produced as part of the mine process; therefore, it will not be discharged to the aquatic environment.</p> <p>However, it is understood that potential nutrient enrichment-related effects are possible and can be linked to increases in mercury in the environment” (p. 8-195).</p> <p>Table 8.5-2 shows that there is mercury present in the tissues of Northern Pike and White Sucker sampled in the waterbodies within the local study area and in Russell Lake. These fish are regularly consumed by nearby communities according to the ERFN 2017 dietary survey.</p> <p>In Section 8.5.3, fish tissue concentrations are compared to Health Canada’s human health risk- based maximum permissible mercury concentration (0.5 µg/g wet weight), which is applicable to most species of commercially sold fish rather than country foods.</p> <p>Rationale: It is recommended that mercury be listed as a COPC considering it is in fact present in fish tissue under existing conditions, the significant consumption of fish by the local Indigenous communities, and its toxicological significance to human health.</p> <p>Further, the Health Canada provisional tolerable daily intake (pTDI) value of 0.2 µg/kg/bw/day (Health Canada, 2007) is a more appropriate reference level when evaluating consumption of mercury in fish by Indigenous people, as it allows for the consideration of food consumption patterns in the risk assessment that differ from the general population and is protective of the most sensitive sub-group (i.e., developing fetus).</p> <p>It is important to note that methylmercury, rather than inorganic mercury, is generally the predominant mercury species present in fish and is also the most toxicologically significant form. The assumption of 100% of mercury in fish and other country food items being present as methylmercury ensures that the potential health risks are not underestimated. It is unclear, however, if the mercury data presented throughout the EIS represent total mercury, inorganic mercury or methylmercury.</p> | <p>1. Include mercury (including methylmercury) as a COPC in the assessment given the baseline presence of mercury in sampled fish, the potential increase of methylmercury in receiving waters due to nutrient enrichment resulting from the project, the significant fish consumption by the local population and that country foods, particularly fish, are an important source of dietary exposure to mercury.</p> <p>2. Assess health risks from fish consumption by calculating hazard quotients for baseline and predicted methylmercury levels in country foods using Health Canada’s pTDI for methylmercury (Health Canada, 2007).</p> <p>3. Clarify whether mercury data represented throughout the EIS represents total mercury, inorganic mercury or methylmercury.</p> <p>Suggestions for mitigation and follow-up measures: Health Canada recommends including methylmercury in the list of COPCs to be monitored in fish throughout all project phases.</p> <p>See also related Advice to the Proponent: AD-31.</p> | <p>1. The intent is not to include mercury (and methylmercury) as a COPC for the assessment. As indicated in EIS Section 8.4.6.1, Residual Effects Characterization, mercury is not associated with the local geology and is not expected to be released in the effluent at measurable levels and was therefore not identified as a COPC. Denison notes that there is potential for increased methylmercury production in the receiving environment under a certain combination of factors to which the Project may contribute, such as increased nutrient levels in the environment; however, prediction of methylmercury production is not practical. Denison commits to monitoring mercury and methylmercury in the aquatic environment over the life of the Project to determine the potential changes in mercury concentrations in fish tissue over time.</p> <p>2. As the Project advances and operational monitoring is underway, Denison will assess health risks from fish consumption by comparing fish tissue data collected during operation from the monitoring program against Health Canada’s mercury guideline of 0.5 ug/g wet weight. This is a human health risk-based maximum permissible concentration.</p> <p>3. Mercury data presented throughout the draft EIS represents total mercury. Denison agrees to included methylmercury as part of the constituents monitored in fish throughout all project phases.</p> | <p>This response has not been accepted.</p> <p>Health Canada does not support the responses to points 1 and 2 of IR-100.</p> <p>1. The response to IR-100 point 1 indicates that mercury (including methylmercury) was not included as a COPC in the assessment because mercury is not associated with the local geology and therefore not expected to be released in the effluent at measurable levels, and because prediction of methylmercury production, based on a variety factors, is not practical. Health Canada continues to recommend that mercury (including methylmercury) be included in the assessment given</p> <p>1. the detected presence of mercury in fish under baseline conditions, and</p> <p>2. the high consumption rates of fish and other country foods by Indigenous land users, particularly intensive land users such as the Trapper receptor.</p> <p>2. The response to IR-100 point 2 continues to state that the HC maximum level (ML) for mercury of 0.5 µg/g (or 0.5 ppm) will be used to assess risks to human health from fish consumption during monitoring. The use of the HC ML for mercury is not appropriate in this case as it was developed for retail fish using consumption rates for the Canadian general population. Health Canada’s provisional tolerable daily intake (pTDI) values of 0.20 µg/kg bw/day day for young children and women of childbearing age (Health Canada, 2007) are more appropriate reference levels when evaluating consumption of mercury in fish by Indigenous people, as it allows for the consideration of food consumption patterns in the risk assessment that differ from those used to develop the ML for retail fish and is protective of the most sensitive sub-group (i.e., developing fetus).</p> <p>For instance, the HC Human Health Risk Assessment of Mercury in Fish and Health Benefits of Fish Consumption (Health Canada, 2007) currently employs 40 g as an estimate of daily fish intake by adults who are at the high end of fish intake. This rate is below the rate of consumption for intensive land users for the Project, which is ~500g of fish per day, meaning that the HC ML may not be protective of all land users/receptors.</p> <p>Health Canada reiterates its recommendation to assess health risks from fish consumption by calculating hazard quotients for baseline and predicted methylmercury levels in country foods using Health Canada’s pTDI values for methylmercury (Health Canada, 2007).</p> | <p>1. The EA scope does not include quantifying current risks that don’t have project activity connections. Per CSA N288.6 <i>Environmental Risk Assessments at Class I Nuclear Facilities and Uranium Mines and Mills</i>, Section 6.2.5.4 “The goal is to identify and describe the contaminants and physical stressors that are relevant to the site and operations and that require further quantitative evaluation. The contaminants identified for further evaluation are then referred to as COPCs. These decisions are based on information gathered during site characterization.”</p> <p>Mercury was not identified as a project issue based on mining and milling methods and though it is understood that mercury is a ubiquitous earth element at trace levels it is not identified as uniquely being associated with the local geology; as such, Denison does not believe it is appropriate to quantify existing risk when there is no incremental project risk. Public or existing concerns about mercury do not make this topic an EA question. At this time there is no way to accurately predict potential methylation rates.</p> <p>While the draft EIS (Section 8) highlights increased sulphate concentrations downstream of the Site during period of effluent discharge as a potential factor related to increased methylation (in the presence sulphate reducing bacteria in sediment), it is one of several factors in combination that would need to occur. For example, the IR highlights nutrient enrichment as a contributing factor –significantly increased primary productivity via enrich resulting in high levels of organic carbon in sediments (through algal senescence, deposition, decomposition). This could in fact be a contributing factor, but no such nutrient enrichment has been predicted in the draft EIS as no incremental Project-related nutrient source has been identified. Additionally, the draft EIS does not raise a concern that the Project would cause anoxia in study area lakes, another prerequisite for methylation driven by sulphate reducing bacteria. Denison and its SME’s believe that the treatment of mercury in the draft EIS is appropriate given the level of risk related to the Project. Denison acknowledges the concerns that have been raised by the Indigenous Communities of Concern through its engagement process, as well as those by the FIRT, and in response to those concerns has committed to implementing a mercury monitoring program.</p> <p>In addition to Denison’s future monitoring programs, there are provincial fish consumption guidelines for consumers available at: https://pubsaskdev.blob.core.windows.net/pubsask-prod/76439/76439-Mercury_in_SK_Fish_-_Guidelines_for_Consumption_-_2015.pdf. The guidelines in Saskatchewan for Russell Lake indicate the recommended number of meals per month for northern pike for the general and sensitive population. Further, the Eastern Athabasca Regional Monitoring Program (https://www.earmp.ca/) provides information on community monitoring programs which includes analysis of mercury in fish tissue. In the most recent 2022 EARMP report mercury was measured in lake trout and lake whitefish and the conclusions were that mercury levels were low (ranging from <0.01 mg/L to 0.5 mg/kg) and it was concluded that fish are safe to eat. Monitoring will continue as part of the program (EARMP+2022+2023+Community+Report.pdf (squarespace.com)). The results of the Wheeler River baseline fish tissue sampling program showed measured fish tissue concentrations near the Project in the range of 0.01 to 0.48 mg/kg, which is consistent with that observed in the EARMP. This would indicate that based on baseline conditions fish are considered safe to eat, and no further baseline assessment is warranted.</p> <p>2. As previously indicated, it is currently not practical to calculate hazard quotients for baseline and predicted methylmercury levels in country foods as there is no information on baseline methylmercury and no way to realistically predict the project related methylmercury. Denison has previously committed to a mercury monitoring program which will include assessment of mercury and methylmercury in fish tissue. That information can feed into future hazard quotient calculations if warranted. Denison agrees to use Health Canada’s 2007 provisional tolerable daily intake (pTDI) values of 0.20 µg/kg bw/day for young children and women of childbearing age for future assessments, or the relevant updated value at that time. Denison has committed to a monitoring and follow-up program, which will include measurements of fish health for comparison to baseline data and regulatory criteria (i.e., Canadian Tissue Residue</p> | <p>This IR remains not accepted. It is unclear what threshold concentration(s) of mercury in fish would trigger further assessment of potential health risks.</p> <p>The response to IR-100 includes a commitment to monitor mercury concentrations in fish, and to assess potential health risks if concentrations are greater than that used to derive the Government of Saskatchewan (GoS) guidelines for fish consumption (last updated in 2015). However, using this concentration as a threshold would not be protective of human health if the local population consumes greater quantities than the published consumption guideline.</p> <p>Please provide the following information:</p> <p>1. Discuss how the fish consumption rates from average and high traditional foods consumer groups (Section 10-A, Table 4-4: Annual Food Intakes for Components of the Human Receptor’s Diet) relate to the GoS fish consumption limits for general and sensitive populations.</p> <p>2. Justify the use of GoS guidelines for fish consumption for mercury monitoring in fish and as a trigger for possible management actions.</p> | <p>1. To clarify, Denison has not committed to using the Government of Saskatchewan guidelines for fish consumption and identified in the Round 2 IR response “Denison agrees to use Health Canada’s 2007 provisional tolerable daily intake (pTDI) values of 0.20 µg/kg bw/day for young children and women of childbearing age for future assessments, or the relevant updated value at that time.” The GoS guideline was provided in the IR response as an example of an existing guideline. Denison acknowledges that traditional food consumers may not be considered in the GoS guidelines or other guidelines. Denison has revised commitment 8-44 related to developing a trigger response mechanism related to interpreting results from country foods sampled, which would also apply to mercury and other constituents of interest such as lead. For completeness, the revised commitment 8-44 is provided here in quotations with revisions from version 1 to version 2 shown in bold:</p> <p>“1. The intent is not to include mercury (and methylmercury) as a COPC for the assessment. As indicated in EIS Section 8.4.6.1, Residual Effects Characterization, mercury is not associated with the local geology and is not expected to be released in the effluent at measurable levels and was therefore not identified as a COPC. Denison notes that there is potential for increased methylmercury production in the receiving environment under a certain combination of factors to which the Project may contribute, such as increased nutrient levels in the environment; however, prediction of methylmercury production is not practical. Denison commits to monitoring mercury and methylmercury in the aquatic environment over the life of the Project to determine the potential changes in mercury concentrations in fish tissue over time.</p> <p>2. As the Project advances and operational monitoring is underway, Denison will assess health risks from fish consumption by comparing fish tissue data collected during operation from the monitoring program against Health Canada’s mercury guideline of 0.5 ug/g wet weight, as applicable. This is a human health risk-based maximum permissible concentration. As part of the country food monitoring document, any site-specific contaminant criteria or trigger mechanisms will be developed to support operational licence applications, and in consultation with Indigenous Nations and communities.”</p> <p>The response to IR-212 in Denison’s round 2 submission provides a conceptual trigger-response mechanism which is reproduced below. The intent is to develop the details of the trigger-response mechanism in discussion and engagement with Indigenous Nations and communities.</p> <p>Response from IR-212 (Round 2) “A conceptual trigger-response mechanism framework related to sampling / monitoring of country foods is described for consideration that would be the basis of detailed plans developed in the next phase of Project approvals.</p> <ul style="list-style-type: none">• Conceptually, screening criteria would be defined in consideration of increasing trends measured in environmental media relative to background.• Where a screening criteria/threshold/benchmark was triggered, an investigation would be initiated to verify the result and to determine if the change in concentration is significant relative to background. This could include lab reanalysis, review of QA/QC data and field notes, reconnaissance, re-sampling or additional sampling and/or additional analyses. Potential causes of the increasing trend would be investigated to establish whether the trend was Project related, and the investigation may be informed by mine operations data (e.g., water treatment performance), climatic data, local and Indigenous knowledge, and background data from reference locations in the region.• If the investigation confirms that the criteria/threshold/benchmark criteria was triggered by the Project, additional analyses such as modelling, toxicity testing, increased sampling may be initiated (as appropriate) or assessment of human health risks may be warranted.• If, based on the additional investigation, modified or additional mitigation measure(s) are identified, such measures may need to be developed, implemented and monitored to address the specific issue identified as being of concern. Monitoring would be adapted to ensure it was capable of monitoring the performance of any mitigations implemented and to demonstrate the risk identified had been mitigated. <p>It is envisioned that Denison would engage its Indigenous Communities of Interest in all aspects of the process. Members of the public and the provincial and federal</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 28, 2024) |
|--------------|----------------|--|--|--|--|---|--|---|
| IR-101 | - | <p>Context: In Section 8.1.1.3 Spatial and Temporal Boundaries the Project Area, Local Study Area (LSA) and Regional Study Area (RSA) are established as they pertain to surface water quantity. The same is done in Section 8.2.1.3 for surface water quality. In Section 8.1.1.3 Figure 8.1-4, the locations of the Project Area, LSA, RSA and surface water features and monitoring stations are provided.</p> <p>However, the locations of wetlands located near the Project area and within the LSA and RSA have not been provided. The location of wetlands within or near the Project footprint, as well as the other wetlands existing within the LSA can be confirmed from Part II_S9 Terrestrial Environment, Section 9.2.3.3 Figure 9.2.-8, including the wetland classifications. There appears to be at least one shallow open water wetland and several bogs located within the Project Area. There is no consideration of wetlands or potential effects to wetland hydrology, surface water or sediment quality throughout the aquatic environment assessments. There is no baseline information regarding wetlands and their status as fish habitat and ecological function, or assessment of potential effects to flow rates, water levels, water quality, sediment quality, or biota.</p> <p>Rationale: There is currently not enough information provided for ECCC to provide advice on the potential risks of the proposed Project to wetland hydrology, surface water and sediment quality within the LSA. This pathway of effects is important to assess in terms of potential effects to wetland habitat availability and quality due to changes in flow rates, water levels, water quality, sediment transport, sediment quality and potential effects to terrestrial and aquatic receptors. It is necessary to evaluate if changes in groundwater and surface water runoff flows and routing will affect water levels and habitat availability within wetlands. Potential effects from COPCs and radionuclides to surface water and sediment, or potential effects to ecological receptors within wetlands have not been evaluated.</p> | <p>1. Provide baseline information regarding wetland characterization within the Project Area and LSA, including: locations, wetland type, size, water surface elevation, depth, water flow pathways, and the presence of wildlife receptors including presence of fish/fish habitat within the Aquatic Environment section of the draft EIS. If this information is available in annexes or baseline studies, summarize it within the main body of the Aquatic Environment section of the draft EIS with references to respective documents for review.</p> <p>2. Provide baseline information on wetland surface water and sediment quality characterization for wetlands within the Project footprint.</p> <p>3. Provide an assessment of potential effects to wetlands within the LSA and potential effects to ecological receptors during all phases of the proposed Project.</p> <p>4. Provide further information on mitigation measures and monitoring that would be applied for the protection of wetlands.</p> | <p>Responses are numbered as listed in the IR. Figures associated with this IR are provided in Attachment IR-101.</p> <p>1) Below indicates the information that is presented in the draft EIS regarding wetland characteristics. This information was housed within the terrestrial environment component and potential impacts to wetlands as a valued component is further assessed under Section 9.2 of the draft EIS, and specifically Section 9.2.6.4. The following list indicates what information was provided in the draft EIS specific to information request #1. As such, repackaging the available information in Section 8 would be redundant and therefore in Denison’s view unnecessary.</p> <p>a. <i>Locations of Wetlands</i> Section 9, Figure 9.2-8 on page 9-83 of the draft EIS presents a map of the RSA and LSA detailing the locations of various wetland features including bogs and fens.</p> <p>b. <i>Wetland Types</i> Section 9, Figure 9.2-8 on page 9-83, and Table 9.2-8 on pages 9-91 to 9-92 of the draft EIS provides the geographical distribution and listing of the following wetland types within the LSA:</p> <p>i.BS17 – Black spruce treed bog ii.BS18 – Labrador tea shrubby bog iii.BS19 – Graminoid bog iv.BS19/24 – Graminoid bog/Graminoid fen v.BS20 – Open bog vi.BS21 – Tamarack treed fen vii.BS23 – Willow shrubby rich fen viii.BS24 – Graminoid fen ix.BS25 – Open fen x.BS27 – Sedge rocky shore (shallow open water)</p> <p>c. <i>Wetland Size</i> Section 9, Table 9.2-8 on pages 9-91 to 9-92 of the draft EIS lists the following wetland types and the cumulative area they encompass within the LSA:</p> <p>i.BS17 – 18.2 ha ii.BS18 – 23.3 ha iii.BS19 – 2.8 ha iv.BS19/24 – 0.8 ha v.BS20 – 0.6 ha vi.BS21 – 1.9 ha vii.BS23 – 0.6 ha viii.BS25 – 0.4 ha ix.BS27 – 4.2 ha</p> <p>d. <i>Wetland Water Surface Elevation</i> Surface elevations for the wetland have been assessed and the information is summarized below and in the Attachment IR-101 Figure 1 Elevations of wetland features in the LSA.</p> <ul style="list-style-type: none">• Wetlands 1.5 km west of the SSA range from 526-524 masl• Waterbodies and their surrounding wetlands directly to the east of the SSA are at an elevation of between 506 and 500 masl• Waterbodies and surrounding wetlands 2 km east of site are approximately between 499 and 497 masl• Wetlands north of the SSA and in the vicinity of the proposed air strip range from 514-508 masl.• Wetlands situated further north of the SSA in the LSA were at an elevation of approximately 526 masl• Southern wetlands that will interact with the proposed hydro corridor extension for the mine have an elevation of 491masl• Most wetland evaluated south of the SSA had elevations ranging from 491-488 masl <p>e. <i>Wetland Depth</i> – information associated with wetland depth for those in the LSA is not available.</p> <p>f. <i>Wetland Flow Pathways</i> - Nearly all wetlands are connected or adjacent to rivers and tributaries, and thus flow</p> | <p>This response has not been accepted for the following reasons:</p> <p>1. The response (#1(d)) by the proponent states that “Surface elevations for the wetland have been assessed and the information is summarized below and in the Attachment IR-101 Figure 1 Elevations of wetland features in the LSA” but it is not indicated that this information will be placed in the EIS. CNSC staff requests proponent to include the information provided in response #1(d) and Attachment IR-101 Figure 1 (Elevations of Wetland Features in the LSA) and Attachment IR-101 Figure 2: (Denison Wheeler River Project SSA and Wetland Feature Distribution) in the EIS.</p> <p>2. The Proponent stated in response #2 (a) and (b) that “surface water quality and sediment quality in wetlands were not specifically sampled in the wetland complexes adjacent to the Project footprint during the original baseline assessment.” CNSC staff requests the proponent to provide justification why they have relied on measurements upstream and downstream of the wetlands over direct measurements in the wetland areas. It is recommended to conduct direct measurements in the wetland areas.</p> <p>3. The information provided did not satisfy the IR. Additional information regarding the potential impacts to wetlands due to changes in surface water quality and sediment quality should be included within Section 8.3 of the main EIS. This is needed to fully understand the scope of potential effects to the aquatic environment.</p> <p>a. Update Section 8.3 to include additional information on predicted water and sediment quality impacts to wetlands from the Proponent's response to directly consider wetlands as fish and fish habitat for the purpose of assessing water quality impacts.</p> <p>b. Update Section 8.3 to provide an assessment of potential effects to wetlands from water and sediment quality changes within the LSA.</p> <p>4. It is stated in response #4 that “[...] Updated baseline information on wetland depths and water-levels may be useful in providing a frame of comparative reference to potential changes during the operation, decommissioning and post-decommissioning phases of the project” and CNSC staff agrees with the proponent and recommend collection of monitoring information on the wetland areas.</p> | <p>1. This information has been incorporated into the EIS as Appendix 8-F.</p> <p>2. Denison is committed to conducting surface water quality and sediment quality in wetlands within the LSA and specifically in wetlands directly adjacent to the Operation prior to construction commencing for the purposes of collecting baseline to further assess the effectiveness of mitigation measures.</p> <p>3(a). Section 8.3 has been updated and specifically sections 8.3.1, 8.3.1.2, 8.3.3, 8.3.4.1, 8.3.4.2 (8.3.4.2.2 and 8.3.4.2.3, 8.3.4.2.5), 8.3.5, 8.3.7, 8.3.9 to include consideration of wetlands as aquatic habitat features within the context of their potential to provide fish and fish habitat. Sections 9.2.4.2.1, 9.2.6.2.1, 9.2.6.4.1, 9.2.7.3, and 9.2.9 have been updated to be aligned with Section 8.</p> <p>3(b). Section 8.3 has been updated and specifically sections 8.3.1, 8.3.1.2, 8.3.3, 8.3.4.1, 8.3.4.2 (8.3.4.2.2 and 8.3.4.2.3, 8.3.4.2.5), 8.3.5, 8.3.7, 8.3.9 to include consideration of wetlands as aquatic habitat features within the context of changes to water quality and sediment quality within the LSA due to the Project. Sections 9.2.4.2.1, 9.2.6.2.1, 9.2.6.4.1, 9.2.7.3, and 9.2.9 have been updated to be aligned with Section 8.</p> <p>4. Denison is committed to conducting surface water quality and sediment quality in wetlands within the LSA and specifically in wetlands directly adjacent to the Operation prior to construction commencing for the purposes of collecting baseline to further assess the success of mitigative measures.</p> | <p>Responses to items one and four have been accepted, but items two and three require additional information.</p> <p>For item two, the Proponent has not included justification regarding why they have relied on measurements upstream and downstream of the wetlands over direct measurements in the wetland areas within their response. Please provide the missing justification for item two, as well as describe how baseline information will be used to further assess the effectiveness of mitigation measures. Water and sediment quality in wetlands differ than those in stream and lakes systems because of their distinct biota and hydrology. In wetlands, there is a greater cycling of nutrients, more nutrients and metals can be sequestered in sediment, and metal toxicity modifying water quality factors such as pH and dissolved organic carbon are not the same as in streams and lakes. Baseline data on water and sediment quality in wetlands are necessary to evaluate potential effects on fish and fish habitat of proposed discharge to Whitefish Lake upstream of the wetlands. The information would also be used to assess possible effectiveness of proposed mitigation measures.</p> <p>For item three, the Proponent has not provided the predicted sediment quality impacts within item three, which is part of the wetlands assessment that was requested.</p> <p>Please also update Section 8.3 to include additional information on predicted sediment quality impacts to wetlands and to provide an assessment of potential effects to wetlands from sediment quality changes within the LSA.</p> <p>This Information is required in order to identify and define potential effect pathways linked to project-related changes to wetland sediment quality and assess effects on wetland functions, fish and fish habitat, and other valued components. Potential effect pathways in wetlands can be different than those in lakes and streams and warrant a separate assessment.</p> | <p>Per the Round 3 IR, responses to items 1 and 4 from the Round 2 IR have been accepted, but items 2 and 3 require additional information.</p> <p>For Item 2, for clarity ECCC specified during the meeting on June 14, 2024, that the wetlands of interest are those located within the nearshore environments of Whitefish Lake (Upper, Mid and Lower) as these lakes will directly receive treated effluent during operation.</p> <p>Water quality was sampled both upstream (river inlet to lake) within the lakes and downstream (river outlet of lakes) (e.g., SA4, SA-5, SA-6, LA-5 and LA-6; refer to Appendix 8-D for the aquatic baseline report including photographs of water quality sampling areas for context). As identified in Denison's response to the IR-107 (round 3), the baseline water quality variability was very low between these stations and therefore overall representative of the LSA and encompassing depositional and non-depositional environments. This was deemed appropriate and suitable for the scale of the EIS.</p> <p>The rationale for using water and sediment quality specific to the inlet/lake/outlet is further described below.</p> <p>Surface water quality modelling included predictions of water and sediment concentrations in Whitefish Lake, the lake into which treated effluent will be released, as well as locations farther downstream. Water quality was predicted as the incremental change in constituent concentrations during periods of effluent discharge on a monthly time step. Sediment quality predictions (as concentrations of constituents in sediment) were made on the same time step from surface water concentrations using the partitioning coefficients (Kd). The Kd values are presented in Table 3-6 of the ERA. They consist of regional published values that have been calibrated on similar sites in northern Saskatchewan over several years and have been checked against Wheeler River measurement data as shown in Figure 3-2 and Figure 3-3 of the ERA.</p> <p>For the purposes of the analysis the Kd value was used for a lake environment meaning that one estimate of sediment quality was assumed to be reasonable for the purposes of the EIS because the wetlands are directly connected to the lake as they are functional nearshore environments of the waterbody itself.</p> <p>The wetland portions under discussion are more accurately described as littoral areas and these wetland portions are not cut-off from or isolated from the main basin of the lake. As such, it can be assumed that the lake environment is likely to be as depositional as the nearshore environment. The lakes of interests are very shallow (on average 1.5 m in depth) and therefore deposition may be as likely in the “offshore” environment as the nearshore.</p> <p>The wetlands are not likely to have a dominating effect on the water quality of Whitefish Lake due to their lesser aerial extent vs. the lake proper and the connectivity between the zones suggests that water quality would be similar between the shoreline and the “offshore” (i.e. likely good exchange).</p> <p>With respect to Item 4, and to further confirm these assumptions discussed above, Denison has committed to the collection of additional baseline information with the wetlands for water quality and sediment quality prior to construction as part of operational licencing (Commitment 8-46).</p> <p>Denison has also committed to conducting a pre-construction preliminary EEM for the site. The EEM study design will be further guided by the final design of the diffuser and the behaviour of the effluent plume (Commitment 8-49).</p> <p>Based on this and if applicable, the EEM study design could include an investigation of the differences in WQ and SQ nearshore and offshore. This would allow for an understanding of the differences in water to sediment contaminant ratios between nearshore and offshore environments.</p> |

| | | | | | | | | |
|--|--|--|--|--|--|--|--|--|
| | | | | <p>pathways are discernable in Figure 9.2-8 of the draft EIS.</p> <p><i>g. Presence of Fish and Fish Habitat</i> For the purposes of this assessment the bogs and fens within the area can be assumed to provide supporting fish habitat to the adjacent lake and river water bodies in the vicinity of the LSA. Section 9.2.6.4.1 of the draft EIS described the estimated change in the aerial extent of wetland due to direct impacts of the Project footprint (see also Figure 9.2-8). The assessment indicated a total loss of 0.5 ha (less than 0.1%) of all wetlands within the Terrestrial RSA.</p> <p>2) As noted in other parts of this IR response, the wetlands within the Project footprint are limited to two areas (i.e., stream crossings along the access road to the airstrip and powerline connection SE of Highway 914 [See Figure 2: Denison Wheeler River Project SSA and Wetland Feature Distribution in Attachment IR-101]) and these wetland areas can be avoided through design and construction mitigations. As such, no direct impact to any wetlands or waterbodies are expected as part of the Wheeler River Project that may impact fish or fish habitat.</p> <p>In regard to baseline information on wetland surface water and sediment quality characterization for wetlands within the Project footprint:</p> <p><i>a. Surface water quality in wetlands –</i> surface water quality was not specifically sampled in the wetland complexes adjacent to the project footprint during the original baseline assessment. However, surface water quality was sampled and assessed at stream and lake stations situated upstream and downstream of wetland areas. These stations were selected for sampling as they were identified as providing repeatability (i.e., relative water depth) and informative with respect to desired segments of the system. For example, water quality was sampled at SA-4, SA-5, LA-6, SA-6 and LA-5 following the flow path from upstream to downstream, respectively. The water quality at these nodes was inclusive of upstream wetland influences. For further reference to surface water sampling station during baseline, please refer to Figure 8.2-4 of the EIS.</p> <p><i>b. Sediment quality in wetlands -</i> sediment quality was not specifically sampled in the wetland complexes adjacent to the project footprint during the original baseline assessment. However, sediment quality was sampled and assessed at depositional lake stations situated upstream and downstream of wetland areas. The sediment quality at these nodes would be inclusive of upstream wetland surface water and sediment influences. For further reference to sediment sampling stations during baseline, please refer to Figure 8.2-4 of the EIS.</p> <p>3) For the purposes of this assessment the bogs and fens within the area can be assumed to provide supporting fish habitat to the adjacent lake and river water bodies in the vicinity of the LSA. Section 9.2.6.4.1 of the draft EIS described the estimated change in the aerial extent of wetland due to direct impacts of the Project footprint (see also Figure 9.2-8). The assessment indicated a total loss of 0.5 ha (less than 0.1%) of all wetlands within the Terrestrial RSA</p> <p>However, when further scrutinizing the potential overprinting of wetland features as a result of the Project it is evident that even this loss is avoidable. The interaction of the Project with wetlands is relegated to those areas where stream crossings for access roads and powerline connections are proposed (See Figure 2: Denison Wheeler River Project SSA and Wetland Feature Distribution (Attachment IR-101)).</p> <p>Wetlands associated with stream crossings have been identified to have mitigative designs (clear-span) to ensure no impacts to fish and fish habitat. The hydro-line as shown in Figure 1 will be constructed to avoid direct impacts to fish and fish habitat following best installation practices. As such, no direct impact to any wetlands or waterbodies are expected as part of the Wheeler River Project that may impact fish or fish habitat.</p> | | | | |
|--|--|--|--|--|--|--|--|--|

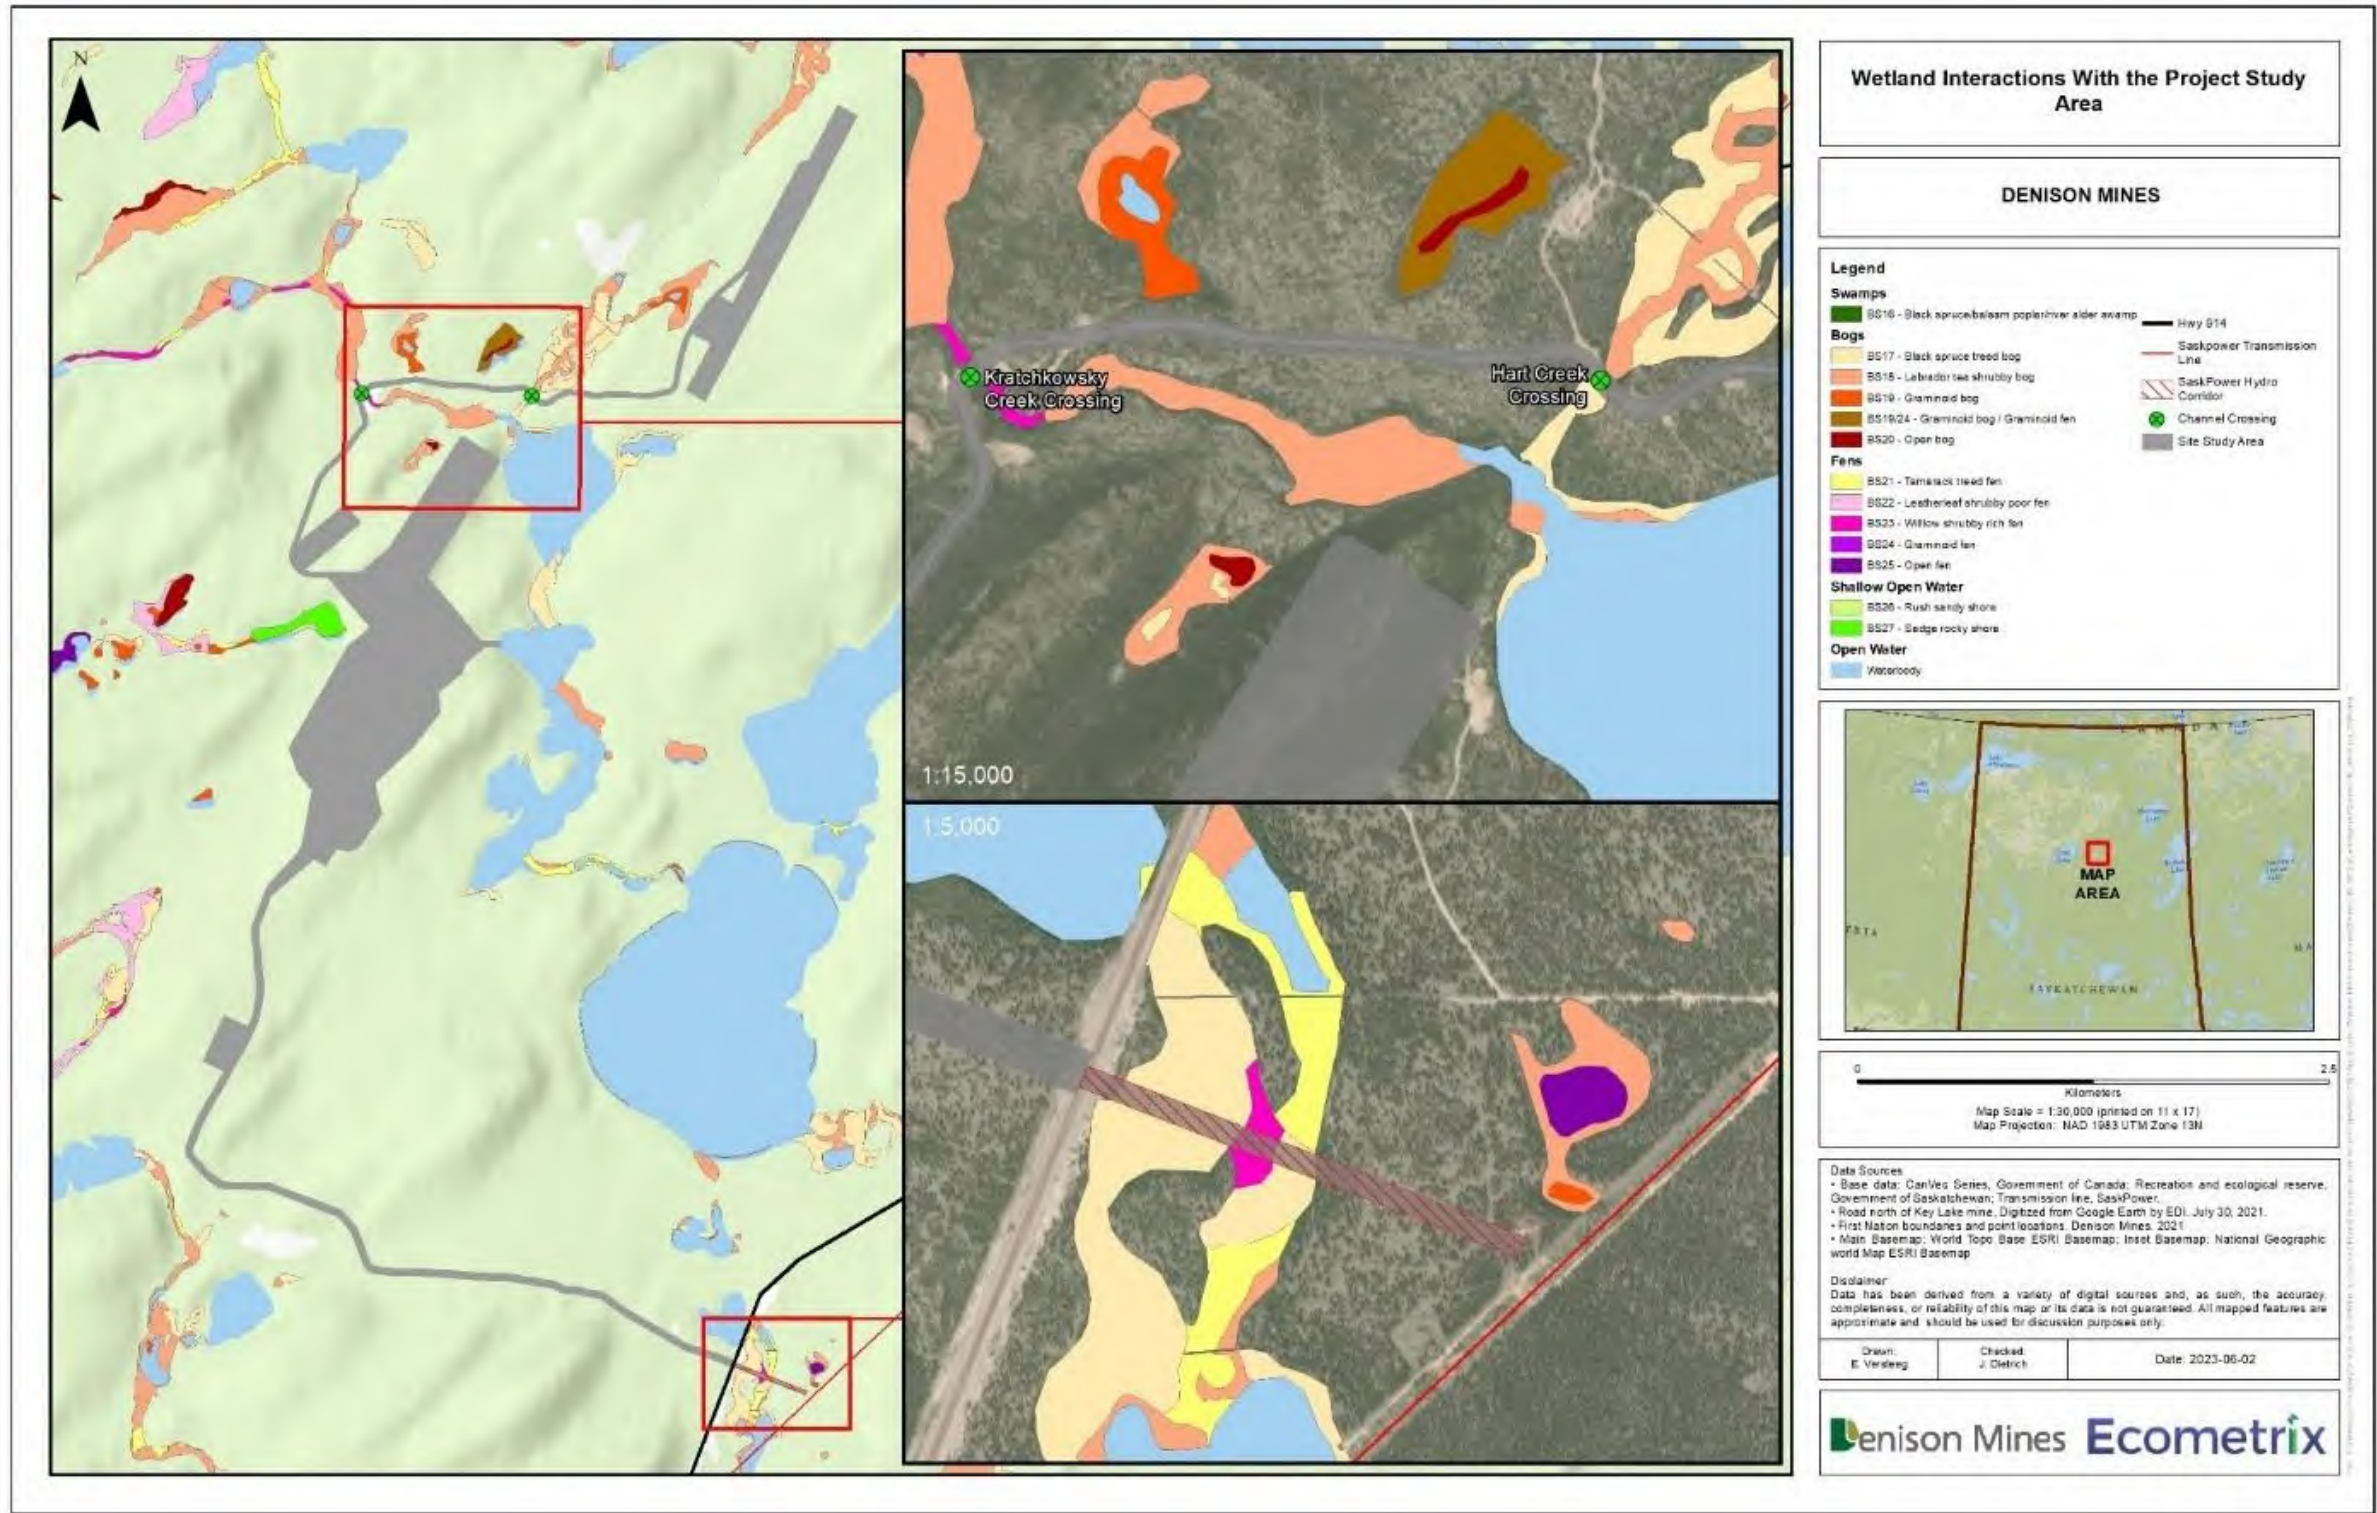

| | | | | | | | | |
|--|--|--|--|--|--|--|--|--|
| | | | | <p>As discussed in Section 8.1.6.1 of the EIS, water levels in the ponds and lakes in the vicinity of the of the Project are expected to experience negligible effects, with magnitudes of changes in water levels predicted to be in the sub-centimeter range. As natural fluctuations in lake water levels were approximately 0.4 m from 2011 to 2019, Project-related changes are not expected to be of a magnitude to compromise the Surface Water Quantity VC. It can then be considered a reasonable assumption that any changes to wetland features will have similar sub-centimeter impacts to water levels due to changes in surface flow and/or groundwater and therefore do not pose an indirect effect to water quantity or fish and fish habitat associated with these wetland features.</p> <p>4) As no impact is expected due to overprinting or due to draw down effects by the ISR, additional mitigation measures are not warranted. Updated baseline information on wetland depths and water-levels may be useful in providing a frame of comparative reference to potential changes during the operation, decommissioning and post-decommissioning phases of the project. However, such changes are expected to be less than measurable.</p> | | | | |

Wetland Effects Assessment Report**DATE:**

19 January 2024

1.0 Introduction

On October 21, 2022, Denison Mines Corp. (Denison) submitted a draft Environmental Impact Statement (EIS) for the proposed Wheeler River Project (the Project). Based on their initial review, the Canadian Nuclear Safety Commission indicated that the submission contained the required information to proceed with the Federal-Indigenous Review Team (FIRT) technical review of the draft EIS. On March 20, 2023, the FIRT provided Denison with a list of information requests (IRs) for Denison to respond to and eventually submit a final EIS document. Responses to these IRs were provided in July and August of 2023. Additional FIRT IRs were provided to Denison on December 5, 2024. Of these IR-101 was not adequately answered and additional information was requested.

This appendix provides additional information to address IR-101 provided by Environment Canada and Climate Change (ECCC) as part of the second round of FIRT comments. The comment included a request for a further summary of wetland characterization information from available sources, baseline information pertaining to water quality and sediment quality, and assessment of potential effects to wetlands within the LSA for all phases of the Project and provide further information on mitigation measures and monitoring that would be applied for the protection of wetlands.

2.0 Scope of the Assessment

This section addresses the potential effects of the Project on the Fish and Fish Habitat VC for which wetland habitats are considered a component. The purpose of this assessment is to assess potential changes to wetlands (as represented by the Fish and Fish Habitat VC) in consideration of all phases of the Project at the Project Area, local, and regional study area scales. Pathways affecting wetlands are directly associated with potential changes to the Surface Water Quantity (hydrology), Surface Water Quality, Sediment Quality, and Benthic Invertebrates VCs. Changes to

hydrology, water quality, sediment quality, and benthic invertebrate communities may directly affect wetlands as both fish and wildlife habitat and food resources. The assessment approach reflects these connections within the environment, as the significance determination for the Surface Water Quantity and Surface Water Quality VCs was conducted at the receptor VC level.

The Vegetation and Ecosystems, Listed Plant Species, and Wetlands VCs are interrelated, to varying extents, and are linked to other VCs, including:

Surface Water Quality – surface water contributes to local moisture regimes, and surface water quality can influence the persistence of Vegetation and Ecosystems, Listed Plant Species, and Wetlands.

Surface Water Quantity – surface water contributes to local moisture regimes, and surface water quantity contributes to site drainage and discharge, which can influence the persistence of Vegetation and Ecosystems, Listed Plant Species, and Wetlands.

Sediment Quality – Vegetation and Ecosystems, Listed Plant Species, and Wetlands contribute to ecosystem form and function that stabilize riparian areas and influence quality of surface water runoff to aquatic systems.

This appendix will focus on the interrelations between these VCs as they apply to Wetland function.

Pathways that are of interest include those associated with site clearing and the potential for erosion-driven mobilization of suspended sediment into local surface waters; groundwater interactions with surface water features including wetlands; the establishment of new subwatershed boundaries and the resulting effects of effluent discharge to the receiving environment; and the potential overprinting of wetland habitat by Project infrastructure.

2.1 Key indicators and Measurable Parameters

The KIs for the wetland component of the Fish and Fish Habitat VC include potential changes in surface water quantity, surface water quality, and available wetland habitat from baseline conditions. The rationale for each KI and associated MPs is summarized in Table 1.

Table 1: Key Indicators and Measurable Parameters for the Wetlands Valued Component

| Key Indicator | Rationale for Key Indicator | Measurable Parameter |
|--|--|--|
| Change in available wetland habitat from baseline conditions | <ul style="list-style-type: none"> Project activities may result in a change in the extent of Wetlands. Of provincial and federal management concern Contributes to biodiversity and habitat for wildlife species and listed plant species. Cultural importance. Contributes to biodiversity, maintenance of hydrologic cycles, nutrient cycling, water quality, and carbon storage. Sensitive to disturbance. Historically addressed for other mining projects in northern Saskatchewan. | Aerial extent (m ² or ha) of overprinted wetland habitat. |
| Change to water levels or flows from baseline conditions | Project activities are expected to result in changes to local hydrology. A reduction or increase in flows may result due to the elimination or redirection of subwatershed area and through Project water management (i.e., water taking, storage, and effluent discharge). These changes in flow to the environment may alter stream flows, lake levels and such feature interactions (inundation) with wetland features required for fish and wildlife during all life stages. | Changes in water levels (m) or percent changes to flow conditions (%). |
| Change in surface water quality from baseline conditions | <p>Changes in water quality are regulated (subsection 36(1) of the <i>Fisheries Act</i> and the MDMER). Changes that may occur as a result of the Project include:</p> <ul style="list-style-type: none"> mobilization of solids into local watersheds; and deposition of deleterious substances into the receiving environment as a result of mine effluent and/or surface runoff. | Change in the concentration of constituents that are directly related to Project activities, measured as a mass of a chemical per unit volume in water (e.g., mg/L). |

2.2 Spatial and Temporal Boundaries

The areas used to assess the effects of the Project on the Vegetation and Ecosystems, Listed Plant Species, and Wetlands VCs are (Figure 1):

Project Area: the area within which the Project and all components/activities are located (i.e., the area of maximum physical disturbance). The Project Area is considered to be a conservative estimate of the area of direct disturbance effects on VCs in this assessment.

Vegetation LSA: the area that surrounds the Project Area where all direct effects and most indirect effects are likely to occur on the Vegetation and Ecosystems, Listed Plant Species, and

Wetlands VCs. The Vegetation LSA is defined as the Project Area plus a 250 m buffer along roads and a 500 m buffer around all other infrastructure (1,161.8 ha).

Terrestrial RSA: the area that surrounds and includes the Vegetation LSA, established to assess the potential, largely indirect effects of the Project on Vegetation and Ecosystems, Listed Plant Species, and Wetlands VCs in a regional context. The Terrestrial RSA (40,173.6 ha) is defined as a minimum 8 km buffer around the Vegetation LSA and has been delineated to capture all indirect effects of the Project on the Vegetation and Ecosystems, Listed Plant Species, and Wetlands VCs and provide context for the type, distribution, extent, and prevalence of plant species and ecosystems in the region. The Terrestrial RSA also defines the area within which cumulative effects are likely to occur (i.e., CEA boundary).

Temporal boundaries identify when an effect is expected to occur in relation to specific Project phases and activities. The temporal boundaries are based on the timing and duration of Project activities, with the associated interactions with each VC and KI (where applicable). In the EA, the temporal boundaries are described as appropriate for each activity and cumulatively for the life of the Project.

The temporal boundaries for the EA represent the timeframes that the Project is expected to interact with and potentially affect Vegetation and Ecosystems, Listed Plant Species, and Wetlands VCs. The temporal boundaries are aligned with the Project development schedule as described in the EIS: Construction; Operation; Decommissioning; and Post-Decommissioning.

3.0 Existing Conditions

Wetlands are defined as “land that is saturated with water long enough to promote wetland or aquatic processes as indicated by poorly drained soils, hydrophytic vegetation and various kinds of biological activity which are adapted to a wet environment” (National Wetlands Working Group 1997). As such, ecosites have been determined to be wetland ecosystems where these conditions are expected to occur. This includes both wetland ecosites and sparsely vegetated ecosites where the water table is within 50 cm of the ground surface (McLaughlan et al. 2010). No wetlands within the Terrestrial RSA have been designated as Ramsar Wetlands of International Importance (The RAMSAR Convention Secretariat 2022).

Project-specific investigations pertaining to the Terrestrial Environment were conducted by Omnia Ecological Consulting (Omnia; Calgary, AB) from 2017 to 2019. Details on the methods, survey parameters and assumptions, and comprehensive data summaries/findings are presented in the Project-specific baseline report (Omnia 2020; see **Error! Reference source not found.** of the EIS) and a supplementary baseline annex report completed in 2021 (EDI 2021; see **Error! Reference source not found.** of the EIS).

Project baseline studies for vegetation presented a description of the ecosystems/habitat types (i.e., ecosite classifications) within the Terrestrial RSA. Vegetation communities and ecosystems are represented by provincial ecosite classifications for the Boreal Shield Ecozone in accordance with the Field Guide to the Ecosites of Saskatchewan's Provincial Forests (McLaughlan et al. 2010). These ecosite classifications were summarized within a 1:20,000 interpreted ecosite mapping product compiled within the Terrestrial RSA with the use of the following inputs:

- 1:5,000 anthropogenic features mapping;
- historical fires data;
- provincial Predicted Ecosite Mapping;
- current and historical imagery; and
- field sampling/ground truthing sites (EIS Appendix 9-B).

As the Boreal Shield Ecozone experiences a largely natural fire regime, much of the vegetation within the Terrestrial RSA (70.6%) is comprised of post-fire regeneration (i.e., shrubby structural stages). Twenty (20) upland ecosites were identified within the RSA with relative percentages by area estimated for each ecosite code.

The assessment also identified fourteen (14) wetland ecosite types within the RSA which included swamps, bogs, fens and shallow open water ecosite codes. The area of these wetlands was also estimated to provide a relative percent area of representation within the RSA.

This cataloguing of ecosite presence and relative area composition across the RSA provides the basis for understanding landscape change and succession over the course of the construction and operation of the Wheeler River Operation.

Waterbodies were conservatively included here as wetlands, as they have the potential to be classified as shallow open water wetlands (i.e., water bodies 2 m deep or less; Warner et al. 1997). Waterbodies represent the most common wetland ecosystem within the Vegetation LSA and the Terrestrial RSA, comprising 3.9% (44.9 ha) and 10.7% (4,101.9 ha), respectively. The black spruce treed bog is the second most common wetland ecosystem within the Vegetation LSA (18.2 ha, 1.6%) and the Terrestrial RSA (1,157.1 ha; 2.9%). The Labrador tea shrubby bog is the most common wetland ecosystem in the Vegetation LSA, comprising 2.0% (23.3 ha), and the second most common wetland ecosystem in the Terrestrial RSA (989.9 ha, 2.5%). All other wetland ecosites are relatively uncommon, each comprising less than 0.5% of the Vegetation LSA and

Terrestrial RSA. The location, size and relative area composition of the wetland features is provided in Table 2 and Figure 1).

Table 2: Summary of Wetlands

| Ecosite Code ¹ | Ecosite Description ¹ | Structure Code ² | Vegetation LSA (ha) | Vegetation LSA (%) | Terrestrial RSA (ha) | Terrestrial RSA (%) |
|---------------------------|--|-----------------------------|---------------------|--------------------|----------------------|---------------------|
| Swamps | | | | | | |

| Waterbody ⁴ | -- | 0 | 44.9 | 3.9 | 4,101.9 | 10.7 |
| Shallow Open Water Subtotal | | | 49.0 | 4.2 | 4,146.3 | 10.3 |
| Total Wetlands⁵ | | | 98.3 | 8.5 | 6,661.1 | 16.6 |

Notes:

- 1 Ecosystems are described in detail in the Guide to the Ecosites of Saskatchewan's Provincial Forests (McLaughlan et al. 2010).
- 2 Modified from the Field Manual for Describing Terrestrial Ecosystems (BC Ministry of Environment, Lands, and Parks, and BC Ministry of Forests 1998). 0 = unvegetated; 1 = sparse / bryophyte / lichen; 2 = herb/graminoid; 3a = low shrub; 3b = tall shrub; 5 = young forest, 6 = mature forest.
- 3 This ecosite type is an artifact of mapping uncertainty, as baseline mappers were unable to distinguish between these ecosites due to a lack of available information (e.g., soil information, vegetation field plots, water quality data). As such, this ecosite has conservatively been split between bog and fen classifications.
- 4 Areas of open water <2 m deep are defined as shallow open water wetland ecosystems (National Wetlands Working Group 1997); as such, unnamed waterbodies and areas of open water observed to exhibit an average depth of <2 m (Ecometrix Incorporated 2020) have been conservatively included as wetland ecosystems.
- 5 Some numbers are rounded for presentation purposes. Therefore, the totals may not equal the sum of the individual values.

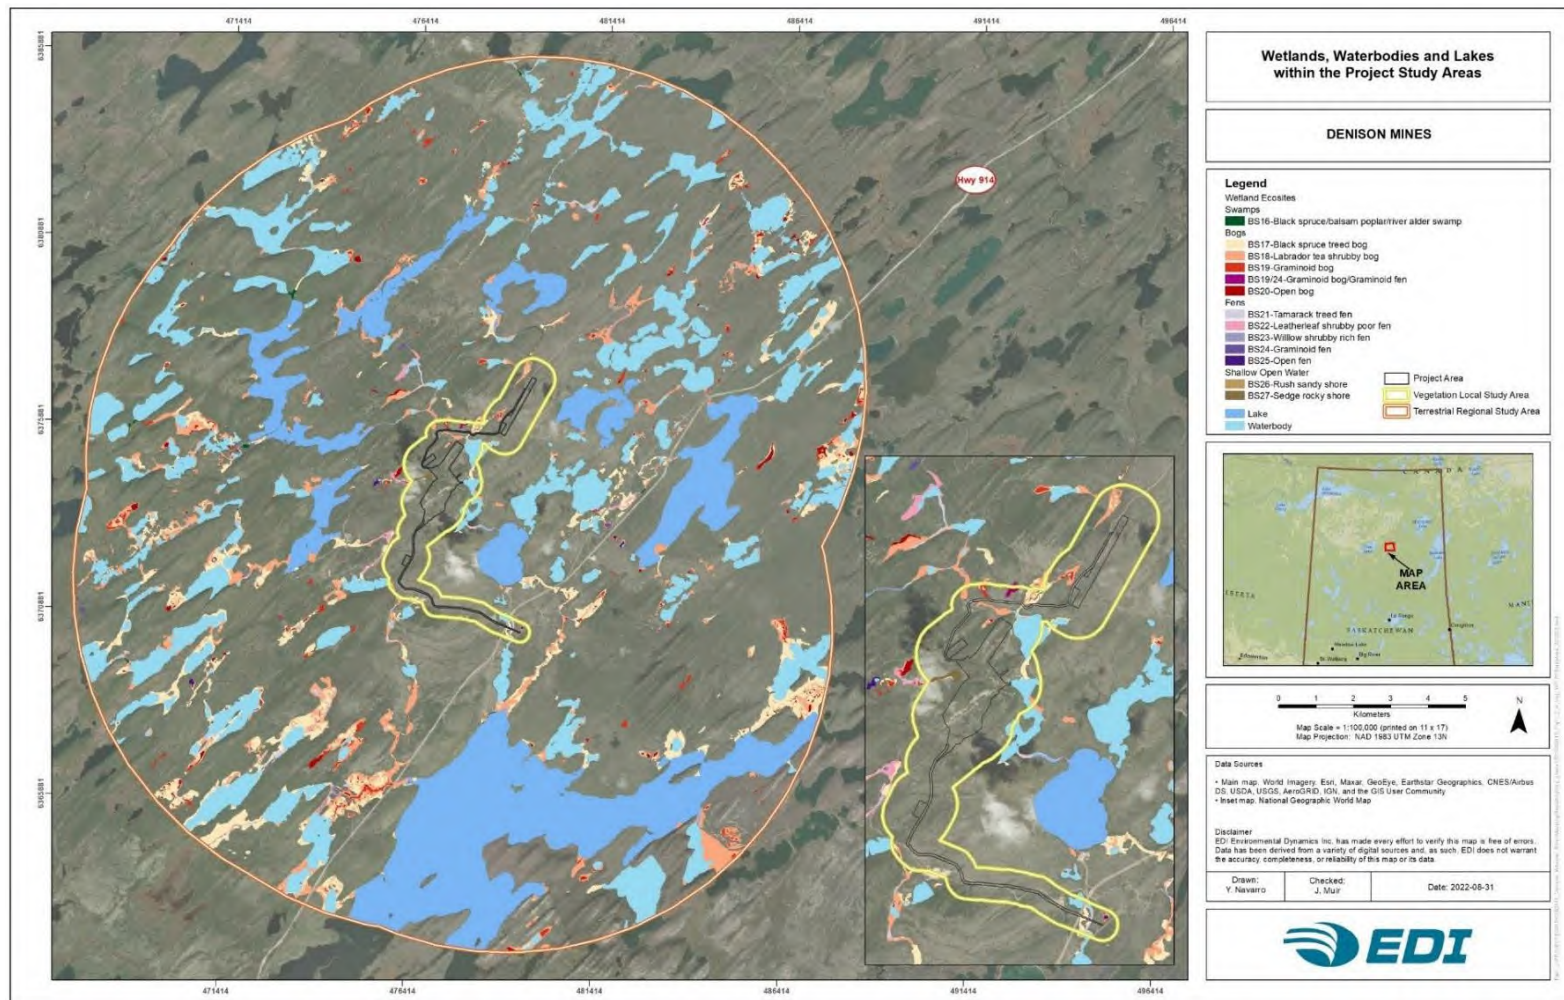

Figure 1: Wetlands, Waterbodies and Lakes within the Project Study Areas

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

Surface elevations for the wetland have been assessed and the information is summarized below and in the Figure 1 .

- Wetlands 1.5 km west of the Project Area range from 526-524 masl
- Waterbodies and their surrounding wetlands directly to the east of the SSA are at an elevation of between 506 and 500 masl
- Waterbodies and surrounding wetlands 2 km east of site are approximately between 499 and 497 masl
- Wetlands north of the Project Area and in the vicinity of the proposed air strip range from 514-508 masl.
- Wetlands situated further north of the Project Area in the LSA were at an elevation of approximately 526 masl
- Southern wetlands that will interact with the proposed hydro corridor extension for the mine have an elevation of 491masl
- Most wetland evaluated south of the Project Area had elevations ranging from 491-488 masl

Wetland depth, presence of fish or fish habitat, water quality and sediment quality are not currently available for the non-waterbody wetlands (i.e. those not identified as a lake or watercourse in Section 8 of the EIS). However, Denison is committed to conducting field surveys to collect this data prior to the initiation of construction of the Operation. This will allow for baseline information to be available to compare future changes and assess the success of mitigation measures and the predicted effects or lack thereof.

For the purposes of this assessment the bogs and fens within the area can be assumed to provide supporting fish habitat to the adjacent lake and river water bodies in the vicinity of the LSA.

4.0 Assessment of Project Related Effects

4.1 Potential Interactions Between the Project and Valued Component/Key Indicators

The Project will require the Construction, Operation, and Decommissioning of several components (as described in Section 2 of the EIS). Potential interactions between these Project components and activities and Fish and Fish Habitat in the form of Wetlands and their associated KIs are summarized by Project phase and activity in Table.

Potential interactions in Table are ranked as:

Primary Interaction (✓): Project activity is expected to interact with the VC / KI which may result in an adverse effect on the VC (i.e., a measurable or detectable change in the MP) and is further considered in the effects assessment as the primary contributor to potential adverse effects.

Other Interaction (✓): Project activity is expected to interact with the VC / KI. While the interaction is further considered in the effects assessment, it is not expected to be a primary contributor to potential adverse effects.

No Interaction: Project activity is not expected to interact with the VC or the KI, no adverse effects are expected, and rationale is provided for not considering this potential interaction further.

Table 4: Potential Project Interactions for Wetlands Valued Component

| Project Phase/Activity | Wetlands Valued Component and Key Indicator |

4.2 Potential Project-related Effects

Based on the timing and nature of the interactions identified in Table 4, the following adverse effects have a potential to occur on the Wetland VC (Table 5). The key indicator of effects to wetlands is the change in areal extent of wetlands in the study area.

4.3 Mobilization of Suspended Materials

Construction

The primary effect pathway during Construction relates to the mobilization of suspended material into natural surface water features including wetlands as a result of land disturbance and clearing. The mobilization of suspended material into natural surface water features is readily mitigatable by virtue of the mine development plan and through the implementation of standard water management and sediment control practices. Water management infrastructure (e.g., collection ditches, ponds, pumping stations) and various aspects of the water management and sediment control management systems will be put into place coincident with the initiation of construction activities. Waters (e.g., runoff) associated with areas under development will be collected and stored within management infrastructure (e.g., clean waste rock pond, see Figure 2.2-14 in Section 2 of the EIS). In the event that releases to the natural environment are necessary, they would only occur once it is safe to do so (i.e., suspended solid levels in the water would be at acceptable levels). No downstream effects on surface waters, natural sediments, fish and fish habitat including wetlands are expected.

Operation

During Operation, mobilization of suspended materials will be managed through the development and operation of water management infrastructure and implementation of surface water management through the Surface Water Management Program. Releases of contact water to the natural environment will be directed through applicable collection ponds, the IWWTP, and the Effluent Monitoring and Release Ponds. No specific discharge is expected to wetland features in the Project Area. Discharge will only occur once it is safe to do so (i.e., suspended solids levels in the water would be at acceptable levels). Denison may employ active means (e.g., filtering), if required, to achieve low TSS levels in discharge, in addition to passive means, such as settling and clarification in the IWWTP to manage TSS in the effluent stream to low levels. No

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

downstream effects on surface waters, natural sediments, or fish and fish habitat including wetlands are expected.

Decommissioning and Post-Decommissioning

During Decommissioning and Post-Decommissioning, the site-wide water management system will continue to operate such that Denison will maintain control of the site aspect affected water through the IWWTP. Surface drainage during Decommissioning activities will continue to be directed to the system of collection ponds, the IWWTP, and the Effluent Monitoring and Release Ponds to facilitate the control of suspended solids and achieve low TSS levels in the discharge, thereby minimizing any potential for adverse changes to water quality, sediment quality, and fish and fish habitat including wetland features.

4.4 Overprinting of Wetlands as Fish Habitat

For the purposes of this assessment the bogs and fens within the area can be assumed to provide supporting fish habitat to the adjacent lake and river water bodies in the vicinity of the LSA.

Bogs are predicted to be the wetland class most affected by the Project, with 0.4 ha (less than 0.1%) of mapped bog ecosystems within the Terrestrial RSA expected to be disturbed within the Project Area during Construction. Fens are the next most affected, with 0.1 ha (0.1%) anticipated to be disturbed during Construction (Figure 3). Less than 0.1 ha (less than 0.1%) of shallow open water wetlands within the Terrestrial RSA are also anticipated to be affected by the Project.

Within these wetland classes, the wetland ecosite expected to be most affected is the willow shrubby rich fen (ecosite BS23) with direct disturbance to 0.1 ha predicted to occur within the Project Area (0.5% of the BS23 ecosite within the Terrestrial RSA). The remaining ecosites anticipated to be directly affected by the Project are locally abundant, with direct disturbance expected to affect <0.1% of these ecosites within the Terrestrial RSA (**Error! Reference source not found. 2**).

Investigation of the potential overprinting of wetland features as a result of the Project it is evident that wetland loss is avoidable. The interaction of the Project with wetlands is isolated to those areas where stream crossings for access roads and hydro-line connections are proposed (Figure 3). With the use of single span bridges and implementation of best management practices, direct wetland disturbance associated with the crossings of Kratchkowsky Creek and Hart Creek is expected to be avoided. It should be noted that SaskPower proposes to tap the existing I3P 138 kV line near Highway 914 and build approximately 4.5 km of new 138 kV line from the I3P tap to the Project site. SaskPower will be responsible for conducting activities such as line routing, environmental studies, and permitting, public consultation, and engineering design work as applicable to the load interconnection. As such, wetland disturbance related to

DATE: 19 January 2024

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

the SaskPower Hydro Corridor is expected to be addressed through the SaskPower permitting process.

Figure 3: Denison Wheeler River Project Area and Wetland Feature Distribution

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

4.5 Controlled Discharge to Receiving Environments

According to the site water balance (Figure 2.2-14 in Section 2 of the EIS), there is no planned discharge to Whitefish Lake during Construction. Other than LA-5 (Whitefish Lake) no other controlled discharge will occur to the natural environment and no wetlands will be impacted as a result.

4.6 Change in Water Levels and Flow

As detailed in Section **Error! Reference source not found.** of the EIS, the projected withdrawal and discharge rates proposed for the Project are the largest influence on the hydrological effects of the Project. The largest predicted change in streamflow rate is -3.1% at the LA-5 and SA-2 nodes (immediately downstream of the Project) during Operation and Decommissioning, as projected against the 5th percentile low flow dataset in March. Lake levels and wetlands are expected to deviate less than ± 0.01 m due to all Project influences. All Project influences on the environment are expected to return to baseline conditions during Post-Decommissioning. These changes are within the range of fluctuation of environmental flows and water levels and are unlikely to affect fish passage or life history environmental cues.

4.7 Introduction and/or Proliferation of Invasive Plants

Vegetation clearing and soil disturbance during Construction are expected to create conditions suitable for the introduction and proliferation of invasive plants. Vehicles and construction equipment can inadvertently transport seeds and other invasive plant propagules in tires or the undercarriage to previously unaffected areas. The effects of invasive plants on native vegetation diversity are well documented and recognized as the second greatest threat to listed species after habitat loss (Enserink 1999). Competition with native species can lead to a reduction in the growth and vigour of native species (including Wetlands), as well as changes in the diversity, structure and function of ecosystems and habitats.

The potential for the introduction and proliferation of invasive plants by transport on vehicles and equipment is expected to continue throughout Operation during wellfield and freeze wall drilling, expansion of ponds and pads, drill waste rock, process precipitates and industrial wastewater treatment plant precipitates, on-site and off-site operation of vehicles and transport of materials, package and transport of nuclear substances, and air transportation for workers (i.e., landing and taking off of airplanes). Progressive decommissioning and reclamation has the potential to introduce invasive plants on vehicles and equipment and if seed used for revegetation is not supplied from a native seed source (Polster 2003) with a certificate of analysis indicating an absence of invasive plant seeds.

The potential for the introduction and proliferation of invasive plants is expected to continue throughout Decommissioning (e.g., during closure of the ISR and freeze wells and infrastructure,

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

asset removal, demolition and disposal of non-salvageable surface infrastructure and materials, remediation of contaminated areas, reclamation of disturbed areas, and operation of vehicles and transportation of materials). The potential for the introduction and proliferation of invasive plants is expected to continue throughout Post-Decommissioning, but at lower levels due to reduced vehicle traffic.

4.8 Edge Effects

Edge habitat refers to an area on either side of a border between vegetation communities. Edges between vegetation communities often result in altered microclimatic conditions that can influence environmental conditions further away from the edge (Bannerman 1998). Edge effects are expected to extend into areas of native vegetation and habitats at the interface of disturbed areas and undisturbed native ecosystems, and could include altered microclimatic conditions that can influence quality in habitat away from the edge (Bannerman 1998). Where edge effects occur, Wetlands may experience changes in light intensity, temperature, wind, moisture, relative humidity, and patterns of snow accumulation and melt relative to undisturbed conditions. This can, in turn, affect plant health and alter natural disturbance regimes (e.g., blowdown), plant population persistence, and the structure and function of ecosystems and habitats. If changes to microclimatic conditions or vegetative structure at an edge exceed a species habitat preference or physiological tolerance, then edge habitat may result in lower occupancy or use, reduced survival, or lowered reproductive success.

Edge effects at the interface of disturbed areas and native ecosystems are expected to occur along the edges of the Project Area resulting from vegetation clearing during site preparation and earthworks during Construction. Edge effects are expected to continue throughout Operation, Decommissioning, and Post-Decommissioning, decreasing over time as revegetation and tree growth within reclaimed areas of the Project create a gradual structural transition at forest edges, aided by natural encroachment.

4.9 Long-Term Transport of Groundwater Solutes to Whitefish Lake in Future Centuries

During the 'future centuries' scenario as described in Section 8.3.1.3 of the EIS, remediation works will be completed and the site naturalized, thereby restoring drainage patterns to report to surface waterbodies. As indicated in Section 7 of the EIS, groundwater plumes may develop from residual mass remaining post-mining based on bench-scale lab tests of core flushing, and numerical modelling of reactive fate and transport. The results of this was described in Section 8.3.4.2.5 with respect to Fish and Fish Habitat and therefore wetlands.

The results of the numerical modelling (as provided in Section 7 and Appendix 10-A in Section 10 of the EIS) support the conclusion that with the implementation of appropriate mitigation during the decommissioning and restoration phases of the Project, the residual effects of the

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

Project on the intermediate Groundwater VC will not result in an adverse effect on surface water. Dissolved constituent concentrations emanating over hundreds to thousands of years in the future from the deep Ore Zone to Whitefish Lake are expected to remain below fresh water environmental quality criteria in Whitefish Lake.

Although the precise location of the groundwater discharge to the surface is somewhat uncertain, the groundwater transport scenarios that have been evaluated (Appendix 7-C of the EIS) to date suggest groundwater discharge impacted from mining will most likely be relegated to Whitefish Lake. The discharge to Whitefish Lake is generally predicted to occur along the eastern shore of the lake, as this is interpreted to be the eastern edge of the underlying desilicified zone. The Laborador Tea Shrubby Bog habitat located on the eastern shore of Whitefish Lake may be in the zone of influence of groundwater discharge, yet chemically will remain below freshwater environmental quality criteria. Groundwater impacts to other surrounding wetlands will be negligible as groundwater is not predicted to discharge within any area beyond the central portion of Whitefish Lake.

4.10 Indirect Effects

Indirect disturbance associated with the potential to adversely affect BS19/24 includes the introduction and/or proliferation of invasive plants, edge effects, changes to water quantity and quality, and dust deposition during all Project phases (as described in Section **Error! Reference source not found.**). Wetland ecosites BS19/24 (graminoid bog/fen) and BS25 (open fen) are peatland ecosystems typically characterized by high water tables (i.e., a very moist or very wet moisture regime), while ecosite BS27 (sedge rocky shore) is a sparsely vegetated ecosystem predominated by rocky substrates, typically occurring adjacent to lakes and ponds (McLaughlan et al. 2010). Because these ecosystems rely on high water tables and existing waterbodies, alteration of water quantity would be expected to have the highest potential to cause an adverse effect. Therefore, maintenance of wetland hydrology is expected to be the most effective mitigation to sustain these wetland ecosites within the Terrestrial LSA throughout the Project lifespan.

5.0 Mitigation Measures

Mitigation measures specific to the wetlands, discussed in the following subsection are applicable during all Operation phases and expected to be effective immediately following implementation and managed through the EMP.

Disturbance Reduction

- Wherever possible, wetlands will be avoided through Project design and instituting proper buffers.

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

- Disturbance to vegetation and soils will be avoided by clearly delineating Project Area boundaries (e.g., with the use of fencing, staking, or flagging), adhering to construction plans and schedules, and by restricting off-site machine use.
- Wetland boundaries in the proximity of planned disturbances will be clearly delineated (e.g., with the use of fencing, staking, or flagging) to facilitate avoidance to the extent practicable.
- Should they occur, areas prone to potential instability and areas in proximity to water bodies and drainage features will be identified and appropriate setbacks will be established and maintained.
- Temporary workspaces or laydown areas will be sited and constructed within existing disturbance or on previously compacted soils, where practicable. In areas requiring clearing only, grubbing will be avoided, and roots and groundcover will be retained to the extent feasible.
- Pre-construction listed plant surveys will be completed within the Project Area.
- Listed plants located adjacent to planned disturbances will be clearly delineated (e.g., with the use of fencing, staking, or flagging) to facilitate avoidance to the extent practicable and reduce the potential for accidental encroachment outside of the Project footprint.
- Should Listed Plants be identified within the Vegetation LSA prior to Construction, site- and species-specific mitigation measures to avoid and/or limit Project effects will be determined by a Qualified Vegetation Ecologist. Specific mitigation measures will depend on the species, its life history characteristics, time of year, and the location of the occurrence in relation to Project activities.
- Herbicide use will be avoided within 100 m of any known listed plant occurrences. Where herbicide use is unavoidable, use will be restricted to direct application instead of broadcast spraying and completed by qualified personnel.

Soil Handling and Reclamation

- Construction activities will be sequenced (i.e., site clearing, grading preparations, major earthworks and construction of infrastructure/facilities) so that surface vegetation, mineral soil and organic matter can be salvaged for later use in Project Decommissioning.
- Soil resources within the Project Area will be stripped/salvaged and stockpiled within the Project Area in accordance with relevant soil management BMPs, i.e., providing guidance on ground-truthing soil conditions, flagging potential hazards and sensitivities, and

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

modifying practices in relation to environmental conditions and avoiding or minimizing inadvertent/incidental disturbance.

- A soil monitoring program/protocol (or equivalent) will be undertaken to verify soil salvage volumes and reclamation suitability (Section 9.1.8.2).
- Soil stockpiling locations will be sited to reduce soil handling and travel distances and designed to minimize the potential for soil degradation and downgradient effects, e.g., having defined height and width that optimize soil storage and stockpile stability, and having integrated erosion control measures and surface water management features (if/where necessary). Sediment and erosion control measures will be implemented in accordance with BMPs and commensurate to site conditions and sensitivities.
- Sediment and erosion control measures and surface water management features will be installed and maintained at the Project. Erosion controls (e.g., sediment fencing, check-damns and/or sediment ponds) will be installed as necessary and at the discretion of construction personnel commensurate to site conditions and sensitivities to manage/mitigate erosion and sedimentation.
- Progressive reclamation and ecosystem-based revegetation will be conducted on disturbed areas as soon as practicable with the use of suitable native species and in accordance with the Reclamation and Closure Plan.

Surface Water Management

- Snow melt and runoff will be controlled within the Project Area to prevent the potential release of contaminated runoff from affecting vegetation in adjacent areas.
- Sediment and erosion control measures will be implemented in accordance with the EMS.
- Surface water management features (e.g., culverts and ditches) will be constructed and maintained (as per Project design specification) along access roads and facility sites to facilitate surface drainage continuity and hydrologic connectivity—especially in proximity to wetlands, water crossings, and waterbodies.
- Hydrologic connectivity is expected to be maintained across the Project Area with the engineering, construction, and maintenance of surface water management features (e.g., culverts and ditches) as appropriate and as per Project design specifications along access roads and at facility sites.

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

Invasive Plant Management

- Equipment and vehicles will arrive at the Project Area clean, and will be inspected for soil, plant material, and seeds, and cleaned as appropriate, to limit the potential for the introduction of invasive plants and noxious weeds.
- Areas with a high risk for the potential spread of invasive plants and noxious weeds (i.e., within or adjacent to existing infestations) will be avoided to the extent practicable; if work must occur in these areas, invasive plant management will be implemented before starting work.
- Gravel, fill, straw matting, or similar materials to be used for erosion control will be inspected to minimize the potential for seeds or propagules of invasive plants being brought to site.
- All employees and contractors on the Project will receive an employee orientation appropriate to the work they are undertaking, including instruction on the definition of invasive plants and their potential effects, mitigation measures to avoid the introduction and spread of invasive plants, and training on the presence and identification of common invasive plant species and those known to occur within the Project Area.
- Invasive plant monitoring will be conducted periodically by personnel skilled in invasive plant identification during all Project phases to assess, evaluate, and document invasive plant occurrences within the Project Area. Invasive plant surveys will be completed during a biologically appropriate time of year (e.g., when invasive plants can be identified) within areas identified as most susceptible to invasive plant introduction and spread, including roads, ROW, debris and vegetation management areas (e.g., slash piles, timber decks, exposed soil or stockpiles) and other regularly disturbed habitats.
- Three general treatment options may be used alone or in combination to control of invasive plants in the Project Area:
 - mechanical control – involves the physical removal of the plants;
 - chemical control – involves application of synthetic and/or natural herbicides; and,
 - biological control measures – involves use of living organisms (e.g., rusts, insects) to control selected invasive plant species.
- The type of treatment option selected for an invasive plant occurrence will be based on a combination of specific information including the identity of the invasive plant species and its provincial designation, the size and extent of the occurrence, time of year, the proximity of the occurrence to other susceptible areas (e.g., rare plant occurrences, wetlands, waterbodies), and the available control options. Where possible, control of

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

invasive plants will be completed in consultation with a qualified professional to minimize potential effects on native vegetation, ecosystems and wetlands.

- Seed used during re-vegetation will be certified weed free, with a valid “Certificate of Seed Analysis”.

6.0 Residual Effects Evaluation

6.1 Residual Effects Characterization

Residual effects on the Vegetation and Ecosystems, Listed Plant Species, and Wetlands VCs have been assessed in relation to the RSA, and characterized in terms of direction, magnitude, geographic extent, frequency, duration, reversibility, context, and likelihood (**Error! Reference source not found.** 6). Residual effect evaluation of residual effects are provided in Tables 7, 8 and 9.

Table 6: Definitions of Effect Characteristics Considered When Determining the Significance of Residual Effects

| Residual Effect Characteristic | Definition | Rating |
|--------------------------------|---|--|
| Direction | Identifies whether the residual effect will be adverse or positive. | Adverse – Negative effect or effect is not desirable. <i>Water Quantity</i> – Effect moves MPs (flow or water level) in a direction detrimental to water quantity relative to baseline conditions. A Project-related increase in surface water flows and levels during flooding, or a decrease in surface water flow below environmental flow requirements. <i>Water Quality</i> – An increase in constituent concentrations attributable to the Project in comparison to baseline conditions and trends. <i>Wetlands / Fish Habitat</i> – A physical loss of available fish habitat (extent of area) in comparison to baseline conditions. Positive – Beneficial effect or effect is desirable. |
| Magnitude | The amount of change in a measurable parameter relative to baseline conditions. | Low <ul style="list-style-type: none">▪ measurable decrease in the spatial extent of Wetlands, but less than a 10% loss; all original wetland classes are present.▪ A measurable change that is not within the variability of baseline conditions but below relevant water quality objectives and criteria. A Project-related change in hydrology (flows or levels) compared to baseline conditions, but where the change is <5% from baseline conditions |

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

| Residual Effect Characteristic | Definition | Rating |
|--------------------------------|--|---|
| | | <p>Moderate</p> <ul style="list-style-type: none">▪ measurable decrease in the spatial extent of Wetlands between 10% and 30% loss; measurable changes in the diversity of wetland classes; some original wetland classes may be absent.▪ A measurable change in water quality that is not within the variability of baseline conditions and not within applicable guidelines, legislated requirements, and/or federal and provincial management objectives. A Project-related change in hydrology (flows or levels) compared to baseline conditions, but where the change is >5% from baseline conditions, and could, therefore, have an adverse effect on Fish and Fish Habitat within the LSA. <p>High</p> <ul style="list-style-type: none">▪ measurable decrease in the spatial extent of Wetlands greater than 30% loss; some original wetland classes are absent.▪ monthly flows (>10%), or lake surface elevation (m) in a waterbody or watercourse that is greater than the range of natural variability and large enough that fish can no longer rely on this habitat to carry out one or more of their life processes. A measurable change in water quality that is not within the variability of baseline conditions and not within applicable guidelines, legislated requirements, and/or federal and provincial management objectives and is likely to have an adverse effect on Wetlands (Fish and Fish Habitat) within the LSA, with the effect extending beyond the LSA. |
| Geographic Extent | The geographic area within which the residual effect is expected to occur. | <p>Project Area – Effect is limited to the Project Area.</p> <p>Local – Effect is limited to the Vegetation LSA.</p> <p>Regional – Effect extends beyond the Vegetation LSA into the Terrestrial RSA.</p> <p>Beyond Regional – Effect extends beyond the Terrestrial RSA.</p> |
| Duration | Length of time over which the residual effect is expected to persist. | <p>Short-term – Less than 3 years (i.e., effect happens during Construction only).</p> <p>Medium-term – 3 years to 38 years (i.e., effect happens from Construction through to the end of Post-Decommissioning).</p> <p>Long-term – More than 38 years (i.e., effect extends beyond Post-Decommissioning).</p> |
| Frequency | How often the residual effect is expected to occur. | <p>Infrequent – Effect occurs several times at sporadic intervals.</p> <p>Frequent – Effect occurs many times on a regular basis.</p> <p>Continuous – Effect occurs continuously.</p> |

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

| Residual Effect Characteristic | Definition | Rating |
|--------------------------------|--|--|
| Reversibility | Whether or not the residual effect can be reversed once the activity causing the residual effect ceases. | Fully Reversible – A residual effect that diminishes to baseline conditions. Partially Reversible – A residual effect that partially diminishes to baseline conditions. Irreversible – A residual effect that will not diminish to baseline conditions. |
| Context | The extent to which the VC or KI has been affected by past and present environmental and socio-economic processes and conditions, its potential sensitivity to the Project-related residual effect, and its ability to recover from that effect (i.e., resilience) | Low – VC/KI has high resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a lack of historic and ongoing anthropogenic or natural disturbance. No listed species present. Moderate – VC/KI has moderate resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or an intermediate level of historic or ongoing anthropogenic or natural disturbance with the capacity to assimilate more change. Presence of listed species High – VC/KI has weak resilience to stress or ecological change. This resilience can be a result of the ecological characteristics of the species or ecosystem, and/or a high level of historic or ongoing anthropogenic or natural disturbance. Presence of SARA-listed species |
| Likelihood | Likelihood that the residual effect will occur including consideration of the likelihood that the mitigation will be successful. | Likely – A moderate to high probability that the residual effect will occur. Unlikely – A low probability that the residual effect will occur. |

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

Table 7: Wetland Fish and Fish Habitat – Summary of the Residual Effect Characteristics for Surface Water Quality

| Residual Effect Characteristic | Rating | Summary Rationale for Rating |
|--------------------------------|------------------|--|
| Direction | Adverse | The Project (specifically the discharge of effluent to the natural environment) will cause a change in the concentration of constituents, as measured as a mass of a chemical per unit volume in water (e.g., mg/L). Surface water quality in the local receiving environment will be adversely affected by effluent discharge to the aquatic environment, thereby providing a pathway to adversely affect surface waters. However, no discharge is planned to wetlands outside of Whitefish Lake. |
| Magnitude | Low | The magnitude of the residual effect is predicted to be low as constituents that may be introduced as part of Project activities are expected to remain below criteria for the protection of aquatic life and human health. |
| Geographic Extent | Local | The geographic extent of the residual effect is predicted to be confined to the immediate waterbody adjacent to the Project (i.e., Whitefish Lake). The estimated mixing zone is less than 5 m, implementing an effluent discharge configuration that promotes mixing. |
| Duration | Long-term | The residual effect is expected to last between 3 to 38 years (i.e., effect expected during Construction through to the end of Post-Decommissioning). |
| Frequency | Continuous | For the purposes of this EIS, a conservative scenario was identified, with effluent discharge being considered as continuous during Operation and Decommissioning. |
| Reversibility | Fully reversible | Surface water quality is expected to return to pre-development levels following Post-Decommissioning as Project-related sources will cease to operate. |
| Context | Low | Wetland health is expected to be resilient to changes in surface water quality in the context of this assessment, as COPC meet protective criteria even at the extreme low water scenario. Therefore, under applicable mitigative measures and average flow conditions, the contextual resilience of the aquatic system to respond to change is considered to be great. |
| Likelihood | Likely | A high probability exists that a change in water quality from background conditions will occur, but be restricted to Whitefish Lake and not other surrounding wetland features. |

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

Table 8: Wetland Fish and Fish Habitat – Summary of the Residual Effect Characteristics for Change in Area Extent

| Residual Effect Characteristic | Rating | Summary Rationale for Rating |
|--------------------------------|----------------------|--|
| Direction | Adverse | Impacts to wetlands in the LSA from physical disturbance or overprinting are expected to be minor in nature and relegated to wetlands located at stream crossings for access roads and the hydro-line corridor. In both cases the approach to design will be one of avoidance and minimal disturbance with clear span bridges and minimal clearing required for hydro-line installation where avoidance of open water areas can be met. |
| Magnitude | Low | The magnitude of the residual effect is predicted to be low. Less than 0.1% of Wetlands within the Terrestrial RSA are predicted to be directly affected as a result of Project Construction, and up to 1.5% may be indirectly affected during all Project phases. |
| Geographic Extent | Local | The residual effect is expected to be limited to the LSA, specifically to wetlands located at stream crossings for access roads and the hydro-line corridor |
| Duration | Long-term | Once natural drainage patterns are re-established following Operation, the structure and function of Wetlands altered as a result of indirect Project effects are expected to re-establish after Post-Decommissioning (more than 38 years). |
| Frequency | Frequent | While direct affects to specific Wetlands will occur over a short time period during Construction, Wetland alteration by indirect effects is anticipated to occur frequently throughout Construction, Operation, and Decommissioning, and infrequently during Post-Decommissioning. |
| Reversibility | Partially Reversible | Wetland effects are predicted to be partially reversible during Decommissioning once natural hydrologic conditions are reinstated. Alterations to wetland extent, structure and/or function as a result of indirect Project effects during all Project phases are predicted to be reversible over time once natural hydrologic conditions are reinstated and edge effects, dust, water quality changes, and invasive plant propagule pressure are reduced at the end of Decommissioning. |
| Context | Moderate | Wetlands can exhibit low resilience and high susceptibility to disturbance; however, disturbance is common within the Terrestrial RSA, and existing Wetlands have been historically disturbed by access roads and exploration activities. |
| Likelihood | Likely | The infrastructure associated with the bridges and the hydro-line are likely to affect the localized area for which they span in a limited way. |

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

Table 9: Wetland Fish and Fish Habitat – Summary of the Residual Effect Characteristics for Change in Surface Water Quantity (Hydrology)

| Residual Effect Characteristic | Rating | Summary Rationale for Rating |
|--------------------------------|------------------|--|
| Direction | Adverse | Water quantity (flow and level) will be reduced in LA-5 as a result of the overprinting of its reporting drainage area by mine infrastructure and through site water balance. Water taking has an additional potential to reduce water levels in LA-5 and associated wetlands. |
| Magnitude | Low | The magnitude of the residual effect is predicted to be low. Under all scenarios, the Project-related change in hydrology (flows or levels) compared to baseline conditions is less than 5% of baseline conditions, and generally less than 3%. |
| Geographic Extent | Local | The residual effect is expected to be limited to the LSA, specifically the lakes and wetlands within proximity to the Project site (i.e., LA-5, LA-6, and LA-1). |
| Duration | Moderate | The residual effect is expected to last between 3 to 38 years (i.e., effect expected during Construction through to the end of Post-Decommissioning). |
| Frequency | Continuously | Although the mine is unlikely to require water taking on a continuous basis, this has been assessed as a bounding scenario and, as such, must be considered as a continuous effect. |
| Reversibility | Fully reversible | Surface water hydrology is expected to return to pre-development levels following Post-Decommissioning. |
| Context | Moderate | Surface water flow regimes are variable, and it is this variability that provides for morphological form to be maintained and for ecological reliance (i.e., wetlands, fish habitat). Some change to environmental flows is tolerated by wetland biota. |
| Likelihood | Low | Due to the localized nature and low magnitude of the effect on surface water hydrology, the likelihood of an effect is considered to be very low; therefore, the likelihood of an effect on Wetlands is expected to be low. |

6.2 Significance and Confidence

The residual effect of change in the areal extent of the Wetlands VC as a result of the Project is not expected to result in a change to the wetlands KI that will alter its integrity within the Terrestrial RSA to the point where it is not sustainable or unavailable to contribute to ecological functions.

The threshold for significance for the Wetlands VC relates to predicted changes in the concentrations of water quality parameters, where changes could result in exceedances of

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

relevant water quality benchmarks that are protective of aquatic biota in waterbodies that receive mine-affected drainage. The threshold for significance for Wetlands also includes predicted changes in surface water flows greater than baseline environmental flows and direct habitat loss.

The significance of the residual effects on the Wetlands VC has been deemed **not significant**. Following mitigation, the residual effects are not expected to cause a change in Wetland habitat (or associated KIs) to the extent that they might alter the ecological integrity of the VC in the LSA beyond an acceptable level.

The predicted confidence with respect to the Wetlands VC is high as the mobilization of suspended materials can be readily mitigated, making the effects prediction relative to this effect pathway easily understood.

Confidence in the assessment of predicted effects on water levels or flow is quite high due to available hydrological data for the LSA. Uncertainty is minimal with the assumptions that the water withdrawal and discharge scenarios presented herein represent the bounding case, and hydrogeological modelling projections are not changed (Section 8.1 of the EIS).

Potential effects on water quality as a result of Project discharges to local receiving environments were assessed by way of numerical modeling. These predictions are generally considered conservative in nature because the assumptions on which they are based are conservative. For example:

- The assessment is based on a continuous (year-round) discharge at an expected average effluent rate of $0.0101 \text{ m}^3/\text{s}$ ($36.5 \text{ m}^3/\text{hr}$) throughout Construction, Operation, and Decommissioning, despite the likelihood that effluent discharge will not be continuous and will only discharge when site water balance requires, based on water storage capabilities.
- The constituents in effluent discharge have been estimated conservatively. Presented discharge concentrations provided herein include contingency factors of one to three times.
- Baseline water quality is defined by the 95th percentile concentrations of individual constituents. Such an assumption is conservative as it constrains the assimilative capacity associated with the receiving environment. By definition, the assimilative capacity of a receiving environment is equal to the incremental difference between the existing baseline condition and the assessment benchmark (i.e., water quality criterion) on which the evaluation is based. Use of the 95th percentile concentration, rather than a measure

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

of central tendency (i.e., 50th percentile, geomean), means that the incremental change in a given constituent concentration that can be assimilated by the receiving environment (whereby use of the receiving environment is protected) is relatively small in magnitude.

Due to the conservative nature of the assumptions on which the numerical assumptions are based, a high degree of confidence can be assumed.

6.3 Summary of Project Related Residual Adverse Effects

The results of the characterizations for these residual effects are summarized in Table 10. The residual effects of the Project on the Wetland KIs were predicted to be **not significant**. Thus, the residual effects of the Project on the Wetlands VC are predicted to be **not significant**.

Table 10: Summary of Project-related Residual Effects

| Valued Component | Residual Effect | Project Phase | Direction | Magnitude | Geographic Extent | Duration | Frequency | Reversibility | Context | Likelihood | Significance |
|------------------|--|---------------|-----------|-----------|-------------------|----------|-----------|---------------|---------|------------|--------------|
| Wetlands | Change in Water Quality | C, O, D | A | L | L | LT | C | FR | L | L | NS |
| | Change in Water Level or Flow | C, O, D | A | L | L | MT | C | FR | L | L | NS |
| | Change in the Areal Extent of Wetlands | C, O, D | A | L | L | LT | F | PR | M | L | NS |

- ¹ Direction: Adverse (A), Positive (P)
- Magnitude: Low (L), Moderate (M), High (H)
- Geographic Extent: Local (L), Regional (R), Beyond Regional (BR)
- Duration: Short-term (ST), Medium-term (MT), Long-term (LT)
- Frequency: Infrequent (IF), Frequent (F), Continuous (C)
- Reversibility: Fully Reversible (FR), Partially Reversible (PR), Irreversible (IR)
- Context: Low (L), Moderate (M), High (H)
- Likelihood: Unlikely (U), Likely (L)
- Significance: Not-Significant (NS), Significant (S)
- Level of Confidence: High (H), Moderate (M), Low (L)

7.0 Cumulative Effects

The cumulative effects are discussed in detail in Section 9.2.7 of the EIS and are not re-examined herein.

8.0 Summary

Bogs are predicted to be the wetland class most affected by the Project, with 0.4 ha (less than 0.1%) of mapped bog ecosystems within the Terrestrial RSA expected to be disturbed within the Project Area during Construction. Fens are the next most affected, with 0.1 ha (0.1%) anticipated to be disturbed during Construction. Less than 0.1 ha (less than 0.1%) of shallow open water wetlands within the Terrestrial RSA are also anticipated to be affected by the Project.

Within these wetland classes, the wetland ecosite expected to be most affected is the willow shrubby rich fen (ecosite BS23) with direct disturbance to 0.1 ha predicted to occur within the Project Area (0.5% of the BS23 ecosite within the Terrestrial RSA). The remaining ecosites anticipated to be directly affected by the Project are locally abundant, with direct disturbance expected to affect <0.1% of these ecosites within the Terrestrial RSA.

Investigation of the potential overprinting of wetland features as a result of the Project it is evident that wetland loss is avoidable. The interaction of the Project with wetlands is relegated to those areas where stream crossings for access roads and hydro-line connections are proposed.

Avoidance through design as well as mitigation measures to control sedimentation to wetland features during construction, operation and decommissioning phases. Water quantity and quality are not expected to cause impacts to wetlands as the change in surface water feature levels and flow are nearly negligible and water will not be discharged to wetlands save for Whitefish Lake, for which effluent will not be released unless meeting criteria for the protection of aquatic life.

Residual effects on the Wetlands VC resulting from the Project were identified and assessed as **not significant**. Existing provincial legislation (Environmental Management and Protection Act [Government of Saskatchewan 2010] and the Water Security Agency Act [Government of Saskatchewan 2019b]) requires written approval (i.e., Aquatic Habitat Protection Permits) prior to any works within a wetland.

To further supplement existing information that exists for the LSA wetlands, Denison is committed to undertaking wetland surveys including the collection of water quality, sediment quality, benthic invertebrates and fish and fish habitat surveys prior to the construction of the operation to provide an updated baseline for assessing the success of mitigation measures and

DATE: 19 January 2024

TO: Denison Mines – Janna Switzer

REF: Wheeler River Project EIS – Appendix 8-F: Wetland Effects Assessment Report

to assess potential effects of the project on wetlands. These locations will then be further considered as part of the EMP for continued monitoring for these media and biota.

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 26 2024) |
|--------------|----------------|---|--|---|--|---------------------------------------|--|---|
| IR-103 | - | <p>Context: The Proponent notes that Intensity duration frequency (IDF) curves are used to estimate the size of water management structures around a site and that the IDF curves are often specific to climate monitoring stations.</p> <p>The Proponent used the IDF_CC Tool 5.0 developed by the Institute for Catastrophic Loss Reduction (2021) which generates Intensity Duration Frequency (IDF) curves at ungauged locations in order to estimate future IDF curve values under influences of climate change. This tool generates sub-daily values at ungauged locations by interpolation and distance weighing from gauged locations.</p> <p>Rationale: IDF trends exhibit random behavior at some locations and correlated behavior at other locations. The choice of gauged locations will infer the statistics for the ungauged locations, including the IDF trends. Without identification of the gauged locations, it is not possible to assess if the modelled data is realistic or not. If the modelled data is not accurate the design of water management structures on the site may not be sufficient resulting in the potential for impacts to the Project from flooding or extreme weather events.</p> | <p>Provide the gauged stations used to generate the sub daily duration values found in Table 8.1-6: Baseline of Intensity Duration Frequency data.</p> <p>Technical Discussion Required: Yes</p> | <p>ECCC correctly notes that the tool generates sub daily values at ungauged locations by interpolation and distance weighing from gauged locations. The closest gauged location to the Project is located 35 km south southwest at the Key Lake Mine (KLM) and the IDF values at KLM for historical and future scenarios (Tables 1 and 2 below) are substantially lower than those predicted for the Project. The IDF CC Tool estimated 1:100 year, 24 hour return period events of 79.9 and 88.6 mm during the current and predicted future values, respectively. As per Tables 1 and 2 those values are substantially larger, and more conservative than, the coincident values of 56.4 and 62.0 mm for KLM. The predicted values for the Project are likely strongly influenced by Cree Lake (4061861; 85 km west southwest) and Collins Bay SK (4061620; 130 km northeast). The interpolation may also be influenced by Stony Rapids A (4067PR5; 196 km north). The Cree Lake, Collins Bay SK and Stony Rapids A stations are all substantially higher than KLM; however, the geography, and likely the climate of KLM, is more similar to those of the Project than from the more distant stations.</p> <p>Despite the potential for the IDF_CC Tool to use weighting factors, the estimates provided by the tool for the purposes of assessing impacts of the project on the surface water hydrology are robust and conservative including in consideration of flooding or extreme weather events.</p> <p>IR-103 Table 1: Key Lake (4063753) – Historical IDF</p> <p>IR-103 Table 2: Key Lake (4063753) – 2020 – 2050 Predicted IDF using CMIP6 Raw GCMs and SSP5.85</p> | <p>This response has not been accepted.</p> <p>In the Context and Rationale of AD-15 in the Annex 1 – Denison Response, ECCC recommends that the Proponent consult CSA PLUS 4013:19 (2019) Technical guide: Development, interpretation and use of rainfall intensity- duration-frequency (IDF) information: Guideline for Canadian water resources practitioners regarding the consideration of future changes in short-duration precipitation extremes. In IR-103, ECCC indicated that in order to assess the accuracy of the Intensity duration frequency (IDF) curves, ECCC required that the Proponent provide the gauged stations generating the values for the modelled data. The Proponent provided the closest gauged stations, however, the future short duration precipitation values were based on statistical relationships fitted between local scale observed extreme precipitation and modelled simulations extremes.</p> <p>Additionally, on page 15-19 of the draft EIS states that: “Denison will apply adaptive management that includes monitoring climate factors so that they can proactively mitigate or prevent adverse climate effects on the Project.” Denison did not provide details on how climate factors will be considered within their adaptive management plans.</p> <p>Rationale: Estimates of future short duration precipitation that are based on statistical relationships fitted between local scale observed extreme precipitation and modelled simulations extremes, such as the approach used by the Proponent, are unlikely to provide reliable projections. This is because the amount of information regarding changes in local-scale observed extreme precipitation contained in short records is not sufficient to constrain a regression (model the statistical relationship) between local and larger scale simulations (Li et al., 2019; ECCC 2022). An alternative approach is to base future projections on a comprehensive assessment that integrates climate science understanding and model projections over a large region. The recent Canadian Standards Association (CSA 2019) guidance on IDF for Canadian Water Resources practitioners provides such an assessment.</p> <p>In terms of adaptive management, the Proponent should clearly outline what climate factors will be monitored to mitigate or prevent adverse climate-related effects. This should include information on when and how the climate factors would be monitored and under what circumstances particular adaptive management approaches would be applied.</p> <p>In order to assess the Proponent’s adaptive management strategies for future extreme precipitation events, ECCC requests that the Proponent consult the CSA (2019) guidance when using future IDF projections in the Project design and provide revised estimates of the potential future changes in short-duration precipitation extremes over the Project’s duration.</p> <p>1. Provide revised estimates of the potential future changes in short-duration precipitation extremes over the Project’s duration as relevant to the Project design.</p> <p>2. Demonstrate how the CSA (2019) guidance will be incorporated in the Project design when developing and considering future IDF projections and estimates of the potential future changes in short-duration precipitation extremes.</p> <p>References</p> <p>CSA Group. (2019). Technical guide: Development, interpretation and use of rainfall intensity- duration-frequency (IDF) information: Guideline for Canadian water resources practitioners. CSA PLUS</p> <p>4013 :19. https ://www.csagroup.org/store/product/2703080/</p> <p>ECCC (2022). Draft Technical guide related to the Strategic Assessment of Climate Change: Assessing climate change resilience. https ://www.strategicassessmentclimatechange.ca/28896/widgets/117114/documents/77106</p> <p>Li, C., Zwiers, F., Zhang, X., & Li, G. (2019). How much information is required to well constrain local estimates of future precipitation extremes? Earth’s Future, 11-24.</p> | <p>Please see Attachment IR-103</p> | <p>See AD-73 in the Advice to Proponent table [reference to come].</p> <p>Note to Denison: This IR is conditionally accepted. Denison’s commitment to providing the requested information related to the IDF (1 in 100 year 24-hour rainfall) and demonstrate climate change resilience of the project (conduct climate risk and resilience assessment) during licensing should be captured in the Commitments Register.</p> <p>Once Denison has added a commitment related to updating the IDF (1 in 100 year 24-hour rainfall) and demonstrate climate change resilience of the project (conduct climate risk and resilience assessment) in the Commitments Register, this can be accepted.</p> <p>Proposed rationale text for posting: This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</p> <p>In the Context and Rationale of AD-15 in the Annex 1 – Denison Response, ECCC recommends that the Proponent consult CSA PLUS 4013:19 (2019) Technical guide: Development, interpretation and use of rainfall intensity- duration-frequency (IDF) information: Guideline for Canadian water resources practitioners regarding the consideration of future changes in short-duration precipitation extremes. In IR-103, ECCC indicated that in order to assess the accuracy of the Intensity duration frequency (IDF) curves, ECCC required that the Proponent provide the gauged stations generating the values for the modelled data. The Proponent provided the closest gauged stations, however, the future short duration precipitation values were based on statistical relationships fitted between local scale observed extreme precipitation and modelled simulations extremes.</p> <p>Additionally, REGDOC-2.9.1 (Appendix 1A) stipulates that “The applicant shall also take into account any potential effects of climate change on the project, including an assessment of whether the project might be sensitive to changes in climate conditions during its lifecycle” and Section 5.1.5 of “ECCC’s Strategic Assessment of Climate Change” states “All proponents will be required... to provide information in the Impact Statement on how the project is resilient to and at risk from both the current and future impacts of a changing climate.” CNSC staff review of Section 15.3.2, 15.4.2 and 15.5.3 of the draft EIS show that the vulnerabilities of the project (infrastructures and project activities) and the associated risk (likelihood and consequence) due to potential increase in climate change hazards (in Section 15.3.2 and 15.4.2) due to climate change throughout the life cycle of the project is not presented in detail. It is also not clear from Section 15.4.2 that the mitigation measures in Table 15.4-1 have considered the additional risk due to the impact of climate change. On page 15-19 of the draft EIS states that: “Denison will apply adaptive management that includes monitoring climate factors so that they can proactively mitigate or prevent adverse climate effects on the Project.” Denison did not provide details on how climate factors will be considered within their adaptive management plans.</p> <p>Rationale: Estimates of future short duration precipitation that are based on statistical relationships fitted between local scale observed extreme precipitation and modelled simulations extremes, such as the approach used by the Proponent, are unlikely to provide reliable projections. This is because the amount of information regarding changes in local-scale observed extreme precipitation contained in short records is not sufficient to constrain a regression (model the statistical relationship) between local and larger scale simulations (Li et al., 2019; ECCC 2022). An alternative approach is to base future projections on a comprehensive assessment that integrates climate science understanding and model projections over a large region. The recent Canadian Standards Association (CSA 2019) guidance on IDF for Canadian Water Resources practitioners provides such an assessment.</p> <p>In terms of adaptive management, the Proponent should clearly outline what climate factors will be monitored to mitigate or prevent adverse climate-related effects. This should include information on when and how the climate factors would be monitored and under what circumstances particular adaptive management approaches would be applied. In addition, considering anticipated project life of 37 years, the climate-infrastructure interactions should be assessed to identify climate vulnerabilities of project infrastructures and operations/activities for all phases of the project. This allows climate risk evaluations and propose adaptation measures accordingly. It is difficult to determine how potential changes in future climate will affect project infrastructures and operations/activities and the associated risk (likelihood and consequences) based on the information provided in Section 15.5.3 (p.15-19) of Draft EIS.</p> <p>In order to assess the Proponent’s adaptive management strategies for future extreme precipitation events, ECCC requests that the Proponent consult the CSA (2019) guidance when using future IDF projections in the Project design and provide revised estimates of the potential future changes in short-duration precipitation extremes over the Project’s duration.</p> <p>1. Provide revised estimates of the potential future changes in short-duration precipitation extremes over the Project’s duration as relevant to the Project design.</p> <p>2. Demonstrate how the CSA (2019) guidance will be incorporated in the Project design when developing and considering future IDF projections and estimates of the potential future changes in short-duration precipitation extremes.</p> <p>3. Demonstrate project resilience to climate change (considering all potential climate sensitive natural hazards including hazards in Section 15.3.2 and 15.4.2) by conducting climate change risk and resilience assessment that includes risk treatment/adaptation measures. CNSC staff recommends proponent to utilize “ECCC (2022). Draft technical guide related to the Strategic Assessment of Climate Change: Assessing climate change resilience” as a guide. Other recommended best practice guides include “Infrastructure Canada (2023). Climate Lens General Guidance – Version 2.1. Infrastructure Canada - Investing in Canada Infrastructure Program Climate Lens - General Guidance “and “MAC (2021). Guide on Climate Change Adaption for the Mining Sector. Mining Association of Canada (MAC)”.</p> <p>References</p> <p>CSA Group. (2019). Technical guide: Development, interpretation and use of rainfall intensity- duration-frequency (IDF) information: Guideline for Canadian water resources practitioners. CSA PLUS</p> <p>4013 :19. https://www.csagroup.org/store/product/2703080/, ECCC (2022). Draft Technical guide related to the Strategic Assessment of Climate Change: Assessing climate change resilience. https://www.strategicassessmentclimatechange.ca/28896/widgets/117114/documents/77106</p> <p>Li, C., Zwiers, F., Zhang, X., & Li, G. (2019). How much information is required to well constrain local estimates of future precipitation extremes? Earth’s Future, 11-24.</p> | <p>As noted in the review comment, this IR was conditionally accepted. Denison’s agrees to providing the requested information related to the IDF (1 in 100 year 24-hour rainfall) and demonstrate climate change resilience of the project (conduct climate risk and resilience assessment per REGDOC - 2.9-1) during licensing and will capture this commitment in the Commitments Register.</p> <p>Additional information with respect to the IDF (1 in 100 year, 24-hour rainfall) as discussed through correspondence with CNSC and ECCC is provided in Attachment IR-103-R3. Specifically, the confidence intervals associated with the IDF identified in the EIS are provided.</p> <p>With this further detail, and commitment above, Denison understands that this IR can be deemed accepted for the purposes of the EIS.</p> |

Attachment IR-103 (Round 2 submission)

A review of the CSA Group (2019) document was undertaken and an estimate of the IDF using this guidance was undertaken. The result of this estimate for the Key Lake Mine Station 4063753 using data corresponding to the period 2014 to 2023 was 69.6 mm for the 1:100-year 24 hours storm event. This estimate is greater than the estimate provided by ECCC of 67.2 mm at Key Lake Mine for the period 2011 to 2021 by approximately 4%

(https://climate.weather.gc.ca/prods_servs/engineering_e.html; https://collaboration.cmc.ec.gc.ca/cmc/climate/Engineer_Climate/IDF/). The calculated estimate is greater than the ECCC estimate likely owing to large rain events occurring in northern Saskatchewan in 2022.

The IDF_CC tool Version 5.0 (<https://www.idf-cc-uwo.ca/>) was used to estimate design events at the Project. The previous results reported based on generalized extreme value (GEV) distribution (79.9 mm in current scenario and 88.6 mm in a future scenario). IDF_CC tool Version 7.0 is the new version of the website and now, using GEV, estimates a 79.9 mm current scenario and 94.7 mm future scenario (RCP8.5 for time period 2015-2100). Within IDF_CC tool Version 7.0, the Gumbel distribution yields 80.9 mm in current scenario and 95.8 mm for future scenario (RCP8.5 and 2015-2100). These data, as well as similar estimates for the Project and Key Lake Mine are summarized in the following table where all estimates reflect a 1:100-year 24 hour precipitation event and all future scenarios assume RCP8.5 for 2015-2100. The Key Lake Mine is approximately 35 km south-southeast of the Project area for reference.

| Scenario Description | Statistical Method | Estimated Period | Location | Data Source | Data period (as indicated) | Estimate (mm) |
|--|-----------------------|------------------|--------------------|--|----------------------------|---------------|
| Environment Canada published IDF curves | Gumbel | Current | Key Lake Mine Site | Key Lake climate station (Station 4063753) | 2011-2021 | 67.2 |
| EIS Document | IDF_CC Tool 5.0 – GEV | Current | Project | Interpolated grid data | Not reported | 79.9 |
| EIS Document | IDF_CC Tool 5.0 – GEV | Predicted Future | Project | Interpolated grid data | RCP8.5 2015-2100 | 88.6 |
| Manual Calculation | Gumbel | 2014-2023 | Key Lake Mine Site | Key Lake climate station (Station 4063753) | 2014-2023 | 69.6 |
| IDF_CC Tool 7.0 | GEV | Current | Key Lake Mine | Key Lake climate station (Station 4063753) | 2011-2021 | 56.4 |
| IDF_CC Tool 7.0 | GEV | Predicted Future | Key Lake Mine | Key Lake climate station (Station 4063753) | RCP8.5 2015-2100 | 68.1 |
| IDF_CC Tool 7.0 | Gumbel | Current | Key Lake Mine | Key Lake climate station (Station 4063753) | 2011-2021 | 67.2 |
| IDF_CC Tool 7.0 | Gumbel | Predicted Future | Key Lake Mine | Key Lake climate station (Station 4063753) | RCP8.5 2015-2100 | 73.9 |
| IDF_CC Tool 7.0 | GEV | Current | Project | Interpolated grid data | 2011-2021 | 79.9 |
| IDF_CC Tool 7.0 | GEV | Predicted Future | Project | Interpolated grid data | RCP8.5 2015-2100 | 94.7 |
| IDF_CC Tool 7.0 | Gumbel | Current | Project | Interpolated grid data | 2011-2021 | 80.9 |
| IDF_CC Tool 7.0 | Gumbel | Predicted Future | Project | Interpolated grid data | RCP8.5 2015-2100 | 95.8 |

As seen in the table, a range of 1:100-year 24 hour rainfall events can be estimated using different methods, data sources and timeframes. The predicted future estimate originally presented using IDF_CC Tool 5.0 (Scenario 3) is lower only than those future estimates via Gumbel and GEV estimated for the same timeframe using IDF_CC Tool 7.0. The IDF_CC tools follows the same methodology as that used by ECCC and recommended by the above-referenced CSA document. The IDF_CC tool also makes use of a gridded climate data set and, though Key Lake Mine is only 35 km from the Project, the projected change in rainfall values is substantial. As such, the use of the IDF_CC tool is conservative. Further to that point, site facilities are designed in

consideration of the Probable Maximum Precipitation event of 493 mm. That event is more than 5 times higher the largest predicted scenario by any of the above presented methodologies.

Despite Denison's reiteration that the PMP is adequate for the EA level design basis, Denison is committed to revisiting the estimates of the IDF as per CNSC's recommendations, as applicable, for the licensing phase of the Project.

Attachment IR-103 (Round 3 submission)

Appendix 8-C of the EIS identified an IDF of 88.61 mm for the Rainfall 1:100, 24-hour return period for the period from 2020 to 2050 (see the table below).

| T (years) | 2 | 5 | 10 | 20 | 25 | 50 | 100 |
|-----------|-------|-------|-------|-------|-------|-------|-------|

These numbers were generated in the following manner:

- Using the IDF Online tool IDF_CC Tool 5.0 – Institute for Catastrophic Loss Reduction, FIDS – Faculty for Intelligent Decision Support and Western University (2021).
- Using the IDF Curves at ungauged locations option to estimate future IDF curve values under influences from climate change IDF.
- The Ungauged location used corresponds to the Wheeler River Project (latitude and longitude) = 57.51103 N, -105.37622 W
- The predictive period for the climate change scenario was set from 2020 to 2050 which is inclusive of the duration of the project up to the end of decommissioning.
- We examined the 1:100-year, 24-hour return period rainfall events.
- The Raw Global Climate Models (GCMs) were utilized in the predictions for the tool and all available models in this category were included for prediction (24 models).
- We assessed the SSP1.26 (RPC2.6 - Representative Concentration Pathway where radiative forcing peaks at 3 W/m² before 2100, declining to 2.6 W/m² by 2100. RCP 2.6 provides a future concentration scenario that would lead to the lowest climate change severity with respect to solar radiation when compared to scenarios associated with RCP 4.5 and 8.5. This may then account for the scenario of lesser evapotranspiration.

The Box Plot for the 1:100, 24-hour return period as generated by the IDF_CC tool is provided below:

IDF Graph: PPT - GEV - SSP1.26 - BoxPlot

Station: Ungauged IDF for: Lat: 57.51103 °, Lon: -105.37622 °, All models, projection period:
2020 to 2050

The median rainfall 1:100 year, 24 hr return period is 88.61 mm. Additional statistics are provided below for further context with respect to variability in this estimate.

Statistics:

Series T = 100

Duration = 24 hours (1440 min)

Lower bound = 75.16 mm

25th Percentile = 80.89 mm

Median = 88.61 mm

75th Percentile = 92.52 mm

95th Percentile = 104.45

Upper bound = 109.95 mm

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 28, 2024) |
|--------------|----------------|---|---|---|---|--|--|--|
| IR-107 | - | <p>Context: Under the methodology and metrics section (8.2.3.1) it is stated baseline water quality was sampled in 2016, 2018, and 2019. Looking at the data in Appendix A of Appendix 8D it seems that some waterbodies have little data available for baseline characterization. For example, Whitefish Lake only has 3 and 5 samples taken between its two sample stations, with sampling frequency seeming intermittent.</p> <p>Rationale: The amount of data available for baseline water quality characterization does not seem sufficient to adequately characterize the baseline and the variation it would experience. An effective baseline characterization is vital to ensure water quality is indeed not being affected by the project. In addition, it is not clear if data quality objectives were applied to determine baseline information was adequate.</p> <p>To meet CEAA 2012 requirements, and CNSC expectations outlined in REGDOC 2.9.1, Environmental Principles Assessments and Protection Measures, the applicant is required to complete a characterization of the baseline environment.</p> <p>As described in REGDOC 2.9.1 Appendix B.2, Characterization of the Baseline Environment for Environmental Assessment Under CEAA 2012, the “baseline information should be sufficient to support the use of an aquatic dispersion model to conduct the site-specific ERA and to support an assessment of the effects of the environment on the facility or activity”</p> <p>In addition, the “applicant or licensee should include an assessment of any limitations or gaps in the quality and extent of baseline data and methods, as well as the method(s) by which they have been addressed.”</p> | <p>Please clarify what data quality objectives were used for the baseline characterization data. Please provide justification whether the number of datapoints collected with inconsistent frequency in baseline surface water characterization is sufficient to meet data quality objectives and to adequately characterize the baseline, and whether Denison is confident that the data collected is enough for a robust water quality baseline characterization.</p> <p>Suggestions for mitigation and follow-up measures: CNSC recommends that additional water samples are collected and analyzed at a consistent frequency to ensure a robust baseline</p> | <p>Surface water quality was sampled through 2016, 2018, and 2019 on a monthly basis which is generally consistent with federal requirements for assessing potential impacts through EA. Hydrological assessment has occurred from 2011 to 2019. Mean Annual Discharge (MAD) (m³/s) as measured at the Water Survey Canada (WSC) Wheeler River Watershed Station (06DA005) during 2016, 2018 and 2019 was 17.07, 17.34 and 19.23, respectively, all of which were slightly above the 43 year (1977 to 2019) average of 16.82. The MAD in 2016 and 2018 can be considered near average, with 2019 being considered an average-high flow year, but well below the maximum observed for the timeseries (27.62 m³/s). Since this period, there have been no land use changes within the area that would constitute a major change in water quality.</p> <p>Baseline water quality samples were collected during years of average to average-high flows in the Wheeler River system and therefore representative of background conditions for assessment of potential impacts in the EIS. Additional conservatism was included in the impact assessment by using the 95th percentile values for baseline parameter concentrations when modelling potential effluent effects. As such, the surface water quality data collected are suitable for the intended purpose of assessing potential impacts and the additional conservativisms that were included as part of the assessment were precautionary.</p> <p>Given the above, Denison feels strongly that the baseline water quality data collected are suitable for the purposes of the EIS and the application of additional conservativisms in the use of the data provide a conservative (i.e., protective) framework for evaluating potential effects.</p> <p>Denison commits to the collection of additional surface water quality baseline data prior to project development starting to ensure updated baseline information is available for identification of any changes that might influence estimates of Project impacts. These data will be used to support permitting and licensing through updates to the ERA.</p> | <p>This response has not been accepted.</p> <p>From the baseline water quality data table (Table A-1 of Appendix 8D) it remains unclear that water quality was sampled on a monthly basis in 2016, 2018, and 2019, mainly due to Table A-1 referring to specific sampling dates, instead of an mean value of 12 samples/year. It is also unclear which federal requirements Denison is referring to using in their response. Staff are supportive of continued baseline monitoring to maintain an accurate dataset of baseline conditions.</p> <p>CNSC and ECCC staff have the following expectations:</p> <p>1. Provide the monthly monitoring data referenced in the response or indicate where it can be found within the EIS and its appendices.</p> <p>2. Confirm which federal requirements were used when assessing potential impacts through EA.</p> <p>3. Confirm which data quality objectives were used to establish the baseline, provide references if available</p> <p>4. Incorporate the additional available baseline data collected into the analysis and conclusions of the finalized EIS and ERA to increase the robustness of the established baseline.</p> | <p>The response to this IR is provided in Attachment IR-107 (below).</p> | <p>Before this IR is accepted, the Proponent is requested to provide the statistical correlation analysis to confirm that data is correlated.</p> <p>Additionally, the four expectations set out in the rationale for status have not been adequately responded to. The Proponent should incorporate the following information into the EIS and ERA:</p> <ol style="list-style-type: none">1. Provide raw baseline data (perhaps in an appendix).2. Provide summary statistics for baseline datasets, which at a minimum should include: mean, standard deviation, 95th percentiles, minimum, maximum, and number of samples. Present summary statistics by season (i.e., freshet, summer, fall and under-ice), and include comparisons to relevant water quality guidelines.3. Identify potential gaps in baseline datasets, and indicate how data gaps will be addressed. Describe the planned baseline monitoring to be conducted including, but not limited to, addressing any data gaps.4. Demonstrate that the combined existing baseline data and planned baseline monitoring will yield dataset(s) that provide robust water quality baseline characterization of seasonal conditions (i.e., freshet, summer, fall, under-ice during winter), including a range of flow conditions. <p>The Proponent should also incorporate the additional baseline data collected into the analysis and conclusions of the finalized EIS and ERA.</p> <p>Concerning the other aspects of the IR, these responses are accepted based on Denison's commitment to conduct periodic sampling prior to construction to strengthen existing environmental data. CNSC staff will review this information to ensure EA predictions remain valid and recommend collecting samples in the fall to spring timeframe, as samples from these seasons is sparse in the current dataset.</p> | <p>Information specific to the statistical correlation or consistency in data between waterbodies during baseline investigations is provided in Attachment IR-107-R3 (below).</p> <p>Additionally, the four expectations outlined by ECCC are discussed herein.</p> <ol style="list-style-type: none">1. All raw baseline data was provided in Appendix A-1 of Appendix 8-D of the EIS.2. Appendix A-1 of Appendix 8-D included the following: mean, SD, 75th percentile, 95th percentile, minimum, maximum, sample size (n) and screening against criteria by date.3. Denison and its SME does not consider that there are data gaps per se, as it concerns the data used for the purpose of the EIS. Denison and its SME feel strongly that the baseline water quality data collected are suitable for the purposes of the EIS and the application of additional conservativisms in the use of the data provide a conservative (i.e., protective) framework for evaluating potential effects. The data are spatially robust (in that they cover various sampling nodes in potentially affected watersheds that at this time are all subject to the same land use (or lack thereof) and samples have been collected during multiple seasons. Denison is in agreement that regular water quality data collection should be instituted and commits (Commitment 8-48 to beginning such periodic sampling prior to construction to provide a more robust dataset and following the CCME Guidance Manual for Optimizing Water Quality Monitoring Program Design (2015). Sampling will be conducted monthly during the open water period and twice under ice. Any new water quality data will be integrated into Denison's application for a licence to operate, along with updated effluent quality data. Additionally, we remind the CNSC that treated mine effluent release does not occur until operational commissioning.4. As noted above, information specific to the statistical correlation or consistency in data between waterbodies during baseline investigations is provided in Attachment IR-107-R3 (below). <p>Given the above (as well as the information provided in Attachment IR-107-R3), Denison and its SME do not feel additional analyses with additional baseline data are needed at this time, as suggested by ECCC, to inform EIS conclusions. Nevertheless, Denison will commit to update the analysis and predictions incorporating any new data collected during pre-construction as part of the operational licensing, however there is no expectation that there would be any change to the EIS conclusions (see IRs 113, 114 and 115 for more detail in this regard).</p> |

Attachment IR-107 (included in Round 2 submission)

Denison's Response:

The water quality sampling for baseline was conducted over several years from 2011 to 2019. In years 2015 and 2017 sampling did not occur. Sampling occurred during the open water period and most consistently in May, June, August, September and October. The reviewer is correct in that sampling did not occur on a monthly basis at each of the sampling locations over all years. The table below provides a summary of the periodicity of sampling as it occurred over the described period at each station.

| Station ID | 2011 | | 2012 | | | 2013 | | 2014 | | 2016 | 2018 | | 2019 | | Total |

1. The table above identifies that monthly sampling was not completed at each station on an annual basis.
2. For the purposes of the EA, a statistical analysis was conducted to identify the correlation between the water quality data for LA-1, LA-5, LA-6, and McGowen Lake and the full dataset for the LSA. Datasets were highly correlated and therefore the full dataset for the LSA was used as background concentrations in the IMPACT model. This approach was taken to meet the criteria of REGDOC 2.9.1 Appendix B.2, Characterization of the Baseline Environment for Environmental Assessment Under CEAA 2012, the “baseline information should be sufficient to support the use

of an aquatic dispersion model to conduct the site-specific ERA and to support an assessment of the effects of the environment on the facility or activity”.

3. Samples were collected following applicable field protocols and analysis was conducted by CALA accredited laboratories. The conceptualization of sampling in this remote location loosely followed the CCME Guidance Manual for Optimizing Water Quality Monitoring Program Design (2015). However, due to the remote nature during the baseline sampling, monthly sampling was not deemed feasible.
4. There are no additional data to add to the analysis at this time for either the near-field or far-field water quality models. It is noted that some additional sampling occurred at Whitefish Lake offshore in the general, vicinity of the proposed discharge (diffuser) location in 2022 and continued in 2023. The concentration of constituents from samples collected in 2022 and 2023 were in the range of those measured previously and as a result no changes to the outcomes of the analyses presented in the Draft EIS and its supporting documents would be expected. Denison agrees that regular water quality data collection at a wider range of sampling stations should be instituted and commits to beginning such periodic sampling prior to construction to provide a more robust dataset and following the CCME Guidance Manual for Optimizing Water Quality Monitoring Program Design (2015). These data would be used to support the licensing process and contribute to the longer term data records for the site.

Attachment IR-107 (Round 3 submission)

Water quality of the waterbodies within the local study area (LSA) of the Wheeler River Project was surveyed over the period 2011 through 2019 as part of the aquatic environment baseline studies. Generally, surface waters within the LSA are soft and have typically low levels of alkalinity, nutrients (nitrate and phosphorus), total dissolved solids, and total suspended solids. The pH of surface waters within the LSA is slightly acidic to neutral. The concentrations of metals and metalloids are similar throughout the study area. Radionuclide concentrations are low, with the majority of measurements lower than their respective laboratory detection limits.

To determine which dataset was more appropriate to be used as baseline concentrations in the IMPACT model for the purposes of the Environmental Assessment, a statistical analysis of water quality data was undertaken to identify the correlation between the water quality data for only the key assessed lakes (LA-1, LA-5, LA-6, LA-7, and Russell Lake) and the full dataset for all waterbodies surveyed within the LSA.

For the purposes of the Environmental Assessment, a statistical analysis was undertaken to identify the correlation between water quality data from the key assessed lakes (LA-1, LA-5, LA-6, LA-7 and Russell Lake) and from the full dataset for the local study area (LSA), to determine which dataset was more appropriate for use as background concentrations in the IMPACT model.

The following provides methods and results and a summary of findings of this analysis.

Water quality data for lakes and creeks in the LSA were obtained for multiple monitoring events from June 2011 to September 2019. The data consisted of measurements of chemical parameters including physical tests (e.g., major ions and metals concentrations), nutrient tests (e.g., ammonia), and radionuclides (e.g., Pb-210). Data were inputted into the Ecometrix database software Environmental Monitoring Modeling Application (EMMA) and contained indicators for when measurements were less than the reported detection limit (RDL). The parameters examined herein are those chemicals of potential concern (COPC) for purposes of the Environmental Assessment (Table 1).

For the comparison, summary statistics were generated for two datasets: the full dataset and a subset of the key assessed lakes and creeks that link the key assessed lakes. The summary statistics including the number of measured samples (N), the number of measured samples below the reported detection limit (N<RDL), the minimum, the 95th percentiles, the maximum, and the geometric mean and standard deviation were calculated for both datasets using EMMA. For measurements below RDL, the detection limit value was used when generating summary statistics. Finally, the percent difference between geometric mean values of the two datasets were calculated per COPC.

The mean percent difference of key assessed lakes relative to the full LSA dataset across all COPC's was 0% (n = 24) with a minimum absolute percent difference of 0% and an absolute maximum percent difference of 16%. There were 20/24 (83%) with an absolute maximum percent difference of 5% and 22/24 (92%) with an absolute maximum percent difference of 10% (Table 1).

These low percent differences indicated that the datasets are highly correlated and because the full dataset also contained more datapoints and waterbodies, the full dataset for all waterbodies surveyed within the LSA was deemed most appropriate to be used as baseline concentrations in the IMPACT model.

Table 1 Summary statistics and percent difference calculations for COPC water quality parameters in the full LSA dataset (shaded) and key assessed lakes (unshaded).

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 28, 2024) |
|--------------|----------------|---|--|---|---|--|--|---|
| IR-108 | - | <p>Context: Tables 8.2-2 and 8.2-3 provide summaries of the baseline surface water quality in the LSA. No justifications for the selection of water quality guidelines have been provided. COPCs that require calculations based on other parameters such as hardness, pH, or temperature to derive guidelines (i.e., ammonia, cobalt, zinc, etc.) should be indicated within the table, with a note specifying the parameter values used in the calculations, so that thresholds may be confirmed. No baseline data for un-ionized ammonia has been provided, which is a Schedule 4 substance requiring monitoring under the MDMER. For cobalt, manganese, and vanadium, Federal Environmental Quality Guidelines (FEQGs) and/or CCME Canadian Water Quality Guidelines (CWQGs) for the Protection of Aquatic Life have not been included. A guideline of 26 mg/L has been provided for molybdenum as a Saskatchewan Environmental Quality Guidelines (SEQG), however the actual SEQG is 31 mg/L and the CCME CWQG is 0.073 mg/L.</p> <p>Rationale: In order to assess potential changes to surface water quality from Project related activities, ECCC requires that data on all parameters that require MDMER effluent and receiving environment monitoring be provided for assessment, including accurate water quality guidelines where available.</p> | <p>1. Update Tables 8.2-2 and 8.2-3 to include all COPCs that require effluent characterization and receiving environment monitoring under the MDMER.</p> <p>2. Update Tables 8.2-2 and 8.2-3 to include missing or corrected water quality guidance thresholds, and information on values used to derive thresholds for COPCs that are dependent on general parameters.</p> | Please see Attachment IR-108. | <p>This response has not been accepted.</p> <p>There are incorrect guidelines remaining in the updated tables, and the supporting information on parameter values used to derive benchmarks has not been provided. This information is required to understand potential changes to surface water quality from Project related activities and facilitate threshold confirmation. Use of the incorrect threshold could allow for effluent to be discharged at concentrations exceeding MDMER limits.</p> <p>See also follow-up IR-108-R1.</p> | Please see response to IR-108 and Attachment IR-108. | <p>The IR has only been partially resolved. In item one, temperature is still missing from updated tables in attachment IR-108, 8.2-2 and 8.2-3. The Proponent should add this to the tables.</p> <p>In item two, Tables 8.2-2 and 8.2-3 still contain numerous incorrect guidelines. Additionally, the information on values used to derive thresholds for COPCs that are dependent on general parameters contain inconsistencies which should be corrected or explained.</p> <p>The table does not specify if metal concentrations are total or dissolved. The long-term benchmark column includes both guidelines for dissolved metals (e.g. aluminum, manganese) and total metals (e.g. iron, selenium). The table should be updated to clarify if metal concentrations are total or dissolved and include the appropriate benchmarks.</p> <p>For metal parameters, for which guidelines are dependent on environmental modifying parameters, site specific environmental parameters should be used to select the most appropriate guideline. Specific inconsistencies noted are:</p> <ul style="list-style-type: none">• Aluminum – guideline may change depending on site specific pH.• Ammonia (as N) – should be calculated at site specific pH and water temperature reached during the summer.• Ammonia (un-ionized) – The CCME long-term guideline is 0.019 mg/L, so the reference is incorrect.• Boron – The CCME has both short- and long-term guidelines for total boron (29 & 1.5 mg/L) which should be included in the tables.• Chromium – The type of chromium should be specified. The benchmark specified is the CCME guideline for hexavalent chromium, it is not clear if this was also used for the measured concentrations.• Cobalt – The FEQG added as a benchmark includes a specific hardness range and does not apply to the soft waters found on site and should be removed. The guideline is for water with hardness between 52-396 mg/L and table footnote #2 states: “<i>Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).</i>”• Copper - the CCME guideline applied for copper is out-dated (1987) and does not reflect the current state of science. The FEQG for copper (2021) reflects the current science utilizing the biotic ligand model and is a more appropriate screening criterion.• Dissolved phosphorous & phosphorous – Table footnote #17 states the guidelines for a meso-eutrophic waterbody were used. Use of this guideline should be justified because all sample locations except one had non-detectable phosphorous and dissolved phosphorous concentrations with a detection limit on the upper end of the oligotrophic cutoff, indicating oligotrophic status. Though dissolved phosphorous concentrations were detected at site LB-2, phosphorous concentrations at this site were not detectable, which suggests issues with the measurements. These measurements are therefore not reliable enough to base a trophic status for the region.• Manganese – Table footnote #3 states pH of 7.5 and hardness of 15 mg/L were used to calculate the benchmark for dissolved manganese. Justification is required for using a hardness above the site-specific hardness used in footnote #2 (5.26 mg/L) and site-specific pH should be used.• Nickel – The long-term benchmark has been changed from the CCME guideline of 0.025 mg/L total nickel to the WHO drinking water guideline of 0.070 mg/L. It is noted that a drinking water quality guideline may not be protective of aquatic life and the more stringent CCME guideline for the protection of aquatic life is the more appropriate benchmark for the receiving environment so the original benchmark should be retained.• Strontium – The guideline added for strontium (205 mg/L) is incorrect. The FEQG for dissolved strontium is 2.5 mg/L | <p>Please refer to Attachment IR-108 / 108-R1 which provides EIS table updates specific to this IR Round 3. Denison and its SME reiterate that any clarifications made in the EIS in response to this IR would not change the conclusions of the assessment.</p> <p>For reference the following are noted:</p> <p>Temperature has been added to both tables.</p> <p>All metal parameter values listed are total metals. The concentrations of metal constituents in total form can only be equal to or greater than dissolved constituent concentrations. There use of dissolved water quality criteria in some instances is therefore a conservative approach, since the comparison to the dissolved criterion is with the measured total concentration.</p> <p>For metal parameters that are listed in the third round IR, please see the updated tables, including updated notes per below.</p> <ul style="list-style-type: none">• Aluminum - Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.• Ammonia (as N)- Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0,• Ammonia (Un-ionized) changed to 0.019 mg/L• Boron – criteria added• Chromium – Measured concentrations were Total Chromium, therefore conservative screening as total chromium would be higher in water than only the hexavalent concentration.• Cobalt was retained in the table using the lowest hardness of 52 mg/L from the FEQG equation for the purposes of consistency with the ERA and to ensure a guideline is available for comparison. We acknowledge that there is some uncertainty with this extrapolation.• Copper was recalculated using the BLM tool (2021) see table notes for further detail, and was used for screening purposes of background concentrations. <p>In certain instances, background copper concentrations were above the BLM calculated screening criteria. However, N288.6 Section 7.2.5.3.2 identifies; <i>Screening criteria should not be set below a reasonable upper end of background.</i> <i>Note: Upper end of background concentrations may be taken from literature sources or determined locally from analysis of measurements in reference areas. In Ontario, OMECP (1993) has defined the upper end of background concentrations for many contaminants in soil.</i></p> <p>For this reasoning, subsequent screening of copper in effluent and in the receiving environment was kept consistent at the CCME guideline of 0.002 mg/L.</p> <ul style="list-style-type: none">• Dissolved phosphorus changed to the oligotrophic benchmark.• Manganese benchmark changed using the consistent modifying factors as used for other parameters (see notes).• Nickel benchmark changed back to 0.025 mg/L which is the more stringent CCME guideline for the protection of aquatic life.• Strontium benchmark was a typo and the correct benchmark has been included as 2.5 mg/L (FEQG). |
| IR-108 | IR-108-R1 | <p>Context: Incorrect benchmark environmental quality guidelines and guidelines that cannot be verified remain within the updated Tables 8.2-2 and 8.2-3 provided in the Proponent's response. The Proponent provided an Aluminum Saskatchewan Environmental Quality Guidelines (SEQG) value of 0.005 mg/L in both tables. This is incorrect and appears to</p> | n/a | n/a | <p>1. Update Tables 8.2-2 and 8.2-3 to include footnotes with the concentrations of environmental modifying parameters such as pH, hardness and DOC used to derive guidelines for Aluminum, Cadmium, Copper, Lead,</p> | Please see response to IR-108 and Attachment IR-108. | <p>Item one has been partially addressed, but additional corrections to the footnotes of Tables 8.2-2 and 8.2-3 are needed for copper, manganese, nickel and zinc. Additionally, table footnote #9 does not specify the DOC, pH or hardness values used to calculate the dissolved zinc benchmark. The Proponent should provide the corrections to Tables 8.2-2 and 8.2-3, as well as specify the DOC, pH and hardness values used to calculate the dissolved zinc benchmark. Follow up to items two and three can be found under IR-108.</p> | <p>Please see Attachment 108-R3 for updates to the table notes, which provide the updated information requested.</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 28, 2024) |
|--------------|----------------|--|--------------------------|---|--|---------------------------------------|----------------------------|---|
| | | <p>be the guideline for irrigation, not the guideline for protection of aquatic biota. The Proponent provided a Molybdenum SEQG of 26 mg/L in both tables.</p> <p>This value is incorrect. The correct SEQG for Molybdenum is 31 mg/L and the Canadian Water Quality Guideline (CWQG) is 0.073 mg/L. The Proponent provided a Nitrate SEQG of 13.29 mg/L in both tables. This value is incorrect. The correct SEQG for Nitrate is 3 mg/L and the CWQG is 13 mg/L.</p> <p>Rationale: In order to verify the benchmark environmental quality guidelines that are calculated based on environmental modifying factors such as pH, hardness and dissolved organic carbon (DOC), the specific concentrations of these environmental modifying parameters used in the calculations must be provided. Additionally, incorrect benchmarks for Aluminum, Molybdenum, and Nitrate remain within the updated tables provided by the Proponent. No benchmark was provided for Manganese. It is not clear if Total Chromium or Hexavalent Chromium was measured as the table does not specify, and the benchmark provided was for Hexavalent Chromium. This information is required to understand potential changes to surface water quality from Project related activities and facilitate threshold confirmation. Use of the incorrect threshold could allow for effluent to be discharged at the wrong concentration.</p> | | | <p>Manganese, Nickel and Zinc.</p> <p>2. Update Tables 8.2-2 and 8.2-3 to include the correct benchmark guideline value for Aluminum, Molybdenum and Nitrate. Include the concentrations of environmental modifying parameters needed for deriving guidelines. If the most stringent guideline value is not selected for use, provide a rationale for use of the chosen guideline.</p> <p>3. Update Tables 8.2-2 and 8.2-3 to include the calculated guideline value for manganese and the environmental modifying parameter concentrations used to calculate the guideline. A benchmark environmental quality guideline has not been provided for Manganese, however a chronic CWQG guideline exists that can be derived based on environmental modifying parameter concentrations.</p> <p>Update Tables 8.2-2 and 8.2-3 to specify if Total Chromium or Hexavalent Chromium was measured.</p> <p>See also related IR-115-R1.</p> | | | |

Attachment: IR-108 (included in Round 1 submission)

Response:

Tables 8.2-2 and 8.2-3 will be updated in the final EIS to include 1) all COPCs that require effluent characterization and receiving environment monitoring under the MDMER and 2) missing or corrected water quality guidance thresholds, and information on values used to derive thresholds for COPCs that are dependent on general parameters. The updated EIS tables are provided below for completeness.

Table 8.2-2: Baseline Surface Water Quality in Local Study Area Lakes and Russell Lake (Updated)

Notes:

Green-highlighted cells indicate values that fall below the analysis detection limit.

Bold values indicate metrics that exceed benchmark values.

Italicized values include a temperature point estimated from an adjacent water body taken in the same season

Blank cells in the "benchmark" column indicate parameters without a prescribed benchmark at this time

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Notes:

Green-highlighted cells indicate values that fall below the analysis detection limit.

Bold values indicate metrics that exceed benchmark values.

Italicized values include a temperature point estimated from an adjacent water body taken in the same season

Blank cells in the "benchmark" column indicate parameters without a prescribed benchmark at this time

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Attachment: IR-108 / IR – 108-R1 (included in Round 2 submission)

Response:

Tables 8.2-2 and 8.2-3 have been updated as requested and are provided below and updated in the EIS in their respective sections.

Table 8.2-2: Baseline Surface Water Quality in Local Study Area Lakes and Russell Lake

Notes:

- (1) Saskatchewan Water Quality Objectives, SEQG on-line (<https://envbrportal.crm.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations, a temperature of 15°C and a pH of 7.0.
- (2) Hardness dependent WQOs are for very soft water (hardness <25 mg CaCO₃/L). Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
- (3) Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 7.5, hardness = 15 mg/L). Guideline is based on dissolved manganese. Benchmark = $\exp(0.878[\ln(\text{hardness})] + 4.76)$ where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO₃ equivalents in mg/L.
- (4) Total ammonia-N calculated from the total ammonia guideline for a temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>)
- (5) Based on a pH of >6.5.
- (6) Based on water hardness >0 to <17 mg/L.
- (7) Based on water hardness >0 to <82 mg/L.
- (8) Based on water hardness >0 to ≤60 mg/L equation used at hardness of 5.26. At hardness >180 mg/L, the CWQG is 7 µg/L
- (9) Guideline is based on dissolved zinc.
- (10) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and site-specific baseline hardness of 15 mg/L.
- (11) ECCC 2020. Federal Environmental Quality Guidelines Strontium. July.
- (12) BC MECCS 2021. British Columbia Approved Water Quality Guidelines: Aquatic Life, Wildlife & Agriculture. https://www2.gov.bc.ca/assets/gov/environment/air-land-water/water/waterquality/water-quality-guidelines/approved-wqgs/wqg_summary_aquaticlife_wildlife_agri.pdf
- (13) Environment Canada 2016. Federal Environmental Quality Guidelines, Vanadium. May.

- (15) BC MECCS 2020. Source Drinking Water Quality Guidelines, Guideline Summary Ministry of Environment & Climate Change Strategy Water Protection & Sustainability Branch .
- (16) WHO 2017. Guidelines for Drinking Water Quality. Fourth Edition Incorporating The First Addendum.
- (17) Framework - guideline for meso-eutrophic waterbody 20-35 µg/L
- (18) Based on water hardness of >0 to <5.3 mg/L
- (19) Based on hardness of 5 mg/L (Short-term equation is $(e^{(0.979123[\ln(\text{hardness})] - 8.64497)}) * 1000$ (SEQG via AEP 1996b)
- (20) Based on benchmark = $\exp(0.833[\ln(\text{hardness mg·L}^{-1})] + 0.240[\ln(\text{DOC mg·L}^{-1})] + 0.526)$. Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6). Site-specific DOC is 2.2 (arithmetic mean for LA-5 and LA-6), induced hardness of 250.5 used as upper limit of extrapolation available.
- (21) based on water hardness of > 250 mg/L (CaCO₃)
(251 mg/L)
- (22) MDMER Schedule 4 - maximum authorized montly mean concentration
- (23) Bold numbers indicate exceedance of long-term criteria
- SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.
- CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.
- SSWQO – Saskatchewan Surface Water Quality Objectives.
- DOC – Dissolved organic carbon.
- TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Notes:

(1) Saskatchewan Water Quality Objectives, SEQG on-line (<https://envrbrportal.crm.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations, a temperature of 15°C and a pH of 7.0.

(2) Hardness dependent WQOs are for very soft water (hardness <25 mg CaCO₃/L). Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).

(3) Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 7.5, hardness = 15 mg/L). Guideline is based on dissolved manganese. Benchmark = $\exp(0.878[\ln(\text{hardness})] + 4.76)$ where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO₃ equivalents in mg/L.

(4) Total ammonia-N calculated from the total ammonia guideline for a temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>)

(5) Based on a pH of >6.5.

(6) Based on water hardness >0 to <17 mg/L.

(7) Based on water hardness >0 to <82 mg/L.

(8) Based on water hardness >0 to ≤60 mg/L equation used at hardness of 5.26. At hardness >180 mg/L, the CWQG is 7 µg/L

(9) Guideline is based on dissolved zinc.

(10) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and site-specific baseline hardness of 15 mg/L.

(15) BC MECCS 2020. Source Drinking Water Quality Guidelines, Guideline Summary Ministry of Environment & Climate Change Strategy Water Protection & Sustainability Branch .

(16) WHO 2017. Guidelines for Drinking Water Quality. Fourth Edition Incorporating The First Addendum.

(17) Framework - guideline for meso-eutrophic waterbody 20-35 µg/L

(18) Based on water hardness of >0 to <5.3 mg/L

(19) Based on hardness of 5 mg/L (Short-term equation is $(e^{(0.979123[\ln(\text{hardness})] - 8.64497)}) * 1000$ (SEQQ via AEP 1996b)

(20) Based on benchmark = $\exp(0.833[\ln(\text{hardness mg-L}^{-1})] + 0.240[\ln(\text{DOC mg-L}^{-1})] + 0.526)$. Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6). Site-specific DOC is 2.2 (arithmetic mean for LA-5 and LA-6), induced hardness of 250.5 used as upper limit of extrapolation available.

(21) based on water hardness of > 250 mg/L (CaCO_3) (251 mg/L)

(22) MDMER Schedule 4 - maximum authorized monthly mean concentration

(23) Bold numbers indicate exceedance of long-term criteria

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Attachment: IR-108 / IR – 108-R1 (Round 3 submission)

Response:

Tables 8.2-2 and 8.2-3 have been updated as requested and are provided below. The updated versions of the tables have also been inserted into the final EIS in their respective sections.

Table 8.2-2: Baseline Surface Water Quality in Local Study Area Lakes and Russell Lake

Notes:

All parameters listed as total concentrations unless otherwise specified.

Saskatchewan Water Quality Objectives, SEQG on-line (<https://envrbrportal.crm.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations.

Bold numbers indicate exceedance of a long-term criterion.

Bold and italicized indicate exceedance of the short-term criterion and long-term criterion.

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Temperature - Maximum Weekly Average Temperature: Thermal additions to receiving waters should be such that the maximum weekly average temperature is not exceeded. Short-term Exposure to Extreme Temperature: Thermal additions to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect the important species.

pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).

- (1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.
- (2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>).
- (3) Based on water hardness of >0 to <5.3 mg/L (Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
- (4) Based on water hardness >0 to <17 mg/L.
- (5) Guideline specific to Chromium VI for conservative comparison to baseline water quality
- (6) Based on hardness of 5.26 mg/L (Short-term equation is $(e^{(0.979123[\ln(\text{hardness})]-8.64497)}) * 1000$ (SEQG via AEP 1996b)
- (7) Federal Water Quality Guideline for Copper Biotic Ligand Model (BLM) Tool and User Manual, (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6)
- (8) Short Term Guideline is based on dissolved manganese. Benchmark = $\exp(0.878[\ln(\text{hardness})] + 4.76)$ where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO₃ equivalents in mg/L. (Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
- (9) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L).

- (10) Framework provides Trigger Ranges for Total Phosphorus ($\mu\text{g/L}$) - guideline for oligotrophic waterbody 4 - 10 $\mu\text{g/L}$
- (11) MDMER Schedule 4 - maximum authorized monthly mean concentration
- (12) Guideline is based on dissolved zinc.
- (13) Short term guideline is based on Benchmark = $\exp(0.833[\ln(\text{hardness mg-L}^{-1})] + 0.240[\ln(\text{DOC mg-L}^{-1})] + 0.526)$. (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
- (14) Long term guideline is based on CWQG = $\exp(0.947[\ln(\text{hardness mg-L}^{-1})] - 0.815[\text{pH}] + 0.398[\ln(\text{DOC mg-L}^{-1})] + 4.625)$. (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.

Notes

All parameters listed as total concentrations unless otherwise specified.

Saskatchewan Water Quality Objectives, SEQG on-line (<https://envrbrportal.crm.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations.

Bold numbers indicate exceedance of a long-term criterion.

Bold and italicized indicate exceedance of the short-term criterion and long-term criterion.

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Temperature - Maximum Weekly Average Temperature: Thermal additions to receiving waters should be such that the maximum weekly average temperature is not exceeded. Short-term Exposure to Extreme Temperature: Thermal additions to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect the important species.

A pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).

- (1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.
- (2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>).
- (3) Based on water hardness of >0 to <5.3 mg/L (Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
- (4) Based on water hardness >0 to <17 mg/L.
- (5) Guideline specific to Chromium VI for conservative comparison to baseline water quality
- (6) Based on hardness of 5.26 mg/L (Short-term equation is $(e^{(0.979123[\ln(\text{hardness})]-8.64497)}) \times 1000$ (SEQG via AEP 1996b)
- (7) Federal Water Quality Guideline for Copper Biotic Ligand Model (BLM) Tool and User Manual, (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6)
- (8) Short Term Guideline is based on dissolved manganese. Benchmark = $\exp(0.878[\ln(\text{hardness})] + 4.76)$ where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO₃ equivalents in mg/L. (Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
- (9) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L).

- (10) Framework provides Trigger Ranges for Total Phosphorus ($\mu\text{g/L}$) - guideline for oligotrophic waterbody 4 - 10 $\mu\text{g/L}$
- (11) MDMER Schedule 4 - maximum authorized monthly mean concentration
- (12) Guideline is based on dissolved zinc.
- (13) Short term guideline is based on Benchmark = $\exp(0.833[\ln(\text{hardness mg}\cdot\text{L}^{-1})] + 0.240[\ln(\text{DOC mg}\cdot\text{L}^{-1})] + 0.526)$. (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
- (14) Long term guideline is based on CWQG = $\exp(0.947[\ln(\text{hardness mg}\cdot\text{L}^{-1})] - 0.815[\text{pH}] + 0.398[\ln(\text{DOC mg}\cdot\text{L}^{-1})] + 4.625)$. (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
- (15) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L.

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 26, 2024) |
|--------------|----------------|--|--|--|---|--|---|--|
| IR-110 | - | <p>Context: It is stated that the diffuser at the final effluent discharge point will be located in approximately 3m of water. However, in Figure 8.2-5 displaying the location of the proposed diffuser and lake bathymetry, the diffuser location seems to be located in 2-2.5m of water. A similar image in Figure 1 Section 2.0 of Appendix 8-E also indicates that the diffuser seems to be located in 2-2.5m of water. Additionally, while thermal effects are unlikely, this cannot be confirmed until a more detailed diffuser design is provided for review.</p> <p>Rationale: The Proponent should confirm the location and depth of the proposed diffuser in order to confirm that modelling predictions for effluent discharged into the receiving environment are accurate.</p> | <p>Provide confirmation of the diffuser depth and location.</p> <p>ECCC requests the opportunity to review the finalized diffuser design once it is available.</p> | <p>The diffuser will be placed at a depth between 2.5 and 3 m. The mapping provided in the draft EIS and Appendix 8-E is based on coarse bathymetric information, which will be supplemented with more robust bathymetric surveys to support final siting and design associated with permitting and licensing.</p> | <p>This response has not been accepted.</p> <p>ECCC requests confirmation that the finalized diffuser design will be available for review once it is completed as reviewing it will be necessary to confirm the location and depth of the proposed diffuser and modelling predictions for effluent discharged into the receiving environment.</p> | <p>It is noted that basic design criteria (e.g., depth, location, port configuration) have been provided in the Draft EIS (Section 8.2) and Appendix 8-E on which modeling was based. While some minor adjustments may be made during preparation of the final diffuser engineering design, the level of mixing predicted in the assessment will be maintained (minimally). The final designs will follow standard engineering practice and be stamped and signed by a professional engineer.</p> <p>As for Denison’s understanding of the regulatory process, the finalized diffuser design information will be included in Denison's license to operate application that will be submitted to the CNSC. Such information will also be provided to the province as part of the provincial approvals process. Should CNSC, or the province, choose to provide this information to ECCC that is their discretion, but Denison doesn’t believe it is within their purview (or appropriate) to make commitments on behalf of others, nor act outside the normal licensing/ approvals processes.</p> | <p>This IR is conditionally accepted. As Denison is unable to provide the finalized diffuser design, a commitment should be captured in the Commitments Register that the final diffuser configuration will not change the environmental assessment conclusions of risk to aquatic receptors and that water quality will remain below guidelines.</p> <p>Once Denison has added a commitment that the final diffuser design will not change the environmental assessment conclusions of risk to aquatic receptors and that water quality will remain below guidelines to the Commitments Register, this can be accepted.</p> <p>Note, if there are deviations from predicted effluent and near-field surface water concentrations of COPCs and risk to aquatic receptors due to the finalized diffuser design, this would be addressed through Denison identifying and implementing mitigation measures (e.g., treatment) to ensure that the environmental assessment conclusions of risk to aquatic receptors will not change and that water quality will remain below guidelines.</p> <p>Proposed rationale text for posting: Denison has captured a commitment in the Commitments Register that the final diffuser configuration will not change the environmental assessment conclusions of risk to aquatic receptors and that water quality will remain below guidelines, so this IR has been accepted.</p> <p>Any outstanding issues will be further assessed as part of licensing technical reviews, prior to the granting of a license.</p> | <p>Commitment 8-9 has been updated in Version 2 of the Commitments Register (additions shows in bold):</p> <p>“The exact diffuser design configuration will be optimized as required during the engineering design and permitting phase to facilitate optimal performance of the diffuser specific to site conditions. The final diffuser configuration will not change the environmental assessment conclusions of risk to aquatic receptors and that water quality will remain at or below guidelines.”</p> |

| IR-113 | - | <p>Context: No quantitative assessment of climate change has been conducted. Representative concentration pathways (RPC) projections for climate change have not been integrated with near- and far-field modelling to assess impacts to surface water quality or sediment quality in the future.</p> <p>Rationale: Changes in air and water temperatures, precipitation, snow melt, ice formation, etc., due to climate change can all influence COPC concentrations in surface water and sediment. It is not possible to assess the potential impacts from climate change on predicted surface water and sediment COPC concentrations with the current information.</p> | Provide a quantitative analysis of the potential impacts of predicted COPCs from mine effluent to surface water and sediment quality with climate change scenarios for the Project lifespan incorporated into modelling. Include modelling predictions regarding the influence of changes to air and water temperatures, precipitation, snow melt, ice formation, etc., on COPC concentrations in surface water and sediment. | <p>Section 8.1.3.4 (and Appendix 8-C) provides a quantitative assessment of the potential changes in surface water quantity due to climate change. The 1:100 year, 24-hour return period rainfall events for the baseline and climate change influenced IDF curves are 79.9 mm and 88.6 mm, respectively. The PMP for the Project is estimated to be 493 mm (refer to IR-15 and AD-15) which is well above both 24-hour maximum precipitation and 1:100, 24 hour return precipitation events. The PMP is very conservative (e.g., assumes effectively a full year of precipitation in one event) under both existing and future conditions (climate change). The potential impacts of climate change to precipitation and therefore flows was summarized in Appendix 6-C, Table 10 with the total annual precipitation and the maximum 1-day events being variable over the next four decades (Table 1). Regardless, the climate change scenario indicates a potential increase in event based assimilative capacity in the receiving environment.</p> <p>TABLE 1- Existing and Predicted Precipitation Data for Key Lake (provided in EIS, Appendix 6-C, Table 10)</p> <table><tr><th>Year</th><th colspan="4">Total Annual (mm)</th><th colspan="4">Maximum 1-day (mm)</th></tr><tr><td></td><td>Measured</td><td>RCP 2.6</td><td>RCP 4.5</td><td>RCP 8.5</td><td>Measured</td><td>RCP 2.6</td><td>RCP 4.5</td><td>RCP 8.5</td></tr><tr><td>2011-2020</td><td>455</td><td>518</td><td>509</td><td>508</td><td>48</td><td>29</td><td>27</td><td>27</td></tr><tr><td>2030</td><td></td><td>528</td><td>503</td><td>537</td><td></td><td>27</td><td>24</td><td>26</td></tr><tr><td>2040</td><td></td><td>487</td><td>498</td><td>514</td><td></td><td>28</td><td>29</td><td>24</td></tr><tr><td>2050</td><td></td><td>504</td><td>524</td><td>520</td><td></td><td>26</td><td>29</td><td>33</td></tr><tr><td>2060</td><td></td><td>513</td><td>515</td><td>523</td><td></td><td>26</td><td>33</td><td>26</td></tr><tr><td>2070</td><td></td><td>527</td><td>534</td><td>568</td><td></td><td>29</td><td>31</td><td>28</td></tr><tr><td>2080</td><td></td><td>539</td><td>551</td><td>547</td><td></td><td>30</td><td>33</td><td>28</td></tr><tr><td>2090</td><td></td><td>543</td><td>545</td><td>548</td><td></td><td>31</td><td>32</td><td>35</td></tr><tr><td>2100</td><td></td><td>546</td><td>535</td><td>559</td><td></td><td>23</td><td>25</td><td>28</td></tr><tr><td colspan="2">Overall Increase:</td><td>28</td><td>26</td><td>51</td><td></td><td>-6</td><td>-2</td><td>1</td></tr></table> <p>To mitigate the potential for unplanned release of deleterious substances into the surface water environment even during the next 40 years of climate change, the PMP of 493 mm was used for water management engineering designs. During a PMP, water requiring management will report to the wellfield runoff pond which will be sized to accommodate a PMP event at the site. This pond has been sized to 38,200 m³ (excluding a freeboard of 1 meter). From the wellfield runoff pond, water will then be sent to the process water pond for treatment if required. In Section 2.8 Project Design Features, Denison notes that “Ponds will be designed to maintain a minimum freeboard of at least 1.0 m to allow for continued functioning during a probable maximum precipitation (PMP) event.” As such, the project has been designed to manage water during PMP and greater, and therefore mitigation of potential impacts to water quality due to climate change has been initially included as part of the EIS. As a result, it is Denison's opinion that a quantitative assessment of potential impacts to surface water quality is not warranted as it is likely to indicate improved results from the conservative assessment of potential water quality changes during operation and decommissioning phases. Continued monitoring of background, effluent and receiver water quality will be undertaken and provide the ability for adaptive management throughout the life of the mine in association with potential climatic changes to the local and regional area.</p> | Year | Total Annual (mm) | | | | Maximum 1-day (mm) | | | | | Measured | RCP 2.6 | RCP 4.5 | RCP 8.5 | Measured | RCP 2.6 | RCP 4.5 | RCP 8.5 | 2011-2020 | 455 | 518 | 509 | 508 | 48 | 29 | 27 | 27 | 2030 | | 528 | 503 | 537 | | 27 | 24 | 26 | 2040 | | 487 | 498 | 514 | | 28 | 29 | 24 | 2050 | | 504 | 524 | 520 | | 26 | 29 | 33 | 2060 | | 513 | 515 | 523 | | 26 | 33 | 26 | 2070 | | 527 | 534 | 568 | | 29 | 31 | 28 | 2080 | | 539 | 551 | 547 | | 30 | 33 | 28 | 2090 | | 543 | 545 | 548 | | 31 | 32 | 35 | 2100 | | 546 | 535 | 559 | | 23 | 25 | 28 | Overall Increase: | | 28 | 26 | 51 | | -6 | -2 | 1 | <p>This response has not been accepted.</p> <p>Based on the information provided it is not possible to assess the resiliency of the Project to potential adverse effects from climate change and potential impacts to surface water and sediment quality. The Proponent should review the guidance documents available on the Strategic Assessment of Climate Change (SACC) website with regards to climate change resilience and provide a quantitative analysis of the potential impacts of predicted COPCs from mine effluent to surface water and sediment quality with climate change scenarios for the Project lifespan incorporated into modelling.</p> <p>Include modelling predictions regarding the influence of changes to air and water temperatures, precipitation, lake levels, flow rates, etc., on COPC concentrations in surface water and sediment. The Proponent should refer to the SACC website for guidance on conducting this quantitative analysis.</p> <p>See also follow-up IR-113-R1.</p> | <p>Please refer to Attachment IR-113_IR-113-R1 for the response.</p> | <p>The Proponent has not adequately responded to the IR. The Proponent suggests that the requested quantitative analysis is not necessary and contends that potential climate change effects on water quality should instead be addressed through mitigation measures, monitoring and adaptive management.</p> <p>The Proponent’s approach does not sufficiently characterize the range of potential effluent and water quality predictions. Climate change analysis is lacking, and a sensitivity analysis was not conducted in order to further understand uncertainty and drivers of the model results. Further, some aspects of water quality modeling are not sufficiently conservative, including use of the geometric mean (instead of the 95th percentile) as the baseline concentration for constituents, and pooling data from all lakes, which would mask any differences between the lakes. It is therefore not known whether water quality exceedances may be predicted under climate change scenarios. Without estimating the potential influence of climate change on water quality, it is unclear whether the proposed water quality mitigation measures are adequate.</p> <p>The Proponent should conduct a sensitivity analysis on water quality predictions for low and high precipitation scenarios, including the potential influences of climate change to assist in fulfilling the IR from the previous round.</p> <p>This information is required to assess the potential for significant adverse effects to the environment. If additional baseline information is required, it should be sourced or otherwise collected.</p> | <p>Denison has considered climate change within the water quality / quantity analysis and based on that considered concluded that quantitative analysis was not warranted as it concerns determination of the significance of residual effects potentially associated with the Project. Denison disagrees that a quantitative climate change assessment is required at this time for the purposes of the EIS as highlighted above because:</p> <ul style="list-style-type: none">• The duration of the project (15 years) is short within the context of climate change thereby making it unlikely that large scale changes in precipitation and temperature will occur. As previously identified as part of IR-103 responses, an assessment of the potential high flow scenario under climate change has been included in the design criteria (i.e., the IDF). Therefore, water management, and the ability to contain water within site infrastructure as designed, mitigates potential water management issues associated with high flow scenarios.• Sufficient conservatism has been included in the water quality assessment, for instance:<ul style="list-style-type: none">◦ Average effluent rate of 36.5 m3/hr and continuous flow – this is an unlikely scenario. Denison intends to recycle process water to the greatest extent possible, thereby reducing the demand for fresh water supply and volume of treated effluent. In an effort to develop a conservative assessment basis for the EA, the water recycle flows from the industrial wastewater treatment plant back into the processing plant and wellfield <i>have not been incorporated</i> into the estimates for freshwater withdrawal and treated effluent discharge.◦ The water quality analysis was conducted for each of the low flow scenarios (i.e., 7Q10 low flow, monthly low flow, and monthly average flow) for the receiving water environment◦ Ninety-fifth percentile (95%) concentrations of constituents at baseline condition were used in modelling potential effects.• Future climate predictions for the general project area indicate an increase in precipitation and not a reduction, thereby increasing the potential assimilative capacity within the receiving environment.• The design basis PMP is robust and inclusive of projected total annual precipitation under a high carbon scenario. As previously identified as part of IR-103 responses, an assessment of the potential high flow scenario under climate change has been included in the design criteria (i.e., IDF). Contact water containment has been designed to ensure that water management infrastructure can contain high flow events (the IDF for non-contact water is based on 1:100 return, 24 hour using climate projections for 2020 to 2050).• Effluent discharge will be monitored as per the MDMER Schedules 4 and 5;• Low flow scenarios have been assessed under the near-field water quality model (i.e. 7Q10). Additionally, and under scenarios of low flow condition, discharge can be limited seasonally or periodically and specific to the assimilative capacity of the receiver (flow proportioned of fixed dilution discharge); and,• Adaptive management and adjustment to discharge timing and volume as needed over time to meet criteria based on climate induced changes in flow. <p>Despite these lines of evidence providing strong rationale for not needing the quantitative assessment, Denison suggests that a sensitivity analysis on water quality predictions for low and high precipitation scenarios, including the potential influences of climate change could be completed as part of operational licensing and as applicable to REGDOC-2.9.2 (Environmental</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 28, 2024) |
|--------------|----------------|--|--------------------------|---|-----------------------------|---|--|--|
| | | | | | | | | <p>Protection: Controlling Releases to the Environment).</p> <p>This would be consistent with the approach of further analyses conducted as part of licensing and following the collection of additional water quality data to support such modelling. We remind the CSNC that treated mine effluent release does not occur until operational commissioning.</p> |
| IR-113 | IR-113 R1 | <p>Context: The Proponent states the following, “The PMP is very conservative (e.g., assumes effectively a full year of precipitation in one event) under both existing and future conditions (climate change)”. This statement suggests that the PMP value utilized considers future climate changes such as possible changes in the frequency or intensity of extreme precipitation events.</p> <p>Rationale: As noted by the Proponent, increases in extreme rainfall are anticipated with a warmer climate. For precipitation extremes across Canada, the relative change in event frequency is expected to be larger for more extreme and rarer events. Given that the extreme precipitation is expected to intensify in the future (Kunkel et al. 2013), the Proponent should consider how these potential changes will influence design values such as PMP.</p> | | | | <p>Please refer to Attachment IR-113_IR-113-R1 for this response.</p> | <p><i>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</i></p> <p>The Proponent has not clarified if climate change has been considered in the PMP value provided or discussed how potential increases in PMP have been or need to be considered in the Project design.</p> <p>Thermodynamic effects on atmospheric moisture will lead to intensification of local extreme precipitation in the future. Probable maximum precipitation (PMP) is defined as the greatest accumulation of precipitation for a given duration meteorologically possible for an area (Kunkel et al., 2013). PMP values may increase with climate change.</p> <p>In the response to IR-113 R1, the Proponent states that “the design basis PMP is robust and inclusive of projected total annual precipitation under a high carbon scenario”. It is unclear from this statement how the analysis provided indicates that the PMP is inclusive of climate change.</p> <p>The Proponent should clarify how the analysis that they provided shows that the design PMP considers climate change, and indicate if or how the potential for increased PMP has informed site water management for the mine life and into post-closure and considered in the development of mitigation measures.</p> <p>Reference: Kunkel, K. E., Karl, T. R., Easterling, D. R., et al. 2013. Probable maximum precipitation and climate change. Geophysical Research Letters 40(7), 1402–1408. Available at: 10.1002/grl.50334</p> | <p>This IR has been accepted for the purposes of the current EA process. Denison agrees that a sensitivity analysis on water quality predictions for low and high precipitation scenarios, including the potential influences of climate change can be completed as part of licensing and as applicable to REGDOC-2.9.2 (Environmental Protection: Controlling Releases to the Environment).</p> |

ATTACHMENT IR-113_IR-113-R1 (included in Round 2 submission)

Denison's Response:

Prairie province hydrology is dominated by cold regions processes so that snowmelt is the primary hydrological event of the year for both the major rivers that derive from the Rocky Mountains and small streams and rivers that arise in Saskatchewan. Climate change impacts on water resources are therefore focused on changes to snow accumulation, snowmelt and infiltration to frozen soils. Climate change scenarios suggest generally warmer and wetter winters for Saskatchewan. Large scale hydrological models that take these scenarios into account suggest changes in the annual streamflow of the South Saskatchewan River ranging from an 8% increase to a 22% decrease, with an 8.5% decrease being an average prediction. Small scale hydrological models for prairie streams suggest a 24% increase in spring runoff by 2050 followed by a 37% decrease by 2080 as the winter snow cover becomes discontinuous. Both model results suggest that there is not a dramatic drying of the prairies to be anticipated under climate change and that in some cases streamflow will increase for certain scenarios and under moderate degrees of climate change. While prairie runoff should increase in the near term, as climate change progresses later in the 21st C there will be dramatic drops in runoff and the flow of small streams to wetlands and depressions and to small prairie rivers (Sauchyn et al 2009).

Changes in temp (warmest max temp) for the region was referenced from the Climate Atlas of Canada (https://climateatlas.ca/data/grid/782/maxmax_2030_45/line0) for the Tomblin Lake watershed.

The primary source of climate model data presented in their maps, charts and tables is the Pacific Climate Impacts Consortium (PCIC) . The PCIC has provided downscaled projections of daily temperature and precipitation data from 24 climate models using two carbon emission scenarios.

The Climate Atlas of Canada use PCIC's statistically downscaled data (Bias Correction with Constructed Analogues and Quantile mapping, Version 2; BCCAQv2) derived from 24 CMIP5 global climate models for two emissions scenarios (RCP4.5 and RCP8.5). The Climate Atlas of Canada call the RCP4.5 and RCP8.5 the "Low Carbon" and "High Carbon" scenarios, respectively. We use PCIC's statistically downscaled data (Bias Correction with Constructed Analogues and Quantile mapping, Version 2; BCCAQv2) derived from 24 CMIP5 global climate models (the complete list of models can be found at (<https://climateatlas.ca/data-sources-and-methods>) (Climate Atlas of Canada, 2023)

The climate model data presented in the Atlas has been statistically downscaled and bias corrected using a method called Bias-Correction/Constructed Analogues with Quantile mapping reordering, Version 2 (BCCAQv2); the work was done by the Pacific Climate Impacts Consortium (PCIC) . [1] This method has been extensively tested by Murdock et al. (2014) and found to outperform many other statistical downscaling methodologies.

The data indicates an ensemble increase in warmest maximum temperature under the high carbon (RCP8.5) scenario of 2.32 degrees Celsius from the background average of 2.59 (1950 to 2022) to 4.91 (2023 to 2065). Increases in temperature can then influence the rates of evapotranspiration thereby reducing water availability. However, in the case of Saskatchewan, the rate of

transpiration on an annual basis is not expected to overbalance the increase in precipitation for the region.

The data indicates an ensemble increase in warmest maximum temperature under the high carbon (RCP8.5) scenario of 2.32 degrees Celsius from the background average of 2.59 (1950 to 2022) to 4.91 (2023 to 2065). Increases in temperature can then influence the rates of evapotranspiration thereby reducing water availability. However, in the case of Saskatchewan, the rate of transpiration on an annual basis is not expected to overbalance the increase in precipitation for the region.

Table 1: Warmest Maximum Temperature Under High Carbon Scenario Historical to Projected Statistics

| Statistic | Historical (1950 – 2022) | | | Projected (Ensemble Data 2023 – 2065) | | |
|-----------|--------------------------|-------------------------|-------------------------|---------------------------------------|-------------------------|-------------------------|
| | Annual Average | 10% Confidence Interval | 90% Confidence Interval | Annual Average | 10% Confidence Interval | 90% Confidence Interval |
| Mean | 2.59 | 1.07 | 4.17 | 4.91 | 3.48 | 7.14 |
| SD | 1.23 | 0.70 | 0.72 | 0.89 | 0.83 | 1.17 |
| Min | 0.00 | -0.45 | 2.80 | 3.00 | 2.05 | 5.10 |
| Max | 5.30 | 3.00 | 6.15 | 7.00 | 5.25 | 9.40 |

The data indicate an ensemble increase in total precipitation under the high carbon (RCP8.5) scenario of 39.21 millimetres from the background average of 454.65 (1950 to 2022) to 493.86 (2023 to 2065). This increase is likely to increase mean annual flows in the Icelander River drainage area thereby increasing the assimilative capacity of the receiving environment of Whitefish Lake.

Table 2: Total Annual Precipitation Under High Carbon Scenario Historical to Projected Statistics

| Statistic | Historical (1950 – 2022) | | | Projected (Ensemble Data 2023 – 2065) | | |
|-----------|--------------------------|-------------------------|-------------------------|---------------------------------------|-------------------------|-------------------------|
| | Annual Average | 10% Confidence Interval | 90% Confidence Interval | Annual Average | 10% Confidence Interval | 90% Confidence Interval |
| Mean | 454.65 | 366.97 | 558.69 | 493.86 | 392.34 | 603.23 |
| SD | 66.85 | 19.66 | 28.74 | 19.35 | 25.36 | 31.79 |
| Min | 264.60 | 325.20 | 506.00 | 459.00 | 344.35 | 555.20 |
| Max | 609.20 | 405.70 | 626.45 | 533.00 | 444.30 | 672.65 |

Several uncertainties apply:

- 1) The background water quality conditions of the Icelander River system in future decades may change appreciably as a result of increases in surface run-off, landscape changes and precipitation event intensity and duration. Such changes are not predictable at this time;
- 2) The long-term accuracy of predictive models for precipitation, temperature and evapotranspiration for the region is not such that an estimate of changes to the receiving environment water quality is reasonable at this time. Any estimates would have a large attributed uncertainty. Furthermore, as mine discharge is not expected to increase in volume or constituent concentrations over the mine life, any increase in flows within the Icelander River system would provide for an increase in assimilative capacity.

As a result, quantitative assessment of the potential change in surface water quality at Whitefish Lake under Climate Change is not needed at this time as:

- the design basis PMP is robust and inclusive of projected total annual precipitation under a high carbon scenario
- the level of variability that is likely in future background water quality is high due to changes in precipitation levels and intensity and therefore run-off contributions to the aquatic environment; and,
- predictive models for the future period (2050s) for the region are variable in accuracy.

Rather, the following mitigation measures, monitoring and adaptive management should be employed.

- 1) Changes in water quality in the receiver should be monitoring on a consistent basis to understand changes in the background water quality prior to effluent mixing;
- 2) Effluent discharge will be monitored as per the MDMER Schedules 4 and 5;
- 3) Under scenarios of low flow condition, discharge can be limited seasonally or periodically and specific to the assimilative capacity of the receiver (flow proportioned of fixed dilution discharge);
- 4) Adaptive management and adjustment to discharge timing and volume as needed over time to meet criteria based on climate induced changes in flow.

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, July 5, 2024) |
|--------------|----------------|--|--|---|---|--|---|--|
| IR-114 | - | <p>Context: Tables 8.2-9, 8.2-10 and 8.2-13 demonstrate predicted maximum effluent concentrations of COPCs and maximum predicted receiving environment concentrations in the near- and far-field. General parameters such as temperature, pH, conductivity, etc. that would require Project thresholds and monitoring under the MDMER have not been provided in this table. Lead, nickel, TSS and un-ionized ammonia were not provided, despite all being Schedule 4 substances with maximum monthly concentrations under the MDMER. Aluminum, iron, nitrate, thallium, and manganese have not been provided despite being required parameters under Schedule 5 Section 4 of the MDMER for effluent characterization.</p> <p>For zinc, it is unclear how guidelines have been calculated when CCME thresholds can only be derived with hardness values <250 mg/L. Additionally, water quality thresholds appear to have been calculated using estimated effluent concentrations rather than receiving environment baseline concentrations.</p> <p>Mercury has been identified as a COPC of interest to Indigenous groups for the proposed Project. Table 8.2-8 indicates that background concentrations of mercury in LA-5 are low, and predicted effluent concentrations are also low. However, no information has been provided on background methylmercury concentrations or expected atmospheric deposition of mercury from Project related emissions. Predicted effluent concentrations of 3915 mg/L of sulphate are quite high, and sulphate is known to increase mercury methylation rates in aquatic environments.</p> <p>Rationale: A review of all modelling results for all COPCs under the MDMER will assist ECCC in understanding the potential risks to the receiving environment. ECCC recommends the use of the most stringent guidelines for the protection of aquatic biota. All water quality thresholds should be derived from receiving environment parameters to determine any baseline receiving environment and effluent COPC exceedances of water quality thresholds.</p> <p>Increased sulphate availability can lead to increased methylation rates of mercury and methylmercury in sediment and surface water. Methylmercury is a toxin that can bioaccumulate within the food chain and present risks to aquatic biota and wildlife consuming aquatic biota. Potential changes to methylmercury concentrations in water quality, sediment and fish tissues should be assessed due to the proposed sulphate loadings in effluent.</p> <p>Additionally, in accordance with the MDMERs, Denison will be required to demonstrate that their effluent quality meets the limits in the MDMER. Denison is expected to provide the predicted effluent quality for lead, nickel, and un-ionized ammonia to demonstrate compliance with the MDMERs.</p> | <p>1. Update all tables to include all COPCs with required monitoring under the MDMER including acute and chronic thresholds.</p> <p>2. Ensure all selected water quality thresholds are derived using baseline receiving environment concentrations and use water quality guidelines that are protective of aquatic biota.</p> <p>3. Provide baseline data on the concentrations of methylmercury in surface water, sediment and fish tissues (i.e., large-bodied sports fish and small-bodied forage fish) in the LSA and RSA receiving environment to establish a baseline prior to potential Project impacts.</p> <p>4. Provide an assessment of risk from methylmercury to ecological receptors due to changes in sulphate concentrations in effluent, and potential deposition of mercury from Project related atmospheric emissions in the receiving environment.</p> | <p>See response in Attachment IR-114.</p> | <p>This response has not been accepted.</p> <p>The Proponent has not updated all tables to include missing data for mercury, aluminum, total suspended solids, iron, thallium, manganese, nitrate, and phosphorous, all of which are COPCs with monitoring requirements under the MDMER.</p> <p>The Proponent has not updated tables to include predictions of total hardness concentration in effluent and the receiving environment or acute water quality thresholds, and water quality thresholds have not been derived using baseline receiving environment concentrations.</p> <p>All water quality thresholds should be derived from receiving environment parameters to determine if any baseline receiving environment and effluent COPCs exceed water quality thresholds.</p> <p>Please:</p> <p>1. Update all tables to include missing data for mercury, aluminum, total suspended solids, iron, thallium, manganese, nitrate and phosphorus.</p> <p>2. Update tables to include predictions of total hardness concentrations (in mg/L CaCO3) in effluent and the receiving environment.</p> <p>3. Update tables to include acute water quality thresholds to ensure COPCs do not have the potential to be acutely lethal at the end-of-pipe.</p> <p>4. Ensure that all selected water quality thresholds are derived using baseline receiving environment concentrations and use water quality guidelines that are protective of aquatic biota.</p> | <p>Please see Attachment IR-114. Briefly, Tables 8.2-9, 8.2-10 and 8.2-13 have been updated in the revised Draft EIS as requested.</p> | <p>In response to the FIRT’s previous review, Denison provided responses to the following outstanding requests from ECCC:</p> <ol style="list-style-type: none">1. Update all tables to include missing data for mercury, aluminum, total suspended solids, iron, thallium, manganese, nitrate and phosphorus.2. Update tables to include predictions of total hardness concentrations (in mg/L CaCO3) in effluent and the receiving environment.3. Update tables to include acute water quality thresholds to ensure COPCs do not have the potential to be acutely lethal at the end-of-pipe.4. Ensure that all selected water quality thresholds are derived using baseline receiving environment concentrations and use water quality guidelines that are protective of aquatic biota. <p>The Proponent has resolved item two and four of the above, but items one and three require additional follow up.</p> <p>Regarding item one, further corrections to Table 8.2-13 are necessary:</p> <ul style="list-style-type: none">• There are several inconsistencies in the footnotes:<ul style="list-style-type: none">○ numbers 2 & 3 are missing in the footnotes at the bottom;○ there is no reference to footnote 2 in the table; and○ The asterisk “*”, which is sometimes used to qualify the source of screening concentration, is not defined.• Screening criteria are missing for aluminum and iron, and should be sourced from CCME or SEQG rather than the MDMER as listed in the table.• Uranium-234 and uranium-238 are missing from the table, even though they have been identified as contaminants of potential concern.• Proposed screening criteria for cobalt, copper, manganese, nickel, phosphorous and un-ionized ammonia are inadequate, see comment in IR-108 & IR-108-R1.• Alkalinity and nitrate have been added to the table as requested, however predicted maximum concentrations are only presented for Whitefish Lake Middle and South. The proponent should describe why there are no estimates for these parameters in other lakes, and how they intend to fill these gaps.• Un-ionized ammonia appears in two separate lines in the table with concentrations differing by 3-4 orders of magnitude and different screening values. A single line entry with accurate values should be retained. The Proponent should provide an explanation for the error in order to give the reviewer confidence that the correct values are retained.• The column with screening values does not always use the most conservative value from Table 8.2-8. See comment IR-115 for request to provide justifications. <p>Table 8.2-14 should be updated with corrections to screening criteria necessary for this IR as well as for IR-108 and IR-115. Additional follow up for Table 8.2-10 can be found under IR-108 and IR-108-R1.</p> <p>In the Proponent’s response to item three of the IR, Table 8.2-10 is missing the source for the short-term screening criteria value for arsenic. The Proponent should update Table 8.2-10 to include the source for the short-term screening criteria value for arsenic.</p> | <p>Item 1 – further corrections to Table 8.2-13 have been made (please see updated Table 8.2-13 in Attachment IR-114-R3) as follows:</p> <ul style="list-style-type: none">• Footnotes were restructured and are provided in Attachment IR-114-R3 for each of the tables that were updated.• Screening criteria were added for aluminum and iron, and sourced from CCME or SEQG.• Uranium-234 and uranium-238 were added to the table.• Proposed screening criteria for cobalt, copper, manganese, nickel, phosphorous and un-ionized ammonia were changed as applicable and are consistent with other tables as associated with IR-108 & IR-108-R1.• Un-ionized ammonia is updated to only be provided in one line. The first line provided previously was associated with a miscalculation of the un-ionized ammonia value and was the unionized ammonia-N value. The values provided as part of Attachment IR-114-R3 should be considered correct for unionized ammonia for comparison against the guideline.• The column with screening values now is consistent across all tables that are presented as part of Section 8 and in Attachments for IRs 108/108-R1, 114 and 115.• Table 8.2-14 was updated with corrections to screening criteria necessary for this IR as well as for IR-108 and IR-115 (please see Attachment IR-114-R3).• Table 8.2-10 was updated to include the source for the short-term screening criteria value for arsenic (please see Attachment IR-114-R3 for updated Table 8.2-10). |

Attachment: IR-114 (included in Round 1 Submission)

1) Please see updated Tables 8.2-9 and 8.2-10 from the draft EIS below. Water quality predictions for the well mixed portion of LA-5 for each of the three flow scenarios (described in Section 8.2.4.2.3 and Table 8.2-7 of the draft EIS) are provided in the updated Table 8.2-10 below. Predicted site discharge concentrations that exceed respective receiver WQOs are bolded. Chloride, sulphate, TDS, arsenic, cadmium, chromium, cobalt, copper, selenium, and uranium, thorium-230, radium-226, lead-210, and polonium-210 predicted discharge concentrations are above receiver WQOs. However, under all three flow scenarios, the predicted water quality for all constituents is below respective WQOs within the well mixed portion of LA-5, indicating that sufficient dilution is present within LA-5 to meet objectives. Updated Table 8.2-13 is provided below. Water quality predictions have been added for MDMER constituents listed under Schedule 4 and Schedule 5. There are no predicted exceedances of water quality guidelines for any of the COPCs during Construction, Operation, or Decommissioning

2) The predictive water quality analysis considered the effects of toxicity modifying factors, such as hardness, on water quality. Specifically, the analysis considered induced hardness - that is hardness that is derived from or includes contributions from on site sources and in this case discharge from the IWWTP. It is a reasonable in this case to utilize induced hardness since the water quality assessment directly considers the potential effect of IWWTP discharge on the receiving environment. The hardness added to the receiver from the discharge represents a constant source during periods of discharge. The effluent hardness value used in the analysis was derived from bench scale testing and is considered to be a reasonable estimate of expected hardness in effluent. With that in mind, the predictive water quality analysis reflects the water quality conditions that are anticipated to prevail in the receiver and therefore presents an appropriate platform on which to base the effects assessment.

3) The table below (IR-114 Table 1) shows a summary of baseline concentrations of total mercury in surface water within the LSA. Sediment was not analyzed for mercury during previous baseline surveys. Baseline water quality in the LSA and RSA showed no indication of total mercury present above detectable limits and as such, the potential for methyl-mercury to be detected was unlikely. Generally, 60 to 95% of total mercury concentrations in fish muscle tissues are present in the form of methyl-mercury. Table 8.5-2 of Section 8.5 of the EIS provides a full summary of tissue constituent concentrations for key species from the Icelder River and Russell Lake. A conservative approach of assuming 95% of mercury in the tissues is present in the methylated form could be used for comparative purposes. These data supplemented with more current baseline data for water, sediment and fish tissues specific to total and methyl-mercury prior to the onset of site development will provide a robust database for comparative purposes during the subsequent development and operation on site.

4) Consistent with CSA N288.1-20, Clause 5.1.5, atmospheric depositions to large water bodies such as lakes, are considered negligible; therefore, the air to surface water pathway has been excluded for the ecological risk assessment. The rationale for exclusion of atmospheric deposition to lakes and rivers is explained in detail in Section G9, Appendix G of the COG DRL Guidance Document (Hart, 2019). Typical transfer parameters from source to air and source to water are on a similar magnitude to each other. The transfer parameter from air to water is orders of magnitude lower indicating that atmospheric deposition to the lake would have a negligible effect. Rationale on the exclusion of the air to water pathway can be included in the ERA in Appendix 10-A. The

following statement will be added to Section 2.2 in Appendix A to Appendix 10-A "Atmospheric deposition to Whitefish Lake is considered negligible. This is consistent with the COG DRL guidance (COG, 2019) which shows (assuming a modest flow rate for a lake of 0.1 m/s and an assumed water depth of 10 m) that the transfer of constituents from the atmosphere to large bodies of water (including lakes and rivers) is considered negligible."

As baseline surface water did not identify measurable concentrations of total mercury in the LSA or RSA (See IR-114 Table 1 below) and deposition to large water bodies such as lakes is not likely to contribute to the methyl mercury concentration in the Wheeler River receiving waters, it is most reasonable to conclude that changes in total and methyl mercury can be adequately monitored in relation to sulphate inputs. Denison will undertake monitoring of total and methyl mercury as it relates to the discharge of sulphate to Whitefish Lake.

|--------------|----------------|---|--|---|--|--|---|---|
| IR-115 | - | <p>Context: Table 8.2-8 demonstrates baseline concentrations of COPCs in LA-5 South Whitefish Lake, their respective water quality guidelines from applicable sources, and proposed Project thresholds. General parameters such as temperature, pH, conductivity, etc. that would require Project thresholds and monitoring under the MDMER have not been provided in this table. Lead, nickel, Total Suspended Solids (TSS) and un-ionized ammonia were not provided, despite all being Schedule 4 substances with maximum monthly concentrations under the MDMER. Aluminum, iron, nitrate, thallium, and manganese have not been provided despite being required parameters under Schedule 5 Section 4 of the MDMER for effluent characterization. Water quality thresholds appear to have been calculated using estimated effluent concentrations rather than receiving environment baseline concentrations. The water quality objective selected for molybdenum is the 31 mg/L SEQG rather than the CCME guideline of 0.073 mg/L.</p> <p>Rationale: ECCC recommends the use of guidelines that will ensure the protection of aquatic biota. All water quality thresholds should be derived from receiving environment parameters to determine any baseline receiving environment and effluent COPC exceedances of water quality thresholds.</p> | <p>1. Update Table 8.2-8 to include all COPCs with required monitoring under the MDMER.</p> <p>2. Ensure all selected water quality thresholds are derived using baseline receiving environment concentrations and are at levels protective of aquatic life.</p> <p>3. Provide additional information to justify the use of the selected water quality guideline for molybdenum.</p> | <p>1. Table 8.2-8 has been updated and provided in Attachment IR-115</p> <p>2. Denison believes that the water quality thresholds used in the assessment (Section 8.2.4.2.3, Aquatic Environment; Appendix 10-A (ERA), Section 3.1.1.1) were appropriate and reflect levels that are protective of aquatic life. The predictive water quality analysis considered the effects of toxicity modifying factors, such as hardness, on water quality. Specifically, the analysis considered induced hardness - that is hardness that is derived from or includes contributions from on site sources and in this case discharge from the IWWTP. It is a reasonable in this case to utilize induced hardness since the water quality assessment directly considers the potential effect of IWWTP discharge on the receiving environment. The hardness added to the receiver from the discharge represents a constant source during periods of discharge. The effluent hardness value used in the analysis was derived from bench scale testing and is considered to be a reasonable estimate of expected hardness in effluent. With that in mind, the predictive water quality analysis reflects the water quality conditions that are anticipated to prevail in the receiver and therefore presents an appropriate platform on which to base the effects assessment.</p> <p>3. Denison has selected the Saskatchewan specific guideline for molybdenum of 31 mg/L to be the most appropriate for the Project. It was derived from recent data following the CCME (2007) protocol. The molybdenum water quality objective based on the 5th percentile (HC5) of the species sensitivity distribution (SSD) according to the CCME protocol; 18 data points for 12 different species were used, mainly EC10 data (WSA, 2017). The CCME guideline is identified as an interim guideline and was based on multiplying the lowest chronic toxicity value, the 28-d LC50 of 0.73 mg/L for rainbow trout (O. mykiss), by a safety factor of 0.1. This original study by Birge (1978) has not been reproducible, either using the original methods or using standard methods (Davies et al. 2005). No changes to the EIS are proposed in this regard.</p> <p>References: Birge, W.J. 1978. Aquatic Toxicology of Trace Elements of Coal and Fly Ash. Special Collections, USDA National Agricultural Library. Accessed February 16, 2023, https://www.nal.usda.gov/exhibits/speccoll/items/show/5224.</p> <p>CCME. 2007. A protocol for the derivation of water quality guidelines for the protection of aquatic life.</p> <p>Davies, T.D., J. Pickard and K.J. Hall. 2005. Acute molybdenum toxicity to rainbow trout and other fish. Journal of Environmental Engineering & Science 4: 481-485.</p> <p>WSA (Saskatchewan Water Security Agency). 2017. Saskatchewan Water Quality Objective for the Protection of Aquatic Life – Molybdenum. Fact Sheet. Report No. WSA 514.</p> | <p>This response has not been accepted.</p> <p>Items 1. And 3. In the Proponent’s response adequately responded to the IR. However, the water quality thresholds in item two have not been derived using baseline receiving environment concentrations and not all COPCs which require monitoring under the MDMER have been included in the updated table. Additionally, the Proponent did not account for changes in baseline hardness concentrations in the receiving environment due to the deposition of effluent. Water hardness is an environmental modifying factor which can influence the toxicity of COPCs in the aquatic environment, therefore requiring the mentioned COPCs as well as background concentrations of total hardness in the receiving environment to accurately determine potential effects of COPCs upon the receiving aquatic environment. The Proponent should also provide rationale to support that all selected water quality thresholds are derived using baseline receiving environment concentrations and are at levels protective of aquatic life.</p> <p>See also follow-up IR-115-R1.</p> | <p>Please see Attachment IR-115_IR115-R1. Briefly, Table 8.2-8 has been updated in the revised Draft EIS as requested.</p> | <p>Please see the response to IR-115-R1 (below).</p> | <p>Please see the response to IR-115-R1 (below).</p> |
| IR-115 | IR-115 R1 | <p>Context: In the Proponent’s response to item two, it is mentioned that the derived water quality thresholds used in Table 8.2-8 and in the assessment (Section 8.2.4.2.3, Aquatic Environment; Appendix 10-A (ERA), Section 3.1.1.1) are based on hardness concentrations found in effluent. The Proponent mentions that hardness derived from IWWTP discharge will consider IWWTP discharge on the receiving environment and provide “a reasonable estimate of expected hardness in effluent”. However, this does not consider induced hardness (i.e., hardness concentration increases in the receiving environment over the lifecycle of the Project) from effluent contributions as a Project effect; the receiving environment baseline concentrations of hardness have been altered due to inputs from Project effluent. Providing only one estimate of expected effluent hardness in the receiving environment is not an appropriate means of conducting the effects assessment.</p> <p>Additionally, the following COPCs have not been included in the updated table provided in the</p> | n/a | <p>n/a</p> | <p>1. Update Table 8.2-8 to include the following COPCs: un-ionized ammonia, aluminum, iron, manganese, thallium and total dissolved solids (TDS).</p> <p>2. Update Table 8.2-8 to include background concentrations of total hardness (in mg/L CaCO3) in the receiving environment.</p> <p>3. Provide rationale that all selected water quality thresholds are derived using baseline receiving environment concentrations and are at levels protective of aquatic life.</p> <p>See also related IR-108-R1</p> | <p>Please see Attachment IR-115_IR115-R1. Briefly, Table 8.2-8 has been updated in the revised Draft EIS as requested.</p> | <p>The Proponent has not fully responded to the previous round’s IR. For items one and two, some of the information provided on contaminants of potential concern (COPCs) and the background concentrations of hardness in the receiving environment is not sufficiently conservative. Item three requested rationale that all selected water quality thresholds (i.e., screening criteria) are at levels protective of aquatic life, which was not provided.</p> <p>The updated Table 8.2-8 provides two short-term and two long-term screening criteria for each parameter. The screening criteria reflect calculated screening criteria for both background hardness and project-induced hardness, however, it is unclear which criteria the Proponent intends to apply in their assessment since four separate criteria are provided (see IR-114).</p> <p>The information presented in Table 8.2-8 indicates there are no background water quality exceedances of guidelines. However, it is noted that several screening criteria do not reflect the most conservative guidelines, which is not consistent with the approach described in Appendix 10-A (Environmental Risk Assessment). For some examples, the short-term screening criteria value of 500 mg/L for nitrate is much higher than the BC MOE nitrate guideline of 32.8 mg/L., the long-term criteria for un-ionized ammonia of 6.87 mg/L is much higher than the CCME guideline of 0.019 mg/L and the MDMER limit, and the long-term phosphorus screening criteria represent a trigger range that is two to three trophic levels above background, which is much higher than the</p> | <p>In response to the reviewer’s comment that several criteria utilized in the water quality section of the EIS do not reflect the most conservative guidelines, which is not consistent with the approach described in Appendix 10-A (Environmental Risk Assessment) the following is provided.</p> <p>To clarify, the approach taken in the ERA with respect to screening criteria followed a hierarchical approach. This was the same approach taken in and described in Section 8 of the EIS.</p> <p>The most stringent of either the Saskatchewan provincial (SEQG) or federal (CCME and/or FEQG) guidelines were used for the screening criteria.</p> <p>Where there was no screening criterion was provided by the province of Saskatchewan or federal government, an appropriate and available criteria from another jurisdiction was used as an alternative.</p> <p>The most stringent criteria in any jurisdiction was not deemed reasonable for the purposes of the EIS nor was this the intention of the methods described in Appendix 10-A or the ERA. The wording in the ERA/EIS can be revised to make the hierarchical process for selection of water quality screening criteria described above clearer.</p> <p>Further rationale as to our (Denison and its SME) belief that water quality thresholds were used that are protective of aquatic life should include the understanding of the hierarchical methods described above as well as the conservatisms that were adopted as part of the water quality assessment, and within the predictive near-field water quality model in particular. These conservatisms were as follows.</p> <p>1. Denison intends to recycle process water to the greatest extent possible, thereby reducing the demand for fresh water supply and volume of treated effluent. In an effort to develop a conservative assessment basis for the EA, the water recycle flows from the industrial wastewater treatment plant back into the processing plant and wellfield have not been incorporated</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, July 4, 2024) |
|--------------|----------------|---|--------------------------|---|-----------------------------|---------------------------------------|--|--|
| | | <p>Proponent’s response: un-ionized ammonia, aluminum, iron, manganese, thallium and total dissolved solids (TDS). It is noted that these COPCs are also subject to monitoring requirements under the <i>Metal and Diamond Mining Effluent Regulations</i> (MDMER).</p> <p>Rationale: Background concentrations of un-ionized ammonia, aluminum, iron, thallium, manganese and TDS are required to determine potential effects to the environment. The Proponent will also require this information to satisfy their obligations under the MDMER.</p> <p>The purpose of the surface water quality assessment is to determine if changes to the receiving environment over the project lifecycle will have significant adverse effects on biota. Changes from baseline in hardness concentrations in the receiving environment due to the deposition of effluent is a Project related effect and therefore providing a single baseline water quality threshold which is applicable only to one set of conditions is not an appropriate method to evaluate impacts across a shifting hardness baseline.</p> <p>Water hardness is an environmental modifying factor, various concentrations of hardness influence the toxicity of other COPCs in the aquatic environment. Using water quality thresholds that have been derived from high effluent hardness concentrations will not be protective of aquatic biota, particularly in the early stages of the project lifecycle when receiving environment water quality will be similar to baseline water quality.</p> | | | | | <p>CCME guidance framework recommends. The Proponent should review and update Table 8.2-8 to provide conservative screening criteria for all parameters, and include a consideration of the CCME, FEQG, SEQG, and BC MOE when selecting the screening criteria. Screening criteria selection should be informed by the most conservative guidelines. Cases where the Proponent does not propose to apply the most conservative screening criteria should be accompanied with a discussion and rationale for the selection. The Proponent should also specifically state which criteria will be used in screening, how these criteria will be or are applied, how the EA conclusions are informed by the criteria, and whether any EA conclusions are altered by changes to screening criteria.</p> | <p>into the estimates for freshwater withdrawal and treated effluent discharge.</p> <p>2. An average and continuous effluent discharge rate of 36.5 m³/hr was used which is an unlikely scenario with discharge likely being more intermittent and at lower rates (as indicated in bullet one).</p> <p>3. The water quality analysis was conducted for each of the low flow scenarios (i.e., 7Q10 low flow, monthly low flow, and monthly average flow) for the receiving water environment.</p> <p>4. The ninety-fifth percentile (95%) concentrations of constituents at baseline condition were used in modelling potential effects thereby providing them most conservative approach to the protection of aquatic life.</p> <p>Further context is provided as follows.</p> <p>The updated Table 8.2-8 (provided in Attachment IR-114-R3) provides two short-term and two long-term screening criteria for each parameter. The screening criteria reflect calculated screening criteria for both background hardness and project-induced hardness.</p> <p>Based on pilot tests completed for the IWWTP to date, sulphate, chromium, molybdenum, TSS, and selenium have been identified as having potential management needs. However, for each of these parameters, the estimated discharge concentrations provided were conservative in nature with a contingency factor of up to 3 times.</p> <p>Parameters where the available assimilative capacity of the receiver was estimated to be less than the max predicted discharge concentration when screening criteria are subject to background water quality include sulphate, chromium, molybdenum, and selenium. For chromium and selenium, the assessment was influenced by background WQ datapoints with values below the detection limit (Nearfield Model).</p> <p>Parameters whose available assimilative capacity exceeded short term criteria listed in Table 8.2-10 (IR Round 2 and revised draft EIS) for both background and induced screening criteria included chloride, TSS, arsenic, cadmium, copper, manganese, uranium, and zinc (Nearfield Model).</p> <p>The Round 3 updates to Table 8.2-10 are provided in Attachment IR-114-R3.</p> <p>The updated results indicate that the parameters previously identified as requiring management consideration remain unchanged with no additional parameters added.</p> <p>Finally, we note that Denison has committed to periodic sampling prior to construction to strengthen existing environmental data and will commit to update the analysis and predictions incorporating any new data collected during the operational licencing process, but there is no expectation that there would be any change to the EIS conclusions.</p> |

Attachment: IR-115 (included in Round 1 submission)

Table 8.2-8 has been updated and provided below.

| Constituent | Unit | LA-5 Background Concentration (95th percentile) | Screening Concentration | Source of Screening Concentration |
|---------------------|------|---|-------------------------|-----------------------------------|

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 28, 2024) |
|--------------|----------------|---|--|--|--|---|--|---|
| IR-124 | - | <p>Context: Table 8.4-7 provides maximum concentrations of surface water COPCs in sediment. The following COPCs, which are required to evaluate the risk from effluent to sediment quality, were not evaluated:</p> <ol style="list-style-type: none">1. COPCs that have monitoring requirements in receiving environment2. COPCs that exceed water quality guidelines in effluent, and,3. COPCs that have baseline concentrations that exceed sediment quality thresholds in the receiving environment. <p>Rationale: Due to the lack of information on COPCs with baseline concentrations that exceed sediment quality guidelines, and COPCs that require monitoring under the MDMER, a determination on risk to sediment quality and aquatic biota cannot be made.</p> | <ol style="list-style-type: none">1. Provide the information on baseline exceedances of COPCs in sediment.2. Provide an assessment of risk for any COPCs that have baseline exceedances of sediment quality thresholds in the receiving environment.3. Provide an assessment of risk from any COPCs that require monitoring in the receiving environment and effluent under the MDMER. Please include any COPCs in effluent that will exceed water quality guidelines. | <p>1) The information on the baseline exceedance of COPCs in sediment are provided as part of Attachment IR-123. The table indicates that only the maximum concentration of cadmium exceeded the CCME ISQG on one occasion when assessing all sediment samples over the course of baseline surveys in the LSA.</p> <p>2) Only one sample concentration for Cadmium of 0.7 µg/g (LAB-2-3) at Russell Lake exceeded the CCME ISQG of 0.6 within the RSA. Another value of 0.6 µg/g (LAB-2-CORE) at Russell Lake equals to the CCME ISQG of 0.6. All other samples had cadmium concentrations below any screening criteria. Cadmium was included as one of the constituents identified as a COPC under the non-radiological Ecological Risk Assessment (Appendix 10-A). No significant adverse effect on either aquatic or terrestrial populations or communities, as a result of releases from the Project, are predicted during the Project phases or during the future centuries. All estimated total HQs for all COPCs (arsenic, cadmium, chromium, cobalt, copper, molybdenum, selenium, uranium, zinc, chloride, and sulphate) for all ecological receptors are predicted to remain below the HQ benchmark of 1.</p> <p>3) Denison has provided an analysis of the parameters that are identified under MDMER Schedule 4 and therefore have specified effluent discharge criteria. Schedule 5 parameters will be monitored as per the MDMER once under this regulation (i.e., meeting regulated criteria of discharge to the environment [50 m3/day). Please refer to Table 8.2-13 of attachment IR-114. In these cases, COPCs including Schedule 4 parameters were below screening criteria.</p> | <p>This response has not been accepted.</p> <p>An updated risk assessment for COPCs that requires monitoring under the MDMER with effluent concentrations that exceed guidelines has not been completed. This information is necessary to facilitate the determination on risk to sediment quality and aquatic biota.</p> <p>See also follow-up IR-124-R1.</p> | <p>1. Section 8.4.3.2.3 of the Draft EIS did not identify any constituents where baseline sediment quality exceeded sediment quality guidelines. Table 8.4-3 and Table 8.4-7 of the revised Draft EIS were updated to include sediment quality guidelines as recommended.</p> <p>2. The were no instances where constituent concentrations in the baseline sediment samples were greater than their respective of sediment quality guidelines; therefore, no further action is needed to address this part of the IR.</p> <p>3. This is not applicable. No additional COPCs need to be carried forward in the environmental risk assessment as the concentrations of COPCs in effluent do not exceed water quality guidelines (see Table 3-1 in the ERA in Appendix 10-A). All relevant constituents identified in Schedule 4 and Schedule 5 in MDMER were considered in the ERA screening with the exception of cyanide and mercury which are not identified as present in the effluent (see IR-100 regarding mercury). Phosphorus and nitrate will be present in the effluent at low levels and estimates of these constituents via the near-field water quality model indicate that levels will remain well below criteria protective of aquatic life in the Whitefish Lake environment (see Tables 8.2-10 and 8.2-13 of Section 8).</p> | <p>The Proponent has not fully responded to the previous round’s IR.</p> <p>The modeling of surface water and sediment COPC’s described in Appendix 10-A show results for the receiving waterbodies, but it is not clear how the results for the COPC concentrations for water quality and sediment quality calculated for each of the water bodies, shown in Figure 6-1 and 6-2 respectively, are being interpreted. The Proponent has not explained if these modeled values are based on the worst-case scenarios that account for environmental variables such as seasonal changes in hydrology and chemistry or if they have only accounted for changes in operational effluent discharge scenarios to consider the upper bound discharge rates. Additionally, it is unclear whether depositional areas for sediment were identified based on hydrological data. Additional information is also needed regarding baseline exceedances of sediment COPC thresholds and the associated risk assessment of mine operations on the receiving water body.</p> <p>The Proponent should consider maximum COPC scenarios for the receiving water bodies in baseline assessments and the risk assessment, including seasonal variability and sediment depositional areas to determine whether the baseline assessment and risk assessment fully considered the effects of the operations of the proposed mine. The Proponent should provide supplemental information to aid in determining if the environmental model has considered environmental variability such as seasonal changes in water levels, flows and sedimentation. The Proponent should also demonstrate that the model has considered a reasonable expected worst case scenario, such as a 100 year return.</p> <p>This IR is addressing quality of inputs (ex. baseline data, conservatism of scenarios modelled, environmental variability, etc.) in to modelling. This information is required to assess the conservatism of modelling the bounding conditions and potential for significant adverse effects to the environment.</p> | <ul style="list-style-type: none">• Denison would like to clarify that the figures that the reviewer is referring to (Figure 6-1 and Figure 6-2 in Appendix 10-A) are the figures for the sensitivity analysis shows the maximum predicted concentrations for each lake, arising from two effluent discharge scenarios: expected and upper bound discharge rates. The sensitivity analysis specifically looks at the difference between expected and upper bound effluent discharge rates. All other parameters are unchanged from the expected case. The concentrations over time (with seasonal variations) for all waterbodies are shown in Figure 3-2 and Figure 3-3 of Appendix 10-A (and reproduced below). The modelling considers COPC concentrations in the receiving water bodies in baseline assessments and the risk assessment, including seasonal variability and sediment depositional areas to determine whether the baseline assessment and risk assessment fully considered the effects of the operations of the proposed mine.• Appendix A to the ERA in Appendix 10-A is called “ Wheeler River Project IMPACT Model” which provides detailed information on the equations used, assumptions made and inputs used in the IMPACT model• The IMPACT Model considers monthly fluctuations in flows in all waterbodies. This is described in Section 3.1 of Appendix A. The IMPACT Model also assumes that all lakes are depositional. The sediment model represents deposition in the whole lake using partition equations and that the dominant process by which sediment quality would change is expected to be partitioning not particle settling – TSS in effluent is low (6 mg/L) and release of particulates is therefore not expected to contribute meaningfully to changes in sediment quality downstream of the discharge. The constituent specific partitioning coefficients (K_{ds}) used in the analysis are described in Appendix 10-A to the ERA and are based on the relationship between sediment quality and water quality for depositional habitats from monitoring data collected over many years in the Wheeler drainage Further, it is noted that it is unclear how the worst-case scenario, such as the 100 year event, is relevant to the sediment quality analysis. In addition to the fact that the dominant process is expected to be partitioning not particle settling such events, up to the design storm which in the case of the contact water management system is equivalent to more than 1 year’s worth of precipitation in a 24 hour period, would be contained with the site infrastructure and there would be no specific need to change treated effluent discharge flow as a result. The contained event water would be treated and released to the environment per standard operations.• For the assessment of impacts on the aquatic environment two different models were utilized for different purposes. The near-field model assessed different flow scenarios including low flow, and the IMPACT Model was used as the regional model for the risk assessment. The risk assessment focuses on the expected case.• There are numerous conservative assumptions in the near-field model (Appendix 8-E)<ul style="list-style-type: none">• The water quality analysis was conducted for each of the low flow scenarios (i.e., 7Q10 low flow, monthly low flow, and monthly average flow) for the receiving water environment.• Ninety-fifth percentile concentrations of constituents at baseline condition were used in modelling potential effects.• Average effluent discharge rate of 36.5 m³/hr and continuous effluent flow – this is conservative.• Effluent quality is conservative, based on pilot tests completed for the IWWTP to date with a contingency factor of 1 to 3 times incorporated for conservatism.• There are numerous conservative assumptions in the IMPACT Model.<ul style="list-style-type: none">• Ecological receptor assumptions: home ranges are selected based on sensitive life stages, 100% residency at exposure locations of interest.• Human receptor assumptions: traditional foods diet is conservative, both average and high consumers assessed. The amount of traditional food obtained from the Project area is conservative based on current understanding of land use.• The results shown in the ERA represent the maximum dose/risk receptors would receive, considering the variation among Project phases• Toxicity reference values incorporate safety and uncertainty factors• Although conservative, the models indicate no significant adverse effects to the environment. |
| IR-124 | IR-124-R1 | <p>Context: In the Proponent’s response it is stated, “Schedule 5 parameters will be monitored as per the MDMER once under this regulation (i.e., meeting regulated criteria of discharge to the environment [50 m3/day). Please refer to Table 8.2-13 of attachment IR-114. In these cases, COPCs</p> | n/a | n/a | <p>Provide an assessment of risk from any MDMER Schedule 5 parameters that are required to be characterized in effluent and in surface water quality in the receiving environment and that have effluent concentrations that will exceed water quality guidelines derived from environmental baseline conditions.</p> | <p>See response to IR-124 and revised Draft EIS Section 8, Table 8.4-3 and Table 8.4-7 and supporting updated documentation in Appendix 8E.</p> | <p>The Proponent has not fully responded to the previous round’s IR. The modeling of surface water and sediment COPC’s described in Appendix 10-A, Figure 6-1 and 6-2 respectively shows results for the receiving waterbodies. However, it is unclear if these modeled values are based on the worst-case scenarios that account for environmental variables such as seasonal changes in hydrology and chemistry, or if they have only accounted for changes in operational</p> | <p>See response to IR-124 above. No additional requests have been made as part of IR-124-R1</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 28, 2024) |
|--------------|----------------|--|--------------------------|---|-----------------------------|---------------------------------------|---|---|
| | | <p>including Schedule 4 parameters were below screening criteria.”</p> <p>If concentrations of Schedule 5 parameters in effluent exceed water quality thresholds, these parameters are necessary for ECCC to examine in the risk assessment to determine the potential for effluent to be acutely lethal and for adverse effects to aquatic biota. These parameters will also be required to be characterized under Section 4, 5 and 7 of the MDMER. As per CSA N288.6-22 Section 7.2.5.2.1, “Screening of environmental concentrations of chemical and radiochemical substances released to the environment should be performed to identify COPCs for further evaluation in the risk assessment. Both measured concentrations and concentrations calculated from release rates may be used in the screening analysis. The screening concentrations should be compared to screening criteria, and chemicals that exceed screening criteria should be identified as COPCs.”</p> <p>As per CSA N288.6-22 Section 7.2.5.4.2, “If COPCs exceed the screening level for one medium, they should be carried forward into the EcoRA for all media that are likely to contribute to exposure. For example, for a given COPC, if a water screening benchmark is exceeded, the same COPC should be carried forward for sediment if its concentration was above the detection limit.”</p> <p>Additionally, updated Table 8.2-13 of attachment IR-114 has been found to be insufficient due to maximum concentrations in surface water for mercury, aluminum, total suspended solids, iron, thallium, manganese, nitrate and phosphorus being absent and the use of incorrect water quality thresholds.</p> <p>Rationale: Due to the lack of information on COPCs with concentrations that exceed water quality thresholds in effluent, a determination on risk to sediment quality and aquatic biota cannot be made.</p> | | | | | <p>effluent discharge scenarios to consider the upper bound discharge rates. The Proponent’s responses regarding baseline exceedances of COPC thresholds in the receiving waterbodies require additional information regarding environmental variability, including but not limited to seasonal changes in water levels, flows and sedimentation, in order to determine whether the model has considered environmental variability. The Proponent should also demonstrate that the model has fully considered a reasonably expected worst case scenario, such as a 100-year return period for the above variables.</p> <p>The Proponent should include a consideration of the maximum COPC scenario for the receiving water bodies in baseline assessments and the risk assessment, including seasonal variability and sediment depositional areas, to consider the effects of the operations of the proposed mine.</p> <p>This IR is addressing quality of inputs (ex. baseline data, conservatism of scenarios modelled, environmental variability, etc.) in to modelling. This information is required to assess the conservatism of modelling the bounding conditions and potential for significant adverse effects to the environment.</p> | |

| IR- 126 | - | <p>Context: The Proponent has used the US Environmental Protection Agency (US EPA) guidelines for the assessment of selenium fish tissue concentrations in Section 8.5.3 of the draft EIS and in the Environmental Risk Assessment (ERA) in Appendix 10-A (ERA) of Section 10.</p> <p>Rationale: ECCC’s Federal Environmental Quality Guidelines of 6.7 ug/g dry weight fish whole body tissue for selenium should be used, as it is more protective than the US EPA guidelines.</p> | Update the selenium fish tissue assessment in the draft EIS and the Wheeler River ERA (Appendix 10-A (ERA) in Section 10) as needed using ECCC’s FEQG. | <p>Denison is aware of the ECCC Federal Environmental Quality Guideline for selenium in fish. The ECCC FEQG is for fish tissue egg-ovary and whole-body. Denison selected the US EPA guideline over the ECCC guideline since US EPA provides guidelines for fish tissue muscle as well. The fish assessed in the ERA were large-bodied fish including northern pike and white sucker. A fish tissue muscle TRV is appropriate for assessment of large-bodied fish; therefore, the US EPA selenium fish tissue muscle benchmark was preferred over the whole body value from ECCC.</p> | <p>ECCC acknowledges that the Proponent prefers the use of the US EPA guidelines due to the ability to perform fish tissue muscle TRV, however, Environmental Effects Monitoring (EEM) would require a study on fish tissue selenium whole- body or egg-ovary concentrations. The current baseline data will not be comparable to future EEM studies using fish tissue muscle concentrations of selenium and US EPA guideline methodology. There is currently EEM guidance under development for conducting selenium fish tissue sampling in fish populations that will utilize the FEQG which applies to fish tissue egg-ovary and whole-body concentrations of selenium. Additionally, the Proponent has made a commitment to utilize the most stringent guidelines available.</p> <p>Based on the Project's proposed effluent concentrations of selenium, fish tissue sampling will be required as part of the EEM monitoring for the Project. The ECCC FEQG is the guideline applied to these studies, and the current use of this guideline will facilitate the comparison to future monitoring studies.</p> <p>Furthermore, the Proponent has not provided sufficient explanation in their response for the use of the less stringent US EPA guideline compared to the more conservative FEQG.</p> <p>The Proponent should explain their use of the US EPA guidelines over the ECCC FEQG or update the selenium fish tissue assessment in the draft EIS and the Wheeler River ERA as needed using ECCC’s FEQG.</p> <p>As noted in IR-126, please update the selenium fish tissue assessment in the draft EIS and the Wheeler River ERA (Appendix 10- A (ERA) in Section 10) as needed using ECCC’s FEQG. If the FEQG will not be used, provide further rationalization for the use of the US EPA guidelines when creating the study on fish tissue selenium concentration in the EEM.</p> | <p>The EIS assessed selenium in fish in terms of muscle tissue because the available baseline data were for muscle tissue. Since the review comment highlights the EEM program and the fish tissue selenium study component more specifically we note that the MDMER (2023) allows use of muscle tissue in the EEM study of selenium in fish (see Schedule 5, 12(1)(e)(iv). It is further noted that Denison has committed to a pre-operational EEM study and will conduct that study in accordance with the regulation and available federal guidance. The pre-operational EEM study will include a study respecting selenium in fish tissue.</p> <p>Regarding the EIS, Denison and its SME stand by the current assessment approach, using muscle tissue. Nevertheless, to address the reviewer’s concern, we have calculated whole-body concentrations from the predicted selenium in muscle (Table B.5 of the revised draft EIS Appendix 10-A), using EPA (2021) conversion factors. The resulting whole-body concentrations do not exceed either EPA (2021) or ECCC (2022) guidelines for whole-body tissue, which are 8.5 µg/g dw and 6.7 µg/g dw, respectively, and therefore the conclusions of the risk assessment are unchanged. No change to the EIS is warranted.</p> <table><tr><th>Fish Species</th><th>Lake</th><th>Muscle ug/g fw</th><th>Muscle ug/g dw</th><th>Whole ug/g dw</th></tr><tr><td rowspan="5">N. Furthermore, in their response the Proponent does not use available species-specific moisture content and conversion factors available for northern pike and lake whitefish when converting muscle selenium concentrations to whole-body selenium concentrations. This means that the Proponent’s prediction likely underestimates the selenium tissue concentrations in the fish. Consequently, the hazard quotients reported are lower than expected.</p> <p>Additionally, the method used by the Proponent to predict selenium concentrations in northern pike and lake whitefish does not appear to include dietary uptake and bioaccumulation of selenium, only direct contact with pore water and overlying water is considered (Table 5-5 in Appendix 10A; Section 2.2.2 of Appendix A to Appendix 10-A). Selenium uptake through the aquatic food web has been shown to result in bioaccumulation of selenium in aquatic-dependent wildlife and resulting in reproductive impairments and malformations (ECCC 2022). Dietary sources of selenium would typically be expected to be the main contribution to tissue concentrations of selenium compared to selenium uptake from water. In most situations, the conversion of inorganic selenium to organic selenium through uptake from water into periphyton/algae is the rate limiting step of selenium bioaccumulation into higher level organisms including benthic invertebrates and fish. This step is affected by many environmental parameters (e.g. temperature, substrate, lentic/lotic environment). Considering that the effluent discharge contains 42 ug/L selenium, consideration of dietary selenium is warranted.</p> <p>The Proponent should update the final EIS with the following information:</p> <p>1. Update the ERA with the assessment of selenium concentrations in fish tissue to include a comparison of selenium fish tissue concentrations to ECCC FEQG guidelines for either fish whole body tissue (6.7 ug/g dry weight) or fish egg/ovary tissue (14.7 ug/g dry weight) using species-specific moisture content and muscle : whole body and/or egg-ovary : muscle conversion factors (see Tables B-1b, Table B-3, Table B-4, and Table B-5 in US EPA (2021)).</p> <p>2. Update the ERA for the assessment of selenium concentrations in fish tissue using a method that considers dietary uptake and bioaccumulation in order to determine predicted fish tissue concentrations of selenium in northern pike and lake whitefish. This is recommended to be done over all Project phases for both the Expected Case and sensitivity scenarios.</p> <p>Provide predicted fish tissue selenium concentrations that include the range of variability of data used to develop the tissue selenium predictions. Only one output value without a confidence interval is provided for each location and species (see Table B.5 in Appendix B of Appendix 10-A).</p> | <p>1. The Round 2 IR response provided a comparison against the ECCC FEQG by converting the muscle tissue concentrations to whole-body tissue concentrations using generic conversion values. The dry weight to fresh weight conversion factor used was 0.25. Based on Denison’s measured dry weight content in fish (northern pike and white sucker) the dry weight content ranged from 0.24 to 0.26 which is consistent with literature values; therefore, there is minimal difference in the moisture content. The species specific conversion factors for whole body and egg ovary for northern pike and white sucker from US EPA (2021) have been used to calculate the whole body and egg ovary tissue concentrations. (see Table in Attachment IR-126 Round 3 below for results). All predicted tissue concentrations for northern pike and white sucker in all lakes are below the FEQG.</p> <p>2. The ERA utilizes a bioaccumulation factor (BAF) model from water to tissue to conservatively reflect all the multi-media contributions to uptake. The BAFs are provided in Appendix A to the ERA in Section 3.6.1. The selenium BAF for northern pike is a non-linear BAF where BAF = 949x^{0.827} (x is in units of µg/L). The selenium BAF for white sucker is 4425 L/kg (the rounded value shown in Figure IR-126-1 is 4400 L/kg). Both BAFs are based on publicly available regional data from other uranium mine sites in northern Saskatchewan (see Appendix A to Appendix 10-A, Section 3.6.1). Additional information on the derivation of the BAFs is provided below in Attachment IR-126 Round 3.</p> <p>3. The fish tissue selenium concentrations represent the maximum concentration over the Project phases. This is the most conservative result.</p> <p>References: US EPA. 2021. 2021 Revision to: Aquatic Life Ambient Water Quality Criterion for Selenium 2016. EPA 822-R-21-006. Attachment IR-126 Round 3

The whole-body concentrations were recalculated from the predicted selenium in muscle tissue concentrations (Table B.5 of the revised draft EIS Appendix 10-A), using site-specific moisture content and the species-specific US EPA (2021) conversion factors. The values used for moisture content and conversion factors for muscle to whole body and egg-ovary to whole body are shown in Table IR-126-1 below. The resulting whole-body concentrations (Table IR-126-2) do not exceed either EPA (2021) or ECCC (2022) guidelines for whole-body tissue, which are 8.5 µg/g dw and 6.7 µg/g dw, respectively, and therefore the conclusions of the risk assessment are unchanged. Note that selenium was identified as a COPC in the risk assessment and a full quantitative risk assessment was completed including calculation of hazard quotients. No change to the EIS is warranted based on the results shown in the Table below. The calculations do not change the conclusions of the EIS of no significant adverse effect. Selenium is included as part of the environmental monitoring program throughout all phases of the Project.

Table IR-126-1: Moisture Content and Conversion Factors used for Selenium Calculations

| Fish Species | Moisture Content (Aquatic Baseline Studies, Table A-17) | Muscle:Whole Body (Table B-4, B-5, US EPA 2021) | Egg-Ovary:Muscle (Table B-3, US EPA 2021) |
|---------------------|--|--|--|
| Northern Pike | 77.98 | 1.27 | 1.88 |
| White Sucker | 76.55 | 1.34 | 1 |

Selenium bioaccumulation factors (BAFs) were derived using regional data. Using measured fish tissue data and measured water concentrations to develop the BAF incorporates the selenium bioaccumulation through the food chain and would represent the transfer (enrichment function and trophic transfer) as shown in the figure below.

Image adapted from Chapman *et al.* (2009)

Large- and small-bodied fish were considered separately because selenium concentrations are based on different tissue analyses for these two groups: wet weight muscle and wet weight whole body, respectively. Tissue data were available for northern pike, cisco, lake trout, longnose sucker, lake whitefish, white sucker, lake chub and spottail shiner. The data comparisons resulted in the following conclusions:

- The same BAF can be applied to a fish species at different lakes;
- The BAF values for longnose sucker, cisco and lake trout were not significantly different from those for northern pike, therefore data from these species were combined to derive a BAF for northern pike;
- The BAF values for lake whitefish and white sucker were significantly different ($p < 0.05$) from that for northern pike; and
- The BAF values for lake chub and spottail shiner were not significantly different ($p > 0.05$) from each other, therefore data for these two species were combined to derive a BAF for small-bodied fish.

Most of the data from fish species evaluated demonstrated a linear relationship between fish tissue and water concentrations. The linear regression line was shown to underestimate selenium in northern pike tissue at low water concentrations. Therefore, a non-linear relationship was adopted for northern pike, where the $BAF = 949x^{0.827}$ (x is in units of $\mu\text{g/L}$). As shown in the figure, the

linear (dotted line) and power function (solid red curve) are quite similar except where the water concentrations were less than 0.001 mg/L. The R^2 values for the linear and power function are similar but the better fit at the lower water concentration values provided a basis for selecting the power function as the preferred model for the northern pike. Correlation analyses of the tissue and water concentration data for selenium indicated that a significant relationship ($p < 0.05$) existed between the water and tissue concentrations in northern pike, white suckers, lake whitefish and small-bodied fish.

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, July 8, 2024) |
|--------------|----------------|---|---|--|--|---|--|--|
| IR-134 | - | <p>Context and Rationale: The draft EIS states in multiple places that vegetation clearing may occur year-round.</p> <p>In order to correspond with the timing of emergence from hibernation, tree clearing should not be conducted during the bat roosting period. If maternity roost trees are removed after pregnant females have established a roost area, there is a higher likelihood of abortion than there would be otherwise.</p> <p>Species-specific mitigations are required to protect bat SAR.</p> | Provide important roosting dates for bat species at risk in the Project area. | <p>Maternity roosts are used by pregnant females in late spring (April/May) either alone or in small groups. Females and their offspring roost in groups in nursery colonies in late summer/early fall prior to hibernation. Denison will adjust the activity timing windows to include the April/May maternity roosting period and the July/August nursery roosting period, to the extent practicable. Pre-construction surveys will identify all sensitive wildlife habitat features, including potential roosting trees (e.g., hollow trees, trees with defects, trees with cavities, and tree stumps). Should potential roosting trees be detected, consultations with the regulators will be initiated, and appropriate mitigation measures will be designed and implemented.</p> <p>This information above is provided in Attachment IR-131. This new SAR appendix (new Appendix 9-D) will be added to Section 9 of the final EIS.</p> | <p>The Proponent provided a complete response regarding the roosting dates for bat species at risk, however follow-up IRs are required.</p> <p>See follow-up IR-134-R1.</p> | n/a | <p>The Proponent provided a complete response regarding the roosting dates for bat species at risk, however follow-up IRs are required.</p> <p>See follow-up IR-134-R1.</p> | n/a |
| IR-134 | IR-134 R1 | <p>Context: The Proponent has committed to conduct pre-construction and pre-clearing surveys for multiple species, however the timing and methods for the surveys were not provided. Knowing the survey methodology for pre-construction and pre-clearing for little brown myotis and northern myotis is important for assessing cumulative impacts, effectiveness of adaptive management strategies as well as determining how bat species were considered in the EIS.</p> <p>Rationale: ECCC can determine whether the methodology the Proponent will use to collect data is appropriate and if the methodology would contribute to a more complete understanding cumulative effects and adaptive management strategies.</p> <p>A clear outline of how timing has been considered and incorporated into the methodologies is required to understand how sensitive periods for bats, such as roosting, have been considered in the EIS. An understanding of the methodologies and how these sensitive periods are being considered is required to evaluate the effectiveness of mitigation strategies and adaptive management strategies which are being developed by the Proponent.</p> | n/a | n/a | <p>The information provided by the Proponent regarding the roosting dates and potential habitat for bats is complete, however, the information related to the pre-construction and pre-clearing surveys is missing details on important habitat features for bat species at risk. As two Species at Risk Act (SARA) schedule 1 listed bat species, little brown myotis (<i>Myotis lucifugus</i>) and northern myotis (<i>Myotis septentrionalis</i>) have been identified in the Project area, effects need to be identified, avoided, lessened and monitored.</p> | <p>For clarification, the pre-construction and pre-clearing surveys will consist of wildlife sweeps conducted by qualified biologists within 7 days prior to any clearing activity at a specific location, and a 100 m buffer, within the Project Footprint. The wildlife sweeps will not be species-specific surveys focused on species at risk but will to be based on timing of Project related activities (i.e., will be completed in advance of site clearing activities). These surveys are intended to identify sensitive wildlife features such as hibernacula, dens, nests, cavities, mineral licks, that would require specific mitigation measures to avoid or minimize adverse effects on identified features and are not species-specific. The methods associated with these pre-construction and pre-clearing sweeps will be tailored to species at risk (including myotis species) that may potentially be using habitats at certain times of the year. Depending on the results of these sweeps, appropriate mitigation measures will be developed and implemented. This is a risk-based approach with the intent of reducing the potential of important wildlife features being adversely affected during vegetation or land disturbance activities. The wildlife sweeps would be conducted within 7 days prior to disturbance activities, year-round, so that sensitive features can be identified, and appropriate mitigation measures (e.g., avoidance, timing delay) can be developed and implemented, as appropriate.</p> | <p>The Proponent indicated that wildlife sweeps would be completed within a period of seven days prior to project activities. Wildlife sweeps will be conducted rather than conducting species-specific surveys focused on species at risk. Sweeps will be based on timing of the Project and related activities focused on identifying features such as hibernacula that may require mitigation.</p> <p>The Proponent also indicated that the methods associated with these sweeps will be tailored to species at risk (including bats) that may potentially be using the habitat.</p> <p>Species specific surveys are required to reliably identify rare species, such as species at risk, which may not be captured by more general wildlife sweeps. It remains unclear how the Proponent will complete wildlife sweeps, identify appropriate mitigation measures and implement those, or how these measures will be assessed for effectiveness.</p> <p>Information is outstanding on how surveys will be tailored to species at risk. It is requested that the Proponent to provide information on the methods that will be used for tailored surveys to species at risk, including bats or for the Proponent to provide a discussion on why these methods cannot be developed as part of this review.</p> <p>For further clarity, Denison is expected to describe how the pre-construction and pre-clearing survey methods are targeted/tailored for each SAR, where surveys will be performed to address SAR habitat, and the approximate timing prior to disturbance along with appropriate scientific rationale. At a minimum, one paragraph must be provided for each SAR specifically addressing the items above.</p> <p>Also see: IR-142-159-167-R1</p> | See response to IR-142-159-167-R1. |

|--------------|----------------|---|---|--|--|--|--|---|
| IR-142 | | <p>Context: The Proponent did not conduct any field work to identify potential wolverine dens in the Project area and therefore did not present any mitigations for the potential impacts to wolverine dens.</p> <p>In Section 9.3.3.2.1, the Proponent states: “Denning females are sensitive to disturbance during denning season in February to April and may abandon their dens and, in some cases, their litter, which may decrease their reproductive success. “</p> <p>In Section 9.3.6, the Proponent states: “In the Project Area, 145.0 ha or 100% of available wolverine habitat is assumed to be removed and will not be available to wolverine for the duration of the Project (Table 9.3-13). Similarly, 145.0 ha (3.4%) of available wolverine habitat within the Wildlife LSA is anticipated to be removed, all from the Project Area, during site clearing in Construction. In the Terrestrial RSA, up to 0.5% (145.0 ha; from the Project Area) of available wolverine habitat is anticipated to be removed during site clearing in Construction.”</p> <p>The residual effect assessment estimates that 8.2% of available wolverine habitat within the Terrestrial RSA may be altered or lost (Table 9.3-20).</p> <p>Rationale: As Wolverine is a Species at Risk Act Schedule 1 listed species, effects need to be identified, avoided, lessened and monitored. Mitigations, such as setback distances, should be used to protect important habitat features, such as dens.</p> <p>Wolverine occupy large home ranges and, therefore, need vast tracts of undisturbed land to maintain viable populations. The species avoids most human footprint types and linear features</p> | <p>1. Please provide additional information on whether the lost and/or altered wolverine habitat overlaps with wolverine home ranges.</p> <p>2. Describe any important wolverine habitat feature (i.e., dens) that may be lost as a result of the Project.</p> <p>3. Assess the need for pre- construction/pre-clearing surveys to identify any wolverine denning sites.</p> <p>4. Please provide additional information on whether the remaining, available, undisturbed wolverine habitat size is suitable to maintain populations.</p> | <p>1. While wolverine were not observed during baseline studies for the Project, it is assumed that the Project (Project Area, LSA) may overlap with wolverine home ranges. As described in the EIS, wolverine occur in low densities across all forest stand and vegetation types but are generally absent from areas of human development and activities.</p> <p>2. No wolverine dens were identified during any of the baseline studies. It is not anticipated that wolverine denning sites will be lost and/or altered because there are no specific landscape features typically used by wolverine as potential denning sites located in the Project footprint. Further, much of the proposed Project footprint will be developed within previously disturbed areas, including roads and cutlines.</p> <p>3. Pre-construction surveys will be completed to identify all sensitive wildlife habitat features, including wolverine denning sites.</p> <p>4. Most of the Project footprint is already disturbed through previous exploration activities. The total expected direct habitat loss of 169.6 ha includes the already disturbed areas. In the Terrestrial RSA, 8.2% of available wolverine habitat may be altered or lost; this includes 0.5% that will be cleared within the Project Area during Construction, and an additional 7.7% that may be altered through indirect effects (sensory disturbance). The magnitude of this effect was characterized as being "moderate" and the residual effect is not expected to result in a change that will alter wolverine habitat integrity to the point where it would not be able to sustain the regional populations of wolverine. This considers that no wolverine were observed during the baseline investigations, the small Project footprint, and the typically large size of a wolverine home range.</p> | <p>The information provided by the Proponent is complete, however, a follow up IR regarding survey methods for all pre-construction and pre-clearing surveys is required. See follow-up IR-142-159-167.</p> | n/a | n/a | n/a |
| IR-159 | | <p>Context and Rationale: Information presented in the draft EIS is insufficient to accurately predict Project impacts to breeding birds. The Proponent collected a single year of breeding songbird point counts and aerial waterfowl surveys (including avian species at risk). A single year of surveys in which birds may be unusually scarce or abundant could severely compromise interpretation of post-construction monitoring data.</p> <p>Additionally, data presented in the draft EIS is from 2017 and ECCC advises that more recent data is needed for a comprehensive baseline to verify Project impacts.</p> <p>Data from the Saskatchewan Conservation Data Centre (HABISask), the Saskatchewan Breeding Bird Atlas and the Boreal Avian Modelling project contain information on avian densities and avian species at risk that could supplement field data.</p> <p>The national standard for major projects recommends a minimum of two years of field surveys to be provided, so that temporal variability can be considered when comparing post-construction against baseline records and other available data.</p> | <p>Supplement breeding bird point count data and aerial waterfowl data collected during 2017 with additional pre-construction field data or existing post-2017 data/modelling to provide a comprehensive baseline that can be used to verify Project impacts during construction and operational phases.</p> | <p>The baseline data presented in the draft EIS are sufficient for the intended purpose – that is the data are sufficient, in conjunction with regionally available data, to identify potential project effects. The data collected as part of the baseline studies for birds was focused on the habitat types and areas most likely to be disturbed as a result of the Project. Conducting additional baseline surveys for waterfowl, raptors, and breeding birds is not anticipated to result in changes to the assessment outcomes and predictions made as part of the effects assessment, which was habitat-based, for avian species. The assessment methods used a conservative approach with the assumption that following the implementation of site-specific mitigation measures, the proposed Project activities would have a residual effect on these species guilds regardless of species presence on site.</p> <p>As described in the EIS, pre-construction surveys will be conducted prior to the commencement of any vegetation clearing or soil disturbance. Avian species will also be routinely monitored throughout the life of the Project. Results from the surveys and monitoring activities are expected to inform the adaptive management process to update Project design and identify the need for additional mitigation measures, if required. Note: Section 9.4.3.3 of the draft EIS includes all available information from the HABISask database at the time of the assessment. While recent surveys from Environment and Climate Change Canada and the Saskatchewan Breeding Bird Atlas have expanded surveys into the northern boreal forest, these data are not yet publicly available or published to make inferences on population trends for migratory songbirds that could use the available habitat in the Terrestrial RSA.</p> | <p>This response has not been accepted.</p> <p>The Proponent’s response indicated that their opinion is that the data presented in the draft EIS is sufficient and that no updates to the draft EIS are needed.</p> <p>However, a single year of baseline data from 2017 is insufficient to assess Project impacts during the follow-up and monitoring program. Although pre-construction surveys prior to clearing can give a very localized picture of the avian community, it does not provide a baseline within the Regional Study Area (RSA) of the bird community and will be of limited use for comparing construction and operational monitoring data to baseline conditions. Use of more recent data or supplemental data can account for interannual variation and any regional effects and will allow for a more accurate review of mitigation and follow-up measures.</p> <p>See follow-up IR-142-159-167-R1</p> | <p>Denison and its SME continue to be of the opinion that the data on which the effects assessment is based are sufficient and fit for purpose as it concerns the EA process. The effects assessment was not based on the 2017 field survey data alone. The EA used an accepted, proven habitat-based EA approach to address the variability of population surveys. Further, the EA used all available, recent/relevant survey data collected in appropriately timed and executed methodologies, including IK. The supplemental avian data received from records from the Saskatchewan Breeding Bird Atlas downloaded through the NatureCounts web portal (Saskatchewan Breeding Bird Atlas 2017), which also includes data received as part of the Saskatchewan Boreal Monitoring Strategy program. These data represent bird observations from 24-point counts conducted on June 7 and June 9, 2019. Nine point-counts are located approximately 6.5 km east of the Project footprint, the majority of which are located in the BS3 ecosite type; 15 point-counts are located approximately 7.7 km south of the Project footprint, the majority of which are located in the BS3/BS7 ecosite type. During this survey effort, 24 migratory songbird species were documented. A summary of the total number of individuals observed for each species across all plots is provided in Appendix 9-F of the revised Draft EIS. While the supplemental data do provide further context for the RSA, they would not be expected to alter the findings or the mitigation measures proposed, nor the conclusions reached in the EA.</p> <p>The above does not preclude the implementation of further breeding bird surveys prior to site development and operations. Denison accepts the comment that additional, more recent information, as well as supplemental data as available, and will provide the basis for a more effective review of mitigation and follow-up measures as the Project moves forward. The details of such follow-up monitoring will be defined as part of the further consideration of planning related to follow up programs.</p> <p>For clarification the pre-clearance wildlife sweeps are intended to identify sensitive wildlife features (e.g., hibernacula, roosting habitat, dens, nests, mineral licks) that would require site-specific mitigation measures to limit or avoid adverse effects. The spatial scale of where these pre-construction sweeps would be completed could be expanded to include other areas beyond the Project Area but within the RSA.</p> | n/a (accepted) | n/a |
| IR-167 | - | <p>Context and Rationale: The Proponent has stated that when it is not practicable to clear outside of the breeding bird window, they will conduct pre-clearing</p> | <p>Provide the following information:</p> | <p>Site clearing and other works that involve disturbance of vegetation and/or soil will be completed during least-risk timing windows for</p> | <p>Response is accepted, but also see AD-57 in the Advice to Proponent</p> | n/a | <p>Response is accepted, but also see AD-57 in the Advice to</p> | <p>See response to IR-142-159-167-R1 below.</p> |

|--------------|-----------------------------|--|---|---|--|--|---|--|
| | | <p>surveys. Section 9.4.5.2.1 states: “Prior to commencing any site clearing (i.e., vegetation clearing and/or soil disturbance) during the nesting season, pre-clearing nest surveys will be conducted at that location within the Project Area.”</p> <p>ECCC does not recommend the use of nest searches or pre-clearing surveys for active bird nests during the breeding season as a mitigation, given the difficulty associated with finding nests reliably and the high likelihood of disturbing nesting birds when searching. Instead, ECCC recommends that clearing and grubbing activities not be conducted during the breeding bird season.</p> <p>The Migratory Birds Regulations 2022 (MBR 2022) brings new scenarios that need to be considered:</p> <ol style="list-style-type: none"> Most migratory birds: <ul style="list-style-type: none"> Nests are protected only when they are in use or when live eggs or chicks are present. Migratory birds listed in MBR 2022 Schedule 1: <ul style="list-style-type: none"> For the 18 species of migratory birds identified on Schedule 1, the MBR 2022 provide year-round nest protection until they can be deemed abandoned. Migratory birds listed under SARA: <ul style="list-style-type: none"> For some SARA listed migratory birds, the residence prohibition (s.33) will protect nests that are not active, but are re-used in subsequent years, and the critical habitat prohibition (s.58) will protect nests that are part of the critical habitat identification. Those prohibitions apply everywhere in Canada and at all times of the year. In these cases, a SARA permit will be required. | <ul style="list-style-type: none"> details on how vegetation clearing related to site development will be conducted to minimize risk to migratory birds and species at risk (SAR). the timing window that will be used for vegetation removal to reduce risk to migratory birds and SAR | <p>migratory birds and SAR (i.e., winter), where practical, to avoid disturbance during sensitive time periods. It is noted that additional information related to timing windows and species as it concerns Project activities has been provided in response to IR-134.</p> <p>Pre-clearing surveys will be conducted and set-back buffers implemented, as needed. The pre-clearance surveys will be completed prior to all clearing events, regardless of the time of year / season when clearing is set to occur. If nests or tree cavities should be encountered during pre-construction surveys or ongoing monitoring activities, any subsequent Project activities will be in accordance with the 2022 Migratory Birds Regulations.</p> | table and follow-up IR-142-159-167-R1. | | Proponent table and follow-up IR-142-159-167-R1. | |
| n/a | IR-142, IR-159, IR-167 - R1 | | n/a | n/a | <p>Provide survey methodology and timing for all preconstruction and pre-clearing surveys, including avian and species at risk surveys (caribou, wolverine).</p> | <p>As noted in the August 2023 IR responses, site clearing and other works that involve disturbance of vegetation and/or soil will be completed during least-risk timing windows for migratory birds and SAR (i.e., winter), where practical, to avoid disturbance during sensitive time periods.</p> <p>However, in the event that site clearing activities or other works are anticipated to occur during a sensitive timing window for migratory birds and SAR, the pre-disturbance wildlife sweeps would be conducted by qualified biologists at least 7 days prior to any scheduled vegetation/land disturbance. The biologist would search the proposed area to be cleared, plus a 100 m buffer, for sensitive wildlife features that may be used by avian SAR (e.g., nests and/or nesting cavities), woodland caribou, and bats (e.g., roosting sites/cavities). The wildlife sweeps will not be species-specific surveys focused on species at risk per se, but will be based on timing of Project related activities (i.e., will be completed in advance of site clearing activities). These surveys are intended to identify sensitive wildlife features such as hibernacula, dens, nests, cavities, mineral licks, that would require specific mitigation measures to avoid or minimize adverse effects on identified features and are not species-specific. Nevertheless, the methods associated with these pre-construction and pre-clearing sweeps will be tailored to species at risk that may potentially be using habitats at certain times of the year. For example, methods will include searching prominent topographic features such as rock outcropping or downed forest trees and debris where wolverine may establish denning sites. In the event the sweeps are conducted during the winter period, methods related to snow tracking would identify wolverine presence based on tracks and potential denning sites in the snow pack within ravines or drainages within the forested areas within the study areas (as per Resources Inventory Committee 1999). Additionally, methods will include searching for potential roost trees for bat species, as per protocols included in the Wildlife Habitat Features Field Guide (BC Ministry of Environment and Climate Change Strategy, Ecosystems Branch 2019). Depending on the results of these sweeps, appropriate mitigation measures will be developed and implemented.</p> <p>If sensitive wildlife features are found, they will be documented (e.g., photographs, GPS location recorded). The data collected would inform the development and implementation of appropriate mitigation measures (e.g., appropriate set-back distances for Project activities and/or consideration of timing windows as per SK MOE (2017), in consideration of applicable laws and regulations (e.g., Migratory Birds Conservation Act, Wildlife Act), as appropriate.</p> <p>References:</p> <p>B.C. Ministry of Environment and Climate Change Strategy Ecosystems Branch. 2019. Wildlife Habitat Features Field Guide (Kootenay Boundary Region). October 2019. Pp. 119</p> | <p>The Proponent notes that:</p> <ul style="list-style-type: none"> Site clearing and other works that involve disturbance of vegetation and/or soil will be completed in winter. Pre-disturbance wildlife sweeps would be conducted by qualified biologists at least seven days prior to any scheduled vegetation/land disturbance. Mitigation measures to avoid or minimize adverse effects on identified features are not species specific. The methods associated with these pre-construction and pre-clearing sweeps will be tailored to species at risk that may potentially be using habitats at certain times of the year. Methods will include searching for potential roost trees for bat species, as per protocols included in the Wildlife Habitat Features Field Guide (BC Ministry of Environment and Climate Change Strategy, Ecosystems Branch 2019). If sensitive features are found, then they will be documented, and data collected would inform the development and implementation of appropriate mitigation measures. <p>It is unclear what is meant by “surveys are not species-specific” but sweeps will be “tailored to the species at risk”. It is also unclear how mitigation measures will be developed and implemented in a seven-day period.</p> <p>In order for ECCC and CNSC to provide advice on potential effects to SAR based on the habitat potential mapping, the development of species-specific mitigation measures needs to be produced for review during this assessment process. The Proponent also needs to provide details on follow up and monitoring programs that are in place to confirm that the mitigation measures implemented are effective.</p> <p>In addition, ongoing monitoring is required for SAR. Denison is expected to describe the planned monitoring and follow-up programs for SAR. Denison must justify how the proposed methods are adequate to provide a baseline for each SAR, to verify</p> | <p>The requested information on species at risk pre-clearance sweeps are summarized below in Attachment IR-142, IR-159, IR-167-R1 (Round 3).</p> <p>Denison and its SMEs believe we have provided sufficient information and analysis in the EIS, associated supporting documents and IR responses for the federal government to make a determination as to the effect of the Project on SAR, within the approved scope of the Project and CEEA 2012.</p> <p>Commensurate with the stage of the Project and EA process conceptual level detail for monitoring and follow-up programs (see EIS Appendix 16F) and a description of the programs fit into the overall environmental management system (EIS Section 2.9) have been provided. Further details regarding these programs have been provided in response to various IRs. Denison continues to refine the program level detail, and in parallel develop its plan level documentation to support CNSC licensing and provincial permitting. Any ongoing monitoring for SAR will be detailed in the Wheeler River Project’s Environmental Management Program documentation, including for example the Biodiversity Management Plan. We also note that ongoing SAR management is under Provincial jurisdiction. For reference, within the EIS, the EMS framework is described in Section 2.9, wildlife monitoring plans are provided in Section 9.3.8, avian monitoring plans are provided in 9.4.8, and a summary of general and species-specific mitigation measures is provided in Appendix 9-D. Briefly, wildlife and avian species will be routinely monitored throughout the life of the Project in accordance with the wildlife monitoring plans. An adaptive management process will be employed, after applicable consultations and approvals, where implemented mitigation measures are found to be unsuccessful.</p> |

Attachment IR-142, IR-159, IR-167-R1 (Round 3)

Table 1: Species at Risk Survey Methods

| Species of Concern | Baseline Survey Results | Assessed in the EIS | Important Habitat and Needs | Survey Target Areas | Survey Technique | Timing | Action if Species Detected | Information Source |
|--------------------------------------|---|---------------------|--|---|---|---|---|--|
| Northern Leopard Frog | Not observed. | Appendix 9-D | From winter sites, adult frogs travel up to 1.6 km to breed. | Wetlands/ water/ riparian / wet/ moist/ scrublands/ bogs/ fens. | Visual searches for egg masses or frogs. | Snow/ice-free early spring and spring season. | Pond setback; 10m (low); 200m (Mod) and 500m (High); | MOE (2017) |
| | | | They breed in the shallow, warm waters of a variety of wetlands including marshes, springs, flooded ditches, dugouts, borrow pits, beaver ponds, margins of lakes, and slow-moving waters of streams and rivers. | | Auditory call surveys. | April 20 to June 10. | | |
| | | | After breeding, adults and sub-adults may disperse up to 8 km from breeding ponds. | | | | | |
| | | | Northern Leopard Frogs usually do not utilize areas that are heavily wooded | | Visual searches for egg masses or frogs. | Snow/ice-free early spring and spring season. | | |
| | | | They forage in the summer in riparian or upland habitats. These areas are moist habitats including meadows, pastures, scrublands, riparian corridors, and drainage or irrigation ditches. | | Visual searches for egg masses or frogs. | Snow/ice-free early spring and spring season. | | |
| Little Brown Myotis and Northern Bat | 34 ultrasonic detections of little brown/northern myotis. | Appendix 9-D | The presence of large snags, tree cavities, is an important attribute in old growth forest stands that provides maternity roosts and day roosts for northern myotis and little brown bats. Building are also used. | Treed areas with the largest diameter and/or older trees. Focus on older forest, or areas with large snags in younger forest within the project footprint (majority is regenerating forest 1-5m). | Daytime visual search of trees and potential roost sites. Systematic meandering search of areas to be cleared during active bat season. Focus on searching for roost features (snags, cracks, stumps, cavities, bark peeling) and bat sign (e.g., guano). | May to Sept | Should a roosting bat be discovered the area will be afforded protection from clearing for 24 hours and re-surveyed. The area will only be cleared if no bats are discovered. A 100 m buffer will be given to nursery roots and 50 m to daily roosting bats. If many roosting bats are recorded compensation will be considered (e.g., bat houses). | COSEWIC (2013a); Resources Information Standards Committee (RISC) (2022) |

| Species of Concern | Baseline Survey Results | Assessed in the EIS | Important Habitat and Needs | Survey Target Areas | Survey Technique | Timing | Action if Species Detected | Information Source |
|--------------------|-------------------------|---------------------|---|--|---|--------------------|---|--|
| | | | Foraging habitat in proximity to roosting sites is also an important factor in roost selection. | Treed areas in proximity to clearings, wetlands and open water. | | Year Round | Roost/Foraging site; 100m(low); 500m (Mod) and 500m (High); | MOE (2017) |
| Wolverine | Not observed. | Section 9.3 | A wide variety of forested and vegetation associations are used by wolverine. Habitats must have an adequate year-round supply of food, mainly consisting of smaller prey such as rodents and Snowshoe Hares, and the carcasses of large ungulates, like Moose, Caribou, and Muskox. | All areas of project activity. | Winter den searches. | Snow cover months. | Setback of 250m when occupied and 100m when unoccupied. | COSEWIC (2014); Environmental Protection and Management Guideline (2024) |
| | | | Females den under snow-covered rocks, logs or within snow tunnels. Wolverines reproduce in areas where snow cover persists at least into April. | | | | | |
| Woodland Caribou | Observed. | Section 9.3 | Woodland caribou may occupy all potential project areas but prefer forests greater than 40 year of age. | All areas of project activity. | Visual search to ensure no caribou are in the area. Ongoing vigilance. | Year Round | If caribou are within the Project area cease operations until they are clear of the area. | SME (2021) |
| Rusty Blackbird | Not observed. | Section 9.4 | Rusty blackbird primarily nests in small conifers, predominantly spruce. In Canada, nests have also been found in Balsam Fir, Eastern White Cedar, Paper Birch, Balsam Poplar, Red Maple, Pin Cherry, emergent sedges, cattails, and on the ground on a beaver dam | All habitat with spruce, white birch and balsam poplar. Very limited suitable (spruce) habitat within project footprint. | Visual search for nests. | MBCA window | A 75 m buffer around coniferous bogs, fens and other wetlands suitable for Rusty blackbirds (Odsen and Pyper 2019). | Environment Canada. (2015); Odsen and Pyper (2019); Wildlife Division (2020) |
| | | | We only have spruce, birch and poplar at Wheeler. | | | May 1 to July 31 | Nest setback of 0-50m (low activity); 150m (Mod activity) and 300m (High activity); | Manitoba Conservation (2021) |
| Yellow Rail | Not observed. | Section 9.4 | Yellow rails inhabit shallow wetlands and other wet areas with grass-like vegetation. | Using available mapping conduct daytime Ecosite verification and stratify surveys in appropriate habitat only. Based on available mapping, no suitable habitat within project footprint. | Mid May to mid to late June. Triplicate nocturnal (23:00-03:00) call-playback surveys spaced at least 4 days apart. Or use Autonomous Recording Units throughout the breeding season. | | | Environment Canada (2012); SME (2014) |
| | | | They breed in wetlands such as damp hay fields or meadows, floodplains, bogs, upper levels of estuaries, salt marshes | | | | | |
| | | | These wetlands are generally dominated by short, fine-stemmed herbaceous vegetation, especially sedges (Carex spp.), as well as other graminoid vegetation of the families Cyperaceae, Poaceae, and Juncaceae. Vegetation structure (e.g. short, grass-like, and dense) is likely more important than its taxon | | | | | |

| Species of Concern | Baseline Survey Results | Assessed in the EIS | Important Habitat and Needs | Survey Target Areas | Survey Technique | Timing | Action if Species Detected | Information Source |
|--------------------|--|---------------------|--|--|-------------------------------------|-------------------|--|------------------------------|
| | | | Breeding habitats may have up to 50 cm of standing water, but typically nesting sites are less than 15 cm deep | | | May 1 to July 15 | Nest site setback; 100m(low); 150m (Mod) and 350m (High); | MOE (2017) |
| Bank Swallow | Not observed. | Appendix 9-D | The Bank Swallow readily breeds in a wide variety of low-elevation (< 900 m), natural and anthropogenic habitats, including: lake and ocean bluffs; stream and river banks; sand and gravel pits; roadcuts; and piles of sand, topsoil, sawdust, coal ash, and other materials. | Survey key habitat features identified as important. | Visual survey during timing window. | May 15 to July 31 | Nesting Colony Setback; 50m (low); 150m (Mod) and 300m (High); | Manitoba Conservation (2021) |
| | | | Nest burrows are nearly always in a vertical or near-vertical bank (range: 76-105° slope; | | | | | COSEWIC (2013b) |
| | | | In some cases, Bank Swallows have nested in drain pipes and in structures designed and built specifically for nesting Bank Swallows | | | | | |
| Barn Swallow | Four visual/auditory detections. | Appendix 9-D | Nest on horizontal and vertical structures that include natural sites, such as cliffs and caves, as well as human-made structures, such as barns, bridges, and culverts . The nesting substrate must be rough, or have a ledge or projecting objects, such as bolts or light fixtures, to provide additional structural support to the nest. | Open areas in proximity to water. All buildings and man made structures. | Visual. | May 15 to Sept 30 | Nest site setback; 50m (low); 100m (Mod) and 100m (High); | Manitoba Conservation (2021) |
| | | | Nesting sites must provide access to open areas with an abundant supply of aerial insects to feed on; features such as wetlands, waterbodies, watercourses, meadows, grazed grassland, and farmland are preferred . Proximity to a waterbody or moist area with a supply of wet mud is needed to facilitate nest construction. | | | | | COSEWIC (2021a) |
| Common Nighthawk | Two nests, five visuals and 76 auditory/visual detections. | Section 9.4 | Nests are typically in open sites with dry, well-drained substrates that will not overheat and that have shade nearby for young to shelter from the sun and predators. Nest sites include forest clearings, bare patches in grassland, gravel pits, outcrops, road or rail sides, and, rarely, fenceposts. | All upland habitat. | Visual searches. | May 1 to Aug 31 | Nest site setback; 0-50m (low); 150m (Mod) and 300m (High); | MOE (2017) |
| Horned Grebe | One observation. | Appendix 9-D | More than 90% of the Horned Grebes in North America breed in ponds and lakes in western and northern Canada. | Water bodies within the project area. | Visual searches. | May 1 to Sept 15 | Nest site setback; 100m (low); 200m (Mod) and 400m (High); | Manitoba Conservation (2021) |
| | | | | | | | | COSEWIC (2009) |

| Species of Concern | Baseline Survey Results | Assessed in the EIS | Important Habitat and Needs | Survey Target Areas | Survey Technique | Timing | Action if Species Detected | Information Source |
|------------------------|-------------------------|---------------------|---|---|-----------------------------------|-------------------|---|---------------------------|
| Olive-sided Flycatcher | Fourteen observations. | Section 9.4 | Olive-sided Flycatcher has been widely observed in open coniferous or mixed coniferous forests, often located near water or wetlands with the presence of tall snags or trees | All conifer and/treed upland areas. | Call-playback or visual searches. | May 1 to Aug 31 | Nest setback; 100m (low); 300m (Mod) and 500m (High); | MOE (2017) |
| | | | Data gathered from points across Canada indicate that mature conifer stands within patchy landscapes influenced by natural disturbance (e.g., recent burns) support the highest densities | | | | | Environment Canada (2016) |
| | | | Olive-sided Flycatcher prefers post-burn areas or wetlands that create open habitats for the species to forage | | | | | |
| Short-eared Owl | Not observed. | Section 9.4 | Nesting generally occurs in large open areas | Open upland and lowland areas with no trees and some shrub cover. | Call-playback or visual searches. | March 25 to Aug 1 | 100m (low); 300m (Mod) and 500m (High); | MOE (2017) |
| | | | Requires a minimum area of about 50-100 ha, consistent with the mean territory size of 82 ha reported in Manitoba. | | | | | COSEWIC (2021b) |
| | | | In the north, nests are primarily in tundra (Sinclair et al. 2003), and sometimes beside a small shrub that provides cover | | | | | |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 2024) |
|--------------|----------------|---|---|--|--|---|---|---|
| IR-149 | - | <p>Context: The EIS describes that ongoing research is performed to inform the development of a Woodland Caribou Management Plan. This includes studies on the effectiveness of linear disruption features on predator/prey movements, and a field program for long-term reclamation planning. Moreover, it is stated that the Plan will include a detailed assessment of the need for habitat offsets.</p> <p>The draft EIS Section 9.3.5.2 states: “A wildlife monitoring plan and a Woodland Caribou Management Plan will be developed to address wildlife-specific mitigation measures based on proven and accepted mitigation following standard industry guidelines and BMPs. The plans will provide guidance to avoid or minimize potential adverse effects of the Project on wildlife and wildlife habitat, including monitoring and follow-up programs, as appropriate. It will be in place during all phases of the Project and will be subject to ongoing review and revision as required. If monitoring identifies a need for additional or revised mitigation measures, a process of adaptive management (as described in the plan) will be triggered.”</p> <p>Rationale: The draft EIS does not present sufficient species-specific mitigation measures for boreal caribou. ECCC is not able to assess potential residual impacts to caribou without specific mitigations.</p> <p>Since the Woodland Caribou Management Plan is still under development, it is difficult to judge whether the measures will be adequate to mitigate and/or offset potential project effects on Woodland caribou and its critical habitat.</p> | <p>Provide the Woodland Caribou Management Plan, to demonstrate effective mitigation of potential project effects, along with wildlife-specific mitigation measures for review.</p> <p>The Plan should be informed by and consistent with the Boreal Caribou Recovery Strategy and demonstrate that avoidance and minimization measures will be applied to mitigate for predicted Project effects to boreal caribou and its critical habitat prior to considering offsetting measures. That is, the Plan should follow the mitigation hierarchy and information should be provided as outlined below:</p> <p>1. AVOID: Describe all measures that will be taken to avoid effects to boreal caribou and avoid the destruction or alteration boreal caribou critical habitat.</p> <p>2. MINIMIZE: Describe all measures that will be taken to minimize the effects to boreal caribou and minimize the destruction of boreal caribou critical habitat.</p> <p>3. RESTORE ON-SITE: describe the measures that will be taken to restore disturbed areas of the project, related to construction, operation and maintenance, on boreal caribou critical habitat, remaining after considering the avoidance and minimization measures.</p> <p>4. Characterize the risk of the adverse effects that are likely to result from the project on boreal caribou and its critical habitat after avoidance minimization, and onsite restoration measures have been considered.</p> <p>5. OFFSET: Describe the measures that will be implemented outside the Designated Project area to mitigate adverse effects, destruction or alteration of boreal caribou critical habitat by the Designated Project during construction and operation.</p> <p>6. Characterize the risk of the adverse effects that are likely to result from the project on boreal caribou and its critical habitat after avoidance, minimization, onsite restoration, and offset measures have been considered.</p> <p>Describe all relevant uncertainties on the effectiveness of the measures to address adverse effects on boreal caribou and the rationale for the selected measure, in light of the mitigation hierarchy.</p> <p>See also related IRs: IR-149 and IR-157.</p> | <p>Denison considers the EA to be a planning and decision-making tool that assesses the potential effects of the Project in a careful and precautionary manner and integrates results of engagement with Indigenous nations and communities. As such, the EA is a process for identifying the Project’s potential interactions with the biophysical and human environment, predicting potential adverse effects, identifying mitigation measures, and evaluating residual and cumulative effects remaining after mitigation. The EA also outlines the proposed efforts for monitoring and reporting to verify compliance with the terms and conditions of EA approval and to assess the accuracy and effectiveness of predictions and mitigation measures presented in the EA. Denison views the EIS as an important planning tool that will be used to support future activities and represents one stage in the rigorous overall approvals process for a uranium mining facility in Canada. Denison is completing a sequential EA and licensing process for the Project. In the EIS, a framework for the Environmental Management System (EMS) is provided along with a clear commitment for Denison to include Project design and species-specific mitigation measures into the EMS documents as they are developed / as the Project proceeds through the licensing and permitting phases.</p> <p>The selection of valued components (VC), with key indicators (KI), and associated measurable parameters is an important part of scoping in each biophysical and human environment assessment. Woodland caribou were selected as a VC in the Terrestrial Environment assessment for a variety of reasons including a recognition of caribou as an important cultural and subsistence species, the conservation status of caribou, and that Project activities and infrastructure may affect woodland caribou populations. For the woodland caribou VC, the KI selected was also woodland caribou. The measurable parameters for the caribou VC/KI were: 1. amount of habitat that may be altered or lost relative to its availability in the Terrestrial RSA; and, 2. woodland caribou mortalities directly or indirectly attributable to the Project.</p> <p>The main Project interactions identified in the caribou assessment were: direct habitat loss, sensory disturbance, collisions with Project vehicles and equipment, and harvest and/or predation. Accordingly, the potential effects evaluated for caribou were: 1. amount of habitat that may be altered or lost relative to its availability in the Terrestrial RSA; and, 2. mortalities directly or indirectly attributable to the Project. Denison undertook the evaluation and assessment of potential effects on caribou in a conservative fashion to provide confidence in the assessment conclusions. For instance, where granular data concerning seasonal distribution and specific landscape uses were not available the approach was to assume the caribou at all life stages were present during all seasons. Additionally, the caribou assessment used conservative assumptions to categorize ‘available’ habitat. Denison also committed to important mitigation measures such as pre-clearance surveys, among other things.</p> <p>The EIS has demonstrated that the Project, as proposed and assessed, is predicted to minimize the potential for environmental adverse effects on caribou and their habitat before any Project specific construction occurs. The conclusions of the assessment predicted that the likely residual effects of the Project on caribou were not significant.</p> <p>Denison met with ECCC representatives on April 20, 2023, and agreed to provide a conceptual caribou mitigation plan as part of the IR response package, and also</p> | <p>This response has not been accepted.</p> <p>The Conceptual Caribou Management Plan does not provide sufficient detail to understand if using the restoration trials as an offset will produce satisfactory habitat compensation to address the Project effects to caribou.</p> <p>Additional clarity on the Proponent’s role in the Developing Eco-restoration Together program is required, such as how the outcomes of these programs will result in mitigation measures and offsetting requirements. Additional clarity on the scope of the program should also be provided so that ECCC can understand the objectives and deliverables of the program.</p> <p>See follow-up IR-149-R1A, IR-149-R1B and AD-71 in the Advice to Proponent table</p> | <p>For context, the responses that have been provided to caribou IR-related elsewhere in this response table (IRs 37, 143, 143-144-R1, 143-145-R1, 144, 145, 148, 151, 155, 156) have relevance to the this, and other IR responses, and it is recommended that all of this information be considered in its entirety. The afore-referenced IR responses include descriptions of additional data that have been obtained and collated and analyses and interpretation that have been completed in relation to the presence of caribou and suitable habitat in Project study areas. At time therefore, Denison and its SME believe there are no material data/information gaps the prevent or constrain the analysis of Project and cumulative effects, defining the appropriate mitigation measures, and establishing the required offset within the provincial offsetting framework.</p> <p>With respect to data gaps, the following is noted:</p> <p>• As described herein, additional data have been obtained and presented in Appendix 9-F. These data help to link caribou data, habitat/ecosite data and habitat suitable into the analysis. It is noted based on the new perspectives the overall conclusions of the caribou assessment are unchanged. While it is acknowledged that data may be lacking on the range level, Denison as a Project proponent is not responsible for and need not a complete a range assessment for the purpose of a Project-specific cumulative effects assessment.</p> <p>With respect to mitigation measures, the following is noted:</p> <p>• Denison and its SME have re-considered the mitigation measures presented in the EIS documentation to date in light of updated caribou-related information and does not see that further mitigation measures are needed at this time.</p> <p>With respect to offset, the following is noted:</p> <p>• Denison continues to work collaboratively with Saskatchewan Ministry of Environment (MOE) on their requirement for an offset for adverse effects on caribou habitat. Denison has advanced the Project-related Caribou Management Framework within the context of the province’s offsetting framework. The updated document is provided with this second round IR submission.</p> <p>With respect to monitoring, the following is noted:</p> <p>• Denison has committed to monitor for the presence of woodland caribou primarily within the Project Footprint as well as other areas within the Terrestrial RSA based on accepted methods that will be developed as part of its wildlife monitoring follow-up program as part of the implementation of its Environmental Management System. As it is understood, aerial surveys to document presence and habitat use are not permitted by the Saskatchewan Ministry of Environment at this time, Denison conceptually proposes to document the presence of woodland caribou using remote cameras placed strategically within representative habitat types within the Terrestrial RSA and a wildlife observation tracking log (based on the Project-wide implementation of the current wildlife card system Denison has in place). As Denison works collaboratively with the Saskatchewan Ministry of Environment to finalize the Caribou Management Framework, further details on monitoring in conjunction with the offset commitment will be developed.</p> <p>In direct response to the questions raised in the review comment the following is noted:</p> <p>• Denison continues to work collaboratively with Saskatchewan Ministry of Environment (MOE) on their requirement for an offset for adverse effects on caribou habitat. Denison has advanced the Project-related Caribou Management Framework within the context of the province’s offsetting framework. The MOE has reviewed the draft framework and has provided Denison a notification of their support. Subject to finalization and provincial acceptance, the framework will provide the means to address/offset all residual adverse effects (i.e., those remaining after the</p> | <p>Note to Denison: This would be accepted if Denison is able to make a commitment as noted below. The IR has not been fully resolved. The Proponent has updated Appendix 9-F to link caribou data, habitat/ecosite data and habitat suitability in its analysis which remain unchanged from conclusions provided in the EIS and has committed to monitoring using remote cameras for presence of caribou within the Project Footprint and within the Terrestrial RSA as part of the Environmental Management System. However, the Caribou Management Framework is still lacking the requested information on the amount of offset required to mitigate effects to caribou. Without the intended outcomes of the offsetting plan, there remains uncertainty regarding whether effects are adequately addressed in a manner that is consistent with the species Recovery Strategy. Additionally, the generic mitigation measures have not been updated to include factors, such as sensory disturbances, during important life stages.</p> <p>In order for ECCC and CNSC to provide additional technical advice on potential impacts to caribou, the Proponent would need to provide the previously requested information on the amount of habitat required to mitigate the adverse effects to caribou resulting from the Project and update the mitigation measures to include factors, such as sensory disturbances, during important life stages.</p> <p>Given that ECCC and CNSC understand that the Province of Saskatchewan and ECCC’s Canadian Wildlife Service are in communication on the Denison’s caribou management plans, and the province’s offsetting plan is underway, if Denison are willing to add a commitment to the Commitments Register, this IR could be resolved. The commitment text would include the commitment that “Denison’s offsetting plan will meet the objectives of the Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal population, in Canada.”</p> <p><i>Proposed rationale text for posting: Denison has captured their commitment related to caribou management and offsetting in the Commitments Register, so this IR has been accepted.</i></p> | <p>Denison’s understanding is that by meeting the Provincial offset requirements, as part of the Saskatchewan range planning, the company will be meeting the objectives of the recovery strategy since the Province is responsible for caribou management. To provide a clear affirmation of Denison’s commitment to offsetting, we have added the following commitment to the Commitment Register (version 2) as Commitment 9-35:</p> <p>“Denison will develop an offsetting plan to satisfy the requirements of the Province of Saskatchewan offsetting framework that the province has created to fulfill its obligations as it concerns implementing the objectives of the Recovery Strategy for the Woodland Caribou (<i>Rangifer tarandus caribou</i>), Boreal population, in Canada.”</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 2024) |
|--------------|----------------|--|--------------------------|---|--|--|--|---|
| | | | | <p>include the conceptual plan in the final EIS. As such, the Project’s Conceptual Caribou Mitigation Plan is provided as Attachment IR-149 and will be included in the final EIS.</p> <p>The framework for the Conceptual Caribou Mitigation Plan (the Plan) was developed during discussions between Denison and Saskatchewan Ministry of Environment (ENV) in May and June 2023. The Plan is an evergreen document. It will be consistent with the management goals of ENV for the SK-1 caribou conservation unit and will be developed/refined in consultation with local communities including English River First Nation and Kineepik Métis Local in Pinehouse and ENV. Since the boreal caribou range plan for SK-1 is under development, it is understood that this Plan will be updated as more information becomes available. The conceptual nature of the Plan at this time is in part due to the absence of range plan priorities and reflects Denison’s commitment to continue to work with ENV to meet the management objectives and management strategies for the SK1 range. This approach acknowledges that the responsibility for woodland caribou management lies with the Province of Saskatchewan. Broadly, the province is responsible for developing range plans or management plans which build on the federal recovery strategy by setting goals and objectives for maintaining sustainable population levels. The EIS has demonstrated that the Project, as proposed and assessed, is predicted to minimize the potential for environmental adverse effects on caribou and their habitat before any Project specific construction occurs. The conclusions of the assessment predicted that the likely residual effects of the Project on caribou were not significant.</p> | | <p>application of the proposed mitigation measures) of the Project on caribou that are under provincial jurisdiction.</p> <p>• We also note that the Eco-restoration Together (ERT) program is no longer considered within the context of the Project-related Caribou Management Framework that outlines the offset plans that Denison has been working closely with Saskatchewan MOE to develop. The ERT program will focus primarily on site restoration techniques for decommissioning. The offset requirements that are being developed are those that will fulfill provincial requirements under their offsetting program scheme.</p> <p>• Further, Denison has committed to monitoring the effects on wildlife, as per the Wildlife Management Plan. The findings of the monitoring programs are expected to inform Denison, through an adaptive management process, of the need, if any, for additional mitigation measures.</p> | | |
| IR-149 | IR-149-R1A | <p>Context: Much of the information presented in the Conceptual Caribou Management Plan is qualitative in nature and does not present specific details regarding a quantitative assessment of impacts following measures to avoid, minimize, and restore on-site and then assess residual effects and determine the offset required to counterbalance the remaining impacts. This is required to understand if offsetting is sufficient to address impacts to caribou. The Proponent also does not provide details on methods that will be used for pre-disturbance wildlife clearance surveys. ECCC is aware that that the Proponent will be participating in restoration trials as part of the ‘Developing Eco-restoration Together’ program.</p> <p>Rationale: ECCC requires the quantitative details on the assessment of impacts to be included within the Conceptual Caribou Management Plan to adequately assess how the Proponent has applied the mitigation hierarchy. Details on the methods that will be used for pre-disturbance wildlife clearance surveys will also be required to verify that the Proponent has adequately considered how they have avoided, mitigated, or restored impacts to caribou.</p> <p>While ECCC understands that the Proponent will be participating in restoration trials as part of the ‘Developing Eco-restoration Together’ program, however, more clarity on the Proponent’s role in the program and the scope of the program is required. Details such as how the outcomes of these programs will result in mitigation measures and offsetting requirements and additional clarity on the scope of the program should also be provided so that ECCC can understand the objectives and deliverables of the program</p> | n/a | n/a | <p>1. Provide a quantitative assessment of impacts following measures to avoid, minimize and restore on-site and then assess residual effects and determine the offset required to counterbalance the remaining impacts.</p> <p>2. Provide details on methods to be used for pre-disturbance wildlife clearance surveys.</p> <p>3. Provide details on the Proponent’s role in the Developing Eco-restoration Together program and how that work may be used in offsetting requirements.</p> <p>4. Provide the scope (i.e., quantitative habitat amount) of the Eco-restoration Together program.</p> | <p>Please see response to IR-149.</p> <p>In addition, in direct response to IR-149-R1A the following is noted.</p> <p>1. Denison continues to work collaboratively with Saskatchewan Ministry of Environment (MOE) on their requirement for an offset for adverse effects on caribou habitat. Denison has advanced the Project-related Caribou Management Framework within the context of the province’s offsetting framework. The MOE has reviewed the draft framework and has provided Denison a notification of their support. Subject to finalization and provincial acceptance, the framework will provide the means to address/offset all residual adverse effects (i.e., those remaining after the application of the proposed mitigation measures) of the Project on caribou that are under provincial jurisdiction.</p> <p>2. For clarification, the pre-construction and pre-clearing surveys will consist of wildlife sweeps conducted by qualified biologists within 7 days prior to any clearing activity at a specific location, and a 100 m buffer, within the Project Footprint. The wildlife sweeps are intended to identify sensitive wildlife features such as hibernacula, dens, nests, cavities, mineral licks, that would require specific mitigation measures to avoid or minimize adverse effects on identified features and are not species-specific but will be based on timing of Project related activities (i.e., will be completed in advance of site clearing activities). This is a risk-based approach with the intent of reducing the potential of important wildlife features being adversely affected during vegetation or land disturbance activities. The methods associated with these pre-construction and pre-clearing sweeps will be tailored to species at risk (including woodland caribou) that may potentially be using habitats at certain times of the year. For example, in the event the sweeps are conducted during the winter period, methods would include snow tracking to identify woodland caribou presence based on tracks and feeding craters observed within the study areas, based on survey protocols provided by the Government of Saskatchewan (2014). This effort would also be combined with use of remote cameras that have been in place throughout the Terrestrial RSA for the past several years, and the photos captured from the cameras can be used to further verify caribou presence with the study areas. The wildlife sweeps would be conducted within 7</p> | <p>Note to Denison: The proposed path forward on this IR is to develop a commitment to be added to Denison’s Commitment Register, related to Denison’s offsetting plan meeting the objectives of the province’s Caribou, Boreal recovery strategy. The language around this is still in discussion, and the text in draft.</p> <p>Item two has not been resolved, but this is also in discussion, given overlap with IR-134.</p> <p>Updated Rationale (item two is still in discussion):</p> <p>In responding to item one, the Proponent has not provided a quantitative assessment of impacts following measures to avoid, minimize, restore on-site or offset. The updated draft Caribou Management Framework indicates that the Proponent will use the SK ENV caribou offset calculator to inform decisions on the required offset amount. Without information on the amount of offsetting that will be implemented, ECCC cannot advise on whether the amount is appropriate in the context of the species Recovery Strategy. A follow up to IR 149-R1A can be found within the Advice to the Proponent document.</p> <p>With regards to Item one, given that ECCC and CNSC understand that the Province of Saskatchewan and ECCC’s Canadian Wildlife Service are in communication on the Denison’s caribou management plans, and the province’s offsetting plan is underway, if Denison are willing to add a commitment to the Commitments Register, this IR could be resolved. The commitment text would include the commitment that “Denison’s offsetting plan will meet the objectives of the Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal population, in Canada.”</p> <p>Proposed rationale text for posting: Denison has captured their commitment related to one, with</p> | Refer to response to IR-149 (above) and response to IR-142-159-167-R1 (in a separate IR table). |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 2024) |
|--------------|----------------|---|--------------------------|---|--|--|---|---|
| | | | | | | <p>days prior to disturbance activities, year-round, so that sensitive features can be identified, and appropriate mitigation measures (e.g., avoidance, timing delay) can be developed and implemented, as appropriate.</p> <p>Further, Denison has committed to monitoring the effects on wildlife, as per the Wildlife Management Plan. The findings of the monitoring programs are expected to inform Denison, through an adaptive management process, of the need, if any, for additional mitigation measures.</p> <p>3. The Eco-restoration Together program is no longer considered within the context of the Project-related Caribou Management Framework that outlines the offset plans that Denison has been working closely with Saskatchewan MOE to develop. The offset requirements that are being developed are those that will fulfill provincial requirements under their offsetting program scheme.</p> <p>4. The Eco-restoration Together program is no longer considered within the context of the Project-related Caribou Management Framework that outlines the offset plans that Denison has been working closely with Saskatchewan MOE to develop. The offset requirements that are being developed are those that will fulfill provincial requirements under their offsetting program scheme.</p> <p>References:</p> <p>Government of Saskatchewan. 2014. Snow Track Survey Protocol. Fish and Wildlife Branch, Ministry of Environment. 8 pp.</p> | <p>regards to caribou management and offsetting in the Commitments Register, so this IR has been accepted.</p> <p>In responding to item two, the Proponent has clarified that the use of wildlife sweeps will be used for pre-construction and pre-clearing surveys, however there is no information on the methodology that will be used to collect data. The Proponent notes that these sweeps will not be species-specific but will be based on timing of Project related activities. Without documenting how data will be collected (i.e., to identify which species are in the area) there is uncertainty as to whether the methodology implemented will provide relevant results. Additionally, the Proponent notes that methods associated with these surveys will be tailored to species at risk that may potentially be using habitats at certain times of the year; but have provided no method on how these sweeps will be tailored. ECCC suggests the Proponent explain how data will be collected during wildlife sweeps and provide the method on how the sweeps will be tailored to species at risk.</p> <p>Items three and four have been resolved as the Proponent is no longer using the Eco-Restoration Together Program as part of their offsetting plan. Items one and two remain outstanding.</p> | |
| IR-149 | IR-149-R1B | <p>Context: Section 4.2.2 of the Conceptual Caribou Mitigation plan states: "locating excessive noise generating activities such as the concrete batching operation as far away from sensitive wildlife locations as possible;". However, no specific mitigation measures are mentioned for impacts to caribou due to noise generated from the Project air strip.</p> <p>Rationale: Noise from the air traffic using the air strip will also generate excessive noise that can impact caribou. Additional information on the timing and frequency of air traffic, as well as specific mitigations related to impacts from air traffic, including mitigations related to frequency and timing of flights, will be necessary to evaluate impacts to caribou due to air strip noise.</p> | n/a | n/a | <p>1. Provide additional information on the timing and frequency of air traffic using the Project air strip.</p> <p>2. Provide specific mitigations related to impacts from air traffic, including mitigations related to frequency and timing of flights.</p> | <p>Please see response to IR-149.</p> <p>In addition, in direct response to IR-149-R1B the following is noted.</p> <p>The flight schedules have not yet been determined at this relatively early stage of planning for the Project.</p> <p>Mitigation measures likely to be incorporated into the operation of the airstrip, with respect to air traffic, would include, as safety allows, maintaining as direct approach and departure flight paths as possible, and obtaining appropriate altitudes, and leaving the LSA and RSA, as quickly as is safely reasonable.</p> | <p>Item two has been accepted as the Proponent has provided potential measures likely to be incorporated into operations of the airstrip, but item one remains outstanding. The information requested was not provided as the Proponent notes it is too early in the planning phase to provide this information. Once flight schedules have been determined, the Proponent should share them for review. If this cannot be provided at this time, the Proponent should provide information on the frequency and approximate timing of flights, as well as any periods of restricted activity planned for mitigation purposes.</p> <p>In addition, Denison is expected to provide details on specific mitigation measures to address sensory impacts to caribou, such as restricted activity periods to accommodate for the caribou calving season, or different flight paths.</p> <p>Please see the related follow up advice for IR-149-R1B in the Advice to the Proponent document.</p> | <p>The EIS concluded there are no significant adverse residual effects on caribou associated with the Project, which included the assessment of habitat alteration due to sensory disturbances, including the operation of an airstrip. We reiterate that the EIS was completed with the appropriate level of detail expected at this stage of the Project.</p> <p>Notwithstanding the above, Denison notes that the anticipated aircraft traffic at the Project airstrip is expected to include approximately five flights per week during Operation (this was noted in the EIS) and opportunities to optimize the flight schedule will be completed by Denison as the Project advances.</p> <p>Denison can commit to the following related to air traffic and this has been added to the commitment register as Commitment 9-36: "Denison will operate the airstrip and flights in a safe manner and will also seek to minimize interactions with wildlife by following guidance and best practice from Saskatchewan and other jurisdictions. Mitigation measures likely to be incorporated into the operation of the airstrip, with respect to air traffic, would include, as safety allows, maintaining as direct approach and departure flight paths as possible, and obtaining appropriate altitudes, and leaving the LSA and RSA, as quickly as is safely reasonable. Flight paths can be adjusted based on the location of caribou observations or known important areas during sensitive periods, as it safe and practical to do so. Details related to airstrip and flight management will be developed as part of Project licensing and permitting."</p> |

Acronyms and Abbreviations

| Term | Definition |
|--|---|
| Anthropogenic | Caused or produced by humans |
| BSCs | biological soil crusts |
| Boreal Caribou | The boreal ecotype of woodland caribou occurs within the boreal forest of Canada. These non-migratory caribou form small aggregations throughout the year and disperse for solitary calving. |
| Committee on the Status of Endangered Wildlife in Canada (COSEWIC) | A committee made up of experts from academic, government and non-government organizations that assess the conservation status of wildlife species that may be at risk of extinction in Canada. |
| Critical Habitat | The habitat that is necessary for the survival of a listed wildlife species and is identified as the species critical habitat in the recovery strategy or action plans for the species. |
| DERT Project | Developing Eco-Restoration Together Project |
| Disturbed habitat (per ECCC 2020) | Habitat showing: i) anthropogenic disturbance visible on Landsat at a scale of 1:50,000, including habitat within a 500 m buffer of the anthropogenic disturbance; and/or ii) fire disturbance in the last 40 years, as identified in data from each provincial and territorial jurisdiction (without buffer). |
| ECCC | Environment and Climate Change Canada |
| EA | environmental assessment |
| EIS | environmental impact statement |
| EMS | environmental management system |
| ENV | Saskatchewan Ministry of Environment |
| ha | hectare |
| Local Populations (ECCC 2020) | Group of boreal caribou occupying a defined area distinguished spatially from areas occupied by other groups of boreal caribou. Local population dynamics are driven primarily by local factors affecting birth and death rates, rather than immigration or emigration among groups. In this recovery strategy, “local population” refers to a group of boreal caribou occupying any of the |

|--|--|
| | three types of boreal caribou ranges (i.e., conservation unit, improved conservation unit, local population unit). |
| Plan | Conceptual Caribou Mitigation Plan |
| Project | Wheeler River Project |
| Range (per ECCC 2020) | <p>The geographic area occupied by a group of individuals that are subject to similar factors affecting their demography and used to satisfy their life history processes (e.g., calving, rutting, wintering) over a defined time frame.</p> <p>Environment and Climate Change Canada (2011) identified three types of boreal caribou ranges categorized based on the degree of certainty in the delineated range boundaries (i.e., conservation unit, improved conservation unit, local population unit).</p> |
| Recovery strategy | A planning document that identifies what needs to be done to stop or reverse the decline of a species. |
| SARA | Species at Risk Act |
| Self-sustaining local population (ECCC 2020) | A local population of boreal caribou that on average demonstrates stable or positive population growth over the short-term (≤ 20 years) and is large enough to withstand stochastic events and persist over the long-term (≥ 50 years), without the need for ongoing active management intervention. |
| Threatened species | A wildlife species that is likely to become endangered if nothing is done to reverse the factors leading to its extirpation or extinction. |
| Undisturbed habitat (per ECCC 2020) | Habitat not showing any: i) anthropogenic disturbance visible on Landsat at a scale of 1:50,000, including habitat within a 500 m buffer of the anthropogenic disturbance; and/or ii) fire disturbance in the last 40 years, as identified in data from each provincial and territorial jurisdiction (without buffer). Disturbance within the 500 m buffer would result in a reduction of the undisturbed habitat. |

Introduction

The Wheeler River Project (the Project) environmental impact statement (EIS) evaluates and assesses potential Project-related effects on the Boreal population of woodland caribou (*Rangifer tarandus caribou*; referred to herein as caribou or boreal caribou) following standard environmental assessment (EA) methodology. The assessment of potential effects considered both direct (i.e., habitat loss) and indirect effects (i.e., habitat alteration) on caribou and their habitat, while assuming that caribou were present year-round and during all of their life stages (i.e., calving, rearing, mating, over wintering). In this way, the EIS took a precautionary or conservative approach to understanding/addressing the likely residual effects (i.e., effects remaining after mitigation measures were considered) of the Project on caribou and their habitat and is using this approach as a planning tool to inform/support future Project-related regulatory approvals processes and follow-up monitoring. The EIS has demonstrated that the Project, as proposed and assessed, is predicted to minimize the potential for environmental adverse effects on caribou and their habitat before any Project specific construction occurs. The conclusions of the assessment predicted that the likely residual effects of the Project on caribou were not significant.

This Conceptual Caribou Mitigation Plan (the Plan), developed proactively by Denison, has a different objective than the EIS. The Plan builds on the assessment of potential Project effects and commitments to mitigate such effects made in the EIS and is expected to be advanced with ongoing consultation with the Saskatchewan Ministry of Environment (ENV), as ENV finalize the caribou range plan for SK1. The EIS is a conservative planning tool, whereas the Plan is a practical, living document designed to define management works associated with caribou. The Plan is not a requirement for EA determination but is provided as a guidance document to help Denison proactively describe and inform the development and implementation of appropriate mitigation measures related to caribou and their habitat.

The Plan is an evergreen document. It will be consistent with the management goals of ENV for the SK-1 caribou conservation unit, and will be developed/refined in consultation with local communities including English River First Nation and Kineepik Métis Local in Pinehouse and regulators (e.g., ENV). As noted above, the boreal caribou range plan for SK-1 is under development and it is understood that this Plan will be updated as more information becomes available. The conceptual nature of the Plan is in part due to the absence of range plan priorities and reflects Denison's commitment to continue to work with the province to meet the management objectives and management strategies for the SK1 range.

Guidance and Regulatory Framework

A brief review highlighting federal and provincial considerations of boreal caribou is provided below for reference.

Federal

Boreal caribou have been designated as *threatened* under the federal *Species at Risk Act* (SARA). Environment and Climate Change Canada (ECCC) released amended recovery strategy for woodland caribou in 2020 (ECCC 2020). A recovery strategy is a planning document that identifies what should be done to stop or reverse the decline of a species.

The Project is located in the Boreal Shield West ecoregion of the Boreal Shield ecozone. The Boreal Shield West ecoregion stretches from Alberta to Ontario (Figure 2-1).

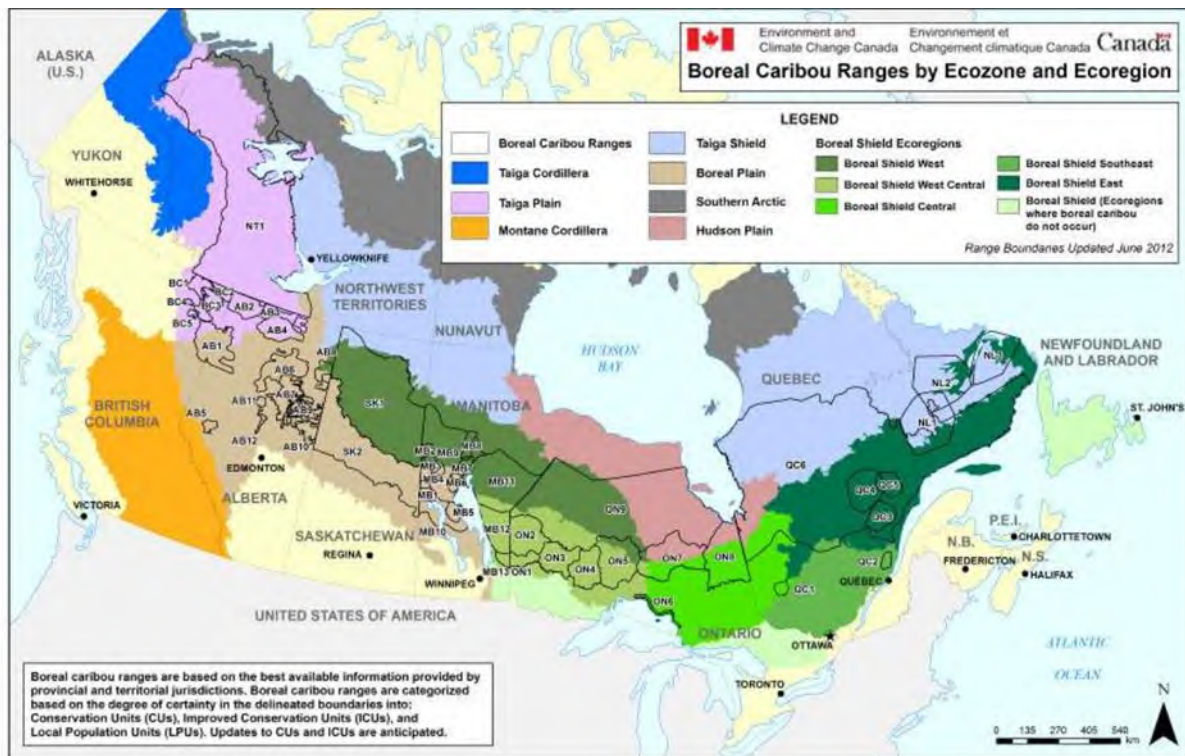

Figure 0-1: Boreal Caribou Distribution Across Ecozones and Ecoregions in Canada (source: ECCC 2020)

The SK1 range comprises more than 18,000,000 hectares (ha) and is characterized by high fire disturbance and low anthropogenic disturbance (ECCC 2020). The likelihood of caribou self-sustainability in the boreal shield range in SK1 is “likely” (ECCC 2020). For SK1, the amended recovery strategy (ECCC 2020) identifies 40% undisturbed habitat in the range as the disturbance management threshold, which provides a measurable probability (71%) for the local population to be self-sustaining. This threshold is considered a minimum threshold because at 40% undisturbed habitat there remains a risk (29%) that the SK1 local population cannot be self-sustaining. Disturbed

habitat (ECCC 2020) is habitat showing: i) anthropogenic disturbance visible on Landsat at a scale of 1:50,000, including habitat within a 500 m buffer of the anthropogenic disturbance; and/or ii) fire disturbance in the last 40 years, as identified in data from each provincial and territorial jurisdiction (without buffer). Undisturbed habitat (ECCC 2020) is habitat not showing any: i) anthropogenic disturbance visible on Landsat at a scale of 1:50,000, including habitat within a 500 m buffer of the anthropogenic disturbance; and/or ii) fire disturbance in the last 40 years, as identified in data from each provincial and territorial jurisdiction (without buffer). Disturbance within the 500 m buffer would result in a reduction of the undisturbed habitat.

Studies (e.g., McLoughlin et al. 2019) indicate that the SK1 local caribou population is likely self-sustaining at current levels of disturbance (60% total disturbance), with a 71% probability of persistence. Environment and Climate Change Canada's analyses also indicate that the SK1 local population is sensitive to small increases anthropogenic disturbance and sensitive to small decreases in adult survival. For these reasons, a higher probability of persistence was selected for critical habitat identification in SK1 (71%) than was selected for the other 50 ranges across Canada (60%) (ECCC 2019).

The precise location of the 40% undisturbed habitat within the range is expected to vary over time. The habitat within the SK1 range should exist in an appropriate spatial configuration such that boreal caribou can move throughout the range and access required habitat when needed. The key to this habitat delineation is achieving and maintaining an overall, ongoing range condition that allows for the dynamic habitat supply system, containing the biophysical attributes upon which caribou depend, to remain sustainable. It is this dynamic habitat supply system within the SK1 range that is the habitat condition considered to be necessary for the caribou.

Provincial

The responsibility for woodland caribou management lies with the Province of Saskatchewan. Broadly, the province is responsible for developing range plans or management plans which build on the federal recovery strategy by setting goals and objectives for maintaining sustainable population levels.

The Saskatchewan Conservation Data Centre (SK-CDC) is responsible for evaluating and assigning a conservation rank to each taxon, resident or transient, found in the province. Woodland caribou's subnational or S-rank conservation rank is S3. This ranking indicates that, provincially, the species is vulnerable/rare to uncommon which is associated with a moderate risk of extinction or extirpation due to a restricted range, relatively few populations, recent and widespread declines, threats, or other factors. Currently, the caribou population in SK-1 is stable (ENV 2023) and the range plan is under development. Engagement is a key component of the range plan process and will be completed with representatives from First Nation, Métis, industry, non-governmental organizations, and communities.

The provincial goal is to sustain and enhance woodland caribou populations, and maintain the ecosystems they require, throughout their current range (ENV 2013). Through the woodland caribou range assessment and range planning program, the province is:

- Gaining a better understanding of woodland caribou ecology;
- Working toward meeting objectives identified in provincial and federal strategies; and

- Improving how the province manages the species and related habitat.

The province's woodland caribou range assessment and range planning program incorporates two key components:

- Woodland caribou range assessment, which enhances the understanding of woodland caribou populations and their interactions with the environment; and
- Woodland caribou range planning, which provides a framework, strategies and objectives that allow for better decisions involving habitat management and self-sustaining caribou populations.

Although the management objectives and management strategies for caribou in SK1 are not yet defined, Denison is committed to working with ENV as the range plan is developed. The Plan will be updated as the Project advances so that it aligns with the conservation objectives as determined by the province as the primary steward of caribou in the province.

SK 1 Caribou Population – Background Information

Background information concerning the condition of the SK 1 caribou population is provided below.

Population Trends

The SK1 Boreal Shield management unit contains high-quality conifer-dominated caribou habitat with greater than 40-year-old stands of jack pine and black spruce forests suitable for lichen colonization, black spruce swamps, and open muskegs supporting relatively high densities of caribou, at 36.9 caribou/1,000 km² or approximately 4,000 caribou across the SK1 Boreal Shield Woodland Caribou Management Unit (McLoughlin et al. 2019).

Research has shown that up to 70% of the year-round diet of caribou may consist of ground and arboreal lichens. If the quantity of available lichen forage is low, caribou can exist without relying entirely on lichens (McLoughlin et al. 2019). Due to their physiology, lichens are resilient to periods of drought and cold temperatures, but because of their slow growth rate, exhibit a slow recovery time after depletion and fire events. In the SK1 range, McLoughlin et al. (2019) found that stand types with the highest potential for adequate lichen biomass for caribou are jack pine and poorly drained black spruce sites.

McLoughlin et al. (2019) observed that, from 2014 to 2018, the caribou population exhibited a high average adult female survival rate and moderate recruitment (0.192 calves per cow in March), ranging from a low of 0.134 calves/cow in March 2016 to 0.244 calves/cow in March 2018. These demographic parameters led the authors to assess the SK1 Boreal Shield caribou population as being stable at the time of their study (McLoughlin et al. 2019).

While calving areas have not been documented within the SK1 range, it is recognized that caribou may use open fen and treed bog habitat types for calving during the spring/summer period. In Saskatchewan, caribou habitat used during the calving season in the SK2 range demonstrated a strong selection for treed muskegs, but avoidance of jack pine, mixed hardwood stands, and roads (Dyke 2008).

Neufeld et al. (2021) summarized results from aerial surveys over a period of eight years in an 87,193 km² study area in the Athabasca Plain and Churchill River Upland ecoregions in the north, that are inclusive of the Terrestrial RSAs that were used in the EIS. During 11 of 16 aerial caribou surveys conducted between 2008 and 2015, woodland caribou were detected in the surveyed areas. The average density of the 16 surveys was estimated at 36.9 caribou/1,000 km² (95% CI = 26.7 to 47.2 caribou/1,000 km²). Across the Neufeld et al. (2021) study area and all years, estimated caribou densities were higher in comparison to averages reported for most other boreal woodland caribou ranges in Canada (i.e., caribou density reported in other areas ranged 4.3 to 18.7/1,000 km²) indicating that caribou can tolerate natural disturbance. One exception to the relatively high caribou densities in northern Saskatchewan was noted: the 2,285 km aerial the Millennium Project in March 2014, 10 km west of the Terrestrial RSA, resulted in lower woodland caribou densities at 5 caribou/1,000 km² (Neufeld et al. 2021).

Eight of the sixteen caribou surveys reported the ratios of male to female and calf to female in their results with the average male:female ratio calculated at 0.571 (95% CI = 0.444 to 0.699) and calf:female at 0.195 (0.158 to 0.232). Again, the 2014 Millennium survey reported a different

male:female ratio, outside the reported range (1.6), concurring with the reported low caribou densities.

Predation

In addition to relatively low predator densities in their study area, McLoughlin et al. (2019) found some spatial separation between caribou and wolves. Caribou did not seem to avoid existing linear features (such as roads, trails, and transmission lines) in the area, while wolves established their territories away from linear features. Unlike caribou, who preferred mature conifer stands, wolves selected for wetlands and patches of deciduous-mixed forest, avoiding stands of mature conifers. Other prey species, such as moose, also occurred at relatively low densities (i.e., 45.7 moose/1,000 km²) (McLoughlin et al. 2019).

McLoughlin et al. (2019) observed that mortality of adult caribou occurred mostly during the snow-free season and only 1 of 94 collared caribou was harvested by a hunter during the four years of the study.

While predation is believed to be a key limiting factor for woodland caribou (Bergerud 1974; Stuart-Smith et al. 1997, DeMars et al. 2011 from ECCO 2020), Neufeld et al. (2021) suggested that habitat- or disturbance-mediated apparent competition only plays a minor role in the Saskatchewan woodland caribou population. Habitat- or disturbance-mediated apparent competition occurs when natural (e.g., forest fires) and anthropogenic (e.g., human development or activities) disturbances increase the abundance of other ungulates, which in turn may increase predator densities, which then increases predation risk to caribou. Neufeld et al. (2021) concluded that Northern Shield and Taiga ecoregions are of low productivity where caribou may compete with only one ungulate species (i.e., moose) and therefore, caribou and wolf dynamics do not follow general habitat- or disturbance-mediated apparent competition models.

Harvest

Indigenous peoples in Saskatchewan have an inherent right to harvest woodland caribou for subsistence purposes (ENV 2013). No other harvest of woodland caribou is currently permitted. Under provincial and federal recovery planning and effective species management, self-sustaining caribou populations will support long-term subsistence use of the species and protect treaty rights. Subsistence harvest levels are assumed to be low but actual numbers are not available because most communities or Indigenous groups are not collecting and/or publishing this information.

No Net Loss and Mitigation Hierarchy

A generic biodiversity mitigation hierarchy (OECD 2016) to achieve no net loss is provided in Figure 0-1. As shown in the hierarchy, an offset can be used to achieve no net loss if residual effects remain following efforts to avoid, minimize, and restore potential project effects. This generic hierarchy is generally consistent with the approach of ENV to manage effects on caribou and their habitat.

The balance of Section 4 of this Plan outlines Denison's approach to avoid, minimize, and restore caribou habitat per commitments made in the draft EIS associated with the Wheeler River Project.

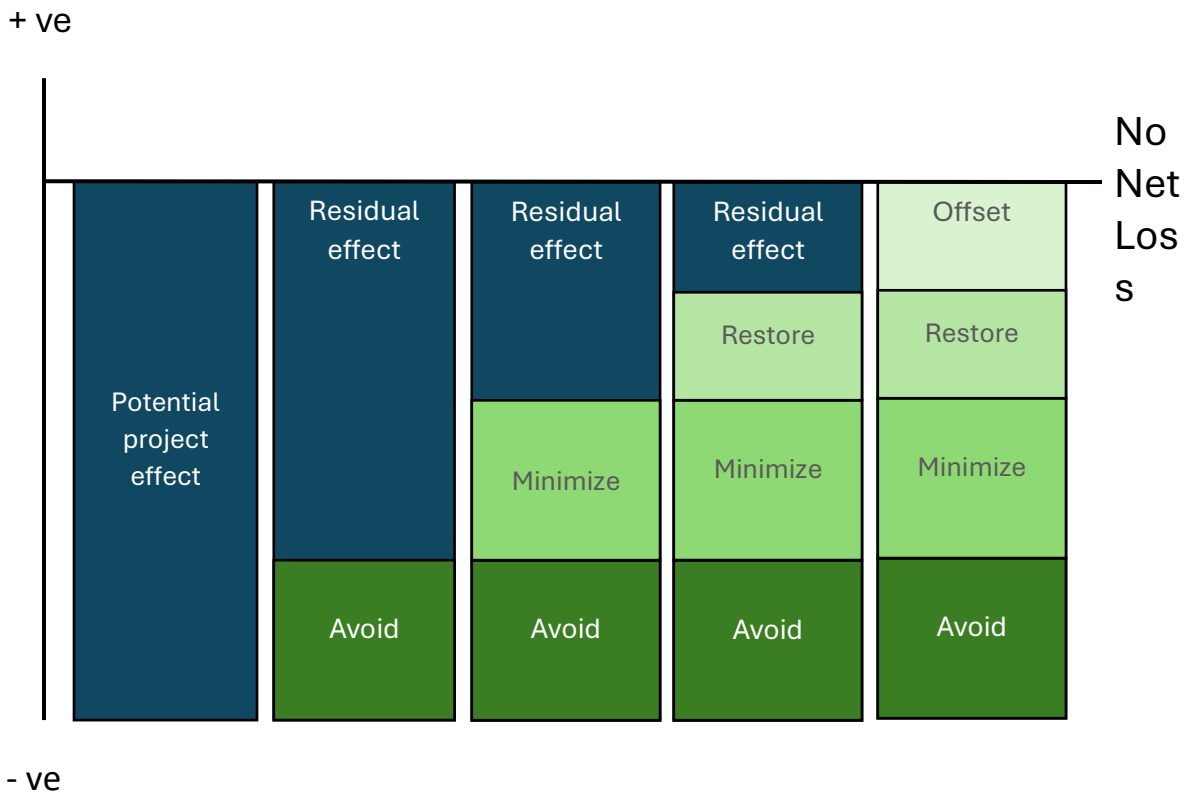

Figure 0-1: Generic No Net Loss and Mitigation Hierarchy (modified from OECD 2016)

Avoid

Potential adverse effects on the caribou have been avoided to the extent possible through Project design, including:

- Selection of in-situ recovery (ISR) mining avoids some direct and indirect effects compared to conventional underground or open-pit mining methods. ISR mining avoids the need for spatially expansive infrastructure such as waste rock piles and tailings management facilities reducing the Project footprint (i.e., avoids direct effects on caribou and their habitat). ISR mining also reduces the potential for interactions between caribou and Project components / activities as it concerns sensory disturbance as it is inherently a less intensive form of mining with reduced noise/light/vibration generation (i.e., avoids indirect effects on caribou and their habitat).

- Site clearing and other works that involve disturbance of vegetation and/or soil will be completed during least-risk timing windows for caribou (for example, outside of wintering/calving period from April 1-July 31, per ENV 2013), where practical, to avoid disturbance during sensitive time periods.
- Pre-disturbance wildlife surveys will be completed to identify caribou presence and work will be postponed if caribou are present.

Minimize

Additional mitigation measures to minimize effects on caribou and their habitat and tailored to Project features have been incorporated into the various Project management and monitoring plans within the Environmental Management System (EMS) including but limited to erosion and sediment controls, soil and vegetation monitoring, Decommissioning Plan, air quality monitoring, fuel spill control and response, Radiation Protection Plan, surface water and effluent monitoring, and Waste Management Plan.

The Project's EMS plans provide direction on monitoring and adaptive management so that issues are identified and mitigation measures are developed and implemented in a timely and effective manner. Mitigation measures specific to caribou are applicable during all Project phases, within all seasons and expected to be effective following appropriate implementation. Examples of the measures to minimize Project effects on wildlife in general, and caribou in particular, are highlighted below.

Disturbance Footprint

- Siting Project components in close proximity to the ISR mining area minimizes indirect effects on caribou and their habitat. The Project components are also west of the known home range of woodland caribou (based on tracking data received by the Ministry of Environment; Figure 0-2), although the absence of data does not mean the absence of caribou and Denison has observed caribou in the area. . Appropriate siting is anticipated to minimize the potential for interactions with woodland caribou and Project activities.
- The Project footprint (i.e., the area of maximum physical disturbance) has been reduced to the extent safely practicable, resulting in limited/minimal habitat loss/disturbance and noise propagation.
- Portions of the proposed Project footprint will be developed within previously disturbed areas, including roads currently used for exploration activities, thereby minimizing additional habitat disturbance.

Denison-Wheeler Study Area - Woodland Caribou Location Data

| RSA Boundary | | |
|------------------------|-------------------|---------------------|
| Data Type | Years | Number of Locations |
| Incidental Observation | 1987, 2017 – 2022 | 89 |
| Telemetry Point* | 2013 – 2016 | 3,848 |

*Data from 15 individual woodland caribou cows

| LSA Boundary | | |
|------------------------|-------------------|---------------------|
| Data Type | Years | Number of Locations |
| Incidental Observation | 2017 – 2022 | 19 |
| Telemetry Point* | 2013, 2015 – 2016 | 62 |

*Data from 4 individual woodland caribou cows

NOTE: Absence of data does not mean absence of woodland caribou.

Figure 0-2 Saskatchewan Ministry of Environment Woodland Caribou Location Data Provided to Denison

Wildlife and Habitat Protection

- Project activities have been assessed for their potential to disturb or remove wildlife and/or wildlife habitat (e.g., site clearing, soil disturbance) to determine potential effects on wildlife and wildlife habitat and the assessment, including proposed mitigation measures, for the Project will guide Project activities.
- Pre-disturbance wildlife clearance surveys will be conducted within the Project Area; results of the clearance surveys will inform the development and implementation of appropriate mitigation (e.g., delay of work) to address the identified issue (e.g., presence of caribou).
- Personal firearms for employees and contractors will be prohibited within the Project Area to prevent hunting activities.
- Policies will be implemented prohibiting employees and contractors from feeding, approaching, or harassing wildlife species within the Project Area.
- To support wildlife habitat regeneration, progressive restoration including ecosystem-based revegetation will be conducted on disturbed areas as soon as practicable in accordance with the Decommissioning Plan.

Wildlife Deterrence and Prevention of Wildlife Entrapment

- In addition to installing secure fencing around all contaminated areas to prevent accidental contaminant exposure, buildings and other Project components will be designed and maintained to exclude wildlife from using buildings for refuge or shelter, and to deter wildlife from potentially becoming entrapped.

Sensory Disturbance

- Noise emitting Project activities will be managed to minimize sensory disturbance of wildlife, especially during sensitive time periods, such as calving. This would include:
 - locating excessive noise generating activities such as the concrete batching operation as far away from sensitive wildlife locations as possible;
 - directing the generator discharge openings away from sensitive locations; and
 - making use of available on-site obstructions to control sound exposure at sensitive areas (i.e., locate sources behind buildings).
- The main sources of noise will be related to transport of people and goods, drilling of holes for the freeze wall and wellfield, operation of the batch plant, operation of the processing plant, and operation of the pumphouses. Low sound emission equipment and the use of silencers or mufflers (whenever practical) will be used to reduce noise

associated with Project activities. There will be regular maintenance of equipment to ensure it is in proper working order and not emitting noise unduly.

- Lighting will be focused on work sites and not surrounding areas, to minimize light trespass and other light-related pollution sources.
- Facilities will be illuminated only to meet standards set for the protection of workers to avoid over-illumination.
- Battery-powered, light vehicles and mobile equipment, and an AC powered dual rotary drill will be used for ISR wellfield development instead of a traditional diesel-powered unit, where practical, to reduce air emissions and noise levels and improve energy efficiency.
- Fugitive dust sources that could lead to deposition of dust on vegetation and waterbodies (including potential deposition of trace metals and radionuclides) will be reduced by:
 - dust suppression techniques on site roadways, such as road watering and traffic management;
 - directing processing plant exhaust from drying and packaging areas through a stack prior to release outside of the building;
 - designing the stack height based on results of air dispersion modelling to be an appropriate height for optimal dispersion;
 - making a wash bay available to clean items, equipment, and vehicles that may have been in contact with potentially contaminated materials. Contaminated water from the wash bay will be collected in a sump tank and routed to the water treatment plant for treatment and discharge; and,
 - conducting radiological clearance scanning as required for any items, equipment, and vehicles leaving the Project Area.

Road and Traffic Management

- Traffic and access control measures will be implemented, including managing traffic volume by scheduling truck convoys, using high-volume haul trucks, and restricting public access (e.g., private vehicles, snowmobiles, all-terrain vehicles, and foot traffic) to the Project site and roads with both north and south security access gates. It is important to note that if any individual were seeking access around the Project area to undertake Aboriginal and / or Treaty Rights, Denison staff would facilitate this, provided it was safe to do so given Project activities in the area.
- Appropriate road signage will be installed (e.g., speed limits, identification of wildlife crossings and areas of high activity) along Project roads to minimize the risk of wildlife-vehicle collisions.
- Speed limits will be implemented to reduce the risk of wildlife-vehicle collisions.

- Wildlife will have the right-of-way on Project roads, unless it is unsafe to stop (i.e., if a collision is imminent). Vehicles will not be used to encourage caribou to move off Project roads and processes will be implemented for employees and contractors to slow down and/or stop vehicles/equipment to allow caribou to move away or off the road before resuming normal road speeds for the area.
- Road watering and regular road maintenance to limit dust dispersion.
- Employees and contractors will report and communicate the location and circumstances of any roadkill observed on or alongside Project roads. Large-bodied wildlife carcasses found will be promptly reported to ENV and disposed of as directed to prevent scavenging.
- Vegetation along Project roads will be managed to reduce attractiveness to wildlife (e.g., forage plants) and maintain appropriate sightlines for drivers to minimize wildlife-vehicle collisions.
- Alternative measures on Project roads for de-icing and winter traction (e.g., sand, gravel) or dust suppression (e.g., water) will be implemented, whenever practicable, to limit the use of specialty chemicals and potential exposure of wildlife including caribou to them.
- Appropriately sized gaps in the roadside snowbanks during winter will be maintained to facilitate caribou crossing and escape and, with that, reducing their risk of vehicle collisions.
- New Project site and access roads will be designed to minimize sightlines for predators, whenever practicable, while still maintaining general road safety.
- Ditches and culverts along Project roads will be designed and maintained to minimize pooling of water as roadside pools may attract caribou.

Water Management, Waste Management, Emissions, and Hazardous Materials Management

- Education on and enforcement of proper water, waste, emissions and hazardous materials management practices will be provided to employees and contractors.
- A freeze wall will be established around the uranium deposit to reduce potential for groundwater disturbance or contamination mitigating the likelihood of exposure of caribou to contaminants in local areas of groundwater discharge to surface.
- The ISR wellfield and processing plant will be designed to re-use most of the solutions inside each circuit, reducing water use requirements to the extent feasible. Make-up water will be preferentially sourced from site runoff (instead of freshwater) where possible.

- Contaminated wastes (e.g., mineralized drill cuttings, process precipitates) will be temporarily stored on double lined pads with leak detection capabilities and an associated monitoring program until final disposal at an approved facility. An adjacent pond will be used to collect contact water from these pads.
- All contact water will be routed to the Industrial Wastewater Treatment Plant for treatment and eventual release to the environment. All treated effluent released to surface water will meet federal and provincial regulatory discharge limits. This will mitigate exposure of caribou to Project-related contaminants released to the environment.
- Surface pipelines will be designed to have secondary containment or catchment and have leak detection systems in place at key locations to mitigate the likelihood of the release of such chemicals to the environment that could result in exposure of caribou to the chemicals.
- Double-walled high-density polyethylene (HDPE) or equivalent piping will be used in the wellfields and will be freeze protected and secured to minimize pipe movement to mitigate the likelihood of the piping failure and the associated release of wellfield chemicals to the environment that could result in exposure of caribou to the chemicals.
- Denison is proposing to segregate and compost organic wastes on site in a composting system, reducing the volume of material in the domestic landfill generating odours and thereby minimizing wildlife attractants.
- Domestic waste will be collected and temporarily stored in wildlife-proof containers to avoid attracting wildlife and reduce the risk for human-wildlife interactions. The wildlife-proof containers will be inspected regularly for evidence of wildlife presence or access to waste disposal facilities. If evidence of wildlife presence or access to waste disposal facilities is detected, modified systems will be implemented and/or off-site waste disposal/incineration frequencies will be increased.
- A "no littering policy" for employees and contractors will be implemented within the Project Area.
- Air emissions will be reduced to the extent practical through implementation of the development of air emissions management and monitoring plans within the EMS.
- All vehicles and equipment will be equipped with industry-standard emission control systems; unnecessary idling of vehicles will be prohibited to reduce emissions.
- The use of hazardous materials will be limited as much as possible.
- Appropriate hazardous materials management practices will be implemented in accordance with industry guidelines to minimize the risk of accidental spills or leakage.

This will mitigate the likelihood of release to the environment that could result in exposure of caribou to the hazardous materials.

- Hazardous materials will be handled, stored, and disposed of appropriately and in accordance to avoid attracting wildlife (e.g., wildlife-proof containers, exclusion fencing) to mitigate the likelihood of exposure of caribou to hazardous materials.
- Physical deterrents (e.g., fencing) will be employed around contaminated areas (e.g., waste ponds and waste pads), the domestic landfill, or hazardous materials storage areas to discourage wildlife use / interaction. The deterrents will be monitored and maintained .
- Appropriate spill response kits will be positioned adjacent to areas where hazardous materials are stored in accordance with the Spill Response Plan to mitigate the likelihood of the release of hazardous material to the environment that could result in exposure of caribou to the material.
- A minimum 100 m distance from any waterbody will be maintained for fuel storage, refueling activities, or equipment servicing in accordance with the Spill Response Plan. This will mitigate the likelihood of a fuel spill to water that could result in exposure of caribou to fuel.
- Appropriate fuel, chemical, and materials management practices will be followed in accordance with the Spill Response Plan to minimize the risk of accidental spills or leakage of diesel fuel, other hydrocarbons, and other hazardous materials and mitigate the likelihood of exposure of caribou to such chemicals.
- All vehicles and equipment will be maintained in good working condition (e.g., no leaks) and furnished with industry-standard spill response kits.

Wildlife Education

- Employees and contractors will be provided with wildlife education and awareness training, including education about potential caribou issues on site and training on the mitigation measures summarized with the EMS and specifically in this Plan to avoid or minimize potential Project effects on caribou and caribou habitat.
- Employees and contractors will be educated on waste and hazardous waste management practices / policies that limit human-wildlife interactions and the potential exposure of wildlife to those wastes.
- Designated employees will be trained in appropriate wildlife deterrent techniques to minimize wildlife interactions with the Project.
- Employees and contractors will be requested to report wildlife observations, including prompt reporting of caribou observations and immediate communication to on-site staff. Wildlife encounters and outcomes will be monitored, and logbooks will be used to

record wildlife observations. Logbooks and reports will be available to employees. Incidental observations recorded by staff will be entered into Species Detection Loadforms and submitted to the Saskatchewan Conservation Data Centre annually.

Restore

The temporal bounds for the Project as stated in the EIS are years 1 to 3 for construction, years 3 to 18 for operation, years 18 to 23 for decommissioning, and fifteen years of post-decommissioning monitoring and inspections from years 23 to 38. Importantly, during physical decommissioning the majority of Project components are scheduled to be removed from site which is expected to facilitate restoration activities. Also, because of the selected ISR mining method, there are no large, permanent Project components, such as waste rock piles or tailings management facilities, for which large scale and potentially complex restoration strategies are needed.

Denison's decommissioning commitment is to return the land back to the Province of Saskatchewan for unrestricted surface land use post-closure. The Project's Conceptual Decommissioning Plan (CDP) is included in the draft EIS. The details of decommissioning and restoration will be refined over time as the Project proceeds. A Preliminary Decommissioning Plan (PDP) will be developed by Denison to support licensing and permitting applications. Prior to executing decommissioning activities, Denison will prepare and submit a Detailed Decommissioning Plan (DDP) to regulators for their review and acceptance, which builds on the PDP.

The CDP outlines plans for physical decommissioning (mining area remediation; asset removal; and decontamination, demolition, and disposal), followed by restoration. A summary of the CDP is provided here.

- Ongoing decommissioning of Project components will be completed when possible.
- Denison has committed to progressively restore areas no longer necessary to support/facilitate Operations to limit the amount of disturbance at any given time. Restoration of inactive areas will take place when/as these areas become available. The progress and success of these activities will be assessed regularly at a schedule commensurate with the expectations of the activities per the decommissioning plan. Progressive restoration including ecosystem-based revegetation will be conducted on disturbed areas as soon as safely and logistically practicable with the use of suitable/appropriate native species and in accordance with the decommissioning plan.
- Once the asset removal, decontamination, demolition, and disposal are completed, and the site has been cleared and leveled, restoration activities, including planting, will take place. Currently this would largely be with jack pine seedlings, but the mix of plants will depend on location and available species. Restoration activities monitored until it is deemed self-sustaining and viable wildlife habitat.
- Future discussions will be held with Indigenous and general public Interested Parties to determine the amount of access to the area they wish to maintain in the future (post-

decommissioning). Based on results of these discussions, transportation corridors including roads or trails associated with the Project site that are no longer needed will be graded, scarified, and vegetated with native, self-sustaining species as required. Access to facilitate safe post-closure monitoring or requested by appropriate Interested Parties (e.g., to facilitate land use) may be left in place. Access to the site may be restricted by gates and/or berms.

- Laydown areas will be scarified, covered with 0.5 to 1.0 m of stockpiled overburden, and vegetated with native, self-sustaining species. The footprints of other infrastructure, such as the camp, will be scarified and vegetated with native, self-sustaining species as required. The topsoil and brush stockpiled during pre-construction activities will be used during restoration.
- Lessons learned from progressive decommissioning and any site-specific restoration studies will be incorporated into the DDP. Additionally, information from other northern Saskatchewan mine sites will be examined to help Denison select the restoration tools, including revegetation options, that will contribute towards decommissioning success.

Closure of the entire Project will be completed in accordance with provincial and federal regulations and guidance documents with the fundamental considerations being to confirm physical and chemical stability of the site to protect human health and the environment.

Progressive decommissioning and restoration will be completed throughout the life of the Project, whenever feasible, and reported to the regulatory agencies as part of the annual reporting requirements throughout Operation. Associated activities will focus on the decontamination, demolition, and disposal of unused buildings and infrastructure, as well as the removal of unused equipment and machinery. Progressive decommissioning and restoration are expected to continue and result in positive effects as revegetation is continued and regeneration occurs. Following decommissioning and restoration, wildlife habitat is expected to recover to baseline conditions.

Habitat Loss Calculation

Habitat Loss in Context of the Disturbance Management Threshold for SK1

To support the Plan with respect to the calculation of habitat loss, a mapping exercise was completed to provide context on the Project-related habitat loss in consideration of the woodland caribou range (SK1) disturbance management threshold (ECCC 2020).

Approach

First the Project infrastructure footprint area was delineated and estimated to be 80 ha. Next, a 500 m buffer was applied to the Project footprint, resulting in a total potential disturbance area of 1,350 ha. This is consistent with the approach for determining direct and indirect effects, as outlined in ECCC (2020).

Finally, an analysis was undertaken to quantify the amount of caribou habitat that is currently disturbed within the Project footprint + 500 m buffer. According to ECCC (2020), there are two contributors to disturbed habitat in SK1: 1. anthropogenic disturbance + 500 m buffer and 2. fire disturbance in the last 40 years, without a buffer. The two factors for disturbed habitat were considered as follows:

1. Existing anthropogenic disturbance + 500 m: For anthropogenic disturbance calculations to inform the Plan, mapping was completed and evaluated to determine the existing anthropogenic disturbance. Although the EIS considered anthropogenic disturbances on IKONOS imagery at the 1:5,000 scale, the mapping exercise to support habitat loss calculations in the Plan used anthropogenic disturbances visible on Landsat at the 1:50,000 scale, to be consistent with the definitions of disturbed habitat from the amended recovery strategy (ECCC 2020).
2. Fire disturbance in the last 40 years, without buffer: To determine ecosites that were in a regenerating phase or having experienced fire disturbance in the last 40 years, the ecosites BS3/BS7-Jack pine-blueberry/Black spruce-blueberry/lichen were used, based on previous ecosite classification work completed to support the EIS.

Results

As shown in Table 0-1 and Figure 0-1, the proposed Project footprint + 500 m buffer is almost entirely located within existing, buffered anthropogenic disturbance. This means the Project footprint + 500 m buffer is located within already disturbed habitat, according to ECCC (2020). Additionally, the mapping exercise shows that approximately half of the Project footprint + 500 m buffer is located within regenerating forest, i.e., forest burned less than 40 years ago (Figure 0-2).

Table 0-1: Existing Disturbed Habitat within Buffered Project Footprint

| | Area within Project Footprint + 500 m buffer (1,350 ha) |
|--|---|
| Existing anthropogenic disturbance (+ 500 m buffer) | 1,298 ha |
| Regenerating forest (fire disturbance in the last 40 years; no buffer) | 730 ha |

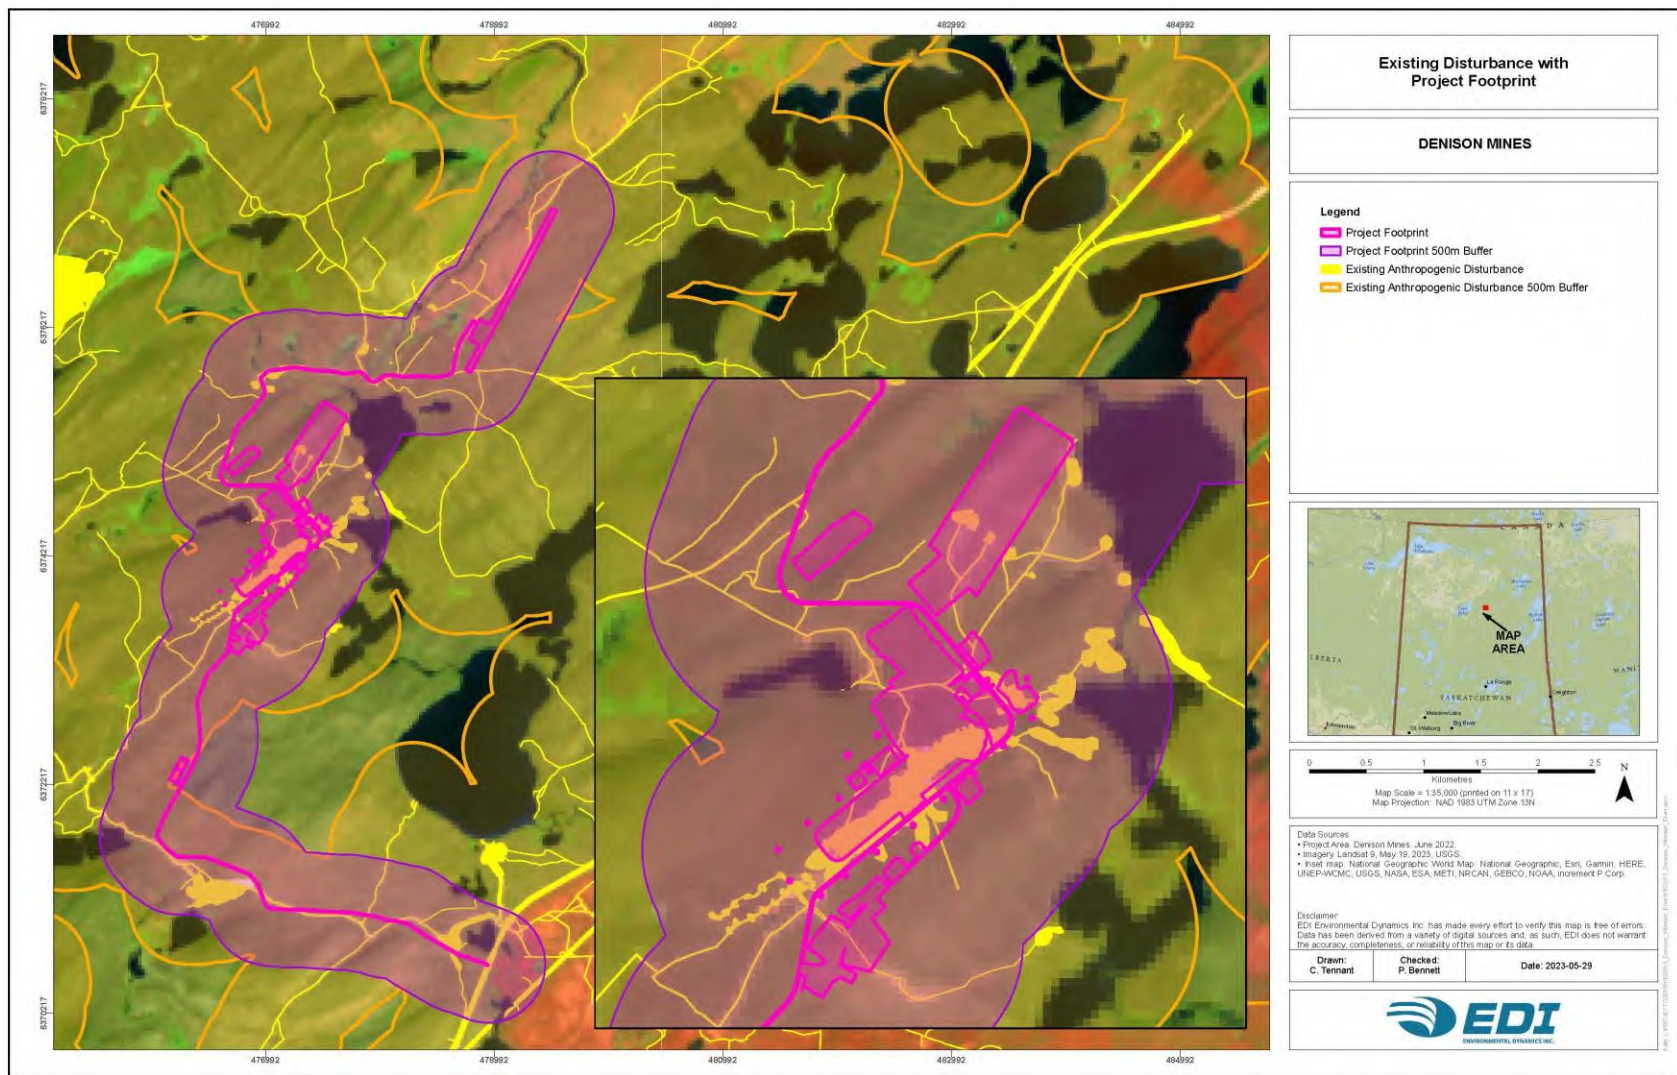

Figure 0-1: Proposed Project Footprint (+ 500 m buffer) with Existing Anthropogenic Disturbance (+ 500 m buffer) Visible on Landsat at 1:50,000

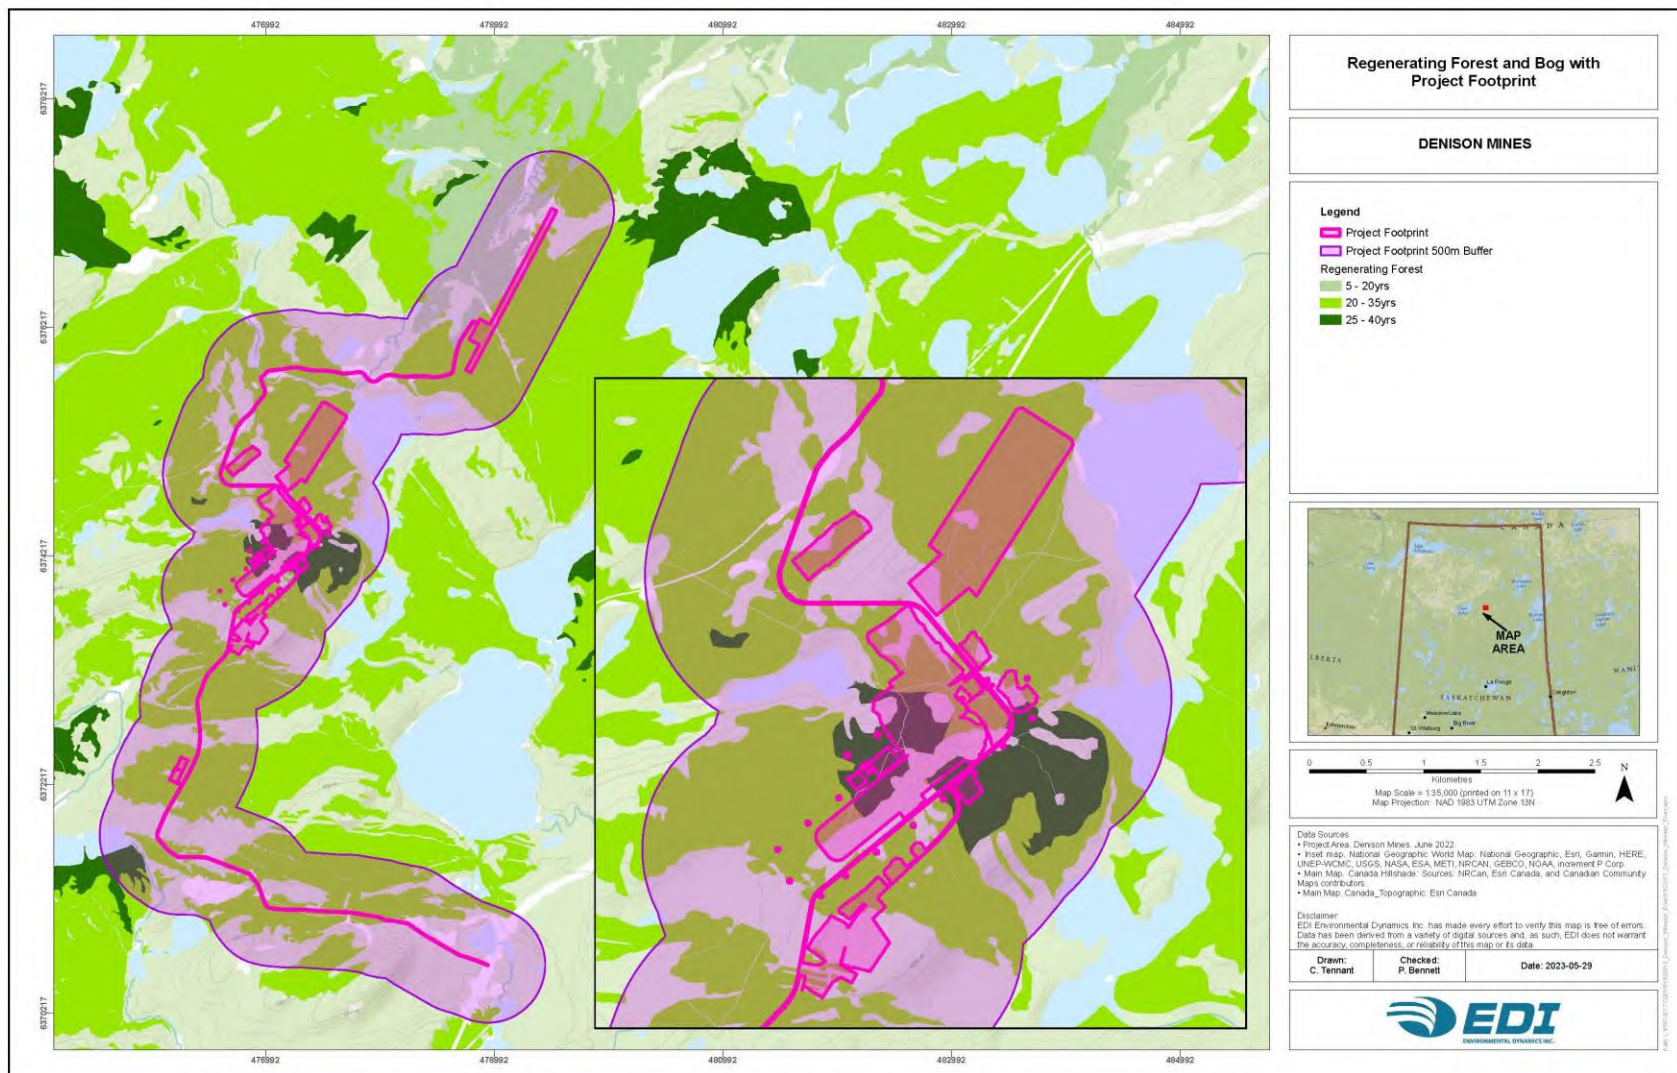

Figure 0-2: Proposed Project Footprint (+ 500 m buffer) with Regenerating Forest

Based on the above analysis using ECCC (2020) criteria, should the Project proceed, the disturbance management threshold for SK1 range would remain unchanged.

Additionally, ECCC (2020) identified the caribou population in the SK1 range as being self-sustaining at a threshold of 40% undisturbed habitat and recommended that total anthropogenic disturbance in the SK1 Boreal Shield range should not exceed 5% with the remainder (i.e., 55%) being attributed to natural disturbance (while maintaining a minimum of 40% undisturbed habitat in the range). ECCC (2020) calculated that approximately 58% of the SK1 Boreal Shield range is currently affected by past forest fires and 3% of the range is affected by anthropogenic disturbances. For additional context, the size of the SK1 Boreal Shield range is estimated at 18,034,870 ha (ECCC 2020). The Project footprint + 500 m buffer (1,350 ha) would represent an estimated Project-related disturbance of 0.007% at the scale of the SK1 Boreal Shield Woodland Caribou Management Unit.

Direct Loss Calculation

The Project infrastructure footprint has been delineated and the area was determined to be 80 ha. Of this area, 12 ha are comprised of previously disturbed land resulting from past activities (e.g., access, exploration camp and laydown areas). The remainder of the Project footprint is comprised of regenerating forest (forest less than 40 years old) habitat which is typically considered to be low quality habitat for caribou (Figure 5.3).

Table 0-2: Land Cover Types within the Project Footprint

| Total Area | |
|--|-------|
| Project footprint | 80 ha |
| Existing anthropogenic disturbance | 12 ha |
| Regenerating forest habitat (i.e., low quality caribou habitat) | 68 ha |

Denison understands that the Project will likely result in a limited residual effect on caribou and their habitat within the RSA; however, these effects are considered to be small in a relative sense when considered in the context of the SK1 range, as described in Section 5.1.

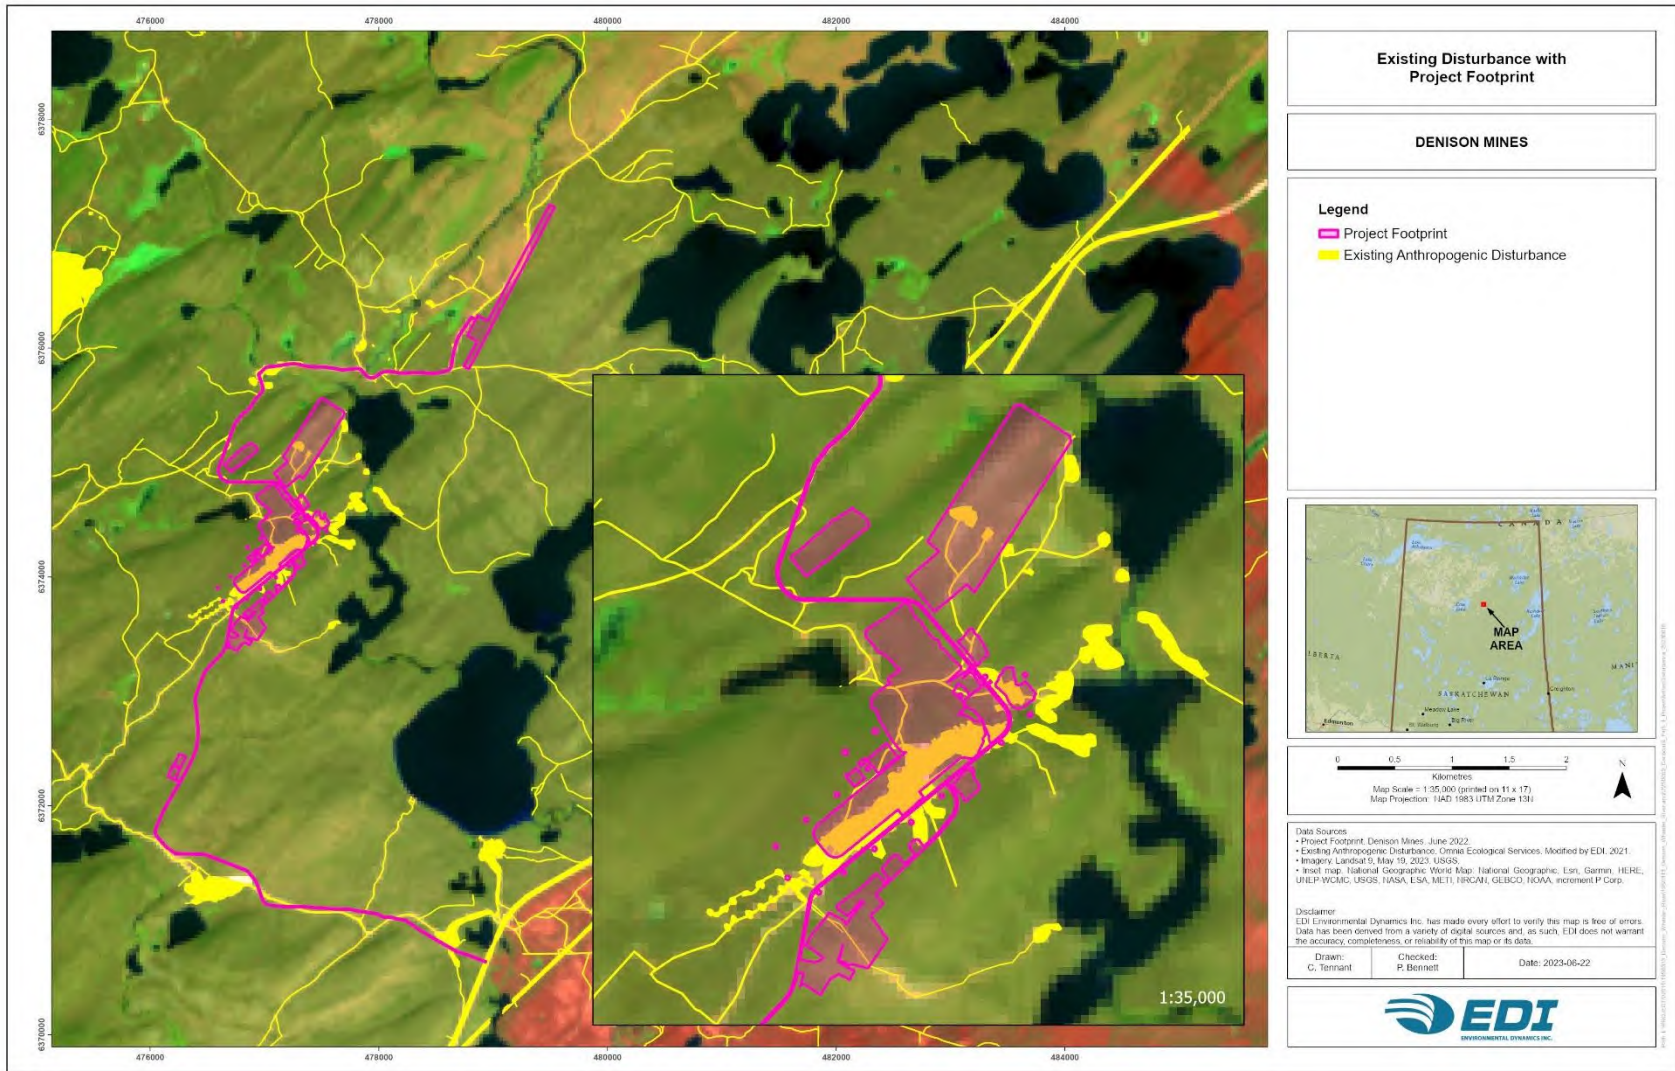

Figure 0-3: Proposed Project Footprint with Existing Anthropogenic Disturbance Visible on Landsat at 1:50,000

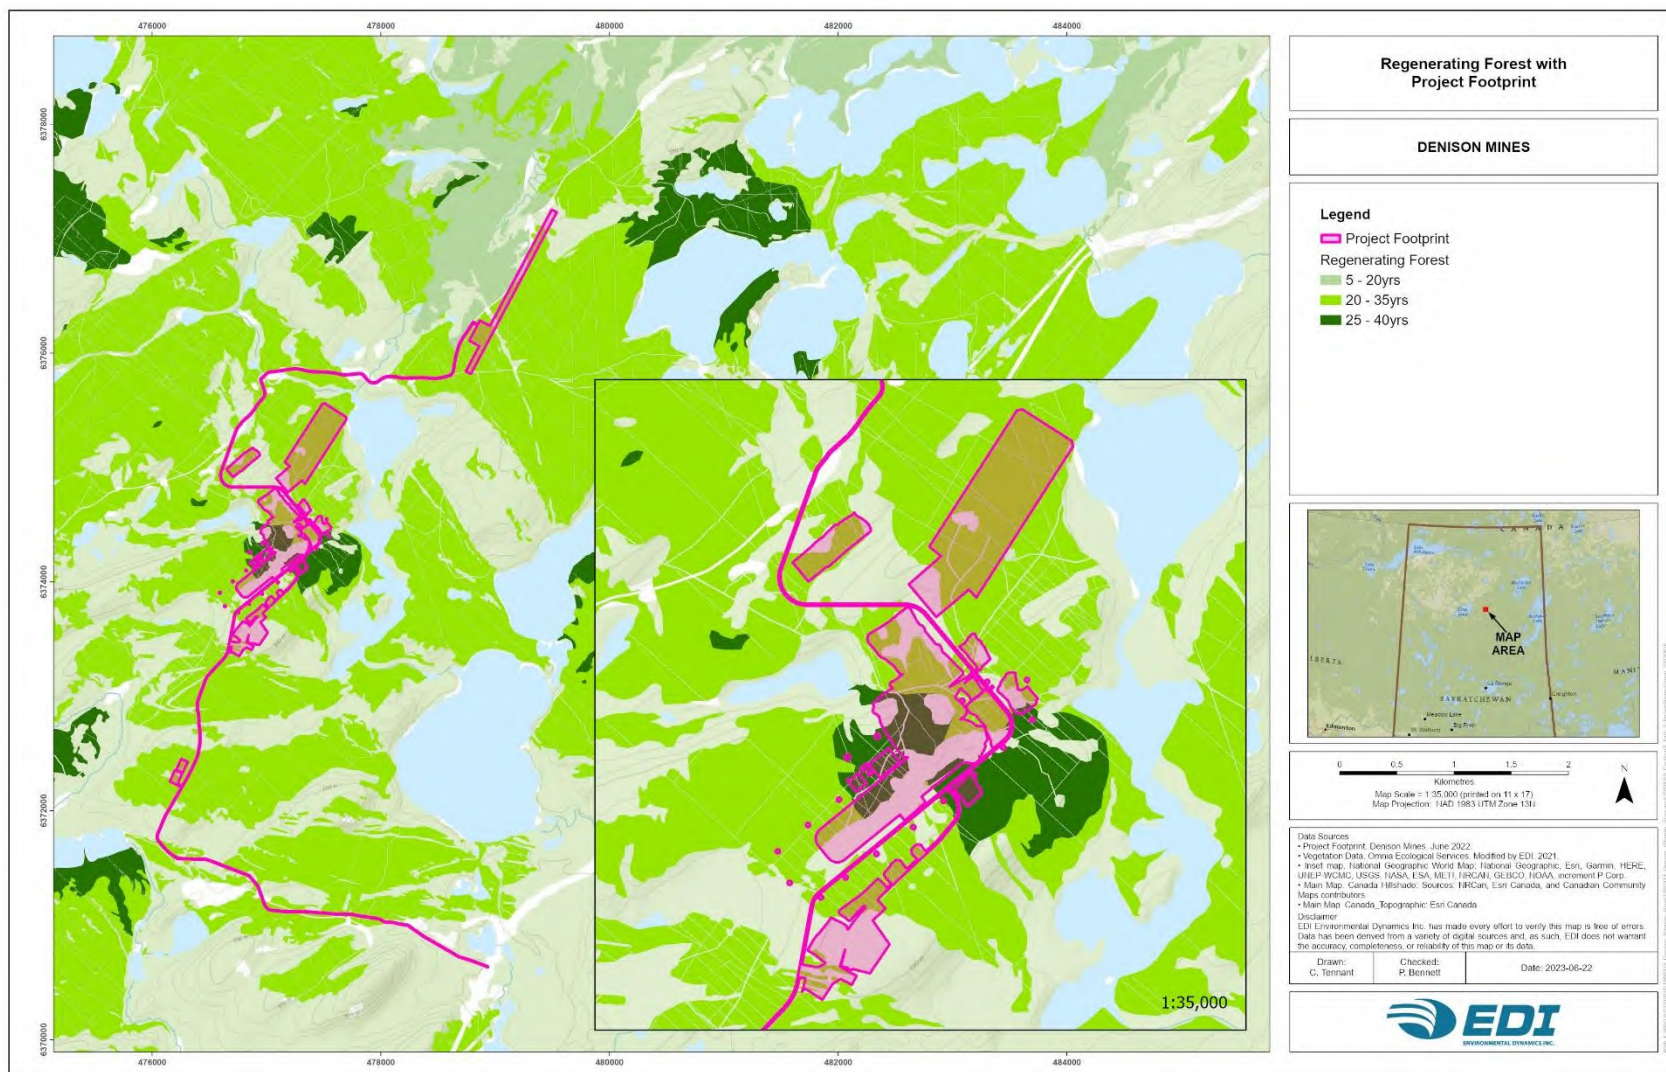

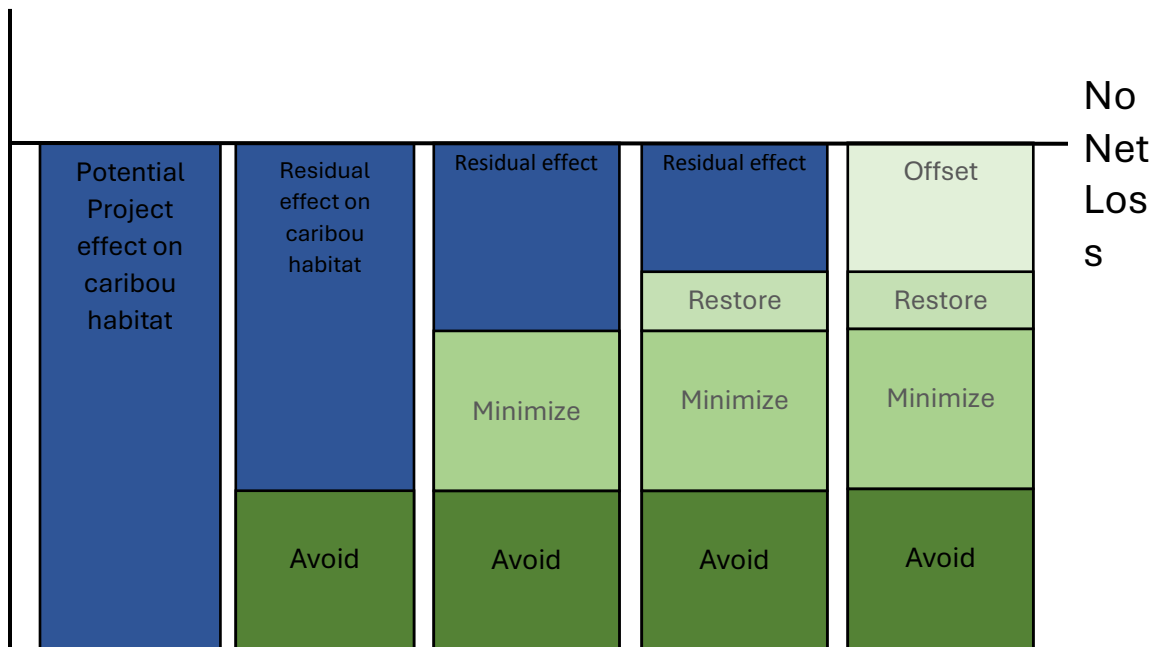

Figure 0-4: Proposed Project Footprint with Regenerating Forest

It is Denison's understanding that currently there are no provisions/requirements for caribou habitat offset by the ENV for projects within the SK1 range. Denison recognizes the importance of woodland caribou to Indigenous groups, the general public, other Interested Parties in Saskatchewan, and Canada. As such, as part of this Plan, Denison is proposing to continue to work with ENV to determine an appropriate offset based on the habitat loss as a result of the Project. Denison expects that the proposed offset calculations would likely include aspects of additionality, temporal considerations, spatial considerations, and other aspects, depending on the expectations/requirements of the caribou habitat offset process that the ENV is currently refining/finalizing. The proposed offset calculations are expected to be refined through ongoing communications with ENV to appropriately address issues at the provincial level related to caribou and habitat.

Future versions of the Plan will include detailed options to develop and advance restoration work and initiatives to provide responsible, proactive environmental stewardship. These offsets (Figure 0-55) are expected to be further refined/defined through Plan updates as the Project proceeds and consultations with ENV advance. Some initial options are presented at a conceptual level in Section **Error! Reference source not found..**

+ ve

- ve

Figure 0-5: Wheeler River Project Conceptual Caribou Mitigation Plan to Achieve No Net Loss

Offset Framework

This section provides a discussion on offset options will become more defined as the Plan advances, in consultation with ENV. This is expected to offset residual effects over the life-of-the-Project and enhance the restoration activities occurring within the Project footprint to result in no net loss of habitat within the RSA as a result of the Project.

Conceptual Offset Opportunities

An opportunity that Denison has proactively identified is a combined linear feature mitigation and restoration option. Denison has implemented a practical and experimental pilot study to investigate the design, implementation, testing, and monitoring of several functional and structural habitat mitigation options. This opportunity involves two components: 1) applying treatments to address (i.e., reduce) lines-of-sight and discourage linear feature use by both caribou and their predators, and 2) restoration focused on re-establishing terrestrial lichen communities co-established with a biological soil crust (BSC) component.

Importantly, to complete this pilot program, Denison has partnered with the University of Saskatchewan and Northwest Communities Environmental Services (an Indigenous-owned environmental company) under the Developing Eco-Restoration Together (DERT) program. This unique project aims to co-create ecological restoration practices that centre Indigenous peoples, worldviews, and values while also braiding knowledge from the land, Indigenous knowledge, and western science. The project is supported by the three partners but is ultimately guided by the Indigenous Project Advisory Board, and the Community Liaison/Education Coordinator. Through restoration trials, community engagement, and various planting techniques, Denison, with their partners are seeking to return ecosystem functions in areas where they have been previously disturbed (e.g., exploration cutlines). Through collaboration with community members, University of Saskatchewan, industry partners, two graduate students, and local youth, this project is expected to ultimately inform the creation of a framework for effective restoration practices in northern Saskatchewan that centre on caribou and Indigenous communities.

Caribou Trail Study

Wildlife, particularly bears, wolves, and woodland caribou, are using anthropogenic linear features to move throughout their habitat with greater ease. This can result in increased chance encounters between predators and prey and could contribute to the reduction in woodland caribou populations (Omnia 2022). Denison is conducting research on the use of linear features predators and prey in the Athabasca Basin to collect relevant data to inform an effective plan designed to disrupt the current risk related to predator/prey movements/interactions.

Currently, ENV has no guidelines or protocols for assessing the status of disturbance features or for evaluating the need for linear feature mitigation. Denison proactively initiated research to collect field-based findings on the effectiveness of linear disruption features on predator/prey movements in the vicinity of the Project. This field program was designed and implemented to deploy and monitor the effectiveness of five linear feature treatments across nine locations. Treatment types include, seeding and/or planting of jack pine, spreading coarse woody debris, tree tipping, constructing biodegradable fencing, and earth/debris mounding. Methods vary by location

but have a common goal: to discourage prolonged disturbance and encourage new growth in areas of disturbance (Omnia 2022). Each treatment area is monitored by game cameras year-round to determine how wildlife interact with the created physical and visual barriers. All treatments are temporary and biodegradable with the purpose of reducing trail use in the near-term so that the forest can regenerate naturally.

Preliminary results are encouraging and indicate that bear use of treated lines was reduced by 43% compared to untreated lines, caribou use was reduced by 95%, and wolf and moose use was reduced by approximately 94%. Overall, use of treated lines by species of interest was reduced by approximately 83% when compared to baseline monitoring rates. These successful preliminary results will guide future work to define potential offset options associated with linear feature mitigation and restoration.

Biological Soil Crust Research

To support restoration planning, additional research will be designed to investigate BSCs and conducted by a soil science graduate student at the University of Saskatchewan. This research is expected to contribute to the goals of the Developing Eco-Restoration Together Project. BSCs are communities of lichen, bryophytes, cyanobacteria, and microorganisms found in the top layer of the soil (Heindel et al. 2019). These surface soil mats are rich in diversity, and play an important role in the broader ecosystem, especially in locations with extreme climate, little moisture, and nutrient-poor soil (Cowden et al., 2022). Research on BSCs has been focused on desert regions, and this research provides insight to BSC's role in boreal ecosystems, specifically in northern Saskatchewan. By gaining a better understanding of how to support BSC establishment and growth, it is expected that the findings can inform restoration activities that would ultimately benefit caribou.

Sampling of BSCs within the region will be based on a fire chronosequence. This is expected to provide a foundation to better understand the functions and species present in BSCs, and how they develop post-disturbance (Coxson and Marsh 2001). Understanding how these communities develop and interact is important, especially considering the gap in knowledge on soil microbial communities, non-vascular species, and their role in restoration techniques.

A critical element in supporting caribou populations is the consideration of caribou forage lichens. Due to the slow-growing nature of lichens, it can be difficult to include them in restoration activities (McMullin and Rapai 2020). Denison is planning to focus on caribou forage, primarily through transplanting and propagation of the appropriate lichen species. Natural regrowth of lichen communities after fires takes place in a complex setting, where BSCs and bryophyte communities stabilize soil surfaces, providing habitats where lichen propagules can establish and grow (Coxson and Marsh 2001). Denison hypothesizes that reestablishment of terrestrial lichen communities will have a better chance of success where these supporting BSC components can be co-established at the same time. The findings from the BSC research within post-fire environments is expected to support lichen communities, restoration activities for the DERT project, and ultimately caribou and caribou habitat within the Wheeler River Project area.

Monitoring and Adaptive Management Framework

An adaptive management framework will be developed to support the implementation of this Plan (Figure 0-1). In this context the adaptive management framework provides the means for the integration of Plan scope, management, and monitoring to systematically evaluate assumptions to adapt and learn. In practical terms the framework will consider the outcomes of actions taken/implemented, whether they have been successful and, if not, how can such actions be adapted to increase the likelihood of success. Outcomes of the Plan would be measured by establishing performance indicators as the way to define and measure progress toward achieving the objectives.

Draft for Discussion

Acronyms and Abbreviations

| Term | Definition |
|-----------------------------------|--|
| Anthropogenic | Caused or produced by humans |
| Boreal Caribou | The boreal ecotype of woodland caribou occurs within the boreal forest of Canada. These non-migratory caribou form small aggregations throughout the year and disperse for solitary calving. |
| CDP | Conceptual Decommissioning Plan |
| Critical Habitat | The habitat that is necessary for the survival of a listed wildlife species and is identified as the species critical habitat in the recovery strategy or action plans for the species. |
| Disturbed habitat (per ECCC 2020) | Habitat showing: i) anthropogenic disturbance visible on Landsat at a scale of 1:50,000, including habitat within a 500 m buffer of the anthropogenic disturbance; and/or ii) fire disturbance in the last 40 years, as identified in data from each provincial and territorial jurisdiction (without buffer). |
| ERFN | English River First Nation |
| ECCC | Environment and Climate Change Canada |
| EA | environmental assessment |
| EIS | environmental impact statement |
| EMS | Environmental Management System |
| ENV | Saskatchewan Ministry of Environment |
| Framework | Caribou Management Framework |
| ha | hectare |
| IK | Indigenous knowledge |
| ISR | in-situ recovery |
| KML | Kineepik Métis Local |
| Project | Wheeler River Project |

| Term | Definition |
|--------------------|--|
| Recovery strategy | A planning document that identifies what needs to be done to stop or reverse the decline of a species. |
| Threatened species | A wildlife species that is likely to become endangered if nothing is done to reverse the factors leading to its extirpation or extinction. |

Draft for Discussion

Introduction

The Wheeler River Project (the Project) draft environmental impact statement (EIS; Denison 2022) evaluated and assessed potential effects on the boreal population of woodland caribou (*Rangifer tarandus caribou*; referred to herein as caribou or boreal caribou) following standard environmental assessment (EA) methodology. The assessment of potential effects, including the assessment of Project-related and cumulative effects, considered both direct (e.g., habitat loss) and indirect effects (e.g., habitat alteration) on caribou and their habitat, while assuming that caribou were present year-round and during all of their life stages (i.e., calving, rearing, mating, over wintering). In this way, the EIS took a precautionary or conservative approach to understanding / addressing the potential residual effects (i.e., effects remaining after mitigation measures were considered) of the Project on caribou and their habitat. Moreover, this precautionary approach provides the basis for planning to inform/support future Project-related regulatory approvals processes and follow-up monitoring. The EIS concluded that in consideration of proposed measures to avoid and minimize potential effects, as well as in consideration of proposed conceptual site restoration, residual Project-related and cumulative effects on caribou and their habitat were not significant.

This Caribou Management Framework (the Framework), developed by Denison for the Project, follows from the environmental assessment (EA) process, though its objective differs from that of related EA / EIS documentation. The Framework builds on the assessment of potential Project effects, including cumulative effects, and commitments to avoid and minimize such effects described in the EIS and provides a further Project-specific management tool to be employed in relation to caribou and their habitat. The Framework is expected to be advanced through ongoing consultation with the Saskatchewan Ministry of Environment (ENV) as ENV finalizes the caribou range plan for the SK1 conservation unit, the caribou conservation unit in which the Project is located. The EIS is a conservative planning tool, whereas the Framework is a practical, living document intended to contribute to the province's overall caribou conservation strategy. The Framework is not a requirement for EA determination but is provided as a guidance document to help Denison proactively describe and inform the development and implementation of appropriate management measures related to caribou and their habitat.

The Framework is an evergreen document but has been developed based on Denison's current understanding of range plan development for SK1 to date. As needed, the Framework will be updated to be consistent with the management goals defined by ENV for SK1 (once established) and will be developed / refined in consultation with local communities including English River First Nation (ERFN), Kineepik Métis Local (KML) in Pinehouse, and regulators (e.g., ENV) as depicted graphically below.

As noted above, the boreal caribou range plan for SK1 is under development, and it is understood that this Framework will be updated as more range plan details become available. Developing the Framework at this early stage is consistent with and reflects Denison's commitment to continue to work with the province to meet the management objectives and management strategies for the SK1 range. It is envisioned that this Framework will be included as a component of the provincial environmental impact statement and should it be accepted through the issuance of a Ministerial Approval, form the basis of a condition of approval pursuant to *The Environmental Assessment Act*.

Draft for Discussion

Regulatory Setting and Indigenous Perspectives Related to Boreal Caribou

A brief review highlighting provincial and federal governments, and Indigenous nations and communities considerations of boreal caribou is provided below for reference. Briefly, in 2002, boreal woodland caribou were recommended for “threatened” status by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) and were listed as “threatened” under the Species at Risk Act (SARA) when it was proclaimed in 2003. As required under SARA, the Government of Canada developed a Recovery Strategy for the Woodland Caribou Boreal Population in Canada (the Recovery Strategy) which was released in October 2012. Saskatchewan is responsible for managing woodland caribou on provincial and private lands, and as signatory to the Accord for the Protection of Species at Risk in Canada, has a responsibility to prepare a provincial range plan for woodland caribou. Range plans, which involve close collaboration between the provincial government and Indigenous nations and communities, provide a path forward for effective landscape management. They provide the federal government with clear information on the measures, tools and targets for woodland caribou habitat management being deployed, and that they effectively protect woodland caribou habitat.

Provincial Government

The responsibility for woodland caribou management lies with the Province of Saskatchewan. As noted above, the province is responsible for developing range plans or management plans which build on the federal recovery strategy by setting goals and objectives for maintaining sustainable population levels.

The Saskatchewan Conservation Data Centre is responsible for evaluating and assigning a conservation rank to each taxon, resident or transient, found in the province. Woodland caribou’s subnational or S-rank conservation rank is S3. This ranking indicates that, provincially, the species is vulnerable/rare to uncommon which is associated with a moderate risk of extinction or extirpation due to a restricted range, relatively few populations, recent and widespread declines, threats, or other factors.

Based on work completed by McLoughlin et al. (2019), which was confirmed by ENV in November 2023 (SK ENV 2023b), the caribou populations in SK1 are stable. The amended federal recovery strategy identifies 40% undisturbed habitat in the SK1 conservation unit as the disturbance management threshold as well as the maintenance of total anthropogenic disturbance in the range at or below 5% while maintaining the minimum 40% undisturbed habitat (ECCC 2020). The SK1 conservation unit has high levels of natural disturbance (fire), but very low levels of human-caused disturbance. At present, the habitat disturbance level in SK1 is 53% (that is, 47% undisturbed habitat) (SK ENV 2023b). Approximately 50% of SK1 is disturbed by wildfires and 3% by anthropogenic features such as roads, communities, power transmission lines, forestry, mineral exploration, and mining (3%).

The provincial goal is to sustain and enhance woodland caribou populations, and maintain the ecosystems they require, throughout their current range (ENV 2013). Through the woodland caribou range assessment and range planning program, the province is:

- Gaining a better understanding of woodland caribou ecology;
- Working toward meeting objectives identified in provincial and federal strategies; and
- Improving how the province manages the species and related habitat.

The province's woodland caribou range assessment and range planning program incorporates two key components:

- Woodland caribou range assessment, which enhances the understanding of woodland caribou populations and their interactions with the environment; and
- Woodland caribou range planning, which provides a framework, strategies and objectives that allow for better decisions involving habitat management and self-sustaining caribou populations.

Additionally, the province has identified that engagement is a key component of the range plan process and will be completed with representatives from First Nation, Métis, industry, non-governmental organizations, and communities¹.

Although the management objectives and management strategies for caribou in SK1 are not yet defined, Denison is committed to working with ENV as the range plan is developed to ensure this project-specific management framework aligns with the conservation objectives as determined by the province as the primary steward of caribou in the province.

Federal Government

Boreal caribou have been designated as *threatened* under the federal *Species at Risk Act*. Environment and Climate Change Canada (ECCC) released amended recovery strategy for woodland caribou in 2020 (ECCC 2020). A recovery strategy is a planning document that identifies what should be done to stop or reverse the decline of a species.

The Project is located in the Boreal Shield West ecoregion of the Boreal Shield ecozone. The Boreal Shield West ecoregion stretches from Alberta to Ontario (Figure 2-1).

¹ [Woodland Caribou Conservation | Woodland Caribou Program | Government of Saskatchewan](#)

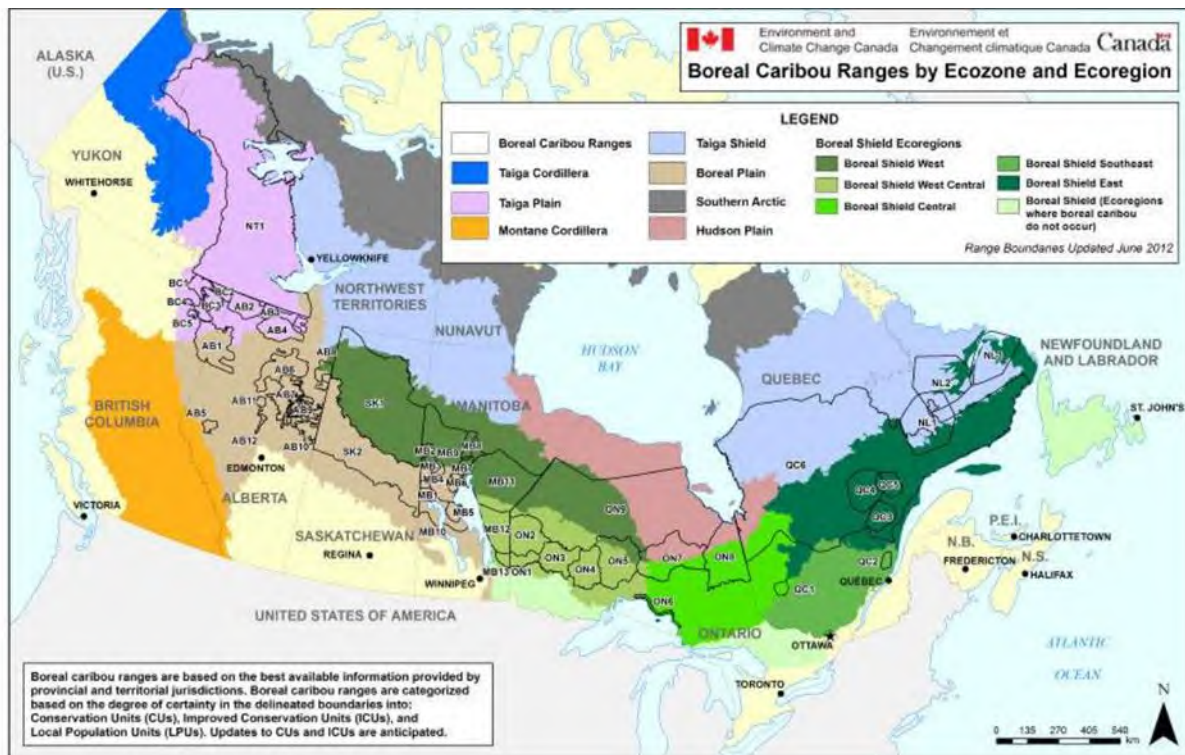

Figure 0-1: Boreal Caribou Distribution Across Ecozones and Ecoregions in Canada (source: ECCC 2020)

The SK1 range comprises more than 18,000,000 hectares (ha) and is characterized by high fire disturbance and low anthropogenic disturbance (ECCC 2020). The likelihood of caribou self-sustainability in the boreal shield range in SK1 is “likely” (ECCC 2020). For SK1, the amended recovery strategy (ECCC 2020) identifies 40% undisturbed habitat in the range as the disturbance management threshold, which provides a measurable probability (71%) for the local population to be self-sustaining. This threshold is considered a minimum threshold because at 40% undisturbed habitat there remains a risk (29%) that the SK1 local population cannot be self-sustaining. Disturbed habitat (ECCC 2020) is habitat showing: i) anthropogenic disturbance visible on Landsat at a scale of 1:50,000, including habitat within a 500 m buffer of the anthropogenic disturbance; and/or ii) fire disturbance in the last 40 years, as identified in data from each provincial and territorial jurisdiction (without buffer). Undisturbed habitat (ECCC 2020) is habitat not showing any: i) anthropogenic disturbance visible on Landsat at a scale of 1:50,000, including habitat within a 500 m buffer of the anthropogenic disturbance; and/or ii) fire disturbance in the last 40 years, as identified in data from each provincial and territorial jurisdiction (without buffer). Disturbance within the 500 m buffer would result in a reduction of the undisturbed habitat.

Studies (e.g., McLoughlin et al. 2019) indicate that the SK1 local caribou population is likely self-sustaining at current levels of disturbance (60% total disturbance), with a 71% probability of persistence. Environment and Climate Change Canada’s analyses also indicate that the SK1 local population is sensitive to small increases anthropogenic disturbance and sensitive to small decreases in adult survival. For these reasons, a higher probability of persistence was selected for critical habitat identification in SK1 (71%) than was selected for the other 50 ranges across Canada (60%) (ECCC 2019).

The precise location of the 40% undisturbed habitat within the range is expected to vary over time. The habitat within the SK1 range should exist in an appropriate spatial configuration such that boreal caribou can move throughout the range and access required habitat when needed. The key to this habitat delineation is achieving and maintaining an overall, ongoing range condition that allows for the dynamic habitat supply system, containing the biophysical attributes upon which caribou depend, to remain sustainable. It is this dynamic habitat supply system within the SK1 range that is the habitat condition considered to be necessary for the caribou.

Indigenous Nations and Communities

Woodland caribou has historically been and continue to be an important part of the culture and diet of Indigenous people in northern Saskatchewan and identified as part of the subsistence harvest by EFRN, and KML. Athabasca Denesųtiné have also described hunting woodland caribou along with Barren-ground caribou and identify deeply with caribou and define their territorial extent with that of the Beverly and Qamanirjuaq caribou ranges. Elders from EFRN have shared that their people have always respected the land and animals and that the tradition to take only what is needed has been passed on through generations (EFRN 2011).

Forest fires are considered the main threat to woodland caribou in the EFRN Traditional Territory. Predators pose a threat as well, but their presence never seemed to have affected the caribou population in the past. In addition, it was pointed out that industry (such as mining and exploration), tourism (in the summer), and hunting by other Indigenous groups may pose additional threats to the caribou population (EFRN 2011).

Knowledge from Indigenous nations and communities will be used to support the management and conservation of caribou in SK1 through the province's range planning process.

SK 1 Caribou Population – Background Information

Background information concerning the condition of caribou populations in the SK1 conservation unit is provided below.

SK1 Conservation Unit

Saskatchewan's boreal woodland caribou range is divided into two woodland caribou conservation units that are based on the boundaries of the boreal ecozones - the Boreal Shield Woodland Caribou Conservation Unit (SK1) and the Boreal Plain Woodland Caribou Conservation Unit (SK2). Per ECCC (2020) information available to delineate boreal caribou ranges varies in certainty and therefore caribou ranges are categorized into three types: conservation units (low certainty), improved conservation units (medium certainty) and local population units (high certainty). ECCC (2020) also recognizes that there will be changes to conservation units and improved conservation units as more information becomes available, which is aligned with the province's range planning work to date in SK2.

While the two conservation units represent important differences in ecological conditions (e.g., habitat types, fire regimes, landforms, etc.) and human land use and management (e.g., overall levels and types of land use, fire management, etc.), the boundary between SK1 and SK2 does not represent a population boundary, as caribou move freely between the two areas, as well as within the individual units.

The Project is located in SK1, with SK1 encompassing the rocky shield, sandy plains and many lakes of northern Saskatchewan. Despite its relatively large size (~176,000 km² or 18 million ha), at present the SK1 unit has not been sub-divided into administrative units, as has been the case with SK2 through its range planning process. The province has noted that SK1 is an area with considerable fire disturbance, ecological differences from west to east, and different levels of development.

Population Trends

Western Science

The SK1 Boreal Shield management unit contains high-quality conifer-dominated caribou habitat with greater than 40-year-old stands of jack pine and black spruce forests suitable for lichen colonization, black spruce swamps, and open muskegs supporting relatively high densities of caribou, at 36.9 caribou/1,000 km² or approximately 4,000 caribou across the SK1 Boreal Shield Woodland Caribou Management Unit (McLoughlin et al. 2019).

Research has shown that up to 70% of the year-round diet of caribou may consist of ground and arboreal lichens. If the quantity of available lichen forage is low, caribou can exist without relying entirely on lichens (McLoughlin et al. 2019). Due to their physiology, lichens are resilient to periods of drought and cold temperatures, but because of their slow growth rate, exhibit a slow recovery time after depletion and fire events. In the SK1 range, McLoughlin et al. (2019) found that stand types with the highest potential for adequate lichen biomass for caribou are jack pine and poorly drained black spruce sites.

McLoughlin et al. (2019) observed that, from 2014 to 2018, the caribou population exhibited a high average adult female survival rate and moderate recruitment (0.192 calves per cow in March), ranging from a low of 0.134 calves/cow in March 2016 to 0.244 calves/cow in March 2018. These demographic parameters led the authors to assess the SK1 boreal shield caribou population as being stable at the time of their study (McLoughlin et al. 2019).

While calving areas have not been documented within the SK1 range, it is recognized that caribou may use open fen and treed bog habitat types for calving during the spring/summer period. In Saskatchewan, caribou habitat used during the calving season in the SK2 range demonstrated a strong selection for treed muskegs, but avoidance of jack pine, mixed hardwood stands, and roads (Dyke 2008).

Neufeld et al. (2021) summarized results from aerial surveys over a period of eight years in an 87,193 km² study area in the Athabasca Plain and Churchill River Upland ecoregions in the north, that are inclusive of the Terrestrial Regional Study Areas that were used in the EIS. During 11 of 16 aerial caribou surveys conducted between 2008 and 2015, woodland caribou were detected in the surveyed areas. The average density of the 16 surveys was estimated at 36.9 caribou/1,000 km² (95% CI = 26.7 to 47.2 caribou/1,000 km²). Across the Neufeld et al. (2021) study area and all years, estimated caribou densities were higher in comparison to averages reported for most other boreal woodland caribou ranges in Canada (i.e., caribou density reported in other areas ranged 4.3 to 18.7/1,000 km²) indicating that caribou can tolerate natural disturbance. One exception to the relatively high caribou densities in northern Saskatchewan was noted: the 2,285 km aerial the Millennium Project in March 2014, 10 km west of the Terrestrial Regional Study Area, resulted in lower woodland caribou densities at 5 caribou/1,000 km² (Neufeld et al. 2021).

Eight of the sixteen caribou surveys reported the ratios of male to female and calf to female in their results with the average male:female ratio calculated at 0.571 (95% CI = 0.444 to 0.699) and calf:female at 0.195 (0.158 to 0.232). Again, the 2014 Millennium survey reported a different male:female ratio, outside the reported range (1.6), concurring with the reported low caribou densities.

Indigenous and Local Knowledge

Information provided by Indigenous knowledge (IK) holders to Denison as part of the Wheeler River Project EA process generally agrees with the science-based findings that show the population of woodland caribou in northern Saskatchewan is stable; however, some IK perspectives differ from the narrative that holds that caribou populations are stable. The difference in perspectives may stem from changes in distribution, as opposed to density, as caribou alter their movements in response to landscape disturbances.

The ERFN trapper, fisher, and resource harvester (ERFN Trapper), whose ancestral lands overlap with the Wheeler River terrestrial RSA and SK1, shared that they have not observed any changes in woodland caribou numbers (i.e., densities); woodland caribou numbers have remained stable over the years (19 -LK-ERFN Trap-134.156; Denison 2022). The ERFN trapper, fisher, and resource harvester (ERFN Trapper) have also shared that caribou are the most frequently sighted big game between Russell and McDougall lakes, which lie immediately to the east and south of the Wheeler River Project (19-LK-ERFNTrap-134.174; Denison 2022).

Some EFRN Elders have shown concern over woodland caribou populations, worrying that future generations will not experience the same abundance of wildlife that they themselves experienced (EFRN 2011). These concerns partly stem from EFRN observations of changing woodland caribou distribution, which is believed to be influenced by wildfire. According to EFRN Elders, wildfires play a role in calving success and impact caribou distribution and population by disturbing habitat and travel routes. Some Elders have also suggested a decline in caribou populations as a result of these wildfire disturbances (EFRN 2011). Participants in an EFRN traditional knowledge study also shared concerns over the potential decline of caribou and moose as an effect from increased access leading to more hunting pressure (EFRN and SVS 2022).

Predation

Western Science

In addition to relatively low predator densities in their study area, McLoughlin et al. (2019) found some spatial separation between caribou and wolves. Caribou did not seem to avoid existing linear features (such as roads, trails, and transmission lines) in the area, while wolves established their territories away from linear features. Unlike caribou, who preferred mature conifer stands, wolves selected for wetlands and patches of deciduous-mixed forest, avoiding stands of mature conifers. Other prey species, such as moose, also occurred at relatively low densities (i.e., 45.7 moose/1,000 km²) (McLoughlin et al. 2019).

McLoughlin et al. (2019) observed that mortality of adult caribou occurred mostly during the snow-free season and only 1 of 94 collared caribou was harvested by a hunter during the four years of the study.

While predation is believed to be a key limiting factor for woodland caribou (Bergerud 1974; Stuart-Smith et al. 1997, DeMars et al. 2011 from ECCC 2020), Neufeld et al. (2021) suggested that habitat- or disturbance-mediated apparent competition only plays a minor role in the Saskatchewan woodland caribou population. Habitat- or disturbance-mediated apparent competition occurs when natural (e.g., forest fires) and anthropogenic (e.g., human development or activities) disturbances increase the abundance of other ungulates, which in turn may increase predator densities, which then increases predation risk to caribou. Neufeld et al. (2021) concluded that Northern Shield and Taiga ecoregions are of low productivity where caribou may compete with only one ungulate species (i.e., moose) and therefore, caribou and wolf dynamics do not follow general habitat- or disturbance-mediated apparent competition models.

Indigenous and Local Knowledge

The perspective of Indigenous knowledge holders is generally consistent with western-scientific findings that show low impacts of wolf predation on woodland caribou; for instance, EFRN knowledge holders have stated that wolves do act as a predation threat to caribou, but their presence has never caused population declines in the past (EFRN 2011). However, the experiences of some knowledge holders contradict the findings that relate to spatial separation of the two species. The EFRN Trapper has described an increase in trails and roads as more cabins are built in the areas where they typically hunt and trap. According to the EFRN Trapper, trails and roads are used by wolves and caribou alike. As the EFRN Trapper recounts, “wolves travel on bush roads. [I] saw a pack of about 18 wolves recently” (19-LK-ERFNTrip-134.159; Denison 2022). On the other

hand, local trappers often see caribou tracks on roads, trails, and hand-cut lines (19-LK-ERFNTrip-134.153; Denison 2022).

The ERFN Trapper believes that wolf populations are increasing, and steps should be taken to curb this growth (21-LK-ERFNTrip-506.2; 21-LK-ERFNTrip-506.3; Denison 2022). One solution put forward was to remediate the extensive network of trails, roads, and cut-lines by blocking access to them (21-LK-ERFNTrip-506.4; Denison 2022). Other IK indicates that wolves are a natural presence on the landscape and not a serious threat to the long-term stability of woodland caribou populations; however, the growing presence of roads, trails, and cut lines poses a potential issue as both caribou and wolves utilize these landscape features, increasing the likelihood of predation opportunities, especially if the wolf population is on an upward trend.

Harvest

Indigenous peoples in Saskatchewan have an inherent right to harvest woodland caribou for subsistence purposes (ENV 2013). No other harvest of woodland caribou is currently permitted.

Under provincial and federal recovery planning and effective species management, self-sustaining caribou populations will support long-term subsistence use of the species and protect treaty rights. Subsistence harvest levels are assumed to be low but actual numbers are not available because most communities or Indigenous groups are not collecting and/or publishing this information.

The ERFN Country Foods Study (2017), highlights the importance of caribou in the diet of the people of this community. Of the traditional meats harvested by ERFN study participants, woodland caribou was the third most consumed mammal species. The Wheeler River ERFN Traditional Knowledge Study (2022), documented woodland caribou harvesting locations in the study area. Three areas that had been used for woodland caribou hunting in the last ten years were recorded (codes: 1003-10, 1004, 09, 1016-09).

Overall Status

As noted previously, based on work completed by McLoughlin et al. (2019), which was confirmed by ENV in November 2023 (SK ENV 2023b), the caribou populations in SK1 are stable. The amended federal recovery strategy specifies a unique disturbance threshold of 40% undisturbed habitat for SK1. Habitat disturbance is assessed by the combination of human-caused disturbance (e.g. roads, industrial infrastructure) with a 500 m buffer and wildfire perimeters (less than 40 years old). Based on the federal assessment and recent preliminary disturbance assessment from ENV, an estimated 53% of SK1 is considered disturbed, with 47% undisturbed (ENV 2023b), indicating that the land use and overall disturbance in the conservation unit remains below the recovery strategy disturbance threshold.

Mitigation Hierarchy

A generic biodiversity mitigation hierarchy is provided in Figure 0-1. As shown in the hierarchy, an offset can be used to address any residual effects following efforts to avoid, minimize, and restore potential project effects. This generic hierarchy is generally consistent with the approach of ENV to manage effects on caribou and their habitat.

The balance of Section 4 of this Plan outlines Denison's approach to avoid, minimize, and restore caribou habitat per commitments made in the draft EIS associated with the Project. The discussion of additional management measures through offsetting is provided in Section 5.

Figure 0-1: Mitigation Hierarchy

Avoid

Potential adverse effects on the caribou have been avoided to the extent possible through Project design, including:

- Selection of in-situ recovery (ISR) mining avoids some direct and indirect effects compared to conventional underground or open-pit mining methods. In-situ recovery mining avoids the need for spatially expansive infrastructure such as waste rock piles and tailings management facilities reducing the Project footprint (i.e., avoids direct effects on caribou and their habitat). In-situ recovery mining also reduces the potential for interactions between caribou and Project components / activities as it concerns sensory disturbance as it is inherently a less intensive form of mining with reduced noise/light/vibration generation (i.e., avoids indirect effects on caribou and their habitat).
- Site clearing and other works that involve disturbance of vegetation and/or soil will be completed during least-risk timing windows for caribou (for example, outside of

wintering/calving period from April 1-July 31, per ENV 2013), where practical, to avoid disturbance during sensitive time periods.

- Pre-disturbance wildlife surveys will be completed to identify caribou presence and work will be postponed if caribou are present.

Minimize

Additional mitigation measures to minimize effects on caribou and their habitat and tailored to Project features have been incorporated into the various Project management and monitoring plans within the Environmental Management System (EMS) including but limited to erosion and sediment controls, soil and vegetation monitoring, Decommissioning Plan, air quality monitoring, fuel spill control and response, Radiation Protection Plan, surface water and effluent monitoring, and Waste Management Plan.

The Project's EMS plans provide direction on monitoring and adaptive management so that if issues are identified, mitigation measures can be developed and implemented in a timely and effective manner. Mitigation measures specific to caribou are applicable during all Project phases, within all seasons and expected to be effective following appropriate implementation. Examples of the measures to minimize Project effects on wildlife in general, and caribou in particular, are highlighted below.

1.1.1 Disturbance Footprint

- Siting Project components in close proximity to the ISR mining area minimizes indirect effects on caribou and their habitat. The Project components are also west of woodland caribou observations from a large-scale caribou collaring program based on tracking data received by the Ministry of Environment (Figure 0-2), although the absence of data does not necessarily mean the absence of caribou and Denison has observed caribou in the area. Appropriate siting is anticipated to minimize the potential for interactions with woodland caribou and Project activities.
- The Project footprint (i.e., the area of maximum physical disturbance) has been reduced to the extent safely practicable, resulting in limited/minimal habitat loss/disturbance and noise propagation.
- Portions of the proposed Project footprint will be developed within previously disturbed areas, including roads currently used for exploration activities, thereby minimizing additional habitat disturbance.

Denison-Wheeler Study Area - Woodland Caribou Location Data

| RSA Boundary | | |
|------------------------|-------------------|---------------------|
| Data Type | Years | Number of Locations |
| Incidental Observation | 1987, 2017 – 2022 | 89 |
| Telemetry Point* | 2013 – 2016 | 3,848 |

*Data from 15 individual woodland caribou cows

| LSA Boundary | | |
|------------------------|-------------------|---------------------|
| Data Type | Years | Number of Locations |
| Incidental Observation | 2017 – 2022 | 19 |
| Telemetry Point* | 2013, 2015 – 2016 | 62 |

*Data from 4 individual woodland caribou cows

NOTE: Absence of data does not mean absence of woodland caribou.

Figure 0-2 Saskatchewan Ministry of Environment Woodland Caribou Location Data Provided to Denison

Wildlife and Habitat Protection

- Project activities have been assessed for their potential to disturb or remove wildlife and/or wildlife habitat (e.g., site clearing, soil disturbance) to determine potential effects on wildlife and wildlife habitat and the assessment, including proposed mitigation measures, for the Project will guide Project activities.
- Pre-disturbance wildlife clearance surveys will be conducted within the Project Area; results of the clearance surveys will inform the development and implementation of appropriate mitigation (e.g., delay of work) to address the identified issue (e.g., presence of caribou).
- Personal firearms for employees and contractors will be prohibited within the Project Area to prevent hunting activities.
- Policies will be implemented prohibiting employees and contractors from feeding, approaching, or harassing wildlife species within the Project Area.
- To support wildlife habitat regeneration, progressive restoration including ecosystem-based revegetation will be conducted on disturbed areas as soon as practicable in accordance with the Decommissioning Plan.

Wildlife Deterrence and Prevention of Wildlife Entrapment

- In addition to installing secure fencing around all contaminated areas to prevent accidental contaminant exposure, buildings and other Project components will be designed and maintained to exclude wildlife from using buildings for refuge or shelter, and to deter wildlife from potentially becoming entrapped.

Sensory Disturbance

- Noise emitting Project activities will be managed to minimize sensory disturbance of wildlife, especially during sensitive time periods, such as calving. This would include:
 - locating excessive noise generating activities such as the concrete batching operation as far away from sensitive wildlife locations as possible;
 - directing the generator discharge openings away from sensitive locations; and
 - making use of available on-site obstructions to control sound exposure at sensitive areas (i.e., locate sources behind buildings).
- The main sources of noise will be related to transport of people and goods, drilling of holes for the freeze wall and wellfield, operation of the batch plant, operation of the processing plant, and operation of the pumphouses. Low sound emission equipment and the use of silencers or mufflers (whenever practical) will be used to reduce noise associated with Project activities. There will be regular maintenance of equipment to ensure it is in proper working order and not emitting noise unduly.
- Lighting will be focused on work sites and not surrounding areas, to minimize light trespass and other light-related pollution sources.
- Facilities will be illuminated only to meet standards set for the protection of workers to avoid over-illumination.
- Battery-powered, light vehicles and mobile equipment, and an AC powered dual rotary drill will be used for ISR wellfield development instead of a traditional diesel-powered unit, where practical, to reduce air emissions and noise levels and improve energy efficiency.

- Fugitive dust sources that could lead to deposition of dust on vegetation and waterbodies (including potential deposition of trace metals and radionuclides) will be reduced by:
 - dust suppression techniques on site roadways, such as road watering and traffic management;
 - directing processing plant exhaust from drying and packaging areas through a stack prior to release outside of the building;
 - designing the stack height based on results of air dispersion modelling to be an appropriate height for optimal dispersion;
 - making a wash bay available to clean items, equipment, and vehicles that may have been in contact with potentially contaminated materials. Contaminated water from the wash bay will be collected in a sump tank and routed to the water treatment plant for treatment and discharge; and,
 - conducting radiological clearance scanning as required for any items, equipment, and vehicles leaving the Project Area.

Transportation Management

- Traffic and access control measures will be implemented, including managing traffic volume by scheduling truck convoys, using high-volume haul trucks, and restricting public access (e.g., private vehicles, snowmobiles, all-terrain vehicles, and foot traffic) to the Project site and roads with both north and south security access gates. It is important to note that if any individual were seeking access around the Project area to undertake Aboriginal and / or Treaty Rights, Denison staff would facilitate this, provided it was safe to do so given Project activities in the area.
- For Project air traffic, as safety allows, planes will be encouraged to use the most direct approach and departure flight paths in order to leave the terrestrial LSA and RSA in an expedient manner.
- Appropriate road signage will be installed (e.g., speed limits, identification of wildlife crossings and areas of high activity) along Project roads to minimize the risk of wildlife-vehicle collisions.
- Speed limits will be implemented to reduce the risk of wildlife-vehicle collisions.
- Wildlife will have the right-of-way on Project roads, unless it is unsafe to stop (i.e., if a collision is imminent). Vehicles will not be used to encourage caribou to move off Project roads and processes will be implemented for employees and contractors to slow down and/or stop vehicles/equipment to allow caribou to move away or off the road before resuming normal road speeds for the area.
- Road watering and regular road maintenance to limit dust dispersion.
- Employees and contractors will report and communicate the location and circumstances of any roadkill observed on or alongside Project roads. Large-bodied wildlife carcasses found will be promptly reported to ENV and disposed of as directed to prevent scavenging.
- Vegetation along Project roads will be managed to reduce attractiveness to wildlife (e.g., forage plants) and maintain appropriate sightlines for drivers to minimize wildlife-vehicle collisions.
- Alternative measures on Project roads for de-icing and winter traction (e.g., sand, gravel) or dust suppression (e.g., water) will be implemented, whenever practicable, to limit the use of specialty chemicals and potential exposure of wildlife including caribou to them.

- Appropriately sized gaps in the roadside snowbanks during winter will be maintained to facilitate caribou crossing and escape and, with that, reducing their risk of vehicle collisions.
- New Project site and access roads will be designed to minimize sightlines for predators, whenever practicable, while still maintaining general road safety.
- Ditches and culverts along Project roads will be designed and maintained to minimize pooling of water as roadside pools may attract caribou.

Water Management, Waste Management, Emissions, and Hazardous Materials Management

- Education on and enforcement of proper water, waste, emissions and hazardous materials management practices will be provided to employees and contractors.
- A freeze wall will be established around the uranium deposit to reduce potential for groundwater disturbance or contamination mitigating the likelihood of exposure of caribou to contaminants in local areas of groundwater discharge to surface.
- The ISR wellfield and processing plant will be designed to re-use most of the solutions inside each circuit, reducing water use requirements to the extent feasible. Make-up water will be preferentially sourced from site runoff (instead of freshwater) where possible.
- Contaminated wastes (e.g., mineralized drill cuttings, process precipitates) will be temporarily stored on double lined pads with leak detection capabilities and an associated monitoring program until final disposal at an approved facility. An adjacent pond will be used to collect contact water from these pads.
- All contact water will be routed to the Industrial Wastewater Treatment Plant for treatment and eventual release to the environment. All treated effluent released to surface water will meet federal and provincial regulatory discharge limits. This will mitigate exposure of caribou to Project-related contaminants released to the environment.
- Surface pipelines will be designed to have secondary containment or catchment and have leak detection systems in place at key locations to mitigate the likelihood of the release of such chemicals to the environment that could result in exposure of caribou to the chemicals.
- Double-walled high-density polyethylene or equivalent piping will be used in the wellfields and will be freeze protected and secured to minimize pipe movement to mitigate the likelihood of the piping failure and the associated release of wellfield chemicals to the environment that could result in exposure of caribou to the chemicals.
- Denison is proposing to segregate and compost organic wastes on site in a composting system, reducing the volume of material in the domestic landfill generating odours and thereby minimizing wildlife attractants.
- Domestic waste will be collected and temporarily stored in wildlife-proof containers to avoid attracting wildlife and reduce the risk for human-wildlife interactions. The wildlife-proof containers will be inspected regularly for evidence of wildlife presence or access to waste disposal facilities. If evidence of wildlife presence or access to waste disposal facilities is detected, modified systems will be implemented and/or off-site waste disposal/incineration frequencies will be increased.
- A "no littering policy" for employees and contractors will be implemented within the Project Area.

- Air emissions will be reduced to the extent practical through implementation of the development of air emissions management and monitoring plans within the EMS.
- All vehicles and equipment will be equipped with industry-standard emission control systems; unnecessary idling of vehicles will be prohibited to reduce emissions.
- The use of hazardous materials will be limited as much as possible.
- Appropriate hazardous materials management practices will be implemented in accordance with industry guidelines to minimize the risk of accidental spills or leakage. This will mitigate the likelihood of release to the environment that could result in exposure of caribou to the hazardous materials.
- Hazardous materials will be handled, stored, and disposed of appropriately and in accordance to avoid attracting wildlife (e.g., wildlife-proof containers, exclusion fencing) to mitigate the likelihood of exposure of caribou to hazardous materials.
- Physical deterrents (e.g., fencing) will be employed around contaminated areas (e.g., waste ponds and waste pads), the domestic landfill, or hazardous materials storage areas to discourage wildlife use / interaction. The deterrents will be monitored and maintained .
- Appropriate spill response kits will be positioned adjacent to areas where hazardous materials are stored in accordance with the Spill Response Plan to mitigate the likelihood of the release of hazardous material to the environment that could result in exposure of caribou to the material.
- A minimum 100 m distance from any waterbody will be maintained for fuel storage, refueling activities, or equipment servicing in accordance with the Spill Response Plan. This will mitigate the likelihood of a fuel spill to water that could result in exposure of caribou to fuel.
- Appropriate fuel, chemical, and materials management practices will be followed in accordance with the Spill Response Plan to minimize the risk of accidental spills or leakage of diesel fuel, other hydrocarbons, and other hazardous materials and mitigate the likelihood of exposure of caribou to such chemicals.
- All vehicles and equipment will be maintained in good working condition (e.g., no leaks) and furnished with industry-standard spill response kits.

1.1.2 Wildlife Education

- Employees and contractors will be provided with wildlife education and awareness training, including education about potential caribou issues on site and training on the mitigation measures summarized with the EMS and specifically in this Plan to avoid or minimize potential Project effects on caribou and caribou habitat.
- Employees and contractors will be educated on waste and hazardous waste management practices / policies that limit human-wildlife interactions and the potential exposure of wildlife to those wastes.
- Designated employees will be trained in appropriate wildlife deterrent techniques to minimize wildlife interactions with the Project.
- Employees and contractors will be requested to report wildlife observations, including prompt reporting of caribou observations and immediate communication to on-site staff. Wildlife encounters and outcomes will be monitored, and logbooks will be used to record wildlife observations. Logbooks and reports will be available to employees. Incidental

observations recorded by staff will be entered into Species Detection Loadforms and submitted to the Saskatchewan Conservation Data Centre annually.

Restore

The temporal bounds for the Project as stated in the EIS are years 1 to 3 for construction, years 3 to 18 for operation, years 18 to 23 for decommissioning, and fifteen years of post-decommissioning monitoring and inspections from years 23 to 38. Importantly, during physical decommissioning (years 18 to 23) the majority of Project components are scheduled to be removed from site which is expected to facilitate restoration activities. Also, because of the selected ISR mining method, there are no large, permanent Project components, such as waste rock piles or tailings management facilities, for which large scale and potentially complex restoration strategies are needed.

Denison's decommissioning commitment is to return the land back to the Province of Saskatchewan for unrestricted surface land use post-closure. The Project's Conceptual Decommissioning Plan (CDP) is included in the draft EIS. The details of decommissioning and restoration will be refined over time as the Project proceeds. A Preliminary Decommissioning Plan will be developed by Denison to support licensing and permitting applications. Prior to executing decommissioning activities, Denison will prepare and submit a Detailed Decommissioning Plan to regulators for their review and acceptance, which builds on the Preliminary Decommissioning Plan.

The CDP outlines plans for physical decommissioning (mining area remediation; asset removal; and decontamination, demolition, and disposal), followed by restoration. A summary of the CDP is provided here.

- Ongoing decommissioning of Project components will be completed when possible.
- Denison has committed to progressively restore areas no longer necessary to support/facilitate Operations to limit the amount of disturbance at any given time. Restoration of inactive areas will take place when/as these areas become available. The progress and success of these activities will be assessed regularly at a schedule commensurate with the expectations of the activities per the decommissioning plan. Progressive restoration including ecosystem-based revegetation will be conducted on disturbed areas as soon as safely and logistically practicable with the use of suitable/appropriate native species and in accordance with the decommissioning plan.
- Once the asset removal, decontamination, demolition, and disposal are completed, and the site has been cleared and leveled, restoration activities, including planting, will take place. Currently this would largely be with jack pine seedlings, but the mix of plants will depend on location and available species. Restoration activities monitored until it is deemed self-sustaining and viable wildlife habitat.
- Future discussions will be held with Indigenous and general public Interested Parties to determine the amount of access to the area they wish to maintain in the future (post-decommissioning). Based on results of these discussions, transportation corridors including roads or trails associated with the Project site that are no longer needed will be graded, scarified, and vegetated with native, self-sustaining species as required. Access to facilitate safe post-closure monitoring or requested by appropriate Interested Parties (e.g., to facilitate land use) may be left in place. Access to the site may be restricted by gates and/or berms.

- Laydown areas will be scarified, covered with 0.5 to 1.0 m of stockpiled overburden, and vegetated with native, self-sustaining species. The footprints of other infrastructure, such as the camp, will be scarified and vegetated with native, self-sustaining species as required. The goal of revegetation would be to restore the site to former state, or something similar including tree cover, to the extent possible. The topsoil and brush stockpiled during pre-construction activities will be used during restoration.
- Lessons learned from progressive decommissioning and any site-specific restoration studies will be incorporated into the Detailed Decommissioning Plan. Additionally, information from other northern Saskatchewan mine sites will be examined to help Denison select the restoration tools, including revegetation options, which will contribute towards decommissioning success.

Closure of the entire Project will be completed in accordance with provincial and federal regulations and guidance documents with the fundamental considerations being to confirm physical and chemical stability of the site to protect human health and the environment.

Progressive decommissioning and restoration will be completed throughout the life of the Project, whenever feasible, and reported to the regulatory agencies as part of the annual reporting requirements throughout Operation. Associated activities will focus on the decontamination, demolition, and disposal of unused buildings and infrastructure, as well as the removal of unused equipment and machinery. Progressive decommissioning and restoration are expected to continue and result in positive effects as revegetation is continued and regeneration occurs. Following decommissioning and restoration, wildlife habitat is expected to recover to baseline conditions.

Additional Caribou Management Measures

As part of its boreal caribou management efforts, the province is working with industry to develop effective and practical approaches to mitigate potential effects of activities on woodland caribou. To this end, the province describes a hierarchy of controls for caribou habitat management. The final element of this hierarchy of controls is termed offset, whereby restoration of habitats outside the project footprint are used to “offset” for project footprint effects where such footprint effects render a given area as unavailable to be functional habitat for an extended time period.

The ENV is developing a boreal caribou habitat offset calculator to address the above-referenced situation. The calculator’s objective is to consistently estimate and calculate appropriate offset requirements for applicable developments. The calculator recognizes that there are a number of key variables influencing both habitat loss and habitat gain calculations. As such, the following key concepts have been integrated into the calculator:

- 1. Not all projects are created equal**

Different types of projects/activities/footprints on the landscape have different potential effects on caribou habitat.

- 2. Reach of effects**

A project’s total effect on caribou habitat and associated habitat offset needs to integrate both direct and indirect (zone of influence) concepts. The total project effect includes the area of direct disturbance plus the surrounding indirect effects (Zone of Influence). Similarly, the total offset includes direct habitat gain or restoration plus indirect habitat benefits.

- 3. Location matters**

The location of the project/activity/footprint has different effects on caribou, based on habitat value. Similarly, the location of the offset has different benefits for caribou when habitat value is factored in.

In consideration of these key concepts, the calculator aims to balance functional habitat that is disturbed or removed with restored functional habitat. Through habitat loss and gain calculations, the calculator estimates habitat offset requirements for a project footprint, expressed as an equivalent length/area of linear features. In SK1 and SK2, legacy roads and trails are expected to be the primary candidate features for habitat offsets and restoration activities. It is also noted that the estimated cost to deliver the required offset is calculated. As an optional mechanism for proponents, Saskatchewan is working to establish a mechanism for in-lieu mitigation payments such that the province can allocate resources based on its caribou habitat restoration priorities.

Through refinements to our final project design, Denison is committed to continue working with the province to finalize our habitat offset requirement using the province’s habitat offset calculator.

- Reference to EIS, appendices, or supporting documentation: Section 9.3.9 Ungulates, Furbearer and Woodland Caribou Summary

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, June 2024) |
|--------------|----------------|---|---|--|---|---|---|--|
| IR-157 | - | <p>Context and Rationale: The Proponent has committed to developing a Woodland Caribou Management Plan, which will include a “detailed assessment for the need for habitat offsets.” The Woodland Caribou Management Plan will support ECCC’s review of the Proponent’s assessment of residual effects following mitigation and offsetting.</p> <p>This plan should consider ECCC’s Operational Framework for Use of Conservation Allowances (ECCC, 2012). ECCC is available to assist the Proponent in the determination of appropriate offsets that would balance against Project adverse effects after the application of measures to avoid, minimize and restore on-site are adopted.</p> <p>Based on the Amended Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal Population, in Canada 2020, anthropogenic impacts to local caribou populations experience a lag effect, which occurs over extended periods. This lag effect needs to be adequately considered when proposing offsets. ECCC is available to assist the Proponent in understanding how critical habitat is described in the Recovery Strategy and the determination of appropriate offsets that would balance against Project effects based on the predicted impacts to caribou habitat.</p> | <p>Provide the Woodland Caribou Management Plan for review. The plan should clearly demonstrate efforts to avoid and minimize any Project effects and restore on-site any disturbed areas prior to the consideration of offsetting. Details on how severity of disturbance and vulnerability of the species were considered should be explained.</p> <p>See also related: IR-149.</p> <p>Suggestions for mitigation and follow-up measures: ECCC notes that the Woodland Caribou Management Plan should clearly explain efforts to address Project effects, including any contribution to cumulative adverse effects, after it has been determined that all options in the previous steps of the mitigation hierarchy (i.e., avoidance, and minimization,) have been fully considered and applied.</p> <p>In the Woodland Caribou Management Plan, provide details on how the factors outlined in the Operational Framework for Use of Conservation Allowances (ECCC, 2012) were considered in determining the offsetting amounts, including the severity of disturbance and vulnerability of the caribou population. Important factors including time lag (the amount of time from restoration work to when the habitat would be considered caribou habitat) would also need to be considered.</p> <p>ECCC typically recommends a minimum offset multiplier of 4:1 (offset outcome: area disturbed). This is a benchmark ratio applied to a project that is in the lower end of the risk spectrum, such as one with a low severity impact adversely affecting a low vulnerability ecological component. In general, the minimum 4:1 multiplier accounts for time-lags to restoration, uncertainty in outcomes, a precautionary approach, and the adverse impact itself in its specific context. Offset multipliers are variable and determined by project-specific circumstances and associated risks and uncertainties.</p> | <p>Refer to response to IR-145 (<i>included here</i>):</p> <p>Denison considers the EA to be a planning and decision-making tool that assesses the potential effects of the Project in a careful and precautionary manner and integrates results of engagement with Indigenous nations and communities. As such, the EA is a process for identifying the Project’s potential interactions with the biophysical and human environment, predicting potential adverse effects, identifying mitigation measures, and evaluating residual and cumulative effects remaining after mitigation. The EA also outlines the proposed efforts for monitoring and reporting to verify compliance with the terms and conditions of EA approval and to assess the accuracy and effectiveness of predictions and mitigation measures presented in the EA. Denison views the EIS as an important planning tool that will be used to support future activities and represents one stage in the rigorous overall approvals process for a uranium mining facility in Canada. Denison is completing a sequential EA and licensing process for the Project. In the EIS, a framework for the Environmental Management System (EMS) is provided along with a clear commitment for Denison to include Project design and species-specific mitigation measures into the EMS documents as they are developed / as the Project proceeds through the licensing and permitting phases.</p> <p>The selection of valued components (VC), with key indicators (KI), and associated measurable parameters is an important part of scoping in each biophysical and human environment assessment. Woodland caribou were selected as a VC in the Terrestrial Environment assessment for a variety of reasons including a recognition of caribou as an important cultural and subsistence species, the conservation status of caribou, and that Project activities and infrastructure may affect woodland caribou populations. For the woodland caribou VC, the KI selected was also woodland caribou. The measurable parameters for the caribou VC/KI were: 1. amount of habitat that may be altered or lost relative to its availability in the Terrestrial RSA; and, 2. woodland caribou mortalities directly or indirectly attributable to the Project.</p> <p>The main Project interactions identified in the caribou assessment were: direct habitat loss, sensory disturbance, collisions with Project vehicles and equipment, and harvest and/or predation. Accordingly, the potential effects evaluated for caribou were: 1. amount of habitat that may be altered or lost relative to its availability in the Terrestrial RSA; and, 2. mortalities directly or indirectly attributable to the Project. Denison undertook the evaluation and assessment of potential effects on caribou in a conservative fashion to provide confidence in the assessment conclusions. For instance, where granular data concerning seasonal distribution and specific landscape uses were not available the approach was to assume the caribou at all life stages were present during all seasons. Additionally, the caribou assessment used conservative assumptions to categorize ‘available’ habitat. Denison also committed to important mitigation measures such as pre-clearance surveys, among other things.</p> <p>The EIS has demonstrated that the Project, as proposed and assessed, is predicted to minimize the potential for environmental adverse effects on caribou and their habitat before any Project specific construction occurs. The conclusions of the assessment predicted that the likely residual effects of the Project on caribou were not significant.</p> <p>The EIS uses "available caribou habitat" as a basis to assess the Project effects. Available habitat was determined as the ecosites in which caribou / caribou sign were detected most frequently during the baseline studies, and the EIS used a precautionary approach by assuming caribou use of these areas during all seasons and life stages.</p> <p>Subsequent to filing of the draft EIS and as committed to ECCC during an April 20, 2023 meeting between Denison and ECCC, Figure 9.3-8 has been updated (included in</p> | <p>This response has not been accepted.</p> <p>The Proponent provided a conceptual Woodland Caribou Monitoring Plan, however, this plan does not include an assessment of the Proponent’s determination of the required amount of habitat offset.</p> <p>ECCC currently recommends a minimum offset multiplier of 4:1 (offset outcome: residual adverse effect) for a project that has a low severity impact of adversely affecting a low vulnerability ecological component. This is a benchmark ratio applied to a project that is in the lower end of the risk spectrum; for example, for a project with a low severity impact adversely affecting a low vulnerability ecological component. In general, the minimum 4:1 multiplier accounts for time-lags to restoration, uncertainty in outcomes, a precautionary approach, and the adverse impact itself in its specific context.</p> <p>Offset multipliers are variable and determined by project-specific circumstances and associated risks and uncertainties.</p> <p>The Proponent provided a conceptual Woodland Caribou Monitoring Plan, however, this plan does not include an assessment of the Proponent’s determination of the required amount of habitat offset.</p> <p>ECCC currently recommends a minimum offset multiplier of 4:1 (offset outcome: residual adverse effect) for a project that has a low severity impact of adversely affecting a low vulnerability ecological component. This is a benchmark ratio applied to a project that is in the lower end of the risk spectrum; for example, for a project with a low severity impact adversely affecting a low vulnerability ecological component. In general, the minimum 4:1 multiplier accounts for time-lags to restoration, uncertainty in outcomes, a precautionary approach, and the adverse impact itself in its specific context.</p> <p>Offset multipliers are variable and determined by project-specific circumstances and associated risks and uncertainties.</p> <p>Based on the Amended Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal Population, in Canada 2020, anthropogenic impacts to local caribou populations experience a lag effect, which occurs over extended periods. This lag effect needs to be adequately considered when proposing offsets.</p> <p>In the absence of sufficient data or information required to validate the level of risk that this Project is likely to have on the species recovery, the implementation of the mitigation hierarchy and offsetting measures to address Project adverse effects, ECCC’s views are based on the precautionary approach.</p> <p>Thus, ECCC preliminary analysis regarding the likelihood of this Project having an adverse effect on boreal caribou recovery is identified as moderate to high, resulting in a precautionary offsetting requirement that should be in terms of amount, much greater than 4:1. The assumptions of ECCC’s risk assessment include:</p> <ul style="list-style-type: none">• The biophysical attributes required for boreal caribou recovery (i.e. habitat for calving, post-calving, rutting, winter and travel) are present within the study area and will be directly or functionally lost,• Sensory disturbance arising from project activities (e.g. air traffic) will cause functional habitat loss for boreal caribou within important habitat areas required for different life stages. <p>Additionally, lack of information supporting the Proponent’s offsetting plans creates uncertainty and thereby warrants a higher offset ratio.</p> <p>ECCC is available to provide information to the Proponent on how critical habitat is described in the Recovery Strategy and the determination of appropriate offsets that would balance against</p> | <p>Please see response to IR-149 (<i>in separate Word file</i>).</p> <p>In addition, in direct response to IR-157 the following is noted.</p> <p>Denison continues to work collaboratively with Saskatchewan Ministry of Environment (MOE) on their requirement for an offset for adverse effects on caribou habitat. Denison has advanced the Project-related Caribou Management Framework within the context of the province’s offsetting framework. The MOE has reviewed the draft framework and has provided Denison a notification of their support. Subject to finalization and provincial acceptance, the framework will provide the means to address/offset all residual adverse effects (i.e., those remaining after the application of the proposed mitigation measures) of the Project on caribou that are under provincial jurisdiction.</p> <p>Further, Denison has committed to monitoring the effects on wildlife, as per the Wildlife Management Plan. The findings of the monitoring programs are expected to inform Denison, through an adaptive management process, of the need, if any, for additional mitigation measures.</p> | <p>Note to Denison: This would be accepted if Denison is able to make a commitment as noted below.</p> <p>Updated Rationale:</p> <p>The updated draft Caribou Management Framework provided by the Proponent is still lacking information regarding offsetting location, amount, habitat type, habitat quality, etc. The Proponent notes that SK ENV is developing a boreal caribou habitat offset calculator, and that the Caribou Management Framework will be finalized using that tool as part of the provincial approvals, but information gaps remain on the amount of habitat offset required to mitigate Project effects.</p> <p>The Caribou Management Framework should be updated with this outstanding information.</p> <p>Given that ECCC and CNSC understand that the Province of Saskatchewan and ECCC’s Canadian Wildlife Service are in communication on the Denison’s caribou management plans, and the province’s offsetting plan is underway, if Denison are willing to add a commitment to the Commitments Register, this IR could be resolved. The commitment text would include the commitment that “Denison’s offsetting plan will meet the objectives of the Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal population, in Canada.”</p> <p>Proposed rationale text for posting: Denison has captured their commitment related to caribou management and offsetting in the Commitments Register, so this IR has been accepted.</p> | <p>Denison’s understanding is that by meeting the Provincial offset requirements, as part of the Saskatchewan range planning, the company will be meeting the objectives of the recovery strategy since the Province is responsible for caribou management. To provide a clear affirmation of Denison’s commitment to offsetting, we have added the following commitment to the Commitment Register (version 2) as Commitment 9-35:</p> <p>“Denison will develop an offsetting plan to satisfy the requirements of the Province of Saskatchewan offsetting framework that the province has created to fulfill its obligations as it concerns implementing the objectives of the Recovery Strategy for the Woodland Caribou (Rangifer tarandus caribou), Boreal population, in Canada.”</p> |

| | | | | <p>Attachment IR-143) to address seasonal use by caribou within the terrestrial study areas.</p> <p>In May 2023, Denison received caribou data from the Province of Saskatchewan that included both incidental observations and telemetry point data within the terrestrial study areas. These data were provided to Denison as a figure, and this figure has been included herein as Attachment IR-145. The information made available to Denison by the Province was not broken down to reflect the timing (seasonality) of the reported data and therefore does not specifically contribute to the description of seasonal use of the Project study areas by caribou.</p> <p>For reference, and based on the data that have been made available, the conservative assessment approach utilized in the draft EIS of assuming caribou presence in the terrestrial study areas throughout all seasons will not be changed.</p> | <p>Project effects based on the predicted impacts to caribou habitat.</p> | | | |

|--------------|----------------|--|--|---|--|---|--|---|
| IR-170 | - | <p>Context and Rationale:</p> <p>The table and map presented by the Proponent do not appear representative of all available habitat for common nighthawk (CONI). Although CONI do preferentially use open areas such as gravel (often an anthropogenic disturbance) and regenerating forest, as identified in the draft EIS, they also use rock outcrops that can be within forested areas. As this area lies within the pre- Cambrian shield, there are likely rock outcrops that are also available habitat.</p> <p>As aerial insectivores, CONI select nesting areas in close proximity to wetlands or lakes where there is abundant forage.</p> <p>Habitat requirements and preferences for all species at risk is required for developing effective mitigations and adaptive management.</p> | <p>1. Provide an updated table and map that considers all available habitat for common nighthawk.</p> <p>2. Additionally, as part of environmental management plans the Proponent should include species-specific mitigations that are biologically relevant to all the species at risk for all Project phases and components.</p> | <p>1. The methodology for the habitat-based assessment appropriately evaluated potential adverse effects on avian species. The VCs and KIs were selected following extensive consultation with Indigenous nations and communities and other Interested Parties; the VCs and KIs appropriately focused the EA; no updated table or map is considered to be required. In addition, further mapping is not expected to affect or change the findings and conclusions of the draft EIS.</p> <p>2. Common Nighthawk were observed in the Project study areas during the baseline studies and are considered to be present and breeding. Rocky outcrops were not reported during the baseline studies (see Section 9.2.3). Pre-clearing surveys will be conducted, set-back buffers implemented, and pre-clearing survey and monitoring results will be used for adaptive management purposes (see also response to IR-159). Species-specific mitigation appropriate for Common Nighthawk is largely related to loss and/or alteration of habitat (including both direct and indirect effects).</p> | <p>This response has not been accepted.</p> <p>Part 1 of the IR was addressed, however, part 2 has not been addressed. ECCC requires this information to properly assess potential the mitigations and adaptive management for Common Nighthawk.</p> | <p>Based on the baseline field survey observations (n=38) for common nighthawk, the majority of observations (n=20) were in association with anthropogenic (disturbed) ecosite types, while the remainder (n=10) were associated with the jack pine-blueberry/black spruce-blueberry/lich (BS3/BS7) ecosite.</p> <p>Updates to Figure 9.4-7, Figure 9.4-12 and Table 9.4-19 of the revised draft EIS have been completed to include all habitat (ecosite) types. See separate response to IR-170: Available Habitat for Common Nighthawk. Figure 9.4-12 in the revised draft EIS has been replaced in the EIS with a revised figure that includes all ecosite types.</p> <p>Mitigation measures that would pertain to common nighthawks are included in Section 9.4.5.2.1 Work Timing Windows and Habitat Disturbance, which state that site clearing and other works that involve disturbance of vegetation and/or soil will be conducted outside of the nesting season, whenever practicable. The nesting season for the Raptors, Migratory Breeding Birds, and Bird Species at Risk VCs in Saskatchewan spans a period from March 15 to August 31.</p> <p>Further, in the event site clearing is necessary within this time frame, pre-clearance wildlife sweeps will be completed where common nighthawks are suspected of nesting; if an occupied nest is found, applicable activity restriction guidelines would be implemented (as per SK MOE 2017).</p> <p>References:</p> <p>Saskatchewan Ministry of Environment (SK MOE). 2017. Saskatchewan Activity Restriction Guidelines for Sensitive Species. https://publications.saskatchewan.ca/api/v1/products/79242/formats/89555/download (accessed July 2021).</p> | <p>Item one was accepted, but item two remains outstanding. In Section 9.4.5.2.1, the Proponent has not included species specific mitigations for all species at risk, including common nighthawk. The Proponent should include species specific mitigations for all species at risk, including common nighthawk, so that ECCC can provide advice on the extent of Project impacts to these species.</p> <p>Additionally, the Proponent indicates that prior to site clearing during the nesting season (period from March 15 to August 31), pre-clearing nest surveys will be conducted. ECCC does not typically recommend nest surveys as a pre-clearing activity (please refer to the Advice to the Proponent relating to IR-170). In some instances, surveying for breeding activity using non-invasive methods could be required to determine species presence, and for some migratory birds SAR it may be required to survey for nest trees (residences) prior to clearing as these have year-round protection through SARA and a permit may be required.</p> <p>Specifically, it is not adequate to group SAR together (e.g., all birds) due to the unique life history and habitat requirements of each individual SAR. Denison is expected to provide species-specific mitigation measures for each SAR separately.</p> | <p>See response to IR-142-159-167-R1.</p> |

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (ROUND 3, July 4, 2024) |
|--------------|----------------|---|---|---|--|--|--|---|
| IR-174 | - | <p>Context and Rationale: The Proponent conducted acoustic surveys for bats and confirmed presence of two Species at Risk Act (SARA) schedule 1 listed bat species in the Project area, little brown myotis (Myotis lucifugus) and northern myotis (Myotis septentrionalis). However, the Proponent did not do an effects assessment of either of these bat species.</p> <p>Although bats are present in the study area, no work was done to identify hibernaculum or maternal roosting sites. All species at risk that are expected to be present in the Project area should be assessed and species-specific mitigations detailed.</p> | <p>1. Conduct an effects assessment for little brown myotis and northern myotis, including the likelihood that tree clearing during the bat roosting period, is likely to ‘kill’, ‘harm’, or ‘harass’ Little Brown Myotis and Northern Myotis and its ability to carry out its life processes.</p> <p>2. Describe and map locations of suitable myotis hibernacula and/or maternal roost habitat within the Local Study Area and Regional Study Area and explain how these habitats may be affected by Project activities.</p> <p>3. Describe what mitigation measures will be taken to avoid the breeding period for bats.</p> <p>4. Describe any pre-construction/pre- clearing surveys will be conducted to identify any hibernaculum and maternal roosting sites. Describe how monitoring will support adaptive management.</p> | <p>As Key Indicators of Valued Components, the EIS includes terrestrial wildlife and avian species that may occur in the Project study areas and are listed on Schedule 1 of the federal Species at Risk Act. Project effects on these species and their habitats are described and assessed, and mitigation measures are included to avoid or reduce the potential for adverse effects on these species and their habitats. The Project effects and associated mitigation measures described in the draft EIS are broadly applicable to SAR species that occupy the same ecological niches.</p> <p>In response to a variety of IRs, including this IR, further information has been developed that is specific to SAR and included as Attachment IR-131. This includes a listing of all SAR species potentially occurring in the Project study areas, with links to applicable and appropriate mitigation measures described in the EIS. It is proposed the content of Attachment IR-131 will be added as a new appendix (Appendix 9-D) to Section 9 of the final EIS. The information provided in the SAR appendix includes a summary of the life history requirements, the expected Project effects, proposed mitigation measures, and anticipated residual effects on these listed species. This new EIS appendix provides information on little brown myotis and northern myotis. We note Denison's commitment to pre-construction surveys to identify potential for maternity and nursery roosting habitat. Refer to response to IR-134 for the timing of clearing activities outside of roosting periods. Results from pre-construction surveys and continuous monitoring (described in Section 9.3.8) will be used in the adaptive management process to update Project design and additional mitigation measures, if required.</p> | <p>This response has not been accepted.</p> <p>Items 1., 3. And 4. of IR-174 are accepted, however, item 2. Of IR-174, which asked for mapping of suitable myotis habitat, was not addressed.</p> <p>Mapping of suitable habitat or results from baseline studies is required to understand Project impacts to Species At Risk (SAR) bat species. This may include providing mapping of bat acoustic results, including locations along with frequency of detections.</p> <p>See also IR-134 and follow-up 134-R1.</p> | <p>Acoustic bat surveys were completed between July 22 and 23, 2019 with 61 survey points sampled across five ecosite types. The location of the survey points, species detected, and frequency of detections are included in Figure 2-9 of Appendix 9-F of the revised draft EIS.</p> <p>The EA used a habitat-based approach to predict the effects of the Project on bat species. Further, in the event that site clearing is necessary, pre-clearance wildlife sweeps will be completed and appropriate mitigation will be developed and implemented.</p> <p>The pre-construction and pre-clearing surveys will consist of wildlife sweeps conducted by qualified biologists within 7 days prior to any clearing activity at a specific location, and a 100 m buffer, within the Project Footprint. The wildlife sweeps will not be species-specific surveys focused on species at risk but will to be based on timing of Project related activities (i.e., will be completed in advance of site clearing activities). These sweeps are intended to identify sensitive wildlife features (including hibernacula or potential roosting sites for myotis species) that would require specific mitigation measures to avoid or minimize adverse effects on identified features and are not species-specific. The methods associated with these pre-construction and pre-clearing sweeps will be tailored to species at risk (including myotis species) that may potentially be using habitats at certain times of the year. Depending on the results of these surveys, appropriate mitigation measures will be developed and implemented. This is a risk-based approach with the intent of reducing the potential of important wildlife features being adversely affected during vegetation or land disturbance activities. The wildlife sweeps would be conducted within 7 days prior to disturbance activities, year-round, so that sensitive features can be identified, and appropriate mitigation measures (e.g., avoidance, timing delay) can be developed and implemented, as appropriate.</p> | <p>Note to Denison: There is additional text being drafted related to this topic, but it is still under review and may provide clarity on the outstanding request.</p> <p>Items one, three, and four have been accepted, but the response to item 2, regarding describing and mapping of locations of suitable myotis hibernacula and/or maternal roost habitat within the Local Study Area and Regional Study Area and an explanation of how these habitats may be affected by Project activities, is outstanding.</p> <p>In responding to item two, the Proponent has provided a map of species detected and frequency of detection in the local study area over two days on July 22 and 23, 2019. ECCC notes that analysis is lacking for the regional study area, despite a few autonomous recording units (ARUs) that were placed outside the LSA.</p> <p>Data from two consecutive days in the same month is not an accepted method to document baseline occurrences associated with suitable habitat. The legend for Figure 2-9 is not clear in that frequency of detection is mapped based on two criteria: little brown myotis and little brown/northern myotis.</p> <p>The Proponent should use a scientifically defensible method to document baseline occurrences associated with suitable habitat. The Proponent should clarify the legend and explain the values found within it, including if the turquoise dot represent occurrence of both little brown and northern myotis. Baseline data for bat SAR must be adequate to capture within and between year variability and to allow for statistically robust comparison to assess potential impacts on SAR over the lifecycle of the project. In this regard, Denison is expected to provide additional baseline data for bat SAR. If Denison chooses to rely on literature data, a justification of applicability to the project is required. Nevertheless, Denison is expected to at a minimum commit to additional baseline monitoring prior to any disturbance, and to provide a description of the monitoring methods for review. These baseline surveys must be focused on suitable habitat for bat SAR that is to be identified through the requested mapping.</p> <p>To close this IR, Denison must:</p> <ol style="list-style-type: none">1. Clarify the legend of Figure 2-9 with respect to frequency of detection2. Provide suitable bat SAR habitat information in the form of a map3. Provide additional baseline data for bat SAR based on literature sources and justify applicability to the project4. Provide a description of proposed methods for bat SAR field monitoring for review5. Commit to an EA commitment to collect additional bat SAR field baseline data prior to disturbance | <p>See IR-174 Round 3 Attachment below for supporting maps associated with responses to parts 2 and 3; the round 3 attachment is located at the end of this file.</p> <p>1. The legend of revised draft EIS Appendix 9-F, Figure 2-9 (with respect to frequency of detection) shows the total number of passes and/or buzzes detected. We note this was available in Appendix 9-B Terrestrial Baseline. For additional reference it is also noted that the acoustic survey method in Appendix 9-B did not reliably allow for differentiation between little brown myotis and northern myotis, hence the two criteria presented on the map: i) little brown myotis and ii) little brown/northern myotis. These clarifications are included in the figures below and are included in Appendix 9-F of the final EIS.</p> <p>2. Refer to IR-174 Round 3 Attachment below for ECCC’s requested map edits, that builds on the information presented in the map provided in revised draft EIS Appendix 9-F Figure 2-9 provided with the Round 2 response. Specifically, please see Figure IR-174 Round 3-1 and Figure IR-174 Round 3-2. These maps present the same information from Appendix 9-F Figure 2-9 only at a different spatial scale and with the Project Area unshaded to facilitate review.</p> <p>3. As noted in Appendix 9-D, habitat for the little brown myotis is composed of (1) overwintering hibernacula that are sufficiently cool and humid and (2) summering areas that provide foraging areas and suitable locations for roosting and maternity colonies (COSEWIC 2013). Hibernacula and maternity sites are reported as being the main limiting habitat features for this species (COSEWIC 2013), and this, as described below, is consistent with conditions at the Project site and surrounding area.</p> <p>Hibernacula occur in parts of caves, mines (openings to surface for ramps and raises for example), and buildings that have stable and specific temperature (~4 to 13°C) and humidity (>80%) conditions (COSEWIC 2013). Based on existing environment information presented in the EIS including the terrain and vegetation and ecosystem existing environment sections, there are no hibernacula anticipated in the Project Area (i.e., caves, mines, buildings with stable and specific temperatures per COSEWIC 2013). Terrain is low relief due to flat-lying sandstone and almost continuous cover of sandy glacial deposits (i.e., surface is predominately sand textured and there are no rocky outcrops or bedrock at surface for cave habitats); there are no man-made structures (e.g., mine openings or buildings) in the Project Area. As noted in the EIS, the terrain and vegetation communities are fairly uniform throughout the study areas and the habitat considerations in the Project Area are considered representative of the landscape in the wildlife LSA and RSA.</p> <p>Maternity sites can occur in large-diameter trees, rock crevices, buildings, and bat houses that offer warm and relatively stable microclimate conditions that allow females to avoid going into torpor so they can focus on caring for their young (COSEWIC 2013a, Slough and Jung 2020). As highlighted above, since there are no rock crevices, buildings, or bat houses in the Project Area, a consideration for maternal roost potential was focused on the areas where larger diameter trees may be present.</p> <p>Existing ecosite information was reviewed and ecosites with higher potential for maternity roosts (i.e., larger diameter trees) were selected. The ecosites with the potential for larger diameter trees are shown in Figure 2-10 below, and include ecosites RF1 (regenerating forest >5m tall; per Appendix 9-B), BS3 jack pine/blueberry/lichen, BS4 jack pine – black spruce/feathermoss, BS7 black spruce/blueberry/lichen, BS9 black spruce – jack pine/feathermoss, BS14 white birch/lingonberry – labrador tea, BS16 black spruce/ balsam poplar/river alder swamp, BS17 black spruce treed bog, and BS21 tamarack treed fen. While these ecosites were selected for the <i>potential</i> to have larger diameter trees, it is important to note that the majority of these ecosites have trees with diameter at breast height <10 cm. Refer Appendix 9-B for representative photos of the selected ecosites.</p> <p>Based on this conservative mapping exercise, the Project Area contains small areas of suitable potential maternal roost habitat. The total Project Area is around 170 ha and potential bat maternal roost ecosites represent less than 49 ha, when as noted above it is assumed that the ecosites identified above provide trees suitable for maternity roosts across their entirety.</p> <p>The above text has been added to Appendix 9-F of the final EIS along with Figure IR-174 Round 3-3. We reiterate that the additional information collated and displayed in the maps provided to support this IR response is consistent with and does not contradict anything presented in the draft EIS documentation.</p> |

|--------------|----------------|-----------------------|--------------------------|---|-----------------------------|---------------------------------------|----------------------------|---|
| | | | | | | | | <p>We also refer the reviewer to Appendix 9-D for a summary of species-specific mitigation measures for bats; text from Section 3.3.3 has been included below in <i>italicized font</i> for ease of review:</p> <p><i>Bat Species</i></p> <ul style="list-style-type: none"><i>Vegetation clearing activities will occur outside of roosting periods, when practical.</i><i>Pre- disturbance wildlife clearance surveys will be completed to identify site-specific habitat features such as maternal roosting sites and hibernacula used by bat species. If features are identified in the Project Footprint, appropriate setbacks and/or timing windows will be implemented in accordance with the SARGSS (SK MOE 2017 (that will also be defined in the Wildlife Management Plan).</i><i>In the event a maternal roosting site is identified on the Project Footprint, exclusionary methods (e.g., installing a one-way bat exit) will be implemented following the summer maternity roost season. This installation would allow for bats to leave but not the ability to re-enter the roosting site.</i><i>Locations of these site-specific habitat features used by bats will be communicated to the appropriate Project personnel and the requirement to limit disturbance in these areas will be implemented.</i><i>Specific exclusion methods will be added as mitigation measures (Section 9.4.5 of the final EIS) to prevent access to buildings and other infrastructure.</i> <p>4. Refer to response to IR-142, IR-159, IR-167-R1 for information on the bat-specific pre-clearance sweeps. We also note that Commitment 9-3 outlines Denison's commitment to pre-disturbance wildlife clearance surveys.</p> <p>5. A commitment to complete pre-construction / disturbance bat surveying has been added to the commitments register as 9-37, as follows:</p> <p>“Acoustic bat surveys will be completed prior to construction, building on the 2019 surveys (Appendix 9-B). The surveys will determine the presence/non-absence, diversity and relative abundance of bat species in the Project Area.”</p> <p>For clarity, this additional pre-construction / disturbance data will be used to inform the execution of site development activities and additionally provides further information that can be used within the context of follow-up monitoring as a basis for temporal comparison. At this time, the intent is not to integrate such information into the EIS, nor does Denison and its SMEs believe the additional information is necessary to for EA determination with respect to potential project-related effects on bats.</p> <p><u>References:</u></p> <p>COSEWIC. 2013. Introduction

Background

On October 21, 2022, Denison Mines Corp. (Denison) submitted a draft Environmental Impact Statement (EIS) for the proposed Wheeler River Project (the Project). Based on their initial review, the Canadian Nuclear Safety Commission indicated that the submission contained the required information to proceed with the Federal-Indigenous Review Team (FIRT) technical review of the draft EIS. On March 20, 2023, the FIRT provided Denison with a list of information requests (IRs) for Denison to respond to and eventually submit a final EIS document.

This Appendix provides additional information to address several IRs provided by Environment and Climate Change Canada (ECCC) as part of the initial round of Federal Indigenous Review Team (FIRT) comments. These IRs were related to 16 wildlife species at risk (SAR) listed under Schedule 1 of the federal *Species at Risk Act* (SARA). The draft EIS approach was conservative in that it considered appropriate representative species as Valued Components (VCs) and Key Indicators (KIs) in sections 9.3 Ungulates, Furbearers, and Woodland Caribou and 9.4 Raptors, Migratory Breeding Birds, and Bird SAR. Of the 16 wildlife SAR listed in Table 0.1, seven had been included as VCs or KIs in the EIS after a thorough scoping process (refer to Section 0 for additional information).

Nine of the sixteen were not included as individual VCs or KIs but are considered important from a regulatory perspective. The SARA-listed species identified by ECCC are listed in Table 0.1. Those noted in bold font indicate those for which further assessment is provided in this appendix.

Table 0.1 Wildlife Species at Risk Listed by Environment and Climate Change Canada

| Common Name | Scientific Name | Discussed in the draft EIS |
|---------------------------------|--|----------------------------|
| Nine-spotted lady beetle | <i>Coccinella ovemnotata</i> | No |
| Transverse lady beetle | <i>Coccinella transversoguttata</i> | No |
| Yellow-banded bumble bee | <i>Bombus terricola</i> | No |
| Northern leopard frog | <i>Lithobates pipiens</i> | No |
| Little brown myotis | <i>Myotis lucifugus</i> | No |
| Northern myotis | <i>Myotis septentrionalis</i> | No |
| Wolverine | <i>Gulo gulo</i> | Yes |
| Woodland caribou | <i>Rangifer tarandus caribou</i> | Yes |
| Bank Swallow | <i>Riparia riparia</i> | No |
| Barn Swallow | <i>Hirundo rustica</i> | No |
| Common Nighthawk | <i>Chordeiles minor</i> | Yes |
| Horned Grebe | <i>Podiceps auritus</i> | No |
| Olive-sided Flycatcher | <i>Contopus cooperi</i> | Yes |

| Common Name | Scientific Name | Discussed in the draft EIS |
|-----------------|-----------------------------------|----------------------------|
| Rusty Blackbird | <i>Euphagus carolinus</i> | Yes |
| Short-eared Owl | <i>Asio flammeus</i> | Yes |
| Yellow Rail | <i>Coturnicops noveboracensis</i> | Yes |

Of the 16 species listed in Table 0.1, seven had been included as VCs or KIs in the EIS after a thorough scoping process, as summarized below.

Valued Component Selection

The VCs considered in the effects assessment for the Project are aspects of the biophysical and human environments that were considered to be likely to be affected (adversely or positively) by the Project. The VCs reflect identified scientific, local knowledge, and Indigenous Knowledge, and community interests regarding the Project and its potential effects. The potential effects are typically identified early in the environmental assessment process as a result of questions and concerns raised through engagement with Indigenous and community groups, government departments and agencies, and the general public.

Denison reviewed and considered all received input to develop a VC list that reflects the key environmental, socio-economic, heritage, and human health components and interests to appropriately focus the EA.

The initial VCs selected to represent bird SAR in the habitat-based assessment that were provided in the Terms of Reference (Denison 2019) were evaluated, consolidated, and organized to allow for the logical assessment of Project effects, and are presented in Table 0.2 and Table 0.3, which formed the basis for the subsequent VC-specific assessment.

Table 0.2 Wildlife Species at Risk Valued Component and Rationale for their Inclusion in the Habitat-based Environmental Assessment for the Denison Wheeler River Project

| Valued Component | Rationale |
|---------------------------------------|---|
| Biophysical Environment | |
| <i>Terrestrial Environment</i> | |
| Furbearers | Project activities and infrastructure may affect local furbearer populations, including species at risk (SAR), resulting in non-compliance with permit conditions (e.g., <i>Species at Risk Act</i> [SARA; Government of Canada 2022], <i>The Wildlife Act 1998</i> [Government of Saskatchewan 2020]). |
| Woodland Caribou | Project activities and infrastructure may affect woodland caribou populations, resulting in non-compliance with permit conditions (e.g., SARA [Government of Canada 2022], <i>The Wildlife Act, 1998</i> [Government of Saskatchewan 2020]). |

| Valued Component | Rationale |
|----------------------|--|
| Bird Species at Risk | Project activities and infrastructure may affect bird SAR (specifically disturbance and/or destruction of eggs, young, and adults) resulting in non-compliance with regulatory requirements (e.g., SARA [Government of Canada 2022], <i>Migratory Birds Convention Act 1994</i> [Government of Canada 2017], <i>Saskatchewan Activity Restriction Guidelines for Sensitive Species</i> [Government of Saskatchewan 2017], <i>The Wildlife Act 1998</i> [Government of Saskatchewan 2020]). |

Table 0.3 Valued Components, Key Indicators, and Measurable Parameters for the Wildlife Component included in the Habitat-based Environmental Assessment for Denison Wheeler River Project

| Valued Component | Key Indicator | Measurable Parameter |
|----------------------|------------------------|---|
| Furbearers | Wolverine | Amount of habitat (km ²) (not necessarily occupied) that may be altered or lost relative to its availability in the Regional Study Area (RSA). The number of wolverine mortalities directly or indirectly attributable to the Project. |
| Woodland Caribou | Woodland caribou | Amount of habitat (km ²) (not necessarily occupied) that may be altered or lost relative to its availability in the RSA. The number of woodland caribou mortalities directly or indirectly attributable to the Project. |
| Bird Species at Risk | Common Nighthawk | Percentage of habitat for Common Nighthawk altered/lost directly or indirectly as a result of Project activities. The number of Common Nighthawk mortalities directly or indirectly attributable to the Project. |
| | Rusty Blackbird | Percentage of habitat for Rusty Blackbird altered/lost directly or indirectly as a result of Project activities. The number of rusty blackbird mortalities directly or indirectly attributable to the Project |
| | Olive-sided Flycatcher | Percentage of habitat for Olive-sided Flycatcher altered/lost directly or indirectly as a result of Project activities. The number of Olive-sided Flycatcher mortalities directly or indirectly attributable to the Project |
| | Short-eared Owl | Percentage of habitat for Short-eared Owl altered/lost directly or indirectly as a result of Project activities. The number of Short-eared Owl mortalities directly or indirectly attributable to the Project. |

| Valued Component | Key Indicator | Measurable Parameter |
|------------------|---------------|--|
| | Yellow Rail | <p>Percentage of habitat for Yellow Rail altered/lost directly or indirectly as a result of Project activities.</p> <p>The number of Yellow Rail mortalities directly or indirectly attributable to the Project.</p> |

The five bird species identified in Table 0.3 were selected as SAR VCs for the habitat-based EA in consideration of information/responses received during extensive Indigenous and community engagement completed by Denison, and they represent wildlife species of local importance. For these five species, additional information is not be provided in this Appendix. Rather, the reader is referred to the applicable sections in the EIS where appropriate information on existing conditions (Section 9.4.3.3), potential project-related effects (Section 9.4.4), mitigation measures (Section 9.4.5), residual effects and their significance (Section 9.4.6), and cumulative effects (Section 9.4.7) is provided.

Supplemental Information

As requested by ECCC, the following subsections provide supplemental information for the remaining nine species listed in Table 0.1 that were not included as VCs or KIs in the EIS. For these nine species, a brief overview of life history requirements (existing environment), a discussion on the effects assessment and mitigation measures, and a summary of residual and cumulative effects are included.

Table 0.1 Wildlife Species At Risk Considered in the Wheeler River Project Environmental Impact Statement

| Common Name | Scientific Name | Provincial Status | Federal Status ¹ | Preferred Habitat | Documented Occurrence in the Local Study Area ² | Reference in the Environmental Impact Statement (EIS) |
|--------------------------|-------------------------------------|-------------------|-----------------------------|---|--|---|
| Arthropods | | | | | | |
| Nine-spotted lady beetle | <i>Coccinella novemnotata</i> | S4 | Endangered | Habitat generalist – uses a diverse range of habitats and consumes a variety of prey. See Section 0 for further details. | Unlikely LSA is located within COSEWIC range; no observations in SKCDC and no Project-specific observations to date. | Not included as a Valued Component (VC) in the EIS. A review of life history requirements and discussion on effects assessment are included in this Appendix. |
| Transverse lady beetle | <i>Coccinella transversoguttata</i> | S4 | Special Concern | Habitat generalist – uses a diverse range of habitats and consumes a variety of prey. See Section 0 for further details. | Unlikely LSA is located within COSEWIC range; no observations in SKCDC and no Project-specific observations to date. | Not included as a VC in the EIS. A review of life history requirements and discussion on effects assessment are included in this Appendix. |
| Yellow-banded bumble bee | <i>Bombus terricola</i> | S4 | Special Concern | Habitat generalist – uses a variety of habitats and consumes nectar and pollen from many different flowering plants. See Section 0 for further details. | Unlikely LSA is located within COSEWIC range; no observations in SKCDC and no Project-specific observations to date. | Not included as a VC in the EIS. A review of life history requirements and discussion on effects assessment are included in this Appendix. |
| Amphibians | | | | | | |
| Northern leopard frog | <i>Lithobates pipiens</i> | S3 | Special Concern | Three district habitats: (1) overwintering waterbodies that are cold, well oxygenated, and do not freeze to | LSA is located within COSEWIC range; no observations in SKCDC | Not included as a VC in the EIS. | | | | | areas and suitable locations for roosting and maternity colonies. See Section 0 for further details. | present in the LSA and RSA (Appendix 9-C). | |
| Terrestrial Wildlife Species | | | | | | |
| Wolverine | <i>Gulo gulo</i> | S2 | Special Concern | See Section 9.3.3.2 of the EIS for details. | LSA is located within COSEWIC range; no observations in SKCDC and no Project-specific observations to date. | Included as a Key Indicator (KI) of the Furbearer VC in the EIS. A review of life history requirements and discussion on effects assessment are included in the EIS (Section 9.3). Additional information for this species is not provided in this Appendix. |
| Woodland caribou | <i>Rangifer tarandus caribou</i> | S3 | Threatened | See Section 9.3.3.3 of the EIS for details. | Documented within the RSA during the baseline field program (Appendix 9-C) | Included as a VC in the EIS. A review of life history requirements and discussion on effects assessment are included in the EIS (Section 9.3). Additional information for this species is not provided in this Appendix. |
| Avian Species | | | | | | |
| Bank Swallow | <i>Riparia riparia</i> | S4B, S5M | Threatened | Nesting colonies are typically characterized by steep embankments with a sand, silt, or clay substrate that can be easily excavated for burrows. They are often adjacent to slow-moving or still waterbodies and may occur in natural habitats or in anthropogenic features. Bank Swallows are aerial insectivores that forage over a variety of | LSA is located within COSEWIC range; no historical observations documented by the SKCDC (2023) and no Project-specific observations to date. | Not included as a KI of the Bird Species at Risk (SAR) VC in the EIS (Common Nighthawk was used as a surrogate species). A review of life history requirements and discussion on effects assessment are included in this Appendix. Any new species-specific mitigation measures identified in this appendix will be added to the final EIS (Section 9.4.5). |

| Common Name | Scientific Name | Provincial Status | Federal Status ¹ | Preferred Habitat | Documented Occurrence in the Local Study Area ² | Reference in the Environmental Impact Statement (EIS) |
|------------------------|-------------------------|-------------------|-----------------------------|--|---|---|
| | | | | open habitats. See Section 0 for further details. | | |
| Barn Swallow | <i>Hirundo rustica</i> | S4B | Threatened | Breeding habitat typically requires a suitable nesting site with a vertical or horizontal surface underneath a roof of some sort, open areas for foraging, and a waterbody with mud for nest building. Anthropogenic features such as barns, houses, bridges, and culverts are commonly used nesting sites. See Section 0 for further details. | Documented during the breeding bird surveys as part of the baseline field program as present in the LSA (Appendix 9-C), and previously observed in the RSA (SKCDC 2023) | Not included as a KI of the Bird SAR VC in the EIS (Common Nighthawk was used as a surrogate species). A review of life history requirements and discussion on effects assessment are included in this Appendix. Any new species-specific mitigation measures identified in this appendix will be added to the final EIS (Section 9.4.5). |
| Common Nighthawk | <i>Chordeiles minor</i> | S4B | Special Concern | See Section 9.4.3.3 of the EIS for details. | Documented during the baseline field program as present in the LSA (Appendix 9-C), and previously observed in the RSA (SKCDC 2023) | Included as a KI of the Bird SAR VC in the EIS. A review of life history requirements and discussion on effects assessment are included in the EIS (Section 9.3). Additional information for this species is not provided in this Appendix. |
| Horned Grebe | <i>Podiceps auritus</i> | S5B | Special Concern | Breeding habitat consists of small to medium-sized freshwater lakes, ponds, and marshes that are shallow with open water (at least 40%), emergent vegetation, anchorage for nests, and concealment for nests and young. See Section 0 for further details. | Documented during the baseline field program as present in the LSA (Appendix 9-C). | Not included as a KI of the Bird SAR VC in the EIS (Yellow Rail was used as a surrogate species). A review of life history requirements and discussion on effects assessment are included in this Appendix. Any new species-specific mitigation measures identified in this appendix will be added to the final EIS (Section 9.4.5).. |
| Olive-sided Flycatcher | <i>Contopus cooperi</i> | S4B | Special Concern | See Section 9.4.3.3 of the EIS for details. | Documented during the baseline field program | Included as a KI of the Bird SAR VC in the EIS. A review of life history requirements and |

|-----------------|-----------------------------------|-------------------|-----------------------------|---|--|---|
| | | | | | as present in the LSA (Appendix 9-C), and previously observed in the RSA (SKCDC 2023) | discussion on effects assessment are included in the EIS (Section 9.3). Additional information for this species is not provided in this Appendix. |
| Rusty Blackbird | <i>Euphagus carolinus</i> | S3B, SUN | Special Concern | See Section 9.4.3.3 of the EIS for details. | LSA is located within COSEWIC range; no historical observations documented by the SKCDC (2023) and no Project-specific observations to date. | Included as a KI of the Bird SAR VC in the EIS. A review of life history requirements and discussion on effects assessment are included in the EIS (Section 9.3). Additional information for this species is not provided in this Appendix. |
| Short-eared Owl | <i>Asio flammeus</i> | S3B, S2N | Special Concern | See Section 9.4.3.3 of the EIS for details. | LSA is located within COSEWIC range; no historical observations documented by the SKCDC (2023) and no Project-specific observations to date. | Included as a KI of the Bird SAR VC in the EIS. A review of life history requirements and discussion on effects assessment are included in the EIS (Section 9.3). Additional information for this species is not provided in this Appendix. |
| Yellow Rail | <i>Coturnicops noveboracensis</i> | S3B | Special Concern | See Section 9.4.3.3 of the EIS for details. | LSA is located within COSEWIC range; no historical observations documented by the SKCDC (2023) and no Project-specific observations to date. | Included as a KI of the Bird SAR VC in the EIS. A review of life history requirements and discussion on effects assessment are included in the EIS (Section 9.3). Additional information for this species is not provided in this Appendix. |

Note: shaded rows indicate SAR was included as a VC or KI in the draft EIS

1 Schedule 1 under the *Species at Risk Act*.

- 2 Potential for Occurrence – based on known species occurrence data from Saskatchewan Conservation Data Centre (2023), Omnia (Appendix 9-C), Birds of Saskatchewan (2019), and Atlas of Saskatchewan Birds (Smith 1996) and/or presence of suitable habitat.

Arthropods

Nine-Spotted Lady Beetle

The nine-spotted lady beetle is a small beetle species found across southern Canada and the continental United States (COSEWIC 2016a). Its northern range limit in Saskatchewan is reported to occur near Lake Athabasca (COSEWIC 2016a). Based on records provided by the Saskatchewan Conservation Data Centre Hunting, Angling and Biodiversity of Saskatchewan (HABISask) database (SKCDC 2023), there are no historical observations of this species documented in the Regional Study Area (RSA).

Source: COSEWIC (2016a).

The nine-spotted lady beetle is a habitat generalist that uses a diverse range of habitats (e.g., open to semi-open forests, grasslands, riparian areas) and consumes a variety of prey (e.g., many species of arthropods [particularly aphids], sap, nectar and pollen) (COSEWIC 2016a). Being a habitat generalist allows the nine-spotted lady beetle to exploit seasonally available prey sources, with prey availability influencing the species' distribution more than habitat availability (COSEWIC 2016a).

The nine-spotted lady beetle has four life stages (i.e., egg, larva, pupa, and adult) and may produce two generations per year (i.e., spring and fall) depending on regional climate conditions (COSEWIC 2016a). Lady beetles, in general, are highly mobile and may undertake short (few hundred metres) and long-distance (18 to 120 km) movements (COSEWIC 2016a). The nine-spotted lady beetle is not migratory nor does it display strong site fidelity (COSEWIC 2016a). The nine-spotted lady beetle overwinters in aggregations in well-ventilated habitats (e.g., in rock crevices, grass tussocks, or leaf litter, or under stones or tree bark), becoming active in the early spring when temperatures start to increase (COSEWIC 2016a).

The nine-spotted lady beetle is federally listed under Schedule 1 of SARA as Endangered (Government of Canada 2023) and is designated as an S4 species in Saskatchewan (i.e., Apparently Secure) (Saskatchewan Conservation Data Centre 2023). The species has undergone significant population declines in Canada since 1975, going from one of the more common lady beetles collected to being rarely collected relative to other lady beetles, despite comprehensive and targeted surveys (COSEWIC 2016a). Reasons for these population declines are currently unknown but are thought to be driven by competition, predation, and introduced diseases from non-native species (including non-native lady beetles), agricultural pesticide use to control aphids, habitat loss via urban expansion, and other human disturbances (COSEWIC 2016a).

Transverse Lady Beetle

The transverse lady beetle is a small beetle species found across the United States and Canada, including all provinces and territories (COSEWIC 2016b). The species is a habitat generalist and uses similar habitat types and consumes similar prey as the nine-spotted lady beetle, which means it is also able to exploit seasonally available prey sources (COSEWIC 2016b). According to the information from the HABISask database, there are no historical observations of this species documented in the RSA.

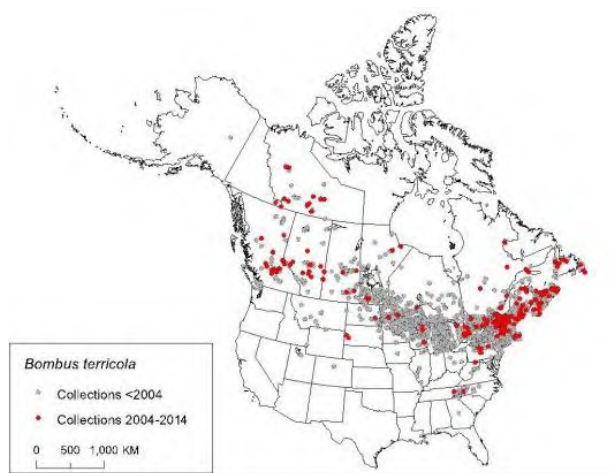

Source: COSEWIC (2016b).

The transverse lady beetle has four life stages (i.e., egg, larva, pupa, and adult) and may produce two generations per year (i.e., spring and fall) depending on regional climate conditions (COSEWIC 2016b). Lady beetles in general are highly mobile and may undertake short (few hundred metres) and long-distance (18 to 120 km) movements (COSEWIC 2016b). The transverse lady beetle is not migratory nor does it display strong site fidelity (COSEWIC 2016b). The transverse lady beetle overwinters in aggregations in well-ventilated habitats (e.g., in rock crevices, grass tussocks, or leaf litter, or under stones or tree bark), becoming active in the early spring when temperatures start to increase (COSEWIC 2016b).

The transverse lady beetle is federally listed under Schedule 1 of SARA as Special Concern (Government of Canada 2023) and is designated as an S4 species in Saskatchewan (i.e., Apparently Secure) (Saskatchewan Conservation Data Centre 2023). The species was once abundant across its range in Canada and was one of the most common lady beetles collected; however, since 1986, the species is now absent, below detection limits, or present in low numbers in many parts of its range (COSEWIC 2016b). The transverse lady beetle has not been detected in Saskatchewan since 2001 (COSEWIC 2016b). Reasons for these population declines are currently unknown but are thought to be driven by the same factors listed for the nine-spotted lady beetle in Section **Error! Reference source not found..**

Yellow-banded Bumble Bee

The yellow-banded bumble bee is a medium-sized bumble bee species found throughout eastern North America, from eastern British Columbia (BC) to Newfoundland and Labrador and from the northern United States up to the southern portion of the territories (COSEWIC 2015). The species is a habitat generalist (e.g., boreal habitats, mixed woodlands, montane meadows) and consumes nectar and pollen from many different flowering plants (COSEWIC 2015). According to the information from the HABISask database, there are no historical observations of this species documented in the RSA.

Source: COSEWIC (2015).

The yellow-banded bumble bee has four life stages (i.e., egg, larva, pupa, and adult) and produces one generation per year, with mated queens establishing new colonies each year (COSEWIC 2015).

After overwintering underground in loose soil or decomposing organic material, the mated queens emerge in the spring and search for potential nest sites, which are typically located underground in existing cavities (e.g., abandoned rodent burrows, rotten logs, openings in dead wood, and grassy hummocks) (COSEWIC 2015). Once a queen has found a suitable nest site, she forages for nectar and pollen and then returns to her nest site to lay eggs, which will develop into her future workers (i.e., unmated daughters that do not typically reproduce) (COSEWIC 2015). After the initial eggs hatch and the larva and pupa develop into adult workers, the workers take over nest and brood care, foraging duties, and colony protection while the queen continues to lay eggs (COSEWIC 2015). Males and potential queens are produced by late summer once the colony reaches maximum worker production, at which point they leave the colony and mate (COSEWIC 2015). All males and workers die by fall while the mated queens hibernate through the winter in suitable overwintering sites (COSEWIC 2015).

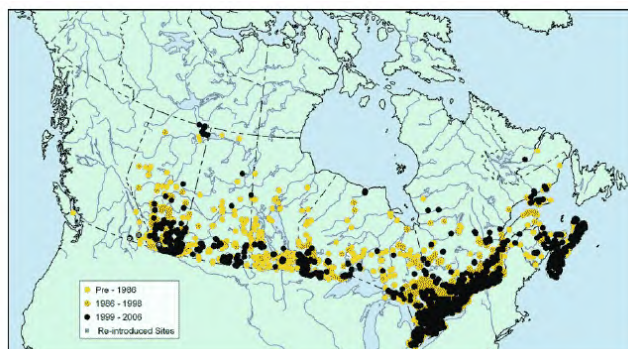

The yellow-banded bumble bee is federally listed under Schedule 1 of SARA as Special Concern (Government of Canada 2023) and is designated as an S4 species in Saskatchewan (i.e., Apparently Secure) (Saskatchewan Conservation Data Centre 2023). Prior to the 1990s, the yellow-banded bumble bee was one of the more common bumble bees collected in eastern and boreal Canada (COSEWIC 2015, Environment and Climate Change Canada 2022a). Population declines started to occur in the early 1990s, with an average rate of decline of 66.5% in proportional abundance across central and southern Canada between 1992 and 2011 (COSEWIC 2015, Environment and Climate Change Canada 2022a). The species is no longer found at several historical collection sites (COSEWIC 2015).

The status of the yellow-banded bumble bee in boreal habitats and Arctic regions is unknown (COSEWIC 2015, Environment and Climate Change Canada 2022a). Reasons for these population declines are currently unknown but are thought to be driven by introduced diseases from managed bumble bee species, agricultural pesticide use, habitat loss via urban and agricultural expansion, and climate change (COSEWIC 2015). The species' unique type of sex determination, where colonies must reach maximum worker production to produce males and potential queens, has been identified as a limiting factor (COSEWIC 2015, Environment and Climate Change Canada 2022a).

Amphibians

Northern Leopard Frog

The northern leopard frog is found across most of west-central and northeastern North America (COSEWIC 2009a). The species is widespread in Canada, ranging from southeastern BC to Labrador, and from southcentral Northwest Territories (COSEWIC 2009a, NCC 2023).

Source: COSEWIC (2009a).

Three distinct habitats are used by the northern leopard frog on an annual basis: (1) overwintering waterbodies that are cold, well oxygenated, and do not freeze to bottom (e.g., rivers, streams, deep lake ponds and creeks, and spillways below dams); (2) breeding and larval waterbodies with shallow, open habitats (e.g., ponds, lakeshores, marshes, and slow-moving streams; may be permanent or semi-permanent), neutral

pH, well vegetated, and no fish; and (3) summering areas in shallow marshes, moist upland meadows, forests and grasslands where grass height is less than 1 m (COSEWIC 2009a, NCC 2023). These habitats must be in proximity with suitable dispersal corridors interconnecting them (e.g., riparian areas and waterways) as the species is not capable of long-distance movements (COSEWIC 2009a, Environment Canada 2013).

Northern leopard frogs emerge from their overwintering waterbodies in early spring shortly after ice off (COSEWIC 2009a). The breeding season extends from mid-April to June, with exact timing dependent on location and latitude (COSEWIC 2009a). Females lay several thousand eggs, attaching them to submerged vegetation, which develop into tadpoles within two weeks depending on water temperatures (COSEWIC 2009a). The tadpoles in turn develop into small frogs over a two-to-three-month period, after which they migrate to their summering areas and forage on a variety of arthropods, worms, and snails, sometimes preying on small birds and smaller frogs (COSEWIC 2009a).

Three populations are recognized for the northern leopard frog in Canada: the Rocky Mountain, the Western Boreal/Prairie, and the Eastern (COSEWIC 2009a, NCC 2023). The Western Boreal/Prairie population is found in Alberta, Saskatchewan, Manitoba, and the Northwest Territories (COSEWIC 2009a, NCC 2023). The Western Boreal/Prairie population is federally listed under Schedule 1 of SARA as Special Concern (Government of Canada 2023) and is designated as an S3 species in Saskatchewan (i.e., Vulnerable) (Saskatchewan Conservation Data Centre 2023).

Population data are limited for the northern leopard frog in Canada (COSEWIC 2009a, Environment Canada 2013). Large-scale population declines occurred in the early 1970s, with populations in western Canada (i.e., BC and Alberta) most dramatically affected (COSEWIC 2009a). Information is lacking on the current status of northern leopard frog populations in Saskatchewan (COSEWIC 2009a, Environment Canada 2013).

Threats to the northern leopard frog include emerging diseases (e.g., *Chytridiomycosis*), introduced non-native species, habitat loss and fragmentation, environmental contamination, and increased frequency and severity of droughts (COSEWIC 2009a). The species' specific habitat requirements and vulnerability to diseases and prolonged periods of drought have been identified as limiting factors (Environment Canada 2013).

Bats

Little Brown Myotis

The little brown myotis is a small bat species found across North America, including across Canada south of the treeline (COSEWIC 2013a). The species is considered a short-distance regional migrant between its summer and winter ranges, with the distance travelled dependent on the location of suitable overwintering hibernacula (COSEWIC 2013a).

Habitat for the little brown myotis is composed of (1) overwintering hibernacula that are sufficiently cool and humid and (2) summering areas that provide foraging areas and suitable locations for roosting and maternity colonies (COSEWIC 2013a). Hibernacula and maternity

Source: COSEWIC (2013a).

sites are the main limiting habitat features for this species (COSEWIC 2013a). Hibernacula occur in parts of caves, mines, and buildings that have stable and specific temperature (-4 to 13°C) and humidity ($>80\%$) conditions (COSEWIC 2013a). Maternity sites occur in large-diameter trees, rock crevices, buildings, and bat houses that offer warm and relatively stable microclimate conditions that allow females to avoid going into torpor so they can focus on caring for their young (COSEWIC 2013a, Slough and Jung 2020). Males are more versatile in their summer roosting requirements and use tree cavities, raised bark, foliage, rock crevices, buildings, and bridges with a broader range of microclimate conditions (COSEWIC 2013a, Johnson et al. 2019). Foraging areas for the little brown myotis include a variety of habitats situated close to roosting and maternity sites, including over water (e.g., wetlands, lakes, ponds, and rivers), along riparian areas and forest edges, and in forest gaps (COSEWIC 2013a).

The little brown myotis is federally listed under Schedule 1 of SARA as Endangered (Government of Canada 2023) and is designated as an S4B, S4N species in Saskatchewan (i.e., Apparently Secure breeding population, Apparently Secure non-breeding population) (Saskatchewan Conservation Data Centre 2023).

The current size of the little brown myotis population in Canada is unknown. Prior to the arrival of White-nose Syndrome in 2010, the population in Canada was estimated to be over one million individuals (COSEWIC 2013a, Environment and Climate Change Canada 2018). White-nose Syndrome is a disease that causes high rates of mortality among hibernating bats, and it has been identified as the main threat for bat populations in Canada (COSEWIC 2013a). Other threats to the little brown myotis include habitat loss, colony eradication, chemical contamination, and wind turbines (COSEWIC 2013a).

Northern Myotis

The northern myotis is a small bat species found across North America, including across Canada south of the treeline (COSEWIC 2013a). The species is considered a short-distance regional migrant between its summer and winter ranges, with the distance travelled dependent on the location of suitable overwintering hibernacula (COSEWIC 2013a).

Habitat for the northern myotis is composed of (1) overwintering hibernacula that are sufficiently cool and humid and (2) summering areas that provide foraging areas and suitable locations for roosting and maternity colonies (COSEWIC 2013a). Hibernacula and maternity sites are the main limiting habitat features for this species (COSEWIC 2013a). Hibernacula occur in parts of caves, mines, and buildings that have stable and specific temperature (0.6 to 14°C) and humidity (>80%) conditions (COSEWIC 2013a). Summer roosting trees are typically found in mature to old-growth forests, swamps, and riparian areas, although retained older trees and snags in younger forests may occasionally provide suitable roosting habitat (Environment and Climate Change Canada 2018). Females strongly prefer tall, large-diameter trees (both living and dead, typically deciduous) with early- to mid-decay for maternity sites (COSEWIC 2013a, Environment and Climate Change Canada 2018). Anthropogenic features (e.g., barns) may occasionally be used as maternity sites in fragmented landscapes with few potential roost trees (Environment and Climate Change Canada 2018). Maternity sites that maintain warm and relatively stable microclimate conditions are important to reproductive females and young as they allow more energy to be directed toward growth and development (Caceres and Barclay 2000, COSEWIC 2013a). Males are more versatile in their summer roosting requirements; they most frequently roost under exfoliating, raised bark but may also roost in the cavities and crevices of trees and snags with early- to mid-decay (Jung et al. 2004, COSEWIC 2013a).

The northern myotis is well adapted to flying in areas of dense or structurally complex vegetation where it catches flying insects on the wing or feeds by gleaning prey from foliage (Caceres and Barclay 2000, Henderson and Broders 2008). The species typically forages within the interior of mature to old-growth deciduous and mixedwood forests, but may also forage in forest gaps, along forest edges and riparian areas, and over rivers (Henderson and Broders 2008, COSEWIC 2013a).

The northern myotis is federally listed under Schedule 1 of SARA as Endangered (Government of Canada 2023) and is designated as an S3 species in Saskatchewan (i.e., Vulnerable) (Saskatchewan Conservation Data Centre 2023). The current size of the northern myotis population in Canada is unknown. Prior to the arrival of White-nose Syndrome in 2010, the population in Canada was estimated to be over one million individuals (COSEWIC 2013a, Environment and Climate Change Canada 2018). White-nose Syndrome has been identified as the main threat for northern myotis

Source: COSEWIC (2013a).

populations in Canada (COSEWIC 2013a). . Other threats to the northern myotis include habitat loss, colony eradication, chemical contamination, and wind turbines (COSEWIC 2013a)

Avian Species

Bank Swallow

The Bank Swallow is a small songbird that occurs on every continent (except Antarctica and Australia), breeds throughout Canada, and winters primarily in South America (COSEWIC 2013b). Nesting colonies are typically characterized by steep embankments with a sand, silt, or clay substrate that can be easily excavated for burrows (COSEWIC 2013b, Government of Canada 2019a). These steep sand, silt, or clay embankments are frequently subject to erosion or slumping (COSEWIC 2013b, Garrison and Turner 2020).

Nesting colonies are often adjacent to slow-moving or still waterbodies (e.g., low gradient rivers or lakes) and may occur in natural habitats or in anthropogenic features (e.g., quarries or road cuts) (COSEWIC 2013b, Government of Canada 2019a, Garrison and Turner 2020). Colony size can range from less than half a dozen burrows to hundreds or thousands of burrows (COSEWIC 2013b, Government of Canada 2019a). Individual burrows within colonies may be recolonized in subsequent years if the integrity of the colony remains intact (i.e., does not erode and collapse) (Garrison and Turner 2020). Bank Swallows are aerial insectivores that forage over a variety of open habitats such as lakes, ponds, rivers, wetlands, grasslands, and agricultural areas (COSEWIC 2013b, Garrison and Turner 2020).

The Bank Swallow is federally listed under Schedule 1 of SARA as Threatened (Government of Canada 2023) and is designated as an S4B, S5M species in Saskatchewan (i.e., Apparently Secure breeding population, Secure aggregating transient population [migrants]) (Saskatchewan Conservation Data Centre 2023). The most recent breeding population estimate for Canada is 2.4 million individuals (Environment and Climate Change Canada 2022b). Based on Breeding Bird Survey (BBS) data collected between 1970 and 2019, the Bank Swallow population in Canada has declined at a rate of 5.3% per year, for an overall decline of 98.0% (Environment and Climate Change Canada 2022b). The long-term population decline appears to be driven by several threats acting cumulatively, including loss of nesting and foraging habitats, incidental take during anthropogenic activities (e.g., aggregate extraction and erosion control), large-scale declines in aerial insect populations, and climate change (COSEWIC 2013b). Bank Swallows are also particularly vulnerable to collisions with vehicles partly due to the attraction of individuals to intraspecific carcasses; one swallow hit by a vehicle could attract several individuals to a road, potentially resulting in subsequent collisions and large mortality events (COSEWIC 2013b, Garrison and Turner 2020).

Although colonial nesting may provide advantages (e.g., predation protection and assistance with thermoregulation), it has been identified as a limiting factor for the Bank Swallow, potentially making

Source: COSEWIC (2013b).

them more vulnerable to natural events or anthropogenic activities, which may result in mass mortality events (Environment and Climate Change Canada 2022b).

Barn Swallow

The Barn Swallow is a medium-sized songbird that occurs on every continent (except Antarctica), breeds throughout Canada, and winters in the southern United States, Mexico, and southwards (COSEWIC 2021). Breeding habitat typically requires a suitable nesting site with a vertical or horizontal surface underneath a roof of some sort, open areas for foraging (e.g., grasslands, fields, wetlands, and shorelines), and a waterbody with mud for nest building (Government of Canada 2019b, Brown and Brown 2020, COSEWIC 2021). Historically, suitable nesting sites were likely provided by caves, cliff faces, rock ledges, tree branches, and hollow trees (Brown and Brown 2020, COSEWIC 2021). Today, nesting sites are usually located within agricultural and rural areas, and along roads and highways (Brown and Brown 2020, COSEWIC 2021). Anthropogenic features such as barns, houses, bridges, and culverts are commonly used for nesting sites (COSEWIC 2021). Barn Swallows nest in colonies or independently and typically return to the same nesting sites each year and may reuse old nests (Government of Canada 2019b, Brown and Brown 2020, COSEWIC 2021).

Source: COSEWIC (2021).

The Barn Swallow is federally listed under Schedule 1 of SARA as Threatened (Government of Canada 2023) and is designated as an S4B species in Saskatchewan (i.e., Apparently Secure breeding population) (Saskatchewan Conservation Data Centre 2023). An estimated 6.4 million individuals currently breed in Canada, with over 60% of the population breeding throughout the prairie provinces (COSEWIC 2021). Based on BBS data collected between 1970 and 2019, the Barn Swallow population in Canada has declined at a rate of 2.34% per year, for an overall decline of 68.6% (COSEWIC 2021). Intensification of agriculture, loss of nesting sites, large-scale declines in aerial insect populations, and climate change are cited as the most imminent threats for the Barn Swallow, and its dependence on aerial insects for prey and low post-fledging survival rates are cited as limiting factors for the species (COSEWIC 2021). The repeated use of anthropogenic features for nesting makes Barn Swallows vulnerable to incidental take, especially if the anthropogenic features require routine maintenance. In addition, their frequent use of anthropogenic features for nesting makes Barn Swallows vulnerable to entrapment (e.g., buildings, pipes, vents, other enclosed spaces) as they search for potential locations to build a nest (COSEWIC 2021).

Horned Grebe

The Horned Grebe is a small waterbird that occurs in North America and Eurasia (COSEWIC 2009b). Within North America, the species breeds across western Canada from BC and Yukon across to the Magdalen Islands in Quebec

and winters along the Pacific and Atlantic coasts (COSEWIC 2009b).

Breeding habitat for the Horned Grebe consists of small to medium-sized freshwater lakes, ponds, and marshes that are shallow with open water (at least 40%), emergent vegetation, anchorage for nests, and concealment for nests and young (COSEWIC 2009b, Stedman 2020).

Source: COSEWIC 2009b

Horned Grebes use a range of waterbody sizes for breeding, but typically prefer waterbodies between 0.3 and 2.0 ha in size (COSEWIC 2009b). Most pairs are solitary, but loose colonies of up to 20 pairs have been found on larger waterbodies with abundant food resources (COSEWIC 2009b, Stedman 2020). Nests are typically located in shallow water near shore on a floating or emerging mass of vegetation (COSEWIC 2009b). Horned Grebes are diving birds that feed on a variety of aquatic arthropods and fish (COSEWIC 2009b, Stedman 2020).

The Western population of the Horned Grebe is federally listed under Schedule 1 of SARA as Special Concern (Government of Canada 2023) and is designated as an S5B species in Saskatchewan (i.e., Secure breeding population) (Saskatchewan Conservation Data Centre 2023). An estimated 200,000 to 500,000 individuals occur in the Western population, with most breeding in southern Alberta and Saskatchewan (COSEWIC 2009b, Environment and Climate Change Canada 2022c). Based on BBS data collected between 1970 and 2019, the Western population of the Horned Grebe in Canada has declined at a rate of 1.7% per year, for an overall decline of 57.0% (Environment and Climate Change Canada 2022c). The reasons for this population decline are unknown. Probable threats include permanent habitat loss, temporary loss of habitat during droughts, eutrophication and degradation of habitat due to fertilizers, predator expansion on the prairies, Type E botulism in the Great Lakes, entanglement in commercial fishing gear, climate change and extreme weather, and oil spills on wintering grounds (COSEWIC 2009b).

Mitigation Measures

The Project will require the construction, operation, and decommissioning of several components (as described in Section 2 of the EIS). Expected interactions between these Project components and activities and the wildlife VCs and their associated KIs are summarized by Project phase and activity in Tables 9.3-6 and 9.4-5 of the EIS. Based on the timing and nature of interactions identified in Tables 9.3-6 and 9.4-5 of the EIS, the following adverse effects on the wildlife VCs, including SAR, are likely to occur during the lifetime of the Project:

- alteration and/or loss of habitat; and
- change in mortality.

These potential effects apply to Wildlife SAR as well. The potential effects are described in Sections 9.3.4.2 and 9.4.4.2 of the EIS for each Project phase as they may affect the wildlife VCs and associated KIs.

Mitigation in this EIS is defined as the elimination, reduction, or control of potential adverse effects of the Project on the environment throughout all Project phases. Project-specific mitigation measures include: Project design; implementation of best management practices; development of management plans; implementation of emergency response programs; and provision of training, education and awareness (Denison 2020). Mitigation measures for each potential effect are described in Sections 9.3.5 and 9.4.5 of the EIS. The following subsections summarize mitigation measures that will be implemented to avoid or minimize adverse effects on the Wildlife SAR.

Project Design Measures

Potential adverse effects on Raptors, Migratory Breeding Birds, and Bird SAR VCs will be avoided or minimized to the extent practical through Project design. All of the Project design measures listed here are consistent with those presented in Section 9 of the EIS (i.e., there are no new Project design measures proposed in this appendix):

- The Project Area (i.e., the area of maximum physical disturbance) has been reduced to the extent practicable resulting in reduced habitat disturbance and noise propagation.
- Much of the proposed footprint will be developed within previously disturbed areas, including roads currently used for exploration activities, thereby minimizing additional habitat disturbance.
- The powerline to the main substation at the site is relatively short (i.e., approximately 7 km) and will be constructed from the existing provincial power line adjacent to Highway 914.
- During Operation, progressive reclamation activities will be completed where possible, and the progress and success of these activities will be assessed annually.
- Cleared brush will be stockpiled when possible, to be used in progressive reclamation.
- Ongoing decommissioning of Project components will be completed when possible.
- Dust deposition on vegetation and waterbodies (including potential deposition of trace metals and radionuclides) will be reduced by:
 - directing processing plant exhaust from drying and packaging areas through a stack prior to release outside of the building;

- designing the stack height based on results of air dispersion modelling to be an appropriate height for optimal dispersion;
 - controlling access to the property with both a north and south security gate (the north gate is on a decommissioned road and the south gate is manned);
 - making a wash bay available to clean items, equipment and vehicles that may have been in contact with potentially contaminated materials. Contaminated water from the wash bay will be collected in a sump tank and routed to the water treatment plant for treatment and discharge;
 - conducting radiological clearance scanning as required for any items, equipment, and vehicles leaving the Project Area; and.
 - watering and traffic controls on roads.
- Battery-powered light vehicles and mobile equipment, and an AC powered dual rotary drill for ISR wellfield development instead of a traditional diesel-powered unit, will be employed, where practical, to reduce air emissions and noise levels and improve energy efficiency.
 - The main sources of noise will be related to transport of people and goods, drilling of holes for the freeze wall and wellfield, operation of the batch plant, operation of the processing plant, and operation of the pumphouses. The use of high-quality, low sound emission equipment and regular maintenance will reduce noise associated with Project activities.
 - Bulk storage tanks for processing chemicals such as sulphuric and/or hydrochloric acid, sodium hydroxide, and hydrogen peroxide will sit inside appropriately designed and sized secondary containment basins, physically separated from the containment basins for other chemical systems.
 - Surface pipelines will be designed to have secondary containment or catchment and have leak detection systems in place at key locations.
 - A freeze wall will be established around the uranium deposit to reduce groundwater disturbance.
 - Mining solution and process water will be reused throughout the mining process, reducing water use requirements to the extent feasible and reducing the volume of treated effluent requiring discharge. Make-up water will be preferentially sourced from site runoff where possible.
 - Double-walled, high-density polyethylene or equivalent piping will be used in the wellfields and will be freeze protected and secured to minimize pipe movement.
 - Contaminated wastes (e.g., mineralized drill cuttings, solid impurities removed from mining solution, dewatered reject solids) will be properly contained on a double lined waste pad with leak detection capabilities and an associated monitoring program. An adjacent pond will be used to collect runoff from the pad and water in the waste pond will be piped to the water treatment plant. Such waste will be disposed of either on site or off site at an approved facility.
 - The ISR wellfield and processing plant will be designed to re-use most of the solutions inside each circuit; any excess water will be released to a surface water body once acceptable water quality is achieved. All treated effluent released to surface water will meet federal and provincial regulatory discharge limits.

- All contaminated areas, such as waste ponds and pads, and the domestic landfill will be fenced to avoid contact with workers and wildlife. Fences will be monitored and maintained.

General Mitigation Measures for Wildlife Species at Risk

Mitigation measures specific to the Wildlife SAR, in accordance with the *Migratory Birds Convention Act* and tailored to Project features will be incorporated into various Project management and monitoring plans such as the erosion and sediment controls, soil and vegetation monitoring, wildlife monitoring, the Decommissioning Plan, air quality monitoring, Spill Response Plan, Radiation Protection Plan, surface water and effluent monitoring and Waste Management Plan.

The management plans within the Environmental Management System (EMS) will provide specific mitigation measures based on proven and accepted mitigation measures following standard industry guidelines and best management practices. The EMS will provide guidance to avoid or minimize potential adverse effects of the Project on avian species and their habitat, including monitoring and follow-up programs, as appropriate. It will be in place during all phases of the Project and will be subject to ongoing review and revision as required. If monitoring identifies a need for additional or revised mitigation measures, a process of adaptive management (as described in the plan) will be triggered. The Project management plans provide direction on monitoring and adaptive management so that responses are timely and effective.

The following subsections provides a description of the mitigation measures that will be applicable during all Project phases and expected to be effective immediately following implementation. Additional mitigation measures specific to the Wildlife SAR that were not included or that were revised from what was described in the draft EIS are provided in **bold text**.

Work Timing Windows and Habitat Disturbance

- Site clearing and other works that involve disturbance of vegetation and/or soil will be conducted outside of the nesting season, when practical. **The nesting season for many Wildlife SAR in Saskatchewan spans a period from March 15 to August 31; however, the dates differ for certain species. The Wildlife Management Plans within the EMS will provide details on nesting windows for avian species, as well as other sensitive time periods (e.g., caribou calving periods) occurring in the Terrestrial RSA based on the Saskatchewan Activity Restriction Guidelines for Sensitive Species (SARGSS), which were established to support the avoidance of sensitive species' habitats during sensitive periods (SK MOE 2017).**
- **Prior to commencing any site clearing (i.e., vegetation clearing and/or soil disturbance) during the nesting and breeding season, pre-disturbance wildlife clearance surveys will be conducted by a Qualified Professional (QP) at that location within the Project Area to identify sensitive species and habitat features (e.g., nests as well as roosts and hibernacula used by bat species).**
- **Active and/or suspected breeding and roosting locations identified during the pre-disturbance wildlife clearance surveys will be protected with a no-disturbance setback buffer consistent with regulatory guidelines (e.g., the 2017 SARGSS [SK MOE 2017]) in accordance with the level of the disturbance and species until the young have successfully fledged, the nest is confirmed as no longer active (e.g., abandoned or depredated), or the nesting window has passed (for suspected nest locations). If guidelines cannot be met, due to safety or operational concerns, SK MOE will be contacted for advice on the appropriate response to the situation.**

Wildlife Education and Awareness

- Employees and contractors will be provided with wildlife education and awareness training, including education about potential Wildlife SAR issues on site and training on the mitigation measures to avoid or minimize potential adverse Project effects on Wildlife SAR and their habitats.
- Employees and contractors will be educated on waste management policies that limit human-avian interactions.
- Designated employees will be trained in appropriate avian deterrent techniques to minimize avian interactions with the Project.
- **Employees and contractors will be requested to report avian observations on site, injured or dead birds (which will be reported to SK MOE). Avian encounters and outcomes will be monitored, and logbooks will be used to record observations. Logbooks and reports will be available to employees.**

Wildlife and Habitat Protection

- Personal firearms will be prohibited for employees and contractors within the Project Area to prevent hunting activities.
- If any individual were seeking access around the Project area to undertake Aboriginal and/or Treaty Rights, Denison staff would facilitate this, provided it were safe to do so given activities in the area.
- Policies will be implemented prohibiting employees and contractors from feeding, approaching, or harassing avian species within the Project Area.
- To support habitat regeneration, progressive reclamation and ecosystem-based revegetation will be conducted on disturbed areas as soon as practicable in accordance with the Reclamation and Closure Plan.

Wildlife Deterrence and Prevention of Wildlife Entrapment

- **Buildings and other Project infrastructure will be designed and maintained to exclude birds (e.g., barn swallows) and bats as much as possible. This would include installing solid barriers (e.g., corner slope panels, wooden panels) or flexible barriers (e.g., netting, tarps or geotextiles) under roof eaves or other exterior surfaces.**
- **Physical, visual, and/or auditory deterrents will be used to discourage bird and bat use of buildings and other Project infrastructure (e.g., water or waste treatment ponds) for refuge, shelter, breeding, and roosting, and to deter birds and bats from potentially becoming entrapped.**
- **Noise emitting Project activities will be managed to minimize sensory disturbance of wildlife SAR species, especially during sensitive time periods (i.e., breeding and nesting).**
- Low sound emission equipment, regular maintenance of equipment, and the use of silencers or mufflers (whenever practical) will be used to reduce noise associated with Project activities, to the extent practical.
- **Directed lighting or light shielding, rather than broad lighting, will be implemented to minimize sensory disturbance on the wildlife SAR, and lighting will be focused on work sites and not surrounding areas.**

- Dust generation and subsequent deposition on vegetation and in waterbodies (including potential deposition of trace metals and radionuclides) will be limited through dust suppression techniques such as road watering and traffic management.

Road and Traffic Management

- Traffic and access control measures will be implemented will include reducing traffic volume by scheduling truck convoys, using high-volume haul trucks, and restricting public access to the Project site and roads (e.g., private vehicles, snowmobiles, all-terrain vehicles, and foot traffic). It is important to note that if any individual were seeking access around the Project area to undertake Aboriginal and / or Treaty Rights, Denison staff would facilitate this, provided it were safe to do so given activities in the area.
- Appropriate road signage will be installed (e.g., speed limits) along Project roads to raise awareness and minimize the potential for wildlife SAR-vehicle collisions.
- Wildlife will have the right-of-way on Project roads, unless it is unsafe to stop (i.e., if a collision is imminent). Vehicles will not be used to encourage wildlife to move off Project roads.
- Processes will be implemented for employees and contractors to slow down and/or stop vehicles/equipment to allow animals to move away or off the road before resuming normal road speeds for the area.
- Employees and contractors will report and communicate the location and circumstances of any roadkill observed on or alongside Project roads. Large-bodied wildlife carcasses found will be reported to SK MOE and disposed of as directed to discourage avian scavengers.
- **Vegetation management, such as mowing and brush cutting, will be implemented along Project roads to reduce site attractiveness for wildlife SAR and maintain appropriate sightlines for drivers to minimize wildlife-vehicle collisions.**
- Alternative measures on Project roads for de-icing and winter traction (e.g., sand, gravel) or dust suppression (e.g., water) will be implemented, whenever practicable.
- Appropriately sized gaps in the roadside snowbanks during winter will be maintained to facilitate wildlife crossing and escape thereby reducing the risk of wildlife-vehicle collisions.
- New Project site and access roads will be designed to minimize sightlines for predators, whenever practicable, while still maintaining general road safety.
- Ditches and culverts along Project roads will be designed and maintained to minimize pooling of water. Roadside pools that form may attract wildlife.

Waste and Hazardous Materials Management

- A "no littering policy" for employees and contractors will be implemented within the Project Area.
- **Vegetation management will be incorporated in the vicinity of waste ponds to discourage wildlife SAR use of potentially affected vegetation.**
- Waste will be collected and temporarily stored in wildlife-proof containers to avoid attracting scavengers and with that increase the risk for human-wildlife interact.
- The wildlife-proof containers will be inspected regularly for evidence of avian presence (e.g., gull species) or access to waste disposal facilities. If evidence of avian presence or

access to waste disposal facilities is detected, modified systems will be implemented and/or off-site waste disposal frequencies will be increased.

- The use of hazardous materials will be limited as much as possible.
- Hazardous materials will be handled, stored, and disposed of appropriately and in accordance with a Waste Management Plan to avoid attracting avian scavengers (e.g., wildlife-proof containers, exclusion fencing).
- Physical deterrents (e.g., fencing) will be employed around contaminated areas (e.g., waste ponds and waste pads), the domestic landfill, or hazardous materials storage areas to discourage wildlife use.
- Appropriate hazardous materials management practices will be implemented in accordance with industry guidelines and a Waste Management Plan to minimize the risk of accidental spills or leakage.
- Appropriate spill response kits will be positioned adjacent to areas where hazardous materials are stored in accordance with the Spill Response Plan.
- A minimum 100 m distance from any waterbody will be maintained for fuel storage, refueling activities, or equipment servicing in accordance with the Spill Response Plan.
- Appropriate fuel, chemical, and materials management practices will be followed in accordance with the Spill Response Plan to minimize the risk of accidental spills or leakage of diesel fuel, other hydrocarbons, and other hazardous materials.
- Air emissions will be reduced to the extent practical through implementation of an air quality monitoring plan within the EMS.
- All vehicles and equipment will be equipped with industry-standard emission control systems; unnecessary idling of vehicles will be prohibited.
- Vehicles and equipment will be maintained in good working condition (e.g., no leaks) and furnished with industry-standard spill response kits.
- Mitigation measures to reduce the potential for dispersion of radiological contaminants of potential concern to vegetation will be implemented in accordance with the Radiation Protection Plan.
- Education on and enforcement of proper waste and hazardous materials management practices will be provided to employees and contractors.

Species-Specific Mitigation Measures for Wildlife Species at Risk

The following provides a summary of the species-specific mitigation measures that will be implemented during Project activities. Mitigation measures specific to the Wildlife SAR that were not included or that were revised from what was described in the draft EIS are provided in **bold text**. These will be added to the final EIS.

Arthropod Species

- Mitigation measures designed for the Soil and Organic Matter / Peat (Section 9.1.5) and Vegetation and Ecosystems (Section 9.2.5) VCs are expected to mitigate adverse effects on the arthropod species that are considered SAR (i.e., nine-spotted lady beetle, transverse lady beetle, and yellow-banded bumble bee) primarily related to limiting the loss and/or disruption of suitable habitat for these species. These include:

- The Project Area (i.e., the area of maximum physical disturbance) has been reduced to the extent safely practicable resulting in reduced habitat disturbance and noise propagation.
- Much of the proposed Project Footprint will be developed within previously disturbed areas, including roads currently used for exploration activities, thereby minimizing additional habitat disturbance.
- During Operation, progressive reclamation will be completed where possible, and the progress and success of these activities will be assessed annually.
- **Herbicide use as part of vegetation management will be limited to the immediate Project Footprint and applied by licensed professional applicators, when necessary, to limit the potential for adverse effects on arthropod species.**

Amphibian Species

- Mitigation measures designed for the Wetlands VC (Section 9.2.5) are expected to mitigate adverse effects on the northern leopard frog primarily related to limiting the loss and/or disruption of suitable habitat for these species. These include:
 - The Project Area (i.e., the area of maximum physical disturbance) has been reduced to the extent safely practicable resulting in reduced habitat disturbance and noise propagation.
 - Much of the proposed Project Footprint will be developed within previously disturbed areas, including roads currently used for exploration activities, thereby minimizing additional habitat disturbance.
 - During Operation, progressive reclamation will be completed where possible, and the progress and success of these activities will be assessed annually.
- **Pre- disturbance wildlife clearance surveys will be conducted to identify site-specific habitat features (e.g., amphibian breeding ponds) and implement the setbacks and/or timing windows (that will be defined in the Wildlife Management Plan).**
- **Locations of site-specific habitat features used by amphibians will be communicated to Project personnel and the requirement to limit disturbance in these areas will be implemented.**
- **Appropriate setback and buffer distances from wetland features where amphibians are known to occur will be implemented and maintained under the direction of a wildlife QP.**
- **Vehicle traffic and construction activities will be restricted to the approved access routes and work areas and will not cross or enter a watercourse or wetland.**

Bat Species

- Vegetation clearing activities will occur outside of roosting periods, when practical.
- **Pre- disturbance wildlife clearance surveys will be completed to identify site-specific habitat features such as maternal roosting sites and hibernacula used by bat species. If features are identified in the Project Footprint, appropriate setbacks and/or timing windows will be implemented in accordance with the SARGSS (SK MOE 2017 (that will also be defined in the Wildlife Management Plan)).**

- In the event a maternal roosting site is identified on the Project Footprint, exclusionary methods (e.g., installing a one-way bat exit) will be implemented following the summer maternity roost season. This installation would allow for bats to leave but not the ability to re-enter the roosting site.
- Locations of these site-specific habitat features used by bats will be communicated to the appropriate Project personnel and the requirement to limit disturbance in these areas will be implemented.
- Specific exclusion methods will be added as mitigation measures (Section 9.4.5 of the final EIS) to prevent access to buildings and other infrastructure.

Avian Species

- Site clearing and other works that involve disturbance of vegetation and/or soil will be conducted outside of the nesting season, when practical. The breeding and nesting season for most avian species in Saskatchewan typically spans a period from March 15 to August 31; however, the dates differ for certain species.
- In the event Project activities such as vegetation clearing and/or soil disturbance are required during the breeding and nesting season, pre-disturbance wildlife clearance surveys will be conducted by a QP at that location within the Project Area before activities commence to identify the presence of avian SAR and/or their nests.
- Active and/or suspected breeding and roosting locations identified during the pre-disturbance wildlife clearance surveys will be protected with a no-disturbance setback buffer consistent with regulatory guidelines (e.g., the 2017 SARGSS [SK MOE 2017]) for other grebe species (as there is currently no activity restriction guidelines for horned grebe in Saskatchewan) in accordance with the level of the disturbance and species until the young have successfully fledged, the nest is confirmed as no longer active (e.g., abandoned or depredated), or the nesting window has passed (for suspected nest locations).
- Locations of nesting sites used by bank swallows, barn swallows, and horned grebe will be communicated to appropriate Project personnel and the requirement to limit disturbance in these areas will be implemented.
- Deterrents designed to discourage or prevent barn swallows from using buildings and other Project infrastructure have been described in Section 3.2.4 of the EIS.
- Buildings and other Project infrastructure will be designed and maintained to exclude birds (e.g., barn swallows) and bats as much as practical. This would include installing solid barriers (e.g., corner slope panels, wooden panels) or flexible barriers (e.g., netting, tarps or geotextiles) under roof eaves or other exterior surfaces.

Residual and Cumulative Effects Summary

The approach to assessing residual Project effects on wildlife VCs followed the methodology outlined in Section 5.8 of the EIS, which included a habitat-based approach. For each VC and associated KI, each residual effect was assessed in the context of the Project activities that will occur within each Project phase. Each residual effect was then characterized based on the combined predicted residual effect for all phases. See Sections 9.3.6 and 9.4.6 of the EIS for specific details regarding the residual effects assessment for wildlife VCs (i.e., residual effect characterization and significance determination). A summary of the environmental assessment considerations and determination for predicted residual effects for Wildlife SAR is provided in Table 0.1. Mitigation measures specific to the Wildlife SAR that were not included or that were revised from what was described in the draft EIS are provided in bold text. These will be added to the final EIS.

The cumulative effects assessment (CEA) followed standard methodology as per provincial (e.g., Guidelines for an Environmental Assessment under the [Saskatchewan] *Environmental Assessment Act* 1980) and federal (e.g., Assessing Cumulative Environmental Effects under the *Canadian Environmental Assessment Act 2012*) guidance, and is discussed in detail in Section 5.9 of the EIS. Similar to the residual effects assessment, the CEA included a habitat-based approach. See Sections 9.3.7 and 9.4.7 of the EIS for specific details regarding the CEA for wildlife VCs. A summary of the significance determination of the cumulative effects on Wildlife SAR is provided in Table 0.2.

Table 0.1 Summary of the Environmental Assessment Considerations and Determination for Predicted Residual Effects for Wildlife Species At Risk

| Component | Wildlife SAR | Measurable Parameters | Project Activities Resulting in Primary Interactions | Project Phase | Species-Specific Mitigation Measures ¹ | Predicted Residual Effect | Significance |
|--------------------------------|--|--|--|---------------|---|--|---|
| Terrestrial Environment | Nine-spotted lady beetle Transverse lady beetle Yellow-banded bumble bee | Amount of habitat that is altered or lost relative to its availability in the Terrestrial Regional Study Area (RSA). | <ul style="list-style-type: none"> Development of access roads and air strip. Site preparation and earthworks; clearing, levelling, and grading of the Project Area. Waste management (composting, domestic and industrial landfill operation, recycling). Water management (including treatment). Surface water withdrawal. On-site and off-site operation of vehicles and transport of materials. Air transportation for workers. | Construction | <ul style="list-style-type: none"> The proposed mitigation measures outlined in the EIS, particularly those designed for the Valued Components (VCs) Soil and Organic Matter / Peat (Section 9.1.5) and Vegetation and Ecosystems (Section 9.2.5), adequately and appropriately address potential for adverse effects on these species, primarily related to limiting the loss and/or disruption of suitable habitat. These include the following: <ul style="list-style-type: none"> The Project Area (i.e., the area of maximum physical disturbance) has been reduced to the extent safely practicable resulting in reduced habitat disturbance and noise propagation. Much of the proposed Project Footprint will be developed within | Alteration and/or loss of habitat: predicted to be low magnitude, local geographical extent, long-term duration, frequent, and fully reversible. | Not Significant: the predicted residual effect of alteration and/or loss of habitat is not expected to alter the integrity of the habitat for the arthropod SAR within the Terrestrial RSA to the point where it is not sustainable or available to contribute to ecological functions. |
| | | | <ul style="list-style-type: none"> Water withdrawal from groundwater or surface water body. Management of surface water (including seepage and site runoff). Water release to groundwater and/or surface water body. On-site and off-site operation of vehicles and transport of materials. Air transportation for workers. | Operation | | | |

Species At Risk – *Myotis* Species

The following information is intended to provide additional context to the responses provided in the IR tracking sheet for IR-174.

Acoustic bat surveys were completed between July 22 and 23, 2019 with 61 survey points sampled across five ecosite types. The location of the survey points, species detected, and frequency of detections are included in Figure 0-1.

Notes

Notes

Estimates of mercury concentration are based on 50% of the detection limit in both background and effluent.

(1) Estimated from near-field model

NE = No estimate for this lake for this parameter

Saskatchewan Water Quality Objectives, SEQG on-line (<https://envrbrportal.crmf.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations, a temperature of 15°C and a pH of 7.0.

Hardness dependent WQOs are for very soft water (hardness <25 mg CaCO₃/L). Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).

(4) Total ammonia-N calculated from the total ammonia guideline for a temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>)

(5) Based on a pH of >6.5.

(6) Based on water hardness >0 to <17 mg/L.

(7) Based on water hardness >0 to <82 mg/L.

(8) Based on water hardness >0 to ≤60 mg/L equation used at hardness of 5.26. At hardness >180 mg/L, the CWQG is 7 µg/L

(9) Guideline is based on dissolved zinc.

(10) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and site-specific baseline hardness of 15 mg/L.

Notes:

All parameters listed as total concentrations unless otherwise specified

Saskatchewan Water Quality Objectives, SEQG on-line (<https://envrbrportal.crm.p.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations

Bold numbers indicate exceedance of long-term criteria

Bold and italicized indicate exceedance of short-term criteria and long-term criteria.

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Narrative – Temperature - Maximum Weekly Average Temperature: Thermal additions to receiving waters should be such that the maximum weekly average temperature is not exceeded. Short-term Exposure to Extreme Temperature: Thermal additions to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect the important species.

- * A pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).
- (1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.

(2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>).

(3) Based on water hardness of >0 to <5.3 mg/L (Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).

(4) Based on water hardness >0 to <17 mg/L.

(5) Guideline specific to Chromium VI for conservative comparison to baseline water quality

(6) Based on hardness of 5.26 mg/L (Short-term equation is (e^{(0.979123[ln(hardness)]-8.64497)})*1000 (SEQQ via AEP 1996b)

(7) Federal Water Quality Guideline for Copper Biotic Ligand Model (BLM) Tool and User Manual, (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6)

(8) Short Term Guideline is based on dissolved manganese. Benchmark = exp(0.878[ln(hardness)] + 4.76) where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO3 equivalents in mg/L. (Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).

(9) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L.

(10) Framework provides Trigger Ranges for Total Phosphorus (µg/L) - guideline for oligotrophic waterbody 4 - 10 µg/L

(11) MDMER Schedule 4 - maximum authorized monthly mean concentration

(12) Guideline is based on dissolved zinc.

(13) Short term guideline is based on Benchmark = exp(0.833[ln(hardness mg·L-1)] + 0.240[ln(DOC mg·L-1)] + 0.526). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.

(14) Long term guideline is based on CWQG = exp(0.947[ln(hardness mg·L-1)] - 0.815[pH] + 0.398[ln(DOC mg·L-1)] + 4.625). (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.

(15) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L

(16) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt. Based on equation and hardness of 250 mg/L for equation of FWQG = $\exp\{(0.414[\ln(\text{hardness})] - 1.887)\}$.

Table 8.2-10: Near-field Receiving Water Quality Results

Notes:

All parameters listed as total concentrations unless otherwise specified

Saskatchewan Water Quality Objectives, SEQG on-line (<https://envrbrportal.crm.p.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations

Bold numbers indicate exceedance of long-term criteria

Bold and italicized indicate exceedance of short-term criteria and long-term criteria.

SEQG – Saskatchewan Environmental Quality Guidelines – Water Quality Guidelines for Freshwater Aquatic Life.

CWQG – Canadian Council of Ministers of the Environment – Canadian Water Quality Guidelines for the Protection of Aquatic Life.

SSWQO – Saskatchewan Surface Water Quality Objectives.

DOC – Dissolved organic carbon.

TDS – Total dissolved solids.

TKN – Total Kjeldahl Nitrogen.

TOC – Total organic carbon.

TSS – Total suspended solids.

Narrative – Temperature - Maximum Weekly Average Temperature: Thermal additions to receiving waters should be such that the maximum weekly average temperature is not exceeded. Short-term Exposure to Extreme Temperature: Thermal additions to receiving waters should be such that the short-term exposures to maximum temperatures are not exceeded. Exposures should not be so lengthy or frequent as to adversely affect the important species.

* A pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002).

(1) Long-term criterion for aluminum based on CCME/SEQG of 0.1 mg/L for dissolved aluminum when pH is greater than 6.5.

(2) Total ammonia-N calculated from the total ammonia guideline for an average annual temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH, Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>).

(3) Based on water hardness of >0 to <5.3 mg/L (Site-specific background hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).

(4) Based on water hardness >0 to <17 mg/L.

(5) Guideline specific to Chromium VI for conservative comparison to baseline water quality

(6) Based on hardness of 5.26 mg/L (Short-term equation is (e^{[0.979123[ln(hardness)]]-8.64497]})*1000 (SEGQ via AEP 1996b)

(7) Federal Water Quality Guideline for Copper Biotic Ligand Model (BLM) Tool and User Manual, (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6)

(8) Short Term Guideline is based on dissolved manganese. Benchmark = exp(0.878[ln(hardness)] + 4.76) where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO3 equivalents in mg/L. (Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).

(9) Long-term guideline for manganese based on Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 6.61, hardness = 5.26 mg/L.

(10) Framework provides Trigger Ranges for Total Phosphorus (µg/L) - guideline for oligotrophic waterbody 4 - 10 µg/L

(11) MDMER Schedule 4 - maximum authorized monthly mean concentration

(12) Guideline is based on dissolved zinc.

- (13) Short term guideline is based on Benchmark = $\exp(0.833[\ln(\text{hardness mg}\cdot\text{L}^{-1})] + 0.240[\ln(\text{DOC mg}\cdot\text{L}^{-1})] + 0.526)$. (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
- (14) Long term guideline is based on CWQG = $\exp(0.947[\ln(\text{hardness mg}\cdot\text{L}^{-1})] - 0.815[\text{pH}] + 0.398[\ln(\text{DOC mg}\cdot\text{L}^{-1})] + 4.625)$. (Site-specific background hardness is 5.26 mg/L, DOC is 2.24 mg/L, pH is 6.61 (95th percentile of LA-5 and LA-6). Note – extrapolated for value outside the hardness range.
- (15) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest hardness for equation of 52 mg/L
- (16) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt. Based on equation and hardness of 250 mg/L for equation of FWQG = $\exp\{(0.414[\ln(\text{hardness})] - 1.887)\}$.

|--------------|----------------|--|---|---|---|---|--|---|
| IR-190 | - | <p>NO2 criteria is not being consistently compared.</p> <p>Context: Provincial and federal air quality criteria/screening values for NO2 have been used inconsistently.</p> <p>Table 3-9 in Appendix 10-A (ERA) uses the 2015 Saskatchewan Ambient Air Quality Standards (SAAQS) value of 300 µg/m3 to compare the maximum concentrations of NO2 at receptor locations for the 1-hour average period, while Table 5 of Appendix 6 uses the 2025 Canadian Ambient Air Quality Standards (CAAQS) of 79µg/m3 for the same average period time.</p> <p>Rationale: By utilizing the SAAQS screening value for NO2, the maximum concentrations at receptor locations exceed the 1-hour threshold solely during the decommissioning stage (Table 3-9). However, if the 2025 CAAQS are applied, the screening values would be exceeded at receptor locations for all project phases. It is best practice to use the more protective air quality standards to evaluate potential human health risks associated with project activities.</p> | <p>1. Compare the predicted maximum concentrations to the most protective applicable air quality standards available. Alternatively, provide a rationale as to why the SAAQS for NO2 were used rather than the more protective 2025 CAAQS to determine potential exceedances and screen for the need for additional mitigation measures.</p> <p>Suggestions for mitigation and follow-up measures: Health Canada recommends use of the standards from the 2025 CAAQS for NO2 in future mitigation and follow-up plans.</p> | <p>The CAAQCs are applicable to measured ambient air concentrations over a three-year period and are not applicable to modelled results from a single facility. In technical meetings between Denison and ENV, the province agreed to the approach of utilizing 1-year of site-specific meteorological data. Use of the CAAQCs would require a three-year site specific data set. Denison agrees to using the 2025 CAAQCs for NO2 in future mitigation and follow-up plans.</p> | <p>This response has not been accepted, as the rationale for not applying the CAAQS in the assessment is not accurate. Health Canada acknowledges the commitment to use the 2025 CAAQS for NO2 in future mitigation and follow-up plans. However, the response to IR-190 did not compare the predicted maximum concentrations to the most protective applicable air quality standards available (i.e., CAAQS), and included the following rationale: The CAAQS are applicable to measured ambient air concentrations over a three-year period and are not applicable to modelled results from a single facility; and, Use of the CAAQCs would require a three-year site specific data set. The statement is incorrect. The CAAQS are national air quality standards, but they are not restricted to applications within the context of the Air Quality Management System (AQMS). The comparison with CAAQS may be considered in determining the nature and severity of the Project’s impact on air quality levels and the resulting mitigation measures that may be required to maintain good air quality levels or to prevent an exceedance of the CAAQS. The CAAQS are generally calculated for specific multi-year averages and for a particular statistical form so that extreme and unpredictable events do not drive risk management. However, if the data is not available for comparison to a full CAAQS timeframe, Health Canada suggests using model results for at least one calendar year to allow for a basic comparison with the CAAQS statistical form. The modelling results should be able to indicate the frequency of CAAQS exceedances, which can be used in the discussion as to whether any anticipated human health impacts are anticipated. Please see the Advice to the Proponent table for further discussion on the use of CAAQS (AD-69), which also notes that, while being more conservative than the NAAQO, Saskatchewan & Alberta’s screening value do not reflect the most recent science, which indicates that there is no apparent threshold for NO2, meaning that health effects may occur at any level of exposure. See also follow-up IR 190-R1.</p> | <p>1. Air quality monitoring for NO₂ is proposed as monthly collection using passive samplers, during all Project phases. The objective of the program is to demonstrate compliance with provincial and federal ambient air quality standards including the CAAQSSs. Monitoring data will also be compared against the modelled data provided in the EIS. Passive samplers will allow for direct comparison against the annual 2025 CAAQSSs. To compare against the 1-hour CAAQSSs Denison will use a commonly utilized averaging equation (such as the Ontario MECP averaging equation Air Dispersion Modelling Guideline for Ontario) to allow for conversion from the monitoring period to a 1-hour averaging period. Denison acknowledges that short-term peaks may not be captured through the passive</p> <p>2. See response to #1. Denison intends to use passive samplers for NO₂ monitoring.</p> <p>References:</p> <p>Ontario MECP. 2017. AIR DISPERSION MODELLING GUIDELINE FOR ONTARIO [GUIDELINE A-11] Version 3.0. Air Dispersion Modelling Guideline for Ontario.</p> | <p>The response to IR-190 acknowledges the predicted exceedances of the CAAQS for NO₂. However, the revised information does not appear to have been carried through to all the health risk assessment documents.</p> <p>HC notes that the new CAAQS for NO₂ also recognizes that there is no population health threshold for human health effects; therefore, any increase in exposure will result in an incremental population risk (Environment Canada and Health Canada, 2012; CCME, 2000). In other words, NO₂ is considered a non-threshold substance, meaning that health effects may occur at any level of exposure. Therefore, guideline values should not be construed as limits to which polluting up to is allowed.</p> <p>Please provide the following information:</p> <ol style="list-style-type: none">1. Present modelled concentrations at the nearest human receptor site (i.e., Risk 2 - seasonal resident at McGowan Lake) in Tables 3-9, 3-10 and 3-11).2. Correct/update Section 3.2.1.3.1: <i>Nitrogen Dioxide</i>, of Revised DRAFT EIS Appendix 10-A (February 2024), as follows:<ol style="list-style-type: none">a. Remove references to the 1970’s National Ambient Air Quality Objectives (NAAQOs) for NO₂. These objectives are no longer relevant and do not support the exclusion of NO₂ from further consideration as a COPC (Ref. AD-67);b. Acknowledge that modelled results exceed the 1-h NO₂ CAAQSSs at the <i>camp workers location</i> and <i>fence line</i> during all project phases; and,c. Consider NO₂ a COPC for further quantitative assessment and characterize the potential health risk related to 1-h exposure to NO₂.3. Characterize potential health risks from 1-h exposure to NO₂ using HC’s guidance. Alternatively, use the updated 2021 WHO Global Air Quality Guidelines for annual and 24-h NO₂ exposures when calculating hazard quotients.4. Discuss how the proposed mitigation measures to minimize residual effects of the Project on air quality, as identified in Section 16.1.1 of the Revised DRAFT EIS (January 2024), address the health risks identified in Chapter 10. Attachment IR-190 (Round 3)

The text below is the updated text in the ERA in Appendix 10-A. The text is provided in “Track Change” for ease of review.

Section 3.2.1.3 Secondary Screening of Air Quality Constituents

Air quality constituents that exceeded a screening value were nitrogen dioxide, particulate matter (TSP, PM₁₀), and uranium (Table Error! No text of specified style in document.-1). These constituents were further evaluated to determine if they require additional quantitative assessment in the ERA.

Table Error! No text of specified style in document.-13-11: Summary of Air Quality Constituents that Exceed a Screening Value

| Constituent | Screening Criteria Exceeded | | Predicted Exceedances at Human/Ecological Locations | Hours/Days Exceeding at Human/Ecological Locations | Frequency of Exceedance at Human/Ecological Locations |

Section 3.2.1.3.1 Nitrogen Dioxide

Screening values were available for 1-hour, 24-hour, and annual averaging periods for nitrogen dioxide. The exceedances are summarized below, followed by a discussion of the critical effects upon which the screening values were based and an overall conclusion related to whether nitrogen dioxide was ultimately retained for further evaluation in the ERA.

Summary of Exceedances at Human/Ecological Locations

1-hour: Exceedances during all project phases; however, the maximum 1-hour NO₂ concentration is during the decommissioning phase. The camp worker location (Risk3) had a predicted max 1-hour NO₂ concentration during decommissioning of 355 µg/m³, which exceeds its screening value from the CAAQS of 79 µg/m³. Exceedances at the camp worker location were noted for a maximum of 5.60-2% of the year (decommissioning), which corresponds to 49421 hours out of 8,760 hours in a year. Exceedances were also noted for 1-hour NO₂ at the fenceline for 0.3% of the year (for approximately 28 hours per year during decommissioning), although concentrations here at the fenceline were lower than at the camp worker location.

There were no exceedances of the 24-hour or annual screening values at any human or ecological locations for any Project phase.

Health/Environmental Effect(s) for Short-term and Long-term Exposures

Long-term (annual): As noted, there are no predicted exceedances of annual screening values at any receptor location during all Project phases; therefore, no long-term effects are expected.

Short-term (1-hour, 24-hour): Health Canada published a national one-hour maximum acceptable level of 400 µg/m³ for NO₂ in ambient air using a risk assessment approach (Health Canada, 2016b). This value considers sensitive human populations. The screening value used in this assessment was 300 µg/m³ from Alberta, which is also based upon health effects. There are no predicted exceedances of 24-hr screening values at any receptor location during all Project phases; however, there are infrequent predicted exceedances of 1-hr NO₂ at the camp worker location and the fenceline. There are no exceedances at other receptor locations.

To put the exceedances of NO₂ into context, hazard quotients (HQ) for all receptors have been calculated using the 1-hr and annual CAAQs as the toxicity reference values (see Table Error! No text of specified style in document.-2). HQs above 1 require further discussion. As shown in Table Error! No text of specified style in document.-2, HQs are below 1 for long-term NO₂ exposure at all receptor locations, and HQs exceed 1 for short-term 1-hr NO₂ exposure only for the on-site receptors (camp worker, on-site ecological location), and the fenceline receptor.

Potential ~~Ad~~verse health effects that are attributed to short-term exposures to ambient nitrogen dioxide include asthma exacerbations and possibly increased risk of cardiopulmonary effects, and to a lesser extent cardiovascular and respiratory mortality (Health Canada, 2016b). Individuals with certain pre-existing diseases such as asthma appear to be sensitive to exposure to ambient NO₂. Although it has been suggested that there may not be a threshold for the health effects of NO₂ even considering short-term (1-hour) exposures (CCME, 2020), at least some reviews (e.g. (Hesterberg TW et al., 2009) do not support this assertion and rather support a 1-hour threshold ~~of 400 µg/m³.~~ Hesterberg et al. (2009) completed a critical review of over 50 human clinical studies in which human volunteers (including sensitive sub-populations: the elderly, children, and asthmatics) were exposed to NO₂ at concentrations ranging from 0.1 to 3.5 ppm (equivalent to 188 to 6,580 µg/m³ [1 ppm = 1880 µg/m³] for periods of 30 minutes to 6 hours, often combined with exercise and co-pollutants. Their findings indicated that there is evidence of no-effect at low concentrations, and that a threshold of approximately 0.2 ppm (or 376 µg/m³) is supported. The maximum predicted concentration of 1-hour NO₂ was 355 µg/m³, which is slightly greater than Alberta's 1-hour screening value of 300 µg/m³ but is less than the concentration that may be associated with measurable health effects in sensitive populations (approximately 400 µg/m³) protective for short-term exposures in asthmatics per Hesterberg et al. (2009). If sensitive individuals are present at the camp worker location or the fenceline during periods when ambient NO₂ concentrations exceed the screening value, it is possible that they could experience minor irritation of the respiratory system. These effects would be reversible and would subside after exposure.

Additionally, as reported in Health Canada (2016b), both the WHO and US EPA concluded ~~Note as well~~ that healthy individuals do not experience any adverse effects at concentrations up to 1 ppm (or 1,880 µg/m³), and as such would not be affected by short-term exposures to NO₂ at the concentrations predicted for the Project.

~~Discussion and~~ Conclusion

Overall, the predicted exceedances of the 1-hour short-term screening value for nitrogen dioxide at the camp worker location (Risk3) and the fenceline would be limited to a small percentage of the time, and any health effects would be reversible and would subside after exposure. The elevated predicted NO₂ concentrations are based on the conservative assumption that backup diesel generators will be used continuously to supply power to support site activities; however, it is anticipated that power will be obtained from the provincial grid during the Project phases. The

~~backup diesel generators make up more than 85% of the NO₂ emission sources, with the remaining coming from vehicle/equipment combustion, propane heaters, and the ISR Plant stacks.~~

Other strategies to reduce NO₂ emissions will include planning vehicle and equipment routes to minimize travel distances and limit idling, and employing standard operating procedures for equipment and machinery use, completing regular inspections of equipment machinery to make sure it is in good working order.

Denison has committed to NO₂ monitoring during all Project phases. Monitoring will include monthly collection using passive samplers, and will follow an adaptive management process to identify if ~~(and when) more frequent monitoring would be needed.~~

~~Considering the above discussion, The maximum predicted concentration of NO₂ during decommissioning was expected to be 355 µg/m³, which is lower than the 400 µg/m³ associated with short-term health effects for sensitive subpopulations (asthmatic children). Therefore, NO₂ was not considered for further assessment in the ERA.~~

| Original IR# | Follow-Up IR # | Context and Rationale | IR (ROUND 1, March 2023) | Denison Response (ROUND 1, August 2023) | IR (ROUND 2, December 2023) | Denison Response (ROUND 2, Feb. 2024) | IR (ROUND 3, May 31, 2024) | Denison Response (Round 3, June 28, 2024) |
|--------------|----------------|--|---|--|---|---|---|---|
| IR-193 | - | <p>Context: Appendix 10-A (ERA) Table 3-1 ‘Screening of Effluent Quality against Surface Water Quality Guidelines for the Wheeler River ERA’ does not include acute water quality thresholds for all COPCs compared against predicted effluent quality. For example, it is stated that the final effluent quality discharge target for uranium is 0.057 mg/L. However, the CCME water short term (acute) water quality guidelines for the protection of aquatic life is 0.033 mg/L. The proposed effluent discharge target for uranium exceeds the acute water quality guidelines, indicating effluent may pose the risk of being acutely lethal to aquatic biota at end-of-pipe.</p> <p>All water quality thresholds should be derived from receiving environment parameters, and there are discrepancies between the values used in Appendix 10-A (ERA) Table 3-1 and the values presented in Tables 8.2-8 and 8.2-10 in Section 8.2.4.2.3 of the draft EIS. No selected screening value for TSS has been calculated from baseline conditions. Un-ionized ammonia, which is a regulated Schedule 4 substance under the MDMER, has not been included.</p> <p>Rationale: A review of all modelling results for all COPCs under the MDMER will assist ECCC in understanding the potential risks to the receiving environment.</p> | <p>1. Provide acute and chronic water quality thresholds for all required COPCs with monitoring required under the MDMER.</p> <p>2. Ensure all water quality thresholds are derived from receiving environment baseline parameters and that these thresholds are consistently applied throughout the draft EIS.</p> | <p>1. The application of acute water quality thresholds will be added to Section 8.2.4.2.3 and will be used to refine the effluent quality during the licensing phase (see the response to IR 114 for the updated mixing zone model results). The effluent presented in Table 8.2-9 is based on maximum effluent concentrations; however, Denison is committed to ensuring all effluent released will be below MDMER limits as well as short-term CCME guidelines for protection of aquatic life.</p> <p>2. Water quality thresholds have been applied appropriately in the draft EIS and fit for purpose. Water quality thresholds in Section 3.1.1.2 of the ERA (Appendix 10-A) were based on site-specific hardness of 5.26 mg/L (95th percentile of LA-5 and LA-6). This was to provide a conservative screening for COPCs to be carried forward for further quantitative assessment in the ERA. Water quality thresholds in Section 8.2.4.2.3 are based on Project induced hardness which is assumed to be 250 mg/L. This results in known discrepancies for some water quality parameters that are hardness induced such as cadmium, copper, zinc, and sulphate.</p> | <p>This response has not been accepted, as the Proponent has not included un-ionized ammonia, mercury and phosphorous in Table 3-1 in Appendix 10-A or provided acute and chronic water quality thresholds for all COPCs, including those with monitoring required under the MDMER, in Table 3-1 in Appendix 10-A (ERA). Water quality thresholds derived from receiving environment baseline parameters have not been consistently applied throughout the draft EIS. It is unclear from the current information provided if predicted effluent concentrations exceed acute water quality guidelines, indicating effluent may pose the risk of being acutely lethal to aquatic biota at end of pipe.</p> <p>The Proponent should:</p> <p>1. Update Table 3-1 in Appendix 10-A to include un-ionized ammonia, mercury and phosphorous. Update the risk assessment to incorporate these parameters as needed.</p> <p>2. Update Table 3-1 in Appendix 10-A and Tables 8.2-8 and 8.2-10 in Section 8.2.4.2.3 of the draft EIS to include both acute and chronic water quality thresholds derived from receiving environment baseline parameters and in accordance with IR- 114.</p> | <p>1.) The ERA in Appendix 10-A is focused on chronic long-term exposure due to routine effluent release during the Project Phases. As such the screening criteria used were chronic criteria. It is acknowledged that effluent quality will not be allowed to exceed acute guidelines. Acute guidelines are now provided in the updated Table 8.2-10 as presented in Attachment IR-114 and in the Final Draft EIS. This table (Table 8.2-10) also includes guidelines for unionized ammonia, phosphorous and mercury. Phosphorus will be present in the effluent at low levels and the near-field water quality model indicates that levels will remain well below criteria protective of aquatic life in the Whitefish Lake environment. Mercury is not identified as present in the effluent (see response to IR-100). No updates to Table 3-1 in Appendix 10-A are needed.</p> <p>2.) Tables 8.2-8 and 8.2-10 have been updated as requested. Please refer to Attachment IR-114 and Attachment IR-115 and Section 8.2.4.2.3 of the updated EIS. No updates to Table 3-1 in Appendix 10-A are needed. The guidelines were derived using baseline environmental conditions such as baseline hardness, DOC, pH, etc.</p> | <p>The previous round’s IR has not been fully met. When responding to item one, the Proponent did not update Table 3-1 in Appendix 10-A. And the rationale provided relates to Table 8.2-10, which is not part of the request. The Proponent should update Table 3-1 in Appendix 10-A to include un-ionized ammonia, mercury and phosphorous and should incorporate these parameters into the risk assessment as needed. The Proponent should also correct the following inconsistencies in Table 3-1 in Appendix 10-A:</p> <ul style="list-style-type: none">• Table footnote #11 refers to the strontium guideline; strontium is not included in the table and the footnote is also not referenced in the table,• Please refer to IR108 for comments on derivation of aluminum, chromium, copper, nickel, manganese and cobalt thresholds. <p>The Proponent responded to item two by modifying Tables 8.2-8 and 8.2-10 to include both acute and chronic water quality thresholds. The Proponent should update Table 3-1 in Appendix 10-A with the corrections flagged in comments IR-108 and IR-114 then update the risk assessment to incorporate these parameters and values as needed.</p> | <p>The ERA is focused on chronic effects, consistent with N288.6 Clause 7.4.3.4. “BVs for contaminants that are continually released should generally be defined based on chronic (long- term) exposure studies. However, there can be acute (short-term) situations of interest, such as boiler blowdown over a period of a few hours. For these situations, acute exposure BVs should be used. The risk assessor should justify the BVs selected, considering relevant exposure scenarios and timeframes.”</p> <p>The ERA in the final EIS will include a statement stating that “While the ERA focuses on chronic effects, it is acknowledged that Denison will not be allowed to release effluent above acute guidelines.” These acute guidelines are provided in Table 8.2-10 which is the appropriate place.</p> <ul style="list-style-type: none">• Footnote #11 for strontium will be removed.• Cobalt water quality guideline will be changed to 0.78 ug/L for lowest hardness of 52 mg/L• Chromium, nickel, and manganese are appropriate guidelines.• Un-ionized ammonia, mercury and phosphorous will be added to Table 3-1 <p>The updated Table 3-1 (with track changes shown) is provided below and will be included in the final EIS. Based on the changes made, there are no additional COPCs for the ERA.</p> |

Notes:

(1) Saskatchewan Water Quality Objectives, SEQG on-line (<https://envbrportal.crmpp.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations, a temperature of 15°C and a pH of 7.0.

(2) Hardness dependent WQOs are for very soft water (hardness <25 mg CaCO₃/L). Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).

(3) Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 7.5, hardness = 15 mg/L). Guideline is based on dissolved manganese.

(4) Total ammonia-N calculated from the total ammonia guideline for a temperature of 15°C and a pH of 7.0.

(5) A pH of 7 and a temperature of 15°C were assumed to convert total ammonia to un-ionized ammonia in accordance with CCME (2002)

(56) Based on a pH of >6.5.

(67) Based on water hardness >0 to <17 mg/L.

(78) Based on water hardness >0 to <82 mg/L.

(89) Based on water hardness >0 to ≤60 mg/L.

(910) Guideline is based on dissolved zinc.

(+911) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and lowest site-specific baseline hardness for equation of ‡52 mg/L.

(12) The Biotic Ligand Model was used. The calculated HCS is below 0.2 µg/L, however, 0.2 µg/L is considered to be the lowest concentration routinely measured and therefore replaces the calculated HC5 value for this water chemistry.

|--------------|----------------|---|---|--|--|--|--|--|
| IR-194 | - | <p>Context: In the ERA, COPCs should be selected for further assessment based upon the following factors:</p> <ol style="list-style-type: none">1. COPC concentrations in effluent that exceed selected water quality guidelines for the protection of aquatic biota, and2. Baseline COPC concentrations in the LSA that exceed selected surface water and sediment quality guidelines for the protection of aquatic biota. <p>However, only COPCs that had concentrations in effluent that exceeded guidelines were assessed further. Baseline concentrations of COPCs in sediment were not considered. In addition to this, not all COPCs that require monitoring under the MDMER had predicted effluent concentrations. From Section 8.2.3.3 Table 8.2-2 of the Aquatic Environment Report, it appears Aluminum in McGowan Lake and Whitefish Lake South and North, and pH in Whitefish Lake North exceed water quality guidelines. Predicted effluent concentrations or near-field surface water concentrations for Aluminum and pH are not provided.</p> <p>Rationale: It is not possible to determine if there is risk from effluent to the receiving environment and aquatic receptors based on the current information provided.</p> | <ol style="list-style-type: none">1. As noted in IR-114, provide the information on predicted effluent quality for COPCs with required monitoring under the MDMER.2. Provide the information on predicted maximum receiving environment surface water concentrations for COPCs with required monitoring under the MDMER in IR-114.3. Update the ERA to assess the risk of any additional MDMER COPC concentrations in effluent that exceed water quality guidelines.4. Update the ERA to assess the risk of COPCs that had elevated baseline water and sediment quality concentrations in the receiving environment. | <ol style="list-style-type: none">1. See response to IR-114 (Attachment IR-114 below). No revisions to Appendix 10-A, ERA are needed based on the response.2. See response to IR-114 for the predicted maximum receiving environment surface water concentrations for constituents regulated under Schedule 4 of MDMER. As indicated in Section 3.1.1 of the ERA in Appendix 10-A a long list of constituents was initially identified for consideration in the ERA based on they are known to be present in treated effluent, have existing water quality guidelines or were identified in MDMER (with the exception of cyanide). The focus of the MDMER constituents were those regulated under Schedule 4. Denison will monitor for all MDMER constituents with required monitoring in the environment. This will be included as part of Denison's Effluent and Emissions Plan to support licensing.3. As indicated in Section 3.1.1.1 of the ERA in Appendix 10-A the long list of constituents was reduced further based on potential for exceedance of a water quality guideline (for both protection of human health and aquatic life). Any MDMER constituent that was identified as exceeding a water quality guideline was considered a COPC and assessed further in the ERA (see Table 3-1 in the ERA). For example, effluent quality for arsenic, copper, and zinc which are all Schedule 4 constituent were identified as COPCs in the ERA based on exceeding a water quality guideline.4. The ERA followed the guidance in CSA N288.6-22 which does not require COPCs with elevated baseline concentrations to be considered COPCs for further quantitative assessment in the ERA. Clause 6.2.5.9 indicates that constituents with naturally elevated concentrations should be excluded from further consideration as a COPC. As indicated in Section 8.2.3.3 of the EIS constituents in baseline water quality that exceeded water quality guidelines included aluminum, and occasional exceedances for cadmium, iron, and lead. All of these constituents were considered in the ERA screening; however, were not identified for further assessment (other than cadmium) since based on a conservative screening of effluent quality water quality guidelines would not be exceeded. Section 8.4.3.2.3 of the EIS did not identify any constituents where baseline sediment quality exceeded sediment quality guidelines. Section 3.1.2.3 of the ERA in Appendix 10-A provides the predicted maximum sediment quality in Whitefish Lake for a list of constituents. These concentrations included background concentrations and are screened against sediment quality guidelines. The only constituents that exceed sediment quality guidelines are molybdenum and selenium; however, other COPCs are assessed further in the ERA (see Table 3-14 in the ERA in Appendix 10-A) even though sediment quality guidelines are not anticipated to be exceeded. | <p>This response has not been accepted, as the Proponent has not updated the ERA to assess elevated baseline concentrations to delineate potential Project effects from background conditions.</p> <p>The Proponent's response states: "The ERA followed the guidance in CSA N288.6-22 which does not require COPCs with elevated baseline concentrations to be considered COPCs for further quantitative assessment in the ERA. Clause 6.2.5.9 indicates that constituents with naturally elevated concentrations should be excluded from further consideration as a COPC."</p> <p>Section 6.2.5.9 of N288.6-22 is specific to the Human Health Risk Assessment, and this statement does not apply to the Ecological Risk Assessment (EcoRA). Section 7 of N288.6-22 is specific to the development of the EcoRA methodology, and in Section 7.2.5.2.6 of N288.6-22 it states: "In addition to screening of effluent and emissions data, concentrations measured in environmental media should be considered, as determined in the EMPs. Maximum concentrations measured in soil, receiving water, or sediment should be compared to screening criteria." Therefore, COPCs that had elevated baseline water and sediment quality concentrations in the receiving environment should be assessed in the ERA.</p> <p>Additionally, in Section 7.2.5.4.2 of N288.6-22 it is stated: "If COPCs exceed the screening level for one medium, they should be carried forward into the EcoRA for all media that are likely to contribute to exposure. For example, for a given COPC, if a water screening benchmark is exceeded, the same COPC should be carried forward for sediment if its concentration was above the detection limit." Therefore, if baseline exceedances occur in one media types, they should be carried forward for all media types in the ERA.</p> <p>It is not possible to determine if there is risk from effluent to the receiving environment and aquatic receptors based on the current information provided. Negative effects to biota from naturally elevated background concentrations of COPCs can be exacerbated by additional input of COPCs from Project effluent into the receiving environment. It is important to characterize and assess those potential effects and delineate potential Project effects from background conditions.</p> <p>Please:</p> <ol style="list-style-type: none">1. Update Table 3-1 in Appendix 10-A to include un-ionized ammonia, mercury and phosphorous. Update the risk assessment to incorporate these parameters as needed.2. Update the ERA to assess the risk of COPCs that had elevated baseline water quality concentrations in the receiving environment: aluminum, iron, and lead. | <ol style="list-style-type: none">1. See response to IR-114. Additional information has been provided for COPCs with requirement for monitoring under Schedule 5 of MDMER. Note that predicted effluent quality for all Schedule 5 parameters, with the exception of mercury, nitrate, and phosphorous were provided in Table 3-1 of the ERA in Appendix 10-A (these constituents were not identified as COPCs in the ERA).2. Information on predicted maximum receiving environment surface water concentrations for COPCs with required monitoring under the MDMER is in the updated EIS (Tables 8.2-10 and 8.2-13 and Appendix 8E. Please refer to Attachment IR-115.3. This is not applicable. No additional COPCs need to be carried forward in the ERA as the concentrations of COPCs in effluent do not exceed water quality guidelines (see Table 3-1 in the ERA in Appendix 10-A). All constituents identified in Schedule 4 and Schedule 5 were considered in the ERA screening with the exception of cyanide and mercury which are not identified as present in the effluent (see IR-100 regarding mercury). Phosphorus and nitrate will be present in the effluent at low levels and estimates of these constituents via the near-field water quality model indicate that levels will remain well below criteria protective of aquatic life in the Whitefish Lake environment (see Tables 8.2-10 and 8.2-13 of Section 8).4. The CSA guidance referenced by the reviewer in this IR (Section 7.2.5.2.6 of N288.6-22) is for exposure situations and not for baseline. The text in Section 7.2.5.2.6 of N288.6-22 is saying that measured concentrations in environmental media should be screened in addition to effluent and emissions data. This is referring to measured concentrations in the environment since they will reflect the impact from releases from the facility. This is not referring to baseline concentrations without influence from effluent. Section 7.2.5.3.1 and 7.2.5.3.2 of N288.6-22 recommend that the most restrictive of applicable federal or provincial guidelines be used as the screening criteria, and screening criteria should not be below a reasonable upper end of background. <p>Additionally, the reviewer points to Section 7.2.5.4.2 to indicate that if a COPC exceeds screening criterion in one medium it should be assessed for all media that are likely to contribute to exposure. This guidance was followed in the ERA – all COPCs identified in water were also assessed in sediment and vice versa, as well as additional food chain pathways. Again, the intent of this clause is for exposure situations and not specific to baseline conditions.</p> <p>The ERA did consider in the screening assessment constituents that had elevated baseline that were also present in the effluent. Aluminum, cadmium, iron, and lead exceeded water quality guidelines in baseline and were considered in the ERA screening; however, only cadmium was identified for further assessment since its concentration in the effluent exceeded its water quality guideline.</p> <p>Table 8.2-4 in the EIS provides a summary of baseline water quality exceedances. Note that the only iron exceedance was in SA-1 which is downstream of McGowan Lake (see Figure 8.2-4) and outside of the direct influence on the Project. Section 8.4.3.2.3 of the EIS did not identify any constituents where baseline sediment quality exceeded sediment quality guidelines.</p> <p>The screening followed the process identified in Figure 3-1 of the ERA (Appendix 10-A) as well as N288.6-22 guidance. No changes to the ERA or EIS are warranted to address Part 4 of this IR.</p> | <p>Note to Denison: There are multiple elements of this IR outstanding. This IR is being conditionally accepted for the purposes of the EA process, but these issues will need to be resolved during the licensing process. It is expected that a fully revised ERA that both incorporates revisions following closure of EA related IRs and addresses outstanding issues that will be further assessed during the licensing review. This commitment should be captured in the Commitments Register, and relates to various IRs in this table.</p> <p>This IR has been accepted for the purposes of the current EA process, and the outstanding issues below will be further assessed as part of licensing technical reviews, prior to the granting of a license.</p> <p>Item one of the IR has been met. However additional information is required for items two, three, and four. Similar to ECCC's rationale provided for IR-124, "the ERA primarily relies on modelling results to identify the maximum predicted levels of COPCs in the receiving environment." However, due to the upper bound discharge rates being the only model input evaluated, it is unclear whether the model considered scenarios where maximum COPCs might occur as the exclusion of other environmental variables may have resulted in inaccurate maximum environmental concentrations of the COPCs.</p> <p>The Proponent's responses regarding baseline exceedances of COPC thresholds in the receiving waterbodies requires additional information. The modeling of surface water and sediment COPC's described in Appendix 10-A, Figures 6-1 and 6-2 respectively, show results for the receiving waterbodies. However, it is unclear if these modeled values are based on the worst-case scenarios that account for environmental variables such as seasonal changes in hydrology and chemistry, or if they have only accounted for changes in operational effluent discharge scenarios to consider the upper bound discharge rates. Including the upper bounds of operational effluent discharges regardless of the variability of the receiving environmental conditions is important factor for determining whether the baseline data and risk assessment fully considered the effects of the operations of the proposed mine, including environmental concentrations of the COPCs, on water quality.</p> <p>The Proponent should provide baseline data and a risk assessment that includes consideration of maximum COPC scenarios for the receiving water bodies, including seasonal variability and sediment depositional areas. The Proponent should provide supplemental information to identify if the environmental model has considered environmental variability such as seasonal changes in water levels, flows and sedimentation. The Proponent should also demonstrate that the model has considered a reasonable expected worst case scenario, such as a 100 year return.</p> | <p>Please see Round 3 response to IR-124. The ERA is a living document and commits to reviewing and updating the ERA according to the periodic review requirements in Clauses 5.4 and 11 of CSA N288.6:22.</p> |

ATTACHMENT IR-114 (included in Round 1 submission)

Response:

1) Please see updated Tables 8.2-9 and 8.2-10 from the draft EIS below. Water quality predictions for the well mixed portion of LA-5 for each of the three flow scenarios (described in Section 8.2.4.2.3 and Table 8.2-7 of the draft EIS) are provided in the updated Table 8.2-10 below. Predicted site discharge concentrations that exceed respective receiver WQOs are bolded. Chloride, sulphate, TDS, arsenic, cadmium, chromium, cobalt, copper, selenium, and uranium, thorium-230, radium-226, lead-210, and polonium-210 predicted discharge concentrations are above receiver WQOs. However, under all three flow scenarios, the predicted water quality for all constituents is below respective WQOs within the well mixed portion of LA-5, indicating that sufficient dilution is present within LA-5 to meet objectives. Updated Table 8.2-13 is provided below. Water quality predictions have been added for MDMER constituents listed under Schedule 4 and Schedule 5. There are no predicted exceedances of water quality guidelines for any of the COPCs during Construction, Operation, or Decommissioning

2) The predictive water quality analysis considered the effects of toxicity modifying factors, such as hardness, on water quality. Specifically, the analysis considered induced hardness - that is hardness that is derived from or includes contributions from on site sources and in this case discharge from the IWWTP. It is reasonable in this case to utilize induced hardness since the water quality assessment directly considers the potential effect of IWWTP discharge on the receiving environment. The hardness added to the receiver from the discharge represents a constant source during periods of discharge. The effluent hardness value used in the analysis was derived from bench scale testing and is considered to be a reasonable estimate of expected hardness in effluent. With that in mind, the predictive water quality analysis reflects the water quality conditions that are anticipated to prevail in the receiver and therefore presents an appropriate platform on which to base the effects assessment.

3) The table below (IR-114 Table 1) shows a summary of baseline concentrations of total mercury in surface water within the LSA. Sediment was not analyzed for mercury during previous baseline surveys. Baseline water quality in the LSA and RSA showed no indication of total mercury present above detectable limits and as such, the potential for methyl-mercury to be detected was unlikely. Generally, 60 to 95% of total mercury concentrations in fish muscle tissues are present in the form of methylmercury. Table 8.5-2 of Section 8.5 of the EIS provides a full summary of tissue constituent concentrations for key species from the Icelander River and Russell Lake. A conservative approach of assuming 95% of mercury in the tissues is present in the methylated form could be used for comparative purposes. These data supplemented with more current baseline data for water, sediment and fish tissues specific to total and methyl-mercury prior to the onset of site development will provide a robust database for comparative purposes during the subsequent development and operation on site.

4) Consistent with CSA N288.1-20, Clause 5.1.5, atmospheric depositions to large water bodies such as lakes, are considered negligible; therefore, the air to surface water pathway has been excluded for the ecological risk assessment. The rationale for exclusion of atmospheric deposition to lakes and rivers is explained in detail in Section G9, Appendix G of the COG DRL Guidance Document (Hart, 2019). Typical transfer parameters from source to air and source to water are on a similar magnitude to each other. The transfer parameter from air to water is orders of magnitude lower indicating that atmospheric deposition to the lake would have a negligible effect. Rationale on the exclusion of the air to water pathway can be included in the ERA in Appendix 10-A. The following statement will be added to Section 2.2 in Appendix A to Appendix 10-A "Atmospheric deposition to Whitefish Lake is considered negligible. This is consistent with the COG DRL guidance (COG, 2019) which shows (assuming a modest flow rate for a lake of 0.1 m/s and an assumed water depth of 10 m) that the transfer of constituents from the atmosphere to large bodies of water (including lakes and rivers) is considered negligible." As baseline surface water did not identify measurable concentrations of total mercury in the LSA or RSA (See IR-114 Table 1 below) and deposition to large water bodies such as lakes is not likely to contribute to the methyl mercury concentration in the Wheeler River receiving waters, it is most reasonable to conclude that changes in total and methyl mercury can be adequately monitored in relation to sulphate inputs. Denison will undertake monitoring of total and methyl mercury as it relates to the discharge of sulphate to Whitefish Lake.

Notes:

- (1) Saskatchewan Water Quality Objectives, SEQG on-line (<https://envrbrportal.crmf.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations, a temperature of 15°C and a pH of 7.0.
- (2) Hardness dependent WQOs are for very soft water (hardness <25 mg CaCO₃/L). Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).
- (3) Scientific Criteria Document for the Development of the Canadian Water Quality Guidelines for the Protection of Aquatic Life - Manganese, Appendix B - Canadian Water Quality Guidelines Calculator (pH = 7.5, hardness = 15 mg/L). Guideline is based on dissolved manganese. Benchmark = $\exp(0.878[\ln(\text{hardness})] + 4.76)$ where the benchmark is expressed in dissolved manganese concentration (µg/L), and hardness is measured as CaCO₃ equivalents in mg/L.
- (4) Total ammonia-N calculated from the total ammonia guideline for a temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>)
- (5) Based on a pH of >6.5.
- (6) Based on water hardness >0 to <17 mg/L.
- (7) Based on water hardness >0 to <82 mg/L.
- (8) Based on water hardness >0 to ≤60 mg/L equation used at hardness of 5.26. At hardness >180 mg/L, the CWQG is 7 µg/L
- (9) Guideline is based on dissolved zinc.
- (10) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and site-specific baseline hardness of 15 mg/L.

Notes

Notes

Estimates of mercury concentration are based on 50% of the detection limit in both background and effluent.

(1) Estimated from near-field model

NE = No estimate for this lake for this parameter

Saskatchewan Water Quality Objectives, SEQG on-line (<https://envrbrportal.crm.saskatchewan.ca/seqg-search/>), SEQG for the protection of aquatic life were selected, based on total concentrations, a temperature of 15°C and a pH of 7.0.

Hardness dependent WQOs are for very soft water (hardness <25 mg CaCO₃/L). Site-specific hardness is 5.26 mg/L (95th percentile of LA-5 and LA-6).

(4) Total ammonia-N calculated from the total ammonia guideline for a temperature of 15°C and a pH of 7.0, Un-ionized Ammonia from Table 1 of temperature and pH Canadian Water Quality Guidelines for the Protection of Aquatic Life - Ammonia (<https://ccme.ca/en/res/ammonia-en-canadian-water-quality-guidelines-for-the-protection-of-aquatic-life.pdf>)

(5) Based on a pH of >6.5.

(6) Based on water hardness >0 to <17 mg/L.

(7) Based on water hardness >0 to <82 mg/L.

(8) Based on water hardness >0 to ≤60 mg/L equation used at hardness of 5.26. At hardness >180 mg/L, the CWQG is 7 µg/L

(9) Guideline is based on dissolved zinc.

(10) Environment Canada 2017. Federal Environmental Quality Guidelines, Cobalt, May. Based on equation and site-specific baseline hardness of 15 mg/L.

| IR-195 | - | <p>Context: Figure 3-2 depicts modelled concentrations of COPCs in the receiving environment surface water during all Project phases. Effluent discharge rates during Operations and Decommissioning are not anticipated to differ significantly. However, COPC concentrations seem to decrease rapidly after the end of the operations period despite effluent releases continuing into the decommissioning phase.</p> <p>Rationale: There has been no information provided on predicted changes in effluent COPC concentrations and discharge rates during the decommissioning phase. It remains unclear how COPC concentrations would decrease so quickly following the end of operations.</p> | <p>1. Provide further information on modelled maximum COPC concentrations for each individual Project phase with estimated timing for peak concentrations to appear in the receiving environment.</p> <p>2. Provide further information on predicted effluent quality during the Project decommissioning phase.</p> <p>3. Update ERA figures and conclusions as needed.</p> | <p>1. Per the draft EIS effluent is conservatively assumed to be discharged to the Whitefish Lake Middle during the operations (15 years) and decommissioning (5 years) phases at the same constant discharge rate of 36.5 m³/hr (10.1 L/s) with the same stable effluent quality as shown in Table 3-2. Therefore, the modelled maximum COPC concentrations in water are the same for operations and decommissioning phases (which is considered conservative), the same peak concentrations appear annually due to the variation of the monthly local inflow. Since COPCs are accumulated in sediment, the modelled maximum COPC concentrations in sediment appear at the end of each individual Project phase, which are year 20 for the operations and year 25 for the decommissioning in Figure 3-3.</p> <p>2. The predicted effluent quality during the Project decommissioning phase is expected to be the same as those during the operations. Effluent was set to be released during operations but not during the decommissioning phase in the current model.</p> <p>3. The model has been updated to include effluent discharge during the decommissioning phase, and the ERA figures and result tables will be updated in the next submission accordingly. See attachment IR-195 for the updated Table 3-3 and Figure 3-2.</p> | <p>This response has not been accepted. Although the Proponent addressed items 2 and 3, further information on maximum predicted concentrations of COPCs in water quality during various Project stages and how hydrological processes affect COPC concentrations from Project effluent is required based on the information provided in the Proponent's response to validate the Proponent's predictions.</p> <p>The Proponent has provided updated tables with modelled maximum COPC concentrations in water and sediment by individual Project phase but did not include the environmental quality guidelines for COPCs which were included in the original tables. The Proponent's response confirmed the predicted effluent quality during the decommissioning phase. In their response the Proponent states: "Therefore, the modelled maximum COPC concentrations in water are the same for operations and decommissioning phases (which is considered conservative), the same peak concentrations appear annually due to the variation of the monthly local inflow. Since COPCs are accumulated in sediment, the modelled maximum COPC concentrations in sediment appear at the end of each individual Project phase, which are year 20 for the operations and year 25 for the decommissioning in Figure 3-3."</p> <p>The figures provided in the response support this statement, however, maximum predicted concentrations of COPCs in receiving water quality occur within a year of operations commencing. COPC concentrations in water also return to baseline within one year after decommissioning is complete. However, maximum predicted concentrations of COPCs in sediment quality do not occur until the end of the Project lifecycle due to accumulation over time, which is expected.</p> <p>Rationale: It is unclear how maximum predicted concentrations of COPCs in water quality occur so quickly and decrease so quickly after Project operations commencement and decommissioning respectively. Further information on the hydrological processes that facilitate this is necessary to validate predictions.</p> <p>Provide further information regarding maximum predicted concentrations of COPCs in water quality during various Project stages and how hydrological processes (i.e. flows, retention time, etc.) facilitate the fast increase and decrease of COPC concentrations from Project effluent. This information should be included in Appendix 10-A, Section 3.1.2.1.</p> | <p>The maximum predicted concentrations of COPCs in water are seen over a relatively short period on the scale shown in the relevant figures as noted by the reviewer due to the short water retention time of the modelled lakes. As shown in the table below, the modelled lakes (excluding the reference lake) are small in size, with lake areas ranging from 0.10 to 1.49 km² and with average depths ranging from 1.0 to 5.5 m. Based on the area, depth and outflow of the modelled exposure lakes, the calculated retention times of the lakes ranged from 0.88 to 51.61 days. These short retention times explain the relatively rapid increase and subsequent decrease in concentrations of COPCs in the lakes during periods of effluent discharge and periods where there is no effluent discharge, respectively.</p> <table><tr><th colspan="6">Waterbody Morphometry for Modelled Lakes</th></tr><tr><th>Waterbody</th><th>Average Depth (m)</th><th>Area (km²)</th><th>Average Outflow (L/s)</th><th>Retention Time (day)</th><th>Retention Time (month)</th></tr><tr><td>Reference Kratchkowsky Lake</td><td>2.9</td><td>0.80</td><td>331.2</td><td>80.66</td><td>2.69</td></tr><tr><td>Whitefish Lake North</td><td>1.6</td><td>0.26</td><td>1379.3</td><td>3.53</td><td>0.12</td></tr><tr><td>Whitefish Lake Middle</td><td>1.1</td><td>0.10</td><td>1398.5</td><td>0.88</td><td>0.03</td></tr><tr><td>Whitefish Lake South</td><td>1.0</td><td>0.32</td><td>1414.3</td><td>2.65</td><td>0.09</td></tr><tr><td>McGowan Lake</td><td>5.5</td><td>1.49</td><td>1832.3</td><td>51.61</td><td>1.72</td></tr><tr><td>Russell Lake Inlet</td><td>3.0</td><td>0.75</td><td>2390.3</td><td>10.92</td><td>0.36</td></tr></table> <p>Updated information has been added to Appendix 10-A, including Table 3-3, Table 3-5, Figure 3-2 and Figure 3-3, as well as Table 3-1 of Appendix A of Appendix 10-A.</p> <p>The revised text in Section 3.1.2.1 (Appendix 10-A) is as follows: "The modelled maximum COPC concentrations in water during decommissioning phase were the same as that during operations (Table 3 3). The peak concentrations of arsenic and polonium-210 appear annually in June, and the peak concentrations of all other COPCs appear annually in March due to the variation of the monthly local inflow during the effluent discharge period (Figure 3 2). It is noted that the maximum predicted concentrations of COPCs in water occurred over short periods of effluent discharge and subsequently decrease relatively quickly during periods when there is no effluent discharge. This is related to the short retention time of the modelled lakes. As shown in Table 3-1 in Appendix A, the modelled lakes (excluding the reference lake) are small, with lake areas ranging from 0.10 to 1.49 km² and with average depths ranging from 1.0 to 5.5 m. Based on the area, depth and outflow, the calculated retention times ranged from 0.88 to 51.61 days. As noted, the short retention times result in rapid increases and decreases of concentrations of COPCs in response to effluent discharge and then its cessation. Since COPCs accumulate in sediment, the peak concentrations of all COPCs in sediment appear at the end of each individual Project phase, which are year 20 for the operations and year 25 for the decommissioning phase, as shown in Figure 3 3."</p> <p>The revised text in Section 3.1.2.3 (Appendix 10-A) is as follows: "The maximum vanadium concentration in sediment is 37.2 mg/kg dw in Whitefish Lake (LA-5), which exceeds its sediment quality guideline of 35.1 mg/kg dw by approximately 6% (REF value from Burnett-Seidel and Liber, 2013). Therefore, vanadium was identified as a COPC in sediment."</p> | Waterbody Morphometry for Modelled Lakes | | | | | | Waterbody | Average Depth (m) | Area (km²) | Average Outflow (L/s) | Retention Time (day) | Retention Time (month) | Reference Kratchkowsky Lake | 2.9 | 0.80 | 331.2 | 80.66 | 2.69 | Whitefish Lake North | 1.6 | 0.26 | 1379.3 | 3.53 | 0.12 | Whitefish Lake Middle | 1.1 | 0.10 | 1398.5 | 0.88 | 0.03 | Whitefish Lake South | 1.0 | 0.32 | 1414.3 | 2.65 | 0.09 | McGowan Lake | 5.5 | 1.49 | 1832.3 | 51.61 | 1.72 | Russell Lake Inlet | 3.0 | 0.75 | 2390.3 | 10.92 | 0.36 | <p>Item one has been partially met. The corrections made to Table 3-3 of Appendix 10-A do not match the values which were submitted as the first round IR response (Tables IR195-1 and IR195-2 (Modelled Maximum COPC Concentrations in Sediment by Individual Project Phase)). The Proponent should confirm which table contains the correct information, and make any necessary corrections to the revised draft EIS with an explanation for the differences.</p> | <p>The corrections made to Table 3-3 of Appendix 10-A in Round 2 do match the values which were submitted in Round 1 in Tables IR195-1 and IR195-2. (Note that the Draft ERA (Appendix 10-A) erroneously used a higher predicted effluent quality for chloride (640 mg/L) and sulphate (5910 mg/L) which was reduced to 600 mg/L for chloride and 3915 mg/L for sulphate due to ability based on lab tests to meet these lower values.</p> <p>In the IR response the modelled maximum COPC concentrations in water and sediment were presented by individual project phase (operations phase and decommissioning phase, respectively) in Round 1 response in Tables IR195-1 and IR195-2, while in Table 3-3 of Appendix 10-A in Round 2, the maximum concentration of COPCs in water and sediment during All project phases (including both operations phase and decommissioning phase).</p> <p>Note that Table IR195-1 below has a mistake for chloride and sulphate for the concentrations in water during the Operations phase. These values should have been updated to the same values as the decommissioning phase. The figures are correct and no changes are required. Table 3-3 in Appendix 10-A is also correct and no changes are required. See updated Table IR195-1 below for the IR response.</p> |

| IR-197 | - | <p>Context: It remains unclear if atmospheric deposition from Project related emissions has been incorporated into modelling for the ERA and surface water and sediment quality assessments.</p> <p>Rationale: While expected Project air emissions are unlikely to have direct impacts on the aquatic receiving environment and aquatic biota, this Project effect pathway may have indirect effects through accumulation of COPCs over time or deposition of contaminants that are not expected in effluent, which should be evaluated with predicted emissions data incorporated into water quality modelling predictions.</p> | Incorporate atmospheric deposition from Project-related emissions into water quality modelling and assess any Project related effects to aquatic receptors from this pathway. | <p>Consistent with CSA N288.1-20, Clause 5.1.5, atmospheric depositions to large water bodies such as lakes, are considered negligible; therefore, the air to surface water pathway has been excluded for the ecological risk assessment. The rationale for exclusion of atmospheric deposition to lakes and rivers is explained in detail in Section G9, Appendix G of the COG DRL Guidance Document (Hart, 2019). Typical transfer parameters from source to air and source to water are on a similar magnitude to each other. The transfer parameter from air to water is orders of magnitude lower indicating that atmospheric deposition to the lake would have a negligible effect. Rationale on the exclusion of the air to water pathway can be included in the ERA in Appendix 10-A. The following statement will be added to Section 2.2 in Appendix A to Appendix 10-A "Atmospheric deposition to Whitefish Lake is considered negligible. This is consistent with the COG DRL guidance (COG, 2019) which shows (assuming a modest flow rate for a lake of 0.1 m/s and an assumed water depth of 10 m) that the transfer of constituents from the atmosphere to large bodies of water (including lakes and rivers) is considered negligible."</p> <p>References: Hart, D. 2019. Derived Release Limits Guidance. COG-06-3090R4-I</p> | <p>This response has not been accepted, as the Proponent has not provided a valid explanation for not incorporating atmospheric deposition from Project-related air emissions into water quality modelling and assessing Project-related effects to aquatic receptors from this pathway.</p> <p>In the Proponent's response it is stated: "Consistent with CSA N288.1-20, Clause 5.1.5, atmospheric depositions to large water bodies such as lakes, are considered negligible; therefore, the air to surface water pathway has been excluded for the ecological risk assessment. The rationale for exclusion of atmospheric deposition to lakes and rivers is explained in detail in Section G9, Appendix G of the COG DRL Guidance Document (Hart, 2019)." However, both of these documents explicitly apply to human dose rate calculations and models for human endpoints from radiation effects of radionuclides; they do not cover non- human biota nor non-radionuclide COPCs or chemical toxicity of radionuclides. Atmospheric deposition rates to large water bodies may be negligible for dose rates to human biota as they are not likely to be directly impacted or in the near-field vicinity. However, this may not be the case for aquatic receptors directly within the receiving environment.</p> <p>A sufficient explanation for exclusion of atmospheric deposition of COPCs to surface water from Project activities has not been provided from an ecological perspective. This Project effect pathway may have effects on the aquatic receiving environment through accumulation of COPCs over time or deposition of contaminants that are not expected in effluent, which should be evaluated with predicted emissions data incorporated into water quality modelling predictions. ECCC requires atmospheric deposition from Project-related emissions to be incorporated into water quality modelling and that the Proponent assess any Project-related effects to aquatic receptors from this pathway in order to assess potential effects on the aquatic receiving environment.</p> <p>Incorporate atmospheric deposition from Project-related emissions into water quality modelling and assess any Project-related effects to aquatic receptors from this pathway. Review CSA N288.6, otherwise, provide valid rationale from an ecological perspective for the elimination of this potential Project effects pathway.</p> | <p>Atmospheric deposition to large waterbodies is explicitly excluded in the CSA N288.1 model. This assumption is valid for both human and ecological assessments. The N288.1 standard indicates in Section 1.5 of the Scope that the models can be used to support dose calculations for non-human biota.</p> <p>The N288.1 rationale is that atmospheric input to water is very small relative to direct input to water. This conclusion applies to assessment for both human and ecological assessments, as well as radionuclides and non-radionuclides. The rationale in the IR response applies. However, calculations have been done for the Project to confirm the expectation that atmospheric input to water will be negligible.</p> <p>The following calculation shows for the Project that the atmospheric input of uranium to Whitefish Lake (LA-5) is very small relative to the direct input to water via effluent.</p> <table><tr><td colspan="4">P01=X1/X0(a)</td></tr><tr><td>X1</td><td>Air Concentration (LA-5) U</td><td>3.45E-05 mg/m³</td><td>EIS Appendix 6</td></tr><tr><td>X0(a)</td><td>Atmospheric Release Rate</td><td>6.83E+01 mg/s</td><td>EIS Appendix 6</td></tr><tr><td>P01</td><td>Transfer source to air</td><td>5.05E-07 s/m³</td><td></td></tr><tr><td colspan="4">P02=X2/X0(w)</td></tr><tr><td>X2</td><td>Water Concentration (LA-5) U</td><td>5.74E-04 mg/L</td><td>From IMPACT Model</td></tr><tr><td>X0(w)</td><td>Effluent Release Rate (U)</td><td>5.78E-01 mg/s</td><td>U Effluent Concentration x Effluent Flowrate</td></tr><tr><td>P02</td><td>Transfer source to water</td><td>9.93E-04 s/L</td><td></td></tr><tr><td colspan="4">P12 = Vg (A/V)10⁻³/(λs+λw)</td></tr><tr><td>Vg</td><td>Atmospheric deposition velocity</td><td>0.003 m/s</td><td>N288.1</td></tr><tr><td>Area</td><td>LA-5</td><td>96940 m²</td><td>site-specific (Appendix A)</td></tr><tr><td>Volume</td><td>LA-5</td><td>106634 m</td><td>site-specific (Appendix A) (Area*Depth)</td></tr><tr><td colspan="4">λs = DR • ρ • Kd • (A/V)</td></tr><tr><td>DR</td><td>Sediment deposition rate</td><td>6.34E-08 mm/s</td><td>Assumption (2mm/yr)</td></tr><tr><td>ρ</td><td>sediment dry bulk density</td><td>0.11 kg/L</td><td>N288.1</td></tr><tr><td>Kd</td><td>partition coefficient</td><td>20000 L/kg</td><td>N288.1</td></tr><tr><td>λs</td><td>sedimentation loss rate constant</td><td>1.27E-07 s⁻¹</td><td></td></tr><tr><td colspan="4">λw = U • CA/V = Q/V</td></tr><tr><td>Q</td><td>Inflow into LA-5</td><td>1.379 m³/s</td><td>site-specific (Appendix A)</td></tr><tr><td>V</td><td>Volume of LA-5</td><td>106634 m³</td><td>Area*Depth</td></tr><tr><td>λw</td><td>loss via water flow rate constant</td><td>1.29E-05 s⁻¹</td><td></td></tr><tr><td colspan="4">P12 = Vg (A/V)10⁻³/(λs+λw)</td></tr><tr><td colspan="2">Water conc'n from air = X0(a)*P01*P12</td><td>7.20E-06 mg/L</td><td></td></tr><tr><td colspan="2">Water conc'n from effluent = X0(w)*P02</td><td>5.74E-04 mg/L</td><td></td></tr><tr><td colspan="2">% Contribution to Water from Air</td><td>1%</td><td></td></tr></table> <p>The following statement has been added to Section 2.2 in Appendix A to Appendix 10-A</p> <p>"Atmospheric deposition to Whitefish Lake is considered negligible. The response refers to guidance from CSA N288.1 (i.e., <i>Guidelines for modelling radionuclide environmental transport, fate and exposure associated with the normal operation of nuclear facilities</i>), however, the information requirement specifies CSA N288.6, which is a different standard. In lieu of requesting information on atmospheric deposition of all contaminants of potential concern (COPC) to surface water and associated effects, the Proponent should:</p> <ol style="list-style-type: none">1. Provide an estimate of atmospheric deposition of mercury (all species) from Project-related emissions. Include a sensitivity analysis as well as expected seasonal variations in the deposition rate with an emphasis on accumulated deposition for the lake ice breakup period.2. Update water quality mercury predictions (all species) for Whitefish Lake using scenario(s) that incorporate atmospheric deposition from Project-related emissions. Based on the findings, assess any Project-related effects to aquatic receptors from mercury (all species). Discuss potential effects on sediment quality.3. Discuss how the response was informed by the CSA N288.6 standard (i.e., <i>Environmental risk assessments at class I nuclear facilities and uranium mines and mills</i>. CSA Group; February 2022). | <ol style="list-style-type: none">1. There are no Project-related emissions of mercury to air therefore the request to estimate atmospheric deposition of mercury from Project-related emissions is not applicable. The Round 2 IR response provided an example for uranium to show how atmospheric deposition to lakes is considered minor.2. There are no Project-related emissions of mercury to air therefore the request to estimate atmospheric deposition of mercury from Project-related emissions is not applicable.3. The CSA N288.6 standard provides guidance on conducting environmental risk assessment, but does not provide detailed guidance on fate and transport models. The CSA N288.6 standard refers to other documents for the details. This includes CSA N288.1. For example, Clause 1.4 of N288.6 states "An understanding of the fate and transport of contaminants in the environment is necessary for performing an ERA; however, a detailed discussion of fate and transport models is outside the scope of this Standard. The risk assessor should consult CSA N288.1 for information on these concepts. Examples of additional models are provided in Clause 6.3.7." The examples of models provided include N288.1 as well as the IMPACT model which implements the equations in N288.1. |

| IR-198 | - | <p>Context: Section 10 Appendix 10-A (ERA) contains Table 4-3 (p. 4.17), which lists ingestion rates for traditional foods and includes the category “organs” for Mammals.</p> <p>Tables B.7 and Table B.8 in Section 10 Appendix 10-A (ERA) Ref. 19-2638 provide the predicted concentrations of radionuclides for ecological receptors during the project phases and during future centuries, respectively. They list the concentrations of radionuclides in moose and in moose organs, which is presented as a single cumulative organ value. Other terrestrial and aquatic animals (such as the black bear and woodland caribou) that are a part of the traditional diet of nearby Indigenous communities have higher concentrations of radionuclides than moose, yet concentrations are not provided for organs of these species.</p> <p>Rationale: While Health Canada is not aware of transfer factors to individual organs, or to organs in animals that are not ruminants, it would be beneficial to have a better understanding of radionuclide concentrations in the organs of other animals that may be consumed by local Indigenous communities.</p> | <p>1. Provide more clarification on how the mammalian organ ingestion rates are calculated (which animals and relative contribution percentages).</p> <p>2. Provide a rationale for why concentrations of radionuclides were not assessed in organs of animals (other than moose) that are consumed as country foods by Indigenous people harvesting in the area.</p> | <p>The response to IR-198 is provided in Attachment IR-198.</p> | <p>This response has not been accepted, as the assessment should consider organ meats from different animals if these are consumed by local population, and estimated consumption rates should be confirmed.</p> <p>The response to IR-198 presents the estimated radionuclide concentrations in moose and caribou organ meats (as mass concentrations), where the concentrations of certain radionuclides (U-238, U-234, Pb-210 and Po-210) in caribou organ meat are indeed estimated to be higher than in moose organ meat. However, the response also indicates that moose organ meat consumption represents the large majority of organ meat consumption (~80%), roughly offsetting the higher concentrations in caribou organs. When calculating tissue concentrations of radionuclides, the higher consumption rate of moose organ meat in comparison to caribou organ meat appears insufficient to compensate for the higher estimated concentrations of U-238, U-234, Pb-210 and Po-210 in caribou meat and as a result, exposures to these radionuclides from organ meat consumption may be underestimated. Health Canada recommends assessing moose and caribou organ meat separately (rather than using moose as a proxy) to confirm that COPCs including radionuclides from organ meat consumption have not been underestimated.</p> <p>IR-198 also includes additional information on organ meat consumption rates for the La Plonge and Patuanak communities to estimate dietary exposure via organ consumption, but it is unclear how these relate to the values used in the Draft EIS and ERA (Appendix 10-A). Specifically, Page 4.16 of Appendix 10-A: Environmental Risk Assessment for Wheeler River (September 9, 2022) states:</p> <p>“As a conservative approach for this assessment, the Patuanak diet was selected to represent the average traditional foods consumer in the HHRA”</p> <p>However, Table 4-4 (p. 4.19) reports an annual organ meat consumption rate of 4.49 kg for the adult average traditional food consumer while the reported daily Patuanak consumption rate for organ meat is 16.2 g (Table 4-3; p.4.17), which equates to an annual rate of 5.91 kg. Health Canada recommends a rationale be provided for this discrepancy, and if necessary, the correct estimated rate and associated assessment calculations.</p> <p>See also follow-up IR-198-R1.</p> | <p>Consistent with the requirements in CSA N288.6:22, the ERA undergoes a periodic review process every 5 years to ensure the assumptions are still valid and to improve modelling and reduce uncertainty. Based on current understanding of the ERFN diet, there is no need to include caribou organs as a separate organ. As indicated in the original IR Response in Attachment IR-198 (See Annex 1), approximately 80% of the organs consumed by ERFN is moose organs, and 20% is caribou organs. Note, that there was a units error in IR-198 Table 3: Estimated Tissue Concentrations of Moose Organs and Woodland Caribou Organs at McGowan Lake. The unit is Bq/kg fw, not mg/kg fw as shown in the table. The numbers in IR-198 Table 3 are correct for Bq/kg fw. The reviewer is asking for clarification on the discrepancy between the annual organ meat consumption rate of 4.49 kg for the adult average traditional food consumer (Table 4-4) versus the reported Patuanak consumption rate for organ meat of 5.91 kg/yr (16.2 g/d) (Table 4-3; p.4.17). The ingestion rates that represent the Patuanak consumption rates from the ERFN study were modified as follows:</p> <ul style="list-style-type: none">- Based on the ERFN study, the total Patuanak organ meat consumption rate was 5.91 kg/year which includes all organs. The ingestion rate was modified to remove organs that were not moose resulting in a moose organ ingestion rate of 4.49 kg/year.- The total large mammal meat consumption rate was 12.95 kg/year (35.5 g/d). The ingestion rate for large mammals was increased to 14.38 kg/year to account for caribou organs in the caribou meat ingestion rate (caribou meat = 1.2 kg/year, caribou organ = 1.4 kg/year).- The total ingestion rate for all country foods is 72.5 kg/year (199 g/d as per Table 4-3 in Appendix 10-A) which is consistent with the total Patuanak ingestion rate from the ERFN study.- Based on the rationale in the above bullets no changes are needed to the diet. <p>As illustrated in the bullets above, caribou organ ingestion was not ignored, but was assessed as part of caribou meat ingestion.</p> <p>To illustrate that the current assumptions used in the HHRA of ingestion of moose organs and caribou as meat only, a comparison is provided in the table below of human dose from moose organs, caribou assessed as meat, and caribou assessed as organs. The total dose to a person eating moose organs is the same order of magnitude as the total dose to a person eating caribou organs (note that this represents total dose, not incremental dose as shown in the ERA and is used for illustrative purposes only). Additionally, there is limited difference in the results whether caribou organ intake is assessed as meat or as organs. For some radionuclides (Ra-226, Po-210) the dose for caribou assessed as meat is higher and for other radionuclides (U-238, U-234, Th-230, Pb-210) the dose for caribou assessed as organs is higher.</p> <table><tr><th>Parameter</th><th>Unit</th><th>U-238</th><th>U-234</th><th>Th-230</th><th>Ra-226</th><th>Pb-210</th><th>Po-210</th><th>Total</th></tr><tr><td>Moose organs Concentration</td><td>Bq/kg</td><td>6.13E-02</td><td>6.13E-02</td><td>3.04E+00</td><td>8.77E-02</td><td>7.15E+00</td><td>1.30E-02</td><td></td></tr><tr><td>Caribou meat Concentration</td><td>Bq/kg</td><td>1.41E-01</td><td>1.41E-01</td><td>1.11E-02</td><td>1.13E-01</td><td>1.80E+00</td><td>8.58E+00</td><td></td></tr><tr><td>Caribou organs Concentration (scaled from meat based on TF)</td><td>Bq/kg</td><td>2.49E-01</td><td>2.49E-01</td><td>3.04E+00</td><td>6.31E-02</td><td>5.66E+01</td><td>8.58E-02</td><td></td></tr><tr><td>Dose Coefficient (DCF)</td><td>Sv/Bq</td><td>4.90E-08</td><td>4.90E-08</td><td>2.10E-07</td><td>2.80E-07</td><td>6.70E-07</td><td>1.20E-06</td><td></td></tr><tr><td>Human Dose - Moose Organs (a)</td><td>mSv/a</td><td>1.35E-05</td><td>1.35E-05</td><td>2.87E-03</td><td>1.10E-04</td><td>2.16E-02</td><td>7.04E-05</td><td>2.47E-02</td></tr><tr><td>Human Dose - Caribou Organs as Meat (b)</td><td>mSv/a</td><td>9.84E-06</td><td>9.84E-06</td><td>3.32E-06</td><td>4.50E-05</td><td>1.72E-03</td><td>1.47E-02</td><td>1.64E-02</td></tr><tr><td>Human Dose - Caribou Organs (b)</td><td>mSv/a</td><td>1.74E-05</td><td>1.74E-05</td><td>9.10E-04</td><td>2.51E-05</td><td>5.40E-02</td><td>1.47E-04</td><td>5.51E-02</td></tr><tr><td colspan="9">a) based on moose organ ingestion rate of 4.5 kg/a</td></tr><tr><td colspan="9">b) based on caribou organ ingestion rate of 1.4 kg/a</td></tr></table> <p>Overall, caribou ingestion is not ignored in the HHRA, and whether or not they are assessed as meat or as organs makes little difference to the total dose from terrestrial animal ingestion, as the dose is dominated by ingestion of mallard as shown in the pie chart below. The caribou contribution to total dose is minimal since the total dose is well below the dose limit of 1 mSv/year; therefore, no changes are made to the ERA at this time.</p>  | Parameter | Unit | U-238 | U-234 | Th-230 | Ra-226 | Pb-210 | Po-210 | Total | Moose organs Concentration | Bq/kg | 6.13E-02 | 6.13E-02 | 3.04E+00 | 8.77E-02 | 7.15E+00 | 1.30E-02 | | Caribou meat Concentration | Bq/kg | 1.41E-01 | 1.41E-01 | 1.11E-02 | 1.13E-01 | 1.80E+00 | 8.58E+00 | | Caribou organs Concentration (scaled from meat based on TF) | Bq/kg | 2.49E-01 | 2.49E-01 | 3.04E+00 | 6.31E-02 | 5.66E+01 | 8.58E-02 | | Dose Coefficient (DCF) | Sv/Bq | 4.90E-08 | 4.90E-08 | 2.10E-07 | 2.80E-07 | 6.70E-07 | 1.20E-06 | | Human Dose - Moose Organs (a) | mSv/a | 1.35E-05 | 1.35E-05 | 2.87E-03 | 1.10E-04 | 2.16E-02 | 7.04E-05 | 2.47E-02 | Human Dose - Caribou Organs as Meat (b) | mSv/a | 9.84E-06 | 9.84E-06 | 3.32E-06 | 4.50E-05 | 1.72E-03 | 1.47E-02 | 1.64E-02 | Human Dose - Caribou Organs (b) | mSv/a | 1.74E-05 | 1.74E-05 | 9.10E-04 | 2.51E-05 | 5.40E-02 | 1.47E-04 | 5.51E-02 | a) based on moose organ ingestion rate of 4.5 kg/a | | | | | | | | | b) based on caribou organ ingestion rate of 1.4 kg/a | | | | | | | | | n/a | n/a |

| IR-198 | IR-198-R1 | Environmental Risk Assessment for Wheeler River (September 9, 2022) does not include an assessment of radionuclides based on their mass concentrations in country foods (the | | | 1. Provide a rationale on why radionuclide mass concentrations were not assessed for their impact to human health. | 1. Uranium was assessed as both a chemical constituent and a radionuclide constituent. The other radionuclides in the U-238 decay chain were assessed for their radiotoxicity and not their chemical toxicity. This is consistent with the PSL2 Assessment Report which indicates that because of uranium’s relatively low specific activity, uranium is the only radionuclide (in the uranium and thorium decay chains) with greater potential to be more chemotoxic than radiotoxic; therefore, it is important to assess its chemical toxicity (GC & EC, 2006). To illustrate, the effluent quality of Pb-210 | Note To Denison: This IR is being conditionally accepted. |--------------|----------------|---|--------------------------|---|---|---|---|---|
| | | <p>assessment is only based on radionuclide concentrations).</p> <p>Context: As part of the response to IR-198 estimated Pb-210 concentrations in moose organ and caribou organ of 7.15 and 49.4 mg/kg (ww) are reported, respectively. However, Appendix 10-A: Environmental Risk Assessment for Wheeler River (September 9, 2022) does not include an assessment of lead among the non-radionuclide COPCs.</p> <p>Using the organ meat consumption figure from the Patuanak community (16.2 g/day), exposure to Pb-210 from caribou organ meat is estimated at over 11 ug/kg bw per day (based on the response to IR-198) which would be close to 10 times greater than the 95th percentile dietary lead exposure estimates for the general Canadian population consuming retail foods.</p> <p>Rationale: While the abundance of radionuclides may pose a health risk with respect to radioactivity, their presence as chemical contaminants may also have an impact on health. This is demonstrated by the case of Pb-210 described above.</p> <p>Due to their potential toxicological significance to human health, Health Canada recommends assessing arsenic, cadmium, lead and mercury as part of country food assessment, regardless of the method employed to determine COPCs.</p> | | | <p>2. Provide an assessment of Lead (Pb) as a chemical contaminant (non-radionuclide) COPC to better understand potential health risks and inform management, mitigation, monitoring and/or follow-up planning.</p> | <p>(as per Table 3-1 in Appendix 10-A) is 4.19E-01 mg/L. Using a specific activity of 2.86E+12 Bq/g for Pb-210 (www.wise-uranium.org/nucv.html), the mass concentration is 1.48E-10 mg/L. This is significantly lower than the lead concentration in the effluent of 3.00E-04 mg/L (as per Table 3-1 in Appendix 10-A) which is based on pilot tests with a safety factor added. As such, consideration of the mass concentration of Pb-210 is not needed.</p> <p>2. The response to IR-198 (Attachment IR-198) erroneously provided the concentrations of Pb-210 in moose organ and caribou organ in units of mg/kg (ww). The corrected units that should have been provided for Pb-210 in moose organ and caribou organ tissues are in Becquerel per kilogram wet weight (Bq/kg ww); that is, the concentrations of Pb-210 in moose and caribou organs are 7.15 Bq/kg ww and 49.4 Bq/kg ww, respectively.</p> <p>The following illustrates that chemical lead (from Pb-210) in organs is not a health concern. The concentrations of Pb-210 in moose organs is 7.15 Bq/kg ww. Using a specific activity of 2.86E+12 Bq/g for Pb-210 (www.wise-uranium.org/nucv.html), the lead concentration in moose organs would be 2.5E-09 mg/kg ww. The daily dose for moose organ consumption would be 4.4E-10 µg/kg bw/day.</p> <p>Dose = 4.5kg/yr*yr/365d*2.5E-09mg/kg/70.7kg*1000ug/mg. The estimated lead exposure dose from Pb-210 in moose organs is far below the 95th percentile dietary lead exposure estimate for the general Canadian population consuming retail foods, and also well below the provisional lead TRV recommended by Health Canada of 0.5 µg/kg bw/day.</p> <p>Therefore, Pb-210 is expected to contribute a negligible amount of lead metal to total lead exposure. Lead as a non-radiological contaminant was considered in Table 3-1 in the ERA (Appendix 10-A) did not screen into the assessment and therefore it is concluded that the potential risks to consumers of country foods due to lead (and Pb-210) are negligible.</p> <p>The project includes an environmental monitoring program which will include analysis of country foods for trace metals, including lead.</p> <p>References: Government of Canada, Environment Canada. 2006. Priority Substances List Assessment Report. Releases of radionuclides from nuclear facilities (Impact on Non-human Biota). September.</p> | <p>potential risk to human health from consumption of country foods, this IR can be resolved.</p> <p>This commitment would include:</p> <ol style="list-style-type: none"> 1. ATTACHMENT IR-198 (Round 1 submission)

1. Mammalian Organ Ingestion Rates

The derivation of the Traditional Foods diet is explained in detail in Section 4.2.4.2 of Appendix 10-A (ERA), which states: “A dietary study was performed for residents of Patuanak and La Plonge to understand which traditional foods were consumed by each community and the approximate amounts consumed. The results of the survey were summarized in CanNorth (2017) by average daily intake in grams (fresh weight) of country foods by species and season, for Patuanak, La Plonge, and an average. A summary of the ERFN traditional food ingestion rates by food type is shown in Table 4-3 and the proportions of food types are shown in Figure 4-3.”

As shown in Table 4-3 in Appendix 10-A the mammalian organ ingestion rate was 6.2 g/d for La Plonge, and 16.2 g/d for Patuanak, and the average was 12.8 g/d for both areas combined. A more detailed breakdown of organ types is provided in IR-198 Table 1 below which indicates that organs are consumed from moose, woodland caribou, and barren-ground caribou. As shown in IR-198 Table 1 below, the greatest contribution to the total organ ingestion rate is from moose organs. Looking at the total organ ingestion rate, approximately 80% of the contribution is from moose liver, kidney, and other parts (see IR-198 Figure 1 below); therefore, it was decided for the ERA to assign the total organ ingestion rate to moose organs.

2. Rationale for Concentrations of Radionuclides in Moose Organs Only

The reviewer also requested rationale for why concentrations of radionuclides are not provided for organs of animals other than moose. The reviewer acknowledges that they are “not aware of transfer factors to individual organs or to organs that are not ruminants, it would be beneficial to have a better understanding of radionuclide concentrations in the organs of other animals that may be consumed by local Indigenous communities.” The transfer factor for moose organs was scaled based on the beef organs transfer factor from CSA N288.1-20 (see Table 3-15 in Appendix A to Appendix 10-A). Limited literature data is available for transfer factors for organs. It was decided to represent organs with moose organs based on the results from the ERFN diet explained above.

Denison acknowledges that the ingestion transfer factors for woodland caribou organs would be higher than the transfer factors for moose. These ingestion transfer factors are summarized in IR-198 Table 2 below for the relevant radionuclides, and the resulting tissue concentrations based on predicted concentrations at McGowan Lake are summarized in IR-198 Table 3. The predicted tissue concentrations for woodland caribou organs ranges from about 0.6 to 6.9 times higher than the predicted tissue concentrations for moose organs for radionuclides in the U-238 decay chain. However, based on the breakdown of organ ingestion rates shown in IR-198 Table 1 below, the caribou organ intake rate is ¼ of the moose organ intake rate, which roughly offsets the higher concentrations in caribou organs. Therefore, representing the organ intake as 100% moose organs is a reasonable approximation.

No changes to the EIS or ERA (Appendix 10-A) were made based on the response to this IR.

IR-198 Table 1: Breakdown of Contribution of Organ Types to Total Organ Ingestion Rate

| Organ Types | La Plonge g/d | Patuanak g/d | All g/d | La Plonge % of Organs | Patuanak % of Organs | All % of Organs |
|---------------------------------|------------------|-----------------|-------------|-----------------------------|----------------------------|-----------------------|
| Moose (other parts) | 2.4 | 5.7 | 4.6 | 39% | 35% | 36% |
| Moose liver | 1.8 | 4.1 | 3.3 | 29% | 25% | 26% |
| Moose kidney | 1.8 | 2.5 | 2.3 | 29% | 15% | 18% |
| Woodland caribou liver | 0.1 | 1.7 | 1.2 | 2% | 10% | 9% |
| Woodland caribou kidney | 0.05 | 1.7 | 1.1 | 1% | 10% | 9% |
| Barren-ground caribou kidney | | 0.2 | 0.1 | 0% | 1% | 1% |
| Barren-ground caribou liver | | 0.2 | 0.1 | 0% | 1% | 1% |
| Caribou (other parts) | 0.02 | 0.1 | 0.1 | 0% | 1% | 1% |
| Total Organs | 6.2 | 16.2 | 12.8 | 100% | 100% | 100% |
